

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

General Description

The MAX1901/MAX1902/MAX1904 are buck-topology, step-down, switch-mode, power-supply controllers that generate logic-supply voltages in battery-powered systems. These high-performance, dual/triple-output devices include on-board power-up sequencing, power-good signaling with delay, digital soft-start, secondary winding control, low dropout circuitry, internal frequency-compensation networks, and automatic bootstrapping.

Up to 97% efficiency is achieved through synchronous rectification and Maxim's proprietary Idle Mode™ control scheme. Efficiency is greater than 80% over a 1000:1 load-current range, which extends battery life in system suspend or standby mode. Excellent dynamic response corrects output load transients within five clock cycles. Strong 1A on-board gate drivers ensure fast external N-channel MOSFET switching.

These devices feature a logic-controlled and synchronizable, fixed-frequency, pulse-width-modulation (PWM) operating mode. This reduces noise and RF interference in sensitive mobile communications and pen-entry applications. Asserting the $\overline{\text{SKIP}}$ pin enables fixed-frequency mode, for lowest noise under all load conditions.

The MAX1901/MAX1902/MAX1904 include two PWM regulators, adjustable from 2.5V to 5.5V with fixed 5.0V and 3.3V modes. All these devices include secondary feedback regulation, and the MAX1902 contains a 12V/120mA linear regulator. The MAX1901/MAX1904 include a secondary feedback input (SECFB), plus a control pin (STEER) that selects which PWM (3.3V or 5V) receives the secondary feedback signal. SECFB provides a method for adjusting the secondary winding voltage regulation point with an external resistor divider, and is intended to aid in creating auxiliary voltages other than fixed 12V.

The MAX1901/MAX1902 contain internal output overvoltage and undervoltage protection features.

Applications

Notebook and Subnotebook Computers
PDAs and Mobile Communicators
Desktop CPU Local DC-DC Converters

*Idle Mode is a trademark of Maxim Integrated Products, Inc.
Dual Mode is a trademark of Maxim Integrated Products, Inc.*

Pin Configurations appear at end of data sheet.

Features

- ◆ 97% Efficiency
- ◆ 4.2V to 30V Input Range
- ◆ 2.5V to 5.5V Dual Adjustable Outputs
- ◆ Selectable 3.3V and 5V Fixed or Adjustable Outputs (Dual Mode™)
- ◆ 12V Linear Regulator
- ◆ Adjustable Secondary Feedback (MAX1901/MAX1904)
- ◆ 5V/50mA Linear Regulator Output
- ◆ Precision 2.5V Reference Output
- ◆ Programmable Power-Up Sequencing
- ◆ Power-Good ($\overline{\text{RESET}}$) Output
- ◆ Output Overvoltage Protection (MAX1901/MAX1902)
- ◆ Output Undervoltage Shutdown (MAX1901/MAX1902)
- ◆ 333kHz/500kHz Low-Noise, Fixed-Frequency Operation
- ◆ Low-Dropout, 98% Duty-Factor Operation
- ◆ 2.5mW Typical Quiescent Power (12V input, both SMPs on)
- ◆ 4 μ A Typical Shutdown Current
- ◆ 28-Pin SSOP Package

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX1901EAI	-40°C to +85°C	28 SSOP
MAX1902EAI	-40°C to +85°C	28 SSOP
MAX1904EAI	-40°C to +85°C	28 SSOP

MAX1901/MAX1902/MAX1904

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

ABSOLUTE MAXIMUM RATINGS

V+ to GND	-0.3V to +36V	DH5 to LX5	-0.3V to (BST5 + 0.3V)
PGND to GND	±0.3V	V _L , REF Short to GND	Momentary
V _L to GND	-0.3V to +6V	12OUT Short to GND	Continuous
BST3, BST5 to GND	-0.3V to +36V	REF Current	+5mA to -1mA
LX3 to BST3	-6V to +0.3V	V _L Current	+50mA
LX5 to BST5	-6V to +0.3V	12OUT Current	+200mA
REF, SYNC, SEQ, STEER, $\overline{\text{SKIP}}$, TIME/ON5, SECFB, RESET to GND	-0.3V to +6V	V _{DD} Shunt Current	+15mA
V _{DD} to GND	-0.3V to +20V	Continuous Power Dissipation (T _A = +70°C)	
RUN/ON3, $\overline{\text{SHDN}}$ to GND	-0.3V to (V+ + 0.3V)	28-Pin SSOP (derate 9.52mW/°C above +70°C)	762mW
12OUT to GND	-0.3V to (V _{DD} + 0.3V)	Operating Temperature Range	-40°C to +85°C
DL3, DL5 to PGND	-0.3V to (V _L + 0.3V)	Storage Temperature Range	-65°C to +160°C
DH3 to LX3	-0.3V to (BST3 + 0.3V)	Lead Temperature (soldering, 10s)	+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

(V+ = 15V, both PWMs on, SYNC = V_L, V_L load = 0, REF load = 0, $\overline{\text{SKIP}}$ = 0, T_A = 0°C to +85°C, unless otherwise noted. Typical values are at T_A = +25°C.)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
MAIN SMPS CONTROLLERS					
Input Voltage Range		4.2		30.0	V
3V Output Voltage in Adjustable Mode	V+ = 4.2V to 30V, CSH3 - CSL3 = 0, CSL3 tied to FB3	2.42	2.5	2.58	V
3V Output Voltage in Fixed Mode	V+ = 4.2V to 30V, 0 < CSH3 - CSL3 < 80mV, FB3 = 0	3.20	3.39	3.47	V
5V Output Voltage in Adjustable Mode	V+ = 4.2V to 30V, CSH5 - CSL5 = 0, CSL5 tied to FB5	2.42	2.5	2.58	V
5V Output Voltage in Fixed Mode	V+ = 5.3V to 30V, 0 < CSH5 - CSL5 < 80mV, FB5 = 0	4.85	5.13	5.25	V
Output Voltage Adjust Range	Either SMPS	REF		5.5	V
Adjustable-Mode Threshold Voltage	Dual-mode comparator	0.5		1.1	V
Load Regulation	Either SMPS, 0 < CSH _n - CSL _n < 80mV		-2		%
Line Regulation	Either SMPS, 5.2V < V+ < 30V		0.03		%/V
Current-Limit Threshold	CSH3 - CSL3 or CSH5 - CSL5	80	100	120	mV
	$\overline{\text{SKIP}}$ = V _L or V _{DD} < 13V or SECFB < 2.44V	-50	-100	-150	
Idle-Mode Threshold	$\overline{\text{SKIP}}$ = 0, not tested	10	25	40	mV
Soft-Start Ramp Time	From enable to 95% full current limit with respect to f _{OSC} (Note 1)		512		clks
Oscillator Frequency	SYNC = V _L	450	500	550	kHz
	SYNC = 0	283	333	383	

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

RESET					
$\overline{\text{RESET}}$ Trip Threshold	With respect to unloaded output voltage, falling edge; typical hysteresis = 1%	-7		-4	% clks
$\overline{\text{RESET}}$ Delay Time	With respect to f _{osc}	27,000		37,000	
INPUTS AND OUTPUTS					
Feedback-Input Leakage Current	FB3, FB5; SECFB = 2.6V			50	nA
Logic Input-Low Voltage	RUN/ON3, $\overline{\text{SKIP}}$, TIME/ON5 (SEQ = REF), $\overline{\text{SHDN}}$, STEER, SYNC			0.6	V
Logic Input-High Voltage	RUN/ON3, $\overline{\text{SKIP}}$, TIME/ON5 (SEQ = REF), $\overline{\text{SHDN}}$, STEER, SYNC	2.4			V
Logic Output-Low Voltage	$\overline{\text{RESET}}$, I _{SINK} = 4mA			0.4	V
Logic Output-High Current	$\overline{\text{RESET}}$ = 3.5V	1			mA
TIME/ON5 Input Trip Level	SEQ = 0 or V _L	2.4		2.6	V
TIME/ON5 Source Current	TIME/ON5 = 0, SEQ = 0 or V _L	2.5		3.5	μA
TIME/ON5 On-Resistance	TIME/ON5; RUN/ON3 = 0, SEQ = 0 or V _L			80	Ω
Gate Driver On-Resistance	High or low			7	Ω

Note 1: Each of the four digital soft-start levels is tested for functionality; the steps are typically in 20mV increments.

Note 2: High duty-factor operation supports low input-to-output differential voltages, and is achieved at a lowered operating frequency (see the *Dropout Operation* section).

Note 3: MAX1902 only.

Note 4: Off mode for the 12V linear regulator occurs when the SMPS that has flyback feedback (V_{DD}) steered to it is disabled. In situations where the main outputs are being held up by external keep-alive supplies, turning off the 12OUT regulator prevents a leakage path from the output-referred flyback winding, through the rectifier, and into V_{DD}.

Note 5: Since the reference uses V_L as its supply, the reference's V₊ line-regulation error is insignificant.

Note 6: Specifications from 0°C to -40°C are guaranteed by design, not production tested.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Typical Operating Characteristics

(Circuit of Figure 1, Table 1, 6A/500kHz components, $T_A = +25^\circ\text{C}$, unless otherwise noted.)

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Pin Description

MAX1901/MAX1902/MAX1904

PIN	NAME	FUNCTION
1	CSH3	Current-Sense Input for the 3.3V SMPS. Current-limit level is 100mV referred to CSL3.
2	CSL3	Current-Sense Input. Also serves as the feedback input in fixed-output mode.
3	FB3	Feedback Input for the 3.3V SMPS. Regulates at FB3 = REF (approx. 2.5V) in adjustable mode. FB3 is a dual-mode input that also selects the 3.3V fixed output voltage setting when tied to GND. Connect FB3 to a resistor-divider for adjustable-output mode.
4	12OUT (MAX1902)	12V/120mA Linear-Regulator Output. Input supply comes from V _{DD} . Bypass 12OUT to GND with 1μF (min).
	STEER (MAX1901/ MAX1904)	Logic-Control Input for Secondary Feedback. Selects the PWM that uses a transformer and secondary feedback signal (SECFB): STEER = GND: 3.3V SMPS uses transformer STEER = V _L : 5V SMPS uses transformer
5	V _{DD} (MAX1902)	Supply Voltage Input for the 12OUT Linear Regulator. Also connects to an internal resistor-divider for secondary winding feedback, and to an 18V overvoltage shunt regulator clamp.
	SECFB (MAX1901/ MAX1904)	Secondary Winding Feedback Input. Normally connected to a resistor-divider from an auxiliary output. SECFB regulates at V _{SECFB} = 2.5V (see the <i>Secondary Feedback Regulation Loop</i> section). Tie to V _L if not used.
6	SYNC	Oscillator Synchronization and Frequency Select. Tie to V _L for 500kHz operation; tie to GND for 333kHz operation. Can be driven at 400kHz to 583kHz for external synchronization.
7	TIME/ON5	Dual-Purpose Timing Capacitor Pin and ON/OFF Control Input. See the <i>Power-Up Sequencing and ON/OFF Controls</i> section.
8	GND	Low-Noise Analog Ground and Feedback Reference Point
9	REF	2.5V Reference Voltage Output. Bypass to GND with 1μF (min).
10	SKIP	Logic-Control Input that Disables Idle Mode when High. Connect to GND for normal use.
11	RESET	Active-Low Timed Reset Output. RESET swings GND to V _L . Goes high after a fixed 32,000 clock-cycle delay following power-up.
12	FB5	Feedback Input for the 5V SMPS. Regulates at FB5 = REF (approx. 2.5V) in adjustable mode. FB5 is a dual-mode input that also selects the 5V fixed output voltage setting when tied to GND. Connect FB5 to a resistor-divider for adjustable-output mode.
13	CSL5	Current-Sense Input for the 5V SMPS. Also serves as the feedback input in fixed-output mode, and as the bootstrap supply input when the voltage on CSL5/V _L is > 4.5V.
14	CSH5	Current-Sense Input for the 5V SMPS. Current-limit level is 100mV referred to CSL5.
15	SEQ	Pin-Strap Input that Selects the SMPS Power-Up Sequence: SEQ = GND: 5V before 3.3V, RESET output determined by both outputs SEQ = REF: Separate ON3/ON5 controls, RESET output determined by 3.3V output SEQ = V _L : 3.3V before 5V, RESET output determined by both outputs

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Pin Description (continued)

PIN	NAME	FUNCTION
16	DH5	Gate-Drive Output for the 5V, High-Side N-Channel Switch. DH5 is a floating driver output that swings from LX5 to BST5, riding on the LX5 switching node voltage.
17	LX5	Switching-Node (Inductor) Connection. Can swing 2V below ground without hazard.
18	BST5	Boost Capacitor Connection for High-Side Gate Drive (0.1 μ F)
19	DL5	Gate-Drive Output for the Low-Side Synchronous-Rectifier MOSFET. Swings 0 to V_L .
20	PGND	Power Ground
21	V_L	5V Internal Linear-Regulator Output. V_L is also the supply-voltage rail for the chip. After the 5V SMPS output has reached 4.5V (typ), V_L automatically switches to the output voltage via CSL5 for bootstrapping. Bypass to GND with 4.7 μ F. V_L supplies up to 25mA for external loads.
22	V_+	Battery Voltage Input, 4.2V to 30V. Bypass V_+ to PGND close to the IC with a 0.22 μ F capacitor. Connects to a linear regulator that powers V_L .
23	$\overline{\text{SHDN}}$	Shutdown Control Input, Active-Low. Logic threshold is set at approximately 1V. For automatic startup, connect $\overline{\text{SHDN}}$ to V_+ through a 220k Ω resistor and bypass $\overline{\text{SHDN}}$ to GND with a 0.01 μ F capacitor.
24	DL3	Gate-Drive Output for the Low-Side Synchronous-Rectifier MOSFET. Swings 0 to V_L .
25	BST3	Boost Capacitor Connection for High-Side Gate Drive (0.1 μ F)
26	LX3	Switching-Node (Inductor) Connection. Can swing 2V below ground without hazard.
27	DH3	Gate-Drive Output for the 3.3V, High-Side N-Channel Switch. DH3 is a floating driver output that swings from LX3 to BST3, riding on the LX3 switching-node voltage.
28	RUN/ON3	ON/ $\overline{\text{OFF}}$ Control Input. See the <i>Power-Up Sequencing and ON/$\overline{\text{OFF}}$ Controls</i> section.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

MAX1901/MAX1902/MAX1904

Figure 1. Standard 3.3V/5V Application Circuit (MAX1901/MAX1904)

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Standard Application Circuit

The basic MAX1901/MAX1904 dual-output 3.3V/5V buck converter (Figure 1) is easily adapted to meet a wide range of applications with inputs up to 28V by substituting components from Table 1. These circuits represent a good set of tradeoffs between cost, size, and efficiency, while staying within the worst-case specification limits for stress-related parameters, such as capacitor ripple current. Don't change the frequency of these circuits without first recalculating component values (particularly inductance value at maximum battery voltage). Adding a Schottky rectifier across each synchronous rectifier improves the efficiency of these circuits by approximately 1%, but this rectifier is otherwise not needed because the MOSFETs required for these circuits typically incorporate a high-speed silicon diode from drain to source. Use a Schottky rectifier rated at a DC current equal to at least one-third of the load current.

Detailed Description

The MAX1901/MAX1902/MAX1904 are dual, BiCMOS, switch-mode power-supply controllers designed primarily for buck-topology regulators in battery-powered applications where high-efficiency and low-quiescent supply current are critical. Light-load efficiency is enhanced by automatic Idle-Mode operation, a variable-frequency pulse-skipping mode that reduces transition and gate-charge losses. Each step-down, power-switching circuit consists of two N-channel MOSFETs, a rectifier, and an LC output filter. The output voltage is the average AC voltage at the switching node, which is regulated by changing the duty cycle of the MOSFET switches. The gate-drive signal to the N-channel high-side MOSFET must exceed the battery voltage, and is provided by a flying-capacitor boost circuit that uses a 100nF capacitor connected to BST_.

The MAX1901/MAX1902/MAX1904 contain ten major circuit blocks (Figure 2).

The two pulse-width-modulation (PWM) controllers each consist of a Dual Mode feedback network and multiplexer, a multi-input PWM comparator, high-side and low-side gate drivers, and logic. MAX1901/MAX1902 contain fault-protection circuits that monitor the main PWM outputs for undervoltage and overvoltage. A power-on sequence block controls the power-up timing of the main PWMs and determines whether one or both of the outputs are monitored for undervoltage faults. The MAX1902 includes a secondary feedback network and 12V linear regulator to generate a 12V output from a coupled-inductor flyback winding. The MAX1901/MAX1904 have a secondary feedback input (SECFB) instead, which allows a quasi-regulated, adjustable output, coupled-inductor flyback winding to be attached to either the 3.3V or the 5V main inductor. Bias generator blocks include the 5V IC internal rail (V_L) linear regulator, 2.5V precision reference, and automatic bootstrap switchover circuit. The PWMs share a common 333kHz/500kHz synchronizable oscillator.

These internal IC blocks aren't powered directly from the battery. Instead, the 5V V_L linear regulator steps down the battery voltage to supply both V_L and the gate drivers. The synchronous-switch gate drivers are directly powered from V_L , while the high-side switch gate drivers are indirectly powered from V_L via an external diode-capacitor boost circuit. An automatic bootstrap circuit turns off the 5V linear regulator and powers the IC from the 5V PWM output voltage if the output is above 4.5V.

PWM Controller Block

The two PWM controllers are nearly identical. The only differences are fixed output settings (3.3V vs. 5V), the V_L /CSL5 bootstrap switch connected to the 5V PWM, and SECFB. The heart of each current-mode PWM controller is a multi-input, open-loop comparator that sums

three signals: the output-voltage error signal with respect to the reference voltage, the current-sense signal, and the slope-compensation ramp (Figure 3). The PWM controller is a direct-summing type, lacking a traditional error amplifier and the phase shift associated with it. This direct-summing configuration approaches ideal cycle-by-cycle control over the output voltage.

When $\overline{\text{SKIP}} = \text{low}$, Idle Mode circuitry automatically optimizes efficiency throughout the load current range. Idle Mode dramatically improves light-load efficiency by reducing the effective frequency, which reduces switching losses. It keeps the peak inductor current above 25% of the full current limit in an active cycle, allowing subsequent cycles to be skipped. Idle Mode transitions seamlessly to fixed-frequency PWM operation as load current increases.

With $\overline{\text{SKIP}} = \text{high}$, the controller always operates in fixed-frequency PWM mode for lowest noise. Each pulse from the oscillator sets the main PWM latch that turns on the high-side switch for a period determined by the duty factor (approximately $V_{\text{OUT}} / V_{\text{IN}}$). As the high-side switch turns off, the synchronous rectifier latch sets; 60ns later, the low-side switch turns on. The low-side switch stays on until the beginning of the next clock cycle.

In PWM mode, the controller operates as a fixed-frequency current-mode controller where the duty ratio is set by the input/output voltage ratio. The current-mode feedback system regulates the peak inductor current value as a function of the output-voltage error signal. In continuous-conduction mode, the average inductor current is nearly the same as the peak current, so the circuit acts as a switch-mode transconductance amplifier. This pushes the second output LC filter pole, normally found in a duty-factor-controlled (voltage-mode) PWM, to a higher frequency. To preserve inner-loop stability and eliminate regenerative inductor current "staircasing", a slope-compensation ramp is summed into the main PWM comparator to make the apparent duty factor less than 50%.

The MAX1901/MAX1902/MAX1904 use a relatively low loop gain, allowing the use of lower-cost output capacitors. The relative gains of the voltage-sense and current-sense inputs are weighted by the values of current sources that bias three differential input stages in the main PWM comparator (Figure 4). The relative gain of the voltage comparator to the current comparator is internally fixed at $K = 2:1$. The low loop gain results in the 2% typical load-regulation error. The low value of loop gain helps reduce output filter capacitor size and cost by shifting the unity-gain crossover frequency to a lower level.

Table 3. SKIP PWM Table

SKIP	LOAD CURRENT	MODE	DESCRIPTION
Low	Light	Idle	Pulse-skipping, supply current = 250 μ A at $V_{IN} = 12V$, discontinuous inductor
Low	Heavy	PWM	Constant-frequency PWM continuous-inductor current
High	Light	PWM	Constant-frequency PWM continuous-inductor current
High	Heavy	PWM	Constant-frequency PWM continuous-inductor current

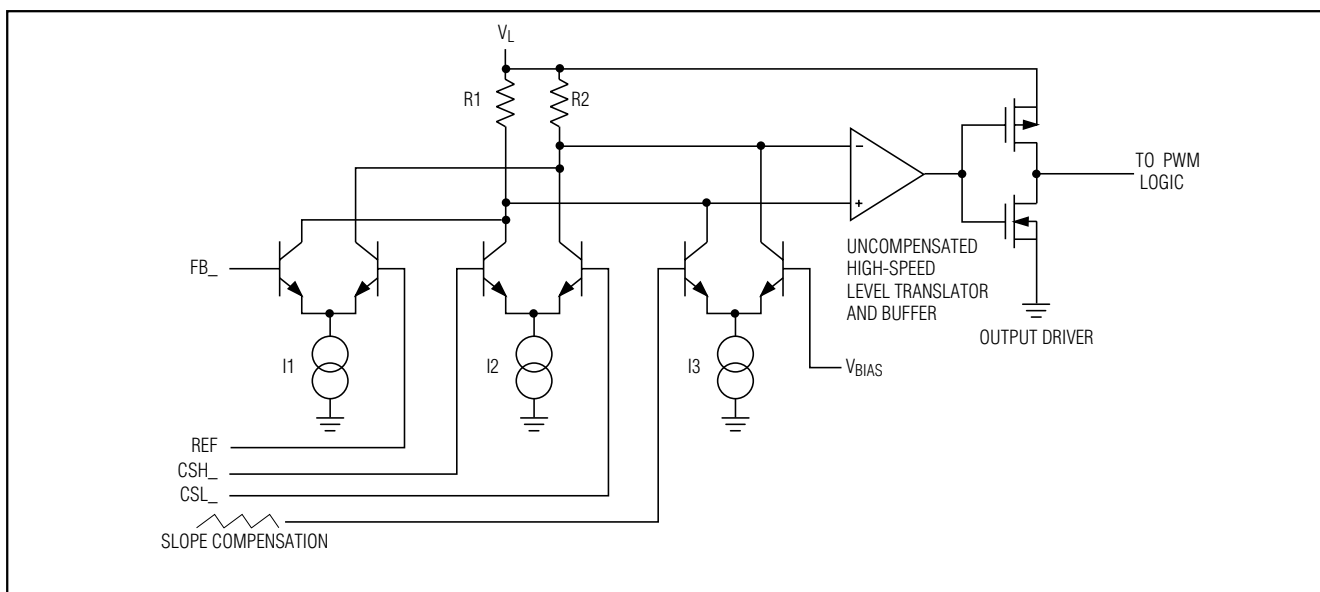

Figure 4. Main PWM Comparator Block Diagram

The output filter capacitors (Figure 1, C1 and C2) set a dominant pole in the feedback loop that must roll off the loop gain to unity before encountering the zero introduced by the output capacitor's parasitic resistance (ESR) (see the *Design Procedure* section). A 50kHz pole-zero cancellation filter provides additional rolloff above the unity-gain crossover. This internal 50kHz low-pass compensation filter cancels the zero due to filter capacitor ESR. The 50kHz filter is included in the loop in both fixed-output and adjustable-output modes.

Synchronous Rectifier Driver (DL)

Synchronous rectification reduces conduction losses in the rectifier by shunting the normal Schottky catch diode with a low-resistance MOSFET switch. Also, the synchronous rectifier ensures proper startup of the boost gate-driver circuit.

If the circuit is operating in continuous-conduction mode, the DL drive waveform is simply the complement of the DH high-side drive waveform (with controlled dead time to prevent cross-conduction or "shoot through"). In discontinuous (light-load) mode, the syn-

chronous switch is turned off as the inductor current falls through zero. The synchronous rectifier works under all operating conditions, including Idle Mode.

The SECFB signal further controls the synchronous switch timing in order to improve multiple-output cross-regulation (see the *Secondary Feedback Regulation Loop* section).

Internal V_L and REF Supplies

An internal regulator produces the 5V supply (V_L) that powers the PWM controller, logic, reference, and other blocks within the IC. This 5V low-dropout linear regulator supplies up to 25mA for external loads, with a reserve of 25mA for supplying gate-drive power. Bypass V_L to GND with 4.7 μ F.

Important: Ensure that V_L does not exceed 6V. Measure V_L with the main output fully loaded. If it is pumped above 5.5V, either excessive boost-diode capacitance or excessive ripple at V_+ is the probable cause. Use only small-signal diodes for the boost circuit (10mA to 100mA Schottky or 1N4148 are preferred), and bypass V_+ to PGND with 4.7 μ F directly at the package pins.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

The 2.5V reference (REF) is accurate to $\pm 2\%$ over temperature, making REF useful as a precision system reference. Bypass REF to GND with $1\mu\text{F}$ minimum. REF can supply up to 5mA for external loads. (Bypass REF with a minimum $1\mu\text{F}/\text{mA}$ reference load current.) However, if extremely accurate specifications for both the main output voltages and REF are essential, avoid loading REF more than $100\mu\text{A}$. Loading REF reduces the main output voltage slightly, because of the reference load-regulation error.

When the 5V main output voltage is above 4.5V, an internal P-channel MOSFET switch connects CSL5 to VL, while simultaneously shutting down the VL linear regulator. This action bootstraps the IC, powering the internal circuitry from the output voltage, rather than through a linear regulator from the battery. Bootstrapping reduces power dissipation due to gate charge and quiescent losses by providing that power from a 90%-efficient switch-mode source, rather than from a much less efficient linear regulator.

Boost High-Side Gate-Drive Supply (BST3 and BST5)

Gate-drive voltage for the high-side N-channel switches is generated by a flying-capacitor boost circuit (Figure 2). The capacitor between BST₋ and LX₋ is alternately charged from the VL supply and placed parallel to the high-side MOSFET's gate-source terminals. On startup, the synchronous rectifier (low-side MOSFET) forces LX₋ to 0V and charges the boost capacitors to 5V. On the second half-cycle, the SMPS turns on the high-side MOSFET by closing an internal switch between BST₋ and DH₋. This provides the necessary enhancement voltage to turn on the high-side switch, an action that "boosts" the 5V gate-drive signal above the battery voltage.

Ringings at the high-side MOSFET gate (DH3 and DH5) in discontinuous-conduction mode (light loads) is a natural operating condition. It is caused by residual energy in the tank circuit, formed by the inductor and stray capacitance at the switching node, LX. The gate-drive negative rail is referred to LX, so any ringing there is directly coupled to the gate-drive output.

Current-Limiting and Current-Sense Inputs (CSH and CSL)

The current-limit circuit resets the main PWM latch and turns off the high-side MOSFET switch whenever the voltage difference between CSH and CSL exceeds 100mV. This limiting is effective for both current flow directions, putting the threshold limit at $\pm 100\text{mV}$. The tolerance on the positive current limit is $\pm 20\%$, so the external low-value sense resistor (R1) must be sized for $80\text{mV}/\text{IPEAK}$, where IPEAK is the required peak-inductor

current to support the full load current, while components must be designed to withstand continuous-current stresses of $120\text{mV}/\text{R1}$.

For breadboarding or for very-high-current applications, it may be useful to wire the current-sense inputs with a twisted pair, rather than PC traces. (This twisted pair need not be special; two pieces of wire-wrap wire twisted together is sufficient.) This reduces the possible noise picked up at CSH₋ and CSL₋, which can cause unstable switching and reduced output current. The CSL5 input also serves as the IC's bootstrap supply input. Whenever $V_{\text{CSL5}} > 4.5\text{V}$, an internal switch connects CSL5 to VL.

Oscillator Frequency and Synchronization (SYNC)

The SYNC input controls the oscillator frequency. Low selects 333kHz; high selects 500kHz. SYNC can also be used to synchronize with an external 5V CMOS or TTL clock generator. SYNC has a guaranteed 400kHz to 583kHz capture range. A high-to-low transition on SYNC initiates a new cycle.

500kHz operation optimizes the application circuit for component size and cost. 333kHz operation provides increased efficiency, lower dropout, and improved load-transient response at low input-output voltage differences (see the *Low-Voltage Operation* section).

Shutdown Mode

Holding $\overline{\text{SHDN}}$ low puts the IC into its $4\mu\text{A}$ shutdown mode. SHDN is logic input with a threshold of about 1V (the V_{TH} of an internal N-channel MOSFET). For automatic startup, bypass $\overline{\text{SHDN}}$ to GND with a $0.01\mu\text{F}$ capacitor and connect it to V+ through a $220\text{k}\Omega$ resistor.

Power-Up Sequencing and ON/OFF Controls

Startup is controlled by RUN/ON3 and TIME/ON5 in conjunction with SEQ. With SEQ tied to REF, the two control inputs act as separate ON/OFF controls for each supply. With SEQ tied to VL or GND, RUN/ON3 becomes the master ON/ $\overline{\text{OFF}}$ control input and TIME/ON5 becomes a timing pin, with the delay between the two supplies determined by an external capacitor. The delay is approximately $800\mu\text{s}/\text{nF}$. The 3.3V supply powers up first if SEQ is tied to VL, and the 5V supply is first if SEQ is tied to GND. When driving TIME/ON5 as a control input with external logic, always place a resistor ($>1\text{k}\Omega$) in series with the input. This prevents possible crowbar current due to the internal discharge pulldown transistor, which turns on in standby mode and momentarily at the first power-up or in shutdown mode.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

RESET Power-Good Voltage Monitor

The power-good monitor generates a system $\overline{\text{RESET}}$ signal. At first power-up, $\overline{\text{RESET}}$ is held low until both the 3.3V and 5V SMPS outputs are in regulation. At this point, an internal timer begins counting oscillator pulses, and $\overline{\text{RESET}}$ continues to be held low until 32,000 cycles have elapsed. After this timeout period (64ms at 500kHz or 96ms at 333kHz), $\overline{\text{RESET}}$ is actively pulled up to V_L . If SEQ is tied to REF (for separate ON3/ON5 controls), only the 3.3V SMPS is monitored—the 5V SMPS is ignored.

Output Undervoltage Shutdown Protection (MAX1901/MAX1902)

The output undervoltage lockout circuit is similar to foldback current limiting, but employs a timer rather than a variable current limit. Each SMPS has an undervoltage protection circuit that is activated 6144 clock cycles after the SMPS is enabled. If either SMPS output is under 70% of the nominal value, both SMPSs are latched off and their outputs are clamped to ground by the synchronous rectifier MOSFETs (see the *Output Overvoltage Protection* section). They won't restart until $\overline{\text{SHDN}}$ or RUN/ON3 is toggled, or until $V+$ power is cycled below 1V. Note that undervoltage protection can make prototype troubleshooting difficult, since you have only 12ms or 18ms to figure out what might be wrong with the circuit before both SMPSs are latched off. In extreme cases, it may be useful to substitute the MAX1904 into the prototype breadboard until the prototype is working properly.

Output Overvoltage Protection (MAX1901/MAX1902)

Both SMPS outputs are monitored for overvoltage. If either output is more than 7% above the nominal regulation point, both low-side gate drivers (DL₋) are latched high until $\overline{\text{SHDN}}$ or RUN/ON3 is toggled, or until $V+$ power is cycled below 1V. This action turns on the synchronous rectifiers with 100% duty, in turn rapidly discharging the output capacitors and forcing both SMPS outputs to ground. The DL outputs are also kept high whenever the corresponding SMPS is disabled, and in shutdown if V_L is sustained.

Discharging the output capacitor through the main inductor causes the output to momentarily go below GND. Clamp this negative pulse with a back-biased 1A Schottky diode across the output capacitor (Figure 1).

To ensure overvoltage protection on initial power-up, connect signal diodes from both output voltages to V_L (cathodes to V_L) to eliminate the V_L power-up delay. This circuitry protects the load from accidental overvoltage caused by a short circuit across the high-side power MOSFETs. This scheme relies on the presence of a fuse, in series with the battery, which is blown by the resulting crowbar current. Note that the overvoltage circuitry will interfere with external keep-alive supplies that hold up the outputs (such as lithium backup or hot-swap power supplies); in such cases, the MAX1904 should be used.

Low-Noise Operation (PWM Mode)

PWM mode (SKIP = high) minimizes RF and audio interference in noise-sensitive applications (such as hi-fi multimedia-equipped systems), cellular phones, RF communicating computers, and electromagnetic pen entry systems. See the summary of operating modes in Table 2. SKIP can be driven from an external logic signal.

Table 4. Operating Modes

$\overline{\text{SHDN}}$	SEQ	RUN/ON3	TIME/ON5	MODE	DESCRIPTION
Low	X	X	X	Shutdown	All circuit blocks turned off. Supply current = 4 μ A.
High	REF	Low	Low	Standby	Both SMPSs off. Supply current = 30 μ A.
High	REF	High	Low	Run	3.3V SMPS enabled/5V off.
High	REF	Low	High	Run	5V SMPS enabled/3.3V off.
High	REF	High	High	Run	Both SMPSs enabled.
High	GND	Low	Timing Capacitor	Standby	Both SMPSs off. Supply current = 30 μ A.
High	GND	High	Timing Capacitor	Run	Both SMPSs enabled. 5V enabled before 3.3V.
High	V_L	Low	Timing Capacitor	Standby	Both SMPSs off. Supply current = 30 μ A.
High	V_L	High	Timing Capacitor	Run	Both SMPSs enabled. 3.3V enabled Before 5V.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Interference due to switching noise is reduced in PWM mode by ensuring a constant switching frequency, thus concentrating the emissions at a known frequency outside the system audio or IF bands. Choose an oscillator frequency for which switching frequency harmonics don't overlap a sensitive frequency band. If necessary, synchronize the oscillator to a tight-tolerance external clock generator. To extend the output-voltage regulation range, constant operating frequency is not maintained under overload or dropout conditions (see the *Dropout Operation* section).

PWM mode ($\overline{\text{SKIP}} = \text{high}$) forces two changes upon the PWM controllers. First, it disables the minimum-current comparator, ensuring fixed-frequency operation. Second, it changes the detection threshold for reverse current limit from 0 to -100mV, allowing the inductor current to reverse at light loads. This results in fixed-frequency operation and continuous inductor-current flow. This eliminates discontinuous-mode inductor ringing and improves cross regulation of transformer-coupled multiple-output supplies, particularly in circuits that don't use additional secondary regulation via SECFB or VDD.

In most applications, tie $\overline{\text{SKIP}}$ to GND to minimize quiescent supply current. VL supply current with $\overline{\text{SKIP}}$ high is typically 30mA, depending on external MOSFET gate capacitance and switching losses.

Internal Digital Soft-Start Circuit

Soft-start allows a gradual increase of the internal current-limit level at startup to reduce input surge currents. Both SMPSs contain internal digital soft-start circuits, each controlled by a counter, a digital-to-analog converter (DAC), and a current-limit comparator. In shutdown or standby mode, the soft-start counter is reset to zero. When an SMPS is enabled, its counter starts counting oscillator pulses, and the DAC begins incrementing the comparison voltage applied to the current-limit comparator. The DAC output increases from 0 to 100mV in five equal steps as the count increases to 512 clocks. As a result, the main output capacitor charges up relatively slowly. The exact time of the output rise depends on output capacitance and load current, and is typically 600 μ s with a 500kHz oscillator.

Dropout Operation

Dropout (low input-output differential operation) is enhanced by stretching the clock pulse width to increase the maximum duty factor. The algorithm follows: If the output voltage (V_{OUT}) drops out of regulation without the current limit having been reached, the SMPS skips an off-time period (extending the on-time). At the end of the cycle, if the output is still out of regulation, the SMPS skips another off-time period. This

action can continue until three off-time periods are skipped, effectively dividing the clock frequency by as much as four.

The typical PWM minimum off-time is 300ns, regardless of the operating frequency. Lowering the operating frequency raises the maximum duty factor above 97%.

Adjustable-Output Feedback (Dual Mode FB)

Fixed, preset output voltages are selected when FB₋ is connected to ground. Adjusting the main output voltage with external resistors is simple for any of the MAX1901/MAX1902/MAX1904, through resistor dividers connected to FB3 and FB5 (Figure 2). Calculate the output voltage with the following formula:

$$V_{\text{OUT}} = V_{\text{REF}} (1 + R1 / R2)$$

where $V_{\text{REF}} = 2.5\text{V}$ nominal.

The nominal output should be set approximately 1% or 2% high to make up for the MAX1901/MAX1902/MAX1904 -2% typical load-regulation error. For example, if designing for a 3.0V output, use a resistor ratio that results in a nominal output voltage of 3.05V. This slight offsetting gives the best possible accuracy. Recommended normal values for R2 range from 5k Ω to 100k Ω . To achieve a 2.5V nominal output, simply connect FB₋ directly to CSL₋.

Remote output-voltage sensing, while not possible in fixed-output mode due to the combined nature of the voltage-sense and current-sense inputs (CSL3 and CSL5), is easy to do in adjustable mode by using the top of the external resistor-divider as the remote sense point.

When using adjustable mode, it is a good idea to always set the "3.3V output" to a lower voltage than the "5V output." The 3.3V output must always be less than VL, so that the voltage on CSH3 and CSL3 is within the common-mode range of the current-sense inputs. While VL is nominally 5V, it can be as low as 4.7V when linearly regulating, and as low as 4.2V when automatically bootstrapped to CSH5.

Secondary Feedback Regulation Loop (SECFB or VDD)

A flyback-winding control loop regulates a secondary winding output, improving cross-regulation when the primary output is lightly loaded or when there is a low input-output differential voltage. If VDD or SECFB falls below its regulation threshold, the low-side switch is turned on for an extra 0.75 μ s. This reverses the induc-

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

tor (primary) current, pulling current from the output filter capacitor and causing the flyback transformer to operate in forward mode. The low impedance presented by the transformer secondary in forward mode dumps current into the secondary output, charging up the secondary capacitor and bringing V_{DD} or SECFB back into regulation. The secondary feedback loop does not improve secondary output accuracy in normal flyback mode, where the main (primary) output is heavily loaded. In this condition, secondary output accuracy is determined by the secondary rectifier drop, transformer turns ratio, and accuracy of the main output voltage. A linear post-regulator may still be needed to meet strict output-accuracy specifications.

MAX1902 has a V_{DD} pin that regulates at a fixed 13.5V, set by an internal resistor-divider. The MAX1901/MAX1904 have an adjustable secondary-output voltage set by an external resistor-divider on SECFB (Figure 5). Ordinarily, the secondary regulation point is set 5% to 10% below the voltage normally produced by the flyback effect. For example, if the output voltage as determined by turns ratio is 15V, set the feedback resistor ratio to produce 13.5V. Otherwise, the SECFB one-shot might be triggered unintentionally, unnecessarily increasing supply current and output noise.

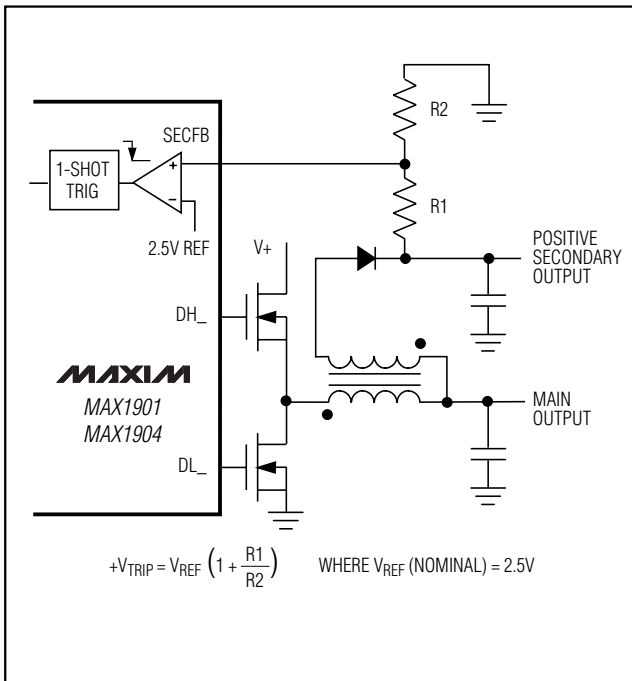

Figure 5. Adjusting the Secondary Output Voltage with SECFB

12V Linear Regulator Output (MAX1902)

The MAX1902 includes a 12V linear regulator output capable of delivering 120mA of output current. Typically, greater current is available at the expense of output accuracy. If an accurate output of more than 120mA is needed, an external pass transistor can be added. The circuit in Figure 6 delivers more than 200mA. Total output current is constrained by the V_+ input voltage and the transformer primary load (see Maximum V_{DD} Output Current vs. Input Voltage graphs in the *Typical Operating Characteristics*).

Design Procedure

The three predesigned 3V/5V standard application circuits (Figure 1 and Table 1) contain ready-to-use solutions for common application needs. Also, one standard flyback transformer circuit supports the 12OUT linear regulator in the *Applications Information* section. Use the following design procedure to optimize these basic schematics for different voltage or current requirements. But before beginning a design, firmly establish the following:

Maximum Input (Battery) Voltage, $V_{IN(MAX)}$. This value should include the worst-case conditions, such as no-load operation when a battery charger or AC adapter is

Figure 6. Increased 12V Linear Regulator Output Current

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

connected but no battery is installed. $V_{IN(MAX)}$ must not exceed 30V.

Minimum Input (Battery) Voltage, $V_{IN(MIN)}$. This should be taken at full load under the lowest battery conditions. If $V_{IN(MIN)}$ is less than 4.2V, use an external circuit to externally hold V_L above the V_L undervoltage lockout threshold. If the minimum input-output difference is less than 1.5V, the filter capacitance required to maintain good AC load regulation increases (see the *Low-Voltage Operation* section).

Inductor Value

The exact inductor value isn't critical and can be freely adjusted to make trade-offs between size, cost, and efficiency. Lower inductor values minimize size and cost, but reduce efficiency due to higher peak-current levels. The smallest inductor is achieved by lowering the inductance until the circuit operates at the border between continuous and discontinuous mode. Further reducing the inductor value below this crossover point results in discontinuous-conduction operation even at full load. This helps lower output-filter capacitance requirements, but efficiency suffers due to high I^2R losses. On the other hand, higher inductor values mean greater efficiency, but resistive losses due to extra wire turns will eventually exceed the benefit gained from lower peak-current levels. Also, high inductor values can affect load-transient response (see the V_{SAG} equation in the *Low-Voltage Operation* section). The equations that follow are for continuous-conduction operation, since the MAX1901/MAX1902/MAX1904 are intended mainly for high-efficiency, battery-powered applications. Discontinuous conduction doesn't affect normal idle-mode operation.

Three key inductor parameters must be specified: inductance value (L), peak current (I_{PEAK}), and DC resistance (R_{DC}). The following equation includes a constant (LIR) which is the ratio of inductor peak-to-peak AC current to DC load current. A higher LIR value allows smaller inductance, but results in higher losses and higher ripple. A good compromise between size and losses is found at a 30% ripple-current to load-current ratio (LIR = 0.3), which corresponds to a peak-inductor current 1.15 times higher than the DC load current.

$$L = \frac{V_{OUT}(V_{IN(MAX)} - V_{OUT})}{V_{IN(MAX)} \times f \times I_{OUT} \times LIR}$$

where: f = switching frequency, normally 333kHz or 500kHz

I_{OUT} = maximum DC load current

LIR = ratio of AC to DC inductor current, typically 0.3; should be >0.15

The nominal peak-inductor current at full load is $1.15 \times I_{OUT}$ if the above equation is used; otherwise, the peak current can be calculated by:

$$I_{PEAK} = I_{LOAD} + \frac{(V_{OUT}(V_{IN(MAX)} - V_{OUT}))}{2 \times f \times L \times V_{IN(MAX)}}$$

The inductor's DC resistance should be low enough that $R_{DC} \times I_{PEAK} < 100\text{mV}$, as it is a key parameter for efficiency performance. If a standard off-the-shelf inductor is not available, choose a core with an LI^2 rating greater than $L \times I_{PEAK}^2$ and wind it with the largest-diameter wire that fits the winding area. Ferrite core material is strongly preferred. Shielded-core geometries help keep noise, EMI, and switching-waveform jitter low.

Current-Sense Resistor Value

The current-sense resistor value is calculated according to the worst-case low current-limit threshold voltage (from the *Electrical Characteristics* tables) and the peak inductor current:

$$R_{SENSE} = \frac{80\text{mV}}{I_{PEAK}}$$

Use I_{PEAK} from the second equation in the *Inductor Value* section.

Use the calculated value of R_{SENSE} to size the MOSFET switches and specify inductor saturation-current ratings according to the worst-case high current-limit threshold voltage:

$$I_{PEAK(MAX)} = \frac{120\text{mV}}{R_{SENSE}}$$

Low-inductance resistors, such as surface-mount metal-film, are recommended.

Input-Capacitor Value

The input filter capacitor is usually selected according to input ripple current requirements and voltage rating, rather than capacitor value. Ceramic capacitors or Sanyo OS-CON capacitors are typically used to handle the power-up surge-currents, especially when connecting to robust AC adapters or low-impedance batteries. RMS input ripple current (I_{RMS}) is determined by the input voltage and load current, with the worst case occurring at $V_{IN} = 2 \times V_{OUT}$:

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

$$I_{RMS} = I_{LOAD} \times \frac{\sqrt{V_{OUT}(V_{IN} - V_{OUT})}}{V_{IN}}$$

Therefore, when V_{IN} is 2 x V_{OUT} :

$$I_{RMS} = \frac{I_{LOAD}}{2}$$

Bypassing V+

Bypass the V+ input with a 4.7 μ F tantalum capacitor paralleled with a 0.1 μ F ceramic capacitor, close to the IC. A 10 Ω series resistor to V_{IN} is also recommended.

Bypassing VL

Bypass the VL output with a 4.7 μ F tantalum capacitor paralleled with a 0.1 μ F ceramic capacitor, close to the device.

Output-Filter Capacitor Value

The output-filter capacitor values are generally determined by the ESR and voltage-rating requirements, rather than actual capacitance requirements for loop stability. In other words, the low-ESR electrolytic capacitor that meets the ESR requirement usually has more output capacitance than is required for AC stability. Use only specialized low-ESR capacitors intended for switching-regulator applications, such as AVX TPS, Sanyo POSCAP, or Kemet T510. To ensure stability, the capacitor must meet both minimum capacitance and maximum ESR values as given in the following equations:

$$C_{OUT} > \frac{V_{REF}(1 + V_{OUT}/V_{IN(MIN)})}{V_{OUT} \times R_{SENSE} \times f}$$

$$R_{ESR} < \frac{R_{SENSE} \times V_{OUT}}{V_{REF}}$$

These equations are worst case, with 45° of phase margin to ensure jitter-free, fixed-frequency operation and provide a nicely damped output response for zero to full-load step changes. Some cost-conscious designers may wish to bend these rules with less-expensive capacitors, particularly if the load lacks large step changes. This practice is tolerable if some bench testing over temperature is done to verify acceptable noise and transient response.

No well-defined boundary exists between stable and unstable operation. As phase margin is reduced, the first symptom is a bit of timing jitter, which shows up as blurred edges in the switching waveforms where the

scope won't quite sync up. Technically speaking, this jitter (usually harmless) is unstable operation, since the duty factor varies slightly. As capacitors with higher ESRs are used, the jitter becomes more pronounced, and the load-transient output-voltage waveform starts looking ragged at the edges. Eventually, the load-transient waveform has enough ringing on it that the peak noise levels exceed the allowable output-voltage tolerance. Note that even with zero phase margin and gross instability present, the output-voltage noise never gets much worse than $I_{PEAK} \times R_{ESR}$ (under constant loads).

The output-voltage ripple is usually dominated by the filter capacitor's ESR, and can be approximated as $I_{RIPPLE} \times R_{ESR}$. There is also a capacitive term, so the full equation for ripple in continuous-conduction mode is $V_{NOISE(p-p)} = I_{RIPPLE} \times [R_{ESR} + 1/(2 \times \pi \times f \times C_{OUT})]$. In idle mode, the inductor current becomes discontinuous, with high peaks and widely spaced pulses, so the noise can actually be higher at light load (compared to full load). In idle mode, calculate the output ripple as follows:

$$V_{NOISE(P-P)} = \frac{0.025 \times R_{ESR}}{R_{SENSE}} + \frac{0.0003 \times L \times [1/V_{OUT} + 1/(V_{IN} - V_{OUT})]}{R_{SENSE}^2 \times C_{OUT}}$$

Transformer Design (for Auxiliary Outputs Only)

Buck-plus-flyback applications, sometimes called "coupled-inductor" topologies, need a transformer to generate multiple output voltages. Performing the basic electrical design is a simple task of calculating turns ratios and adding the power delivered to the secondary to calculate the current-sense resistor and primary inductance. However, extremes of low input-output differentials, widely different output loading levels, and high turns ratios can complicate the design due to parasitic transformer parameters such as interwinding capacitance, secondary resistance, and leakage inductance. For examples of what is possible with real world transformers, see the Maximum V_{DD} Output Current vs. Input Voltage graph in the *Typical Operating Characteristics*.

Power from the main and secondary outputs is combined to get an equivalent current referred to the main output voltage (see the *Inductor Value* section for parameter definitions). Set the current-sense resistor value at $80mV / I_{TOTAL}$.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

P_{TOTAL} = The sum of the output power from all outputs

$I_{TOTAL} = P_{TOTAL} / V_{OUT}$ = The equivalent output current referred to V_{OUT}

$$L_{PRIMARY} = \frac{V_{OUT}(V_{IN(MAX)} - V_{OUT})}{V_{IN(MAX)} \times f \times I_{TOTAL} \times LIR}$$

$$\text{Turns Ratio } N = \frac{V_{SEC} + V_{FWD}}{V_{OUT(MIN)} + V_{RECT} + V_{SENSE}}$$

where: V_{SEC} = the minimum required rectified secondary output voltage

V_{FWD} = the forward drop across the secondary rectifier

$V_{OUT(MIN)}$ = the minimum value of the main output voltage (from the *Electrical Characteristics* tables)

V_{RECT} = the on-state voltage drop across the synchronous rectifier MOSFET

V_{SENSE} = the voltage drop across the sense resistor

In positive-output applications, the transformer secondary return is often referred to the main output voltage, rather than to ground, to reduce the needed turns ratio. In this case, the main output voltage must first be subtracted from the secondary voltage to obtain V_{SEC} .

Selecting Other Components

MOSFET Switches

The high-current N-channel MOSFETs must be logic-level types with guaranteed on-resistance specifications at $V_{GS} = 4.5V$. Lower gate threshold specifications are better (i.e., 2V max rather than 3V max). Drain-source breakdown voltage ratings must at least equal the maximum input voltage, preferably with a 20% derating factor. The best MOSFETs will have the lowest on-resistance per nanocoulomb of gate charge. Multiplying $R_{DS(ON)} \times Q_G$ provides a good figure for comparing various MOSFETs. Newer MOSFET process technologies with dense cell structures generally perform best. The internal gate drivers tolerate >100nC total gate charge, but 70nC is a more practical upper limit to maintain best switching times.

In high-current applications, MOSFET package power dissipation often becomes a dominant design factor. I^2R power losses are the greatest heat contributor for both high-side and low-side MOSFETs. I^2R losses are

distributed between Q1 and Q2 according to duty factor (see the following equations). Generally, switching losses affect only the upper MOSFET, since the Schottky rectifier clamps the switching node in most cases before the synchronous rectifier turns on. Gate charge losses are dissipated by the driver and don't heat the MOSFET. Calculate the temperature rise according to package thermal-resistance specifications to ensure that both MOSFETs are within their maximum junction temperature at high ambient temperature. The worst-case dissipation for the high-side MOSFET occurs at both extremes of input voltage, and the worst-case dissipation for the low-side MOSFET occurs at maximum input voltage:

$$P_{D_{upperFET}} = I_{LOAD}^2 \times R_{DS(ON)} \times DUTY + V_{IN} \times I_{LOAD} \times f \times \left(\frac{V_{IN} \times C_{RSS}}{I_{GATE}} + 20ns \right)$$

$$P_{D_{upperFET}} = I_{LOAD}^2 \times R_{DS(ON)} \times (1-DUTY) \\ DUTY = (V_{OUT} + V_{Q2}) / (V_{IN} - V_{Q1})$$

where: On-state voltage drop $V_{Q_1} = I_{LOAD} \times R_{DS(ON)}$

C_{RSS} = MOSFET reverse transfer capacitance

I_{GATE} = DH driver peak output current capability (1A typ)

20ns = DH driver inherent rise/fall time

Under output short-circuit, the MAX1904 synchronous rectifier MOSFET suffers extra stress because its duty factor can increase to greater than 0.9. It may need to be oversized to tolerate a continuous DC short circuit. During short circuit, the MAX1901/MAX1902's output undervoltage shutdown protects the synchronous rectifier under output short-circuit conditions.

To reduce EMI, add a 0.1 μ F ceramic capacitor from the high-side switch drain to the low-side switch source.

Rectifier Clamp Diode

The rectifier diode is a clamp across the low-side MOSFET that catches the negative inductor swing during the 60ns dead time between turning one MOSFET off and each low-side MOSFET on. The latest generations of MOSFETs incorporate a high-speed Schottky diode, which serves as an adequate clamp diode. For MOSFETs without integrated Schottky diodes, place a Schottky diode in parallel with the low-side MOSFET.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Use a Schottky diode with a DC current rating equal to one third of the load current. The Schottky diode's rated reverse breakdown voltage must be at least equal to the maximum input voltage, preferably with a 20% derating factor.

Boost-Supply Diode

A signal diode such as a 1N4148 works well in most applications. If the input voltage can go below +6V, use a small (20mA) Schottky diode for slightly improved efficiency and dropout characteristics. Don't use large power diodes, such as 1N5817 or 1N4001, since high junction capacitance can pump up V_L to excessive voltages.

Rectifier Diode (Transformer Secondary Diode)

The secondary diode in coupled-inductor applications must withstand flyback voltages greater than 60V, which usually rules out most Schottky rectifiers. Common silicon rectifiers, such as the 1N4001, are also prohibited because they are too slow. This often makes fast silicon rectifiers such as the MURS120 the only choice. The flyback voltage across the rectifier is related to the $V_{IN} - V_{OUT}$ difference, according to the transformer turns ratio:

$$V_{FLYBACK} = V_{SEC} + (V_{IN} - V_{OUT}) \times N$$

where: N = the transformer turns ratio SEC/PRI

V_{SEC} = the maximum secondary DC output voltage

V_{OUT} = the primary (main) output voltage

Subtract the main output voltage (V_{OUT}) from $V_{FLYBACK}$ in this equation if the secondary winding is returned to V_{OUT} and not to ground. The diode reverse-breakdown rating must also accommodate any ringing due to leakage inductance. The rectifier diode's current rating should be at least twice the DC load current on the secondary output.

Low-Voltage Operation

Low input voltages and low input-output differential voltages each require extra care in their design. Low absolute input voltages can cause the V_L linear regulator to enter dropout and eventually shut itself off. Low input voltages relative to the output (low $V_{IN} - V_{OUT}$ differential) can cause bad load regulation in multi-output flyback applications (see the design equations in the *Transformer Design* section). Also, low $V_{IN} - V_{OUT}$ differentials can also cause the output voltage to sag when the load current changes abruptly. The amplitude of the sag is a function of inductor value and maximum duty factor (an

Electrical Characteristics parameter, 97% guaranteed over temperature at $f = 333\text{kHz}$), as follows:

$$V_{SAG} = \frac{I_{STEP}^2 \times L}{2 \times C_{OUT} \times (V_{IN(MIN)} \times D_{MAX} - V_{OUT})}$$

The cure for low-voltage sag is to increase the output capacitor's value. Take a 333kHz/6A application circuit as an example, at $V_{IN} = +5.5\text{V}$, $V_{OUT} = +5\text{V}$, $L = 6.7\mu\text{H}$, $f = 333\text{kHz}$, $I_{STEP} = 3\text{A}$ (half-load step), a total capacitance of $470\mu\text{F}$ keeps the sag less than 200mV. The capacitance is higher than that shown in the *Typical Application Circuit* because of the lower input voltage. Note that only the capacitance requirement increases, and the ESR requirements don't change. Therefore, the added capacitance can be supplied by a low-cost bulk capacitor in parallel with the normal low-ESR capacitor.

Applications Information

Heavy-Load Efficiency Considerations

The major efficiency-loss mechanisms under loads are, in the usual order of importance:

- $P(I^2R) = I^2R$ losses
- $P(\text{tran})$ = transition losses
- $P(\text{gate})$ = gate-charge losses
- $P(\text{diode})$ = diode-conduction losses
- $P(\text{cap})$ = input capacitor ESR losses
- $P(\text{IC})$ = losses due to the IC's operating supply current

Inductor core losses are fairly low at heavy loads because the inductor's AC current component is small. Therefore, they aren't accounted for in this analysis. Ferrite cores are preferred, especially at 300kHz, but powdered cores, such as Kool-Mu, can work well:

$$\begin{aligned} \text{Efficiency} &= P_{OUT}/P_{IN} \times 100\% \\ &= P_{OUT}/(P_{OUT} + P_{TOTAL}) \times 100\% \\ P_{TOTAL} &= P(I^2R) + P(\text{tran}) + P(\text{gate}) + P(\text{diode}) + \\ &\quad P(\text{cap}) + P(\text{IC}) \\ P(I^2R) &= I_{LOAD}^2 \times (R_{DC} + R_{DS(ON)} + R_{SENSE}) \end{aligned}$$

where R_{DC} is the DC resistance of the coil, $R_{DS(ON)}$ is the MOSFET on-resistance, and R_{SENSE} is the current-sense resistor value. The $R_{DS(ON)}$ term assumes identical MOSFETs for the high-side and low-side switches: because they time-share the inductor current. If the MOSFETs aren't identical, their losses can be estimated by averaging the losses according to duty factor.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Table 5. Low-Voltage Troubleshooting Chart

SYMPTOM	CONDITION	ROOT CAUSE	SOLUTION
Sag or droop in V _{OUT} under step-load change	Low V _{IN} - V _{OUT} differential, <1.5V	Limited inductor-current slew rate per cycle.	Increase bulk output capacitance per formula (see the <i>Low-Voltage Operation</i> section). Reduce inductor value.
Dropout voltage is too high (V _{OUT} follows V _{IN} as V _{IN} decreases)	Low V _{IN} - V _{OUT} differential, <1V	Maximum duty-cycle limits exceeded.	Reduce operation to 333kHz. Reduce MOSFET on-resistance and coil DCR.
Unstable—jitters between different duty factors and frequencies	Low V _{IN} - V _{OUT} differential, <0.5V	Normal function of internal low-dropout circuitry.	Increase the minimum input voltage or ignore.
Secondary output won't support a load	Low V _{IN} - V _{OUT} differential, V _{IN} < 1.3 × V _{OUT(MAIN)}	Not enough duty cycle left to initiate forward-mode operation. Small AC current in primary can't store energy for flyback operation.	Reduce operation to 333kHz. Reduce secondary impedances; use a Schottky diode, if possible. Stack secondary winding on the main output.
Poor efficiency	Low input voltage, <5V	V _L linear regulator is going into dropout and isn't providing good gate-drive levels.	Use a small 20mA Schottky diode for boost diode. Supply V _L from an external source.
Won't start under load or quits before battery is completely dead	Low input voltage, <4.5V	V _L output is so low that it hits the V _L UVLO threshold.	Supply V _L from an external source other than V _{IN} , such as the system 5V supply.

$$P(\text{tran}) = V_{IN} \times I_{LOAD} \times f \times \frac{3}{2} \times [(V_{IN} \times C_{RSS} / I_{GATE}) - 20\text{ns}]$$

where C_{RSS} is the reverse transfer capacitance of the high-side MOSFET (a data sheet parameter), I_{GATE} is the DH gate-driver peak output current (1.5A typical), and 20ns is the rise/fall time of the DH driver (20ns typ).

$$P(\text{gate}) = Q_G \times f \times V_L$$

where V_L is the internal-logic-supply voltage (5V), and Q_G is the sum of the gate-charge values for low-side and high-side switches. For matched MOSFETs, Q_G is twice the data sheet value of an individual MOSFET. If V_{OUT} is set to less than 4.5V, replace V_L in this equation with V_{BATT}. In this case, efficiency can be improved by connecting V_L to an efficient 5V source, such as the system 5V supply:

$$P(\text{diode}) = I_{LOAD} \times V_{FWD} \times t_D \times f$$

where t_D is the diode-conduction time (120ns typ) and V_{FWD} is the forward voltage of the diode.

This power is dissipated in the MOSFET body diode if no external Schottky diode is used:

$$P(\text{cap}) = (I_{RMS})^2 \times R_{ESR}$$

where I_{RMS} is the input ripple current as calculated in the *Design Procedure* and *Input-Capacitor Value* sections.

Light-Load Efficiency Considerations

Under light loads, the PWM operates in discontinuous mode, where the inductor current discharges to zero at some point during the switching cycle. This makes the inductor current's AC component high compared to the load current, which increases core losses and I²R losses in the output filter capacitors. For best light-load efficiency, use MOSFETs with moderate gate-charge levels, and use ferrite, MPP, or other low-loss core material.

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

Lossless-Inductor Current Sensing

The DC resistance (DCR) of the inductor can be used to sense inductor current to improve the efficiency and to reduce the cost by eliminating the sense resistor. Figure 7 shows the sense circuit, where L is the inductance, R_L is the inductor DCR, R_S, and C_S form an RC low-pass sense network. If the time constant of the inductor is equal to that of the sense network, i.e.:

$$\frac{L}{R_L} = R_S C_S$$

then the voltage across C_S becomes

$$V_S = R_L \times I_L$$

where I_L is the inductor current.

Determine the required sense-resistor value using the equation given in the *Current-Sense Resistor Value* section. Choose an inductor with DCR equal or greater than the sense-resistor value. If the DCR is greater than the sense-resistor value, use a divider to scale down the voltage. Use the maximum inductance and minimum DCR to get the maximum possible inductor time constant. Select R_S and C_S so that the maximum sense network time constant is equal or greater than the maximum inductor time constant.

Reduced Output Capacitance Application

In applications where higher output ripple is acceptable, lower output capacitance or higher ESR output capacitors can be used. In such cases, cycle-by-cycle stability is maintained by adding feedforward compensation to offset for the increased output ESR. Figure 8 shows the addition of the feedforward compensation circuit. C_{FB} provides noise filtering, R_{FF} is the feedforward resistor and C_{LX} provides DC blocking. Use 100pF for C_{FB} and C_{LX}. Select R_{FF} according to the equation below:

$$R_{FF} \leq \frac{4 \times R_3 \times L \times f}{ESR}$$

Set the value for R_{FF} close to the calculation. Do not make R_{FF} too small as that will introduce too much feedforward, possibly causing an overvoltage to be seen at the feedback pin, and changing the mode of operation to a voltage mode.

PC Board Layout Considerations

Good PC board layout is required in order to achieve specified noise, efficiency, and stability performance. The PC board layout artist must be given explicit instructions, preferably a pencil sketch showing the placement of power-switching components and high-current routing. A ground plane is essential for optimum

Figure 7. Lossless Inductor Current Sensing

Figure 8. Adding Feedforward Compensation

500kHz Multi-Output, Low-Noise Power-Supply Controllers for Notebook Computers

performance. In most applications, the circuit will be located on a multilayer board, and full use of the four or more copper layers is recommended. Use the top layer for high-current connections, the bottom layer for quiet connections (REF, SS, GND), and the inner layers for an uninterrupted ground plane. Use the following step-by-step guide:

- 1) Place the high-power components (Figure 1, C1, C3, C4, Q1, Q2, L1, and R1) first, with their grounds adjacent.
 - Priority 1: Minimize current-sense resistor trace lengths and ensure accurate current sensing with Kelvin connections (Figure 9).
 - Priority 2: Minimize ground trace lengths in the high-current paths (discussed below).
 - Priority 3: Minimize other trace lengths in the high current paths.
 - Use >5mm-wide traces
 - CIN to high-side MOSFET drain: 10mm max length
 - Rectifier diode cathode to low-side MOSFET: 5mm max length
 - LX node (MOSFETs, rectifier cathode, inductor): 15mm max length

Ideally, surface-mount power components are butted up to one another with their ground terminals almost touching. These high-current grounds are then connected to each other with a wide filled zone of top-layer copper so they don't go through vias. The resulting top layer "sub-ground-plane" is connected to the normal inner-layer ground plane at the output ground terminals, which ensures that the IC's analog ground is sensing at the supply's output terminals without interference from IR drops

Figure 9. Kelvin Connections for the Current-Sense Resistors

and ground noise. Other high-current paths should also be minimized, but focusing primarily on short ground and current-sense connections eliminates about 90% of all PC board layout problems.

- 2) Place the IC and signal components. Keep the main switching nodes (LX nodes) away from sensitive analog components (current-sense traces and REF capacitor). Place the IC and analog components on the opposite side of the board from the power-switching node. **Important:** the IC must be no more than 10mm from the current-sense resistors. Keep the gate-drive traces (DH_, DL_, and BST_) shorter than 20mm and route them away from CSH_, CSL_, and REF.
- 3) Use a single-point star ground where the input ground trace, power ground (sub-ground-plane), and normal ground plane meet at the supply's output ground terminal. Connect both IC ground pins and all IC bypass capacitors to the normal ground plane.
