

Low-Cost, High-Speed, Single-Supply, Gain of +2 Buffers with Rail-to-Rail Outputs in SOT23

General Description

The MAX4014/MAX4017/MAX4019/MAX4022 are precision, closed-loop, gain of +2 (or -1) buffers featuring high slew rates, high output current drive, and low differential gain and phase errors. These single-supply devices operate from +3.15V to +11V, or from $\pm 1.575V$ to $\pm 5.5V$ dual supplies. The input voltage range extends 100mV beyond the negative supply rail and the outputs swing Rail-to-Rail®.

These devices require only 5.5mA of quiescent supply current while achieving a 200MHz -3dB bandwidth and a 600V/ μ s slew rate. In addition, the MAX4019 has a disable feature that reduces the supply current to 400 μ A. Input voltage noise for these parts is only 10nV/ \sqrt{Hz} and input current noise is only 1.3pA/ \sqrt{Hz} . This buffer family is ideal for low-power/low-voltage applications that require wide bandwidth, such as video, communications, and instrumentation systems. For space-sensitive applications, the MAX4014 comes in a tiny 5-pin SOT23 package.

Selector Guide

PART	NO. OF AMPS	ENABLE	PIN-PACKAGE
MAX4014	1	No	5-Pin SOT23
MAX4017	2	No	8-Pin SO/ μ MAX
MAX4019	3	Yes	14-Pin SO, 16-Pin QSOP
MAX4022	4	No	14-Pin SO, 16-Pin QSOP

Applications

Portable/Battery-Powered Instruments
Video Line Driver
Analog-to-Digital Converter Interface
CCD Imaging Systems
Video Routing and Switching Systems

Rail-to-Rail is a registered trademark of Nippon Motorola Ltd.

Features

- ◆ Internal Precision Resistors for Closed-Loop Gains of +2 or -1
- ◆ High Speed:
 - 200MHz -3dB Bandwidth
 - 30MHz 0.1dB Gain Flatness (6MHz min)
 - 600V/ μ s Slew Rate
- ◆ Single 3.3V/5.0V Operation
- ◆ Outputs Swing Rail-to-Rail
- ◆ Input Voltage Range Extends Beyond VEE
- ◆ Low Differential Gain/Phase: 0.04%/0.02°
- ◆ Low Distortion at 5MHz:
 - 78dBc Spurious-Free Dynamic Range
 - 75dB Total Harmonic Distortion
- ◆ High Output Drive: $\pm 120mA$
- ◆ Low, 5.5mA Supply Current
- ◆ 400 μ A Shutdown Supply Current
- ◆ Space-Saving SOT23-5, μ MAX, or QSOP Packages

Low-Cost, High-Speed, Single-Supply, Gain of +2 Buffers with Rail-to-Rail Outputs in SOT23

Detailed Description

The MAX4014/MAX4017/MAX4019/MAX4022 are single-supply, rail-to-rail output, voltage-feedback, closed-loop buffers that employ current-feedback techniques to achieve 600V/μs slew rates and 200MHz bandwidths. These buffers use internal 500Ω resistors to provide a preset closed-loop gain of +2V/V in the non-inverting configuration or -1V/V in the inverting configuration. Excellent harmonic distortion and differential gain/phase performance make these buffers an ideal choice for a wide variety of video and RF signal-processing applications.

Local feedback around the buffer's output stage ensures low output impedance, which reduces gain sensitivity to load variations. This feedback also produces demand-driven current bias to the output transistors for ±120mA drive capability, while constraining total supply current to less than 7mA.

Applications Information

Power Supplies

These devices operate from a single +3.15V to +11V power supply or from dual supplies of ±1.575V to ±5.5V. For single-supply operation, bypass the VCC pin to ground with a 0.1μF capacitor as close to the pin as possible. If operating with dual supplies, bypass each supply with a 0.1μF capacitor.

Selecting Gain Configuration

Each buffer in the MAX4014 family can be configured for a voltage gain of +2V/V or -1V/V. For a gain of

+2V/V, ground the inverting terminal. Use the noninverting terminal as the signal input of the buffer (Figure 1a). Grounding the noninverting terminal and using the inverting terminal as the signal input configures the buffer for a gain of -1V/V (Figure 1b).

Since the inverting input exhibits a 500Ω input impedance, terminate the input with a 56Ω resistor when the device is configured for an inverting gain in 50Ω applications (terminate with 88Ω in 75Ω applications). Terminate the input with a 49.9Ω resistor in the noninverting case. Output terminating resistors should directly match cable impedances in either configuration.

Layout Techniques

Maxim recommends using microstrip and stripline techniques to obtain full bandwidth. To ensure that the PC board does not degrade the buffer's performance, design it for a frequency greater than 1GHz. Pay careful attention to inputs and outputs to avoid large parasitic capacitance. Whether or not you use a constant-impedance board, observe the following guidelines when designing the board:

- Don't use wire-wrapped boards. They are too inductive.
- Don't use IC sockets. They increase parasitic capacitance and inductance.
- Use surface-mount instead of through-hole components for better high-frequency performance.
- Use a PC board with at least two layers; it should be as free from voids as possible.
- Keep signal lines as short and as straight as possible. Do not make 90° turns; round all corners.

Input Voltage Range and Output Swing

The input range for the MAX4014 family extends from $(V_{EE} - 100\text{mV})$ to $(V_{CC} - 2.25\text{V})$. Input ground sensing increases the dynamic range for single-supply applications. The outputs drive a $2\text{k}\Omega$ load to within 60mV of the power-supply rails. With heavier loads, the output swing is reduced as shown in the *Electrical Characteristics* and the *Typical Operating Characteristics*. As the load increases, the input range is effectively limited by

the output-drive capability, since the buffers have a fixed voltage gain of +2 or -1.

For example, a 50Ω load can typically be driven from 40mV above V_{EE} to 1.6V below V_{CC} , or 40mV to 3.4V when operating from a single +5V supply. If the buffer is operated in the noninverting, gain of +2 configuration with the inverting input grounded, the effective input voltage range becomes 20mV to 1.7V , instead of the -100mV to 2.75V indicated by the *Electrical Characteristics*. Beyond the effective input range, the buffer output is a nonlinear function of the input, but it will not undergo phase reversal or latching.

Enable

The MAX4019 has an enable feature (EN_{-}) that allows the buffer to be placed in a low-power state. When the buffers are disabled, the supply current will not exceed $550\mu\text{A}$ per buffer.

As the voltage at the EN_{-} pin approaches the negative supply rail, the EN_{-} input current rises. Figure 2 shows a graph of EN_{-} input current versus EN_{-} pin voltage. Figure 3 shows the addition of an optional resistor in series with the EN_{-} pin, to limit the magnitude of the current increase. Figure 4 displays the resulting EN_{-} pin input current to voltage relationship.

Figure 5. Input Protection Circuit

Figure 7. Driving a Capacitive Load through an Isolation Resistor

Figure 6. Small-Signal Gain vs. Frequency with Load Capacitance and No Isolation Resistor

Disabled Output Resistance

The MAX4014/MAX4017/MAX4019/MAX4022 include internal protection circuitry that prevents damage to the precision input stage from large differential input voltages, as shown in Figure 5. This protection circuitry consists of five back-to-back Schottky diodes between IN₊ and IN₋. These diodes lower the disabled output resistance from 1kΩ to 500Ω when the output voltage is 3V greater or less than the voltage at IN₊. Under these

conditions, the input protection diodes will be forward biased, lowering the disabled output resistance to 500Ω.

Output Capacitive Loading and Stability

The MAX4014/MAX4017/MAX4019/MAX4022 provide maximum AC performance with no load capacitance. This is the case when the load is a properly terminated transmission line. However, they are designed to drive up to 25pF of load capacitance without oscillating, but with reduced AC performance.

Driving large capacitive loads increases the chance of oscillations occurring in most amplifier circuits. This is especially true for circuits with high loop gains, such as voltage followers. The buffer's output resistance and the load capacitor combine to add a pole and excess phase to the loop response. If the frequency of this pole is low enough to interfere with the loop response and degrade phase margin sufficiently, oscillations can occur.

A second problem when driving capacitive loads results from the amplifier's output impedance, which looks inductive at high frequencies. This inductance forms an L-C resonant circuit with the capacitive load, which causes peaking in the frequency response and degrades the amplifier's gain margin.

Figure 6 shows the frequency response of the MAX4014/MAX4017/MAX4019/MAX4022 under different capacitive loads. To drive loads with greater than 25pF of capacitance or to settle out some of the peaking, the output requires an isolation resistor like the one shown in

Low-Cost, High-Speed, Single-Supply, Gain of +2 Buffers with Rail-to-Rail Outputs in SOT23

MAX4014/MAX4017/MAX4019/MAX4022

Figure 8. Capacitive Load vs. Isolation Resistance

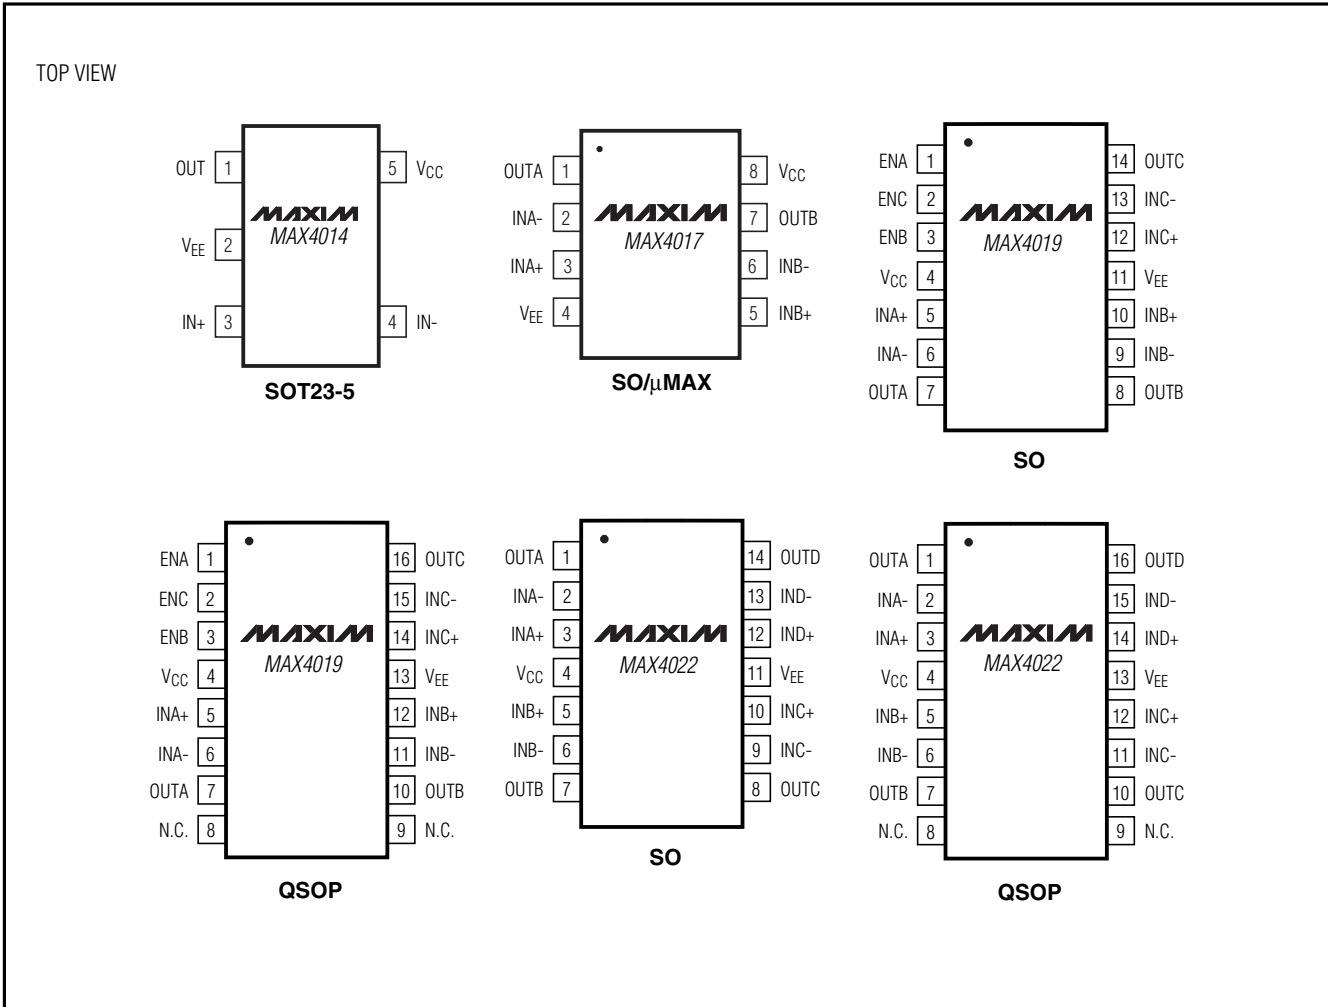

Figure 9. Small-Signal Gain vs. Frequency with Load Capacitance and 27 Ω Isolation Resistor

Figure 7. Figure 8 is a graph of the optimal isolation resistor versus load capacitance. Figure 9 shows the frequency response of the MAX4014/MAX4017/MAX4019/MAX4022 when driving capacitive loads with a 27 Ω isolation resistor.

Coaxial cables and other transmission lines are easily driven when properly terminated at both ends with their characteristic impedance. Driving back-terminated transmission lines essentially eliminates the lines' capacitance.
