The PAL™ Concept

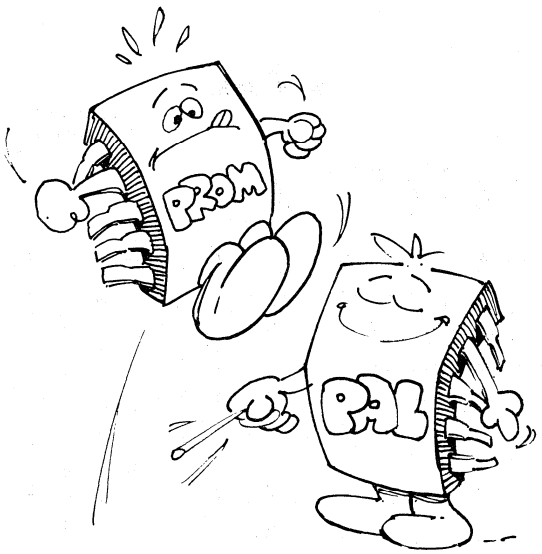
Monolithic Memories' family of PAL devices gives designers a powerful tool with unique capabilities for use in new and existing logic designs. The PAL saves time and money by solving many of the system partitioning and interface problems brought about by increases in semiconductor device technology.

Rapid advances in large scale integration technology have led to larger and larger standard logic functions; single I.C.s now perform functions that formerly required complete circuit cards. While LSI offers many advantages, advances have been made at the expense of device flexibility. Most LSI devices still require large numbers of SSI/MSI devices for interfacing with user systems. Designers are still forced to turn to random logic for many applications.

The designer is confronted with another problem when a low to medium complexity product is designed. Often the function is well defined and could derive significant benefits from fabrication as an integrated circuit. However, the design cycle for a custom circuit is long and the costs can be very high. This makes the risk significant enough to deter most users. The technology to support maximum flexibility combined with fast turn around on custom logic has simply not been available. Monolithic Memories offers the programmable solution.

The PAL family offers a fresh approach to using fuse programmable logic. PALs are a conceptually unified group of devices which combine programmable flexibility with high speed and an extensive selection of interface options. PALs can lower inventory, cut design cycles and provide high complexity with maximum flexibility. These features, combined with lower package count and high reliability, truly make the PAL a circuit designer's best friend.

The PAL—Teaching Old PROMs New Tricks



MMI developed the modern PROM and introduced many of the architectures and techniques now regarded as industry standards. As the world's largest PROM manufacturer, MMI has the proven technology and high volume production capability required to manufacture and support the PAL.

The PAL is an extension of the fusible link technology pioneered by Monolithic Memories for use in bi-polar PROMs. The fusible link PROM first gave the digital systems designer the power to "write on silicon." In a few seconds he was able to transform a blank PROM from a general purpose device into one containing a custom algorithm, microprogram, or Boolean transfer function. This opened up new horizons for the use of PROMs in computer control stores, character generators, data storage tables and many other applications. The wide acceptance of this technology is clearly demonstrated by today's multi-million dollar PROM market.

The key to the PROM's success is that it allows the designer to quickly and easily customize the chip to fit his unique requirements. The PAL extends this programmable flexibility by utilizing proven fusible link technology to implement logic functions. Using PALs the designer can quickly and effectively implement custom logic varying in complexity from random gates to complex arithmetic functions.

ANDs and ORs

The PAL implements the familiar sum of products logic by using a programmable AND array whose output terms feed a fixed OR array. Since the sum of products form can express any Boolean transfer function, the PAL's uses are only limited by the number of terms available in the AND - OR arrays. PALs come in different sizes to allow for effective logic optimization.

Figure 1 shows the basic PAL structure for a two input, one output logic segment. The general logic equation for this segment is

$$\text{Output} = (I_1+\bar{f}_1)(\bar{I}_1+\bar{f}_2)(I_2+\bar{f}_3)(\bar{I}_2+\bar{f}_4) + (I_1+\bar{f}_5)(\bar{I}_1+\bar{f}_6)(I_2+\bar{f}_7)(\bar{I}_2+\bar{f}_8)$$

where the "f" terms represent the state of the fusible links in the PAL's AND array. An unblown link represents a logic 1. Thus,

fuse blown, f = 0

fuse intact, f = 1

An unprogrammed PAL has all fuses intact.

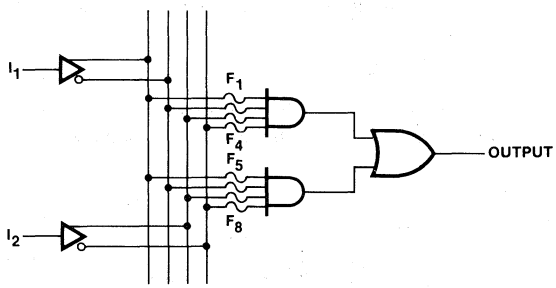


Figure 1

PAL Notation

Logic equations, while convenient for small functions, rapidly become cumbersome in large systems. To reduce possible confusion, complex logic networks are generally defined by logic diagrams and truth tables. Figure 2 shows the logic convention adopted to keep PAL logic easy to understand and use. In the figure, an "x" represents an intact fuse used to perform the logic AND function. (Note: the input terms on the common line with the x's are not connected together.) The logic symbology shown in Figure 2 has been informally adopted by integrated circuit manufacturers because it clearly establishes a one-to-one correspondence between the chip layout and the logic diagram. It also allows the logic diagram and truth table to be combined into a compact and easy to read form, thereby serving as a convenient shorthand for PALs. The two input - one output example from Figure 1 redrawn using the new logic convention is shown in Figure 3.

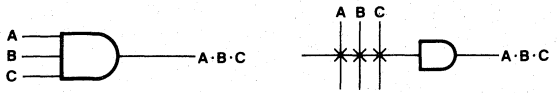

Figure 2

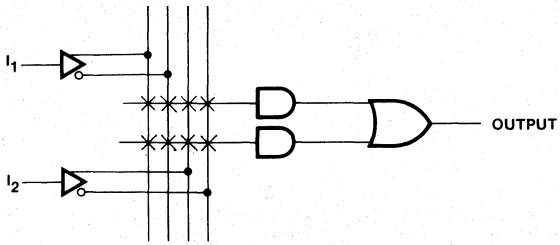

Figure 3

As a simple PAL example, consider the implementation of the transfer function:

$$\text{Output} = I_1\overline{I_2} + \overline{I_1}I_2$$

The normal combinatorial logic diagram for this function is shown in figure 4, with the PAL logic equivalent shown in figure 5.

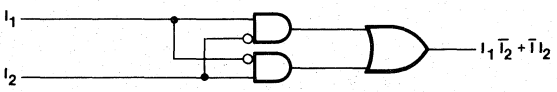

Figure 4

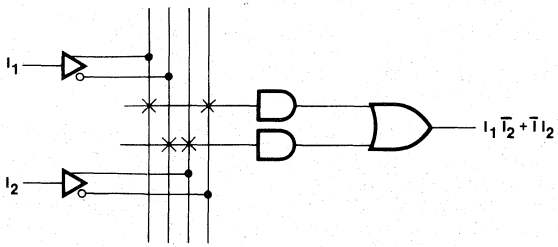

Figure 5

Using this logic convention it is now possible to compare the PAL structure to the structure of the more familiar PROM and PLA. The basic logic structure of a PROM consists of a fixed AND array whose outputs feed a programmable OR array (figure 6). PROMs are low-cost, easy to program, and available in a variety of sizes and organizations. They are most commonly used to store computer programs and data. In these applications the fixed input is a computer memory address; the output is the contents of that memory location.

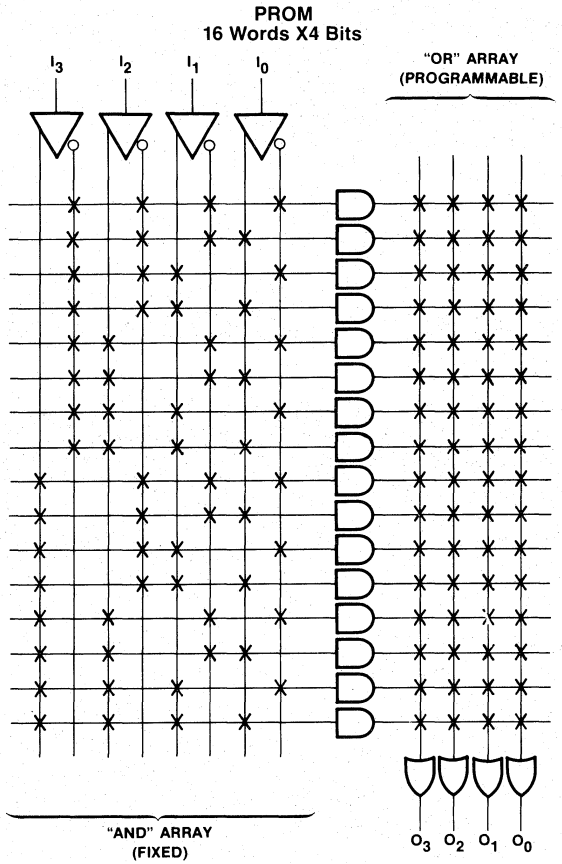

Figure 6

The basic logic structure of the PLA consists of a programmable AND array whose outputs feed a programmable OR array (Figure 7). Since the designer has complete control over all inputs and outputs, the PLA provides the ultimate flexibility for implementing logic functions. They are used in a wide variety of applications. However, this generality makes PLAs expensive, quite formidable to understand, and costly to program (they require special programmers).

The basic logic structure of the PAL, as mentioned earlier, consists of a programmable AND array whose outputs feed a fixed OR array (Figure 8). The PAL combines much of the flexibility of the PLA with the low cost and easy programmability of the PROM. Table 1 summarizes the characteristics of the PROM, PLA, and PAL logic families.

[1] Simultaneous AND-OR and AND-NOR outputs

Table 2

PALs For Every Task

The members of the PAL family and their characteristics are summarized in Table 2. They are designed to cover the spectrum of logic functions at reduced cost and lower package count. This allows the designer to select the PAL that best fits his application. PALs come in the following basic configurations:

Gate Arrays

PAL gate arrays are available in sizes from 12x10 (12 input terms, 10 output terms) to 20x2, with both active high and active low output configurations available (figure 9). This wide variety of input/output formats allows the PAL to replace many different sized blocks of combinatorial logic with single packages.

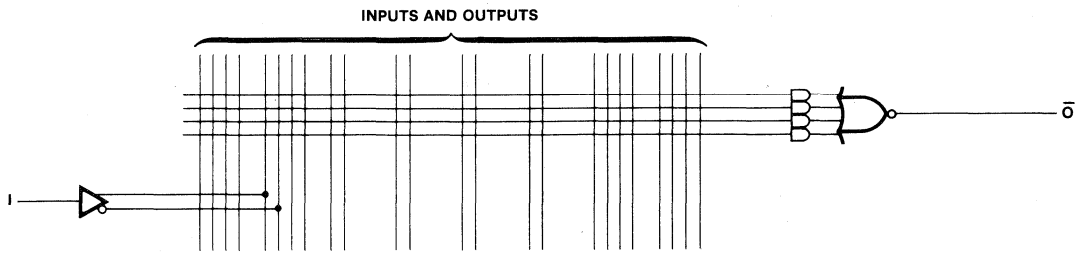

Figure 9

Programmable I/O

A feature of the high-end members of the PAL family is programmable input/output. This allows the product terms to directly control the outputs of the PAL (Figure 10). One product term is used to enable the three-state buffer, which in turn gates the summation term to the output pin. The output is also fed back into the PAL array as an input. Thus the PAL drives the I/O pin when the three-state gate is enabled; the I/O pin is an input to the PAL array when the three-state gate is disabled. This feature can be used to allocate available pins for I/O functions or to provide bi-directional output pins for operations such as shifting and rotating serial data.

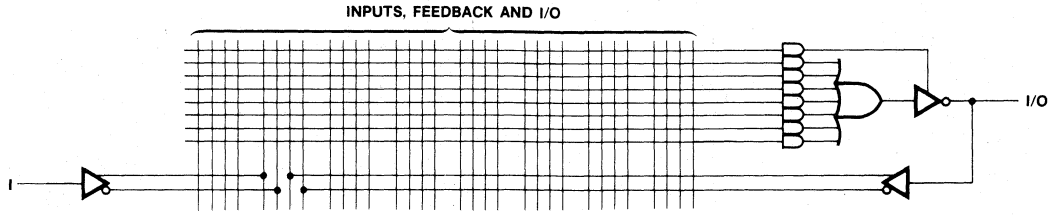

Figure 10

Registered Outputs with Feedback

Another feature of the high end members of the PAL family is registered data outputs with registered feedback. Each product term is stored into a D-type output flip-flop on the rising edge of the system clock (Figure 11). The Q output of the flip-flop can then be gated to the output pin by enabling the active low three-state buffer.

In addition to being available for transmission, the Q output is fed back into the PAL array as an input term. This feedback allows the PAL to "remember" the previous state, and it can alter its function based upon that state. This allows the designer to configure the PAL as a state sequencer which can be programmed to execute such elementary functions as count up, count down, skip, shift, and branch. These functions can be executed by the registered PAL at rates of up to 20 MHz.

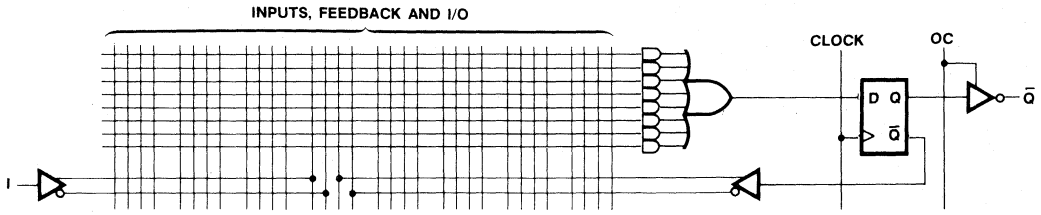

Figure 11

XOR PALs

These PALs feature an exclusive OR function. The sum of products is segmented into two sums which are then exclusive ORed (XOR) at the input of the D-type flip-flop (Figure 12). All of the features of the Registered PALs are included in the XOR PALs. The XOR function provides an easy implementation of the HOLD operation used in counters and other state sequencers.

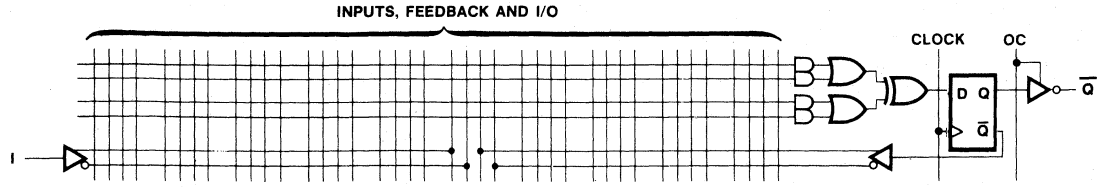

Figure 12

Arithmetic Gated Feedback

The arithmetic functions (add, subtract, greater than, and less than) are implemented by addition of gated feedback to the features of the XOR PALs. The XOR at the input of the D-type flip-flop allows carrys from previous operations to be XORed with two variable sums generated by the PAL array. The flip-flop Q output is fed back to be gated with input terms A (Figure 13). This gated feedback provides any one of the 16 possible Boolean combinations which are mapped in the Karnaugh map (Figure 15). Figure 14 shows how the PAL array can be programmed to perform these 16 operations. These features provide for versatile operations on two variables and facilitate the parallel generation of carrys necessary for fast arithmetic operations.

x-	$A+\overline{B}$	$\overline{B}$	$\overline{A}*\overline{B}$	A:*:B

Figure 15

It should now be clear that the PAL family can replace most Small-Scale Integrated Logic (SSI) logic in use today, thereby lowering product cost and giving the designer even greater flexibility in implementing logic functions.

PAL Programming

PALs can be programmed in most standard PROM programmers with the addition of a PAL personality card. The PAL appears to the programmer as a PROM. During programming half of the PAL outputs are selected for programming while the other outputs and the inputs are used for addressing. The outputs are then switched to program the other locations. Verification uses the same procedure with the programming lines held in a low state.

PALASM (PAL Assembler)

PALASM is the software used to define, simulate, build, and test PALs. PALASM accepts the PAL Design Specification as an input file. It verifies the design against an optional function table and generates the fuse plot which is used to program the PALs. PALASM is available upon request in many source code media and is documented in the PAL Design Concepts section.

HALs (Hard Array Logic)

The HAL family is the mask programmed version of a PAL. The HAL is to a PAL just as a ROM is to a PROM. A standard wafer is fabricated to the 6th mask. Then a custom metal mask is used to fabricate Aluminum links for a HAL instead of the programmable Ti-W fuse array used in a PAL.

The HAL is a cost-effective solution for large quantities and is unique in that it is a gate array with a programmable prototype.

HMSI (HAL Medium Scale Integration)

The HMSI family is derived from the PAL using HAL technology. These devices perform predetermined functions which are not available in the existing TTL family. Because they are produced in volume, the user receives the benefit of volume pricing. HMSI PAL designs are given in the Applications section with their 74S number in line 2 of the PAL Design Specification.

PAL Technology

PALs are manufactured using the proven TTL Schottky bipolar Ti-W fuse process to make fusible-link PROMs. An NPN emitter follower array forms the programmable AND array. PNP inputs provide high-impedance inputs (0.25 mA max) to the array. All outputs are standard TTL drivers with internal active pull-up transistors. Typical PAL propagation delay time is 25 ns, and all PALs are packaged in space saving 20-pin and 24-pin SKINNYDIP™.

PAL Data Security

The circuitry used for programming and logic verification can be used at any time to determine the logic pattern stored in the PAL array. For security, the PAL has a "last fuse" which can be blown to disable the verification logic. This provides a significant deterrent to potential copiers, and it can be used to effectively protect proprietary designs.

Figure 16

PAL Part Numbers

The PAL part number is unique in that the part number code also defines the part's logic operation. The PAL parts code system is shown in Figure 17. For example, a PAL14L4CN would be a 14 input term, 4 output term, active-low PAL with a commercial temperature range packaged in a 20-pin plastic dip.

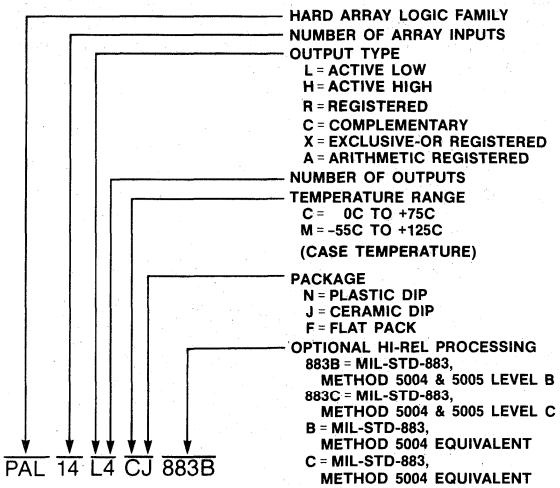

Figure 17

PAL Logic Symbols

The logic symbols for each of the individual PAL devices gives a concise functional description of that PAL's logic function. This symbol makes a convenient reference when selecting the PAL that best fits a specific application. Figure 18 shows the logic symbol for a PAL10H8 gate array.

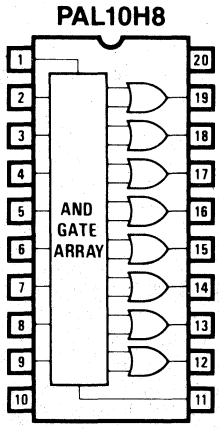

Figure 18

A PAL Example

As an example of how the PAL enables the designer to reduce costs and simplify logic design, consider the design of a simple, high-volume consumer product: an electronic dice game. This type of product will be produced in extremely high volume, so it is essential that every possible production cost be minimized.

The electronic dice game is simply constructed using a free running oscillator whose output is used to drive two asynchronous modulo six counters. When the user "rolls" the dice (presses a button), the current state of the counters is decoded and latched into a display resembling the pattern seen on an ordinary pair of dice.

A conventional logic diagram for the dice game is shown in Figure 16. (A detailed logic derivation is shown in the PAL applications section of this handbook). It is implemented using standard TTL, SSI and MSI parts, with a total I.C. count of eight: six quad gate packages and two quad D-latches. Looks like a nice, clean logic design, right? Wrong!!

PAL Goes to the Casino

A brief examination of Figure 16 reveals two basic facts: first, the circuit contains mostly simple, combinatorial logic, and second, it uses a clocked state transition sequence. Remembering that the PAL family contains ample provision for these features, the PAL catalog is consulted. The PAL16R8 has all the required functions, and the entire logic content of the circuit can be programmed into a single PAL shown in Figure 19.

In this example, the PAL effected an eight to one package count reduction and a significant cost savings. This is typical of the power and cost effective performance that the PAL family brings to logic design.

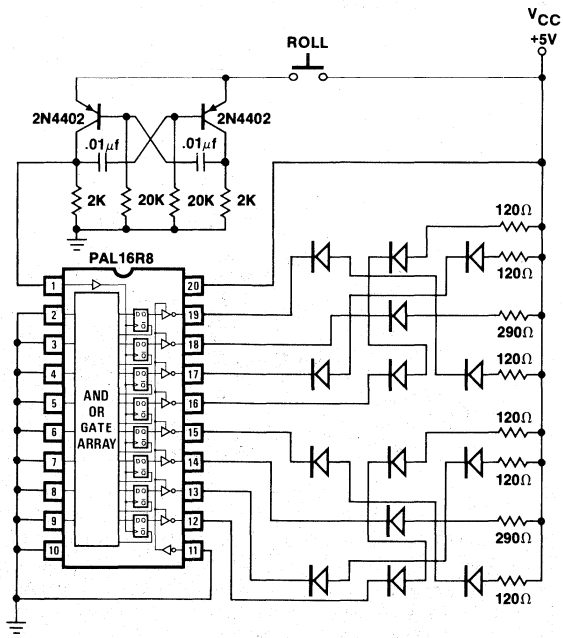

Figure 19

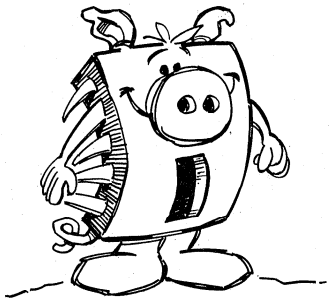
Advantages of Using PALs



The PAL has a unique place in the world of logic design. Not only does it offer many advantages over conventional logic, it also provides many features not found anywhere else. The PAL family:

- Programmable replacement for conventional TTL logic.
- Reduces IC inventories substantially and simplifies their control.
- Reduces chip count by at least 4 to 1.
- Expedites and simplifies prototyping and board layout.
- Saves space with 20-pin and 24-pin Skinny DIP packages.
- High speed: 25ns typical propagation delay.
- Programmed on standard PROM programmers.
- Programmable three-state outputs.
- Special feature eliminates possibility of copying by competitors.

All of these features combine together to lower product development costs and increase product cost effectiveness. The bottom line is that PALs save money.

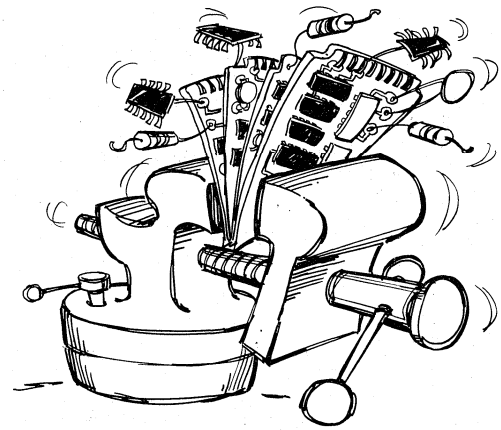
Direct Logic Replacement

In both new and existing designs the PAL can be used to replace various logic functions. This allows the designer to optimize a circuit in many ways never before possible. The PAL is particularly effective when used to provide interfaces required by many LSI functions. PAL flexibility combined with LSI function density makes a powerful team.

Design Flexibility

The PAL offers the systems logic designer a whole new world of options. Until now, the decision on logic system implementation was usually between SSI/MSI logic functions on one hand and microprocessors on the other. In many cases the function required is too awkward to implement the first way and too simple to justify the second. Now the PAL offers the designer high functional density, high speed, and low cost. Even better, PALs come in a variety of sizes and functions, thereby further increasing the designer's options.

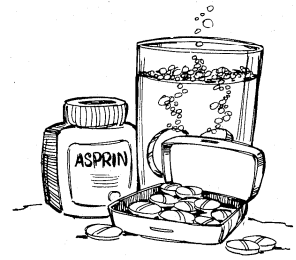
Space Efficiency



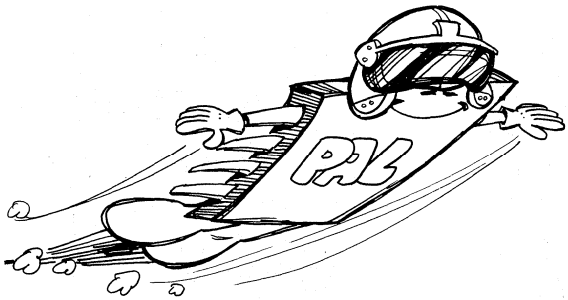
By allowing designers to replace many simple logic functions with single packages, the PAL allows more compact P.C. board layouts. The PAL's space saving 20 pin "skinny dip" helps to further reduce board area while simplifying board layout and fabrication. This means that many multi-card systems can now be reduced to one or two cards, and that can make the difference between a profitable success or an expensive disaster.

Smaller Inventory

The PAL family can be used to replace up to 90% of the conventional TTL family with just 25 parts. This considerably lowers both shelving and inventory cataloging requirements. Even better, small custom modifications to the standard functions are easy for PAL users, not so easy for standard TTL users.



High Speed

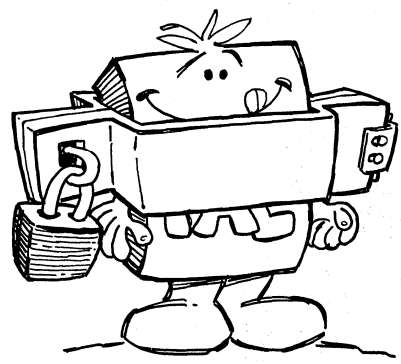


The PAL family runs faster or equal to the best of bipolar logic circuits. This makes the PAL the ideal choice for most logical operations or control sequence which requires a medium complexity and high speed. Also, in many microcomputer systems, the PAL can be used to handle high speed data interfaces that are not feasible for the microprocessor alone. This can be used to significantly extend the capabilities of the low-cost, low-speed NMOS microprocessors into areas formerly requiring high-cost bipolar microprocessors.

Easy Programming

The members of the PAL family can be quickly and easily programmed using standard PROM programmers. This allows designers to use PALs with a minimum investment in special equipment. Many types of programmable logic, such as the FPLA, require an expensive, dedicated programmer.

Secure Data



The PAL verification logic can be completely disabled by blowing out a special "last link." This prevents the unauthorized copying of valuable data, and makes the PAL perfect for use in any application where data integrity must be carefully guarded.

Summary

The 25 member PAL family of logic devices offers logic designers new options in the implementation of sequential and combinatorial logic designs. The family is fast, compact, flexible, and easy to use in both new and existing designs. It promises to reduce costs in most areas of design and production with a corresponding increase in product profitability.

Selecting the Right PAL

The 25-member PAL Family offers a wide range of complexity to choose from. Starting with the PAL10H8 (10 inputs, 8 active high outputs), the first 15 PALs can replace random SSI gate functions by at least a 4 to 1 chip count reduction. With a variety of input/output pin ratios and Active High or Active Low outputs, this group, described as combinatorial, is designed to provide the Low Power Schottky (LS) fan-out and fan-in characteristics of 8 mA output sink (I_{OL}) for totem-pole outputs and 0.25 mA input loading (I_{IL}).

The rest of the PAL family provides the additional features of three-state outputs, programmable I/O pins, registered outputs with feedback, Exclusive OR operator, and arithmetic gated feedback.

The three-state outputs drive the standard LS output sink of 24 mA (I_{OL}) providing bus-driving capabilities.

The programmable I/O pins, allow individual product terms to directly control output data flow. The control logic can be used to either gate product terms out of the three-state buffer or to route data into the product term matrix. This bi-directional capability can be used to implement shift and rotate functions as well as programmable allocation of input and output pins.

The registered outputs allow individual product sums to be clocked into the internal D flip-flops on the rising edge of the clock. The stored data can then be gated to the output buffer by enabling the three-state buffer. The true or complement of the data can also be fed back into the array. This facilitates the construction of state machines in a single chip.

The Exclusive OR operator allows for easy implementation of the HOLD function needed in counters and other state sequencers.

The arithmetic gated feedback allows for any of the 16 possible Boolean operations to be performed between the feedback and input pin. This provides arithmetic and logic operations. A provision for carry propagation required for fast arithmetic operations is also available.

In all PALs unused inputs should be tied to either V_{CC} or GND. The series resistor required for unused inputs on standard TTL is NOT required for PALs, thus using less parts.

Defining the Pinout

The first step in designing a PAL is selecting the pinout. The example shown below (Figure 1) shows a method for circling a section of conveniently drawn logic to define a boundary for a PAL function. This boundary will dictate a specific number of input pins and output pins. For this example, 8 inputs and 6 outputs are required, well within the capability of the PAL10L8. Assignment of inputs and outputs to specific pins can now be done using the PAL Logic Symbol as shown below.

NOTE: This pinout can later be changed to suit printed circuit board.

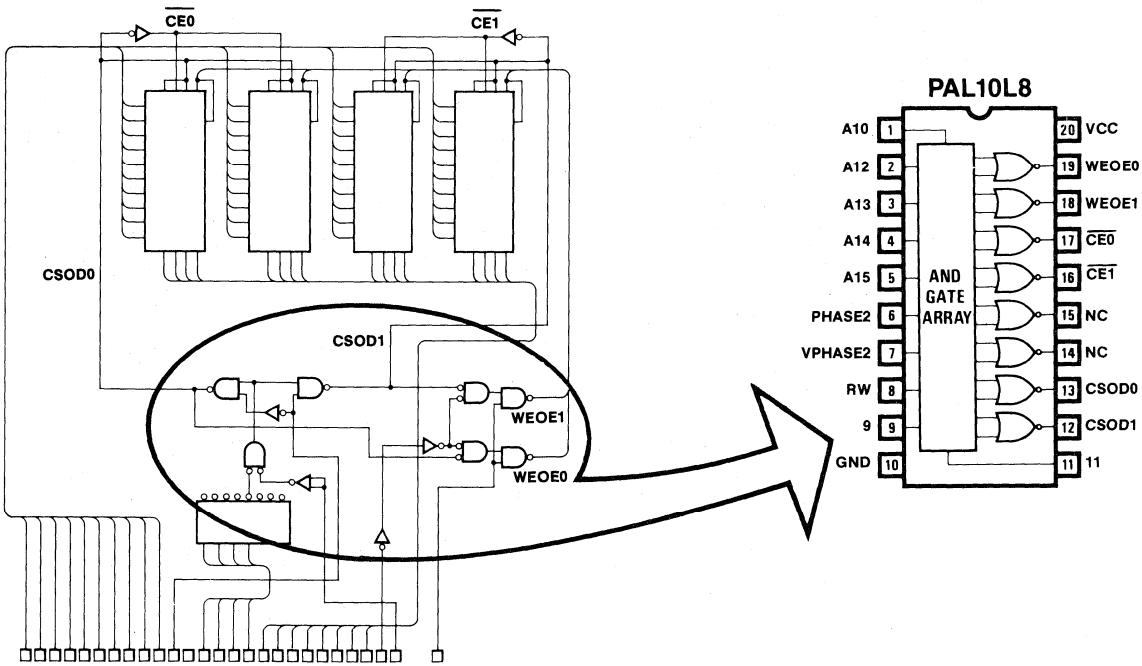

Figure 1. Using PAL to replace random logic in 6800 Microprocessor Bus

Specifying the Design

The next step is to write the Boolean logic equations (in sum of products form) which will transform the inputs into the desired outputs. These explicit logic equations specify the design precisely. They are easily simulated and edited.

Since PALs have predominately active low outputs, it may be necessary to apply DeMorgan's Law to change the output polarity of an equation when implementing it in a PAL. DeMorgan's Law states that the inverse or complement of any Boolean expression can be found by successively applying the following theorems:

$$\overline{(X + Y)} = \overline{X} * \overline{Y} \quad \text{and} \quad \overline{(X * Y)} = \overline{X} + \overline{Y}$$

Examples of equations written with active high and active low outputs are shown in the following table:

ACTIVE HIGH OUTPUT	ACTIVE LOW OUTPUT
$O = \overline{I1}$	$\overline{O} = I1$
$O = \overline{I1} \cdot \overline{I2}$	$\overline{O} = I1 + I2$
$O = I1 + \overline{I2}$	$\overline{O} = \overline{I1} \cdot I2$
$O = I1 + \overline{I2} \cdot I3$	$\overline{O} = \overline{I1} \cdot I2 + \overline{I1} \cdot \overline{I3}$
$O = I1 :+: I2$	$\overline{O} = I1 :\cdot: I2$

Some designers may prefer to consult the PAL Logic Diagram before writing the equations. The basic method is simply to choose the appropriate logic diagram, label the corresponding pin names, and mark the fuse interconnections needed to implement the desired logic transform function.

Fuses left intact are indicated on the logic diagram by an "X" at the intersection of the input line and the AND gate product line. A blown fuse is not marked. The PAL Logic Diagrams are provided with no fuses marked, allowing the designer to use the diagram as a coding form. Actually, the unprogrammed PAL is shipped with all Xs (all fuses) intact.

The Boolean logic equations can then be read directly from the logic diagram.

Design Verification and Documentation

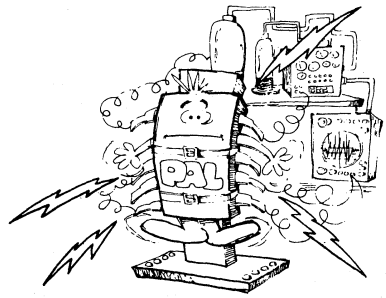
An optional FUNCTION TABLE and DESCRIPTION may be included. The FUNCTION TABLE serves the dual purpose of documenting and verifying the design (using the PALASM simulator). The device operation and application are described in the DESCRIPTION.

Phantom Fuses

Phantom fuse locations are those locations where a fuse does not exist. Unprogrammed PALs with phantom fuse locations appear to a PROM programmer as being partially programmed. Since the PROM programmer will expect to verify all possible fuse locations, the PAL programming format must provide the expected pattern to verify non-existent fuse nodes. PALASM and PAL programmers tweek the fuse plot for the phantom fuses automatically so these nodes will be treated properly when verified. The following PALs have phantom fuses:

PAL10H8	PAL10L8	PAL12L10
PAL12H6	PAL12L6	PAL14L8
PAL14H4	PAL14L4	PAL16L6
PAL16H2	PAL16L2	PAL18L4
	PAL16C1	PAL20L2
		PAL20C1

PROGRAMMING



3

PALASM

PALASM is the key tool used in automating the process of "designing your own chip." PALASM is a FORTRAN IV program which assembles the PAL Design Specification translating the logic equation to a PAL fuse pattern. The fuse pattern may be generated in a format compatible with either a PAL or a PROM programmer.

PALASM also contains a simulator which exercises the Function Table vectors in the logic equations. Inconsistencies between the vectors and the equations are reported as errors. The simulator also translates the Function Table vectors to a set of universal test vectors which may be used for functional testing after the device is fabricated.

PALASM source code is available to users on the following pages. Other source code media is available upon request.

PAL Design Specification

The PAL Design Specification is the input file used with PALASM. It is also the recommended data sheet format for describing the function of a PAL once it has acquired the unique personality of a particular fuse pattern. The format for the PAL Design Specification as shown on the opposite page is:

Line 1 PAL part number left justified followed by PAL DESIGN SPECIFICATION

Line 2 User's part number followed by originator's name and the date

Line 3 Device application name

Line 4 User's company name, city, state

Line 5 **Pin List.**
The pin list is a sequence of symbolic names separated by one or more spaces on one or more lines in order of the device pin numbers. Each symbolic name is unique (except for unused pins which may have the same name.) All pins including power and ground must be named. Names may use any printable character except the operator: "=:*+/()". The prefix "/", may be used to logically complement the name.

Line m **Equations.**
The transfer function of the device is expressed in the following three forms:

1. SYMBOL = EXPRESSION
2. IF (PRODUCT) SYMBOL = EXPRESSION
3. SYMBOL: = EXPRESSION

The following terms are used to construct the equations:

SYMBOL	Pin name with optional prefix, "/".
PRODUCT	A sequence of SYMBOLS separated by the AND operator, "*".
IF	Conditional equality, when the PRODUCT is logically true. Otherwise, high impedance (high-Z).
EXPRESSION	A sequence of SYMBOLS separated by operators.

OPERATORS (in hierarchy of evaluation)

;	Comment follows
/	Complement, prefix to a pin name.
*	AND (product)
+	OR (sum)
:+:	XOR (exclusive OR)
:*:	XNOR (exclusive NOR)
( )	Conditional three-state (IF STATEMENT) or fixed symbol
=	Equality
:=	Replaced by after the low to high transition of the clock.

Line n **Function Table.** (optional)
The function table begins with the keyword, "FUNCTION TABLE." It is followed by a pin list which may be in a different order and polarity from the pin list in Line 5. VCC and GND cannot be listed. The pin list is followed by a dashed line; e.g., ---------- (length optional), which in turn is followed by a list of vectors, one vector per line. One state must be specified for each pin name and optionally separated by spaces. A vector is a sequence of states listed in the same order as the pin list and followed by an optional comment. The vector list is followed by another dashed line.

Definition of Function Table States:

H	HIGH LEVEL
L	LOW LEVEL
X	IRRELEVANT
C	TRANSITION FROM LOW TO HIGH LEVEL
Z	OFF (HIGH IMPEDANCE)

Line o **Description.** (Optional if following Function Table).
This section begins with the keyword, "DESCRIPTION." The device operation and application are described here.

PAL Applications

Introduction to PAL Applications

The PAL family brings a unique flexibility to the field of logic design. Using PALs, designers can both replace conventional logic in existing products and optimize the design of new products. Previous sections discussed the PAL concept and provided information on the advantages gained and the techniques used when designing with PALs. This section shows PALs at work in applications ranging from simple logic gate replacement to complete system designs.

Each example is presented as a complete PAL design. The required logic function is described, the PAL that best solves the problem is selected, and the actual PAL logic implementation is shown. The PAL logic is shown as both the PAL design specification and the actual PALASM output for the PAL programmer. This makes the examples complete enough to serve as guides for designers using PALs in their own systems.

The PAL is a versatile device whose applications are practically unlimited. These applications examples, combined with the PAL design information contained in the rest of this book, will help designers to get the feel of PAL design procedures. With a little practice and study, PAL design will become a natural extension of the normal logic design process.

IMPORTANT
NOTES

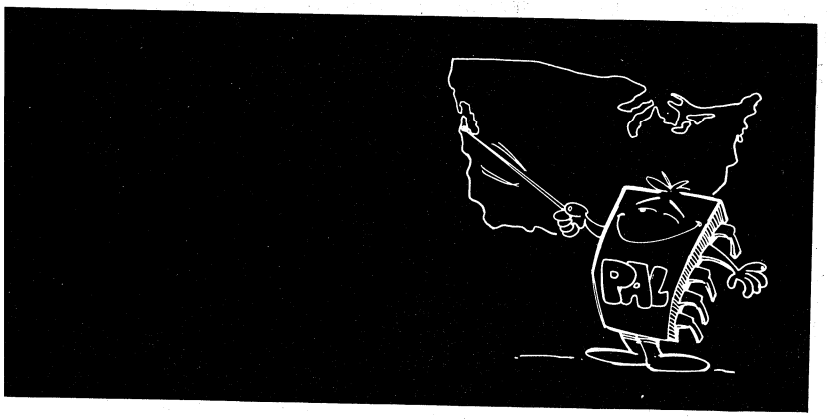
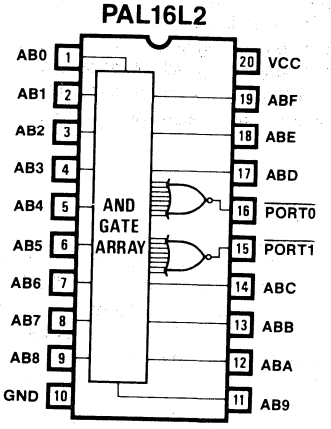
Memory Mapped I/O





Memory Mapped I/O

Functional Description

Memory mapped I/O interfaces I/O devices to a computer by treating the device's physical address as a memory address. This removes the requirement for special I/O decoding and enhances the flexibility of the I/O system. The PAL provides a simple and direct method for implementing memory mapped I/O in mini and micro computer systems.

Circuit Operation

The circuits shown in Figure 1 are typical of those found in memory mapped I/O applications. The inputs to the decode logic are the system memory address lines, A0-AF. The logic compares the address on the memory bus with the programmed comparison address. When an address on the bus matches, the I/O port enable signal is set. This enable signal can then be used in conjunction with other system control signals to transfer data to and from the system data bus. Other examples in this applications section cover this I/O control decoding in more detail.

PAL Design

The PAL is used to monitor the system memory address bus. Typical microcomputers use a 16 bit address, so fully decoding the I/O addresses for two ports can be accomplished using the PAL 16L2. Partial decoding for a larger number of ports can be performed by other members of the PAL family.

The logic equations for the memory mapped I/O logic are as follows:

$$\text{PORT 0} = \overline{AB0} \cdot \overline{AB1} \cdot \overline{AB2} \cdot AB3 \cdot AB4 \cdot AB5 \cdot AB6 \cdot \overline{AB7} \cdot AB8 \cdot AB9 \cdot ABA \cdot ABB \cdot ABC \cdot \overline{ABD} \cdot \overline{ABE} \cdot \overline{ABF}$$

$$\text{PORT 1} = AB0 \cdot \overline{AB1} \cdot \overline{AB2} \cdot AB3 \cdot AB4 \cdot AB5 \cdot AB6 \cdot \overline{AB7} \cdot AB8 \cdot AB9 \cdot ABA \cdot ABB \cdot ABC \cdot \overline{ABD} \cdot \overline{ABE} \cdot \overline{ABF}$$

The above example shows address decoding for memory locations 1F78 hex and 1F79 hex. Equation terms can be changed to accommodate any 16 bit address.

In operation, the PAL enable outputs will go high whenever one of the programmed addresses matches the address on the system memory address bus. Since the PAL fully decodes the address, any two I/O address may be used.

Conclusion

The PAL provides a single chip decoder for use in memory mapped I/O operations. This technique lowers interface parts counts and allows users an effective way to interface I/O devices to the microcomputer system.

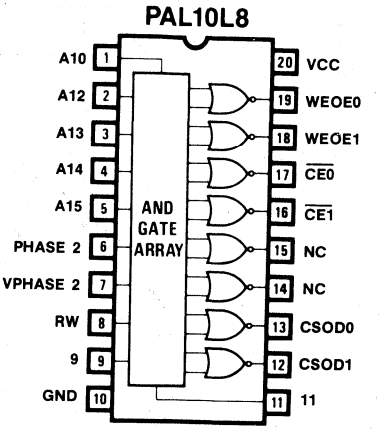
Memory Interface Logic for 6800 Microprocessor Bus



Memory Interface Logic for 6800 Microprocessor Bus

Logic Schematic

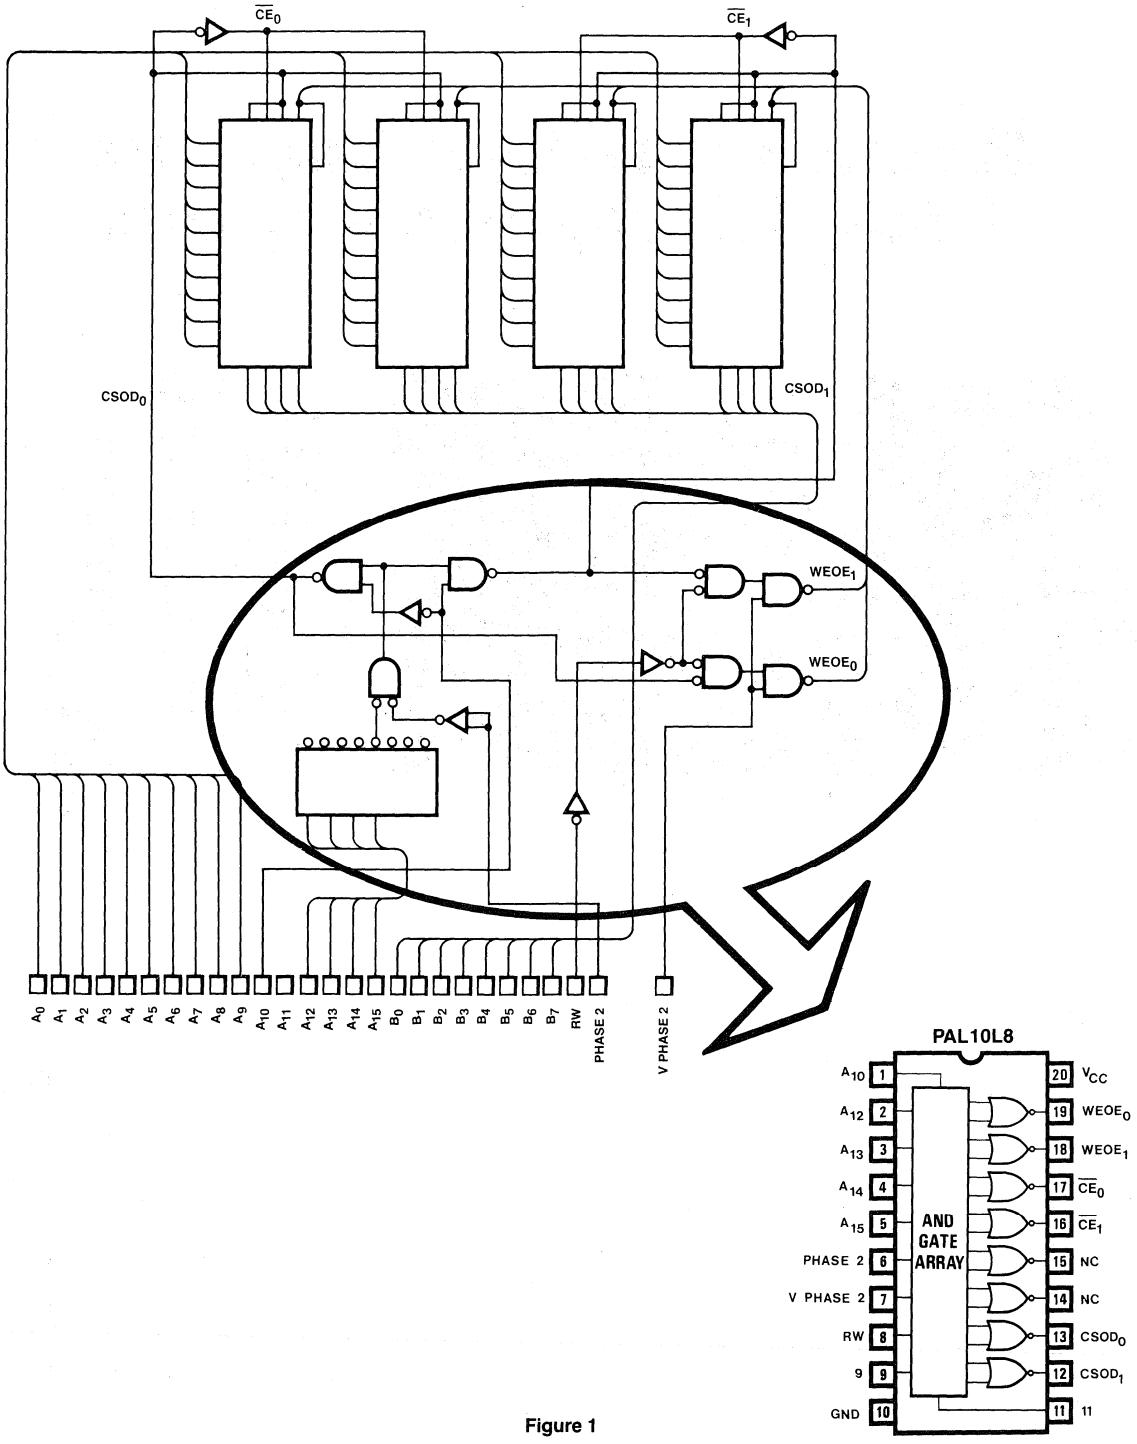


Figure 1

M6800 Memory Interface

Functional Description

The M6800 microprocessor is interfaced to memories by decoding the system memory address bus and several system control lines to generate the required memory control signals. This function is normally performed by combinatorial logic. In many applications, however, the PAL provides a more effective solution.

Circuit Operation

The logic schematic shown in Figure 1 is typical of most M6800 memory interfaces. The circuit shown is a 2048 x 8 bit static memory organized as four 1k x 4 bit RAM chips. The inputs to the RAM are the 10 memory address lines to select the individual memory location, the read/write line to determine whether data is to be read from or written into the memory, and the chip enable line to allow the device to perform the requested data transfer. Data to be written into the memory must be stable on the system data bus when the write signal is given. Data read from the memory will be placed on the data bus within one memory access time after the address has been decoded and the read signal given.

The circled area of combinatorial logic in Figure 1 is used to decode the 6800 address and control signals. Address bits 0-9 are routed directly to all four memory chips. Bit 10 is used to select whether chips 0 and 1 or chips 2 and 3 are to be selected. Bits 12-15 are connected to the A inputs of a digital comparator whose B inputs are jumpered to select the memory page address. If the memory is to be located from 0-800H (the first 2k page in the memory), all four comparator B inputs would be grounded. Then, whenever an address with bits 12-15 low appeared on the bus, a match would occur and the memory would be selected. Changing the jumpers allows the memory to be used anywhere in the 6800's address space or allows the use of multiple cards to construct a larger memory.

The read/write control logic for the memory is generated by decoding the read/write (R/W), phase 2 clock (Phase2), and valid memory address (Vphase2) system control lines. A logic high on the R/W line indicates a memory read; a logic high indicates a memory write.

The valid memory address line (Vphase2) is used to enable the address decoder output. When this enable occurs, the state of the address select and read/write logic is established. Then, when the phase 2 clock goes high, the memory transfer is performed. The relationship between the signals for both read and write operations is shown in Figure 2. (Consult 6800 data book for detailed design information.)

PAL Implementation

All of the combinatorial logic in the circled area of figure 1 can be replaced by a single PAL. This will lower system cost by reducing the device package count and lowering P.C. board area. The logic section has eight input terms and six output terms. Referring to the PAL family table it is seen that the PAL 10L8 fits the task nicely. The only tricky part of the transition from combinatorial logic to a PAL is encountered in the address decoding section. In the original circuit the decoder is jumpered with a match address for use during the address comparison. With the PAL, the address is programmed directly into the gate array.

The general logic equations for the decoder are as follows:

$$\overline{WEOE0} = \overline{A10} \cdot \overline{A12} \cdot \overline{A13} \cdot A14 \cdot \overline{A15} \cdot PHASE2 \cdot VPHASE2 \cdot \overline{RW}$$
$$\overline{WEOE1} = A10 \cdot \overline{A12} \cdot \overline{A13} \cdot A14 \cdot A15 \cdot PHASE2 \cdot VPHASE2 \cdot \overline{RW}$$
$$CSOD0 = \overline{A10} \cdot \overline{A12} \cdot \overline{A13} \cdot \overline{A14} \cdot \overline{A15} \cdot PHASE2$$
$$CSOD1 = A10 \cdot \overline{A12} \cdot \overline{A13} \cdot A14 \cdot \overline{A15} \cdot PHASE2$$
$$CE0 = \overline{CSOD0}$$
$$CE1 = \overline{CSOD1}$$

The above equations show the decoder set for page 0 (0-800H), but this could be easily changed by modifying the address terms. Note that the CE0 and CE1 terms can either be derived directly or by feeding the CSOD0 and CSOD1 terms back into the PAL as inputs.

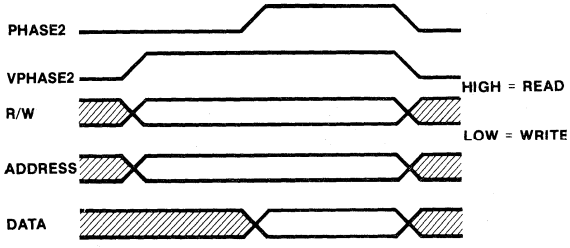

Figure 2

Conclusion

The PAL makes an effective direct logic replacement in many combinatorial logic applications. This can make both new and old designs more cost effective. In this example, the PAL both lowers package count and increases circuit reliability in a typical microcomputer memory application. These advantages can be easily extended to similar designs.

DESCRIPTION

THIS DEVICE PROVIDES THE INTERFACE LOGIC BETWEEN A 6800 MICROPRESSOR BUS AND FOUR STATIC 4k MEMORY CHIPS. ADDRESS BUS (A), READ/WRITE (RW), PHASE 2 CLOCK (PHASE2), AND VALID MEMORY ADDRESS (VPHASE2) ARE DECODED TO PRODUCE THE PROPER WRITE ENABLE (WEOE), CHIP ENABLE (CE), AND OUTPUT DISABLE (CSOD) SIGNALS FOR MEMORY DATA TRANSFERS.

NOTE THAT /CE0 AND /CE1 ARE THE COMPLEMENTS OF CSOD0 AND CSOD1, RESPECTIVELY. THESE FUNCTIONS ARE IMPLEMENTED BY THE EXTERNAL CONNECTIONS CSOD0 TO PIN 9 AND CSOD1 TO PIN 11.

Functional Description

Many microcomputer systems use a CRT monitor or conventional television rather than a VDU perhaps because of cost reduction or because a color display is necessary.

The circuit diagram shows all of the TTL chips used on a video interface board.

The top portion is the color and blanking drive decoding and the lower is the enable logic for PROMs and registers containing driving data. The LS03s are open collector drivers and the two bank drive decoders are wire-ORed using 2kΩ resistors.

PAL Implementation

All of the logic can be put into one PAL20L10, also eliminating the pull-up resistors. This provides a dramatic reduction in component count and board size. The wire-OR configuration is an obvious candidate for PAL implementation, since the logic function /F = A * B + C * D is exactly in the PAL configuration.

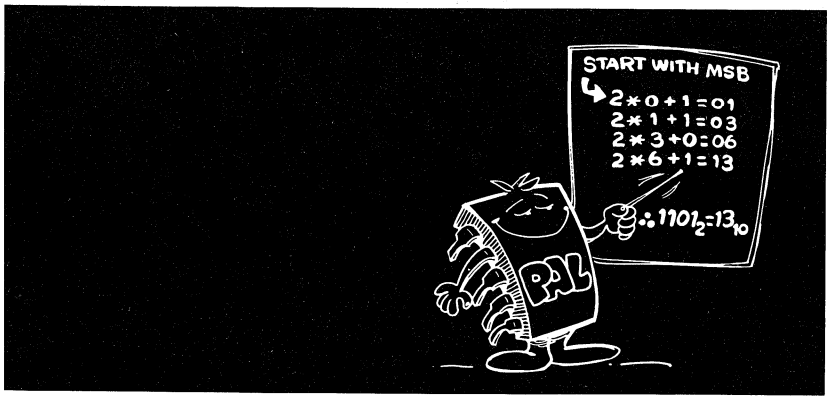
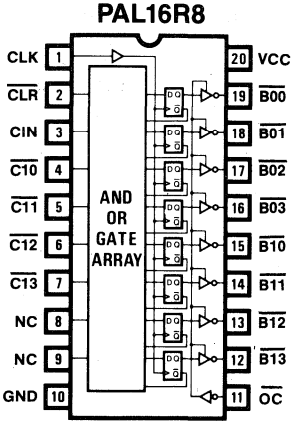
Binary to BCD Converter





Serial Binary to Parallel BCD Conversion

The purpose of this circuit is to convert a serial stream of binary data into a parallel BCD representation as depicted by Figure 1.

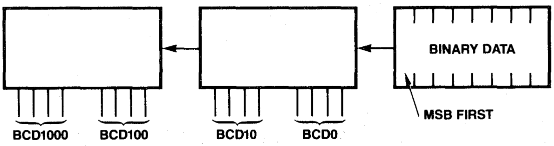


Figure 1. Conceptual Diagram of Binary to BCD Converter

Couleur's Technique (BIDEC)

In this conversion technique (Ref. 1), the input binary data is shifted left (starting with the MSB) into the BCD register. The beauty of this method is that after each clock pulse, the BCD output contains correct BCD representation for the "relative" binary data shifted so far. We illustrate the last statement in Figure 2.

Logic Design

The overall conversion problem can be segmented into four-bit binary blocks. Each block represents one BCD digit and is expandable by C_{IN} and C_{OUT}. The BCD building block, is shown in Figure 3 as a state machine.

The combinational network can be designed from a "next-state" truth table. The truth table can be constructed by observing that a left shift is a multiplication by 2, and a carryin adds 1 to the LSB.

In equation form:

BCD (next state): = 2* BCD (present state) + C_{IN}

Of course, if it were binary it will be simply,

$$Q_n := Q_{n-1}$$

However, BCD requires some corrections as will be shown shortly. For simplicity we analyze the three relevent cases:

a) BCD (present state): = 0 − 4
then BCD (next state): = 0 − 8 which are representable in BCD format

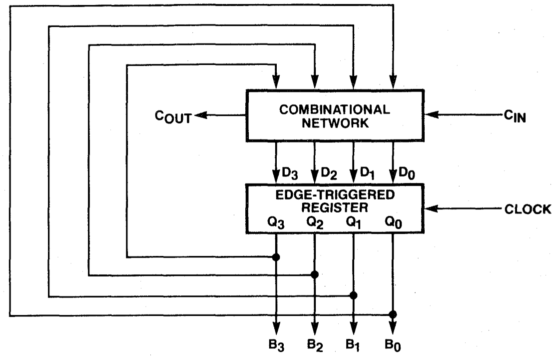

Figure 3, BCD Converter Building Block.

b) BCD (present state): = 5 − 9
then BCD (next state): = 10 − 18 which are not representable in one BCD digit, and a carry out is generated.
e.g. If BCD (present state): = 6
then BCD (next state): = 2 and C_{OUT} = 1

c) If C_{IN} = 1 then it is simply shifted into the LSB of the BCD digit (the old LSB was shifted left leaving a zero in its original position).
Thus, regardless of the BCD (present state) value, the following is true:

BO (next state): = C_{IN}

Truth Table

The preceding discussion is summarized by Tables 1 and 2.

PRESENT STATE B_3-B_0	NEXT STATE B_3-B_0	C_{OUT}
0-4	0-8	0
5-9	0-8	1

Figure 2: Tabular Representation of the Conversion Cycle.

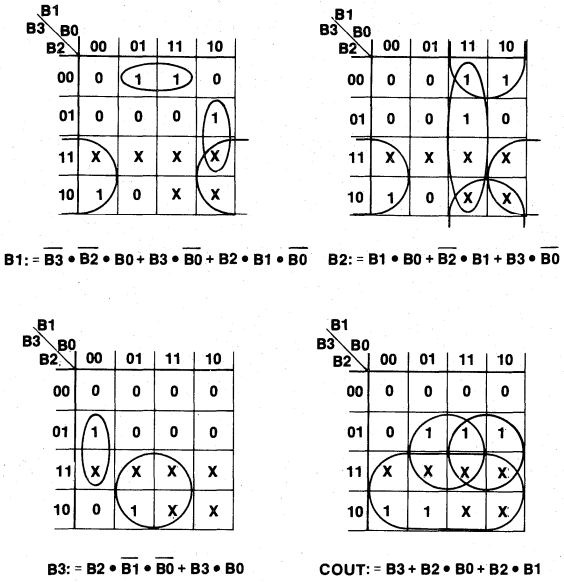

Figure 4. Karnaugh Maps

PAL Implementation

The PAL16R8 implements two BCD digits. One of the pins is assigned to the clear (CLR) function. The BCD conversion register must be initialized to zero before shifting of the binary input data is started. The eight output registers are assigned to the two BCD digits.

At this point, it seems that we are short of one output pin for the C_{OUT} in expanding to more BCD digits. However, the basic equations indicate that C_{OUT} is a function of the four preceding BCD bits. Therefore, by inputting these four bits to the next stage, the C_{OUT} is derived internally by the latter stage. A similar trick is used in each chip to cascade internally.

This expansion solution implies that in the least significant BCD stage the equation is:

(1) BO: = C_{IN}

whereas in later stages the equation is:

(2) BO: = $C_{13} + C_{12} \cdot C_{10} + C_{12} \cdot C_{11}$

where the C terms are driven by the corresponding B terms of a preceding stage. However, in order to have a universal solution, we OR the two equations. If the PAL is used as the least significant stage C_{10}, C_{11}, C_{12} and C_{13} are grounded and equation (1) holds. If the PAL is used as an intermediate stage, C_{IN} is grounded and equation (2) holds.

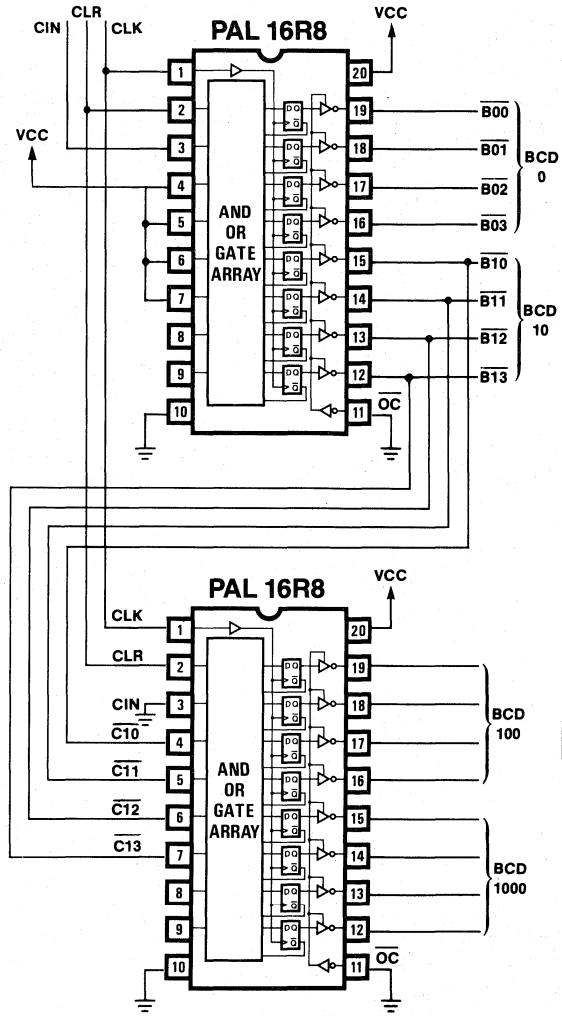

Figure 5. Logic Schematic

Summary

A similar algorithm was described in Ref. 2, where the two BCD digits were implemented with four ICs and could be clocked at 80 ns. Here we described one chip implementation that can be clocked at 60 ns.

DESCRIPTION

THE FUNCTION OF THIS PAL IS TO CONVERT A SERIAL STREAM OF BINARY DATA INTO A PARALLEL BCD REPRESENTATION. AFTER EACH CLOCK PULSE, THE BCD OUTPUT CONTAINS THE CORRECT BCD REPRESENTATION FOR THE RELATIVE BINARY DATA SHIFTED SO FAR.

THE INPUT BINARY DATA IS SHIFTED LEFT (STARTING WITH THE MSB) INTO THE BCD REGISTER. THIS TECHNIQUE IS KNOWN AS COULEUR'S TECHNIQUE (BIDEC).

THE COMBITORIAL NETWORK IS DESIGNED FROM THE FOLLOWING NEXT-STATE TABLE:

PRESENT STATE B3-B0	NEXT STATE B3-B0	COUT
0-4	0-8	0
5-9	0-8	1
10-15	X	X

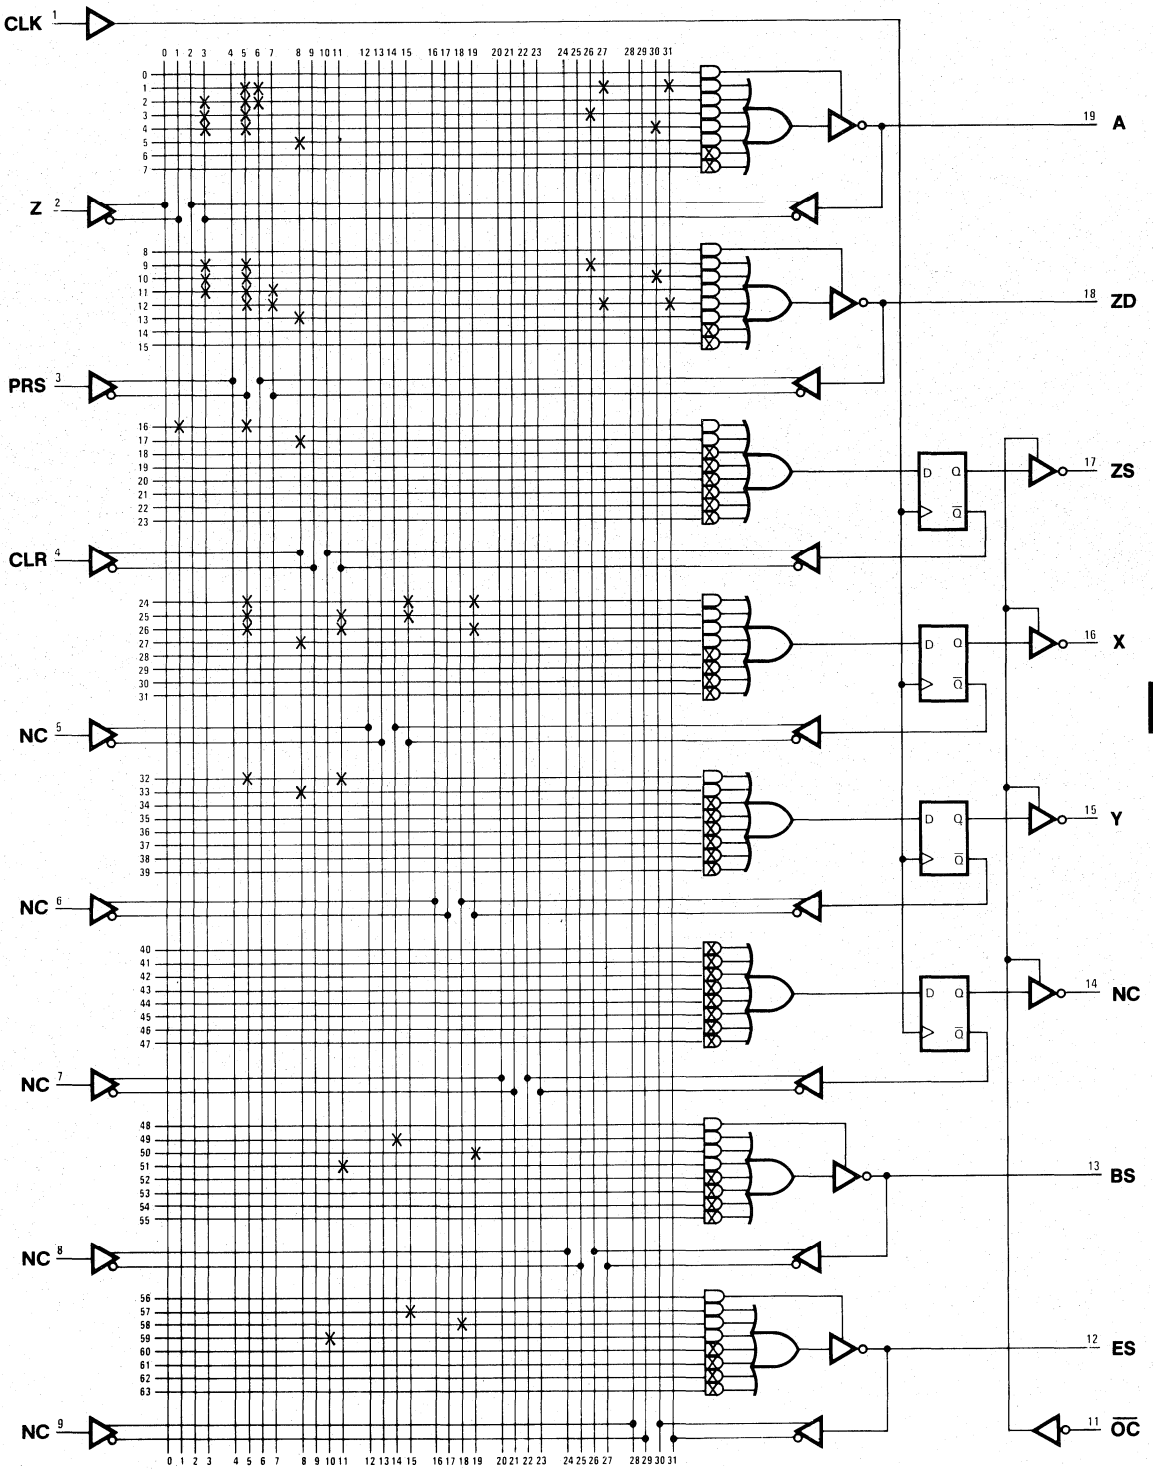
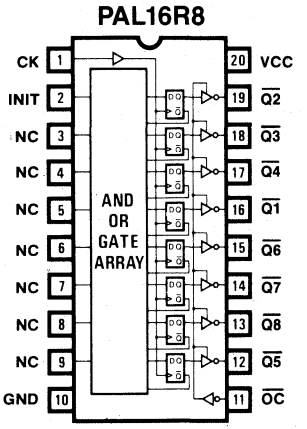
Logic Diagram PAL16R4



IMPORTANT
NOTES

Electronic Dice Game



Logic Design Using Standard TTL

In one die, seven LEDs make up the display (Figure 1). Notice they can be connected such that only four lines are required to drive them. The LEDs are turned on when the appropriate line is driven low. Since there are four lines to be driven it is necessary to use four D-type flip-flops for each die. For reference the outputs of the flip-flops are labeled Q_1-Q_4 and the inputs are labeled D_1-D_4 (Figure 2). By using the inverting output of the Flip-Flop we can use positive logic in the design. That is, a logical "1" at a Q output represents an LED being turned on.

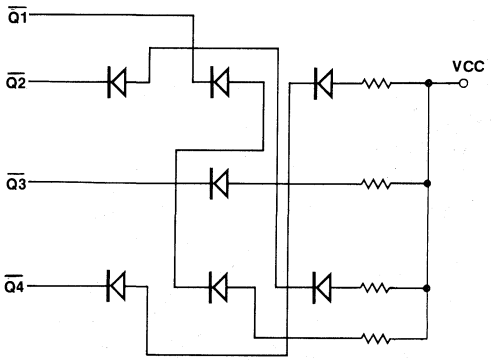


Figure 1

Looking at the Karnaugh Maps (Figure 3), it may be noticed that the simplest logic equations were not generated. This was to insure a path to a valid state from all invalid states.

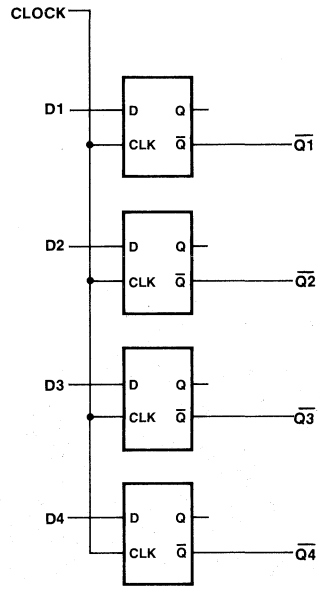

Figure 2

The present state of table 1 shows the preferred sequence in which the LEDs should turn on. The next state shows the conditions necessary to increment when clocked. From these two tables the Karnaugh Maps of Figure 3 were made. Using the Karnaugh Maps the following equations are obtained;

$D_1 = \overline{Q_1}\, Q_2\, Q_3$ $\qquad$ $D_2 = \overline{Q_1}\, Q_3 + \overline{Q_1}\, Q_4$

$D_3 = \overline{Q_3}$ $\qquad$ $D_4 = \overline{Q_1}\, Q_2 + \overline{Q_1}\, Q_4$

These equations satisfy the requirements for one die. By substituting Q_5-Q_8 for Q_1-Q_4 and D_5-D_8 for D_1-D_4 we have the following equations;

$D_5 = \overline{Q_5}\, Q_6\, Q_7$ $\qquad$ $D_6 = \overline{Q_5}\, Q_7 + \overline{Q_5}\, Q_8$

$D_7 = \overline{Q_7}$ $\qquad$ $D_8 = \overline{Q_5}\, \overline{Q_7} + \overline{Q_5}\, Q_8$

	PRESENT STATE				NEXT STATE			
STATE	Q_4	Q_3	Q_2	Q_1	D_4	D_3	D_2	D_1
1	0	1	0	0	0	0	1	0
2	0	0	1	0	1	1	0	0
3	1	1	0	0	1	0	1	0
4	1	0	1	0	1	1	1	0
5	1	1	1	0	1	0	1	1
6	1	0	1	1	0	1	0	0

10	0	X	X	X

Note: X means Don't Care

Figure 3

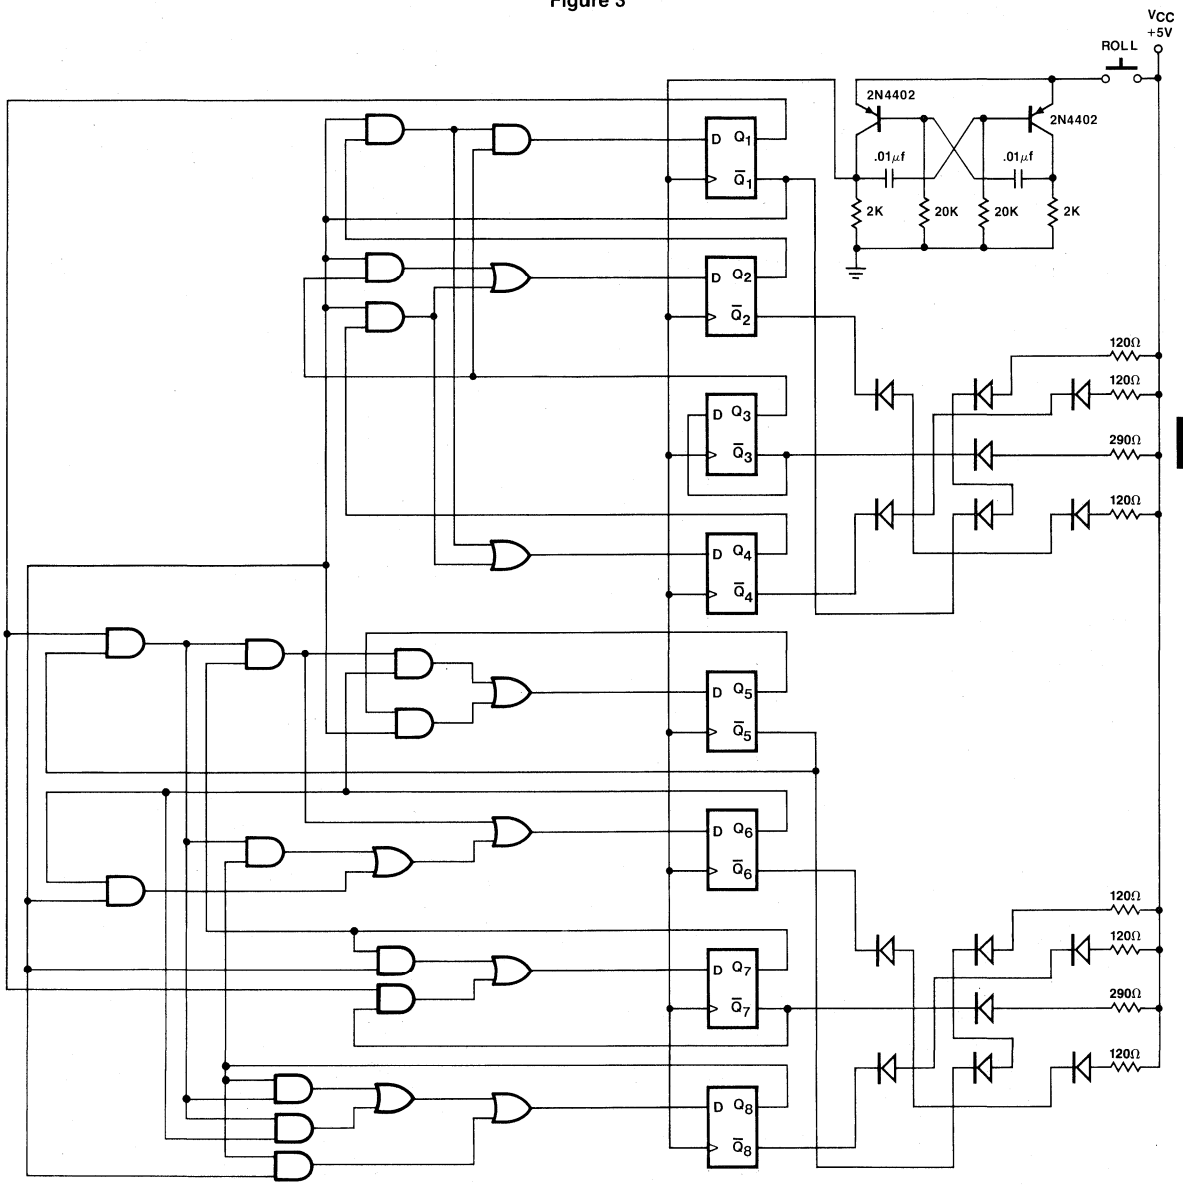

Figure 4

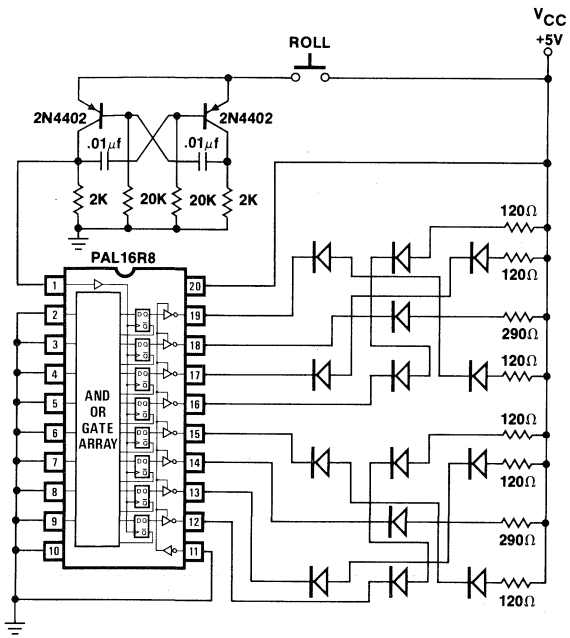
However, since this is a synchronous design the clocks of the two die are common. If the same equations are used for both die there will be only six different states. To get around this the first die is allowed to go through each of the six states incrementing with each clock. The second die is inhibited from incrementing except when the first die goes from the 6th state to the 1st state. At this time the second die is allowed to increment one time. Looking at the present state of table 1 it is noticed that whenever output Q_1 is high, the next clock should increment the second die. Whenever Q_1 is low the second die should remain the same. From this we now write all the equations.

$$D_1 = \overline{Q_1}\, Q_2\, Q_3$$
$$D_2 = \overline{Q_1}\, Q_3 + \overline{Q_1}\, Q_4$$
$$D_3 = \overline{Q_3}$$
$$D_4 = \overline{Q_1}\, Q_2 + \overline{Q_1}\, Q_4$$
$$D_5 = \overline{Q_1}\, Q_5 + Q_1\, \overline{Q_5}\, Q_6\, Q_7$$
$$D_6 = \overline{Q_1}\, Q_6 + Q_1\, \overline{Q_5}\, Q_7 + Q_1\, \overline{Q_5}\, Q_8$$
$$D_7 = \overline{Q_1}\, Q_7 + Q_1\, \overline{Q_7}$$
$$D_8 = \overline{Q_1}\, Q_8 + Q_1\, \overline{Q_5}\, Q_6 + Q_1\, \overline{Q_5}\, Q_8$$

From these equations the logic diagram can be drawn. (Figure 4)

Logic Design Using PALs

The design requires 8 registered outputs. Looking at the PAL Data Sheet we determine that a PAL16R8 best suits this application. The equations developed above can be used here without change. The PAL Design Specification shows the implementation of these equations. Note that the pinout is chosen to convenience PC board layout which is shown below.



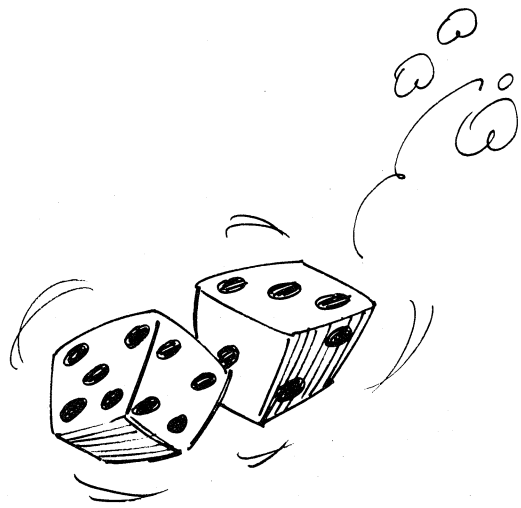
Applications

Rules for CRAPS

The following is a set of rules that apply whether you are playing in Las Vegas with dice or at home with a PAL.

The first roll is called the come-out and you win on a 7 or 11 or you "crap-out" on a 2 (snake eyes), 3 (ace caught a deuce) or 12 (box cars). If none of the above happens you will have rolled a number between 4 and 10. Mark this number well, you will need to roll it again to win. At this point no "crap" can hurt you, but unless you've programmed your PAL right, a seven can. Normal probabilities in 36 throws:

7 will appear	6 times
6	5
8	5
5	4
9	4
4	3
10	3
3	2
11	2
2	1
12	1



```

DESCRIPTION

THE DUAL MODULO-SIX COUNTER INCREMENTS ON THE RISING EDGE OF THE CLOCK (CK). THE THREE-STATE OUTPUTS ARE HIGH-Z WHEN THE OUTPUT CONTROL LINE (/OC) IS HIGH AND ENABLED WHEN THE OUTPUT CONTROL LINE (/OC) IS LOW.

THE "INIT" LINE IS NEEDED TO INITIALIZE THE COUNTER SO THAT THE FUNCTION TABLE SIMULATION COULD BE PERFORMED AND THE PART COULD BE TESTED AT THE TIME OF FABRICATION. THIS LINE AS WELL AS ALL OTHER UNUSED INPUTS SHOULD BE TIED TO GND.

THERE ARE 36 DIFFERENT STATES TO THE COUNT SEQUENCE. EACH STATE CORRESPONDS TO ONE OF THE NUMBER COMBINATIONS TO BE DISPLAYED ON THE DICE.

NOTE THAT THE PINOUT IS CHOSEN TO CONVENIENCE PC BOARD LAYOUT.

DESCRIPTION

THIS 9-BIT REGISTER LOADS THE DATA (D8-D0) ON THE RISING EDGE OF THE CLOCK (CLK) IF THE LOAD LINE (/LD) IS ASSERTED (LOW ON PIN 11) AND OTHERWISE HOLDS THE ORIGINAL VALUE.

THE 9-BIT ARCHITECTURE MAKES THIS REGISTER IDEAL FOR PARITY BUS INTERFACING IN MICROPROGRAMMED SYSTEMS.

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN OPERATIONS TABLE:

/OC	CLK	/LD	D8-D0	Q8-Q0	OPERATION

DESCRIPTION

THIS IS AN 8-BIT SYNCHRONOUS REGISTER WITH PARALLEL LOAD, LOAD COMPLEMENT, PRESET, CLEAR, AND HOLD CAPABILITIES. FOUR CONTROL INPUTS (/LD,POL,/CLR,/PR) PROVIDE ONE OF FOUR OPERATIONS WHICH OCCUR SYNCHRONOUSLY WITH THE CLOCK (CLK).

THE LOAD OPERATION LOADS THE INPUTS (D7-D0) INTO THE OUTPUT REGISTER (Q7-Q0), WHEN POL=H OR LOADS THE COMPLEMENT OF THE INPUTS WHEN POL=L. THE CLEAR (/CLR) OPERATION RESETS THE OUTPUT REGISTERS TO ALL LOWS. THE PRESET (/PR) OPERATION PRESETS THE OUTPUT REGISTERS TO ALL HIGHS. THE HOLD OPERATION HOLDS THE PREVIOUS VALUE REGARDLESS OF CLOCK TRANSITIONS.

CLEAR OVERRIDES PRESET, PRESET OVERRIDES LOAD, AND LOAD OVERRIDES HOLD.

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE OPERATIONS TABLE:

/OC	CLK	/CLR	/PR	/LD	POL	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	X	X	Z	HI-Z
L	C	L	X	X	X	X	L	CLEAR
L	C	H	L	L	X	X	H	PRESET
L	C	H	H	H	X	X	Q	HOLD
L	C	H	H	L	H	D	D	LOAD TRUE
L	C	H	H	L	L	D	/D	LOAD COMP

DESCRIPTION

THE I/O PRIORITY INTERRUPT ENCODER PRIORITIZES 8 I/O LINES (I1 THRU I8) PRODUCING 111 (Q3, Q2, AND Q1 RESPECTIVELY) FOR THE HIGHEST PRIORITY I/O DEVICE (I1) AND 000 FOR AN INTERRUPT FROM THE LOWEST PRIORITY I/O DEVICE (I8).

OUTPUT Q4 SERVES AS THE INTERRUPT FLAG AND GOES LOW WHEN ANY OF THE 8 I/O INPUTS GO HIGH.

THE PRIORITY INTERRUPT ENCODER REGISTERS ARE UPDATED ON THE RISING EDGE OF THE INTERRUPT CLOCK INPUT (CLK). THE 3-STATE OUTPUTS ARE HIGH-Z WHEN THE OUTPUT CONTROL LINE (/OC) IS LOW.

DESCRIPTION

FOUR IDENTICALLY PROGRAMMED PALS ARE USED TO DRIVE EIGHT OF HP'S NUMERIC AND HEX INDICATORS (5082-7340). EACH PAL CONSISTS OF TWO FOUR BIT COUNTERS. STAGE 1 IS THE LSB AND STAGE 2 IS THE MSB. CARRYOUT OF STAGE 1 IS CALLED INTERNAL CARRY (COUT1) AND IS FED EXTERNALLY TO STAGE 2. COUT2 IS FED INTO THE NEXT PAL. CARRYOUT AND INTERNAL CARRYS FROM THE LOWER PAL ARE CONNECTED TO ALL OF THE HIGHER PALS TO PERFORM THE CARRY LOOK AHEAD OPERATION.

THESE PALS HAVE TESTABILITY BUILT INTO THEM. COUT1 IS CONNECTED TO CIN EXTERNALLY AND CAN FORCE COUT1 TO GO HIGH, THUS STAGE 2 MAY START COUNTING AT THE SAME TIME AS STAGE 1 WHICH REDUCES THE NUMBER OF TEST VECTORS IN THE FUNCTION TABLE.

THIS COUNTER OPERATES AT 10 MHz AND CAN PERFORM THE FOLLOWING OPERATIONS:

HEX	CLR	OPERATION
X	H	CLEAR
L	L	COUNT BCD
H	L	COUNT HEX

DESCRIPTION

TWO IDENTICALLY PROGRAMMED PAL20X4 CAN PERFORM THE 64k DYNAMIC RAM REFRESH CONTROL FUNCTION.

EITHER COLUMN OR ROW ADDRESSES TO THE RAM ARE SELECTED DEPENDING ON ROW ENABLE (ROWEN).

AN ADDRESS COUNTER (C3-C0) IS SELECTED DURING REFRESH WHEN ROW ENABLE (ROWEN) IS HIGH.

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMERIZED IN THE OPERATIONS TABLE:

/OC	COUNT	REFEN	ROWEN	O3-O0	OPERATION
H	X	X	X	Z	HI-Z
L	C	L	L	A3-A0	SELECT LOW ADDR BITS
L	C	L	H	A11-A8	SELECT UPPER ADDR BITS
L	C	H	H	C3-C0	SELECT REFRESH ADDR BITS
L	C	H	L	H	SET REFRESH COUNTER

DESCRIPTION

IN MANY SEQUENTIAL CIRCUITS IT IS DESIRABLE TO KNOW THE STATE OF THE SYSTEM. THIS PAL16R4 APPLICATION IS AN EXAMPLE OF A STATE COUNTER FOR THE MMI SEQUENTIAL MULTIPLIER/DIVIDER.

THE STATES ARE REPRESENTED BY A FOUR BIT COUNTER WHERE Q1 IS THE LEAST SIGNIFICANT BIT AND Q4 IS THE MOST SIGNIFICANT BIT.

THE NEXT-STATE OF THE COUNTER AND THE MULTIPLIER/DIVIDER IS A FUNCTION THE PRESENT STATE AND THE INSTRUCTION LINES I2-I0. FOR EXAMPLE IF THE MACHINE IS AT STATE 0 AND THE INSTRUCTION IS 0,1,2 OR 3 THEN THE NEXT STATE IS 4 (MULTIPLY INSTRUCTION), IF THE INSTRUCTION IS 5 (DIVIDE INSTRUCTION), ETC.

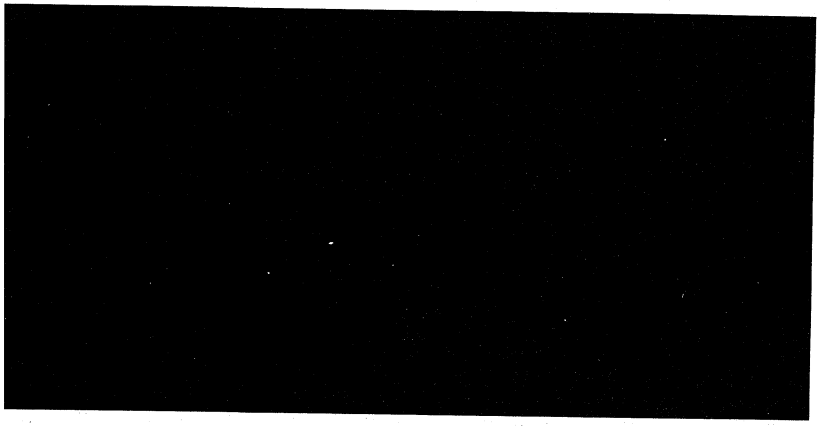
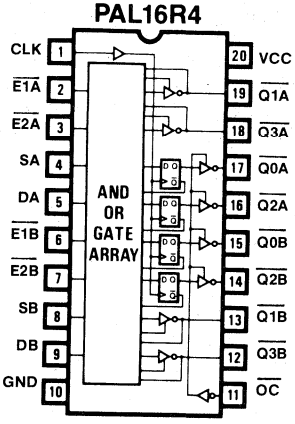
IMPORTANT NOTES

Stepper Motor Controller





Functional Description

Stepper motors and linear actuators are used in a variety of applications requiring precise rotational and/or linear movement. Examples are printers, floppy disc drives, mechanical valves, etc. Stepper motors are two-phase permanent magnet motors which provide discrete angular movement every time the polarity of a winding is changed. In the case of linear actuators, the angular movement is converted to a linear movement via a load screw. In essence, they are dc motors without brushes, where the user provides commutation with external logic.

Circuit Operation

One type of drive circuit, unipolar drive, is shown in Figure 1 below. Two drive sequences are given in Tables 1A and 1B. Angular rotation is achieved by saturating the transistor drivers in the sequence shown in the appropriate table (full or half step). Now, assume the circuit of Figure 1 is connected to a stepper motor designed for 7.5° steps. By following the step sequence of Table 1A (full step), the shaft will rotate 7.5° each time the state is changed. If the sequence of Table 1B is followed, a 3.75° (half step) rotation will result for each change of state. For both step sequences, the direction can be reversed by stepping backwards through the table (step 4-3-2-1-4-etc.).

PAL Implementation

In this application, one PAL16R4 can be used to provide the logic levels required to drive two stepper motors in the full step mode. Due to the high current drive required (100-400 mA/phase), external inverting high current buffers would be used (ULN 2001 or equivalent). In the design, the following features are provided within the PAL:

- Enable/Disable inputs to enable stepping of either section. (/E inputs).
- Select clockwise or counter-clockwise rotation.
- Set the motor to logic state step 1.

A block diagram/pinout is shown in Figure 2.

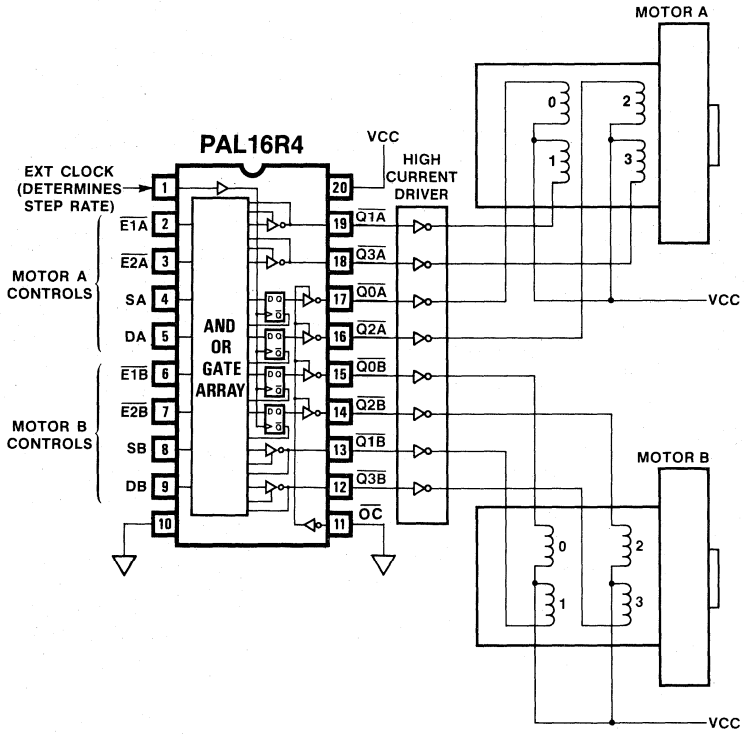

Figure 2

A function table for each motor control section is given below.

CLOCK	$\overline{E1}$	$\overline{E2}$	S	D	FUNCTION
X	1	X	X	X	Hold motor in current position
X	X	1	X	X	Hold motor in current position
↑	0	0	1	X	Set outputs to step 1 levels
↑	0	0	0	0	Step motor clockwise
↑	0	0	0	1	Step motor counter-clockwise

The full step sequence (Table 1A) can be simplified from 4 outputs to 2 outputs since Q1 = Q0 and Q3 = Q2. The sequences can then be expressed as follows:

	D = 0		D = 1	
STEP	Q0	Q2	Q0	Q2
1	1	1	1	1
2	1	0	0	1
3	0	0	0	0
4	0	1	1	0
1	1	1	1	1

$Q1 = \overline{Q0}$ $Q3 = \overline{Q2}$

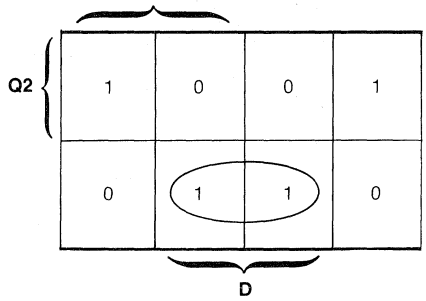
when S = 1:

Q0 = 1 Q1 = 0 Q2 = 1 Q3 = 0

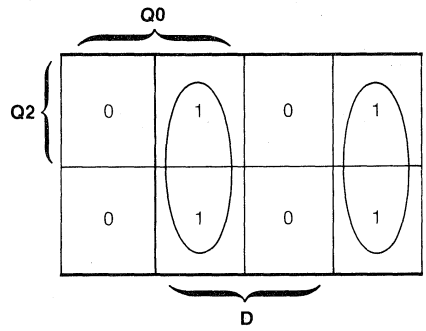
when E1 = 1 or E2 = 1

Q0 = q0 Q1 = q1 Q2 = q2 Q3 = q3

The step sequences can be converted to equations by use of a Karnaugh map.



$Q0 = Q2 \cdot \overline{D} + \overline{Q2} \cdot D$



$Q2 = Q0 \cdot D + \overline{Q0} \cdot \overline{D}$

Factor in E1 and E2:

$Q0 = \overline{E1} \cdot \overline{E2} \cdot Q2 \cdot \overline{D} + \overline{E1} \cdot \overline{E2} \cdot \overline{Q2} \cdot \overline{D}$

$Q2 = \overline{E1} \cdot \overline{E2} \cdot Q0 \cdot D + \overline{E1} \cdot \overline{E2} \cdot \overline{Q0} \cdot \overline{D}$

Express the set function as an equation:

$Q0 = \overline{E1} \cdot E2 \cdot S \qquad Q2 = \overline{E1} \cdot \overline{E2} \cdot S$

Express the hold function (when E1 or E2 = 1)

$Q0 = q0 \cdot E1 + q0 \cdot E2 \quad Q2 = q2 \cdot E1 + q2 \cdot E2$

Combining all the above:

$Q0 := \overline{E1} \cdot \overline{E2} \cdot S + Q0 \cdot E1 + Q0 \cdot E2 + \overline{E1} \cdot \overline{E2} \cdot Q2 \cdot \overline{D} + \overline{E1} \cdot \overline{E2} \cdot \overline{Q2} \cdot D$

$Q1 := Q0$

$Q2 := \overline{E1} \cdot \overline{E2} \cdot S + Q2 \cdot E1 + Q2 \cdot E2 + \overline{E1} \cdot \overline{E2} \cdot Q0 \cdot D + \overline{E1} \cdot \overline{E2} \cdot \overline{Q0} \cdot \overline{D}$

$Q3 := Q2$

Conclusion

Although this example could be used "as is" in a stepper motor application, the programmability of PAL's could allow for any desired modifications. Changes to the circuit might include:

1. Drive only one stepper motor, using a PAL16R6. The other flip-flops could be used as a programmable counter, allowing for different speed settings.
2. Drive only one stepper motor, using the extra inputs and outputs to handle other circuit functions.
3. Drive only one stepper motor, using a PAL16R6. The other flip-flops could be used as a 4-bit position counter.
4. The substitution of a PAL16R8, and another *inverting* buffer would allow the driving and control of four stepper motors.
5. Re-program for half-step operation.

DESCRIPTION

THIS PAL16R4 PROVIDES THE LOGIC LEVELS REQUIRED TO DRIVE TWO STEPPER MOTORS IN THE FULL STEP MODE.

THE FOLLOWING OPERATIONS MAY BE PERFORMED FOR EACH STEPPER MOTOR CONTROLLER INDIVIDUALLY:

CLK	/E1	/E2	S	D	OPERATION
X	H	X	X	X	HOLD MOTOR IN CURRENT POSITION
X	X	H	X	X	HOLD MOTOR IN CURRENT POSITION
C	L	L	H	X	SET OUTPUTS TO STEP 1 LEVELS
C	L	L	L	L	STEP MOTOR CLOCKWISE
C	L	L	L	H	STEP MOTOR COUNTER-CLOCKWISE

DESCRIPTION

THE PAL CONTROLS A 4-BIT UP/DOWN COUNTER WITH THE OUTPUTS "UP" AND "DOWN". (UP=H MEANS COUNT UP; DOWN=H MEANS COUNT DOWN)

THIS DESIGN WITH GLITCHLESS OUTPUTS WILL SERVE WELL IN ELECTRICALLY NOISY INDUSTRIAL ENVIRONMENTS.

THE PINNING AND THE OUTPUT POLARITY ARE GIVEN AS A FIRST PROPOSAL AND CAN BE CHANGED ACCORDING TO THE PC BOARD LAYOUT.

DESCRIPTION

THIS IS AN EXAMPLE OF A DUAL 8-TO-1 MULTIPLEXER USING A PAL20L2. A STROBE LINE (S) IS PROVIDED TO GATE THE OUTPUTS OFF (Y=H) WHEN THE STROBE INPUT IS HIGH. THE SELECT LINES A,B,C ARE ENCODED IN BINARY, WITH A REPRESENTING THE LSB.

OPERATIONS TABLE:

```

DESCRIPTION

THIS IS AN EXAMPLE OF A 16-TO-1 MULTIPLEXER USING A PAL20C1. BOTH TRUE (Y) AND COMPLIMENT (W) OUTPUTS ARE PROVIDED. THE SELECT LINES A,B,C,D ARE ENCODED IN BINARY, WITH A REPRESENTING THE LSB AND D REPRESENTING THE MSB.

OPERATIONS TABLE:

INPUTS SELECT LINES				OUTPUTS	
D	C	B	A	W	Y

DESCRIPTION

THIS PAL IS AN 8-BIT SHIFT REGISTER WITH PARALLEL LOAD AND HOLD CAPABILITY. TWO FUNCTION SELECT INPUTS (I0,I1) PROVIDE ONE OF FOUR OPERATIONS WHICH OCCUR SYNCHRONOUSLY ON THE RISING EDGE OF THE CLOCK (CLK). THESE OPERATIONS ARE:

/OC	CLK	I1	I0	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	Z	HI-Z
L	C	L	L	X	L	HOLD
L	C	L	H	X	SR(Q)	SHIFT RIGHT
L	C	H	L	X	SL(Q)	SHIFT LEFT
L	C	H	H	D	D	LOAD

TWO OR MORE OCTAL SHIFT REGISTERS MAY BE CASCADED TO PROVIDE LARGER SHIFT REGISTERS. RILO AND LIRO ARE LOCATED ON PINS 14 AND 23 RESPECTIVELY, WHICH PROVIDES FOR CONVENIENT INTERCONNECTIONS WHEN TWO OR MORE OCTAL SHIFT REGISTERS ARE CASCADED TO IMPLEMENT LARGER SHIFT REGISTERS.

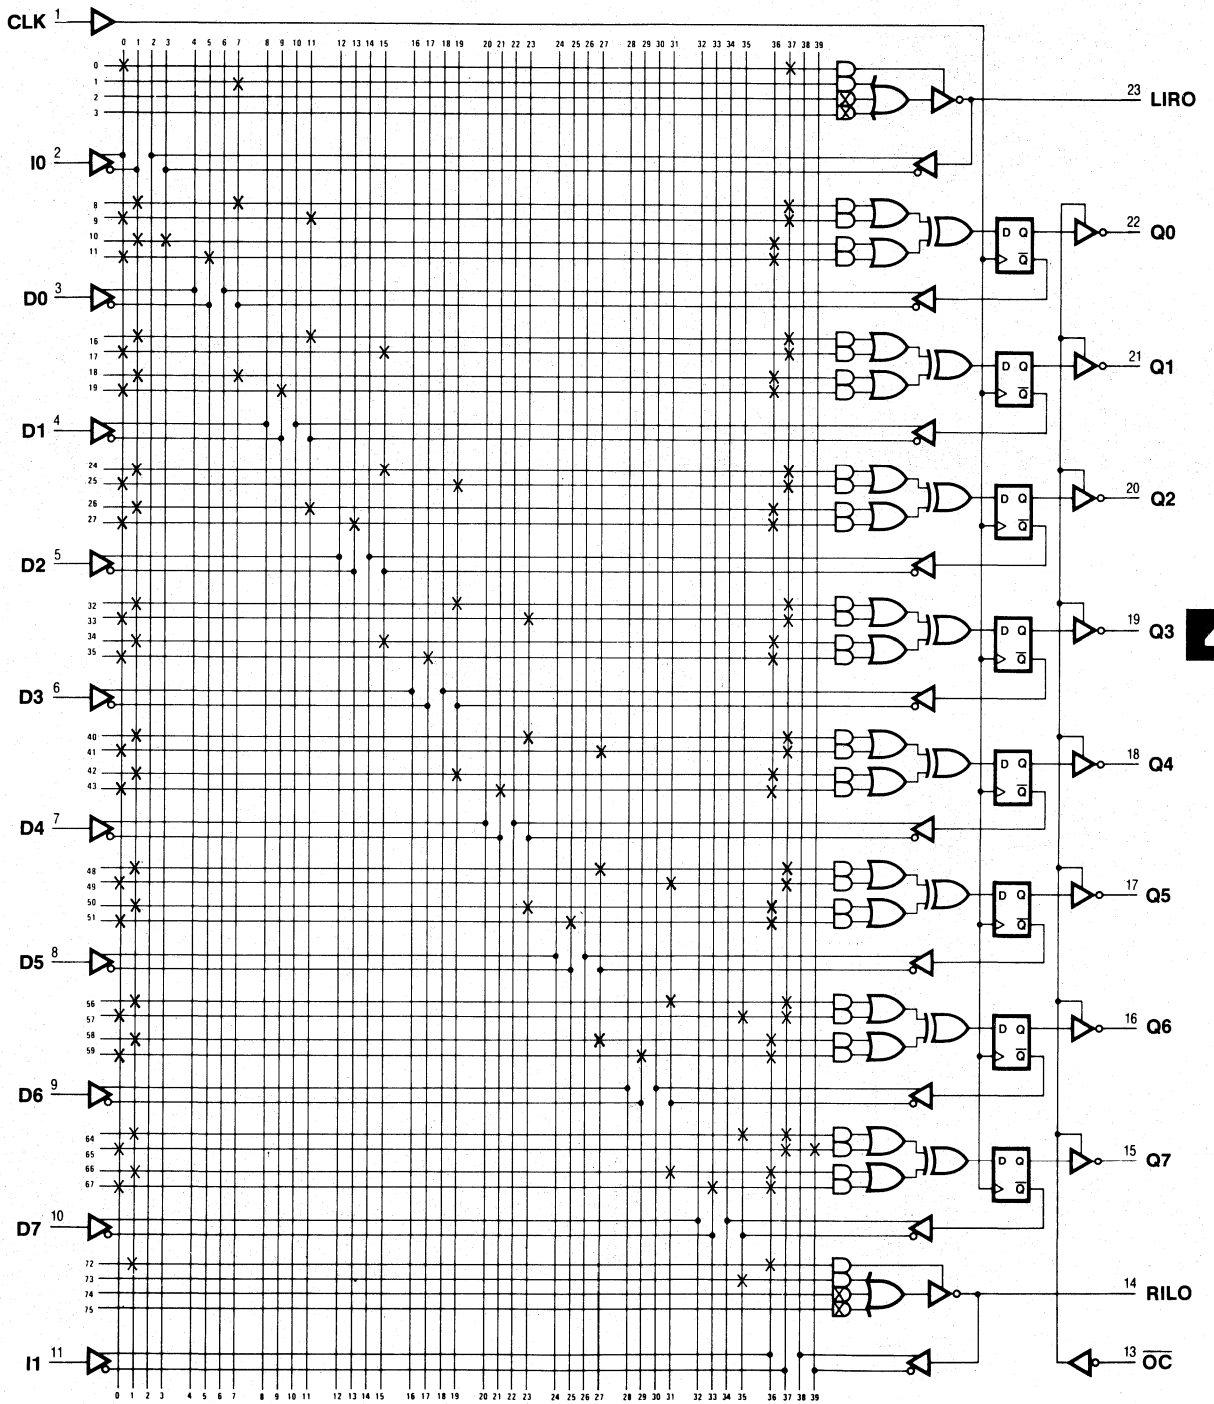
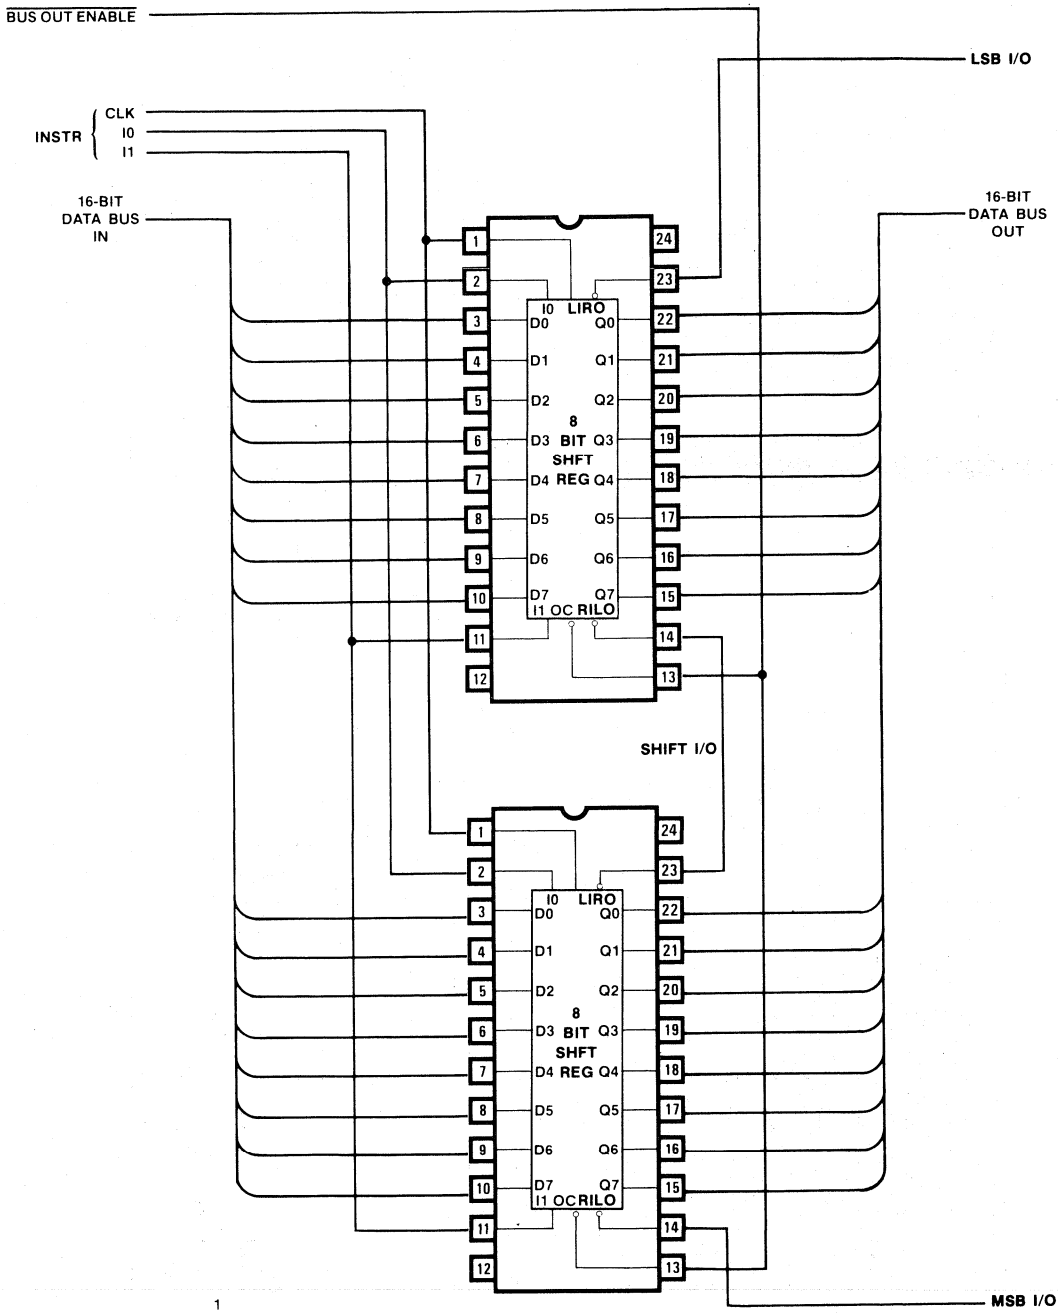
Logic Diagram PAL20X8



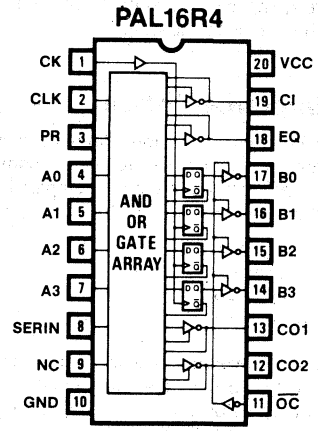
Application

16-Bit Shift Register



NOTE: $f_{MAX} = \frac{1}{t_{PD\ CLK\ TO\ LIRO} + t_{SU}}$

4-Bit
Shift Register/Comparator



Functional Description

Frequently it is necessary to take a serial bit stream and convert it to a parallel form for storage. It is also necessary, in some cases, to monitor the same bit stream for certain patterns e.g., floppy disk file headers, RS232 ASCII characters, etc.

Using a PAL it is possible to combine these two functions.

Circuit Description

The circuit shows a 16 bit serial/parallel convertor, with three-state outputs and a compare true output (EQ). Four PAL16R4s are cascaded for this design. There is also a synchronous preset (PR) pin available. The circuit takes positive true Non-Return-To-Zero (NRZ) data with a central positive edge clock and converts it into parallel data. When the A and B inputs are equal, a negative going clock is output, with the negative (leading) edge in the center of the output data.

PAL Implementation

A PAL16R4 is used, the four flip-flops comprising the shift register and the other gates are used to compare the data and output on appropriate pulse if the compare is true. For the shift register the equations are:

B0 := /SERIN*/PR
B1 := /B0*/PR
B2 := /B1*/PR
B3 := /B2*/PR

The inputs are inverted because of the inverting output buffer on each stage. To compare two inputs A and B, the boolean equivalence operator is A ≡ B (or A :*: B).

The equations using AND-OR-INVERT logic are:

A1, A2 ≡ B1, B2 = (/A1*/B1)*(/A2*/B2) + (A1*B1)*(/A2*/B2)
+ (/A1*/B1)*(A2*B2) + (A1*B1)*(A2*B2)

So for 3 inputs we require 8 sum of products and so on. This means that we have to cascade 2 stages in the 16R4 as there are only 7 product terms available per output. Hence, compare 1 (CO1) is:

= A0*B0*A1*B1*/CI
+ A0*B0*/A1*B1*/CI
+ /A0*/B0*A1*B1*/CI
+ /A0*/B0*/A1*/B1*/CI

/CI = COMPARE IN FROM PREVIOUS STAGE

Compare Output 2 (CO2) is:
= A2*B2*A3*B3*/C*1 and so on.

On the final stage, the clock is inverted and gated with CO2. This causes a negative going pulse to be output when the A and B inputs are equal, the leading edge being at data center. This pulse is the EQ output. For a 16 bit register, the final CO2 output can have a maximum delay of 4x2x25ns = 200ns, so for a EQ pulse at data center the maximum clock frequency would be 5 MHz.

But, by using a carry-look-ahead technique, this could be increased to 7.2 MHz. In practice clock frequencies of greater than 10 MHz could be used (causing the EQ pulse leading edge to shift off center).

Conclusion

By feeding the outputs of the shift register into a bank of FIFOs (67401 or similar) a practical serial communication channel can be buffered into a microcomputer system. Using PALs the design can be tailored for use in different communication systems.

DESCRIPTION

THIS 4-BIT SHIFT REGISTER/COMPARATOR ACCEPTS POSITIVE NRZ INPUT DATA ON THE RISING EDGE OF THE CLOCK (CK) AND PRODUCES A PARALLEL OUTPUT (B) WITH A 'COMPARE TRUE PULSE' ON THE NEGATIVE EDGE OF THE CLOCK (CLK).

THE THREE-STATE OUTPUTS (B) ARE HIGH-Z WHEN THE OUTPUT CONTROL LINE (/OC) IS HIGH AND ENABLED WHEN THE OUTPUT CONTROL LINE (/OC) IS LOW.

DESCRIPTION

THIS IS AN 8-BIT SYNCHRONOUS COUNTER WITH PARALLEL LOAD, CLEAR, AND HOLD CAPABILITY. THE LOAD OPERATION LOADS THE INPUTS (D7-D0) INTO THE OUTPUT REGISTER (Q7-Q0). THE CLEAR OPERATION RESETS THE OUTPUT REGISTER TO ALL LOWS. THE HOLD OPERATION HOLDS THE PREVIOUS VALUE REGARDLESS OF CLOCK TRANSITIONS. THE INCREMENT OPERATION ADDS ONE TO THE OUTPUT REGISTER WHEN THE CARRY-IN IS TRUE (/CI=L), OTHERWISE THE OPERATION IS A HOLD. THE CARRY-OUT (/CO) IS TRUE (/CO=L) WHEN THE OUTPUT REGISTER (Q7-Q0) IS ALL HIGHS, OTHERWISE FALSE (/CO=H).

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE OPERATIONS TABLE:

/OC	CLK	I1	I0	/CI	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	X	Z	HI-Z
L	C	L	L	X	X	L	CLEAR
L	C	L	H	X	X	Q	HOLD
L	C	H	L	X	D	D	LOAD
L	C	H	H	H	X	Q	HOLD
L	C	H	H	L	X	Q PLUS 1	INCREMENT

TWO OR MORE OCTAL COUNTERS MAY BE CASCADED TO PROVIDE LARGER COUNTERS. THE OPERATION CODES WERE CHOSEN SUCH THAT WHEN I1 IS HIGH, I0 MAY BE USED TO SELECT BETWEEN LOAD AND INCREMENT AS IN A PROGRAM COUNTER (JUMP/INCREMENT). ALSO, CARRY-OUT (/CO) AND CARRY-IN (/CI) ARE LOCATED ON PINS 14 AND 23 RESPECTIVELY, WHICH PROVIDES FOR CONVENIENT INTERCONNECTIONS WHEN TWO OR MORE OCTAL COUNTERS ARE CASCADED TO IMPLEMENT LARGER COUNTERS.

DESCRIPTION

THIS PAL IS AN 8-BIT SYNCHRONOUS UP/DOWN COUNTER WITH PARALLEL LOAD AND HOLD CAPABILITY. THREE FUNCTION SELECT INPUTS (/LD,/UD,/CBI) PROVIDE ONE OF FOUR OPERATIONS WHICH OCCUR SYNCHRONOUSLY ON THE RISING EDGE OF THE CLOCK (CLK). THE LOAD OPERATION LOADS THE INPUTS (D7-D0) INTO THE OUTPUT REGISTERS (Q7-Q0). THE HOLD OPERATION HOLDS THE PREVIOUS VALUE REGARDLESS OF CLOCK TRANSITIONS. THE INCREMENT OPERATION ADDS ONE TO THE OUTPUT REGISTER WHEN CARRY-IN INPUT IS TRUE (/CBI=L), OTHERWISE THE OPERATION IS A HOLD. THE CARRY-OUT (/CBO) IS TRUE (/CBO=L) WHEN THE OUTPUT REGISTER (Q7-Q0) IS ALL HIGHS, OTHERWISE FALSE (/CBO=H). THE DECREMENT OPERATION SUBTRACTS ONE FROM THE OUTPUT REGISTER WHEN THE BORROW-IN INPUT IS TRUE (/CBI=L), OTHERWISE THE OPERATION IS A HOLD. THE BORROW-OUT (/CBO) IS TRUE (/CBO=L) WHEN THE OUTPUT REGISTER (Q7-Q0) IS ALL LOWS, OTHERWISE FALSE (/CBO=H).

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE OPERATIONS TABLE:

/OC	CLK	/LD	/UD	/CBI	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	X	Z	HI-Z
L	C	L	X	X	D	L	LOAD
L	C	H	L	H	X	Q	HOLD
L	C	H	L	L	X	Q PLUS 1	INCREMENT
L	C	H	H	H	X	Q	HOLD
L	C	H	H	L	X	Q MINUS 1	DECREMENT

THIS OCTAL COUNTER IS IMPLEMENTED WITH A SINGLE PAL20X8. CARRY/BORROW-OUT (/CBO) AND CARRY/BORROW-IN (/CBI) ARE LOCATED ON PINS 14 AND 23 RESPECTIVELY, WHICH PROVIDES FOR CONVENIENT INTERCONNECTIONS WHEN TWO OR MORE OCTAL UP/DOWN COUNTERS ARE CASCADED TO IMPLEMENT LARGER COUNTERS.

DESCRIPTION

THE 10-BIT COUNTER CAN COUNT UP, COUNT DOWN, SET, AND LOAD 2 LSB'S (D0,D1), 2 MSB'S (D8,D9) AND 6 MIDDLE BITS (D2-7) HIGH OR LOW AS A GROUP.

SET OVERRIDES LOAD (/LD), COUNT (/CNT), AND HOLD. LOAD OVERRIDES COUNT. COUNT IS CONDITIONAL ON CARRY IN (/CIN), OTHERWISE IT HOLDS.

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE OPERATIONS TABLE:

/OC	CLK	SET	/LD	/CNT	/CIN	/UP	D9-D0	Q9-Q0	OPERATION
H	X	X	X	X	X	X	X	Z	HI-Z
L	C	H	X	X	X	X	X	H	SET ALL HIGH
L	C	L	L	X	X	X	D	D	LOAD D
L	C	L	H	H	X	X	X	Q	HOLD (/CNT=H)
L	C	L	H	L	H	X	X	Q	HOLD (/CIN=H)
L	C	L	H	L	L	L	X	Q PLUS 1	INCREMENT
L	C	L	H	L	L	H	X	Q MINUS 1	DECREMENT

```

DESCRIPTION

THE 4-BIT UP/DOWN COUNTER WITH SHIFT REGISTER AND COMPARATOR WILL COUNT UP, COUNT DOWN, SHIFT RIGHT, SHIFT LEFT, COMPARE GREATER THAN OR EQUAL TO, COMPARE LESS THAN OR EQUAL TO, CLEAR, SET, LOAD, OR HOLD AS SPECIFIED BY THE INSTRUCTION LINES (I2,I1,I0) AND CLEAR (CLR). ALL OPERATIONS OCCUR SYNCHRONOUSLY ON THE RISING EDGE OF THE CLOCK (CLK) EXCEPT FOR THE COMPARISION OPERATIONS WHICH ARE PERFORMED ASYNCHRONOUSLY AND WITH NO INSTRUCTION LINES REQUIRED.

THE COMPARISION OPERATIONS (/GE AND /LE) WILL COMPARE THE INPUT DATA (B) WITH THE DATA IN THE REGISTERS (A) AND SUPPLY THE FOLLOWING STATUS:

COMPARISION	/GE	/LE
B IS GREATER THAN A	L	H
B IS EQUAL TO A	L	L
B IS LESS THAN A	H	L

NOTE THAT BORROW, CARRY, AND SHIFT LEFT AND RIGHT INPUT/OUTPUTS SHARE THE SAME I/O LINES (/LIO AND /RIO) AND THESE LINES ARE INVERTED (ACTIVE LOW).

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE OPERATIONS TABLE BELOW:

/OC	CLK	CLR	I2	I1	I0	B3-B0	/GE	/LE	/LIO	/RIO	A3-A0	OPERATION

DESCRIPTION

THE 4-BIT FLASH ANALOG-TO-DIGITAL CONVERTER CONVERTS AN ANALOG SIGNAL INTO A 4-BIT GRAY CODE. GRAY CODE IS CHOSEN TO ELIMINATE GLITCHES AT BINARY ROLL OVER POINTS.

THE MAXIUM SAMPLE RATE IS EQUAL TO 1/tpd OF THE PAL20X4. NOTE THAT NO FEEDBACK PROPAGATION DELAY IS INTRODUCED.

DESCRIPTION

THE 4-BIT FLASH DIGITAL-TO-ANALOG CONVERTER CONVERTS A 4-BIT GRAY CODE (G) INTO A 4-BIT BINARY CODE (B), WHICH IS THEN CONVERTED INTO ANALOG OUTPUTS (A).

ANALOG OUTPUTS (A) ARE EITHER LOW OR HI-Z WHICH ALLOWS THE CONDITIONAL THREE-STATE OUTPUTS TO PERFORM THE OPEN COLLECTOR FUNCTION THAT IS NEEDED TO DRIVE THE RESISTOR NETWORK.

DESCRIPTION

THE DEVICE CONTINUOUSLY COMPARES THE VALUE OF BUS (B3-B0) WITH THE VALUE OF THE REGISTER (A3-A0) AND REPORTS THE STATUS ON OUTPUTS LT, EQ, NE, AND GT:

* LT INDICATES THAT B IS LESS THAN A
* EQ INDICATES THAT B IS EQUAL TO A
* NE INDICATES THAT B IS NOT EQUAL TO A
* GT INDICATES THAT B IS GREATER THAN A

DESCRIPTION

THE BETWEEN LIMITS LOGIC CHECKS THE LT, EQ, AND GT STATUS FROM THE
COMPARATOR REGISTERS TO DETERMINE IF THE DATA IS BETWEEN THE UPPER
AND LOWER LIMITS LOADED IN THE COMPARATOR REGISTERS.  BOTH BETWEEN
LIMITS (BTWL) AND OUT OF LIMITS (OUTL) OUTPUTS ARE PROVIDED.

DESCRIPTION

THIS IS A MEMORY DECODER FOR A PRINTER.  THE PRINTER
IS MAPPED TO HEX ADDRESS 37E8.  THE WRITE OR READ LINES
GO HIGH WHEN ADDRESS LINES ARE CORRECT AND A WRITE OR
READ STROBE RESPECTIVELY IS PRESENT.

THIS IS THE FIRST IC OF A 2-PAL PRINTER INTERFACE FOR
THE STANDARD CENTRONICS-TYPE PRINTER.

DESCRIPTION

REGISTERED DATA FROM THE SYSTEM BUSS IS PRESENTED TO THE PRINTER WHEN A WRITE STROBE FROM THE DECODER IS PRESENT (DJPR1).

PRINTER STATUS DATA (PRINTER BUSY AND OUT OF PAPER) IS TRANSFERED TO THE SYSTEM DATA BUSS WHEN A READ STROBE FROM THE DECODER IS PRESENT.

THIS IS THE SECOND IC OF THE 2-PAL PRINTER INTERFACE FOR THE STANDARD CENTRONICS-TYPE PRINTER.

A Game of Chance

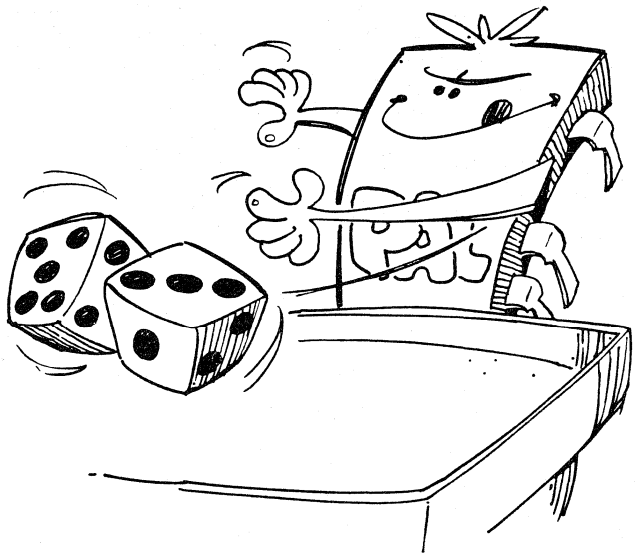
This application note describes the use of PALs to simulate the dice game "Craps". The design requirements were derived from the basic rules of the game which are listed below.

1. The player throws two dice. The number will be between 2 and 12.
2. He wins if the number is 7 or 11. He loses if the number is 2, which is called "snake eyes".
3. Any number other than 2, 7, or 11 is the player's point.
4. Player continues to roll if a point is indicated on the first roll.
5. The player loses if he throws 7 or 11 on a subsequent roll.
6. The player wins if he throws a point on a subsequent roll.
7. The player continues to roll until a win or a loss is indicated.

There are four PALs used in this design, which are:

IC1 8-State Machine and Win-Lose Decoder
IC2 36-State Machine
IC3 Dice Decoder
IC4 Store Point and /2, /7, and /11 Decode

Not included in this application note are three more ICs. These are a 74LS85 (Magnitude Comparitor), used to compare the stored point to the roll of the dice on second and subsequent rolls, and two Binary-to-Seven Segment Decoders, used to drive the LED displays.



```

DESCRIPTION

THIS PAL SERVES AS THE MAIN LOGIC UNIT. IT IS THE 8 STATE MACHINE WHICH CONTROLS WHERE WE ARE IN THE GAME. IT ALSO DETECTS THE WIN AND LOSE STATES. PIN /T IS USED TO INITIATE THE GAME TO STATE 000 FOR I.C. TEST EQUIPMENT.

DESCRIPTION

THIS PAL DECODES THE 36 STATE MACHINE INTO A BINARY REPRESENTATION OF THE ROLL OF THE DICE (2 THRU 12). THERE ARE 36 POSSIBLE COMBINATIONS FOR THE TWO DICE. THE NUMBERS ARE DECODED SO THAT THE PROPER ODDS ARE MAINTAINED FOR THE ROLL OF EACH NUMBER.

```

DESCRIPTION

THIS PAL IS USED TO STORE THE POINT IN THE GAME. IT ALSO DECODES THE NUMBERS 2, 7, AND 11 TO BE USED IN DETERMINING WIN OR LOSE.

STORE POINT /2, /7, AND /11 DECODE

```

4

An Example of Sequential Logic Design with PALs

Figure 1 illustrates a simple traffic intersection consisting of two one-way streets, direction A and direction B. Each direction has a signal consisting of red, yellow and green lamps which are activated with appropriately named active low signals. Also, each direction has a sensor which provides an active low signal indicating the presence of an oncoming vehicle. Our controller is to manage this intersection with the sensors as inputs and the lamps as outputs, as shown in Figure 2.

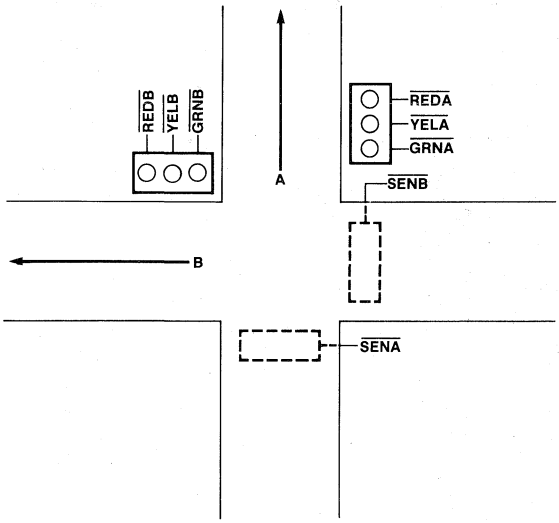

Figure 1. Traffic Intersection

Figure 2 also includes the system clock and an initialize (or reset) signal, which drives the controller to a pre-defined initial state. This raises two important issues in designing sequential logic with PALs. First, all circuit implementations of sequential logic with PALs are totally synchronous. This implies that all state variables (flip-flops) change at the same time, precisely after the rising edge of the clock. Second, PAL sequential logic designs should include a means for initialization to implement test programs and ensure reliable circuit operation.

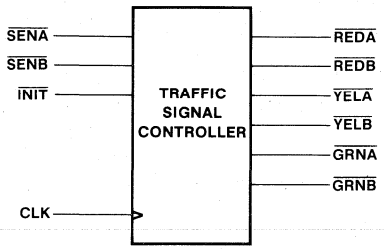

Figure 2. Traffic Signal Controller

The specifies of the controller operations are detailed with a state graph, shown in Figure 3.

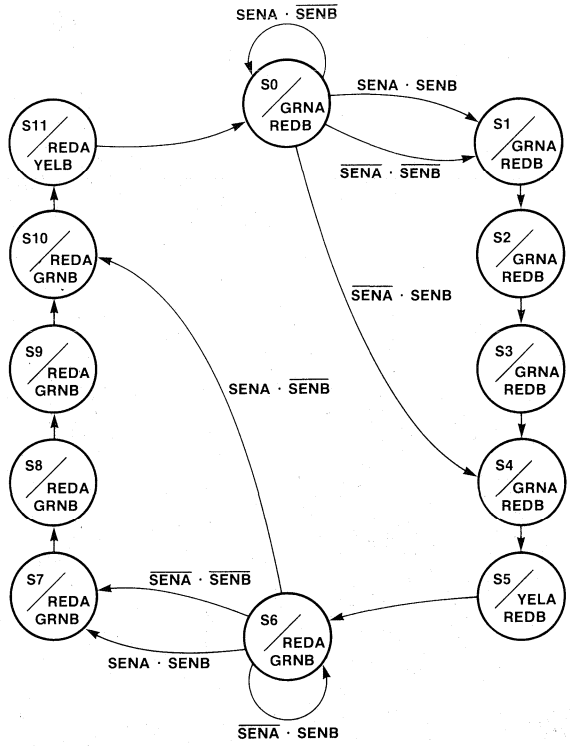

Figure 3. State Graph — Traffic Signal Controller

In this format, each bubble represents a stable state, i.e., an output configuration, lasting at least one clock cycle. Inside the bubble is the name of the state (S0–S11) and the outputs associated with that state. This particular circuit's outputs are specified to be a function of the state of the flip-flops only, and are not directly affected by the inputs. For the sake of simplicity in the state graph, the transitions involving INIT are omitted; INIT simply drives the circuit to S0 from any state, regardless of other inputs.

Another method of expressing the state graph information is with a state table, shown in Figure 4. Each row in the state table corresponds to a state (or bubble from the state graph). The first four columns give the next state for each of the possible input combinations. The output is also given for each state in the table. The state graph may be omitted but a state table is generally required to design the circuit.

The next step in the design is to assign state variables. This process also involves selecting the PAL or PALs to be used. Referring to Figures 2 and 3, the circuit requirements are seen to be 4 input, 6 output and 12 internal states. Since the intput/output pin requirements do not impose restrictions in either a 20 or 24 pin package, the states requirement will be addressed first. A PAL16R4 can implement the 12 states with its 4 flip flops. However, only 4 combinatorial outputs are available. This means that the flip-flop outputs (or state variables) will need to

be utilized as circuit outputs as well. One such approach is to take advantage of the fact that REDA = $\overline{\text{REDB}}$ and implementing REDA with one flip-flop, and REDB with an external inverter. Such a state variable assignment and resulting transition table is in Figure 5. This is generated by substituting the variable assignments into the state table.

NEXT STATE / CURRENT STATE	INPUT SENA, SENB 00	01	10	11	OUTPUT REDA	YELA	GRNA	REDB	YELB	GRNB

Figure 5. State Assignment No. 1/Transition Table

From this table, Karnaugh maps for D flip flop next state equations and output functions can be written, by transcription from the transition table, and minimized equations derived. This is shown in Figures 6 through 10. The state machine and PAL implementation follows. Note that the INIT term is simply AND'ed with all next state products to generate the initialize function.

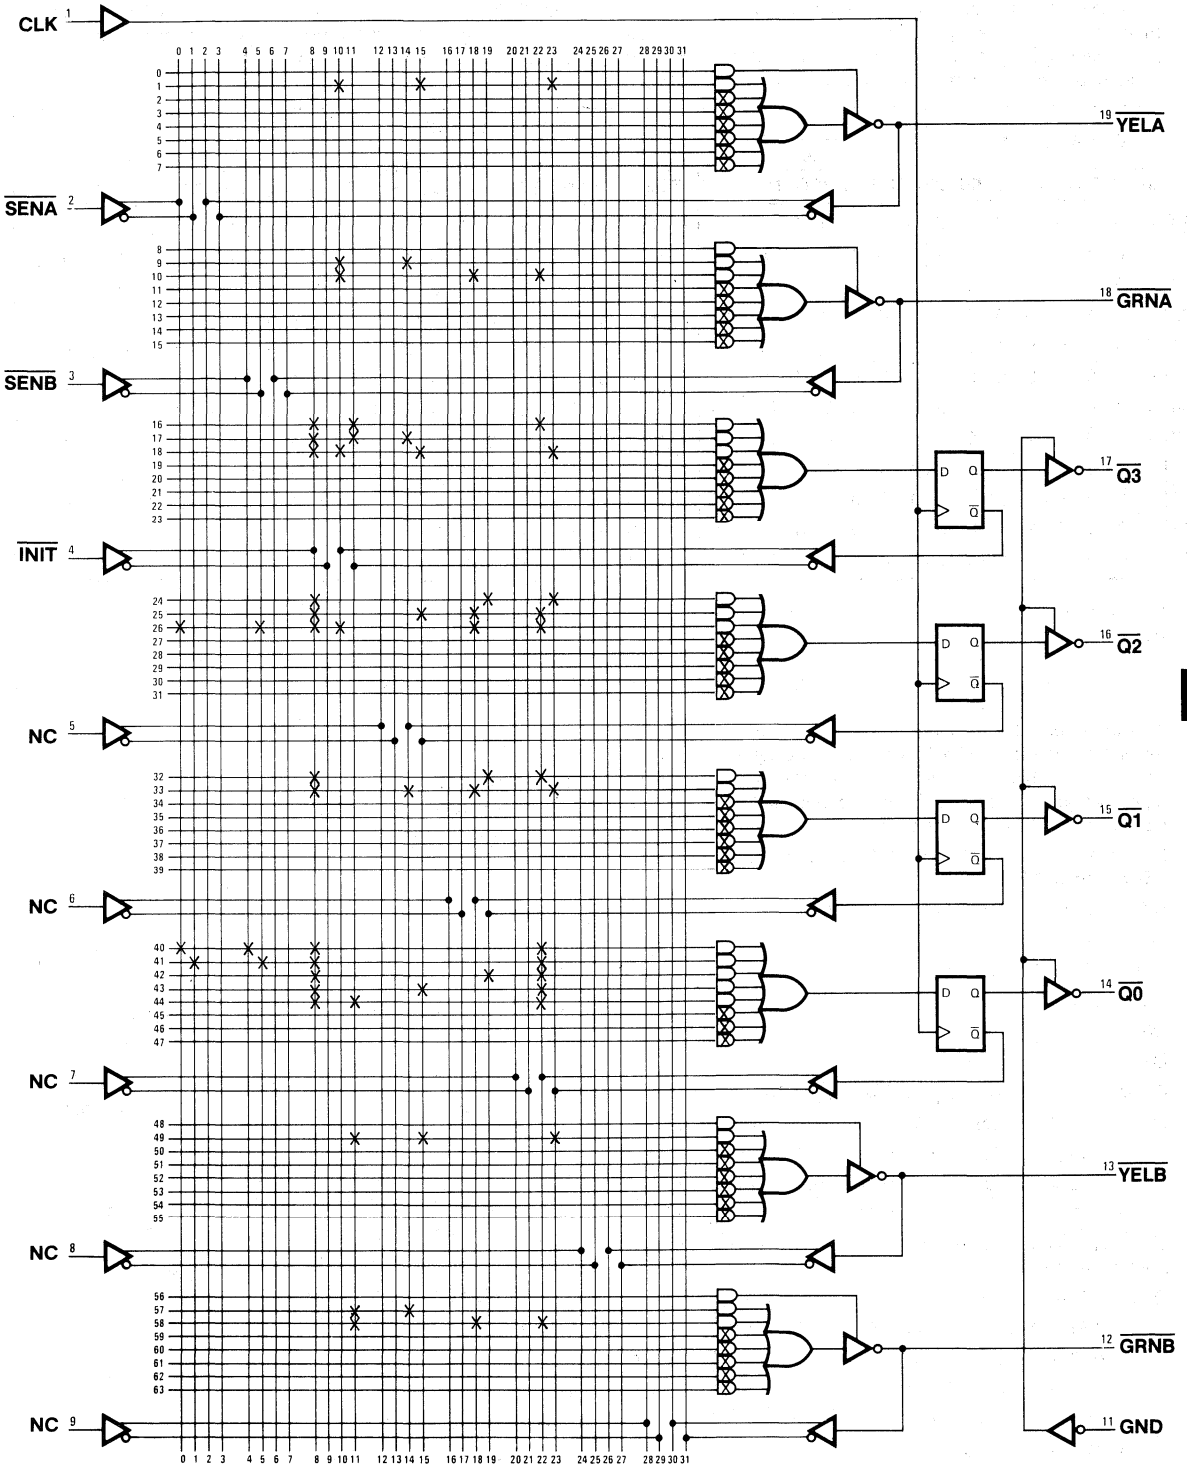
Traffic Signal Controller No. 1

Logic Diagram PAL16R4



Another approach to the circuit implementation is to assign one flip-flop (state variable) per output. When this is done with PALs, no penalty in chip count need be paid. In addition, such an implementation offers higher throughput than one which uses combinatorial outputs as one layer of delay is eliminated. Once again referring to Figure 4, we see that the outputs do not change in 2 sets of 5 states. Thus, a 3-bit counter is needed to count the states in which the outputs are common. This leaves only 5 flip-flops in a PAL16R8, so we will use the REDA = REDB trick once again. Figure 13 shows a new state assignment to re-implement the circuit with this approach.

	CURRENT STATE								INPUT/NEXT STATE

Figure 13. State Assignment No. 2/Transition Table

This transition table would translate into 10 variable Karnaugh maps. Instead, we can simply write down the equations for each next state variable and minimize by inspection (especially if the 8 product per output restriction is exceeded). Initially we will use state names rather than state variables.

By inspection, Q7+, Q6+, Q5+, Q4+, Q3+, Q1+, not depend on SENA and SENB:

Q7+ = S5 + S6 + S7 + S8 + S9 + S10

Q6+ = S4

Q5+ = S0 + S1 = S2 + S3 + S11

Q4+ = S10

Q3+ = S5 + S6 + S7 + S8 + S9

Q1+ = S1 + S2 + S7 + S8

Q2+ and Q0+ do depend on SENA and SENB:

Q2+ = /SENA * /SENB * (S3 + S9) [2 products]
+ /SENA * SENB * (S0 + S3 + S9) [3 products]
+ SENA * /SENB * (S3 + S6 + S9) [3 products]
+ SENA * SENB * (S3 + S9) [2 products]

Since Q2+ needs 10 products as written, we minimize by Boolean manipulation:

Q2+ = /SENA * /SENB * (S3 + S9) } /SENA * (S3 + S9)
+ /SENA * SENB * (S3 + S9) }
+ /SENA * SENB + (S0) } S3 + S9
+ SENA * /SENB * (S3 + S9) } SENA * (S3 + S9)
+ SENA * SENB * (S3 + S9) }
+ SENA * SENB * (S6)

Thus,

Q2+ = S3 + S9
+ /SENA * SENB * S0
+ SENA * SENB * S6

Next,

Q0+ = /SENA * /SENB * (S0 + S2 + S6 + S8) [4 products]
+ /SENA * SENB * (S2 + S8) [2 products]
+ SENA * /SENB * (S2 + S8) [2 products]
+ SENA * SENB * (S0 + S2 + S6 + S8) [4 products]

Q0+ = /SENA * /SENB * (S0 + S6)
+ /SENA * /SENB * (S2 + S8) } /SENA * (S2 + S8)
+ /SENA * SENB * (S2 + S8) }
+ SENA * /SENB * (S2 + S8) } SENA * (S2 + S8) } S2 + S8
+ SENA * SENB * (S2 + S8) }
+ SENA * SENB * (S0 + S6)

Q0+ + S2 + S8
+ /SENA * /SENB * (S0 + S6)
+ SENA * SENB * (S0 + S6)

The full equations (note that minimization is optional for less than 8 product sums):

$Q7^+ = /Q7 * Q6 * /Q5 * /Q4 * /Q3 * /Q2 * /Q1 * /Q0$
$+ Q7 * /Q6 * /Q5 * /Q4 * Q3 * /Q2 * /Q1 * /Q0$

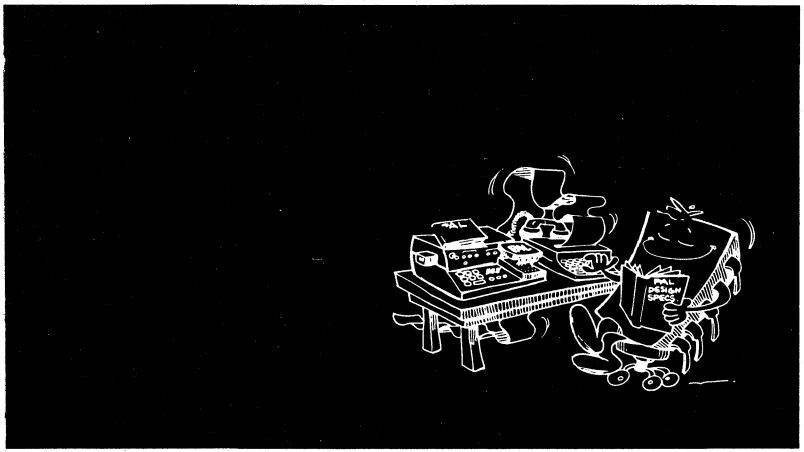
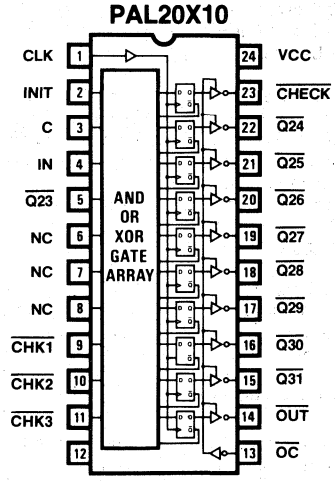
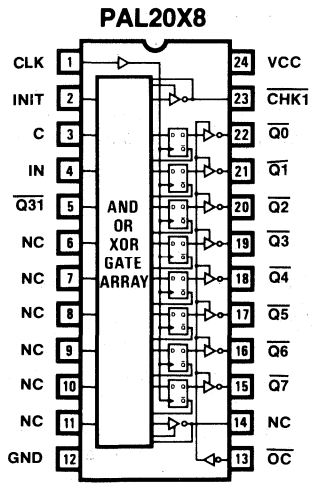
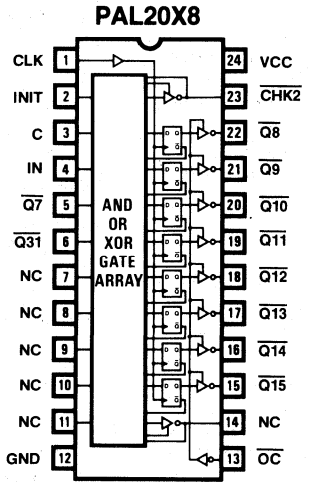
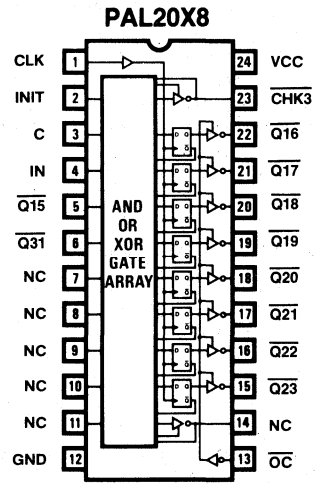
32-Bit CRC (Cyclical Redundancy Checking) Error Detection











CYCLIC REDUNDANCY CHECK (CRC) USING PALS

Programmable Array Logic Devices Provide Efficient Implementation of Popular Local Network Error Checking Protocol

There is a growing interest in providing data communication links to connect several processors and peripherals into one local area network. One of the most popular networks is the Ethernet. To insure reliable communications in the network an efficient error detection scheme is required. The Ethernet protocol specifies a 32-bit cycle redundancy which must operate at 10 Mbits/sec.

The following application opens with a tutorial on the CRC and then shows a detailed implementation of the Ethernet CRC using PAL. The use of fuse programmable devices allows easy modification to accommodate other data communications protocols as well as other applications (CRC in disk drives, etc.), that operate at rates up to 13 Mbits/sec.

Introduction

The growing number of high speed digital links and the need for reliable communication requires implementation of efficient error detection schemes at rates of 10 Mbits/sec and higher. A 32-bit CRC using PALs meets these requirements.

What is CRC ?

CRC is the acronym for Cyclic Redundancy Check, an error detection technique widely used in serial communication systems from computer to computer or from computer to peripheral devices. This technique operates on serial bits of information treated as the coefficients of a binary polynomial, P(x), and processes these bits in modulo-2 arithmetic.

The basic coding concept of the CRC is to modify the polynomial, P(x), so that it is exactly divisible by a fixed polynomial, G(x); the divisor G(x) is referred to as the generator polynomial. The modified polynomial, M(x), is transmitted. M(x) is divided by the same G(x) when received or fetched. If the remainder is zero, all bits are assumed to be correct; otherwise, a flag is set to indicate an error.

An Example Using CRC

A 6-bit message (101110) can be represented in polynomial form as:

$$P(x) = 1 + 0x + 1x^2 + 1x^3 + 1x^4 + 0x^5$$

or

$$P(x) = x^4 + x^3 + x^2 + 1$$

The highest power of x is attached to the least significant bit (LSB). The LSB is the first bit transmitted in communication channels. In general P(x) will not be exactly divisible by G(x); the division will generate a quotient, Q(x), and a remainder, R(x). P(x) is prescaled to insure that the order of P(x) is greater than the order of G(x) so that the remainder is always different than the message itself.

Specifically, P(x) is prescaled by x^n where n is the degree of G(x).

$$x^n P(x) = Q(x)\, G(x) + R(x) \qquad (1)$$

For a 3-bit CRC and $G(x) = x^3 + 1$ equation (1) becomes:

$$x^3 (x^4 + x^3 + x^2 + 1) = (x^4 + x^3 + x^2 + x)(x^3 + 1) + (x^2 + x)$$

The operation is performed using modulo-2 arithmetic where the sum and difference are synonymous.
Equation 1 can equivalently be written as:

$$x^n P(x) - R(x) = x^n P(x) + R(x) = Q(x)\, G(x) = M(x)$$

M(x) is exactly divisible by G(x) and it is M(x) that is transmitted. The message M(x) is formed by adding the remaining bits, R(x), of a fixed length n to the message bits. Because the message was prescaled, addition is equivalent to appending the remainder at the end of the data bits. For the example given (remembering that LSB is sent first) the information transmitted is: 011 101110. Three redundancy bits are appended to facilitate error detection.

In conclusion when performing CRC, the transmitter will generate and append R(x) while the receiver will verify the exact division of M(x) by G(x) and signal the occurrence of an error.

Why CRC ?

Compared to other error detection schemes such as parity checking CRC is more powerful:

- all errors within n successive bits are detected
- for even G(x) all errors with an odd number of bits in error are detected (50% of all possible random errors)
- all error patterns that are not divisible by G(x) are detected

CRC is also more efficient (for large frame of information). Efficiency is defined as the number of data bits divided by the total number of bits transmitted. For example: in the Ethernet

specification the number of data bits ranges from 60 to 1500 bytes, the total number of bits transmitted will contain only an extra 32-bits (if 32-bit CRC is used) instead of an extra 60 to 1500 parity bits (if we assume one parity bit per byte of information is used.)

Implementation

A binary division that ignores the quotient but retains the remainder, R(x), is conventionally implemented with a shift register. A feedback path from the output of the last stage returns to the input of the stages corresponding to the powers of x that have non zero coefficient in the generating polynomial. At each such input, a modulo-2 adder (Exclusive OR) combines the feedback signal with the output from the previous stage.

This is equivalent to a shift subtract on each clock cycle. The example in Fig. 1 shows a 32-bit CRC where G(x), the generator polynomial, (used in ETHERNET and AUTOBAUD II) is given by:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Transmitter operation:

1. Initialize shift register to all Hs. (INIT = H)
2. Data is shifted in the feedback shift register to generate R(x) and fed to the output. (Control C = H)
3. After last data bit has been processed, the complimented R(x) is shifted out for transmission. (Control C = L)

Receiver operation:

1. Initialize shift register to all Hs.
2. Data is shifted in the feedback shift register to regenerate R(x).
3. After last data bit has been processed, Control remains High and the complement of R(x) is shifted (as generated by transmitter).

If the two R(x) match, the final content of the shift register is:

X31 X0
1100011100000100110111010111101 1 (residue)

4) This value is tested. (Check = L indicates no error, as shown in Fig. 2)

The same hardware can perform both the transmitter and receiver function if the respective inputs are multiplexed.

PAL Configuration

Four PALs are used to implement the 32-bit CRC. This configuration can process serial streams of data at rates of 10 Mbits/sec. The PAL interconnections are shown in Fig. 2. Eight bits of the 32-bit shift register are distributed in each PAL. The logic to check for the residue is distributed among the four PALs as shown in Fig. 3.

Summary

The lack of standardization in data communication equipment makes the use of PALs very attractive due to their flexibility and ease of design modification. A good example is this 32-bit CRC which achieves the speed requirements of 13 Mbits/sec while being cost effective.

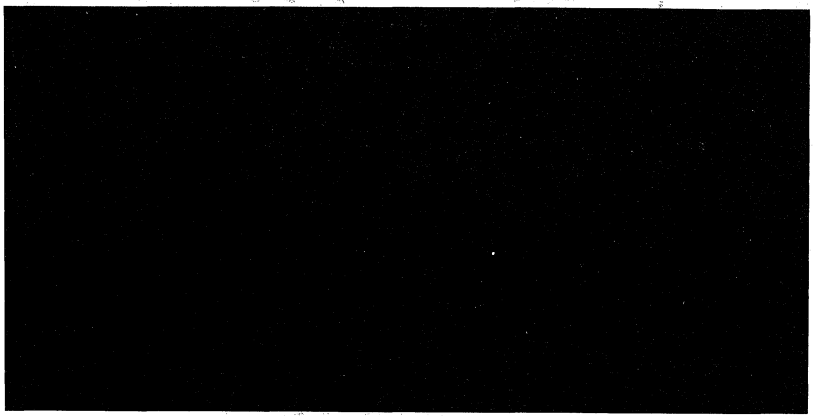
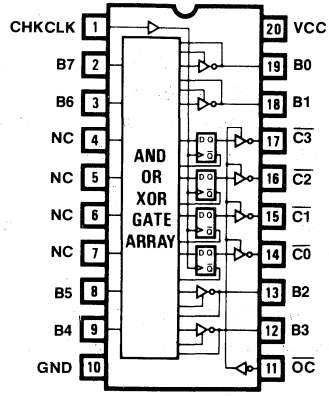
IMPORTANT
NOTES

8-Bit Error Detection and Correction

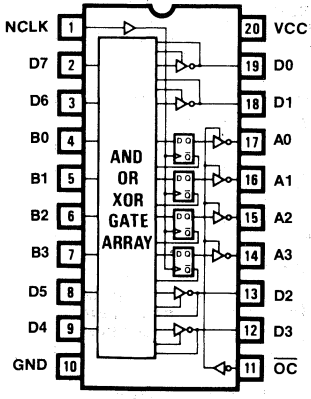


PAL16X4

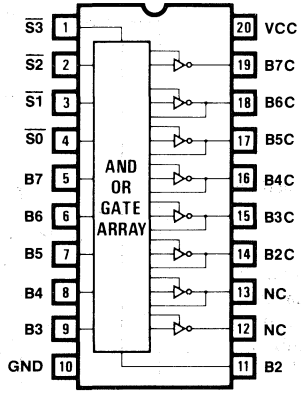


4

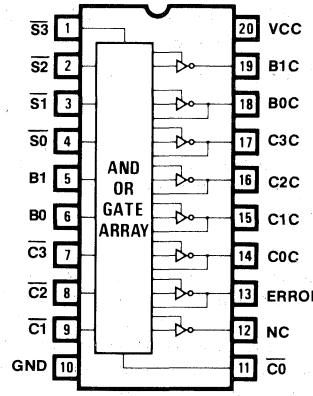
PAL16X4



PAL16L8



PAL16L8



Single bit error detection and correction for an 8-bit data word requires 4 check bits, making a 12-bit code word. The simplest code to design is a 12-bit Hamming code. To arrive at the code, we set up the following matrix:

	B7	B6	B5	B4	B3	B2	B1	B0	C3	C2	C1	C0
S3	X	X	X	X					X			
S2	X				X	X	X			X		
S1		X	X		X	X		X			X	
S0		X		X	X		X	X				X

The vertical columns are in a counting pattern, excluding the single bit values of 8, 4, 2, 1. The single bit values are assigned to the check bits C3-C0. By reading horizontally across the rows of the matrix, we get the check equations by exclusive OR'ing the data bits with X's in that row and equating that to the check bit with an X in that row:

$$C3 = B7 \oplus B6 \oplus B5 \oplus B4$$
$$C2 = B7 \oplus B3 \oplus B2 \oplus B1$$
$$C1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0$$
$$C0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0$$

The check bits are stored along with the data bits in the following message format:

M12	M11	M10	M9	M8	M7	M6	M5	M4	M3	M2	M1
B7	B6	B5	B4	C3	B3	B2	B1	C2	B0	C1	C0

When a read occurs, the check bits are recalculated and compared with the stored bits to generate the 4 bit syndrome:

$$S3 = B7 \oplus B6 \oplus B5 \oplus B4 \oplus C3$$
$$S2 = B7 \oplus B3 \oplus B2 \oplus B1 \oplus C2$$
$$S1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0 \oplus C1$$
$$S0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0 \oplus C0$$

The 4 syndrome bits indicate the location of any single bit errors in the 12-bit message format which may than be corrected by inversion.

The Hamming code works by introducing enough other code words to create a difference of exactly 3 bits between legal code words. All other code words are illegal. If, in storage, one bit flips, the result is an illegal word. In addition, there is only one word in the set of legal code words from which it could have come, hence the correction.

The Hamming matrix and resultant sets of check bit and syndrome equations are selected so that when a single bit error occurs, the syndrome gives the position of that bit (either data or check) in the 12-bit message format.

Example **B7** **B0**

random data word: 1 1 0 1 1 1 0 0

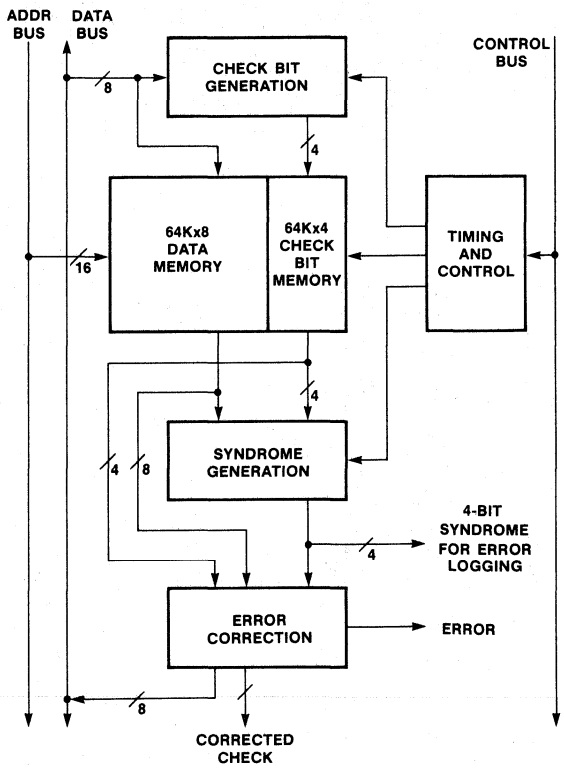
check bits:

$$C3 = B7 \oplus B6 \oplus B5 \oplus B4 = 1 \oplus 1 \oplus 0 \oplus 1 = 1$$
$$C2 = B7 \oplus B3 \oplus B2 \oplus B1 = 1 \oplus 1 \oplus 1 \oplus 0 = 1$$
$$C1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0 = 1 \oplus 0 \oplus 1 \oplus 1 \oplus 0 = 1$$
$$C0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0 = 1 \oplus 1 \oplus 1 \oplus 0 \oplus 0 = 1$$

message:

M12	M11	M10	M9	M8	M7	M6	M5	M4	M3	M2	M1
1	1	0	1	1	1	1	0	1	0	1	1
B7	B6	B5	B4	C3	B3	B2	B1	C2	B0	C1	C0

EDAC System Block Diagram



assume no error:

$$S3 = B7 \oplus B6 \oplus B5 \oplus B4 \oplus C3$$
$$= 1 \oplus 1 \oplus 0 \oplus 1 \oplus 1 = 0$$
$$S2 = B7 \oplus B3 \oplus B2 \oplus B1 \oplus C2$$
$$= 1 \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 0$$
$$S1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0 \oplus C1$$
$$= 1 \oplus 0 \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 0$$
$$S0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0 \oplus C0$$
$$= 1 \oplus 1 \oplus 1 \oplus 0 \oplus 0 \oplus 1 = 0$$

syndrome 0000 indicates no error

assume data bit B7 flips (1 → 0):

$$S3 = \underline{0} \oplus 1 \oplus 0 \oplus 1 \oplus 1 = 1$$
$$S2 = \underline{0} \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 1$$
$$S1 = 1 \oplus 0 \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 0$$
$$S0 = 1 \oplus 1 \oplus 1 \oplus 0 \oplus 0 \oplus 1 = 0$$

syndrome 1100 indicates M12 or B7 is in error

assume check bit C3 flips (1 → 0):

$$S3 = 1 \oplus 1 \oplus 0 \oplus 1 \oplus \underline{0} = 1$$
$$S2 = 1 \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 0$$
$$S1 = 1 \oplus 0 \oplus 1 \oplus 1 \oplus 0 \oplus 1 = 0$$
$$S0 = 1 \oplus 1 \oplus 1 \oplus 0 \oplus 0 \oplus 1 = 0$$

syndrome 1000 indicates M8 or C3 is in error

While the check bits can be generated with a 256x4 PROM if the tolerances are loose, high performance systems will need to latch or register the check bits to meet cycle time requirements. Similarly, the syndrome bits can be generated with a 4096x4 PROM but in both cases the PAL16X4 is the high performance choice.

The worst case equations are S1 and S0 with a 6 term exclusive OR. We use 2 properties of the exclusive OR to fit the equations into the 16X4:

1. Associativity
   $A \oplus B \oplus C = (A \oplus B) \oplus C$
2. $A \oplus B \oplus C = A\overline{B}\,\overline{C} + \overline{A}B\overline{C} + \overline{A}\overline{B}C + ABC$

Since a 3 term exclusive OR can be realized with a 4 product sum in sum of products form, a 6 term exclusive OR can be realized by exclusive OR of 2 4 product sums. This is exactly the 16X4 configuration.

Check Bit Equations

$$C3 = B7 \oplus B6 \oplus B5 \oplus B4$$
$$= (B7 \cdot \overline{B6} + \overline{B7} \cdot B6) \oplus (B5 \cdot \overline{B4} + \overline{B5} \cdot B4)$$

$$C2 = B7 \oplus B3 \oplus B2 \oplus B1$$
$$= (B7 \cdot \overline{B3} + \overline{B7} \cdot B3) \oplus (B2 \cdot \overline{B1} + \overline{B2} \cdot B1)$$

$$C1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0$$
$$= (B6 \cdot B5 \cdot B3 + \overline{B6} \cdot \overline{B5} \cdot B3 + \overline{B6} \cdot B5 \cdot \overline{B3} + B6 \cdot \overline{B5} \cdot \overline{B3}) \oplus (B2 \cdot \overline{B0} + \overline{B2} \cdot \quad)$$

$$C0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0$$
$$= (B6 \cdot B4 \cdot B3 + \overline{B6} \cdot \overline{B4} \cdot B3 + \overline{B6} \cdot B4 \cdot \overline{B3} + B6 \cdot \overline{B4} \cdot \overline{B3}) \oplus (B1 \cdot \overline{B0} + \overline{B1} \cdot B0)$$

Syndrome Bit Equations

$$S3 = B7 \oplus B6 \oplus B5 \oplus B4 \oplus C3$$
$$= (B7 \cdot B6 \cdot B5 + \overline{B7} \cdot \overline{B6} \cdot B5 + \overline{B7} \cdot B6 \cdot \overline{B5} + B7 \cdot \overline{B6} \cdot \overline{B5}) \oplus (B4 \cdot \overline{C3} + \overline{B4} \cdot C3)$$

$$S2 = B7 \oplus B3 \oplus B2 \oplus B1 \oplus C2$$
$$= (B7 \cdot B3 \cdot B2 + \overline{B7} \cdot \overline{B3} \cdot B2 + \overline{B7} \cdot B3 \cdot \overline{B2} + B7 \cdot \overline{B3} \cdot \overline{B2}) \oplus (B1 \cdot \overline{C2} + \overline{B1} \cdot C2)$$

$$S1 = B6 \oplus B5 \oplus B3 \oplus B2 \oplus B0 \oplus C1$$
$$= (B6 \cdot B5 \cdot B3 + \overline{B6} \cdot \overline{B5} \cdot B3 + \overline{B6} \cdot B5 \cdot \overline{B3} + B6 \cdot \overline{B5} \cdot \overline{B3}) \oplus (\overline{B2} \cdot \overline{B0} \cdot C1 + \overline{B2} \cdot \overline{B0} \cdot C1 + B2 \cdot B0 \cdot \overline{C1} + B2 \cdot \overline{B0}$$

$$S0 = B6 \oplus B4 \oplus B3 \oplus B1 \oplus B0 \oplus C0$$
$$= (B6 \cdot B4 \cdot B3 + \overline{B6} \cdot \overline{B4} \cdot B3 + \overline{B6} \cdot B4 \cdot \overline{B3} + B6 \cdot \overline{B4} \cdot \overline{B3}) \oplus (B1 \cdot B0 \cdot C0 + \overline{B1} \cdot \overline{B0} \cdot C0 + \overline{B1} \cdot B0 \cdot \overline{C0} + B1 \cdot \overline{B0} \quad)$$

The error correction block decodes the 4 syndrome bits, and, if they are not 0000, inverts the indicated bit in the message format. The equations:

$$M12\ (= B7C) = S3 \cdot S2 \cdot \overline{S1} \cdot \overline{S0} \oplus B7$$
$$= S3 \cdot S2 \cdot \overline{S1} \cdot \overline{S0} \cdot \overline{B7} + \overline{(S3 \cdot S2 \cdot \overline{S1} \cdot \overline{S0})} \cdot B7$$
$$= S3 \cdot S2 \cdot \overline{S1} \cdot \overline{S0} \cdot \overline{B7} + \overline{S3} \cdot B7 + S2 \cdot B7 + S1 \cdot B7 + \overline{S0} \cdot B7$$

$$M11\ (= B6C) = S3 \cdot \overline{S2} \cdot S1 \cdot S0 \cdot \overline{B6} \cdot \overline{S3} \cdot B6 \cdot S2 \cdot B6 + \overline{S1} \cdot B6 \cdot \overline{S0} \cdot B6$$

$$M10\ (= B5C) = S3 \cdot \overline{S2} \cdot S1 \cdot \overline{S0} \cdot \overline{B5} + \overline{S3} \cdot B5 + S2 \cdot B5 + \overline{S1} \cdot B5 + S0 \cdot B5$$

$$M9\ (= B4C) = S3 \cdot \overline{S2} \cdot \overline{S1} \cdot S0 \cdot \overline{B4} + \overline{S3} \cdot B4 + S2 \cdot B4 + S1 \cdot B4 + \overline{S0} \cdot B4$$

$$M8\ (= C3C) = S3 \cdot \overline{S2} \cdot \overline{S1} \cdot \overline{S0} \cdot \overline{C3} + \overline{S3} \cdot C3 + S2 \cdot C3 + S1 \cdot C3 + S0 \cdot C3$$

$$M7\ (= B3C) = \overline{S3} \cdot S2 \cdot S1 \cdot S0 \cdot \overline{B3} + S3 \cdot B3 + \overline{S2} \cdot B3 + \overline{S1} \cdot B3 + \overline{S0} \cdot B3$$

$$M6\ (= B2C) = \overline{S3} \cdot S2 \cdot S1 \cdot \overline{S0} \cdot \overline{B2} + S3 \cdot B2 + \overline{S2} \cdot B2 + \overline{S1} \cdot B2 + S0 + B2$$

$$M5\ (= B1C) = \overline{S3} \cdot S2 \cdot \overline{S1} \cdot S0 \cdot \overline{B1} + S3 \cdot B1 + \overline{S2} \cdot B1 + S1 \cdot B1 + \overline{S0} \cdot B1$$

$$M4\ (= C2C) = \overline{S3} \cdot S2 \cdot \overline{S1} \cdot \overline{S0} \cdot \overline{C2} + S3 \cdot C2 + \overline{S2} \cdot C2 + S1 \cdot C2 + S0 \cdot C2$$

$$M3\ (= B0C) = \overline{S3} \cdot \overline{S2} \cdot S1 \cdot S0 \cdot \overline{B0} + S3 \cdot B0 + S2 \cdot B0 + \overline{S1} \cdot B0 + \overline{S0} \cdot B0$$

$$M2\ (= C1C) = \overline{S3} \cdot \overline{S2} \cdot S1 \cdot \overline{S0} \cdot \overline{C1} + S3 \cdot C1 + S2 \cdot C1 + \overline{S1} \cdot C1 + S0 \cdot C1$$

$$M1\ (= C0C) = \overline{S3} \cdot \overline{S2} \cdot \overline{S1} \cdot S0 \cdot \overline{C0} + S3 \cdot C0 + S2 \cdot C0 + S1 \cdot C0 + \overline{S0} \cdot C0$$

$$ERROR = \overline{\overline{S3} \cdot \overline{S2} \cdot \overline{S1} \cdot \overline{S0}}$$

ERROR is an active high error indicator available for error logging along with the 4 syndrome bits.

To use 2 PAL16L8's for the error correction block, we need only invert the message bits to get active true outputs.

Logic Diagram PAL16L8

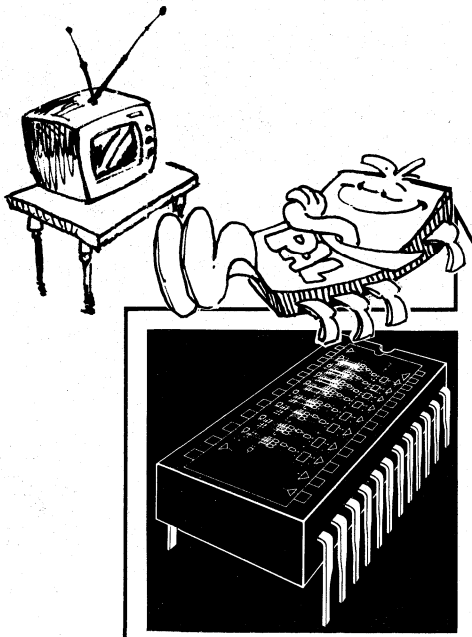
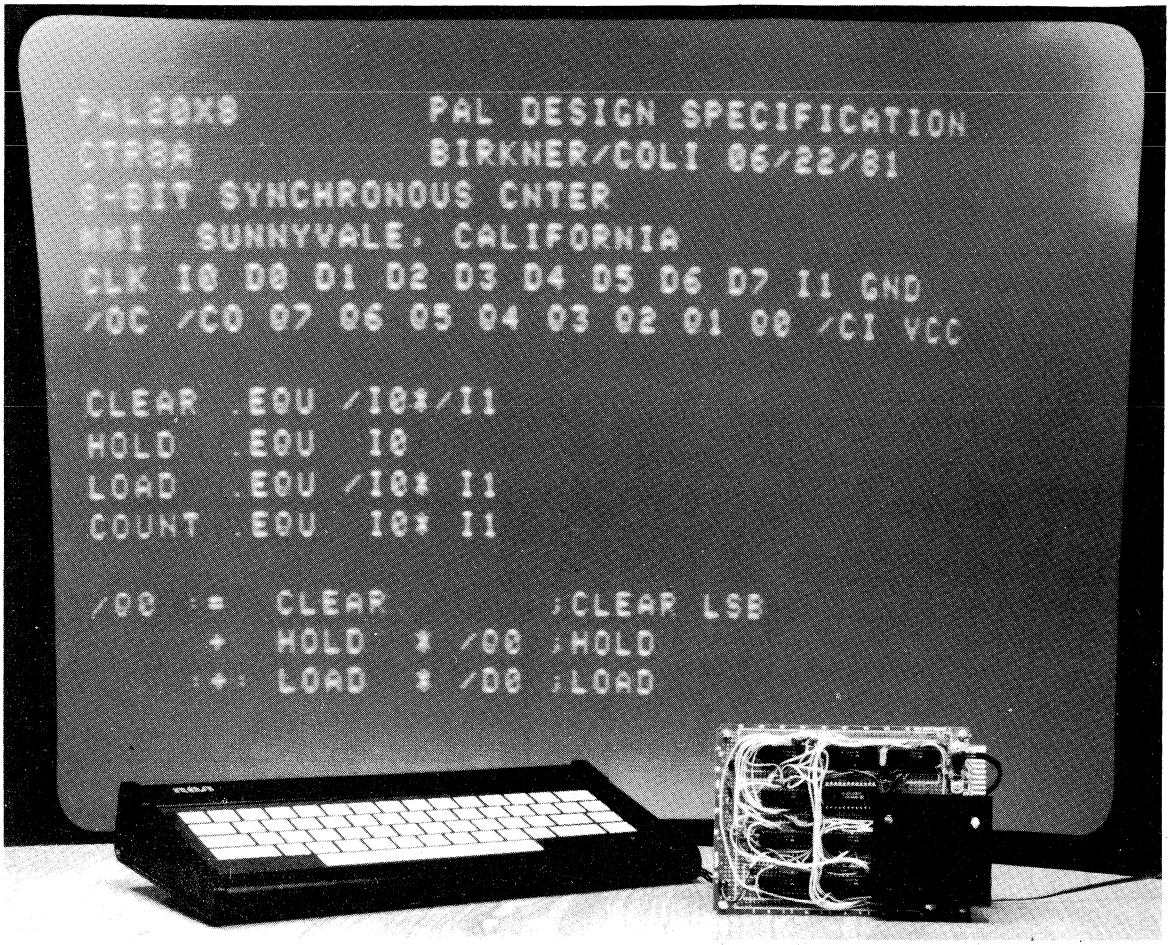
IMPORTANT
NOTES





Introduction to Video Section

Computer graphics is a rapidly growing field in the computer industry. It enables communication between the human being and the computer. The human eye can absorb information displayed in diagrams, numbers, letters and images much faster than it can absorb tables with numbers only. Computer graphics is penetrating into almost every professional field and the "video games" syndrome is spreading into more and more living rooms.

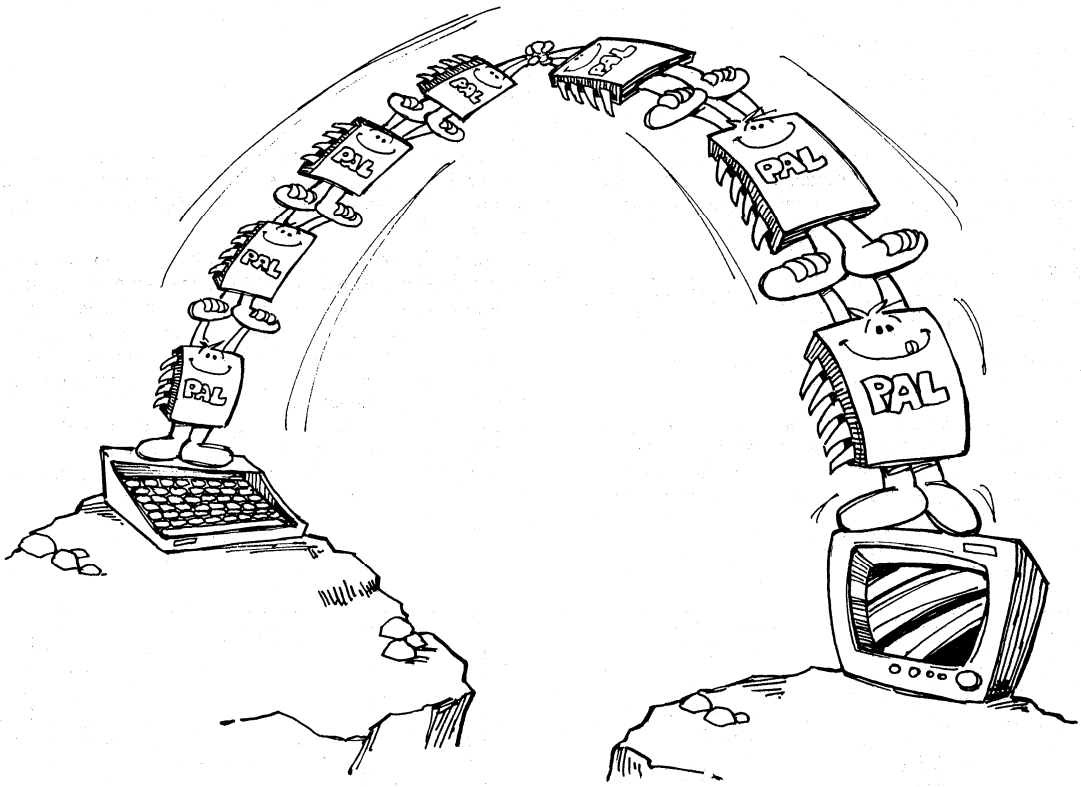
The PAL family teams up to help the wide-spread use of computer graphics. By using high speed PALs, the designer can implement simulations and real time systems in an efficient way.

The following designs are examples of the use of PALs in the video world.

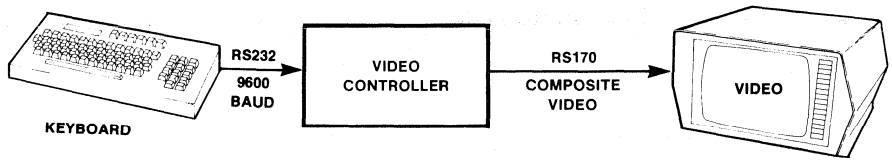
1. **10 BIT COUNTER [SN54/74LS491]** This is ideal for video synch generation for CRT graphics including video games. This counter provides the vertical and horizontal coordinates required to address the graphic data. Video resolution is usually 9 or 10 bits in the vertical and horizontal which in the past was supplied by three LS161's. These, of course, can be replaced by one LS491. This counter can also count down which allows screen coordinate reversal.
2. Analog to digital and digital to analog converters, change analog signal into an equivalent digital code and vice versa. This function is commonly required in a digital system when the analog information has to be stored and then shown as a displacement on a CRT.
3. The video logic design shows the reduction in the number of parts on a video-interface board using PALs.
4. The video-controller board is an example of how to implement a video system using PALs.

Implementing a Video Controller Using Programmable Array Logic

by Ehud "Udi" Gordon



The use of video is definitely a sign of the times and will be with us into the future. The video-controller board is the bridge between the outside world and the screen. There are many possibilities to implement the video-controller board, but an efficient one uses PALs. The following will simplify the construction of a video-controller board and will assist the designer in eliminating board space problems. PALs are the backbone of this application.



Overview

There are words that belong to specific concepts within the video industry. For a clear understanding of how the video-controller board works we need to define some of them:

FRAME — A single complete picture

SCANNING — The process of analyzing successively, according to a predetermined method, the light values of picture elements which constitute the total picture area

FRAME FREQUENCY — The number of times per second the picture area is completely scanned

The frame frequency has been standardized at 30 frames per second, which gives a satisfactory illusion of motion continuity, although the individual picture elements are transmitted one after the other. A frequency of 30 frames per second is equal to half the power-line frequency in most locations. Using this standardized rate, the entire screen is illuminated 30 times per second. This is too slow to give the impression of a truly steady light, so a flickering occurs.

To overcome the flickering problem it is common to use the **INTERLACED SCANNING METHOD**. In this method the screen is divided into 525 lines and into two fields. There is an odd numbered field and an even numbered field. Each of these fields is made up of one-half of the screen by dividing the frame into odd and even numbered lines. First, all the odd numbered lines 1, 3, 5, ... are scanned from top to bottom. After scanning a total of 262.5 odd numbered lines, the even numbered lines are scanned from top to bottom, for the total of 525 lines. Each scanning period from top to bottom is 1/60 of a second and is called a **FIELD**. Two fields constitute a frame.

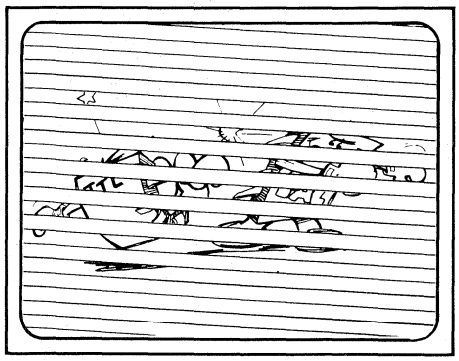


Figure 1a. Odd Numbered Lines Scanned Generate the Odd Field

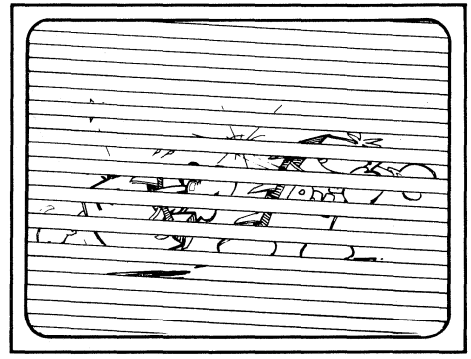

Figure 1b. Even Numbered Lines Scanned Generate the Even Field

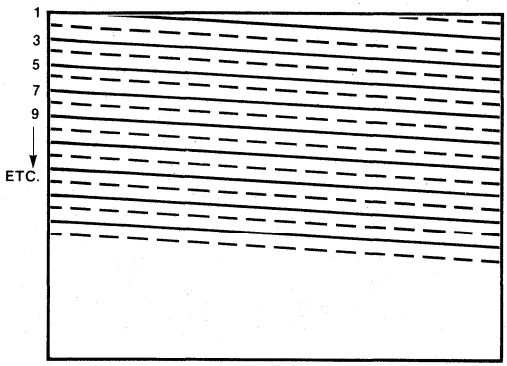

Figure 1c. The Solid Lines 1, 3, 5, . . . Represent the Odd Field. The Dashed Lines 2, 4, 6 . . . Represent the Even Field

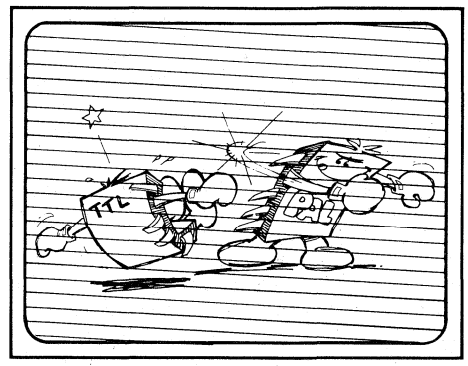

Figure 1d. The Odd and Even Fields Combined Generate One Frame

FIELD FREQUENCY — The number of times per second the field is completely scanned

The field frequency has been standardized at 60 fields per second. At this rate, the screen gets illuminated 60 times per second which results in the disappearance of the flickering. (Notice that the frame frequency is still 1/30 of a second.)

At the end of each scan line the electron beam moves rapidly from right to left on the screen which gives the horizontal retrace. Then it moves across the next odd/even numbered scan line and returns retracing right to left. While the beam retraces, blanking pulses are transmitted which blank out the total screen for this time period.

A HORIZONTAL SYNCHRONIZED PULSE is used to time the start of each horizontal scan line. The rate of the horizontal synchronizing pulse is equal to the total number of lines per frame multiplied by the number of frames transmitted per second:

$$525 \text{ lines} * 30 \text{ frames} = 15750 \text{ pulses/second}$$

A VERTICAL SYNCHRONIZED PULSE is used to time the start of each field. It occurs at the end of each field and causes the beam to go from bottom to top of the screen. During the vertical retrace, blanking pulses are transmitted which blank out the total screen for this time period. The rate of the vertical synchronizing pulse is equal to the number of fields transmitted per second: 60 pulses/second.

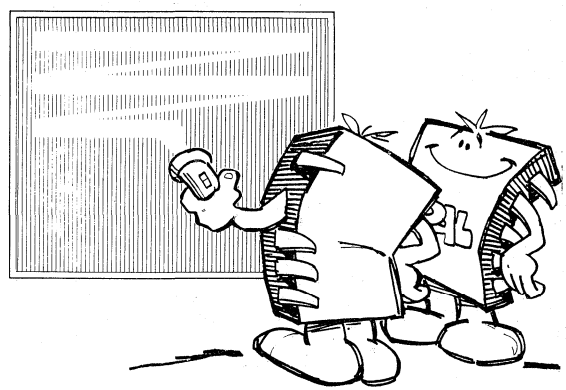

Figure 2. Horizontal Scanned Lines With the Retraces

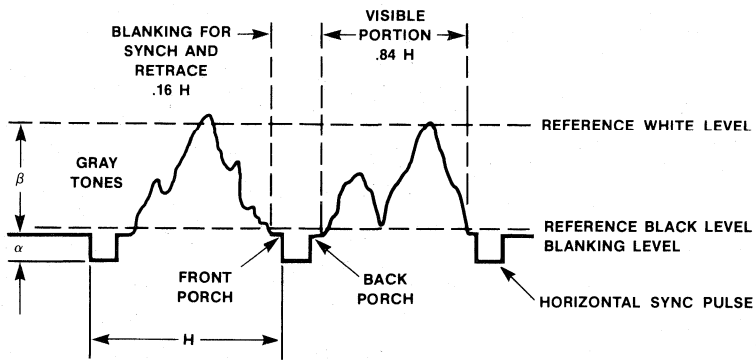

Figure 3. Composite Video Signal

$\beta = 1.0 \pm 0.05$ Volts
$\alpha = 0.4 \pm 0.05\beta$ Volts
H = Time From Start of One Line to Start of Next Line

A picture signal is defined as voltage levels which when combined with the synchronizing pulses generate **A COMPOSITE VIDEO SIGNAL**. There are two reference voltage levels; i.e., a high voltage level = white and a low voltage level = black (see Figure 3). In between these reference levels are the gray tones. The synchronizing pulses are below the black level so they do not produce light.

The horizontal and vertical pulses along with the picture signals constitute a frame where 15,750 horizontal lines are scanned every second making one complete horizontal cycle of approximately 63.5 microsceonds (commonly called 1H). Because of the front and the back porches (see Figure 3) that are used for retrace time and synchronization, the visible portion lasts approximately 54 microseconds. The time from the start of one field to the start of the next field is 262.5H or 1V.

Figure 6 illustrates the relationship between (a) the horizontal and vertical sweeps and (b) the line and the field blanking. A field blanking signal starts at Point A which is the initiation of the vertical retrace where the electron beam is at the bottom of the screen. During the vertical retrace period, the beam moves back and forth across the screen until it reaches the top of the screen (see Figure 5). The field remains blank until the beam reaches Point B. From Point B the beam is visible until it nears the right edge of the screen. At this time, horizontal blanking occurs and the beam moves from the right edge to the left edge of the screen. Horizontal blanking occurs 263 times for each field. At Point C, a new vertical retrace for the next field is initiated. At Point D, the beam finishes the scan of the entire screen for one frame. This point corresponds to Point A in the first field, so a field blanking occurs again.

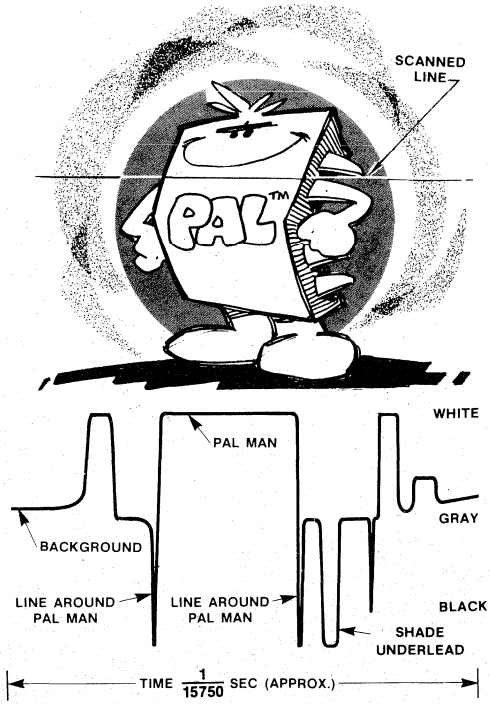

Figure 4. A Waveform of Video Voltage Produced by Scanning One Line on a Televised Screen

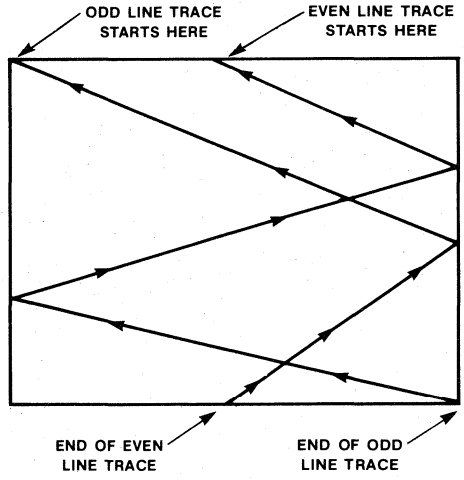

Figure 5. Vertical Retraces for the Odd and Even Fields

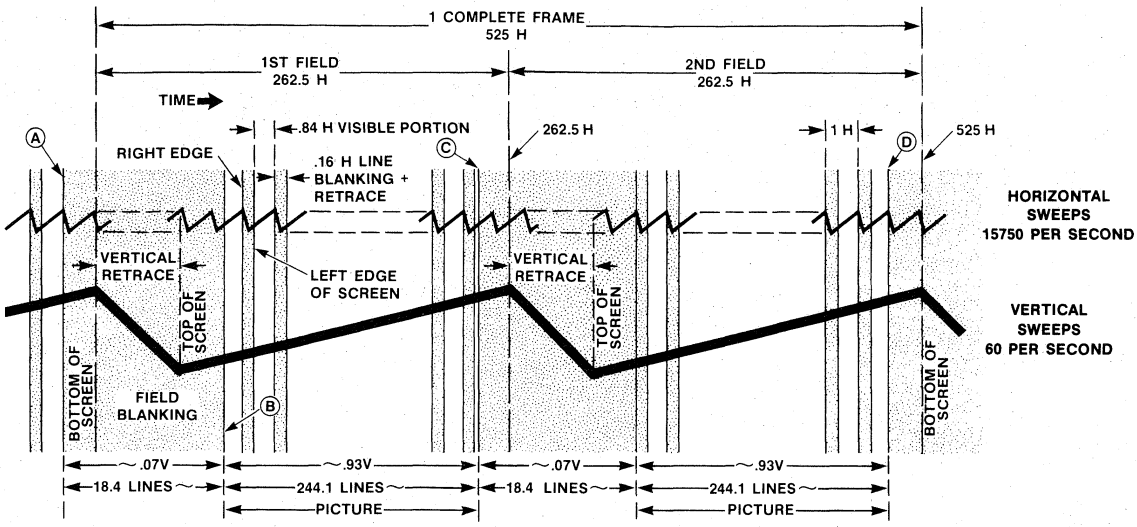

Figure 6. Vertical and Horizontal Sweeps, and Blanking Within a Frame

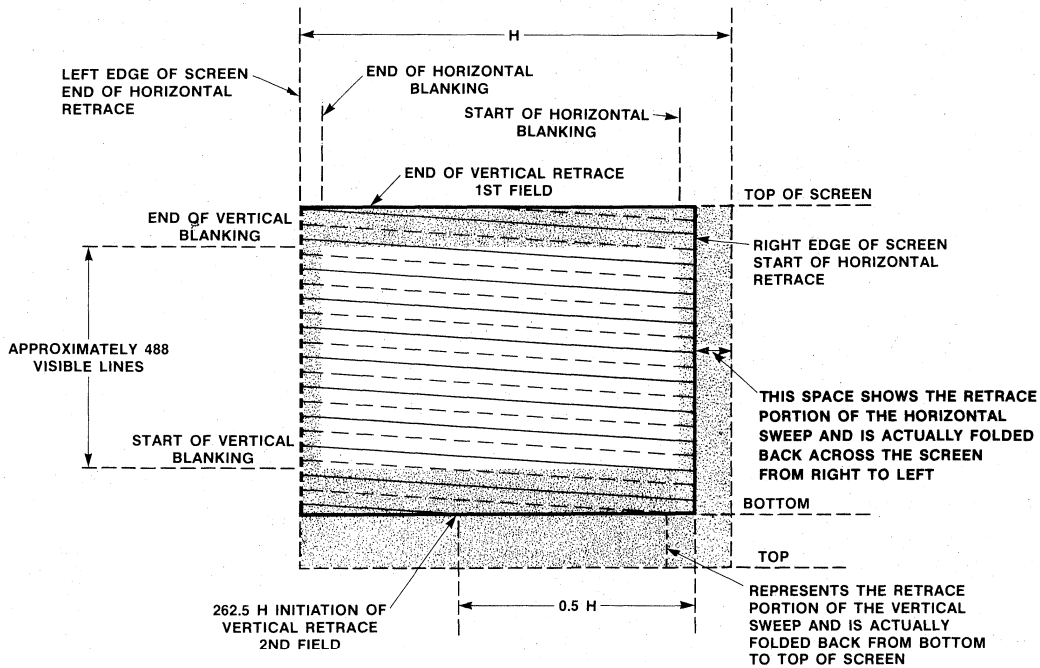

Figure 7. Effect of Vertical and Horizontal Blanking on the Screen

Figure 7 shows the actual movement of the beam and the effect of the line and the field blanking on the screen. The shaded portions at the top and bottom of the screen represent field blanking, while the shaded portion at the left and right edges of the screen represent line blanking. The combination of the shaded portions with the unshaded portions represent the available screen size, if no retracing were necessary.

From a single scan line to a complete picture which defines a frame, we have presented the concept and the process for sending information (a composite video signal) to a video receiver.

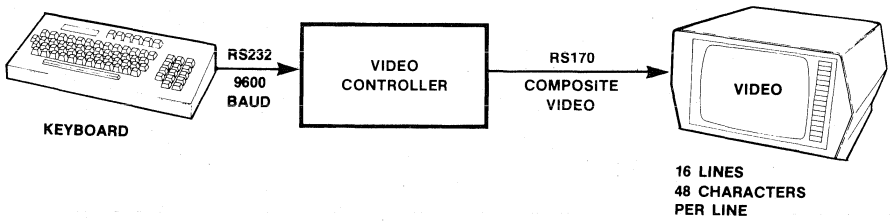

Figure 8. A Very Simplified Diagram

From the Keyboard to the Video Controller

The input to our video controller comes from a keyboard terminal or a computer. The information is transferred via an RS232 port to the video controller, one bit at a time. Each character is represented in ASCII code and is detected by the video controller only if a start signal was first issued.

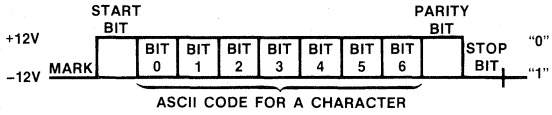

Figure 9. Each Character Consists of 10 Bits
- **1 Start Bit**
- **7 ASCII Bits**
- **1 Parity Bit**
- **1 Stop Bit**

The design is based on using 260 scan lines and an 8 MHz crystal. In order to obtain the standard horizontal period of 63.5 microseconds, each horizontal line is divided into 512 cycles giving a line period of 512/8 = 64.0 microseconds. The frequency of the electron beam is equal to the power line frequency (60 Hz) so in a clear environment (without noise) the picture is clear and steady.

$$\text{FRAME RATE} = \frac{8\ \text{MHz}}{260\ \text{scan lines} * 512\ \text{cycles per line}} = 60.09\ \text{Hz}$$

These figures and calculations are explained and diagrammed in detail in the section on implementation.

From the Video Controller to the Video Screen

Our video controller uses a **NON-INTERLACED METHOD** for scanning (see Figrue 10). In this method, the traced lines are adjacent and each frame consists of 260 scanned lines. Each field is equal to a frame which changes the definition of a field so that a complete frame is now transmitted in 1/60 of a second.

Figure 11 shows the horizontal and the vertical sweeps which cut in half the common frame frequency and now generate two frames for the same amount of time. At the end of each horizontal line, the electron beam moves rapidly from the right edge to the left edge of the screen while blanking pulses are transmitted (Points C-D in Figure 11).

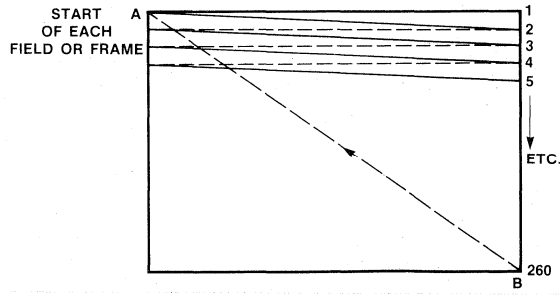

Figure 10. Non-interlaced Scanning. 260 Solid Lines Represent a Frame. The Dashed Lines are the Retrace Lines.

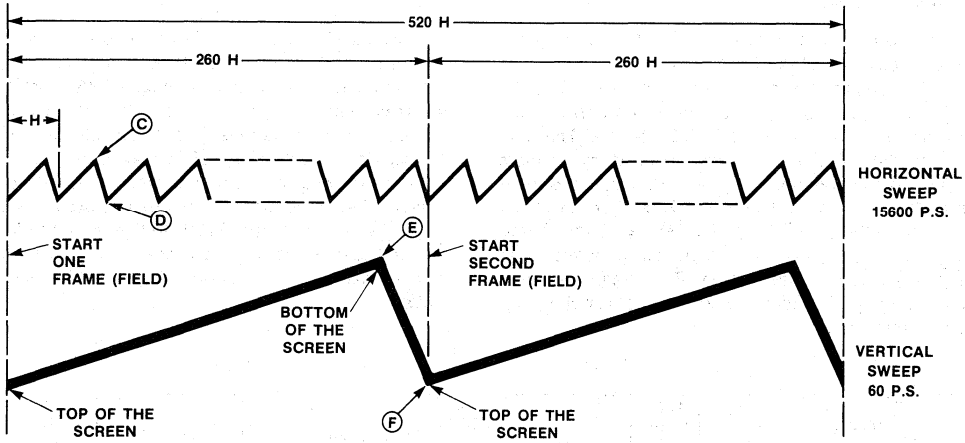

Figure 11. 520 Horizontal Lines Generate Two Fields Which Constitute Two Frames in A Non-interlaced Scanning

At the end of 260 horizontal lines, the electron beam is blanked out while it goes back from the bottom to the top of the screen (Points E-F in Figure 11).

The video controller can display a maximum of 16 visible character-lines with 48 visible characters per character-line. Each character is produced by a 5×7 character generator. A character-line on the screen consists of twelve dot-lines: seven dot-lines for the character and five blank dot-lines for space between the character-lines. Each dot in a dot-line is called a **PIXEL**.

Figure 12 shows one character-line with the characters "U, D, I" and all the pixels that built these three characters on the screen. These pixels or character elements are sent one after the other in an orderly sequence across the dot-line. Twelve dot-lines are rapidly transmitted to create one character-line. This is called **SUCCESSIVE METHOD OF TRANSMISSION** (see Figure 13).

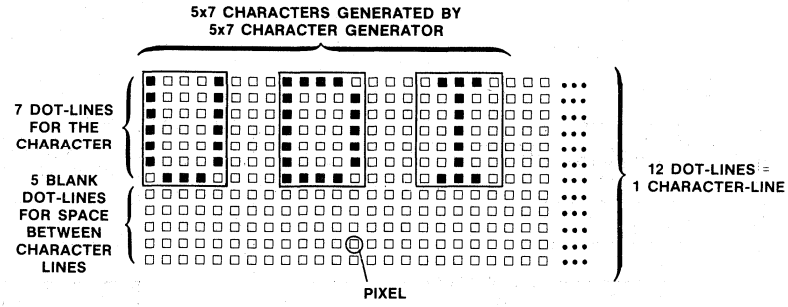

Figure 12. One Character-line With Three Characters

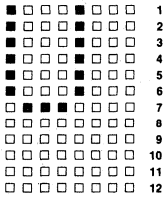

Figure 13. Successive Method of Transmission. For Simplicity Assume Only One Character 'U'. Each Dot-line is Sent in Orderly Sequence.

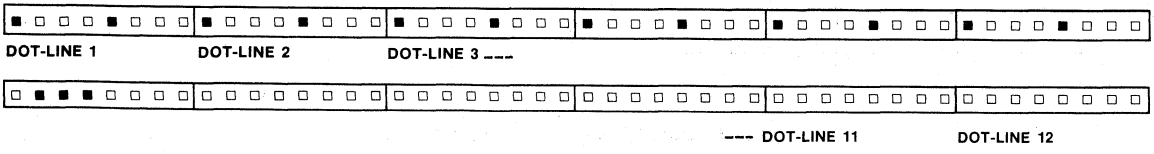

Implementation

Our video-controller board is divided into two subsystems which are connected by a RAM. The RAM is time shared by the two subsystems and provides the effect of a multi-port RAM. An 8-bit ASCII code is entered into the system through a "write only" port which is connected by the RS232 interface. The code is written into the RAM in locations indicated by pointers "SCROL" and "CURS". We don't write every cycle, but we read every cycle. The code is read from the RAM from locations indicated by pointers "LINES" and "CHAR" and transferred through a "read only" port to a character generator that generates the pixels for the screen. The "read" is done continuously so the picture looks steady. "Write" is done upon receipt of a special signal.

To build the video-controller board we used a RAM, a character generator and counters that are used as pointers/special module counters. Monolithic Memories' PALs provide an excellent replacement for TTL counters. They can be programmed to count in any desired mode. The PAL meets the requirements of the standard TTL SSI/MSI of 25 nsec propagation delay while reducing the chip count on the board. The PAL can generate non-standard functions which are not available on standard chips. By customizing the PAL to give only the functions that are needed, the user can save board space. The following is a detailed design of a video controller using Monolithic Memories PALs.

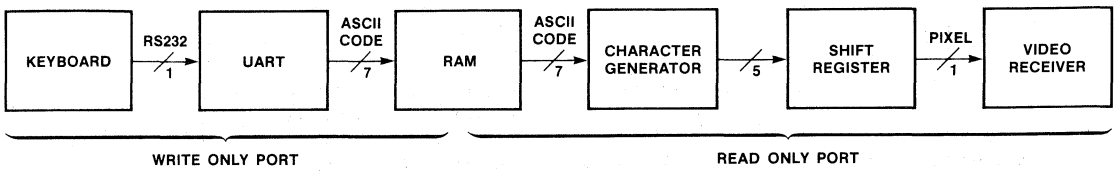

Figure 14. The RAM Divides the Board into Two Subsystems:
a) Write Only Subsystem; From the Keyboard to the RAM.
b) Read Only Subsystem; From the RAM to the Video Receiver.

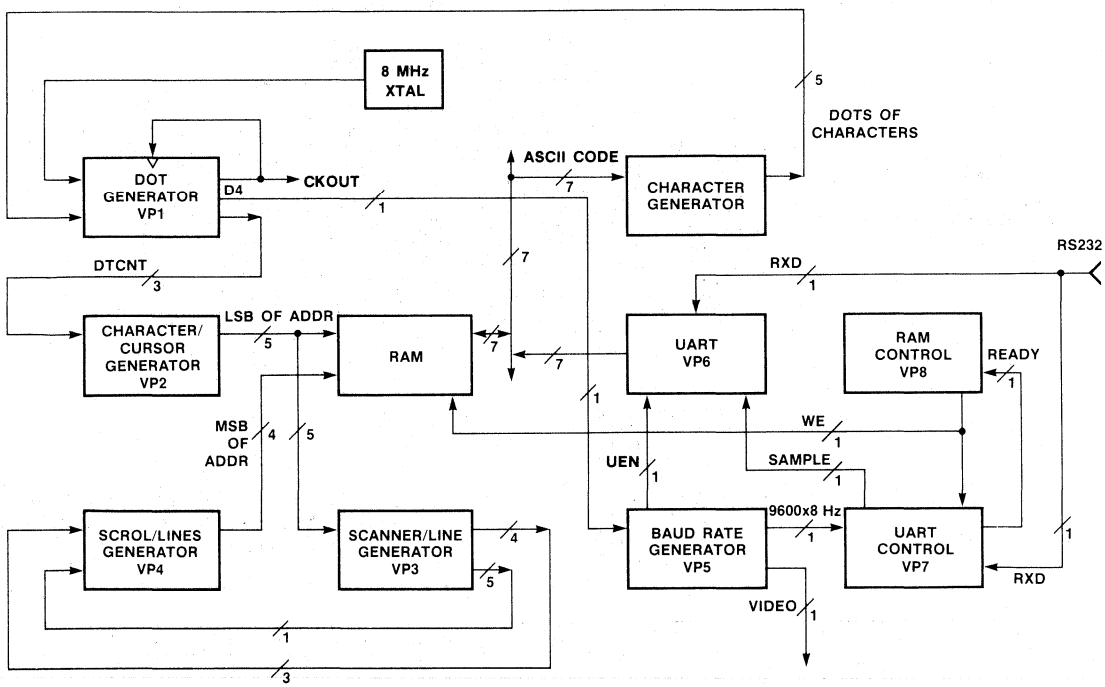

Figure 15. Block Diagram of the Video Controller

NOTES:

1. VP1 is a shift register for the dots in a dot-line of each character. "DTCNT" counts 8 dots for each character (PAL20X8).
2. VP2 generates the 5 least significant bits of the address to the RAM (PAL20X10): "CHAR", when reading from the RAM; "CURS", when writing into the RAM.
3. VP3 counts 12 dot-lines per 1 character-line and the number of lines in the whole screen (PAL20X10).
4. VP4 generates the 4 most significant bits of the address to the RAM (PAL20X10): "LINES", when reading from the RAM, "SCROL", when writing into the RAM.
5. VP5 generates the baud rate and the composite video signal (PAL20X8).
6. VP6 is a shift register. It loads the ASCII bits in serial form from the RXD line (PAL20X8).
7. VP7 generates the "SAMPLE" pulses, the "READY" signal when a code for a character is in the UART, and detects a false "START" signal (PAL20X10).
8. VP8 controls the RAM (PAL20X10).
9. Monolithic Memories' 6055 is used as a character generator.
10. Hitachi HM6116P: 2048 words x 8 bits high speed static CMOS RAM is used in our design.

Video Controller Specifications

The Video controller provides a 16 line by 48 character display for use with standard CRT monitors and televisions. The controller "listens" to standard RS232C serial data via a 25 pin DB-25 plug/socket pair inserted into any Computer/Terminal RS232C interface. The controller stores the serial data in a 2Kx8 RAM and continuously displays it on the RS170 composite video output. Eight PALs and one character generator provide the control circuitry, mounted on a 5x7 inch PCB.

lines per frame	16
characters per line	48
character format	5x7
ASCII character set	64 (upper case)
scanning method	non-interlace
scans per frame	260 (312 optional)
scans per line	12
frame period	16.64 milli seconds (19.968 optional)
scan period	64 micro seconds
character period	1 micro second
dot period	125 nano seconds
input specification	RS232C
speed	9600 Baud (4800,2400,1200 optional)
format	7 bits, mark parity, one stop bit
low level	-3 to -12 Volts
high level	+6 to +12 Volts
input impedance	30K Ohm
input connector	25 pin DB-25P/DB-25S
output specification	RS170 (composite video)
sync pulse	4 micro seconds
horizontal blanking	16 micro seconds
sync level	0.4 Volts
black level	0.8 Volts
white level	1.8 Volts
output drive	75 Ohm termination
output connector	RCA Audio Jack
power	12 Watts
input voltage	100-120 Volts AC (200-240 optional)
line frequency	50/60 Hz
card size	5x7x1 inches

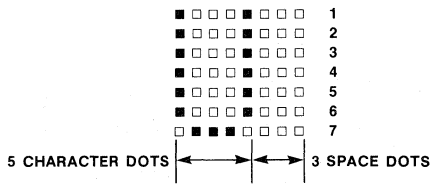
DESCRIPTION

THE DOT GENERATOR PROVIDES THE OSCILLATOR/CLOCK DRIVER, THE DOT SHIFT REGISTER AND THE 3-BIT DOT COUNTER. IT IS LOADED WITH THE 5 DOTS GENERATED BY THE CHARACTER GENERATOR. THESE DOTS ARE SHIFTED OUT THROUGH A SHIFT REGISTER, ONE DOT AT A TIME AND DISPLAYED ON THE SCREEN. "DTCNT" COUNTS UNTIL 8: 5 COUNTS FOR THE CHARACTER AND 3 COUNTS FOR SPACE BETWEEN CHARACTERS.



THE 20X8 IS A REGISTERED PAL. DATA SHOULD BE VALID AND STABLE ON THE INPUT PINS ONE CYCLE BEFORE IT APPEARS ON THE OUTPUT PINS. THE REGISTER IS TRIGGERED ON THE RISING EDGE OF THE CLOCK AND THE DATA IS AVAILABLE ON THE OUTPUT PINS DURING THE NEXT CLOCK CYCLE.

"DTCNT" CAN BE INITIALIZED, CAN COUNT AND CAN HOLD.

"HBLANK" IS A SIGNAL FOR THE END OF ONE DOT LINE (48 CHARACTERS).

"LINE4" IS SET WHEN 16 LINES ARE DISPLAYED ON THE SCREEN.

"SCAN3" IS SET WHEN 7 DOT LINES ARE DISPLAYED.

"DOT" IS A SHIFT REGISTER. IT CAN BE LOADED OR CAN SHIFT LEFT.

WHEN "LINE4" AND/OR "SCAN3" ARE SET, "DOT" SENDS BLANK DOTS TO THE SCREEN FOR GENERATING SPACES BETWEEN CHARACTER LINES AND FOR THE MARGINS OF THE SCREEN. THE OUTPUT FROM THE REGISTER TO THE SCREEN IS THROUGH "DOT4".

DESCRIPTION

"CHAR" AND "CURS" COUNT THE NUMBER OF CHARACTERS PER LINE. THEY ARE ALSO USED AS POINTERS TO THE RAM. "CURS" IS USED WHEN A CHARACTER IS WRITTEN INTO THE RAM AND "CHAR" WHEN A CHARACTER IS READ FROM THE RAM. "CURS" IS ALWAYS POINTED TO THE NEXT AVAILABLE LOCATION IN THE RAM WHERE A NEW CHARACTER CAN BE STORED.

"CHAR" IS INCREMENTED AT THE END OF 8 PIXELS MEANING IT COUNTS AFTER EACH CHARACTER. IT COUNTS FROM 0 TO 63 ALTHOUGH ONLY 48 CHARACTERS ARE VISIBLE. THE HORIZONTAL SYNC PULSE IS GIVEN BETWEEN CHARACTERS 56 AND 59. DURING THE COUNTS OF CHAR FROM 48 TO 63, BLACK SIGNALS ARE TRANSMITTED TO THE SCREEN. "CURS" IS INCREMENTED FOR ANY OPERATION ON THE KEY BOARD. THE TWO POINTERS USE THE RAM IN INTERLIVED FASHION. READ IS DONE EVERY CYCLE, BUT WRITE IS DONE ONLY WHEN A WRITE SIGNAL IS GIVEN. THE WRITE SIGNAL IS SET WHEN A NEW CHARACTER ENTERS THE SYSTEM THROUGH THE RS232 PORT.

THE FUNCTION TABLE ABOVE DESCRIBES OPERATIONS OF READ AND WRITE FOR A CERTAIN LINE. WHEN THIS LINE WAS PRINTED, 64 CHARACTERS WERE READ AND 15 CHARACTERS WERE WRITTEN.

SIGNALS CHAR0, CURS0, SWAPC, WRITE AND INCSCR ARE DERIVED IN PAL VP8.

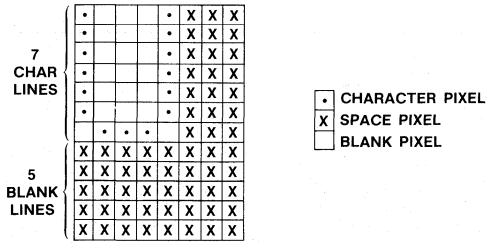
DESCRIPTION

EACH CHARACTER ON THE SCREEN CONSISTS OF 12 DOT LINES: 7 LINES FOR THE CHARACTER AND 5 LINES FOR SPACE BETWEEN CHARACTERS. THE FOLLOWING FIGURE SHOWS THE LETTER "U" AND THE SPACE WITH ALL THE PIXELS AROUND IT AS IT IS DISPLAYED BY THE VIDEO CONTROLLER.

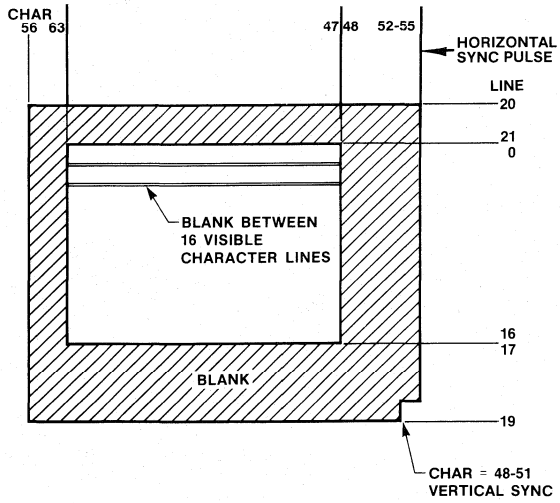


"SCAN" IS A MODULE 12 COUNTER THAT COUNTS THE NUMBER OF THE DOT LINES FOR EACH CHARACTER.

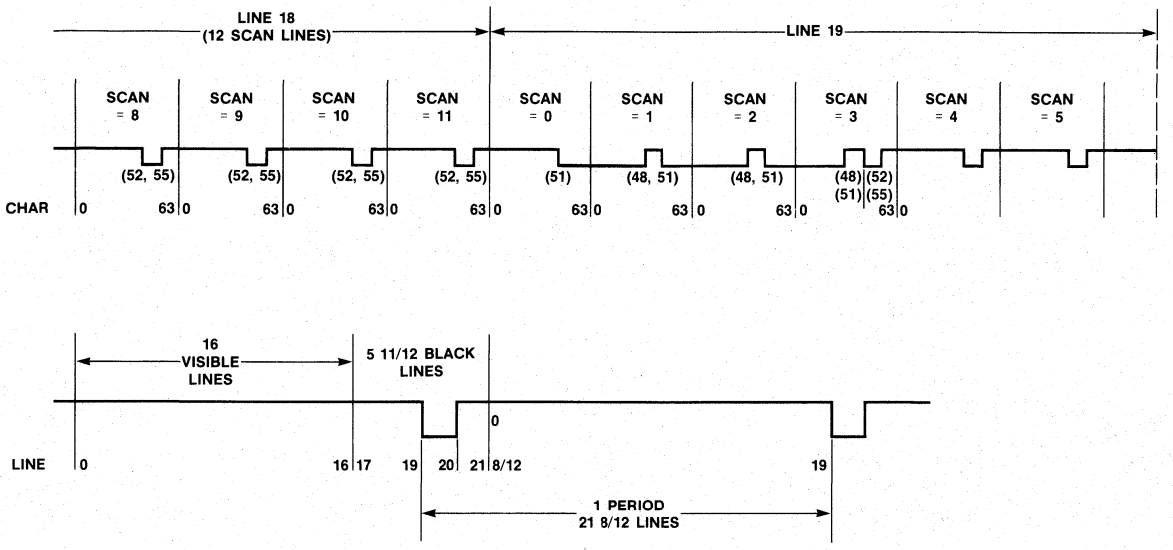
"LINE" COUNTS THE NUMBER OF THE CHARACTER LINES. EACH CHARACTER LINE IS 12 SCAN LINES. THE COUNTER COUNTS UNTIL 21 ALTHOUGH ONLY 16 LINES ARE VISIBLE ON THE SCREEN.

THE HORIZONTAL SYNC PULSES ARE GIVEN IN EVERY SCANNED LINE BETWEEN CHAR 52 AND 55. THE VERTICAL SYNC PULSE IS GIVEN WHEN THE LINE COUNT IS 19, SCAN IS BETWEEN 0 AND 3, AND CHAR IS BETWEEN 48 AND 51.

THE NEXT FIGURE SHOWS THE SCREEN WITH THE CORRESPONDING LINE AND CHAR COUNTERS, AND THE SYNC PULSES.

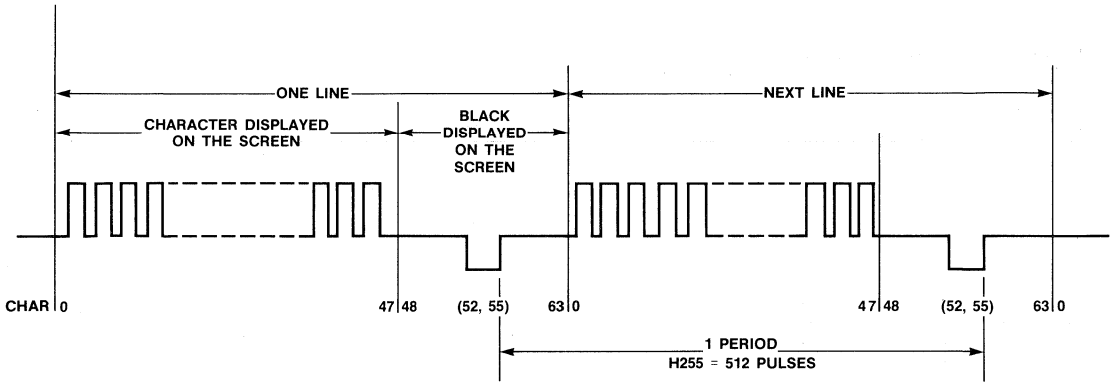


Vertical Sync



12 dot-lines generate one-character line. The total number of scanned lines is 260 or 21 8/12 character-lines. Out of the 21 8/12 character lines only 16 lines are visible. The vertical sync pulse is asserted during Line 19.

Horizontal Sync



One character is represented in 8 pulses. Then the 512 pulses cause "CHAR" to count from 0 to 63. Out of the 64 characters only 48 characters are visible on the screen. The horizontal sync pulse is asserted during "CHAR" position 52 through and including "CHAR" 55.

DESCRIPTION

"SCROL" AND "LINES" ARE COUNTERS AND POINTERS TO THE RAM. "LINES" IS A POINTER TO THE LINE THAT IS READ FROM THE RAM. "SCROL" IS A POINTER TO THE LOCATION IN THE RAM WHERE A NEW LINE CAN BE STORED. BOTH OF THEM COUNT UP TO A MAXIMUM OF 16 LINES.

THE BIT "SWAP" ENABLES THE TWO COUNTERS TO TALK TO THE SAME ADDRESS LINES OF THE RAM.

THE NEXT FIGURE SHOWS ALL THE POINTERS THAT HAVE BEEN DESCRIBED.

"W" MEANS WRITING INTO THE RAM, "R" MEANS READING FROM THE RAM AND "C" IS A TEMPORARY POINTER.

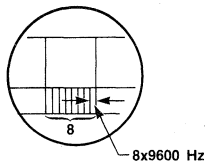
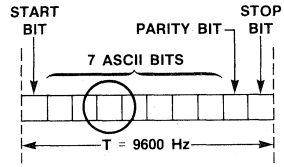
DESCRIPTION

THIS PAL GENERATES THE BAUD RATE, THE VIDEO AND THE SYNC SIGNALS WHICH ARE COMBINED AT THE OUTPUTS TO FORM THE COMPOSITE VIDEO SIGNAL, AND THE "UEN" SIGNAL WHICH ENABLE THE "UART".

EVERY CHARACTER CONSISTS OF 10 BITS: 1 START BIT, 7 ASCII CODE BITS, 1 PARITY BIT, AND 1 STOP BIT. THE CHARACTER RATE IS 9600 Hz. EACH BIT IS DIVIDED INTO 8 SMALL BITS SO THE NUMBER OF BITS PER SECOND REQUIRED FOR OUR SYSTEM IS 9600*8 = 76800 OR 76800 Hz.

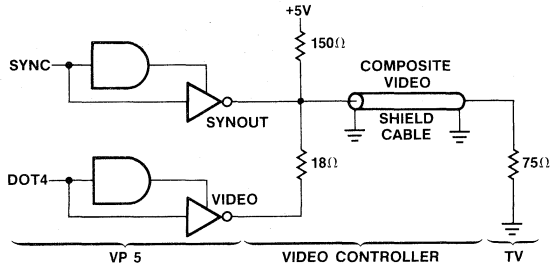




T = 1/76800 = 13 MICROSECOND
THE CLOCK FREQUENCY IS 8000000 Hz.
WE NEED TO DIVIDE THE CLOCK FREQUENCY BY 104 TO GENERATE A FREQUENCY OF 76800 Hz.

8000000/76800 = 104 = 13*8

"DTCNT" COUNTS 8, AND "BAUD" COUNTS 13. TO GET 104 COUNTS WE NEED TO COUNT FROM 0 TO 103. BECAUSE THERE IS ONE CLOCK CYCLE DELAY UNTIL THE DATA IS AVAILABLE ON THE OUTPUT PINS (REGISTERED PAL), MODULE 104 IS DETECTED BY COUNT 102 WHICH IS EQUAL TO 102/8 = 12 6/8.



$\frac{18}{150 + 18} * 4.6 = 0.49V$

$\frac{75}{150 + 75} * 5 = 1.66V$

When SYNC = H the output is at 0.4V.

DESCRIPTION

THE "UART" SHIFT REGISTER IS A SEVEN BIT REGISTER FOR THE SEVEN BIT ASCII CODE. THE INFORMATION ENTERS THE SHIFT REGISTER IN D6, ONE BIT AT A TIME. IT COMES THROUGH RXD PIN WHICH IS THE TRANSMIT OR THE RECEIVE LINE OF THE RS232. THE OUTPUTS ARE TRANSFERED IN PARALLEL TO THE RAM. "UEN" ENABLES THE THREE STATE FOR THESE OUTPUTS. WHEN BITS D6 AND D5 TOGETHER IN THE ASCII CODE ARE ZEROES OR WHEN THE "CLRLIN" BIT IS SET, A "SPACE" CODE IS SHIFTED INTO THE "UART" REGISTER. THE SPACE CODE PRINTS A BLANK SPACE ON THE SCREEN. "SPACE" IN ASCII CODE IS 0100000 = 20 HEX.

ASCII Code System and Character Set

D6, D5 — CONTROL CHARACTERS ARE DETECTED WHEN D6, D5 = 0,0

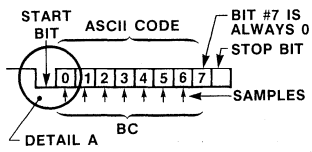
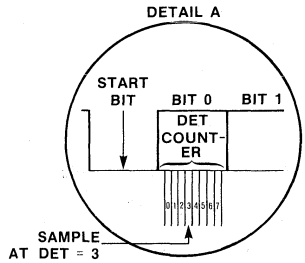
DESCRIPTION





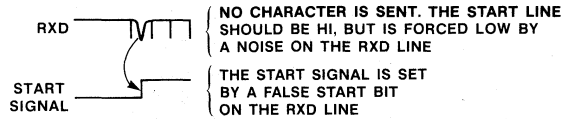
"BC" IS A COUNTER FOR THE ASCII CODE BITS. A SAMPLE FROM EACH ASCII BIT IS TAKEN WHEN "DET" = 3.

THE "START" SIGNAL IS SET WHEN A START BIT IS DETECTED ON THE RXD LINE AND REMAINS SET UNTIL THE LAST ASCII BIT OF THE CHARACTER THAT IS SAMPLED. AFTER ALL THE 7 BITS OF THE ASCII CODE WERE SAMPLED, A WRITE SIGNAL IS SENT TO THE RAM AND THE 7 BITS (A CODE FOR A CHARACTER) ARE WRITTEN IN PARALLEL INTO THE RAM.

WHEN "BC" COUNTS 8 THE "READY" SIGNAL GOES HIGH, "START" GOES LOW AND READY TO BE SET AGAIN IF A NEW START BIT IS DETECTED. A NEW CODE FOR A NEW CHARACTER WILL START TO BE SAMPLED.

BUT

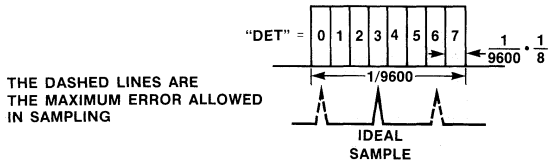
ASSUME THAT A NOISE OCCURS ON THE RXD LINE WHICH SET THE "START" SIGNAL.



TO DETERMINE IF THIS IS A TRUE OR FALSE START, WE CHECK THE RXD LINE. IF THE RXD LINE IS NOT SET, WE KNOW THAT NO CHARACTER WAS SENT ON THE RS232 LINE; THEREFORE, A NOISE/FALSE SIGNAL WAS DETECTED.

ERROR ANALYSIS FOR SAMPLING
==========

SINCE BOTH A TRANSMITTER AND A RECEIVER ARE USED IN OBTAINING INFORMATION,
AN ERROR CAN OCCUR THAT INVOLVES BOTH OF THESE COMPONENTS.
ASSUME: ERROR IN TRANSMITTING FREQUENCY = EX
ERROR IN RECEIVING FREQUENCY = ER
THEN THE TOTAL ERROR FOR ONE BIT OF INFORMATION IS (EX + ER).
AND THE TOTAL ERROR FOR THE N'TH BIT OF INFORMATION IS N*(EX + ER).
WHEN COUNTER "DET" IS EQUAL 3, WE HAVE THE IDEAL BIT FOR SAMPLING.
THE MAXIMUM ERROR THAT IS ALLOWED DUE TO THE TOLERANCES IN THE FREQUENCIES
IN BOTH TRANSMITTER AND RECEIVER, WILL BE WHEN THE SAMPLE IS TAKEN AT
"DET" = 0 OR AT "DET" = 6, AS SHOWN HERE:



THE FREQUENCY FOR EACH BIT OF INFORMATION IS 1/9600 Hz (104 MICROSECOND).
EACH BIT OF INFORMATION IS DIVIDED INTO EIGHT TIME SLOTS.

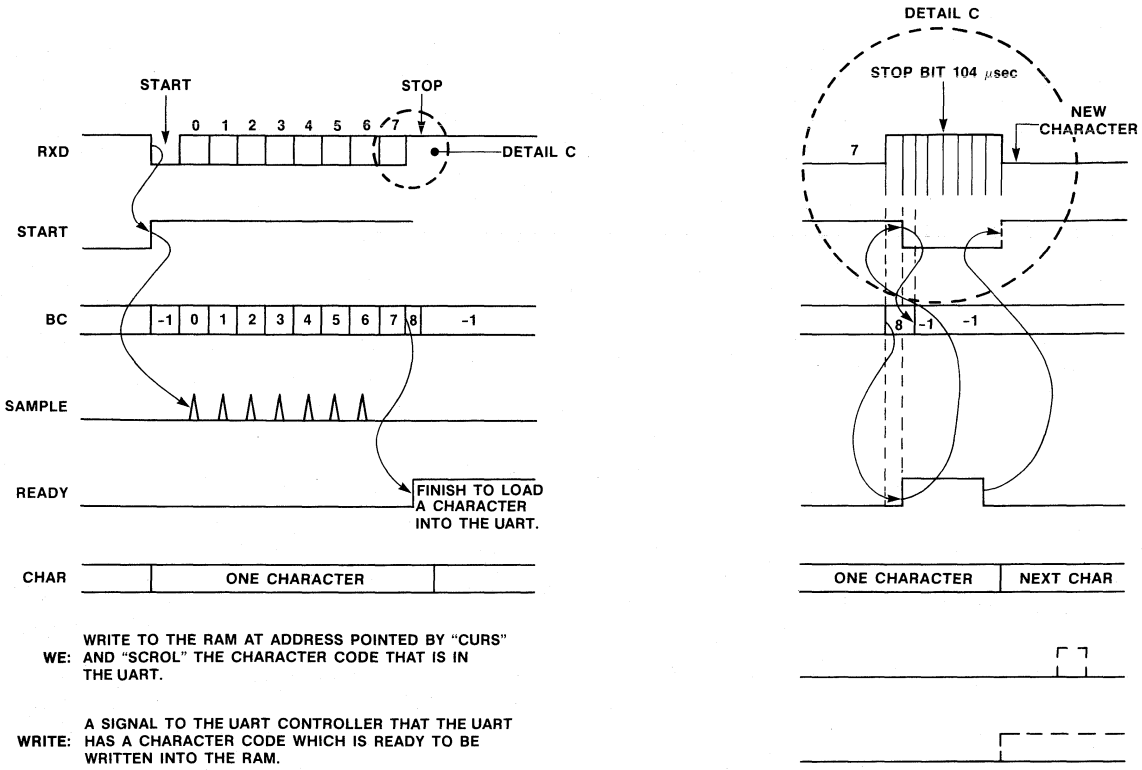
THE TOTAL ERROR ALLOWED FOR THE 7'TH BIT OF INFORMATION IS:

7 * (EX + ER) = (1/9600) * (3/8)

THE TOTAL ERROR ALLOWED FOR ONE BIT OF INFORMATION IS:

(EX + ER) = 104 * (3/8) * (1/7) = 5.5 MICROSECOND

THE FREQUENCY RATE BETWEEN RS232 AND THE RXD LINE FOR EVERY BIT OF
INFORMATION SHOULD BE BETWEEN 10150 Hz AND 9130 Hz.



Timing diagram for detecting a character and writing it into the RAM. Signals "WRITE" and "WE" are explained and derived in the next PAL specification VP8.

DESCRIPTION

THIS PAL CONTROLS BOTH THE TIMING FOR WRITING A CHARACTER INTO THE RAM AND THE TIMING FOR READING A CHARACTER FROM THE RAM.

"WRITE" IS A SIGNAL THAT DATA IS AVAILABLE AND CAN BE WRITTEN INTO THE RAM WHEN "DTCNT" IS BETWEEN 0 AND 5.

"SWAP" AND "SWAPC" SWAP POINTERS TO ENABLE WRITING AND READING BY ADDRESSING THE RAM THROUGH THE SAME ADDRESS LINES.

"UEN" ENABLES THE UART.

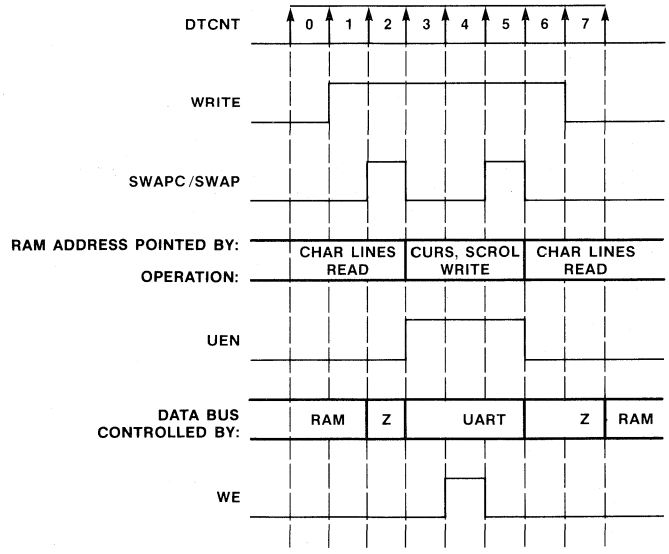
"WE" WRITES TO THE RAM THE DATA THAT IS IN THE UART REGISTER.

"INCSCR" IS A SIGNAL THAT DETECT LINEFEED AND 48 CHARACTERS PER LINE.

"CLRLIN" ERASES EARLIER INFORMATION AND ALLOWS TO WRITE TO THAT LOCATION. WHEN THE "LF" KEY IS PUSHED, THE CLRLIN SIGNAL IS SET. IT REMAINS SET AS LONG AS A WRITE IS DONE TO THIS LOCATION.

"H255" DETECTS END OF LINE.

"HBLANK" BLANK OUT THE SCREEN WHEN "CHAR" IS BETWEEN 48 AND 63.



WRITE and READ signals to the RAM for one character code (when CHAR = 63). (Z = THREE STATE)

Summary

This paper conveys the message that a video-controller board can be designed in an efficient way by using PALs. The above video controller was developed and is used by Monolithic Memories, Inc.

We have presented the basic vocabulary and processes that are presently common to the industry with an explanation of how we developed our video-controller board.

Boolean transfer function equations, function tables, descriptions, simulations and fuse-plots are all offered within our PAL specifications. These were developed on the company in-house computer and are available from Monolithic Memories.

SINGLE-CHIP CONTROLLER INCREASES MICROPROCESSOR THROUGHPUT

Design technique uses semicustom logic to minimize hardware in a DMA controller that combines fast response with the potential to service multiple input or output devices and the flexibility to handle many different applications

Alan W. Bentley

Cubic Corporation
9333 Balboa Ave, San Diego, CA 92123

Microprocessors have a broad range of capabilities; yet they are unable to perform specific functions efficiently without hardware augmentation. One such function is transfer of blocks of data to or from processor controlled memory. Under specific conditions, such blocks may be moved efficiently by direct memory access. Data must be sequentially ordered, a starting address must be specified for both the processor associated memory and the external source or destination, and the data block length must be specified. When these three conditions are met, data transfer responsibility passes to a hardware controller, and data moves rapidly because instruction processing is eliminated during the transfer.

Although direct memory access (DMA) efficiently transfers blocks of data between a source and a destination, it normally interfaces memory with only a single external device and is unable to move data between memory and a distributed network. The need to interface a microprocessor with a network of distributed devices led to a generalized concept that can be structured to transfer data rapidly in either direction.

This concept is analogous to the DMA function in that blocks of sequential data are transferred to or from memory. It differs in that, externally, each data word has an associated device location. Implementing the transfer function in terms of this concept increases the data transfer rate while imposing four constraints on the system: the data block length must be constant; data must occupy sequential memory locations; the distributed devices are always serviced in the same sequence; and each implementation is committed to either input or output.

Controller Design Objectives

Conceptually, the controller accepts data transfer responsibility from the microprocessor upon command; steps through the data block, sequentially creating data paths between memory and various external devices; then returns control to the microprocessor. Functionally, upon receipt of the transfer mode command, the controller places the central processing unit (CPU) in the 3-state mode, generates all

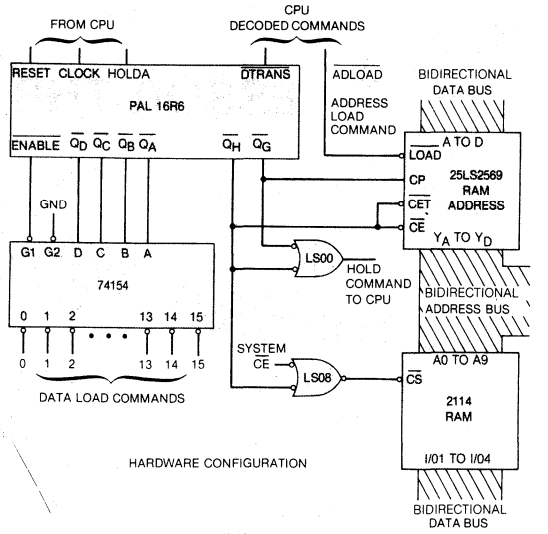
RAM TIMING REQUIREMENTS



HARDWARE CONFIGURATION

GENERAL

1. CPU HOLD COMMAND IS $Q_G + Q_H$ (STATE 1, 2, OR 3)
2. STATE 2 IS ENTERED UPON RECEIPT OF HOLDA (CPU IN HOLD, CPU ADDRESS AND DATA BUSES 3-STATE)
3. IN STATES 2 AND 3 RAM ADDRESS COUNTER OUTPUT IS REMOVED FROM 3-STATE MODE AND ITS COUNT CAPABILITY ENABLED THROUGH $\overline{CET}$
4. AT TRANSITION FROM STATE 3 TO STATE 2, BOTH DATA COUNTER AND RAM COUNTER ADDRESS ARE DECREMENTED BY RISING EDGE OF Q_G
5. UPON COMPLETION OF DATA TRANSFER (END), STATE 0 IS ENTERED FROM STATE 3. DATA COUNTER IS SET AT ITS INITIAL COUNT, ADDRESS COUNTER IS PLACED IN 3-STATE MODE, AND HOLD COMMAND TO CPU IS RELEASED

SPECIFIC (TRANSFER CPU MEMORY TO EXTERNAL DEVICES)

1. RAM IS SELECTED IN STATES 2 AND 3, $\overline{Q_H}$
2. IN STATE 3, ENABLE SELECTS DEMULTIPLEXER, AND CONTENTS OF DATA COUNTER (Q_A THROUGH Q_D) ARE DECODED TO GENERATE DATA LOAD (WRITE ENABLE) PULSE

SEQUENCE OF EVENTS

Fig 1 Transfer from CPU memory to device. PAL implements two categories of Boolean expressions, data counters that control destination selection and state equations that control sequence of events shown in state diagram

required timing and control signals, sequentially creates the data paths, and transfers data through each path. Upon completion of the data transfer, it relinquishes control to the microprocessor, which then resumes instruction processing.

Increased throughput is the implementation rationale; therefore, the two primary design objectives are to enter and leave the data transfer mode in a minimum number of clock periods and to transfer one data word every two clock periods. This transfer rate allows one clock period to establish each data path, with the write pulse created in the second period to complete the transfer. Secondary design objectives relate to implementation and allow modification to meet varying applications using a minimal amount of additional circuitry.

Design approaches that meet these objectives include use of a state sequencer to meet the control transfer and data transmission timing requirements, and use of fusible link, semicustom logic to meet the circuit flexibility and minimization requirements. A simplified microprocessor interface is achieved by incorporating the microprocessor clock and hold capabilities into the sequencer design.

State Sequencer

The state sequencer organizes and concentrates logical functions to realize the high density capabilities of semicustom logic. What determines the number of control flipflops is the number of required states; therefore,

SEQUENCE OF EVENTS

Fig 2 Transfer from device to CPU memory. Similar to Fig 1, with hardware configuration and state diagram modified to transfer data in opposite direction

performing all logic functions in four states reduces the sequencer design requirement to two flipflops and helps meet the secondary design objective. These four states are idle, when the CPU has system control; transitional, while the CPU is entering the hold mode and relinquishing control; and two data transfer, one permitting address and data stabilization, and the other creating the write command (Figs 1 and 2).

In this application, both flipflops are reset in the idle state ($\overline{Q}_H$,$\overline{Q}_G$, state 0) awaiting a software generated command ($\overline{DTRANS}$), which sets the G flipflop, advances the sequencer to state 1 ($\overline{Q}_H$,$\overline{Q}_G$), and initiates a CPU hold command, sustained until the sequencer returns to state 0. The CPU tests its hold command input each machine cycle and, upon sensing a command, enters the hold state, placing its data bus, address bus, and some control lines in the 3-state mode. It remains in this state until the hold command is released by the sequencer.

When it enters the hold state, the CPU issues a hold acknowledge (HOLD). Upon receipt of HOLDA, the

sequencer advances to state 2 (Q_H,$\overline{Q}_G$), which completes transfer of the data handling function from the CPU to the controller. It then toggles between state 2 and state 3 (Q_H,Q_G), processing one data word each cycle until the preestablished number of data words have been transferred (END). Then, the sequencer returns to state 0 and releases the hold command, allowing resumption of instruction processing by the CPU.

While the sequence of states is the same for data transfer in either direction, the events that occur within states 2 and 3 differ. During transfer of data from memory to external devices, state 2 is memory access time and state 3 generates the load command for the specific device. When leaving state 3, the edge of the G flipflop ($\overline{Q}_G$) advances the memory address counter. When data from external devices are read into memory, state 2 time is used to select the external source and stabilize the data. The memory write enable pulse is generated by state 3, and leaving state 3 changes the memory address counter. Transfer states ST2 and ST3 are identified by the output of the H flipflop, which activates the random access memory (RAM) address counter outputs, enables address counting, and, additionally, selects either the RAM or the multiplexer when transferring to or from the external devices, respectively.

Programmed Array Logic

Utilizing semicustom integrated circuitry satisfies the requirement for logic minimization and design flexibility. This approach increases logic density by mitigating two factors that increase random logic package count: function partitioning and pin limitation. To maximize these benefits, the programmable logic chip must contain AND, OR, and flipflop functions, as well as internal feedback. Flipflop functions are required to implement the sequencer and, additionally, a counter that is decremented at the completion of each data transfer (state 3 to state 2 transition). The counter serves a dual purpose: the demultiplexed count selects external devices and, by monitoring the count, the controller determines completion of the data block transfer (END).

Data block length determines the number of counters and demultiplexers required. With three counters and a 3 to 8 demultiplexer (74138), block lengths up to eight may be accommodated. With four counters and a 4 to 16 demultiplexer (74157), the block length may be extended to 16. An increase to six counters will allow block length expansion to 64, with additional demultiplexers. This approach focuses on design for a block length of 16 words so that the flipflops and associated input decoding can be contained on one fusible link, programmable array logic (PAL) integrated circuit.

PAL 16R6 contains six D flipflops (registers) connected to a common clock input. Output Q of each register is available externally through an inverting, 3-state buffer ($\overline{Q}$). Input D of each register is an 8-input OR gate, each input a programmable AND combination of the available terms. Each gate array must be true to set the register on the following clock pulse or false to allow the register to reset. Thus, Boolean expressions state the conditions that cause the registers to become or remain set.

Two additional, non-register, AND-OR gate outputs and the six register outputs have internal feedback paths. With the eight available inputs, they become the 16 terms available when implementing Boolean expressions.

Boolean Expressions

Six counter equations are shown in Fig 3. For a maximum block length of 16, the four least significant counts (A through D) are required; expansion up to length 32 requires equation E; equation F must be implemented for block lengths between 33 and 64. The counter flipflops are held set during states 0 and 1. States 2 and 3 require only one clock period each; hence, from leaving state 1 until completion of data transmission and return to state 0, there is a state transition in every clock cycle.

During this interval, each equation must establish the condition of its counter flipflop for the following state. When entering state 2 from state 1, the counter flipflops are set as established by state 1. Since it is necessary to change the counter on the transition from state 3 to state 2, the counting decision must be made during state 3, and the new count must be established when entering state 2. The counter register content must be maintained during state 2 to prevent change at the transition from state 2 to 3.

Fig 3 also shows the 2-state sequencer equations. Equation G is independent of block length, and equation H

$$Q_F = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_F + Q_H \cdot Q_G (Q_F \cdot Q_E + Q_F \cdot Q_D + Q_F \cdot Q_C + Q_F \cdot Q_B + Q_F \cdot Q_A)$$

$$Q_E = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_E + Q_H \cdot Q_G (Q_E \cdot Q_D + Q_E \cdot Q_C + Q_E \cdot Q_B + Q_E \cdot Q_A + \overline{Q_E} \cdot \overline{Q_D} \cdot \overline{Q_C} \cdot \overline{Q_B} \cdot \overline{Q_A})$$

$$Q_D = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_D + Q_H \cdot Q_G (Q_D \cdot Q_C + Q_D \cdot Q_B + Q_D \cdot Q_A + \overline{Q_D} \cdot \overline{Q_C} \cdot \overline{Q_B} \cdot \overline{Q_A})$$

$$Q_C = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_C + Q_H \cdot Q_G (Q_C \cdot Q_B + Q_C \cdot Q_A + \overline{Q_C} \cdot \overline{Q_B} \cdot \overline{Q_A})$$

$$Q_B = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_B + Q_H \cdot Q_G (Q_B \cdot Q_A + \overline{Q_B} \cdot \overline{Q_A})$$

$$Q_A = \overline{Q_H} + Q_H \cdot \overline{Q_G} \cdot Q_A + Q_H \cdot Q_G \cdot \overline{Q_A}$$

$$Q_G = \overline{\text{RESET}} (\overline{Q_H} \cdot \overline{Q_G} \cdot \overline{\text{DTRANS}} + \overline{Q_H} \cdot Q_G \cdot \overline{\text{HOLDA}} + Q_H \cdot \overline{Q_G})$$

$$Q_H = \overline{\text{RESET}} [\overline{Q_H} \cdot Q_G \cdot \text{HOLDA} + Q_H \cdot \overline{Q_G} + Q_H \cdot Q_G (\overline{\text{END}})]$$

Fig 3 Boolean statements. PAL registers implement data counter and state controller equations. Control equation G is independent of block length. Control equation H must be expanded by expression for $\overline{\text{END}}$ to establish block length

incorporates the block length ($\overline{END}$) decoding. The table, Block Length Control, shows the expressions for $\overline{END}$, when six counters are used, organized by remainder of a modulo 16 number. For shorter block lengths, references to unimplemented counters are ignored. Both control flipflops are reset (expressions false) when the computer issues a RESET command, establishing state 0. This state is maintained until the CPU issues $\overline{DTRANS}$, advancing the sequencer to state 1 by setting G.

A hold command is generated by the sequencer, which waits in state 1 until the CPU responds with HOLDA, verifying that it has stopped instruction processing and that its buses are 3-stated. HOLDA resets G and sets H, advancing the sequencer to state 2. The G flipflop then toggles, causing the sequencer to cycle between states 2 and 3. H remains set during both states but tests the content of the data counter during state 3 to determine if data transmission is complete ($\overline{END}$ expression false). $\overline{END}$ false also causes the H flipflop to reset at the completion of state 3, returning the sequencer to state 0 and releasing the hold command to the CPU.

Block Length Control*

*Required to complete equation H in Fig 3, $\overline{END}$ expressions are listed by modulo 16 remainder of data word count. Counter F is not required for block sizes less than 33. Counter E is not required for block sizes less than 17. Single word transmission is a trivial solution

Implementation

System parameters were developed for use with the model 8085 microprocessor, the 2114 bidirectional RAM, and the 25LS2569 binary up/down counter. Attributes of these components that help meet the design goals are (a) availability of the CPU interface signals reset, clock out, hold, and hold

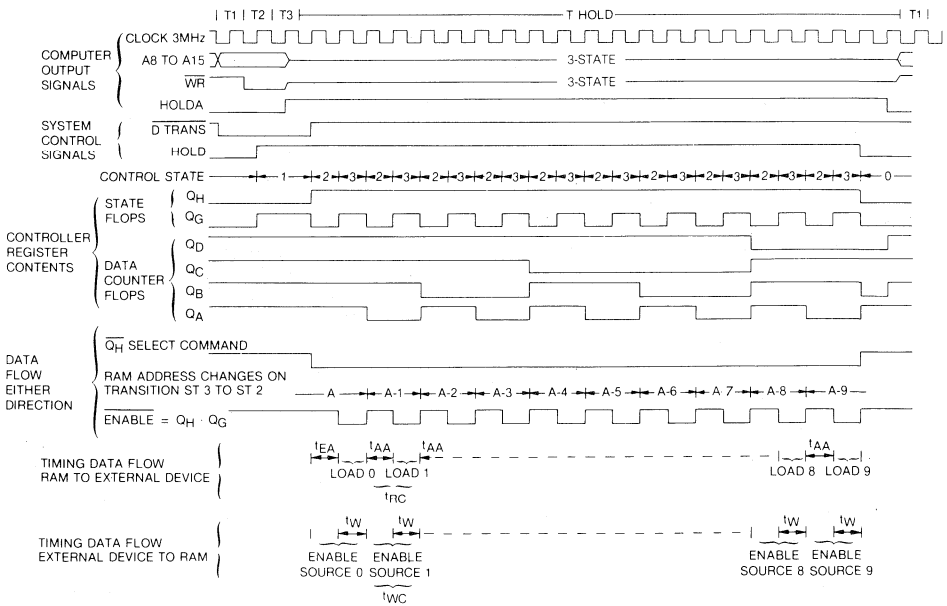

Fig 4 8085 timing and interface signals. Register contents reflect state controller interaction with computer commands. Control states reflect state flipflop outputs. Signals common to transfer in either direction are grouped. Current RAM address starts at A and decreases during successive cycles. Memory timing, shown for data flow both from and to RAM, relates to RAM timing requirements for Fig 1 and Fig 2, respectively

acknowledge; (b) the RAM's high density, 4-bit data word, bidirectional data bus, and simplified dual control line interface; and (c) the counter synchronized load, increment, and decrement controls, and also its 3-state output and cascading capabilities. Additionally, the response and operating speeds of the RAM and counter are compatible with the microprocessor clock.

Figs 1, 2, and 4 show the configuration and timing relationships achieved by using these components. Microprocessor choice establishes the system clock rate and the method of passing control between the microprocessor and the data controller. The method of implementing the data controller, which meets the dual requirements of simplicity and high throughput, restricts RAM selection. In Figs 1 and 2, t_{RC} and t_{WC} cannot exceed two clock periods. When moving data to external devices, the devices must be able to function within the constraints of t_{AA} and t_{EA}. When moving data to the CPU memory, its write requirements, t_W and t_{DW}, must be less than one clock period. Because of the controller structure, t_{DH} and t_{WR} must both be zero, a restriction satisfied by many RAMs currently available.

Adaptation

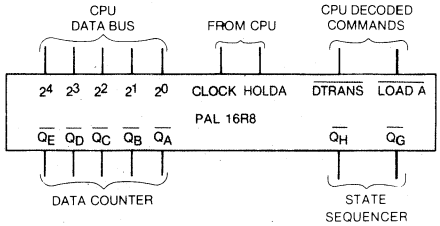
Distributed data port servicing is the primary functional requirement of the data controller, and the specific number of ports is a parameter written into the Boolean expressions implemented by a member of the PAL family. The inherent flexibility arising from implementation of many of the logic functions by easily modified Boolean expressions can be demonstrated by extending the application requirements to include program control of the data block length. Now, the design objectives are to incorporate this feature with minimal hardware reconfiguration and to retain all the operational attributes of the original DMA controller.

Although the state sequencer remains conceptually unchanged, its interaction with the data counter must be modified to implement a variable block length. The original concept has a fixed data block length, with the data counter starting at all 1s and decrementing to a predetermined end count. Its advantages are that the CPU interface is minimized and that all data ports are serviced during each DMA cycle. To implement the variable block length feature, the CPU loads the data counter with the actual count; then during data transfer, the state sequencer decrements the count to 0, the end count that terminates the operation.

It is desirable to implement the state sequencer and data counter on a single programmable chip while maximizing the data counter length. To achieve this, a 16R8 programmable logic chip replaces the 16R6 used previously. This change increases the number of registers by two at the expense of the two gated outputs. The chip configuration now offers eight data inputs; eight D registers, each with an inverting output; a register clock input; and a 3-state control input.

Of the eight registers, two are required for the state sequencer, allowing a maximum block length of 64 in a single-chip implementation. However, three control lines are required: $\overline{\text{HOLDA}}$ and $\overline{\text{DTRANS}}$, as in the original concept, plus a software generated $\overline{\text{LOADA}}$, which transfers the content of the data bus to the data registers. Additionally, the $\overline{\text{LOADA}}$ command must be used to initialize the state counter (Fig 5). With this approach, five inputs remain for the data bus, limiting the block size to 32 words.

An alternative configuration using only three data bits allows loading of the six flipflops in two instruction cycles



DATA COUNTERS

$Q_E = \overline{\text{LOAD A}} \cdot 2^4 + Q_E(\overline{Q_H} + Q_H \cdot \overline{Q_G}) + Q_H \cdot Q_G \cdot Q_E(Q_D + Q_C + Q_B + Q_A)$

$Q_D = \overline{\text{LOAD A}} \cdot 2^3 + Q_D(\overline{Q_H} + Q_H \cdot \overline{Q_G}) + Q_H \cdot Q_G[Q_D(Q_C + Q_B + Q_A) + \overline{Q_D} \cdot \overline{Q_C} \cdot \overline{Q_B} \cdot \overline{Q_A}]$

STATE CONTROLLER

$$Q_G = \overline{\text{RESET}}(\overline{Q_H} \cdot \overline{Q_G} \cdot \overline{\text{DTRANS}} + \overline{Q_H} \cdot Q_G \cdot \overline{\text{HOLDA}} + Q_H \cdot \overline{Q_G})$$

$$Q_H = \overline{\text{RESET}}[\overline{Q_H} \cdot Q_G \cdot \text{HOLDA} + Q_H \cdot \overline{Q_G} + Q_H \cdot Q_G(Q_F + Q_E + Q_D + Q_C + Q_B + Q_A)]$$

Fig 6 Extending block length. Additional modification increases block length to 64 words by using all internal registers. All capabilities of previous configuration have been maintained across both modifications

by implementing a second load command, $\overline{\text{LOADB}}$. The DMA controller now handles block lengths as long as 64 data words, and the RESET command can be used to initialize the state counter as in the original concept (Fig 6).

Summary

Generally, a design approach and its means of implementation should be complementary. Specifically, the controller design objectives are met by utilizing a state sequencer, and implementation compatibility is assured by such features of semicustom logic as multiple storage elements with internal feedback paths, dense gating arrays, and interconnection flexibility.

The process of creating a state sequencer to solve a design problem results in a series of Boolean expressions that define the controller capability and the gate array that must be effected. Several partially dedicated gating and register arrays constitute the semicustom logic family. After the most suitable array configuration is selected, the interconnections, as expressed by Boolean statements, are completed to implement the design. This creates a unique logic pattern whose dense gating contributes to chip count minimization. Design variations can be accommodated by restructuring the gating arrays with minimal hardware reconfiguration. Thus, the system can be tailored to the original operating requirements and yet be easily adapted if modifications are desired.

FPLA ARBITER CONCEPT ADAPTS TO APPLICATION NEEDS

Field programmable logic implements efficient, easily customized arbiter whose versatile Boolean statement format meets numerous system requirements

Alan W. Bentley Cubic Corporation
9333 Balboa Ave, San Diego, CA 92123

Today's trends toward shared resources, multiprocessing, and decentralized, bus oriented system organization underscore the demand for arbiters that work independently and issue grants according to predetermined algorithms. Functionally, a requirement for stable processing of system requests is created when several processors use a common device and each requests service asynchronously. It is the arbiter's task to issue grants for sequential access in accordance with a preestablished algorithm. By using a versatile Boolean statement format to express its algorithms, an arbiter can be customized to interface with single-array, multiple-array, and hybrid logic configurations. Designing arbiters to be flexible in implementing algorithms can help to meet the demand for cost-effective data processing systems and bring heretofore expensive, hence scarce, devices into wider use.

Arbiter Interface

From the system's perspective of the interface, when a system is ready for service from the device, it raises a request line. The arbiter responds by issuing a grant to the system that clears it to conduct transactions with the device. Upon completion of service, the system drops its request line. The arbiter, in turn, cancels the grant and is then free to issue a grant to the next pending request.

Stable system requests are necessary because all requests and grants are evaluated each clock period. These requests are generated asynchronously and are synchronized through a set of input latches. If a 2-phase balanced clock is used, with requests synchronized on phase 0 and grants issued or released on phase 1, the maximum time from a system request for service until synchronization of that request is one clock period. Minimum time from completion of the transaction to release of the synchronized request is the system's internal delay, as it drops the request line, plus the setup time of the synchronizing latches. At the completion of a transaction, there is a half-clock period, the time from phase 0 to phase 1, when a unique signal combination exists—a grant issued to a system that does not have a synchronized request. During this half-period, all other synchronized requests are examined and, according to the servicing algorithm, the recipient of the next sequential grant is determined. Then, on phase 1, the existing (unsolicited) grant is canceled and the next grant issued.

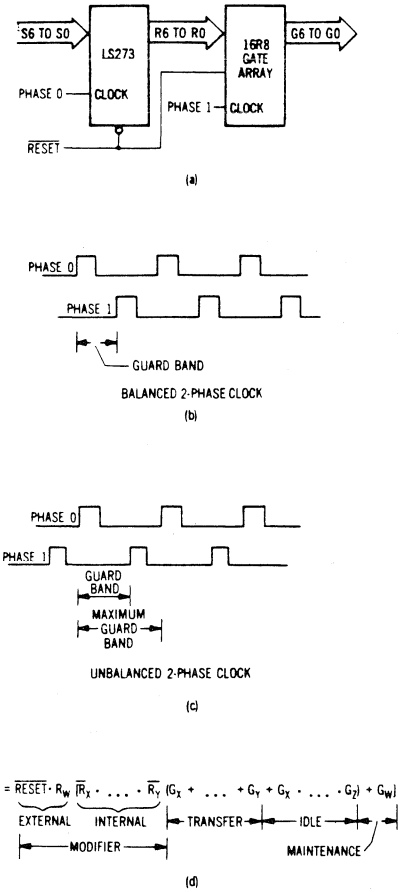

Fig 1 Arbiter circuitry, timing, and grant expression format. In (a), S6 to S0 are system requests. Latch outputs R6 to R0 are synchronized requests that arbiter algorithm converts to system grants, G6 to G0. Unbalanced clock phases increase guard band (b and c), with maximum guard band needing only one phase. Logic equation for algorithm (d) combines four subexpressions

The sum of the requesting system's internal delay in dropping its request line, the synchronizing latch setup time, and one-half the clock period, act as a guard band to ensure separation of systems interacting with the device. Arbiter clock frequency, therefore, is a major factor in determining guard band time. For a given arbiter clock frequency, the guard band can be increased by unbalancing the clock, increasing the time between phase 0 and phase 1 to more than half the clock period. The limiting case occurs when the time between phase 0 and phase 1 is increased until it equals the clock period. This makes phase 0 and phase 1 coincident, requires only a single-phase clock, and maximizes the guard band for a given clock frequency. The limiting case relies on the propagation delay of the latch flipflops and the setup time of the array logic grant flipflops to ensure a delay of one clock period between release of the synchronized request and the associated grant. Start of the guard band signifies completion of the current transaction, and guard band time is used to determine the next grant recipient; then, at the start of the next clock period, the current grant will be canceled, and, if one or more requests are pending, the next grant issued.

Octal D flipflops (LS273) are used to synchronize the input requests, and a programmable gate array (16R8) is used to evaluate the requests and issue grants. In the 2-phase clock, phase 0 synchronizes requests and phase 1 issues grants (Fig 1). Both the octal flipflops and the logic array are 20-pin packages. In addition to the clock and 3-state control inputs, the logic array has 8 data inputs and 8 D flipflop outputs. The Q output of each flipflop is inverted and buffered, and is a 3-state output; the $\overline{Q}$ output is returned to the array internally, where the 8 flipflop settings and the 8 data inputs are complemented and are available in both original and complement form at 8-input OR gates. There are eight OR gates, each forming the D input for one of the eight flipflops.

By programming through fusable links, the set condition of each flipflop is established from the eight data inputs, the current state of the eight flipflops, and the complements of both. Each flipflop's set condition can be represented as a Boolean expression of up to eight ORed statements. Each statement is created by ANDing terms drawn from the data inputs, the flipflop status, and their complements. Limiting parameters of this configuration are the 8 data inputs and the fixed 8-term OR gate at the D input of each flipflop. Boolean expressions implemented through the programmable fuses must be true when the flipflop is to be set or maintained in the set state, and false when the flipflop is to be reset or to remain reset.

Single-Array Configuration

Any of several servicing algorithms, expressed as Boolean statements, can be implemented with a single logic array that will process service requests for up to seven systems. The first two algorithms represent the organizational extremes. "Priority service" algorithm has a strict priority ranking from R6 to R0: a grant will be issued only if no higher priority system has a pending request. The other extreme is the "polled service" algorithm; here, all systems place equal demand on the device and are serviced through a rotating, or "round-robin," method. In this case, when one transaction has been completed, the following grant is issued in response to the next ranking request (eg, next lower number). Circular continuity is maintained by having R6 follow R0 in the granting sequence. Between the extremes, algorithms 3 and 4 represent hybrid organizations. The "executive and polled service" algorithm allows a single, high priority executive system (R6), with the remaining systems (R5 to R0) equal and polled in a

ALGORITHM 1: PRIORITY SERVICE

circular pattern by decreasing number (R5 follows R0). The other hybrid algorithm, "declining priority and polled service," services three systems in declining priority (R6 to R4), and allocates four systems the lowest priority; R3 to R0 have equal priority and are polled in a circular pattern by decreasing number (R3 follows R0).

In each configuration, the eight inputs consist of a RESET command and seven synchronized requests. Outputs are the seven corresponding grants, each the set output of a flipflop, buffered and inverted. When activated, the RESET command negates all expressions, resetting all grant flipflops. After a synchronized request is received, the appropriate expression becomes true, and the grant flipflop is set at the following clock edge. Upon completion of the transaction, the grant is released one clock period following the clock edge that terminates its synchronized request. This interval, when the grant is true and its synchronized request is false, denotes the completion of the service cycle. If one or more synchronized requests are pending, all expressions are evaluated, and, based on the servicing sequence expressed by the Boolean statements, the next grant is issued. If at the completion of a grant there are no pending requests, then all grant flipflops are reset and the device reverts to the idle state.

When the device is idle, all synchronized requests are scanned each clock period. Detection of a single synchronized request causes a grant to be issued at the following clock edge. If two or more requests are synchronized simultaneously, the expressions must provide a hierarchical method for issuing the initial grant. If the systems are organized from highest to lowest priority, the issuing of an initial grant follows the same seniority pattern. However, if all systems polled are of equal priority, the initial grant hierarchy must be established arbitrarily; in these examples, the grant hierarchy is based on highest to lowest sequence, systems R6 to R0. All these factors are apparent in the Boolean statements that implement the various grant algorithms. Each statement is the D input of a flipflop, and when a statement is true, the corresponding flipflop becomes (or remains) set at the following clock edge, issuing (or maintaining) a grant. As grants must be issued sequentially, the statements must be interlocked to prevent multiple flipflop settings.

The format set forth in the Boolean expressions of algorithms 1 through 4 [compare Fig 1(d)] is used when writing all statements. It consists of four sections: a modifier divided into an external and an internal portion, a transfer expression, an idle expression, and a maintenance expression. The external modifier, which operates on the entire contents of each statement, is the $\overline{\text{RESET}}$ term ANDed with the appropriate synchronized request. This establishes the basic requirement that RESET not be issued—and that the synchronized request be present—to consider whether to issue or to maintain a grant. The internal modifier operates on the transfer and idle expressions, and is the AND of synchronized requests that must be false for a specific grant to be issued. Since in a complete or partial priority structure, the highest numbered system (R6) always takes precedence, the internal modifier for the G6 expression is nonexistent.

The transfer expression identifies the completion of a transaction through the combination of a grant with its corresponding request. In conjunction with the modifiers, the transfer expression evaluates the pending requests to determine the next sequential grant. If one or several simultaneous requests are synchronized when grants are not active, the idle expression, in conjunction with the modifiers, determines which grant will be issued according to the established priority. The maintenance expression, the set output of the grant flipflop, maintains an established grant until its external modifier becomes false.

There are at least two other practical hybrid combinations: two prioritized systems with the remaining five polled, and four prioritized systems with the remaining three polled. Expressions for these two configurations can be derived from the four examples just discussed.

Multiple-Array Configuration

The single-array configuration handles up to seven systems with a broad selection of operation modes and is suitable for a configuration that has a limited number of systems with high rates of interaction with the device. When there is a large number of systems that have low rates of interaction individually, it is necessary to scan blocks of synchronized requests rapidly in order to minimize response time, thereby maximizing device

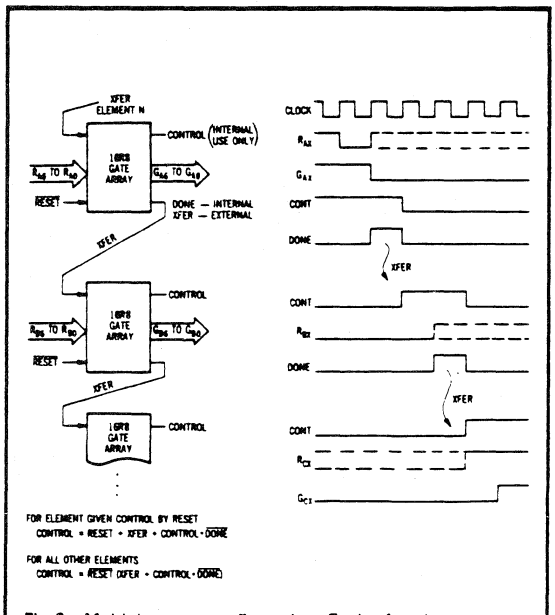

Fig 2 Multiple-array configuration. Each of n elements can service six systems arranged in circular (ie, polled or "round-robin") configuration. RESET issues control to one element. Then, as systems are serviced, DONE and CONTROL commands pass control function among elements as shown

utilization. This is accomplished by using the same 8-register programmable array device, with 6 of the registers issuing grants and the remaining 2 used to transfer the control and done commands. Devices thus organized become elements in a daisy chain configuration that is, in theory, infinitely expandable. Within the daisy chain, the element whose control flipflop is set is empowered to issue grants. Each element, while completing its last transaction, clears the grant flipflop, and, on the same clock edge, sets the done flipflop for one clock cycle. (See Fig 2.) Output of the done flipflop serves as an inhibit command within the element, and externally as a transfer (XFER) command to set the control flipflop of the next element.

Upon receipt of control, if one or more requests are pending, they are evaluated and a grant is issued at the next clock edge; if there are no requests, the clock edge instead sets the done flipflop to again transfer the control capability. Within an element, the same clock edge releases a completed grant and initiates a new grant, as was the case in the single-array configuration; among elements, there is a 2-period delay between succesive grants for sequencing of the done and control flipflops. Therefore, if the device is idle, an element that monitors six system requests is scanned each two clock cycles as the control function is sequenced through the elements.

Since this configuration can be expanded to accommodate servicing of numerous inputs, the elements are polled and equally weighted. However, within each element a protocol for responding to requests must be established; in these examples, priority is from the highest to the lowest number (R5 to R0). Algorithms 5 and 6 are variations of this configuration. In the "multiple-array polling" algorithm, the element retains control and services all requests in a declining polling sequence; control is relinquished only when there are no remaining requests. In the "multiple-array priority" algorithm, requests are serviced in a strict order of declining priority (ie, decreasing request numbers), and control is released in the absence of requests or upon completion of a device service period when no lower numbered systems have pending requests. In an application, these two configurations can be intermixed because the element interfaces are identical. The

ALGORITHM 5: MULTIPLE-ARRAY POLLING

$$G5 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R5\,[\overline{R0}\,(G0 + G1 \cdot \overline{R1} + G2 \cdot \overline{R2} \cdot \overline{R1} + G3 \cdot \overline{R3} \cdot \overline{R2} \cdot \overline{R1} + G4 \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} \cdot \overline{R1}) + \overline{G4} \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0} + G5]$$

$$G4 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R4\,[\overline{R5}\,(G5 + G0 \cdot \overline{R0} + G1 \cdot \overline{R1} \cdot \overline{R0} + G2 \cdot \overline{R2} \cdot \overline{R1} \cdot \overline{R0} + G3 \cdot \overline{R3} \cdot \overline{R2} \cdot \overline{R1} \cdot \overline{R0} + \overline{G5} \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0}) + G4]$$

$$G3 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R3\,[\overline{R4}\,(G4 + G5 \cdot \overline{R5} + G0 \cdot \overline{R0} \cdot \overline{R5} + G1 \cdot \overline{R1} \cdot \overline{R0} \cdot \overline{R5} + G2 \cdot \overline{R2} \cdot \overline{R1} \cdot \overline{R0} \cdot \overline{R5} + \overline{R5} \cdot \overline{G5} \cdot \overline{G4} \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0}) + G3]$$

$$G2 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R2\,[\overline{R3}\,(G3 + G4 \cdot \overline{R4} + G5 \cdot \overline{R5} \cdot \overline{R4} + G0 \cdot \overline{R0} \cdot \overline{R5} \cdot \overline{R4} + G1 \cdot \overline{R1} \cdot \overline{R0} \cdot \overline{R5} \cdot \overline{R4} + \overline{R5} \cdot \overline{R4} \cdot \overline{G5} \cdot \overline{G4} \cdot \overline{G3} \cdot \overline{G1} \cdot \overline{G0}) + G2]$$

$$G1 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R1\,[\overline{R2}\,(G2 + G3 \cdot \overline{R3} + G4 \cdot \overline{R4} \cdot \overline{R3} + G5 \cdot \overline{R5} \cdot \overline{R4} \cdot \overline{R3} + G0 \cdot \overline{R0} \cdot \overline{R5} \cdot \overline{R4} \cdot \overline{R3} + \overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{G5} \cdot \overline{G4} \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G0}) + G1]$$

$$G0 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R0\,[\overline{R1}\,(G1 + G2 \cdot \overline{R2} + G3 \cdot \overline{R3} \cdot \overline{R2} + G4 \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + G5 \cdot \overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + \overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} \cdot \overline{G5} \cdot \overline{G4} \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G1}) + G0]$$

$$DONE = \overline{RESET} \cdot CONT \cdot \overline{DONE} \cdot \overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} \cdot \overline{R1} \cdot \overline{R0}$$

CONT = CONTROL (SEE FIG 2)

ALGORITHM 6: MULTIPLE-ARRAY PRIORITY

$$G5 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{G4} \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0} \cdot R5$$

$$G4 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{G3} \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0} \cdot R4\,[\overline{R5} + G4]$$

$$G3 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{G2} \cdot \overline{G1} \cdot \overline{G0} \cdot R3\,[\overline{R4}\,(\overline{R5} + G4) + G3]$$

$$G2 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{G1} \cdot \overline{G0} \cdot R2\,[\overline{R3}\,(\overline{R5} \cdot \overline{R4} + G4 \cdot \overline{R4} + G3) + G2]$$

$$G1 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{G0} \cdot R1\,[\overline{R2}\,(\overline{R5} \cdot \overline{R4} \cdot \overline{R3} + G4 \cdot \overline{R4} \cdot \overline{R3} + G3 \cdot \overline{R3} + G2) + G1]$$

$$G0 = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot R0\,[\overline{R1}\,(\overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + G4 \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + G3 \cdot \overline{R3} \cdot \overline{R2} + G2 \cdot \overline{R2} + G1) + G0]$$

$$DONE = \overline{RESET} \cdot \overline{DONE} \cdot CONT \cdot \overline{R0}\,[\overline{R1}\,(\overline{R5} \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + G4 \cdot \overline{R4} \cdot \overline{R3} \cdot \overline{R2} + G3 \cdot \overline{R3} \cdot \overline{R2} + G2 \cdot \overline{R2} + G1) + G0]$$

CONT = CONTROL (SEE FIG 2)

differences are within the elements—ie, the methods used when evaluating requests to issue grants and when generating the transfer command. Since only one element can have a set control flipflop and the associated authority to issue grants, one control flipflop must be set, and all others reset, during initialization. During implementation, the system start of poll (established by RESET) must be selected, and each element's control equation implemented accordingly. (See Fig 2.)

The Boolean statements in algorithms 5 and 6 are configured in the format shown in Fig 1(d). In algorithm 5, the external modifier has two additional terms, CONT and DONE, both establishing that the element has control. The remainder of the terms is similar in content to the terms in algorithm 2, and, with the exception of the idle expression, also similar in concept. Since an element does not retain control in the idle state, this term instead establishes the initial grant upon receipt of the control function. Subsequent grants are issued through the transfer expression, and when all requests are satisfied, the done flipflop is set for one period, initiating a transfer of control to the next element.

Hybrid Configuration

Single- and multiple-array configurations have limitations. The single-array concept services only seven systems, but offers flexibility in configuring the response patterns. Conversely, the multiple-array configuration can handle a large (theoretically unlimited) number of systems, but is not flexible in configuring response patterns because the control function must cycle through elements in a prescribed sequence. By restructuring the control lines, designers can interconnect elements in a hierarchical fashion, both increasing the number of systems serviced and providing service flexibility. An example that consists of two elements, each servicing six systems, is shown in Fig 3. The two elements are labeled "upper" and "lower" to denote their relative priorities. Each element has a control flipflop whose output is an input to the other element.

The control flipflop of the upper element is set whenever it has a synchronized request, and is a DEMAND for control. The control flipflop of the lower element is set when it receives a demand and does not have an active grant; it is a RELEASE of control. Thus, the upper element DEMANDs and receives control when it has a request. When all upper element requests are satisfied, the demand flipflop is reset and control shifts to the lower element by default. The control equations for the upper and lower elements are shown in Fig 3, along with the format for the grant equations and one sample grant equation for each element. Because the equations for the hybrid configuration are similar to those for the single-array configuration, the grant equations are modifications of those shown in algorithms 1 through 4. When in the idle state, the default location for control is in the lower element; therefore, the equation for the upper element does not require an idle section.

Efficient transfer of control and prevention of inadvertent simultaneous grant issuance during the transition sequence are primary considerations in arbiter

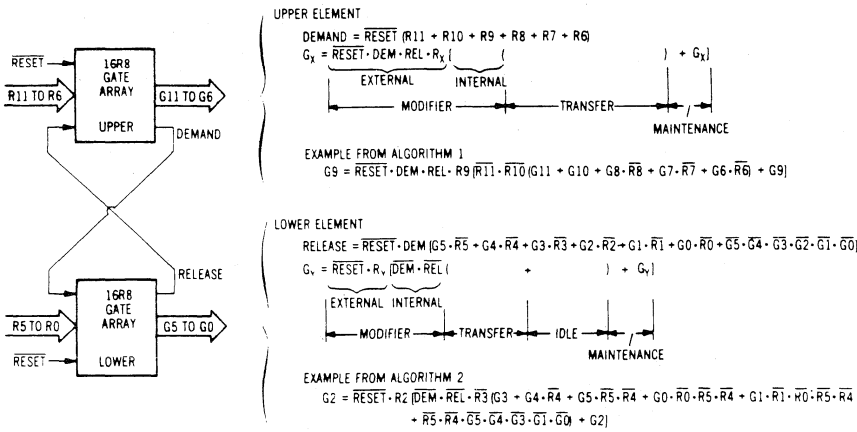

Fig 3 Hybrid configuration. Two elements have hierarchical structure. Upper element demands control when request is pending, thereby preventing lower element from issuing grants and gaining control when lower element becomes idle. Modified grant expression format and typical grant expression appear for each element. Release expression is also shown. Each element offers full flexibility shown in algorithms 1 to 4

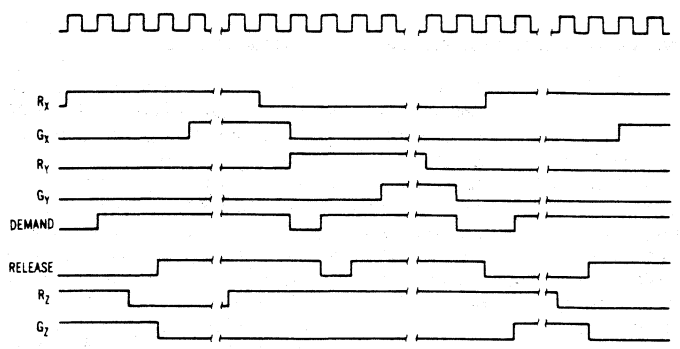

Fig 4 Hybrid configuration timing. Diagram shows timing relationship as control function passes between upper and lower elements. At left, control passes from lower element to upper element upon completion of G_Z. In second sector, upper element releases control and reestablishes demand during same clock period (adverse situation). Lower element with pending request must reinitiate release, causing 3-period delay between grants. In two right sectors, upper element releases control and reestablishes demand one clock period later. Lower element issues grant for its pending request and releases control upon completion of service

design. Control equations and modifier sections of the grant equations, respectively, fulfill these design requirements. Three transitional sequences for hybrid configuration are shown in the timing diagram. (See Fig 4.)

Summary

The increased desirability of sharing resources among several systems has increased the requirements for arbiters that can function independently. Such arbiters enhance the profitability of shared resource data processing systems. A versatile Boolean statement format can implement efficient control protocol and grant algorithms in field programmable logic. The flexibility and logic density of register arrays can facilitate efficient custom arbiter implementation.

Programmable Array Logic Leads to Flexible Application of 8-Bit Wide Memories

Bernard Brafman

Introduction

The flexible application of memory devices in small microprocessor based systems have been enhanced by the introduction of 8-bit wide static random access memories. These devices have pinouts and operating characteristics that are similar to those of read only and programmable read only memories. Thus, the configuration of both read/write and read only memories can be simplified to meet changing system requirements. For example, this flexibility allows a single printed circuit board to be used in several different product configurations, from fixed program intensive (large read only memory requirements) to data intensive (large read/write memory requirements). Using programmable logic technology in conjunction with 8-bit wide memory devices adds even more flexibility and helps to reduce parts count.

To provide for the simple substitution of parts, a printed circuit (PC) board must be developed that allows interchangeability among the memory sockets of 8k-, 16k-, and 64k-memory devices, both random access memory (RAM) and programmable read only memory (P/ROM), or read only memory (ROM). A method must be created also to define flexibly the addressing of these parts to accommodate varying address space requirements. The first task is physical — e.g., some 64k devices have 28 pins while others have 24 pins. To be most flexible, the PC board will have a 28-pin socket with jumpers to allow the use of either 24- or 28-pin devices. Socket interchangeability also necessitates an examination of the timing requirements of the target memory devices and microprocessor, since differences exist in setup or prechange or hold times for address and data, and control signal interactions. Some systems will need additional gating or delays to ensure flexibility. Such timing information is easily found in application notes published by both microprocessor and memory manufacturers.

The second task is to implement decoding schemes for the selection of the appropriate devices in the memory array. One method uses hardwired discrete logic. This alternative is not viable because high configurability requires an excessive use of space consuming jumpers and also results in unused logic on the PC board. Programmable logic, on the other hand, implements the requisite configurably in fuses on silicon, not on the PC board, and consolidates several integrated circuit (IC) packages into one.

Design Tradeoffs

The choices in programmable logic are programmable logic arrays (PLAs), P/PROMs, and programmable array logic (PAL®). PLAs must be ruled out since their 2-fuse array structure, while awarding some versatility, uses up too much board space. PLAs are implemented in 0.6 in. (1.5 cm), 28-pin packages; the job can be done with smaller 0.3 in. (0.8 cm), 16- or 20-pin packages when P/ROMs or PALs are used.

While P/ROMs are frequently employed in such applications, there are compelling reasons to consider the use of PAL. First, any P/ROM with an adequate number of input and output pins to replace the required external logic consumes more power than a comparable PAL. For example, providing control signals for four memory devices requires four chip enables and at least one output enable signal. These signals must be derived from at least six address lines and generally three and often four control signals. In such a case, the programmable logic device must have ten inputs and five outputs. For a PROM, this would be an 8K, 20 or 24-pin device, organized as 1Kx8. Typically, a commercial 8K bipolar PROM has an I_{CC} of 190 mA over temperature, as compared with 90 mA for a 10-input, 8-output PAL. Even if external logic were employed, so that a 1K PROM, organized as 256x4 were used, the I_{CC} would by typically 130 mA over temperature.

PALs are not susceptible to the "glitching" characteristics of PROMs during the access time from address. To combat glitching, the PROM must be used with registers or, if the control signals are active low only, open collector with pullup resistors for the outputs. Generally, a processor control signal or its derivative serves as the clock for the register or output enable to the PROM, an example of increasing parts count and costs in an attempt to overcome an implementation detail. While the technique usually employed to generate the fuse pattern, or programming, for PROMs is manual, a useful and uniform design tool exists for configuring PALs. A FORTRAN IV program called PALASM (for PAL assembler) is available on the National CSS timeshare network or as source code at no charge for any machine that supports a FORTRAN environment. PALASM converts logic equations describing the function of the target device directly into a fuse pattern format that is compatible with the several PROM programmers which support PAL programming. This assembler allows simple, rapid, and complete design and documentation of PAL configurations in a format useful for communication between engineers. Finally, like PROMs, PALs have a masked counterpart, hard array logic (HAL). HALs are plug compatible with the corresponding PAL, and offer significant cost reductions for high volume applications.

Implementation Example

A typical design with memory device interchangeability, is the 6802 microprocessor based instrument required to have four sockets capable of accepting 2kx8 static RAMs, 2kx8 erasable programmable read only memories (EPROMs), or 4kx8 EPROMs. The four chip enable signals ($\overline{CE}_1$, $\overline{CE}_2$, $\overline{CE}_3$, and $\overline{CE}_4$), the common output enable (OE), and the common read/write control (R/$\overline{W}$) are compatible with the devices selected so that no special gating is needed. The programmable logic device will have as inputs the five high order address bits A_{11} through A_{15} and the control signals VMA (valid memory address) and E (enable). While R/$\overline{W}$ may be used directly for write enable ($\overline{WE}$), it is needed to generate $\overline{OE}$. (See Fig. 1.).

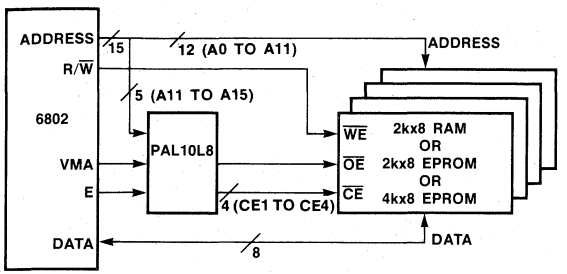

Fig. 1. 6802 based system. Block diagram outlines system's capability to accept 2kx8 static RAMs, 2kx8 EPROMs, or 4kx8 EPROMs.

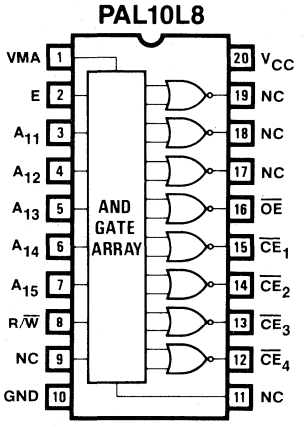
The programmable logic device requires eight inputs and five outputs. PAL10L8 and PAL12L6 meet both the input and output pin requirements. The PAL10L8 has been selected for this discussion because the three outputs are left unused and are available for logic replacement. (See Fig. 2.). Internally, the PAL10L8 generates eight 2-term OR sums, each sum composed of two 10-term AND products. Each of the products may be connected to any of the input signals or its complement.



GND = GROUND
NC = NOT CONNECTED

Fig. 2. PAL10L8 pinout. Device generates eight 2-term OR sums, each composed of two 10-term AND products.

While there are 81 unique combinations of the three memory devices in the four sockets, there are only 16 distinct decoding schemes implementing either a 2k- or 4k-deep device in any of the four sockets; these 16 schemes are set forth in "Address Ranges of 16 Device Combinations." See "PAL Design Specifications," which can also include a function or truth table, for a description of the arbitrary pinout shown in Fig. 2; this pinout may be altered simply by switching the elements of the pin list on line 5 on both design specifications. Notice that the chip enables and output enable are inverted in the pin list and true in the equations. This is to keep expressions in the sum-of-products form for PALASM, which expects equations summed at the node before the inversion for active low PALs. Also, there are two unused inputs and three unused outputs that may be applied to reduce logic elsewhere in the system.

```

Summary

The combination of 8-bit wide memory devices and programmable array logic allows designers to implement highly flexible microprocessor based designs with minimal chip count and reduced overall costs. PALASM serves as a useful tool for expediting prototype cycles and documenting PAL designs; this can reduce future problems when changes must be made by designers unfamiliar with the original design. Finally, products with high volume in a specific configuration may switch over to mask programmable array logic, HAL, to reduce costs further.

PAL: Quick Turnaround Alternative to Gate Arrays

Shlomo Waser

Abstract

The first part of the paper will describe the PAL family including the second generation to be introduced shortly, and the HAL, which is a gate array with fusible prototype.

The second part will address the PAL software support tools with emphasis on HDL (Hardware Description Language), design verification via function tables, simulation and automatic test vector generation.

Introduction

The Part Number Problem

As the capability of the semiconductor industry to integrate more and more logic into a single chip, a unique problem has arisen; how to define a common chip that will have enough volume to justify the tremendous design costs associated with high degree of integration. Let us illustrate this with an example: Back in the '60s when the integration capability was below 10 gates per chip, we made quad NAND gates and similar SSI. Everybody that made digital systems could use a quad NAND so there was no volume problem. But in the '80s, we can put thousands of gates per chip and the design cost is measured in millions of dollars. As long as we provide memories and microprocessors, there are always enough customers that have common requirements to request large volume. So in the '80s, we don't have a problem with memories and microprocessors, but we do have a problem with what to do with the rest of the required components. Especially the components that are unique to special systems and there is no chance that there will be enough volume generated to justify the large design cost.

The SSI/MSI Solution

One solution to the above problem is to use SSI gates and construct the desired function. This is an undesirable solution since it does not take advantage of the increased integration available nowadays.

The Custom Solution

If the special function has enough volume, a custom design is justified economically, provided the long design cycle associated with custom is acceptable.

The Programmable Solution

There is a big void between the undesirable SSI solutions and the uneconomical custom. This void is now being addressed by semi-custom approaches. Three semi-custom approaches are generally available (in increasing order with gate densities):

1. Fuse programmable logic (PAL, FPLA, and PROM)
2. Gate Arrays
3. Standard Cells

It is estimated that by 1990, half of the semiconductor market will be made of programmable system components. This paper will focus on only the PAL approach to semi-custom, but will compare the PAL to other alternatives.

The PAL Family

The First Generation: PAL20

The PAL is an abbreviation for Programmable Array Logic. The PAL was invented and patented by John Birkner of Monolithic Memories, Inc. The family is made of 15 different parts. All are housed in 20-pin DIP, and are fuse programmable by the user. Of the 15 different parts, 9 are combinatorial and 6 are registered for sequential operations. Figure 1 illustrates the use of a combinatorial PAL to perform address decoding in a typical microprocessor system.

Each PAL is made of one or more of the following cells:

- AND-OR/NOR cell used for combinatorial logic (Figure 2)
- Registered cell with internal feedback. Used to implement sequential logic (Figure 3).
- Programmable I/O cells enable the user to dynamically change the pin function from input to output and vice versa. This feature is very useful for bidirectional communication (Figure 4).

Figure 5 is a general block diagram of a state machine. The state of the machine is determined by the contents of the output register while the next state is a function of the present state and some input variables. Figure 6 depicts the implementation of this classic structure by a registered PAL. Note that the present state information is fed back to the combinatorial network via the internal feedback, thus conserving the use of precious pins.

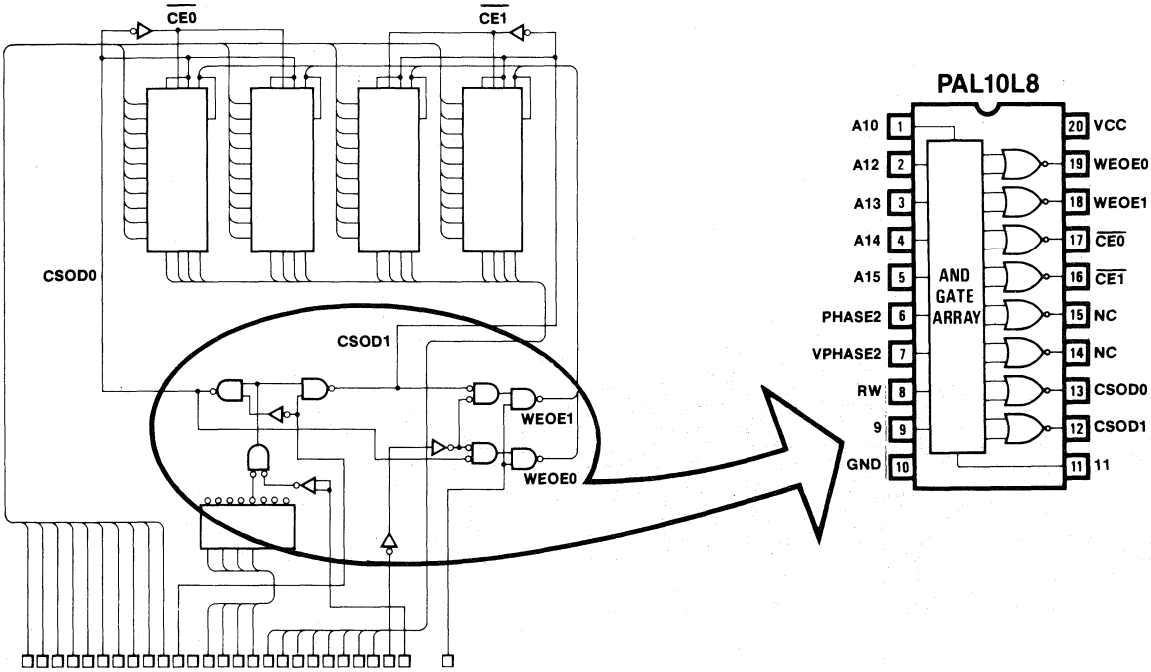

Figure 1. Using PAL to Replace Random Logic in 6800 Microprocessor Bus

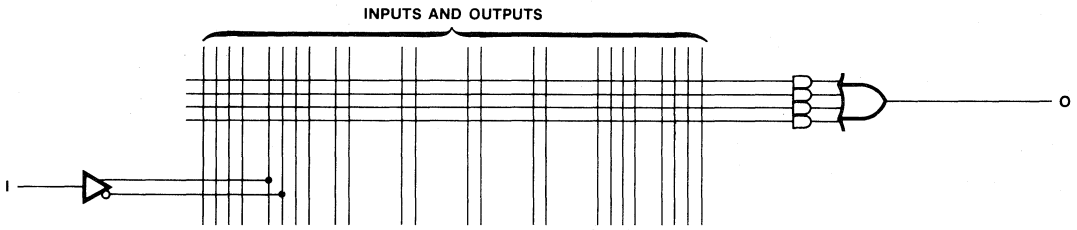

Figure 2. AND-OR Cell

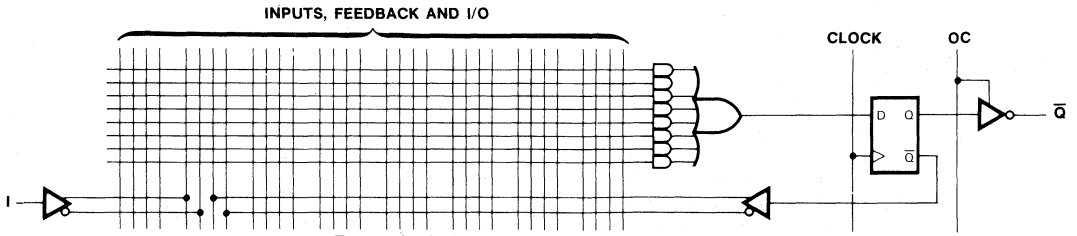

Figure 3. Registered Cell With Internal Feedback

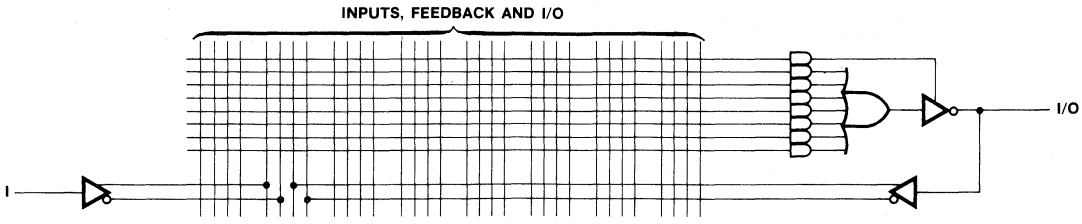

Figure 4. Programmable I/O Cell

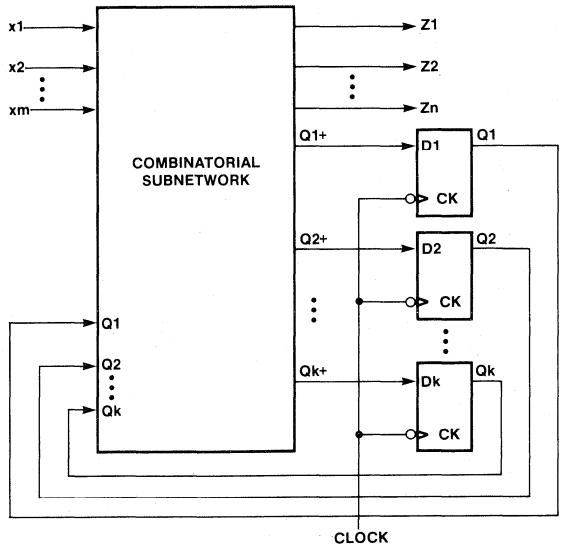

Figure 5. State Machine Block Diagram

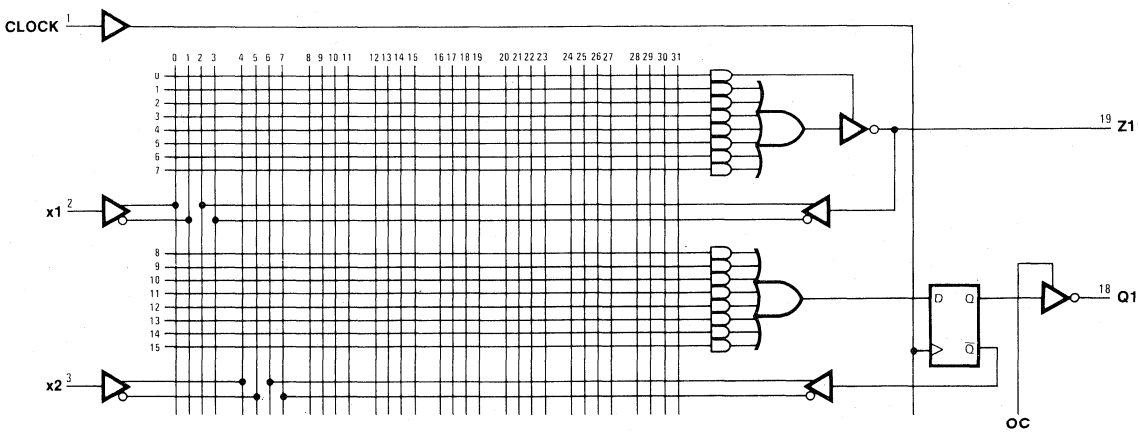

Figure 6. Section of a PAL16R6 Logic Diagram

The Second Generation: PAL24

The PAL24 is an evolution of the PAL20 and similarly has combinatorial and registered parts. However, in the combinatorial circuits, it is now possible to decode simultaneously up to 20 inputs. The registered parts now have as many as 10 outputs, but the important thing to note about the architecture of the registered part is the addition of a new cell: "AND-OR-EXOR" as illustrated in Figure 7. The significance of the cell is for implementing various types of counters. Figure 8 shows the logic diagram for the PAL20X8 that can be easily programmed to implement an octal counter.

PAL Performance: Present and Future

The most critical parameter for the PAL performance is the propagation delay for the combinatorial cells and the set-up time for the registered cells. These two parameters are equal in the PAL family and are listed below as function of time:

	1979	1981	1982	1983
$t_{PD} = t_{SU}$	40 ns	35 ns	25 ns	15 ns

These numbers are worst case for commercial temperature and supply ranges. Add 5 ns to get the worst case numbers for military temperature and supply.

PAL — Industry Standard

The PAL has been accepted as an industry standard and is being manufactured under license by National Semiconductor (NSC). In addition, it was announced by Texas Instruments (TI). It is very significant to note that TI and NSC, who are the leaders in the TTL market have recognized that PAL will eventually replace the present TTL. The PAL20 was adopted by the JEDEC 42.1 Committee as a de facto standard and it further proposed that the PAL24 be also adopted.

HAL — Hard Array Logic

The HAL to a PAL is the same as a ROM to a PROM. Instead of having a fuse mask, a metal mask is used. This technique reduces the PAL price almost by a factor of two. The HAL is similar to a gate array. Both are customized in the last fabrication stage by applying a unique metal mask to otherwise standard wafer. However, the HAL is the only gate array in the market with a fusible prototype.

PAL20X8

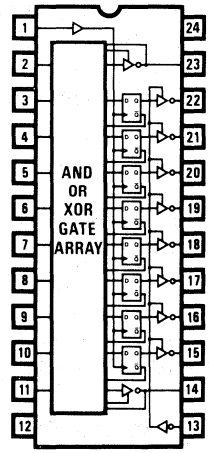

Figure 8. PAL20X8

PAL vs Other Alternatives

PAL Advantages Over SSI/MSI

The PAL can replace from 4-10 SSI/MSI and consequently it reduces the board space required for a function. It also increases reliability by moving the interconnections from the less reliable PC solder connections to the silicon chip. Since the PAL is programmable, it expedites the prototyping and debugging process as compared to conventional SSI/MSI. Last but not least, is the PAL security fuse which makes it impossible to copy the contents of a PAL.

6

PAL vs Gate Arrays

Gate arrays typically have higher gate density than a PAL. However, they have several drawbacks. The turn-around time for gate array is 2-4 months for the first silicon and typically two iterations are required to get a completely functional unit. Thus, the actual turn-around time is 4-8 months. By contrast, a PAL can be programmed in a few minutes and if several iterations are required, the total turn-around time is still measured in hours, not in months. Even if a customer selects to go with HAL (which has a turn-around time similar to gate arrays), he still does not lose time since he can use the PAL as his fusible prototype to build the first systems.

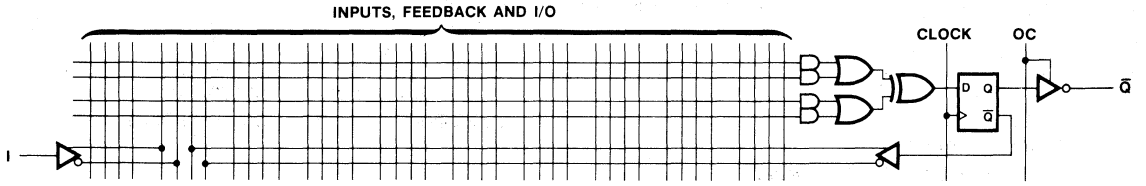

Figure 7. Registered Cell Using XOR Gate

Gate array development cost is estimated to be $20-$50K per circuit, this compared with less than $1K for HAL mask charges or nothing if only PAL is used.

Finally, at the time of writing this paper, the PAL is multi-sourced while gate arrays are single sourced.

PAL vs FPLA

Both approaches use AND array followed by OR array. In the FPLA, both arrays are programmable while in the PAL, only the AND array is programmable. The FPLA approach is academically more flexible but in practicality this flexibility costs time delay and power dissipation. The PAL with its programmable AND array is an engineering trade-off, since the majority of the TTL applications can be implemented by the single programmable array while increasing speed and saving power dissipation.

PROMs Complements the PAL

In few applications, we find that the PAL does not have sufficient product-terms to implement a certain function (especially arithmetic functions). In cases like this, the PROM has a clear advantage since it has all possible product-terms for a given number of inputs. For example: to build a 4x4 multiplier, only 8 inputs and 8 outputs are required; but the number of product terms is more than the 8 available in PAL. Thus, a 256x8 PROM can be used to implement this multiplier (since a 256 words PROM has 8 address lines).

PAL Design Specifications

Motivation

The PAL design specifications serve two functions which are very critical to any user who customizes his own chip:

(a) Documenting the customized function on a computerized data sheet form so that retrieving and updating are easily accomplished.

(b) Automating the design process, i.e., only logic equations are necessary in specifying a new function. The translation of these logic-equations to physcial fuse pattern should be transparent to the user.

The Specifications

The following items constitute the total specs:

- PAL part number
- Heading on user and function
- Pin list
- Logic equations
- Function table (optional)
- Description (optional)

Let us illustrate these specs by going though an example of a 24-pin PAL which is customized as an octal counter. This octal synchronous counter can perform 4 operations. Each operation is selected by a two bit code:

I1	I0	
0	0	Clear
0	1	Hold
1	0	Load
1	1	Increment

The counter has 8 data outputs which are called, "Q0" through "Q7" and 8 data inputs which are called "D0" through "D7", where "D0" is the LSB.

So now we are ready to go through the detailed specifications. The first 4 lines are specified in the following way:

- Line 1 specifies that the device is PAL20X8
- Line 2 specifies user part number
- Line 3 is the device application name
- Line 4 is the user's company name, city and state

```
PAL20X8                                  PAL DESIGN SPECIFICATION
74LS461                                  BIRKNER/KAZMI/BLASCO 02/10/81
OCTAL COUNTER
MMI SUNNYVALE, CALIFORNIA
```

- Line 5 is the beginning of the pin list. In our case there are 24-pins:

  Pin 1 is the clock pin called "CLK"

  Pin 2 is a select line called "I0"

  Pin 3 is the LSB of the input called "D0," and so forth.

```
CLK  I0 D0 D1 D2 D3 D4 D5 D6 D7  I1 GND
/OC /CO Q7 Q6 Q5 Q4 Q3 Q2 Q1 Q0 /CI VCC
```

Logic-equations follow the pin list:

```
/Q0 :=  /I1*/I0                              ;CLEAR LSB
     +       I0 * /Q0                        ;COUNT/HOLD
    :+:   I1*/I0 * /D0                       ;LOAD D0 (LSB)
     +    I1* I0 * CI                        ;COUNT

/Q1 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q1                        ;COUNT/HOLD
    :+:   I1*/I0 * /D1                       ;LOAD D1
     +    I1* I0 * CI*Q0                     ;COUNT

/Q2 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q2                        ;COUNT/HOLD
    :+:   I1*/I0 * /D2                       ;LOAD D2
     +    I1* I0 * CI*Q0*Q1                  ;COUNT

/Q3 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q3                        ;COUNT/HOLD
    :+:   I1*/I0 * /D3                       ;LOAD D3
     +    I1* I0 * CI*Q0*Q1*Q2               ;COUNT

/Q4 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q4                        ;COUNT/HOLD
    :+:   I1*/I0 * /D4                       ;LOAD D4
     +    I1* I0 * CI*Q0*Q1*Q2*Q3            ;COUNT

/Q5 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q5                        ;COUNT/HOLD
    :+:   I1*/I0 * /D5                       ;LOAD D5
     +    I1* I0 * CI*Q0*Q1*Q2*Q3*Q4         ;COUNT

/Q6 :=  /I1*/I0                              ;CLEAR
     +       I0 * /Q6                        ;COUNT/HOLD
    :+:   I1*/I0 * /D6                       ;LOAD D6
     +    I1* I0 * CI*Q0*Q1*Q2*Q3*Q4*Q5      ;COUNT

/Q7 :=  /I1*/I0                              ;CLEAR MSB
     +       I0 * /Q7                        ;COUNT/HOLD
    :+:   I1*/I0 * /D7                       ;LOAD D7 (MSB)
     +    I1* I0 * CI*Q0*Q1*Q2*Q3*Q4*Q5*Q6   ;COUNT

IF (VCC)  CO = CI*Q0*Q1*Q2*Q3*Q4*Q5*Q6*Q7    ;CARRY OUT
```

Following the logic equations, a FUNCTION TABLE is given. Note that the FUNCTION TABLE includes some basic test information:

```
FUNCTION TABLE

CLK /OC I1 I0 D7 D6 D5 D4 D3 D2 D1 D0 /CI /CO Q7 Q6 Q5 Q4 Q3 Q2 Q1 Q0

```

Finally, it is highly recommended that a description be a part of this computerized data sheet.

```
THIS IS AN 8-BIT SYNCHRONOUS COUNTER WITH PARALLEL LOAD, CLEAR, AND HOLD
CAPABILITY.  THE LOAD OPERATION LOADS THE INPUTS (D7-D0) INTO THE OUTPUT
REGISTER (Q7-Q0).  THE CLEAR OPERATION RESETS THE OUTPUT REGISTER TO ALL LOWS.
THE HOLD OPERATION HOLDS THE PREVIOUS VALUE REGARDLESS OF CLOCK TRANSITIONS.
THE INCREMENT OPERATION ADDS ONE TO THE OUTPUT REGISTER WHEN THE CARRY-IN IS
TRUE (/CI=L), OTHERWISE THE OPERATION IS A HOLD.  THE CARRY-OUT (/CO) IS TRUE
(/CO=L) WHEN THE OUTPUT REGISTER (Q7-Q0) IS ALL HIGHS, OTHERWISE FALSE (/CO=H).

THESE OPERATIONS ARE EXERCISED IN THE FUNCTION TABLE AND SUMMARIZED IN THE
OPERATIONS TABLE:
```

/OC	CLK	I1	I0	/CI	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	X	Z	HI-Z

CAD Software for PAL

PALASM

PALASM is a software which translates the LOGIC EQUATIONS to a fuse pattern. The output of the PALASM is in a format compatible with either a PAL or a PROM programmer. The user needs to specify only his "block-box" description and the programmer will blow the corresponding fuse pattern.

PALASM also uses the FUNCTION TABLE to perform two critical operations for the semi-custom user:

- Design Verification — Each entry of the FUNCTION TABLE is checked against the logic equations and any inconsistency is flagged as an error.
- Test Vectors — Each entry of the FUNCTION TABLE is translated to a universal test vector, so there is a way of testing the customized PAL once it is fabricated

PALASM is written in FORTRAN IV and it resides on an IBM 370/168. Users can access the program by calling the NCSS time-share network. Additionally, Monolithic Memories makes the source code of PALASM available to users at no cost. PALASM is presently running on quite a few computers at customer sites. Several examples of such computers are the DEC PDP/11, DG NOVA, HP2100, MDS800, and many others.

An example of the test-vectors generated from the FUNCTION TABLE of the octal counter is given at right:

Testability

The test vectors which resulted from the FUNCTION TABLE are referred to as basic test vector and they indeed guarantee that the part is functioning according to each entry in the FUNCTION TABLE. However, to increase the confidence level that the device will not "misbehave" (when unspecified inputs are applied) it is necessary to insure that all nodes are toggled during the testing. Monolithic Memories has an automatic test-vector generation program which is used to test HAL, the software uses the basic test-vectors as seed vector and from there it iteratively adds more test vectors until all nodes have been toggled.

It is important to note that for testability it is always necessary to have an initiallization mechanism, e.g., in the octal counter when I0 = I1 = 0, the counter is cleared to all zeros.

HMSI: Dedicated HAL Functions

In general, the PAL and HAL are programmed according to user specifications. However, as an aid to customers, we make certain dedicated 24-pin HAL. For example:

- Octal Counter
- 10-Bit Counter
- 16:1 MUX and several other "new" TTL functions

PAL and the Military

Bipolar Technology

The PALs are fabricated using bipolar Schottky technology which has been proven to be much more reliable at extreme temperatures than the MOS technology. The PAL is being programmed by blowing TiW fusible links which has proven reliability on PROMs. The fusible link technique is much more reliable than the EPROM or EEPROM which use a stored charge that leaks with time and has a questionable operation at the military temperature range.

Low-Volume

Low-volume requirement has been a continuous problem to the military market place, but with PALs obviously the low-volume requirement can be satisfied by customizing as little as one chip at a time.

Obsolete SSI/MSI

Anytime the demand for ICs exceeds the available supply, the semiconductor manufacturer stops producing the least profitable ICs. As the labor cost increases and the silicon cost decreases, SSI/MSI devices (which are labor intensive) are the first to become obsolete. With the fast turn-around time of the PAL. These TTL devices can be quickly reduced by PAL.

Leadless Packages

The PAL is also available in the space saving leadless chip carriers (LLC). These carriers are made according to JEDEC outline (Type B) with 50 mil centers and 75 mil package thickness. The 20-pin LCC is 350x350 mils and occupies only 40% of the space required by the equivalent of 20-pin DIP.

Military Processing

PALs, like all other Monolithic Memories' products, can be processed to meet the HI-REL requirements of MIL-STD-883B. This processing is available for both LCC and DIP packages and also for dice where they are visually inspected by method 2010B and are shipped in a standard waffle pack.

Summary

The PAL family is already a valuable semi-custom approach in the commercial market place. It will even be more valuable to the military market that has been looking for a solution to the problem of low-volume requirement.

The PAL, which is implemented in bipolar technology, presents a high reliability programmable solution to the demanding needs of the military market.

High Speed/Low Cost Fuse Link Arrays Compete with TTL 74S/LS

John Birkner/Wescon 78

Random Logic has remained virtually impenetrable by today's state of the art LSI technology. This fact is dramatically evidenced by the high percentage of TTL 74S/LS logic found in currently introduced small board computers based on MOS microprocessors, and also high performance minicomputers based on bipolar bit slice chip sets.

LSI has vastly reduced the well defined, regular logic functions found in these systems because of the wide appeal, thus, high volume and low cost. When the regular functions are applied to the specific needs of a particular systems manufacturer, however, individual interfacing requirements demand additional logic not available in LSI functions. The present solution is to use standard SSI/MSI logic functions at a high cost in chip count, assembly/test labor and reliability.

To answer the need for LSI Random Logic, a family of fuse Programmable Array Logic devices (PAL) has recently been introduced. This family meets the speed requirements of competing TTL SSI/MSI with typical 25ns propogation and set up delays while reducing chip count 4 to 1.

Total system cost using PALs is comparable with SSI/MSI, yet design time and inventory costs are reduced. The 15 part family utilizes the latest improvements in bipolar Schottky fusible link technology with the proven reliability track record of bipolar PROMs. Titanium-tungsten fuses and emitter follower arrays are used to achieve the 25ns delays through three levels of logic.

DEFINING THE PROBLEM

Increasing the logic function density per chip is the name of the game in the integrated circuit industry. The standard procedure is to identify a logical block which is common to many applications and users, and then to integrate that function onto a single chip. The problem with integrating the random and irregular functions which are so prevalent in today's digital systems is to identify a common denominator which can provide a generalized solution that meets cost and performance goals.

A Decade of TTL

The growth of TTL SSI/MSI during the last decade provides a wealth of knowledge about the elements that designers need to build digital systems. This family of devices was defined by many users and manufacturers over many years and is, therefore, an evolutionary, emperical data base from which we can extrapolate generalized logical primatives for LSI implementation.

The Primitives

SSI/MSI functions can be classified as either combinatorial or sequential. Combinatorial includes the basic gates, AND-OR-INVRT gates, Multiplexors, de-multiplexors and priority encoders. More complex combinatorial includes arithmetic functions such as comparitors, adders, and ALUs. The common denominator among the simple combinatorial elements is the sum of products. An additional primative in the arithmetic elements is a high density of Exclusive-ORs.

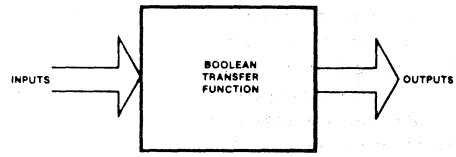

Figure 1: Combinatorial Function

Sequential includes all the registered functions such as counters, shift registers, registered multi-pliexors, accumulators, and registered encoders. The common denominator of these sequential elements is a register driven by a combinatorial element whose inputs are both external and internal from the register. All of the sequential devices may be described as simple state machines.

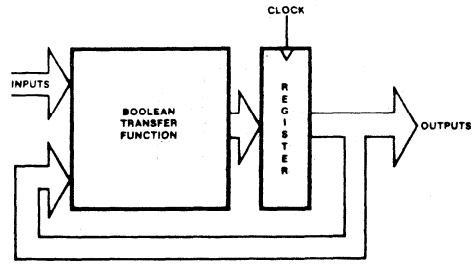

Figure 2: Sequential Function

Both the combinatorial and the sequential functions may have the optional characteristic of three-state outputs. That is, the output function may be disconnected as a driving source by placing the outputs in a high impedance state (High-Z)

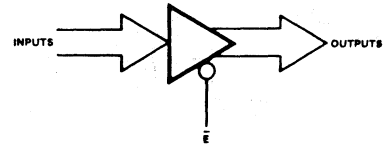

Figure 3: Three-State Output Gate

Definition of Terms

Before we can rigorously define the basic logical primitives, we first need a precise language which unambiguously describes the transfer functions.

Definitions:

= Equality, after the propogation time, t_{PD}, from any input change.

:= Replaced by, after the propogation delay, t_{PD}, from the low to high transition of the clock.

IF Conditional Equality, after the propogation delay, t_{PD}, from the enabling condition. Otherwide, high impedance (High-Z).

/ Complement, Boolean operator, placed to the left of a Boolean variable.

* AND, Boolean operator.

+ OR, Boolean operator.

:+: XOR, Boolean operator.

( ) Parenthetical separators.

hierarchical order / * + :+:
where / is evaluated first.

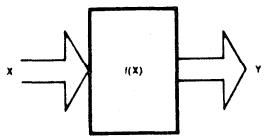
Given these definitions, we can formulate rigorous logical descriptions of standard SSI/MSI functions.

Rigorous Statement of Primitives

We can now state, in equation form, a generalized set of equations suitable for LSI implementation.

For an input vector X and an output vector Y, a combinatorial function is described as,

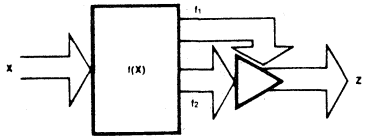
$$Y = f(X)$$



where f is Boolean sum of products transfer function.

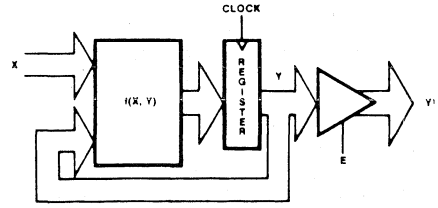
A three state combinatorial function is described as,

$$IF\ (\ f_1(X)\ )\quad Z = f_2(X)$$



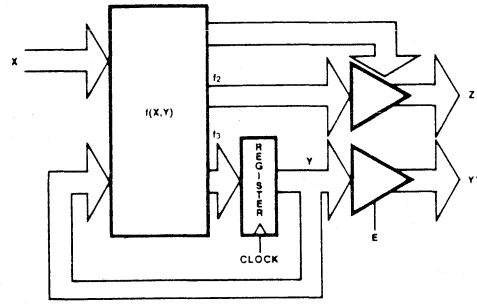
A sequential function is described as,

$$Y := f(X, Y)$$
$$IF(E)\ Y^1 = Y$$



Combining sequential, combinatorial and three-state we now have,

$$IF\ (\ f_1(X, Y)\ )\ Z = f_2(X, Y)$$
$$Y: = f_3(X, Y)$$
$$IF\ (E)\quad Y^1 = Y$$



The above generalized Boolean functions are a super set of virtually all of the standard SSI/MSI functions.

For an LSI implementation to provide a better solution than existing SSI/MSI it must meet the following requirements:

1. Reduce package count
2. Match or improve performance.
3. Reduce System Cost.

The Programmable Array Logic (PAL) family was designed to meet these requirements.

THE PROGRAMMABLE LSI SOLUTION

A family of 15 PAL devices are manufactured by Monolithic Memories, Inc. which provide a range of logic functions including combinatorial, three-state, sequential, and arithmetic sequential. The TTL devices utilize a platinum Silicide Schottky process and Titanium Tungsten fuse links to form a single programmable emitter follower AND array which drives a fixed OR array as shown in Figure 4.

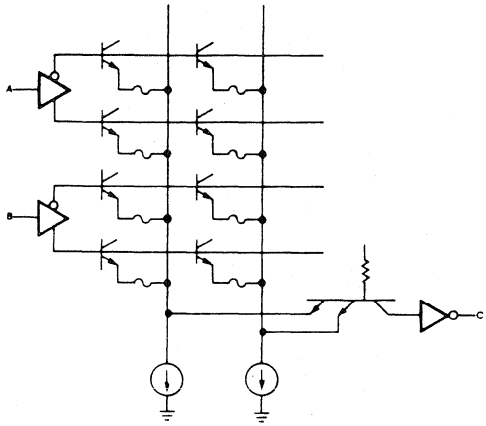

Figure 4: AND-OR Circuit Diagram

The AND-OR array is described logically by a distributed AND gate symbol to facilitate ease of drawing. (Conventional AND symbol with single input rail where X indicates a diode and a fuse.)

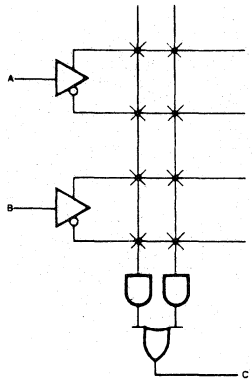

Figure 5: AND-OR Logic Diagram

Basic Combinatorial Cell

The basic combinatorial cell implements the sum of products over a range of input-output pin ratios. All combinatorial output drivers conform to the Low Power Schottky TTL electrical characteristics for totempole drivers. e.g., I_{OL} = 8mA.

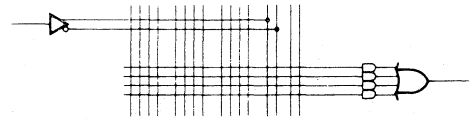

Figure 6: Combinatorial Cell

Programmable I/O

A more complex combinatorial cell incorporates three-state drivers where the enable function is programmable. This allows a pin to be allocated as an input, an output, or dynamically I/O. All three-state outputs are designed to meet the Low Power Schottky TTL three-state bus standard of 24mA I_{OL}.

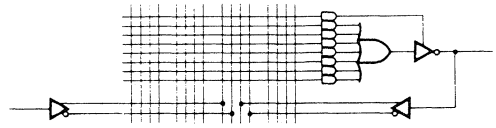

Figure 7: Programmable I/O Cell

Registered Feedback Cell

A D-type Register at the output of a combinatorial cell forms the state machine primative. This cell can be used to implement regular state sequences such as count and shift, but more importantly, it can be used to implement random state sequences not available as standard functions.

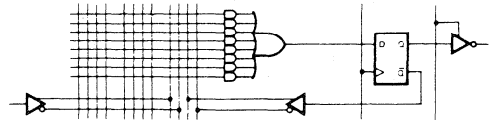

Figure 8: Registered Feedback Cell

Arithmetic Cell

The most complex of the PAL cells includes an exclusive OR and a gated feedback to implement basic arithmetic operations such as greater than, less than, add and subtract.

The register forms an accumulator while the combinatorial network forms an ALU.

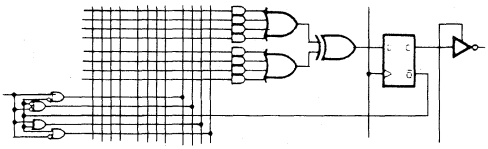

Figure 9: Arithmetic Cell

Structured Pinouts

The 15 PALs are packaged in the popular 20 pin 300 mil wide Skinny DIP™. Input pins are generally to the left while output pins and I/O pins are to the right. This feature conveniences PC board layout and allows the Pinout/Logic Symbol to be a Block diagram.

PALs: Programmable Logic Functions Help Minimize Hardware

John Birkner/Wescon 79

Taking advantage of PROM on-the-spot programmability, the PALs offer a range of logic replacement capabilities — from random gates to complex arithmetic circuits. Using a programmable AND array to feed a fixed OR array, PALs permit compact realizations of sum-of-products expressions. This paper will provide an overview of the PAL family, a basic understanding of the PAL structure, some guidelines as to how systems can be partitioned to take advantage of the PALs and a design example.

The Problem

A look at the three[1] billion dollar digital integrated circuit marketplace provides insight into the needs of systems designers. First, Figure 1 breaks out the dollar marketplace into four major areas.

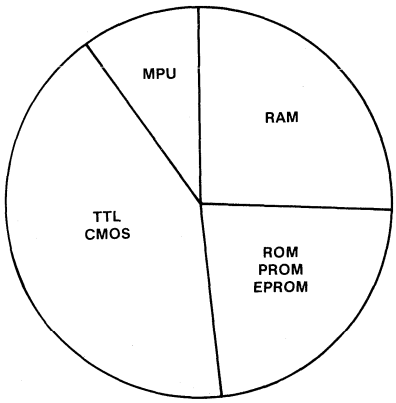

Figure 1. $ Digital IC Marketplace

As the average system should contain a similar percentage cost of silicon for MPU, RAM, ROM/PROM/EPROM, TTL/CMOS, it is of particular interest to note the high percentage of Random Logic; e.g., TTL/CMOS. In spite of the great microprocessor revolution, the systems marketplace spends 35% of its dollars on random logic. To make this point shockingly clear, Figure 2 shows the three billion *unit* marketplace for MPU, RAM, ROM/PROM/EPROM, TTL/CMOS.

The systems marketplace devotes 87% of its IC chip count to TTL/CMOS. Dramatic evidence of this fact is demonstrated by observing the high percentage of 16 and 20 pin DIPs on today's small board computers and microprocessor systems.

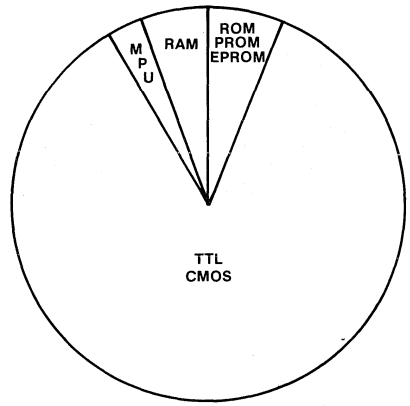

Figure 2. Unit Digital IC Marketplace

Comparison of Figure 1 and Figure 2 along with some quick arithmetic shows the ASP (Average Selling Price) of the MPU, RAM, ROM/PROM/EPROM is around $4.00, whereas, the ASP of TTL/CMOS is around $.50. As a ball-park cost of placing an IC on a board is around $1.00 (board cost, assembly and test), the major cost of using the TTL/CMOS is the overhead, not the silicon.

Programmable Logic

Semiconductor manufacturers have been busy designing a host of programmable logic devices to meet the challenge of integrating this last holdout to LSI, namely random logic gates/muxes/decoders/flip-flops. For the system designer, programmable logic holds the promise of balancing the level of integration of his digital ICs while still further reducing the printed circuit board real estate required per system. Further, programmable logic gives the user a custom IC which he can buy as an inexpensive high volume/multiple sourced virgin device, then customize on commonly available programmers.

The first and most common programmable logic device suitable for logic replacement is the bipolar PROM. Available in a wide variety of input/output pin ratios, the PROM transforms an input variable (address lines) to a desired output condition (data out) with a propagation delay in the range of 50 to 80 nanoseconds. Normally thought of as a memory, the PROM is a sum of products, boolean transfer function which will transform all possible input vectors to any desired output vector. Caution! PROM outputs glitch during the propagation delay of any input change. This is true as any input change causes the source of data to move from one product to another where there may be a gap, overlap, or a third product causing unpredictable outputs. Figure 3 shows a PROM architecture in sum of products form.

PROM

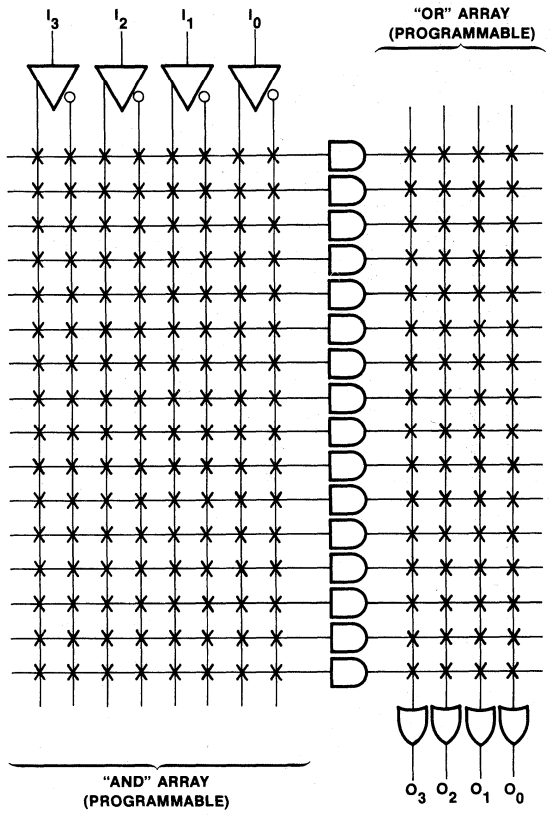

Figure 4. FPLA Architecture

The first programmable logic device designed specifically for logic replacement was the FPLA. The programmable AND array overcomes the previous glitch problem in the PROM and allows more input variables. Figure 4 shows an FPLA architecture with programmable AND and programmable OR arrays.

A recent entry into the programmable logic marketplace is the PAL^2 (Programmable Array Logic). The PAL architecture is a complement of the PROM architecture as the AND array is programmable and the OR array is fixed. The architecture affords simple programming in existing PROM programmers plus a fast propagation time of 40 nanoseconds maximum over the commercial V_{CC} and temperature ranges. In addition, PALs have additional output options of Registers and I/O as summarized in Figure 6. Figure 5 shows the PAL architecture with programmable AND array and fixed OR array.

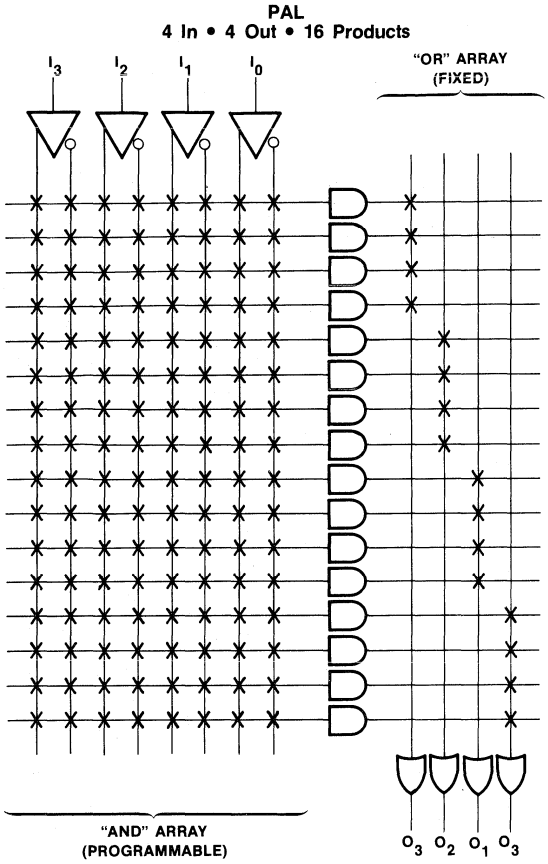

Figure 5. PAL Architecture

Figure 6. Programmable Logic Summary

PALs — A Family of 15

Fifteen PALs provide a family approach to the replacement of random logic gates, muxs, decoders and flip-flops at a greater than 4 to 1 chip count reduction. The die sizes range from 13K square mils to 19K square mils which compare to 2K PROM and 4K PROM die sizes which sell in the $2.00 to $4.00 range. Two major semiconductor manufacturers are now supplying PALs with a third to appear shortly.

A description of the family is shown in Table 1 below.

PART NUMBER	DESCRIPTION
PAL10H8	Octal 10 Input And-Or Gate Array
PAL12H6	Hex 12 Input And-Or Gate Array
PAL14H4	Quad 14 Input And-Or Gate Array
PAL16H2	Dual 16 Input And-Or Gate Array
PAL16C1	16 Input And-Or/And-Or-Invert Gate Array
PAL10L8	Octal 10 Input And-Or-Invert Gate Array
PAL12L6	Hex 12 Input And-Or-Invert Gate Array
PAL14L4	Quad 14 Input And-Or-Invert Gate Array
PAL16L2	Dual 16 Input And-Or-Invert Gate Array
PAL16L8	Octal 16 Input And-Or-Invert Gate Array
PAL16R8	Octal 16 Input Registered And-Or Gate Array
PAL16R6	Hex 16 Input Registered And-Or Gate Array
PAL16R4	Quad 16 Input Registered And-Or Gate Array
PAL16X4	Quad 16 Input Registered And-Or-Xor Gate Array
PAL16A4	Quad 16 Input Registered And-Carry-Or-Xor Gate

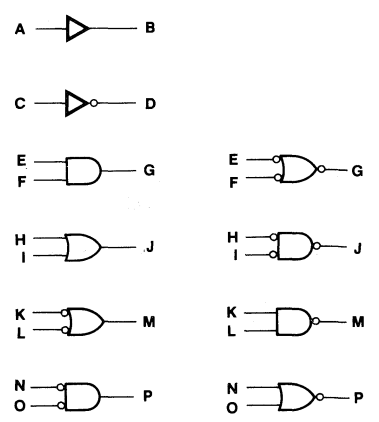
Table 1. PAL Family

Ranging in complexity from simple gates to complex arithmetic functions the PAL Family can functionally replace up to 90% of the 7400 Series TTL.

A Simple Example

To demonstrate a PAL implementation, consider the following Boolean functions:

```
B = A
D = /C
G = E * F
J = H + I
M = /K + /L
P = /N * /O
```



Choosing the PAL10H8, these functions are now implemented as shown in the logic symbol of Figure 7.

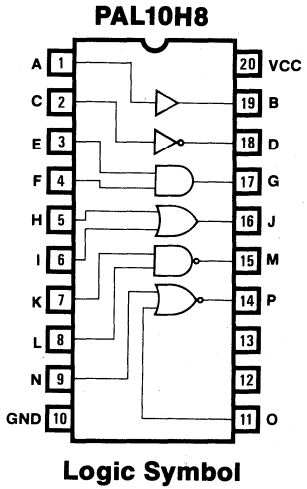


Figure 7. Example Gates Logic Symbol

The functions are described by the logic diagram of Figure 8. The buffer which connects Pin 1 (A) to Pin 19 (B) is formed by the single "X" placed at the intersection of product term 0 (top horizontal line) and input line 2 (far left vertical line). The "X" is a shorthand expression for an intact fuse connecting the product line (AND gate) to the input line thru an NPN transistor. The absence of an "X" indicates a blown fuse. The AND gate is formed by two "Xs" on the same line which signifies ANDing as all "Xed" inputs on the single rail AND symbol are ANDed together. The OR function is formed by two "Xs" on different product lines.

This example has shown the implementation of common gate structures. The versatility of the PAL is demonstrated by some not so common gate structures shown below. Figure 9 shows a PAL implementation of those gates.

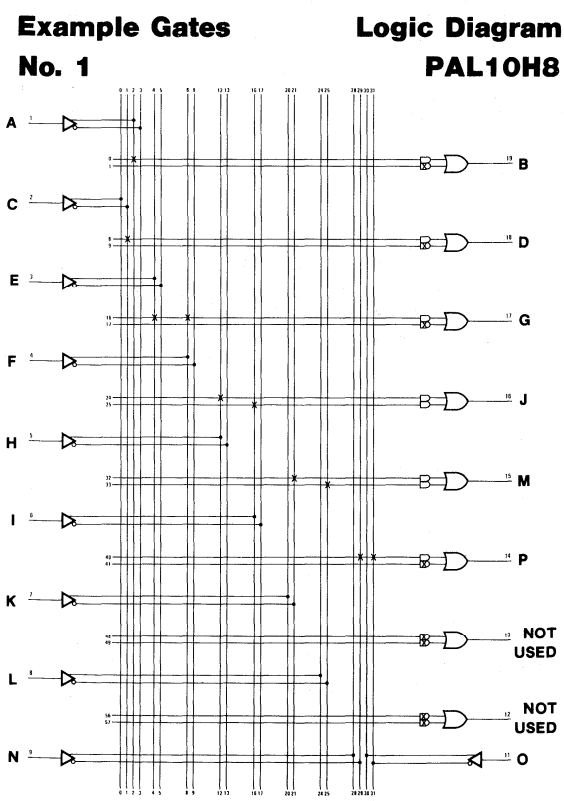

Figure 8. Example Gates Logic Diagram

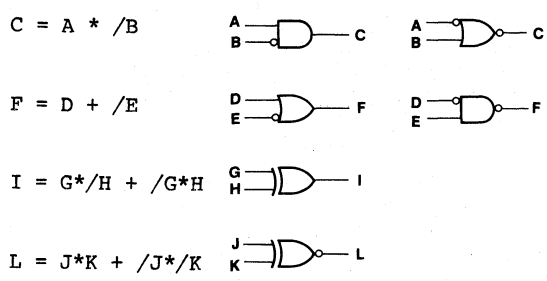

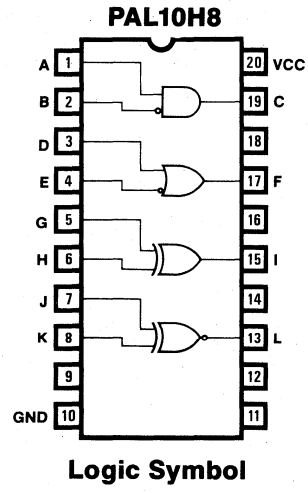

Figure 9. Example Gates Logic Symbol

Partitioning System Logic for PALs

The sum of products Boolean transfer function is the common denominator and basic primitive of all digital logic systems. From the sum of products, not only can all the gate functions be derived, but so also can latches, edge triggered registers, MUXs, encoders and decoders. The first nine PALs (PAL10H8 thru PAL16L2) implement a variety of input/output pin ratios and product terms per output. Input pin loading is less than 0.25 mA while output drive is 8 mA sink and 3.2 mA source. A typical gate configuration is shown in Figure 10.

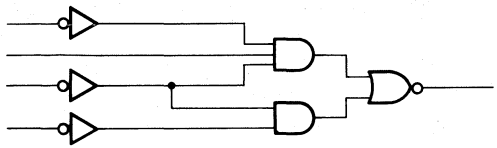

Figure 10. Typical Sum of Products

Three-state buses are commonly used in TTL systems to reduce interconnect densities by sharing signal lines. The PAL16L8 thru PAL16A4 output drivers are all three-state outputs which sink 24 mA, compatible with the low power Schottky three state standard. This 24 mA sink is sufficient to drive many standard buses including the Intel Multibus.

The PAL three-state outputs are of two types. First, the register outputs are controlled by a common enable pin for parallel bus enabling. Second, the combinatorial outputs are individually controlled by a product term. This feature allows an open collector configuration to be logically derived as required in bus-shared control signals such as memory transfer acknowledge. The latter type is shown in Figure 11.

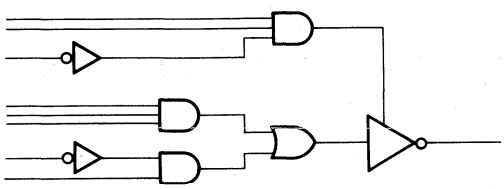

Figure 11. Three-State Driver with Individual Enable

Latch circuits can be implemented as shown in Figure 12. The PAL16L8 is commonly used for this function as six of the eight outputs are internally connected to an array input line. Edge triggered flip flops can be constructed from two latches where individual clocking is required.

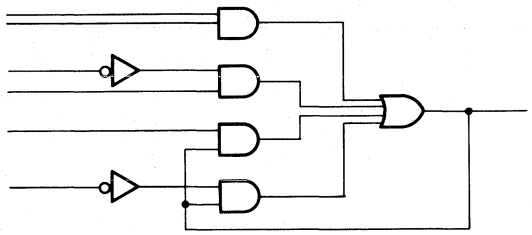

Figure 12. Latch Circuit

Control logic containing D-type or J-K flip-flops is common among memory, processor and controller interfaces. This logic can generally be classified as state-sequence logic or small-state machines. The PAL types PAL16R8, PAL16R6 and PAL16R4 contain output registers with feedback which can implement simple state-sequences. Figure 13 shows a typical control logic configuration.

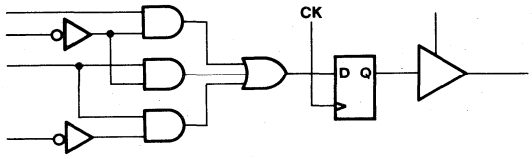

Figure 13. Registered Sum of Products

Design Example

A typical control logic problem is the memory to processor handshake on memory transfer used in many computer architectures. The processor makes a transfer request by activating a request line (REQ) and specifies a read or write operation on a Read/Write line (R/W).

During a read operation the processor waits for a Data Available signal at which time the data bus is sampled and the request line lowered, completing the cycle. During a write operation, the processor places data on the bus and waits for a write complete signal after the write cycle is finished. Upon write complete, the request line is lowered, completing the cycle. This handshaking operation is described in the timing diagram of Figure 14.

The memory-board logic to implement this function may be designed with gates and edge triggered flip flops as shown in Figure 15. This particular design would require about five SSI/MSI packages. The same design is implemented in Figure 16 by a single PAL16R8.

Gate Arrays Logjam Test Engineering

John Birkner/Wescon 80

Gate arrays give logic designers the ability to create numerous semi-custom ICs in a relatively short amount of time. The number of unique patterns may vary from 10 to 200 for a typical new systems design. When the new system is transferred to production, the Test Engineering department is faced with one to two work weeks per pattern. Systems manufacturers, using gate arrays for the first time, are cautioned to plan for the increased demands on Test Engineering, or they will find a logjam in testing. This paper examines the problems and solutions in testing gate arrays and semicustom logic.

Definitions

Many terms have recently appeared to describe the host of integrated circuits which are configured late in the manufacturing process. These ICs are most generally described as uncommitted logic. More specifically, there are classifications such as semicustom logic, gate arrays, programmable logic arrays, field programmable logic arrays, programmable array logic and hard array logic.

All of these devices provide the systems designer with common advantages; higher board density, lower power, higher speed, etc. For the purposes of this discussion, they will all be classified as gate arrays. The specific example chosen for this discussion will be hard array logic, HAL, and its programmable counterpart, PAL.

Replacing PCBs With Silicon

The problem of testing digital logic is steadily moving from the printed circuit board (PCB) to the LSI chip. In the case of gate arrays, the etched lines which connected the random assortment of SSI/MSI gates and flip flops is being lifted from the PCB and placed on silicon. Test engineers, who complain that the new gate arrays create a testing problem, forget that they once tested that same logic on the PCB.

Gate arrays don't create new testing problems; they just move the old testing problem from the PCB onto the silicon chip. This may be viewed as an opportunity to structure the testing problem in the more regular environment of a fixed package, structured array. We must be more clever, however, in generating our test programs without the aid of internal test points which were available on the PCB.

The Logjam

Testing LSI logic is certainly not a new problem. Standard LSI chips, like the microprocessor and the variety of special purpose controllers, are regularly tested. The new problem lies in large numbers of gate array patterns which can be quickly designed and fabricated.

For a single systems design, a few design engineers can create as many as 200 new and unique gate array patterns. At one week per pattern, this translates to four work years of test engineering time.

Test Vectors

Test programs for LSI devices consist of electrical, switching and functional tests. The electrical and switching characteristics are tested by the semiconductor manufacturer, and may be optionally tested by the user. The function test is supplied to the manufacturer by the user. It consists of a list of test vectors, which specify for each pin, instructions for driving high or low, or testing high or low, or not driving and not testing.

The time consuming job for the user is the generation of test vectors. At this time, work is under way toward automating the generation of test vectors, thus far with some success. Even with automated programs, manual intervention and human interaction make the task time consuming. In addition, the automated programs are not self starting. They need manually generated seed vectors.

Responsibility of the Designer

When a new system is transferred to production, the systems designer hands over the responsibility for the system to the test engineering department who now determines how and what tests should be performed to ensure proper operation of the system. At this pont the systems designer transmits the necessary information for understanding the system operation. Unfortunately, much information is lost at this point. All too often continuity is broken and while the systems designer is off designing the next great project, the test engineer is left to struggle with understanding how the system works. This struggle is exaggerated when system complexity is increased by the use of gate arrays.

It is the design engineer who best knows the operation of his gate array design, and it is the design engineer who can quickly specify a few seed vectors to give the test engineer a starting point or to give the automatic vector generator a starting point. The problem at hand is to entice designers into this task.

Tools for the Designer

The first step toward luring the designer into providing test vector information is to give him a standard format for specifying the vectors. The format should be easy to understand and convenient to write down either on paper or, preferably, into a computer terminal. Fortunately, there is a format that already exists, which with slight modification, will suit our purpose. The format is the well known "Function Table" format found in the Texas Instruments TTL *Databook* and accepted by JEDEC. Let us now redefine that format as follows:

Function Table

The function table begins with the keyword, "FUNCTION TABLE." It is followed by a pin list which symbolically

defines each pin. The pin list is followed by a dashed line, e.g.-------(length optional), which in turn is followed by a list of vectors, one vector per line. A vector is a sequence of states in order of the pin list followed by an optional comment. The vector list is followed by another dashed line.

Definition of States

```
H    HIGH LEVEL

L    LOW LEVEL

C    TRANSITION FROM LOW TO HIGH

X    IRRELEVANT

Z    OFF (HIGH IMPEDANCE)
```

With this definition, let us now write a function Table for a simple two input AND Gate having inputs A and B with output C.

```
FUNCTION TABLE

A  B  C
--------------
L  L  L
H  L  L
L  H  L
H  H  H
--------------
```

The second step in persuading the designer into providing test vectors is to combine the Function Table with the gate array design specification so as to provide one document with design and functional information.

The real objective here is to give the designer a format to mimic the data sheet format which he is accustomed to seeing for standard TTL components.

This is the approach taken to specify designs for Hard Array Logic, HAL, the mask version of Programmable Array Logic, PAL. The design specification is a computer file which contains part number, name of device, symbolic pin list, design equations and a Function Table.

Outsmarting the Designer

Providing just the format for specifying test vector information is not likely to seduce the busy systems designer into such a boring task. We have to be a bit more clever to snare him. Fortunately, we can charm him with a decoy, gate array simulation.

Gate Array Simulation

The systems designer is impressed with computer-aided tools that help him in his design task. What if he had a computer program which would simulate his gate array design and tell him if it works as he wants it to? Would he use it? This author is betting that he will.

A simulator has been added to the PAL Assembler, PALASM, which reads the Function Table and simulates the device as specified in the state equations which specify the transfer function. Inconsistencies between the Function Table and the transfer function are reported as errors. The simulator checks the operation of the gate array against the equations, thus verifying the designer's intention for the device. What the designer perhaps will never realize is that he has also provided seed vectors for test engineering.

Future Considerations

The test vector generation problem is generally considered to be one of starting with the transfer function and synthesizing the state table. The engineering problem is just the reverse. That is, the designer starts off with the state table and he synthesizes the transfer fucntion. A challenge for gate array manufacturers is to provide their customers with computer-aided tools to automatically generate gate arrays from state tables.

High Level Language for Programmable Array Logic

John Birkner/Wescon 81

Introduction

Standards for silicon definition languages are under consideration by semiconductor manufacturers in order to provide a means of communication between vendor and customer for specifying semicustom ICs. The objective of an industry standard language is to provide a hardware-independent, manufacturer-independent, user-independent, unambiguous definition of an IC. So far, the debates in subcommittees, ranging from what symbol to use for an AND gate to whether there should be a standard at all, would indicate that many standards will evolve.

Digital machines are most efficiently defined by explicit Boolean state equations. These equations are unambiguous, they are easily simulated, and they can be readily expanded to systems of machines. This paper discusses such an equation-implemented language as applied to Programmable Array Logic.

Logic Schematics Fall Short

The predominant hardware description language of today is the logic schematic. The predominant hardware verification technique of today is the hardware prototype. These tools are inadequate for the development of silicon hardware.

The logic schematic may be a fine tool for human understanding of a digital system, but is is quite awkward to input it into a computer for generation of photolithographic plates used in making semicustom or custom ICs. Likewise, the hardware prototype is an awkward means of design verification of an IC. Differences in propagation delay, circuit implementation, and logic implementation degrade the effectiveness of the hardware emulation. Also, the manual interaction increases the probability of error, especially in high complexity logic systems. The cost of an error in making an IC is tens and thousands of dollars and months of delay. The cost of multiple errors is years of delay, which often kills the project.

TTL 7400-series logic schematics are commonly submitted to semiconductor vendors for implementation in semicustom or custom ICs. The semiconductor manufacturer then makes a choice as to whether to implement the function exactly as shown on the schematic, or to optimize the design to the particular circuit technique.

If the vendor implements the TTL function exactly as shown, the user will pay the price of extra die size. If the vendor optimizes the design, he must understand it, at a high cost of engineering development time. In either case, the vendor is subject to the risk that the IC version will not operate identically to the TTL version. Figure 1 demonstrates the risk of copying TTL logic directly. The 74LS161 four-bit counter is asynchronously set to zero when the count reaches 12. Will this circuit hazard operate the same when it is forged into one piece of silicon? Or, will it oscillate?

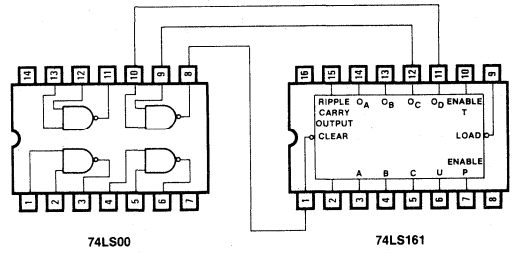

Figure 1. Common Circuit Hazard

Testability is another common trap for the semiconductor vendor. The user's TTL prototype may work fine in his system and also be virtually untestable. A frequent example is the clock phase generator which has no initialize control pin. Without a known initial state, the tester must sequence the device until a recognizable pattern is observed. Most IC testers do not have this capability.

Discipline for Semicustom Users

Successful use of semicustom logic is best achieved when the user understands the vendors manufacturing cycle and when the user participates in that cycle. The production of a semicustom IC is basically the same as that required for a standard IC, with the exception that the user takes part in some of the steps. The major steps are outlined below.

1. Define
2. Simulate
3. Build
4. Test

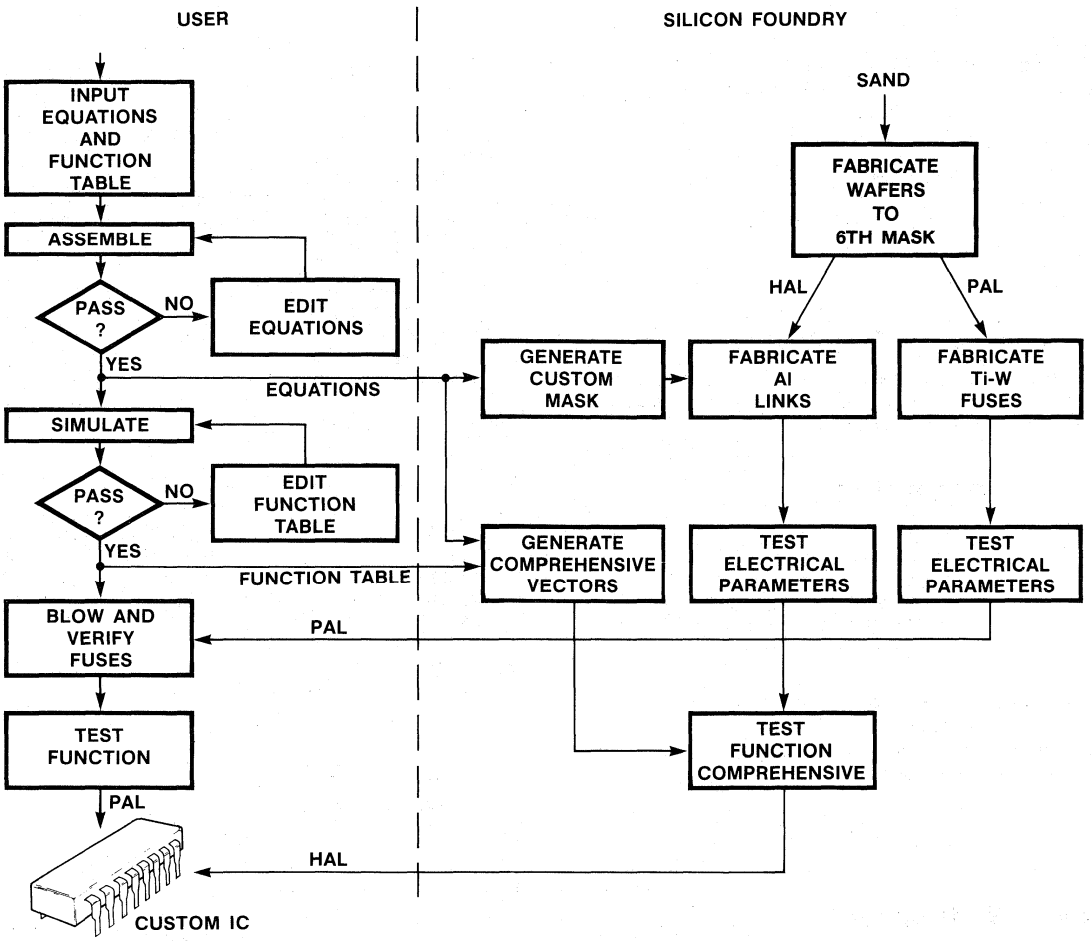

Figure 2. PAL/HAL Development Cycle

These four steps are demonstrated in the diagram above for the development of PAL, Programmable Array Logic, and HAL, Hard Array Logic. The user begins by defining his logic functions using Boolean logic equations. These equations are automatically assembled into hardware routing instructions by the PAL assembler, PALASM. Syntax errors are reported. The user edits and reassembles, repeating the process until no syntax errors are reported.

The user then inputs a Function Table to verify his design. PALASM simulates the PAL/HAL, using the equations, and executes the Function Table on the simulated device. Simulation errors are reported. The user corrects the Function Table and/or equations until no simulation errors occur. This completes the design verification process.

The automatic routing instructions from PALASM may now be used to generate a custom mask for fabrication of a HAL. Aluminum links implement the logic equations, providing a semicustom device. Comprehensive Test vectors are generated using the Function Table as seed vectors. One hundred percent coverage for stuck-high/low test conditions is usually achieved with fewer than 200 vectors.

HALs are cost-effective in volumes of 1000 or above. For lower volumes, the programmable version, PAL, may be programmed by the user on low-cost programmers. The HAL is unique in that it is a semicustom device that has a programmable prototype, the PAL.

Equations Simplify

"Our life is frittered away by detail . . . Simplify, simplify."

Thoreau

Hardware Description Languages most often use network topology to specify the interconnection of gates and flipflops. Propagation delays are individually specified; wire lists are generated; long lists of generally unreadable network interconnection are printed out.

Explicit Boolean equations are a much simpler method of writing logic functions. They are easily interpreted and can be readily commented. An example of an AND gate feeding an OR gate with a comment is shown below.

F = A*B + C ; This is a comment

The AND gate is symbolized by "*" and the OR gate is symbolized by "+".

Function Table Simulates

Equations are easily simulated and can be exercised by HIGHs and LOWs specified in a Function Table. A simulation of the above equations is implemented in the Function Table below.

```
FUNCTION TABLE

A B C  F
-------------------------
L L L  L TEST OUTPUT LOW
H H L  H TEST OUTPUT HIGH
L L H  H TEST OUTPUT HIGH
-------------------------
```

The simulation is now used to generate test vectors and may also be used as seed vectors for automatic generation of comprehensive test vectors until a 100% coverage of stuck-high/low conditions is achieved.

Design Verification

The design verification performed by a user in the PAL/HAL development cycle of Figure 2 is now demonstrated in a real example. What follows is a computer printout from the terminal of a PAL Development System during a development session. Two errors are intentionally made during the session. First, a syntax error, then a simulation error is made to demonstrate the corrective feedback in the development cycle.

Programmable Array Logic Family

PAL® Series 20

U.S. Patent 4124899

March 1981

Features/Benefits

- **Programmable replacement for conventional TTL logic.**
- **Reduces IC inventories substantially and simplifies their control.**
- **Reduces chip count by 4 to 1.**
- **Expedites and simplifies prototyping and board layout.**
- **Saves space with 20-pin SKINNY DIP® packages.**
- **High speed: 25ns typical propagation delay.**
- **Programmed on standard PROM programmers.**
- **Programmable three-state outputs.**
- **Special feature reduces possibility of copying by competitors.**

Description

The PAL family utilizes an advanced Schottky TTL process and the Bipolar PROM fusible link technology to provide user programmable logic for replacing conventional SSI/MSI gates and flip-flops at reduced chip count.

The family lets the systems engineer "design his own chip" by blowing fusible links to configure AND and OR gates to perform his desired logic function. Complex interconnections which previously required time-consuming layout are thus "lifted" from PC board etch and placed on silicon where they can be easily modified during prototype check-out or production.

The PAL transfer function is the familiar sum of products. Like the PROM, the PAL has a single array of fusible links. Unlike the PROM, the PAL is a programmable AND array driving a fixed OR array (the PROM is a fixed AND array driving a programmable OR array). In addition the PAL provides these options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback
- Arithmetic capability

PAL® is a registered trademark of Monolithic Memories

PART NUMBER	PKG	DESCRIPTION
PAL10H8	N,J,F	Octal 10 Input And-Or Gate Array
PAL12H6	N,J,F	Hex 12 Input And-Or Gate Array
PAL14H4	N,J,F	Quad 14 Input And-Or Gate Array
PAL16H2	N,J,F	Dual 16 Input And-Or Gate Array
PAL16C1	N,J,F	16 Input And-Or/And-Or-Invert Gate Array
PAL10L8	N,J,F	Octal 10 Input And-Or-Invert Gate Array
PAL12L6	N,J,F	Hex 12 Input And-Or-Invert Gate Array
PAL14L4	N,J,F	Quad 14 Input And-Or-Invert Gate Array
PAL16L2	N,J,F	Dual 16 Input And-Or-Invert Gate Array
PAL16L8	N,J,F	Octal 16 Input And-Or-Invert Gate Array
PAL16R8	N,J,F	Octal 16 Input Registered And-Or Gate Array
PAL16R6	N,J,F	Hex 16 Input Registered And-Or Gate Array
PAL16R4	N,J,F	Quad 16 Input Registered And-Or Gate Array
PAL16X4	N,J	Quad 16 Input Registered And-Or-Xor Gate Array
PAL16A4	N,J	Quad 16 Input Registered And-Carry-Or-Xor Gate

Unused inputs are tied directly to V_{CC} or GND. Product terms with all fuses blown assume the logical high state, and product terms connected to both true and complement of any single input assume the logical low state. Registers consist of D type flip-flops which are loaded on the low to high transition of the clock. PAL Logic Diagrams are shown with all fuses blown, enabling the designer use of the diagrams as coding sheets.

The entire PAL family is programmed on inexpensive conventional PROM programmers with appropriate personality and socket adapter cards. Once the PAL is programmed and verified, two additional fuses may be blown to defeat verification. This feature gives the user a proprietary circuit which is very difficult to copy.

Programming

PAL fuses are programmed using a low-voltage linear-select procedure which is common to all 15 PAL types. The array is divided into two groups, products 0 thru 31 and products 32 thru 63, for which pin identifications are shown in Pin Configurations below. To program a particular fuse, both an input line and a product line are selected according to the following procedure:

Step 1 Raise Output Disable, OD, to V_{IHH}

Step 2 Select an input line by specifying I_0, I_1, I_2, I_3, I_4, I_5, I_6, I_7 and L/R as shown in Table 1.

Step 3 Select a product line by specifying A_0, A_1 and A_2 one-of-eight select as shown in Table 2.

Step 4 Raise V_{CC} (pin 20) to V_{IHH}

Step 5 Program the fuse by pulsing the output pins, O, of the selected product group to V_{IHH} as shown in Programming Waveform.

Step 6 Lower V_{CC} (pin 20) to 6.0 V

Step 7 Pulse the CLOCK pin and verify the output pin, O, to be Low for active Low PAL types or High for active High PAL types.

Step 8 Lower V_{CC} (pin 20) to 4.5 V and repeat step 7.

Step 9 Should the output not verify, repeat steps 1 thru 8 up to five (5) times.

This procedure is repeated for all fuses to be blown (see Programming Waveforms).

To prevent further verification, two last fuses may be blown by raising pin 1 and pin 11 to V_P. V_{CC} is not required during this operation.

Voltage Legend

L = Low-level input voltage, V_{IL}
H = High-level input voltage, V_{IH}
HH = High-level program voltage, V_{IHH}
Z = High impedance (e.g., 10kΩ to 5.0V)

Programmable Array Logic Family

PAL® Series 24

U.S. Patent 4124899

Features/Benefits

- **Programmable replacement for conventional TTL logic.**
- **Reduces IC inventories substantially and simplifies their control.**
- **Reduces chip count by 5 to 1.**
- **Expedites and simplifies prototyping and board layout.**
- **Saves space with 24-pin SKINNYDIP™ packages.**
- **Programmed on standard PROM programmers.**
- **Programmable three-state outputs.**
- **Special feature reduces possibility of copying by competitors.**

Description

The PAL Series 24 family complements the PAL Series 20 family by providing two additional inputs and two additional outputs, allowing more complex functions in a single package. This new family is made feasible by the Monolithic Memories new and revolutionary 24-pin SKINNYDIP™.

In addition to providing more logic function per chip, 24 pins allows for many natural functions which were previously unavailable in skinny 300 mil-wide packages. Examples include:

- 8-bit parallel-in parallel-out counters
- 8-bit parallel-in parallel-out shift registers
- 16-Line-to-1-Line Multiplexors
- Dual 8-Line-to-1-Line Multiplexors
- Quad 4-Line-to-1-Line Multiplexors

These natural functions provide twice the density of traditional 16-pin packages.

The PAL family utilizes an advanced Schottky TTL process and the Bipolar PROM fusible link technology to provide user programmable logic for replacing conventional SSI/MSI gates and flip-flops at reduced chip count.

The family lets the systems engineer "design his own chip" by blowing fusible links to configure AND and OR gates to perform his desired logic function. Complex interconnections which previously required time-consuming layout are thus "lifted" from PC board etch and placed on silicon where they can be easily modified during prototype check-out or production.

The PAL transfer function is the familiar sum of products. Like the PROM, the PAL has a single array of fusible links. Unlike the PROM, the PAL is a programmable AND array driving a fixed OR array (the PROM is a fixed AND array driving a programmable OR array). In addition the PAL provides these options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback

PART NUMBER	PKG	DESCRIPTION
PAL12L10	J,N	Deca 12 Input And-Or-Invert Gate Array
PAL14L8	J,N	Octal 14 Input And-Or-Invert Gate Array
PAL16L6	J,N	Hex 16 Input And-Or-Invert Gate Array
PAL18L4	J,N	Quad 18 Input And-Or-Invert Gate Array
PAL20L2	J,N	Dual 20 Input And-Or-Invert Gate Array
PAL20C1	J,N	20 Input And-Or/And-Or Invert Gate Array
PAL20L10	J,N	Deca 20 Input And-Or-Invert Gate Array
PAL20X10	J,N	Deca 20 Input Registered And-Or-Xor Gate Array
PAL20X8	J,N	Octal 20 Input Registered And-Or-Xor Gate Array
PAL20X4	J,N	Quad 20 Input Registered And-Or-Xor Gate Array

Unused inputs are tied directly to V_{CC} or GND. Product terms with all fuses blown assume the logical high state, and product terms connected to both true and complement of any single input assume the logical low state. Registers consist of D type flip-flops which are loaded on the low to high transition of the clock. PAL Logic Diagrams are shown with all fuses blown, enabling the designer use of the diagrams as coding sheets.

To design a PAL, the user writes the logic equations using PAL DESIGN SPECIFICATION standard format (F108). This specification may be submitted to Monolithic Memories where it is computer processed and assigned a bit pattern number, eg P0123. Monolithic Memories accepts the PAL DESIGN SPECIFICATION in one of the three forms:

1. Computer generated listings.
2. Typed or hand-written forms F107 and F108.
3. Direct on line data transmission to Monolithic Memories Timeshare computer system via telephone (local telephone network to major U.S. cities, London and Paris) or TWX online Boston TWX No.).

The entire PAL family is programmed on inexpensive conventional PROM programmers with appropriate personality and socket adapter cards. Once the PAL is programmed and verified, two additional fuses may be blown to defeat verification. This feature gives the user a proprietary circuit which is very difficult to copy.

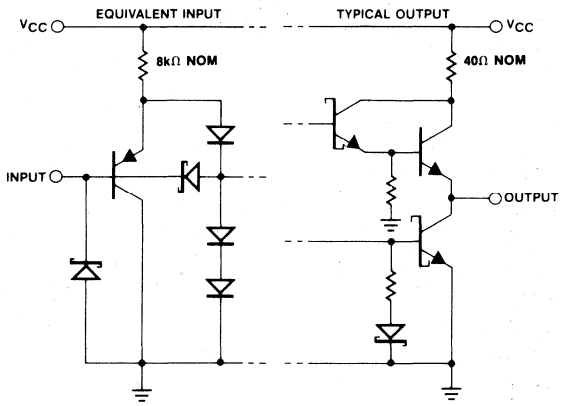
Schematic of Inputs and Outputs



Programming

PAL fuses are programmed using a low-voltage linear-select procedure which is common to all PAL types. The array is divided into two groups, products 0 thru 39 and products 40 thru 79, for which pin identifications are shown in Pin Configurations below. To program a particular fuse, both an input line and a product line are selected according to the following procedure:

Step 1 Raise Output Disable, OD, to V_{IHH}.

Step 2 Select an input line by specifying I_0, I_1, I_2, I_3, I_4, I_5, I_6, I_7, I_8, I_9 and L/R as shown in Table 1.

Step 3 Select a product line by specifying A_0, A_1 and A_2 one-of-eight select as shown in Table 2.

Step 4 Raise V_{CC} (pin 24) to V_{IHH}.

Step 5 Program the fuse by pulsing the output pins, O, of the selected product group to V_{IHH} as shown in Programming Waveform.

Step 6 Lower V_{CC} (pin 24) to 6.0 V.

Step 7 Pulse the CLOCK pin and verify the output pin, O, to be Low for active Low PAL types or High for active High PAL types.

Step 8 Lower V_{CC} (pin 24) to 4.5 V and repeat step 7.

Step 9 Should the output not verify, repeat steps 1 thru 8 up to five (5) times.

This procedure is repeated for all fuses to be blown (see Programming Waveforms).

To prevent further verification, two last fuses may be blown by raising pin 1 and pin 13 to V_P. V_{CC} is not required during this operation.

Hard Array Logic Family

HAL Series 20 Data Sheet

Features/Benefits

- Gate array equivalent of up to 200 gates.
- Semi-custom solution
- Reduces SSI/MSI chip count greater than 4 to 1.
- Prototype using field-programmable version — PAL.
- Cost savings up to 40% compared to PAL.
- Security link disabled for design secrecy.
- Test and simulation made simple with PALASM Function Table.
- Saves space with 20-pin SKINNYDIP™ packages.
- Power consumption is directly proportional to logic complexity.

Description

The HAL family utilizes standard Low-Power Schottky TTL process and automated mask pattern generation directly from logic equations to provide a semi-custom gate array for replacing conventional SSI/MSI gates and flip-flops at reduced chip count.

The family lets the systems engineer "design his own chip" by AND and OR gates to perform his desired logic function. Complex interconnections which previously required time-consuming layout are thus "lifted" from PC board etch and placed on silicon where they can be easily modified during prototype check-out or production.

The HAL transfer function is the familiar sum of products. Like the ROM, the HAL has a single array of selectable gates. Unlike the ROM, the HAL is a selectable AND array driving a fixed OR array (the ROM is a fixed AND array driving a selectable OR array). In addition the HAL provides these options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback
- Arithmetic capability

Unused inputs are tied directly to V_{CC} or GND. Product terms with all fuses blown assume the logical high state, and product terms connected to both true and complement of any single input assume the logical low state. Registers consist of D type flip-flops which are loaded on the low-to-high transition of the clock. HAL Logic Diagrams are shown with all fuses blown, enabling the designer to use the diagrams as coding sheets.

To design a HAL, the user first programs and debugs a PAL using PALASM and the "PAL DESIGN SPECIFICATION" standard format. This specification is submitted to Monolithic Memories where it is computer processed and assigned a bit pattern number, e.g. P01234.

PART NUMBER	PKG	DESCRIPTION
HAL10H8	J,N,F	Octal 10 Input And-Or Gate Array

HAL16R8	J,N,F	Octal 16 Input Registered And-Or Gate Array
HAL16R6	J,N,F	Hex 16 Input Registered And-Or Gate Array
HAL16R4	J,N,F	Quad 16 Input Registered And-Or Gate Array
HAL16X4	J,N,F	Quad 16 Input Registered And-Or-Xor Gate Array
HAL16A4	J,N,F	Quad 16 Input Registered And-Carry-Or-Xor Gate

Monolithic Memories accepts the PAL DESIGN SPECIFICATION in one of three forms:

1. Computer generated listing.
2. Typed or hand-written forms F109 and F110. See example on pages 6-7 and forms on pages 23-24.
3. Direct online data transmission to Monolithic Memories Timeshare computer system via telephone (local telephone network to major US cities, London and Paris) or TWX (online Boston TWX no.).

Monolithic Memories will provide a PAL sample for customer qualification. The user then submits a purchase order for a HAL of the specified bit pattern number, e.g. HAL14L4 P01234. See Ordering Information below.

Hard Array Logic Family
HAL Series 24 Data Sheet

Features/Benefits

- **Gate array equivalent of up to 300 gates.**
- **Semi-custom solution**
- **Reduces SSI/MSI chip count greater than 5 to 1**
- **Prototype using field-programmable version — PAL.**
- **Cost savings up to 40% compared to PAL**
- **Security link disabled for design secrecy.**
- **Test and simulation made simple with PALASM Function Table**
- **Saves space with 24-pin SKINNYDIP™ packages**

PART NUMBER	PKG	DESCRIPTION

HAL20X10	J,N,F	Deca 20 Input Registered And-Or-Xor Gate Array
HAL20X8	J,N,F	Octal 20 Input Registered And-Or-Xor Gate Array
HAL20X4	J,N,F	Quad 20 Input Registered And-Or-Xor Gate Array

Description

The HAL family utilizes standard Low-Power Schottky TTL process and automated mask pattern generation directly from logic equations to provide a semi-custom gate array for replacing conventional SSI/MSI gates and flip-flops at reduced chip count.

The family lets the systems engineer "design his own chip" by AND and OR gates to perform his desired logic function. Complex interconnections which previously required time-consuming layout are thus "lifted" from PC board etch and placed on silicon where they can be easily modified during prototype check-out or production.

The HAL transfer function is the familiar sum of products. Like the ROM, the HAL has a single array of selectable gates. Unlike the ROM, the HAL is a selectable AND array driving a fixed OR array (the ROM is a fixed AND array driving a selectable OR array). In addition the HAL provides thee options:

- Variable input/output pin ratio
- Programmable three-state outputs
- Registers with feedback
- Exclusive-OR gates

Unused inputs are tied directly to V_{CC} or GND. Product terms with all fuses blown assume the logical high state, and product terms connected to both true and complement of any single input assume the logical low state. Registers consist of D type flip-flops which are loaded on the low-to-high transition of the clock. HAL Logic Diagrams are shown with all fuses blown, enabling the designer to use the diagrams as coding sheets.

SKINNYDIP is a registered trademark of Monolithic Memories

To design a HAL, the user first programs and debugs a PAL using PALASM and the "PAL DESIGN SPECIFICATION" standard format. This specification is submitted to Monolithic Memories where it is computer processed and assigned a bit pattern number, e.g., P01234. Monolithic Memories accepts the PAL DESIGN SPECIFICATION in one of three forms:

1. Computer generated listing.
2. Typed or hand-written forms F107 and F108. See example on pages 7-30, 7-31 and forms on pages 7-42 and 7-43.
3. Direct online data transmission to Monolithic Memories Timeshare computer system via telephone (local telephone network to major US cities, London and Paris) or TWX (online Boston TWX no.).

Monolithic Memories will provide a PAL sample for customer qualification. The user then submits a purchase order for a HAL of the specified bit pattern number, e.g., HAL18L4 P01234. See Ordering Information below.

Octal Counter
SN54/74LS461

Features/Benefits

- **Octal counter for microprogram-counter, DMA controller and general purpose counting applications**
- **8 bits match byte boundaries**
- **Bus-structured pinout**
- **24-pin Skinny DIP® saves space**
- **3-state outputs drive bus lines**
- **Low current PNP inputs reduce loading**
- **Expandable in 8-bit increments**

Ordering Information

PART NUMBER	PACKAGE	TEMPERATURE
SN54LS461	JS	MIL
SN74LS461	NS, JS	COM

Description

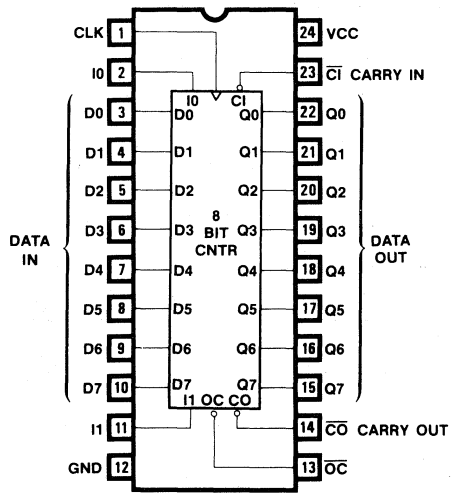
The LS461 is an 8-bit synchronous counter with parallel load, clear, and hold capability. Two function select inputs (I_0, I_1) provide one of four operations which occur synchronously on the rising edge of the clock (CLK).

The LOAD operation loads the inputs (D_7-D_0) into the output register (Q_7-Q_0). The CLEAR operation resets the output register to all LOWs. The HOLD operation holds the previous value regardless of clock transitions. The INCREMENT operation adds one to the output register when the carry-in input is TRUE ($\overline{CI}$ = LOW), otherwise the operation is a HOLD. The carry-out ($\overline{CO}$) is TRUE ($\overline{CO}$ = LOW) when the output register (Q_7-Q_0) is all HIGHs, otherwise FALSE ($\overline{CO}$ = HIGH).

The output register (Q_7-Q_0) is enabled when OC is LOW, and disabled (HI-Z) when $\overline{OC}$ is HIGH. The output drivers will sink the 24 mA required for many bus interface standards.

Two or more LS461 octal counters may be cascaded to provide larger counters. The operation codes were chosen such that when I_1 is HIGH, I_0 may be used to select between LOAD and INCREMENT as in a program counter (JUMP/INCREMENT).

Logic Symbol



Function Table

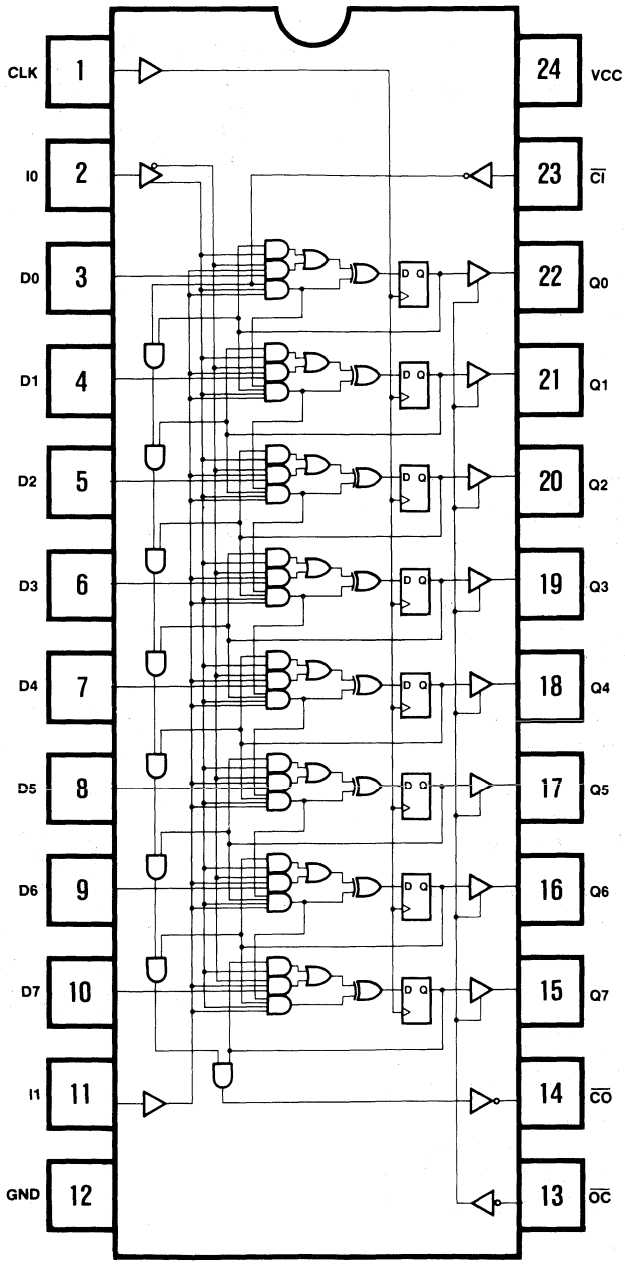
Octal Counter



Octal Shift Register
SN54/74LS498

Features/Benefits

- **Octal shift register for serial to parallel and parallel to serial applications**
- **8 bits match byte boundaries**
- **Bus-structured pinout**
- **24-pin SKINNYDIP™ saves space**
- **3-state outputs drive bus lines**
- **Low current PNP inputs reduce loading**
- **Expandable in 8-bit increments**

Ordering Information

PART NUMBER	PACKAGE	TEMPERATURE
SN54LS498	JS	MIL
SN74LS498	NS, JS	COM

Description

The LS498 is an 8-bit synchronous shift register with parallel load and hold capability. Two function select inputs (I_0, I_1) provide one of four operations which occur synchronously on the rising edge of the clock (CLK).

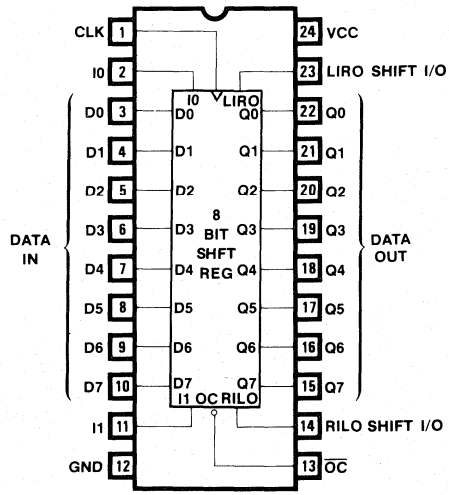
The LOAD operation loads the input (D_7-D_0) into the output register (Q_7-Q_0). The HOLD operation holds the previous value regardless of clock transitions. The SHIFT LEFT operation shifts the output register, Q, one bit to the left; Q_0 is replaced by LIRO. RILO outputs Q_7.

The SHIFT RIGHT operation shifts the output register, Q, one bit to the right; Q_7 is replaced by RILO. LIRO outputs Q_0.

The output register (Q_7-Q_0) is enabled when $\overline{OC}$ is LOW, and disabled (HI-Z) when $\overline{OC}$ is HIGH. The output drivers will sink the 24 mA required for many bus interface standards.

Two or more LS498 octal shift registers may be cascaded to provide larger shift registers as shown in the application section.

Logic Symbol



Function Table

$\overline{OC}$	CLK	I_1	I_0	D_7-D_0	Q_7-Q_0	OPERATION
H	X	X	X	X	Z	HI-Z
L	↑	L	L	X	L	HOLD
L	↑	L	H	X	SR(Q)	SHIFT RIGHT
L	↑	H	L	X	SL(Q)	SHIFT LEFT
L	↑	H	H	D	D	LOAD

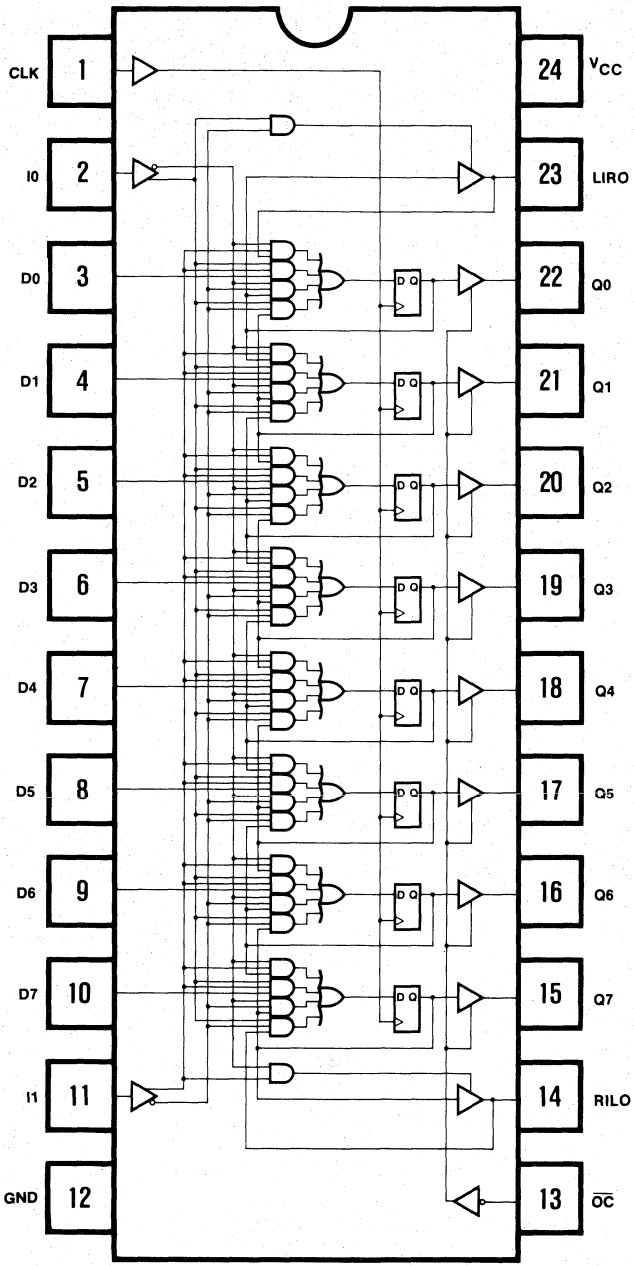
Octal Shift Register



Multifunction Octal Register
SN54/74LS380

Features/Benefits

- **Octal Register for general purposes interfacing applications**
- **8 bits match byte boundaries**
- **Bus-structured pinout**
- **24-pin SKINNYDIP™ saves space**
- **3-state outputs drive bus lines**
- **Low current PNP inputs reduce loading**

Ordering Information

PART NUMBER	PACKAGE	TEMPERATURE
SN54LS380	JS	MIL
SN74LS380	NS, JS	COM

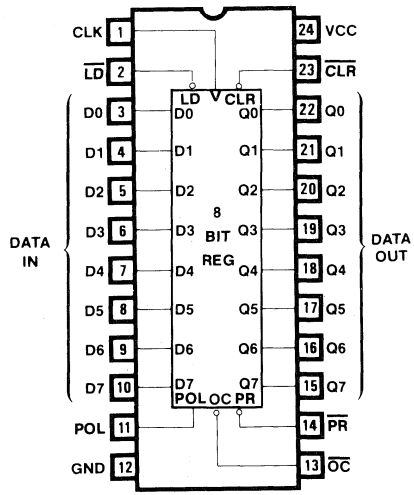
Description

The LS380 is an 8-bit synchronous register with parallel load, load compliment, preset, clear, and hold capacity. Four control inputs ($\overline{LD}$, POL, $\overline{CLR}$, $\overline{PR}$) provide one of four operations which occur synchronously on the rising edge of the clock (CLK). The LS380 combines the features of the LS374, LS377, LS273 and LS534 into a single 300 mil wide package.

The LOAD operation loads the inputs (D_7-D_0) into the output register (Q_7-Q_0), when POL is HIGH, or loads the compliment of the inputs when POL is LOW. The CLEAR operation resets the output register to all LOWs. The PRESET operation presets the output register to all HIGHs. The HOLD operation holds the previous value regardless of clock transitions. CLEAR overrides PRESET, PRESET overrides LOAD, and LOAD overrides HOLD.

The output register (Q_7-Q_0) is enabled when OC is LOW, and disabled (HI-Z) when $\overline{OC}$ is HIGH. The output drivers will sink the 24 mA required for many bus interface standards.

Logic Symbol



Function Table

$\overline{OC}$	CLK	$\overline{LD}$	POL	$\overline{CLR}$	$\overline{PR}$	D7-D0	Q7-Q0	OPERATION
H	X	X	X	X	X	X	Z	HI-Z
L	↑	X	X	L	X	X	L	CLEAR

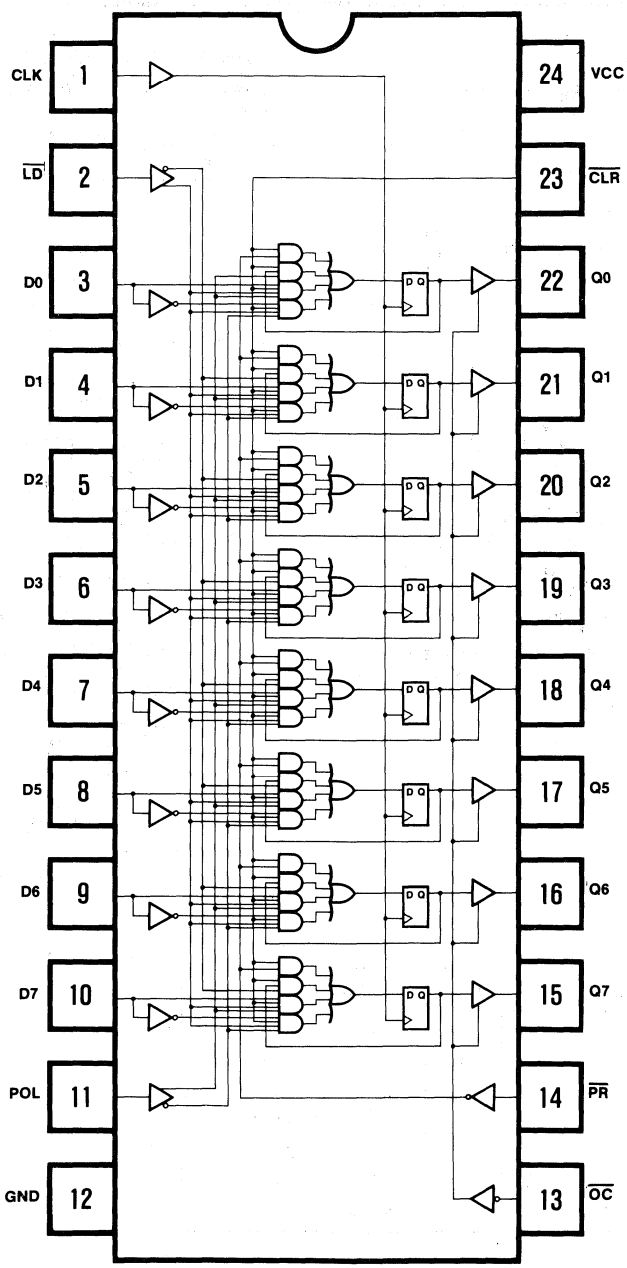
Logic Diagram

Octal Register



10-Bit Counter
SN54/74LS491

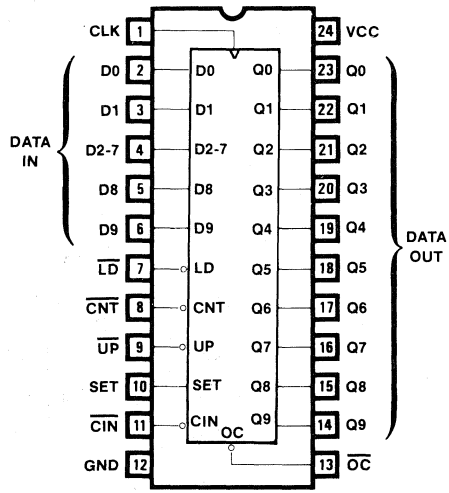
Features/Benefits

- **CRT vertical and horizontal timing generation**
- **Bus-structured pinout**
- **24-pin SKINNYDIP™ saves space**
- **3-state outputs drive bus lines**
- **Low current PNP inputs reduce loading**

Ordering Information

PART NUMBER	PACKAGE	TEMPERATURE
SN54LS491	JS	MIL
SN74LS491	NS, JS	COM

Logic Symbol



Description

The ten-bit counter can count up, count down, set, and load 2 LSB's, 2 MSB's and 6 middle bits high or low as a group. All operations are synchronous with the clock. SET overrides LOAD, COUNT and HOLD. LOAD overrides COUNT. COUNT is conditional on CIN, otherwise it holds.

All outputs are enabled when OC is low, otherwise HIGH-Z. The 24 mA I_{OL} outputs are suitable for driving RAM/PROM address lines in video graphics systems.

Function Table

$\overline{OC}$	CLK	SET	$\overline{LD}$	$\overline{CNT}$	$\overline{CIN}$	$\overline{UP}$	D9-D0	Q9-Q0	OPERATION
H	X	X	X	X	X	X	X	Z	HI-Z

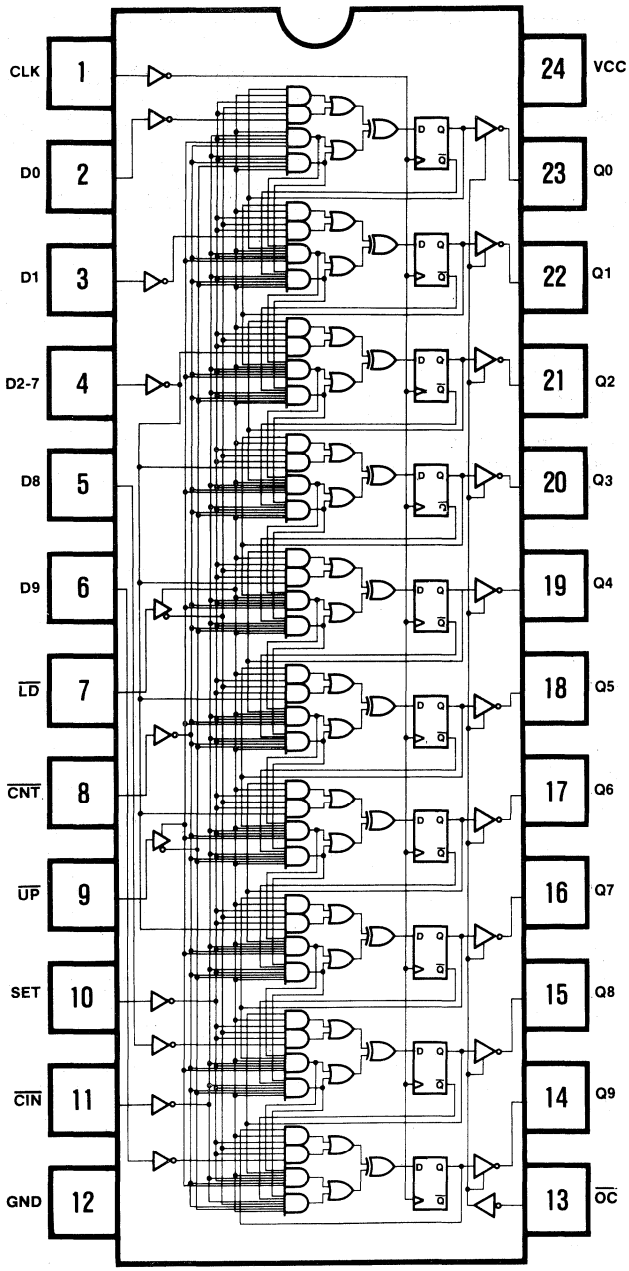
L	↑	L	H	L	H	X	X	Q	HOLD
L	↑	L	H	L	L	L	X	Q plus 1	Count UP
L	↑	L	H	L	L	H	X	Q minus 1	Count DN

For supplementary information see appendix this section.

Logic Diagram

10-Bit Up/Down Counter



16:1 Mux
SN54/74LS450

Features/Benefits

- 24-pin SKINNYDIP™ saves space
- Similar to 74150 (Fat DIP)
- Low current PNP inputs reduce loading

Ordering Information

PART NUMBER	PACKAGE	TEMPERATURE
SN54LS450	JS	MIL
SN74LS450	NS, JS	COM

Description

The 16:1 Mux selects one of sixteen inputs, E0 through E15, specified by four binary select inputs, A, B, C, and D. The true data is output on Y and the inverted data on W. Propagation delays are the same for both inputs and addresses and are specified for 50 pF loading. Outputs conform to the standard 8 mA LS totem pole drive standard.

Function Table

INPUT SELECT				OUTPUT	
				W	Y
