

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

## General Description

The MAX8758 includes a high-performance step-up regulator, a high-speed operational amplifier, and a logic-controlled, high-voltage switch-control block with programmable delay. The device is optimized for thin-film transistor (TFT) liquid-crystal display (LCD) applications.

The step-up DC-DC regulator provides the regulated supply voltage for the panel source driver ICs. The converter is a high-frequency (640kHz/1.2MHz), current-mode regulator with an integrated 14V n-channel power MOSFET. The high-switching frequency allows the use of ultra-small inductors and ceramic capacitors. The current-mode control architecture provides fast transient response to pulsed loads. The regulator achieves efficiencies over 85% by bootstrapping the supply rail of the internal gate driver from the step-up regulator output. The step-up regulator features undervoltage lockout (UVLO), soft-start, and internal current limit. The high-current operational amplifier is designed to drive the LCD backplane (VCOM). The amplifier features high output current ( $\pm 150\text{mA}$ ), fast slew rate ( $7.5\text{V}/\mu\text{s}$ ), wide bandwidth (12MHz), and rail-to-rail inputs and outputs.

The MAX8758 is available in a 24-pin, 4mm x 4mm, thin QFN package with a maximum thickness of 0.8mm for ultra-thin LCD panels. The device operates over the  $-40^\circ\text{C}$  to  $+85^\circ\text{C}$  temperature range.

## Applications

Notebook Displays  
LCD Monitors

## Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX8758ETG	$-40^\circ\text{C}$ to $+85^\circ\text{C}$	24 Thin QFN-EP* 4mm x 4mm

\*EP = Exposed pad.

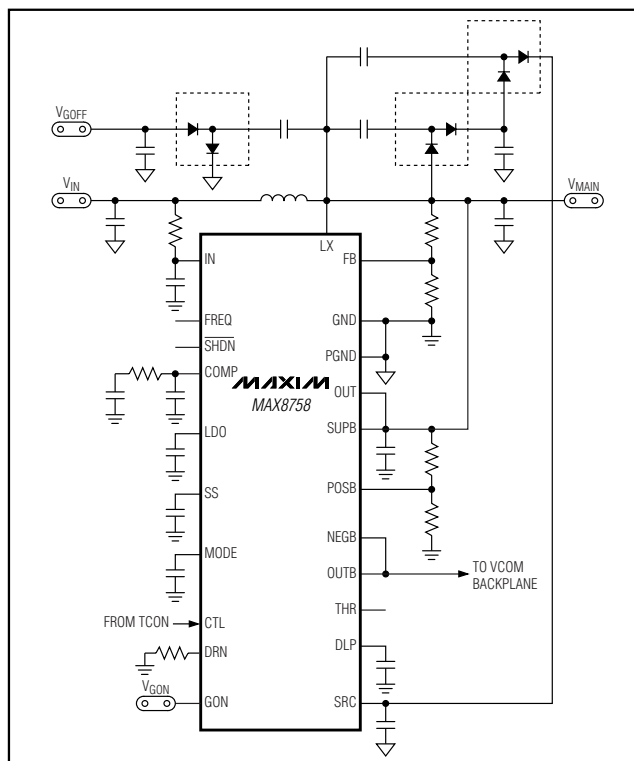

Pin Configuration appears at end of data sheet.

DualMode is a trademark of Maxim Integrated Products, Inc.

## Features

- ◆ 1.8V to 5.5V Input Voltage Range
- ◆ Input Undervoltage Lockout
- ◆ 0.5mA Quiescent Current
- ◆ 640kHz/1.2MHz Current-Mode Step-Up Regulator
  - Fast Transient Response
  - High-Accuracy Output Voltage (1.5%)
  - Built-In 14V, 2.5A, 115m $\Omega$  MOSFET
  - High Efficiency
  - Programmable Soft-Start
  - Current Limit with Lossless Sensing
  - Timer-Delay Fault Latch
- ◆ High-Speed Operational Amplifier
  - $\pm 150\text{mA}$  Output Current
  - 7.5V/ $\mu\text{s}$  Slew Rate
  - 12MHz, -3dB Bandwidth
  - Rail-to-Rail Inputs/Outputs
- ◆ Dual-Mode™, Logic-Controlled, High-Voltage Switch with Programmable Delay
- ◆ Thermal-Overload Protection
- ◆ 24-Pin, 4mm x 4mm, Thin QFN Package

## Pin Description

MAX8758

PIN	NAME	FUNCTION
1	GND	Analog Ground
2	GON	Internal High-Voltage-Switch Common Connection. GON is the output of the high-voltage-switch-control block. GON is internally pulled to PGND through a 1k $\Omega$ resistor in shutdown. See the <i>High-Voltage Switch Control</i> section for details.
3	CTL	High-Voltage, Switch-Control Block Timing Pin. See the <i>High-Voltage Switch Control</i> section for details.
4	DLP	High-Voltage, Switch-Control Block Delay Pin. Connect a capacitor from DLP to GND to set the delay time. A 5 $\mu$ A current source charges C <sub>DLP</sub> . DLP is internally pulled to GND by a resistor in shutdown. See the <i>High-Voltage Switch Control</i> section for details.
5	THR	GON Falling Regulation Adjustment Pin. Connect THR to the center of a resistive voltage-divider between LDO or OUT and GND to adjust the V <sub>GON</sub> falling regulation level. The actual regulation level is 10 x V <sub>THR</sub> . See the <i>High-Voltage Switch Control</i> section for details.
6	SUPB	Operational Amplifier Supply Input. Bypass SUPB to GND with a 0.1 $\mu$ F capacitor.
7	OUTB	Operational Amplifier Output
8	NEGB	Operational Amplifier Inverting Input
9	POSB	Operational Amplifier Noninverting Input
10	N.C.	No Connection. Not internally connected.
11	LDO	5V Internal Linear Regulator Output. This regulator powers all internal circuitry except the operational amplifier. Bypass LDO to GND with a 0.22 $\mu$ F or greater ceramic capacitor.
12	OUT	Internal Linear Regulator Supply Pin. OUT is the supply input of the internal 5V linear regulator. Connect OUT directly to the output of the step-up regulator.
13	I.C.	Internally Connected. Make no connection to this pin.
14	SS	Soft-Start Control Pin. Connect a capacitor between SS and GND to set the soft-start period of the step-up regulator. See the <i>Bootstrapping and Soft-Start</i> section for details.
15	COMP	Error Amplifier Compensation Pin. See the <i>Step-Up Regulator Loop Compensation</i> section for details.
16	FREQ	Frequency-Select Pin. Connect FREQ to GND for 600kHz operation, and connect FREQ to IN for 1.2MHz operation.
17	IN	Supply Pin. Bypass IN to GND with a 1 $\mu$ F ceramic capacitor. Place the capacitor close to the IN pin.
18	LX	Switching Node. LX is the drain of the internal power MOSFET. Connect the inductor and the Schottky diode to LX and minimize trace area for low EMI.
19	$\overline{\text{SHDN}}$	Shutdown Control Pin. Pull $\overline{\text{SHDN}}$ low to turn off the step-up regulator, the operational amplifier, and the switch control block.
20	FB	Feedback Pin. The FB regulation point is 1.24V (typ). Connect FB to the center of a resistive voltage-divider between the step-up regulator output and GND to set the step-up regulator output voltage. Place the divider close to the FB pin.
21	PGND	Power Ground
22	MODE	High-Voltage, Switch-Control Block-Mode Selection Timing-Adjustment Pin. See the <i>High-Voltage Switch Control</i> section for details. MODE is high impedance when it is connected to LDO. MODE is internally pulled down by a 1k $\Omega$ resistor during UVLO, when V <sub>DLP</sub> < 0.5 x V <sub>LDO</sub> , or in shutdown.
23	DRN	High-Voltage, Switch-Control Input. DRN is the drain of the internal high-voltage p-channel MOSFET connected to GON.
24	SRC	High-Voltage Switch-Control Input. SRC is the source of the internal high-voltage p-channel MOSFET.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

## Typical Operating Circuit

The typical operating circuit (Figure 1) of the MAX8758 is a power-supply solution for TFT LCD panels in notebook computers. The circuit generates a +8.5V source driver supply, and approximately +22V and -7V gate

driver supplies. The input voltage range for the IC is from +1.8V to +5.5V, but the Figure 1 circuit is designed to run from 2.7V to 3.6V. Table 1 lists some selected components and Table 2 lists the contact information of component suppliers.

## Detailed Description

The MAX8758 is designed primarily for TFT LCD panels used in notebook computers. It contains a high-performance step-up regulator, a high-speed operational amplifier, a logic-controlled, high-voltage switch-control block with programmable delay, and an internal linear regulator for bootstrapping operation. Figure 2 shows the MAX8758 functional block diagram.

### Step-Up Regulator

The step-up regulator is designed to generate the LCD source driver supply. It employs a current-mode, fixed-frequency PWM architecture to maximize loop bandwidth and provide fast transient response to pulsed loads typical of TFT LCD panel source drivers. The internal oscillator offers two pin-selectable frequency options (640kHz/1.2MHz), allowing users to optimize their designs based on the specific application requirements.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

The internal n-channel power MOSFET reduces the number of external components. The supply rail of the internal gate driver is bootstrapped to the internal linear regulator output to improve the efficiency at low-input voltages. The external-capacitor, soft-start function effectively controls inrush currents. The output voltage can be set from  $V_{IN}$  to 13V with an external resistive voltage-divider.

### PWM Control Block

Figure 3 is the block diagram of the step-up regulator. The regulator controls the output voltage and the power delivered to the output by modulating the duty cycle (D) of the internal power MOSFET in each switching cycle. The duty cycle of the MOSFET is approximated by:

$$D \approx \frac{V_{OUT} - V_{IN}}{V_{OUT}}$$

where  $V_{OUT}$  is the output voltage of the step-up regulator.

On the rising edge of the internal oscillator clock, the controller sets a flip-flop, turning on the n-channel MOSFET and applying the input voltage across the inductor. The current through the inductor ramps up linearly, storing energy in its magnetic field. A transconductance error amplifier compares the FB voltage with a 1.24V (typ) reference voltage. The error amplifier changes the COMP voltage by charging or discharging the COMP capacitor. The COMP voltage is compared with a ramp, which is the sum of the current-sense signal and a slope compensation signal. Once the ramp signal exceeds the COMP voltage, the controller resets the flip-flop and turns off the MOSFET. Since the inductor current is continuous, a transverse potential develops across the inductor that turns on the Schottky diode (D1 in Figure 1). The voltage across the inductor then becomes the difference between the output voltage and the input voltage. This discharge condition forces the current through the inductor to ramp down, transferring the energy stored in the magnetic field to the output capacitor and the load. The MOSFET remains off for the rest of the clock cycle.

Figure 3. Step-Up Regulator Block Diagram

### Bootstrapping and Soft-Start

The MAX8758 features bootstrapping operation. In normal operation, the internal linear regulator supplies power to the internal circuitry. The input of the linear regulator (OUT) should be directly connected to the output of the step-up regulator. The step-up regulator is enabled when the input voltage at OUT is above 1.75V,  $\overline{\text{SHDN}}$  is high, and the fault latch is not set.

After being enabled, the regulator starts open-loop switching to generate the supply voltage for the linear regulator with a controlled duty cycle. The internal reference block turns on when the LDO voltage exceeds 2.7V (typ). When the reference voltage reaches regulation, the PWM controller and the current-limit circuit are enabled and the step-up regulator enters soft-start.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

The soft-start timing can be adjusted with an external capacitor connected between SS and GND. After the step-up regulator is enabled, the SS pin is immediately charged to 0.5V. Then the capacitor is charged at a constant current of 4 $\mu$ A (typ). During this time, the SS voltage directly controls the peak inductor current, allowing a linear ramp from zero up to the full current limit. The maximum load current is available after the voltage on SS exceeds 1.5V. The soft-start capacitor is discharged to ground when SHDN is low. The soft-start routine minimizes inrush current and voltage overshoot and ensures a well-defined startup behavior (see the Step-Up Regulator Heavy Load Soft-Start waveform in the *Typical Operating Characteristics*).

## Fault Protection

During steady-state operation, the MAX8758 monitors the FB voltage. If the FB voltage is below 1V (typ), the MAX8758 activates an internal fault timer. If there is a continuous fault for the fault-timer duration, the MAX8758 sets the fault latch, shutting down all the outputs. Once the fault condition is removed, cycle the input voltage to clear the fault latch and reactivate the device. The fault-detection circuit is disabled during the soft-start time.

The MAX8758 monitors the OUT voltage for undervoltage and overvoltage conditions. If the OUT voltage is below 1.4V (typ) or above 13.5V (typ), the MAX8758 disables the gate driver of the step-up regulator and prevents the internal MOSFET from switching. The OUT undervoltage and overvoltage conditions do not set the fault latch.

## Thermal-Overload Protection

The thermal-overload protection prevents excessive power dissipation from overheating the MAX8758. When the junction temperature exceeds  $T_J = +160^\circ\text{C}$ , a thermal sensor immediately activates the fault protection, which sets the fault latch and shuts down all the outputs, allowing the device to cool down. Once the device cools down by approximately  $15^\circ\text{C}$ , cycle the input voltage or toggle SHDN to clear the fault latch and restart the device.

The thermal-overload protection protects the controller in the event of fault conditions. For continuous operation, do not exceed the absolute maximum junction temperature rating of  $T_J = +150^\circ\text{C}$ .

## Frequency Selection (FREQ)

The FREQ pin selects the switching frequency. Table 3 shows the switching frequency based on the FREQ connection. High-frequency (1.2MHz) operation optimizes the application for the smallest component size, trading off efficiency due to higher switching losses. Low-frequency (600kHz) operation offers the best overall efficiency at the expense of component size and board space.

**Table 3. Frequency Selection**

FREQ	SWITCHING FREQUENCY (kHz)
GND	600
IN	1200

## Operational Amplifier

The MAX8758's operational amplifier is typically used to drive the LCD backplane (VCOM) or the gamma-correction-divider string. The operational amplifier features  $\pm 150\text{mA}$  output short-circuit current, 7.5V/ $\mu\text{s}$  slew rate, and 12MHz bandwidth. The rail-to-rail input and output capability maximizes system flexibility.

## Short-Circuit Current Limit

The operational amplifier limits short-circuit current to approximately  $\pm 150\text{mA}$  if the output is directly shorted to SUPB or to GND. If the short-circuit condition persists, the junction temperature of the IC rises until it reaches the thermal shutdown threshold ( $+160^\circ\text{C}$  typ). Once the junction temperature reaches the thermal shutdown threshold, an internal thermal sensor immediately sets the thermal fault latch, shutting off all the IC's outputs. The device remains inactive until the input voltage is cycled or SHDN is toggled.

## Driving Pure Capacitive Load

The operational amplifier is typically used to drive the LCD backplane (VCOM) or the gamma-correction divider string. The LCD backplane consists of a distributed series capacitance and resistance, a load that can be easily driven by the operational amplifier. However, if the operational amplifier is used in an application with a pure capacitive load, steps must be taken to ensure stable operation.

As the operational amplifier's capacitive load increases, the amplifier's bandwidth decreases and gain peaking increases. A  $5\Omega$  to  $50\Omega$  small resistor placed between OUTB and the capacitive load reduces peaking but also reduces the gain. An alternative method of reducing peaking is to place a series RC network (snubber) in parallel with the capacitive load. The RC network does not continuously load the output or reduce the gain. Typical values of the resistor are between  $100\Omega$  and  $200\Omega$  and the typical value of the capacitor is 10pF.

## High-Voltage Switch Control

The MAX8758's high-voltage switch-control block (Figure 5) consists of two high-voltage, p-channel MOSFETs: Q1, between SRC and GON and Q2, between GON and DRN. The switch-control block is enabled when  $V_{DLP}$  exceeds  $V_{LDQ}/2$  and then Q1 and Q2 are controlled by CTL and MODE. There are two different modes of operation (see the *Typical Operating Characteristics* section.)

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

Activate the first mode by connecting MODE to LDO. When CTL is logic high, Q1 turns on and Q2 turns off, connecting GON to SRC. When CTL is logic low, Q1 turns off and Q2 turns on, connecting GON to DRN. GON can then be discharged through a resistor connected between DRN and PGND or AVDD. Q2 turns off and stops discharging GON when VGON reaches 10 times the voltage on THR.

When V<sub>MODE</sub> is less than  $0.9 \times V_{LDO}$ , the switch control block works in the second mode. The rising edge of V<sub>CTL</sub> turns on Q1 and turns off Q2, connecting GON to SRC. An internal n-channel MOSFET Q3 between MODE and GND is also turned on to discharge an external capacitor between MODE and GND. The falling edge of V<sub>CTL</sub> turns off Q3, and an internal 50 $\mu$ A current source starts charging the MODE capacitor. Once V<sub>MODE</sub> exceeds  $0.5 \times V_{REF}$ , the switch control block turns off Q1 and turns on Q2, connecting GON to DRN. GON can then be discharged through a resistor connected between DRN and GND or AVDD. Q2 turns off and stops discharging GON when VGON reaches 10 times the voltage on THR.

The timing of enabling the switch control block can be adjusted with an external capacitor connected between DLP and GND. An internal current source starts charging the DLP capacitor if the input voltage is above 1.75V (typ), SHDN is high, and the fault latch is not set. The voltage on DLP linearly rises because of the constant-charging current. When VDLP goes above 2.5V (typ), the switch control block is enabled. The switch control block is disabled and DLP is held low when the MAX8758 is shut down or in a fault state.

## Linear Regulator (LDO)

The MAX8758 includes an internal 5V linear regulator. OUT is the input of the linear regulator and should be directly connected to the output of the step-up regulator. The input voltage range is between 4.5V and 13V. The output of the linear regulator (LDO) is set to 5V (typ). The regulator powers all the internal circuitry including the gate driver. This feature significantly improves the efficiency at low input voltages. Bypass the LDO pin to GND with a 0.22 $\mu$ F or greater ceramic capacitor.

## Design Procedure

### Step-Up Regulator

#### Step-Up Regulator Inductor Selection

The inductance value, peak-current rating, and series resistance are factors to consider when selecting the inductor. These factors influence the converter's efficiency, maximum output-load capability, transient response time, and output voltage ripple. Physical size and cost are also important factors to be considered.

The maximum output current, input voltage, output voltage, and switching frequency determine the inductor value. Very high inductance values minimize the current ripple and, therefore, reduce the peak current, which decreases core losses in the inductor and I<sup>2</sup>R losses in the entire power path. However, large inductor values also require more energy storage and more turns of wire, which increase physical size and can increase I<sup>2</sup>R losses in the inductor. Low inductance values decrease the physical size but increase the current ripple and peak current. Finding the best inductor involves choosing the best compromise between circuit efficiency, inductor size, and cost.

The equations used here include a constant LIR, which is the ratio of the inductor peak-to-peak ripple current to the average DC inductor current at the full-load current. The best trade-off between inductor size and circuit efficiency for step-up regulators generally has an LIR between 0.3 and 0.5. However, depending on the AC characteristics of the inductor core material and ratio of inductor resistance to other power-path resistances, the best LIR can shift up or down. If the inductor resistance is relatively high, more ripple can be accepted to reduce the number of turns required and increase the wire diameter. If the inductor resistance is relatively low, increasing inductance to lower the peak current can decrease losses throughout the power path. If extremely thin high-resistance inductors are used, as is common for LCD panel applications, the best LIR can increase to between 0.5 and 1.0.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

MAX8758

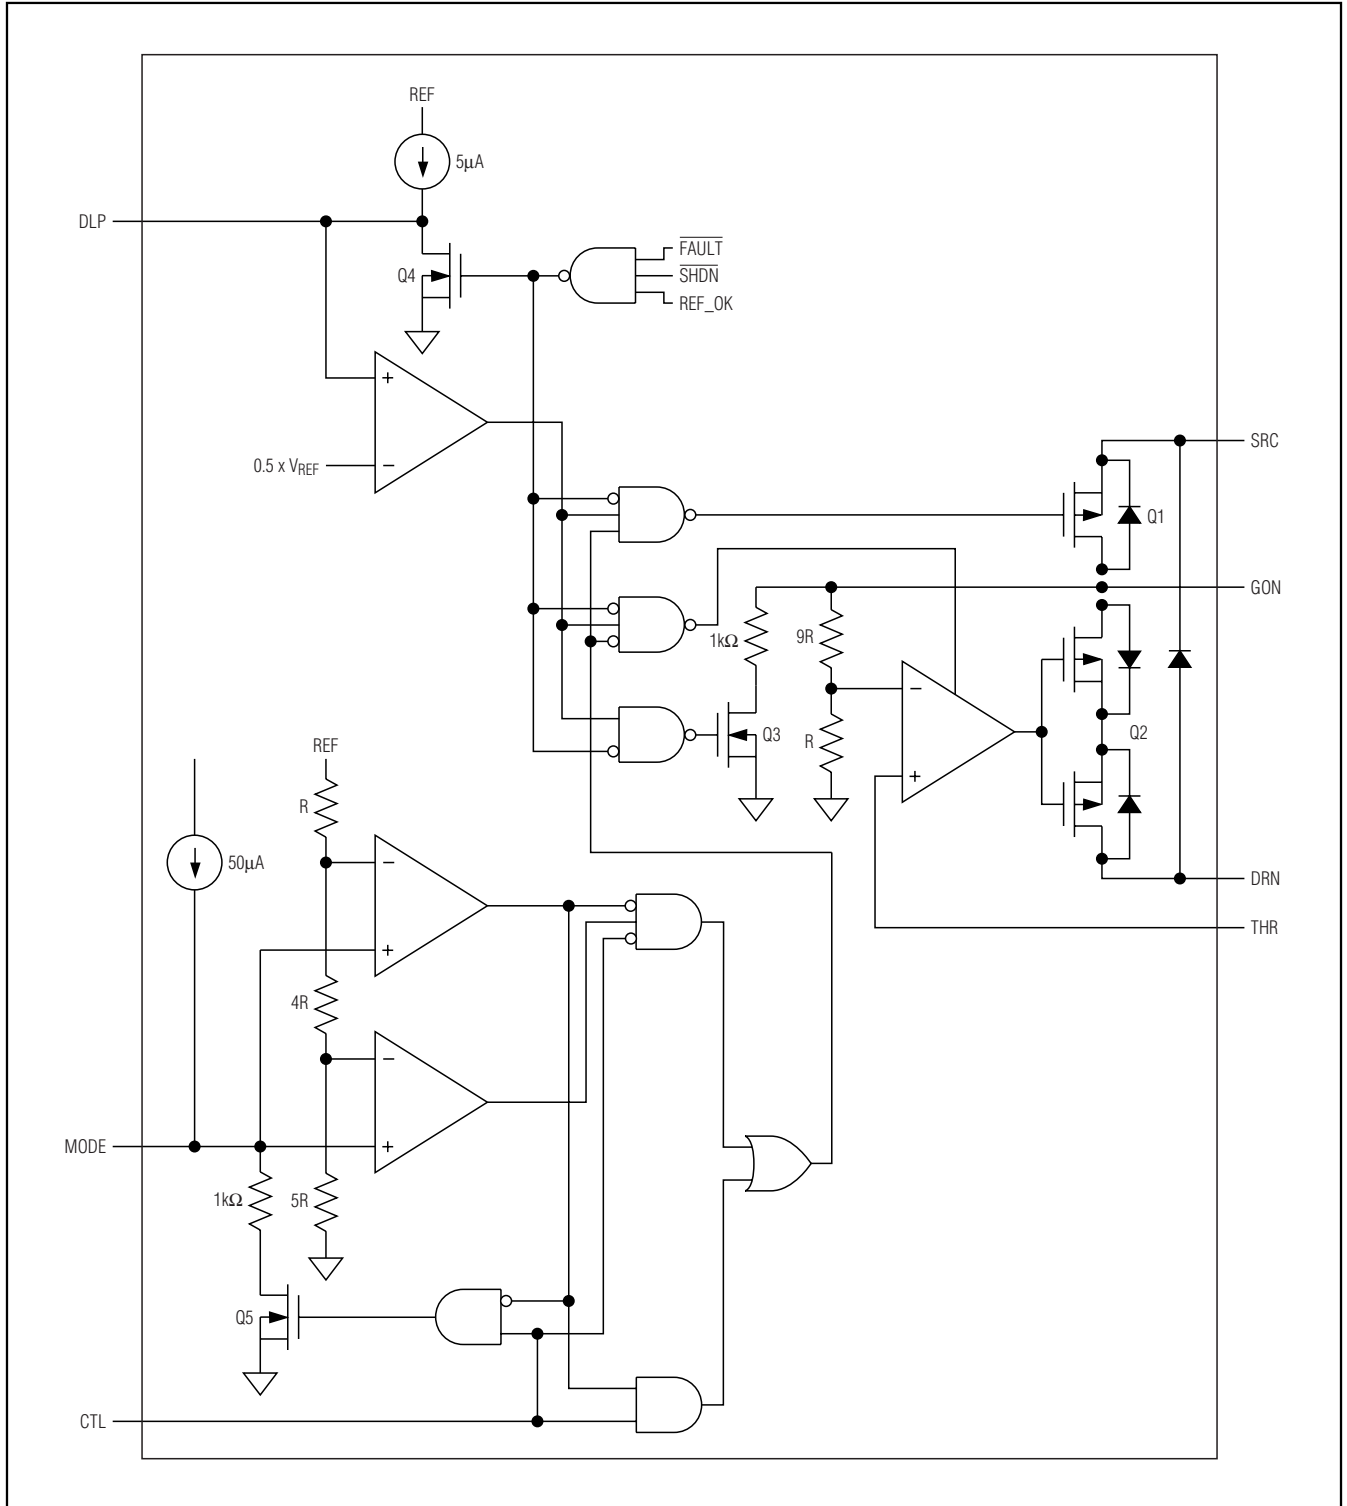

Figure 4. Switch Control

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

In Figure 1's *Typical Operating Circuit*, the LCD's gate-on and gate-off voltages are generated from two unregulated charge pumps driven by the step-up regulator's LX node. The additional load on LX must therefore be considered in the inductance calculation. The effective maximum output current  $I_{MAIN(EFF)}$  becomes the sum of the maximum load current on the step-up regulator's output plus the contributions from the positive and negative charge pumps:

$$I_{MAIN(EFF)} = I_{MAIN(MAX)} + n_{NEG} \times I_{NEG} + (n_{POS} + 1) \times I_{POS}$$

where  $I_{MAIN(MAX)}$  is the maximum output current,  $n_{NEG}$  is the number of negative charge-pump stages,  $n_{POS}$  is the number of positive charge-pump stages,  $I_{NEG}$  is the negative charge-pump output current, and  $I_{POS}$  is the positive charge-pump output current, assuming the pump source for  $I_{POS}$  is  $V_{MAIN}$ .

The required inductance can then be calculated as follows:

$$L = \left( \frac{V_{IN}}{V_{MAIN}} \right)^2 \times \left( \frac{V_{MAIN} - V_{IN}}{I_{MAIN(EFF)} \times f_{OSC}} \right) \times \left( \frac{\eta_{TYP}}{LIR} \right)$$

where  $V_{IN}$  is the typical input voltage and  $\eta_{TYP}$  is the expected efficiency obtained from the appropriate curve in the *Typical Operating Characteristics*.

Choose an available inductor value from an appropriate inductor family. Calculate the maximum DC input current at the minimum input voltage  $V_{IN(MIN)}$  using conservation of energy and the expected efficiency at that operating point ( $\eta_{MIN}$ ) taken from an appropriate curve in the *Typical Operating Characteristics*:

$$I_{IN(DC,MAX)} = \frac{I_{MAIN(EFF)} \times V_{MAIN}}{V_{IN(MIN)} \times \eta_{MIN}}$$

Calculate the ripple current at that operating point and the peak current required for the inductor:

$$I_{RIPPLE} = \frac{V_{IN(MIN)} \times (V_{MAIN} - V_{IN(MIN)})}{L \times V_{MAIN} \times f_{OSC}}$$

$$I_{PEAK} = I_{IN(DC,MAX)} + \frac{I_{RIPPLE}}{2}$$

The inductor's saturation current rating and the guaranteed minimum value of the MAX8758's LX current limit ( $I_{LIM}$ ) should exceed  $I_{PEAK}$  and the inductor's DC current rating should exceed  $I_{IN(DC,MAX)}$ . For good efficiency, choose an inductor with less than  $0.1\Omega$  series resistance.

Considering the *Typical Operating Circuit*, the maximum load current ( $I_{MAIN(MAX)}$ ) is 300mA for the step-up regulator, 20mA for the two-stage positive charge pump, and 20mA for the one-stage negative charge pump. Altogether, the effective maximum output current,  $I_{MAIN(EFF)}$  is 360mA with an 8.5V output and a typical input voltage of 3.3V. The switching frequency is set to 1.2MHz. Choosing an LIR of 0.4 and estimating efficiency of 85% at this operating point:

$$L = \left( \frac{3.3V}{8.5V} \right)^2 \times \left( \frac{8.5V - 3.3V}{0.36A \times 1.2MHz} \right) \times \left( \frac{0.85}{0.4} \right) \approx 4.2\mu H$$

Using the circuit's minimum input voltage (3V) and estimating efficiency of 80% at that operating point:

$$I_{IN(DC,MAX)} = \frac{0.36A \times 8.5V}{3V \times 0.8} \approx 1.28A$$

The ripple current and the peak current are:

$$I_{RIPPLE} = \frac{3V \times (8.5V - 3V)}{4.2\mu H \times 8.5V \times 1.2MHz} \approx 0.4A$$

$$I_{PEAK} = 1.28A + \frac{0.4A}{2} \approx 1.48A$$

The peak-inductor current does not exceed the guaranteed minimum value of the LX current limit in the *Electrical Characteristics* table.

## Step-Up Regulator Output Capacitor Selection

The total output voltage ripple has two components: the capacitive ripple caused by the charging and discharging of the output capacitance, and the ohmic ripple due to the capacitor's equivalent series resistance (ESR):

$$V_{RIPPLE} = V_{RIPPLE(C)} + V_{RIPPLE(ESR)}$$

$$V_{RIPPLE(C)} \approx \frac{I_{MAIN}}{C_{MAIN}} \times \left( \frac{V_{MAIN} - V_{IN}}{V_{MAIN} \times f_{SW}} \right)$$

and

$$V_{RIPPLE(ESR)} \approx I_{PEAK} \times RESR$$

where  $I_{PEAK}$  is the peak inductor current (see the *Step-Up Regulator Inductor Selection* section). For ceramic capacitors, the output voltage ripple is typically dominated by  $V_{RIPPLE(C)}$ . The voltage rating and temperature characteristics of the output capacitor must also be considered.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

## Step-Up Regulator Input Capacitor Selection

The input capacitor reduces the current peaks drawn from the input supply and reduces noise injection into the IC. Two 10 $\mu$ F ceramic capacitors are used in the *Typical Applications Circuit* (Figure 1) because of the high source impedance seen in typical lab setups. Actual applications usually have much lower source impedance since the step-up regulator often runs directly from the output of another regulated supply. Typically, the input capacitance can be reduced below the values used in the *Typical Applications Circuit*.

## Step-Up Regulator Rectifier Diode

The MAX8758's high switching frequency demands a high-speed rectifier. Schottky diodes are recommended for most applications because of their fast recovery time and low forward voltage. In general, a 2A Schottky diode complements the internal MOSFET well.

## Step-Up Regulator Output Voltage Selection

The output voltage of the step-up regulator can be adjusted by connecting a resistive voltage-divider from the output (V<sub>OUT</sub>) to GND with the center tap connected to FB (see Figure 1). Select R<sub>2</sub> in the 10k $\Omega$  to 50k $\Omega$  range. Calculate R<sub>1</sub> with the following equation:

$$R_1 = R_2 \times \left( \frac{V_{\text{MAIN}}}{V_{\text{FB}}} - 1 \right)$$

where V<sub>FB</sub>, the step-up regulator's feedback set point, is 1.25V. Place R<sub>1</sub> and R<sub>2</sub> close to the IC.

## Step-Up Regulator Loop Compensation

Choose R<sub>COMP</sub> (R<sub>3</sub> in Figure 1) to set the high-frequency integrator gain for fast transient response. Choose C<sub>COMP</sub> (C<sub>7</sub> in Figure 1) to set the integrator zero to maintain loop stability.

For low-ESR output capacitors, use the following equations to obtain stable performance and good transient response:

$$R_{\text{COMP}} \approx \frac{315 \times V_{\text{IN}} \times V_{\text{MAIN}} \times C_{\text{MAIN}}}{L \times I_{\text{MAIN(MAX)}}$$

$$C_{\text{COMP}} \approx \frac{V_{\text{MAIN}} \times C_{\text{MAIN}}}{10 \times I_{\text{MAIN(MAX)}} \times R_{\text{COMP}}}$$

To further optimize transient response, vary R<sub>COMP</sub> in 20% steps and C<sub>COMP</sub> in 50% steps while observing transient-response waveforms.

Place C<sub>COMP2</sub> (C<sub>8</sub> in Figure 1) from COMP to GND to add an additional high-frequency pole. Use C<sub>COMP2</sub> between 10pF and 47pF.

## Step-Up Regulator Soft-Start Capacitor

The soft-start capacitor should be large enough that it does not reach final value before the output has reached regulation. Calculate the soft-start capacitor (C<sub>SS</sub>) value using:

$$C_{\text{SS}} = 21 \times 10^{-6} \times C_{\text{MAIN}} \times \left( \frac{V_{\text{MAIN}}^2 - V_{\text{IN}} \times V_{\text{MAIN}}}{V_{\text{IN}} \times I_{\text{NRUSH}} - I_{\text{MAIN}} \times V_{\text{MAIN}}} \right)$$

where C<sub>MAIN</sub> is the total output capacitance, V<sub>MAIN</sub> is the maximum output voltage, and I<sub>NRUSH</sub> is the peak inrush current allowed, I<sub>MAIN</sub> is the maximum output current, and V<sub>IN</sub> is the minimum input voltage.

The load must wait for the soft-start cycle to finish before drawing a significant amount of load current. The duration after which the load can begin to draw maximum load current is:

$$t_{\text{MAX}} = 6.77 \times 10^5 \times C_{\text{SS}}$$

## Charge Pumps

### Selecting the Number of Charge-Pump Stages

For highest efficiency, always choose the lowest number of charge-pump stages that meet the output voltage requirement.

The number of positive charge-pump stages is given by:

$$n_{\text{POS}} = \frac{V_{\text{GON}} - V_{\text{MAIN}}}{V_{\text{MAIN}} - 2 \times V_{\text{D}}}$$

where n<sub>POS</sub> is the number of positive-charge-pump stages, V<sub>GON</sub> is the positive-charge-pump output, V<sub>MAIN</sub> is the main step-up regulator output, and V<sub>D</sub> is the forward voltage drop of the charge-pump diode.

The number of negative charge-pump stages is given by:

$$n_{\text{NEG}} = \frac{-V_{\text{GOFF}}}{V_{\text{MAIN}} - 2 \times V_{\text{D}}}$$

where n<sub>NEG</sub> is the number of negative-charge-pump stages, V<sub>GOFF</sub> is the negative charge-pump output, V<sub>MAIN</sub> is the main step-up regulator output, and V<sub>D</sub> is the forward voltage drop of the charge-pump diode.

# Step-Up Regulator with Switch Control and Operational Amplifier for TFT LCD

## Charge-Pump Flying Capacitors

Increasing the flying capacitor (C6, C17, C18) value lowers the effective source impedance and increases the output-current capability. Increasing the capacitance indefinitely has a negligible effect on output-current capability because the diode impedance places a lower limit on the source impedance. Ceramic capacitors of 0.1µF or greater work well in most applications that require output currents in the order of 10mA to 20mA.

The flying capacitor's voltage rating must exceed the following:

$$V_C > n \times V_{\text{MAIN}}$$

where  $n$  is the stage number in which the flying capacitor appears, and  $V_{\text{MAIN}}$  is the output voltage of the main step-up regulator.

## Charge-Pump Output Capacitor

Increasing the output capacitance or decreasing the ESR reduces the output voltage ripple and the peak-to-peak voltage during load transients. With ceramic capacitors, the output voltage ripple is dominated by the capacitance value. Use the following equation to approximate the required capacitor value:

$$C_{\text{MAIN\_CP}} \geq \frac{I_{\text{LOAD\_CP}}}{2 \times f_{\text{OSC}} \times V_{\text{RIPPLE\_CP}}}$$

where  $C_{\text{MAIN\_CP}}$  is the output capacitor of the charge pump,  $I_{\text{LOAD\_CP}}$  is the load current of the charge pump, and  $V_{\text{RIPPLE\_CP}}$  is the peak-to-peak value of the output ripple.

The charge-pump output capacitor is typically also the input capacitor for a linear regulator. Often, its value must be increased to maintain the linear regulator's stability.

## Charge-Pump Rectifier Diodes

Use low-cost, silicon-switching diodes with a current rating equal to or greater than two times the average charge-pump input current. If it helps avoid an extra stage, some or all of the diodes can be replaced with Schottky diodes with equivalent current ratings.

## PC Board Layout and Grounding

Careful PC board layout is important for proper operation. Use the following guidelines for good PC board layout:

- 1) Minimize the area of high-current loops by placing the step-up regulator's inductor, diode, and output capacitors near its input capacitors, its LX, and PGND pin. The high-current input loop goes from

the positive terminal of the input capacitor to the inductor, to the IC's LX pin, out of PGND, and to the input capacitor's negative terminal. The high-current output loop is from the positive terminal of the input capacitor to the inductor, to the output diode (D1), to the positive terminal of the output capacitors, reconnecting between the output capacitor and input capacitor ground terminals. Connect these loop components with short, wide connections. Avoid using vias in the high-current paths. If vias are unavoidable, use many vias in parallel to reduce resistance and inductance.

- 2) Create a power ground island (PGND) for the step-up regulator, consisting of the input and output capacitor grounds and the PGND pin. Maximizing the width of the power ground traces improves efficiency and reduces output voltage ripple and noise spikes. Create an analog ground plane (GND) consisting of the GND pin, the feedback-divider ground connection, the COMP and DLP capacitor ground connections, and the device's exposed backside pad. Connect the PGND and GND islands by connecting the two ground pins directly to the exposed backside pad. Make no other connections between these separate ground planes.
- 3) Place the feedback voltage-divider resistors as close to the feedback pin as possible. The divider's center trace should be kept short. Placing the resistors far away causes the FB trace to become antennas that can pick up switching noise. Care should be taken to avoid running the feedback trace near LX.
- 4) Place the IN pin bypass capacitor as close to the device as possible. The ground connection of the IN bypass capacitor should be connected directly to the GND pin with a wide trace.
- 5) Minimize the length and maximize the width of the traces between the output capacitors and the load for best transient responses.
- 6) Minimize the size of the LX node while keeping it wide and short. Keep the LX node away from feedback node (FB) and analog ground. Use DC traces as shield if necessary.

Refer to the MAX8758 evaluation kit for an example of proper board layout.
