

MOTOROLA

LINEAR INTEGRATED CIRCUITS

Prepared by
Technical Information Center

This Linear Integrated Circuits Data Book contains technical information on a portion of Motorola Linear's product offering. Detailed information on Comparators and Interface products is contained in a separate Interface Data Book. For your convenience, this book contains the following:

- Cross-Reference
- Selector Guides (by Product Category)
- Data Sheets
- Package Information and Mounting Hardware
- Abstracts Covering Application Notes and Engineering Bulletins.

Motorola reserves the right to make changes to any products herein to improve reliability, function or design. Motorola does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its present patent rights nor the rights of others.

MOTOROLA

LINEAR

INTEGRATED CIRCUITS

**MDTL, MECL, MECL 10,000, MHTL, MRTL, M TTL,
SWITCHMODE, and TRIMFET are trademarks of Motorola Inc.**

CONTENTS

	Page
CHAPTER 1 — MASTER INDEX AND CROSS-REFERENCE GUIDE	1-1
Master Index	1-2
Cross-Reference Guide	1-10
CHAPTER 2 — RELIABILITY ENHANCEMENT PROGRAMS	2-1
The "Better" Program	2-2
Standard HI-REL Programs	2-3
MIL-M-38510 JAN-Qualified Product	2-4
JEDEC Processed Product	2-5
Screening Procedures	2-6
CHAPTER 3 — OPERATIONAL AMPLIFIERS	3-1
Selection Guide	3-3
Data Sheets (See Page 3-2 for page numbers.)	
CHAPTER 4 — VOLTAGE REGULATORS	4-1
Selection Guide	4-3
Data Sheets (See Page 4-2 for page numbers.)	
CHAPTER 5 — CONSUMER CIRCUITS	5-1
Selection Guide	5-3
Data Sheets (See Page 5-2 for page numbers.)	
CHAPTER 6 — OTHER LINEAR CIRCUITS	6-1
Selection Guides:	
High-Frequency Amplifiers	6-3
Special-Purpose Circuits	6-4
Data Sheets (See Page 6-2 for page numbers.)	
CHAPTER 7 — INTERFACE/COMPARATOR SELECTOR GUIDE	7-1
Bus Interface	7-2
Memory Interface	7-9
Computer and Terminal Interface	7-15
Peripheral Interface	7-17
Numeric Display Interface	7-18
Precision Circuits - Data Conversion	7-19
Voltage Comparators	7-22
Communication Interface (Telephony)	7-25
CHAPTER 8 — PACKAGE INFORMATION AND MOUNTING HARDWARE	8-1
Package Dimensions	8-2
Mounting Hardware	8-11
CHAPTER 9 — APPLICATION NOTE ABSTRACTS	9-2

Master Index and Cross-Reference Guide

1

MASTER INDEX

This index includes *all* devices in Motorola Linear's product line. Devices with *Interface* in the page number column are fully characterized in the separate **Interface Data Book**; however, selection characteristics are given in Chapter 7 of this volume for your convenience.

1

Device Number	Function	Page
AM26LS31	Quad RS-422 Line with Three-State Output	Interface
CA3054	Dual Differential Amplifier	5-8
DS8641	Quad Unified Bus Transceiver	Interface
HA1199	AM Radio Subsystem	5-10
LF155	Monolithic JFET Operational Amplifier	3-7
LF155A	Monolithic JFET Operational Amplifier	3-7
LF156	Monolithic JFET Operational Amplifier	3-7
LF156A	Monolithic JFET Operational Amplifier	3-7
LF157	Monolithic JFET Operational Amplifier	3-7
LF157A	Monolithic JFET Operational Amplifier	3-7
LF255	Monolithic JFET Operational Amplifier	3-7
LF256	Monolithic JFET Operational Amplifier	3-7
LF257	Monolithic JFET Operational Amplifier	3-7
LF355	Monolithic JFET Operational Amplifier	3-7
LF355A	Monolithic JFET Operational Amplifier	3-7
LF355B	Monolithic JFET Operational Amplifier	3-7
LF356	Monolithic JFET Operational Amplifier	3-7
LF356A	Monolithic JFET Operational Amplifier	3-7
LF356B	Monolithic JFET Operational Amplifier	3-7
LF357	Monolithic JFET Operational Amplifier	3-7
LF357A	Monolithic JFET Operational Amplifier	3-7
LF357B	Monolithic JFET Operational Amplifier	3-7
LM101A	General Purpose Adjustable Operational Amplifier	3-19
LM104	Adjustable Negative Voltage Regulator	4-7
LM105	Adjustable Positive Voltage Regulator	4-9
LM107	General-Purpose Operational Amplifier	3-23
LM108	Precision Operational Amplifier	3-27
LM108A	Precision Operational Amplifier	3-27
LM109	Positive Voltage Regulator	4-11
LM111	Voltage Comparator	Interface
LM117	Positive Voltage Regulator	4-16
LM117L	Positive Voltage Regulator	4-24
LM124	Quad Operational Amplifier	3-32
LM139	Quad Comparator (Single Supply)	Interface
LM139A	Quad Comparator (Single Supply)	Interface
LM140	Series of Positive Voltage Regulators	4-32
LM148	Quad Differential Input Operational Amplifiers	3-38
LM158	Dual Operational Amplifier	3-38
LM193	Dual Comparators	7-11
LM193A	Dual Comparators	7-11
LM201A	General-Purpose Operational Amplifier	3-19
LM204	Adjustable Negative Voltage Regulator	4-7
LM205	Adjustable Positive Voltage Regulator	4-9
LM207	General-Purpose Operational Amplifier	3-23
LM208	Precision Operational Amplifier	3-27
LM208A	Precision Operational Amplifier	3-27
LM209	Positive Voltage Regulator	4-11
LM211	Voltage Comparator	Interface
LM217	Adjustable Voltage Regulator	4-16
LM217L	Adjustable Voltage Regulator	4-24
LM224	Quad Operational Amplifier	3-32
LM239	Quad Comparator (Single Supply)	Interface
LM239A	Quad Comparator (Single Supply)	Interface

LM358	Dual Operational Amplifier	3-38
LM393	Dual Comparators	7-11
LM393A	Dual Comparators	7-11
LM2901	Quad Comparator	Interface
LM2902	Quad Operational Amplifier	3-32
LM2903	Dual Comparators	7-11
LM2904	Dual Operational Amplifier	3-38
MC8T13	Dual Line Driver	Interface
MC8T14	Triple Line Receiver with Hysteresis	Interface
MC8T23	Dual Line Driver	Interface
MC8T24	Triple Line Receiver with Hysteresis	Interface
MC8T26A	Quad Three-State Bus Transceiver	Interface
MC8T28	Non-Inverting Bus Transceiver	Interface
MC8T95	Hex Three-State Buffer/Inverter	Interface
MC8T96	Hex Three-State Buffer/Inverter	Interface
MC8T97	Hex Three-State Buffer/Inverter	Interface
MC8T98	Hex Three-State Buffer/Inverter	Interface
MC26S10	Quad Open-Collector Bus Transceiver	Interface
MC26S11	Quad Open-Collector Bus Transceiver	Interface
MC75S110	Dual Line Driver	Interface
MC1302	7-Stage Divider	5-10
MC1306	1/2-Watt Audio Amplifier	5-12
MC1309	FM Stereo Demodulator	5-17
MC1310	FM Stereo Demodulator	5-19
MC1323	Triple Doubly Balanced Chroma Demodulator	5-32
MC1324	Dual Doubly Balanced Chroma Demodulator	5-37
MC1327	Dual Doubly Balanced Chroma Demodulator	5-27
MC1330A	Low-Level Video Detector	5-32
MC1349	IF Amplifier	5-38
MC1350	IF Amplifier	5-43
MC1351	TV Sound Circuit	5-60
MC1352	TV Video IF Amplifier	5-64
MC1355	Limiting FM IF Amplifier	5-47
MC1357	IF Amplifier and Quadrature Detector	5-73
MC1358	TV Sound IF Amplifier	5-51
MC1364	Automatic Frequency Control	5-84
MC1372	Color TV Video Modulator	5-88
MC1373	TV Video Modulator	5-96
MC1391	TV Horizontal Processor	5-56
MC1393A	TV Vertical Processor	5-104
MC1394	TV Horizontal Processor	5-99
MC1398	TV Color Processing Circuit	5-107
MC1399	TV Color Processing Circuit	5-113
MC1400	Precision Voltage Reference	Interface
MC1400A	Precision Voltage Reference	Interface

MASTER INDEX**Device****Number****Function****Page**

MC1403	Precision Low-Voltage Reference	4-42
MC1403A	Precision Low-Voltage Reference	4-42
MC1404	Precision Low-Drift Voltage Reference	4-46
MC1404A	Precision Low-Drift Voltage Reference	4-46
MC1405	Analog-to-Digital Converter Subsystem	Interface
MC1406	6-Bit Multiplying Digital-to-Analog Converter	Interface
MC1408	8-Bit Multiplying Digital-to-Analog Converter	Interface
MC1411	Peripheral Driver Array	Interface
MC1412	Peripheral Driver Array	Interface
MC1413	Peripheral Driver Array	Interface
MC1414	Dual Differential Comparator	Interface
MC1416	Peripheral Driver Array	Interface
MC1420	Differential Output Operational Amplifier	3-44
MC1417	Peripheral Driver Arrays	5-29
MC1422	Timing Circuit with Adjustable Threshold	6-7
MC1430	Operational Amplifier	3-48
MC1431	Operational Amplifier	3-48
MC1433	Operational Amplifier	3-52
MC1435	Dual Operational Amplifier	3-57
MC1436	High-Voltage Operational Amplifier	3-50
MC1436C	High-Voltage Operational Amplifier	3-50
MC1437	Dual Operational Amplifier	3-54
MC1438	Power Booster	6-14
MC1439	High-Slew-Rate Operational Amplifier	3-58
MC1444	AC-Coupled 4-Channel Sense Amplifier	Interface
MC1445	Wideband Amplifier	6-20
MC1454	1-Watt Power Amplifier	6-36
MC1455	Timing Circuit	6-40
MC1456	High-Performance Operational Amplifier	3-66
MC1456C	High-Performance Operational Amplifier	3-66
MC1458	Dual Operational Amplifier	3-72
MC1458C	Dual Operational Amplifier	3-72
MC1458N	Low-Noise Dual Operational Amplifier	3-72
MC1458S	High-Slew-Rate Dual Operational Amplifier	3-77
MC1463	Adjustable Negative Voltage Regulator	4-51
MC1466	Voltage and Current Regulator	4-67
MC1468	Dual \pm 15-Volt Tracking Regulator	4-77
MC1469	Adjustable Positive Voltage Regulator	4-82
MC1472	Dual Peripheral Positive NAND Driver	Interface
MC1488	Quad MDTL Line Driver	Interface
MC1489	Quad MDTL Line Receiver	Interface
MC1489A	Quad MDTL Line Receiver	Interface
MC1494	Four-Quadrant Multiplier	6-56
MC1495	Four-Quadrant Multiplier	6-70
MC1496	Balanced Modulator-Demodulator	6-86
MC1500	Precision Voltage Reference	Interface
MC1500A	Precision Voltage Reference	Interface
MC1503	Precision Low-Voltage Reference	4-42
MC1503A	Precision Low-Voltage Reference	4-42
MC1504	Precision Low-Drift Voltage Reference	4-46
MC1504A	Precision Low-Drift Voltage Reference	4-46
MC1505	Analog-to-Digital Converter Subsystem	Interface
MC1506	6-Bit Multiplying Digital-to-Analog Converter	Interface
MC1508	8-Bit Multiplying Digital-to-Analog Converter	Interface
MC1514	Dual Differential Comparator	Interface
MC1520	Differential Output Operational Amplifier	3-44
MC1530	Operational Amplifier	3-48
MC1531	Operational Amplifier	3-48
MC1533	Operational Amplifier	3-52
MC1535	Dual Operational Amplifier	3-57
MC1536	High-Voltage Operational Amplifier	3-50
MC15	Dual Operational Amplifier	3-54

MC1566	Voltage and Current Regulator	4-67
MC1568	Dual ± 15 -Volt Tracking Regulator	4-77
MC1569	Adjustable Positive Voltage Regulator	4-82
MC1590	Wideband Amplifier with AGC	6-47
MC1594	Four-Quadrant Multiplier	6-56
MC1595	Four-Quadrant Multiplier	6-70
MC1596	Balanced Modulator-Demodulator	6-86
MC1709	General-Purpose Operational Amplifier	3-83
MC1709A	General-Purpose Operational Amplifier	3-83
MC1709C	General-Purpose Operational Amplifier	3-83
MC1710	Differential Comparator	Interface
MC1710C	Differential Comparator	Interface
MC1711	Dual Differential Comparator	Interface
MC1711C	Dual Differential Comparator	Interface
MC1712	Wideband DC Amplifier	3-87
MC1712C	Wideband DC Amplifier	3-87
MC1723	Adjustable Positive or Negative Voltage Regulator	4-101
MC1723C	Adjustable Positive or Negative Voltage Regulator	4-101
MC1733	Differential Video Amplifier	6-96
MC1733C	Differential Video Amplifier	6-96
MC1741	General-Purpose Operational Amplifier	3-92
MC1741C	General-Purpose Operational Amplifier	3-92
MC1741N	Low-Noise Operational Amplifier	3-92
MC1741NC	Low-Noise Operational Amplifier	3-92
MC1741S	High-Slew-Rate Operational Amplifier	3-97
MC1741SC	High-Slew-Rate Operational Amplifier	3-97
MC1747	Dual MC1741 Operational Amplifier	3-103
MC1747C	Dual MC1741C Operational Amplifier	3-103
MC1748	General-Purpose Operational Amplifier	3-107
MC1748C	General-Purpose Operational Amplifier	3-107
MC1776	Programmable Operational Amplifier	3-111
MC1776C	Programmable Operational Amplifier	3-111
MC26S10	Quad Open-Collector Bus Transceiver	Interface
MC26S11	Quad Open-Collector Bus Transceiver	Interface
MC3232A	Memory Address Multiplexer and Refresh Address Counter	Interface
MC3242A	Memory Address Multiplexer and Refresh Address Counter	Interface
MC3245	Quad TTL-to-MOS Driver	Interface
MC3301	Quad Operational Amplifier	3-120
MC3302	Quad Comparator	Interface
MC3303	Quad Differential-Input Operational Amplifier	3-136
MC3310	Wide-Band Amplifier	5-118
MC3325	Automotive Voltage Regulator	5-61
MC3333	Vari-Dwell Ignition	5-65
MC3340	Electronic Attenuator	5-68
MC3344	Programmable Frequency Switch	6-104
MC3346	General-Purpose Transistor Array	5-71
MC3357	Low-Power FM IF	5-74
MC3358	Dual Low-Power Operational Amplifier	3-142
MC3360	1/4-Watt Audio Amplifier	5-139
MC3370	Zener Voltage Switch	5-110

MOTOROLA

LINEAR INTEGRATED CIRCUITS

MOTOROLA — LINEAR INTEGRATED CIRCUITS CROSS REFERENCE

... provides a complete interchangeability list linking over 3000 devices offered by most major Linear Integrated Circuits manufacturers to the nearest equivalent Motorola device. The "Motorola Direct Replacement" column lists devices with identical pin connections and package and the same or better electrical characteristics and tempera-

ture range. The "Motorola Functional Equivalent" column provides a device which performs the same function but with possible differences in package configurations, pin connections, temperature range or electrical specifications.

709BE — AD559S

Reliability Enhancement Programs

The "Better" Program

2

Motorola's reliability and quality-enhancement program was developed to provide improved levels of quality and reliability for standard commercial products.

THE "BETTER" program is offered on CMOS, Linear, TTL, TTL/LS, DTL, HTL, and NMOS in dual-in-line ceramic and plastic packages.

Motorola standard commercial integrated circuits are manufactured under stringent in-process controls and quality inspections combined with the industry's finest outgoing quality inspections. The "BETTER" program offers three levels of extra processing, each tailored to meet different user needs at nominal costs.

The program is designed to:

- Eliminate incoming electrical inspection
- Eliminate need for independent test labs and associated extra time and costs
- Reduce field failures
- Reduce service calls
- Reduce equipment downtime
- Reduce board and system rework
- Reduce infant mortality
- Save time and money
- Increase end-customer satisfaction

BETTER PROCESSING - STANDARD PRODUCT PLUS:

100% SCREEN	LEVEL I "S"	LEVEL II "D"	LEVEL III "DS"
TEMP CYCLE, 10 CYCLES -25°C to +150°C	X		X
BURN-IN - MIL-STD-883		X	X
POST BURN-IN ELECTRICAL		X	X
100°C FUNCTIONAL	X		X
DC PARAMETRIC AT 25°C*	X	X	X
TIGHTENED QA SAMPLE	X	X	X

*NMOS does Functional and dc 100% at 100°C.

"BETTER" AQL GUARANTEES

TEST	CONDITION	AQL		
		LEVEL I	LEVEL II	LEVEL III
HIGH TEMPERATURE FUNCTIONAL	T _A = 100°C	0.15		0.15
DC PARAMETRIC	T _A = 25°C	0.28	0.28	0.28
DC PARAMETRIC	T _A MIN, T _A MAX	0.40	0.40	0.40
DC PARAMETRIC (LINEAR AND NMOS)	T _A MIN, T _A MAX	0.65	0.65	0.65
AC PARAMETRIC	T _A = 25°C	0.65	0.65	0.65
DYNAMIC TEST (LINEAR AND NMOS)	T _A = 25°C	0.65	0.65	0.65
EXTERNAL VISUAL AND MECHANICAL	MAJOR	0.11	0.11	0.11
	MINOR	2.50	2.50	2.50
HERMETICITY (NOT APPLICABLE TO PLASTIC PACKAGES)	GROSS	0.40	0.40	0.40
	FINE	1.00	1.00	1.00

PART MARKING

The Standard Motorola part number with the corresponding "BETTER" suffix can be ordered from your local authorized Motorola distributor or Motorola sales offices. "BETTER" pricing will be quoted as an adder to standard commercial product price.

The Motorola Standard HIGH REL Programs

2

Motorola, a pioneer in the manufacture of *high-reliability* integrated circuits*, now offers you a two-way program for Hi Rel products.

1. A growing line of JAN-QUALIFIED integrated circuits.
2. An extensive program to supply JEDEC PROCESSED devices that approaches the Qualified Reliability goals without the delay and high cost of the actual qualification program.

Motorola stocks many circuits which meet JAN-QUALIFIED specifications, and is actively pursuing an expansion of this qualification listing with product in all IC categories — encompassing Bipolar Digital, Linear and MOS technologies.

Motorola JEDEC PROCESSED products complement JAN-QUALIFIED products by making available hi-rel versions of nearly all Motorola full-temperature range circuits, while adding the advantage of hi-rel standardization.

The Motorola JEDEC Program offers you these benefits:

1. Standardization of environmental and electrical test procedures.
2. Less specification writing required.
3. Less time required in negotiating specifications.
4. Fast delivery.
5. Lower costs.

*Motorola, in early 1971, was the first company to be qualified as a MIL-M-38510 approved facility by the Defense Electronics Supply Center of DOD.

Screening Procedures

2

For MIL-M-38510 Jan-Qualified and JEDEC Processed Product (To MIL-STD-883 Requirements)

In recognition of the fact that the level of screening has a direct impact on the cost of the product, as well as its quality and reliability, two standard levels of screening are provided to coincide with two device classes, or levels of quality assurance.

Flexibility is provided in the choice of test conditions and stress levels to provide screens tailored to a particular product or

application. Selection of a level better than that required for the specific product and application will result in unnecessary expense. A level less than that required may result in a risk that reliability requirements will not be met. For general hi-rel applications, the Class B screening levels should be considered.

SCREEN	CLASS B		CLASS C

<p>1 When specified in the applicable device specification 100% of the devices shall be tested.</p> <p>2 MIL-M-38510 QUALIFIED product is tested per applicable 38510 detail specification. JEDEC PROCESSED product is tested per the Motorola standard data sheet electrical specification.</p> <p>3 For JEDEC PROCESSED product, Groups A and B per 5005 and JEDEC Publication No. 101. Groups C and D are available upon request.</p>				

A high-magnification micrograph of an integrated circuit die. The image shows a complex network of metal interconnects, including long horizontal and vertical lines, and various rectangular and circular structures representing different functional blocks. The layout is symmetrical about a central vertical axis. The background is a dark, textured surface, likely the silicon substrate.

Operational Amplifiers

OPERATIONAL AMPLIFIERS

Motorola offers a broad line of operational amplifiers to meet a wide range of usages. From low-cost industry-standard types to high precision circuits, the span encompasses a large range of performance capabilities. These linear integrated circuits are available as single, dual, and quad monolithic devices in a variety of package styles as well as standard chips.

Single Operational Amplifiers

Programmable quad operational amplifier

The TCA3002 is an array of four independent operational amplifiers on a single silicon chip. The operating current of the array is externally controlled by a single resistor or current source, allowing the user to trade-off power dissipation for bandwidth.

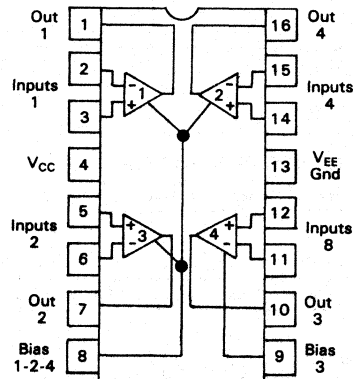

- Wide Input Voltage and Common Mode Range
- Externally Programmable
- Internal Frequency Compensation
- No Latch-Up
- Matched Parameters
- Short-Circuit Protection: 4 mA min guarantee
- Gain Bandwidth Product: 3.5 MHz (typical)

The TCA3003 gives the same features as the TCA3002. The only difference is 3 op amps, programmable together, and the last one alone.

Specifications and Applications Information

MONOLITHIC JFET INPUT OPERATIONAL AMPLIFIERS

These internally compensated operational amplifiers incorporate highly matched JFET devices on the same chip with standard bipolar transistors. The JFET devices enhance the input characteristics of these operational amplifiers by more than an order of magnitude over conventional amplifiers.

This series of op amps combines the low current characteristics typical of FET amplifiers with the low initial offset voltage and offset voltage stability of bipolar amplifiers. Also, nulling the offset voltage does not degrade the drift or common mode rejection.

- Low Input Bias Current – 30 pA
- Low Input Offset Current – 3.0 pA
- Low Input Offset Voltage – 1.0 mV
- Temperature Compensation of Input Offset Voltage – $3.0 \mu\text{V}/^\circ\text{C}$
- Low Input Noise Current – $0.01 \text{ pA}/\sqrt{\text{Hz}}$
- High Input Impedance – $10^{12}\Omega$
- High Common-Mode Rejection Ratio – 100 dB
- High DC Voltage Gain – 106 dB

SERIES FEATURES

APPLICATIONS

The LF series is suggested for all general purpose FET input amplifier requirements where precision and frequency response flexibility are of prime importance.

Specific applications include:

- Sample and Hold Circuits
- High Impedance Buffers
- Fast D/A and A/D Converters
- Precision High-Speed Integrators
- Wideband, Low Noise, Low Drift Amplifiers

*** NOTE:** The LF 157 series is designed for wider bandwidth applications. The series is decompensated ($A_{V\text{min}} = 5$).

NOTES

- Unless otherwise specified, the absolute maximum negative input voltage is equal to the negative power supply.
- $T_{low} = -55^\circ\text{C}$ for LF155A/156A/157A
 0°C for LF355A/356A/357A
 $T_{high} = +125^\circ\text{C}$ for LF155A/156A/157A
 $+70^\circ\text{C}$ for LF355A/356A/357A
- The temperature coefficient of the adjusted input offset voltage changes only a small amount (0.5 $\mu\text{V}/^\circ\text{C}$ typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.
- The input bias currents approximately double for every 10°C rise in junction temperature, T_J . Due to limited test time, the input bias currents are correlated to junction temperature. Use of a heat sink is recommended if input bias current is to be kept to a minimum.
- Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.
- Settling time is defined here, for a unity gain inverter connection using 2.0 k resistors for the LF155/6. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10 V step input is applied to the inverter. For the LF157, $A_V = -5.0$, the feedback resistor from output to input is 2.0 k and the output step is 10 V (see settling time test circuit).

NOTES

- Unless otherwise specified, the absolute maximum negative input voltage is equal to the negative power supply.
- $T_{low} = -55^\circ\text{C}$ for LF155/156/157
 $= -25^\circ\text{C}$ for LF255/256/257
 $= 0^\circ\text{C}$ for LF355/355B/356/356B/357/357B
 $T_{high} = +125^\circ\text{C}$ for LF155/156/157
 $= +85^\circ\text{C}$ for LF255/256/257
 $= +70^\circ\text{C}$ for LF355/355B/356/356B/357/357B
- The temperature coefficient of the adjusted input offset voltage changes only a small amount (0.5 $\mu\text{V}/^\circ\text{C}$ typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.
- The input bias currents approximately double for every 10°C rise in junction temperature, T_J . Due to limited test time, the input bias currents are correlated to junction temperature. Use

- of a heat sink is recommended if input bias current is to be kept to a minimum.
- Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.
- The Min. slew rate limits apply for the LF156/256/356B and the LF157/257/357B, but do not apply for the LF356 or LF357.
- Settling time is defined here, for a unity gain inverter connection using 2.0 k resistors for the LF155/6. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10 V step input is applied to the inverter. For the LF157, $A_V = -5.0$, the feedback resistor from output to input is 2.0 k and the output step is 10 V (see settling time test circuit).

TYPICAL CIRCUIT CONNECTIONS

FIGURE 31 – DRIVING CAPACITIVE LOADS

Due to a unique output stage design these amplifiers have the ability to drive large capacitive loads and still maintain stability.
 $C_{L(max)} \approx 0.01 \mu F$
 Overshoot $\leq 20\%$
 Settling time (t_s) $\approx 5.0 \mu s$

FIGURE 32 – LARGE POWER BANDWIDTH AMPLIFIER

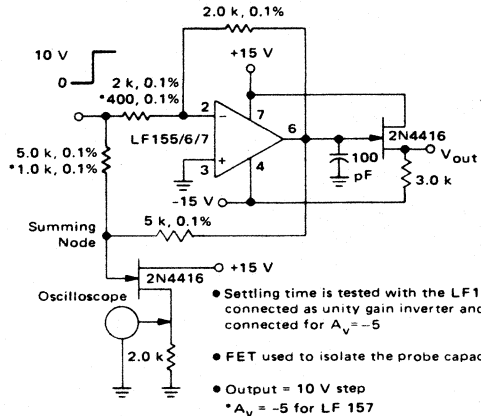

For distortion $< 1\%$ and a 20 Vp-p V_{out} swing, power bandwidth is: 500 kHz.

FIGURE 33 – INPUT OFFSET VOLTAGE ADJUSTMENT

- V_{IO} is adjusted with a 25 k potentiometer
- The potentiometer wiper is connected to V_{CC}
- For potentiometers with temperature coefficient of 100 ppm/ $^{\circ}C$ or less the additional drift with adjust is $\approx 0.5 \mu V/^{\circ}C/mV$ of adjustment.
- Typical overall drift: $5.0 \mu V/^{\circ}C$ ($0.5 \mu V/^{\circ}C/mV$ of adjustment.)

FIGURE 34 – SETTLING TIME TEST CIRCUIT

- Settling time is tested with the LF155/6 connected as unity gain inverter and LF157 connected for $A_v = -5$
- FET used to isolate the probe capacitance
- Output = 10 V step
- $A_v = -5$ for LF157

$$R1C \geq \frac{1}{(2\pi)(5 \text{ MHz})}$$

$$R1 = \frac{R2 + R_S}{4}$$

$$A_V(DC) = 1$$

$$f_{-3dB} \approx 5 \text{ MHz}$$

FIGURE 36 – INVERTING UNITY GAIN FOR LF157

$$R1C \geq \frac{1}{(2\pi)(5 \text{ MHz})}$$

$$R1 = \frac{R2}{4}$$

$$A_V(DC) = -1$$

$$f_{-3dB} \approx 5 \text{ MHz}$$

TYPICAL APPLICATIONS

FIGURE 37 - WIDE BW, LOW NOISE, LOW DRIFT AMPLIFIER

- Power BW: $f_{max} = \frac{S_r}{2\pi V_p} \approx 240 \text{ kHz}$
- Parasitic input capacitance ($C1 \approx 3 \text{ pF}$ for LF155, LF156, and LF157 plus any additional layout capacitance) interacts with feedback elements and creates undesirable high frequency pole. To compensate add C2 such that: $R2C2 \approx R1C1$.

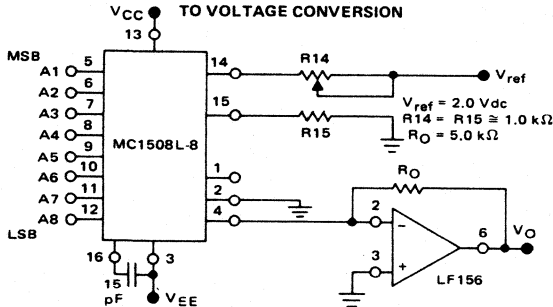

FIGURE 38 - ISOLATING LARGE CAPACITIVE LOADS

- Overshoot 6%
- $t_s = 10 \mu s$
- When driving large C_L , the V_{out} slew rate is determined by C_L and $I_{out(max)}$:

$$\frac{\Delta V_{out}}{\Delta t} = \frac{I_{out}}{C_L} \approx \frac{0.02}{0.5} \text{ V}/\mu s = 0.04 \text{ V}/\mu s \text{ (with } C_L \text{ shown)}$$

FIGURE 39 - 8-BIT D/A WITH OUTPUT CURRENT TO VOLTAGE CONVERSION

Theoretical V_O

$$V_O = \frac{V_{ref}(R_O)}{R_{14}} \left[\frac{A1}{2} + \frac{A2}{4} + \frac{A3}{8} + \frac{A4}{16} + \frac{A5}{32} + \frac{A6}{64} + \frac{A7}{128} + \frac{A8}{256} \right]$$
 Adjust V_{ref} , R_{14} , or R_O so that V_O with all digital inputs at high level is equal to 9.961 volts.

$$V_O = \frac{2V}{1k} (5k) \left[\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \frac{1}{64} + \frac{1}{128} + \frac{1}{256} \right]$$

$$= 10 \text{ V} \left[\frac{255}{256} \right] = 9.961 \text{ V}$$

FIGURE 41 - LONG INTERVAL RC TIMER

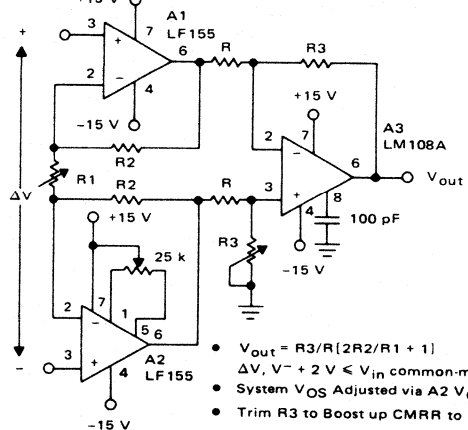

Time $t = R4C \ln(V_R/(V_R - V_1))$, $R3 = R4$, $R5 = 0.1 R6$
 If $R1 = R2$: $t = 0.693 R4C$
 Design Example: 100 Second Timer
 $V_R = 10 \text{ V}$ $C = 1 \mu F$ $R3 = R4 = 144 \text{ M}$
 $R6 = 20 \text{ k}$ $R5 = 2 \text{ k}$ $R1 = R2 = 1 \text{ k}$

FIGURE 40 - PRECISION CURRENT MONITOR

- $V_O = 5 R1/R2$ (V/mA of I_S)
- $R1, R2, R3$: 0.1% Resistors
- Use LF155 for -
 - ▲ Common-Mode Range to Supply Range
 - ▲ Low I_{IB}
 - ▲ Low V_{IO}
 - ▲ Low Supply Current

FIGURE 42 - HIGH IMPEDANCE, LOW DRIFT INSTRUMENTATION AMPLIFIER

- $V_{out} = R3/R[2R2/R1 + 1]$
- $\Delta V, V^- + 2V < V_{in} \text{ common-mode} < V^+$
- System V_{OS} Adjusted via A2 V_{OS} Adjust
- Trim $R3$ to Boost up CMRR to 120 dB

OPERATIONAL AMPLIFIER

A general purpose operational amplifier that allows the user to choose the compensation capacitor best suited to his needs. With proper compensation summing amplifier slew rates to 10 V/ μ s can be obtained.

- Low Input Offset Current – 20 nA maximum Over Temperature Range
- External Frequency Compensation for Flexibility
- Class AB Output Provides Excellent Linearity
- Output Short-Circuit Protection
- Guaranteed Drift Characteristics

Note 1. For supply voltages less than $\pm 15\text{ V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 2. For operating at elevated temperatures, the device must be derated based on a maximum junction temperature of $+150^\circ\text{C}$ for the LM107, and 100°C for the LM207 and LM307. The TO-99 package is derated based on a thermal resistance of $+150^\circ\text{C}/\text{W}$, junction to ambient, or $+45^\circ\text{C}/\text{W}$, junction to case.

Note 3. Unless otherwise noted, these specifications apply for:
 T_{low} T_{high}
 $\pm 5.0\text{ V} \leq V_S \leq \pm 20\text{ V}$, $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, LM107
 $\pm 5.0\text{ V} \leq V_S \leq \pm 20\text{ V}$, $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$, LM207
 $\pm 5.0\text{ V} \leq V_S \leq \pm 15\text{ V}$, $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$, LM307

PRECISION OPERATIONAL AMPLIFIERS

The LM108/LM208/LM308 Series operational amplifiers provide high input impedance, low input offsets and temperature drifts, and low noise. These characteristics are made possible by use of a special Super Beta processing technology. This series of amplifiers is particularly useful for applications where high-accuracy and low-drift performance are essential. In addition high-speed performance may be improved by employing feed-forward compensation techniques to maximize slew rate without compromising other performance criteria.

The LM108A/LM208A/LM308A Series offers extremely low input offset voltage and drift specifications allowing usage in even the most critical applications without external offset nulling.

- Operation From a Wide Range of Power Supply Voltages
- Low Input Bias and Offset Currents
- Low Input Offset Voltage and Guaranteed Offset Voltage Drift Performance
- High Input Impedance
- Laser Trimmed and Ion Implanted

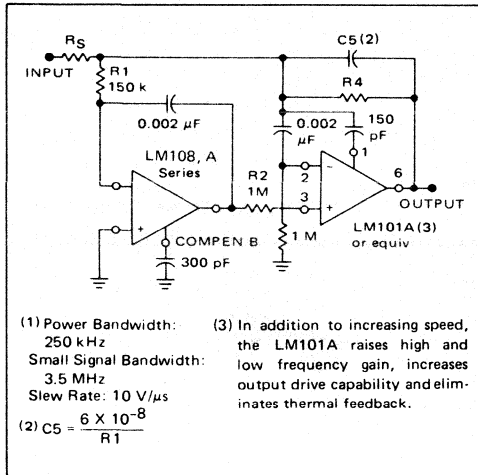

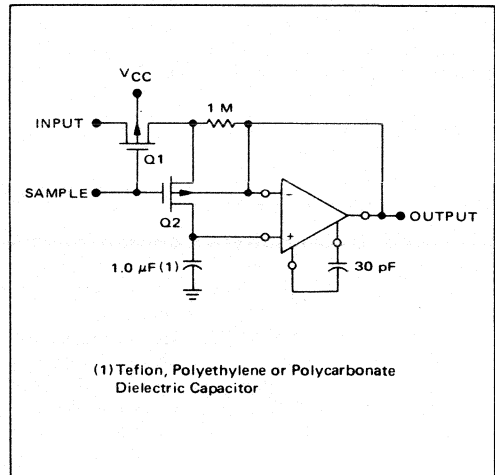

FIGURE 8 – SAMPLE AND HOLD

INPUT GUARDING

Special care must be taken in the assembly of printed circuit boards to take full advantage of the low input currents of the LM108, A amplifier series. Boards must be thoroughly cleaned with TCE or alcohol and blown dry with compressed air. After cleaning, the boards should be coated with epoxy or silicone rubber to prevent contamination.

Even with properly cleaned and coated boards, leakage currents may cause trouble at +125°C, particularly since the input pins are adjacent to pins that are at supply potentials. This leakage can be significantly reduced by using guarding to lower the voltage difference between the inputs and adjacent metal runs. Input guarding of the 8-lead TO-99 type package is accomplished by using a 10-lead pin circle, with the leads of the device formed so that the holes adjacent to the inputs are empty when it is inserted in the boards. The guard, which is a conductive ring surrounding the inputs, is connected to a low-impedance point that is at approximately the same voltage as the inputs. Leakage currents from high-voltage pins are then absorbed by the guard.

The pin configuration of the dual in-line package is designed to facilitate guarding, since the pins adjacent to the inputs are not used (this is different from the standard MC1741 and LM101A pin configuration).

Specifications and Applications Information

QUAD LOW POWER OPERATIONAL AMPLIFIERS

The LM124 Series are low-cost, quad operational amplifiers with true differential inputs. These have several distinct advantages over standard operational amplifier types in single supply applications. The quad amplifier can operate at supply voltages as low as 3.0 Volts or as high as 32 Volts with quiescent currents about one fifth of those associated with the MC1741 (on a per amplifier basis). The common mode input range includes the negative supply, thereby eliminating the necessity for external biasing components in many applications. The output voltage range also includes the negative power supply voltage.

- Short Circuit Protected Outputs
- True Differential Input Stage
- Single Supply Operation: 3.0 to 32 Volts
- Low Input Bias Currents: 250 nA Max
- Four Amplifiers Per Package
- Internally Compensated
- Common Mode Range Extends to Negative Supply
- Industry Standard Pinouts

NOTES:

- $T_{\text{low}} = -55^\circ\text{C}$ for LM124 $T_{\text{high}} = +125^\circ\text{C}$ for LM124
 $= -40^\circ\text{C}$ for LM2902 $= +85^\circ\text{C}$ for LM2902
 $= -25^\circ\text{C}$ for LM224 and LM224
 $= 0^\circ\text{C}$ for LM324 $= +70^\circ\text{C}$ for LM324
- The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than

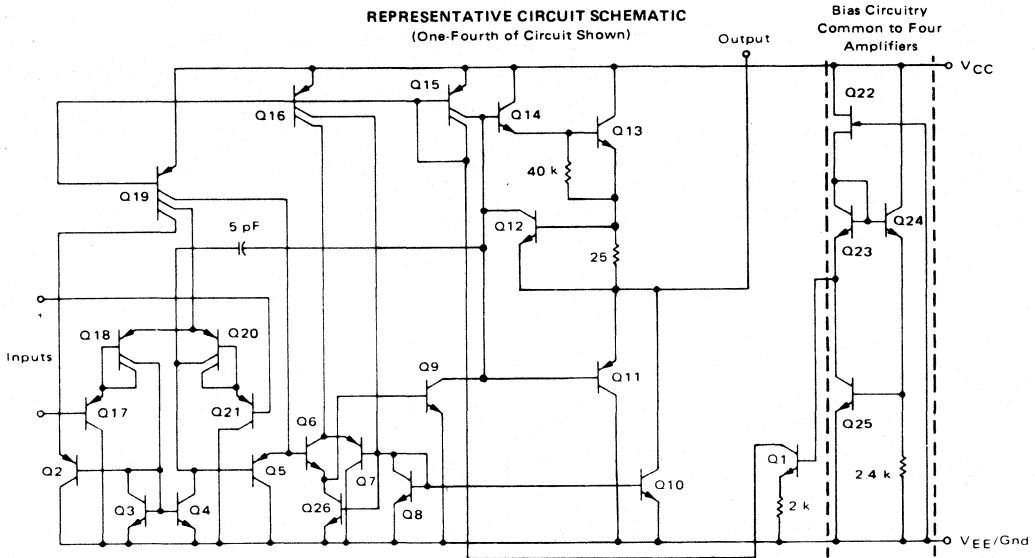

0.3 V. The upper end of the common mode voltage range is $V_{CC} - 1.7\text{ V}$, but either or both inputs can go to $+32\text{ V}$ without damage ($+26\text{ V}$ for LM2902).

- Short circuits from the output to V_{CC} can cause excessive heating and eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

LM124, LM224, LM324, LM2902

REPRESENTATIVE CIRCUIT SCHEMATIC
(One-Fourth of Circuit Shown)

LARGE SIGNAL VOLTAGE FOLLOWER RESPONSE

CIRCUIT DESCRIPTION

The LM124 Series is made using four internally compensated, two-stage operational amplifiers. The first stage of each consists of differential input devices Q20 and Q18 with input buffer transistors Q21 and Q17 and the differential to single ended converter Q3 and Q4. The first stage performs not only the first stage gain function but also performs the level shifting and transconductance reduction functions. By reducing the transconductance a smaller compensation capacitor (only 5 pF) can be employed, thus saving chip area. The transconductance reduction is accomplished by splitting the collectors of Q20 and Q18. Another feature of this input stage is that the input common-mode range can include the negative supply or ground, in single supply operation, without saturating either the input devices or the differential to single-ended converter. The second stage consists of a standard current source load amplifier stage.

Each amplifier is biased from an internal voltage regulator which has a low temperature coefficient thus giving each amplifier good temperature characteristics as well as excellent power supply rejection.

Given f_o = Center Frequency
 $A(f_o)$ = Gain at Center Frequency

Choose Value f_o, C

Then:

$$R3 = \frac{Q}{\pi f_o C}$$

$$R1 = \frac{R3}{2 A(f_o)}$$

$$R2 = \frac{R1 R3}{4Q^2 R1 - R3}$$

For less than 10% error from operational amplifier

$$\frac{Q_o f_o}{BW} < 0.1 \quad \text{Where } f_o \text{ and BW are expressed in Hz.}$$

If source impedance varies, filter may be preceded with voltage follower buffer to stabilize filter parameters.

LM148 LM248 LM348

Specifications and Applications Information

QUAD MC1741 OPERATIONAL AMPLIFIERS

The LM148 series is a true quad MC1741. Integrated on a single monolithic chip are four independent, low power operational amplifiers which have been designed to provide operating characteristics identical to those of the industry standard MC1741, and can be applied with no change in circuit performance. In addition, the total supply current for all four amplifiers is comparable to the supply current of a single MC1741. Other features include input offset currents and input bias currents which are much less than the MC1741 industry standard.

The LM148 can be used in applications where amplifier matching or high packing density is important. Other applications include high impedance buffer amplifiers and active filter amplifiers.

- Each Amplifier is Functionally Equivalent to the MC1741
- Low Input Offset and Input Bias Currents
- Class AB Output Stage Eliminates Crossover Distortion
- Pin Compatible with MC3503 and LM124
- True Differential Inputs-
- Internally Frequency Compensated
- Short Circuit Protection
- Low Power Supply Current (0.6 mA/Amplifier)

Specifications and Applications Information

DUAL LOW POWER OPERATIONAL AMPLIFIERS

Utilizing the circuit designs perfected for recently introduced Quad Operational Amplifiers, these dual operational amplifiers feature 1) low power drain, 2) a common mode input voltage range extending to ground/ V_{EE} , 3) Single Supply or Split Supply operation and 4) pin outs compatible with the popular MC1558 dual operational amplifier. The LM158 Series is equivalent to one-half of an LM124.

These amplifiers have several distinct advantages over standard operational amplifier types in single supply applications. They can operate at supply voltages as low as 3.0 Volts or as high as 32 Volts with quiescent currents about one-fifth of those associated with the MC1741 (on a per amplifier basis). The common mode input range includes the negative supply, thereby eliminating the necessity for external biasing components in many applications. The output voltage range also includes the negative power supply voltage.

- Short Circuit Protected Outputs
- True Differential Input Stage
- Single Supply Operation: 3.0 to 32 Volts
- Low Input Bias Currents
- Internally Compensated
- Common Mode Range Extends to Negative Supply
- Single and Split Supply Operation
- Similar Performance to the Popular MC1558

NOTES:

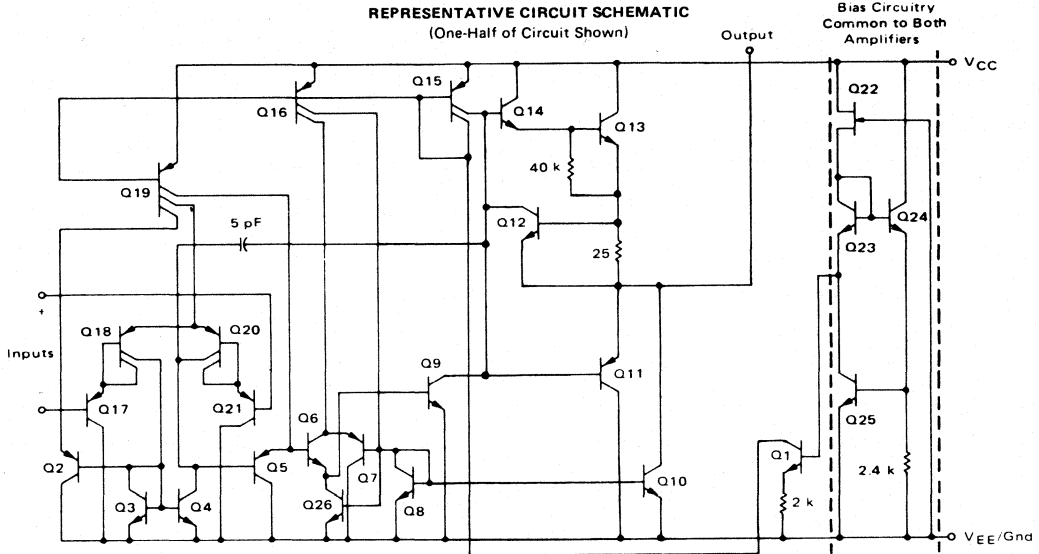

- $T_{\text{low}} = -55^\circ\text{C}$ for LM158 $T_{\text{high}} = +125^\circ\text{C}$ for LM158
 $= -40^\circ\text{C}$ for LM2904 $= +85^\circ\text{C}$ for LM2904
 $= -25^\circ\text{C}$ for LM258 and LM258
 $= 0^\circ\text{C}$ for LM358 $= +70^\circ\text{C}$ for LM358
- The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than

0.3 V. The upper end of the common-mode voltage range is $V_{CC} - 1.7\text{ V}$, but either or both inputs can go to $+32\text{ V}$ without damage ($+26\text{ V}$ for LM2904).

- Short circuits from the output to V_{CC} can cause excessive heating and eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

LM158, LM258, LM358, LM2904

**LARGE SIGNAL VOLTAGE
FOLLOWER RESPONSE**

CIRCUIT DESCRIPTION

The LM158 Series is made using two internally compensated, two-stage operational amplifiers. The first stage of each consists of differential input devices Q20 and Q18 with input buffer transistors Q21 and Q17 and the differential to single ended converter Q3 and Q4. The first stage performs not only the first stage gain function but also performs the level shifting and transconductance reduction functions. By reducing the transconductance a smaller compensation capacitor (only 5 pF) can be employed, thus saving chip area. The transconductance reduction is accomplished by splitting the collectors of Q20 and Q18. Another feature of this input stage is that the input common-mode range can include the negative supply or ground, in single supply operation, without saturating either the input devices or the differential to single-ended converter. The second stage consists of a standard current source load amplifier stage.

Each amplifier is biased from an internal voltage regulator which has a low temperature coefficient thus giving each amplifier good temperature characteristics as well as excellent power supply rejection.

APPLICATIONS INFORMATION (continued)

FIGURE 12 – FUNCTION GENERATOR

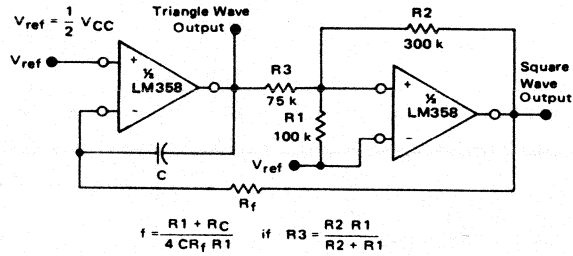

FIGURE 13 – MULTIPLE FEEDBACK BANDPASS FILTER

Given f_o = Center Frequency
 $A(f_o)$ = Gain at Center Frequency

Choose Value f_o, C

Then:

$$R3 = \frac{Q}{\pi f_o C}$$

$$R1 = \frac{R3}{2 A(f_o)}$$

$$R2 = \frac{R1 R3}{4Q^2 R1 - R3}$$

For less than 10% error from operational amplifier

$$\frac{Q_o f_o}{BW} < 0.1 \quad \text{Where } f_o \text{ and BW are expressed in Hz.}$$

If source impedance varies, filter may be preceded with voltage follower buffer to stabilize filter parameters.

UNCOMPENSATED OPERATIONAL AMPLIFIER

... designed for use as a summing amplifier, integrator, or amplifier with operating characteristics as a function of the external feedback components. For detailed information see Motorola Application Note AN-439.

- Low Input Offset Voltage – 3.0 mV max
- Low Input Offset Current – 60 nA max
- Large Power-Bandwidth – 20 V_{p-p} Output Swing at 20 kHz min
- Output Short-Circuit Protection
- Input Over-Voltage Protection
- Class AB Output for Excellent Linearity
- High Slew Rate – 34 V/μs typ

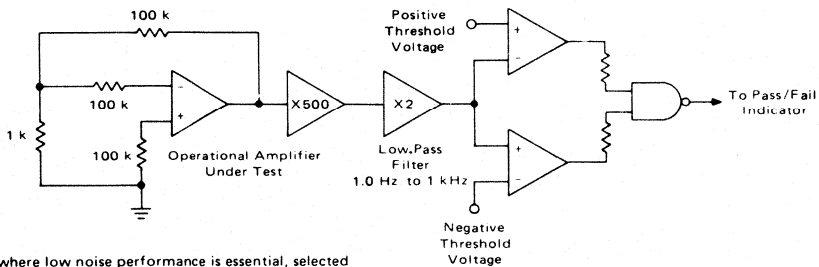

FIGURE 5 – BURST NOISE TEST CIRCUIT (N Suffixes Devices Only)

For applications where low noise performance is essential, selected devices denoted by an N suffix are offered. These units have been 100% tested for burst noise pulses on a special noise test system. Unlike conventional peak reading or RMS meters, this system was especially designed to provide the quick response time essential to burst (popcorn) noise testing.

The test time employed is 10 seconds and the 20 μV peak limit refers to the operational amplifier input thus eliminating errors in the closed-loop gain factor of the operational amplifier under test.

DUAL HIGH SLEW-RATE INTERNALLY-COMPENSATED OPERATIONAL AMPLIFIERS

The MC1558S is functionally equivalent, pin compatible, and possesses the same ease of use as the popular MC1558 circuit, yet offers 20 times higher slew rate and power bandwidth. This device is ideally suited for D/A converters due to its fast settling time and high slew rate.

- High Slew Rate — 10 V/μs Guaranteed Minimum (for inverting unity gain only)
- No Frequency Compensation Required
- Short-Circuit Protection
- Offset Voltage Null Capability
- Wide Common-Mode and Differential Voltage Ranges
- Low Power Consumption
- No Latch-Up

TYPICAL APPLICATION OUTPUT CURRENT TO VOLTAGE TRANSFORMATION FOR A D-TO-A CONVERTER

Settling time to within 1/2 LSB ($\pm 19.5 \text{ mV}$) is approximately 4.0 μs from the time that all bits are switched.

*The value of C may be selected to minimize overshoot and ringing ($C \approx 68 \text{ pF}$).

Theoretical V_O

$$V_O = \frac{V_{ref}}{R_1} (R_O) \left[\frac{A1}{2} + \frac{A2}{4} + \frac{A3}{8} + \frac{A4}{16} + \frac{A5}{32} + \frac{A6}{64} + \frac{A7}{128} + \frac{A8}{256} \right]$$

Adjust V_{ref} , R_1 or R_O so that V_O with all digital inputs at high level is equal to 9.961 volts.

$$V_O = \frac{2 \text{ V}}{1 \text{ k}} (5 \text{ k}) \left[\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \frac{1}{64} + \frac{1}{128} + \frac{1}{256} \right] = 10 \text{ V} \left[\frac{255}{256} \right] = 9.961 \text{ V}$$

SETTLING TIME

In order to properly utilize the high slew rate and fast settling time of an operational amplifier, a number of system considerations must be observed. Capacitance at the summing node and at the amplifier output must be minimal and circuit board layout should be consistent with common high-frequency considerations. Both power supply connections should be adequately bypassed as close as possible to the device pins. In bypassing, both low and high-frequency components should be considered to avoid the possibility of excessive ringing. In order to achieve optimum damping, the selection of a capacitor in parallel with the feedback resistor may be necessary. A value too small could result in excessive ringing while a value too large will degrade slew rate and settling time.

SETTLING TIME MEASUREMENT

In order to accurately measure the settling time of an operational amplifier, it is suggested that the "false" summing junction approach be taken as shown in Figure 11. This is necessary since it is difficult to determine when the waveform at the output of the operational amplifier settles to within 0.1% of its final value. Because the output and input voltages are effectively subtracted from each other at the amplifier inverting input, this seems like an ideal node for the measurement. However, the probe capacitance at this critical node can greatly affect the accuracy of the actual measurement.

FIGURE 11 – WAVEFORM AT FALSE SUMMING NODE (Inverting Mode)

FIGURE 12 – EXPANDED WAVEFORM AT FALSE SUMMING NODE (Inverting Mode)

The solution to these problems is the creation of a second or "false" summing node. The addition of two diodes at this node clamps the error voltage to limit the voltage excursion to the oscilloscope. Because of the voltage divider effect, only one-half of the actual error appears at this node. For extremely critical measurements, the capacitance of the diodes and the oscilloscope, and the settling time of the oscilloscope must be considered. The expression

$$t_{setlg} = \sqrt{x^2 + y^2 + z^2}$$

can be used to determine the actual amplifier settling time, where

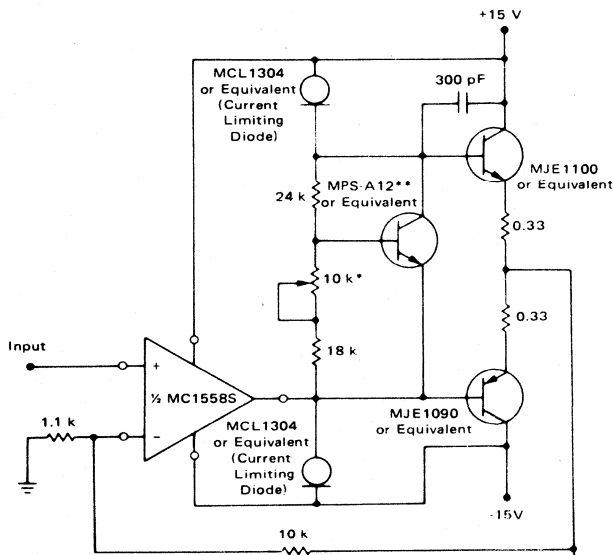

- t_{setlg} = observed settling time
- x = amplifier settling time (to be determined)
- y = false summing junction settling time
- z = oscilloscope settling time

It should be remembered that to settle within $\pm 0.1\%$ requires $7RC$ time constants.

The $\pm 0.1\%$ factor was chosen for the MC1558S settling time as it is compatible with the $\pm 1/2$ LSB accuracy of the MC1508L 8 digital-to-analog converter. This D-to-A converter features $\pm 0.19\%$ maximum error.

TYPICAL APPLICATION

FIGURE 13 – 12.5-WATT WIDEBAND POWER AMPLIFIER

Delivers 12.5 watt into 4.0 ohms with less than 1% THD to 100 kHz. Pins not shown are not connected.

- * Bias current adjustment to eliminate Crossover Distortion.
- ** Epoxy to power transistor heat sink or case for maximum Thermal Feedback.

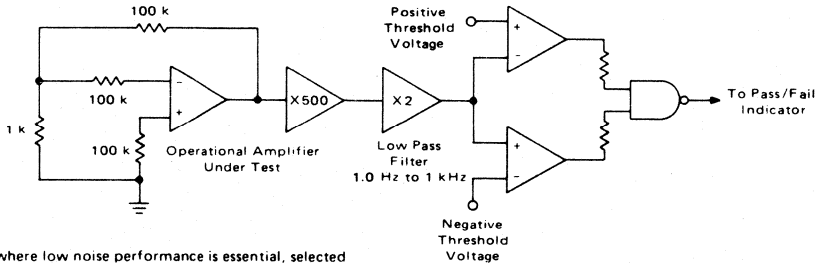

FIGURE 5 – BURST NOISE TEST CIRCUIT (N Suffixed Devices Only)

For applications where low noise performance is essential, selected devices denoted by an N suffix are offered. These units have been 100% tested for burst noise pulses on a special noise test system. Unlike conventional peak reading or RMS meters, this system was especially designed to provide the quick response time essential to burst (popcorn) noise testing.

The test time employed is 10 seconds and the 20 μV peak limit refers to the operational amplifier input thus eliminating errors in the closed-loop gain factor of the operational amplifier under test.

MC1741S MC1741SC

HIGH SLEW-RATE INTERNALLY-COMPENSATED OPERATIONAL AMPLIFIER

The MC1741S/MC1741SC is functionally equivalent, pin compatible, and possesses the same ease of use as the popular MC1741 circuit, yet offers 20 times higher slew rate and power bandwidth. This device is ideally suited for D-to-A converters due to its fast settling time and high slew rate.

- High Slew Rate – 10 V/μs Guaranteed Minimum (for unity gain only)
- No Frequency Compensation Required
- Short-Circuit Protection
- Offset Voltage Null Capability
- Wide Common-Mode and Differential Voltage Ranges
- Low Power Consumption
- No Latch-Up

TYPICAL APPLICATION OUTPUT CURRENT TO VOLTAGE TRANSFORMATION FOR A D-TO-A CONVERTER

Pins not shown are not connected.

Setting time to within 1/2 LSB (±19.5 mV) is approximately 4.0 μs from the time that all bits are switched.
 *The value of C may be selected to minimize overshoot and ringing (C > 68 pF).

Theoretical V_O

$$V_O = \frac{V_{ref}}{R_1} (R_O) \left[\frac{A1}{2} + \frac{A2}{4} + \frac{A3}{8} + \frac{A4}{16} + \frac{A5}{32} + \frac{A6}{64} + \frac{A7}{128} + \frac{A8}{256} \right]$$

Adjust V_{ref}, R1 or R_O so that V_O with all digital inputs at high level is equal to 9.961 volts.

$$V_O = \frac{2V}{1k} (5k) \left[\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \frac{1}{64} + \frac{1}{128} + \frac{1}{256} \right] = 10V \left[\frac{255}{256} \right] = 9.961V$$

FIGURE 9 — POWER CONSUMPTION versus POWER SUPPLY VOLTAGES

FIGURE 10 — LARGE-SIGNAL TRANSIENT WAVEFORMS

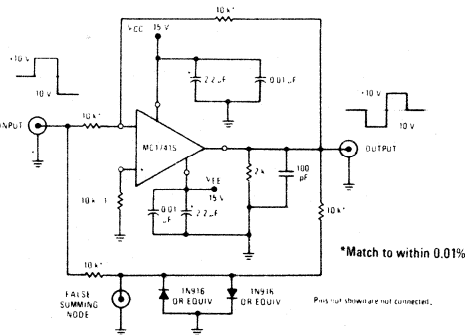

FIGURE 11 — SETTLING TIME AND SLEW RATE TEST CIRCUIT

SETTLING TIME

In order to properly utilize the high slew rate and fast settling time of an operational amplifier, a number of system considerations must be observed. Capacitance at the summing node and at the amplifier output must be minimal and circuit board layout should be consistent with common high-frequency considerations. Both power supply connections should be adequately bypassed as close as possible to the device pins. In bypassing, both low and high-frequency components should be considered to avoid the possibility of excessive ringing. In order to achieve optimum damping, the selection of a capacitor in parallel with the feedback resistor may be necessary. A value too small could result in excessive ringing while a value too large will degrade slew rate and settling time.

SETTLING TIME MEASUREMENT

In order to accurately measure the settling time of an operational amplifier, it is suggested that the "false" summing junction approach be taken as shown in Figure 11. This is necessary since it is difficult to determine when the waveform at the output of the operational amplifier settles to within 0.1% of its final value. Because the output and input voltages are effectively subtracted from each other at the amplifier inverting input, this seems like an ideal node for the measurement. However, the probe capacitance at this critical node can greatly affect the accuracy of the actual measurement.

The solution to these problems is the creation of a second or "false" summing node. The addition of two diodes at this node clamps the error voltage to limit the voltage excursion to the oscilloscope. Because of the voltage divider effect, only one-half of the actual error appears at this node. For extremely critical measurements, the capacitance of the diodes and the oscilloscope, and the settling time of the oscilloscope must be considered. The expression

$$t_{\text{setlg}} = \sqrt{x^2 + y^2 + z^2}$$

can be used to determine the actual amplifier settling time, where

- t_{setlg} = observed settling time
- x = amplifier settling time (to be determined)
- y = false summing junction settling time
- z = oscilloscope settling time

It should be remembered that to settle within $\pm 0.1\%$ requires 7RC time constants.

The $\pm 0.1\%$ factor was chosen for the MC1741S settling time as it is compatible with the $\pm 1/2$ LSB accuracy of the MC1508L8 digital-to-analog converter. This D-to-A converter features $\pm 0.19\%$ maximum error.

Specifications and Applications Information

MONOLITHIC MICROPOWER PROGRAMMABLE OPERATIONAL AMPLIFIER

This extremely versatile operational amplifier features low power consumption and high input impedance. In addition, the quiescent currents within the device may be programmed by the choice of an external resistor value or current source applied to the I_{set} input. This allows the amplifier's characteristics to be optimized for input current and power consumption despite wide variations in operating power supply voltages.

- ± 1.2 V to ± 18 V Operation
- Wide Programming Range
- Offset Null Capability
- No Frequency Compensation Required
- Low Input Bias Currents
- Short-Circuit Protection

RESISTIVE PROGRAMMING (See Figure 1.)

R_{set} to GROUND

Typical R_{set} Values

V_{CC}, V_{EE}	$I_{set} = 1.5 \mu A$	$I_{set} = 15 \mu A$
± 6.0 V	3.6 M Ω	360 k Ω
± 10 V	6.2 M Ω	620 k Ω
± 12 V	7.5 M Ω	750 k Ω
± 15 V	10 M Ω	1.0 M Ω

R_{set} to NEGATIVE SUPPLY (Recommended for supply voltage less than ± 6.0 V.)

Typical R_{set} Values

V_{CC}, V_{EE}	$I_{set} = 1.5 \mu A$	$I_{set} = 15 \mu A$
± 1.5 V	1.6 M Ω	160 k Ω
± 3.0 V	3.6 M Ω	360 k Ω
± 6.0 V	7.5 M Ω	750 k Ω
± 15 V	20 M Ω	2.0 M Ω

ORDERING INFORMATION

Device	Temperature Range	Package
MC3301L	-40°C to +85°C	Ceramic DIP
MC3301P	-40°C to +85°C	Plastic DIP

QUAD SINGLE-SUPPLY OPERATIONAL AMPLIFIER FOR AUTOMOTIVE APPLICATIONS

These internally compensated operational amplifiers are designed specifically for single positive power supply applications found in automotive and consumer electronics. Each MC3301 contains four independent amplifiers — making it ideal for automotive safety, pollution, and comfort controls. Some typical applications are tachometer, voltage regulator, logic circuits, power control and other similar usages.

- Wide Operating Temperature Range — -40 to +85°C
- Single-Supply Operation — +4.0 to +28 Vdc
- Internally Compensated
- Wide Unity Gain Bandwidth — 4.0 MHz typical
- Low Input Bias Current — 50 nA typical
- High Open-Loop Gain — 2000 V/V typical

NOTES:

- The quiescent current drain will increase approximately 0.3 mA for each inverting or noninverting input that is grounded.
- Input bias current can be defined only for the inverting input. The noninverting input is not a true "differential input" — as with a conventional IC operational amplifier. As such this input does not have a requirement for input bias current.
- Current mirror gain is defined as the current demanded at the inverting input divided by the current into the noninverting input.
- Bandwidth and phase margin are defined with respect to the voltage gain from the inverting input to the output.

OPERATION AND APPLICATIONS

Basic Amplifier

The basic amplifier is the common emitter stage shown in Figures 15 and 16. The active load I_1 is buffered from the input transistor by a PNP transistor, Q4, and from the output by an NPN transistor, Q2. Q2 is biased class A by the current source I_2 . The magnitude of I_2 (specified I_{sink}) is a limiting factor in capacitively coupled

linear operation at the output. The sink current of the device can be forced to exceed the specified level by keeping the output dc voltage above ≈ 1.0 volt resulting in an increase in the distortion appearing at the output. Closed loop stability is maintained by an on-the-chip 3-pF capacitor shown in Figure 18 on the following page. No external compensation is required.

FIGURE 15
BLOCK DIAGRAM

A noninverting input is obtained by adding a current mirror as shown in Figure 17. Essentially all current which enters the non-inverting input, I_r , flows through the diode CR1. The voltage drop across CR1 corresponds to this input current magnitude and this same voltage is applied to a matched device, Q3. Thus Q3 is biased to conduct an emitter current equal to I_r . Since the alpha

current gain of Q3 ≈ 1 , its collector current is approximately equal to I_r also. In operation this current flows through an external feedback resistor which generates the output voltage signal. For inverting applications, the noninverting input is often used to set the dc quiescent level at the output. Techniques for doing this are discussed in the "Normal Design Procedure" section.

FIGURE 16 – A BASIC GAIN STAGE

Biasing Circuitry

The circuitry common to all four amplifiers is shown in Figure 19, see next page. The purpose of this circuitry is to provide biasing voltage for the PNP and NPN current sources used in the amplifiers. The voltage drops across diodes CR2, CR3 and CR4 are used as references. The voltage across resistor R1 is the sum of the drops across CR4 and CR3 minus the V_{BE} of Q8. The PNP current sources (Q5, etc.) are set to the magnitude $V_{BE}/R1$ by transistor

FIGURE 17 – OBTAINING A NONINVERTING INPUT

Q6. Transistor Q7 reduces base current loading. The voltage across resistor R2 is the sum of the voltage drops across CR2, CR3 and CR4, minus the V_{BE} drops of transistor Q9 and diode CR5. The current thus set is established by CR5 in all the NPN current sources (Q10, etc.). This technique results in current source magnitudes which are relatively independent of the supply voltage. Q11 (Figure 15) provides circuit protection from signals that are negative with respect to ground.

OPERATION AND APPLICATIONS (continued)

FIGURE 18 — A BASIC OPERATIONAL AMPLIFIER

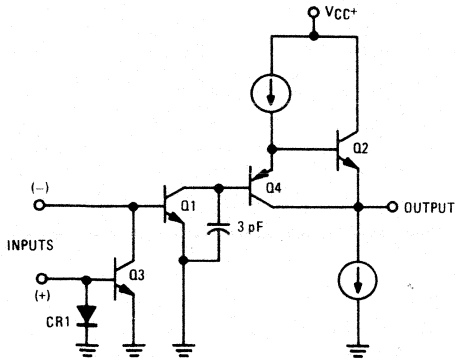

FIGURE 19 — BIASING CIRCUITRY

NORMAL DESIGN PROCEDURE

1. Output Q-Point Biasing

A. A number of techniques may be devised to bias the quiescent output voltage to an acceptable level. However, in terms of loop gain considerations it is usually desirable to use the noninverting input to effect the biasing as shown in Figures 3 and 4 (see the first page of this specification). The high impedance of the collector of the noninverting "current mirror" transistor helps to achieve the maximum loop gain for any particular configuration. It is desirable that the noninverting input current be in the 10 μ A to 200 μ A range.

B. V_{CC} Reference Voltage (see Figures 3 and 4)

The noninverting input is normally returned to the V_{CC} voltage (which should be well filtered) through a resistor, R_r , allowing the input current, I_r , to be within the range of 10 μ A to 200 μ A. Choosing the feedback resistor, R_f , to be equal to $\frac{1}{2} R_r$ will now bias the amplifier output dc level to approximately $\frac{V_{CC}}{2}$. This allows the maximum dynamic range of the output voltage.

C. Reference Voltage other than V_{CC} (see Figure 20)

The biasing resistor R_r may be returned to a voltage (V_r) other than V_{CC} . By setting $R_f = R_r$ (still keeping I_r between 10 μ A and 200 μ A) the output dc level will be equal to V_r . The expression for determining V_{Odc} is:

$$V_{Odc} = \frac{(A_1)(V_r)(R_f)}{R_r} + \left(1 - \frac{R_f}{R_r} A_1\right) \phi$$

where ϕ is the V_{BE} drop of the input transistors (approximately 0.6 Vdc @ +25°C and assumed equal). A_1 is the current mirror gain.

2. Gain Determination

A. Inverting Amplifier

The amplifier is normally used in the inverting mode. The input may be capacitively coupled to avoid upsetting the dc bias and the output is normally capacitively coupled to eliminate the dc voltage across the load. Note that when the output is capacitively coupled to the load, the value of

FIGURE 20 — INVERTING AMPLIFIER WITH ARBITRARY REFERENCE

FIGURE 21 — INVERTING AMPLIFIER WITH $A_v = 100$ AND $V_r = V_{CC}$

NORMAL DESIGN PROCEDURE (continued)

I_{sink} becomes a limitation with respect to the load driving capabilities of the device. The limitation is less severe if the device is direct coupled. In this configuration, the ac gain is determined by the ratio of R_f to R_i , in the same manner as for a conventional operational amplifier:

$$A_v = - \frac{R_f}{R_i}$$

The lower corner frequency is determined by the coupling capacitors to the input and load resistors. The upper corner frequency will usually be determined by the amplifier internal compensation. The amplifier unity gain bandwidth is typically 4.0 MHz and with the gain roll-off at 20 dB per decade, bandwidth will typically be 400 kHz with 20 dB of closed loop gain or 40 kHz with 40 dB of closed loop gain. The exception to this occurs at low gains where the input resistor selected is large. The pole formed by the amplifier input capacitance, stray capacitance and the input resistor may occur before the closed loop gain intercepts the open loop response curve. The inverting input capacity is typically 3.0 pF.

B. Noninverting Amplifier

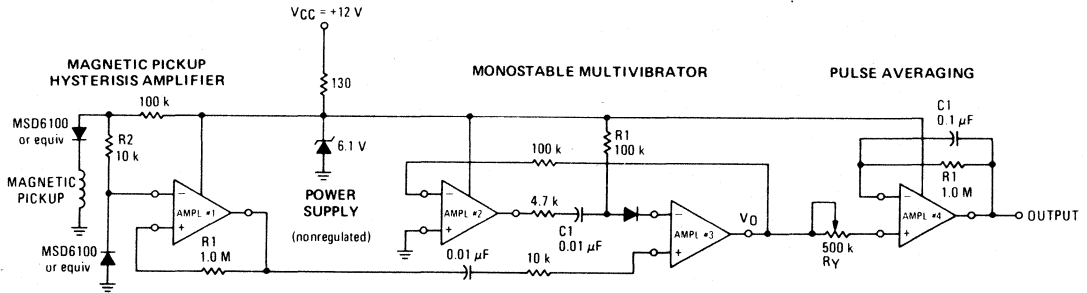

The MC3301 may be used in the noninverting mode (see Figure 4, first page). The amplifier gain in this configuration is subject to the current mirror gain. In addition, the resistance of the input diode must be included in the value of the input resistor. This resistance is approximately $\frac{26}{I_f}$ ohms, where I_f is input current in milliamperes. The noninverting ac gain expression is given by:

$$A_v = \frac{(R_f)(A_i)}{R_i + \frac{26}{I_f} \text{ (mA)}}$$

The bandwidth of the noninverting configuration for a given R_f value is essentially independent of the gain chosen. For $R_f = 510 \text{ k}\Omega$ the bandwidth will be in excess of 200 kHz for noninverting gains of 1, 10, or 100. This is a result of the loop gain remaining constant for these gains since the input resistor is effectively isolated from the feedback loop.

Specifications and Applications Information

QUAD SINGLE-SUPPLY OPERATIONAL AMPLIFIER

These internally compensated operational amplifiers are designed specifically for single positive power supply applications found in industrial control systems and automotive electronics. Each MC3401 device contains four independent amplifiers — making it ideal for applications such as active filters, multi-channel amplifiers, tachometer, oscillator and other similar usages.

- Single-Supply Operation — +5.0 Vdc to +18 Vdc
- Internally Compensated
- Wide Unity Gain Bandwidth — 5.0 MHz typical
- Low Input Bias Current — 50 nA typical
- High Open-Loop Gain — 1000 V/V minimum

NOTES

- Open loop voltage gain is defined as the voltage gain from the inverting input to the output.
- The quiescent current will increase approximately 0.3 mA for each noninverting input which is grounded. Leaving the noninverting input open causes the apparent input bias current to increase slightly (100 nA) at high temperatures.
- Input bias current can be defined only for the inverting input. The noninverting input is not a true "differential input" — as with a conventional IC operational amplifier. As such this input does not have a requirement for input bias current.
- Sink current is specified for linear operation. When the device is used as a gate or a comparator (non-linear operation), the sink capability of the device is approximately 5.0 milliamperes.
- When used as a noninverting amplifier, the minimum output voltage is the V_{BE} of the inverting input transistor.
- Peak-to-peak restrictions are due to the variations of the quiescent dc output voltage in the standard configuration (Figure 8).
- Power supply rejection is specified at closed loop unity gain, and therefore indicates the supply rejection of both the biasing circuitry and the feedback amplifier.

OPERATION AND APPLICATIONS

Basic Amplifier

The basic amplifier is the common emitter stage shown in Figures 15 and 16. The active load I_1 is buffered from the input transistor by a PNP transistor, Q4, and from the output by an NPN transistor, Q2. Q2 is biased class A by the current source I_2 . The magnitude of I_2 (specified I_{sink}) is a limiting factor in capacitively coupled

linear operation at the output. The sink current of the device can be forced to exceed the specified level with an increase in the distortion appearing at the output. Closed loop stability is maintained by an on-the-chip 3-pF capacitor shown in Figure 18. No external compensation is required.

FIGURE 15

A noninverting input is obtained by adding a current mirror as shown in Figure 17. Essentially all current which enters the non-inverting input, I_{in2} , flows through the diode CR1. The voltage drop across CR1 corresponds to this input current magnitude and this same voltage is applied to a matched device, Q3. Thus Q3 is biased to conduct an emitter current equal to I_{in2} . Since the

alpha current gain of Q3 ≈ 1 , its collector current $\approx I_{in2}$ also. In operation this current flows through an external feedback resistor which generates the output voltage signal. For inverting applications, the noninverting input is often used to set the dc quiescent level at the output. Techniques for doing this are discussed in the "Normal Design Procedure" section.

FIGURE 16 - A BASIC GAIN STAGE

Biasing Circuitry

The circuitry common to all four amplifiers is shown in Figure 19. The purpose of this circuitry is to provide biasing voltage for the PNP and NPN current sources used in the amplifiers.

The voltage drops across diodes CR2, CR3 and CR4 are used as references. The voltage across resistor R1 is the sum of the drops across CR4 and CR3 minus the V_{BE} of Q8. The PNP current sources (Q5, etc.) are set to the magnitude $V_{BE}/R1$ by transistor

FIGURE 17 - OBTAINING A NONINVERTING INPUT

Q6. Transistor Q7 reduces base current loading. The voltage across resistor R2 is the sum of the voltage drops across CR2, CR3 and CR4, minus the V_{BE} drops of transistor Q9 and diode CR5. The current thus set is established by CR5 in all the NPN current sources (Q10, etc.). This technique results in current source magnitudes which are relatively independent of the supply voltage.

OPERATION AND APPLICATIONS (continued)

FIGURE 18 — A BASIC OPERATIONAL AMPLIFIER

FIGURE 19 — BIASING CIRCUITRY

NORMAL DESIGN PROCEDURE

1. Output Q-Point Biasing

A. A number of techniques may be devised to bias the quiescent output voltage to an acceptable level. However, in terms of loop gain considerations it is usually desirable to use the noninverting input to effect the biasing as shown in Figures 3 and 4. The high impedance of the collector of the non-inverting "current mirror" transistor helps to achieve the maximum loop gain for any particular configuration. It is desirable that the noninverting input current be in the 5 μ A to 100 μ A range.

B. V_{CC} Reference Voltage (see Figures 3 and 4)
The noninverting input is normally returned to the V_{CC} voltage (which should be well filtered) through a resistor, R_r , allowing the input current, I_r , to be within the range of 5 μ A to 100 μ A. Choosing the feedback resistor, R_f , to be equal to $\frac{1}{2} R_r$ will now bias the amplifier output dc level to approximately $\frac{V_{CC}}{2}$. This allows for maximum dynamic range of the output voltage.

C. Reference Voltage other than V_{CC} (See Figure 20).
The biasing resistor R_r may be returned to a voltage (V_r)

other than V_{CC} . By setting $R_f = R_r$ (still keeping I_r between 5 μ A and 100 μ A) the output dc level will be equal to V_r . Neglecting error terms, the expression for determining V_{Odc} is:

$$V_{Odc} = \frac{(V_r)(R_f)}{R_r} + \left(1 - \frac{R_f}{R_r}\right) \phi$$

where ϕ is the V_{BE} drop of the input transistors (approximately 0.7 Vdc @ +25°C).

The error terms not appearing in the above equation can cause the dc operating point to vary up to 20% from the expected value. Error terms are minimized by setting the input current within the range of 5 μ A to 100 μ A.

2. Gain Determination

A. Inverting Amplifier

The amplifier is normally used in the inverting mode. The input may be capacitively coupled to avoid upsetting the dc bias and the output is normally capacitively coupled to eliminate the dc voltage across the load. Note that when the output is capacitively coupled to the load, the value of

FIGURE 20 — INVERTING AMPLIFIER WITH ARBITRARY REFERENCE

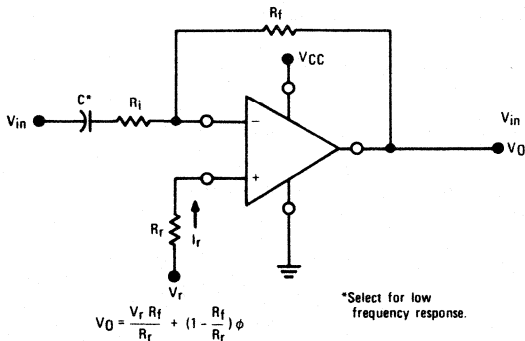

FIGURE 21 — INVERTING AMPLIFIER WITH $A_v = 100$ AND $V_r = V_{CC}$

NORMAL DESIGN PROCEDURE (continued)

I_{sink} becomes a limitation with respect to the load driving capabilities of the device. The limitation is less severe if the device is direct coupled. In this configuration, the ac gain is determined by the ratio of R_f to R_i , in the same manner as for a conventional operational amplifier:

$$A_v = - \frac{R_f}{R_i}$$

The lower corner frequency is determined by the coupling capacitors to the input and load resistors. The upper corner frequency will usually be determined by the amplifier internal compensation. The amplifier unity gain bandwidth is typically 5.0 MHz and with the gain roll-off at 20 dB per decade, bandwidth will typically be 500 kHz with 20 dB of closed loop gain or 50 kHz with 40 dB of closed loop gain. The exception to this occurs at low gains where the input resistor selected is large. The pole formed by the amplifier input capacitance, stray capacitance and the input resistor may occur before the closed loop gain intercepts the open loop response curve. The inverting input capacity is typically 3.0 pF.

B. Noninverting Amplifier

Although recommended as an inverting amplifier, the MC3401 may be used in the noninverting mode (see Figure 4). The amplifier gain in this configuration is subject to the same error terms that affect the output Q point biasing so the gain may deviate as much as $\pm 20\%$ from that expected. In addition, the resistance of the input diode must be included in the value of the input resistor. This resistance is approximately $\frac{26}{I_f}$ ohms, where I_f is input current in milli-amperes. The noninverting gain expression is given by:

$$A_v = \frac{R_f}{R_i + \frac{26}{I_f} \text{ (mA)}} \pm 20\%$$

The bandwidth of the noninverting configuration for a given R_f value is essentially independent of the gain chosen. For, $R_f = 510 \text{ k}\Omega$ the bandwidth will be in excess of 200 kHz for noninverting gains of 1, 10, or 100. This is a result of the loop gain remaining constant for these gains since the input resistor is effectively isolated from the feedback loop.

Specifications and Applications Information

QUAD LOW POWER OPERATIONAL AMPLIFIERS

The MC3503 is a low-cost, quad operational amplifier with true differential inputs. The device has electrical characteristics similar to the popular MC1741. However, the MC3503 has several distinct advantages over standard operational amplifier types in single supply applications. The quad amplifier can operate at supply voltages as low as 3.0 Volts or as high as 36 Volts with quiescent currents about one third of those associated with the MC1741 (on a per amplifier basis). The common mode input range includes the negative supply, thereby eliminating the necessity for external biasing components in many applications. The output voltage range also includes the negative power supply voltage.

- Short Circuit Protected Outputs
- Class AB Output Stage for Minimal Crossover Distortion
- True Differential Input Stage
- Single Supply Operation: 3.0 to 36 Volts
- Split Supply Operation: ± 1.5 to ± 18 Volts
- Low Input Bias Currents: 500 nA Max
- Four Amplifiers Per Package
- Internally Compensated
- Similar Performance to Popular MC1741

MC3403P, L, MC3503L, MC3303P, L

CIRCUIT DESCRIPTION

The MC3503/3403/3303 is made using four internally compensated, two-stage operational amplifiers. The first stage of each consists of differential input devices Q24 and Q22 with input buffer transistors Q25 and Q21 and the differential to single ended converter Q3 and Q4. The first stage performs not only the first stage gain function but also performs the level shifting and transconductance reduction functions. By reducing the transconductance a smaller compensation capacitor (only 5 pF) can be employed, thus saving chip area. The transconductance reduction is accomplished by splitting the collectors of Q24 and Q22. Another feature of this input stage is that the input common-mode range can include

the negative supply or ground, in single supply operation, without saturating either the input devices or the differential to single-ended converter. The second stage consists of a standard current source load amplifier stage.

The output stage is unique because it allows the output to swing to ground in single supply operation and yet does not exhibit any crossover distortion in split supply operation. This is possible because class AB operation is utilized.

Each amplifier is biased from an internal-voltage regulator which has a low temperature coefficient thus giving each amplifier good temperature characteristics as well as excellent power supply rejection.

Specifications and Applications Information

DUAL LOW POWER OPERATIONAL AMPLIFIERS

Utilizing the circuit designs perfected for recently introduced Quad Operational Amplifiers, these dual operational amplifiers feature 1) low power drain, 2) a common mode input voltage range extending to ground/ V_{EE} , 3) Single Supply or Split Supply operation and 4) pin outs compatible with the popular MC1558 dual operational amplifier. The MC3558 Series is equivalent to one-half of a MC3503.

These amplifiers have several distinct advantages over standard operational amplifier types in single supply applications. They can operate at supply voltages as low as 3.0 Volts or as high as 36 Volts with quiescent currents about one-fifth of those associated with the MC1741 (on a per amplifier basis). The common mode input range includes the negative supply, thereby eliminating the necessity for external biasing components in many applications. The output voltage range also includes the negative power supply voltage.

- Short Circuit Protected Outputs
- True Differential Input Stage
- Single Supply Operation: 3.0 to 36 Volts
- Low Input Bias Currents
- Internally Compensated
- Common Mode Range Extends to Negative Supply
- Class AB Output Stage for Minimum Crossover Distortion
- Single and Split Supply Operations Available
- Similar Performance to the Popular MC1558

MC3476

LOW-COST PROGRAMMABLE OPERATIONAL AMPLIFIER

The MC3476 is a low-cost selection of the popular, industry-standard MC1776 programmable operational amplifier. This extremely versatile operational amplifier features low power consumption and high input impedance. In addition, the quiescent currents within the device may be programmed by the choice of an external resistor value or current source applied to the I_{set} input. This allows the amplifier's characteristics to be optimized for input current and power consumption despite wide variations in operating power supply voltages.

- ± 6.0 V to ± 18 V Operation
- Wide Programming Range
- Offset Null Capability
- No Frequency Compensation Required
- Low Input Bias Currents
- Short-Circuit Protection

RESISTIVE PROGRAMMING (See Figure 1.)

DUAL WIDEBAND OPERATIONAL AMPLIFIER

The MC4558, MC4558AC, and MC4558C combine all the outstanding features of the MC1458 and, in addition, possess three times the unity gain bandwidth of the industry standard.

- 2.5 MHz Unity Gain Bandwidth Guaranteed on MC4558 and MC4558AC
- 2 MHz Unity Gain Bandwidth Guaranteed on MC4558C
- Internally Compensated
- Short-Circuit Protection
- Gain and Phase Match between Amplifiers
- Low Power Consumption
- Low Noise Selections Offered – N Suffix

FIGURE 4 – SPECTRAL NOISE DENSITY

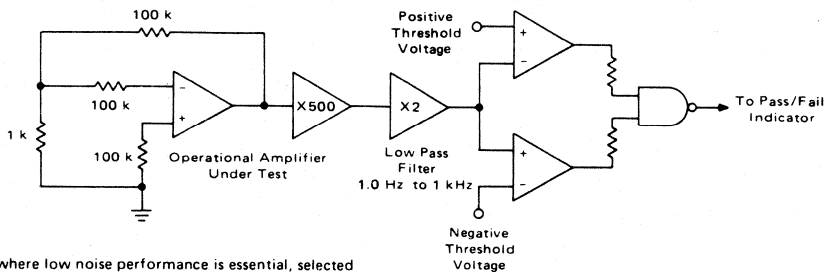

FIGURE 5 – BURST NOISE TEST CIRCUIT (N Suffixes Devices Only)

For applications where low noise performance is essential, selected devices denoted by an N suffix are offered. These units have been 100% tested for burst noise pulses on a special noise test system. Unlike conventional peak reading or RMS meters, this system was especially designed to provide the quick response time essential to burst (popcorn) noise testing.

The test time employed is 10 seconds and the $20\text{ }\mu\text{V}$ peak limit refers to the operational amplifier input thus eliminating errors in the closed-loop gain factor of the operational amplifier under test.

Specifications and Applications Information

QUAD MC1741 OPERATIONAL AMPLIFIERS

The MC4741 series is a true quad MC1741. Integrated on a single monolithic chip are four independent, low-power operational amplifiers which have been designed to provide operating characteristics identical to those of the industry standard MC1741, and can be applied with no change in circuit performance.

The MC4741 can be used in applications where amplifier matching or high packing density is important. Other applications include high impedance buffer amplifiers and active filter amplifiers.

- Each Amplifier is Functionally Equivalent to the MC1741
- Class AB Output Stage Eliminates Crossover Distortion
- True Differential Inputs
- Internally Frequency Compensated
- Short Circuit Protection
- Low Power Supply Current (0.6 mA/Amplifier)

Advance Information

TRIMFET FAMILY OF JFET INPUT OPERATIONAL AMPLIFIERS

These low cost TRIMFET operational amplifiers combine two state-of-the-art linear technologies on a single monolithic integrated circuit. Each internally compensated operational amplifier has well matched high voltage JFET input devices with a laser trimmed input offset voltage. The BIFET technology provides wide bandwidths and fast slew rates with low input bias currents, input offset currents, and supply currents. The laser trimming technology provides input offset voltage specification options which range from 2.0 to 10 millivolts maximum.

The Motorola TRIMFET family offers single, dual and quad operational amplifiers which are pin-compatible with the industry standard MC1741, MC1458, and the MC3403/LM324 bipolar devices. The MC35001/35002/35004 series are specified over the military operating temperature range of -55°C to $+125^{\circ}\text{C}$ and the MC34001/34002/34004 series are specified from 0°C to $+70^{\circ}\text{C}$.

- Laser Trimmed Input Offset Voltage Options of 2.0, 5.0, and 10 mV Maximum
- Low Input Bias Current – 40 pA
- Low Input Offset Current – 10 pA
- Low Input Noise Voltage – $16 \text{ nV}/\sqrt{\text{Hz}}$
- Wide Gain Bandwidth – 4 MHz
- High Slew Rate – $13 \text{ V}/\mu\text{s}$
- Low Supply Current – 1.8 mA per Amplifier
- High Input Impedance – $10^{12} \Omega$
- High Common-Mode and Supply Voltage Rejection Ratios – 100 dB
- Industry Standard Pinouts

Advance Information

TRIMFET PRECISION DUAL JFET INPUT OPERATIONAL AMPLIFIERS

The MC34022/35022 series of TRIMFET dual operational amplifiers combine two state-of-the-art linear technologies on a single monolithic chip to provide precision input characteristics at a low cost. These internally compensated operational amplifiers have well matched high voltage JFET input devices with laser trimmed input offset voltages. BIFET technology provides a wide bandwidth and a fast slew rate while maintaining low input bias currents, input offset currents, and supply currents. Laser trimming technology provides input offset voltage specification options which range from 0.5 to 2.0 millivolts maximum with a typical temperature coefficient of $5.0 \mu\text{V}/^\circ\text{C}$.

These Motorola TRIMFET dual operational amplifiers are pin-compatible with the industry standard MC1458/1558 bipolar devices. The MC35022A/35022B series are specified over the military operating temperature range of -55°C to $+125^\circ\text{C}$, and the MC34022/34022A/34022B series are specified from 0°C to $+70^\circ\text{C}$.

- Laser Trimmed Input Offset Voltage Options of 0.5, 1.0, and 2.0 mV Maximum
- Temperature Coefficient of Input Offset Voltage – $5.0 \mu\text{V}/^\circ\text{C}$
- Low Input Bias Current – 30 pA
- Low Input Offset Current – 10 pA
- Low Input Noise Voltage – $16 \text{ nV}/\sqrt{\text{Hz}}$
- Wide Gain Bandwidth – 4 MHz
- High Slew Rate – $13 \text{ V}/\mu\text{s}$
- Low Supply Current – 1.8 mA per Amplifier
- High Input Impedance – $10^{12} \Omega$
- High Common-Mode and Supply Voltage Rejection Ratios – 100 dB
- Industry Standard Pinouts

APPLICATIONS

The MC34022/35022 series of TRIMFET dual operational amplifiers is suggested for all general-purpose BIFET amplifier requirements where precision input characteristics are needed in addition to the features normally furnished by other BIFET amplifiers.

- Fast D/A and A/D Converters
- Sample and Hold Circuits
- Precision High-Speed Integrators
- High Impedance Buffers
- Wideband, High Slew, Low Current Amplifiers

Advance Information

PROGRAMMABLE QUAD OPERATIONAL AMPLIFIER

The TCA3002 is an array of four independent operational amplifiers on a single silicon chip. The operating current of the array is externally controlled by a single resistor or current source, allowing the user to trade-off power dissipation for bandwidth.

- Wide Input Voltage and Common Mode Range
- Externally Programmable
- No Latch-up
- Matched Parameters
- Micropower Operation
- Gain Bandwidth Product: 2.5 MHz (typ.) @ $I_{SET} = 75 \mu A$
- Low Supply Current: 150 μA /Amplifier @ $I_{SET} = 8 \mu A$
- Low Noise Voltage: 25 nV/ \sqrt{Hz} @ $I_{SET} = 75 \mu A$

Notes: ¹ All tests refer to a single Op-amp unless otherwise specified.

² Tests apply for parameter matching between any Op-amp pair.

³ Tests apply to four Op-amps and bias network.

TCA3002-DP, TCA3002-DC

Programming Equations

- Gain Bandwidth Product: 50 KHz x I_{SET} (μA)

Total Supply Current (50 I_{SET})

$$I_{SET} = \frac{V_{EE} - 2 V_{BE}}{R_{(SET)}}$$

with $V_{BE} \approx 0.65 \text{ V}$
(Typical Diode Voltage drop at 25 °C).

TYPICAL CHARACTERISTICS (T_A = +25 °C unless otherwise noted.)

ADVANCE INFORMATION

PROGRAMMABLE QUAD OPERATIONAL AMPLIFIER (3 + 1)

The TCA3003 consists of four independent, operational amplifier, high gain, internally compensated, low power, programmable amplifiers. Two external resistors (Rset) allow the user to program the gain bandwidth product, slew rate, supply current, input bias current, input offset current, and input noise.

- Wide input voltage and common mode range
- Micropower operation
- Matched parameters
- No latched up
- Except for the two programming pins at the end of the package, the TCA3003 pin out is the same as the MC3403 and MLM324.

Voltage Regulators

VOLTAGE REGULATORS

Fixed Output Voltage Regulators

- Low-cost monolithic circuits for positive and/or negative regulation at currents from 100 mA to 1.5A
- Ideal for on-card regulation of subsystems
- Internal current limiting thermal shutdown and safe-area compensation

FIXED-VOLTAGE, 3-TERMINAL REGULATORS FOR POSITIVE OR NEGATIVE POLARITY POWER SUPPLIES.

Switching Regulators

Used as the control circuit in PWM, push-pull, bridge and series type switchmode supplies. The devices include the reference, oscillator, pulse-width modulator, phase splitter and output sections. Frequency and duty cycle are independently adjustable.

LM104 LM204 LM304

MONOLITHIC NEGATIVE VOLTAGE REGULATOR

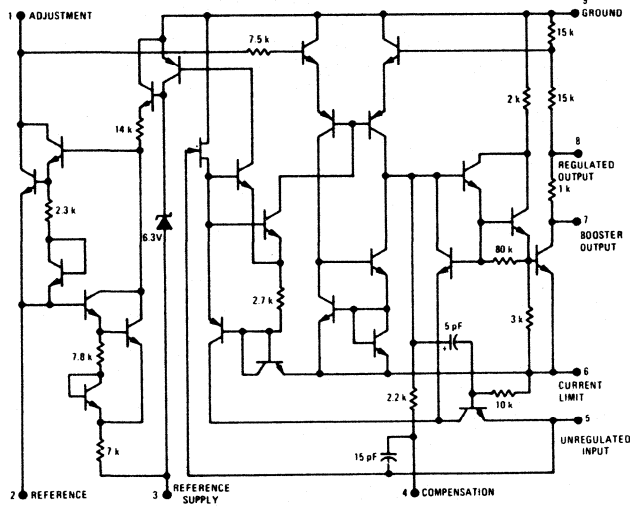

The LM104H, LM204H, and LM304H are precision negative voltage regulators which can be programmed by a single external resistor to supply an output voltage from 40 volts down to zero volts.

- Regulation No Load to Full Load – 1.0 mV
- Line Regulation – 0.01%/V
- Ripple Rejection – 0.2 mV/V
- Temperature Stability Over Temperature Range – 0.3%

Note 1:

The maximum junction temperature of the LM104 is $+150^\circ\text{C}$, for the LM204 $+100^\circ\text{C}$, and for the LM304 $+85^\circ\text{C}$. For operating at elevated temperatures, the package must be derated based on a thermal resistance of $150^\circ\text{C}/\text{W}$ — junction to ambient, or $45^\circ\text{C}/\text{W}$ — junction to case.

Note 2:

These specifications apply for junction temperatures of -55°C to $+150^\circ\text{C}$ for the LM104; -25°C to $+100^\circ\text{C}$ for the LM204; and 0 to $+85^\circ\text{C}$ for the LM304. The specifications also apply for input and output voltages within the indicated ranges (unless otherwise specified). Load and line regulation specifications given are for constant junction temperature. Temperature drift effects must be taken into account separately when the device is operating under conditions of high power dissipation.

LM105 LM205 LM305

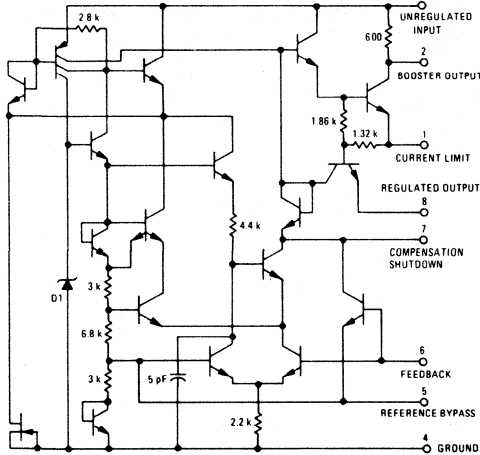

MONOLITHIC POSITIVE VOLTAGE REGULATOR

The LM105H, LM205H, and LM305H are precision voltage regulators which can be programmed by a single external resistor to supply an output voltage from 4.5 volts to 40 volts.

- Output Currents in Excess of 10 A Possible by Addition of External Transistors
- Load Regulation Better than 0.1%, Full Load with Current Limiting
- DC Line Regulation, 0.03%/V
- Ripple Rejection, 0.01%/V

Specifications also apply for input and output voltages within the indicated ranges and for a divider impedance sensed by the feedback terminal of 2.0 kilohms (unless otherwise specified). Load and line regulation specifications given are for constant junction temperature. Temperature drift effects must be taken into account separately when the device is operating under conditions of high power dissipation.

LM109 LM209 LM309

POSITIVE VOLTAGE REGULATOR

MONOLITHIC POSITIVE THREE - TERMINAL FIXED VOLTAGE REGULATOR

A versatile positive fixed +5.0-volt regulator designed for easy application as on-card, local voltage regulator for digital logic systems. Current limiting and thermal shutdown are provided to make the units extremely rugged.

In most applications only one external component, a capacitor, is required in conjunction with the LM109 Series devices. Even this component may be omitted if the power-supply filter is not located an appreciable distance from the regulator.

- High Maximum Output Current – Over 1.0 Ampere in TO-3 type Package – Over 200 mA in TO-39 type Package.
- Minimum External Components Required
- Internal Short-Circuit Protection
- Internal Thermal Overload Protection
- Excellent Line and Load Transient Rejection
- Designed for Use with Popular MDTL and MTTL Logic

3-TERMINAL ADJUSTABLE OUTPUT POSITIVE VOLTAGE REGULATOR

The LM117/217/317 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 1.5 A over an output voltage range of 1.2 V to 37 V. These voltage regulators are exceptionally easy to use and require only two external resistors to set the output voltage. Further, they employ internal current limiting, thermal shutdown and safe area compensation, making them essentially blow-out proof.

The LM117 series serve a wide variety of applications including local, on card regulation. This device also makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM117 series can be used as a precision current regulator.

- Output Current in Excess of 1.5 Ampere in TO-3 and TO-220 Packages
- Output Current in Excess of 0.5 Ampere in TO-39 Package
- Output Adjustable between 1.2 V and 37 V
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting Constant with Temperature
- Output Transistor Safe-area Compensation
- Floating Operation for High Voltage Applications
- Standard 3-lead Transistor Packages
- Eliminates Stocking Many Fixed Voltages

STANDARD APPLICATION

* = C_{in} is required if regulator is located an appreciable distance from power supply filter.

** = C_o is not needed for stability, however it does improve transient response.

$$V_{out} = 1.25 V \left(1 + \frac{R_2}{R_1} \right) + I_{Adj} R_2$$

Since I_{Adj} is controlled to less than 100 μA , the error associated with this term is negligible in most applications

APPLICATIONS INFORMATION

BASIC CIRCUIT OPERATION

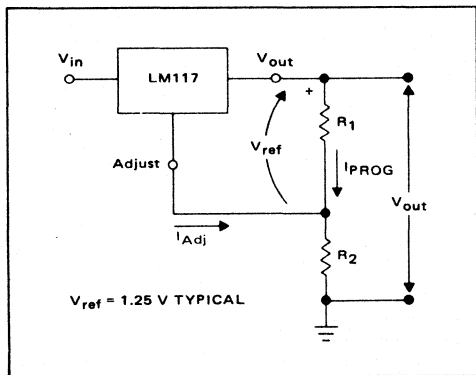

The LM117 is a 3-terminal floating regulator. In operation, the LM117 develops and maintains a nominal 1.25 volt reference (V_{ref}) between its output and adjustment terminals. This reference voltage is converted to a programming current (I_{PROG}) by R_1 (see Figure 17), and this constant current flows through R_2 to ground. The regulated output voltage is given by:

$$V_{out} = V_{ref} \left(1 + \frac{R_2}{R_1} \right) + I_{Adj} R_2$$

Since the current from the adjustment terminal (I_{Adj}) represents an error term in the equation, the LM117 was designed to control I_{Adj} to less than 100 μA and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM117 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

FIGURE 17 – BASIC CIRCUIT CONFIGURATION

LOAD REGULATION

The LM117 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor (R_1) should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of R_2 can be returned near the load ground to provide remote ground sensing and improve load regulation.

EXTERNAL CAPACITORS

A 0.1 μF disc or 1 μF tantalum input bypass capacitor (C_{in}) is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor (C_{ADJ}) prevents ripple from being amplified as the output voltage is increased. A 10 μF capacitor should improve ripple rejection about 15dB at 120 Hz in a 10 volt application.

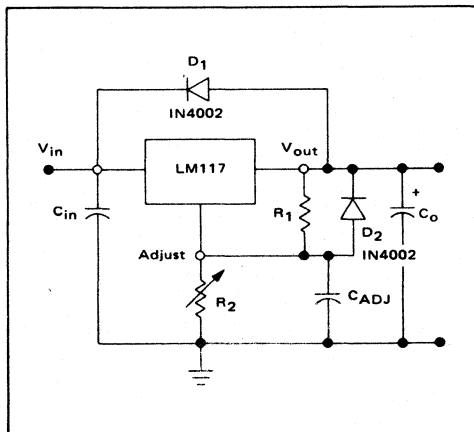

Although the LM117 is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance (C_o) in the form of a 1 μF tantalum or 25 μF aluminum electrolytic capacitor on the output swamps this effect and insures stability.

PROTECTION DIODES

When external capacitors are used with any I.C. regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the LM117 with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values ($C_o > 25 \mu F$, $C_{ADJ} > 10 \mu F$). Diode D_1 prevents C_o from discharging thru the I.C. during an input short circuit. Diode D_2 protects against capacitor C_{ADJ} discharging through the I.C. during an output short circuit. The combination of diodes D_1 and D_2 prevents C_{ADJ} from discharging through the I.C. during an input short circuit.

Advance Information

3-TERMINAL ADJUSTABLE OUTPUT POSITIVE VOLTAGE REGULATOR

The LM117L/217L/317L are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 100 mA over an output voltage range of 1.2 V to 37 V. These voltage regulators are exceptionally easy to use and require only two external resistors to set the output voltage. Further, they employ internal current limiting, thermal shutdown and safe area compensation, making them essentially blow-out proof.

The LM117L series serves a wide variety of applications including local, on card regulation. This device also makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM117L series can be used as a precision current regulator.

- Output Current in Excess of 100 mA
- Output Adjustable Between 1.2 V and 37 V
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Floating Operation for High Voltage Applications
- Standard 3-Lead Transistor Packages
- Eliminates Stocking Many Fixed Voltages

STANDARD APPLICATION

* - C_{in} is required if regulator is located an appreciable distance from power supply filter.

** - C_o is not needed for stability, however it does improve transient response.

$$V_{out} = 1.25 \text{ V} \left(1 + \frac{R_2}{R_1} \right) + I_{Adj} R_2$$

Since I_{Adj} is controlled to less than 100 μA , the error associated with this term is negligible in most applications

APPLICATIONS INFORMATION

BASIC CIRCUIT OPERATION

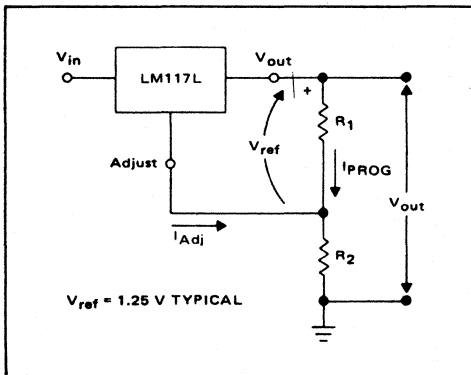

The LM117L is a 3-terminal floating regulator. In operation, the LM117L develops and maintains a nominal 1.25 volt reference (V_{ref}) between its output and adjustment terminals. This reference voltage is converted to a programming current (I_{PROG}) by R_1 (see Figure 13), and this constant current flows through R_2 to ground. The regulated output voltage is given by:

$$V_{out} = V_{ref} \left(1 + \frac{R_2}{R_1} \right) + I_{Adj} R_2$$

Since the current from the adjustment terminal (I_{Adj}) represents an error term in the equation, the LM117L was designed to control I_{Adj} to less than 100 μA and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM117L is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

FIGURE 13 – BASIC CIRCUIT CONFIGURATION

LOAD REGULATION

The LM117L is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor (R_1) should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of R_2 can be returned near the load ground to provide remote ground sensing and improve load regulation.

EXTERNAL CAPACITORS

A 0.1 μF disc or 1 μF tantalum input bypass capacitor (C_{in}) is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor (C_{ADJ}) prevents ripple from being amplified as the output voltage is increased. A 10 μF capacitor should improve ripple rejection about 15dB at 120 Hz in a 10 volt application.

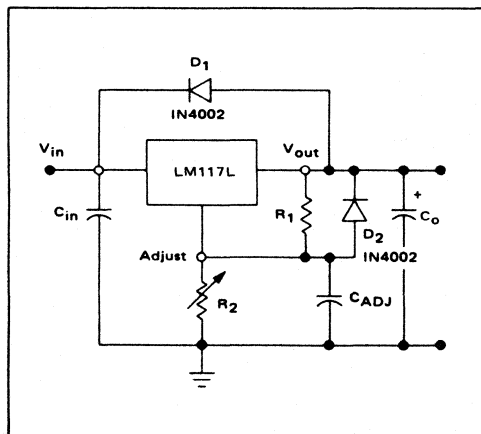

Although the LM117L is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance (C_o) in the form of a 1 μF tantalum or 25 μF aluminum electrolytic capacitor on the output swamps this effect and insures stability.

PROTECTION DIODES

When external capacitors are used with any I.C. regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 14 shows the LM117L with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values ($C_o > 10 \mu F$, $C_{ADJ} > 5 \mu F$). Diode D_1 prevents C_o from discharging thru the I.C. during an input short circuit. Diode D_2 protects against capacitor C_{ADJ} discharging through the I.C. during an output short circuit. The combination of diodes D_1 and D_2 prevents C_{ADJ} from discharging through the I.C. during an input short circuit.

3-TERMINAL POSITIVE VOLTAGE REGULATORS

The LM140/340 series of three-terminal positive voltage regulators are monolithic integrated circuits designed for a wide variety of applications including local on-board regulation. Available in seven fixed output voltage options from 5.0 to 24 volts, these regulators employ internal current limiting, thermal shut-down, and safe area compensation — making them virtually blow-out proof. The LM140/340 series is guaranteed to have line and load regulation that is a factor of two better than the 7800 series. Although the LM140/340 series was designed primarily as a fixed regulator, it can be used with external components to obtain adjustable voltages.

- Output Currents in Excess of 1.0 A
- Internal Thermal Overload Protection
- Internal Short Circuit Limiting
- Output Transistor Safe-Area Compensation
- No External Components Required
- Available in Both Commercial and Military Temperature Ranges

METAL PACKAGE
CASE 1
(TO-3 TYPE)

(bottom view)

Pins 1 and 2 electrically isolated from case. Case is third electrical connection.

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

* = C_{in} (solid tantalum) is required, if regulator is located an appreciable distance from power supply filter.

** = C_o is not needed for stability; however, it does improve transient response. If needed, its value should be greater than 0.1 μ F.

LOW-VOLTAGE REFERENCE

A precision band-gap voltage reference designed for critical instrumentation and D/A converter applications. This unit is designed to work with Motorola MC1506, MC1508, and MC3510 D/A converters, and MC14433 A/D systems. Low temperature drift is a prime design consideration.

- Output Voltage = 2.5 V \pm 25 mV
- Input Voltage Range = 4.5 V to 40 V
- Quiescent Current = 1.2 mA typ
- Output Current = 10 mA
- Temperature Coefficient = 10 ppm/ $^{\circ}$ C typ
- Guaranteed Temperature Drift Specification
- Equivalent to AD580
- Standard 8-Pin DIP Package

Typical Applications

- Voltage Reference for 8-12 Bit D/A Converters
- Low T_C Zener Replacement
- High Stability Current Reference
- Voltmeter System Reference

PROVIDING THE REFERENCE CURRENT FOR MOTOROLA MONOLITHIC D/A CONVERTERS

The MC1403/1503 makes an ideal reference for the Motorola monolithic D/A converters. The MC1406/1506, MC1408/1508, MC3410/3510 and MC3408 D/A converters all require a stable current reference of nominally 2.0 mA. This can be easily obtained from the MC1403/1503 with the addition of a series resistor, R1. A variable resistor, R2, is

recommended to provide means for full-scale adjust on the D/A converter.

The resistor R3 improves temperature performance by matching the impedance on both inputs of the D/A reference amplifier. The capacitor decouples any noise present on the reference line. It is essential if the D/A converter is located any appreciable distance from the reference.

A single MC1403/1503 reference can provide the required current input for up to five of the monolithic D/A converters.

3-1/2-DIGIT VOLTMETER – COMMON ANODE DISPLAYS, FLASHING OVERRANGE

An example of a 3-1/2-digit voltmeter using the MC14433 is shown in the circuit diagram of Figure 8. The reference voltage for the system uses an MC1403 2.5 V reference IC. The full scale potentiometer can calibrate for a full scale of 199.9 mV or 1.999 V. When switching from 2 V to 200 mV operation, R_1 is also changed, as shown on the diagram.

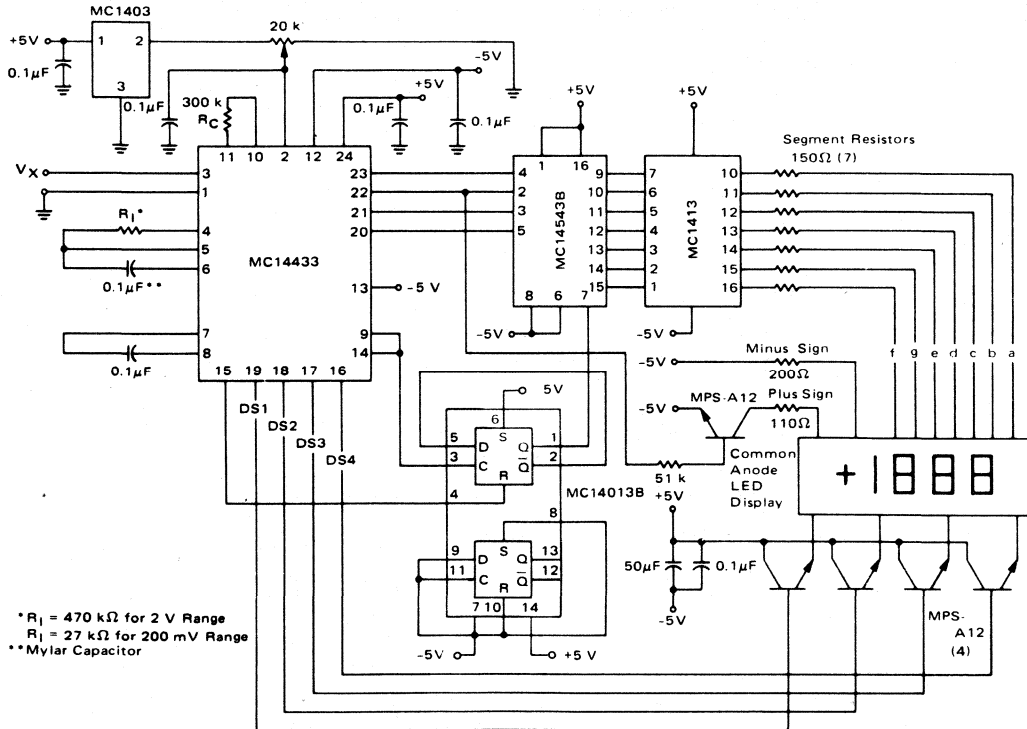

When using R_C equal to 300 k Ω , the clock frequency for the system is about 66 kHz. The resulting conversion time is approximately 250 ms.

When the input is overrange, the display flashes on and off. The flashing rate is one-half the conversion rate.

This is done by dividing the EOC pulse rate by 2 with 1/2 MC14013B flip-flop and blanking the display using the blanking input of the MC14543B.

The display uses an LED display with common anode digit lines driven with an MC14543B decoder and an MC1413 LED driver. The MC1413 contains 7 Darlington transistor drivers and resistors to drive the segments of the display. The digit drive is provided by four MPS-A12 Darlington transistors operating in an emitter-follower configuration. The MC14543B, MC14013B and LED displays are referenced to V_{EE} via pin 13 of the MC14433. This places the full power supply voltage across the display. The current for the display may be adjusted by the value of the segment resistors shown as 150 ohms in Figure 8.

Advance Information

LOW-VOLTAGE REFERENCE FAMILY

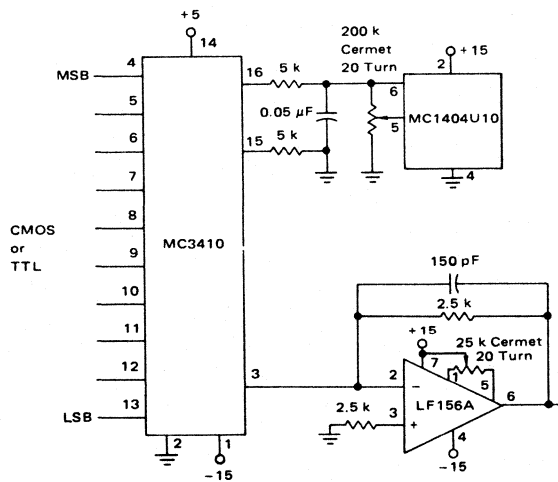

The MC1404 series of ICs is a family of temperature-compensated voltage references for precision data conversion applications, such as A/D, D/A, V/F, and F/V. Advances in laser-trimming and ion-implanted devices, as well as monolithic fabrication techniques, make these devices stable and accurate to 12 bits over both military and commercial temperature ranges. In addition to excellent temperature stability, these parts offer excellent long-term stability and low noise.

- Output Voltages: Standard, 5.0 V, 6.25 V, 10 V
- Trimmable Output: $> \pm 6\%$
- Wide Input Voltage Range: $V_{REF} + 2.5 V$ to 40 V
- Low Quiescent Current: 1.25 mA Typical
- Temperature Coefficient: 10 ppm/ $^{\circ}C$ Typical
- Low Output Noise: 12 μV p-p Typical
- Excellent Ripple Rejection: > 80 dB Typical

TYPICAL APPLICATIONS

- Voltage Reference for 8 – 12 Bit D/A Converters
- Low T_C Zener Replacement
- High Stability Current Reference
- MPU D/A and A/D Applications

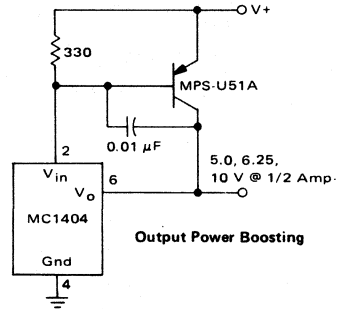

FIGURE 10 — OUTPUT TRIM CONFIGURATION

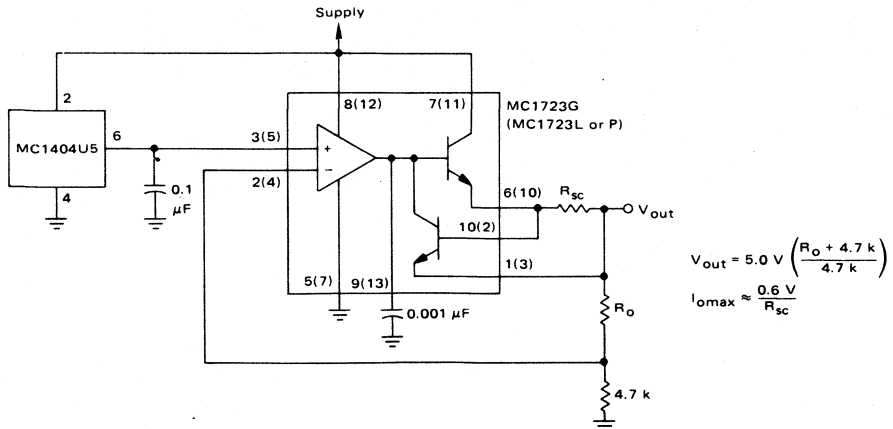

The MC1404 trim terminal can be used to adjust the output voltage over a ±6% range. For example, the output can be set to 10.000 V or to 10.240 V for binary applications. For trimming, Bourns type 3059, 100 kΩ or 200 kΩ trimpot is recommended.

FIGURE 11 — PRECISION SUPPLY USING MC1404

The addition of a power transistor, a resistor, and a capacitor converts the MC1404 into a precision supply with one ampere capability. At V₊ = 15 V, the MC1404 can carry in excess of 14 mA of load current with good regulation. If the power transistor current gain exceeds 75, a one ampere supply can be realized.

Specifications and Applications Information

NEGATIVE VOLTAGE REGULATOR

The MC1563/MC1463 is a "three terminal" negative regulator designed to deliver continuous load current up to 500 mA and provide a maximum negative input voltage of -40 Vdc. Output current capability can be increased to greater than 10 Adc through use of one or more external transistors.

Specifications and performance of the MC1563/MC1463 Negative Voltage Regulator are nearly identical to the MC1569/MC1469 Positive Voltage Regulator. For systems requiring both a positive and negative power supply, these devices are excellent for use as complementary regulators and offer the advantage of operating with a common input ground.

The MC1563R/MC1463R case can be mounted directly to a grounded heat sink which eliminates the need for an insulator.

- Case is at Ground Potential (R package)
- Electronic "Shutdown" and Short-Circuit Protection
- Low Output Impedance - 20 Milliohms typical
- High Power Capability - 9.0 Watts
- Excellent Temperature Stability - $\Delta V_O/\Delta T = \pm 0.002\%/^{\circ}\text{C}$ typical
- High Ripple Rejection - 0.002% typical
- 500 mA Current Capability

MC1463, MC1563

Note 1. "Minimum Input Voltage" is the minimum "total instantaneous input voltage" required to properly bias the internal zener reference diode.

Note 2. This parameter states that the MC1563/MC1463 will regulate properly with the input-output voltage differential $|V_I - V_O|$ as low as 2.7 Vdc and 3.0 Vdc respectively. Typical units will regulate properly with $|V_I - V_O|$ as low as 1.5 Vdc as shown in the typical column.

Note 3. "Temperature Coefficient of Output Voltage" is defined as:

$$\Delta V_O / \Delta T = \frac{\pm (V_O \text{ max} - V_O \text{ min}) (100)}{\Delta T_A (V_O @ T_A = +25^\circ\text{C})}$$

where $\Delta T_A = +180^\circ\text{C}$ for the MC1563
 $+75^\circ\text{C}$ for the MC1463

The output-voltage adjusting resistors (R_A and R_B) must have matched temperature characteristics in order to maintain a constant ratio independent of temperature.

Note 4. Input regulation is the percentage change in output voltage per volt change in the input voltage and is expressed as

$$\text{Input Regulation} = \frac{V_O}{V_O (V_I)} 100 \text{ (\%}/V_O\text{)}$$

where v_o is the change in the output voltage V_O for the input change v_{in} .

The following example illustrates how to compute maximum output voltage change for the conditions given:

$$\begin{aligned} \text{Reg}_{in} &= 0.015\%/V_O \\ V_O &= 10 \text{ Vdc} \\ v_{in} &= 1.0 \text{ V(rms)} \\ V_O &= \frac{(\text{Reg}_{in})(V_I)(V_O)}{100} \\ &= \frac{(0.015)(1.0)(10)}{100} \\ &= 0.0015 \text{ V(rms)} \end{aligned}$$

Note 5. Temperature drift effect must be taken into account separately for conditions of high junction temperature changes due to the thermal feedback that exists on the monolithic chip.

$$\text{Load Regulation} = \frac{V_O|_{I_L = 1.0 \text{ mA}} - V_O|_{I_L = 50 \text{ mA}}}{V_O|_{I_L = 1.0 \text{ mA}}} \times 100$$

Note 6. Not to exceed maximum package power dissipation.

FIGURE 7 - OUTPUT IMPEDANCE

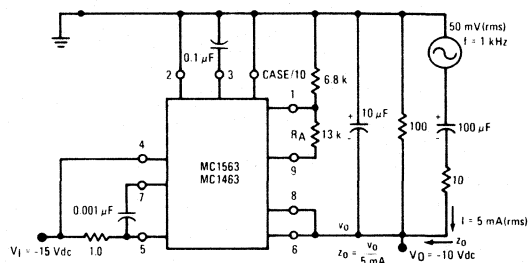

FIGURE 8 - SHUTDOWN CURRENT

MC1463, MC1563

GENERAL DESIGN INFORMATION

1. Output Voltage, V_O

- a) Output Voltage is set by resistors R_A and R_B (see Figure 9). Set $R_B = 6.8 \text{ k ohms}$ and determine R_A from the graph of Figure 11 or from the equation:

$$R_A \approx (2 |V_O| - 7) \text{ k}\Omega$$

- b) Output voltage can be varied by making R_A adjustable as shown in Figures 9 and 10.
- c) Output voltage, V_O , is determined by the ratio of R_A and R_B therefore optimum temperature performance can be achieved if R_A and R_B have the same temperature coefficient.
- d) $V_O = V_{ref} (1 + \frac{R_A}{R_B})$; therefore the tolerance on output voltage is determined by the tolerance of V_{ref} and R_A and R_B .

2. Short-Circuit Current, I_{SC}

Short-Circuit Current, I_{SC} is determined by R_{SC} . R_{SC} may be chosen with the aid of Figure 11 when using the typical circuit connection of Figure 9.

3. Compensation, C_C

A $0.001 \mu\text{F}$ capacitor (C_C , see Figure 9), will provide adequate compensation in most applications, with or without current boost. Smaller values of C_C will reduce stability and larger values of C_C will degrade pulse response and output impedance versus frequency. The physical location of C_C should be close to the MC1563/MC1463 with short lead lengths.

4. Noise Filter Capacitor, C_N

A $0.1 \mu\text{F}$ capacitor, C_N , from Pin 3 to ground will typically reduce the output noise voltage to $120 \mu\text{V(rms)}$. The value of C_N can be increased or decreased, depending on the noise voltage requirements of a particular application. A minimum value of $0.001 \mu\text{F}$ is recommended.

5. Output Capacitor, C_O

The value of C_O should be at least $10 \mu\text{F}$ in order to provide good stability.

6. Shutdown Control

One method of turning "OFF" the regulator is to draw 1 mA from Pin 2 (See Figure 8). This control can be used to eliminate power consumption by circuit loads which can be put in "standby" mode. Examples include, an ac or dc "squelch" control for communications circuits, and a dissipation control to protect the regulator under sustained output short-circuiting. As the magnitude of the input-threshold voltage at Pin 2 depends directly upon the junction temperature of the integrated circuit chip, a fixed dc voltage at Pin 2 will cause automatic shutdown for high junction temperatures. This will protect the chip, independent of the heat sinking used, the ambient temperature, or the input or output voltage levels. Standard Logic levels of MRTL, MDTL* or MTTL* can also be used to turn the regulator "ON" or "OFF".

7. Remote Sensing

The connection to Pin 8 can be made with a separate lead direct to the load. Thus, "remote sensing" can be achieved and the effect of undesired impedances (including that of the milliammeter used to measure I_L) on z_O can be greatly reduced.

Voltage Boosting	12		

THEORY OF OPERATION

The usual series voltage regulator shown in Figure 23, consists of a reference voltage, an error amplifier, and a series control element. The error amplifier compares the output voltage with the reference voltage and adjusts the output accordingly until the error is essentially zero. For applications requiring output voltages larger than the reference, there are two options. The first is to use a resistive divider across the output and compare only a fraction of the output voltage to the reference. This approach suffers from reduced feedback to the error amplifier due to the attenuation of the resistive divider. This degrades load regulation especially at high voltage levels.

The alternative is to eliminate the resistive divider and to shift the reference voltage instead. To accomplish this, another amplifier is employed to amplify (or level shift) the reference voltage using an operational amplifier as shown in Figure 24. The gain-determining resistors may be external, enabling a wide range of output voltages. This

is exactly the same approach used in the first option. That is, the output is being resistively divided to match the reference voltage. There is however, one big difference in that the output of this "regulator" is driving the input of another regulator (the error amplifier). The output of the reference amplifier has a relatively low impedance as compared to the input impedance of the error amplifier. Changes in the load of the output of the error amplifier are buffered to the extent that they have virtually no effect on the reference amplifier. If the feedback resistors are external (as they are on the MC1563) a wide range of reference voltages can be established.

The error amplifier can now be operated at unity gain to provide excellent regulation. In fact, this "regulator-within-a-regulator" concept permits the load regulation to be specified in terms of output impedance rather than as some percentage change of the output voltage. This approach was used in the design of the MC1563 negative voltage regulator.

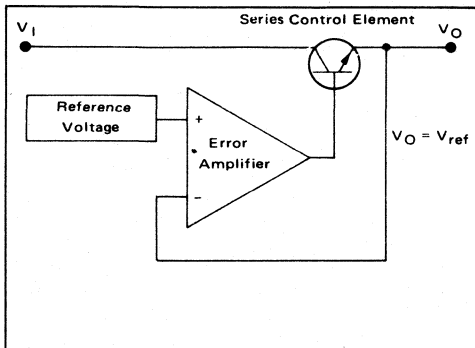

FIGURE 23 - Series Voltage Regulator

Circuit diagrams utilizing Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information has been carefully checked and is

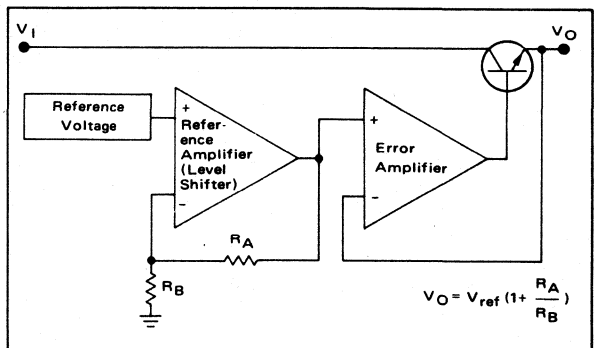

FIGURE 24 - The "Regulator-Within-A-Regulator" Approach

believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

MC1463, MC1563

The shutdown control, in effect, consists of a PNP transistor across the reference zener diode. When this transistor is turned "ON", via Pin 2, the reference voltage is reduced to essentially zero volts and the regulator is forced to shut-down. During shutdown the current drain of the complete IC regulator drops to $V_{in}/60\text{ k}\Omega$ or $500\text{ }\mu\text{A}$ for a -30 V input.

Bias

A zener diode is the main reference element and forms the heart of the bias circuitry. Its positive temperature coefficient is balanced by the negative temperature coefficients of forward biased diodes in a ratio determined by the resistors in the diode string. The result is a reference voltage of approximately -3.5 Vdc with a typical temperature coefficient of $0.002\%/^{\circ}\text{C}$. In addition, this circuit also provides a reference current which is used to bias all current sources in the remaining regulator circuitry.

DC Level Shift

The reference voltage is used as the input to a Darlington differential amplifier. The gain of this amplifier is quite high and it therefore may be considered to function as a conventional operational amplifier. Consequently, negative feedback can be employed using two external resistors (R_A and R_B) to set the closed-loop gain and to boost the reference voltage to the desired output voltage. A capacitor, C_n , is introduced externally into the level shift network (via Pin 3) to stabilize the amplifier and to filter the zener noise. The recommended value for this capacitor is $0.1\text{ }\mu\text{F}$ and should have a voltage rating in excess of the desired output voltage. Smaller capacitors ($0.001\text{ }\mu\text{F}$ minimum) may be used but will cause a slight increase in output noise. Larger values of C_n will reduce the noise as well as delay the start-up of the regulator.

Output Regulator

The output of the shift amplifier is fed internally to the noninverting input of the output error amplifier. The

inverting input to this amplifier is the Output Sense connection (Pin 8) of the regulator. A Darlington connected NPN power transistor is used to handle the load current. The short-circuit current limiting resistor, R_{SC} , is connected in the emitter of this transistor to sample the full load current. This connection enables a four-diode string to limit the drive current to the power transistors in a conventional manner.

Stability and Compensation

As has been seen, the MC1563 employs two amplifiers, each using negative feedback. This implies the possibility of frequency instability due to excessive phase shift at high frequencies. Since the error amplifier is normally used at unity gain (the worst case for stability) a high impedance node is brought out for compensation. For normal operation, a capacitor is connected between this point (Pin 7) and Pin 5. The recommended value of $0.001\text{ }\mu\text{F}$ will insure stability and still provide acceptable transient response (see Figure 21). It is also necessary to use an output capacitor, C_O , (typically $10\text{ }\mu\text{F}$) directly from the output (Pin 6) to ground. When an external transistor is used to boost the current, $C_O = 100\text{ }\mu\text{F}$ is recommended (see Figure 26).

NPN CURRENT BOOSTING

For applications requiring more than 500 mA of load current, or for minimizing voltage variations due to temperature changes in the IC regulator arising from changes of the internal power dissipation, the NPN current-boost circuits of Figure 2 or 26, are recommended. The circuit shown in Figure 26 can supply up to approximately 4.0 amperes (subject to safe area limitations). At higher currents the V_{BE} of the pass transistor may itself exceed the threshold of the current limit even for $R_{SC} = 0$. Figure 2 illustrates the use of an additional external diode from Pin 4 for higher current operation or for pass transistors exhibiting higher V_{BE} 's. It will probably be necessary to determine R_{SC} experimentally for each case where a pass transistor is used because V_{BE} varies from device to device.

The circuit of Figure 26 when set up for a -10 V output

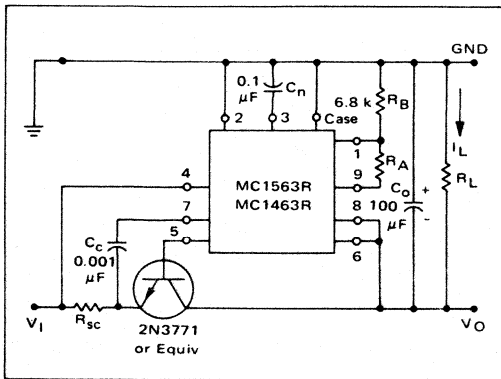

FIGURE 26 - Typical NPN Current Boost Connection

FIGURE 27 - I_{SC} versus R_{SC} (reference Figure 26)

MC1463, MC1563

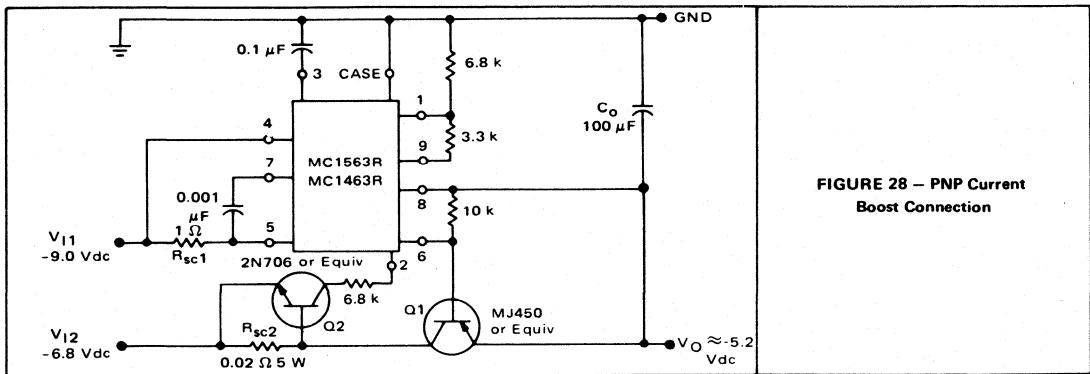

FIGURE 28 – PNP Current Boost Connection

($R_A = 13 \text{ k}\Omega$) supply and operating with a -15 V input, with a R_{SC} of 0.1Ω , will yield a change in output voltage of only 26 mV over a load current range of from 1 mA to 3.5 A . This corresponds to a dc output impedance of only 7.5 milliohms or a percentage load regulation of 0.26% for a full 3.5-ampere load current change. Figure 27 indicates how the short circuit current varies with the value of R_{SC} for this circuit.

PNP CURRENT BOOSTING

A PNP power transistor can also be used to boost the load current capabilities. To improve the efficiency of the PNP boost configuration, particularly for small output voltages, the circuit of Figure 28, is recommended. An auxiliary -9 volt supply is used to power the IC regulator and the heavy load current is obtained from a second supply of lower voltage. For the 10-ampere regulator of Figure

28 this represents a savings of 22 watts when compared with operating the regulator from the single -9 V supply. It can supply current to 10 amperes while requiring an input voltage to the collector of the pass transistor of -6.8 volts minimum. The pass transistor is limited to 10 amperes by the added short-circuit current network in its emitter (R_{SC2}) and the IC regulator is limited to 500 mA in the conventional manner (R_{SC1}). The MJ450 exhibits a minimum h_{FE} of 20 at 10 amperes , thus requiring only 500 mA from the MC1563R. Regulation of this circuit is comparable to that of the NPN boost configuration.

For higher output voltages the additional unregulated power supply is not required. The collector of the PNP boost transistor can tie directly to Pin 5 and the internal current limit circuit will provide short-circuit protection using R_{SC} (see Figure 11). Transistor Q2 and R_{SC2} will not be required and Pin 2 should be returned to ground.

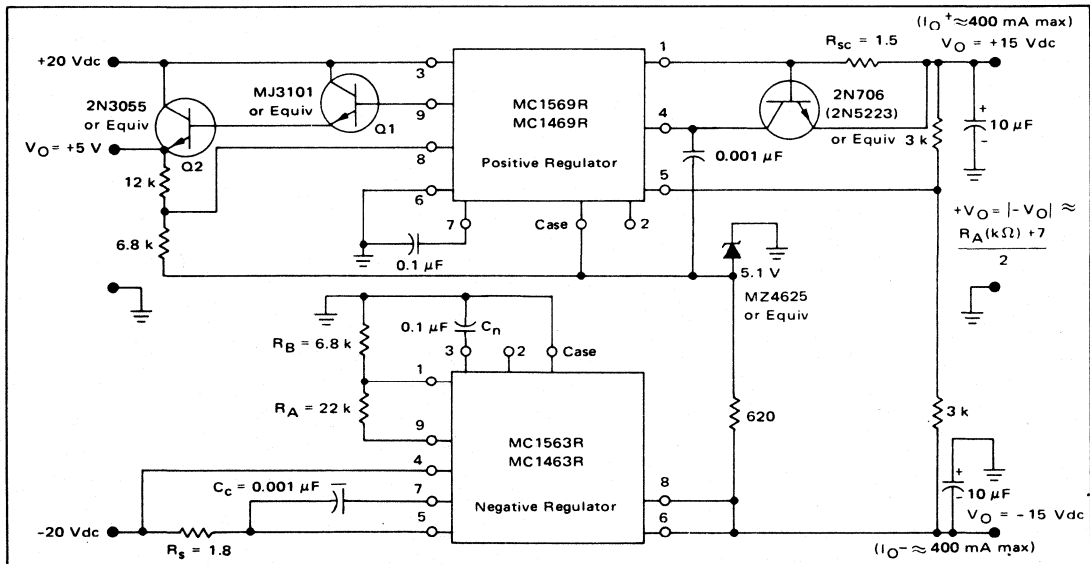

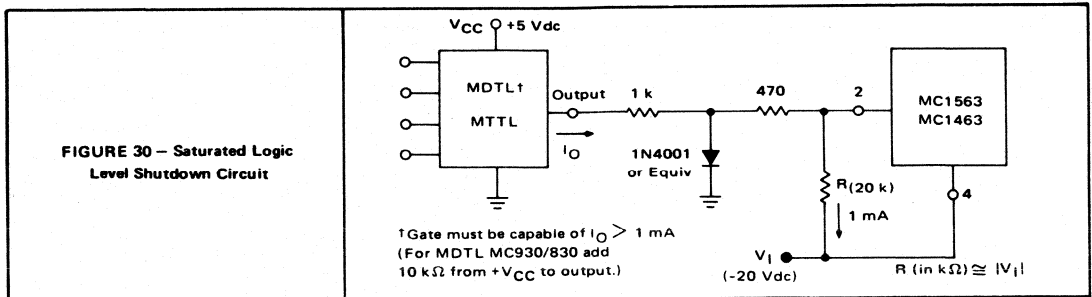

FIGURE 29 – A $\pm 15 \text{ Vdc}$ Complementary Tracking Regulator With Auxiliary $+5.0 \text{ V}$ Supply

POSITIVE AND NEGATIVE POWER SUPPLIES

If the MC1563 is driven from a floating source it is possible to use it as a positive regulator by grounding the negative output terminal. The MC1563 may also be used with the MC1569 to provide completely independent positive and negative power regulators with comparable performance. When used in this manner a silicon diode such as the 1N4001 must be connected as a clamp on the output with the cathode to ground and the anode to the negative output voltage. This is to prevent the positive voltage in the system from forcing the output to a positive value and preventing the MC1563 from starting up.

Some applications may require complementary tracking in which both supplies arrive at the voltage level simultaneously, and variations in the magnitudes of the two voltages track. Figures 3 and 29 illustrate this approach. In this application, the MC1563 is used as the reference regulator, establishing the negative output voltage. The MC1569 positive regulator is used in a tracking mode by grounding one side of the differential amplifier (Pin 6 of the MC1569) and using the other side (Pin 5 of the MC1569) to sense the voltage developed at the junction of the two 3 k-ohm resistors. This differential amplifier controls the MC1569 series pass transistor such that the voltage at Pin 5 will be zero. When the voltage at pin 5 equals zero, $+|V_O|$ must equal $-|V_O|$.

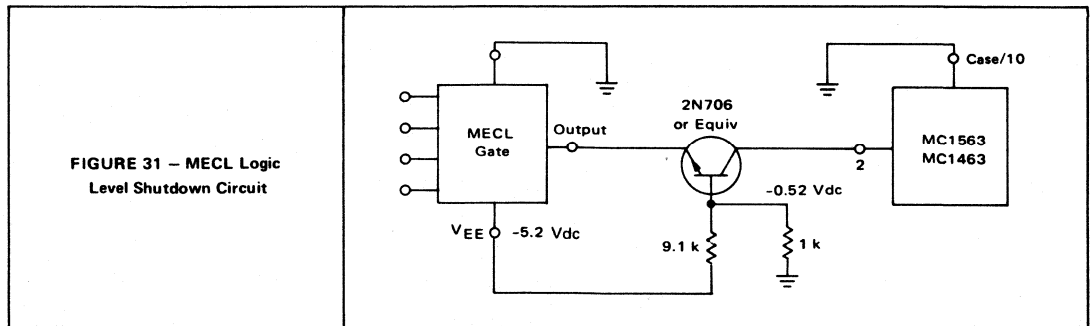

For the configuration shown in Figure 29, the level shift amplifier in the MC1569 is employed to generate an auxiliary +5-volt supply which is boosted to a 2-ampere capability by Q1 and Q2. (The +5-volt supply, as shown,

is not short-circuit protected.) The -15-volt supply varies less than 0.1 mV over a zero to -300 mAdc current range and the +15-volt supply tracks this variation. The +15-volt supply varies 20 mV over the zero to +300-mAdc load current range. The +5-volt supply varies less than 5 mV for $0 \leq I_L \leq 200 \text{ mA}$ with the other two voltages remaining unchanged. See MC1561 data sheet or MC1569 data sheet for information concerning latch-up when using plus and minus regulations.

SHUTDOWN TECHNIQUES

Pin 2 of the MC1563 is provided for the express purpose of shutting the regulator "OFF". Referring to the schematic, it can be seen that pin 2 goes to the base of a PNP transistor; which, if turned "ON", will deny current to all the biasing current sources. This action causes the output to go to essentially zero volts and the only current drawn by the IC regulator will be the small start current through the 60 k-ohm start resistor ($V_{in}/60 \text{ k}\Omega$). This feature provides additional versatility in the applications of the MC1563. Various sub-systems may be placed in a "standby" mode to conserve power until actually needed. Or the power may be turned "OFF" in response to other occurrences such as over-heating, over-voltage, shorted output, etc.

As an illustration of the first case, consider a system consisting of both positive-supply logic (MTTL) and negative-supply logic (MECL). The MECL logic may be used in a high-speed arithmetic processor whose services are not continuously required. Substantial power may

MC1463, MC1563

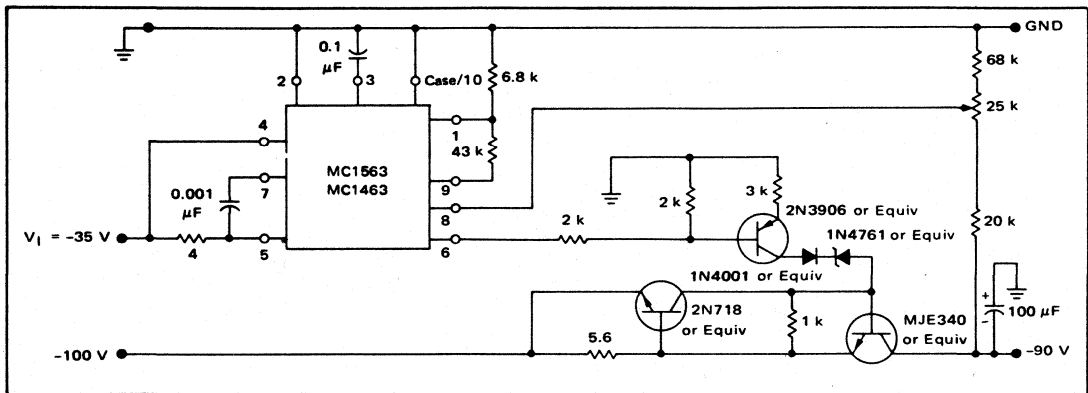

FIGURE 32 – Voltage Boosting Circuit

thus be conserved if the MECL circuitry remains unpowered except when needed. The negative regulator can be shutdown using any of the standard logic swings. For saturated logic control, Figure 30 shows a circuit that allows the normal positive output swing to cause the regulator to shutdown when the logic output is in the low voltage state. The negative output levels of a MECL gate can also be used for shutdown control as shown in Figure 31.

VOLTAGE BOOSTING

Some applications may require a high output voltage which may exceed the voltage rating of the MC1563. This must be solved by assuring that the IC regulator is operated within its limits. Three points in the regulator need to be considered:

1. The input voltage (Pin 4),
2. the output voltage (Pin 6) and,
3. the output sense lead (Pin 8).

A reduced input voltage can be provided by using a separate supply. The output voltage may be zener-level shifted, and the sense line can tie to a portion of the output voltage through a resistive divider. The voltage boost circuit of Figure 32 uses this approach to provide a -90 volt supply. This circuit will exhibit regulation of 0.001% over a 100 mA load current range.

REMOTE SENSING

The MC1563 offers a remote sensing capability. This is important when the load is remote from the regulator, as the resistances of the interconnecting lines (V_{EE} and GND) are added directly to the output impedance of the regulator. By remote sensing, this resistance is included inside the control loop of the regulator and is essentially eliminated. Figure 33 shows how remote sensing is accomplished using both a separate sense line from Pin 8 and a separate ground line from the regulator to the remote load.

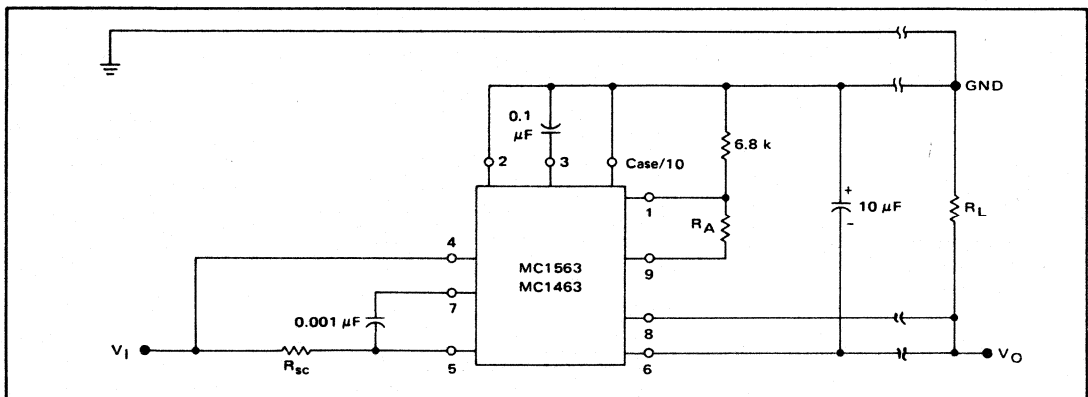

FIGURE 33 – Remote Sensing Circuit

MC1463, MC1563

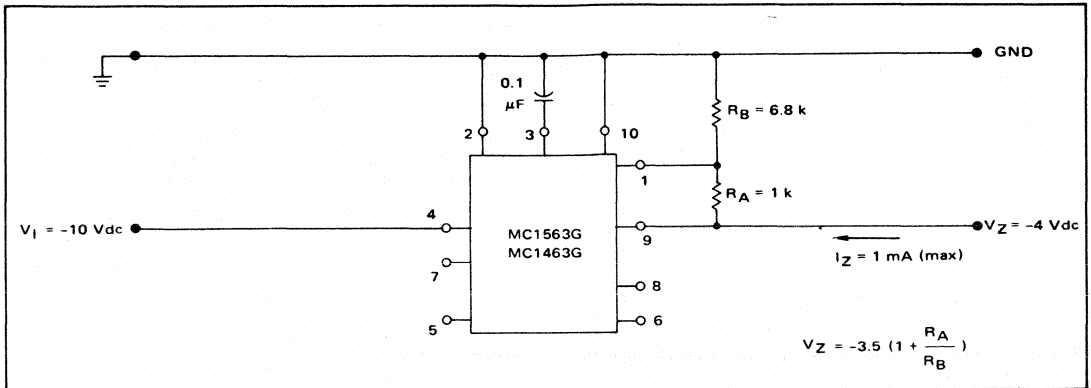

FIGURE 34 – An Adjustable “Zero-TC” Voltage Source

AN ADJUSTABLE ZERO-TEMPERATURE-COEFFICIENT (0-TC) VOLTAGE REFERENCE SOURCE

The MC1563, when used in conjunction with low-TC resistors, makes an excellent reference-voltage generator. If the -3.5 volt reference voltage of the IC regulator is a satisfactory value, then Pins 1 and 9 can be tied together and no resistors are needed. This will provide a voltage reference having a typical temperature coefficient of 0.002%/°C. By adding two resistors, R_A and R_B , any voltage between -3.5 Vdc and -37 Vdc can be obtained with the same low TC (see Figure 34)

THERMAL SHUTDOWN

By setting a fixed voltage at Pin 2, the MC1563 chip can be protected against excessive junction temperatures caused by power dissipation in the IC regulator. This is based on the negative temperature coefficient of the base-emitter junction of the shutdown transistor (-1.9 x

$10^{-3}V/°C$). By setting -0.61 Vdc externally, at Pin 2, the regulator will shutdown when the chip temperature reaches approximately 140°C. Figure 35 shows a circuit that uses a zero-TC zener diode and a resistive divider to obtain this voltage.

In the case where an external pass transistor is employed; its temperature, rather than that of the IC regulator, requires control. A technique similar to the one just discussed can be used by directly monitoring the case temperature of the pass transistor as is indicated in Figure 36. The case of the normally “OFF” thermal monitoring transistor, Q2, should be in thermal contact with, but electrically isolated from, the case of the boost transistor, Q1.

THERMAL CONSIDERATIONS

Monolithic voltage regulators are subjected to internal heating similar to a power transistor. Since the degree of internal heating is a function of the specific application,

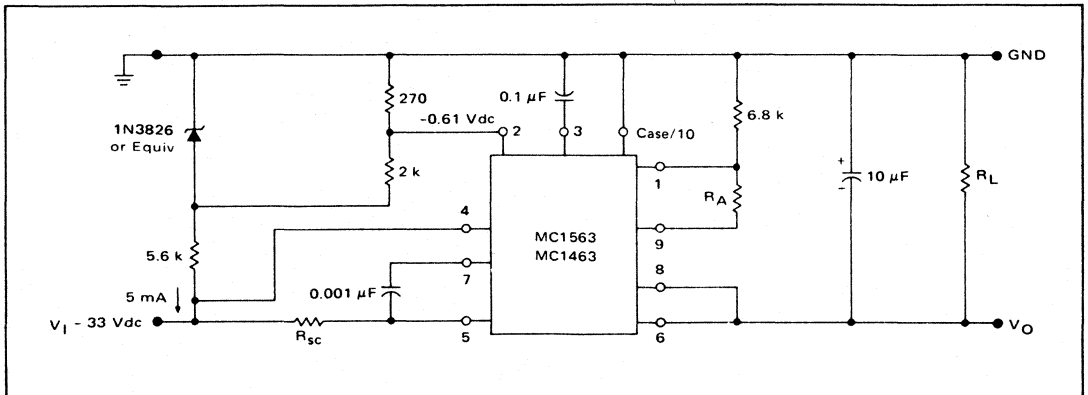

FIGURE 35 – Junction Temperature Limiting Shutdown Circuit

MC1463, MC1563

the designer must use caution not to exceed the specified maximum junction temperature (+175°C). Exceeding this limit will reduce reliability at an exponential rate. Good heatsinking not only reduces the junction temperature for a given power dissipation; it also tends to improve the dc stability of the output voltage by reducing the junction temperature change resulting from a change in the power dissipation of the IC regulator. By using the derating factors or thermal resistance values given in the Maximum Ratings Table of this data sheet, junction temperature can be computed for any given application in the same manner as for a power transistor. A short-circuit on the output terminal can produce a "worst-case" thermal condition especially if the maximum input voltage is applied simultaneously with the maximum value of short-circuit load current (500 mA). Care should be taken not to exceed the maximum junction temperature rating during this fault condition and, in addition, the dc safe operating area limit (see Figure 22).

Thermal characteristics for a voltage regulator are useful in predicting performance since dc load and line regulation are affected by changes in junction temperature. These temperature changes can result from either a change in the ambient temperature, T_A , or a change in the power dissipated in the IC regulator. The effects of ambient

temperature change on the dc output voltage can be estimated from the "Temperature Coefficient of Output Voltage" characteristic parameter shown as $\pm 0.002\%/^{\circ}\text{C}$, typical. Power dissipation is typically changed in the IC regulator by varying the dc load current. To estimate the dc change in output voltage due to a change in the dc load current, three effects must be considered:

1. junction temperature change due to the change in the power dissipation
2. output voltage decrease due to the finite output impedance of the control amplifier
3. thermal gradient on the IC chip.

A temperature differential does exist across a power IC chip and can cause a dc shift in the output voltage. A "gradient coefficient," GCV_O , can be used to describe this effect and is typically $+0.03\%/watt$ for the MC1563R. For an example of the relative magnitudes of these effects, consider the following conditions:

Given: MC1563R
 with $V_I = -10\text{ Vdc}$
 $V_O = -5\text{ Vdc}$
 and $I_L = 100\text{ mA to } 200\text{ mA}$
 ($\Delta I_L = 100\text{ mA}$)
 assume $T_A = +25^{\circ}\text{C}$
 TO-66 Type Case with heatsink

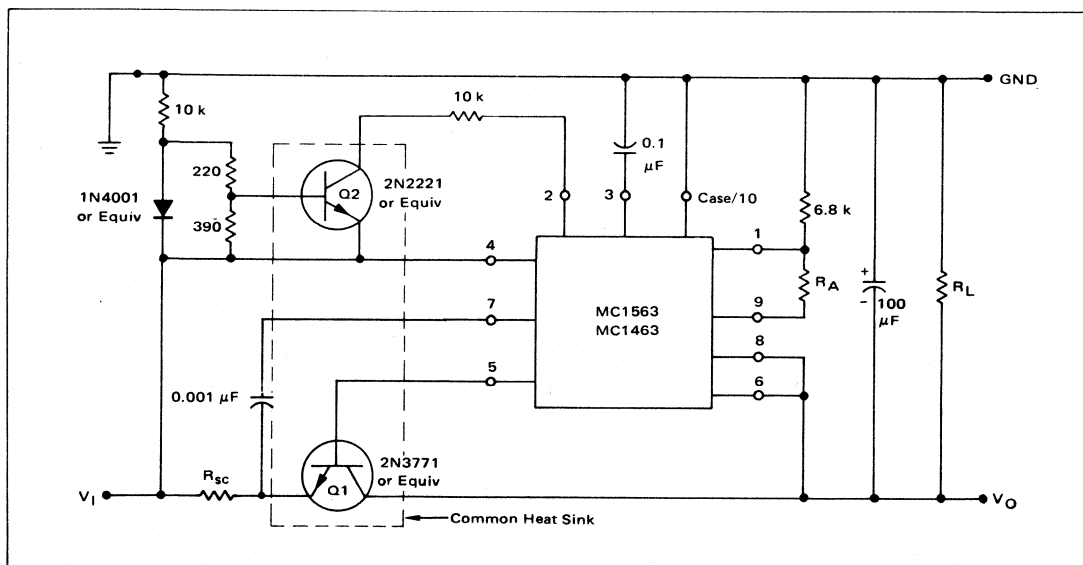

FIGURE 36 – Thermal Shutdown When Using External Pass Transistors

MC1463, MC1563

assume $R_{\theta CS} = 0.2^{\circ}\text{C/W}$

and $R_{\theta SA} = 2^{\circ}\text{C/W}$

It is desired to find the ΔV_O which results from this ΔI_L . Each of the three previously stated effects on V_O can now be separately considered.

1. ΔV_O due to ΔT_J

$$\Delta V_O = (V_O)(\Delta P_D)(\Delta V_O/\Delta T)(R_{\theta JC} + R_{\theta CS} + R_{\theta SA})$$

OR

$$\Delta V_O = (5 \text{ V})(5 \text{ V} \times 0.1 \text{ A})(\pm 0.002\%/^{\circ}\text{C})(19.2^{\circ}\text{C/W})$$

$$\Delta V_O \approx \pm 1.0 \text{ mV}$$

2. ΔV_O due to z_o

$$|\Delta V_O| = (-z_o)(I_L)$$

$$|\Delta V_O| = -(2 \times 10^{-2})(10^{-1}) = -2 \text{ mV}$$

3. ΔV_O due to gradient coefficient, $\Delta V_O/\Delta G$

$$|\Delta V_O| = (\Delta V_O/\Delta G)(V_O)(\Delta P_D)$$

$$|\Delta V_O| = (+3 \times 10^{-4}/\text{W})(5 \text{ volts})(5 \times 10^{-1} \text{ W})$$

$$|\Delta V_O| = +0.8 \text{ mV}$$

Therefore the total ΔV_O is given by

$$|\Delta V_O \text{ total}| = \pm 1.0 - 2.0 + 0.8 \text{ mV}$$

OR

$$-2.2 \text{ mV} \leq |V_O \text{ total}| \leq -0.2 \text{ mV}$$

Other operating conditions may be substituted and computed in a similar manner to evaluate the relative effects of the parameters.

Typical Printed Circuit Board Layout

FIGURE 37 – Location of Components

Note 1:

When R_{adj} is used it is necessary to remove the copper which shorts out R_{adj} .

Note 2:

Extra holes are available in the circuit board to permit two resistors to be paralleled to obtain the desired value of R_{sc} .

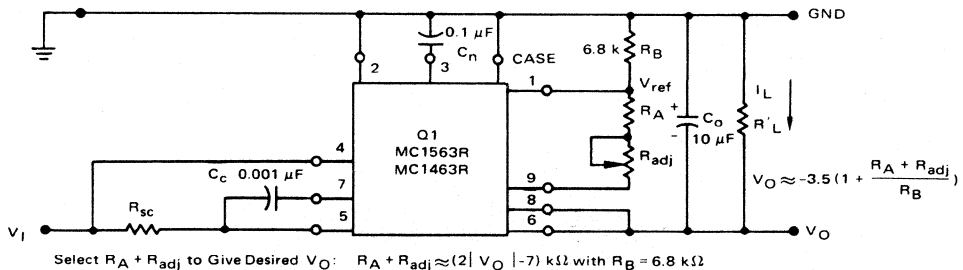

Note 3:

If Pin 2 is used to shut down the regulator, remove the copper which shorts Pin 2 to ground.

Note 4:

Remote sensing can be achieved by removing the copper which shorts Pin 8 to Pin 6 and connecting Pin 8 directly to the "minus" load terminal. The circuit board ground should be connected to the unregulated power supply ground at the "plus" load terminal.

Typical Circuit Connection for Output Voltages Between -3.5 and -37 Volts

Specifications and Applications Information

MONOLITHIC VOLTAGE AND CURRENT REGULATOR

This unique "floating" regulator can deliver hundreds of volts — limited only by the breakdown voltage of the external series pass transistor. Output voltage and output current are adjustable. The MC1466/MC1566 integrated circuit voltage and current regulator is designed to give "laboratory" power-supply performance.

- Voltage/Current Regulation with Automatic Crossover
- Excellent Line Voltage Regulation, 0.01% +1.0 mV
- Excellent Load Voltage Regulation, 0.01% +1.0 mV
- Excellent Current Regulation, 0.1% +1.0 mA
- Short-Circuit Protection
- Output Voltage Adjustable to Zero Volts
- Internal Reference Voltage
- Adjustable Internal Current Source

MC1466L, MC1566L

NOTE 1:

The instantaneous input voltage, V_{aux} , must not exceed the maximum value of 30 volts for the MC1466 or 35 volts for the MC1566. The instantaneous value of V_{aux} must be greater than 20 volts for the MC1566 or 21 volts for the MC1466 for proper internal regulation.

NOTE 2:

The auxiliary supply voltage V_{aux} , must "float" and be electrically isolated from the unregulated high voltage supply, V_{in} .

NOTE 3:

Reference current may be set to any value of current less than 1.2 mA_{dc} by applying the relationship:

$$I_{ref} \text{ (mA)} = \frac{8.55}{R_1 \text{ (k}\Omega\text{)}}$$

NOTE 4:

A built-in offset voltage (15 mVdc nominal) is provided so that the power supply output voltage or current may be adjusted to zero.

NOTE 5:

Load Voltage Regulation is a function of two additive components, ΔV_{ioV} and ΔV_{ref} , where ΔV_{ioV} is the change in input offset voltage (measured between pins 8 and 9) and ΔV_{ref} is the change in voltage across R2 (measured between pin 8 and ground). Each component may be measured separately or the sum may be measured across the load. The measurement procedure for the test circuit shown is:

- With S1 open ($I_L = 0$) measure the value of $V_{ioV} (1)$ and $V_{ref} (1)$
- Close S1, adjust R4 so that $I_L = 500 \mu A$ and note $V_{ioV} (2)$ and $V_{ref} (2)$.

Then $\Delta V_{ioV} = V_{ioV} (1) - V_{ioV} (2)$

% Reference Regulation =

$$\frac{[V_{ref} (1) - V_{ref} (2)]}{V_{ref} (1)} (100\%) = \frac{\Delta V_{ref}}{V_{ref}} (100\%)$$

Load Voltage Regulation =

$$\frac{\Delta V_{ref}}{V_{ref}} (100\%) + \Delta V_{ioV}$$

NOTE 6:

Line Voltage Regulation is a function of the same two additive components as Load Voltage Regulation, ΔV_{ioV} and ΔV_{ref} (see note 5). The measurement procedure is:

- Set the auxiliary voltage, V_{aux} , to 22 volts for the MC1566 or the MC1466. Read the value of $V_{ioV} (1)$ and $V_{ref} (1)$.
- Change the V_{aux} to 28 volts for the MC1566 or the MC1466 and note the value of $V_{ioV} (2)$ and $V_{ref} (2)$. Then compute Line Voltage Regulation:

$$\Delta V_{ioV} = V_{ioV} (1) - V_{ioV} (2)$$

% Reference Regulation =

$$\frac{[V_{ref} (1) - V_{ref} (2)]}{V_{ref} (1)} (100\%) = \frac{\Delta V_{ref}}{V_{ref}} (100\%)$$

Line Voltage Regulation =

$$\frac{\Delta V_{ref}}{V_{ref}} (100\%) + \Delta V_{ioV}$$

NOTE 7:

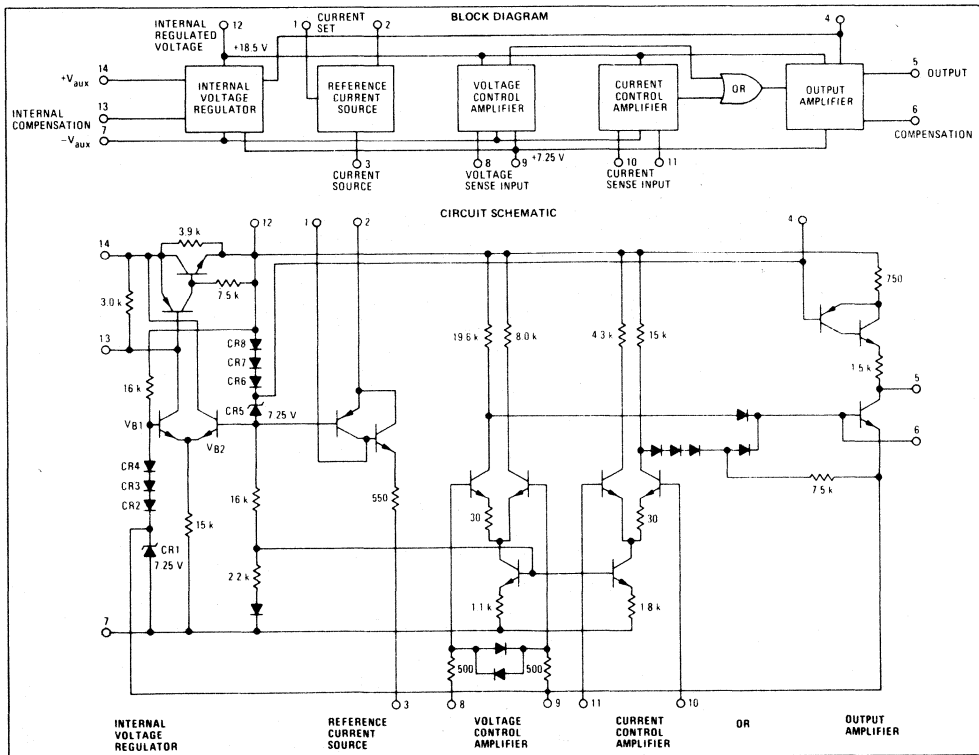

Load Current Regulation is measured by the following procedure:

- With S2 open, adjust R3 for an initial load current, $I_L (1)$, such that V_O is 8.0 Vdc.
- With S2 closed, adjust R_T for $V_O = 1.0$ Vdc and read $I_L (2)$. Then Load Current Regulation =

$$\frac{[I_L (2) - I_L (1)]}{I_L (1)} (100\%) + I_{ref}$$

where I_{ref} is 1.0 mA_{dc}. Load Current Regulation is specified in this manner because I_{ref} passes through the load in a direction opposite that of load current and does not pass through the current sense resistor, R_S .

FIGURE 5

MC1466L, MC1566L

FIGURE 6 – TYPICAL CIRCUIT CONNECTION

NORMAL DESIGN PROCEDURE AND DESIGN CONSIDERATIONS

- Constant Voltage:**
For constant voltage operation, output voltage V_O is given by:
$$V_O = (I_{ref}) (R_2)$$
where R_2 is the resistance from pin 8 to ground and I_{ref} is the output current of pin 3.
The recommended value of I_{ref} is 1.0 mAdc. Resistor R_1 sets the value of I_{ref} :
$$I_{ref} = \frac{8.5}{R_1}$$
where R_1 is the resistance between pins 2 and 12.
- Constant Current:**
For constant current operation:
(a) Select R_S for a 250 mV drop at the maximum desired regulated output current, I_{max} .
(b) Adjust potentiometer R_3 to set constant current output at desired value between zero and I_{max} .
- If V_{in} is greater than 20 Vdc, CR2, CR3, and CR4 are necessary to protect the MC1466/MC1566 during short-circuit or transient conditions.
- In applications where very low output noise is desired, R2 may be bypassed with C1 (0.1 µF to 2.0 µF). When R2 is bypassed, CR1 is necessary for protection during short-circuit conditions.
- CR5 is recommended to protect the MC1466/MC1566 from simultaneous pass transistor failure and output short-circuit.
- The RC network (10 pF, 240 pF, 1.2 k ohms) for compensation. The values shown are valid for all applications. However, the 10 pF capacitor may be omitted if f_T of Q1 and Q2 is greater than 0.5 MHz.
- For remote sense applications, the positive voltage sense terminal (pin 9) is connected to the positive load terminal through a separate sense lead; and the negative sense terminal (the ground side of R2) is connected to the negative load terminal through a separate sense lead.
- C_0 may be selected by using the relationship:
$$C_0 = (100 \mu F) I_{L(max)}$$
where $I_{L(max)}$ is the maximum load current in amperes.
- C2 is necessary for the internal compensation of the MC1466/MC1566.
- For optimum regulation, current out of pin 5, I_5 , should not exceed 0.5 mAdc. Therefore select Q1 and Q2 such that:
$$\frac{I_{max}}{\beta_1 \beta_2} \leq 0.5 \text{ mAdc}$$
where: I_{max} = maximum short-circuit load current (mAdc)
 β_1 = minimum beta of Q1
 β_2 = minimum beta of Q2
Although Pin 5 will source up to 1.5 mAdc, $I_5 > 0.5 \text{ mAdc}$ will result in a degradation in regulation.
- CR6 is recommended when $V_O > 150 \text{ Vdc}$ and should be rated such that Peak Inverse Voltage $> V_O$.
- In applications where R2 might be rapidly reduced in value, it is recommended that CR3 be replaced by Q2 and R4.

This design consideration prevents R2 from being destroyed by excessive discharge current from C_0 . Components Q2 and R4 should be selected such that:

$$R4 = \frac{R2}{10} \text{ and}$$

$$BV_{CEO} \text{ of } Q2 > V_O$$

MC1466L, MC1566L

OPERATION AND APPLICATIONS

This section describes the operation and design of the MC1566/MC1466 voltage and current regulator and also provides information on useful applications.

SUBJECT SEQUENCE

<p>Theory of Operation Applications Transient Failures Voltage/Current-Mode Indicator</p>
--

THEORY OF OPERATION

The schematic of Figure 5 can be simplified by breaking it down into basic functions, beginning with a simplified version of the voltage reference, Figure 7. Zener diodes CR1 and CR5 with their associated forward biased diodes CR2 through CR4 and CR6 through CR8 form the stable reference needed to balance the differential amplifier. At balance ($V_{B1} = V_{B2}$), the output voltage, ($V_{12} - V_7$), is at a value that is twice the drop across either of the two diode strings: $V_{12} - V_7 = 2 (V_{CR1} + V_{CR2} + V_{CR3} + V_{CR4})$. Other voltages, temperature compensated or otherwise, are also derived from these diode strings for use in other parts of the circuit.

The voltage controlled current source (Figure 8) is a PNP-NPN composite which, due to the high NPN beta,

yields a good working PNP from a lateral device working at a collector current of only a few microamperes. Its base voltage (V_{B2}) is derived from a temperature compensated portion of the diode string and consequently the overall current is dependent on the value of emitter resistor R1. Temperature compensation of the base emitter junction of Q3 is not important because approximately 9 volts exists between V_{B2} and V_{12} , making the ΔV_{BE} 's very small in percentage. Circuit reference voltage is derived from the product of I_R and R_R ; if I_R is set at 1 mA ($R_1 = 8.5 \text{ k}\Omega$), then R_R (in $\text{k}\Omega$) = V_O . Other values of current may be used as long as the following restraints are kept in mind: 1) package dissipation will be increased by about 11 mW/mA and 2) bias current for the voltage control amplifier is 3 μA , temperature dependent, and is extracted from the reference current. The reference current should

FIGURE 7 - REFERENCE VOLTAGE REGULATOR

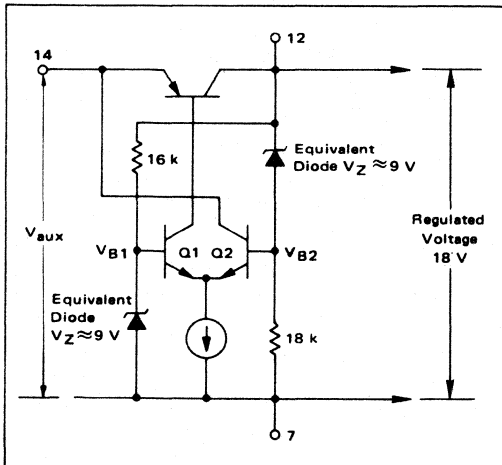

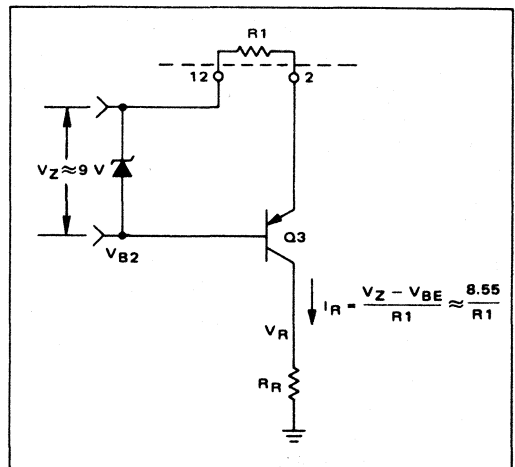

FIGURE 8 - VOLTAGE CONTROLLED CURRENT SOURCE

MC1466L, MC1566L

be at least two orders of magnitude above the largest expected bias current.

Loop amplification in the constant voltage mode is supplied by the voltage controlled amplifier (Figure 9), a standard high-gain differential amplifier. The inputs are diode-protected against differential overvoltages and an emitter degenerating resistor, R_{OS} , has been added to one of the transistors. For an emitter current in both Q5 and Q6 of 1/2 milliampere there will exist a preset offset voltage in this differential amplifier of 15 mV to insure that the output voltage will be zero when the reference voltage is zero. Without R_{OS} , the output voltage could be a few millivolts above zero due to the inherent offset. Since the load resistor is so large in this stage compared with the load (Q9) it will be more instructive to look at the gain on a transconductance basis rather than voltage gain. Transconductance of the differential stage is defined for small signals as:

$$g_m = \frac{1}{2r_e + R_E} \quad (1)$$

where

$$r_e \approx \frac{0.026}{I_E} \text{ and}$$

R_E = added emitter degenerating resistance.

For $I_E = 0.5 \text{ mA}$,

$$g_m = \frac{1}{104 + 30} = \frac{1}{134} = 7.5 \text{ mA/volt.} \quad (2)$$

FIGURE 9 - VOLTAGE CONTROL AMPLIFIER

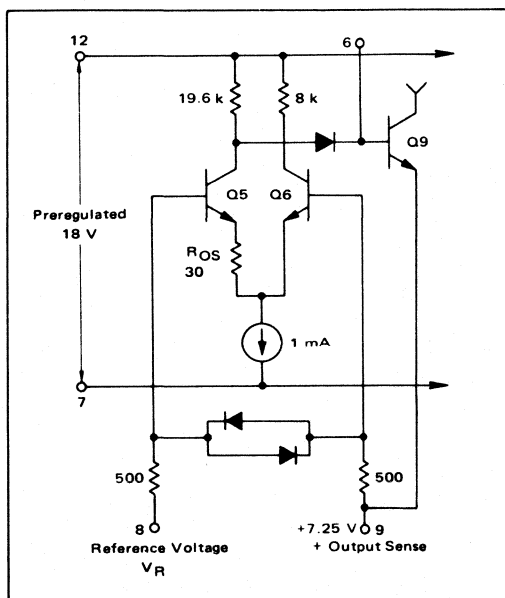

FIGURE 10 - CURRENT CONTROL CIRCUIT

This level is further boosted by the output stage such that in the constant voltage mode overall transconductance is about 300 mA/volt.

A second differential stage nearly identical to the first stage, serves as the current control amplifier (Figure 10). The gain of this stage insures a rapid crossover from the constant voltage to constant current modes and provides a convenient point to control the maximum deliverable load current. In use, a reference voltage derived from the preregulator and a voltage divider is applied to pin 10 while the output current is sampled across R_S by pin 11. When $I_L R_S$ is 15 mV below the reference value, voltage V_1 begins to rapidly rise, eventually gaining complete control of Q9 and limiting output current to a value of V_2/R_S . If V_2 is derived from a variable source, short circuit current may be controlled over the complete output current capability of the regulator. Since the constant-voltage to constant-current change-over requires only a few millivolts the voltage regulation maintains its quality to the current limit and accordingly shows a very sharp "knee" (1% +1 mA, Figure 11). Note that the regulator can switch back into the constant voltage mode if the output voltage reaches a value greater than V_R . Operation through zero milliamperes is guaranteed by the inclusion of another emitter offsetting resistor.

FIGURE 11 - V_1 CURVE FOR 0-TO-40 V, 0.5-AMPERE REGULATOR

MC1466L, MC1566L

Transistor Q9 and five diodes comprise the essential parts of the output stage (Figure 12). The diodes perform an "OR" function which allows only one mode of operation at a time - constant current or constant voltage. However, an additional stage (Q9) must be included to invert the logic and make it compatible with the driving requirements of series pass transistors as well as provide additional gain. A 1.5 mA collector current source sets the maximum deliverable output current and boosts the output impedance to that of the current source.

Note that the negative (substrate) side of the MC1566/MC1466 is 7.25 volts lower than the output voltage, and the reference regulator guarantees that the positive side is 11 volts above the output. Thus the IC remains at a voltage (relative to ground) solely dependent on the output, "floating" above and below V_O . V_{CE} across Q9 is only two or three V_{BE} 's depending on the number of transistors used in the series pass configuration.

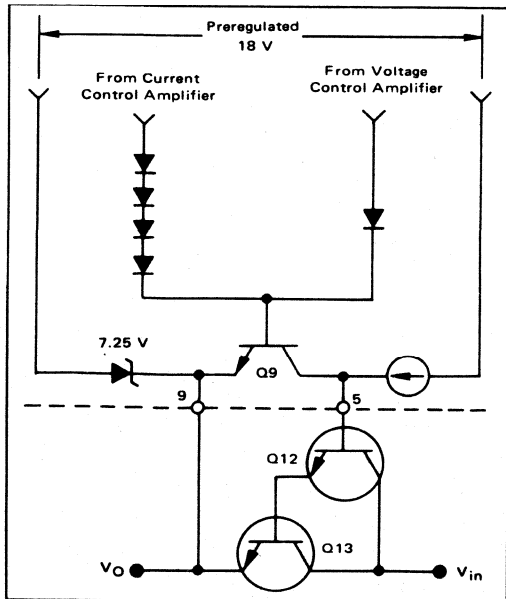

Performance characteristics of the regulator may be approximately calculated for a given circuit (Figure 2). Assuming that the two added transistors (Q12 and Q13) have minimum beta's of 20, then the overall regulator transconductance will be:

$$g_{mT} = (400) 300 \text{ mA/volt} = 120 \text{ A/volt.} \quad (3)$$

For a change in current of 500 mA the output voltage will drop only:

$$\Delta V = \frac{0.5}{120} = 4.2 \text{ mV.} \quad (4)$$

FIGURE 12 - MC1566 OUTPUT STAGE

The analysis thus far does not consider changes in V_R due to output current changes. If I_L increases by 500 mA the collector current of Q9 decreases by 1.25 mA, causing the collector current of Q5 to increase by 30 μA . Accordingly, I_R will be decreased by $\approx 0.30 \mu\text{A}$ which will drop the output by 0.03%. This figure may be improved considerably by either using high beta devices as the pass transistors, or by increasing I_R . Note again, however, that the maximum power rating of the package must be kept in mind. For example if $I_R = 4 \text{ mA}$, power dissipation is

$$P_D = 20 \text{ V} (8 \text{ mA}) + (11 \text{ V} \times 3 \text{ mA}) = 193 \text{ mW.} \quad (5)$$

This indicates that the circuit may be safely operated up to 118°C using 20 volts at the auxiliary supply voltage. If, however, the auxiliary supply voltage is 35 volts,

$$P_D = 35 \text{ V} (8 \text{ mA}) + 26 \text{ V} (3 \text{ mA}) = 358 \text{ mW.} \quad (6)$$

which dictates that the maximum operating temperature must be less than 91°C to keep package dissipation within specified limits.

Line voltage regulation is also a function of the voltage change between pins 8 and 9, and the change of V_{ref} . In this case, however, these voltages change due to changes in the internal regulator's voltages, which in turn are caused by changes in V_{aux} . Note that line voltage regulation is not a function of V_{in} . Note also that the instantaneous value of V_{aux} must always be between 20 and 35 volts.

Figure 6 shows six external diodes (CR₁ to CR₆) added for protective purposes. CR₁ should be used if the output voltage is less than 20 volts and CR₂, CR₃ are absent. For V_O higher than 20 volts, CR₁ should be discarded in favor of CR₂ and CR₃. Diode CR₄ prevents IC failure if the series pass transistors develop collector-base shorts while the main power transistor suffers a simultaneous open emitter. If the possibility of such a transistor failure mode seems remote, CR₄ may be deleted. To prevent instantaneous differential and common-mode breakdown of the current sense amplifier, CR₅ must be placed across the current limit resistor R_S .

Load transients occasionally produce a damaging reversal of current flow from output to input $V_O > 150$ volts (which will destroy the IC). Diode CR₆ prevents such reversal and renders the circuit immune from destruction for such conditions, e.g., adding a large output capacitor after the supply is turned "on". Diodes CR₁, CR₂, CR₃, and CR₅ may be general purpose silicon units such as 1N4001 or equivalent whereas CR₄ and CR₆ should have a peak inverse voltage rating equal to V_{in} or greater.

APPLICATIONS

Figure 2 shows a typical 0-to-40 volts, 0.5-ampere regulator with better than 0.01% performance. The RC network between pins 5 and 6 and the capacitor between pins 13 and 14 provide frequency compensation for the MC1566/MC1466. The external pass transistors are used to boost load current, since the output current of the regulator is less than 2 mA.

MC1466L, MC1566L

Figure 1 is a 0-to-15 volts, 10-ampere regulator with the pass transistor configuration necessary to boost the load current to 10 amperes. Note that C_O has been increased to 1000 μF following the general rule:

$$C_O = 100 \mu\text{F}/A I_L.$$

The prime advantage of the MC1566/MC1466 is its use as a high voltage regulator, as shown in Figure 3. This 0-to-250 volts 0.1-ampere regulator is typical of high voltage applications, limited only by the breakdown and safe areas of the output pass transistors.

The primary limiting factor in high voltage series regulators is the pass transistor. Figure 13 shows a safe area curve for the MJ413. Looking at Figure 3, we see that if the output is shorted, the transistor will have a collector current of 100 mA, with a V_{CE} approximately equal to 260 volts. Thus this point falls on the dc line of the safe area curve, insuring that the transistor will not enter secondary breakdown.

In this respect (Safe Operating Area) the foldback circuit of Figure 14 is superior for handling high voltages and yet is short-circuit protected. This is due to the fact that load current is diminished as output voltage drops (V_{CE} increases as V_O drops) as seen in Figure 15. By careful design the load current at a short, I_{SC} can be made low enough such that the combined V_{CE} (V_{in}) and I_{SC} still falls within the dc safe operating area of the transistor. For the illustrated design (Figure 14), an input voltage of 210 volts is compa-

table with a short-circuit current of 100 mA. Yet current foldback allows us to design for a maximum regulated load current of 500 mA. The pertinent design equations are:

$$\text{Let } R_2 \text{ (k}\Omega\text{)} = V_O$$

$$\alpha = \frac{0.25}{V_O} \left[\frac{I_k}{I_{SC}} - 1 \right]$$

$$R_1 \text{ (k}\Omega\text{)} = \frac{\alpha}{1 - \alpha} V_O$$

$$R_{SC} = \frac{0.25}{(1 - \alpha) I_{SC}}$$

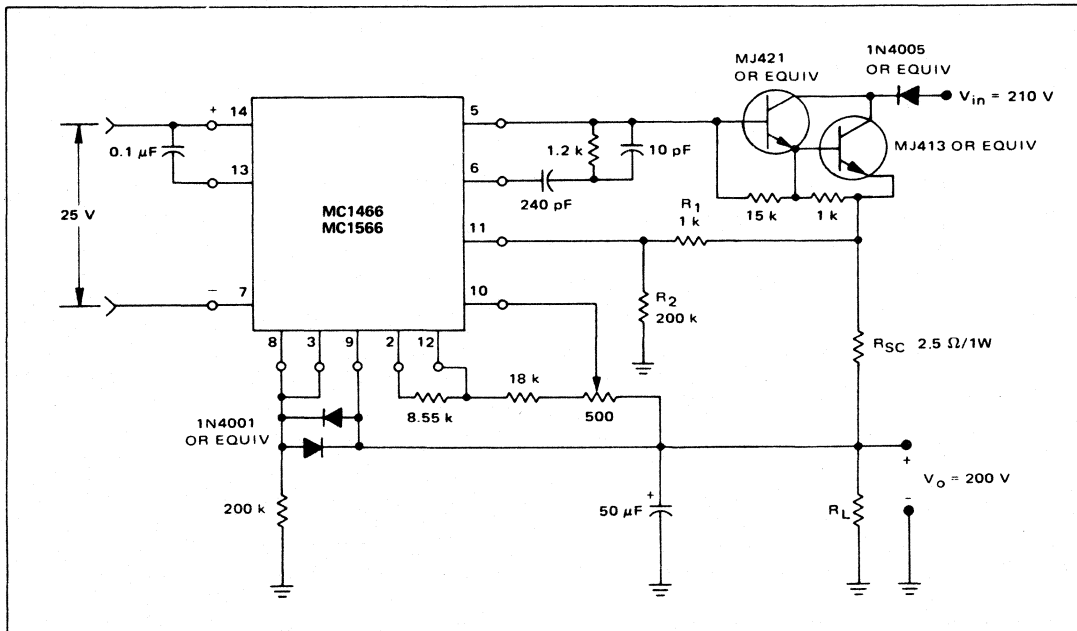

FIGURE 14 - A 200 V, 0.5-AMPERE REGULATOR WITH CURRENT FOLDBACK

MC1466L, MC1566L

The terms I_{SC} and I_k correspond to the short-circuit current and maximum available load current as shown in Figure 15.

Figure 16 shows a remote sense application which should be used when high current or long wire lengths are used. This type of wiring is recommended for any application where the best possible regulation is desired. Since the sense lines draw only a small current, large voltage drops do not destroy the excellent regulation of the MC1566/MC1466.

TRANSIENT FAILURES

In industrial areas where electrical machinery is used

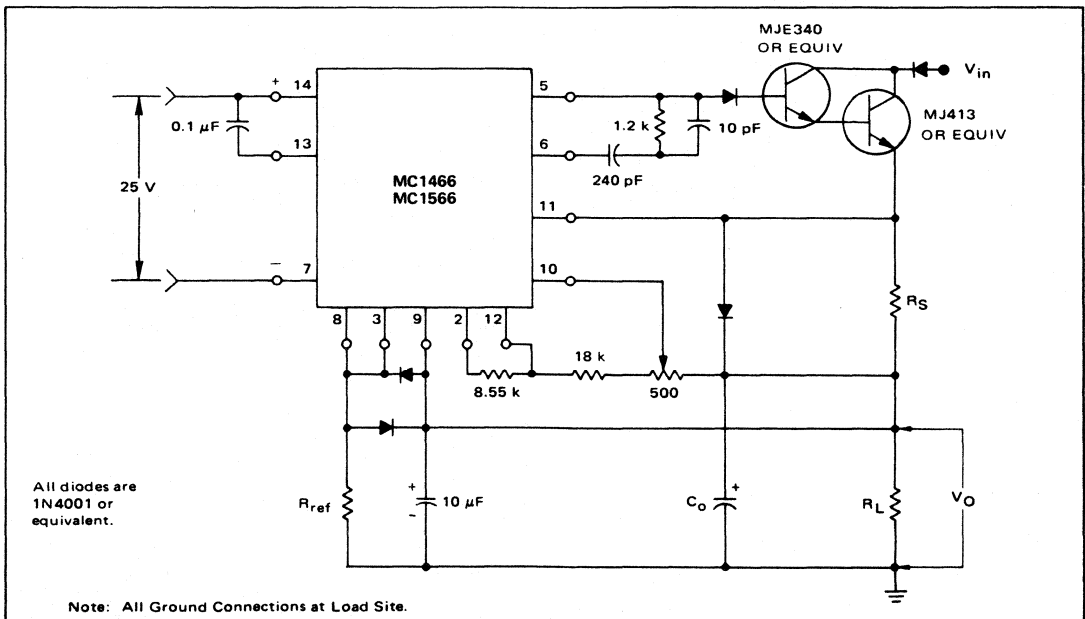

the normal ac line often contains bursts of voltage running from hundreds to thousands of volts in magnitude and only microseconds in duration. Under some conditions this energy is dissipated across the internal zener connected between pins 9 and 7. This transient condition may produce a total failure of the regulator device without any apparent explanation. This type of failure is identified by absence of the 7-volt zener (CR1) between pin 9 and pin 7. To prevent this failure mode the use of a shielded power transformer is recommended, as shown in Figure 6. In addition, it is recommended that C1, C3 and C4 be included to aid in transient repression. These capacitors should have good high frequency characteristics.

If the possibility of transients on the output exists, the addition of a resistor and zener diode between pins 9 and 7 as shown on Figure 17 should be added.

VOLTAGE/CURRENT – MODE INDICATOR

There may be times when it is desirable to know when the MC1566/MC1466 is in the constant current mode or constant voltage mode. A mode indicator can be easily added to provide this feature. Figure 18 shows how a PNP transistor has replaced a protection diode between pins 8 and 9 of Figure 2. When the MC1566/MC1466 goes from constant voltage mode to constant current mode, V_O will drop below V_g and the PNP transistor will turn on. The 1-mA current supplied by pin 8 will now be shunted to base of Q2 thereby turning on the indicator device I1.

DUAL ± 15 -VOLT REGULATOR

The MC1568/MC1468 is a dual polarity tracking regulator designed to provide balanced positive and negative output voltages at currents to 100 mA. Internally, the device is set for ± 15 -volt outputs but an external adjustment can be used to change both outputs simultaneously from 8.0 to 20 volts. Input voltages up to ± 30 volts can be used and there is provision for adjustable current limiting. The device is available in three package types to accommodate various power requirements.

- Internally set to ± 15 V Tracking Outputs
- Output Currents to 100 mA
- Outputs Balanced to within 1% (MC1568)
- Line and Load Regulation of 0.06%
- 1% Maximum Output Variation due to Temperature Changes
- Standby Current Drain of 3.0 mA
- Externally Adjustable Current Limit
- Remote Sensing Provisions
- Case is at Ground Potential (R suffix package)

CIRCUIT SCHEMATIC

Pin numbers adjacent to terminals are for the G and R suffix packages only. Pin numbers in parentheses are for the L suffix package only.

Pin 10 is ground for the G suffix package only. For the R package, the case is ground.

TYPICAL APPLICATIONS

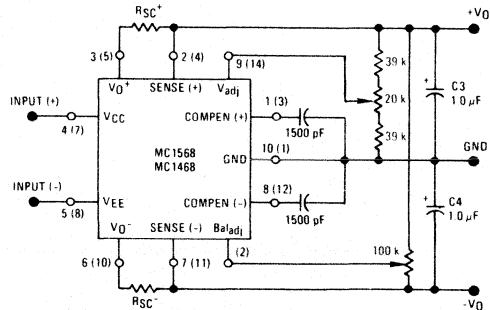

FIGURE 1 – BASIC 50-mA REGULATOR

C1 and C2 should be located as close to the device as possible. A 0.1 μF ceramic capacitor (C_{in}) may be required on the input lines if the device is located an appreciable distance from the rectifier filter capacitors.

C3 and C4 may be increased to improve load transient response and to reduce the output noise voltage. At low temperature operation, it may be necessary to bypass C4 with a 0.1 μF ceramic disc capacitor.

Specifications and Applications Information

MONOLITHIC VOLTAGE REGULATOR

The MC1569/MC1469 is a positive voltage regulator designed to deliver continuous load current up to 500 mA dc. Output voltage is adjustable from 2.5 Vdc to 37 Vdc. The MC1569 is specified for use within the military temperature range (-55 to +125°C) and the MC1469 within the 0 to +70°C temperature range.

For systems requiring a positive regulated voltage, the MC1569 can be used with performance nearly identical to the MC1563 negative voltage regulator. Systems requiring both a positive and negative regulated voltage can use the MC1569 and MC1563 as complementary regulators with a common input ground.

- Electronic "Shut-Down" Control
- Excellent Load Regulation (Low Output Impedance - 20 milliohms typ)
- High Power Capability: up to 17.5 Watts
- Excellent Temperature Stability: $\pm 0.002\% / ^\circ\text{C}$ typ
- High Ripple Rejection: 0.002 %/V typ

= $+125^\circ\text{C}$ for MC1569

MC1469, MC1569

Note 1. "Minimum Input Voltage" is the minimum "total instantaneous input voltage" required to properly bias the internal zener reference diode. For output voltages greater than approximately 5.5 Vdc the minimum "total instantaneous input voltage" must increase to the extent that it will always exceed the output voltage by at least the "input-output voltage differential".

Note 2. This parameter states that the MC1569/MC1469 will regulate properly with the input-output voltage differential ($V_{in} - V_O$) as low as 2.7 Vdc and 3.0 Vdc respectively. Typical units will regulate properly with ($V_{in} - V_O$) as low as 2.1 Vdc as shown in the typical column. (See Figure 21.)

Note 3. "Temperature Coefficient of Output Voltage" is defined as:

$$MC1569, TCV_O = \frac{\pm (V_O \text{ max} - V_O \text{ min}) (100)}{(180^\circ\text{C}) (V_O @ 25^\circ\text{C})} = \%/^\circ\text{C}$$

$$MC1469, TCV_O = \frac{\pm (V_O \text{ max} - V_O \text{ min}) (100)}{(75^\circ\text{C}) (V_O @ 25^\circ\text{C})} = \%/^\circ\text{C}$$

The output-voltage adjusting resistors (R1 and R2) must have matched temperature characteristics in order to maintain a constant ratio independent of temperature.

Note 4. Input regulation is the percentage change in output voltage per volt change in the input voltage and is expressed as

$$\text{Input Regulation} = \frac{V_O}{V_{in}} 100 (\%/V_O)$$

where v_o is the change in the output voltage V_O for the input change v_{in} .

The following example illustrates how to compute maximum output voltage change for the conditions given:

$$\begin{aligned} \text{Reg}_{in} &= 0.015 \% / V_O \\ V_O &= 10 \text{ Vdc} \\ V_{in} &= 1.0 \text{ V (rms)} \\ v_o &= \frac{(\text{Reg}_{in}) (v_{in}) (V_O)}{100} \\ &= \frac{(0.015) (1.0) (10)}{100} \\ &= 0.0015 \text{ V (rms)} \end{aligned}$$

Note 5. Load regulation is specified for small ($\leq +17^\circ\text{C}$) changes in junction temperature. Temperature drift effect must be taken into account separately for conditions of high junction temperature changes due to the thermal feedback that exists on the monolithic chip.

$$\text{Load Regulation} = \frac{[V_O]_{I_L = 1.0 \text{ mA}} - [V_O]_{I_L = 50 \text{ mA}}}{V_O |_{I_L = 1.0 \text{ mA}}} \times 100$$

Note 6. The resulting low level output signal (v_o) will require the use of a tuned voltmeter to obtain a reading. Special care should be used to insure that the measurement technique does not include connection resistance, wire resistance, and wire lead inductance (i.e., measure close to the case). Note that No. 22 AWG hook-up wire has approximately 4.0 milliohms/in. dc resistance and an inductive reactance of approximately 10 milliohms/in. at 100 kHz. Avoid use of alligator clips or banana plug-jack combination.

FIGURE 9 - SHUTDOWN CURRENT

GENERAL DESIGN INFORMATION

1. Output Voltage, V_O
 - a) For $V_O \geq 3.5$ Vdc – Output voltage is set by resistors R1 and R2 (see Figure 4). Set $R_2 = 6.8$ k ohms and determine R1 from the graph of Figure 10 or from the equation:

$$R_1 \approx (2 V_O - 7) \text{ k}\Omega$$

- b) For $2.5 \leq V_O \leq 3.5$ Vdc – Output voltage is set by resistors R1 and R2 (see Figure 5). Resistors R1 and R2 can be determined from the graph of Figure 11 or from the equations:

$$R_2 \approx 2 (V_O) \text{ k}\Omega$$

$$R_1 \approx (7 \text{ k}\Omega - R_2) \text{ k}\Omega$$

- c) Output voltage, V_O , is determined by the ratio of R1 and R2, therefore optimum temperature performance can be achieved if R1 and R2 have the same temperature coefficient.
 - d) Output voltage can be varied by making R1 adjustable as shown in Figure 43.
 - e) If $V_O = 3.5$ Vdc (to supply MRTL* for example), tie pins 6, 8 and 9 together. R1 and R2 are not needed in this case.

2. Short Circuit Current, I_{sc}
Short Circuit Current, I_{sc} , is determined by R_{sc} . R_{sc} may be chosen with the aid of Figure 12 or the expression:

$$R_{sc} \approx \frac{0.6 \text{ ohm}}{I_{sc}}$$

where I_{sc} is measured in amperes. This expression is also valid when current is boosted as shown in Figure 2.

3. Compensation, C_C
A 0.001 μF capacitor, C_C , from pin 4 to ground will provide adequate compensation in most applications, with or without current boost. Smaller values of C_C will reduce stability and larger values of C_C will degrade pulse response and output impedance versus frequency. The physical location of C_C should be close to the MC1569/MC1469 with short lead lengths.

4. Noise Filter Capacitor, C_N
A 0.1 μF capacitor, C_N , from pin 7 to ground will typically reduce the output noise voltage to 150 μV (rms). The value of C_N can be increased or decreased, depending on the noise voltage requirements of a particular application. A minimum value of 0.001 μF is recommended.

5. Output Capacitor, C_O
The value of C_O should be at least 1.0 μF in order to provide good stability. The maximum value recommended is a function of current limit resistor R_{sc} :

$$C_O \text{ max} \approx \frac{250 \mu\text{F}}{R_{sc}}$$

where R_{sc} is measured in ohms. Values of C_O greater than this will degrade the pulse response characteristics and increase the settling time.

6. Shut-Down Control
One method of turning "OFF" the regulator is to apply a dc voltage at pin 2. This control can be used to eliminate power consumption by circuit loads which can be put in "standby" mode. Examples include, an ac or dc "squelch" control for communications circuits, and a dissipation control to protect the regulator under sustained output short-circuiting. As the magnitude of the input-threshold voltage at Pin 2 depends directly upon the junction temperature of the integrated circuit chip, a fixed dc voltage at Pin 2 will cause automatic shut-down for high junction temperatures. This will protect the chip, independent of the heat sinking used, the ambient temperature, or the input or output voltage levels. Standard Logic levels of MRTL, MDTL* or MTTL* can also be used to turn the regulator "ON" or "OFF".

7. Remote Sensing
The connection to pin 5 can be made with a separate lead direct to the load. Thus, "remote sensing" can be achieved and the effect of undesired impedances (including that of the milliammeter used to measure I_L) on z_O can be greatly reduced.

--	--	--

THEORY OF OPERATION

The usual series voltage regulator shown in Figure 25, consists of a reference voltage, an error amplifier, and a series control element. The error amplifier compares the output voltage with the reference voltage and adjusts the output accordingly until the error is essentially zero. For applications requiring output voltages larger than the reference, there are two options. The first is to use a resistive divider across the output and compare only a fraction of the output voltage to the reference. This approach suffers from reduced feedback to the error amplifier due to the attenuation of the resistive divider. This degrades load regulation especially at high voltage levels.

The alternative is to eliminate the resistive divider and to shift the reference voltage instead. To accomplish this, another amplifier is employed to amplify (or level shift) the reference voltage using an operational amplifier as shown in Figure 26. The gain-determining resistors may be external, enabling a wide range of output voltages. This

is exactly the same approach used in the first option. That is, the output is being resistively divided to match the reference voltage. There is however, one big difference in that the output of this "regulator" is driving the input of another regulator (the error amplifier). The output of the reference amplifier has a relatively low impedance as compared to the input impedance of the error amplifier. Changes in the load of the output of the error amplifier are buffered to the extent that they have virtually no effect on the reference amplifier. If the feedback resistors are external (as they are on the MC1569) a wide range of reference voltages can be established.

The error amplifier can now be operated at unity gain to provide excellent regulation. In fact, this "regulator-within-a-regulator" concept permits the load regulation to be specified in terms of output impedance rather than as some percentage change of the output voltage. This approach was used in the design of the MC1569 positive-voltage regulator.

FIGURE 25 - SERIES VOLTAGE REGULATOR

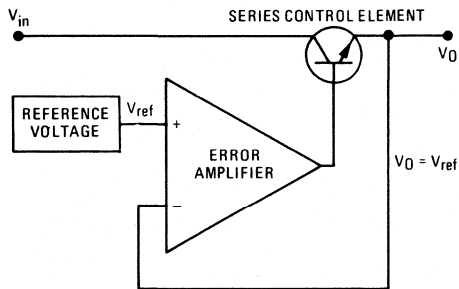

FIGURE 26 - THE "REGULATOR-WITHIN-A-REGULATOR" APPROACH

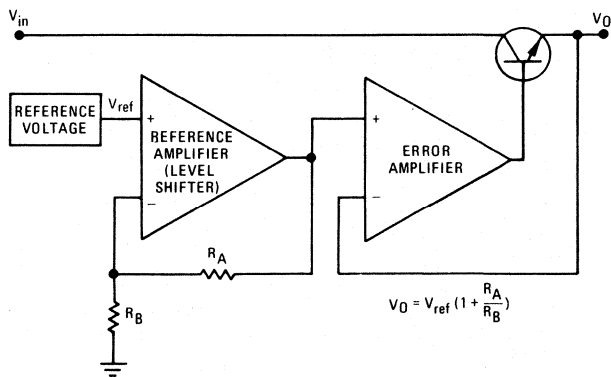

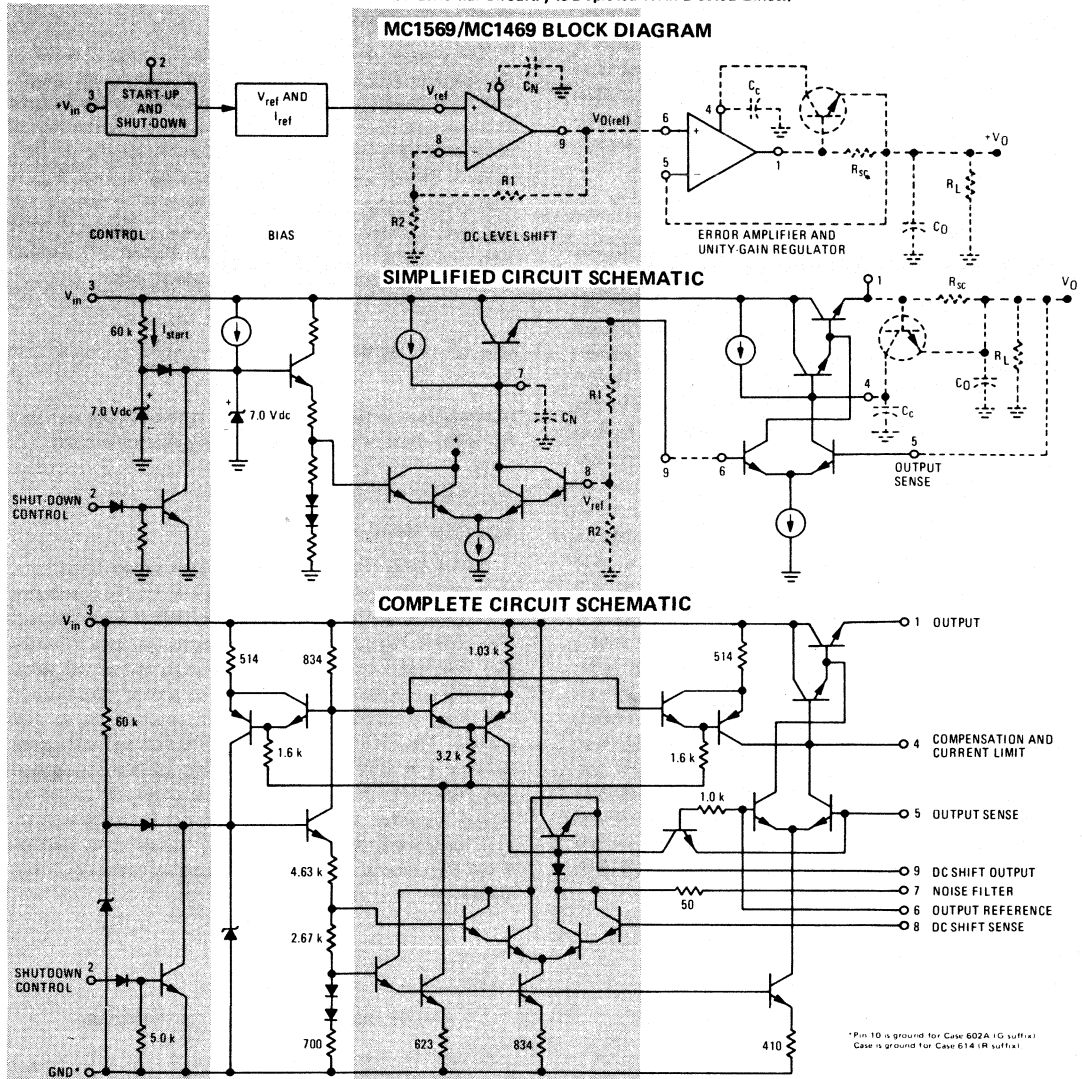

FIGURE 27
(Recommended External Circuitry is Depicted With Dotted Lines.)

MC1569 Operation

Figure 27 shows the MC1569 Regulator block diagram, simplified schematic, and complete schematic. The four basic sections of the regulator are: Control, Bias, DC Level Shift, and Output (unity gain) Regulator. Each section is detailed in the following paragraphs.

Control

The control section involves two basic functions, start-up and shutdown. A start-up function is required since the biasing is essentially independent of the unregulated

input voltage. It makes use of two zener diodes having the same breakdown voltage. A first or auxiliary zener is driven directly from the input voltage line through a resistor (60 kΩ) and permits the regulator to initially achieve the desired bias conditions. This permits the second, or reference zener to be driven from a current source. When the reference zener enters breakdown, the auxiliary zener is isolated from the rest of the regulator circuitry by a diode disconnect technique. This is necessary to keep the added noise and ripple of the auxiliary zener from degrading the performance of the regulator.

MC1469, MC1569

The shutdown control consists of an NPN transistor across the reference zener diode. When this transistor is turned "ON", via pin 2, the reference voltage is reduced to essentially zero volts and the regulator is forced to shut-down. During shutdown the current drain of the complete IC regulator drops to $V_{in}/60\text{ k}\Omega$ or $500\text{ }\mu\text{A}$ for a 30 V input.

Bias

A zener diode is the main reference element and forms the heart of the bias circuitry. Its positive temperature coefficient is balanced by the negative temperature coefficients of forward biased diodes in a ratio determined by the resistors in the diode string. The result is a reference voltage of approximately 3.5 Vdc with a typical temperature coefficient of $0.002\text{ }\%/\text{ }^\circ\text{C}$. In addition, this circuit also provides a reference current which is used to bias all current sources in the remaining regulator circuitry.

DC Level Shift

The reference voltage is used as the input to a Darlington differential amplifier. The gain of this amplifier is quite high and it therefore may be considered to function as a conventional operational amplifier. Consequently, negative feedback can be employed using two external resistors (R1 and R2) to set the closed-loop gain and to boost the reference voltage to the desired output voltage. A capacitor, C_N , is introduced externally into the level shift network (via pin 7) to stabilize the amplifier and to filter the zener noise. The recommended value for this capacitor is $0.1\text{ }\mu\text{F}$ and should have a voltage rating in excess of the desired output voltage. Smaller capacitors ($0.001\text{ }\mu\text{F}$ minimum) may be used but will cause a slight increase in output noise. Larger values of C_N will reduce the noise as well as delay the start-up of the regulator.

Output Regulator

The output of the level shift amplifier (pin 9) is fed to the noninverting input (pin 6) of the output error amplifier. The inverting input to this amplifier is the Output Sense connection (pin 5) of the regulator. A Darlington connected NPN power transistor is used to handle the load current. The short-circuit current limiting resistor, R_{SC} , is connected in the emitter of this transistor to sample the full load current. By placing an external low-level NPN transistor across R_{SC} as shown in Figure 27, output current can be limited to a predetermined value:

$$I_L \text{ max} \approx \frac{0.6}{R_{SC}} \text{ or } R_{SC} = \frac{0.6}{I_L \text{ max}}$$

where $I_L \text{ max}$ is the maximum load current (amperes) and R_{SC} is the value of the current limiting resistor (ohms).

Stability and Compensation

As has been seen, the MC1569 employs two amplifiers, each using negative feedback. This implies the possibility of instability due to excessive phase shift at high frequencies. Since the error amplifier is normally used at unity gain (the worst case for stability) a high impedance node is brought out for compensation. For normal operation, a capacitor is connected between this point (pin 4) and ground. The recommended value of $0.001\text{ }\mu\text{F}$ will insure stability and still provide acceptable transient response (see Figure 28, A and B). It is also necessary to use an output capacitor, C_O (typically $1.0\text{ }\mu\text{F}$) from the output, V_O , to ground. When an external transistor is used to boost the current, $C_O = 1.0\text{ }\mu\text{F}$ is also recommended (see Figure 2).

TYPICAL NPN CURRENT BOOST CONNECTIONS

FIGURE 29A - 5 VOLT 5-AMPERE REGULATOR

FIGURE 29B - 5-VOLT 5-AMPERE REGULATOR

FIGURE 30 - PNP CURRENT BOOST CONNECTION

NPN CURRENT BOOSTING

For applications requiring more than 500 mA of load current, or for minimizing voltage variations due to temperature changes in the IC regulator arising from changes of the internal power dissipation, the NPN current-boost circuits of Figure 3 or 29 are recommended. The transistor shown in Figure 29A, the 2N3055 can supply currents to 5.0 amperes (subject, of course, to the safe area limitations). To improve the efficiency of the NPN

boost configuration, particularly for small output voltages, the circuit of Figure 29 is recommended. An auxiliary 9.5-volt supply is used to power the IC regulator and the heavy load current is obtained from a second supply of lower voltage. For the 5.0 ampere regulator of Figure 29 this represents a savings of 17.5 watts when compared with operating the regulator from the single 9.5 V supply. It can supply current to 5.0 amperes while requiring an input voltage to the collector of the pass transistor of 6.0 volts minimum. The pass transistor is limited to 5.0 amperes by the added short-circuit current network in its emitter (R_{SC}), (Figure 29B).

PNP CURRENT BOOSTING

A typical PNP current boost circuit is shown in Figure 30. Voltages from 2.5 Vdc to 37 Vdc and currents of many amperes can be obtained with this circuit.

Since the PNP transistor must not be turned on by the MC1569 bias current (I_{IB}) the resistor R_{in} must meet the following condition

$$R_{in} < \frac{V_{BE}}{I_{IB}}$$

where V_{BE} is the base-to-emitter voltage required to turn on the PNP pass transistor, (typically 0.6 Vdc for silicon and 0.2 Vdc for germanium).

For germanium pass transistors, a silicon diode may be placed in series with the emitter to provide an additional voltage drop. This allows a larger value of R_{in} than would be possible if the diode were omitted. The diode will, however, be required to carry the maximum load current.

SELF-OSCILLATING SWITCHING REGULATOR

In all of the current boosting circuits shown thus far it has been assumed that the input-output voltage differential can be minimized to obtain maximum efficiency in both the external pass element as well as the MC1569. This may not be possible in applications where only a single supply voltage is available and high current levels preclude zener diode pre-regulating approaches. In such applications a switching-mode voltage regulator is highly desirable since the pass device is either ON or OFF. The theoretical efficiency of an ideal switching regulator is 100%. Realizable efficiencies of 90% are within the realm of possibility thus obviating the need for large power dissipating components. The output voltage will contain a ripple component; however, this can be made quite small if the switching frequency is made relatively high so filtering techniques are effective. Figure 31 shows a functional diagram for a self-oscillating voltage regulator. The comparator-driver will sense the voltage across the inductor, this voltage being related to the load current, I_L , by

MC1469, MC1569

$$L \frac{dI_L}{dt} = V.$$

For a first approximation this can be assumed to be a linear relationship.

Initially, V_O will be low and Q1 will be ON. The voltage at the non-inverting input will approach $\beta_1 V_{in}$, when:

$$\beta_1 V_{in} = \frac{V_{ref} R_a}{R_a + R_b} + \frac{V_c R_b}{R_a + R_b}.$$

When this output voltage is reached the comparator will switch, turning Q1 OFF. The diode, CR1, will now become forward biased and will supply a path for the inductor current. This current and the sense voltage will start to decrease until the output voltage reaches

$$\beta_2 V_{in} = \frac{V_{ref} R_a}{R_a + R_b}$$

where the comparator will again switch turning Q1 ON, and the cycle repeats. Thus the output voltage is approximately V_{ref} plus a ripple component.

The frequency of oscillation can be shown to be

$$f = \frac{V_O (V_{in} - V_O)}{L V_C I(\max) - I_O} \quad (1)$$

where

$I(\max)$ = The maximum value of inductor current

I_O = The minimum inductor current.

Normally this frequency will be in the range of approximately 2 kHz to 6 kHz. In this range, inductor values can be small and are compatible with the switching times of the pass transistor and diode. The switching time of the comparator is quite fast since positive feedback aids both turn-on and turn-off times. The limiting factors are the diode and pass transistor rise and fall times which should be quite fast or efficiency will suffer.

Figure 32 shows a self oscillating switching regulator which in many respects is similar to the PNP current boost previously discussed. The 6.8 kΩ resistor in conjunction with R1 sets the reference voltage, V_{ref} . Q1 and CR1 are selected for fast switching times as well as the necessary power dissipation ratings. Since a linear inductor is assumed, the inductor cannot be allowed to saturate at maximum load currents and should be chosen accordingly. If core saturation does occur, peak transistor and diode currents will be large and power dissipation will increase.

FIGURE 31 – BASIC SELF-OSCILLATING SWITCHING REGULATOR

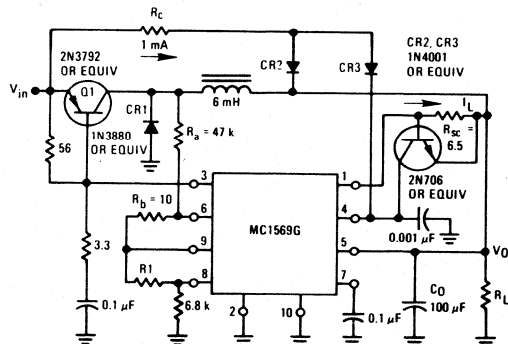

FIGURE 32 – MC1569 SELF-OSCILLATING SWITCHING REGULATOR

MC1469, MC1569

As a design center is required for a practical circuit, assume the following requirements:

$$V_{in} = +28 \text{ Volts}$$

$$V_O = +10 \text{ Volts}$$

$$\Delta V_O = 50 \text{ mV}$$

$$f \approx 5 \text{ kHz}$$

$$I(\text{max}) = 1.125 \text{ A}$$

$$I_O = 1 \text{ A}$$

$$\Delta V \approx V_{in} \frac{R_b}{R_a} \quad (2)$$

Using Equation (1), the inductor value can be found:

$$L = \frac{(28-10)}{2(1.125-1)} \frac{10}{28} \left(\frac{1}{5 \times 10^3} \right) \\ \approx 7 \text{ mH.}$$

For the test circuit, a value of 6 mH was selected. Using for a first approximation

$$C_O = \frac{(V_{in} - V_O)(V_O)}{8L f^2 V_{in} (\Delta V)} \\ = \frac{(28 - 10)10}{8(7 \times 10^{-3})(5 \times 10^3)^2 (28)(50 \times 10^{-3})} \\ \approx 95 \mu\text{F.}$$

As shown, a value of 100 μF was selected. Since little current is required at pin 6, R_a can be large. Assume $R_a = 47 \text{ k}\Omega$ and then use Equation (2) to determine R_b :

$$50 \times 10^{-3} = \frac{28}{47 \text{ k}\Omega} R_b \\ R_b = \frac{47}{28} 50 \approx 85 \Omega.$$

Since the internal impedance presented by pin 9 is on the order of 60 Ω , a value of $R_b = 10\Omega$ is adequate.

Diodes CR2, CR3, and R_C may be added to prevent saturation of the error amplifier to increase switching

speed. When the output stage of the error amplifier approaches saturation, CR2 becomes forward biased and clamps the error amplifier. Resistor R_C should be selected to supply a total of 1 mA_{dc} to CR2 and CR3.

To show correlation between the predicted and tested specifications the following data was obtained:

$$V_{in} = +28 (\pm 1\%) \text{ Volts}$$

$$V_O = +10 \text{ Volts}$$

$$\Delta V_O = 60 \text{ mV}$$

$$f = 7 \text{ kHz}$$

$$@ I_L = 1 \text{ A}$$

which checks quite well with the predicted values. R_b can be adjusted to minimize the ripple component as well as to trim the operating frequency. Also this frequency will change with varying loads as is normal with this type of circuit. Pin 2 can still be used for shut-down if so desired. R_{SC} should be set such that the ratio of load current to base drive current is 10:1 in this case $I_1 \approx 100 \text{ mA}$ and $R_{SC} = 6.5\Omega$.

POSITIVE AND NEGATIVE POWER SUPPLIES

If the MC1569 is driven from a floating source it is possible to use it as a negative regulator by grounding the positive output terminal. The MC1569 may also be used with the MC1563 to provide completely independent positive and negative voltage regulators with comparable performance.

Some applications may require complementary tracking in which both supplies arrive at the voltage level simultaneously, and variations in the magnitudes of the two voltages track. Figures 1 and 33 illustrate this approach. In this application, the MC1563 is used as the reference regulator, establishing the negative output voltage. The MC1569 positive regulator is used in a tracking mode by grounding one side of the differential amplifier (pin 6 of the MC1569) and using the other side (pin 5 of the MC1569) to sense the voltage developed at the junction of the two 3-k ohm resistors. This differential amplifier controls the MC1569 series pass transistor such that the voltage at pin 5 will be zero. When the voltage at pin 5 equals zero, $+V_O$ must equal $|-V_O|$.

For the configuration shown in Figure 33, the level shift amplifier in the MC1569 is employed to generate an auxiliary +5-volt supply which is boosted to a 2-ampere capability by Q1 and Q2. (The +5-volt supply, as shown,

MC1469, MC1569

FIGURE 34 – ELECTRONIC SHUT-DOWN USING A MDTL GATE

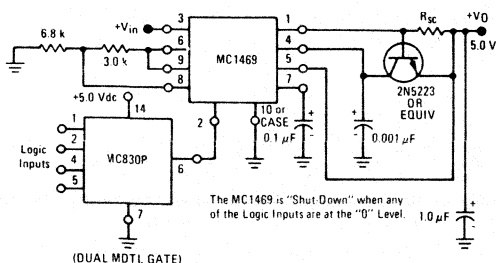

FIGURE 35 – AUTOMATIC LATCH INTO SHUT-DOWN WHEN OUTPUT IS SHORT-CIRCUITED WITH MANUAL RE-START

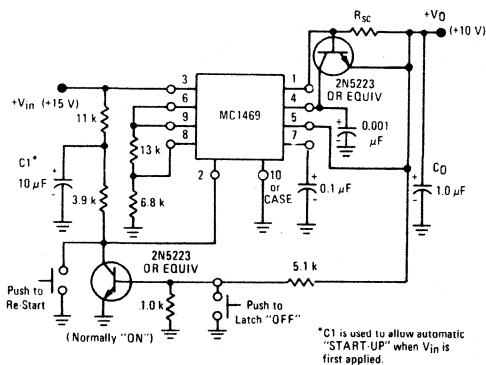

FIGURE 36 – VOLTAGE BOOSTING CIRCUIT

Figure 34 shows how the regulator can be controlled by a logic gate. Here, it is assumed that the regulator operates in its normal mode — as a positive regulator referenced to ground — and that the logic gate is of the saturating type, operating from a positive supply to ground. The high logic level should be greater than about 1.5 V and should source no more than 10 mA into pin 2.

The gate shown is of the MDTL type. MRTL and MTL can also be used as long as the drive current is within safe limits (this is important when using MTL, where the output stage uses an active pull-up).

In some cases a regulator can be designed which can handle the power dissipation resulting from normal operation but cannot safely dissipate the power resulting from a sustained short-circuit. The circuit of Figure 35 solves this problem by shutting down the regulator when the output is short-circuited.

VOLTAGE BOOSTING

The MC1569 has a maximum output voltage capability of 37 volts which covers the bulk of the user requirements. However, it is possible to obtain higher output voltages. One such voltage boosting circuit is shown in Figure 36.

Since high voltage NPN silicon devices are readily available, the only problem is the voltage limitations of the MC1569. This can be overcome by using voltage shift techniques to limit the voltage to 35 volts across the MC1569 while referencing to a higher output voltage.

The zener diode in the base lead of the NPN device is used to shift the output voltage of the MC1569 by approximately 75 volts to the desired high voltage level, in this case 100 volts. Another voltage shift is accomplished by the resistor divider on the output to accommodate the required 25 volt reference to the MC1569. The 2 kΩ resistor is used to bias the zener diode so the current through the 4.7 kΩ resistor can be controlled by the MC1569. The 1N4001 diode protects the MC1569 from supplying load current under short circuit conditions and Q2 serves to limit base current to Q1. For R_{sc} as shown, the short circuit current will be approximately 100 mA.

In order to use a single supply voltage, V_{in}(2) can be derived from V_{in}(1) with a zener diode, shunt pre-regulator.

It can be seen that loop gain has been reduced by the resistor divider and hence the closed loop bandwidth will be less. This of course will result in a more stable system, but regulator performance is degraded to some degree.

REMOTE SENSING

The MC1569 offers a remote sensing capability. This is important when the load is remote from the regulator,

MC1469, MC1569

as the resistance of the interconnecting lines (V_O and GND) are added directly to the output impedance of the regulator. By remote sensing, this resistance is included inside the control loop of the regulator and is essentially eliminated. Figure 37 shows how remote sensing is accomplished using both a separate sense line from pin 8 and a separate ground line from the regulator to the remote load.

AN ADJUSTABLE ZERO-TEMPERATURE-COEFFICIENT (0-TC) VOLTAGE REFERENCE SOURCE.

The MC1569, when used in conjunction with low TC resistors, makes an excellent reference-voltage generator. If the 3.5 volt reference voltage of the IC regulator is a satisfactory value, then pins 8 and 9 can be tied together and no resistors are needed. This will provide a voltage

reference having a typical temperature coefficient of 0.002%/°C. By adding two resistors, R1 and R2, any voltage between 3.5 Vdc and 37 Vdc can be obtained with the same low TC (see Figure 38).

THERMAL SHUTDOWN

By setting a fixed voltage at pin 2, the MC1569 chip can be protected against excessive junction temperatures caused by power dissipation in the IC regulator. This is based on the negative temperature coefficient of the base-emitter junction of the shutdown transistor and the diode in series with pin 2 ($-3.4 \times 10^{-3} \text{V}/^\circ\text{C}$). By setting 1.0 Vdc externally at pin 2, the regulator will shutdown when the chip temperature reaches approximately +140°C. Figure 39 shows a circuit that uses a zero-TC zener diode and a resistive divider to obtain this voltage.

FIGURE 37 - REMOTE SENSING CIRCUIT

FIGURE 39 - JUNCTION TEMPERATURE LIMITING SHUTDOWN CIRCUIT

FIGURE 39A - USING A ZERO TC REFERENCE

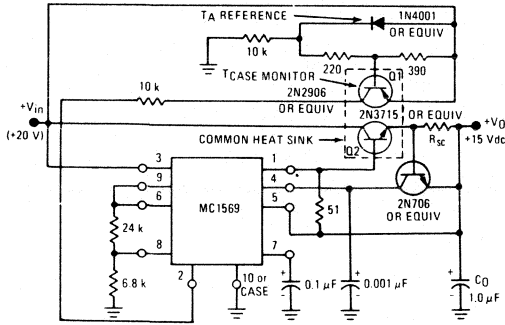

FIGURE 39B - USING A TA REFERENCE

MC1469, MC1569

FIGURE 40 – THERMAL SHUTDOWN WHEN USING EXTERNAL PASS TRANSISTORS

In the case where an external pass transistor is employed, its temperature, rather than that of the IC regulator, requires control. A technique similar to the one just discussed can be used by directly monitoring the case temperature of the pass transistor as is indicated in Figure 40. The case of the normally "OFF" thermal monitoring transistor, Q2, should be in thermal contact with, but electrically isolated from, the case of the boost transistor, Q1.

THERMAL CONSIDERATIONS

Monolithic voltage regulators are subjected to internal heating similar to a power transistor. Since the degree of internal heating is a function of the specific application, the designer must use caution not to exceed the specified maximum junction temperature (+150°C). Exceeding this limit will reduce reliability at an exponential rate. Good heatsinking not only reduces the junction temperature for a given power dissipation; it also tends to improve the dc stability of the output voltage by reducing the junction temperature change resulting from a change in the power dissipation of the IC regulator. By using the derating factors or thermal resistance values given in the Maximum Ratings Table of this data sheet, junction temperature can be computed for any given application in the same manner as for a power transistor*. A short-circuit on the output terminal can produce a "worst-case" thermal condition especially if the maximum input voltage is applied simultaneously with the maximum value of short-circuit load current. Care should be taken not to

*For more detailed information of methods used to compute junction temperature, see Motorola Application Note AN-226, Measurement of Thermal Properties of Semiconductors.

FIGURE 41 – DC SAFE OPERATING AREA

exceed the maximum junction temperature rating during this fault condition and, in addition, the dc safe operating area limit (see Figure 41).

Thermal characteristics for a voltage regulator are useful in predicting performance since dc load and line regulation are affected by changes in junction temperature. These temperature changes can result from either a change in the ambient temperature, T_A, or a change in the power dissipated in the IC regulator. The effects of ambient temperature change on the dc output voltage can be estimated from the "Temperature Coefficient of Output Voltage" characteristic parameter shown as ±0.002%/°C, typical. Power dissipation is typically changed in the IC regulator by varying the dc load current. To estimate the dc change in output voltage due to a change in the dc load current, three effects must be considered:

1. junction temperature change due to the change in the power dissipation
2. output voltage decrease due to the finite output impedance of the control amplifier
3. thermal gradient on the IC chip.

A temperature differential does exist across a power IC chip and can cause a dc shift in the output voltage. A "gradient coefficient," GCV_O, can be used to describe this effect and is typically 0.06%/watt for the MC1569. For an example of the relative magnitudes of these effects, consider the following conditions:

Given MC1569

with V_{in} = 10 Vdc

V_O = 5 Vdc

MC1469, MC1569

and $I_L = 100 \text{ mA to } 200 \text{ mA}$

$$(\Delta I_L = 100 \text{ mA})$$

assume $T_A = +25^\circ\text{C}$

TO-66 Case with heatsink

assume $\theta_{CS} = 0.2^\circ\text{C/W}$

and $\theta_{SA} = 2^\circ\text{C/W}$

$\theta_{JC} = 7.15^\circ\text{C/W}$ (from maximum ratings table)

It is desired to find the ΔV_O which results from this ΔI_L . Each of the three previously stated effects on V_O can now be separately considered.

1. ΔV_O due to ΔT_J

$$\Delta V_O = (V_O)(\Delta P_D)(TCV_O)(\theta_{JC} + \theta_{CS} + \theta_{SA})$$

OR

$$\Delta V_O = (5V)(5 \text{ V} \times 0.1A)(\pm 0.002\%/^\circ\text{C})(9.35^\circ\text{C/W})$$

$$\Delta V_O \approx \pm 0.5 \text{ mV}$$

2. ΔV_O due to z_o

$$|\Delta V_O| = (-z_o)(I_L)$$

$$|\Delta V_O| = -(2 \times 10^{-2})(10^{-1}) = -2 \text{ mV}$$

3. ΔV_O due to gradient coefficient, GCV_O

$$|\Delta V_O| = (GCV_O)(V_O)(\Delta P_D)$$

$$|\Delta V_O| = (-6 \times 10^{-4}/\text{W})(5 \text{ volts})(5 \times 10^{-1}\text{W})$$

$$|\Delta V_O| = -1.6 \text{ mV}$$

Therefore the total ΔV_O is given by

$$|\Delta V_O \text{ total}| = \pm 0.5 - 2.0 - 1.6 \text{ mV}$$

OR

$$-4.1 \text{ mV} \leq |V_O \text{ total}| \leq -3.1 \text{ mV}$$

Other operating conditions may be substituted and computed in a similar manner to evaluate the relative effects of the parameters.

*Optional		

LATCH-UP

Latch-up of these and other regulators can occur if:

1. There are plus and minus voltages available
2. A load exists between V_O⁺ and V_O⁻ (This "common load" may be something inconspicuous – e.g. an operational amplifier. Nearly everyone who uses + and - voltages will have a common load from V_{CC} to V_{EE}.)
3. V_{in}⁺ and V_{in}⁻ are not applied at the same time.

The above conditions result in one of the two outputs becoming reverse-biased which prevents the regulator from turning ON. Latch-up can be prevented by the circuit configurations shown in Figures 44 and 45.

FIGURE – 44

Note: This configuration increases minimum input output differential voltage by 0.7 V.

FIGURE – 45

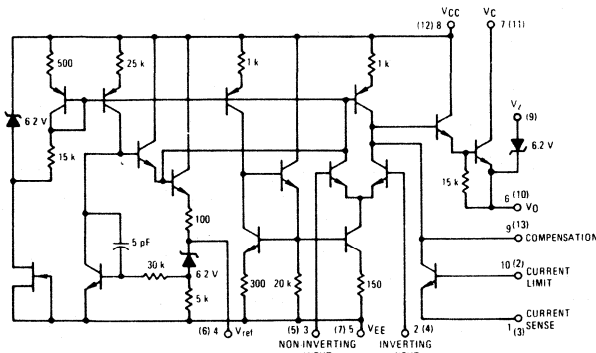

MC1723 MC1723C

MONOLITHIC VOLTAGE REGULATOR

The MC1723 is a positive or negative voltage regulator designed to deliver load current to 150 mA dc. Output current capability can be increased to several amperes through use of one or more external pass transistors. MC1723 is specified for operation over the military temperature range (-55°C to +125°C) and the MC1723C over the commercial temperature range (0 to +70°C)

- Output Voltage Adjustable from 2 Vdc to 37 Vdc
- Output Current to 150 mA dc Without External Pass Transistors
- 0.01% Line and 0.03% Load Regulation
- Adjustable Short-Circuit Protection

MC3420 MC3520

SWITCHMODE REGULATOR CONTROL CIRCUIT

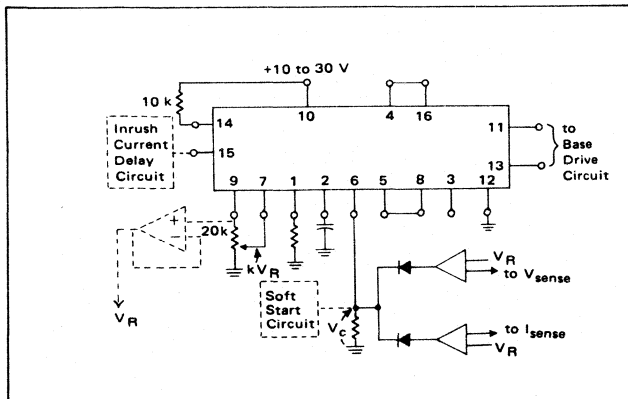

The MC3520/3420 is an inverter control unit which provides all the control circuitry for PWM push-pull, bridge and series type switchmode power supplies.

These devices are designed to supply the pulse width modulated drive to the base of two external power transistors. Other applications where these devices can be used are in transformerless voltage doublers, transformer coupled dc-to-dc converters and other power control functions.

The MC3520 is specified over the military operating range of -55°C to $+125^{\circ}\text{C}$. The MC3420 is specified from 0°C to $+70^{\circ}\text{C}$.

- Includes Symmetrical Oscillator
- On Chip Pulse Width Modulator, Voltage Reference, Dead Time Comparator, and Phase Splitter
- Output Frequency Adjustable (2 kHz to 100 kHz)
- Inhibit and Symmetry Correction Inputs Available
- Controlled Start-Up
- Frequency and Dead Time are Independently Adjustable (0% to 100%)
- Can be Slaved to Other MC3420s
- Open Collector Outputs
- Output Capability 50 mA (Max.)
- On Chip Protection Against Double Pulsing of Same Output During Load Transient Condition

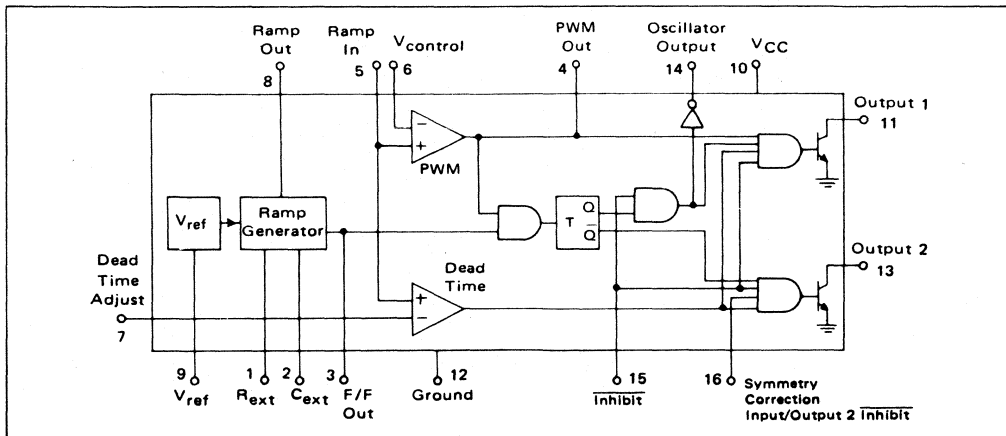

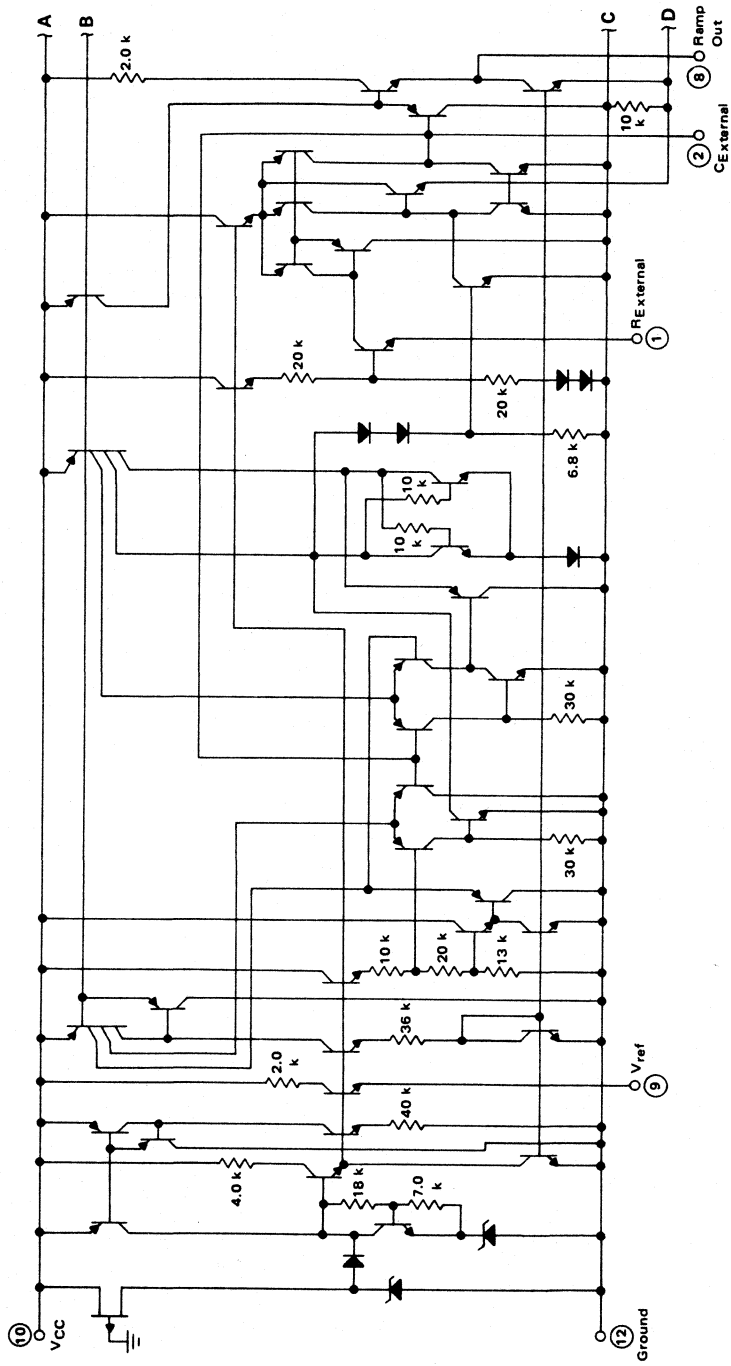

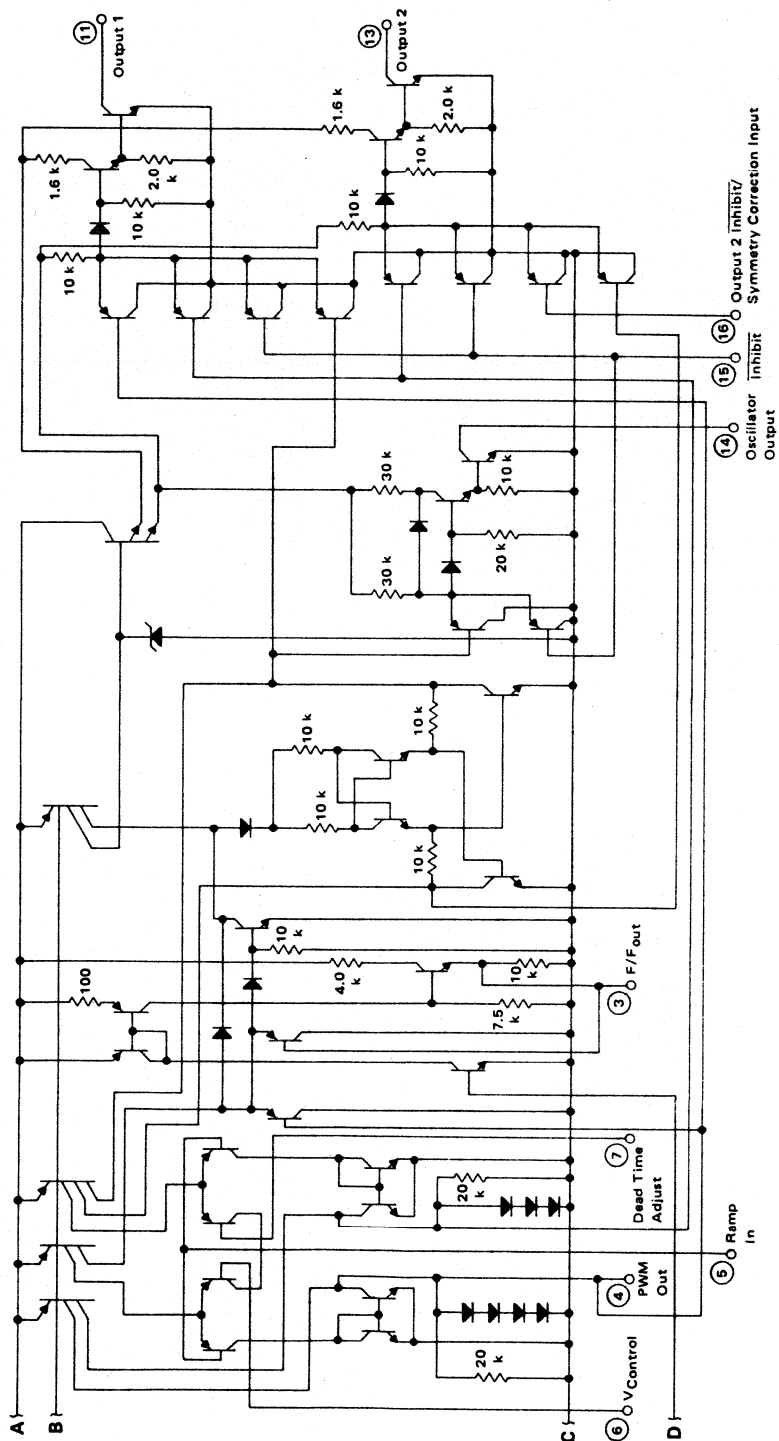

FIGURE 3 - CIRCUIT SCHEMATIC
(continued next page)

(continued) FIGURE 3 - CIRCUIT SCHEMATIC

GENERAL INFORMATION

The internal block diagram of the MC3420 is shown in Figure 2, and consists of the following sections:

Voltage Reference

A stable reference voltage is generated by the MC3420 primarily for internal use. However, it is also available externally at Pin 9 (V_{ref}) for use in setting the dead time (Pin 7) and for use as a reference for the external control loop error amplifiers.

Ramp Generator

The ramp generator section produces a symmetrical triangular waveform ramping between 2.4 V and 6.0 V, with frequency determined by an external resistor (R_{ext}) and capacitor (C_{ext}) tied from Pins 1 and 2, respectively, to ground.

PWM Comparator

The output of the ramp generator at pin 8 is normally connected to Pin 5, RAMP IN. The PWM (pulse width modulation) comparator compares the voltage at Pin 6 ($V_{control}$) to the ramp generator output. The level of $V_{control}$ determines the outputs' pulse width or duty cycle. The duty cycle of each output can vary, exclusive of dead time, from 50% (when $V_{control}$ is at approximately 2.4 V) to 0% ($V_{control}$ approximately 6.0 V).

Dead Time Comparator

An additional comparator has been included in MC3420 to allow independent adjustment of system dead time or maximum duty cycle. By dividing down V_{ref} at Pin 9 with a resistive divider or potentiometer, and applying this voltage to Pin 7, a stable dead time is obtained for prevention of inverter switching transistor cross conduction at high duty cycles due to storage time delays.

Phase Splitter

A phase splitter is included to obtain two 180° out of phase outputs for use in multiple transistor inverter systems. It consists of a toggle flip-flop whose clock signal is derived by "ANDing" the output of the PWM comparator and a signal from the ramp generator section. This "AND" gate ensures that the outputs truly alternate under control loop transient conditions. Better understanding of this feature and MC3420 operation may be gained by studying the circuit waveforms, shown in Figure 4.

OPERATION AND APPLICATIONS INFORMATION

The Voltage Reference

The temperature coefficient of V_{ref} has been optimized for a $400 \mu A$ ($\approx 20 k\Omega$) load. If increased current capability is required, an op amp buffer may be used, as shown in Figure 22.

FIGURE 22

Output Frequency

The values of R_{ext} and C_{ext} for a given output frequency, f_o , can be found from:

$$f_o \approx \frac{0.55}{R_{ext} C_{ext}} ; 5.0 k\Omega \leq R_{ext} \leq 20 k\Omega \text{ (Eq. 1)}$$

or from the graph shown in Figure 23.

Note that f_o refers to the frequency of Output 1 (Pin 11) or Output 2 (Pin 13). The frequency of the ramp generator output waveform at Pin 8 will be twice f_o .

FIGURE 23

Dead Time

Figure 24 illustrates how to set or adjust the MC3420 outputs' dead time or maximum duty cycle. For minimum dead time drift with temperature or supply voltage, $V_{D.T.}$ should be derived from V_{ref} as shown.

FIGURE 24

Connections to the $V_{control}$ Pin

In many systems, it is necessary to make multiple connections to the $V_{control}$ Pin in order to implement features in addition to voltage regulation such as current limiting, soft start, etc. These can be made by the use of a simple "diode-OR" connection, as shown in Figure 25. This allows whichever control element is seeking the lowest PWM duty cycle to dominate. Note that a resistor, R_1 , whose value is $\leq 50 k\Omega$ is placed from the $V_{control}$ Pin to ground. This is necessary to provide a dc path for the PWM comparator input bias current under all conditions.

The system duty cycle is given by:

$$D.C. (\%) \approx \frac{V_{control} - 2}{4} \times 100 \text{ (Eq. 2)}$$

FIGURE 25

MC3420, MC3520

Soft Start

In most PWM switching supplies, a soft start feature is desired to prevent output voltage overshoots and magnetizing current imbalances in the power transformer primary. This feature forces the duty cycle of the switching elements to gradually increase from zero to their normal operating point during initial system power-up or after an inhibit. This feature can be easily implemented with the MC3420. One method is shown in Figure 26.

FIGURE 26

After an inhibit command or during power-up, the voltage on R1 and Pin 6 exponentially decays from V_{CC} toward ground with a time constant of R_1C_1 , allowing a gradual increase in duty cycle. Diodes D2 - D4 provide a diode-or function at the $V_{control}$ Pin, while Q1 serves to reset the timing capacitor, C1, when an inhibit command is received thereby reinitializing the soft-start feature. D1 allows C1 to reset when power (V_{CC}) is turned off.

Inrush Current Limiting

Since many PWM switching supplies are operated directly off the rectified 110 Vac line with capacitive input filters, some means of preventing rectifier failure due to inrush surge currents is usually necessary. One method which can be used is shown in Figure 27.

In this circuit, a series resistor, R_S , is used to provide inrush surge current limiting. After the filter capacitor, C1, is charged, Q1 receives a trigger signal from the control circuitry through T1 and shorts R_S out of the circuit, eliminating its otherwise larger power dissipation. The trigger signal for Q1 may be derived from either the oscillator output (Pin 14) or one of the MC3420's outputs. If the oscillator output is used, it will be necessary

FIGURE 27

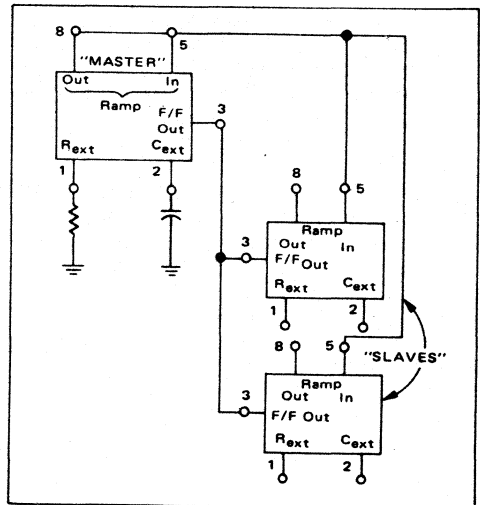

to provide a time delay on the inhibit pin to keep it low until the input filter capacitor, C1, has had time to charge, whereas the initial portion of the soft start timing cycle can be used for this delay if this signal is derived from one of the output pins. However, using the Oscillator Output Pin does offer the advantage that its waveform has a constant 50% duty cycle, independent of the outputs' duty cycle which can simplify the design of a drive circuit for T1.

Slaving

In some applications, as when one PWM inverter/converter is used to feed another, it may be desired that their frequencies be synchronized. This can be done with multiple MC3420s as shown in Figure 28. By omitting their R_{ext} and C_{ext} , up to two MC3420s may be slaved to a master MC3420.

FIGURE 28 - SLAVING THE MC3420

MC3420, MC3520

15 V, 2 A DC-to-DC Converter

Figure 29 illustrates the use of the MC3520 in a PWM switching power supply utilizing a single series switching element (see Appendix for description of PWM switching supply configurations). The series switching transistor, Q1, chops the dc input voltage, V_{in} , at a frequency of $\cong 25$ kHz, and the resulting waveform is filtered by L1 and C1 to provide the dc output voltage. The frequency is set by R4 and C3, and since the outputs of the MC3520 are wire-ORed together, f_o is twice that given by Equation 1 and Figure 23. V_o is regulated by comparing its value to the MC3520's reference voltage and amplifying the error voltage with U1. The output of U1 is fed into the MC3520 to provide PWM to Q1, thereby controlling its duty cycle and thus the value of V_o .

C2 provides a soft-start feature during power up to prevent output voltage overshoots and excessive start up currents through Q1.

Short circuit protection is provided by R_{SC} , Q3 and Q4. When an overcurrent condition occurs, Q3 is turned on by the voltage across R_{SC} ; Q3 drives Q4 on, which raises the voltage at pin 6 ($V_{control}$) of the MC3520, reducing Q1's duty cycle and maintaining a constant output current of $\cong 2.5$ A.

5 V, 50 A Line-Operated Supply

A 5 V, 50 A line-operated 20 kHz switching power supply using the MC3520 is shown in Figures 30a and b. An explanation of the operation of each section of the supply follows.

Input Section

The 120 Vac line is full wave voltage doubled by CR1, CR2, C1 and C2 to provide 310 Vdc to the power section of the supply. Inrush surge current limiting is provided by R1, which is shorted out of the circuit by Q1 after C1 and C2 are initially charged.

Power Section

The supply utilizes two switching transistors, Q2 and Q3, in a half-bridge configuration (see Appendix) to drive the high frequency power transformer, T2.

The bases of Q2 and Q3 are driven by T3 and T4, respectively, to provide isolation from the control and base drive sections of the supply. CR3, CR5, CR6, and CR8 constitute anti-saturation (Baker) clamps which provide increased and more uniform switching speeds for

Q2 and Q3. CR4 and CR7 allow reverse base currents during turn off.

Output Section

The output of T2 is rectified by Schottky diodes, CR9 and CR10. VR1 is a transient suppressor to protect CR9 and CR10 from transients that might cause reverse breakdown. L1 and C4 constitute the output filter. C4 should have very low ESR (equivalent series resistance) at 20 kHz to provide the most effective filtering. L2 and C5 make up a high-frequency filter to reduce commutation spikes which pass L1 due to its interwinding capacitance. R_{SC} provides output overcurrent sensing to the control section.

Control Section

The MC3520 provides the PWM control for the supply. R2 is adjusted to obtain a 20 kHz operating frequency. R3 adjusts the dead time ($\cong 5$ μ s each half-cycle). U1A and U1B are the output current and output voltage error amplifiers, respectively. R5 sets the output voltage while R4 determines the output current limit. C7 and C8 are the current and voltage loop compensation capacitors.

C6 provides the soft-start feature while Q4 ensures a soft-start after each system inhibit (pin 15 low).

Base Drive Section

Turn on drive to the power section switching transistors occurs when each of the outputs of the MC3520 saturate. Q5 or Q6 are therefore turned on, and 15 V applied to the primaries of T3 or T4, supplying forward base drive to Q2 or Q3.

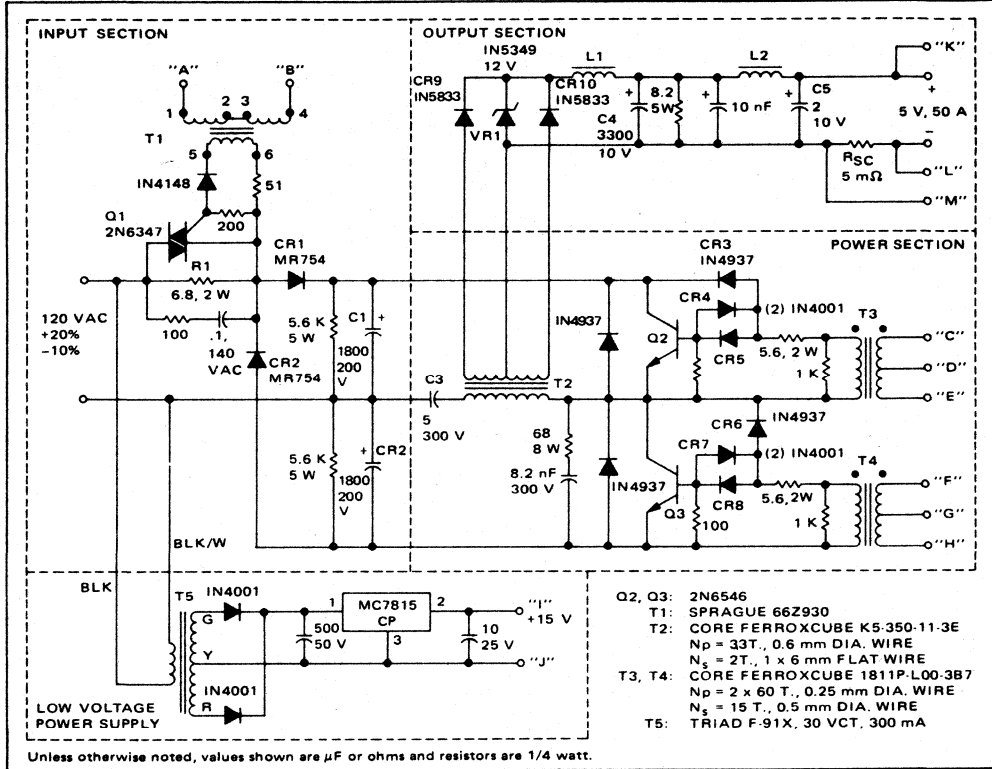

Turn off drive occurs when Q5 or Q6 turn off, and the magnetizing energy stored in T3 or T4's core is transformed into a negative "flyback" voltage at their secondaries, providing reverse base drive to Q2 or Q3. CR11 and CR12 act as clamps, to prevent this flyback voltage from exceeding -5 V at T3 or T4's secondary (30 V on Q5 or Q6's collector).

Q1 Driver Section

Q7 and T1 provide the gate drive to Q1. Q7 starts operating after an initial delay of 100 ms created by the soft-start circuit, thereby allowing C1 and C2 to charge up before firing Q1.

APPENDIX: BASIC PWM SWITCHING SUPPLY POWER CIRCUIT CONFIGURATIONS

The material given in this section is intended to acquaint the designer with the basic switching transistor configurations used in PWM power supplies. Circuit configurations, collector voltage and current waveforms of the switching transistors, and required transistor specifications for the most commonly utilized configurations are shown in Figures 1A through 4A. It should be noted that the waveforms and specifications are idealized, in that the effects of leakage inductance voltage spikes, stray circuit capacitance, snubber networks, clamp diode overshoots, diode reverse recovery and saturation voltages have been neglected. For more information on these effects, the configurations, or switching supplies in general, consult the references listed in the References section.

Series Configuration

The single transistor series configuration is shown in Figure 1A. This configuration is usually limited to applications in which $0.2 V_{CC} < V_o < 0.8 V_{CC}$ and where input-output isolation is not required.

Push-Pull Configuration

Figure 2A shows the two-transistor push-pull configuration. Unlike the series configuration, it can be used to either step-up or step-down the input voltage, V_{CC} , and also provides input-output isolation. It does, however, have the disadvantage that additional circuitry must be used to provide symmetry correction for the prevention of transformer saturation.

Half-Bridge Configuration

The half-bridge configuration, shown in Figure 3A, does not suffer from the symmetry problems of the push-pull configuration since the transformer primary is capacitively coupled. This prevents transformer core saturation since no net dc current is allowed to flow in its primary.

Note that for the same input power, bus voltage, and duty cycle, the half-bridge requires switching transistors

which have twice the current and half the voltage requirements as those of the push-pull configuration.

Full-Bridge Configuration

By replacing the bridge capacitors, C, of the half-bridge configuration of Figure 4A results. With this configuration, double the power of the half-bridge configuration can be obtained at the expense of two additional switching transistors and their associated circuitry.

ABBREVIATIONS USED IN FIGURES 1A THROUGH 4A

- I_C : Switching transistor collector current
- V_{CE} : Switching transistor collector-to-emitter-voltage
- P_{in} : Average input power
- D.C.: Inverter duty cycle
- V_{CC} : DC bus voltage
- $V_{CEO(sus)}$: V_{CE} that transistor must withstand during turn-on
- V_{CEX} : V_{CE} that transistor must block during non-conduction period.

Advance Information

3-TERMINAL POSITIVE VOLTAGE REGULATORS

These voltage regulators are monolithic integrated circuits designed as fixed-voltage regulators for a wide variety of applications including local, on-card regulation. These regulators employ internal current limiting, thermal shutdown, and safe-area compensation. With adequate heatsinking they can deliver output currents in excess of 1.0 ampere. Although designed primarily as a fixed voltage regulator, these devices can be used with external components to obtain adjustable voltages and currents.

- Output Current in Excess of 1.0 Ampere
- No External Components Required
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Output Voltage Offered in 2% and 4% Tolerance

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

XX = these two digits of the type number indicate voltage.

* = C_{in} is required if regulator is located an appreciable distance from power supply filter.

** = C_O is not needed for stability; however, it does improve transient response.

DEFINITIONS

Line Regulation — The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation — The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation — The maximum total device dissipation for which the regulator will operate within specifications.

Quiescent Current — That part of the input current that is not delivered to the load.

Output Noise Voltage — The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability — Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

APPLICATIONS INFORMATION

Design Considerations

The MC7800 Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short-circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected

to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A 0.33 μF or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

FIGURE 13 – CURRENT REGULATOR

The MC7800 regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC7805C is chosen in this application. Resistor R determines the current as follows:

$$I_O = \frac{5 \text{ V}}{R} + I_Q$$

$$I_Q \approx 1.5 \text{ mA over line and load changes}$$

For example, a 1-ampere current source would require R to be a 5-ohm, 10-W resistor and the output voltage compliance would be the input voltage less 7 volts.

FIGURE 14 – ADJUSTABLE OUTPUT REGULATOR

$$V_O: 7.0 \text{ V to } 20 \text{ V}$$

$$V_{IN} \quad V_O \geq 2.0 \text{ V}$$

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 2.0 volts greater than the regulator voltage.

FIGURE 15 – CURRENT BOOST REGULATOR

XX = 2 digits of type number indicating voltage.

The MC7800 series can be current boosted with a PNP transistor. The MJ2955 provides current to 5.0 amperes. Resistor R in conjunction with the V_{BE} of the PNP determines when the pass transistor begins conducting; this circuit is not short-circuit proof. Input-output differential voltage minimum is increased by V_{BE} of the pass transistor.

FIGURE 16 – SHORT-CIRCUIT PROTECTION

XX = 2 digits of type number indicating voltage.

The circuit of Figure 15 can be modified to provide supply protection against short circuits by adding a short-circuit sense resistor, R_{sc} , and an additional PNP transistor. The current sensing PNP must be able to handle the short-circuit current of the three-terminal regulator. Therefore, a four-ampere plastic power transistor is specified.

MC78L00C, AC Series

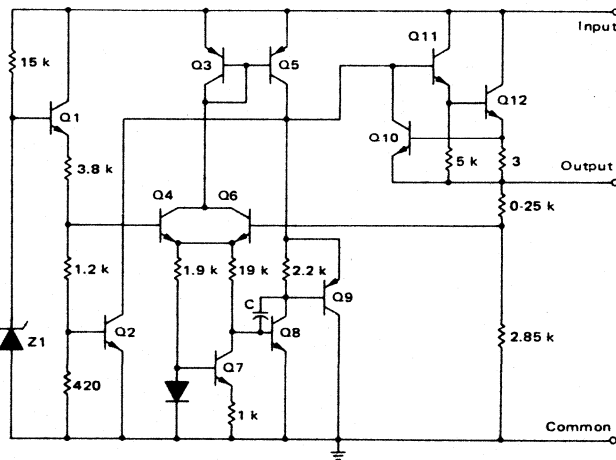

THREE-TERMINAL POSITIVE VOLTAGE REGULATORS

The MC78L00 Series of positive voltage regulators are inexpensive, easy-to-use devices suitable for a multitude of applications that require a regulated supply of up to 100 mA. Like their higher powered MC7800 and MC78M00 Series cousins, these regulators feature internal current limiting and thermal shutdown making them remarkably rugged. No external components are required with the MC78L00 devices in many applications.

These devices offer a substantial performance advantage over the traditional zener diode-resistor combination. Output impedance is greatly reduced and quiescent current is substantially reduced.

- Wide Range of Available, Fixed Output Voltages
- Low Cost
- Internal Short-Circuit Current Limiting
- Internal Thermal Overload Protection
- No External Components Required
- Complementary Negative Regulators Offered (MC79L00 Series)
- Available in Either $\pm 5\%$ (AC) or $\pm 10\%$ (C) Selections

(Case connected to pin 3)

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

* = C_1 is required if regulator is located an appreciable distance from power supply filter.

** = C_0 is not needed for stability; however, it does improve transient response.

APPLICATIONS INFORMATION

Design Considerations

The MC78L00C Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be

selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu\text{F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

FIGURE 7 - CURRENT REGULATOR

The MC78L00C regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC78L05C is chosen in this application. Resistor R determines the current as follows:

$$I_O = \frac{5 \text{ V}}{R} + I_{IB}$$

$I_{IB} = 3.8 \text{ mA}$ over line and load changes

For example, a 100 mA current source would require R to be a 50-ohm, 1/2-W resistor and the output voltage compliance would be the input voltage less 7 volts.

FIGURE 8 - ±15 V TRACKING VOLTAGE REGULATOR

FIGURE 9 - POSITIVE AND NEGATIVE REGULATOR

MC78M00B

series

THREE-TERMINAL POSITIVE FIXED VOLTAGE REGULATORS

MC78M00B SERIES THREE-TERMINAL POSITIVE VOLTAGE REGULATORS

The MC78M00 Series positive voltage regulators are identical to the popular MC7800B Series devices, except that they are specified for only half the output current. Like the MC7800C devices, the MC78M00B three-terminal regulators are intended for local, on-card voltage regulation.

Internal current limiting, thermal shutdown circuitry and safe-area compensation for the internal pass transistor combine to make these devices remarkably rugged under most operating conditions. Maximum output current, with adequate heatsinking is 500 mA.

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Packaged in the Plastic Case 313 (TO-220 Type)

T SUFFIX
PLASTIC PACKAGE
CASE 313
(TO-220 Type)

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

* = C_{in} is required if regulator is located an appreciable distance from power supply filter.

** = C_O improves stability and transient response.

THERMAL INFORMATION

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature, can be found from the equation:

$$P_D(T_A) = \frac{T_J(\text{max}) - T_A}{R_{\theta JA}(\text{Typ})} \geq V_I I_S - V_O I_O$$

Where: $P_D(T_A)$ = Power Dissipation allowable at a given operating ambient temperature.

$T_J(\text{max})$ = Maximum Operating Junction Temperature as listed in the Maximum Ratings Section

T_A = Maximum Desired Operating Ambient Temperature

$R_{\theta JA}(\text{Typ})$ = Typical Thermal Resistance Junction to Ambient

I_S = Total Supply Current

DEFINITIONS

Line Regulation — The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation — The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation — The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current — That part of the input current that is not delivered to the load.

Output Noise Voltage — The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability — Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

APPLICATIONS INFORMATION

Design Considerations

The MC78M00B Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short-circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected

to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A 0.33 μF or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

FIGURE 5 - CURRENT REGULATOR

The MC7800B regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC7805C is chosen in this application. Resistor R determines the current as follows:

$$I_O = \frac{5 \text{ V}}{R} + I_Q$$

$I_Q = 1.5 \text{ mA}$ over line and load changes

For example, a 500 mA current source would require R to be a 10-ohm, 10-W resistor and the output voltage compliance would be the input voltage less 7 volts.

FIGURE 6 - ADJUSTABLE OUTPUT REGULATOR

$$V_O = 7.0 \text{ V to } 20 \text{ V}$$

$$V_{IN} - V_O \geq 2.0 \text{ V}$$

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 2.0 volts greater than the regulator voltage.

FIGURE 7 - CURRENT BOOST REGULATOR

XX - 2 digits of type number indicating voltage.

The MC78M00B series can be current boosted with a PNP transistor. The MJ2955 provides current to 5.0 amperes. Resistor R in conjunction with the V_{BE} of the PNP determines when the pass transistor begins conducting, this circuit is not short-circuit proof Input-Output differential voltage minimum is increased by V_{BE} of the pass transistor.

FIGURE 8 - SHORT-CIRCUIT PROTECTION

XX - 2 digits of type number indicating voltage

The circuit of Figure 7 can be modified to provide supply protection against short circuits by adding a short-circuit sense resistor, R_{SC} , and an additional PNP transistor. The current sensing PNP must be able to handle the short-circuit current of the three-terminal regulator. Therefore, a two-ampere plastic power transistor is specified.

MC78M00C series

MC78M00C SERIES THREE-TERMINAL POSITIVE VOLTAGE REGULATORS

The MC78M00 Series positive voltage regulators are identical to the popular MC7800C Series devices, except that they are specified for only one-third the output current. Like the MC7800C devices, the MC78M00C three-terminal regulators are intended for local, on-card voltage regulation.

Internal current limiting, thermal shutdown circuitry and safe-area compensation for the internal pass transistor combine to make these devices remarkably rugged under most operating conditions. Maximum output current, with adequate heatsinking is 500 mA.

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Packaged in the Plastic Case 221A and Case 79 (TO-220 and Hermetic TO-39)

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

* = C_{in} is required if regulator is located an appreciable distance from power supply filter.

** = C_O improves stability and transient response.

DEFINITIONS

Line Regulation — The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation — The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation — The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current — That part of the input current that is not delivered to the load.

Output Noise Voltage — The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability — Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

APPLICATIONS INFORMATION

Design Considerations

The MC78M00C Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short-circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected

to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A 0.33 μF or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

FIGURE 5 – CURRENT REGULATOR

The MC7800C regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC7805C is chosen in this application. Resistor R determines the current as follows:

$$I_O = \frac{5 \text{ V}}{R} + I_Q$$

$I_Q = 1.5 \text{ mA}$ over line and load changes

For example, a 500 mA current source would require R to be a 10-ohm, 10-W resistor and the output voltage compliance would be the input voltage less 7 volts.

FIGURE 6 – ADJUSTABLE OUTPUT REGULATOR

V_O , 7.0 V to 20 V
 V_{IN} $V_O \geq 2.0 \text{ V}$

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 2.0 volts greater than the regulator voltage.

FIGURE 7 – CURRENT BOOST REGULATOR

XX = 2 digits of type number indicating voltage.

The MC78M00C series can be current boosted with a PNP transistor. The MJ2955 provides current to 5.0 amperes. Resistor R in conjunction with the V_{BE} of the PNP determines when the pass transistor begins conducting; this circuit is not short-circuit proof. Input-output differential voltage minimum is increased by V_{BE} of the pass transistor.

FIGURE 8 – SHORT-CIRCUIT PROTECTION

XX = 2 digits of type number indicating voltage.

The circuit of Figure 7 can be modified to provide supply protection against short circuits by adding a short-circuit sense resistor, R_{sc} , and an additional PNP transistor. The current sensing PNP must be able to handle the short-circuit current of the three-terminal regulator. Therefore, a two-ampere plastic power transistor is specified.

MC7900C Series

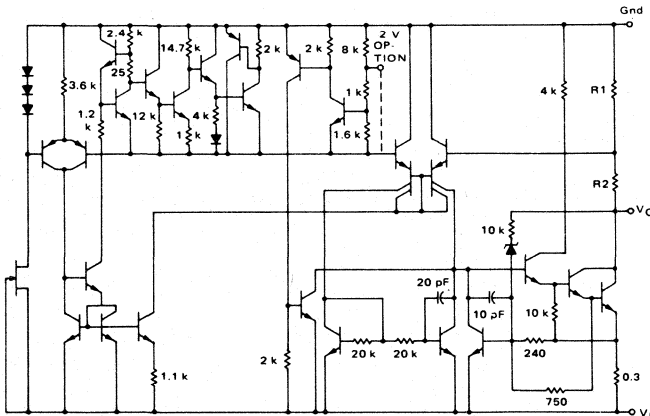

MC7900C SERIES THREE-TERMINAL NEGATIVE VOLTAGE REGULATORS

The MC7900C Series of fixed output negative voltage regulators are intended as complements to the popular MC7800C Series devices. These negative regulators are available in the same seven-voltage options as the MC7800C devices. In addition, two extra voltage options commonly employed in MECL systems are also available in the negative MC7900C Series.

Available in fixed output voltage options from -2.0 to -24 volts, these regulators employ current limiting, thermal shutdown, and safe-area compensation — making them remarkably rugged under most operating conditions. With adequate heat-sinking they can deliver output currents in excess of 1.0 ampere.

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Packaged in the Plastic Case 221A and Case 1 (TO-220 and Hermetic TO-3)

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V more negative even during the high point on the input ripple voltage.

XX = these two digits of the type number indicate voltage.

* = C_{in} is required if regulator is located an appreciable distance from power supply filter.

** = C_o improves stability and transient response.

DEFINITIONS

Line Regulation – The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation – The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation – The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current – That part of the input current that is not delivered to the load.

Output Noise Voltage – The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability – Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

APPLICATIONS INFORMATION

Design Considerations

The MC7900C Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short-circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected

to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A 0.33 μF or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

FIGURE 8 – CURRENT REGULATOR

The MC7902, -2.0 V regulator can be used as a constant current source when connected as above. The output current is the sum of resistor R current and quiescent bias current as follows:

$$I_O = \frac{2 \text{ V}}{R} + I_B$$

The quiescent current for this regulator is typically 4.3 mA. The 2.0 volt regulator was chosen to minimize dissipation and to allow the output voltage to operate to within 6.0 V below the input voltage.

FIGURE 9 – CURRENT BOOST REGULATOR
(-5.0 V @ 4.0 A, with 5.0 A current limiting)

*Mounted on common heat sink, Motorola MS-10 or equivalent.

When a boost transistor is used, short-circuit currents are equal to the sum of the series pass and regulator limits, which are measured at 3.2 A and 1.8 A respectively in this case. Series pass limiting is approximately equal to 0.6 V/R_{SC}. Operation beyond this point to the peak current capability of the MC7905C is possible if the regulator is mounted on a heat sink; otherwise thermal shutdown will occur when the additional load current is picked up by the regulator.

FIGURE 10 – OPERATIONAL AMPLIFIER SUPPLY
($\pm 15 \text{ V} @ 1.0 \text{ A}$)

The MC7815 and MC7915 positive and negative regulators may be connected as shown to obtain a dual power supply for operational amplifiers. A clamp diode should be used at the output of the MC7815 to prevent potential latch-up problems.

FIGURE 11 – TYPICAL MECL SYSTEM POWER SUPPLY
(-5.2 V @ 4.0 A and -2.0 V @ 2.0 A; for PC Board)

When current-boost power transistors are used, 47-ohm base-to-emitter resistors (R) must be used to bypass the quiescent current at no load. These resistors, in conjunction with the V_{BE} of the NPN transistors, determine when the pass transistors begin conducting. The 1-ohm and 4-ohm dropping resistors were chosen to reduce the power dissipated in the boost transistors but still leave at least 2.0 V across these devices for good regulation.

MC79L00C, AC series

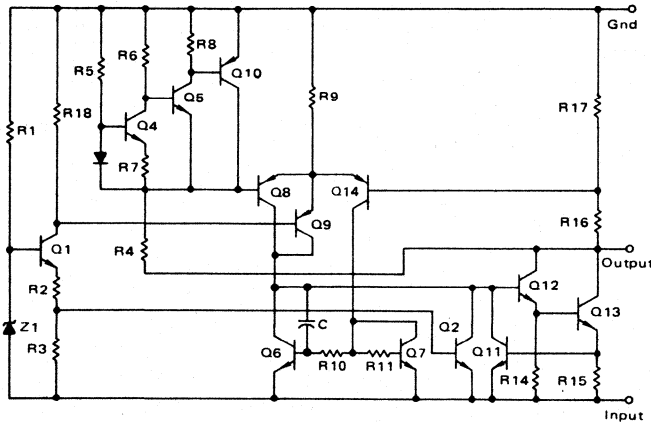

THREE-TERMINAL NEGATIVE VOLTAGE REGULATORS

The MC79L00 Series negative voltage regulators are inexpensive, easy-to-use devices suitable for numerous applications requiring up to 100 mA. Like the higher powered MC7900 Series negative regulators, this series features thermal shutdown and current limiting, making them remarkably rugged. In most applications, no external components are required for operation.

The MC79L00 devices are useful for on-card regulation or any other application where a regulated negative voltage at a modest current level is needed. These regulators offer substantial advantage over the common resistor/zener diode approach.

- No External Components Required
- Internal Short-Circuit Current Limiting
- Internal Thermal Overload Protection
- Low Cost
- Complementary Positive Regulators Offered (MC78L00 Series)
- Available in Either $\pm 5\%$ (AC) or $\pm 10\%$ (C) Selections

STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

* = C_1 is required if regulator is located an appreciable distance from power supply filter.

** = C_0 improves stability and transient response.

APPLICATIONS INFORMATION

Design Considerations

The MC79L00C Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short-Circuit Protection that limits the maximum current the circuit will pass.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be

selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33\text{ }\mu\text{F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

CURRENT REGULATOR

The MC79L03, -3.0 V regulator can be used as a constant current source when connected as above. The output current is the sum of resistor R current and quiescent bias current as follows:

$$I_O = \frac{3\text{ V}}{R} + I_B$$

The quiescent current for this regulator is typically 3.8 mA. The -3.0 volt regulator was chosen to minimize dissipation and to allow the output voltage to operate to within 6.0 V below the input voltage.

Advance Information

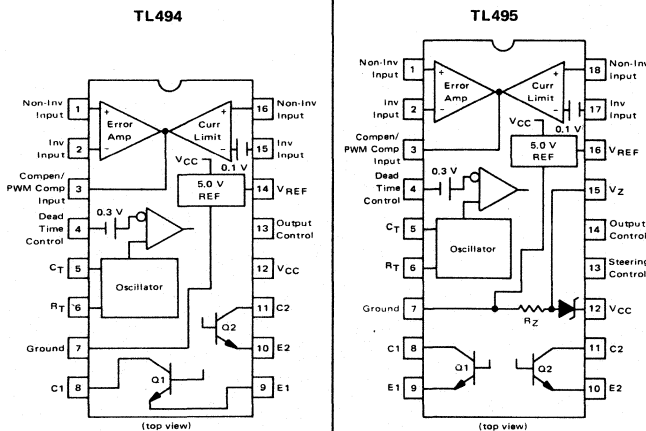

SWITCHMODE PULSE WIDTH MODULATION CONTROL CIRCUITS

The TL494 and TL495 combine the best features of existing PWM control circuits and add other on-chip functions. These devices provide, on a single monolithic chip, all the control circuitry for PWM push-pull, bridge and series type switchmode power supplies.

The TL494M/495M are specified over the military operating range of -55°C to $+125^{\circ}\text{C}$. The TL494C/495C are specified from 0°C to $+70^{\circ}\text{C}$.

- Uncommitted Output Transistors Capable of 250 mA Source or Sink
- On-Chip Error Amplifier and Current Limit Sense Amplifier
- On-Chip 5 V Reference
- Internal Protection from Double Pulsing of Outputs with Narrow Pulse Widths or with Supply Voltages below Specified Limits
- Dead Time Control Comparator
- Pulse-Steering Flip-Flop and Output Control Circuitry
- Easily Synchronized (Slaved) to Other Circuits
- On-Chip 39 V Zener for High Voltage ($V_{IN} > 40\text{ V}$) Applications (TL495 only)
- Output Steering Control Pin Overrides Internal Pulse Steering Flip-Flop (TL495 only)

THERMAL INFORMATION

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature, can be found from the equation:

$$P_D(T_A) = \frac{T_{J(max)} - T_A}{R_{\theta JA}(Typ)} \geq I_C V_{CC}$$

Where: $P_D(T_A)$ = Power Dissipation allowable at a given operating ambient temperature.

$T_{J(max)}$ = Maximum Operating Junction Temperature as listed in the Maximum Ratings Section
 T_A = Maximum Desired Operating Ambient Temperature
 $R_{\theta JA}(Typ)$ = Typical Thermal Resistance Junction to Ambient
 I_C = Total Sink Current
 V_{CC} = Supply Voltage

Advance Information

DUAL INDEPENDENT DIFFERENTIAL AMPLIFIER

The CA3054 consists of two independent differential amplifiers with associated constant-current transistors on a common monolithic substrate. The six NPN transistors which comprise the amplifiers are general purpose devices useful from dc to 120 MHz.

The monolithic construction of the CA3054 provides close electrical and thermal matching of the amplifiers which makes this device particularly useful in dual channel applications where matched performance of the two channels is required.

- Two differential amplifiers on a common substrate
- Independently accessible inputs and outputs
- Maximum input offset voltage – ± 5 mV

DESIGN CONSIDERATIONS

The MC1306P provides the designer with a means to control preamplifier gain, power amplifier gain, input impedance, and frequency response. The following relationships will serve as guides.

1. Gain

The Preamplifier Stage Voltage Gain is:

$$A_{VA} \approx \frac{R_f}{R_s}$$

and is limited only by the open-loop gain (270 V/V). For good preamplifier dc stability R_f should be no larger than 1.0-megohm.

The Power Amplifier Voltage Gain is controlled in a similar manner where:

$$A_{VB} \approx \frac{10\text{ k}}{R_p}$$

The 10-k ohm feedback resistor is provided in the integrated circuit.

Recommended values of R_p range from 500-ohms to 3.3-k ohms. The low end is limited primarily by low-level distortion and the upper end is limited due to the voltage drive capabilities of the pre-amplifier. (A resistor can be added in the dc feedback loop, from pin 6 to ground, to increase this drive). The Overall Voltage Gain, then, is:

$$A_{VT} = \frac{R_f 10\text{ k}}{R_s R_p}$$

2. Input Impedance

The Preamplifier Input Impedance is:

$$Z_{inA} \approx R_s$$

and the Power Amplifier Input Impedance is:

$$Z_{inB} \approx R_p$$

3. Frequency Response

The low frequency response is controlled by the cumulative effect of the series coupling capacitors C1, C2, and C3. High-frequency response can be determined by the feedback capacitor, C_f , and the -3.0 dB point occurs when

$$X_{C_f} = R_f$$

Additional high frequency roll-off and noise reduction can be achieved by placing a capacitor from the center point of R_p to ground as shown in Figure 10.

Capacitor C4 and the RC network shown in dotted lines may be needed to prevent high frequency parasitic oscillations. The RF choke, shown in series with the output, and capacitor C6 are used to prevent the high-frequency components in a large-signal clipped audio output waveform from radiating into the RF or IF sections of a radio (Figure 10).

4. Battery Operation

The increase of battery resistance with age has two undesirable effects on circuit performance. One effect is the increasing of amplifier distortion at low signal levels. This is readily corrected by increasing the size of the filter capacitor placed across the battery (as shown in Figure 8; a 300- μ F filter capacitor gives distortions at low-tonal levels that are comparable to the "stiff" supply). The second effect of supply impedance is a lowering of power output capability for steady signals. This condition is not correctable, but is of questionable importance for music and voice signals.

5. Application Examples: (1) The audio section of the AM-FM radio (Figure 1) is adjusted for a preamplifier gain of 100 with an input impedance of 10-k ohms. The power amplifier gain is set at 10, which gives an overall voltage gain of 1000. The bandwidth has been set at 10-kHz. (2) The phono amplifier (Figure 2) is designed for a preamplifier gain of unity and a power amplifier gain of 10. The input impedance is 1.0-megohm. An adjustable treble control is provided within the feedback loop.

FIGURE 5 – CHANNEL SEPARATION versus VCO FREE-RUNNING FREQUENCY

FIGURE 6 – CHANNEL SEPARATION versus SUPPLY VOLTAGE

FIGURE 7 – THD versus COMPOSITE INPUT LEVEL*

FIGURE 8 – DISTORTION versus FREQUENCY*

*Measured with Low Pass Filter (BW = 15 kHz).

CIRCUIT OPERATION

Figure 13, on the previous page, shows the system block diagram. The upper line, comprising the 38-kHz regeneration loop operates as follows: the internal oscillator running at 76-kHz and feeding through two divider stages returns a 19-kHz signal to the input modulator. There the returned signal is multiplied with the incoming signal so that when a 19-kHz pilot tone is received a dc component is produced. The dc component is extracted by the low pass filter and used to control the frequency of the internal oscillator which consequently becomes phase-locked to the pilot tone. With the oscillator phase-locked to the pilot the 38-kHz output from the first divider is in the correct phase for decoding a stereo signal. The decoder is essentially another modulator in which the incoming signal is multiplied by

the regenerated 38-kHz signal. The regenerated 38-kHz signal is fed to the stereo decoder via an internal switch, which closes when a sufficiently large 19 kHz pilot tone is received.

The 19-kHz signal returned to the 38-kHz regeneration loop modulator is in quadrature with the 19-kHz pilot tone when the loop is locked. With the third divider state appropriately connected, a 19-kHz signal in phase with the pilot tone is generated. This is multiplied with the incoming signal in the stereo switch modulator yielding a dc component proportional to the pilot tone amplitude. This component after filtering is applied to the trigger circuit which activates both the stereo switch and an indicator lamp.

APPLICATIONS INFORMATION

(Component numbers refer to Figure 1)

External Component Functions and Values

- C1 Input coupling capacitor; 2.0 μ F is recommended but a lower value is permissible if reduced separation at low frequencies is acceptable.
- R1, R2, C2, C3 See Maximum Load Resistance section.
- C4 Filter capacitor for stereo switch level detector; time constant is $C4 \times 53$ kilohms $\pm 30\%$, maximum dc voltage appearing across C4 is 0.25 V (pin 8 positive) at 100 mV(RMS) pilot level. The signal voltage across C4 is negligible.
- C5 See Phase Compensation section.
- R3, C6, C8 Phase-locked loop filter components; the following network is recommended:

When less performance is required a simpler network consisting of $R3 = 100$ ohms and $C6 = 0.25 \mu F$ may be used (omit C8). See Figure 9.

- R4, R5, C7 Oscillator timing network; recommended values:
 C7 = 470 pF 1%
 R4 = 16 k Ω 1%
 R5 = 5 k Ω Preset

These values give $\pm 3.5\%$ typical capture range. Capture range may be increased by reducing C7 and increasing R4, R5 proportionally but at the cost of increasing beat-note distortion (due to oscillator-phase jitter) at high-signal levels. See Figure 12.

- Stereo Lamp Nominal rating up to 75 mA at 12 V; the circuit includes surge limiting which restricts cold-lamp current to approximately 250 mA.
- 19-kHz Output A buffer output providing a 3.0-V_{pk} square wave at 19 kHz is available at pin 10. A frequency counter may be connected to this point to measure the oscillator free-running frequency for alignment. See Alignment section.

External Monaural/Stereo Switching

If it is desired to maintain the circuit in monaural mode, the following procedure must be followed. First, the stereo switch must be disabled to prevent false lamp triggering. This can be accomplished by connecting pin 8 negative or pin 9 positive by 0.3 volt. Pin 8 may be grounded directly if desired. Note that the voltage across C4 increases to approximately 2 volts with pin 9 positive when pin 8 is grounded.

Second, the 76-kHz oscillator must be killed to prevent interference when on AM. This can be accomplished by connecting pin 14 to ground via a current limiting resistor (3.3 kilohms is recommended).

Phase Compensation/IF Roll-off Compensation

Phase-shifts in the circuit cause the regenerated 38-kHz sub-carrier to lead the original 38 kHz by approximately 2° . The coupling capacitor C5 generates an

APPLICATIONS INFORMATION (continued)

additional lead of 3.5° (for $C5 = 0.05 \mu F$) giving a total lead of 5.5° .

The circuit is so designed that phase lag may be generated by adding a capacitor from pin 3 to ground. The source resistance at this point is 500 ohms. A capacitance of 820 pF compensates the 5.5° phase lead: increase above this value causes the regenerated sub-carrier to lag the original. However, a 5.5° phase error if left noncompensated will not degrade separation appreciably.

Note that these phase shifts occur within the phase-locked loop and affect only the regenerated 38-kHz sub-carrier: the circuit causes no significant phase or amplitude variation in the actual stereo signal prior to decoding.

Most IF amplifiers have a frequency response that limits separation to a value significantly lower than the capability of the MC1310. For example, if the response produces a 1-dB roll-off at 38 kHz, the separation will be limited to about 32 dB. This error can be compensated by using an RC lead network as shown in Figure 14. The exact values will be determined by the IF amplifier design. However, the values shown in Figure 14 are suitable for use with the MC1357 and MC1375 IF amplifiers.

FIGURE 14 – IF COMPENSATION NETWORK

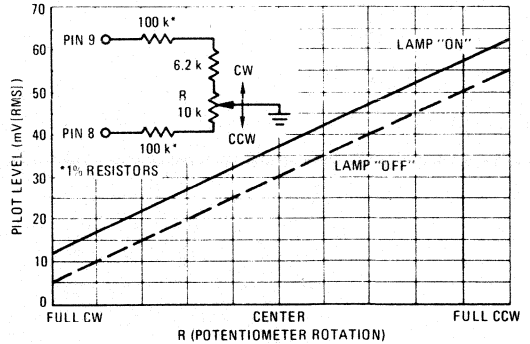

Voltage Control Oscillator Compensation

Figure 10 illustrates noncompensated Oscillator Drift versus temperature. The recommended T_C of the R4, R5, C7 combination is -300 PPM. This will hold the oscillator drift to approximately $\pm 1\%$ over a temperature range of -40 to $+85^\circ C$. Allowing $\pm 2\%$ for aging of the timing components acceptable performance is still obtained.

Lamp Sensitivity

It may be desirable in some cases, to change the lamp sensitivity due to differing signal levels produced by various FM detectors. The lamp sensitivity can be changed by making use of the external circuit shown. Typical sensitivities versus potentiometer rotation are also shown in Figure 15.

FIGURE 15 – PILOT SENSITIVITY versus POTENTIOMETER ROTATION

Alignment Procedure

The optimum alignment procedure, with no input signal applied, is to adjust R5 until 19.00 kHz is read at pin 10 on the frequency counter.

Another procedure requiring no equipment, other than the receiver itself, will result in separation of within a few dB of optimum. This latter method is merely to tune the receiver to a stereo broadcast and adjust R5 until the pilot lamp turns "on". To find the center of the lock-in range, rotate the potentiometer back and forth until the center of the lamp "on" range is found. This completes the alignment.

Alternate Timing Network

The alternate timing network shown, incorporating a trimmer capacitor rather than a potentiometer, may be used if desired. Again, to provide correct temperature compensation, the temperature coefficient of the timing network must be approximately -300 PPM.

FIGURE 16

Maximum Load Resistance

The curve shown gives absolute maximum load resistance values versus supply voltage used for full-signal handling capability. With desired load resistance choose C2, C3 capacitors to provide standard $75 \mu s$ de-emphasis.

APPLICATIONS INFORMATION (continued)

FIGURE 17 – MAXIMUM LOAD RESISTANCE versus SUPPLY VOLTAGE

Audio Output

The ratio $G = \frac{\text{p-p audio output (one-channel)}}{\text{p-p input signal}}$ for

different types of input is as follows:

INPUT	
Single-Channel	Monaural
Composite Signal	Signal
0.45	0.5

These figures are for 3.9-kilohm load resistors and for low-audio frequencies where de-emphasis roll-off is insignificant.

Capture Range versus Timing Components

The capture range can be changed to some extent by use of different timing components. Typical values are shown in Figure 12.

Composite Signal

Due to confusion concerning the measurement of the stereo composite signal, a curve showing both RMS and p-p composite levels versus pilot level follows, see Figure 18.

FIGURE 18 – COMPOSITE LEVEL versus PILOT (L or R Modulation Only)

LOW-LEVEL VIDEO DETECTOR

... an integrated circuit featuring very linear video characteristics and wide bandwidth. Designed for color and monochrome television receivers, replacing the third IF, detector, video buffer and AFC buffer.

- Conversion Gain – 33 dB (Typ)
- Excellent Differential Phase and Gain
- High Rejection of IF Carrier Feedthrough
- High Video Output – 8.0 V(p-p)
- Fully Balanced Detector
- Output Temperature Compensated
- Improved Versions of the MC1330P

**LOW-LEVEL VIDEO
DETECTOR**
**SILICON MONOLITHIC
INTEGRATED CIRCUIT**

PLASTIC PACKAGE
CASE 626

CIRCUIT DESCRIPTION

The MC1330A video detector is a fully balanced multiplier detector circuit that has linear amplitude and phase characteristics. The signal is divided into two channels, one a linear amplifier and the other a limiting amplifier that provides the switching carrier for the detector.

The switching carrier has a buffered output for use in providing the AFT function.

The video amplifier output is an improved design that reduces the differential gain and phase distortion associated with previous video output systems. The output is wide band, > 8.0 MHz, with normal negative polarity. A separate narrow bandwidth, positive video output is also provided.

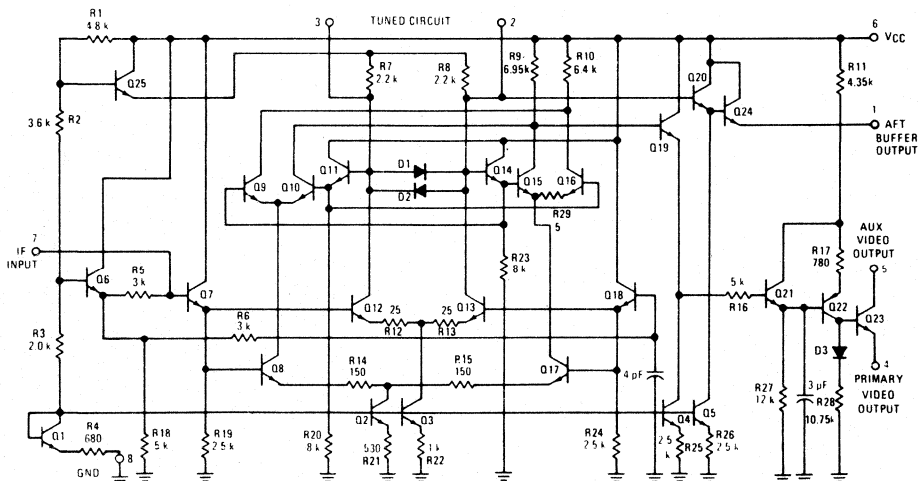

OUTPUT VOLTAGE SELECTION

The MC1330A1P is identical to the MC1330A2P with the following exception:

ZERO SIGNAL DC
OUTPUT VOLTAGE

MC1330A1P	7.0 to 8.2 Vdc
MC1330A2P	7.8 to 9.0 Vdc

TV-IF Amplifier Information

A very compact high performance IF amplifier constructed as shown in Figure 14 minimizes the number of overall components and alignment adjustments. It can be readily combined with normal tuners and input tuning-trapping circuitry to provide the performance demanded of high quality receivers. This configuration will provide approximately 93 dB voltage gain and can accommodate the usual low impedance input network or, if desired, can take advantage of an impedance step-up from tuner to MC1349P input.

The burden of selectivity, formerly found between the third IF and detector, must now be placed at the interstage. The nominal 3 volt peak-to-peak output can be varied from 0 to 7.0 V with excellent linearity and freedom from spurious output products.

Alignment is most easily accomplished with an AM generator, set at a carrier frequency of 45.75 MHz, modulated with a video frequency sweep. This provides the proper realistic conditions necessary to operate to low-level detector (LLD). The detector tank is first adjusted for maximum detected dc (with a CW input), next, the video sweep modulation is applied and the interstage and input circuits aligned, step by step, as in a standard IF amplifier.

Note: A normal IF sweep generator, essentially an FM generator, will not serve properly without modification. The LLD tank attempts to "follow" the sweep input frequency, and results in variations of switching amplitude in the detector. Hence, the apparent overall response becomes modified by the response of the LLD tank, which a real signal doesn't do.

This effect can be prevented by resistively adding a 45.75 MHz CW signal to the output of the sweep generator approximately 3 dB greater than the sweep amplitude. See Figures 12 and 13 below. For a more detailed description of the MC1330AP see application note AN-545.

MC1330A General Information

The MC1330A offers the designer a new approach to an old problem. Now linear detection can be performed at

much lower power signal levels than possible with a detector diode.

Offering a number of distinct advantages, its easy implementation should meet with ready acceptance for television designs. Some specific features and information on systems design with this device are given below:

1. The device provides excellent linearity of output versus input, as shown in Figures 6 and 7. These graphs also show that video peak-to-peak amplitude (ac) does not change with supply voltage variation. (Slopes are parallel. Visualize a given variation of input CW and use the figure as a transfer function.)

2. The dc output level does change linearly with supply voltage shown in Figure 8. This can be accommodated by regulating the supply or by referencing the subsequent video amplifier to the same power supply.

3. The choice of Q for the tuned circuit of pins 2 and 3 is not critical. The higher the Q, the better the rejection of 920 kHz products but the more critical the tuning accuracy required. See Figure 11. Values of Q from 20 to 50 are recommended. (Note the internal resistance.)

4. A video output with positive-going sync is available at pin 5 if required. This signal has a higher output impedance than pin 4 so it must be handled with greater care. If not used, pin 5 may be connected directly to the supply voltage (pin 6). The video response will be altered somewhat. See Figure 10.

5. An AFT output (pin1) provides 460 mV of IF carrier output, sufficient voltage to drive an AFT ratio detector, with only one additional stage.

6. AGC lockout can occur if the input signal presented in the MC1330A is greater than that shown in the input overload section of the design characteristics shown on Page 3. If these values are exceeded, the turns ratio between the primary and secondary of T₁ should be increased. Another solution to the problem is to use an input clamp diode D₁ shown in Figure 14.

7. The total I.F. noise figure at high gain reductions can be improved by reflecting ≈ 1 k source impedance to the input of the MC1330AP. This will cause some loss in overall IF voltage gain.

FIGURE 2 – CIRCUIT SCHEMATIC

GENERAL INFORMATION

The MC1349P is an improved version of the MC1350P. Featuring higher gain, a lower noise figure, and greater AGC range; in addition, an emitter of the input amplifier is available for bypassing. This provides a low input impedance with good gain, useful for untuned input configurations.

Both input and output IF amplifier sections are gain-controlled in the MC1349P, with the input amplifier also serving as an AGC amplifier for the output section. During the initial part of AGC gain reduction, the gain of the input amplifier decreases only a few dB while the output section decreases 15 dB; further AGC acts upon the input section. Although the gain reduction curve was taken with 5.1 kilohms at pin 5, higher series resistance can be used to reduce the voltage and temperature sensitivity of the AGC. Pin 5 currents are shown on the AGC curve, see Figure 10.

In use, it is important to bypass pin 2, both for IF frequencies

and for low frequencies, (as shown in the test circuits). This is due to the dual function of the input amplifier. If replacing MC-1350P take precaution not to ground pin 3, (not used in the MC1350P). Due to the significantly higher gain of the MC1349P, extra care in layout should be exercised.

NOTE 1: The references to bypasses at pin 3 do not give specific values (C4, see Figures 1 and 4). In all cases, measurements were taken with a bypass at a standard value as near as possible to series resonance. The values are dependent on test frequency and circuit layout. Fully bypassing pin 3 reduces the input signal handling capability before distortion from over 100 mV(RMS) to approximately 25 mV(RMS). C4 = 0.002 μF at f = 45 MHz is a typical value for printed circuit applications.

GENERAL OPERATING INFORMATION

The input amplifiers (Q1 and Q2) operate at constant emitter currents so that input impedance remains independent of AGC action. Input signals may be applied single-ended or differentially (for ac) with identical results. Terminals 4 and 6 may be driven from a transformer, but a dc path from either terminal to ground is not permitted.

AGC action occurs as a result of an increasing voltage on the base of Q4 and Q5 causing these transistors to conduct more heavily thereby shunting signal current from the interstage amplifiers Q3 and Q6. The output amplifiers are supplied from an active current source to maintain constant quiescent bias thereby holding output admittance nearly constant. Collector voltage for the output amplifier must be supplied through a center-tapped tuning coil to Pins 1 and 8. The 12-volt supply (V^+) at Pin 2 may be used for this purpose, but output admittance remains more nearly constant if a separate 15-volt supply (V^{++}) is used, because the base voltage on the output amplifier varies with AGC bias.

CIRCUIT OPERATION

The MC1391P and MC1394P contain the oscillator, phase detector and predriver sections needed for a television horizontal APC loop.

The oscillator is an RC type with one pin (Pin 7) used to control the timing. The basic operation can be explained easily. If it is assumed that Q7 is initially off, then the capacitor connected from Pin 7 to ground will be charged by an external resistor (R_C) connected to Pin 6. As soon as the voltage at Pin 7 exceeds the potential set at the base of Q8 by resistors R8 and R10, Q7 will turn on and Q6 will supply base current to Q5 and Q10. Transistor Q10 will set a new, lower potential at the base of Q8 determined by R8, R9 and R10. Then, transistor Q5 will discharge the capacitor through R4 until the base bias of Q7 falls below that of Q8, at which time Q7 will turn off and the cycle repeats.

The sawtooth generated at the base of Q4 will appear across R3 and turn off Q3 whenever it exceeds the bias set on Pin 8. By adjusting the potential at Pin 8, the duty cycle (MSR) at the predriver output pin (Pin 1) can be changed to accommodate either

tube or transistor horizontal output stages.

The phase detector is isolated from the remainder of the circuit by R14 and Z2. The phase detector consists of the comparator Q15, Q16 and the gated current source Q17. Negative going sync pulses at Pin 3 turn off Q12 and the current division between Q15 and Q16 will be determined by the phase relationship of the sync and the sawtooth waveform at Pin 4, which is derived from the horizontal flyback pulse. If there is no phase difference between the sync and sawtooth, equal currents will flow in the collectors of Q15 and Q16 each for half the sync pulse period. The current in Q15 is turned around by Q18 so that there is no net output current at Pin 5 for balanced conditions. When a phase offset occurs, current will flow either in or out of Pin 5. This pin is connected via an external low-pass filter to Pin 7, thus controlling the oscillator.

Shunt regulation for the circuit is obtained with a zero temperature coefficient from the series combination of D1, D2 and Z1.

MC1391P

APPLICATION INFORMATION

Although it is an integrated circuit, the MC1391P and MC1394P have all the flexibility of a conventional discrete component horizontal APC loop.

The internal temperature compensated voltage regulator allows a wide supply voltage variation to be tolerated, enabling operation from nonregulated power supplies. A minimum value for supply current into Pin 6 to maintain zener regulation is about 18 mA. Allowing 2mA for the external dividers

$$R_A + R_B = \frac{V_{\text{nonreg(min)}} - 8.8}{20 \times 10^{-3}}$$

Components R_A , R_B and C_A are used for ripple rejection. If the supply voltage ripple is expected to be less than 100 mV (for a 30 Volt supply) then R_A and R_B can be combined and C_A omitted.

The output pulse width can be varied from 6 μ s to 48 μ s by changing the voltage at Pin 8 (see Figure 5). However, care should be taken to keep the lead lengths to Pin 8 as short as possible to prevent ringing which can result in erroneous output pulses at Pin 1. The parallel impedance of R_D and R_E should be close to 1 k Ω to ensure stable pulse widths.

For 15 mA drive at saturation

$$R_F = \frac{V_{\text{nonreg}} - 0.3}{15 \times 10^{-3}}$$

The oscillator free-running frequency is set by R_C and C_B connected to Pin 7. For values of $R_C \gg R_{\text{discharge}}$ (R_4 in Figure 6), a useful approximation for the free-running frequency is

$$f_0 = \frac{1}{0.6 R_C C_B}$$

Proper choice of R_C and C_B will give a wide range of oscillator frequencies — operation at 31.5 kHz for count-down circuits is possible for example. As long as the product $R_C C_B \approx 10^{-4}$ many combinations of values of R_C and C_B will satisfy the free-running frequency requirement of 15.734 kHz. However, the sensitivity of the oscillator (β) to control-current from the phase detector is directly dependent on the magnitude of R_C , and this provides a

convenient method of adjusting the dc loop gain (f_c).

For a given phase detector sensitivity (μ) = 1.60×10^{-4} A/rad

$$f_c = \mu\beta \text{ and } \beta = 3.15 \times R_C \text{ Hz/mA}$$

Increasing R_C will raise the dc loop gain and reduce the static phase error (S.P.E.) for a given frequency offset. Secondary effects are to increase the natural resonant frequency of the loop (ω_n) and give a wider pull-in range from an out-of-lock condition. The loop will also tend to be underdamped with fast pull-in times, producing good airplane flutter performance. However, as the loop becomes more underdamped impulse noise can cause shock excitation of the loop. Unlimited increase in the dc loop gain will also raise the noise bandwidth excessively causing horizontal jitter with thermal noise. Once the dc loop gain has been selected for adequate S.P.E. performance, the loop filter can be used to produce the balance between other desirable characteristics. Damping of the loop is achieved most directly by changing the resistor R_X with respect to R_Y which modifies the ac/dc gain ratio (m) of the loop. Lowering this ratio will reduce the pull-in range and noise bandwidth (f_{nn}). (Note: very large values of R_Y will limit the control capability of the phase detector with a corresponding reduction in hold-in range).

Static phasing can be adjusted simply by adding a small resistor between the flyback pulse integrating capacitor and ground. The sync coupling capacitor should not be too small or it can charge during the vertical pulse and this may result in picture bends at the top of the CRT.

NOTE:

In adjusting the loop parameters, the following equations may prove useful:

$$f_{nn} = \frac{1 + \chi^2 T \omega_c}{4 \chi T}$$

$$\chi = \frac{R_X}{R_Y}$$

$$\omega_n = \sqrt{\frac{\omega_c}{(1 + \chi) T}}$$

$$\omega_c = 2 \pi f_c$$

$$T = R_Y C_C$$

$$K = \frac{\chi^2 T \omega_c}{4}$$

where:

K = loop damping coefficient

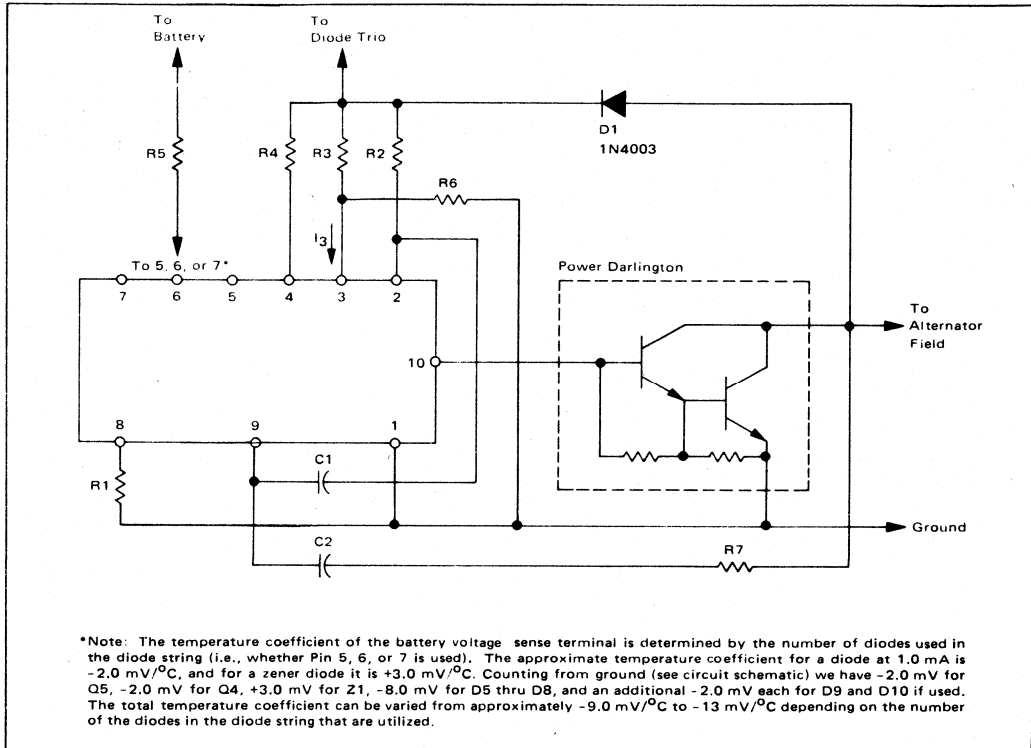

FIGURE 5 – APPLICATION CIRCUIT

APPLICATIONS CIRCUIT INFORMATION
(See Figure 5)

- R1 Determines the temperature coefficient by setting the value of current in the diode string. As the value of R1 decreases, so does the effective TC. R1 should be chosen so that the current in the diode string is between 0.5 mA and 1.0 mA.
- R5 This resistor determines the V_{reg} voltage as defined by the following equation:

$$V_{reg} = (1 + \frac{R5}{R1}) 8.4 + (n + \frac{R5}{5k}) (0.7)$$

$$n = \text{number of diodes used in diode string}$$

$$(4 \leq n \leq 6)$$
- R4 Used as a current limiting resistor on Pin 4 in case of an open battery voltage sense lead.
- R3 Used as a current limiting resistor on Pin 3 in case of overvoltage at the diode trio. Voltage at Pin 3 will run approximately 7.5 volts. R3 should be chosen so that the current (I_3) at maximum overvoltage is between 2.0 mA and 6.0 mA.

- R2 This resistor determines the output drive current. Refer to specifications for the darlington driver and select the value for R2 that will provide enough drive to the output when the diode trio voltage is at a minimum.

$$I_{Drive} \cong \frac{V_{min} - 2.8 V}{R2 + 50 \Omega}$$
- R6 This resistor in conjunction with R3 is used to set the maximum overvoltage.

$$\text{Maximum overvoltage} \cong \frac{R3 + R6}{R6} (7.5)$$
- R7 Used for compensation (Approximately 3.0 kΩ)
- C1, C2 Used for compensation (Approximately 0.01 μF)

CIRCUIT DESCRIPTION

The MC3357 is a low power FM IF circuit designed primarily for use in voice communication scanning receivers.

The mixer-oscillator combination converts the input frequency (e.g., 10.7 MHz) down to 455 kHz, where, after external bandpass filtering, most of the amplification is done. The audio is recovered using a conventional quadrature FM detector. The absence of an input signal is indicated by the presence of noise above the desired audio frequencies. This "noise band" is monitored by an active filter and a detector. A squelch trigger circuit indicates the presence of noise (or a tone) by an output which can be used to control scanning. At the same time, an internal switch is operated which can be used to mute the audio.

The oscillator is an internally-biased Colpitts type with the collector, base, and emitter connections at pins 4, 1, and 2 respectively. A crystal can be used in place of the usual coil.

The mixer is doubly-balanced to reduce spurious responses. The input impedance at pin 16 is set by a 3 k Ω internal biasing resistor and has low capacitance, allowing the circuit to be preceded by a crystal filter. The collector output at pin 3 must be dc connected to B+, below which it can swing 0.5 V.

After suitable bandpass filtering (ceramic or LC) the signal goes to the input of a five-stage limiter at pin 5.

The output of the limiter at pin 7 drives a multiplier, both internally directly, and externally through a quadrature coil, to detect the FM. The output at pin 7 is also used to supply dc feedback to pin 5. The other side of the first limiter stage is decoupled at pin 6.

The recovered audio is partially filtered, then buffered giving an impedance of around 400 Ω at pin 9. The signal still requires de-emphasis, volume control and further amplification before driving a loudspeaker.

A simple inverting op amp is provided with an output at pin 11 providing dc bias (externally) to the input at pin 10 which is referred internally to 2 V. A filter can be made with external impedance elements to discriminate between frequencies. With an external AM detector the filtered audio signal can be checked for the presence of noise above the normal audio band, or a tone signal. This information is applied to pin 12.

An external positive bias to pin 12 sets up the squelch trigger circuit such that pin 13 is low at an impedance level of around 60 k Ω , and the audio mute (pin 14) is open circuit. If pin 12 is pulled down to 0.7 V by the noise or tone detector, pin 13 will rise to approximately 0.5 Vdc below supply where it can support a load current of around 500 μ A and pin 14 is internally short-circuited to ground. There is 100 mV of hysteresis at pin 12 to prevent jitter. Audio muting is accomplished by connecting pin 14 to a high-impedance ground-reference point in the audio path between pin 9 and the audio amplifier.

MC3393P

Advance Information

TWO MODULUS PRESCALER

The MC3393P can divide by 15 and 16, and can be used with Motorola CMOS frequency synthesizers MC145146, 52, 56 for commercial AM-FM radio, land mobile and marine two-way radios, avionic radios, and scanner receivers.

TEST CIRCUITS

APPLICATIONS CIRCUIT INFORMATION

R1 Determines the temperature coefficient by setting the value of current in the diode string. As the value of R1 decreases, so does the effective TC. R1 should be chosen so that the current in the diode string is between 0.5 mA and 1.0 mA.

R5 This resistor determines the V_{reg} voltage as approximated by the following equation:

$$V_{reg} \cong \left(1 + \frac{R5}{R1}\right) 8.4 + n(0.7)$$

n = number of diodes used in diode string = 6

R4 Used as a current limiting resistor on pin 4 in case of overvoltage at the diode trio, or an open battery voltage sense lead. Voltage at pin 4 will run approximately 8.6 volts. R4 should be chosen so that the current (I_4) at maximum overvoltage is between 2 mA and 6 mA.

R3 This resistor determines the output drive current. Refer to specifications for the Darlington driver and select the value for R3 that will provide enough drive to the output when the diode trio voltage is at a minimum.

$$I_{Drive} \cong \frac{V_{min} - 2.8 V}{R3 + 10 \Omega}$$

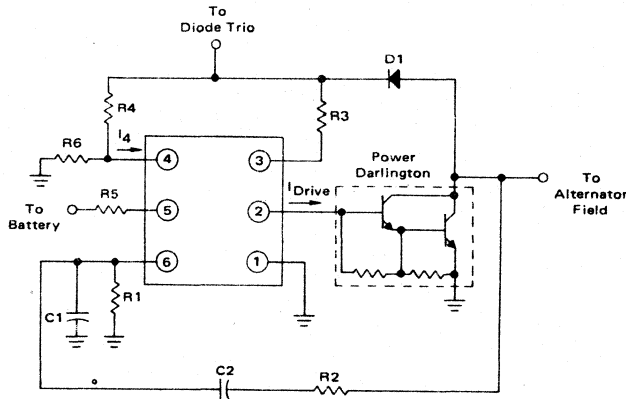

R6 This resistor in conjunction with R4 is used to set the maximum overvoltage

$$\text{Maximum Overvoltage} = \frac{R4 + R6}{R6} \quad (8.6)$$

R2 Used for compensation (Approximately 3 k Ω)

C1, C2 Used for compensation (Approximately 0.01 μ F)

FIGURE 5 - APPLICATIONS CIRCUIT

BONDING DIAGRAM AND DEVICE DIMENSIONS

PACKAGING AND HANDLING

The flip-chip consists of a silicon chip with solder bumps on the geometry surface to provide easy mechanical mounting and electrical connection. These devices are protected by a thin layer of phosphorsilicate passivation which covers the interconnect metalization and active areas of the die.

Care must be exercised when removing the dice from the shipping carrier to avoid scratching the solder bumps. A vacuum pickup is useful for the handling of dice. Tweezers are not recommended for this purpose.

The non-spill type shipping carrier consists of a compartmentalized tray and fitted cover. Die are placed in the carrier with geometry side up.

MCCF3333

FLIP-CHIP VARI-DWELL IGNITION CIRCUIT

... designed for use in conjunction with a flux averaging sensor and a high energy ignition coil to provide regulated current pulses to the coil from information supplied by the sensor.

- Wide Supply Voltage Operating Range (4 to 24 V)
- Externally Adjustable Overvoltage Shutdown
- Externally Adjustable Dwell Time and Spark Energy
- Extremely Stable Output Current Pulses
- Variable Input Threshold Compensates for Low Supply Voltage Conditions
- Low Static Current Drain
- Also Available in Plastic Package (MC3333P) and Standard Chip (MCC3333) Form

PACKAGING AND HANDLING

The flip-chip consists of a silicon chip with solder bumps (90-10 solder on a chrome-copper-gold base) on the geometry surface to provide easy mechanical mounting and electrical connection. These devices are protected by a thin layer of phosphosilicate passivation which covers the interconnect metallization and active areas of the die.

Care must be exercised when removing the dice from the shipping carrier to avoid scratching the solder bumps. A vacuum pickup is useful for the handling of dice. Tweezers are not recommended for this purpose.

The non-spill type shipping carrier consists of a compartmentalized tray and fitted cover. Dice are placed in the carrier with geometry side up.

NE565N

PHASE-LOCKED LOOP SILICON MONOLITHIC INTEGRATED CIRCUIT

Case 646

PHASE-LOCKED LOOP

The NE565N is designed for general-purpose phase-locked loop applications to 500 kHz.

- Stable Center Frequency – 200 ppm/°C (Typ)
- Flexible Power Supply Range – ± 5 to ± 12 Volts with Small Frequency Drift – 100 ppm/% (Typ)
- Low Total Harmonic Distortion of Demodulator Output – 1.5% (Max)
- Linear Triangle Wave Output – 0.5% (Typ)
- TTL, DTL Compatible Inputs and Outputs
- Adjustable Hold In Range – $\pm 1\%$ to $\geq 60\%$.

FIGURE 8 – AM REJECTION CHARACTERISTICS

Circuit diagrams utilizing Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information has been carefully checked and

is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

GENERAL APPLICATIONS INFORMATION

The following formulas are useful when designing with the NE565N:

1. Center Frequency –
$$f_o \approx \frac{1}{3.7 R_O C_O}$$

Where: f_o is the frequency of the VCO without input signal. For R_O, C_O circuit location see Figure 2.

2. Loop Gain – $K_O K_D A$

Definitions:

K_O – VCO Conversion Gain – the conversion factor between VCO frequency and control voltage.

$$K_O = 4.12 f_o \text{ (units are in radians/sec/volt)}$$

Example: for VCO Sensitivity @ 10 kHz (in Hz/volt)

$$K_O = \frac{4.12 \times 10^4}{2\pi \text{ radians}} = 6600 \text{ Hz/Volt}$$

K_D –Phase Detector Gain Factor – the conversion factor between the phase detector output voltage and the phase difference between input and VCO signals. Units are in volts/radian.

$$K_D = \frac{8.1 \bullet A}{V_{CC}}$$

Where: $A = f(R6 \text{ AND } R7)$

Hence:
$$K_D = \frac{8.1}{V_{CC}} [f(R6-R7)]$$

Where: V_{CC} is total system supply voltage, $f(R6-R7)$ is internal amplifier gain (See Figure 9). V_{CC} - total supply voltage to the circuit.

3. Lock Range – $f_L = \pm \frac{8f_o}{V_{CC}}$

Where: f_L is the range of frequencies in the area of f_o over which the VCO, once locked to the input signal, will remain locked.

4. Capture Range – $f_c \approx \pm \frac{1}{2\pi} \sqrt{\frac{2\pi f_L}{\tau}}$

Where: f_c is that range of frequencies around f_o over which the loop will acquire lock with an input signal initially starting out of lock.

(τ = Time Constant at Pin 7)

TBA 120 C TBA 120 D*

FM IF AMPLIFIER, LIMITER AND DETECTOR

An integrated circuit specifically designed for use in the sound section of TV-receivers and the FM/IF portion of radio receivers.

The TBA 120 C is pin for pin and function compatible with the proelectron type TBA 120 S but includes an improved D.C. volume control, which makes "grouping" or selection unnecessary.

The TBA 120 D is pin for pin compatible with the proelectron type TBA 120, which is using external phase shift capacitors.

Features:

- Excellent 3dB limiting
- High A.M. rejection
- Wide supply voltage range
- Auxiliary zener diode & transistor
- Minimum number of external components required.

Burst Gate Operating Voltage	5	2.0		5.0	V
Chrominance Output D.C. Current 1. Colour killer operating 2. Colour killer off		200		4.0	μA μA

APPLICATION NOTES

1. Normal decoupling precautions must be taken. For example pin 2 (8.4 volt circuit supply point) must be decoupled closely to pin 6 (ground) thus preventing sub-carrier components leaking into sensitive areas of the circuit.
2. To prevent the radiation of sub-carrier harmonics, the connection from pin 9 (reference output) and pin 8 (crystal feedback) must be kept as short as possible.
3. The connection from pin 1 (chroma output) should be also as short as possible to prevent capacitive loading of the 1K8 Ω output resistor.

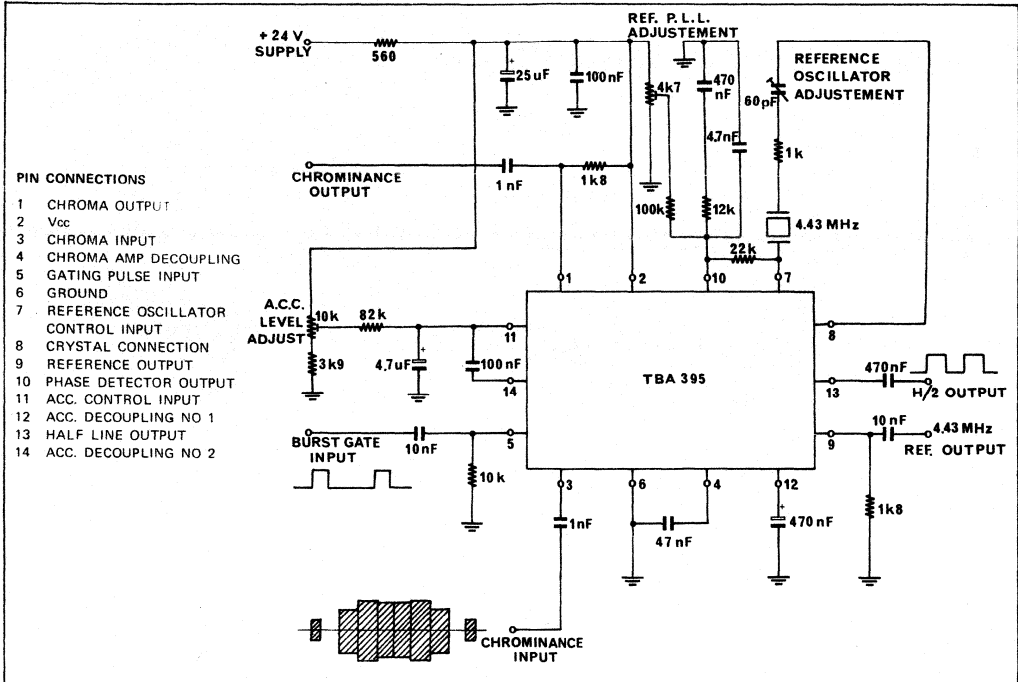

SETTING-UP NOTES

For subcarrier oscillator adjustment the chrominance input must be bypassed to ground via a 1 nf capacitor. The Acc potentiometer is then set to 1.2 volts below pin 2 voltage using a high input impedance oscilloscope or Voltmeter ($>10\text{M}\Omega$). While the adjustment is made burst gate pulses must be applied to pin 5.

The oscillator free-running frequency can then be adjusted to sub-carrier value $\pm 10\text{ Hz}$. The loop will lock if a chrominance signal is re-connected.

With a peak to peak signal of 250 mV (100 $^{\circ}$ /o bars) the output on pin 1 should be adjusted to 400 mV peak to peak using the A.C.C. control potentiometer.

Chrominance phase shift with contrast control				± 3	$\%$
Chrominance/Luminance tracking error with contrast control				± 2	dB
Threshold of beam limiter	10	1.8	2.0	2.2	V

APPLICATION NOTES

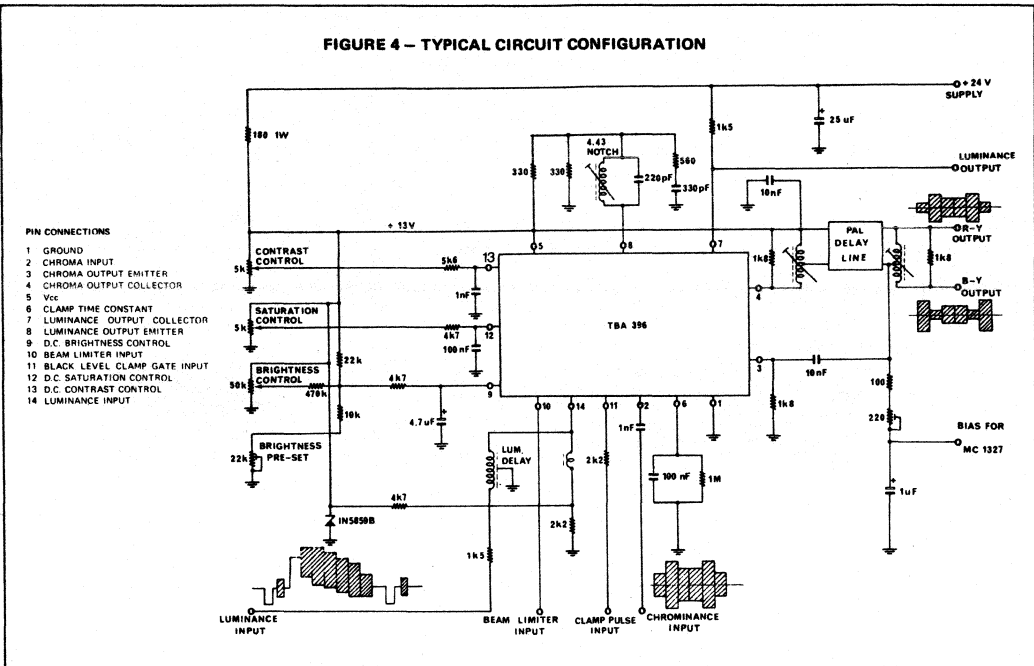

1. The d.c. controls are relatively insensitive to interference if the decoupling associated with these lines is close to the I.C.
2. Good decoupling is required close to the "cold" end of the PAL delay line driving coil to prevent spurious subcarrier components reaching the I.C. supply line.

SETTING UP NOTES

The pre-set brilliance control must be adjusted to give the correct black level of - 16.5 V at pin 7. If the color demodulator IC MC1327 is used to complete the system a voltage of - 7.5 V at the chroma outputs can be set using the same procedure.

This operation must be performed with the brilliance control at the centre of its range.

TBA920 TBA920S

HORIZONTAL COMBINATION

The TBA920 is a line oscillator combination integrated circuit for use in television receivers with transistor or thyristor output stages. It combines the following features:

- Line oscillator
- Noise gated sync separator
- Phase comparison between flyback pulse and oscillator
- Loop gain and time constant switching (also for VCR applications)
- Output stage to drive a variety of line output stages

Advance Information

FM STEREO DEMODULATOR DESIGNED FOR USE IN HI-FI STEREO RECEIVERS AND CAR RADIOS

- Wide Supply Range: 8 – 16 Vdc
- Excellent Channel Separation Maintained Over Entire Audio Frequency Range (Fixed or Adjustable)
- Variable Blend Control
- Low Distortion: 0.3% THD at 2.5 Vp-p Composite Input Signal
- Excellent Rejection of ARI Subcarrier (57 kHz)
- Excellent Rejection of Pilot Tone Harmonics including 114 kHz
- Wide Dynamic Range: 0.5 – 2.5 Vp-p Composite Input Signal
- Up to 6 dB Gain (Monaural)
- Low Output Impedance
- Transient-free Mono/Stereo Switching
- 50 dB Supply Ripple Rejection
- Integrated Stereo/Monaural Switch – 100 mA Lamp Driving Capability
- Requires No Inductors

TCA4500A

CIRCUIT DESCRIPTION

INTRODUCTION

The TCA4500A is a phase-lock-loop stereo decoder which incorporates a variable separation control, and in which sensitivity to the third harmonics of both the pilot and sub-carrier frequencies has been eliminated by the use of appropriate, digitally generated, waveforms in the phase-lock-loop and decoder sections.

The variable separation control may be operated manually, or by a receiver's AGC or S meter signals, to provide smooth transitions between monaural and stereo reception. It operates only during stereo reception: the circuit switches automatically to monaural if the 19 kHz pilot tone is absent.

The elimination of sensitivity to the third harmonic (114 kHz) of the sub-carrier (38 kHz) excludes interference from the 100 kHz (European Spacing) spaced side bands of adjacent transmitters, while elimination of sensitivity to the third harmonic (57 kHz) of the pilot tone (19 kHz) excludes interference from the ARI* system employed in Europe.

*Auto Radio Information.

CIRCUIT OPERATION

The block diagram of the circuit, shown in Fig. 10, consists of three sections: the phase-lock-loop, including the digital waveform generator; the stereo switch; and the decoder, in which the composite stereo signal is demodulated and matrixed to separate L and R channels.

In the phase-lock-loop the internal RC oscillator, operating at 228 kHz, feeds a 3 stage Johnson counter, via a binary divider, to generate a series of 19 kHz square waves. By the use of suitably connected NAND and EXCLUSIVE OR gates, the waveforms shown in Fig. 11, which are used to drive the various modulators in the circuit, are developed.

The use of such drive waveforms produces the modulating functions also shown in Fig. 11. The usual square-waveforms have been replaced in the PLL and decoder sections by 3-level forms which contain no third harmonic (actually no harmonics which are multiples of 2 or 3 are present). This eliminates the frequency translation of interference from these bands into the low frequency region. Such translation may produce audible components in the decoder section from the sidebands of adjacent channel FM signals, and may produce phase jitter, and consequent intermodulation distortion, in the PLL, from the modulated 57 kHz tones of the ARI system. The TCA 4500A is inherently free from these effects.

The stereo switch section is of conventional form (e.g. MC1310).

The decoder section consists of a modulator (driven by the waveforms shown in Fig. 11) whose outputs are the inverted and non-inverted channel difference signals. These signals pass to the output amplifiers via the variable

blend circuit in which they are partially combined, and hence mutually attenuated, according to the control voltage applied.

Matrixing occurs at the inputs of the output amplifiers, where the unmodified composite signal is added to the blended channel difference signals. The stereo separation may be progressively reduced from maximum to zero, dependent on the blending. The control law has been made non-linear, as the major redistribution of sound energy occurs at very low separation levels. For monaural, or very weak stereo signals, the modulator in the decoder section is deactivated by the stereo switch circuit. The variable separation control is thus, also, automatically disabled.

FIGURE 11 - DIGITAL WAVEFORM

APPLICATION INFORMATION

GAIN AND DE-EMPHASIS

The gain and de-emphasis characteristics of the circuit are defined by shunt feedback via the external RC networks (R3, C6, R4, C7 of Fig. 1) around the output amplifiers. The gain is unity when resistors of 5.1 kΩ are used. Higher gains may be obtained by using networks of the form shown in Fig. 12.

The resistors R6, R7 are added to correct the output quiescent voltage levels which are optimized for R3, R4 = 5.1 kΩ and which would, if uncorrected, become too low with higher value resistors. Suitable network values are as follows:

FIGURE 12 - OUTPUT AMPLIFIER FEEDBACK NETWORKS

APPLICATION INFORMATION (continued)

Gain (dB)	R3, R4	C6, C7		R6, R7
		50 μ s	75 μ s	
0	5.1k Ω	10 nF	15 nF	47k \pm 10% 27k \pm 10%
3	6.8k Ω	6.8 nF	10 nF	
6	10k	4.7 nF	6.8 nF	

The maximum output level is 1 Vrms; consequently the max. input is limited to 1.4 Vp-p if the gain is set to 6 dB.

SEPARATION ADJUSTMENT

A separation adjustment may be added, as shown below, (Fig. 13), to compensate for the receiver's IF characteristics.

FIGURE 13 – NETWORK PROVIDING ADJUSTABLE SEPARATION

This network reduces the amplification of the channel sum signal in the decoder, to compensate the attenuation of the channel difference signal in the receiver's IF section. The network shown will compensate for up to 2 dB attenuation at 38 kHz. The decoder gain is, obviously, reduced by an amount equal to the compensation required. When used as described, the adjustment also corrects the inherent separation of the decoder, which may be optimized on one channel. Optimization of both channels is possible if separate potentiometers are used to feed each output amplifier.

FIGURE 14 – BLEND CONTROL INPUT CIRCUIT

VARIABLE SEPARATION (BLEND) CONTROL AND 19 kHz OUTPUT

To retain the 16-pin package, the blend control has been combined with the 19 kHz output on pin 11. The internal circuit providing this combination is shown in Fig.14.

If pin 11 is left open-circuit, the 19 kHz signal appears at a mean dc level of 4 V. The blend circuit is inoperative at this level and the decoder provides full separation. The 19 kHz signal can be used to tune the internal oscillator.

To reduce the separation, the voltage on pin 11 is lowered. At 3.2 V, T2 ceases conduction and the 19 kHz signal disappears.

At 2.3 V, the blend circuit comes into operation and the separation decreases according to the curve shown in Fig. 15.

FIGURE 15 – SEPARATION CONTROL VOLTAGE

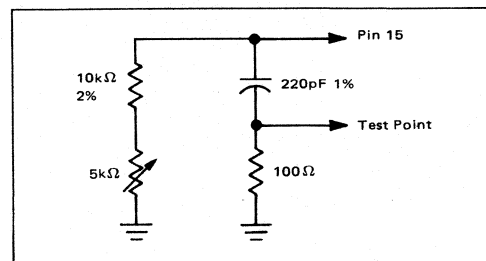

FIGURE 16 – OSCILLATOR NETWORK FOR DIRECT FREQUENCY MEASUREMENT

OSCILLATOR TUNING

If the variable separation facility is not required, pin 11 is left open-circuit and the 19 kHz signal which then appears may be used to indicate the oscillator frequency. If the variable separation is used, and the drive circuit prevents access to the 19 kHz signal, then the oscillator frequency must be measured directly. A test point should be obtained by modifying the oscillator RC network as shown in Fig. 16.

TCA4500A

The output is a pulse train of approximately 1.5 Volts amplitude. Connecting frequency counters of up to 300 pF input capacitance produces less than 0.3% change of the oscillator frequency, which should be set to 228 kHz.

HIGH LOOP GAIN COMPONENTS

For applications demanding operation under low pilot level (e.g., car radio) the following component changes to Fig. 1 are recommended.

R1 = 12k	C3 = 150 pF
R2 = 1.5k	C4 = 330 nF
R8 = 330	C5 = 150 nF
P1 = 10k	

EXTERNAL MONO-STEREO SWITCHING AND OSCILLATOR KILLING

If required, the TCA 4500A can be forced into mono mode simply by grounding pin 9 (see Fig. 1). The 228 kHz oscillator will be automatically killed.

The conditions governing Mono/Stereo switching on

pin 9 are the following:

- Quiescent voltage: +2.3 Vdc
- Current required to ensure mono operator (with 100 mVrms pilot level): 10 μ A (from pin 9 to ground)
- Hysteresis: 0.7 μ A
- Stereo/mono switching and oscillator killing: less than +500 mV
- Maximum stray capacitance between pin 9 and ground: 100 pF

EXTERNAL COMPONENT FUNCTIONS

- P1 - 19 kHz frequency adjustment
- P2 - channel separation adjustment and compensation for IF roll-off.
- R3, R6 - gain fixing resistors. The values shown in the schematic are for unity gain.
- C6, C7 - de-emphasis capacitors. Value to give: RC = 50 μ s.

Values shown in Fig. 1 are recommended for applications with input level higher than 1.0 Vrms.

Circuit diagrams utilizing Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information has been carefully checked and

is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

TCA 5500

PRODUCT PREVIEW

STEREO SOUND CONTROL SYSTEM

The TCA5500 is a single chip stereo balance, volume, bass and treble control circuit designed for use in car radios, TV and audio systems. Simple DC inputs allow the control to be effected by four inexpensive potentiometers or a remote control system. The bass and treble responses are defined by a single capacitor per control per channel.

- Four high impedance DC controls – Vol, Bass, Treble, Balance
- A single external capacitor defines each tone control's characteristic
- Low distortion, 0.1% at nominal input level, 12dB gain with the tone controls flat
- Channel separation better than 45dB
- Wide power supply tolerance, 8 to 18V DC
- ± 14 dB of tone control
- More than 75dB of volume control
- Wide dynamic range: 25mV to 150mV RMS input signal
- Low output impedance
- Easily added loudness compensation

TDA1085A

Advance Information

UNIVERSAL MOTOR SPEED CONTROLLER

The TDA1085A has all the necessary functions for the speed control of universal (AC series) motors in an open or closed loop configuration, additionally it has the facility for defining the initial speed/time characteristic. The circuit provides a phase angle varied trigger pulse to the motor control triac.

- Guaranteed full wave triac drive
- Soft start from power-up
- On-chip frequency/voltage convertor and ramp generator
- Current limiting incorporated
- Direct drive from AC line.

NOTES:

- ¹ Pins 1, 2, 11, 12, 14 and 15 not connected; pins 4, 5, 6 and 7 grounded to pin 8: $V_{CC} = 15.5\ V$
- ² When $V_{pin\ 5}$ is $\leq 80\ mV$, the internal monitoring circuit interprets it as a true zero, thus minimising the effects of control amplifier offsets.
- ³ This value should be accounted for when externally setting the distribute acceleration charging current.

⁴ V_{off} is defined as being the voltage difference between pin 4 and 5 with no current flow on pin 16.

⁵ The negative swing is clamped to $-0.3\ V$.

⁶ $V_{pin\ 4} = K \cdot C_{pin\ 11} \cdot (V_{CC} - V_a) \cdot R_{pin\ 4} \cdot \left(\frac{1}{R_{pin\ 11}} + 1\right) \cdot freq_{in}$.

Where: $9 < K < 13$ & $V_a = 1.3\ V$.

⁷ The timing given is when $C_{pin\ 14} = 47\ nF$

* These figures apply for the application shown in figure 4.

INPUT/OUTPUT FUNCTIONS

VOLTAGE REGULATOR — (pins 8, 9, 10). This is a parallel type voltage regulator able to sink a large amount of current while offering good regulation characteristics.

A resistor between pins 9 and 10 reduces the internal power dissipation. Under minimal current sink conditions (min. current from the unregulated supply, max. consumption by the circuitry) at least 1 mA should flow through this resistor. Under max. sink conditions (max. current from the unregulated supply, min. consumption by the circuitry) the maximum resistor value is chosen so that the voltage at pin 10 falls towards 3 V, but not lower. The above, fixed dynamic range of the regulator must not be exceeded within one line cycle.

A power supply failure causes shut-down.

For operation from an externally regulated voltage, pin 10 is not connected.

SPEED SENSING — (pin 4, 11, 12). Speed sensing can be achieved either digitally (tachogenerator frequency) or analogously (tachogenerator amplitude).

For digital sensing a bipolar signal, with respect to ground, is applied to pin 12. During positive excursions $C_{pin 11}$ is charged. An internal mirror delivers ten times

the charge on $C_{pin 11}$ via pin 4. However, due to internal circuitry the charge on pin 4 can vary in the region of 9 to 13 times the charge on $C_{pin 11}$. For that reason it is necessary to calibrate the Frequency/Voltage Converter (F/V/C) with a variable resistor on pin 4. Thus as can be seen the relationship between speed and $V_{pin 4}$ is defined by $R_{pin 4}$ and $C_{pin 11}$.

To maintain linearity in the high speed ranges it is important that $C_{pin 11}$ is fully charged across an equivalent resistor of about 180 k Ω . It should be borne in mind that the impedance on pin 11 should be kept as low as possible as $C_{pin 11}$ has a large influence on the temperature coefficient of the FV/C. The time constant on pin 4 should also be kept as low as possible.

Pin 12 is also an impedance monitoring input; at high impedances $V_{pin 12}$ increases. Should $V_{pin 12}$ exceed 5 V the triac trigger pulses are inhibited and the circuit resets.

A 470 k Ω resistor from pin 11 to +V_{CC} significantly reduces the leakage current and reduces the device temperature coefficient to almost zero.

For analogue sensing input 12 should be grounded and a positive signal, with respect to ground, pin 8, applied to pin 4.

FIGURE 2 — RAMP GENERATOR TRANSFER CHARACTERISTIC

The shape of the curve is determined by $C_{R_{pin 7}}$; where $C_{pin 7}$ defines the high acceleration slope and $R_{pin 7}$ defines that of the low acceleration.

FIGURE 3 — FREQUENCY/VOLTAGE CONVERTER OUTPUT CHARACTERISTIC

INPUT/OUTPUT FUNCTIONS (continued)

RAMP GENERATOR — (pin 5, 6, 7) (refer to figure 2). A pre-set voltage applied to pin 5 will initiate the generation of a ramp whose final value is determined by the voltage applied to pin 5. The voltage applied to pin 6 will determine how much of the full ramp, shown in figure 2, is used. The charging current passing through pin 7 to the ramp generator timing capacitor determines the ramp slope.

When pin 6 is held at $-V_{CC}$ a charging current of 1.2 mA is delivered to pin 7, regardless of the voltage of pin 5. This represents the high acceleration period shown in figure 2.

If the pre-set voltage applied to pin 5 is equal to or less than the voltage on pin 6 the charging current will be 1.2 mA, high acceleration.

If the pre-set voltage applied to pin 5 is between $V_{pin\ 6}$ and $2 V_{pin\ 6}$ the charging current is 1.2 mA, high acceleration, until the voltage at the reference input of the control amplifier equals $V_{pin\ 6}$. At this point the charging current will switch to $5\ \mu A$; i.e. low acceleration.

If the pre-set voltage applied to pin 5 is greater than $2 V_{pin\ 6}$ the charging current will be 1.2 mA, high acceleration, until the control amplifier's reference input reaches $V_{pin\ 6}$ when it will switch to $5\ \mu A$, low acceleration, until $2 V_{pin\ 6}$ is reached. At this point the charging current will revert to 1.2 mA, high acceleration, until the final value, $V_{pin\ 5}$, is reached.

Should the pre-set voltage at pin 5 fall below 80 mV the triac trigger pulses are inhibited and the circuit resets. This fact should be borne in mind when switching from one pre-set value to another.

As long as the voltages applied at pins 5 and 6 are derived from the internal voltage regulator they and the voltage on pin 4 are ratioed and thus independent of the voltage regulator spread and temperature coefficient.

CURRENT LIMITER — (pin 3). Safe operation of the motor and triac under all conditions is ensured by reducing the motor speed if a pre-set current limit is exceeded.

This is achieved as follows: The motor current will set up an alternating current, consisting of positive and

negative peaks, through the shunt resistor ($0.05\ \Omega$ in figure 4).

The negative peaks of this current are fed through a resistor to pin 3 where they are compared with a pre-set current, defined by a further resistor between pin 3 and $+V_{CC}$. An excessive shunt current will try to pull pin 3 below $-V_{CC}$, but the current limiter becomes active at this point and reduces the charge on $C_{pin\ 7}$ consequently reducing the motor speed.

Thus the value of the shunt and the ratio of the two resistors to pin 3 fix the level at which the limiter becomes active while the parallel equivalent of the two resistors determines the magnitude of the discharge current and thus how rapidly the circuit responds to an over current condition.

CONTROL AMPLIFIER — (pin 16). Connected to this pin is a network which compensates electrically for the mechanical characteristics of the motor and its load to give the circuit optimum closed loop stability and transient response.

The component values are best determined empirically by connecting R and C substitution boxes and looking for the best results.

TRIGGER PULSE GENERATOR — (pins 1, 2, 13, 14, 15). This circuit performs four functions:

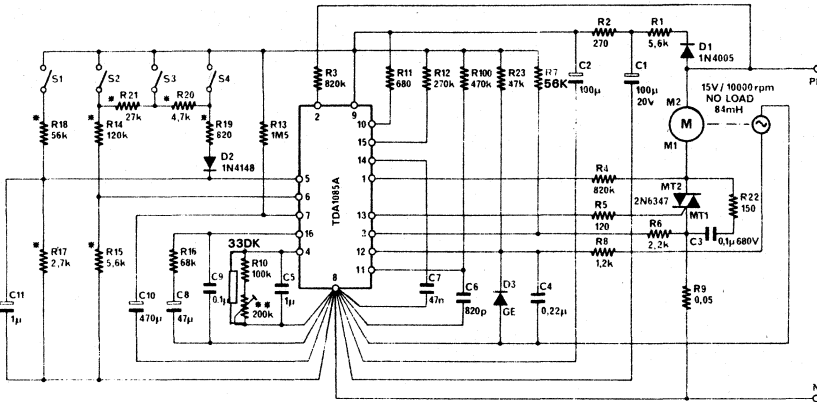

1. The conversion of the control amplifier's DC output level to a proportional firing angle positioned to within half a line cycle.
2. The calibration of the pulse width.
3. The repetition of the firing pulse if the triac fails to latch, or if the current is interrupted by brush bounce.
4. To delay the firing pulse until the current crosses zero at wide firing angles.

$R_{pin\ 15}$ and $C_{pin\ 14}$ fix the sawtooth while $C_{pin\ 14}$ also determines the pulse width.

Pin 13 is the trigger pulse output. A current limiting resistor is essential on this pin. This configuration will drive two thyristors controlling a bridge if the supply for the speed controller is isolated.

TYPICAL APPLICATIONS

FIGURE 4 – CLOSED LOOP, FULLY PROGRAMMED, MULTI-SPEED SYSTEM WITH CURRENT LIMITING

- * Chosen to suit the speeds required
- ** Adjust for the highest speed

Speed Control Resistor Network Equations

R17	=	given
R18	=	$R17 \left(\frac{15.5 V}{V_W} - 1 \right)$
R19	=	$R17 \left(\frac{14.8 V}{V_{spin 2}} - 1 \right)$
R20	=	$R17 \left(\frac{14.8 V}{V_{spin 1}} - 1 \right) - R19$
R21	=	$R17 \left(\frac{14.8 V}{K \cdot V_W} - 1 \right) - R19 - R20$
R15	=	$R21 \left(\frac{K \cdot V_W}{15.5 V (2-K)} \right)$
R14	=	$R15 \left(\frac{15.5 V}{V_W} - 1 \right)$

The ratio distribute speed to wash speed can be chosen as:

$$\frac{V_{DIST}}{V_{WASH}} \leq 2 = K$$

Note:

When changing from one speed to another $V_{pin 5}$ must not be allowed to fall below 80 mV—otherwise the circuit will reset and restart from zero.

	S1	S2	S3	S4	$V_{pin 5}$	$V_{pin 6}$
Wash	sc	oc	oc	oc	V_W	0
Distribute	oc	sc	oc	oc	KV_W	V_W
Spin 1	oc	oc	sc	oc	$>KV_W$	$\frac{K}{2}V_W$
Spin 2	oc	oc	oc	sc	$>>KV_W$	$\sim \frac{K}{2}V_W$

sc = switch closed, oc = open

The component values given in figure 4 correspond to:

- V_W = 0.7 V
- V_D = 1.13 V
- $V_{spin 1}$ = 5 V
- $V_{spin 2}$ = 11 V
- K = 1.6

TRIAC FIRING ANGLE CONTROL CIRCUIT

The TDA1185 generates gate trigger pulses for a triac with a controllable phase delay. Feedback loop control is possible, for applications such as motor speed control. Another typical application is for the soft start-up of power circuitry:

- Low external component count
- AC supply 50/60 Hz
- Full wave triac drive
- Circuit reset in case of power down
- Repetition of firing pulse if triac fails to latch or current interrupted by brush bounce
- Typically 1 mA current consumption
- Soft-start
- Low cost applications.

CIRCUIT DESCRIPTION

PHASE ANGLE CONTROL I.C.

The TDA1185 generates trigger pulses for a triac for phase control of the power in the load. The position of the phase angle of the pulses is derived in the usual way by comparison of a ramp voltage synchronised to the AC line, and a required value. A single capacitor on pin 4 determines the ramp slope and the trigger pulse width.

CURRENT CONSUMPTION

The current consumed by the integrated circuit is typically 1 mA. The current consumption in a typical application is the sum of the internal consumption of the I.C. and the average of the trigger pulse current, which is about 2 mA total. This allows a low power dropping resistor to be used (1.5 W) in deriving power from the A.C. line. The I.C. supply voltage is 8.6 V allowing low cost electrolytic capacitors to be used.

PHASE ANGLE POSITIONING

The comparison of the ramp voltage with a required value sets the firing angle. The required value is the sum of the set value on pin 12 and the feedback value on pin 8. Capacitor C3 on pin 8 integrates the feedback voltage which is the accurately full-wave rectified input to pin 9. The arrangement shown in the diagram thus allows tor-

que compensation of a loaded motor since for a given set speed the motor current increases with load.

SOFT-START AND CIRCUIT RESET

The required value for comparison with the synchronising ramp is increased gradually from zero at the moment power is applied to the circuit. The rate of increase toward the set value is determined by C2 on pin 13, to allow a programmable soft-start. Capacitor C2 is discharged if the power supply is interrupted (e.g. power down) so that a soft-start follows any brief interruption of power.

CURRENT AND VOLTAGE SYNCHRONISATION

Synchronisation with the line zero-crossing voltage is derived through pin 7. In controlling inductive loads the current lags the voltage in the load so current synchronisation is also included, via pin 6.

TRIAC TRIGGERING SECURITY

To avoid the problems of motor noise, and assymmetric use of the line half cycle when controlling universal motors, the trigger pulse is repeated if the triac fails to ignite. The value of C1 in the diagram sets the repetition delay, as well as the ramp slope and trigger pulse width.

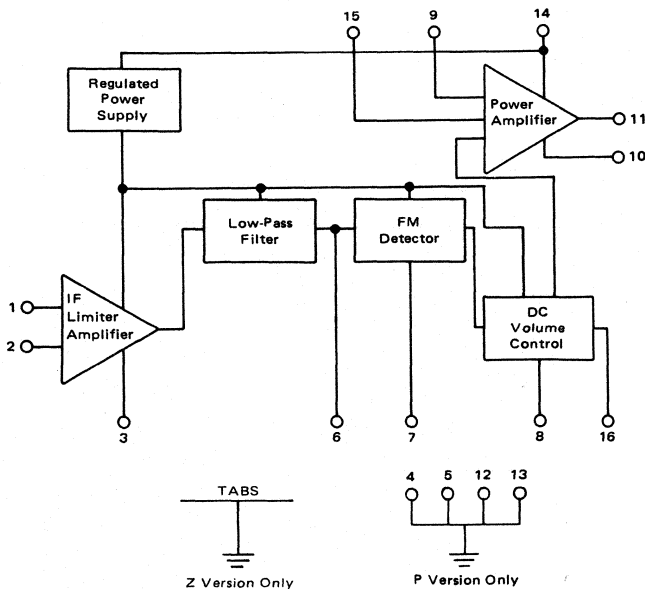

TDA1190Z TDA1190P

TV SOUND SYSTEM

The TDA1190Z 4.0 watt sound system is designed for television and related applications. The TDA1190P is a low-power version. Functions performed by these devices include: IF Limiting, IF amplifier, low pass filter, FM detector, DC volume control, audio preamplifier, and audio power amplifier.

- 4.0 Watts Output Power – TDA1190Z
($V_{CC} = 24\text{ V}$, $R_L = 16\ \Omega$)
- 1.3 Watts Output Power – TDA1190P
($V_{CC} = 18\text{ V}$, $R_L = 32\ \Omega$)
- Linear Volume Control
- High AM Rejection
- Low Harmonic Distortion
- High Sensitivity

TYPICAL CIRCUIT CONFIGURATION

OUTLINE DIMENSIONS

THERMAL INFORMATION

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature, can be found from the equation:

$$P_{D(T_A)} = \frac{T_{J(max)} - T_A}{R_{\theta JA}(Typ)}$$

Where: $P_{D(T_A)}$ = Power Dissipation allowable at a given operating ambient temperature. This must be greater than

the sum of the products of the supply voltages and supply currents at the worst case operating condition.

$T_{J(max)}$ = Maximum Operating Junction Temperature as listed in the Maximum Ratings Section

T_A = Maximum Desired Operating Ambient Temperature

$R_{\theta JA}(Typ)$ = Typical Thermal Resistance Junction to Ambient

Circuit diagrams utilizing Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information has been carefully checked and

is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

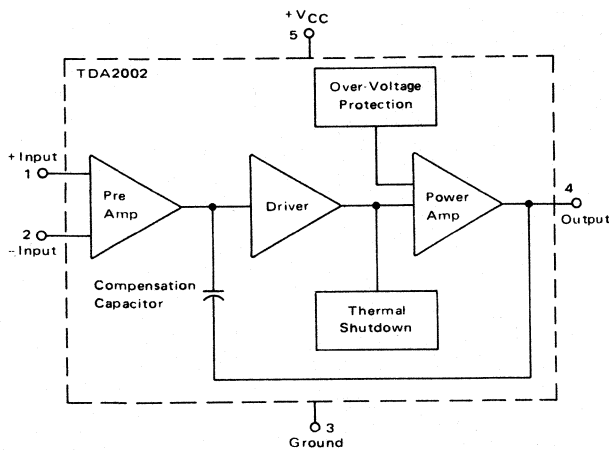

TDA2002 TDA2002A

8 WATT AUDIO POWER AMPLIFIER

The TDA2002 and TDA2002A are Class B power amplifiers designed for automotive and general-purpose audio applications. High output current capability (3.5 A) enables these devices to drive low-impedance loads (down to 1.6 Ω) with low harmonic and crossover distortion. High-voltage protection is available (TDA2002) which enables the amplifier to withstand 40 V transients. These devices provide an output power of 8 watts (typ) with $R_L = 2 \Omega$ and 4.8 watts (min) with $R_L = 4 \Omega$ at 14.4 volts.

- Internal Thermal Overload Protection
- Internal Short-Circuit Current Limiting
- Supply Over Voltage Protection
- Wide Supply Voltage Range (8–18 Volts)
- Low External Component Count

APPLICATION NOTES

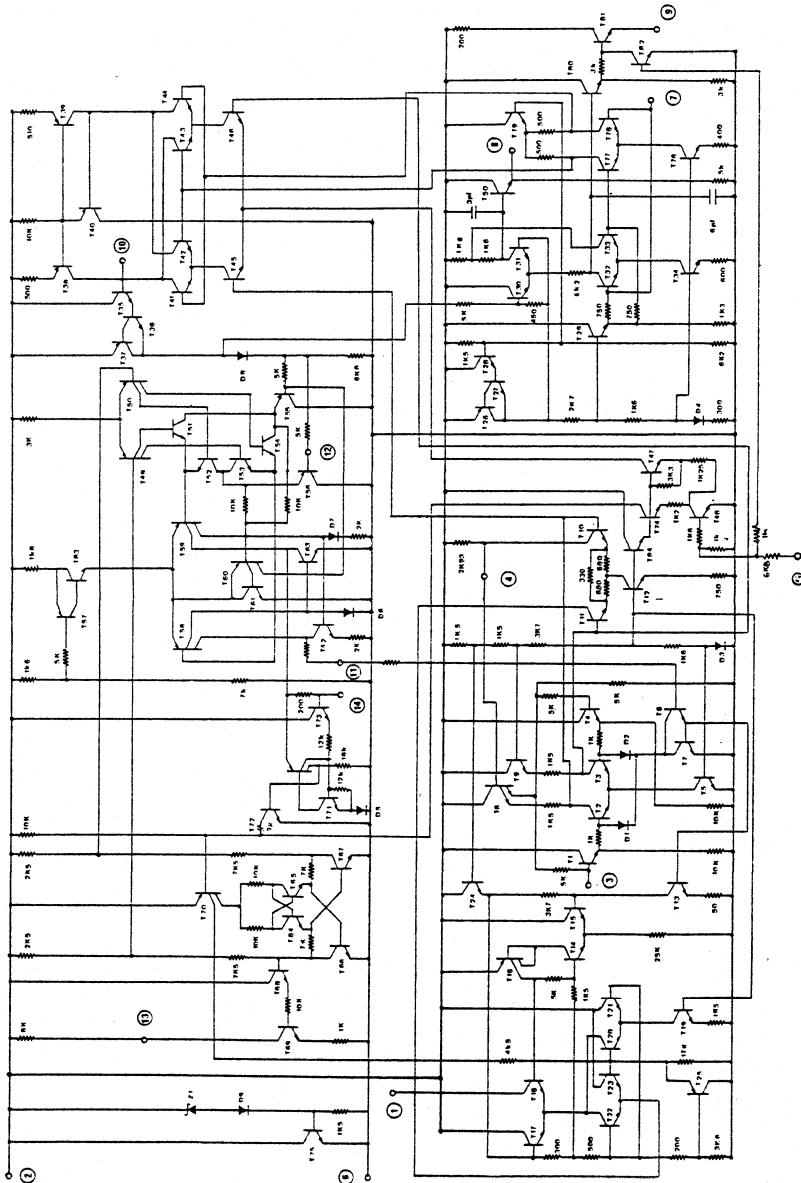

1. Normal decoupling precautions must be taken. For example pin 2 must be decoupled closely to pin 6 (ground) thus preventing sub-carrier components leaking into sensitive areas of the circuit.
2. To prevent the radiation of sub-carrier harmonics, the connection from pin 9 (reference output) and pin 8 (crystal feedback) must be kept as short as possible.

SETTING UP NOTES

Disconnect the burst gate pulses and adjust the P.L.L. potentiometer to give "Zero beat" from the sub-carrier reference oscillator. Reconnect the burst gate pulses.

μ A758A

Advance Information

PHASE LOCK LOOP FM STEREO DEMODULATOR

The μ A758A is an improved FM stereo multiplex decoder with an extended operating supply voltage range.

It is a direct replacement for the μ A758 and LM1800.

- Requires No Inductors
- Low External Part Count
- Excellent Channel Separation Without Adjustment
- Only Single Potentiometer Oscillator Frequency Adjustment Necessary
- 100 mA Lamp or LED Driving Capability With Current Limiting
- Automatic, Transient-Free Stereo/Mono Switching
- Wide Supply Range: 8–16 Vdc
- Excellent SCA Rejection
- 50 dB Power Supply Rejection
- Low Impedance, Buffered Output

UAA 1004-DP UAA 1004-CM

ZERO VOLTAGE SWITCH

Designed for use in high volume AC power switching applications with output drive capable of triggering SCR's or triacs. Other operational features include:

- Direct AC line or DC operation.
- A zero voltage crossing detector that synchronises the SCR or the triac at the zero crossing of the AC line voltage.
- High impedance input differential amplifier.
- Built-in hysteresis which avoids a DC current component through the load.
- Fail safe: a high impedance differential amplifier which supervises the sensor and insures that the triac will never turn "on" due to sensor failure.
- High power, asymmetric gate trigger pulses for power saving with internal current limitation. (Negative pulses)
- Voltage regulator for the supply of the sensor or other external circuits.

Typical Applications:

- | | |
|----------------------|------------------------|
| • heater control | • valve control |
| • hot plate control | • on-off power control |
| • photo control | • relay driver |
| • threshold detector | • lamp driver |

NOTES

- As the input amplifier has a common pin with the fail safe amplifier, the input bias current of each amplifier is defined as:

$$I_{bin} = \frac{1}{4} (I_{ba} + I_{b1} + I_{b2})$$

- This characteristic can be measured as in Fig. 5. The function generator must be connected between pins 1 & 2 and the input amplifier must be biased with pin 8 positive and pin 1 negative.
- Measured with $I_{Aux} = 0$
- Measured at $V_{CC} = 14\text{ V}$
- Measured with $I_{out} = 0$ and $I_{Aux} = 0$

UAA1008A-DP

Advance Information

TUNING SYSTEM LINEAR PROCESSOR CIRCUIT

The UAA1008A provides the interfacing between the digital section of the tuning memory system and the TV set. In addition, it supplies the necessary functions and stabilized voltages for operating the complete system.

When used in conjunction with the MC14425/29 and MC14426 it will perform the following:

- D/A conversion of varicap voltage
- 34 Volt regulation
- 5 volt regulation for supply of all VDD external lines
- Supply voltage supervisory control
- Band decoding and driver (35 mA)
- TV station capture control with help of fly-back, video, and AFC signals.

FIGURE 2 – AFC TRANSFER FUNCTION

FIGURE 3 – FILTER/AMP FREQUENCY RESPONSE

INPUT/OUTPUT FUNCTIONS

AFC INPUT & OUTPUT – The AFC input (pin 11) generates UP & DOWN commands whenever the input level varies by more than $V_{DD} \pm 50$ mV.

At the same time the AFC voltage is converted into a proportional AFC output current (pin 10) limited to an excursion of $\pm 200 \mu A$ (see Fig. 2). The AFC output current source is gated by the Enable input function (pin 18). See enable functional table.

UP & DOWN – The UP output (pin 16) changes to high whenever the AFC input (pin 11) is higher than $V_{DD} + 50$ mV, the DOWN output (pin 15) when lower than $V_{DD} - 50$ mV.

For pin 11 voltage included between $V_{DD} - 50$ mV and $V_{DD} + 50$ mV no UP or DOWN commands will be generated. By means of an RC time constant on pin 14 it is possible to delay the falling edge of the UP command to make it overlap with the DOWN command provided that ENABLE IN (pin 18) is high.

Should it be necessary to defeat the UP and/or DOWN commands, the correspondent pin 16 and 15 can be grounded.

FILTER & AMPLIFIER – (Inverting input: pin 9; non-inverting input: pin 8; output: pin 7.) This operational amplifier provides the integration of the MC14425/9 binary rate multiplier output and the amplification of the same (usually around 6.5 times) to cover the required varicap tuning voltage range, according to the typical configuration of Fig 4.

Under these conditions only the critical components R_1 and R_2 are used to determine the voltage gain of the integrator. It is recommended to use good stability resistors with tracking temperature coefficient. (See Fig. 3 and 4.)

BAND DRIVER – Fully decoded outputs for tuner band switching are provided at outputs VHF 1 (pin 3), VHF III (pin 1), UHF (pin 2) according to the following logic table. See also MC14425/9 data sheet.

Input Code		Decoded Output		
Pin 4	Pin 5	Pin 3	Pin 1	Pin 2
0	0	X	X	H
1	0	X	H	X
0	1	H	X	X
1	1	X	X	X

NOTES:

- ¹ X state correspond to an open PNP collector.
- ² The control circuit supplying the coded band information can be looped-back to skip the following codes: (11) for three band only and (11) (10) for two band only.

FLYBACK – (pin 13.) This input is driven by the positive line flyback signal commonly available in TV sets. In conjunction with the SYNC signal controls TIME BASE output.

It is recommended to differentiate the flyback pulse to insure that coincidence between sync pulses and flyback occurs only when the picture is actually synchronised (see Fig. 4).

SYNC – (pin 12.) This input is driven by the video signal (negative modulation/positive going sync) through the sync separator network of Fig. 4.

Should separate positive sync pulses be available they can be used to drive pin 12 directly.

TIME BASE – (pin 20.) This output goes to high whenever coincidence is detected between flyback and sync signals, it is an indication of the presence of a valid TV signal.

It is possible to activate time base output also in absence of the above signals by grounding pin 17 via a 10K resistor. Presence of Time Base is checked at the end of the verification time in the control circuit MC14425/9 to definitely activate the AFC output at pin 10.

SUPPLY OK – (pin 21.) Purpose of this function is to protect the memory contents in case of failure or discontinuity of any supply voltage.

Should the 34 V varicap supply fail or the power supply V_{CC} fall below 10 V, SUPPLY OK output, normally at V_{DD} (5.2 V) will immediately drop to zero volts.

This function is normally used to enable data cycling in the memory circuit MC14426 and the UP/DOWN counter in the control circuit MC14425/9.

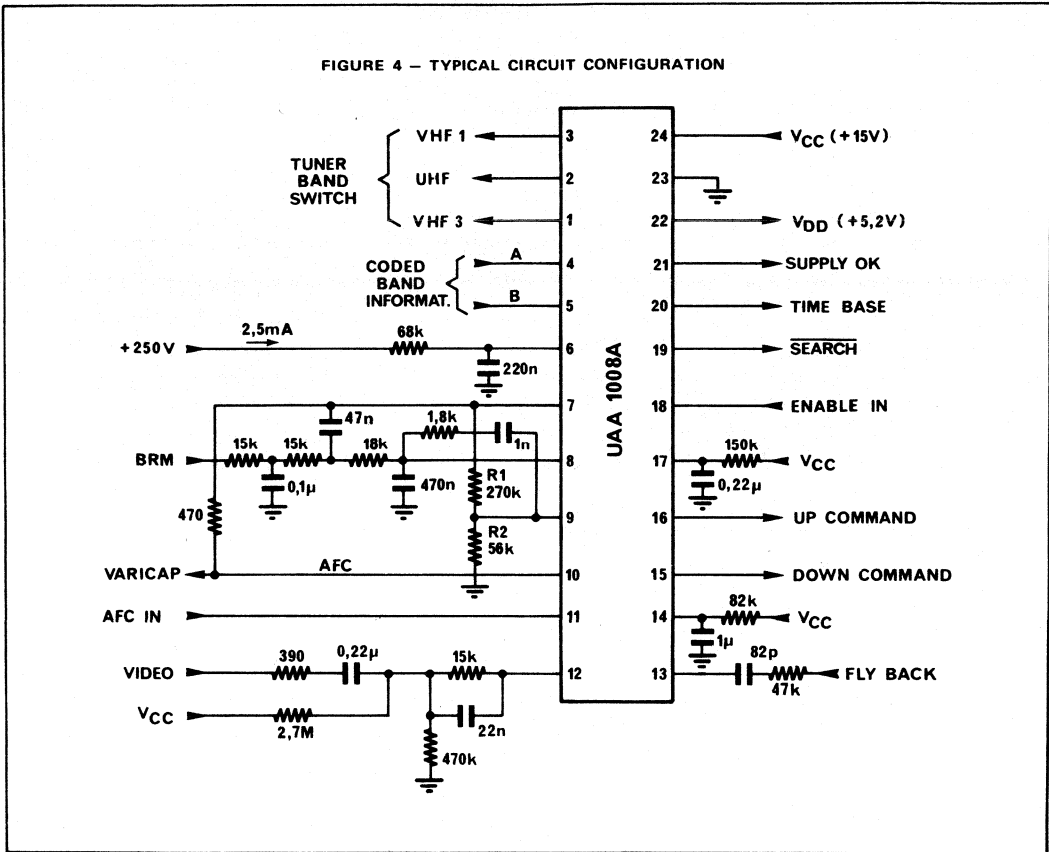

ENABLE IN – (pin 18.) This function is provided by the control circuit MC14425/9 and is primarily used to turn off and on the AFC output in conjunction with TIME BASE, as shown in the enable functional table.

Enable-in goes high whenever a ramp is started and returns to low as soon as an UP/DOWN overlap is detected. It also insures that following an UP/DOWN overlap the UP delay is removed.

SEARCH – (pin 19) this output goes to low whenever the system is in the search mode and can be used to control external functions as necessary.

ADVANCE INFORMATION

ZERO VOLTAGE BURST CONTROL

Designed for high volume AC power switching application in conjunction with a triac.

Features:

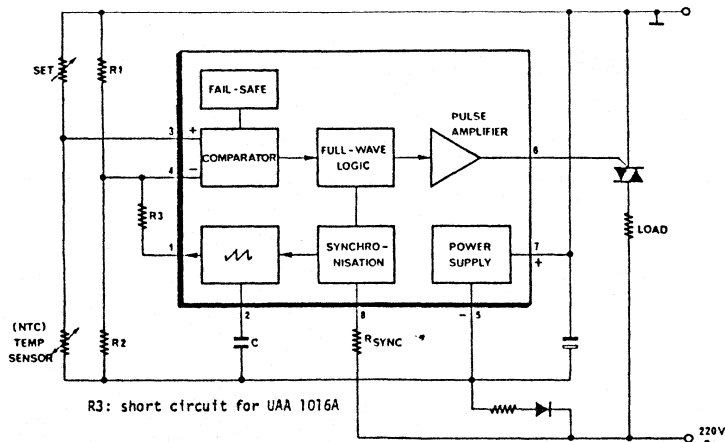

- AC line or DC operation.
- Low external component count.
- Full-wave and zero crossing logic eliminate load d.c. current component and RFI.
- Negative output current pulse, short circuit protected.
- Linear ramp generator allows precise proportional temperature control, and setting of the burst frequency.
- Sensor fail-safe.
- Allows requirements of EN 50.006 to be satisfied.

ELECTRICAL CHARACTERISTICS

Characteristic	Typ Value	Unit
Battery voltage range	8 - 18	V
Flashing cadence 'normal'	85.7	flashes/min
Flashing cadence 'out of service' note 1	171.4	flashes/min
Flash duration 'normal'	350	ms
Flash duration 'out of service' note 2	117	ms
Temperature coefficient of cadence and duration of flash	± 150	ppm
Relay drive current available at pin 7 at a battery voltage of 18 V	> 300	mA
Relay output voltage at pin 7 for I_{out} of 150 mA	< 1.5	V
Time to first flash (max) note 3	< 124	ms

Conditions for detection of an 'out of service' lamp

V_{batt}	$I_{pin 2}$	$I_{pin 2} - I_{pin 1}$	$V_{pin 2} - V_{pin 1}$
8 V	7.25 - 12.25 μ A	0 - 1.69 μ A	102 - 124.3 mV
13 V	13.58 - 22.96 μ A	0 - 2.54 μ A	129 - 149.4 mV
18 V	19.9 - 33.53 μ A	0 - 3.38 μ A	167 - 181.5 mV

Note 1 The measurement is made across the external oscillator network of 390 k and 100 nF at a battery voltage of 13.5 V.

Note 2 The measurement is made on the waveform across the relay coil.

Note 3 The time taken to the first flash is a function of the flashing cadence. Delay to first flash = 10/number of flashes per minute. Thus, for a reduced delay of, say, 100 ms a cadence of 100 flashes per minute would be necessary.

Circuit diagrams utilizing Motorola products are included as a means of illustrating typical semiconductor applications; consequently, complete information sufficient for construction purposes is not necessarily given. The information has been carefully checked and

is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of the semiconductor devices described any license under the patent rights of Motorola Inc. or others.

UAA 2000A

Advance Information

PHASE LOCKED LOOP SYNTHESISER & DRIVER

The UAA2000 is designed to control the phase locked loops in frequency synthesisers as used in TV applications. Realised in P²L/EFL bipolar technology it contains all the necessary digital and linear functions. It uses an input data format which makes it well suited for use with microprocessor control.

- 14-bit variable divider & 4-bit band select
- PLL with phase and frequency comparator
- Filter and tuning voltage amplifier
- 16 MHz max input frequency
- Pin option for 125 kHz or 62.5 kHz resolution
- 4 band driver outputs

CIRCUIT OPERATION

The circuit operation can be followed by reference to figure 1, the UAA2000 block diagram, and figure 2, a phase locked loop using the UAA2000, a microprocessor and a TV tuner.

The tuner's local oscillator output is divided, in an external prescaler, by 64 and then fed to the $\div 2$ prescaler inputs of the UAA2000. This feed may be either via both inputs or single ended using pin 23 or pin 24. The output from this is, in turn, fed to the variable divider where it is further divided by a number determined by the microprocessor. The variable divider output frequency, consisting of narrow pulses, called preset pulses, see the timing diagram figure 5, is compared with a reference frequency. The result of this comparison is used as the control voltage for the local oscillator varicap.

The UAA2000 also receives band switching information from the microprocessor and applies it to the tuner. To ensure loop stability the filter response is flat around the frequency where the overall loop gain is unity, see figure 3.

The digital circuitry of the UAA2000 is realised in I^2L and EFL integrated logic.

The data controlling the division ratio of the variable divider and the band buffers is moved serially into a shift register by means of the three logical inputs, \overline{VDR} , Data and \overline{CLOCK} , see figures 1, 2 and 7. The \overline{VDR} input enables the circuit when the data and clock inputs are operated from busses.

Data are transferred from the shift register into latches which, by means of logic, are isolated from the shift register during a shift operation.

The variable divider is, essentially, a presettable synchronous counter. Once all stages are at a logical 0 a preset pulse is generated, this opens the AND gates and presets the variable divider to the number stored in the latches.

The reference frequency, f_{ref} , is generated on-chip by binary division of a 4MHz crystal oscillator signal, alternatively it can be applied externally to pin 20. A buffer stage permits external circuitry to be driven by the 4MHz source.

To provide operation at two different frequency resolutions the system's division ratio of the reference frequency divider can be changed by the use of pin 18; 125 or 62.5kHz steps. With the pin grounded the 62.5

kHz resolution results. The division ratios resulting are 4096 and 8192.

The phase comparator is phase and frequency sensitive with a buffered tristate output. The states of the outputs are defined in the following page, Input/Output Functions.

Figure 5 shows the timing diagram for the situation when the TV channel is changed. With the negative going \overline{VDR} edge, t_1 , the latches are disconnected and the clock input to the shift register is released, allowing access to new data. Since the \overline{VDR} signal and the preset pulses occur asynchronously, the variable divider latches have to be reconnected on the negative edge of the preset pulse, t_4 .

Thus at t_3 the variable divider is preset to the old division ratio. The new division ratio is loaded with the second preset pulse after the positive going \overline{VDR} edge, t_5 . Band information, which is signalled to the UAA2000 by the MPU changes at t_6 . This allows a periodic refresh of the division ratio when the TV channel is unchanged.

The filter amplifier is an operational amplifier, designed for a very low input bias current, with the positive input internally biased. The standard filter set up is shown in figures 2 and 8 with the frequency response shown in figure 3. However, the filter may be set up around the op amp only (see figure 9) to allow use of the non-linear amplifier which compensates for the characteristics of the tuner's varicaps. The degree of compensation can be controlled from pin 8, between two extremes, see figure 4. If pin 8 is connected to pin 7 the transfer function is linear, if however pin 8 is grounded the function takes on its extreme non-linear form. Intermediate shapes can be achieved by controlling pin 8 with a potentiometer.

The 30V output buffer supplies the varicap tuning voltage. The analogue outputs, pins 7 and 9, are short circuit protected. To minimise interference the ground and supply lines of the digital and analogue sections of the system are brought out on separate pins.

To guarantee optimum operation, the analogue supply voltage, between pins 10 and 5, has to be sufficiently free of ripple in the range of about 5Hz to 1kHz, since any interference on this line is transferred to the varicap output, pin 9, at approximately the same amplitude.

INPUT/OUTPUT FUNCTIONS

I² L SUPPLY — (pin 1) This is the current supply for the I² L injectors. The characteristic of the pin is that of a forward biased diode to pin 17.

VDR — (pin 2) This pin is the chip select and is active when low, = 0.

DATA — (pin 3) Data is entered into the device, serially via this pin, and passed directly into the shift register. In its turn this controls the variable divider and the band buffers.

CLOCK — (pin 4) This pin delivers the clock signal to the shift register, which accepts data on the positive going edge. It should be noted that within the VDR window, when VDR = low, the clock has to be high at the beginning and the end of the clock pulse train.

OP. AMP IN — (pin 6) This pin is the inverting input to the operational amplifier. The non-inverting input is internally biased.

OP. AMP OUT — (pin 7) This pin is the output of the operational amplifier and the input to the non-linear amplifier.

NON-LINEARITY CONTROL — (pin 8) This pin controls the input of the non-linear amplifier. It gives a linear transfer characteristic between pins 7 and 9 when pin 8 is connected to pin 7 and non-linear performance when pin 8 is grounded.

TUNING VOLTAGE — (pin 9) This is the tuning voltage output ready for direct control of the varicap diode.

VCC2 — (pin 10) This is the supply voltage for the linear section of the circuit. The external supply must have a current limit lower than 20mA when shorted to ground.

BAND DRIVER OUTPUTS — (pins 11, 12, 13 & 15)

These outputs, which get their information from the data line, are able to drive the tuner directly and can deliver up to 40mA.

VCC1 — (pin 14) This pin supplies the voltage for the band buffers.

PHASE COMPARATOR OUTPUT — (pin 16) This is a tristate output. The output is in the tristate condition, i.e. high impedance, when the divided input frequency is in phase with the on-chip reference.

When the divided input frequency phase leads that of the on-chip reference the output is a series of 'high' going pulses — the high state — with reference to the tristate condition.

When the divided input frequency phase lags that of the on-chip reference the output is a series of 'low' going pulses — the low state — again with reference to the tristate condition.

62.5/125kHz RESOLUTION — (pin 18) This pin serves to change the division ratio of the reference divider. It is an I² L gate input, which means that its characteristic is that of a diode to ground. The resolution is 62.5kHz if the pin is grounded.

4MHz XTAL OUT — (pin 19) This is a low impedance output which drives the crystal of the 4MHz oscillator in the series resonance mode.

4MHz XTAL IN — (pin 20) The oscillator input with an input impedance of 20kΩ.

f IN — (pins 23 & 24) These are the inputs for the frequency to be divided by the variable divider. Both inputs may be driven in antiphase or only one input, with the unused input decoupled via a 1nF capacitor to ground. If driven in the single ended mode the minimum voltage is 200mV peak to peak.

CIRCUIT DESCRIPTION

The circuit operation can be followed by reference to fig 1, the UAA 2001 block diagram, and fig 2, a phase locked loop using the UAA 2001, the MC6805T2 MPU and a TV tuner.

The tuner's local oscillator output frequency is divided in an external prescaler by 64 and then fed to the MC6805T2, which includes a variable divider, controlled by the processor, a reference divider and a phase comparator. By means of this circuitry the local oscillator frequency is further divided by a number determining the TV channel and compared to a fixed reference frequency inside the MPU. The output voltage of the phase comparator is filtered by using the operational amplifier of the UAA 2001 and then serves as the control voltage for the local oscillator varicap.

To facilitate filtering of the reference frequency the op amp is designed for a very low input bias current (1nA typ). The standard filter set up is shown in fig 2 with the frequency response shown in fig 3. To ensure loop stability the response is flat around the frequency where the overall loop gain is unity.

The UAA 2001 also receives band switching information from the MPU and applies it to the tuner by means of a shift register, latches, and buffers. The 5-bit band switching information is transferred by the signals DATA,

$\overline{\text{CLOCK}}$ and $\overline{\text{VDR}}$ (chip select); these inputs are designed to accept TTL levels. The $\overline{\text{CLOCK}}$ and DATA lines can be shared with other systems having other I/O devices.

Fig 4 shows the circuit's timing diagram. On the negative going $\overline{\text{VDR}}$ edge the latches are disconnected from the shift register and new information is shifted in. On the

positive going $\overline{\text{VDR}}$ edge the latches are reconnected thus transferring new band information to the buffers and the tuner.

The shift register also has a data output, this allows the MPU to pass data through the UAA 2001 and drive further circuits from the same DATA and chip select pins. The UAA 2001 shifts and outputs data on the positive going clock edge where the following circuits are intended to shift data on the negative going edge. For reliable data transfer the UAA 2001 should always be the first circuit in line as the clock signal consists of negative going pulses.

The latches control five buffers. Buffer B1 has an open collector output (see fig 5) and may be used to output any information from the MPU. Buffers B2 to B5 are band buffers specially designed to drive the tuner. Their drive capability is 60mA.

INPUT/OUTPUT FUNCTIONS

POS. INPUT — (pin 1) This is the non-inverting input to the operational amplifier and needs an external reference bias.

OP. AMP. OUT — (pin 2) This is the tuning voltage output, designed for direct control of the tuner's varicap.

V_{CC2} — (pin 3) This is the op amp supply voltage.

DATA OUT — (pin 4) This pin is the data output of the shift register. The output is designed to allow cascading other circuits using the same $\overline{\text{VDR}}$ signal.

B1 — (pin 5) This pin is an open collector buffer output of the first shifted bit. When shifting a logic '1' the output transistor is ON.

BAND DRIVER OUTPUTS — (pins 6, 7, 9, 10) These outputs can directly drive the tuner and deliver up to 60mA. When shifting a logic '1' the appropriate band buffer is ON.

V_{CC1} — (pin 8) This is the supply voltage for the band buffers.

I² L SUPPLY — (pin 11) This pin needs an external resistance to set up the I² L injector currents. The characteristic of the pin is that of a forward biased diode to pin 15 (ground) plus a series resistance of about 60Ω.

$\overline{\text{VDR}}$ — (pin 12) This is the chip select and is active when low.

$\overline{\text{CLOCK}}$ — (pin 13) This pin delivers the clock signal to the shift register, which accepts shifts and outputs data on the positive going edge. It should be noted that within the $\overline{\text{VDR}}$ window, when $\overline{\text{VDR}}$ is low, the clock has to be high at the beginning and end of the clock pulse train.

DATA — (pin 14) Data is entered serially into the circuit via this pin and passed directly to the shift register. In turn this controls the latches and band buffers.

NEG. INPUT — (pin 16) This is the inverting input of the op amp with a typical input bias current of 1nA, reducing with increasing temperature.

Advance Information

SYNTHESIZER AMPLIFIER & DRIVER

The UAA 2010 is designed for use in frequency synthesizers. It is particularly suitable for use with the MC 6805T2 microprocessor (MPU) in a TV synthesizer where it forms the interface between the tuner and the MPU. The circuit is realised in bipolar and I²L Technology.

- Direct tuner drive from 4 band drivers
- Direct control of the tuner's varicap diode
- Interface for external open collector band drivers
- Extremely low input current (1nA typical)

CIRCUIT DESCRIPTION

The circuit operation can be followed by reference to fig 1, the UAA 2010 block diagram, and fig 2, a phase locked loop using the UAA 2010, the MC6805T2 MPU and a TV tuner.

The tuner's local oscillator output frequency is divided in an external prescaler by 64 and then fed to the MC6805T2, which includes a variable divider, controlled by the processor, a reference divider and a phase comparator. By means of this circuitry the local oscillator frequency is further divided by a number determining the TV channel and compared to a fixed reference frequency inside the MPU. The output voltage of the phase comparator is filtered by using the operational amplifier of the UAA 2010 and then serves as the control voltage for the local oscillator varicap.

To facilitate filtering of the reference frequency the op amp is designed for a very low input bias current (1nA typ). The standard filter set up is shown in fig 2 with the frequency response shown in fig 3. To ensure loop stability the response is flat around the frequency where the overall loop gain is unity.

The UAA 2010 also receives band switching information from the MPU and applies it to the tuner by means of a shift register, latches, and buffers. The 5-bit band switching information is transferred by the signals DATA,

$\overline{\text{CLOCK}}$ and $\overline{\text{VDR}}$ (chip select); these inputs are designed to accept TTL levels. The $\overline{\text{CLOCK}}$ and DATA lines can be shared with other systems having other I/O devices.

Fig 4 shows the circuit's timing diagram. On the negative going $\overline{\text{VDR}}$ edge the latches are disconnected from the shift register and new information is shifted in. On the

positive going $\overline{\text{VDR}}$ edge the latches are reconnected thus transferring new band information to the buffers and the tuner.

The shift register also has a data output, this allows the MPU to pass data through the UAA 2010 and drive further circuits from the same DATA and chip select pins. The UAA 2010 shifts and outputs data on the positive going clock edge where the following circuits are intended to shift data on the negative going edge. For reliable data transfer the UAA 2010 should always be the first circuit in line as the clock signal consists of negative going pulses.

The latches control five buffers. Buffer B1 has an open collector output (see fig 5) and may be used to output any information from the MPU. Buffers B2 to B5 are band buffers specially designed to control external PNP drive transistors.

INPUT/OUTPUT FUNCTIONS

POS. INPUT — (pin 1) This is the non-inverting input to the operational amplifier and needs an external reference bias.

OP. AMP. OUT — (pin 2) This is the tuning voltage output, designed for direct control of the tuner's varicap.

V_{CC2} — (pin 3) This is the op amp supply voltage.

DATA OUT — (pin 4) This pin is the data output of the shift register. The output is designed to allow cascading other circuits using the same $\overline{\text{VDR}}$ signal.

B1 — (pin 5) This pin is an open collector buffer output of the first shifted bit. When shifting a logic '1' the output transistor is ON.

BAND DRIVER OUTPUTS — (pins 6, 7, 9 & 10) These outputs control external PNP transistors for band switching. When shifting a logic '1' the appropriate band buffer (external PNP) is ON.

V_{CC1} — (pin 8) This is the supply voltage for the band buffers.

I²L SUPPLY — (pin 11) This pin needs an external resistance to set up the I²L injector currents. The characteristic of the pin is that of a forward biased diode to pin 15 (ground) plus a series resistance of about 60Ω.

$\overline{\text{VDR}}$ — (pin 12) This is the chip select and is active when low.

$\overline{\text{CLOCK}}$ — (pin 13) This pin delivers the clock signal to the shift register, which accepts shifts and outputs data on the positive going edge. It should be noted that within the $\overline{\text{VDR}}$ window, when $\overline{\text{VDR}}$ is low, the clock has to be high at the beginning and end of the clock pulse train.

DATA — (pin 14) Data is entered serially into the circuit via this pin and passed directly to the shift register. In turn this controls the latches and band buffers.

NEG. INPUT — (pin 16) This is the inverting input of the op amp with a typical input bias current of 1nA, reducing with increasing temperature.

- DIMENSION "L" TO CENTER OF LEADS WHEN FORMED PARALLEL

A detailed micrograph of a printed circuit board (PCB) showing various linear circuit components and traces. The image displays a complex network of conductive paths, including several large, rectangular components with internal structures, likely integrated circuits or specialized linear components. The traces are densely packed and interconnected, forming a complex circuit layout. The overall appearance is that of a high-density, multi-layer PCB.

Other Linear Circuits

High Frequency Amplifiers

A variety of high-frequency circuits with features ranging from low-cost simplicity to multi-function versatility marks Motorola's line of integrated RF/IF amplifiers. Devices described here are intended for industrial and communications applications.

AGC AMPLIFIERS

MC1545/MC1445 – Gated 2-Channel Input

Differential input and output amplifier with gated 2-channel input for a wide variety of switching purposes. Typical 75 MHz bandwidth makes it suitable for high-frequency applications such as video switching, FSK circuits, multiplexers, etc. Gating circuit is useful for AGC control. See Application Notes AN-475 and AN-491 for design details.

GATE CHARACTERISTICS

MC1550 – Low Cost Building Block

Single-stage cascade connected amplifier with delayed AGC characteristics, for operation at frequencies to 100 MHz. Has typical power gain of 25 dB @ 60 MHz. See Application Notes AN-215A, AN-247A and AN-299 for design details.

CIRCUIT SCHEMATIC

MC1590 – Wide-Band General Purpose

Has differential inputs and outputs with unneutralized power gain as high as 35 dB typical at 100 MHz in tuned amplifier service. Effective AGC voltage range from 5 to 7 volts for a 30 dB gain reduction. See Application Note AN-513 for design details.

UNNEUTRALIZED POWER GAIN versus FREQUENCY

NON-AGC AMPLIFIERS

MC1552/MC1553 – Low Distortion Amplifier

Extremely high performance amplifier with internal series feedback for stable voltage gain and low distortion. Temperature compensation stabilizes operating point. Has selectable gain option and well characterized data that permits accurate response shaping (see graph). Useful for critical applications such as wideband linear amplifiers or fast-rise pulse amplifiers.

FREQUENCY RESPONSE

MC1733/MC1733C – Utility Amplifier

Differential input and output amplifier provides three fixed gain options with bandwidth to 120 MHz. External resistor permits any gain setting from 10 to 400 V/V. Extremely fast rise time (2.5 ns typ) and propagation delay time (3.6 ns typ) makes this unit particularly useful as pulse amplifier in tape, drum, or disc memory read applications.

GAIN versus FREQUENCY

6

SE/NE592 – Differential two stage video amplifiers. A monolithic, two state differential output, wideband video amplifier. It offers fixed gain of 100 and 400 without external components and adjustable gains from 400 to 0 with one external resistor. The input stage has been designed so that with the addition of a few external reactive elements between the gain select terminals, the circuit can function as a high pass, low pass or band pass filter. This feature makes the circuit ideal for use as a video or pulse amplifier in communications, magnetics memories, display and video recorder systems.

MC3505/3405 – Monolithic Dual Op Amp and Dual Comparator

This device contains two differential input operational amplifiers and two comparators each set capable of single supply operation. This op amp, comp circuit will find its applications as a general purpose product for automotive circuits and as an industrial building block.

- op amp equivalent in performance to MC3403
- comparator similar in performance to MLM339
- op amps are internally frequency compensated
- supply operation 3.0 V to 36 Volts
- dual supply operation also available.

MC3523/3423 – Overvoltage Protection Circuit

This overvoltage protection circuit protects sensitive electronic circuitry from overvoltage transients or regulator failure. It senses the overvoltage condition and quickly "crowbars" or short circuits the supply, forcing supply current limiting or opening the fuse or circuit breaker.

* To be introduced

*** MC3524/3424 – Over/under Voltage Protection Circuit**

- Same Features as the MC3523/3423 plus:
 - Sensing under voltage condition.
 - Externally Programmable hysteresis for noise immunity.

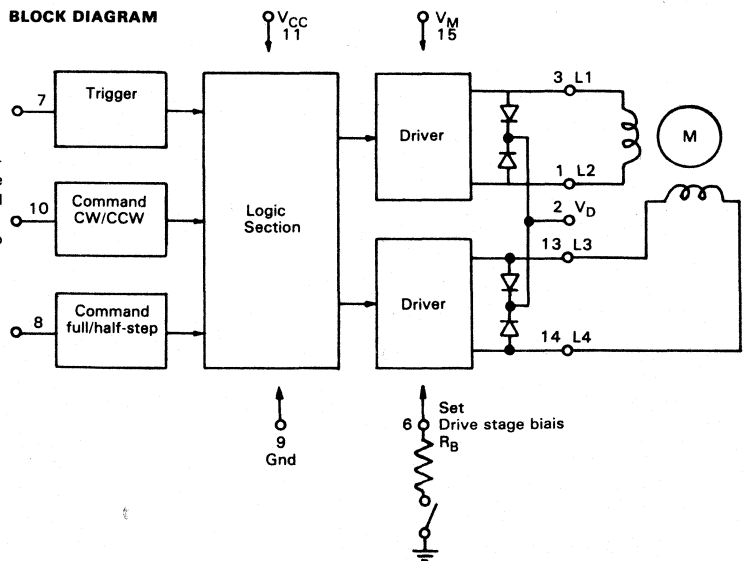

6

BLOCK DIAGRAM

SAA1042-Stepper Motor Driver

The SAA 1042 circuit is designed for driving a two-phase Stepper Motor in bipolar drive mode. The device contains three input stages, logic section and two output stages.

- Drive stage designed for motor voltages of 6 to 12 V.
- 500 mA/Coil current drive capability.
- Built in clamp diodes for over voltage suppression.
- Large variation of logical supply voltage ($V_{CC} = 5 \text{ V to } 18 \text{ V}$).
- Commands for CW/CCW and full/half-step operations.
- Schmitt trigger inputs compatible with many popular families like MOS, TTL, DTL. The threshold is set internally by V_{CC} .
- Set input for defined output state.
- Drive stage bias in accordance to motor power dissipation for best efficiency.
- Angel power plastic package. 16 pins (case 721-02).

MC1422

Specifications and Applications Information

MONOLITHIC TIMING CIRCUIT WITH EXTERNALLY ADJUSTABLE THRESHOLD LEVEL

The MC1422 monolithic timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. For astable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200 mA or drive MTTL circuits.

- Useable as a Differential Comparator Timer
- Timing From Microseconds Through Hours
- Operates in Both Astable and Monostable Modes
- Adjustable Duty Cycle
- High Current Output Can Source or Sink 200 mA
- Output Can Drive MTTL
- Temperature Stability of 0.005% per °C
- Normally "On" or Normally "Off" Output

TYPICAL APPLICATIONS

- Time Delay Generation
- Precision Timing
- Missing Pulse Detection
- Sequential Timing
- Pulse Generation
- Pulse Width Modulation
- Linear Sweep Generation
- Pulse Shaping
- Pulse Position Modulation

GENERAL INFORMATION

The MC1422 is a monolithic timing circuit similar in performance and function to the MC1455 timer. It can be used in both the astable and monostable modes with frequency and duty cycle controlled by the capacitor and resistor values. While the timing is dependent upon the external passive components, the monolithic circuit provides the starting circuit, voltage comparison and other functions needed for a complete timing circuit. Internal to the integrated circuit are two comparators, one for the input signal and the other for capacitor voltage; also a flip-flop and digital output are offered. The reference voltage of the trigger comparator is a fixed ratio of the supply voltage while the reference voltage of the threshold comparator is completely adjustable.

The MC1422 offers a completely independent variable threshold terminal. This feature allows it to be used as a modulation terminal as well as a synchronization terminal giving an additional degree of freedom in circuit design. The reference voltage pin (pin 5) for the threshold comparator is completely adjustable.

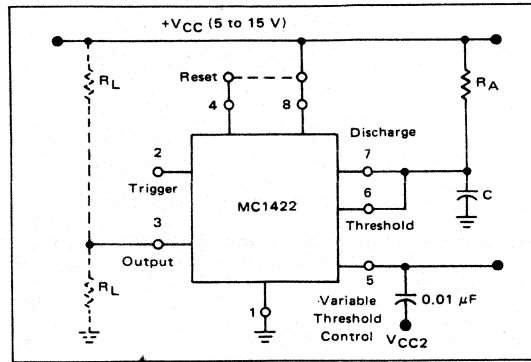

A reset pin is provided to discharge the capacitor thus interrupting the timing cycle. As long as the reset pin is low, the capacitor discharge transistor is turned "on" and prevents the capacitor from charging. While the reset volt-

age is applied the digital output will remain low. The reset pin should be tied to the supply voltage when not in use.

Monostable Mode

In the monostable mode, a capacitor and a single resistor are used for the timing network. Both the threshold and the discharge transistor terminal are connected together in this mode, refer to circuit Figure 14. When the input voltage to the trigger comparator falls below 1/3 V_{CC} the comparator output triggers the flip-flop so that it's output sets low. This turns the capacitor discharge transistor "off" and drives the digital output to the high state. This condition allows the capacitor to charge at an exponential rate which is set by the RC time constant. When the capacitor voltage reaches the external reference voltage the threshold comparator resets the flip-flop. This discharges the timing capacitor and returns the digital output to the low state. Once the flip-flop has been triggered by an input signal, it cannot be retriggered until the present timing period has been completed. The time that the output is high is given by the equation $t = 1.1 R_A C$. Various combinations of R and C and their associated times are shown in Figure 15. The trigger pulse width must be less than the timing period.

FIGURE 14 – MONOSTABLE CIRCUIT

APPLICATIONS INFORMATION

In general, the MC1422 can be used in any application where the MC1455/NE555 is currently being used as long as an external reference is supplied. (Refer to MC1455 data sheet for these applications.) The applications listed below are unique to the MC1422 and its design.

Zero Crossing Cycler

This circuit (see Figure 15) is most useful where it is necessary to cycle a thyristor at some frequency and duty cycle at line zero crossing only. This cycling at zero crossing only will reduce EMI, and current surges if capacitive loads are used.

Circuit Description

In order to have exact zero crossing cycling a phase shift network (R3)(C2) is used. Diodes CR1 and CR2 limit

the line voltage to V- and V+. This limited line voltage, which appears somewhat like a square wave, is used as a sync pulse when differentiated by C1 and attenuated to 1/3 by R1 and R2. Cycle time is dependent on R4 and C3. The duty cycle is set by potentiometer R4.

It should be noted that this zero crossing cycler is intended for low frequency cycling, much lower than the line frequency used.

$$T_{\text{cycle}} = 0.69 (R4)(C3) \text{ or } f_{\text{cycle}} = \frac{1.44}{(R4)(C3)}$$

FIGURE 15 – ZERO CROSSING CYCLER

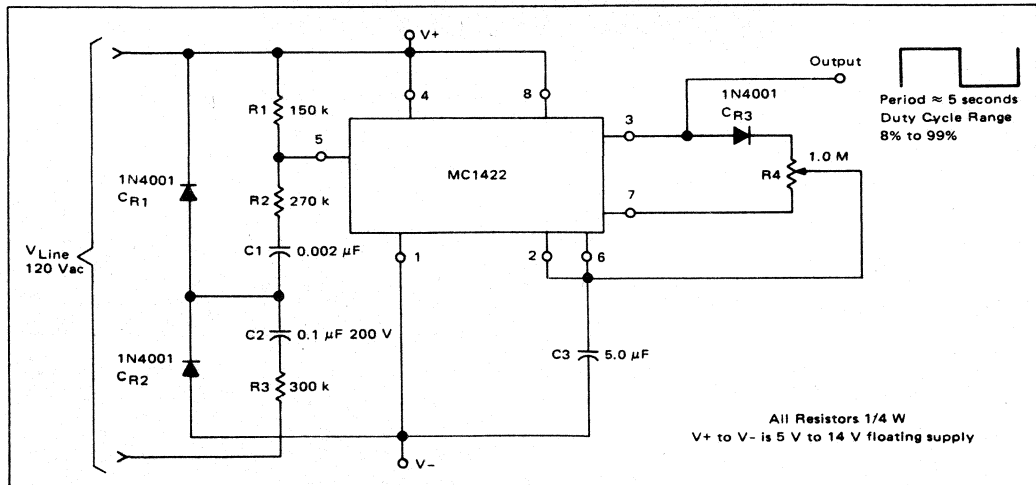

FIGURE 16 – PULSE WIDTH MODULATOR

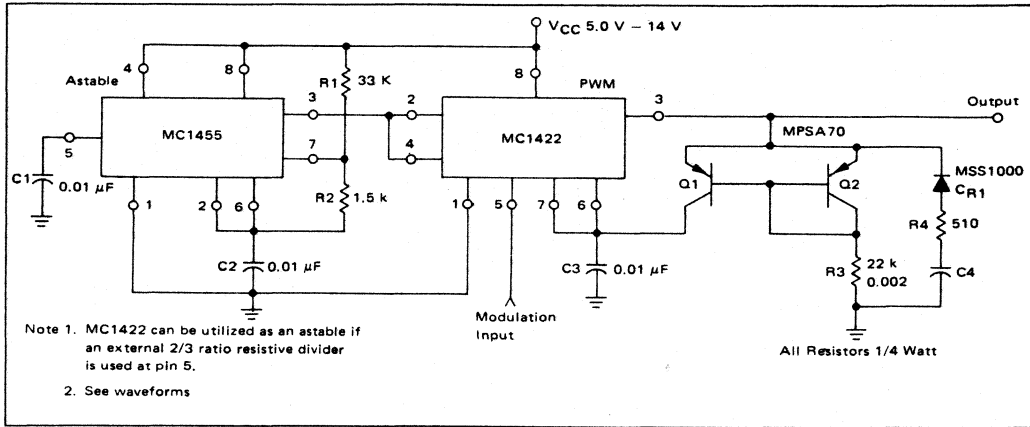

FIGURE 17 – PULSE WIDTH MODULATOR WAVEFORMS

Pulse Width Modulator

The MC1422 is used as a pulse width modulator (PWM) with the MC1455 being utilized as an astable. The MC1422 can be used as an astable in place of the MC1455 if an external reference of approximately 2/3 V_{CC} is used at Pin 5.

The transistors Q1 and Q2 are configured as a current mirror to provide a linear voltage ramp across C3. This constant current scheme attributes a relatively linear transfer characteristic for the pulse width modulator.

Several considerations must be made when using this circuit.

1. The minimum duty cycle out is limited to the complement of the input signal. (i.e., a 95% duty cycle astable driving the PWM will give a minimum duty cycle output of $\approx 5\%$.)

The maximum duty cycle out will also be limited to the maximum duty cycle in.

2. For the astable frequency:

$$f = 1/T = \frac{1.44}{(R_1 + 2R_2)C}$$

3. Duty cycle (D.C.) for the astable:

$$DC = \frac{R_2}{R_1 + 2R_2}$$

For best results the charge time of C3 in the pulse width modulator should be equal to the period of the astable.

$$\frac{I_{Q1}}{C_3 (V_{CC} - 1)} = f_{in} = \frac{1}{T_{C3}} \quad I_{Q1} \approx I_{Q2} = \frac{V_{CC} - V_{BE}}{R_3}$$

$V_{CC} = 10$ V linearity typically 3% modulation input from 2 volts to 8 volts.

MC1422

Voltage Controlled Oscillator

The VCO circuit, which has a nonlinear transfer characteristic will operate satisfactorily up to 200 kHz. The VCO input range is effective from $1/3 V_{CC}$ to $V_{CC} - 2 V$, with the highest control voltage producing the lowest output frequency. The equation for the frequency is:

$$f_{out} \approx \frac{1}{\ln \left(1 - \frac{V_5 - 1/3 V_{CC}}{2/3 V_{CC}} \right) (R_1 + R_2) C_1 + \ln \left(\frac{V_5 - 1/3 V_{CC}}{V_5} \right) R_2 C_1}$$

$V_5 =$ VCO input control voltage

It should be noted that, the output duty cycle will vary somewhat over the VCO input control range.

FIGURE 18 – VOLTAGE CONTROLLED OSCILLATOR

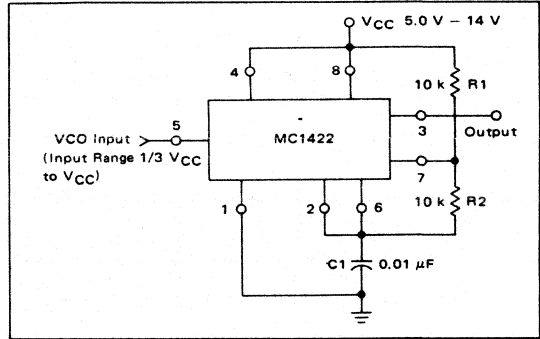

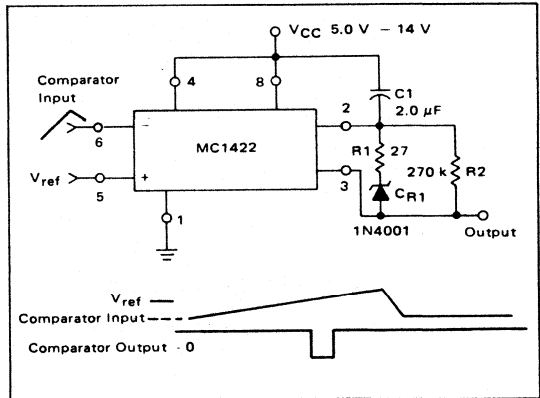

FIGURE 19

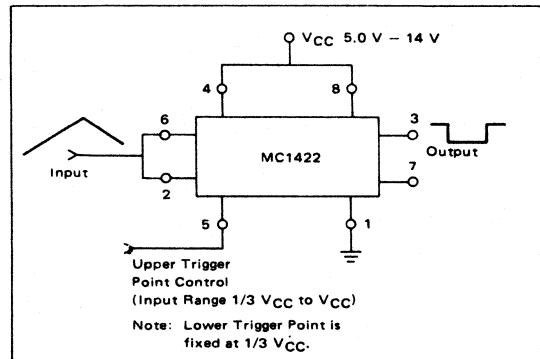

Comparator with Time Out

The MC1422 is used as a comparator with the capability of a timing output pulse when the inverting input (Pin 6) is \geq the non-inverting input (Pin 5). The frequency of the pulses for the values of R2 and C1 as shown in Figure 19 is approximately 2.0 Hz, and the pulse width 0.3 ms, $f_p =$ frequency of pulses while Pin 6 voltage is above voltage at Pin 5.

The function of R1 is to limit di/dt, when charging C1.

$$f_p \approx \frac{1}{R_2 C_1} \text{ or } T_p \approx R_2 C_1$$

FIGURE 20

Schmitt Trigger

The MC1422 is very useful as a Schmitt Trigger as shown in Figure 20. The lower trigger point is fixed at $1/3 V_{CC}$, but the upper trigger point is adjustable by means of Pin 5 from $1/3 V_{CC}$ to slightly less than V_{CC} . The Schmitt trigger will operate with input frequencies up to 50 kHz.

MC1538R	-55°C to +125°C	Metal Power

MC1438R MC1538R

POWER BOOSTER

The MC1538/MC1438 is designed as a high current gain amplifier (70 dB), with unity voltage gain that can deliver load currents up to ± 300 mA dc. This device is ideally suited to follow an operational amplifier (such as MC1556/MC1456) for driving low impedance loads and improving the overall circuit performance.

- **High Input Impedance** – 0.4 Meg-Ohm typ – when driving the MC1538/MC1438, the gain of an operational amplifier will approach the unloaded open-loop gain. Internal power dissipation of the operational amplifier will be independent of output voltage and therefore thermal drift will be reduced.
- **Large Power Bandwidth** – 1.5 MHz typ – considerably better than present operational amplifiers. Bandwidth and slew rate will be limited by the operational amplifier, not the MC1538/MC1438.
- **Low Output Impedance** – 10 Ohms typ – allows the MC1538/MC1438 to drive a capacitive load with greatly reduced phase shift compared with an operational amplifier. Output voltage swing capability is much increased when driving small load impedances.
- **Adjustable Current Limit** – ± 5.0 mA dc to ± 300 mA dc
- **Excellent Power-Supply Rejection** – 1.0 mV/V typ
- **Current Gain** – 3000 typ

POWER SUPPLY SPLITTER

SERVO/POWER AMPLIFIER

Under some conditions of circuit layout and loading, the MC1538R/MC1438R will oscillate when driven into current limiting. Oscillation during positive current limiting can usually be suppressed by placing a 0.02 μ F capacitor between Pins 7 and 5. Oscillations during negative current limit can usually be suppressed by placing a 0.02 μ F capacitor between Pins 1 and 2. 100 Ohms in series with this capacitor will reduce any cross-over distortion occurring when driving extremely low impedance loads.

CIRCUIT SCHEMATIC

CIRCUIT DESCRIPTION

The MC1550 is built with monolithic fabrication techniques utilizing diffused resistors and small-geometry transistors. Excellent AGC performance is obtained by shunting the signal through the AGC transistor Q_3 , maintaining the operating point of the input transistor Q_1 . This keeps the input impedance constant over the entire AGC range.

The amplifier is intended to be used in a common-emitter, common-base configuration (Q_1 and Q_2) with Q_3 acting as an AGC transistor. The input signal is applied between pins 1 and 4, where pin 4 is ac-coupled to ground. DC source resistance between pins 1 and 4 should be small (less than 100 ohms). Pins 2 and 3 should be connected together and grounded. Pins 8 and 10 should be bypassed to ground. The positive supply voltage is applied at pin 9 and at higher frequencies, pin 9 should also be bypassed to ground. The output is taken between pins 6 and 9. The substrate is connected to pin 7 and should be grounded. AGC voltage is applied to pin 5.

FIGURE 17 - y_{11} , INPUT-ADMITTANCE versus FREQUENCY

FIGURE 19 - s_{11} AND s_{22} , INPUT AND OUTPUT REFLECTION COEFFICIENT

The y_{12} shown in Figure 16 illustrates the extremely low feedback of the MC1550 with no contribution from the external mounting circuitry. However, in many cases the external circuitry may contribute as much or more to the total feedback than does the MC1550.

To perform more accurate design calculations of gain, stability, and input - output impedances it is recommended that the designer first determine the total feedback of device plus circuitry.

This can be done in one of two ways:

- (1) Measure the total y_{12} or s_{12} of the MC1550 installed in its mounting circuitry, or
- (2) Measure the y_{12} of the circuitry alone (without the MC1550 installed) and add the circuit y_{12} to the y_{12} for the MC1550 given in Figure 16.

VIDEO AMPLIFIERS

These devices consist of a three-stage, direct-coupled, common-emitter cascade incorporating series feedback to achieve stable voltage gain, low distortion, and wide bandwidth. They employ a temperature-compensated dc feedback loop to stabilize the operating point and a current-biased emitter follower output and are intended for use as either wide-band linear amplifiers or as fast rise pulse amplifiers.

- High Gain - 34 dB \pm 1 dB (MC1552)
52 dB \pm 1 dB (MC1553)
- Wide Bandwidth - 40 MHz (MC1552)
35 MHz (MC1553)
- Low Distortion - 0.2% at 200 kHz
- Low Temperature Drift - \pm 0.002 dB/ $^{\circ}$ C

NOTES

- Ground Pin 6 as close to package as possible to minimize overshoot. Best results are usually obtained by directly grounding the package.
- If large input and output coupling capacitors are used, place a shield between them to avoid input-output coupling.
- A high-frequency capacitor must always be used to bypass the power supply. This capacitor should be as close to the circuit as possible.
- Voltage gain can be adjusted to any value between 50 and 3000 by connecting an external resistor from Pin 4 to ground on MC1552, or from Pin 3 to ground on MC1553, as shown in

Figure 8. Under these conditions, the following equations must be used to determine C1 and C2 rather than the circuits shown in Figure 5.

$$\text{Fig. 5b } C1 = \frac{1}{2\pi f_c (1.7 \times 10^4)} \text{ Farads; } C2 = 8 C1 (V_O/V_i) \text{ Farads}$$

$$\text{Fig. 5c } C1 = \frac{V_O/V_i}{2\pi f_c (1.5 \times 10^4)} \text{ Farads}$$

$$\text{Fig. 5d } C2 = \frac{V_O/V_i}{2\pi f_c (3 \times 10^3)} \text{ Farads}$$

FIGURE 7 – SINGLE SUPPLY OPERATION VOLTAGE
GAIN (A_V) = 10, $f_{LOW} \approx 100$ Hz

RECOMMENDED OPERATING CONDITIONS

In order to avoid local VHF instability, the following set of rules must be adhered to:

1. An R-C stabilizing network (0.1 μF in series with 10 ohms) should be placed directly from pin 9 to ground, as shown in Figures 6 and 7, using short leads, to eliminate local VHF instability caused by lead inductance to the load.
2. Excessive lead inductance from the V_{CC} supply to pin 10 can cause high frequency instability. To prevent this, the V_{CC} -by-pass capacitor should be connected with short leads from the V_{CC} pin to ground. If this capacitor is remotely located a series R-C network (0.1 μF and 10 ohms) should be used directly from pin 10 to ground as shown in Figures 6 and 7.

3. Lead lengths from the external components to pins 7, 9, and 10 of the package should be as short as possible to insure good VHF grounding for these points.

Due to the large bandwidth of the amplifier, coupling must be avoided between the output and input leads. This can be assured by either (a) use of short leads which are well isolated, (b) narrow-banding the overall amplifier by placing a capacitor from pin 1 to ground to form a low-pass filter in combination with the source impedance, or (c) use of a shielded input cable. In applications which require upper band-edge control the input low-pass filter is recommended.

Specifications and Applications Information

TIMING CIRCUIT

The MC1555/MC1455 monolithic timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor. For astable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200 mA or drive MTTL circuits.

- Direct Replacement for NE555/SE555 Timers
- Timing From Microseconds Through Hours
- Operates in Both Astable and Monostable Modes
- Adjustable Duty Cycle
- High Current Output Can Source or Sink 200 mA
- Output Can Drive MTTL
- Temperature Stability of 0.005% per °C
- Normally "On" or Normally "Off" Output

FIGURE 13 – REPRESENTATIVE
CIRCUIT SCHEMATIC

GENERAL OPERATION

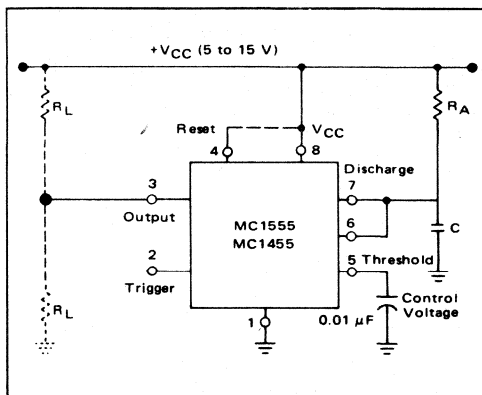

The MC1555 is a monolithic timing circuit which uses as its timing elements an external resistor – capacitor network. It can be used in both the monostable (one-shot) and astable modes with frequency and duty cycle controlled by the capacitor and resistor values. While the timing is dependent upon the external passive components, the monolithic circuit provides the starting circuit, voltage comparison and other functions needed for a complete timing circuit. Internal to the integrated circuit are two comparators, one for the input signal and the other for capacitor voltage; also a flip-flop and digital output are included. The comparator reference voltages are always a fixed ratio of the supply voltage thus providing output timing independent of supply voltage.

Monostable Mode

In the monostable mode, a capacitor and a single resistor are used for the timing network. Both the threshold terminal and the discharge transistor terminal are connected together in this mode, refer to circuit Figure 14. When the input voltage to the trigger comparator falls below $1/3 V_{CC}$ the comparator output triggers the flip-flop so that its output sets low. This turns the capacitor discharge transistor "off" and drives the digital output to the high state. This condition allows the capacitor to charge at an exponential rate which is set by the RC time constant. When the capacitor voltage reaches $2/3 V_{CC}$ the threshold comparator resets the flip-flop. This action discharges the timing capacitor and returns the digital output to the low state. Once the flip-flop has been triggered by an input signal, it cannot be retriggered until the present timing period has been completed. The time that the output is high is given by the equation $t = 1.1 R_A C$. Various combinations of R and C and their associated times are shown in Figure 16. The trigger pulse width must be less than the timing period.

A reset pin is provided to discharge the capacitor thus interrupting the timing cycle. As long as the reset pin is low, the capacitor discharge transistor is turned "on" and prevents the capacitor from charging. While the reset voltage is applied the digital output will remain the same. The reset pin should be tied to the supply voltage when not in use.

FIGURE 14 – MONOSTABLE CIRCUIT

GENERAL OPERATION (continued)

FIGURE 15 – MONOSTABLE WAVEFORMS

$t = 50 \mu\text{s/cm}$
 $(R_A = 10 \text{ k}\Omega, C = 0.01 \mu\text{F}, R_L = 1.0 \text{ k}\Omega, V_{CC} = 15 \text{ V})$

FIGURE 16 – TIME DELAY

Astable Mode

In the astable mode the timer is connected so that it will retrigger itself and cause the capacitor voltage to oscillate between $1/3 V_{CC}$ and $2/3 V_{CC}$. See Figure 17.

The external capacitor charges to $2/3 V_{CC}$ through R_A and R_B and discharges to $1/3 V_{CC}$ through R_B . By varying the ratio of these resistors the duty cycle can be varied. The charge and discharge times are independent of the supply voltage.

The charge time (output high) is given by: $t_1 = 0.695 (R_A + R_B) C$
 The discharge time (output low) by: $t_2 = 0.695 (R_B) C$
 Thus the total period is given by: $T = t_1 + t_2 = 0.695 (R_A + 2R_B) C$

The frequency of oscillation is then: $f = \frac{1}{T} = \frac{1.44}{(R_A + 2R_B) C}$
 and may be easily found as shown in Figure 19.

The duty cycle is given by: $DC = \frac{R_B}{R_A + 2R_B}$

To obtain the maximum duty cycle R_A must be as small as possible; but it must also be large enough to limit the discharge current (pin 7 current) within the maximum rating of the discharge transistor (200 mA).

The minimum value of R_A is given by:

$$R_A > \frac{V_{CC} (V_{dc})}{I_7 (A)} > \frac{V_{CC} (V_{dc})}{0.2}$$

 $(R_A = 5.1 \text{ k}\Omega, C = 0.01 \mu\text{F}, R_L = 1.0 \text{ k}\Omega;$
 $R_B = 3.9 \text{ k}\Omega, V_{CC} = 15 \text{ V})$

FIGURE 19 – FREE-RUNNING FREQUENCY

APPLICATIONS INFORMATION

Linear Voltage Ramp

In the monostable mode, the resistor can be replaced by a constant current source to provide a linear ramp voltage. The capacitor still charges from 0 to 2/3 V_{CC}. The linear ramp time is given by

$$t = \frac{2}{3} \frac{V_{CC}}{I}$$

where $I = \frac{V_{CC} - V_B - V_{BE}}{R_E}$. If V_B is much larger than V_{BE},

then t can be made independent of V_{CC}.

FIGURE 20 – LINEAR VOLTAGE SWEEP CIRCUIT

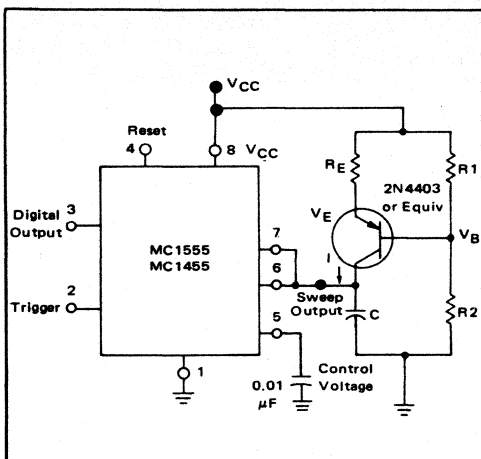

FIGURE 21 – LINEAR VOLTAGE RAMP WAVEFORMS
(R_E = 10 kΩ, R₂ = 100 kΩ, R₁ = 39 kΩ, C = 0.01 μF, V_{CC} = 15 V)

t = 100 μs/cm

Missing Pulse Detector

The timer can be used to produce an output when an input pulse fails to occur within the delay of the timer. To accomplish this, set the time delay to be slightly longer than the time between successive input pulses. The timing cycle is then continuously reset by the input pulse train until a change in frequency or a missing pulse allows completion of the timing cycle, causing a change in the output level.

FIGURE 22

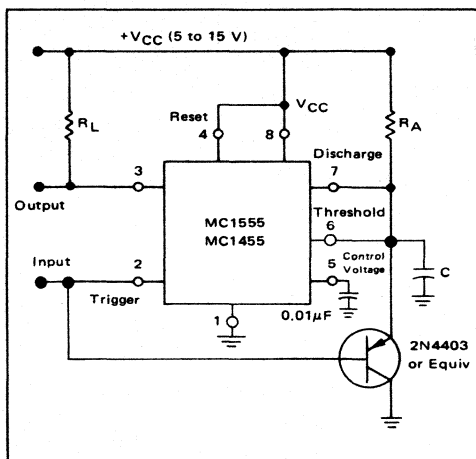

FIGURE 23 – MISSING PULSE DETECTOR WAVEFORMS
(R_A = 2.0 kΩ, R_L = 1.0 kΩ, C = 0.1 μF, V_{CC} = 15 V)

t = 500 μs/cm

APPLICATIONS INFORMATION (continued)

Pulse Width Modulation

If the timer is triggered with a continuous pulse train in the monostable mode of operation, the charge time of the capacitor can be varied by changing the control voltage at pin 5. In this manner, the output pulse width can be modulated by applying a modulating signal that controls the threshold voltage.

FIGURE 24

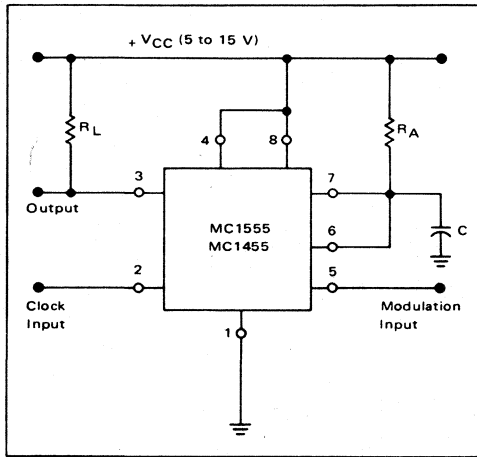

FIGURE 25 — PULSE WIDTH MODULATION WAVEFORMS
($R_A = 10\text{ k}\Omega$, $C = 0.02\text{ }\mu\text{F}$, $V_{CC} = 15\text{ V}$)

Test Sequences

Several timers can be connected to drive each other for sequential timing. An example is shown in Figure 26 where the sequence is started by triggering the first timer which runs for 10 ms. The output then switches low momentarily and starts the second timer which runs for 50 ms and so forth.

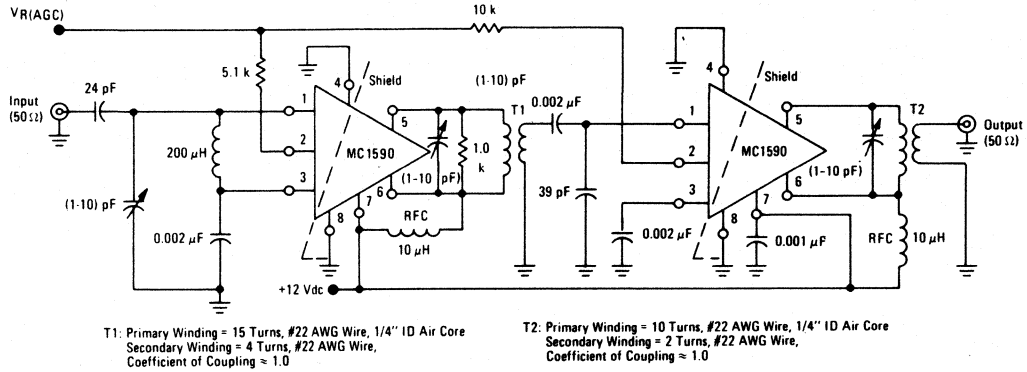

FIGURE 30 – SPEECH COMPRESSOR

DESCRIPTION OF SPEECH COMPRESSOR

The amplifier drives the base of a PNP MPS6517 operating common-emitter with a voltage gain of approximately 20. The control R1 varies the quiescent Q point of this transistor so that varying amounts of signal exceed the level V_r . Diode D1 rectifies the positive peaks of Q1's output only when these peaks are greater than $V_r \approx 7.0$ Volts. The resulting output is filtered by C_x , R_x .

R_x controls the charging time constant or attack time. C_x is involved in both charge and discharge. R2 (the 150 k Ω and input resistance of the emitter-follower Q2) controls the decay time. Making the decay long and attack short is accomplished by making R_x small and R2 large. (A Darlington emitter-follower may be needed if extremely slow decay times are required.)

The emitter-follower Q2 drives the AGC Pin 2 of the MC1590 and reduces the gain. R3 controls the slope of signal compression. The following graph (Figure 31) details performance with R3 set to 15 k Ω .

Specifications and Applications Information

MONOLITHIC FOUR-QUADRANT MULTIPLIER

... designed for use where the output voltage is a linear product of two input voltages. Typical applications include: multiply, divide, square root, mean square, phase detector, frequency doubler, balanced modulator/demodulator, electronic gain control.

The MC1594/1494 is a variable transconductance multiplier with internal level-shift circuitry and voltage regulator. Scale factor, input offsets and output offset are completely adjustable with the use of four external potentiometers. Two complementary regulated voltages are provided to simplify offset adjustment and improve power-supply rejection.

- Operates With ± 15 V Supplies
- Excellent Linearity – Maximum Error (X or Y): $\pm 0.5\%$ (MC1594) $\pm 1.0\%$ (MC1494)
- Wide Input Voltage Range $-\pm 10$ volts
- Adjustable Scale Factor, K (0.1 nominal)
- Single Ended Output Referenced to Ground
- Simplified Offset Adjust Circuitry
- Frequency Response (3 dB Small-Signal) – 1.0 MHz
- Power Supply Sensitivity – 30 mV/V typical

MC1494, MC1594

GENERAL INFORMATION

1. CIRCUIT DESCRIPTION

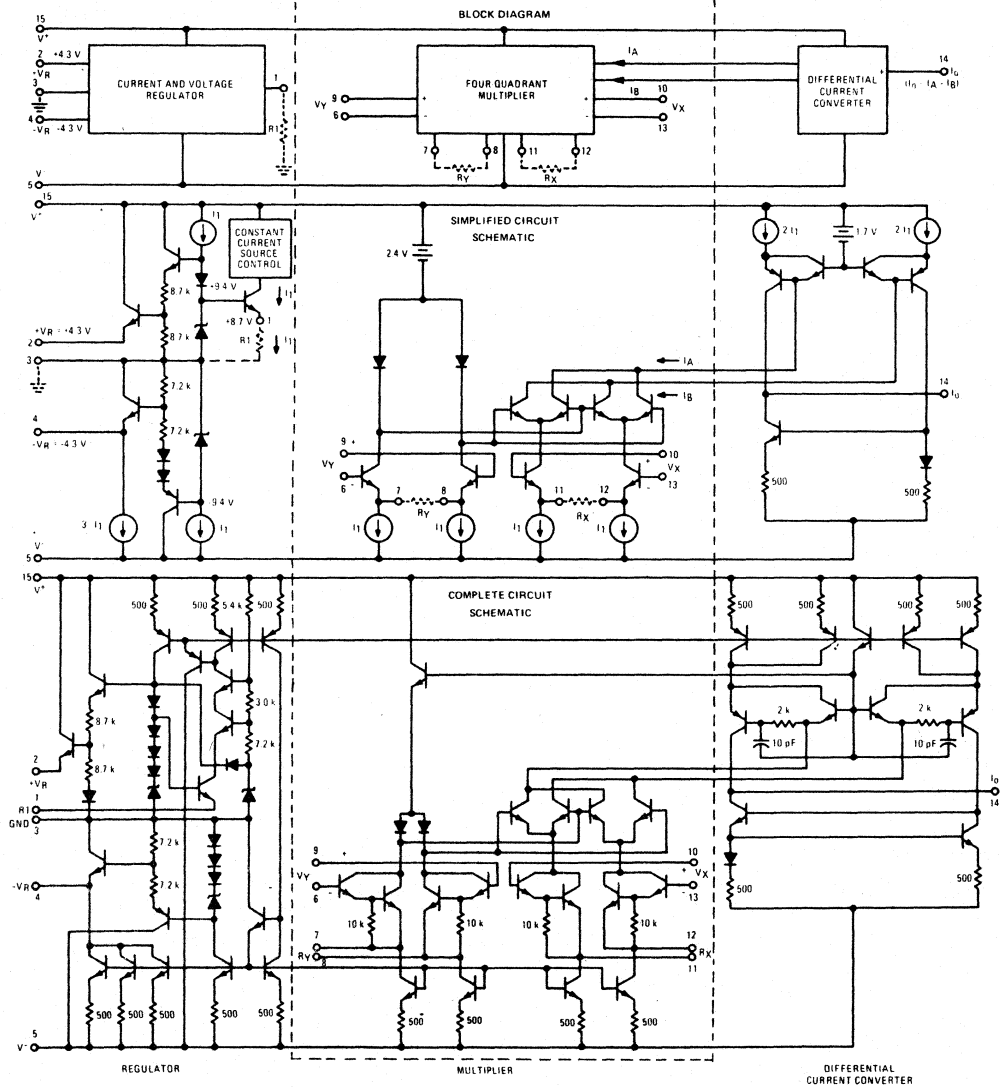

1.1 Introduction

The MC1594 is a monolithic, four-quadrant multiplier that operates on the principle of variable transconductance. It features a single-ended current output referenced to ground and provides two complementary regulated voltages for use

with the offset adjust circuits to virtually eliminate sensitivity of the offset voltage nulls to changes in supply voltage.

As shown in Figure 15, the MC1594 consists of a multiplier proper and associated peripheral circuitry to provide these features.

FIGURE 15
(Recommended External Circuitry is Depicted With Dotted Lines)

1.2 Regulator (Figure 15)

The regulator biases the entire MC1594 circuit making it essentially independent of supply variation. It also provides two convenient regulated supply voltages which can be used in the offset adjust circuitry. The regulated output voltage at pin 2 is approximately +4.3 V while the regulated voltage at pin 4 is approximately -4.3 V. For optimum temperature stability of these regulated voltages, it is recommended that $|I_2| = |I_4| = 1.0$ mA (equivalent load of 8.6 k Ω). As will be shown later, there will normally be two 20 k-ohm potentiometers and one 50 k-ohm potentiometer connected between pins 2 and 4.

The regulator also establishes a constant current reference that controls all of the constant current sources in the MC1594. Note that all current sources are related to current I_1 which is determined by R1. For best temperature performance, R1 should be 16 k Ω so that $I_1 \approx 0.5$ mA for all applications.

1.3 Multiplier (Figure 15)

The multiplier section of the MC1594 (center section of Figure 15) is nearly identical to the MC1595 and is discussed in detail in Application Note AN-489, "Analysis and Basic Operation of the MC1595". The result of this analysis is that the differential output current of the multiplier is given by:

$$I_A - I_B = \Delta I \approx \frac{2V_X V_Y}{R_X R_Y I_1}$$

Therefore, the output is proportional to the product of the two input voltages

1.4 Differential Current Converter (Figure 15)

This portion of the circuitry converts the differential output current ($I_A - I_B$) of the multiplier to a single-ended output current (I_O):

$$I_O = I_A - I_B$$

or

$$I_O = \frac{2V_X V_Y}{R_X R_Y I_1}$$

The output current can be easily converted to an output voltage by placing a load resistor R_L from the output (pin 14) to ground (Figure 17) or by using an op-amp, as a current-to-voltage converter (Figure 16). The result in both circuits is that the output voltage is given by:

$$V_O = \frac{2R_L V_X V_Y}{R_X R_Y I_1} = K V_X V_Y$$

where K (scale factor) = $\frac{2R_L}{R_X R_Y I_1}$

2. DC OPERATION

2.1 Selection of External Components

For low frequency operation the circuit of Figure 16 is recommended. For this circuit, $R_X = 30$ k Ω , $R_Y = 62$ k Ω , $R_1 = 16$ k Ω and hence $I_1 \approx 0.5$ mA. Therefore, to set the scale factor, K, equal to 1/10, the value of R_L can be calculated to be:

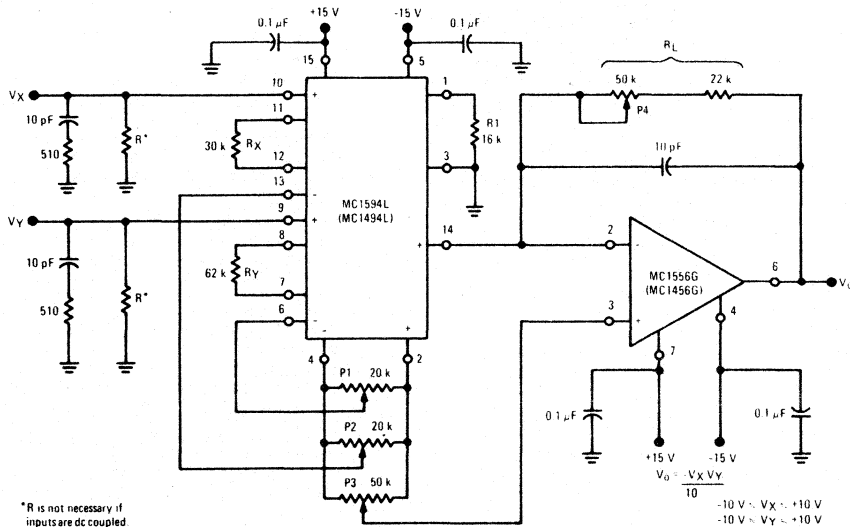

$$K = \frac{1}{10} = \frac{2R_L}{R_X R_Y I_1}$$

or $R_L = \frac{R_X R_Y I_1}{(2)(10)} = \frac{(30 \text{ k})(62 \text{ k})(0.5 \text{ mA})}{20}$

$$R_L = 46.5 \text{ k}$$

Thus, a reasonable accuracy in scale factor can be achieved by making R_L a fixed 47 k Ω resistor. However, if it is desired

FIGURE 16 - TYPICAL MULTIPLIER CONNECTION

that the scale factor be exact, R_L can be comprised of a fixed resistor and a potentiometer as shown in Figure 16. It should be pointed out that there is nothing magic about setting the scale factor to 1/10. This is merely a convenient factor to use if the V_X and V_Y input voltages are expected to be large, say ± 10 V. Obviously with $V_X = V_Y = 10$ V and a scale factor of unity, the device could not hope to provide a 100 V output, so the scale factor is set to 1/10 and provides an output scaled down by a factor of ten. For many applications it may be desirable to set $K = 1/2$ or $K = 1$ or even $K = 100$. This can be accomplished by adjusting R_X , R_Y and R_L appropriately.

The selection of R_L is arbitrary and can be chosen after resistors R_X and R_Y are found. Note in Figure 16 that R_Y is 62 k Ω while R_X is 30 k Ω . The reason for this is that the "Y" side of the multiplier exhibits a second order non-linearity whereas the "X" side exhibits a simple non-linearity. By making the R_Y resistor approximately twice the value of the R_X resistor, the linearity on both the "X" and "Y" sides are made equal. The selection of the R_X and R_Y resistor values is dependent upon the expected amplitude of V_X and V_Y inputs. To maintain a specified linearity, resistors R_X and R_Y should be selected according to the following equations:

$$R_X \geq 3 V_X (\text{max}) \text{ in k}\Omega \text{ when } V_X \text{ is in volts}$$

$$R_Y \geq 6 V_Y (\text{max}) \text{ in k}\Omega \text{ when } V_Y \text{ is in volts}$$

For example, if the maximum input on the "X" side is ± 1 volt, resistor R_X can be selected to be 3 k Ω . If the maximum input on the "Y" side is also ± 1 volt, then resistor R_Y can be selected to be 6 k Ω (6.2 k Ω nominal value). If a scale factor of $K = 10$ is desired, the load resistor is found to be 47 k Ω . In this example, the multiplier provides a gain of 20 dB.

2.2 Operational Amplifier Selection

The operational amplifier connection in Figure 16 is a simple but extremely accurate current-to-voltage converter. The output current of the multiplier flows through the feedback resistor R_L to provide a low impedance output voltage from the op-amp. Since the offset current and bias currents of the op-amp. will cause errors in the output voltage, particularly with temperature, one with very low bias and offset currents is recommended. The MC1556/MC1456 or MC1741/MC1741C are excellent choices for this application.

Since the MC1594 is capable of operation at much higher frequencies than the op-amp., the frequency characteristics of the circuit in Figure 16 will be primarily dependent upon the op-amp.

2.3 Stability

The current-to-voltage converter mode is a most demanding application for an operational amplifier. Loop gain is at its maximum and the feedback resistor in conjunction with stray or input capacitance at the multiplier output adds additional phase shift. It may therefore be necessary to add (particularly in the case of internally compensated op-amps.) a small feedback capacitor to reduce loop gain at the higher frequencies. A value of 10 pF in parallel with R_L should be adequate to insure stability over production and temperature variations, etc.

An externally compensated op-amp. might be employed using slightly heavier compensation than that recommended for unity-gain operation.

2.4 Offset Adjustment

The non-inverting input of the op-amp. provides a convenient point to adjust the output offset voltage. By connecting this point to the wiper arm of a potentiometer (P3), the output

offset voltage can be adjusted to zero (see offset and scale factor adjustment procedure).

The input offset adjustment potentiometers, P1 and P2 will be necessary for most applications where it is desirable to take advantage of the multiplier's excellent linearity characteristics. Depending upon the particular application, some of the potentiometers can be omitted (see Figures 17, 19, 22, 24 and 25).

2.5 Offset and Scale Factor Adjustment Procedure

The adjustment procedure for the circuit of Figure 16 is:

- A. X Input Offset
 - (a) connect oscillator (1 kHz, 5 Vpp sine wave) to the "Y" input (pin 9)
 - (b) connect "X" input (pin 10) to ground
 - (c) adjust X-offset potentiometer, P2 for an ac null at the output
- B. Y Input Offset
 - (a) connect oscillator (1 kHz, 5 Vpp sine wave) to the "X" input (pin 10)
 - (b) connect "Y" input (pin 9) to ground
 - (c) adjust Y-offset potentiometer, P1 for an ac null at the output
- C. Output Offset
 - (a) connect both "X" and "Y" inputs to ground
 - (b) adjust output offset potentiometer, P3, until the output voltage V_O , is zero volts dc
- D. Scale Factor
 - (a) apply +10 Vdc to both the "X" and "Y" inputs
 - (b) adjust P4 to achieve -10.00 V at the output
 - (c) apply -10 Vdc to both "X" and "Y" inputs and check for $V_O = -10.00$ V
- E. Repeat steps A through D as necessary.

The ability to accurately adjust the MC1594 is dependent on the offset adjust potentiometers. Potentiometers should be of the "infinite" resolution type rather than wirewound. Fine adjustments in balanced-modulator applications may require two potentiometers to provide "coarse" and "fine" adjustment. Potentiometers should have low temperature coefficients and be free from backlash.

2.6 Temperature Stability

While the MC1594 provides excellent performance in itself, overall performance depends to a large degree on the quality of the external components. Previous discussion shows the direct dependence on R_X , R_Y , and R_L and indirect dependence on R1 (through I_1). Any circuit subjected to temperature variations should be evaluated with these effects in mind.

2.7 Bias Currents

The MC1594 multiplier, like most linear IC's, requires a dc bias current into its input terminals. The device cannot be capacitively coupled at the input without regard for this bias current. If inputs V_X and V_Y are able to supply the small bias current ($\approx 0.5 \mu A$) resistors, R (Figure 16) can be omitted. If the MC1594 is used in an ac mode of operation and capacitive coupling is used the value of resistor R can be any reasonable value up to 100 k Ω . For minimum noise and optimum temperature performance, the value of resistor R should be as low as practical.

2.8 Parasitic Oscillation

When long leads are used on the inputs, oscillation may occur. In this event, an RC parasitic suppression network similar to the ones shown in Figure 16 should be connected directly to each input using short leads. The purpose of the network

is to reduce the "Q" of the source-tuned circuits which cause the oscillation.

Inability to adjust the circuit to within the specified accuracy may be an indication of oscillation.

3. AC OPERATION

3.1 General

For ac operation, such as balanced modulation, frequency doubler, AGC, etc., the op-ampl. will usually be omitted as well as the output offset adjust potentiometer. The output offset adjust potentiometer is omitted since the output will normally be ac-coupled and the dc voltage at the output is of no concern providing it is close enough to zero volts that it will not cause clipping in the output waveform. Figure 17

shows a typical ac multiplier circuit with a scale factor $K \approx 1$. Again, resistor R_X and R_Y are chosen as outlined in the previous section, with R_L chosen to provide the required scale factor.

The offset voltage then existing at the output will be equal to the offset current times the load resistance. The output offset current of the MC1594 is typically 17 μA and 35 μA maximum. Thus, the maximum output offset would be about 160 mV.

3.2 Bandwidth

The bandwidth of the MC1594 is primarily determined by two factors. First, the dominant pole will be determined by the load resistor and the stray capacitance at the output terminal. For the circuit shown in Figure 17, assuming a total output capacitance (C_O) of 10 pF, the 3 dB bandwidth would be approximately 3.4 MHz. If the load resistor were 47 k Ω , the bandwidth would be approximately 340 kHz.

Secondly, a "zero" is present in the frequency response characteristic for both the "X" and "Y" inputs which causes the output signal to rise in amplitude at a 6 dB/octave slope at frequencies beyond the breakpoint of the "zero". The "zero" is caused by the parasitic and substrate capacitance which is related to resistors R_X and R_Y and the transistors associated with them. The effect of these transmission

"zeros" is seen in Figures 9 and 10. The reason for this increase in gain is due to the bypassing of R_X and R_Y at high frequencies. Since the R_Y resistor is approximately twice the value of the R_X resistor, the zero associated with the "Y" input will occur at approximately one octave below the zero associated with the "X" input. For $R_X = 30 k\Omega$ and $R_Y = 62 k\Omega$, the zeros occur at 1.5 MHz for the "X" input and 700 kHz for the "Y" input. These two measured breakpoints correspond to a shunt capacitance of about 3.5 pF. Thus, for the circuit of Figure 17, the "X" input zero and "Y" input zero will be at approximately 15 MHz and 7 MHz respectively.

It should be noted that the MC1594 multiplies in the time domain, hence, its frequency response is found by means of complex convolution in the frequency (Laplace) domain. This means that if the "X" input does not involve a frequency, it is not necessary to consider the "X" side frequency response in the output product. Likewise, for the "Y" side. Thus, for applications such as a wideband linear AGC amplifier which has a dc voltage as one input, the multiplier frequency response has one zero and one pole. For applications which involve an ac voltage on both the "X" and "Y" side, such as a balanced modulator, the product voltage response will have two zeros and one pole, hence, peaking may be present in the output.

From this brief discussion, it is evident that for ac applications; (1) the value of resistors R_X , R_Y and R_L should be kept as small as possible to achieve maximum frequency response, and (2) it is possible to select a load resistor R_L such that the dominant pole (R_L, C_O) cancels the input zero ($R_X, 3.5 pF$ or $R_Y, 3.5 pF$) to give a flat amplitude characteristic with frequency. This is shown in Figures 9 and 10. Examination of the frequency characteristics of the "X" and "Y" inputs will demonstrate that for wideband amplifier applications, the best tradeoff with frequency response and gain is achieved by using the "Y" input for the ac signal.

For ac applications requiring bandwidths greater than those specified for the MC1594, two other devices are recommended. For modulator-demodulator applications, the MC1596 may be used up to 100 MHz. For wideband multiplier applications, the MC1595 (using small collector loads and ac coupling) can be used.

3.3 Slew-Rate

The MC1594 multiplier is not slew-rate limited in the ordinary sense that an op-ampl. is. Since all the signals in the multiplier are currents and not voltages, there is no charging and discharging of stray capacitors and thus no limitations beyond the normal device limitations. However, it should be noted that the quiescent current in the output transistors is 0.5 mA and thus the maximum rate of change of the output voltage is limited by the output load capacitance by the simple equation:

$$\text{Slew-Rate} \frac{\Delta V_O}{\Delta T} = \frac{I_O}{C}$$

Thus, if C_O is 10 pF, the maximum slew-rate would be:

$$\frac{\Delta V_O}{\Delta T} = \frac{0.5 \times 10^{-3}}{10 \times 10^{-12}} = 50 \text{ V}/\mu\text{s}$$

This can be improved if necessary by addition of an emitter-follower or other type of buffer.

3.4 Phase-Vector Error

All multipliers are subject to an error which is known as the phase-vector error. This error is a phase error only and does not contribute an amplitude error per se. The phase-vector

error is best explained by an example. If the "X" input is described in vector notation as

$$X = A \angle \theta^{\circ}$$

and the "Y" input is described as

$$Y = B \angle \phi^{\circ}$$

then the output product would be expected to be

$$V_o = AB \angle \theta^{\circ} \text{ (see Figure 18)}$$

However, due to a relative phase shift between the "X" and "Y" channels, the output product will be given by

$$V_o = AB \angle \phi$$

Notice that the magnitude is correct but the phase angle of the product is in error. The vector, V , associated with this error is the "phase-vector error". The startling fact about the phase-vector error is that it occurs and accumulates much more rapidly than the amplitude error associated with frequency response. In fact, a relative phase shift of only 0.57° will result in a 1% phase-vector error. For most applications, this error is meaningless. If phase of the output product is not important, then neither is the phase-vector error. If phase is important, such as in the case of double sideband modulation or demodulation, then a 1% phase-vector error will represent a 1% amplitude error at the phase angle of interest.

FIGURE 18 - PHASE-VECTOR ERROR

3.5 Circuit Layout

If wideband operation is desired, careful circuit layout must be observed. Stray capacitance across R_X and R_Y should be avoided to minimize peaking (caused by a zero created by the parallel RC circuit).

4. DC APPLICATIONS

4.1 Squaring Circuit

If the two inputs are connected together, the resultant function is squaring:

$$V_o = KV^2$$

where K is the scale factor (see Figure 19).

However, a more careful look at the multiplier's defining equation will provide some useful information. The output voltage, without initial offset adjustments is given by:

$$V_o = K(V_x + V_{ioX} - V_{x\ off})(V_y + V_{ioY} - V_{y\ off}) + V_{oo}$$

(See "Definitions" for an explanation of terms).

With $V_x = V_y = V$ (squaring) and defining

$$\epsilon_x = V_{ioX} - V_{x\ off}$$

$$\epsilon_y = V_{ioY} - V_{y\ off}$$

The output voltage equation becomes

$$V_o = K V_x^2 + KV_x(\epsilon_x + \epsilon_y) + K\epsilon_x\epsilon_y + V_{oo}$$

This shows that all error terms can be eliminated with only three adjustment potentiometers, eliminating one of the input offset adjustments. For instance, if the "X" input offset adjustment is eliminated, ϵ_x is determined by the internal offset, V_{ioX} , but ϵ_y is adjustable to the extent that the $(\epsilon_x + \epsilon_y)$ term can be zeroed. Then the output offset adjustment is used to adjust the V_{oo} term and thus zero the remaining error terms. An ac procedure for nulling with three adjustments is:

A. AC Procedure:

1. Connect oscillator (1 kHz, 15 Vpp) to input
2. Monitor output at 2 kHz with tuned voltmeter and adjust P4 for desired gain (Be sure to peak response of voltmeter)
3. Tune voltmeter to 1 kHz and adjust P1 for a minimum output voltage
4. Ground input and adjust P3 (output offset) for zero volts dc out
5. Repeat steps 1 through 4 as necessary.

FIGURE 19 - MC1594 SQUARING CIRCUIT

FIGURE 22 – BASIC SQUARE ROOT CIRCUIT

nator voltage. As a result, if V_X is set to 10 volts and 0.5% accuracy is available, then 5% accuracy can be expected when V_X is only 1 volt.

In accordance with an earlier statement, V_X may have only one polarity, positive, while V_Z may be either polarity.

4.3 Square Root

A special case of the divide circuit in which the two inputs to the multiplier are connected together results in the square root function as indicated in Figure 22. This circuit too may suffer from latch-up problems similar to those of the divide circuit. Note that only one polarity of input is allowed and diode clamping (see Figure 23) protects against accidental latch-up.

This circuit too, may be adjusted in the closed-loop mode:

1. Set $V_Z = -0.01$ Vdc and adjust P3 (output offset) for $V_0 = 0.316$ Vdc.
2. Set V_Z to -0.9 Vdc and adjust P2 ("X" adjust) for $V_0 = +3$ Vdc.
3. Set V_Z to -10 Vdc and adjust P4 (gain adjust) for $V_0 = +10$ Vdc.

Steps 1 through 3 may be repeated as necessary to achieve desired accuracy.

Note: Operation near zero volts input may prove very inaccurate, hence, it may not be possible to adjust V_0 to 0 but rather only to within 100 to 400 mV of zero.

5. AC APPLICATIONS

5.1 Wideband Amplifier With Linear AGC

If one input to the MC1594 is a dc voltage and a signal voltage is applied to the other input, the amplitude of the output signal can be controlled in a linear fashion by varying the dc voltage. Hence, the multiplier can function as a dc coupled, wideband amplifier with linear AGC control.

In addition to the advantage of Linear AGC control, the multiplier has three other distinct advantages over most other types of AGC systems. First, the AGC dynamic range is theoretically infinite. This stems from the basic fact that with zero volts dc applied to the AGC, the output will be zero regardless of the input. In practice, the dynamic range is limited by the ability to adjust the input offset adjust potentiometers. By using cermet multi-turn potentiometers, a dynamic range of 80 dB can be obtained. The second advantage of the multiplier is that variation of the AGC voltage has no effect on the signal handling capability of the signal port, nor does it alter the input impedance of the signal port. This feature is particularly important in AGC systems which are phase sensitive. A third advantage of the multiplier is that the output-voltage-swing capability and output impedance are unchanged with variations in AGC voltage.

The circuit of Figure 24 demonstrates the linear AGC amplifier. The amplifier can handle 1 V(rms) and exhibits a gain of approximately 20 dB. It is AGC'd through a 60 dB dynamic range with the application of an AGC voltage from 0 Vdc to 1 Vdc. The bandwidth of the amplifier is determined by the load resistor and output stray capacitance. For this reason, an emitter-follower buffer has been added to extend the bandwidth in excess of 1 MHz.

5.2 Balanced Modulator

When two-time variant signals are used as inputs, the result-

FIGURE 23 – SQUARE ROOT CIRCUIT

MC1494, MC1594

ing output is suppressed-carrier double-sideband modulation. In terms of sinusoidal inputs, this can be seen in the following equation:

$$V_o = K(e_1 \cos \omega_m t)(e_2 \cos \omega_c t)$$

where ω_m is the modulation frequency and ω_c is the carrier frequency. This equation can be expanded to show the suppressed carrier or balanced modulation:

$$V_o = \frac{Ke_1e_2}{2} [\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)t]$$

Unlike many modulation schemes, which are non-linear in nature, the modulation which takes place when using the MC1594 is linear. This means that for two sinusoidal inputs, the output will contain only two frequencies, the sum and difference, as seen in the above equation. There will be no spectrum centered about the second harmonic of the carrier, or any multiple of the carrier. For this reason, the filter requirements of a modulation system are reduced to the minimum. Figure 25 shows the MC1594 configuration to perform this function.

FIGURE 24 – WIDEBAND AMPLIFIER WITH LINEAR AGC

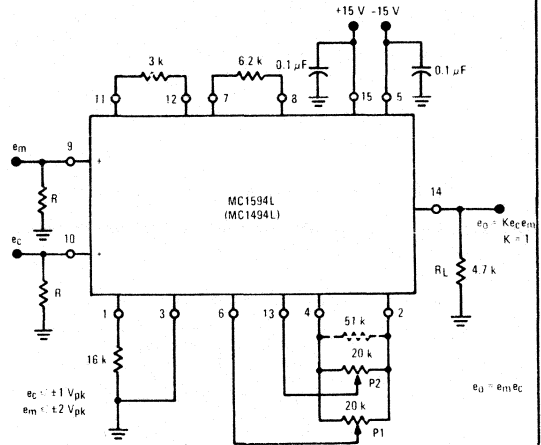

Notice that the resistor values for R_X , R_Y , and R_L have been modified. This has been done primarily to increase the bandwidth by lowering the output impedance of the MC1594 and then lowering R_X and R_Y to achieve a gain of 1. The e_c can be as large as 1 volt peak and e_m as high as 2 volts peak. No output offset adjust is employed since we are interested only in the ac output components.

The input R 's are used to supply bias current to the multiplier inputs as well as provide matching input impedance. The output frequency range of this configuration is determined by the 4.7 k ohm output impedance and capacitive loading. Assuming a 6 pF load, the small-signal bandwidth is 5.5 MHz.

The circuit of Figure 25 will provide a typical carrier rejection of ≥ 70 dB from 10 kHz to 1.5 MHz.

FIGURE 25 – BALANCED MODULATOR

The adjustment procedure for this circuit is quite simple.

- (1) Place the carrier signal at pin 10. With no signal applied to pin 9, adjust potentiometer P1 such that an ac null is obtained at the output.
- (2) Place a modulation signal at pin 9. With no signal applied to pin 10, adjust potentiometer P2 such that an ac null is obtained at the output.

Again, the ability to make careful adjustment of these offsets will be a function of the type of potentiometers used for P1 and P2. Multiple turn cermet type potentiometers are recommended.

5.3 Frequency Doubler

If for Figure 25 both inputs are identical;

$$e_m = e_c = E \cos \omega t$$

Then the output is given by

$$e_o = e_m e_c = E^2 \cos^2 \omega t$$

which reduces to

$$e_o = \frac{E^2}{2} (1 + \cos 2\omega t)$$

This equation states that the output will consist of a dc term equal to one half the peak voltage squared and the second harmonic of the input frequency. Thus, the circuit acts as a frequency doubler. Two facts about this circuit are worthy of note. First, the second harmonic of the input frequency is the only frequency appearing at the output. The fundamental does not appear. Second, if the input is sinusoidal, the output will be sinusoidal and requires no filtering.

The circuit of Figure 25 can be used as a frequency doubler with input frequencies in excess of 2 MHz.

5.4 Amplitude Modulator

The circuit of Figure 25 is also easily used as an amplitude modulator. This is accomplished by simply varying the input offset adjust potentiometer (P1) associated with the modu-

lation input. This procedure places a dc offset on the modulation input of the multiplier such that the carrier still passes thru the multiplier when the modulating signal is zero. The result is amplitude modulation. This is easily seen by examining the basic mathematical expression for amplitude modulation given below. For the case under discussion, with $K = 1$,

$$e_o = (E + E_m \cos \omega_m t) (E_c \cos \omega_c t)$$

where E is the dc input offset adjust voltage. This expression can be written as:

$$e_o = E_o [1 + M \cos \omega_c t] \cos \omega_c t$$

where $E_o = EE_c$

and $M = \frac{E_m}{E} = \text{modulation index}$

This is the standard equation for amplitude modulation. From this, it is easy to see that 100% modulation can be achieved by adjusting the input offset adjust voltage to be exactly equal to the peak value of the modulation, E_m . This is done by observing the output waveform and adjusting the input offset potentiometer, P1, until the output exhibits the familiar amplitude modulation waveform.

5.5 Phase Detector

If the circuit of Figure 25 has as its inputs two signals of identical frequency but having a relative phase shift the output will be a dc signal which is directly proportional to the cosine of phase difference as well as the double frequency term.

$$e_c = E_c \cos \omega_c t$$

$$e_m = E_m \cos(\omega_c t + \phi)$$

$$e_o = e_c e_m = E_c E_m \cos \omega_c t \cos(\omega_c t + \phi)$$

or
$$e_o = \frac{E_c E_m}{2} [\cos \phi + \cos(2\omega_c t + \phi)]$$

The addition of a simple low pass filter to the output (which eliminates the second cosine term) and return of R_L to an offset adjustment potentiometer will result in a dc output voltage which is proportional to the cosine of the phase difference. Hence, the circuit functions as a synchronous detector.

6. DEFINITIONS OF SPECIFICATIONS

Because of the unique nature of a multiplier, i.e., two inputs and one output, operating specifications are difficult to define and interpret. Indeed the same specification may be defined in several completely different ways depending upon which manufacturer is doing the defining. In order to clear up some of this mystery, the following definitions and examples are presented.

6.1 Multiplier Transfer Function

The output of the multiplier may be expressed by this equation:

$$V_o = K(V_x \pm V_{ioX} - V_{xoff})(V_y \pm V_{ioY} - V_{yoff}) \pm V_{oo} \quad (1)$$

where $K = \text{scale factor}$ (see 6.5)

- $V_x = \text{"x" input voltage}$
- $V_y = \text{"y" input voltage}$
- $V_{ioX} = \text{"x" input offset voltage}$
- $V_{ioY} = \text{"y" input offset voltage}$
- $V_{xoff} = \text{"x" input offset adjust voltage}$

- $V_y \text{ off} = \text{"y" input offset adjust voltage}$
- $V_{oo} = \text{output offset voltage}$

The voltage transfer characteristic below indicates "X", "Y" and output offset voltages.

FIGURE 26

6.2 Linearity

Linearity is defined to be the maximum deviation of output voltage from a straight line transfer function. It is expressed as a percentage of full-scale output and is measured for V_x and V_y separately either using an "X-Y" plotter (and checking the deviation from a straight line) or by using the method shown in Figure 1. The latter method nulls the output signal with the input signal, resulting in distortion components proportional to the linearity.

Example: 0.35% linearity means

$$V_o = \frac{V_x V_y}{10} \pm (0.0035) (10 \text{ volts})$$

6.3 Input Offset Voltage

The input offset voltage is defined from Equation (1). It is measured for V_x and V_y separately and is defined to be that dc input offset adjust voltage ("x" or "y") that will result in minimum ac output when ac (5 Vpp, 1 kHz) is applied to the other input ("y" or "x" respectively). From Equation (1) we have:

$$V_o(ac) = K(0 \pm V_{ioX} - V_{xoff})(\sin \omega t)$$

adjust V_{xoff} so that $(\pm V_{ioX} - V_{xoff}) = 0$.

6.4 Output Offset Current and Voltage

Output offset current (I_{oo}) is the dc current flowing in the output lead when $V_x = V_y = 0$ and "X" and "Y" offset voltages are adjusted to zero.

Output offset voltage (V_{oo}) is:

$$V_{oo} = I_{oo} R_L$$

where R_L is the load resistance.

Note: Output offset voltage is defined by many manufacturers with all inputs at zero but without adjusting "X" and "Y" offset voltages to zero. Thus it includes input offset terms, an output offset term and a scale factor term.

6.5 Scale Factor

Scale factor is the K term in Equation (1). It determines the "gain" of the multiplier and is expressed approximately by the following equation.

$$K = \frac{2R_L}{R_x R_y I_1} \text{ where } R_x \text{ and } R_y \gg \frac{kT}{qI_1}$$

and I_1 is the current out of pin 1.

6.6 Total DC Accuracy

The total dc accuracy of a multiplier is defined as error in multiplier output with dc (± 10 Vdc) applied to both inputs. It is expressed as a percent of full scale. Accuracy is not specified for the MC1594 because error terms can be nulled by the user.

6.7 Temperature Stability (Drift)

Each term defined above will have a finite drift with temperature. The temperature specifications are obtained by re-adjusting the multiplier offsets and scale factor at each new temperature (see previous definitions and the adjustment procedure) and noting the change.

Assume inputs are grounded and initial offset voltages have been adjusted to zero. Then output voltage drift is given by:

$$\Delta V_o = \pm [K \pm K (TCK) (\Delta T)] \{ [(TCV_{ioX}) (\Delta T)] [(TCV_{ioY}) (\Delta T)] \pm (TCV_{oo}) (\Delta T)$$

6.8 Total DC Accuracy Drift

This is the temperature drift in output voltage with 10 volts applied to each input. The output is adjusted to 10 volts at $T_A = +25^\circ\text{C}$. Assuming initial offset voltages have been adjusted to zero at $T_A = +25^\circ\text{C}$, then:

$$V_o = [K \pm K (TCK) (\Delta T)] \{ [10 \pm (TCV_{ioX}) (\Delta T)] [10 \pm (TCV_{ioY}) (\Delta T)] \pm (TCV_{oo}) (\Delta T)$$

6.9 Power Supply Rejection

Variation in power supply voltages will cause undesired variation of the output voltage. It is measured by superimposing a 1-volt, 100-Hz signal on each supply (± 15 V) with each input grounded. The resulting change in the output is expressed in mV/V.

6.10 Output Voltage Swing

Output voltage swing capability is the maximum output voltage swing (without clipping) into a resistive load (note: output offset is adjusted to zero).

If an op-ampl. is used, the multiplier output becomes a virtual ground — the swing is then determined by the scale factor and the op-ampl. selected.

OPERATION AND APPLICATIONS INFORMATION

1. Theory of Operation

The MC1595 (MC1495) is a monolithic, four-quadrant multiplier which operates on the principle of variable transconductance. The detailed theory of operation is covered in Application Note AN-489, Analysis and Basic Operation of the MC1595. The result of this analysis is that the differential output current of the multiplier is given by

$$I_A - I_B = \Delta I = \frac{2V_X V_Y}{R_X R_Y I_3}$$

where I_A and I_B are the currents into pins 14 and 2, respectively, and V_X and V_Y are the X and Y input voltages at the multiplier input terminals.

2. Design Considerations

2.1 General

The MC1595 (MC1495) permits the designer to tailor the multiplier to a specific application by proper selection of external components. External components may be selected to optimize a given parameter (e.g. bandwidth) which may in turn restrict another parameter (e.g. maximum output voltage swing). Each important parameter is discussed in detail in the following paragraphs.

2.1.1 Linearity, Output Error, E_{R_X} or E_{R_Y}

Linearity error is defined as the maximum deviation of output voltage from a straight line transfer function. It is expressed as error in percent of full scale (see figure below).

For example, if the maximum deviation, $V_{E(max)}$, is ± 100 mV and the full scale output is 10 volts, then the percentage error is

$$E_R = \frac{V_{E(max)}}{V_{O(max)}} \times 100 = \frac{100 \times 10^{-3}}{10} \times 100 = \pm 1.0\%$$

Linearity error may be measured by either of the following methods:

- Using an X - Y plotter with the circuit shown in Figure 5, obtain plots for X and Y similar to the one shown above.
- Use the circuit of Figure 4. This method nulls the level shifted output of the multiplier with the original input. The peak output of the null operational amplifier will be equal to the error voltage, $V_{E(max)}$.

One source of linearity error can arise from large signal non-linearity in the X and Y-input differential amplifiers. To avoid introducing error from this source, the emitter degeneration resistors R_X and R_Y must be chosen large enough so that non-linear base-emitter voltage variation can be ignored. Figures 17 and 18 show the error expected from this source as a function of the values of R_X and R_Y with an operating current of 1.0 mA in each side of the differential amplifiers (i.e., $I_3 = I_{13} = 1.0$ mA).

2.1.2 3 dB-Bandwidth and Phase Shift

Bandwidth is primarily determined by the load resistors and the stray multiplier output capacitance and/or the operational amplifier used to level shift the output. If wideband operation is desired, low value load resistors and/or a wideband operational amplifier should be used. Stray output capacitance will depend to a large extent on circuit layout.

Phase shift in the multiplier circuit results from two sources: phase shift common to both X and Y channels (due to the load resistor-output capacitance pole mentioned above) and relative phase shift between X and Y channels (due to differences in transmittance in the X and Y channels). If the input to output phase shift is only 0.6° , the output product of two sine waves will exhibit a vector error of 1%. A 3° relative phase shift between V_X and V_Y results in a vector error of 5%.

2.1.3 Maximum Input Voltage

$V_{X(max)}$, $V_{Y(max)}$ maximum input voltages must be such that:

$$V_{X(max)} < I_{13} R_Y$$

$$V_{Y(max)} < I_3 R_Y$$

Exceeding this value will drive one side of the input amplifier to "cutoff" and cause non-linear operation.

Currents I_3 and I_{13} are chosen at a convenient value (observing power dissipation limitation) between 0.5 mA and 2.0 mA, approximately 1.0 mA. Then R_X and R_Y can be determined by considering the input signal handling requirements.

$$\text{For } V_{X(max)} = V_{Y(max)} = 10 \text{ volts;}$$

$$R_X = R_Y > \frac{10 \text{ V}}{1.0 \text{ mA}} = 10 \text{ k}\Omega$$

$$\text{The equation } I_A - I_B = \frac{2V_X V_Y}{R_X R_Y I_3}$$

$$\text{is derived from } I_A - I_B = \frac{2V_X V_Y}{(R_X + \frac{2kT}{qI_3})(R_Y + \frac{2kT}{qI_3}) I_3}$$

$$\text{with the assumption } R_X \gg \frac{2kT}{qI_3} \text{ and } R_Y \gg \frac{2kT}{qI_3}$$

$$\text{At } T_A = +25^\circ\text{C and } I_{13} = I_3 = 1 \text{ mA,}$$

$$\frac{2kT}{qI_3} = \frac{2kT}{qI_3} = 52 \Omega$$

Therefore, with $R_X = R_Y = 10 \text{ k}\Omega$ the above assumption is valid. Reference to Figure 19 will indicate limitations of $V_{X(max)}$ or $V_{Y(max)}$ due to V_1 and V_7 . Exceeding these limits will cause saturation or "cutoff" of the input transistors. See Step 4 of Section 3 (General Design Procedure) for further details.

2.1.4 Maximum Output Voltage Swing

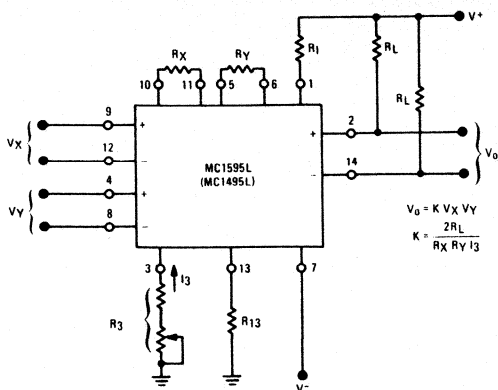

The maximum output voltage swing is dependent upon the factors mentioned below and upon the particular circuit being considered.

For Figure 20 the maximum output swing is dependent upon V^+ for positive swing and upon the voltage at pin 1 for negative swing. The potential at pin 1 determines the quiescent level for transistors Q_5 , Q_6 , Q_7 , and Q_8 . This potential

OPERATION AND APPLICATIONS INFORMATION (continued)

should be related so that negative swing at pins 2 or 14 does not saturate those transistors. See Section 3 for further information regarding selection of these potentials.

FIGURE 20 - BASIC MULTIPLIER

If an operational amplifier is used for level shift, as shown in Figure 21, the output swing (of the multiplier) is greatly reduced. See Section 3 for further details.

3. General Design Procedure

Selection of component values is best demonstrated by the following example: assume resistive dividers are used at the X and Y inputs to limit the maximum multiplier input to ± 5.0 volts ($V_X = V_Y [\max]$) for a ± 10 -volt input ($V_X' = V_Y' [\max]$). (See Figure 21). If an overall scale factor of 1/10 is desired, then

$$V_o = \frac{V_X' V_Y'}{10} = \frac{(2V_X)(2V_Y)}{10} = 4/10 V_X V_Y.$$

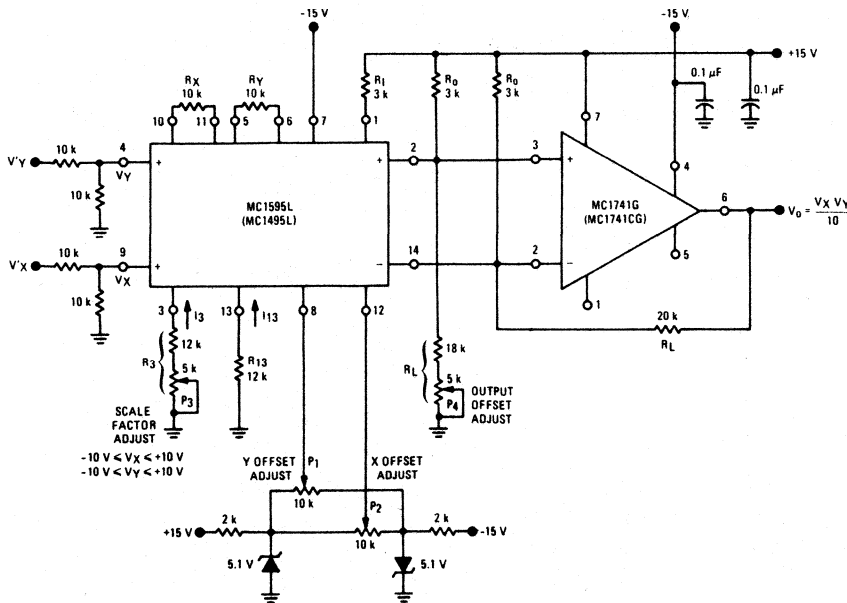

Therefore, $K = 4/10$ for the multiplier (excluding the divider network).

Step 1. The first step is to select current I_3 and current I_{13} . There are no restrictions on the selection of either of these currents except the power dissipation of the device. I_3 and I_{13} will normally be one or two milliamperes. Further, I_3 does not have to be equal to I_{13} , and there is normally no need to make them different. For this example, let

$$I_3 = I_{13} = 1 \text{ mA.}$$

To set currents I_3 and I_{13} to the desired value, it is only necessary to connect a resistor between pin 13 and ground, and between pin 3 and ground. From the schematic shown in Figure 3,

FIGURE 21 - MULTIPLIER WITH OP-AMPL. LEVEL SHIFT

OPERATION AND APPLICATIONS INFORMATION (continued)

it can be seen that the resistor values necessary are given by:

$$R_{13} + 500 \Omega = \frac{|V^-| - 0.7 \text{ V}}{I_{13}}$$

$$R_3 + 500 \Omega = \frac{|V^-| - 0.7 \text{ V}}{I_3}$$

Let $V^- = -15 \text{ V}$

Then $R_{13} + 500 = \frac{14.3 \text{ V}}{1 \text{ mA}}$ or $R_{13} = 13.8 \text{ k}\Omega$

Let $R_{13} = 12 \text{ k}\Omega$

Similarly, $R_3 = 13.8 \text{ k}\Omega$

Let $R_3 = 15 \text{ k}\Omega$

However, for applications which require an accurate scale factor, the adjustment of R_3 and consequently, I_3 , offers a convenient method of making a final trim of the scale factor. For this reason, as shown in Figure 21, resistor R_3 is shown as a fixed resistor in series with a potentiometer.

For applications not requiring an exact scale factor (balanced modulator, frequency doubler, AGC amplifier, etc.), pins 3 and 13 can be connected together and a single resistor from pin 3 to ground can be used. In this case, the single resistor would have a value of one-half the above calculated value for R_{13} .

Step 2. The next step is to select R_X and R_Y . To insure that the input transistors will always be active, the following conditions should be met:

$$\frac{V_X}{R_X} < I_{13} \quad \frac{V_Y}{R_Y} < I_3$$

A good rule of thumb is to make $I_3 R_Y \geq 1.5 V_{Y(\text{max})}$ and $I_{13} R_X \geq 1.5 V_{X(\text{max})}$.

The larger the $I_3 R_Y$ and $I_{13} R_X$ product in relation to V_Y and V_X respectively, the more accurate the multiplier will be (see Figures 17 and 18).

Let $R_X = R_Y = 10 \text{ k}\Omega$

Then $I_3 R_Y = 10 \text{ V}$

$I_{13} R_X = 10 \text{ V}$

since $V_{X(\text{max})} = V_{Y(\text{max})} = 5.0 \text{ volts}$ the value of $R_X = R_Y = 10 \text{ k}\Omega$ is sufficient.

Step 3. Now that R_X , R_Y and I_3 have been chosen, R_L can be determined:

$$K = \frac{2R_L}{R_X R_Y I_3} = \frac{4}{10}$$

$$\text{or } \frac{(2)(R_L)}{(10 \text{ k})(10 \text{ k})(1 \text{ mA})} = \frac{4}{10}$$

Thus $R_L = 20 \text{ k}\Omega$.

Step 4. To determine what power-supply voltage is necessary for this application, attention must be given to the circuit schematic shown in Figure 3. From the circuit schematic it can be seen that in order to maintain transistors Q_1 , Q_2 , Q_3 and Q_4 in an active

region when the maximum input voltages are applied ($V_X' = V_Y' = 10 \text{ V}$ or $V_X = 5.0 \text{ V}$, $V_Y = 5.0 \text{ V}$), their respective collector voltage should be at least a few tenths of a volt higher than the maximum input voltage. It should also be noticed that the collector voltage of transistors Q_3 and Q_4 are at a potential which is two diode-drops below the voltage at pin 1. Thus, the voltage at pin 1 should be about two volts higher than the maximum input voltage. Therefore, to handle +5.0 volts at the inputs, the voltage at pin 1 must be at least +7.0 volts. Let $V_1 = 9.0 \text{ Vdc}$.

Since the current flowing into pin 1 is always equal to I_{13} , the voltage at pin 1 can be set by placing a resistor, R_1 from pin 1 to the positive supply:

$$R_1 = \frac{V^+ - V_1}{I_{13}}$$

Let $V^+ = +15 \text{ V}$

Then $R_1 = \frac{15 \text{ V} - 9 \text{ V}}{(2)(1 \text{ mA})}$

$R_1 = 3 \text{ k}\Omega$.

Note that the voltage at the base of transistors Q_5 , Q_6 , Q_7 and Q_8 is one diode-drop below the voltage at pin 1. Thus, in order that these transistors stay active, the voltage at pins 2 and 14 should be approximately halfway between the voltage at pin 1 and the positive-supply voltage. For this example, the voltage at pins 2 and 14 should be approximately 11 volts.

Step 5. Level Shifting

For dc applications, such as the multiply, divide and square-root functions, it is usually desirable to convert the differential output to a single-ended output voltage referenced to ground. The circuit shown in Figure 22 performs this function. It can be shown that the output voltage of this circuit is given by:

$$V_o = (I_2 - I_{14}) R_L$$

And since $I_A - I_B = I_2 - I_{14} = \frac{2I_X I_Y}{I_3} = \frac{2 V_X V_Y}{I_3 R_X R_Y}$

Then $V_o = \frac{2R_L V_X' V_Y'}{4R_X R_Y I_3}$ where $V_X' V_Y'$ is the voltage at the input to the voltage dividers.

FIGURE 22 – LEVEL SHIFT CIRCUIT

OPERATION AND APPLICATIONS INFORMATION (continued)

For most dc applications, all three offset adjust potentiometers (P₁, P₂, P₄) will be necessary. One or more offset adjust potentiometers can be eliminated for ac applications (See Figures 28, 29, 30, 31).

If well regulated supply voltages are available, the offset adjust circuit of Figure 13 is recommended. Otherwise, the circuit of Figure 14 will greatly reduce the sensitivity to power supply changes.

4.2 Scale Factor

The scale factor, K, is set by P₃ (Figure 21). P₃ varies I₃ which inversely controls the scale factor K. It should be noted that current I₃ is one-half the current through R₁. R₁ sets the bias level for Q₅, Q₆, Q₇, and Q₈ (See Figure 3). Therefore, to be sure that these devices remain active under all conditions of input and output swing, care should be exercised in adjusting P₃ over wide voltage ranges (see Section 3, General Design Procedure).

4.3 Adjustment Procedures

The following adjustment procedure should be used to null the offsets and set the scale factor for the multiply mode of operation. (See Figure 21)

1. X Input Offset
 - (a) Connect oscillator (1 kHz, 5 Vpp sinewave) to the "Y" input (pin 4)
 - (b) Connect "X" input (pin 9) to ground
 - (c) Adjust X offset potentiometer, P₂, for an ac null at the output
2. Y Input Offset
 - (a) Connect oscillator (1 kHz, 5 Vpp sinewave) to the "X" input (pin 9)
 - (b) Connect "Y" input (pin 4) to ground
 - (c) Adjust "Y" offset potentiometer, P₁, for an ac null at the output
3. Output Offset
 - (a) Connect both "X" and "Y" inputs to ground
 - (b) Adjust output offset potentiometer, P₄, until the output voltage V_O is zero volts dc
4. Scale Factor
 - (a) Apply +10 Vdc to both the "X" and "Y" inputs
 - (b) Adjust P₃ to achieve +10.00 V at the output.
5. Repeat steps 1 through 4 as necessary.

The ability to accurately adjust the MC1595 (MC1495) depends upon the characteristics of potentiometers P₁ through P₄. Multi-turn, infinite resolution potentiometers with low-temperature coefficients are recommended.

5. DC Applications

5.1 Multiply

The circuit shown in Figure 21 may be used to multiply signals from dc to 100 kHz. Input levels to the actual multiplier are 5.0 V (max). With resistive voltage dividers the maximum could be very large — however, for this application two-to-one dividers have been used so that the maximum input level is 10 V. The maximum output level has also been designed for 10 V (max).

5.2 Squaring Circuit

If the two inputs are tied together, the resultant function is squaring; that is V_O = KV² where K is the scale factor. Note that all error terms can be eliminated with only three adjustment potentiometers, thus eliminating one of the input offset adjustments. Procedures for nulling with adjustments are given as follows:

1. AC Procedure:
 - (a) Connect oscillator (1 kHz, 15 Vpp) to input
 - (b) Monitor output at 2 kHz with tuned voltmeter and adjust P₃ for desired gain (be sure to peak response of the voltmeter)
 - (c) Tune voltmeter to 1 kHz and adjust P₁ for a minimum output voltage
 - (d) Ground input and adjust P₄ (output offset) for zero volts dc output
 - (e) Repeat steps a through d as necessary.
2. DC Procedure:
 - (a) Set V_X = V_Y = 0 V and adjust P₄ (output offset potentiometer) such that V_O = 0.0 Vdc
 - (b) Set V_X = V_Y = 1.0 V and adjust P₁ (Y input offset potentiometer) such that the output voltage is +0.100 volts
 - (c) Set V_X = V_Y = 10 Vdc and adjust P₃ such that the output voltage is +10.00 volts
 - (d) Set V_X = V_Y = -10 Vdc. Repeat steps a through d as necessary.

FIGURE 24 — BASIC DIVIDE CIRCUIT

5.3 Divide Circuit

Consider the circuit shown in Figure 24 in which the multiplier is placed in the feedback path of an operational amplifier. For this configuration, the operational amplifier will maintain a "virtual ground" at the inverting (-) input. Assuming that the bias current of the operational amplifier is negligible, then I₁ = I₂ and

$$\frac{KV_X V_Y}{R_1} = \frac{-V_Z}{R_2} \quad (1)$$

Solving for V_Y,

$$V_Y = \frac{-R_1}{R_2 K} \frac{V_Z}{V_X} \quad (2)$$

If R₁ = R₂

$$V_Y = \frac{-V_Z}{KV_X} \quad (3)$$

If R₁ = KR₂

$$V_Y = \frac{-V_Z}{V_X} \quad (4)$$

OPERATION AND APPLICATIONS INFORMATION (continued)

FIGURE 26 – BASIC SQUARE ROOT CIRCUIT

as indicated in Figure 26. This circuit may suffer from latch-up problems similar to those of the divide circuit. Note that only one polarity of input is allowed and diode clamping (see Figure 27) protects against accidental latch-up.

This circuit also may be adjusted in the closed-loop mode as follows:

1. Set V_Z to -0.01 volts and adjust P_4 (output offset) for $V_O = +0.316$ volts, being careful to approach the output from the positive side to preclude the effect of the output diode clamping.
2. Set V_Z to -0.9 volts and adjust P_2 (X adjust) for $V_O = +3.0$ volts.
3. Set V_Z to -10 volts and adjust P_3 (scale factor adjust) for $V_O = +10$ volts.
4. Steps 1 through 3 may be repeated as necessary to achieve desired accuracy.

6. AC Applications

The applications that follow demonstrate the versatility of the monolithic multiplier. If a potted multiplier is used for these cases, the results generally would not be as good because the potted units have circuits that, although they optimize dc multiplication operation, can hinder ac applications.

6.1 Frequency doubling often is done with a diode where the fundamental plus a series of harmonics are generated. However, extensive filtering is required to obtain the desired harmonic, and the second harmonic obtained under this technique usually is small in magnitude and requires amplification.

When a multiplier is used to double frequency the second harmonic is obtained directly, except for a dc term, which can be removed with ac coupling.

$$e_o = KE^2 \cos^2 \omega t$$

$$e_o = \frac{KE^2}{2} (1 + \cos 2\omega t).$$

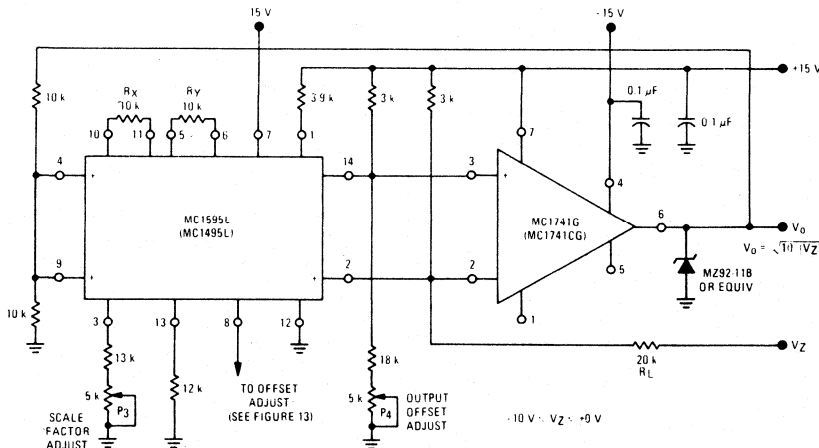

A potted multiplier can be used to obtain the double frequency component, but frequency would be limited by its internal level-shift amplifier. In the monolithic units, the amplifier is omitted.

In a typical doubler circuit, conventional ± 15 -volt supplies are used. An input dynamic range of 5.0 volts peak-to-peak is allowed. The circuit generates wave-forms that are double frequency; less than 1% distortion is encountered without filtering. The configuration has been successfully used in excess of 200 kHz, reducing the scale factor by decreasing the load resistors can further expand the bandwidth.

A slightly modified version of the MC1595 (MC1495) — the MC1596 (MC1496) — has been successfully used as a doubler to obtain 400 MHz. (See Figure 28.)

6.2 Figure 29 represents an application for the monolithic multiplier as a balanced modulator. Here, the audio input signal is 1.6 kHz and the carrier is 40 kHz.

FIGURE 27 – SQUARE ROOT CIRCUIT

OPERATION AND APPLICATIONS INFORMATION (continued)

FIGURE 28 – FREQUENCY DOUBLER

When two equal cosine waves are applied to X and Y, the result is a wave shape of twice the input frequency. For this example the input was a 10 kHz signal, output was 20 kHz.

FIGURE 29 – BALANCED MODULATOR

(B)

The defining equation for balanced modulation is

$$K(E_m \cos \omega_m t)(E_c \cos \omega_c t) =$$

$$\frac{KE_c E_m}{2} [\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)t]$$

where ω_c is the carrier frequency, ω_m is the modulator frequency and K is the multiplier gain constant.

AC coupling at the output eliminates the need for level translation or an operational amplifier; a higher operating frequency results.

A problem common to communications is to extract the intelligence from single-sideband received signal. The ssb signal is of the form

$$e_{ssb} = A \cos(\omega_c + \omega_m)t$$

and if multiplied by the appropriate carrier waveform, $\cos \omega_c t$,

$$e_{ssb} e_{carrier} = \frac{AK}{2} [\cos(2\omega_c + \omega_m)t + \cos(\omega_c)t]$$

If the frequency of the band-limited carrier signal, ω_c , is ascertained in advance the designer can insert a low-pass filter and obtain the $(AK/2) \cos(\omega_c t)$ term with ease. He also can use an operational amplifier for a combination level shift-active filter, as an external component. But in potted multipliers, even if the frequency range can be covered, the operational amplifier is inside and not accessible, so the user must accept the level shifting provided, and still add a low-pass filter.

6.3 Amplitude Modulation

The multiplier performs amplitude modulation, similar to balanced modulation, when a dc term is added to the modulating signal with the Y offset adjust potentiometer. (See Figure 30.)

Here, the identity is

$$E_m(1 + m \cos \omega_m t)E_c \cos \omega_c t = KE_m E_c \cos \omega_c t + \frac{KE_m E_c m}{2} [\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)t]$$

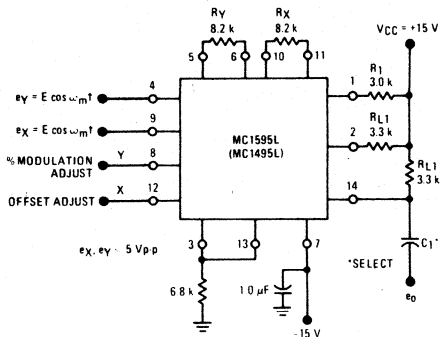

where m indicates the degree of modulation. Since m is adjustable, via potentiometer P_1 , 100% modulation is possible. Without extensive tweaking, 96% modulation may be obtained where ω_c and ω_m are the same as in the balanced-modulator example.

6.4 Linear Gain Control

To obtain linear gain control, the designer can feed to one of the two MC1595 (MC1495) inputs a signal that will vary the unit's gain. The following example demonstrates the feasibility of this application. Suppose a 200 kHz sine wave, 1.0 volt peak-to-peak, is the signal to which a gain control will be added. The dynamic range of the control voltage V_C is 0 to +1.0 volt. These must be ascertained and the proper values of R_X and R_Y can be selected for optimum performance. For the 200-kHz operating frequency, load resistors of 100 ohms were chosen to broaden the operating bandwidth of the multiplier, but gain was sacrificed. It may be made up with an amplifier operating at the appropriate frequency. (See Figure 31.)

OPERATION AND APPLICATIONS INFORMATION (continued)

FIGURE 30 — AMPLITUDE MODULATION

(B)

The signal is applied to the unit's Y input. Since the total input range is limited to 1.0 volt p-p, a 2.0-volt swing, a current source of 2.0 mA and an R_Y value of 1.0 kilohm is chosen. This takes best advantage of the dynamic range and insures linear operation in the Y-channel.

Since the X input varies between 0 and +1.0 volt, the current source selected was 1.0 mA and the R_X value chosen was 2.0 kilohms. This also insures linear operation over the X input dynamic range.

Choosing $R_L = 100$ assures wide-bandwidth operation. Hence, the scale factor for this configuration is

$$K = \frac{R_L}{R_X R_Y I_3}$$

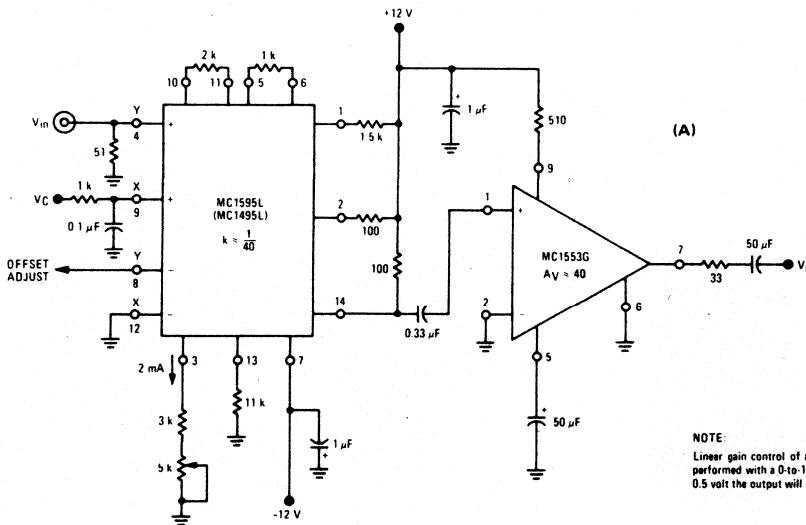

$$= \frac{100}{(2\text{ k})(1\text{ k})(2 \times 10^{-3})} \text{ V}^{-1}$$

$$= \frac{1}{40} \text{ V}^{-1}$$

The 2 in the numerator of the equation is missing in this scale-factor expression because the output is single-ended and ac coupled.

To recover the gain, an MC1552 video amplifier with a gain of 40 is used. An operational amplifier also could have been used with frequency compensation to allow a gain of 40 at 200 kHz. The MC1539 operational amplifier can be tailored for this use; and the MC1520 operational amplifier does it directly.

FIGURE 31 — LINEAR GAIN CONTROL

(A)

NOTE:
Linear gain control of a 1-volt peak-to-peak signal is performed with a 0-to-1-volt control voltage. If V_C is 0.5 volt the output will be 0.5 volt p-p.

GENERAL OPERATING INFORMATION *

Note 1 — Carrier Feedthrough

Carrier feedthrough is defined as the output voltage at carrier frequency with only the carrier applied (signal voltage = 0).

Carrier null is achieved by balancing the currents in the differential amplifier by means of a bias trim potentiometer (R_1 of Figure 5).

Note 2 — Carrier Suppression

Carrier suppression is defined as the ratio of each sideband output to carrier output for the carrier and signal voltage levels specified.

Carrier suppression is very dependent on carrier input level, as shown in Figure 22. A low value of the carrier does not fully switch the upper switching devices, and results in lower signal gain, hence lower carrier suppression. A higher than optimum carrier level results in unnecessary device and circuit carrier feedthrough, which again degenerates the suppression figure. The MC1596 has been characterized with a 60 mV(rms) sine wave carrier input signal. This level provides optimum carrier suppression at carrier frequencies in the vicinity of 500 kHz, and is generally recommended for balanced modulator applications.

Carrier feedthrough is independent of signal level, V_S . This carrier suppression can be maximized by operating with large signal levels. However, a linear operating mode must be maintained in the signal-input transistor pair — or harmonics of the modulating signal will be generated and appear in the device output as spurious sidebands of the suppressed carrier. This requirement places an upper limit on input-signal amplitude (see Note 3 and Figure 20). Note also that an optimum carrier level is recommended in Figure 22 for good carrier suppression and minimum spurious sideband generation.

At higher frequencies circuit layout is very important in order to minimize carrier feedthrough. Shielding may be necessary in order to prevent capacitive coupling between the carrier input leads and the output leads.

Note 3 — Signal Gain and Maximum Input Level

Signal gain (single-ended) at low frequencies is defined as the voltage gain,

$$A_{VS} = \frac{V_O}{V_S} = \frac{R_L}{R_e + 2r_e} \quad \text{where } r_e = \frac{26 \text{ mV}}{I_5 \text{ (mA)}}$$

A constant dc potential is applied to the carrier input terminals to fully switch two of the upper transistors "on" and two transistors "off" ($V_C = 0.5 \text{ Vdc}$). This in effect forms a cascode differential amplifier.

Linear operation requires that the signal input be below a critical value determined by R_E and the bias current I_5

$$V_S \leq I_5 R_E \text{ (Volts peak)}$$

Note that in the test circuit of Figure 10, V_S corresponds to a maximum value of 1 volt peak.

Note 4 — Common-Mode Swing

The common-mode swing is the voltage which may be applied to both bases of the signal differential amplifier, without saturating the current sources or without saturating the differential amplifier itself by swinging it into the upper switching devices. This swing is variable depending on the particular circuit and biasing conditions chosen (see Note 6).

Note 5 — Power Dissipation

Power dissipation, P_D , within the integrated circuit package should be calculated as the summation of the voltage-current products at each port, i.e. assuming $V_9 = V_6$, $I_5 = I_6 = I_9$ and ignoring

base current, $P_D = 2 I_5 (V_6 - V_{10}) + I_5 (V_5 - V_{10})$ where subscripts refer to pin numbers.

Note 6 — Design Equations

The following is a partial list of design equations needed to operate the circuit with other supply voltages and input conditions. See Note 3 for R_e equation.

A. Operating Current

The internal bias currents are set by the conditions at pin 5. Assume:

$$I_5 = I_6 = I_9$$

$$I_B \ll I_C \text{ for all transistors}$$

then:

$$R_5 = \frac{V - \phi}{I_5} - 500 \Omega \quad \text{where: } R_5 \text{ is the resistor between pin 5 and ground}$$

$$\phi = 0.75 \text{ V at } T_A = +25^\circ\text{C}$$

The MC1596 has been characterized for the condition $I_5 = 1.0 \text{ mA}$ and is the generally recommended value.

B. Common-Mode Quiescent Output Voltage

$$V_6 = V_9 = V^+ - I_5 R_L$$

Note 7 — Biasing

The MC1596 requires three dc bias voltage levels which must be set externally. Guidelines for setting up these three levels include maintaining at least 2 volts collector-base bias on all transistors while not exceeding the voltages given in the absolute maximum rating table;

$$30 \text{ Vdc} \geq [(V_6, V_9) - (V_7, V_8)] \geq 2 \text{ Vdc}$$

$$30 \text{ Vdc} \geq [(V_7, V_8) - (V_1, V_4)] \geq 2.7 \text{ Vdc}$$

$$30 \text{ Vdc} \geq [(V_1, V_4) - (V_5)] \geq 2.7 \text{ Vdc}$$

The foregoing conditions are based on the following approximations:

$$V_6 = V_9, \quad V_7 = V_8, \quad V_1 = V_4$$

Bias currents flowing into pins 1, 4, 7, and 8 are transistor base currents and can normally be neglected if external bias dividers are designed to carry 1.0 mA or more.

Note 8 — Transadmittance Bandwidth

Carrier transadmittance bandwidth is the 3-dB bandwidth of the device forward transadmittance as defined by:

$$Y_{21C} = \left. \frac{i_o \text{ (each sideband)}}{v_s \text{ (signal)}} \right|_{V_O = 0}$$

Signal transadmittance bandwidth is the 3-dB bandwidth of the device forward transadmittance as defined by:

$$Y_{21S} = \left. \frac{i_o \text{ (signal)}}{v_s \text{ (signal)}} \right|_{V_C = 0.5 \text{ Vdc}, V_O = 0}$$

OPERATIONS INFORMATION

The MC1596/MC1496, a monolithic balanced modulator circuit, is shown in Figure 23.

This circuit consists of an upper quad differential amplifier driven by a standard differential amplifier with dual current sources. The output collectors are cross-coupled so that full-wave balanced multiplication of the two input voltages occurs. That is, the output signal is a constant times the product of the two input signals.

Mathematical analysis of linear ac signal multiplication indicates that the output spectrum will consist of only the sum and difference of the two input frequencies. Thus, the device may be used as a balanced modulator, doubly balanced mixer, product detector, frequency doubler, and other applications requiring these particular output signal characteristics.

The lower differential amplifier has its emitters connected to the package pins so that an external emitter resistance may be used. Also, external load resistors are employed at the device output.

Signal Levels

The upper quad differential amplifier may be operated either in a linear or a saturated mode. The lower differential amplifier is operated in a linear mode for most applications.

For low-level operation at both input ports, the output signal will contain sum and difference frequency components and have an amplitude which is a function of the product of the input signal amplitudes.

For high-level operation at the carrier input port and linear operation at the modulating signal port, the output signal will contain sum and difference frequency components of the modulating signal frequency and the fundamental and odd harmonics of the carrier frequency. The output amplitude will be a constant times the modulating signal amplitude. Any amplitude variations in the carrier signal will not appear in the output.

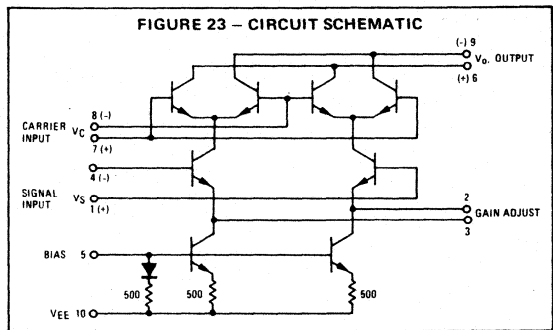

FIGURE 24 – TYPICAL MODULATOR CIRCUIT

Pin number references pertain to this device when packaged in a metal can. To ascertain the corresponding pin numbers for plastic or ceramic packaged devices refer to the first page of this specification sheet.

OPERATIONS INFORMATION (continued)

The linear signal handling capabilities of a differential amplifier are well defined. With no emitter degeneration, the maximum input voltage for linear operation is approximately 25 mV peak. Since the upper differential amplifier has its emitters internally connected, this voltage applies to the carrier input port for all conditions.

Since the lower differential amplifier has provisions for an external emitter resistance, its linear signal handling range may be adjusted by the user. The maximum input voltage for linear operation may be approximated from the following expression:

$$V = \left(\frac{1}{5}\right) (R_E) \text{volts peak.}$$

This expression may be used to compute the minimum value of R_E for a given input voltage amplitude.

**FIGURE 25 – TABLE 1
VOLTAGE GAIN AND OUTPUT FREQUENCIES**

Carrier Input Signal (V_C)	Approximate Voltage Gain	Output Signal Frequency(s)
Low-level dc	$\frac{R_L V_C}{2(R_E + 2r_e) \left(\frac{KT}{q}\right)}$	f_M
High-level dc	$\frac{R_L}{R_E + 2r_e}$	f_M
Low-level ac	$\frac{R_L V_C(\text{rms})}{2\sqrt{2} \left(\frac{KT}{q}\right) (R_E + 2r_e)}$	$f_C \pm f_M$
High-level ac	$\frac{0.637 R_L}{R_E + 2r_e}$	$f_C \pm f_M, 3f_C \pm f_M, 5f_C \pm f_M, \dots$

The gain from the modulating signal input port to the output is the MC1596/MC1496 gain parameter which is most often of interest to the designer. This gain has significance only when the lower differential amplifier is operated in a linear mode, but this includes most applications of the device.

As previously mentioned, the upper quad differential amplifier may be operated either in a linear or a saturated mode. Approximate gain expressions have been developed for the MC1596/MC1496 for a low-level modulating signal input and the following carrier input conditions:

- 1) Low-level dc
- 2) High-level dc
- 3) Low-level ac
- 4) High-level ac

These gains are summarized in Table 1, along with the frequency components contained in the output signal.

NOTES:

1. Low-level Modulating Signal, V_M , assumed in all cases. V_C is Carrier Input Voltage.
2. When the output signal contains multiple frequencies, the gain expression given is for the output amplitude of each of the two desired outputs, $f_C + f_M$ and $f_C - f_M$.
3. All gain expressions are for a single-ended output. For a differential output connection, multiply each expression by two.
4. R_L = Load resistance.
5. R_E = Emitter resistance between pins 2 and 3.
6. r_e = Transistor dynamic emitter resistance, at +25°C;

$$r_e \approx \frac{26 \text{ mV}}{I_E (\text{mA})}$$

7. K = Boltzmann's Constant, T = temperature in degrees Kelvin, q = the charge on an electron.

$$\frac{KT}{q} \approx 26 \text{ mV at room temperature}$$

APPLICATIONS INFORMATION

Double sideband suppressed carrier modulation is the basic application of the MC1596/MC1496. The suggested circuit for this application is shown on the front page of this data sheet.

In some applications, it may be necessary to operate the MC1596/MC1496 with a single dc supply voltage instead of dual supplies. Figure 26 shows a balanced modulator designed for operation with a single +12 Vdc supply. Performance of this circuit is similar to that of the dual supply modulator.

AM Modulator

The circuit shown in Figure 27 may be used as an amplitude modulator with a minor modification.

All that is required to shift from suppressed carrier to AM operation is to adjust the carrier null potentiometer for the proper amount of carrier insertion in the output signal.

However, the suppressed carrier null circuitry as shown in Figure 27 does not have sufficient adjustment range. Therefore, the modulator may be modified for AM operation by changing two resistor values in the null circuit as shown in Figure 28.

Product Detector

The MC1596/MC1496 makes an excellent SSB product detector (see Figure 29).

This product detector has a sensitivity of 3.0 microvolts and a dynamic range of 90 dB when operating at an intermediate frequency of 9 MHz.

The detector is broadband for the entire high frequency range. For operation at very low intermediate frequencies down to 50 kHz the 0.1 μF capacitors on pins 7 and 8 should be increased to 1.0 μF . Also, the output filter at pin 9 can be tailored to a specific intermediate frequency and audio amplifier input impedance.

As in all applications of the MC1596/MC1496, the emitter resistance between pins 2 and 3 may be increased or decreased to adjust circuit gain, sensitivity, and dynamic range.

This circuit may also be used as an AM detector by introducing carrier signal at the carrier input and an AM signal at the SSB input.

The carrier signal may be derived from the intermediate frequency signal or generated locally. The carrier signal may be introduced with or without modulation, provided its level is sufficiently high to saturate the upper quad differential amplifier. If the carrier signal is modulated, a 300 mV(rms) input level is recommended.

MC1496, MC1596

APPLICATIONS INFORMATION (continued)

Doubly Balanced Mixer

The MC1596/MC1496 may be used as a doubly balanced mixer with either broadband or tuned narrow band input and output networks.

The local oscillator signal is introduced at the carrier input port with a recommended amplitude of 100 mV(rms).

Figure 30 shows a mixer with a broadband input and a tuned output.

Frequency Doubler

The MC1596/MC1496 will operate as a frequency doubler by introducing the same frequency at both input ports.

Figures 31 and 32 show a broadband frequency doubler and a tuned output very high frequency (VHF) doubler, respectively.

Phase Detection and FM Detection

The MC1596/MC1496 will function as a phase detector. High-level input signals are introduced at both inputs. When both inputs are at the same frequency the MC1596/MC1496 will deliver an output which is a function of the phase difference between the two input signals.

An FM detector may be constructed by using the phase detector principle. A tuned circuit is added at one of the inputs to cause the two input signals to vary in phase as a function of frequency. The MC1596/MC1496 will then provide an output which is a function of the input signal frequency.

Pin number references pertain to this device when packaged in a metal can. To ascertain the corresponding pin numbers for plastic or ceramic packaged devices refer to the first page of this specification sheet.

APPLICATIONS INFORMATION

FIGURE 25 – VOLTAGE CONTROLLED OSCILLATOR

By changing the voltage V_C the gain will vary over a range of 10 to 400. This will give a frequency variation about the value set by the capacitor and shown in Figure 26.

FIGURE 26 – OSCILLATOR FREQUENCY FOR VARIOUS CAPACITOR VALUES

TAPE, DRUM OR DISC MEMORY READ AMPLIFIERS

The first of several methods to be discussed is shown in Figure 27. This block diagram describes a simple Read circuit with no threshold circuitry. Each block represents a basic function that must be performed by the Read circuit. The first block, referred to as "amplification", increases the level of the signal available from the Read head to a level adequate to drive the peak detector. Obviously, these signal levels will vary depending on factors such as tape speed, whether the system used is disc or tape, and the type of head and the circuitry used. For a representative tape system, levels of 7 to 25 mV for the signal from the Read head and 2 V for the signal to the peak detector are typical. These signal levels are "peak-to-peak" unless otherwise specified. On the basis of the signal levels mentioned above, the overall amplification required is 38 to 49 dB.

How the overall gain requirement is implemented will depend somewhat on the system used. For instance, a tape cassette system with variable tape speed may utilize a first stage for gain and a second stage primarily for gain control. Thus, a typical circuit would utilize 35 dB in the first stage and 10 to 15 dB in the second stage.

Devices suitable for use as amplifiers fall into one of two categories, operational amplifiers or wideband video amplifiers. Lower speed equipment with low transfer rates commonly uses low cost operational amplifiers. Examples of these are the MC1741, MC1458, MC1709, and MLM301. Equipment requiring higher transfer rates, such as disc systems normally use wideband amplifiers such as the MC1733. The actual cross-over point where wideband amplifiers are used exclusively varies with equipment de-

sign. For purposes of comparison, the MLM301 has slightly less than a 40 dB open-loop gain at 100 kHz; the MC1741, a compensated op-amp, has approximately 20 dB open loop gain at 100 kHz; the MC1733 has approximately 33 dB of gain out to 100 MHz (depending on gain option and loading).

There are a number of ways to implement the peak detector function. However, the simplest and most widely used method is a passive differentiator that generates "zero-crossings" for each of the data peaks in the Read signal.

The actual circuitry used to differentiate the Read signal varies from a differential LC type in disc systems to a simple RC type in reel and cassette systems. Either type, of course, attenuates the signal by an amount depending on the circuit used and system specifications. A good approximation of attenuation using the RC type is 20 dB. Thus, the 2 V signal going into the differentiator is reduced to 200 mV.

The next block in Figure 27 to be discussed is the zero-crossing detector. In most cases detection of the zero-crossings is combined with the limiter. These functions serve to generate a TTL compatible pulse waveform with "edges" corresponding to zero-crossings. For low transfer rates, the circuit often used consists of an operational amplifier with series or shunt limiting. For higher transfer rates (greater than 100K B/S) comparators are used.

The method described above is often modified to include threshold sensing. In Figure 28, the function called "double-ended, limit-detector" enables the output NAND gate when either the negative or positive data peaks of the Read signal exceed a predetermined threshold. This function can be implemented in either of two ways. One method first rectifies the signal before it is applied to a comparator with a set threshold. The other method utilizes two comparators, one comparator for positive-going peaks and the other for negative-going peaks. These comparator outputs are then combined in the output logic gates.

FIGURE 27 – TYPICAL READ CIRCUIT (METHOD 1)

APPLICATIONS INFORMATION (continued)

FIGURE 28 – READ CIRCUIT (METHOD 2)

Another common technique is shown in Figure 29. The branch labeled rectifiers, peak detector, etc., provides a clock transition of the D flip-flop that corresponds to the peak of both the positive and negative-going data peaks. This branch may include threshold circuitry prior to the peak detector. The detector in the lower path detects whether the signal peaks are positive or negative and feeds this data to the flip-flop. This detector can be implemented using a comparator with pre-set threshold.

FIGURE 29 – READ CIRCUIT (METHOD 3)

The technique shown in Figure 30 uses separate circuits with threshold provisions for both negative and positive peaks. The peak detectors and threshold detectors

may be implemented with two comparators and two passive differentiators.

Each of the methods shown offer certain intrinsic advantages or disadvantages. The overall decision as to which method to use however often involves other important considerations. These could include cost and system requirements or circuitry other than simply the Read circuitry. For instance, if cost is the predominate overall factor, then approach one may be the only feasible alternative.

Method four was included as a design example because it illustrates several unique advantages. First, it uses threshold sensing to reduce noise peak errors. Second, it may be implemented using only integrated circuits. Third, it offers separate, direct threshold sensing for both positive and negative peaks.

APPLICATIONS INFORMATION

The voltage regulator and bias section provides the proper biasing and regulated supply voltage to the integrated circuit.

A square wave, when applied to the RC differentiator, provides input current pulses to the IC. The input circuit discharges and clamps, for a predetermined time, the voltage across capacitor C_R . This establishes the initial ramp voltage (V_{sat}) and allows initiation of a new voltage ramp after each positive transistion of the input waveform.

The voltage, V_{CR} , ramps from V_{sat} to the final value, V_{Reg} , charging through R_R .

If V_{CR} is never allowed to reach V_{Ref} due to quick reset pulses, the second integrator amplifier will not be activated, and capacitor C_{AB} is allowed to charge through the 12 k Ω resistor until V_{CA} is greater than V_{Ref} . At this point, D1 will switch ON and D2 will switch OFF. By connecting either D1 or D2 to the D3 drive pin, the output drive transistor may be either switched ON or OFF at the switch point.

If V_{CR} is allowed to ramp above V_{Ref} before being reset, the second integrator amplifier is driven ON which discharges and resets capacitor C_{AB} keeping V_{CA} low with respect to V_{Ref} .

V_{CA} will always be low with respect to V_{Ref} if the time from reset C_R to $V_{CR} = V_{Ref}$ is less than the time

from reset C_{AB} to $V_{CA} = V_{Ref}$.

Resistor R_H provides hysteresis around the switch point (i.e., frequency to switch the output driver ON, when connected to the D1 terminal, is higher than the frequency required to switch the output driver OFF). If no hysteresis is desired then the R_H resistor should be omitted and pin 12 grounded.

Circuit Equations:

The first integrator time constant is
 $T1 = R_H \parallel R_R C_R$. If R_H is omitted then
 $T1 = R_R C_R$.

The second integrator time constant is
 $T2 = (12 \text{ k}) (hFE2) (C_{AB})$.

$$f1 = \text{Switch Point frequency} \cong \frac{1}{1.39 R_R C_R}$$

$$f2 = \text{Hysteresis Switch Point frequency} \cong$$

$$\frac{1}{R_R \parallel R_H C_R \ln \left[\frac{R_H}{0.25 R_H - 0.75 R_R} \right]}$$

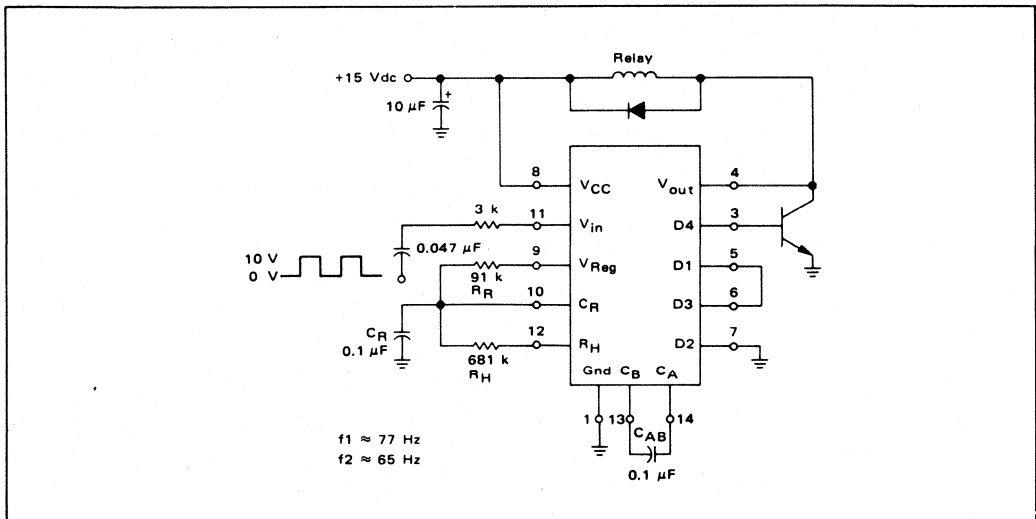

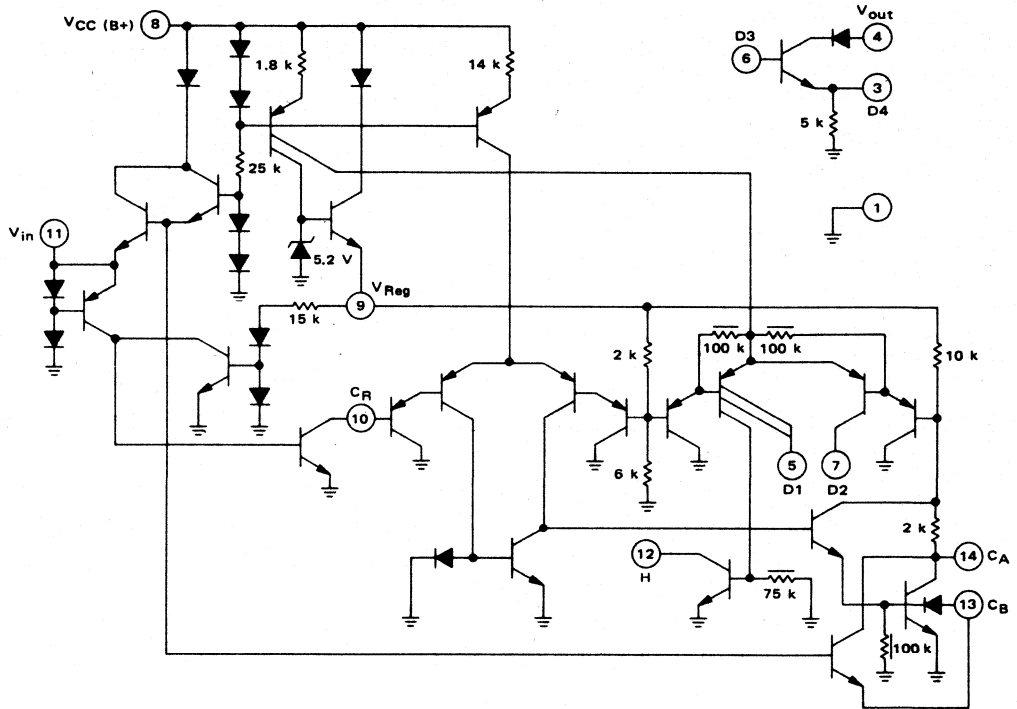

FIGURE 12 - CIRCUIT SCHEMATIC

MC3405 MC3505

DUAL OPERATIONAL AMPLIFIER AND DUAL COMPARATOR

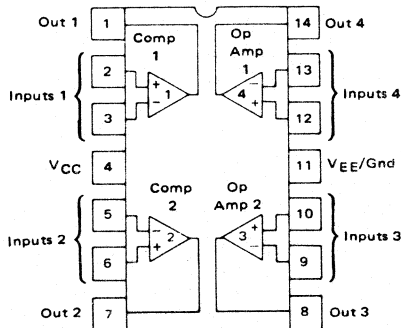

The MC3405/3505 contains two differential-input operational amplifiers and two comparators, each set capable of single supply operation. This operational amplifier-comparator circuit fulfills its applications as a general purpose product for automotive and consumer circuits as well as an industrial building block.

The MC3405 is specified over the commercial operating temperature range of 0 to +70°C, while the MC3505 is specified over the military operating range of -55 to +125°C.

- Operational Amplifiers Equivalent in Performance to MC3403/3503
- Comparators Similar in Performance to LM339/139
- Single Supply Operation: 3.0 to 36 Volts
- Split Supply Operation: ± 1.5 to ± 18 Volts
- Low Supply Current Drain
- Operational Amplifiers Are Internally Frequency Compensated
- Comparators TTL and CMOS Compatible

Specifications and Applications Information

OVERVOLTAGE "CROWBAR" SENSING CIRCUIT

These overvoltage protection circuits (OVP) protect sensitive electronic circuitry from overvoltage transients or regulator failures when used in conjunction with an external "crowbar" SCR. They sense the overvoltage condition and quickly "crowbar" or short circuit the supply, forcing the supply into current limiting or opening the fuse or circuit breaker.

The protection voltage threshold is adjustable and the MC3423/3523 can be programmed for minimum duration of overvoltage condition before tripping, thus supplying noise immunity.

The MC3423/3523 is essentially a "two terminal" system, therefore it can be used with either positive or negative supplies.

APPLICATIONS INFORMATION

BASIC CIRCUIT CONFIGURATION

The basic circuit configuration of the MC3423/3523 OVP is shown in Figure 3 for supply voltages from 4.5 V to 36 V, and in Figure 4 for trip voltages above 36 V. The threshold or trip voltage at which the MC3423/3523 will trigger and supply gate drive to the crowbar SCR, Q1, is determined by the selection of R1 and R2. Their values can be determined by the equation given in Figures 3 and 4, or by the graph shown in Figure 8. The minimum value of the gate current limiting resistor, R_G , is given in Figure 9. Using this value of R_G , the SCR, Q1, will receive the greatest gate current possible without damaging the MC3423/3523. If lower output currents are required, R_G can be increased in value. The switch, S1, shown in Figure 3 may be used to reset the SCR crowbar. Otherwise, the power supply, across which the SCR is connected, must be shut down to reset the crowbar. If a non current-limited supply is used, a fuse or circuit breaker, F1, should be used to protect the SCR and/or the load.

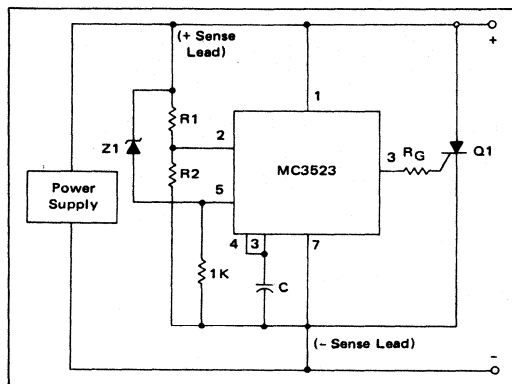

The circuit configurations shown in Figures 3 and 4 will have a typical propagation delay of 1.0 μ s. If faster operation is desired, pin 3 may be connected to pin 2 with pin 4 left floating. This will result in decreasing the propagation delay to approximately 0.5 μ s at the expense of a slightly increased TC for the trip voltage value.

CONFIGURATION FOR PROGRAMMABLE MINIMUM DURATION OF OVERVOLTAGE CONDITION BEFORE TRIPPING

In many instances, the MC3423/3523 OVP will be used in a noise environment. To prevent false tripping of the OVP circuit by noise which would not normally harm the load, MC3423/3523 has a programmable delay feature. To implement this feature, the circuit configuration of Figure 5 is used. In this configuration, a capacitor is connected from pin 3 to V_{EE} . The value of this capacitor determines the minimum duration of the overvoltage condition which is necessary to trip the OVP. The value of C can be found from Figure 10. The circuit operates in the following manner: When V_{CC} rises above the trip point set by R1 and R2, an internal current source (pin 4) begins charging the capacitor, C, connected to pin 3. If the overvoltage condition disappears before this occurs, the capacitor is discharged at a rate $\cong 10$ times faster than the charging rate, resetting the timing feature until the next overvoltage condition occurs.

Occasionally, it is desired that immediate crowbarring of the supply occur when a high overvoltage condition occurs, while retaining the false tripping immunity of Figure 5. In this case, the circuit of Figure 6 can be used. The circuit will operate as previously described for small overvoltages, but will immediately trip if the power supply voltage exceeds $V_{Z1} + 1.4$ V.

FIGURE 6 – CONFIGURATION FOR PROGRAMMABLE DURATION OF OVERVOLTAGE CONDITION BEFORE TRIP/WITH IMMEDIATE TRIP AT HIGH OVERVOLTAGES

ADDITIONAL FEATURES

1. Activation Indication Output

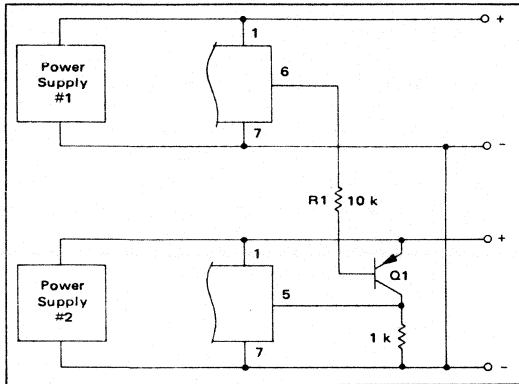

An additional output for use as an indicator of OVP activation is provided by the MC3423/3523. This output is an open collector transistor which saturates when the OVP is activated. It will remain in a saturated state until the SCR crowbar pulls the supply voltage, V_{CC} , below 4.5 V as in Figure 5. This output can be used to clock an edge triggered flip-flop whose output inhibits or shuts down the power supply when the OVP trips. This reduces or eliminates the heatsinking requirements for the crowbar SCR.

2. Remote Activation Input

Another feature of the MC3423/3523 is its remote activation input, pin 5. If the voltage on this CMOS/TTL compatible input is held below 0.8 V, the MC3423/3523 operates normally. However, if it is raised to a voltage above 2.0 V, the OVP output is activated independent of whether or not an overvoltage condition is present. It should be noted that pin 5 has an internal pull-up current source. This feature can be used to accomplish an orderly and sequenced shutdown of system power supplies during a system fault condition. In addition, the activation indication output of one MC3423/3523 can be used to activate another MC3423/3523 if a single transistor inverter is used to interface the former's indication output to the latter's remote activation input, as shown in Figure 7. In this circuit, the indication output (pin 6) of the MC3423 on power supply 1 is used to activate the MC3423 associated with power supply 2. Q1 is any small PNP with adequate voltage rating.

MC3423, MC3523

FIGURE 7 – CIRCUIT CONFIGURATION FOR ACTIVATING ONE MC3523 FROM ANOTHER

Note that both supplies have their negative output leads tied together (i.e., both are positive supplies). If their positive leads are common (two negative supplies) the emitter of Q1 would be moved to the positive lead of supply 1 and R1 would therefore have to be resized to deliver the appropriate drive to Q1.

CROWBAR SCR CONSIDERATIONS

Referring to Figure 11, it can be seen that the crowbar SCR, when activated, is subject to a large current surge from the output capacitance, C_{out}^1 . This surge current is illustrated in Figure 12, and can cause SCR failure or degradation by any one of three mechanisms: di/dt , absolute peak surge, or I^2t . The interrelationship of these failure methods and the breadth of the application make specification of the SCR by the semiconductor manufacturer difficult and expensive. Therefore, the designer must empirically determine the SCR and circuit elements which result in reliable and effective OVP operation. However, an understanding of the factors which influence the SCR's di/dt and surge capabilities simplifies this task.

1. di/dt

As the gate region of the SCR is driven on, its area of conduction takes a finite amount of time to grow, starting as a very small region and gradually spreading. Since the anode current flows through this turned-on gate region, very high current densities can occur in the gate region if high anode currents appear quickly (di/dt). This can result in immediate destruction of the SCR or gradual degradation of its forward blocking voltage capabilities – depending on the severity of the occasion.

¹ C_{out} consists of the power supply output caps, the load's decoupling caps, and in the case of Figure 11A, the supply's input filter caps.

CROWBAR SCR SELECTION GUIDE

As an aid in selecting an SCR for crowbar use, the following selection guide is presented.

DEVICE	I _{RMS}	I _{TSM}	PACKAGE
2N6400 Series	16A	160A	TO220 Plastic
2N6504 Series	25A	160A	TO220 Plastic
2N1842 Series	16A	125A	Metal Stud
2N2573 Series	25A	260A	Metal TO-3 Type
2N681 Series	25A	200A	Metal Stud
MCR3935-1 Series	35A	350A	Metal Stud
MCR81-5 Series	80A	1000A	Metal Stud

The value of di/dt that an SCR can safely handle is influenced by its construction and the characteristics of the gate drive signal. A center-gate-fire SCR has more di/dt capability than a corner-gate-fire type and heavily overdriving (3 to 5 times I_{GT}) the SCR gate with a fast (< 1 μs) rise time signal will maximize its di/dt capability. A typical maximum number in phase control SCRs of less than 50 Arms rating might be 200 A/μs, assuming a gate current of five times I_{GT} and < 1 μs rise time. If having done this, a di/dt problem is seen to still exist, the designer can also decrease the di/dt of the current waveform by adding inductance in series with the SCR, as shown in Figure 13. Of course, this reduces the circuit's ability to rapidly reduce the dc bus voltage and a tradeoff must be made between speedy voltage reduction and di/dt.

2. Surge Current

If the peak current and/or the duration of the surge is excessive, immediate destruction due to device overheating will result. The surge capability of the SCR is directly proportional to its die area. If the surge current cannot be reduced (by adding series resistance – see Figure 13) to a safe level which is consistent with the system's requirements for speedy bus voltage reduction, the designer must use a higher current SCR. This may result in the average current capability of the SCR exceeding the steady state current requirements imposed by the dc power supply.

A WORD ABOUT FUSING

Before leaving the subject of the crowbar SCR, a few words about fuse protection are in order. Referring back to Figure 11A, it will be seen that a fuse is necessary if the power supply to be protected is not output current limited. This fuse is not meant to prevent SCR failure but rather to prevent a fire!

In order to protect the SCR, the fuse would have to possess an I²t rating less than that of the SCR and yet have a high enough continuous current rating to survive normal supply output currents. In addition, it must be capable of successfully clearing the high short circuit currents from the supply. Such a fuse as this is quite expensive, and may not even be available.

The usual design compromise then is to use a garden variety fuse (3AG or 3AB style) which cannot be relied on to blow before the thyristor does, and trust that if the SCR does fail, it will fail short circuit. In the majority of the designs, this will be the case, though this is difficult to guarantee. Of course, a sufficiently high surge will cause an open. These comments also apply to the fuse in Figure 11B.

Specifications and Applications Information

DUAL TIMING CIRCUIT

The MC3556/MC3456 dual timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor per timer. For astable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor per timer. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200 mA or drive M TTL circuits.

- Direct Replacement for NE556/SE556 Timers
- Timing From Microseconds Through Hours
- Operates in Both Astable and Monostable Modes
- Adjustable Duty Cycle
- High Current Output Can Source or Sink 200 mA
- Output Can Drive M TTL
- Temperature Stability of 0.005% per °C
- Normally "On" or Normally "Off" Output
- Dual Version of the Popular MC1555/MC1455 Timer

FIGURE 13 — 1/2 REPRESENTATIVE CIRCUIT SCHEMATIC

GENERAL OPERATION

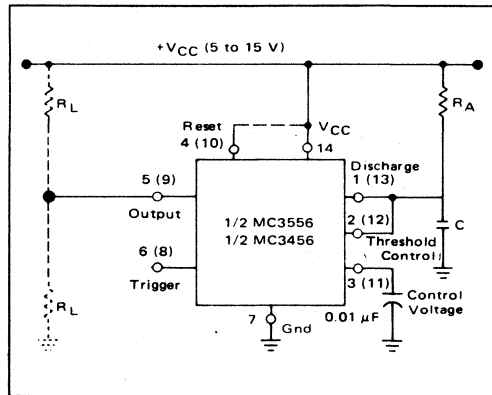

The MC3556 is a dual timing circuit which uses as its timing elements an external resistor — capacitor network. It can be used in both the monostable (one-shot) and astable modes with frequency and duty cycle controlled by the capacitor and resistor values. While the timing is dependent upon the external passive components, the monolithic circuit provides the starting circuit, voltage comparison and other functions needed for a complete timing circuit. Internal to the integrated circuit are two comparators, one for the input signal and the other for capacitor voltage; also a flip-flop and digital output are included. The comparator reference voltages are always a fixed ratio of the supply voltage thus providing output timing independent of supply voltage.

Monostable Mode

In the monostable mode, a capacitor and a single resistor are used for the timing network. Both the threshold terminal and the discharge transistor terminal are connected together in this mode, refer to circuit Figure 14. When the input voltage to the trigger comparator falls below $1/3 V_{CC}$ the comparator output triggers the flip-flop so that its output sets low. This turns the capacitor discharge transistor "off" and drives the digital output to the high state. This condition allows the capacitor to charge at an exponential rate which is set by the RC time constant. When the capacitor voltage reaches $2/3 V_{CC}$ the threshold comparator resets the flip-flop. This action discharges the timing capacitor and returns the digital output to the low state. Once the flip-flop has been triggered by an input signal, it cannot be retriggered until the present timing period has been completed. The time that the output is high is given by the equation $t = 1.1 R_A C$. Various combinations of R and C and their associated times are shown in Figure 16. The trigger pulse width must be less than the timing period.

A reset pin is provided to discharge the capacitor thus interrupting the timing cycle. As long as the reset pin is low, the capacitor discharge transistor is turned "on" and prevents the capacitor from charging. While the reset voltage is applied the digital output will remain the same. The reset pin should be tied to the supply voltage when not in use.

FIGURE 14 — MONOSTABLE CIRCUIT

GENERAL OPERATION (continued)

FIGURE 15 – MONOSTABLE WAVEFORMS

 $(R_A = 10 \text{ k}\Omega, C = 0.01 \mu\text{F}, R_L = 1.0 \text{ k}\Omega, V_{CC} = 15 \text{ V})$

FIGURE 16 – TIME DELAY

Astable Mode

In the astable mode the timer is connected so that it will retrigger itself and cause the capacitor voltage to oscillate between $1/3 V_{CC}$ and $2/3 V_{CC}$. See Figure 17.

The external capacitor charges to $2/3 V_{CC}$ through R_A and R_B and discharges to $1/3 V_{CC}$ through R_B . By varying the ratio of these resistors the duty cycle can be varied. The charge and discharge times are independent of the supply voltage.

The charge time (output high) is given by: $t_1 = 0.695 (R_A + R_B) C$

The discharge time (output low) by: $t_2 = 0.695 (R_B) C$

Thus the total period is given by: $T = t_1 + t_2 = 0.695 (R_A + 2R_B) C$

The frequency of oscillation is then: $f = \frac{1}{T} = \frac{1.44}{(R_A + 2R_B) C}$

and may be easily found as shown in Figure 19.

The duty cycle is given by: $DC = \frac{R_B}{R_A + 2R_B}$

To obtain the maximum duty cycle R_A must be as small as possible; but it must also be large enough to limit the discharge current (pin 7 current) within the maximum rating of the discharge transistor (200 mA).

The minimum value of R_A is given by:

$$R_A \geq \frac{V_{CC} (V_{dc})}{I_7 (A)} \geq \frac{V_{CC} (V_{dc})}{0.2}$$

FIGURE 17 – ASTABLE CIRCUIT

FIGURE 19 – FREE-RUNNING FREQUENCY

APPLICATIONS INFORMATION

TONE BURST GENERATOR

For a tone burst generator the first timer is used as a monostable and determines the tone duration when triggered by a positive pulse at Pin 6. The second timer is enabled by the high output of the monostable. It is connected as an astable and determines the frequency of the tone.

DUAL ASTABLE MULTIVIBRATOR

This dual astable multivibrator provides versatility not available with single timer circuits. The duty cycle can be adjusted from 5% to 95%. The two outputs provide two phase clock signals often required in digital systems. It can also be inhibited by use of either reset terminal.

FIGURE 20 – TONE BURST GENERATOR

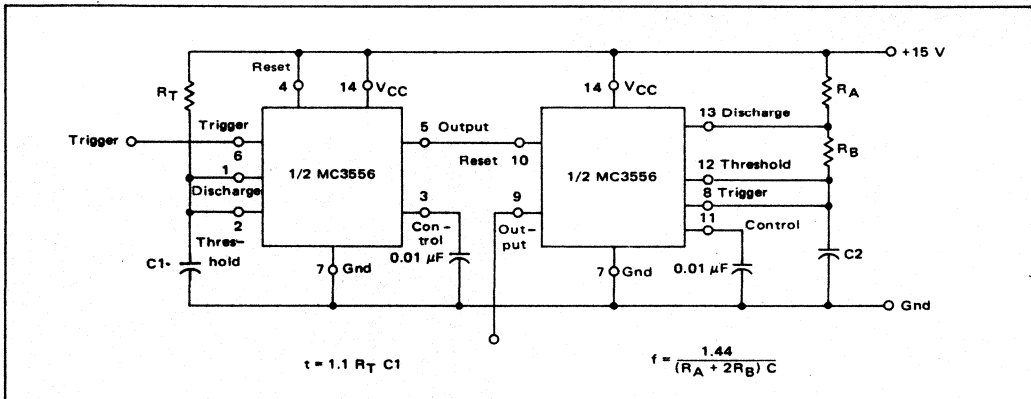

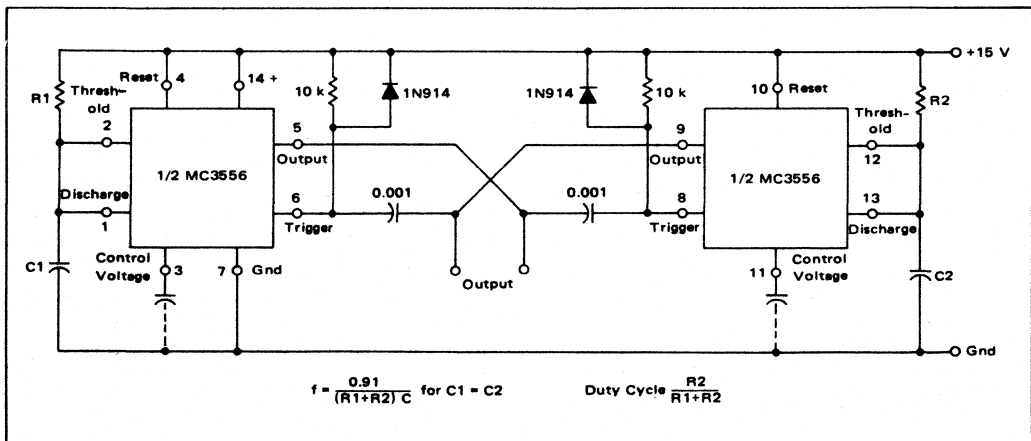

FIGURE 21 – DUAL ASTABLE MULTIVIBRATOR

APPLICATIONS INFORMATION (continued)

Pulse Width Modulation

If the timer is triggered with a continuous pulse train in the monostable mode of operation, the charge time of the capacitor can be varied by changing the control voltage at pin 3. In this manner, the output pulse width can be modulated by applying a modulating signal that controls the threshold voltage.

FIGURE 22

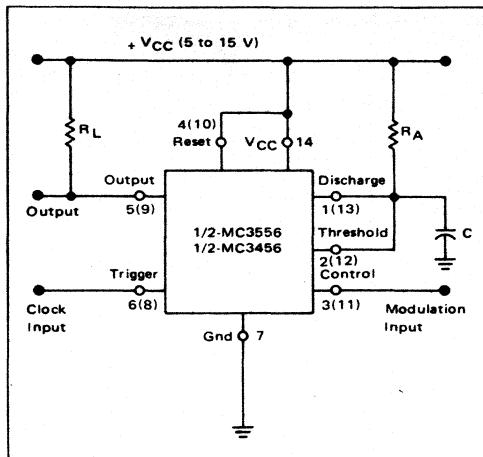

FIGURE 23 – PULSE WIDTH MODULATION WAVEFORMS
($R_A = 10\text{ k}\Omega$, $C = 0.02\text{ }\mu\text{F}$, $V_{CC} = 15\text{ V}$)

Test Sequences

Several timers can be connected to drive each other for sequential timing. An example is shown in Figure 24 where the sequence is started by triggering the first timer which runs for 10 ms. The output then switches low momentarily and starts the second timer which runs for 50 ms and so forth.

GENERAL APPLICATIONS INFORMATION

The following formulas are useful when designing with the NE565N:

1. Center Frequency – $f_0 \approx \frac{1}{3.7 R_0 C_0}$

Where: f_0 is the frequency of the VCO without input signal. For R_0, C_0 circuit location see Figure 2.

2. Loop Gain – $K_0 K_D A$

Definitions:

K_0 – VCO Conversion Gain – the conversion factor between VCO frequency and control voltage.

$K_0 = 4.12 f_0$ (units are in radians/sec/volt)

Example: for VCO Sensitivity @ 10 kHz (in Hz/volt)

$K_0 = \frac{4.12 \times 10^4}{2 \pi \text{ radians}} = 6600 \text{ Hz/Volt}$

K_D – Phase Detector Gain Factor – the conversion factor between the phase detector output voltage and the phase difference between input and VCO signals. Units are in volts/radian.

$K_D = \frac{8.1 \bullet A}{V_{CC}}$

Where: $A = f(R6 \text{ to } R7)$

Hence: $K_D = \frac{8.1}{V_{CC}} [f(R6-R7)]$

Where: V_{CC} is total system supply voltage, $f(R6-R7)$ is internal amplifier gain (See Figure 9). V_{CC} – total supply voltage to the circuit.

3. Lock Range – $f_L = \pm \frac{8f_0}{V_{CC}}$

Where: f_L is the range of frequencies in the area of f_0 over which the VCO, once locked to the input signal, will remain locked.

4. Capture Range – $f_c \approx \pm \frac{1}{2\pi} \sqrt{\frac{2\pi f_L}{\tau}}$

Where: f_c is that range of frequencies around f_0 over which the loop will acquire lock with an input signal initially starting out of lock.

(τ = Time Constant at Pin 7)

FIGURE 9 – INTERNAL AMPLIFIER GAIN CHARACTERISTICS

NE592 SE592

DIFFERENTIAL TWO-STAGE VIDEO AMPLIFIER

The SE/NE592 is a monolithic, two-stage, differential output, wideband video amplifier. It offers fixed gains of 100 and 400 without external components and adjustable gains from 400 to 0 with one external resistor. The input stage has been designed so that with the addition of a few external reactive elements between the gain select terminals, the circuit can function as a high pass, low pass, or band pass filter. This feature makes the circuit ideal for use as a video or pulse amplifier in communications, magnetic memories, display and video recorder systems. The 592 is a pin-for-pin replacement for the MC1733.

- 90 MHz Bandwidth
- Adjustable Gains From 0 to 400
- Adjustable Pass Band
- No Frequency Compensation Required

	Band Reject	$\frac{1.4 \times 10^4}{R} \left[\frac{s^2 + 1/LC}{s^2 + 1/LCs + s/RC} \right]$

NOTE
In the networks above, the R value used is assumed to include $2r_e$, or approximately 30 Ohms.

SAA1042

Advance Information

STEPPER MOTOR DRIVER

The SAA1042 drives a two phase stepper motor in the bipolar mode. The device contains; three input stages, a logic section and two output stages.

- Drive stages designed for motors from 6 to 12 V
- 500 mA/coil drive capability
- Built in clamp diodes for over voltage protection
- Wide logic supply voltage range ($V_{CC} = 5\text{ V to }18\text{ V}$)
- Accepts commands for CW/CCW and Half/Full Step operation
- Inputs compatible with popular logic families; MOS, TTL, DTL
- Set input for defined output state
- Drive stage bias adaptable to motor power dissipation for optimum efficiency

INPUT/OUTPUT FUNCTIONS

CLOCK — (pin 7) This master timing input is active on the positive going edge of the clock pulse and is able to accept logical '1' input levels dependant on the supply voltage with a hysteresis for noise immunity.

CW/CCW — (pin 10) This input determines the motor's rotational sense. When the input is held low, 0V (see the electrical characteristics) the motor's sense is nominally clockwise (CW). When the input is in the high state, logical '1', the motor sense will be nominally counter clockwise (CCW), depending on the motor connections.

FULL/HALF STEP — (pin 8) This input determines the angular rotation of the motor for each clock pulse. In the low state the motor will make a full step for each applied clock pulse while in the high state the motor will make half a step.

V_D — (pin 2) This pin is used to protect the outputs where large positive going spikes occur due to switching the motor coils. Motor efficiency is improved if a zener diode is connected between pins 2 and 15 (motor supply voltage — V_M). The diode with the internal diodes (see figure 5) should limit transients to V_M + 6 V. (See also the application example figure 7.)

Pins 2 and 15 may be linked but, this will reduce the motor's performance.

SET INPUT — (pin 6) This input accepts a SET control signal via a resistor (R_B in figures 1 and 6) which is chosen to adapt the circuit to the motor according to figure 2.

Figure 2 — Bias Resistor R_B Vs. Motor Current

Figure 3 — Drive Stage Power Dissipation Vs. Motor Current

Figure 4 — Power Dissipation P_L Vs. Logic Supply Voltage V_{CC}

Figure 5 — Clamp Diode Forward Current Vs. Forward Voltage

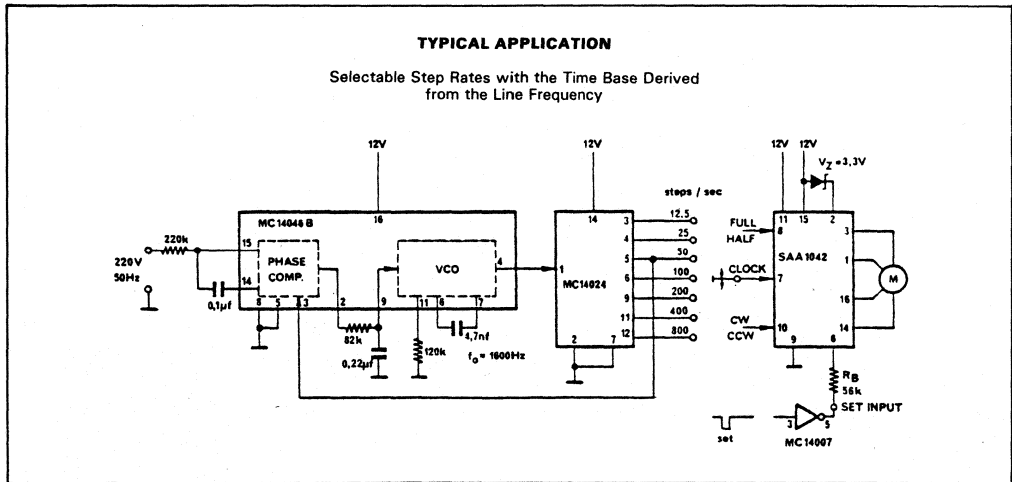

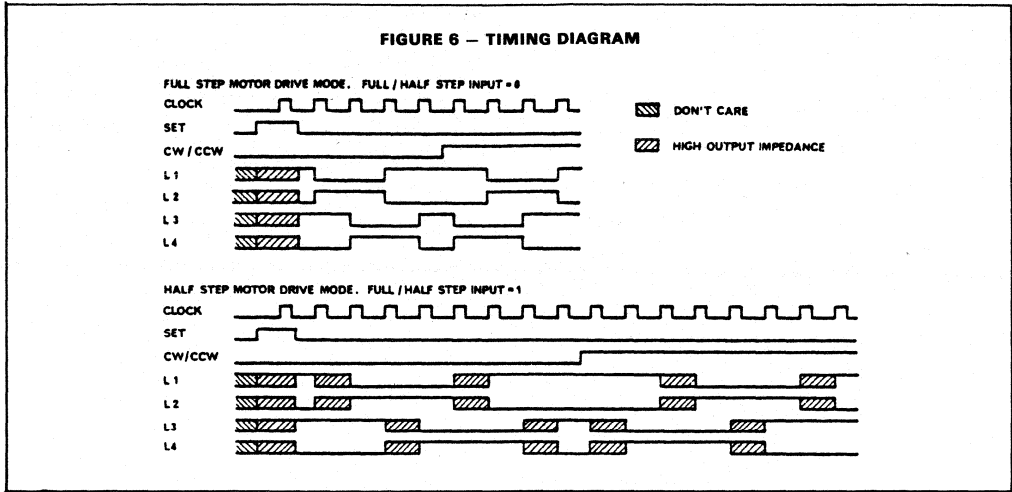

Figure 7 illustrates a typical application where the SAA1042 is driving a 12V stepper motor with a current consumption of 200 mA/coil.

The bias resistor R_B of 56kΩ is chosen according to figure 2.

The maximum voltage permitted at the output pins is $V_M + 6V$ (see the Maximum Ratings), in this application $V_M = 12V$, therefore the maximum voltage is 18V. The outputs are protected by the internal diodes and an external zener connected between pins 2 and 15.

From figure 5 it can be seen that the voltage drop across the internal diodes is about 1.7V at 200 mA. This results in a zener voltage between pins 2 and 15 of: $V_Z = 6V - 1.7V = 4.3V$. To allow for production tolerances and a safety margin a 3.9V zener has been chosen for this example.

The clock is derived from the line frequency to which it is phase locked by the MC14046B and MC14024.

The voltage on the clock input, pin 7, is normally low, logical '0' and the motor steps on the positive going transition of the clock pulse.

A logical '0' applied to the Full/Half input, pin 8, operates the motor in the Full Step mode. A logical '1' at this input will result in the Half Step mode. The logical voltage state on the CW/CCW input, pin 10, and the connection of the motor coils to the outputs determines the rotational sense of the motor.

These two inputs should be biased to a logical '0' or '1' and not left floating. In the event of non-use they should be tied to ground or the logic supply line V_{CC} .

SAA1042

The output drivers can be set to a fixed departure point by use of the SET input, the 'bottom' of the bias resistor R_B . A positive pulse to this input turns the drivers off and sets the logic state of the outputs.

After the negative going transition of the SET pulse and until the first positive going transition of the clock the outputs will be: L1 = L3 = high and L2 = L4 = low. (See figure 6, the timing diagram.)

The SET input can be driven by a MC14007B or a transistor

whose collector resistor is R_B . If the input is not used the 'bottom' of R_B must be grounded.

The total power dissipation of the circuit can be determined from figures 3 and 4. $P_T = 0.9W + 0.05W = 0.95W$. This results in a temperature difference between the junction and ambient of:

$t_j - t_a = 70^\circ C/W \cdot 0.95W = 66.5^\circ C$ or a maximum ambient temperature of $58.5^\circ C$. For operation at elevated ambient temperatures a heat sink is obligatory.

The background of the page is a detailed, grayscale microchip layout. It shows a complex network of circuit traces, pads, and various functional blocks. On the left side, there are several large, rectangular blocks with internal grid-like patterns, likely representing memory arrays or logic blocks. On the right side, there are more vertical, elongated structures with internal patterns, possibly representing peripheral controllers or interface blocks. The overall layout is dense and intricate, typical of a high-performance integrated circuit.

Interface/Comparator Selector Guide

BUS INTERFACE

Microprocessor Bus

This family of devices is designed to extend the limited drive capabilities of today's standard 6800 and 8080 type NMOS microprocessors. All devices are fabricated with Schottky TTL technology for high speed.

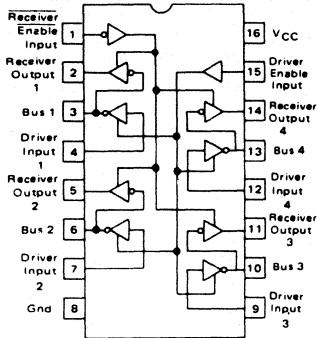

General features include:

- Single +5.0 V Power Supply Requirement
- Three-State Logic Output
- Low Input Loading – 200 μA Max.

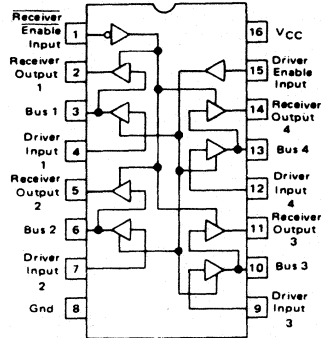

DATA BUS EXTENDERS

Quad, Bidirectional; with 3-State Outputs

*MC6880A/MC8T26A# – Inverting

*MC6889/MC8T28# – Non-inverting

These devices may be ordered by either of the paired numbers.

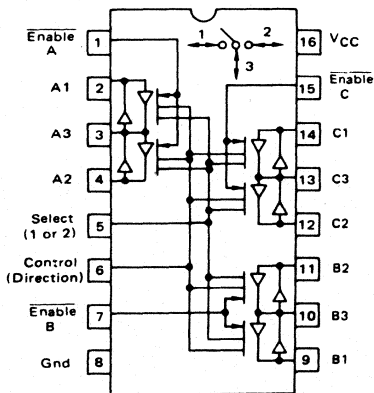

Both types:
 $T_A = 0$ to 75°C

Packages:
L Suffix – Case 620
P Suffix – Case 648

Device Number	Input Current		I_{OHL} Output Disabled Leakage Current – High Logic State μA Max	t_{PLH} , t_{PHL} Propagation Delay Time – High to Low or Low to High ns Max

*Fault Protection

GENERAL-PURPOSE I/O INTERFACE

Line drivers and receivers designed to operate compatibly. The MC8T13/MC8T14 combination is specified

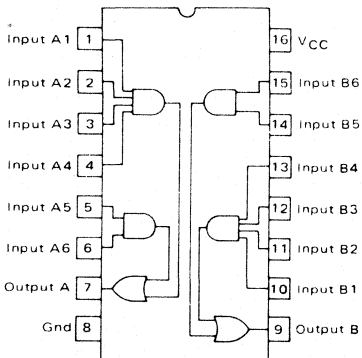

for general TTL system applications. The MC8T23/MC8T24 combination is oriented toward older IBM 360/370 system requirements.

DUAL LINE DRIVERS

MC8T13 – Open emitter driver; specified for general TTL systems.
MC8T23 – Open emitter driver; specified to meet older IBM system requirements.

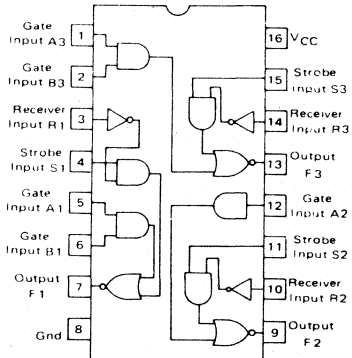

TRIPLE LINE RECEIVERS

MC8T14 – Hysteresis-equipped receiver; specified for general TTL systems.
MC8T24 – Hysteresis-equipped receiver; specified to meet older IBM system requirements.

All four devices:
 $T_A = 0 \text{ to } 75^\circ\text{C}$

Packages:
L Suffix – Case 620
P Suffix – Case 648

Device Number	V_{OH} @ $I_{OH} = -75 \text{ mA}$ @ $I_{OH} = -59.3 \text{ mA}^*$ Volts Max	I_{OS} @ $V_O = 0$ mA Max	t_{PLH} @ $C_L = 15 \text{ pF}$ ns Max

MC8T14	0.3	0.17	30
MC8T24	0.2	0.17*	30

7

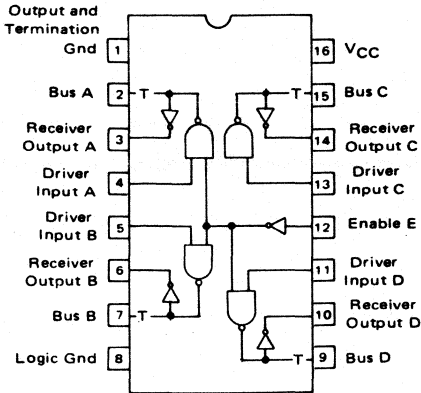

QUAD INTERFACE TRANSCEIVERS

These devices are designed to meet the GPIB bus specification of IEEE Standard 488-1978, for the inter-connection of Measurement Apparatus.

MC3440AP — Three drivers with common Enable input; one driver without Enable.

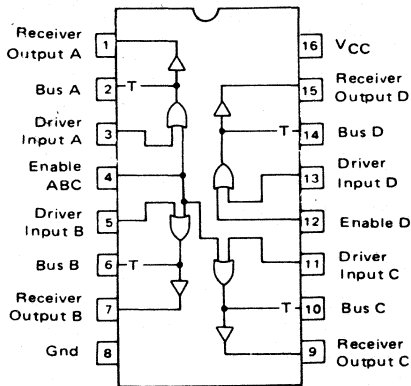

MC3441AP — Four drivers with common Enable input.

MC3443P — Four drivers with common Enable input; no termination resistors.

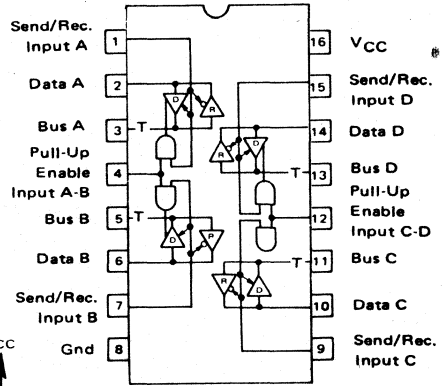

MC3446AP — For low-power instruments, including MOS.

MC3448A — For common Send-Receive bus; bidirectional.

Packages:
L Suffix — Case 620
P Suffix — Case 648

All types:
 $T_A = 0 \text{ to } 70^\circ\text{C}$

Device Number	Receiver Input Hysteresis mV Min	Drive Output Voltage $I_{OL} = 48 \text{ mA}$ Volts Max	Bus Divider Voltage Volts	t_{PHL} (Driver or Receiver) ns Max
MC3440AP	400	0.4	2.6 to 3.75	30
MC3441AP	400	0.4	2.6 to 3.75	30
MC3443P	400	0.4	—	25(D) 22(R)
MC3446AP	400	0.4	2.5 to 3.7	50
MC3448A	400	0.4	2.5 to 3.7	35

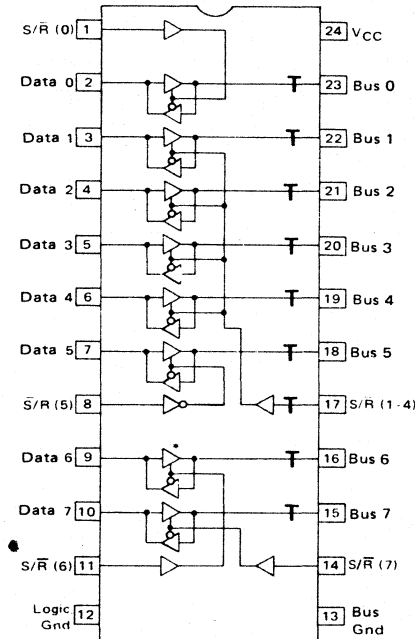

BUS INTERFACE (continued)

Instrumentation Bus (continued)

OCTAL LOW-POWER INTERFACE TRANSCEIVER

These devices are designed to meet the GPIB bus specifications of IEEE Standard 488-1978, for the interconnection of Measurement Apparatus.

MC3447 — Open collector, 3-State outputs with terminations.

All types:
 $T_A = 0 \text{ to } 70^\circ\text{C}$

Packages:
L Suffix — Case 623
P3 Suffix — Case 724
(Narrow)

Device Number	Receiver Input Hysteresis mV Min	Drive Output Voltage @ $I_{OL} = 48 \text{ mA}$; Volts Max	t_{PHL} (Driver or Receiver) ns Max
MC3447	400	0.5	30 (D) 22 (R) *

* Fast Channel.

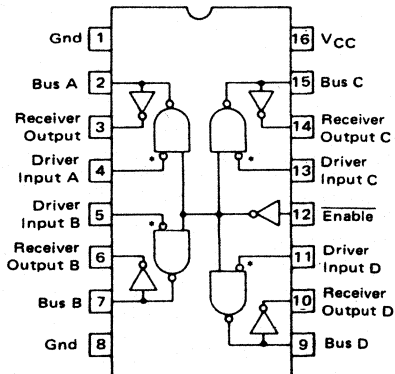

HIGH-CURRENT PARTY-LINE BUS TRANSCEIVERS

Devices for industrial control and data communication.

MC26S10 — Inverting

MC26S11 — Non-inverting

Quad transceivers with open-collector drivers and PNP-buffered inputs for MOS compatibility.

* Inverter on MC26S11 only.

Packages:
L Suffix — Case 620
P Suffix — Case 648

Test	Condition	Limits
V_{OL} (D)	$I_{OL} = 100 \text{ mA}$	0.8 Volts Max
I_O (D)	$V_{OH} = 4.5 \text{ V}$	100 μA Max
I_{O1} (D)	$V_{CC} = 0 \text{ V}$, $V_{OH} = 4.5 \text{ V}$	100 μA Max

t_P (D)	MC26S10	15 ns Max
	MC26S11	19 ns Max
t_P (R)	Both Types	15 ns Max

MEMORY INTERFACE AND CONTROL

NMOS Memories to TTL Systems

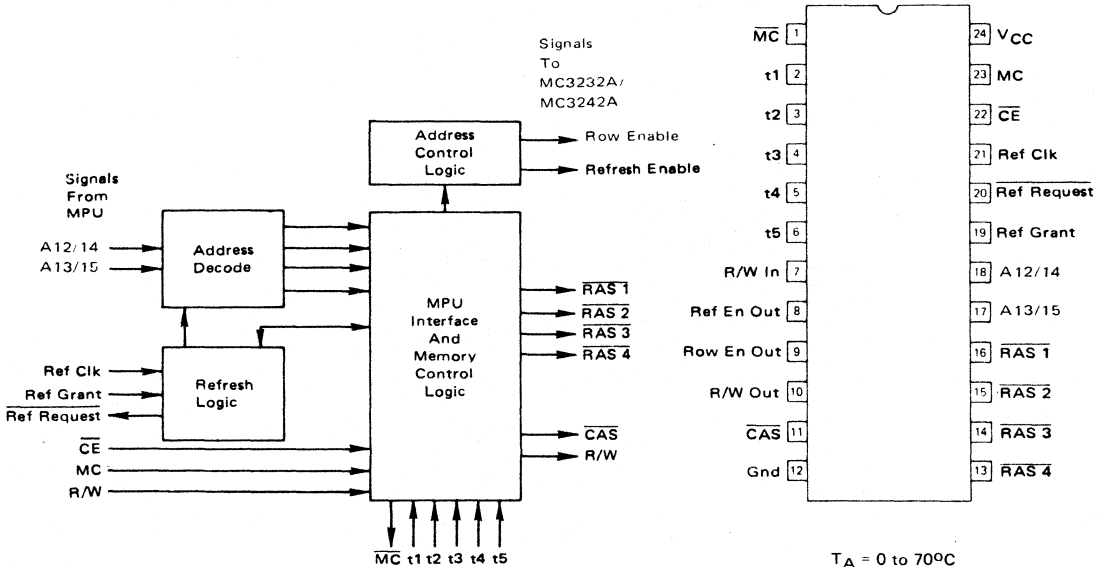

MULTIPLEXED 16-PIN RAM CONTROL (For 4K, 16K, and 64K Dynamic Memories)

MC3480 — Memory Controller. Used with all three levels of RAM.

The memory controller chip is designed to greatly simplify the interface logic required to control popular 16-pin 4K, 16K, or 64K dynamic NMOS RAMs in a microprocessor system such as the M6800. The controller will generate, on command from the microprocessor, the proper RAS and timing signals required to successfully transfer data between the microprocessor and the NMOS memories. The controller, in con-

junction with an oscillator, will also generate the necessary signals required to ensure that the dynamic memories are refreshed for the retention of data.

With Schottky TTL technology for high performance, and high input impedance for minimum loading of the MPU bus, the MC3480 reduces package count, and reduces system access/cycle times by 30%. The chip enable allows expansion to larger-word capacity.

Designed to interface directly with MC3232A or MC3242A address/multiplexers/refresh counters.

Packages:
L Suffix — Case 623
P Suffix — Case 649

MEMORY INTERFACE AND CONTROL (continued)

NMOS Memories to TTL Systems (continued) Multiplexed 16-Pin RAM Control (continued) (For 4K, 16K, and 64K Dynamic Memories)

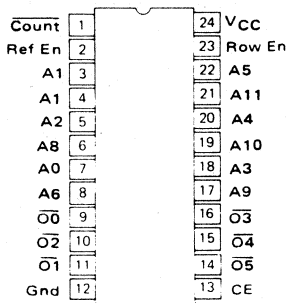

MC3232A – 6-Bit (4K RAM) Address Multiplexer/Refresh Counter

MC3242A – 7-Bit (16K RAM) Address Multiplexer/Refresh Counter

MC3482A/B – 8-Bit Address Multiplexer (See Microprocessor Bus Section)

MC3232A – Designed for multiplexing 12 address lines into 6 for the 16-pin multiplexed 4K RAMs, while also containing a 6-bit refresh counter.

MC3242A – Designed for multiplexing 14 address lines into 7 for the 16-pin multiplexed 16K RAMs, while also containing a 7-bit refresh counter.

Both types:
 $T_A = 0$ to 75°C

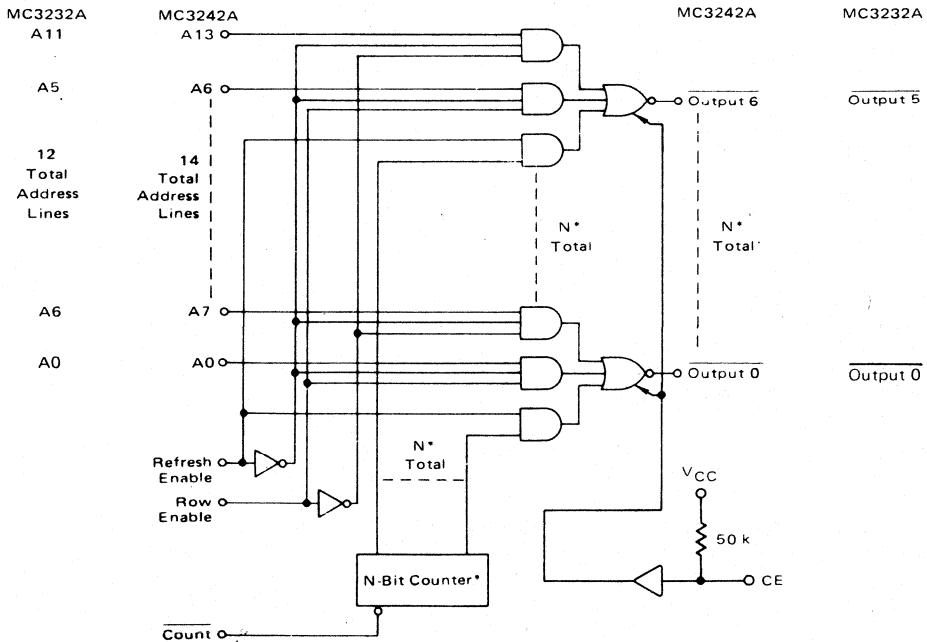

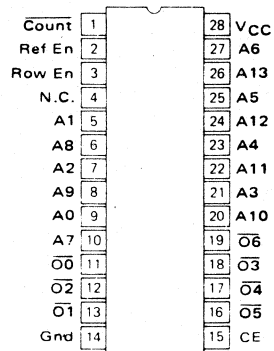

Packages:

MC3232A – L Suffix – Case 623

P Suffix – Case 649

MC3242A – L Suffix – Case 733

P Suffix – Case 710

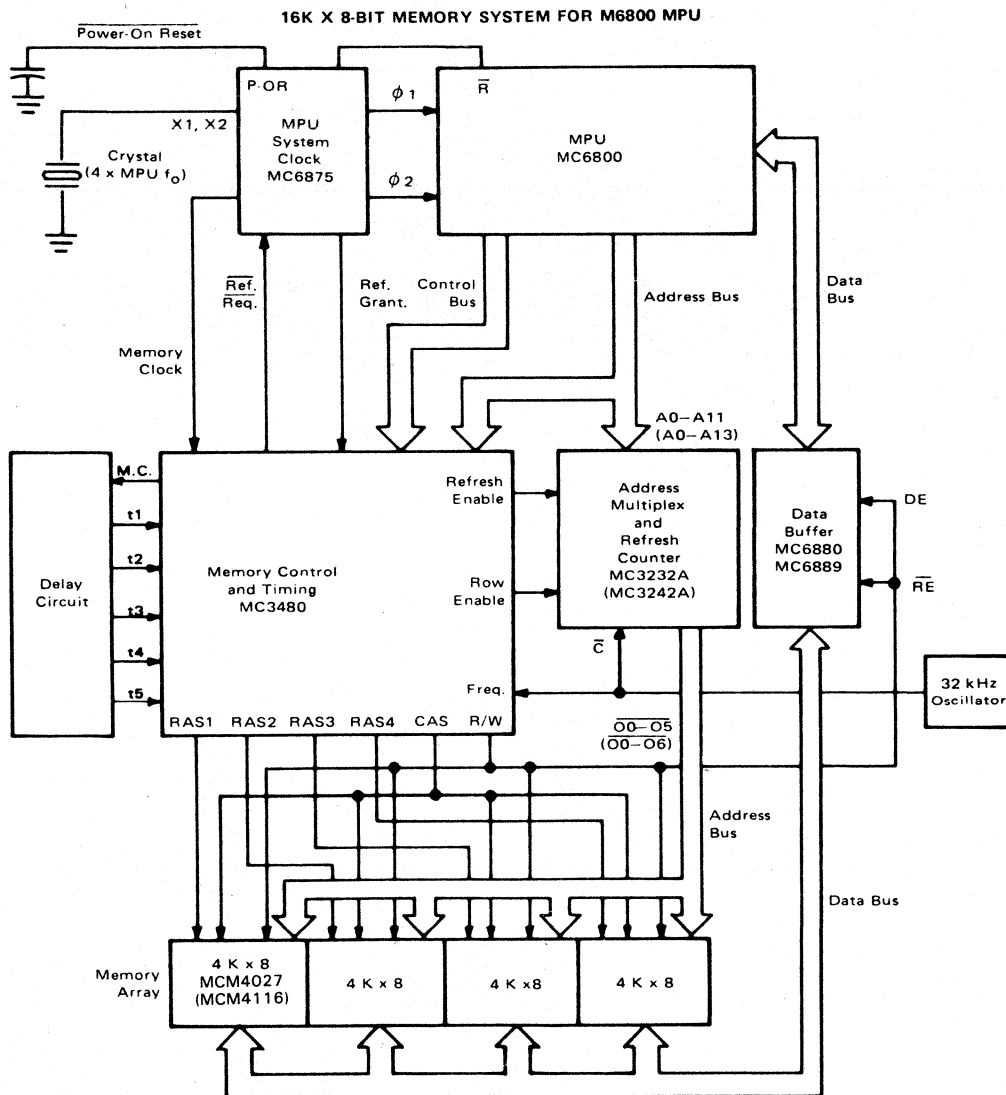

*N = 6-Bit for MC3232A
= 7-Bit for MC3242A

NMOS Memories to TTL Systems (continued)

Data and Address Line Drivers (Low Level) (continued)

TYPICAL APPLICATION

NOTE

* @ $V_1 - V_{EE}$

Magnetic Memories to TTL Systems

SENSE AMPLIFIERS

... for Magnetic Tape Memories

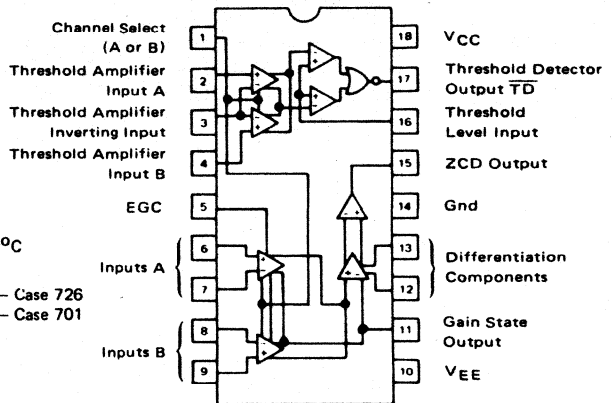

A two-component preamplifier/amplifier combination that provides the interface between magnetic tape heads and digital logic. Suitable for both open reel and cartridge tape systems. Triple preamp has individually adjustable gain controls. LSI Read Amplifier performs peak detection and threshold detection functions, as required for NRZI/phase encoded recording formats.

MC3467 – Triple Preamplifier

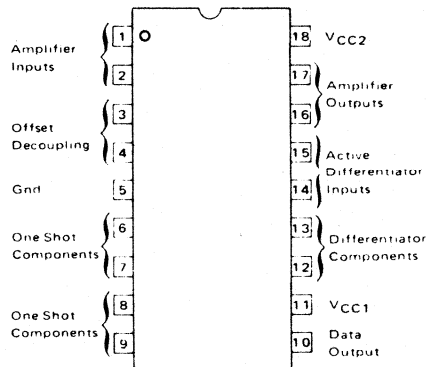

Both types:
 $T_A = 0 \text{ to } 70^\circ\text{C}$
 Packages:
 L Suffix – Case 726
 P Suffix – Case 701

MC3468 – Read Amplifier

MC3470 – Designed as a monolithic READ Amplifier System for obtaining digital information from floppy disk storage.

$T_A = 0 \text{ to } 70^\circ\text{C}$
 Package:
 P Suffix – Case 701

CORE DRIVER

MC55325 - $T_A = -55$ to 125°C

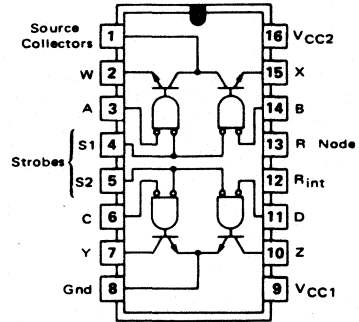

MC75325 - $T_A = 0$ to 70°C

Contains two source switches and two sink switches.
Source and sink selection is determined by one of two logic inputs, and turn-on is determined by the appropriate strobe.

Packages:

L Suffix - Case 620

P Suffix - Case 648 (MC75325 only)

Device Number	V_{sat} @ I_{sink} or $I_{source} = 600$ mA Volts Max	I_{off} @ $V_{CC2} = 24$ V μA Max	t_{PLH} (Source) ns Max	t_{PLH} (Sink) ns Max
MC55325	0.70	150	50	45
MC75325	0.75	200	50	45

PRECISION CIRCUITS — DATA CONVERSION

Low-cost building blocks for construction of D-A/A-D systems. Involves use of advanced technologies such as ion implantation, laser trimming and CMOS

processing where necessary to achieve the required functional capability, operating accuracy and production repeatability.

D-A Converters — General Purpose

Multiplying D-A converters designed to supply an output current that is a linear product of an analog input reference voltage and a digital input word. Devices for 6-, 8- and 10-bit digital word inputs are available.

Device Number	Error % Max	P_D @ $V_{EE} = -5V$ mW Max	$t_{Settling}$ ns Typ	I_O @ $V_{Ref} = 2V$ mA	Suffix	Case

Devices without asterisk: $T_A = 0$ to $70^\circ C$.

D-A Converters — High Speed

MC10318 — A high speed 8-bit D/A converter capable of data conversion rates in excess of 25 MHz. It is intended for applications in high speed instrumentation and communication equipment, display processing, storage oscilloscopes, radar processing, and TV broadcast systems. The inputs are compatible with MECL 10,000 series logic, while the complementary current outputs have 51 mA full scale capability. 8-bit accurate ($\pm 1/2$ LSB) and monotonic over the full temperature range, the outputs typically settle in less than 15 ns.

$T_A = 0$ to $70^\circ C$

Packages:
L Suffix — Case 620/690

Device Number	Error % Max	P_D @ $V_{EE} = -5.2V$ mW Max	$t_{Settling}$ ns Typ	I_O & \bar{I}_O @ $V_{Ref} = 10.56V$ mA Typ

PRECISION CIRCUIT — DATA CONVERSION (continued)

D-A Converters — High speed (continued)

(1) DAC08 — 8 BITH HIGH SPEED MULTIPLYING D/A CONVERTER

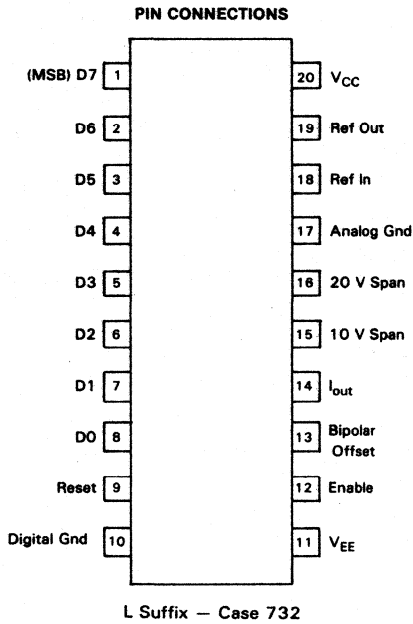

FEATURES

- Fast settling output Current: 85 nsec
- Direct interface to TTL, CMOS, ECL, MTL, PMOS
- Non linearity to $\pm 0.1\%$ max over temp. range
- Differential current outputs

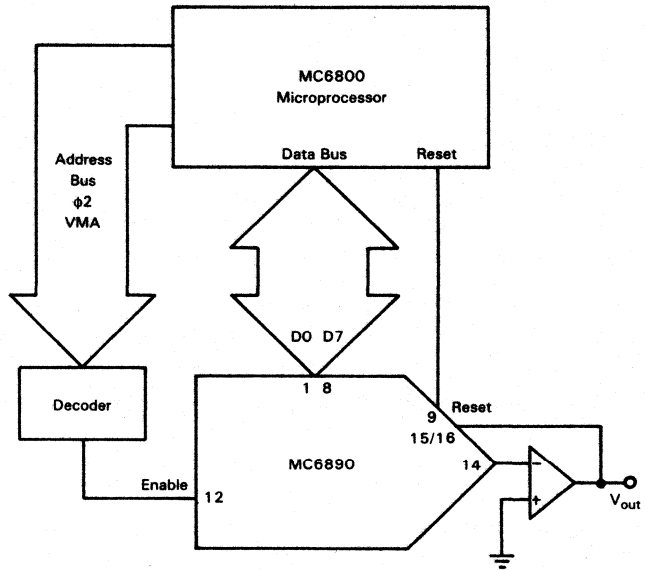

(1) MC6890 — BUS-COMPATIBLE 8-BIT MPU D-TO-A CONVERTER

The MC6890 is a self-contained, bus-compatible, 8-bit ($\pm 0.19\%$ accuracy) D-to-A converter system capable of interfacing directly with 8-bit microprocessors.

OPERATION WITH MC6800

(1) MC3412 — COMPLETE 12-BIT HIGH-SPEED MONOLITHIC D/A CONVERTER

The MC3412 is a monolithic single-chip 12-bit D/A converter. It contains a high-stability voltage reference and both offset and span resistors. Active laser trimming of the thin-film ladder network and voltage reference provide accuracy and linearity of better than $\pm 1/2$ LSB. 12-bit accuracy and fast settling time (typically better than 200 ns to $\pm 1/2$ LSB) make this converter an ideal display driver or fast A/D converter building block.

L Suffix — Case 623

P Suffix — Case 649

VOLTAGE COMPARATORS (continued)

Quad Comparators ... for applications requiring multiple comparators.

MC3430 }
MC3431 } - High-speed quad comparators with three-state Enable common to all four devices; ± 5 volt supply; $T_A = 0$ to 70°C .

MC3432 }
MC3433 } - Quad comparators with open collector outputs, common strobe input; ± 5 volt supply; $T_A = 0$ to 70°C .

LM139 }
LM139A } - $T_A = -55$ to 125°C

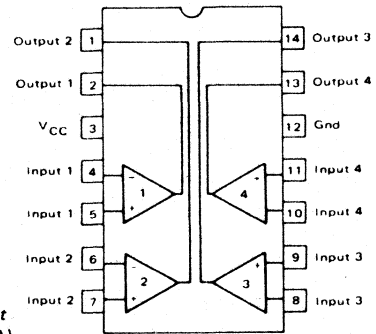

MC3302 }
LM2901 }
LM239 }
LM239A } - $T_A = -40$ to 85°C

LM339 }
LM339A } - $T_A = 0$ to 70°C

Single supply voltage comparators.

Packages:
J Suffix - Case 632
N Suffix - Case 646 (For all devices *except* LM139, LM139A)

Device Number	V_{IS} mV Max	I_{IB} μA Max	t_{PHL} ns Max
MC3430	± 6.0	20	45
MC3431	± 10	20	45
MC3432	± 6.0	20	50
MC3433	± 10	20	50

Device Number	V_{IO} @ 25°C mV Max	I_{IB} @ 25°C nA Max	I_{sink} @ $V_{OL} = 500$ mV mA Min	V_{OL} @ $I_{OL} = 2.0$ mA* @ $I_{OL} = 3.0$ mA** @ $I_{OL} = 4.0$ mA mV Max
MC3302	20	1000	-	400*
LM2901	7.0	250	6.0	400**
LM139	5.0	100	6.0	500
LM139A	2.0	100	6.0	500
LM239	5.0	250	6.0	500
LM239A	2.0	250	6.0	500
LM339	5.0	250	6.0	500
LM339A	2.0	250	6.0	500

COMMUNICATION INTERFACE (Telephony)

Crosspoint Switch

MC3416 – Low-cost solid-state crosspoint switch offers important advantages in modern telephone exchanges employing space-division switching. Features 4 x 4 two-wire monolithic structure for PABX applications. Select inputs are both CMOS and TTL compatible.

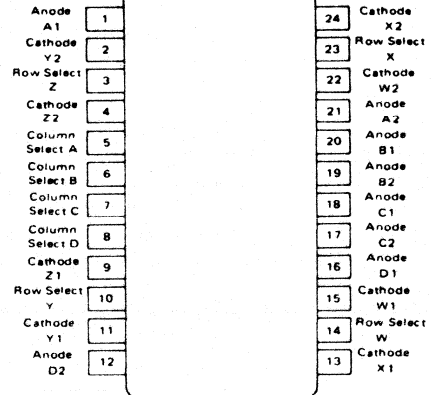

$T_A = 0$ to 70°C

Packages:

P Suffix – Case 649

L Suffix – Case 623

r_{off} @ $V_{AK} = 10\text{ V}$ M Ω Min	r_{on} @ $I_{AK} = 20\text{ mA}$ Ohms Max	BV_{AK} BV_{KA} Volts Min	V_{AK} V_{KA} @ $I_{AK} = 20\text{ mA}$ Volts Max
100	10	25	1.1

Voice Encoding/ Decoding

Simplified voice encoding/decoding using continuous Variable Slope Delta Modulator (CVSD) technique.

MC3417/MC3517 – 3-bit algorithm; for military secure communication and general-purpose low-sampling rate applications.

MC3418/MC3518 – 4-bit algorithm; telephone quality.

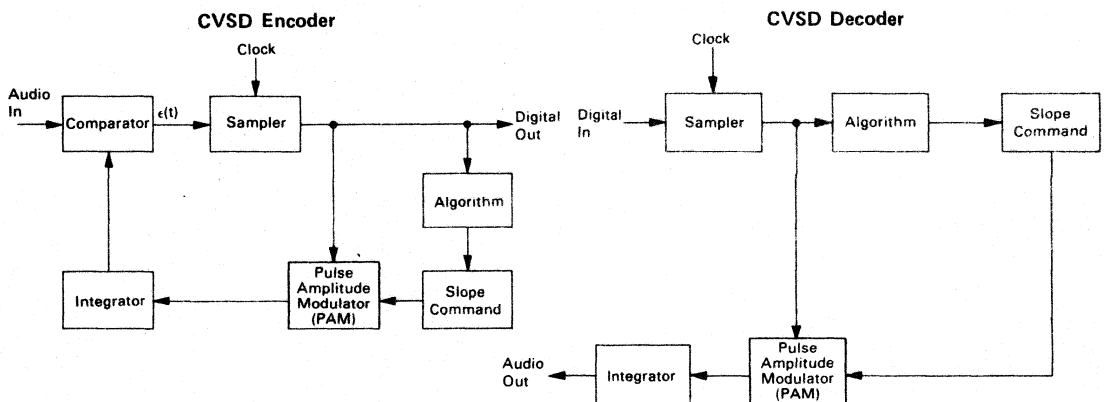

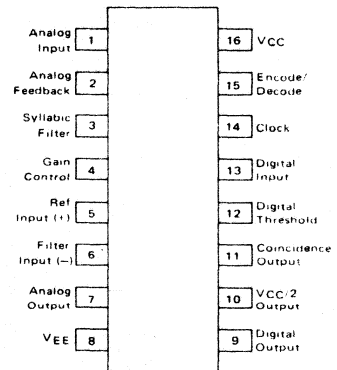

$T_A = 0$ to 70°C – MC3417/MC3418
= -55 to $+125^\circ\text{C}$ – MC3517/MC3518

Packages:

L Suffix – Case 620

P Suffix – Case 648

Device Number	Sample Rate Samples/s Typ	Total Loop Offset Voltage mV Max	t_{PD} , Clock Trigger to Output μs Max
MC3417/MC3517	16 k	± 5.0	2.5
MC3418/MC3518	38 k	± 2.0	2.5

Digital Voice Channel

SUBSCRIBER LOOP INTERFACE CIRCUIT

MC3419/MC3519 – Designed to replace the hybrid transformer in Class 5, PBAX and Subscriber Carrier Equipment, this circuit provides signal separation for two-wire differential to four-wire single-ended conversions and suppression of longitudinal signals at the two-wire input. The trans-hybrid gain is externally selected

and provides dc line current for powering the telset. It operates from up to a 60 V supply. On-hook power is below 5 mW and current sensing outputs are provided for off-hook status from both tip and ring leads. It offers size and weight reduction over present approaches and is compatible with IEEE and REA specifications.

$T_A = 0$ to 70°C – MC3419
 $= -40$ to $+85^\circ\text{C}$ – MC3519

Packages:
 L Suffix – Case 726
 P Suffix – Case 701

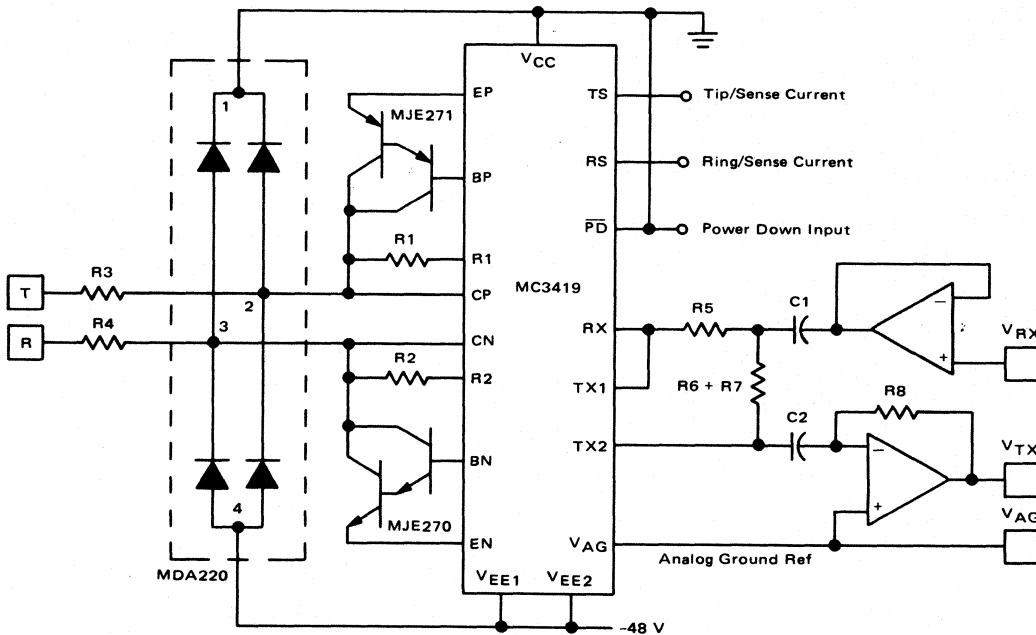

Figure 1 – Block Diagram and Pin Assignment

L Suffix – Case 632

Voltage Comparator

TCA1005 DUAL HIGH VOLTAGE COMPARATOR

The TCA1005 is a dual high voltage comparator specially designed for level sensing in -48 V telephone systems—applications envisaged for the circuit include: loop sensing, ring tripping and similar applications.

CASE OUTLINE DIMENSIONS

The packaging availability for each device type is indicated on the individual data sheets and the Selector Guide. All of the outline dimensions for the packages are given in this section.

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature can be found from the equation:

$$P_{D(T_A)} = \frac{T_{J(max)} - T_A}{R_{\theta JA}(Typ)}$$

where: $P_{D(T_A)}$ = Power Dissipation allowable at a given operating ambient temperature. This must be greater than the sum of the products of the supply voltages and supply currents at the worst case operating condition.

$T_{J(max)}$ = Maximum Operating Junction Temperature as listed in the Maximum Ratings Section. See individual data sheets for $T_{J(max)}$ information.

T_A = Maximum Desired Operating Ambient Temperature

$R_{\theta JA}(Typ)$ = Typical Thermal Resistance Junction to Ambient

CASE 1 (TO-3)

Metal Package

$R_{\theta JA} = 45^{\circ} \text{ C/W}(Typ)$

$R_{\theta JC} = 5.5^{\circ} \text{ C/W}(Typ)$

APPLICATION NOTE ABSTRACTS

The application notes listed in this section have been prepared to acquaint the circuits and systems engineer with Motorola Linear integrated circuits and their applications. To obtain copies of the notes, simply list the AN number or numbers and send your request on your company letterhead to: Technical Information Center, Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix, Arizona 85036.

AN-245A An Integrated Core Memory Sense Amplifier

This application note discusses core memories and related design considerations for a sense amplifier. Performance and environmental specifications for the amplifier design are carefully established so that the circuit will work with any computer using core memories. The final circuit design is then analyzed and measured performance is discussed. The amplifier features a small uncertainty region (6 mV max), adjustable voltage gain, and fast cycle time (0.5 μ s).

AN-273A More Value out of Integrated Operational Amplifier Data Sheets

The operational amplifier is rapidly becoming a basic building block in present day solid state electronic systems. The purpose of this application note is to provide a better understanding of the open loop characteristics of the amplifier and their significance to overall circuit operation. Also, each parameter is defined and reviewed with respect to closed loop considerations. The importance of loop gain stability and bandwidth is discussed at length. Input offset circuits are also reviewed with respect to closed loop operation.

AN-290B Mounting Procedure for, and Thermal Aspects of, Thermopad Plastic Power Devices

Many Motorola power devices are now available in the Plastic Thermopad packages. Three package types are presently available. This application note provides information concerning the handling and mounting of these packages, as well as information on some thermal aspects.

AN-401 The MC1554 One-Watt Monolithic Integrated Circuit Power Amplifier

This application note discusses four different applications for the MC1554, along with a circuit description including DC characteristics, frequency response, and distortion. A section of the note is also devoted to package power dissipation calculations including the use of the curves on the power amplifier data sheet.

AN-404 A Wideband Monolithic Video Amplifier

This note describes the basic principles of AC and DC operation of the MC1552G and MC1553G, characteristics obtained as a function of the device operating modes, and typical circuit applications.

AN-411 The MC1535 Monolithic Dual Op Amp

This note discusses two dual operational amplifier applications and an input compensation scheme for fast slew rate for the MC1535. A complete AC and DC circuit analysis is presented in addition to many of the pertinent electrical characteristics and how they might affect the system performance.

AN-421 Semiconductor Noise Figure Considerations

A summary of many of the important noise figure considerations related with the design of low noise amplifiers is presented. The basic fundamentals involving noise, noise figure, and noise figure-frequency characteristics are then discussed with the emphasis on characteristics common to all semiconductors. A brief introduction is made to various methods of data sheet presentation of noise figure and a summary is given for the various methods of measurement. A discussion of low noise circuit design, utilizing many of the previously discussed considerations, is included.

AN-471 Analog-to-Digital Conversion Techniques

The subject of analog-to-digital conversion and many of the techniques that can be used to accomplish it are discussed. The paper is written in general terms from a system point of view and is intended to assist the reader in determining which conversion technique is best suited for a given application.

AN-489 Analysis and Basic Operation of the MC1595

The MC1595 monolithic linear four-quadrant multiplier is discussed. The equations for the analysis are given along with performance that is characteristic of the device. A few basic applications are given to assist the designer in system design.

APPLICATION NOTE ABSTRACTS (Continued)

AN-491 Gated Video Amplifier Applications Using The MC1545

This application note reviews the basic operation of the MC1545 and discusses some of the more popular applications for the MC1545. Included are several modulator types, temperature compensation of the active gate, AGC, gated oscillators, FSK systems, and single supply operation.

AN-513 A High Gain Integrated Circuit RF-IF Amplifier with Wide Range AGC

This note describes the operation and application of the MC1590G, a monolithic RF-IF amplifier. Included are several applications for IF amplifiers, a mixer, video amplifiers, single and two-stage RF amplifiers.

AN-522 The MC1556 Operational Amplifier and its Applications

This application note discusses the MC1556, a second generation, internally compensated monolithic operational amplifier. Particular emphasis is placed on its distinct advantages over the early 709-type amplifier and the more recent 741-type amplifier.

Along with a description of its operation this note presents a discussion on various applications of the MC1556, highlighting its capabilities, and points out its characteristics so the reader may make effective use of the device.

AN-531 MC1596 Balanced Modulator

The MC1596 monolithic circuit is a highly versatile communications building block. In this note, both theoretical and practical information are given to aid the designer in the use of this part. Applications include modulators for AM, SSB, and suppressed carrier AM; demodulators for the previously mentioned modulation forms; frequency doublers and HF/VHF double balanced mixers.

AN-533 Semiconductors for Plated-Wire Memories

An introduction to the operation and electrical characteristics of plated-wire memories is provided in conjunction with the applications of semiconductors that interface with the plated-wire memories.

Devices discussed include drivers, sense amplifiers, and decoders. Memory organization and memory-related semiconductor applications are also mentioned.

AN-543A Integrated Circuit IF Amplifiers for AM/FM and FM Radios

This application note discusses the design and performance of four IF amplifiers using integrated circuits. The IF amplifiers discussed include a high performance circuit, a circuit utilizing a quadrature detector, a composite AM/FM circuit, and an economy model for use with an external discriminator.

AN-545 Television Video IF Amplifier Using Integrated Circuits

This applications note considers the requirements of the video IF amplifier section of a television receiver, and gives working circuit schematics using integrated circuits which have been specifically designed for consumer oriented products. The integrated circuits used are the MC1350, MC1352, MC1353 and the MC1330.

AN-547 A High-Speed Dual Differential Comparator, The MC1514

This application note discusses a few of the many uses for the MC1514 dual comparator. Many applications such as sense amplifiers, multivibrators, and peak level detectors are presented.

AN-553 A New Generation of Integrated Avionic Synthesizers

The need to generate signals of a multitude of different frequencies for avionic systems has resulted in complex solutions in the past. With the introduction of certain standard product integrated circuits, frequency synthesis using digital phase locked loop techniques presents a more practical solution. Several different types of servo phase locked loop systems are discussed and a practical design example is given. Results of design examples are presented along with possible applications.

AN-557 Analog-to-Digital Cyclic Converter

The A/D cyclic converter discussed in this note provides medium speed (1-5 μ s/ bit) and medium accuracy (7 or 8 bits) operation. A Cyclic converter uses the successive approximation technique in which an unknown analog input voltage is successively compared to a reference voltage to determine each bit of the digital output.

The cyclic converter offers continuous operation, automatic generation of the digital output in Gray-code form, and a building block structure. This structure uses a separate but identical circuit for each resolution bit. The cyclic converter finds use primarily in control and process applications.

AN-559 Simple Ramp A/D Converter

A simple single ramp A/D converter which incorporates a calibration cycle to insure an accuracy of 12 bits is discussed. The circuit uses standard ICs and requires only one precision part—the reference voltage used in the calibration. This converter is useful in a number of instrumentation and measurement applications.

AN-564 An ADF Frequency Synthesizer Utilizing Phase-Locked Loop Integrated Circuits

This application note describes an IC phase locked-loop frequency synthesizer suitable for the local oscillator function in aircraft Automatic Direction Finder (ADF) equipment.

APPLICATION NOTE ABSTRACTS (Continued)

AN-587 Analysis and Design of the Op Amp Current Source

A voltage controlled current source utilizing an operational amplifier is discussed. Expressions for the transfer function and output impedances are developed using both the ideal and non-ideal op amp models. A section on analysis of the effects of op amp parameters and temperature variations on circuit performance is presented.

AN-590 Servo Motor Drive Amplifiers

The design of transformerless, AC servo amplifiers using power darlington transistors and IC op amps are discussed. Two types of power amplifiers are illustrated, one using single +28 Volt power supply, the second using high voltage transistors in complementary configuration for operating directly off the line.

Four different op amp preamplifiers and 90° phase shifters are also described.

AN-599 Mounting Techniques for Metal Packaged Power Semiconductors

For cooler, more reliable operation, proper mounting procedures must be followed if the interface thermal resistance between the semiconductor package and heat sink is to be minimized. Discussed are aspects of preparing the mounting surface, using thermal compounds, and fastening techniques. Typical interface thermal resistance is given for a number of packages.

AN-702 High Speed Digital-To-Analog and Analog-To-Digital Techniques

A brief overview of some of the more popular techniques for accomplishing D/A and A/D techniques. In particular those techniques which lead themselves to high speed conversion.

AN-703 Designing Digitally-Controlled Power Supplies

This application note shows two design approaches; a basic low voltage supply using an inexpensive MC1723 voltage regulator and a high current, high voltage, supply using the MC1466 floating regulator with optoelectronic isolation. Various circuit options are shown to allow the designer maximum flexibility in an application.

AN-708A Line Driver and Receiver Considerations

This report discusses many line driver and receiver design considerations such as system description, definition of terms, important parameter measurements, design procedures and application examples. An extensive line of devices is available from Motorola to provide the designer with the tools to implement the data transmission requirements necessary for almost every type of transmission system.

AN-710 Communication System Transmission Losses

This report shows the derivation of the equations used to calculate the insertion loss associated with various component parts of a communications channel. The combinations of components form a system whose overall loss may not be equal to the sum of the losses of the various parts.

AN-711 The Recovery of Recorded Digital Information in Drum, Disk and Tape Systems

The use of magnetic recording techniques has long been an important means of sorting digital information, as evidenced by the wide variety of equipment currently in use. Representative systems utilize drums, disks and tape as the recording medium.

All three techniques share the common problem of recovering the recorded digital information. The analog signal obtained by passing the recording medium by a magnetic sensor (Read Head) must be converted to a suitable digital format.

This application note reviews the general problem and discusses a number of specific circuit approaches.

AN-713 Binary D/A Converters can Provide BCD-Coded Conversion

This note describes the application and use of integrated circuit D/A converters for use in providing a BCD-coded conversion. The technique is illustrated using a 2-1/2 digit digital voltmeter.

AN-714 A Personalized Heart-Rate Monitor with Digital Readout

Using the micropower operational amplifier MC1776 and CMOS digital integrated circuits, entirely self-contained portable electro-medical monitoring equipment can be built. This note details the construction of a heart-rate monitor giving a digital indication, beat-by-beat.

AN-716 Successive Approximation A/D Conversion

Recent advances in integrated circuit design and technology have resulted in reduced cost of high performance successive approximation analog to digital converters. This note describes and illustrates two examples of how modern IC components have changed this well known technique.

AN-717 Battery Powered 5-MHz Frequency Counter

This application note describes a battery-powered 5-MHz frequency counter using the CMOS logic family for low-power operation. The basic counter is optimized, at a 12-volt supply for maximum performance with a linear input-signal

APPLICATION NOTE ABSTRACTS (Continued)

conditioner. Several options are discussed which optimize the basic counter for minimum power dissipation. These options include a CMOS input signal-conditioner and multiplexed LED displays.

AN-719 A New Approach to Switching Regulators

This article describes a 24-Volt, 3-Ampere switching mode supply. It operates at 20 kHz from a 120 Vac line with an overall efficiency of 70%. New techniques are used to shape the load line. The control portion uses a quad comparator and an opto coupler and features short circuit protection.

AN-720 Interfacing with MECL 10,000

This article describes some of the MECL circuits used to interface with signals not meeting MECL input or output requirements. The characteristics of these circuits such as; input impedance, output drive, gain and bandwidth allow the system designer to use these parts to optimize his system. MECL interface circuits overcome a problem area of many system designs, which is the efficient coupling of non-compatible signals.

AN-732A A Non-Volatile Microprocessor Memory Using 4K N-Channel MOS RAMs

NMOS semiconductor technology has made inroads into high density/high performance circuit design. The one-chip microprocessor, Random Access Memories, and Read Only Memories, are changing system implementation from random logic designs to software and firmware programmable microcomputing systems. Such systems frequently require relatively large amounts of memory.

This paper describes the design of an 8192-byte non-volatile Random Access Memory system using the MCM6605A 4Kx1 RAM. The system is designed to work with the Motorola MC6800, an 8-bit microprocessor.

AN-737A Switched Mode Power Supplies—Highlighting A 5-V, 40-A Inverter Design

This application note identifies the features of various regulator circuits that are in use today in AC to DC power supplies. The note also illustrates how these circuits may be used as complementary building blocks in a system design. Primary emphasis is on switched mode regulators because they fill the present need for energy and space savings.

A complete 5-V, 40-A line operated inverter supply is described in detail including design procedures for the magnetic components. The inverter itself is a "state-of-the-art" design which features CMOS logic, high voltage power transistors, Schottky rectifiers and an optoelectronic coupler. It operates with a full load efficiency of 80% at a frequency of 20 kHz.

AN-739 A Synthetic Spectrum Tuning System for TV

A tuning system is described which uses a complete spectrum of TV channel markers to achieve precise tuning to any channel.

AN-741 Interface Considerations for Numeric Display Systems

This application note describes several methods of multiplexing multi-digit, seven-segment displays. The logic devices illustrated are primarily CMOS with two examples describing TTL. The displays discussed are liquid crystal, LED, gas discharge, incandescent and fluorescent. How to interface between the logic and these displays, and what the interface considerations are, are described in detail.

AN-744 A Phase-Locked Loop Tuning System for Television

This note describes a frequency domain tuning system which utilizes direct digital countdown of the varactor tuner's local oscillator to obtain the proper local oscillator frequency for the channel number selected. The system features direct-channel access with equal ease of tuning and an exact channel readout for all VHF and UHF channels.

AN-746 A 3½ Digit DVM Using an Integrated Circuit Dual Ramp System

This application note describes the design of a 3½-digit DVM (digital voltmeter) using the MC1405 and the MC14435 dual ramp A/D system. The performance criteria is that of a lab quality DVM with both 3½-digit resolution and accuracy while still retaining a low cost and low parts count instrument. Features of the DVM include circuitry for a high impedance input, autopolarity and overrange indication.

AN-751 A Disassociated Intercarrier Television Video IF Amplifier

This application note discusses a unique video IF system, incorporating the MC1331, low-level multiplier detector. Problem areas in IF design are discussed and the specific solutions are shown.

AN-752 An 80-Watt Switching Regulator for CATV and Industrial Applications

This application note describes a 24-Volt, 3-Ampere switching, regulated power supply that operates above 18 kHz from a 40-to 60-Volt, 60-Hz square wave source (CATV power line from a ferroresonant transformer) or a dc standby source with input output isolation. The control circuit consists of a dual operational amplifier and a linear integrated circuit timer which are used to vary the on time of a new high-speed power transistor. The circuit provides good efficiency, good regulation, low output ripple and incorporates input and output voltage over shutdown protection.

APPLICATION NOTE ABSTRACTS (Continued)

AN-757 Analog-to-Digital Conversion Techniques with the MC6800 Microprocessor System

This application note describes several analog-to-digital conversion systems implemented with the M6800 microprocessor and external linear and digital IC's. Systems consisting of an 8- and 10-bit successive approximation approach, as well as dual ramp techniques of 3½- and 4½-digit BCD and 12-bit binary, are shown with flow diagrams, source programs and hardware schematics. System tradeoffs of the various schemes and programs for binary-to-BCD and BCD-to-7 segment code are discussed.

AN-760 Application of The MC3416 Crosspoint Switch

The operation and application of the MC3416 4 x 4 balanced crosspoint switch is described in detail. Special emphasis is given to balanced switching systems like those in space division PABX. Discussion of the total system design using the MC3416 is also included.

AN-763 The MC1323—A Fully Programmable Demodulator

The MC1323 is a monolithic integrated circuit demodulator specifically designed for decoding the NTSC color television signal, even when non-standard receiver display tube phosphor primaries are used. The unique design allows independent adjustment of demodulator conversion gains and demodulation axes. This note describes the circuit operation of the MC1323 and several applications including low cost driving of unitized gun picture tubes and obtaining R-G-B demodulated outputs.

AN-765 An Approach To A Low-Noise TV IF System

This note describes a technique of measurement of the IF contribution and ways of minimization of the IF noise. An IF design, following these procedures, is described to meet the desired noise performance.

AN-767 A Line Operated, Regulated 5V/50A Switching Power Supply

This application note describes a regulated 220 V ac to 5 Vdc converter using high voltage switching transistors and Schottky barrier rectifiers. The control functions are all performed by integrated circuits.

AN-775 M6800 Systems Utilizing the MC6875 Clock Generator/Driver

This application note describes the use of the MC6875 clock generator/driver in M6800 based systems. Design examples will demonstrate the capabilities of the driver in systems using slow and/or dynamic memories. Multiprocessing and DMA methods are also covered.

AN-781 Revised Data-Interface Standards

Revised data-interface standards permit faster data rates and longer cables. New chips, and RS232 adapters, simplify their use.

AN-787 An M6800 Clock System That Handles DMA and Memory Refresh Cycle Stealing

Dynamic memory and three-state cycle stealing for Direct Memory Access transfers require a clock generator and priority logic to maintain proper refresh times of the dynamic MPU and dynamic memory. The design presented here demonstrates use of the MC6875 clock generator with an MC6800 MPU.

ENGINEERING BULLETIN ABSTRACTS

EB-20 Multiplier/Op Amp Circuit Detects True RMS

Two op amps and two multipliers are used in the circuit described by EB-20 to obtain the true rms of an input voltage ranging from 2 to 10 Vpk.

EB-21 DAC Key To Inexpensive 2 $\frac{2}{3}$ Digit Voltmeter.

EB-21 presents an idea for the core of an economical 2 $\frac{2}{3}$ digit voltmeter. Built around Motorola's MC1408 8-bit D/A converter, the meter can measure to 2.55 V in 10 mV steps.

EB-24A Input Buffer Circuits For The MC1505 Dual Ramp A-To-D Converter Subsystem

Several bipolar op amp buffers of medium-high impedance are described in this bulletin. It also discusses FET input op amp buffers providing high impedance and temperature drift under 1 mV over the 0°C to 50°C range.

EB-50 Build This Simple, Battery-Powered 3 $\frac{1}{2}$ Digit DVM From Standard Parts

EB-50 describes a simple, battery-powered 3 $\frac{1}{2}$ digit DVM capable of measuring up to 20 volts that can be built from readily obtained standard parts. Sufficient information is provided to construct the circuit including schematic, PC board layout, parts list and calibration instructions.

EB-51 Successive Approximation BCD A/D Converter

A successive approximation A/D converter in which a digital-to-analog converter in a feedback loop produces a BCD digital output from an analog input is described in EB-51.

EB-52 Control Your Switching Regulator With The MC3380 Astable Multivibrator

Engineering Bulletin EB-52 describes the operation and characteristics of the MC3380 astable multivibrator and details the design of a 200 volt switching regulator circuit for gas discharge displays using this device as the control element.

EB-57 An Economical FM Transmitter Voice Processor from a Single IC

An MC3401 Quad OP-Amp is used as a Microphone/Modulation interface in an FM transmitter.

EB-58 Analog Data Acquisition Network for Digital Processing Using the MC1405-MC14435 A/D System

An MC1405-MC14435 combination is used to form a dual-slope A/D converter for analog data acquisition.

EB-66 A Symmetry Correcting Circuit for Use with the MC3420

EB-66 shows a method of implementing an external symmetry-correction circuit with the MC3420 Switchmode Regulator Control IC to insure balanced operation of the power transformer in push-pull inverter configurations.

EB-78 NEW ICs In Switching Supplies

This bulletin describes a regulated 220 Vac to 5 Vdc converter design incorporating the MC3420 and MC3423 for the control and ancillary functions.

EB-85 Full-Bridge Switching Power Supplies

This bulletin provides selection information on devices for a full-bridge configuration supply in the 500-1000 watt power range.

EB-86 Half-Bridge Switching Power Supplies

This bulletin provides selection information on devices for a half-bridge configuration supply in the 100-500 watt power range.

EB-87 Flyback Switching Power Supplies

This bulletin provides selection information on devices for a flyback configuration supply in the 100-250 watt power range.

EB-88 Push-Pull Switching Power Supplies

This bulletin provides selection information on devices for a push-pull configuration supply in the 100-500 watt power range.
