168-pin, 4 Clock, 1-bank, based on 2 M × 8 Bit SDRAMs with SPD

### DESCRIPTION

The Fujitsu MB8502S072AG is a fully decoded, CMOS Synchronous Dynamic Random Access Memory (SDRAM) Module consisting of nine MB81117822A devices which organized as two banks of 2 M × 8 bits and a 2K-bit serial EEPROM on a 168-pin glass-epoxy substrate.

The MB8502S072AG features a fully synchronous operation referenced to a positive edge clock whereby all operations are synchronized at a clock input which enables high performance and simple user interface coexistence.

The MB8502S072AG is optimized for those applications requiring high speed, high performance and large memory storage, and high density memory organizations.

This module is ideally suited for workstations, PCs, laser printers, and other applications where a simple interface is needed.

Parameter		MB8502S072AG-100	MB8502S072AG-84	MB8502S072AG-67
Clock Frequency		100 MHz max.	84 MHz max.	67 MHz max.
Burst Mode Cycle Time		10 ns max. (CL = 3) 15 ns max. (CL = 2)	12 ns max. (CL = 3) 17 ns max. (CL = 2)	15 ns max. (CL = 3) 20 ns max. (CL = 2)
RAS Access Time		54 ns max.	56 ns max.	60 ns max.
CAS Access Time		24 ns max.	26 ns max.	30 ns max.
Output Valid from Clock		8.5 ns max. (CL = 3) 9 ns max. (CL = 2)	8.5 ns max. (CL = 3) 9 ns max. (CL = 2)	9 ns max. (CL = 3) 10 ns max. (CL = 2)
Power Dissipation	Burst Mode	4374 mW max.	4050 mW max.	3726 mW max.
	Power Down Mode	64.8 mW max.		

- Unbuffered 168-pin DIMM Socket Type (Lead pitch: 1.27 mm)
- Conformed to JEDEC Standard (4 CLK)
- Organization: 2,097,152 words × 72 bits
- Memory: MB81117822A (2 M × 8, 2-bank) × 9 pcs.
- 3.3 V ±0.3 V Supply Voltage
- All input/output LVTTTL compatible
- 2048 Refresh Cycle every 32.8 ms
- Auto and Self Refresh
- CKE Power Down Mode
- DQM Byte Masking (Read/Write)
- Serial Presence Detect (SPD) with Serial EEPROM: JEDEC Standard SPD Format
- Module size: 1.0" (height) × 5.25" (length) × 0.157" (thickness)

Output Current (D.C.)	$I_{OUT}$	-50	+50	mA

\* : Voltages referenced to  $V_{SS}$  (= 0 V)

**WARNING:** Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

## ■ RECOMMENDED OPERATING CONDITIONS

Parameter	Notes	Symbol	Value			Unit
			Min.	Typ.	Max.	
Supply Voltage	*1	$V_{CC}$	3.0	3.3	3.6	V
		$V_{SS}$	0	0	0	V

Input Low Voltage, All Inputs	*1, 3	$V_{IL}$	-0.5	—	0.8	V
Ambient Temperature		$T_A$	0	—	+70	°C

\*1. Voltages referenced to  $V_{SS}$  (= 0 V)

\*2. Overshoot limit:  $V_{IH}$  (max.) =  $V_{CC} + 1.5$  V with a pulsewidth  $\leq 5$  ns.

\*3. Undershoot limit:  $V_{IL}$  (min.) =  $-1.5$  V with a pulsewidth  $\leq 5$  ns.

**WARNING:** Recommended operating conditions are normal operating ranges for the semiconductor device. All the device's electrical characteristics are warranted when operated within these ranges.

Always use semiconductor devices within the recommended operating conditions. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representative beforehand.

- Notes:**
- \*1. Assumes  $t_{RCD}$  and  $t_{CAC}$  are satisfied.
  - \*2.  $t_{AC}$  also specifies the access time at burst mode except for first access.
  - \*3. Specified where output buffer is no longer driven.
  - \*4. Actual clock count of  $t_{RC}$  ( $I_{RC}$ ) will be sum of clock count of  $t_{RAS}$  ( $I_{RAS}$ ) and  $t_{RP}$  ( $I_{RP}$ ).
  - \*5.  $t_{RAC}$  is a reference value. Maximum value is obtained from the sum of  $t_{RCD}$  (min) and  $t_{CAC}$  (max).
  - \*6. Assumes  $t_{RAC}$  and  $t_{AC}$  are satisfied.
  - \*7. Operation within the  $t_{RCD}$  (min) ensures that  $t_{RAC}$  can be met; if  $t_{RCD}$  is greater than the specified  $t_{RCD}$  (min), access time is determined by  $t_{CAC}$  and  $t_{AC}$ .
  - \*8. All base values are measured from the clock edge at the command input to the clock edge for the next command input.  
All clock counts are calculated by a simple formula:  
clock count equals base value divided by clock period (round off to a whole number).
  - \*9. The  $I_{CAC}$  (CAS latency: CL) is programmed by the mode register.
  - \*10. An initial pause (DESL on NOP) of 200  $\mu$ s is required after power-up followed by a minimum of eight Auto-refresh cycles.
  - \*11. 1.4 V or  $V_{REF}$  is the reference level for measuring timing of signals.  
Transition times are measured between  $V_{IH}$  (min) and  $V_{IL}$  (max).
  - \*12. AC characteristics assume  $t_r = 1$  ns and 30 pF of capacitive load.

# MB8502S072AG-100/-84/-67

## ■ SERIAL PRESENCE DETECT (SPD) FUNCTION

### 1. PIN DESCRIPTIONS

#### SCL (Serial Clock)

SCL input is used to clock all data input/output of SPD

#### SDA (Serial Data)

SDA is a common pin used for all data input/output of SPD. The SDA pull-up resistor is required due to the open-drain output.

#### SA<sub>0</sub>, SA<sub>1</sub>, SA<sub>2</sub> (Address)

Address inputs are used to set the least significant three bits of the eight bits slave address. The address inputs must be fixed to select a particular module and the fixed address of each module must be different each other.

### 2. SPD OPERATIONS

#### CLOCK and DATA CONVENTION

Data states on the SDA can change only during SCL = Low. SDA state changes during SCL = High are indicated start and stop conditions. Refer to Fig. 1 below.

#### START CONDITION

All commands are preceded by a start condition, which is a transition of SDA state from High to Low when SCL = High. SPD will not respond to any command until this condition has been met.

#### STOP CONDITION

All read or write operation must be terminated by a stop condition, which is a transition of SDA state from Low to High when SCL = High. The stop condition is also used to make the SPD into the state of standby power mode after a read sequence.

Fig. 1 – START AND STOP CONDITIONS

START = High to Low transition of SDA state when SCL is High

STOP = Low to High transition of SDA state when SCL is High

**ACKNOWLEDGE**

Acknowledge is a software convention used to indicate successful data transfer. The transmitting device, either master or slave, will release the bus after transmitting eight bits. During the ninth clock cycle the receiver will put the SDA line to Low in order to acknowledge that it received the eight bits of data.

The SPD will respond with an acknowledge when it received the start condition followed by slave address issued by master.

In the read operation, the SPD will transmit eight bits of data, release the SDA line and monitor the line for an acknowledge. If an acknowledge is detected and no stop condition is issued by master, the SPD will continue to transmit data. If an acknowledge is not detected, the SPD will terminated further data transmissions. The master must then issue a stop condition to return the SPD to the standby power mode.

In the write operation, upon receipt of eight bits of data the SPD will respond with an acknowledge, and await the next eight bits of data, again responding with an acknowledge until the stop condition is issued by master.

**SLAVE ADDRESS ADDRESSING**

Following a start condition, the master must output the eight bits slave address. The most significant four bits of the slave address are device type identifier. For the SPD this is fixed as 1010[B]. Refer to the Fig. 2 below.

The next three significant bits are used to select a particular device. A system could have up to eight SPD devices—namely up to eight modules—on the bus. The eight addresses for eight SPD devices are defined by the state of the SA<sub>0</sub>, SA<sub>1</sub> and SA<sub>2</sub> inputs.

The last bit of the slave address defines the operation to be performed. When R/ $\bar{W}$  bit is “1”, a read operation is selected, when R/ $\bar{W}$  bit is “0”, a write operation is selected.

Following the start condition, the SPD monitors the SDA line comparing the slave address being transmitted with its slave address (device type and state of SA<sub>0</sub>, SA<sub>1</sub>, and SA<sub>2</sub> inputs). Upon a correct compare the SPD outputs an acknowledge on the SDA line. Depending on the state of the R/ $\bar{W}$  bit, the SPD will execute a read or write operation.

## 3. READ OPERATIONS

### CURRENT ADDRESS READ

Internally the SPD contains an address counter that maintains the address of the last data accessed, incremented by one. Therefore, if the last access (either a read or write operation) was to address(n), the next read operation would access data from address(n+1). Upon receipt of the slave address with the R/W bit = "1", the SPD issues an acknowledge and transmits the eight bits of data during the next eight clock cycles. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 3 for the sequence of address, acknowledge and data transfer.

Fig. 3 – CURRENT ADDRESS READ

### RANDOM READ

Random Read operations allow the master to access any memory location in a random manner. Prior to issuing the slave address with the R/W bit = "1", the master must first perform a "dummy" write operation on the SPD. The master issues the start condition, and the slave address followed by the word address. After the word address acknowledge, the master immediately reissues the start condition and the slave address with the R/W bit = "1". This will be followed by an acknowledge from the SPD and then by the eight bits of data. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 4 for the sequence of address, acknowledge and data transfer.

Fig. 4 – RANDOM READ

# MB8502S072AG-100/-84/-67

## SEQUENTIAL READ

Sequential Read can be initiated as either a current address read or random read. The first data are transmitted as with the other read mode, however, the master now responds with an acknowledge, indicating it requires additional data. The SPD continues to output data for each acknowledge received. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 5 for the sequence of address, acknowledge and data transfer.

The data output is sequential, with the data from address(n) followed by the data from address(n+1). The address counter for read operations increments all address bits, allowing the entire memory contents to be serially read during one operation. At the end of the address space (address 255), the counter “rolls over” to address 0 and the SPD continues to output data for each acknowledge received.

FUJITSU semiconductor devices are intended for use in standard applications (computers, office automation and other office equipment, industrial, communications, and measurement equipment, personal or household devices, etc.).

#### CAUTION:

Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with FUJITSU sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

Any semiconductor devices have inherently a certain rate of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.
