

850kHz 700mA Synchronous Buck DC/DC Converter

General Description

The AAT1151 SwitchReg™ is a step-down switching converter ideal for applications where high efficiency is required over the full range of output load conditions. The 2.7V to 5.5V input voltage range makes the AAT1151 ideal for single-cell lithium-ion/polymer battery applications. Capable of more than 700mA with internal MOSFETs, the current-mode controlled IC provides high efficiency using synchronous rectification. Fully integrated compensation simplifies system design and lowers external parts count.

The device operates at a fixed 850kHz switching frequency and enters Pulse Frequency Modulation (PFM) mode for light load current to maintain high efficiency across all load conditions.

The AAT1151 is available in Pb-free MSOP-8 and QFN33-16 packages and is rated over the -40°C to +85°C temperature range.

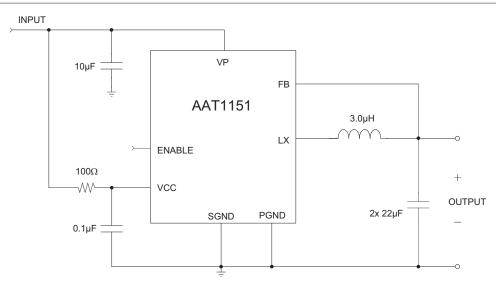

Features

- V_{IN} Range: 2.7V to 5.5V
- Up to 95% Efficiency
- High Initial Accuracy ±1%
- $110m\Omega$ R_{DS(ON)} Internal Switches
- <1µA Shutdown Current
- 850kHz Switching Frequency
- Fixed V_{OUT} or Adjustable V_{OUT} ≥ 1.0V
- Integrated Power Switches
- Synchronous Rectification
- Current Mode Operation
- Internal Compensation
- Stable with Ceramic Capacitors
- PFM for Optimum Efficiency for All Load Conditions
- Internal Soft Start
- Over-Temperature Protection
- Current Limit Protection
- MSOP-8 and QFN33-16 Packages
- -40°C to +85°C Temperature Range

Applications

- · Cellular Phones
- Digital Cameras
- MP3 Players
- Notebook Computers
- PDAs
- USB-Powered Equipment
- Wireless Notebook Adapters

Typical Application

SwitchReg[™]

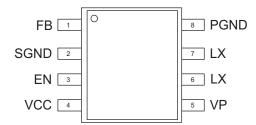

850kHz 700mA Synchronous Buck DC/DC Converter

Pin Descriptions

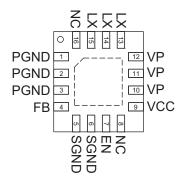

Pin #			
MSOP-8	QFN33-16	Symbol	Function
1	4	FB	Feedback input pin. This pin is connected to the converter output. It is used to set the output of the converter to regulate to the desired value via an internal resistive divider. For an adjustable output, an external resistive divider is connected to this pin on the 1V model.
2	5, 6	SGND	Signal ground. Connect the return of all small signal components to this pin. (See board layout rules.)
3	7	EN	Enable input pin. A logic high enables the converter; a logic low forces the AAT1151 into shutdown mode reducing the supply current to less than 1μ A. The pin should not be left floating.
4	9	VCC	Bias supply. Supplies power for the internal circuitry. Connect to input power via low pass filter with decoupling to SGND.
5	10, 11, 12	VP	Input supply voltage for the converter power stage. Must be closely decoupled to PGND.
6, 7	13, 14, 15	LX	Connect inductor to these pins. Switching node internally connected to the drain of both highand low-side MOSFETs.
8	1, 2, 3	PGND	Main power ground return pin. Connect to the output and input capacitor return. (See board layout rules.)
	8, 16	NC	Not internally connected.
	EP		Exposed paddle (bottom); connect to PGND directly beneath package

Functional Block Diagram

Operation

Control Loop

8

The AAT1151 is a peak current mode buck converter. The inner wide bandwidth loop controls the peak current of the output inductor. The output inductor current is sensed through the P-channel MOSFET (high side) and is also used for short-circuit and overload protection. A fixed slope compensation signal is added to the sensed current to maintain stability. The loop appears as a voltage programmed current source in parallel with the output capacitor.

The voltage error amplifier output programs the current loop for the necessary inductor current to force a constant output voltage for all load and line conditions. The voltage feedback resistive divider is internal, dividing the output voltage to the error amplifier reference voltage of 1.0V. The voltage error amplifier does not have the large DC gain typical of most error amplifiers. This eliminates the need for external compensation components, while still providing sufficient DC loop gain for load regulation.

The voltage loop crossover frequency and phase margin are set by the output capacitor value only.

PFM/PWM Operation

Light load efficiency is maintained by way of PFM control. The AAT1151 PFM control forces the peak inductor current to a minimum level regardless of load demand. At medium to high load demand, this has no effect on circuit operation and normal PWM controls take over. PFM reduces the switching frequency at light loads, thus reducing the associated switching losses.

Soft Start/Enable

Soft start increases the inductor current limit point in discrete steps when the input voltage or enable input is applied. It limits the current surge seen at the input and eliminates output voltage overshoot. When pulled low, the enable input forces the AAT1151 into a low-power, non-switching state. The total input current during shutdown is less than $1\mu A$.

850kHz 700mA Synchronous Buck DC/DC Converter

Power and Signal Source

Separate small signal ground and power supply pins isolate the internal control circuitry from the noise associated with the output MOSFET switching. The low pass filter R1 and C2 in schematic Figure 1 filters the noise associated with the power switching.

Current Limit and Over-Temperature Protection

For overload conditions, the peak input current is limited. As load impedance decreases and the output voltage falls closer to zero, more power is dissipated internally, raising the device temperature. Thermal protection completely disables switching when internal dissipation becomes excessive, protecting the device from damage. The junction over-temperature threshold is 140°C with 10°C of hysteresis.

Inductor

The output inductor is selected to limit the ripple current to some predetermined value, typically 20% to 40% of the full load current at the maximum input voltage. Manufacturer's specifications list both the inductor DC current rating, which is a thermal limitation, and the peak current rating, which is determined by the saturation characteristics. The inductor should not show any appreciable saturation under normal load conditions. During overload and transient conditions, the average

current in the inductor can meet or exceed the current limit point of the AAT1151. These conditions can tolerate greater saturation in the inductor without degradation in converter performance. Some inductors may meet the peak and average current ratings yet result in excessive losses due to a high DCR. Always consider the losses associated with the DCR and its effect on the total converter efficiency when selecting an inductor.

For a 1.0A load and the ripple set to 40% at the maximum input voltage, the maximum peak-to-peak ripple current is 280mA. The inductance value required is 2.84 μ H.

$$L = \frac{V_{OUT}}{I_{O} \cdot k \cdot F_{S}} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right)$$
$$= \left(\frac{1.5V}{1A \cdot 0.4 \cdot 850 \text{kHz}}\right) \left(\cdot 1 - \frac{1.5V}{4.2V}\right)$$
$$= 2.84 \mu \text{H}$$

The factor "k" is the fraction of full load selected for the ripple current at the maximum input voltage. For ripple current at 40% of the full load current, the peak current will be 120% of full load. Selecting a standard value of 3.0µH gives 38% ripple current. A 3.0µH inductor selected from the Sumida CDRH5D28 series has a 24m Ω DCR and a 2.4A DC current rating. At full load, the inductor DC loss is 24mW, which amounts to a 1.6% loss in efficiency.

9

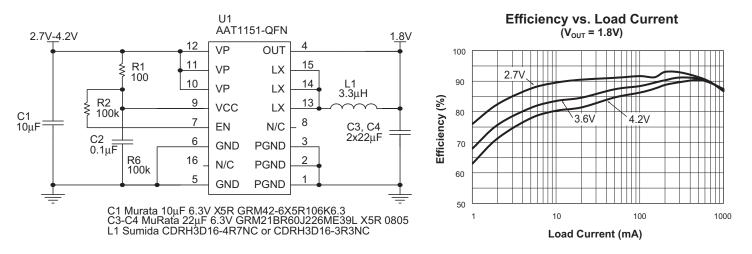

Figure 1: AAT1151 Evaluation Board.

850kHz 700mA Synchronous Buck DC/DC Converter

Input Capacitor

The primary function of the input capacitor is to provide a low impedance loop for the edges of pulsed current drawn by the AAT1151. A low ESR/ESL ceramic capacitor is ideal for this function. To minimize stray inductance, the capacitor should be placed as close as possible to the IC. This keeps the high frequency content of the input current localized, minimizing radiated and conducted EMI while facilitating optimum performance of the AAT1151. Ceramic X5R or X7R capacitors are ideal for this function. The size required will vary depending on the load, output voltage, and input voltage source impedance characteristics. A typical value is around $10\mu F$. The input capacitor RMS current varies with the input voltage and the output voltage. The equation for the RMS current in the input capacitor is:

$$I_{RMS} = I_O \bullet \sqrt{\frac{V_O}{V_{IN}} \bullet \left(1 - \frac{V_O}{V_{IN}}\right)}$$

The input capacitor RMS ripple current reaches a maximum when $V_{\rm IN}$ is two times the output voltage where it is approximately one half of the load current. Losses associated with the input ceramic capacitor are typically minimal and are not an issue. Proper placement of the input capacitor can be seen in the reference design layout in Figures 2 and 4.

Output Capacitor

Since there are no external compensation components, the output capacitor has a strong effect on loop stability. Lager output capacitance will reduce the crossover frequency with greater phase margin. For the 1.5V 1A design using the 4.1 μ H inductor, two 22 μ F capacitors provide a stable output. In addition to assisting stability, the output capacitor limits the output ripple and provides

holdup during large load transitions. The output capacitor RMS ripple current is given by:

$$I_{RMS} = \frac{1}{2 \cdot \sqrt{3}} \cdot \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{L \cdot F_{S} \cdot V_{IN}}$$

For a ceramic capacitor, the ESR is so low that dissipation due to the RMS current of the capacitor is not a concern. Tantalum capacitors with sufficiently low ESR to meet output voltage ripple requirements also have an RMS current rating well beyond that actually seen in this application.

Layout

Figures 2 through 5 display the suggested PCB layout for the AAT1151. The following guidelines should be used to help ensure a proper layout.

- The input capacitor (C1) should connect as closely as possible to VP (Pin 5) and PGND (Pin 8).
- C2 and L1 should be connected as closely as possible.
 The connection L1 to the LX node should be as short as possible.
- The feedback trace (Pin 1) should be separate from any power trace and connect as closely as possible to the load point. Sensing along a high-current load trace will degrade DC load regulation.
- The resistance of the trace from the load return to the PGND (Pin 8) should be kept to a minimum. This will help to minimize any error in DC regulation due to differences in the potential of the internal signal ground and the power ground.
- Low pass filter R1 and C3 provide a cleaner bias source for the AAT1151 active circuitry. C3 should be placed as closely as possible to SGND (Pin 2) and VCC (Pin 4). See Figures 2 and 7.

Thermal Calculations

There are two types of losses associated with the AAT1151 output switching MOSFET: switching losses and conduction losses. Conduction losses are associated with the $R_{DS(ON)}$ characteristics of the output switching device. At the full load condition, assuming continuous conduction mode (CCM), a simplified form of the total losses is given by:

$$P = \frac{I_O^2 \cdot (R_{DS(ON)H} \cdot V_O + R_{DS(ON)L} \cdot (V_{IN} \cdot V_O))}{V_{IN}}$$
$$+ (t_{SW} \cdot F_S \cdot I_O \cdot V_{IN} + I_O) \cdot V_{IN}$$

where I_q is the AAT1151 quiescent current.

Once the total losses have been determined, the junction temperature can be derived from the θ_{JA} for the MSOP-8 package.

$$T_J = P \cdot \theta_{JA} + T_{AMB}$$

Adjustable Output

For applications requiring an output other than the fixed available, the 1V version can be programmed externally. Resistors R3 and R4 of Figure 7 force the output to regulate higher than 1V. R4 should be 100 times less than the $1M\Omega$ internal resistance of the FB pin (recommended $10k\Omega$). Once R4 is selected, R3 can be calculated. For a 1.25 volt output with R4 set to $10.0k\Omega$, R3 is $2.55k\Omega$.

$$R3 = (V_0 - 1) \cdot R4 = 0.25 \cdot 10k\Omega = 2.55k\Omega$$
