

ANALOG DEVICES

Fully Accurate 12-/14-/16-Bit V_{OUT} nanoDAC™ SPI Interface 2.7 V to 5.5 V in a TSSOP

Preliminary Technical Data

AD5024/AD5044/AD5064

FEATURES

- Low power Quad 16/14/12 bit DAC, ± 1 LSB INL
- Pin compatible and performance upgrade to AD5666
- Individual and common voltage reference pin options
- Rail-to-rail operation
- 2.7 V to 5.5 V power supply
- Power-on reset to zero scale or midscale
- 3 power-down functions
- Per channel power down
- Low glitch on power up
- Hardware LDAC with LDAC override function
- CLR Function to programmable code
- SDO daisy-chaining option
- 14/16-lead TSSOP

APPLICATIONS

- Process control
- Data acquisition systems
- Portable battery-powered instruments
- Digital gain and offset adjustment
- Programmable voltage and current sources
- Programmable attenuators

GENERAL DESCRIPTION

The AD5024/44/64 are low power, quad 12-/14-/16-bit buffered voltage-out DACs offering relative accuracy specs of 1 LSB INL with individual and common reference pin options and can operate from a single 2.7 V to 5.5 V supply. The AD5024/44/64 parts also offer a differential accuracy specification of ± 1 LSB. The parts use a versatile 3-wire, low power Schmitt trigger serial interface that operates at clock rates up to 50 MHz and is compatible with standard SPI®, QSPI™, MICROWIRE™, and DSP interface standards. A reference buffer is also provided on-chip. The AD5024/44/64 incorporates a power-on reset circuit that ensures the DAC output powers up to zero scale or midscale and remains there until a valid write takes place to the device. The AD5024/44/64 contain a power-down feature that reduces the current consumption of the device to typically 400 nA at 5 V and provides software selectable output loads while in power-down mode. Total unadjusted error for the parts is < 2 mV.

FUNCTIONAL BLOCK DIAGRAMS

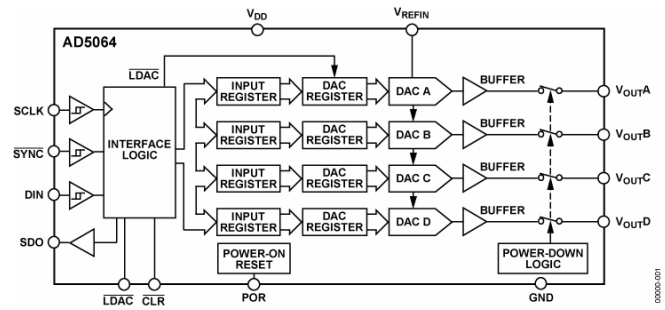

Figure 1. AD5064 Functional equivalent and pin compatible with AD5666

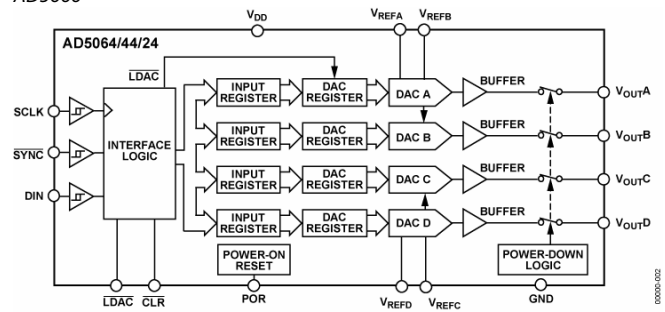

Figure 2. AD5064/44/24

PRODUCT HIGHLIGHTS

- Quad channel available in 14/16-lead TSSOP package.
- 14-lead TSSOP option provides a pin compatible and performance upgrade to the AD5666 with individual and common voltage reference pin options.
- 16 bit accurate, 1 LSB INL.
- Low glitch on power-up.
- High speed serial interface with clock speeds up to 50 MHz.
- Reset to known output voltage (zero scale or midscale).

Table 1. Related Devices

Part No.	Description
AD5666	Quad, 16-bit buffered D/A, 16 LSB INL, TSSOP
AD5066	Quad, 16-bit unbuffered D/A, 1 LSB INL, TSSOP
AD5065/45/25	Dual 16-bit nanoDAC, 1 LSB INL, TSSOP
AD5063/62	16-bit nanoDAC, 1 LSB INL, MSOP
AD5061	16-/14bit nanoDAC, 4 LSB INL, SOT-23
AD5060/40	16-/14bit nanoDAC, 1 LSB INL, SOT-23

		60		$\text{nV}/\sqrt{\text{Hz}}$	DAC code = 0x8400, 10 kHz
Output Noise		6		$\mu\text{V p-p}$	0.1 Hz to 10 Hz

¹ Guaranteed by design and characterization; not production tested.

² See the Terminology section.

³ Temperature range is -40°C to $+105^\circ\text{C}$, typical at 25°C .

TIMING CHARACTERISTICS

All input signals are specified with $t_r = t_f = 1 \text{ ns/V}$ (10% to 90% of V_{DD}) and timed from a voltage level of $(V_{IL} + V_{IH})/2$. See Figure 4 and Figure 6. $V_{DD} = 2.7 \text{ V}$ to 5.5 V . All specifications T_{MIN} to T_{MAX} , unless otherwise noted.

Table 4.

Parameter	Limit at T_{MIN} , T_{MAX} $V_{DD} = 2.7 \text{ V}$ to 5.5 V	Unit	Conditions/Comments
t_1^1	20	ns min	SCLK cycle time
t_2	10	ns min	SCLK high time
t_3	10	ns min	SCLK low time
t_4	16.5	ns min	$\overline{\text{SYNC}}$ to SCLK falling edge set-up time
t_5	5	ns min	Data set-up time
t_6	5	ns min	Data hold time
t_7	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge
t_8	1.9	us min	Minimum $\overline{\text{SYNC}}$ high time (single channel update)
t_8	10.5	us min	Minimum $\overline{\text{SYNC}}$ high time (all channel update)
t_9	16.5	ns min	$\overline{\text{SYNC}}$ rising edge to SCLK fall ignore
t_{10}	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ fall ignore
t_{11}	20	ns min	$\overline{\text{LDAC}}$ pulse width low
t_{12}	20	ns min	SCLK falling edge to $\overline{\text{LDAC}}$ rising edge
t_{13}	10	ns min	$\overline{\text{CLR}}$ pulse width low
t_{14}	10	ns min	SCLK falling edge to $\overline{\text{LDAC}}$ falling edge
t_{15}	10.6	us min	$\overline{\text{CLR}}$ pulse activation time
$t_{16}^{2,3}$	22	ns max	SCLK rising edge to SDO valid
t_{17}^3	5	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge
t_{18}^3	8	ns min	$\overline{\text{SYNC}}$ rising edge to SCLK rising edge
t_{19}^3	0	ns min	$\overline{\text{SYNC}}$ rising edge to $\overline{\text{LDAC}}$ falling edge

¹ Guaranteed by design and characterization; not production tested.

² Measured with the load circuit of Figure 18. t_{16} determines the maximum SCLK frequency in daisy-chain mode.

³ Daisy-chain mode only.

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 5.

Parameter	Rating
V_{DD} to GND	-0.3 V to +7 V
Digital Input Voltage to GND	-0.3 V to $V_{DD} + 0.3$ V
V_{OUT} to GND	-0.3 V to $V_{DD} + 0.3$ V
V_{REF} to GND	-0.3 V to $V_{DD} + 0.3$ V
Operating Temperature Range	
Industrial	-40°C to $+125^\circ\text{C}$
Storage Temperature Range	-65°C to $+150^\circ\text{C}$
Junction Temperature ($T_{J\text{ MAX}}$)	$+150^\circ\text{C}$
TSSOP Package	
Power Dissipation	$(T_{J\text{ MAX}} - T_A)/\theta_{JA}$
θ_{JA} Thermal Impedance	150.4°C/W
Reflow Soldering Peak Temperature	
SnPb	240°C
Pb Free	260°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 6. 14-Lead TSSOP (RU-14)

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	$\overline{\text{LDAC}}$	Pulsing this pin low allows any or all DAC registers to be updated if the input registers have new data. This allows all DAC outputs to simultaneously update. Alternatively, this pin can be tied permanently low.
2	$\overline{\text{SYNC}}$	Active Low Control Input. This is the frame synchronization signal for the input data. When $\overline{\text{SYNC}}$ goes low, it powers on the SCLK and DIN buffers and enables the input shift register. Data is transferred in on the falling edges of the next 32 clocks. If $\overline{\text{SYNC}}$ is taken high before the 32nd falling edge, the rising edge of $\overline{\text{SYNC}}$ acts as an interrupt and the write sequence is ignored by the device.
3	V_{DD}	Power Supply Input. These parts can be operated from 2.7 V to 5.5 V, and the supply should be decoupled with a 10 μF capacitor in parallel with a 0.1 μF capacitor to GND.
4	V_{OUTA}	Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
5	V_{OUTC}	Analog Output Voltage from DAC C. The output amplifier has rail-to-rail operation.
6	POR	Power-on Reset Pin. Tying this pin to GND powers up the part to 0 V. Tying this pin to V_{DD} powers up the part to midscale.
7	V_{REFIN}	This is a common pin for reference input for DACA,B,C and D.
8	SDO	Serial Data Output. Can be used for daisy-chaining a number of these devices together or for reading back the data in the shift register for diagnostic purposes. The serial data is transferred on the rising edge of SCLK and is valid on the falling edge of the clock.
9	$\overline{\text{CLR}}$	Asynchronous Clear Input. The $\overline{\text{CLR}}$ input is falling edge sensitive. When $\overline{\text{CLR}}$ is low, all $\overline{\text{LDAC}}$ pulses are ignored. When $\overline{\text{CLR}}$ is activated, the input register and the DAC register are updated with the data contained in the $\overline{\text{CLR}}$ code register—zero, midscale, or full scale. Default setting clears the output to 0 V.
10	V_{OUTD}	Analog Output Voltage from DAC D. The output amplifier has rail-to-rail operation.
11	V_{OUTB}	Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
12	GND	Ground Reference Point for All Circuitry on the Part.
13	DIN	Serial Data Input. This device has a 32-bit shift register. Data is clocked into the register on the falling edge of the serial clock input.
14	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates of up to 50 MHz.

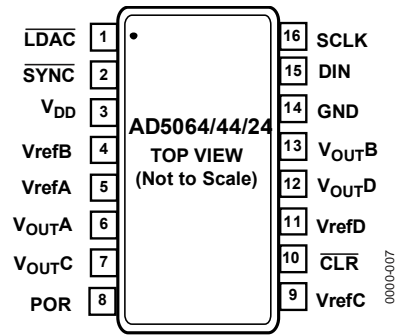

Figure 7. 16-Lead TSSOP (RU-16)

Table 7. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	LDAC	Pulsing this pin low allows any or all DAC registers to be updated if the input registers have new data. This allows all DAC outputs to simultaneously update. Alternatively, this pin can be tied permanently low.
2	SYNC	Active Low Control Input. This is the frame synchronization signal for the input data. When SYNC goes low, it powers on the SCLK and DIN buffers and enables the input shift register. Data is transferred in on the falling edges of the next 32 clocks. If SYNC is taken high before the 32nd falling edge, the rising edge of SYNC acts as an interrupt and the write sequence is ignored by the device.
3	V _{DD}	Power Supply Input. These parts can be operated from 2.7 V to 5.5 V, and the supply should be decoupled with a 10 μF capacitor in parallel with a 0.1 μF capacitor to GND.
4	V _{REFB}	Dac B reference input .This is the reference voltage input pin for Dac B.
5	V _{REFA}	Dac A reference input .This is the reference voltage input pin for Dac A.
6	V _{OUTA}	Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
7	V _{OUTC}	Analog Output Voltage from DAC C. The output amplifier has rail-to-rail operation.
8	POR	Power-on Reset Pin. Tying this pin to GND powers up the part to 0 V. Tying this pin to V _{DD} powers up the part to midscale.
9	V _{REFC}	Dac B reference input .This is the reference voltage input pin for Dac C.
10	CLR	Asynchronous Clear Input. The CLR input is falling edge sensitive. When CLR is low, all LDAC pulses are ignored. When CLR is activated, the input register and the DAC register are updated with the data contained in the CLR code register—zero, midscale, or full scale. Default setting clears the output to 0 V.
11	V _{REFD}	Dac A reference input .This is the reference voltage input pin for Dac D.
12	V _{OUTD}	Analog Output Voltage from DAC D. The output amplifier has rail-to-rail operation.
13	V _{OUTB}	Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
14	GND	Ground Reference Point for All Circuitry on the Part.
15	DIN	Serial Data Input. This device has a 32-bit shift register. Data is clocked into the register on the falling edge of the serial clock input.
16	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates of up to 50 MHz.

TERMINOLOGY

Relative Accuracy

For the DAC, relative accuracy, or integral nonlinearity (INL), is a measure of the maximum deviation in LSBs from a straight line passing through the endpoints of the DAC transfer function. Figure 8 shows a plot of typical INL vs. code.

Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ± 1 LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. Figure 9 shows a plot of typical DNL vs. code.

Offset Error

Offset error is a measure of the difference between the actual V_{OUT} and the ideal V_{OUT} , expressed in millivolts in the linear region of the transfer function. Offset error is measured on the AD5064 with Code 200 loaded into the DAC register. It can be negative or positive and is expressed in millivolts.

Zero-Code Error

Zero-code error is a measure of the output error when zero code (0x0000) is loaded into the DAC register. Ideally, the output should be 0 V. The zero-code error is always positive in the AD5064, because the output of the DAC cannot go below 0 V. It is due to a combination of the offset errors in the DAC and output amplifier. Zero-code error is expressed in millivolts. Figure 17 shows a plot of typical zero-code error vs. Supply.

Gain Error

Gain error is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from the ideal, expressed as a percentage of the full-scale range.

Zero-Code Error Drift

Zero-code error drift is a measure of the change in zero-code error with a change in temperature. It is expressed in $\mu\text{V}/^\circ\text{C}$.

Gain Temperature Coefficient

Gain error drift is a measure of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range)/ $^\circ\text{C}$.

Full-Scale Error

Full-scale error is a measure of the output error when full-scale code (0xFFFF) is loaded into the DAC register. Ideally, the output should be $V_{DD} - 1$ LSB. Full-scale error is expressed as a percentage of the full-scale range.

Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-s and is measured when the digital input code is changed by 1 LSB at the major carry transition (0x7FFF to 0x8000). See Figure 31 and Figure 36.

DC Power Supply Rejection Ratio (PSRR)

PSRR indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in V_{OUT} to a change in V_{DD} for full-scale output of the DAC. It is measured in decibels. V_{REF} is held at 2 V, and V_{DD} is varied $\pm 10\%$.

DC Crosstalk

DC crosstalk is the dc change in the output level of one DAC in response to a change in the output of another DAC. It is measured with a full-scale output change on one DAC (or soft power-down and power-up) while monitoring another DAC kept at midscale. It is expressed in microvolts.

DC crosstalk due to load current change is a measure of the impact that a change in load current on one DAC has to another DAC kept at midscale. It is expressed in microvolts per milliamp.

Reference Feedthrough

Reference feedthrough is the ratio of the amplitude of the signal at the DAC output to the reference input when the DAC output is not being updated (that is, $\overline{\text{LDAC}}$ is high). It is expressed in decibels.

Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of a DAC from the digital input pins of the device, but is measured when the DAC is not being written to ($\overline{\text{SYNC}}$ held high). It is specified in nV-s and measured with a full-scale change on the digital input pins, that is, from all 0s to all 1s or vice versa.

Digital Crosstalk

Digital crosstalk is the glitch impulse transferred to the output of one DAC at midscale in response to a full-scale code change (all 0s to all 1s or vice versa) in the input register of another DAC. It is measured in standalone mode and is expressed in nV-s.

Analog Crosstalk

Analog crosstalk is the glitch impulse transferred to the output of one DAC due to a change in the output of another DAC. It is measured by loading one of the input registers with a full-scale code change (all 0s to all 1s or vice versa) while keeping $\overline{\text{LDAC}}$ high, and then pulsing $\overline{\text{LDAC}}$ low and monitoring the output of the DAC whose digital code has not changed. The area of the glitch is expressed in nV-s.

DAC-to-DAC Crosstalk

DAC-to-DAC crosstalk is the glitch impulse transferred to the output of one DAC due to a digital code change and subsequent output change of another DAC. This includes both digital and analog crosstalk. It is measured by loading one of the DACs with a full-scale code change (all 0s to all 1s or vice versa) with $\overline{\text{LDAC}}$ low and monitoring the output of another DAC. The energy of the glitch is expressed in nV-s.

Multiplying Bandwidth

The amplifiers within the DAC have a finite bandwidth. The multiplying bandwidth is a measure of this. A sine wave on the reference (with full-scale code loaded to the DAC) appears on the output. The multiplying bandwidth is the frequency at which the output amplitude falls to 3 dB below the input.

Total Harmonic Distortion (THD)

Total harmonic distortion is the difference between an ideal sine wave and its attenuated version using the DAC. The sine wave is used as the reference for the DAC, and the THD is a measure of the harmonics present on the DAC output. It is measured in decibels.

THEORY OF OPERATION

D/A SECTION

The AD5024/44/64 are single 12-/14 and 16-bit, serial input, voltage output DACs. The parts operate from supply voltages of 2.7 V to 5.5 V. Data is written to the AD5024/44/64 in a 32-bit word format via a 3-wire serial interface. The AD5024/44 and AD5064 incorporate a power-on reset circuit that ensures the DAC output powers up to a known out-put state. The devices also have a software power-down mode that reduces the typical current consumption to less than 1 μ A.

Because the input coding to the DAC is straight binary, the ideal output voltage when using an external reference is given by

$$V_{OUT} = V_{REFIN} \times \left(\frac{D}{2^N} \right)$$

where:

D = decimal equivalent of the binary code that is loaded to the DAC register. 0 to 65,535 for AD5064 (16 bits). N = the DAC resolution.

DAC ARCHITECTURE

The DAC architecture of the AD5064 consists of two matched DAC sections. A simplified circuit diagram is shown in Figure 43. The four MSBs of the 16-bit data word are decoded to drive 15 switches, E1 to E15. Each of these switches connects one of 15 matched resistors to either GND or V_{REF} buffer output. The remaining 12 bits of the data word drive switches S0 to S11 of a 12-bit voltage mode R-2R ladder network.

Figure 44. Dac Ladder Structure

REFERENCE BUFFER

The AD5024/44 and AD5064 operate with an external reference. Depending upon the device model (see Figure 6, Figure 7 and the Ordering Guide), the Package will either have a single common voltage reference pin that is connected to all four DACs or alternatively each DAC will have a dedicated voltage reference pin. In either case the reference input pin has an input range of 2 V to V_{DD} . This input voltage is then used to provide a buffered reference for the DAC core.

OUTPUT AMPLIFIER

The output buffer amplifier can generate rail-to-rail voltages on its output, which gives an output range of 0 V to V_{DD} . The amplifier is capable of driving a load of 5 k Ω in parallel with 1,000 pF to GND. The source and sink capabilities of the output amplifier can be seen in (TBD) and (TBD). The slew rate is 1.5 V/ μ s with a 1/4 to 3/4 scale settling time of 10 μ s.

SERIAL INTERFACE

The AD5024/44/64 has a 3-wire serial interface (\overline{SYNC} , SCLK, and DIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards as well as most DSPs. See Figure 4 for a timing diagram of a typical write sequence.

STANDALONE MODE

The write sequence begins by bringing the \overline{SYNC} line low. Data from the DIN line is clocked into the 32-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high as 50 MHz, making the AD5024/44/64 compatible with high speed DSPs. On the 32nd falling clock edge, the last data bit is clocked in and the programmed function is executed, that is, a change in DAC register contents and/or a change in the mode of operation. At this stage, the \overline{SYNC} line can be kept low or be brought high. In either case, it must be brought high for a minimum of 15 ns before the next write sequence so that a falling edge of \overline{SYNC} can initiate the next write sequence. Because the \overline{SYNC} buffer draws more current when $V_{IN} = 2$ V than it does when $V_{IN} = 0.8$ V, \overline{SYNC} should be idled low between write sequences for even lower power operation of the part. As is mentioned previously, however, \overline{SYNC} must be brought high again just before the next write sequence.

Table 8. Command Definitions

Command				Description
C3	C2	C1	C0	
0	0	0	0	Write to Input Register n
0	0	0	1	Update DAC Register n
0	0	1	0	Write to Input Register n, update all (software LDAC)
0	0	1	1	Write to and update DAC Channel n
0	1	0	0	Power down/power up DAC
0	1	0	1	Load clear code register
0	1	1	0	Load \overline{LDAC} register
0	1	1	1	Reset (power-on reset)
1	0	0	0	Set up DCEN register ¹ (Daisy chain enable)
1	0	0	1	Reserved
1	1	1	1	Reserved

¹ Available in AD5024/44/64 16 TSSOP package only.

Table 9. Address Commands

Address (n)				Selected DAC Channel
A3	A2	A1	A0	
0	0	0	0	DAC A
0	0	0	1	DAC B
0	0	1	0	DAC C
0	0	1	1	DAC D
1	1	1	1	All DACs

INPUT SHIFT REGISTER

The AD5024/44/64 input shift register is 32 bits wide (see Figure 45). The first four bits don't cares. The next four bits are the command bits, C3 to C0 (see Table 9), followed by the 4-bit DAC address bits, A3 to A0 (see Table 10) and finally the bit data-word. The data-word comprises either 12-/14 or 16-bit input code followed by 8-/6 or 4 don't care bits for the AD5024/44/64 (see Figure 45). These data bits are transferred to the DAC register on the 32nd falling edge of SCLK.

SYNC INTERRUPT

In a normal write sequence, the $\overline{\text{SYNC}}$ line is kept low for at least 32 falling edges of SCLK, and the DAC is updated on the 32nd falling edge. However, if $\overline{\text{SYNC}}$ is brought high before the 32nd falling edge, this acts as an interrupt to the write sequence. The shift register is reset, and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs (see Figure 48).

Figure 45. AD5064 Input Register Content

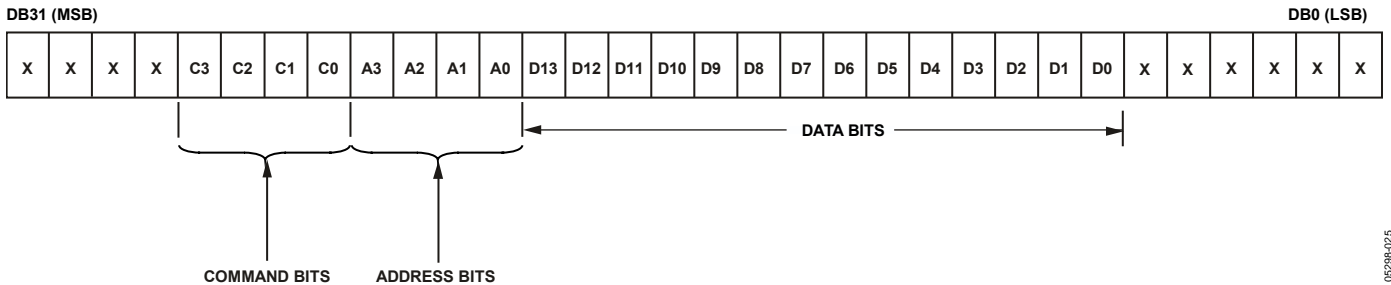

Figure 46. AD5044 Input Register Content

Figure 48. $\overline{\text{SYNC}}$ Interrupt Facility

DAISY-CHAINING

For systems that contain several DACs, or where the user wishes to read back the DAC contents for diagnostic purposes, the SDO pin (pin available in 14-Lead AD5024/44/64 only see Ordering Guide) can be used to daisy-chain several devices together and provide serial read-back.

The daisy-chain mode is enabled through a software executable DCEN command. Command 1000 is reserved for this DCEN function (see Table 8). The daisy-chain mode is enabled by setting a bit (DB1) in the DCEN register. The default setting is standalone mode, where Bit DCEN = 0. Table 10 shows how the state of the bits corresponds to the mode of operation of the device.

The SCLK is continuously applied to the input shift register when SYNC is low. If more than 32 clock pulses are applied, the data ripples out of the shift register and appears on the SDO line. This data is clocked out on the rising edge of SCLK and is valid on the falling edge. By connecting this line to the DIN input on the next DAC in the chain, a multi-DAC interface is constructed. Each DAC in the system requires 32 clock pulses; therefore, the total number of clock cycles must equal 32N, where N is the total number of devices in the chain.

When the serial transfer to all devices is complete, SYNC is taken high. This prevents any further data from being clocked into the input shift register.

If SYNC is taken high before 32 clocks are clocked into the part, it is considered an invalid frame and the data is discarded.

The serial clock can be continuous or a gated clock. A continuous SCLK source can be used only if the SYNC can be held low for the correct number of clock cycles. In gated clock mode, a burst clock containing the exact number of clock cycles must be used, and SYNC must be taken high after the final clock to latch the data.

POWER-ON RESET

The AD5024/44/64 contains a power-on reset circuit that controls the output voltage during power-up. By connecting the POR pin low, the AD5666 output powers up to 0 V; by connecting the POR pin high, the AD5024/44/64 output powers up to midscale. The output remains powered up at this level until a valid write sequence is made to the DAC. This is useful in applications where it is important to know the state of the output of the DAC while it is in the process of powering up. There is also a software executable reset function that resets the DAC to the power-on reset code. Command 0111 is reserved for this reset function (see Table 8). Any events on LDAC or CLR during power-on reset are ignored.

POWER-DOWN MODES

The AD5024/44/64 contains four separate modes of operation. Command 0100 is reserved for the power-down function (see Table 8). These modes are software-programmable by setting two bits, Bit DB9 and Bit DB8, in the control register (refer to Table 13). Table 12 shows how the state of the bits corresponds to the mode of operation of the device. Any or all DACs (DAC D to DAC A) can be powered down to the selected mode by setting the corresponding four bits (DB3, DB2, DB1, DB0) to 1. See Table 13 for the contents of the input shift register during power-down/ power-up operation.

When both Bit DB9 and Bit DB8, in the control register are set to 0, the part works normally with its normal power consumption of TBD at 5 V. However, for the three power-down modes, the supply current falls to TBD at 5 V (TBD at 3 V). Not only does the supply current fall, but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode. There are three different options. The output is connected internally to GND through either a 1 kΩ or a 100 kΩ resistor, or it is left open-circuited (three-state). The output stage is illustrated in Figure 49.

The bias generator, output amplifier, resistor string, and other associated linear circuitry are shut down when the power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 2.5 μs for V_{DD} = 5 V and V_{DD} = 3 V (see Figure 30).

Any combination of DACs can be powered up by setting PD1 and PD0 to 0 (normal operation). The output powers up to the value in the input register (LDAC Low) or to the value in the DAC register before powering down (LDAC high).

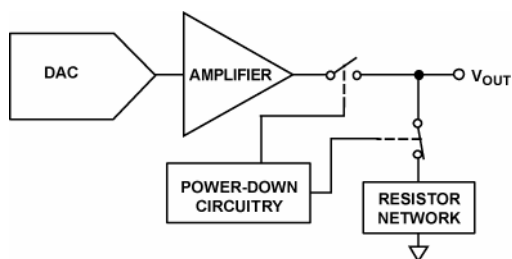

Figure 49. Output Stage During Power-Down

CLEAR CODE REGISTER

The AD5024/44/64 has a hardware $\overline{\text{CLR}}$ pin that is an asynchronous clear input. The $\overline{\text{CLR}}$ input is falling edge sensitive. Bringing the $\overline{\text{CLR}}$ line low clears the contents of the input register and the DAC registers to the data contained in the user-configurable $\overline{\text{CLR}}$ register and sets the analog outputs accordingly. (see **Table 14**) This function can be used in system calibration to load zero scale, midscale, or full scale to all channels together. These clear code values are user-programmable by setting two bits, Bit DB1 and Bit DB0, in the control register (see **Table 14**). The default setting clears the outputs to 0 V. Command 0101 is reserved for loading the clear code register (see **Table 8**).

The part exits clear code mode on the 32nd falling edge of the next write to the part. If $\overline{\text{CLR}}$ is activated during a write sequence, the write is aborted.

The $\overline{\text{CLR}}$ pulse activation time—the falling edge of $\overline{\text{CLR}}$ to when the output starts to change—is typically **TBD** ns. However, if outside the DAC linear region, it typically takes **TBD** ns after executing $\overline{\text{CLR}}$ for the output to start changing (see **Figure 40**).

See **Table 15** for contents of the input shift register during the loading clear code register operation

LDAC FUNCTION

The outputs of all DACs can be updated simultaneously using the hardware $\overline{\text{LDAC}}$ pin.

Synchronous $\overline{\text{LDAC}}$: After new data is read, the DAC registers are updated on the falling edge of the 32nd SCLK pulse. $\overline{\text{LDAC}}$ can be permanently low or pulsed as in **Figure 4**

Asynchronous $\overline{\text{LDAC}}$: The outputs are not updated at the same time that the input registers are written to. When $\overline{\text{LDAC}}$ goes low, the DAC registers are updated with the contents of the input register.

Alternatively, the outputs of all DACs can be updated simultaneously using the software $\overline{\text{LDAC}}$ function by writing to Input Register n and updating all DAC registers. Command 0010 is reserved for this software $\overline{\text{LDAC}}$ function.

An $\overline{\text{LDAC}}$ register gives the user extra flexibility and control over the hardware $\overline{\text{LDAC}}$ pin. This register allows the user to select which combination of channels to simultaneously update when the hardware $\overline{\text{LDAC}}$ pin is executed. Setting the $\overline{\text{LDAC}}$ bit register to 0 for a DAC channel means that this channel's update is controlled by the $\overline{\text{LDAC}}$ pin. If this bit is set to 1, this channel

updates synchronously; that is, the DAC register is updated after new data is read, regardless of the state of the $\overline{\text{LDAC}}$ pin. It effectively sees the $\overline{\text{LDAC}}$ pin as being tied low. (See **Table 16** for the $\overline{\text{LDAC}}$ register mode of operation.) This flexibility is useful in applications where the user wants to simultaneously update select channels while the rest of the channels are synchronously updating.

Writing to the DAC using command 0110 loads the 4-bit $\overline{\text{LDAC}}$ register (DB3 to DB0). The default for each channel is 0; that is, the $\overline{\text{LDAC}}$ pin works normally. Setting the bits to 1 means the DAC channel is updated regardless of the state of the $\overline{\text{LDAC}}$ pin. See **Table 17** for the contents of the input shift register during the load $\overline{\text{LDAC}}$ register mode of operation.

POWER SUPPLY BYPASSING AND GROUNDING

When accuracy is important in a circuit, it is helpful to carefully consider the power supply and ground return layout on the board. The printed circuit board containing the AD5666 should have separate analog and digital sections. If the AD5666 is in a system where other devices require an AGND-to-DGND connection, the connection should be made at one point only. This ground point should be as close as possible to the AD5666.

The power supply to the AD5024/44/64 should be bypassed with 10 μF and 0.1 μF capacitors. The capacitors should physically be as close as possible to the device, with the 0.1 μF capacitor ideally right up against the device. The 10 μF capacitors are the tantalum bead type. It is important that the 0.1 μF capacitor has low effective series resistance (ESR) and low effective series inductance (ESI), such as is typical of common ceramic types of capacitors. This 0.1 μF capacitor provides a low impedance path to ground for high frequencies caused by transient currents due to internal logic switching.

The power supply line should have as large a trace as possible to provide a low impedance path and reduce glitch effects on the supply line. Clocks and other fast switching digital signals should be shielded from other parts of the board by digital ground. Avoid crossover of digital and analog signals if possible. When traces cross on opposite sides of the board, ensure that they run at right angles to each other to reduce feedthrough effects through the board. The best board layout technique is the microstrip technique, where the component side of the board is dedicated to the ground plane only and the signal traces are placed on the solder side. However, this is not always possible with a 2-layer board.

MICROPROCESSOR INTERFACING

AD5024/44/6 to Blackfin® ADSP-BF53X Interface

Figure 50 shows a serial interface between the AD5024/44/64 and the *Blackfin ADSP-BF53X* microprocessor. The ADSP-BF53X processor family incorporates two dual-channel synchronous serial ports, SPORT1 and SPORT0, for serial and multiprocessor communications. Using SPORT0 to connect to the AD5623R/AD5643/AD5663R, the setup for the interface is as follows: DTOPRI drives the DIN pin of the AD5623R/AD5643/AD5663R, while TSCLK0 drives the SCLK of the parts. The SYNC is driven from TFS0.

¹ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 50. AD5024/44/64 to Blackfin ADSP-BF53X Interface

AD5024/44/64 to 68HC11/68L11 Interface

Figure 51 shows a serial interface between the AD5024/44/64 and the 68HC11/68L11 microcontroller. SCK of the 68HC11/68L11 drives the SCLK of the AD5024/44/64, and the MOSI output drives the serial data line of the DAC.

¹ADDITIONAL PINS OMITTED FOR CLARITY.

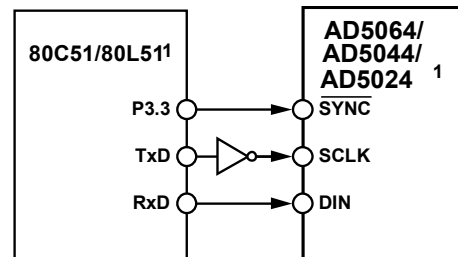

Figure 51. AD5024/44/64 to 68HC11/68L11 Interface

The SYNC signal is derived from a port line (PC7). The setup conditions for correct operation of this interface are as follows: The 68HC11/68L11 is configured with its CPOL bit as 0, and its CPHA bit as 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured as described previously, data appearing on the MOSI output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. To load data to the AD5024/44/64, PC7 is left low after the first eight bits are transferred, and a second

serial write operation is performed to the DAC. PC7 is taken high at the end of this procedure.

AD5024/44/64 to 80C51/80L51 Interface

Figure 52 shows a serial interface between the AD5024/44/64 and the 80C51/80L51 microcontroller. The setup for the interface is as follows: TxD of the 80C51/80L51 drives SCLK of the AD5024/44/64, and RxD drives the serial data line of the part. The SYNC signal is again derived from a bit-programmable pin on the port. In this case, Port Line P3.3 is used. When data is to be transmitted to the AD5024/44/64, P3.3 is taken low. The 80C51/80L51 transmit data in 8-bit bytes only; thus, only eight falling clock edges occur in the transmit cycle. To load data to the DAC, P3.3 is left low after the first eight bits are transmitted, and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken high following the completion of this cycle. The 80C51/80L51 output the serial data in a format that has the LSB first. The AD5024/44/64 must receive data with the MSB first. The 80C51/80L51 transmit routine should take this into account.

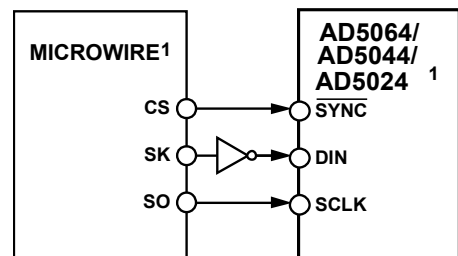

¹ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 52. AD5024/44/64 to 80C51/80L51 Interface

AD5024/44/6 to MICROWIRE Interface

Figure 53 shows an interface between the AD5024/44/64 and any MICROWIRE-compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the AD5024/44/64 on the rising edge of the SCLK.

¹ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 53. AD5024/44/64 to MICROWIRE Interface

APPLICATIONS

USING A REFERENCE AS A POWER SUPPLY FOR THE AD5024/44/64

Because the supply current required by the AD5024/44/64 is extremely low, an alternative option is to use a voltage reference to supply the required voltage to the parts (see Figure 54). This is especially useful if the power supply is quite noisy or if the system supply voltages are at some value other than 5 V or 3 V, for example, 15 V. The voltage reference outputs a steady supply voltage for the AD5024, AD5044 and AD5064. If the low dropout REF195 is used, it must supply 500 μA of current to the AD5024/ AD5044 / AD5064, with no load on the output of the DAC. When the DAC output is loaded, the REF195 also needs to supply the current to the load. The total current required (with a 5 kΩ load on the DAC output) is

$$500 \mu\text{A} + (5 \text{ V}/5 \text{ k}\Omega) = 1.5 \text{ mA}$$

The load regulation of the REF195 is typically 2 ppm/mA, which results in a 3 ppm (15 μV) error for the 1.5 mA current drawn from it. This corresponds to a 0.196 LSB error.

Figure 54. REF195 as Power Supply to the AD5024/44/64

BIPOLAR OPERATION USING THE AD5024/44/64

The AD5024/44/64 has been designed for single-supply operation, but a bipolar output range is also possible using the circuit in Figure 55. The circuit gives an output voltage range of ±5 V. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

The output voltage for any input code can be calculated as follows:

$$V_o = \left[V_{DD} \times \left(\frac{D}{65,536} \right) \times \left(\frac{R1 + R2}{R1} \right) - V_{DD} \times \left(\frac{R2}{R1} \right) \right]$$

where *D* represents the input code in decimal (0 to 65,535). With $V_{DD} = 5 \text{ V}$, $R1 = R2 = 10 \text{ k}\Omega$,

$$V_o = \left(\frac{10 \times D}{65,536} \right) - 5 \text{ V}$$

This is an output voltage range of ±5 V, with 0x0000 corresponding to a −5 V output, and 0xFFFF corresponding to a +5 V output.

Figure 55. Bipolar Operation with the AD5024/44/64

USING THE AD5024/44/64 WITH A GALVANICALLY ISOLATED INTERFACE

In process control applications in industrial environments, it is often necessary to use a galvanically isolated interface to protect and isolate the controlling circuitry from any hazardous common-mode voltages that can occur in the area where the DAC is functioning. *iCoupler*® provides isolation in excess of 2.5 kV. The AD5024/44/64 uses a 3-wire serial logic interface, so the ADuM1300 three-channel digital isolator provides the required isolation (see Figure 56). The power supply to the part also needs to be isolated, which is done by using a transformer. On the DAC side of the transformer, a 5 V regulator provides the 5 V supply required for the AD5024/44/64.
