

General Description

The AAT3105 is a charge-pump based, current-source white LED driver capable of driving one to four LEDs up to 30mA, each. It automatically switches between 1x mode and 2x mode to maintain the highest efficiency and optimal LED current matching.

The AAT3105 charge pump's 1x mode (bypass mode) has very low resistance, allowing LED current regulation to be maintained with input supply voltage approaching the LED forward voltage.

LED brightness is controlled using a universal PWM interface. The AAT3105 is available in a Pb-free, 2x2mm 10-lead SC70JW-10 package

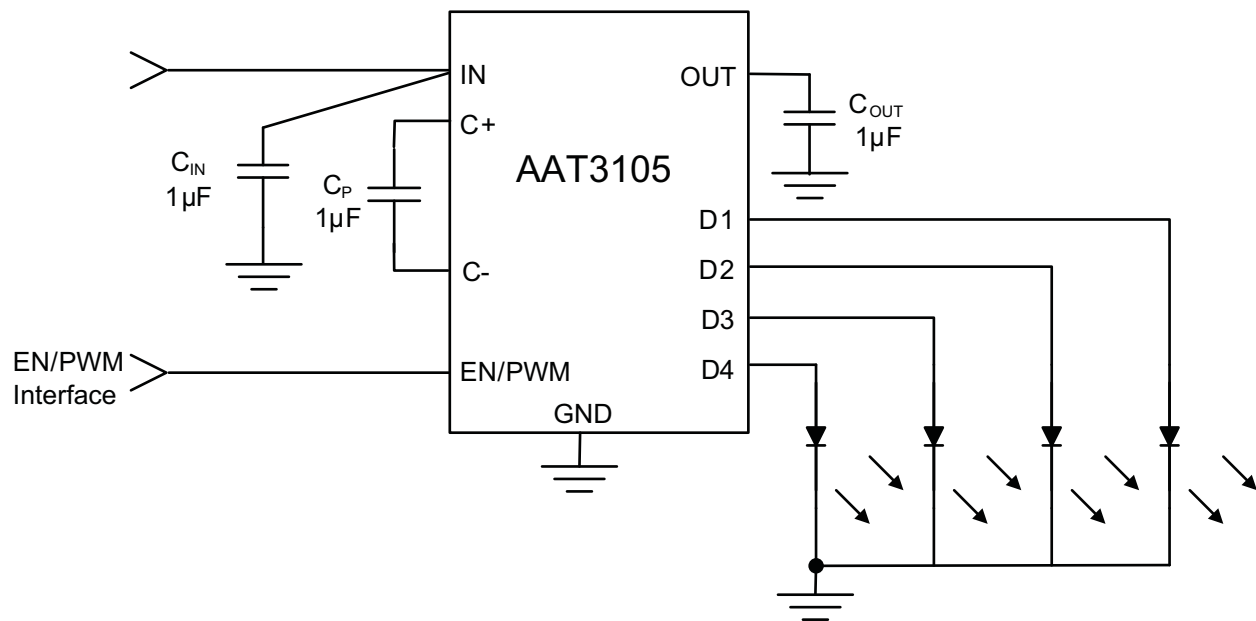

Features

- Drives up to 4 LEDs at up to 30mA each
- Automatic Switching Between 1x and 2x Modes
- 0.85MHz Switching Frequency
- Linear LED Output Current Control
- Universal PWM Interface
- $\pm 10\%$ LED Output Current Accuracy
- $\pm 3\%$ LED Output Current Matching
- Low-current Shutdown Mode
- Built-in Thermal Protection
- Automatic Soft-start
- Available in 2x2mm SC70JW-10 Package

Applications

- Cell Phones
- Digital Still Cameras
- MP3 Players
- Personal Data Assistants (PDAs)

Typical Application

Pin Description

Pin #	Name	Function
1	D2	LED2 Current Source Output. D2 is the output of LED2 current source. Connect LED2's anode to D2 and its cathode to GND.
2	D1	LED1 Current Source Output. D1 is the output of LED1 current source. Connect LED1's anode to D1 and its cathode to GND.
3	OUT	Charge Pump Output. OUT is the output of the charge pump. Bypass OUT to GND with a 1 μ F or larger ceramic capacitor.
4	C-	Charge Pump Capacitor Negative Node.
5	C+	Charge Pump Capacitor Positive Node. Connect a 1 μ F ceramic capacitor between C+ and C-.
6	GND	Analog Ground. Connect this pin to the system's analog ground plane.
7	EN/PWM	LED Enable and control input. EN/PWM is the ON/OFF control for the LED and the PWM input for the AAT3105 to control the LED brightness.
8	IN	Power source input. Connect IN to the power source, typically the battery. Bypass IN to GND with a 1 μ F or larger ceramic capacitor.
9	D4	LED4 Current Source Output. D4 is the output of LED4 current source. Connect LED4's anode to D4 and its cathode to GND.
10	D3	LED3 Current Source Output. D3 is the output of LED3 current source. Connect LED3's anode to D3 and its cathode to GND.

Functional Block Diagram

Functional Description

The AAT3105 is a low-cost charge-pump solution designed to drive up to four white LEDs. The charge pump operates from a 2.7V to 5.5V power source and converts it to voltage levels necessary to drive the LEDs. LED current is individually controlled through integrated current sources powered from the output of the charge pump. Low 1x charge-pump output resistance and low dropout voltage current sources allow the charge pump to stay in 1x mode with an input voltage as low as 3.8V and LED forward voltages of 3.5V. After entering 2x mode, the charge pump remains in 2x mode until the device resets.

The AAT3105 requires only three external components: one 1 μ F ceramic capacitor for the charge pump flying capacitor (C_P), one 1 μ F ceramic input capacitor (C_{IN}),

one 1 μ F ceramic output capacitor (C_{OUT}). The four constant current outputs of the AAT3105 (D1 to D4) can drive four individual LEDs with a maximum current of 30mA each. A PWM interface enables the AAT3105 to change the LED current through the EN/PWM pin.

PWM Interface

The AAT3105 uses a simple PWM interface to control the effective LED current (RMS) of its current source outputs. The PWM signal should fit the requirements listed in the electrical characteristic table for proper operation. When the EN/PWM pin is constantly pulled high, which means 100% duty ratio, the source current per channel is typically 30mA. When the EN/PWM pin is pulled low for less than 150 μ s, the current source will output 0mA of current and the charge pump status will remain

unchanged. By feeding the EN/PWM pin with a proper PWM signal, the RMS current of current source outputs is proportional to the duty ratio of the PWM signal with very little error, which is introduced timing delay. If EN/PWM is kept low for longer than 1ms, the device will enter shutdown mode. In shutdown mode, the device draws less than 1µA current and all current source outputs are inactive.

The relationship between PWM duty ratio and LED current per channel is shown in Table 1. The PWM signal should meet the timing requirements shown in the Electrical Characteristics section of this datasheet in order to guarantee proper operation and accuracy. For example, if the minimum PWM duty ratio is designed as 10%, then the PWM frequency should be higher than 6Khz to meet the minimum limit of the EN/PWM input off time, which is 150µs.

EN/PWM Duty Cycle ($F_{PWM} = 25Khz$)	D1-D4 Current (mA)
100%	29.9
90%	26.7
80%	23.8
70%	20.8
60%	17.9
50%	15
40%	12
30%	9.1
20%	6.2
10%	3.2

Application Information

LED Selection

The AAT3105 is specifically designed for driving white LEDs. However, the device design will allow the AAT3105 to drive most types of LEDs with forward voltage specifications ranging from 2.2V to 4.7V. LED applications may include mixed arrangements for display backlighting, keypad display, and any other application that demands a constant current source generated from a varying input voltage. Since the D1 to D4 constant current sources are matched with negligible supply voltage dependence, the constant current channels will be matched regardless of their respective LED forward voltage (V_f) levels.

The low dropout current sources in the AAT3105 maximize performance and make it capable of driving LEDs with high forward voltages. Multiple channels can be combined to obtain a higher LED drive current without complication.

Any unused channel should be connected to GND; the device will detect and shut down the channel. Do not connect any unused channel to the OUT pin.

Device Switching Noise Performance

The AAT3105 operates at a fixed frequency of approximately 0.85MHz to control noise and limit harmonics that can interfere with the RF operation of mobile communication devices. Back-injected noise appearing on the input pin of the charge pump is 20mV peak-to-peak, typically ten times less than inductor-based DC/DC boost converter white LED backlight solutions. The AAT3105 soft-start feature prevents noise transient effects associated with inrush currents during start-up of the charge pump circuit.

Shutdown

Since the current switches are the only power returns for all loads, there is no leakage current when all source switches are disabled. To enter shutdown operation, the EN/PWM input for the AAT3105 should be strobed low. After t_{OFF} (500µs), the AAT3105 will be shut down and typically draws less than 1µA from the input. Registers are reset to 0 in shutdown.

Power Efficiency and Device Evaluation

The charge pump efficiency discussion in the following sections accounts only for efficiency of the charge pump section itself. Due to the unique circuit architecture and design of the AAT3105, it is very difficult to measure efficiency in terms of a percent value comparing input power over output power.

Since the AAT3105 outputs are pure constant current sources and typically drive individual loads, it is difficult to measure the output voltage for a given output to derive an overall output power measurement. For any given application, white LED forward voltage levels can differ, yet the output drive current will be maintained as a constant.

This makes quantifying output power a difficult task when taken in the context of comparing to other white LED driver circuit topologies. A better way to quantify total device efficiency is to observe the total input power to the device for a given LED current drive level. The best white LED driver for a given application should be based on trade-offs of size, external component count, reliability, operating range, and total energy usage, not just output power over input power efficiency.

The AAT3105 efficiency may be quantified under very specific conditions and is dependent upon the input voltage versus the output voltage across the loads applied to outputs D1 through D4 for a given constant current setting. Depending on the combination of V_{IN} and voltages sensed at the current sources, the device will operate in load switch mode. When any one of the voltages sensed at the current sources nears dropout, the device will operate in 2x charge pump mode.

Each of these modes will yield different efficiency values. Refer to the following two sections for explanations for each operational mode.

1x Mode Efficiency

The AAT3105 1x mode is operational at all times and functions alone to enhance device power conversion efficiency when V_{IN} is higher than the voltage across the load. When in 1x mode, voltage conversion efficiency is defined as output power divided by input power.

$$\eta = \frac{P_{OUT}}{P_{IN}} = \frac{V_F \cdot I_{LED}}{V_{IN} \cdot I_{IN}} = \frac{V_F \cdot I_{LED}}{V_{IN} \cdot I_{OUT}} \approx \frac{V_F}{V_{IN}}$$

An expression for the ideal efficiency (η) in 1x charge-pump mode can be expressed as:

$$\eta (\%) = \frac{V_F}{V_{IN}} \cdot 100$$

For a charge pump led driver with V_F of 3.2V and 4.2V input voltage, the theoretical efficiency is 76%. Due to internal switching losses and IC quiescent current consumption, the actual efficiency can be measured at 73%.

2x Charge Pump Mode Efficiency

The AAT3105 contains a charge pump which will boost the input supply voltage in the event where V_{IN} is less than the voltage required to supply the output. The efficiency (η) can be simply defined as a linear voltage regulator with an effective output voltage that is equal to one and two times the input voltage. Efficiency (η) for an ideal 2x charge pump can typically be expressed as the output power divided by the input power.

$$\eta = \frac{P_F}{P_{IN}}$$

In addition, with an ideal 2x charge pump, the output current may be expressed as 1/3 of the input current. The expression to define the ideal efficiency (η) can be rewritten as

$$\eta = \frac{P_{OUT}}{P_{IN}} = \frac{V_F \cdot I_{LED}}{V_{IN} \cdot I_{IN}} = \frac{V_F \cdot I_{LED}}{V_{IN} \cdot 2 \cdot I_{OUT}} \approx \frac{V_F}{2 \cdot V_{IN}}$$

-or-

$$\eta (\%) = \frac{V_F}{2 \cdot V_{IN}} \cdot 100$$

For a charge pump current source driver with V_F of 3.2V and 2.7V input voltage, the theoretical efficiency is 59%. Due to internal switching losses and IC quiescent current consumption, the actual efficiency can be measured at 57%. Efficiency will decrease substantially as load current drops below 1mA or when the voltage level at V_{IN} approaches the voltage level at V_{OUT} .

Additional Applications

The current sources of the AAT3105 can be combined freely to drive higher current levels through one LED. As an example, a single LED can be driven at 120mA by combining together D1 through D4 outputs.

For lower-cost applications, the flying capacitor can be removed; C+ and C- should be floating. This will force the AAT3105 to operate in 1x mode. To maintain regulated LED current, the input supply voltage has to be higher than the charge pump's dropout voltage in 1x mode plus the forward voltage of the LED at the preset LED current.

PCB Layout Considerations

When designing a PCB for the AAT3105, the key requirements are:

1. Place the flying capacitor C1 as close to the chip as possible; otherwise 2x mode performance will be compromised.
2. Place the input and output decoupling capacitors C2 and C3 as close to the chip as possible to reduce switching noise and output ripple.
