# TMC22x5yA

## Multistandard Digital Video Decoder

### Three-Line Adaptive Comb Decoder Family, 8 & 10 bit

## Features

- Very high performance, low cost
- Adaptive comb-based decoding
- Multiple pin-compatible versions
  - 3-line, 2-line, and band-split
  - 8- and 10-bit processing
- Internal digital linestores
- Supports NTSC/PAL field and NTSC frame based decoding
- Multiple input formats
  - CCIR-601/624 (D1), D2, CVBS, YC
- Multiple output formats
  - CCIR-601/624 (D1), RGB, $YC_BC_R$
- 10-18 Mpps data rate
- Parallel and serial control interface
- Single +5V power supply

## Applications

- Studio television equipment
- Personal computer video input
- MPEG and JPEG compression inputs

## Description

The TMC22x5yA family of Digital Video Decoders offers unprecedented, broadcast-quality video processing performance in a single chip. It accepts line-locked or subcarrier-locked composite, YC, or D1 digital video and produces digital components in a variety of formats.

An internal three-line adaptive comb decoder structure produces optimal picture quality with a wide range of source material. NTSC/PAL field and NTSC frame based decoding is supported with external memory. Full comb programmability allows the user to tailor the decoder's response to a particular systems goals.

A family of products offers 3-line, 2-line, and simple decoders in 8-bit and 10-bit versions—all in a pin and software-compatible format. Serial and parallel control ports are provided. These submicron CMOS devices are packaged in a 100-lead Metric Quad Flat Pack (MQFP).

## General Description

The TMC22x5yA digital decoder can be used as a universal input to digital video processing systems by decoding digital composite video and transcoding digital component inputs into a common data format.

The digital comb filter decoder implements one of sixteen comb filter architectures to produce luminance and color difference component signals which are virtually free of the cross-color and cross-luminance artifacts associated with simple bandsplit filter decoders.

**Table 1. TMC22x5yA Decoder Family**

Because the cost/performance tradeoff varies among applications, the TMC22x5yA decoder has been developed as a family of six parts. They are all assembled in the same package, and fit the same footprint. The register maps are identical.

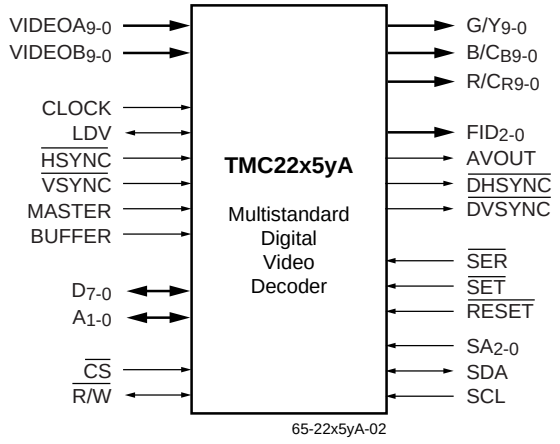

**Figure 1. Logic Symbol**

The devices come in 8- and 10-bit resolution versions (see Figure 2 for data alignment between 8- and 10-bit versions). Within each resolution version there are three models, offering three-line adaptive comb filtering, two-line adaptive comb filtering, and simple decoding. The TMC22153A 10-bit three-line comb filter can be programmed to emulate any of the other parts. All prototyping can be performed with this version to evaluate performance tradeoffs, and lower-cost versions are easily substituted in production.

### Input Processor

The digitized video and clocks provided to the decoder can be either locked to the line frequency or the subcarrier frequency of the digitized waveform, providing broadcast quality decoding from the NTSC square pixel rate of 12.27 MHz to the PAL four times subcarrier pixel rate of 17.73 MHz.

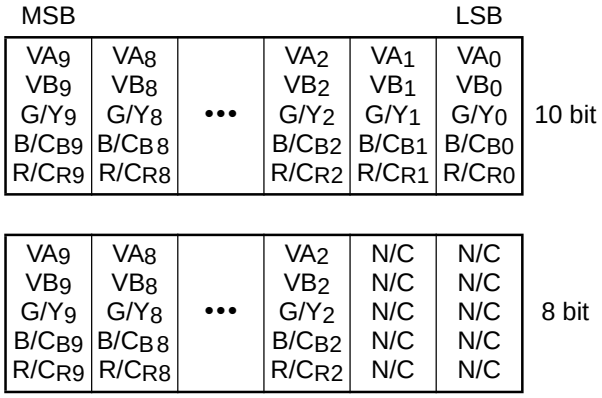

**Figure 2. Pixel Data Format**

Inputs containing embedded GRS (Fairchild Video Input Processors), TRS words (D1 multiplexed component signals), and TRS-ID words (deserialized D2 signals) can be used to lock the internal horizontal and vertical state machines to the embedded information. If this information is not provided, external horizontal and vertical syncs are required for all line-locked input formats, and are optional for NTSC inputs locked to four times the subcarrier (4*Fsc). A simple sync separator is provided for digitized inputs locked to the subcarrier frequency: the internal sync separator locks to the mid point of syncs during the vertical field group, then flywheels during the active portion of the field. For this reason, the $\overline{\text{DHSYNC}}$ and $\overline{\text{DVSYNC}}$ operations are not guaranteed in subcarrier mode.

### Adaptive Comb Filter

The line based adaptive comb filter in the TMC22x5yA adds or subtracts the high frequency data from three adjacent field lines to produce the average of the high frequency luminance by canceling the chrominance signals, which in flat fields of color are 180 degrees apart. Unfortunately flat fields of color are rare and, when vertical transitions in the picture occur, the output of the comb filter contains a mixture of both high frequency luminance and chrominance, at which time the comb fails. To avoid the comb filter artifacts that occur when this happens, three sets of error signals are sent to a user-programmable lookup table, allowing the output of the comb filter to be mixed with the output of an internal bandsplit decoder.

To produce these comb fail error signals, the video on each of the inputs to the comb filter is passed through a simple bandsplit decoder. The low-frequency portion of the signal is

assumed to be luminance and the high frequency portion is processed as chrominance to find the magnitude and phase of the chrominance vector. These three components are then compared across the (0H & 1H) and (1H & 2H) taps of the comb filter to produce the difference in luminance, chrominance magnitude, and chrominance phase. These differences are then translated in the user-programmable lookup table to produce the "K" signal which controls the complementary mix between the output of the comb filter and the simple bandsplit decoder. That is, the "K" signals controls how much of the combed high frequency luminance signal is subtracted from the simple bandsplit chrominance for chroma combs, or added to the low frequency output of the bandsplit for luma comb filters.

### Output Processor

The demodulated chrominance signal and the luminance signal are passed through a programmable output matrix, producing RGB, YUV, or $YC_BC_R$. When the clock is at 27MHz, a D1 signal can be produced on the R/V output with the embedded TRS words fixed to the external $\overline{HSYNC}$ and $\overline{VSYNC}$ timing.

### Parallel and Serial Microprocessor Interfaces

The parallel microprocessor interface employs 12 pins, the serial port uses 5. A single pin, $\overline{SER}$, selects between the two interface modes.

In parallel interface mode, one address line is decoded for access to the internal control register and its pointer. Controls are reached by loading a desired address through the 8-bit $D_{7-0}$ port, followed by the desired data (read or write) for that address. The control register address pointer auto-increments to address 3Fh and then remains there.

A 2-line serial interface may also be used for initialization and control. The same set of registers accessed by the parallel port is available to the serial port. The device address in the serial interface is selected via pins $SA_{2-0}$.

The $\overline{RESET}$ pin sets all internal state machines to their initialized conditions and places the decoder in a power-down mode. All register data are maintained while in power-down mode.

## Pin Assignments

Preliminary Information

## Pin Descriptions

| Pin Name | Pin Number | Value | Pin Function Description |
|---|---|---|---|
| **Inputs** | | | |
| VIDEOA$_{9-0}$ | 86, 85, 84, 83, 82, 81, 80, 79, 78, 77 | TTL | **Video input A.** An 8 or 10 bit data input to the input multiplexer. For 8-bit versions (TMC2205yA) the data are left-justified (VIDEOA$_{9-2}$). |
| VIDEOB$_{9-0}$ | 75, 74, 73, 72, 71, 70, 69, 68, 67, 66 | TTL | **Video input B.** An 8 or 10 bit data input to the input multiplexer. For 8-bit versions (TMC2205yA) the data are left-justified (VIDEOB$_{9-2}$). |
| $\overline{\text{VSYNC}}$ | 49 | TTL | **Vertical sync input.** A vertical sync signal (active low) occurring at the start of the first vertical sync pulse in a vertical field group. A falling edge of $\overline{\text{VSYNC}}$ which is coincident with a falling edge of $\overline{\text{HSYNC}}$ indicates field 1. This signal is active only when SPGIP$_{1-0}$ = 00. |
| $\overline{\text{HSYNC}}$ | 48 | TTL | **Horizontal sync input.** A horizontal sync signal (active low) occurring at the falling edge of the video sync. This signal is active only when SPGIP$_{1-0}$ = 00. |
| MASTER$_{1-0}$ | 88, 87 | TTL | **Master decoder control.**<br>00 Adaptive comb decoder<br>01 Simple bandsplit decoder<br>10 Reserved<br>11 Flat notched luma and simple bandsplit chroma |
| BUFFER | 50 | TTL | **Control register select.** This signal switches between two sets of registers which control the gain or hue values in the output matrix. When BUFFER = 0, registers 17-1F are active. When BUFFER = 1, registers 27-2F take control. |
| CLOCK | 89 | TTL | **Master processing clock.** The clock signal can either be at twice the pixel data rate in the line locked modes, or at four times the subcarrier frequency in the subcarrier mode. The interpretation of the CLOCK signal is set by the CKSEL register bit. |
| $\overline{\text{SET}}$ | 52 | TTL | **Programmable function pin.** The function specified by the SET register is active when $\overline{\text{SET}}$ is low. The decoder returns to its previous operation when $\overline{\text{SET}}$ goes high. |
| **Outputs** | | | |
| G/Y$_{9-0}$ | 93, 94, 95, 96, 97, 98, 99, 100, 1, 2 | TTL | **Green or Luminance digital output.** For 8-bit versions (TMC2205yA) the data are left-justified (G/Y$_{9-2}$). |
| B/C$_{B9-0}$ | 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 | TTL | **Blue or $C_B$ digital output.** For 8-bit versions (TMC2205y) the data are left-justified (B/C$_{B\ 9-2}$). |
| R/C$_{R9-0}$ | 18, 19, 20, 21, 22, 23, 24, 25, 26, 27 | TTL | **Red or $C_R$ digital output.** For 8-bit versions (TMC2205yA) the data are left-justified (R/C$_{R\ 9-2}$). |
| $\overline{\text{DVSYNC}}$ | 35 | TTL | **Vertical sync output.** The $\overline{\text{DVSYNC}}$ signal occurs once per field and lasts for 1 video line. |
| $\overline{\text{DHSYNC}}$ | 34 | TTL | **Horizontal sync output.** The $\overline{\text{DHSYNC}}$ signal occurs once per line and lasts for 64 clock periods. |
| LDV | 3 | TTL | **Data synchronization output.** LDV can be an internally or externally generated clock signal. The internal LDV signal is produced when the CLOCK input is at twice the pixel data rate (PXCK); and is a pixel data rate clock phase locked to the falling edge of the HSYNC. The external LDV can be selected under software control, and must be at the CLOCK, or a sub multiple of the CLOCK, frequency. |

## Pin Descriptions (cont.)

| Pin Name | Pin Number | Value | Pin Function Description |
|---|---|---|---|
| DREF | 30 | TTL | **Decoder reference signal.** This is a dual function pin, controlled by register 24, that can function as an active video output indicator or output as a clamp pulse. When set to the active video output function, the DREF pin is HIGH during the video portion of each line and LOW during the horizontal and vertical blanking levels. When set to output a clamp pulse, the clamp pulse is controlled by register 24 and 25 allowing a user to program when a 0.5 μSec pulse is output relative to HSYNC. |
| $FID_{2-0}$ | 33, 32, 31 | TTL | **Field identification output.** A 3 bit field ident from the DRS signal. |
| **μP Interface** | | | |
| $D_{7-0}$ | 45, 44, 43, 42, 41, 38, 37, 36 | TTL | **Parallel control port data I/O.** All control parameters are loaded into and read back over this 8 bit data port. |
| $A_{1-0}$ | 63, 62 | TTL | **Parallel control port address inputs.** These pins govern whether the microprocessor interface selects a table/register address or reads/ writes table/register contents. |
| $\overline{CS}$ | 60 | TTL | **Parallel control port chip select.** When $\overline{CS}$ is high the microprocessor interface port, $D_{7-0}$, is set to HIGH impedance and ignored. When $\overline{CS}$ is LOW, the microprocessor can read or write parameters over $D_{7-0}$. |
| $\overline{R/W}$ | 61 | TTL | **Parallel control port read/write control.** When $\overline{R/W}$ and $\overline{CS}$ are LOW, the microprocessor can write to the control registers or XLUT over $D_{7-0}$. When $\overline{R/W}$ is HIGH and $\overline{CS}$ is LOW, it can read the contents of any selected XLUT address or control register over $D_{7-0}$. |
| $\overline{RESET}$ | 51 | TTL | **Chip master reset.** Bringing $\overline{RESET}$ LOW sets the software reset control bit, $\overline{SRESET}$, LOW and disables the digital outputs. If HRESET is LOW the decoder outputs remain disabled after $\overline{RESET}$ goes HIGH until the $\overline{SRESET}$ bit is set high by the host. If HRESET is HIGH when $\overline{RESET}$ goes HIGH the decoder the internal state machines are enabled. |
| $\overline{SER}$ | 53 | TTL | **Serial/parallel interface select.** This pin will select between a parallel (HIGH) or serial (LOW) interface port. |
| SDA | 58 | R-Bus | **Serial data interface.** Bi-directional serial interface to the control port. |
| SCL | 59 | R-Bus | **Serial interface clock.** |
| $SA_{2-0}$ | 56, 55, 54 | TTL | **Serial Address.** Three bits providing the lsbs of the serial chip ID used to identify the decoder. |
| **Power Supply** | | | |
| $V_{DD}$ | 5, 17, 29, 40, 47, 65, 91 | +5 V | **Power Supply.** Positive power supply for digital circuits, +5V. |
| GND | 4, 16, 28, 39, 46, 57, 64, 76, 90, 92 | 0.0 V | **Ground.** Ground for digital circuits, 0V. |

## Control Register Map

The TMC22x5yA is initialized and controlled by a set of registers which determine the operating modes.

An external controller is employed to write and read the Control Registers through either the 8-bit parallel or 2-line serial interface port. The parallel port, $D_{7-0}$, is governed by pins $\overline{CS}$, $\overline{R/W}$, and $A_{1-0}$. The serial port is controlled by SDA and SCL.

| Reg | Bit | Name | Function |

**Notes:**

1. Functions are listed in the order of reading and writing.
2. For each register listed above up to register 3F, all bits not specified are reserved and must be set to zero to ensure proper operation.

# Control Register Definitions

## Global Control Register (00)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| $\overline{\text{SRST}}$ | HRST | SET | | | DHVEN | STD | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 00 | 7 | $\overline{\text{SRST}}$ | **Software reset.** When LOW, resets and holds internal state machines and disables outputs. When HIGH (normal), starts and runs state machines and enables outputs. This bit is ignored while HRST is high. |
| 00 | 6 | HRST | **Hardware reset.** When HRST is HIGH, $\overline{\text{SRST}}$ is forced low when $\overline{\text{RESET}}$ pin is taken LOW. State machines are reset and held. When HRST is low the $\overline{\text{RESET}}$ pin can be taken HIGH at any time. The state machines remain disabled until $\overline{\text{SRST}}$ is programmed HIGH. When HRST is high the state machines are enabled as soon as the $\overline{\text{RESET}}$ pin goes HIGH. |
| 00 | 5-3 | SET | **$\overline{\text{SET}}$ pin function.** These bits control the set function when the $\overline{\text{SET}}$ pin goes low.<br>A = all outputs high-impedance<br>B = internal state machines<br>C = burst locked loop<br><br>**SET** / **Function**<br>000 — Reset and hold A, B, & C.<br>001 — Set output to BLUE and flywheel B & C. (RGB outputs) Set output to "color" and flywheel B & C ($YC_BC_R$ outputs)<br>010 — Hold A, lock B & C to external input<br>011 — Reset C only<br>100 — Reset B & C<br>101 — Set output to BLUE and lock B & C to input video (RGB output)<br>110 — Line and pixel grab depending on $VMCR_{6-0}$ (reg 30)<br>111 — Toggle reset function of SET = 010. For each $\overline{\text{SET}}$ = 0 pulse the chip operation will change from normal to that of SET = 010 or visa versa.<br><br>The first $\overline{\text{SET}}$ pulse after a software or hardware reset, with SET = 111, causes a toggle to SET = 010. |
| 00 | 2 | DHVEN | **Output H&V sync enable.** Disables $\overline{\text{DHSYNC}}$ and $\overline{\text{DVSYNC}}$ signals when HIGH. |
| 00 | 1-0 | STD | **Selects video standard.** Selects video standard.<br><br>**SET** / **Function**<br>00 — NTSC<br>01 — reserved<br>10 — PAL/M<br>11 — All PAL standards except PAL/M |

Preliminary Information

## Control Register Definitions (continued)

### Input Processor Control (01)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | IPMUX | IP8B | TDEN | TBLK | IPCMSB | ABMUX | CKSEL |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 01 | 7 | Reserved | **Reserved, set to zero.** |
| 01 | 6 | IPMUX | **Input mux control.** Used to select the Video Input Processor, D1, or D2 data as the VA input to the input processor.<br>VIDEOA is selected for VA and VIDEOB is selected for VB when IPMUX is set LOW. VIDEOB is selected for VA and VIDEOA for VB when IPMUX is set HIGH. For YC inputs, the luma data must be passed through the VA input and chroma through the VB input.<br>IPMUX should be set LOW for line locked composite inputs. |
| 01 | 5 | IP8B | **8 bit input format.** Bottom two bits of inputs $VIDEOA_{9-0}$ and $VIDEOB_{9-0}$ are set to zero when HIGH. |
| 01 | 4 | TDEN | **TRS detect enable.** When HIGH, the TRS words embedded in incoming video are used to reset the horizontal and vertical state machines. When LOW the externally provided or internally generated HSYNC and VSYNC are used to reset the horizontal and vertical state machines. |
| 01 | 3 | TBLK | **TRS blank enable.** Blanks the TRS and AUX data words when HIGH. For line locked and D1 data, the TRS and AUX data words are set to the luma and chroma blanking levels as appropriate. For D2 ($4*f_{SC}$) data, the TRS and AUX data words are set to the sync tip level. |
| 01 | 2 | IPCMSB | **Chroma input msb invert.** The msb of the chroma or $C_BC_R$ data are inverted when HIGH. |
| 01 | 1 | ABMUX | **AB mux control.** Selects the primary and secondary inputs to the decoder from the DA and DB outputs of the input processor. When ABMUX is LOW, DA is selected as the primary and DB as the secondary decoder input. |
| 01 | 0 | CKSEL | **Input clock rate select.** Set HIGH for line locked clocks and LOW for subcarrier locked clocks. Line locked clocks should be at twice the pixel data rate, and the subcarrier clock should be at four times the subcarrier frequency. |

## Control Register Definitions (continued)

### Burst Loop Control (02)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| BLLRST | VIPEN | LOCK | | BLM | KILD | DMODBY | CINT |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 02 | 7 | BLLRST | **BLL reset enable.** When LOW, the automatic BLL reset is disabled. When HIGH, the BLL will be reset if the BLL loses lock and fails to reacquire lock within 8 fields. |
| 02 | 6 | VIPEN | **Video Input Processor enable.** Selects interface protocol for Fairchild video input devices. Active only when $LOCK_{1-0}$ = 10.<br><br>**VIPEN** / **Function**<br>0 – Video Input Processor Interface<br>1 – TMC22071 Interface |
| 02 | 5-4 | LOCK | **Global Lock mode.** Sets the decoder locking mode.<br><br>**LOCK** / **Function**<br>00 – Line Locked Mode<br>01 – Subcarrier Locked Mode<br>10 – Video Input Processor Mode<br>11 – D1 Mode |
| 02 | 3 | BLM | **BLL lock mode.** Sets the decoder burst locking mode.<br><br>**BLM** / **Function**<br>0 – Frequency Lock<br>1 – Phase Lock |
| 02 | 2 | KILD | **Color kill disable.** Color killer is disabled when HIGH. |
| 02 | 1 | DMODBY | **Demod bypass.** Chroma data bypasses the demodulator when HIGH. |
| 02 | 0 | CINT | **$C_BC_R$ interpolation enable.** Interpolation of $C_BC_R$ input data from 0:2:2 to 0:4:4 is enabled when HIGH. |

Preliminary Information

## Control Register Definitions (continued)

### Chroma Processor Control (03)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| BLFS | | | CCEN | CCOR | | GAUBY | GAUSEL |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 03 | 7-5 | BLFS | **Burst loop filter select.** |
| 03 | 4 | CCEN | **Chroma coring enable.** Enables Chroma Coring when HIGH. |
| 03 | 3-2 | CCOR | **Chroma coring threshold.** Sets the Chroma Coring threshold. |
| 03 | 1 | GAUBY | **Gaussian filter bypass.** The chroma data bypasses the Gaussian LPF when HIGH. |
| 03 | 0 | GAUSEL | **Gaussian LPF select.** Selects the Gaussian filter response to be used on the demodulated chrominance. |

| BLFS | fS (Mpps) | Recommended Criteria |
|---|---|---|
| 000 | 13.5 | PAL, Line-Locked YC |
| 000 | 15 | PAL, Line-Locked YC |
| 001 | 12.27 | NTSC, Line-Locked YC |
| 001 | 13.5 | PAL, Line-Locked Composite |
| 010 | 13.5 | NTSC, Line-Locked YC |
| 010 | 15 | PAL, Line-Locked Composite |
| 011 | 14.32 | NTSC, Subcarrier-Locked YC |
| 011 | 17.73 | PAL, Subcarrier-Locked Composite |
| 100 | 17.73 | PAL, Subcarrier-Locked YC |
| 101 | 13.5 | NTSC, Line-Locked Composite |
| 110 | 12.27 | NTSC, Line-Locked Composite |
| 111 | 14.32 | NTSC, Subcarrier-Locked Composite |

| CCOR | Function |
|---|---|
| 00 | 1 lsb |
| 01 | 2 lsb |
| 10 | 3 lsb |
| 11 | 4 lsb |

| GAUSEL | Function |
|---|---|
| 0 | Select Gaussian LPF resp. 2 |
| 1 | Select Gaussian LPF resp. 1 |

See Figure 22 for filter responses.

Preliminary Information

## Control Register Definitions (continued)

### Burst Threshold (04)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| BTH | | | | | | | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 04 | 7-0 | BTH | **Burst threshold.** The 8 bit value to be compared against the demodulated U and V component data. If over 127 lines occur in a field in which the burst is below this threshold, then the color is set to chroma black for the next field. |

### Pedestal (05)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| PED | | | | | | | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 05 | 7-0 | PED | **Pedestal level.** An 8 bit magnitude subtracted from the luma data to remove the setup before processing by the output matrix. |

### Luma Processor Control (06)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| Reserved | | ANEN | ANR | ANT | | YSEL | NOTCH |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 06 | 7-6 | Reserved | **Reserved, set to zero.** |
| 06 | 5 | ANEN | **Adaptive notch enable.** Enables adaptive notch when HIGH. |
| 06 | 4 | ANR | **Adaptive notch rounding.** Sets adaptive notch rounding point.<br>ANR: 0 = Round to 10 bits; 1 = Round to 8 bits |
| 06 | 3-2 | ANT | **Adaptive notch threshold level.** Sets the adaptive notch threshold.<br>ANT: 00 = Magnitude difference less than 32; 01 = Magnitude difference less than 24; 10 = Magnitude difference less than 16; 11 = Magnitude difference less than 8 |
| 06 | 1 | YSEL | **Adaptive notch select.** Selects adaptive notch filter response.<br>YSEL: 0 = Adaptive notch response ANF1; 1 = Adaptive notch response ANF2 |
| 06 | 0 | NOTCH | **Notch enable.** Adaptive notch filter ANF3 selected when HIGH and ANEN is HIGH, non-adaptive notch filter selected when HIGH and ANEN is LOW. Function may be overridden by XSF (Reg 0E, bits 5-4). |

## Control Register Definitions (continued)

### Comb Processor Control (07)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| LS1BY | LS1IN | LS2DLY | SPLIT | BSFBY | BSFSEL | BSFMSB | GRSDLY |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 07 | 7 | LS1BY | **Line store 1 bypass.** Bypasses linestore 1 when HIGH. |
| 07 | 6 | LS1IN | **Line store 1 input.** Selects the input of linestore 1:<br><br>**LS1IN** / **Function**<br>0 – Primary Input<br>1 – Secondary Input |
| 07 | 5 | LS2DLY | **Line store 2 delay.** LSTORE2 uses STS to store 1H when LOW and uses VL to store SAV to EAV (or max count) when HIGH. |
| 07 | 4 | SPLIT | **Line store 2 delay.** Splits data through LSTORE2, 9 bits chroma and 7 bits luma when HIGH (chroma combs) and 8 bits chroma and 8 bits luma when LOW (luma comb). |
| 07 | 3 | BSFBY | **Bandsplit filter bypass.** Bandsplit filter is bypassed when HIGH. |
| 07 | 2 | BSFSEL | **Bandsplit filter select.** Selects the bandsplit filter to be used:<br><br>**BSFSEL** / **Function**<br>0 – Select bandsplit filter response 1<br>1 – Select bandsplit filter response 2 |
| 07 | 1 | BSFMSB | **Inverts msb of bandsplit filter.** When HIGH, inverts the msb of the input to the bandsplit filter. |
| 07 | 0 | GRSDLY | **Delays input to GRS decode.** When HIGH, delays the input to the GRS extraction circuit by 1H. Genlock only. |

### Mid-Sync Level (08)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| MIDS | | | | | | | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 08 | 7-0 | MIDS | **Mid sync level.** Sets the mid point of syncs for the mixed sync separator, in the subcarrier locked mode. |

## Control Register Definitions (continued)

### Extended DRS (09)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| PCKF | | | | VSTD | | | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 09 | 7-4 | PCKF | **Clock rate.** |
| 09 | 3-0 | VSTD | **Video Standard.** Selects the video standard. |

| PCKF | Function |
|---|---|
| 0000 | 13.50 MHz |
| 0001 | reserved |
| 0010 | reserved |
| 0011 | reserved |

| 1101 | reserved |
| 1110 | reserved |
| 1111 | reserved |

## Control Register Definitions (continued)

### Output Control (0A)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| OP8B | OPLMT | OPLMT | MSEN | | OPCMSB | YBAL | BUREN |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0A | 7 | OP8B | **Output rounded to 8 bits.** Rounds the outputs to 8 bits when HIGH. The two lsbs are set to zero. |
| 0A | 6-5 | OPLMT | **Output limit select.** Sets the output format and limiters: |
| 0A | 4-3 | MSEN | **Mixed sync enable.** Sets composite sync output format: |
| 0A | 2 | OPCMSB | **Chroma output msb invert.** Inverts the msb of the $C_BC_R$ or Chroma output when HIGH. |
| 0A | 1 | YBAL | **Luma color correction.** Setting this bit HIGH forces the chroma to zero whenever the luma equals or exceeds the luma limit. |
| 0A | 0 | BUREN | **Output burst enable.** When HIGH, passes the burst through on the chroma channel. Sets the burst region to zero when LOW. |

| OPLMT | Function |
|---|---|
| 00 | RGB output format<br>limited to 4 to 1016 |
| 01 | $YC_BC_R$ output format<br>Y limited to 4 to 1016<br>$C_BC_R$ limited to ±504 |
| 10 | RGB output format<br>limited to 4 to 1016 |
| 11 | $YC_BC_R$ output format<br>Y limited to 64 to 940<br>$C_BC_R$ limited to ±448 |

| MSEN | Function |
|---|---|
| 00 | No sync, & “super blacks” disabled |
| 01 | No sync, & “super blacks” disabled |
| 10 | Sync on G/Y output only, & “super blacks” enabled |
| 11 | Sync on RGB outputs, & “super blacks” enabled |

**Notes:**

1. To enable “super blacks” and disable syncs of the output simply set MSEN[1] HIGH and the sync gain to zero.

## Control Register Definitions (continued)

### Output Control (0B)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| FMT422 | CDEC | YUVT | Reserved | | | DRSEN | DRSCK |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0B | 7 | FMT422 | **Enables $C_BC_R$ output mux.** When HIGH, multiplexes the $C_B$ and $C_R$ data onto the same data bus. The chroma or multiplexed $C_BC_R$ output appears on the B/$C_B$ output. The R/$C_R$ output is forced low. |
| 0B | 6 | CDEC | **$C_BC_R$ decimation enable.** When HIGH, the $C_BC_R$ data are decimated to 0:2:2 in the output processor. |
| 0B | 5 | YUVT | **Enables D1 output.** When HIGH, enables 4:2:2 multiplexed $YC_BC_R$ onto the R/$C_R$ data output with TRS words inserted into the output data stream. The Y data are still available on the G/Y output and multiplexed $C_BC_R$ is available on the B/U output. |
| 0B | 4-2 | Reserved | **Reserved, set to zero.** |
| 0B | 1 | DRSEN | **DRS output enable.** When HIGH, enables the DRS onto the G/Y output. |
| 0B | 0 | DRSCK | **DRS data rate.** Sets the DRS output data rate.<br><br>**DRSCK** — **Function**<br>0 — Embeds data bytes (8 bits) at PCK clock rate<br>1 — Embeds data nibbles (4 bits) at PXCK clock rate |

Preliminary Information

## Control Register Definitions (continued)

### Comb Filter Control (0C)

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|
| ADAPT | | YCES | YCSEL | COMB | | | |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0C | 7-6 | ADAPT | **Adaption mode.** Sets the 3-line comb filter adaption mode in NTSC. |

| ADAPT[1:0] | Function |
|---|---|
| 00 | Adapts to best of 3 types of line based comb filters in NTSC only. |
| 01 | Adapts to the best of two field or frame based comb filters in NTSC only. |
| 10 | 3 line (tap) comb only. Never adapts to a 2 line (tap) filter. The higher set of comb filter error signals are sent to the XLUT. NTSC or PAL comb filter. |
| 11 | Adapts to best of two 3 line chroma comb filters in PAL only. |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0C | 5 | YCES | **YC input error signal control.** Error signal control for YC input, luma comb. |

| YCES | Function |
|---|---|
| 0 | LPF and HPF error signal, between (0H & 1H) or (1H & 2H) in NTSC or between (0H & 2H) in PAL,are sent to XLUT |
| 1 | LPF error signal, between (0H & 1H) and (1H & 2H) in NTSC or between (0H & 2H) in PAL, are sent to XLUT |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0C | 4 | YCSEL | **Luma/chroma comb filter select.** Selects luma or chroma comb filter. |

| YCSEL | Function |
|---|---|
| 0 | Chroma comb filter |
| 1 | Luma comb filter |

| Reg | Bit | Name | Description |
|---|---|---|---|
| 0C | 3-0 | COMB | **Comb filter architecture.** |

| COMB | Function |
|---|---|
| *YC or composite comb filter architectures* | |
| 0000 | PAL or NTSC 3 line comb |
| 0001 | NTSC 3 line comb (0H & 1H) |
| 0010 | NTSC 3 line comb (1H & 2H) |
| 0011 | NTSC 2 line comb (0H & 1H) |
| 0100 | NTSC (2 line) field comb |
| 0101 | NTSC or PAL field comb |
| 0110 | NTSC (2 line) frame comb |
| 0111 | NTSC frame comb |
| *D1 comb filter architectures* | |
| 1000 | 3 line comb |

## Decoder Introduction

All composite video decoders perform fundamentally the same operation. The first stage is to separate the luminance and chrominance. The second stage is to lock the internally generated sine and cosine waveforms to the burst on the decoded chrominance signal, demodulate, and then filter the chrominance signal to produce the color difference signals. The last stage either scales the luminance and color difference signals, or converts them into red, green, and blue component video signals. These three stages are shown in Figure 3.

The complete separation of composite video signals into pure luminance (luma) and chrominance (chroma) signals is practically impossible, especially when the input source contains intraframe motion. Therefore, the luminance (luma) signal will generally contain some high frequency chrominance, termed *cross luma*, and the chroma signal will contains some of the high frequency luma signal, centered around the subcarrier frequency, termed *cross color.*
The degree of cross luma and cross color is directly proportional to the filter used for the YC separation, the picture content, and the complexity of any post processing of the decoded signals.

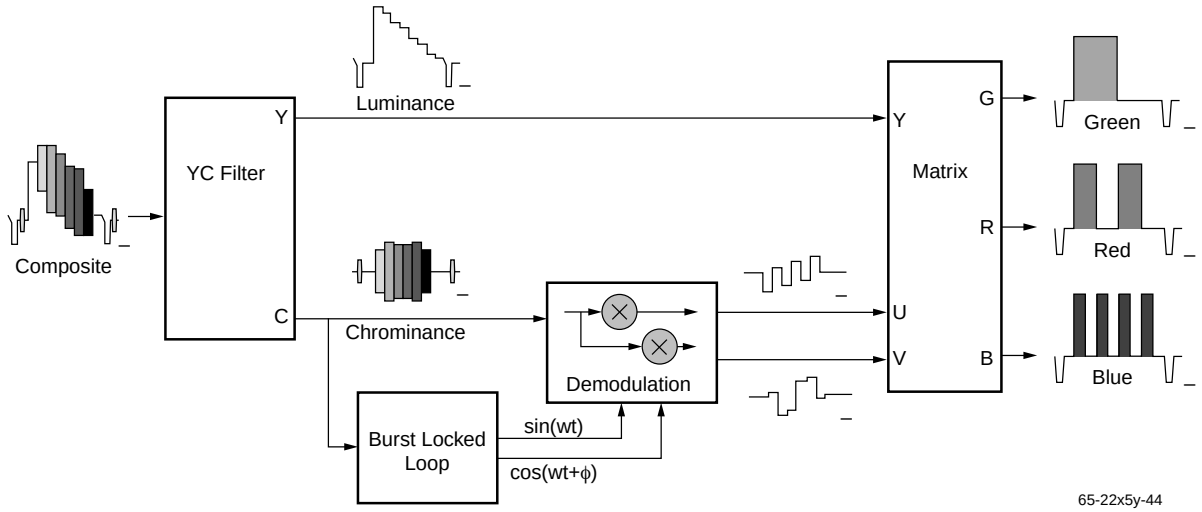

**Figure 3. Fundamental Decoder Block Diagram**

### YC Separation

The relationship between the chrominance and luminance bandwidths is shown for both PAL and NTSC in Figure 4, wherein the shaded area denotes the part of the composite video frequency spectrum shared by both the chrominance and high frequency luminance signals.

#### The *Luma Notch and Chroma Bandpass* Technique for YC Separation

The simplest method of separating these chrominance and luminance signals, is to assume the chroma bandwidth is limited to a few hundred kilohertz around the subcarrier frequency. In this case a notch filter designed to remove just these frequencies from the composite video frequency spectrum provides the luma signal, while a bandpass filter

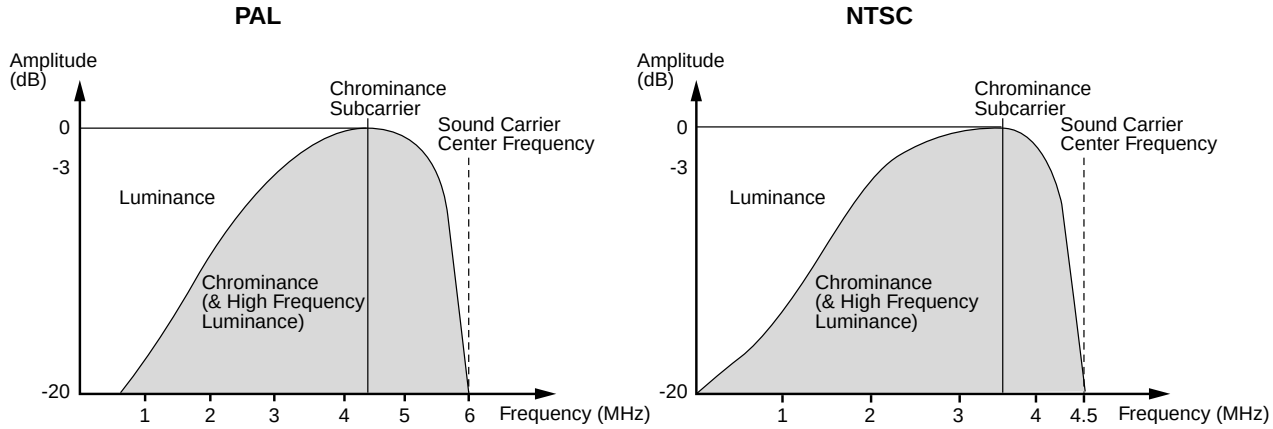

**Figure 4. Comparison of the Frequency Spectrum of NTSC and PAL Composite Video Signals**

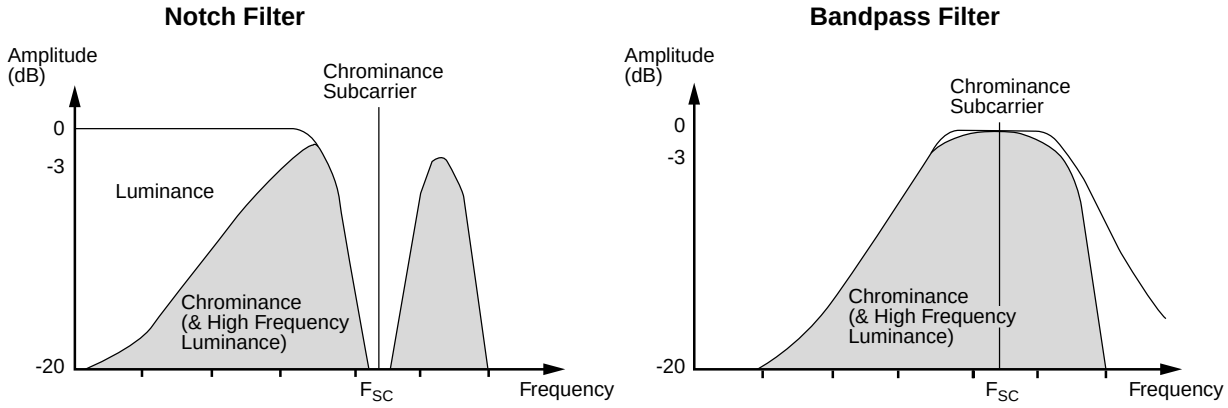

**Figure 5. Examples of Notch and Bandpass Filters**

centered at the subcarrier frequency produces the chroma signal. This simple technique works well in pictures containing large flat areas of color, however this is rarely the case. If, as is generally true, the picture contains high frequency luma and chroma transitions, for example herring bone suit jackets, branches of trees, text, etc., cross color and cross luma artifacts are evident.

The presence of cross color or cross luma is generally acceptable when viewing the decoded picture on a monitor from several feet, as would be the case in most homes on commercial television sets. However, these artifacts become increasingly difficult to process, or ignore, when the image is to be compressed or manipulated. In these cases more sophisticated methods of separating the luma and chroma signals, such as frame, field, or line based comb filter decoders, are required.

Another important disadvantage of the "luma notch filter and bandpass chroma" technique is that once a notch filter has been used on the luminance channel this portion of the luminance frequency spectrum is lost. This effect becomes increasingly objectionable if the decoder component outputs are subsequently re-encoded into a composite video signal.

## Comb Filter Architectures for YC Separation

A comb filter uses the relationship between the number of subcarrier cycles per line period, to cancel the chrominance signal over multiple line periods. This is shown for an NTSC two line comb filter in Figure 6. In NTSC there a 227.5 subcarrier cycles per line period, therefore the subcarrier can be canceled by simply adding two consecutive field scan lines. In PAL(B/I/ etc.) there are 283.7516 subcarrier cycles per line period, ignoring the 0.0016 cycle advance caused by the 25Hz offset, the PAL subcarrier can be canceled by adding the first and third line of three consecutive field scan lines. Due to the 270 degree advance, it is not possible to use information from consecutive field lines without adding a PAL modifier. A PAL modifier produces a 90 degree phase shift in the chrominance signal by multiplying the chrominance signal by a signal at two times the subcarrier frequency that is phased locked to the subcarrier burst reference in the composite video waveform. In addition the PAL modifier inverts the V component of the chrominance signal. This document refers to line based comb decoders when discussing decoders that use inputs from sequential scan lines, i.e. lines from the same field, field based comb decoders when describing decoders that use inputs from sequential fields, and finally frame based comb decoders when examining decoders that use inputs from sequential frames.

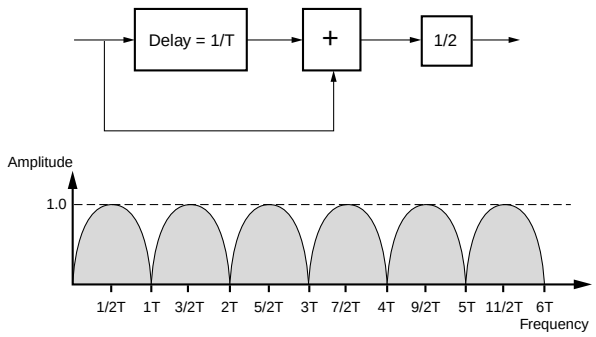

**Figure 6.**

### Composite Line-Based Comb Decoders

The phase relationship of the quadrature modulated chrominance signal can also be represented as in Figure 7. The three line comb based decoder is clearly biased towards 1H which illustrates the inherent one line delay through a 3 line comb, while a two line comb based decoder is biased towards 0H. In the following discussions a flat color represents video of constant luma and chroma magnitude and phase.

In NTSC, adding two adjacent lines of flat color will cancel the chroma and leave the luma whereas subtracting two lines of flat color will cancel the luma and leave the chroma. In a 3 line comb filter the flat color on 0H and 2H is added to provide the flat color average before adding or subtracting from 1H.

In PAL, adding the flat color from 0H and 2H will cancel the chroma and leave the luma while subtracting the flat color from 0H and 2H will cancel the luma and leave the chroma. However, chroma generated in this manner has no simple

phase relationship to the chroma on 1H. Therefore normally 0H and 2H are added together to produce the average luma across 3 lines and this is then subtracted from 1H to produce the combed chroma.

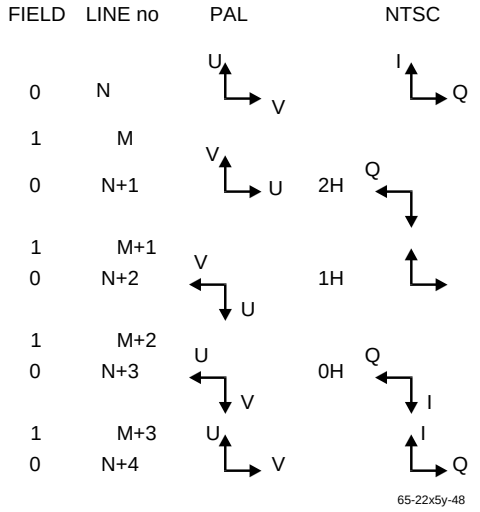

**Figure 7. Chrominance Vector Rotation in PAL and NTSC**

### YC Line-Based Comb Filters

The luminance and chrominance signals, are by definition, already separated for YC inputs. However, if the original source was composite, there is a distinct possibility that there is some residual luminance (cross color) in the chrominance signal and some residual chrominance (cross luma) in the luminance signal. It is therefore legitimate to treat these signals as if they were simply the output from bandsplit filters and process the luma and chroma signals accordingly.

### D1 Line-Based Comb Filters

A D1 data stream consists of multiplexed Y, $C_B$ and $C_R$ component data. If the original source was composite there maybe luminance (cross color) in $C_BC_R$ and chrominance (cross luma) in Y. In the first case any luminance that was passed through a demodulator along with the chroma to produce the baseband $C_BC_R$ color difference signals would have the same characteristics as chroma. That is to say, the cross color would advance by 180° every line in NTSC and every 2 lines in PAL. It is therefore possible to remove this cross color in a comb filter. In the latter case any chrominance that is still in the Y data can obviously be removed in a comb filter as well.

The original source for the D1 signal could also have been computer graphics. In this case, the comb filter can be used to remove the picture flicker and convert the output to RGB.

## NTSC Frame and Field Based Decoders

### Composite Frame-Based Comb Filters

In NTSC the chrominance vectors advance by 180 degrees every line, therefore after 525 lines the 2 adjacent frame lines 0H and FR0H and the two consecutive field lines FR0H and FR1H are 180 degrees apart. The flat color on FR0H and FR1H can be added or subtracted to provide the luminance or chrominance to subtract from 0H.

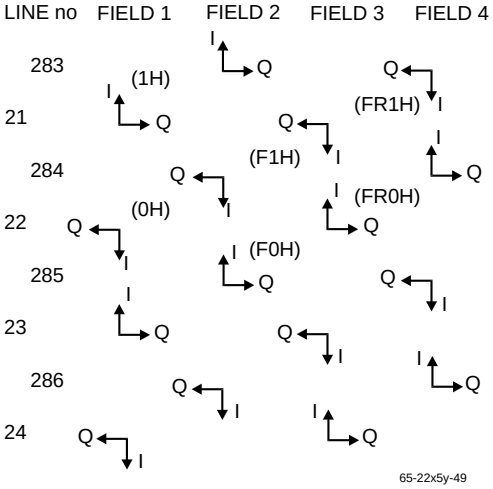

**Figure 8. Chrominance Vector Rotation Over 4 Fields in NTSC**

### Composite Field-Based Comb Filters

In NTSC field based comb decoders, there is an external delay of 263 lines, therefore the 2 adjacent picture lines 0H and F0H and the two consecutive field lines F0H and F1H are 180 degrees apart. The flat color on F0H and F1H can be added or subtracted to provide the luminance or chrominance to subtract from 0H.

## PAL Field Decoders

#### Composite, PAL Field Comb Filters

In PAL field based comb decoders, there is an external delay of 312 lines, therefore the 2 adjacent picture lines 0H and F0H are 180 degrees apart. In fields 5, 6, 7, and 8 the U and V vectors are 180 degrees advanced from fields 1, 2, 3, and 4.

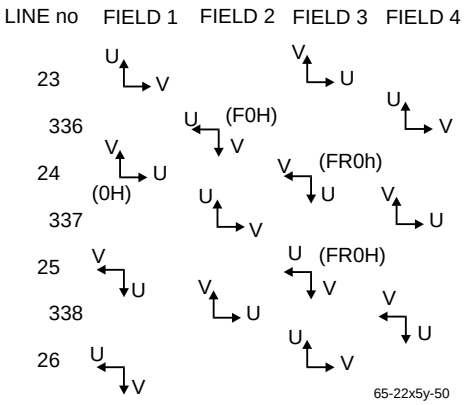

**Figure 9. Chrominance Vector Rotation Over 4 Fields in PAL**

## The TMC22x5yA Comb Filter Architecture

The TMC22x5yA, when implementing a line based comb filter, has a core architecture as shown in Figure 10. The concept of the complementary bandsplit filter is also observed in the complementary comb filter architecture. It is therefore possible to adapt between the complementary comb filter and bandsplit filter without throwing away any of the original composite video frequency spectrum.

The first step in the complementary comb filter is to separate the high frequency luminance from the chrominance signal. This combed high frequency luma signal is shown as *YCOMB* in Figure 10. The second step is to produce an array of comb filter error signals that indicate the degree of confidence that the *YCOMB* signal is just the high frequency luma and not a combination of high frequency luma and chroma smeared over the number of lines used in the comb filter. The signal representing this degree of confidence is termed “K” in Figure 10. The last step is to provide a complementary cross fade between the *YCOMB* signal and the output of the complementary bandsplit filter, shown as *SIMPLE* in Figure 10. The *FLAT* signal is simply a delayed version of the input to the comb filter, therefore the sum of *Output1* and *Output2* will always be equal to the *FLAT* video input.

The TMC22x53A comb filter architecture has three taps. These taps are three consecutive field lines in a line based comb, three consecutive picture lines in a field based comb, or lines that are one frame and one field line apart in the frame based comb. In addition to these different inputs to the comb filter, NTSC and PAL video signals comb over different taps in different architectures, as described in the comb filter introduction.

The total internal pipeline latency is 1H + 40 pixels for 3 line comb filters, for all other comb filter and simple decoder architectures the pipeline latency is 40 pixels.

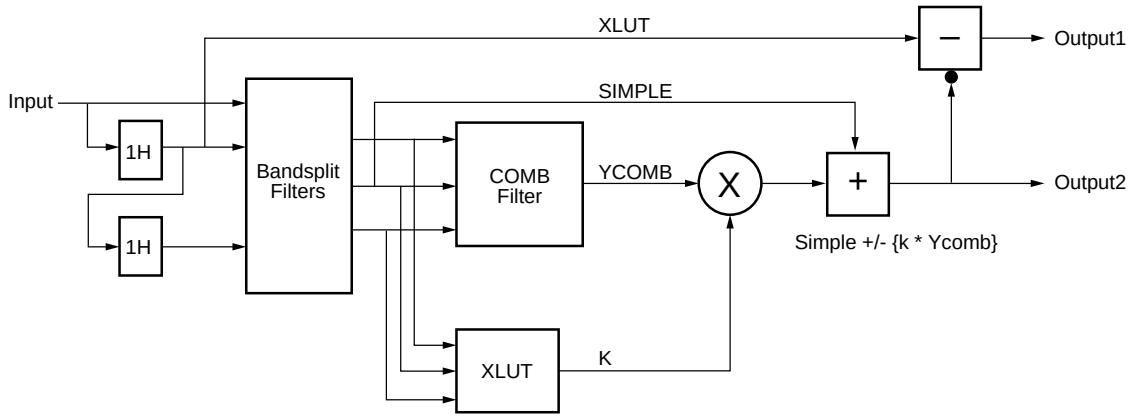

**Figure 10. TMC22x5yA Line Based Comb Filter Architecture**

# TMC22x5yA Functional Description

## Input Processor

The input processor selects between the two external video sources on VIDEO A and VIDEO B. If the TRS stripper or GRS stacker is active, then the user must select the input with either the GRS (in genlock mode) or with the embedded TRS words as output VA. If the input data are separate luma and chroma or Y and $C_BC_R$ data the input processor must be programmed to put the chrominance or $C_BC_R$ onto output VB and the luminance or Y onto VA.

To ensure that the chrominance data or the $C_BC_R$ data are in two's complement arithmetic format, the register bit MSBI inverts the msb of the DB input. For composite inputs, the IPCMSB register bit should be set LOW, as the ABMUX register bit is used to select the input(s) to the comb filter.

## Bandsplit Filter (BSF)

In its simple mode of operation, the TMC22x5yA uses a complementary bandsplit filter, instead of a notch filter for the luma and a bandpass for the chroma. The notch and bandpass filter technique, removes frequency bands from the composite video spectrum which can never be retrieved. The complementary bandsplit filter technique, shown in Figure 12, allows the decoded component video signals to be re-encoded into a composite video signal with the minimum of losses to the composite video spectrum.

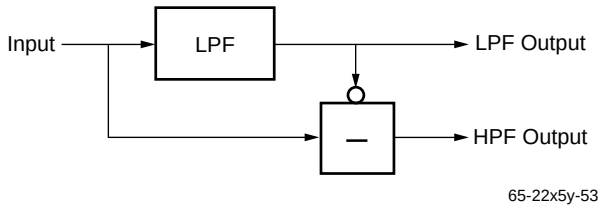

**Figure 12. Complementary Bandsplit Filter**

The complementary bandsplit filter separates the base band composite video into two bands by passing it through a low pass filter and subtracting the low pass (luma) data from the composite video to produce the high pass (chroma) data. As the base bandwidths and subcarrier frequencies of the different NTSC and PAL video formats are so different, and the decoder has to be capable of working over a large frequency range, it is necessary to provide two low pass filters. These filters are selectable by the BSFSEL register bit and are independent of the video standard. A comparison of the different data rates to normalized subcarrier frequencies is provided in Table 2.

The complementary bandsplit low pass frequency response is shown in Figure 13 and Figure 14.

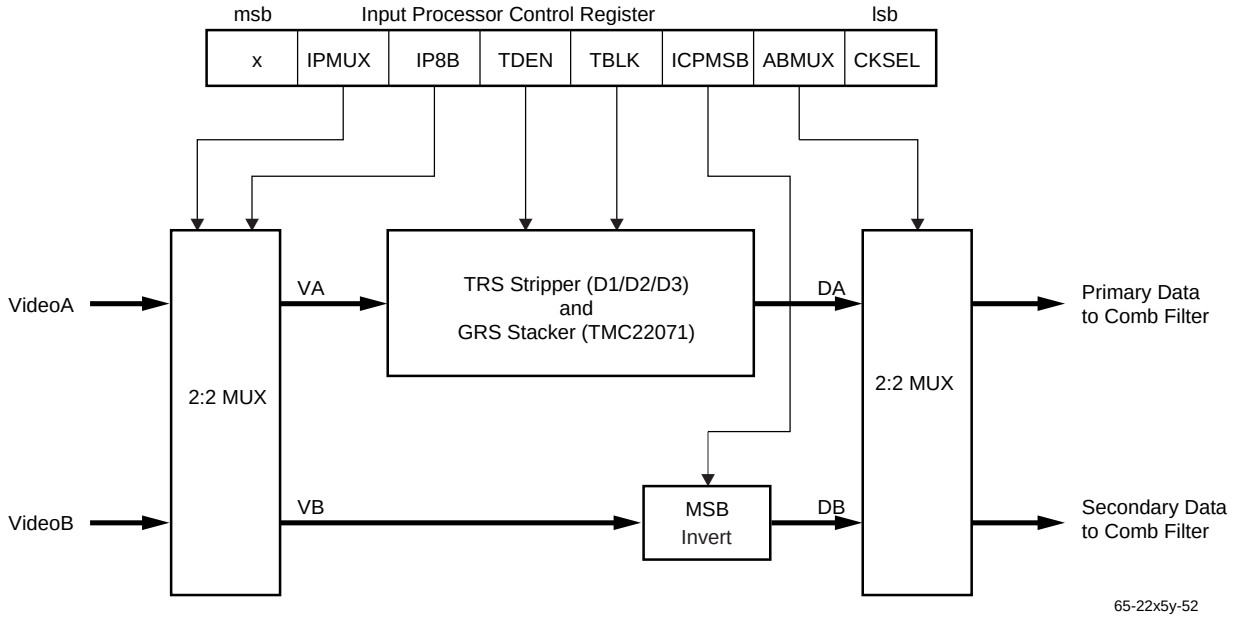

**Figure 11. Input Processor**

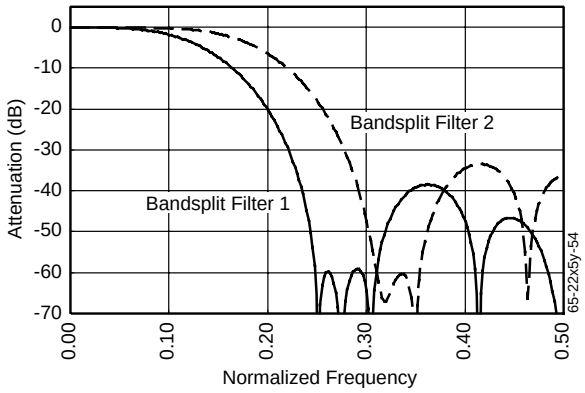

**Figure 13. Bandsplit Filter, Full Frequency Response**

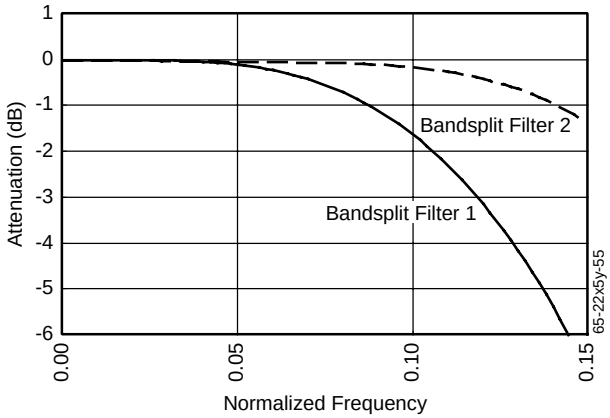

**Figure 14. Bandsplit Filter, Passband Response**

**Table 2. Normalized Subcarrier Frequency as a Function of Pixel Data Rates**

| Pixel Rate (MHz) | $F_{SC}$ (MHz) | Normalized $F_{SC}$ | Comments |
|---|---|---|---|
| 12.27 | 3.57954545 | 0.2917 | NTSC square pixel rate |
| 13.50 | 3.57954545 | 0.2652 | NTSC D1 pixel rate |
| 13.50 | 4.43361875 | 0.3284 | PAL-I D1 pixel rate |
| 14.32 | 3.57954545 | 0.2500 | NTSC four times subcarrier (D2/D3) |
| 14.75 | 4.43361875 | 0.3006 | PAL-I square pixel rate |
| 15.00 | 4.43361875 | 0.2956 | PAL-I square pixel rate |
| 17.73 | 4.43361875 | 0.2500 | PAL-I four times subcarrier (D2/D3) |
| 13.5 | 3.57561149 | 0.2649 | PAL-M D1 pixel rate |
| 13.5 | 3.58205625 | 0.2653 | PAL-N D1 pixel rate |
| 14.30 | 3.57561149 | 0.2500 | PAL-M four times subcarrier (D2/D3) |

## Comb Filter Input

The inputs to the comb filter are selected from either the high frequency outputs of the bandsplit filters, if using a chroma comb filter, or the full composite waveforms when implementing a luma comb. The two sets of high and low frequency signals from the bandsplit filters are used for both the luma and chroma *SIMPLE* signals, and in the generation of the comb fail signals. These signals are denoted xHL, xHH, and xHF where L denotes the low frequency portion of the signal, H the high frequency portion of the signal and F the full frequency spectrum of the input signal from line x; and are shown in Figure 15.

Preliminary Information

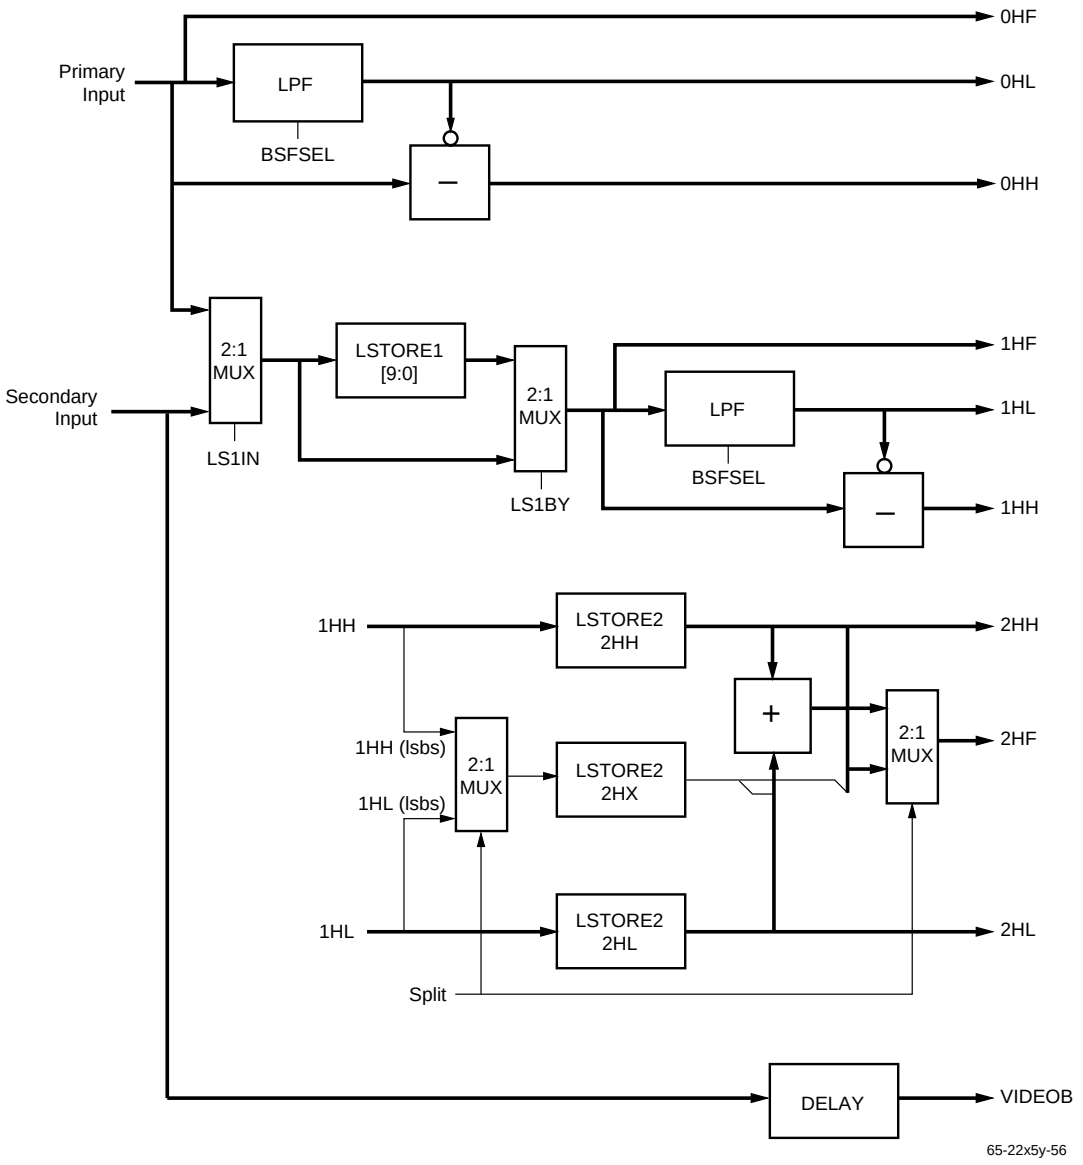

**Figure 15. Block Diagram of Comb Filter Input**

The primary and secondary inputs are selected within the input processor. The primary input is normally the undelayed composite video signal in line, field, and frame based comb filters or either the luma or chroma channel when processing YC or D1 signals. The secondary provides the field or frame delayed composite input for field and frame based comb filters and the chroma or luma channel when processing YC or D1 signals.

When implementing a line based comb filter the outputs of 1H bandsplit filter, ie 1HH, 1HL, are delayed through the second line store, LSTORE2. The number of bits delayed is dependent upon the type of comb filter being implemented. For chroma comb filters all the bits of the 1HH signal are delayed, as this information supplies the outer tap of the chroma comb filter, while only the upper bits of 1HL are delayed as this data is used only in the generation of the luma error signals. In the case of luma combs an equal number of bits of the 1HH and 1HL signals are delayed and summed together to produce the 2HF signal for the outer tap of the luma comb filter. The configuration of LSTORE2 is determined by the SPLIT register bit.

It is important to note that when implementing a field or frame based comb filter the secondary input must be selected by setting the LSIN register bit HIGH, and the first line store, LSTORE1, must be bypassed by setting the LS1BY register bit HIGH.

For YC and D1 processing the secondary input bypasses the comb filter completely and provides the VIDEOB signal input the 3:1 multiplexer used to select the FLAT signal, see Figure 16.

## Adaptive Comb Filter

The IPCF[1:0] register bits select the inputs to the adaptive comb filter, this would normally be xHH for chroma combs, xHF for luma combs, and xHL if the luminance signal was to be sampled dropped on the output of the TMC22x5yA. The Gaussian filters in the sample drop mode already limit the chrominance bandwidth to 1.3MHz allowing a [2:1:1] data format on the output, with the luminance signal having been vertically filtered by a fixed 3 line comb filter.

The SIMP selection bit is an internally generated signal based upon the comb filter selected. If a 3 line chroma, luma, or D1 comb filter is selected, due to the internal 1H delay inherent with this type of comb filter, the 1HL and 1HH signals are selected for the respective luma and chroma *SIMPLE* data signals. When any other type of comb filter is selected 0HL and 0HH are selected.

The DLYF selection bit is also internally generated from the type of comb filter selected and whether or not the input is in either the YC or Y & CbCr (ie D1 input) data formats. The *VIDEOB* data is always selected when the YCCOMP register bit is HIGH, ie for YC inputs. The selection of 1HF or 0HF depends upon the SIMP selection bit only when the YCCOMP register bit is LOW. Therefore, when YCCOMP is LOW and 0Hx is selected by SIMP then 0HF is selected for the *FLAT* signal, and when 1Hx is selected by SIMP then 1HF is selected for the *FLAT* signal. This ensures that the *FLAT* and *SIMPLE* data selected for any comb filter is delayed by the same amount as the data processed through the comb filter to produce the *COMB* output.

The final selection is the output required for the combed luminance and chrominance data. The output selection can be *SIMPLE*, *COMB*, *FLAT-COMB*, or *FLAT*. Generally *COMB* is selected based upon whether a luma or chroma comb was selected and the complementary output selects *FLAT-COMB*. In the YC and Y & CbCr data modes the *FLAT* signal selects the secondary data and *SIMPLE* or *COMB* can be used to select the primary signal. In these modes the bandsplit filter can be bypassed or used to remove low frequency noise from the chrominance signal if chroma was selected as the primary signal.

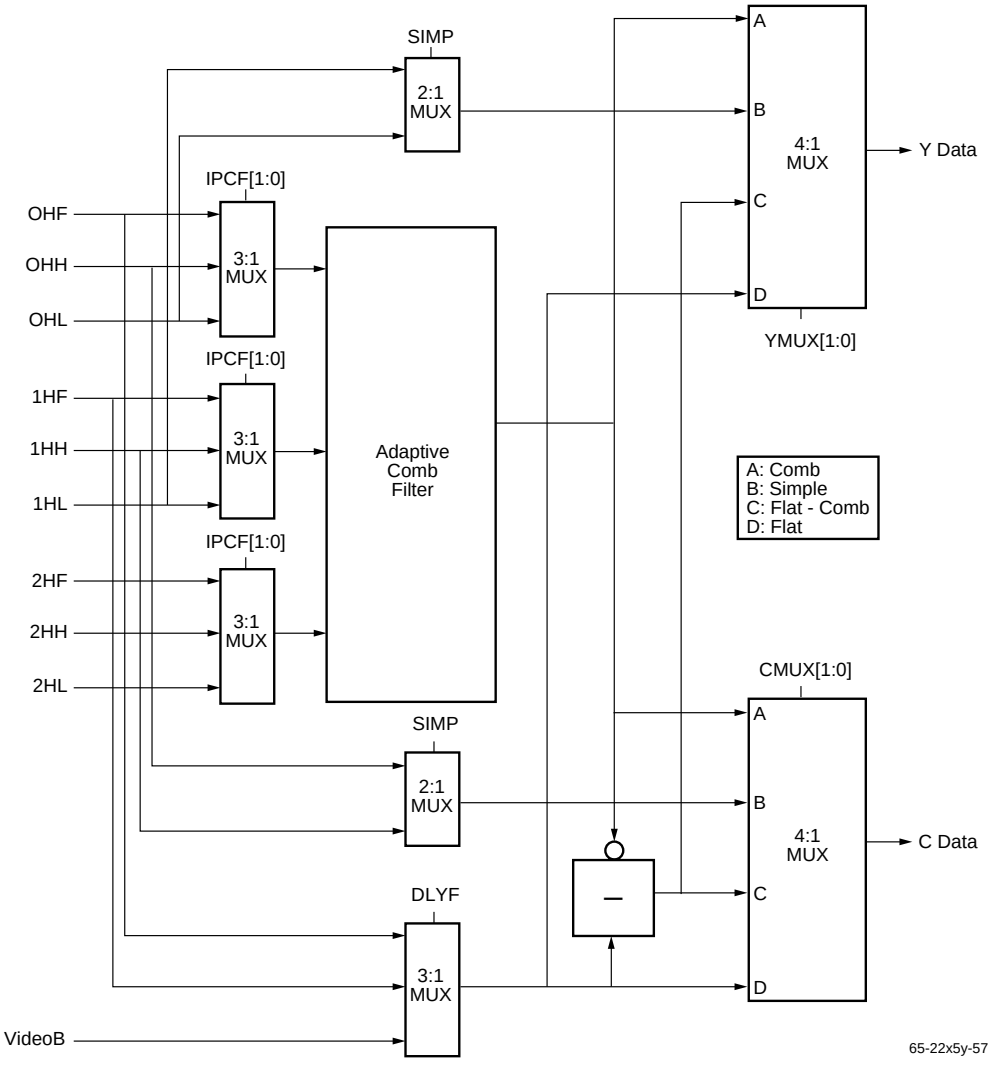

**Figure 16. Signal Flow Around the Adaptive Comb Filter.**

The comb filter architecture performs chrominance or luminance comb filtering on PAL or NTSC video signals, by implementing one of sixteen independent chroma and luma comb filter algorithms. The highest level of the adaptive comb filter configuration is determined by the STA[3:0] register bits as shown in Table 3.

**Table 3. Comb Filter Architecture**

| STA[3:0] | Comb Filter Description |
|---|---|
| 0 | YC or Composite, PAL or NTSC, 3 line comb |
| 1 | YC or Composite, NTSC, 3 line comb (0H & 1H) |
| 2 | YC or Composite, NTSC, 3 line comb (1H & 2H) |
| 3 | YC or Composite, NTSC, 2 line comb (0H & 1H) |
| 4 | YC or Composite, NTSC, (2 line) field comb |
| 5 | YC or Composite, NTSC or PAL, field comb |
| 6 | YC or Composite, NTSC, (2 line) frame comb |
| 7 | YC or Composite, NTSC, frame comb |
| 8 | D1, Y or $C_BC_R$, 3 line comb |
| 9 | D1, Y or $C_BC_R$, 3 line comb (0H & 1H) |
| 10 | D1, Y or $C_BC_R$, 3 line comb (1H & 2H) |
| 11 | D1, Y or $C_BC_R$, 3 line comb (0H & 2H) |
| 12 | D1, Y or $C_BC_R$, (2 line) field comb |
| 13 | D1, Y or $C_BC_R$, field or 2 line comb (0H & 1H) |
| 14 | D1, Y or $C_BC_R$, (2 line) frame comb |
| 15 | D1, Y or $C_BC_R$, Frame |

The *COMB* signal can be produced in two ways. The first method uses the comb fail detection circuits to select one of several comb filter architectures. These comb filter architectures weight the three lines by varying degrees depending upon the degree of picture correlation between the inputs to the comb filter. The simple example in Table 4 shows how this process works, in which upper denotes error comparisons between the two lines stores and lower denotes error comparisons between the input and the first line store. The 0H, 1H, and 2H terms used in the mathematical description of the comb filter selection refer to the position with respect to the internal line stores. The 0H term is the undelayed input, 1H is the output of line store 1, and 2H is the output of line store 2.

In this example a 3 line comb is implemented when in the flat areas of blue or yellow. However, when a difference between the inputs is detected the 3 line comb filter adapts to the 2 line comb filter whose inputs have the smallest difference. This illustrated on line n+4, at which time the comb filter adapts to inputs from 1H (blue) and 2H (blue) and ignores the 0H (yellow) inputs. In cases where there is a difference between all inputs to the comb filter, a 3 line comb filter is selected and the highest set of comb fail signals are sent to the XLUT input logic.

This technique would work well if pictures only contained vertical transitions, which is obviously not the case. Therefore the weighting of these comb filter taps, (0H, 1H, and 2H), are rarely just the simple ratios shown in Table 4. It is worth noting that comb filters that use an even number of lines in the comb filter architecture produce chrominance and luminance signals that are vertically offset by one picture line, i.e. in the middle of the even number of lines used in the comb filter input. While comb filters that use an odd number of lines, in the comb filter architecture, the chrominance and luminance produced is referenced to the center, i.e. the middle line, of the comb filter. This approach can consequentially cause aliasing in decoding composite video signals containing high frequency diagonal transitions. The FAST register bit, when set LOW, filters the comb filter selection to decrease the sensitivity of the adaption algorithm. The second method completely disables the adaption between different comb filters, by setting the ADAPT[1:0] register bits accordingly, see Table 5.

**Table 4. Simple Example of an Adaptive Comb Filter Architecture**

| Line no. | Input color | Error signals | | | | | | Comb filter selection |
|---|---|---|---|---|---|---|---|---|
| | | upper luma | upper sat. | upper hue | lower luma | lower sat. | lower hue | |
| n+6 | blue | x | x | x | x | x | x | unknown without line n+7 |
| n+5 | blue | 0 | 0 | 0 | 0 | 0 | 0 | [0H/4] + [1H/2] + [2H/4] |
| n+4 | blue | 0 | 0 | 0 | >0 | 0 | 180 | [0] + [1H/2] + [2H/2] |
| n+3 | yellow | >0 | 0 | 180 | 0 | 0 | 0 | [0H/2] + [1H/2] + [0] |
| n+2 | yellow | 0 | 0 | 0 | 0 | 0 | 0 | [0H/4] + [1H/2] + [2H/4] |
| n+1 | yellow | 0 | 0 | 0 | >0 | >0 | >0 | [0] + [1H/2] + [2H/2] |
| n | black | x | x | x | x | x | x | unknown without line n-1 |

In either of these methods, the *"K"* signal can be used to cross fade between the *YCOMB* and the *SIMPLE* bandsplit signals. The resulting comb filter equation can be expressed as:

Combed Luma = Simple + (K * Combed High Frequency Luma)

Combed Chroma = Simple - (K * Combed High Frequency Luma)

In the case of the chroma comb, the weighted combed high frequency luma is subtracted from the *SIMPLE* high pass filter output to produce the combed chroma signal, and for luma comb filters the weighted combed high frequency luma is added to the *SIMPLE* low pass filter output to provide the combed luminance signal.

## Comb Fails

The inputs to the comb filter are monitored to detect discontinuities that would cause the comb filter operation to fail. Whenever a significant failure is predicted, the comb filter architecture is modified and an error signal proportional to the discontinuity is produced. For flat areas of color, it is a relatively simple to produce an error signal that switches between the outputs of the comb filter and the simple band split filter without visibly softening the picture horizontally or vertically. However, as horizontal frequencies increase during vertical transitions, so the decision for switching between the comb and simple bandsplit decoder becomes more complex.

A line based comb filter can separate the luma and chroma signals from line repetitive composite video signals, with no loss of luma or chroma bandwidth. However, if there is a vertical transition, i.e. a change from one scan line to the next, as shown for a NTSC two line comb in Figure 17, a *comb fail* occurs. The comb fail shown in Figure 17, clearly illustrates the resulting vertical smearing of the luma and chroma signals.

In addition to the smearing, the resulting phase of the chrominance signal with respect to the burst can cause hue errors in the demodulated picture. In this example, the chrominance signal would be demodulated with a 180 degree phase error. Unlike the "simple" decoder technique any errors in the comb filter decoding produce components that if re-encoded will never reproduce the original composite video waveform. It is therefore imperative that the number and magnitude of comb fails be kept to its absolute minimum. This is not possible with non-adaptive comb filter architectures, and all vertical and diagonal transitions in the picture will cause irreversible picture degradation. For this reason, all the TMC22x5yA comb filter decoders implement an adaptive comb filter architecture.

To aid in this decision making process, comprehensive comb fail signals are generated and fed to a user-programmable lookup table (XLUT). The output of the lookup table provides the control for the cross fade between the comb and simple bandsplit decoder.

### Comb Fail Detection

The traditional approach of using the low frequency data to look for vertical luma transitions, and rectifying the high frequency data to estimate vertical transitions in the chroma provides adequate comb fail detection. However, chroma signals that are equal in magnitude but 180 degrees apart in phase, which can also have a small difference in luma level, for example green and magenta, can produce undetected comb fails in the comb filter output.

To overcome problems with simpler comb fail measurement techniques, the TMC22x5yA generates an array of patented comb fail and comb filter control signals. To produce these signals each input to the comb filter is passed through a simple bandsplit decoder. This provides a luma signal from the low frequency portion of the comb filter input, and the hue (phase) and saturation (magnitude) from the high frequency portion of the comb filter input. These signals are compared and the differences in luma, hue, and saturation are used to determine the type of comb filter used to generate the *YCOMB* signal and to provide the cross fade control signal *"K"*. The *"K"* signal can be weighted within the XLUT lookup table, allowing the user to tailor the comb filter response to their system requirements.

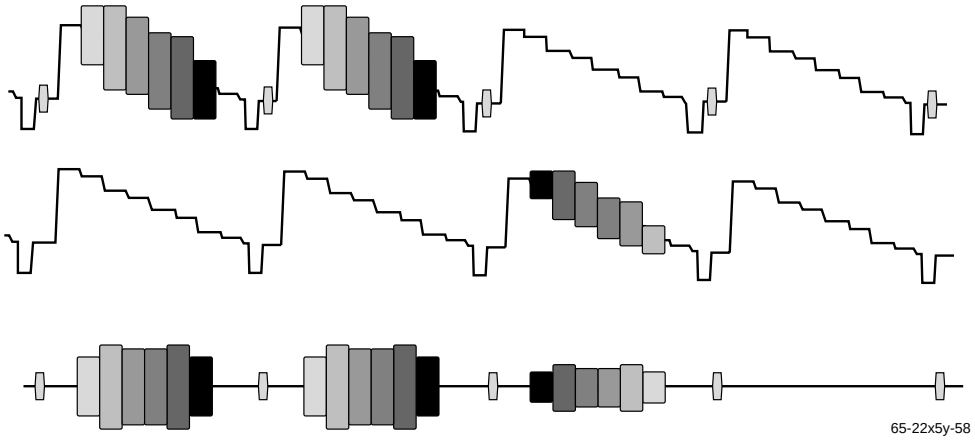

**Figure 17. Example of a Comb Fail Using a NSTC Two Line Comb Filter**

# Generation of the Comb Fail Signals

## Luma Error Signals

The signals from the 3 low pass filters, 0HL, 1HL, and 2HL are subtracted from one another to produce an error signal proportional to the luma comb fail. The resulting signals (0HL - 1HL), produces *LYE*, and either (1HL - 2HL) in NTSC or (0HL - 2HL) in PAL produces *UYE*. The *LYE* and *UYE* luma error signals are rectified if negative. In cases where the luminance component is constant, the error will be zero. Where the luminance goes from black to white over 2 lines, the error signal will go to its maximum value.

The luma error signals can be doubled to facilitate inputs with low picture levels by setting the YESG register bit HIGH. The resulting signal is clipped to ensure no overflow occurs

## Hue and Saturation Error Signals

In the past, comb decoders have relied upon comparing the difference in chroma magnitude between two lines to determine a comb fail. In fact, this chroma signal is normally the output of the high-pass or band-pass filter, and therefore contains all the high frequency luminance information as well. As this signal was never demodulated, the sign bit was immaterial and was used only to rectify the chroma signal. This allowed chroma signals which where equal in magnitude but opposite in phase, and high frequency luminance signals, to fool the comb fail circuit.

The TMC22x5yA uses a new, innovative approach to overcome this problem. To detect comb failures in the high-frequency portion of the video signal the outputs from the three high-pass filters, 0HH, 1HH, and 2HH, are passed through simple demodulators. The outputs from which provide the phase and magnitude of the in-phase and quadrature components of the high frequency data. These components are compared to determine the difference in phase and magnitude between 0H & 1H in all configurations, *LME* and *LPE*, and between 1H & 2H in NTSC or 0H & 2H in PAL, *UME* and *UPE*. The magnitude error signals can be doubled to facilitate inputs with low picture levels by setting the CESG register bit HIGH. The doubled magnitude error signals are limited to ensure no overflow occurs.

The algorithm used to separate the quadrature components depends upon the relationship between the normalized subcarrier frequency and the number of pixels per line. This algorithm is preset for either a NTSC/M or PAL/I subcarrier frequency and a pixel data rate of 13.5MHz. It is therefore necessary to compensate for other pixel data rates by selecting the appropriate default using the CEST[1:0] register bits.

## Picture Correlation

The degree of picture correlation depends upon the differences between the *UYE, UME,* and *UPE* upper error signals and the *LYE, LME,* and *LPE* lower error signals, and is measured as a percentage of full scale error. In flat fields of color you would have 0% error in picture correlation, however in sharp vertical transitions say between yellow and blue you would have large % errors between *UYE* and *LYE* and between *UPE* and *LPE*, while there would be 0% error between *UME* and *LME*.

## Adapting the Comb Filter

In NTSC it is possible to switch from a 3 line comb to a 2 line comb, and then to a simple decoder output. The 3 line comb to 2 line comb switch can be disabled, forcing the 3 line comb to switch directly to simple. The switching between these two comb architectures is independent of the

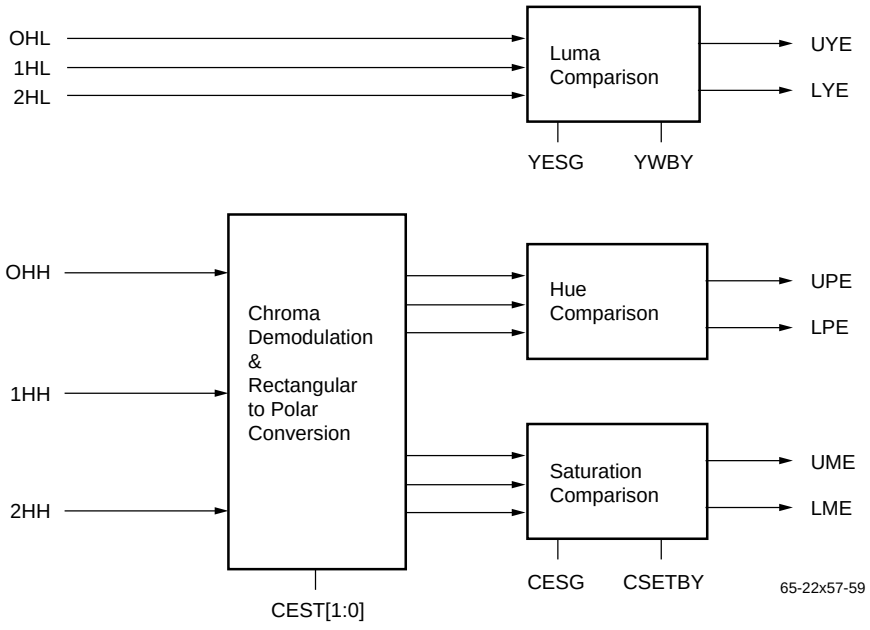

**Figure 18. Generation of Upper and Lower Comb Fail Signals**

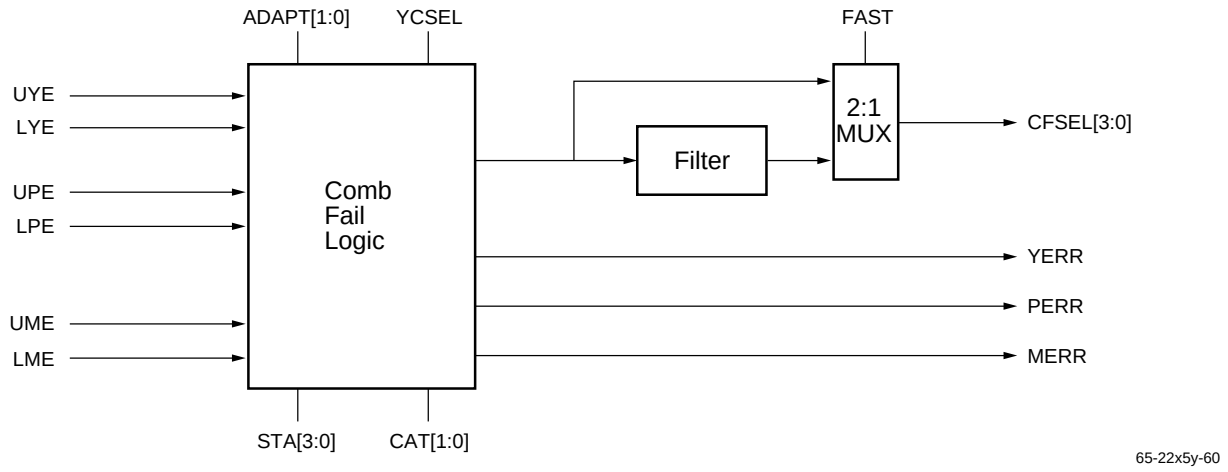

**Figure 19. Comb Filter Selection**

mix signal, K. For 3-line Y/C comb filters, an external 1H delay is required in the uncombed channel to compensate for the comb filter delay.

This principle is equally true for NTSC frame and field based comb decoders. The feature is not available for any of the PAL comb filter architectures.

The Comb filter Adaption Threshold register bits CAT[1:0] determine if 5%, 15%, 25%, or 50% errors in picture correlation is required to adapt the NTSC comb filter. In NTSC, due to the 180 degree advance in subcarrier phase per line, it is possible to switch between the 3 line comb and the choice of either the upper two line comb or the lower two line comb. If this switching occurs on a pixel by pixel basis the picture will contain vertical alias components. This artifact can be reduced by either setting the FAST register bit LOW, which filters the comb filter selection, and/ or setting the CAT[1:0] register bits to a higher percentage threshold.

The comb filter adaption is further controlled by the ADAPT[1:0] register bit selection, when the COMB[3:0] register bits select a 3 line comb. These bits control if the comb filter adapts from a 3 line comb to the best of the upper or lower 2 line combs, from a 3 line comb to just the lower 2 line comb, performs a fixed 3 line comb, or implements a best of two 3 line combs in PAL. If the COMB[3:0] register bits select one of the 2 line comb filters, the ADAPT[1:0] register bits are ignored, and no adaption is implemented. The CFSEL[1:0] signal, shown in Figure 19, controls which comb filter is selected on a pixel by pixel basis, and can be externally monitored by reading CFSTAT[1:0] in register 4Bh.

**Table 5. Adaption Modes**

| ADAPT[1:0] | Function |
|---|---|
| 00 | Adapts to the best of 3 types of line based comb filters in NTSC only. |
| 01 | 3 line (tap) comb always adapts to lower 2 line (tap) comb, when the 3 line (tap) comb fails. Normally used with NTSC field and frame based comb filters. |
| 10 | 3 line (tap) comb only. Never adapts to a 2 line(tap) filter. The higher set of comb filter error signals are sent to the XLUT. NTSC or PAL comb filter. |
| 11 | Adapts to best of two 3 line comb filters in PAL only. |

## XLUT

The comb fail signals control both the comb filter adaption and the cross fade between the adaptive comb filter output *YCOMB* and the *SIMPLE* bandsplit signal. Which of the fail signals is fed to the XLUT is determined by which comb filter is selected in NTSC. When a 3 line comb filter is selected, the larger set of error signals are sent to the XLUT, when a upper 2 line comb is selected *UYE*, *UME*, and *UPE* error signals are selected, and when a lower two line comb filter is selected the *LYE*, *LME*, and *LPE* error signals are selected.

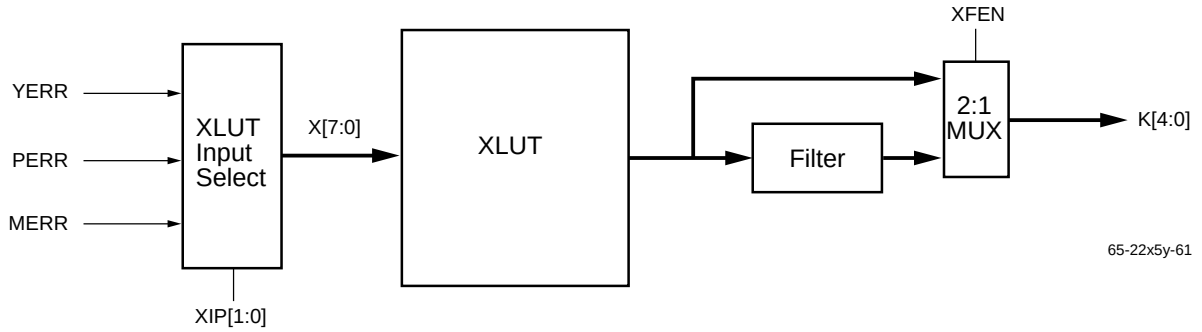

**Figure 20. XLUT Input Selection**

For PAL comb filters the *LYE*, *LME*, and *LPE* errors signals are always selected by default. In this way the error signals into the XLUT always represent the comb filter being implemented. The resolution of the error signals selected is controlled by the XIP[1:0] register bits as shown in Table 6: XLUT Input Selection. The position of these error signals on the XLUT input address X[7:0] is also shown.

### Table 6. XLUT Input Selection

| XIP[1:0] | Function |
|---|---|
| 00 | 2 bits of phase error (X[7:6]), 3 bits of chroma (X[5:3]) and luma magnitude error (X[3:0]). |
| 01 | 4 bits of chroma (X[7:4]) and luma magnitude error (X[3:0]). |
| 10 | 3 bits of phase error (X[7:5]), 3 bits of chroma magnitude error (X[4:2]), and 2 bits of luma magnitude error (X[1:0]). |
| 11 | 4 bits of phase error (X[7:4]) and chroma magnitude error (X[3:0]). |

The selected comb fail signals are translated by the user-programmed configuration within the 256*5 XLUT into the mix signal (K) which controls the 30 levels of cross-fade between the weighted comb filter and the band split filters. The 1 to 31 mix signal is modified on the input to the cross-fade to produce a 0 to 32 control signal, as shown in Table 7.

### Table 7. XLUT Output Function.

| XLUT OUTPUT | K |
|---|---|
| 0 | Special function (e.g. luma comb and HPF on chroma) |
| 1 | 0 - 100% Bandsplit |
| 2 | 2 |
| 3 | 3 |
| : | : |

### Table 7. XLUT Output Function. (cont.)

| XLUT OUTPUT | K |
|---|---|
| 16 | 16 - 50% Bandsplit, 50% Comb |
| : | : |
| 29 | 29 |
| 30 | 30 |
| 31 | 32 - 100% Comb |

The special function assigned to K = 0 is programmed into the XSF[1:0] register bits, as shown in Table 8.

### Table 8. XLUT Special Function Definitions

| $KIP_{1-0}$ | XLUT special function selection | |
|---|---|---|
| | Y | C |
| 00 | comb | simple |
| 01 | simple | comb |
| 10 | flat with notch | simple |
| 11 | flat with notch | comb |

The “Flat with notch” selection passes the *FLAT* input through onto the luminance channel and selects the notch filter, centered at 0.25 of the normalized clock frequency. This mode is therefore only useful with inputs at 4*Fsc or in cases when a notch at 0.25 of the normalized clock frequency is adequate for application.

The XLUT output, is fed through a bypassable low-pass filter KLPF to avoid switching between comb and simple decoders on a pixel by pixel basis. When the special function is selected (K = 0) the input to the KLPF is held and the filter is automatically bypassed. The output of the XLUT can be externally monitored by reading XOP[4:0] in register 4Bh.

.

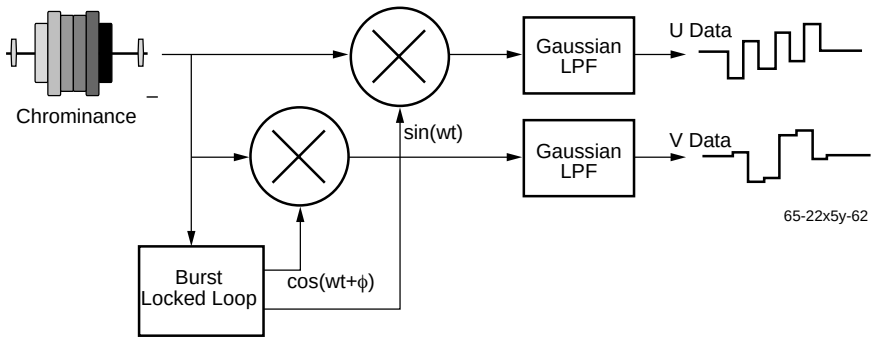

**Figure 21. Block Diagram of Digital Burst Locked Loop**

## Digital Burst Locked Loop

The digital burst locked loop provides sine and cosine signals which are phase locked to the incoming burst signal. These sine and cosine signals are used to demodulate the chrominance data, producing the U and V color-difference signals. The U data are phase-referenced to sin(wt) and the V data to cos(wt). The demodulated signal is passed through a low pass filter to remove signals at twice the subcarrier frequency. The magnitude of the U and V data within the demodulated burst signal provides the error signal which, after filtering, is used to adjust the frequency and/or phase of the subcarrier DDS. The output of the subcarrier DDS is translated into sine and cosine signals in ROM-based lookup tables.
The PALODD signal is low on lines without the 180 degree phase advance in the modulated V signal, termed NTSC lines, and high for lines with the 180 degree phase advance, termed PAL lines. This signal is used in the burst locked loop to advance the phase of the cosine table on PAL lines. PALODD is always low for NTSC.

## Color Kill Counter

The demodulated U and V components are compared to a programmable burst level threshold. If both the U and V data fall below this threshold, a color kill flag is set high. The color kill counter is incremented once per line if the color kill flag is high. If the count reaches 127 within one field, the color kill circuit becomes active during the next field group. When this occurs, the input video will be passed unaltered on the luminance channel and the color difference signals will be set to chroma black.

The color kill signal remains active until a field with less than 127 lines without burst is encountered, at which time, during the next vertical blanking period, the decoder is reset. The operation of the color kill logic can be monitored externally by reading the MONO register bit in register 44h. The MONO bit is HIGH for composite and YC video signals and LOW for monochrome signals.

### Field Flag, FLD

The FLD signal is the lsb of the field count $FID_{2-0}$ and is LOW for fields where the first vertical sync occurs in the first half of the line and is HIGH for fields when it occurs in the second half of the line. This signal is synchronized with the frame and color frame flags in the FID generator.

### Frame Bit

NTSC
The middle bit (frame bit) of the field count is determined, by the phase of the subcarrier on a given pixel and on a given line. The signal used to determine this is NFDET (New Field DETect), and occurs when the line count is zero and the pixel count is one of four programmable pixel positions, zero, one, two, or three.

PAL
The frame bit in PAL is detected through the Bruch blanking sequence. The error signal control circuit generates a color kill flag whenever a line is detected without a burst. It is therefore possible to compare this signal with specific line idents to determine the field sequence in both PAL-I and PAL-M. A set of specific patterns determine the correct phase of $FID_1$; if any of these patterns is detected then $FID_1$ is forced to a known state and then flywheels until the next fixed pattern is detected.

**Table 9. PAL-B,G,H,I Bruch Blanking Sequence**

| Internal line # | Burst present | Internal frame # | Internal field # |
|---|---|---|---|
| 5 | No | 0 or 2 | 0 or 4 |
| 309 | No | 0 or 2 | 0 or 4 |
| 6 | Yes | 0 or 2 | 1 or 5 |
| 309 | No | 0 or 2 | 1 or 5 |
| 5 | Yes | 1 or 3 | 2 or 6 |
| 309 | Yes | 1 or 3 | 2 or 6 |
| 6 | No | 1 or 3 | 3 or 7 |
| 309 | Yes | 1 or 3 | 3 or 7 |

The frame bit is low for frames 0 and 2 and high for frames 1 and 3.

Preliminary Information

**Table 10. PAL-M Bruch Blanking Sequence**

| Internal line # | Burst present | Internal frame # | Internal field # |
|---|---|---|---|
| 7 | No | 0 or 2 | 0 or 4 |
| 258 | Yes | 0 or 2 | 0 or 4 |
| 7 | No | 0 or 2 | 1 or 5 |
| 259 | No | 0 or 2 | 1 or 5 |
| 7 | Yes | 1 or 3 | 2 or 6 |
| 258 | No | 1 or 3 | 2 or 6 |
| 7 | Yes | 1 or 3 | 3 or 7 |
| 259 | Yes | 1 or 3 | 3 or 7 |

The frame bit is low for frames 0 and 2 and high for frames 1 and 3.

## PAL Color Frame Bit

The PAL color frame bit is the msb of the field count, $FID_2$. In NTSC this is always low, as NTSC has only a 4 field sequence. For both PAL-I and PAL-M inputs, the PAL color frame bit is determined in the same way the frame bit is determined in NTSC, by using the phase of the subcarrier on a given pixel and on a given line.

## Hue Control

One of two programmable 16 bit system phase offsets can be added to the subcarrier oscillator between SAV and EAV. The selection is made by the BUFFER pin. This feature allows the user to change the picture hue on known frames without affecting the burst locked loop.

## System Monitoring of the Burst Loop Error

The burst loop error signal is stored once per line in an 8 bit register that can be accessed over the microprocessor port. This allows the user to check for non-mathematical PAL inputs and to the change the decoder architecture from frame-based to line-based or simple decoder depending on this information.

### Demodulation Low Pass Filter

There are two different demodulation low pass filters that can be selected under software. For PAL inputs with normalized subcarrier frequencies greater than 0.3 of the sampling frequency, it is recommended you use “demodulator filter 2” to stop aliasing of the second harmonic of the demodulation chrominance signal and the baseband color difference signals. Gaussian filters are used for both demodulation filters as they have no negative coefficients and therefore have no undershoots or overshoots which could cause in-band ringing.

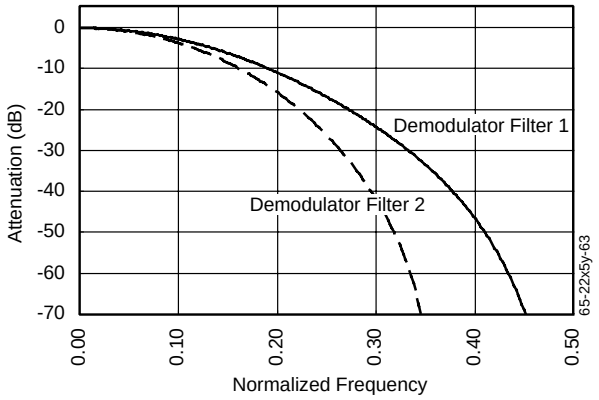

**Figure 22. Gaussian Low Pass Filters**

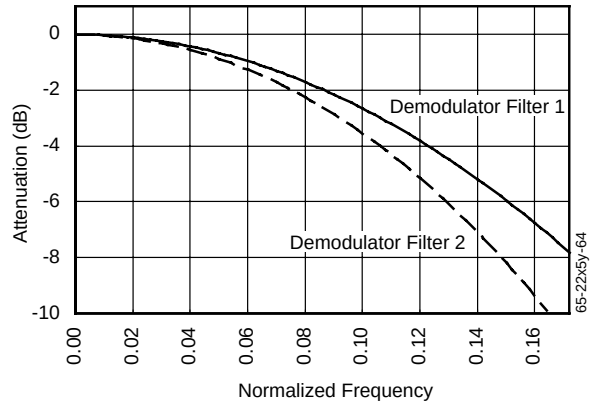

**Figure 23. Gaussian LPF Passband Detail**

### Bypassing the Chrominance Demodulator

The demodulation of the chrominance signal needs to be bypassed when the decoder is processing $C_BC_R$ component data or when a YC output is required. The bypass operation is controlled by the DMODBY register bit.

### Bypassing the Demodulation Low Pass Filter

The demodulation low pass filter needs to be bypassed when processing $C_BC_R$ component data or when a YC output is required. The $C_BC_R$ data can also be passed through the Gaussian filter if the bandwidth needs to be reduced. The bypass operation is controlled by the GAUBY register bit.

### Chrominance Coring

Chrominance coring, when active, sets the lsbs of the chroma channel (below a programmable threshold) to zero.

### $VMCR_5$ Operation

When $VMCR_5$ is HIGH, the decoder will grab one line of video in LSTORE1. This effectively removes the comb filter from the decoding process, and the comb filter output is forced to simple mode.

# Output Processor

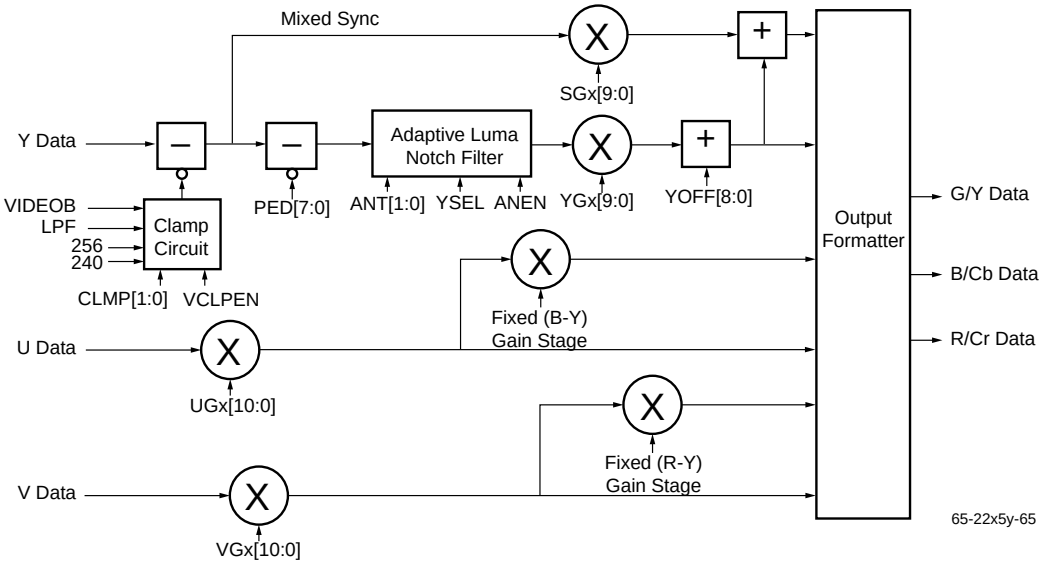

**Figure 24. Output Processor Block Diagram**

## Clamp Circuit

A clamp pulse generated by the Burst Gate signal is used to grab either a sample of the low-pass-filtered luma during the video back porch, the signal on VIDEOB, or one of two internally generated levels. The selection is made by the CLMP[1:0] register bits.

### Table 11. Blanking Level Selection

| CLMP[1:0] | Blanking Selection |
|---|---|
| 00 | Internal 240 level |
| 01 | Internal 256 level |
| 10 | External VIDEOB Input |
| 11 | Internal LPF Output |

The blanking level is subtracted from the decoded luma. If the sign is negative, the result is assumed to be mixed sync and is passed through a delay and into the sync gain stage within the output matrix. If the sign is positive, the result is assumed to be pure luma (blanking to peak white) and is fed to the pedestal removal circuit.

## Pedestal Removal

The 8 bit programmable pedestal is subtracted from the pure luma signal. The negative super black signals are clipped to zero when register 0Ah bit 4 is set LOW, or the super black signals are passed through the luma scalar when register 0Ah bit 4 is HIGH.

## Clamp Generator

The TMC22x5yA has the unique option to output a negative going clamp pulse that is 0.5 μsec wide. This pulse can be output on the AVOUT pin by placing a HIGH on register 24 bit 7. The pulse's position relative to HSYNC can be varied by register 25. This value is the number of PCK clock cycles after an HSYNC that the pulse will be output to the pin. The clamp pulse can be used to control where an analog clamp circuit grabs the analog reference to establish the correct voltage level into the A/D. Usually the clamp pulse is generated on the back porch or duing the sync tip of a video line.

### Adaptive Notch Filter

The PAL line-locked comb decoder can never provide perfect subcarrier cancellation due to the 25Hz offset in the subcarrier frequency. This 25Hz offset causes residual and phase modified subcarrier to be left on the luminance signal which can produce a visible dot crawl on flat areas of color. However, for all comb filter structures, the quality of the comb depends on the quality of the sampling clock, as line to line clock jitter will also cause small phase changes between the inputs to the comb filter. It is therefore possible that NTSC comb decoders may also require some coring of the luma output. To meet the wide range of sample frequencies that the decoder must deal with two separate coring filters are selectable.

The luma signal from the pedestal stripper is compared against the preceding pixel to detect the magnitude change between pixels. This magnitude difference will be almost zero for flat areas of picture, and large for high frequency changes in the picture. The magnitude difference is compared to one of four programmable thresholds. The programmable threshold is selected by the $ANT_{1-0}$ register bits as shown in Table 12.

### Table 12. Adaptive Notch Threshold Control

| $ANT_{1-0}$ | Magnitude difference |
|---|---|
| 00 | less than 16 |
| 01 | less than 12 |
| 10 | less than 8 |
| 11 | less than 4 |

If either of the error signals indicates that the magnitude difference is above the programmed threshold, or if ANEN is LOW, the adaptive notch filter is bypassed. The output of the adaptive notch filter is rounded to 8 or 10 bits, or the luma data that bypasses the coring filter is truncated to 8 or 10 bits depending upon the CORO register bit.

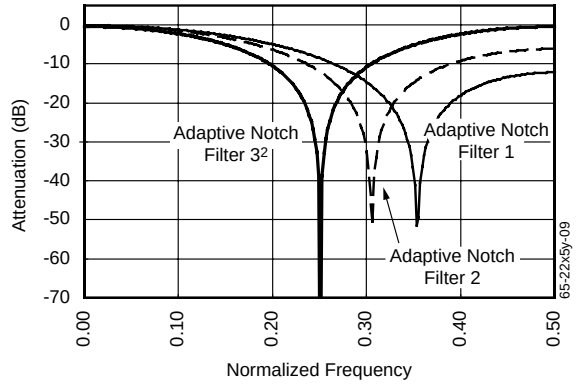

**Figure 25. Adaptive Notch Filters**

## Luma Notch Filter

The simple luma notch filter is centered at 0.25 of normalized frequency, it therefore intended for use only in the subcarrier mode (4 * fSC) and for limited use with 13.5MHz NTSC as the subcarrier sits at 0.265 of normalized frequency. The notch filter is enabled by setting the NOTCH register bit HIGH.

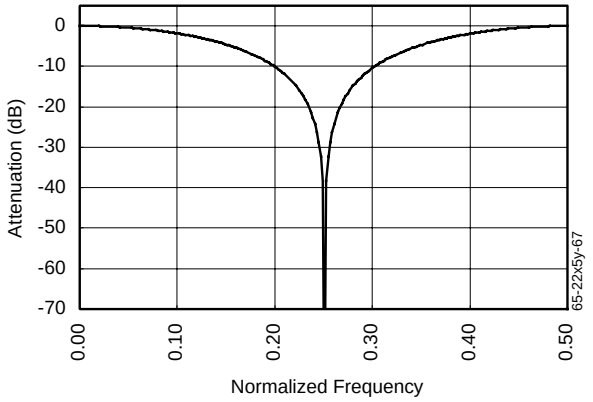

**Figure 26. Luminance Notch Filter**

## Matrix

The magnitude of the decoded luminance and color difference signals will vary, not only with the standard, but also with the input mode. For this reason the output matrix contains programmable multipliers, and not just fixed scaling factors. The following sub sections explain the different scalar in the output matrix. The gain term in the Y, mixed sync, U and V scalar is the same - only the weighting makes them different. The scalar are capable of independently providing 6dB of gain if required.

## Programmable U Scalar

The U scalar (UGx) provides the weighting required to produce (B-Y) or $C_B$ from the demodulated U signal.

hence

$$(B\text{-}Y) = UGx * U$$

where UGx = gain / 0.493, and

$$C_B = UGx * U$$

where UGx = (gain * 448) / Umax

UGx has a scaling range of 0 to (2047/256).

## Programmable V Scalar

The V scalar (VGx) provides the weighting required to produce (R-Y) or $C_R$ from the demodulated V signal.

hence

$$(R\text{-}Y) = VGx * V$$

where VGx = gain / 0.877, and

$$C_R = VGx * V$$

where VGx = (gain * 448) / Vmax

VGx has a scaling range of 0 to (1023/256).

## Programmable Y Scalar

The Y scalar (YGx) provides the scaling for the luminance signal if the output is $YC_BC_R$, or controls the magnitude of the RGB output along with the U scalar and V scalar. It is not possible to control the magnitude of the RGB signals independently.

YGx has a scaling range of 0 to (1023/256).

## Programmable MS Scalar

The sync scalar (SGx) provides the scaling for the sync signal if the output requires sync on RGB. The programmed sync scaling factor is used during the horizontal and vertical burst blanking periods. During the active lines, the luma scaling factor is used to allow scaling of “super blacks” etc., which will be passed down the mixed sync path because they fall below the clamp level.

SGx has a scaling range of 0 to (1023/256).

## Fixed (B-Y) and (R-Y) Scalars

These two scalars are zero when the output is $YC_BC_R$ and provide the (B-Y) and (R-Y) weighting when the output is RGB. These are fixed scaling factors and are derived from the following equations.

$$(G\text{-}Y) = -[(0.299/0.587) * (R\text{-}Y)] - [(0.114/0.587) * (B\text{-}Y)]$$

or

$$(G\text{-}Y) = -[(1043/2048) * (R\text{-}Y)] - [(398/2048) * (B\text{-}Y)]$$

## Y Offset

The 8 bit Y offset adds any offset required in the Y or RGB data outputs. For example 64 (16) for the 64 (16) to 940 (235) 10 bit (8 bit) 601 outputs. When the output is $YC_BC_R$ this offset is applied to the luminance data only. The Y offset also provides the blanking level for RGB outputs with syncs.

## Matrix Limiters

The different limiters are listed below, 10 bit data is assumed.

### Table 13. Matrix Limiters

| $LMT_{1-0}$ | Comments |
|---|---|
| 00 | RGB output format, limited from 0 to 1023 |
| 01 | $YC_BC_R$ output format, Y limited from 0 to 1023 and $C_BC_R$ limited to +/- 511. |
| 10 | RGB output format, limited from 64 to 940 |
| 11 | $YC_BC_R$ output format, Y limited from 64 to 940 and $C_BC_R$ limited to +/- 448 |

## Examples of Output Matrix Operation

From the SMPTE-170M specification:

| Color | Y | U | V |
|---|---|---|---|
| White | 584 | 0 | 0 |
| Yellow | 523 | -236 | 54 |
| Cyan | 423 | 79 | -332 |
| Green | 361 | -156 | -278 |
| Magenta | 267 | 156 | 278 |
| Red | 205 | -79 | 332 |
| Blue | 105 | 236 | -54 |
| Black | 44 | 0 | 0 |

$YC_BC_R$ data ranges are:

Y data range is 64 to 940 (876)
$C_BC_R$ data ranges are 64 to 960 (+/- 448)

Matrix programming:

YGx = (876 / 540) = 1 + (159/256)
UGx = (448 / 236) = 1 + (230/256)
VGx = (448 / 332) = 1 + (89/256)
YOFF = 64
PED = 44

| Color | Decoder Output | | | CCIR 601 Spec | | |
|---|---|---|---|---|---|---|
| | Y | $C_B$ | $C_R$ | Y | $C_B$ | $C_R$ |
| White | 939 | 0 | 0 | 940 | 0 | 0 |
| Yellow | 841 | -448 | 73 | 840 | -448 | 72 |
| Cyan | 678 | 150 | -447 | 678 | 151 | -448 |
| Green | 578 | -296 | -376 | 578 | -296 | -375 |
| Magenta | 426 | 296 | 376 | 426 | 296 | 375 |
| Red | 325 | -150 | 447 | 326 | -151 | 448 |
| Blue | 163 | 448 | -73 | 164 | 448 | -72 |
| Black | 64 | 0 | 0 | 64 | 0 | 0 |

PAL digital composite input and RGB (0-1023) outputs:

| Color | Y | U | V |
|---|---|---|---|
| White | 572 | 0 | 0 |
| Yellow | 507 | -250 | 57 |
| Cyan | 401 | 84 | -352 |
| Green | 336 | -165 | -295 |
| Magenta | 236 | 165 | 295 |
| Red | 171 | -84 | 352 |
| Blue | 65 | 250 | -57 |
| Black | 0 | 0 | 0 |

The nominal scaling factors are simply:

YGx = 1023/572 = 1 + (202/256)
UGx = (1023/572)*(1/0.492) = 3 + (163/256)
VGx = (1023/572)*(1/0.877) = 2 + (10/256)
YOFF= 0
PED = 0

| Color | G | R | B |
|---|---|---|---|
| White | 1023 | 1023 | 1023 |
| Yellow | 1023 | 1023 | 0 |
| Cyan | 1023 | 0 | 1023 |
| Green | 1023 | 0 | 1 |
| Magenta | 0 | 1023 | 1022 |
| Red | 0 | 1023 | 1 |
| Blue | 0 | 0 | 1023 |
| Black | 0 | 0 | 0 |

It is also possible with the architecture supplied to use the limiters on the output of the matrix to clip the output video deliberately by using a slightly larger gain than is required. The Y_Offset can achieve the same by setting its value to be one lsb less than the minimum clip level.

#### Buffer Registers

The BUFFER pin allows the user to externally switch between two sets of internal registers that have the same function. This register buffering allows the matrix gain, picture hue, and luma offset to be changed at a known time relative to the input data.

Registers 17 to 1D are selected when the BUFFER pin is LOW and registers 27 to 2D are selected when the BUFFER pin is HIGH. If the msb of the decoder product code $DPC_2$ is LOW, an 8 bit decoder has been selected and the bottom 2 bits of registers 17 to 1A and 27 to 2A are forced to zero.

## Simple Luma Color Correction

If the YBAL register bit is set HIGH, and the luma data reaches or exceeds the luma limits, there should be no $C_BC_R$ or UV data at that time; therefore the color data are set to ZERO. If YBAL is set LOW then the $C_BC_R$/UV data are unaffected by the luma data.

## $C_BC_R$ MSB Inversion

The msb of the $C_BC_R$ data can be inverted by setting the MSBO register bit HIGH. As this would affect the chroma blanking level, this circuit appears at the output of the MATRIX circuit.

## Output Rounding

For compatibility with 8 bit systems, the output of the matrix can be rounded to 8 bits by setting the RND8 register bit HIGH.

## Output Formats

### RGB Outputs

The RGB data are simply passed through to the decoder output. When the DRSEN register bit is HIGH the DRS data are inserted into the green data path only.

### YUV Outputs

The YUV data are simply passed through to the decoder output. When the DRSEN register bit is HIGH the DRS data are inserted into the luminance data path only.

### $YC_BC_R$ Outputs

The $YC_BC_R$ data can be output in 3 ways, depending upon the CDEC, F422, and YUVT register bits. These output modes are summarized in .

When CDEC is HIGH and F422 is HIGH, the G/Y output is set to 64 and the B/U output is set to 512 between the EAV TRS data word and the first preamble word of the SAV TRS, i.e. during the digital horizontal blanking period. When YUVT is HIGH, R/V is set to 512, 64, 512, 64, etc., starting after the EAV TRS data word and finishing before the SAV preamble.

## Decimating $C_BC_R$ Data

Whenever the CDEC register bit is set HIGH the B/U and R/V data are simply sample dropped, with respect to CBSEL, to produce the multiplexed $C_BC_R$ data stream at the PCK clock rate. If the input was initially D1 then the dropped samples will be the interpolated samples produced by the chroma interpolation filter. If however the $C_BC_R$ data are simply weighted UV data then the sample dropped demodulated color difference signals (UV) will alias around 0.25 of the normalized sample frequency.

## Multiplexed $YC_BC_R$ Output (TRS Words Inserted)

When both the CDEC and YUVT register bits are HIGH the Y, $C_B$, and $C_R$ component data are multiplexed into a single 27MHz (PXCK) data stream with embedded TRS words. The TRS words are generated based on the $\overline{\text{HSYNC}}$ or $\overline{\text{VSYNC}}$ pulses provided to the decoder, and the internally derived horizontal blanking ($\overline{\text{HBLK}}$), vertical blanking ($\overline{\text{VBLK}}$), and the field flag (FLD). This mode of operation is only available if a line locked PXCK clock, at 27MHz, is provided. The TRS words will be generated with respect to the HSYNC\ signal as per the ANSI/SMPTE 125M-1992 and CCIR 656 specifications.

## YC Outputs

The YC data are passed through to the decoder output. When the DRSEN register bit is HIGH the DRS data are inserted into the luminance data path only. The luminance appears on G/Y, chrominance is on B/U and the R/V output is set to zero, by setting the V_scalar to zero.

## The LDV Clock

The decoder can accept clocks at either the pixel clock rate (PCK) or at twice the pixel clock rate (PXCK). In the cases where the clock provided is PXCK, for example the genlock mode, the output data still needs to be at the PCK clock rate. To aid in the design of external circuitry a LDV clock is provided if the LDVIO register bit is LOW, if LDVIO is HIGH then the LDV pin becomes an input for an external clock.

If an external LDV clock is employed the user must ensure that the rising edge of the external LDV meets the specified setup and hold times relative to the input CLOCK pin. The selection of which clock to use on the decoder output is set by the OPSEL register bit. When OPSEL is set LOW the output is clocked at the same rate as the clock on the CLOCK pin, and when OPSEL is set HIGH the output is clocked by the internal or external clock on the LDV pin.

**Table 14. Output Format**

| CDEC | YUVT | F422 | G/Y | B/U | R/V | Comments |
|---|---|---|---|---|---|---|
| 0 | x | x | G or Y | B or $C_B$ | R or $C_R$ | [4:4:4] data |
| 1 | 0 | 0 | Y | $C_B$ | $C_R$ | [4:2:2] data |
| 1 | 0 | 1 | Y | $C_BC_R$ | 0 | [4:2:2] data |
| 1 | 1 | x | Y | $C_BC_R$ | D1 data | [4:2:2] data & D1 output |

## Sync Pulse Generator

The vertical and horizontal references to the decoder can be from external VSYNC and HSYNC pulses, decoded from TRS and TRS-ID words, or from the internal sync separator which extracts the sync information from the digitized input video.

The sync pulse generator (SPG) provides all the clock and enable pulses required to synchronize the decoder operation to the incoming video signal. These pulses are described below, along with the microprocessor data required to control them.

### Internal Field and Line Numbering Scheme

The internal line numbering of the digital decoder differs from the standard video line numbering as shown in the following tables. The internal line numbers for a 3 line comb advance the numbering by 1 line with respect to the input, but are identical with respect to the internally one line delayed decoded video.

**Table 15. NTSC Field and Line Numbering**

| Standard Field # | Standard Line # | Internal Field # | Internal Line # |
|---|---|---|---|
| 1 & 3 | 1 - 3 | 1 & 3 | 260 - 262 |
| 1 & 3 | 4 - 263 | 0 & 2 | 0 - 259 |
| 2 & 4 | 264 - 265 | 0 & 2 | 260 - 261 |
| 2 & 4 | 266 - 525 | 1 & 3 | 0 - 259 |

**Table 16. PAL B,G,H,I Field and Line Numbering**

| Standard Field # | Standard Line # | Internal Field # | Internal Line # |
|---|---|---|---|
| 1 & 5 | 1 - 312 | 0 & 4 | 0 - 311 |
| 2 & 6 | 313 - 625 | 1 & 5 | 0 - 312 |
| 3 & 7 | 626 - 937 | 2 & 6 | 0 - 311 |
| 4 & 8 | 938 - 1250 | 3 & 7 | 0 - 312 |

**Table 17. PAL M Field and Line Numbering**

| Standard Field # | Standard Line # | Internal Field # | Internal Line # |
|---|---|---|---|
| 1 & 5 | 1 - 262 | 0 & 2 | 0 - 261 |
| 2 & 6 | 263 - 525 | 1 & 3 | 0 - 262 |
| 3 & 7 | 1 - 262 | 0 & 2 | 0 - 261 |
| 4 & 8 | 263 - 525 | 1 & 3 | 0 - 262 |

**HSTBG (Burst gate)***
The burst gate starts the 16 clock period average of the demodulated burst envelope. The position of the burst gate is programmed into a register as the number of clock periods from the falling edge of sync to the burst envelope.

* Signal is available over the microprocessor data bus.

**$\overline{\text{HBLK}}$ (Horizontal Blanking Period)***
The horizontal blanking period is LOW between the start of SAV and the end of EAV. This signal is used in several places:

a) To clear the SYSPH offset when LOW, this is required for correct operation of the subcarrier phase locked loop,
b) To aid in the comb filter management,
c) To remove the burst envelope on the demodulated UV data,
d) To remove the syncs on the BLUE and RED outputs.

**$\overline{\text{BBLK}}$ (Vertical Burst Blanking Period)**
The vertical burst blanking blanks the lines with no burst from the burst phase locked loop. This signal is decoded from the line ident, $LID_{4-0}$, and is modified by the video standard and the field count.

**$\overline{\text{MBLK}}$ (Mixed Blanking)**
This signal is used in the matrix to switch between the sync scalar and the luma scalar. The $\overline{\text{MBLK}}$ signal is active whenever $\overline{\text{HBLK}}$ is active or becomes active when $\overline{\text{VBLK}}$ becomes active. $\overline{\text{MBLK}}$ is also active in PAL on line 310 when both VACT1 and FLD are HIGH and in NTSC and PAL M on line 259 when VACT2 is HIGH and FLD is LOW.

**FLD***
The FLD is LOW for field 1 and HIGH for field 2.

**$LID_{4-0}$***
The line ID signals are used in the vertical comb filter management to control the comb filter on the leading and trailing lines of active video around the vertical blanking period, to start and stop the VINDO operation, and in generating the vertical blanking and burst blanking periods.

**VACT2***
VACT2 is HIGH during the second half of all active lines.

**GRABF***
The GRABF signal goes HIGH when the internal field count is equal to the programmed field number for the GRAB operation. f a pixel grab is being, this signal is held HIGH to not inhibit the GRABS signal on each line.

**GRABL***
The GRABL signal goes HIGH when the internal line count is equal to the programmed line number for the GRAB operation. If a pixel grab is being performed, this signal is held HIGH to not inhibit the GRABS signal on each line.

**GRABP***
The GRABP signal goes HIGH when the internal pixel count is equal to the programmed pixel number for the GRAB operation.

**$\overline{\text{DVSYNC}}$ and $\overline{\text{DHSYNC}}$ (Output Pins)**
The $\overline{\text{DVSYNC}}$ and $\overline{\text{DHSYNC}}$ signals are active when $GCR_2$ is LOW. When $GCR_2$ is HIGH these signals are three stated. Three line comb based decoders have an inherent line delay, therefore the input $\overline{\text{VSYNC}}$ and $\overline{\text{HSYNC}}$ signals can not be just delayed by a few registers and output as $\overline{\text{DVSYNC}}$ and $\overline{\text{DHSYNC}}$: they need to be delayed by one complete line. In all other comb filter configurations the $\overline{\text{DVSYNC}}$ and

$\overline{\text{DHSYNC}}$ are referenced to the input data (0HFLAT) and not the output of the LSTORE1, i.e. 1HFLAT.

The duration of the $\overline{\text{DVSYNC}}$ signal is fixed to one line and the duration of the $\overline{\text{DHSYNC}}$ signal is 64 clock periods. Both these signals are generated by the internal horizontal and vertical state machines.

The falling edge of these signals relative to the data matches the requirements of the TMC22x91 family of digital encoders.

#### AVOUT Active Video (Output Pin)

The decoder produces an active video signal starting 4 PCK before the programmed start of active video and ending 4 PCK after the programmed end of active video. This signal is used in both the video mixer (TMC22x8x) family and the digital encoder (TMC22x9x) family. The end points of this signal are flagged by the internally generated SAV and EAV signals.

#### $\overline{\text{VBLK}}$ (Vertical Blanking Period)**

The vertical blanking period conforms to the CCIR 656 specification for D1 component data streams. This signal is decoded from the line ident, $LID_{4-0}$, and is active low.

**Table 18. Vertical Blanking Period**

| | Internal field no | Internal line no |
|---|---|---|
| **NTSC** | 0,2 | 0 - 5 |
| | | 260 & 261 |
| | 1,3 | 0 - 6 |
| | | 260 - 262 |
| **PAL** | 0, 2, 4, & 6 | 0 - 21 |
| | | 310 & 311 |
| | 1, 3, 5, & 7 | 0 - 22 |
| | | 311 & 312 |
| **PAL-M** | 0, 2, 4, & 6 | 0 - 5 |
| | | 260 & 261 |
| | 1, 3, 5, & 7 | 0 - 6 |
| | | 260 & 262 |

#### $\overline{\text{BBLK}}$ (Vertical Burst Blanking Period)

The vertical burst blanking blanks the lines with no burst from the burst phase locked loop. This signal is controlled by the video standard and the field count. The burst blanking signal is active low.

** Signal is available over the microprocessor data bus.

**Table 19. Vertical Burst Blanking Period**

| | Internal field no | Internal line no |
|---|---|---|
| **NTSC** | 0,2 | 0 - 5 |
| | | 259 - 261 |
| | 1,3 | 0 - 6 |
| | | 260 - 262 |
| **PAL** | 0 & 4 | 0 - 5 |
| | | 309 - 311 |
| | 1 & 5 | 0 - 5 |
| | | 309 - 312 |
| | 2 & 6 | 0 - 4 |
| | | 310 & 311 |
| | 3 & 7 | 0 - 6 |
| | | 310 - 312 |
| **PAL-M** | 0 & 4 | 0 - 7 |
| | | 259 - 261 |
| | 1 & 5 | 0 - 7 |
| | | 259 - 262 |
| | 2 & 6 | 0 - 6 |
| | | 258 & 261 |
| | 3 & 7 | 0 - 6 |
| | | 260 - 262 |

#### $LID_{4-0}$ List of Line Idents

The line numbers required to produce all the decoder control signals are summarized in

**Table 20. Table of Line Idents, LID[4:0]**

| Line no: | $LID_{4-0}$ |
|---|---|
| 0 | 00 |
| 1 - 4 | 01 |
| 5 | 02 |
| 6 | 03 |
| 7 | 04 |
| 8 | 05 |
| 9 - 16 | 06 |
| 17 | 07 |
| 18 | 08 |
| 19 - 21 | 09 |
| 22 | 0A |
| 23 | 0B |
| 24 | 0C |
| 25 - 257 | 0D |
| 258 | 0E |
| 259 | 0F |

**Table 20. Table of Line Idents, LID[4:0]** (cont.)

| Line no: | $LID_{4-0}$ |
|---|---|
| 260 & 261 | 10 |
| 262 | 11 |
| 263 - 307 | 12 |
| 308 | 13 |

# Timing Parameters

## Subcarrier Programming

The color subcarrier is produced by an internal 28 bit Direct Digital Synthesizer (DDS) which is phase locked to the burst signal of the digitized video input. The nominal frequency is programmed into the DDS as follows:

FREQ = (number of subcarrier cycles per line / number of pixels per line) * 2^28

An example would be NTSC subcarrier mode

FREQ = (227.5 / 910) * 2^28 = 4000000 hex

## Horizontal Timing

The horizontal video line is broken down into four horizontal timing parameters.

STS: The number of pixels between sync pulses

STB: The number of pixels between the nominal mid point of sync and the start of the 16 pixel burst gate. This value is modified depending upon the mode of operation.

**Table 21. Timing Offsets**

| Standard | Mode | Offset required |
|---|---|---|
| x | Genlock | -8 |
| x | Line locked | -8 |
| x | Subcarrier | -22 |
| PAL | D2 mode | -12 |
| NTSC | D2 mode | -8 |
| x | D1 mode | +12 |

BTV: The number of pixels between the start of the 16 pixel burst gate and the nominal start of active video.

AV: The number of active pixels in the active video line.

The difference between the sum of STB+BTV+AV subtracted from STS provides the nominal front porch.

## Horizontal and Vertical Timing Parameters

When external horizontal and vertical syncs are provided the timing shown in Figure 28 is required to synchronize the internal state machines to beginning of a field (3, 5, or 7). For field 2 (4, 6, or 8) the falling edge of $\overline{VSYNC}$ must occur at least 2 clock periods but not more than (H-2) clock periods after the falling edge of $\overline{HSYNC}$, where H is the total number of pixels in an active video line.

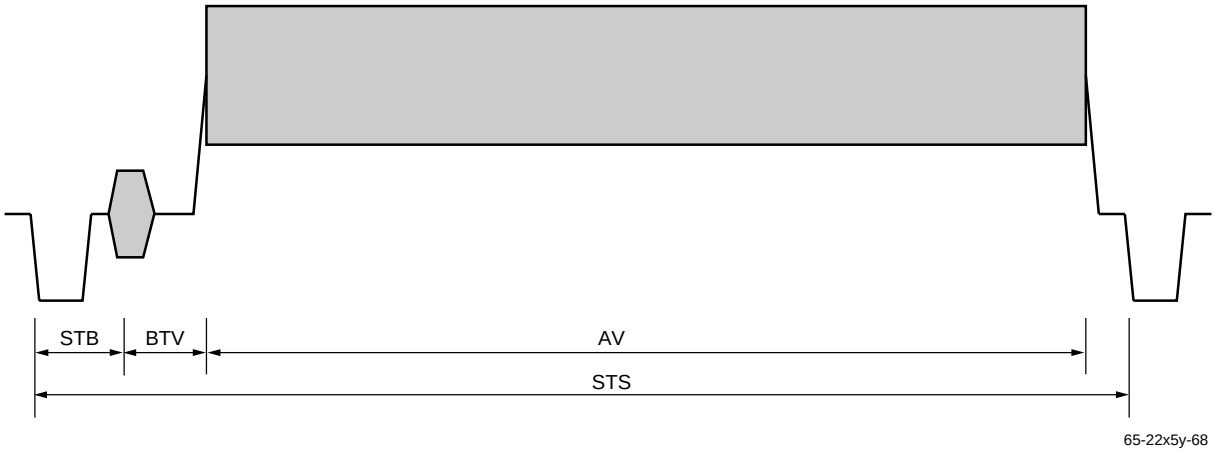

**Figure 27. Horizontal Timing**

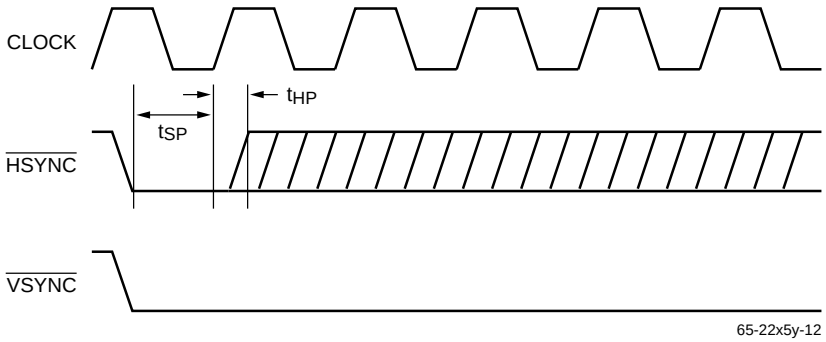

**Figure 28. External HSYNC and VSYNC Timing for Field 1 (3, 5, or 7)**

## Vertical Blanking

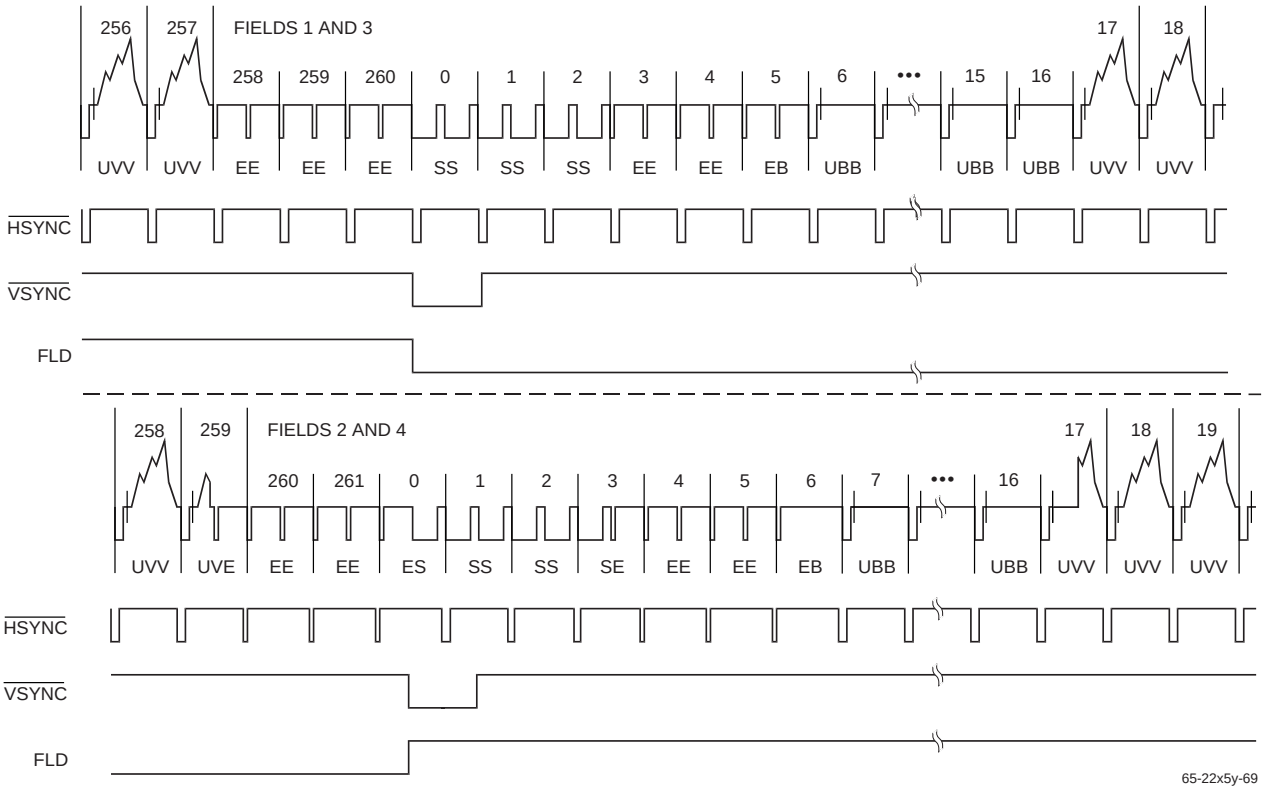

**Figure 29. NTSC Vertical Interval**

Preliminary Information

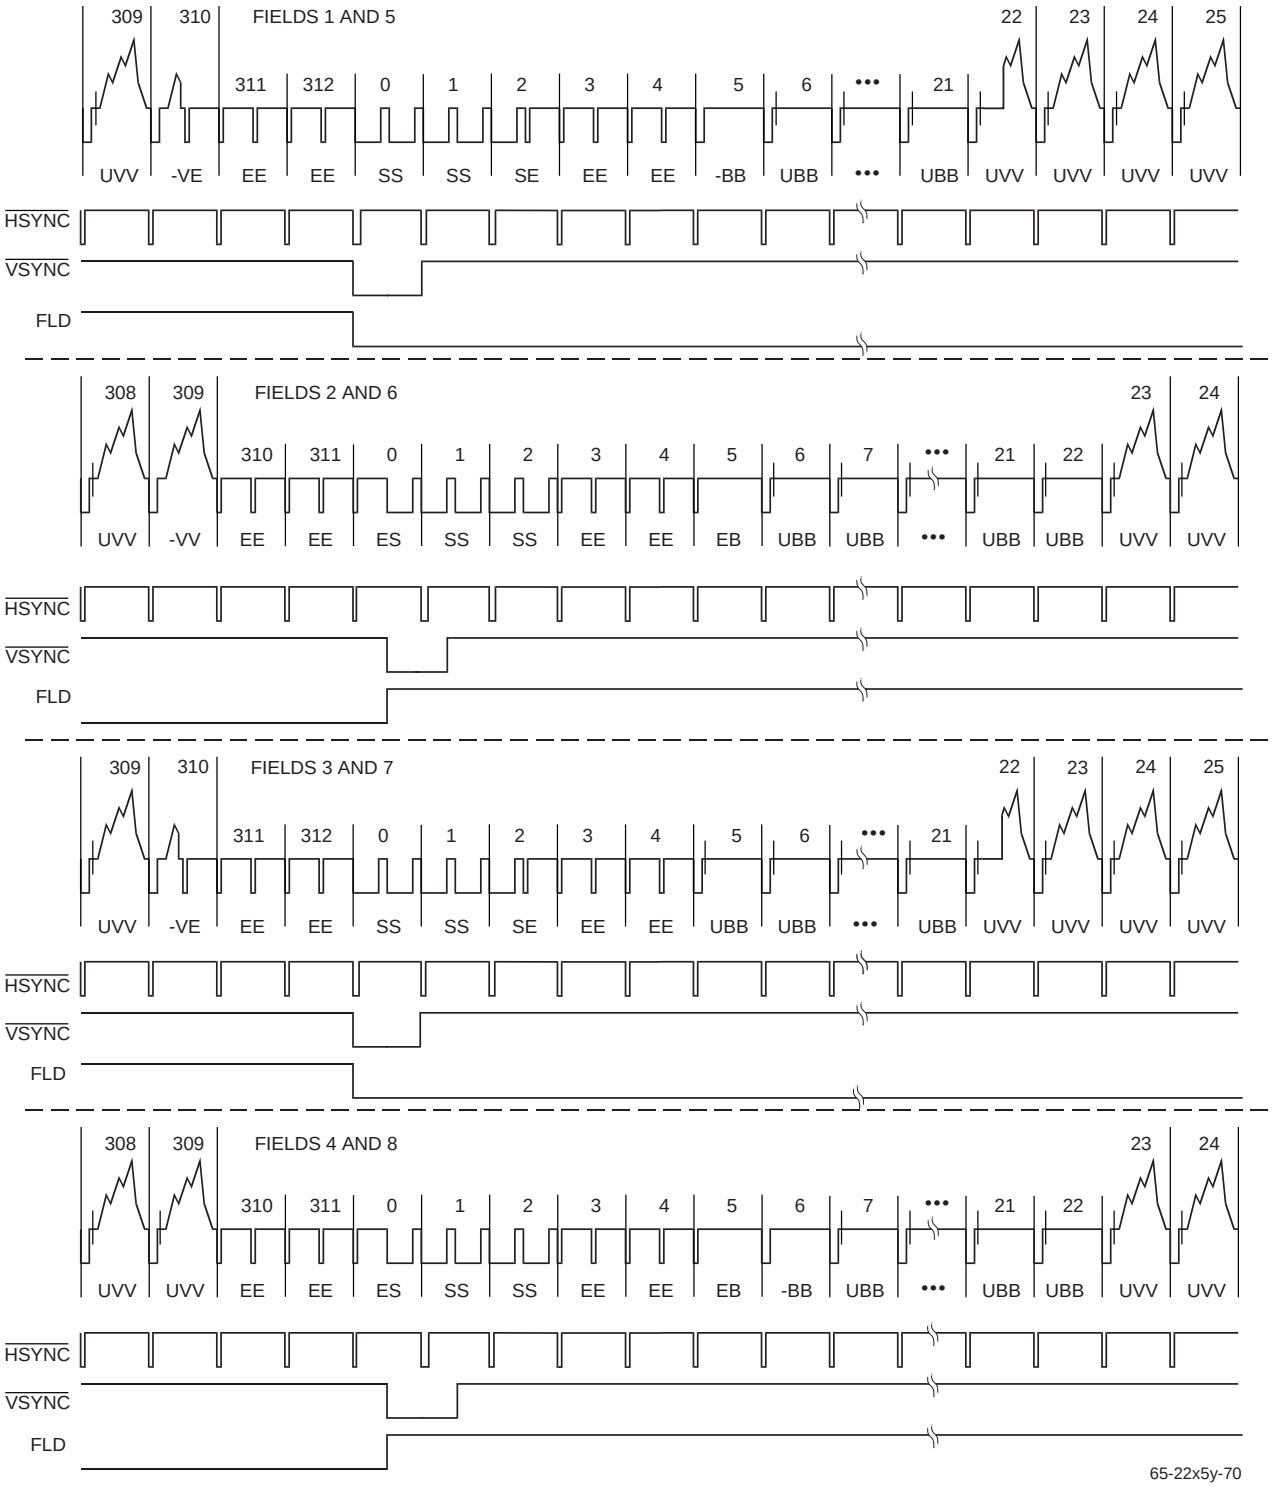

**Figure 30. PAL-B,G,H,I,N Vertical Interval**

Preliminary Information

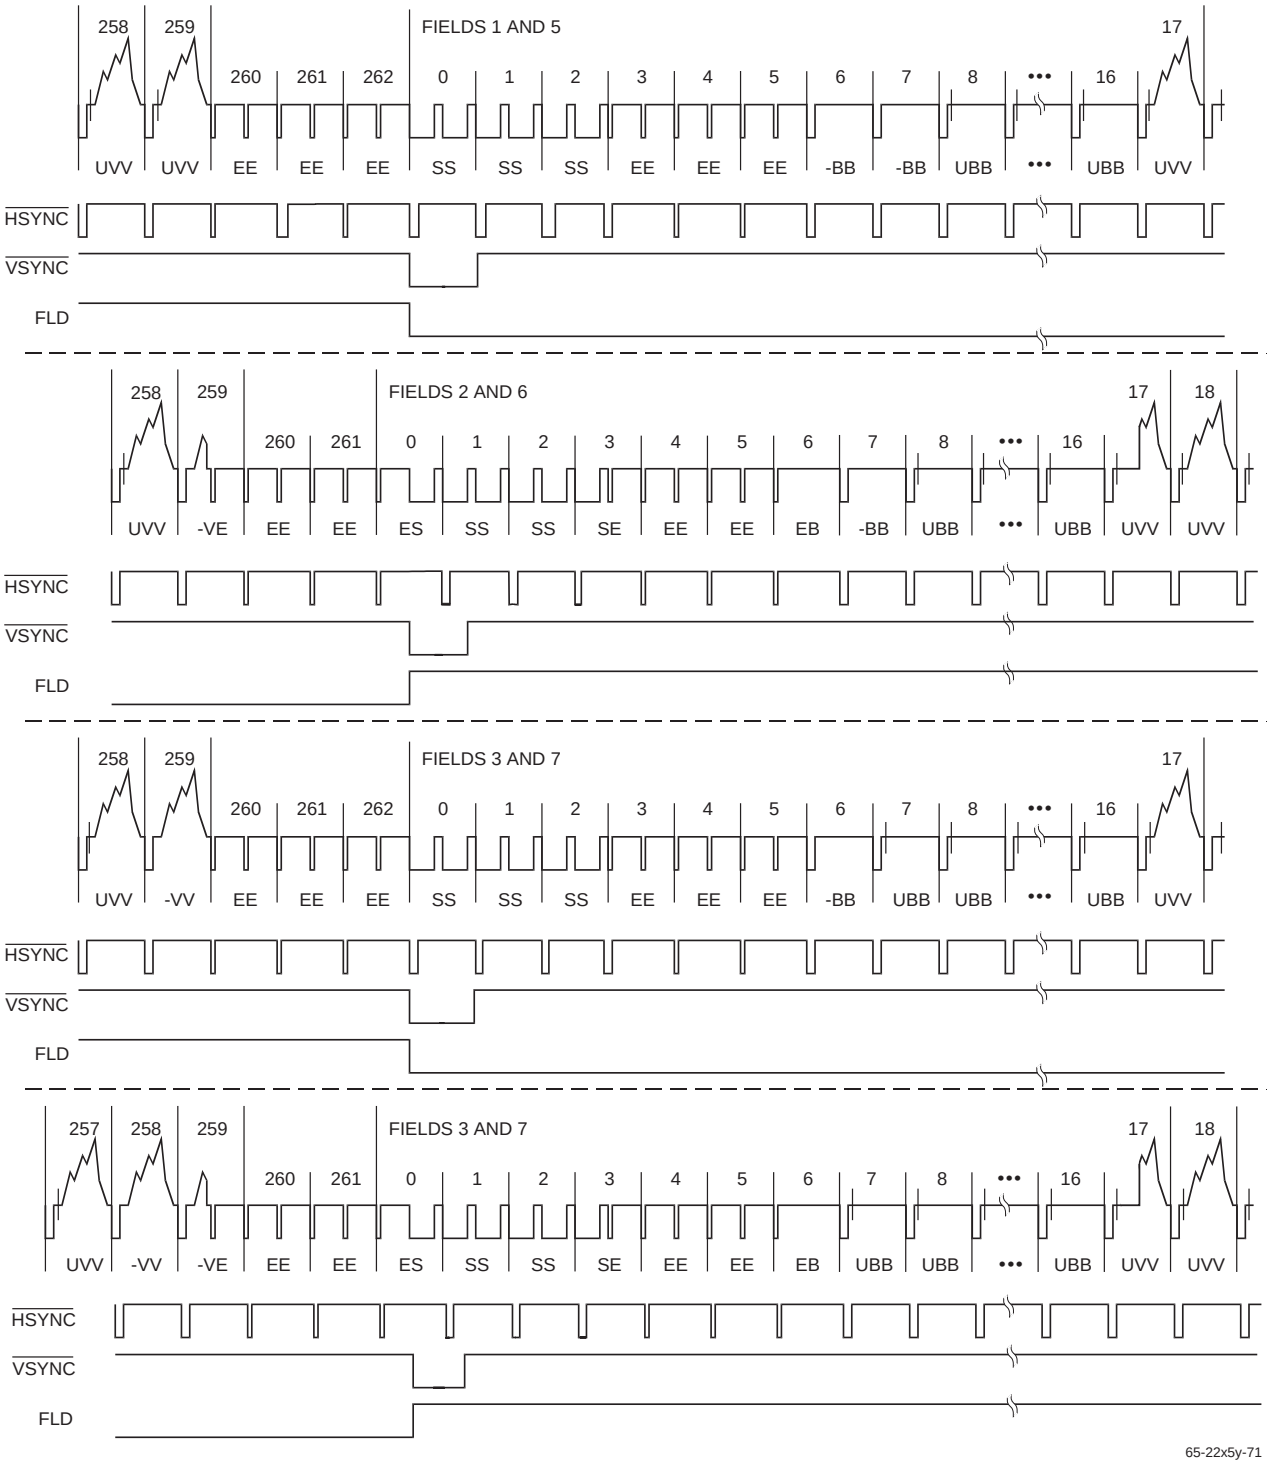

**Figure 31. PAL-M Vertical Interval**

### VINDO Operation

The VINDO circuit uses the line idents on $LID_{4-0}$, and the blanking signals to control the comb filter output and the blanking of the YUV data in the output matrix during the vertical blanking period.

The vertical window VINDO starts on the first line after the last equalizing pulse, at $LID_{4-0}$ = 02. The VINDO stays HIGH from this line until the VINDO count = $VINDO_{4-0}$, or the $\overline{VBLK}$ signal goes HIGH, at which time the VINDO goes LOW. While the VINDO is HIGH the decoder operation is controlled by VDIV, and during the time the VINDO and $\overline{VBLK}$ are LOW the decoder operation is controlled by VDOV.

**Table 22. PAL VINDO operation**

| $LID_{4-0}$ | VINDO | VDIV | VDOV | Y | C |
|---|---|---|---|---|---|
| 00 - 01 | x | x | x | normal | normal |
| 02 - 0A | 1 | 0 | x | simple | simple |
| 02 - 0A | 1 | 1 | x | flat | black |
| 02 - 0A | 0 | x | 0 | black | black |
| 02 - 0A | 0 | x | 1 | simple | black |
| 0B - 17 | x | x | x | normal | normal |

**NTSC VINDO operation**

| $LID_{4-0}$ | VINDO | VDIV | VDOV | Y | C |
|---|---|---|---|---|---|
| 00 - 02 | x | x | x | normal | normal |
| 03 - 06 | 1 | 0 | x | simple | simple |
| 03 - 06 | 1 | 1 | x | flat | black |
| 03 - 06 | 0 | x | 0 | black | black |
| 03 - 06 | 0 | x | 1 | simple | black |
| 07 - 17 | x | x | x | normal | normal |

## Video Measurement

The TMC22x5yA supports a comprehensive set of video measurement techniques to aid the user in setting up the gain, phase, etc. of the decoder and in tracking down system errors.

### Pixel Grab

The pixel grab allows the user to grab one pixel every line, or one pixel out of the four field sequence in NTSC or the 8 field sequence in PAL, under software control. The SET pin can also be used to produce the pixel grab pulse if $SET_{2-0}$ = 110 and PGEXT is set HIGH.

The 10 bit G/Y, B/U, R/V outputs are stored in one set of four 8 bit registers in the FORMAT block, while the 10 bit luma and mixed sync data and the 10 bit demodulated U and V color difference signals are stored in a set of five 8 bit registers in the GRAB circuit block. The pixel grab signal, PIXEL, whether internally or externally generated, is internally delayed to ensure that the all the grabbed data are from the same pixel relative to the line sync pulse. The PIXEL signal is equal to PGRAB or the logical AND of PGRAB with FGRAB and LGRAB, and is controlled by the LPGEN, PGEN, and PGEXT register bits.

The luma and mixed sync signals are multiplexed on the YMS data bus and the U and V signals are multiplexed on the UV data bus, at the PXCK clock rate. The pixel grab signal accommodates for this when grabbing these components.

An example of the pixel grab feature, is grabbing a pixel in the center of the burst period allowing the user to check the burst height by reading the magnitude of the demodulated U and V components. This allows the user to compensate for any chrominance gain errors in the output matrix.

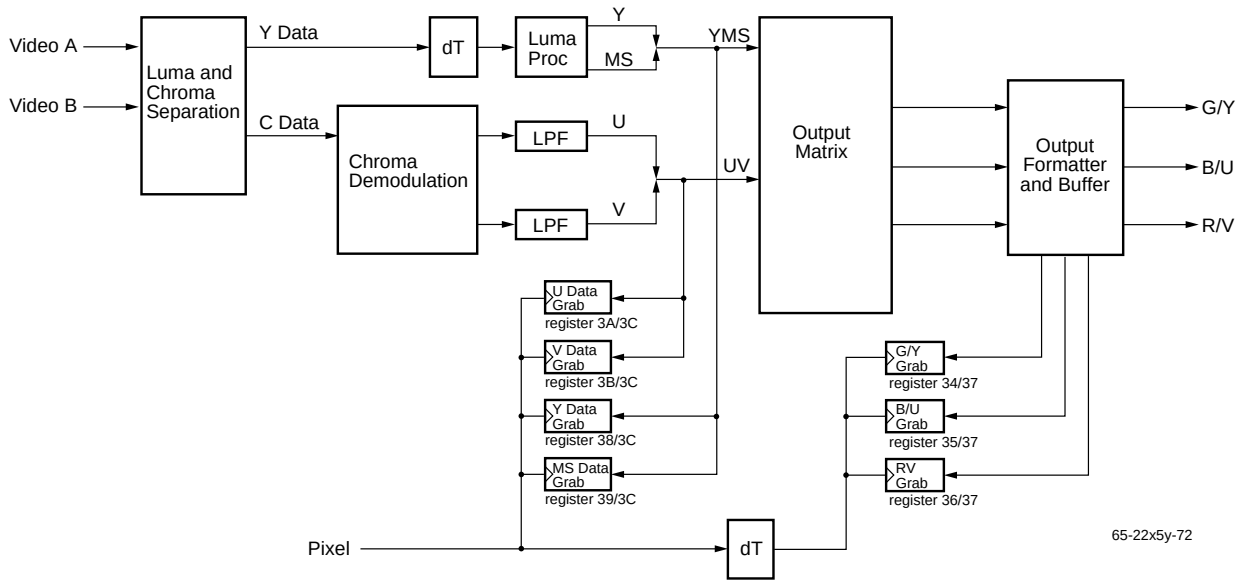

**Figure 32. Pixel Grab Locations**

**Table 23. Pixel Grab Control**

| LGEXT | PGEN | PGEXT | LGEN | GRABS signal |
|---|---|---|---|---|
| 0 | 0 | x | x | GRABS = 0 |
| 0 | 1 | 0 | 0 | GRABS = PGRAB |
| 0 | 1 | 0 | 1 | GRABS = FGRAB & LGRAB & PGRAB |
| 0 | 1 | 1 | x | GRABS = NOT (SET pin) |
| 1 | x | 0 | x | GRABS = PGRAB |
| 1 | x | 1 | x | GRABS = NOT (SET pin) |

If a single pixel every 4 fields in NTSC and 8 fields in PAL is required to be grabbed, PGG and PGEN in register 30h should be set HIGH. The pixel grab signal is the logical AND of the GRABP, GRABL, and GRABF signals. GRABP goes HIGH whenever the pixel count equals the programmed pixel grab number, GRABL goes HIGH for one line whenever the line count equals the programmed line number, and the GRABF goes HIGH for a field whenever the field number equals the programmed field count.

If the same pixel on every line is required to be grabbed, then PGG should be set LOW, which internally forces GRABL and GRABF to be forced HIGH enabling the pixel grab whenever GRABP goes HIGH.

The SET pin can be used to provide an external grab signal when PGEXT is set HIGH in register 30h and the SET function in register 00h, SET[2:0] is programmed to 110 (binary). In this mode the falling edge on the SET pin triggers the pixel grab.

The GRABP, GRABL, and GRABF signals are available on bits 0,1, and 2 respectively of the read only register 41. An example of the pixel grab feature, would be grabbing a pixel in the center of the burst period allowing the user to check the burst height by reading the magnitude of the demodulated U and V components. This would then allow the user to compensate for any chrominance gain errors in the output matrix.

The pixel grab value is delayed by 29 pixels from the pixel count. This is the delay for all the pixel grab registers. Figure 33 shows this delay relative to GHSYNC. This means that if 29 is placed in the PG value, the actual pixel grabbed is pixel 0.

The top two bits of the PG value provide the quadrant and the bottom 9 bits provide the offset within that quadrant. The integer part of STS/4 gives the maximum count for each quadrant while the fractional result (bottom two bits) provides the 0,1,2, or 3 count offset for the last quadrant.

For pixels value <= 4*Int(STS/4)
PG[10:9] = quadrant number
PG[8:0] = max quadrant count - Int(STS/4) + pixel offset

For pixels value > 4*Int(STS/4)
The quadrant is always number 3, ie PG[10:9] = 11 while the pixel in excess of 4*Int(STS/4) is added to 1536.

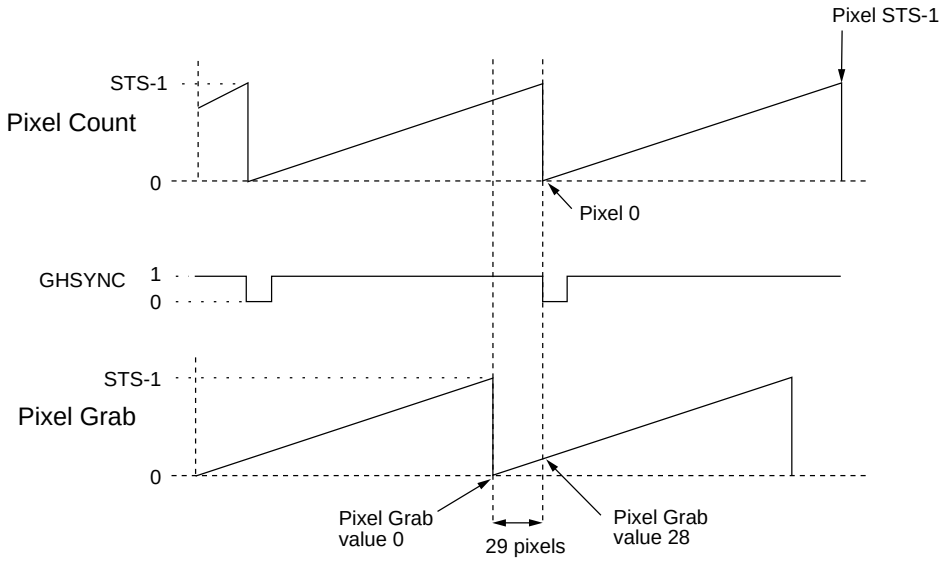

**Figure 33. Relationship Between Pixel Count and Pixel Grab Value**

**Examples:**

NTSC std with STS programmed to 858.
Base pixels per quadrant = Int(858/4) = 214

Pixel 0:
1. Pixel 0 <= 4*Int(858/4)
2. Required pixel 0 < 214 therefore quadrant = 0, [PG[10:9] = 00]
3. PG[10:0] = 511 - 214 + (0+[0*214]) = 297

Pixel 56:
1. Pixel 56 <= 4*Int(858/4)
2. Required pixel 56 < 214 therefore quadrant = 0 [PG[10:9] = 00]
3. PG[10:0] = 511 - 214 + (56-[0*214]) = 353

Pixel 250:
1. Pixel 250 <= 4*Int(858/4)
2. Required pixel 250 > 214 therefore quadrant =/= 0
3. Required pixel 250 < 428 therefore quadrant = 1, [PG[10:9] = 01]
4. PG[10:0] = 1023 - 214 + (250-[1*214]) = 845

Pixel 800:
1. Pixel 800 <= 4*Int(858/4)
2. Required pixel 800 > 214 therefore quadrant =/= 0
3. Required pixel 800 > 428 therefore quadrant =/= 1
4. Required pixel 800 > 642 therefore quadrant =/= 2
5. Required pixel 800 < 858 therefore quadrant = 3, [PG[10:9] = 11]
6. PG[10:0]= 2047 - 214 + (800-[3*214]) = 1991

Pixel 856:
1. Pixel <= 4*Int(858/4)
2. Required pixel 856 > 214 therefore quadrant =/= 0
3. Required pixel 856 > 428 therefore quadrant =/= 1
4. Required pixel 856 > 642 therefore quadrant =/= 2
5. Required pixel 856 < 858 therefore quadrant = 3, [PG[10:9] = 11]
6. PG[10:>0] = 2047 - 214 + (856-[3*214]) = 2047

Pixel 857:
1. Pixel 857 > 4*Int(858/4)
2. Therefore quadrant = 3, [PG[10:9] = 11]
3. PG[10:0] = 1536 + (857-[4*214]) = 1537

## Composite Line Grab

The composite line grab is only available in the 3 line comb based decoders (TMC22053A and TMC22153A), and allows the user to grab any line from the 4 field sequence in NTSC or 8 field sequence in PAL when LGEN is set HIGH. When the LGEN register bit is set HIGH the decoder automatically switches to operate as a “simple” bandsplit decoder. The SET pin can also be used to produce the line grab pulse if $SET_{2-0}$ = 110 and LGEXT is set HIGH.

Once the line grab has been activated the subcarrier oscillator is frozen with the SEED and phase from the beginning of the line, and the composite video in the 1H line store is frozen by disabling the write signals in LSTORE1. The read cycle for the frozen line store is still clocked by PCK. The subcarrier DDS and the internal read only registers will be updated once per clock period as normal, but will reload the DRS SEED and PHASE values at the beginning of each line. The G/Y, B/U, and R/V outputs will remain active, and the $\overline{DHSYNC}$ and $\overline{DVSYNC}$ signals will remained locked to the input or flywheel if the input has been removed.

The pixel grab function can be used in conjunction with the frozen line to examine individual pixels inside the decoder.

## Parallel Microprocessor Interface

The parallel microprocessor interface, active when $\overline{SER}$ is HIGH, employs a 12-line interface, with an 8-bit data bus and one address bit: two addresses are required for device programming and pointer-register management. Address bit 0 selects between reading/writing the register addresses and reading/writing register data. When writing, the address is presented along with a LOW on the $\overline{R/W}$ pin during the falling edge of $\overline{CS}$ Eight bits of data are presented on $D_{7-0}$ during the subsequent rising edge of $\overline{CS}$. One additional falling edge of $\overline{CS}$ is needed to move input data to its assigned working registers.

In read mode, the address is accompanied by a HIGH on the $\overline{R/W}$ pin during a falling edge of $\overline{CS}$. The data output pins go to a low-impedance state $t_{DOZ}$ after $\overline{CS}$ falls. Valid data are present on $D_{7-0}$ $t_{DOM}$ after the falling edge of $\overline{CS}$. Because this port operates asynchronously with the pixel timing, there is an uncertainty in this data valid output delay of one PXCK period. This uncertainty does not apply to $t_{DOZ}$.

Writing data to specific control registers of the TMC22x5yA requires that the 8-bit address of the control register of interest be written. This control register address is the base address for subsequent write operations. The base address autoincrements by one for each byte of data written after the data byte intended for the base address. If more bytes are transferred than there are available addresses, the address will not increment and remain at its maximum value of 3Fh.

### Table 24. Parallel Port Control

| $A_{1-0}$ | $\overline{R/W}$ | Action |
|---|---|---|
| 00 | 0 | Load $D_{7-0}$ into Control Register pointer (block 00) |
| 00 | 1 | Read Control Register pointer on $D_{7-0}$ |
| 01 | 0 | Load $D_{7-0}$ into addressed XLUT Location pointer (block 01) |
| 01 | 1 | Read addressed XLUT Location pointer on $D_{7-0}$. |
| 10 | 0 | Write $D_{7-0}$ to addressed Control Register |
| 10 | 1 | Read addressed Control Register on $D_{7-0}$ |
| 11 | 0 | Write $D_{7-0}$ to addressed XLUT Location |
| 11 | 1 | Read addressed XLUT Location on $D_{7-0}$ |

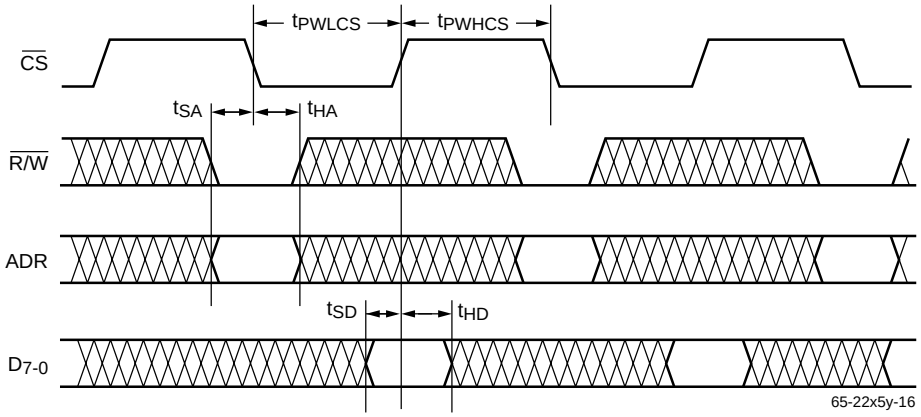

**Figure 33. Microprocessor Parallel Port – Write Timing**

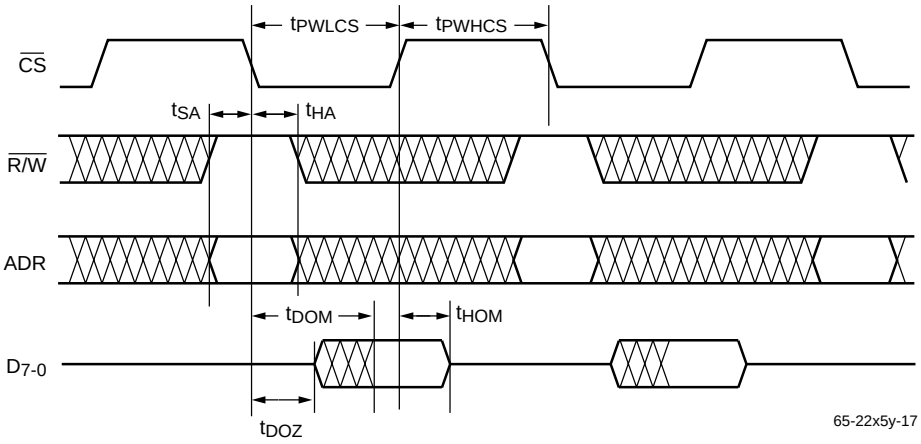

**Figure 34. Microprocessor Parallel Port – Read Timing**

## Serial Control Port (R-Bus)

In addition to the 12-wire parallel port, a 2-wire serial control interface is provided, and active when $\overline{SER}$ is LOW. Either port alone can control the entire chip. Up to eight TMC22x5yA devices may be connected to the 2-wire serial interface with each device having a unique address.

The 2-wire interface comprises a clock (SCL) and a bi-directional data (SDA) pin. The Decoder acts as a slave for receiving and transmitting data over the serial interface. When the serial interface is not active, the logic levels on SCL and SDA are pulled HIGH by external pull-up resistors.

Data received or transmitted on the SDA line must be stable for the duration of the positive-going SCL pulse. Data on SDA must change only when SCL is LOW. If SDA changes state while SCL is HIGH, the serial interface interprets that action as a start or stop sequence.

There are six components to serial bus operation:

- Start signal
- Slave address byte
- Block Pointer
- Base register address byte
- Data byte to read or write
- Stop signal

When the serial interface is inactive (SCL and SDA are HIGH) communications are initiated by sending a start signal. The start signal is a HIGH-to-LOW transition on SDA while SCL is HIGH. This signal alerts all slaved devices that a data transfer sequence is coming.

The first eight bits of data transferred after a start signal comprise a seven bit slave address (the first seven bits) and a single $\overline{R/W}$ bit (the eighth bit). The $\overline{R/W}$ bit indicates the direction of data transfer, read from or write to the slave device. If the transmitted slave address matches the address of the device (set by the state of the $SA_{2-0}$ input pins in Table 20), the TMC22x5yA acknowledges by bringing SDA LOW on the 9th SCL pulse. If the addresses do not match, the TMC22x5yA does not acknowledge.

## Table 25. Serial Port Addresses

| bit 7 $A_6$ (MSB) | bit 6 $A_5$ | bit 5 $A_4$ | bit 4 $A_3$ | bit 3 $A_2$ ($SA_2$) | bit 2 $A_1$ ($SA_1$) | bit 1 $A_0$ ($SA_0$) |
|---|---|---|---|---|---|---|
| 1 | 0 | 1 | 1 | 0 | 0 | 0 |
| 1 | 0 | 1 | 1 | 0 | 0 | 1 |
| 1 | 0 | 1 | 1 | 0 | 1 | 0 |
| 1 | 0 | 1 | 1 | 0 | 1 | 1 |
| 1 | 0 | 1 | 1 | 1 | 0 | 0 |
| 1 | 0 | 1 | 1 | 1 | 0 | 1 |
| 1 | 0 | 1 | 1 | 1 | 1 | 0 |
| 1 | 0 | 1 | 1 | 1 | 1 | 1 |

### Data Transfer via Serial Interface

For each byte of data read or written, the MSB is the first bit; that is, bit 7 of the 8-bit sequence.

If the TMC22x5yA does not acknowledge the master device during a write sequence, the SDA remains HIGH so the master can generate a stop signal. If the master device does not acknowledge the TMC22x5yA during a read sequence, the Decoder interprets this as “end of data.” The SDA remains HIGH so the master can generate a stop signal.

Writing data to specific control registers of the TMC22x5yA requires that the 8-bit address of the control register of interest be written after the slave address has been established. This control register address is the base address for subsequent write operations. The base address autoincrements by one for each byte of data written after the data byte intended for the base address. If more bytes are transferred than there are available addresses, the address will not increment and remain at its maximum value of 3Fh. Any base address higher than 3Fh will not produce an ACKnowledge signal.

Data are read from the control registers of the TMC22x5yA in a similar manner. Reading requires two data transfer operations:

The base address must be written with the R/W\ bit of the slave address byte LOW to set up a sequential read operation.

Reading (the $\overline{R/W}$ bit of the slave address byte HIGH) begins at the previously established base address. The address of the read register autoincrements after each byte is transferred.

To terminate a write sequence to the TMC22x5yA, a stop signal must be sent. A stop signal comprises a LOW-to-HIGH transition of SDA while SCL is HIGH. To terminate a read sequence simply do not acknowledge (NOACK) the last byte received and the TMC22x5yA will terminate the sequence.

A repeated start signal occurs when the master device driving the serial interface generates a start signal without first generating a stop signal to terminate the current communication. This is used to change the mode of communication (read, write) between the slave and master without releasing the serial interface lines.

### Serial Interface Read/Write Examples

Write to one control register

- Start signal
- Slave Address byte ($\overline{R/W}$ bit = LOW)
- Block Pointer (00)
- Base Address byte
- Data byte to base address
- Stop signal

Write to four consecutive XLUT locations

- Start signal
- Slave Address byte ($\overline{R/W}$ bit = LOW)
- Block Pointer (01)
- Base Address byte
- Data byte to base address
- Data byte to (base address + 1)
- Data byte to (base address + 2)
- Data byte to (base address + 3)
- Stop signal

Read from one XLUT location

- Start signal
- Slave Address byte ($\overline{R/W}$ bit = LOW)

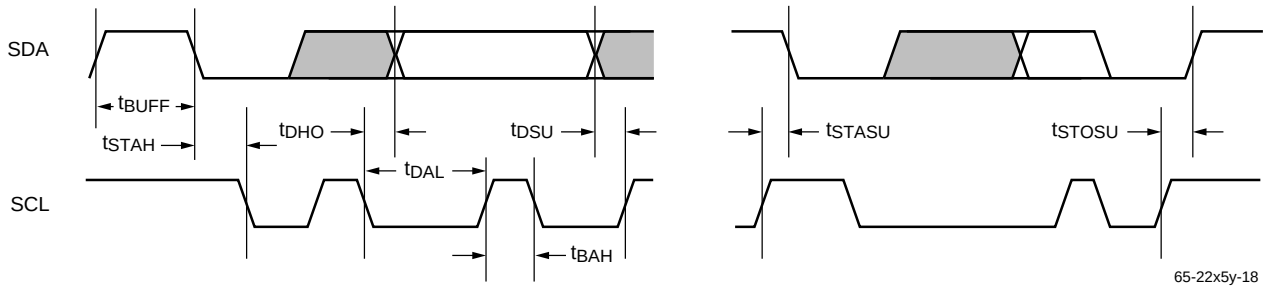

**Figure 35. Serial Port Read/Write Timing**

- Block Pointer (01)
- Base Address byte
- Stop signal
- Start signal
- Slave Address byte ($\overline{R/W}$ bit = HIGH)
- Data byte from base address
- Stop signal

Read from four consecutive control registers

- Start signal
- Slave Address byte ($\overline{R/W}$ bit = LOW)
- Block Pointer (00)
- Base Address byte
- Stop signal
- Start signal
- Slave Address byte ($\overline{R/W}$ bit = HIGH)
- Data byte from base address
- Data byte from (base address + 1)
- Data byte from (base address + 2)
- Data byte from (base address + 3)
- Stop signal

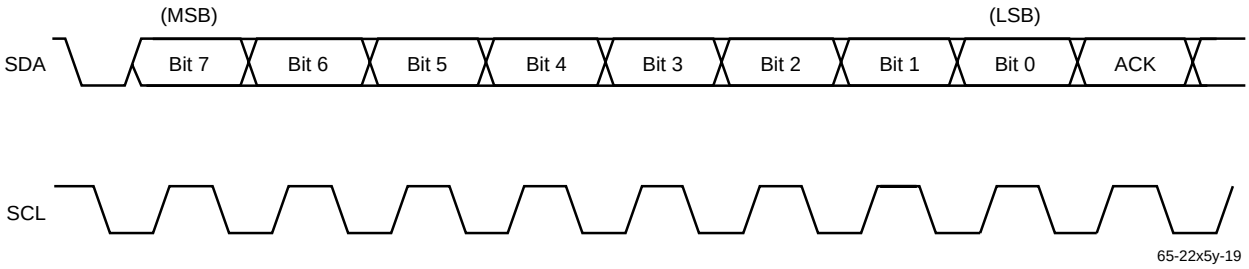

**Figure 36. Serial Interface – Typical Byte Transfer**

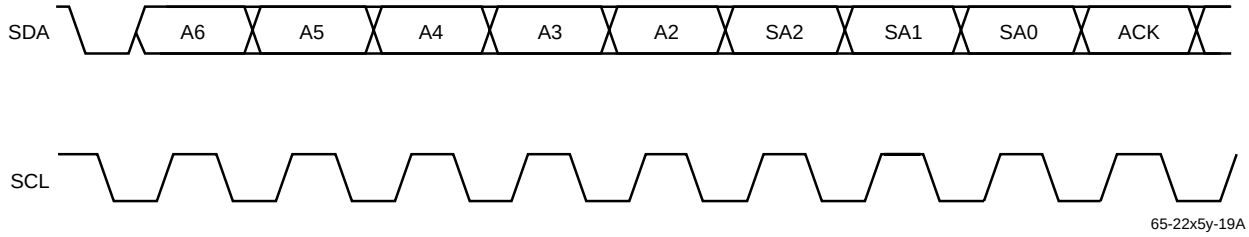

**Figure 37. Serial Interface – Chip Address**

***Note:**

To read from the XLUT, the initial read must be a dummy read. This means, for example, to read back XLUT location 0x02, read back location 0x01, then read back 0x02 and ignore the information read back from the 0x01 location. This only needs to be done once in a sequence. To read back the entire XLUT, set the pointer to 0xFF and ignore the data read from this register. The pointer will then auto-increment to 0x00 allowing the next 256 locations read to be valid.

## Equivalent Circuits and Threshold Levels

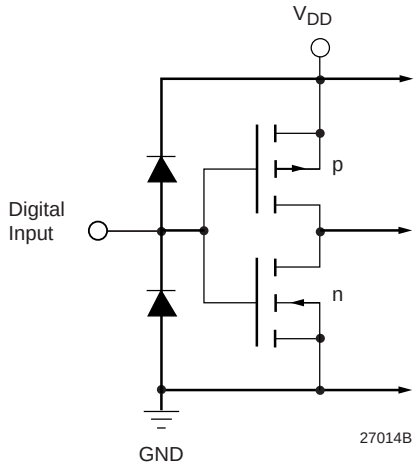

**Figure 38. Equivalent Digital Input Circuit**

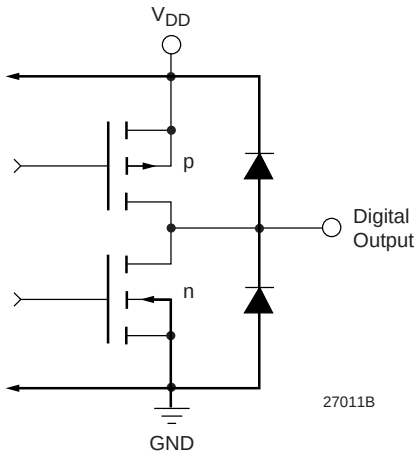

**Figure 39. Equivalent Digital Output**

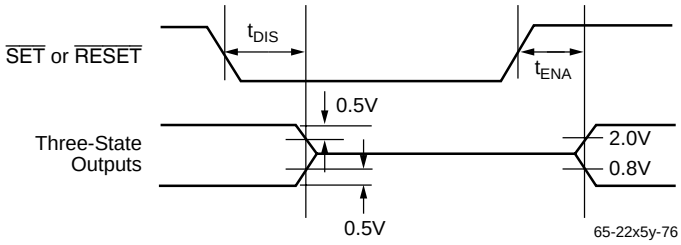

**Figure 40. Threshold Levels for Three-state**

Preliminary Information

## Absolute Maximum Ratings (beyond which the device may be damaged)[1]

| Parameter | Min. | Max. | Unit |
|---|---|---|---|
| **Power Supply voltage** | -0.5 | +7.0 | V |
| **Digital Inputs** | | | |
| Applied Voltage | -0.5 | $V_{DD}$+0.5 | V |
| Forced current [3, 4] | -20.0 | +20.0 | mA |
| **Digital Outputs** | | | |
| Applied voltage [2] | -0.5 | $V_{DD}$+0.5 | V |
| Forced current [3, 4] | -3.0 | +6.0 | mA |
| Short circuit duration (single output in HIGH state to ground) | | 1 second | |
| **Analog Output Short circuit duration (all outputs to ground)** | | infinite | |
| **Temperature** | | | |
| Operating, ambient | -20 | 110 | °C |
| junction | | 140 | °C |
| Lead, soldering (10 seconds) | | 300 | °C |
| Vapor Phase soldering (1 minute) | | 220 | °C |
| Storage | | 150 | °C |

**Notes:**

1. Absolute maximum ratings are limiting values applied individually while all other parameters are within specified operating conditions. Functional operation under any of these conditions is NOT implied. Performance and reliability are guaranteed only if Operating Conditions are not exceeded.
2. Applied voltage must be current limited to specified range.
3. Forcing voltage must be limited to specified range.
4. Current is specified as conventional current flowing into the device.

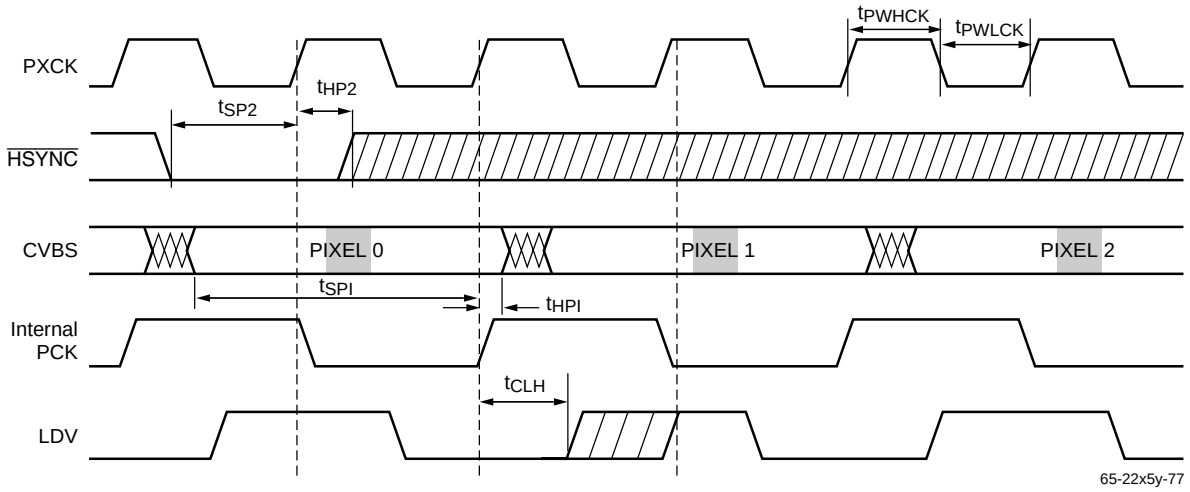

**Figure 41. Input Timing Parameters**

## Operating Conditions

| Parameter | | Min. | Nom. | Max. | Units |
|---|---|---|---|---|---|
| $V_{DD}$ | Power Supply Voltage | 4.75 | 5.0 | 5.25 | V |
| $V_{IH}$ | Input Voltage, Logic HIGH | | | | |
| | TTL Compatible Inputs | 2.0 | | $V_{DD}$ | V |
| | Serial Port (SDA and SCL) | 0.7*$V_{DD}$ | | | V |
| $V_{IL}$ | Input Voltage, Logic LOW | | | | |
| | TTL Compatible Inputs | GND | | 0.8 | V |
| | Serial Port (SDA and SCL) | GND | | 0.3*$V_{DD}$ | V |
| $I_{OH}$ | Output Current, Logic HIGH | | | -2.0 | mA |
| $I_{OL}$ | Output Current, Logic LOW | | | 4.0 | mA |
| $T_A$ | Ambient Temperature, Still Air | 0 | | 70 | °C |
| **Pixel Interface (input)** | | | | | |
| $f_{CLK}$ | Pixel Rate (CKSEL = 0) | 10 | | 18 | MHz |
| | Master Clock Rate = 2X pixel rate (CKSEL = 1)[1] | 20 | | 36 | MHz |
| $t_{PWHCK}$ | CLOCK pulse width, HIGH | 8 | | | ns |
| $t_{PWLCK}$ | CLOCK pulse width, LOW | 13 | | | ns |
| $t_{SP}$ | Pixel Data Input Setup Time | 8 | | | ns |
| $t_{HP}$ | Pixel Data Input Hold Time | 2 | | | ns |
| $t_{SP}$ | $\overline{HSYNC}$, $\overline{VSYNC}$, and BUFFER setup time | 5 | | | ns |
| $t_{HP}$ | $\overline{HSYNC}$, $\overline{VSYNC}$, and BUFFER hold time | 6 | | | ns |

**Notes:**

1. Tested at $f_{CLK}$ = 30MHz

To aid in the understanding of the timing relationship between the PXCK and LDV clock, when the LDV signal is used as the TMC22x5yA output clock, the following block diagram of the TMC22x5yA output stage is provided.

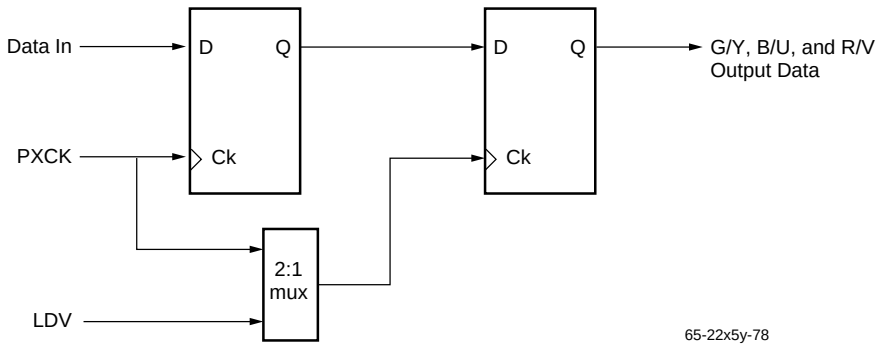

**Figure 42. Functional Block Diagram of the TMC22x5yA G/Y, B/U, and R/V Output Stage**

## Operating Conditions (continued)

| Parameter | | Min. | Nom. | Max. | Units |
|---|---|---|---|---|---|
| **Pixel Interface (output)** | | | | | |
| $t_{POD}$ | CLOCK to $\overline{DHSYNC}$ and $\overline{DVYSNC}$, AVOUT, and $FID_{[2:0]}$ Propagation Time | 4 | 15 | 18 | ns |
| $t_{POD}$ | CLOCK to data, Propagation Time | 4 | 15 | 18 | ns |
| $t_{POD}$ | Int. or Ext. LDV to data, Propagation Time | 4 | 15 | 18 | ns |
| $t_{HOD}$ | Clock to $\overline{DHSYNC}$ and $\overline{DVSYNC}$, AVOUT, and $FID_{[2:0]}$ Hold Time | 2.5 | | | ns |
| $t_{HOD}$ | Clock to Data, Hold Time | 2.5 | | | ns |
| $t_{HOD}$ | Int. or Ext. LDV to Data, Hold Time | 2.5 | | | ns |
| $t_{ENA}$ | Enable to Low Z on Output Data | | 23 | 30 | ns |
| $t_{DIS}$ | Disable to High Z on Output Data | | 23 | 30 | ns |
| $t_{CLH}$ | CLOCK to LDV (i/p) signal HIGH | 9 | | 0 | ns |
| $t_{CLH}$ | CLOCK to LDV (o/p) signal HIGH | | 10 | 14 | ns |

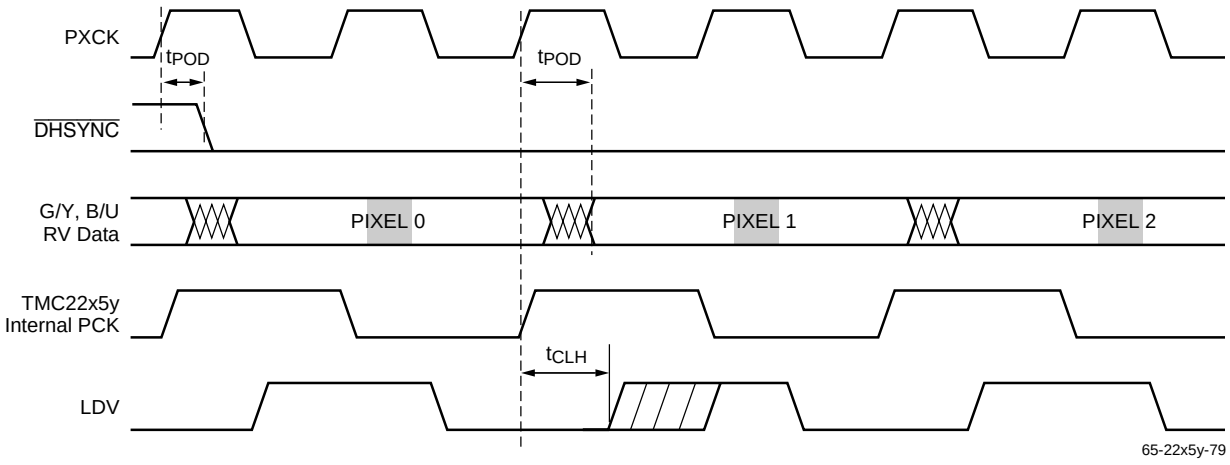

**Figure 436974. Output Timing Parameters**

Preliminary Information

## Operating Conditions (continued)

| Parameter | | Min. | Nom. | Max. | Units |
|---|---|---|---|---|---|
| **Parallel Microprocessor Interface** | | | | | |
| $t_{PWLCS}$ | $\overline{CS}$ Pulse Width, LOW | 2 | | | Pixels |
| $t_{PWHCS}$ | $\overline{CS}$ Pulse Width, HIGH | 3 | | | Pixels |
| $t_{SA}$ | Address Setup Time | 8 | | | ns |
| $t_{HA}$ | Address Hold Time | 2 | | | ns |
| $t_{SD}$ | Data Setup Time (write) | 8 | | | ns |
| $t_{HD}$ | Data Hold Time (write) | 2 | | | ns |
| **Serial Microprocessor Interface** | | | | | |
| $t_{DAL}$ | SCL Pulse Width , LOW | 1.0 | | | µs |
| $t_{DAH}$ | SCL Pulse Width, HIGH | 0.48 | | | µs |
| $t_{STAH}$ | Hold Time for START or Repeated START | 0.48 | | | µs |
| $t_{STASU}$ | Setup Time for START or Repeated START | 0.48 | | | µs |
| $t_{STOSU}$ | Setup time for STOP | 0.48 | | | µs |
| $t_{BUFF}$ | Bus Free Time Betweeen a STOP and a START condition | 1.0 | | | µs |
| $t_{DSU}$ | Data Setup Time | 80 | | | ns |

## Electrical Characteristics

| Parameter | | Conditions | Min. | Typ. | Max. | Units |
|---|---|---|---|---|---|---|
| $I_{DD}$ | Power Supply Current[1] | $V_{DD}$ = Max, $f_{PXCK}$ = 27MHz | | 225 | 275 | mA |
| $I_{DDQ}$ | Power Supply Current, Disabled | $V_{DD}$ = Max | | | 50 | mA |
| $I_{IH}$ | Input Current, HIGH | $V_{DD}$ = Max, $V_{IN}$ = $V_{DD}$ | | | ±10 | µA |
| $I_{IL}$ | Input Current, LOW | $V_{DD}$ = Max, $V_{IN}$ = 0V | | | ±10 | µA |
| $I_{OZH}$ | Hi-Z Output Leakage Current, Output HIGH | $V_{DD}$ = Max, $V_{IN}$ = $V_{DD}$ | | | ±10 | µA |
| $I_{OZL}$ | Hi-Z Output Leakage Current, Output LOW | $V_{DD}$ = Max, $V_{IN}$ = 0V | | | ±10 | µA |
| $I_{OS}$ | Short-Circuit Current | | -20 | | -80 | mA |
| $V_{OH}$ | Output Voltage, HIGH | $G/Y_{9-0}$, etc[2]., $I_{OH}$ = MAX | 2.4 | | | V |
| $V_{OL}$ | Output Voltage, LOW | $G/Y_{9-0}$, etc[2]., $I_{OL}$ = MAX | | | 0.4 | V |
| | | SDA, $I_{OL}$ = 3mA | | | 0.4 | V |
| | | SDA, $I_{OL}$ = 6mA | | | 0.6 | V |
| $C_I$ | Digital Input Capacitance | | | 4 | 10 | pF |
| $C_O$ | Digital Output Capacitance | | | 10 | | pF |

**Notes:**

1. Typical $I_{DD}$ with $V_{DD}$ = NOM and $T_A$ = NOM, Maximum $I_{DD}$ with $V_{DD}$ = 5.25V and $T_A$ = 70°C
2. $G/Y_{[9:0]}$, $B/Y_{[9:0]}$, $R/V_{[9:0]}$ , $\overline{DVSYNC}$, $\overline{DHSYNC}$, LDV, AVOUT, $FID_{[2:0]}$

Preliminary Information

## Switching Characteristics

| Parameter | | Conditions | Min. | Typ. | Max. | Units |
|---|---|---|---|---|---|---|
| $t_{DOZ}$ | Output Delay, $\overline{CS}$ to low-Z | | 9 | | | ns |
| $t_{HOM}$ | Output Hold Time, $\overline{CS}$ to high-Z | | 10 | | | ns |
| $t_{DOM}$ | Output Delay, $\overline{CS}$ to Data Valid | | | 30 | 40 | ns |

**Note:**
Timing reference points are at the 50% level, digital output load <40pF.

## System Performance Characteristics

| Parameter | | Conditions | Min. | Typ. | Max. | Units |
|---|---|---|---|---|---|---|
| RES | Video Processing Resolution | TMC2205xA | | 8 | | bits |
| | | TMC2215xA | | 10 | | bits |

## Programming Examples

**Standard:** NTSC-M

**Mode:** Line-Locked

**Input Format:** 13.5 Composite

**Output Format:** RGB (0-1023) Sync on Green

**Decoder:** Adaptive 3-Line Chroma Comb Filter

**Register Map:**

| | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | C | D | E | F |

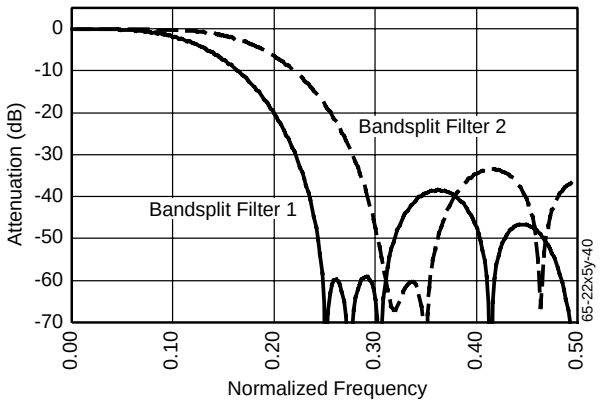
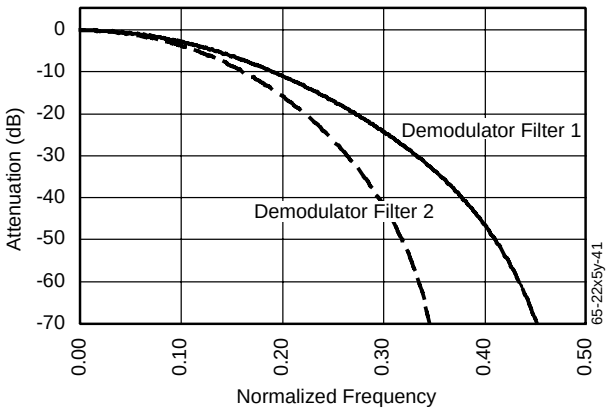
| 1 | | | | | | | | | | | | | | | | |
| 2 | | | | | | | | XX | XX | XX | XX | XX | XX | XX | XX | XX |

The DRS appears on the output at the rate.

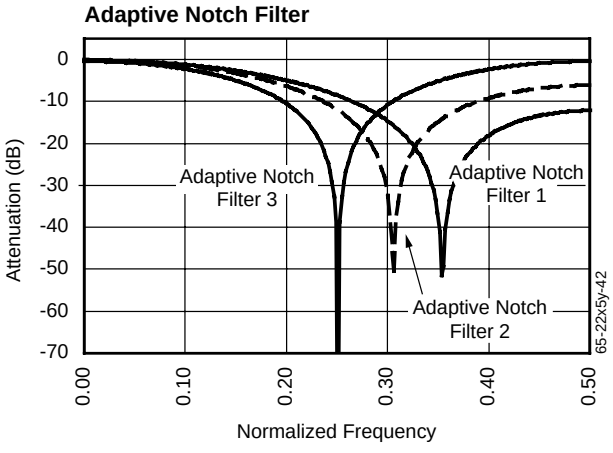
**Bandsplit Filter**



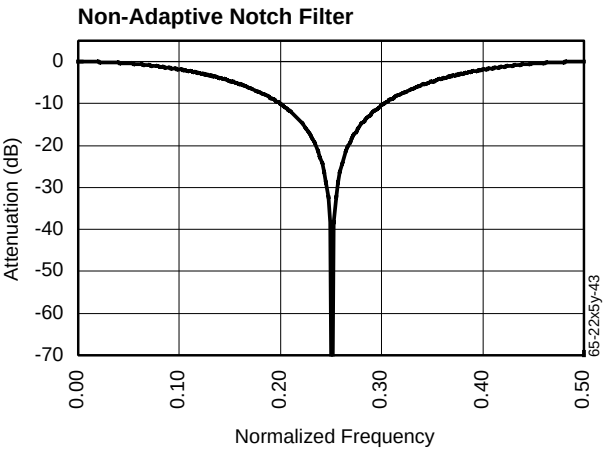
**Demodulation Filter**



**Adaptive Notch Filter**



**Non-Adaptive Notch Filter**



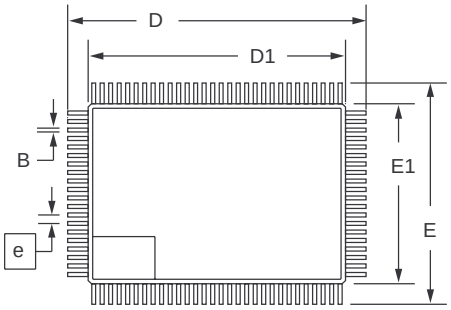
## Notes

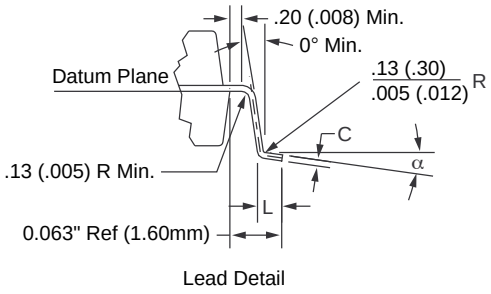
# Mechanical Dimensions – 100 Lead MQFP Package

| Symbol | Inches | | Millimeters | | Notes |
|---|---|---|---|---|---|
| | Min. | Max. | Min. | Max. | |
| A | — | .134 | — | 3.40 | |
| A1 | .010 | — | .25 | — | |
| A2 | .100 | .120 | 2.55 | 3.05 | |
| B | .009 | .015 | .23 | .38 | 3, 5 |
| C | .005 | .009 | .13 | .23 | 5 |
| D | .904 | .923 | 22.95 | 23.45 | |
| D1 | .783 | .791 | 19.90 | 20.10 | |
| E | .667 | .687 | 16.95 | 17.45 | |
| E1 | .547 | .555 | 13.90 | 14.10 | |
| e | .0256 BSC | | .65 BSC | | |
| L | .025 | .037 | .65 | .95 | 4 |
| N | 100 | | 100 | | |
| ND | 30 | | 30 | | |
| NE | 20 | | 20 | | |
| α | 0° | 7° | 0° | 7° | |
| ccc | — | .004 | — | .10 | |

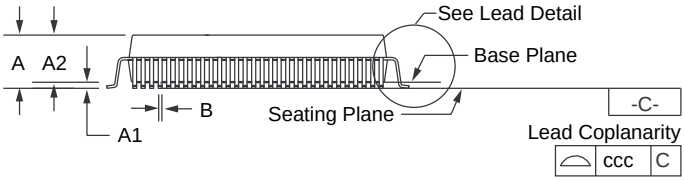
**Notes:**

1. All dimensions and tolerances conform to ANSI Y14.5M-1982.
2. Controlling dimension is millimeters.
3. Dimension "B" does not include dambar protrusion. Allowable dambar protrusion shall be .08mm (.003in.) maximum in excess of the "B" dimension. Dambar cannot be located on the lower radius or the foot.
4. "L" is the length of terminal for soldering to a substrate.
5. "B" & "C" includes lead finish thickness.





Lead Detail



## Ordering Information

| Product Number | Temperature Range | Decoding | Resolution | Package | Package Marking |
|---|---|---|---|---|---|
| TMC22051AKHC | 0°C to 70°C | Simple | 8 bit | 100-Lead MQFP | 22051AKHC |
| TMC22052AKHC | 0°C to 70°C | 2-Line Comb | 8 bit | 100-Lead MQFP | 22052AKHC |
| TMC22053AKHC | 0°C to 70°C | 3-Line Comb | 8 bit | 100-Lead MQFP | 22053AKHC |
| TMC22151AKHC | 0°C to 70°C | Simple | 10 bit | 100-Lead MQFP | 22151AKHC |
| TMC22152AKHC | 0°C to 70°C | 2-Line Comb | 10 bit | 100-Lead MQFP | 22152AKHC |
| TMC22153AKHC | 0°C to 70°C | 3-Line Comb | 10 bit | 100-Lead MQFP | 22153AKHC |
