HARRIS SEMICONDUCTOR POWER MOSFET PRODUCTS

This MOSFET databook offers an extensive line of power MOSFET products for use in a wide range of consumer, industrial and high-reliability applications. This databook contains detailed technical information on the broad line of more than 1000 power MOSFETs, including standard power MOSFETs (the popular RF-series types, the IRF-series of industry replacement types, and JEDEC types), MegaFETs, logic-level power MOSFETs (L^2FETs), ruggedized power MOSFETs, enhancement-mode insulated gate bipolar transistors (IGBTs), advanced discrete, high-reliability and radiation-hardened power MOSFETs.

The databook is divided into fifteen major sections. Section 1 includes a complete index of types and industry replacement guides. Brief profiles of the of the various product categories are then presented.

Separate data sections provide definitive ratings and characteristics for each major category of devices. Data pages for individual devices are organized in numeric-alphanumerical sequence for each section. Because some devices are grouped together to show similarity of function or data, some individual types numbers may be out of sequence. If you don't find the type number that you are looking for where you expect it to be, check the Index of Devices, Section 1.

For complete, current and detailed technical specifications on any Harris device please contact the nearest Harris sales, representative or distributor office; or direct literature requests to:

Harris Semiconductor Literature Department
P.O. Box 883, MS CB1-28
Melbourne, FL 32901

Harris Semiconductor products are sold by description only. All specifications in this product guide are applicable only to packaged products; specifications for die are available upon request. Harris reserves the right to make changes in circuit design, specifications and other information at any time without prior notice. Accordingly, the reader is cautioned to verify that information in this publication is current before placing orders. Reference to products of other manufacturers are solely for convenience of comparison and do not imply total equivalency of design, performance, or otherwise.

RURD1520	15A Ultrafast Dual Diode With Soft Recovery Characteristic	12-35
RURD1540	15A Ultrafast Dual Diode With Soft Recovery Characteristic	12-38
RURD1550	15A Ultrafast Dual Diode With Soft Recovery Characteristic	12-38
RURD1560	15A Ultrafast Dual Diode With Soft Recovery Characteristic	12-38
RURD1610	Dual 16A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers	12-41
RURD1615	Dual 16A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers	12-41
RURD1620	Dual 16A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers	12-41
RURD3010	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-43
RURD3015	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-43
RURD3020	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-43
RURD3040	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-46
RURD3050	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-46
RURD3060	30A Ultrafast Dual Diode With Soft Recovery Characteristics	12-46
SP306	Intelligent Power 60V/30A High Side Switch	11-57
SP600	Half-Bridge 500 VDC Driver	11-60
SP601	Half-Bridge 500 VDC Driver	11-66
SP605	Intelligent Power Half-Bridge 500 VDC Driver	11-72
SP606	Intelligent Power Half-Bridge 600 VDC Driver	11-75
SP630	500 VDC 3 Phase Bridge Driver	11-78
TA13349	Transient Suppressor Protected Power Switch	10-44
TA14832	Dual 5V Regulator with Logic Controlled Startup for Automotive Applications	10-46
TA50060	1A High Side Driver with Over-Load Protection	10-49

IRFP460, IRFP462	N-Channel Power MOSFETs Avalanche Energy Rated	4-526
IRFPC40R, IRFPC42R	N-Channel Power MOSFETs Avalanche Energy Rated	4-531
IRFPG40, IRFPG42	High Voltage N-Channel Enhancement-Mode Power Field-Effect Transistors	4-537

* R Suffix Types Only

N-CHANNEL POWER MOSFETs (Continued)

		PAGE
IRFR120, IRFR121, IRFU120, IRFU121	N-Channel Power MOSFETs Avalanche Energy Rated	4-542
IRFR220/221/222, IRFU220/221/222	N-Channel Power MOSFETs Avalanche Energy Rated	4-547
IRFR320/321/322, IRFU320/321/322	N-Channel Power MOSFETs Avalanche Energy Rated	4-552
IRFR420/421/422, IRFU420/421/422	N-Channel Power MOSFETs Avalanche Energy Rated	4-557
RFL1N08, RFL1N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-562
RFL1N12, RFL1N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-566
RFL1N18, RFL1N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-570
RFL2N05, RFL2N06	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-574
RFP2N08, RFP2N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-578
RFP2N12, RFP2N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-582
RFP2N18, RFP2N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-586
RFM3N45, RFM3N50, RFP3N45, RFP3N50	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-590
RFL4N12, RFL4N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-598
RFM4N35, RFM4N40, RFP4N35, RFP4N40	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-602
RFP4N100	High Voltage N-Channel Enhancement-Mode Power Field-Effect Transistor	4-606
RFM6N45, RFM6N50, RFP6N45, RFP6N50	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-610
RFM7N35, RFM7N40, RFP7N35, RFP7N40	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-614
RFM8N18, RFM8N20, RFP8N18, RFP8N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-618
RFM10N12, RFM10N15, RFP10N12, RFP10N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-622
RFH10N45, RFH10N50	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-626
RFM10N45, RFM10N50	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-630
RFM12N08, RFM12N10, RFP12N08, RFP12N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-634
RFM12N18, RFM12N20, RFP12N18, RFP12N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-638
RFH12N35, RFH12N40	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-642
RFM12N35, RFM12N40	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-646
RFD14N05, RFD14N05SM, RFP14N05	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-650
RFM15N05, RFM15N06, RFP15N05, RFP15N06	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-655
RFM15N12, RFM15N15, RFP15N12, RFP15N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-661
RFD16N05, RFD16N05SM	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-665
RFD16N10, RFD16N10SM	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-669
RFM18N08, RFM18N10, RFP18N08, RFP18N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-674
RFP22N10	N-Channel Enhancement-Mode Power Field-Effect Transistor (MegaFET)	4-678
RFP25N05	N-Channel Enhancement-Mode Power Field-Effect Transistor (MegaFET)	4-682
RFM25N06, RFP25N06	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-687
RFH25N18, RFH25N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-691
RFK25N18, RFK25N20	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-695
RFH30N12, RFH30N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-699
RFK30N12, RFK30N15	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-703
RFH35N08, RFH35N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-707

N-CHANNEL POWER MOSFETs (Continued)

		PAGE
RFK35N08, RFK35N10	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-711
RFG40N10, RFP40N10	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-715
RFH45N05, RFH45N06	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-720
RFK45N05, RFK45N06	N-Channel Enhancement-Mode Power Field-Effect Transistors	4-724
RFP50N05, RFG50N05	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-728
RFG75N05E, RFH75N05E	N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	4-733
RFA100N05E	N-Channel Enhancement-Mode Power Field-Effect Transistor (MegaFET)	4-738

P-CHANNEL POWER MOSFETs

2N6804	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-3
2N6849	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-8
2N6851	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-13
2N6895	P-Channel Enhancement-Mode Power MOS Field-Effect Transistors	5-18
2N6896	P-Channel Enhancement-Mode Power MOS Field-Effect Transistors	5-22
2N6897	P-Channel Enhancement-Mode Power MOS Field-Effect Transistors	5-26
2N6898	P-Channel Enhancement-Mode Power MOS Field-Effect Transistors	5-30
IRF9130, IRF9131, IRF9132, IRF9133	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-34
IRF9140, IRF9141, IRF9142, IRF9143	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-39
IRF9150, IRF9151	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-44
IRF9230, IRF9231, IRF9232, IRF9233	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-50
IRF9240, IRF9241, IRF9242, IRF9243	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-55
IRF9510, IRF9511, IRF9512, IRF9513	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-60
IRF9520, IRF9521, IRF9522, IRF9523	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-65
IRF9530, IRF9531, IRF9532, IRF9533	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-70
IRF9540, IRF9541, IRF9542, IRF9543	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-75
IRF9620, IRF9621, IRF9622, IRF9623	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-80
IRF9630, IRF9631, IRF9632, IRF9633	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-85
IRF9640, IRF9641, IRF9642, IRF9643	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-90
IRFD9110, IRFD9113	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-95
IRFD9120, IRFD9123	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-100
IRFD9220, IRFD9223	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-105
IRFF9120, IRFF9121, IRFF9122, IRFF9123	Avalanche-Energy-Rated P-Channel Power MOSFETs	5-110
IRFF9130, IRFF9131, IRFF9132, IRFF9133	Avalanche Energy-Rated P-Channel Power MOSFETs	5-115
IRFF9220, IRFF9221, IRFF9222, IRFF9223	Avalanche Energy-Rated P-Channel Power MOSFETs	5-120
IRFF9230, IRFF9231, IRFF9232, IRFF9233	Avalanche Energy-Rated P-Channel Power MOSFETs	5-125
IRFP9140R/P9141R, IRFP9142R/P9143R	Avalanche Energy-Rated P-Channel Power MOSFETs	5-130
IRFP9150, IRFP9151	Avalanche Energy-Rated P-Channel Power MOSFETs	5-135
IRFP9240R/P9241R, IRFP9242R/P9243R	Avalanche Energy-Rated P-Channel Power MOSFETs	5-140
RFL1P08, RFL1P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-145

		PAGE
RFP2P08, RFP2P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-149
RFM5P12, RFM5P15, RFP5P12, RFP5P15	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-153
RFM6P08, RFM6P10, RFP6P08, RFP6P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-157
RFD8P05/05SM, RFP8P05	P-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	5-161
RFM8P08, RFM8P10, RFP8P08, RFP8P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-166
RFM10P12/M10P15, RFP10P12/P10P15	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-170
RFM12P08/M12P10, RFP12P08/P12P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-174
RFD15P05/05SM, RFP15P05	P-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	5-178
RFH25P08/H25P10, RFK25P08/K25P10	P-Channel Enhancement-Mode Power Field-Effect Transistors	5-183
RFG30P05, RFP30P05	P-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	5-187
RFG30P06, RFP30P06	P-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	5-192
RFG60P05E, RFG60P06E	P-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)	5-197

PREVIEW PRODUCTS

HGTG30N120E2	N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)	10-3
HGTG34N100E2	N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)	10-7
HV250	Half Bridge Complimentary MOSFET Driver	10-11
HV255	Half Bridge Complimentary MOSFET Driver	10-15
HV350	Half Bridge N-Channel MOSFET Driver	10-19
HV400	High Speed MOSFET Driver	10-23
RFA14N50BE	N-Channel Enhancement-Mode Power Field-Effect Transistor	10-26
RFW2N06RLE	N-Channel Logic Level Enhancement-Mode Power Field-Effect Transistor (MegaFET)	10-29
RFD3N08L, RFD3N08LSM	N-Channel Logic Level Power Field Effect Transistors	10-31
RFD4N06L, RFD4N06LSM	N-Channel Logic Level Power Field Effect Transistors	10-33
RFP15N08L	N-Channel Logic Level Power Field-Effect Transistor	10-35
RLP1N06CLE	Voltage Clamping - Current Limiting ESD Protected N-Channel Enhancement Mode Power Field-Effect Transistor	10-37
TA13349	Transient Suppressor Protected Power Switch	10-44
TA14832	Dual 5V Regulator with Logic Controlled Startup for Automotive Applications	10-46
TA50060	1A High Side Driver with Over-Load Protection	10-49

ULTRA-FAST RECTIFIERS

MUR810, MUR815, MUR820 RUR810, RUR815, RUR820	8A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers	12-3

Power MOSFETs

The line of solid state power devices includes a series of standard state-of-the-art n- and p-channel enhancement-mode field-effect transistors. These power MOSFETs are designed for such applications as dc-to-dc converters, motor drive and control circuits, solenoid and relay drive circuits, linear and switching regulators, drivers for high-power bipolar devices, and automotive load switching and control circuits.

The designs of power MOSFET structures are optimized to achieve simultaneously high voltage, current, and dissipation capability, together with fast switching speeds, on competitively sized chips. The critical considerations are:

1. A low on-state resistance, $r_{DS(ON)}$, from the drain to the source.
2. The resistivity and spacings of the silicon layers necessary to assure the required drain-to-source voltage breakdown capability.
3. A uniform gate-to-source threshold voltage.
4. A structure to minimize the effect of device junction capacitances on switching speed.

The resultant structures feature low leakage currents, good thermal characteristics (low thermal resistance and excellent thermal stability), large safe-operating areas, and high operating efficiencies.

Features

- Fast switching speeds and low switching losses, both of which are independent of temperature
- Minimal storage time and no temperature dependent delay times
- High resistance to thermal runaway
- Simple drive circuitry
- Safe operating area limited only by device dissipation ratings
- Stable gain and switching response over a wide temperature range

Operation

A positive voltage applied to the gate of an n-type MOSFET creates an electric field in the channel region beneath the gate; that is, the positive electric charge on the gate converts the p-region beneath the gate to an n-type material. In effect, the MOSFET becomes an n-n-n device when in this state. The region between the drain and source can then be represented as a temperature-dependent resistor.

Further development has expanded the power MOSFET line to include the following families of devices:

1. Logic-Level Power MOSFETs-L^2FETs, devices which allow on-off switching directly from logic-level voltage of 5 volts rather than the nominal 10 volts required for standard power MOSFETs.
2. Insulated-Gate Bipolar Transistors (IGBTs), devices which combine the characteristics of a power MOS transistor and a bipolar transistor, making them cost effective for many power switching and control applications.
3. Rugged Power MOSFETs, devices which are designed, tested and guaranteed to withstand a specific level of electrical stress in the breakdown avalanche mode of operation.

Packaged Devices and Chips

The power MOSFET product line currently includes more than 1000 types. The Harris RF series are identified by a coded type number which indicates the current and voltage ratings, whether n- or p-channel, and specifies the package type.

The devices are supplied in 12 package styles: TO-202, TO-204, TO-205, TO-218, TO-220, TO-247, TO-251, TO-252, TO-254, MO-093, TS-001 and a 4 pin DIP. Power MOSFET chips are also available for use in hybrid circuits. Chips may be purchased either in wafer form or as separated die.

MegaFETs

The MegaFET series of power MOSFETs represent an advancement in processing technology that achieves unmatched $r_{DS(ON)}$ performance per unit area of silicon. This application of VLSI IC dimensions and processing techniques allows for the integration of nearly 2 million cells per square inch of active silicon area. This represents a minimum two-fold and, more typically, a four-fold increase in cell density.

The MegaFET design achieves several important advantages. Among these are:

- More volt-ampere capability per unit cost
- Small die size for the same $r_{DS(ON)}$
- Lower $r_{DS(ON)}$ for the same die size
- 40% die size reduction at 50V BV_{DSS}

The MegaFET series is also specified for avalanche energy capability.

Additional product introductions are anticipated. Among these are:

- N-Channel 0.200, 0.100, 0.050Ω $r_{DS(ON)}$ at BV_{DSS} = 100V

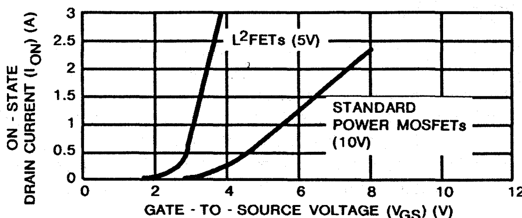
Staggered lead forms for horizontal and vertical mounting are available.

Logic Level Power MOSFETs

Logic level power MOSFETs (L^2FETs) feature a thinner gate oxide separation layer that is typically one-half the industry standard for power MOSFETs. The surface inversion of the MOS channel is a direct function of this gate oxide thickness; consequentially, the gate-to-source threshold voltage — i.e., the applied gate voltage required for uncompromised drain characteristics — on this series of devices is only halve that of conventional power MOSFETs.

The reduced gate drive requirement allows on-off switching of L^2FETs directly from logic level voltages of 5 volts, rather than the nominal 10 volts required for conventional power MOSFETs. The L^2FETs feature the same low on resistance characteristics, drain current ratings, and blocking voltage capability of corresponding types with the higher gate drive requirements. In addition, the L^2FETs offer twice the tranconductance and half the threshold voltage temperature coefficient of conventional types having the same on resistance and voltage ratings and demonstrate a comparable switching speed for the same gate drive power.



COMPARISON OF STANDARD POWER MOSFETs AND L^2FETs

Special Features

- 5 Volt Gate Drive
- Compatible with CMOS, High Speed CMOS, TTL, PMOS and NMOS Logic Circuits
- Compatible with Automotive Drive Requirements

Rugged Power MOSFETs

The Rugged Series of Power MOSFETs are designed, tested and guaranteed to withstand a specified level of circuit induced electrical stress in the breakdown avalanche mode of operation. These are n-channel enhancement mode polysilicon gate power field effect transistors designed for applications such as switching regulators, switching converters, motor and relay drivers and drivers for high power bipolar switching transistors requiring high speed and low gate drive power.

Using state-of-the-art integrated circuit processing techniques these Rugged MOSFETs provide superior performance in inductance switching applications. The design is optimized to suppress the parasitic bipolar transistor and improve system reliability. These types can be driven directly from integrated circuits.

Rugged Series devices are identified by the suffix letter R following the type number.

Features

- Single pulse avalanche energy rated
- SOA is power dissipation limited
- Nanosecond switching speeds
- Linear transfer characteristics
- High input impedance
- Allows reduced protection circuitry
- Reduced drive requirements
- Increased system reliability

Insulated-Gate Bipolar Transistors (IGBTs)

The IGBT, or Insulated Gate Bipolar Transistor, is a discrete power switch that combines the characteristics of a power MOS transistor, a bipolar transistor, and a thyristor. As a result, it is cost effective for many power switching and control applications. It features an exceptionally low nonlinear on-resistance, $r_{DS(ON)}$, that is nearly independent of blocking voltage level and temperature. In addition, its fast turn on speed is very similar to that of standard power FETs, and its rise time characteristics are easily controlled by the gate driving circuit. These characteristics enable the designer to control EMI and RFI generation more easily than with other power semiconductor devices, which may require elaborate circuit schemes to limit rapidly rising in-rush currents.*

There are now available n-channel enhancement mode insulated gate bipolar transistors which range from 400V to 1200V and currents of 6A to 34A. These types are designed for use in high voltage, low on-dissipation applications such as switching regulators and motor drivers. They can be operated directly from low power CMOS integrated circuits.

Features

• Voltage Gated	Requires small gate power. Similar to standard power MOSFET.
• Turn Off	Turns off when gate drive is removed
• On-State Voltage Drop	Nonlinear. Like that of an SCR. Temperature independent. Unlike the typical 2X variation of a power MOSFET.
• Turn-On Speed	Fast! Comparable to a standard power MOSFET
• Turn-Off Speed	Comparable to a bipolar transistor.

* These structures, however, trade off turn-off switching speed for this enhanced $r_{DS(ON)}$ performance. They have the small turn-off delay times standard MOSFETs and fall times comparable to bipolar transistors.

Handling Precautions for Power MOSFETs

Insulated-Gate Field-Effect Transistors (MOSFETs) are susceptible to gate-insulation damage by the electrostatic discharge of energy through the devices. When handling a MOSFET, care should be exercised to assure that the static charge built in the handler's body capacitance is not discharged through the device. With proper handling and application procedures, however, MOS transistors are currently being extensively used in production by numerous equipment manufacturers in military, industrial and consumer applications with virtually no damage problems due to electrostatic discharge.

MOSFETs can be handled safely if the following basic precautions are taken:

1. Prior to assembly into a circuit, all leads should be kept shorted together either by the use of metal shorting springs or by the insertion into conductive materials such as "ECCOSORB* LD26" or equivalent.
2. When devices are removed by hand from their carriers, the hands being used should be grounded by any suitable means — for example, with a metallic wristband.
3. Tips of soldering irons be grounded.
4. Devices should never be inserted into or removed from circuits with power on.
5. Gate Voltage Rating — Never exceed the gate-voltage rating of ±20V. Exceeding the rated V_{GS} can result in permanent damage to the oxide layer in the gate region.
6. Gate Termination — The gates of these devices are essentially capacitors. Circuits that leave the gate open-circuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.
7. Gate Protection — These devices do not have an internal monolithic zener diode from gate to source. If gate protection is required an external zener is recommended.

2N6755
2N6756

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 12A and 14A, 60V - 100V
- $r_{DS(on)}$ = 0.18Ω and 0.25Ω
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6755 and 2N6756 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

These types are supplied in the JEDEC TO-204AA steel package.

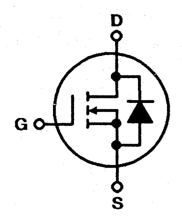
N-CHANNEL ENHANCEMENT MODE



Absolute Maximum Ratings (T_C = +25°C) Unless Otherwise Specified

		2N6755	2N6756	UNITS
Drain-Source Voltage	V_{DS}	60*	100*	V
Drain-Gate Voltage (R_{GS} = 20kΩ)	V_{DGR}	60*	100*	V
Continuous Drain Current				
T_C = +25°C	I_D	12*	14*	A
T_C = +100°C	I_D	8.0*	9.0*	A
Pulsed Drain Current	I_{DM}	25	30	A
Gate-Source Voltage	V_{GS}	±20	±20	V
Maximum Power Dissipation				
T_C = +25°C (See Fig. 11)	P_D	75*	75*	W
T_C = +100°C (See Fig. 11)	P_D	30*	30*	W
Linear Derating Factor (See Fig. 11)		0.6*	0.6*	W/°C
Inductive Current, Clamped (See Figures 1 and 2, L = 100μH)	I_{LM}	25	30	A
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150*	-55 to +150*	°C
Maximum Lead Temperature for Soldering (0.063" (1.6mm) from case for 10s)	T_L	300*	300*	°C

*JEDEC registered values

CAUTION: These devices are sensitive to electrostatic discharge. Proper I.C. handling procedures should be followed.

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- **4.0A and 4.5A, 450V - 500V**
- **$r_{DS(on)}$ = 1.5Ω and 2.0Ω**
- **SOA is Power-Dissipation Limited**
- **Nanosecond Switching Speeds**
- **Linear Transfer Characteristics**
- **High Input Impedance**
- **Majority Carrier Device**

Description

The 2N6761 and 2N6762 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

These types are supplied in the JEDEC TO-204AA steel package.

N-Channel Enhancement-Mode Power MOS Field-Effect Transistors

August 1991

Features

- 12A and 14A, 350V - 400V
- $r_{DS(on)}$ = 0.4Ω and 0.3Ω
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6767 and 2N6768 are n-channel enhancement-mode silicon-gate power MOS field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

These types are supplied in the JEDEC TO-204AA steel package.

2N6784

August 1991

N-Channel Enhancement-Mode Power MOS Field-Effect Transistor

Features

- 2.25A, 200V
- $r_{DS(on)} = 1.5\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6784 is an n-channel enhancement-mode silicon-gate power MOS field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The 2N6784 is supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

2N6792

August 1991

N-Channel Enhancement-Mode Power MOS Field-Effect Transistor

Features

- 2A, 400V
- $r_{DS(on)} = 1.8\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6792 is an n-channel enhancement-mode silicon-gate power MOS field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The 2N6792 is supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

NOTES:
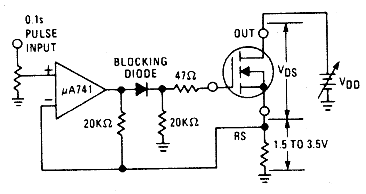
WHEN MEASURING RISE TIME, $V_{GS(on)}$ SHALL BE AS SPECIFIED ON THE INPUT WAVEFORM. WHEN MEASURING FALL TIME, $V_{GS(off)}$ SHALL BE SPECIFIED ON THE INPUT WAVEFORM. THE INPUT TRANSITION AND DRAIN VOLTAGE RESPONSE DETECTOR SHALL HAVE RISE AND FALL RESPONSE TIMES SUCH THAT DOUBLING THESE RESPONSES WILL NOT AFFECT THE RESULTS GREATER THAN THE PRECISION OF MEASUREMENT. THE CURRENT SHALL BE SUFFICIENTLY SMALL SO THAT DOUBLING IT DOES NOT AFFECT TESTS RESULTS GREATER THAN THE PRECISION OF MEASUREMENT.

Fig. 15 – Switching Time Test Circuit



NOTES:
1. SET V_{DS} TO THE VALUE SPECIFIED UNDER DETAILS USING A 0.1s PULSE WIDTH WITH A MINIMUM OF 1 MINUTE BETWEEN PULSES. INCREASE V_{GS} UNTIL THE SPECIFIED VALUE OF I_D AND V_{DS} ARE OBTAINED. CASE TEMPERATURE = 25°C.
2. SELECT R_S SUCH THAT $I_D \bullet R_S = 2.5 \pm 1.0$ Vdc.

2N6798

August 1991

N-Channel Enhancement-Mode Power MOS Field-Effect Transistor

Features

- 5.5A, 200V
- $r_{DS(on)} = 0.4\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6798 is an n-channel enhancement-mode silicon-gate power MOS field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The 2N6798 is supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

BUZ20

N-Channel Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- 12A, 100V
- $r_{DS(on)} = 0.2\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The BUZ20 is an n-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The BUZ20 is supplied in the JEDEC TO-220AB plastic package.

Package

BUZ42

August 1991

N-Channel Enhancement-Mode Power Field-Effect Transistor

Features

- 4.0A, 500V
- $r_{DS(on)} = 2.0\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The BUZ42 is an n-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The BUZ42 is supplied in the JEDEC TO-220AB plastic package.

BUZ60B

August 1991

N-Channel Enhancement-Mode Power Field-Effect Transistor

Features

- 4.5A, 400V
- $r_{DS(on)} = 1.5\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The BUZ60B is an n-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The BUZ60B is supplied in the JEDEC TO-220AB plastic package.

BUZ76

N-Channel Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- 3A, 400V
- $r_{DS(on)} = 1.8\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The BUZ76 is an n-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The BUZ76 is supplied in the JEDEC TO-220AB plastic package.

IRF130R/131R/132R/133R

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 12A and 14A, 80V - 100V
- $r_{DS(on)}$ = 1.16Ω and 1.23Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF130, IRF131, IRF132, and IRF133 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF130R, IRF131R, IRF132R, and IRF133R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

IRF140R/141R/142R/143R

N-Channel Power MOSFETs
Avalanche Energy Rated*

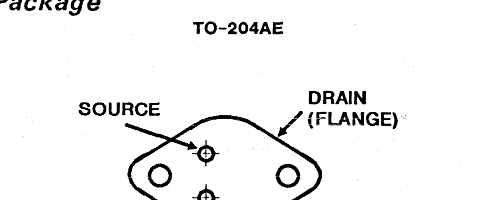
August 1991

Features

- 28A and 25A, 80V - 100V
- $r_{DS(on)}$ = 0.077Ω and 0.10Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Package

TO-204AE



Description

The IRF140, IRF141, IRF142, and IRF143 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF140R, IRF141R, IRF142R, and IRF143R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AE steel package.

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 8.0A and 9.0A, 150V - 200V
- $r_{DS}(on) = 0.4\Omega$ and 0.6Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF230, IRF231, IRF232, and IRF233 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF230R, IRF231R, IRF232R and IRF233R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

Package

TO-204AA

IRF240/241/242/243
IRF240R/241R/242R/243R

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 16A and 18A, 200V, 150V
- $r_{DS}(on)$ = 0.18Ω and 0.22Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF240, IRF241, IRF242, and IRF243 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF240R, IRF241R, IRF242R and IRF243R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF-types are supplied in the JEDEC TO-204AE steel package.

N-Channel Power MOSFETs Avalanche Energy Rated

August 1991

Features

- 22A and 20A, 275V - 250V
- $r_{DS(on)}$ = 0.14Ω and 0.17Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- 275, 250V DC Rated - 120V AC Line System Operation

Description

The IRF254, IRF255, IRF256, and IRF247 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AE steel package.

IRF340/341/342/343
IRF340R/341R/342R/343R

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 10A and 8.3A, 400V - 350V
- $r_{DS(on)}$ = 0.55Ω and 0.80Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF340, IRF341, IRF342, and IRF343 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF340R, IRF341R, IRF342R, and IRF343R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

IRF420, IRF421 IRF422, IRF423

N-Channel Enhnancement Mode Power Field-Effect Transistors

August 1991

Features

- 2.2A and 2.5A, 450V - 500V
- $r_{DS}(on)$ = 3.0Ω and 4.0Ω
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The IRF420, IRF421, IRF422, and IRF423 are n-channel enhancement mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF-types are supplied in the JEDEC TO-204AA steel package.

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 4.0A and 4.5A, 450V - 500V
- $r_{DS}(on)$ = 1.5Ω and 2.0Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF430, IRF431, IRF432, and IRF433 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF430R, IRF431R, IRF432R and IRF433R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 11A and 13A, 450V - 500V
- r_{DS}(on) = 0.4Ω and 0.5Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF450, IRF451, IRF452, and IRF453 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF450R, IRF451R, IRF452R and IRF453R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

Package

TO-204AA

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 25A and 28A, 80V - 100V
- $r_{DS}(on)$ = 0.077Ω and 0.10Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF540, IRF541, IRF542, and IRF543 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF540R, IRF541R, IRF542R and IRF543R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

N-Channel Power MOSFETs
Avalanche Energy Rated

August 1991

Features

- 3.8A and 3.3A, 250V - 275V
- $r_{DS}(on)$ = 1.1Ω and 1.5Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- 250/275V DC Rating - 120V AC Line System Operation

Description

The IRF624, IRF625, IRF626, and IRF627 are advanced power MOSFETs designed, tested and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF-types are supplied in the JEDEC TO-220AB plastic package.

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- **16A and 18A, 150V - 200V**
- **$r_{DS}(on)$ = 0.18Ω and 0.22Ω**
- **Single Pulse Avalanche Energy Rated***
- **SOA is Power-Dissipation Limited**
- **Nanosecond Switching Speeds**
- **Linear Transfer Characteristics**
- **High Input Impedance**

Description

The IRF640, IRF641, IRF642, and IRF643 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF640R, IRF641R, IRF642R and IRF643R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

IRF710/711/712/713
IRF710R/711R/712R/713R

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 1.7A and 2.0A, 350V - 400V
- $r_{DS}(on)$ = 3.6Ω and 5.0Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF710, IRF711, IRF712, and IRF713 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF710R, IRF711R, IRF712R and IRF713R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 8A and 10A, 350V - 400V
- $r_{DS}(on)$ = 0.55Ω and 0.8Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF740, IRF741, IRF742, and IRF743 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF740R, IRF741R, IRF742R and IRF743R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

Package

August 1991

Features

- 4.0A and 4.5A, 450V - 500V
- $r_{DS}(on)$ = 1.5Ω and 2.0Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF830, IRF831, IRF832, and IRF833 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRF830R, IRF831R, IRF832R and IRF833R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

N-CHANNEL POWER MOSFETs

IRFAC40R
IRFAC42R

N-Channel Power MOSFETs
Avalanche Energy Rated

August 1991

Features

- 6.2A and 5.4A, 600V
- $r_{DS(on)}$ = 1.2Ω and 1.6Ω
- Repetitive Avalanche Ratings
- Simple Drive Requirements
- Ease of Paralleling

Description

The IRFAC40R and IRFAC42R are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFAC types are supplied in the JEDEC TO-204AA steel package.

IRFBC40R
IRFBC42R

N-Channel Power MOSFETs Avalanche Energy Rated

August 1991

Features

- 6.2A and 5.4A, 600V
- $r_{DS(on)}$ = 1.2Ω and 1.6Ω
- Repetitive Avalanche Ratings
- Simple Drive Requirements
- Ease of Paralleling

Description

The IRFBC40R and IRFBC42R are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFAC types are supplied in the JEDEC TO-220AB steel package.

IRFD1Z0, IRFD1Z1 IRFD1Z2, IRFD1Z3

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 0.4A and 0.5A, 60V - 100V
- $r_{DS(on)}$ = 2.4Ω and 3.2Ω
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The IRFD1Z0, IRFD1Z1, IRFD1Z2, and IRFD1Z3 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFD types are supplied in the 4-pin DIP package.

Package

Description

The IRFD210, IRFD211, IRFD212, and IRFD213 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFD210R, IRFD211R, IRFD212R, and IRFD213R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFD types are supplied in the 4-pin dual-in-line plastic package.

IRFD2Z0, IRFD2Z1 IRFD2Z2, IRFD2Z3

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 0.30A and 0.32A, 150V - 200V
- $r_{DS(on)}$ = 5.0Ω and 6.5Ω
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The IRFD2Z0, IRFD2Z1, IRFD2Z2, and IRFD2Z3 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFD types are supplied in the 4-pin DIP package.

Package

Description

The IRFD310, IRFD311, IRFD312, and IRFD313 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFD310R, IRFD311R, IRFD312R, and IRFD313R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFD types are supplied in the 4-pin dual-in-line plastic package.

IRFF110/111/112/113
IRFF110R/111R/112R/113R

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 3.0A and 3.5A, 80V - 100V
- $r_{DS(on)}$ = 0.6Ω and 0.8Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF110, IRFF111, IRFF112, and IRFF113 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFF110R, IRFF111R, IRFF112R, and IRFF113R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

N-Channel Power MOSFETs Avalanche Energy Rated*

August 1991

Features

- 1.8A and 2.2A, 150V - 200V
- $r_{DS(on)}$ = 1.5Ω and 2.4Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF210, IRFF211, IRFF212, and IRFF213 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFF210R, IRFF211R, IRFF212R, and IRFF213R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

August 1991

Features

- 4.5A and 5.5A, 150V - 200V
- $r_{DS(on)} = 0.4\Omega$ and 0.6Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF230, IRFF231, IRFF232, and IRFF233 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFF230R, IRFF231R, IRFF232R, and IRFF233R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

Package

TO-205AF

IRFF330/331/332/333
IRFF330R/331R/332R/333R

N-Channel Power MOSFETs
Avalanche Energy Rated*

August 1991

Features

- 3.0A and 3.5A, 350V - 400V
- $r_{DS(on)}$ = 1.0Ω and 1.5Ω
- Single Pulse Avalanche Energy Rated*
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF330, IRFF331, IRFF332, and IRFF333 are n-channel enhancement-mode silicon-gate power field-effect transistors. IRFF330R, IRFF331R, IRFF332R, and IRFF333R types are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. All of these power MOSFETs are designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

Package

TO-205AF

IRFP140R, IRFP141R IRFP142R, IRFP143R

N-Channel Power MOSFETs Avalanche Energy Rated

August 1991

Features

- 27A and 31A, 80V - 100V
- $r_{DS(on)}$ = 0.077Ω and 0.099Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFP140R, IRFP141R, IRFP142R, and IRFP143R are advanced power MOSFETs designed, tested and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP types are supplied in the JEDEC TO-247 plastic package.

N-Channel Power MOSFETs Avalanche Energy Rated

August 1991

Features

- 15A and 14A, 275V - 250V
- $r_{DS(on)}$ = 0.28Ω and 0.34Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- 275V, 250V DC Rated - 120V AC Line System Operation

Description

The IRFP244, IRFP245, IRFP246, and IRFP247 are advanced power MOSFETs designed, tested and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP types are supplied in the JEDEC TO-247 plastic package.

Description

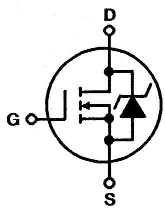
The IRFP254, IRFP255, IRFP256, and IRFP257 are advanced power MOSFETs designed, tested and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP types are supplied in the JEDEC TO-247 plastic package.

Terminal Diagram

N-CHANNEL ENHANCEMENT MODE



Absolute Maximum Ratings (T_C = +25°C), Unless Otherwise Specified

		IRFP254	IRFP255	IRFP256	IRFP257	UNITS
Drain-Source Voltage (1)	V_{DS}	250	250	275	275	V
Drain-Gate Voltage (R_{GS} = 20kΩ) (1)	V_{DGR}	250	250	275	275	V
Continuous Drain Current						
T_C = +25°C	I_D	23	21	23	21	A
T_C = +100°C	I_D	15	13	15	13	A
Pulsed Drain Current (3)	I_{DM}	92	84	92	84	A
Gate-Source Voltage	V_{GS}	±20	±20	±20	±20	V
Maximum Power Dissipation						
T_C = +25°C	P_D	180	180	180	180	W
Linear Derating Factor		1.44	1.44	1.44	1.44	W/°C
Single Pulse Avalanche Energy Rating (4)	E_{as}	1000	1000	1000	1000	mJ
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150	-55 to +150	-55 to +150	-55 to +150	°C
Maximum Lead Temperature for Soldering (0.063" (1.6mm) from case for 10s)	T_L	300	300	300	300	°C

NOTES:
1. T_J = +25°C to +150°C.
2. Pulse Test: Pulse width ≤ 300μs, Duty Cycle ≤ 2%.
3. Repetitive Rating: Pulse width limited by max. junction temperature. See Transient Thermal Impedance Curve (Figure 5).
4. V_{DD} = 50V, starting T_J = +25°C, L = 3.1mH, R_{GS} = 25Ω, I_{PEAK} = 23A. See Figures 14 and 15.

CAUTION: These devices are sensitive to electrostatic discharge. Proper I.C. handling procedures should be followed.

N-Channel Power MOSFETs
Avalanche-Energy Rated

August 1991

Features

- **20A and 23A, 400V**
- **$r_{DS}(on)$ = 0.20Ω and 0.25Ω**
- **Single Pulse Avalanche Energy Rated**
- **SOA is Power-Dissipation Limited**
- **Nanosecond Switching Speeds**
- **Linear Transfer Characteristics**
- **High Input Impedance**

Description

The IRFP360 and IRFP362 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP-types are supplied in the JEDEC TO-247 plastic package.

IRFP460
IRFP462

N-Channel Power MOSFETs
Avalanche-Energy Rated

August 1991

Features

- 20A and 17A, 500V
- $r_{DS}(on)$ = 0.27Ω and 0.35Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFP460 and IRFP462 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP-types are supplied in the JEDEC TO-247 plastic package.

IRFPC40R
IRFPC42R

N-Channel Power MOSFETs
Avalanche-Energy-Rated

August 1991

Features

- 6.8A, 5.9V and 600V
- $r_{DS(ON)}$ = 1.2Ω and 1.6Ω
- Isolated Central Mounting Hole
- Repetitive Avalanche Ratings
- Simple Drive Requirements
- Ease of Paralleling

Description

The IRFPC40R and IRFPC42R are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFPC types are supplied in the JEDEC TO-247 plastic package.

N-CHANNEL POWER MOSFETs

IRFR120/IRFR121
IRFU120/IRFU121

N-Channel Power MOSFETs
Avalanche-Energy-Rated

August 1991

Features

- 8.4A, 80V and 100V
- $r_{DS(on)} = 0.27\Omega$
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFR120, IRFR121, IRFU120, IRFU121 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFU series is supplied in the TO-251AA plastic package and the IRFR series is supplied in the TO-252AA surface-mount plastic package.

Because of space limitations branding (marking) on type IRFR120 is IRF120, IRFR121 is IFR121, IRFU120 is IFU120 and IRFU121 is IFU121.

IRFR220/221/222
IRFU220/221/222

N-Channel Power MOSFETs
Avalanche-Energy-Rated

August 1991

Features

- 3.8A and 4.6A, 150V and 200V
- $r_{DS(on)}$ = 0.80Ω and 1.2Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFR220, IRFR221, IRFR222, IRFU220, IRFU221 and IRFU222 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are n-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFU series is supplied in the TO-251AA plastic package and the IRFR series is supplied in the TO-252AA surface-mount plastic package.

Because of space limitations branding (marking) on type IRFR220 is IRF220, IRFR221 is IFR221, IRFR222 is IRF222, IRFU220 is IFU220 and IRFU221 is IFU221, IRFU222 is IFU222.

RFL1N08
RFL1N10

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 1A, 80V and 100V
- $R_{DS(on)} = 1.2\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFL1N08 and RFL1N10 are n-channel enhancement mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFL-series types are supplied in the JEDEC TO-205AF metal package.

Package

TO-205AF

RFP2N08
RFP2N10

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 2A, 80V and 100V
- $r_{DS}(on) = 1.05\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFP2N08 and RFP2N10 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFP-types are supplied in the JEDEC TO-220AB plastic package.

RFL4N12
RFL4N15

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 4A, 120V and 150V
- $r_{DS}(on) = 0.4\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFL4N12 and RFL4N15 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFL-series types are supplied in the JEDEC TO-205AF metal package.

Package

TO-205AF

RFM7N35/7N40
RFP7N35/7N40

N-Channel Enhancement Mode Power Field Effect Transistors

August 1991

Features

- 7A, 350V and 400V
- $r_{DS(on)} = 0.75\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFM7N35 and RFM7N40 and the RFP7N35 and RFP7N40 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFM-series types are supplied in the JEDEC TO-204AA steel package and the RFP-series types in the JEDEC TO-220AB plastic package.

RFM12N08/12N10
RFP12N08/12N10

N-Channel Enhancement Mode Power Field Effect Transistors

August 1991

Features

- 12A, 80V and 100V
- $r_{DS(on)} = 0.2\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFM12N08 and RFM12N10 and the RFP12N08 and RFP12N10 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFM-series types are supplied in the JEDEC TO-204AA steel package and the RFP-series types in the JEDEC TO-220AB plastic package.

RFD14N05/05SM RFP14N05

N-Channel Enhancement Mode Power Field Effect Transistors (MegaFETs)

May 1991

Features

- 14A, 50V
- $R_{DS(on)} = 0.1\Omega$
- UIS SOA Rating Curve (Single Pulse)
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- +175°C Operating Temperature

Description

The RFD14N05, RFD14N05SM, and RFP14N05 n-channel power MOSFETs are manufactured using the MegaFET process. This process which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers, and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFD14N05 is supplied in the JEDEC TO-251 plastic package, the RFD14N05SM in the JEDEC TO-252 plastic package and the RFP14N05 in the JEDEC TO-220AB plastic package.

- +175°C Operating Temperature

Description

The RFD16N05 and RFD16N05SM n-channel power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers, and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFD16N05 is supplied in the JEDEC TO-251AA plastic package and the RFD16N05SM in the TO-252AA plastic package.

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 18A, 80V and 100V
- $r_{DS(on)} = 0.1\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFM18N08 and RFM18N10 and the RFP18N08 and RFP18N10 are n-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFM series types are supplied in the JEDEC TO-204AA steel package and the RFP series types in the JEDEC TO-220AB plastic package.

RFM25N06
RFP25N06

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 25A, 50V and 60V
- $r_{DS(on)} = 0.07\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFM25N06 and RFP25N06 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFM-type is supplied in the JEDEC TO-204AA steel package and the RFP-type in the JEDEC TO-220AB plastic package.

RFG40N10
RFP40N10

N-Channel Enhancement-Mode Power Field-Effect Transistors (MegaFETs)

August 1991

Features

- 40A, 100V
- $r_{DS(on)} = 0.040\Omega$
- UIS SOA Rating Curve (Single Pulse)
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- +175°C Operating Temperature

Description

The RFG40N10 and RFP40N10 n-channel ESD rated power MOSFET's are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFP40N10 is supplied in the JEDEC TO-220AB plastic package and the RFG40N10 is supplied in the TO-247 plastic package.

RFK45N05
RFK45N06

N-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- 45A, 50V and 60V
- $r_{DS}(on) = 0.040\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFK45N05 and RFK45N06 are n-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFK-types are supplied in the JEDEC TO-204AE steel package.

Package

TO-204AE

2N6804

Avalanche-Energy-Rated P-Channel Power MOSFETs

August 1991

Features

- -11A, -100V
- $r_{DS(on)} = 0.30\Omega$
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The 2N6804 is an advanced power MOSFET designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. This is a p-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The 2N6804 is supplied in the JEDEC TO-204AA steel package.

P-CHANNEL POWER MOSFETs

Absolute Maximum Ratings (T_C = +25°C) Unless Otherwise Specified

		2N6804	UNITS
Drain-Source Voltage	V_{DS}	-100*	V
Drain-Gate Voltage (R_{GS} = 20kΩ)	V_{DGR}	-100*	V
Continuous Drain Current			
T_C = +25°C	I_D	-11*	A
T_C = +100°C	I_D	-7.0*	A
Pulsed Drain Current (Note 2)	I_{DM}	-50*	A
Gate-Source Voltage	V_{GS}	±20*	V
Maximum Power Dissipation			
T_C = +25°C (See Figure 14)	P_D	75*	W
Above T_C = +25°C, Derate Linearly (See Figure 14)		0.6*	W/°C
Single Pulse Avalanche Energy (Note 3)	E_{AS}	500	mJ
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150*	°C
Maximum Lead Temperature for Soldering (0.063" (1.6mm) from case for 10s)	T_L	300	°C

NOTES:

*JEDEC registered values

1. Pulse Test: Pulse width ≤ 300μs, Duty Cycle ≤ 2%.
2. Repetitive Rating: Pulse width limited by maximum junction temperature, See Transient Thermal Impedance Curve (Figure 5).
3. V_{DD} = 25V, Starting T_J = 25°C, L = 6.2mH, R_G = 25Ω, Peak I_L = 11A, (See Figure 15 and 16).

CAUTION: These devices are sensitive to electrostatic discharge. Proper I.C. handling procedures should be followed.

2N6851

Avalanche-Energy-Rated P-Channel Power MOSFETs

August 1991

Features

- -4.0A, -200V
- $r_{DS(on)} = 0.80\Omega$
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The 2N6851 is an advanced power MOSFET designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. This is a p-channel enhancement-mode silicon-gate power field-effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. This type can be operated directly from integrated circuits.

The 2N6851 is supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

Package

P-CHANNEL POWER MOSFETs

Absolute Maximum Ratings (T_C = +25°C) Unless Otherwise Specified

		2N6851	UNITS
Drain-Source Voltage	V_{DS}	-200*	V
Drain-Gate Voltage (R_{GS} = 20kΩ)	V_{DGR}	-200*	V
Continuous Drain Current			
T_C = +25°C	I_D	-4.0*	A
T_C = +100°C	I_D	-2.4*	A
Pulsed Drain Current (Note 2)	I_{DM}	-20*	A
Gate-Source Voltage	V_{GS}	±20*	V
Maximum Power Dissipation			
T_C = +25°C (See Figure 14)	P_D	25*	W
Above T_C = +25°C, Derate Linearly (See Figure 14)		0.2*	W/°C
Single Pulse Avalanche Energy (Note 3)	E_{AS}	500	mJ
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150*	°C
Maximum Lead Temperature for Soldering (0.063" (1.6mm) from case for 10s)	T_L	300	°C

NOTES:

*JEDEC registered values

1. Pulse Test: Pulse width ≤ 300μs, Duty Cycle ≤ 2%.
2. Repetitive Rating: Pulse width limited by maximum junction temperature, See Transient Thermal Impedance Curve (Figure 5).
3. V_{DD} = 50V, Starting T_J = 25°C, L = 46.9mH, R_G = 25Ω, Peak I_L = 4.0A, (See Figure 15 and 16).

CAUTION: These devices are sensitive to electrostatic discharge. Proper I.C. handling procedures should be followed.

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -10A and -12A, -60V and -100V
- $r_{DS(ON)}$ = 0.30Ω and 0.40Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF9130, IRF9131, IRF9132 and IRF9133 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -25A, -60V and -100V
- $r_{DS(ON)} = 0.150\Omega$
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF9150 and IRF9151 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The P-channel IRF9150 is an approximate electrical complement to the N-channel IRF9150.

The IRF types are supplied in the JEDEC TO-204AE metal package.

IRF9230, IRF9231
IRF9232, IRF9233

Avalanche Energy Rated
P-Channel Power MOSFETs

August 1991

Features

- **-5.5A and -6.5A, -150V and -200V**
- **$r_{DS(ON)}$ = 0.80Ω and 1.2Ω**
- **Single Pulse Avalanche Energy Rated**
- **SOA is Power-Dissipation Limited**
- **Nanosecond Switching Speeds**
- **Linear Transfer Characteristics**
- **High Input Impedance**

Description

The IRF9230, IRF9231, IRF9232 and IRF9233 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-204AA steel package.

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -5A and -6A, -60V and -100V
- $r_{DS(ON)}$ = 0.6Ω and 0.8Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF9520, IRF9521, IRF9522 and IRF9523 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -3A and -3.5A, -150V and -200V
- $r_{DS(ON)}$ = 1.5Ω and 2.4Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRF9620, IRF9621, IRF9622 and IRF9623 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRF types are supplied in the JEDEC TO-220AB plastic package.

IRFD9110
IRFD9113

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -0.6A and -0.7V, -60V and -100V
- $r_{DS(ON)}$ = 1.2Ω and 1.6Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFD9110 and IRFD9113 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFD types are supplied in the 4-Pin dual-in-line plastic package.

P-CHANNEL POWER MOSFETs

IRFF9120, IRFF9121 IRFF9122, IRFF9123

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -3.5A and -4A, -60V and -100V
- $r_{DS(ON)} = 0.60\Omega$ and 0.80Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF9120, IRFF9121, IRFF9122 and IRFF9123 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -3.5A and -4.0A, -150V and -200V
- $r_{DS(ON)}$ = 0.8Ω and 1.20Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFF9230, IRFF9231, IRFF9232 and IRFF9233 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFF types are supplied in the JEDEC TO-205AF (Low Profile TO-39) metal package.

IRFP9150
IRFP9151

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -25A, -60V and -100V
- $r_{DS(ON)} = 0.150\Omega$
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFP9150 and IRFP9151 are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The P-channel IRFP9150 is an approximate electrical complement to the N-channel IRF9150.

The IRFP types are supplied in the JEDEC TO-247 plastic package.

P-CHANNEL POWER MOSFETs

Absolute Maximum Ratings ($T_C = 25^oC$) Unless Otherwise Specified

		IRFP9150	IRFP9151	UNITS
Drain-Source Voltage	V_{DS}	-100	-60	V
Continuous Drain Current				
$T_C = 25^oC$	I_D	-25	-25	A
$T_C = 100^oC$	I_D	-18	-18	A
Pulsed Drain Current	I_{DM}	-100	-100	A
Gate-Source Voltage	V_{GS}	±20	±20	V
Maximum Power Dissipation (See Figure 18)	P_D	150	150	W
Linear Derating Factor		1.2	1.2	W/^{o}C
Single Pulse Avalanche Energy Rating (3) (See Figure 14)	E_{as}	1300	1300	mJ
Avalanche Current (Repetitive or Nonrepetitive)	I_{AR}	-25	-25	A
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150	-55 to +150	^{o}C
Maximum Lead Temperature for Soldering (0.063" (1.6mm) from case for 10s)	T_L	300	300	^{o}C

NOTES:

1. Pulse Test: Pulse width $\leq$ 300μs, Duty Cycle $\leq$ 2%
2. Repetitive Rating: Pulse width limited by max. junction temperature. See Transient Thermal Impedance Curve (Figure 5)
3. V_{DD} = 25V, Start T_J = +25°C, L = 3.2mhy, R_G = 25Ω, Peak I_L = 25A (See Figures 14 and 15)

CAUTION: These devices are sensitive to electrostatic discharge. Proper I.C. handling procedures should be followed.

IRFP9240R/P9241R IRFP9242R/P9243R

Avalanche Energy Rated P-Channel Power MOSFETs

August 1991

Features

- -10A and -12A, -200V and -150V
- $r_{DS(ON)}$ = 0.50Ω and 0.7Ω
- Single Pulse Avalanche Energy Rated
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The IRFP9240R, IRFP9241R, IRFP9242R and IRFP9243R are advanced power MOSFETs designed, tested, and guaranteed to withstand a specified level of energy in the breakdown avalanche mode of operation. These are p-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The IRFP types are supplied in the JEDEC TO-247 plastic package.

RFM5P12/5P15
RFP5P12/5P15

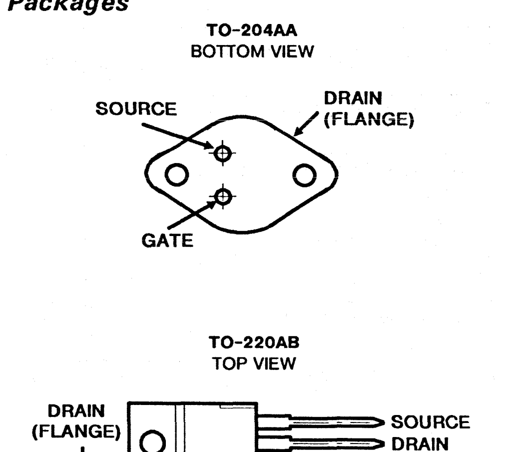
P-Channel Enhancement-Mode Power Field-Effect Transistors

August 1991

Features

- -5A, -120V and -150V
- $r_{DS(on)} = 1\Omega$
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Packages



Description

The RFM5P12 and RFM5P15 and the RFP5P12 and RFP5P15 are p-channel enhancement-mode silicon gate power field-effect transistors designed for high-speed applications such as switching regulators, switching converters, relay drivers, and drivers for high-power bipolar switching transistors.

The RFM series types are supplied in the JEDEC TO-204AA metal package and the RFP series types in the JEDEC TO-220AB plastic package. All these types are supplied without an internal gate zener diode.

RFD8P05/05SM RFP8P05

P-Channel Enhancement Mode Power Field Effect Transistors (MegaFETs)

August 1991

Features

- -8A, -50V
- $r_{DS(on)} = 0.300\ \Omega$
- UIS SOA Rating Curve (Single Pulse)
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The RFD8P05, RFD8P05SM and RFP8P05 p-channel power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers, and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFD8P05 is supplied in the JEDEC TO-251AA plastic package and the RFD8P05SM in the TO-252AA plastic package. The RFP8P05 is supplied in the JEDEC TO-220AB plastic package.

- Majority Carrier Device

Description

The RFM10P12 and RFM10P15 and the RFP10P12 and RFP10P15 are p-channel enhancement-mode silicon gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers, and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFM series types are supplied in the JEDEC TO-204AA steel package and the RFP series types in the JEDEC TO-220AB plastic package.

RFD15P05/05SM RFP15P05

P-Channel Enhancement Mode Power Field Effect Transistors (MegaFETs)

August 1991

Features

- -15A, -50V
- $r_{DS(on)} = 0.150\ \Omega$
- UIS SOA Rating Curve (Single Pulse)
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance

Description

The RFD15P05, RFD15P05SM and RFP15P05 p-channel power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers, and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFD15P05 is supplied in the JEDEC TO-251AA plastic package and the RFD15P05SM in the TO-252AA plastic package. The RFP15P05 is supplied in the JEDEC TO-220AB plastic package.

RFG30P06
RFP30P06

P-Channel Enhancement Mode Power Field Effect Transistors (MegaFETs)

August 1991

Features

- -30A, -60V
- $r_{DS(on)} = 0.075\ \Omega$
- UIS SOA Rating Curve (Single Pulse)
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- 175°C Operating Temperature

Description

The RFG30P06 and RFP30P06 p-channel power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use in applications such as switching regulators, switching converters, motor drivers, relay drivers, and emitter switches for bipolar transistors. These transistors can be operated directly from integrated circuits.

The RFG30P06 is supplied in the JEDEC TO-247 plastic package and the RFP30P06 in the TO-220AB plastic package.

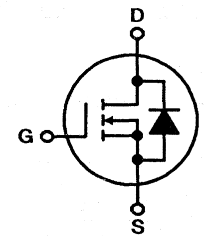
N-CHANNEL ENHANCEMENT MODE



Description

The 2N6901 is an N-channel enhancement-mode silicon-gate power MOS field-effect transistor specifically designed for use with logic level (5V) driving sources in applications such as programmable controllers, automotive switching, and solenoid drivers. This performance is accomplished through a special gate oxide design which provides full rated conduction at gate biases in the 3V - 5V range, therefore facilitating true on-off power control directly from logic circuit supply voltages.

The 2N6901 is supplied in the JEDEC TO-205AF metal package.

Absolute Maximum Ratings (T_C = +25°C), Unless Otherwise Specified

		2N6901	UNITS
Drain-Source Voltage	V_{DS}	100*	V
Drain-Gate Voltage (R_{GS} = 1MΩ)	V_{DGR}	100*	V
Continuous Drain Current			
T_C = +25°C	I_D	1.69*	A
Pulsed Drain Current	I_{DM}	5*	A
Gate-Source Voltage	V_{GS}	±10*	V
Maximum Power Dissipation			
T_C = +25°C	P_D	8.33*	W
Above T_C = +25°C, Derate Linearly		0.0667*	W/°C
Operating and Storage Junction Temperature Range	T_J, T_{STG}	-55 to +150*	°C
Maximum Lead Temperature for Soldering	T_L	260*	°C
At distance > 1/8 in. (3.17mm) from seating plane for 10s max			

*JEDEC registered values

2N6902

N-Channel Logic Level Power MOS Field-Effect Transistors (L^2FET)

August 1991

Features

- 12A, 100V
- $r_{DS(on)} = 0.2\Omega$
- Design Optimized for 5V Gate Drive
- Can be Driven Directly from QMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The 2N6901 is an N-channel enhancement-mode silicon-gate power MOS field-effect transistor specifically designed for use with logic level (5V) driving sources in applications such as programmable controllers, automotive switching, and solenoid drivers. This performance is accomplished through a special gate oxide design which provides full rated conduction at gate biases in the 3V - 5V range, therefore facilitating true on-off power control directly from logic circuit supply voltages.

The 2N6902 is supplied in the JEDEC TO-204AA steel package.

RFL1N18L
RFL1N20L

N-Channel Logic Level Power Field-Effect Transistors (L^2FET)

August 1991

Features

- 1A, 180V and 200V
- $r_{DS(ON)} = 3.65\Omega$
- Design Optimized for 5V Gate Drives
- Can be Driven Directly from QMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanoscecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFL1N18L and RFL1N20L are N-channel enhancement-mode silicon-gate power field-effect transistors specifically designed for use with logic level (5V) driving sources in applications such as programmable controllers, automotive switching, and solenoid drivers. This performance is accomplished through a special gate oxide design which provides full rated conduction at gate biases in the 3V - 5V range, thereby facilitating true on-off power control directly from logic circuit supply voltages.

The RFL series types are supplied in the JEDEC TO-205AF metal package.

N-Channel Logic Level Power Field-Effect Transistors (L^2FET)

August 1991

Features

- 4A, 50V and 60V
- $r_{DS(ON)} = 0.8\Omega$
- Design Optimized for 5V Gate Drives
- Can be Driven Directly from QMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanoscecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFP4N05L and RFP4N06L are N-channel enhancement-mode silicon-gate power field-effect transistors designed for applications such as switching regulators, switching converters, motor drivers, relay drivers and drivers for high-power bipolar switching transistors requiring high speed and low gate-drive power. These types can be operated directly from integrated circuits.

The RFP series types are supplied in the JEDEC TO-220AB plastic package.

N-Channel Logic Level Enhancement-Mode Power Field-Effect Transistors (MegaFETs)

August 1991

Features

- 12A, 60V
- $r_{DS(on)} = 0.135\Omega$ (12N06)
- $r_{DS(on)} = 0.180\Omega$ (3055)
- Electrostatic Discharge Rated
- UIS SOA Rating Curve (Single Pulse)
- Design Optimized for 5V Gate Drive
- Can be Driven Directly from CMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

These N-channel logic-level ESD protected power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits, gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use with logic-level (5V) driving sources in applications such as programmable controllers, automotive switching, switching regulators, switching converters, motor drivers, relay drivers and emitter switches for bipolar transistors. This performance is accomplished through a special gate oxide design which provides full rated conductance at gate biases in the 3V - 5V range, thereby facilitating true on-off power control directly from logic circuit supply voltages.

The RFD12N06RLE and RFD3055RLE are supplied in the JEDEC TO-251, RFD12N06RLESM and RFD3055RLESM in the JEDEC T0-252, and RFP12N06RLE and RFP3055RLE in the JEDEC TO-220AB plastic package.

RFM12N08L/10L
RFP12N08L/10L

N-Channel Logic Level Power Field-Effect Transistors (L^2FET)

August 1991

Features

- 12A, 80V and 100V
- $r_{DS(ON)} = 0.2\Omega$
- Design Optimized for 5V Gate Drives
- Can be Driven Directly from QMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanoscecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFM12N08L and RFM12N10L and the RFP12N08L and RFP12N10L are N-channel enhancmement-mode silicon-gate power field-effect transistors specifically designed for use with logic level (5V) driving sources in applications such as programmable controllers, automotive switching and solenoid drivers. This performance is accomplished through a special gate oxide design which provides full rated conduction at gate biases in the 3V - 5V range, thereby facilitating true on-off power control directly from logic circuit supply voltages.

The RFM series types are supplied in the JEDEC TO-204AA steel package and the RFP series types in the JEDEC TO-220AB plastic package.

Because of space limitations branding (marking) on type RFP12N08L is F12N08L and on type RFP12N10L is F12N10L.

LOGIC LEVEL POWER MOSFETs

RFP17N06L

N-Channel Logic Level Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- 17A, 60V
- $r_{DS(ON)} = 0.100\Omega$
- Design Optimized for 5V Gate Drives
- Can be Driven Directly from QMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanoscecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFP17N06L is an N-Channel enhancement mode silicon-gate power field effect transistor designed for applications such as switching regulators, switching converters, motor drivers, relay drivers and drivers for high power bipolar transistors requiring high speed and low gate drive power. This type can be operated directly from integrated circuits. This performance is accomplished through a special gate oxide design which provides full rated conductance at gate biases in the 3V - 5V range, thereby facilitating true on-off power control directly from logic circuit supply voltages.

The RFP17N06L is supplied in the JEDEC TO-220AB plastic package.

LOGIC LEVEL POWER MOSFETs

RFP50N05L
RFG50N05L

N-Channel Logic Level Enhancement-Mode Power Field-Effect Transistors (MegaFETs)

August 1991

Features

- UIS SOA Rating Curve (Single Pulse)
- Design Optimized for 5V Gate Drive
- Can be Driven Directly from CMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device

Description

The RFP50N05L and RFG50N05L N-channel logic-level power MOSFETs are manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits gives optimum utilization of silicon, resulting in outstanding performance. They were designed for use with logic-level (5V) driving sources in applications such as programmable controllers, automotive switching, switching regulators, switching converters, motor relay drivers, and emitter switches for bipolar transistors. This performance is accomplished through a special gate oxide design which provides full rated conductance at gate bias in the 3V - 5V range, thereby facilitating true on-off power control directly from integrated circuit supply voltages.

The RFP50N05L is supplied in the JEDEC TO-220AB plastic package and the RFG50N05L is supplied in the TO-247 plastic package.

HARRIS

2N6975, 2N6976, 2N6977, 2N6978

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs)

August 1991

Features

- 5A, 400V and 500V
- $V_{CE(ON)}$: 2V
- T_{fi}: 1μs, 0.5μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance

Applications

- Power Supplies
- Motor Drives
- Protection Circuits

Description

The 2N6975, 2N6976, 2N6977 and the 2N6978 are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high-voltage, low on-dissipation applications such as switching regulators and motor drivers. These types can be operated directly from low-power integrated circuits.

These types are supplied in the JEDEC TO-204AA steel package.

HGTD6N50E1/E1S

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs)

August 1991

Features

- 6 Amp, 400 and 500 Volt
- $V_{CE(ON)}$: 2.5V Max.
- T_{Fall}: 1μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance

Applications

- Power Supplies
- Motor Drives
- Protective Circuits

Description

The HGTD6N40E1, HGTD6N40E1S, HGTD6N50E1, and HGTD6N50E1S are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high voltage, low on-dissipation applications such as switching regulators and motor drivers. These types can be operated directly from low power integrated circuits. The HGTD6N40E1 and the HGTD6N50E1 are supplied in the JEDEC TO-251AA plastic package. The HGTD6N40E1S and the HGTD6N50E1S are supplied in the JEDEC TO-252AA surface-mount plastic package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs) with Anti-Parallel Ultra-Fast Diode

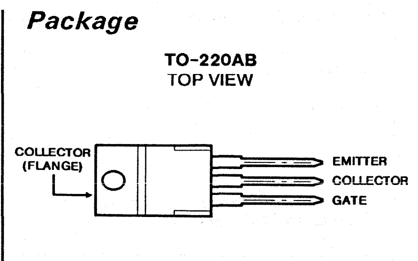
May 1991

Features

- 6 Amp, 400 and 500 Volt
- Latch Free Operation
- Typical Fall Time < 1.1μs
- High Input Impedance
- Low Conduction Loss
- With Anti-Parallel Diode
- t_{rr} < 60ns

Package

TO-220AB
TOP VIEW



Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between 25°C and 150°C. The diode used in parallel with the IGBT is an ultrafast (t_{rr} < 60ns) with soft recovery characteristic.

The IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

These devices are supplied in the JEDEC TO-220 package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs)

August 1991

Features

- 10 Amp, 400 and 500 Volt
- $V_{CE(ON)}$: 2.5V Max.
- T_{Fall}: 1.4μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance

Applications

- Power Supplies
- Motor Drives
- Protective Circuits

Description

The HGTD10N40F1, HGTD10N40F1S, HGTD10N50F1, and HGTD10N50F1S are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high voltage, low on-dissipation applications such as switching regulators and motor drivers. These types can be operated directly from low power integrated circuits.

The HGTD10N40F1 and the HGTD10N50F1 are supplied in the JEDEC TO-251AA plastic package. The HGTD10N40F1S and the HGTD10N50F1S are supplied in the JEDEC TO-252AA surface-mount plastic package.

- **Protective Circuits**

Description

The HGTP10N40C1D, HGTP10N40E1D, HGTP10N50C1D, and HGTP10N50E1D are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high voltage, low on-dissipation applications such as switching regulators and motor drivers. They feature a discrete anti-parallel diode that shunts current around the IGBT in the reverse direction without introducing carriers into the depletion region. These types can be operated directly from low power integrated circuits.

They are supplied in the JEDEC TO-220AB plastic package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs) with Anti-Parallel Ultra-Fast Diode

May 1991

Features

- 10 Amp, 400 and 500 Volt
- Latch Free Operation
- Typical Fall Time < 1.4μs
- High Input Impedance
- Low Conduction Loss
- With Anti-Parallel Diode
- t_{rr} < 60ns

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between 25°C and 150°C. The diode used in parallel with the IGBT is an ultrafast (t_{rr} < 60ns) with soft recovery characteristic.

IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

These devices are supplied in the JEDEC TO-220 package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs) with Anti-Parallel Ultra-Fast Diode

August 1991

Features

- 12 Amp, 400 and 500 Volt
- $V_{CE(ON)}$: 2.5V Max.
- T_{Fall}: 1μs, 0.5μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance
- Anti-Parallel Diode

Applications

- Power Supplies
- Motor Drives
- Protective Circuits

Description

The HGTH12N40C1D, HGTH12N40E1D, HGTH12N50C1D, and HGTH12N50E1D are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high voltage, low on-dissipation applications such as switching regulators and motor drivers. They feature a discrete anti-parallel diode that shunts current around the IGBT in the reverse direction without introducing carriers into the depletion region. These types can be operated directly from low power integrated circuits.

They are supplied in the JEDEC TO-218AC plastic package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT) with Anti-Parallel Ultra-Fast Diode

Features

- **12 Amp, 600 Volt**
- **Latch Free Operation**
- **Typical Fall Time <500ns**
- **Low Conduction Loss**
- **With Anti-Parallel Diode**
- **t_{rr} < 60ns**

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C. The diode used in parallel with the IGBT is an ultrafast (t_{rr} < 60ns) with soft recovery characteristic.

The IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

This type is supplied in the JEDEC TO-247 style package.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temeprature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. $t_{d(off)i}$ deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \times I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} - 0A).

The switching power loss (Figure 10) is defined as $f_{max1} \times W_{off}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

HGTM12N60D1

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)

August 1991

Features

- **12 Amp, 600 Volt**
- **Latch Free Operation**
- **Typical Fall Time <500ns**
- **High Input Impedance**
- **Low Conduction Loss**

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C.

IGBTs are ideal for many high voltage switching applications operating at moderate frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

This type is supplied in the JEDEC TO-204AA package.

HARRIS

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs)

August 1991

Features

- 15A and 20A, 400V and 500V
- $V_{CE(ON)}$: 2.5V
- T_{Fi}: 1μs, 0.5μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance
- No Anti-Parallel Diode

Applications

- Power Supplies
- Motor Drives
- Protection Circuits

Description

The HGTH20N40C1, HGTH20N40E1, HGTH20N50C1, HGTH20N50E1, HGTM20N40C1, HGTM20N40E1, HGTM20N50C1, HGTM20N50E1, HGTP15N40C1, HGTP15N40E1, HGTP15N50C1 and HGTP15N50E1 are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high-voltage, low on-dissipation applications such as switching regulators and motor drivers. These types can be operated directly from low-power integrated circuits.

The HGTH-types are supplied in the JEDEC TO-218AC plastic package and the HGTP-types in the JEDEC TO-220AB plastic package.

The HGTM-types are supplied in the JEDEC TO-204AA steel package.

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistors (IGBTs) with Anti-Parallel Ultra-Fast Diode

August 1991

Features

- 20 Amp, 400 and 500 Volt
- $V_{CE(ON)}$: 2.5V Max.
- T_{Fall}: 1μs, 0.5μs
- Low On-State Voltage
- Fast Switching Speeds
- High Input Impedance
- Anti-Parallel Diode

Applications

- Power Supplies
- Motor Drives
- Protective Circuits

Description

The HGTH20N40C1D, HGTH20N40E1D, HGTH20N50C1D and HGTH20N50E1D are n-channel enhancement-mode insulated gate bipolar transistors (IGBTs) designed for high voltage, low on-dissipation applications such as switching regulators and motor drivers. They feature a discrete anti-parallel diode that shunts current around the IGBT in the reverse direction without introducing carriers into the depletion region. These types can be operated directly from low power integrated circuits.

They are supplied in the JEDEC TO-218AC plastic package.

HGTG20N50C1D

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT) with Anti-Parallel Ultra-Fast Diode

May 1991

Features

- 20 Amp, 500 Volt
- Latch Free Operation
- Typical Fall Time < 500ns
- High Input Impedance
- Low Conduction Loss
- With Anti-Parallel Diode
- t_{rr} < 60ns

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between 25°C and 150°C. The diode used in parallel with the IGBT is an ultrafast (t_{rr} < 60ns) with soft recovery characteristic.

IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

This type is supplied in the JEDEC TO-247 package.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temeprature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. $t_{d(off)i}$ deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \times I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} - 0A).

The switching power loss (Figure 10) is defined as $f_{max1} \times W_{off}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

HGTG24N60D1

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)

May 1991

Features

- 24 Amp, 600 Volt
- Latch Free Operation
- Typical Fall Time <500ns
- High Input Impedance
- Low Conduction Loss

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C.

IGBTs are ideal for many high voltage switching applications operating at moderate frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

This type is supplied in the JEDEC TO-247 package.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temeprature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. $t_{d(off)i}$ deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \times I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} - 0A).

The switching power loss (Figure 10) is defined as $f_{max1} \times W_{off}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between 25°C and 150°C.

IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

This type is supplied in the JEDEC TO-218 (5-lead) package.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temeprature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. $t_{d(off)i}$ deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \times I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} - 0A).

The switching power loss (Figure 10) is defined as $f_{max1} \times W_{off}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temeprature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. $t_{d(off)i}$ deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. the allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \cdot I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} - 0A).

The switching power loss (Figure 10) is defined as $f_{max1} \cdot W_{off}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

- $r_{DS(ON)}$ 0.27Ω
- Low $V_{CE(SAT)}$ at 25A .... 2.5V Typ
- Ultra-fast Turn-On .... 100ns Typ
- Polysilicon MOS Gate - Voltage Controlled Turn On/Off
- High Current Handling at +100°C 10A
- Current Sensing Pilot

Description

The HGTB12N60D1C Insulated-Gate Bipolar Transistor is a MOS-gate turn on/off power switching device combining the best advantages of power MOSFETs and bipolar transistors, and current sensing pilots. The result is a device that has the high input impedance of MOSFETs and the low on-state conduction losses similar to bipolar transistors. The device design and gate characteristics of the IGBT are also similar to power MOSFETs. An important difference is the equivalent $r_{DS(ON)}$ drain resistance which is modulated to a low value (ten times lower) when the gate is turned on. The much lower on-state voltage drop also varies only moderately between +25°C and +150°C, offering extended power handling capability.

The IGBT is ideal for many high-voltage switching applications operating at low frequencies and where low conduction losses are essential, such as AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

The HGTB12N60D1C is supplied in a 5 lead JEDEC TS-001 package.

Current Sensing N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)

Features

- 24A, 600V
- $r_{DS(ON)}$ = 0.105Ω
- Low $V_{CE(SAT)}$ at 25A .... 1.8V Typ
- Ultra-fast Turn-On .... 150ns Typ
- Polysilicon MOS Gate - Voltage Controlled Turn On/Off
- High Current Handling at +85°C 25A
- Current Sensing Pilot

Description

The HGTA24N60D1C Insulated-Gate Bipolar Transistor is a MOS-gated power-switching device combining the best features of power MOSFETs and bipolar transistors with current sensing pilots. The result is a device that has the high input impedance of MOSFETs and the low on-state conduction losses of bipolar transistors. The gate characteristics of the IGBT are similar to power MOSFETs but its equivalent $r_{DS(ON)}$ drain resistance is ten times lower and varies only moderately between +25°C and +150°C, thus offering extended power handling capability.

The IGBT is ideal for many high voltage switching applications up to 5kHz where low conduction losses are essential; AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

They are supplied in 5 lead JEDEC MO-093 style packages.

RLP1N08LE

Current Limited ESD Protected N-Channel Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- 1A, 80V
- $r_{DS(ON)} = 0.75\Omega$
- I_{LIMIT} at +150°C .... 1.5A Max
- Built-In Current Limiting
- ESD Protected
- Controlled Switching Limits EMI and RFI
- Specified for +150°C Operation

Description

The RLP1N08LE is a semi-smart monolithic power circuit which incorporates a lateral bipolar transistor, two resistors, a zener diode, and a PowerMOS transistor. Good control of the current-limiting levels allows use of these devices where a shorted load condition may be encountered. "Logic level" gates allow this device to be fully biased on with only 5 volts from gate to source. The zener diode provides ESD protection up to 2kV. These devices can be produced on the standard PowerMOS production line.

The RLP-series types are supplied in the JEDEC TO-220AB plastic packages.

Temperature Dependence of Current Limiting and Switching Speed

The RLP1N08LE is a monolithic power device which incorporates a Logic Level PowerMOS transistor with a resistor in series with the source. The base and emitter of a lateral bipolar transistor is connected across this resistor, and the collector of the bipolar transistor is connected to the gate of the PowerMOS transistor. When the voltage across the resistor reaches the value required to forward bias the emitter base junction of the bipolar transistor, the bipolar transistor "turns on". A series resistor is incorporated in series with the gate of the PowerMOS transistor allowing the bipolar transistor to drive the gate of the PowerMOS transistor to a voltage which just maintains a constant current in the PowerMOS transistor. Since both the resistance of the resistor in series with the PowerMOS transistor source and the voltage required to forward bias the base emitter junction of the bipolar transistor vary with the temperature, the current at which the device limits is a function of temperature. This dependence is shown in Figure 8.

The resistor in series with the gate of the PowerMOS transistor results in much slower switching than in most PowerMOS transistors. This is an advantage where fast switching can cause EMI or RFI. The switching speed is very predictable, and a minimum as well as maximum fall time is given in the device characteristics for this type.

DC Operation of the RLP1N08LE

The limit on drain-to-source voltage for operation in current limiting on a steady state (dc) basis is shown as Figure A. The dissipation in the device is simply the applied drain-to-source voltage multiplied by the limiting current. This device, like most PowerMOS devices today, is limited to 150°C. The maximum voltage allowable can, therefore, be expressed as:

$$V_s = \frac{(150 - \text{Tambient})}{I_{lim}\,(R_{\theta JC} + R_{\theta})}$$

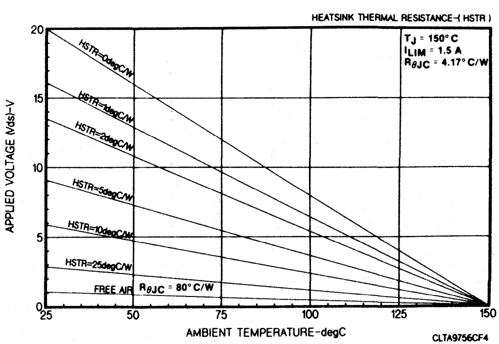

Fig. A - DC operation in current limiting.

Duty Cycle Operation of the RLP1N08LE

In many applications either the drain-to-source voltage or the gate drive is not available 100% of the time. The copper header on which the RLP1N08LE is mounted has a very large thermal storage capability, so for pulse widths of less than 100 milliseconds, the temperature of the header can be considered a constant case temperature calculated simply as:

$$T_c = (V_{SD} * I_D * D * R_{\theta CA}) + \text{Tambient}$$

Generally the heat storage capability of the silicon chip in a power transistor is ignored for duty cycle calculations. Making this assumption, limiting junction temperature to 150°C and using the T_C calculated above, the expression for maximum V_{SD} under duty cycle operation is:

$$V_{SD} = \frac{150 - T_c}{I_{lim} * D * R_{\theta JC}}$$

These values are plotted as Figures B1 - B5 for various heat sink thermal resistances.

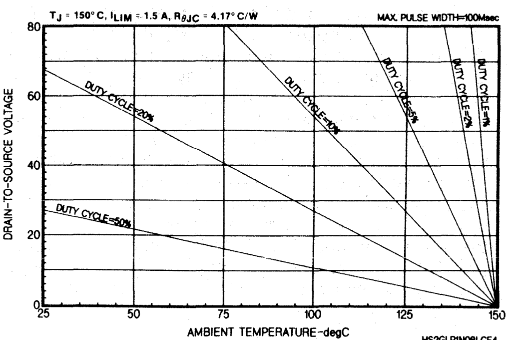

Fig. B1 - Maximum V_{DS} vs. ambient temperature in current limiting. (Heatsink thermal resistance = 2°C/W)

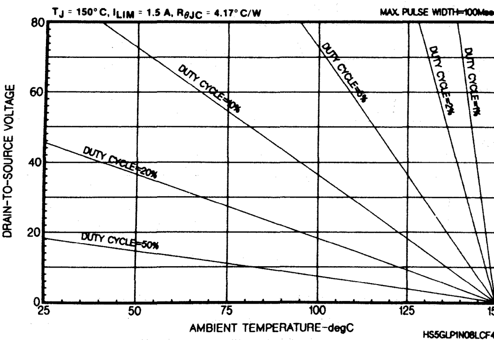

Fig. B2 - Maximum V_{DS} vs. ambient temperature in current limiting. (Heatsink thermal resistance = 5°C/W)

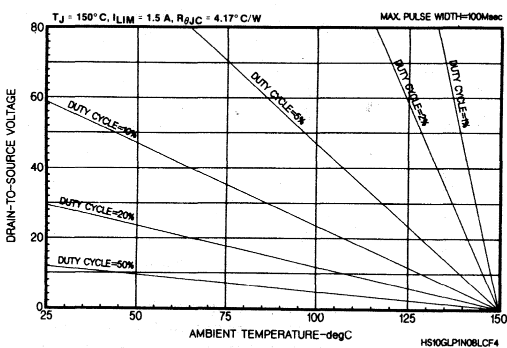

Fig. B3 - Maximum V_{DS} vs. ambient temperature in current limiting. (Heatsink thermal resistance = 10°C/W)

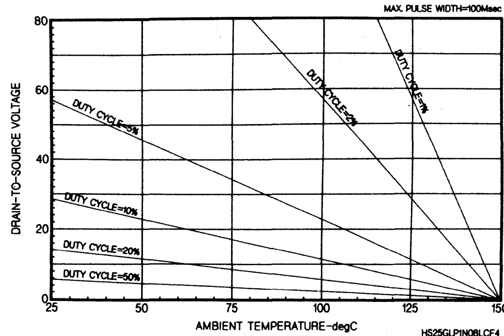

Fig. B4 - Maximum V_{DS} vs. ambient temperature in current limiting. (Heatsink thermal resistance = 25°C/W)

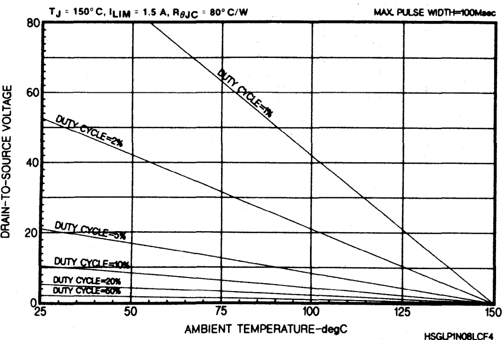

Fig. B5 - Maximum V_{DS} vs. ambient temperature in current limiting. (No external heatsink)

Limited Time Operations of the RLP1N08LE

Protection for a limited period of time is sufficient for many applications. As stated above the heat storage in the silicon chip can usually be ignored for computations of over 10 milliseconds and the thermal equivalent circuit reduces to a simple enough circuit to allow easy computation on the limiting conditions. The variation in limiting current with temperature complicates the calculation of junction temperature, but a simple straight line approximation of the variation is accurate enough to allow meaningful computations. The curves shown as Figures C1 - C5 give an accurate indication of how long the specified voltage can be applied to the device in the current limiting mode without exceeding the maximum specified 150°C junction temperature. In practice this tells you how long you have to alleviate the condition causing the current limiting to occur.

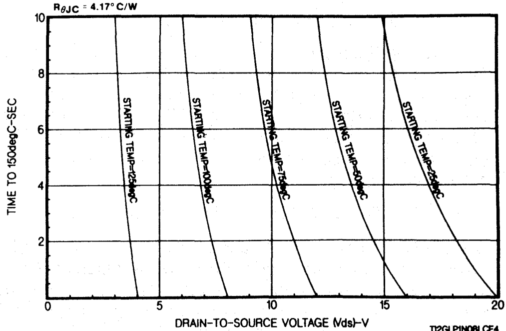

Fig. C1 - Time to 150° C in current limiting. (Heatsink thermal resistance = 2° C/W Heatsink thermal capacitance = 4 j/° C)

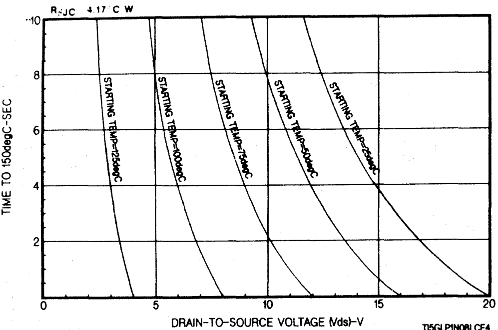

Fig. C2 - Time to 150° C in current limiting. (Heatsink thermal resistance = 5° C/W Heatsink thermal capacitance = 2 j/° C)

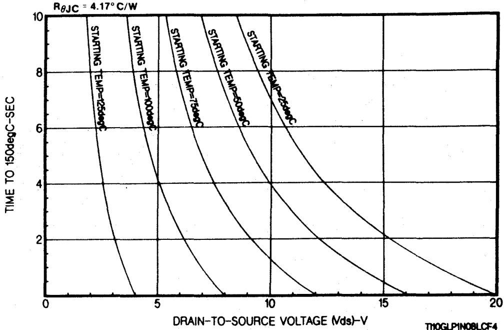

Fig. C3 - Time to 150° C in current limiting. (Heatsink thermal resistance = 10° C/W Heatsink thermal capacitance = 1 j/° C)

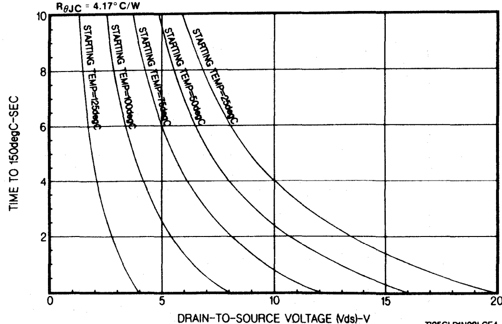

Fig. C4 - Time to 150° C in current limiting. (Heatsink thermal resistance = 25° C/W Heatsink thermal capacitance = 5 j/° C)

RFB18N10CS/ CSVM/CSHM

Current Limited ESD Protected N-Channel Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- **18A, 100V**
- **$r_{DS(ON)}$ 0.1Ω**
- **Built-In Current Sensing Ratio .... 1560 ± 2.5%**
- **UIS SOA Rating Curve (Single Pulse)**
- **-55°C to +175°C Operating and Storage Temperature**

Description

The RFB18N10CS, RFB18N10CSVM, RFB18N10CSHM are n-channel enhancement-mode silicon-gate power field-effect transistors which have a built-in current sensing function. The current sense lead provides an accurate fraction of the drain current that can be used as a feedback signal for control and/or protection. These devices can be repeatedly and economically produced on the standard PowerMOS production line.

The RFB-series are supplied in various lead configurations of the TS-001 (5 lead) case style plastic package.

Because of space limitations, branding (marking) on types RFB18N10CS, RFB18N10CSVM and RFB18N10CSHM is F18N10CS.

INTELLIGENT DISCRETES

RLP5N08LE

Current Limited ESD Protected N-Channel Enhancement-Mode Power Field-Effect Transistor

August 1991

Features

- 5.5A, 80V
- $R_{DS(ON)}$ 0.12Ω
- I_{Limit} .... 5.5A to 8.5A at +150°C
- Built In Current Limiting
- E_{SD} Protected .... 2KV Min
- Controlled Switching Limits EMI and RFI
- Specified For +150°C Operation
- +175°C Rated Junction Temperature
- Logic Level Gate

Description

The RLP5N08LE is an "Intelligent Discrete" monolithic power circuit which incorporates a small signal bipolar transistor, two resistors, a zener diode, and a PowerMOS transistor. Low $R_{DS(ON)}$ is achieved by the use of separate current sensing cells. Good control of the current limiting levels allows these devices to be used where it is anticipated that a shorted load condition may be encountered. "Logic Level" gates allow this device to be fully biased on with only 5.0V from gate to source. The zener diode provides E_{SD} protection of 2KV minimum.

Temperature Dependence of Current Limiting and Switching Speed Performance

The RLP5N08LE is a monolithic power device which incorporates a Logic Level PowerMOS transistor with a current sensing scheme and control circuitry to enable the device to self limit drain-source current flow. The current sensing scheme supplies current to a resistor that is connected across the base to emitter of a bipolar transistor in the control section. The collector of this bipolar transistor is connected to the gate of the PowerMOSFET. When the ratiometric current from the current sensing reaches the value required to forward bias the base-emitter

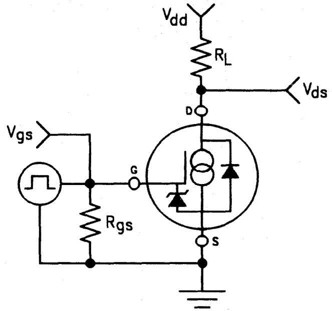

FIGURE 11. SWITCHING TEST CIRCUIT

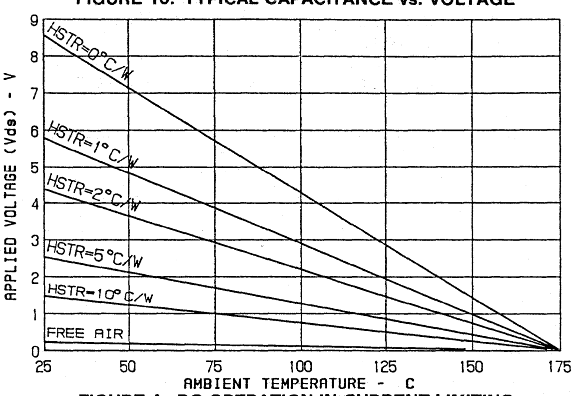

FIGURE A. DC OPERATION IN CURRENT LIMITING

junction of this bipolar transistor, the bipolar "turns-on". A resistor is incorporated in series with the gate of the PowerMOSFET allowing the bipolar transistor to adjust the drive on the gate of the PowerMOSFET to a voltage which then maintains a constant current in the PowerMOSFET. Since both the ratiometric current sensing scheme and the base-emitter junction voltage of the bipolar transistor vary with temperature, the current at which the device limits is a function of temperature. This dependence is shown in Figure 9.

The resistor in series with the gate of the PowerMOSFET also results in much slower switching performance than in standard PowerMOSFETs. This is an advantage where fast switching can cause EMI or RFI. Switching speed is very predictable; a minimum as well as a maximum fall time is given in the device characteristics for this type.

DC Operation of the RLP5N08LE

The limit of drain-to-source voltage for operation in current limiting on a steady state (DC) basis is shown in equation below. The dissipation in the device is simply the applied drain-to-source voltage multiplied by the limiting current. This device, like most PowerMOSFET devices, is limited to +175°C. The maximum voltage allowable can, therefore, be expressed as:

$$V_{DS} = \frac{+175^{\circ}C - T_{Ambient}}{I_{LIMIT} \times (R\theta_{JC} + HSTR)}$$

The results of this equation are plotted in Figure A for various heatsinks.

Duty Cycle Operation of the RLP5N08LE

In many applications either drain-to-source voltage or gate drive is not available 100% of the time. The copper header on which the RLP5N08LE is mounted has a very large thermal storage capability, so for pulse widths of less than 1 ms header temperature can be considered a constant. Thereby, junction temperature can be calculated simply as:

$$T_J = (V_{DS} \times I_{DS} \times D \times R\theta_{J\text{-}Amb}) + T_{ambient}$$

Generally the heat storage capability of the silicon chip in a power transistor is ignored for duty cycle calculations. Making this assumption, limiting junction temperature to +175°C and using T_C calculated above, the expression for maximum V_{DS} under duty cycle operation is:

$$V_{DS} = \frac{+175^{\circ}C - T_{ambient}}{I_{LIMIT} \times D \times R\theta_{J\text{-}ambient}}$$

These values are plotted as Figures B1 - B6 for various heatsink thermal resistances.

Performance Curves (Continued)

Limited Time Operations of the RLP5N08LE

Protection for a limited period of time is sufficient for many applications. As previously stated, heat storage in the silicon chip can usually be ignored for computations of over 10 milliseconds and the thermal equivalent circuit reduces to a simple enough circuit to allow easy computation on the limiting conditions. The variation in limiting current with temperature complicates the calculation of junction temperature, but a simple straight line approximation of the variation is accurate enough to allow meaningful computations. The curves shown as Figures C1 - C5 give an accurate indication of how long the specified voltage can be applied to the device in the current limiting mode without exceeding the maximum specified +175°C junction temperature. In practice this tells you how long you have to alleviate the condition causing the current limiting to occur.

Military Power Products

Military and aerospace requirements for high-reliability solid-state devices are extremely large and diverse, not only in terms of performance, operating conditions, and reliability, but also in terms of logistics and procurement. As a result of these requirements, the military services have jointly developed specifications and standards under which most military end-use solid-state devices are procured. To simplify procurement, logistics, and the development of reliability data, MIL specs are not issued for the full spectrum of devices manufactured: rather, they are restricted to those devices for which significant need is demonstrated and are specified so that the device can have as wide applicability as possible. Although the limits for operating conditions may exceed these required for some applications, they simplify procurement and assure a supply of devices for the majority of military equipment. These standards also cover a wide range of requirements for the manufacturer on such things as:

(a) The procedure and requirements for a manufacturer to become certified to manufacture MIL-spec parts.

(b) The requirements for qualifying parts.

(c) Product-assurance provisions, in such areas as quality control, inspection procedures, personnel training, cleanliness, failure analysis, and documentation.

(d) Test methods and procedures.

(e) Marking and identification of product.

(f) Preservation and packing.

2. Group B environmental, mechanical and life tests (storage and operating) performed on a lot sample basis.
3. Group C environmental and life tests performed on a time period basis.
4. Tests shall be performed in the order as shown.

JANTX and JANTXV Solid-State Power Devices

The major military specification used for the procurement of discrete solid-state devices by the military is MIL-S-19500.

MIL-S-19500 is the specification for the familiar "JAN" type solid state devices. Detailed electrical specifications are prepared as needed by the three military services and coordinated by the Defense Electronic Supply Center (DESC).

Levels of reliability are defined by MIL-S-19500. JANTX types receive 100 percent process conditioning, and power conditioning, and are subjected to lot acceptance based on delta parameter criteria in addition to Group A, Group B, and Group C lot sampling. JANTXV types are subjected to 100 percent (JTXV) internal visual inspection in addition to all of the JANTX tests in accordance with MIL-STD-750 test methods and MIL-S-19500.

DESC publishes "QPL-19500", a Qualified Products List of all types and suppliers approved to produce and brand devices in accordance with MIL-S-19500.

The following tables list approved "QPL" types that Harris can supply.

Most of Harris Power MOSFETs can also be supplied with similar process and power conditioning tests and delta criteria.

Military Screening For Non QPL Types

New discrete devices not yet covered by military specifications, offer technological advances or have special performance characteristics which have advantages to the designer of Military and Aerospace equipment. Harris cooperates with the users in establishment of specifications patterned after MIL standards.

Harris Military Power Products are processed in accordance with provisions of MIL STD. The desired screening test sequence can be chosen from the models shown in the screening table.

Group B and Group C tests will be performed when requested in accordance with MIL-S-19500.

Introduction To Rad Hard MOSFETs

Tactical Applications

- Radiation Hardness Assurance Program
- Rated at 10K Rads (Si)

The Harris Semiconductor Sector has formed a Radiation Hardness Assurance Program (RHAP) directed toward certain TACTICAL rad hard users which assures a minimum level of hardness for "off the shelf" needs where the volume of application mandates economy. Power MOSFET's from the FR series are a part of the RHAP effort. The FR parts are not selected from standard commercial product but are semiconductor die specially designed, processed, and treated for SECOND GENERATION hardened power MOSFET'S. Pre radiation specifications are met after exposure to 10 KRAD (Si) total dose.

Strategic Applications

- Rated at 100K and 1000K Rad(Si)

The Harris Semiconductor Sector has designed a series of SECOND GENERATION hardened power MOSFET's of both N and P channel enhancement types with ratings from 100 to 500 volts, 1 to 60 amperes, and on resistance as low as 40 milliohms. Total dose hardness is offered at 100K and 1000K RAD(Si) with neutron hardness ranging from 1E13 n/cm2 for 500 volt product to 1E14 n/cm2 for 100 volt product. Dose rate hardness (GAMMA DOT) exists for rates to 1E9 rads/sec without current limiting and 2E12 rads/sec with current limiting. Heavy ion survival from single event drain burn-out exists for linear energy transfer (LET) of 35 at 80% of rated voltage.

HGTG30N120E2

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)

August 1991

Features

- 50 Amp 1200 Volt
- Latch Free Operation
- Typical Fall Time - 580ns
- High Input Impedance
- Low Conduction Loss

Description

The HGTG30N120E2* is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C.

The IGBTs are ideal for many high voltage switching applications operating at moderate frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

*Formerly Developmental Type #49010

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temperature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. td(off)i deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) and the conduction losses (P_C) are approximated by $P_C = (V_{CE} \bullet I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I_{CE} = 0A).

The switching power loss (Figure 10) is defined as $f_{max2} \bullet W_{off}$. Turn-on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

HGTG34N100E2

N-Channel Enhancement-Mode Insulated Gate Bipolar Transistor (IGBT)

August 1991

Features

- 55 Amp 1000 Volt
- Latch Free Operation
- Typical Fall Time - 710ns
- High Input Impedance
- Low Conduction Loss

Description

The HGTG34N100E2* is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C.

The IGBTs are ideal for many high voltage switching applications operating at moderate frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{max1} or f_{max2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temperature.

f_{max1} is defined by $f_{max1} = 0.05/t_{d(off)i}$. td(off)i deadtime (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{d(off)i}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional frequency limiting condition for an application other than T_{JMAX}. $t_{d(off)i}$ is important when controlling output ripple under a lightly loaded condition.

f_{max2} is defined by $f_{max2} = (P_D - P_C)/W_{off}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C)/R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 10) and the conduction losses (P_C) are approximated by $P_C = (V_{CE} \bullet I_{CE})/2$. W_{off} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero ($I_{CE} = 0A$).

The switching power loss (Figure 10) is defined as $f_{max2} \bullet W_{off}$. Turn-on switching losses are not included because they can be greatly influenced by external circuit conditions and components.

HV250

PRELIMINARY

May 1991

Half Bridge Complementary MOSFET Driver

Features

- Bipolar or Unipolar Supply Operation
- Wide Supply Range .... ±40V to +450V, -100V
- Complete MOSFET Protection
- High Output to Logic Supply Isolation
- High Peak Output Current 2A
- Fast Switching Times 100ns
- Frequency Range .... DC -30kHz

Applications

- High Switchmode Power Supplies
- PWM Servo Drives
- Stepper Motor Drives
- DC-DC Converters
- Uninterruptible Power Supplies

Ordering Information

PART NUMBER	TEMPERATURE RANGE	DESCRIPTION
HV250CP	$0^oC \leq T_A \leq +75^oC$	16 Pin Plastic DIP
HV250IP	$-40^oC \leq T_A \leq +85^oC$	16 Pin Plastic DIP
HV250MJ*	$-55^oC \leq T_A \leq +125^oC$	16 Pin Ceramic DIP

Description

The HV250 is a monolithic dielectrically isolated high voltage integrated circuit. The circuit provides an interface from digital signals to the gates of complementary power MOSFETs. The circuit has wide supply voltage range, from 80VDC to 450VDC in unipolar connection or ±40VDC to +450VDC and -100VDC. In addition the logic supply can float within the high voltage rails.

The inputs are TTL compatible when the logic supply is 5V, but will operate up to 15V logic supply.

The outputs provide up to 2A current spikes to drive the gates of power MOSFETs. The actual voltage that the gates are driven to is set by the user, up to 20V for V_{GS}.

Also on board the chip is an overcurrent sense circuit, which independently sense overcurrent on the high side and the low side. An overcurrent condition sets a latch that disables both outputs. In order to enable the output the reset input must be toggled.

HV350

PRELIMINARY

May 1991

Half Bridge N-Channel MOSFET Driver

Features

- Unipolar Supply Operation
- Wide Supply Range .... +40V to +450V
- Complete MOSFET Protection
- High Output to Logic Supply Isolation
- High Peak Output Current 2A
- Fast Switching Times 100ns
- Frequency Range .... DC -30kHz

Applications

- Switchmode Power Supplies
- PWM Servo Drives
- Stepper Motor Drives
- DC-DC Converters
- Uninterruptible Power Supplies

Ordering Information

PART NUMBER	TEMPERATURE RANGE	DESCRIPTION
HV350CP	$0^oC \leq T_A \leq +75^oC$	16 Pin Plastic DIP
HV350IP	$-40^oC \leq T_A \leq +85^oC$	16 Pin Plastic DIP
HV350MJ*	$-55^oC \leq T_A \leq +125^oC$	16 Pin Ceramic DIP

Description

The HV350 is a monolithic dielectrically isolated high voltage integrated circuit. The circuit provides an interface from digital signals to the gates of totem pole power MOSFETs or IGBTs. The circuit has wide supply voltage range, from 40VDC to 450VDC. In addition the logic supply can float within the high voltage rails.

The inputs are TTL compatible when the logic supply is 5V, but will operate up to 15V logic supply.

The outputs provide up to 2A current spikes to drive the gates of power MOSFETs or IGBTs. The actual voltage that the gates are driven to is set by the user, up to 20V for V_{GS}.

Also on board the chip is an overcurrent sense circuit, which independently sense overcurrent on the high side and the low side. An overcurrent condition sets a latch that disables both outputs. In order to enable the output the reset input must be toggled. An oscillator and charge pump current are integrated for high side operation.

HV400IP	-40°C to +85°C	8 Pin Plastic Mini-DIP
HV400IB	-40°C to +85°C	8 Pin Plastic SOIC

Description

The HV400 is a single monolithic, non-inverting high speed driver designed to drive large capacitive loads at high slew rates. The device is optimized for capacitive loads in the 5,000pF to 100,000pF range. It featues an output stage capable of sourcing up to 6A through the high-side NPN switch and sinking up to 30A through the low-side SCR switch. Rise and fall times of 70ns and 30ns respectively are achieved driving a 20,000pF load. The output high and low side switches are pinned out separately allowing independent control of power MOSFET gate rise and fall times.

Special features are included in the device to provide a simple, high speed gate drive circuit for power MOSFET in application using pulse transformers. An optional on-chip diode works with an external storage capacitor to store energy from the pulse transformer after the gate drive pulse has completed its low to high transition. The storage capacitor supplies the gate drive current to turn on the MOSFET wich overcomes the di/dt limitations of the pulse transformer. The high current drive capability of the HV400 using the floating supply provides a cost effective improvement over existing methods.

Another feature of the HV400 is the absence of quiescent current. When used with PWM control ICs, additional low voltage supply current to power the MOSFET driver during startup, is not needed.

The device is fabricated in the High Frequency Bipolar DI process which provides latchproof operation in the presence of transients on the power and signal lines. It is available in the 8 pin Plastic DIP and 8 pin SOIC (Commercial and Industrial grades).

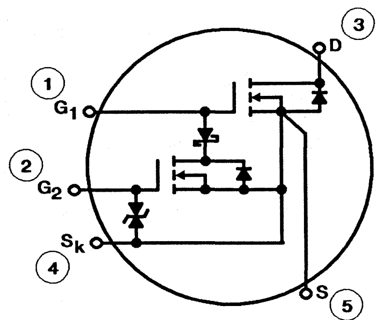
N-CHANNEL ENHANCEMENT MODE



Description

The RFA14N50BE is an n-channel fast switching MOSFET transistor that is designed for switching regulators, inverters and motor drivers. The RFA14N50BE is a monolithic structure incorporating a high voltage, high current MOSFET, a control MOSFET and Esd protection diodes. As indicated in the symbol to the right, the turn on of the main MOSFET is controlled by Gate 1 (G1). The control MOSFET, controlled by Gate 2 (G2), is distributed throughout the structure and provides a very low impedance and low inductive path to discharge the gate of the main MOSFET rapidly when very fast turn-off is desired. A separate return connection, Source Kelvin (Sk), is provided for the gate drive circuits to avoid voltage induced transients from the output circuits during switching. The RFA14N50BE MOSFET transistor can be operated directly from integrated circuits.

The RFA14N50BE is supplied in the JEDEC MO-093 (5-lead) plastic package.

RFW2N06RLE

N-Channel Logic Level Enhancement-Mode Power Field-Effect Transistor (MegaFET)

August 1991

Features

- 2A, 60V
- $R_{DS(ON)} = 0.160\Omega$
- UIS SOA Rating Curve (Single Pulse)
- Design Optimized for 5 Volt Gate Drive
- Can be Driven Directly from CMOS, NMOS, TTL Circuits
- Compatible with Automotive Drive Requirements
- SOA is Power-Dissipation Limited
- Nanosecond Switching Speeds
- Linear Transfer Characteristics
- High Input Impedance
- Majority Carrier Device
- Electrostatic Discharge Protected

Description

The RFW2N06RLE n-channel logic level ESD protected power MOSFET is manufactured using the MegaFET process. This process, which uses feature sizes approaching those of LSI integrated circuits gives optimum utilization of silicon, resulting in outstanding performance. The RFW2N06RLE was designed for use with logic level (5 Volt) driving sources in applications such as programmable controllers, automotive switching, switching regulatoars, switching converters, motor drivers, relay drivers and emitter switches for bipolar transistors. This performance is accomplished through a special gate oxide design which provides full rated conductance at gate biases in the 3-5 volt range, thereby facilitating true on-off power control directly from logic circuit supply voltages.

The RFW2N06RLE is supplied in the 4-Pin dual-in-line plastic package.

- High Input Impedance

Description

The RFD3N08L is an n-channel enhancement mode silicon gate power field effect transistor specifically designed for use with logic level (5 volt) driving sources in applications such as programmable controllers, automotive switching, and solonoid drivers. This performance is accomplished through a special gate oxide design which provides full rated conduction at gate biases in the 3-5 volt range, thereby facilitating true on-off power control from logic circuit supply voltages.

The RFD3N08L is supplied in the JEDEC TO-251 plastic package and the RFD3N08LSM is supplied in the JEDEC TO-252 plastic package.

Voltage-Clamping Current-Limited ESD-Protected N-Channel Enhancement-Mode Power Field-Effect Transistor

Features

- **1A, 55V**
- **$R_{DS(ON)}$ 0.75Ω**
- **I_{Limit} .... 1.1A to 1.5A Max @ +150°C**
- **Built In Voltage Clamp**
- **Built In Current Limiting**
- **E_{SD} Protected .... 2KV Min**
- **Controlled Switching Limits EMI and RFI**
- **+175°C Rated Junction Temperature**
- **Logic Level Gate**

Description

The RLP1N06CLE is an intelligent monolithic power circuit which incorporates a lateral bipolar transistor, resistors, zener diodes, and a PowerMOS transistor. The current limiting of this device allows it to be used safely in circuits where it is anticipated that a shorted load condition may be encountered. The drain-source voltage clamping offers precision control of the circuit voltage when switching inductive loads. "Logic Level" gates allow this device to be fully biased on with only 5.0V from gate to source. Input protection is provided for ESD up to 2KV.

Temperature Dependence of Current Limiting and Switching Speed

The RLP1N06CLE is a monolithic power device which incorporates a Logic Level PowerMOS transistor with a resistor in series with the source. The base and emitter of a lateral bipolar transistor is connected across this resistor, and the collector of the bipolar transistor is connected to the gate of the PowerMOS transistor. When the voltage across the resistor reaches the value required to forward bias the emitter base junction of the bipolar transistor, the bipolar transistor "turns on". A series resistor is incorporated in series with the gate of the PowerMOS transistor allowing the bipolar transistor ot drive the gate of the PowerMOS transistors to a voltage which just maintains a constant current in the PowerMOS transistor. Since both the resistance of the resistor in series with the PowerMOS transistor source and voltage required to forward bias the base emitter junction of the bipolar transistor vary with the temperature, the current at which the device limits is a function of temperature. This dependence is shown in Figure 8.

The risistor in series with the gate of the PowerMOS transistor results in much slower switching than in most PowerMOS transistors. This is an advantage where fast switching can cause EMI or RFI. The switching speed is very predictable, and a minimum as well as maximum fall time is given in the device characteristics for this type.

Performance Curves (Continued)

DC Operation of the RLP1N06CLE

The limit of the drain-to-source voltage for operation in current limiting on a steady state (DC) basis is shown as Figure A. The dissipation in the device is simply the applied drain-to-source voltage multiplied by the limiting current. This device, like most PowerMOSFET devices today, is limited to +150°C. The maximum voltage allowable can, therefore, be expressed as:

$$V_S = \frac{+150^{o}C - T_{Ambient}}{I_{LIMIT} \times (R\theta_{JC} + R\theta)}$$

Duty Cycle Operation of the RLP1N06CLE

In many applications either the drain-to-source voltage or the gate drive is not available 100% of the time. The copper header on which the RLP1N06CLE is mounted has a very large thermal storage capability, so for pulse widths of less than 100 milliseconds, the temperature of the header can be considered a constant case temperature calculated simply as:

$$T_C = (V_{SD} \times I_D \times D \times R\theta_{CA}) + T_{ambient}$$

Generally the heat storage capability of the silicon chip in a power transistor is ignored for duty cycle calculations. Making this assumption, limiting junction temperature to +150°C and using the T_C calculated above, the expression for maximum V_{SD} under duty cycle operation is:

$$V_{SD} = \frac{+175^{o}C - T_C}{I_{LIMIT} \times D \times R\theta_{JC}}$$

These values are plotted as Figures B1 - B5 for various heatsink thermal resistances.

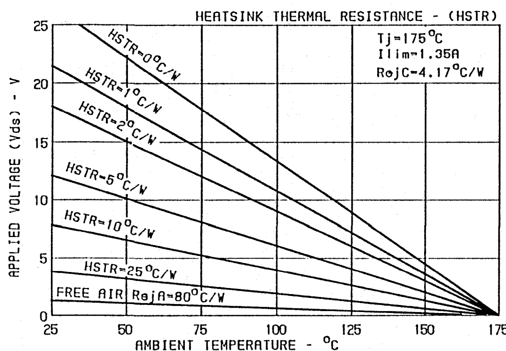

FIGURE A. DC OPERATION IN CURRENT LIMITING

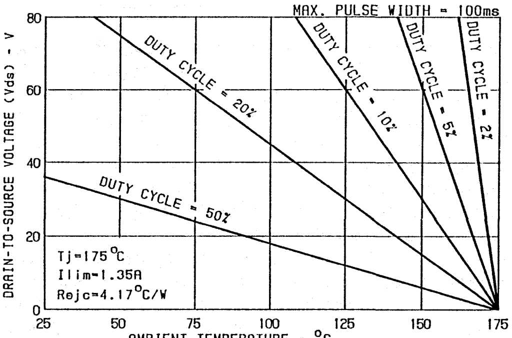

FIGURE B1. MAXIMUM V_{DS} vs. AMBIENT TEMPERATURE IN CURRENT LIMITING. (HEATSINK THERMAL RESISTANCE = 2°C/W)

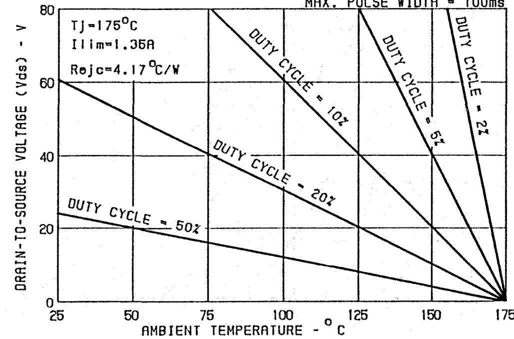

FIGURE B2. MAXIMUM V_{DS} vs. AMBIENT TEMPERATURE IN CURRENT LIMITING. (HEATSINK THERMAL RESISTANCE = 5°C/W)

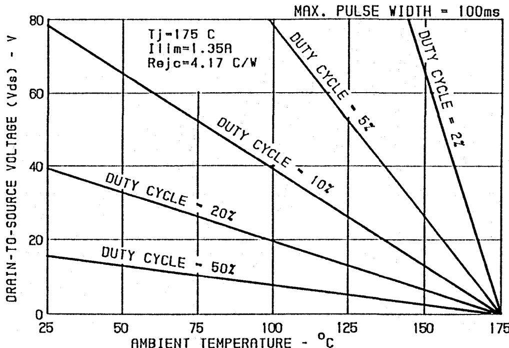

FIGURE B3. MAXIMUM V_{DS} vs. AMBIENT TEMPERATURE IN CURRENT LIMITING. (HEATSINK THERMAL RESISTANCE = 10°C/W)

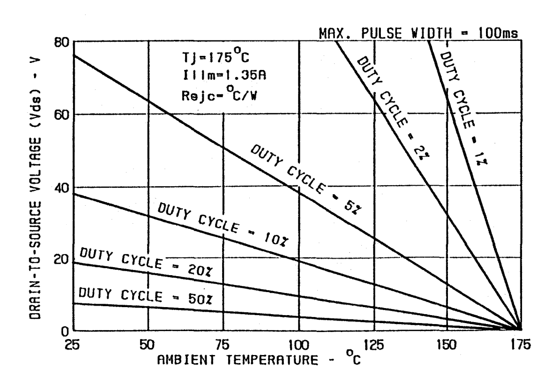

FIGURE B4. MAXIMUM V_{DS} vs. AMBIENT TEMPERATURE IN CURRENT LIMITING. (HEATSINK THERMAL RESISTANCE = 25°C/W)

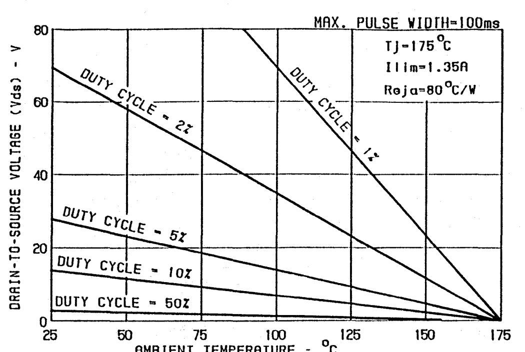

FIGURE B5. MAXIMUM V_{DS} vs. AMBIENT TEMPERATURE IN CURRENT LIMITING. (NO EXTERNAL HEATSINK)

Limited Time Operations of the RLP1N06CLE

Protection for a limited period of time is sufficient for many applications. As stated above the heat storage in the silicon chip can usually be ignored for computations of over 10 milliseconds and the thermal equivalent circuit reduces to a simple enough circuit to a allow easy computation on the limiting conditions. The variation in limiting current with temperature complicates the calculation of junction temperature, but a simple straight line approximation of the variation is accurate enough to allow meaningful computations. The curves shown as Figures C1-C5 give an accurate indication of how long the specified voltage can be applied to the device in the current limiting mode without exceeding the maximum specified 175°C junction temperature. In practice this tells you how long you have to alleviate the condition causing the current limiting to occur.

TA13349

ADVANCE INFORMATION

August 1991

Transient Suppressor Protected Power Switch

Features

- ±90V Transient Suppression
- 4V to 16V Operating Voltage
- 0.8A Current Load Capability
- Over-Voltage Shutdown Protected
- Short-Circuit Current Limiting
- Over-Temperature Shutdown Protected Thermal Shutdown at 150°C (T_j)
- -40°C to +105°C Operating Temperature Range

Description

The TA13349 is a Power Integrated Circuit designed to suppress potentially damaging overvoltage transients up to ±90V in amplitude. The device is designed to be operated in a pass-thru mode which allows the current to flow through the IC with minimal voltage drop. The protected load circuit is connected to the output of the TA13349. As such, the Transient Suppressor IC is designed to operate as a protected power switch which is capable of driving resistive, inductive or lamp loads with minimum risk of damage under stress conditions of over voltage or over current. The TA13349 is supplied in a 3 lead TO-220AB package.

Dual 5V Regulator With Logic Controlled Startup For Automotive Applications

Features

- **Dual 5V Regulator**
  - **VOUT1 5V 50mA - Standby**
  - **VOUT2 5V 80mA - Enabled**
  - **Regulated 6.2V to 18V**
  - **Bandgap Voltage References**
- **Overvoltage Shutdown**
- **Short Circuit Current Limiting**
- **Thermal Shutdown Protection**
- **Power ON Delayed Reset Control**
- **Ignition Comparator & Logic Switch**
- **Data Comparator & Logic Switch**
- **100x Current Multiplier/Amplifier**

Description

The TA14832 is a Dual 5 Voltage Regulator IC in standard silicon bipolar technology. It is supplied with features that are complementary to the shutdown and startup requirements of the microcontroller. It has short circuit current and overvoltage protection plus thermal shutdown protection to meet the wide ranging requirements of Automotive applications. The TA14832 functions are complementary to the needs of microcontroller and memory circuits. The ignition comparator provides a switched output to the microcontroller port input and the microcontroller provides a logic switched output to the regulator enable input. The standby output of the regulator supplies the microcontroller/memory circuits. Other functions of the TA14832 include a data comparator and a logic switch to transfer remote data to the microcontroller at a 5V logic level (RDI input). Data is transmitted from the microcontroller (TDO output) to the input of the TA14832 current amplifier which amplifies and translates the signal to a high level from the output of an npn transistor open collector.

TA50060

ADVANCE INFORMATION

August 1991

1A High Side Driver With Over-Load Protection

Features

- 1A Current Switching Capability
- 0.7 Ohm ON Resistance
- 4.5 to 24 Volt Operating Range
- Over-Voltage Shutdown Protected
- Over-Current Limiting
- Thermal Shutdown Protection
- 60 Volt Load Dump
- Reverse Battery Protection
- -40°C to +125°C Operating Temperature Range

Description

The TA50060 is a Power Integrated Circuit designed as a High Side Driver to switch power to output loads. It is the equivalent of a PNP pass transistor operated as a high side current switch in either the saturated ON mode or switched OFF. The TA50060 is designed with internal circuitry to protect the pass transistor from being damaged by over stress conditions of current, voltage or temperature. The TA50060 is intended for general purpose, automotive and potentially high stress applications. The TA50060 is supplied in a 5 lead TO-220 package.

HARRIS

CA3242E

Quad-Gated Inverting Power Driver For Interfacing Low-Level Logic to High Current Loads

August 1991

Features

- **Driven Outputs Capable of Switching 600mA Load Currents Without Spurious Changes in Output State**
- **Inputs Compatible with TTL or 5 Volt CMOS Logic**
- **Suitable for Resistive or Inductive Loads**
- **Output Overload Protection**
- **Power-Frame Construction for Good Heat Dissipation**

Description

The CA3242E quad-gated inverting power driver contains four gate switches for interfacing low-level logic to inductive and resistive loads such as: relays, solenoids, AC and DC motors, heaters, incandescent displays, and vacuum flourescent displays.

Output overload protection is provided when the load current (approximately 1.2A) causes the output $V_{CE(sat)}$ to rise above 1.3V. A built-in time delay, nominally 25µs, is provided during output turn-on as output drops from V_{DD} to V_{SAT}. That output will be shut down by its protection network without affecting the other outputs. The corresponding Input or Enable must be toggled to reset the output protection circuit.

Steering diodes in the outputs in conjunction with external zener diodes protect the IC against voltage transients due to switching inductive loads.

To allow for maximum heat transfer from the chip, the two center leads are directly connected to the die mounting pad. In free air, junction-to-air thermal resistance ($R_{\theta JA}$) is 50°C/W* (typical), This coefficient can be lowered to 40°C/W (typical) by suitable design of the PC board to which the CA3242E is soldered.

Quad-Gated Inverting Power Driver For Interfacing Low-Level Logic to High Current Loads

Features

- **Independent Over-Current Limiting On Each Output**
- **Independent Over-Temperature Limiting On Each Output**
- **Driven Outputs Capable of Switching 200mA Load Currents Without Spurious Changes In Output State**
- **Inputs Compatible With TTL Or 5 Volt CMOS Logic**
- **Suitable For Resistive Or Inductive Loads**
- **Power-Frame Construction For Good Heat Dissipation**
- **CA3262AQ and CA3262AE Operational to +125°C**
- **CA3262E Operational to +85°C**

Applications

- Solenoid
- Relay
- Light
- Steppers
- Motors
- Displays

System Applications

- Automotive
- Appliance
- Industrial Control
- Robotics

Description

The CA3262 quad-power NAND driver contains four NAND-gate switches for interfacing low-level logic to inductive and resistive loads such as: relays, solenoids, AC and DC motors, heaters, incandescent displays, and vacuum fluoresecent displays.

Steering diodes in the outputs in conjunction with external zener diodes protect the IC against voltage transients due to switching inductive loads.

To allow for maximum heat transfer from the chip, all ground leads on DIL and PLCC are directly connected to the die substrate and to the ground bond pads. In free air, junction-to-air thermal resistance ($R_{\theta JA}$) is 50°C/W (typical) for the DIL, 40°C/W (typical) for the chip carrier (PLCC).

This coefficient can be lowered to 40°C/W (typical) for the DIL, 30°C/W (typical) for the PLCC by suitable design of the PC board to which the CA3262 is soldered.

The individual outputs are protected with over-current limiting (I_{LIM}) and over-temperature (T_{LIM}) limiting.

If an output load is shorted, the remaining three outputs function normally unless the junction temperature (typically +155°C) of those outputs is exceeded. The output stage does not change state (oscillate) when in the current limiting and thermal limiting modes.

The CA3262 can drive four incandescent lamp loads without modulating their brilliance when "cold" lamps are energized. Outputs can be "ganged" to drive large loads. The CA3262E/AE is pin-for-pin compatible with the CA3219A, CA3242, and CA3252.

The CA3262 is supplied in a 16 lead dual-in-line plastic package (E, AE suffix) and in a plastic 28 leaded chip carrier, PLCC (AQ suffix).

DESIGN PARAMETER						
Over Temperature Limiting (Junction Temperature)			155 (Typical)			°C

*With voltage on the collector of the output transistor as indicated (V_{OUT} = 4.5V to 24.5V) and with that output transistor turned on, the current will increase to a limiting value which will be a value of 0.7A minimum. That output will shortly (≈5ms) thereafter go into over temperature limiting. (Excessive dissipation during thermal limiting may damage the chip.)

- **Light**
- **Steppers**
- **Motors**
- **Displays**

System Applications

- **Automotive**
- **Appliance**
- **Industrial Control**
- **Robotics**

Description

The CA3272Q quad-power NAND driver contains four NAND-gate switches for interfacing low-level logic to inductive and resistive loads such as: relays, solenoids, AC and DC motors, heaters, incandescent displays, and vacuum fluoresecent displays.

To allow for maximum heat transfer from the chip, all ground leads are directly connected to the die substrate and to the ground bond pads. In free air, junction-to-air thermal resistance ($R_{\theta JA}$) is 40°C/W (typical).

This coefficient can be lowered to 30°C/W (typical) by suitable design of the PC board to which the CA3272Q is soldered.

The individual outputs are protected with over-current limiting (I_{LIM}) and over-temperature (T_{LIM}) shutdown. Any one output that faults (see Fault Logic Table) will switch Pin 1 to a constant current pulldown.

If an output load is shorted, the remaining three outputs function normally unless the junction temperature (typically +165°C) of those outputs is exceeded. The output stage does not change state (oscillate) when in the current limit mode.

All inputs and enable have internal pulldowns to turn "off" the outputs when inputs are floating.

The CA3272Q can drive four incandescent lamp loads without modulating their brilliance when "cold" lamps are energized. Outputs can be "ganged" to drive large loads.

The CA3272Q is supplied in a plastic 28 leaded chip carrier, PLCC (Q suffix).

DESIGN PARAMETER					
Over Temperature Limiting (Junction Temperature)			165 (Typical)		°C

*With voltage on the collector of the output transistor as indicated (V_{OUT} = 4.5V to 24.5V) and with that output transistor turned on, the current will increase to a limiting value which will be a value of 0.7A minimum. That output will shortly (≈5ms) thereafter go into over temperature shutdown. (Excessive dissipation during thermal shutdown may damage the chip.)

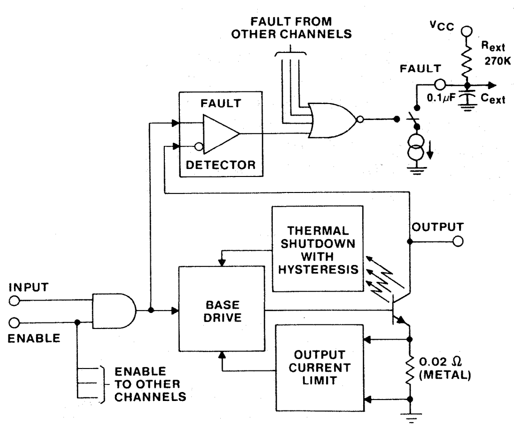

FIGURE 3. QUAD-GATED INVERTING POWER DRIVER (QDR) OUTPUT EQUIVALENT CIRCUIT. THE FAULT OUTPUT REQUIRES A PULL-UP LOAD SUCH AS AN EXTERNAL RESISTOR (R_{ext}). A CAPACITOR, C_{ext} SHOULD BE USED TO SUPPRESS SWITCHING SPIKES

CA3273

August 1991

High-Side Driver

Features

- Equivalent High Pass p-n-p Transistor
- Current Limiting, 0.6 to 1.0 Amps
- Over-Voltage Shutdown, 25 to 40 Volts
- 150°C Junction Temperature Thermal Limit
- Equivalent Beta of 25 @ 400mA/0.5 Volt
- Internal Bandgap Voltage and Current Reference

Applications

- Fuel Pump Driver
- Relay Driver
- Solenoid Driver
- Stepper Motor Driver
- Remote Power Switch
- Logic Control Switch

Description

The CA3273 is a power IC equivalent of a p-n-p pass transistor operated as a high-side-driver current switch in either the saturated (ON) or cutoff (OFF) modes. The CA3273 incorporates circuitry to protect the pass transistor from being damaged by large pass currents, excessive input voltage, and thermal overstress. The high-side driver is intended for general purpose, automotive and potentially high-stress applications. If high-stress conditions exist, the use of an external zener diode of 35 volts or less between supply and load terminals may be required to prevent damage due to severe conditions (such as load dump, reverse battery and positive or negative transients). The CA3273 is designed to withstand a nominal reverse-battery (V_{BAT} = 13V) condition without permanent damage to the IC. The CA3273 is supplied in a modified 3 lead TO-202 plastic power package.

Current Limiting Power Switch With Current Limiter Sense Flag

Features

- Drive-Current Limiting at Output
- Current-Sense Buffer and Reference
- 200mA Driver Current Capability
- Logic-Level Control Input
- Current Limiting Flag Output
- 50dB Minimum PSRR
- 5μS typical Switch Time
- Separate Signal and Power Grounds

Applications

- Solenoid Switch Driver
- Relay Driver
- Lamp Control Switch
- Ignition Coil Pre-Driver
- Constant Current Driver
- Current Limiting Switch
- Fault Output Sense Applicance
- Power Supply Fault Mode Control

Description

The CA3274 is a controlled current switch and may be used in general purpose switching applications that require specified maximum levels of current. The functional block diagram of the CA3274 is shown and a typical application circuit is shown in Figure 1. An internal emitter follower has 200mA of source drive output capability. The Control Input is a Schmitt trigger buffer amplifier for noise immunity in the environments typical of industrial and automotive control systems.

Current sensing in the emitter circuit of a power-darlington output stage is fed back from a sampling resistor to the sense input of the CA3274 which has a 335mV typical offset. For the example shown in Figure 2, a sampling resistor of 0.056 ohm permits 6.0 amperes (0.335/0.056) of current in the emitter of the output driver. When the current limiter is activated, the flag output changes state conditionally. If the control input is the "0" state, the flag output will remain in a "1" state. If the control input is in the "1" state and the sense input is less than the voltage reference level of 335mV, the flag output will remain in the "1" state. If the control input is the "1" state and the sense input is equal to or greater than the 335mV reference level, the flag output goes to the "0" state. The output flag switch may be used to accurately establish dwell timing in automotive applications. When the control input goes to "0", the flag is reset to "1". Noise-immunity hold-off is used to prevent pre-triggering of the flag output and is noted as t_d in the timing diagram of Figure 2.

The flag output may be used for diagnostic feedback via the current sense input to detect a fault mode. In this case the sampled drive current is either from the emitter of the CA3274 internal power transistor or an external output amplifier, such as a darlington power transistor or power-FET output stage. The CA3274 has separate power and signal grounds to minimize transient-loop feedback to the input ground and thus prevent false triggering of the output. Optionally, the output from the CA3274 may be taken from the open collector (DRIVE IN) at pin 6. An external resistor at pin 6 may be used to set the level at which Q2 will saturate, providing additional limiting protection for the maximum forward-drive from the CA3274.

- **μP Controlled Sensor Data Displays**
- **Speedometer Displays**
- **Tachometer Displays**
- **Stepper Motors**
- **Slave Position Indicators**

Description

The CA3275E Dual-H Driver is intended for general-purpose applications requiring Dual-H drive or switching, including direction and pulse-width modulation for position control. While all features of the IC may not be utilized or required, they would normally be used in instrumentation systems with quadrature coils, such as air-core gauges, where the coils would be driven at frequencies ranging from 200 to 400Hz. The coils are wrapped at 90o angles for independent direction control. coils wound in this physical configuration are controlled by pulse width modulation, where each coil drive is a function of the sine or cosine versus degrees of movement. The direction control is used to change the direction of the current in the H-Driver coil.

The switch rate capability of the IC is typically 30kHz regardless of the inductive load. Over-current limiting is used to limit short circuit current. Over-voltage protection (in the range of 18 to 40V) causes the device to shut down the output current drive. Thermal shutdown limits power dissipation on the chip.

The CA3275E is supplied in a 14 lead dual-in-line plastic package.

HV-1205

UL RECOGNIZED

August 1991

Single Chip Power Supply

Features

- Direct AC to DC Conversion
- Wide Input Voltage Range 18Vrms-132Vrms
- Multiple Output Voltages
- Guaranteed Output Current 50mA
- Output Voltage .... 5V to 24V
- Line and Load Regulation ....<2%
- UL Recognition, File # E130808

Applications

- Compact, Low Cost, Power Supply for Non-Isolated Applications
- Appliance Control
- Battery Back-Up Systems
- Dual Output Supply for OFF-LINE Motor Controls

Description

The HV-1205 is a single chip power supply that can supply 5V to 24V at 50mA output current. Just a few inexpensive external components are needed to provide a compact, light weight, cost effective power supply. The HV-1205 replaces a transformer, rectifier, and voltage regulator. This chip is made in the new Harris High Voltage Dielectric Isolation Process. This high breakdown process (400V) allows a patented switching circuit to draw current from the AC line only as necessary to supply the load. The HV-1205 operates from -40°C to +85°C (with no derating necessary due to package power dissipation). The HV-1205 is available in an 8 Pin Plastic Mini-DIP.

CAUTION: This Product Does Not Provide Isolation From the AC Line

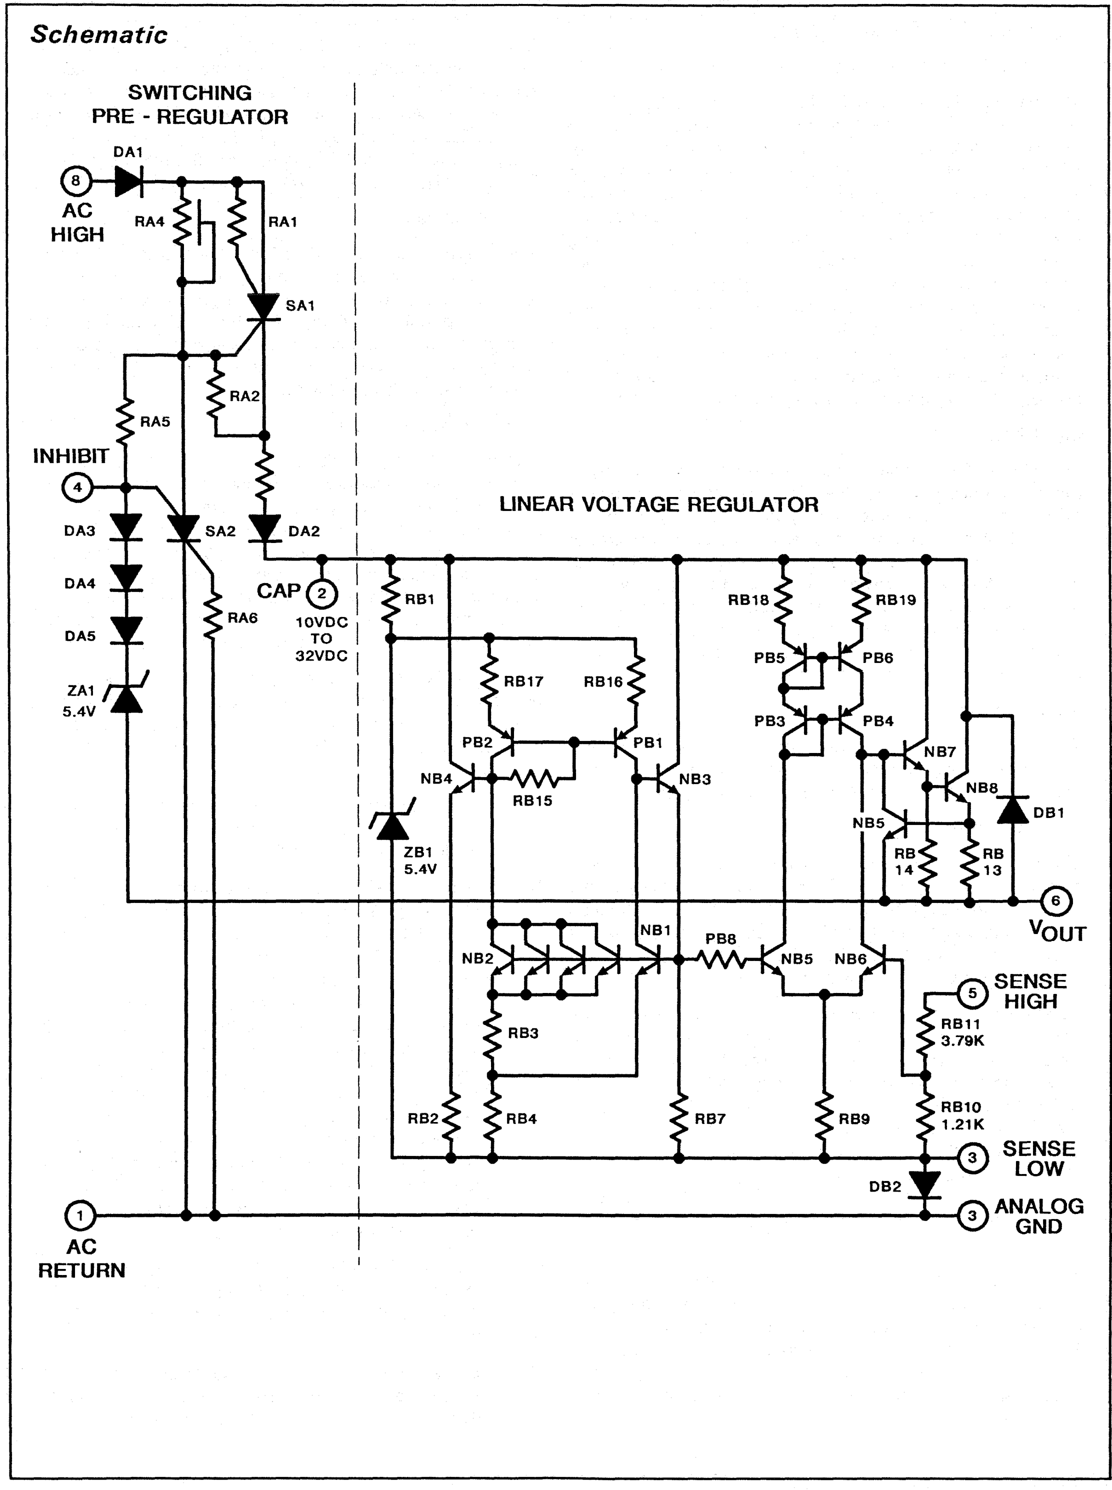
Schematic



Application Information

How The HV-1205 Works

The HV-1205 converts AC voltage into regulated DC voltage to power low voltage components such as integrated circuits. This is accomplished in two stages on the monolithic chip. First, the pre-regulator momentarily connects a large capacitor to the AC high line until it charges to about 6V above the selected output voltage. The pre-regulator then switches to a blocking mode and stays in that blocking mode until the next line cycle begins. The large capacitor supplies power to the series pass regulator, providing DC current to power the user's circuit. Providing current to the post regulator causes the large cap to discharge at a rate dependent on load current. Each line cycle refreshes the charge on the electrolytic capacitor. For a detailed explanation of HV-1205 operation see Application Note 558.

Input Voltage

The HV-1205 operates over a wide range of input voltages. Most applications will use the 120Vrms line from the power grid. A standard circuit for this application is shown in Figure 2. Much smaller input voltages can be used. The size of the external components used will be determined by the output voltage and current required and the input voltage available. Several graphs have been provided to help choose component values for a specific application. The section below called Component Selection discusses trade-offs related to component sizing.

Input Frequency

The HV-1205 is designed to operate from 48Hz to 380Hz. Higher operating frequency in possible. Keep in mind that the HV-1205 will refresh C2 once per line cycle.

Setting Output Voltage

The HV-1205 can be set to provide a regulated output voltage anywhere from 5V to $24V_{DC}$. Refer to Figures 4, 5 and 6 for several ways of adjusting output voltage. Any time an output voltage greater than 5V is chosen, a 10µF capacitor between the output and the sense pin is required. That capacitor allows C2 to charge gradually.

As seen in Figure 1, output voltage is set by feedback to the sense pin. The output will rise to the voltage necessary to keep the sense pin at 5V. For a 5V output, pins 5 and 6 are shorted together. There are three ways to increase the output voltage beyond 5V. The simplest method is to increase the feedback resistor by adding an external resistor between pins 5 and 6. The disadvantage is that the internal circuit resistors have a tolerance of approximately ±15% which limits the accuracy of the predicted output (see graph). The internal thin film resistors have low temperature coefficients.

An external voltage divider as shown in Figure 5 improves the accuracy as long as the external resistors are much lower in value than those of the internal divider. Approximately 1mA flows into pin 5. If a potentiometer is used as the divider, an additional resistor between the lower leg and ground will insure that the output never exceeds its maximum rated voltage.

A zener diode between pins 5 and 6, as shown in Figure 6, sets the output voltage above 5V by the zener's breakdown voltage at 1mA. This voltage has the accuracy and tolerance of the zener. An added advantage is that two outputs are now available, pin 5 at 5V and pin 6 at V_Z + 5V. All the current from the 5V supply flows through the reference diode. The sum of both output currents should not exceed 50mA.

Output Current

Any current draw up to 50mA continuous is acceptable. More current can be drawn momentarily. Care should be taken to make sure C2 is not discharged below the dropout voltage and that the duty cycle of the excess current is low enough to not cause a package power dissipation problem. The output is current limited as shown in the graph to protect against shorted loads.

Component Selection

One of the most powerful features of the HV-1205 is its flexibility. One standard configuration allows enormous variation in input voltage and output current while still maintaining a regulated output. For example, with R_1 = 150Ω, C2 = 470µF and V_{OUT} = 5V, the HV-1205 will provide a regulated 50mA output when input voltage is anywhere from $132V_{AC}$ down to about $28V_{AC}$. The designer can choose components tailored to his application in order to save cost, space, power dissipation etc.

Below is a list of external components, description of their purpose, and a recommended value. This is a full list of possible components all of which may not be required for an intended application. Most designs will use a subset of this list.

F1: Fuse. Opens the connections to the power line should chip fail. Recommended value = 1/4A, 2AG similar to Littlefuse 225.250®.

R_1: Source Resistance. Limits current into HV-1205. Needs to be large enough to limit inrush current when C2 is discharged fully. V_{PEAK}/R_1 = 1.1A Maximum. R_1 will dissipate power as shown in the graphs. The equation for Pd in R_1 is:
$Pd = 1.33 \sqrt{\pi R_1}\ V_{PEAK} (I_{OUT})^3$. Low average output currents would allow for source resistors with lower Pd ratings. Similarly, lower V_{AC} or smaller value R_1 will cause less dissipation in R_1. Sizing of R_1 should be tailored to the intended application keeping in mind not to let the maximum inrush current be exceeded. Should an external method of limiting inrush current be used (such as NTC resistors) then the value of R_1 and its associated heat could be reduced. Recommended value = 150Ω. To reduce Pd see App. Note AN9107.

C1: Snubber Capacitor. R_1 and C1 form a low pass filter thereby limiting the rate of voltage rise at the input of the HV-1205. Recommended value = 0.05µF, AC rated.

MOV: Surge suppressor. Metal Oxide Varistor clamps voltage to a level that the HV-1205 can handle. Recommended value = V130LA20 or equivalent.

Littlefuse 225.250® is a Registered Trademark of Tracor, Inc.

Application Information (Continued)

C2: Pre-Regulator capacitor. This capacitor is charged once each line cycle. The post-regulator portion of HV-1205 is powered by C2 for most of the line cycle. Normally the smallest C2 that will supply the load current (see graph) is used. Using a large C2 will supply temporary high load currents or normal load current during a short power loss. Using a larger C2 will reduce ripple at Pin 2, the input to the post regulator, which will reduce output ripple. C2 should have a ripple current rating consistent with the application. Small capacitors with high ESR may not store enough charge to maintain load current. See graph. Recommended value = 470μF, voltage rating should be about 10V greater than chosen V_{OUT}.

C3: Inhibit capacitor. Keeps the HV-1205 from turning on during input transients. If sized too large, HV-1205 will never turn on. If sized too small, no protection from transients is offered. For 60Hz (or 50Hz) use the recommended value of 150pF, voltage rating should be at about 10V greater than V_{OUT}. For 400Hz use 47pF.

C4: Output filter capacitor. At least 1μF is required to maintain stability of the output stage. Larger values will not reduce ripple but will reduce spiking which may occur on the output coincident with the HV-1205 going into blocking mode. 100μF reduces the spike amplitude to about 25mVp-p.

R2: Feedback component. A resistor or diode that causes a voltage drop between the SENSE and OUTPUT pins and thereby adjusting the output voltage. See voltage adjustment equivalent circuit. Also see graph for approximate resistor value.

HV-2405E

UL RECOGNIZED

August 1991

World-Wide Single Chip Power Supply

Features

- Direct AC to DC Conversion
- Wide Input Voltage Range 18Vrms-264Vrms
- Multiple Output Voltages
- Guaranteed Output Current 50mA*
- Output Voltage.......................... 5V to 24V
- Line and Load Regulation ....<2%
- UL Recognition, File # E130808

Applications

- Compact, Low Cost, Power Supply for Non-Isolated Applications
- Appliance Control
- Battery Back-Up Systems
- Dual Output Supply for OFF-LINE Motor Controls
- Housekeeping Supply for Switch-Mode Power Supplies

CAUTION: This Product Does Not Provide Isolation From the AC Line

***See App Note AN9101 for 250mA output.**

Description

The HV-2405E is a single chip power supply that can supply 5V to 24V at 50mA output current. Just a few inexpensive external components are needed to provide a compact, light weight, cost effective power supply. The HV-2405E replaces a transformer, rectifier, and voltage regulator. This chip is made in the new Harris High Voltage Dielectric Isolation Process. This high breakdown process (500V) allows a patented switching circuit to draw current from the AC line only as necessary to supply the load.

The wide input voltage range makes the HV-2405E an excellent choice for use in equipment which must operate from either 240V or 120V. Unlike competitive AC-DC convertors, the HV-2405E can use the same external components for operation from either voltage. In addition the HV-2405E can be connected across any two phases of a 3-phase system (208Vrms)*. This great flexibility in input voltage allows a single design for worldwide use.

The HV-2405E is pin for pin compatible with the HV-1205 but allows twice the input voltage. Additionally, the output and sense pins are connected through a zener diode to limit output voltage should the sense pin to output connection become open.

Further flexibility can be obtained from the HV-2405E by using it with other Harris chips. For example, the high efficiency ICL-7660S and ICL-7662 provide positive to negative voltage conversion. For automatic switch-over to battery back-up use the ICL 7673. Harris also offers a line of extremely low power op amps.

*** CAUTION: When used in this mode, GND and AC RETURN operate at high voltage with respect to earth ground.**

Equivalent Circuit For Output Voltage Adjustment

$R_2 = V_{OUT} - 5V$ Where R_2 is the Approximate Value of Resistor Between Pin 5 and Pin 6 (in KΩ), V_{OUT} is the Desired Output Voltage. See Graph.

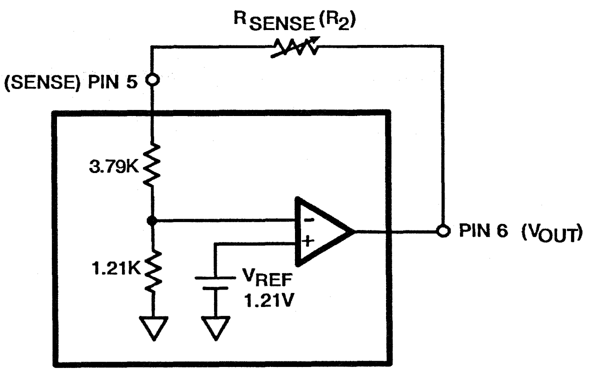

FIGURE 1.

Schematic

Patent pending on the above circuit.

Application Information

How The HV-2405E Works

The HV-2405E converts AC voltage into regulated DC voltage to power low voltage components such as integrated circuits. This is accomplished in two stages on the monolithic chip. First, the pre-regulator momentarily connects a large capacitor to the AC high line until it charges to about 6V above the selected output voltage. The pre-regulator then switches to a blocking mode and stays in that blocking mode until the next line cycle begins. The large capacitor supplies power to the series pass regulator, providing DC current to power the user's circuit. Providing current to the post regulator causes the large cap to discharge at a rate dependent on load current. Each line cycle refreshes the charge on the electrolytic capacitor.

Input Voltage

The HV-2405E operates over a wide range of input voltages. Most applications will use the 240Vrms or 120Vrms line from the power grid. A standard circuit for this application is shown in Figure 2. Much smaller input voltages can be used. The size of the external components used will be determined by the output voltage and current required and the input voltage available. Several graphs have been provided to help choose component values for a specific application. The section below called Component Selection discusses trade-offs related to component sizing.

Input Frequency

The HV-2405E is designed to operate from 48Hz to 380Hz. Higher operating frequency is possible. Keep in mind that the HV-2405E will refresh C2 once per line cycle.

Setting Output Voltage

The HV-2405E can be set to provide a regulated output voltage anywhere from 5V to $24V_{DC}$. Refer to Figures 4, 5 and 6 for several ways of adjusting output voltage.

As seen in Figure 1, output voltage is set by feedback to the sense pin. The output will rise to the voltage necessary to keep the sense pin at 5V. For a 5V output , pins 5 and 6 are shorted together. There are three ways to increase the output voltage beyond 5V. The simplest method is to increase the feedback resistor by adding an external resistor between pins 5 and 6. The disadvantage is that the internal circuit resistors have a tolerance of approximately ±15% which limits the accuracy of the predicted output (see graph). The internal thin film resistors have low temperature coefficients.

An external voltage divider as shown in Figure 5 improves the accuracy as long as the external resistors are much lower in value than those of the internal divider. Approximately 1mA flows into pin 5.

A zener diode between pins 5 and 6, as shown in Figure 6, sets the output voltage above 5V by the zener's breakdown voltage at 1mA. This voltage has the accuracy and tolerance of the zener. An added advantage is that two outputs are now available, pin 5 at 5V and pin 6 at $V_Z + 5V$. All the current from the 5V supply flows through the reference diode. The sum of both output currents should not exceed 50mA.

The HV-2405E has an internal zener diode to clamp the output above the 24V maximum but below a damaging level.

Output Current

Any current draw up to 50mA continuous is acceptable. More current can be drawn momentarily. Care should be taken to make sure C2 is not discharged below the dropout voltage and that the duty cycle of the excess current is low enough to not cause a package power dissipation problem. The output is current limited as shown in the graph to protect against shorted loads.

Component Selection

One of the most powerful features of the HV-2405E is its flexibility. One standard configuration allows enormous variation in input voltage and output current while still maintaining a regulated output. For example, with $R_1 = 150\Omega$, C2 = 470µF and V_{OUT} = 5V, the HV-2405E will provide a regulated 50mA output when input voltage is anywhere from $264V_{AC}$ down to about $28V_{AC}$. The designer can choose components tailored to his application in order to save cost, space, power dissipation etc.

Below is a list of external components, description of their purpose, and a recommended value. This is a full list of possible components all of which may not be required for an intended application. Most designs will use a subset of this list.

F1: Fuse. Opens the connections to the power line should chip or C2 fail. Recommended value = 1/2A, 2AG similar to Littlefuse 225.500®.

R_1: Source Resistance. Limits current into HV-2405E. Needs to be large enough to limit inrush current when C2 is discharged fully. V_{PEAK}/R_1 = 2.5A Maximum. R_1 will dissipate power as shown in the graphs. The equation for Pd in R_1 is:
$Pd = 1.33 \sqrt{\pi R_1}\, V_{PEAK}(I_{OUT})^3$.
Low average output currents would allow for source resistors with lower Pd ratings. Similarly, lower V_{AC} or smaller value R_1 will cause less dissipation in R_1. Sizing of R_1 should be tailored to the intended application keeping in mind not to let the maximum inrush current be exceeded. Should an external method of limiting inrush current be used (such as NTC resistors) then the value of R_1 and its associated heat could be reduced. Recommended value = 150Ω. To reduce Pd see App Note AN9107.

C1: Snubber Capacitor. R_1 and C1 form a low pass filter thereby limiting the rate of voltage rise at the input of the HV-2405E. Recommended value = 0.05µF, AC rated.

MOV: Surge suppressor. Metal Oxide Varistor clamps voltage to a level that the HV-2405E can handle. Recommended value = V130LA20 or equivalent for 120V applications and gas tube which arcs over at less than 500V for 240V applicatons.

Littlefuse 225.500® is a Registered Trademark of Tracor, Inc.

Application Information (Continued)

C2: Pre-Regulator capacitor. This capacitor is charged once each line cycle. The post-regulator portion of HV-2405E is powered by C2 for most of the line cycle. Normally the smallest C2 that will supply the load current (see graph) is used. Using a large C2 will supply temporary high load currents or normal load current during a short power loss. Using a larger C2 will reduce ripple at Pin 2, the input to the post regulator, which will reduce output ripple. C2 should have a ripple current rating consistent with the application. Small capacitors with high ESR may not store enough charge to maintain load current. See graph. Recommended value = 470μF, voltage rating should be about 10V greater than chosen V_{OUT}.

C3: Inhibit capacitor. Keeps the HV-2405E from turning on during input transients. If sized too large, HV-2405E will never turn on. If sized too small, no protection from transients is offered. For 50Hz or 60Hz use the recommended value of 150pF, voltage rating should be at about 10V greater than V_{OUT}.

C4: Output filter capacitor. At least 1μF is required to maintain stability of the output stage. Larger values will not reduce ripple but will reduce spiking which may occur on the output coincident with the HV-2405E going into blocking mode.

R2: Feedback component. A resistor or zener diode that causes a voltage drop between the SENSE and OUTPUT pins and thereby adjusting the output voltage. See voltage adjustment equivalent circuit. Also see graph for approximate resistor value. About 1mA flows through this component.

NOTES:

1. RA, RB voltage divider sets voltage of false ground anywhere between VOUT of HV-2405E and ground.
2. RA and RB should be large values (e.g. 470K)
3. Circuits powered with this method must ALL be referred to "False Gnd"
4. Op amp must be able to source/sink load current
5. Example: RA = 470K, RB = 470K, VOUT set to 24V. +VSUPPLY would be ≈ +12V
   -VSUPPLY would be ≈ -12V

Dual Power MOSFET Driver

August 1991

Features

- Fast Rise and Fall Times
  - 30ns with 1000pF Load
- Wide Supply Voltage Range
  - V_{CC} = 4.5 to 15V
- Low Power Consumption
  - 4mW with Inputs Low
  - 20mW with Inputs High
- TTL/CMOS Input Compatible Power Driver
  - R_{OUT} = 7Ω Typ
- Direct Interface with Common PWM Control ICs
- Pin Equivalent to DS0026/DS0056; TSC426

Typical Applications

- Switching Power Supplies
- DC/DC Converters
- Motor Controllers

Description

The ICL7667 is a dual monolithic high-speed driver designed to convert TTL level signals into high current outputs at voltages up to 15V. Its high speed and current output enable it to drive large capacitive loads with high slew rates and low propagation delays. With an output voltage swing only millivolts less than the supply voltage and a maximum supply voltage of 15V, the ICL7667 is well suited for driving power MOSFETs in high frequency switched-mode power converters. The ICL7667's high current outputs minimize power losses inthe power MOSFETs by rapidly charging and discharging the gate capacitance. The ICL7667's input are TTL compatible and can be directly driven by common pulse-width modulation control ICs.

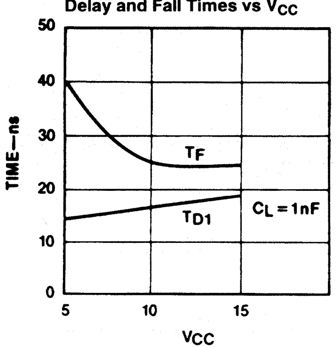
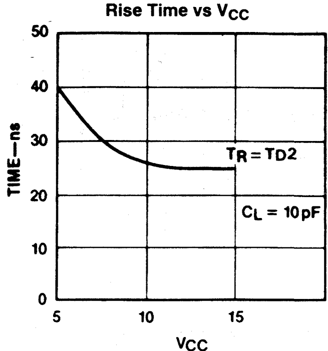
Typical Performance Characteristics (Continued)





DETAILED DESCRIPTION

The ICL7667 is a dual high-power CMOS inverter whose inputs respond to TTL levels while the outputs can swing as high as 15V. Its high output current enables it to rapidly charge and discharge the gate capacitance of power MOSFETs, minimizing the switching losses in switchmode power supplies. Since the output stage is CMOS, the output will swing to within millivolts of both ground and V_{CC} without any external parts or extra power supplies as required by the DS0026/56 family. Although most specifications are at $V_{CC} = 15V$, the propagation delays and specifications are almost independent of V_{CC}.

In addition to power MOS drivers, the ICL7667 is well suited for other applications such as bus, control signal, and clock drivers on large memory of microprocessor boards, where the load capacitance is large and low propagation delays are required. Other potential applications include peripheral power drivers and charge-pump voltage inverters.

INPUT STAGE

The input stage is a large N-channel FET with a P-channel constant-current source. This circuit has a threshold of about 1.5V, relatively independent of the V_{CC} voltage. This means that the inputs will be directly compatible with TTL over the entire 4.5 – 15V V_{CC} range. Being CMOS, the inputs draw less than 1μA of current over the entire input voltage range of ground to V_{CC}. The quiescent current or no load supply current of the ICL7667 is affected by the input voltage, going to nearly zero when the inputs are at the 0 logic level and rising to 7mA maximum when both inputs are at the 1 logic level. A small amount of hysteresis, about 50 – 100mV at the input, is generated by positive feedback around the second stage.

OUTPUT STAGE

The ICL7667 output is a high-power CMOS inverter, swinging between ground and V_{CC}. At $V_{CC} = 15V$, the output impedance of the inverter is typically 7Ω. The high peak current capability of the ICL7667 enables it to drive a 1000pF load with a rise time of only 40ns. Because the output stage impedance is very low, up to 300mA will flow through the series N- and P-channel output devices (from V_{CC} to ground) during output transitions. This crossover current is responsible for a significant portion of the internal power dissipation of the ICL7667 at high frequencies. It can be minimized by keeping the rise and fall times of the input to the ICL7667 below 1μs.

APPLICATION NOTES

Although the ICL7667 is simply a dual level-shifting inverter, there are several areas to which careful attention must be paid.

GROUNDING

Since the input and the high current output current paths both include the ground pin, it is very important to minimize any common impedance in the ground return. Since the ICL7667 is an inverter, any common impedance will generate negative feedback, and will degrade the delay, rise and fall times. Use a ground plane if possible, or use separate ground returns for the input and output circuits. To minimize any common inductance in the ground return, separate the input and output circuit ground returns as close to the ICL7667 as is possible.

BYPASSING

The rapid charging and discharging of the load capacitance requires very high current spikes from the power supplies. A parallel combination of capacitors that has a low impedance over a wide frequency range should be used. A 4.7μF tantalum capacitor in parallel with a low inductance 0.1μF capacitor is usually sufficient bypassing.

OUTPUT DAMPING

Ringing is a common problem in any circuit with very fast rise or fall times. Such ringing will be aggravated by long inductive lines with capacitive loads. Techniques to reduce ringing include:

1) Reduce inductance by making printed circuit board traces as short as possible.
2) Reduce inductance by using a ground plane or by closely coupling the output lines to their return paths.
3) Use a 10 to 30Ω resistor in series with the output of the ICL7667. Although this reduces ringing, it will also slightly increase the rise and fall times.
4) Use good bypassing techniques to prevent supply voltage ringing.

NOTE: All typical values have been characterized but are not tested.

POWER DISSIPATION

The power dissipation of the ICL7667 has three main components:

1) Input inverter current loss
2) Output stage crossover current loss
3) Output stage I^2R power loss

The sum of the above must stay within the specified limits for reliable operation.

As noted above, the input inverter current is input voltage dependent, with an I_{CC} of 0.2mA maximum with a logic 0 input and 6mA maximum with a logic 1 input.

The output stage crowbar current is the current that flows through the series N- and P-channel devices that form the output. This current, about 300mA, occurs only during output transitions. **Caution:** The inputs should never be allowed to remain between V_{IL} and V_{IH} since this could leave the output stage in a high current mode, rapidly leading to destruction of the device. If only one of the drivers is being used, be sure to tie the unused input to a ground. **NEVER** leave an input floating. The average supply current drawn by the output stage is frequency dependent, as can be seen in I_{CC} vs. Frequency graph in the Typical Characteristics Graphs.

The output stage I^2R power dissipation is nothing more than the product of the output current times the voltage drop across the output device. In addition to the current drawn by any resistive load, there will be an output current due to the charging and discharging of the load capacitance. In most high frequency circuits the current used to charge and discharge capacitance dominates, and the power dissipation is approximately

$$P_{AC} = CV_{CC}^2 f$$

Where C = Load Capacitance
f = Frequency

In cases where the load is a power MOSFET and the gate drive requirements are described in terms of gate charge, the ICL7667 power dissipation will be

$$P_{AC} = Q_G V_{CC} f$$

Where Q_G = Charge required to switch the gate, in Coulombs.
f = Frequency

POWER MOS DRIVER CIRCUITS

POWER MOS DRIVER REQUIREMENTS

Because it has a very high peak current output, the ICL7667 excels at driving the gate of power MOS devices. The high current output is important since it minimizes the time the power MOS device is in the linear region. Figure 4 is a typical curve of charge vs. gate voltage for a power MOSFET. The flat region is caused by the Miller capacitance, where the drain-to-gate capacitance is multiplied by the voltage gain of the FET. This increase in capacitance occurs while the power MOSFET is in the linear region and is dissipating significant amounts of power. The very high current output of the ICL7667 is able to rapidly overcome this high capacitance and quickly turns the MOSFET fully on or off.

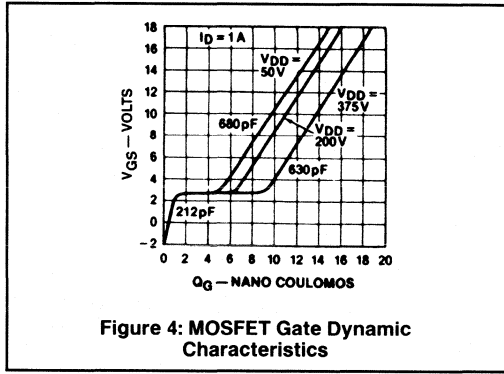


Figure 4: MOSFET Gate Dynamic Characteristics

DIRECT DRIVE OF MOSFETs

Figure 6 shows interfaces between the ICL7667 and typical switching regulator ICs. Note that unlike the DS0026, the ICL7667 does not need a dropping resistor and speed-up capacitor between it and the regulator IC. The ICL7667, with its high slew rate and high voltage drive can directly drive the gate of the MOSFET. The 1527 IC is the same as the 1525 IC, except that the outputs are inverted. This inversion is needed since ICL7667 is an inverting buffer.

TRANSFORMER COUPLED DRIVE OF MOSFETs

Transformers are often used for isolation between the logic and control section and the power section of a switching regulator. The high output drive capability of the ICL7667 enables it to directly drive such transformers. Figure 6 shows a typical transformer coupled drive circuit. PWM ICs with either active high or active low outputs can be used in this circuit, since any inversion required can be obtained by reversing the windings on the secondaries.

BUFFERED DRIVERS FOR MULTIPLE MOSFETs

In very high power applications which use a group of MOSFETs in parallel, the input capacitance may be very large and it can be difficult to charge and discharge quickly. Figure 8 shows a circuit which works very well with very large capacitance loads. When the input of the driver is zero, Q1 is held in conduction by the lower half of the ICL7667 and Q2 is clamped off by Q1. When the input goes positive, Q1 is turned off and a current pulse is applied to the gate of Q2 by the upper half of the ICL7667 through the transformer, T1. After about 20ns, T1 saturates and Q2 is held on by its own C_{gs} and the bootstrap circuit of C1, D1 and R1. This bootstrap circuit may not be needed at frequencies greater than 10kHz since the input capacitance of Q2 discharges slowly.

NOTE: All typical values have been characterized but are not tested.

OTHER APPLICATIONS

RELAY AND LAMP DRIVERS

The ICL7667 is suitable for converting low power TTL or CMOS signals into high current, high voltage outputs for relays, lamps and other loads. Unlike many other level translator/driver ICs, the ICL7667 will both source and sink current. The continuous output current is limited to 200mA by the I^2R power dissipation in the output FETs.

CHARGE PUMP OR VOLTAGE INVERTERS AND DOUBLERS

The low output impedance and wide V_{CC} range of the ICL7667 make it well suited for charge pump circuits. Figure 8 shows a typical charge pump voltage inverter circuit and a typical performance curve. A common use of this circuit is to provide a low current negative supply for analog circuitry or RS232 drivers. With an input voltage of +15V, this circuit will deliver 20mA at −12.6V. By increasing the size of the capacitors, the current capability can be increased and the voltage loss decreased. The practical range of the input frequency is 500Hz to 250kHz. As the frequency goes up, the charge pump capacitors can be made smaller, but the internal losses in the ICL7667 will rise, reducing the circuit efficiency.

Figure 9, a voltage doubler, is very similar in both circuitry and performance. A potential use of Figure 8 would be to supply the higher voltage needed for EEPROM or EPROM programming.

CLOCK DRIVER

Some microprocessors (such as the 68XX and 65XX families) use a clock signal to control the various LSI peripherals of the family. The ICL7667's combination of low propagation delay, high current drive capability and wide voltage swing make it attractive for this application. Although the ICL7667 is primarily intended for driving power MOSFET gates at 15V, the ICL7667 also works well as a 5V high-speed buffer. Unlike standard 4000 series CMOS, the ICL7667 uses short channel length FETs and the ICL7667 is only slightly slower at 5V than at 15V.

NOTE: All typical values have been characterized but are not tested.

SP306

PRELIMINARY

August 1991

Intelligent Power™ 60V/30A High Side Switch

Features

- Over Current Protection
- Over Temperature Protection
- Missing Load Detection
- Over Voltage Lockout
- ESD Protection
- 5 V_{DC} Logic
- Diagnostic Flag
- Grounded Case Package Requires No Awkward Isolators

Description

Designed with a PowerASIC™ macro based library, the SP306 high side switch provides predictable performance over the full operating range. Intended for a wide variety applications, the device will support 30 amps inrush current associated with cold lamp filaments, capacitive loads and solenoids.

SP306 Operation

Perhaps the most brutal loads are lamps. These exhibit a dynamic load line characteristic dependent upon filament temperature which is primarily a function of current. Resultant inrush current is typically 10-12 times greater than steady state.

The SP306 employs a soft start scheme which optimizes performance economically. Cold filament inrush is managed by a control algorithm which combines over current and temperature protection. At turn on the load current builds up until over current is detected initiating a current limit mode. Under short circuit load the switch will shut off from an over temperature.

All faults automatically reset upon removal of fault condition.

SP600

October 1990

Half-Bridge 500 VDC Driver

Features

- 500 Volt Maximum Rating
- Ability to Interface and Drive Standard and Current Sensing n-Channel Power MOSFET/ IGBT Devices
- Creation and Management of a Floating Power Supply for Upper Rail Drive
- Simultaneous Conduction Lockout
- Overcurrent Protection
- Single Low Current Bias Supply Operation
- Latch Immune CMOS Logic
- Peak Drive in Excess of 0.5 Amp

Description:

The SP600 is a smart power high voltage integrated circuit (HVIC) optimized to drive MOS gated power devices in half-bridge topologies. It provides the necessary control and management for PWM motor drive, power supply, and UPS applications.

(1) Care must be taken in the application of V_{BIAS} as not to impose high peak dissipation demands on a relatively small metallized noise dropping resistor (R_{ND}). Prolonged high peak currents may result if +15V_{DC} is applied abruptly and/or if the local bypass capacitor C_{DD} is large. It is suggested that C_{DD} be ≤10MFD. If it is desirable to switch the 15V_{DC} source or if a C_{DD} is larger, additional series impedance may be required.

Functional Description

The SP600 provides a flexible, digitally controlled power function which is intended to be used as PWM drivers of n-channel MOSFETs and/or IGBTs for up to 240VAC line rectified totem-pole applications. The CMOS driveable inputs are filtered and captured by the control logic to determine the output state. The logic includes fixed timing to prohibit simultaneous conduction of the external power switches and, thru the V_{OUT} sense detector, verifies the output voltage state is in agreement with the controlled inputs. The > 11VDC floating power supply required to drive the upper rail external power device is created and managed by the HVIC through Cf and Df. This capacitor is refreshed from the Vdd supply each time V_{OUT} goes low. If the upper channel is commanded on for a long period of time, the bootstrap capacitor Cf is automatically refreshed by bringing V_{OUT} low. This is accomplished by turning off the upper rail MOSFET/IGBT, momentarily turning on the lower rail output device, followed by returning control back to the upper switch. Otherwise, Cf would gradually deplete its charge allowing the upper switch to come out of saturation. The upper and lower gate drivers allow for controlled charge and discharge rates as well as facilitate the use of nearly lossless current sensing power MOS devices. The over current trip level can be boosted 30% on a pulse by pulse basis by logic level '1' applied to I trip select. A $\overline{\text{FAULT}}$ output signal is generated when any of the following occurs:

V bias is low
Over current is detected
V phase doesn't agree with the input signal

Reset of $\overline{\text{FAULT}}$ is provided by externally removing power or by holding both TOP and BOT inputs low for the required reset time (trt_{MAX}).

Each application can be individually optimized by the selection of external components tailored to ensure proper overall system operation including:

Determining the ratings and sizing of MOSFETs and IGBTs, mixed or matched, as well as flyback diodes (FBD).

The selection of separate gate charge (Rc) & discharge (Rd) impedance chosen per the load capacitance, frequency of operation, and Di/Dt dependent recovery characteristics of the associated FBDs. Rd should also be sized to prevent simultaneous bridge conduction by ensuring gate discharge in the allotted turn off pulse width (t_{OFF} MIN).

The selection of over current detection resistors (Rp), compatible with current sense MOSFETs/IGBTs or shunt(s) may be used.

For the floating bootstrap supply Df & Cf must be determined. Df must support the worse case system bus voltage and handle the charging currents of Cf. Proper selection should take into consideration Trr and Tfr per the desired operating frequency. Proper selection of Cf is a trade off between the minimum t_{ON} time of the lower rail to charge up the capacitor, the amount of charge transfer required by the load, and cost. Due to automatic refresh the capacitor is replenished every 350μs TYP (or even sooner if input commands the TOP to switch at a faster repetition rate).

The local filter capacitor (Cdd) should be sized sufficiently large enough to transfer the charge to Cf without causing a significant droop in Vdd. As a rule of thumb it should be at least 10 times larger than Cf and be located adjacent to the Vdd and Vss pins to minimize series resistance and inductance.

Refer to application note AN-8829 for more details about module operation and selection of external components.

SP601

October 1990

Half-Bridge 500 VDC Driver

Features

- 500 Volt Maximum Rating
- Ability to Interface and Drive Standard and Current Sensing n-Channel Power MOSFET/ IGBT Devices
- Creation and Management of a Floating Power Supply for Upper Rail Drive
- Simultaneous Conduction Lockout
- Overcurrent Protection
- Single Low Current Bias Supply Operation
- Latch Immune CMOS Logic
- Peak Drive in Excess of 0.5 Amp

Description

The SP601 is a smart power high voltage integrated circuit (HVIC) optimized to drive MOS gated power devices in half-bridge topologies. It provides the necessary control and management for PWM motor drive, power supply, and UPS applications.

(1) Care must be taken in the application of V_{BIAS} as not to impose high peak dissipation demands on a relatively small metallized noise dropping resistor (R_{ND}). Prolonged high peak currents may result if +15V_{DC} is applied abruptly and/or if the local bypass capacitor C_{DD} is large. It is suggested that C_{DD} be <10MFD. If it is desirable to switch the 15V_{DC} source or if a C_{DD} is larger, additional series impedance may be required.

(2) Consult factory for additional package offerings.

SP630

PRODUCT PREVIEW

March 1991

500 VDC 3 Phase Bridge Driver

Features

- Maximum Rating 500V
- Ability to Interface and Drive N-Channel Power Devices
- Latch-Up Immune CMOS Logic

Applications

- Motor Control
- Compressors
- Heat Pumps
- Air Conditioners
- Appliances
- Industrial Drives

Description

The SP630 is a high voltage integrated circuit (HVIC) optimized to drive MOS gate power devices in 3 phase bridge topologies.

Functional Description

The SP630 driver easily controls 3 upper power switches (either NIGT or NMOS). Logic level signals from 16V to 4.5V referenced to the negative rail of a bridge inverter control these switches. The SP630 provides a very low cost solution to driving bridge inverters.

The SP630 operates on bus voltages to 500VDC and 3 pins of the 18-pin package are strategically placed to enhance creepage and strike clearances to facilitate layout.

Each upper driver section is under-voltage protected and a single "enable" pin controls all upper drivers. A single 15V bias voltage is required for low side power and bootstrapped high side power.

When a bootstrap capacitor voltage falls below the UV-threshold, that switch is turned off. The inductive nature of the load and connections to the load pull the V_S terminal terminal to common or lower (by one diode drop). This charges the bootstrap capacitor until a voltage approximately one volt lower than V_{CC} is sensed, after which the upper driver is allowed to turn on again. Should the users' PWM frequency and minimum off-time of the upper switch be enough to maintain voltage on the bootstrap capacitor above the VUV threshold, then no forced refreshing will occur.

Since turn-on/turn-off and minimum on/off times are short, it is up to the user to provide sufficient dead-time (also known as underlap time) to avoid cross-conduction.

Guidelines for sizing the bootstrap capacitors which are related to V_{CC} voltage, required gate turn-on charge and PWM frequency can be obtained in Harris application note AN9010, **SP606 High Voltage Half Bridge Driver IC.**

MUR810 RUR810 MUR815 RUR815 MUR820 RUR820

8A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers

August 1991

Features

- Ultrafast Recovery Time (t_{rr} < 35ns)
- Low Forward Voltage
- Low Thermal Resistance
- Planar Design
- Wire-Bonded Construction

Applications

- General Purpose
- Power Switching Circuits to 100kHz
- Output Rectification in Switchng Power Supplies

Description

MUR810, MUR815, MUR820 and RUR810, RUR815, RUR820 are low forward voltage drop ultrafast recovery rectifiers (t_{rr} < 50ns). They use a glass-passivated ion-implanted, epitaxial construction.

These devices are intended for use as output rectifiers and flywheel diodes in a variety of high-frequency pulse-width modulated switching regulators. Their low stored charge and attendant fast reverse-recovery behavior minimize electrical noise generation and in many circuits markedly reduce the turn-on dissipation of the associated power switching transistors.

All are supplied in TO-220AC packages.

8A Ultrafast Diode With Soft Recovery Characteristic

May 1991

Features

- Ultrafast with Soft Recovery Characteristic (t_{rr} < 75ns)
- +175°C Rated Junction Temperature
- Reverse Voltage Up to 1000V
- Avalanche Energy Rated

Applications

- Switching Power Supply
- Power Switching Circuits
- General Purpose

Description

MUR870E, MUR880E, MUR890E, MUR8100E and RUR870, RUR880, RUR890, RUR8100 are ultrafast dual diodes (t_{rr} < 75ns) with soft recovery characteristics ($t_a/t_b \approx 0.5$). They have a low forward voltage drop and are of planar, silicon nitride passivated, ion-implanted, epitaxial construction.

These devices are intended for use as energy steering/clamping diodes and rectifiers in a variety of switching power supplies and other power switching applications. Their low stored charge and ultrafast recovery with soft recovery characteristics minimizes ringing and electrical noise in many power switching circuits thus reducing power loss in the switching transistor.

All are supplied in TO-220AC packages.

Definitions

V_F = Instantaneous forward voltage (pw = 300μs, D = 2%).

I_R = Instantaneous reverse current (pw = 300μs, D = 2%).

t_{rr} = Reverse recovery time at dI_F/dt = 100A/μs (See Figure 2), summation of $t_a + t_b$.

t_a = Time to reach peak reverse current at dI_F/dt = 100A/μs (See Figure 2).

t_b = Time from peak I_{RM} to projected zero crossing of I_{RM} based on a straight line from peak I_{RM} through 25% of I_{RM}. (See Figure 2)

$R_{\Theta jc}$ = Thermal resistance junction to case.

W_{avl} = Controlled avalanche energy (See Figures 7 & 8).

pw = pulse width.

D = duty cycle.

15A Ultrafast Diode With Soft Recovery Characteristic

May 1991

Features

- Ultrafast with Soft Recovery Characteristic (t_{rr} < 30ns)
- +175°C Rated Junction Temperature
- Reverse Voltage Up to 200V
- Avalanche Energy Rated

Applications

- Switching Power Supply
- Power Switching Circuits
- General Purpose

Description

MUR1510, MUR1515, MUR1520 and RUR1510, RUR1515, RUR1520 are ultrafast dual diodes (t_{rr} < 30ns) with soft recovery characteristics ($t_a/t_b \approx 1$). They have a low forward voltage drop and are of planar, silicon nitride passivated, ion-implanted, epitaxial construction.

These devices are intended for use as energy steering/clamping diodes and rectifiers in a variety of switching power supplies and other power switching applications. Their low stored charge and ultrafast recovery with soft recovery characteristics minimizes ringing and electrical noise in many power switching circuits thus reducing power loss in the switching transistor.

All are supplied in TO-220AC packages.

Definitions

V_F = Instantaneous forward voltage (pw = 300μs, D = 2%).

I_R = Instantaneous reverse current (pw = 300μs, D = 2%).

t_{rr} = Reverse recovery time at dI_F/dt = 100A/μs (See Figure 2), summation of $t_a + t_b$.

t_a = Time to reach peak reverse current at dI_F/dt = 100A/μs (See Figure 2).

t_b = Time from peak I_{RM} to projected zero crossing of I_{RM} based on a straight line from peak I_{RM} through 25% of I_{RM}. (See Figure 2)

$R_{\Theta jc}$ = Thermal resistance junction to case.

W_{avl} = Controlled avalanche energy (See Figures 7 & 8).

pw = pulse width.

D = duty cycle.

$t_1 \geq 5\ t_a$ (max)
$t_2 > t_{rr}$
$t_3 > 0$
$\frac{L_1}{R_4} \leq \frac{t_a(min)}{10}$

V_1 amplitude controls I_F
V_2 amplitude controls di/dt
L_1 = self inductance of R_4

ULTRA-FAST RECTIFIERS

RUR3070/3080, RUR3090/30100

30A Ultrafast Diode With Soft Recovery Characteristic

August 1991

Features

- Ultrafast with Soft Recovery Characteristic (t_{rr} < 110ns)
- +175°C Rated Junction Temperature
- Reverse Voltage Up to 1000V
- Avalanche Energy Rated
- Planar Construction

Applications

- Switching Power Supply
- Power Switching Circuits
- General Purpose

Description

RUR3070, RUR3080, RUR3090, RUR30100 are ultrafast diodes with soft recovery characteristics (t_{rr} < 110ns). They have a low forward voltage drop and are silicon nitride passivated, ion-implanted, epitaxial construction.

These devices are intended for use as flywheel/clamping diodes and rectifiers in a variety of switching power supplies and other power switching applications. Their low stored charge and ultrafast recovery with soft recovery characteristics minimizes ringing and electrical noise in many power switching circuits thus reducing power loss in the switching transistor.

All are supplied in TO-220AC packages.

RURD810
RURD815
RURD820

Dual 8A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers

August 1991

Features

- Ultrafast Recovery Time (t_{rr} < 35ns)
- Low Forward Voltage
- Low Thermal Resistance
- Planar Design
- Wire-Bonded Construction

Applications

- General Purpose
- Power Switching Circuits to 100kHz
- Full-Wave Rectification

Description

The RURD810, RURD815, RURD820 are low forward voltage drop ultrafast rectifiers (t_{rr} < 35ns). They use a glass passivated ion-implanted, epitaxial construction.

These devices are intended for use as output rectifiers and flywheel diodies in a variety of high frequency pulse width modulated and switching regulators. Their low stored charge and attendant fast reverse recovery behavior minimize electrical noise generation and in many circuits markedly reduce the turn-on dissipation of the associated power switching transistors.

All are supplied in TO-220AB plastic packages.

15A Ultrafast Dual Diode With Soft Recovery Characteristic

May 1991

Features

- Ultrafast with Soft Recovery Characteristic (t_{rr} < 30ns)
- +175°C Rated Junction Temperature
- Reverse Voltage Up to 200V
- Avalanche Energy Rated

Applications

- Switching Power Supply
- Power Switching Circuits
- General Purpose

Description

MUR3010CT, MUR3015CT, MUR3020CT and RURD1510, RURD1515, RURD1520 are ultrafast dual diodes (t_{rr} < 30ns) with soft recovery characteristics ($t_a/t_b \approx 1$). They have a low forward voltage drop and are of planar, silicon nitride passivated, ion-implanted, epitaxial construction.

These devices are intended for use as energy steering/ clamping diodes and rectifiers in a variety of switching power supplies and other power switching applications. Their low stored charge and ultrafast recovery with soft recovery characteristics minimizes ringing and electrical noise in many power switching circuits thus reducing power loss in the switching transistor.

All are supplied in TO-218AC packages.

15A Ultrafast Dual Diode With Soft Recovery Characteristic

May 1991

Features

- Ultrafast with Soft Recovery Characteristic (t_{rr} < 55ns)
- +175°C Rated Junction Temperature
- Reverse Voltage Up to 600V
- Avalanche Energy Rated

Applications

- Switching Power Supply
- Power Switching Circuits
- General Purpose

Description

MUR3040CT, MUR3050CT, MUR3060CT and RURD1540, RURD1550, RURD1560 are ultrafast dual diodes (t_{rr} < 55ns) with soft recovery characteristics ($t_a/t_b \approx 1$). They have a low forward voltage drop and are of planar, silicon nitride passivated, ion-implanted, epitaxial construction.

These devices are intended for use as energy steering/clamping diodes and rectifiers in a variety of switching power supplies and other power switching applications. Their low stored charge and ultrafast recovery with soft recovery characteristics minimizes ringing and electrical noise in many power switching circuits thus reducing power loss in the switching transistor.

All are supplied in TO-218AC packages.

Dual 16A High-Speed, High-Efficiency Epitaxial Silicon Rectifiers

August 1991

Features

- Ultrafast Recovery Time (t_{rr} < 35ns)
- Low Forward Voltage
- Low Thermal Resistance
- Planar Design
- Wire-Bonded Construction

Applications

- General Purpose
- Power Switching Circuits to 100kHz
- Full-Wave Rectification

Description

The RURD1610, RURD1615, RURD1620 are low forward voltage drop ultrafast rectifiers (t_{rr} < 35ns). They use an ion-implanted planar epitaxial construction.

These devices are intended for use as output rectifiers and flywheel diodies in a variety of high frequency pulse width modulated and switching regulators. Their low stored charge and attendant fast reverse recovery behavior minimize electrical noise generation and in many circuits markedly reduce the turn-on dissipation of the associated power switching transistors.

All are supplied in TO-204AA hermetic packages.

UNDERSTANDING POWER MOSFETs

Author: Tom McNulty

Power MOSFETs (Metal Oxide Semiconductor, Field-Effect Transistors) differ from bipolar transistors in operating principles, specifications, and performance. In fact, the performance characteristics of MOSFETs are generally superior to those of bipolar transistors: significantly faster switching time, simpler drive circuitry, the absence of a second-breakdown failure mechanism, the ability to be paralleled, and stable gain and response time over a wide temperature range. This Note provides a basic explanation of general MOSFET characteristics, and a more thorough discussion of structure, thermal characteristics, gate parameters, operating frequency, output characteristics, and drive requirements.

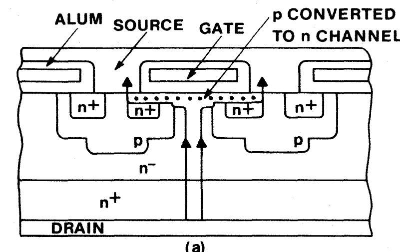
General Characteristics

A conventional n-p-n bipolar power transistor is a current-driven device whose three terminals (base, emitter, and collector) are connected to the body by silicon contacts. Bipolar transistors are described as minority-carrier devices in which injected minority carriers recombine with majority carriers. A drawback of recombination is that it limits the device's operating speed. And because of its current-driven base-emitter input, a bipolar transistor present a low-impedance load to its driving circuit. In most power circuits, this low-impedance input requires somewhat complex drive circuitry.

By contrast, a power MOSFET is a voltage-driven device whose gate terminal, Fig. 1(a), is electrically isolated from its silicon body by a thin layer of silicon dioxide (SiO_2). As a majority-carrier semiconductor, the MOSFET operates at much higher speed than its bipolar counterpart because there is no charge-storage mechanism. A positive voltage applied to the gate of an n-type MOSFET creates an electric field in the channel region beneath the gate; that is, the electric charge on the gate causes the p-region beneath the gate to convert to an n-type region, as shown in Fig. 1(b). This conversion, called the surface-inversion phenomenon, allows current to flow between the drain and source through an n-type material. In effect, the MOSFET ceases to be an n-p-n device when in this state. The region between the drain and source can be represented as a resistor, although it does not behave linearly, as a conventional resistor would. Because of this surface-inversion phenomenon, then, the operation of a MOSFET is entirely diffent from that of a bipolar transistor, which always retain its n-p-n character.

By virture of its electrically-isolated gate, a MOSFET is described as a high-input impedance, voltage-controlled device, whereas a bipolar transistor is a low-input-impedance, current-controlled device. As a majority-carrier semiconductor, a MOSFET stores no charge, and so can switch faster than a bipolar device. Majority-carrier semiconductors also tend to slow down as temperature increases. This effect, brought about by another phenomenon called carrier mobility (where mobility is a term that defines the average velocity of a carrier in terms of the electrical field imposed on it) makes a MOSFET more resistive at elevated temperatures, and much more immune to the thermal-runaway problem experienced by bipolar devices.

A useful byproduct of the MOSFET process is the internal parasitic diode formed between source and drain, Fig. 1(c). (There is no equivalent for this diode in a bipolar transistor other than in a bipolar darlington transistor.) Its characteristics make it useful as a clamp diode in inductive-load switching.



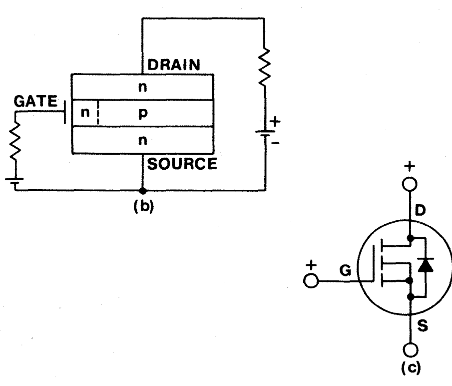


Fig. 1 - The MOSFET, a voltage-controlled device with an electrically isolated gate, uses majority carriers to move current from source to drain (a). The key to MOSFET operation is the creation of the inversion channel beneath the gate when an electric charge is applied to the gate (b). Because of the MOSFET's construction, an integral diode is formed on the device (c), and the designer can use this diode for a number of circuit functions.

Structure

Harris Power MOSFETs are manufactured using a vertical double-diffused process, called VDMOS or simply DMOS. A DMOS MOSFET is a single silicon chip structured with a large number of closely packed, hexagonal cells. The number of cell varies according to the dimensions of the chip. For example, a 120-mil^2 chip contains about 5,000 cells; a 240-mil^2 chip has more than 25,000 cells.

One of the aims of multiple-cells construction is to minimize the MOSFET parameter $r_{DS(on)}$, or resistance from drain to source, when the device is in the on-state. When $r_{DS(on)}$ is minimized, the device provides superior power-switching performance because the voltage drop from drain to source is also minimized for a given value of drain-to-source current.

Since the path between drain and source is essentially resistive, because of the surface-inversion phenomenon, each cell in the device can be assumed to contribute an amount, R_n, to the total resistance. An individual cell has a fairly low resistance, but to minimize $r_{DS(on)}$, it is necessary to put a large number of cells in parallel on a chip. In general, therefore, the greater the number of paralleled cells on a chip, the lower its $r_{DS(on)}$ value:

$r_{DS(on)} = R_N/N$

where N is the number of cells.

In reality, $r_{DS(on)}$ is composed of three separate resistances. Fig. 2 shows a curve of the three resistive components for a single cell and their contributions to the overall value of $r_{DS(on)}$. The value of $r_{DS(on)}$ at any point of the curve is found by adding the values of the three components at that point:

$r_{DS(on)} = R_{bulk} + R_{chan} + R_{ext}$

where R_{chan} represents the resistance of the channel beneath the gate, and R_{ext} includes all resistances resulting from the substrate, solder connections, leads, and the package. R_{bulk} represents the resistance resulting from the narrow neck of n material between the two p layers, as shown in Fig. 1(a), plus the resistance of the current path below the neck and through the body of the device to the drain.

Note in Fig. 2 that R_{chan} and R_{ext} are completely independent of voltage, while R_{bulk} is highly dependent on applied voltage. Note also that below about 150 volts, $r_{DS(on)}$ is dominated by the sum of R_{chan} and R_{ext}. Above 150 volts, $r_{DS(on)}$ is increasingly dominated by R_{bulk}. Table I gives a percentage breakdown of the contribution of each resistance for three values of voltage.

Two conclusions, inherent consequences of the laws of semiconductor physics, and valid for any DMOS device, can be drawn from the preceding discussion: First, $r_{DS(on)}$ obviously increases with increasing breakdown-voltage capability of a MOSFET. Second, minimum $r_{DS(on)}$ performance must be sacrificed if the MOSFET must withstand ever-higher breakdown voltages.

The significance of R_{bulk} in devices with a high voltage capability is due to the fact that thick, lightly doped epi layers are required for the drain region in order to avoid producing high electric fields (and premature breakdown) within the device. And as the epi layers are made thicker and more resistive to support high voltages, the bulk component of resistance rapidly increases (see Fig. 2) and begins to dominate the channel and external resistance. The $r_{DS(on)}$ therefore, increases with increasing breakdown voltage capability, and low $r_{DS(on)}$ must be sacrificed if the MOSFET is to withstand even higher breakdown voltages.

There is a way around these obstacles. The $r_{DS(on)}$ in Fig. 2 holds only for a relatively small chip. Using a larger chip results in a lower value for $r_{DS(on)}$ because a large chip has more cells (See Fig. 3). A larger chip also increases MOSFET breakdown voltage capability.

The penalty for using a larger chip, however, is an increase in cost, since chip size is a major cost factor. And because chip area increases exponentially, not linearly, with voltage, the additional cost can be substantial. For example, to obtain a given $r_{DS(on)}$ at a breakdown voltage twice as great as the original, the new chip requires an area four or five times larger than the orginal. Although the cost does not rise exponentially, it is substantially more than the original cost.

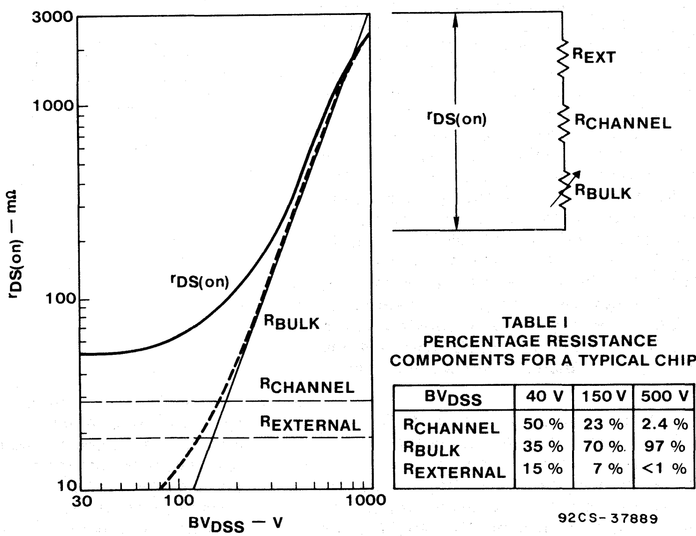

TABLE I
PERCENTAGE RESISTANCE COMPONENTS FOR A TYPICAL CHIP

BV_{DSS}	40 V	150 V	500 V
$R_{CHANNEL}$	50 %	23 %	2.4 %
R_{BULK}	35 %	70 %	97 %
$R_{EXTERNAL}$	15 %	7 %	<1 %

Fig. 2 - The drain-to-source resistance ($r_{DS(on)}$) of a MOSFET is not one but three separate resistance components.

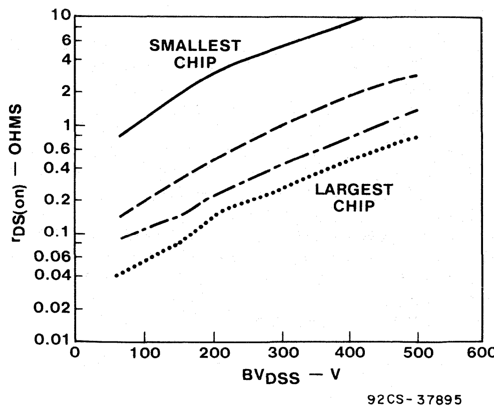

Fig. 3 - As chip size increases, $r_{DS(on)}$ decreases, and voltage handling capability increases.

Effects of Temperature

The high operating temperatures of bipolar transistors are a frequent cause of failure. The high temperatures are caused by hot-spotting, the tendency of current in a bipolar device to concentrate in areas around the emitter. Unchecked, this hot-spotting results in the mechanism of thermal runaway, and eventual destruction of the device. MOSFETs do not suffer this disadvantage because their current flow is in the form of majority carriers. The mobility of majority carriers (where, again, mobility is a term that defines the average velocity of a carrier in terms of the electrical field imposed on it) is temperature dependent in silicon: mobility decreases with increasing temperature. This inverse relationship dicates that the carriers slow down as the chip gets hotter. In effect, the resistance of the silicon path is increased, which prevents the concentrations of current that lead to hot spots. In fact, if hot spots do attempt to form in a MOSFET, the local resistance increases and defocuses or spreads out the current, rerouting it to cooler portions of the chip.

Because of the character of its current flow, a MOSFET has a positive temperature coefficient of resistance, as shown by the curves of Fig. 4.

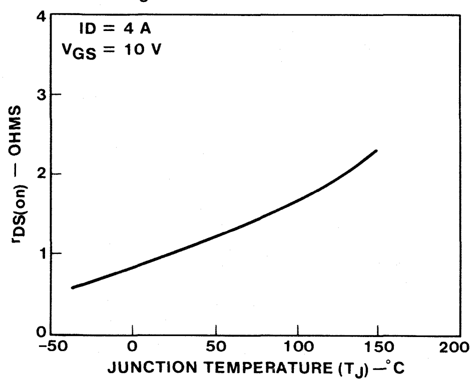

Fig. 4 - MOSFETs have a positive temperature coefficient of resistance, which greatly reduces the possibility of thermal runaway as temperature increases.

The positive temperature coefficient of resistance means that a MOSFET is inherently stable with temperature fluctuation, and provides its own protection against thermal runaway and second breakdown. Another benefit of this characteristic is that MOSFETs can be operated in parallel without fear that one device will rob current from the others. If any device begins to overheat, its resistance will increase, and its current will be directed away to cooler chips.

Gate Parameters

To permit the flow of drain-to-source current in an n-type MOSFET, a positive voltage must be applied between the gate and source terminals. Since, as described above, the gate is electrically isolated from the body of the device, theoretically no current can flow from the driving source into the gate. In reality, however, a very small current, in the range of tens of nanoamperes, does flow, and is identified on data sheets as a leakage current, I_{GSS}. Because the gate current is so small, the input impedance of a MOSFET is extremely high (in the megohm range) and, in fact, is largely capacitive rather than resistive (because of the isolation of the gate terminal).

Fig. 5 illustrates the basic input circuit of a MOSFET. The elements are equivalent, rather than physical, resistance, R, and capacitance, C. The capacitance, called C_{iss} on MOSFET data sheets, is a combination of the device's internal gate-to-source and gate-to-drain capacitance. The resistance, R, represents the resistance of the material in the gate circuit. Together, the equivalent R and C of the input circuit determine the upper frequency limit of MOSFET operation.

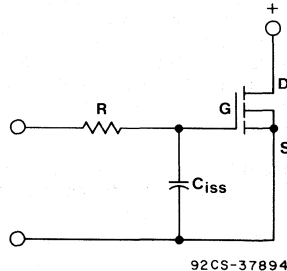

Fig. 5 - A MOSFET's switching speed is determined by its input resistance R and its input capacitance C_{iss}.

Operating Frequency

Most DMOS processes develop the polysilicon gate structure rather than the older metal-gate type. If the resistance of the gate structure (R in Fig. 5) is high, the switching time of the DMOS device is increased, thereby reducing its upper operating frequency. Compared to a metal gate, a polysilicon gate has a higher gate resistance. This property accounts for the frequent use of metal-gate MOSFET in high-frequency (greater than 20 MHz) applications, and polysilicon-gate MOSFETs in higher-power but lower-frequency systems.

Since the frequency response of a MOSFET is controlled by the effective R and C of its gate terminal, a rough estimate can be made of the upper operating frequency from data-sheet parameters. The resistive portion depends on the sheet resistance of the polysilicon-gate overlay structure, a value of approximately 20 Ω/□. But whereas the total R value is not found on data sheets, the C value (C_{iss}) is; it is recorded as both a maximum value and in graphical form as

a function of drain-to-source voltage. The value of C_{iss} is closely related to chip size; the larger the chip, the greater the value. Since the RC combination of the input circuit must be charged and discharged by the driving circuit, and since the capacitance dominates, larger chips will have slower switching times than smaller chips, and are, therefore, more useful in lower-frequency circuits. In general, the upper frequency limit of most power MOSFETs spans a fairly broad range, from 1 to 10 MHz.

Output Characteristics

Probably the most used MOSFET graphical data is the output characteristics or plot of drain-to-source voltage (V_{DS}) as a function of drain-to-source current (I_D). A typical characteristic, shown in Fig. 6, gives the drain current that flows at various V_{DS} values as a function of the gate-to-source voltage ($_{gs}$). The curve is divided into two regions: a linear region in which V_{DS} is small and drain current increases linearly with drain voltage, and a saturated region in which increasing drain voltage has no effect on drain current (the device acts as a constant-current source). The current level at which the linear portion of the curve joins with the saturated portion is called the pinch-off region.

Drive Requirements

When considering the V_{gs} level required to operate a MOSFET, note, from Fig. 6, that the device is not turned on (no drain current flows) unless V_{gs} is greater than a certain level (called the threshold voltage). In other words, the threshold voltage must be exceeded before an appreciable increase in drain current can be expected. Generally V_{gs} for many types of DMOS devices is at least 2 volts. This is an important consideration when selecting devices or designing circuits to drive a MOSFET gate: the gate-drive circuit must provide at least the threshold-voltage level, but preferably, a much higher one.

As Fig. 6 shows, a MOSFET must be driven by a fairly high voltage, on the order of 10 volts, to ensure maximum saturated drain-current flow. However, integrated circuits, such as TTL types, cannot deliver the necessary voltage levels unless they are modified with external pull-up resistors. Even with a pull-up to 5 volts, a TTL driver cannot fully saturate most MOSFETs. Thus, TTL drivers are most suitable when the current to be switched is far less than the rated current of the MOSFET. CMOS ICs can run from supplies of 10 volts, and these devices are capable of driving a MOSFET into full saturation. On the other hand, a CMOS driver will not switch the MOSFET gate circuit as fast as a TTL driver. The best results, whether TTL or CMOS ICs provide the drive, are achieved when special buffering chips are inserted between the IC output and gate input to match the needs of the MOSFET gate.

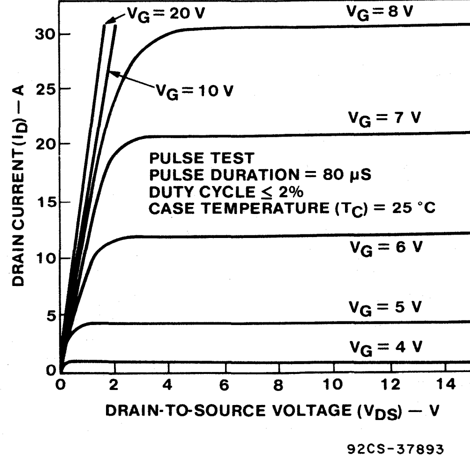

Fig. 6 - MOSFETs require a high input voltage (at least 10 V) in order to deliver their full rated drain current.

SWITCHING WAVEFORMS OF THE L^2FET: A 5 VOLT GATE-DRIVE POWER MOSFET

Author: C. Frank Wheatley, Jr. and Harold R. Ronan, Jr.

The switching waveforms of a newly announced series of power-MOSFET devices called Logic-Level-FETs (L^2FETs) and featuring a 5-volt gate drive are presented and contrasted with those of the more conventional 10-volt-gate-drive devices. A new method of characterizing MOSFET switching performance is discussed in which the MOSFET is treated as a vertical JFET driven in cascode from a low-voltage lateral MOS. The 2:1 advantage in rise and fall-time and the 4:1 reduction in switching "dynamic V(sat)" dissipation with constant drive power of the L^2FET over the 10-volt MOSFET are demonstrated and discussed.

BACKGROUND

A new series of power-MOSFET devices called Logic-Level FETs, or L^2FETs, is compatible with the 5-volt power supply used for logic circuitry. L^2FETs retain the on-resistance, drain-current, and blocking-voltage ratings of their 10-volt predecessors, but operate from a much less costly 5-volt supply.

The reduction in gate-drive voltage is the result of halving the thickness of the gate insulator from the industry standard 100 nm to 50 nm (500 Å). Since the surface inversion of the MOS channel is determined by the gate-insulator voltage field, halving the insulator thickness halves the applied gate voltage without compromising drain characteristics.

The apparent conclusion from a study of the switching waveforms of the new device that halving the gate-oxide thickness would double the gate capacitance and halve the switching speed does not prove true. Measurements demonstrate empirically a 2:1 increase in switching speed for the L^2FET over its 100-nm predecessor, where gate drive power is the same for both devices. The "dynamic V(sat)" dissipation is lowered by a factor of four. The apparent anomalies are explained with the aid of a new method of switching characterization developed by treating the power MOSFET as a grounded-gate, depletion-mode, vertical JFET driven in cascode by a grounded-source, enhancement-mode, lateral MOS. The waveforms and switching characterization methods are described in detail below.

L^2FET Characteristics Compared to Standard Types—A Brief Review

Thirty-two different power MOSFETs of the L^2FET structure have been announced. These devices were designed to be totally interchangeable with the standard power MOSFET with respect to output characteristics, while offering twice the gate sensitivity, as shown in Figs. 1, 2, and 3, which are comparisons of the industry-standard RFM10N15 with its Logic-Level-FET counterpart, the RFM10N15L. (Although the L suffix notation in the type number will ultimately be valid for the entire product matrix, the L^2FET product currently available is limited to n-channel devices handling 200 volts or less, with 15 ampere ratings or less.)

Figs. 1 and 2 are plots of drain current versus drain voltage with gate voltage as the running parameter. The L^2FET gate voltage is in parenthesis. The low-drain-voltage curves of Fig. 2 demonstrate that R_{on} has not been sacrificed in the L^2FET. Fig. 3 is the transfer characteristic comparison for

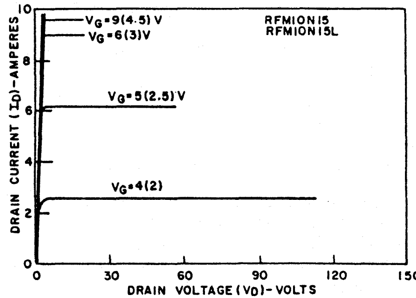

Fig. 1 - Drain-current versus drain-voltage curves for representative standard and L^2FET devices.

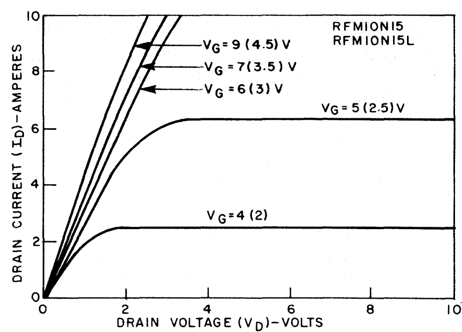

Fig. 2 - Drain-current versus low-drain-voltage curves for representative standard and L^2FET devices demonstrating that R_{on} has not been sacrificed in the L^2FET.

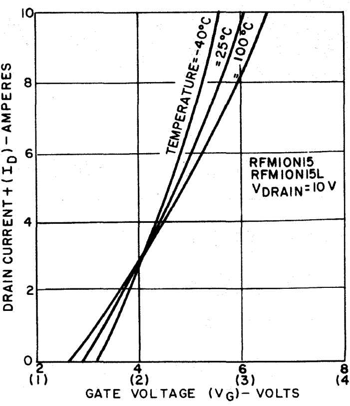

Fig. 3 - Transfer characteristic.

three different temperatures. The abscissa has two scales to reflect the different gate sensitivities; again, L^2FET values are in parentheses. It is evident from this curve that:

1. The threshold voltage is scaled down by a factor of two for the L^2FET.
2. The threshold-voltage temperature coefficient in mV/° C is scaled down.
3. The current level for zero temperature coefficient is unchanged.
4. The transconductance is scaled up by a factor of two.

All other L^2FETs have similar relationships to their respective predecessors.

SWITCHING WAVEFORMS WITH CONVENTIONAL DRIVE

The first concern when comparing devices with such a large difference of transfer sensitivity is one of "other things being equal." If the standard device is driven between zero and ten volts with an R_g of 25 ohms, impedance transformation dictates that the L^2FET should be driven between zero and five volts with an R_g of 6-1/4 ohms, thereby transforming open-circuit voltage and short-circuit current by factors of 2 (or 1/2). With these parameters, either drive system will supply a peak R_g, or generator dissipation, of one watt.

Fig. 4 displays the drain voltage versus time of the RFM10N15 and the RFM10N15L when each is driven as described above with a 5-ampere, 75-volt resistive load line. The time scale is 100 nanoseconds per division. The table under the graph compares on-delay time, rise time, off-delay time, and fall time for each device. The times are measured in the normal manner, that is, involving the 10% and 90% points of the input-voltage and output-voltage waveforms.

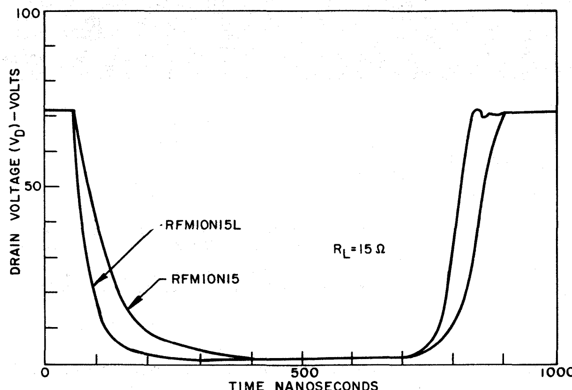
Note that:

1. The rise and fall times are not symmetrical.
2. The L^2FET is faster.
3. There is a "dynamic V(sat)" type of behavior.
4. The "dynamic V(sat)" is of a lesser amplitude for the L^2FET.

These observations are discussed below.

SWITCHING WAVEFORMS WITH CONSTANT CURRENT DRIVE

The power MOSFET is a current-driven device during transitions due to the charging or discharging of capacitances. In actual applications, most drive circuits exhibit a first-order approximation to a constant current where the



Type	Gate Drive	R_g (ohms)	td(on) (ns)	t(rise) (ns)	td(off) (ns)	t(fall) (ns)
RFM10N15 (100 nm)	0-10V	25	15	120	123	73
RFM10N15L (50 nm)	0-5V	6.25	11	57	104	62

Fig. 4 - Drain voltage versus time curves for representative standard and L^2FET devices.

voltage compliance is determined by ground potential or the drive-circuit power-supply voltage. The on current may not equal the off current; this situation is addressed below.

Fig. 5 presents the curves for the RFM10N15 and RFM10N15L when each is driven from a current generator whose $I_{g1} = I_{g2}$, with gate-voltage limits of zero and 10 or (5) volts. The drive current is kept the same for both devices in this case even though the L^2FET receives less drive power or energy. The value for I_{g1} and I_{g2} was chosen as 5 mA; the time scale is 1 μs/division.

Note that:

1. The rise and fall times of a given device are the same with current drive.
2. The two devices have similar output waveforms in most regions.
3. There is a persistent "dynamic V(sat)" even at slow switching speeds.

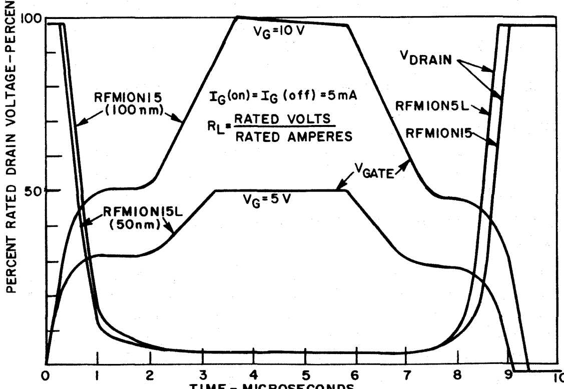


Fig. 5 - Characterization curves for representative devices driven from a current generator.

4. The "dynamic V(sat)" curves are symmetrical during the low-drain-voltage portion of the turn-on and turn-off portion.
5. The "dynamic V(sat)" curves are lower in amplitude by a factor of approximately two for the L^2FET.

LARGE-SIGNAL EQUIVALENT CIRCUIT OF THE MOSFET

If we are to understand the differences and similarities of the L^2FET relative to the conventional power MOSFET, the conventional power MOSFET must first be understood. Fig. 6 shows a properly proportioned cross-sectional view of the power MOSFET.

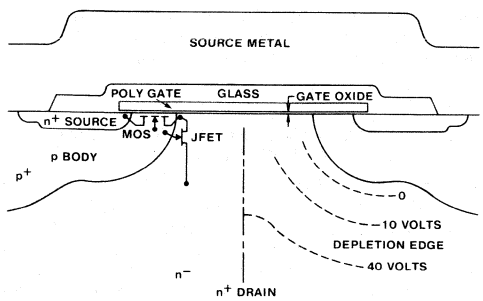

Fig. 6 - Cross section of power MOSFET.

When the drain voltage is very low and the gate is forward biased, an accumulation layer exists for the n^- region beneath the gate. This layer may be thought of as serving the function of the drain for the lateral MOS. In addition, it serves as a source for a vertical depletion-mode JFET. The gate of the JFET is formed by the body diffusion, particularly in the neck region. The JFET drain is the n^+ region usually thought of as being the MOSFET drain. This situation is shown in Fig. 6, where the cross-sectional view of the MOSFET is shown. The lateral MOS and the vertical JFET are schematically implied by the left half of Fig. 6. The right half indicates the edge of the depletion width for several drain voltages. Note how the JFET pinches off, such that increased drain voltage is supported predominately by the JFET. This structure is schematically represented as shown in Fig. 7. Note that the third-quadrant diode is caused by the p-n junction associated with the gate and drain characteristic (common to all JFETs). A parasitic n-p-n transistor is not shown, nor is it discussed in this Note. Voltage node (4) is within the device, and is not precisely a single node, as represented.

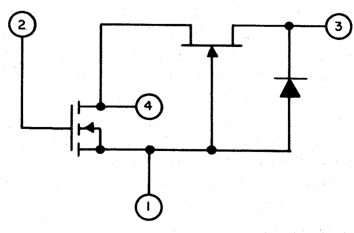

Fig. 7 - Schematic representation of the cross section of Fig. 6.

Interelectrode Capacitance

The equivalent circuit of Fig. 7 contains four voltage nodes. Therefore, six capacitors will exist to couple these nodes. The switching waveforms are determined by these capacitors and the small-signal equivalent circuit of the MOS and the JFET. Of course, the MOS and JFET small-signal equivalent circuits are nonlinear functions of voltage and current and invariant with frequency. Similarly, the capacitors are nonlinear with voltage and current.

Industry data sheets show three-terminal characterization of this four-node network at zero drain current. Under this condition, the transconductance and output resistance are zero and infinity for both the MOS and the JFET. This condition reduces the power MOSFET to the capacitor network of Fig. 8, which may be replaced by three capacitors. Note that this situation is valid only when no MOSFET current flows.

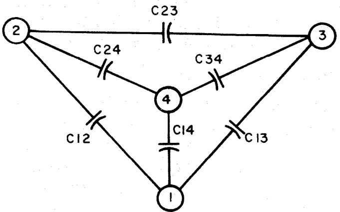

Fig. 8 - Capacitor-network representation of the power MOSFET.

When current does flow, node (4) of Fig. 7 is a low-impedance node due to the source-follower characteristic of the JFET. Similarly, nodes (1) and (3) are generally low impedance nodes by virtue of the ground reference and the load resistance. Therefore, capacitive currents will usually be significant only to the input node, (2). Capacitors C_{12}, C_{23}, and C_{24} are examined below over most of the switching regime when current is flowing.

Gate-To-Source Capacitance, C_{12}

When all of the die except the actual MOSFET cells are ignored, Fig. 6 shows that the gate-to-source capacitance (C_{12}) is that from the poly gate upward through the thick oxide to the source metal. In addition, there is a contribution from the poly gate to the n^+ source through the thin gate oxide. Additionally a fringing capacitance exists at the edge of the polysil gate. These components of C_{12} are invariant with voltage and current. There is a fourth component from the poly gate to a region about half way along the MOS channel through the gate oxide. This component is actually distributed, and varies somewhat with current and voltage.

Gate-To-Drain Capacitance, C_{23}

Capacitor C_{23} exists only when no accumulation layer is present beneath the poly gate. Otherwise, the accumulation layer acts as an electrostatic shield. This layer exists whenever the drain voltage immediately beneath the gate oxide is essentially negative relative to the poly gate. In addition, the capacitive coupling from drain to gate diminishes greatly when the JFET is pinched off. Therefore, C_{23} exists for only a small range of drain voltage. In addition, it should decrease rapidly as the pinch-off voltage level is approached because the effective area of concern is closed off similarly to the aperture of a camera (for a hex cell).

Gate-to-Internal-Electrode Capacitance, C_{24}

Capacitor C_{24} is rather large for positive gate voltages. It is made up of that area between the poly gate and the accumulation layer, plus some of the area between the poly gate and the middle of the MOS channel. In both cases, the dielectric is the thin gate oxide. So long as the gate voltage is positive relative to the n^- layer beneath the poly gate, the accumulation layer exists and C_{24} is invariant. This accumulation layer ceases to exist when the external drain voltage minus the IR drop through the n^- neck region approximately equals the gate voltage. The area associated with the accumulation layer (JFET cathode) rapidly decreases with increased drain voltage. In addition, a depletion layer may now form, leading to a further reduction of C_{24}.

WAVEFORMS EXPECTED FROM THE MODEL

The following discussion relates the prior model discussion to the waveforms of Fig. 5. The discussion begins with the gate voltage at +5 or +10 volts and the gate current equal to zero. This condition corresponds to saturated behavior, where the drain current is approximately equal to $I_D(max)$ and the drain voltage equals $I_D(max)$ times $r_{DS}(on)$.

Gate-Voltage Slope — t_{off} Delay

As time progresses, I_g = –5 mA, which must flow through $C_{12} + C_{23} + C_{24}$ of Fig. 8 because the MOS and the JFET are both heavily biased into conduction. Therefore, $dV_4/dt = dV_3/dt$ = nearly 0. With large positive gate bias and drain voltage near zero, C_{23} is zero and C_{12} and C_{24} are constant. As a result, the gate voltage should be a straight line with a slope equal to:

$$dV_g/dt = I_g/(C_{12} = C_{24}) \quad (1)$$

Gate-Voltage Plateau

As the gate voltage decreases, the drain voltage will increase imperceptibly at first until the gate voltage drops enough to bias the MOS into its constant-current mode. At this point, the very high transconductance of the MOS is consistent with very little change in gate voltage to reduce the current by several percent. Several percent change in drain current corresponds to many volts in drain voltage. As a result, the gate current no long flows from C_{12} during the constant gate-voltage plateau.

Drain-Voltage Shallow Slope

Since C_{23} is still zero, all gate current must flow from C_{24}. Assuming that the gate voltage is plateaued and that the JFET is still heavily forward biased, node 4 of Fig. 7 must ramp at a linear rate. Therefore, the JFET must also ramp at this same rate.

$$dV_d/dt = I_g/C_{24} \quad (2)$$

Again this curve will approximate a straight line.

Drain-Transition Voltage

As mentioned above, C_{24} rapidly decreases once the drain voltage is slightly greater than the gate voltage. (Actually, this voltage is the n^- voltage directly beneath the gate oxide, and differs from the drain voltage by an amount nearly equal to $I_D r_{DS}[on]$.)

Since the drain voltage is still fairly low and the drain current has not changed much, the gate plateau voltage still exists. Equation 2 still applies except that the value of C_{24} has materially decreased and C_{23} has become finite. This situation results in a substantial increase in dV_d/dt.

JFET Pinch-Off Voltage — Drain-Voltage Steep Slope

As the drain voltage approaches the pinch-off voltage of the JFET, the JFET comes out of saturation and starts to support MOSFET drain voltage. The voltage gain of the active JFET permits large changes in the JFET drain voltage for small changes in its source-to-gate voltage. But the JFET source-to-gate voltage is the lateral MOS drain-to-source voltage, which is dominated by equation 2 (but for low values of C_{24}).

Gate-Voltage Curvature from Plateau

As the drain voltage increases, the drain current decreases. This condition requires significant decrease in gate voltage until the gate threshold is approached. A significant portion of the gate current must now flow through C_{12}. This flow produces a gradual transition in the gate voltage and some slowing of the drain-voltage waveform.

Gate-Voltage Slope — t(on) Delay

When the drain is totally off, most of the gate current flows from C_{12}. Again, this capacitance is constant, so that the waveform is a straight line with a slope equal to:

$$dV_g/dt = I_g/C_{12} \quad (3)$$

NEW SWITCHING CHARACTERIZATION FOR POWER MOSFETS

The above discussion suggests that a new method of characterization may be provided for resistive switching with power MOSFETs, where constant-current gate drive is employed during the transition time.[1] The below method bears some similarity to the gate-charge concept.[2] The state of the gate charge is a continuous plot in this work, however, rather than a single point. This approach permits a knowledge of all waveforms with any drive circuitry, rather than just the total elapsed time. In addition, the total elapsed time is fixed (at just under 50 microseconds) by choosing the required value of constant gate current. Circuit designers are usually more comfortable with milliamperes and microseconds (although the product is charged in nanocoulombs).

Test Circuit — Drive

A test circuit is shown in Fig. 9. The heart of this circuit is the Harris CA3280 integrated circuit. This is an operational transconductance amplifier (OTA) operated as a comparator. An OTA is a current output circuit where the output current and output transconductance are programmed by the amplifier bias current (I_{ABC}). Internal chip circuit feedback assures an extremely high output impedance within a compliance range established by the supply voltages. The circuit of Fig. 9 is actually two OTA's in parallel. The linearizing diodes on this chip are not used.

A value of I_{ABC} is established from the collector of the 2N4036. The current into the load (the gate of the MOSFET under test) may be varied between $+I_{ABC}$ and $-I_{ABC}$ times a constant of proportionality (approximately 0.9). The actual value depends upon the input differential-input voltage. As a comparator, the differential voltage is large, resulting in saturated behavior of $\pm I_{ABC}$. If the gate voltage comes within a volt of the rail voltages, this current goes to zero, producing a clamping voltage. For the purposes of this Note, these supply voltages are adjusted to clamp 0 volts and +10 volts for the normal n-channel MOSFET. The behavior of this IC is excellent from submicroamperes to about 2.5 mA. Higher current may be achieved by stacking many CA3280 packages one on top of another and soldering the leads to parallel the chips rather than wiring many sockets. However, this arrangement may require an increase in the bypass-capacitor values.

A CA3240E MOS input op amp is used as a unity gain follower. Otherwise, the 1 megohm or 10 megohm shunting impedance of the scope would load the high-impedance circuitry associated with the MOSFET gate.

Fig. 9 - Test circuit. 92CS-37501

Testing Conditions

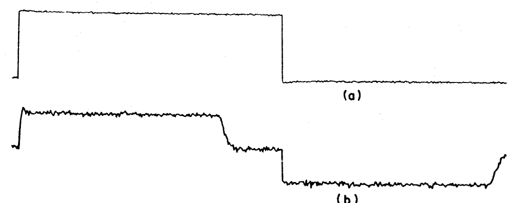
A pulse generator is set for 50-μs on-time duration and approximately 25-ms repetition rate (about 0.2% duty cycle). The $\pm$ clamp voltages are set to the appropriate values. The power-MOSFET load resistor is chosen to equal the maximum-rated voltage divided by the maximum-rated current.

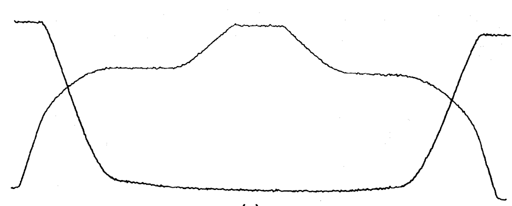
With a low value of drain supply voltage, observe the gate voltage while adjusting I_{ABC}. A convenient set of conditions occurs when a short dwell time of several microseconds exists at the +10-volt level. Minor adjustments may be desired for I_{ABC} as the drain supply voltage is increased to maximum-rated value. The L^2FETs would be tested at +5-volts gate clamp.

Fig. 10 exhibits the pertinent waveforms for an RFM15N15. All power MOSFETs have similar waveforms. Fig. 10(a) is the 3-volt signal to the CA3280. Fig. 10(b) is the power-MOSFET gate current. In this example, the amplitude is $\pm$1 mA with a third state of 0 mA. Fig. 10(c) displays the gate voltage and the drain voltage, 10 volts peak-to-peak and 150 volts peak-to-peak. Fig. 10(d) is a piece-wise linear approximation of Fig. 10(c). The datum line is zero volts and applies to both waveforms. The time scale of the waveforms of Fig. 10 is 100 microseconds full scale.

There are some features of the gate and drain-voltage waveforms that should be noted. These features are consistent with the equivalent-model discussion.

1. The waveforms during the positive gate-current time are symmetrical to those during the negative gate-current time. Exceptions will occur for very fast or very slow switching, and for nonsymmetrical current drive. These exceptions are discussed below.
2. The drain-voltage waveform contains a rather steep slope with a fairly constant dv/dt over most of the drain-voltage excursion.
3. The drain voltage contains a rather shallow slope with a fairly constant dv/dt over the remainder of the drain-voltage excursion.
4. The drain transition voltage (defined as the intercept of the above two near straight lines) typically occurs when the drain voltage equals the sum of the gate voltage (at that instant of time) plus the product of the drain current times r_{DS}(on).
5. The gate-voltage waveform contains three near-straight-line segments during the positive-gate-current transition time.





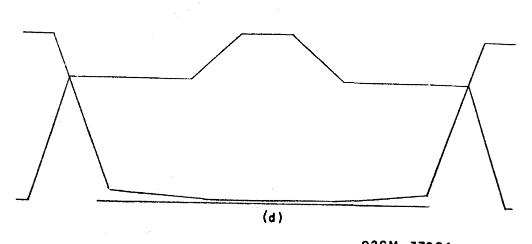


Fig. 10 - (a) 3-volt signal to the CA3280, (b) power-MOSFET gate current, (c) gate and drain voltage, (d) piece-wise linear approximation of 10(c).

Application of the Switching Data

Fig. 11 is a family of curves similar to Fig. 10(c), where the drain supply voltage is fixed at four values. Note that the ordinate is 10-volts full scale for the gate voltage, while it is normalized to 100% of maximum-rated drain voltage for the drain-voltage curves. All four sets of curves are taken with a predetermined gate current, $\pm I_T$. The abscissa is also normalized to 100 (I_T/I_g) microseconds full scale, where I_g is the actual gate-drive current. With this characteristic curve, switching behavior may be readily predicted for almost any driving circuit, provided the load is resistive.

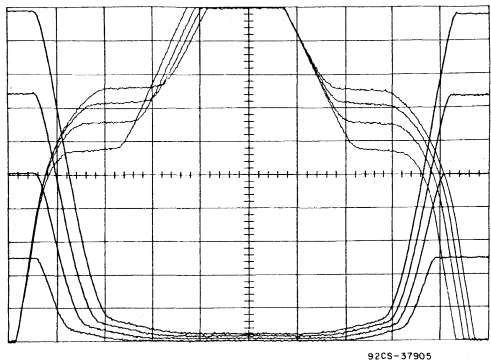

Fig. 11 - Curves similar to those of Fig. 10(c) with drain supply voltage fixed at four values.

Symmetrical Current Drive

Waveforms of Fig. 11 will scale in an inverse manner with gate current. Driving current was varied from ±200 mA to ±2 μA for the device of Fig. 11. Measurements of delay time (on), rise time, delay time (off), and fall time are plotted in Fig. 12 and compared to the inverse scaling suggested by Fig. 11.

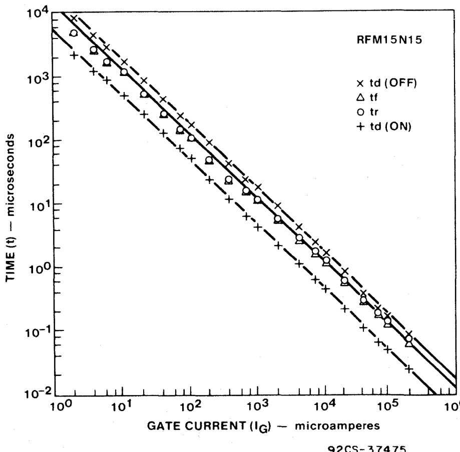

Fig. 12 - Various time measurements compared to the inverse scaling suggested by Fig. 11.

It is anticipated that very slow switching (in the millisecond region) will result in the chip thermally tracking the power dissipation, which would cause some deviation from the inverse scaling. This condition was not noted on Fig. 12 for gate currents as low as ±2 μA.

Large gate currents result in very fast switching waveforms. The gate of each hex cell is accessed through a gate pad and gate runners, which are of a low resistivity metal followed by buried polysilicon of a moderate resistivity. As a result, the high gate currents cause a propagation delay to exist for those cells far removed from the gate runners. This effect is not seen in Fig. 12, even though the gate current was increased to ±200 mA.

Asymmetrical Current Drive

The positive and negative gate drive will often be dissimilar. Of course, the scaling must reflect this situation. At other times the gate current varies with amplitude. This condition is always true when driving from a pulse generator of fixed resistance. Piece-wise linear methods will yield the gate current, which will permit the proper piece-wise linear scaling. This calculation could be done in the following manner:

1. Mark eleven small x's along the gate waveform of Fig. 11, dividing it into 10 equal voltage segments; for example, V_g = 0, 1, 2, ... 9, 10 volts.
2. Draw a vertical line through each x the full height of the figure, creating 10 time segments.
3. If the driving-pulse amplitude is 0 to 10 volts with an internal resistance of 100 ohms, calculate the piece-wise linear gate current for each time segment. I_{g1} = (10 - 0.5)/100 = 95 mA, I_{g2} = (10 - 1.5)/100 = 85 mA, etc.
4. Then scale each waveform within the pertinent time segment by the proper gate current.
5. Smooth the curves.
6. Create 10 more time segments for the right half of Fig. 11 corresponding to an average gate voltage of 9.5, 8.5, ... 1.5, 0.5 volts. Call these segments 11, 12, ... 19, 20.
7. In that the pulse-generator voltage is now zero volts, calculate I_g as:
   I_{g11} = (0 - 9.5)/100 = -95 mA, I_{g12} = (0 - 8.5)/100 = -85 mA, etc.
8. Repeat 4 and 5. L^2FETs would be treated with smaller voltage segments.

Generally, the gate-voltage plateau of Fig. 11 will not be located at the middle of the pulse-generator amplitude (5 volts). As a result, rise and fall times measured this way experience differing gate currents and are "nonsymmetrical". This type of measurement will also lead one to observe temperature sensitivities, load-current sensitivities, and device-to-device variability, all of which are more circuit dependent than device dependent.

Source-Lead Inductance

The gate-voltage waveforms may be corrected by the voltage across the source-lead inductance and external inductance, which may be mutually common to the input and output current loops. This voltage, L di/dt, may be approximated and applied to the gate-voltage waveform after scaling Fig. 12 for the actual gate currents. Generally, this effect is not appreciable for gate current small relative to ±100 mA. A very loose circuit wiring arrangement with inches of mutually common source wire will exaggerate this effect.

GATE-VOLTAGE PROPAGATION EFFECTS

Most power-MOSFET applications need switch no faster than tenths of a microsecond, but should faster switching be required, this section will become important. It must be understood that the power MOSFET appears as a distributed network of many cells when used for very fast switching.

The thousands of individual MOSFET cells are connected in parallel with highly conductive metal for the sources and drains. However, the gates are paralleled with a moderately conductive film of doped polysilicon. As a result, a very steep voltage wavefront applied to the gate pad will bias those cells close by, but a delay will occur for turn on or turn off. Because of the nonlinear "input capacitance" of each cell, the delay cannot be characterized by a pure number of so many nanoseconds.

Presently, most manufacturers characterize typical switching speed for a single test condition. The test conditions are usually chosen to present the most favorable result, usually near the upper limit of usefulness.

Figs. 13(a), (b), and (c) show the increasing effect of gate-voltage propagation. The gate waveform is the only one shown because the drain is not affected so drastically. This is true because some cells are overdriven, offsetting the effect of the starved cells. Care must be exercised when operating with large gate effects similar to those of Fig. 13(c).

Gate-propagation effects may be reduced by the following design methods:

1. Many gate runners.
2. More conductive polysilicon.
3. Silicide rather than polysilicon gates.
4. Less cells (resulting in lower transconductance and higher R_{ON}).
5. Substantially different lateral and vertical structure.
6. High-frequency packaging.

None of the above methods will yield "breakthrough" devices unless used in combination.

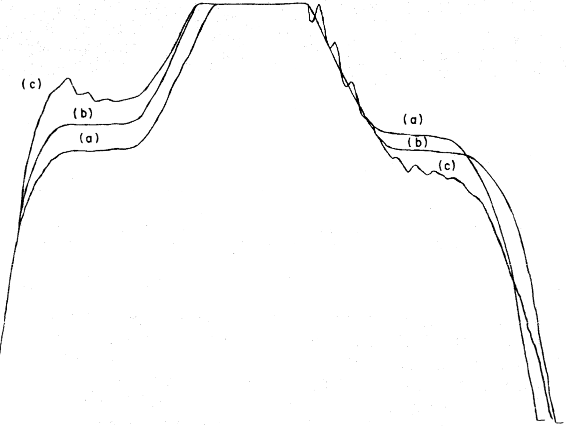

Fig. 13 - Curves showing the increasing effect of gate-voltage propagation.

Any of the above methods require trade-offs which would not be attractive to the needs of most components users. These trade-offs are in the realm of:

1. Reduction of R_{ON} per unit area.
2. Decreased yield.
3. Added cost (beyond the cost of yield impact).
4. RFI, self-oscillation, and other problems characteristic of very fast devices.

POWER MOSFET SWITCHING WAVEFORMS: A NEW INSIGHT

Author: Harold R. Ronan, Jr. and C. Frank Wheatley, Jr.

The examination of power MOSFET voltage and current waveforms during switching transitions reveals that the device characterization now practiced by industry is inadequate. In this Note, device waveforms are explained by considering the interaction of a vertical JFET driven in cascode from a lateral MOSFET in combination with the interelectrode capacitances. Particular attention is given to the drain-voltage waveform and its dual-slope nature. The three terminal capacitances now published by the industry are shown to be valid only for zero drain current. For cases where the gate drive is a voltage step generator with internal fixed resistance, the drain voltage characteristics are inferred from the gate current drive behavior and compared to observed waveforms. The nature of the "asymmetric switching times" is explained.

A waveform family is proposed as a more descriptive and accurate method of characterization. This new format is a plot of drain voltage and gate voltage versus normalized time. A family of curves is presented for a constant load resistance with V_{DD} varied. Gate drive during switching transitions is a constant current with voltage compliance limits of 0 and 10 volts. Time is normalized by the value of gate driving current. The normalization shows excellent agreement with data over five orders of magnitude, and is bounded on one extreme by gate propagation effects and on the other by transition time self-heating (typically tens of nanoseconds to hundreds of microseconds).

DEVICE MODELS

The keystone of an understanding of power MOSFET switching performance is the realization that the active device is bimodal and must be described using a model that accounts for the dual nature. Buried in today's power MOSFET devices is the equivalent of a depletion layer JFET that contributes significantly to switching speed. Fig. 1 is a cross-sectional view of a typical power MOSFET, with MOSFET/JFET symbols superimposed on the structure.

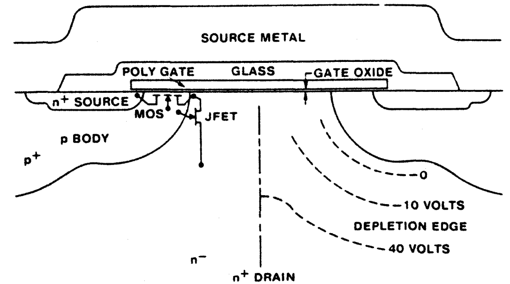

Fig. 1 - Cross-sectional view of MOSFET showing equivalent MOS transistor and JFET.

Fig. 2 is obtained by taking the lateral MOS and vertical JFET from this conception and adding all the possible node-to-node capacitances. Computed values of the six capacitances for a typical device structure suggest that device behavior may be adequately modeled using only three capacitors in the manner of Fig. 3. This is the model to be employed for analysis and study.

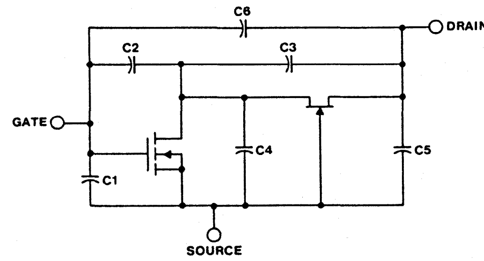

Fig. 2 - MOS transistor with cascode-connected JFET and all capacitors.

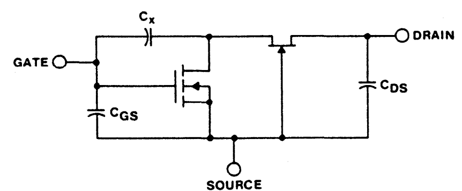

Fig. 3 - Fig. 2 simplified.

GATE DRIVE: CONSTANT VOLTAGE OR CONSTANT CURRENT

Before moving on to the study of the equivalent circuit states of the model, a gate-drive forcing function which is easy to represent, relates to reality, and best illustrates device behavior must be chosen. The choice may be immediately narrowed to two:

(1) An instantaneous step voltage with internal resistance R, Fig. 4.
(2) An instantaneous step current with infinite internal resistance, Fig. 5.

Power MOSFET devices are highly capacitive in nature; hence, simple capacitor responses to the forcing functions offer a good vehicle for comparison. The advantageous choice is immediately obvious: Fig. 5. Voltage/time responses dominated by capacitance are straight lines (when constant current is used). The slope of these lines is

proportional to current and inversely proportional to capacitance. Analytically, then, constant current is most convenient. It is quite another matter, however, to build a bidirectional current drive that is accurate across the many decades of both current and time required to establish experimental verification.

SIX STATES

To completely characterize power MOSFET switching waveforms, the six states that a device assumes, Fig. 6, must be addressed:

STATE	MOS	JFET
Turn-on 1	Off	Off
Turn-on 2	Active	Active
Turn-on 3	Active	Saturated*
Turn-off 4	Saturated	Saturated
Turn-off 5	Active	Saturated
Turn-off 6	Active	Active

*The term saturated is taken to mean a constant low-voltage drain-source condition.

Equivalent Circuit

The lumped-parameter model of Fig. 3, with the cascode-connected JFET, can now be reduced to the linear equivalent circuit of Fig. 7, and the six device states investigated from full off to full on.

State 1: MOS Off, JFET Off

In a power-MOSFET device, no drain current will flow until the device gate threshold voltage, V_T, is reached. During this time, the gate current drive is only charging the gate-source capacitance. More accurately, I_G is charging C_{iss} ($C_{iss} = C_{GS} + C_{GD}$, C_{DS} shorted), the capacitance designation published by the industry.

The current generators, g_mV_G and $g_{mJ}V_x$ are open circuits for zero drain current, and R_L is presumed to be so low as to represent a short circuit (generally true for practical applications). This is academic however since C_{GS} is very much larger that C_6. The time to reach threshold, then, is simply:

$$t = \frac{C_{iss} V_T}{I_G}$$

State 2: MOS Active, JFET Active

This state graphically illustrates the dramatic influence that the JFET has on the power MOSFET drain-voltage waveform. Instead of having to discharge Cx from V_{DD} to ground, the lateral MOSFET need only swing v_x to ground, a much smaller voltage thanks to the grounded gate JFET. Since

the interaction of R_L with the device capacitances has a second-order effect on the drain voltage, the equivalent circuit of Fig. 7 predicts a drain voltage change of:

$$dv_G/dt = g_m R_L I_G/[C_{GS} + C_x(1 + g_m/g_{mJ})]$$

In all but the smallest power-MOSFET devices, C_x is several thousand picofarads and g_m/g_{mJ} is of the order of 3:1. Power-MOSFET devices exhibit a high dv_D/dt switching rate because of the cascode-connected JFET, not because C_{rss} ($C_{rss} = C_{GD}$) is a small value, as zero-drain-current data-sheet capacitance values might lead one to believe. If C_{rss} were, in actuality, small, long drain voltage tails would not exist. The tail response is a direct result of JFET saturation. In order to delineate the transition from state 2 to state 3, a drain voltage at which the transition occurs must be defined. V_{DK} is the knee voltage at which linear extrapolations of drain-voltage slopes intersect. The time duration of state 2 is:

$$t = (V_{DD} - V_{DK})[C_{GS} + C_x(1 + g_m/g_{mJ})]/g_m R_L I_G$$

State 3: MOS Active, JFET Saturated

When the JFET saturates, the $g_{mJ}v_x$ current generator becomes a short circuit and the equivalent circuit predicts:

$$dv_D/dt = g_m R_L I_G/[C_{GS} + C_x(1 + g_m R_L)]$$

This is the Miller effect so often referred to in older texts that describe the behavior of grounded-cathode vacuum-tube amplifier circuits. Allowing for the fact that $1 + g_m R_L$ is approximately equal to $g_m R_L$ and $C_x(1 + g_m R_L)$ is very much larger than C_{GS}, the expression for drain-voltage tail time is:

$$t = (V_{DK} - V_D[sat])C_x/I_G$$

State 4: MOS Saturated, JFET Saturated (Turn-Off)

In this state, in addition to $g_{mJ}V_x$ being shorted, the $g_m V_G$ current generator is shorted, and I_G is occupied with charging C_x and C_{GS}, in parallel, from the peak value of V_G to V_G(sat). The time required for this is:

$$t = (V_G - V_G(sat)(C_{GS} + C_x)/I_G$$

Since a value for C_{GS} may be measured independently of switching time, the method described is the simplest way of determining C_x.

On turn-off, the state time equations are equally applicable, but in reverse order (states 5 and 6); see the idealized waveform of Fig. 4.

Experimental Verification

The four switching states just analyzed indicate that for a given device, all four switching state times are inversely proportional to the magnitude of the gate drive current. Fig. 8 illustrates the switching performance of a typical power MOSFET across three decades of gate drive current and time. In each case the data slope is almost a perfect -1.

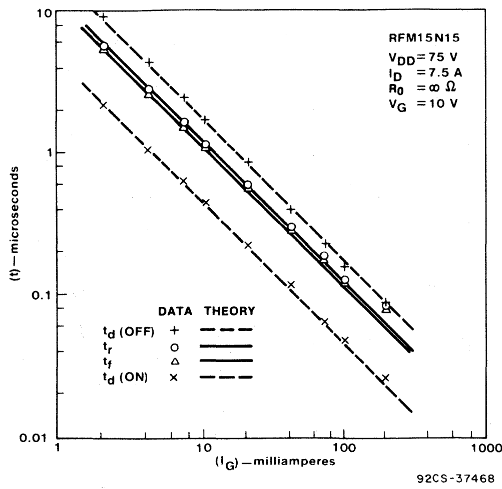

Fig. 8 - Constant gate current switching time.

Fig. 9 is such a plot for the RFM15N15 power MOSFET. With such a plot, a designer can estimate device switching performance under any resistive gate/drain conditions.

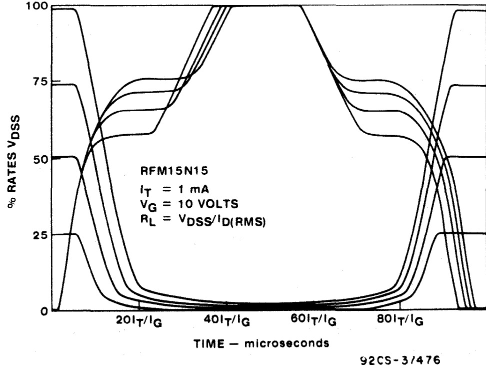

Fig. 9 - Normalized RFM15N15 switching waveforms for constant gate-current drive.

A NEW DEVICE CHARACTERIZATION

Fig. 8 could not be a reasonable device data sheet presentation because it does not give the designer any information on a typical value for C_x, nor does it convey how V_{DK}, g_m, g_m/g_{mJ}, and V_G(sat) vary with drain current. What would be of enormous value to the designer is a plot of $v_D(t)$, $v_G(t)$ for selected values of V_{DD} and I_D within device ratings. A reasonable characterization would be as follows:

1. The x axis would be normalized in terms of gate current drive.
2. The y axis would be normalized in terms of percent maximum rated V_D (0 to 100%).
3. $R_L = V_D(max)/I_D(max)$ would define the drain load resistance.
4. Four plots of $v_D(t)$, $v_G(t)$ at 100%, 75%, 50%, and 25% V_D(max) would be shown.

STEP-VOLTAGE GATE DRIVE

The majority of power MOSFET applications employ a step gate-voltage input with a finite source resistance R_o. Often R_o for turn-on is not the same as R_o for turn-off. How can switching times for these situations be estimated using the switching characterization curves just described? The analysis for resistive step voltage inputs, which is complex because the gate current is no longer constrained to be constant, but is a function of device gate-voltage response, is covered in Appendix A. (A second, shorter appendix, B, has been added to illustrate the estimation of R_o for some practical gate drive circuits.) Table I summarizes the common switching equations, and indicates the appropriate I_G to be used in each state for relating step voltage drives to the characterization curves.

Table I - Common Switching Equations

	CONSTANT CURRENT	STATE	CONSTANT VOLTAGE
TURN ON		STATE 1: MOS OFF, JFET OFF	
	$t = \frac{C_{iss} V_T}{I_G}$		$t = R_o C_{iss} \ln \frac{[1]}{[1 - V_T/V_G]}$
	$I_G = I_T$	STATE 2: ACTIVE, ACTIVE	$I_G = (V_G - V_T)/R_o$
		$t = \frac{[V_{DD} - V_{DK}]\,[C_{GS} + C_x(1 + g_m/g_{mJ})]}{g_m R_L I_G}$	
	$I_G = I_T$	STATE 3: ACTIVE, SATURATED	$I_G = (V_G - V_{Gsat})/R_o$
		$t = \frac{(V_{DK} - V_{Dsat})C_x}{I_G}$	
TURN OFF	$I_G = -I_T$	STATE 4: SATURATED, SATURATED	$I_G = -V_G/R_o$
	$t = \frac{(C_{GS} + C_x)(V_G - V_{Gsat})}{I_G}$		$t = R_o(C_{GS} + C_x) \ln (V_G/V_{Gsat})$
	$I_G = -I_T$	STATE 5: ACTIVE, SATURATED	$I_G = -V_{Gsat}/R_o$
		$t = \frac{(V_{DK} - V_{Dsat})C_x}{I_G}$	
	$I_G = -I_T$	STATE 6: ACTIVE, ACTIVE	$I_G = -V_{Gsat}/R_o$
		$t = \frac{[V_{DD} - V_{DK}]\,[C_{GS} + C_x(1 + g_m/g_{mJ})]}{g_m R_L I_G}$	

92CS-37469

Experimental Verification

Since the switching equations for step currents and voltages differ only by gate-current magnitudes for the same device type, one would expect a plot of switching time versus $1/R_o$ to be of the same form as those obtained for a step current drive. This is exactly the case, as Fig. 10 is merely a variation of Fig. 8. Using the relationships of Table I, the observed differences between Figs. 7 and 9 can be pinpointed. The two sets of experimental curves confirm that, on the basis of the short-circuit drive current V_G/R_o equalling the constant I_G, $t_d(on)$, t_r, $t_d(off)$, and t_f will all be longer, as predicted by the ratios of the gate drive currents of Table I. Notice also that t_r, t_f switching symmetry is disrupted by the use of a step voltage with source resistance R_o.

For states 2 and 6 the time ratio is:

$$\frac{t_{turn\text{-}on}}{t_{turn\text{-}off}} = \frac{V_G(sat)}{V_G - V_T}$$

For states 3 and 5 the time ratio is:

$$\frac{t_{turn\text{-}on}}{t_{turn\text{-}off}} = \frac{V_G(sat)}{V_G - V_G(sat)}$$

Utilization of available maximum gate drive voltage and current can be optimized for fastest power MOSFET switching speed through the use of constant-current gate drive at the expense of increased gate-drive circuit complexity.

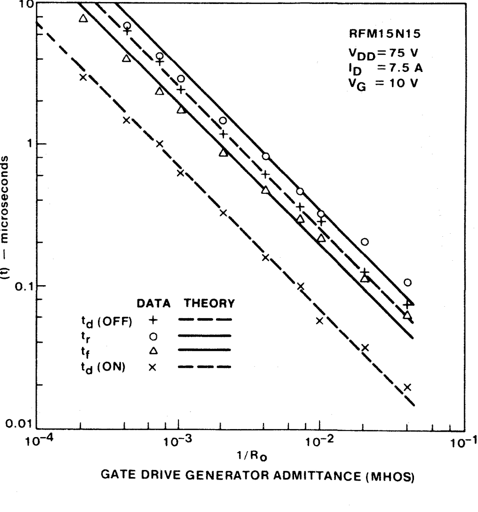

Fig. 10 - Constant gate voltage switching time.

USING THE CHARACTERIZATION CURVES, FIG. 9

To estimate the switching times for an RFM15N15 power MOSFET under the conditions $V_G = 10V$, $V_{DD} = 75V$, $R_o = 100$ ohms, and $R_L = 10$ ohms, proceed as follows.

State 1: MOS Off, JFET Off

This time can be estimated without recourse to the curves.

$$t = 100(1200\times10^{-12})\ \ln[1/(1 - 4/10)]$$

$$t = 61\ \text{ns}$$

State 2: MOS Active, JFET Active

$$I_G = (10 - 4)/100 = 60\ \text{mA}$$

$$t = \frac{(\text{curve divisions}) \times I_T\ \mu s}{60} = \frac{9}{60} = 150\ \text{ns}$$

State 3: MOS Active, JFET Saturated

$$I_G = (10 - 7)/100 = 30\ \text{mA}$$

$$t = \frac{(\text{curve division}) \times I_T\ \mu s}{30} = \frac{14}{30} = 467\ \text{ns}$$

State 4: MOS Saturated, JFET Saturated

$$C_{GS} + C_x = (\text{gate voltage slope})\ (\text{test current})$$
$$= (1.5 \times 10^{-6}\text{s}/5\ \text{volts})\ (10\ \text{mA})$$
$$= 3000\ \text{pF}$$

$$t = 100(3000 \times 10^{-12})\ \ln[10/6.6]$$

$$t = 125\ \text{ns}$$

State 5: MOS Active, JFET Saturated

$$I_G = 6.6/100 = 66\ \text{mA}$$

$$t = \frac{(\text{curve divisions}) \times I_T\ \mu s}{66} = \frac{8}{66} = 121\ \text{ns}$$

Fig. 11 shows RFM15N15 waveforms using the conditions specified in the example.

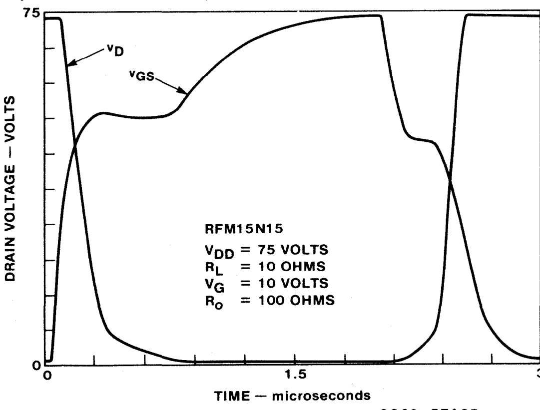

Fig. 11 - Step gate voltage input to an RFM15N15.

State	Calculated Time (t_c, ns)	Measured Time (t_m, ns)	Ratio (t_c/t_m)
1	61	60	1.02
2 + 3	671	670	0.92
4	125	137	0.91
5 + 6	318	375	0.85

For peak gate voltages other than 10 volts, and load resistances other than $V_{DSS}/I_{D(rms)}$, the equations of Table I may be used in conjunction with slope estimates from the characterization curves for C_x and $C_{GS} + C_x(1 + g_m/g_{mJ})$ at the appropriate drain-current level.

CHARACTERIZATION-CURVE LIMITS

The switching-time range over which the characterization can be applied is very impressive. For gate currents of the order of microamperes, device dissipation is the limiting factor. For gate currents of the order of amperes, the device response will be slowed by gate propagation delay. This delay, of course, degrades the linear switching relationship to gate current. However, as Fig. 12 graphically shows, the characterization is valid across five decades of gate current and switching time, allowing all but a very few switching applications to be described by the characterization curves of Fig. 9.

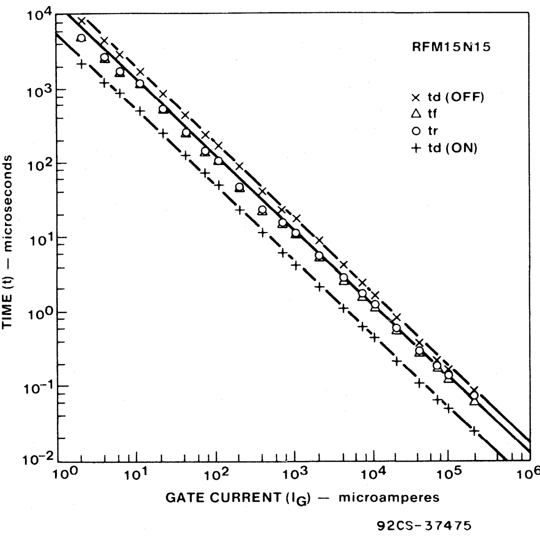

Fig. 12 - Five decades of linear response.

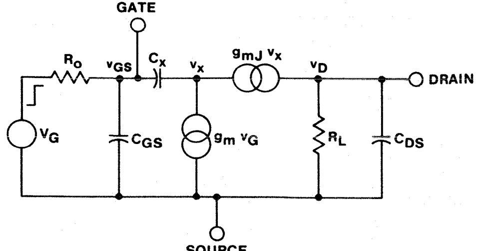
CONCLUSIONS

The viability of the proposed characterization curves using constant current has been demonstrated and the limits of application defined. The existence of a vertical JFET in a power MOSFET makes data-sheet capacitances of little use for estimating switching times. The classical method of defining switching time by 10% and 90% is a poor representation for power MOSFETs because of the dual-slope nature of the drain waveforms. Switching influences are masked because the 10% level is controlled by one mechanism and the 90% level by another. Device comparisons based on the classical switching definition can be very misleading.

APPENDIX A - ANALYSIS FOR RESISTIVE STEP VOLTAGE INPUTS

STEP VOLTAGE GATE DRIVE

To obtain the necessary relationships, six device switching states must be examined using the same device equivalent circuit as was used for the constant-gate-current case, but with the forcing function replaced with a step voltage with internal resistance R_o, Fig. A-1.



LEGEND

92CS-37470

Fig. A-1 - Power MOSFET equivalent circuit.

STATE 1: MOS OFF, JFET OFF

As before, both current generators are open circuits, reducing the equivalent circuit to simply charging C_{iss} through R_o.

$$t = R_oC_{iss}\ln(1/(1 - V_T/V_G))$$

$$I_{PK1} = V_G/R_o$$

STATE 2: MOS ACTIVE, JFET ACTIVE

Before proceeding, it is wise to examine an actual device response and make use of available simplifications. Fig. A-2 shows $i_G(t)$ and $i_D(t)$ for a typical power MOSFET driven by a step gate voltage. For truly resistive switching, realize that these waveforms are only mirror images of their voltage counterparts $v_G(t)$ and $v_D(t)$. Using Fig. A-2, applicable gate currents for each of the device states may be listed.

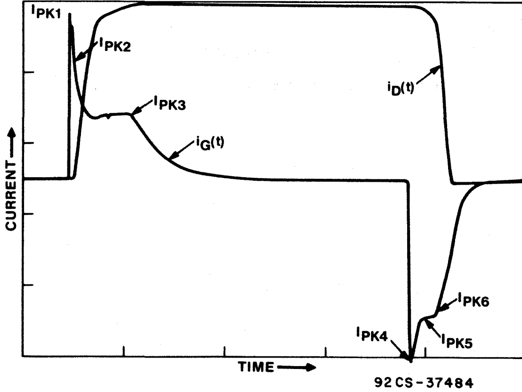

Fig. A-2 - $i_G(t)$ and $i_D(t)$ for a typical power MOSFET driven by a step gate voltage.

Turn-On

State 1: MOS Off, JFET Off
$I_{PK1} = V_G/R_o$

State 2: MOS Active, JFET Active
$I_{PK2} = (V_G - V_T)/R_o$

State 3: MOS Active, JFET Saturated
$I_{PK3} = (V_G - V_G(sat))/R_o$

Turn-Off

State 4: MOS Saturated, JFET Saturated
$I_{PK4} = V_G/R_o$

State 5: MOS Active, JFET Saturated
$I_{PK5} = V_G(sat)/R_o$

State 6: MOS Active, JFET Active
$I_{PK6} = V_G(sat)/R_o$

The equivalent circuit of Fig. A-1 predicts that:

$$dv_D/dt = -g_mR_L(V_G - V_T)e^{-t/T1}/T1$$

where $T_1 = R_oC_{GS} + (1 + g_m/g_{mJ})R_oC_x$

Note that $g_mR_L(V_G - V_T)$ is usually an order of magnitude greater than V_{DD}, indicating that the drain voltage is discharging toward a very large negative value. The device operation, then, is on the early, almost linear, portion of the exponential, where $e^{-t/T1}$ approximates unity. The drain current of Fig. A-2, and hence the drain voltage, does indeed exhibit a linear decrease with time.

Thus, for state 2:

$$t = \frac{[V_{DD} - V_{DK}][C_{GS} + C_x(1 + g_m/g_{mJ})]}{g_mR_L\,I_{PK2}}$$

where $I_{PK2} = (V_G - V_T)/R_o$

STATE 3: MOS ACTIVE, JFET SATURATED

Because of the Miller effect, the gate voltage and, hence, the gate current, is almost constant during the tail time. The equivalent circuit then predicts:

$$\frac{dv_D}{dt} = \frac{g_mR_LI_G}{C_{GS} + (1 + g_mR_L)C_x} = \frac{I_G}{C_x}$$

$$I_G = I_{PK3} = (V_G - V_G[sat])/R_o$$

$$\text{and } t = \frac{(V_{DK} - V_D[sat])C_x}{I_{PK3}}$$

STATE 4: MOS SATURATED, JFET SATURATED (TURN-OFF)

Both equivalent-circuit generators are short circuits, and the gate drive is discharging C_x in parallel with C_{GS} through R_o.

$$t = R_o(C_{GS} + C_x)\ln[V_G/V_G(sat)]$$

$$I_{PK4} = V_G/R_o$$

APPENDIX A (Cont'd)

STATE 5: MOS ACTIVE, JFET SATURATED

The JFET current generator $v_x g_{mJ}$ remains shorted and the MOS generator, $v_G g_m$, is operative.

$$t = \frac{(V_{DK} - V_D[sat])C_x}{I_{PK5}}$$

$I_{PK5} = V_G(sat)/R_o$

STATE 6: MOS ACTIVE, JFET ACTIVE

The Miller effect is now reduced by the activation of $V_G g_{mJ}$, and the equivalent circuit predicts:

$$t = \frac{[V_{DD} - V_{DK}][C_{GS} + C_x(1 + g_m/g_{mJ})]}{g_m R_L I_{PK6}}$$

$I_{PK6} = V_G(sat)/R_o$

APPENDIX B - ESTIMATING R_O FOR SOME TYPICAL GATE-DRIVE CIRCUITS

CASE 1: TYPICAL PULSE-GENERATOR DRIVE, FIG. B-1

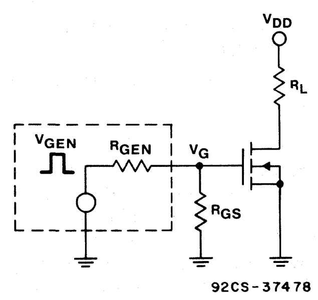

Fig. B-1 - Typical pulse-generator drive circuit.

Turn-On and Turn-Off

$R_o = R_{GEN}R_{GS}/(R_{GEN} + R_{GS})$

For the typical case where R_{GEN} = 50 ohms, and a coaxial-cable termination of 50 ohms, R_o = 25 ohms and $V_G = V_{GEN}/2$

CASE 2: VOLTAGE-FOLLOWER GATE DRIVE, FIG. B-2

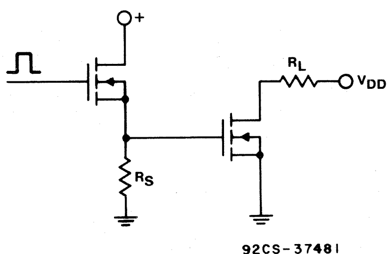

Fig. B-2 - Voltage-follower gate-drive circuit.

Turn-On

R_o is approximately equal to $1/g_m$ for R_s very much greater than $1/g_m$.

g_m = transconductance of driving MOSFET transistor.

Turn Off

$R_o = R_s$

CASE 3: COMMON-SOURCE GATE DRIVE, FIG. B-3

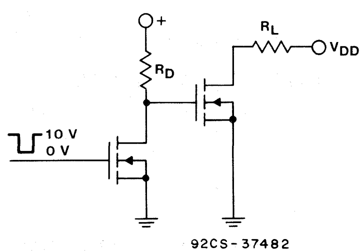

Fig. B-3 - Common-source gate-drive circuit.

Turn-On

THE APPLICATION OF CONDUCTIVITY-MODULATED FIELD-EFFECT TRANSISTORS

Author: Jack Wojslawowicz

SUMMARY

The development of conductivity-modulated field-effect transistors, FETs, makes available to the system designer another solid-state device that can be used to implement power switching control. This paper reviews differences between the standard and the newly developed FET. It shows the significant advantages that the conductivity-modulated FET has over the standard FET. Several applications are presented to show that this new type of device works well in practical situations. The relative inmaturity of the conductivity-modulated FET may limit its initial utilization. But as the family grows and product innovation and refinement takes place, this newest member of the power semiconductor family will become a viable alternative to the other members.

GENERAL CONSIDERATIONS

The development of the power field-effect transistor has made available to the power-stage designer an entire new family of power semiconductors. Over the past 5 to 6 years, the breadth of product has grown to encompass the requirements of a large number of applications. A limiting factor that has slowed the utilization of power FETs in the high-current, high-voltage applications is the fact that the on-state resistance ($R_{DS}(on)$) in a standard FET is related to its breakdown voltage (BV_{DSS}) by a nearly cubic power, i.e., $R_{DS}(on) \approx BV_{DSS}$ 2.8. What this implies, as Fig. 1 shows, is that as the breakdown voltage increases, the on-state resistance climbs even faster.

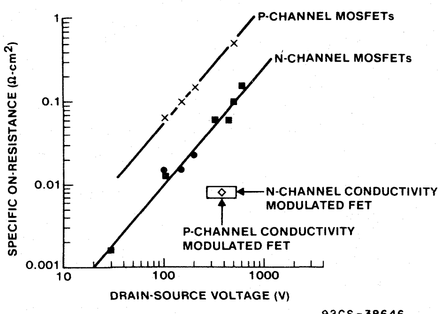

Fig. 1 - Specific on-resistance of p and n-channel MOSFETs and conductivity-modulated FETs versus forward blocking voltage.

The MOSFET on-state resistance is contributed to primarily by three components of the transistor: the MOS channel, the neck region, and the extended drain region. The extended drain region contributes the most to the on-state resistance in high-voltage MOSFETs. To achieve a lower on-state resistance at a given blocking voltage, the usual technique is simply to make the die larger. However, increasing the die size has its limitations from a manufacturing point of view, since MOSFETs, with their very fine horizontal geometries, are highly defect-yield sensitive. As die size increases, the likelihood of a defect resulting in a nonfunctional part increases exponentially. This tendency, combined with a smaller number of parts per wafer, limits the availability of low-on-state-resistance, high-voltage MOSFETs.

A change in the horizontal geometry of the MOSFET can lower the specific on-state resistance per unit area. By using more channel width with smaller source cells placed closer together, a reduction in on-state resistance can be achieved. A limitation on how close these cells can be placed arises from a possible localization of field concentrations that will limit the voltage breakdown of the structure to less than the theoretical rating due only to impurity concentrations. Therefore, for a given breakdown voltage, there exists a minimum spacing of the cell structure. Generally, the higher the required breakdown voltage, the further apart the cells must be placed.

As stated earlier, the extended drain region of the MOSFET generally contributes the most to the on-state resistance in high-voltage MOSFETs. As the required blocking voltage is increased, this region must be made thicker and more lightly doped to be able to support the desired voltage. It is this region's contribution to on-state resistance that the condictivity-modulated field-effect transistor drastically reduces. This reduction occurs as the result of the injection of minority carriers from the substrate and, in specific on-state resistance per unit area, is about 10 times less than in a standard MOSFET at the 400-volt BV_{DSS} level, as shown in Fig. 1.

Further analysis has shown that the specific on-state resistance may be nearly independent of blocking-voltage level. This finding implies that at a BV_{DSS} of 1000 volts, the reduction in conductivity-modulated FETs over the standard MOSFETs could be perhaps 50 to 1. These reductions in on-state resistance per unit area that the conductivity-modulated FETs can achieve present the possibility that high-voltage high-current FET-type devices can become more readily available because of the smaller die sizes associated with conductivity-modulated FETs.

COMPARISON OF STANDARD AND CONDUCTIVITY-MODULATED FETs

Standard and conductivity-modulated FETs share some characteristics, but are substantially different in others. Shown in Table I is a listing of the major characteristics that make the conductivity-modulated FETs unique among power semiconductor families. Foremost, it is a voltage-gated device; its input characteristics are similar to standard power MOSFETs of comparable chip size. Very little drive power is required at low to moderate switching frequencies. The device remains under the control of the gate within its normal operating conditions. It exhibits the normal linear mode as well as the fully saturated on-state of conventional power MOSFETs. When the gate voltage is removed, the device turns off, unlike the thyristor family of power semiconductors, which must be either externally or naturally (internally) commutated.

Table I - Conductivity-Modulated FET Characteristics

Characteristic		Description
Voltage Gated	—	Small gate power required. Similar to standard power MOSFET.
Turn Off	—	When gate drive is removed... Unlike an SCR!
Nonlinear On-State Voltage Drop	—	Like that of an SCR.
Turn On Speed	—	Fast! - Comparable to a standard power MOSFET.
Turn-Off Speed	—	Slow! - Comparable to a bipolar transistor.
Temperature Independent On-State Voltage Drop	—	Unlike the typical 2x variation of a power MOSFET.

The on-state voltage drop or resistance characteristic of a conductivity-modulated FET is markedly different from that of a standard power MOSFET, and is similar to that of a thyristor family member, the SCR. There is an offset voltage component (typically 0.6 volt) due to the p-n junction on the drain side, and a somewhat nonlinear resistive component, both of which are in series between the drain and source terminals. This series arrangement results in a highly nonlinear equivalent resistance, unlike the linear resistive characteristic of $V_{DS}(on)$ of a standard FET.

The structure of the conductivity-modulated FET operates during its turn on just as a standard FET does, hence its turn-on speed is very similiar to that of a standard FET. With its high input impedance and its short propagation delay, the turn-on transistion of the conductivity-modulated FET, as well as the standard power FET, is easily controlled by the gate driving circuit. This characterstic allows the designer the ability to control EMI and RFI generation easily. With other power semiconductors, it may be necessary to employ elaborate circuit schemes to limit rapidly rising in-rush currents.

A significant characteristic that must be considered in power switching applications is that of turn-off speed. The internal action that makes the conductivity-modulated FET such a silicon-efficient device also makes it an inherently slower device during turn-off. The injection of the minority carriers during the on-state conduction of current results in these carriers being present at the moment of turn-off. Without any way of removing these carriers by external means, they must recombine within the structure itself before the device can revert to its fully off-state condition. The quantity of these carriers and how fast they can deplete themselves determines the turn-off switching speed of the conductivity-modulated FET. This process of recombination is considerably slower than the simple discontinuance of majority carrier flow by which the standard power FET turns off. Hence, again, the conductivity-modulated FET is an inherently slower device. Its turn-off speed lies somewhere between the performance of a thyristor and that of a bipolar transistor.

The final characteristic that makes the conductivity-modulated FET different from a conventional FET is the variance of on-state voltage with temperature. The characteristic of the conductivity-modulated FET is similar to that of an SCR, varying about -0.6 mV/°C. The conventional FET has a positive temperature coefficient such that on high-voltage devices the $R_{DS}(on)$ will double from its 25°C value when the junction temperature reaches 150°C. The system designer must take this characteristic into consideration when the heat sink is being designed for the system.

It is these similarities and differences that make the conductivity-modulated FET a unique member of the family of power-semiconductor switching devices. Applications of this alternative power switching device invariably make use of one or more of its unique characteristics.

APPLICATIONS

Automotive Ignition

An application that can take advantage of the low drive-power capability of the conductivity-modulated FET is the electronic automotive ignition system. In Fig. 2, the control IC takes the signal from the pickup coil located in the distributor and regulates the current through the ignition coil. At the proper time, the IC removes base drive from the bipolar transistor, which all systems currently employ as their coil driver. This removal of base drive allows the transistor to shut off which, in turn, causes a rapid decrease in the ignition-coil primary current. As the primary current decreases to zero, the energy stored in the field surrounding the primary is transferred to the secondary coil. The secondary coil, consisting of many more turns than the primary, transforms this energy into a higher voltage, resulting in a spark being generated in the cylinder. The control IC determines when this spark occurs, so as to derive usable power. With the use of a bipolar transistor, it is estimated that approximately two-thirds of the power dissipation that occurs in the control IC is the result of the need to be able to drive the required base current of the ignition output transistor. The high-impedance input of the conductivity-modulated FET virtually eliminates the base-current drive dissipation of the control IC.

With improved silicon usage, the conductivity-modulated FET brings to power semiconductor switching devices the die size necessary to attain the required voltage and current-handling capabilities of the electronic ignition. This smaller-sized die makes possible smaller modules, whether they be hybrid or standard PC-based systems, than those currently implemented with bipolar-transistor technology.

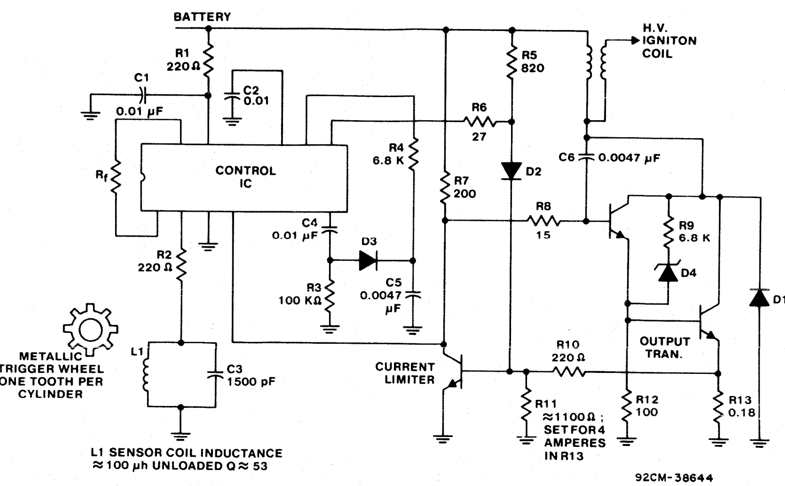

Fig. 2 - Typical ignition system.

Brushless DC Motors

Another emerging application that can make use of conductivity-modulated FETs is the emerging field of brushless dc motors. In this class of application, the solid-state devices are used to electronically switch the voltage to the multiplicity of windings that are employed. The motor consists of an armature that has a number of N and S poles consisting of high-strength permanent magnets. The stator is made up of the multiplicity of windings that were mentioned above; the windings are spaced incrementally about the outside frame of the housing. The voltages to these windings are all electronically switched to create a rotating magnetic field. The armature then rotates to maintain its relative position within the moving magnetic field. The switching of the voltage on the stator windings is done by means of power semiconductor devices. A basic block diagram of such a system is shown in Fig. 3.

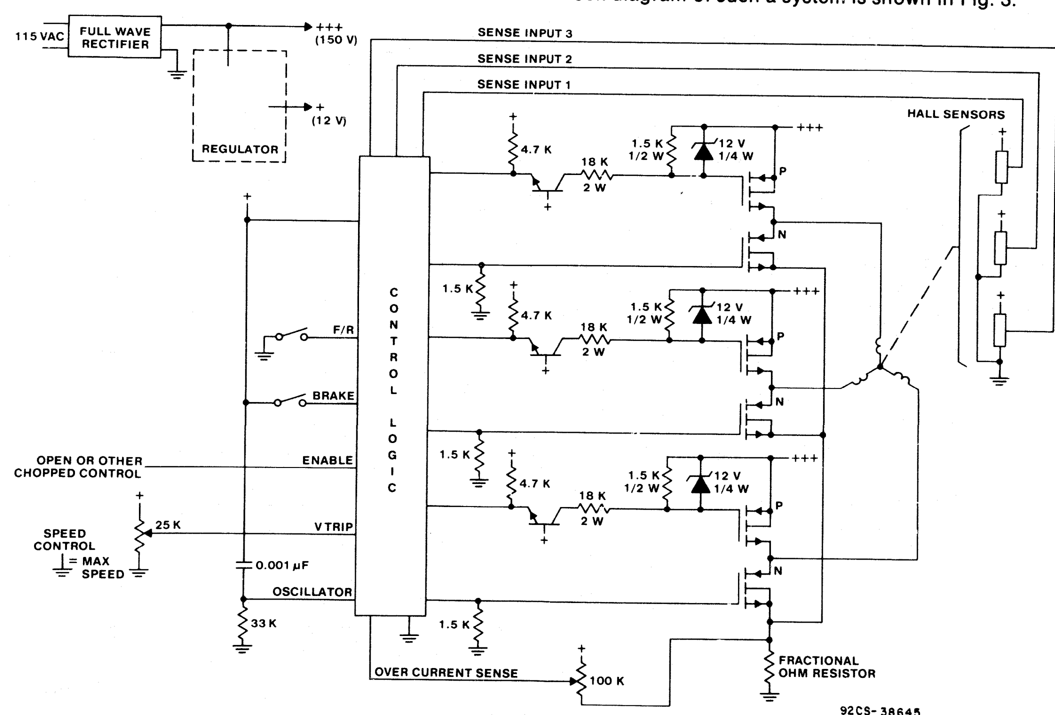

Fig. 3 - Control circuit for three-phase brushless dc motor.

The control logic provides the proper sequence of drive signals based on the rotation direction desired, the speed desired, and the enable input. These requirements are combined with the inputs from the hall-effect sensors to determine which power devices should be activated. Since the current through the stator windings must be bidirectional, the half-bridge or totem-pole output configuration is used to steer the current. This circuit implementation is generally performed with complementary devices, although single-polarity devices can be used with increased circuit complexity.

In a typical 120-volt off-line system, like the one shown in Fig. 3, the switching devices must have a 300 to 400-volt blocking capability. For larger size motors, where larger currents are necessary, the use of power FETs generally implies the use of large die to achieve a low power dissipation to meet the heat-dissipation capability of the packaging. The conductivity-modulated FET, with its temperature-independent on-state-voltage-drop characteristic, helps this situation by keeping the dissipation lower than can be achieved with a standard power FET because of the increasing R_{DS}(on) characteristic of that device. The small die size of the conductivity-modulated FET, the result of better silicon utilization, again makes them the practical choice in motor control not only because of their electrical characteristics, but also because of the lower manufacturing cost of the die.

As stated above, system complexity can be reduced with complementary devices. Although p-channel conductivity-modulated FETs are not yet commerically available, laboratory samples have been fabricated which offers better silicon utilization efficiency than their conventional p-channel counterparts. This statement is based on the fact that p-channel MOSFETs require a 2.5 times larger area than an n-channel device for the same R_{DS}(on).

The easier drive requirements for the n-channel (directly driven from the control IC) and the simplified voltage-translation circuit for driving the p-channel devices, combined with the smaller die size with potentially lower device cost for comparable power handling capability, makes the conductivity-modulated FET a natural for the brushless dc motor application.

Switching Power Supply

One final application that has the potential for conductivity-modulated FET usage is the switching power supply. A half bridge configuration implementation is presented in Fig. 4. The system shown uses a standard PWM control IC to drive the conductivity-modulated FETs through the T2 transformer. The voltage drive characteristic of these devices makes the design of transformer T2 quite simple. The control IC is more lightly loaded because it does not have to supply a continuous base drive, as would be necessary with bipolar transistors.

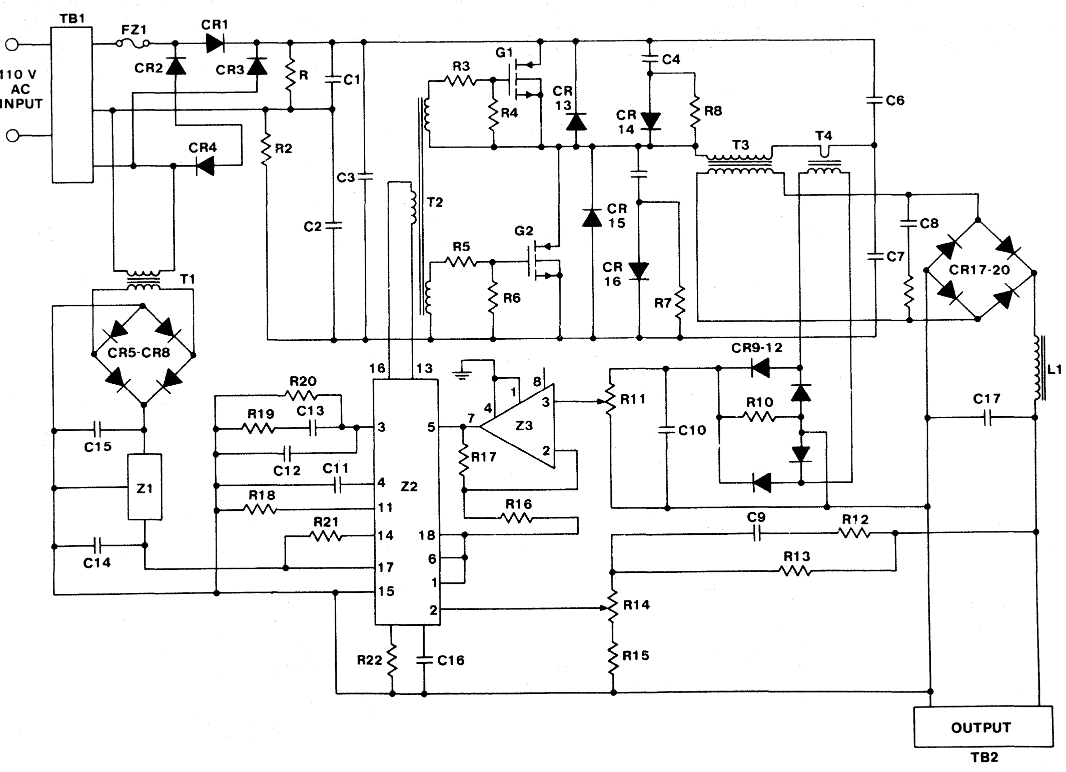

Fig. 4 - Half-bridge switching power supply.

92CL-38647

The operating frequency and the "dead time" are the limitations placed on this system when conductivity-modulated FETs are used. The inherent lower switching speeds of these types of devices make these limitations necessary. The system is currently limited to the 20 to 30-kHz range, with dead times as low as 1 to 2 microseconds. This characteristic is comparable to many existing bipolar systems.

Improvements in switching speeds will occur as the conductivity-modulated FET matures. It is, however, unlikely that they will ever have the same switching speeds as standard power FETs. This limitation prohibits their use in some of the newer higher-frequency power supplies being designed now with conventional FETs. However, in higher-power supplies, where conventional FETs must be paralled to achieve a low enough $R_{DS}(on)$ for good efficiency, the conductivity-modulated FET may present a viable alternative with its smaller die size. Although the operating frequency of the system may have to be compromised to use them.

CONCLUSION

The conductivity-modulated FET represents a progression in the ever-advancing state-of-the-art development that occurs in the world of solid-state devices. The unique structure of these devices presents characteristics that make them equivalent in many ways to conventional FETs but superior in other ways. The system designer must take into account these similar and dissimilar characteristics to properly use them. The capabilities of the conductivity-modulated FETs allow them to make inroads into applications currently served by bipolar transistors, and in some cases conventional power FETs. As the devices mature through innovation and product refinement, conductivity-modulated FETs will become vital members of the family of solid-state power-semiconductor devices.

THE COMFET - A NEW HIGH CONDUCTANCE MOS-GATED DEVICE

Author: J.P. Russell, A.M. Goodman, L.A. Goodman and J.M. Neilson

ABSTRACT

A new MOS gate-controlled power switch with a very low on-resistance is described. The fabrication process is similar to that of an n-channel power MOSFET but employs an n^--epitaxial layer grown on a p^+ substrate. In operation, the epitaxial region is conductivity modulated (by excess holes and electrons) thereby eliminating a major component of the on-resistance. For example, on-resistance values have been reduced by a factor of about 10 compared with those of conventional n-channel power MOSFETs of comparable size and voltage capability.

INTRODUCTION

Vertical MOSFETs have become increasingly important in discrete power device applications due primarily to their high input impedance, rapid switching times, and low on-resistance. However, the on-resistance of such devices increases with increasing drain-source voltage capability, [1-3] thereby limiting the practical value of power MOSFETs to applications below a few hundred volts. In this letter, we describe the fabrication and characteristics of a new vertical power MOSFET structure that provides an on-resistance value about 10 times smaller than that of conventional power MOSFETs of the same size and voltage capability. In this device, the conductivity of the epitaxial drain region of a conventional MOSFET is dramatically increased (modulated) by injected carriers; this mechanism results in a significant reduction in the device on-resistance and leads to the acronym COMFET (COnductivity-Modulated FET).

This device, while similar in structure to the MOS-gated thyristor,[4, 5] is different in a fundamental way; it maintains gate control (doesn't latch) over a wide range of anode current and voltage.[6] The structure and the equivalent circuit for the COMFET are shown in Fig. 1(a) and (b); they are similar to those of an MOS-gated thyristor, except for the presence of the shunting resistance R_S in each unit cell. The fabrication is like that of a standard n-channel power MOSFET except that the n^--epitaxial Si layer is grown on a p^+ substrate instead of an n^+ substrate. The heavily doped p^+ region in the center of each unit cell, combined with the sintered aluminum contact shorting the n^+ and p^+ regions, provides the shunting resistance shown in Fig. 1(b). This has the effect of lowering the current gain of the n-p-n transistor ($\alpha_{n\text{-}p\text{-}n}$) so that $\alpha_{n\text{-}p\text{-}n} + \alpha_{p\text{-}n\text{-}p} < 1$. Thus latching is prevented and gate control is maintained within a large operating range of anode voltage and current.[6]

In the remainder of this note we describe the operation and characteristics of this device.

DEVICE OPERATION

The COMFET is a four-layer (n-p-n-p) device with an MOS-gated channel connecting the two n-type regions. In the normal mode of operation, a positive voltage is applied to the anode (A) relative to the cathode (K). When the gate (G) is at zero potential with respect to K, no anode current (i_A) flows for anode voltage v_A below the breakdown level V_{BF}. When $v_A < V_{BF}$ and the gate voltage is larger than the threshold value V_{gt}, electrons pass into the n^--region (base of the p-n-p transistor). These electrons lower the potential of the n^--region, forward biasing the $p^+ - n^-$ (substrate-epi-layer) junction, thereby causing holes to be injected from the p^+ substrate into the n^- epi-layer region. The excess electrons and holes modulate the conductivity of the high-resistivity n^- region, which dramatically reduces the on-resistance of the device. During normal operation, the shunting resistor (R_S) keeps the emitter current of the n-p-n transistor very low, which keeps α_{n-p-n} very low. However, for sufficiently large i_A, significant emitter injection may occur in the n-p-n transistor, causing α_{n-p-n} to increase; in this case the four-layer device may latch, accompanied by loss of control by the MOS gate. In this event, the device may be turned off by lowering i_A below some "holding" value, as is typical of a thyristor.

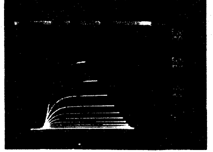
DEVICE CHARACTERIZATION

Two different lots of COMFET structures, consisting of about 10 wafers/lot, have been successfully prepared to date. From these wafers, 1.5 and 3-mm square devices were fabricated using a standard HEXFET geometry[7] with a polysilicon gate electrode over an SiO_2 gate dielectric. Several hundred COMFETs were mounted in standard TO-3 and TO-66 packages and characterized under dc and pulsed conditions, as described below.

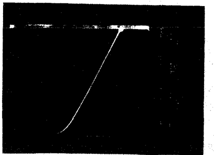
With zero gate bias, the forward characteristic of a COMFET shows very low current (< 1 nA) up to about 390 V, where it breaks up sharply to much larger current levels with only a slight increase in voltage. If the internal junction between the p^+ substrate and the n^- epitaxial layer had been edge-passivated, a similar reverse breakdown characteristic would be expected. The actual reverse breakdown voltage for our devices was about 100 V because edge passivation was not used.

Fig. 2(a) shows the MOSFET-like transfer characteristics of a COMFET in the low gate-voltage region. A noteworthy feature of the COMFET characteristic is the ~ 0.7 V offset, from the origin, of the steeply rising portion of the i(v) characteristics. This offset is the voltage required to forward bias the $p^+ - n^-$ (substrate-epi-layer) junction, and is an integral characteristic of the present device.

Fig. 2(b) shows the i(v) characteristic of a COMFET with v_g = 20 V, and demonstrates the low on-resistance of the device (~ 0.084 Ω at 20 A). The on-resistance values of nearly all of the many COMFETs fabricated to date have been less than 0.1 Ω (at 20 A) for the 3-mm square devices. Such values compare very favorably with those of conventional power MOS structures, as illustrated in Fig. 3. Here, the open data points (and the upper curve) are from data sheet specifications of commercial power MOSFETs (Harris, IRC, and Motorola). The solid data points (and the lower curve) are those of Baliga, which he labelled "state-of-the-art",[3] supplemented with some of the "best" of Harris' commercial



a) MOSFET - Like Characteristic



b) COMFET i(v) with v_g = 20V

Fig. 2 - (a) MOSFET-like characteristic; (b) COMFET i(v) with v_g = 20 V.

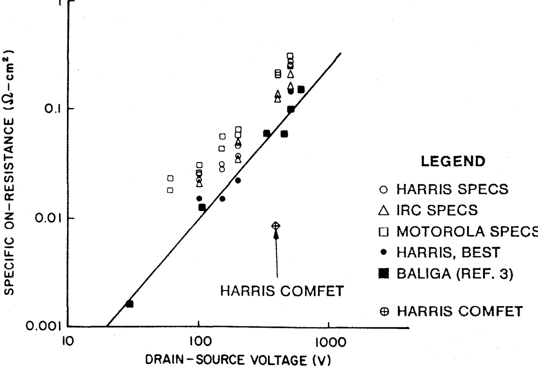


Fig. 3 - Specific on-resistance versus drain-source voltage capability for state-of-the-art power MOSFETs and the COMFET.

and developmental MOSFETs. Note that the on-resistance of the COMFETs is approximately 10 times less than that of a 400-V state-of-the-art MOSFET. Moreover, similarly low on-resistance values should be obtainable from COMFETs designed for higher drain-source voltages. This is due to the fact that the resistance of the modulated region is determined by the concentrations and mobilities of the excess carriers (as in a p-i-n diode)[8] rather than by the background doping of the layer. In particular, the epi-layer doping and thickness of our present COMFET structures were designed for 600 V, but V_{BF} was limited to 400 V by the edge design of the device. An improved edge design should provide a blocking capability closer to bulk breakdown, without altering the on-resistance of the device. This would make the COMFET on-resistance of less than 0.1 Ω even more attractive for high-voltage applications.

TRANSIENT RESPONSE MEASUREMENT

Switching time measurements under pulsed gate-voltage operation were used to characterize the transient operation of the device. The response of the anode current to a square-wave gate-voltage pulse is comprised of a rapid turn-on (with a typical time less than 1 μs) and a somewhat slower turn-off. We observed that the turn-off transient consists of an initial "fast" component, followed by a "slow" tail, as shown in Fig. 4.

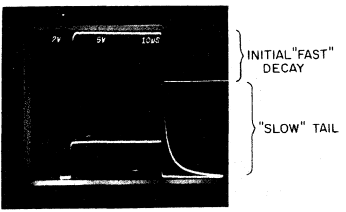

Fig. 4 - Gate voltage (lower trace) and anode current (upper trace) waveforms for $i_A(max) = 8$ A.

We believe that the initial rapid decay is due to the turn-off of the MOS portion of the equivalent circuit, and the turn-off tail is due to the time required for the excess carriers in the epitaxial drain region to decay. In general, turn-off times in the range of 5 to 20 μs were observed, with the precise value depending on circuit conditions and the turn-off time of the gate pulse.

The n-p-n-p structure of the COMFET is similar to that of a thyristor and can be forced to latch under sufficiently high drive conditions. We have observed latching currents in the range 10-30 A in 3-mm square chips. The magnitude of the latching current has been found to depend on both anode voltage and temperature, decreasing with increasing anode voltage or increasing temperature.

More interestingly, the latching current is also strongly influenced by the gate voltage turn-off time. Slow gate turn-off (~ 10 μs) permits anode currents up to 30 A without latching. However, rapid gate turn-off ($\lesssim$ 1 μs) leads to latching at a much lower anode current level (~ 10 A) in the same device. We believe that latching during rapid turn-off of the gate voltage is due to current being forced through the n-p-n transistor causing α_{n-p-n} to increase, and leading to the condition for latching, $\alpha_{n-p-n} + \alpha_{p-n-p} = 1$. Slow turn-off of the gate voltage prevents this, since the induced channel turns off slowly and partially shunts the n-p-n transistor; the small current through this transistor keeps α_{n-p-n} sufficiently low to avoid latching.

SUMMARY

A new MOS-gate-controlled power device, the COMFET, has been described. The device has the desirable feature of a very low on-resistance similar to that of a thyristor, but is capable of maintaining gate control of the anode current over a wide range of operating conditions. The low on-resistance is due to conductivity modulation of the n^- epitaxial layer equivalent to the extended drain in a power MOSFET; this carries with it the penalty of slow switching compared with that of a conventional power MOSFET.

IMPROVED COMFETs WITH FAST SWITCHING SPEED AND HIGH-CURRENT CAPABILITY

Author: A.M. Goodman, J.P. Russell, L.A. Goodman, C.J. Nuese and J.M. Neilson

ABSTRACT

Conventional vertical power MOSFETs are limited at high voltages (>500 V) by the appreciable resistance of their epitaxial drain region. In a new MOS-gate controlled device called a COMFET (or an IGR), this limitation is overcome by modulating the conductivity of the resistive drain region, thereby reducing the on-resistance of the device by a factor of at least 10. However, the device previously described is slow in turn-off, having a fall time in the range 8 to 40 μs.

The purpose of our present work has been to reduce the fall time significantly and to increase the latching current level of the COMFET, while retaining its desirable features. By modification of the epitaxial structure and addition of recombination centers, we have achieved fall times as low as 0.1 μs and latching currents as high as 50 A, while retaining on-resistance values < 0.2 ohm for a 0.09 cm^2 chip area. The techniques used for the introduction of recombination centers include electron, gamma-ray, and neutron irradiation, as well as heavy metal doping. For a series of COMFETs (with forward-blocking voltage capabilities of 400-600 V), the fall time can be reduced by more than one order of magnitude with a penalty of less than a 20% increase in on-resistance.

INTRODUCTION

Vertical MOSFETs have become increasingly important in discrete power device applications due primarily to their high input impedance, rapid switching times and low on-resistance. However, the on-resistance of such devices increases with increasing drain-source voltage capability,[1-3] thereby limiting the practical value of power MOSFETs to applications below a few hundred volts. This limitation has been effectively overcome by the development of a new MOS power device in which the conductivity of the n-type epitaxial drain region is greatly increased (modulated) by the injection of minority carriers from a p-type substrate.[4-6] We have called this device a COMFET—an acronym for COnductivity Modulated Field Effect Transistor;[4] the device has also been called an IGR or insulated gate rectifier.[5]

The devices, as originally described, had most of the advantages of conventional power MOSFETs; in addition, they exhibited more than an order-of-magnitude reduction in high current on-resistance values, permitting improved utilization of silicon chip area. However, they also had two disadvantages:

1. When a COMFET (or IGR) is turned off, the injected minority carriers that remain in the epitaxial drain region decay by recombination with majority carriers at a rate determined by the minority-carrier lifetime, τ. Large values of τ resulted in anode-current fall time, t_f, in the range 8-40 μs.[4, 5]
2. The maximum operating current is limited by latchup of the parasitic thyristor that is inherent in the device structure. Typical latching current levels of $I_L \lesssim 10$ A were observed in 0.09 cm^2 area devices when the gate voltage was turned off rapidly (< 1 μs); for slower gate voltage turnoff (~ 10 μs), I_L values as high as ~ 30 A were observed.

The purpose of the present work has been to reduce t_f and to increase I_L while retaining the desirable features of the device. By modifying the epitaxial structure and adding recombination centers to the epitaxial drain region, we have achieved t_f values as low as 100 ns and I_L values as high as 50 A with rapid gate voltage turnoff.

MODIFIED STRUCTURE

A schematic diagram of the original COMFET structure[4] is shown in Fig. 1(a), and the equivalent circuit is shown in Fig. 1(b); they are similar to those of an MOS-gated thyristor

except for the presence of the shunting resistance R_S in each unit cell. The fabrication is like that of a standard n-channel power MOSFET, except that the n^--epitaxial layer is grown on a p^+ substrate instead of an n^+ substrate. The heavily doped p^+ region in the center of each unit cell, combined with the aluminum contact shorting the n^+ and p^+ regions, provides the shunting resistance R_S. This has the effect of lowering the current gain of the n-p-n transistor in the equivalent circuit so that $\alpha_{npn} + \alpha_{pnp} < 1$, thereby preventing latching over a large operating range of anode voltage v_A and anode current i_A. However, for sufficiently large i_A, emitter injection in the n-p-n transistor will increase, accompanied by an increase in α_{npn}. When $\alpha_{npn} + \alpha_{pnp}$ increases to 1, the four-layer device will latch; the level of i_A at which this occurs is the latching current level, I_L. Thus, it can be seen that a structure modification that lowers α_{pnp} will allow a greater range of i_A (and α_{npn}) without latching; that is, a reduction in α_{pnp} corresponds to an increase in I_L.

The modified structure shown in Fig. 1(c) differs from that in Fig. 1(a) by the addition of a thin (~ 10 μm) layer of n^+ silicon in the epitaxial structure between the n^- region and the p^+ substrate. This n^+ layer lowers the emitter injection efficiency of the p-n-p transistor in the equivalent circuit, and results in an increase in I_L by a factor of 2 to 3. In addition, there is also a reduction in t_f.

These results are illustrated in Fig. 2, in which t_f is plotted versus i_A for each device structure. It should be noted that COMFETs with the modified structure can block high voltage only in the forward voltage direction since the emitter junction (p^+ - n^+) of the p-n-p transistor breaks down at a low level when the polarity of the applied voltage is reversed.

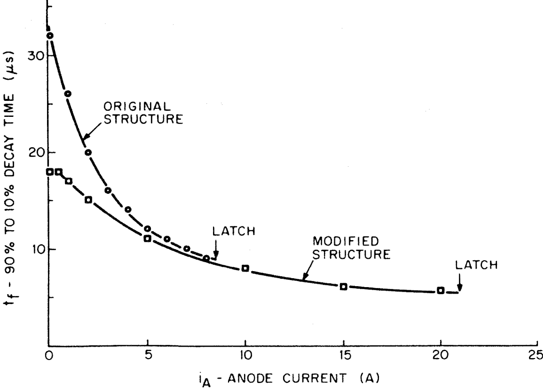

Fig. 2 - Anode-current fall time t_f versus anode current for original structure and modified structure.

ADDITION OF RECOMBINATION CENTERS

We have used a variety of techniques to add recombination centers to COMFETs; these include high-energy electron, gamma-ray, and fast-neutron irradiation, as well as heavy metal doping. The irradiations were carried out after completion of all of the high-temperature processing steps, but in each case an additional heat treatment was necessary to stabilize the devices by annealing out gate-oxide charge, as well as those radiation-induced defects in the silicon (recombination centers) that would otherwise anneal out slowly at the device operating temperature.[7] Typical values of t_f of the order of 1 μs or less were achievable using any of the techniques.

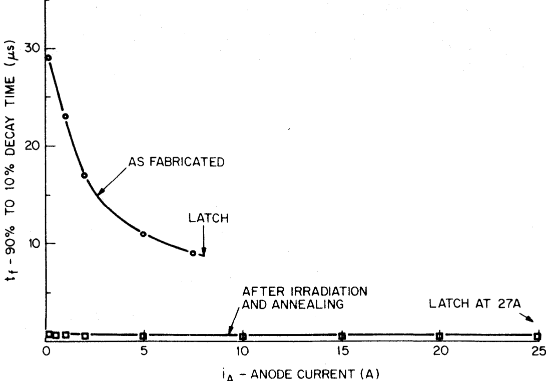

Fig. 3 - Anode-current fall time t_f versus anode current for an as-fabricated device and after 14 MeV neutron irradiation (10^{13}n/cm^2)followed by annealing at 300° C.

An example of the variation of t_f with i_A (1) as fabricated and (2) after irradiation with 14 MeV neutrons and annealing is shown in Fig. 3. Here, the neutron fluence was ~ 10^{13} n/cm^2; this was followed by annealing at 300° C. Note that t_f has not only been drastically reduced, but is virtually constant at ~ 0.6 μs; i.e., almost independent of i_A.

It is possible to lower t_f still further by appropriate irradiation and annealing or by heavy metal doping procedures, although this is not necessarily desirable for reasons that are discussed below. The smallest values of t_f that we have obtained for fully stabilized COMFETs are in the range 100 to 200 ns. This is illustrated in Fig. 4.

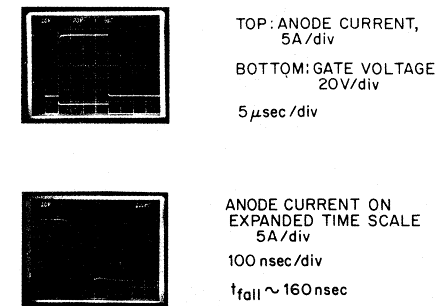

Fig. 4 - COMFET anode current and gate voltage waveforms.

The reduction in minority-carrier lifetime that allows faster switching also carries with it a penalty—higher forward voltage drop when the device is turned on; i.e., higher on-resistance. Since, in the forward conduction of a COMFET, current and voltage are not linearly related, it is necessary to specify a current level at which to compare on-resistance values of different devices. In Fig. 5 we plot the on-resistance (at i_A=20 A) of a series of devices with 0.09 cm^2 chip area against their t_f values after irradiation and annealing. All t_f values shown were obtained at i_A=5 A; for the devices with short switching times, t_f is virtually independent of i_A. Clearly, there is a tradeoff involved, and the optimum choice of a value for t_f and the corresponding

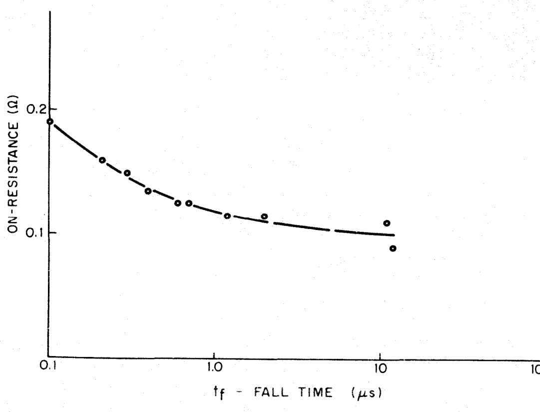

Fig. 5 - On-resistance versus anode-current fall time t_f for a series of COMFETs after various irradiation and annealing treatments.

on-resistance value will depend, to some extent, on the intended application. However, even for the shortest switching times shown (100 ns), the on-resistance value of 0.2 ohm is approximately an order-of-magnitude less than that of comparably-sized n-channel MOSFETs.

TEMPERATURE DEPENDENCE OF t_f AND I_L

All of the device performance data presented thus far have been measured at room temperature. However, power devices are often operated at elevated temperatures, and it is important to determine how their performance varies with temperature. In Fig. 6 the variation of t_f and I_L for a device

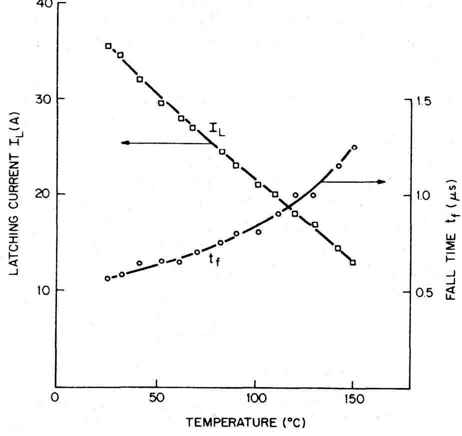

Fig. 6 - Variation of anode-current fall time t_f and latching current I_L with temperature.

that has been irradiated and annealed is plotted versus temperature in the range 25 to 150°C. This behavior is typical of all of the devices we have tested; i.e., t_f increases and I_L decreases with increasing temperature, both by a factor of between 2 and 3 in the interval 25°C to 150°C.

SUMMARY

By modification of the epitaxial structure of the COMFET and the addition of recombination centers, we have achieved anode-current fall times as low as 100 ns in COMFETs with latching currents as high as 50 A for a 0.09 cm² chip area. We have described the tradeoff between on-resistance and anode-current fall time that may be obtained, and have demonstrated the variation of anode-current fall time and latching current with operating temperature.

ACKNOWLEDGMENT

The authors are indebted to D. Bergman, R. Ford, F. DiGeronimo, G. Looney, P. Robinson, W. Romito, L. Skurkey, M. Snowden, R. Stolzenberger, and the staff of the Integrated Circuit Technology Center at RCA Laboratories for their various contributions to the fabrication and characterization of the COMFETs. A special thank you goes to F. Taft, Z. Streletz, and H. Hendel who carried out the device irradiations.

SPICING-UP SPICE II SOFTWARE FOR POWER MOSFET MODELING

Author: C.F. Wheatley, Jr., H.R. Ronan, Jr., G.M. Dolny

The SPICE II simulation software package is familiar to most designers working in computer-aided design of integrated circuits. Developed by L. W. Nagel in 1973, SPICE II has become a widely available, well-understood design tool for IC modeling and analysis. But, SPICE II has a shortcoming: its standard simulation programs were developed when all MOSFETs were low-power devices. Power MOS devices are growing in use today, both as discrete components and, potentially, as output stages of power integrated circuits. SPICE II in its current form doesn't recognize these new developments. Its built-in FET models aren't able to simulate all the modes of new power MOS device operation. For example, SPICE II doesn't recognize the way a power MOSFET's internal capacitances change with bias conditions, the presence of a cascode JFET that complicates both static and dynamic operation, or the presence of a parasitic body diode that affects operation in the third quadrant. Without this information, SPICE II will predict power MOSFET performance that is incorrect.

Since SPICE II's internal device models can't be easily changed for all existing copies, we looked for another approach to update the capabilities of this widely used simulation package in its standard form. Adding a "subcircuit" of external components that complement the devices within the SPICE II software, so as to form a true, equivalent circuit of a power MOSFET, is the answer.

The subcircuit works nicely with the standard SPICE II software, providing a model with all the terminal characteristics of a power MOSFET. Parameters of the subcircuit model can be determined from simple terminal measurements or from standard data sheets, using the algorithmic and empirical approach described below. Once these parameters are in place, SPICE II can be used to accurately simulate either p-channel or n-channel power MOSFET devices over a wide range of currents and voltages. The subcircuit functions as an embedded subroutine, so it can be used repetitively for any number of power MOSFETs in a design. This technique can be used to model power MOSFETs with any version of the SPICE II program presently available, without any modifications to its internal source code. The technique can also be used with other commercially available or in-house-developed circuit simulators.

Modeling The Power MOSFET

A cross-sectional view of a cell of a Harris IRF130 power MOSFET is shown in Fig. 1. The easiest way to understand its electrical characteristics is to think of it as a vertical JFET, driven in cascode from a low-voltage lateral MOSFET.[1,2] When the gate is positively biased with respect to the n-bulk, an accumulation layer forms in the n-region beneath the gate. This layer acts as the drain of the lateral MOSFET, as well as the source of the vertical JFET. The JFET channel is the n-region between the two p-type body diffusions, which act as the gate of the JFET. The JFET drain is the n+ bulk, usually thought of as the power MOSFET drain.

When you look at the power MOSFET this way, it becomes possible to use the standard SPICE II built-in device models, because SPICE II can simulate both the vertical JFET and the lateral MOSFET. When we use the subcircuit to add the rest of the Harris IRF130 power MOSFET to these SPICE II-simulated devices, we get a satisfactory equivalent circuit, shown in Fig. 2.

The gate-to-source capacitance of the Harris IRF130 power MOSFET is represented by C21. It is really a composite of two capacitances. The first is formed between the polysilicon gate and source metal (with the thick oxide as a dielectric). The second is formed between the gate and the n+ source (with the thin oxide acting as the dielectric). The value of C21 is essentially unchanged by voltage or current.

Capacitor C24 is formed between the power MOSFET gate and the accumulation layer, with the thin gate oxide as a dielectric. So long as the gate is positive with respect to the n-neck region, the accumulation layer exists and C24 doesn't change. But, if the external drain voltage (less the IR voltage drop across the n-drift region) approaches the gate voltage, the accumulation layer starts to disappear. When that happens, C24 abruptly drops in value. This sudden change has to be taken into consideration.

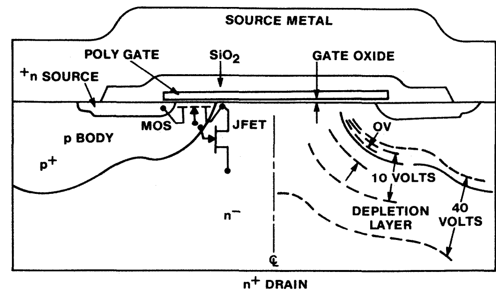

Fig. 1 - A cross-sectional view shows the physical make-up of the lateral low-voltage MOSFET and vertical JFET that operate in cascode as the power MOSFET.

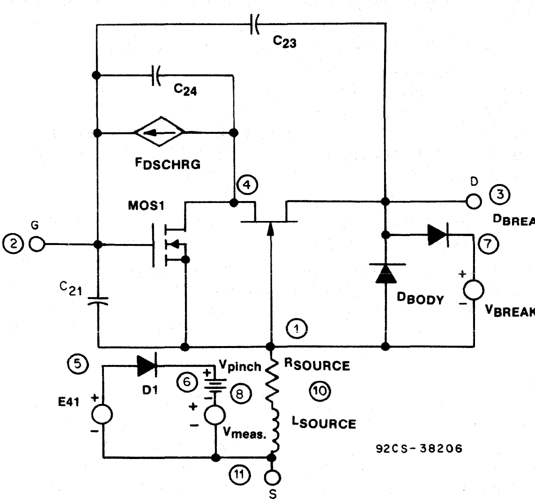

Fig. 2 - The equivalent circuit of the power MOSFET is made by combining SPICE II model elements with software-specified components on a "subcircuit."

Capacitor C23 represents the gate-to-drain capacitance of the Harris IRF130 power MOSFET. Because the accumulation layer normally acts as an electrostatic shield, C23 has no significance until the layer ceases to exist under the conditions just described. When it does disappear, the effect upon C23 is abrupt, and also has to be taken into consideration. The sudden changes in C24 and C23 cannot be easily modeled with the standard SPICE II software.

Fig. 2 illustrates what happens: If the JFET source voltage (node 4) is very low compared to its pinch-off voltage, the JFET will be highly conductive, tightly coupling C24 to the JFET drain (which is also the drain of the Harris IRF130 power MOSFET). However, as the node 4 voltage approaches the pinch-off voltage (V_{pinch}) of the JFET, it operates in a constant-current mode. This action decouples C24 from the JFET drain, making possible a much faster slew-rate, determined by C23. If the node 4 voltage is allowed to exceed V_{pinch} of the JFET, errors will exist in the output waveforms predicted by the standard SPICE II model.

To correct the situation, the added subcircuit includes a current-controlled current source, F_{dschrg}, and a current-sense network containing D1. If node 4 voltage begins to exceed V_{pinch} of the JFET, D1 conducts, and its current is sensed at V_{meas}. The high-gain current source F_{dschrg} is turned-on rapidly and partially discharges C24, pinning node 4 voltage at the pinch-off voltage of the JFET. In setting up the parameters of the subcircuit, the ideality factor of D1 is set at 0.03 to assure that node 4 voltage will never exceed V_{pinch} of the JFET by more than a few millivolts. This condition results in waveform predictions from the SPICE II model that represent the true characteristics of the power MOSFET.

The body diode (D_{body} in Fig. 2) is formed by the drain-to-body diffusion pn junction of the Harris IRF130 power MOSFET. D_{body} is added as an external component in the subcircuit because the built-in gate-to-drain diode of the SPICE II JFET model is inconvenient when it comes to modeling third-quadrant conduction of a power MOSFET. We want most of the third-quadrant current to flow in D_{body}. So, we effectively delete the SPICE II model's built-in diode by setting its saturation current parameter to an artificially low value, such as 10^{-20} ampere.

Avalanche breakdown of a power MOSFET such as the Harris IRF130 is best simulated by adding a clamp circuit, such as diode D_{break}, Fig. 2, to the subcircuit in series with a voltage source, V_{break} in Fig. 2. This arrangement yields a better "fit" between predicted and measured breakdown characteristics of power MOSFETs. Convergence properties are also improved, compared to the implicit-diode-breakdown models built into SPICE II.

To round-out the subcircuit, a resistor value is chosen for the JFET drain of the SPICE II model to represent the series resistance of the n-drain region of the Harris IRF130 power MOSFET.[3] We also add resistor R_{source} to represent the series source resistance of the Harris IRF130 power MOSFET: a composite of resistances in the n+ source region, contact resistance, and source-metal series resistance. Finally, we add inductor L_{source} to represent the source inductance of the power MOSFET contributed by the source metallization and bond wires.

Choosing Parameters to Simulate A Power MOSFET

To accurately simulate the terminal characteristics of the physical power MOSFET you are working with, you will need to adjust the SPICE II model parameters and select subcircuit component values. Look first at adjustment of the SPICE II model. The static current-voltage characteristics of the power MOSFET are determined by the low-voltage lateral MOSFET included in the SPICE II model; Fig. 2. In saturation (large values of V_{DS}), the lateral MOSFET device is modeled according to the following equation:

$$I_{DS} = \frac{(K_p)W\,(V_{GS}-V_{TO})^2}{2\,L}$$

where

K_P = process transconductance parameter
V_{TO} = threshold voltage
W = L = 1 μm (fixed in this Note for convenience).
I_{DS} = MOSFET drain current
V_{GS} = MOSFET gate-to-source voltage

Continuing with the example device, the Harris IRF130 power MOSFET, a plot of the square root of I_{DS} versus gate voltage (V_{GS}) provides the curves shown in Fig. 3 for V_{DS} = 10 volts. These curves provide the process transconductance parameter, $(K_P/2)^{0.5}$, and threshold voltage, V_{TO}, directly. This data can then be used to find the value of source resistance, R_{source}. This series resistance is important because it causes the curve produced by plotting the square root of I_{DS} versus V_{GS} to depart from linearity at high current levels. Departure at very low current levels is caused by subthreshold conduction, which we ignore in this model.

To find the JFET drain resistance, we use the value of source resistance, R_{source}, and plots of I_{DS} versus V_{DS} for operation in the linear region, as shown in Fig. 4.

To find the current, resistance and capacitance parameters of the body diode (D_{body} in Fig. 2), first plot log I_{DS} versus V_{DS}, as shown in Fig. 5, holding the gate voltage, V_{GS}, negative for third-quadrant operation; i.e., where V_{DS} is less

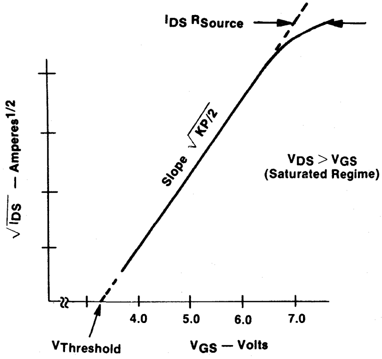

Fig. 3 - This plot of the square root of drain current vs gate voltage defines the threshold voltage, V_{TO}, $(K_P/2)^{0.5}$, and R_{source} for the power MOSFET.

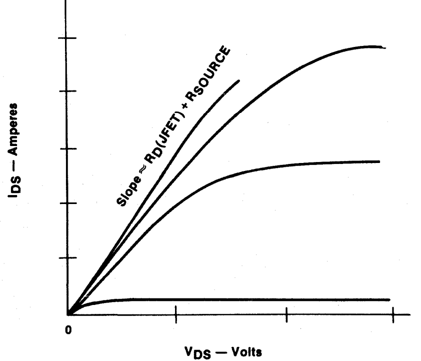

Fig. 4 - Drain current vs drain voltage of the power MOSFET plotted using constant gate voltages. This curve defines the on resistance of the device.

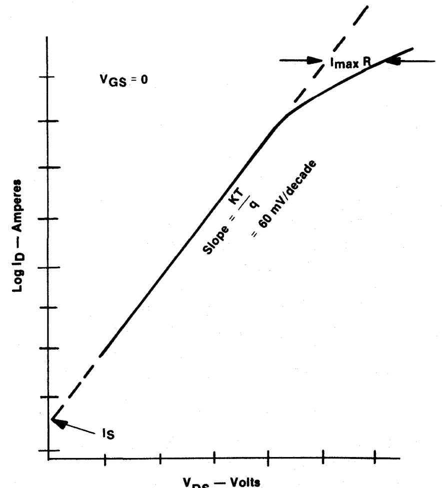

Fig. 5 - This plot of log I_D vs V_{DS} in third-quadrant operation of the power MOSFET defines I_s and R_s of the parasitic body diode, D_{body}.

than 0. This plot gives the saturation current and resistance of D_{body}. The minority-carrier transit-time parameter (TT) of the SPICE II program is chosen to provide the best fit to measured transient reverse-recovery data. The junction capacitance value of D_{body} is equal to the power MOSFET device output capacitance, C_{OSS}, at zero volts. This value can be obtained from the device data sheet, or by bridge measurement. It is usually specified at 25 volts, and may be converted to zero volts by multiplying by 6.

To properly simulate avalanche breakdown voltage with the added clamp circuit (diode D_{break} and voltage source V_{break} in Fig. 2), first set the voltage level of V_{break} equal to the measured value of drain breakdown voltage. Then, adjust the SPICE II model parameters I_S, N, and R_S for D_{break} to obtain the best fit to the measured breakdown voltage curve.

Selection of capacitors C21, C23, and C24, and the parameters of the JFET (all shown in Fig. 2), can be made using the curves of Fig. 6. This is a plot of drain and gate voltage versus time for a power MOSFET driven with constant gate current (I_G).[1] The initial slope of the V_{GS} curve defines C21 (since for any value of gate voltage, V_{GS}, less than threshold voltage, V_{TO}, the power MOSFET is in its off-state, so that the gate-to-source capacitance, C21, charges linearly under constant-current conditions). As V_{TO} is reached, the low-voltage lateral MOSFET (Fig. 2) turns on, and its drain voltage drops toward its minimum value.

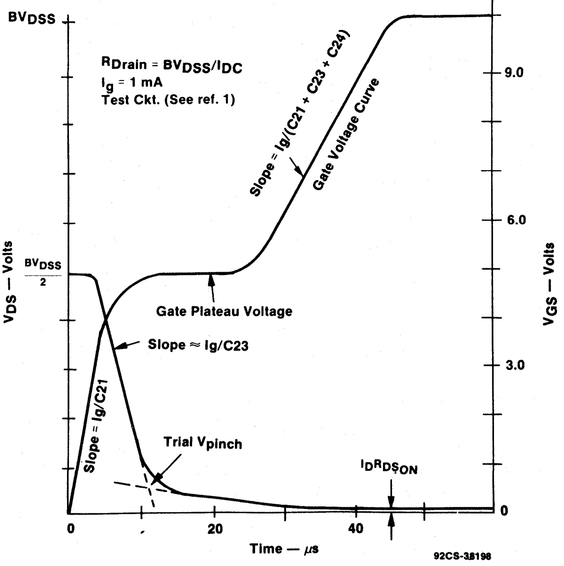

Fig. 6 - Plotting drain and gate voltages of the power MOSFET vs time determines the values of C21, C23, C24, and V_{pinch}.

At the outset, the JFET is operating beyond pinch-off, and the slope of the V_{DS}-versus-time curve is controlled by C23. However, when the drain voltage falls below V_{pinch}, the JFET conducts, strongly coupling C24 to the JFET drain and greatly reducing the drain voltage slew rate. Thus, the value of C23 can be approximated from the steep slope of the V_{DS}

curve in Fig. 6, while the value of C21+C23+C24 corresponds to the labelled V_{GS} slope. These values can be adjusted slightly to give the best slope fit. A trial value of V_{pinch} (and V_{TO}) is given by the labelled intercept of the V_{DS} curve. Adjustments of this value will control the length of the gate plateau voltage needed to complete the curve fit.

Table I lists the preferred algorithm for parameter extraction; Table II summarizes the required empirical inputs. Together, these tables will aid in setting up the parameters for evaluation of a power MOSFET with SPICE II and the subcircuit. As an example, Table III summarizes the input parameters for the SPICE II model and subcircuit, determined for the Harris IRF130 power MOSFET, using the approach just described. The IRF130 is rated at 14 amperes and has a 100-volt blocking capability.

Table I - Preferred Algorithm for Parameter Extraction

1. Determine K_P of lateral MOS
2. Determine V_{TO} of lateral MOS
3. Determine C21
4. Determine C21 + C23 + C24
5. Determine R_{source} and JFET drain resitance
6. Assign beta of JFET = 100 x K_P of lateral MOS
7. Use trial V_{pinch}
8. Use trial C23 and calculate C24
9. Curve fit for slope by repeating step 8 with different values of C23.
10. Adjust V_{pinch} and V_{TO} of JFET to fix gate-voltage plateau

Implementing The Subcircuit in SPICE II

Table IV is the input listing for the implementation of the power MOSFET subcircuit in SPICE II software. Nodes are identified for drain, gate, and source of the power MOSFET. The subcircuit then "hooks" to these nodes wherever specified in the SPICE II simulation. Any number of power MOSFETs can be specified. The parameters listed are for an IRF130 power MOSFET.

The Results

The real test of the enhanced SPICE II model is how closely its predicted performance compares with actual measurements. Using the input parameters for the Harris IRF130 device example given in Table III, we calculated transfer and output curves for the model. These curves were then compared against measured static data. Figs. 7 and 8 show the precise fit between predicted and measured static data, even at low values of drain voltage.

To see how the model performs in dynamic prediction, we simulated first-quadrant operation (including avalanche mode) and third-quadrant operation for the Harris IRF130 power MOSFET. Once again, the predicted performance of the enhanced SPICE II model fits actual measurements satisfactorily over the entire operating range of the Harris IRF130, as shown in Figs. 9 and 10.

To compare calculated switching performance versus actual measurement on the Harris IRF130, we used the enhanced SPICE II model to generate switching curves. Fig. 11 shows drain and gate voltages versus time with a constant gate-current drive. Fig. 12 shows drain and gate voltages versus time for a step gate-voltage input. Actual measured data was then taken and overlaid on the points predicted by the enhanced SPICE II model. Again, the fit was accurate in each case.

APPLICATION NOTES

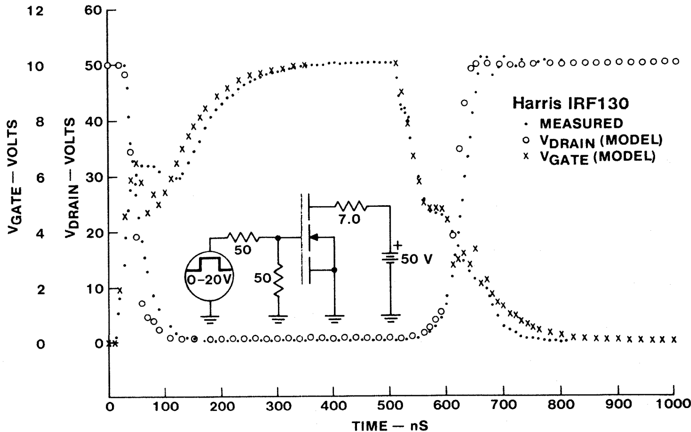

Fig. 12 - Switching performance of the Harris IRF130 power MOSFET is closely predicted by the enhanced SPICE II model in this plot of measured and calculated values of drain and gate voltages vs time in a standard switching circuit.

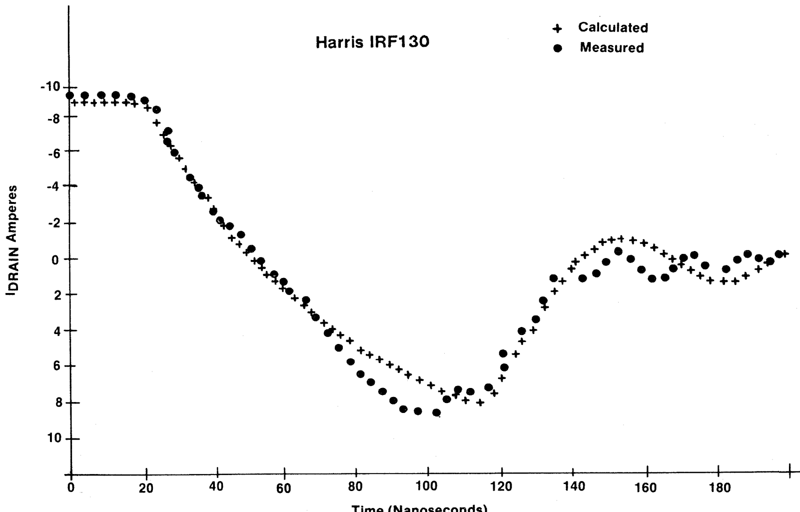

Fig. 13 - The calculated third-quadrant diode recovery waveform of the enhance SPICE II model shows good agreement with that actually measured for the Harris IRF130 power MOSFET.

Finally, the enhanced model was used to compare calculated and measured body diode (D_{body} in Fig. 2) recovery time curves in third-quadrant operation of the Harris power MOSFET. Fig. 13 shows the good agreement between predicted and actual results.

This approach provides excellent results when there is a need to model the performance of a power MOSFET. Not only will the approach update SPICE II (or other circuit simulation CAD program) so that it will simulate the latest state-of-the-art in MOS power, but it will allow quick analysis of every static and dynamic characteristic for suitability in a proposed design.

Intelligent Power™ Products

SP600 and SP601 An HVIC MOSFET/IGT Driver For Half-Bridge Topologies

By Dean F. Henderson

The interfacing of low-level logic to power half-bridge configurations can be accomplished by an 500VDC intelligent IC, the SP600-series driver, which is designed for up to 230VAC line-rectified operation. The primary function of the high-voltage integrated circuit (HVIC) is to drive n-channel MOS-gated power devices in totem-pole configuration. Compatible with current-sensing MOS-FETs/IGTs, this HVIC provides overcurrent shutdown, simultaneous conduction protection, and undervoltage lockout. Logic-level inputs provide noise-immune control of power-element switching.

The SP600 has demonstrated high-frequency (130 kHz) operation as well as the ability to withstand high dv/dt. Its semicustom design flexibility makes it easily adaptable to a wide range of single and multiple-phase applications. Other salient features of the device are described below.

Technology Overview

BiMOS structures are implemented in a junction-isolation process, known as "lateral charge control",[1] that supports high voltage laterally. By the use of this thin-epi process, low-voltage analog and digital circuitry can be combined monolithically with high-voltage transistors. Low-voltage circuits can be constructed to float up to 500VDC with respect to the substrate. Additionally, 500VDC NMOS and n-p-n transistors can also be fabricated.[2] Since this process conforms to mainstream low-voltage IC manufacturing, it is cost effective.

Totem-Pole Drivers

Historically, designers have been faced with awkward decisions regarding the upper-rail drive of bridge topologies. P-channel MOSFETs, while easy to drive, are more than twice as expensive as equivalent n-channel devices having the same r_{ds}(on). Economic barriers and product availability generally prohibit design beyond 200VDC. On the other hand, the driving of upper-rail n-channel MOS-gated devices requires a floating gate supply that must be 5 to 20VDC greater than the upper-rail link. While several discrete approaches for implementing this floating supply are known, the designer is burdened with additional components and potential dv/dt problems associated with voltage translation.

The SP600-series driver provides the economical solution as an intelligent totem-pole n-channel driver. With the addition of as few as five, user-defined, external, passive components (three if current detection isn't employed) a functional half-bridge driver can be built that has the following features:

- Creation and management of a 15VDC upper-rail power supply
- Ability to interface and drive standard and current-sensing n-channel MOSFETs/IGTs
- Shoot-through protection
- Overcurrent protection
- Undervoltage lockout
- CMOS logic-level input compatibility
- Semicustom flexibility through metal-mask changes
- Standard 22-pin DIP packaging

Theory of Operation

Figure 1 is the basic block diagram of the SP600. CMOS logic-compatible input signals are filtered to ensure reliable operation when the device is subjected to noisy industrial environments. Digital commands at TOP and BOTTOM inputs cause the upper or lower drivers, respectively, to turn on or off. The $I_{TRIP\ SELECT}$ input provides a higher than nominal current limit on a pulse-by-pulse basis. The input signals are decoded to drive the appropriate output device. High-voltage translation is provided by current-mirror pulses used to communicate upward to the top gate driver to initiate turn on or off (I_{on}/I_{off} pulses). These momentary pulses are captured by local latches to maintain the desired state. This feature minimizes power dissipation in the level shifter and provides added noise immunity as well. The bottom gate-driver circuitry is similar. The floating bootstrap power supply is provided by low-voltage capacitor C_f and high-voltage diode D_f. Each time the V_{out} node goes low, C_f charges to roughly a diode drop less than V_{dd} (15VDC). This situation prevails each time the lower output device is activated or, in the case of an inductive load, whenever the upper device is switched off and freewheeling load current forces the output node to a diode drop below ground. In either case, D_f is forward biased, allowing C_f to charge through the current-limiting resistor R_{bs} to approximately V_{dd}. Noise-dropping resistor R_{nd}, along with capacitor C_{dd}, provides localized filtering of the bias supply and bypasses bias suply series inductance facilitating fast and complete bootstap refresh.

Each output device is protected on a pulse-by-pulse basis from overcurrent (OC) by sense-resistor R_s, which is connected to 100-millivolt comparators. This arrangement permits the designer to take advantage of nearly lossless current-sensing MOSFETs or IGTs.

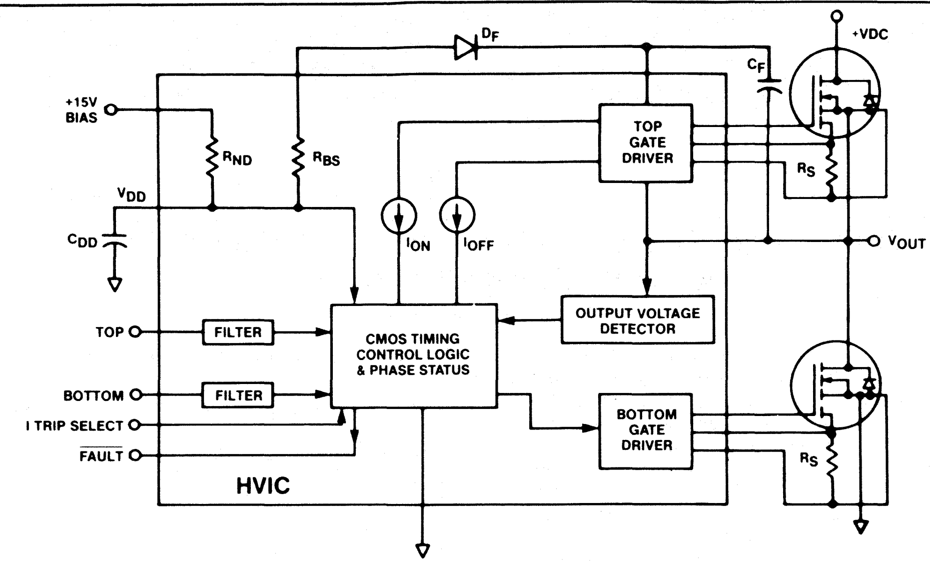

FIGURE 1. BLOCK DIAGRAM OF THE HVIC

Upon detection of any OC, the output is immediately disabled. In the case of the lower switch, a FAULT is directly detected and reported. Upper-rail OC FAULTs are indirectly reported via the output-voltage monitor when it detects an output state not in agreement with the commanded TOP input signal. With local OC detection and shutdown of the upper device, an inductive load will force V_{Out} low due to freewheeling. This "out of status" detector recognizes a fault when V_{Out} is typically less than 5.5VDC.

Logic And Timing

Figure 2 is a detailed functional circuit of the SP600. The filtered inputs, TOP, BOTTOM, and $I_{TRIP\ SELECT}$, ignore pulse widths less than typically 400 nanoseconds to prevent false triggering. During the generation of I_{on} and I_{off} pulses, the control logic ignores further changes in the input signal. For each Ion pulse, an I_{off} pulse is simultaneously sent to the opposite driver, thus eliminating

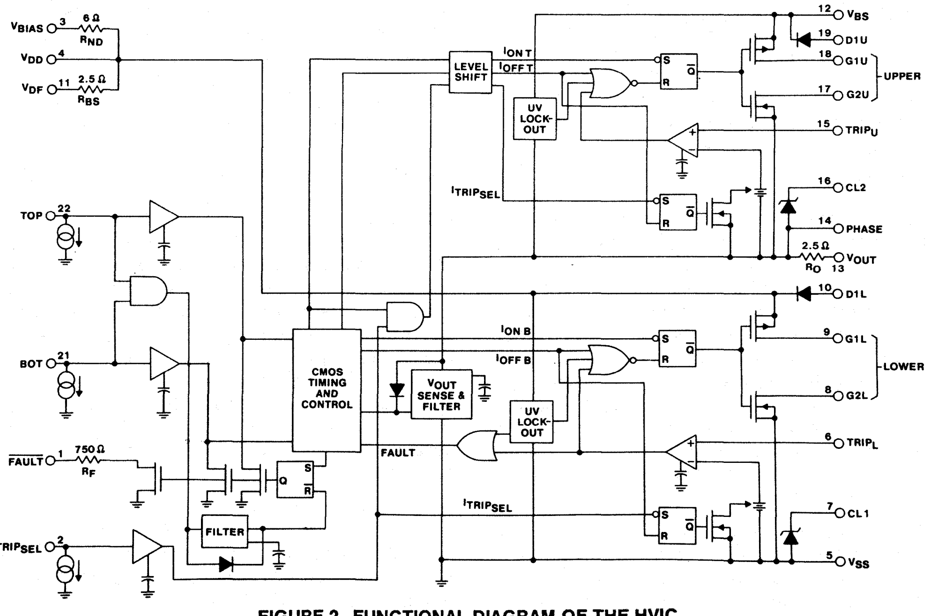

FIGURE 2. FUNCTIONAL DIAGRAM OF THE HVIC.

the possibility of spurious shoot-through caused by high-voltage, high-speed switching. These features aid in providing predictable operation of the floating upper-rail driver section, which is capable of slewing over 10,000 volts per microsecond.

PHASE serves as a common reference for the floating bootstrap supply (V_{bs}) and all upper-rail logic. V_{out}, for all practical purposes, is at the same potential as PHASE, being separated from it electrically by only a few ohms (R_O). This additional series output resistance helps to limit the peak current being drawn from the HVIC when an external lower flyback diode, undergoing forward recovery, forces V_{out} negative.

An automatic refresh algorithm is generated by the CMOS timing and control block to ensure that the bootstrap capacitor remains charged. As mentioned above, C_f is refreshed each time the V_{out} node swings to common. At power up, with zero voltage on C_f, there are two ways to refresh the bootstrap capacitor. The first is by initially commanding the bottom device to turn on, forcing V_{out} low. The second occurs when an automatic refresh is invoked if the TOP has been commanded on for longer than 200 to 500 microseconds. The logic momentarily ignores the inputs, and turns on the lower output (subsequent to an I_{off} TOP) for typically 2.0 microseconds, charges C_f and finally restores control to the input commands. Automatic refresh is overridden at switching rates greater than 5kHz, the minimum refresh timer period.

A dual-level current-limit provision allows for a 30% higher current trip point (above nominal) on a pulse-by-pulse basis. A logic-level 1 applied to $I_{TRIP\ SELECT}$ provides a boosted current limit suited for applications like uninterruptable power supplies (UPS), which may have occasional shifted peak-power requirements. This feature may allow for a more optimally selected output device. Benefits of current boost have been demonstrated in an off-line PWM motor controller where $I_{TRIP\ SELECT}$ is momentarily applied to overcome the inertia associated with rotor start-up.[3]

Both outputs are disabled and a FAULT reported as a result of:

- Overcurrent
- V_{dd} (lower bias) and V_{bs} (upper bias) undervoltage
- V_{out}/PHASE out-of-status
- Simultaneously commanded TOP and BOTTOM input (outputs disabled, no FAULT reported)

The fault can be cleared by a logic 0 at both TOP and BOTTOM inputs for the required fault reset delay time of 3.4 to 6.6 microseconds.

Power Driver Section

The upper and lower driver output sections are nearly identical, Figure 3.[4] Separate sink and source transistors are separately bonded out for application-specific designs requiring additional series gate impedance(s) for slower charge and discharge rates. This circuit property becomes particularly important with IGTs, where a minimum turn-off impedance of 100 ohms may be required to ensure full SOA. Regardless of the switching element used, companion flyback-diode characteristics may necessitate slower turn-on to reduce peak reverse-recovery current by increasing the gate impedance by means of R_{charge}.

A nominal 100mVDC comparator provides overcurrent (OC) protection when used with either current-sensing IGTs or MOSFETS. OC can also be implemented by using low-impedance shunts with noncurrent-sensing power-output devices, Figure 4.

Clamp CL1 in Figure 4 provides overvoltage protection for current-sensing structures during switching intervals, and protects the comparator from any voltage transients due to external lead inductances. To avoid nuisance OC trips caused by reverse-recovery current during turn-on transitions, the comparator's output is blanked for approximately 3-microseconds.

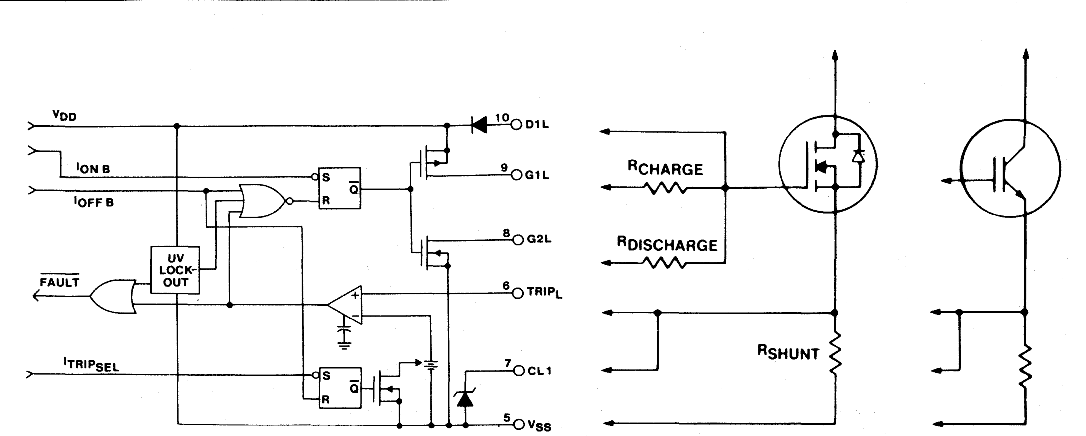

FIGURE 4. POWER-OUTPUT SECTION INTERFACING WITH NONCURRENT-SENSING MOSFET OR IGT.

System Performance

The half-bridge test circuit in Figure 5 was built to demonstrate the SP600 as a high-frequency driver of MOSFETs. The load is referenced to one-half the battery voltage, allowing bidirectional load current. This circuit characteristic emulates power configurations of half bridges with split supply or full bridges implemented with multiple HVICs.

For ultimate switching speed, no additional series gate impedances were used. Peak MOSFET gate charge and discharge current waveforms of 400 and 510mADC, respectively, were observed, Figure 6.

High-frequency, high-voltage operation requires that upper-rail drive and level-translator circuitry be immune to high dv/dt, as this section floats with respect to V_{out}/PHASE. Interjunction capacitance can dynamically inject displacement currents, raising havoc in circuit performance or even causing catastrophic failures, including the breakdown of voltage-isolation tubs or latch-up in adjacent four-layer structures.

FIGURE 7. OUTPUT LOAD CURRENT AT 130kHz USING IRF842s.

At rail voltages of 200 to 400VDC, rise and fall transitions of Vout/PHASE were measured in the 20 to 35 nanosecond region. The HVIC operated flawlessly while being subjected to output swings beyond 11,000 volts per microsecond. Figure 7 demonstrates the HVIC's ability to sustain such dv/dt when driving IRF820 devices.

IRF 842s were driven at 130 kHz in this same half-bridge circuit, Figure 8. The ultimate switching speed of the SP600-series HVIC will depend on gate capacitance and the duty-cycle limits dictated by the minimum I_{on} and I_{off} times. A minimum Ion time (1.6 to 3.1 microseconds) ensures time for refresh, while a minimum I_{off} time (1.3 to 3.4 microseconds) prevents simultaneous conduction by allowing for gate discharge prior to an opposite I_{on} pulse. The same promising technology has been shown to operate a half-bridge resonant converter at frequencies up to 600 kHz.[6]

FIGURE 7. V_{out} TRANSITION AT TURN-ON OF LOWER IRF820.

Semicustom Capability

The SP600 family can be customized by inexpensive, final-metal-mask alterations. Application-specific designs are possible for variations in the following parameters:

- Minimum I_{on}/I_{off} pulses
- OC trip-response time
- Input-signal conditioning filters
- OC trip level
- Inclusion of $R_{charge/discharge}$
- $I_{TRIP\ SELECT}$ boost level
- FAULT reset timer

Other system-related options include:

- Input protocol
- Automatic FAULT reset
- Ability to disable the automatic-refresh algorithm

Appendix

Timing Waveforms (See page 7)

Although both SP600 and SP601 timing diagrams are shown the SP601 was chosen to provide further explanation.

$t_0 < t < t_1$ At t_0, with the enable high, the outputs are simultaneously commanded to switch from lower to upper which is also known as Bistate operation. After delay t_{offD}, the lower is turned off, followed by the uppers turned on. Dead time, $t_{D.T.}$, the difference between the lower off transition to the upper on transition is internally set. Since this timing sets the margin of safety for simultaneous conduction, it's the user's responsibility to ensure that proper external gate impedance is selected to ensure ample time for power transistor charging/discharging.

$t_1 < t < t_2$ The lower is turned on at t_1 and continues for a relatively long period, long enough that at t_2 an automatic refresh will be invoked.

$t_2 < t < t_3$ The HVIC has blinded itself to the logic inputs during this refresh mode. The upper is turned off, with its associated turn off delay, t_{offD}. After the fixed dead time, $t_{D.T.}$, the lower is briefly turned on, ton, providing a charge refresh path for the bootstrap capacitor, C_f. Once again the dead time is observed before turning the upper back on again and restoring control to the user inputs. This refresh cycle can be detected as a few microsecond wide pulse of lower MOSFET/IGT current.

$t_3 < t < t_5$ The upper remains commanded on for a period of time less than t_{REF}. At t_4, the UP/$\overline{\text{DOWN}}$ time is brought low, commanding a lower turn on. Similar to the t_0-t_1 interval, the upper turns off after delay t_{offD} and the lower turns on after the dead time, $t_{D.T.}$

$t_5 < t < t_7$ The SP601 is disabled by the ENABLE line low at t_5. Previously conducting lower turns off after its delay, t_{offD}. Since the ENABLE line was previously brought low and neither output transistors are conducting, termed as tristate mode. The state of the output phase waveform remains unknown. At t_6, the ENABLE is once again pulled high. The lower turns on after delay, t_{onDB}.

$t_7 < t < t_9$ At t7, the SP601 is disabled and the UP/DOWN line is toggled to the upper position. The lower turns off and the power devices go into a tristate mode. At t_8, upper turn on sequence begins. Since the auto one shot hasn't timed out yet, the turn on delay, t_{onDB}, is relatively short.

$t_9 < t < t_{11}$ The chip shuts off as the ENABLE line is brought low at t_9, and is enabled again at t_{10} as the UP/DOWN line had remained high. Since the disable period was long and the refresh one shot had timed out, the turn on delay, t_{onDT}, is slow. Keep in mind that the delay time includes the time for automatic refresh. In an attempt to not further complicate the drawing, the detailed refresh cycle isn't actually shown.

$t_{11} < t < t_{13}$ Both inputs are brought low at t_{11} for a duration longer than t_{REF}. At t_{13} the ENABLE is restored, initiating the turn on sequence for the lower. This follows a long period of time where the one shot had timed out, b ut in this case the lower is commanded on. Since it doesn't need the refresh algorithm, the turn on delay, t_{onDB}, is fast.

$t_{11} < t < t_{13}$ This sequence of events depicts the detection of a lower overcurrent trip. Between t_{13}-t_{14}, the lower is on. Beyond the filter delay, t_{offTN}, the overcurrent trip shuts off the lower driver. A fraction of a microsecond later, t_{FN}, the flag report delay, FAULT goes low.

$t_{15} < t < t_{16}$ $t_{18} < t < t_{19}$ By holding both ENABLE and UP/$\overline{\text{DOWN}}$ lines low for the required fault filter reset time, $t_{R.T.}$, the fault is cleared.

$t_{16} < t < t_{17}$ The upper is turned on and an overcurrent trip begins. Beyond the filter delay, t_{OFFTN}, the overcurrent comparator shuts off the upper drive at t_{17}. Since the control logic can only communicate upwards, there is no direct means of reporting an upper trip. As the fault has been remotely captured by the floating upper section, shutdown has occurred. The Phase or V_{OUT} node will quickly fall to a diode drop below common due to inductive flyback current. Via the V_{OUT}/VPHASE monitor this is detected as not being in agreement with the commanded input and reports the fault. Reporting this phase out of status delay is t_{OSVF}.

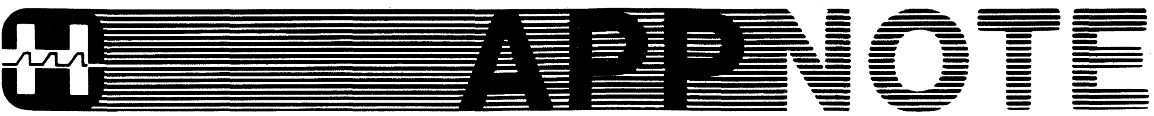
APPLICATION NOTES



SP606 HIGH VOLTAGE (600VDC) HALF BRIDGE DRIVER IC

Author: George E. Danz

Introduction

The SP606 is a high voltage, high speed dual driver for MOS gated power devices. The drivers are isolated from each other, each controlled by an independent input line referenced to the system common voltage. The SP606 was designed using the same proprietary technology which was started more than 5 years ago, resulting in the first products in the HVIC family, the SP600/SP601 Half Bridge Drivers. Many of the benefits of the SP600/SP601 family also apply to the SP606. For example, these HVICs offer a very inexpensive means for driving an n-channel power switch from low-side referenced logic without special isolation circuitry, such as opto-coupler (not known for extreme reliability) or transformer means (often too expensive). Highly integrated low level logic and high-level drive circiutry minimize propagation delays, allowing higher switching frequencies and often lower switching losses than would be attainable using more conventional techniques. In addition to cost savings and performance increases, the HVIC simplifies and reduces the effort needed to design an efficient driver for MOS gated high and low side switches. Features specific to the SP606 are discussed below.

The SP606 enjoys some features which the SP600/SP601 lacks. These are a smaller 14 pin dip package, significantly higher output drive capability (2A peak) and lower transport delays from input to output. In order to maintain noise immunity, CMOS Schmitt triggered inputs with pull down are incorporated on all inputs. By shedding some of the features of the SP600/601 family such as over-current trip and shoot-through protection, the SP606 can operate at PWM frequencies up to 1MHz, having gate rise and fall times of typically 14 and 10 nano-seconds, respectively into 1000pF load. The high side turn-on and turn-off propagation delays are very low at 85 and 100 nano-seconds typically.

The blocking voltage of the SP606 has been increased to 600VDC in keeping with industry requests for 600V blocking capability for bridge components for use on rectified 230VAC lines.

While the burden of shoot-through protection is now squarely with the user, the added flexibility of precise user gate control allows some other interesting circuit topologies. For example the double forward converter configuration popular with power supply, stepper motor control and switched reluctance motor control can now be implemented. Capacitor C_F must be fully charged before

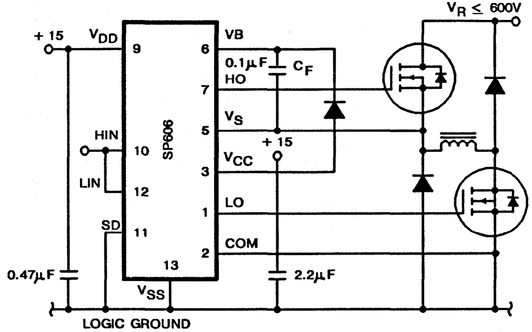


FIGURE 1. DOUBLE FOWARD CONVERTER SCHEMATIC

turning the upper switch on the first time by holding the lower switch on long enough to charge C_F through the load impedance. See Figure 1.

Also with the SP606 it is possible to drive a high-side switch which can be switched independently from the low side switch. The load itself could supply initial bootstrap voltage and an appropriate flyback diode would be required in parallel with the load to avoid severe negative excursions of the power switch's source lead. An example of this is shown in Figure 2.

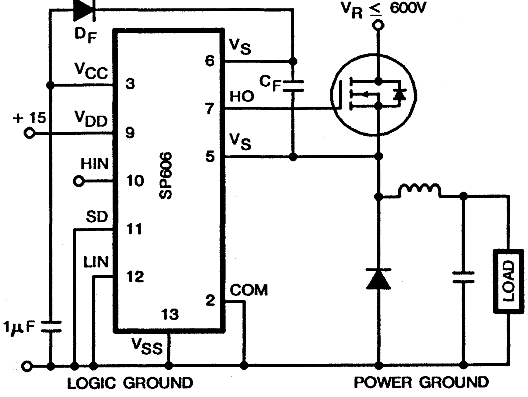

FIGURE 2. HIGH SIDE SWITCH OR "BUCK CONVERTER"

Description of the SP606

The block diagram of the SP606 is shown in Figure 3. The SP606 is comprised of a ground referenced gate drive circuit and a high voltage bus referenced (floating) gate drive circuit. The input logic circuit for the high side driver incorporates level translation circuitry to interface between the low voltage logic section and the high voltage logic section which controls the upper (or floating) gate driver.

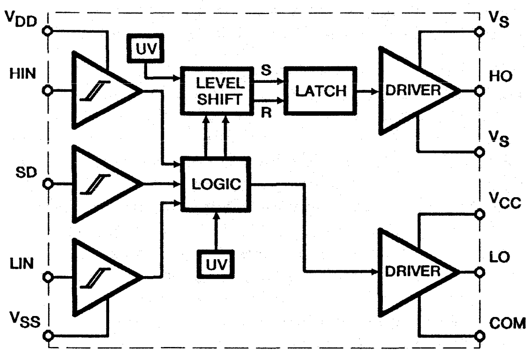

FIGURE 3. SP606 FUNCTIONAL BLOCK DIAGRAM

Shutdown is accomplished by a logic level 1 at the SD input. This input must be at logic level 0 to "gate" the HIN and LIN inputs to their respective drivers. The SD logic also removes bias to the high voltage translation pulse circuits, thereby reducing bias current to the SP606 when in shutdown mode.

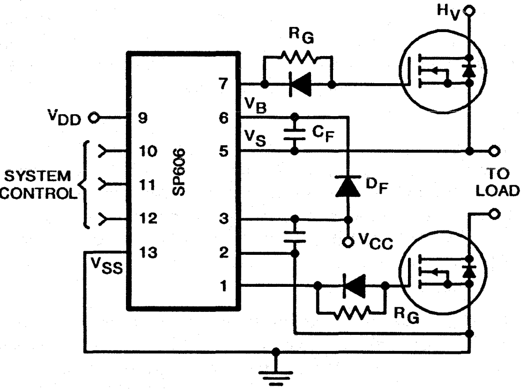

FIGURE 4. SIMPLIFIED SHOOT-THROUGH CONTROL

Input Logic

There are three inputs to the SP606; HIN controls the floating high side driver, LIN controls the low side (ground referenced) driver and SD which controls the "shutdown" function. All inputs pass through Schmitt buffers employing hysteresis with transition thresholds proportional to the logic supply V_{DD}. Slower or ramped inputs therefore are squared up before being passed to the level translation circuits, which translate the logic level inputs to signal levels compatible with the fixed driver (10V to 15V) supply. The level translation circuit allows the ground reference of the logic supply (V_{SS} on pin 13) to swing plus or minus by a couple of volts with respect to the power ground (COM on pin 2) thereby enhancing noise immunity.

Each channel, including the shutdown input, is independently controlled. The gate drive responds within a short (typically 100 nanoseconds) propagation delay of the input signal. In applications where deadtime is required to prevent conduction overlap or "shoot-through", the HI and LO input commands must be spaced by external circuitry. For example in a half bridge configuration, where the upper and lower switches are series connected between the high and low sides of the power bus, effort must be taken to turn off each of the switches in advance of turning on the other. The designer must ensure that one switch is completely off before trying to turn on the other or high currents can flow through both, often leading to destruction of one or both power switches. Often a few passive components added to delay switch turn-on without delaying turn-off can effectively control shoot-through (see the diode-resistor parallel combination in Figure 4). As power levels and power switch devices become larger, passive techniques may not be reliable and more deliberate means may be necessary to provide turn-on blanking of one switch while the other switch is turning off.

Protection Features

The SP606 is protected internally from insufficient bootstrap supply voltage (in the case of the upper floating driver) and insufficient bias supply voltage (in the case of the lower driver). Also circuitry is provided which allows the high voltage power to be applied prior to the low voltage control power without inducing false gating from the SP606.

The undervoltage circuitry functions differently for upper and lower drivers. The lower undervoltage lockout blocks drive to both upper and lower power switches. Upon re-establishment of proper lower supply voltage levels the drive signals are un-blocked and gate drive to both upper and lower switches is re-established provided the appropriate LIN and HIN signals are enabled. The upper undervoltage circuit controls only the gating of the upper (floating) switch which is latched off when an undervoltage is sensed. Latching is released when the upper undervoltage circuit is satisfied. A subsequent "on" pulse from the HIN terminal is necessary to trigger the upper switch. The HIN terminal must have previously gone low since all communications with the upper driver are "edge" triggered. The purpose for latching the upper driver off in the event of an undervoltage condition is to ensure direct control from the HIN input. Without latching, the undervoltage circuit could cycle at a frequency dependent upon the size of the bootstrap capacitor, gate capacitance, and undervoltage hysteresis levels. Latching the undervoltage detector provides in essence an "alarm" that an undervoltage condition has occurred. The circuit designer must pick values of bootstrap capacitance which ensures that undervoltage cycling is not encountered at the desired PWM frequency. Guidance on choosing the right value can be found under "FLOATING SUPPLY CONSIDERATIONS" later in this note.

Driver Circuits

The driver circuits for the upper and lower gate drives are identical. Since it is desirable to provide the greatest possible gate drive voltage consistent with the user supplied voltage, p-channel mosfets have been used in the output stage of the drivers for sourcing gate current to the power device. Likewise, n-channel devices have been employed for sinking current from the gates of the power devices. This approach allows more complete utilization of the V_{CC} voltage. Also changes in mosfet threshold voltages with temperature will not effect power device gate bias levels.

The sink and source currents of the gate drivers are fully capable of supplying peak currents of at least 2.0 amps, which means that a power mosfet device with 3000pF gate-source capacitance can be fully charged in under 20 nano-seconds. Discharge of the gate-source capacitance will be just as rapid, since R_{DSon} of sink and source drivers are matched.

The high side driver section is built into an "isolation tub" which is capable of floating +600VDC above substrate potential with respect to power ground (COM pin 2). Pin 6 (V_S) is the common potential for the upper drive circuitry and is the most negative voltage within the floating tub. V_B (pin 5) is the positive rail within the floating tub and is usually +15 above V_S. The gate drive output, HO (pin 7) swings between V_S and V_B according to the state of the HIN input pin.

Floating Supply Considerations

The floating supply which ties between V_B and V_S is supplied typically by a capacitor, C_F, referred to as the bootstrap capacitor. A fast recovery, low leakage diode, DF, refreshes or charges this capacitor whenever the V_S terminal swings to common (see figure 4). A low leakage, fast recovery diode should be chosen for the bootstrap diode and should exhibit low reverse recovery charge. Accomplish this by choosing a diode with a blocking voltage rating greater than 600VDC. For example, the Harris A114P diode is a high voltage 1A, fast recovery diode rated at 1000V blocking. It is used with great success on rectified 230VAC circuits where normally a 500V or 600V diode would be used. The high voltage diode results in a naturally lower junction capacitance than would be attainable in a comparable low voltage diode.

The refresh charging "loop" is a circuit beginning at the V_{CC} node and comprising the bootstrap diode (forward biased), the bootstrap capacitor, either the lower power device or the flyback diode and the COM terminal. Normally VS voltage will be one diode drop below the COM terminal whenever the upper power switch is turned off due to the inductive nature of the load current commutating from the upper switch to the lower flyback (or body) diode around the lower power switch. When no inductive load current is flowing through the lower flyback diode, then the V_S terminal voltage will operate at a voltage above the COM terminal determined by the current in the lower power device and that devices' forward drop. The ultimate voltage attained on the bootstrap capacitor is dependent on whether it was refreshed through the flyback diode or the lower power switch device. Lead inductance associated with the flyback diode can actually cause the V_S terminal to transiently go 5 to 20 volts below COM. This occurs when the upper switch is turned off very rapidly and the load current is rapidly commutated to the lower flyback diode. Although this can help to dump some charge very quickly onto the bootstrap capacitor, it can cause trouble with the HVIC if allowed to exceed more than about 4 volts. It is wise to minimize this inductance by tight power circuit layout practices.

A number of considerations in the implementation of this bootstrap arrangement which must be kept in mind. The series inductance in the loop comprised of the bootstrap diode, capacitor and the V_{CC} supply and COM return path must be kept very low. Ideally under normal conditions the charging time for refreshing the capacitor is short. This must be so when very high PWM duty cycles are desired. In fact overmodulation must be avoided so that approximately 1 to 2 fsecs. is reserved for refreshing the bootstrap capacitor. The actual time required depends on the series resistance of the bootstrap loop, the series inductance (hopefully zero) and the size of the bootstrap capacitor. An upper limit on the PWM frequency is then given by:

$$f_{PWM} \leq \frac{(1 - DC)}{t_{REF}}$$

where: DC = Duty cycle fraction

t_{REF} = refresh time (sec.)

f_{PWM} = PWM frequency (Hz)

Another consideration in the design of the bootstrap circuit concerns the sizing of the bootstrap capacitor. If it is assumed that all of the gate charge comes from the bootstrap capacitor, which is a good assumption, then enough charge must be placed on the bootstrap capacitor such that when it "dumps" the turn-on gate charge to the power switch, there is still enough voltage on the bootstrap capacitor such that undervoltage lockout is not triggered. For turn-on gate charge of Q_G, flying capacitor of C_F, supply voltage V_{CC} and final gate voltage V_G (which must be greater than the maximum value for the undervoltage trip threshold), the minimum bootstrap capacitor is given by:

$$C_F > \frac{Q_G}{V_{CC} - V_G}$$

The above assumes an inductive load which would tend to cause the bootstrap diode drop to be approximately cancelled by the drop associated with the body diode (mosfet) or flyback diode in parallel with an IGBT. If the load is not somewhat inductive, the bootstrap diode drop must be subtracted from V_{CC} along with any drop associated with the lower switch. The effects of leakage current in the reverse-biased bootstrap diode and the small quiescent bias current of the upper driver circuit must be taken into account when sizing C_F. Therefore the sum of the above currents and the charge removed from C_F in charging the gate capacitance, Q_G, determines the minimum size of C_F. Therefore:

$$C_F > \frac{Q_G + (I_{QBS} + I_R) \bullet t_{ON}(max)}{V_{CC} - V_G}$$

The previous discussion on refreshing has been made with a half bridge or "totem-pole" configuration of the power switches in mind. Other topologies are of interest such as the "double forward converter" configuration shown in Figure 1. Once current is established in the inductor of the double forward converter, simply turning off the switches causes the inductor current to freewheel through the commutating diodes. The V_S lead will be pulled to approximately a diode drop below COM while the inductor current ramps to zero.

This action will charge the bootstrap capacitor in all cases but those wherein the inductor current is minute. During start-up when there is no current in the inductor, it is necessary to pre-charge the bootstrap capacitor. This can be accomplished in a number of ways, but one can simply turn on the lower MOSFET or IGBT long enough to charge up the capacitor. Voltage overshoot due to the resulting series RLC circuit will be clamped by the internal zener clamps and/or the substrate diode within the SP606. Alternatively, a small auxiliary MOSFET can be placed around the lower flyback diode and driven by an inverted LO gate drive signal. When the lower is turned "off", the auxiliary MOSFET will be turned "on" thereby supplying a charging path for the bootstrap capacitor.

The buck converter (Figure 2) is another possible application for the SP606. With this type of converter configuration, as soon as the SP606 bias supply power is applied, the bootstrap capacitor will be charged through the load impedance. After having waited for complete charging of the capacitor, it is then possible to operate the SP606 normally. Subsequent refreshing will occur each time the buck converter switch is turned off. Refreshing will occur very rapidly in the case of a predominantly inductive load which is really the only practical load for a buck converter.

Level Shifting Circuits

As shown in Figure 4, the high side channel input commands require level-shifting from a level near COM to a level near that at which the high voltage tub is floating, which can be 600V. The on/off commands for the high side are transformed into narrow current source commands which sink current through burden resistors in the high side circuit. After squaring up these pulses they are "and" gated with the output from the under-voltage circuit and latched before being sent to the driver section.

Switching dv/dt as high as 50V/ns is possible with the SP606. Also, when the upper switch is turned off, the short-lived negative excursions of the V_S terminal due to so-called "forward recovery" and lead wire inductance in series with the upper and lower power switches will not cause problems with SP606 operation.

Power Dissipation

Power dissipation in the SP606 results from static losses and switching losses. The static losses are due to the bias supply in both upper and lower driver sections and leakage losses in the high voltage level translation transistors. The sum of all these losses is approximately 8.7mW at +25°C. At +125°C these losses are not normally over 20mW.

The dynamic losses are due to low voltage and high voltage switching losses. The low voltage switching losses derive primarily from the upper and lower driver output stages. The energy required in charging and discharging the gate of the power switches must flow through the resistance in the gates of the power devices, the R_{DSon} of the driver output stage, and all of the lumped wiring and connection and supply sources resistances. The sharing of these resistances between the SP606 and the external source and switch devices must be known before an accurate calculation of losses can be attempted. The total loss, however can easily be calculated once the PWM frequency, supply voltage and power device gate charge is known as follows:

$$P_{total} = 2 \bullet f_{PWM} \bullet Q_G \bullet V_{CC}$$

The high voltage switching losses are due predominantly to the level translation transistors. These losses are a function of the PWM frequency, the level translation current and pulse width and the bus and V_{CC} voltages. The level translation power dissipation then is:

$$P_{level\ trans.} = f_{PWM} \bullet (V_S + V_{CC}) \bullet 400 \times 10^{-12}$$

APPNOTE

Harris Intelligent Power

HVIC/IGBT HALF BRIDGE CONVERTER EVALUATION CIRCUIT

The HVIC high-voltage integrated circuit is designed to drive n-channel IGBTs or MOSFETs in a half-bridge configuration up to 500VDC. Power supply and motor control inverters can be configured for voltages up to 230VAC using the HVIC, IGBTs and a few other components.

A few precautions should be taken in using the circuit. Lead lengths between the external power circuit (including gate and pilot leads), the 15V bypass capacitor (C_{DD}), the bootstrap diode (D_F) and capacitor (C_F) and the HVIC should be minimized.

The basic components required to evaluate the features of the SP601 are shown in the simplified schematic. The recommended load is largely resistive so that the largest current component will flow through the IGBTs, IGT1 and IGT2.

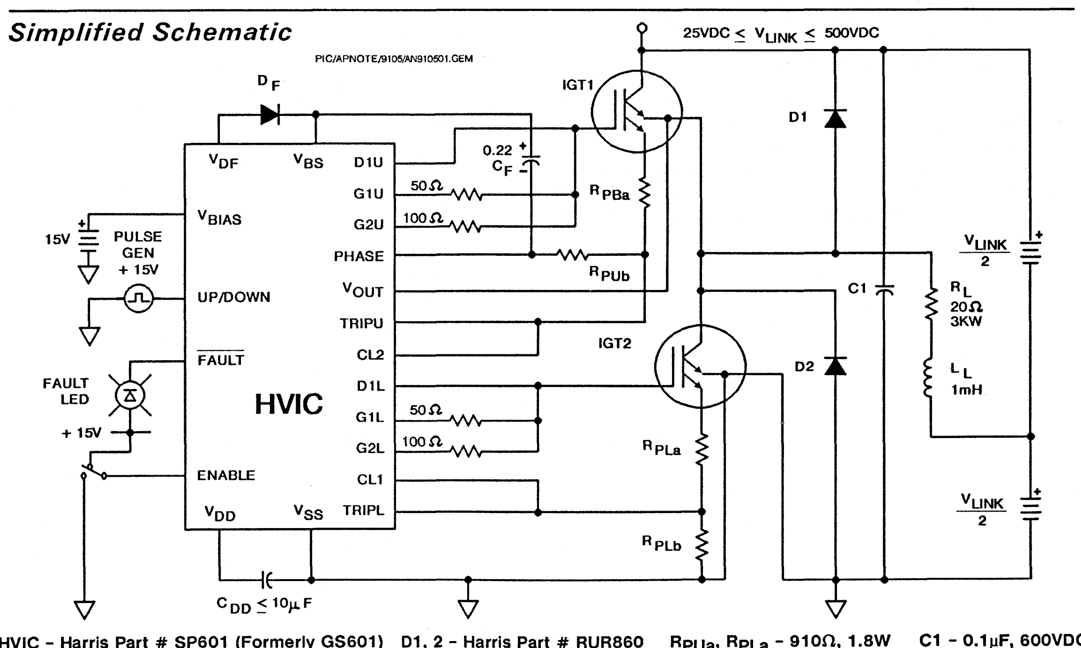
The flyback diodes, D1 and D2, rated 8A, will carry a much smaller flyback current component. A small amount of load inductance will cause the switching waveforms to simulate the conditions which would normally be observed with motor or transformer loads, while limiting the current carried by the lower rated flyback diodes in this circuit.

The values for R_{PUa}, R_{PUb}, etc., have been chosen to result in overcurrent trip at approximately 25Apk. At this level of current, heat sinking for the IGTs and flyback diodes is required. The series resistance of the upper and lower pilot resistor dividers would be approximately 1Kohm; the divider ratio should cause 0.1V at the tap at the desired trip current.

When first energizing your evaluation circuit, begin with a reduced bus voltage of about 20VDC to 30VDC to verify proper circuit operation before proceeding to higher voltages.

More specific information can be found in File Number 2428 and File Number 2429 Half-Bridge 500VDC Driver data sheets and in the Application Note, AN-8829.1.

Simplified Schematic



HVIC - Harris Part # SP601 (Formerly GS601)
IGT1, 2 - Harris Part # HGTA24N60D1C
D1, 2 - Harris Part # RUR860
D_F - Harris Part # A114M
R_{PUa}, R_{PLa} - 910Ω, 1.8W
R_{PUb}, R_{PLb} - 68Ω, 1.8W
C1 - 0.1μF, 600VDC
R_L - 20Ω, 3KW
