

### FEATURES

Stereo, 24-bit analog-to-digital and digital-to-analog converters

DAC SNR: 100 dB (A-weighted), THD: -80 dB at 48 kHz, 3.3 V

ADC SNR: 90 dB (A-weighted), THD: -80 dB at 48 kHz, 3.3 V

Highly efficient headphone amplifier

Stereo line input and monaural microphone input

Low power

7 mW stereo playback (1.8 V/1.5 V supplies)

14 mW record and playback (1.8 V/1.5 V supplies)

Low supply voltages

Analog: 1.8 V to 3.6 V

Digital core: 1.5 V to 3.6 V

Digital I/O: 1.8 V to 3.6 V

256/384 oversampling rate in normal mode; 250/272 oversampling rate in USB mode

Audio sampling rates: 8 kHz, 11.025 kHz, 12 kHz, 16 kHz, 22.05 kHz, 24 kHz, 32 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, and 96 kHz

28-lead, 5 mm × 5 mm LFCSP (QFN) package

### APPLICATIONS

Mobile phones

MP3 players

Portable gaming

Portable electronics

Educational toys

### GENERAL DESCRIPTION

The SSM2602 is a low power, high quality stereo audio codec for portable digital audio applications with one set of stereo programmable gain amplifier (PGA) line inputs and one monaural microphone input. It features two 24-bit analog-to-digital converter (ADC) channels and two 24-bit digital-to-analog (DAC) converter channels.

The SSM2602 can operate as a master or a slave. It supports various master clock frequencies, including 12 MHz or 24 MHz for USB devices; standard 256  $f_s$  or 384  $f_s$  based rates, such as 12.288 MHz and 24.576 MHz; and many common audio sampling rates, such as 96 kHz, 88.2 kHz, 48 kHz, 44.1 kHz, 32 kHz, 24 kHz, 22.05 kHz, 16 kHz, 12 kHz, 11.025 kHz, and 8 kHz.

The SSM2602 can operate at power supplies as low as 1.8 V for the analog circuitry and as low as 1.5 V for the digital circuitry. The maximum voltage supply is 3.6 V for all supplies.

The SSM2602 software-programmable stereo output options provide the user with many application possibilities because the device can be used as a headphone driver or as a speaker driver. Its volume control functions provide a large range of gain control of the audio signal.

The SSM2602 is specified over the industrial temperature range of -40°C to +85°C. It is available in a 28-lead, 5 mm × 5 mm lead frame chip scale package (LFCSP).

## ABSOLUTE MAXIMUM RATINGS

At 25°C, unless otherwise noted.

Table 8.

Parameter	Rating
Supply Voltage	5 V
Input Voltage	$V_{DD}$
Common-Mode Input Voltage	$V_{DD}$
Storage Temperature Range	-65°C to +150°C
Operating Temperature Range	-40°C to +85°C
Junction Temperature Range	-65°C to +165°C
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 9. Thermal Resistance

Package Type	$\theta_{JA}$	$\theta_{JC}$	Unit
28-Lead, 5 mm × 5 mm LFCSP	28	32	°C/W

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

## THEORY OF OPERATION

### DIGITAL CORE

Inside the SSM2602 digital core is one central clock source, called the master clock (MCLK), that produces a reference clock for all internal audio data processing and synchronization.

When using an external clock source to drive the MCLK pin, great care should be taken to select a clock source with less than 50 ps of jitter. Without careful generation of the MCLK signal, the digital audio quality will most likely suffer.

To enable the SSM2602 to generate the central reference clock in a system, connect a crystal oscillator between the MCLK/XTI input pin and the XTO output pin.

To allow an external device to generate the central reference clock, apply the external clock signal directly through the MCLK/XTI input pin. In this configuration, the oscillator circuit of the SSM2602 can be powered down by using the OSC bit (Register R6, Bit D5) to reduce power consumption.

To accommodate applications with very high frequency master clocks, the internal core reference clock of the SSM2602 can be set to either MCLK or MCLK divided by 2. This is enabled by adjusting the setting of the CLKDIV2 bit (Register R8, Bit D6). Complementary to this feature, the CLKOUT pin can also drive external clock sources with either the core clock signal or core clock divided by 2 by enabling the CLKODIV2 bit (Register R8, Bit D7).

### ADC AND DAC

The SSM2602 contains a pair of oversampling  $\Sigma$ - $\Delta$  ADCs. The maximum ADC full-scale input level is 1.0 V rms when AVDD = 3.3 V. If the input signal to the ADC exceeds this level, data overloading occurs and causes audible distortion.

The ADC can accept analog audio input from either the stereo line inputs or the monaural microphone input. Note that the ADC can only accept input from a single source, so the user

must choose either the line inputs or the microphone input as the source using the INSEL bit (Register R4, Bit D2). The digital data from the ADC output, once converted, is processed using the ADC filters.

Complementary to the ADC channels, the SSM2602 contains a pair of oversampling  $\Sigma$ - $\Delta$  DACs that convert the digital audio data from the internal DAC filters into an analog audio signal. The DAC output can also be muted by setting the DACMU bit (Register R5, Bit D3) in the control register.

### ADC HIGH-PASS AND DAC DE-EMPHASIS FILTERS

The ADC and DAC employ separate digital filters that perform 24-bit signal processing. The digital filters are used for both record and playback modes and are optimized for each individual sampling rate used.

For recording mode operations, the unprocessed data from the ADC enters the ADC filters and is converted to the appropriate sampling frequency, and then is output to the digital audio interface.

For playback mode operations, the DAC filters convert the digital audio interface data to oversampled data, using a sampling rate selected by the user. The oversampled data is processed by the DAC and then is sent to the analog output mixer by enabling the DACSEL (Register R4, Bit D4).

Users have the option of setting up the device so that any dc offset in the input source signal is automatically detected and removed. To accomplish this, enable the digital high-pass filter (see Table 2 for characteristics) contained in the ADC digital filters by using the ADCHPF bit (Register R5, Bit D0).

In addition, users can implement digital de-emphasis by using the DEEMPH bits (Register R5, Bit D1 and Bit D2).

## AUTOMATIC LEVEL CONTROL (ALC)

The SSM2602 codec has an automatic level control (ALC) that can be activated to suppress clipping and improve dynamic range even if a sudden, loud input signal is introduced. This is achieved by continuously adjusting the PGA gain so that the signal level at the ADC input remains constant.

### Decay (Gain Ramp-Up) Time

Decay time is the time taken for the PGA gain to ramp up to 90% of its range. The time for the recording level to return to its target value, therefore, depends on both the decay time and the gain adjustment required. If the gain adjustment is small, the time to return to the target value will be less than the decay time.

### Attack (Gain Ramp-Down) Time

Attack time is the time taken for the PGA gain to ramp down through 90% of its range. The time for the recording level to

return to its target value, therefore, depends on both the attack time and the gain adjustment required. If the gain adjustment is small, the time to return to the target value will be less than the attack time.

### Noise Gate

When the ALC function is enabled but the input signal is silent for long periods, an audible hissing sound may be introduced by a phenomenon called noise pumping. To prevent this occurrence, the SSM2602 employs a noise gate function. A user-selected threshold can be set by using the NGTH bits (Register R18, Bit D3 to Bit D7). When the noise gate is enabled, the ADC output is either muted or held at a constant gain to prevent the noise-pumping phenomenon. For more information about the noise gate settings, see Table 42.

# SSM2602

## ANALOG INTERFACE

### Signal Chain

The SSM2602 includes stereo single-ended line and monaural microphone inputs to the on-board ADC. Either the line inputs or the microphone input, but not both simultaneously, can be connected to the ADC by setting the INSEL bit (Register R4, Bit D2). In addition, the line or microphone inputs can be routed and mixed directly to the output terminals via the SIDETONE\_EN (Register R4, Bit D5) and BYPASS (Register R4, Bit D3) bits. The SSM2602 also includes line and headphone outputs from the on-board DAC.

### Stereo Line and Monaural Microphone Inputs

The SSM2602 contains a set of single-ended stereo line inputs (RLINEIN and LLINEIN) that are internally biased to VMID by way of a voltage divider between AVDD and AGND. The line input signal can be connected to the internal ADC and, if desired, routed directly to the outputs via the bypass path by using the BYPASS bit (Register R4, Bit D3).

Figure 19. Line Input to ADC

The line input volume can be adjusted from  $-34.5$  dB to  $+33$  dB in steps of  $+1.5$  dB by setting the LINVOL (Register R0, Bit D0 to Bit D5) and RINVOL (Register R1, Bit D0 to Bit D5) bits. Volume control, by default, is independently adjustable on both right and left line inputs. However, the LRINBOTH or RLINBOTH bit, if selected, simultaneously loads both sets of volume control with the same value. The user can also set the LINMUTE (Register R0, Bit D7) and RINMUTE (Register R1, Bit D7) bits to mute the line input signal to the ADC.

The high impedance, low capacitance monaural microphone input pin (MICIN) has two gain stages and a microphone bias level (MICBIAS) that is internally biased to the VMID voltage level by way of a voltage divider between AVDD and AGND. The microphone input signal can be connected to the internal ADC and, if desired, routed directly to the outputs via the sidetone path by using the SIDETONE\_EN bit (Register R4, Bit D5).

Figure 20. Microphone Input to ADC

The first gain stage is composed of a low noise operational amplifier set to an inverting configuration with integrated  $50$  k $\Omega$  feedback and  $10$  k $\Omega$  input resistors. The default microphone input signal gain is  $14$  dB. An external resistor ( $R_{EXT}$ ) can be connected in series with the MICIN pin to reduce the first-stage gain of the microphone input signal to as low as  $0$  dB by using the following equation:

$$\text{Microphone Input Gain} = 50 \text{ k}\Omega / (10 \text{ k}\Omega + R_{EXT})$$

The second-stage gain of the microphone signal path is derived from the internal microphone boost circuitry. The available settings are  $0$  dB,  $20$  dB, and  $40$  dB and are controlled by the MICBOOST (Register R4, Bit D0) and MICBOOST2 (Register R4, Bit D8) bits. To achieve  $20$  dB of secondary gain boost, the user can select either MICBOOST or MICBOOST2. To achieve  $40$  dB of secondary microphone signal gain, the user must select both MICBOOST and MICBOOST2.

In similar functionality to the line inputs, the user can set the MUTEMIC bit (Register R4, Bit D1) to mute the microphone input signal to the ADC.

Note that when sourcing audio data from both line and microphone inputs, the maximum full-scale input of the ADC is  $1.0$  V rms when  $AVDD = 3.3$  V. Do not source any input voltage larger than full scale to avoid overloading the ADC, which causes distortion of sound and deterioration of audio quality. For best sound quality in both microphone and line inputs, gain should be carefully configured so that the ADC receives a signal equal to its full scale. This maximizes the signal-to-noise ratio for best total audio quality.

### Bypass and Sidetone Paths to Output

The line and microphone inputs can be routed and mixed directly to the output terminals via the SIDETONE\_EN (Register R4, Bit D5) and BYPASS (Register R4, Bit D3) software control register selections. In both of these modes, the analog input signal is routed directly to the output terminals and is not digitally converted. The bypass signal at the output mixer is the same level as the output of the PGA associated with each line input.

The sidetone signal at the output mixer must be attenuated by a range of  $-6$  dB to  $-15$  dB in steps of  $-3$  dB by configuring the SIDETONE\_ATT (Register R4, Bit D6 and Bit D7) control register bits. The selected level of attenuation occurs after the initial microphone signal amplification from the microphone first- and second-stage gains.

### Line and Headphone Outputs

The DAC outputs, the microphone (the sidetone path), and the line inputs (the bypass path) are summed at an output mixer. This output signal can be present at both the stereo line outputs and stereo headphone outputs.

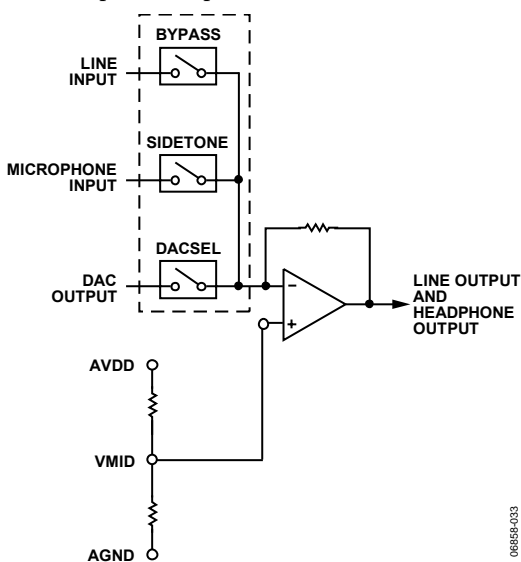

Figure 21. Output Signal Chain

The SSM2602 has a set of efficient headphone amplifier outputs, LHPOUT and RHPOUT, that are able to drive  $16 \Omega$  or  $32 \Omega$  headphone speakers.

Figure 22. Headphone Output

In similar functionality to the line inputs, the LHPOUT and RHPOUT volumes, by default, are independently adjusted by setting the LHPVOL (Register R2, Bit D0 to Bit D6) and RHPVOL (Register R3, Bit D0 to Bit D6) bits of the headphone output control registers. The headphone outputs can be muted by writing codes less than 0110000 to the LHPVOL and RHPVOL bits. The user is also able to simultaneously load the volume control of both channels by writing to the LRHPBOTH (Register R2, Bit D8) and RLHPBOTH (Register R3, Bit D8) bits of the left- and right-channel DAC volume registers.

The maximum output level of the headphone outputs is  $1.0$  V rms when  $AVDD$  and  $HPVDD = 3.3$  V. To suppress audible pops and clicks, the headphone and line outputs are held at the VMID dc voltage level when the device is set to standby mode or in the event that the headphone outputs are muted.

The stereo line outputs of the SSM2602, the LOUT and ROUT pins, are able to drive a load impedance of  $10 \text{ k}\Omega$  and  $50 \text{ pF}$ . The line output signal levels are not adjustable at the output mixer, having a fixed gain of  $0$  dB. The maximum output level of the line outputs is  $1.0$  V rms when  $AVDD = 3.3$  V.

# SSM2602

## DIGITAL AUDIO INTERFACE

The digital audio input can support the following four digital audio communication protocols: right-justified mode, left-justified mode, I<sup>2</sup>S mode, and digital-signal processor (DSP) mode.

The mode selection is performed by writing to the FORMAT bits of the digital audio interface register (Register R7, Bit D1 and Bit D0). All modes are MSB first and operate with data of 16 to 32 bits.

### Recording Mode

On the RECDAT output pin, the digital audio interface can send digital audio data for recording mode operation. The digital audio interface outputs the processed internal ADC digital filter data onto the RECDAT output. The digital audio data stream on RECDAT comprises left- and right-channel audio data that is time domain multiplexed.

The RECLRC is the digital audio frame clock signal that separates left- and right-channel data on the RECDAT lines.

The BCLK signal acts as the digital audio clock. Depending on if the SSM2602 is in master or slave mode, the BCLK signal is either an input or an output signal. During a recording operation, RECDAT and RECLRC must be synchronous to the BCLK signal to avoid data corruption.

### Playback Mode

On the PBDAT input pin, the digital audio interface can receive digital audio data for playback mode operation. The digital audio data stream on PBDAT comprises left- and right-channel audio data that is time domain multiplexed. The PBLRC is the digital audio frame clock signal that separates left- and right-channel data on the PBDAT lines.

The BCLK signal acts as the digital audio clock. Depending on if the SSM2602 is in master or slave mode, the BCLK signal is either an input or an output signal. During a playback operation, PBDAT and PBLRC must be synchronous to the BCLK signal to avoid data corruption.

## Digital Audio Data Sampling Rate

To accommodate a wide variety of commonly used DAC and ADC sampling rates, the SSM2602 allows for two modes of operation, normal and USB, selected by the USB bit (Register R8, Bit D0).

In normal mode, the SSM2602 supports digital audio sampling rates from 8 kHz to 96 kHz. Normal mode supports 256 f<sub>s</sub> and 384 f<sub>s</sub> based clocks. To select the desired sampling rate, the user must set the appropriate sampling rate register in the SR control bits (Register R8, Bit D2 to Bit D5) and match this selection to the core clock frequency that is pulsed on the MCLK pin. See Table 30 and Table 31 for guidelines.

In USB mode, the SSM2602 supports digital audio sampling rates from 8 kHz to 96 kHz. USB mode is enabled on the SSM2602 to support the common universal serial bus (USB) clock rate of 12 MHz, or to support 24 MHz if the CLKDIV2 control register bit is activated. The user must set the appropriate sampling rate in the SR control bits (Register R8, Bit D2 to Bit D5). See Table 30 and Table 31 for guidelines.

Note that the sampling rate is generated as a fixed divider from the MCLK signal. Because all audio processing references the core MCLK signal, corruption of this signal, in turn, corrupts the outgoing audio quality of the SSM2602. The BCLK/RECLRC/RECDAT or BCLK/PBLRC/PBDAT signals must be synchronized with MCLK in the digital audio interface circuit. MCLK must be faster or equal to the BCLK frequency to guarantee that no data is lost during data synchronization.

The BCLK frequency should be greater than

$$\text{Sampling Rate} \times \text{Word Length} \times 2$$

Ensuring that the BCLK frequency is greater than this value guarantees that all valid data bits are captured by the digital audio interface circuitry. For example, if a 32 kHz digital audio sampling rate with a 32-bit word length is desired,  $\text{BCLK} \geq 2.048 \text{ MHz}$ .

## SOFTWARE CONTROL INTERFACE

The software control interface provides access to the user-selectable control registers and can operate with a 2-wire (I<sup>2</sup>C) or 3-wire (SPI) interface, depending on the setting of the MODE pin. If the MODE pin is set to 0, the 2-wire interface is selected; if 1, the 3-wire interface is selected.

Within each control register is a control data-word consisting of 16 bits, MSB first. Bit B15 to Bit B9 are the register map address, and Bit B8 to Bit B0 are register data for the associated register map.

When 2-wire (I<sup>2</sup>C) mode is selected, SDIN generates the serial control data-word, SCLK clocks the serial data, and CSB determines the I<sup>2</sup>C device address. If the CSB pin is set to 0, the address selected is 0011010; if 1, the address is 0011011.

When 3-wire (SPI) mode is selected, SDIN generates the control data-word, SCLK clocks the control data-word into the SSM2602, and CSB latches in the control data-word.

<sup>1</sup> BCLK frequency is for master mode and slave right-justified mode only.

**ACTIVE, ADDRESS 0x09**

Table 33. Active Register Bit Map

D8	D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	0	ACTIVE

Table 34. Descriptions of Active Register Bit

Bit Name	Description	Settings
ACTIVE	Digital core activation control	0 = disable digital core (default) 1 = activate digital core

**RESET, ADDRESS 0x0F**

Table 35. Software Reset Register Bit Map

D8	D7	D6	D5	D4	D3	D2	D1	D0
RESET [8:0]								

Table 36. Descriptions of Software Reset Register Bits

Bit Name	Description	Settings
RESET [8:0]	Write all 0s to this register to set all registers to their default settings. Other data written to this register has no effect.	0 = reset (default)

# SSM2602

## ALC CONTROL 1, ADDRESS 0x10

Table 37. ALC Control 1 Register Bit Map

D8	D7	D6	D5	D4	D3	D2	D1	D0
ALCSEL [1:0]		MAXGAIN [2:0]			ALCL [[3:0]			

Table 38. Descriptions of ALC Control 1 Register Bits

Bit Name	Description	Settings
ALCSEL [1:0]	ALC select	00 = ALC disabled (default) 01 = ALC enabled on right channel only 10 = ALC enabled on left channel only 11 = ALC enabled on both channels
MAXGAIN [2:0]	PGA maximum gain	000 = -12 dB 001 = -6 dB ... 6 dB steps up to 111 = 30 dB (default)
ALCL [3:0]	ALC target level	0000 = -28.5 dBFS 0001 = -27 dBFS ... 1011 = -12 dBFS (default) ... 1.5 dB steps up to 1111 = -6 dBFS

## ALC CONTROL 2, ADDRESS 0x11

Table 39. ALC Control 2 Register Bit Map

D8	D7	D6	D5	D4	D3	D2	D1	D0
0	DCY [3:0]				ATK [3:0]			

Table 40. Descriptions of ALC Control 2 Register Bits

Bit Name	Description	Settings
DCY [3:0]	Decay (release) time control	0000 = 24 ms 0001 = 48 ms 0010 = 96 ms 0011 = 192 ms (default) ... (Time doubles with every step) 1010 = 24.576 sec
ATK [3:0]	ALC attack time control	0000 = 6 ms 0001 = 12 ms 0010 = 24 ms (default) ... (Time doubles with every step) 1010 = 6.144 sec

**NOISE GATE, ADDRESS 0x12****Table 41. Noise Gate Register Bit Map**

D8	D7	D6	D5	D4	D3	D2	D1	D0
0	NGTH [4:0]					NGG [1:0]		NGAT

**Table 42. Descriptions of Noise Gate Register Bits**

Bit Name	Description	Settings
NGTH [4:0]	Noise gate threshold	00000 = -76.5 dBFS (default) 00001 = -75 dBFS ... 1.5 dB steps up to 11110 = -31.5 dBFS 11111 = -30 dBFS
NGG [1:0]	Noise gate type	X0 = hold PGA gain constant (default) <sup>1</sup> 01 = mute output 11 = reserved
NGAT	Noise gate control	0 = noise gate disable (default) 1 = noise gate enable

<sup>1</sup> X = don't care.
