MOTOROLA

CMOS LOGIC DATA

2

DATA CLASSIFICATION

Product Preview

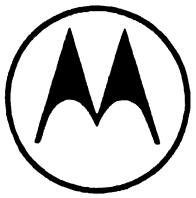
This heading on a data sheet indicates that the device is in the formative stages or in design (under development). The disclaimer at the bottom of the first page reads: "This document contains information on a product under development. Motorola reserves the right to change or discontinue this product without notice."

Advance Information

This heading on a data sheet indicates that the device is in sampling, pre-production, or first production stages. The disclaimer at the bottom of the first page reads: "This document contains information on a new product. Specifications and information herein are subject to change without notice."

Fully Released

A fully released data sheet contains neither a classificaiton heading nor a disclaimer at the bottom of the first page. This document contains information on a product in full production. Guaranteed limits will not be changed without written notice to your local Motorola Semiconductor Sales Office.



MOTOROLA

CMOS LOGIC DATA

Prepared by
Technical Information Center

This book presents technical data for the broad line of CMOS logic integrated circuits and demonstrates Motorola's continued commitment to Metal-Gate CMOS. Complete specifications are provided in the form of data sheets. In addition, a Product Selector Guide and a Handling and Design Guidelines chapter have been included to familiarize the user with these circuits.

Series C

Printed in U.S.A.
Previous Edition ©1988

Master Index 1

MASTER INDEX

1

This index includes Motorola's entire MC14000 series CMOS products, although this book contains data sheets for Logic Devices only. Data sheets for devices in the CMOS/NMOS Special Functions Data book (DL130) are designated in the page number column as SF.

Products which have been cancelled are designated in the page number column as —.

Product Selection Guide 2

CMOS Selection Guide by Function

2

The "Better" Program 3

THE "BETTER" PROGRAM

The "BETTER" program is offered on logic only, in dual-in-line plastic packages.

3

Better Processing — Standard Product Plus:

LEVEL II (Suffix D)

- 100% burn-in to MIL-STD-883 test conditions — 160 hours at +125°C or 1.0 eV Arrhenius time/temperature equivalent.
- 100% post burn-in functional and dc parametric tests at 25°C (or max rated T_A at Motorola's option). Maximum PDA of 2% (functional) and 5% (DC and functional).

HOW TO ORDER

MC14000B	CP	D
Part Identification	Standard Package Suffix	BETTER PROCESSING LEVEL II = SUFFIX D

Part Marking

The Standard motorola part number with the corresponding "BETTER" suffix can be ordered from your local authorized Motorola distributor or Motorola sales offices. "BETTER" pricing will be quoted as an adder to standard commercial product price.

"RAP" Reliability Audit Program for Logic Integrated Circuits

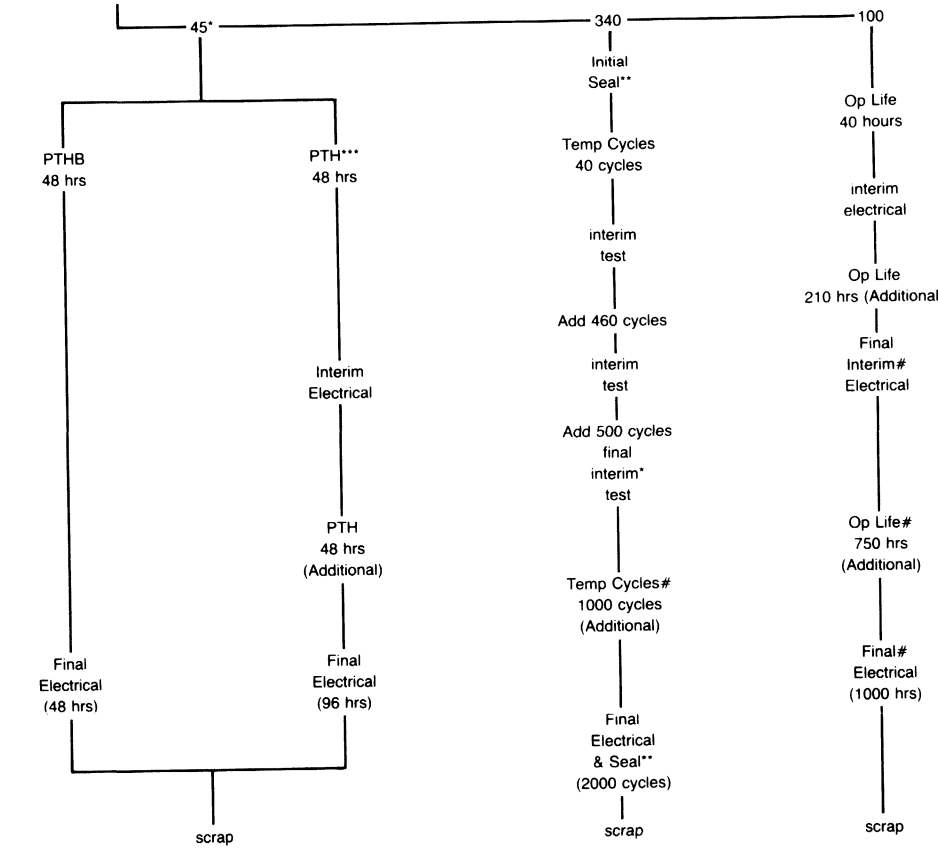
1.0 INTRODUCTION

The Reliability Audit Program developed in March 1977 is the Motorola internal reliability audit which is designed to assess outgoing product performance under accelerated stress conditions. Logic Reliability Engineering has overall responsibility for RAP, including updating its requirements, interpreting its results, administration at offshore locations, and monthly reporting of results. These reports are available at all sales offices. Also available is the "Reliability and Quality Handbook" which contains data for all Motorola Semiconductors (#BR518S).

RAP is a system of environmental and electrical tests performed periodically on randomly selected samples of standard products. Each sample receives the tests specified in section 2.0. Frequency of testing is specified per internal document 12MRM15301A.

2.0 RAP TEST FLOW

Pull 500* piece sample from lot following Group A acceptance.



#One sample per month for FAST, LS, 10H, 10K, MG CMOS, and HSL CMOS
*PTHB or PTH not required for hermetic products: reduce total sample size to 450 pcs.
**Seal (Fine & Gross Leak) required only for hermetic products.
***PTH to be used when sockets for PTHB are not available.

3.0 TEST CONDITIONS AND COMMENTS

PTHB — 15 psig/121°C/100% RH at rated V_{CC} or V_{EE} — to be performed on plastic encapsulated devices only.

TEMP CYCLING — MIL-STD-883, Method 1010, Condition C, −65°C/+150°C.

OP LIFE — MIL-STD-883, Method 1005, Condition C (Power plus Reverse Bias), T_A = 145°C.

NOTES:

1. All standard 25°C dc and functional parameters will be measured Go/No/Go at each readout.
2. Any indicated failure is first verified and then submitted to the Product Analysis Lab for detailed analysis.
3. Sampling to include all package types routinely.
4. Device types sampled will be by generic type within each logic I/C product family (CMOS, TTL, etc.) and will include all assembly locations (Korea, Philippines, Malaysia, etc.)
5. 16 hrs. PTHB is equivalent to approximately 800 hours of 85°C/85% RH THB for $V_{CC} \leq 15$ V.
6. Only moisture related failures (like corrosion) are criteria for failure on PTHB test.
7. Special device specifications (48A's) for logic products will reference 12MRM15301A as source of generic data for any customer required monthly audit reports.

3

B and UB Series Family Data 4

B AND UB SERIES CMOS FAMILY DATA

The CMOS Devices in this volume which have a B or UB suffix meet the minimum values for the industry-standardized# family specification. These standardized values are shown in the Maximum Ratings and Electrical Characteristics Tables. In addition to a standard minimum specification for characteristics the B/UB devices feature:

- 3-18 volt operational limits
- Capable of driving two low-power TTL loads or one low-power Schottky TTL load over the rated temperature range
- Direct Interface to High-Speed CMOS
- Maximum input current of ± 1 μA at 15 volt power supply over the temperature range
- Parameters specified at 5.0, 10, and 15 volt supply
- Noise margins: B Series
  1.0 V min @ 5.0 V supply
  2.0 V min @ 10 V supply
  2.5 V min @ 15 V supply

  UB Series
  0.5 V min @ 5.0 V supply
  1.0 V min @ 10 V supply
  1.0 V min @ 15 V supply

The industry-standardized maximum ratings are shown at the bottom of this page. Limits for the static characteristics are shown in two formats: Table 1 is in the industry format and Table 2 is in the equivalent Motorola format. The Motorola format is used throughout this data book. Additional specification values are shown on the individual data sheets.

Switching characteristics for the B and UB series devices are specified under the following conditions:

Load Capacitance, C_L, of 50 pF
Input Voltage equal to V_{SS} – V_{DD} (Rail-to-Rail swing)
Input pulse rise and fall times of 20 ns
Propagation Delay times measured from 50% point of input voltage to 50% point of output voltage
Three different supply voltages: 5, 10, and 15 V

Exceptions to the B and UB Series Family Specification

There are a number of devices which have a B or UB suffix whose inputs and/or outputs vary somewhat from the family specification because of functional requirements. Some categories of notable exceptions are:

Devices with specialized outputs on the chip, such as NPN emitter-follower drivers or transmission gates, do not meet output specifications.

Devices with specialized inputs, such as oscillator inputs, have unique input specifications.

#Specifications coordinated by EIA/JEDEC Solid-State Products Council.

Input Voltage

The input voltage specification is interpreted as the worst-case input voltage to produce an output level of "1" or "0". This "1" or "0" output level is defined as a deviation from the supply (V_{DD}) and ground (V_{SS}) levels. For a 5.0 V supply, this deviation is 0.5 V; for a 10 V supply, 1.0 V; and for 15 V, 1.5 V. As an example, in a device operating at a 5.0 V supply, the device with the input starting at ground is guaranteed to switch on or before 3.5 V and not to switch up to 1.5 V. Switching and not switching are defined as within 0.5 V of the ideal output level for the example with a 5.0 V supply. The actual switching level referred to the input is between 1.5 V and 3.5 V.

Noise Margin

The values for input voltages and the defined output deviations lead to the calculated noise margins. Noise margin is defined as the difference between V_{IL} or V_{IH} and V_{out} (output deviation). As an example, for a noninverting buffer at V_{DD} = 5.0 volts: V_{IL} = 1.5 volts and V_{out} = 0.5 volts. Therefore, Noise Margin equals V_{IL} – V_{out} = 1.0 volt. This figure is useful while cascading stages (See Figure 1). With the input to the first stage at a worst-case voltage level (V_{IL} = 1.5 V), the output is guaranteed to be no greater than 0.5 volts with a 5.0 volt supply. Since the maximum allowable logic 0 for the second stage is 1.5 volts, this 0.5 volt output provides a 1.0 volt margin for noise to the next stage.

Output Drive Current

Devices in the B Series are capable of sinking a minimum of 0.36 mA over the temperature range with a 5.0 V supply. This value guarantees that these CMOS devices will drive one low-power Schottky TTL input.

B Series vs UB CMOS

The primary difference between B series and UB series devices is that UB series gates and inverters are constructed with a single inverting stage between input and output. The decreased gain caused by using a single stage results in less noise immunity and a transfer characteristic that is less ideal.

The decreased gain is quite useful when CMOS Gates and inverters are used in a "Linear" mode to form oscillators, monostables, or amplifiers. The decreased gain results in increased stability and a "cleaner" output waveform. In addition to linear operation, the UB gates and inverters offer an increase in speed, since only a single stage is involved.

The B and UB series, and devices with no suffix can be used interchangeably in digital circuits that interface to other CMOS devices, such as High-Speed CMOS Logic.

MAXIMUM RATINGS* (Voltages Referenced to V_{SS})

Symbol	Parameter	Value	Unit
V_{DD}	DC Supply Voltage	– 0.5 to + 18.0	V
V_{in}, V_{out}	Input or Output Voltage (DC or Transient)	– 0.5 to V_{DD} + 0.5	V
I_{in}, I_{out}	Input or Output Current (DC or Transient), per Pin	± 10	mA
P_D	Power Dissipation, per Package†	500	mW
T_{stg}	Storage Temperature	– 65 to + 150	°C
T_L	Lead Temperature (8-Second Soldering)	260	°C

*Maximum Ratings are those values beyond which damage to the device may occur.
†Temperature Derating: Plastic "P" Package: – 12mW/°C from 65°C to 85°C
Ceramic "L" Package: – 12mW/°C from 100°C to 125°C

CMOS Handling and Design Guidelines 5

HANDLING AND DESIGN GUIDELINES

HANDLING PRECAUTIONS

All MOS devices have insulated gates that are subject to voltage breakdown. The gate oxide for Motorola CMOS devices is about 900 Å thick and breaks down at a gate-source potential of about 100 volts. To guard against such a breakdown from static discharge or other voltage transients, the protection networks shown in Figures 1A and 1B are used on each input to the CMOS device.

Static damaged devices behave in various ways, depending on the severity of the damage. The most severely damaged inputs are the easiest to detect because the input has been completely destroyed and is either shorted to V_{DD}, shorted to V_{SS}, or open-circuited. The effect is that the device no longer responds to signals present at the damaged input. Less severe cases are more difficult to detect because they show up as intermittent failures or as degraded performance. Another effect of static damage is that the inputs generally have increased leakage currents.

Although the input protection network does provide a great deal of protection, CMOS devices are not immune to large static voltage discharges that can be generated during handling. For example, static voltages generated by a person walking across a waxed floor have been measured in the 4-15 kV range (depending on humidity, surface conditions, etc.). Therefore, the following precautions should be observed:

1. Do not exceed the Maximum Ratings specified by the data sheet.
2. All unused device inputs should be connected to V_{DD} or V_{SS}.
3. All low-impedance equipment (pulse generators, etc.) should be connected to CMOS inputs only after the device is powered up. Similarly, this type of equipment should be disconnected before power is turned off.
4. Circuit boards containing CMOS devices are merely extensions of the devices, and the same handling precautions apply. Contacting edge connectors wired directly to device inputs can cause damage. Plastic wrapping should be avoided. When external connections to a PC board are connected to an input of a CMOS device, a resistor should be used in series with the input. This resistor helps limit accidental damage if the PC board is removed and brought into contact with static generating materials. The limiting factor for the series resistor is the added delay. This is caused by the time constant formed by the series resistor and input capacitance. Note that the maximum input rise and fall times should not be exceeded. In Figure 2, two possible networks are shown using a series resistor to reduce ESD (Electrostatic Discharge) damage. For convenience, an equation for added propagation delay and rise time effects due to series resistance size is given.
5. All CMOS devices should be stored or transported in materials that are antistatic. CMOS devices must not be inserted into conventional plastic "snow", styrofoam, or plastic trays, but should be left in their original container until ready for use.
6. All CMOS devices should be placed on a grounded bench surface and operators should ground themselves prior to handling devices, since a worker can be statically charged with respect to the bench surface. Wrist straps in contact with skin are strongly recommended. See Figure 3 for an example of a typical work station.
7. Nylon or other static generating materials should not come in contact with CMOS devices.
8. If automatic handlers are being used, high levels of static electricity may be generated by the movement of the device, the belts, or the boards. Reduce static build-up by using ionized air blowers or room humidifiers. All parts of machines which come into contact with the top, bottom, or sides of IC packages must be grounded to metal or other conductive material.
9. Cold chambers using CO_2 for cooling should be equipped with baffles, and the CMOS devices must be contained on or in conductive material.
10. When lead-straightening or hand-soldering is necessary, provide ground straps for the apparatus used and be sure that soldering ties are grounded.
11. The following steps should be observed during wave solder operations:
    a. The solder pot and conductive conveyor system of the wave soldering machine must be grounded to an earth ground.
    b. The loading and unloading work benches should have conductive tops which are grounded to an earth ground.
    c. Operators must comply with precautions previously explained.
    d. Completed assemblies should be placed in antistatic containers prior to being moved to subsequent stations.

5

INPUT PROTECTION NETWORK

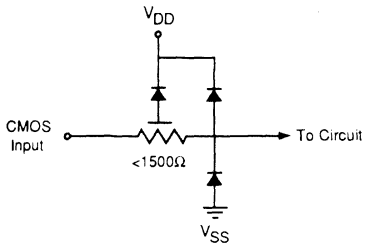

FIGURE 1A — INPUT PROTECTION NETWORK
Double Diode

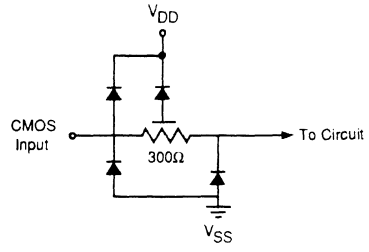

FIGURE 1B — INPUT PROTECTION NETWORK
Triple Diode

12. The following steps should be observed during board-cleaning operations:
    a. Vapor degreasers and baskets must be grounded to an earth ground.
    b. Brush or spray cleaning should not be used.
    c. Assemblies should be placed into the vapor degreaser immediately upon removal from the antistatic container.
    d. Cleaned assemblies should be placed in antistatic containers immediately after removal from the cleaning basket.
    e. High velocity air movement or application of solvents and coatings should be employed only when assembled printed circuit boards are grounded and a static eliminator is directed at the board.
13. The use of static detection meters for production line surveillance is highly recommended.
14. Equipment specifications should alert users to the presence of CMOS devices and require familiarization with this specification prior to performing any kind of maintenance or replacement of devices or modules.
15. Do not insert or remove CMOS devices from test sockets with power applied. Check all power supplies to be used for testing devices to be certain there are no voltage transients present.
16. Double check test equipment setup for proper polarity of V_{DD} and V_{SS} before conducting parametric or functional testing.
17. Do not recycle shipping rails or trays. Repeated use causes deterioration of their antistatic coating.

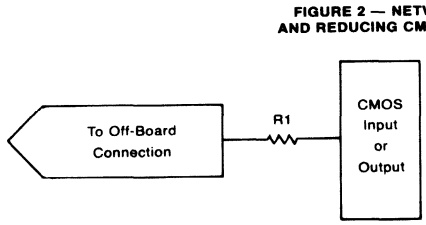
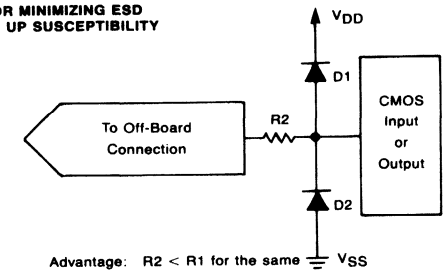
FIGURE 2 — NETWORKS FOR MINIMIZING ESD AND REDUCING CMOS LATCH UP SUSCEPTIBILITY



Advantage: Requires minimal board area

Disadvantage: R1 > R2 for the same level of protection, therefore rise and fall times, propagation delays, and output drives are severely affected.



Advantage: R2 < R1 for the same level of protection. Impact on ac and dc characteristics is minimized

Disadvantage: More board area, higher initial cost

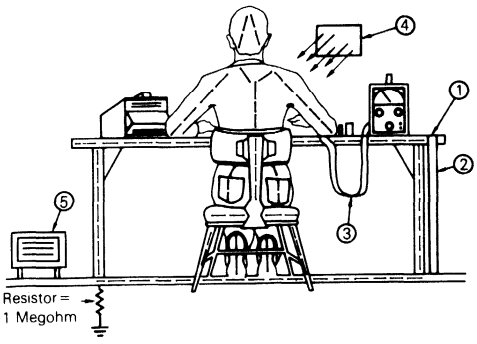
Note: These networks are useful for protecting the following
A digital inputs and outputs
B analog inputs and outputs
C 3-state outputs
D bidirectional (I/O) ports

PROPAGATION DELAY AND RISE TIME vs. SERIES RESISTANCE

$$R \approx \frac{t}{C \cdot k}$$

where:
R = the maximum allowable series resistance in ohms
t = the maximum tolerable propagation delay or rise time in seconds
C = the board capacitance plus the driven device's input capacitance in farads
k = 0.7 for propagation delay calculations
k = 2.3 for rise time calculations

FIGURE 3 — TYPICAL MANUFACTURING WORK STATION



NOTES:
1. 1/16 inch conductive sheet stock covering bench top work area.
2. Ground strap.
3. Wrist strap in contact with skin.
4. Static neutralizer. (Ionized air blower directed at work.) Primarily for use in areas where direct grounding is impractical.
5. Room humidifier. Primarily for use in areas where the relative humidity is less than 45%. Caution: building heating and cooling systems usually dry the air causing the relative humidity inside of buildings to be less than outside humidity.

5

POWER SUPPLIES

CMOS devices have low power requirements and the ability to operate over a wide range of supply voltages. These two characteristics allow CMOS designs to be implemented using inexpensive, conventional power supplies, instead of switching power supplies and power supplies with cooling fans. In addition, batteries may be used as either a primary power source or for emergency backup.

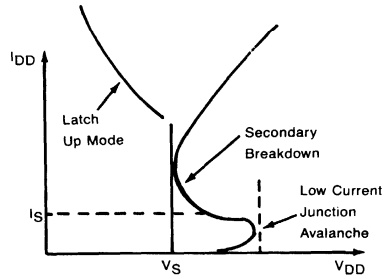
The *absolute* maximum power supply voltage for 14000 Series Metal-gate CMOS is 18.0 Vdc. Figure 4 offers some insight as to how this specification was derived. In the figure, V_S is the maximum power supply voltage and I_S is the sustaining current of the latch-up mode. The value of V_S was chosen so that the secondary breakdown effect may be avoided.

In an ideal system design, a power supply should be designed to deliver only enough current to insure proper operation of all devices. The obvious benefit of this type design is cost savings; an added benefit is protection against the possibility of latch-up related failures. This system protection can be provided by the power supply filter and/or voltage regulator.

CMOS devices can be used with battery or battery backup systems. A few precautions should be taken when designing battery-operated systems:

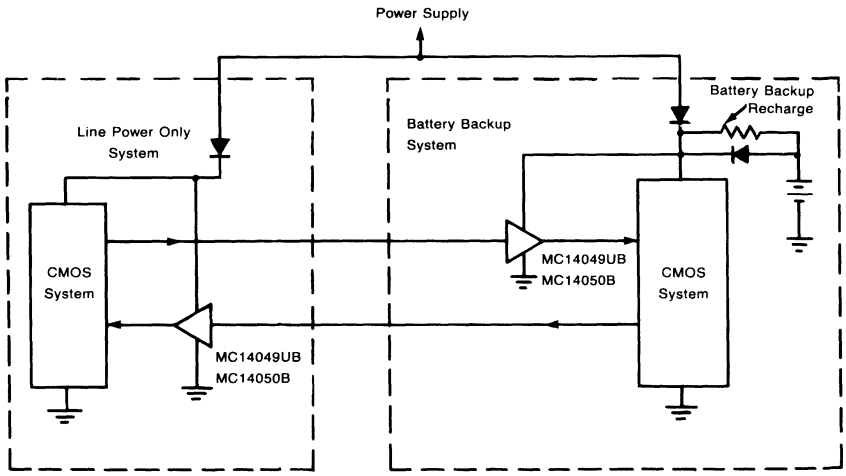
1. The recommended power supply voltage should be observed. For battery backup systems such as the one in Figure 5, the battery voltage must be at least 3.7 Volts (3 Volts from the minimum power supply voltage and 0.7 Volts to account for the voltage drop across the series diode).
2. Inputs that might go above the battery backup voltage should either use a series resistor to limit the input current to less than 10 mA or use the MC14049UB or MC14050B high-to-low voltage translators.
3. Outputs that are subject to voltage levels above V_{DD} or below V_{SS} should be protected with a series resistor to limit the current to less than 10 mA or with clamping diodes.

FIGURE 4 — SECONDARY BREAKDOWN CHARACTERISTICS



V_S = Data Sheet Maximum Supply Rating

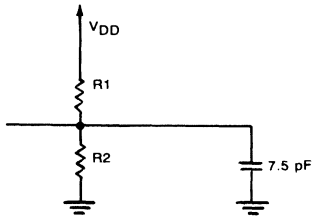
FIGURE 5 — BATTERY BACKUP INTERFACE



INPUTS

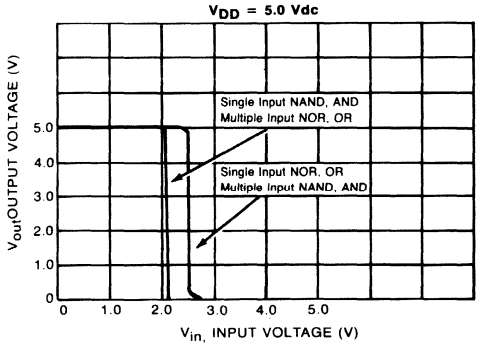
All inputs, while in the recommended operating range ($V_{SS} \leq V_{in} \leq V_{DD}$) can be modeled as shown in Figure 6. For input voltages in this range, diodes D1 and D2 are modeled as resistors, representing the reverse bias impedance of the diodes. The maximum input current is worst case, 1 μA, when the inputs are at V_{DD} or V_{SS}, and V_{DD} = 15.0 V. This model does not apply to inputs with pull-up or pull-down resistors.

FIGURE 6 — INPUT MODEL FOR $V_{SS} \leq V_{In} \leq V_{DD}$



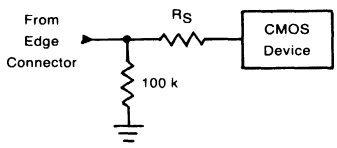
When left open-circuited, the inputs may self-bias at or near the typical switchpoint, where both the P-channel and N-channel transistors are conducting, causing excessive current drain. Due to the high gain of the inverters (see Figure 7), the device may also go into oscillation from any noise in the system. Since CMOS devices dissipate the most power during switching, this oscillation can cause very large current drain and undesired switching.

FIGURE 7 — TYPICAL TRANSFER CHARACTERISTICS FOR BUFFERED DEVICES



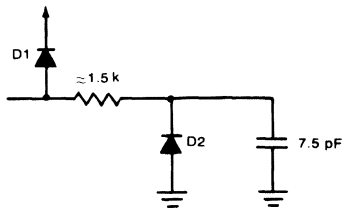
For these reasons, all unused inputs should be connected either to V_{DD} or V_{SS}. For applications with inputs going to edge connectors, a 100 kilohm resistor to V_{SS} should be used, as well as a series resistor for static protection and current limiting (Figure 8). The 100 kilohm resistor will help eliminate any static charges that might develop on the printed circuit board. See Figure 2 for other possible protection arrangements.

FIGURE 8 — EXTERNAL PROTECTION



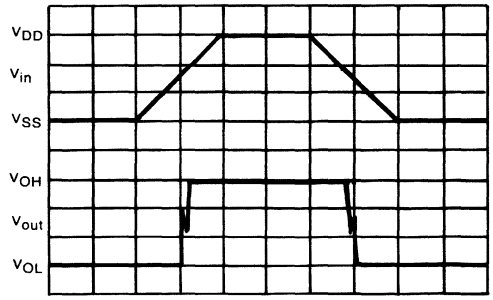
For input voltages outside of the recommended operating range, the CMOS input is modeled as in Figure 9. The resistor-diode protection network allows the user greater freedom when designing a worst case system. The device inputs are guaranteed to withstand voltages from V_{SS} − 0.5 V to V_{DD} + 0.5 V and a maximum current of 10 mA. With the above input ratings, most designs will require no special terminations or design considerations.

FIGURE 9 — INPUT MODEL FOR $V_{In} > V_{DD}$ or $V_{In} < V_{SS}$



Other specifications that should be noted are the maximum input rise and fall times. Figure 10 shows the oscillations that may result from exceeding the 15 μs maximum rise and fall time at V_{DD} = 5.0 V, 5 μs at 10 V, or 4 μs at 15 V. As the voltage passes through the switching threshold region with a slow rise time, any noise that is on the input is amplified, and passed through to the output, causing oscillations. The oscillation may have a low enough frequency to cause succeeding stages to switch, giving unexpected results. If input rise or fall times are expected to exceed 15 μs at 5.0 V, 5 μs at 10 V, or 4 μs at 15 V, Schmitt-trigger devices such as the MC14093B, MC14583B, MC14584B, MC14106B, HC14, or HC132 are recommended for squaring-up these slow transitions.

FIGURE 10 — MAXIMUM RISE AND FALL TIME VIOLATIONS



OUTPUTS

All CMOS B-Series outputs are buffered to insure consistent output voltage and current performance. All buffered outputs have guaranteed output voltages of V_{OL} = 0.05 V and V_{OH} = V_{DD} − 0.05 V for V_{in} = V_{DD} or V_{SS} and I_{out} = 0 μA. The output drives for all buffered CMOS devices are such that 1 LSTTL load can be driven across the full temperature range.

CMOS outputs are limited to externally forced output voltages of V_{SS} − 0.5 V ≤ V_{out} ≤ V_{DD} + 0.5 V. When voltages are forced outside of this range, a silicon controlled rectifier (SCR) formed by parasitic transistors can be triggered, causing the device to latch up. For more information on this, see the explanation of CMOS Latch Up in this section.

The maximum rated output current for most outputs is 10 mA. The output short-circuit currents of these devices typically exceed these limits. Care must be taken not to exceed the maximum ratings found on every data sheet.

For applications that require driving high capacitive loads where fast propagation delays are needed (e.g., driving power MOSFETs), two or more outputs on the same chip may be externally paralleled.

CMOS LATCH UP

Latch up will not be a problem for most designs, but the designer should be aware of it, what causes it, and how to prevent it.

Figure 11 shows the cross-section of a typical CMOS inverter and Figure 12 shows the parasitic bipolar devices. The circuit formed by the parasitic transistors and resistors is the basic configuration of a silicon controlled rectifier, or SCR. In the latch up condition, transistors Q1 and Q2 are turned ON, each providing the base current necessary for the other to remain in saturation, thereby latching the devices in the ON state. Unlike a conventional SCR, where the device is turned ON by applying a voltage to the base of the NPN transistor, the parasitic SCR is turned ON by applying a voltage to the emitter of either transistor. The two emitters that trigger the SCR are the same point, the CMOS output. Therefore, to latch up the CMOS device, the output voltage must be greater than V_{DD} + 0.5 V or less than V_{SS} − 0.5 V and have sufficient current to trigger the SCR. The latch-up mechanism is similar for the inputs.

Once a CMOS device is latched up, if the supply current is not limited, the device will be destroyed. Ways to prevent such occurrences are listed below:

1. Insure that inputs and outputs are limited to the maximum rated values, as follows:
   $-0.5\ V \leq V_{in}$ or $V_{out} \leq V_{DD} + 0.5\ V$ (referenced to V_{SS})
   $|I_{in}$ or $I_{out}| \leq 10$ mA (unless otherwise indicated on the data sheet)
2. If voltage transients of sufficient energy to latch up the device are expected on the inputs or outputs, external protection diodes can be used to clamp the voltage. Another method of protection is to use a series resistor to limit the expected worst case current to the maximum rating of 10 mA. (See Figure 2).
3. Sequence power supplies so that the inputs or outputs of CMOS devices are not active before the supply pins are powered up (e.g., recessed edge connectors and/or series resistors may be used in plug-in board applications).
4. Voltage regulating or filtering should be used in board design and layout to insure that power-supply lines are free of excessive noise.
5. Limit the available power supply current to the devices that are subject to latch-up conditions. This can be accomplished with the power supply filtering network or with a current-limiting regulator.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μH (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001 × the number of exercised gates per package.

6

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

VOLTAGE TRANSFER CHARACTERISTICS

FIGURE 8 – V_{DD} = 5.0 Vdc

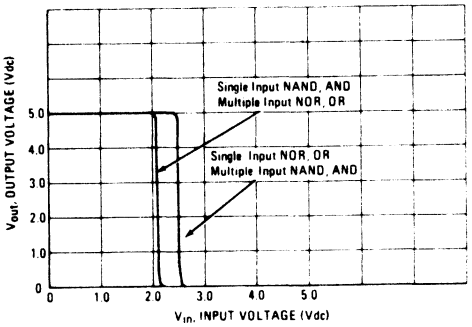

FIGURE 9 – V_{DD} = 10 Vdc

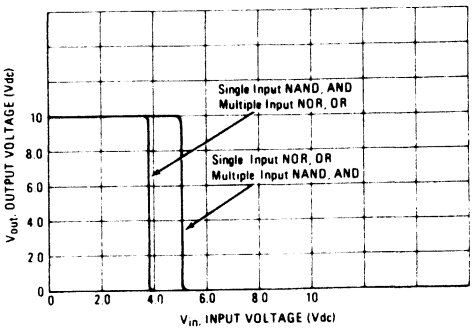

FIGURE 10 – V_{DD} = 15 Vdc

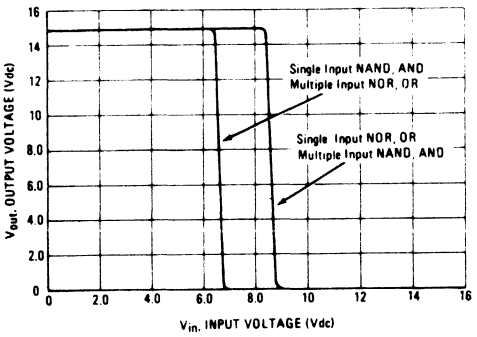

DC NOISE MARGIN

The DC noise margin is defined as the input voltage range from an ideal "1" or "0" input level which does not produce output state change(s). The typical and guaranteed limit values of the input values V_{IL} and V_{IH} for the output(s) to be at a fixed voltage V_O are given in the Electrical Characteristics table. V_{IL} and V_{IH} are presented graphically in Figure 11.

Guaranteed minimum noise margins for both the "1" and "0" levels =

1.0 V with a 5.0 V supply
2.0 V with a 10.0 V supply
2.5 V with a 15.0 V supply

UB-SUFFIX SERIES CMOS GATES

The UB Series logic gates are constructed with P and N channel enhancement mode devices in a single monolithic structure (Complementary MOS). Their primary use is where low power dissipation and/or high noise immunity is desired. The UB set of CMOS gates are inverting non-buffered functions.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Linear and Oscillator Applications
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range.
- Double Diode Protection on All Inputs
- Pin-for-Pin Replacements for Corresponding CD4000 Series UB Suffix Devices

T_A = −55° to 125°C for all packages.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

18-BIT STATIC SHIFT REGISTER

The MC14006B shift register is comprised of four separate shift register sections sharing a common clock: two sections have four stages, and two sections have five stages with an output tap on both the fourth and fifth stages. This makes it possible to obtain a shift register of 4, 5, 8, 9, 10, 12, 13, 14, 16, 17, or 18 bits by appropriate selection of inputs and outputs. This part is particularly useful in serial shift registers and time delay circuits.

- Output Transitions Occur on the Falling Edge of the Clock Pulse
- Fully Static Operation
- Can be Cascaded to Provide Longer Shift Register Lengths
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4006B

MOTOROLA

MC14007UB

DUAL COMPLEMENTARY PAIR PLUS INVERTER

The MC14007UB multi-purpose device consists of three N-channel and three P-channel enhancement mode devices packaged to provide access to each device. These versatile parts are useful in inverter circuits, pulse-shapers, linear amplifiers, high input impedance amplifiers, threshold detectors, transmission gating, and functional gating.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4007A or CD4007UB
- This device has 2 outputs without ESD Protection. Anti-static precautions must be taken.

DUAL TYPE D FLIP-FLOP

The MC14013B dual type D flip-flop is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Each flip-flop has independent Data, (D), Direct Set, (S), Direct Reset, (R), and Clock (C) inputs and complementary outputs (Q and $\overline{Q}$). These devices may be used as shift register elements or as type T flip-flops for counter and toggle applications.

- Static Operation
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Logic Edge-Clocked Flip-Flop Design – Logic state is retained indefinitely with clock level either high or low; information is transferred to the output only on the positive-going edge of the clock pulse
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4013B

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0 10 15	I_T = (0.75 μA/kHz) f + I_{DD} I_T = (1.5 μA/kHz) f + I_{DD} I_T = (2.3 μA/kHz) f + I_{DD}							μAdc

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.002.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14015B

DUAL 4-BIT STATIC SHIFT REGISTER

The MC14015B dual 4-bit static shift register is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. It consists of two identical, independent 4-state serial-input/parallel-output registers. Each register has independent Clock and Reset inputs with a single serial Data input. The register states are type D master-slave flip-flops. Data is shifted from one stage to the next during the positive-going clock transition. Each register can be cleared when a high level is applied on the Reset line. These complementary MOS shift registers find primary use in buffer storage and serial-to-parallel conversion where low power dissipation and/or noise immunity is desired.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Logic Edge-Clocked Flip-Flop Design – Logic state is retained indefinitely with clock level either high or low; information is transferred to the output only on the positive going edge of the clock pulse.
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range.

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0	I_T = (1.2 μA/kHz) f + I_{DD}							μAdc
		10	I_T = (2.4 μA/kHz) f + I_{DD}							
		15	I_T = (3.6 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.002.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14016B

QUAD ANALOG SWITCH/QUAD MULTIPLEXER

The MC14016B quad bilateral switch is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Each MC14016B consists of four independent switches capable of controlling either digital or analog signals. The quad bilateral switch is used in signal gating, chopper, modulator, demodulator and CMOS logic implementation.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Linearized Transfer Characteristics
- Low Noise — 12 nV/$\sqrt{\text{Cycle}}$, f ≥ 1.0 kHz typical
- Pin-for-Pin Replacements for CD4016B, CD4066B (Note improved transfer characteristic design causes more parasitic coupling capacitance than CD4016)
- For Lower R_{ON}, Use The HC4016 High-Speed CMOS Device or The MC14066B
- This Device Has Inputs and Outputs Which Do Not Have ESD Protection. Antistatic Precautions Must Be Taken.

APPLICATIONS INFORMATION

Figure A illustrates use of the Analog Switch. The 0-to-5 V Digital Control signal is used to directly control a 5 V_{p-p} analog signal.

The digital control logic levels are determined by V_{DD} and V_{SS}. The V_{DD} voltage is the logic high voltage; the V_{SS} voltage is logic low. For the example, V_{DD} = +5V = logic high at the control inputs; V_{SS} = GND = 0V = logic low.

The maximum analog signal level is determined by V_{DD} and V_{SS}. The analog voltage must not swing higher than V_{DD} or lower than V_{SS}.

The example shows a 5 V_{p-p} signal which allows no margin at either peak. If voltage transients above V_{DD} and/or below V_{SS} are anticipated on the analog channels, external diodes (D_X) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The *absolute* maximum potential difference between V_{DD} and V_{SS} is 18.0V. Most parameters are specified up to 15V which is the *recommended* maximum difference between V_{DD} and V_{SS}.

FIGURE A — APPLICATION EXAMPLE

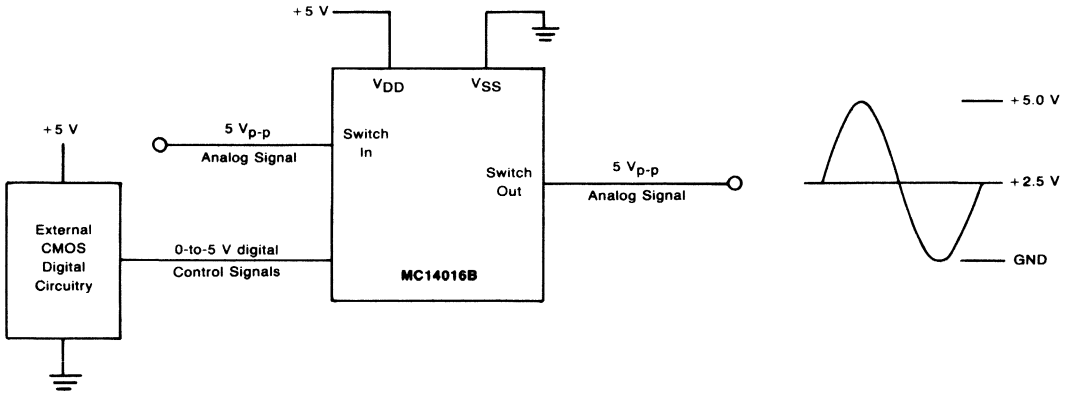

FIGURE B — EXTERNAL GERMANIUM OR SCHOTTKY CLIPPING DIODES

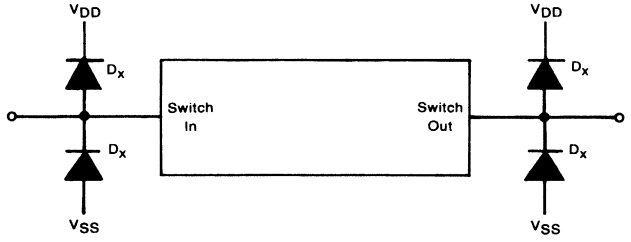

6

MC14017B

DECADE COUNTER

The MC14017B is a five-stage Johnson decade counter with built-in code converter. High speed operation and spike-free outputs are obtained by use of a Johnson decade counter design. The ten decoded outputs are normally low, and go high only at their appropriate decimal time period. The output changes occur on the positive-going edge of the clock pulse. This part can be used in frequency division applications as well as decade counter or decimal decode display applications.

- Fully Static Operation
- DC Clock Input Circuit Allows Slow Rise Times
- Carry Out Output for Cascading
- Divide-by-N Counting
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4017B

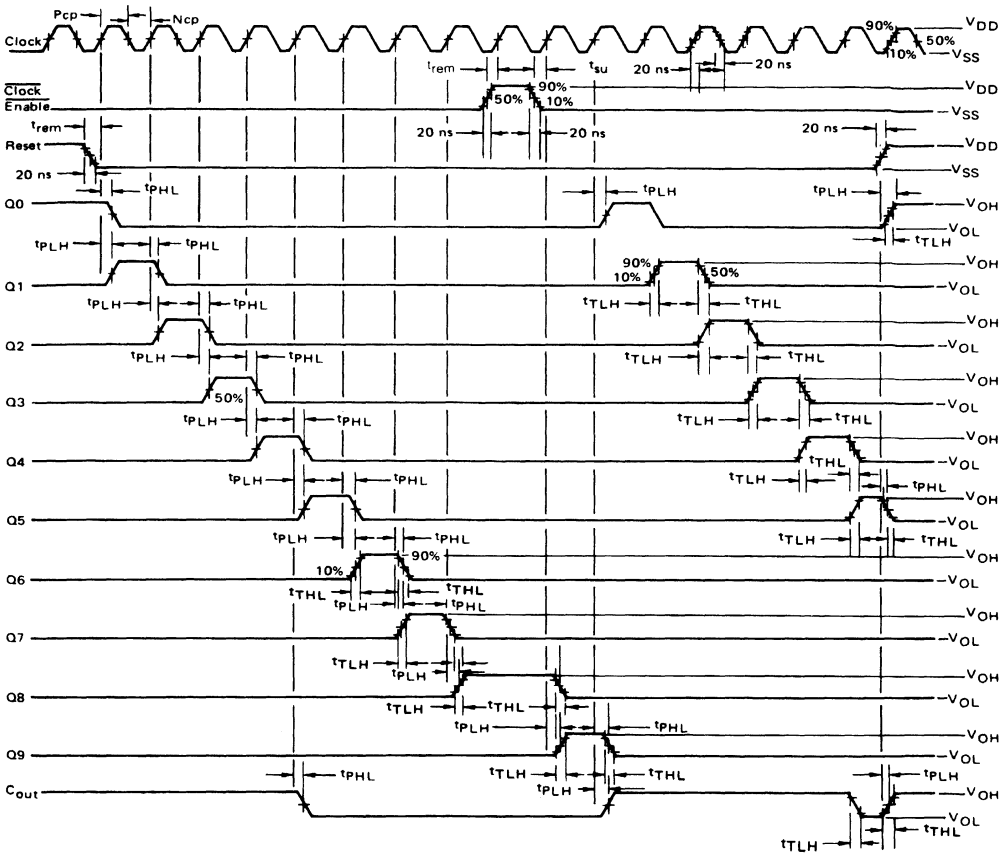
FIGURE 4 – AC MEASUREMENT DEFINITION AND FUNCTIONAL WAVEFORMS



MOTOROLA

MC14018B

PRESETTABLE DIVIDE-BY-N COUNTER

The MC14018B contains five Johnson counter stages which are asynchronously presettable and resettable. The counters are synchronous, and increment on the positive going edge of the clock.

Presetting is accomplished by a logic 1 on the preset enable input. Data on the Jam inputs will then be transferred to their respective $\overline{Q}$ outputs (inverted). A logic 1 on the reset input will cause all $\overline{Q}$ outputs to go to a logic 1 state.

Division by any number from 2 to 10 can be accomplished by connecting appropriate $\overline{Q}$ outputs to the data input, as shown in the Function Selection table. Anti-lock gating is included in the MC14018B to assure proper counting sequence.

- Fully Static Operation
- Schmitt Trigger on Clock Input
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4018B

MOTOROLA

MC14020B

14-BIT BINARY COUNTER

The MC14020B 14-stage binary counter is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. This part is designed with an input wave shaping circuit and 14 stages of ripple-carry binary counter. The device advances the count on the negative-going edge of the clock pulse. Applications include time delay circuits, counter controls, and frequency-dividing circuits.

- Fully Static Operation
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Buffered Outputs Available from stages 1 and 4 thru 14
- Common Reset Line
- Pin-for-Pin Replacement for CD4020B

MOTOROLA

MC14022B

OCTAL COUNTER

The MC14022B is a four-stage Johnson octal counter with built-in code converter. High-speed operation and spike-free outputs are obtained by use of a Johnson octal counter design. The eight decoded outputs are normally low, and go high only at their appropriate octal time period. The output changes occur on the positive-going edge of the clock pulse. This part can be used in frequency division applications as well as octal counter or octal decode display applications.

- Fully Static Operation
- DC Clock Input Circuit Allows Slow Rise Times
- Carry Out Output for Cascading

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4022B

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0	I_T = (0.28 μA/kHz) f + I_{DD}							μAdc
		10	I_T = (0.56 μA/kHz) f + I_{DD}							
		15	I_T = (0.85 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.00125.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14027B

DUAL J-K FLIP-FLOP

The MC14027B dual J-K flip-flop has independent J, K, Clock (C), Set (S) and Reset (R) inputs for each flip-flop. These devices may be used in control, register, or toggle functions.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Logic Swing Independent of Fanout
- Logic Edge-Clocked Flip-Flop Design – Logic state is retained indefinitely with clock level either high or low; information is transferred to the output only on the positive-going edge of the clock pulse
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4027B

MOTOROLA

MC14028B

BCD-TO-DECIMAL DECODER
BINARY-TO-OCTAL DECODER

The MC14028B decoder is constructed so that an 8421 BCD code on the four inputs provides a decimal (one-of-ten) decoded output, while a 3-bit binary input provides a decoded octal (one-of-eight) code output with D forced to a logic "0". Expanded decoding such as binary-to-hexadecimal (one-of-16), etc., can be achieved by using other MC14028B devices. The part is useful for code conversion, address decoding, memory selection control, demultiplexing, or readout decoding.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Positive Logic Design
- Low Outputs on All Illegal Input Combinations
- Similar to CD4028B.

			10	I_T = (0.6 μA/kHz) f + I_{DD}							
			15	I_T = (0.9 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC s potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

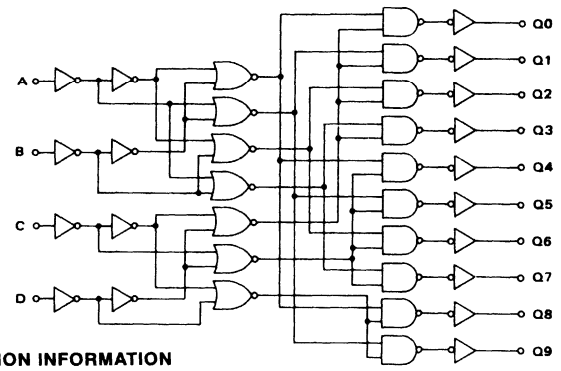
LOGIC DIAGRAM



APPLICATION INFORMATION

Expanded decoding can be performed by using the MC14028B and other CMOS Integrated Circuits. The circuit in Figure 2 converts any 4-bit code to a decimal or hexadecimal code. The accompanying table shows the input binary combinations, the associated "output numbers" that go "high" when selected, and the "redefined output numbers" needed for the proper code. For example: For the combination DCBA = 0111 the output number 7 is redefined for the 4-bit binary, 4-bit gray, excess-3, or excess-3 gray codes as 7, 5, 4, or 2, respectively. Figure 3 shows a 6-bit binary 1-of-64 decoder using nine MC14028B circuits and two MC14069UB inverters.

The MC14028B can be used in decimal digit displays, such as, neon readouts or incandescent projection indicators as shown in Figure 4.

MOTOROLA

MC14029B

BINARY/DECADE UP/DOWN COUNTER

The MC14029B Binary/Decade up/down counter is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. The counter consists of type D flip-flop stages with a gating structure to provide toggle flip-flop capability. The counter can be used in either Binary or BCD operation. This complementary MOS counter finds primary use in up/down and difference counting and frequency synthesizer applications where low power dissipation and/or high noise immunity is desired. It is also useful in A/D and D/A conversion and for magnitude and sign generation.

- Diode Proection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Internally Synchronous for High Speed
- Logic Edge-Clocked Design – Count Occurs on Positive Going Edge of Clock
- Asynchronous Preset Enable Operation
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin for Pin Replacment for CD4029B

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MC14038B

TRIPLE SERIAL ADDERS

The MC14032B and MC14038B triple serial adders have the clock and carry reset inputs common to all three adders. The carry is added on the positive-going clock transition for the MC14032B, and on the negative-going clock transition for the MC14038B. Typical applications include serial arithmetic units, digital correlators, digital servo control systems, datalink computers, and flight control computers.

- Buffered Outputs
- Single-Phase Clocking
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range.
- Pin-for-Pin Replacement for CD4032B and CD4038B.

MOTOROLA

MC14034B

8-BIT UNIVERSAL BUS REGISTER

The MC14034B is a bidirectional 8-bit static parallel/serial, input/output bus register. The device contains two sets of input/output lines which allows the bidirectional transfer of data between two buses; the conversion of serial data to parallel form, or the conversion of parallel data to serial form. Additionally the serial data input allows data to be entered shift/right, while shift/left can be accompolished by hard-wiring each parallel output to the previous parallel bit input.

Other useful applications for this device include pseudo-random code generation, sample and hold register, frequency and phase-comparator, address or buffer register, and serial/parallel input/output conversions.

- Bidirectional Parallel Data Input
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range.
- Pin-for-Pin Replacement for CD4034B.

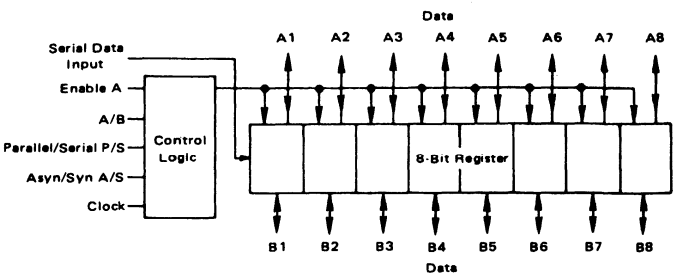
X = Don't Care

†Outputs change at positive transition of clock in the serial mode and when the A/S input is low in the parallel mode. During transfer from parallel to serial operation, A/S should remain low in order to prevent D_S transfer into flip-flops.

EXPANDED BLOCK DIAGRAM



OPERATING CHARACTERISTICS

The MC14034B is composed of eight register cells connected in cascade with additional control logic. Each register cell is composed of one "D" master-slave flip-flop with separate internal clocks, and two data transfer gates allowing the data to be transferred bidirectionally from bus A to bus B and from bus B to bus A, and to be memorized. Besides the single phase clock and the serial data inputs, the control logic provides four other features:

A Enable Input – When high, this input enables the bus A data lines.

A/B Input (Data A or B) – This input controls the direction of data flow: when high, the data flows from bus A to bus B; when low, the data flows from bus B to bus A.

P/S Input (Parallel/Serial) – This input controls the data input mode (parallel or serial). When high, the data is transferred to the register in a parallel asynchronous mode or a parallel synchronous mode (positive clock transition). When low, the data is entered into the register in a serial synchronous mode (positive clock transition).

A/S Input (Asynchronous/Synchronous to the Clock) – When this input is high, the data is transferred independently from the clock rate; when low, the clock is enabled and the data is transferred synchronously.

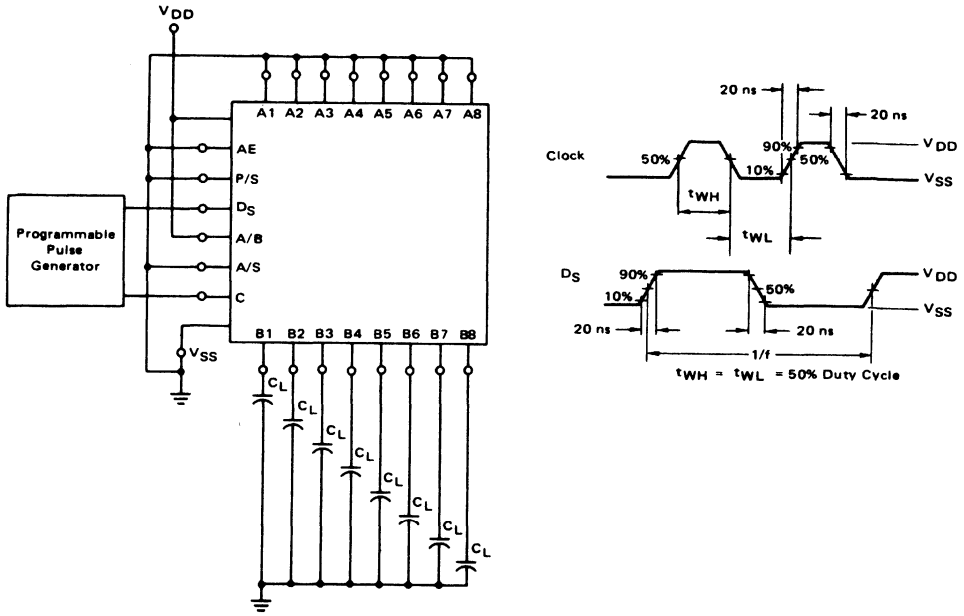

FIGURE 5 – 16-BIT PARALLEL IN/PARALLEL OUT, PARALLEL IN/SERIAL OUT, SERIAL IN/PARALLEL OUT, SERIAL IN/SERIAL OUT REGISTER

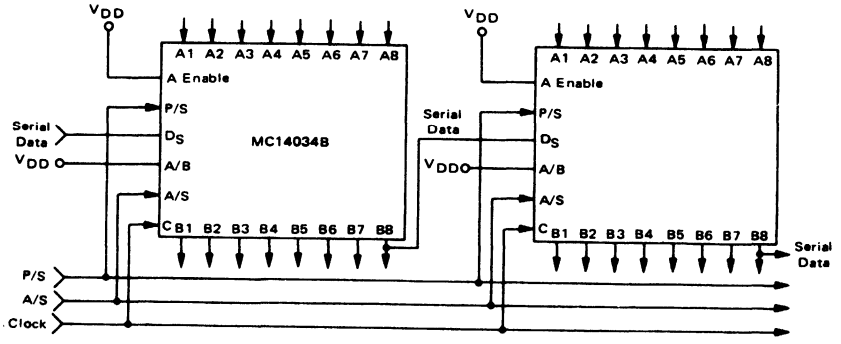

FIGURE 6 – SHIFT RIGHT/SHIFT LEFT WITH PARALLEL INPUTS

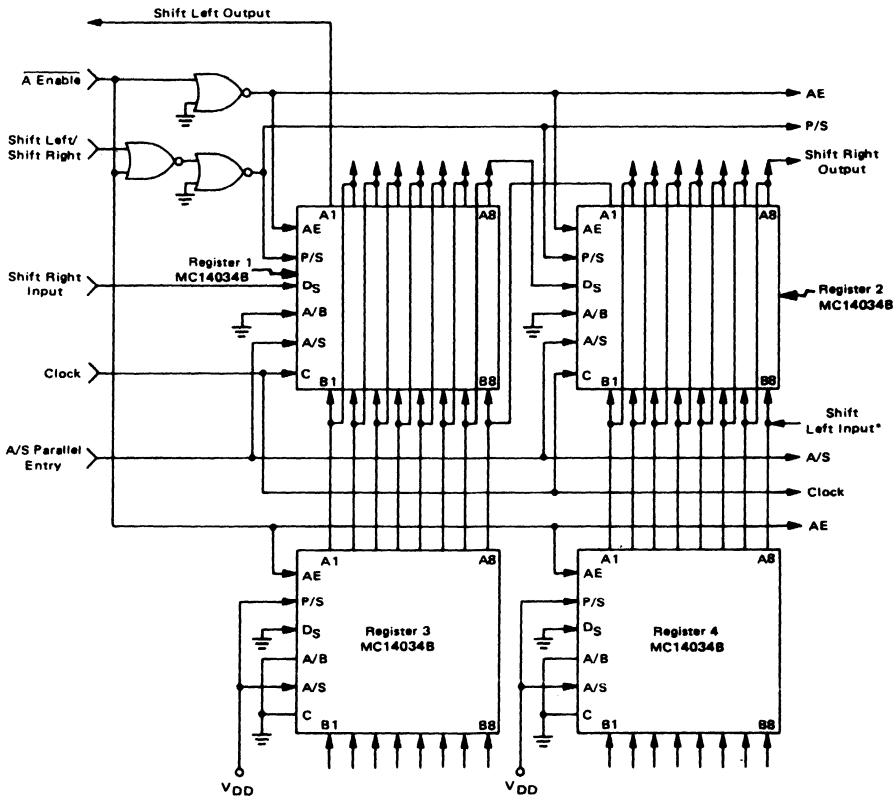

A "High" ("Low") on the Shift Left/Shift Right input allows serial data on the Shift Left Input (Shift Right Input) to enter the register on the positive transition of the clock signal. A "high" on the "A" Enable Input disables the "A" parallel data lines on Reg. 1 and 2 and enables the "A" data lines on registers 3 and 4 and allows parallel data into registers 1 and 2. Other logic schemes may be used in place of registers 3 and 4 for parallel loading.

When parallel inputs are not used Reg. 3 and 4 and associated logic are not required.

*Shift left input must be disabled during parallel entry.

6

MOTOROLA

MC14035B

4-BIT PARALLEL-IN/PARALLEL-OUT SHIFT REGISTER

The MC14035B 4-bit shift register is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. It consists of a 4-stage clocked serial-shift register with synchronous parallel inputs and buffered parallel outputs. The Parallel/Serial (P/S) input allows serial-right shifting of data or synchronous parallel loading via inputs D_{P0} thru D_{P3}. The True/Complement (T/C) input determines whether the outputs display the Q or $\overline{Q}$ outputs of the flip-flop stages. J-K logic forms the serial input to the first stage. With the J and K inputs connected together they operate as a serial "D" input.

This device may be effectively used for shift-right/shift-left registers, parallel-to-serial/serial-to-parallel conversion, sequence generation, up/down Johnson or ring counters, pseudo-random code generation, frequency and phase comparators, sample and hold registers, etc. . .

- 4-Stage Clocked Serial-Shift Operation
- Synchronous Parallel Loading of all Four Stages
- J-K Serial Inputs on First Stage
- Asynchronous True/Complement Control of all Outputs
- Fully Static Operation
- Asynchronous Master Reset
- Data Transfer Occurs on the Positive-Going Clock Transition
- No Limit on Clock Rise and Fall Times
- All Inputs are Buffered
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001.

6

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$. Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

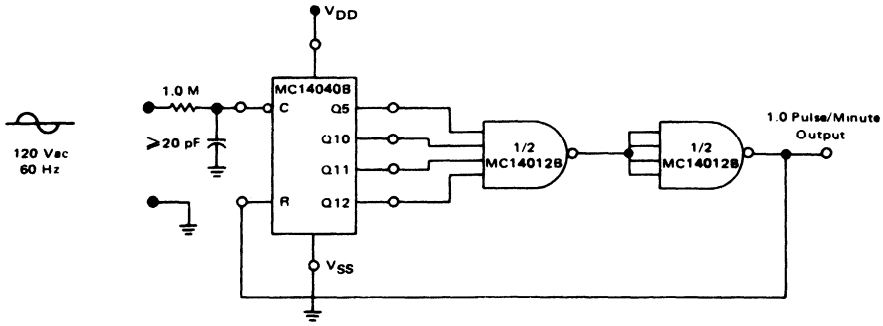
APPLICATIONS INFORMATION

TIME-BASE GENERATOR

A 60 Hz sinewave obtained through a 1.0 Megohm resistor connected directly to a standard 120 Vac power line is applied to the clock input of the MC14040B. By selecting outputs Q5, Q10, Q11, and Q12 division by 3600 is accomplished. The MC14012B decodes the counter outputs, produces a single output pulse, and resets the binary counter. The resulting output frequency is 1.0 pulse/minute.



MOTOROLA

MC14042B

QUAD TRANSPARENT LATCH

The MC14042B Quad Transparent Latch is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Each latch has a separate data input, but all four latches share a common clock. The clock polarity (high or low) used to strobe data through the latches can be reversed using the polarity input. Information present at the data input is transferred to outputs Q and $\overline{Q}$ during the clock level which is determined by the polarity input. When the polarity input is in the logic "0" state, data is transferred during the low clock level, and when the polarity input is in the logic "1" state the transfer occurs during the high clock level.

- Buffered Data Inputs
- Common Clock
- Clock Polarity Control
- Q and $\overline{Q}$ Outputs
- Double Diode Input Protection
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0 10 15	I_T = (1.0 μA/kHz) f + I_{DD} I_T = (2.0 μA/kHz) f + I_{DD} I_T = (3.0 μA/kHz) f + I_{DD}							μAdc

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.004.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MC14046B

PHASE LOCKED LOOP

The MC14046B phase locked loop contains two phase comparators, a voltage-controlled oscillator (VCO), source follower, and zener diode. The comparators have two common signal inputs, PCA_{in} and PCB_{in}. Input PCA_{in} can be used directly coupled to large voltage signals, or indirectly coupled (with a series capacitor) to small voltage signals. The self-bias circuit adjusts small voltage signals in the linear region of the amplifier. Phase comparator 1 (an exclusive OR gate) provides a digital error signal $PC1_{out}$, and maintains 90^{o} phase shift at the center frequency between PCA_{in} and PCB_{in} signals (both at 50% duty cycle). Phase comparator 2 (with leading edge sensing logic) provides digital error signals, $PC2_{out}$ and LD, and maintains a 0^{o} phase shift between PCA_{in} and PCB_{in} signals (duty cycle is immaterial). The linear VCO produces an output signal VCO_{out} whose frequency is determined by the voltage of input VCO_{in} and the capacitor and resistors connected to pins $C1_A$, $C1_B$, R1, and R2. The source-follower output SF_{out} with an external resistor is used where the VCO_{in} signal is needed but no loading can be tolerated. The inhibit input Inh, when high, disables the VCO and source follower to minimize standby power consumption. The zener diode can be used to assist in power supply regulation.

Applications include FM and FSK modulation and demodulation, frequency synthesis and multiplication, frequency discrimination, tone decoding, data synchronization and conditioning, voltage-to-frequency conversion and motor speed control.

- Buffered Outputs Compatible with MHTL and Low-Power TTL
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 to 18 V
- Pin-for-Pin Replacement for CD4046B
- Phase Comparator 1 is an Exclusive Or Gate and is Duty Cycle Limited
- Phase Comparator 2 switches on Rising Edges and is not Duty Cycle Limited

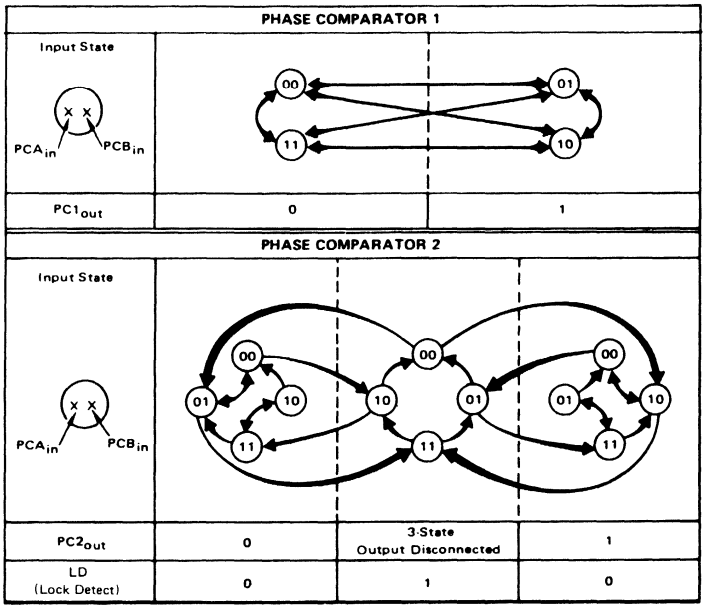
FIGURE 1 – PHASE COMPARATORS STATE DIAGRAMS



Refer to Waveforms in Figure 3.

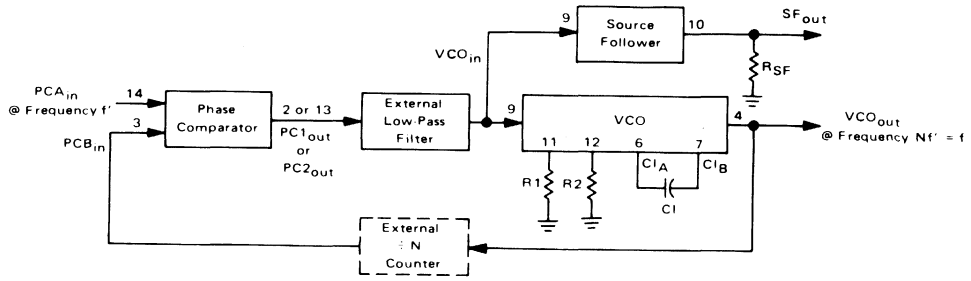
FIGURE 2 – DESIGN INFORMATION

Characteristic	Using Phase Comparator 1	Using Phase Comparator 2
No signal on input PCA$_{in}$.	VCO in PLL system adjusts to center frequency (f_0).	VCO in PLL system adjusts to minimum frequency (f_{min}).
Phase angle between PCA$_{in}$ and PCB$_{in}$.	90° at center frequency (f_0), approaching 0° and 180° at ends of lock range ($2f_L$).	Always 0° in lock (positive rising edges).
Locks on harmonics of center frequency.	Yes	No
Signal input noise rejection.	High	Low
Lock frequency range ($2f_L$).	The frequency range of the input signal on which the loop will stay locked if it was initially in lock. $2f_L$ = full VCO frequency range = $f_{max} - f_{min}$.	
Capture frequency range ($2f_C$).	The frequency range of the input signal on which the loop will lock if it was initially out of lock.	
	Depends on low-pass filter characteristics (see Figure 3). $f_C < f_L$	$f_C = f_L$
Center frequency (f_0).	The frequency of VCO$_{out}$, when VCO$_{in}$ = 1/2 V_{DD}	
VCO output frequency (f).	$f_{min} = \frac{1}{R_2(C_1 + 32\ pF)}$ (V_{CO} input = V_{SS}) $f_{max} = \frac{1}{R_1(C_1 + 32\ pF)} + f_{min}$ (V_{CO} input = V_{DD}) Where: 10K < R_1 < 1M 10K < R_2 < 1M 100pF < C_1 < .01 μF	

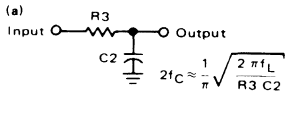
Note: These equations are intended to be a design guide. Since calculated component values may be in error by as much as a factor of 4, laboratory experimentation may be required for fixed designs. Part to part frequency variation with identical passive components is typically less than ± 20%.

6

FIGURE 3 – GENERAL PHASE-LOCKED LOOP CONNECTIONS AND WAVEFORMS



Typical Low-Pass Filters



Typically:

$$R_4 C_2 = \frac{6N}{f_{max}} - \frac{N}{2\pi\Delta f}$$

$$(R_3 + 3{,}000\Omega)\, C_2 = \frac{100N\Delta f}{f_{max}^2} - R_4 C_2$$

$$\Delta f = f_{max} - f_{min}$$

Note: Sometimes R3 is split into two series resistors each R3 ÷ 2. A capacitor C_C is then placed from the midpoint to ground. The value for C_C should be such that the corner frequency of this network does not significantly affect ω_n. In Figure B, the ratio of R3 to R4 sets the damping, R4 ≅ (0.1)(R3) for optimum results.

Definitions: N = Total division ratio in feedback loop

$K\phi = V_{DD}/\pi$ for Phase Comparator 1

$K\phi = V_{DD}/4\pi$ for Phase Comparator 2

$$K_{VCO} = \frac{2\pi\Delta f_{VCO}}{V_{DD} - 2\,V}$$

for a typical design $\omega_n \cong \frac{2\pi f_f}{10}$ (at phase detector input)

$\zeta \cong 0.707$

LOW-PASS FILTER

Filter A	Filter B
$\omega_n = \sqrt{\frac{K\phi K_{VCO}}{NR_3C_2}}$	$\omega_n = \sqrt{\frac{K\phi K_{VCO}}{NC_2(R_3+R_4)}}$
$\zeta = \frac{N\omega_n}{2K\phi K_{VCO}}$	$\zeta = 0.5\,\omega_n(R_3C_2 + \frac{N}{K\phi K_{VCO}})$
$F(s) = \frac{1}{R_3C_2S+1}$	$F(s) = \frac{R_3C_2S+1}{S(R_3C_2+R_4C_2)+1}$

MOTOROLA

MC14049UB
MC14050B

HEX BUFFERS

The MC14049UB hex inverter/buffer and MC14050B non-inverting hex buffer are constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These complementary MOS devices find primary use where low power dissipation and/or high noise immunity is desired. These devices provide logic-level conversion using only one supply voltage, V_{DD}. The input-signal high level (V_{IH}) can exceed the V_{DD} supply voltage for logic-level conversions. Two TTL/DTL Loads can be driven when the devices are used as CMOS-to-TTL/DTL converters (V_{DD} = 5.0 V, $V_{OL} \leq$ 0.4 V, $I_{OL} \geq$ 3.2 mA). Note that pins 13 and 16 are not connected internally on these devices; consequently connections to these terminals will not affect circuit operation.

- High Source and Sink Currents
- High-to-Low Level Converter
- Supply Voltage Range = 3.0 V to 18 V
- Meets JEDEC UB Specifications—MC14049UB
  Meets JEDEC B Specification—MC14050B
- V_{IN} can exceed V_{DD}

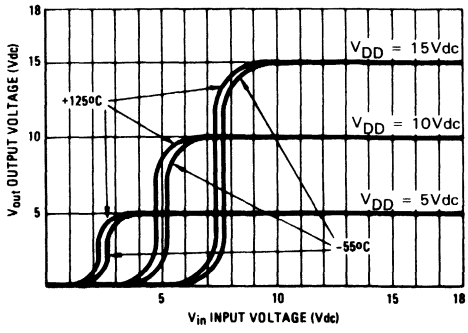

FIGURE 2 – TYPICAL OUTPUT SOURCE CHARACTERISTICS

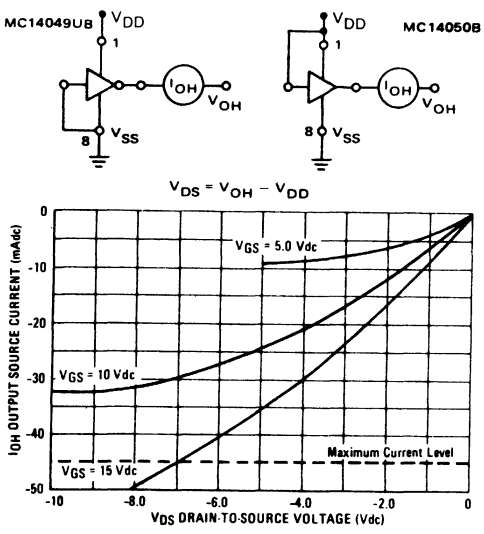

FIGURE 3 – TYPICAL OUTPUT SINK CHARACTERISTICS

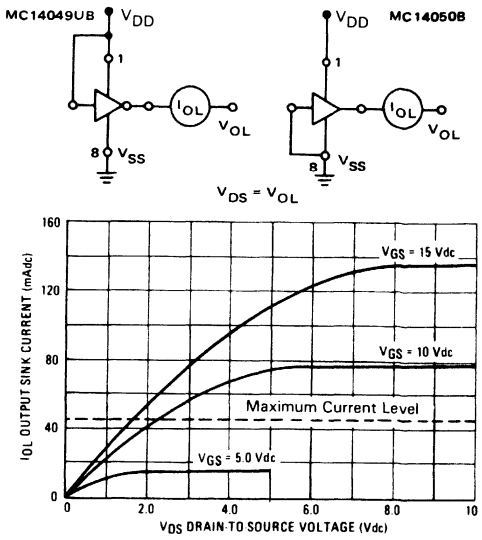

FIGURE 4 – AMBIENT TEMPERATURE POWER DERATING

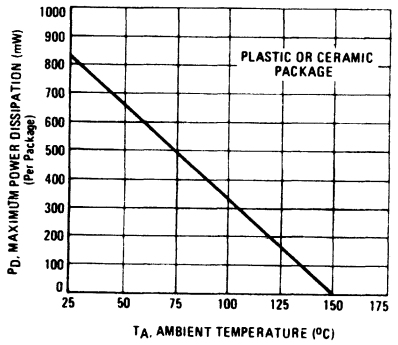

FIGURE 5 – SWITCHING TIME TEST CIRCUIT AND WAVEFORMS

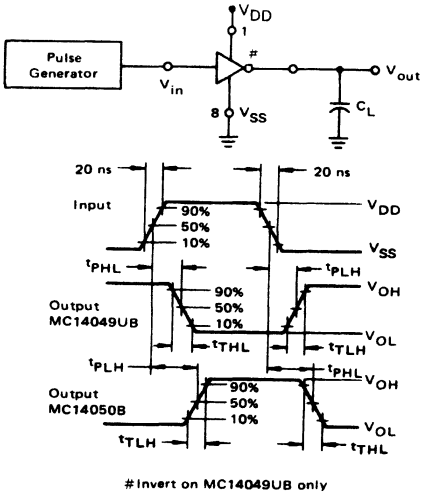
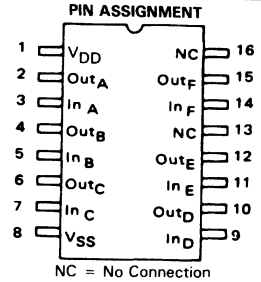


Invert on MC14049UB only

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields **referenced to the V_{SS} pin, only.** Extra precautions must be taken to avoid applications of any voltage higher than the maximum rated voltages to this high-impedance circuit. For proper operation, the ranges $V_{SS} \leq V_{in} \leq 18$ V and $V_{SS} \leq V_{out} \leq V_{DD}$ are recommended.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

PIN ASSIGNMENT



NC = No Connection

MOTOROLA

MC14051B
MC14052B
MC14053B

ANALOG MULTIPLEXERS/DEMULTIPLEXERS

The MC14051B, MC14052B, and MC14053B analog multiplexers are digitally-controlled analog switches. The MC14051B effectively implements an SP8T solid state switch, the MC14052B a DP4T, and the MC14053B a Triple SPDT. All three devices feature low ON impedance and very low OFF leakage current. Control of analog signals up to the complete supply voltage range can be achieved.

- Switch Function is Break Before Make
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Analog Voltage Range ($V_{DD} - V_{EE}$) = 3.0 to 18 V
  Note: V_{EE} must be $\leq V_{SS}$
- Linearized Transfer Characteristics
- Low-noise — 12 nV/$\sqrt{\text{Cycle}}$, f $\geq$ 1.0 kHz Typical
- Pin-for-Pin Replacement for CD4051, CD4052, and CD4053
- For 4PDT Switch, See MC14551B
- For Lower R_{ON}, Use the HC4051, HC4052, or HC4053 High-Speed CMOS Devices

#Data labeled "Typ" is not to be used for design purposes, but is intended as an indication of the IC's potential performance.

**For voltage drops across the switch (ΔV_{switch}) >600 mV (>300 mV at high temperature), excessive V_{DD} current may be drawn; i.e. the current out of the switch may contain both V_{DD} and switch input components. The reliability of the device will be unaffected unless the Maximum Ratings are exceeded. (See first page of this data sheet.)

*The formulas given are for the typical characteristics only at 25°C.

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS}, V_{EE}, or V_{DD}). Unused outputs must be left open.

APPLICATIONS INFORMATION

Figure A illustrates use of the on-chip level converter detailed in Figures 2, 3, and 4. The 0-to-5 V Digital Control signal is used to directly control a 9 V_{p-p} analog signal.

The digital control logic levels are determined by V_{DD} and V_{SS}. The V_{DD} voltage is the logic high voltage; the V_{SS} voltage is logic low. For the example, V_{DD} = +5 V = logic high at the control inputs; V_{SS} = GND = 0 V = logic low.

The maximum analog signal level is determined by V_{DD} and V_{EE}. The V_{DD} voltage determines the maximum recommended peak above V_{SS}. The V_{EE} voltage determines the maximum swing below V_{SS}. For the example, V_{DD} − V_{SS} = 5 V maximum swing above V_{SS}; V_{SS} − V_{EE} = 5 V maximum swing below V_{SS}. The example shows a ± 4.5 V signal which allows a ½ volt margin at each peak. If voltage transients above V_{DD} and/or below V_{EE} are anticipated on the analog channels, external diodes (D_X) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The *absolute* maximum potential difference between V_{DD} and V_{EE} is 18.0 V. Most parameters are specified up to 15 V which is the *recommended* maximum difference between V_{DD} and V_{EE}.

Balanced supplies are not required. However, V_{SS} must be greater than or equal to V_{EE}. For example, V_{DD} = +10 V, V_{SS} = +5 V, and V_{EE} = −3 V is acceptable. See the Table below.

FIGURE A — APPLICATION EXAMPLE

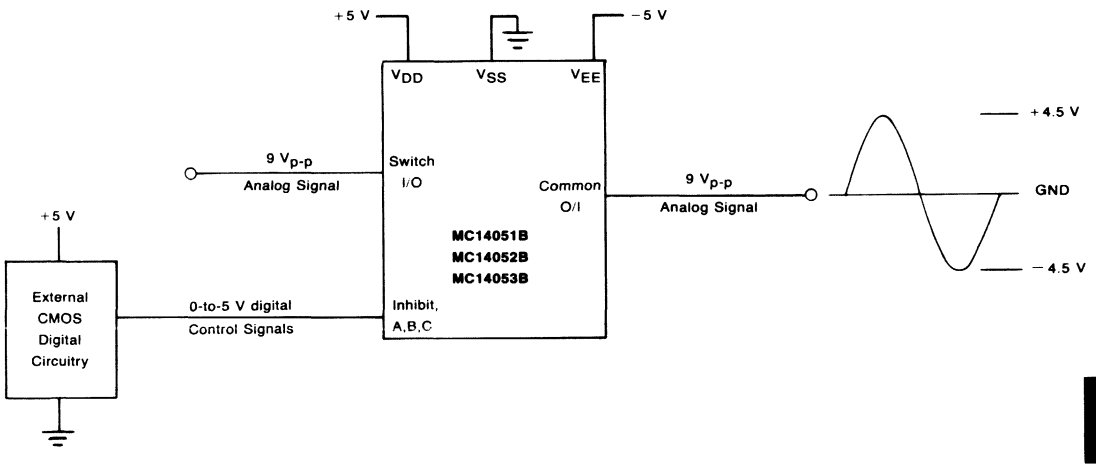

FIGURE B — EXTERNAL GERMANIUM OR SCHOTTKY CLIPPING DIODES

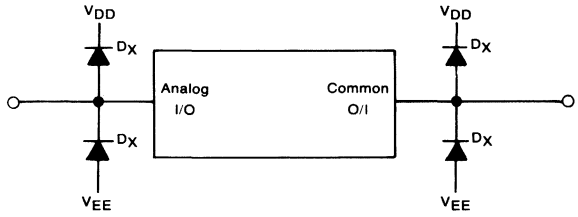

POSSIBLE SUPPLY CONNECTIONS

V_{DD} in Volts	V_{SS} in Volts	V_{EE} in Volts	Control Inputs Logic High/Logic Low in Volts	Maximum Analog Signal Range in Volts
+8	0	−8	+8/0	+8 to −8 = 16 V_{p-p}
+5	0	−12	+5/0	+5 to −12 = 17 V_{p-p}
+5	0	0	+5/0	+5 to 0 = 5 V_{p-p}
+5	0	−5	+5/0	+5 to −5 = 10 V_{p-p}
+10	+5	−5	+10/+5	+10 to −5 = 15 V_{p-p}

MOTOROLA

MC14060B

14-BIT BINARY COUNTER AND OSCILLATOR

The MC14060B is a 14-stage binary ripple counter with an on-chip oscillator buffer. The oscillator configuration allows design of either RC or crystal oscillator circuits. Also included on the chip is a reset function which places all outputs into the zero state and disables the oscillator. A negative transition on Clock will advance the counter to the next state. Schmitt trigger action on the input line permits very slow input rise and fall times. Applications include time delay circuits, counter controls, and frequency dividing circuits.

- Fully static operation
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 V to 18 V
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Buffered Outputs Available from Stages 4 Through 10 and 12 Through 14
- Common Reset Line
- Pin-for-Pin Replacement for CD4060B

MC14066B

QUAD ANALOG SWITCH/QUAD MULTIPLEXER

The MC14066B consists of four independent switches capable of controlling either digital or analog signals. This quad bilateral switch is useful in signal gating, chopper, modulator, demodulator and CMOS logic implementation.

The MC14066B is designed to be pin-for-pin compatible with the MC14016B, but has much lower ON resistance. Input voltage swings as large as the full supply voltage can be controlled via each independent control input.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Linearized Transfer Characteristics
- Low Noise – 12 nV/$\sqrt{\text{Cycle}}$, f ≥ 1 kHz typical
- Pin-for-Pin Replacement for CD4016, CD4066, MC14016B
- For Lower R_{ON}, Use The HC4066 High-Speed CMOS Device

*The formulas given are for the typical characteristics only at 25°C.
#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

6

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

APPLICATIONS INFORMATION

Figure A illustrates use of the Analog Switch. The 0-to-5 volt digital control signal is used to directly control a 5 volt peak-to-peak analog signal.

The digital control logic levels are determined by V_{DD} and V_{SS}. The V_{DD} voltage is the logic high voltage; the V_{SS} voltage is logic low. For the example, V_{DD} = +5 V = logic high at the control inputs; V_{SS} = GND = 0 V = logic low.

The maximum analog signal level is determined by V_{DD} and V_{SS}. The analog voltage must not swing higher than V_{DD} or lower than V_{SS}.

The example shows a 5 volt peak-to-peak signal which allows no margin at either peak. If voltage transients above V_{DD} and/or below V_{SS} are anticipated on the analog channels, external diodes (D_X) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The *absolute* maximum potential difference between V_{DD} and V_{SS} is 18.0 volts. Most parameters are specified up to 15 volts which is the *recommended* maximum difference between V_{DD} and V_{SS}.

MOTOROLA

MC14067B
MC14097B

ANALOG MULTIPLEXERS/DEMULTIPLEXERS

The MC14067 and MC14097 multiplexers/demultiplexers are digitally controlled analog switches featuring low ON resistance and very low leakage current. These devices can be used in either digital or analog applications.

The MC14067 is a 16-channel multiplexer/demultiplexer with an inhibit and four binary control inputs A, B, C, and D. These control inputs select 1-of-16 channels by turning ON the appropriate analog switch (see MC14067 truth table.)

The MC14097 is a differential 8-channel multiplexer/demultiplexer with an inhibit and three binary control inputs A, B, and C. These control inputs select 1 of 8 pairs of channels by turning ON the appropriate analog switches (see MC14097 truth table).

- Low OFF Leakage Current
- Matched Channel Resistance
- Low Quiescent Power Consumption
- Low Crosstalk Between Channels
- Wide Operating Voltage Range: 3 to 18 V
- Low Noise
- Pin for Pin Replacement for CD4067B and CD4097B

APPLICATIONS INFORMATION

Figure A illustrates use of the Analog Multiplexer/ Demultiplexer. The 0-to-5 volt Digital Control signal is used to directly control a 5 V_{p-p} analog signal.

The digital control logic levels are determined by V_{DD} and V_{SS}. The V_{DD} voltage is the logic high voltage; the V_{SS} voltage is logic low. For the example, V_{DD} = +5 V = logic high at the control inputs; V_{SS} = GND = 0 V = logic low.

The maximum analog signal level is determined by V_{DD} and V_{SS}. The analog voltage must swing neither higher than V_{DD} nor lower than V_{SS}. The example shows a 5 V_{p-p} signal which allows no margin at either peak. If voltage transients above V_{DD} and/or below V_{SS} are anticipated on the analog channels, external diodes (D_X) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The *absolute* maximum potential difference between V_{DD} and V_{SS} is 18.0 volts. Most parameters are specified up to 15 V which is the *recommended* maximum difference between V_{DD} and V_{SS}.

MOTOROLA

MC14069UB

HEX INVERTER

The MC14069UB hex inverter is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These inverters find primary use where low power dissipation and/or high noise immunity is desired. Each of the six inverters is a single stage to minimize propagation delays.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperatur Range
- Triple Diode Protection on All Inputs (see Page 5-2)
- Pin-for-Pin Replacement for CD4069UB
- Meets JEDEC UB Specifications

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.002.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14076B

4-BIT D-TYPE REGISTER with THREE-STATE OUTPUTS

The MC14076B 4-Bit Register consists of four D-type flip-flops operating synchronously from a common clock. OR gated output-disable inputs force the outputs into a high-impedance state for use in bus organized systems. OR gated data-disable inputs cause the Q outputs to be fed back to the D inputs of the flip-flops. Thus they are inhibited from changing state while the clocking process remains undisturbed. An asynchronous master reset is provided to clear all four flip-flops simultaneously independent of the clock or disable inputs.

- Three-State Outputs with Gated Control Lines
- Fully Independent Clock Allows Unrestricted Operation for the Two Modes: Parallel Load and Do Nothing
- Asynchronous Master Reset
- Four Bus Buffer Registers
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range
  Schottky TTL Load Over the Rated Temper

QUAD 2-INPUT "NAND" SCHMITT TRIGGER

The MC14093B Schmitt trigger is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These devices find primary use where low power dissipation and/or high noise immunity is desired. The MC14093B may be used in place of the MC14011B quad 2-input NAND gate for enhanced noise immunity or to "square up" slowly changing waveforms.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range
- Double Diode Protection on All Inputs
- Pin-for-Pin Compatible with CD4093
- Can be Used to Replace MC14011B
- Independent Schmitt-Trigger at each Input

MC14094B

8-STAGE SHIFT/STORE REGISTER WITH THREE-STATE OUTPUTS

The MC14094B combines an 8-stage shift register with a data latch for each stage and a three-state output from each latch.

Data is shifted on the positive clock transition and is shifted from the seventh stage to two serial outputs. The Q_S output data is for use in high-speed cascaded systems. The Q'_S output data is shifted on the following negative clock transition for use in low-speed cascaded systems.

Data from each stage of the shift register is latched on the negative transition of the strobe input. Data propagates through the latch while strobe is high.

Outputs of the eight data latches are controlled by three-state buffers which are placed in the high-impedance state by a logic Low on Output Enable.

- Three-State Outputs
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range
- Input Diode Protection
- Data Latch
- Dual Outputs for Data Out on Both Positive and Negative Clock Transitions
- Useful for Serial-to-Parallel Data Conversion
- Pin-for-Pin Compatible with CD4094B

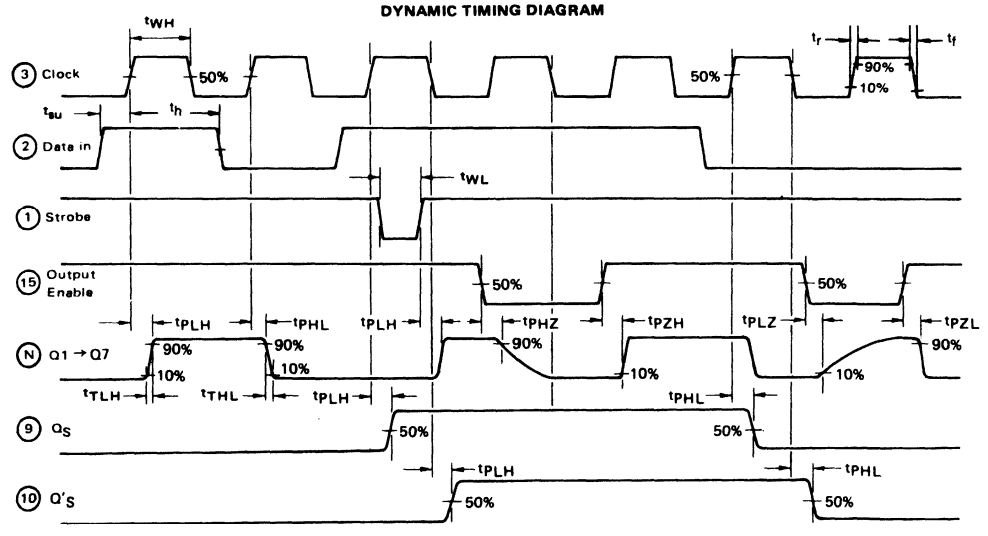
DYNAMIC TIMING DIAGRAM



MOTOROLA

MC14099B
MC14599B

8-BIT ADDRESSABLE LATCHES

The MC14099B and MC14599B are 8-bit addressable latches. Data is entered in serial form when the appropriate latch is addressed (via address pins A0, A1, A2) and write disable is in the low state. Chip enable must be high for writing into MC14599B. For the MC14599B the data pin is a bidirectional data port and for the MC14099B the input is a unidirectional write only port. The Write/$\overline{\text{Read}}$ line controls this port in the MC14599B.

The data is presented in parallel at the output of the eight latches independently of the state of Write Disable, Write/$\overline{\text{Read}}$ or Chip Enable.

A Master Reset capability is available on both parts.

- Serial Data Input
- Parallel Output
- Master Reset
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-Power Schottky TTL Load over the Rated Temperature Range
- MC14099B pin for pin compatible with CD4099B

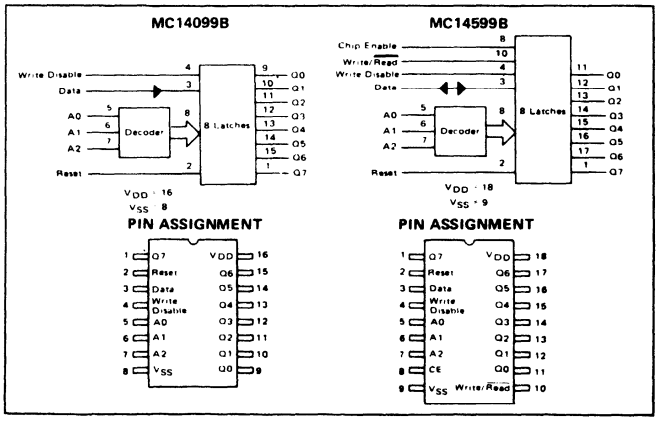
P_D	Power Dissipation, per Package†	500	mW
T_{stg}	Storage Temperature	−65 to +150	°C
T_L	Lead Temperature (8-Second Soldering)	260	°C

*Maximum Ratings are those values beyond which damage to the device may occur.
†Temperature Derating: All Packages: −7.0 mW/°C from 65°C to 125°C.



This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14106B

HEX SCHMITT TRIGGER

The MC14106B hex Schmitt Trigger is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These devices find primary use where low power dissipation and/or high noise immunity is desired. The MC14106B may be used in place of the MC14069UB hex inverter for enhanced noise immunity or to "square up" slowly changing waveforms.

- Increased Hysteresis Voltage Over the MC14584B
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD40106B and MM74C14
- Can Be Used to Replace the MC14584B or MC14069UB

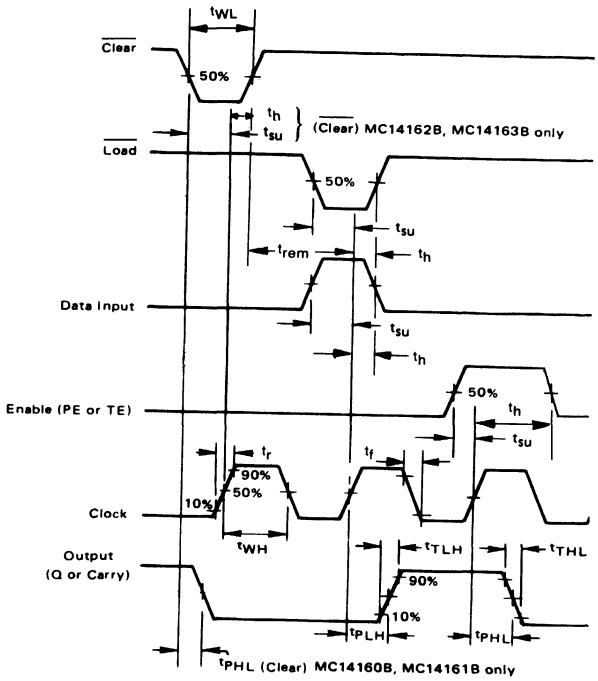
SWITCHING WAVEFORMS



FUNCTIONAL DESCRIPTION

6

These counters are fully programmable; that is the outputs may be preset to either level. As presetting is synchronous, setting up a low level at the load input disables the counter and causes the outputs to agree with the setup data after the next clock pulse regardless of the levels of the enable inputs. The clear function for the MC14160B, MC14161B is asynchronous and a low level at the clear input sets all four of the flip-flop outputs low regardless of the levels of the clock, load or enable inputs. The clear function for the MC14162B and MC14163B is synchronous and a low level at the clear inputs sets all four of the flip-flop outputs low after the next clock pulse, regardless of the levels of the enable inputs. This synchronous clear allows the count length to be modified easily; decoding the maximum count desired can be acomplished with one external NAND gate. The gate output is connected to the clear input to synchronously clear the counter to 0000 (LLLL).

The carry look-ahead circuitry provides for cascading counters for n-bit synchronous applications without additional gating. Instrumental in accomplishing this function are two count-enable inputs and a carry output. Both count-enable inputs (PE, TE) must be high to count, and enable input TE fed forward to enable the carry output. The carry output thus enabled will produce a positive output pulse with a duration approximately equal to the positive portion of the Q1 output. This positive overflow carry pulse can be used to enable successive cascaded stages.

MOTOROLA

MC14174B

HEX TYPE D FLIP-FLOP

The MC14174B hex type D flip-flop is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Data on the D inputs which meets the setup time requirements is transferred to the Q outputs on the positive edge of the clock pulse. All six flip-flops share common clock and reset inputs. The reset is active low, and independent of the clock.

- Static Operation
- All Inputs and Outputs Buffered
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-Power Schottky TTL Load over the Rated Temperature Range
- Functional Equivalent to TTL 74174

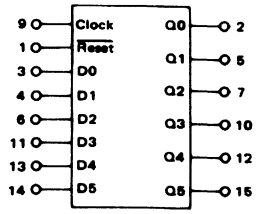
BLOCK DIAGRAM



V_{DD} = Pin 16
V_{SS} = Pin 8

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MC14175B

QUAD TYPE D FLIP-FLOP

The MC14175B quad type D flip-flop is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Each of the four flip-flops is positive-edge triggered by a common clock input (C). An active-low reset input ($\overline{R}$) asynchronously resets all flip-flops. Each flip-flop has independent Data (D) inputs and complementary outputs (Q and $\overline{Q}$). These devices may be used as shift register elements or as type T flip-flops for counter and toggle applications.

MOTOROLA

MC14194B

4-BIT BIDIRECTIONAL UNIVERSAL SHIFT REGISTER

The MC14194B is a 4-bit static shift register capable of operating in the parallel load, serial shift left, serial shift right, or hold mode. The asynchronous $\overline{\text{Reset}}$ input, when at a low level, overrides all other inputs, resets all stages, and forces all outputs low. When $\overline{\text{Reset}}$ is at a logic 1 level, the two mode control inputs, S0 and S1, control the operating mode as shown in the truth table. Both serial and parallel operation are triggered on the positive-going transition of the Clock input. The Parallel Data, Data Shift, and mode control inputs must be stable for the specified setup and hold times before and after the positive-going Clock transition.

- Synchronous Right/Left Serial Operation
- Synchronous Parallel Load
- Asynchronous Hold (Do Nothing) Mode
- Functional Pin for Pin Equivalent of LS194

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0 10 15	I_T = (0.95 μA/kHz) f + I_{DD} I_T = (1.90 μA/kHz) f + I_{DD} I_T = (2.90 μA/kHz) f + I_{DD}							μAdc

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.002.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

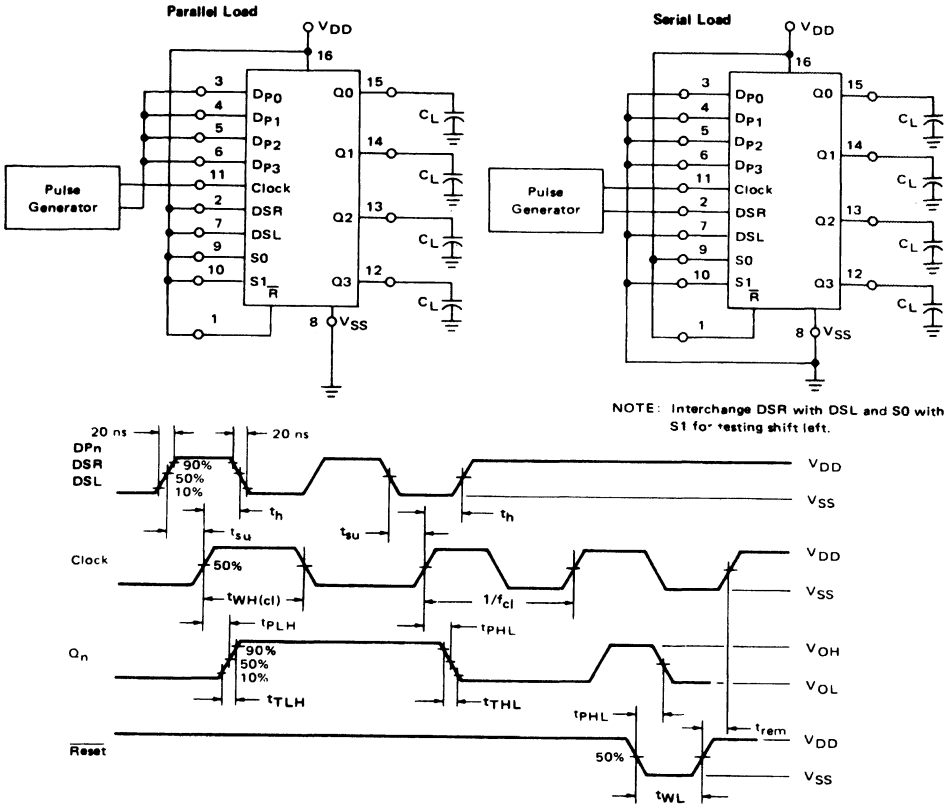

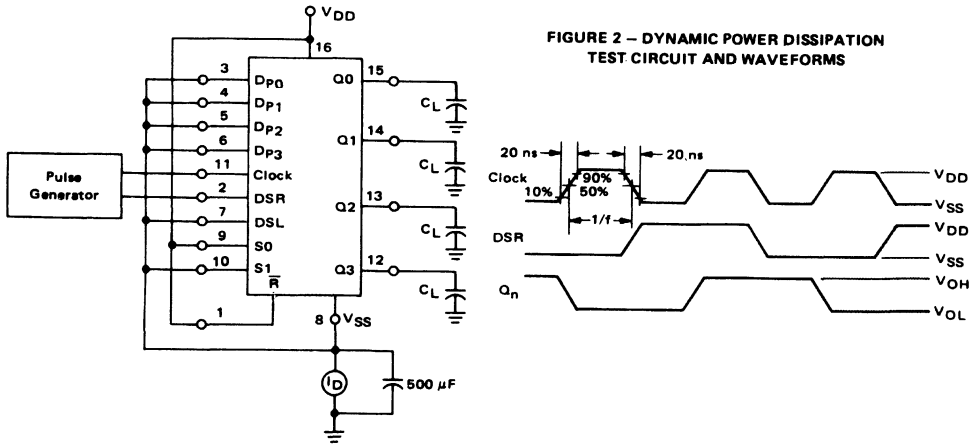

FIGURE 2 – DYNAMIC POWER DISSIPATION TEST CIRCUIT AND WAVEFORMS

MOTOROLA

MC14415

QUAD PRECISION TIMER/DRIVER

MC14415 quad timer/driver is constructed with complementary MOS enhancement mode devices. The output pulse width of each digital timer is a function of the input clock frequency. Once the proper input sequence is detected the output buffer is set (turned on), and after 100 clock pulses are counted, the output buffer is reset (turned off).

The MC14415 was designed specifically for application in high speed line printers to provide the critical timing of the hammer drivers, but may be used in many applications requiring precision pulse widths.

- Four Precision Digital Time Delays
- Schmitt Trigger Clock Conditioning
- NPN Bipolar Output Drivers
- Timing Disable Capability Using Inhibit Output
- Positive or Negative Edge Strobing on the Inputs
- Synchronous Polynomial Counters Used for Delay Counting

MOTOROLA

MC14490

HEX CONTACT BOUNCE ELIMINATOR

The MC14490 is constructed with complementary MOS enhancement mode devices, and is used for the elimination of extraneous level changes that result when interfacing with mechanical contacts. The digital contact bounce eliminator circuit takes an input signal from a bouncing contact and generates a clean digital signal four clock periods after the input has stabilized. The bounce eliminator circuit will remove bounce on both the "make" and the "break" of a contact closure. The clock for operation of the MC14490 is derived from an internal R-C oscillator which requires only an external capacitor to adjust for the desired operating frequency (bounce delay). The clock may also be driven from an external clock source or the oscillator of another MC14490 (see Figure 5).

NOTE: Immediately after power-up, the outputs of the MC14490 are in indeterminate states.

- Diode Protection on All Inputs
- Six Debouncers Per Package
- Internal Pullups on All Data Inputs
- Can Be Used as a Digital Integrator, System Synchronizer, or Delay Line
- Internal Oscillator (R-C), or External Clock Source
- TTL Compatible Data Inputs/Outputs
- Single Line Input, Debounces Both "Make" and "Break" Contacts
- Does Not Require "Form C" (Single Pole Double Throw) Input Signal
- Cascadable for Longer Time Delays
- Schmitt Trigger on Clock Input (Pin 7)
- Supply Voltage Range = 3.0 V to 18 V
- Chip Complexity: 546 FETs or 136.5 Equivalent Gates

***POWER-DOWN CONSIDERATIONS**

Large values of C_{ext} may cause problems when powering down the MC14490 because of the amount of energy stored in the capacitor. When a system containing this device is powered down, the capacitor may discharge through the input protection diodes at Pin 7 or the parasitic diodes at Pin 9. Current through these internal diodes must be limited to 10 mA, therefore the turn-off time of the power supply must not be faster than $t = (V_{DD} - V_{SS}) \cdot C_{ext}/(10\ mA)$. For example, if $V_{DD} - V_{SS} = 15$ V and $C_{ext} = 1\ \mu F$, the power supply must turn off no faster than $t = (15\ V) \cdot (1\ \mu F)/10\ mA = 1.5$ ms. This is usually not a problem because power supplies are heavily filtered and cannot discharge at this rate.

When a more rapid decrease of the power supply to zero volts occurs, the MC14490 may sustain damage. To avoid this possibility, use external clamping diodes, D1 and D2, connected as shown in Figure 2.

FIGURE 1 – SWITCHING WAVEFORMS

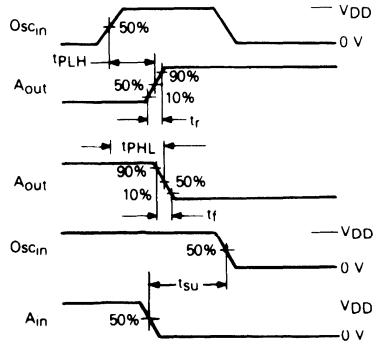

FIGURE 2 – DISCHARGE PROTECTION DURING POWER DOWN

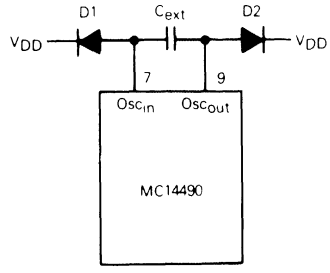

THEORY OF OPERATION

The MC14490 Hex Contact Bounce Eliminator is basically a digital integrator. The circuit can integrate both up and down. This enables the circuit to eliminate bounce on both the leading and trailing edges of the signal, shown in the timing diagram of Figure 3.

Each of the six Bounce Eliminators is composed of a 4½-bit register (the integrator) and logic to compare the input with the contents of the shift register, as shown in Figure 4. The shift register requires a series of timing pulses in order to shift the input signal into each shift register location. These timing pulses (the clock signal) are represented in the upper waveform of Figure 3. Each of the six Bounce Eliminator circuits has an internal resistor as shown in Figure 4. A pullup resistor was incorporated rather than a pulldown resistor in order to implement switched ground input signals, such as those coming from relay contacts and push buttons. By switching ground, rather than a power supply lead, system faults (such as shorts to ground on the signal input leads) will not cause excessive currents in the wiring and contacts. Signal lead shorts to ground are much more probable than shorts to a power supply lead.

When the relay contact is closed, (see Figure 4) the low level is inverted, and the shift register is loaded with a high on each positive edge of the clock signal. To understand the operation, we assume all bits of the shift register are loaded with lows and the output is at a high level.

At clock edge 1 (Figure 3) the input has gone low and a high has been loaded into the first bit or storage location of the shift register. Just after the positive edge of clock 1, the input signal has bounced back to a high. This causes the shift register to be reset to lows in all four bits — thus starting the timing sequence over again.

During clock edges 3 to 6 the input signal has stayed low. Thus, a high has been shifted into all four shift register bits and, as shown, the output goes low during the positive edge of clock pulse 6.

It should be noted that there is a 3½ to 4½ clock period delay between the clean input signal and output signal. In this example there is a delay of 3.8 clock periods from the beginning of the clean input signal.

After some time period of N clock periods, the contact is opened and at N + 1 a low is loaded into the first bit. Just after N + 1, when the input bounces low, all bits are set to a high. At N + 2 nothing happens because the input and output are low and all bits of the shift register are high. At time N + 3 and thereafter the input signal is a high, clean signal. At the positive edge of N + 6 the output goes high as a result of four lows being shifted into the shift register.

Assuming the input signal is long enough to be clocked through the Bounce Eliminator, the output signal will be no longer or shorter than the clean input signal plus or minus one clock period.

The amount of time distortion between the input and output signals is a function of the difference in bounce characteristics on the edges of the input signal and the clock frequency. Since most relay contacts have more bounce when making as compared to breaking, the overall delay, counting bounce period, will be greater on the leading edge of the input signal than on the trailing edge. Thus, the output signal will be shorter than the input signal — if the leading edge bounce is included in the overall timing calculation.

The only requirement on the clock frequency in order to obtain a bounce free output signal is that four clock periods do not occur while the input signal is in a false state. Referring to Figure 3, a false state is seen to occur three times at the beginning of the input signal. The input signal goes low three times before it finally settles down to a valid low state. The first three low pulses are referred to as false states.

If the user has an available clock signal of the proper frequency, it may be used by connecting it to the oscillator input (pin 7). However, if an external clock is not available the user can place a small capacitor across the oscillator input and output pins in order to start up an internal clock source (as shown in Figure 4). The clock signal at the oscillator output pin may then be used to clock other MC14490 Bounce Eliminator packages. With the use of the MC14490, a large number of signals can be cleaned up, with the requirement of only one small capacitor external to the Hex Bounce Eliminator packages.

6

FIGURE 3 — TIMING DIAGRAM

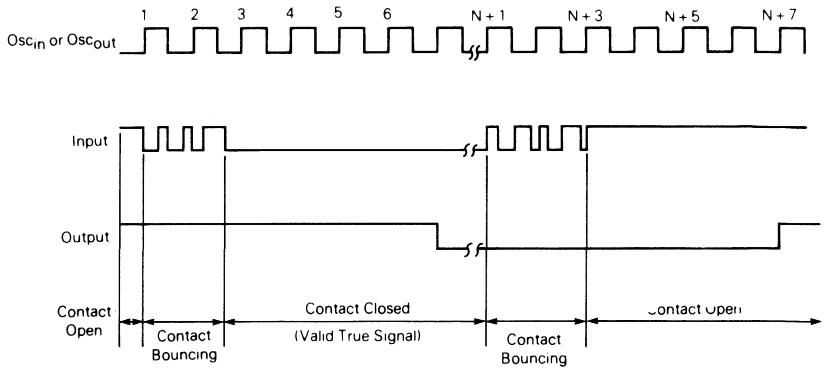

FIGURE 4 – TYPICAL "FORM A" CONTACT DEBOUNCE CIRCUIT
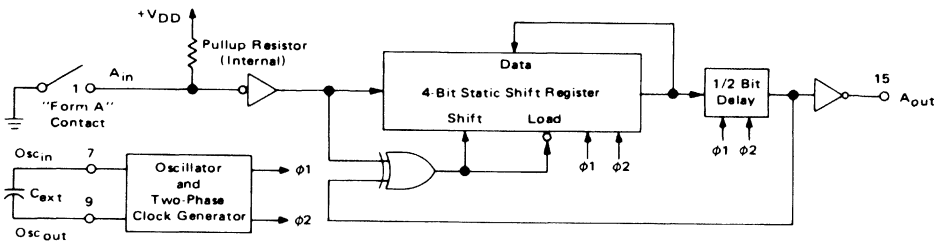
(Only One Debouncer Shown)



OPERATING CHARACTERISTICS

The single most important characteristic of the MC14490 is that it works with a single signal lead as an input, making it directly compatible with mechanical contacts (Form A and B).

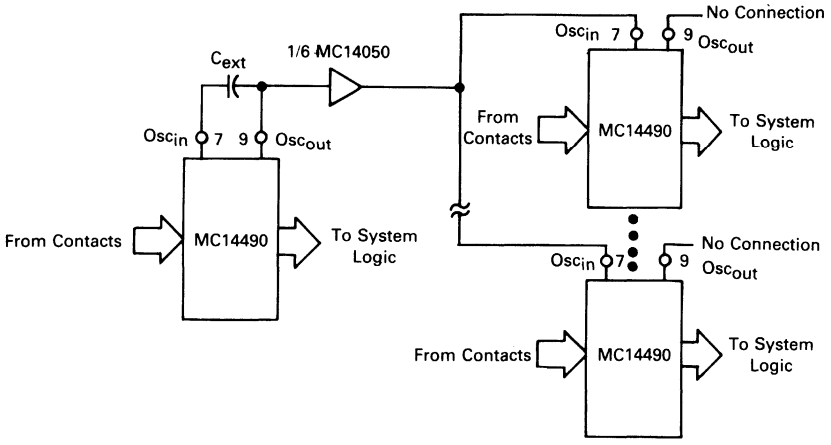
The circuit has a built in pullup resistor on each input. The worst case value of the pullup resistor (determined from the Electrical Characteristics table) is used to calculate the contact wetting current. If more contact current is required, an external resistor may be connected between V_{DD} and the input.

Because of the built-in pullup resistors, the inputs cannot be driven with a single standard CMOS gate when V_{DD} is below 5 V. At this voltage, the input should be driven with paralleled standard gates or by the MC14049 or MC14050 buffers.

The clock input circuit (pin 7) has Schmitt trigger shaping such that proper clocking will occur even with very slow clock edges, eliminating any need for clock preshaping. In addition, other MC14490 oscillator inputs can be driven from a single oscillator output buffered by an MC14050 (see Figure 5). Up to six MC14490s may be driven by a single buffer.

The MC14490 is TTL compatible on both the inputs and the outputs. When V_{DD} is at 4.5 V, the buffered outputs can sink 1.6 mA at 0.4 V. The inputs can be driven with TTL as a result of the internal input pullup resistors.

FIGURE 5 – TYPICAL SINGLE OSCILLATOR DEBOUNCE SYSTEM

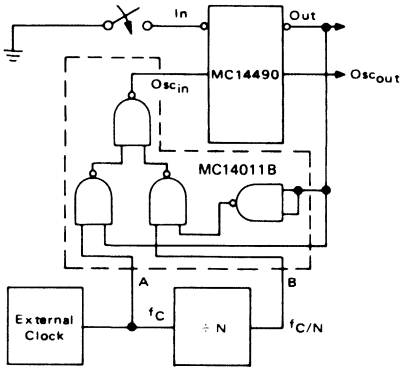


TYPICAL APPLICATIONS

ASYMMETRICAL TIMING

In applications where different leading and trailing edge delays are required (such as a fast attack/slow release timer.) Clocks of different frequencies can be gated into the MC14490 as shown in Figure 6. In order to produce a slow attack/fast release circuit leads A and B should be interchanged. The clock out lead can then be used to feed clock signals to the other MC14490 packages where the asymmetrical input/output timing is required.

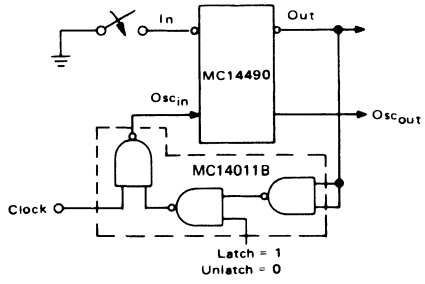
FIGURE 6 – FAST ATTACK/SLOW RELEASE CIRCUIT



LATCHED OUTPUT

The contents of the Bounce Eliminator can be latched by using several extra gates as shown in Figure 7. If the latch lead is high the clock will be stopped when the output goes low. This will hold the output low even though the input has returned to the high state. Any time the clock is stopped the outputs will be representative of the input signal four clock periods earlier.

FIGURE 7 – LATCHED OUTPUT CIRCUIT



MULTIPLE TIMING SIGNALS

As shown in Figure 8, the Bounce Eliminator circuits can be connected in series. In this configuration each output is delayed by four clock periods relative to its respective input. This configuration may be used to generate multiple timing signals such as a delay line, for programming other timing operations.

One application of the above is shown in Figure 9, where it is required to have a single pulse output for a single operation (make) of the push button or relay contact. This only requires the series connection of two Bounce Eliminator circuits, one inverter, and one NOR gate in order to generate the signal $\overline{A}B$ as shown in Figures 9 and 10. The signal $\overline{A}B$ is four clock periods in length. If the inverter is switched to the A output, the pulse $A\overline{B}$ will be generated upon release or break of the contact. With the use of a few additional parts many different pulses and waveshapes may be generated.

6

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14500B

INDUSTRIAL CONTROL UNIT

The MC14500B Industrial Control Unit (ICU) is a single-bit CMOS processor. The ICU is designed for use in systems requiring decisions based on successive single-bit information. An external ROM stores the control program. With a program counter (and output latches and input multiplexers, if required) the ICU in a system forms a stored-program controller that replaces combinatorial logic. Applications include relay logic processing, serial data manipulation and control. The ICU also may control an MPU or be controlled by an MPU.

- 16 Instructions
- DC to 1.0 MHz Operation at V_{DD} = 5 V
- On-Chip Clock (Oscillator)
- Executes One Instruction per Clock Cycle
- 3 to 18 V Operation
- Low Quiescent Current Characteristic of CMOS Devices
- Capable of Driving One Low-Power Schottky Load or Two Low-Power TTL Loads over Full Temperature Range

TABLE 1. MC14500B INSTRUCTION SET

Instruction Code	Mnemonic	Action
0 0000	NOPO	No change in registers. RR → RR, Flag O → ⎍
1 0001	LD	Load result register. Data → RR
2 0010	LDC	Load complement. $\overline{Data}$ → RR
3 0011	AND	Logical AND. RR·Data → RR
4 0100	ANDC	Logical AND complement. RR·$\overline{Data}$ → RR
5 0101	OR	Logical OR. RR + Data → RR
6 0110	ORC	Logical OR complement. RR + $\overline{Data}$ → RR
7 0111	XNOR	Exclusive NOR. If RR = Data, RR → 1
8 1000	STO	Store. RR → Data Pin, Write → ⎍
9 1001	STOC	Store complement. $\overline{RR}$ → Data Pin, Write → ⎍
A 1010	IEN	Input enable. Data → IEN Register
B 1011	OEN	Output enable. Data → OEN Register
C 1100	JMP	Jump. JMP Flag → ⎍
D 1101	RTN	Return. RTN Flag → ⎍ and skip next instruction
E 1110	SKZ	Skip next instruction if RR = 0
F 1111	NOPF	No change in registers. RR → RR, Flag F → ⎍

MOTOROLA

MC14501UB

TRIPLE GATE
DUAL 4-INPUT "NAND" GATE
2-INPUT "NOR/OR" GATE
8-INPUT "AND/NAND" GATE

The MC14501UB is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These complementary MOS logic gates find primary use where low power dissipation and/or high noise immunity is desired. Additional characteristics can be found on the Family Data Sheet.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Logic Swing Independent of Fanout
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

6

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14503B

HEX NON-INVERTING 3-STATE BUFFER

The MC14503B is a hex non-inverting buffer with 3-state outputs, and a high current source and sink capability. The 3-state outputs make it useful in common bussing applications. Two disable controls are provided. A high level on the Disable A input causes the outputs of buffers 1 through 4 to go into a high impedance state and a high level on the Disable B input causes the outputs of buffers 5 and 6 to go into a high impedance state.

- 3-State Outputs
- TTL Compatible – Will Drive One TTL Load Over Full Temperature Range
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Two Disable Controls for Added Versatility
- Pin for Pin Replacement for MM80C97 and 340097

MOTOROLA

MC14504B

HEX LEVEL SHIFTER FOR TTL to CMOS or CMOS to CMOS

The MC14504B is a hex non-inverting level shifter using CMOS technology. The level shifter will shift a TTL signal to CMOS logic levels for any CMOS supply voltage between 5 and 15 volts. A control input also allows interface from CMOS to CMOS at one logic level to another logic level. Either up or down level translating is accomplished by selection of power supply levels V_{DD} and V_{CC}. The V_{CC} level sets the input signal levels while V_{DD} selects the output voltage levels.

- UP Translates from a Low to a High Voltage or DOWN Translates from a High to a Low Voltage
- Input Threshold Can Be Shifted for TTL Compatibility
- No Sequencing Required on Power Supplies or Inputs for Power Up or Power Down
- 3 to 18 Vdc Operation for V_{DD} and V_{CC}
- Diode Protected Inputs to V_{SS}
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

MOTOROLA

MC14506UB

DUAL 2-WIDE, 2-INPUT EXPANDABLE AND-OR-INVERT GATE

The MC14506UB is an expandable AND-OR-INVERT gate with inhibit and 3-state output. The expand option allows cascading with any other gate, which may be carried as far as desired as long as the propagation delay added with each gate is considered. For example, the second AOI gate in this device may be used to expand the first gate, giving an expanded 4-wide, 2-input AOI gate. This device is useful in data control and digital multiplexing applications.

- 3-State Output
- Separate Inhibit Line
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

MOTOROLA

MC14508B

DUAL 4-BIT LATCH

The MC14508B dual 4-bit latch is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. The part consists of two identical, independent 4-bit latches with separate Strobe (ST) and Master Reset (MR) controls. Separate Disable inputs force the outputs to a high impedance state and allow the devices to be used in time sharing bus line applications.

These complementary MOS latches find primary use in buffer storage, holding register, or general digital logic functions where low power dissipation and/or high noise immunity is desired.

- 3-State Output
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range.

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.008.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

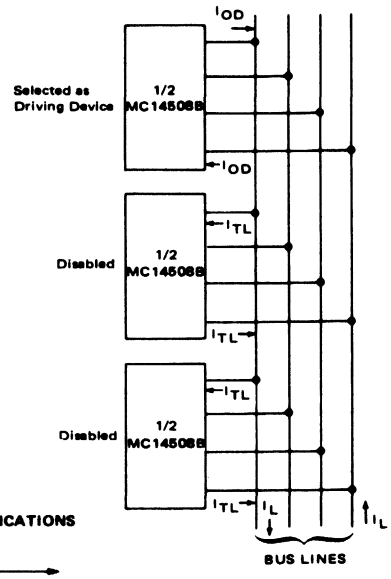
3-STATE MODE OF OPERATION

The MC14508B can be used in bussed systems as shown. The output terminals of N 4-bit latches can be directly wired to a bus line, and to one of the 4-bit latches selected. The selected latch controls the logic state of the bus line, and the remaining (N-1) 4-bit latches are disabled into a high impedance "off" state. The number of latches, N, which may be connected to a bus line is determined from the output drive current, I_{OD}, the 3-state or disabled output leakage current, I_{TL}, and the load current, I_L, required to drive the bus line (including fanout to other device inputs) and can be calculated by the following:

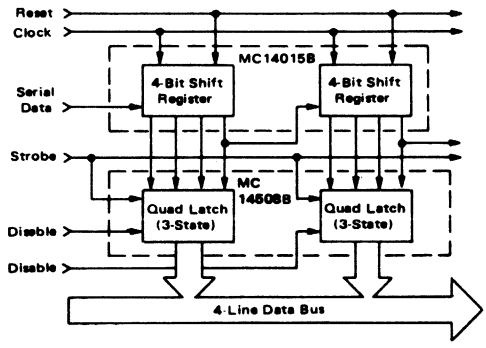
$$N = \frac{I_{OD} - I_L}{I_{TL}} + 1$$

N must be calculated for both high and low logic states of the bus line.



TYPICAL 3-STATE APPLICATIONS

EXAMPLE 1



EXAMPLE 2

MOTOROLA

MC14510B

BCD UP/DOWN COUNTER

The MC14510B synchronous up/down BCD counter is constructed with MOS P-channel and N-channel enhancement mode devices in a monolithic structure. The counter consists of type D flip-flop stages with a gating structure to provide type T flip-flop capability.

This counter can be preset by applying the desired value in BCD to the Preset inputs (P1, P2, P3, P4) and then bringing the Preset Enable (PE) high. The direction of counting is controlled by applying a high (for up counting) or a low (for down counting) to the UP/DOWN input. The state of the counter changes on the positive transition of the clock input.

Cascading can be accomplished by connecting the $\overline{\text{Carry Out}}$ to the $\overline{\text{Carry In}}$ of the next stage while clocking each counter in parallel. The ouputs (Q1, Q2, Q3, Q4) can be reset to a low state by applying a high to the Reset (R) pin.

This CMOS counter finds primary use in up/down and difference counting. Other applications include: (1) Frequency synthesizer applications where low power dissipation and/or high noise immunity is desired, (2) Analog-to-digital and digital-to-analog conversions, and (3) Magnitude and sign generation.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Internally Synchronous for High Speed
- Logic Edge-Clocked Design – Count Occurs on Positive Going Edge of Clock
- Asynchronous Preset Enable Operation
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range.

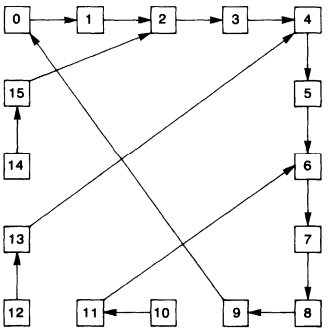
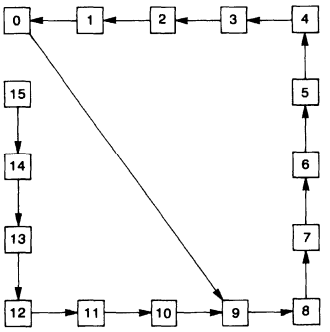
STATE DIAGRAM FOR UP COUNTING



STATE DIAGRAM FOR DOWN COUNTING



PIN DESCRIPTIONS

INPUTS

P1, P2, P3, P4, Preset Inputs (Pins 4, 12, 13, 3) — Data on these inputs is loaded into the counter when PE is taken high.

$\overline{\text{Carry In}}$, (Pin 5) — Active-low input used when cascading stages. Usually connected to $\overline{\text{Carry Out}}$ of the previous stage. While high, clock is inhibited.

Clock, (Pin 15) — BCD data is incremented or decremented, depending on the direction of count, on the positive transition of this signal.

OUTPUTS

Q1, Q2, Q3, Q4, BCD outputs (Pins 6, 11, 14, 2) — BCD data is present on these outputs with Q1 corresponding to the least significant bit.

$\overline{\text{Carry Out}}$, (Pin 7) — Used when cascading stages, this pin is usually connected to $\overline{\text{Carry In}}$ of the next stage. This synchronous output is active low and may also be used to indicate terminal count.

CONTROLS

PE, Preset Enable (Pin 1) — Asynchronously loads data on the Preset Inputs. This pin is active high and will inhibit the clock when high.

R, Reset, (Pin 9) — Asynchronously resets the Q outputs to a low state. This pin is active high and will inhibit the clock when high.

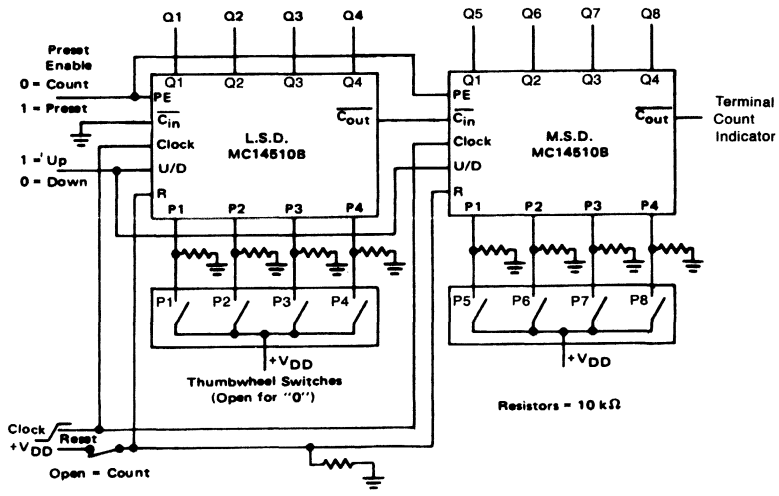
Up/Down, (Pin 10) — Controls the direction of count: high for up count, low for down count.

SUPPLY PINS

V_{SS}, Negative Supply Voltage, (Pin 8) — This pin is usually connected to ground.

V_{DD}, Positive Supply Voltage, (Pin 16) — This pin is connected to a positive supply voltage ranging from 3.0 Vdc to 18.0 Vdc.

FIGURE 3 — PRESETTABLE CASCADED 8-BIT UP/DOWN COUNTER



Note: The Least Significant Digit (L.S.D.) counts from a preset value once Preset Enable (PE) goes low. The Most Significant Digit (M.S.D.) does not change while $\overline{C}_{in}$ is high. When the count of the L.S.D. reaches 0 (count down mode) or reaches 9 (count up mode), $\overline{C}_{out}$ goes low for one complete clock cycle, thus allowing the next counter to decrement/increment one count. The L.S.D. now counts through another cycle (10 clock pulses) and the above cycle is repeated.

6

TIMING DIAGRAM FOR THE PRESETTABLE CASCADED 8-BIT UP/DOWN COUNTER

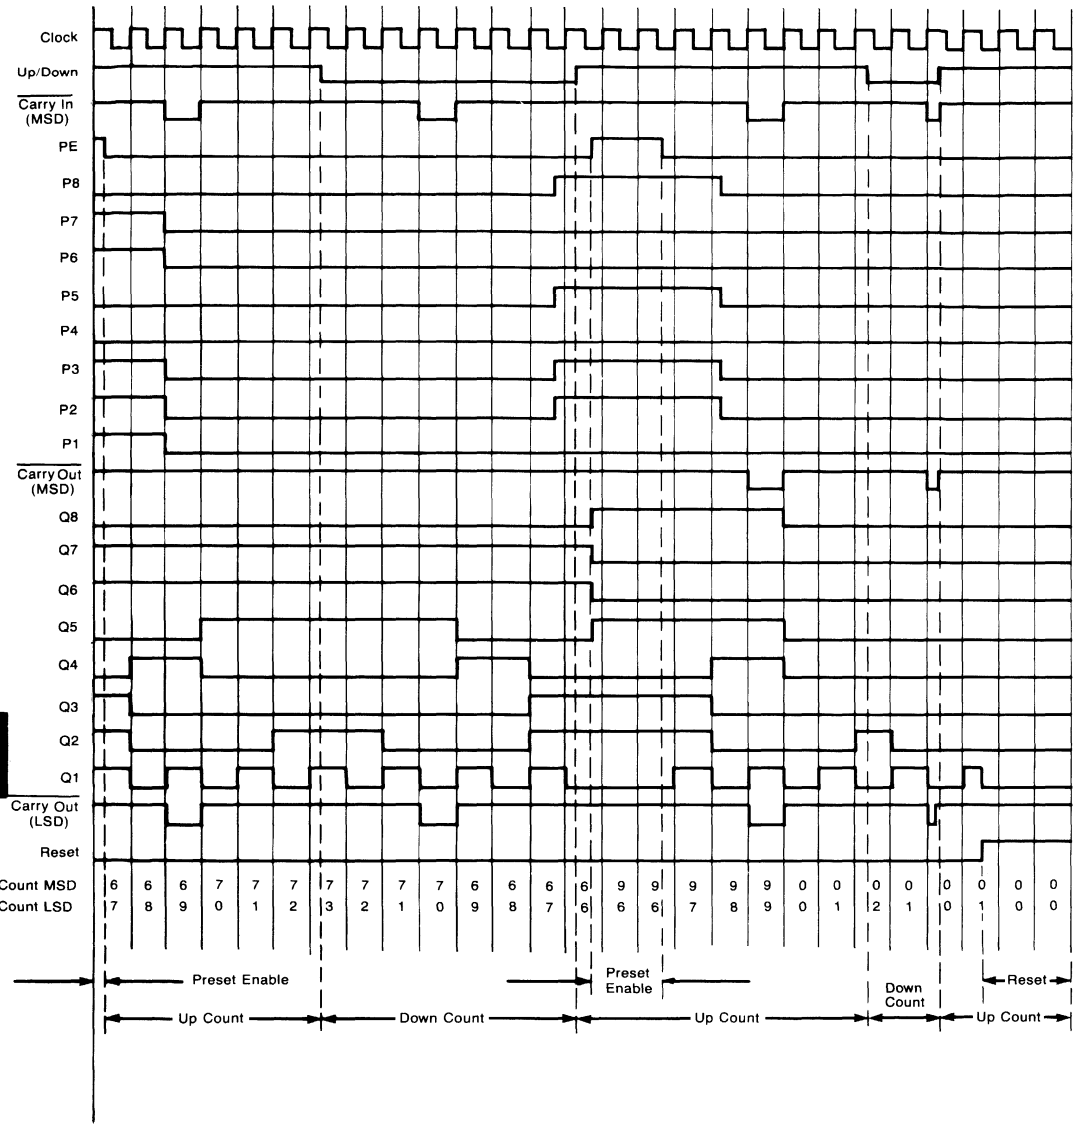


FIGURE 4 — PROGRAMMABLE CASCADED FREQUENCY DIVIDER

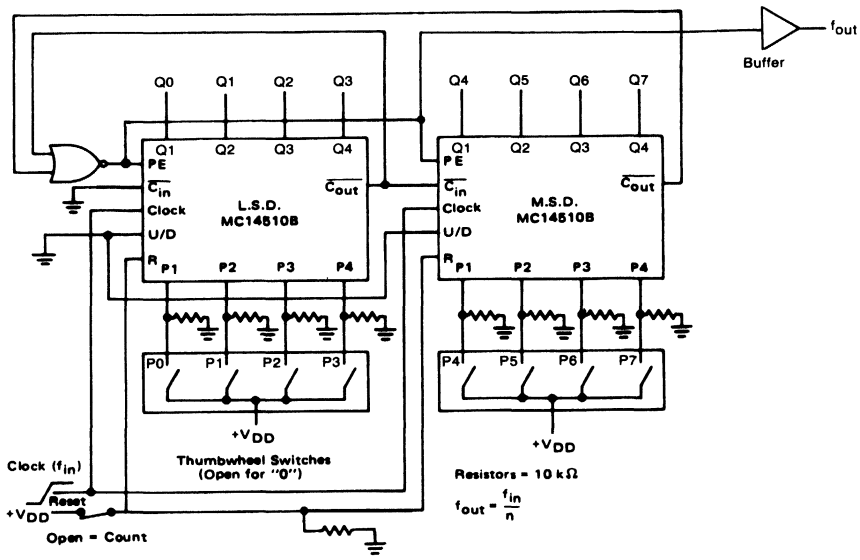

Note: The programmable frequency divider can be set by applying the desired divide ratio, in BCD, to the preset inputs. For example, the maximum divide ratio of 99 may be obtained by applying a 10011001 to the preset inputs P0 to P7. For this divide operation, both counters should be configured in the count down mode. The divide ratio of zero is an undefined state and should be avoided.

6

MC14511B

BCD-TO-SEVEN SEGMENT LATCH/DECODER/DRIVER

The MC14511B BCD-to-seven segment latch/decoder/driver is constructed with complementary MOS (CMOS) enhancement mode devices and NPN bipolar output drivers in a single monolithic structure. The circuit provides the functions of a 4-bit storage latch, an 8421 BCD-to-seven segment decoder, and an output drive capability. Lamp test ($\overline{LT}$), blanking ($\overline{BI}$), and latch enable (LE) inputs are used to test the display, to turn-off or pulse modulate the brightness of the display, and to store a BCD code, respectively. It can be used with seven-segment light emitting diodes (LED), incandescent, fluorescent, gas discharge, or liquid crystal readouts either directly or indirectly.

Applications include instrument (e.g., counter, DVM, etc.) display driver, computer/calculator display driver, cockpit display driver, and various clock, watch, and timer uses.

- Low Logic Circuit Power Dissipation
- High-Current Sourcing Outputs (Up to 25 mA)
- Latch Storage of Code
- Blanking Input
- Lamp Test Provision
- Readout Blanking on all Illegal Input Combinations
- Lamp Intensity Modulation Capability
- Time Share (Multiplexing) Facility
- Supply Voltage Range = 3.0 V to 18 V
- Capable of Driving Two Low-power TTL Loads, One Low-power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range.
- Chip Complexity: 216 FETs or 54 Equivalent Gates

Maximum Continuous Output Power (Source) per Output ‡	P_{OHmax}	50	mW

‡ $P_{OHmax} = I_{OH}(V_{DD} - V_{OH})$
*Maximum Ratings are those values beyond which damage to the device may occur.
†Temperature Derating: All Packages: −7.0 mW/°C from 65°C to 125°C.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. A destructive high current mode may occur if V_{in} and V_{out} are not constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Due to the sourcing capability of this circuit, damage can occur to the device if V_{DD} is applied, and the outputs are shorted to V_{SS} and are at a logical 1 (See Maximum Ratings).

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

LOGIC DIAGRAM

3-STATE MODE OF OPERATION

Output terminals of several MC14512B 8-Bit Data Selectors can be connected to a single data bus as shown. One MC14512B is selected by the 3-state control, and the remaining devices are disabled into a high-impedance "off" state. The number of 8-bit data selectors, N, that may be connected to a bus line is determined from the output drive current, I_{OD}, 3-state or disable output leakage current, I_{TL}, and the load current, I_L, required to drive the bus line (including fanout to other device inputs), and can be calculated by:

$$N = \frac{I_{OD} - I_L}{I_{TL}} + 1$$

N must be calculated for both high and low logic state of the bus line.

6

MOTOROLA

MC14513B

BCD-TO-SEVEN SEGMENT LATCH/DECODER/DRIVER

The MC14513B BCD-to-seven segment latch/decoder/driver is constructed with complementary MOS (CMOS) enhancement mode devices and NPN bipolar output drivers in a single monolithic structure. The circuit provides the functions of a 4-bit storage latch, an 8421 BCD-to-seven segment decoder, and has output drive capability. Lamp test ($\overline{LT}$), blanking ($\overline{BI}$), and latch enable (LE) inputs are used to test the display, to turn-off or pulse modulate the brightness of the display, and to store a BCD code, respectively. The Ripple Blanking Input (RBI) and Ripple Blanking Output (RBO) can be used to suppress either leading or trailing zeroes. It can be used with seven-segment light emitting diodes (LED), incandescent, fluorescent, gas discharge, or liquid crystal readouts either directly or indirectly.

Applications include instrument (e.g., counter, DVM, etc.) display driver, computer/calculator display driver, cockpit display driver, and various clock, watch, and timer uses.

- Low Logic Circuit Power Dissipation
- High-current Sourcing Outputs (Up to 25 mA)
- Latch Storage of Binary Input
- Blanking Input
- Lamp Test Provision
- Readout Blanking on all Illegal Input Combinations
- Lamp Intensity Modulation Capability
- Time Share (Multiplexing) Capability
- Adds Ripple Blanking In, Ripple Blanking Out to MC14511B
- Supply Voltage Range = 3.0 V to 18 V
- Capable of Driving Two Low-Power TTL Loads, One Low-power Schottky TTL Load to Two HTL Loads Over the Rated Temperature Range.

6

MAXIMUM RATINGS* (Voltages referenced to V_{SS}).

Rating	Symbol	Value	Unit
DC Supply Voltage	V_{DD}	-0.5 to +18	V
Input Voltage, All Inputs	V_{in}	-0.5 to V_{DD} + 0.5	V
DC Current Drain per Input Pin	I	10	mA
Operating Temperature Range	T_A	-55 to +125	°C
Storage Temperature Range	T_{stg}	-65 to +150	°C
Maximum Continuous Output Drive Current (Source) per Output	I_{OHmax}	25	mA
Maximum Continuous Output Power (Source) per Output ‡	P_{OHmax}	50	mW

‡$P_{OHmax} = I_{OH}(V_{DD} - V_{OH})$

*Maximum Ratings are those values beyond which damage to the device may occur.

†Temperature Derating: All Packages: − 7.0 mW/°C from 65°C to 125°C.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. A destructive high current mode may occur if V_{in} and V_{out} is not constrained to the range $V_{SS} \leqslant (V_{in}$ or $V_{out}) \leqslant V_{DD}$.

Due to the sourcing capability of this circuit, damage can occur to the device if V_{DD} is applied, and the outputs are shorted to V_{SS} and are at a logical 1 (see Maximum Ratings).

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

MC14514B
MC14515B

4-BIT TRANSPARENT LATCH/4-TO-16 LINE DECODER

The MC14514B and MC14515B are two output options of a 4 to 16 line decoder with latched inputs. The MC14514B (output active high option) presents a logical "1" at the selected output, whereas the MC14515B (output active low option) presents a logical "0" at the selected output. The latches are R-S type flip-flops which hold the last input data presented prior to the strobe transition from "1" to "0". These high and low options of a 4-bit latch/4 to 16 line decoder are constructed with N-channel and P-channel enhancement mode devices in a single monolithic structure. The latches are R-S type flip-flops and data is admitted upon a signal incident at the strobe input, decoded, and presented at the output.

These complementary circuits find primary use in decoding applications where low power dissipation and/or high noise immunity is desired.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.002.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

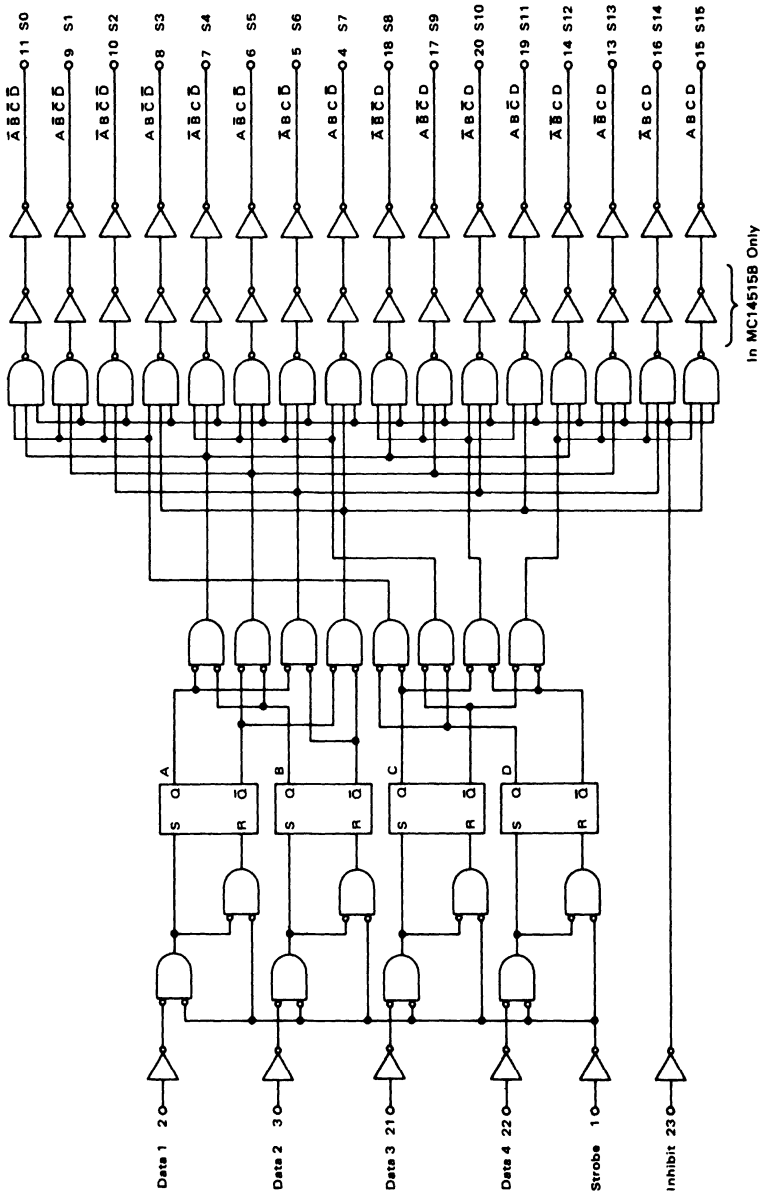
LOGIC DIAGRAM



COMPLEX DATA ROUTING

Two MC14512 eight-channel data selectors are used here with the MC14514B four-bit latch/decoder to effect a complex data routing system. A total of 16 inputs from data registers are selected and transferred via a 3-state data bus to a data distributor for rearrangement and entry into 16 output registers. In this way sequential data can be re-routed or intermixed according to patterns determined by data select and distribution inputs.

Data is placed into the routing scheme via the eight inputs on both MC14512 data selectors. One register is assigned to each input. The signals on A0, A1, and A2 choose one of eight inputs for transfer out to the 3-state data bus. A fourth signal, labelled Dis, disables one of the MC14512 selectors, assuring transfer of data from only one register.

In addition to a choice of input registers, 1 thru 16, the rate of transfer of the sequential information can also be varied. That is, if the MC14512 were addressed at a rate that is eight times faster than the shift frequency of the input registers, the most significant bit (MSB) from each register could be selected for transfer to the data bus. Therefore, all of the most significant bits from all of the registers can be transferred to the data bus before the next most significant bit is presented for transfer by the input registers.

Information from the 3-state bus is redistributed by the MC14514B four-bit latch/decoder. Using the four-bit address, D1 thru D4, the information on the inhibit line can be transferred to the addressed output line to the desired output registers, A thru P. This distribution of data bits to the output registers can be made in many complex patterns. For example, all of the most significant bits from the input registers can be routed into output register A, all of the next most significant bits into register B, etc. In this way horizontal, vertical, or other methods of data slicing can be implemented.

DATA ROUTING SYSTEM

MOTOROLA

MC14516B

BINARY UP/DOWN COUNTER

The MC14516B synchronous up/down binary counter is constructed with MOS P-channel and N-channel enhancement mode devices in a monolithic structure.

This counter can be preset by applying the desired value, in binary, to the Preset inputs (P0, P1, P2, P3) and then bringing the Preset Enable (PE) high. The direction of counting is controlled by applying a high (for up counting) or a low (for down counting) to the UP/DOWN input. The state of the counter changes on the positive transition of the clock input.

Cascading can be accomplished by connecting the $\overline{\text{Carry Out}}$ to the $\overline{\text{Carry In}}$ of the next stage while clocking each counter in parallel. The outputs (Q0, Q1, Q2, Q3) can be reset to a low state by applying a high to the reset (R) pin.

This CMOS counter finds primary use in up/down and difference counting. Other applications include: (1) Frequency synthesizer applications where low power dissipation and/or high noise immunity is desired, (2) Analog-to-digital and digital-to-analog conversions, and (3) Magnitude and sign generation.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Internally Synchronous for High Speed
- Logic Edge-Clocked Design – Count Occurs on Positive Going Edge of Clock
- Single Pin Reset
- Asynchronous Preset Enable Operation
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky Load Over the Rated Temperature Range

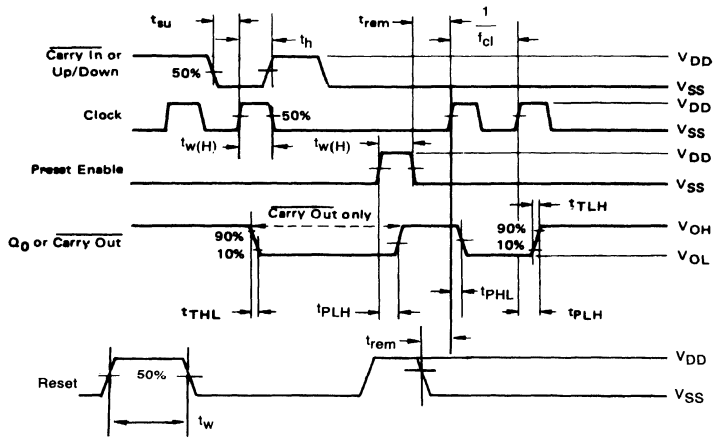
FIGURE 2 – SWITCHING TIME WAVEFORMS



PIN DESCRIPTIONS

INPUTS

P0, P1, P2, P3, Preset Inputs (Pins 4, 12, 13, 3) — Data on these inputs is loaded into the counter when PE is taken high.

Carry In, (Pin 5) — This active-low input is used when cascading stages. Carry In is usually connected to Carry Out of the previous stage. While high, Clock is inhibited.

Clock, (Pin 15) — Binary data is incremented or decremented, depending on the direction of count, on the positive transition of this input.

OUTPUTS

Q0, Q1, Q2, Q3, Binary outputs (Pins 6, 11, 14, 2) — Binary data is present on these outputs with Q0 corresponding to the least significant bit.

Carry Out, (Pin 7) — Used when cascading stages, Carry Out is usually connected to Carry In of the next stage. This synchronous output is active low and may also be used to indicate terminal count.

CONTROLS

PE, Preset Enable, (Pin 1) — Asynchronously loads data on the Preset Inputs. This pin is active high and inhibits the clock when high.

R, Reset, (Pin 9) — Asynchronously resets the Q outputs to a low state. This pin is active high and inhibits the clock when high.

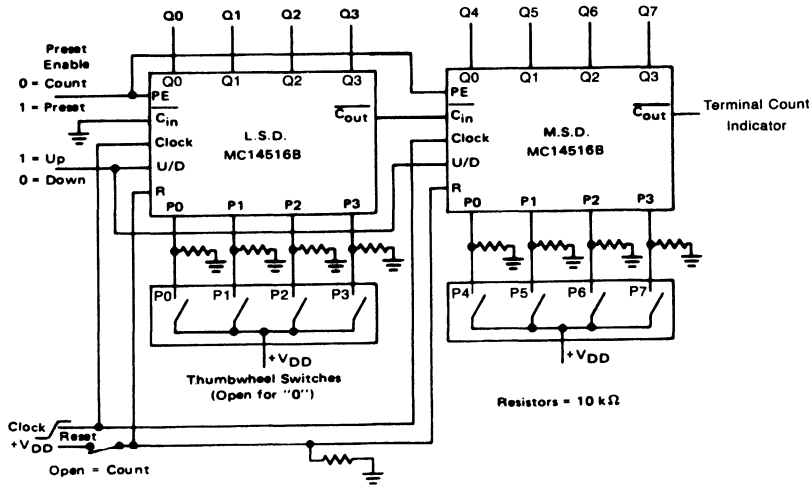
Up/Down, (Pin 10) — Controls the direction of count, high for up count, low for down count.

SUPPLY PINS

V_{SS}, Negative Supply Voltage, (Pin 8) — This pin is usually connected to ground.

V_{DD}, Positive Supply Voltage, (Pin 16) — This pin is connected to a positive supply voltage ranging from 3.0 volts to 18.0 volts.

FIGURE 3 — PRESETTABLE CASCADED 8-BIT UP/DOWN COUNTER



Note: The Least Significant Digit (L.S.D.) counts from a preset value once Preset Enable (PE) goes low. The Most Significant Digit (M.S.D.) is disabled while $\overline{C_{in}}$ is high. When the count of the L.S.D. reaches 0 (count down mode) or reaches 15 (count up mode), $\overline{C_{out}}$ goes low for one complete clock cycle, thus allowing the next counter to decrement/increment one count. (See Timing Diagram) The L.S.D. now counts through another cycle (15 clock pulses) and the above cycle is repeated.

6

TIMING DIAGRAM FOR THE PRESETTABLE CASCADED 8-BIT UP/DOWN COUNTER

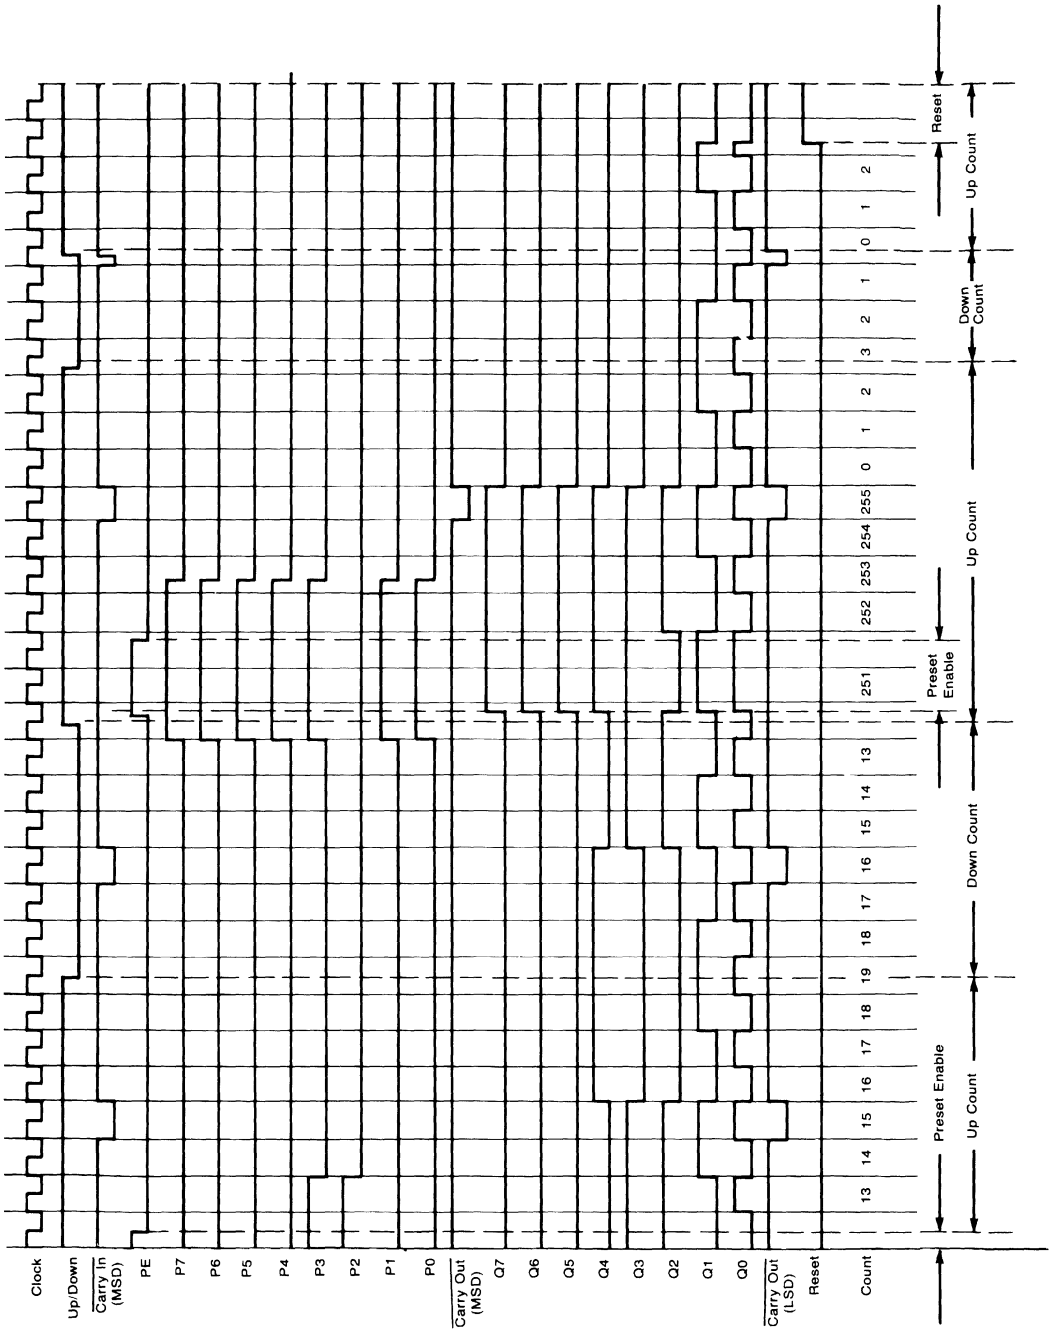


FIGURE 4 — PROGRAMMABLE CASCADED FREQUENCY DIVIDER

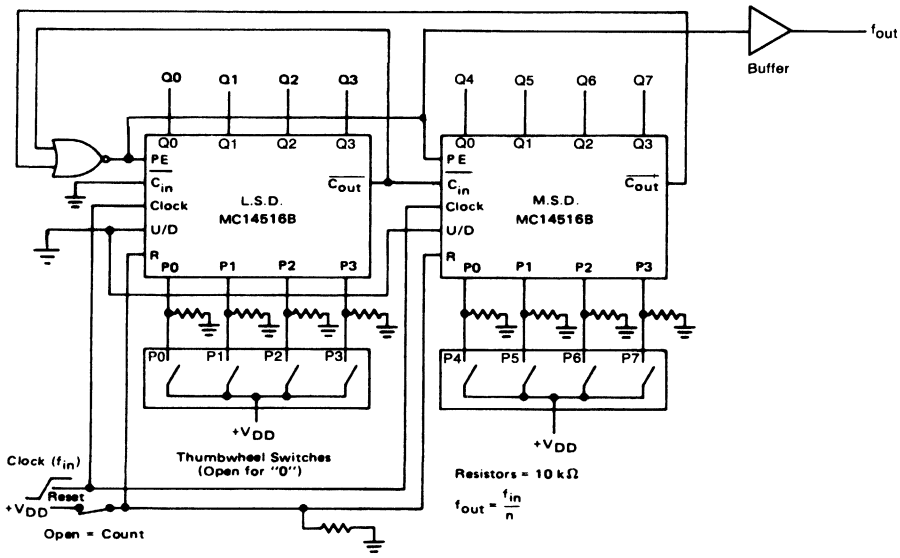

Note: The programmable frequency divider can be set by applying the desired divide ratio, in binary, to the preset inputs. For example, the maximum divide ratio of 255 may be obtained by applying a 1111 1111 to the preset inputs P0 to P7. For this divide operation, both counters should be configured in the count down mode. The divide ratio of zero is an undefined state and should be avoided.

6

MOTOROLA

MC14517B

DUAL 64-BIT STATIC SHIFT REGISTER

The MC14517B dual 64-bit static shift register consists of two identical, independent, 64-bit registers. Each register has separate clock and write enable inputs, as well as outputs at bits 16, 32, 48, and 64. Data at the data input is entered by clocking, regardless of the state of the write enable input. An output is disabled (open circuited) when the write enable input is high. During this time, data appearing at the data input as well as the 16-bit, 32-bit, and 48-bit taps may be entered into the device by application of a clock pulse. This feature permits the register to be loaded with 64 bits in 16 clock periods, and also permits bus logic to be used. This device is useful in time delay circuits, temporary memory storage circuits, and other serial shift register applications.

- Diode Protection on All Inputs
- Fully Static Operation
- Output Transitions Occur on the Rising Edge of the Clock Pulse
- Exceedingly Slow Input Transition Rates May Be Applied to the Clock Input
- 3-State Output at 64th-Bit Allows Use in Bus Logic Applications
- Shift Registers of any Length may be Fully Loaded with 16 Clock Pulses
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.004.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14518B
MC14520B

DUAL UP COUNTERS

The MC14518B dual BCD counter and the MC14520B dual binary counter are constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. Each consists of two identical, independent, internally synchronous 4-stage counters. The counter stages are type D flip-flops, with interchangeable Clock and Enable lines for incrementing on either the positive-going or negative-going transition as required when cascading multiple stages. Each counter can be cleared by applying a high level on the Reset line. In addition, the MC14518B will count out of all undefined states within two clock periods. These complementary MOS up counters find primary use in multi-stage synchronous or ripple counting applications requiring low power dissipation and/or high noise immunity.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Internally Synchronous for High Internal and External Speeds
- Logic Edge-Clocked Design – Incremented on Positive Transition of Clock or Negative Transition on Enable
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

MC14519B

4-BIT AND/OR SELECTOR
or
QUAD 2-CHANNEL DATA SELECTOR
or
QUAD EXCLUSIVE "NOR" GATE

The MC14519B is constructed with MOS P-channel and N-channel enhancement mode devices in a monolithic structure. These complementary MOS logic gates find primary use where low power dissipation and/or high noise immunity is desired.

This device provides three functions in one package; a 4-Bit AND/OR Selector, a Quad 2-Channel Data Selector, or a Quad Exclusive NOR Gate.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Plug-In Replacement for CD4019 in Most Applications

1	1	1	X0 ⊕ Y0	X1 ⊕ Y1	X2 ⊕ Y2	X3 ⊕ Y3	Exclusive OR

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14521B

24-STAGE FREQUENCY DIVIDER

The MC14521B consists of a chain of 24 flip-flops with an input circuit that allows three modes of operation. The input will function as a crystal oscillator, an RC oscillator, or as an input buffer for an external oscillator. Each flip-flop divides the frequency of the previous flip-flop by two, consequently this part will count up to 2^{24} = 16,777,216. The count advances on the negative going edge of the clock. The outputs of the last seven-stages are available for added flexibility.

- All Stages are Resettable
- Reset Disables the RC Oscillator for Low Standby Power Drain
- RC and Crystal Oscillator Outputs Are Capable of Driving External Loads
- Test Mode to Reduce Test Time
- V_{DD}' and V_{SS}' Pins Brought Out on Crystal Oscillator Inverter to Allow the Connection of External Resistors for Low-Power Operation
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range.

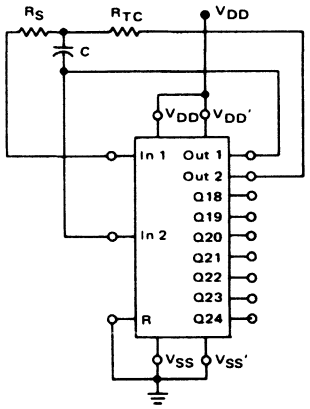

FIGURE 8 – FUNCTIONAL TEST CIRCUIT

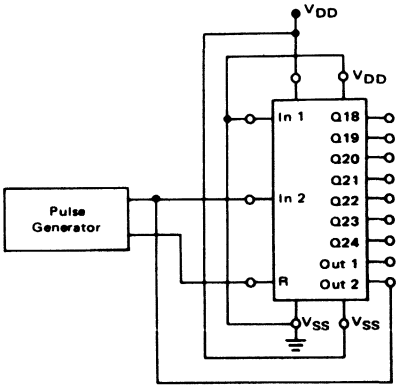

FUNCTIONAL TEST SEQUENCE

A test function (see Figure 8) has been included for the reduction of test time required to exercise all 24 counter stages. This test function divides the counter into three 8-stage sections, and 255 counts are loaded in each of the 8-stage sections in parallel. All flip-flops are now at a logic "1". The counter is now returned to the normal 24-stages in series configuration. One more pulse is entered into Input 2 (In 2) which will cause the counter to ripple from an all "1" state to an all "0" state.

INPUTS		OUTPUTS				COMMENTS
Reset	In 2	Out 2	V_{SS}'	V_{DD}'	Q18 thru Q24	
1	0	0	V_{DD}	Gnd	0	Counter is in three 8-stage sections in parallel mode. Counter is reset. In 2 and Out 2 are connected together.
0	1	1				First "0" to "1" transition on In 2, Out 2 node.
	0	0				255 "0" to "1" transitions are clocked into this In 2, Out 2 node.
	1	1				
	–	–				
	–	–				
	–	–				
	1	1			1	The 255th "0" to "1" transition.
	0	0			1	
	0	0	Gnd		1	
	1	0		V_{DD}	1	Counter converted back to 24-stages in series mode.
	1	0			1	Out 2 converts back to an output.
	0	1			0	Counter ripples from an all "1" state to an all "0" stage.

MOTOROLA

MC14522B
MC14526B

PRESETTABLE 4-BIT DOWN COUNTERS

The MC14522B BCD counter and the MC14526B binary counter are constructed with MOS P-channel and N-channel enhancement mode devices in a monolithic structure.

These devices are presettable, cascadable, synchronous down counters with a decoded "0" state output for divide-by-N applications. In single stage applications the "0" output is applied to the Preset Enable input. The Cascade Feedback input allows cascade divide-by-N operation with no additional gates required. The Inhibit input allows disabling of the pulse counting function. Inhibit may also be used as a negative edge clock.

These complementary MOS counters can be used in frequency synthesizers, phase-locked loops, and other frequency division applications requiring low power dissipation and/or high noise immunity.

- **Supply Voltage Range = 3.0 Vdc to 18 Vdc**
- Logic Edge-Clocked Design — Incremented on Positive Transition of Clock or Negative Transition of Inhibit
- **Asynchronous Preset Enable**
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

Notes:
* Output "0" is low when reset goes high only if PE and CF are low.
** Output "0" is high when reset is low, only if CF is high and count is 0000.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

PIN DESCRIPTIONS

Preset Enable (Pin 3) — If Reset is low, a high level on the Preset Enable input asynchronously loads the counter with the programmed values on P0, P1, P2, and P3.

Inhibit (Pin 4) — A high level on the Inhibit input prevents the Clock from decrementing the counter. With Clock (pin 6) held high, Inhibit may be used as a negative edge clock input.

Clock (Pin 6) — The counter decrements by one for each rising edge of Clock. See the Function Table for level requirements on the other inputs.

Reset (Pin 10) — A high level on Reset asynchronously forces Q0, Q1, Q2, and Q3 low and, if Cascade Feedback is high, causes the "0" output to go high.

"0" (Pin 12) — The "0" (Zero) output issues a pulse one clock period wide when the counter reaches terminal count (Q0 = Q1 = Q2 = Q3 = low) if Cascade Feedback is high and Preset Enable is low. When presetting the counter to a value other than all zeroes, the "0" output is valid after the rising edge of Preset Enable (when Cascade Feedback is high). See the Function Table.

Cascade Feedback (Pin 13) — If the Cascade Feedback input is high, a high level is generated at the "0" output when the count is all zeroes. If Cascade Feedback is low, the "0" output depends on the Preset Enable input level. See the Function Table.

P0, P1, P2, P3 (Pins 5, 11, 14, 2) — These are the preset data inputs. P0 is the LSB.

Q0, Q1, Q2, Q3 (Pins 7, 9, 15, 1) — These are the synchronous counter outputs. Q0 is the LSB.

V_{SS} (Pin 8) — The most negative power supply potential. This pin is usually ground.

V_{DD} (Pin 16) — The most positive power supply potential. V_{DD} may range from 3 to 18 V with respect to V_{SS}.

APPLICATIONS INFORMATION

Divide-By-N, Single Stage

Figure 11 shows a single stage divide-by-N application. The MC14522B (BCD version) can accept a number greater than 9 and count down in binary fashion. Hence, the BCD and binary single stage divide-by-N counters (as shown in Figure 11) function the same.

To initialize counting a number, N is set on the parallel inputs (P0, P1, P2, and P3) and reset is taken high asynchronously. A zero is forced into the master and slave of each bit and, at the same time, the "0" output goes high. Because Preset Enable is tied to the "0" output, preset is enabled. Reset must be released while the Clock is high so the slaves of each bit may receive N before the Clock goes low. When the Clock goes low and Reset is low, the "0" output goes low (if P0 through P3 are unequal to zero).

The counter downcounts with each rising edge of the Clock. When the counter reaches the zero state, an output pulse occurs on "0" which presets N. The propagation delays from the Clock's rising and falling edges to the "0" output's rising and falling edges are about equal, making the "0" output pulse approximately equal to that of the Clock pulse.

The Inhibit pin may be used to stop pulse counting. When this pin is taken high, decrementing is inhibited.

Cascaded, Presettable Divide-By-N

Figure 12 shows a three stage cascade application. Taking Reset high loads N. Only the first stage's Reset pin (least significant counter) must be taken high to cause the preset for all stages, but all pins could be tied together, as shown.

When the first stage's Reset pin goes high, the "0" output is latched in a high state. Reset must be released while Clock is high and time allowed for Preset Enable to load N into all stages before Clock goes low.

When Preset Enable is high and Clock is low, time must be allowed for the zero digits to propagate a Cascade Feedback to the first non-zero stage. Worst case is from the most significant bit (M.S.B.) to the L.S.B., when the L.S.B. is equal to one (i.e. N = 1).

After N is loaded, each stage counts down to zero with each rising edge of Clock. When any stage reaches zero and the leading stages (more significant bits) are zero, the "0" output goes high and feeds back to the preceding stage. When all stages are zero, the Preset Enable automatically loads N while the Clock is high and the cycle is renewed.

FIGURE 11 — ÷N COUNTER

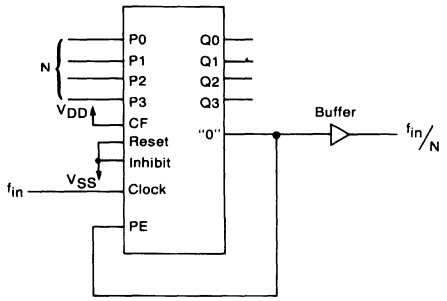

FIGURE 12 — 3 STAGES CASCADED

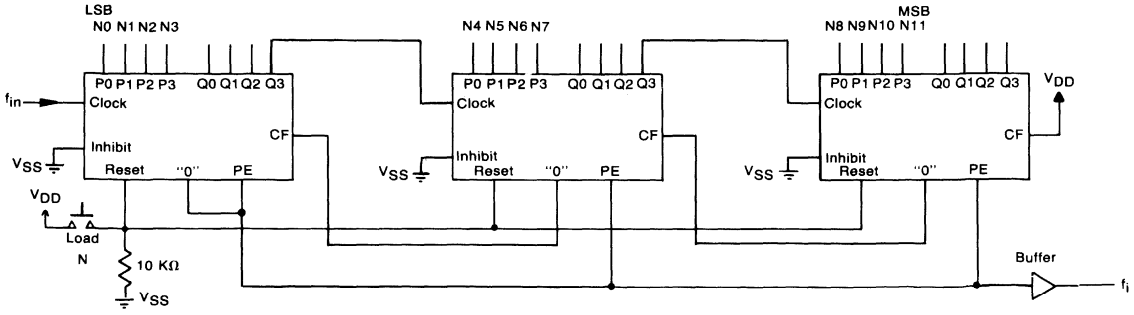

MOTOROLA

MC14527B

BCD RATE MULTIPLIER

The MC14527B BCD rate multiplier (DRM) provides an output pulse rate based upon the BCD input number. For example, if 6 is the BCD input number, there will be six output pulses for every ten input pulses. This part may be used for arithmetic operations including multiplication and division. Typical applications include digital filters, motor speed control and frequency synthesizers.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Output Clocked on the Negative Going Edge of Clock
- Strobe for Inhibiting or Enabling Outputs
- Enable and Cascade Inputs for Cascade Operation of Two or More DRMs
- "9" Output for the Parallel Enable Configuration and DRMs in Cascade
- Complementary Outputs
- Clear and Set to Nine Inputs

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.0012.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14528B

DUAL MONOSTABLE MULTIVIBRATOR

The MC14528B is a dual, retriggerable, resettable monostable multivibrator. It may be triggered from either edge of an input pulse, and produces an output pulse over a wide range of widths, the duration of which is determined by the external timing components, C_X and R_X.

- Separate Reset Available
- Diode Protection on All Inputs
- Triggerable from Leading or Trailing Edge Pulse
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-Pin Replacement with the MC14538B

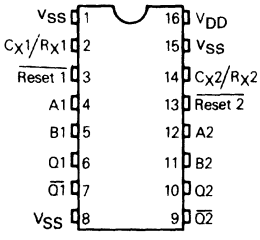
PIN ASSIGNMENT



This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14529B

DUAL 4-CHANNEL ANALOG DATA SELECTOR

The MC14529B analog data selector is a dual 4-channel or single 8-channel device depending on the input coding. The device is suitable for digital as well as analog application, including various one-of-four and one-of-eight data selector functions. Since the device has bidirectional analog characteristics it can also be used as a dual binary to 1-of-4 or a binary to 1-of-8 decoder.

- Data Paths Are Bidirectional
- 3-State Outputs
- Linear "On" Resistance
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range.

MOTOROLA

MC14530B

DUAL 5-INPUT MAJORITY LOGIC GATE

The MC14530B dual five-input majority logic gate is constructed with P-channel and N-channel enhancement mode devices in a single monolithic structure. Combinational and sequential logic expressions are easily implemented with the majority logic gate, often resulting in fewer components than obtainable with the more basic gates. This device can also provide numerous logic functions by using the W and some of the logic (A thru E) inputs as control inputs.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

6

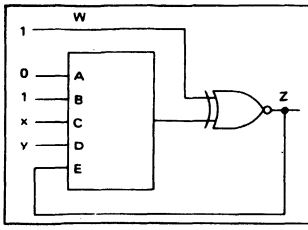
SEQUENTIAL LOGIC APPLICATIONS

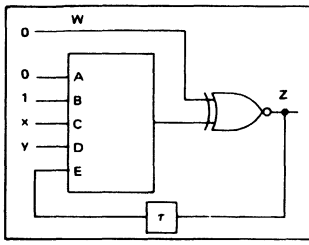
COINCIDENT FLIP-FLOP



x	y	Q_{n+1}
0	0	0
0	1	Q
1	0	Q
1	1	1

A flip-flop that will change only when both inputs agree.

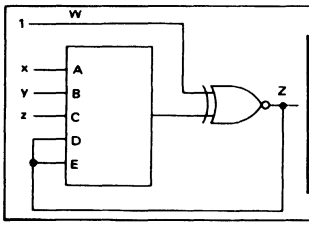
ASTABLE MULTIVIBRATOR



x	y	Q_{n+1}
0	0	1
0	1	2τ
1	0	2τ
1	1	0

A flip-flop with three output conditions, where the third state is in oscillation between "1" and "0". The period of oscillation is twice the delay of the gate and the feedback element.

COINCIDENT FLIP-FLOP



x	y	z	Q_{n+1}
0	0	0	0
0	0	1	Q_n
0	1	0	Q_n
0	1	1	Q_n
1	0	0	Q_n
1	0	1	Q_n
1	1	0	Q_n
1	1	1	1

The flip-flop changes state only when all "1's" or all "0's" are entered. This configuration may be extended by cascading M_5 gates to cover n-inputs where all inputs must be "1's" or "0's" before the output will change. As an example, this configuration is useful for controlling an n-stage up/down counter that is to cycle from a minimum to maximum count and back again without flipping over (from all "1's" to all "0's".)

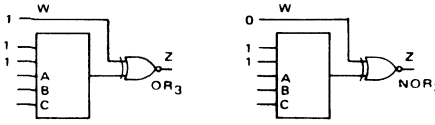
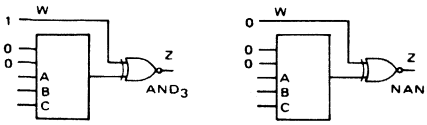
3-Input Majority Gates



3-Input OR Gate

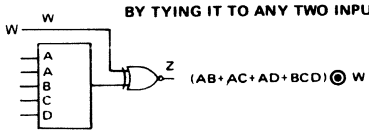
3-Input NOR Gate



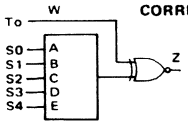
3-Input AND Gate

3-Input NAND Gate

DOUBLING THE WEIGHT OF INPUT VARIABLE A BY TYING IT TO ANY TWO INPUTS

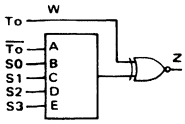


CORRELATION OF MULTIPLE SAMPLES WITH A TEST BIT

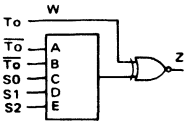


Correlation of 60%, 80%, 100%

The gate will have a "1" output if the test bit To matches or correlates with 3, 4 or 5 of the sample bits S0-S4.



Correlation of 75%, 100%.



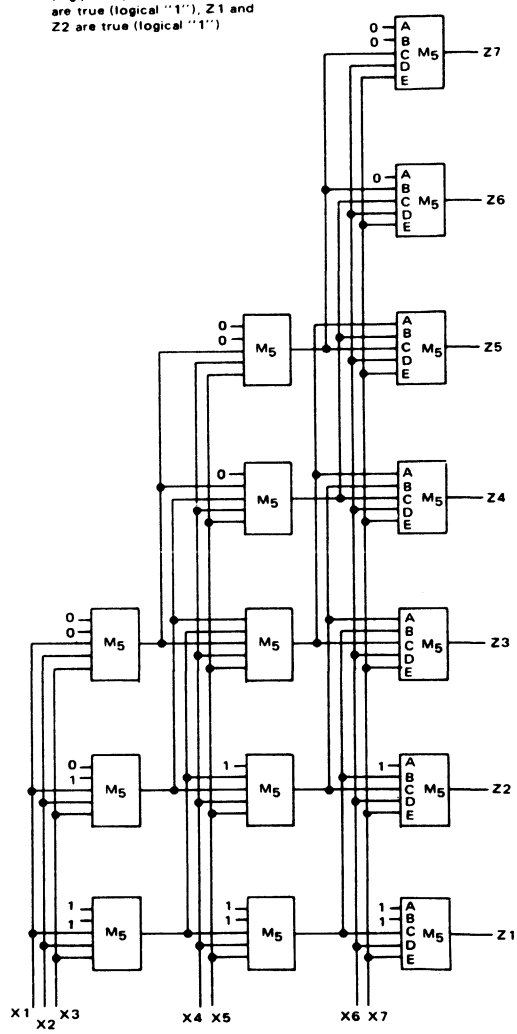
Correlation of 100%

5-INPUT MAJORITY LOGIC GATE APPLICATIONS

Each package labeled M_5 is a single majority logic gate using five inputs, A thru E, and one output Z.

1. Majority Logic Gate Array yielding the symetric function of 1 thru 7 variables true, out of 7 input variables (X1 . . . X7)

(e.g., if any two input variables are true (logical "1"), Z1 and Z2 are true (logical "1")



6

MOTOROLA

MC14531B

12-BIT PARITY TREE

The MC14531B 12-bit parity tree is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. The circuit consists of 12 data-bit inputs (D0 thru D11), and even or odd parity selection input (W) and an output (Q). The parity selection input can be considered as an additional bit. Words of less than 13 bits can generate an even or odd parity output if the remaining inputs are selected to contain an even or odd number of ones, respectively. Words of greater than 12-bits can be accommodated by cascading other MC14531B devices by using the W input. Applications include checking or including a redundant (parity) bit to a word for error detection/correction systems, controller for remote digital sensors or switches (digital event detection/correction), or as a multiple input summer without carries.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- All Outputs Buffered
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range
- Variable Word Length
- Diode Protection on All Inputs

MOTOROLA

MC14532B

8-BIT PRIORITY ENCODER

The MC14532B is constructed with complementary MOS (CMOS) enhancement mode devices. The primary function of a priority encoder is to provide a binary address for the active input with the highest priority. Eight data inputs (D0 thru D7) and an enable input (E_{in}) are provided. Five outputs are available, three are address outputs (Q0 thru Q2), one group select (GS) and one enable output (E_{out}).

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-Power Schottky TTL Load over the Rated Temperature Range

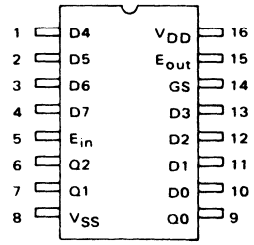
PIN ASSIGNMENT



This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

FIGURE 4 – TWO MC14532B's CASCADED FOR 4-BIT OUTPUT

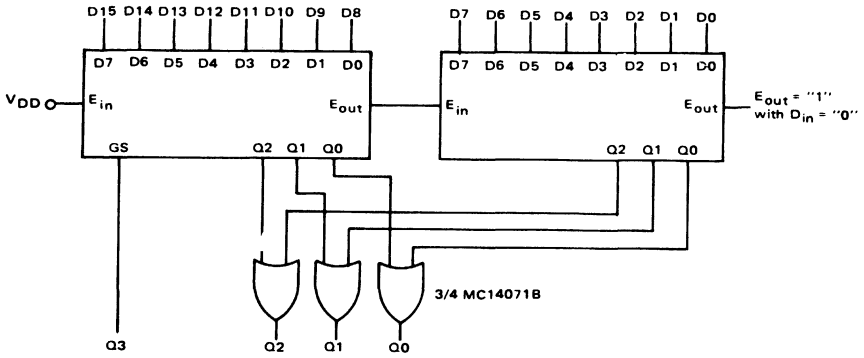

FIGURE 5 – DIGITAL TO ANALOG AND ANALOG TO DIGITAL CONVERTER

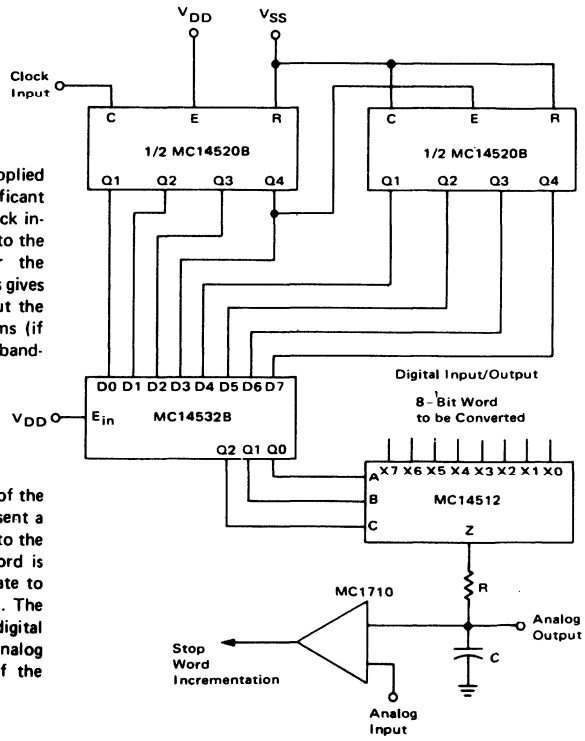

DIGITAL TO ANALOG CONVERSION

The digital eight-bit word to be converted is applied to the inputs of the MC14512 with the most significant bit at X7 and the least significant bit at X0. A clock input of up to 2.5 MHz (at V_{DD} = 10 V) is applied to the MC14520B. A compromise between I_{bias} for the MC1710 and ΔR between N and P-channel outputs gives a value of R of 33 k ohms. In order to filter out the switching frequencies, RC should be about 1.0 ms (if R = 33 k ohms, C ≈ 0.03 μF). The analog 3.0 dB bandwidth would then be dc to 1.0 kHz.

ANALOG TO DIGITAL CONVERSION

An analog signal is applied to the analog input of the MC1710. A digital eight-bit word known to represent a digitized level less than the analog input is applied to the MC14512 as in the D to A conversion. The word is incremented at rates sufficient to allow steady state to be reached between incrementations (i.e. 3.0 ms). The output of the MC1710 will change when the digital input represents the first digitized level above the analog input. This word is the digital representation of the analog word.

MOTOROLA

MC14534B

5 CASCADED BCD COUNTERS

The MC14534B is composed of five BCD ripple counters that have their respective outputs multiplexed using an internal scanner. Outputs of each counter are selected by the scanner and appear on four (BCD) pins. Selection is indicated by a logic high on the appropriate digit select pin. Both BCD and digit select outputs have three-state controls providing an "open-circuit" when these controls are high and allowing multiplexing. Cascading may be accomplished by using the carry-out pin. The counters and scanner can be independently reset by applying a high to the counter master reset (MR) and the scanner reset (SR). The MC14534B was specifically designed for application in real time or event counters where continual updating and multiplexed displays are used.

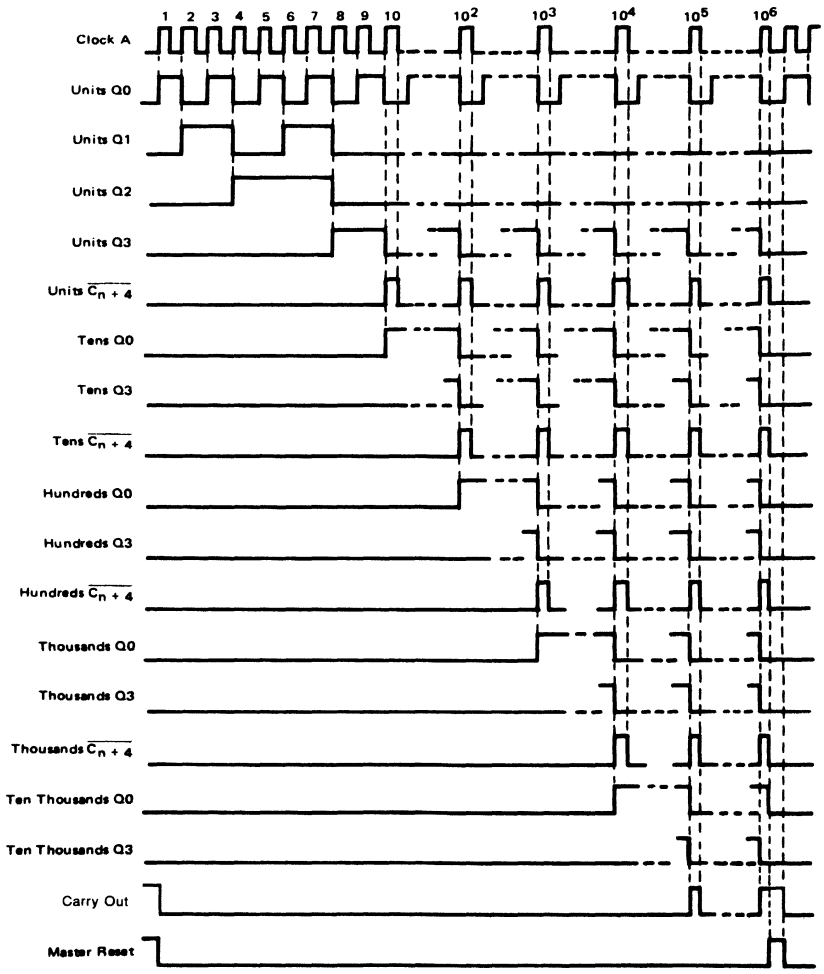
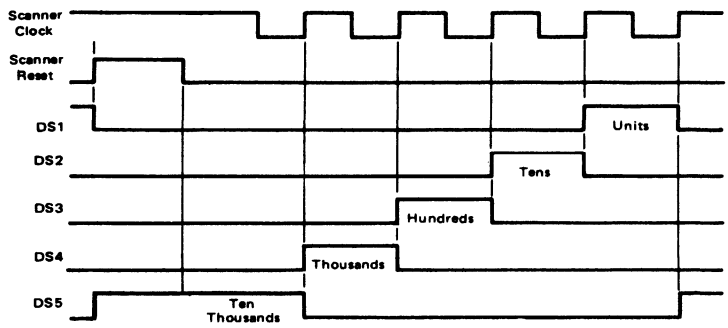
COUNTER TIMING DIAGRAM



MODE CONTROL TRUTH TABLE

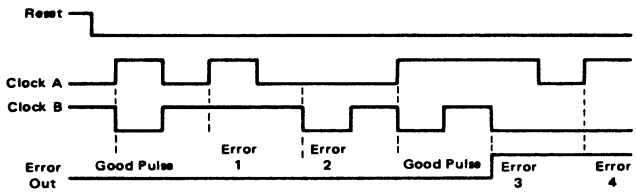
Mode A	Mode B	First Stage Output	Carry to Second Stage	Application
0	0	Normal Count and Display	At 9 to 0 transition of first stage	5-digit Counter
0	1	Inhibited	Input Clock	Test Mode: Clock directly into stages 1, 2, and 4.
1	1	Inhibited	At 4 to 5 transition of first stage	4-digit counter with ÷ 10 and roundoff at front end.
1	0	Counts 3, 4, 5, 6, 7 = 5 Counts 8, 9, 0, 1, 2 = 0	At 7 to 8 transition of first stage	4-digit counter with 1/2 pence capability.

SCANNER TIMING DIAGRAM



Note: If Mode B = 1, the first decade is inhibited and S1 will not go high, and the cycle will be shortened to four stages.
DS5 is selected automatically when Scanner Reset goes high.

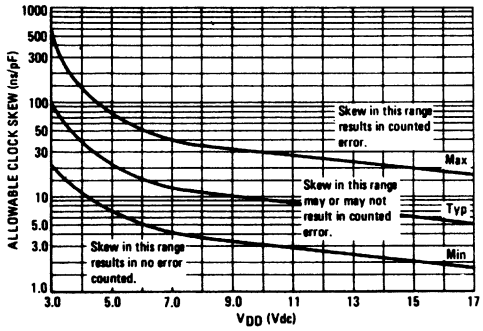
ERROR DETECTION TIMING DIAGRAM



Note: Error detector looks for inverted pulse on Clock B. Whenever a positive edge at Clock A is not accompanied by a negative pulse at Clock B (or vice-versa) within a time period of the one-shots an error is counted. Three errors result in Error Out to go to a "1". If error detection is not needed, tie Clock B high or low and leave Pins 1 and 22 unconnected.

6

CLOCK SKEW RANGE

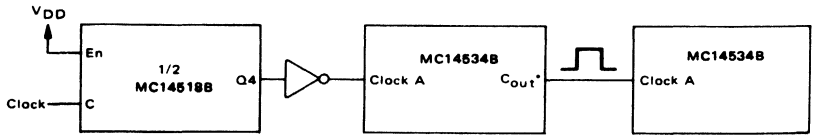


Notes:

1. The skew is the time difference between the low-to-high transition of C_A to the high-to-low transition of C_B or vice-versa. Capacitors C1 = C22 tied from pins 1 and 22 to V_{SS}.
2. This graph is accurate for C1 = C22 $\geq$ 100 pF.
3. When the error detection circuitry is not used, pins 1 and 22 are left open.

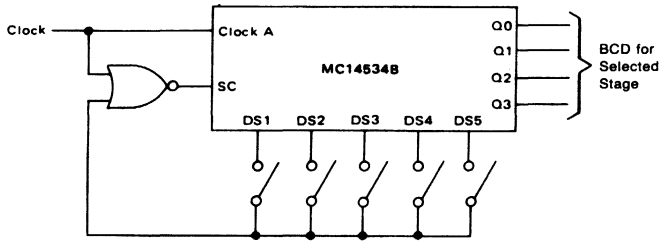
APPLICATIONS INFORMATION

FIGURE 1 – CASCADE OPERATION



*Carry Out is high for a single clock period when all five BCD stages go to zero. (Carry Out also goes high when MR is applied.)

FIGURE 2 — FORCING A BCD STAGE TO THE Q OUTPUTS



When the Q outputs of a given stage are required, this configuration will lock up the selected stage within four clock cycles. The select line feedback may be hardwired or switched.

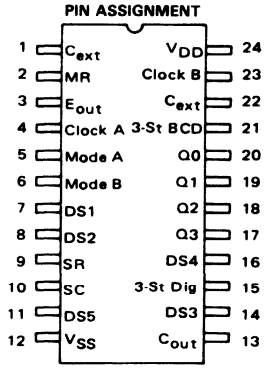
PIN ASSIGNMENT



MOTOROLA

MC14536B

PROGRAMMABLE TIMER

The MC14536B programmable timer is a 24-stage binary ripple counter with 16 stages selectable by a binary code. Provisions for an on-chip RC oscillator or an external clock are provided. An on-chip monostable circuit incorporating a pulse-type output has been included. By selecting the appropriate counter stage in conjunction with the appropriate input clock frequency, a variety of timing can be achieved.

- 24 Flip-Flop Stages – Will Count From 2^0 to 2^{24}
- Last 16 Stages Selectable By Four-Bit Select Code
- 8-Bypass Input Allows Bypassing of First Eight Stages
- Set and Reset Inputs
- Clock Inhibit and Oscillator Inhibit Inputs
- On-Chip RC Oscillator Provisions
- On-Chip Monostable Output Provisions
- Clock Conditioning Circuit Permits Operation With Very Long Rise and Fall Times
- Test Mode Allows Fast Test Sequence
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

6

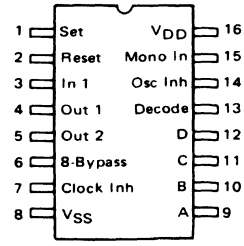
This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

PIN ASSIGNMENT



PIN DESCRIPTIONS

INPUTS

SET (Pin 1) — A high on Set asynchronously forces Decode Out to a high level. This is accomplished by setting an output conditioning latch to a high level while at the same time resetting the 24 flip-flop stages. After Set goes low (inactive), the occurrence of the first negative clock transition on IN_1 causes Decode Out to go low. The counter's flip-flop stages begin counting on the second negative clock transition of IN_1. When Set is high, the on-chip RC oscillator is disabled. This allows for very low-power standby operation.

RESET (Pin 2) — A high on Reset asynchronously forces Decode Out to a low level; all 24 flip-flop stages are also reset to a low level. Like the Set input, Reset disables the on-chip RC oscillator for standby operation.

IN_1 (Pin 3) — The device's internal counters advance on the negative-going edge of this input. IN_1 may be used as an external clock input or used in conjunction with OUT_1 and OUT_2 to form an RC oscillator. When an external clock is used, both OUT_1 and OUT_2 may be left unconnected or used to drive 1 LSTTL or several CMOS loads.

8-BYPASS (Pin 6) — A high on this input causes the first 8 flip-flop stages to be bypassed. This device essentially becomes a 16-stage counter with all 16 stages selectable. Selection is accomplished by the A, B, C, and D inputs. (See the truth tables.)

CLOCK INHIBIT (Pin 7) — A high on this input disconnects the first counter stage from the clocking source. This holds the present count and inhibits further counting. However, the clocking source may continue to run. Therefore, when Clock Inhibit is brought low, no oscillator start-up time is required. When Clock Inhibit is low, the counter will start counting on the occurrence of the first negative edge of the clocking source at IN_1.

OSC INHIBIT (Pin 14) — A high level on this pin stops the RC oscillator which allows for very low-power standby operation. May also be used, in conjunction with an external clock, with essentially the same results as the Clock Inhibit input.

MONO-IN (Pin 15) — Used as the timing pin for the on-chip monostable multivibrator. If the Mono-In input is connected to V_{SS}, the monstable circuit is disabled, and Decode Out is directly connected to the selected Q output. The monostable circuit is enabled if a resistor is connected between Mono-In and V_{DD}. This resistor and the device's internal capacitance will determine the minimum output pulse widths. With the addition of an external capacitor to V_{SS}, the pulse width range may be extended. For reliable operation the resistor value should be limited to the range of 5 kΩ to 100 kΩ and the capacitor value should be limited to a maximum of 1000 pf. (See figures 3, 4, 5, and 10).

A, B, C, D (Pins 9, 10, 11, 12) — These inputs select the flip-flop stage to be connected to Decode Out. (See the truth tables.)

OUTPUTS

OUT_1, OUT_2 (Pin 4, 5) — Outputs used in conjunction with IN_1 to form an RC oscillator. These outputs are buffered and may be used for 2^0 frequency division of an external clock.

DECODE OUT (Pin 13) — Output function depends on configuration. When the monostable circuit is disabled, this output is a 50% duty cycle square wave during free run.

TEST MODE

The test mode configuration divides the 24 flip-flop stages into three 8-stage sections to facilitate a fast test sequence. The test mode is enabled when 8-Bypass, Set and Reset are at a high level. (See Figure 8.)

FIGURE 6 — POWER DISSIPATION TEST CIRCUIT AND WAVEFORM

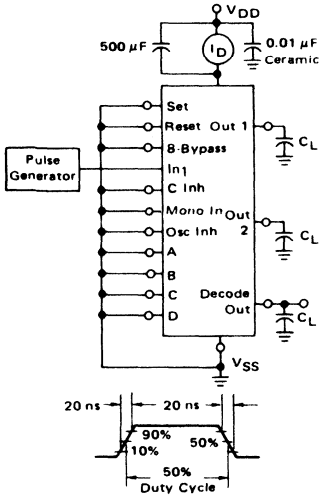

FIGURE 7 — SWITCHING TIME TEST CIRCUIT AND WAVEFORMS

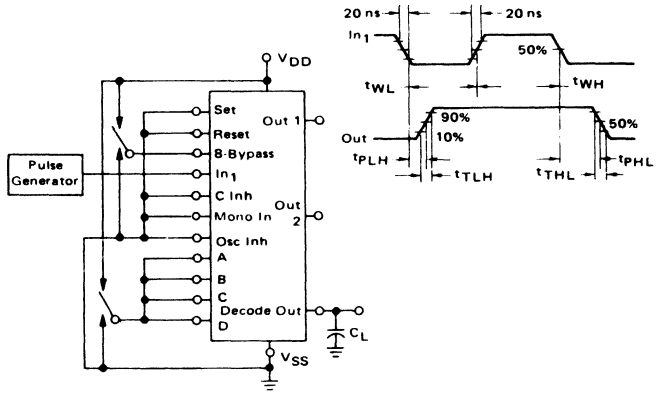

FIGURE 8 — FUNCTIONAL TEST CIRCUIT

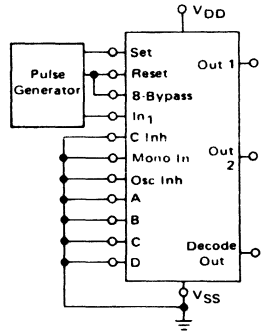


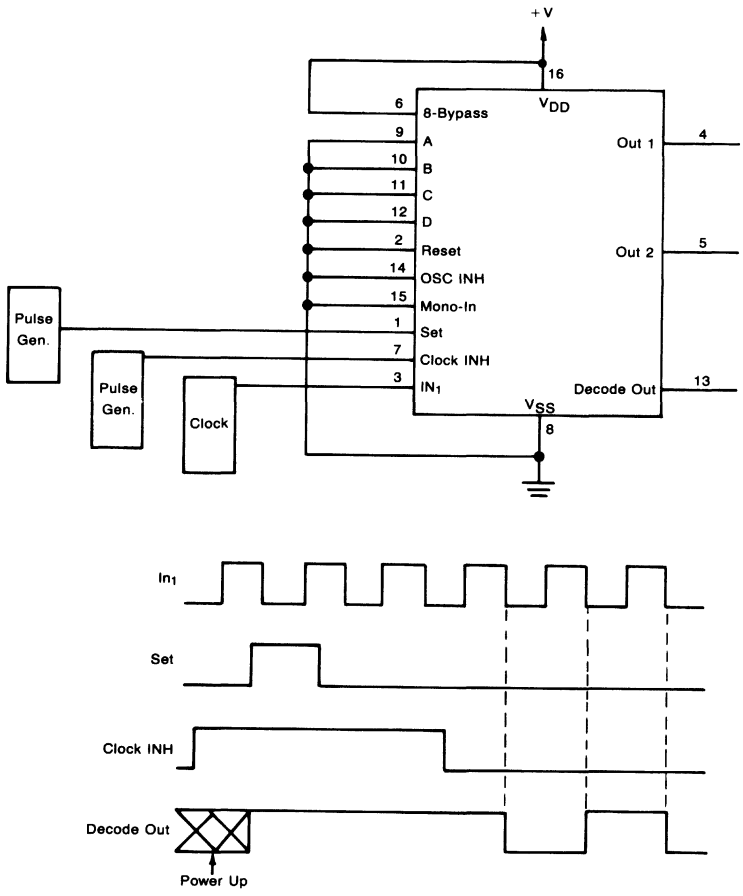
FUNCTIONAL TEST SEQUENCE

Test function (Figure 8) has been included for the reduction of test time required to exercise all 24 counter stages. This test function divides the counter into three 8-stage sections and 255 counts are loaded in each of the 8-stage sections in parallel. All flip-flops are now at a "1". The counter is now returned to the normal 24-stages in series configuration. One more pulse is entered into In_1 which will cause the counter to ripple from an all "1" state to an all "0" state.

FUNCTIONAL TEST SEQUENCE

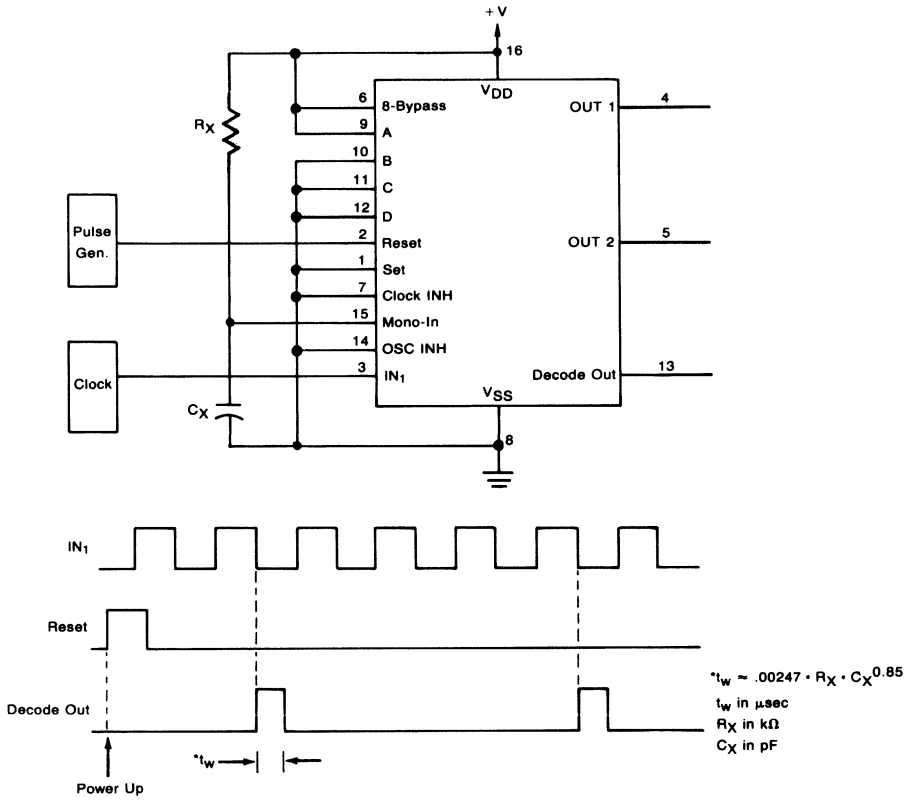
INPUTS				OUTPUTS	COMMENTS
In_1	Set	Reset	8-Bypass	Decade Out Q1 thru Q24	
1	0	1	1	0	All 24 stages are in Reset mode.
1	1	1	1	0	Counter is in three 8-stage sections in parallel mode.
0	1	1	1	0	First "1" to "0" transition of clock.
1 0 – – –	1	1	1		255 "1" to "0" transitions are clocked in the counter.
0	1	1	1	1	The 255 "1" to "0" transition.
0	0	0	0	1	Counter converted back to 24 stages in series mode. Set and Reset must be connected together and simultaneously go from "1" to "0".
1	0	0	0	1	In_1 Switches to a "1".
0	0	0	0	0	Counter Ripples from an all "1" state to an all "0" state.

FIGURE 9 — TIME INTERVAL CONFIGURATION USING AN EXTERNAL CLOCK, SET, AND CLOCK INHIBIT FUNCTIONS (DIVIDE-BY-2 CONFIGURED)



Note: When power is first applied to the device, Decode Out can be either at a high or low state. On the rising edge of a Set pulse the output goes high if initially at a low state. The output remains high if initially at a high state. Because Clock Inh is held high, the clock source on the input pin has no effect on the output. Once Clock Inh is taken low, the output goes low on the first negative clock transition. The output returns high depending on the 8-Bypass, A, B, C, and D inputs, and the clock input period. A 2^n frequency division (where n = the number of stages selected from the truth table) is obtainable at Decode Out. A 2^0 -divided output of IN_1 can be obtained at OUT_1 and OUT_2.

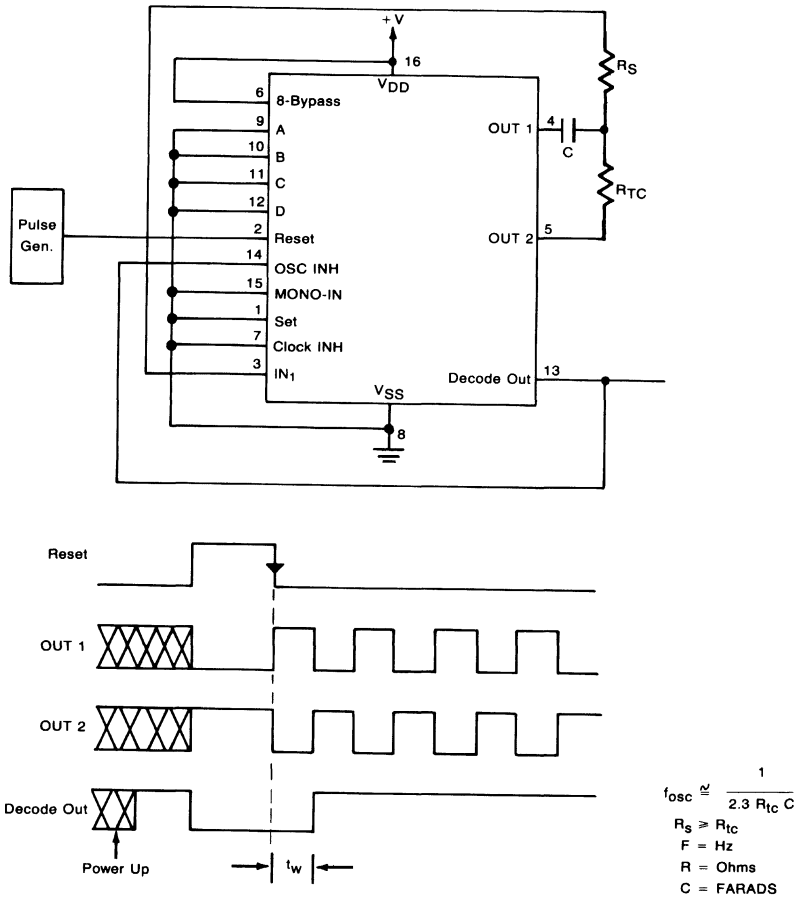
FIGURE 10 — TIME INTERVAL CONFIGURATION USING AN EXTERNAL CLOCK, RESET, AND OUTPUT MONOSTABLE TO ACHIEVE A PULSE OUTPUT. (DIVIDE-BY-4 CONGIFURED).



Note: When Power is first applied to the device with the Reset input going high, Decode Out initializes low. Bringing the Reset input low enables the chip's internal counters. After Reset goes low, the $2^n/2$ negative transition of the clock input causes Decode Out to go high. Since the Mono-In input is being used, the output becomes monostable. The pulse width of the output is dependent on the external timing components. The second and all subsequent pulses occur at $2^n \times$ (the clock period) intervals where n = the number of stages selected from the truth table.

6

FIGURE 11 — TIME INTERVAL CONFIGURATION USING ON-CHIP RC OSCILLATOR AND RESET INPUT TO INITIATE TIME INTERVAL (DIVIDE-BY-2 CONFIGURED)



Note: This circuit is designed to use the on-chip oscillation function. The oscillator frequency is determined by the external R and C components. When power is first applied to the device, Decode Out initializes to a high state. Because this output is tied directly to the Osc-Inh input, the oscillator is disabled. This puts the device in a low-current standby condition. The rising edge of the Reset pulse will cause the output to go low. This in turn causes Osc-Inh to go low. However, while Reset is high, the oscillator is still disabled (i.e.: standy condition). After Reset goes low, the output remains low for $2^n/2$ of the oscillator's period. After the part times out, the output again goes high.

MOTOROLA

MC14538B

DUAL PRECISION RETRIGGERABLE/RESETTABLE MONOSTABLE MULTIVIBRATOR

The MC14538B is a dual, retriggerable, resettable monostable multivibrator. It may be triggered from either edge of an input pulse, and produces an accurate output pulse over a wide range of widths, the duration and accuracy of which are determined by the external timing components, C_X and R_X.

- Unlimited Rise and Fall Time Allowed on the A Trigger Input
- Pulse Width Range = 10 μs to 10 s
- Latched Trigger Inputs
- Separate Latched Reset Inputs
- 3.0 Vdc to 18 Vdc Operational Limits
- Triggerable from Positive (A Input) or Negative-Going Edge (B-Input)
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin-for-pin Compatible with MC14528B and CD4528B (CD4098)
- Use the MC54/74HC4538A for Pulse Widths Less Than 10 μs with Supplies Up to 6 V.

OPERATING CONDITIONS

External Timing Resistance	R_X	–	5.0	–	*	kΩ
External Timing Capacitance	C_X	–	0	–	No Limit†	µF

* The maximum usable resistance R_X is a function of the leakage of the capacitor C_X, leakage of the MC14538B, and leakage due to board layout and surface resistance. Susceptability to externally induced noise signals may occur for $R_X > 1$ MΩ.

† If $C_X \geq 15$ µF, use discharge protection diode per Fig. 11.

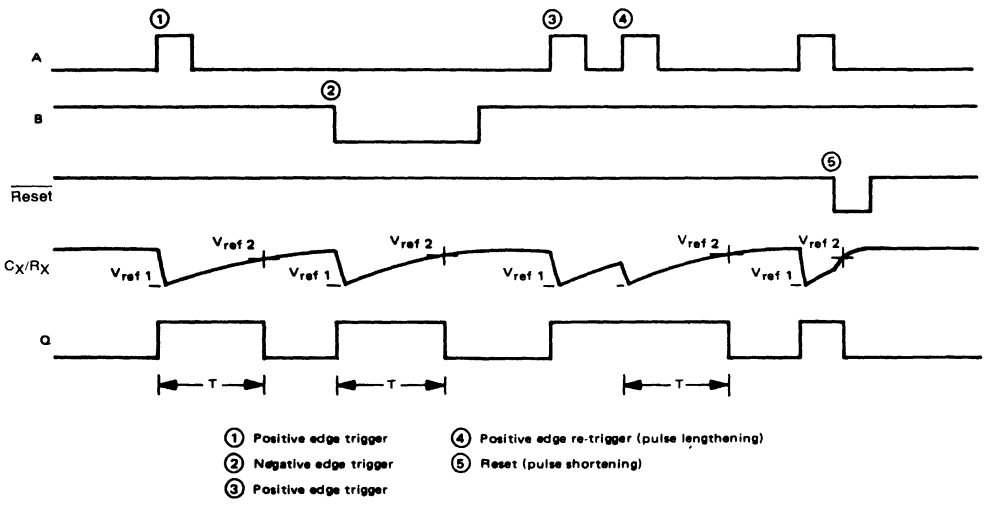
THEORY OF OPERATION

FIGURE 10 — Timing Operation



6

TRIGGER OPERATION

The block diagram of the MC14538B is shown in Figure 1, with circuit operation following.

As shown in Figure 1 and 10, before an input trigger occurs, the monostable is in the quiescent state with the Q output low, and the timing capacitor C_X completely charged to V_{DD}. When the trigger input A goes from V_{SS} to V_{DD} (while inputs B and $\overline{Reset}$ are held to V_{DD}) a valid trigger is recognized, which turns on comparator C1 and N-channel transistor N1 ①. At the same time the output latch is set. With transistor N1 on, the capacitor C_X rapidly discharges toward V_{SS} until V_{ref1} is reached. At this point the output of comparator C1 changes state and transistor N1 turns off. Comparator C1 then turns off while at the same time comparator C2 turns on. With transistor N1 off, the capacitor C_X begins to charge through the timing resistor, R_X, toward V_{DD}. When the voltage across C_X equals $V_{ref\ 2}$, comparator C2 changes state, causing the output latch to reset (Q goes low) while at the same time disabling comparator C2 ②. This ends at the timing cycle with the monostable in the quiescent state, waiting for the next trigger.

In the quiescent state, C_X is fully charged to V_{DD} causing the current through resistor R_X to be zero. Both comparators are "off" with total device current due only to reverse junction leakages. An added feature of the MC14538B is that the output latch is set via the input trigger without regard to the capacitor voltage. Thus, propagation delay from trigger to Q is independent of the value of C_X, R_X, or the duty cycle of the input waveform.

RETRIGGER OPERATION

The MC14538B is retriggered if a valid trigger occurs ③ followed by another valid trigger ④ before the Q output has returned to the quiescent (zero) state. Any retrigger, after the timing node voltage at pin 2 or 14 has begun to rise from $V_{ref\ 1}$, but has not yet reached $V_{ref\ 2}$, will cause an increase in output pulse width T. When a valid retrigger is initiated ④, the voltage at C_X/R_X will again drop to $V_{ref\ 1}$ before progressing along the RC charging curve toward V_{DD}. The Q output will remain high until time T, after the last valid retrigger.

RESET OPERATION

The MC14538B may be reset during the generation of the output pulse. In the reset mode of operation, an input pulse on $\overline{\text{Reset}}$ sets the reset latch and causes the capacitor to be fast charged to V_{DD} by turning on transistor P1 ⑤. When the voltage on the capacitor reaches $V_{ref\ 2}$, the reset latch will clear, and will then be ready to accept another pulse. If the $\overline{\text{Reset}}$ input is held low, any trigger inputs that occur will be inhibited and the Q and $\overline{Q}$ outputs of the output latch will not change. Since the Q output is reset when an input low level is detected on the $\overline{\text{Reset}}$ input, the output pulse T can be made significantly shorter than the minimum pulse width specification.

POWER-DOWN CONSIDERATIONS

Large capacitance values can cause problems due to the large amount of energy stored. When a system containing the MC14538B is powered down, the capacitor voltage may discharge from V_{DD} through the standard protection diodes at pin 2 or 14. Current through the protection diodes should be limited to 10 mA and therefore the discharge time of the V_{DD} supply must not be faster than (V_{DD}). (C)/(10 mA). For example, if V_{DD} = 10 V and C_X = 10 μF, the V_{DD} supply should discharge no faster than (10 V) × (10 μF)/(10 mA) = 10 ms. This is normally not a problem since power supplies are heavily filtered and cannot discharge at this rate.

When a more rapid decrease of V_{DD} to zero volts occurs, the MC14538B can sustain damage. To avoid this possibility use an external clamping diode, D_X, connected as shown in Fig. 11.

MOTOROLA

MC14539B

DUAL 4-CHANNEL DATA SELECTOR/MULTIPLEXER

The MC14539B data selector/multiplexer is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. The circuit consists of two sections of four inputs each. One input from each section is selected by the address inputs A and B. A "high" on the Strobe input will cause the output to remain "low".

This device finds primary application in signal multiplexing functions. It permits multiplexing from N-lines to 1-line, and can also perform parallel-to-serial conversion. The Strobe input allows cascading of n-lines to n-lines.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

MOTOROLA

MC14541B

PROGRAMMABLE TIMER

The MC14541B programmable timer consists of a 16-stage binary counter, an integrated oscillator for use with an external capacitor and two resistors, an automatic power-on reset circuit, and output control logic.

Timing is initialized by turning on power, whereupon the power-on reset is enabled and initializes the counter, within the specified V_{DD} range. With the power already on, an external reset pulse can be applied. Upon release of the initial reset command, the oscillator will oscillate with a frequency determined by the external RC network. The 16-stage counter divides the oscillator frequency (f_{osc}) with the n^{th} stage frequency being $f_{osc}/2^n$.

- Available Outputs 2^8, 2^{10}, 2^{13} or 2^{16}
- Increments on Positive Edge Clock Transitions
- Built-in Low Power RC Oscillator
  (± 2% accuracy over temperature range and ± 20% supply and ± 3% over processing at < 10 kHz)
- Oscillator May Be Bypassed if External Clock Is Available (Apply external clock to Pin 3)
- External Master Reset Totally Independent of Automatic Reset Operation
- Operates as 2^n Frequency Divider or Single Transition Timer
- Q/$\overline{Q}$ Select Provides Output Logic Level Flexibility
- Reset (auto or master) Disables Oscillator During Resetting to Provide No Active Power Dissipation
- Clock Conditioning Circuit Permits Operation with Very Slow CLock Rise and Fall Times
- Automatic Reset Initializes All Counters On Power Up
- Supply Voltage Range = 3.0 Vdc to 18 Vdc with Auto Reset Disabled (Pin 5 = V_{DD})
  = 8.5 Vdc to 18 Vdc with Auto Reset Enabled (Pin 5 = V_{SS})

		10	I_D = (0.8 μA/kHz) f + I_{DD}							
		15	I_D = (1.2 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†When using the on chip oscillator the total supply current (in μAdc) becomes: $I_T = I_D + 2\ C_{tc}\ V_{DD}\ f \times 10^{-3}$ where I_D is in μA, C_{tc} is in pF, V_{DD} in Volts DC, and f in kHz. (see Fig. 3) Dissipation during power-on with automatic reset enabled is typically 50 μA @ V_{DD} = 10 Vdc.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

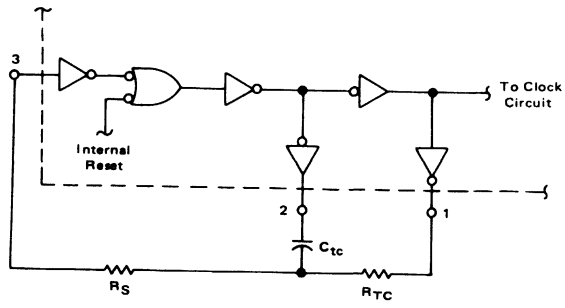
FIGURE 3 – OSCILLATOR CIRCUIT USING RC CONFIGURATION



TYPICAL RC OSCILLATOR CHARACTERISTICS

FIGURE 4 – RC OSCILLATOR STABILITY

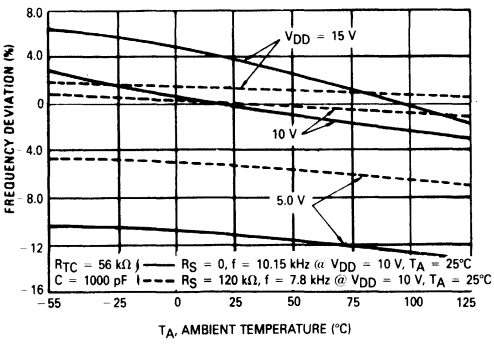


FIGURE 5 – RC OSCILLATOR FREQUENCY AS A FUNCTION OF R_{TC} AND C_{TC}

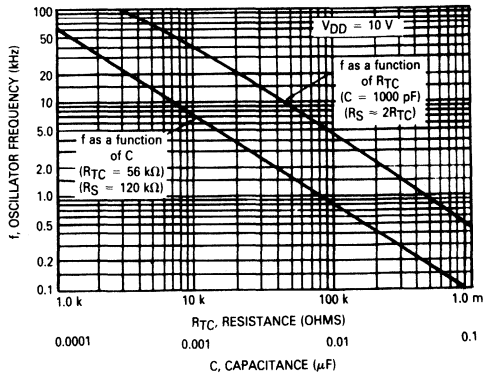


OPERATING CHARACTERISTICS

With Auto Reset pin set to a "0" the counter circuit is initialized by turning on power. Or with power already on, the counter circuit is reset when the Master Reset pin is set to a "1". Both types of reset will result in synchronously resetting all counter stages independent of counter state. Auto Reset pin when set to a "1" provides a low power operation.

The RC oscillator as shown in Figure 3 will oscillate with a frequency determined by the external RC network i.e.,

$$f = \frac{1}{2.3 R_{tc} C_{tc}} \quad \text{if } (1 \text{ kHz} \leq f \leq 100 \text{ kHz})$$

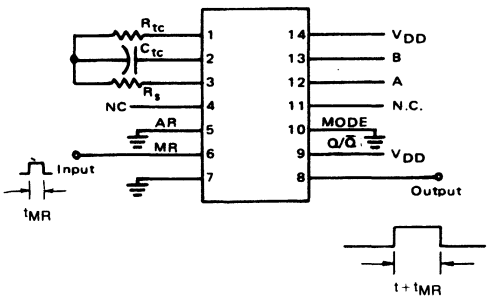
and $R_S \approx 2 R_{tc}$ where $R_S \geq 10$ kΩ

The time select inputs (A and B) provide a two-bit address to output any one of four counter stages (2^8, 2^{10}, 2^{13} and 2^{16}). The 2^n counts as shown in the Frequency Selection Table represents the Q output of the N^{th} stage of the counter. When A is "1", 2^{16} is selected for both states of B. However, when B is "0", normal counting is interrupted and the 9th counter stage receives its clock directly from the oscillator (i.e., effectively outputing 2^8).

The Q/$\overline{Q}$ select output control pin provides for a choice of output level. When the counter is in a reset condition and Q/$\overline{Q}$ select pin is set to a "0" the Q output is a "0", correspondingly when Q/$\overline{Q}$ select pin is set to a "1" the Q output is a "1"

When the mode control pin is set to a "1", the selected count is continually transmitted to the output. But, with mode pin "0" and after a reset condition the RS flip-flop (see Expanded Block Diagram) resets, counting commences, and after 2^{n-1} counts the RS flip-flop sets which causes the output to change state. Hence, after another 2^{n-1} counts the output will not change. Thus, a Master Reset pulse must be applied or a change in the mode pin level is required to reset the single cycle operation.

DIGITAL TIMER APPLICATION



When Master Reset (MR) receives a positive pulse, the internal counters and latch are reset. The Q output goes high and remains high until the selected (via A and B) number of clock pulses are counted, the Q output then goes low and remains low until another input pulse is received.

This "one shot" is fully retriggerable and as accurate as the input frequency. An external clock can be used (pin 3 is the clock input, pins 1 and 2 are outputs) if additional accuracy is needed.

Notice that a setup time equal to the desired pulse width output is required immediately following initial power up, during which time Q output will be high.

MC14543B

BCD-TO-SEVEN SEGMENT LATCH/DECODER/DRIVER for LIQUID CRYSTALS

The MC14543B BCD-to-seven segment latch/decoder/driver is designed for use with liquid crystal readouts, and is constructed with complementary MOS (CMOS) enhancement mode devices. The circuit provides the functions of a 4-bit storage latch and an 8421 BCD-to-seven segment decoder and driver. The device has the capability to invert the logic levels of the output combination. The phase (Ph), blanking (BI), and latch disable (LD) inputs are used to reverse the truth table phase, blank the display, and store a BCD code, respectively. For liquid crystal (LC) readouts, a square wave is applied to the Ph input of the circuit and the electrically common backplane of the display. The outputs of the circuit are connected directly to the segments of the LC readout. For other types of readouts, such as light-emitting diode (LED), incandescent, gas discharge, and fluorescent readouts, connection diagrams are given on this data sheet.

Applications include instrument (e.g., counter, DVM etc.) display driver, computer/calculator display driver, cockpit display driver, and various clock, watch, and timer uses.

- Latch Storage of Code
- Blanking Input
- Readout Blanking on All Illegal Input Combinations
- Direct LED (Common Anode or Cathode) Driving Capability
- Supply Voltage Range = 3.0 V to 18 V
- Capable of Driving Two Low-power TTL Loads, One Low-power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range
- Pin-for-Pin Replacement for CD4056A (with Pin 7 Tied to V_{SS}).
- Chip Complexity: 207 FETs or 52 Equivalent Gates

MC14544B

BCD-TO-SEVEN SEGMENT LATCH/DECODER/DRIVER FOR LIQUID CRYSTALS

The MC14544B BCD-to-seven segment latch/decoder/driver is designed for use with liquid crystal readouts, and is constructed with complementary MOS (CMOS) enhancement mode devices. The circuit provides the functions of a 4-bit storage latch and an 8421 BCD-to-seven segment decoder and driver. The device has the capability to invert the logic levels of the output combination. The phase (Ph), blanking (BI), and latch disable (LD) inputs are used to reverse the truth table phase, blank the display, and store a BCD code, respectively. For liquid crystal (LC) readouts, a square wave is applied to the Ph input of the circuit and the electrically common backplane of the display. The outputs of the circuit are connected directly to the segments of the LC readout. The Ripple Blanking Input (RBI) and the Ripple Blanking Output (RBO) can be used to suppress either leading or trailing zeroes.

For other types of readouts, such as light-emitting diode (LED), incandescent, gas discharge, and fluorescent readouts, connection diagrams are given on this data sheet.

Applications include instrument (e.g., counter, DVM etc.) display driver, computer/calculator display driver, cockpit display driver, and various clock, watch, and timer uses.

- Latch Storage of Code
- Blanking Input
- Readout Blanking on All Illegal Input Combinations
- Direct LED (Common Anode or Cathode) Driving Capability
- Supply Voltage Range = 3.0 V to 18 V
- Capability for Suppression of Non-significant zero
- Capable of Driving Two Low-power TTL Loads, One Low-power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range

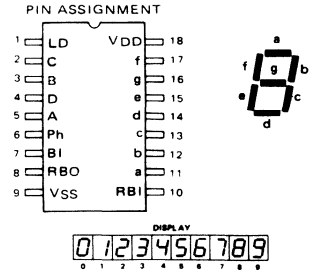
PIN ASSIGNMENT



MAXIMUM RATINGS* (Voltages referenced to V_{SS})

Rating	Symbol	Value	Unit
DC Supply Voltage	V_{DD}	−0.5 to +18	Vdc
Input Voltage, All Inputs	V_{in}	−0.5 to V_{DD} + 0.5	Vdc
DC Input Current per Pin	I_{in}	±10	mAdc
Operating Temperature Range	T_A	−55 to +125	°C
Storage Temperature Range	T_{stg}	−65 to +150	°C
Maximum Continuous Output Drive Current (Source or Sink) per Output	I_{OHmax} I_{OLmax}	10	mAdc
Maximum Continuous Output Power* (Source or Sink) per Output	P_{OHmax} P_{OLmax}	70	mW

*$P_{OHmax} = I_{OH}(V_{OH} - V_{DD})$ and $P_{OLmax} = I_{OL}(V_{OL} - V_{SS})$
*Maximum Ratings are those values beyond which damage to the device may occur.
†Temperature Derating: All Packages: −7.0 mW/°C from 65°C to 125°C.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

MC14547B

HIGH CURRENT BCD-TO-SEVEN SEGMENT DECODER/DRIVER

The MC14547 BCD-to-seven segment decoder/driver is constructed with complementary MOS (CMOS) enhancement mode devices and NPN bipolar output drivers in a single monolithic structure. The circuit provides the functions of an 8421 BCD-to-seven segment decoder with high output drive capability. Blanking (BI), can be used to turn off or pulse modulate the brightness of the display. The MC14547 can drive seven-segment light-emitting diodes (LED), incandescent, fluorescent or gas discharge readouts either directly or indirectly.

Applications include instrument (e.g., counter, DVM, etc.) display driver, computer/calculator display driver, cockpit display driver, and various clock, watch, and timer uses.

- High Current Sourcing Outputs (Up to 65 mA)
- Low Logic Circuit Power Dissipation
- Supply Voltage Range = +3.0 V to +18 V
- Blanking Input
- Readout Blanking on All Illegal Combinations
- Lamp Intensity Modulation Capability
- Multiplexing Capability
- Capable of Driving Two Low-Power TTL Loads, One Low-Power Schottky TTL Load or Two HTL Loads over the Rated Temperature Range
- Use MC14511B for Applications Requiring Data Latches

Storage Temperature Range	T_{stg}	−65 to +150	°C
Maximum Continuous Output Drive Current (Source) per Output	I_{OHmax}	65	mA
Maximum Continuous Power Dissipation	P_{OHmax}	1200†	mW

*Maximum Ratings are those values beyond which damage to the device may occur.
†Temperature Derating: All Packages: −7.0 mW/°C from 65°C to 125°C.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. A destructive high current mode may occur if V_{in} and V_{out} is not constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Due to the sourcing capability of this circuit, damage can occur to the device if V_{DD} is applied, and the outputs are shorted to V_{SS} and are at a logical 1 (See Maximum Ratings).

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

MC14559B

SUCCESSIVE APPROXIMATION REGISTERS

The MC14549B and MC14559B successive approximation registers are 8-bit registers providing all the digital control and storage necessary for successive approximation analog-to-digital conversion systems. These parts differ in only one control input. The Master Reset (MR) on the MC14549B is required in the cascaded mode when more than 8 bits are desired. The Feed Forward (FF) of the MC14559B is used for register shortening where End-of-Conversion (EOC) is required after less than eight cycles.

Applications for the MC14549B and MC14559B include analog-to-digital conversion, with serial and parallel outputs.

- Totally Synchronous Operation
- All Outputs Buffered
- Single Supply Operation
- Serial Output
- Retriggerable
- Compatible with a Variety of Digital and Analog Systems such as the MC1408 8-Bit D/A Converter
- All Control Inputs Positive-Edge Triggered
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads, One Low-Power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range
- Chip Complexity: 488 FETs or 122 Equivalent Gates

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD})

OPERATING CHARACTERISTICS

Both the MC14549B and MC14559B can be operated in either the "free run" or "strobed operation" mode for conversion schemes with any number of bits. Reliable cascading and/or recirculating operation can be achieved if the End of Convert (EOC) output is used as the controlling function, since with EOC = 0 (and with SC = 1 for MC14549B but either 1 or 0 for MC14559B) no stable state exists under continual clocked operation. The MC14559B will automatically recirculate after EOC = 1 during externally strobed operation, provided SC = 1.

All data and control inputs for these devices are triggered into the circuit on the positive edge of the clock pulse.

Operation of the various terminals is as follows:

C = Clock – A positive-going transition of the Clock is required for data on any input to be strobed into the circuit.

SC = Start Convert – A conversion sequence is initiated on the positive-going transition of the SC input on succeeding clock cycles.

D = Data In – Data on this input (usually from a comparator in A/D applications) is also entered into the circuit on a positive-going transition of the clock. This input is Schmitt triggered and synchronized to allow fast response and guaranteed quality of serial and parallel data.

MR = Master Reset (MC14549B only) – Resets all output to 0 on positive-going transitions of the clock. If removed while SC = 0, the circuit will remain reset until SC = 1. This allows easy cascading of circuits.

FF = Feed Forward (MC14559B only) – Provides register shortening by removing unwanted bits from a system.

For operation with less than 8 bits, tie the output *following* the least significant bit of the circuit to EOC. E.g., for a 6-bit conversion, tie Q1 to FF; the part will respond as shown in the timing diagram less two bit times. Not that Q1 and Q0 will still operate and must be disregarded.

For 8-bit operation, FF is tied to V_{SS}.

For applications with more than 8 but less than 16 bits, use the basic connections shown in Figure 1. The FF input of the MC14559B is used to shorten the setup. Tying FF directly to the least significant bit used in the MC14559B allows EOC to provide the cascading signal, and results in smooth transition of serial information from the MC14559B to the MC14549B. The Serial Out (S_{out}) inhibit structure of the MC14559B remains inactive one cycle after EOC goes high, while S_{out} of the MC14549B remains inhibited until the second clock cycle of its operation.

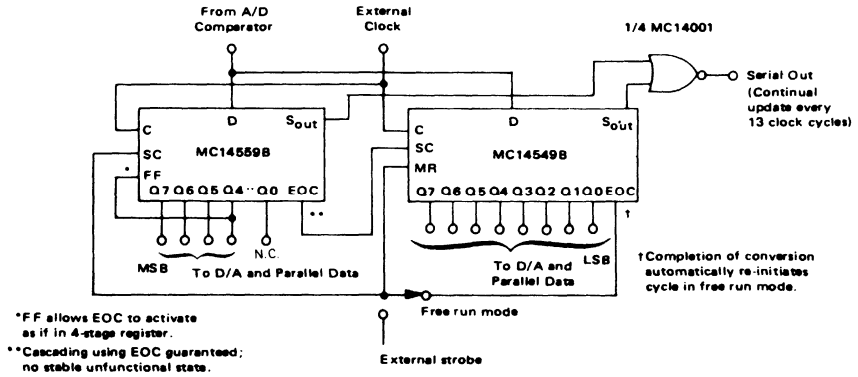
Q_n = Data Outputs – After a conversion is initiated the Q's on succeeding cycles go high and are then conditionally reset dependent upon the state of the D input. Once conditionally reset they remain in the proper state until the circuit is either reset or reinitiated.

EOC = End of Convert – This output goes high on the negative-going transition of the clock following FF = 1 (for the MC14559B) or the conditional reset of Q0. This allows settling of the digital circuitry prior to the End of Conversion indication. Therefore either level or edge triggering can indicate complete conversion.

S_{out} = Serial Out – Transmits conversion in serial fashion. Serial data occurs during the clock period when the corresponding parallel data bit is conditionally reset. Serial Out is inhibited on the initial period of a cycle, when the circuit is reset, and on the second cycle after EOC goes high. This provides efficient operation when cascaded.

6

FIGURE 1 – 12-BIT CONVERSION SCHEME



TYPICAL APPLICATIONS

Externally Controlled 6-Bit ADC (Figure 2)

Several features are shown in this application:

- Shortening of the register to six bits by feeding the seventh output bit into the FF input.
- Continuous conversion, if a continuous signal is applied to SC.
- Externally controlled updating (the start pulse must be shorter than the conversion cycle).
- The EOC output indicating that the parallel data are valid and that the serial output is complete.

Continuously Cycling 8-Bit ADC (Figure 3)

This ADC is running continuously because the EOC signal is fed back to the SC input, immediately initiating a new cycle on the next clock pulse.

Continuously Cycling 12-Bit ADC (Figure 4)

Because each successive approxiamtion register (SAR) has a capability of handling only an eight-bit word, two must be cascaded to make an ADC with more than eight bits.

When it is necessary to cascade two SAR's, the second SAR must have a stable resettable state to remain in while awaiting a subsequent start signal. However, the first stage must not have a stable resettable state while recycling, because during switch-on or due to outside influences, the first stage has entered a reset state, the entire ADC will remain in a stable non-functional condition.

This 12-bit ADC is continuously recycling. The serial as well as the parallel outputs are updated every thirteenth clock pulse. The EOC pulse indicates the completion of

FIGURE 2 – EXTERNALLY CONTROLLED 6-BIT ADC

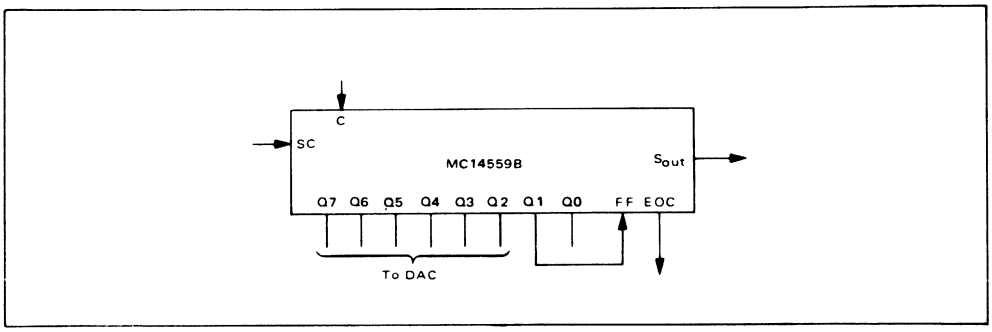


FIGURE 3 – CONTINUOUSLY CYCLING 8-BIT ADC

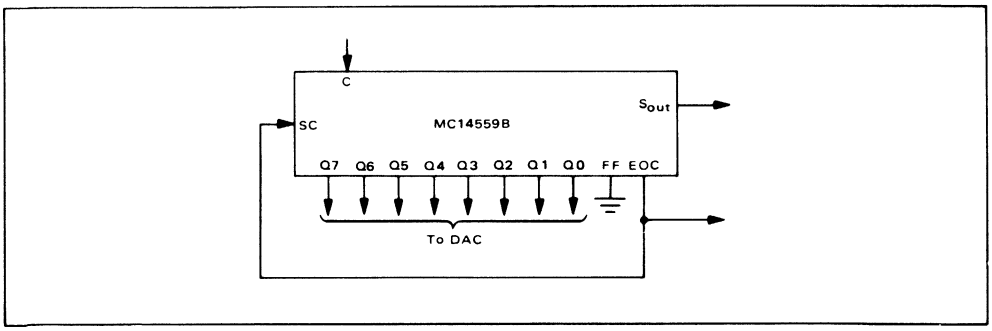
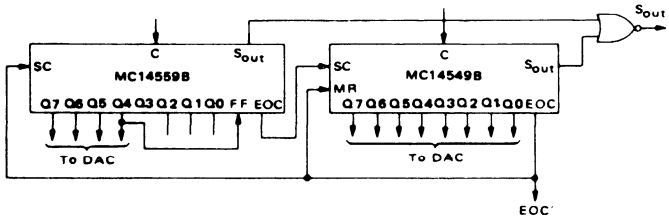


6

FIGURE 4 – CONTINUOUSLY CYCLING 12-BIT ADC



the 12-bit conversion cycle, the end of the serial output word, and the validity of the parallel data output.

Externally Controlled 12-Bit ADC (Figure 5)

In this circuit the external pulse starts the first SAR and simultaneously resets the cascaded second SAR. When Q4 of the first SAR goes high, the second SAR starts conversion, and the first one stops conversion. EOC indicates that the parallel data are valid and that the serial output is complete. Updating the output data is started with every external control pulse.

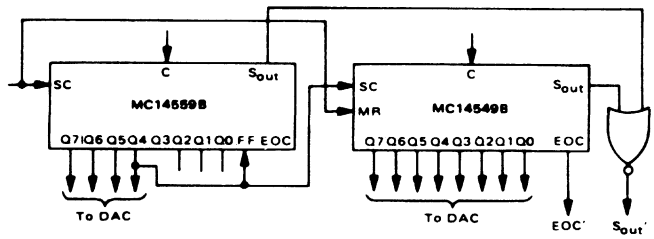
Additional Motorola Parts for Successive Approximation ADC

Monolithic digital-to-analog converters – The MC1408/1508 converter has eight-bit resolution and is available with 6, 7, and 8-bit accuracy. **The amplifier-comparator block** – The MC1407/1507 contains a high speed operational amplifier and a high speed comparator with adjustable window.

With these two linear parts it is possible to construct SA-ADCs with an accuracy of up to eight bits, using as the register one MC14549B or one MC14559B. An additional CMOS block will be necessary to generate the clock frequency.

Additional information on successive approximation ADC is found in Motorola Application Note AN-716.

FIGURE 5 – EXTERNALLY CONTROLLED 12-BIT ADC



MOTOROLA

MC14551B

QUAD 2-CHANNEL ANALOG MULTIPLEXER/DEMULTIPLEXER

The MC14551B is a digitally-controlled analog switch. This device implements a 4PDT solid state switch with low ON impedance and very low OFF Leakage current. Control of analog signals up to the complete supply voltage range can be achieved.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Analog Voltage Range ($V_{DD} - V_{EE}$) = 3.0 to 18 V
  Note: V_{EE} must be $\leq V_{SS}$
- Linearized Transfer Characteristics
- Low Noise — 12 nV/$\sqrt{Cycle}$, f $\geq$ 1.0 kHz typical
- For Low R_{ON}, Use The HC4051, HC4052, or HC4053 High-Speed CMOS Devices
- Switch Function is Break Before Make

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$ for control inputs and $V_{EE} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$ for Switch I/O.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS}, V_{EE}, or V_{DD}). Unused outputs must be left open.

APPLICATIONS INFORMATION

Figure A illustrates use of the on-chip level converter detailed in Figure 2. The 0-to-5 volt Digital Control signal is used to directly control a 9 V_{p-p} analog signal.

The digital control logic levels are determined by V_{DD} and V_{SS}. The V_{DD} voltage is the logic high voltage; the V_{SS} voltage is logic low. For the example, V_{DD} = +5 V = logic high at the control inputs; V_{SS} = GND = 0 V = logic low.

The maximum analog signal level is determined by V_{DD} and V_{EE}. The V_{DD} voltage determines the maximum recommended peak above V_{SS}. The V_{EE} voltage determines the maximum swing below V_{SS}. For the example, V_{DD} − V_{SS} = 5 volt maximum swing above V_{SS}; V_{SS} − V_{EE} = 5 volt maximum swing below V_{SS}. The example shows a ±4.5 volt signal which allows a 1/2 volt margin at each peak. If voltage transients above V_{DD} and/or below V_{EE} are anticipated on the analog channels, external diodes (D_X) are recommended as shown in Figure B. These diodes should be small signal types able to absorb the maximum anticipated current surges during clipping.

The *absolute* maximum potential difference between V_{DD} and V_{EE} is 18.0 volts. Most parameters are specified up to 15 volts which is the *recommended* maximum difference between V_{DD} and V_{EE}.

Balanced supplies are not required. However, V_{SS} must be greater than or equal to V_{EE}. For example, V_{DD} = +10 volts, V_{SS} = +5 volts, and V_{EE} = −3 volts is acceptable. See the table below.

MOTOROLA

MC14553B

3-DIGIT BCD COUNTER

The MC14553B 3-digit BCD counter consists of 3 negative edge triggered BCD counters that are cascaded synchronously. A quad latch at the output of each counter permits storage of any given count. The information is then time division multiplexed, providing one BCD number or digit at a time. Digit select outputs provide display control. All outputs are TTL compatible.

An on-chip oscillator provides the low-frequency scanning clock which drives the multiplexer output selector.

This device is used in instrumentation counters, clock displays, digital panel meters, and as a building block for general logic applications.

- TTL Compatible Outputs
- On-Chip Oscillator
- Cascadable
- Clock Disable Input
- Pulse Shaping Permits Very Slow Rise Times on Input Clock
- Output Latches

FIGURE 1 — 3-DIGIT COUNTER TIMING DIAGRAM (Reference Figure 3)

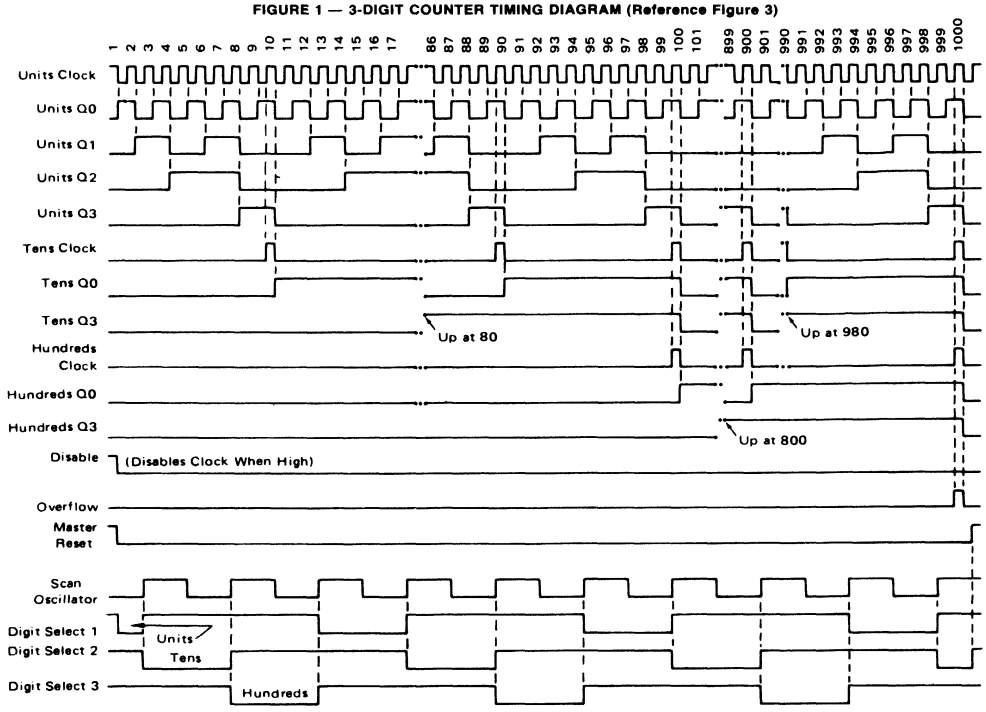

FIGURE 2 — SWITCHING TIME TEST CIRCUITS AND WAVEFORMS

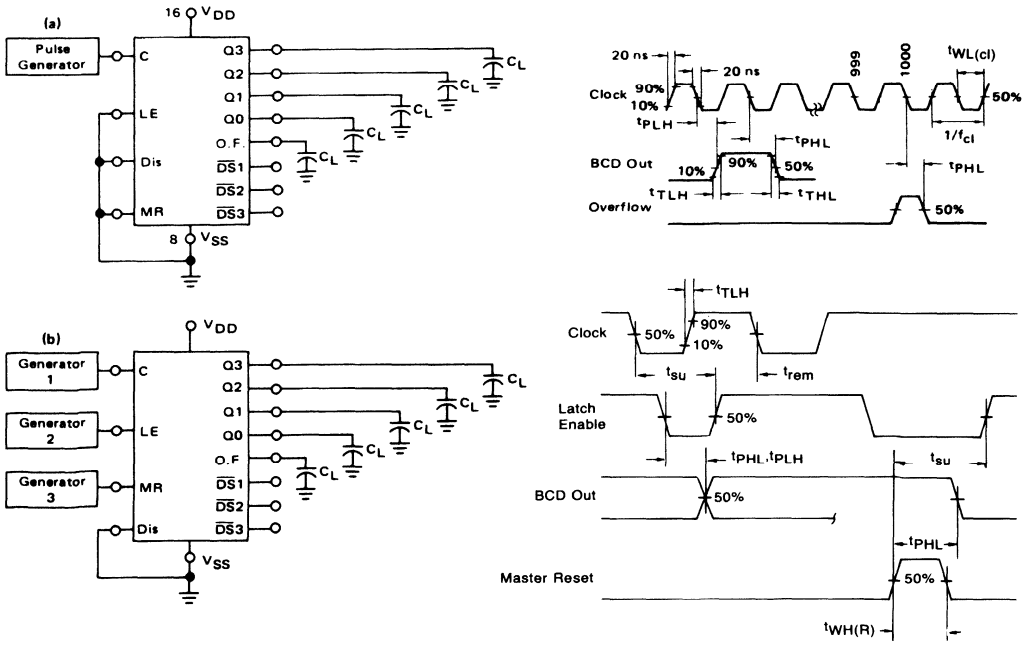

OPERATING CHARACTERISTICS

The MC14553B three-digit counter, shown in Figure 3, consists of three negative edge-triggered BCD counters which are cascaded in a synchronous fashion. A quad latch at the output of each of the three BCD counters permits storage of any given count. The three sets of BCD outputs (active high), after going through the latches, are time division multiplexed, providing one BCD number or digit at a time. Digit select outputs (active low) are provided for display control. All outputs are TTL compatible.

An on-chip oscillator provides the low frequency scanning clock which drives the multiplexer output selector. The frequency of the oscillator can be controlled externally by a capacitor between pins 3 and 4, or it can be overridden and driven with an external clock at pin 4. Multiple devices can be cascaded using the overflow output, which provides one pulse for every 1000 counts.

The Master Reset input, when taken high, initializes the three BCD counters and the multiplexer scanning circuit. While Master Reset is high the digit scanner is set to digit one; but all three digit select outputs are disabled to prolong display life, and the scan oscillator is inhibited. The Disable input, when high, prevents the input clock from reaching the counters, while still retaining the last count. A pulse shaping circuit at the clock input permits the counters to continue operating on input pulses with very slow rise times. Information present in the counters when the latch input goes high, will be stored in the latches and will be retained while the latch input is high, independent of other inputs. Information can be recovered from the latches after the counters have been reset if Latch Enable remains high during the entire reset cycle.

MOTOROLA

MC14554B

2-BIT BY 2-BIT PARALLEL BINARY MULTIPLIER

The MC14554B 2 x 2-bit parallel binary multiplier is constructed with complementary MOS (CMOS) enhancement mode devices. The multiplier can perform the multiplication of two binary numbers and simultaneously add two other binary numbers to the product. The MC14554B has two multiplicand inputs (X0 and X1), two multiplier inputs (Y0 and Y1), five cascading or adding inputs (K0, K1, M0, M1, and M2), and five sum and carry outputs (S0, S1, S2, C1 [S3], and C0). The basic multiplier can be expanded into a straightforward m-bit by n-bit parallel multiplier without additional logic elements.

Application areas include arithmetic processing (multiplying/adding, obtaining square roots, polynomial evaluation, obtaining reciprocals, and dividing), Fast Fourier Transform processing, digital filtering, communications (convolution and correlation), and process and machine controls.

- Diode Protection on All Inputs
- All Outputs Buffered
- Straight-forward m-Bit By n-Bit Expansion
- No Additional Logic Elements Needed for Expansion
- Multiplies and Adds Simultaneously
- Positive Logic Design
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

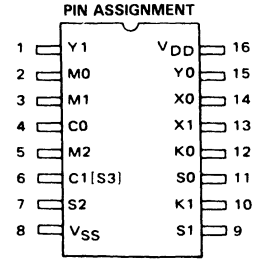
PIN ASSIGNMENT



EQUATIONS

$S = (X \times Y) + K + M$

Where:
x Means Arithmetic Times.
+ Means Arithmetic Plus.
S = S3 S2 S1 S0, X = X1X0, Y = Y1Y0,
K = K1 K0, M = M1 M0 (Binary Numbers).

Example:

Given: X = 2(1), Y = 3(11)
K = 1(01), M = 2(10)

Then: S = (2 x 3) + 1 + 2 = 9
S = (10 x 11) + 01 + 10 = 1001

Note: C0 connected to M2 for this size multiplier.
See general expansion diagram for other size multipliers.

MOTOROLA

MC14555B
MC14556B

DUAL BINARY TO 1-OF-4 DECODER/DEMULTIPLEXER

The MC14555B and MC14556B are constructed with complementary MOS (CMOS) enhancement mode devices. Each Decoder/Demultiplexer has two select inputs (A and B), an active low Enable input (E), and four mutually exclusive outputs (Q0, Q1, Q2, Q3). The MC14555B has the selected output go to the "high" state, and the MC14556B has the selected output go to the "low" state. Expanded decoding such as binary-to-hexadecimal (1-of-16), etc., can be achieved by using other MC14555B or MC14556B devices.

Applications include code conversion, address decoding, memory selection control, and demultiplexing (using the Enable input as a data input) in digital data transmission systems.

- Diode Protection on All Inputs
- Active High or Active Low Outputs
- Expandable
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- All Outputs Buffered
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

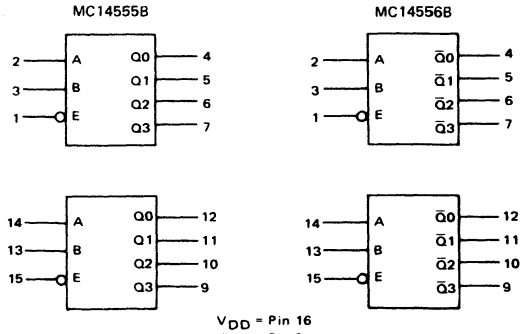
BLOCK DIAGRAM



V_{DD} = Pin 16
V_{SS} = Pin 8

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14557B

1-TO-64 BIT VARIABLE LENGTH SHIFT REGISTER

The MC14557B is a static clocked serial shift register whose length may be programmed to be any number of bits between 1 and 64. The number of bits selected is equal to the sum of the subscripts of the enabled Length Control inputs (L1, L2, L4, L8, L16, and L32) plus one. Serial data may be selected from the A or B data inputs with the A/B select input. This feature is useful for recirculation purposes. A Clock Enable (CE) input is provided to allow gating of the clock or negative edge clocking capability.

The device can be effectively used for variable digital delay lines or simply to implement odd length shift registers.

- 1-64 Bit Programmable Length
- Q and $\overline{Q}$ Serial Buffered Outputs
- Asynchronous Master Reset
- All Inputs Buffered
- No Limit On Clock Rise and Fall Times
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or one Low-power Schottky TTL Load Over the Rated Temperature Range

MC14558B

BCD-TO-SEVEN SEGMENT DECODER

The MC14558B decodes 4-bit binary coded decimal data dependent on the state of auxiliary inputs, Enable and $\overline{RBI}$, and provides an active-high seven-segment output for a display driver.

An auxiliary input truth table is shown, in addition to the BCD to seven-segment truth table, to indicate the functions available with the two auxiliary inputs.

Leading Zero blanking is easily obtained with an external flip-flop in time division multiplexed systems displaying most significant decade first.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Segment Blanking for All Illegal Input Combinations
- Lamp Test Function
- Capability for Suppression of Non-Significant Zeros
- Lamp Intensity Function
- Capable of Driving Two Low-power TTL Loads, One Low-power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range

		10	I_T = (2.4 μA/kHz) f + I_{DD}							
		15	I_T = (3.6 μA/kHz) f + I_{DD}							

#Noise immunity specified for worst-case input combination.
Noise Margin for both "1" and "0" level = 1.0 V min @ V_{DD} = 5.0 V
2.0 V min @ V_{DD} = 10 V
2.5 V min @ V_{DD} = 15 V

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + 3.5 \times 10^{-3} (C_L - 50) V_{DD} f$$

where: I_T is in μA (per package), C_L in pF, V_{DD} in V, and f in kHz is input frequency.

**The formulas given are for the typical characteristics only at 25°C.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.
Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

MOTOROLA

MC14560B

NBCD ADDER

The MC14560B adds two 4-bit numbers in NBCD (natural binary coded decimal) format, resulting in sum and carry outputs in NBCD code.

This device can also subtract when one set of inputs is complemented with a 9's Complementer (MC14561B).

All inputs and outputs are active high. The carry input for the least significant digit is connected to V_{SS} for no carry in.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

APPLICATIONS INFORMATION

INTRODUCTION

Frequently in small digital systems, simple decimal arithmetic is performed. Decimal data enters and leaves the system arithmetic unit in a binary coded decimal (BCD) format. The adder/subtracter in the airthmetic unit may be required to accept sign as well as magnitude, and generate sign, magnitude, and overflow. In the past, it has been cumbersome to build sign and magnitude adder/subtracters. Now, using Motorola's MSI CMOS functions, the MC14560 NBCD Adders and MC14561 9's Complementers, NBCD adder/subtracters may be built economically, with surprisingly low package count and moderate speed.

Some background information on BCD arithmetic is presented here, followed by simple circuits for unsigned adder/subtracters. The final circuit discussed is an adder/subtracter for signed numbers with complete overflow and sign correction logic.

DECIMAL NUMBER REPRESENTATION

Because logic elements are binary or two-state devices, decimal digits are generally represented as a group of bits in a weighted format. There are many possible binary codes which can be used to represent a decimal number. One of the most popular codes using 4 binary digits to represent 0 thu 9 is Natural Binary Coded Decimal (NBCD or 8-4-2-1 code).

NBCD is a weighted code. If a value of "0" or "1" is assigned to each of the bit positions, where the rightmost position is 2^0 and the leftmost is 2^3, and the values are summed for a given code, the result is equal to the decimal digit represented by the code. Thus, 0110 equals $0{\cdot}2^3 + 1{\cdot}2^2 + 1{\cdot}2^1 + 0{\cdot}2^0 = 4 + 2 = 6$. The 1010, 1011, 1100, 1101, 1110, and 1111 binary codes are not used. Because of these illegal states, the addition and subtraction of NBCD numbers is more complex than similar calculations on straight binary numbers.

6

ADDITION OF UNSIGNED NBCD NUMBERS

When 2 NBCD digits, A and B, and a possible carry, C, are added, a total of 20 digit sums (A + B + C) are possible as shown in Table 1.

The binary representations for the digit sums 10 thru 19 are offset by 6, the number of unused binary states, and are not correct. An algorithm for obtaining the correct sum is shown in Figure 1. A conventional method of implementing the BCD addition algorithm is shown in Figure 2(a). The NBCD digits, A and B, are summed by a 4 bit binary full adder. The resultant (sum and carry) is input to a binary/BCD code converter which generates the correct BCD code and carry.

An NBCD adder block which performs the above function is available in a single CMOS package (MC14560). Figure 2(b) shows n decades cascaded for addition of n digit unsigned NBCD numbers. Add time is typically 0.1 + 0.2n μs for n decades. When the carry out of the most significant decade is a logical "1", an overflow is indicated.

COMPLEMENT ARITHMETIC

Complement arithmetic is used in NBCD subtraction. That is, the "complement" of the subtrahend is added to the minuend. The complementing process amounts to biasing the subtrahend such that all possible sums are positive. Consider the subtraction of the NBCD numbers, A and B:

$$R = A - B$$

where R is the result. Now bias both sides of the equation by $10^N - 1$ where N is the number of digits in A and B.

$$R + 10^N - 1 = A - B + 10^N - 1$$

Rearranging,

$$R + 10^N - 1 = A + (10^N - 1 - B)$$

The term $(10^N - 1 - B)$, $-B$ biased by $10^N - 1$, is known as the 9's complement of B. When A>B, $R + 10^N - 1 > 10^N - 1$; thus R is a positive number. To obtain R, 1 is added to $R + 10^N - 1$, and the carry term, 10^N, is dropped. The addition of 1 is called End Around Carry (EAC).

When $A < B$, $R + 10^N - 1 < 10^N - 1$, no EAC results and R is a negative number biased by $10^N - 1$; thus $R + 10^N - 1$ is the 9's complement of R.

SUBTRACTION OF UNSIGNED NBCD NUMBERS

Nine's complement arithmetic requires an element to perform the complementing function. An NBCD 9's complementer may be implemented using a 4 bit binary adder and 4 inverters, or with combinatorial logic. The Motorola MC14561 9's complementer is available in a single package. It has true and inverted complement disable, which allow straight-through or complement modes of operation. A "zero" line forces the output to "0". Figure 3 shows an NBCD subtracter block using the MC14560 and MC14561. Also shown are n cascaded blocks for subtraction of n digit unsigned numbers. Subtract time is 0.6 + 0.4n μs for n stages. Underflow (borrow) is indicated by a logical "0" on the carry output of the most significant digit. A "0" carry also indicates that the difference is a negative number in 9's complement form. If the result is input to a 9's complementer, as shown, and its mode controlled by the carry out of the most significant digit, the output of the complementer will be the correct negative magnitude. Note that the carry out of the most significant digit (MSD) is the input to carry in of the least significant digit (LSD). This End Around Carry is required because subtraction is done in 9's complement arithmetic.

By controlling the complement and overflow logic with an add/subtract line, both addition and subtraction are performed using the basic subtracter blocks (Figure 4).

ADDITION AND SUBTRACTION OF SIGNED NBCD NUMBERS

Using MC14560 NBCD Adders and MC14561 9's Complementers, a sign and magnitude adder/subtracter can be configured (Figure 5). Inputs A and B are signed positive (A_S, B_S = "0") or negative (A_S, B_S = "1"). B is added to or subtracted from A under control of an Add/Sub line (subtraction = "1"). The result, R, of the operation is positive signed, positive signed with overflow, negative signed, or negative signed with overflow. Add/subtract time is typically 0.6 + 0.4n μs for n decades.

An exclusive-OR of Add/Sub line and B_S produces B′, which controls the B complementers. If B_S, the sign of B, is a logical "1" (B is negative) and the Add/Sub line is a "0" (add B to A), then the output of the exclusive-OR (B_S′) is a logical "1" and B is complemented. If B_S = "1" and Add/Sub = "1", B is not complemented since subtracting a negative number is the same as adding a positive number. When Add/Sub is a "1" and B_S = "0", B_S′ is a "1" and B is complemented. The A complementer is controlled by the A sign bit, A_S. When A_S = "1", A is complemented.

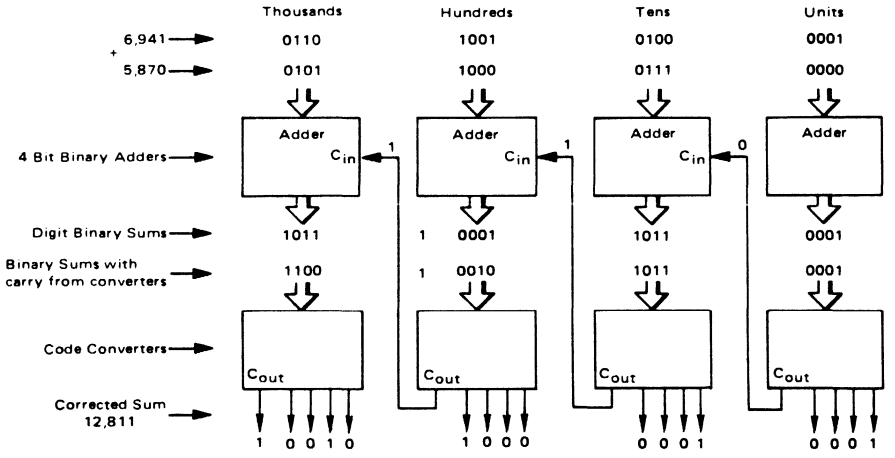

FIGURE 4 — Unsigned NBCD Addition Algorithm

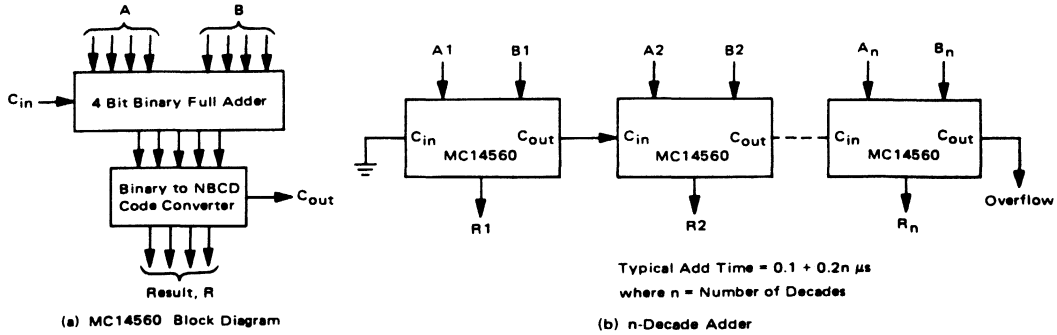

(a) MC14560 Block Diagram

(b) n-Decade Adder

FIGURE 5 — Addition of Unsigned NBCD Numbers

The truth table and Karnaugh maps for sign, overflow, and End Around Carry are shown in Figures 6 and 7. Note the use of B_S' from the exclusive-OR of Add/Sub and B_S. B_S' eliminates Add/Sub as a variable in the truth table. As an example of truth table generation, consider an n decade adder/subtracter where A_S = "0", B_S = "1", and Add/Sub = "0". B is in 9's complement form, $10^N - 1 - B$. Thus $A + (10^N - 1 - B) = 10^N - 1 + (A - B)$. There is no carry when $A \leq B$, and the sign is negative (sign = "1"). When A_S and B_S are opposite states and Add/Sub is a "0" (add mode), no overflow can occur (overflow = "0"). The other output states are determined in a similar manner (see Figure 6).

From the Karnaugh maps it is apparent that End Around Carry is composed of the two symmetrical functions S2 and S3 of three variables with A_S B_S' C_{out} as the center of symmetry. This is the definition of the majority logic function $M_3(ABC)$. Similarly the Sign is composed of the symmetrical functions S2(3) and S3(3) but with the center of symmetry translated to $A_S B_S'$ C_{out}. This is equivalent to the majority function $M_3(A_S B_S' \bar{C}_{out})$. Further evaluation of the maps and truth table reveal that Overflow can be generated by the exclusive-OR function of End Around Carry and Carry Out. This analysis results in a minimum device count consisting of one exclusive-OR package and one dual Majority Logic package to implement B_S', EAC, Sign and Overflow. The logic connections of these devices are shown in Figure 5.

The output sign, R_S, complements the result of the add/subtract operation when R_S = "1". This is required because the adder performs 9's complement arithmetic. Complementing, when R_S indicates the result is negative, restores sign and magnitude convention.

Several variations of the adder/subtracter are possible. For example, 9's complement is available at the output of the NBCD adders, and output complementers are eliminated if sign and magnitude output is not required.

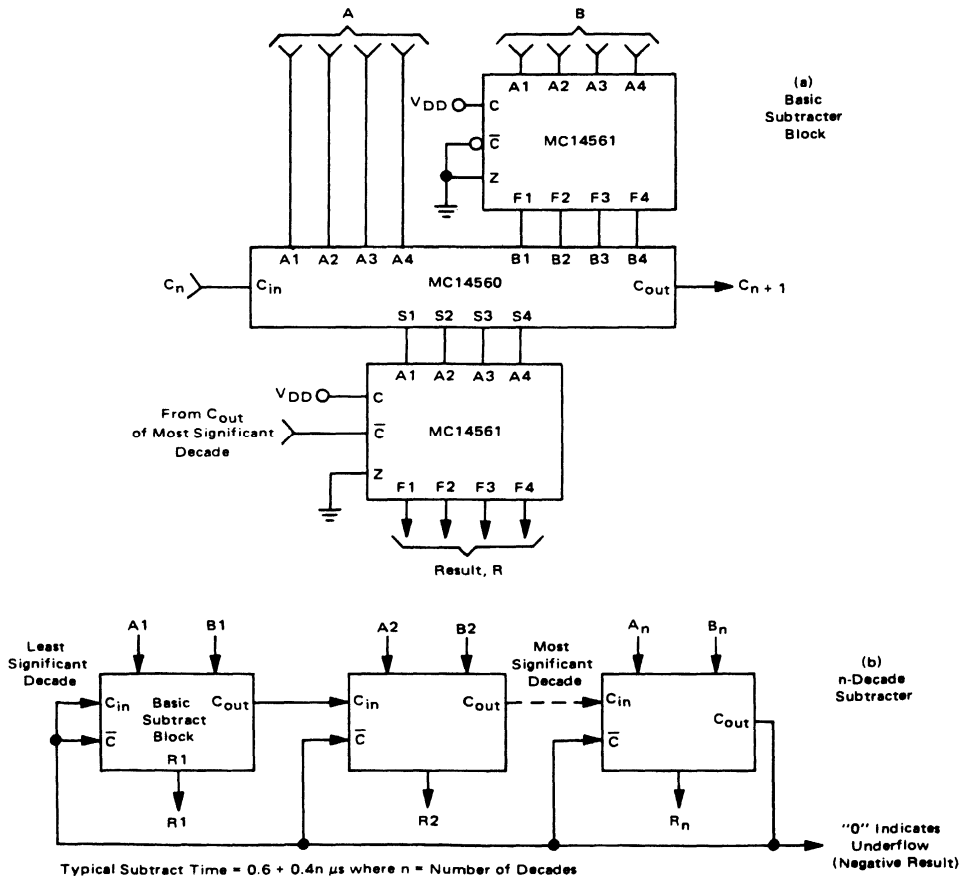

FIGURE 6 — Subtraction of Unsigned NBCD Numbers

SUMMARY

The concepts of binary code representations for decimal numbers, addition, and complement subtraction were discussed in detail. Using the basic Adder and Complementer MSI blocks, adder/subtracters for both signed and unsigned numbers were illustrated with examples.

MOTOROLA

MC14561B

9's COMPLEMENTER

The MC14561B 9's complementer is a companion to the MC14560B NBCD adder to allow BCD subtraction. A BCD number (8-4-2-1 code) is applied to the inputs ($A1 = 2^0$, $A2 = 2^1$, $A3 = 2^2$, $A4 = 2^3$). If the complement control (Comp) is low, the BCD number appears at the outputs unmodified. The complement disable ($\overline{Comp}$) allows the complement control to be gated, or an inverted control signal to be used. If the complement input is high and the disable input low, the 9's complement of the number is displayed at the outputs. The zero control (Z), when high, forces the outputs low regardless of the state of the other inputs.

When the MC14561B is used to perform BCD subtraction in conjunction with the MC14560B NBCD adder, the complement control becomes an add/subtract control.

- All Inputs Buffered
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-Power TTL Loads or One Low-Power Schottky TTL Load Over the Rated Temperature Range

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14566B

INDUSTRIAL TIME BASE GENERATOR

The MC14566B industrial time base generator is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. This device consists of a divide-by-10 ripple counter and a divide-by-5 or divide-by-6 ripple counter to permit stable time generation from a 50 or 60 Hz line. By cascading this device as divide-by-60 counters, seconds and minutes can be counted and are available in BCD format at the circuit outputs. An internal monostable multivibrator is included whose output can be used as a reset or clock pulse providing additional frequency flexibility. Also a pin has been included to allow divide-by-5 counting for generating 1.0 Hz from European 50 Hz line. Pin 11 = V_{DD} will cause ÷5.

- Negative Edge Triggered Counters for Ease of Cascading
- Pulse Shapers on Counter Inputs Accept Slow Input Rise Times
- Monostable Multivibrator Positive or Negative Edge Triggered
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0	I_T = (1.0 μA/kHz) f + I_{DD}							μAdc
		10	I_T = (2.0 μA/kHz) f + I_{DD}							
		15	I_T = (3.0 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14568B

PHASE COMPARATOR AND PROGRAMMABLE COUNTERS

The MC14568B consists of a phase comparator, a divide-by-4, 16, 64 or 100 counter and a programmable divide-by-N 4-bit binary counter (all positive-edge triggered) constructed with MOS P-channel and N-channel enhancement mode devices (complementary MOS) in a monolithic structure.

The MC14568B has been designed for use in conjunction with a programmable divide-by-N counter for frequency synthesizers and phase-locked loop applications requiring low power dissipation and/or high noise immunity.

This device can be used with both counters cascaded and the output of the second counter connected to the phase comparator (CTL high), or used independently of the programmable divide-by-N counter, for example cascaded with a MC14569B, MC14522B or MC14526B (CTL low).

- Supply Voltage Range = 3.0 to 18 V
- Capable of Driving Two Low-Power TTL Loads, One Low-Power Schottky TTL Load or Two HTL Loads Over the Rated Temperature Range.
- Chip Complexity: 549 FETs or 137 Equivalent Gates

OPERATING CHARACTERISTICS

The MC14568B contains a phase comparator, a fixed divider (÷ 4, ÷ 16, ÷ 64, ÷ 100) and a programmable divide-by-N 4-bit counter.

PHASE COMPARATOR

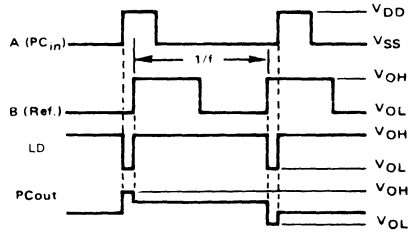
The phase comparator is a positive edge controlled logic circuit. It essentially consists of four flip-flops and an output pair of MOS transistors. Only one of its inputs (PC_{in}, pin 14) is accessible externally. The second is connected to the output of one of the two counters D1 or D2 (see block diagram).

Duty cycles of both input signals (at A and B) need not be taken into consideration since the comparator responds to leading edges only.

If both input signals have identical frequencies but different phases, with signal A (pin 14) leading signal B (Ref.), the comparator output will be high for the time equal to the phase difference.

If signal A lags signal B, the output will be low for the same time. In between, the output will be in a three-state condition and the voltage on the capacitor of an RC filter normally connected at this point will have some intermediate value (see Figure 4). When used in a phase locked loop, this value will adjust the Voltage Controlled Oscillator frequency by reducing the phase difference between the reference signal and the divided VCO frequency to zero.

FIGURE 4 – PHASE COMPARATOR WAVEFORMS



If the input signals have different frequencies, the output signal will be high when signal B has a lower frequency than signal A, and low otherwise.

Under the same conditions of frequency difference, the output will vary between V_{OH} (or V_{OL}) and some intermediate value until the frequencies of both signals are equal and their phase difference equal to zero, i.e. until locked condition is obtained.

Capture and lock range will be determined by the VCO frequency range. The comparator is provided with a lock indicator output, which will stay at logic 1 in locked conditions.

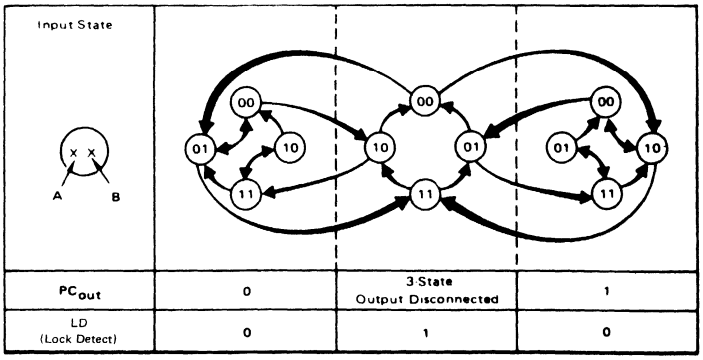
The state diagram (Figure 5) depicts the internal state transitions. It assumes that only one transition on either signal occurs at any time. It shows that a change of the output state is always associated with a positive transition of either signal. For a negative transition, the output does not change state. A positive transition may not cause the output to change; this happens when the signals have different frequencies.

DIVIDE BY 4, 16, 64 OR 100 COUNTER (D1)

This counter is able to work at an input frequency of 5 MHz for a V_{DD} value of 10 volts over the standard temperature range when dividing by 4, 64 and 100. Programming is accomplished by use of inputs F and G (pins 10 and 11) according to the truth table shown. Connecting the Control input (CTL, pin 15) to V_{DD} allows cascading this counter with the programmable divide-by-N counter provided in the same package. Independent operation is obtained when the Control input is connected to V_{SS}.

The different division ratios have been chosen to generate the reference frequences corresponding to the channel spacings normally required in frequency synthesizer applications. For example, with the division ratio 100 and a 5 MHz crystal stabilized source a reference frequency of 50 kHz is supplied to the comparator. The lower division ratios permit operation with low frequency crystals.

FIGURE 5 – PHASE COMPARATOR STATE DIAGRAM



PC_{out}	0	3-State Output Disconnected	1
LD (Lock Detect)	0	1	0

If used in cascade with the programmable divide-by-N counter, practically all usual reference frequencies, or channel spacings of 25, 20, 12.5, 10, 6.25 kHz, etc. are easily achievable.

PROGRAMMABLE DIVIDE-BY-N 4-BIT COUNTER (D2)

This counter is programmable by using inputs D_{P0} . . . D_{P3} (pins 7 . . . 4). The Preset Enable input enables the parallel preset inputs D_{P0} . . . D_{P3}. The "0" output must be externally connected to the PE input for single stage applications. Since there is not a cascade feedback input, this counter, when cascaded, must be used as the most significant digit. Because of this, it can be cascaded with binary counters as well as with BCD counters (MC14569B, MC14522B, MC14526B).

TYPICAL APPLICATIONS

FIGURE 6 – CASCADING MC14568B AND MC14522B OR MC14526B WITH MC14569B

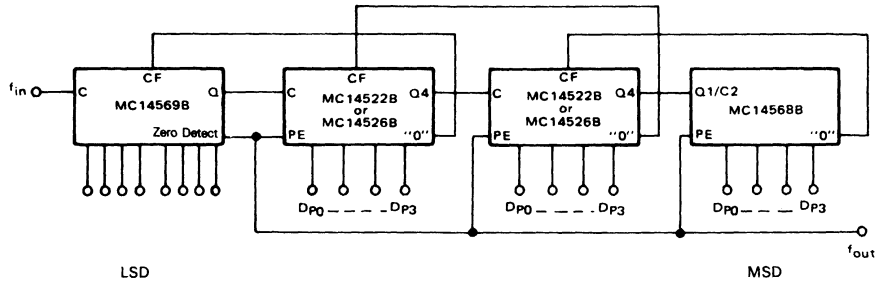


FIGURE 7 – FREQUENCY SYNTHESIZER WITH MC14568B and MC14569B USING A MIXER (Channel Spacing 10 kHz)

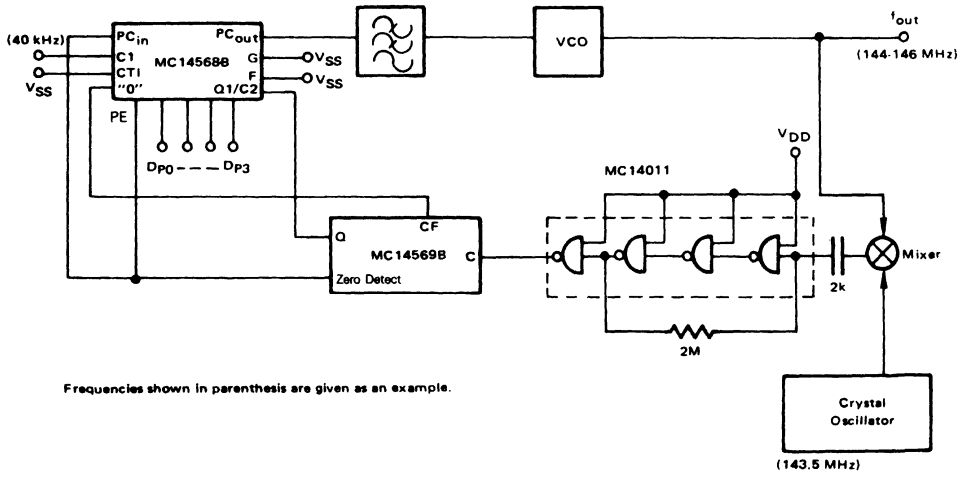
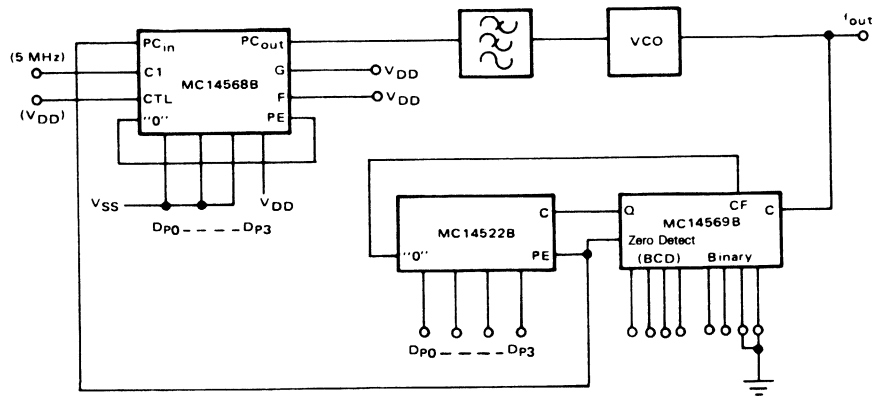


Frequencies shown in parenthesis are given as an example.

FIGURE 8 – FREQUENCY SYNTHESIZER USING MC14568B, MC14569B AND MC14522B
(Without Mixer)



N_1	N_2	N_3
(0–5)	(0–9)	(0, 4, 8, 12)
(625 kHz steps)	(62.5 kHz steps)	(6.25 kHz steps)

Divide ratio = $160N_1 + 16N_2 + N_3$

Example:
$f_{out} = N_1$ (MHz) + N_2 (x100 kHz) + N_3 (x25 kHz)
Frequency range = 5 MHz
Channel spacing = 25 kHz
Reference frequency = 6.25 kHz

Figures shown in parenthesis refer to example.

MC14569B

PROGRAMMABLE DIVIDE-BY-N DUAL 4-BIT BINARY / BCD DOWN COUNTER

The MC14569B is a programmable divide-by-N dual 4-bit binary or BCD down counter constructed with MOS P-channel and N-channel enhancement mode devices (complementary MOS) in a monolithic structure.

This device has been designed for use with the MC14568B phase comparator/counter in frequency synthesizers, phase-locked loops, and other frequency division applications requiring low power dissipation and/or high noise immunity.

- Speed-up Circuitry for Zero Detection
- Each 4-Bit Counter Can Divide Independently in BCD or Binary Mode
- Can be Cascaded With MC14568B, MC14522B or MC14526B for Frequency Synthesizer Applications
- All Outputs are Buffered
- Schmitt Triggered Clock Conditioning

Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0 10 15	I_T = (0.58 μA/kHz) f + I_{DD} I_T = (1.20 μA/kHz) f + I_{DD} I_T = (1.95 μA/kHz) f + I_{DD}							μAdc

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.001.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

PIN DESCRIPTIONS

INPUTS

P0, P1, P2, P3 (Pins 3, 4, 5, 6) — Preset Inputs. Programmable inputs for the least significant counter. May be binary or BCD depending on the control input.

P4, P5, P6, P7 (Pins 11, 12, 13, 14) — Preset Inputs. Programmable inputs for the most significant counter. May be binary or BCD depending on the control input.

Clock (Pin 9) — Preset data is decremented by one on each positive transition of this signal.

OUTPUTS

Zero Detect (Pin 1) — This output is normally low and goes high for one clock cycle when the counter has decremented to zero.

Q (Pin 15) — Output of the last stage of the most significant counter. This output will be inactive unless the preset input P7 has been set high.

CONTROLS

Cascade Feedback (Pin 7) — This pin is normally set high. When low, loading of the preset inputs (P0 through P7) is inhibited, i.e., P0 through P7 are "don't cares." Refer to Table 1 for output characteristics.

CTL_1 (Pin 2) — This pin controls the counting mode of the least significant counter. When set high, counting mode is BCD. When set low, counting mode is binary.

CTL_2 (Pin 10) — This pin controls the counting mode of the most significant counter. When set high, counting mode is BCD. When set low, counting mode is binary.

SUPPLY PINS

V_{SS} (Pin 18) — Negative Supply Voltage. This pin is usually connected to ground.

V_{DD} (Pin 16) — Positive Supply Voltage. This pin is connected to a positive supply voltage ranging from 3.0 volts to 18.0 volts.

OPERATING CHARACTERISTICS

The MC14569B is a programmable divide-by-N dual 4-bit down counter. This counter may be programmed (i.e., preset) in BCD or binary code through inputs P0 to P7. For each counter, the counting sequence may be chosen independently by applying a high (for BCD count) or a low (for binary count) to the control inputs CTL_1 and CTL_2.

The divide ratio N (N being the value programmed on the preset inputs P0 to P7) is automatically loaded into the counter as soon as the count 1 is detected. Therefore, a division ratio of one is not possible. After N clock cycles, one pulse appears on the Zero Detect output. (See Timing Diagram.) The Q output is the output of the last stage of the most significant counter (See Tables 1 through 5, Mode Controls.)

When cascading the MC14569B to the MC14568B, MC14522B or the MC14526B, the Cascade Feedback input, Q, and Zero Detect outputs must be respectively connected to "0", Clock, and Load of the following counter. If the MC14569B is used alone, Cascade Feedback must be connected to V_{DD}.

MOTOROLA

MC14572UB

HEX GATE

The MC14572UB hex functional gate is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These complementary MOS logic gates find primary use where low power dissipation and/or high noise immunity is desired. The chip contains four inverters, one NOR gate and one NAND gate.

- Diode Protection on All Inputs
- Single Supply Operation
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- NOR Input Pin Adjacent to V_{SS} Pin to Simplify Use As An Inverter
- NAND Input Pin Adjacent to V_{DD} Pin to Simplify Use As An Inverter
- NOR Output Pin Adjacent to Inverter Input Pin For OR Application
- NAND Output Pin Adjacent to Inverter Input Pin For AND Application
- Capable of Driving Two Low-power TTL Loads or One Low-Power Schottky TTL Load over the Rated Temperature Range

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

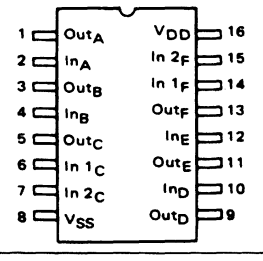
**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.006.

PIN ASSIGNMENT



This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$. Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

SWITCHING CHARACTERISTICS* (C_L = 50 pF, T_A = 25°C)

MOTOROLA

MC14580B

4 x 4 MULTIPORT REGISTER

The MC14580B is a 4 by 4 multiport register useful in small scratch pad memories, arithmetic operations when coupled with an adder, and other data storage applications. It allows independent reading of any two words (or the same word at both outputs) while writing into any one of four words.

Address changing and data entry occur on the rising edge of the clock. When the write enable input is low, the contents of any word may be accessed but not altered.

- No Restrictions on Clock Input Rise or Fall Times
- 3-State Outputs
- Single Phase Clocking
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or one Low-power Schottky TTL Load Over the Rated Temperature Range
- Pin Compatible with CD40108

MOTOROLA

MC14581B

4-BIT ARITHMETIC LOGIC UNIT

The MC14581B is a CMOS 4-bit ALU capable of providing 16 functions of two Boolean variables and 16 binary arithmetic operations on two 14-bit words. The level of the mode control input determines whether the output function is logic or arithmetic. The desired logic function is selected by applying the appropriate binary word to the select inputs (S0 thru S3) with the mode control input high, while the desired arithmetic operation is selected by applying a low voltage to the mode control input, the required level to carry in, and the appropriate word to the select inputs. The word inputs and function outputs can be operated with either active high or active low data.

Carry propagate ($\overline{P}$) and carry generate ($\overline{G}$) outputs are provided to allow a full look-ahead carry scheme for fast simultaneous carry generation for the four bits in the package. Fast arithmetic operations on long words are obtainable by using the MC14582B as a second order look ahead block. An inverted ripple carry input (C_n) and a ripple carry output (C_{n+4}) are included for ripple through operation.

When the device is in the subtract mode (LHHL), comparison of two 4-bit words present at the $\overline{A}$ and $\overline{B}$ inputs is provided using the A = B output. It assumes a high-level state when indicating equality. Also, when the ALU is in the subtract mode the C_{n+4} output can be used to indicate relative magnitude as shown in this table:

Data Level	C_n	C_{n+4}	Magnitude
Active High	H	H	A ≤ B
	L	H	A < B
	H	L	A > B
	L	L	A ≥ B
Active Low	L	L	A ≤ B
	H	L	A < B
	L	H	A > B
	H	H	A ≥ B

- Functional and Pinout Equivalent to 74181.
- Diode Protection on All Inputs
- All Outputs Buffered
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range

		15	—	20	—	0.015	20	—	600	
Total Supply Current**† (Dynamic plus Quiescent, Per Package) (C_L = 50 pF on all outputs, all buffers switching)	I_T	5.0	I_T = (1.8 μA/kHz) f + I_{DD}							μAdc
		10	I_T = (3.7 μA/kHz) f + I_{DD}							
		15	I_T = (5.5 μA/kHz) f + I_{DD}							

#Data labelled "Typ" is not to be used for design purposes but is intended as an indication of the IC's potential performance.

**The formulas given are for the typical characteristics only at 25°C.

†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.008.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

MOTOROLA

MC14582B

LOOK-AHEAD CARRY BLOCK

The MC14582B is a CMOS look-ahead carry generator capable of anticipating a carry across four binary adders or groups of adders. The device is cascadable to perform full look-ahead across n-bit adders. Carry, generate-carry, and propagate-carry functions are provided as enumerated in the pin designation table shown below.

- Expandable to any Number of Bits
- All Buffered Outputs
- Low Power Dissipation
- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-Power Schottky TTL Load over the Rated Temperature Range

6

MOTOROLA

MC14583B

DUAL SCHMITT TRIGGER

The MC14583B is a dual Schmitt trigger constructed with complementary P-channel and N-channel MOS devices on a monolithic silicon substrate. Each Schmitt trigger is functionally independent except for a common 3-state input and an internally-connected Exclusive OR output for use in line receiver applications. Trigger levels are adjustable through the positive, negative, and common terminals with the use of external resistors. Applications include the speed-up of a slow waveform edge in interface receivers, level detectors, etc.

- Diode Protection on All Inputs
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Single Supply Operation
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load Over the Rated Temperature Range
- Resistor Adjustable Trigger Levels

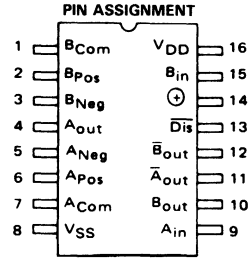
†To calculate total supply current at loads other than 50 pF:

$$I_T(C_L) = I_T(50\ pF) + (C_L - 50)\ Vfk$$

where: I_T is in μA (per package), C_L in pF, V = (V_{DD} − V_{SS}) in volts, f in kHz is input frequency, and k = 0.005.

PIN ASSIGNMENT



This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

SWITCHING CHARACTERISTICS* (C_L = 50 pF, T_A = 25°C)

MOTOROLA

MC14584B

HEX SCHMITT TRIGGER

The MC14584B Hex Schmitt Trigger is constructed with MOS P-channel and N-channel enhancement mode devices in a single monolithic structure. These devices find primary use where low power dissipation and/or high noise immunity is desired. The MC14584B may be used in place of the MC14069UB hex inverter for enhanced noise immunity to "square up" slowly changing waveforms.

- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range
- Double Diode Protection on All Inputs
- Can Be Used to Replace MC14069UB
- For Greater Hysterisis, Use MC14106B which is Pin-for-Pin Replacement for CD40106B and MM74C14

MOTOROLA

MC14585B

4-BIT MAGNITUDE COMPARATOR

The MC14585B 4-Bit Magnitude Comparator is constructed with complementary MOS (CMOS) enhancement mode devices. The circuit has eight comparing inputs (A3, B3, A2, B2, A1, B1, A0, B0), three cascading inputs (A<B, A=B, and A>B), and three outputs (A<B, A=B, and A>B). This device compares two 4-bit words (A and B) and determines whether they are "less than", "equal to", or "greater than" by a high level on the appropriate output. For words greater than 4-bits, units can be cascaded by connecting outputs (A>B), (A<B), and (A=B) to the corresponding inputs of the next significant comparator. Inputs (A<B), (A=B), and (A>B) on the least significant (first) comparator are connected to a low, a high, and a low, respectively.

Applications include logic in CPU's, correction and/or detection of instrumentation conditions, comparator in testers, converters, and controls.

- Diode Protection on All Inputs
- Expandable
- Applicable to Binary or 8421-BCD Code
- Supply Voltage Range = 3.0 Vdc to 18 Vdc
- Capable of Driving Two Low-power TTL Loads or One Low-power Schottky TTL Load over the Rated Temperature Range
- Can be Cascaded - See Fig. 3

MOTOROLA

MC14597B
MC14598B

8-BIT BUS-COMPATIBLE LATCHES

The MC14597B and MC14598B are 8-bit latches, one addressed with an internal counter and the other addressed with an external binary address. The 8 latch-outputs are high drive, three-state and bus line compatible. The drive capability allows direct applications with MPU systems such as the Motorola 6800 family.

With MC14597B, a 3-bit address counter (clocked on the falling edge of Increment) selects the appropriate latch. The latches of the MC14598B are accessed via the Address pins, A0, A1, and A2. A $\overline{\text{Full}}$ Flag is provided on the MC14597B to indicate the position of the Address counter.

All 8 outputs from the latches are available in parallel when $\overline{\text{Enable}}$ is in the low state. Data is entered into a selected latch from the Data pin when the Strobe is high. Master reset is available on both parts.

- Serial Data Input
- Three-State Bus Compatible Parallel Outputs
- Three-State Control Pin ($\overline{\text{Enable}}$) TTL Compatible Input
- Open Drain $\overline{\text{Full}}$ Flag (Multiple Latch Wire-O Ring)
- Master Reset
- Level Shifting Inputs on All Except $\overline{\text{Enable}}$
- Diode Protection – All Inputs
- Supply Voltage Range – 3.0 Vdc to 18 Vdc
- Capable of Driving TTL Over Rated Temperature Range

MAXIMUM RATINGS* (Voltages Referenced to V_{SS})

Symbol	Parameter	Value	Unit
V_{DD}	DC Supply Voltage	−0.5 to +18.0	V
V_{in}	Input Voltage, $\overline{\text{Enable}}$ (DC or Transient)	−0.5 to V_{DD} +0.5	V
V_{in}	Input Voltage, All other Inputs (DC or Transient)	−0.5 to V_{DD} +12	V
V_{out}	Output Voltage (DC or Transient)	−0.5 to V_{DD} +0.5	V
I_{in}, I_{out}	Input or Output Current (DC or Transient), per Pin	±10	mA
P_D	Power Dissipation, per Package†	500	mW
T_{stg}	Storage Temperature	−65 to +150	°C
T_L	Lead Temperature (8-Second Soldering)	260	°C

This device contains protection circuitry to guard against damage due to high static voltages or electric fields. However, precautions must be taken to avoid applications of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation, V_{in} and V_{out} should be constrained to the range $V_{SS} \leq (V_{in}$ or $V_{out}) \leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}). Unused outputs must be left open.

*Maximum Ratings are those values beyond which damage to the device may occur.

†Temperature Derating: All Packages: −7.0 mW/°C from 65°C to 125°C.

CMOS Reliability 7

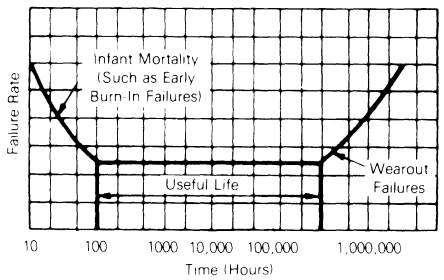
RELIABILITY

Paramount in the mind of every semiconductor user is the question of device performance versus time. After the applicability of a particular device has been established, its effectiveness depends on the length of troublefree service it can offer. The reliability of a device is exactly that — an expression of how well it will serve the customer. The following discussion will attempt to present an overview of Motorola's reliability efforts.

BASIC CONCEPTS

It is essential to begin with an explanation of the various parameters of Reliability. These are probably summarized best in the Bathtub Curve (Figure 1). The reliability performance of a device is characterized by three phases: infant mortality, useful life, and wearout. When a device is produced, there is often a small distribution of failure mechanisms which will exhibit themselves under relatively moderate stress levels and therefore appear early. This period of early failures, termed infant mortality is reduced significantly through proper manufacturing controls and screening techniques. The most effective period is that in which only occasional random failure mechanisms appear. The useful life typically spans a long period of time with a very low failure rate. The final period is that in which the devices literally wear out due to continuous phenomena which existed at the time of manufacture. Using strictly controlled design techniques and selectivity in applications, this period is shifted well beyond the lifetime required by the user.

FIGURE 1



7

Both the infant mortality and random failure rate regions can be described through the same types of calculations. During this time the probability of having no failures to a specific point in time can be expressed by the equation:

$$P_o = e^{-\lambda t}$$

where λ is the failure rate and t is time. Since λ is changing rapidly during infant mortality, the expression does not become useful until the random period, where λ is relatively constant. In this equation λ is failures per unit of time. It is usually expressed in percent failures per thousand hours. Other forms include FIT (Failures in Time = $(\%/10^3$ hrs) $\times$ 10^{-4} = 10^{-9} failures per hour) and MTTF (Mean Time To Failure) or MTBF (Mean Time Between Failures), both being equal to $1/\lambda$ and having units of hours.

Since reliability evaluations usually involve only samples of an entire population of devices, the concepts of the Central Limit Theorem apply and λ is calculated using x^2 distribution through the equation:

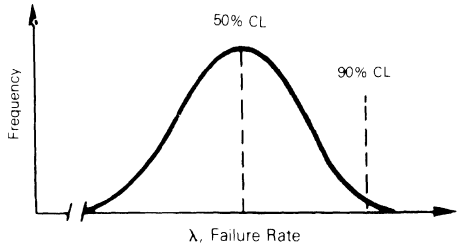
$$\lambda \leq \frac{x^2 (x, 2r + 2)}{2nt}$$

$$\text{where } x = \frac{100 - CL}{100}$$

CL = Confidence Limit in percent
r = Number of rejects
n = Number of devices
t = Duration of test

The confidence limit is the degree of conservatism desired in the calculation. The Central Limit Theorem states that the values of any sample of units out of a large population will produce a normal distribution. A 50% confidence limit is termed the best estimate and is the mean of this distribution. A 90% confidence limit is a very conservative value and results in a higher λ which represents the point at which 90% of the area of the distribution is to the left of that value (Figure 2). The term $(2r + 2)$ is called the degrees of freedom and is an expression of the number of rejects in a form suitable to x^2 tables.

FIGURE 2



The number of rejects is a critical factor since the definition of rejects often differs between manufacturers. While Motorola uses data sheet limits to determine failures, sometimes rejects are counted only if they are catastrophic. Due to the increasing chance of a test not being representative of the entire population, as sample size and test time are decreased, the x^2 calculation produces surprisingly high values of λ for short test durations even though the true long term failure rate may be quite low. For this reason relatively large amounts of data must be gathered to demonstrate the real long term failure rate.

Since this would require years of testing on thousands of devices, methods of accelerated testing have been developed.

Years of semiconductor device testing has shown that temperature will accelerate failures and that this behavior fits the form of the Arrhenius equation:

$$R(t) = R_0(t)e - \Theta/kT$$

where R(t) = Reaction rate as a function of time and temperature

R_0 = A constant
t = Time
Θ = Activation energy in electron volts
k = Boltzman's constant
T = Temperature in degrees Kelvin

To provide time-temperature equivalents this equation is applied to failure rate calculations in the form:

$$t = t_0 e^{\Theta/kT}$$

where t = time

t_0 = A constant

The Arrhenius equation essentially states that reaction rate increases exponentially with temperature. This produces a straight line when plotted in log-linear paper with a slope expressed by Θ. Θ may be physically interpreted as the energy threshold of a particular reaction or failure mechanism. The activation energy exhibited by semiconductors varies from about 0.3 eV. Although the relationships do not prohibit devices from having poor failure rates and high activation energies, good performance usually does not imply a high Θ. Studies by Bell Telephone Laboratories have indicated that an overall Θ for semiconductors is 1.0 eV. This value has been accepted by the Rome Air Development Command for time-temperature acceleration in powered burn-in. Data taken by Motorola on Integrated Circuits have verified this number and it is therefore applied as our standard time-temperature regression for extrapolation of high temperature failure rates to temperatures at which the devices will be used (Figure 3). For Discrete products, 0.7 eV is generally applied.

To accomplish this, the time in device hours (t1) and temperature (T1) of the test are plotted as point P1. A vertical line is drawn at the temperature of interest (T2) and a line with a 1.0 eV slope is drawn through point P1.

Its intersection with the vertical line defines point P2, and determines the number of equivalent device hours (t2). This number may then be used with the x^2 formula to determine the failure rate at the temperature of interest. Assuming T1 of 125°C at t1 of 10,000 hours, a t2 of 7.8 million hours results at a T2 of 50°C. If one reject results in the 10,000 device hours of testing at 125°C, the failure rate at that temperature will be 0.1%/1,000 hours using a 60% confidence level. One reject at the equivalent 7.8 million device hours at 50°C will result in a 0.0008%/1,000 hour failure rate, as illustrated in Figure 4.

Three parameters determine the failure rate quoted by the manufacturer: the failure rate at the test temperature, the activation energy employed, and the difference between the test temperature and the temperature of the quoted λ. A term often used in this manipulation is the "acceleration factor" which is simply the equivalent device hours at the lower temperature divided by the actual test device hours.

Every device will eventually fail, but with the present techniques in Semiconductor design and applications, the wearout phase is extended far beyond the lifetime required. During wearout, as in infant mortality, the failure rate is changing rapidly and therefore loses its value. The parameter used to describe performance in this area is "Median Life" and is the point at which 50% of the devices have failed. There are currently only few significant wearout mechanisms: electromigration of circuit metallization, electrolytic corrosion in plastic devices and metal fatigue for Power devices.

FIGURE 3
NORMALIZED TIME-TEMPERATURE REGRESSIONS FOR VARIOUS ACTIVATION ENERGY VALUES

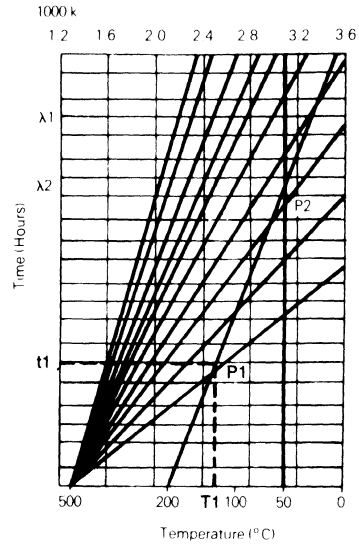


FIGURE 4
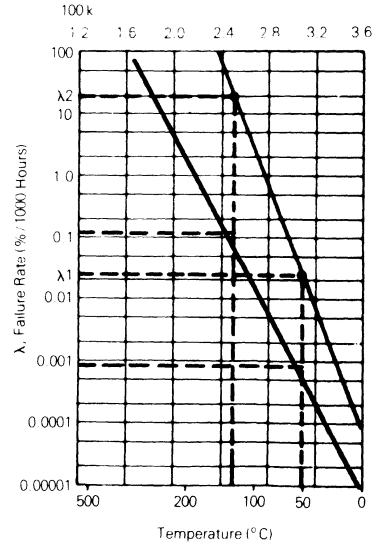
FAILURE RATE



For increased flexibility in working with a broad range of device hours, the time-temperature regression lines have been normalized to 500°C and the time scale omitted, permitting the user to define the scale based on his own requirements.

7

THERMAL MANAGEMENT

Circuit performance and long-term circuit reliability are affected by die temperature. Normally, both are improved by keeping the IC junction temperatures low.

Electrical power dissipated in any integrated circuit is a source of heat. This heat source increases the temperature of the die relative to some reference point, normally the ambient temperature of 25°C in still air. The temperature increase, then, depends on the amount of power dissipated in the circuit and on the net thermal resistance between the heat source and the reference point.

The temperature at the junction is a function of the packaging and mounting system's ability to remove heat generated in the circuit — from the junction region to the ambient environment. The basic formula for converting power dissipation to estimated junction temperature is:

$$T_J = T_A + P_D(\bar{\theta}_{JC} + \bar{\theta}_{CA}) \quad (1)$$

or

$$T_J = T_A + P_D(\bar{\theta}_{JA}) \quad (2)$$

where

T_J = maximum junction temperature
T_A = maximum ambient temperature
P_D = calculated maximum power dissipation including effects of external loads (see Power Dissipation in section III).
$\bar{\theta}_{JC}$ = average thermal resistance, junction to case
$\bar{\theta}_{CA}$ = average thermal resistance, case to ambient
$\bar{\theta}_{JA}$ = average thermal resistance, junction to ambient

This Motorola recommended formula has been approved by RADC or DESC for calculating a "practical" maximum operating junction temperature for MIL-M-38510 (JAN) devices.

Only two terms on the right side of equation (1) can be varied by the user — the ambient temperature, and the device case-to-ambient thermal resistance, $\bar{\theta}_{CA}$. (To some extent the device power dissipation can also be controlled, but under recommended use the V_{CC} supply and loading dictate a fixed power dissipation.) Both system air flow and the package mounting technique affect the $\bar{\theta}_{CA}$ thermal resistance term. $\bar{\theta}_{JC}$ is essentially independent of air flow and external mounting method, but is sensitive to package material, die bonding method, and die area.

FIGURE 5 — THERMAL RESISTANCE VALUES FOR STANDARD I/C PACKAGES

Thermal Resistance in Still Air								
Package Description								
No. Leads	Body Style	Body Material	Body W x L	Die Bonds	Die Area (Sq. Mils)	Flag Area (Sq. Mils)	θ_{JC} (°C/Watt)	
							Avg.	Max.
14	DIL	Epoxy	1/4" x 3/4"	Epoxy	4096	6,400	38	61
16	DIL	Epoxy	1/4" x 3/4"	Epoxy	4096	12,100	34	54

NOTES:
1. All plastic packages use copper lead frames.
2. Body style DIL is "Dual-In-Line."
3. Standard Mounting Method: Dual-In-Line Socket or P/C board with no contact between bottom of package and socket or P/C board.

For applications where the case is held at essentially a fixed temperature by mounting on a large or temperature-controlled heat sink, the estimated junction temperature is calculated by:

$$T_J = T_C + P_D(\bar{\theta}_{JC}) \quad (3)$$

where T_C = maximum case temperature and the other parameters are as previously defined.

The maximum and average $\bar{\theta}_{JC}$ resistance values for standard IC packages are given in Figure 4-1. In Figure 4-2, this basic data is converted into graphs showing the maximum power dissipation allowable at various ambient temperatures (still air) for circuits mounted in the different packages, taking into account the maximum permissible operating junction temperature for long term life (≥ 100,000 hours for ceramic packages).

AIR FLOW

The effect of air flow over the packages on $\bar{\theta}_{JA}$ (due to a decrease in $\bar{\theta}_{CA}$) reduces the temperature rise of the package, therefore permitting a corresponding increase in power dissipation without exceeding the maximum permissible operating junction temperature.

Even though different device types mounted on a printed circuit board may each have different power dissipations, all will have the same input and output levels provided that each is subject to identical air flow and the same ambient air temperature. This eases design, since the only change in levels between devices is due to the increase in ambient temperatures as the air passes over the devices, or differences in ambient temperature between two devices.

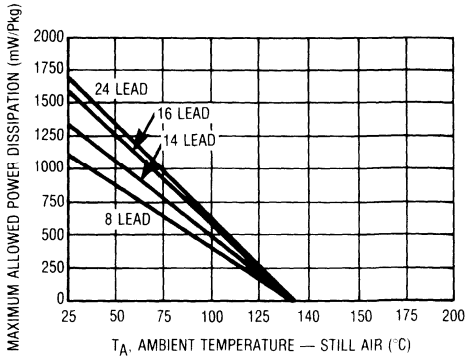


FIGURE 6 — AMBIENT TEMPERATURE DERATING CURVES (PLASTIC DUAL-IN-LINE PACKAGE TEST ENVIRONMENT)

The majority of users employ some form of air-flow cooling. As air passes over each device on a printed circuit board, it absorbs heat from each package. This heat gradient from the first package to the last package is a function of the air flow rate and individual package dissipations. Figure 4-3 provides gradient data at power levels of 200 mW, 250 mW, 300 mW, and 400 mW with an air flow rate of 500 lfpm. These figures show the proportionate increase in the junction temperature of each dual in-line package as the air passes over each device. For higher rates of air flow the change in junction temperature from package to package down the airstream will be lower due to greater cooling.

FIGURE 7 — THERMAL GRADIENT OF JUNCTION TEMPERATURE (16-PIN DUAL-IN-LINE PACKAGE)

Power Dissipation (mW)	Junction Temperature Gradient (°C/Package)
200	0.4
250	0.5
300	0.63
400	0.88

Devices mounted on 0.062" PC board with Z axis spacing of 0.5". Air flow is 500 lfpm along the Z axis.

OPTIMIZING THE LONG TERM RELIABILITY OF PLASTIC PACKAGES

Todays plastic integrated circuit packages are as reliable as ceramic packages under most environmental conditions. However when the ultimate in system reliability is required, thermal management must be considered as a prime system design goal.

Modern plastic package assembly technology utilizes gold wire bonded to aluminum bonding pads throughout the electronics industry. When exposed to high temperatures for protracted periods of time an intermetallic compound can form in the bond area resulting in high impedance contacts and degradation of device performance. Since the formation of intermetallic compounds is directly related to device junction temperature, it is incumbent on the designer to determine that the device junction temperatures are consistent with system reliability goals.

Predicting Bond Failure Time:

Based on the results of almost ten (10) years of +125°C operating life testing, a special arrhenius equation has been developed to show the relationship between junction temperature and reliability.

$$(1)\ T = (6.376 \times 10^{9})e\left[\frac{11554.267}{273.15 + T_J}\right]$$

Where: T = Time in hours to 0.1% bond failure (1 failure per 1,000 bonds).
T_J = Device junction temperature, °C.

And:

$$(2)\ T_J = T_A + P_D\theta_{JA} = T_A + \Delta T_J$$

Where: T_J = Device junction temperature, °C.
T_A = Ambient temperature, °C.
P_D = Device power dissipation in watts.
θ_{JA} = Device thermal resistance, junction to air, °C/Watt.
ΔT_J = Increase in junction temperature due to on-chip power dissipation.

Table 1 shows the relationship between junction temperature, and continuous operating time to 0.1% bond failure, (1 failure per 1,000 bonds).

TABLE 1 — DEVICE JUNCTION TEMPERATURE versus TIME TO 0.1% BOND FAILURES.

Junction Temperature °C	Time, Hours	Time, Years
80	1,032,200	117.8
90	419,300	47.9
100	178,700	20.4
110	79,600	9.4
120	37,000	4.2
130	17,800	2.0
140	8,900	1.0

Table 1 is graphically illustrated in Figure 4-4 which shows that the reliability for plastic and ceramic devices are the same until elevated junction temperatures induces intermetallic failures in plastic devices. Early and mid-life failure rates of plastic devices are not effected by this intermetallic mechanism.

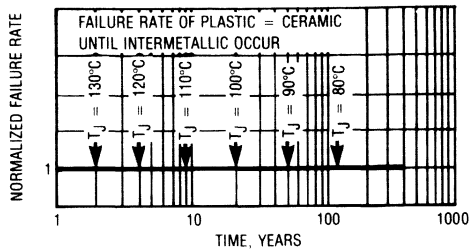

FIGURE 8 — FAILURE RATE versus TIME JUNCTION TEMPERATURE

Procedure

After the desired system failure rate has been established for failure mechanisms other than intermetallics, each device in the system should be evaluated for maximum junction temperature. Knowing the maximum junction temperature, refer to Table 1 or Equation 1 to determine the continuous operating time required to 0.1% bond failures due to intermetallic formation. At this time, system reliability departs from the desired value as indicated in Figure 4-4.

Air flow is one method of thermal management which should be considered for system longevity. Other commonly used methods include heat sinks for higher powered devices, refrigerated air flow and lower density board stuffing. Since θ_{CA} is entirely dependent on the application, it is the responsibility of the designer to determine its value. This can be achieved by various techniques including simulation, modeling, actual measurement, etc.

The material presented here emphasizes the need to consider thermal management as an integral part of system design and also the tools to determine if the management methods being considered are adequate to produce the desired system reliability.

7

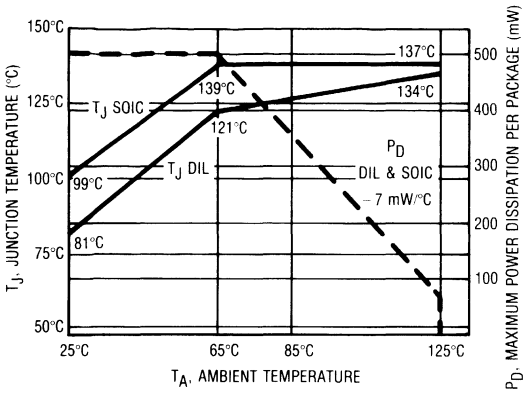

FIGURE 9 — JUNCTION TEMPERATURE FOR WORST CASE CMOS LOGIC DEVICE

This graph illustrates junction temperature for the worst case CMOS Logic device (MC14007UB) — smallest die area operating at maximum power dissipation limit in still air. The solid line indicates the junction temperature, T_J, in a Dual-In-Line (DIL) package and in a Small Outline IC (SOIC) package versus ambient temperature, T_A. The dotted line indicates maximum allowable power dissipation derated over the ambient temperature range, 25°C to 125°C.

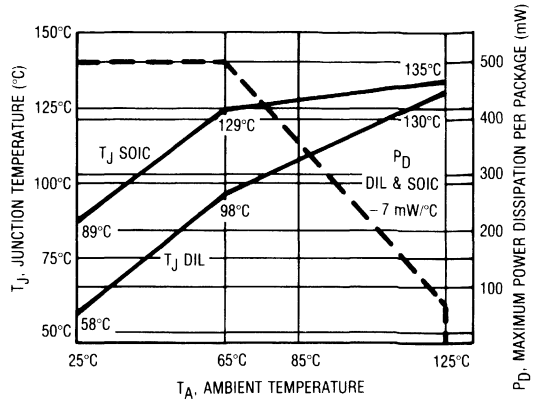

FIGURE 10 — JUNCTION TEMPERATURE FOR TYPICAL CMOS LOGIC DEVICE

This graph illustrates junction temperature for a CMOS Logic device (MC14053B) — average die area operating at maximum power dissipation limit in still air. The solid line indicates the junction temperature, T_J, in a Dual-In-Line (DIL) package and in a Small Outline IC (SOIC) package versus ambient temperature, T_A. The dotted line indicates maximum allowable power dissipation derated over the ambient temperature range, 25°C to 125°C.

Equivalent Gate Count 8

EQUIVALENT GATE COUNT

The following is a list of equivalent gate counts for some of Motorola's CMOS devices. In general for CMOS, the number of equivalent gates is equal to the total number of transistors on chip divided by four. This list includes only those devices with equivalent gate counts known at the time of this printing.

DEVICE	EQUIVALENT GATE COUNT	DEVICE	EQUIVALENT GATE COUNT

Packaging Information Including Surface Mounts

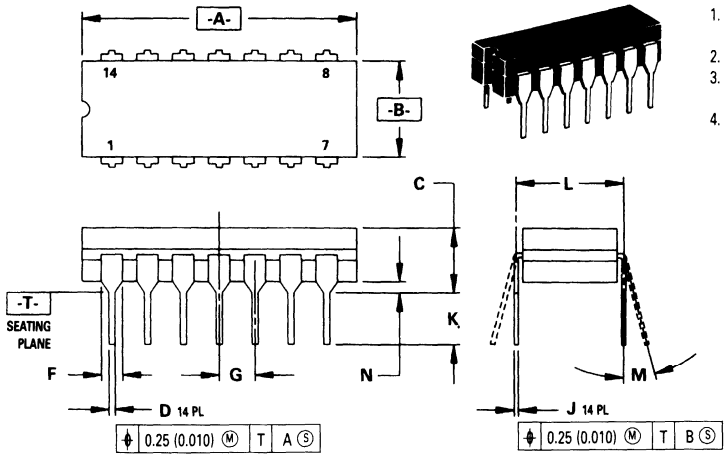
9

PACKAGE DIMENSIONS

The standard package availability for each device is indicated on the front page of the individual data sheets. Dimensions for the packages are given in this chapter. Surface mount packages may be special ordered by specifying the following suffixes: "D" (narrow SOIC), "DW" (wide SOIC), or "FN" (PLCC). For example, to order a quad NOR gate, use MC14001BD.

14-PIN PACKAGE

CERAMIC PACKAGE
CASE 632-08



NOTES:
1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: INCH.
3. DIMENSION L TO CENTER OF LEAD WHEN FORMED PARALLEL.
4. DIM F MAY NARROW TO 0.76 (0.030) WHERE THE LEAD ENTERS THE CERAMIC BODY.

Errata to

DL131 REV 2, Q1/91 – CMOS LOGIC DATA BOOK

March 5, 1991

This errata applies to the DL131, Rev 2 (Q1/91) CMOS Logic Data book. The following pages have been amended.

Page:

4-2 In the **MAXIMUM RATINGS** table, in the lower left of the page:
Change the footnote for P_D, (Power Dissipation) to read:
"Temperature Derating: Plastic "P & D/DW" Packages: –7.0 mW/°C From 65°C To 125°C
Ceramic "L" Packages: –12 mW/°C From 100°C To 125°C"

4-3 thru 4-6
Tables 1 and 2, **ELECTRICAL CHARACTERISTICS,** at the top of each table in the parameter limit columns, Replace: "T_{LOW}" with "–55°C"
"T_{HIGH}" with "+125°C"
Delete the footnotes referencing "T_{LOW}" and "T_{HIGH}".
Within the tables:
Delete all references to "**(CL/CP)** and associated parameter information".
Delete all occurrences of the words, "**(AL)** or **(AL Device)**".
See notes 2 and 3.

6-28 MC14008B. In the **ELECTRICAL CHARACTERISTICS** table, "**Quiescent Current**" block, correct I_{DD} **Max** for V_{DD} is as follows:

V_{DD}	–55°C	+25°C	
5	5	5	µAdc
10	10	10	µAdc
15	20	20	µAdc

6-114 MC14042B, In the **SWITCHING CHARACTERISTICS** table, "**Propagation Delay Time, Clock To Q, $\overline{Q}$**" block:
Change: V_{DD} from 25 to 15.

6-122 MC14046B, In the **ELECTRICAL CHARACTERISTICS** table, under the Minimum and Maximum limit columns:
Delete column with "**CL/CP**" in the title heading.
Delete the word "**AL Device**".

6-125 MC14049UB, MC14050B, In the **MAXIMUM RATINGS** table:
Change the "**Power Dissipation, Per Package, P_D**" values to read:
(Plastic/Ceramic), 825 mW
(SOIC), 740 mW.

6-128 Disregard Figure 4 plot.

6-252, 262, 378, 383 and 425
MC14511B, MC14513B, MC14543B, MC14544B and MC14558: In the **MAXIMUM RATINGS** table:
Add: "**Power Dissipation, Per Package, P_D**" with a value of 500 mW.

6-389 MC14547B, In the **MAXIMUM RATINGS** table, in the "**Maximum Continuous Power Dissipation**" row:
Change: "**P_{OH}max**" to "**P_D**".

7-3 Figure 4 Failure Rate Plot:
Replace with new Figure 4 plot on this page.

7-4 In the first column, fifth paragraph:
Change the reference to Figure 4-1 to Figure 5.
Delete the remainder of the paragraph.
At the bottom of the right column:
Delete Figure 6.

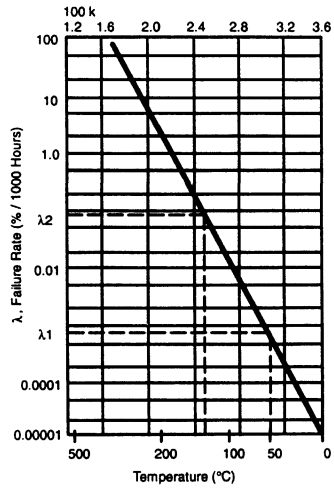
7-5 In the first column, first paragraph:
Change the reference to Figure 4-3 to Figure 7.
In the right column, the third paragraph:
Change Figure 4-4 to Figure 8.

7-6 The "P_D" plots in Figures 9 and 10:
These plots refer only to Plastic (DIP/SOIC) derating.

Notes:

1. Add the page 4-2 temperature derating footnote to the **MAXIMUM RATINGS** table of all data sheets in the data book.
2. In the past, Motorola offered Military Temperature Range (–55°C to +125°C) product designated with the "AL" suffix and Commercial Temperature Range (–40°C to +85°C) product designated by the suffix "CL/CP". The "CL/CP, D/DW" products have been upgraded to meet the Military Temperature Range (–55°C to +125°C). The "AL" suffix is no longer needed and has been deleted from this product line.
3. Parameter information which previously applied only to "AL" products, now applies to all products.

Figure 4
Failure Rate



Hex Buffer

MC14049B

The MC14049B Hex Inverter/Buffer is constructed with MOS P-Channel and N-Channel enhancement mode devices in a single monolithic structure. This complementary MOS device finds primary use where low power dissipation and/or high noise immunity is desired. This device provides logic level conversion using only one supply voltage, V_{DD}.

The input-signal high level (V_{IH}) can exceed the V_{DD} supply voltage for logic level conversions. Two TTL/DTL loads can be driven when the device is used as a CMOS-to-TTL/DTL converter ($V_{DD} = 5.0$ V, $V_{OL} \leq 0.4$ V, $I_{OL} \geq 3.2$ mA).

Note that pins 13 and 16 are not connected internally on this device; consequently connections to these terminals will not affect circuit operation.

- High Source and Sink Currents
- High-to-Low Level Converter
- Supply Voltage Range = 3.0 V to 18 V
- V_{IN} can exceed V_{DD}
