

# TLE42754

Low Dropout Linear Fixed Voltage Regulator

Automotive Power

Never stop thinking

## 1 Overview

### Features

- Output Voltage 5 V  $\pm$  2%
- Output Current up to 450 mA
- Very low Current Consumption
- Power-on and Undervoltage Reset with Programmable Delay Time
- Reset Low Down to  $V_Q = 1$  V
- Very Low Dropout Voltage
- Output Current Limitation
- Reverse Polarity Protection
- Overtemperature Protection
- Suitable for Use in Automotive Electronics
- Wide Temperature Range from -40 °C up to 150 °C
- Input Voltage Range from -42 V to 45 V
- Green Product (RoHS compliant)
- AEC Qualified

### Description

The TLE42754 is a monolithic integrated low-dropout voltage regulator in a 5-pin TO-package, especially designed for automotive applications. An input voltage up to 42 V is regulated to an output voltage of 5.0 V. The component is able to drive loads up to 450 mA. It is short-circuit proof by the implemented current limitation and has an integrated overtemperature shutdown. A reset signal is generated for an output voltage  $V_{Q,rt}$  of typically 4.65 V. The power-on reset delay time can be programmed by the external delay capacitor.

### Dimensioning Information on External Components

An input capacitor  $C_1$  is recommended for compensation of line influences. An output capacitor  $C_Q$  is necessary for the stability of the control loop.

**Circuit Description**

The control amplifier compares a reference voltage to a voltage that is proportional to the output voltage and drives the base of the series transistor via a buffer. Saturation control as a function of the load current prevents any oversaturation of the power element. The component also has a number of internal circuits for protection against:

- Overload
- Overtemperature
- Reverse polarity

2) Specified  $R_{thJA}$  value is according to Jedec JESD51-2,-5,-7 at natural convection on FR4 2s2p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm<sup>3</sup> board with 2 inner copper layers (2 x 70µm Cu, 2 x 35µm Cu). Where applicable a thermal via array under the exposed pad contacted the first inner copper layer.

3) Specified  $R_{thJA}$  value is according to JEDEC JESD 51-3 at natural convection on FR4 1s0p board; The Product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm<sup>3</sup> board with 1 copper layer (1 x 70µm Cu).

## 5 Block Description and Electrical Characteristics

### 5.1 Voltage Regulator

The output voltage  $V_Q$  is controlled by comparing a portion of it to an internal reference and driving a PNP pass transistor accordingly. The control loop stability depends on the output capacitor  $C_Q$ , the load current, the chip temperature and the poles/zeros introduced by the integrated circuit. To ensure stable operation, the output capacitor's capacitance and its equivalent series resistor ESR requirements given in the table **“Functional Range” on Page 7** have to be maintained. For details see also the typical performance graph **“Output Capacitor Series Resistor ESR(CQ) versus Output Current IQ” on Page 12**. As the output capacitor also has to buffer load steps it should be sized according to the application's needs.

An input capacitor  $C_I$  is strongly recommended to compensate line influences. Connect the capacitors close to the component's terminals.

A protection circuitry prevent the IC as well as the application from destruction in case of catastrophic events. These safeguards contain an output current limitation, a reverse polarity protection as well as a thermal shutdown in case of overtemperature.

In order to avoid excessive power dissipation that could never be handled by the pass element and the package, the maximum output current is decreased at input voltages above  $V_I = 28\text{ V}$ .

The thermal shutdown circuit prevents the IC from immediate destruction under fault conditions (e.g. output continuously short-circuited) by switching off the power stage. After the chip has cooled down, the regulator restarts. This leads to an oscillatory behaviour of the output voltage until the fault is removed. However, junction temperatures above  $150\text{ °C}$  are outside the maximum ratings and therefore significantly reduce the IC's lifetime.

The TLE42754 allows a negative supply voltage. In this fault condition, small currents are flowing into the IC, increasing its junction temperature. This has to be considered for the thermal design, respecting that the thermal protection circuit is not operating during reverse polarity conditions.

### 5.3 Reset Function

The reset function provides several features:

#### Output Undervoltage Reset:

An output undervoltage condition is indicated by setting the Reset Output RO to “low”. This signal might be used to reset a microcontroller during low supply voltage.

#### Power-On Reset Delay Time:

The power-on reset delay time  $t_{rd}$  allows a microcontroller and oscillator to start up. This delay time is the time frame from exceeding the reset switching threshold  $V_{RT}$  until the reset is released by switching the reset output “RO” from “low” to “high”. The power-on reset delay time  $t_{rd}$  is defined by an external delay capacitor  $C_D$  connected to pin D charged by the delay capacitor charge current  $I_{D,ch}$  starting from  $V_D = 0$  V.

If the application needs a power-on reset delay time  $t_{rd}$  different from the value given in [Item 5.3.6](#), the delay capacitor’s value can be derived from the specified values in [Item 5.3.6](#) and the desired power-on delay time:

$$C_D = \frac{t_{rd,new}}{t_{rd}} \times 47\text{nF}$$

with

- $C_D$ : capacitance of the delay capacitor to be chosen
- $t_{rd,new}$ : desired power-on reset delay time
- $t_{rd}$ : power-on reset delay time specified in this datasheet

For a precise calculation also take the delay capacitor’s tolerance into consideration.

#### Reset Reaction Time:

The reset reaction time avoids that short undervoltage spikes trigger an unwanted reset “low” signal. The reset reaction time  $t_{rr}$  considers the internal reaction time  $t_{rr,int}$  and the discharge time  $t_{rr,d}$  defined by the external delay capacitor  $C_D$  (see typical performance graph for details). Hence, the total reset reaction time becomes:

$$t_{rr} = t_{rd,int} + t_{rr,d}$$

with

- $t_{rr}$ : reset reaction time
- $t_{rr,int}$ : internal reset reaction time
- $t_{rr,d}$ : reset discharge

#### Reset Output Pull-Up Resistor $R_{RO}$ :

The Reset Output RO is an open collector output requiring an external pull-up resistor to a voltage  $V_{IO}$ , e.g.  $V_Q$ . In [Table “Electrical Characteristics Reset Function” on Page 18](#) a minimum value for the external resistor  $R_{RO}$  is given for the case it is connected to  $V_Q$  or to a voltage  $V_{IO} < V_Q$ . If the pull-up resistor shall be connected to a voltage  $V_{IO} > V_Q$ , use the following formula:

$$R_{RO} = \frac{5\text{k}\Omega}{V_Q} \times V_{IO}$$
