## Precision Monolithic Dual Operational Amplifier

### Features

- Low Noise –  $0.35 \mu\text{V}_{\text{p-p}}$  (0.1 Hz to 10 Hz)
- Ultra-low  $V_{\text{OS}}$  –  $75 \mu\text{V}$
- Ultra-low  $V_{\text{OS}}$  drift –  $1.3 \mu\text{V}/^\circ\text{C}$
- Long term  $V_{\text{OS}}$  stability –  $0.2 \mu\text{V}/\text{Mo}$
- Low input bias and offset currents –  $\pm 5 \text{ nA}$
- High gain –  $400 \text{ V/mV}$
- Fits 4558 socket
- Industry standard pinout
- 8-lead mini-DIP

### Description

Designed for low level signal conditioning and instrumentation applications, the 4207 is a precision dual amplifier combining excellent DC input specifications with low input noise characteristics. Ultra low input offset voltage, low drift, high CMRR, and low input bias currents serve to reduce input related errors to less than 0.01% in a typical high gain instrumentation amplifier system ( $A_V = 1000$ ). The 4207 contains two separate amplifiers with a high degree of isolation between them; each is complete requiring no external compensation capacitors or offset nulling potentiometers.

The inherent  $V_{\text{OS}}$  is typically less than  $150 \mu\text{V}$ , resulting in superior temperature drift, and this low initial offset is further reduced by "Zener-zap" nulling when the wafers are tested.

Advanced thin film and nitride dielectric processing allows the 4207 to achieve its high performance and small size (the 4207 is offered in 8-lead DIPs). The 4207 fits the industry standard 8-lead op amp pin-out.

### Notes:

1. Functional operation under any of these conditions is NOT implied. Performance and reliability are guaranteed only if Operating Conditions are not exceeded.
2. For supply voltages less than ±18V, the absolute maximum input voltage is equal to the supply voltage.
3. Observe package thermal characteristics.

### Notes:

1. Long Term Input Offset Voltage Stability refers to the averaged trend line of VOS vs. Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in VOS during the first 30 operating days are typically 2.5  $\mu V$ .
2. Guaranteed by design.
3. Input Offset Voltage measurements are performed by automated test equipment approximately 0.5 seconds after application of power.
4. The input protection diodes do not allow the device to be removed or inserted into the circuit without first removing power.
