

MAXIM

2.5Gbps, Low-Power, +3.3V Clock Recovery and Data Retiming IC

MAX3876

General Description

The MAX3876 is a compact, low-power clock recovery and data retiming IC for 2.488Gbps SDH/SONET applications. The fully integrated phase-locked loop (PLL) recovers a synchronous clock signal from the serial NRZ data input. The data is retimed by the recovered clock. Differential CML outputs are provided for both clock and data signals, and an additional 2.488Gbps serial input is available for system loopback diagnostic testing. The device also includes a TTL-compatible loss-of-lock (LOL) monitor.

The MAX3876 is designed for both section-regenerator and terminal-receiver applications in OC-48/STM-16 transmission systems. Its jitter performance exceeds all of the SONET/SDH specifications.

This device operates from a +3.3V or +5.0V single supply over a -40°C to +85°C temperature range. Power consumption is typically only 445mW with a +3.3V supply. The MAX3876 is available in a 32-pin TQFP package as well as in die form.

Applications

SDH/SONET Receivers and Regenerators
Add/Drop Multiplexers
Digital Cross-Connects
2.488Gbps ATM Receiver
Digital Video Transmission
SDH/SONET Test Equipment
Intrarack/Subrack Interconnects

Features

- ◆ Exceeds ANSI, ITU, and Bellcore SONET/SDH Regenerator Specifications
- ◆ 440mW Power Dissipation (at +3.3V)
- ◆ Clock Jitter Generation: 3.7mUI_{RMS}
- ◆ +3.3V or +5V Single Power Supply
- ◆ Fully Integrated Clock Recovery and Data Retiming
- ◆ Additional High-Speed Input Facilitates System Loopback Diagnostic Testing
- ◆ Tolerates >2500 Consecutive Identical Digits
- ◆ Loss-of-Lock Indicator
- ◆ Differential CML Data and Clock Outputs

Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE
MAX3876EHJ	-40°C to +85°C	32 TQFP
MAX3876E/D	-40°C to +85°C	Dice*

*Dice are designed to operate over this range, but are tested and guaranteed at $T_A = +25^\circ\text{C}$ only. Contact factory for availability.

Pin Configuration appears at end of data sheet.

2.5Gbps, Low-Power, +3.3V Clock Recovery and Data Retiming IC

ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V_{CC}-0.5V to +7.0V
 Input Voltage Levels
 (SDI+, SDI-, SLBI+, SLBI-)($V_{CC} - 0.5V$) to ($V_{CC} + 0.5V$)
 Input Current Levels (SDI+, SDI-, SLBI+, SLBI-)..... $\pm 11mA$
 CML Output Current Levels
 (SDO+, SDO-, SCLKO+, SCLKO-) $\pm 22mA$
 Voltage at \overline{LOL} , SIS, FIL+, FIL-.....-0.5V to ($V_{CC} + 0.5V$)

Continuous Power Dissipation ($T_A = +85^\circ C$)
 32-Pin TQFP (derate 16.1mW/ $^\circ C$ above +85 $^\circ C$).....1.0W
 Operating Temperature Range
 MAX3876EHJ.....-40 $^\circ C$ to +85 $^\circ C$
 Operating Junction Temperature Range (die) ..-55 $^\circ C$ to +150 $^\circ C$
 Storage Temperature Range-60 $^\circ C$ to +160 $^\circ C$
 Processing Temperature (die)+400 $^\circ C$
 Lead Temperature (soldering, 10s)+300 $^\circ C$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DC ELECTRICAL CHARACTERISTICS

($V_{CC} = +3.0V$ to +5.5V, $T_A = -40^\circ C$ to +85 $^\circ C$, unless otherwise noted. Typical values are at +3.3V and $T_A = +25^\circ C$.) (Note 1)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS

MAX3876

Pin Description (continued)

PIN	NAME	FUNCTION
19	SCLKO+	Positive Serial Clock Output, CML, 2.488GHz. SDO+ is clocked out on the rising edge of SCLKO+.
22	SDO-	Negative Data Output, CML, 2.488Gbps
23	SDO+	Positive Data Output, CML, 2.488Gbps
25	$\overline{\text{LOL}}$	Loss-of-Lock Output, TTL, PLL loss-of-lock monitor, active low (internal 10k Ω pull-up resistor)
30	FIL-	Negative Filter Input. PLL loop filter connection. Connect a 1.0 μ F capacitor between FIL+ and FIL-.
31	FIL+	Positive Filter Input. PLL loop filter connection. Connect a 1.0 μ F capacitor between FIL+ and FIL-.

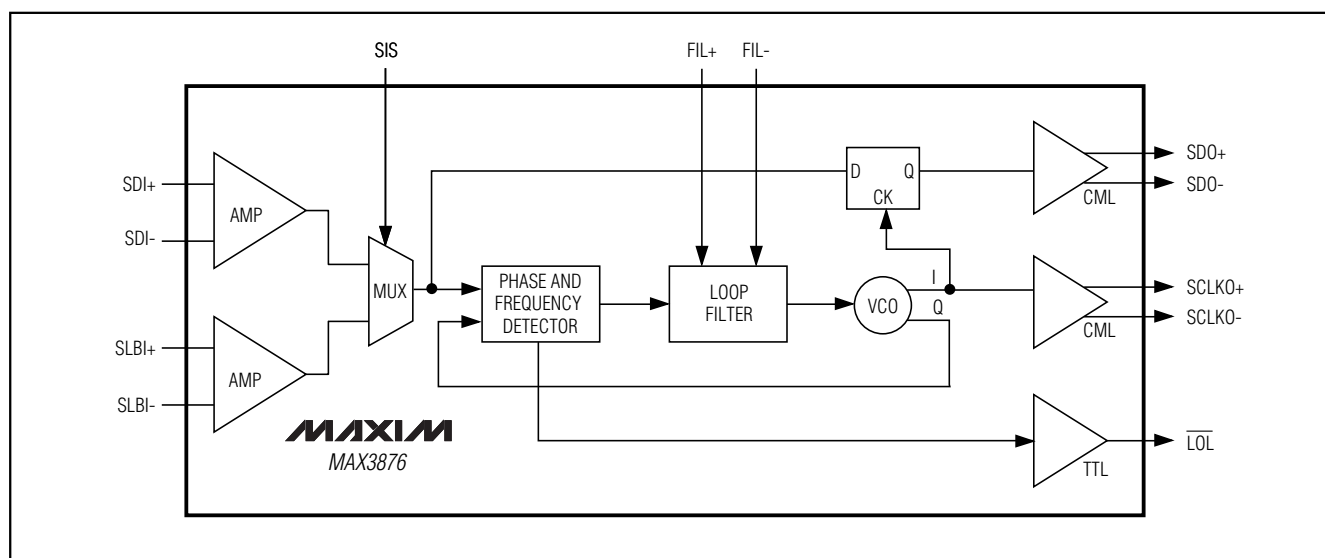

Figure 3. Functional Diagram

Detailed Description

The MAX3876 consists of a fully integrated phase-locked loop (PLL), input amplifier, data retiming block, and CML output buffer (Figure 3). The PLL consists of a phase/frequency detector (PFD), a loop filter, and a voltage-controlled oscillator (VCO).

This device is designed to deliver the best combination of jitter performance and power dissipation by using a fully differential signal architecture and low-noise design techniques.

Input Amplifier

Input amplifiers are implemented for both the main data and system loopback inputs. These amplifiers accept DC-coupled differential input amplitudes from 50mVp-p

up to 1000mVp-p. With AC-coupling, differential input signal amplitudes can be increased to a maximum of 1600mVp-p. The bit error rate is better than $1 \cdot 10^{-10}$ for input signals as small as 10mVp-p, though the jitter tolerance performance will be degraded. For interfacing with PECL signal levels, see *Applications Information*.

Phase Detector

The phase detector incorporated in the MAX3876 produces a voltage proportional to the phase difference between the incoming data and the internal clock. Because of its feedback nature, the PLL drives the error voltage to zero, aligning the recovered clock to the center of the incoming data eye for retiming.

2.5Gbps, Low-Power, +3.3V Clock Recovery and Data Retiming IC

Frequency Detector

The digital frequency detector (FD) aids frequency acquisition during start-up conditions. The frequency difference between the received data and the VCO clock is derived by sampling the in-phase and quadrature VCO outputs on the rising edge of the data input signal. Depending on the polarity of the frequency difference, the FD drives the VCO until the frequency difference is reduced to zero. Once frequency acquisition is complete, the FD returns to a neutral state. False locking is completely eliminated by this digital frequency detector.

Loop Filter and VCO

The phase detector and frequency detector outputs are summed into the loop filter. An external capacitor, C_F , is required to set the PLL damping ratio. See *Design Procedure* for guidelines on selecting this capacitor.

The loop filter output controls the on-chip LC VCO running at 2.488GHz. The VCO provides low-phase noise and is trimmed to the correct frequency. Clock jitter generation is typically 1.5psRMS within a jitter bandwidth of 12kHz to 20MHz.

Loss-of-Lock Monitor

A loss-of-lock ($\overline{\text{LOL}}$) monitor is incorporated in the MAX3876 frequency detector. A loss-of-lock condition is signaled immediately with a TTL low. When the PLL is frequency locked, $\overline{\text{LOL}}$ switches to TTL high in approximately 800ns.

Note: The $\overline{\text{LOL}}$ monitor is valid only when a data stream is present on the inputs to the MAX3876. As a result, $\overline{\text{LOL}}$ does not detect a loss-of-power condition due to loss of the incoming signal.

Design Procedure

Setting the Loop Filter

The MAX3876 is designed for both regenerator and receiver applications. Its fully integrated PLL is a classic second-order feedback system, with a loop bandwidth (f_L) fixed at 1.5MHz. The external capacitor, C_F , can be adjusted to set the loop damping. Figures 4 and 5 show the open-loop and closed-loop transfer functions.

The PLL zero frequency, f_z , is a function of external capacitor C_F , and can be approximated according to:

$$f_z = \frac{1}{2\pi(60) C_F}$$

Figure 4. Open-Loop Transfer Function

Figure 5. Closed-Loop Transfer Function

For an overdamped system ($f_z/f_L < 0.25$), the jitter peaking (M_p) of a second-order system can be approximated by:

$$M_p = 20 \log \left(1 + \frac{f_z}{f_L} \right)$$

For example, using $C_F = 0.1\mu\text{F}$ results in a jitter peaking of 0.2dB. Reducing C_F below $0.01\mu\text{F}$ may result in PLL instability. The recommended value for C_F is $1.0\mu\text{F}$ to guarantee a maximum jitter peaking of less than 0.1dB. C_F must be a low TC, high-quality capacitor of type X7R or better.

2.5Gbps, Low-Power, +3.3V Clock Recovery and Data Retiming IC

Input and Output Terminations

The MAX3876's digital outputs (SDO+, SDO-, SCLKO+, SCLKO-) are internally terminated with 50Ω to V_{CC} (Figure 6). See the *DC Electrical Characteristics* for signal swing and common-mode voltage levels. To ensure best performance, the differential outputs must have balanced loads. The input termination can be driven differentially or can be driven single-ended by externally biasing SDI- or SLBI- to the center of the voltage swing.

Jitter Tolerance and Input Sensitivity Trade-Offs

When the received data amplitude is higher than 50mVp-p, the MAX3876 provides a typical jitter tolerance of 0.51UI at jitter frequencies greater than 10MHz. The SDH/SONET jitter tolerance specification is 0.15UI, leaving a jitter allowance of 0.36UI for receiver preamplifier and postamplifier design.

The BER is better than $1 \cdot 10^{-10}$ for input signals greater than 10mVp-p. At this input level, jitter tolerance will be degraded but will still be above the SDH/SONET requirement. The user can make a trade-off between jitter tolerance and input sensitivity according to the specific application. See the *Typical Operating Characteristics* for Jitter Tolerance and BER vs. Input Amplitude graphs.

Jitter Tolerance vs. Pulse-Width Distortion

The MAX3876 can typically tolerate up to 0.20UI of pulse-width distortion (PWD) and still exceed ITU and Bellcore specifications for sinusoidal jitter tolerance. Refer to the *Typical Operating Characteristics* for Jitter Tolerance and PWD vs. Jitter Frequency graphs.

Applications Information

Consecutive Identical Digits (CIDs)

The MAX3876 has a low phase and frequency drift in the absence of data transitions. As a result, long runs of consecutive zeros and ones can be tolerated while maintaining a BER of $1 \cdot 10^{-10}$. The CID tolerance is tested using a $2^{13} - 1$ PRBS, substituting a long run of zeros to simulate the worst case. A CID tolerance of 2500 bits is typical.

System Loopback

The MAX3876 is designed to allow system loopback testing. The user can connect a serializer output in a transceiver directly to the SLBI+ and SLBI- inputs of the MAX3876 for system diagnostics. To select the SLBI± inputs, apply a TTL logic high to the SIS pin.

PECL Input Levels

When interfacing with differential PECL input levels, it is important to attenuate the signal while still maintaining 50Ω termination (Figure 7). AC-coupling is also required to maintain the input common-mode level.

Layout

The MAX3876's performance can be significantly affected by circuit board layout and design. Use good high-frequency design techniques, including minimizing ground inductance and using fixed-impedance transmission lines on the data and clock signals. Power-supply decoupling should be placed as close to V_{CC} as possible. Take care to isolate the input from the output signals to reduce feedthrough.
