Frequency (MHz)	Series Equivalent Complex Impedance (R + jX) (Ω)	Parallel Resistance Rp (Ω)	Parallel Capacitance Cp (pF)
90	190 – j380	950	4.7
100	160 – j360	970	4.4
110	130 – j340	1020	4.2
120	110 – j320	1040	4.2
130	97 – j300	1030	4.0
140	82 – j280	1040	4.0
150	71 – j270	1100	4.0
160	59 – j260	1200	3.9
170	52 – j240	1160	3.9
180	44 – j230	1250	3.8
190	38 – j220	1300	3.8

A series LC network to ground (which is V_{CC}) is comprised of the inductance of the base lead of the on–chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 24) to cancel the negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C_o, provides a feedback path that is low enough in reactance at frequencies of 5th overtone or higher to cause trouble. C_o has little effect near resonance because of the low impedance of the crystal motional arm (R_m–L_m–C_m). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned off the crystal resonant frequency, it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor (L_o) is placed in parallel with the crystal. L_o is chosen to resonant with the crystal parallel capacitance (C_o) at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

UHF Application

Figure 22 shows a 318.5 to 320 MHz receiver which drives the mixer with an external varactor controlled (307.8 to 309.3 MHz) LC oscillator using an MPS901 (RF low power transistor in a TO–92 plastic package; also MMBR901 is available in a SOT–23 surface mount package). With the 50 kΩ 10 turn potentiometer this oscillator is tunable over a range of approximately 1.5 MHz. The MMBV909L is a low voltage varactor suitable for UHF applications; it is a dual back–to–back varactor in a SOT–23 package. The input matching network uses a 1:4 impedance matching transformer (Recommended sources are Mini–Circuits and Coilcraft).

Using the same IF ceramic filters and quadrature detector circuit as specified in the applications circuit in Figure 17, the 12 dB SINAD performance is –95 dBm for a f_{mod} = 1.0 kHz sinusoidal waveform and f_{dev} ±40 kHz.

This circuit is breadboarded using the evaluation PC board shown in Figures 32 and 33. The RF ground is V_{CC} and path lengths are minimized. High quality surface mount components were used except where specified. The absolute values of the components used will vary with layout placement and component parasitics.

RSSI Response

Figure 26 shows the full RSSI response in the application circuit. The 10.7 MHz, 110 kHz wide bandpass ceramic filters (recommended sources are TOKO part # SK107M5–AO–10X or Murata Erie SFE10.7MHY–A) provide the correct bandpass insertion loss to linearize the curve between the limiter and IF portions of RSSI. Figure 25 shows that limiting occurs at an input of –100 dBm. As shown in Figure 26, the RSSI output linear from –100 dBm to –30 dBm.

The RSSI rise and fall times for various RF input signal levels and R20 values are measured at Pin 20 without 10 nF filter capacitor. A 10 kHz square wave pulses the RF input signal on and off. Figure 27 shows that the rise and fall times are short enough to recover greater than 10 kHz ASK data; with a wider IF bandpass filters data rates up to 50 kHz may be achieved. The circuit used is the application circuit in Figure 17 with no RSSI output filter capacitor.

45 MHz Narrowband Receiver

The above application examples utilize a 10.7 MHz IF. In this section a narrowband receiver with a 455 kHz IF will be described. Figure 23 shows a full schematic of a 45 MHz receiver that uses a 3rd overtone crystal with the on–chip oscillator transistor. The oscillator configuration is similar to the one used in Figure 17; it is called an impedance inversion Colpitts. A 44.545 MHz 3rd overtone, series resonant crystal is used to achieve an IF frequency at 455 kHz. The ceramic IF filters selected are Murata Erie part # SFG455A3. 1.2 kΩ chip resistors are used in series with the filters to achieve the terminating resistance of 1.4 kΩ to the filter. The IF decoupling is very important; 0.1 μF chip capacitors are used at Pins 6, 7, 11 and 12. The quadrature detector tank circuit uses a 455 kHz quadrature tank from Toko.

The 12 dB SINAD performance is –109 dBm for a f_{mod} = 1.0 kHz and a f_{dev} = ±4.0 kHz. The RSSI dynamic range is approximately 80 dB of linear range (see Figure 24).

Receiver Design Considerations

The curves of signal levels at various portions of the application receiver with respect to RF input level are shown in Figure 28. This information helps determine the network topology and gain blocks required ahead of the MC13156 to achieve the desired sensitivity and dynamic range of the receiver system. In the application circuit the input third order intercept (IP3) performance of the system is approximately –25 dBm (see Figure 29).

BER TESTING AND PERFORMANCE

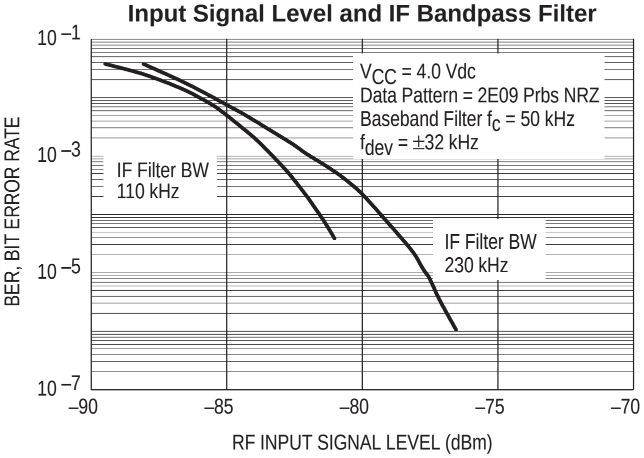
Description

The test setup shown in Figure 30 is configured so that the function generator supplies a 100 kHz clock source to the bit error rate tester. This device generates and receives a repeating data pattern and drives a 5 pole baseband data filter. The filter effectively reduces harmonic content of the baseband data which is used to modulate the RF generator which is running at 144.45 MHz. Following processing of the signal by the receiver (MC13156), the recovered baseband sinewave (data) is AC coupled to the data slicer. The data slicer is essentially an auto–threshold comparator which tracks the zero crossing of the incoming sinewave and provides logic level data at its ouput. Data errors associated with the recovered data are collected by the bit error rate receiver and displayed.

Bit error rate versus RF signal input level and IF filter bandwidth are shown in Figure 31. The bit error rate data was taken under the following test conditions:

- Data rate = 100 kbps
- Filter cutoff frequency set to 39% of the data rate or 39 kHz.
- Filter type is a 5 pole equal–ripple with 0.5° phase error.
- V_{CC} = 4.0 Vdc
- Frequency deviation = ±32 kHz.

Figure 31. Bit Error Rate versus RF Input Signal Level and IF Bandpass Filter



Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 32 and 33). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates.

MOTOROLA

MC13158

Wideband FM IF Subsystem

The MC13158 is a wideband IF subsystem that is designed for high performance data and analog applications. Excellent high frequency performance is achieved, with low cost, through the use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13158 has an on–board grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multi–channel operation. The mixer is useful to 500 MHz and may be used in a balanced differential or single ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has an Off function to shut the output off to save current. An enable control is provided to power down the IC for power management in battery operated applications.

Applications include DECT, wideband wireless data links for personal and portable laptop computers and other battery operated radio systems which utilize GFSK, FSK or FM modulation.

- Designed for DECT Applications
- 1.8 to 6.0 Vdc Operating Voltage
- Low Power Consumption in Active and Standby Mode
- Greater than 600 kHz Detector Bandwidth
- Data Slicer with Special Off Function
- Enable Function for Power Down of Battery Operated Systems
- RSSI Dynamic Range of 80 dB Minimum
- Low External Component Count

CIRCUIT DESCRIPTION

General

The MC13158 is a low power single conversion wideband FM receiver incorporating a split IF. This device is designated for use as the backend in digital FM systems such as Digital European Cordless Telephone (DECT) and wideband data links with data rates up to 2.0 Mbps. It contains a mixer, oscillator, Received Signal Strength Indicator (RSSI), IF amplifier, limiting IF, quadrature detector, power down or enable function, and a data slicer with output off function. Further details are covered in the Pin Function Description which shows the equivalent internal circuit and external circuit requirements.

Current Regulation/Enable

Temperature compensating voltage independent current regulators which are controlled by the enable pin (Pin 25) where “low” powers up and “high” powers down the entire circuit.

Mixer

The mixer is a double–balanced four quadrant multiplier and is designed to work up to 500 MHz. It can be used in differential or in single ended mode by connecting the other input to the positive supply rail. The linear gain of the mixer is approximately 22 dB at 100 mVrms LO drive level. The mixer gain and noise figure have been emphasized at the expense of intermodulation performance. RSSI measurements are added in the mixer to extend the range to higher signal levels. The single–ended parallel equivalent input impedance of the mixer is Rp ~ 1.0 kΩ and Cp ~ 2.0 pF. The buffered output of the mixer is internally loaded resulting in an output impedance of 330 Ω.

Local Oscillator

The on–chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. Third overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 180 MHz is feasible using the on–chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor bias is increased by adding an external resistor from Pin 29 to V_{EE}; however, with an external resistor the oscillator stays on during power down. Typically, –10 dBm of local oscillator drive is needed to adequately drive the mixer. With an external oscillator source, the IC can be operated up to 500 MHz.

RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the mixer, IF and limiting amplifier stages. An increase in RSSI dynamic range, particularly at higher input signal levels is achieved. The RSSI circuit is designed to provide typically 85 dB of dynamic range with temperature compensation.

Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB and 330 Ω source and load impedance. For higher data rates used in DECT and related applications, LC bandpass filtering is necessary to acquire the desired bandpass response; however, the RSSI linearity will require the same insertion loss.

RSSI Buffer

The RSSI output current creates a voltage across an external resistor. A unity voltage–gain amplifier is used to buffer this voltage. The output of this buffer has an active pull–up but no pull–down, so it can also be used as a peak detector. The negative slew rate is determined by external capacitance and resistance to the negative supply.

IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal DC feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 40 dB at 10.7 MHz.

The fixed internal input impedance is 330 Ω. When using ceramic filters requiring source and loss impedances of 330 Ω, no external matching is necessary. Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 330 Ω.

Limiter

The limiter section is similar to the IF amplifier section except that five differential stages are used. The fixed internal input impedance is 330 Ω. The total gain of the limiting amplifier section is approximately 70 dB. This IF limiting amplifier section internally drives the quadrature detector section and it is also brought out on Pin 12.

Quadrature Detector

The quadrature detector is a doubly balanced four quadrant multiplier with an internal 5.0 pF quadrature capacitor between Pins 12 and 13. An external capacitor may be added between these pins to increase the IF signal to the external parallel RLC resonant circuit that provides the 90 degree phase shift and drives the quadrature detector. A single pin (Pin 13) provides for the external LC parallel resonant network and the internal connection to the quadrature detector.

Internal low pass filter capacitors have been selected to control the bandwidth of the detector. The recovered signal is brought out by the inverting amplifier buffer. An external feedback resistor from the output (Pin 17) to the input of the inverting amplifier (Pin 15) controls the output amplitude; it is combined with another external resistor from the input to the negative supply (Pin 16) to set the output dc level. For a resistor ratio of 1, the DC level at the detector output is 2.0 V_{BE} (see Figure 12). A small capacitor C_{17} across the first resistor (from Pin 17 to 15) can be used to reduce the bandwidth.

Data Slicer

The data slicer is a comparator that is designed to square up the data signal. Across the data slicer inputs (Pins 18 and 20) are back to back diodes.

The recovered data signal from the quadrature detector can be DC coupled to the data slicer DS IN1 (Pin 18). In the application circuit shown in Figure 1 it will be centered at 2.0 V_{BE} and allowed to swing ± V_{BE}. A capacitor is placed from DS IN2 (Pin 20) to V_{EE}. The size of this capacitor and the nature of the data signal determine how faithfully the data slicer shapes up the recovered signal. The time constant is short for large peak to peak voltage swings or when there is a change in DC level at the detector output. For small signal or for continuous bits of the same polarity which drift close to the threshold voltage, the time constant is longer.

A unique feature of the data slicer is that the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22 – DS Gnd) to V_{EE} rather than internally to V_{EE}. This is provided in order to reduce switching feedback to the front end. A control pin is provided to shut the data slicer output off (DS “off” – Pin 19). With DS “off” pin at V_{CC} the data slicer output is shut off by shutting down the base drive to the output transistor. When a channel is being monitored to make an RSSI measurement, but not to collect data, the data output may be shut off to save current.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1	Mix Out		**Mixer Output** The mixer output impedance is 330 Ω; it matches to 10.7 MHz ceramic filters with 330 Ω input impedance.
2	V_{CC1}		**Supply Voltage (V_{CC1})** This pin is the V_{CC} pin for the Mixer, Local Oscillator, and IF Amplifer. The operating supply voltage range is from 1.8 Vdc to 5.0 Vdc. In the PCB layout, the V_{CC} trace must be kept as wide as possible to minimize inductive reactances along the trace; it is best to have it completely fill around the surface mount components and traces on the circuit side of the PCB.
3	IF In		**IF Input** The input impedance at Pin 3 is 330 Ω. It matches the 330 Ω load impedance of a 10.7 MHz ceramic filter. Thus, no external matching is required.
4	IF Dec1		**IF DEC1 & DEC2** IF decoupling pins. Decoupling capacitors should be placed directly at the pins to enhance stability. Two capacitors are decoupled to the RF ground V_{CC1}; one is placed between DEC1 & DEC2.
5	IF Dec2		
6	IF Out		**IF Output** The output impedance is 330 Ω; it matches the 330 input resistance of a 10.7 MHz ceramic filter.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
7	V_{CC2}		**Supply Voltage (V_{CC2})** This pin is V_{CC} supply for the Limiter, Quadrature Detector, data slicer and RSSI buffer circuits. In the application PC board this pin is tied to a common V_{CC} trace with V_{CC1}.
8	Lim In		**Limiter Input** The limiter input impedance is 330 Ω.
9	Lim Dec1		**Limiter Decoupling** Decoupling capacitors are placed directly at these pins and to V_{CC} (RF ground). Use the same procedure as in the IF decoupling.
10	Lim Dec2		
11,14, 27 & 28	N/C		**No Connects** There is no internal connection to these pins; however it is recommended that these pins be connected externally to V_{CC} (RF ground).
12	Lim Out		**Limiter Output** The output impedance is low. The limiter drives a quadrature detector circuit with in–phase and quadrature phase signals.
13	Quad		**Quadrature Detector Circuit** The quadrature detector is a doubly balanced four–quadrant multiplier with an internal 5.0 pF capacitor between Pins 12 and 13. An external capacitor may be added to increase the IF signal to Pin 13. The quadrature detector pin is provided to connect the external RLC parallel resonant network which provides the 90 degree phase shift and drives the quadrature detector.
15	Det Gain		**Detector Buffer Amplifier** This is an inverting amplifier. An external feed-back resistor from Pin 17 to 15, (the inverting input) controls the output amplitude; another resistor from Pin 15 to the negative supply (Pin 16) sets the DC output level. A 1:1 resistor ratio sets the output DC level at two V_{BE} with respect to V_{EE}. A small capacitor from Pin 17 to 15 can be used to set the bandwidth.
17	Det Out		
16	V_{EE2}		**Supply Ground (V_{EE2})** In the PCB layout, the ground pins (also applies to Pin 26) should be connected directly to chassis ground. Decoupling capacitors to V_{CC} should be placed directly at the ground pins.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
19 21 22	DS “off” DS Out DS Gnd		**Data Slicer Off** The data output may be shut off to save current by placing DS “off” (Pin 19) at V_{CC}. **Data Slicer Output** In the application example a 10 kΩ pull–up resistor is connected to the collector of the output transistor at Pin 21. **Data Slicer Ground** All the inverting switching stages in the comparator are supplied through the emitter pin of the output transistor (Pin 22) to ground rather than internally to V_{EE} in order to reduce switching feedback to the front end.
18 20	DS In1 DS In2		**Data Slicer Inputs** The data slicer has differential inputs with back to back diodes across them. The recovered signal is DC coupled to DS IN1 (Pin 18) at nominally V_{18} with respect to V_{EE}; thus, it will maintain $V_{18} \pm V_{BE}$ at Pin 18. DS IN2 (Pin 20) is AC coupled to V_{EE}. The choice of coupling capacitor is dependent on the nature of the data signal. For small signal or continuous bits of the same polarity, the response time is relatively large. On the other hand, for large peak to peak voltage swings or when the DC level at the detector output changes, the response time is short. See the discussion in the application section for external circuit design details.
23 24	RSSI Buf RSSI		**RSSI Buffer** A unity gain amplifier is used to buffer the voltage at Pin 24 to 23.The output of the unity gain buffer (Pin 23) has an active pull up but no pull down. An external resistor is placed from Pin 23 to V_{EE} to provide the pull down. **RSSI** The RSSI output current creates a voltage drop across an external resistor from Pin 24 to V_{EE}. The maximum RSSI current is 26 μA; thus, the maximum RSSI voltage using a 100 kΩ resistor is approximately 2.6 Vdc. Figure 22 shows the RSSI Output Voltage versus Input Signal Level in the application circuit. The negative slew rate is determined by an external capacitor and resistor to V_{EE} (negative supply). The RSSI rise and fall times for various RF input signal levels and R_{24} values without the capacitor, C_{24} are displayed in Figure 24. This is the maximum response time of the RSSI.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
25 26	Enable V_{EE1}		**Enable** The IC regulators are enabled by placing this pin at V_{EE}.
			**V_{CC} and V_{EE} ESD Protection** ESD protection diodes exist between the V_{CC} and V_{EE} pins. It is important to note that significant differences in potential (> 0.5 V_{BE}) between the two V_{CC} pins or between the V_{EE} pins can cause these structures to start to conduct, thus compromising isolation between the supply busses. V_{CC1} & V_{CC2} should be maintained at the same DC potential, as should V_{EE1} & V_{EE2}.
28 29	Osc Base Osc Emitter		**Oscillator Base** This pin is connected to the base lead of the common collector transistor. Since there is no internal bias resistor to the base, V_{CC} is applied through an external choke or coil. **Oscillator Emitter** This pin is connected to the emitter lead; the emitter is connected internally to a current source of about 200 μA. Additional emitter current may be obtained by connecting an external resistor to V_{EE}; $I_E = V_{29}/R_{29}$. Details of circuits using overtone crystal and LC varactor controlled oscillators are discussed in the application section.
31 32	Mix In1 Mix In2		**Mixer Inputs** The parallel equivalent differential input impedance of the mixer is approximately 2.0 kΩ in parallel with 1.0 pF. This equates to a single ended input impedance of 1.0 kΩ in parallel with 2.0 pF. The application circuit utilizes a SAW filter having a differential output that requires a 2.0 kΩ II 2.0 pF load. Therefore, little matching is required between the SAW filter and the mixer inputs. This and alternative circuits are discussed in more detail in the application section.

APPLICATIONS INFORMATION

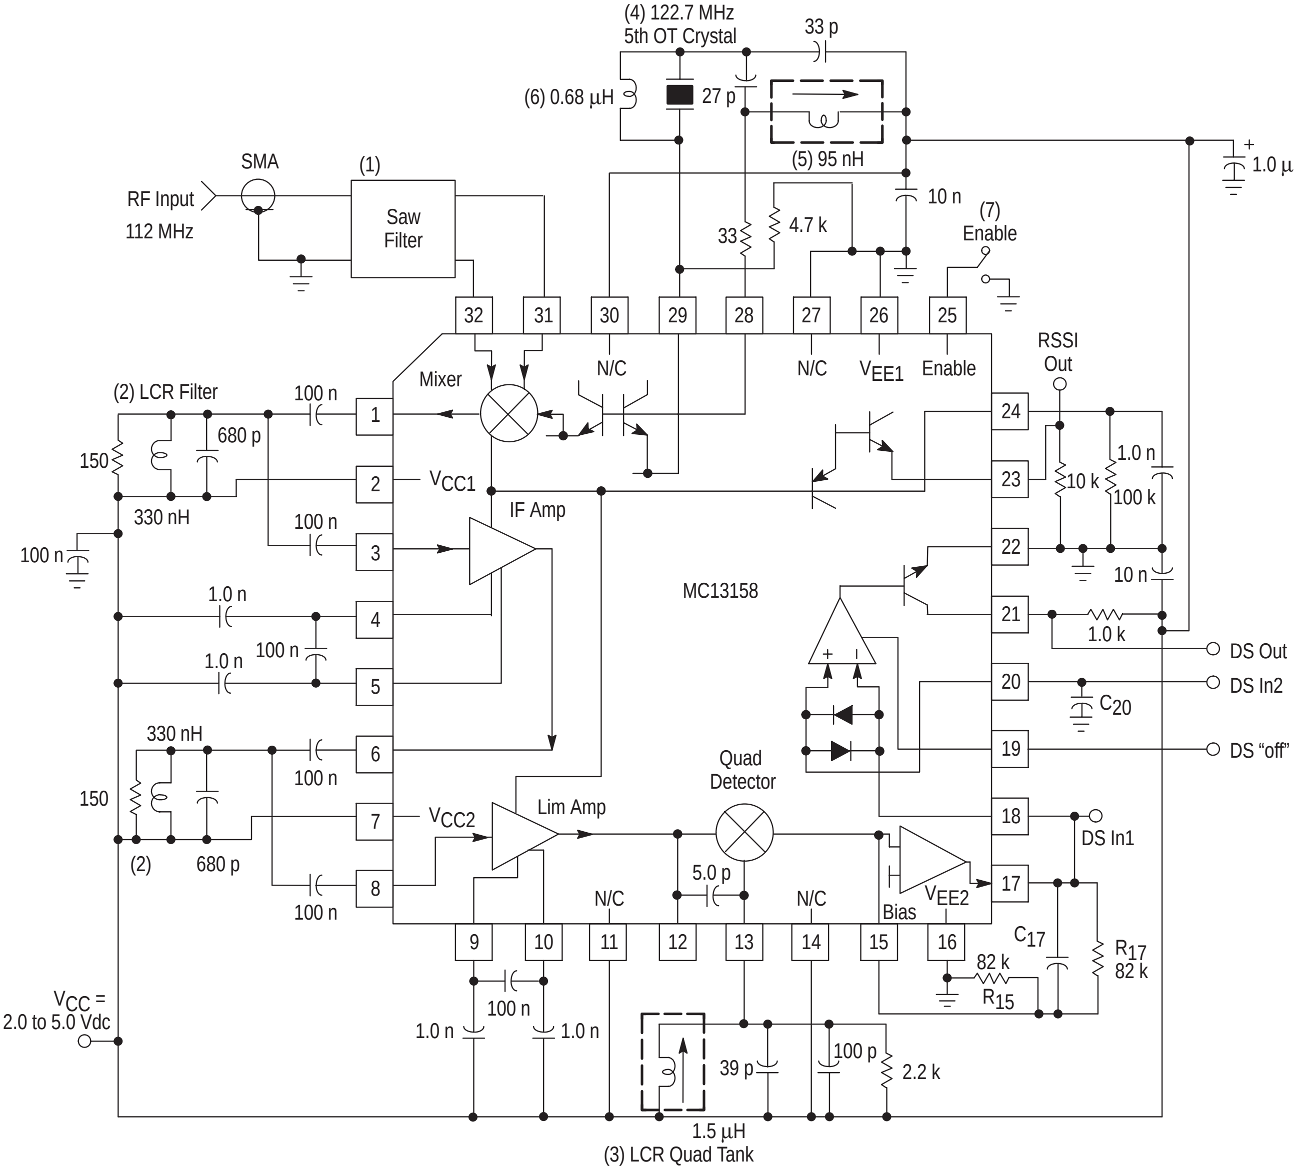
Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 29 and 30). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. Figures 13 and 14 show the placement for the components specified in the application circuit (Figure 12). The application circuit schematic specifies particular components that were used to achieve the results shown in the typical curves and tables but alternate components should give similar results.

Figure 12. Application Circuit



NOTES:
1. Saw Filter – Siemens part number Y6970M(5 pin SIP plastic package).
2. An LCR filter reduces the broadband noise in the IF; ceramic filters may be used for data rates under 500 kHz. 4.0 dB insertion loss filters optimize the linearity of RSSI.
3. The quadrature tank components are chosen to optimize linearity of the recovered signal while maintaining adequate recovered signal level. 1.5 µH 7.0 mm variable shielded inductor: Toko part # 292SNS–T1373Z. The shunt resistor is approximately equal to Q(2πfL), where Q ~ 18 (3.0 dB BW = 600 kHz).
4. The local oscillator circuit utilizes a 122.7 MHz, 5th overtone, series resonant crystal specified with a frequency tolerance of 25 PPM, ESR of 120 Ω max. The oscillator configuration is an emitter coupled butler.
5. The 95 NH (Nominal) inductor is a 7.0 mm variable shielded inductor: Coilcraft part # 150–04J08S or equivalent.
6. 0.68 µH axial lead chokes (molded inductor): Coilcraft part # 90–11.
7. To enable the IC, Pin 25 is taken to V_{EE}. The external pull down resistor at Pin 29 could be linked to the enable function; otherwise if it is taken to V_{EE} as shown, it will keep the oscillator biased at about 500 µA depending on the V_{CC} level.
8. The other resistors and capacitors are surface mount components.

Figure 13. Circuit Side Component Placement

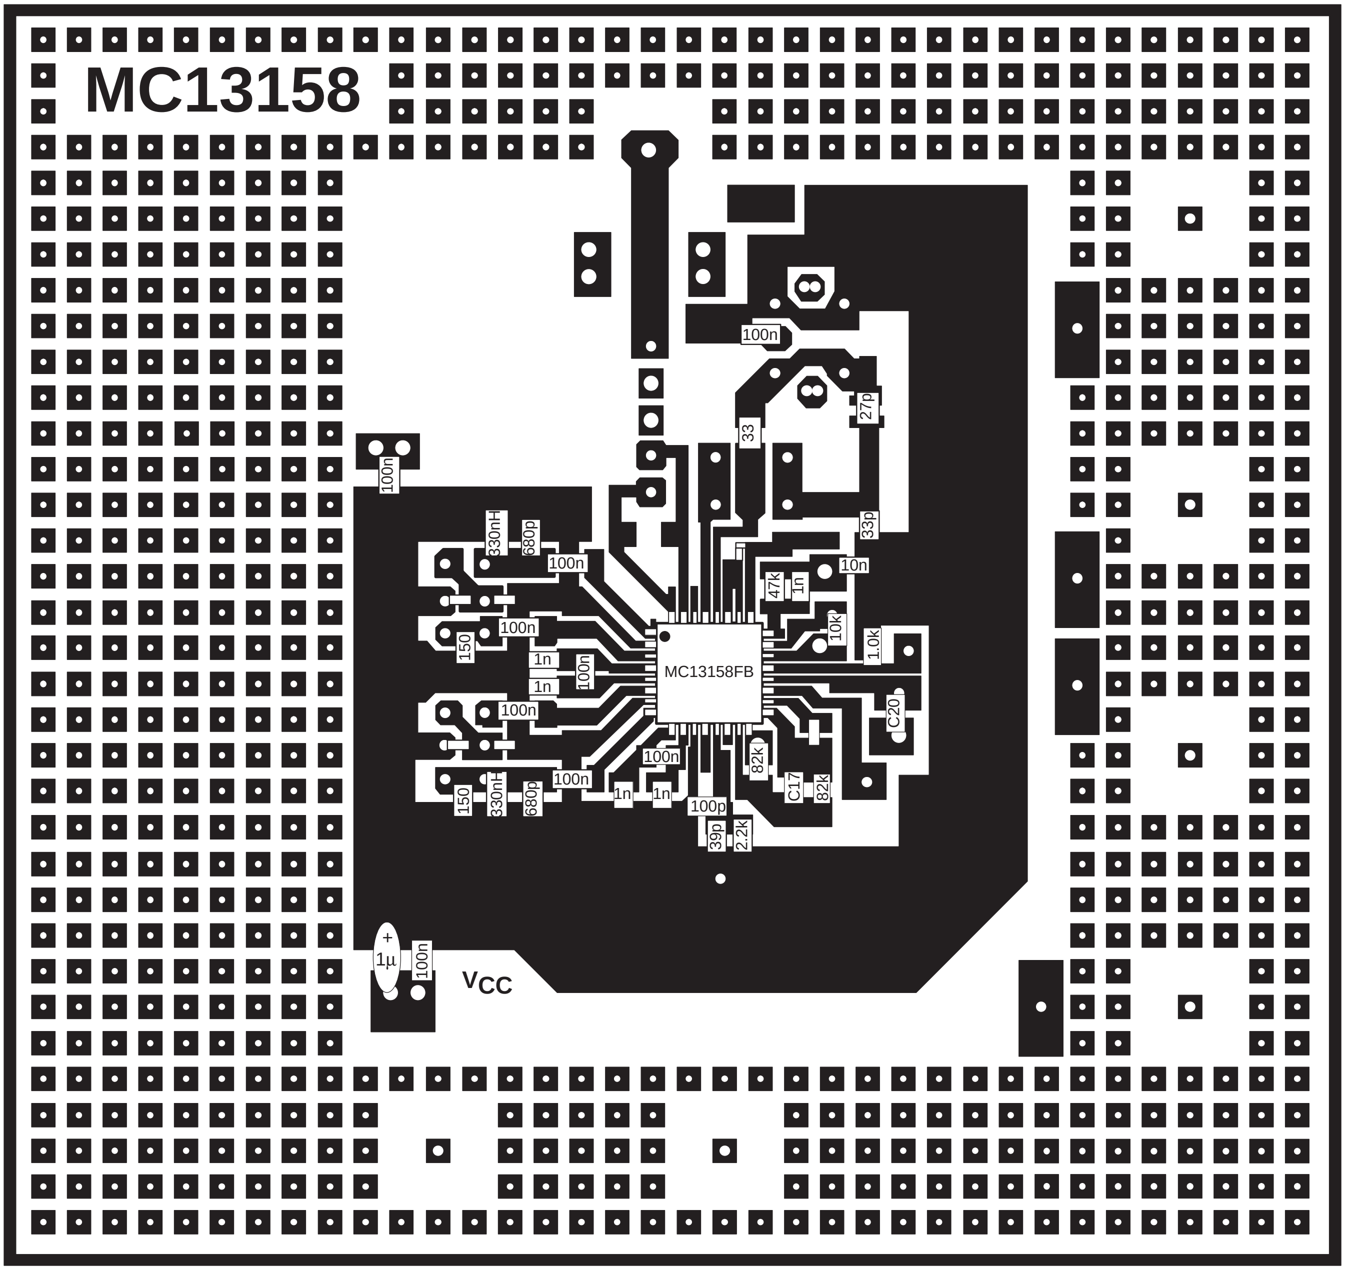


Figure 14. Ground Side Component Placement

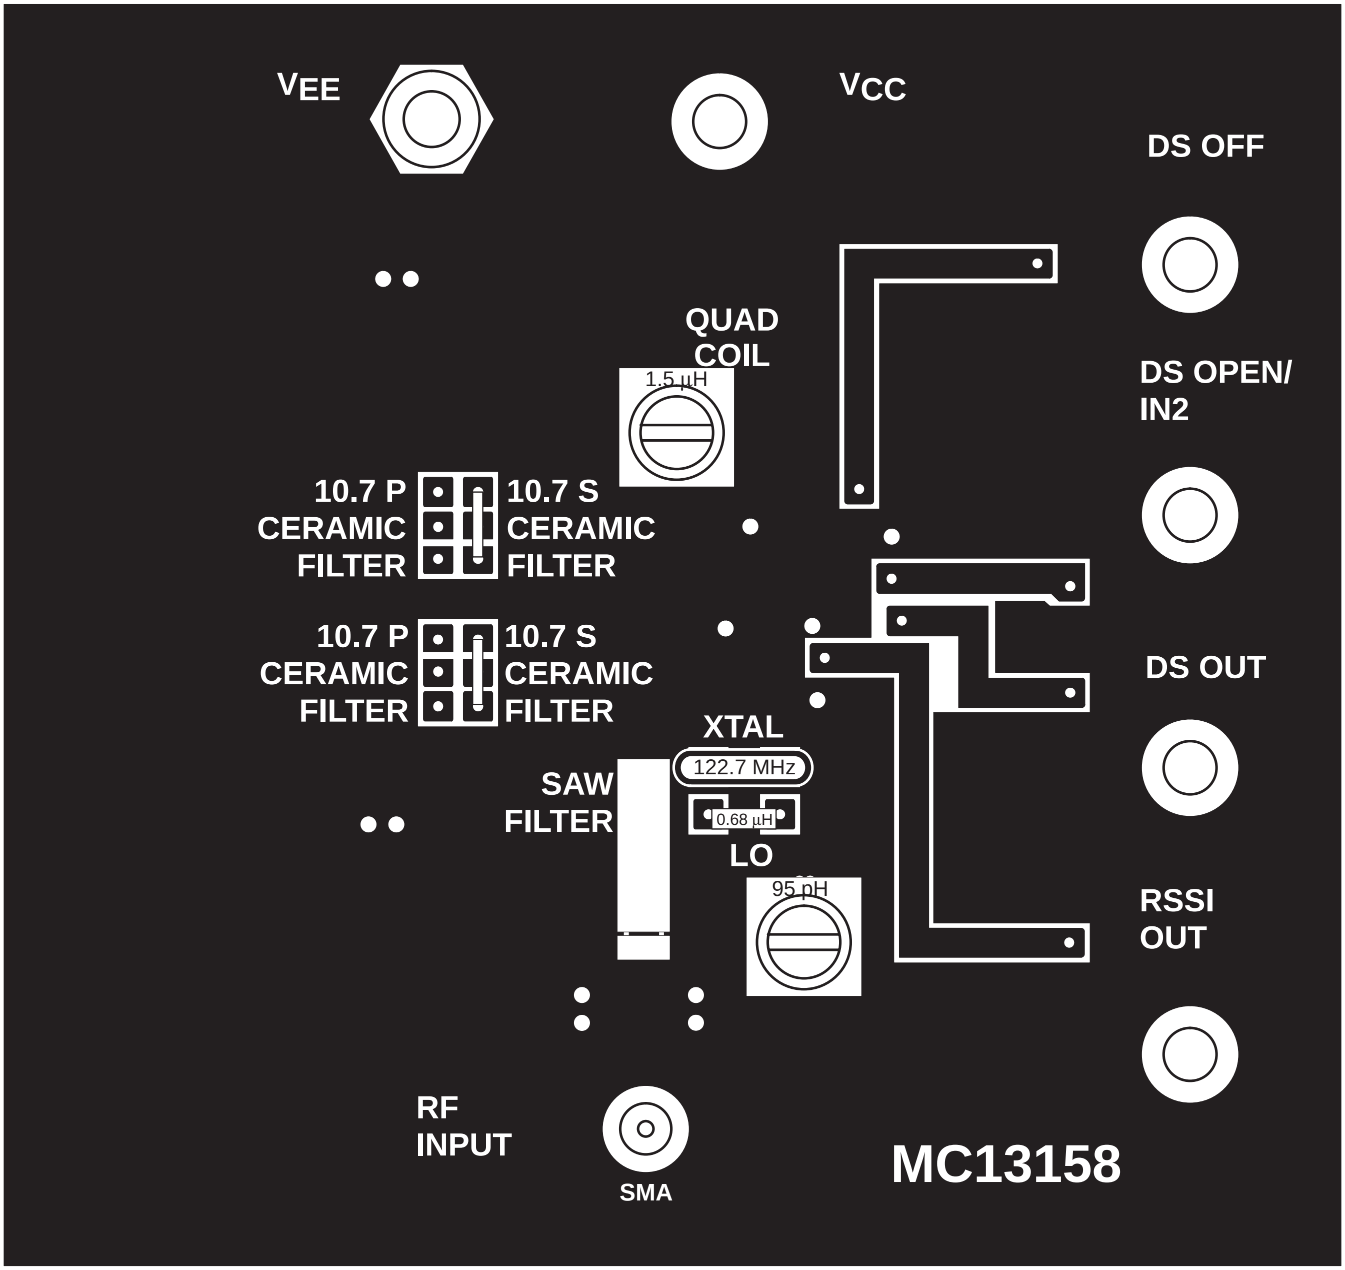

Input Matching/Components

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection. In a wideband system the primary sensitivity of the receiver backend may be achieved before the last mixer. Bandpass filtering in the limiting IF is costly and difficult to achieve for bandwidths greater than 280 kHz.

The SAW filter should be selected to easily interface with the mixer differential input impedance of approximately 2.0 kΩ in parallel with 1.0 pF. The PC board is dedicated to the Siemens SAW filter (part number Y6970M); the part is designed for DECT at 112 MHz 1st IF frequency. It is designed for a load impedance of 2.0 kΩ in parallel with 2.0 pF; thus, no or little input matching is required between the SAW filter and the mixer.

The Siemens SAW filter has an insertion loss of typically 10 dB and a 3.0 dB bandwidth of 1.0 MHz. The relatively high insertion loss significantly contributes to the system noise and a filter having lower insertion loss would be desirable. In existing low loss SAW filters, the required load impedance is 50 Ω; thus, interface matching between the filter and the mixer will be required. Figure 15 is a table of the single–ended mixer input impedance. A careful noise analysis is necessary to determine the secondary contribution to system noise.

Figure 15. Mixer Input Impedance

(Single–ended)

f (MHz)	Rs (Ω)	Xs (Ω)	Rp (Ω)	Xp (Ω)	Cp (pF)
50	930	–350	1060	–2820	1.1
100	480	–430	865	–966	1.6
150	270	–400	860	–580	1.8
200	170	–320	770	–410	1.9
250	130	–270	690	–330	1.85
300	110	–250	680	–300	1.8
400	71	–190	580	–220	1.8
500	63	–140	370	–170	1.9
600	49	–110	300	–130	2.0

System Noise Considerations

The system block diagram in Figure 16 shows the cascaded noise stages contributing to the system noise; it represents the application circuit in Figure 12 and a low noise preamp using a MRF941 transistor (see Figure 17). The preamp is designed for a conjugately matched input and output at 2.0 Vdc V_{CE} and 3.0 mAdc I_c. S–parameters at 2.0 V, 3.0 mA and 100 MHz are:

S11 = 0.86, –20
S21 = 9.0, 164
S12 = 0.02, 79
S22 = 0.96, –12

The bias network sets V_{CE} at 2.0 V and I_c at 3.0 mA for V_{CC} = 3.0 to 3.5 Vdc. The preamp operates with 18 dB gain and 2.7 dB noise figure.

In the cascaded noise analysis the system noise equation is:

$$F_{system} = F1 + [(F2–1)/G1] + [(F3–1)]/[(G1)(G2)]$$

where:

F1 = the Noise Factor of the Preamp
G1 = the Gain of the Preamp
F2 = the Noise factor of the SAW Filter
G2 = the Gain of the SAW Filter
F3 = the Noise factor of the Mixer

Note: the proceeding terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

$$F = \log^{-1}[(\text{NF in dB})/10] \quad \text{and similarly}$$

$$G = \log^{-1}[(\text{Gain in dB})/10]$$

The noise figure and gain measured in dB are shown in the system block diagram. The mixer noise figure is typically 14 dB and the SAW filter adds typically 10 dB insertion loss. Addition of a low noise preamp having a 18 dB gain and 2.7 dB noise figure not only improves the system noise figure but it increases the reverse isolation from the local oscillator to the antenna input at the receiver. Calculating in terms of gain and noise factor yields the following:

$F1 = 1.86;\ G1 = 63.1$
$F2 = 10;\ G2 = 0.1$
$F3 = 25.12$

Thus, substituting in the equation for system noise factor:

$F_{system} = 5.82;\ NF_{system} = 7.7\ \text{dB}$

Figure 16. System Block Diagram for Noise Analysis

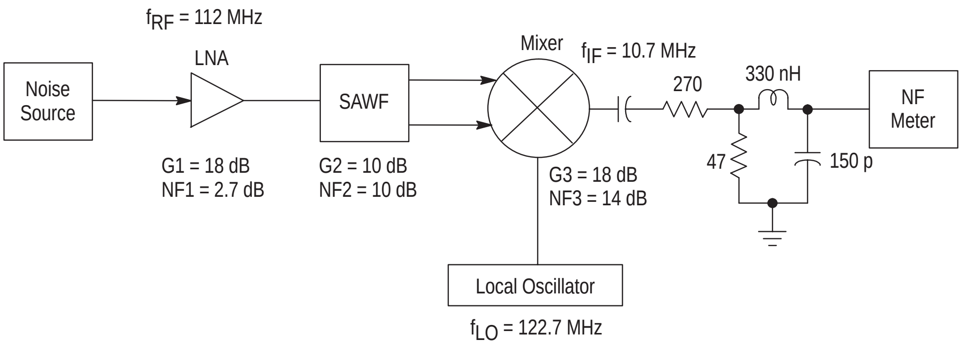

Figure 17. 112 MHz LNA

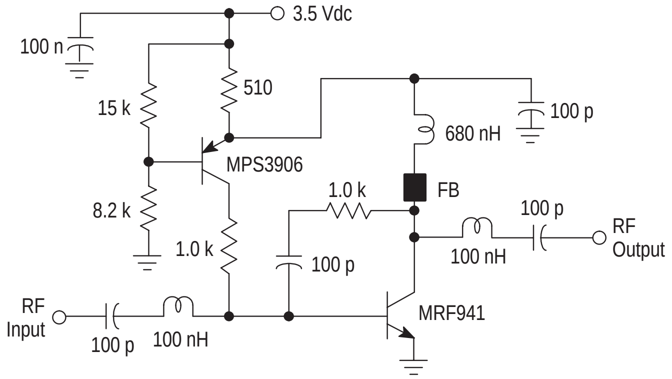


LOCAL OSCILLATORS

VHF Applications

The on–chip grounded collector transistor may be used for HF and VHF local oscillator with higher order overtone crystals. The local oscillator in the application circuit (Figure 12) shows a 5th overtone oscillator at 122.7 MHz. This circuit uses a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on–chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have tight enough tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start–up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ground (which is V_{CC}) is comprised of the inductance of the base lead of the on–chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 28) to cancel the negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C_o, provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble. C_o has little effect near resonance because of the low impedance of the crystal motional arm (R_m–L_m–C_m). As the tunable inductor which forms the resonant tank with the tap capacitors is tuned “off” the crystal resonant frequency it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor, L_o, is placed in parallel with the crystal. L_o is chosen to be resonant with the crystal parallel capacitance, C_o, at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

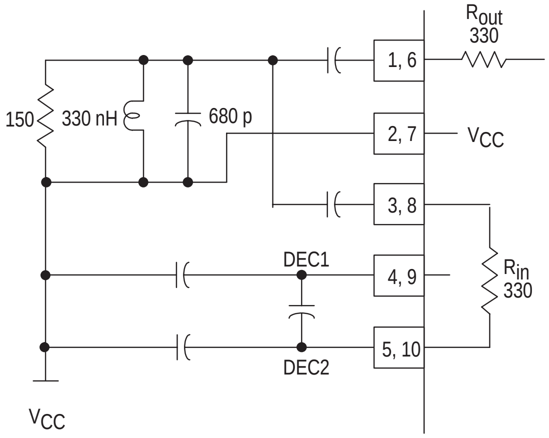
IF Filtering/Matching

In wideband data systems the IF bandpass needed is greater than can be found in low cost ceramic filters operating at 10.7 MHz. It is necessary to bandpass limit with LC networks or series–parallel ceramic filter networks. Murata offers a series–parallel resonator pair (part number

KMFC545) with a 3.0 dB bandwidth of ± 325 kHz and a maximum insertion loss of 5.0 dB. The application PC board is laid out to accommodate this filter pair (a filter pair is used at both locations of the split IF). However, even using a series parallel ceramic filter network yields only a maximum bandpass of 650 kHz. In some applications a wider band IF bandpass is necessary.

A simple LC network yields a bandpass wider than the SAW filter but it does reduce an appreciable amount of wideband IF noise. In the application circuit an LC network is specified using surface mount components. The parallel LC components are placed from the outputs of the mixer and IF amplifier to the V_{CC} trace; internal 330 loads are connected from the mixer and IF amplifier outputs to DEC2 (Pin 5 and 10 respectively).This loads the outputs with the optimal load impedance but creates a low insertion loss filter. An external shunt resistor may be used to widen the bandpass and to acquire the 10 dB composite loss necessary to linearize the RSSI output. The equivalent circuit is shown in Figure 18.

Figure 18. IF LCR Filter



The following equations satisfy the 12 dB loss (1:4 resistive ratio):

$$(\text{Rext})(330)/(\text{Rext} + 330) = \text{Requivalent}$$
$$\text{Requivalent}/(\text{Requivalent} + 330) = 1/4$$

Solve for Requivalent:

$$4(\text{Requivalent}) = \text{Requivalent} + 330$$
$$3(\text{Requivalent}) = 330$$
$$\text{Requivalent} = 110$$

Substitute for Requivalent and solve for Rext:

$$330(\text{Rext}) = 110(\text{Rext}) + (330)(110)$$
$$\text{Rext} = (330)(110)/220$$
$$\text{Rext} = 165\ \Omega$$

The IF is 10.7 MHz although any IF between 10 to 20 MHz could be used. The value of the coil is lowered from that used in the quadrature circuit because the unloaded Q must be maintained in a surface mount component. A standard value component having an unloaded Q = 100 at 10.7 MHz is 330 nH; therefore the capacitor is 669 pF. Standard values have been chosen for these components;

$$\text{Rext} = 150\ \Omega$$
$$C = 680\ \text{pF}$$
$$L = 330\ \text{nH}$$

Computation of the loaded Q of this LCR network is

$$Q = \text{Requivalent}/X_L$$

where: $X_L = 2\pi fL$ and Requivalent is 103 Ω

$$\text{Thus,}\ Q = 4.65$$

The total system loss is

$$20\ \log\ (103/433) = -12.5\ \text{dB}$$

Quadrature Detector

The quadrature detector is coupled to the IF with an internal 5.0 pF capacitor between Pins 12 and 13. For wideband data applications, the drive to the detector can be increased with an additional external capacitor between these pins; thus, the recovered signal level output is increased for a given bandwidth

The wideband performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

$$Q = R_T/X_L \qquad [1]$$

where R_T is the equivalent shunt resistance across the LC Tank

X_L is the reactance of the quadrature inductor at the IF frequency ($X_L = 2\pi fL$).

The inductor and capacitor are chosen to form a resonant LC tank with the PCB and parasitic device capacitance at the desired IF center frequency as predicted by

$$f_c = [2\pi\ (LC_p)^{1/2}]^{-1} \qquad [2]$$

where L is the parallel tank inductor C_p is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a wideband detector at 10.7 MHz and a loaded Q of 18. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 10.7 MHz and an IF bandpass of 600 kHz, the IF bandpass Q is approximately 6.4.

Example:

Let the external Cext = 139 pF. (The minimum value here should be much greater than the internal device and PCB parasitic capacitance, Cint ≈ 3.0 pF). Thus, C_p = Cint + Cext = 142 pF.

Rewrite equation (2) and solve for L:

$$L = (0.159)^2/(C_p fc^2)$$

$L = 1.56\ \mu H$; Thus, a standard value is choosen:

$$L = 1.56\ \mu H \text{ (tunable shielded inductor)}$$

The value of the total damping resistor to obtain the required loaded Q of 18 can be calculated by rearranging equation (1):

$$R_T = Q(2\pi fL)$$
$$R_T = 18(2\pi)(10.7)(1.5) = 1815\ \Omega$$

The internal resistance, Rint at the quadrature tank Pin 13 is approximately 13 kΩ and is considered in determining the external resistance, Rext which is calculated from

$$\text{Rext} = ((R_T)(\text{Rint}))/(\text{Rint} - R_T)$$

$\text{Rext} = 2110$; Thus, choose the standard value:

$$\text{Rext} = 2.2\ \text{k}\Omega$$

It is important to set the DC level of the detector output at Pin 17 to center the peak to peak swing of the recovered signal. In the equivalent internal circuit shown in the Pin Function Description, the reference voltage at the positive terminal of the inverting op amp buffer amplifier is set at 1.0 V_{BE}. The detector DC level, V_{17} is determined by the following equation:

$$V_{17} = [((R_{15}/R_{17}) + 1)/(R_{15}/R_{17})]\ V_{BE}$$

Thus, for a 1:1 ratio of R_{15}/R_{17}, V_{17} = 2.0 V_{BE} = 1.4 Vdc. Similarly for a 2:1, V_{17} = 1.5 V_{BE} = 1.05 Vdc; and for 3:1, V_{17} = 1.33 V_{BE} = 0.93 Vdc.

Figure 19 shows the detector “S–Curves”, in which the resistor ratio is varied while maintaining a constant gain (R_{17} is held at 62 k). R_{15} is 62 k for a 1:1 ratio; while R_{15} = 120 k and 180 k to produce the 2:1 and 3:1 ratios. The IF signal into the detector is swept ± 500 kHz about the 10.7 MHz IF center frequency. The resulting curve show how the resistor ratio and the supply voltage effects the symmetry of the “S–curve” (Figure 21 Test Setup). For the 3:1 and 2:1 ratio, symmetry is maintained with V_S from 2.0 to 5.0 Vdc; however, for the 1:1 ratio, symmetry is lost at 2.0 Vdc.

Figure 19. Detector Output Voltage versus Frequency Deviation

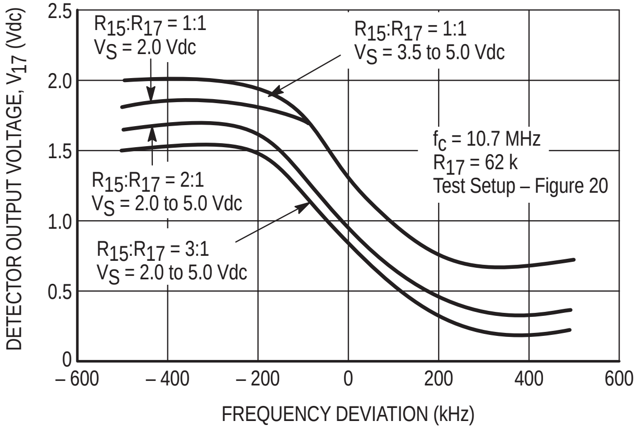


Figure 20. Demodulator “S–Curve” Test Setup

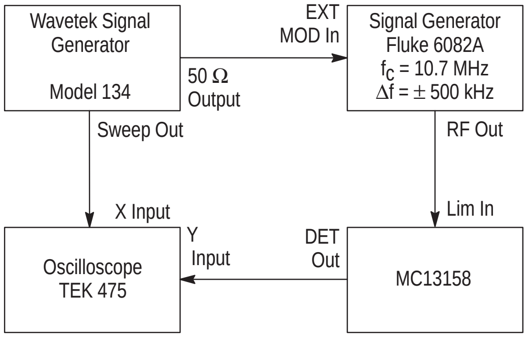


Data Slicer Circuit

C_{20} at the input of the data slicer is chosen to maintain a time constant long enough to hold the charge on the capacitor for the longest strings of bits at the same polarity. For a data rate at 576 kHz a bit stream of 15 bits at the same polarity would equate to an apparent data rate of approximately 77 kbps or 38 kHz. The time constant would be approximately 26 µs. The following expression equates the time constant, t, to the external components:

$$t = 2\pi\ (R_{18})(C_{20})$$

Solve for C_{20}:

$$C_{20} = t/2\pi\ (R_{18})$$

where the effective resistance R_{18} is a complex function of the demodulator feedback resistance and the data slicer input circuit. In the data input network the back to back diodes form a charge and discharge path for the capacitor at Pin 20; however, the diodes create a non–linear response. This resistance is loaded by the ß, beta of the detector output transistor; beta =100 is a typical value (see Figure 21). Thus, the apparent value of the resistance at Pin 18 (DS IN1) is approximately equal to:

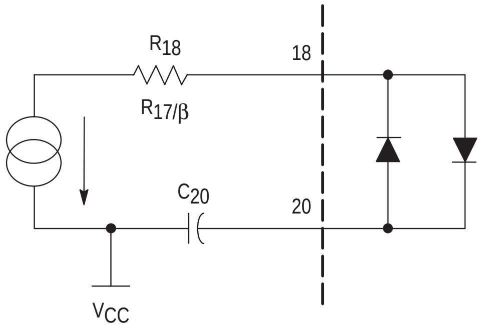
$$R_{18} \frown R_{17}/100$$

where R_{17} is 82 kΩ, the feedback resistor from Pin 17 to 15. Therefore, substituting for R_{18} and solving for C_{20}:

$$C_{20} = 15.9\ (t)/R_{17} = 5.04\ \text{nF}$$

The closest standard value is 4.7 nF.

Figure 21. Data Slicer Equivalent Input Circuit



SYSTEM PERFORMANCE DATA

RSSI

In Figure 22, the RSSI versus RF Input Level shows the linear response of RSSI over a 65 dB range but it has extended capability over 80 dB from –80 dBm to +10 dBm. The RSSI is measured in the application circuit (Figure 12) in which a SAW filter is used before the mixer; thus, the overall sensitivity is compromised for the sake of selectivity. The curves are shown for three filters having different bandwidths:

1) LCR Filter with 2.3 MHz 3.0 dB BW (Circuit and Component Placement is shown in Figure 12)
2) Series–Parallel Ceramic Filter with 650 kHz 3.0 dB BW (Murata Part # KMFC–545)
3) Ceramic Filter with 280 kHz 3.0 dB BW.

SINAD Performance

Figure 24 shows a test setup for a narrowband demodulator output response in which a C–message filter and an active de–emphasis filter is used following the demodulator. The input is matched using a 1:4 impedance transformer. The SINAD performance is shown in Figure 25 with no preamp and in Figure 26 with a preamp (Preamp – Figure 16). The 12 dB SINAD sensitivity is –101 dBm with no preamp and –113 dBm with the preamp.

MOTOROLA

MC13159

WIDEBAND FM IF SUBSYSTEM FOR PHS AND DIGITAL APPLICATIONS

SEMICONDUCTOR TECHNICAL DATA

Advance Information

Wideband FM IF Amp

The MC13159 is a wideband FM IF subsystem that is designed for high performance data and digital applications. Excellent high frequency performance is achieved, with low cost, through the use of Motorola’s RF bipolar process. The MC13159 includes a mixer, Local Oscillator Buffer amplifier, IF amplifier, Limiter amplifier and RSSI functions. The mixer is useful for 240 MHz input used in a single–ended/balanced differential configuration. The IF and Limiter amplifier are separated for using the external filter in series or connecting directly by an external capacitor. RSSI output is derived by summing the output of both IF and Limiter sections. An enable control is provided to power down the IC for power management in battery operated applications.

Applications are suitable for PHS, DECT, PDC, GSM, PCS, wideband wireless data links and other battery operated radio systems.

- Designed for PHS Applications
- 2.7 to 5.5 V Operating Voltage
- Low Drain Current: 5.5 mA (Typ)
- Wide Input Dynamic Range of Mixer (Maximum –16 dBm Input)
- Enable Function for Power Down Mode
- Over 80 dB of RSSI Dynamic Range (AC Coupling Between IF Amplifier and Limiter Amplifier)
- Low External Component Count

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description
1	Mix Decoup		**Mixer Decoupling** Mixer decoupling pin. 220 pF is decoupled to the RF ground. This pin also can be used for differential input with Mix_{in}.
16	Mix_{in}		**Mixer Input** Input impedance is about 400 Ω at 240 MHz. Single–ended matching section at 240 MHz is referenced at application circuit.
2	V_{CC}		**Supply Voltage** Supply voltage range range is from 2.7 Vdc to 5.5 Vdc. 1.0 nF of decoupling capacitor is placed directly at this pin to reduce the floor noise.
3	LO_{in}		**Local Oscillator Input** Connected to external local oscillator. Input impedance is about 900 Ω at 230 MHz.
4	RSSI		**RSSI** The RSSI current creates a voltage drop across an internal 15 kΩ resistor.
5 7	LIM_{Dec2} LIM_{Dec1}		**Limiter Decoupling** Limiter decoupling pins. Decoupling capacitors are connected to the RF ground, and one is placed between Dec1 and Dec2.
8	LIM_{in}		**Limiter Input** The input impedance is 330 Ω; it matches the 330 input resistance of a 10.7/10.8 MHz ceramic filter.
6	LIM_{out}		**Limiter Output** The output level is about 0.5 Vpp.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description
9	IF_{out}		**IF Output** The output impedance is 330 Ω; it matches the 330 input resistance of a 10.7/10.8 MHz ceramic filter.
10 11	IF_{Dec2} IF_{Dec1}		**IF Decoupling** IF decoupling pins. Decoupling capacitor is connected from Dec1 to the RF ground, and one is placed between Dec1 and Dec2.
12	IF_{in}		**IF Input** The input impedance is 330 Ω; it matches the 330 input resistance of a 10.7/10.8 MHz ceramic filter.
13	Enable		**Enable** The IC regulators are enabled by placing this pin at V_{EE}.
14	Mix_{out}		**Mixer Output** The mixer output impedance is 330 Ω; it matches the 330 input resistance of a 10.7/10.8 MHz ceramic filter.
15	V_{EE}		**Supply Ground**

MOTOROLA

MC13173

Infrared Integrated Transceiver IC

INFRARED TRANSCEIVER

SEMICONDUCTOR TECHNICAL DATA

The MC13173 is a low power infrared integrated system (IRIS). It is a unique blend of a split IF wideband FM receiver and a specialized infrared LED transmitter. This device was designed to provide communications between portable computers via a half duplex infrared link at data rates up to 200 kbps.

The receiver includes a mixer, IF amplifier and limiter and data slicer. The IF amplifier is split to accommodate two low cost cascaded filters. The RSSI output is derived by summing the output of both IF sections.

The transmitter section includes a frequency synthesizer, FSK modulator, harmonic low pass filter and an IR LED driver.

- Transmitter Operates in Two Modes:
  - On/Off Pulsing for Remote Control
  - FSK Modulation at 1.4 MHz for Data Communications
- Over 70 dB of RSSI Range
- Split IF for Improved Filtering and Extended RSSI Range
- Digitally controlled Via a Six Line Interface Bus
- Individual Circuit Blocks Can Be Powered Down When Not In Use for Power Conservation

CIRCUIT DESCRIPTION

General

The MC13173 infrared transceiver integrates a split IF wideband FM receiver and an IR LED transmitter into a single IC. The transmitter is comprised of an FSK modulator, harmonic low pass filter, and IR LED driver. The receiver consists of a mixer, IF amplifier and limiting IF, detector, and data slicer. It includes RSSI and carrier detect functions.

The transmitter is capable of two modes of operation. It was primarily designed for use in the Communications Mode, which enables point–to–point data links, such as the communication from keyboard to computer, or for the exchange of data between portable computers. In this mode it is capable of 200 kbps half duplex FSK operation.

The transmitter can also operate in an “A/V” Mode, which pulses the LED on and off with no carrier. (See Figure 11).

Digital Interface Bus

The MC13173 is controlled via a six line 3.3 V digital interface bus. That includes three control pins, data in and out pins, and a carrier detect pin. Listed below is a brief description of each pin and its function.

Table 1. Digital Interface Pin Descriptions

Pin	Pin Name	Symbol	I/O	Description
28	Transmit Enable	T	I	High – Transmitter is enabled Low – Transmitter is disabled
27	Data In	DI	I	Data Input – 38.2 kbps Communication Mode
3	Receive Enable	R	I	High – Receiver is enabled Low – Receiver is disabled
22	Data Out	DO	O	Demodulated Output Signal
17	Carrier Detect	CD	O	High – Carrier is present Low – Carrier is not present
26	Transmit Modulation Enable	E	I	High – Transmitter is in A/V Mode Low – Transmitter is in Communications Mode

This transceiver was designed for use in battery powered, hand–held consumer products. To minimize power consumption, the digital interface enables individual system blocks to be powered down while not in use. The following diagram shows the mode of the IC and the power state of each circuit block for a given set of control levels.

Table 2. Power State Table

Control Pins*				Circuit Block Power States (See Figures 2 and 3)				Supply Current (Typical)
T	R	E	Mode	Master VCO	FSK Modulator	Receiver	LED Driver	
0	0	0	OFF	Off	Off	Off	Off	10 nA
0	0	1	OFF	Off	Off	Off	Off	70 μA
0	1	X	Receive	On	Off	On	Off	6.5 mA

1	1	0	Transmit – Comm Mode	On	On	On	On	9.0 mA
1	0	0	Transmit – Comm Mode	On	On	Off	On	4.75 mA
1	0	1	Transmit – A/V Mode	Off	Off	Off	On	1.5 mA

* With Data In Pin Low

Master VCO/PLL

The master VCO provides the reference frequency for the FSK modulator and the LO frequency for the receiver downconverter. With a 32.768 kHz input frequency to the master VCO on Pin 1, the LO frequency for the receiver will be at 12.075 MHz. The reference frequency for the FSK modulator will be at approximately 1.1 MHz. The master VCO and FSK modulator are not used when the transmitter is used in A/V mode, and both are powered down.

Receiver Description

The single conversion receiver portion of the MC13173 is low power and wideband, and incorporates a split IF. This section includes a mixer, IF amplifier, limiting IF, quadrature detector and data slicer.

Mixer

The mixer is a double balanced four quadrant multiplier. It can be driven either differentially or single–ended by connecting the unused input to the positive supply rail.

The buffered output is internally loaded for an output impedance of 330 Ω for use with a standard ceramic filter.

IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal DC feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 40 dB. The fixed internal input impedance is 330 Ω for use with a 10.7 MHz ceramic filter. The output of the IF amplifier is buffered and the impedance is 330 Ω.

Limiter

The limiter section is similar to the IF amplifier section, except that four stages are used with the last three contributing to the RSSI. This IF limiting amplifier section drives the quadrature detector internally.

RSSI/Carrier Detect

The received signal strength indicator (RSSI) outputs a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the IF and limiting amplifier stages. An external resistor sets the output voltage range.

The carrier detect threshold is set at approximately 1.2 Vdc. When the RSSI level exceeds that threshold, the carrier detect output will go high. A large resistor may be added externally between the comparator output and the positive input for hysteresis.

Quadrature Detector

The demodulator is a conventional quadrature type with an external LC tank driven through an internal 5 pF capacitor. The output is buffered to give an output impedance of less than 1.0 kΩ at an average DC level of around 1.1 V.

Data Slicer

The data slicer is designed to square up the data signal. It is self centering at about 1.1 V, and clips at about 0.75 V and 1.45 V. There is a short time constant for large peak–to–peak voltage swings or when there is a change in DC level at the detector output. The time constant is longer for small signals or for continuous bits of the same polarity which drift close to the threshold voltage.

Transmission Description

The MC13173 uses a dual modulus PLL to frequency shift key (FSK) modulate the baseband digital input signal, producing the necessary logic high and low frequencies for transmission. The transmit frequency for a logic high is 1.427 MHz, and the frequency for a low is 1.317 MHz with a 32.768 kHz reference frequency.

FSK Modulator

In the communications mode, the FSK modulator uses the reference frequency from the Master VCO to produce the two frequencies required for a logic high and a logic low. In the A/V mode, the FSK modulator is not used and is powered down.

LED Driver Stage

A low pass filter following the FSK modulator removes the undesired harmonic frequencies from the square–wave output of the divider circuits in PLLs. The resulting sinusoidal waveforms are fed into a unity gain difference amplifier, which drives the base of an external transistor, modulating the IR LED.

In A/V mode, the data is input directly into the inverting input of the op amp, and the low pass filter is not used.

APPLICATIONS INFORMATION

The MC13173 transceiver is specially designed to operate from a 32.768 kHz reference which is readily available in most computer applications. The frequency synthesizer on chip generates a receiver local oscillator frequency and the transmit mark and space frequencies from this fixed reference frequency, eliminating the need for additional crystals or manual tuning.

Large divide ratios are needed to generate these frequencies, however. For example, the receiver LO frequency is 368.5 times the 32.768 kHz reference frequency. This requires that the reference frequency be both accurate and stable. A two percent error in the reference frequency would pull the LO off frequency by over 240 kHz, putting the IF frequency out of the usable bandwidth of the filters and discriminator. For this reason, a 32.768 kHz oscillator circuit has been included on the demonstration board design. Although TTL crystal oscillators are available, this oscillator circuit uses an inexpensive tuning fork crystal and a hex inverter to generate a square wave reference frequency, which is then filtered and level adjusted to a 1.0 Vp–p triangle wave to drive pin 32. A TTL Clock Oscillator could also be used with the filter circuit as shown.

Frequency Synthesizer

The recommended op amp for the external loop filter is the MC33202. For low voltage operation, ($V_{CC} \leq 3.3$ V) an op amp that is rail–to–rail on both the input and output is advisable to obtain the widest possible output voltage range without distortion. Sufficient distortion from the op amp such as phase reversal on the output caused by overdriving the inputs could prevent the loop from locking to the reference.

In debugging the loop filter, it is important to note that the FSK Modulator phase locked loop will not lock until the Master VCO is locked to the reference. If the application circuit in Figure 15 is used, both loops should lock without the need for any additional tweaking. Since the VCO has ±2.0 MHz of range using the MV209 varactor diode (see Figure 11), neither precision components nor tuning should be required. To ensure both loops are operating properly, first evaluate each VCO with the loop open and a voltage equal to $V_{CC}/2$ applied to the resistor in series with the varactor. Since there is a relatively small capacitance (<40 pF) in series with the LC tank circuit, the VCO pin is sensitive to any parasitic capacitance. Thus when using a standard oscilloscope probe having 10 to 20 pF capacitance it is difficult to measure the VCO frequency without shifting its frequency. A low capacitance FET probe used with a frequency counter will enable you to accurately measure the VCO frequency without altering it in the process.

The free running frequency of the VCO should be approximately on frequency when the loop is open and the varactor is biased at mid–supply. The VCO for the Master PLL should run at 12.05 MHz. The free running frequency of the FSK Modulator should be at 13.72 MHz, midway between the two VCO frequencies needed to generate the transmit mark and space frequencies. The FSK Modulator loop is only active when the transmitter is enabled and the device is in the communications mode (see Tables 1 & 2). **If either the “T” pin is low or the “E” pin is high, the VCO will be off and you will see no oscillation on Pin 29.**

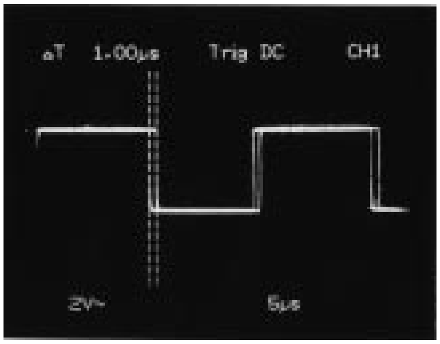
Once the loops are closed, the VCO frequencies should track the reference frequency within the hold–in range of the loop. Although the FSK Modulator loop is dependent on the Master VCO, the Master VCO is completely independent of the FSK Modulator. In fact, the FSK Modulator can be powered down (see Table 2) without affecting the Master VCO operation. In the application circuit in Figure 15 a single reference voltage for both op amps in the loop filters is provided by two diodes to V_{CC}. If the Master VCO is affected by the FSK Modulator loop, this generally indicates a problem with the common reference voltage to the op amp, and may mean the diodes are in backwards.

Once the loops are closed you should see a phase detector output such as is shown in the Pin Function Description in Table 3. If the VCO was on frequency when the loop was open, the phase detector outputs should swing around mid supply and not hit against either the positive or negative rail. Latching to V_{CC} or V_{EE} may indicate the loop filter circuitry is not implemented correctly.

Due to the digital design of the phase detectors, the transmitter can only transition between mark and space frequencies on a clock edge. On the receive side this may be seen as a double image on the detector output, with a discrete time delay which does not vary with the frequency of the data input (see Figure 10). This is a normal consequence of using a digital phase detector and should not be confused with jitter from the data slicer.

Figure 10. Receive Data Output

(Data Transmitted from Companion MC13173)



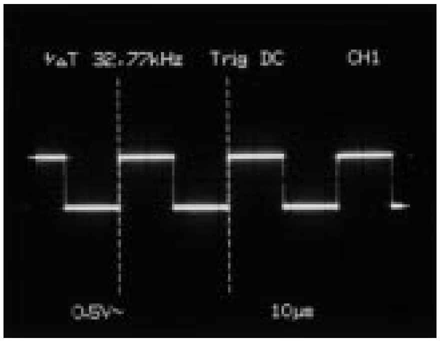
Transmitter

The light emitting diode (LED) driver in the transmitter is capable of 6.0 to 10 mA of pull–up current. Selection of the external transistor and biasing resistor will depend on the LEDs used. Typical infrared LEDs require 50 to 100 mA of current and have a forward voltage of 1.5V. Sufficient current is needed to obtain the maximum power output without distorting the output by overdriving the LED. Key specifications include rise and fall time, wavelength, beam width (generally given in half–angle), maximum power output and efficiency. Choice of wavelengths is generally determined by cost and power efficiency, which may vary between vendors. The LEDs used in this application are at 880 nm and were chosen for best efficiency. However LEDs in general are very inefficient, converting only 1 or 2 percent of the electrical power into optical power. Multiple LEDs can be used to increase transceiver range.

Disabling the transmitter via the data bus turns off the output of the LED driver, removing the base current from the external transistor and thereby turning off the IR LED. Because of the high current drawn by the LED, this offers considerable power savings when the transmitter is not in use and can be easily controlled by a microcontroller with no additional circuitry.

In the “A/V” transmit mode, the data output is on/off keyed, with the LED on for a data high, and off for a data low. It is a baseband signal, with no carrier present (see Figure 11).

Figure 11. LED Driver Output in A/V Mode



Receiver

The receiver portion of the MC13173 is similar to the design of Motorola’s MC13156 Wideband FM Receiver. Instead of using the mixer to downconvert from a higher RF frequency, this application is designed to upconvert the 1.372 MHz input to a 10.7 MHz IF. The wide deviation, relative to the RF input frequency, requires a low Q tuned circuit to recover this bandwidth:

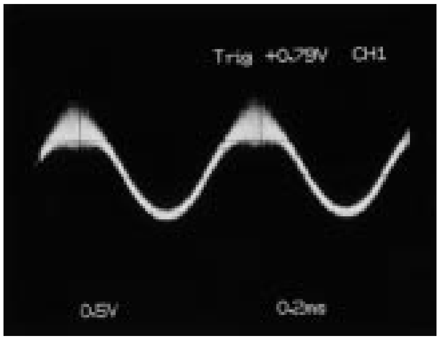
$$Q \approx \frac{f_C}{BW_{3\ dB}},\ \text{where } f_C = 1.372\ \text{MHz}$$

By Carson’s Rule, the BW = 2(fdev + fmod). Since for mark/space frequencies of 1.317 MHz and 1.427 MHz the deviation is fixed at ±50 kHz, the bandwidth for a 50 kHz square wave (100 kbps) would be 200 kHz, and the tuned input requires a Q of less than 7. The low Q of the tank circuit reduces both the selectivity and the sensitivity of the receiver. For a Q of 7, the resistor required across the 56 µH inductor can be calculated:

$$R = QX_L = (7) \bullet (2\pi) \bullet (1.372\ E6) \bullet (56\ E{-}6)$$
$$R = 3.3\ k\Omega$$

The 10.7 MHz ceramic filters also need to be wide enough to pass the full frequency range which will include some harmonics. In the application circuit in Figure 15, Toko filters with a bandwidth of 330 kHz or 360 kHz are recommended to accommodate higher data rates. If the IF filters are too narrow, the recovered signal may have noise on the peaks (see Figure 12).

Figure 12. Receive Data Output



The RSSI has over 70 dB of dynamic range and 20 µA of current range. The RSSI output provides the input to the carrier detect comparator (see Figure 13) and a logarithmic output proportional to the input signal level. It can, therefore, be used to recover amplitude shift keyed (ASK) data.

The key specifications for the infrared detectors are response time, sensitivity, acceptance angle, and wavelength. Some vendors offer detectors in a black package with a built–in daylight filter. Although the transparent packages offer better sensitivity, the detectors with the daylight filter offer a much better signal to noise ratio. Response time (or maximum frequency) of the system is generally limited by the capability of the emitters rather than the detectors. For this application, a rise and fall time of 500 ns is sufficient.

Design and Layout Considerations

Although the frequencies in this design are low by RF standards, careful layout and good decoupling are still good practice. The high gain limiter and IF blocks should be decoupled as shown in the application circuit as near the IC as possible for best receiver performance. Also the TTL levels from the reference oscillator and the wide current swing applied to the IR LEDs can easily be picked up on V_{CC}, creating problems for the sensitive phase detector circuits and receiver RF inputs. Avoid long parallel traces and use plenty of decoupling to keep the supply rail clean.

MOTOROLA

MC13175
MC13176

UHF FM/AM Transmitter

UHF FM/AM TRANSMITTER

SEMICONDUCTOR TECHNICAL DATA

The MC13175 and MC13176 are one chip FM/AM transmitter subsystems designed for AM/FM communication systems. They include a Colpitts crystal reference oscillator, UHF oscillator, ÷ 8 (MC13175) or ÷ 32 (MC13176) prescaler and phase detector forming a versatile PLL system. Targeted applications are in the 260 to 470 MHz band and 902 to 928 MHz band covered by FCC Title 47; Part 15. Other applications include local oscillator sources in UHF and 900 MHz receivers, UHF and 900 MHz video transmitters, RF Local Area Networks (LANs), and high frequency clock drivers. The MC13175/76 offer the following features:

- UHF Current Controlled Oscillator
- Uses Easily Available 3rd Overtone or Fundamental Crystals for Reference
- Fewer External Parts Required
- Low Operating Supply Voltage (1.8 to 5.0 Vdc)
- Low Supply Drain Currents
- Power Output Adjustable (Up to +10 dBm)
- Differential Output for Loop Antenna or Balun Transformer Networks
- Power Down Feature
- ASK Modulated by Switching Output On and Off
- (MC13175) $f_o = 8 \times f_{ref}$; (MC13176) $f_o = 32 \times f_{ref}$

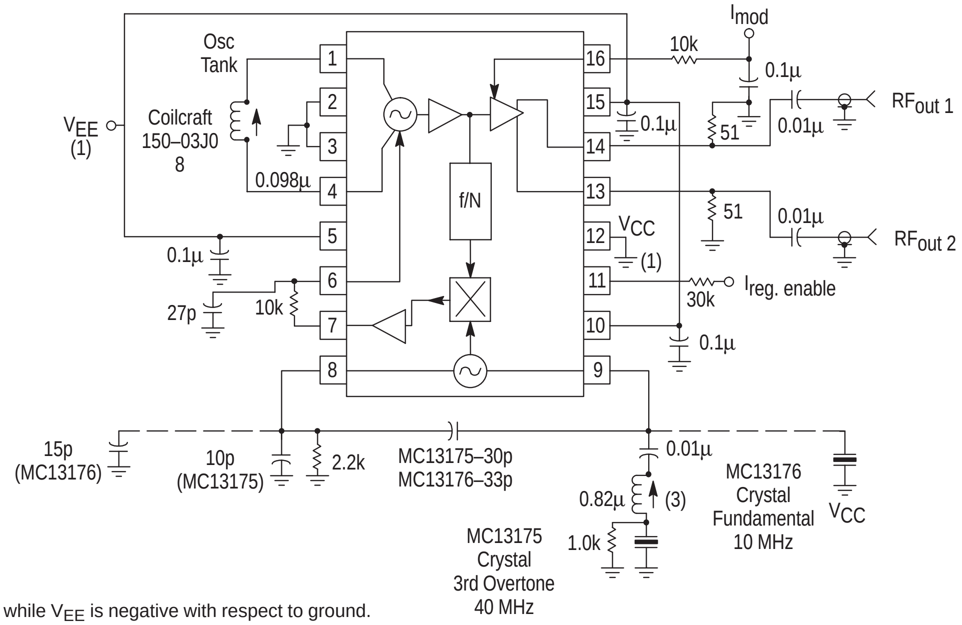
* For testing purposes, V_{CC} is ground (see Figure 2).

Figure 2. 320 MHz Test Circuit



NOTES: 1. V_{CC} is ground; while V_{EE} is negative with respect to ground.
2. Pins 5, 10 and 15 are brought to the circuit side of the PCB via plated through holes. They are connected together with a trace on the PCB and each Pin is decoupled to V_{CC} (ground).
3. Recommended source is Coilcraft "slot seven" inductor, part number 7M3–821.

PIN FUNCTION DESCRIPTIONS

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1 & 4	Osc 1, Osc 4		**CCO Inputs** The oscillator is a current controlled type. An external oscillator coil is connected to Pins 1 and 4 which forms a parallel resonance LC tank circuit with the internal capacitance of the IC and with parasitic capacitance of the PC board. Three base–emitter capacitances in series configuration form the capacitance for the parallel tank. These are the base–emitters at Pins 1 and 4 and the base–emitter of the differential amplifier. The equivalent series capacitance in the differential amplifier is varied by the modulating current from the frequency control circuit (see Pin 6, internal circuit). A more thorough discussion is found in the Applications Information section.
5	V_{EE}		**Supply Ground (V_{EE})** In the PCB layout, the ground pins (also applies to Pins 10 and 15) should be connected directly to chassis ground. Decoupling capacitors to V_{CC} should be placed directly at the ground returns.
6	I_{Cont}		**Frequency Control** For V_{CC} = 3.0 Vdc, the voltage at Pin 6 is approximately 1.55 Vdc. The oscillator is current controlled by the error current from the phase detector. This current is amplified to drive the current source in the oscillator section which controls the frequency of the oscillator. Figures 9 and 10 show the Δf_{osc} versus I_{Cont}, Figure 5 shows the Δf_{osc} versus I_{Cont} at – 40°C, + 25°C and + 85°C for 320 MHz. The CCO may be FM modulated as shown in Figure 17, MC13176 320 MHz FM Transmitter. A detailed discussion is found in the Applications Information section.
7	PD_{out}		**Phase Detector Output** The phase detector provides ± 30 µA to keep the CCO locked at the desired carrier frequency. The output impedance of the phase detector is approximately 53 kΩ. Under closed loop conditions there is a DC voltage which is dependent upon the free running oscillator and the reference oscillator frequencies. The circuitry between Pins 7 and 6 should be selected for adequate loop filtering necessary to stabilize and filter the loop response. Low pass filtering between Pin 7 and 6 is needed so that the corner frequency is well below the sum of the divider and the reference oscillator frequencies, but high enough to allow for fast response to keep the loop locked. Refer to the Applications Information section regarding loop filtering and FM modulation.

PIN FUNCTION DESCRIPTIONS

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
8	Xtale		**Crystal Oscillator Inputs** The internal reference oscillator is configured as a common emitter Colpitts. It may be operated with either a fundamental or overtone crystal depending on the carrier frequency and the internal prescaler. Crystal oscillator circuits and specifications of crystals are discussed in detail in the applications section. With V_{CC} = 3.0 Vdc, the voltage at Pin 8 is approximately 1.8 Vdc and at Pin 9 is approximately 2.3 Vdc. 500 to 1000 mVp–p should be present at Pin 9. The Colpitts is biased at 200 μA; additional drive may be acquired by increasing the bias to approximately 500 μA. Use 6.2 k from Pin 8 to ground.
9	Xtalb		
10	Reg. Gnd		**Regulator Ground** An additional ground pin is provided to enhance the stability of the system. Decoupling to the V_{CC} (RF ground) is essential; it should be done at the ground return for Pin 10.
11	Enable		**Device Enable** The potential at Pin 11 is approximately 1.25 Vdc. When Pin 11 is open, the transmitter is disabled in a power down mode and draws less than 1.0 μA I_{CC} if the MOD at Pin 16 is also open (i.e., it has no current driving it). To enable the transmitter a current source of 10 μA to 90 μA is provided. Figures 3 and 4 show the relationship between I_{CC}, V_{CC} and $I_{reg.\ enable}$. Note that I_{CC} is flat at approximately 10 mA for $I_{reg.\ enable}$ = 5.0 to 100 μA (I_{mod} = 0).
12	V_{CC}		**Supply Voltage (V_{CC})** The operating supply voltage range is from 1.8 Vdc to 5.0 Vdc. In the PCB layout, the V_{CC} trace must be kept as wide as possible to minimize inductive reactances along the trace; it is best to have it completely fill around the surface mount components and traces on the circuit side of the PCB.
13 & 14	Out 1 and Out 2		**Differential Output** The output is configured differentially to easily drive a loop antenna. By using a transformer or balun, as shown in the application schematic, the device may then drive an unbalanced low impedance load. Figure 6 shows how much the Output Power and Free–Running Oscillator Frequency change with temperature at 3.0 Vdc; I_{mod} = 2.0 mA.
15	Out_Gnd		**Output Ground** This additional ground pin provides direct access for the output ground to the circuit board V_{EE}.
16	I_{mod}		**AM Modulation/Power Output Level** The DC voltage at this pin is 0.8 Vdc with the current source active. An external resistor is chosen to provide a source current of 1.0 to 3.0 mA, depending on the desired output power level at a given V_{CC}. Figure 23 shows the relationship of Power Output to Modulation Current, I_{mod}. At V_{CC} = 3.0 Vdc, 3.5 dBm power output can be acquired with about 35 mA I_{CC}. For FM modulation, Pin 16 is used to set the desired output power level as described above. For AM modulation, the modulation signal must ride on a positive DC bias offset which sets a static (modulation off) modulation current. External circuitry for various schemes is further discussed in the Applications Information section.

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB, shown in Figures 26 and 27, is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side of the PCB (see Figures 28 and 29). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

Current Controlled Oscillator (Pins 1 to 4)

It is critical to keep the interconnect leads from the CCO (Pins 1 and 4) to the external inductor symmetrical and equal in length. With a minimum inductor, the maximum free running frequency is greater than 1.0 GHz. Since this inductor will be small, it may be either a microstrip inductor, an air wound inductor or a tuneable RF coil. An air wound inductor may be tuned by spreading the windings, whereas tuneable RF coils are tuned by adjusting the position of an aluminum core in a threaded coilform. As the aluminum core coupling to the windings is increased, the inductance is decreased. The temperature coefficient using an aluminum core is better than a ferrite core. The UniCoil™ inductors made by Coilcraft may be obtained with aluminum cores (Part No. 51–129–169).

Ground (Pins 5, 10 and 15)

Ground Returns: It is best to take the grounds to a backside ground plane via plated through holes or eyelets at the pins. The application PCB layout implements this technique. Note that the grounds are located at or less than 100 mils from the devices pins.

Decoupling: Decoupling each ground pin to V_{CC} isolates each section of the device by reducing interaction between sections and by localizing circulating currents.

Loop Characteristics (Pins 6 and 7)

Figure 11 is the component block diagram of the MC1317XD PLL system where the loop characteristics are described by the gain constants. Access to individual components of this PLL system is limited, inasmuch as the loop is only pinned out at the phase detector output and the frequency control input for the CCO. However, this allows for characterization of the gain constants of these loop components. The gain constants K_p, K_o and K_n are well defined in the MC13175 and MC13176.

Phase Detector (Pin 7)

With the loop in lock, the difference frequency output of the phase detector is DC voltage that is a function of the phase difference. The sinusoidal type detector used in this IC has the following transfer characteristic:

$$I_e = A \text{ Sin } \theta_e$$

The gain factor of the phase detector, K_p (with the loop in lock) is specified as the ratio of DC output current, I_e to phase error, θ_e:

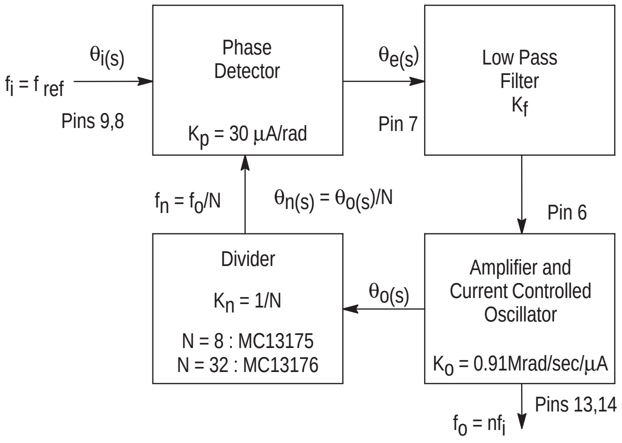
$K_p = I_e/\theta_e$ (Amps/radians)
$K_p = A \text{ Sin } \theta_e/\theta_e$
$\text{Sin } \theta_e \sim \theta_e$ for $\theta_e \leq 0.2$ radians;
thus, $K_p = A$ (Amps/radians)

Figures 7 and 8 show that the detector DC current is approximately 30 µA where the loop loses lock at $\theta_e = \pm \pi/2$ radians; therefore, K_p is 30 µA/radians.

Current Controlled Oscillator, CCO (Pin 6)

Figures 9 and 10 show the non–linear change in frequency of the oscillator over an extended range of control current for 320 and 450 MHz applications. K_o ranges from approximately 6.3×10^5 rad/sec/µA or 100 kHz/µA (Figure 9) to 8.8×10^5 rad/sec/µA or 140 kHz/µA (Figure 10) over a relatively linear response of control current (0 to 100 µA). The oscillator gain factor depends on the operating range of the control current (i.e., the slope is not constant). Included in the CCO gain factor is the internal amplifier which can sink and source at least 30 µA of input current from the phase detector. The internal circuitry at Pin 6 limits the CCO control current to 50 µA of source capability while its sink capability exceeds 200 µA as shown in Figures 9 and 10. Further information to follow shows how to use the full capabilities of the CCO by addition of an external loop amplifier and filter (see Figure 15). This additional circuitry yields at K_o = 0.145 MHz/µA or 9.1×10^5 rad/sec/µA.

Figure 11. Block Diagram of MC1317XD PLL



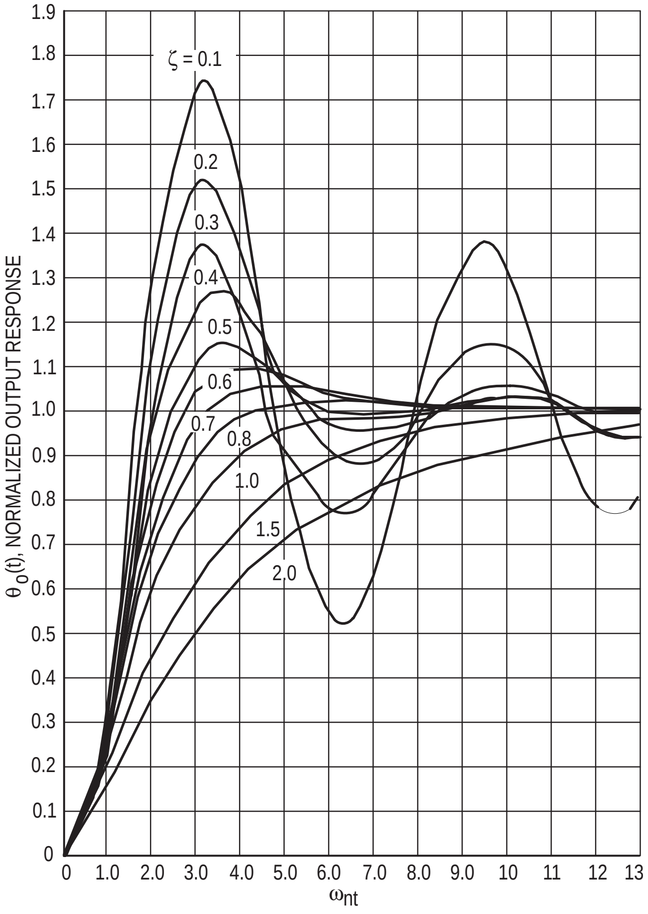
Where: K_p = Phase detector gain constant in µA/rad; K_p = 30 µA/rad
K_f = Filter transfer function
K_n = 1/N; N = 8 for the MC13175 and N = 32 for the MC13176
K_o = CCO gain constant in rad/sec/µA
K_o = 9.1 x 10^5 rad/sec/µA

Loop Filtering

The fundamental loop characteristics, such as capture range, loop bandwidth, lock–up time and transient response are controlled externally by loop filtering.

The natural frequency (ω_n) and damping factor (∂) are important in the transient response to a step input of phase or frequency. For a given ∂ and lock time, ω_n can be determined from the plot shown in Figure 12.

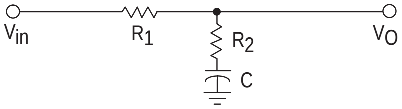
Figure 12. Type 2 Second Order Response



For ∂ = 0.707 and lock time = 1.0 ms;
then ω_n = 5.0/t = 5.0 krad/sec.

The loop filter may take the form of a simple low pass filter or a lag–lead filter which creates an additional pole at origin in the loop transfer function. This additional pole along with that of the CCO provides two pure integrators ($1/s^2$). In the lag–lead low pass network shown in Figure 13, the values of the low pass filtering parameters R_1, R_2 and C determine the loop constants ω_n and ∂. The equations $t_1 = R_1C$ and $t_2 = R_2C$ are related in the loop filter transfer functions $F(s) = 1 + t_2s/1 + (t_1 + t_2)s$.

Figure 13. Lag–Lead Low Pass Filter



The closed loop transfer function takes the form of a 2nd order low pass filter given by,

$$H(s) = K_vF(s)/s + K_vF(s)$$

From control theory, if the loop filter characteristic has F(0) = 1, the DC gain of the closed loop, K_v is defined as,

$$K_v = K_pK_oK_n$$

and the transfer function has a natural frequency,

$$\omega_n = (K_v/t_1 + t_2)^{1/2}$$

and a damping factor,

$$\partial = (\omega_n/2)\,(t_2 + 1/K_v)$$

Rewriting the above equations and solving for the MC13176 with ∂ = 0.707 and ω_n = 5.0 k rad/sec:

$$K_v = K_pK_oK_n = (30)\,(0.91 \times 10^6)\,(1/32) = 0.853 \times 10^6$$
$$t_1 + t_2 = K_v/\omega_n2 = 0.853 \times 10^6/(25 \times 106) = 34.1 \text{ ms}$$
$$t_2 = 2\partial/\omega_n = (2)\,(0.707)/(5 \times 10^3) = 0.283 \text{ ms}$$
$$t_1 = (K_v/\omega_n2) - t_2 = (34.1 - 0.283) = 33.8 \text{ ms}$$

For $C = 0.47\ \mu$;

then, $R_1 = t_1/C = 33.8 \times 10^{-3}/0.47 \times 10^{-6} = 72\ k$

dthus, $R_2 = t_2/C = 0.283 \times 10^{-3}/0.47 \times 10^{-6} = 0.60\ k$

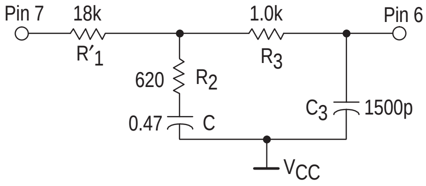
In the above example, the following standard value components are used,

$$C = 0.47\ \mu;\ R_2 = 620 \text{ and } R'_1 = 72\ k - 53\ k \sim 18\ k$$

(R'_1 is defined as R_1 – 53 k, the output impedance of the phase detector.)

Since the output of the phase detector is high impedance (~50 k) and serves as a current source, and the input to the frequency control, Pin 6 is low impedance (impedance of the two diode to ground is approximately 500 Ω), it is imperative that the second order low pass filter design above be modified. In order to minimize loading of the R_2C shunt network, a higher impedance must be established to Pin 6. A simple solution is achieved by adding a low pass network between the passive second order network and the input to Pin 6. This helps to minimize the loading effects on the second order low pass while further suppressing the sideband spurs of the crystal oscillator. A low pass filter with R_3 = 1.0 k and C_2 = 1500 p has a corner frequency (f_c) of 106 kHz; the reference sideband spurs are down greater than – 60 dBc.

Figure 14. Modified Low Pass Loop Filter



Hold–In Range

The hold–in range, also called the lock range, tracking range and synchronization range, is the ability of the CCO frequency, f_o to track the input reference signal, $f_{ref} \bullet N$ as it gradually shifted away from the free running frequency, f_f. Assuming that the CCO is capable of sufficient frequency deviation and that the internal loop amplifier and filter are not overdriven, the CCO will track until the phase error, θ_e approaches $\pm\pi/2$ radians. Figures 5 through 8 are a direct measurement of the hold–in range (i.e. $\Delta f_{ref} \times N = \pm\Delta f_H \times 2\pi$). Since $\sin \theta_e$ cannot exceed ±1.0, as θ_e approaches $\pm\pi/2$ the hold–in range is equal to the DC loop gain, $K_v \times N$.

$$\pm\Delta\omega_H = \pm K_v \times N$$

$$\text{where, } K_v = K_p K_o K_n.$$

In the above example,

$$\pm\Delta\omega_H = \pm\ 27.3 \text{ Mrad/sec}$$
$$\pm\Delta f_H = \pm\ 4.35 \text{ MHz}$$

Extended Hold–in Range

The hold–in range of about 3.4% could cause problems over temperature in cases where the free–running oscillator drifts more than 2 to 3% because of relatively high temperature coefficients of the ferrite tuned CCO inductor. This problem might worsen for lower frequency applications where the external tuning coil is large compared to internal capacitance at Pins 1 and 4. To improve hold–in range performance, it is apparent that the gain factors involved must be carefully considered.

K_n = is either 1/8 in the MC13175 or 1/32 in the MC13176.

K_p = is fixed internally and cannot be altered.

K_o = Figures 9 and 10 suggest that there is capability of greater control range with more current swing. However, this swing must be symmetrical about the center of the dynamic response. The suggested zero current operating point for ±100 µA swing of the CCO is at about + 70 µA offset point.

Ka = External loop amplification will be necessary since the phase detector only supplies ± 30 µA.

In the design example in Figure 15, an external resistor (R_5) of 15 k to V_{CC} (3.0 Vdc) provides approximately 100 µA of current boost to supplement the existing 50 µA internal source current. R_4 (1.0 k) is selected for approximately 0.1 Vdc across it with 100 µA. R_1, R_2 and R_3 are selected to set the potential at Pin 7 and the base of 2N4402 at approximately 0.9 Vdc and the emitter at 1.55 Vdc when error current to Pin 6 is approximately zero µA. C_1 is chosen to reduce the level of the crystal sidebands.

Figure 15. External Loop Amplifier

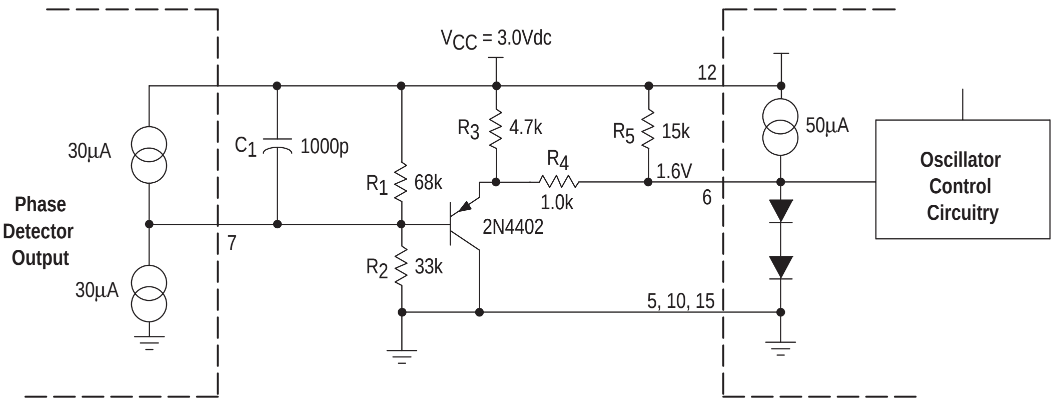


Figure 16 shows the improved hold–in range of the loop. The Δf_{ref} is moved 950 kHz with over 200 µA swing of control current for an improved hold–in range of ±15.2 MHz or ± 95.46 Mrad/sec.

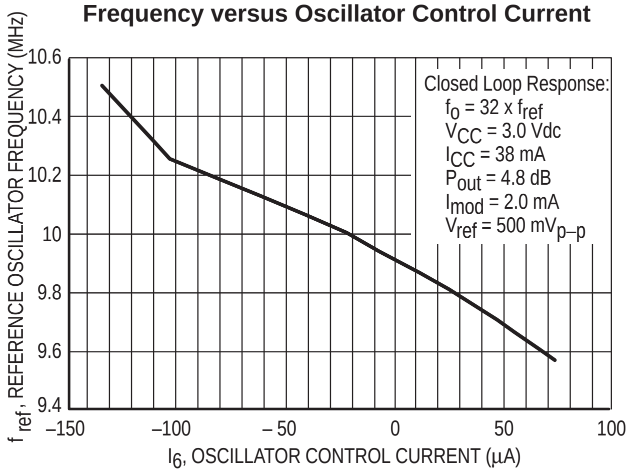
Figure 16. MC13176 Reference Oscillator Frequency versus Oscillator Control Current



Lock–in Range/Capture Range

If a signal is applied to the loop not equal to free running frequency, f_f, then the loop will capture or lock–in the signal by making $f_s = f_o$ (i.e. if the initial frequency difference is not too great). The lock–in range can be expressed as $\Delta\omega_L \sim \pm 2\partial\omega_n$

FM Modulation

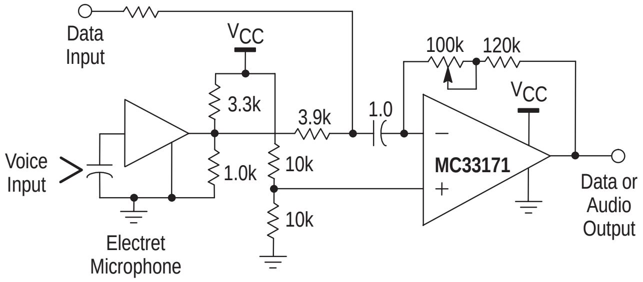
Noise external to the loop (phase detector input) is minimized by narrowing the bandwidth. This noise is minimal in a PLL system since the reference frequency is usually derived from a crystal oscillator. FM can be achieved by applying a modulation current superimposed on the control current of the CCO. The loop bandwidth must be narrow enough to prevent the loop from responding to the modulation frequency components, thus, allowing the CCO to deviate in frequency. The loop bandwidth is related to the natural frequency ω_n. In the lag–lead design example where the natural frequency, ω_n = 5.0 krad/sec and a damping factor, ∂ = 0.707, the loop bandwidth = 1.64 kHz. Characterization data of the closed loop responses for both the MC13175 and MC13176 at 320 MHz (Figures 7 and 8, respectively) show satisfactory performance using only a simple low–pass loop filter network. The loop filter response is strongly influenced by the high output impedance of the push–pull current output of the phase detector.

f_c = 0.159/RC;
For R = 1.0 k + R_7 (R_7 = 53 k) and C = 390 pF
f_c = 7.55 kHz or ω_c = 47 krad/sec

The application example in Figure 17a of a 320 MHz FM transmitter demonstrates the FM capabilities of the IC. A high value series resistor (100 k) to Pin 6 sets up the current source to drive the modulation section of the chip. Its value is dependent on the peak to peak level of the encoding data and the maximum desired frequency deviation. The data input is AC coupled with a large coupling capacitor which is selected for the modulating frequency. The component placements on the circuit side and ground side of the PC board are shown in Figures 28 and 29, respectively. Figure 18a illustrates the input data of a 10 kHz modulating signal at 1.6 Vp–p. Figures 18b and 18c depict the deviation and resulting modulation spectrum showing the carrier null at – 40 dBc. Figure 18d shows the unmodulated carrier power output at 3.5 dBm for V_{CC} = 3.0 Vdc.

For voice applications using a dynamic or an electret microphone, an op amp is used to amplify the microphone's low level output. The microphone amplifier circuit is shown in Figure 19. Figure 17b shows an application example for NBFM audio or direct FSK in which the reference crystal oscillator is modulated.

Figure 19. Microphone Amplifier



Local Oscillator Application

To reduce internal loop noise, a relatively wide loop bandwidth is needed so that the loop tracks out or cancels the noise. This is emphasized to reduce inherent CCO and divider noise or noise produced by mechanical shock and environmental vibrations. In a local oscillator application the CCO and divider noise should be reduced by proper selection of the natural frequency of the loop. Additional low pass filtering of the output will likely be necessary to reduce the crystal sideband spurs to a minimal level.

Reference Crystal Oscillator (Pins 8 and 9)

Selection of Proper Crystal: A crystal can operate in a number of mechanical modes. The lowest resonant frequency mode is its fundamental while higher order modes are called overtones. At each mechanical resonance, a crystal behaves like a RLC series–tuned circuit having a large inductor and a high Q. The inductor L_S is series resonance with a dynamic capacitor, C_S determined by the elasticity of the crystal lattice and a series resistance R_S, which accounts for the power dissipated in heating the crystal. This series RLC circuit is in parallel with a static capacitance, C_p which is created by the crystal block and by the metal plates and leads that make contact with it.

Figure 20 is the equivalent circuit for a crystal in a single resonant mode. It is assumed that other modes of resonance are so far off frequency that their effects are negligible.

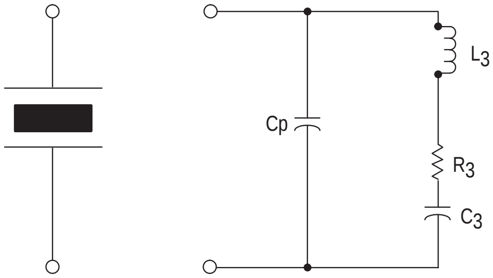
Series resonant frequency, f_S is given by;

$$f_S = 1/2\pi(L_S C_S)^{1/2}$$

and parallel resonant frequency, f_p is given by;

$$f_p = f_S(1 + C_S/C_p)^{1/2}$$

Figure 20. Crystal Equivalent Circuit



the frequency separation at resonance is given by;

$$\Delta f = f_p – f_S = f_S[1 – (1 + C_S/C_p)^{1/2}]$$

Usually f_p is less than 1% higher than f_S, and a crystal exhibits an extremely wide variation of the reactance with frequency between f_p and f_S. A crystal oscillator circuit is very stable with frequency. This high rate of change of impedance with frequency stabilizes the oscillator, because any significant change in oscillator frequency will cause a large phase shift in the feedback loop keeping the oscillator on frequency.

Manufacturers specify crystal for either series or parallel resonant operation. The frequency for the parallel mode is calibrated with a specified shunt capacitance called a “load capacitance.” The most common value is 30 to 32 pF. If the load capacitance is placed in series with the crystal, the equivalent circuit will be series resonance at the specified parallel–resonant frequency. Frequencies up to 20 MHz use parallel resonant crystal operating in the fundamental mode, while above 20 MHz to about 60 MHz, a series resonant crystal specified and calibrated for operation in the overtone mode is used.

Application Examples

Two types of crystal oscillator circuits are used in the applications circuits: 1) fundamental mode common emitter Colpitts (Figures 1, 17a, 17b, and 21), and 2) third overtone impedance inversion Colpitts (also Figures 1 and 21).

The fundamental mode common emitter Colpitts uses a parallel resonant crystal calibrated with a 32 pf load capacitance. The capacitance values are chosen to provide excellent frequency stability and output power of > 500 mVp–p at Pin 9. In Figures 1 and 21, the fundamental mode reference oscillator is fixed tuned relying on the repeatability of the crystal and passive network to maintain the frequency, while in the circuit shown in Figure 17, the oscillator frequency can be adjusted with the variable inductor for the precise operating frequency.

The third overtone impedance inversion Colpitts uses a series resonance crystal with a 25 ppm tolerance. In the application examples (Figures 1 and 21), the reference oscillator operates with the third overtone crystal at 40.0000 MHz. Thus, the MC13175 is operated at 320 MHz (f_o/8 = crystal; 320/8 = 40.0000 MHz. The resistor across the crystal ensures that the crystal will operate in the series resonant mode. A tuneable inductor is used to adjust the oscillation frequency; it forms a parallel resonant circuit with the series and parallel combination of the external capacitors forming the divider and feedback network and the base–emitter capacitance of the device. If the crystal is shorted, the reference oscillator should free–run at the frequency dictated by the parallel resonant LC network.

The reference oscillator can be operated as high as 60 MHz with a third overtone crystal. Therefore, it is possible to use the MC13175 up to at least 480 MHz and the MC13176 up to 950 MHz (based on the maximum capability of the divider network).

Enable (Pin 11)

The enabling resistor at Pin 11 is calculated by:

$$R_{eg.\ enable} = V_{CC} - 1.0\ Vdc/I_{reg.\ enable}$$

From Figure 4, $I_{reg.\ enable}$ is chosen to be 75 µA. So, for a V_{CC} = 3.0 Vdc $R_{reg.\ enable}$ = 26.6 kΩ, a standard value 27 kΩ resistor is adequate.

Layout Considerations

Supply (Pin 12): In the PCB layout, the V_{CC} trace must be kept as wide as possible to minimize inductive reactance along the trace; it is best that V_{CC} (RF ground) completely fills around the surface mounted components and interconnect traces on the circuit side of the board. This technique is demonstrated in the evaluation PC board.

Battery/Selection/Lithium Types

The device may be operated from a 3.0 V lithium battery. Selection of a suitable battery is important. Because one of the major problems for long life battery powered equipment is oxidation of the battery terminals, a battery mounted in a clip–in socket is not advised. The battery leads or contact post should be isolated from the air to eliminate oxide build–up. The battery should have PC board mounting tabs which can be soldered to the PCB. Consideration should be given for the peak current capability of the battery. Lithium batteries have current handling capabilities based on the composition of the lithium compound, construction and the battery size. A 1300 mA/hr rating can be achieved in the cylindrical cell battery. The Rayovac CR2/3A lithium–manganese dioxide battery is a crimp sealed, spiral wound 3.0 Vdc, 1300 mA/hr cylindrical cell with PC board mounting tabs. It is an excellent choice based on capacity and size (1.358″ long by 0.665″ in diameter).

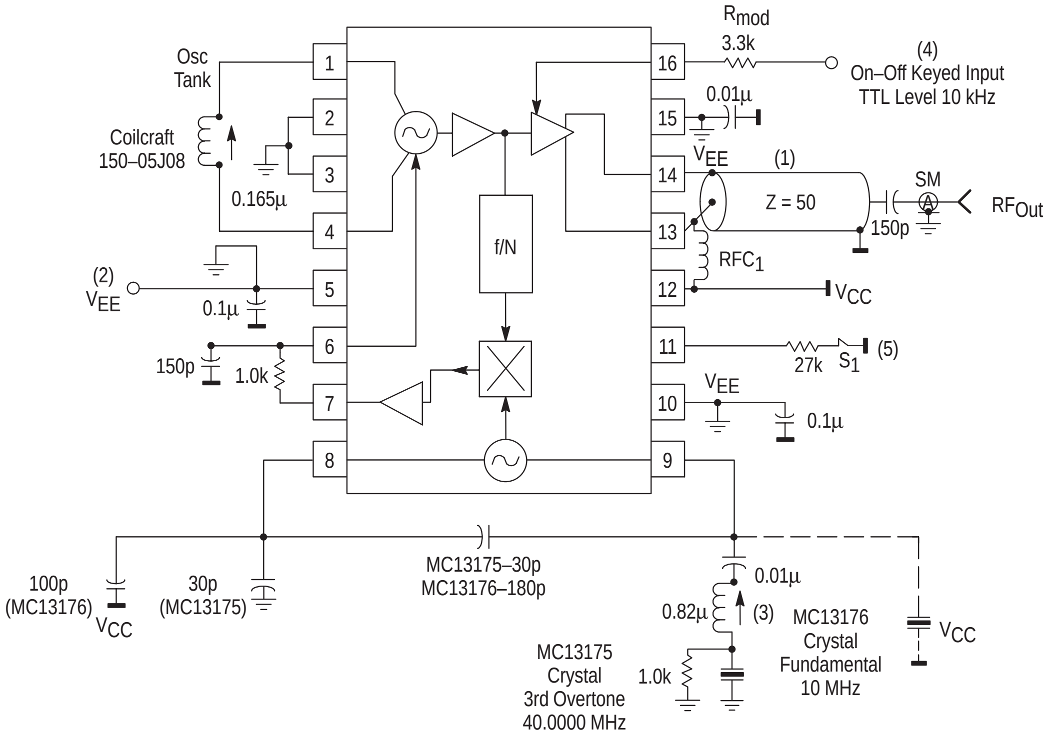
Differential Output (Pins 13, 14)

The availability of micro–coaxial cable and small baluns in surface mount and radial–leaded components allows for simple interface to the output ports. A loop antenna may be directly connected with bias via RFC or 50 Ω resistors. Antenna configuration will vary depending on the space available and the frequency of operation.

AM Modulation (Pin 16)

Amplitude Shift Key: The MC13175 and MC13176 are designed to accommodate Amplitude Shift Keying (ASK). ASK modulation is a form of digital modulation corresponding to AM. The amplitude of the carrier is switched between two or more values in response to the PCM code. For the binary case, the usual choice is On–Off Keying (often abbreviated OOK). The resultant amplitude modulated waveform consists of RF pulses called marks, representing binary 1 and spaces representing binary 0.

Figure 21. ASK 320 MHz Application Circuit



NOTES: 1. 50 Ω coaxial balun, 1/10 wavelength line (1.5″) provides the best match to a 50 Ω load.

2. Pins 5, 10 and 15 are ground and connnected to V_{EE} which is the component/DC ground plane side of PCB. These pins must be decoupled to V_{CC}; decoupling capacitors should be placed as close as possible to the pins.

3. The crystal oscillator circuit may be adjusted for frequency with the variable inductor (MC13175); 1.0 k resistor shunting the crystal prevents it from oscillating in the fundamental mode. Recommended source is Coilcraft “slot seven” 7.0 mm tuneable inductor, part #7M3–821.

4. The On–Off keyed signal turns the output of the transmitter off and on with TTL level pulses through R_{mod} at Pin 16. The “On” power and I_{CC} is set by the resistor which sets I_{mod} = VTTL – 0.8 / R_{mod}. (see Figure 23).

5. S1 simulates an enable gate pulse from a microprocessor which will enable the transmitter. (see Figure 4 to determine precise value of the enabling resistor based on the potential of the gate pulse and the desired enable.)

Figure 21 shows a typical application in which the output power has been reduced for linearity and current drain. The current draw on the device is 16 mA I_{CC} (average) and – 22.5 dBm (average power output) using a 10 kHz modulating rate for the on–off keying. This equates to 20 mA and – 2.3 dBm “On”, 13 mA and – 41 dBm “Off”. In Figure 22a, the device’s modulating waveform and encoded carrier are displayed. The crystal oscillator enable time is needed to set the acquisition timing. It takes typically 4.0 msec to reach full magnitude of the oscillator waveform (see Figure 22b, Oscillator Waveform, at Pin 8). A square waveform of 3.0 V peak with a period that is greater than the oscillator enable time is applied to the Enable (Pin 11).

Figure 22a. ASK Input Waveform and Modulated Carrier

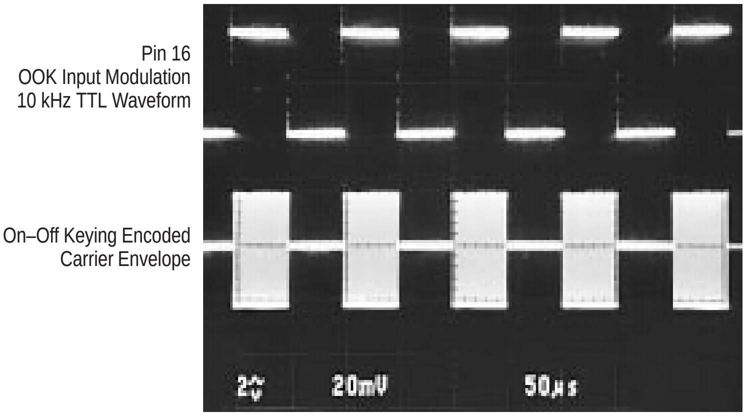


Figure 22b. Oscillator Enable Time, T_{enable}

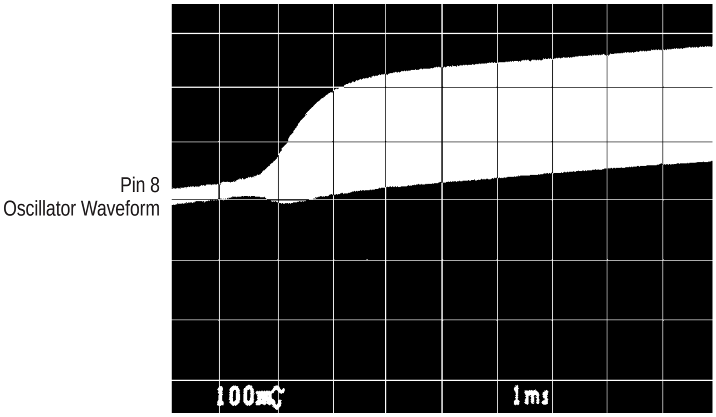

Figure 23. Power Output versus Modulation Current

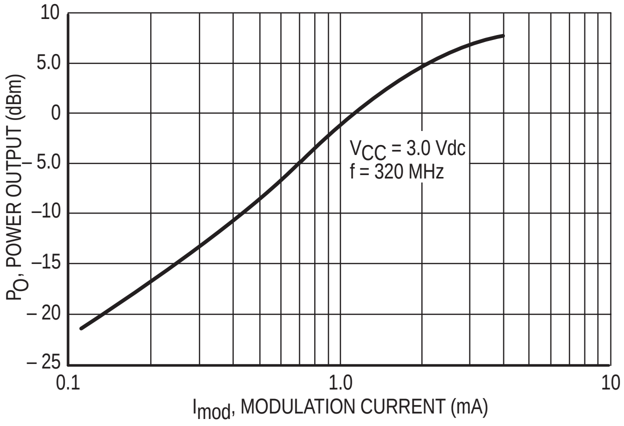

Analog AM

In analog AM applications, the output amplifier’s linearity must be carefully considered. Figure 23 is a plot of Power Output versus Modulation Current at 320 MHz, 3.0 Vdc. In order to achieve a linear encoding of the modulating sinusoidal waveform on the carrier, the modulating signal must amplitude modulate the carrier in the linear portion of its power output response. When using a sinewave modulating signal, the signal rides on a positive DC offset called V_{mod} which sets a static (modulation off) modulation current, I_{mod}. I_{mod} controls the power output of the IC. As the modulating signal moves around this static bias point the modulating current varies causing power output to vary or to be AM modulated. When the IC is operated at modulation current levels greater than 2.0 mAdc the differential output stage starts to saturate.

In the design example, shown in Figure 24, the operating point is selected as a tradeoff between average power output and quality of the AM.

For V_{CC} = 3.0 Vdc; I_{CC} = 18.5 mA and I_{mod} = 0.5 mAdc and a static DC offset of 1.04 Vdc, the circuit shown in Figure 24 completes the design. Figures 25a, 25b and 25c show the results of – 6.9 dBm output power and 100% modulation by the 10 kHz and 1.0 MHz modulating sinewave signals. The amplitude of the input signals is approximately 800 mVp–p.

Where R_{mod} = (V_{CC} – 1.04 Vdc)/0.5 mA = 3.92 k, use a standard value resistor of 3.9 k.

Addendum
An Introduction to Motorola RF Communications IC Applications

In Brief . . .

The RF devices described in Chapter 8 are targeted for the consumer communications market. In addition, most of these parts are capable of superior performance in professional and industrial applications. These devices represent the latest technology in cost effective RF and audio subsystems for cordless telephones (CT-1), RF LANs, land mobile radio, scanners, cellular telephones, remote control spread spectrum, and amateur radio. The purpose of this addendum is to help the user explore all the opportunities presented by this growing family of wireless communications ICs from Motorola Analog.

Page

REGULATORY ISSUES

Each country has its own specific set of regulations regarding radio frequency systems and equipment built and sold within its jurisdiction. These regulations are strongly applicable to transmitting devices. The rules are based on both local needs and international treaties. The regulations are established to provide maximum utilization of the limited available radio spectrum. Motorola strongly recommends that you, the user of these communication ICs, obtain the applicable regulations and abide by them.

In the United States, the regulations of the Federal Communications Commission (F.C.C.) are published in the Code of Federal Regulations (CFR), Title 47, Parts 0 through 99. In the U.S. most of the consumer applications fall under CFR 47, Part 15, covering nonlicensed intentional radiators, or Part 68 which covers public network interconnections. CFR 47 may be obtained at most libraries (in the reference section), or from the U.S. Government Printing Office. You may call their office at (213) 894-5841, or (202) 274-2054 for price and availability. In addition, private contractors such as the Rules Service Company, (301) 424-9402 can provide both the CFR data and an automatic update service. In the U.S., further information is available from the FCC field organization.

For the address and telephone number of the nearest office, contact:

FCC CONSUMER OFFICE AND
SMALL BUSINESS DIVISION
1919 M STREET WEST
WASHINGTON, D.C. 20554
(202) 632-7000

In other countries, the Ministry of Posts or Telecommunications should be contacted. *Motorola Semiconductor does not warrant that the applications shown in this data book meet all the conditions prescribed by government regulations.*

INDUSTRY STANDARDS

Throughout the world the telecommunications industry has established working standards committees to ensure equipment compatibility by setting minimum standards. These standards also help make the best use of the available radio spectrum. In the U.S., the Electronic Industries Association (E.I.A.) has developed a series of these recommended standards which have become the defacto global guidelines.

The following EIA Standards apply to Frequency Modulation (FM) systems.

EIA/TIA-204C	FM/PM RECEIVER STANDARDS
EIA/TIA-152B	FM/PM TRANSMITTER STANDARDS
EIA/TIA-316B	TEST CONDITIONS, PORTABLE PERSONAL RADIO

For additional information and pricing, contact the E.I.A. at the following address:

ELECTRONIC INDUSTRIES ASSOCIATION

WASHINGTON, D.C. 20006
(202) 457-4900

COMMUNICATIONS SYSTEMS

For the most part, the devices described in Chapter 8 use frequency modulation (FM) for both analog voice and data. FM is generally considered the simplest and most cost efficient type of modulation today. FM offers excellent: noise rejection; good sensitivity; reduction of interference due to the FM capture effect; simple circuitry; and an array of test equipment, most of which has spun-off the land mobile market. Direct digital transmission may also be accomplished using Frequency Shift Keying (FSK) or Amplitude Shift Keying (ASK).

The devices shown in Chapter 8 are designed to operate at frequencies below 1.0 GHz (1000 MHz). Today, that frequency range offers the best compromise among performance, complexity and cost. Over the next decade there will be an increasing movement to 1.0 to 3.0 GHz, as the demand for more complex personal communications systems comes on-line. Motorola will add products to its portfolio as these microwave applications become better defined.

Several reference books on Communications Theory and Design are listed below. These books are generally available at major public and university libraries.

THE RADIO AMATEUR'S HANDBOOK, American Radio Relay League, Newington, CT.

MICROWAVE THEORY AND APPLICATIONS, Steven F. Adam, Hewlett Packard, Prentice Hall.

SOLID STATE RADIO ENGINEERING, Herbert L. Krauss, Charles W. Bosdan, F.H. Raab, Wiley 1980.*R*

F CIRCUIT DESIGN, Chris Bowick, Howard Sams & Co., 1982.

INTRODUCTION TO COMMUNICATIONS SYSTEMS, Ferrel Stremler, Addison Wesley.

ARRL ANTENNA HANDBOOK, American Radio Relay League, Newington, CT.

STANDARD RADIO COMMUNICATIONS MANUAL, R.H. Kinley, CET, Prentice Hall, 1985.

In addition, you may find very timely design and component information in the following magazines:

R.F. DESIGN, Cardiff Publishing (708) 647-0756.
MICROWAVES AND RF, Penton Publishing (216) 696-7000.

PASSIVE COMPONENTS

The availability of passive components; coils, filters, crystals, capacitors, resonators, resistors, etc., is often a larger problem than finding the RF or analog IC to meet a designer's needs. The Motorola applications engineering team considers this a key issue when developing the circuits shown in our data sheets. Analog Applications has worked with many suppliers to develop practical and reasonably priced passive component selections. Suppliers who have a global support structure and can supply both prototype and production quantities are listed. The following table lists a number of suppliers which have been used in recent applications. The design engineer will also need information on the performance of the components as a function of temperature, frequency, solderability and reliability. Most of these suppliers have applications-engineering support with a wealth of specific technical information. *Motorola, however, cannot warrant the suppliers' quality, availability, or prices.*

Motorola suggests contacting the suppliers directly to obtain technical information and competitive quotes.

In many cases, recommendations have been made to use readily available sources such as “Radio Shack” for small parts and construction material. The user is encouraged to develop a core of dependable and local, if possible, suppliers for his or her passive components. Please note that many data sheets have specific passive components which have been used to develop and characterize the integrated circuit. Constructing a benchmark circuit with these components is an excellent starting point in the development of a new design.

COMPONENT SUPPLIERS

QUARTZ CRYSTALS — FREQUENCY CONTROL:

California Crystal Laboratories	(800) 333-9825
Fox Electronics	(813) 693-0099
International Crystals	(405) 236-3741
Standard Crystal Corporation	(818) 443-2121

GENERAL COMPONENTS — PROTOTYPE QUANTITIES — ASSEMBLY MATERIAL — PC BOARD MATERIAL:

Digi-Key Corporation	(800) 344-4539
Radio Shack Division, Tandy Corporation	(See local telephone directory)

INDUCTORS, COILS, RF TRANSFORMERS, FIXED AND VARIABLE:

Toko America, Inc.	(708) 297-0070

CERAMIC FILTERS AND RESONATORS, IF FILTERS — AM & FM TYPES:

muRata Erie	(404) 436-1300 (Todd Brown, Harry Moore)
TDK Corporation of America	(708) 803-6100
Toko America, Inc.	(708) 297-0070

BREADBOARDING

Breadboarding RF or other high speed analog circuits can be a very frustrating process for the newcomer or even an experienced digital designer. Most of these circuits deal with very high gain (100+ dB), very small signals of less than a few microvolts, or with very high frequencies with wavelengths that are a fraction of a meter. Once “friendly” 0.1 µF capacitors may act as inductors, due to their parasitic inductance, while conventional construction methods may yield only circuits that oscillate.

What to avoid (never use these):

- Wire wrap for RF or high frequency breadboards.
- Conventional push-in prototype boards.
- Digital printed protoboards with ground and power supply bus lines.

What to use:

- Carefully laid-out double-sided groundplane PC boards.
- Grid boards with a backside ground plane.
- Single-sided PC layouts with continuous full ground fill.
- High frequency qualified components.
- Adequate decoupling.

The RF designer will find recommended PC board layouts for most of the communications circuits in Chapter 8. These layouts are strongly recommended as starting points for new designs. They will allow you to develop your own benchmark standard circuit to be used as a standard of comparison during further design iterations. Many Motorola communications ICs have supporting development kits which include a PC board. These boards are meant to provide performance equivalent to the data sheet specifications, and are easy to modify for other uses however, these boards are not optimized or intended for production applications. Contact your Motorola sales office or Motorola distributor for information on the availability of these development kits.

In addition, there are many PC and Macintosh-based CAD programs available today. In general, these programs work well for digital and low frequency analog circuits, but are of very limited value in RF applications. SPICE models are not currently available for the communications circuits. Several circuits do show S-Parameter data or admittance plane information which may be used to optimize input or output matching for gain or noise. The most useful method of utilizing the applications circuits at different frequencies is simple linear scaling of the tuning and reactive elements. This method is generally applicable over a 2:1 frequency range lower than the documented application.

Many communication applications include some digital signaling, data conversion, or microcontroller interface. The RF Designer must take great caution to avoid interference with the low level analog circuits in these mixed-mode systems. The receivers are particularly susceptible to interference as they respond to signals of only a few microvolts. Make sure the clock frequency is not a submultiple of the receiver input or IF frequencies. Be sure to keep the dc supply lines for the digital and analog portions separate. Avoid ground paths carrying common digital and analog currents. Common sense as well as analytical skill is required for a successful RF design. A good consultant may well save many times their fee in material, lost time, and rework expenses.

TEST EQUIPMENT

Establishing a new RF/Communications lab can be a very costly investment. The normal DVMs and regulated power supplies are generally acceptable, if they do not generate spurious RF, and are not sensitive to RF voltages. The Designer should choose an oscilloscope with a frequency response three or more times higher than the operating frequency. In addition, a low capacitance probe, a FET probe, would be useful. Remember, while conventional probes have very high input resistance, their capacitive reactance decreases with frequency and becomes a limiting factor above 30 MHz. For most transmitter work, a basic spectrum analyzer is a must to help confirm power output, spurious output levels, stability, and modulation characteristics.

Rental and used equipment are often a good source of test equipment. Communications System Analysers have recently become available at very moderate prices. The Motorola R2600, for example, combines 16 different instruments into one portable package. The signal generator, receiver, counter, oscilloscope and a “best-in-class” modulation meter make this instrument a very attractive design and production test tool. Further information, including a demonstration, are available from your local Motorola Communications and Electronics sales office.

WORLDWIDE CORDLESS TELEPHONE FREQUENCIES

The following tables contain CT–1 USA and Asia Pacific (CT–0 Europe) frequencies for cordless telephone. These tables reference application information provided in MC13109, MC13110, and MC13111 Universal Cordless Telephone Subsystem Integrated Circuit Technical Data Sheets. Channel number, T_X channel frequency, 1st LO frequency, and T_X and R_X divider values are listed in this addendum. The device data sheets can be found in Chapter 8 of this Data Book (DL128).

Note: USA cordless frequency band listed herein is specified in the Code of Federal Regulations (CFR), Title 47 (FCC Rules), Part 15, paragraph 15.233, dated June 5, 1995 (25 channel band).

Consumer Electronic Circuits

In Brief . . .

These integrated circuits reflect Motorola's continuing commitment to semiconductor products necessary for consumer system designs. This tabulation is arranged to simplify selection of consumer integrated circuit devices that satisfy the primary functions for home entertainment products, including television, hi–fi audio and AM/FM radio.

Entertainment Radio Receiver Circuits

Table 1. Entertainment Receiver RF/IF

Function	Features	Suffix/ Package	Device
E.T.R. Front End	Mixer/VCO/AGC for Electronically Tuned AM Stereo Receivers	P/648, D/751B	MC13025
AMAX Front End	Mixer/VCO/AGC with RF and Audio Noise Blanking	DW/751D, P/738	MC13027
Dual Conversion AM Receiver	1st Mixer/OSC, 2nd Mixer/OSC, High Gain IF, AGC, Detector	DW/751F	MC13030

Table 2. C–Quam® AM Stereo Decoders

Function	Features	Suffix/ Package	Device
Basic AM Stereo Decoder	Monaural/Stereo AM Detector/Indicator, 6.0 to 10 V Operation	P/738	MC13020
Advanced AM Stereo Decoder	Medium Voltage 4.0 to 10 V, Decoder and IF Amp	P/710, DW/751F	MC13022
Advanced AM Stereo Decoder	Medium Voltage 6.0 to 10 V, Decoder and IF Amp	P/710, DW/751F	MC13022A
Low V AM Stereo Receiver	IF/Decoder for Advanced C–Quam Receivers	P/648, D/751B	MC13028A
Medium V AM Stereo Decoder	IF/Decoder for Advanced C–Quam Receivers with AM/FM Switch	DW/751D, H/738	MC13029A
AMAX Stereo Decoder	Am Stereo Decoder with Audio Noise Blanker	DW/751F, P/710	MC13122

Table 3. Audio Amplifiers

Function	P_O (Watts)	V_{CC} Vdc Max	V_{in} @ Rated P_O mV Typ	I_D mA Typ	R_L (Ohms)	Suffix/ Package	Device
Mini Watt SOIC Audio Amp	1.0 W	35	80	11	16	D/751	MC13060
Low Power Audio Amp	500 mW	16	–	2.5 mA	8 – ∞	D/751, P/626, DTB/948J	MC34119

Video Circuits

Table 4. Video Circuits

Function	Features	Suffix/ Package	Device
Encoders			
RGB to PAL/NTSC Encoder	RGB and Sync inputs, Composite Video out; PAL/NTSC selectable.	P/738, DW/751D	MC1377
Video Overlay Synchronizer	Complete Color TV Video Overlay Synchronizer, remote or local system control and RGB encoder.	P/711, FN/777	MC1378
Advanced RGB to PAL/NTSC Encoder	RGB and Sync inputs, Composite Video and S–VHS out; PAL/NTSC selectable; subcarrier from crystal or external source.	P/738, DW/751D	MC13077
TV Decoder			
Chroma 4 Multistandard Decoders (TV Set)	PAL/NTSC/SECAM decoding, Composite Video/S–VHS Inputs, RGB Outputs, horizontal and vertical drive outputs, geometry correction and beam current monitor, digital internal filters, no external tank, 16:9 capability, µP and crystal controlled.	P/711	MC44002
	Same as MC44002, but without SECAM decoding.	P/711	MC44007
	Same as MC44002, but with internal chroma delay line.	P/711	MC44030
	Same as MC44030, but without SECAM decoding.	P/711	MC44035
Video Capture Chip Sets			
Chroma 4 Multistandard Video Processor (Multimedia)	PAL/NTSC/S–VHS input, RGB/YUV outputs; horizontal and vertical timing outputs; all digital internal filters, no external tanks; µP and crystal controlled.	FN/777, FB/824E	MC44011
Chroma Digital Delay Line	For PAL and SECAM applications of the MC44011, MC44002, MC44007.	P/648, DW/751G	MC44140
Pixel Clock PLL/Sync Sep.	PAL/NTSC sync separator, 6.0–40 MHz pixel clock PLL.	D/751A	MC44145
Triple 8–Bit Video DAC	TTL inputs, 75 Ω drive outputs.	FB/824A	MC44200
Triple 8–Bit Video A/D	Video clamps for RGB/YUV, 18 MHz, High Z TTL outputs.	FN/777	MC44251
TV Picture–in–Picture			
Picture–in–Picture (PIP) Controller	Completely self–contained NTSC picture–in–picture function.	B/859	MC44461
Y–C Picture–in–Picture (PIP) Controller	Completely self–contained NTSC picture–in–picture function, with Y–C input and output capability, for use in high performance S–Video systems.	B/859	MC44462
Replay and Multiple Picture–in–Picture (PIP) Controller	Offers either multiple PIP windows or several seconds of replay. Used with external DRAM.	B/859	MC44463
Comb Filters			
Enhanced Comb Filter	Fast 8–Bit A/D Converter, Two 8–Bit D/A Converters, Two Line–Delay Memories, utilizes NTSC Subcarrier Frequency clock, CMOS Technology.	FU/898	MC141620
Advanced Comb Filter (ACF)	Composite Video input; YC outputs in digital and analog form; all digital internal filters.	FU/898	MC141621A
Advanced Comb Filter – II (ACF–II)	Composite Video input; YC outputs in digital and analog form; all digital internal filters; vertical enhancer circuit.	P/898	MC141622A
Advanced Comb Filter – I (ACF–I)	Low cost Ih filter.	FU/873 SP/TBD	MC141624
Advanced PAL/NTSC Comb Filter	Composite Video input; YC outputs in digital and analog form; all digital internal filters.	FB/898	MC141627
Deflection			
Horizontal Processor	Linear balanced phase detector, oscillator and predriver, adjustable DC loop gain and duty cycle.	P/626	MC1391
TV IF Circuits			
IF Amplifier	1st and 2nd video IF amplifiers, 50 dB gain at 45 MHz, 60 dB AGC range.	D/751, P/626	MC1350

Table 4. Video Circuits (continued)

Function	Features	Suffix/ Package	Device
Tuner PLL Circuits			
PLL Tuning Circuits	1.3 GHz, 10 mV sensitivity selectable prescaler (MC44817), op amp, 4 band buffers, 3–wire bus interface, lock detect.	D/751B	MC44817, B
	1.3 GHz, 10 mV sensitivity prescaler, op amp, 4 band buffers, I^2C interface, lock detect.	D/751B	MC44818
	1.3 GHz, 10 mV sensitivity prescaler, 3 band buffers, I^2C interface, replacement for Siemens MPG3002.	D/751, D/751B	MC44824, MC44825
	Similar to MC44817, with lower power consumption, push–pull lock detector output, no divide–by–8 bypass, in a TSSOP package.	DTB/948F	MC44827
	Similar to MC44818, with lower power consumption, push–pull lock detector output, in a TSSOP package.	DTB/948F	MC44828
	1.3 GHz prescaler, 10 mV sensitivity 50 to 950 MHz, op amp, 3 band buffers, Mixer/Osc Decoder and I^2C Bus.	D/751A	MC44829
	1.3 GHz, 10 mV sensitivity selectable prescaler, op amp, 4 band buffers, I^2C interface, 3 DACs for automatic tuner alignment.	M/967	MC44864
Modulator			
Color TV Modulator with Sound	RF oscillator/modulator, and FM sound oscillator/modulator.	P/646	MC1374
UHF TV Modulator	Multi–standard PLL tuned UHF TV modulator with AM or FM sound.	DTB/948E, DW/751D	MC44353, MC44354, MC44355
Video Data Converters			
Single Channel A/D	8–Bit, 25 MHz, 2.0 V input range, ±5.0 V supplies, TTL output, no pipeline delay.	P/709, DW/751E	MC10319
Triple 8–Bit Video A/D	Video clamps for RGB/YUV, 18 MHz conversion, high Z outputs.	FN/777	MC44251
Triple 8–Bit Video DAC	TTL inputs, 75 Ω drive outputs.	FB/824	MC44200
Monitor Subsystem			
Multimode Color Monitor Processor	Adaptable to 30 kHz to 64 kHz horizontal, 45 to 100 Hz vertical frequency, multiple sync including sync–on–green, horizontal and vertical drive outputs, double PLL, 70 MHz RGB pre–amps, contrast and brightness controls.	B/859	MC13081X
RGB Video Processor	80 MHz bandwidth, blank and clamp inputs, main contrast and subcontrast controls.	P/738	MC13280AY
	Same as above, except 100 MHz bandwidth.	P/738	MC13281B
	Same as above, except 100 MHz bandwidth and pin compatible with MC13282A.	P/724	MC13281A
RGB Video Processor with OSD Inputs	100 MHz bandwidth, blank and clamp inputs, main contrast and subcontrast controls, OSD inputs, OSD contrast control, pin compatible with MC13281A.	P/724	MC13282A
	Same as above, except 130 MHz bandwidth.	P/724	MC13283
Sound			
Sound IF Detector	Interchangeable with ULN2111A.	P/646, D/751A	MC1357
Miscellaneous			
Subcarrier Reference Generator	Provides continuous subcarrier sine wave and 4x subcarrier, locked to incoming burst.	P/626, D/751	MC44144
Closed Caption Decoder	Conforms to FCC, NTSC standards, underline and italics control.	P/707	MC144143
Enhanced Closed Caption Decoder	Conforms to FCC, NTSC, XDS standards, underline, italics and OSC.	P/707	MC144144
Sync Separator/Pixel Clock PLL	PAL/NTSC sync separator with vertical and composite sync output, 6 to 40 MHz pixel clock PLL.	D/751A	MC44145
Dual Video Amplifiers	Gain @ 4.43 MHz = 6.0 dB ±1.0 dB, fixed gain, internally compensated, CMOS Technology.	P/626, F/904	MC14576C
	Gain @ 5.0 MHz = 10 dB max, 10 MHz = 6.0 dB max, adjustable gain, internally compensated, CMOS Technology.	P/626, F/904	MC14577C

Table 4. Video Circuits (continued)

Function	Features	Suffix/ Package	Device
Miscellaneous			
Transistor Array	One differential pair and 3 isolated transistors, 15 V, 50 mA.	P/646, D/751A	MC3346
General Purpose Transistor Array	One differential pair and 3 isolated transistors, 130 V, 50 mA.	D/751A	CA3146

Table 5. Video Decoders

Function	MC44002	MC44007	MC44030(1)	MC44035	MC44011
For TV Set Applications (RGB Outputs for CRT Driver)	Yes		Yes		No
For Video Capture Applications (RGB/YUV Outputs)	No		No		Yes
PAL/NTSC Decoding	Yes		Yes		Yes
SECAM Decoding	Yes	No	Yes	No	No
Chroma Delay Line	External		Internal		External
Composite Video Inputs	2		2		2
Y/C Inputs	1 set (Note 2)		1 set (Note 2)		1 set (Note 2)
RGB Inputs (3 Pins)	1 set		1 set		1 set
YUV Outputs/Inputs	Yes		Yes		Yes
Video Output for Teletext or Closed Caption	No		No		No
16:9 Capability on 4:3 Screen	Yes		Yes		No
Single 5.0 V Supply	Yes		Yes		Yes
Supply Current (Typical)	120 mA		150 mA		110 mA
Video Mute (Blanking Control)	No		Yes		No
Pixel Clock Generator for A/D	No		No		Yes

NOTES: 1. The MC44030 with integrated chroma delay line can replace the MC44002 + MC44140. A single PC board pattern can be made to accept either device and the software can be written to be compatible, although the MC44030 has several additional functions.
2. In Y/C mode the two CVBS inputs become Y and C inputs.
3. One set uses SCART Video input as Y and SCART Red input as C. The second set are independent inputs.

Digitally Controlled Video Processor for Multimedia Applications

MC44011FN, FB

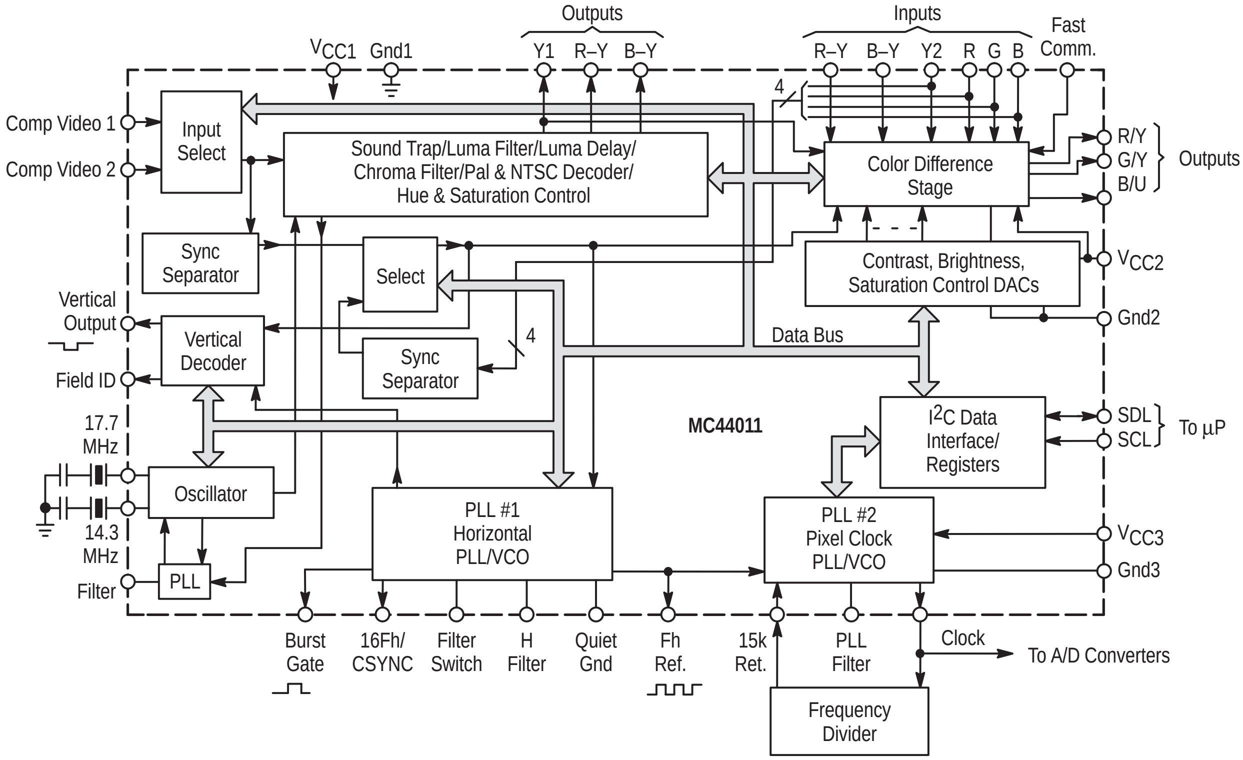
Case 777, 824E

The MC44011, a member of the MC44000 Chroma 4 family, is designed to provide RGB or YUV outputs from a variety of inputs. The inputs may be either PAL or NTSC composite video (two inputs), S–VHS, RGB, and color difference (R–Y, B–Y).

The MC44011 provides a sampling clock output for use by a subsequent analog to digital converter. The sampling clock (6.0 to 40 MHz) is phase–locked to the horizontal frequency. Additional outputs include composite sync, vertical sync, field identification, luminance, burst gate, and horizontal frequency.

Control of the MC44011, and reading of status flags is accomplished via an I^2C bus.

- Multistandard Decoder, Accepts NTSC and PAL Composite Video
- Dual Composite Video or S–VHS Inputs
- All Chroma and Luma Channel Filtering, and Luma Delay Line are Integrated Using Sampled Data Filters Requiring no External components
- Digitally Controlled via I^2C Bus
- Auxiliary Y, R–Y, B–Y Inputs
- Switched RGB Inputs with Separate Saturation Control
- Line–Locked Sampling Clock for Digitizing Video Signals
- Burst Gate Pulse Output for External Clamping
- Vertical Sync and Field Ident Outputs
- Software Selectable YUV or RGB Outputs Able to Drive A/D Converters



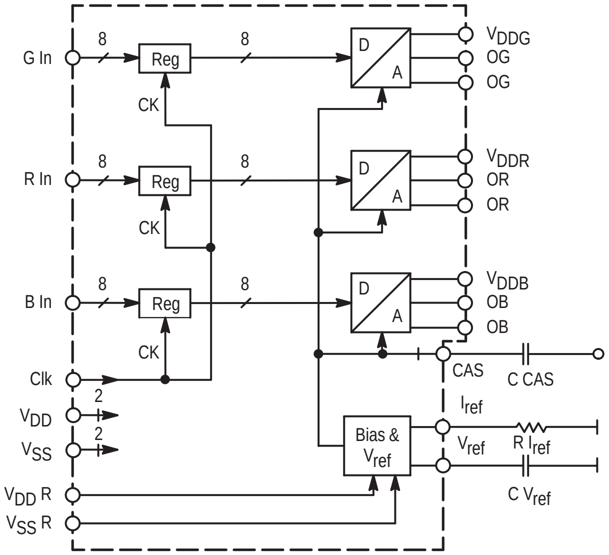
Triple 8–Bit D/A Converter

MC44200FB

Case 824A

The MC44200 is a monolithic digital to analog converter for three independent channels fabricated in CMOS technology. The part is specifically designed for video applications. Differential outputs are provided, allowing for a large output voltage range.

- 8–Bit Resolution
- Differential Outputs
- 55 msps Conversion Speed
- Large Output Voltage Range
- Low Current Mode
- Single 5.0 V Power Supply
- TTL Compatible Inputs
- Integrated Reference Voltage



Triple 8–Bit A/D Converter

MC44251FN

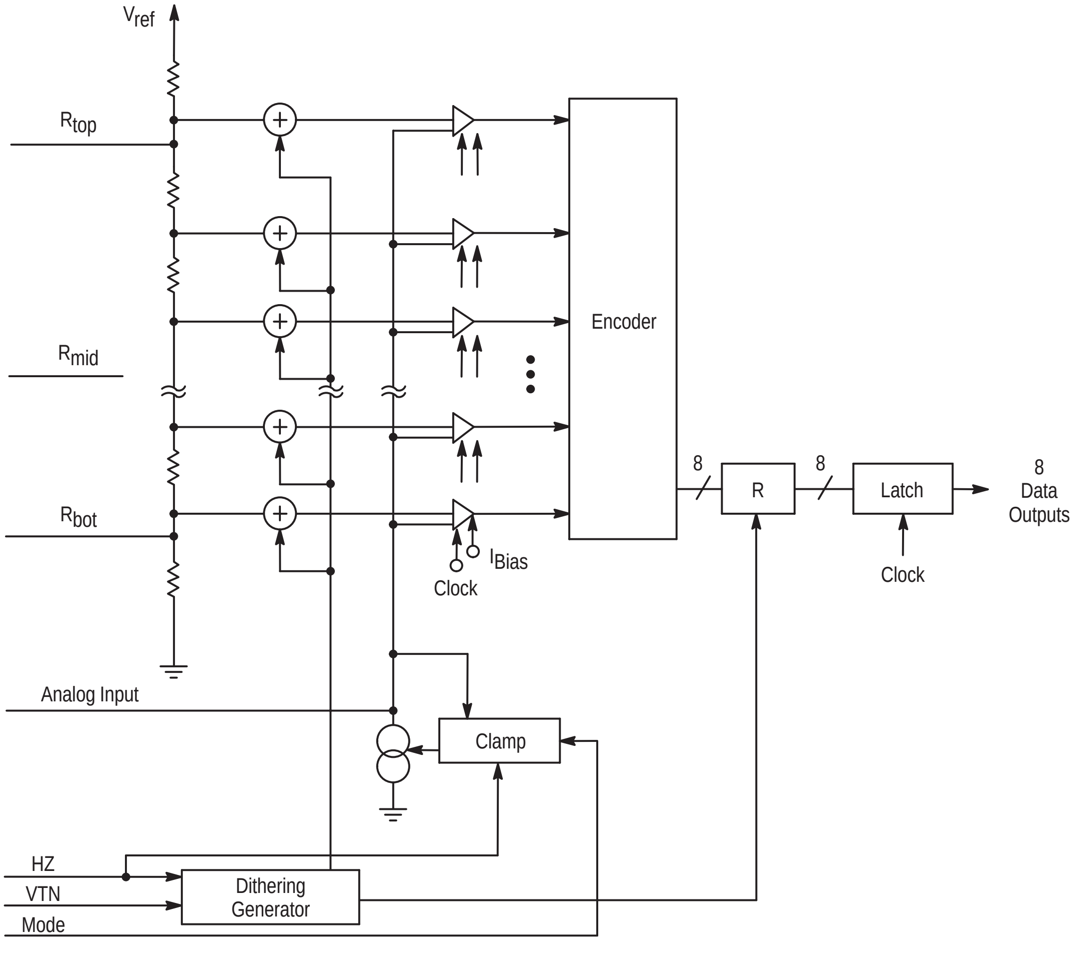
Case 777

The MC44251 contains three independent parallel analog to digital converters. Each ADC consists of 256 latching comparators and an encoder. Input clamps allow for AC coupling of the input signals, and dc coupling is also allowed. For video processing performance enhancements, a dither generator with subsequent digital correction is provided to each ADC. The outputs of the MC44251 can be set to a high impedance state.

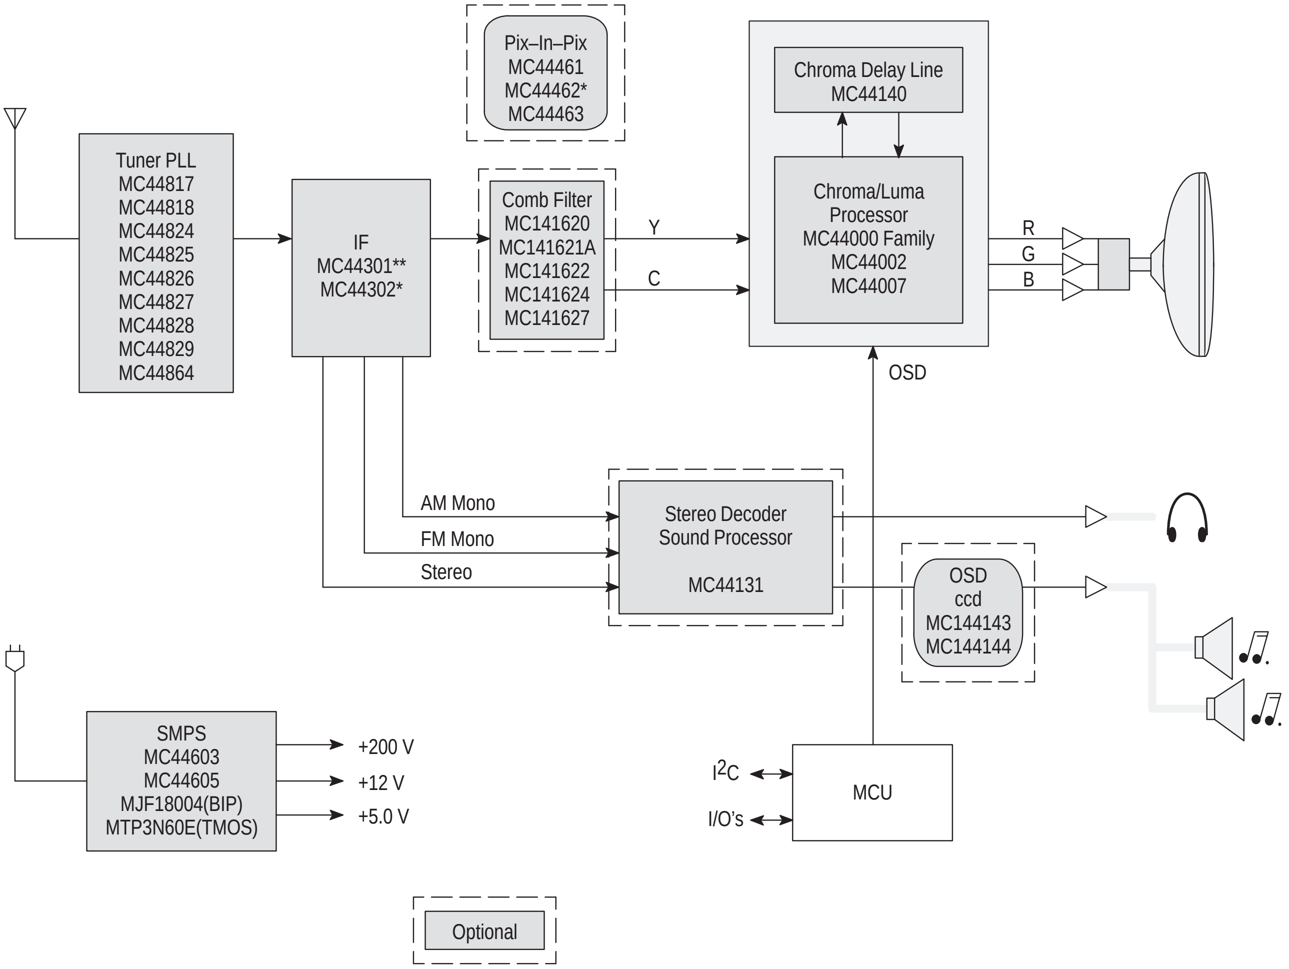
These A/Ds are especially suitable as front end converters in TV picture processing.

- 18 MHz Maximum Conversion Speed (MC44251)
- Input Clamps Suitable for RGB and YUV Applications
- Built–in Dither Generator with Subsequent Digital Correction
- Single 5.0 V Power Supply

Simplified Diagram of One of the ADCs



Color TV Block Diagram



* In Development
** Not recommended for new designs.

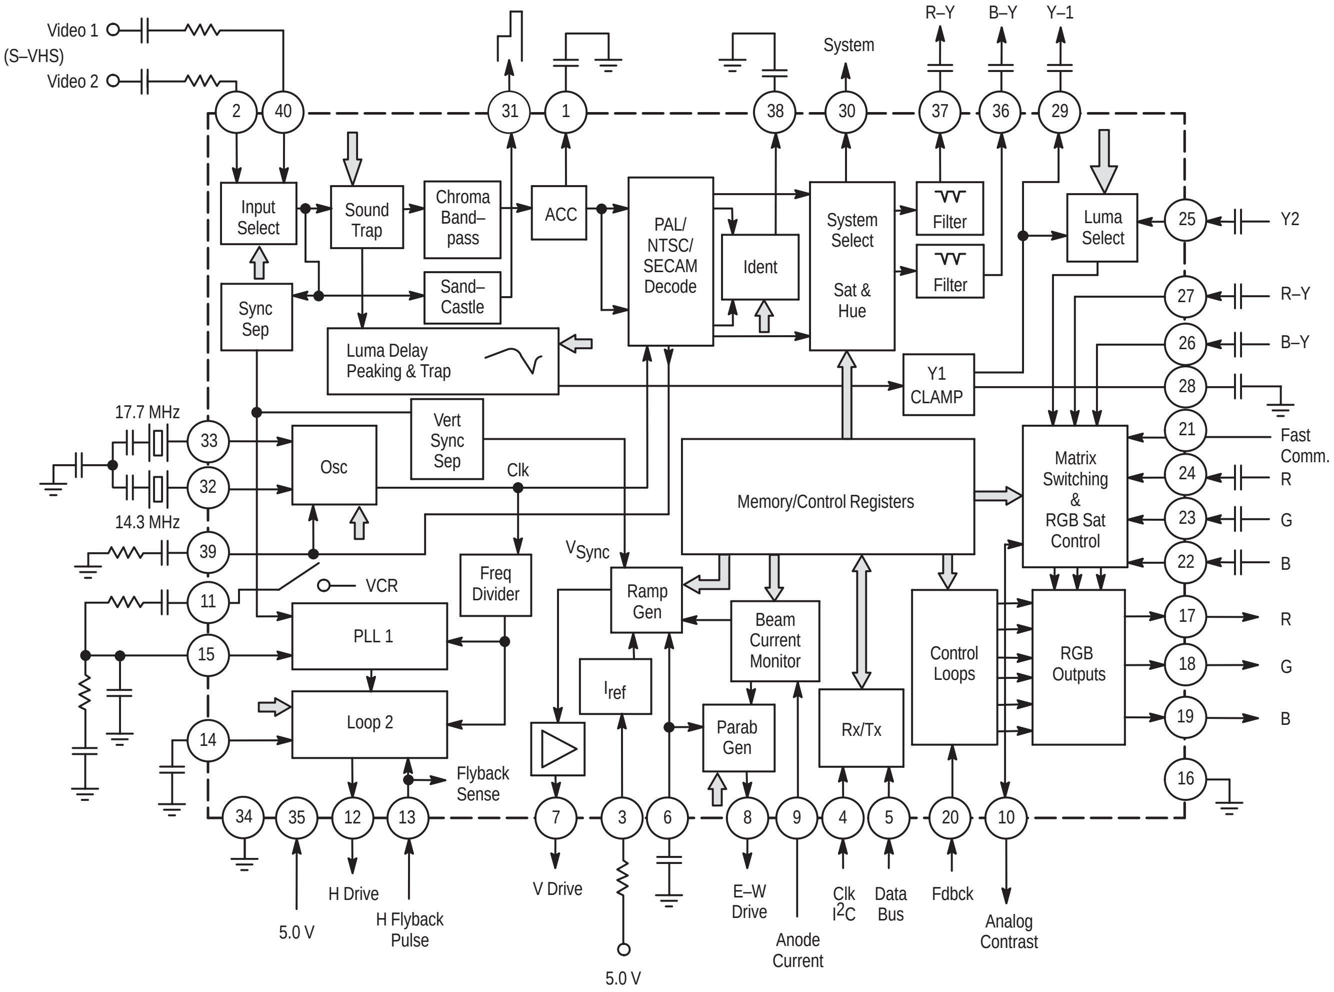
Multistandard Video/Timebase Processor

MC44002P, MC44007P

Case 711

The MC44002/7 is a highly advanced circuit which performs most of the basic functions required for a color TV. All of its advanced features are under processor control via an I^2C bus, enabling potentiometer controls to be removed completely. In this way the component count may be reduced dramatically to allow significant cost savings and the possibility of implementing sophisticated automatic test routines. Using the MC44002/7, TV manufacturers will be able to build a standard chassis for anywhere in the world.

- Operation from a Single 5.0 V Supply; Typical Current Consumption Only 120 mA
- Full PAL/SECAM/NTSC Capability (MC44002 Only)
- MC44007 Decodes PAL/NTSC Only
- Dual Composite Video or S–VHS Inputs
- All Chroma/Luma Channel Filtering, and Luma Delay Line are Integrated Using Sampled Data Filters Requiring No External Components
- Filters Automatically Commutate with Change of Standard
- Chroma Delay Line is Realized with Companion Device (MC44140)
- RGB Drives Incorporate Contrast and Brightness Controls and Auto Gray Scale
- Switched RGB Inputs with Saturation Control
- Auxiliary Y, R–Y, B–Y Inputs
- Line Timebase Featuring H–Phase Control and Switchable Phase Detector Gain and Time Constant
- Vertical Timebase Incorporating the Vertical Geometry Corrections
- E–W Parabola Drive Incorporating the Horizontal Geometry Corrections
- Beam Current Monitor with Breathing Compensation
- 16:9 Display Mode Capability

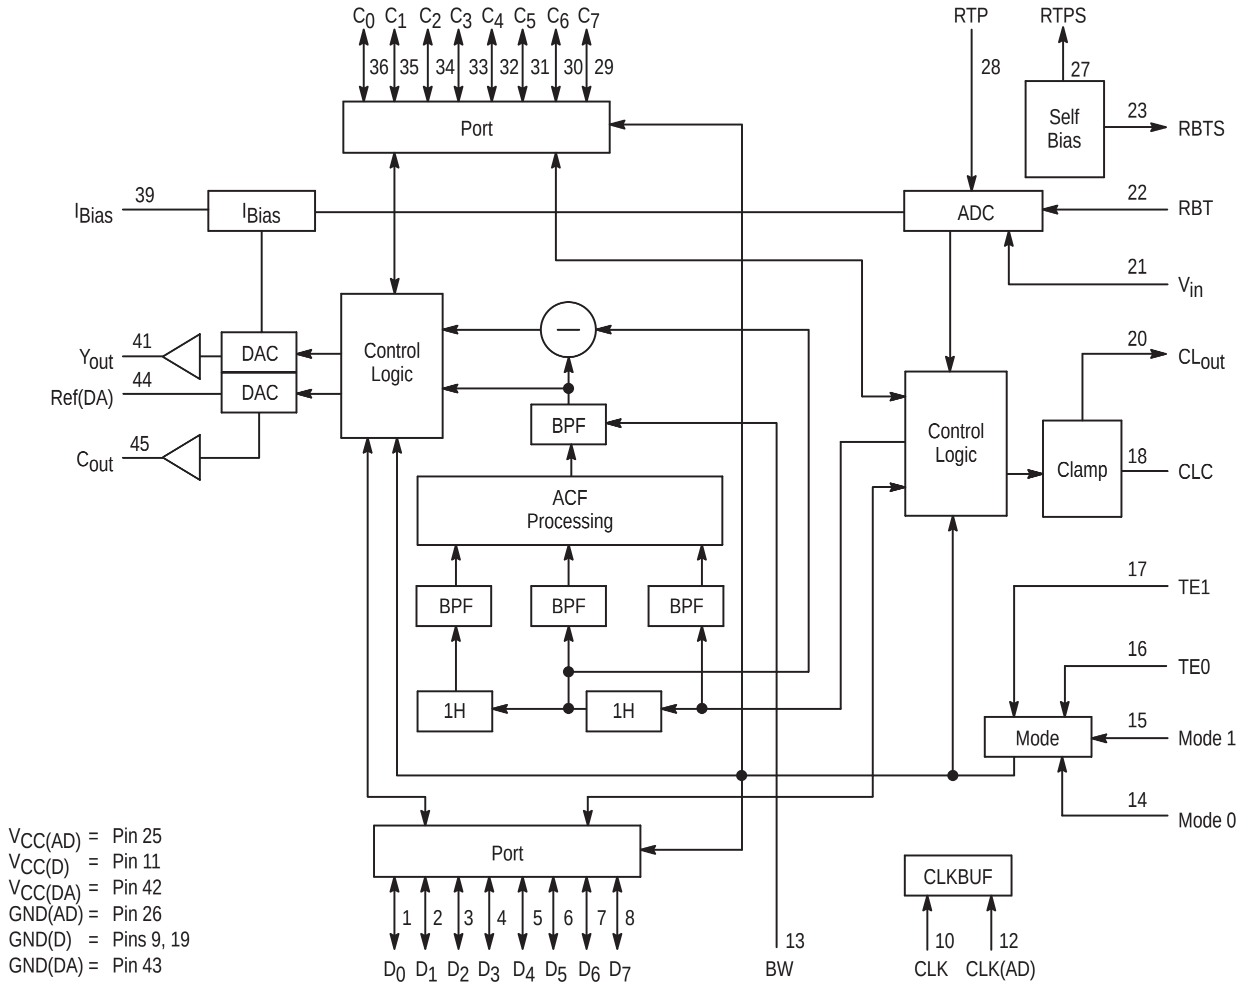


Advanced NTSC Comb Filter

MC141621FB
Case 898

The MC141621 is an advanced NTSC comb filter for VCR and TV applications. It separates the luminance (Y) and chrominance (C) signals from the NTSC composite video signal by using digital signal processing techniques. This filter allows a video signal input of an extended frequency bandwidth by using a 4.0 F_{SC} clock. In addition, the filter minimizes dot crawl and cross color effects. The built–in A/D and D/A converters allow easy connections to analog video circuits.

- Built–in High Speed 8–Bit A/D Converter
- Two Line Memories (1820 Bytes)
- Advanced Combing Process
- Two 8–Bit D/A Converters
- Built–in Clamp Circuit
- On–Chip Reference Voltage Regulator for ADC
- Digital Interface Mode



$V_{CC(AD)}$ = Pin 25
$V_{CC(D)}$ = Pin 11
$V_{CC(DA)}$ = Pin 42
GND(AD) = Pin 26
GND(D) = Pins 9, 19
GND(DA) = Pin 43

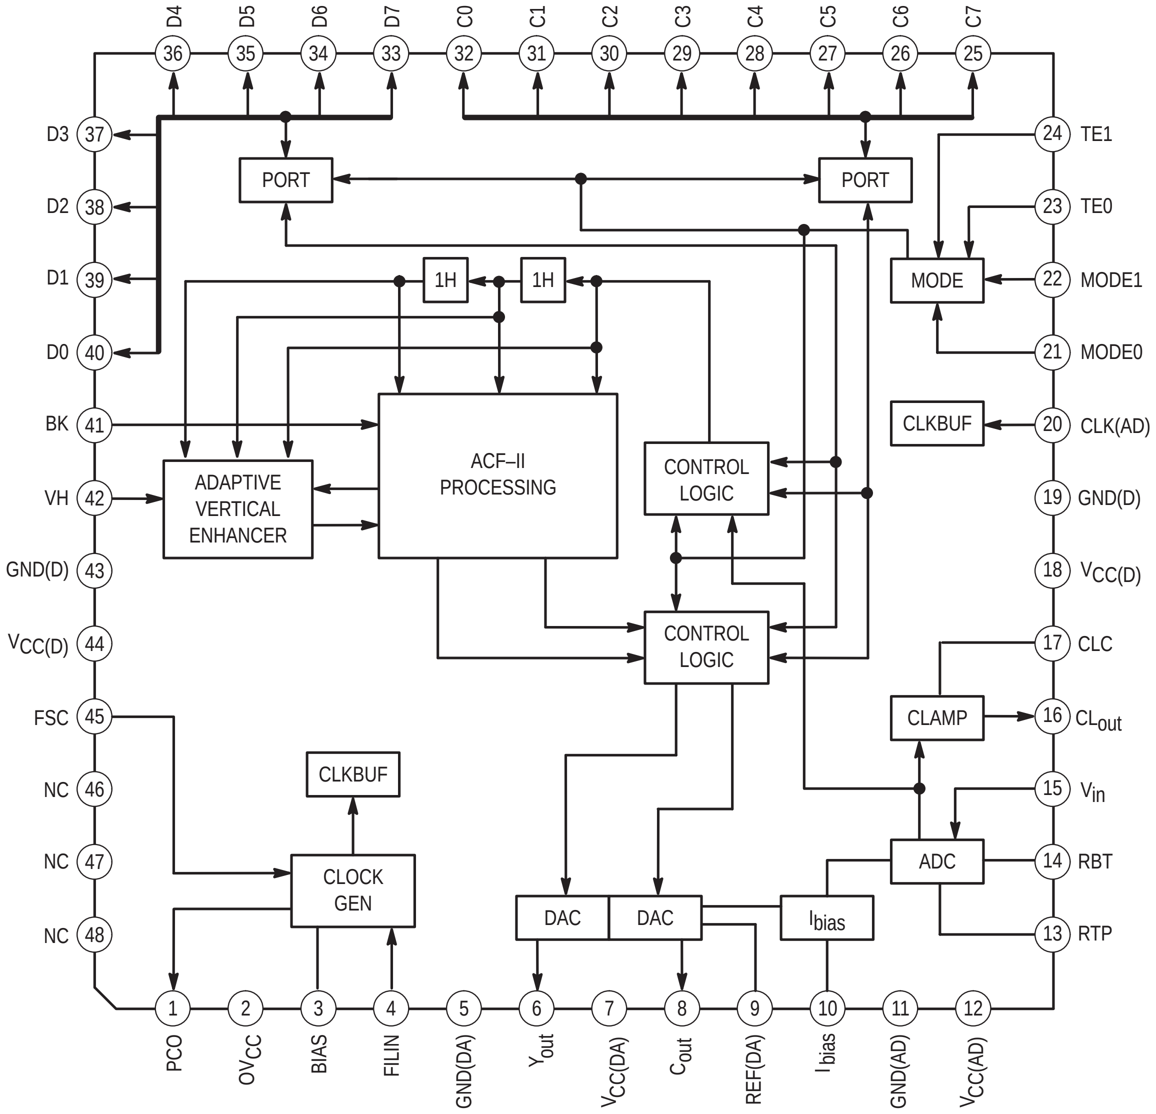
Advanced Comb Filter–II (ACF–II)

MC141622AFU

Case 898

The Advanced Comb Filter–II is a video signal processor for VCRs and TVs. It's function is to separate the Luminance Y and Chrominance C signals from the NTSC composite video signal. The ACF–II minimizes dot–crawl and cross–color. A built–in PLL provides a 4xfsc clock from either an NTSC subcarrier signal or a 4xfsc input. This allows a video signal input of an extended frequency bandwidth. The built–in vertical enhancer circuit improves the quality of the Luminance Y signal. The built–in A/D and D/A converters allow easy connection to analog video circuits.

- Built–in High Speed 8–Bit A/D Converter
- Two Line Memories (1820 Bytes)
- Advanced Comb–II Process
- Vertical Enhancer Circuit
- Two High Speed 8–Bit D/A Converters
- 4xfsc PLL Circuit
- Built–in Clamp Circuit
- Digital Interface Mode
- On–Chip Reference Voltage Regulator for A/D Converter

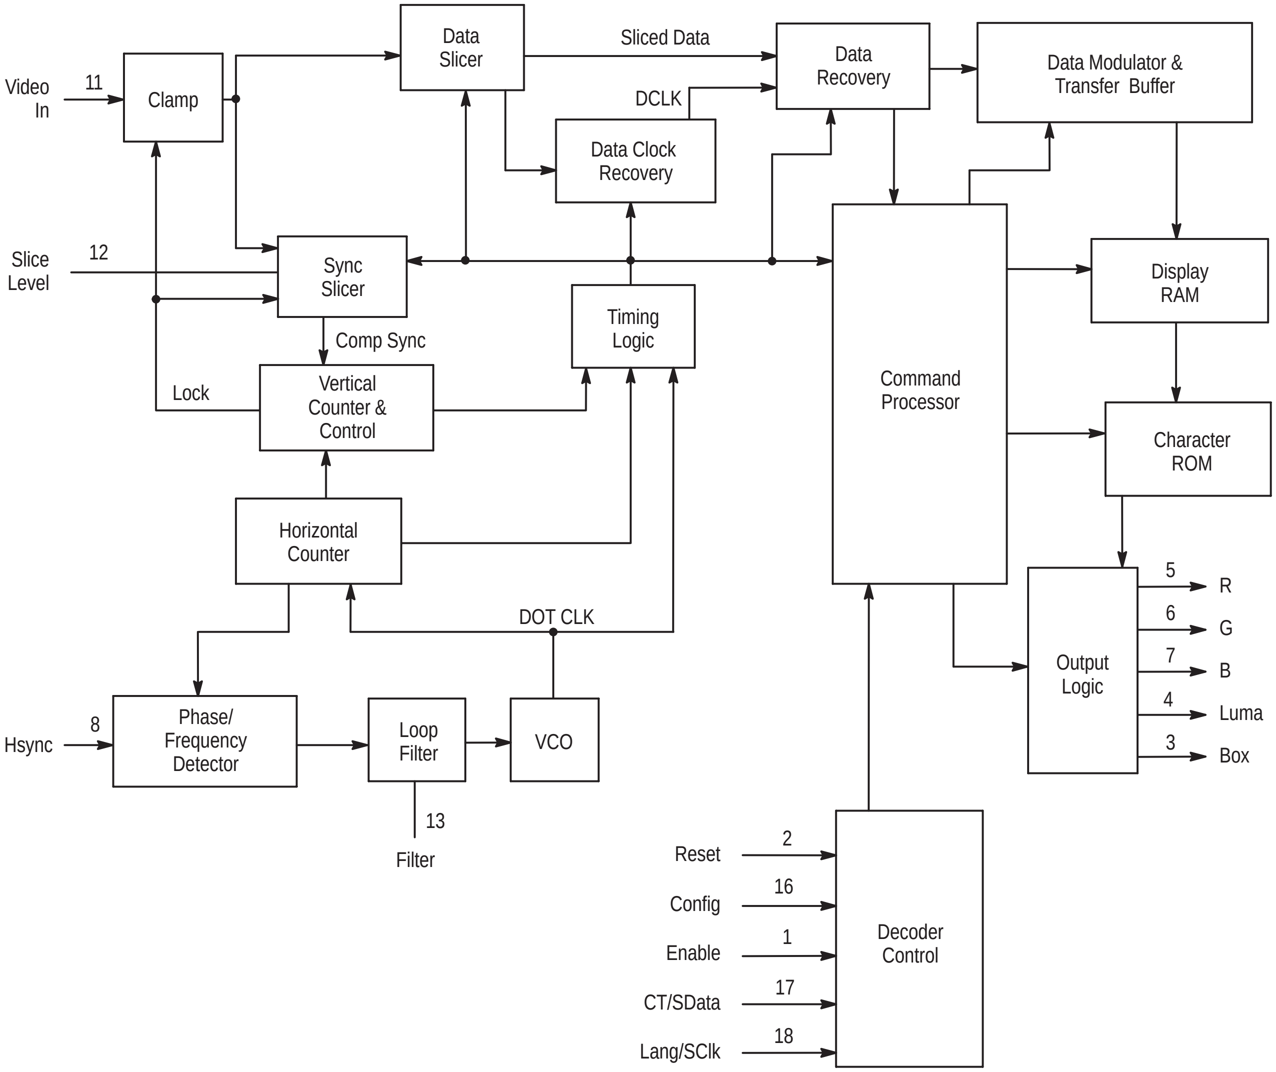


Closed–Caption Decoder

MC144143P
Case 707

The MC144143 is a Line 21 closed–caption decoder for use in television receivers or set top decoders conforming to the NTSC broadcast standard. Capability for processing and displaying all of the latest standard Line 21 closed–caption format transmissions is included. The device requires a closed–caption encoded composite video signal, a horizontal sync signal, and an external keyer to produce captioned video. RGB outputs are provided, along with a luminance and a box signal, allowing simple interface to both color and black and white receivers.

- Conforms to the FCC Report and Order as Amended by the Petition for Reconsideration on Gen. Doc. 91–1
- Supports Four Different Data Channels, Time Multiplexed within the Line 21 Data Stream: Captions Utilizing Languages 1 & 2, Plus Text Utilizing Languages 1 & 2
- Output Logic Provides Hardware Underline Control and Italics Slant Generation
- Single Supply Operating Voltage Range: 4.75 to 5.25 V
- Composite Video Input Range: 0.7 to 1.4 V_{pp}
- Horizontal Sync Input Polarity can be either Positive or Negative
- Internal Timing/Sync Signals Derived from On–Chip VCO



Enhanced Closed–Caption Decoder

MC144144P
Case 707

The MC144144 is a Line 21 closed–caption decoder for use in television receivers or set–top decoders conforming to the NTSC standard. Capability for processing and displaying all of the latest standard Line 21 closed–caption format transmissions is included. The device requires a closed–caption encoded composite video signal, a horizontal sync signal, and an external keyer to produce captioned video. RGB and box signal outputs are provided, which along with the mode select, allow simple interfacing to either color or black–and–white TV receivers.

Display storage is accomplished with an on–chip RAM. A modified ASCII character set, which includes several non–English characters, is decoded by an on–chip ROM. An on–screen character appears as a white or colored dot matrix on a black background.

Captions (video–related information) can be up to four rows appearing anywhere on the screen and can be displayed in two modes: roll–up, paint–on, or pop–on. With rollup captions, the row scrolls up and new information appears at the bottom row each time a carriage return is received. Pop–on captions work with two memories. One memory is displayed while the other is used to accumulate new data. A special command causes the information to be exchanged in the two memories, thus causing the entire caption to appear at once.

When text (non–video related information) is displayed, the rows contain a maximum of 32 characters over a black box which overwrites the screen. Fifteen rows of characters are displayed in the text mode.

An on–chip processor controls the manipulation of data for storage and display. Also controlled are the loading, addressing, and clearing of the display RAM. The processor transfers the data received to the RAM during scan lines 21 through 42. The operation of the display RAM, character ROM, and output logic circuits are controlled during scan lines 43 through 237. The functions of the MC144144 are controlled via a serial port which may be configured to be either I^2C or SPI.

- Conforms to FCC Report and Order as Amended by the Petition for Reconsideration on Gen. Doc. 91–1
- Conforms to EIA–608 for XDS Data Structure
- Supports Four Different Data Channels for Field 1 and Five Different Data Channels for Field 2, Time Multiplexed within the Line 21 Data Stream: Captions Utilizing Languages 1 and 2, Text Utilizing Languages 1 and 2 and XDS Support
- Output Logic Provides Hardware Underline Control and Italics Slant Generation
- Single Supply, Operating Voltage Range: 4.75 to 5.25 V
- Supply Current: 20 mA (Preliminary)
- Operating Temperature Range: 0 to 70°C
- Composite Video Input Range: 0.7 to 1.4 V_{pp}
- Horizontal Input Polarity: Either Positive or Negative
- Internal Timing and Sync Signals Derived from On–Chip VCO

PLL Tuning Circuits with 3–Wire Bus

MC44817BD, D

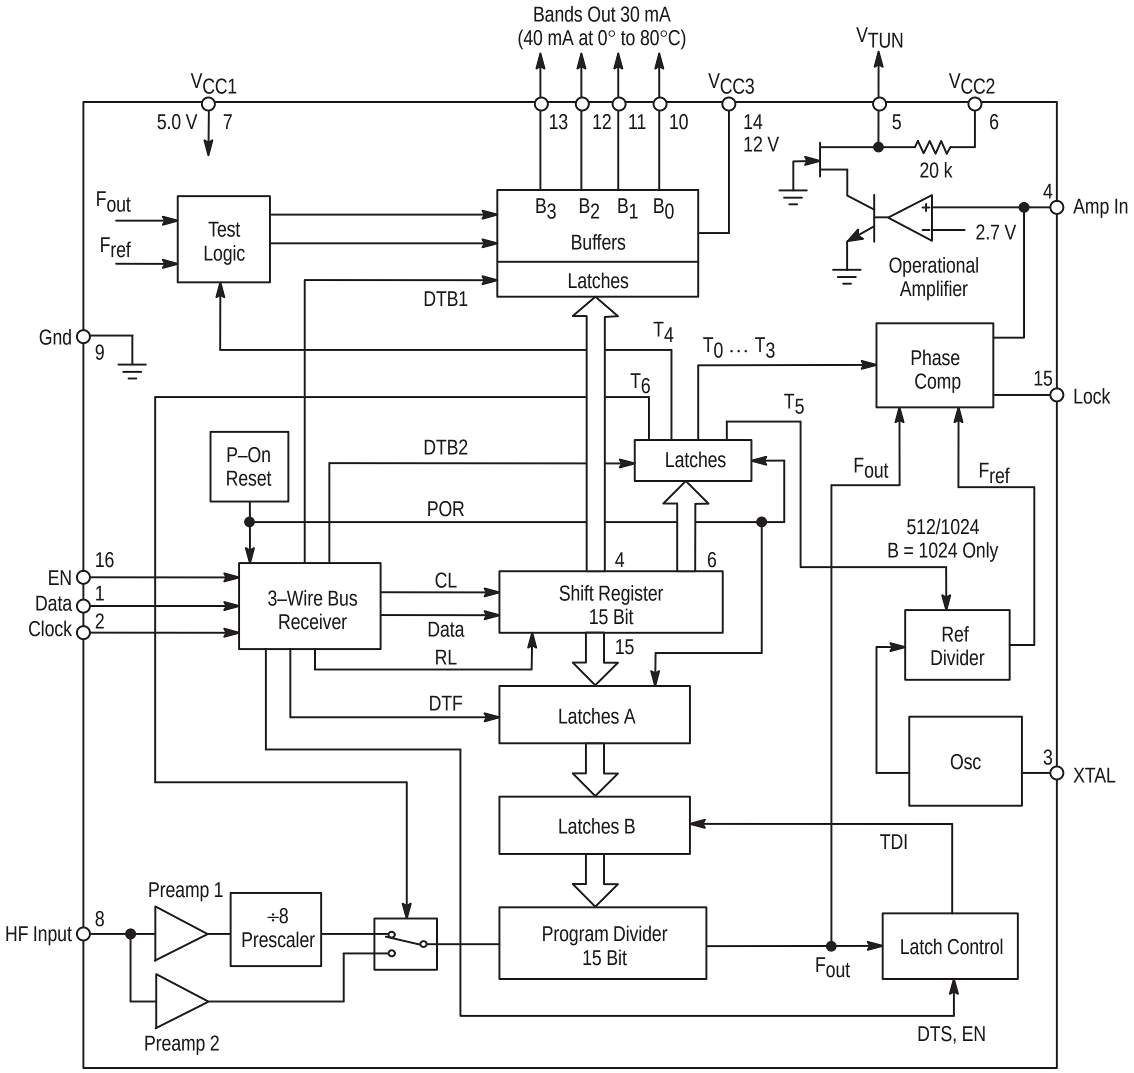
Case 751B

The MC44817/17B are tuning circuits for TV and VCR tuner applications. They contain on one chip all the functions required for PLL control of a VCO. The integrated circuits also contain a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44817 has programmable 512/1024 reference dividers while the MC44817B has a fixed reference divider of 1024.

The MC44817/17B are manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (3–Wire Bus). Data and Clock Inputs are IIC Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Reference Divider: Programmable for Division Ratios 512 and 1024. The MC44817B has a Fixed 1024 Reference Divider
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Integrated PNP Band Buffers for 40 mA (V_{CC1} to 14.4 V)
- Output Options for the Reference Frequency and the Programmable Divider
- Bus Protocol for 18 or 19 Bit Transmission
- Extra Protocol for 34 Bit for Test and Further Features
- High Sensitivity Preamplifier
- Circuit to Detect Phase Lock
- Fully ESD Protected



PLL Tuning Circuit with I^{2}C Bus

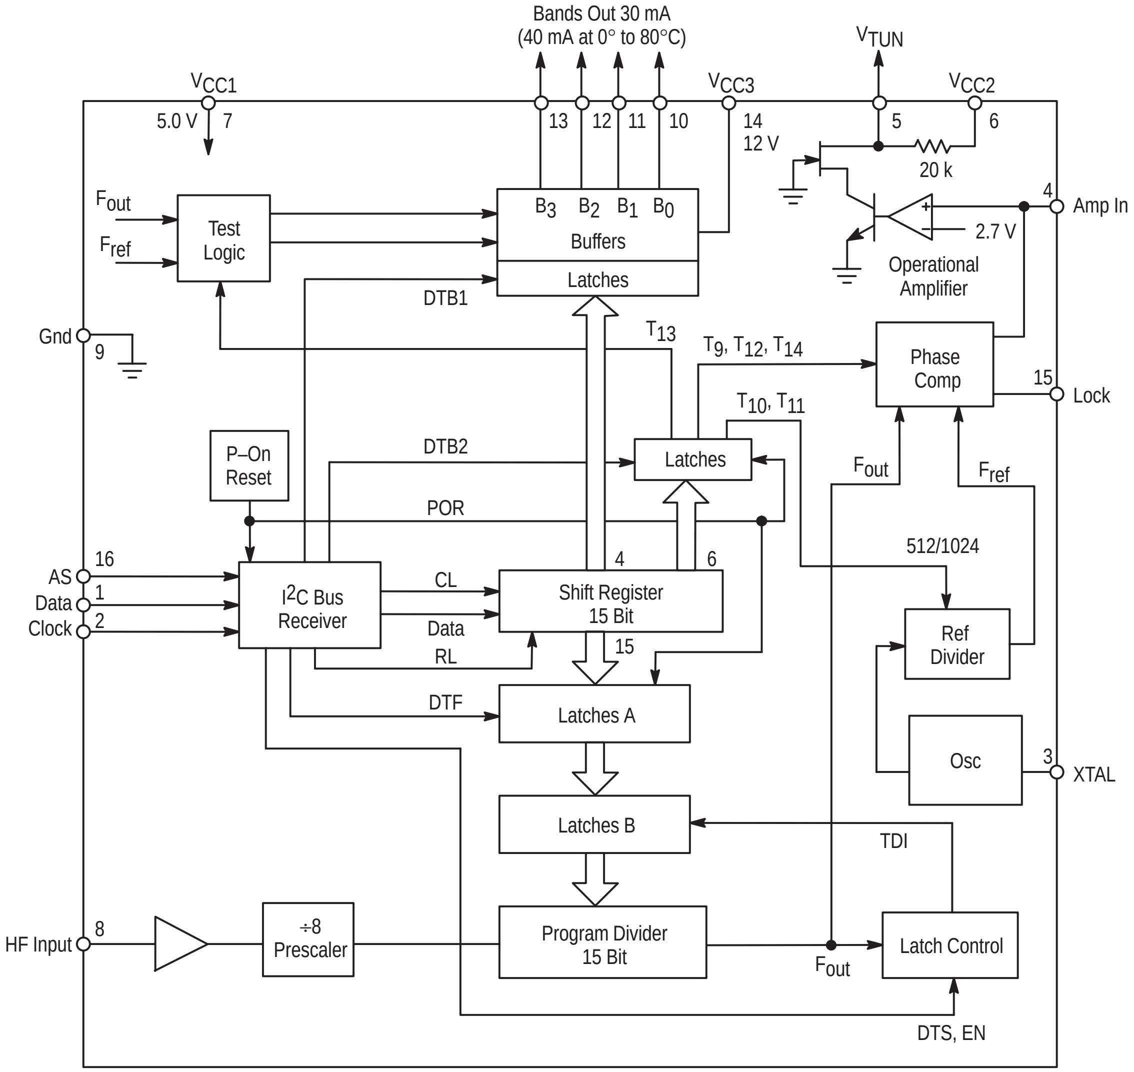
MC44818D

Case 751B

The MC44818 is a tuning circuit for TV and VCR tuner applications. It contains, on one chip, all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz. The MC44818 is a pin compatible drop–in replacement for the MC44817, where the only difference is the MC44818 has a fixed divide–by–8 prescaler (cannot be bypassed) and the MC44817 uses the three wire bus.

The MC44818 has programmable 512/1024 reference dividers and is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus). Data and Clock Inputs are 3–Wire Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Reference Divider: Programmable for Division Ratios 512 and 1024.
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Integrated PNP Band Buffers for 40 mA (V_{CC1} to 14.4 V)
- Output Options for the Reference Frequency and the Programmable Divider
- High Sensitivity Preamplifier
- Circuit to Detect Phase Lock
- Fully ESD Protected



PLL Tuning Circuits with I^{2}C Bus

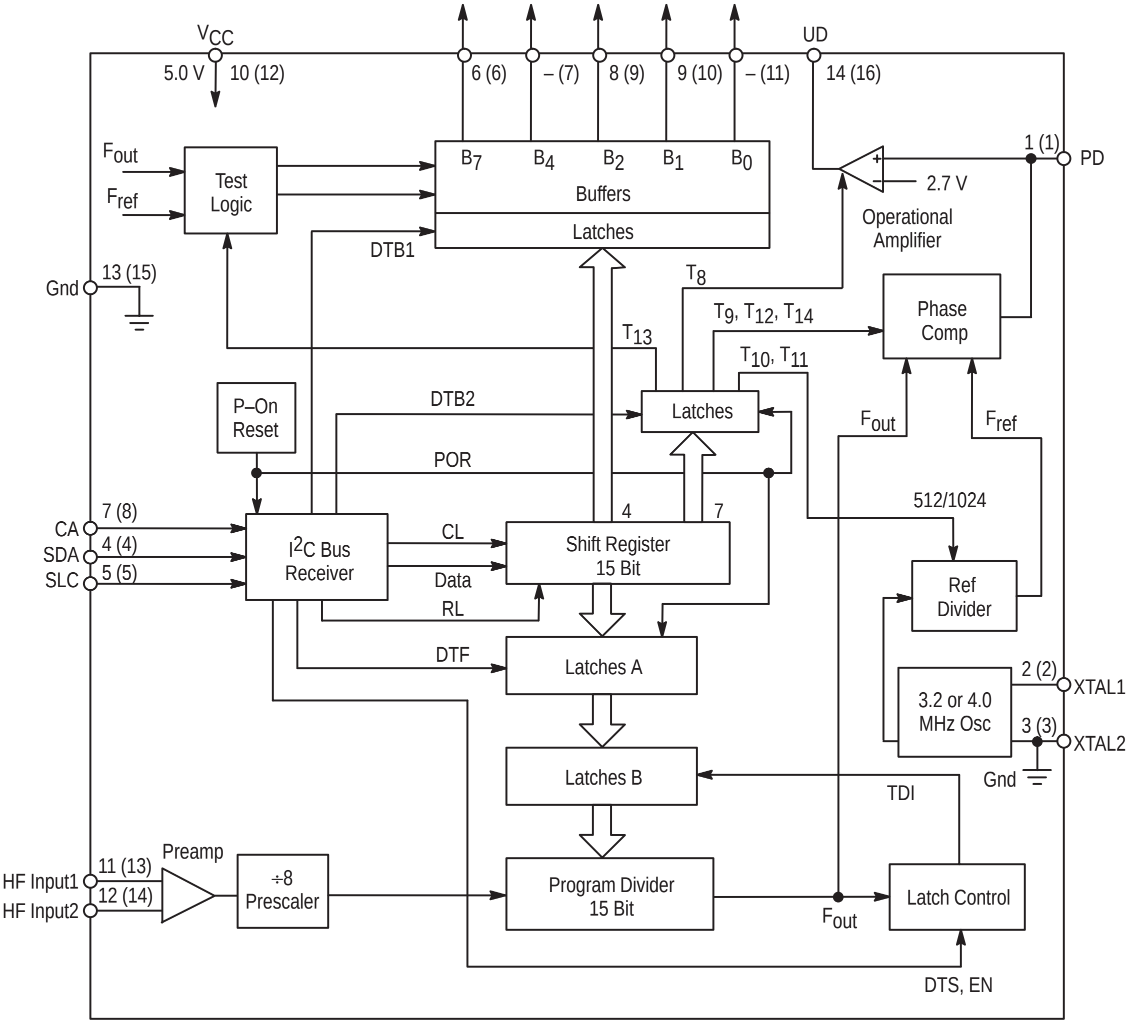
MC44824/25D

Case 751A, 751B

The MC44824/25 are tuning circuits for TV and VCR tuner applications. They contain on one chip all the functions required for PLL control of a VCO. The integrated circuits also contain a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44824/25 are manufactured on a single silicon chip using Motorola’s high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus). Data and Clock Inputs are 3–Wire Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider
- Reference Divider: Programmable for Division Ratios 512 and 1024
- 3–State Phase/Frequency Comparator
- 4 Programmable Chip Addresses
- 3 Output Buffers (MC44824) respectively; 5 Output Buffers (MC44825) for 10 mA/15 V
- Operational Amplifier for use with External NPN Transistor
- SO–14 Package for MC44824 and SO–16 for MC44825
- High Sensitivity Preamplifier
- Fully ESD Protected



MC44825 Pin Numbers ( )

PLL Tuning Circuit with 3–Wire Bus

MC44827DTB

Case 948F

The MC44827 is a tuning circuit for TV and VCR tuner applications. This device contains on one chip all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44827 is controlled by a 3–wire bus. It has the same function as the MC44828 which is I^2C bus controlled. The MC44827 and MC44828 can replace each other to allow conversion between 3–wire bus and I^2C bus control.

The MC44827 is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

The MC44827 has the same features as MC44817 with the following differences:

- Lower Power Consumption, 200 mW Typical
- Improved Prescaler with Higher Margins for Sensitivity and Temperature Range. (A typical device is functional in a temperature range greater than –40 to 100°C.)
- Lock Detector with Push–Pull Output
- No Bypass of Divide–by–8 Prescaler
- TSSOP Package

PLL Tuning Circuit with I^2C Bus

MC44828DTB

Case 948F

The MC44828 is a tuning circuit for TV and VCR tuner applications. This device contains on one chip all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44828 is controlled by an I^2C bus. It has the same function as the MC44827 which is 3–wire bus controlled. The MC44827 and MC44828 can replace each other to allow conversion between 3–wire bus and I^2C bus control.

The MC44828 is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

The MC44828 has the same features as MC44818 with the following differences:

- Lower Power Consumption, 200 mW Typical
- Improved Prescaler with Higher Margins for Sensitivity and Temperature Range. (A typical device is functional in a temperature range greater than –40 to 100°C.)
- Lock Detector with Push–Pull Output
- TSSOP Package

PLL Tuning Circuit with I^2C Bus

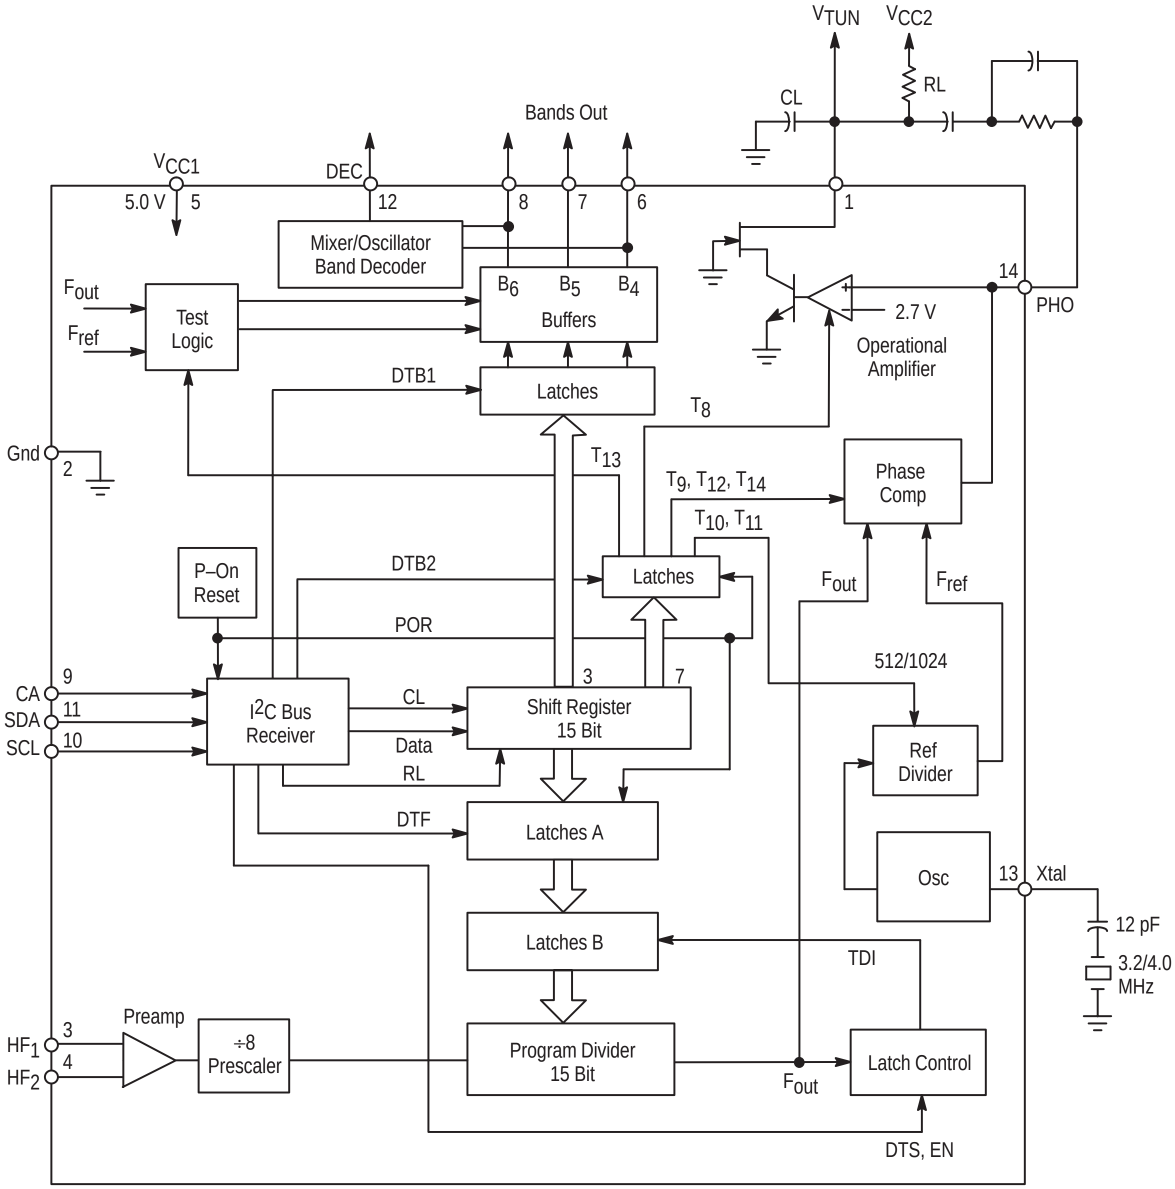
MC44829D

Case 751A

The MC44829 is a tuning circuit for TV and VCR tuner applications. It contains, on one chip, all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz. The circuit has a band decoder that provides the band switching signal for the mixer/oscillator circuit. The decoder is controlled by the buffer bits.

The MC44829 has programmable 512/1024 reference dividers and is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^2C Bus)
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider
- Reference Divider: Programmable for Division Ratios 512 and 1024
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Programmable Chip Addresses
- Integrated Band Decoder for the Mixer/Oscillator Circuit
- Band Buffers with Low "On" Voltage (0.4 V Maximum at 5.0 mA)
- Fully ESD Protected to MIL–STD–883C, Method 3015.7 (2000 V, 1.5 kΩ, 150 pF)



Advanced PAL/NTSC Encoder

MC13077P, DW

Case 738, 751D

The MC13077 is an economical, high quality, RGB encoder for PAL or NTSC applications. It accepts red, green, blue and composite sync inputs and delivers either composite PAL or NTSC video, and S–Video Chroma and Luma outputs. The MC13077 is manufactured using Motorola's high density, bipolar MOSAIC® process.

- Single 5.0 V Supply
- Composite Output
- S–Video Outputs
- PAL/NTSC Switchable
- PAL Squarewave Output
- PAL Sequence Resettable
- Internal/External Burst Flag
- Modulator Angles Accurate to 90°
- Burst Position/Duration Determined Digitally
- Subcarrier Reference from a Crystal or External Source

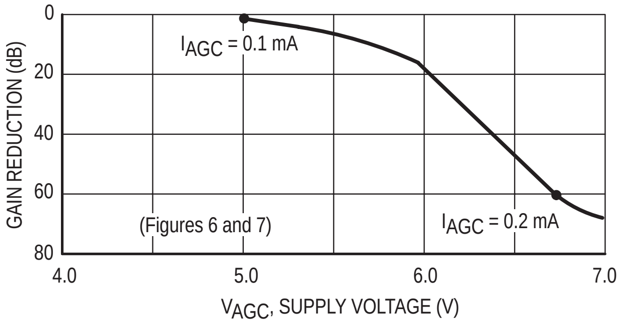

Figure 3. Noise Figure versus Gain Reduction

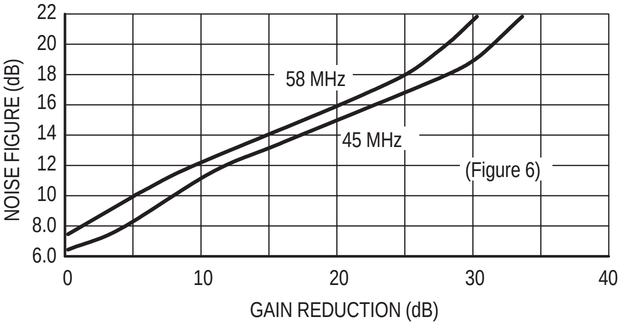

GENERAL OPERATING INFORMATION

The input amplifiers (Q1 and Q2) operate at constant emitter currents so that input impedance remains independent of AGC action. Input signals may be applied single–ended or differentially (for ac) with identical results. Terminals 4 and 6 may be driven from a transformer, but a dc path from either terminal to ground is not permitted.

AGC action occurs as a result of an increasing voltage on the base of Q4 and Q5 causing these transistors to conduct more heavily thereby shunting signal current from the interstage amplifiers Q3 and Q6. The output amplifiers are supplied from an active current source to maintain constant quiescent bias thereby holding output admittance nearly constant. Collector voltage for the output amplifier must be supplied through a center–tapped tuning coil to Pins 1 and 8. The 12 V supply (V^+) at Pin 2 may be used for this purpose, but output admittance remains more nearly constant if a separate 15 V supply (V^{++}) is used, because the base voltage on the output amplifier varies with AGC bias.

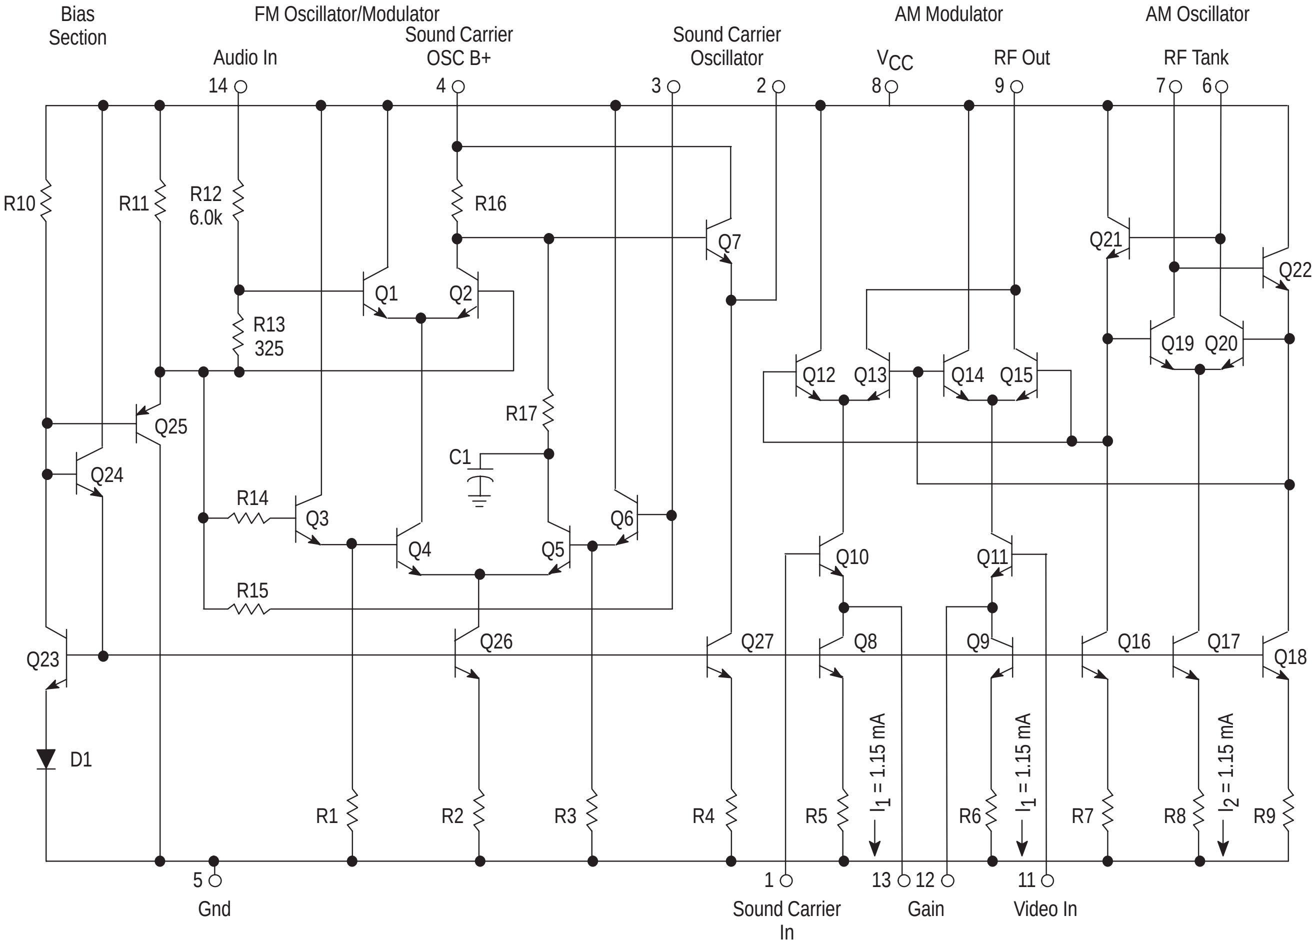
Figure 2. TV Modulator



GENERAL INFORMATION

The MC1374 contains an RF oscillator, RF modulator, and a phase shift type FM modulator, arranged to permit good printed circuit layout of a complete TV modulation system. The RF oscillator is similar to the one used in MC1373, and is coupled internally in the same way. Its frequency is controlled by an external tank on Pins 6 and 7, or by a crystal circuit, and will operate to approximately 105 MHz. The video modulator is a balanced type as used in the well known MC1496. Modulated sound carrier and composite video information can be put in separately on Pins 1 and 11 to minimize unwanted crosstalk. A single resistor on Pins 12 and 13 is selected to set the modulator gain. The RF output at Pin 9 is a current source which drives a load connected from Pin 9 to V_{CC}.

The FM system was designed specifically for the TV intercarrier function. For circuit economy, one phase shift circuit was built into the ship. Still, it will operate from 1.4 MHz to 14 MHz, low enough to be used in a cordless telephone base station (1.76 MHz), and high enough to be used as an FM IF test signal source (10.7 MHz). At 4.5 MHz, a deviation of ±25 kHz can be achieved with 0.6% distortion (typical).

In the circuit above, devices Q1 through Q7 are active in the oscillator function. Differential amplifier Q3, Q4, Q5, and Q6 acts as a gain stage, sinking current from input section Q1, Q2 and the phase shift network R17, C1. Input amplifier Q1, Q2 can vary the amount of “in phase” Q4 current to be combined with phase shifter current in load resistor R16. The R16 voltage is applied to emitter follower Q7 which drives an external L–C circuit. Feedback from the center of the L–C circuit back to the base of Q6 closes the loop. As audio input is applied which would offset the stable oscillatory phase, the frequency changes to counteract. The input to Pin 14 can include a dc feedback current for AFC over a limited range.

The modulated FM signal from Pin 3 is coupled to Pin 1 of the RF modulator and is then modulated onto the AM carrier.

AM Section

The AM modulator transfer function in Figure 3 shows that the video input can be of either polarity (and can be applied at either input). When the voltages on Pin 1 and Pin 11 are equal, the RF output is theoretically zero. As the difference between $V_{Pin\ 11}$ and $V_{Pin\ 1}$ increases, the RF output increases linearly until all of the current from both I_1 current sources (Q8 and Q9) is flowing in one side of the modulator. This occurs when $\pm(V_{Pin11} - V_{Pin1}) = I_1 R_G$, where I_1 is typically 1.15 mA. The peak–to–peak RF output is the $2I_1 R_L$. Usually the value of R_L is chosen to be 75 Ω to ease the design of the output filter and match into TV distribution systems. The theoretical range of input voltage and R_G is quite wide, but noise and available sound level limit the useful video (sync tip) amplitude to between 0.25 Vpk and 1.0 Vpk. It is recommended that the value of R_G be chosen so that only about half of the dynamic range will be used at sync tip level.

The operating window of Figure 5 shows a cross–hatched area where Pin 1 and Pin 11 voltages must always be in order to avoid saturation in any part of the modulator. The letter ϕ represents one diode drop, or about 0.75 V. The oscillator Pins 6 and 7 must be biased to a level of $V_{CC} - \phi - 2I_1 R_L$ (or lower) and the input Pins 1 and 11 must always be at least 2ϕ below that. It is permissible to operate down to 1.6 V, saturating the current sources, but whenever possible, the minimum should be 3ϕ above ground.

The oscillator will operate dependably up to about 105 MHz with a broad range of tank circuit component values. It is desirable to use a small L and a large C to minimize the dependence on IC internal capacitance. An operating Q between 10 and 20 is recommended. The values of R_1, R_2 and R_3 are chosen to produce the desired Q and to set the Pin 6 and 7 dc voltage as discussed above. Unbalanced operation, i.e., Pin 6 or 7 bypassed to ground, is not recommended. Although the oscillator will still run, and the modulator will produce a useable signal, this mode causes substantial base–band video feedthrough. Bandswitching, as Figure 1 shows, can still be accomplished economically without using the unbalanced method.

The oscillator frequency with respect to temperature in the test circuit shows less than ±20 kHz total shift from 0° to 50°C as shown in Figure 7. At higher temperatures the slope approaches 2.0 kHz/°C. Improvement in this region would require a temperature compensating tuning capacitor of the N75 family.

Crystal control is feasible using the circuit shown in Figure 21. The crystal is a 3rd overtone series type, used in series resonance. The L1, C2 resonance is adjusted well below the crystal frequency and is sufficiently tolerant to permit fixed values. A frequency shift versus temperature of less than 1.0 Hz/°C can be expected from this approach. The resistors Ra and Rb are to suppress parasitic resonances.

Coupling of output RF to wiring and components on Pins 1 and 11 can cause as much as 300 kHz shift in carrier (at 67 MHz) over the video input range. A careful layout can keep this shift below 10 kHz. Oscillator may also be inadvertently coupled to the RF output, with the undesired effect of preventing a good null when $V_{11} = V_1$. Reasonable care will yield carrier rejection ratios of 36 to 40 dB below sync tip level carrier.

In television, one of the most serious concerns is the prevention of the intermodulation of color (3.58 MHz) and sound (4.5 MHz) frequencies, which causes a 920 kHz signal to appear in the spectrum. Very little (3rd order) nonlinearity is needed to cause this problem. The results in Figure 6 are unsatisfactory, and demonstrate that too much of the available dynamic range of the MC1374 has been used. Figures 8 and 10 show that by either reducing standard signal level, or reducing gain, acceptable results may be obtained.

At VHF frequencies, small imbalances within the device introduce substantial amounts of 2nd harmonic in the RF output. At 67 MHz, the 2nd harmonic is only 6 to 8 dB below the maximum fundamental. For this reason, a double pi low pass filter is shown in the test circuit of Figure 3 and works well for Channel 3 and 4 lab work. For a fully commercial application, a vestigial sideband filter will be required. The general form and approximate values are shown in Figure 19. It must be exactly aligned to the particular channel.

FM Section

The oscillator center is approximately the resonance of the inductor L_2 from Pin 2 to Pin 3 and the effective capacitance C_3 from Pin 3 to ground. For overall oscillator stability, it is best to keep X_L in the range of 300 Ω to 1.0 kΩ.

The modulator transfer characteristic at 4.5 MHz is shown in Figure 15. Transfer curves at other frequencies have a very similar shape, but differ in deviation per input volt, as shown in Figures 13 and 17.

Most applications will not require DC connection to the audio input, Pin 14. However, some improvements can be achieved by the addition of biasing circuitry. The unaided device will establish its own Pin 14 bias at 4 θ, or about 3.0 V. This bias is a little too high for optimum modulation linearity. Figure 14 shows better than 2 to 1 improvement in distortion between the unaided device and pulling Pin 14 down to 2.6 V to 2.7 V. This can be accomplished by a simple divider, if the supply voltage is relatively constant.

The impedance of the divider has a bearing on the frequency versus temperature stability of the FM system. A divider of 180 kΩ and 30 kΩ (for V_{CC} = 12 V) will give good temperature stabilization results. However, as Figure 18 shows, a divider is not a good method if the supply voltage varies. The designer must make the decisions here, based on considerations of economy, distortion and temperature requirements and power supply capability. If the distortion requirements are not stringent, then no bias components are needed. If, in this case, the temperature compensation needs to be improved in the high ambient area, the tuning capacitor from Pin 3 to ground can be selected from N75 or N150 temperature compensation types.

Another reason for DC input to Pin 14 is the possibility of automatic frequency control. Where high accuracy of inter–carrier frequency is required, it may be desirable to feed back the DC output of an AFC or phase detector for nominal carrier frequency control. Only limited control range could be used without adversely affecting the distortion performance, but very little frequency compensation will be needed.

One added convenience in the FM section is the separate Pin "oscillator B+" which permits disabling of the sound system during alignment of the AM section. Usually it can be hard wired to the V_{CC} source without decoupling.

Standard practice in television is to provide pre–emphasis of higher audio frequencies at the transmitter and a matching de–emphasis in the TV receiver audio amplifier. The purpose of this is to counteract the fact that less energy is usually present in the higher frequencies, and also that fewer modulation sidebands are within the deviation window. Both factors degrade signal to noise ration. Pre–emphasis of 75 µs is standard practice. For cases where it has not been provided, a suitable pre–emphasis network is covered in Figure 20.

It would seem natural to take the FM system output from Pin 2, the emitter follower output, but this output is high in harmonic content. Taking the output from Pin 3 sacrifices somewhat in source impedance but results in a clean output fundamental, with all harmonics more than 40 dB down. This choice removes the need for additional filtering components. The source impedance of Pin 3 is approximately 2.0 kΩ, and the open circuit amplitude is about 900 mV pp for the test circuit shown in Figure 11.

The application circuit of Figure 1 shows the recommended approach to coupling the FM output from Pin 3 to the AM modulator input, Pin 1. The input impedance at Pin 1 is very high, so the intercarrier level is determined by the source impedance of Pin 3 driving through C4 into the video bias circuit impedance of R4 and R5, about 2.2 k. This provides an intercarrier level of 500 mV pp, which is correct for the 1.0 V peak video level chosen in this design. Resistor R6 and the input capacitance of Pin 1 provide some decoupling of stray pickup of RF oscillator or AM output which may be coupled to the sound circuitry.

2. Subcarrier leakage can be reduced to less than 10 mV with optional circuitry (see Figure 12).

PIN FUNCTION DESCRIPTIONS

Symbol	Pin	Description
t_r	1	External components at this pin set the rise time of the internal ramp function generator (see Figure 10).
Sync	2	Composite sync input. Presents 10 kΩ resistance to input.
R	3	Red signal input. Presents 10 kΩ impedance to input. 1.0 V_{pp} required for 100% saturation.
G	4	Green signal input. Presents 10 kΩ impedance to input. 1.0 V_{pp} required for 100% saturation.
B	5	Blue signal Input. Presents 10 kΩ impedance to input. 1.0 V_{pp} required for 100% saturation.
$–Y_{out}$	6	Luma (–Y) output. Allows external setting of luma delay time.
V_{clamp}	7	Video Clamp pin. Typical connection is a 0.01 μF capacitor to ground.
$–Y_{in}$	8	Luma (–Y) input. Presents 10 kΩ input impedance.
CV_{out}	9	Composite Video output. 50 Ω output impedance.
$Chroma_{In}$	10	Chroma input. Presents 10 kΩ input impedance.
$B–Y_{clamp}$	11	B–Y clamp. Clamps B–Y during blanking with a 0.1 μF capacitor to ground. Also used with R–Y clamp to null residual color subcarrier in output.
$R–Y_{clamp}$	12	R–Y clamp. Clamps R–Y during blanking with a 0.1 μF capacitor to ground. Also used with B–Y clamp to null residual color subcarrier in output.
$Chroma_{Out}$	13	Chroma output. 50 Ω output impedance.
V_{CC}	14	Power supply pin for the IC; +12, ± 2.0 V, required at 35 mA (typical).
Gnd	15	Ground pin.
V_B	16	8.2 V reference from an internal regulator capable of delivering 10 mA to external circuitry.
Osc_{in}	17	Oscillator input. A transistor base presents 5.0 kΩ to an external subcarrier input, or is available for constructing a Colpitts oscillator (see Figure 4).
Osc_{out}	18	Oscillator output. The emitter of the transistor, with base access at Pin 17, is accessible for completing the Colpitts oscillator. See Figure 4.
$\varnothing_m$	19	Quad decoupler. With external circuitry, R–Y to B–Y relative angle errors can be corrected. Typically, requires a 0.01 μF capacitor to ground.
NTSC/PAL Select	20	NTSC/PAL switch. When grounded, the MC1377 is in the NTSC mode; if unconnected, in the PAL mode.

FUNCTIONAL DESCRIPTION

Figure 2. Power Supply and V_B

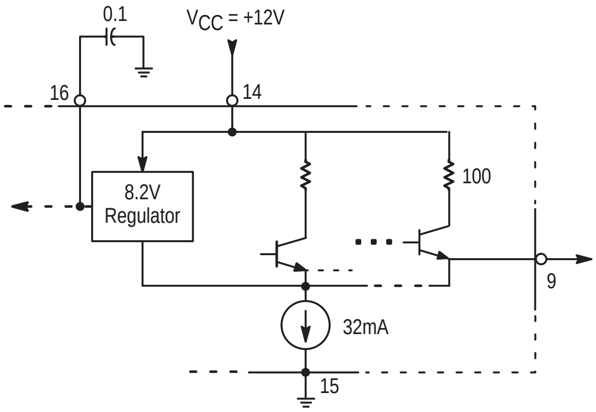

Figure 3. RGB Input Circuitry

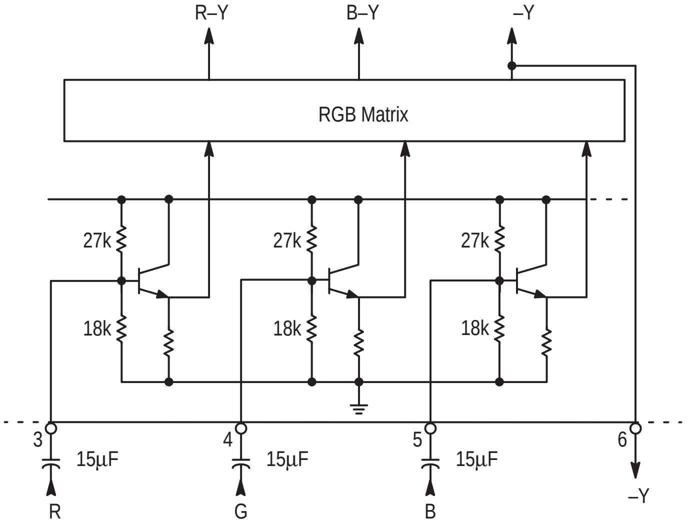

Figure 4. Chroma Section

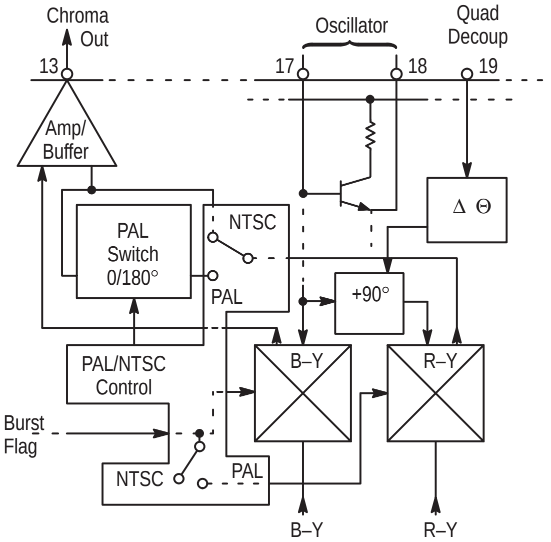

Power Supply and V_B (8.2 V Regulator)

The MC1377 pin for power supply connection is Pin 14. From the supply voltage applied to this pin, the IC biases internal output stages and is used to power the 8.2 V internal regulator (V_B at Pin 16) which biases the majority of internal circuitry. The regulator will provide a nominal 8.2 V and is capable of 10 mA before degradation of performance. An equivalent circuit of the supply and regulator is shown in Figure 2.

R, G, B Inputs

The RGB inputs are internally biased to 3.3 V and provide 10 kΩ of input impedance. Figure 3 shows representative input circuitry at Pins 3, 4, and 5.

The input coupling capacitors of 15 µF are used to prevent tilt during the 50/60 Hz vertical period. However, if it is desired to avoid the use of the capacitors, then inputs to Pins 3, 4, and 5 can be dc coupled provided that the signal levels are always between 2.2 V and 4.4 V.

After input, the separate RGB information is introduced to the matrix circuitry which outputs the R–Y, B–Y, and –Y signals. The –Y information is routed out at Pin 6 to an external delay line (typically 400 ns).

DSBSC Modulators and 3.58 MHz Oscillator

The R–Y and B–Y outputs (see (B–Y)/(R–Y) Axes versus I/Q Axes, Figure 22) from the matrix circuitry are amplitude modulated onto the 3.58/4.43 MHz subcarrier. These signals are added and color burst is included to produce composite chroma available at Pin 13. These functions plus others, depending on whether NTSC or PAL operation is chosen, are performed in the chroma section. Figure 4 shows a block diagram of the chroma section.

The MC1377 has two double balanced mixers, and regardless of which mode is chosen (NTSC or PAL), the mixers always perform the same operation. The B–Y mixer modulates the color subcarrier directly, the R–Y mixer receives a 90° phase shifted color subcarrier before being modulated by the R–Y baseband information. Additional operations are then performed on these two signals to make them NTSC or PAL compatible.

In the NTSC mode, the NTSC/PAL control circuitry allows an inverted burst of 3.58 MHz to be added only to the B–Y signal. A gating pulse or “burst flag” from the timing section permits color burst to be added to the B–Y signal. This color burst is 180° from the B–Y signal and 90° away from the R–Y signal (see Figure 22) and permits decoding of the color information. These signals are then added and amplified before being output, at Pin 13, to be bandpassed and then reintroduced to the IC at Pin 10.

In the PAL mode, NTSC/PAL control circuitry allows an inverted 4.43 MHz burst to be added to both R–Y and B–Y equally to produce the characteristic PAL 225°/135 burst phase. Also, the R–Y information is switched alternately from 180° to 0° of its original position and added to the B–Y information to be amplified and output.

Timing Circuitry

The composite sync input at Pin 2 performs three important functions: it provides the timing (but not the amplitude) for the sync in the final output; it drives the black level clamps in the modulators and output amplifier; and it triggers the ramp generator at Pin 1, which produces burst envelope and PAL switching. A representative block diagram of the timing circuitry is shown in Figure 5.

In order to produce a color burst, a burst envelope must be generated which “gates” a color subcarrier into the R–Y and B–Y modulators. This is done with the ramp generator at Pin 1.

The ramp generator at Pin 1 is an R–C type in which the pin is held low until the arrival of the *leading* edge of sync. The rising ramp function, with time constant R–C, passes through two level sensors – the first one starts the gating pulse and the second stops it (see Figure 10). Since the “early” part of the exponential is used, the timing provided is relatively accurate from chip–to–chip and assembly–to–assembly. Fixed components are usually adequate. The ramp continues to rise for more than half of the line interval, thereby inhibiting burst generation on “half interval” pulses on vertical front and back porches. The ramp method will produce burst on the vertical front and back “porches” at full line intervals.

R–Y, B–Y Clamps and Output Clamp/Amplifier

The sync signal, shown in the block diagram of Figure 6, drives the R–Y and B–Y clamps which clamp the R–Y and B–Y signals to reference black during the blanking periods. The output amplifier/clamp provides this same function plus combines and amplifies the chroma and luma components for composite video output.

Application Circuit

Figure 7 illustrates the block diagram of the MC1377 and the external circuitry required for typical operation.

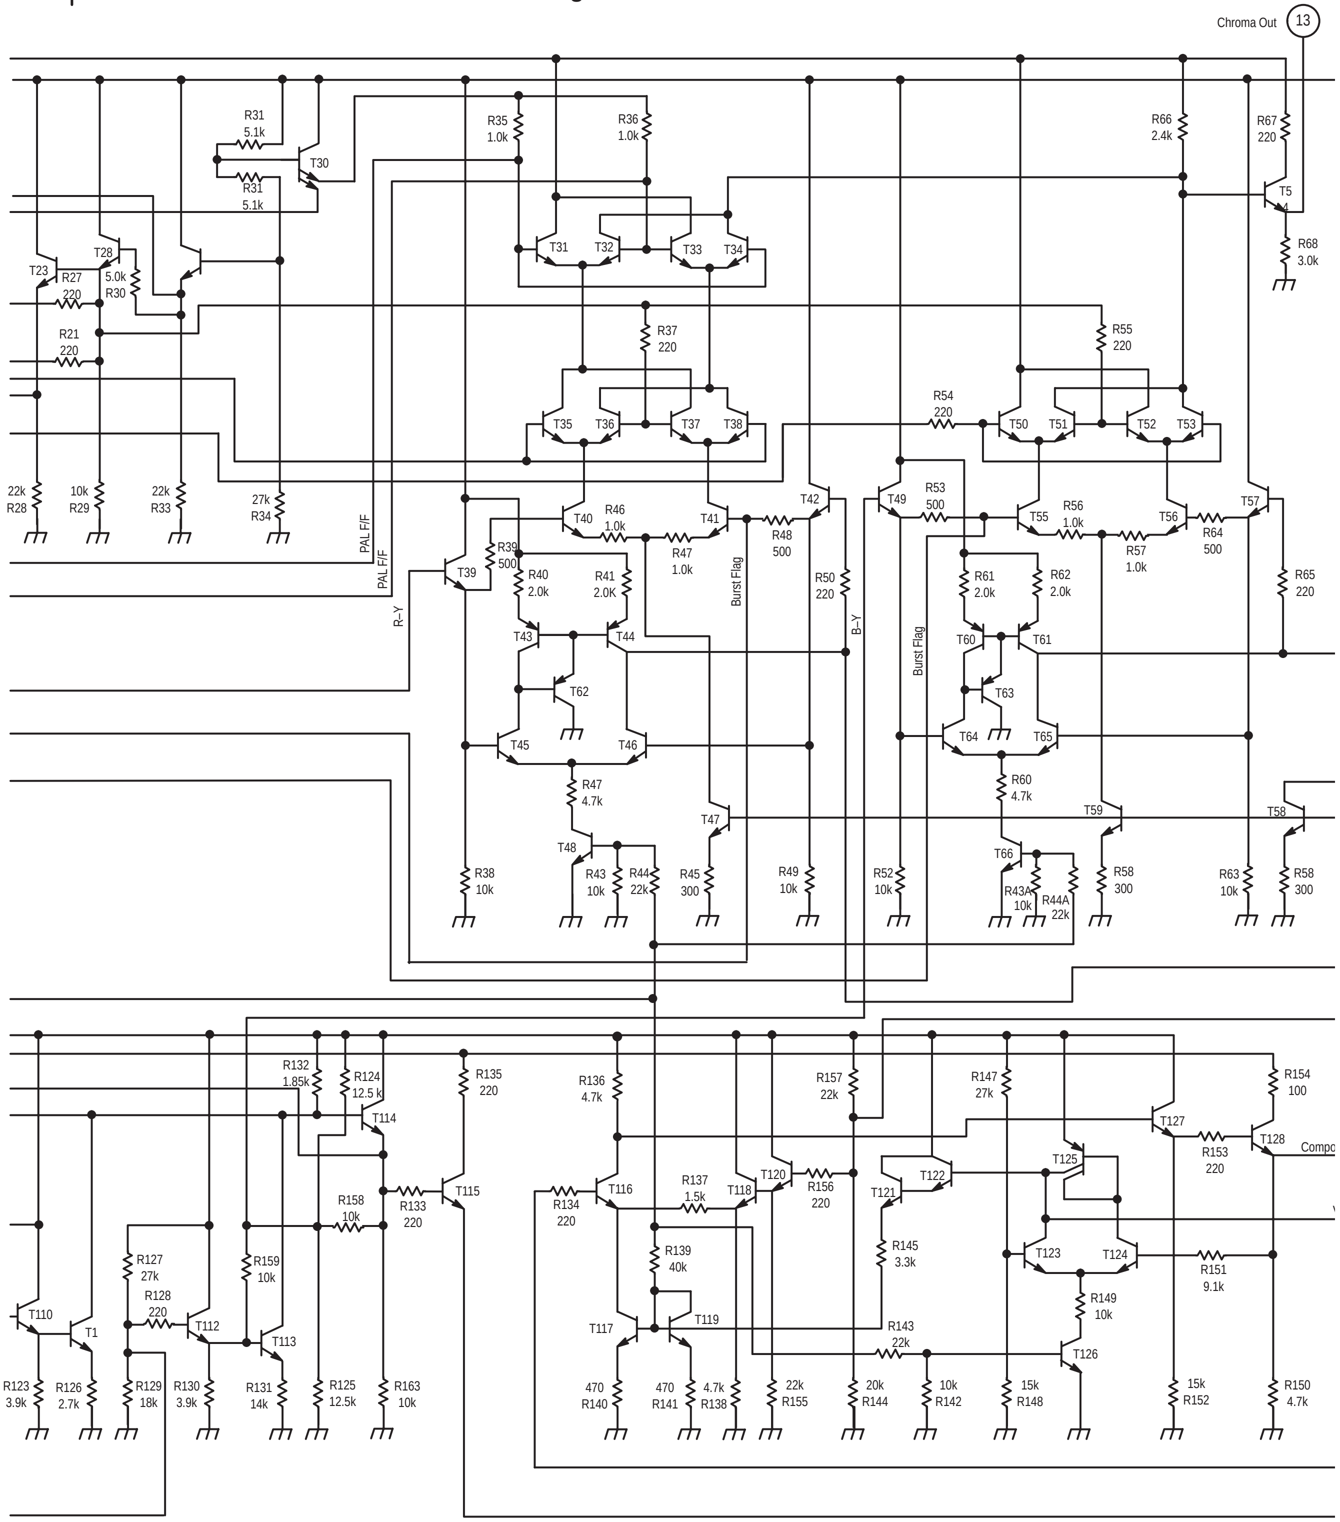
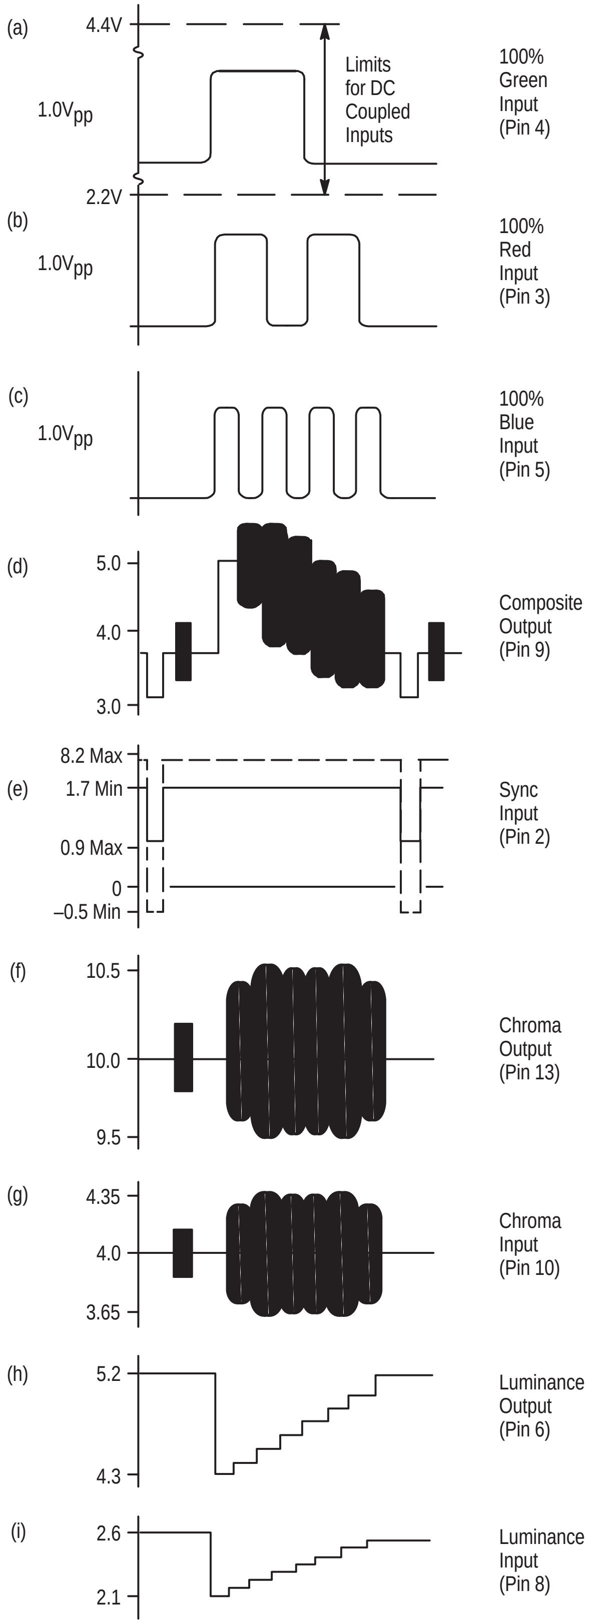
Figure 8. Internal Schematic



APPLICATION INFORMATION

Figure 8. Signal Voltages (Circuit Values of Figure 7)



R, G, B Input Levels

The signal levels into Pins 3, 4, 5 should be 1.0 V_{pp} for fully saturated, standard composite video output levels as shown in Figure 9(d). The inputs require 1.0 V_{pp} since the internally generated sync pulse and color burst are at fixed and predetermined amplitudes.

Further, it is essential that the portion of each input which occurs during the sync interval represent black for that input since that level will be clamped to reference black in the color modulators and output stage. This implies that a refinement, such as a difference between black and blanking levels, must be incorporated in the RGB input signals.

If Y, R–Y, B–Y and burst flag components are available and the MC1377 is operating in NTSC, inputs may be as follows: the Y component can be coupled through a 15 pF capacitor to Pins 3, 4 and 5 tied together; the (–[R–Y]) component can be coupled to Pin 12 through a 0.1 µF capacitor, and the (–[B–Y]) and burst flag components can be coupled to Pin 11 in a similar manner.

Sync Input

As shown in Figure 9(e), the sync input amplitude can be varied over a wide latitude, but will require bias pull–up from most sync sources. The important requirements are:

1) The voltage level between sync pulses must be between 1.7 V and 8.2 V, see Figure 9(e).
2) The voltage level for the sync tips must be between +0.9 V and – 0.5 V, to prevent substrate leakage in the IC, see Figure 9(e).
3) The width of the sync pulse should be no longer than 5.2 µs and no shorter than 2.5 µs.

For PAL operation, correctly serrated vertical sync is necessary to properly trigger the PAL divider. In NTSC mode, simplified “block” vertical sync can be used but the loss of proper horizontal timing may cause “top hook” or “flag waving” in some monitors. An interesting note is that composite video can be used directly as a sync signal, provided that it meets the sync input criteria.

Latching Ramp (Burst Flag) Generator

The recommended application is to connect a close tolerance (5%) 0.001 µF capacitor from Pin 1 to ground and a resistor of 51 kΩ or 56 kΩ from Pin 1 to V_B (Pin 16). This will produce a burst pulse of 2.5 µs to 3.5 µs in duration, as shown in Figure 10. As the ramp on Pin 1 rises toward the charging voltage of 8.2 V, it passes first through a burst “start threshold” at 1.0 V, then a “stop threshold” at 1.3 V, and finally a ramp reset threshold at 5.0 V. If the resistor is reduced to 43 kΩ, the ramp will rise more quickly, producing a narrower and earlier burst pulse (starting approx. 0.4 µs after sync and about 0.6 µs wide). The burst will be wider and later if the resistor is raised to 62 kΩ, but more importantly, the 5.0 V reset point may not be reached in one full line interval, resulting in loss of alternate burst pulses.

As mentioned earlier, the ramp method does produce burst at full line intervals on the “vertical porches.” If this is not desired, and the MC1377 is operating in the NTSC mode, burst flag may be applied to Pin 1 provided that the tip of the pulse is between 1.0 Vdc and 1.3 Vdc. In PAL mode this method is not suitable, since the ramp isn't available to drive the PAL flip–flop. Another means of inhibiting the burst pulse is to set Pin 1 either above 1.3 Vdc or below 1.0 Vdc for the duration that burst is not desired.

Color Reference Oscillator/Buffer

As stated earlier in the general description, there is an on–board common collector Colpitts color reference oscillator with the transistor base at Pin 17 and the emitter at Pin 18. When used with a common low–cost TV crystal and capacitive divider, about 0.6 V_{pp} will be developed at Pin 17. The frequency adjustment can be done with a series 30 pF trimmer capacitor over a total range of about 1.0 kHz. Oscillator frequency should be adjusted for each unit, keeping in mind that most monitors and receivers can pull in 1200 Hz.

If an external color reference is to be used exclusively, it must be continuous. The components on Pins 17 and 18 can be removed, and the external source capacitively coupled into Pin 17. The input at Pin 17 should be a sine wave with amplitude between 0.5 V_{pp} and 1.0 V_{pp}.

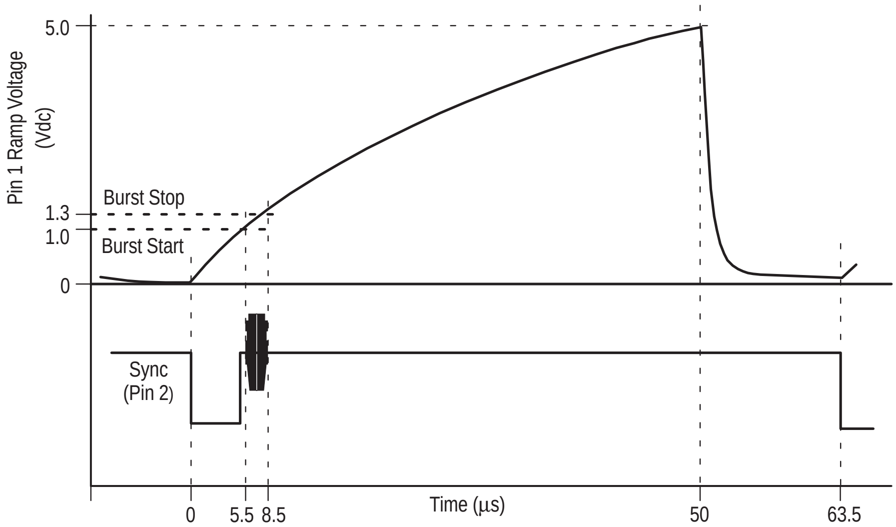
Also, it is possible to do both; i.e., let the oscillator "free run" on its own crystal and override with an external source. An extra coupling capacitor of 50 pF from the external source to Pin 17 was adequate with the experimentation attempted.

Voltage Controlled 90°

The oscillator drives the (B–Y) modulator and a voltage controlled phase shifter which produces an oscillator phase of 90° ± 5° at the (R–Y) modulator. In most situations, the result of an error of 5° is very subtle to all but the most expert eye. However, if it is necessary to adjust the angle to better accuracy, the circuit shown in Figure 11 can be used.

Pulling Pin 19 up will increase the (R–Y) to (B–Y) angle by about 0.25°/µA. Pulling Pin 19 down reduces the angle by the same sensitivity. The nominal Pin 19 voltage is about 6.3 V, so even though it is unregulated, the 12 V supply is best for good control. For effective adjustment, the simplest approach is to apply RGB color bar inputs and use a vectorscope. A simple bar generator giving R, G, and B outputs is shown in Figure 26.

Figure 9. Ramp/Burst Gate Generator



Residual Feedthrough Components

As shown in Figure 9(d), the composite output at Pin 9 for fully saturated color bars is about 2.6 V_{pp}, output with full chroma on the largest bars (cyan and red) being 1.7 V_{pp}. The typical device, due to imperfections in gain, matrixing, and modulator balance, will exhibit about 20 mV_{pp} residual color subcarrier in both white and black. Both residuals can be reduced to less than 10 mV_{pp} for the more exacting applications.

The subcarrier feedthrough in black is due primarily to imbalance in the modulators and can be nulled by sinking or sourcing small currents into clamp Pins 11 and 12 as shown in Figure 12. The nominal voltage on these pins is about 4.0 Vdc, so the 8.2 V regulator is capable of supplying a pull up source. Pulling Pin 11 down is in the 0° direction, pulling it up is towards 180°. Pulling Pin 12 down is in the 90° direction, pulling it up is towards 270°. Any direction of correction may be required from part to part.

White carrier imbalance at the output can only be corrected by juggling the relative levels of R, G, and B inputs for perfect balance. Standard devices are tested to be within 5% of balance at full saturation. Black balance should be adjusted first, because it affects all levels of gray scale equally. There is also usually some residual baseband video at the chroma output (Pin 13), which is most easily observed by disabling the color oscillator. Typical devices show 0.4 V_{pp} of residual luminance for saturated color bar inputs. This is not a major problem since Pin 13 is always coupled to Pin 10 through a bandpass or a high pass filter, but it serves as a warning to pay proper attention to the coupling network.

Figure 10. Adjusting Modulator Angle

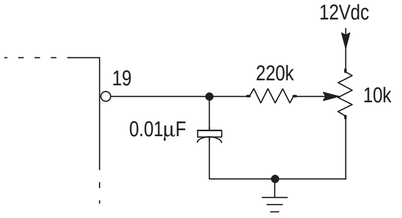


Figure 11. Nulling Residual Color in Black

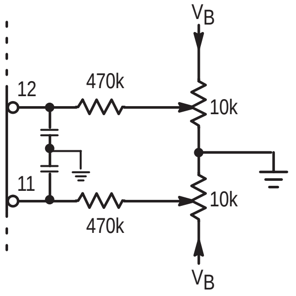

Figure 12. Delay of Chroma Information

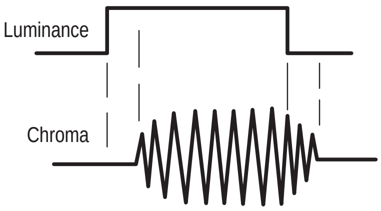


The Chroma Coupling Circuits

With the exception of S–VHS equipped monitors and receivers, it is generally true that most monitors and receivers have color IF 6.0 dB bandwidths limited to approximately ±0.5 MHz. It is therefore recommended that the encoder circuit should also limit the chroma bandwidth to approximately ±0.5 MHz through insertion of a bandpass circuit between Pin 13 and Pin 10. However, if S–VHS operation is desired, a coupling circuit which outputs the composite chroma directly for connection to a S–VHS terminal is given in the S–VHS application (see Figure 19).

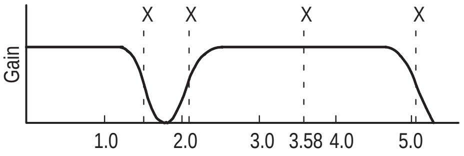
For proper color level in the video output, a ±0.5 MHz bandwidth and a midband insertion loss of 3.0 dB is desired. The bandpass circuit shown in Figure 7, using the TOKO fixed tuned transformer, couples Pin 10 to Pin 13 and gives this result. However, this circuit introduces about 350 ns of delay to the chroma information (see Figure 13). This must be accounted for in the luminance path.

A 350 ns delay results in a visible displacement of the color and black and white information on the final display. The solution is to place a delay line in the luminance path from Pins 6 to 8, to realign the two components. A normal TV receiver delay line can be used. These delay lines are usually of 1.0 kΩ to 1.5 kΩ characteristic impedance, and the resistors at Pins 6 and 8 should be selected accordingly. A very compact, lumped constant delay line is available from TDK (see Figure 25 for specifications). Some types of delay lines have very low impedances (approx. 100 Ω) and should not be used, due to drive and power dissipation requirements.

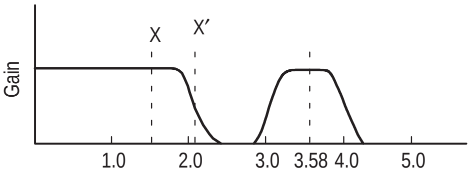
In the event of very low resolution RGB, the transformer and the delay line may be omitted from the circuit. Very low resolution for the MC1377 can be considered RGB information of less than 1.5 MHz. However, in this situation, a bandwidth reduction scheme is still recommended due to the response of most receivers.

Figure 14(a) shows the output of the MC1377 with low resolution RGB inputs. If no bandwidth reduction is employed then a monitor or receiver with frequency response shown in Figure 14(b), which is fairly typical of non–comb filtered monitors and receivers, will detect an incorrect luma sideband at X′. This will result in cross–talk in the form of chroma information in the luma channel. To avoid this situation, a simpler bandpass circuit as shown in Figure 15(a), can be used.

Figure 13. MC1377 Output with Low Resolution RGB Inputs



(a) Encoder Output with Low Resolution Inputs and No Bandpass Transformer



(b) Standard Receiver Response

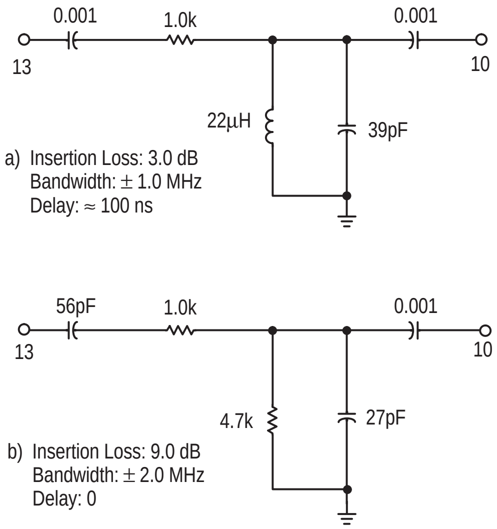
A final option is shown in Figure 15(b). This circuit provides very little bandwidth reduction, but enough to remove the chroma to luma feedthrough, with essentially no delay. There is, however, about a 9 dB insertion loss from this network.

It will be left to the designer to decide which, if any, compromises are acceptable. Color bars viewed on a good monitor can be used to judge acceptability of step luminance/chrominance alignment and step edge transients, but signals containing the finest detail to be encountered in the system must also be examined before settling on a compromise.

The Output Stage

The output amplifier normally produces about 2.0 V_{pp} and is intended to be loaded with 150 Ω as shown in Figure 16. This provides about 1.0 V_{pp} into 75 Ω, an industry standard level (RS–343). In some cases, the input to the monitor may be through a large coupling capacitor. If so, it is necessary to connect a 150 Ω resistor from Pin 9 to ground to provide a low impedance path to discharge the capacitor. The nominal average voltage at Pin 9 is over 4.0 V. The 150 Ω dc load causes the current supply to rise another 30 mA (to approximately 60 mA total into Pin 14). Under this (normal) condition the total device dissipation is about 600 mW. The calculated worst case die temperature rise is 60°C, but the typical device in a test socket is only slightly warm to the touch at room temperature. The solid copper 20–pin lead frame in a printed circuit board will be even more effectively cooled.

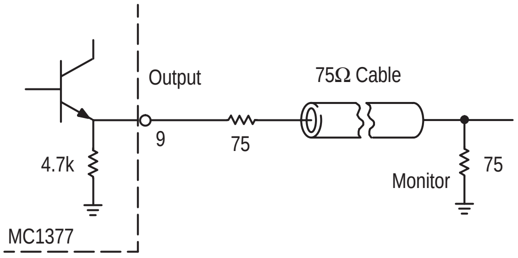
Figure 14. Optional Chroma Coupling Circuits



Power Supplies

The MC1377 is designed to operate from an unregulated 10 V to 14 Vdc power supply. Device current into Pin 14 with open output is typically 35 mA. To provide a stable reference for the ramp generator and the video output, a high quality 8.2 V regulator can supply up to 10 mA for external uses, with an effective source impedance of less than 1.0 Ω. This regulator is convenient for a tracking dc reference for dc coupling the output to an RF modulator. Typical turn–on drift for the regulator is approximately –30 mV over 1 to 2 minutes in otherwise stable ambient conditions.

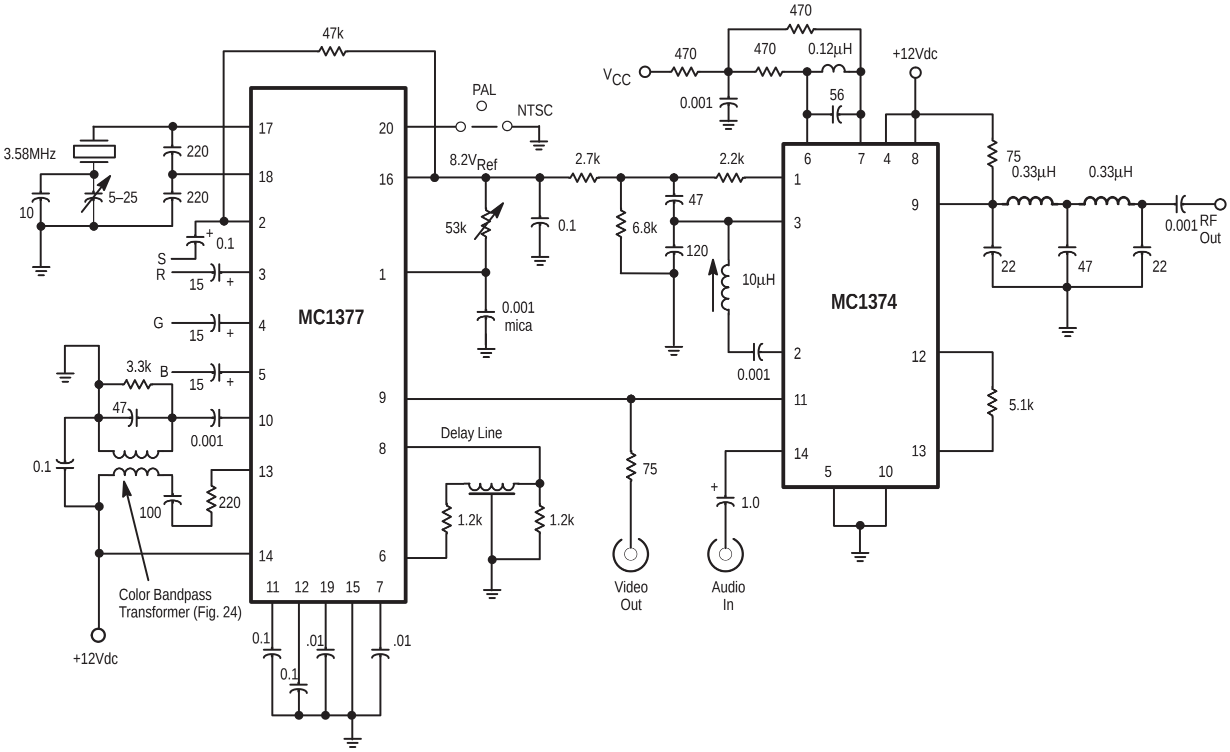
Figure 15. Output Termination



SUMMARY

The preceding information was intended to detail the application and basis of circuit choices for the MC1377. A complete MC1377 application with the MC1374 VHF modulator is illustrated in Figure 17. The internal schematic diagram of the MC1377 is provided in Figure 8.

Figure 16. Application with VHF Modulator



APPLICATIONS INFORMATION

S–VHS

In full RGB systems (Figure 18), three information channels are provided from the signal source to the display to permit unimpaired image resolution. The detail reproduction of the system is limited only by the signal bandwidth and the capability of the color display device. Also, higher than normal sweep rates may be employed to add more lines within a vertical period and three separate projection picture tubes can be used to eliminate the “shadow mask” limitations of a conventional color CRT.

Figure 21 shows the “baseband” components of a studio NTSC signal. As in the previous example, energy is concentrated at multiples of the horizontal sweep frequency. The system is further refined by precisely locating the color subcarrier midway between luminance spectral components. This places all color spectra between luminance spectra and can be accomplished in the MC1377 only if “full interlaced” external color reference and sync are applied. The individual components of luminance and color can then be separated by the use of a comb filter in the monitor or receiver. This technique has not been widely used in consumer products, due to cost, but it is rapidly becoming less expensive and more common. Another technique which is gaining popularity is S–VHS (Super VHS).

In S–VHS, the chroma and luma information are contained on separate channels. This allows the bandwidth of both the chroma and luma channels to be as wide as the monitors ability to reproduce the extra high frequency information. An output coupling circuit for the composite chroma using the TOKO transformer is shown in Figure 19. It is composed of the bandpass transformer and an output buffer and has the frequency performance shown in Figure 20. The composite output (Pin 9) then produces the luma information as well as composite sync and blanking.

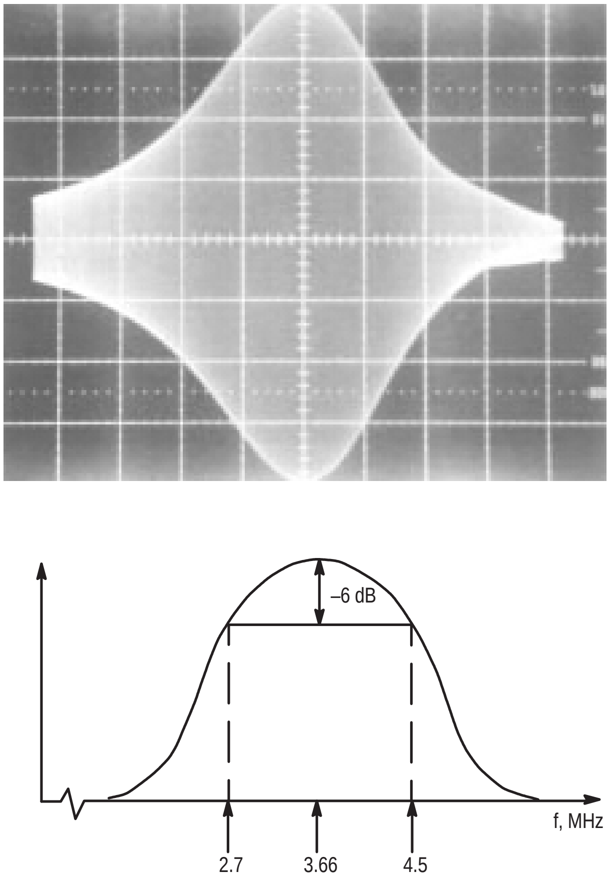
Figure 19. Frequency Response of Chroma Coupling Circuit



I/Q System versus (R–Y)/(B–Y) System

The NTSC standard calls for unequal bandwidths for I and Q (Figure 21). The MC1377 has no means of processing the unequal bandwidths because the I and Q axes are not used (Figure 22) and because the outputs of the (R–Y) and the (B–Y) modulators are added before being output at Pin 13. Therefore, any bandwidth reduction intended for the chroma information must be performed on the composite chroma information. This is generally not a problem, however, since most monitors compromise the standard quite a bit.

Figure 23 shows the typical response of most monitors and receivers. This figure shows that some crosstalk between luma and chroma information is always present. The acceptability of the situation is enhanced by the limited ability of the CRT to display information above 2.5 MHz. If the signal from the MC1377 is to be used primarily to drive conventional non–comb filtered monitors or receivers, it would be best to reduce the bandwidth at the MC1377 to that of Figure 23 to lessen crosstalk.

MOTOROLA

MC1378

Color Television Composite Video Overlay Synchronizer

The MC1378 is a bipolar composite video overlay encoder and microcomputer synchronizer. The MC1378 contains the complete encoder function of the MC1377, i.e., quadrature color modulators, RGB matrix, and blanking level clamps, plus a complete complement of synchronizers to lock a microcomputer–based video source to any remote video source. The MC1378 can be used as a local system timing and encoding source, but it is most valuable when used to lock the microcomputer source to a remotely originated video signal.

- Contains All Needed Reference Oscillators
- Can Be Operated in PAL or NTSC Mode, 625 or 525 Line
- Wideband, Full–Fidelity Color Encoding
- Local or Remote Modes of Operation
- Minimal External Components
- Designed to Operate from 5.0 V supply
- Will Work with non standard Video

Description of Operation – Refer to Figures 3, 4

Remote Mode	Local Mode
The incoming remote video signal (Pin 24) supplies all synchronizing information. A discussion of the function of the phase detectors helps to clarify the lockup method: PD1 — locks the internally counted–down 4 MHz horizontal VCO to the incoming horizontal sync. It is fast acting, to follow VCR source fluctuations. PD2 — locks the 36 MHz clock VCO, which is divided down by the video system, to the divided down horizontal VCO. PD3 — is a gated phase detector which locks the 14 MHz crystal oscillator, divided by 4, to the incoming color burst. PD4 — controls an internal phase shifter to assure that the outgoing color burst is the same phase as incoming burst at PD3. PD5 — not used in REMOTE MODE Vertical lock is obtained by continuously resetting the sync generator in the video system with separated vertical sync from the MC1378, Pin 38. This signal is TTL level vertical block sync, negative going. The horizontal sync from the video system to Pin 40 is also TTL level with sync negative going. The local/remote switch, Pin 1, is in local mode when grounded, remote mode when taken to 5.0 V. The overlay control, Pin 25, has an analog characteristic, centered about 1.0 V, which allows fading from local to remote.	The MC1378 and a video system combine to provide a fully synchronized standard signal source. In this case, composite sync must be supplied by the video system or other time base system. In the MC1378 the phase detectors operate as follows: PD1 — locks the internally counted–down 4 MHz horizontal VCO to a Horizontal Sync signal (at Pin 40) from the video system (counted down from 36 MHz) PD2 — not used in LOCAL MODE. PD3 — not used in LOCAL MODE. PD4 — active, but providing an arbitrary phase shift setting between the color oscillator and the output burst phase. PD5 — locks the 36 MHz clock VCO (which is divided down by the video system) to the 14 MHz (crystal) color oscillator. The 14 MHz is, therefore, the system standard in LOCAL MODE, and is not DC controlled.
	COMPOSITE VIDEO GENERATION The color encoding at the RGB signals is done exactly as in the MC1377. Composite chroma is looped out at Pins 18 and 20 to allow the designer to choose band shaping. Luminance is similarly brought out (Pins 17 and 22) to permit installation of the appropriate delay. Composite sync output, Pin 39, and burst gate output, Pin 5, are provided for convenience only.

CIRCUIT OPERATION

The MC1391P contains the oscillator, phase detector and predriver sections needed for a television horizontal APC loop.

The oscillator is an RC type with one pin (Pin 7) used to control the timing. The basic operation can be explained easily. If it is assumed that Q7 is initially off, then the capacitor connected from Pin 7 to ground will be charged by an external resistor (R_C) connected to Pin 6. As soon as the voltage at Pin 7 exceeds the potential set at the base of Q8 by resistors R8 and R10, Q7 will turn on and Q6 will supply base current to Q5 and Q10. Transistor Q10 will set a new, lower potential at the base of Q8 determined by R8, R9 and R10. At the same time, transistor Q5 will discharge the capacitor through R4 until the base bias of Q7 falls below that of Q8, at which time Q7 will turn off and the cycle repeats.

The sawtooth generated at the base of Q4 will appear across R3 and turn off Q3 whenever it exceeds the bias set on Pin 8. By adjusting the potential at Pin 8, the duty cycle (MSR) at the predriver output pin (Pin 1) can be changed to accommodate either tube or transistor horizontal output stages.

The phase detector is isolated from the remainder of the circuit by R14 and Z2. The phase detector consists of the comparator Q15, Q16 and the gated current source Q17. Negative going sync pulses at Pin 3 turn off Q12 and the current division between Q15 and Q16 will be determined by the phase relationship of the sync and the sawtooth waveform at Pin 4, which is derived from the horizontal flyback pulse. If there is no phase difference between the sync and sawtooth, equal currents will flow in the collectors of Q15 and Q16 each of half the sync pulse period. The current in Q15 is turned around by Q18 so that there is no net output current at Pin 5 for balanced conditions. When a phase offset occurs, current will flow either in or out of Pin 5. This pin is connected via an external low–pass filter to Pin 7, thus controlling the oscillator.

Shunt regulation for the circuit is obtained with a zero temperature coefficient from the series combination of D1, D2 and Z1.

APPLICATION INFORMATION

Although it is an integrated circuit, the MC1391P has all the flexibility of a conventional discrete component horizontal APC loop. The internal temperature compensated voltage regulator allows a wide supply voltage variation to be tolerated, enabling operation from nonregulated power supplies. A minimum value for supply current into Pin 6 to maintain zener regulation is about 18 mA. Allowing 2.0 mA for the external dividers

$$R_A + R_B = \frac{V_{nonreg(min)} - 8.8}{20 \times 10^{-3}}$$

Components R_A, R_B and C_A are used for ripple rejection. If the supply voltage ripple is expected to be less than 100 mV (for a 30 V supply) then R_A and R_B can be combined and C_A omitted.

The output pulse width can be varied from 6.0 µs to 48 µs by changing the voltage at Pin 8 (see Figure 5). However, care should be taken to keep the lead lengths to Pin 8 as short as possible at Pin 1. The parallel impedance of R_D and R_E should be close to 1.0 kΩ to ensure stable pulse widths. For 15 mA drive at saturation

$$R_F = \frac{V_{nonreg} - 0.3}{15 \times 10^{-3}}$$

The oscillator free–running frequency is set by R_C and C_B connected to Pin 7. For values of $R_C \geq R_{discharge}$ (R4 in Figure 6), a useful approximation for the free–running frequency is

$$f_O = \frac{1}{0.6\, R_C C_B}$$

Proper choice of R_C and C_B will give a wide range of oscillator frequencies – operation at 31.5 kHz for countdown circuits is possible for example. As long as the product $R_C C_B \approx 10^{-4}$ many combinations of values of R_C and C_B will satisfy the free–running frequency requirement of 15.734 kHz. However, the sensitivity of the oscillator (β) to control–current from the phase detector is directly dependent on the magnitude of R_C, and this provides a convenient method of adjusting the dc loop gain (fc).

For a given phase detector sensitivity (µ) = 1.60 x 10^{-4} A/rad

$$fc = \mu\beta \text{ and } \beta = 3.15 \times R_C \text{ Hz/mA}$$

Increasing R_C will raise the dc loop gain and reduce the static phase error (S.P.E.) for a given frequency offset. Secondary effects are to increase the natural resonant frequency of the loop (ω_n) and give a wider pull–in range from an out–of–lock condition. The loop will also tend to be underdamped with fast pull–in times, producing good airplane flutter performance. However, as the loop becomes more underdamped impulse noise can cause shock excitation of the loop. Unlimited increase in the dc loop gain will also raise the noise bandwidth excessively causing horizontal jitter with thermal noise. Once the dc loop gain has been selected for adequate SPE performance, the loop filter can be used to produce the balance between other desirable characteristics. Damping of the loop is achieved most directly by changing the resistor R_X with respect to R_Y which modifies the ac/dc gain ration (m) of the loop. Lowering this ratio will reduce the pull–in range and noise bandwidth (fnn). (Note: very large values of R_Y will limit the control capability of the phase detector with a corresponding reduction in hold–in range.)

Static phasing can be adjusted simply by adding a small resistor between the flyback pulse integrating capacitor and ground. The sync coupling capacitor should not be too small or it can charge during the vertical pulse and this may result in picture bends at the top of the CRT.

Note: In adjusting the loop parameters, the following equations may prove useful:

$$f_{nn} = \frac{1 \times \chi^2 T\omega_C}{4\chi T} \qquad \chi = \frac{R_X}{RY}$$

$$w_n = \sqrt{\frac{\omega_C}{(1 + c)T}} \qquad \omega_C = 2\pi fc$$

$$T = Ry\, CC$$

$$K = \frac{\chi^2 T\omega_C}{4}$$

where: K = loop damping coeffecient

MOTOROLA

MC3340

Electronic Attenuator

The MC3340 is a simple but very effective electronic attenuator. This device offers up to 80 dB of attenuation control for frequencies to 1.0 MHz. THD (distortion) is less than 1% – up to 15 dB attenuation and less than 3% – up to 40 dB.

Typical uses include instrumentation control, remote control audio amplifiers, electronic games, and CATV (cable TV) set–top converter audio control.

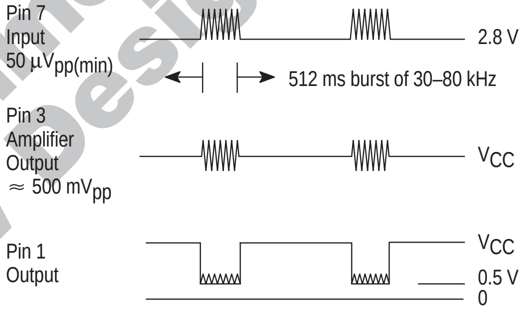
APPLICATIONS INFORMATION

The MC3373 is a specialized high gain amplifier/signal processor bipolar analog IC designed to be the core of infrared carrier signaling systems. The amplifier section has an Automatic Bias Level Control (ABLC) for simplified direct connection to an IR detector diode. Generally, it is operated ac coupled, utilizing an input high–pass filter to eliminate power line related noise, particularly that from florescent and gas vapor lamps. The use of a high frequency carrier is strongly recommended as opposed to simply detecting “dc” bursts of IR energy. In the carrier mode setup the MC3373 acts like an AM receiver subsystem, amplifying the incoming signal, demodulating it, and providing some basic wave shaping of the demodulated envelope. The tuned circuit at Pin 3 provides the main system selectivity reducing random noise interference and permitting multichannel operation in the same physical area without falsing. In the multichannel case the carriers must not be harmonically related. The bandwidth is determined primarily by the “Q” of the coil. Bandwidth may be increased by loading, shunting, the coil with a resistor.

Since this is a very high gain system operating at relatively high frequencies, care **must** be taken in the circuit layout and construction. Do not use wire wrap or non–ground plane protoboard. A simple single sided PCB with ground fill or a two–sided board with a solid groundplane and top side point–to–point will provide consistent high performance. There is a wide array of IR emitter/detectors available. The Motorola MLED81 and MRD821 are an excellent low cost combination to use with the MC3373. Multiple emitters are recommended for extended range.

Figure 6. Typical Signal Waveforms



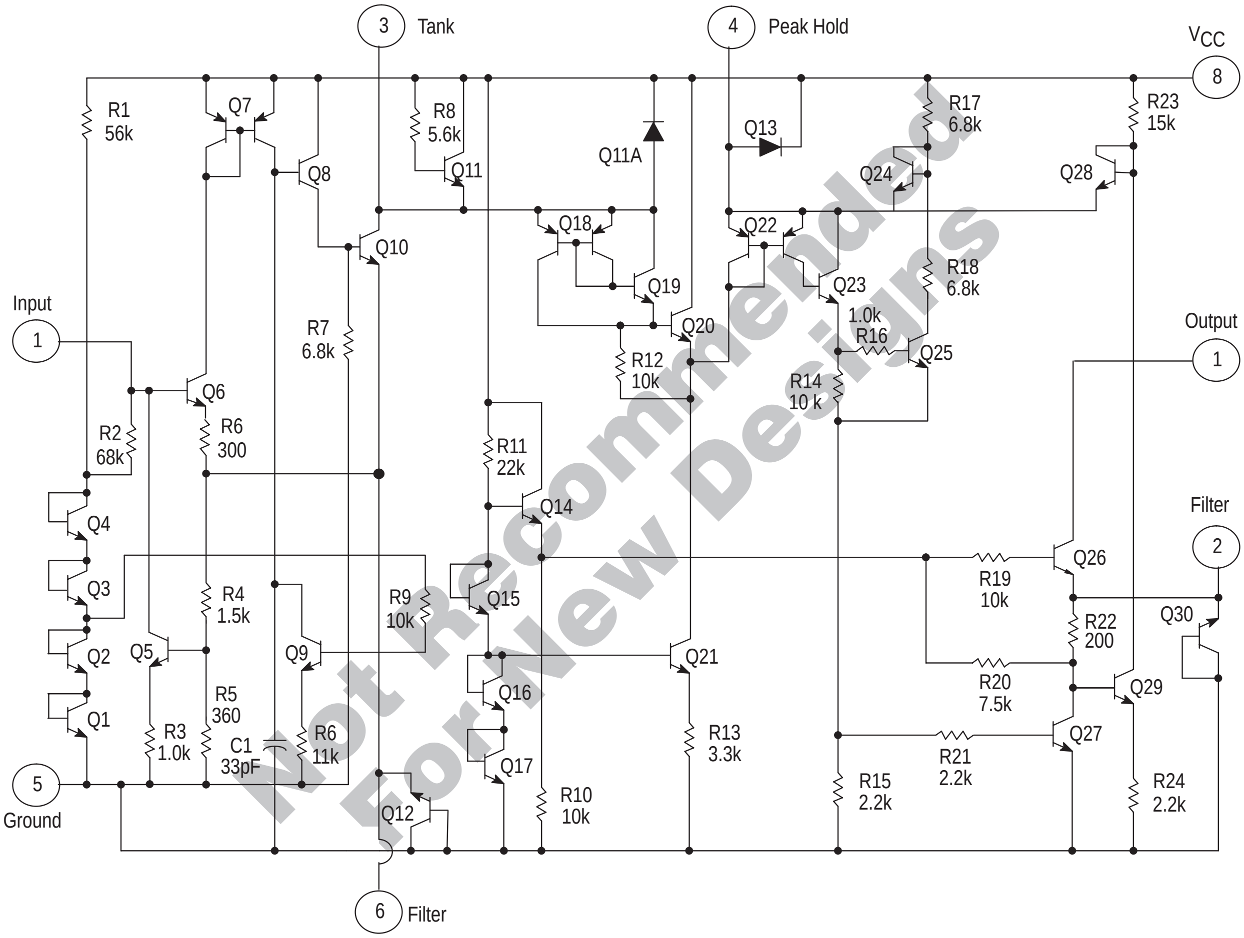
The input amplifier gain is approximately equal to the load impedance at Pin 3, divided by the resistor from Pin 6 to ground. Again, the low frequency gain can be reduced by using a small coupling capacitor in series with the Pin 6 resistor.

The load may be resistive, with only, or tuned, as in the test circuit. The amplifier output is limited by back–to–back clamping diodes, level shifted, buffered and fed to a negative peak detector. The detector threshold is set by the external resistor on Pin 4, and an internal 6.8 kΩ resistor and diode to V_{CC}. The capacitor from V_{CC} to Pin 4 quickly charges during the negative peaks and then settles toward the set–up voltage between signal bursts at a rate roughly determined by the value of the capacitor and the 6.8 k resistor. The external capacitor at Pin 2 filters the ultrasonic carrier from the pulses.

CIRCUIT DESCRIPTION

Q1 to Q4 set the bias on the amplifier input at approximately 2.8 V. Q6 to Q10 form the input amplifier, which has a gain of about 80 dB when R(Pin 6) = 0, Q5 sinks input current from the photo diode and keeps the amplifier properly biased. Q18 to Q20 level shift and buffer the signal to the negative peak detector, Q22 and Q23. Output devices Q26 and Q27 conduct during peaks and pull the output (Pin 1) low. The capacitor on Pin 2 filters out the carrier.

Figure 7. Representative Schematic Diagram



MC13020

Motorola C-QUAM® AM Stereo Decoder

This circuit is a complete one ship, full feature AM stereo decoding and pilot detection system. It employs full–wave envelope signal detection at all times for the L + R signal, and decodes L – R signals only in the presence of valid stereo transmission.

- No Adjustments, No Coils
- Few Peripheral Components
- True Full–Wave Envelope Detection for L + R
- PLL Detection for L – R
- 25 Hz Pilot Presence Required to Receive L – R
- Pilot Acquisition Time 300 ms for Strong Signals, Time Extended for Noise Conditions to Prevent “Falsing”
- Internal Level Detector can be used as AGC Source

MOTOROLA C–QUAM® – COMPATIBLE QUADRATURE AM STEREO

Introduction

In C–QUAM®, conventional quadrature amplitude modulation has been modified by multiplying each axis by cosθ as shown in Figures 2 and 3. The resulting carrier envelope is 1 + L + R, i.e., a correct sum signal for monaural receivers and for stereo receivers operating in monaural mode. A 25 Hz pilot signal is added to the L – R information at a 4% modulation level.

Decoder

The MC13020P takes the output of the AM IF amplifier and performs the complete C–QUAM® decoding function. In the absence of a good stereo signal, it produces an undegraded monaural output. Note in Figure 4 that the L + R information delivered to the output always comes from the envelope detector (Env DET).

The MC13020P decodes the stereo information by first converting the C–QUAM® signal to QUAM, and then detecting QUAM. The conversion is accomplished by comparing the output of the Env DET and the I DET in the Err AMP. This provides 1/cosθ correction factor, which is then multiplied by the C–QUAM® incoming signal in the Var Gain block. Thus, the output of the Var Gain block is a QUAM signal, which can then be synchronously detected by conventional means. The I and Q detectors are held at 0° and 90° relative demodulation angles by reference signals from the phase–locked, divided–down VCO. The output of the I DET is 1 + L + R, with the added benefit (over the Env DET) of being able to produce a negative output on strong co–channel or noise interference. This is used to tell the Lock circuit to go to monaural operation. The output of the Q DET is the L – R and pilot information.

VCO

The VCO operates at 8 times the IF input frequency, which ensures that it is out–of–band, even when a 260 kHz IF frequency is used. Typically, a 450 kHz IF frequency is used with synthesized front ends. This places the VCO at 3.6 MHz, which permits economic crystal and ceramic resonators. A crystal VCO is very stable, but cannot be pulled very far to follow front–end mis–tuning. Pull–in capability of ±100 Hz at 450 kHz is typical, and de–Q–ing with a resistor (see Figure 7) can increase the range only slightly. Therefore, the crystal approach can only be used with very accurate, stable front–ends. By comparison, ceramic and L – C VCO circuits offer pull–in range in the order of ±2.5 kHz (at 450 kHz). Ceramic devices accurate enough to avoid trimming adjustment can be obtained with a matched capacitor for Cs (see Figure 1 and 5).

In the PLL filter circuit on Pin 19, C1 is the primary factor in setting a loop corner frequency of 8.0 to 10 Hz, in–lock. An internally controlled fast pull–in is provided. R2 is selected to slightly overdamp the control loop, and C2 prevents high frequency instability.

The Level DET block senses carrier level and provides an optional tuner AGC source. It also operates on the Q AGC block to provide a constant amplitude of 25 Hz pilot at Pin 11, and it delivers information to the pilot decoder regarding signal strength.

Pilot and Co–Channel Filters

The Q AGC output drives a low pass filter, made up of 400 Ω internal and 430 Ω and 5 μF external. From this point, an active 25 Hz band–pass filter is coupled to the Pilot Decoder, Pin 14, and another low–pass filter is connected to the Co–channel Input, Pin 12. A 2:1 reduction of 25 Hz pilot level to the Pilot Decode circuit will cause the system to go monaural, with the components shown. Refer to Figure 8 for the formulas governing the active band–pass filter. The co–channel input signal contains any low frequency intercarrier beat notes, and, at the selected level, prevents the Pilot Decode circuit from going into stereo. The co–channel input, Pin 12, gain can be adjusted by changing the external 1.5 k resistor. The values shown set the “trip” level at about 7% modulation. The 25 Hz pilot signal at the output of the active filter is opposite in phase to the pilot signal coming from the second low–pass filter. The 56 k resistor from Pin 14 to Pin 12 causes the pilot to be cancelled at the co–channel input. This allows a more sensitive setting of the co–channel trip level.

Pilot Decoder

The Pilot Decoder has two modes of operation. When signal conditions are good, the decoder will switch to stereo after 7 consecutive cycles of the 25 Hz pilot tone. When signal conditions are bad, the detected interference changes the pilot counter so as to require 37 consecutive cycles of pilot to go to stereo. In a frequency synthesized radio. the logic that mutes the audio when tuning can be connected to Pin 9. When this pin is held low it holds the decoder in monaural mode and switches it to the short count. This pin should be held low until the synthesizer and decoder have both locked onto a new station. A 300 ms delay should be sufficient. If the synthesizer logic does not provide sufficient delay, the circuit shown in Figure 9 may be added. Once Pin 9 goes high, the Pilot Decoder starts counting. If no pilot is detected for seven consecutive counts, it is assumed to be a good monaural station and the decoder is switched to the long count. This reduces the possibility of false stereo triggering due to signal level fluctuation or noise. If the PLL goes out of lock, or interference is detected by the co–channel protection circuit before seven cycles are counted, the decoder goes into the long count mode. Each disturbance will reset the counter to zero. The Level Detector will keep the decoder from going into stereo if the IF input level drops 10 dB, but will not change the operation of the pilot counter.

Once the decoder has gone into the stereo mode, it will go instantly back to monaural if either the lock detector on Pin 10 goes low, or if the carrier level drops below the present threshold. Seven consecutive counts of no pilot will also put the decoder in monaural. In stereo, the co–channel input is disabled, and co–channel or other noise is detected by negative excursions of the I DET, as mentioned earlier. When these excursions reach a level caused by approximately 20% modulation of co–channel, the lock detector puts the system in monaural, even though the PLL may still actually be locked. This higher level of co–channel tolerance provides the hysteresis to prevent chattering in and out of stereo on a marginal signal.

When all inputs to the Pilot Decode block are correct, and it has completed its count, it turns on the Switch, sending the L – R to the Matrix, and switches the pilot lamp pin to a low impedance to ground.

Summary

It should be noted that in C–QUAM®, with both channels AM modulated, the noise increase in stereo is a maximum of 3.0 dB, less on program material. Therefore, this is not the major concern in the choice of monaural to stereo switching point as it was in FM, and blend is not needed.

PIN FUNCTION DESCRIPTION

Pin	Description
1, 2	Detector Filters, R_{out} = 4.3 k, recommend 0.0033 μF to V_{CC} to filter 450 kHz components.
3	IF Signal Input
4	Level Detector filter pin, R_{out} = 8.2 k, 10 μF to ground sets the AGC time constant. High impedance output, needs buffer.
5	Error Amp compensation to stabilize the Var Gain feedback loop
6	V_{CC}, 6.0 to 10 Vdc, suitable for low V_{bat} automotive operation, but must be protected from “high line” condition.
7, 8	Left and Right Outputs, NPN emitter–followers
9	Forced Monaural, MOS or TTL controllable
10	Lock detector filter, R_{out} = 27 k, recommend 2.2 μF to ground
11	AGC’d Q output, NPN emitter–follower with 400 Ω from emitter to Pin 11
12	Co–channel input, 2.0 k series in and 47 k feedback
13	Pilot Filter input to op amp, see Figure 8.
14	Pilot Decode Input (op amp output) emitter–follower, R_{out} = 100 Ω
15	Stereo Lamp, open–collector of an NPN common emitter stage, can sink 50 mA, V_{sat} = 0.3 V at 5.0 mA.
16	Ground
17	Oscillator input, R_{in} = 10k, do not DC connect to Pin 18 or ground.
18	Oscillator feedback, NPN emitter, R_{out} = 100 Ω
19	Phase Detector output, current source to filter.
20	Detector Filter, R_{out} = 4.3 k, recommend 0.0033 μF to V_{CC} to filter 450 kHz.

$$R_c = \frac{Q}{\pi f_O C}$$

$$R_a = \frac{R_c}{2 A_o}$$

$$R_b = \frac{R_a R_c}{4Q^2 R_a - R_c}$$

C ± 5%	R_a ± 5%	R_b ± 1%	R_c ± 1%
0.47 µF	4.7 k	910	220 k
0.33 µF	8.2 k	1.3 k	330 k

NOTE: Capacitor C should be a good grade, low ESR.

Where in this application: f_O = center frequency = 25 Hz
A_o = gain at $f_O \le 25$
$Q \le 10$

Choose values for f_O, A_o, Q, and convenient C, solve for resistors.

MOTOROLA

MC13022

Advanced Medium Voltage AM Stereo Decoder

The MC13022 is designed for home, portable and automotive AM stereo radio applications. The circuits and functions included in the design allow implementation of a full–featured C–QUAM® AM stereo radio with relatively few, inexpensive external parts. It is available in either 28–lead DIP or EIAJ compatible wide–bodied 28–lead SOIC.

- Operation from 4.0 V to 10 V Supply with Current Drain of 18 mA Typ
- IF Amplifier with Two Speed AGC
- Post Detection Filters that Allow Manual or Automatic Adjustable Audio Bandwidth Control and 9.0 or 10 kHz Notch Filtering
- Signal Quality Controlled Stereo Blend and Noise Reduction
- Noise and Co–Channel Discriminating Stop–On–Station
- Signal Strength Indicator Output for RF AGC and/or Meter Drive
- Signal Strength Controlled IF and Audio Bandwidth
- Noise Immune Pilot Detector Needs no Precision Filter Components
- MC13023 Complementary Tuning System IC

EXPLANATION OF FEATURES

Blend and Noise Reduction

Although AM stereo does not have the extreme difference in S/N between mono and stereo that FM does (typically less than 3.0 dB versus greater than 20 dB for FM), sudden switching between mono and stereo is quite apparent. Some forms of interference such as co–channel have a large L–R component that makes them more annoying than would ordinarily be expected for the measured level. The MC13022 measures the interference level and reduces L–R as interference increases, blending smoothly to monaural. The pilot indicator remains on as long as a pilot signal is detected, even when interference is severe, to minimize annoying pilot light flickering.

RF AGC/Meter Drive

A dc voltage proportional to the log of signal strength is provided at Pin 6. This can be used for RF AGC, signal strength indication, and/or control of the post detection filter. Normal operation is above 2.2 V as shown is Figure 4.

Stop Sense

Multiplexed with the signal strength information is the stop sense signal. The stop sense is activated when scanning by externally pulling the blend capacitor on Pin 23 below 0.5 V. This would typically be done from the mute line in a frequency synthesizer.

If at any time Pin 23 is low and there is either no signal in the IF or a noisy signal of a predetermined interference level, Pin 6 will go low. This low can be used to tell the frequency synthesizer to immediately scan to the next channel. The interference detection prevents stopping on many unlistenable stations, a feature particularly useful at night when many frequencies may have strong signals from multiple co–channel stations.

IF Bandwidth Control

IF AGC attenuates the signal by shunting the signal at the IF input. This widens the IF bandwidth by decreasing the loaded Q of the input coupling coil as signal strength increases.

Post Detection Filtering

With weak, noisy signals, high frequency rolloff greatly improves the sound. Conventional tone controls do not attenuate the highs sufficiently to control noise without also significantly affecting the mid–range. Also, notch filters are necessary with any wide–band AM radio to eliminate the 10 kHz whistle from adjacent stations.

By using a twin–T filter with variable feedback to the normally grounded center leg, a variable Q notch filter is formed that provides both the 10 kHz notch and variable high frequency rolloff functions. Typical range of response is shown in Figure 3. Response is controlled by the dc voltage on Pin 15.

Pin 15 could interface with a dc operated tone control such as the TDA1524, or could be tied to Pin 6 for automatic audio bandwidth control as a function of signal strength.

MC13022A

Advance Information

Advanced Medium Voltage AM Stereo Decoder

The MC13022A is designed for home and automotive AM stereo radio applications. The circuits and functions included in the design allow implementation of a full–featured C–QUAM® AM stereo radio with relatively few, inexpensive external parts. It is available in either 28–lead DIP or EIAJ compatible wide–bodied 28–lead SOIC. Functionally, the MC13022A and MC13022 are very similar. The MC13022A has 10 dB more audio output and a CMOS compatible logic level output (Pin 15) for stop sense. The stop sense/AGC function has been internally connected to the output notch filter control.

- Operation from 6.0 V to 10 V Supply with Current Drain of 20 mA Typ
- IF Amplifier with Two Speed AGC
- Post Detection Filters that Allow Automatic Adjustable Audio Bandwidth Control and Notch Filtering (9.0 or 10 kHz)
- Signal Quality Controlled Stereo Blend and Noise Reduction
- Noise and Co–Channel Discriminating Stop–On–Station
- Signal Strength Indicator Output for Stop Sense and/or Meter Drive
- Signal Strength Controlled IF and Audio Bandwidth
- Noise Immune Pilot Detector Needs no Precision Filter Components
- MC13025 Complementary Electronically Tuned Radio Front End
- CMOS Compatible Driver for Stop Sense

NOTES:
1. Q1 is switched on when the Blend Pin 23 is externally held low and the signal is weak or has 110% negative modulation. In this condition Q1 pulls Pin 6 low (0.25 to 1.3 V). At all other times, Pin 6 follows the curve in Figure 4.
2. Q2 (Pin 15) is switched on when Pin 6 voltage is below 1.7 V. Q2 could then be used as a logic output to the tuning system, telling the tuning system to continue searching for a good signal.
3. User is cautioned not to require more than 1.0 mA from Pin 6.

EXPLANATION OF FEATURES

Blend and Noise Reduction

Although AM stereo does not have the extreme difference in S/N between mono and stereo that FM does (typically less than 3.0 dB versus greater than 20 dB for FM), sudden switching between mono and stereo is quite apparent. Some forms of interference such as co–channel have a large L–R component that makes them more annoying than would ordinarily be expected for the measured level. The MC13022A measures the interference level and reduces L–R as interference increases, blending smoothly to monaural. The pilot indicator remains on as long as a pilot signal is detected, even when interference is severe, to minimize annoying pilot light flickering.

Signal Strength

A dc voltage proportional to the log of signal strength is provided at Pin 6. This can be used for signal strength indication, and it directly controls the post detection filter. Normal operation is above 2.2 V as shown is Figure 4.

Stop Sense

The signal strength information is multiplexed with the stop sense signal. The stop sense is activated when scanning by externally pulling the blend, Pin 23, below 0.3 V. This would typically be done from the mute line in a frequency synthesizer.

If at any time Pin 23 is low and there is either no signal in the IF or a noisy signal of a predetermined interference level, Pins 6 and 15 will go low. This low can be used to tell the frequency synthesizer to immediately scan to the next channel. The interference detection prevents stopping on many unlistenable stations, a feature particularly useful at night when many frequencies may have strong signals from multiple co–channel stations. Pin 6 drives a comparator which has a 1.7 V reference. Therefore the comparator output, Pin 15, is low if Pin 6 is <1.7 V and high if Pin 6 is >1.7 V.

IF Bandwidth Control

IF AGC attenuates the signal by shunting the signal at the IF input. This widens the IF bandwidth by decreasing the loaded Q of the input coupling coil as signal strength increases.

Post Detection Filtering

With weak, noisy signals, high frequency rolloff greatly improves the sound. Conventional tone controls do not attenuate the highs sufficiently to control noise without also significantly affecting the mid–range. Also, notch filters are necessary with any wide–band AM radio to eliminate the 10 kHz whistle from adjacent stations.

By using a twin–T filter with variable feedback to the normally grounded center leg, a variable Q notch filter is formed that provides both the 10 kHz notch and variable high frequency rolloff functions. Typical range of response is shown in Figure 3. Response is controlled by Pin 6 for automatic audio bandwidth control as a function of signal strength.

MOTOROLA

MC13025

Electronically Tuned Radio Front End

ETR® FRONT END for C–QUAM® AM STEREO

SEMICONDUCTOR TECHNICAL DATA

The MC13025 is the complementary ETR® Electronically Tuned Radio front–end for the second generation MC13022 C–QUAM® AM stereo IF and decoder. The MC13025 provides a high dynamic range mixer, voltage controlled oscillator, and first IF that with the MC13022 and synthesizer form a complete digitally controlled AM stereo tuner system. This system in turn may drive a dual channel audio processor and high power amplifiers for car radio or home stereo applications. Other applications include portable radio “boom boxes”, table radios and component stereo systems.

- Operates Over a Wide Range of Supply Voltages: 6.0 V_{CC} to 10 V_{CC}
- Wideband AGC Voltage to RF Amp for Extended Dynamic Range
- Buffered VCO Output to Frequency Synthesizer
- No External RF Amp Needed for Most Home Stereo and Portable Radios
- IF Drive Output Matches the MC13022 for Optimum Performance
- VCO Operates at Four Times Local Oscillator Injection Frequency

AMAX Stereo Chipset

AMAX STEREO IC CHIPSET

The MC13027 and MC13122 have been specifically designed for AM radio which can meet the EIA/NAB AMAX requirements. They are essentially the same as the MC13022A and MC13025 with the addition of noise blanking circuitry. The noise blanker consists of a wide band amplifier with an RF switch for blanking ahead the IF amplifier and a stereo audio blanker with adjustable delay and blanking times.

- Operating Voltage Range of 6.0 V to 10 V
- RF Blanker with Built–In Wide Band AGC Amplifier
- Audio Noise Blanker with Audio Track and Hold
- Mixer Third Order Intercept of 8.0 dBm (115 dBμV)
- Wide Band AGC Detector for RF Amplifier
- Local Oscillator VCO Divide–by–4 for Better Phase Noise
- Buffered Local Oscillator Output at the Fundamental Frequency
- Fast Stereo Decoder Lock
- Soft Stereo Blend
- Signal Quality Detector to Control Variable Q–Notch Filters for Adaptive Audio Bandwidth and Whistle Reduction
- Signal Quality Detector for AM Stereo
- Very Low Distortion Envelope and Synchronous Detectors
- Variable Bandwidth IF

AMAX STEREO CHIPSET

What is AMAX?

In 1993, a joint proposal by the EIA (Electronic Industries Association) and the NAB (National Association of Broadcasters) was issued. It included a unified standard for pre–emphasis and distortion for broadcasters as well as a set of criteria for the certification of receivers. The purpose of this proposal was to restore quality and uniformity to the AM band and to make it possible for the consumer to receive high quality signals using the AM band. The FCC has been supportive of this initiative and has required all new broadcast licensees to meet AMAX standards. The NAB and EIA have continued to encourage receiver manufacturers by offering the AMAX certification logo to be displayed on all qualifying radios. This logo is shown below.

or

The Receiver Criteria

An AMAX receiver must have wide bandwidth: 7.5kHz for home and auto, 6.5 kHz for portables. It must have some form of bandwidth control, either manual or automatic, including at least two bandwidth provisions, such as “narrow” and “wide”. It must meet NRSC receiver standards for distortion and deemphasis. It must have provisions for an external antenna. It must be capable of tuning the expanded AM band (up to 1700 kHz). And finally, home and auto receivers must have effective noise blanking. All of these requirements, except the noise blanking, have been met by Motorola’s previous AM radio products, such as MC13025 Front End and the MC13022A C–QUAM stereo decoder. It is the Noise Blanker requirement which is met by the two devices on this data sheet, the MC13027 and MC13122.

Noise blanking, especially in AM auto radios, has become extremely important. The combination of higher energy ignitions, using multiple spark coils, along with increased use of plastic in the auto body, have increased the noise energy at the radio. Also, the consumer has learned to expect higher quality audio due to advances in many other media. For the AM band to sustain interest to the consumer, a truly effective noise blanker is required.

The block diagram below shows the Motorola AMAX stereo chipset. It offers a two–pronged approach to noise blanking which is believed to be the most effective yet offered in the consumer market. The initial blanking takes place in the output of the mixer, using a shunt circuit triggered by a carefully defined wideband receiver. For most noises, some residual audible disturbance is almost always still present after this process. The disturbance becomes stretched and delayed as it passes through the rest of the selectivity in the receiver. The stretching and delay are predictable, so the MC13027 can provide a noise blanking pulse with the correct delay and stretch to the output stages of the MC13122 decoder. The MC13122 has a Track and Hold circuit which receives the blanking signal from the Front End and uses it to gently hold the audio wherever it is as the pulse arrives, and hold that value until the noise has passed. The combined effect is dramatic. A wide range of types of noise is successfully suppressed and the resulting audio seems almost clean until the noise is so intense that the blanking approaches full–time.

The amount of extra circuitry to accomplish noise blanking is relatively small. The external components for this added capability are shown in Figure 3. In the MC13027 Front end, the noise receiver/detector requires two capacitors. The presettings for blanking timing and blanking delay require three external fixed resistors. Finally the decoder requires two track and hold capacitors to store the “audio” voltage during the track and hold function.

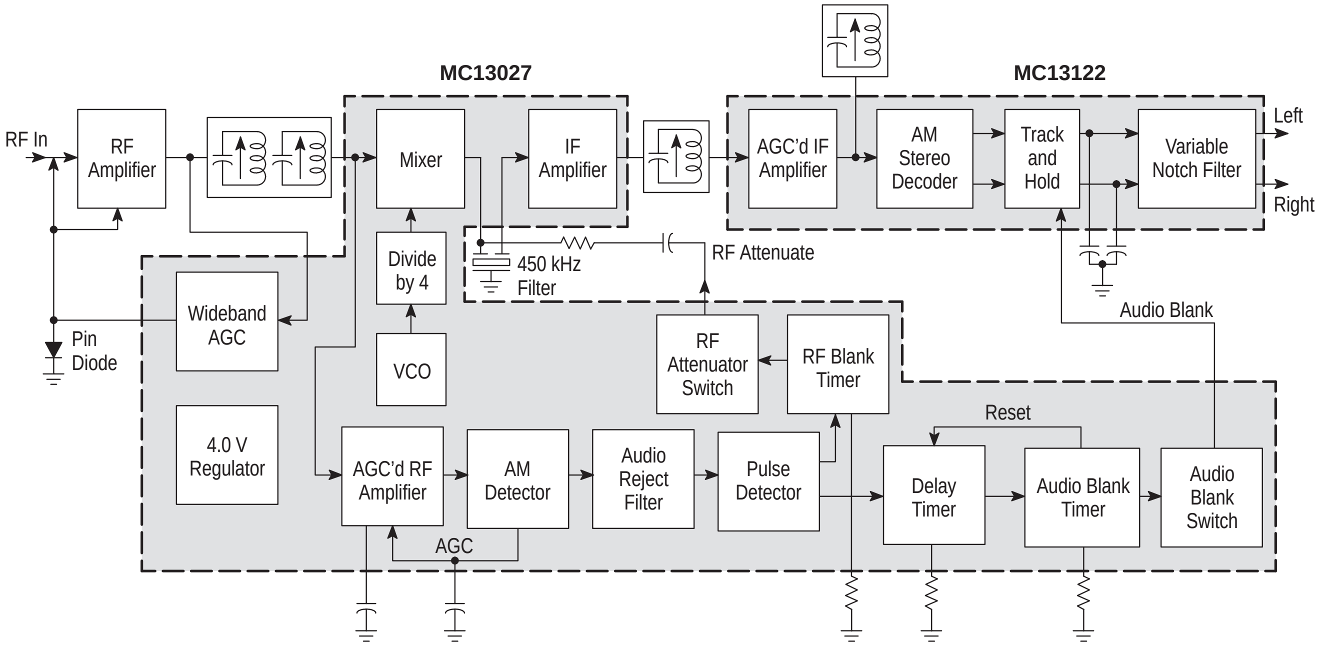

Figure 4. MC13027 Internal Block Diagram

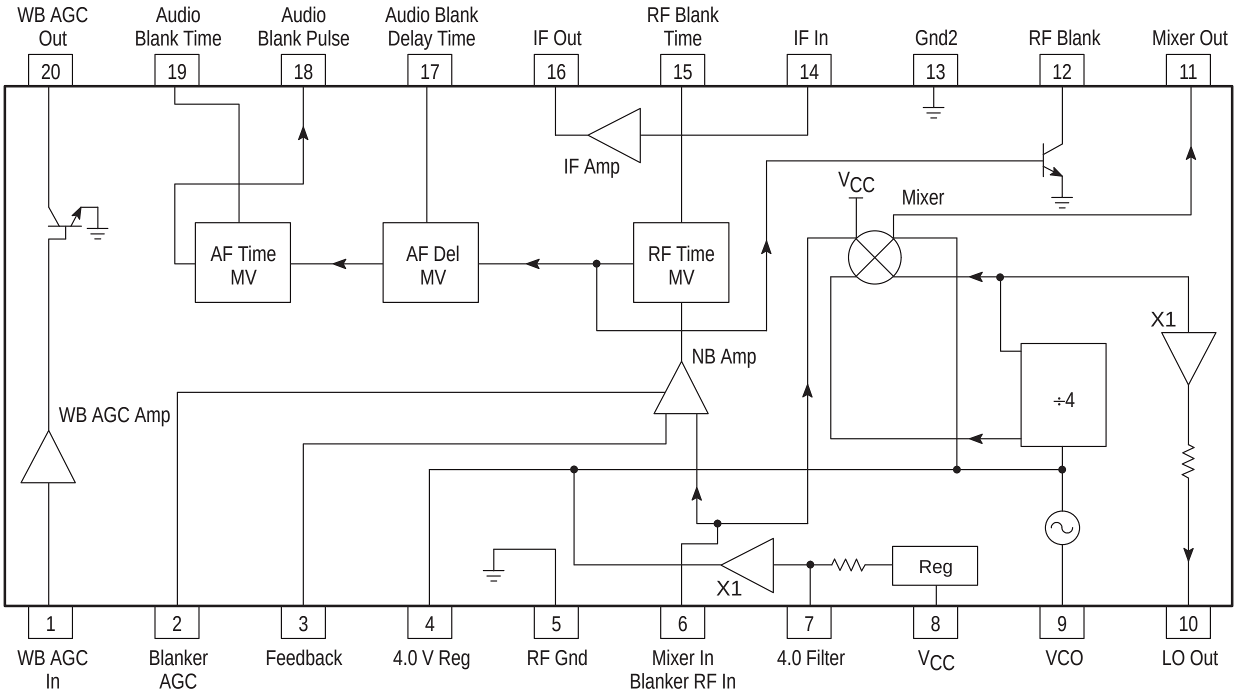


MC13027 FUNCTIONAL DESCRIPTION

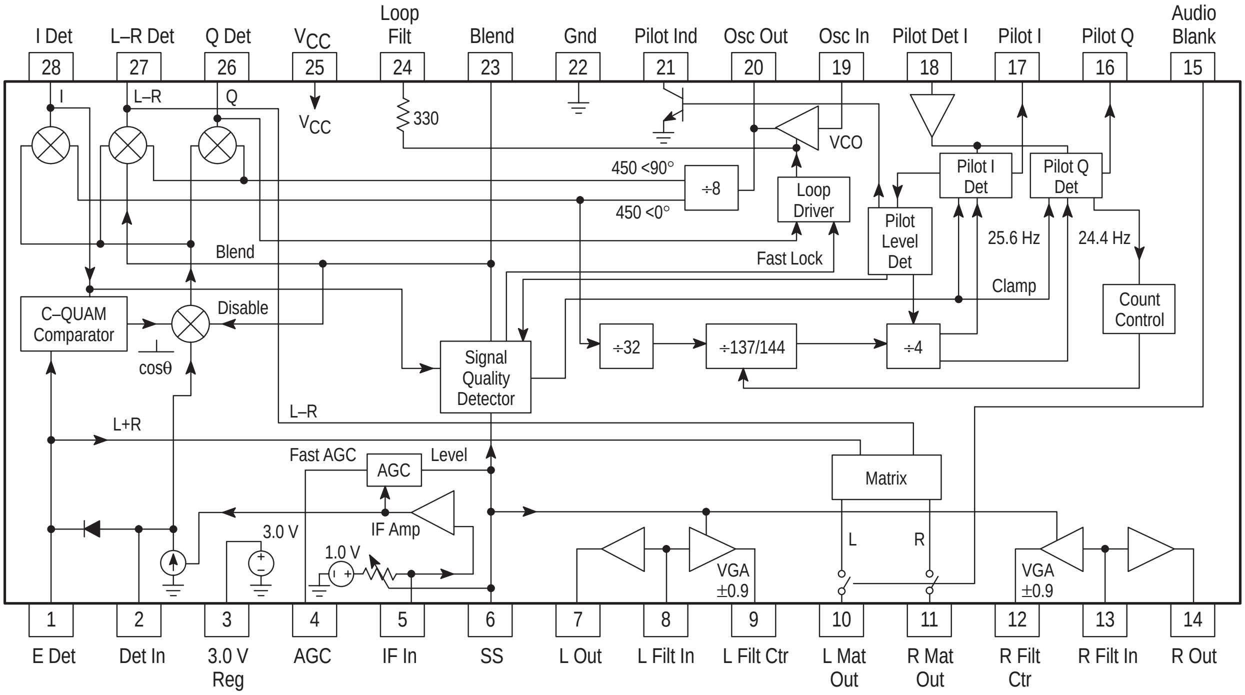
The MC13027 contains the mixer, wide band AGC system, local oscillator, IF pre–amplifier and noise blanker for an AM radio receiver. It is designed to be used with the MC13122 to produce a complete AM stereo receiver. The VCO runs at 4 (F_{in}+F_{IF}) and is divided internally by 4 for the mixer input and local oscillator buffered output. Dividing the VCO reduces the phase noise for AM stereo applications.

The noise blanker input is connected in parallel with the mixer input at Pin 6. The noise blanker circuitry contains a high gain amplifier with its own AGC so it remains linear throughout the mixer's linear range. It can detect noise pulses as low as 120 µV and generates three pulses when the noise threshold is exceeded. The width and timing of the blanking pulses is set by the resistors connected to Pins 15, 17 and 19. The resistor on Pin 15 sets the length of the RF blanking pulse and determines the time the transistor on Pin 12 is "on". The audio blanking pulse delay is set by the resistor on Pin 17 and the width by the resistor on Pin 19. This is necessary because the IF filtering delays and stretches the noise as it arrives at the detector. The transistor on Pin 18 goes "on" to cause noise blanking in the track and hold circuit in the MC13122 (Pin 15).

Wideband AGC is used in auto receivers to prevent overload – it drives the base of a cascode transistor RF amplifier and also a pin diode at the antenna (See Figures 6 and 7).

A low gain IF amplifier between Pins 14 and 16 is used as a buffer amplifier between the mixer output filter and IF filter. The input resistance of the IF amplifier is designed to match a ceramic IF filter. The gain of the IF amplifier is determined by the impedance of the load on Pin 16.

Figure 5. MC13122 Internal Block Diagram



MC13122 FUNCTIONAL DESCRIPTION

The MC13122 is designed to accept a 450 kHz C–QUAM input signal from approximately 1.0 mV to 1.0 V and produce L and R audio output signals. It has additional features: stop signal, variable bandwidth IF and audio response, stereo indicator driver and track and hold noise blanking.

The IF amplifier on Pin 5 has its own AGC system. It operates by varying the input resistance on Pin 5. With weak signals below approximate 5.0 mV, the input resistance is very high and the amplifier is at maximum gain. For this AGC to be effective, it is necessary to feed the IF input signal from a relatively high impedance. The input resistance variation also reduces the Q of the coil (T1 in the application) so the receiver bandwidth is narrow for weak signals and wide for strong signals. The value of the input resistor (R5) is selected for the desired loading of the IF coil. The impedance of the IF coil on Pin 2 determines the IF gain. Pin 2 is also the input to the C–QUAM decoder.

The IF signal drives the envelope (E), in–phase (I), quadrature (Q) and (L–R) detectors. The E detector is a quasi–synchronous true envelope detector. The others are true synchronous detectors. The E detector output provides the L+R portion of the C–QUAM signal directly to the matrix. The AGC signal of the IF amplifier drives the signal strength output at Pin 6. An external resistor on Pin 6 (sets the gain of the AGC). The Pin 6 voltage is used to control the Q of the audio notch filter, causing the audio bandwidth and depth of the 10 kHz notch to change with signal strength. It is also used as one of the inputs to the signal quality detector which generates the stop–sense and blend signal on Pins 6 and 23 respectively and tells the signal quality detector that the RF input is below the AGC threshold.

VCO

The 3.6 MHz ceramic resonator on Pins 19 and 20 is part of a phase locked loop which locks to the 450 kHz IF signal. The 3.6 MHz is divided by 8 to produce in–phase and quadrature signals for the I, Q and L–R detectors. It is also divided by 32, and 137/144 to provide signals for the pilot I and Q detectors. The pilot detector is a unique circuit which does not need filtering to detect the 25 Hz pilot.

Blend Circuit

The purpose of the blend circuit is to provide an AM stereo radio with the capability of very fast lock times, protection against stereo falsing when there is no pilot present and control of the L–R signal so as to provide as much stereo information as possible, while still sounding good in the presence of noise or interference. The circuit also provides an optional stop–sense usable by a radio with seek and/or scan. The stop–sense signal provides a “stop” signal only when the radio is locked on station, signal strength is above minimum level, and the level of interference is less than a predetermined amount. The last feature prevents stopping on frequencies where there is is a multiplicity of strong co–channel stations. It is common for AM radios without this capability to stop on many frequencies with unlistenable stations, especially at night.

The blend circuit controls the PLL fast lock, pilot detector, IF amplifier AGC rate, decoder L–R gain, cosθ compensation and stop–sense as a function of the voltage on a signal external blend capacitor. Timing is determined by the rate of change of voltage on the blend cap. Timing is changed by varying charge and discharge current and pulled down by a current source, switch, and optionally an external switch. The current sources and switches are controlled by various measures of signal quality, signal strength, and presence or absence of pilot tone.

Detectors

In AM stereo operation, the Q detector delivers pilot signal via an external low–pass filter to the pilot detector input (Pin 18). The E and I detectors drive the C–QUAM comparator. The L–R signal and the output of the envelope detector are combined in the matrix to produce the L and R signals. The C–QUAM system modifies the in–phase and quadrature components of the transmitted signal by the cosine of the phase angle of the resultant carrier, for proper stereo decoding. An uncompensated L–R would be distorted, primarily by second harmonics. Where there is noise or interference in the L–R, it has been subjectively determined that reducing the cosθ compensation at the expense of increased distortion sounds better than full decoding. The blend line operates over a small voltage range to eliminate cosine compensation.

Signal Quality Detector – Blend Voltage Control

The signal quality detector output is dependent on signal strength, over–modulation, and whether or not the blend pin has been pulled low prior to searching. Over–modulation usually occurs when a radio is tuned one channel away from a desired strong signal, so this prevents stopping one channel away from a strong signal.

In a radio tuned to a strong, interference free C–QUAM station, the blend voltage will be approximately 3.6 V. In the presence of noise or interference, when the modulation envelope is at a minimum, it is possible for the I detector to produce a negative, or below zero carrier signal. The Signal Quality Detector produces an output each time the negative I exceeds 4%. The output of the detector sets a latch. The output of the latch turns on current source which pulls down the voltage of the blend cap at a predetermined rate. The latch is then reset by a low frequency signal from the pilot detector logic. This produces about a 200 mV change each time 4% negative I is detected. Tables 1 and 2 describe the blend behavior under various conditions.

When the blend voltage reaches 2.2 V a blend control circuit starts to reduce the amplitude of the L–R signal fed to the decoder matrix. By 1.5 V the L–R has been reduced by about 40 dB. At lower voltages it is entirely off and the decoder output is monaural. This reduction of L–R signal, or blend as it is commonly called when done in FM stereo radios, reduces undesirable interference effects as a function of the amount of interference present.

Stop–Sense

Stop–sense is enabled when the blend voltage is externally pulled below 0.45 V. An input from the AGC indicating minimum signal, or detection of 10% negative I will cause the stop–sense pin to be pulled low. With signals greater than the AGC corner and less than 10% interference the stop–sense will be a minimum of 1.0 V below the 3.0 V line. Very rapid scanning is possible because the radio can scan to the next frequency as soon as the stop–sense goes low. The maximum wait time, set by the radio, is only reached on good stations.

The decoder will not lock on an adjacent channel because it is out of the lock range of the PLL. The beat note produced in the I detector by the out of lock condition will trigger the 10% negative I detector.

Sequence For Seek Scan

- Change Station – Pull–Down Blend
- Wait Approximately 50 ms for Synthesizer and Decoder PLL to Lock
- Observe Pin 6 Voltage
- If it is Above 2.0 V and Stays Above 2.0 V for Approximately 800 ms, Stay on the Station
- No IF Count Now Needed
- No AGC Level Detector Needed

Table 1. Normal Sequence When Changing Stations

External Pull–Down of Blend Capacitor to Under 0.47 V	– Increased Current Supplied to Loop Driver for Fast Lock – Fast AGC Activated – Extra Current Pull–Up Activated on Blend Capacitor – Pilot Detector Disabled – Loop Locks – Stop–Sense Activated
Blend Released	– Blend Capacitor Pulled Up to 0.7 V – Stops – Fast Lock Current Removed – Fast AGC Turned Off – Pilot Detector Enabled
Pilot Detected	– Stereo Indicator Pin Pulled Low – Blend Voltage Pulled Positive Rapidly
Blend Voltage Reaches 1.4 V	– Audio Starts Into Stereo – 10% Negative I Detector Enabled
Blend Voltage Reaches 2.2 V	– Stereo Separator Reaches 20 to 25 dB – Rapid Current Pull–Up Turned Off – 4% Negative I Detector Enabled
Blend Voltage Reaches 3.0 V	– cosθ Enabled – Full C–QUAM Decoding – Blend Voltage Continues to Rise to 3.6 V and Stops

Table 2. Operation In Adverse Conditions

4% Negative I Detected	– Blend Pulls Down Approximately 200 mV for Each Event – Acts Like One–Shot – Stops at 2.2 V – cosθ Has Been Defeated, Almost Full Stereo Remains
10% Negative I Detected	– Blend Pulls Down 200 mV for Each Event – Stops at 1.4 V – Stereo Has Blended to Mono – Resets Fast Pull–Up if Blend Has Not Been Above 2.2 V
50% Negative I Detected (Out of Lock)	– Blend Pulls Down Fast During Event – Stops at 0.47 V – Resets Fast Pull–Up – Pilot Indicator Turned Off
Minimum Signal Level Detected	– Resets Fast Pull–Up – Pulls Down to 0.7 V

MC13027 PIN FUNCTION DESCRIPTION

Pin	Name	Internal Equivalent Circuit	Description
1	WB AGC In		**Wideband AGC Input** The input impedance to the WB AGC detector is 15 k and is internally biased so it must be coupled through a capacitor. The threshold can be increased by adding a resistor in series with the input. The WB AGC begins at about 1.0 mV. In car radios, this input should be connected to the collector of the RF amplifier cascode stage through a resistor and capacitor. A 68 pF to ground will prevent undesired high frequency signals from activating the WB AGC and make the sensitivity more uniform across the band.
2	Blanker AGC		**Blanker AGC** The capacitor to ground is the bypass for the noise blanker AGC circuit. The noise blanker can be disabled by grounding this pin. 10 µF is used in the application, but it can be changed to match the time constant of the main IF AGC in the MC13122, Pin 4.
3	Feedback		**Blanker Feedback** This pin is the dc feedback to the input stage of the wide band amplifier.
4	4.0 V Reg		**4.0 V Regulator** The 4.0 V regulator supplies low impedance bias to many of the circuits in the IC. It should be bypassed to a ground near Pin 5.
7	4.0 V Filt		**4.0 V Filter** The external capacitor works with internal 4.7 k to filter noise from the bandgap regulator.
5	Gnd		**RF Ground** This pin is the ground for the RF section, blanker RF, filters and all radio circuits except the IF. In the PCB layout, the ground pin should be used as the internal return ground in the RF circuits.
6	Blk$_{RF}$/Mix$_{In}$		**Mixer Input/Blanker RF Input** The blanker RF input must be biased from the 4.0 V on Pin 4. The mixer input is to two bases of the upper mixer transistors. A low impedance dc path to the 4.0 V on Pin 4 is required. Normally, this would be a coil secondary connected between Pins 6 and 4.
11	Mixer Out		**Mixer Output** A single ended output of a double balanced mixer. A load resistor to supply is chosen to match the ceramic filter, typically 1.5 k to 1.8 k. Output current is 830 µA.

MC13027 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
8	V_{CC}		**Supply Voltage** The normal operating voltage range is 6.0 to 10 V.
9	VCLO		**Voltage Control Local Oscillator** The oscillator is a cross coupled negative resistance type and this pin must be connected through a low dc resistance to Pin 4, the 4.0 V regulator. Normally, this would be the secondary of the oscillator coil. The impedance of the secondary winding should be around 2.8 kΩ to guarantee that the oscillator will run. It operates at 4 times the LO frequency: $f_{osc} = 4(F_{in}+F_{IF})$.
10	LO Out		**Local Oscillator Output** This is an emitter follower for LO output to drive a synthesizer. It is a square wave output, the internal series resistance and allows a small bypass to reduce high frequency harmonics.
12	RF Blank		**RF Blanker** An unbiased NPN acts as a SHUNT impedance when turned on. The 100 k resistor provides a dc path for the capacitor.
13	Gnd2		**IF Ground** Pin 13 is the ground for the IF section and the timing and switching circuits in the blanker. In the application circuit this should be common to the MC13122 ground.
14	IF In		**IF Input** A degenerated differential amplifier internally biased to 4.0 V. The IF input impedance is approximately 1.8 k to match a ceramic filter. The IF amplifier is used as a buffer between the ceramic filter and the detector coil and has a fixed gain determined by the impedance of the output coil.
16	IF Out		**IF Output** An open collector provides high–impedance drive to the MC13122; the IF gain is set by the ac impedance on this pin.
15	RF Time		**RF Blank Time** A resistor to ground sets the RF blanking time. The time is set to the minimum required to attenuate the pulse received. This is normally longest at the low end of the band. The value is best approved by ear. A fixed value can be chosen for production. (50 µs is typical.)

MC13027 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
17	Delay Time		**Audio Blank Delay Time** A resistor to ground sets the delay time from the beginning of the RF blanking pulse to the beginning of the audio blanking pulse. This normally is about 50 µs for a wide AMAX filter. The ear is the most sensitive measure of the correct delay; start low, say 20 µs, and vary delay until noise is heard, and then reduce somewhat.
18	Audio Blank Cntl		**Audio Blank Pulse** When the blanker is operating, a positive pulse from this pin is fed to Pin 15 of the MC13122 to blank the audio signal.
19	Audio Time		**Audio Blank Time** A resistor to ground sets the width of the blanking pulse on Pin 18. This is usually selected by applying a pulse to the antenna of the receiver and adjusting a variable resistor. The blanking signal should be just long enough to suppress the audio pulse. Again the ear is the most sensitive tool. Start long, approximately 250 µs and reduce until noise is audible then increase.
20	WB AGC Out		**Wideband AGC Output** A push–pull current output. The resistor to voltage source (normally V_{CC}) determines the gain. Used to bias a cascode transistor in series with the input FET and can also be used to drive a PNP transistor which drives a pin diode attenuator (refer to Application Circuit Figure 6.)

MC13122 PIN FUNCTION DESCRIPTION

Pin	Name	Internal Equivalent Circuit	Description
1	E Detector		**Envelope Detector** This is the output of the envelope detector and is used for one input to the comparator that generates cosθ signal and the L+R input to the matrix. It is a quasi–synchronous full wave detector with very low distortion (<1% at 100% modulation). The output impedance is 6.2 k, and it is bypassed to V_{CC} with 1.0 nF to eliminate 900 kHz components. The bypass capacitor must be the same as the one on Pin 27 and 28 for lowest stereo distortion and best separation.
2	Detector In		**IF Out/Decoder Input** The IF coil is connected from Pin 2 to Pin 3, the 3.0 V regulator. The IF amplifier output is a current source. The gain is determined by the impedance between Pins 2 and 3. Bandwidth and gain is set by the resistance across the coil.
3	3.0 V Reg		**3.0 V Regulator** This bandgap regulator supplies bias to many of the circuits in the IC.
4	AGC Byp		**IF AGC Bypass** The AGC has a fast and slow time constant. The fast AGC is 18X the slow one and is active when the 450 kHz loop is not locked. This allows for fast scanning in car radios. This capacitor should be selected for distortion for low frequencies at 80% modulation.
5	IF In		**IF Input** The IF AGC varies the current through attenuator diodes. The diodes vary the input impedance shunting the IF signal. The varying impedance also varies the Q and therefore the bandwidth. The IF AGC is accomplished by turning on the diodes and lowering the IF input impedance.

MC13122 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
6	SS		**Signal Strength/Stop–Sense** The signal strength is a push–pull circuit. The voltage is 2.2 V at minimum signal and 3.5 to 5.0 V at strong signal. This dc voltage is also used to control the audio output notch filters. If the Blend pin is low the stop–sense is activated and this pin can go low. This can be used to control the seek–scan in the radio.
7 14	Left Out Right Out		**Filtered Left and Filtered Right Output** This can drive a de–emphasis filter to bring audio contour to AMAX specifications. Since the output is an emitter follower, the output impedance is low, and a series R should be used with the de–emphasis network as shown on the application circuit.
8 13	L Filt In R Filt In		**Input to Notch Filter** DC bias is supplied through the external filter components.
9 12	L Filt Ctr R Filt Ctr		**Left Filter and Right Filter Center** Drives the center leg of a twin–T filter, varying the Q. At strong signal, positive feedback narrows the notch, and there is little HF roll–off. At weak signal, negative feedback produces a broad notch and HF roll–off.
10 11	L Matrix Out R Matrix Out		**Track and Hold Output** This is a unity gain operational amplifier output. The current is turned off by the blanking pulse. The capacitor holds output voltage constant until unblanked. Internal feedback causes the output impedance to be low.
15	AF Blank In		**Audio Blank Control** The current to the output drivers is turned off.

MC13122 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
16	Pilot Q		**Pilot Q** This is the output of a quadrature detector of a narrowband phase locked loop system. It is used to control the pilot detector circuitry. The pilot Q is clamped to the 3.0 V reference when the blend voltage is pulled low. This results in faster pilot detection when a stereo station is tuned in. If the blend is not pulled low, the pilot Q will drift up approximately 0.5 V when there is no pilot, and it will take longer to detect the pilot. The capacitor to ground is the loop filter. It sets the pilot loop bandwidth: if it is too large, the loop bandwidth maybe too small, and the pilot may not be re–acquired if it is lost unless the blend pin is externally pulled low again.
17	Pilot I		**Pilot I** When the loop is locked to a 25 Hz AM stereo pilot, this is the output of a an in–phase synchronous detector. The capacitor filters the output, which is used to drive the pilot indicator driver on Pin 21. The time constant for the pilot indicator output is determined by this capacitor and the internal 47 k resistor. If the capacitor is too small, it can lead to pilot falsing due to noise. If the capacitor is too large, the acquisition time increases. The cap is charged to 3.0 V when the blend voltage is low to shorten lock time.
18	Pilot Det In		**Pilot Detector Input** The pilot detector will detect a pilot tone between 24.4 and 25.6 Hz. The pilot signal is fed from Q detector through a low pass filter on Pin 26. The audio signals from the Q detector must be filtered out, so a low–pass filter is used. The capacitor in series with Pin 18 blocks dc and prevents large low frequency transients from knocking the decoder out of stereo mode.
19	Osc In		**Oscillator Input** The input impedance is 10 k, but the recommended circuit adds 3.9 k in parallel with this to control the capture range of the VCO to be around ±3.0 kHz. using the recommended ceramic resonator.
20	Osc Out		**Oscillator Output** The internal phase shift of the VCO is 90 degrees, and the output impedance is low. It is designed to drive a resonant circuit with a 90 degree phase shift at the center frequency.

MC13122 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
21	Pilot Indicator		**Pilot Indicator** The maximum current is internally limited to protect the IC, but it should be operated with a current limiting resistor.
22	Gnd		**Ground** Use good practices to keep oscillator returns and RF bypasses to good copper near this point
23	Blend Cont		**Blend Control** There are pull–up and pull–down currents provided to this pin. The external capacitor controls the rate of change of this voltage and 22 µF is recommended. This is an important voltage affecting many functions in the IC.
24	Loop Filt		**Loop Filter** The phase detector is a current source, so only a single RC loop filter is needed for a second order loop. The internal 330 Ω resistor together with a 47 µF gives the correct corner frequency and damping for the proper operation on the decoder loop. The cap should be low leakage to avoid static phase error.
25	V_{CC}		**V_{CC}** The operating voltage is normally 8.0 to 10 V in car radios. The MC13122 will work from 6.0 to 10 V.
26	Q Detector		**Q Detector Output** This is a synchronous detector in quadrature with the 450 kHz IF signal. The output impedance is 11 k. This signal is normally used for input to the pilot detector and internally for the fast lock.

MC13122 PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Internal Equivalent Circuit	Description
27	L–R Detector		**L–R Detector** This is similar to the Q detector output but its level is controlled by the blend circuit. When the blend is active, the L–R output is reduced in level by reducing the dc current until mono operation is reached. It operates in the same way as the blend circuit in FM stereo decoders. The bypass capacitor should be 1.0 nF as on Pin 1 for optimum channel separation.
28	I Detector		**I Detector** This is a synchronous detector in phase with the 450 kHz IF signal. It is used internally to generate the cosθ signal and as an input to the signal quality detector. The bypass capacitor should be the same as the one on Pin 1 for best separation and lowest stereo distortion.

CAR RADIO APPLICATION

Figure 6 shows a car radio circuit using a TOKO pre–tuned RF module. The RF module includes a 4 diode tracking circuit to eliminate mistracking between the oscillator and RF circuits over the 530 to 1700 kHz AM band. This is important for stereo performance because mistracking will cause mono distortion and will significantly reduce the stereo separation. The THB122 module contains the variable 10 kHz notch filter. This module can be replaced with discrete components as shown in Figure 8, using 1% resistors and 5% capacitors.

Some manufacturers add a PIN diode attenuator at the antenna input. An example is shown in Figure 7.

The WB AGC sensitivity can be adjusted by changing R4 in series with the WB AGC input, Pin 1. The internal input resistance is 15 k.

R15, R17 and R19 are the blanker timing resistors. They were setup for this circuit and can be changed if desired.

FL1 is a linear phase IF filter . We recommend a Gaussian (rounded) filter, such as SFG or SFH for lower distortion and better separation than one with a flatter amplitude response. The SFG types of filters have poorer selectivity than the ones with flat GDT (group delay time) so some compromise has been made on adjacent channel selectivity.

The blanker can be disabled for testing by grounding the blanker AGC on Pin 2 in the MC13027.

The blanker and mixer inputs must be biased from the 4.0 V regulator through a low dc resistance like the secondary winding of the RF coil.

The receiver VCO operates at 4 times the local oscillator frequency and is divided internally in the MC13027 so that both the mixer input and the LO out is the same as in other receivers. This receiver can be connected to an existing synthesizer. For AM stereo, the synthesizer must have low phase noise. The Motorola MC145173 is recommended. For bench testing of this receiver, the Motorola MC145151 parallel input synthesizer may be useful. It will operate on 9.0 V and the phase detector can provide tuning voltage without a buffer amplifier.

The SS (stop–sense) output can be used for station searching and scanning. The best way to use it is to connect the SS signal to a comparator or A–D converter in the control microprocessor. If Pin 23 is grounded during searching by turning on Q3, the SS voltage changes from less than 0.5 V to around 2.2 V when an RF threshold is exceeded, as is shown in the graph in Figure 15. This system results in very reliable stopping on usable signals and fast detection of AM stereo signals. After a station is detected, Q3 should be turned off.

This receiver is very easy to set up because the TOKO module is pre–aligned. The only adjustments are to tune T1 and T2 for maximum voltage of the SS out line or maximum audio with a weak signal. If desired, they can be changed slightly to maximize stereo separation.

If different components are used, the blanker resistors can be setup as follows:

Ground Pin 2 of the MC13027. Apply a 1.0 μs pulse or 50 Hz square wave of about 10 mV through a dummy antenna and synchronize an oscilloscope to the pulse generator. Observe the signal at the mixer collector (Pin 11). It should be a sine wave burst. Remove the ground on Pin 2 and adjust R15 so the burst is just suppressed. Check the performance at the ends and middle of the band because the width might change due to RF circuit bandwidth.

Mix the pulse signal with a CW signal of about 300 μV with a power combiner and connect the oscilloscope to Pin 7 or Pin 14 of the MC13122. Adjust R17 so the blanking starts at the beginning of the audio pulse and R19 so the audio blanking is just long enough to suppress the audio pulse. The audio blanking time should not be made longer than necessary because it will be more noticeable in the normal program. The effectiveness of the blanker can be determined in field testing by connecting a switch from Pin 2 of the MC13027 to ground and bringing it outside the radio.

Figures 10 to 19 refer to the performance of the Application Circuit of Figure 6.

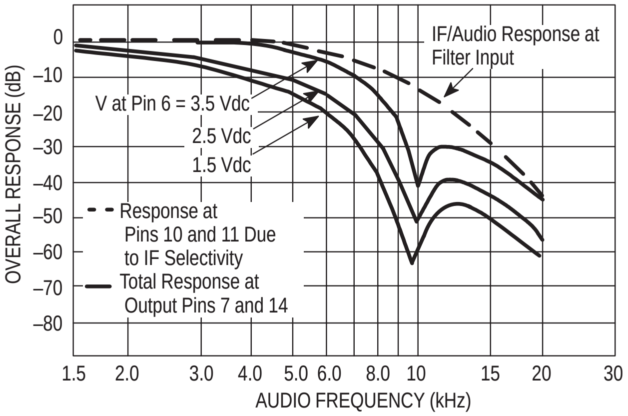

Figure 10. Blend Voltage versus RF Input Level

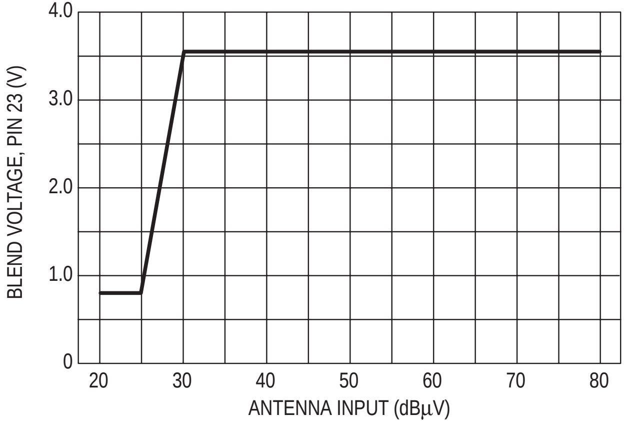
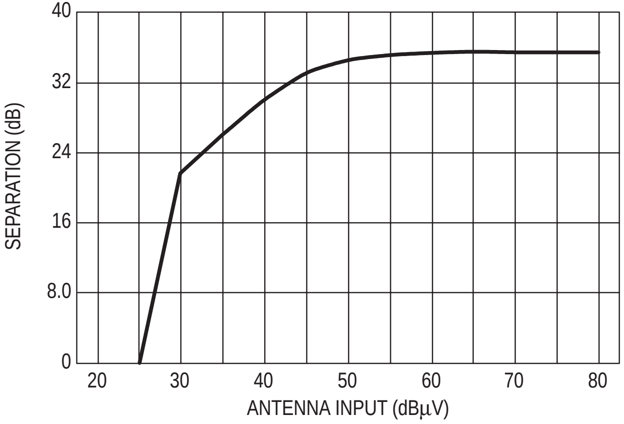


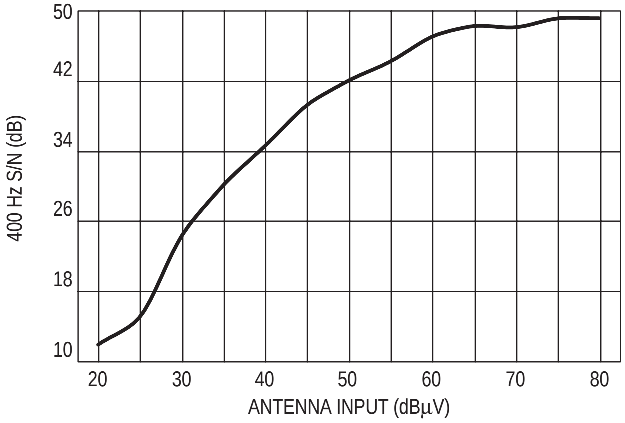
NOTE: The graphs on this page were made using the 15/60 pF dummy antenna and the Application Circuit of Figure 6.

Figure 11. Separation versus RF Input Level



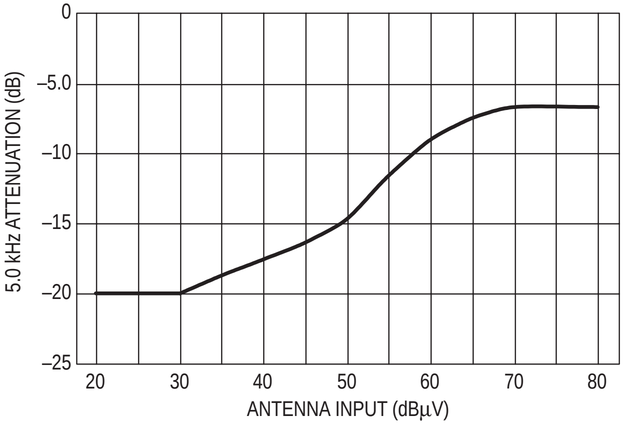
NOTE: The radio stays in mono until the stereo signal is sufficiently large and then makes a smooth transition to stereo. This is similar to FM receivers with variable blend.

Figure 12. Signal to Noise versus RF Input Level



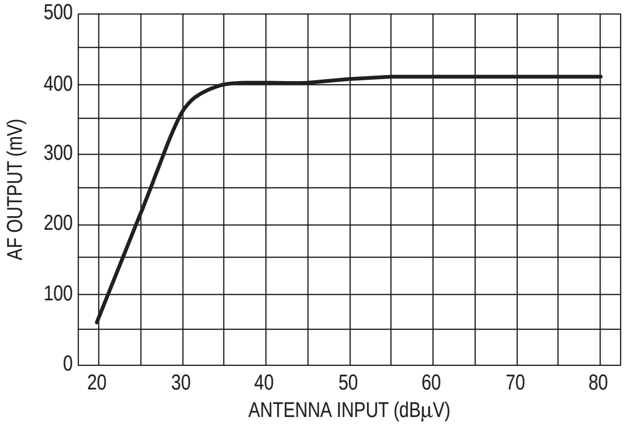
NOTE: The slightly abrupt change at around 25 dBµV is due to the decoder switching into stereo.

Figure 13. 5.0 kHz Attentuation versus RF Input Level



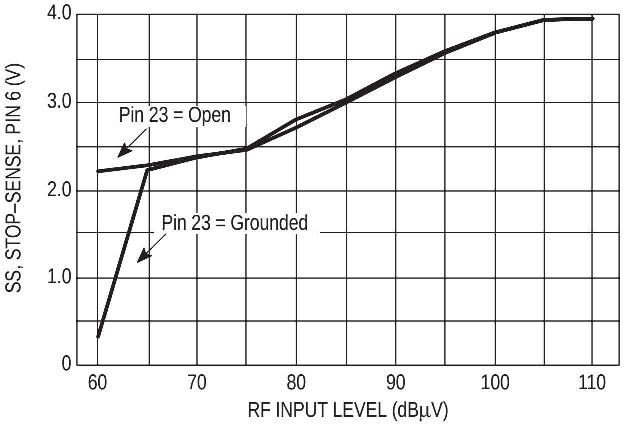
NOTE: This curve shows the effect of the variable audio bandwidth control of the MC13122. It is due to the variable loading of the IF coil and the variable 10 kHz notch filter in the output.

Figure 14. Audio Output Level versus RF Input Level



NOTE: All the curves of performance versus RF input level were generated using the car radio receiver circuit shown in Figure 6. Using a 15/60 pF dummy antenna input and a 50% L only stereo signal.

Figure 15. Stop–Sense Voltage versus RF Input Level



NOTE: This measurement was made on the MC13122 alone with a 10 k series input resistor. It will enable the designer to determine the stop–sense level if the gain of receiver RF section is known. Note that if Pin 23 is held low, the SS voltage on Pin 6 rises from about 0.3 to 2.2 V over a small change in RF level. This can be used to generate a very reliable stop signal. If Pin 23 is not held low, the SS voltage starts out at 2.2 V and rises slowly to a maximum of around 4.0 V.

Figure 16. Audio Blanking Delay versus R17

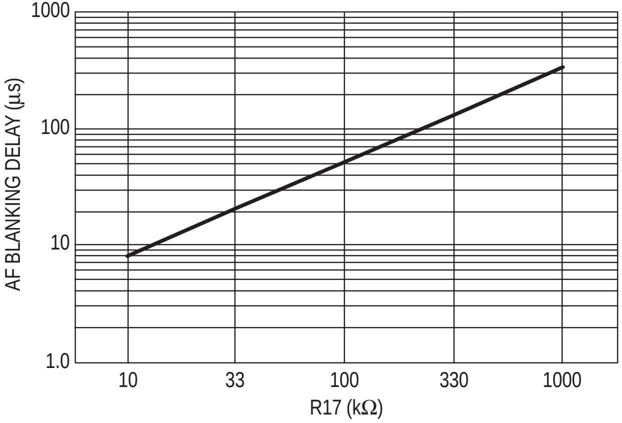


Figure 17. RF Blanking Time versus R15

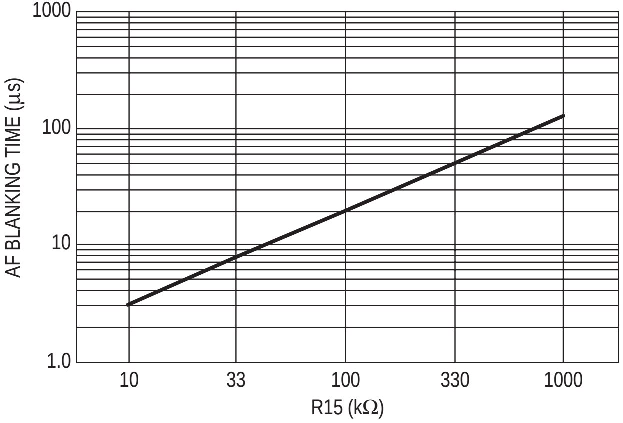

Figure 18. Audio Blanking Time versus R19

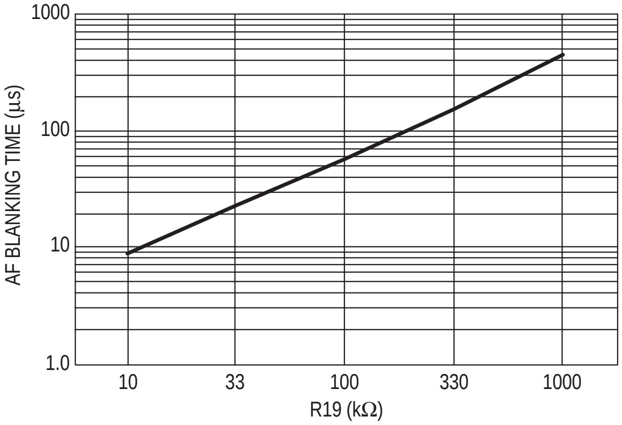

Figure 19. WB AGC Output Voltage (Pin 20) versus RF Input Level

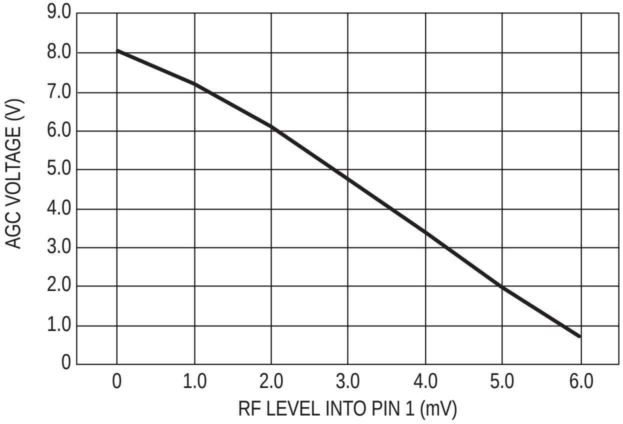

NOTE: This was measured by applying an RF signal through a capacitor directly to Pin 1. The input resistance is 15 k, so the desired threshold can be increased by adding a resistor in series with the input.

AMAX STEREO CHIPSET

The RF Module

In the early development phase of this AMAX Stereo Chipset, Motorola worked with TOKO America Inc. to develop an RF tuning module. Part number TMG522E was assigned and is available from TOKO now. This module provides the “tracked” tuning elements for the RF (T1 and T2 and associated capacitors and varicaps) and the VCO (T3 et al). Some radio designers may prefer to develop their own tuning system using discrete coils and components, but the TOKO approach offers good performance, compactness and ease of application. Motorola recommends that every designer use this approach at least for initial system development and evaluation.

As refinement of the application progressed, it was found that a modification of the TMG522E was needed which would reduce the amount of VCO leakage into the Mixer through the power supply connections. This modification is described below. Motorola will work with TOKO to develop a new part number incorporating this change. In the meantime, it is necessary that the user perform these simple changes, because the radio circuits throughout this data sheet assume this modified design.

Modifying the TMG522E

Referring to Figures 20 and 21, there are three simple steps to the modification:

1. Cut the thin copper trace from Pin 2 to Pin 5 as shown.
2. Cut the thin copper trace from Pin 8 to the bottom of the 120 Ω resistor. Removal of the resistor is optional.
3. Connect a wire from Pin 5 to the top of the 120 Ω resistor (or the upper pad for the resistor).

MOTOROLA

MC13028A

Advanced Wide Voltage IF and C-QUAM® AM Stereo Decoder

The MC13028A is a third generation C–QUAM stereo decoder targeted for use in low voltage, low cost AM/FM E.T.R. radio applications. Advanced features include a signal quality detector that analyzes signal strength, signal to noise ratio, and stereo pilot tone before switching to the stereo mode. A “blend function” much like FM stereo has been added to improve the transition from mono to stereo. The audio output level is adjustable to allow easy interface with a variety of AM/FM tuner chips. The external components have been minimized to keep the total system cost low.

- Adjustable Audio Output Level
- Stereo Blend Function
- Stereo Threshold Adjustment
- Operation from 2.2 V to 12 V Supply
- Precision Pilot Tone Detector
- Forced Mono Function
- Single Pinout VCO
- IF Amplifier with IF AGC Circuit
- VCO Shutdown Mode at Weak Signal Condition

The purchase of the Motorola C–QUAM® AM Stereo Decoder does not carry with such purchase any license by implication, estoppel or otherwise, under any patent rights of Motorola or others covering any combination of this decoder with other elements including use in a radio receiver. Upon application by an interested party, licenses are available from Motorola on its patents applicable to AM Stereo radio receivers.

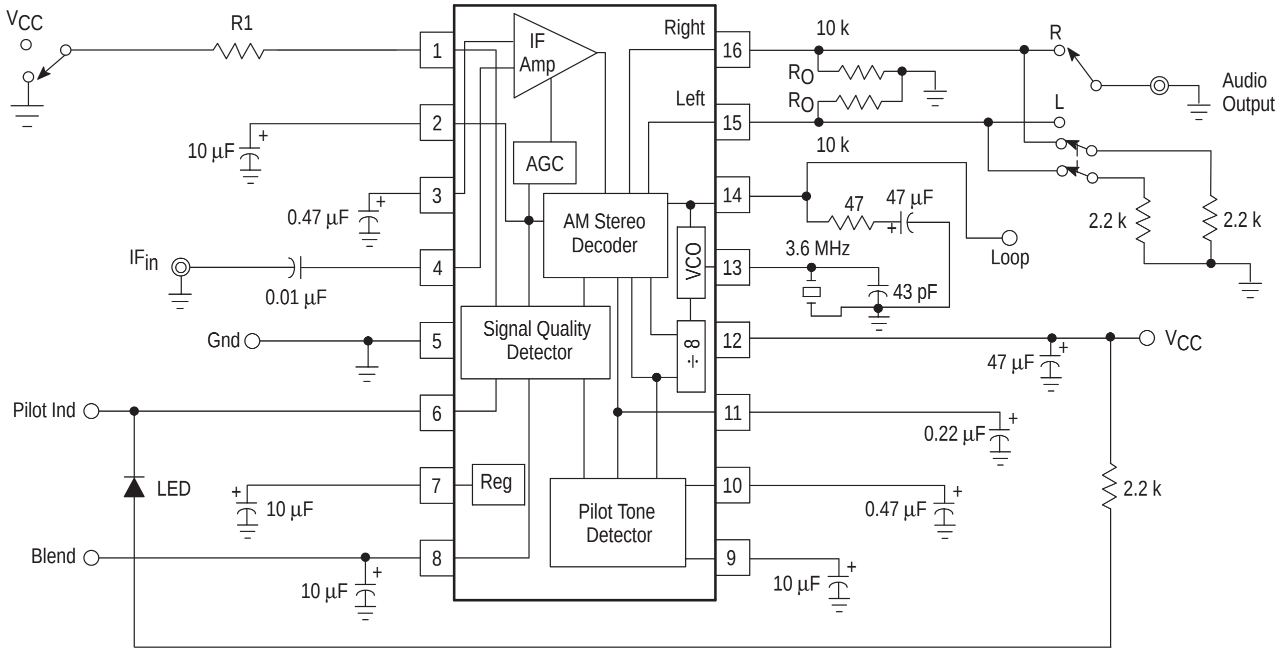
Standard Test Circuit



PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1	S_{TA}		**Stereo Threshold Adjustment Pin** The function of this circuit is to provide the freedom to achieve a desired value of incoming IF signal level which will cause full stereo operation of the decoder. The level can be determined by the value of R1, a resistor from Pin 1 that can be connected to either V_{CC} or to ground. This resistor may also be omitted in some designs (Pin 1 left open). The approximate dc level with the pin left open is 0.6 Vdc.
2	AGC_{cap}		**AGC Filter Bypass Capacitor** An electrolytic capacitor is used as a bypass filter and it sets the time constant for the AGC circuit action. The recommended capacitor value is 10 µF from Pin 2 to ground. The dc level at this pin varies as shown in the curve in Figure 13, AGC Voltage versus Input Level.
3	IF_{FBcap}		**IF Amplifier Feedback Capacitor** A capacitor which is specified to have a low ESR at 450 kHz is normally used at Pin 3. The value recommended for this capacitor is 0.47 µF from Pin 3 to ground. This component forms a low pass filter which has a corner frequency around 30 kHz.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
4	IF_{in}		**IF Amplifier Input** Pin 4 is the IF input pin. The typical input impedance at this pin is 10 k. The input should be ac coupled through a 0.01 µF capacitor.
5	Gnd		**Supply Ground** In the PCB layout, the ground pin should be connected to the chassis ground directly. This pin is the internal circuit ground and the silicon substrate ground.
6	S_{IND}		**Stereo Indicator Driver** This driver circuit is intended to light an LED or other indicator when the decoder receives the proper input signals and switches into the stereo mode. The maximum amount of current that the circuit can sink is 10 mA. A current limiting resistor is applied externally to control LED brightness versus total power supply current.
7	V_{Ref}		**Regulated Voltage, 1.0 V** An electrolytic capacitor used as a bypass filter is recommended from Pin 7 to ground. The capacitor value should be 10 µF.
8	CAP_{Blend}		**Blend Capacitor** The value of the capacitor on this pin will effect the time constant of the decoder blend function. The recommended value is 10 µF from Pin 8 to ground. The dc level at Pin 8 is internally generated in response to input signal level and signal quality. This pin is a key indicator of the operational state of the IC (see text Functional Description). It is recommended to discharge the blend capacitor externally when changing stations.
9	I_{Pilot}		**Pilot I Detector Output** The Pilot I Detector output requires a 10 µF electrolytic capacitor to ground. The value of this capacitor sets the pilot acquisition time. The dc level at Pin 9 is approximately 1.0 Vdc, unlocked, and 1.1 to 2.4 Vdc in the locked condition.

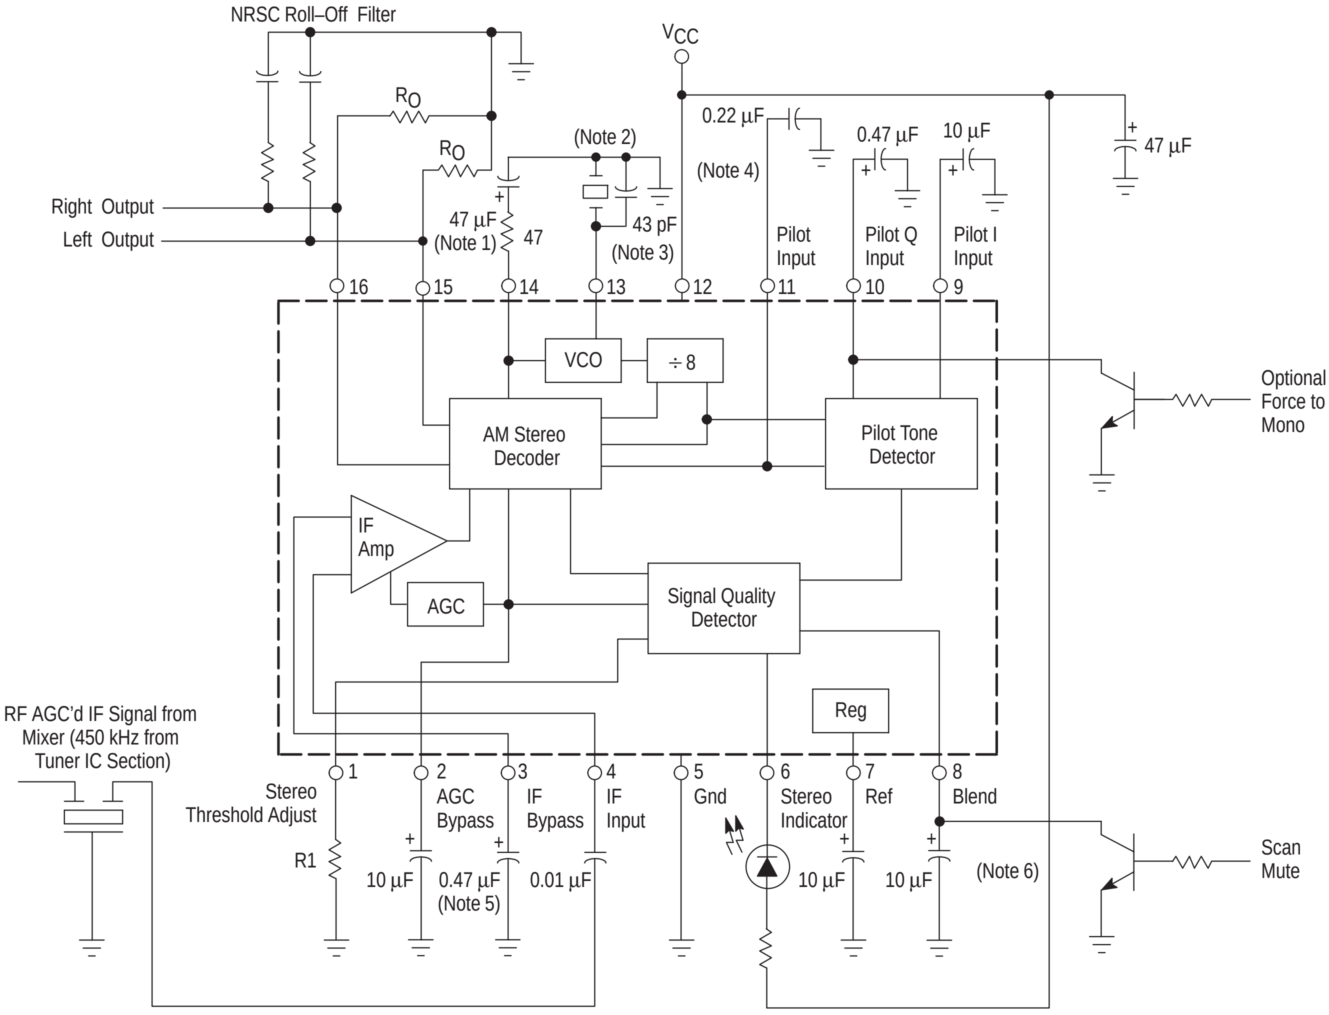
PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
10	Q_{Pilot}		**Pilot Q Detector Output** This pin is connected to the Pilot Q detector and requires a 0.47 µF capacitor to ground to filter the error line voltage at the PLL pilot tone detector. If the value of this capacitor is made too large, the decoder may be prevented from coming back into stereo after a signal drop out has been experienced in the field. The force to mono function is also accomplished at this pin by pulling the dc voltage level at the pin below 1.0 V.
11	$PILOT_{fil}$		**Pilot Signal Input** A capacitor to ground forms a filter for the pilot input signal. The recommended value of the capacitor is 0.22 µF. The dc level at Pin 11 is approximately 1.0 Vdc.
12	V_{CC}		**Supply Voltage (V_{CC})** The operating supply voltage range is from 1.8 Vdc to 12 Vdc.
13	OSC_{in}		**Oscillator Input** The oscillator pin requires a ceramic resonator and parallel capacitor connected to ground. The recommended source for the ceramic resonator is Murata, part number CSA 3.60MGF108. A 43 pF NPO capacitor is in parallel with the resonator. The dc level at Pin 13 is approximately 1.1 Vdc.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
14	$LOOP_{Filter}$		**Loop Filter** A capacitor which forms the loop filter is connected from Pin 14 to ground. The recommended value is 47 µF in series with 47 Ω. This capacitor should be of good construction quality so it will have a very low specification for leakage current in order to prevent stereo distortion. The 47 Ω resistor in series with the capacitor controls the PLL corner frequency response, keeping the response shape critically damped and not peaked up. The dc level at Pin 14 is approximately 0.6 Vdc in the locked condition.
15	$LEFT_{out}$		**Left Channel Audio Output** This is the left channel audio output pin from which the IC can provide 1.3 μA_{pp} drive current for each percent of mono modulation. A resistor to ground sets the level of the audio output. For example, *100%* (mono mod) x 1.3 μA_{pp} (IC drive per % mod) = 130 μA_{pp} flowing through the load resistor. (For a 2.2 k load, 286 mV_{pp} is then the output signal voltage.) When dealing with stereo signals, multiply the mod level by 2; i.e. *50%* (left only mod) x 2 (stereo factor) x 1.3 μA_{pp} (IC drive per % mod) = 130 μA_{pp} flowing through the load resistor.
16	$RIGHT_{out}$		**Right Channel Audio Output** This is the right channel audio output pin. A resistor to ground sets the level of the audio output. See the explanation under the Left Channel Audio Output description above.

Figure 1. Typical Circuit for E.T.R. Applications



NOTES:
1. The 47 µF capacitor is recommended to be a low leakage type capacitor. Leakage current due to this capacitor causes increase in stereo distortion and decreased separation performance.
2. The recommended source for this part is Murata Products. CSA3.60MGF108. The location of this part should be carefully considered during the layout of the decoder circuit. This part should not be near the audio signal paths, the 25 Hz pilot filter lines, or the V_{CC} high current lines, and the ceramic element ground line should be direct to the chassis ground lead in order to avoid any oscillator inter–modulation.
3. The 43 pF capacitor is recommended to be a NPO type ceramic part. Changing the value of this capacitor alters the lock range of the decoder PLL.
4. The tolerance on the value of the 0.22 µF capacitor should be within ±20% for the full design temperature range of operation. Any reduction in the value of this capacitor due to temperature excursions will reduce the pilot tone circuit sensitivity.
5. The 0.47 µF capacitor is recommended to be a low ESR type capacitor, (less than 1.5 Ω) in order to avoid increased audio output distortions under weak input signal conditions with higher modulation levels.
6. The scan/mute function is located on the Blend pin at Pin 8. To provide this function, Pin 8 should be pulled down below 0.3 V until the decoder and the synthesizer have both locked to a new station.

FUNCTIONAL DESCRIPTION

Introduction

The MC13028A is designed as a low voltage, low cost decoder for the C–QUAM AM Stereo technology and is completely compatible with existing monaural AM transmissions. The IC requires relatively few, inexpensive external parts to produce a full featured C–QUAM AM Stereo implementation. The layout is straightforward and should produce excellent stereo performance. This device performs the function of IF amplification, AGC, modulation detection, pilot tone detection, signal quality inspection, and left and right audio output matrix operation. The IC is targeted for use in portable and home AM Stereo radio applications.

A simple overview follows which traces the path of the input signal information to the MC13028A all the way to the audio output pins of the decoder IC.

From the appropriate pin of an AM IC, the IF amplifier circuit of the MC13028A receives its input at Pin 4 as a 450 kHz, typically modulated C–QUAM signal. The input signal level for stereo operation can vary from 47 dBμV to about 90 dBμV. A specific threshold level between these limits can be designed into a receiver by the choice of the resistor value for R1 connected to Pin 1. This IC design incorporates feedback in the IF circuit section which provides excellent dc balance in the IF amplifier. This balanced condition also guarantees excellent monophonic performance from the decoder. An IF feedback filter at Pin 3 is formed by a 0.47 μF low leakage capacitor. It is used to filter out the unwanted audio which is present on the IF amplifier feedback line at higher modulation levels under weak input RF signal conditions. Elimination of the unwanted signal helps to decrease the amount of distortion in the audio output of the stereo decoder under these particular input conditions. An AGC circuit controls the level of IF signal which is subsequently fed to the detector circuits. An AGC bypass capacitor is connected to Pin 2 and forms a single pole low pass filter. The value of this part also sets the time constant for the AGC circuit action.

The amplified C–QUAM IF signal is fed simultaneously to the envelope detector circuit, and to a C–QUAM converter circuit. The envelope detector provides the L+R (mono) signal output which is fed to the stereo matrix. In the converter circuit, the C–QUAM signal is restored to a Quam signal. This is accomplished by dividing the C–QUAM IF signal by the demodulated cos ϕ term. The cos ϕ term is derived from the phase modulated IF signal in an active feedback loop. Cosine ϕ is detected by comparing the envelope detector and the in–phase detector outputs in the high speed comparator/feedback loop. Cosine ϕ is extracted from the I detector output and is actively transferred through feedback to the output of the comparator. The output of the comparator is in turn fed to the control input of the divider, thus closing the feedback loop of the converter circuit. In this process, the cos ϕ term is removed from the divider IF output, thus allowing direct detection of the L–R by the quadrature detector. The audio outputs from both the envelope and the L–R detectors are first filtered to minimize the second harmonic of the IF signal. Then they are fed into a matrix circuit where the Left channel and the Right channel outputs can be extracted at Pins 15 and 16. (The outputs from the I and Q detectors are also filtered similarly.) At this time, a stereo indicator driver circuit, which can sink up to 10 mA, is also enabled. The stereo output will occur if the input IF signal is: larger than the stereo threshold level, not too noisy, and if a proper pilot tone is present. If these three conditions are not met, the blend circuit will begin to force monaural operation at that time.

A blend circuit is included in this design because conditions occur during field use that can cause input signal strength fluctuation, strong unwanted co–channel or power line interference, and/or multi–path or re–radiation. When these aberrant conditions occur, rapid switching between stereo and mono might occur, or the stereo quality might be degraded enough to sound displeasing. Since these conditions could be annoying to the normal listener, the stereo information is blended towards a monaural output. This circuit action creates a condition for listening where these aberrant effects are better tolerated by the consumer.

Intentional mono operation is a feature sometimes required in receiver designs. There are several ways in which to accomplish this feat. First, a resistor from Pin 10 to ground can be switched into the circuit. A value of 1.0 k is adequate as is shown in the schematic in Figure 18. A second method to force the decoder into mono is simply to shunt Pin 10 to ground through an NPN transistor (collector to Pin 10, emitter to ground), where the base lead is held electrically “high” to initiate the action.

A third method to force a mono condition upon the decoder is to shunt Pin 8 of the decoder to ground through an NPN transistor as described above. Effectively, this operation discharges the blend capacitor (10 μF), and the blend function takes over internally forcing the decoder into mono. This third method does not necessarily require extra specific parts for the forced mono function as the first two examples do. The reason for this is that most electronically tuned receiver designs require an audio muting function during turn on/turn off, tuning/scanning, or band switching (FM to AM). When the muting function is designed into an AM Stereo receiver, it also should include a blend capacitor reset (discharge) function which is accomplished in this case by the use of an NPN transistor shunting Pin 8 to ground, (thus making the addition of a forced mono function almost “free”). The purpose of the blend reset during muting is to re–initialize the decoder back into the “fast lock” mode from which stereo operation can be attained much quicker after any of the interruptive activities mentioned earlier, (i.e. turn on, tuning, etc.).

The VCO in this IC is a phase shift oscillator type design that operates with a ceramic resonator at eight times the IF frequency, or 3.60 MHz. With IF input levels below the stereo threshold level, the oscillator is not operational. This feature helps to eliminate audio tweets under low level, noisy input conditions.

The phase locked loop (PLL) in the MC13028A is locked to the L–R signal. This insures good stereo distortion performance at the higher levels of left only or right only modulations. Under normal operating conditions, the PLL remains locked because of the current flow capability of the loop driver circuit. This high gain, high impedance circuit performs optimally when the current flow is balanced. The balanced condition is enhanced by the loop driver filter circuit connected between Pin 14 and ground. The filter circuit consists of a 47 Ω resistor in series with a 47 μF capacitor. The 47 Ω resistor is to set the Fast Lock rate. It is recommended that the capacitor be a very low leakage type electrolytic, or a tantalum composition part because any significant amount of leakage current flowing through the capacitor will unbalance the loop driver circuit and result in less than optimum stereo performance, see Figures 10 and 11.

The pilot tone detector circuit is fed internally from the Q detector output signal. The circuit input employs a low pass filter at Pin 11 that is designed to prevent the pilot tone detector input from being overloaded by higher levels of L–R modulation. The filter is formed by a 0.22 μF capacitor and the input impedance of the first amplifier. A pilot I detector circuit employs a capacitor to ground at Pin 9 to operate in conjunction with an internal resistor to create an RC integration time. The value of the capacitor determines the amount of time required to produce a stereo indication. This amount must include the time it takes to check for the presence of detector falsing due to noise or interference, station retuning by the customer, and pilot dropout in the presence of heavy interference. The pilot Q detector utilizes a filter on its pilot tone PLL error line at Pin 10. This capacitor to ground (usually 0.47 μF) is present to filter any low frequency L–R information that may be present on the error line. If the value of this capacitor is allowed to be too small, L–R modulation ripple on the error line may get large enough to cause stereo dropout. If the capacitor value is made too large, the pilot tone may be prevented from being reacquired if it is somehow lost due to fluctuating field conditions.

A 1.0 V reference level is created internally from the V_{CC} source to the IC. This regulated line is used extensively by circuits throughout the MC13028A design. An electrolytic capacitor from Pin 7 to ground is used as a filter for the reference voltage.

DISCUSSION OF GRAPHS AND FIGURES

If the general recommendations put forth in this application guide are followed, excellent stereo performance should result.

The curves in Figures 2 through 7 depict the separation and the distortion performance in stereo for 30%, 50%, and 65% single channel modulations respectively. The data for these figures were collected under the conditions of V_{CC} = 8.0 V and R_O = 10 k in both the left and the right channels as applied to the application circuit of Figure 1. A very precise laboratory generator was used to produce the AM Stereo test signal of 450 kHz at 70 dBμV fed to Pin 4. An NRSC post detection filter was not present at the time of these measurements. The audio separation shows an average performance at 30% and 50% modulations of –45 dB in the frequency range of 2.0 kHz to 5.0 kHz. The corresponding audio distortions under these conditions are about 0.28% at 30% modulation, and about 0.41% at 50% modulation.

Figure 6 shows that the typical separation at 65% modulation in the 2.0 kHz to 5.0 kHz region is about –37 dB, and the corresponding audio distortion shown in Figure 7 is about 1.0%. The performance level of these sinusoidal signals is somewhat less than those discussed in the previous paragraph due to the internal operation of the clamping circuits. In the field, the transmitters at AM Stereo radio stations are not usually permitted to modulate single channel levels past 70%. Therefore these conditions do not occur very often during normal broadcast material.

The roll–off at both the low and high frequencies of the 30% single channel driven responses is due to the fact that a post detection bandpass filter of 60 Hz to 10 kHz was used in the measurement of the data, while a post detection filter of 2.0 Hz to 20 kHz was used for the collection of data in the 50% and 65% modulation examples. The tighter bandwidth was used while collecting the performance data at 30% modulation levels in order to assure that the distortion measurement was indicative of the true distortion products measured near the noise floor and thus not encumbered by residual noise and hum levels which would erroneously add to the magnitude of the harmonic distortion data. Note in Figure 8 the traces of noise response for the four different bandwidths of post detection filtering. It can be seen that the noise floors improve steadily with increasing levels of incoming 450 kHz as the value of the lower corner frequency of the filter is increased. Data for the stereo noise floors was collected with the decoder in the forced stereo mode.

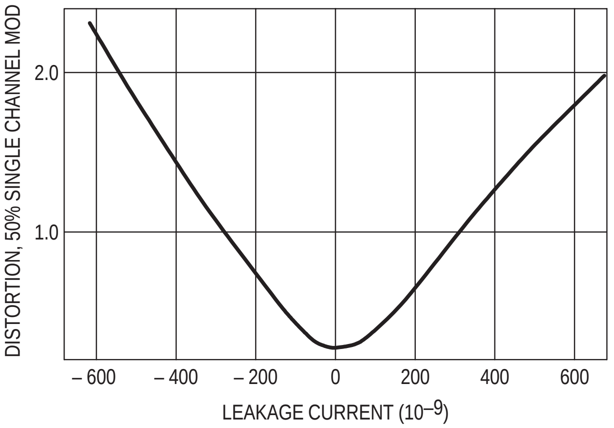

Figure 12. Low Frequency Corner of PLL Response

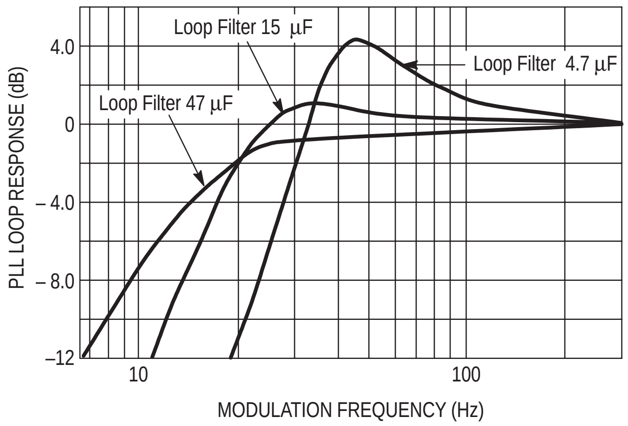

Figure 13. AGC Voltage versus Input Signal Level

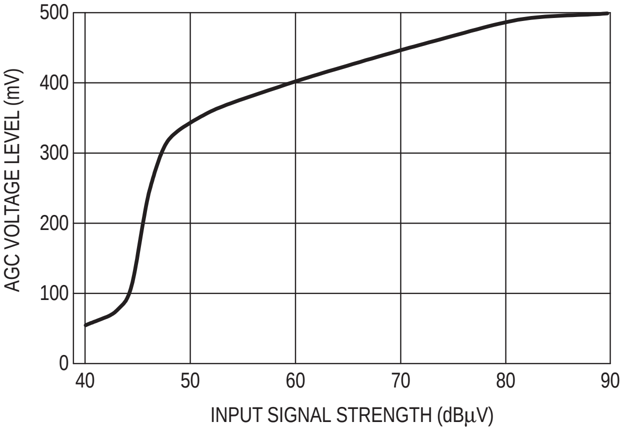

Figure 9 presents more detailed information with respect to the value of resistor R1 at Pin 1 versus the desired incoming signal level for stereo threshold.

Figures 10 and 11, discussed briefly in the Pin Function Description Section, show the importance of using a quality component at Pin 14 to ground. It can be seen that an electrolytic capacitor leakage current of 600 nA can unbalance the PLL to the point where stereo performance may degrade to only 25 dB of separation with a corresponding 2.0% distortion at 50% modulation levels.

The value of the capacitor connected to Pin 14 (47 µF) is also a factor in the determination of the low frequency corner of the PLL circuit response. Three traces of PLL response appear in Figure 12 where they have been plotted for three different values of loop filter capacitor. The recommended value of 47 µF provides the best response shape in this particular circuit set–up where a Murata Products CSA3.60MGF108 part is used.

Figure 13 presents the response of the AGC voltage versus decoder input signal level. This is a typical response when the IC is used as shown in the application schematic of Figure 1. The trace begins approximately at the point of decoder sensitivity, and rises rapidly until reaching the area of stereo sensitivity, approximately 50 dBµV. Thereafter, the circuit responds in a linear fashion for the next 30 dB of input signal increase.

Figures 14 through 17 inclusively depict the V_{CC} ripple rejection performance for the MC13028A under mono and stereo conditions for nominal and for low values of V_{CC}. It should be noted that this data was collected without any V_{CC} filtering. As one might expect, the ripple rejection is better in mono than in stereo. When the decoder operates in stereo, the VCO is functional, thus the decoder becomes more susceptible to audio ripple on the V_{CC} line. Under normal operating conditions, with the recommended value of 47 µF at Pin 12 and 10 µF at Pin 7, a V_{CC} ripple reading will be virtually the same as measuring the noise floor of the IC.

AM STEREO TUNER / FM STEREO IF

Description of Application

This application combines a Sanyo LA1832M with the Motorola MC13028A AM Stereo decoder IC. The LA1832 provides an FM IF, FM multiplex detection, AM tuning, and the AM IF functions. The MC13028A provides the AM Stereo detection as well as Left and Right audio outputs. An MC145151 synthesizer provides the frequency control of the local oscillator contained within the LA1832. Frequency selection is by means of a switch array attached to the synthesizer. The application circuit is shown in Figure 18.

Circuit Board Description

The copper side layout and the component locations are shown in Figure 19. The view is from the plating side of the board, with the components shown in hidden view. Several jumper wires are placed on the component side of the board to complete the circuit. Posts are provided for electrical connections to the circuit. The circuit board has been scaled to fit the page, however, the dimensions provide the true size.

Circuit Description

The Sanyo data sheet for the LA1832 should be consulted for an understanding of the FM detection and multiplex decoding.

Special Parts

The following information provides circuit function, part number, and the manufacturer’s name for special parts identified by their schematic symbol. Where the part is not limited to a single source, a description sufficient to select a part is given.

U1	IC – AM Stereo Decoder MC13028AD by Motorola
U2	IC – AM/FM IF and Multiplex Tuner LA1832M by Sanyo
U3	IC – Frequency Synthesizer MC145151DW2 by Motorola
T1	AM IF Coil A7NRES–11148N by TOKO
F1	AM IF Ceramic Filter SFG450F by Murata
F2	FM IF Detector Resonator CDA10.7MG46A by Murata
F3	FM Multiplex Decoder Resonator CSB456F15 by Murata
F4	AM Tuner Block BL–70 by Korin Giken

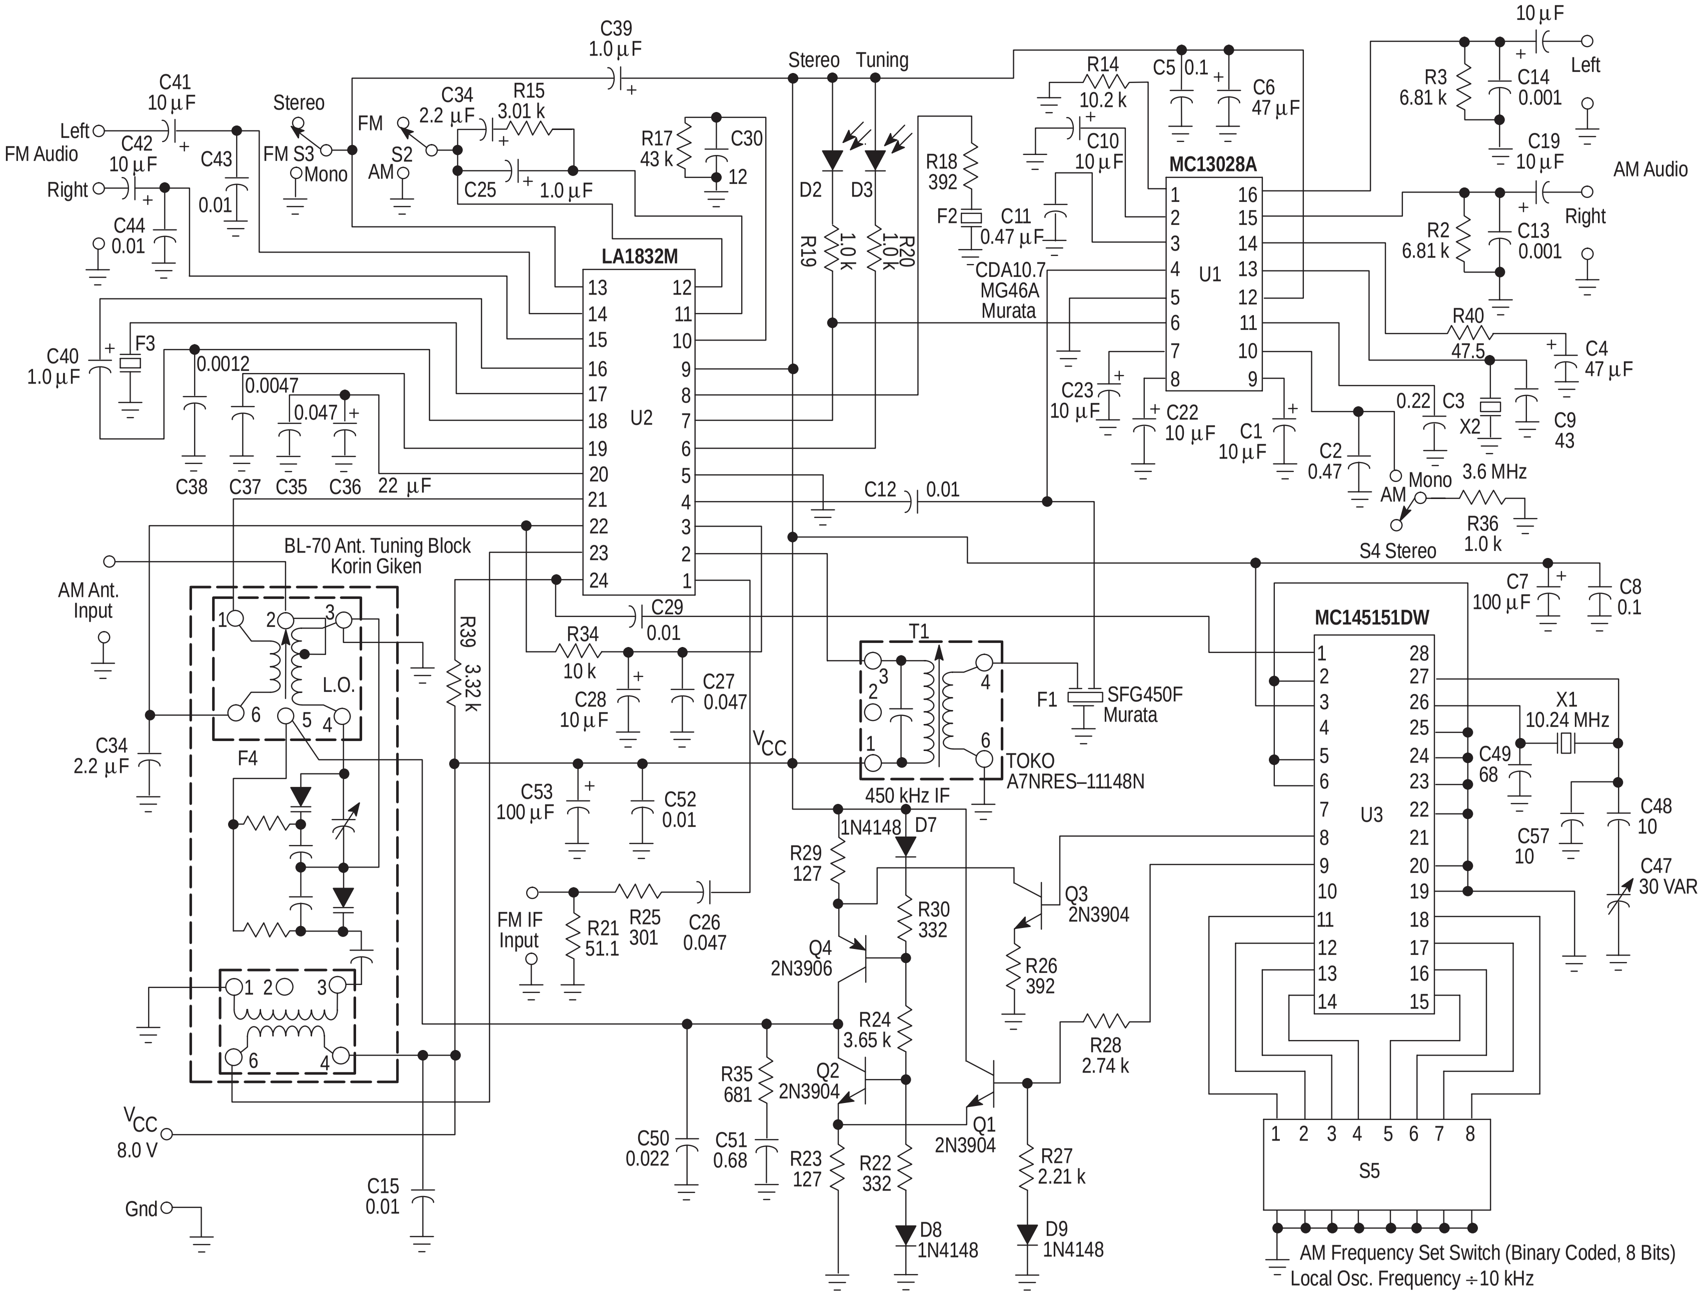

Figure 19. MC13028A Decoder IC Application Circuit Board

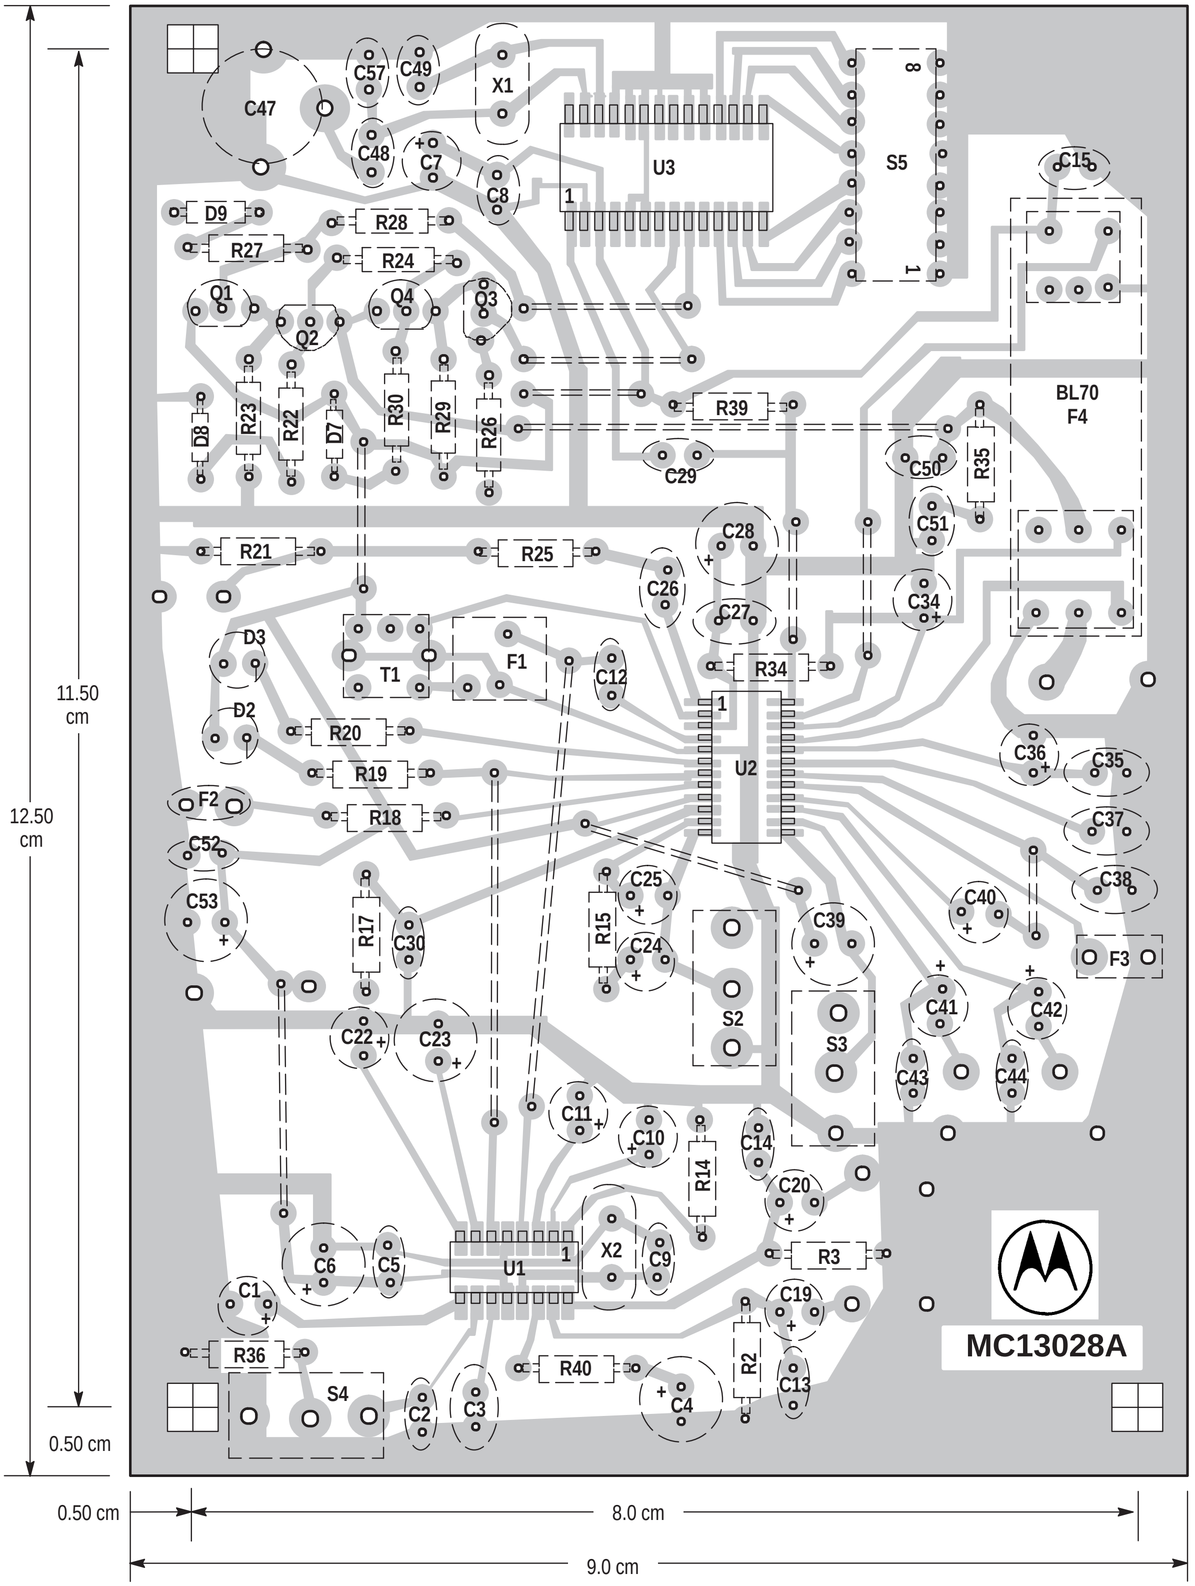


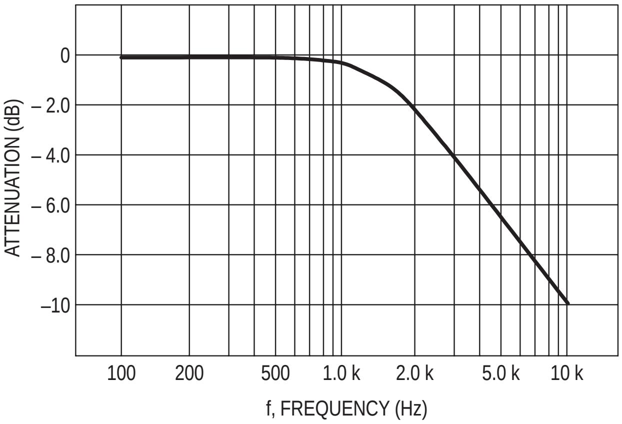
The LA1832 tuner IC (U2) is set for AM operation by switch S2 connecting Pin 12 to ground. An AM Stereo signal source is applied to Pin 2 of the RF coil contained within the BL–70 tuning block. That coil applies the signal to Pin 21 of U2. The L.O. coil is connected from Pin 23 to V_{CC}. The secondary is tuned by a varactor which is controlled by a dc voltage output from the synthesizer circuit. The reactance of this oscillator tank is coupled back to Pin 23. It is through this reactance that the frequency of the L.O. is determined. A buffered output from the L.O. emerges at Pin 24. This signal is routed to Pin 1 of the synthesizer (U3), thus completing the frequency control loop.

The mixer output at Pin 2 is applied to the IF coil T1. Coil T1 provides the correct impedance to drive the ceramic bandpass filter F1. The IF signal returns to U2 through Pin 4, and also to the input, Pin 4 of the AM Stereo decoder (U1). The ceramic filter F1 is designed to operate into a load resistance of 2.0 kΩ. This load is provided at Pin 4 of U2.

The stereo outputs exit from Pins 15 and 16 of U1. The design amplitudes of the audio outputs will vary according to the values used for the resistors to ground at Pins 15 and 16 of the decoder, (labeled R_O in the Electrical Characteristics Table and the Test Circuit on page 2 and 3, and in Figure 1, and called R2 and R3 in Figure 18). While the values chosen for R_O are left to the discretion of the designer, the numbers chosen in this data sheet are reflective of those required to set the general industry standard levels of audio outputs in receiver designs.

Pins 15 and 16 are also good locations for the insertion of simple RC filters that are used to comply with the United States NRSC requirement for the shape of the overall receiver audio response. The following curve, Figure 20, shows the response of this U.S. standard.

Figure 20. NRSC De–Emphasis Curve for the United States



There are many design factors that affect the shape of the receiver response, and they must all be considered when trying to approximate the NRSC de–emphasis response. The mixer output transformer (IF coil, T1), and ceramic filter probably have the greatest contribution to the frequency response. The ceramic filter can be tailored from its rated response by the choice of transformer impedance and bandwidth. When designing an overall audio response shape, the response of the speakers or earphones should also be considered.

Component Values.

The Pin Function Description table gives specific information on the choice of components to be used at each pin of U1. A similar section in the Sanyo LA1832 data sheet should be consulted as to the components to be used with U2.

Tuning

The frequency to which the test circuit will tune is set by the eight binary switches contained in the S5 assembly, numbered from 1 to 8. Number 1 connects to Pin 11 of U3 and number 8 connects to Pin 18. The other switches connect to the pins in between and in order. Each individual switch is a SPST type.

To tune to a specific RF frequency, a computation must be made in order to ascertain the divide ratio to input to the synthesizer via the switch array. The divide ratio is simply the eight digit binary equivalent number for the local oscillator frequency divided by 10 kHz. The local oscillator frequency is the desired RF frequency plus 450 kHz, the IF frequency. Any local oscillator value within the AM band can be represented by a binary number. Each binary bit represents a switch setting where a “1” is an open switch and a “0” is a closed switch. The most significant bit represents switch 8 which is connected to Pin 18.

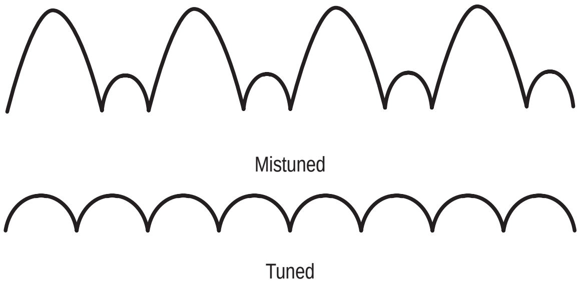
To illustrate, consider the setting for an input frequency of 1070 kHz. (This frequency was used to test the circuit board as described further on.) The local oscillator frequency is 1070 kHz plus 450 kHz which equals 1520 kHz. Dividing by 10 kHz yields the number 152. The binary number for 152 is 10011000. Thus the switches are set to:

Switch	Position	Number
8	Open	1
7	Closed	0
6	Closed	0
5	Open	1
4	Open	1
3	Closed	0
2	Closed	0
1	Closed	0

Circuit Adjustments

The FM circuit requires no adjustment. The AM L.O. must be able to tune from 980 to 2150 kHz to cover the broadcast range. Adjust the core of the L.O. coil if needed in order to be able to cover this range. The AM RF coil and trimmer can be adjusted for best signal after connection to the loop antenna. The coil is adjusted near the low end of the band, and the trimmer is adjusted at the top of the band. The IF coil, T1, is first adjusted for maximum signal out of the filter, F1. This is a “coarse” adjustment. The final “fine tune” adjustment occurs after the following conditions are met. From an AM Stereo generator with the pilot tone off, feed the decoder an input signal of approximately 70 dBμV that is modulated with an 80% L–R audio signal at 3.0 kHz. While monitoring either the left or the right output from the decoder on an oscilloscope, precisely fine tune the IF coil for a minimum residual signal, see the following diagram. If there is no sideband tilt in the system, this adjustment should hold for both channels. Otherwise, the best compromise adjustment for both channels should be used.

Figure 21. Decoder Signal Output for Mistuned and Tuned Condition with Input Signal of 80% L–R at 3.0 kHz



AM Circuit Test

The connections for test are as shown in Figure 22. A 50 Ω resistor is placed on the AM antenna input. The AM Stereo generator is connected to the AM antenna input. Measurements of audio level in mono mode are made with an audio voltmeter connected through a FET probe (pilot signal “off”). Measurements of audio level and distortion in stereo mode (pilot signal “on”) are made using a pilot rejection filter ahead of the distortion analyzer or the audio meter. The pilot rejection filter has a rejection ratio that should exceed 20 to 25 dB. Typical data is shown in Figures 23–26. Figures 23 and 24 were read on the left channel in mono mode. Figures 25–26 were in stereo mode.

Advance Information

Advanced Medium Voltage IF and C-QUAM® AM Stereo Decoder with FM Amplifier and AM/FM Internal Switch

C–QUAM AM STEREO ADVANCED MEDIUM VOLTAGE IF AND DECODER FOR E.T.R. RADIOS

The MC13029A is a third generation C–QUAM stereo decoder targeted for use in medium voltage, CD/Cassette, Mini–Component, and Hi–Fi AM/FM Electronically Tuned radio applications. Advanced features include a signal quality detector that analyzes signal strength, signal to noise ratio, and stereo pilot tone before switching to the stereo mode. A “blend function” has been added to improve the transition from both mono to stereo and stereo to mono. The audio output level is adjustable to allow easy interface with a variety of AM/FM tuner chips. The IC further includes an AM/FM switch, an audio mute and internal high pass filtering on AM. The external components have been minimized to keep the total system cost low.

- Operation From 4.0 to 12 V Supply
- IF Amplifier with IF AGC Circuit
- Single Pin–Out, Temperature Compensated VCO
- VCO Shut Down Mode at Weak Signal Condition
- Precision Pilot Tone Detector
- Stereo Blend Function
- Forced Mono Function
- Adjustable Audio Output Level
- AM/FM Switch
- Separate AM De–Emphasis
- Mute Function
- Internal AM High Pass Filters

PIN FUNCTION DESCRIPTION

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
1	AM/FM		**AM/FM Mode Switch** The dc level applied to this pin will determine whether the AM or FM audio is switched to output Pins 16 and 17. A voltage greater than 1.2 V will cause the FM audio to be output.
2	AGC_{cap}		**AGC Filter Bypass Capacitor** An electrolytic capacitor is used as a bypass filter and it sets the time constant for the AGC circuit action. The recommended capacitor value is 10 μF from Pin 2 to ground. The dc level at this pin varies as shown in the curve in Figure 13. AGC Voltage versus Input Level.
3	IF_{FBcap}		**IF Amplifier Feedback Capacitor** A capacitor which is specified to have a low ESR at 450 kHz is normally used at Pin 3. The value recommended for this capacitor is 0.47 μF from Pin 3 to ground. This component forms a low pass filter which has a corner frequency around 30 kHz.
4	IF_{in}		**IF Amplifier Input** Pin 4 is the IF input pin. The typical input impedance at this pin is 10 k. The input should be ac coupled through a 0.01 μF capacitor.
5	Gnd		**Supply Ground** In the PCB layout, the ground pin should be connected to the chassis ground directly. This pin is the internal circuit ground and the silicon substrate ground.
6	S_{IND}		**Stereo Indicator Driver** This driver circuit is intended to light an LED or other indicator when the decoder receives the proper input signals and switches into the stereo mode. The maximum amount of current that the circuit can sink is 10 mA. A current limiting resistor is applied externally to control LED brightness versus total power supply current.

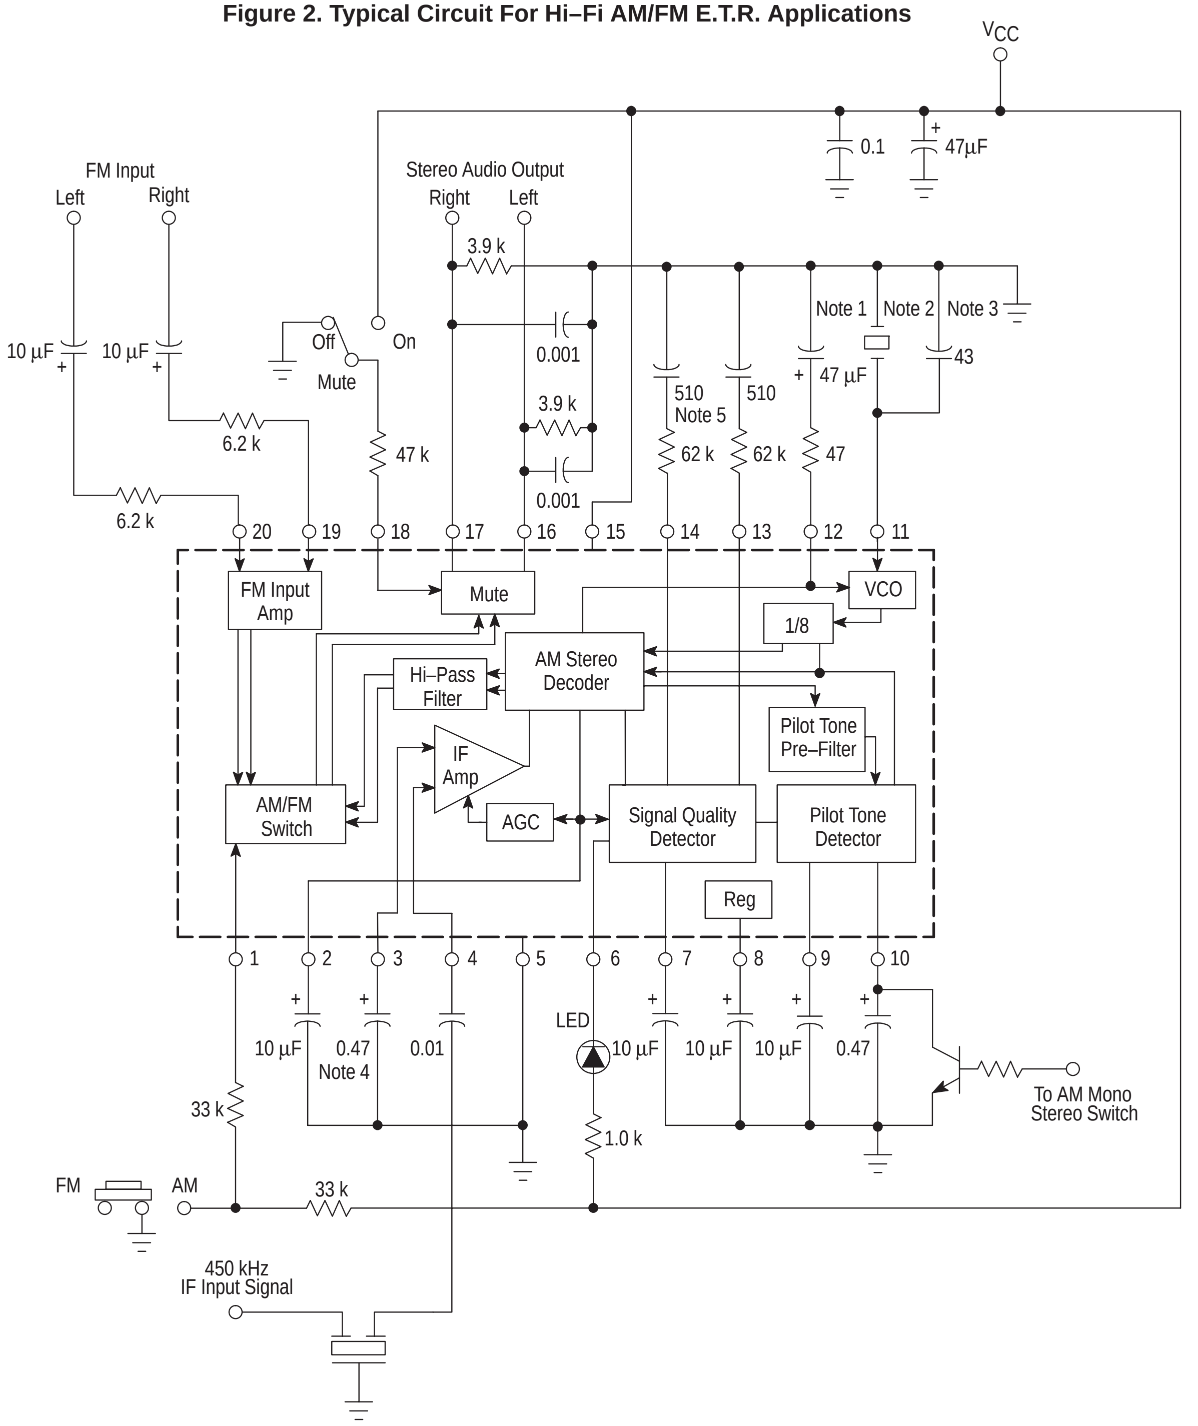
PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
7	$\text{CAP}_{\text{Blend}}$		**Blend Capacitor** The value of the capacitor on this pin will effect the time constant of the decoder blend function. The recommended value is 10 µF from Pin 7 to ground. The dc level at Pin 7 is internally generated in response to input signal level and signal quality. This pin is a key indicator of the operational state of the IC (see text Functional Description). It is recommended to discharge the Blend Capacitor externally when changing stations.
8	V_{ref}		**Regulated Voltage, 1.0 V** An electrolytic capacitor used as a bypass filter is recommended from Pin 8 to ground. The capacitor value should be 10 µF.
9	I_{Pilot}		**Pilot I Detector Output** The Pilot I Detector Output requires a 10 µF electrolytic capacitor to ground. The value of this capacitor sets the pilot acquisition time. The dc level at Pin 9 is approximately 1.0 Vdc, unlocked, and 1.1 to 2.4 Vdc in the locked condition.
10	Q_{Pilot}		**Pilot Q Detector Output** This pin is connected to the Pilot Q Detector and requires a 0.47 µF capacitor to ground to filter the error line voltage at the PLL pilot tone detector. If the value of this capacitor is made too large, the decoder may be prevented from coming back into stereo after a signal dropout has been experienced in the field. The force to mono function is also accomplished at this pin by pulling the dc voltage level at the pin below 1.0 V.
11	OSC_{in}		**Oscillator Input** The Oscillator pin requires a ceramic resonator and parallel capacitor connected to ground. The recommended source for the ceramic resonator is Murata, part number CSA 3.60MGF108. A 43 pF NPO capacitor is in parallel with the resonator. The dc level at Pin 11 is approximately 1.1 Vdc.
12	$\text{LOOP}_{\text{Filter}}$		**Loop Filter** A capacitor which forms the Loop Filter is connected from Pin 12 to ground. The recommended value is 47 µF in series with 47 Ω. This capacitor should be of good construction quality so it will have a very low specification for leakage current in order to prevent stereo distortion. The 47 Ω resistor in series with the capacitor controls fast lock rate. The dc level at Pin 12 is approximately 0.6 Vdc in the locked condition.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Internal Equivalent Circuit	Description/External Circuit Requirements
13 14	DE–L DE–R		**AM De–Emphasis, Left Channel/Right Channel** An RC network attached at this pin can be used to add de–emphasis to the AM tone response. The AM tone response is primarily shaped by the IF filter. Additional roll–off may be applied here.
15	V_{CC}		**Supply Voltage (V_{CC})** The operating supply voltage range is from 4.0 Vdc to 12 Vdc.
16 17	LEFT_{out} $\text{RIGHT}_{\text{out}}$		**Audio Output** Output is approximately 1.3 μA_{pp} drive current for each percent of mono modulation. A resistor to ground sets the voltage level of the audio output.
18	Mute		**Mute Input** A dc voltage exceeding 1.5 V applied to this pin will cause a shutting down of the left and right channel outputs at Pins 16 and 17.
19	FM–R		**FM Audio Right Channel Input** The audio output from the FM detector is input at this pin. The dc level applied at Pin 1, the AM/FM Mode Switch, then determines whether this audio, or that from the AM channel will be output at Pin 17. An external series resistor between this pin and the FM detector is used to set the FM audio levels at the output Pin 17.
20	FM–L		**FM Audio Left Channel Input** The audio output from the FM detector is input at this pin. The dc level applied at Pin 1, the AM/FM Mode Switch, then determines whether this audio or that from the AM channel will be output at Pin 16. An external series resistor, between this pin and the FM detector, is used to set the FM audio levels at the output Pin 16.

Figure 2. Typical Circuit For Hi–Fi AM/FM E.T.R. Applications



NOTES:
1. This part is recommended to be a low leakage type capacitor. Leakage current due to this capacitor causes increase in stereo distortion and poor separation performance.
2. The recommended source for this part is Murata Products, CSA3.60MGF108. The location of this part should be carefully considered during the layout of the decoder circuit. This part should not be near the audio signal paths, the 25 Hz pilot filter lines, or the V_{CC} high current lines, and the ceramic element ground line should be direct to the chassis ground lead in order to avoid any oscillator inter–modulation.
3. This capacitor is recommended to be an NPO type ceramic part. Changing the value of this capacitor alters the lock range of the decoder PLL.
4. This part is recommended to be a low ESR type capacitor, (less than 1.5 Ω) in order to avoid increased audio output distortions under weak input signal conditions with higher modulation levels.
5. Component values for this stage of the NRSC filter will vary from receiver manufacturer to manufacturer due to the additive nature of the particular response slopes of the frequency selective parts, (RF and IF coils, and the ceramic IF filter) within a radio design. Since these responses may vary somewhat in each custom design, the filters at Pins 13 and 14 are included to provide any remaining response roll–off that might be necessary to comply with the overall NRSC frequency standard.

FUNCTIONAL DESCRIPTION

Introduction

The MC13029A is designed as a medium voltage decoder for the C–QUAM AM Stereo technology and is completely compatible with existing monaural AM transmissions. The IC requires relatively few, inexpensive external parts to produce a multi–featured C–QUAM AM Stereo implementation. The layout is straightforward and should produce excellent stereo performance results. This device performs the function of IF amplification, AGC, modulation detection, pilot tone detection, signal quality inspection, blend, left and right channel FM input amplification, muting, AM and FM switching function, and amplified left and right audio output levels which are adjustable. The IC is targeted for use in CD/Radio/Cassette, Mini–Component, and Hi–Fi AM/FM E.T.R. AM Stereo radio applications.

From the output of a ceramic IF filter and through a coupling capacitor, the IF amplifier circuit of the MC13029A receives its input at Pin 4 as a 450 kHz, typically modulated C–QUAM signal. The input signal level for stereo operation can vary from 50 dBμV to about 90 dBμV. This IC design incorporates feedback in the IF circuit section which provides excellent dc balance in the IF amplifier. This balanced condition also guarantees excellent monophonic performance from the decoder. An IF feedback filter at Pin 3 is formed by a 0.47 μF, low leakage, low ESR capacitor. It is used to filter out the 450 kHz signal which is present on the IF amplifier feedback line. An AGC circuit controls the level of IF signal which is subsequently fed to the detector circuits. An AGC bypass capacitor is connected to Pin 2 and forms a single pole, low pass filter. The value of this part also sets the time constant for the AGC circuit action.

The amplified C–QUAM IF signal is fed simultaneously to the envelope detector circuit, and to a C–QUAM converter circuit. The envelope detector provides the L+R (mono) signal output which is fed to the stereo matrix. In the converter circuit, the C–QUAM signal is changed into a Quam signal when it is divided by the cos ϕ term. The Quam IF signal is then fed into the I detector, the L–R detector, and the Q detector circuits. The outputs of the Envelope detector and the I detector circuits feed back into a comparator circuit which looks at both signals and uses the differences to create the cos ϕ signal. The Quam IF signal fed to the L–R and the Q detectors is multiplied by a 450 kHz signal that is phased 90° from the one in the I detector circuit. This quadrature relationship is necessary in order to detect the L–R (or stereo) audio information from the Quam signal. The audio outputs from both the Envelope and the L–R detectors are first filtered to minimize the harmonics of the IF signal that are created in the mixing process. (The outputs from the I and Q detectors are also filtered similarly.) Then they are fed into a matrix circuit where the Left channel and the Right channel outputs are extracted and fed into a high pass filter block. Here the audio signals are conditioned so they can be fed to an output amplifier which, if left unmuted, delivers the left and the right output at Pins 16 and 17. At this time, a stereo output will occur if the input IF signal is: a.) larger than the stereo threshold level, b.) not too noisy, and c.) a proper pilot tone is present. At Pin 6, the stereo indicator driver circuit, which can sink up to 10 mA, is also enabled.

After turn on or tune in, if the input signal level threshold for stereo operation is not exceeded, or if the incoming signal is too noisy, the blend circuit, at Pin 7, (even in the presence of a pilot signal) will hold the decoder in the monaural mode. A blend circuit is included in this design because of the effects of conditions which occur during field use that can cause input signal strength fluctuation, strong unwanted co–channel or power line interference, and/or multi–path or re–radiation. When these aberrant conditions occur, rapid switching between stereo and mono might occur, or the stereo quality might be degraded. Since these effects could be annoying to the listener, the stereo information is blended towards a monaural output. This creates a condition for listening where the aberrant effects are more tolerable.

Intentional mono operation is a feature sometimes required in receiver designs. There are several ways in which to accomplish this. First, a 10 k resistor from Pin 10 to ground can be switched into the circuit, as is shown in Figure 18. A second method is to shunt Pin 10 to ground through an NPN transistor as shown in Figure 2.

A third method to force a mono condition on the decoder is to shunt Pin 7 of the decoder to ground through an NPN transistor. This discharges the blend capacitor (10 μF), and the blend function internally forces the decoder into mono. This third method does not necessarily require extra parts as most electronically tuned receiver designs require an audio muting function during turn on/turn off, tuning/scanning, or band switching (FM to AM). When the muting function is designed into an AM Stereo receiver, it also should include a blend capacitor reset (discharge) function. The purpose of the blend reset during muting is to re–initialize the decoder back into the “fast lock” mode from which stereo operation can be attained much quicker after any of the interruptive activities mentioned earlier, (i.e. turn on, tuning, etc.).

The VCO in this IC is a phase shift oscillator type that operates with a ceramic resonator at eight times the IF frequency, or 3.60 MHz. With IF input levels below the stereo threshold level, the oscillator is not operational. This feature helps to eliminate audio tweets under low level, noisy input conditions.

The phase locked loop (PLL) in the MC13029A is locked to the L–R signal. This insures good stereo distortion performance at the higher levels of Left only or Right only modulations. Under normal operating conditions, the PLL remains locked because of the current capability of the loop driver circuit. This high gain, high impedance circuit is filtered by a 47 Ω resistor in series with a 47 μF capacitor from Pin 12 to ground. It is recommended that the capacitor be a very low leakage type electrolytic (less than 200 μA), or a tantalum part. Any significant leakage through the capacitor will unbalance the loop driver circuit and result in less than optimum stereo performance, see Figures 10 and 11.

The pilot tone detector circuit is fed internally by a signal from the Q detector output and is filtered by an internal, 50 Hz low pass pilot pre–filter. This filter is designed to prevent the pilot tone detector input from being overloaded by higher levels of L–R audio modulation. A pilot I detector circuit employs a capacitor to ground at Pin 9 to operate in conjunction with an internal resistor to create an RC integration time. The value of the capacitor affects the amount of time required to produce a stereo indication. The minimal time period must be long enough to include the time it takes for the circuit to check for detector falsing due to noise or interference, station re–tuning by the customer, and pilot drop–out in the presence of heavy interference. The pilot Q detector incorporates a filter on its pilot tone PLL error line at Pin 10. This capacitor to ground (usually 0.47 µF) is utilized to filter any low frequency information that may be present on the error line. If the value of this capacitor is allowed to be too small, the level of interference near the pilot tone frequency of 25 Hz may become large enough to cause stereo drop–out. If the capacitor value is made too large, the pilot tone may be prevented from being re–acquired if it is somehow lost due to fluctuating field conditions.

A 1.0 V reference level is created within the IC. This regulated line is used extensively by circuits throughout the MC13029A design. An electrolytic capacitor from Pin 8 to ground is used as a filter for the reference voltage.

At Pin 1, the MC13029A provides a function which allows the user to switch between AM and FM audio signals. The actual switching is controlled by dc level with a low for AM and a high for FM audio output.

The level of the audio output at Pins 16 and 17 can be set by the value of a resistor to ground at these pins. The output pins are connected to the collectors of PNP audio output amplifiers. At strong signal, these amplifiers can supply about 1.3 μA_{pp} of drive current for each percentage of mono modulation present. In other words, for a 100% LTR signal, 130 μA_{pp} will flow through the load. Thus, the value of resistor to ground will determine the peak–to–peak output.

The MC13029A IC provides a true mute function, controlled at Pin 18. A dc level of about 2.6 Vdc is sufficient to ensure muting of the audio outputs at Pins 16 and 17. This feature is useful when tuning in a different radio station, and the designer may also choose to utilize muting when switching between AM and FM.

The FM input audio signals are fed through series external resistors to Pins 19 and 20. Since AM broadcasters normally use heavy audio processing, the value of these resistors is chosen so that the audio output levels of FM are approximately 2.0 dB higher than the audio output levels of AM for the same modulation levels. Under these conditions, there will be only minimal volume differences perceived by the consumer when the MC13029A is switched between AM and FM outputs.

In order to comply with the FCC ruling on the NRSC AM audio response, a connection for de–emphasis circuitry in the MC13029A is provided at Pins 13 and 14 for left and right AM channels respectively. Typically, a series R–C network to ground will provide sufficient additional response shaping to the overall AM response so that the NRSC standard shape can be achieved. The values of these de–emphasis components will vary from design to design. The AM RF and IF coil responses, ceramic filter response and NRSC circuit response all contribute in an additiive manner to the shape of the overall AM audio responses at the IC output pins.

DISCUSSION OF GRAPHS AND FIGURES

The curves in Figures 3 through 8 depict the separation and the distortion performance in stereo for 30%, 50% and 65% single channel modulations respectively. The data for these figures was collected under the conditions of V_{CC} = 8.0 V and R_O = 3.9 k in both the left and the right channels as recommended in the application circuit of Figure 2. A very precise laboratory generator was used to produce the AM Stereo test signal of 450 kHz at 75 dBμV fed to Pin 4. An NRSC post detection filter was not used. The audio separation shows an average performance at 30% and 50% modulations of –38 dB in the frequency range of 1.0 to 5.0 kHz. The corresponding audio distortions are about 0.3% at 30% modulation and about 0.4% or better at 50% modulation.

Figure 7 shows that the typical separation performance at 65% modulation in the 1.0 to 5.0 kHz region is about –35 dB, and the corresponding audio distortion shown in Figure 8 is about 0.9% or better. The performance level of these sinusoidal signals is somewhat less than those discussed in the previous paragraph due to the internal operation of the clamping circuits. In the field, the transmitters at AM Stereo radio stations are not usually permitted to modulate single channel levels past 70%.

Note the –3.0 dB of roll–off at 80 Hz in the output responses of this decoder. These are the top traces (Desired Channel) in Figures 3, 5 and 7. That roll–off appears by design as a feature to help minimize switching transients present when between AM and FM. This roll–off also provides additional attenuation of pilot tone residuals in the detected audio.

The graphs in Figure 9 show the traces of noise response for four different bandwidths of post detection filtering, measured with respect to 30% mono modulation. It can be seen that the noise floors improve steadily with increasing levels of incoming 450 kHz as the value of the lower corner frequency of the filter is increased. Data for the stereo noise floors was collected with the decoder in the forced stereo mode. The upper trace in Figure 9, labeled Audio Level, shows the response, of the 30% mono signal transmitted, as it appears at the decoder output. The change in response level around 55 dBmV shows the characteristic of the total decoder gain at lower signal inputs.

Figures 10 and 11, discussed briefly in the Function Description Section, show the importance of using a quality component at Pin 12 to ground. It can be seen that an electrolytic capacitor leakage current of 600 nA can unbalance the PLL to the point where stereo performance may degrade to only 25 dB of separation with a corresponding 2.0% distortion at 50% modulation levels.

The value of the capacitor connected to Pin 12 (47 μF) is also a factor in the determination of the low frequency corner of the PLL circuit response. PLL responses appear in Figure 12, plotted for three different values of loop filter capacitor. The recommended value of 47 μF provides the best response shape in this circuit where a Murata Products CSA3.60MGF108 part is used.

Figure 13 presents the response of the AGC voltage versus decoder input signal level in the application schematic of Figure 2. The trace begins approximately at the point of decoder sensitivity, and rises until reaching the area of stereo sensitivity. Thereafter, the circuit responds in a near linear fashion for the next 35 dB of input signal increase.

Figures 14 through 17 depict the V_{CC} ripple rejection performance for the MC13029A under mono and stereo conditions for maximum and for no NRSC filtering. It should be noted that this data was collected without any V_{CC} filtering. As one might expect, the ripple rejection is excellent during mono conditions with approximately 45 dB of 50 Hz to 100 Hz ripple rejection at the high level of NRSC filtering. Under stereo operation, the rejection is the same or better in the 6.0 to 12 V range of operation, as can be seen in Figure 16. When the decoder operates in stereo, the VCO is functional, thus the decoder becomes more susceptible to audio ripple on the V_{CC} line. Under normal operating conditions, with the recommended value of 47 μF at Pin 15 and 10 μF at Pin 8, a V_{CC} ripple reading will be virtually the same as measuring the noise floor of the IC.

AM STEREO TUNER/FM STEREO IF

Description of Application

The MC13029A AM Stereo Decoder is combined with a Sanyo LA1832 Tuner. The combination results in an AM stereo tuner, along with an FM IF and FM stereo detector. The MC13029A provides the means to switch the left and right channel audio between the AM and FM. A MC145151 synthesizer controls the L.O. contained within the LA1832. The circuit schematic is shown in Figure 18.

Circuit Board Description

The copper side layout and component locations are shown in Figure 19. The dimensions in the figure give the true size of the circuit board. With the exception of U2 and U3, all components and jumpers are mounted on the side of the board, away from the viewer.

Special Parts

Table 1 provides the circuit function, part number, and the manufacturer's name for special parts. The parts are identified by their schematic symbol. Where the part is not limited to a single source, a description sufficient to select a part is given.

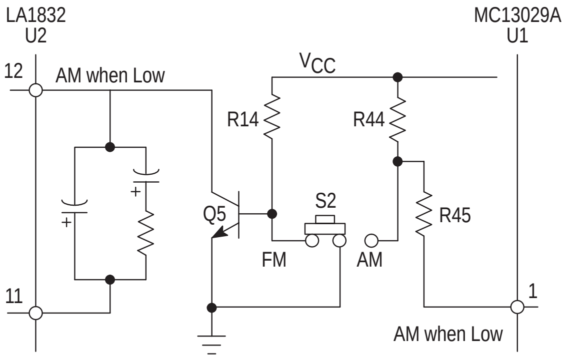
CIRCUIT DESCRIPTION

To set the circuit to AM mode, Pin 12 of U2 must be pulled to ground, as is Pin 1 of U1. This operation is shown in Figure 20. Pin 12 of U2 must be isolated by a high impedance when in FM mode. To allow switch S2 to accomplish the switching of both ICs, the transistor Q5 performs the switching of Pin 12 of U2.

Figure 20. AM/FM Switch

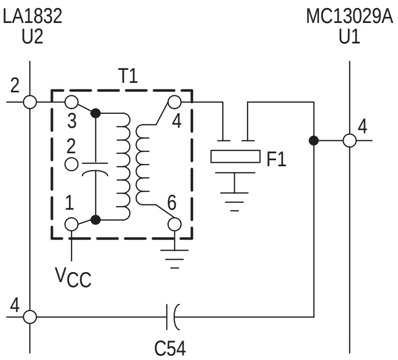


The AM local oscillator is contained in U2 with the L.O. coil located within the tuning block F4, and the coil connected to Pin 23 of U2. See Figure 18. The secondary of the coil is tuned by a varacter contained in F4, and controlled by the synthesizer IC U3. A buffer amplifier outputs the L.O. frequency from U2 Pin 24, This sample of the L.O. frequency is input to Pin 1 of the synthesizer IC U3.

The station signal is applied from a loop antenna (not shown in Figure 18) to the primary of the RF coil contained within the tuning block F4. The primary is tuned by a varactor located within F4, and controlled by the synthesizer U3. The coil secondary applies the signal to Pin 21 of U2 along with a bias voltage from Pin 22 of U2.

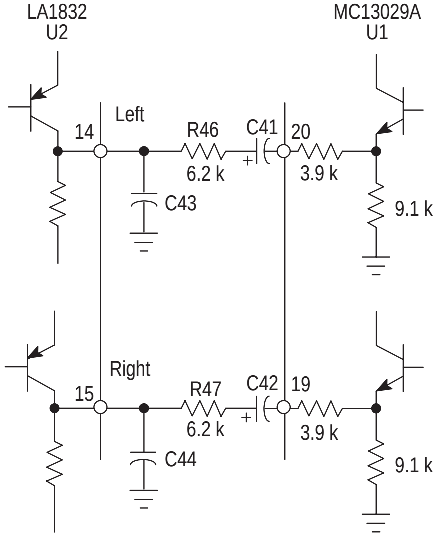
The 450 kHz IF signal from the mixer is output from Pin 2 of U2. Refer to Figure 21. The IF signal is applied through the IF coil T1 to the ceramic band pass filter F1. The signal is then applied to Pin 4 of the tuner IC, U2 and to Pin 4 of the decoder, U1. C54 is necessary to provide dc isolation between Pin 4 of U2 and Pin 4 of U1.

Figure 21. IF Connection



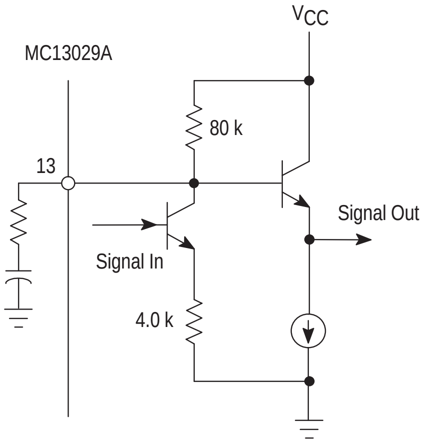
Switching of the audio between AM and FM modes takes place in the decoder IC, U1. The FM audio is conducted from the tuner IC, U2 to the decoder as shown in Figure 22. R46 and R47 provide for the desired balance in audio levels between AM and FM modes. FM de–emphasis is provided by the capacitors C43 and C44. The output impedance of the tuner at Pins 14 and 15 is 5.0 k. The series resistance R46 and R47 in combination with the input resistance at Pins 19 and 20 of U1 bring the effective resistance down to approximately 4.0 k. For a 50 µs de–emphasis, a capacitance value of 0.012 µF would be used for C43 and C44.

Figure 22. FM Audio Connection Tuner to Decoder



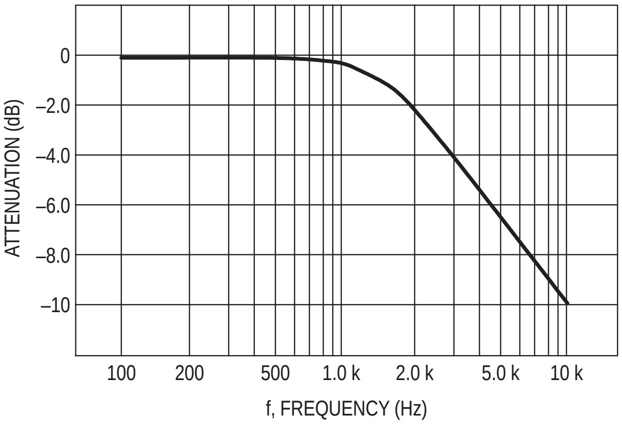
Provision for the application of AM de–emphasis is at Pins 13 (left) and 14 (right) of the decoder U1. This is shown in Figure 23. The tone response in AM mode is primarily set by the IF bandpass filter F1. This response is shown in Figure 28.

Figure 23. AM De–Emphasis Left Channel Shown



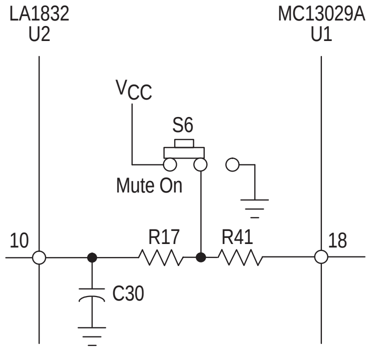
The NRSC recommended tone response is as shown in Figure 24. The tones falling within the IF filter bandpass can be contoured to this response by RC networks at Pins 13 and 14 of the decoder, U1.

Figure 24. NRSC De–Emphasis Curve for the United States



For muting, Pin 10 of U2 and Pin 18 of U1 must be pulled high. This is done by switch S6 as is shown in Figure 25.

Figure 25. Mute Switching



The AM can be forced to mono by pulling Pin 10 of U1 to ground. This is done by switch S4. Refer to Figure 18. The FM can be forced to mono by pulling Pin 13 of U2 to ground. This is accomplished by switch S3.

Component Choice

The pin function section of this data sheet gives the information to select the proper components to be used with the MC13029A decoder. A similar section in the LA1832 data sheet provides the information to choose the components for the tuner.

Tuning

The frequency to which the AM tuner will tune is set by the eight switches contained in the S5 assembly. S5 consists of eight SPST switches. The switches are numbered from 1 to 8. Switch 8 connects to Pin 18 of the synthesizer, U3.

To tune each frequency, the switches are set to a pattern corresponding to that frequency. The pattern is derived from a binary number, equal to the local oscillator frequency divided by 10 kHz.

As an example, consider tuning to 1070 kHz. The local oscillator is 1070 kHz + 450 kHz or 1520 kHz. 1520 kHz/10 kHz is 152. The binary equivalent of 152 is 10011000. The 1 represents an open switch. The 0 represents a closed switch. The left most bit of the binary number is switch 8. Switch 8 is set open. Switch 7 is set closed. This process is continued for all eight bits of the binary number. Table 2 summarizes the switch settings for 1070 kHz.

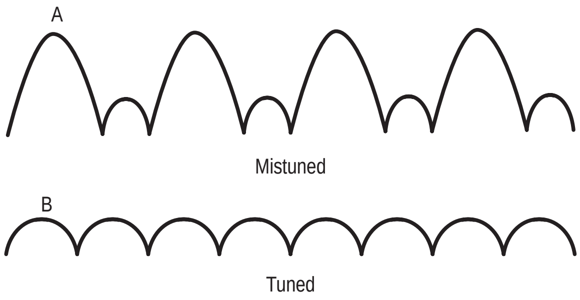
Table 2

Switch	Number	Position
8	1	Open
7	0	Closed
6	0	Closed
5	1	Open
4	1	Open
3	0	Closed
2	0	Closed
1	0	Closed

Circuit Adjustments

The FM circuit requires no adjustments. The AM L.O. must be able to tune from 990 to 2050 kHz to cover the broadcast range. Adjust the core of the L.O. coil, if needed, to be able to cover this range. The AM RF coil and trimmer can be adjusted for best signal after connection to the loop antenna. The coil is adjusted near the low end of the band, and the trimmer is adjusted at the top of the band. The IF coil T1 is first adjusted for maximum signal out of the filter F1. Final adjustment is shown in Figure 26.

Figure 26. Decoder Signal Output for Mistuned and Tuned Condition with Input Signal of 80% L–R and 3.0 kHz



Apply an AM Stereo signal modulated with a 3.0 kHz tone at 80% L–R. Set the pilot tone off. Observe either the left or right channel audio. When T1 is properly adjusted, the waveform should appear as waveform B shown in Figure 26. Adjust T1 as required. If the waveform can only be adjusted to appear as waveform A, then adjust for least amplitude and equal amplitudes on both the left and right channels.

AM Circuit Test

The connections for test are as shown in Figure 27. A 50 Ω resistor is placed on the AM antenna input. The AM Stereo generator is connected to the AM antenna input. Measurements of audio level are made with an audio voltmeter with a high input impedance (1.0 MΩ). Measurements of distortion in stereo mode are made using a 400 Hz high pass filter ahead of the distortion analyzer. Typical data is shown in Figures 28 through 34.

Advance Information

Dual Conversion AM Receiver

The MC13030 is a dual conversion AM receiver designed for car radio applications. It includes a high dynamic range first mixer, local oscillator, second mixer and second oscillator, and a high gain AGC'd IF and detector. Also included is a signal strength output, two delayed RF AGC outputs for a cascode FET/bipolar RF amplifier and diode attenuator, a buffered IF output stage and a first local oscillator output buffer for driving a synthesizer. Frequency range of the first mixer and oscillator is 100 kHz to 50 MHz.

Applications include single band and multi–band car radio receivers, and shortwave receivers.

- Operation from 7.5 to 9.0 Vdc
- First Mixer, 3rd Order Intercept = 20 dBm
- Buffered First Oscillator Output
- Second Mixer, 3rd Order Intercept = +5.0 dBm
- No Internal Beats Between 1st and 2nd Oscillator Harmonics
- Signal Strength Output
- Limited 2nd IF Output for Frequency Counter Station Detector
- Adjustable IF Output Station Detector Level
- Adjustable RF AGC Threshold for Both Mixer Inputs
- Two Delayed AGC Outputs for Cascode RF Stage and Diode Attenuator

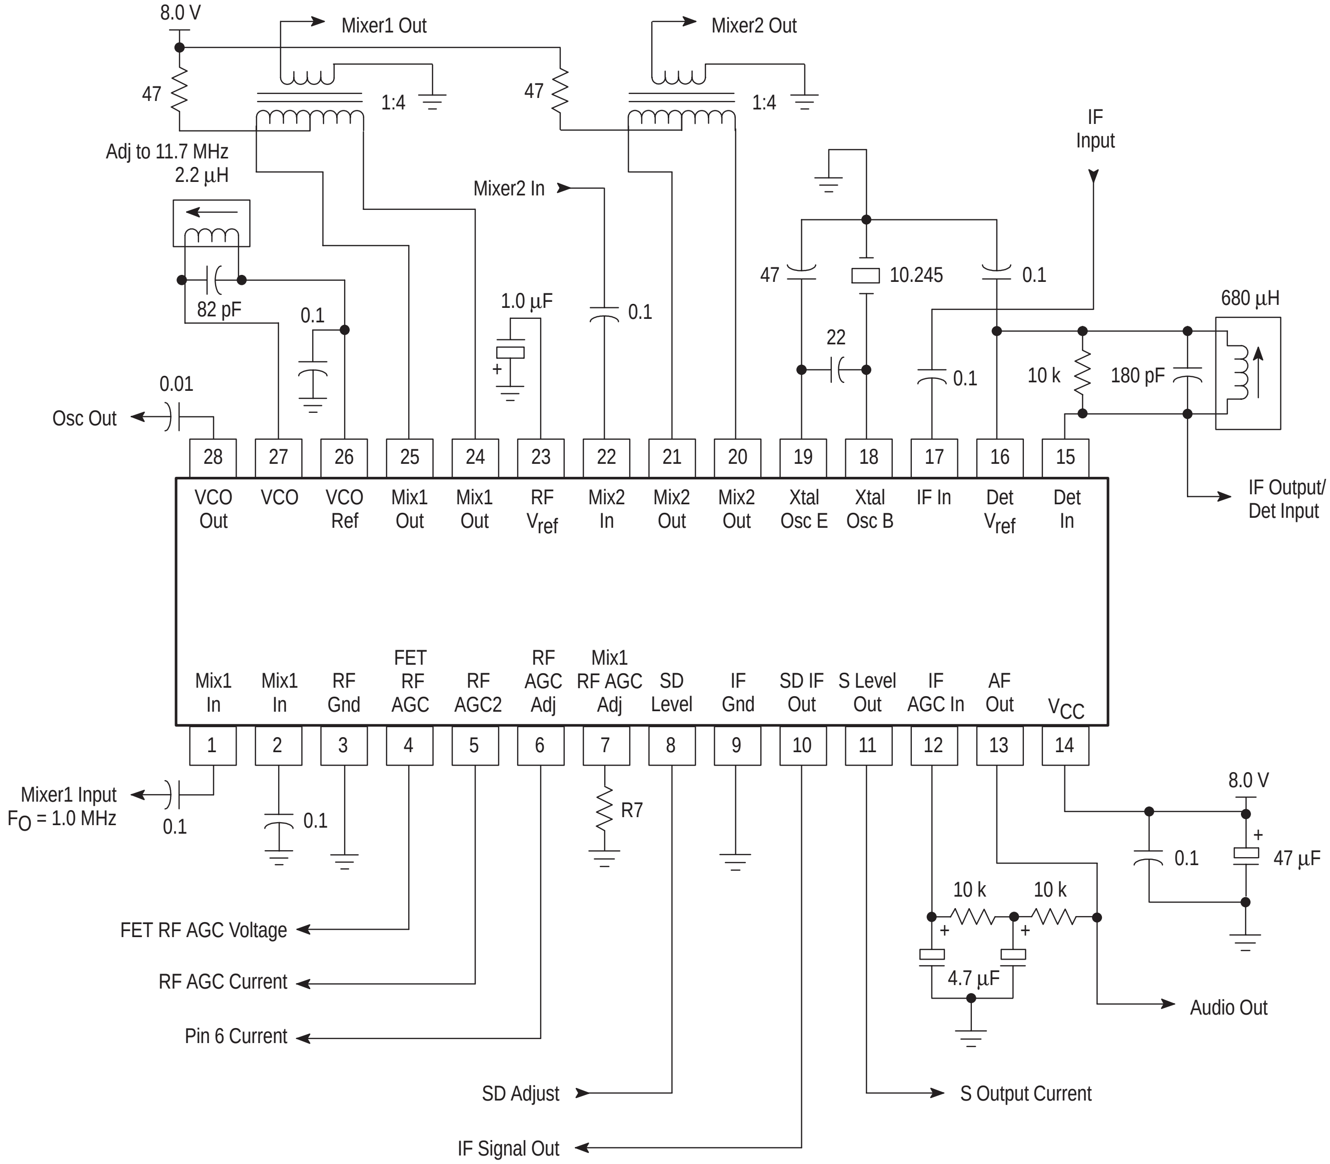
Figure 1. Test Circuit



NOTES:
1. The transformers used for at the output of the mixers are wideband 1:4 impedance ratio. The secondary load is the 50 Ω input of the spectrum analyzer, so the impedance across the collectors of the mixer output is 200 Ω.
2. Since the VCO frequency is not critical for this measurement, a fixed tuned oscillator tuned to 11.7 MHz is used. This gives an input frequency of 1.0 MHz.
3. The detector coil is loaded with a 10 k resistor to reduce the tuned circuit Q and to present a 10 kΩ load to the IF output for determination of IF transconductance.
4. The RF AGC current, S output current and Pin 6 current are measured by connecting a current measuring meter to these pins, so they are effectively shorted to ground.
5. SD adjust is adjusted by connecting a power supply or potentiometer and voltmeter to Pin 8.

FUNCTIONAL DESCRIPTION

The MC13030 contains all the necessary active circuits for an AM car radio or shortwave receiver.

The first mixer is a multiplier with emitter resistors in the lower, signal input transistors to give a high dynamic range. It is internally connected to the first oscillator (VCO). The input pins are 1 and 2. The input can be to either Pins 1 or 2, or balanced. These pins are internally biased, so a dc path between them is allowable but not necessary. The mixer outputs are open collectors on Pins 25 and 26. They are normally connected to a tuned transformer.

The first oscillator on Pin 27 is a negative resistance type with automatic level control. The level is low so the signal does not modulate the tuning diode capacitance and cause distortion. Pin 26 is the reference voltage for the oscillator coil. This reference is also the supply for the mixer circuits. The upper bases of the mixer are 0.7 V below this reference.

The second mixer is similar to the first, but it is single–ended input on Pin 22. Its outputs are open collectors on Pins 20 and 21 which are connected to a tuned transformer. The dynamic range of this mixer is less than the first. It is also connected internally to an oscillator which is normally crystal controlled. The oscillator is a standard Colpitts type with the emitter on Pin 19 and the base on Pin 18.

The IF amplifier input is Pin 17. The AGC operates on the input stage to obtain maximum dynamic range and minimum distortion. The IF output, Pin 15, is a current source.

Therefore, its gain is determined by the load impedance connected between Pins 15 and 16. Pin 16 is a voltage reference for the output. The output is internally connected to the AM detector, and Pin 13 is the detector output. This detector also provides the AGC signal for the IF amplifier. An RC filter from Pin 13 to 12 removes the audio, leaving a dc level proportional to the carrier level for AGC.

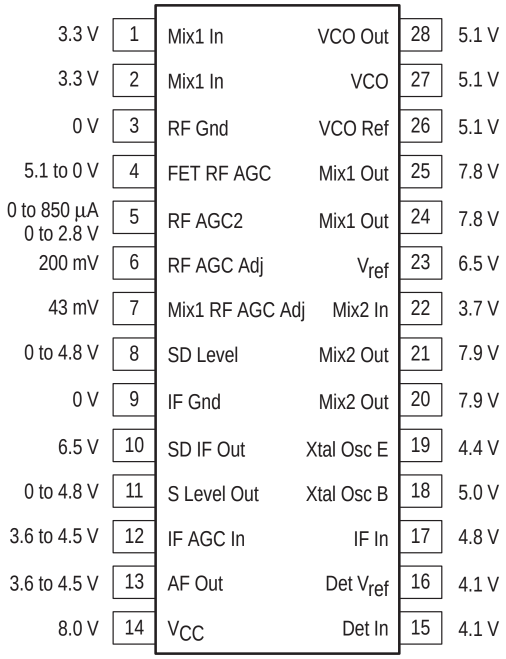
Pin 11 provides a current proportional to signal strength. It is a current source so a resistor must be connected from Pin 11 to ground to select the desired dc voltage range. The current is proportional to the signal level at Pin 17, the IF amplifier input.

A high–gain limiting amplifier is used to derive the station detect (SD) signal output on Pin 10; this output is present only if it is turned on by the voltage on Pin 8. If the voltage on Pin 8 is less than the voltage on Pin 11, the output on Pin 10 is "on". The station detector IF output on Pin 10 is used with synthesizers which have a frequency counting signal detector.

The RF AGC outputs on Pins 4 and 5 are controlled by the signal levels at Mixer1 or Mixer2. Bypass capacitors are required on Pins 6 and 4 to remove audio signals from the AGC outputs. Pin 4 is designed to control the NPN transistor in series with the RF amplifier FET. The voltage on Pin 4 is 5.1 V with no input signal and decreases with increasing input signal. Pin 5 is designed to control an additional AGC circuit at the antenna input. The voltage on Pin 5 is at 0 V with no input signal and increases with increasing input signals. The voltage on Pin 5 does not increase until the voltage on Pin 4 has decreased to about 1.3 V. In most cases, Pin 5 is used to drive a diode shunt. Maximum output current is about 850 µA.

The RF AGC sensitivity is about 40 mVrms input to Mixer1 or about 2.0 mVrms input to Mixer2 at 1.0 MHz. The AGC sensitivity for both mixers can be decreased by adding a resistor from Pin 6 to ground. There is also an additional amplifier between Mixer1 and its AGC rectifier. The gain of this amplifier and AGC sensitivity for Mixer1 can be increased by adding a resistor from Pin 7 to ground. Therefore, the desired AGC sensitivity for both mixers can be achieved by changing the resistors on Pins 6 and 7.

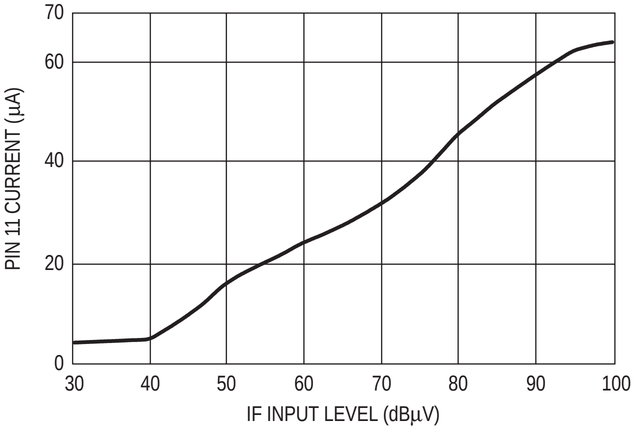
Figure 2. Pin Connections and DC Voltages



S Out versus IF Input:

The S output current at Pin 11 is provided by two collectors, one a PNP source and the other a sink to ground. The desired S output voltage can be selected using the curve of Figure 3 and calculating the value of the required resistor.

Figure 3. S Output Current versus IF Input Level



RF FET AGC versus Mixer1 and Mixer2 Input Level:

Figures 4 and 5 are generated with no external resistance on Pins 4 or 6, so they represent the minimum RF AGC sensitivity of Mixer1 and Mixer2.

Figure 4. RF AGC Voltage versus Mixer1 Input

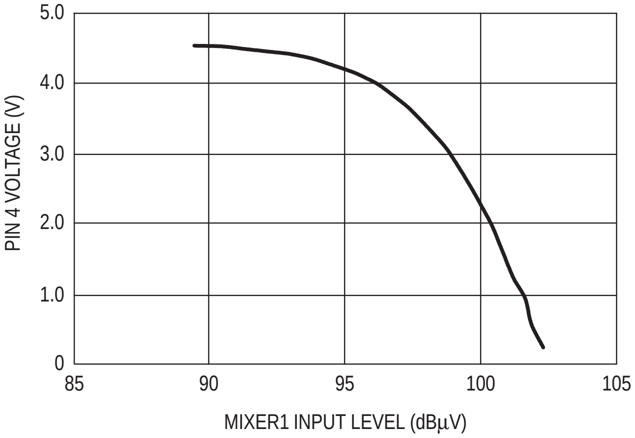


Figure 5. RF AGC Voltage versus Mixer2 Input

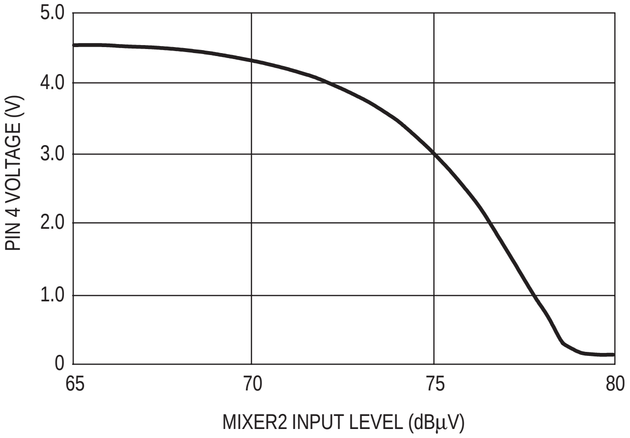

Pin 6 Current versus Mixer1 and Mixer2 Input Level:

The internal resistance from Pin 6 to ground is 39 k. The RF AGC voltage on Pin 4 is 2.0 V when the voltage on Pin 6 is 1.2 V. Therefore, the desired AGC thresholds for either mixer can be set with these curves. The design steps are described in the design notes.

Figure 6. Pin 6 Current versus Mixer1 Input Level

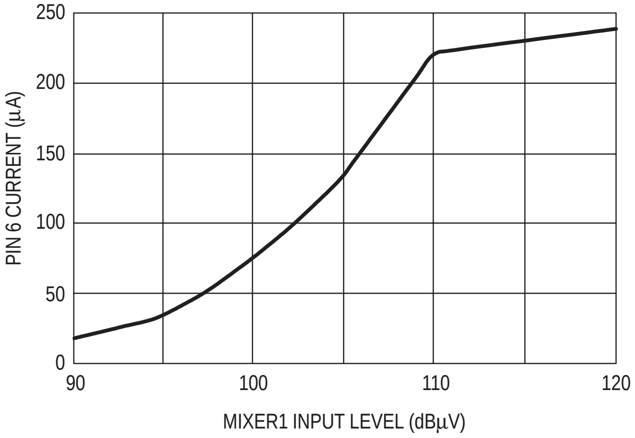

Figure 7. Pin 6 Current versus Mixer2 Input Level

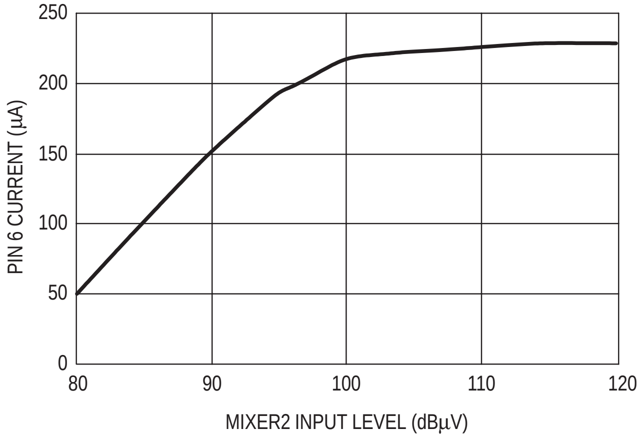
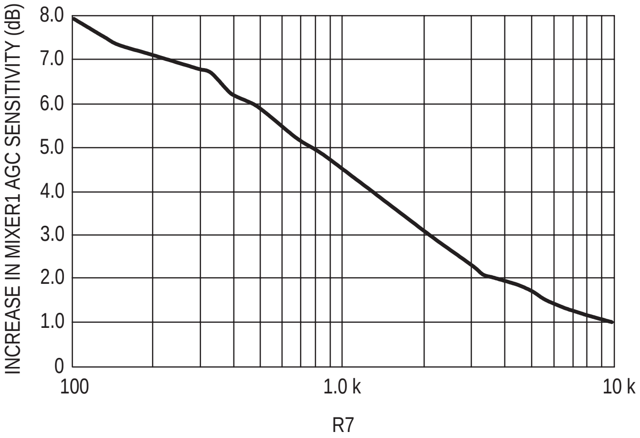


Mixer1 AGC Gain Increase versus R7:

Adding a resistor from Pin 7 to ground increases the AGC sensitivity of Mixer1. The range of increase in dB can be found from this curve. This is useful after setting up the AGC threshold of Mixer2.

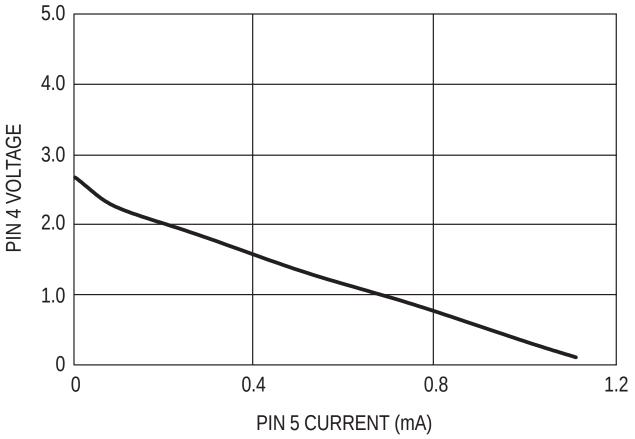
Figure 8. Mixer1 AGC Gain Increase versus R7



Pin 5 Current versus Pin 4 Voltage:

All the curves give Pin 4 AGC voltage versus some other input level. This curve can be used to determine the auxiliary AGC current from Pin 5 at a given Pin 4 voltage.

Figure 9. Pin 5 Current versus Pin 4 Voltage



PIN FUNCTION DESCRIPTION

Pin No.	Internal Equivalent Circuit	Description
1, 2	 	**Mixer1 Input** Pins 1 and 2 are equivalent. In the application circuit, 2 is grounded with a capacitor and 1 is the input. If a load resistor is needed for the input filter, it can be placed across Pins 1 and 2. Input impedance for each pin is 10 k. IP3 (third order intercept) at the input is 20 dBm (127 dBμ). To guarantee –50 dB IM3, the input level should not be greater than 3.5 dBm (103 dBμ) (150 mVrms).
3	 	**RF Ground** This should be connected to the ground used for the RF circuits.
4	 	**FET RF AGC Output** This is the AGC for the cascode transistor connected to the RF amplifier FET. The no–signal voltage is 5.1 V. The voltage decreases with increasing input signals. A bypass capacitor and electrolytic capacitor must be added to filter out RF signals on the transistor and audio signals in the AGC signal. See Figures 4 and 5.
5		**RF AGC2 Output** The voltage on this pin starts at 0 and increases with increasing input signals. It is normally used to turn on diodes or a transistor connected across the antenna input and is AGC delayed until Pin 6 reaches 2.7 V. If the voltage on Pin 5 decreases below 2.0 V, the voltage on this pin will decrease from 3.1 down to about 1.5 V. The maximum output current is about 850 μA.
6		**RF AGC Adjust** An electrolytic capacitor of 1.0 μF must be connected to prevent audio modulation of the AGC circuits. If there is no resistor on this pin, the RF AGC starts at an input level to Mixer1 ≈ 40 mVrms or Mixer2 ≈ 2.0 mVrms. Connecting a resistor from Pin 6 to ground increases RF levels required for AGC to start. It should be used to set the desired AGC level of Mixer2. If a resistor is not connected to Pin 6, unwanted RF signals will cause the AGC to start at a very low level, and desired signals may be suppressed.
7	 	**Mixer1 RF Level Adjust** A resistor from Pin 7 to ground will increase the gain of an amplifier from the input of Mixer1 to the AGC circuit. It can be used to set the RF AGC level of Mixer1. The minimum value of R7 is about 680 Ω.
8	 	**Station Detector Signal Level Adjust** A voltage on Pin 8 will set the desired signal strength at which the SD IF Out on Pin 10 appears. The other input to this comparator is the S (signal strength) signal. If Pin 8 is grounded, a square wave of the 2nd IF (usually 450 of 455 kHz) is present with very small input levels. This output could also be used to drive an FM detector if desired.
9	 	**IF Ground** Pin 9 is the ground for the IF section.

PIN FUNCTION DESCRIPTION (continued)

Pin No.	Internal Equivalent Circuit	Description
10		**Station Detector IF Output** This output is "on" when V11 > V8. The output is an amplified and limited 2nd IF signal. The signal level is ≈ 250 mVpp when it is 100% "on".
11		**S Level Output** This is a dc current proportional to IF input level. With a load resistor of 75 k, the dc voltage is 0 to 5.1 V.
12		**IF AGC In** The IF gain is controlled by the dc voltage on this pin. It is normally connected to Pin 13 through an RC network to filter out the audio signal on Pin 13. The IF gain is maximum when V13 ≈ 3.6 V. When V13 increases, the IF gain decreases.
13		**Audio Output** The dc voltage on Pin 13 is ≈ 3.6 V with no input signal and increases to ≈ 4.5 V at minimum IF gain. A nonpolarized electrolytic capacitor may be required to couple to the audio circuits if the audio amplifier dc bias voltage is between these voltages.
14		**Supply Voltage** The nominal operating voltage is 8.0 V.
15		**IF Amplifier Output and Detector Input** The detector coil must be connected between Pin 15 and 16. The IF amplifier output is a current source, the IF amplifier is a transconductance amplifier; the gain is determined by the impedance between Pins 15 and 16. The IF amplifier g_m ≈ 0.028 mho. If a wide bandwidth IF is desired, the detector coil can be connected between Pins 15 and 16 without a tap and then loaded with a resistor across the coil.
16		**Detector Reference Voltage** One side of the detector coil is connected to this pin. It should be bypassed with a 0.1 µF capacitor.

PIN FUNCTION DESCRIPTION (continued)

Pin No.	Internal Equivalent Circuit	Description
17		**IF Input** The IF input impedance is 2.0 k to match most ceramic 455 or 450 kHz filters. For a ceramic filter requiring a 1.5 k load, a 5.6 k resistor in series with a 0.01 µF capacitor should be connected from Pin 17 to ground.
18		**Crystal Oscillator Base** The crystal oscillator is a simple Colpitts type, operating at a low current. The crystal should operate at 10.250 MHz for 450 kHz IF or 10.245 MHz for 455 kHz IF with a 20 pF load capacitance. The oscillator signal to the second mixer is coupled from Pin 18 through an emitter follower. If a synthesizer such as the Motorola MC145170 with a 15 bit programmable R counter is used, the 10.245 MHz crystal can be connected to the synthesizer, and a 200 mVpp oscillator signal from the synthesizer can be capacitively coupled to Pin 18, so only one crystal is needed.
19		**Crystal Oscillator Emitter** The capacitive divider from Pin 18 is connected as shown in the application circuits of Figures 10, 11, 12.
20, 21		**Mixer2 Output** The maximum AC collector voltage is about 5.8 Vpp or 2.0 Vrms. The mixer conversion transconductance g_C = 0.0046 mho. The load impedance should be selected so the mixer output does not overload before the input.
22		**Mixer2 Input** The input impedance is 2.4 k. A series R–C network from Pin 22 to ground or a resistor from the filter to Pin 22 can be used to properly match the filter. In most cases, a 10.7 MHz crystal filter can be connected to Pin 22 directly without any additional components. IP3 (third order intercept) at the input is 5.0 dBm (112 dBµ). To guarantee –50 dB IM3, the input level should not be greater than –20 dBm (87 dBµ) (22.7 mVrms).
23		**V_{ref}** This is the main reference voltage for most of the circuits in the IC and should be bypassed with a 1.0 µF capacitor.
24, 25		**Mixer1 Output** The maximum collector voltage is about 5.8 Vpp or 2.0 Vrms. The mixer conversion transconductance g_C = 0.0022. The load impedance should be selected so the mixer output does not overload before the input.

PIN FUNCTION DESCRIPTION (continued)

Pin No.	Internal Equivalent Circuit	Description
26		**VCO Reference** The first oscillator coil is connected from Pin 26 to 27. Pin 26 must be bypassed to ground with a capacitor which has a low impedance at the oscillator frequency. This capacitor also will reduce the phase noise of the VCO.
27		**VCO** The VCO is a negative resistance type and has an internal level control circuit so a tapped coil or one with a secondary is not needed. The level is fixed at 0.8 Vpp so the oscillator signal does not modulate the tuning diode, thus keeping the distortion low. The oscillator stray capacitance is ≈ 12 pF and the tuned circuit impedance should be greater than 3.0 k to guarantee oscillation. Oscillator range is up to 45 MHz so it can be used for SW receivers.
28		**VCO Out** The output level is 240 mVrms (108 dBμ), high enough to drive any CMOS synthesizer.

AM CAR RADIO DESIGN NOTES

The MC13030 AM Radio IC is intended for dual conversion AM radios. In most cases, the 1st IF frequency (F_{IF1}) is upconverted above the highest input frequency. The first oscillator (VCO) is tuned by a synthesizer and operates at $F_{in} + F_{IF1}$. For the 530 to 1700 kHz AM band with a 10.7 MHz first IF, the VCO goes from 11.23 to 12.40 MHz. Therefore, F_{max}/F_{min} for VCO is only 1.104, so one low–cost tuning diode can be used. Since the required tuning voltage range can be made less than 5.0 V, it may also be possible to drive the tuning diode directly or from the phase detector of the synthesizer IC, such as the Motorola MC145170, operating from 5.0 V, without using a buffer amplifier or transistor.

If the VCO is above the incoming frequency, the image frequency of the first mixer is at $f_{OSC} + F_{IF1}$. For the AM broadcast receiver, it is around 22 MHz, so a simple LPF can be used between the RF stage and Mixer1 input. However, if a LPF is used, an additional coil is still needed to supply the collector voltage of the RF amplifier. For this reason, a BPF filter was used in the application circuit instead, since it uses the same number of coils and gives better performance. It is simply a lowpass to bandpass conversion. The lowpass filter is designed to have a cutoff frequency equal to the desired bandwidth. In this case, it would be 1700 – 530 kHz = 1170 kHz. Then, it is transformed to be resonant at 949 kHz, the geometric mean of the end frequencies: $\sqrt{1700 \times 530} = 949$ kHz.

A balanced–to–unbalanced transformer is required at the output of both mixers. The first one is designed so that Mixer1 has enough gain to overcome the loss of the 10.7 MHz filter and so that the output of the mixer will not overload before the input. The primary impedance of the transformer is relatively low, and it may be difficult to control with commonly available 7.0 mm transformers because the number of primary turns is quite small. It would also require a large tuning capacitance. A better solution is to tune the secondary with a small capacitance and then use a capacitive divider to match the tuned circuit to the filter. This allows one transformer to be used for either a ceramic or crystal filter. The capacitors can be adjusted to match the filter. The recommended coil is made this way.

If the formula: $P_{in} = \text{IP3} - \text{DR}/2$ is used, the maximum input level to the mixer can be calculated for a desired dynamic range.

IP3 = 3rd order intercept level in dB (dBm or dBμ)

DR = dynamic range in dB between the desired signals and 3rd order intermodulation products

P_{in} = input level in dBm or dBμ

The RF AGC level can then be adjusted so that P_{in} does not exceed this level.

Whether or not a narrow bandwidth crystal or wide bandwidth ceramic filter is used between the first and second mixers depends on the receiver requirements. It is possible to achieve about 50 dB adjacent channel and IM rejection with a ceramic filter because of the wide dynamic range of the mixers. If more than this is required, a crystal filter should be used. If a crystal filter is used, a lower cost CFU type of 455 kHz second IF filter can be used. If a ceramic filter is used, a CFW type filter should be used because there is no RF section selectivity in this type of radio.

Since the wideband AGC system is quite sensitive, it can be set to eliminate all spurious responses present at the receiver output. However, the RF AGC will sometimes eliminate or reduce the level of desired signals if there is a strong signal somewhere in the bandpass of the RF circuit.

The second mixer is designed like the first and requires a balanced output. Since its load impedance is higher, the transformer can be designed to be tuned on the primary or secondary, but, like with the one for the first mixer, if the secondary is tuned, the tap can be adjusted for the impedance of the 455 kHz filter. Wideband filters usually have a higher terminating resistance than the narrowband ones. The recommended coil is made this way.

The IF amplifier is basically a transconductance amplifier because the output is a current source. The output is also internally connected to a high impedance AM detector. g_m for the IF amplifier is ≈ 0.028 mho. The voltage gain will be the detector coil impedance x 0.028. This can be designed to give the desired audio output level for a given RF input level. If it is set too high, the receiver may oscillate with no input signal. The application circuit was designed for a relatively narrow bandwidth, so a tapped detector coil is used to get the desired gain. If a wide bandwidth receiver is desired, the detector coil can be untapped, and a resistor can be added across the coil to get the desired Q.

The detector output on Pin 13 is a low impedance. It supplies the IF AGC signal to Pin 12, so the audio must be filtered out. The time constant of this filter is up to the designer. The main requirement is usually the allowable audio distortion at 100 Hz, 80% modulation. If the time constant is made too long, the audio level will be slow to correct when changing stations.

The Signal Strength (S) output is dependent only on the IF amplifier input level. Its maximum voltage is about 5.0 V with a 75 k load resistor. The range can be reduced by using a lower value for the resistor on Pin 11. The S signal will stop increasing when the RF AGC circuits become active, so if the RF AGC threshold is set too low, or there is too much loss from the Mixer2 output to the IF input, the maximum S signal will be reduced. The desired load resistor on Pin 11 (R11) can be determined using the curve of Pin 11 current versus IF input.

Setting the RF AGC threshold is probably the most difficult because a trade–off between allowable interference and suppression of desired signals must be made.

First select the values for both mixers:

d. Using the formula P_{in} = IP3 – DR/2
Select the desired dynamic range and calculate the maximum input levels for both mixers. Remember that all levels must be in dB, dBμV or dBm. Let DR = 50 dB. IP3 for Mixer2 = 112 dBμV. Therefore, P_{inmax} = 87 dBμV. IP3 for Mixer1 = 127 dBμV. Therefore, P_{inmax} = 102 dBμV.

e. First, adjust the resistor from Pin 6 to ground to give the desired maximum input level to Mixer2. From the curve of Pin 6 current versus Mixer2 input level, R6 = 1.2/110 μA = 11 k. R_{int} = 39 k, so R_{6ext} = 15 k.

f. From the curve of Pin 6 current versus Mixer1 input level, determine how much more gain would be required in the Mixer1 AGC circuit to achieve the desired dynamic range for Mixer1. From the curve of Relative Sensitivity versus R7 determine the value of R7. Alternatively, R7 can be adjusted to give the desired maximum input level to Mixer1.

The resulting R7 may be too small to set the AGC threshold of Mixer1 as low as desired. Also, if R7 is less than 680 Ω, the AGC sensitivity for the Mixer1 input falls off at higher frequencies, so in these cases, the resistor from Pin 6 to ground must be reduced to achieve the desired level because the overload of Mixer1 provides the most important spurious response rejection. However, if the AGC level is set too high, the IF in signal may become too large and the IF amplifier can overload with strong signals. The values used in the application are more conservative.

The gain from the antenna input to the point being measured are shown on the AM radio application. These are helpful when calculating audio sensitivity and troubleshooting a new radio.

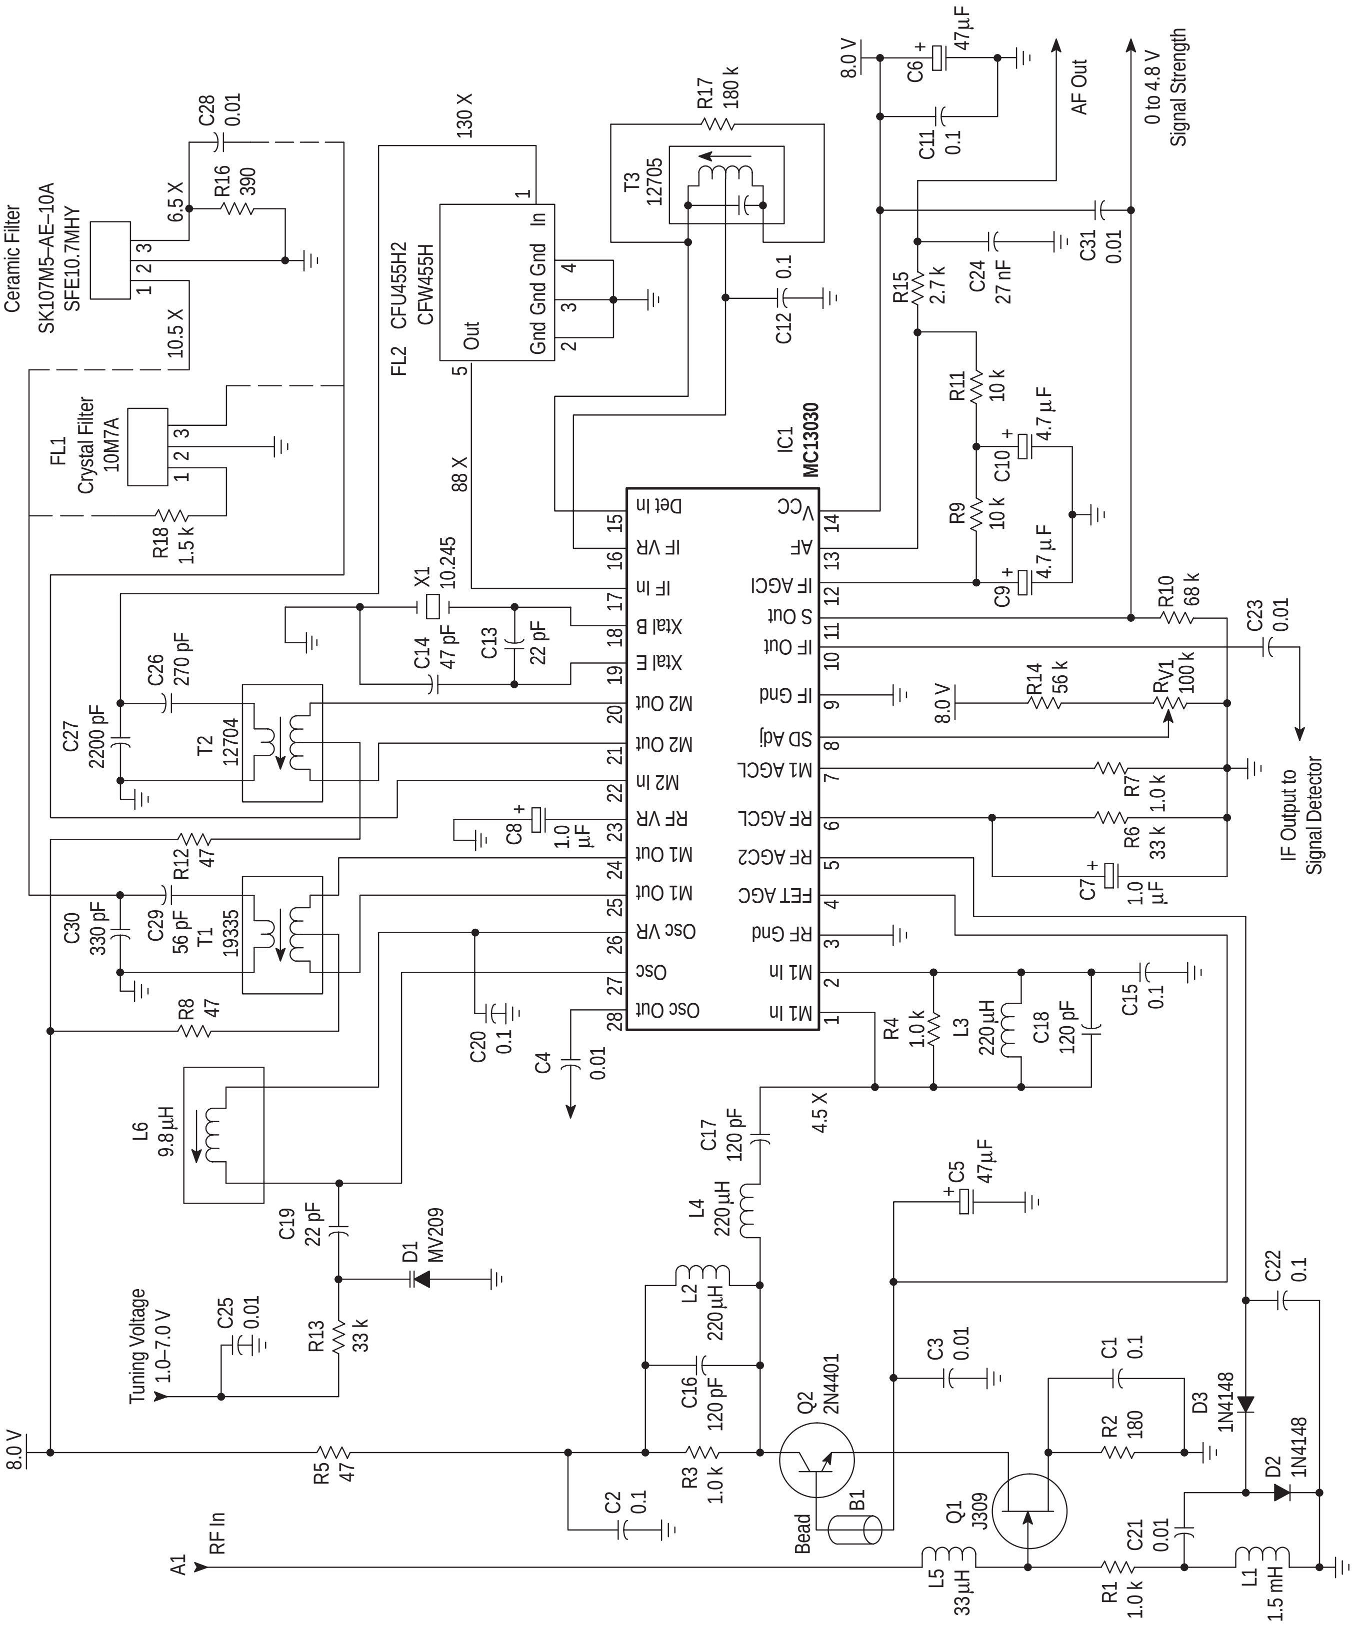


Figure 10. AM Radio Application

SW RADIO DESIGN NOTES

The shortwave receiver was designed to cover from 5.0 to 10 MHz. This MC13030 radio has better performance than most receivers because of the high dynamic range and spurious rejection of the mixers.

The RF stage bandpass filter for this radio is the same type as the one used for the car radio, but the series tuned section was scaled down in impedance to reduce the inductance of the coil.

Since most SW receivers include an SSB and CW mode, the detector coil could have a secondary winding to supply the second IF signal to this section.

The capacitors C10 and C23 have been reduced from those in the AM radio so that the AGC system can follow variations in signal level due to fading.

CB RADIO DESIGN NOTES

The RF stage bandpass filter for this radio consists of a tuned input and a double tuned interstage filter. For lower cost radios, a single tuned interstage filter could be used.

The schematic also shows a crystal 10.7 MHz 1st IF filter, but a ceramic or coil filter could also be used. An intermodulation rejection of 50 dB can be obtained with a ceramic 1st IF filter.

A bipolar transistor is shown for the RF stage. A dual gate CMOS FET could also be used with G2 connected to the AGC voltage on Pin 4. A PIN diode is recommended for D2.

GENERAL DESCRIPTION

The MC13060 is a quasi–complementary audio power amplifier, mounted in the SOP 8 (power SOIC package). It is well suited to a variety of 1.0 W and 2.0 W applications in radio, TV, intercom, and other speaker driving tasks. It requires the usual external components for high frequency stability and for gain adjustment.

The output signal voltage and the power supply drain current are very linearly related, as shown in Figure 5. Both are quite constant over wide variation of the power supply voltage (above minimum V_{CC} for clipping, of course). The amplifier can best be described as a voltage source with about 1.0 A_{pp} capability. On a good heatsink, it can deliver over 2.0 W at 70°C ambient.

The MC13060 will automatically go into shutdown at a die temperature of about 150°C, effectively protecting itself, even on fairly stiff power supplies. This eliminates the need for decoupling the power supply, which degrades performance and requires extra components.

Input Pins 5 and 8 are internally biased at 0.7 Vdc and should not be driven below ground.

Advanced PAL/NTSC Encoder

ADVANCED
PAL/NTSC ENCODER

SEMICONDUCTOR
TECHNICAL DATA

The MC13077 is a high quality RGB/YUV to NTSC/PAL encoder with Composite Video and S–Video outputs. The IC integrates the color difference and luma matrix circuitry, chroma modulators, subcarrier oscillator, and logic circuitry to encode component video into a composite video signal compatible with the NTSC/PAL standards. The IC operates off a standard +5.0 V supply and typically requires less than 75 mA, making it useful in PC environments. The high degree of integration saves board space and cost, as only passive external components are required for operation. The IC is manufactured using Motorola's MOSAIC™ process and is available in a 20 pin DIP or SOIC package.

- Single 5.0 V Supply
- Composite Output
- S–Video Outputs
- PAL/NTSC Switchable
- PAL Squarewave Output
- PAL Sequence Resettable

PIN DESCRIPTIONS

Pin	Symbol	Internal Equivalent Schematic	Description	Expected Waveforms
1	V_{CC}		Supply Voltage	+ 5.0 Vdc ±10%
2	Comp Video		Composite Video output. The external 75 Ω series resistor determines the impedance of the output. The output will drive a 75 Ω load through a 75 Ω coax.	1.0 Vpp (75% Color Saturation), 1.23 Vpp (100% Color Saturation) at the 75 Ω load.
3	Luma S–Video		Luminance S–Video output. The external 75 Ω series resistor determines the impedance of the output. The output will drive a 75 Ω load through a 75 Ω coax.	1.0 Vpp with sync (100% output) at the 75 Ω load.
4	Chroma S–Video		Chrominance S–Video output. The external 75 Ω series resistor determines the impedance of the output. The output will drive a 75 Ω load through a 75 Ω coax.	885 mVpp (100% output) when at the 75 Ω load.
5	Luma Clamp		Luminance Output Clamp storage capacitor. A 0.01 µF capacitor should be connected from this pin to ground.	3.4 Vdc.
6	Y_{In}		Luminance input from the delay line. The delayed Luma from Pin 10 is applied at this pin.	500 mVpp of Composite Luma when 100% saturated RGB inputs are applied.
7	Sync In/ Sync Sep		Composite Sync input. Negative going sync should be applied at this pin. The input has a threshold of 1.4 V.	The peak voltage may not exceed V_{CC}. Minimum voltage should not be less than 0 V. See Figure 2 for input requirements.
8	4x f_{SC} Xtal /4x f_{SC} In		Four times Subcarrier Frequency Crystal Oscillator pin. This pin provides for the connection of the oscillator resonant element. Pin may also be driven directly with a 4x subcarrier signal.	300 to 600 mVpp 4x subcarrier input if the pin is being externally driven. Approximately 40 mVpp, if a crystal is being used.
9	3.58/ 4.43 MHz In/PLL Off		External Subcarrier Input. This pin provides an input to a Phase Detector and PLL and allows phase–lock of the 4x oscillator to an external subcarrier reference. To disable the PLL, this pin should be grounded. 400 Hz of pull–in and lock–in range is possible with a crystal.	0.10 to 3.0 Vpp (AC coupled) of subcarrier to phase–lock 4x oscillator or grounded to disable the PLL.

PIN DESCRIPTIONS (continued)

Pin	Symbol	Internal Equivalent Schematic	Description	Expected Waveforms
10	Y_{Out}		Luminance Delay Line Drive Output. A delay should be inserted between this pin and Pin 6 to match the delay incurred by the Chroma.	1.0 Vpp with sync (100% saturated Color Bar output).
11	Gnd		Ground	Ground
12	Red_{In}		Red Video input.	0.7 Vpp AC coupled (100% Color Bars).
13	$Green_{In}$	See Pin 12	Green Video input.	0.7 Vpp AC coupled (100% Color Bars).
14	$Blue_{In}$	See Pin 12	Blue Video input.	0.7 Vpp AC coupled (100% Color Bars).
15	B–Y Clamp		B–Y Clamp storage capacitor. A 0.01 µF capacitor should be connected from this pin to ground, unless the pin is used as an input.	If not used as an input the pin is clamped during sync to 2.4 Vdc. Can be used as a B–Y input (AC coupled, 350 mVpp, 100% color saturation). Burst Flag, if disabled at Pin 18, must be inserted here with the following signal levels; –170 mV (NTSC), –121 mV (PAL).
16	R–Y Clamp		R–Y Clamp storage capacitor. A 0.01 µF capacitor should be connected from this pin to ground, unless the pin is used as an input.	If not used as an input the pin is clamped during sync to 2.4 Vdc. Can be used as a R–Y input (AC coupled, 490 mVpp, 100% color saturation). Burst Flag, if disabled at Pin 18, must be inserted here with the following signal level; +121 mV for PAL.
17	Chroma Out		Chroma Bandpass Drive Output.	2.8 Vpp (100% Color Bars)
18	Burst Flag Out/Force Burst Flag		Burst Flag Output Disable and Force pin. If left unconnected, internally generated color burst will appear at Pins 2 and 4. Burst Flag will appear at this pin (18). If grounded, the Burst Flag will be disabled. If externally driven from another source of burst flag, the internal flags will be overriden.	1.8 Vpp burst flag pulses if unconnected.
19	PAL Square–wave Out/Force NTSC		PAL/NTSC system switch. If grounded, the MC13077 will encode NTSC, and if left open, PAL.	In PAL mode, a PAL squarewave appears at this pin, the phase of which can be reset by momentarily forcing the pin to ground during the high state of the squarewave.
20	Chroma In		Chroma Bandpass input. Output from chroma bandpass filter should be applied at this pin.	1.4 Vpp (100% Color Bars) with bandpass filter and 1.0 kΩ matching resistors.

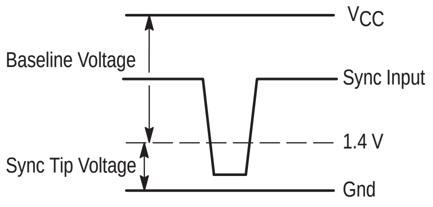
FUNCTIONAL DESCRIPTION

Composite Sync Input

Other than the component video inputs to be encoded, only Composite Sync is required for encoding the components into a composite signal compatible with either the NTSC or PAL standard. The Composite Sync input is used internally for determining which standard to encode to, for driving the black level clamps, and to set the timing of the composite sync in the outputs.

The Composite Sync/Sync Separator input was designed to accept AC or DC coupled inputs making it possible to drive the sync input from a variety of sources. An interesting note is that composite video can also be used for sync input. The threshold of the sync input is 1.4 Vdc. Figure 2 shows the requirements for sync input.

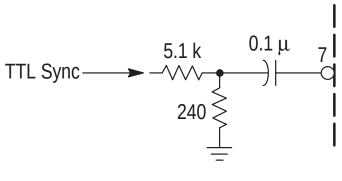
Figure 2. Sync Input Amplitude Requirements



Both serrated and block vertical sync can be used for NTSC applications. PAL applications require a serrated vertical sync. The serrations at the horizontal rate trigger the PAL flip–flop to generate the swinging burst.

Even though the sync input of the MC13077 is well suited for TTL interface, some functions of the IC are susceptible to the high energy present in such signals and may be disturbed. This disturbance may take the form of a noise spike in the video outputs and/or a disturbance of the 4x oscillator resulting in an incorrect encoding of the chroma information. Therefore, it is recommended that if TTL or other fast–edged inputs are going to be used for the sync input, then either the amplitude and/or the edge speed of the sync input pulse should be reduced. 300 mVpp of sync without a reduction of edge speed has to be shown to produce disturbance free operation. Also, a sync input of 4.0 Vpp and edge rates of 225 ns have been shown to produce similar results. Figure 3 shows a recommended coupling circuit for TTL type composite sync.

Figure 3. TTL Sync Input Circuit



Luma and Color Difference Clamps

Clamping for the MC13077 occurs once every horizontal line during sync. The absence of color creates a color difference component voltage of zero, this null is used to generate a reference voltage for black in the video outputs. The clamp capacitors at Pins 5, 15 and 16 are used to store the reference voltage during the line period.

RGB Inputs

To encode RGB, the component video inputs (Pins 12, 13, 14) are applied to the Luma (Y) and color difference (R–Y, B–Y) matrix. The color difference signals are then conditioned by Sallen–key low pass filters (f–3dB = 4.0 MHz). The inputs are designed so that 700 mVpp RGB provides 100% color saturation.

The first color difference component (R–Y) is created by matrixing the RGB components with the following weights:

$$R–Y = 0.70R – 0.59G – 0.11B \quad (1)$$

The second color difference signal (B–Y) is created in a similar fashion by the equation:

$$B–Y = 0.89B – 0.59G – 0.30R \quad (2)$$

These two components then receive burst flag before being modulated by the color subcarrier to create composite chroma.

The luma is also the result of a weighted matrixing of the RGB components. The components and corresponding weights are:

$$Y = 0.30R + 0.59G + 0.11B \quad (3)$$

Composite sync is then added to the result of Equation 3 to create composite luma.

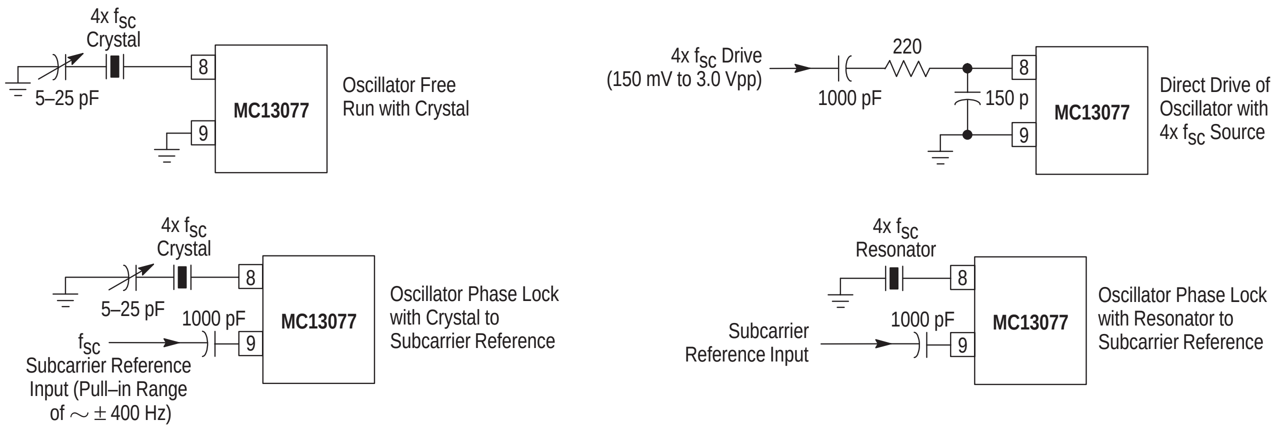
The luma information thus created must be eventually recombined with the chroma information. However, since the chroma information created by Equations 1 and 2 is filtered internally before being modulated then bandlimited externally, the resultant encoded chroma experiences a group delay that is the sum of the delay imposed by the internal and external filtering. So, the composite luma is output at Pin 10 so that an external delay can be inserted in the path to match the delay incurred by the composite chroma. The delayed composite luma is then input back into the MC13077 at Pin 6.

Color Difference Inputs

If the MC13077 is intended to encode color difference signals (YUV or Y, R–Y, B–Y), it becomes necessary to bypass the color difference and luma matrix circuitry. This can be accomplished by inputing directly to the color modulators the color difference signals. 491 mVpp and 349 mVpp should be input to the R–Y and B–Y Clamp pins (Pin 16 and Pin 15) respectively, to achieve 100% color saturation in the composite video output. The luma information can be input in two ways. The luma can be input directly into the RGB inputs (700 mVpp without sync), or through the delay line (1.0 Vpp with sync, sync tip–to–peak white) in which case the RGB inputs should be cap–coupled to ground. In either case, composite sync still needs to be input to the MC13077 at Pin 7 (see Figures 11, 12 and 13).

If the R–Y and B–Y inputs also have burst flag, it can also be input along with the color difference signals at these pins. Of course, now since the color difference modulator pre–filtering is circumvented, the delay for the luma information should be matched only to the delay of the bandpass filter.

Figure 4. Versatility of the 4x f_{SC} Oscillator



4X Subcarrier Oscillator

To encode the color difference components, an accurate and reliable subcarrier source is required. The MC13077 has an on–chip single pin oscillator that will free–run with a 4x f_{SC} crystal, phase–lock to an external subcarrier reference with a 4x f_{SC} crystal or resonator, or be driven externally from a 4x f_{SC} source. If the 4x f_{SC} oscillator is going to be free run, the subcarrier input (Pin 9) should be grounded. If the 4x f_{SC} oscillator is going to be phase–locked to an external subcarrier source, the external reference should be capacitor–coupled to Pin 9. If the 4x f_{SC} oscillator is going to be driven externally, Pin 8 should be driven from a network that increases the impedance of the source at frequencies capable of producing off–frequency oscillations. The 4x f_{SC} subcarrier source, thus being defined, makes it possible to produce accurate quadrature subcarriers for the modulators. The 4x source is internally divided by a ring counter to produce the quadrature subcarrier signals. These signals in turn are provided to the color difference modulators to produce the modulated chroma. The oscillator was designed so that if a crystal is chosen as the resonant element of the 4x oscillator, the crystal specifications would be common. Crystal specifications for an adequate crystal are shown in 1

Table 1. Crystal Specifications

Frequency: 14.31818 MHz (NTSC) 17.734475 MHz (PAL)
Mode: Fundamental
Frequency Tolerance (@25°C), 40 ppm
Frequency Tolerance df/dfo (0° – 70°C), 40 ppm
Load Capacitance: 20 pF
ESR: 50 Ω
C1(Internal Series Capacitance), 15 mpF

This crystal is a common variety and is specified as a parallel resonant.

Burst Flag Decoding

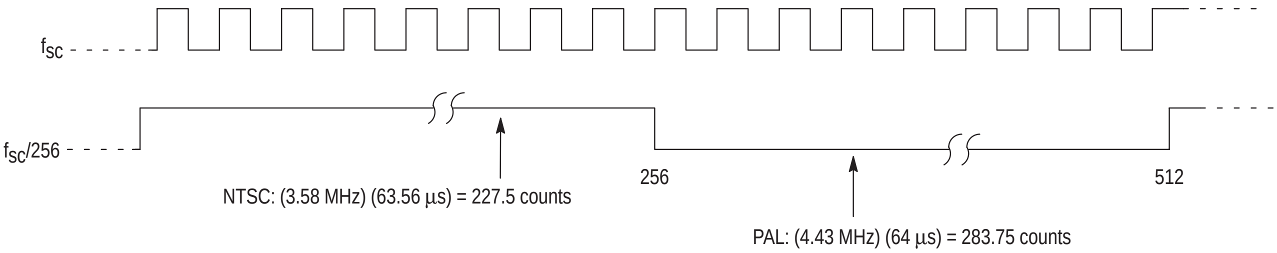
In order to encode to either NTSC or PAL compatibility, the MC13077 must first determine which is the intended standard. The MC13077 accomplishes this with an internal decode using the sync input and the output of the divide by 4 ring counter. Internally, the Sync separator circuitry provides an output that is sampled by the subcarrier signal from the ring counter. The result is an internal sync representative of externally input sync but synchronized to the internal subcarrier signal. This signal provides a reset for an internal 9–bit counter that provides divisions of the subcarrier signal from the ring counter at powers of 2 (i.e. 2^1, 2^2, 2^3,...2^9 = 512). The eighth bit of the counter gives the output, $f_{SC} \div 256$. The decision to provide burst gate timing for PAL or NTSC is based upon the state of this output after one period of the horizontal sync. Figure 5 shows the relationship between the clock and the eighth bit of the counter.

Triggering of the burst PAL flip–flop due to equalizing pulses is also inhibited by the decode circuitry. This is done by counting out beyond a half line interval before generating burst flag.

If the MC13077 is encoding 525/60 component video to NTSC and the MC13077 is generating the burst flag, the start of burst will occur 18 counts after the leading edge of sync has been sampled, and will continue until nine cycles of burst have occurred. Since the reset pulse of the 9–bit counter has a resolution of $1.0/f_{SC}$, this implies that the start of burst will occur 5.17 ± 0.1397 µs after the leading edge of sync and also that the start (and end) of burst may differ by as much as 279.4 ns from line–to–line. If the MC13077 is encoding 625/50 to PAL, the subcarrier frequency will be 4.43361875 MHz and that implies a resolution of 225.5 ns for the burst position. For PAL encoding, 24 counts of the subcarrier are necessary before burst is initiated. So ten cycles of subcarrier will occur 5.53 ± 0.1128 µs after the leading edge of sync. After the timing of the burst gate is selected, the burst gate envelope is added to the color difference components.

Another alternative to the internal determination of burst flag is the external input of burst flag. This allows the user to externally define the exact timing and duration of color burst. If external burst flag is available, it can be inserted at Pin 18. The threshold level is nominally $V_{CC}/2$ and the input should not exceed V_{CC}. Burst will begin when the leading edge of the burst flag input exceeds $V_{CC}/2$ and will stop when it falls below $V_{CC}/2$. If it is desired to disable the burst flag, Pin 18 can be pulled low. It is also possible to insert burst flag with the R–Y and B–Y components. This is done at the clamp pins with the respective color difference inputs with the internal burst flag generation disabled (Pin 18 grounded).

Figure 5. Relationship Showing the Counts of a 3.58 MHz Clock versus a 4.43 MHz Clock at the End of a Horizontal Period



Chroma Band Limiting and Luma Delay

Once the color difference and burst flag envelopes have been modulated, the two components are internally summed and applied to an output buffer that will drive the external bandpass circuitry before entering the chip again at Pin 20. The sum of the color difference modulators produces an output that is high in harmonic content. For this reason, and to reduce the possibility of cross color, a chroma bandpass transformer is used to band–limit the chroma. Suggested bandpass filters and specifications for NTSC and PAL are shown in Figure 7a and 7b. For each of these filters, approximately 300 ns of group delay is experienced by the filtered chroma. There is also an internal delay on the order of 100 ns due to internal filtering that must be considered. Thus a 400 ns luma delay line is used to equalize the timing of the luma and the chroma. Suitable 400 ns delay lines are the TOKO H321LNP–1436PBAB and the TDK DL122401D–1533. The delay of the luma channel is inserted between Pins 10 and 6. Pin 10 is the buffered output of the luma from the RGB matrix. This output is capable of driving the external passive delay line with no external gain or buffering required.

5.13	3.0 ± 3.0	0.24
6.50	12 (min)	0.05

Chroma Encoding

Modulation of the color difference components is performed by two double–balanced mixers that are driven from quadrature signals provided by an internal ring counter. The quadrature signals are derived from a ring counter that is driven by the 4x oscillator, and which makes highly accurate quadrature angles possible.

If PAL encoding is selected, negative burst flag envelope is provided to both B–Y and R–Y components equally, then the R–Y envelope phase is switched positive and negative from line–to–line to provide the PAL alternating burst phase characteristic. An internal flip–flop that provides the internal $f_H/2$ switching is enabled by opening the connection at Pin 19. If enabled, the pin will exhibit the internally generated half line frequency squarewave. If it is desired to reverse the sense of the PAL swinging burst, it can be done at this pin by pulling Pin 19 low when the squarewave is high. The component envelopes with the proper PAL burst phase are then modulated to produce the composite chroma.

If the MC13077 is encoding to NTSC, only the B–Y color difference component is provided a negative burst flag. This envelope when modulated results in the characteristic –180° phase difference between the color burst and the subcarrier for the B–Y component. Pin 19 should be grounded for NTSC operation to disable the PAL flip–flop.

Video Outputs

After being filtered, the composite chroma is recombined with the composite luma information for the Composite Video output. The composite chroma and composite luma components are also kept separate and buffered for the chroma S–Video and luma S–Video outputs. The video outputs are provided with low impedance emitter–follower stages and, therefore, require an external 75 Ω impedance determining series resistor (see Figure 7). The outputs are designed to drive a 75 Ω load through the external 75 Ω series resistor.

The Composite Video output will provide 1.23 Vpp of video (sync tip–to–peak chroma) for 100% saturated video at the 75 Ω load. Luma S–Video will be 1.0 Vpp (sync tip–to–peak white) at the 75 Ω load and the Chroma S–Video output will provide 885 mVpp at the 75 Ω load.

PIN FUNCTION DESCRIPTION

Pin	Name	Equivalent Internal Circuit	Description
1	Vertical Oscillator Capacitor		This capacitor should be 100 nF film type to give good temperature stability.
2	Vertical Hold Control		The potentiometer at Pin 2 adjusts the free running frequency of the oscillator. It should normally be set for about 55 Hz with no vertical signal input such that it will lock to 60 Hz.
3	Vertical Integrator Capacitor		The capacitor on this pin integrates the sync pulses with a long time constant. C3 is typically 0.01 µF.
4	Vertical TTL Sync		Vertical TTL Sync input. The input threshold voltage at this pin is 2.0 V.
5	Horizontal TTL Sync		Composite or Horizontal TTL Sync input. The input threshold voltage at this pin is 2.0 V.
6	Composite Video Input		This pin requires a coupling of min 100 nF. The composite sync input should consist of $-V_E$ sync signal only with amplitude > 500 mVpp. The source impedance of the sync signal should be <1.0 kΩ. Sync information at Pin 5 will override this pin, but signals at Pin 4 will not. Minimum pulse width is 2.0 µs.
7, 8	N/C		These two pins are internally connected to each other, and nothing else.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
9	5.0 V Regulator Output		5.0 V (±5%) regulator. Minimum 10 µF capacitor is required for noise filtering and compensation. Up to 20 mA can be supplied to external circuitry. It can source but not sink current. Output impedance is ≈ 10 Ω. This 5.0 V regulator is recommended for use as a reference only.
10	Phase Detector 1 Filter		External components at this pin will determine the PLL gain and phase characteristics. The capacitors should be non–polarized. The voltage at this pin nominally ranges from 1.5 V to 5.0 V with corresponding horizontal frequency from 25 kHz to 68 kHz.
11	Automatic Frequency Control		Pin 11 is a buffered equivalent of Pin 10, and ranges from a minimum of 1.5 V at horizontal high frequency to near 5.0 V at low frequency. Pin 11 can sink a maximum of 1.0 mA, but cannot source current.
12	Horizontal Frequency Range		The current out of Pin 12 determines the horizontal frequency by a current transfer constant of ≈ 122 Hz/µA. Pin 12 is internally maintained at 5.0 V.
13	Timebase Ground		Ground for the timebase section. Connect to a clean, low impedance ground.
14, 16	FH Switch A, B		Pin 14 (Switch A), and Pin 16 (Switch B) are open collector NPN switches to ground. Each switch is "on" when the horizontal frequency is higher than the set points set by resistors at Pins 15 and 17, respectively. Maximum voltage is 8.0 V, and maximum sink current is 20 mA.
15, 17	FH Switch A, B Threshold Setting		Pin 15 and Pin 17 are current mirror at 1/2 of Pin 12 current. External resistors at these pins set the horizontal frequency at which Pins 14 and 16 will switch, respectively. The threshold voltage is 5.0 V.
18	Contrast Control		The input control range is from 0 to 5.0 V. An increase of voltage increases contrast.
19	Brightness Control		The input control range is from 0 to 5.0 V. An increase of voltage increases brightness.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
 20 24 26	Subcontrast Control Channel 1 Channel 2 Channel 3		Subcontrast controls the gain of each video channel. 0 V for maximum gain, and 2.0 V for minimum gain.
21, 22	N/C		These two pins are internally connected to each other, and nothing else.
 23 25 27	Video Inputs Channel 1 Channel 2 Channel 3		The input coupling capacitor is used for input clamp storage. The maximum source impedance is 100 Ω. Polarity of the input video signal is positive. Amplitude should be nominally 0.7 Vpp.
28	Video Ground		Ground for the video section (video amplifiers, contrast and brightness controls, subcontrast, and video reference voltage). Noise from the timebase section, and other digital circuits, should not be allowed to produce ground bounce at this pin.
29	Video V_{CC1}		Connected to a 8.0, V ±5%, dc supply. Decoupling is required at this pin.
 38 33 30	Video Clamp Channel 1 Channel 2 Channel 3		Normally a 100 nF capacitor is connected to each of these pins.
  39 34 31 40 37 32	Video Emitter Output Channel 1 Channel 2 Channel 3 Video Collector Output Channel 1 Channel 2 Channel 3		Pins 39, 34, and 31 are the emitter outputs of the three video amplifier, and have an internal 33 Ω resistor. The emitter dc voltage is controlled by the brightness control. The current through each collector and emitter should not exceed 40 mA.
35, 36	N/C		These two pins are internally connected to each other, and nothing else.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
41	X–Ray Shutdown		If the voltage at this pin is > 0.58 V, the horizontal driver device (Pins 42 and 43) will be “on” until power is removed, or the voltage on this pin is taken below 0.4 V.
42	Horizontal Drive Ground		This emitter pin must be connected externally to a low impedance ground. Pin 43 is an open collector pin and normally is pulled up by a resistor to V_{CC}. Maximum current through Pins 42 and 43 must be less than 40 mA.
43	Horizontal Drive		
44	Horizontal Drive Width		Varying the voltage at this pin will change the horizontal drive duty cycle. As the voltage of this pin is increased, the “on” time at Pin 43 is decreased. Input impedance is ≈ 30 kΩ.
45	Secondary Phase Detector Filter		Typically a 10 to 100 nF decoupling capacitor is connected to this pin.
46	Horizontal Flyback		The flyback signal should be a $+V_E$ pulse of peak voltage 8.0 V. The internal switching voltage is 0.7 V and it controls the secondary PLL Input impedance is ≈ 10 kΩ
47	Video Blanking Input		The video blanking signal should be positive pulse in the range of 1.5 to 4.0 V.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
48	Vertical Ramp Output		This ramp signal drives the external vertical output devices. Voltage ramps from 2.0 V to less than 5.0 V, depending on frequency and components at Pins 51 and 52. Loading on this pin must be > 30 kΩ to avoid distorting or clipping the ramp.
49, 50	N/C		These two pins are internally connected to each other, and nothing else.
51	Vertical Ramp Capacitor		The slope of the output ramp is determined by the components at Pins 51 and 52. The resistor at Pin 52 sets the charging current of the capacitor, and therfore the vertical height of the picture. The linearity of the ramp can be modified by external feedback.
52	Vertical Size Control		
53	Vertical Sync Polarity Detector		The output goes low when the vertical sync input polarity is positive. It goes high when the vertical sync input polarity is negative.
54	Horizontal Sync Polarity Detector		The output goes low when the horizontal sync input polarity is positive. It goes high when the horizontal sync input polarity is negative.
55	Horizontal Position Control		Varying the voltage at this pin will change the horizontal position of the picture. Input impedance is ≈ 31 kΩ.
56	Timebase V_{CC2}		Connected to a 8.0 V, ±5%, dc supply. Decoupling is required at this pin.

APPLICATION INFORMATION

The MC13081X is an integrated multisync color monitor processor. It combines horizontal/vertical deflection processing circuitry and video pre–amplifiers into a single device.

The overall timebase section consists of two parts: horizontal and vertical. The horizontal timebase can be operated from 30 kHz to 64 kHz, and can be driven from TTL separate sync, composite sync, or a composite video signal. There are two PLLs which ensure proper timing throughout the whole system. The first PLL provides line locking of the horizontal sync signal with the built–in oscillator, while the second one maintains fixed timing with the horizontal flyback signal such that a stable display can be achieved.

The vertical timebase section operates from 45 Hz to 100 Hz, and can receive various sync signals as the horizontal one does. This section consists of an oscillator and a ramp generator. Adjustments include linearity, ramp amplitude, and minimum free running frequency in the absence of sync signal.

The video section has three 70 MHz bandwidth pre–amplifiers. The outputs of these amplifiers are uncommitted collector/emitter facilitating cascode configuration with subsequent stages. Controls include brightness and contrast. In addition, the voltage gain of each amplifier can be adjusted individually which provides flexibility in adjusting color correctness. Blanking and clamping signals are provided to the amplifiers internally from the timebase section. Additionally, a blanking signal can also be supplied externally.

Separate power supply and ground pins are provided to the timebase and video section in order to minimize the cross interference between these two sections.

VR2	5.0 kΩ
VR3	200 kΩ
VR4	1.0 MΩ

The following describes a step–by–step procedure in using the MC13801 for a typical multisync color monitor chassis; component notations refer to Figure 2.

1. Horizontal Frequency Range Resistor Network (Pins 11, 12)

F_{Hm} = Minimum Horizontal Frequency
F_{Hx} = Maximum Horizontal Frequency
Oscillator Transfer Constant = 122 Hz/µA

$$R5 = \frac{6.35 \text{ x } 10^8}{F_{Hx} - F_{Hm}}$$

$$R6 = \frac{5}{\dfrac{F_{Hx}}{122 \text{ x } 10^6} - \dfrac{3.5}{R5}}$$

$$R4 \leq \frac{V_{CC} - 6.0}{1.5} \text{ x } R5 \text{ and } \frac{V_{CC} - 1.5}{R4} < 1.0 \text{ mA}$$

For most applications, R4 = R5 provides the required results.

NOTE: In order to compensate device/component tolerance, a potentiometer is recommended in series with R6, as VR1.

2. Horizontal Frequency Range Phase Detector Filter Network (Pin 10)

Typical values are:
C10 = 1.0 nF
C11 = 100 nF
R15 = 5.6 k
C11 ≥ 100 x C10

NOTE: C10 and C11 should have less than 1.0 µA leakage.

3. Horizontal Free Running Frequency

The voltage at Pin 10 will be buffered to Pin 11, and hence control the internal oscillator. In the absence of horizontal sync signal, the free running horizontal frequency will vary between preset minimum and maximum horizontal frequency values.

If an undetermined free running frequency value is not desired, a large impedance resistor can be used to pull Pin 10 to V_{CC} or Gnd, and the free running frequency will be equal to F_{Hm} or F_{Hx}, respectively.

The free running frequency can also be set to any value within the horizontal frequency range by using a voltage divider, as R7 and R8 indicate.

$$V11 = V_D \text{ x } \frac{R7}{R7 + R8}$$

$$I12 = \frac{V11}{R6 + VR1} - \frac{V11 - 5}{5}$$

$$\text{Free Running Frequency} = I12 \text{ µA x } \frac{122 \text{ Hz}}{\text{µA}}$$

The above formula provides the ratio of R7 and R8. The values chosen should be similar to those shown in Figure 2.

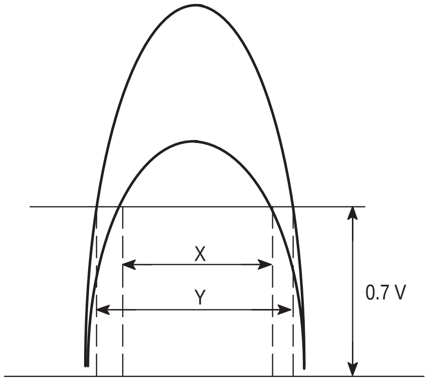
4. Horizontal Flyback Input (Pin 46)

The horizontal flyback signal not only provides proper timing reference for the horizontal drive output, but also supplies the necessary blanking for the video outputs.

There are two precautions for the flyback input. First, the signal should have a zero volt reference, and second, the peak value should be as near to V_{CC} as possible.

The threshold voltage for Pin 46 is 0.7 V. The blanking period depends on the amplitude, as shown in Figure 3 (X and Y, respectively). A larger amplitude provides better consistency and control of the blanking period.

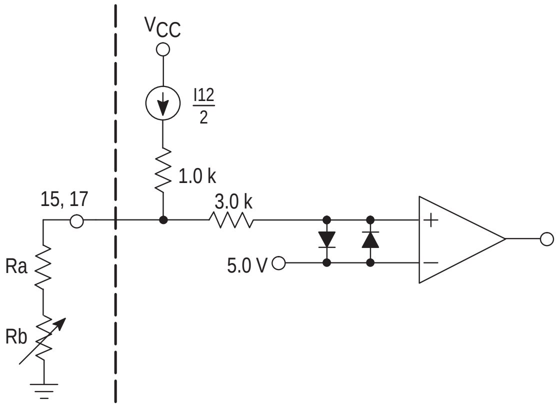
Figure 3. Voltage for Flyback



5. Frequency Switch (Pin 14 to 17)

There are two frequency switches available for screen size compensation for different timing standards. Each switch will turn on at the switch frequency set with its external resistor. See Figure 4.

Figure 4. FH Switches



The switch frequency is calculated as follow:

$$SF = \text{Switch Frequency} \qquad SF = \frac{5 \text{ x } 2 \text{ x } 122 \text{ x } 10^6}{Ra + Rb}$$

In considering the ratio of Ra to Rb, the following parameters, and their tolerances, need to be clarified:

1. I_{osc}	±10%
2. 5.0 V_{ref}	±5%
3. V_{hys}	±5%
4. Ra, Rb	±?%

Internally, the lock–in horizontal frequency will build up a current reference, and half of this current reference is used for setting up a voltage and then compared with the internal 5.0 V_{ref}. Looking at the four parameters above, the first three are IC related, while the last item depends on the external component tolerance.

By adding up the first three items, the value of Ra and Rb should be chosen to compensate for about 20% of system tolerance.

Therefore, if Ra is chosen to be 70% of the calculated value (Ra + Rb), Rb should be 60% of (Ra + Rb). That means, the overall adjustment is about 70% to 130%, which provides additional ±10% margin.

During normal operation, the frequency switch will switch “off” when the pin voltage falls 60 mV below the 5.0 V reference voltage (≈ 4.94 V), and will switch “on” when the pin voltage rises to 40 mV above the 5.0 V reference (≈ 5.04 V).

An Example: Require Trip Point @ 35 kHz

$$I12 = \frac{35 \times 10^3}{122}\ \mu A$$

$$\text{Trip Point Reference Current} = \frac{I12}{2}$$

$$= \frac{35\ k}{122 \times 2}\ \mu A$$

$$Ra + Rb = \frac{5.0\ V}{\frac{35\ k}{122 \times 2}\ \mu A}$$

$$= 34857\ \Omega$$

$$\text{Hysteresis @ 35 kHz} = \frac{5.04 - 4.94\ V}{34857\ \Omega} \times \frac{122\ Hz}{\mu A}$$

$$\approx 350\ Hz$$

From above, Ra + Rb = 34857 Ω

Select Ra = 24 k, and Rb = 20 k Trim Pot

The Temperature Coefficient of the potentiometer can also be considered. If the value of the potentiometer and Ra vary by 1% (for example) over temperature, the error would be:

$$5 \times \left\{\frac{1}{34857 \times 0.99} - \frac{1}{34857 \times 1.01}\right\} \times \frac{122\ Hz}{\mu A}$$

$$\approx 350\ Hz$$

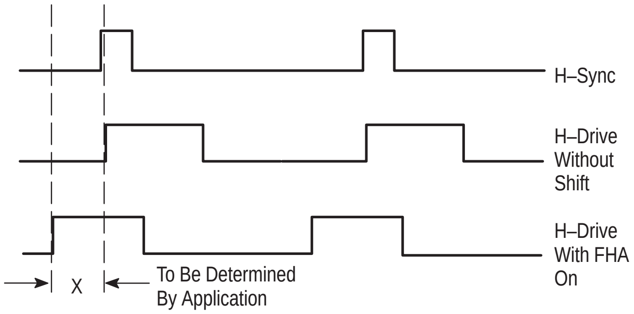
6. Horizontal Position Compensation for Selected Scan Frequency in Using FHA Switch

Refering to Figure1 (block diagram), there is an output from the FHA switch to the horizontal drive output. When the FHA switch is switched on, at a specified horizontal frequency, there is a 1/8th horizontal line shift of H–Ramp1. Referring to Figures 5 and 9, a shift of H–Ramp1 will result in a shift of the H–Drive output timing with respect to flyback input.

The exact H–Drive output shift will be determined by the PD2 voltage (Pin 45), which is generated by the flyback input and the internal Comp1 output. That is related to the H–Drive output transistor storage time.

This function is particularly useful for high frequency scan rates. The higher the frequency, the more significant the storage time becomes, compared to the horizontal scan time.

Figure 5.



7. Proper Horizontal Phase Control

The horizontal adjustment range depends on the phase angle between the H–Sync signal and the horizontal flyback input. In reality, the actual adjustment range is a combination of horizontal frequency, front porch/back porch timing, flyback pulse width, and horizontal output transistor storage time. The following paragraph conveys the concept for normal operation.

There are two clamping situations for video signals. In case 1, separate VTTL and HTTL sync are provided, the video signal is clamped at sync tip, and the dc voltage built up is used for black level reference. In this instance, the clamp pulse has the same pulse width as H–Sync, and nearly the same position. This clamp pulse is blanked out internally. In order to allow the video output to complete the blanking action during horizontal retrace, the horizontal phase should not be over–adjusted. See Figure 6 for a pictorial perception. Accordingly, the total horizontal position adjustment range is calculated as the sum of Δt1 and Δt2.

Should the phase of horizontal flyback/H–Sync move further left or right from the normal adjustment range, the black level reference voltage will be restored, and consequently a slightly brighter than screen dark region will be observed on–screen. See Figure 7 for pictorial explanation.

$$\text{Horizontal Blanking Time} = FP_{time} + \text{Sync Width} + BP_{time} = T_{HB}$$

Criterion for Normal Operation:

$$|\Delta t1| < \frac{T_{HB}}{2} \qquad |\Delta t2| < \frac{T_{HB}}{2}$$

In other words, the left/right 0.7 V threshold flyback reference should be within the H–Sync pulse (shaded area of Figure 6).

Figure 6. Horizontal Position Adjustment at Normal Operation

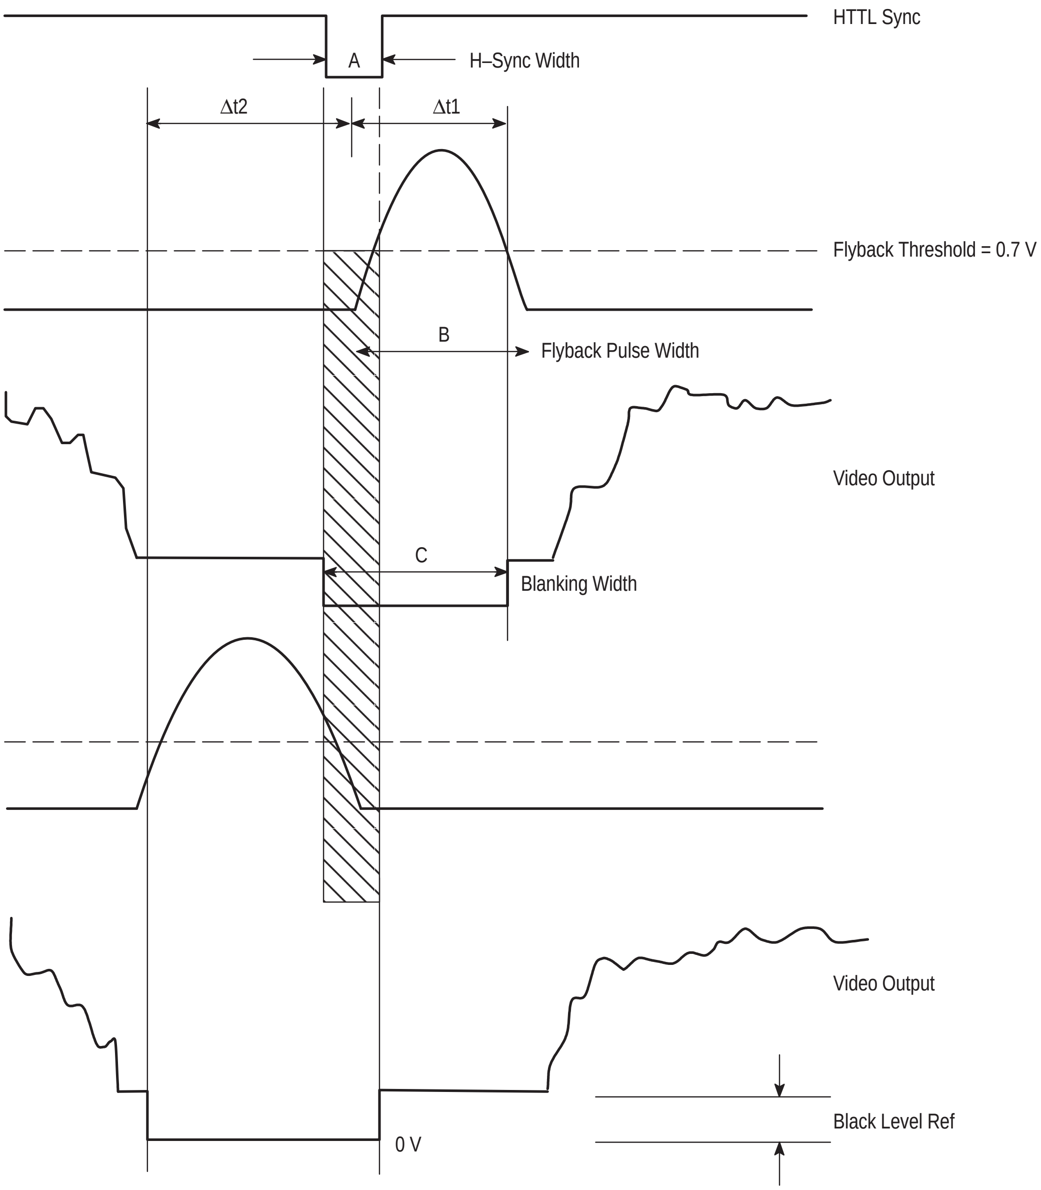


Figure 7. Horizontal Position Adjustment at Overscan Operation

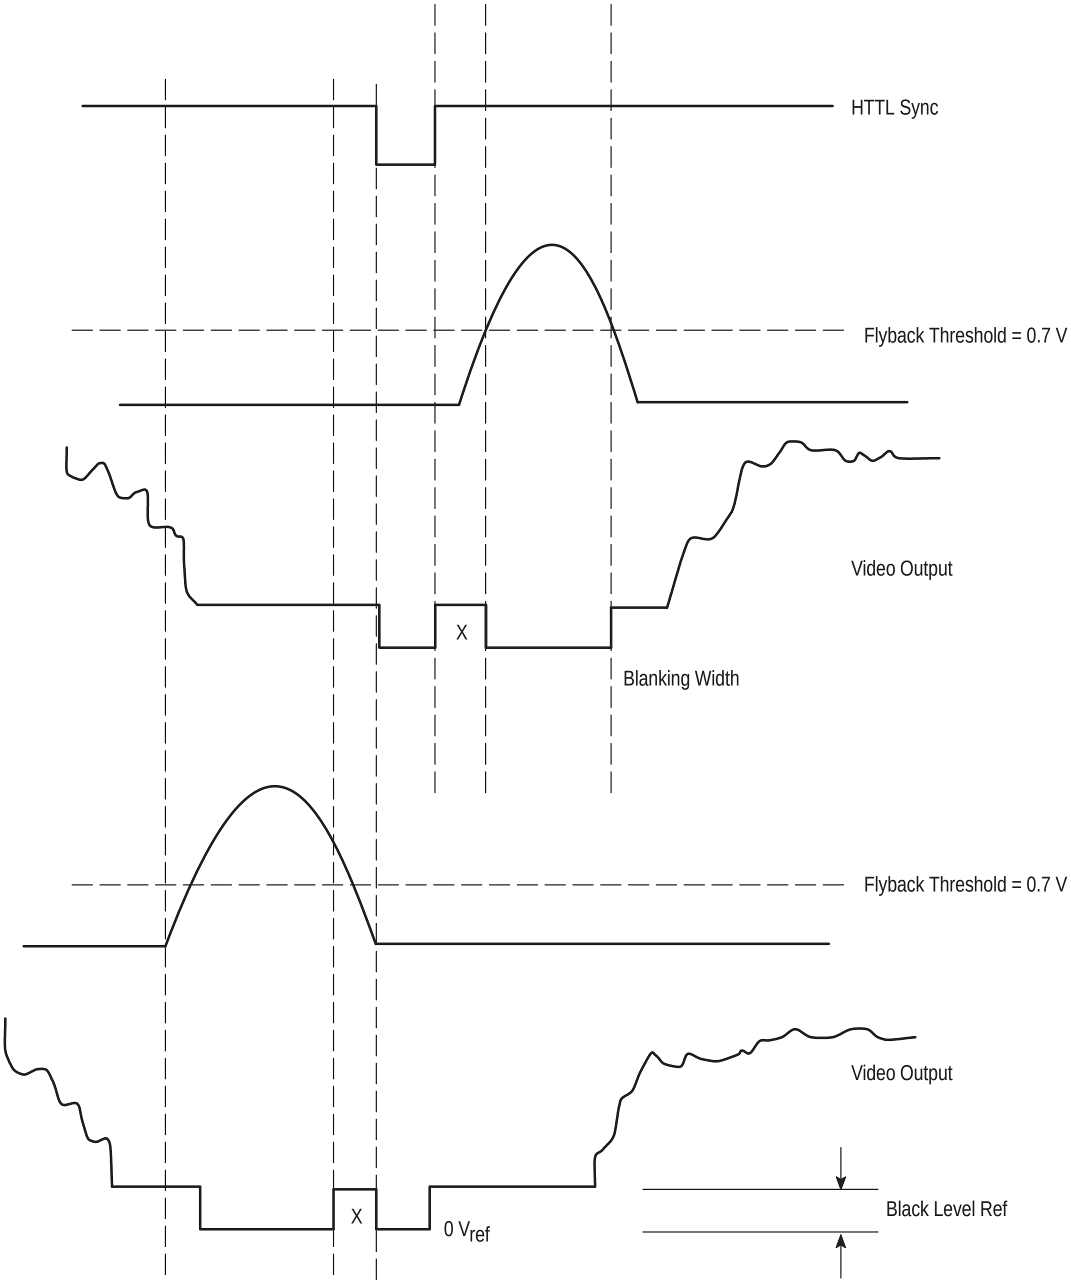
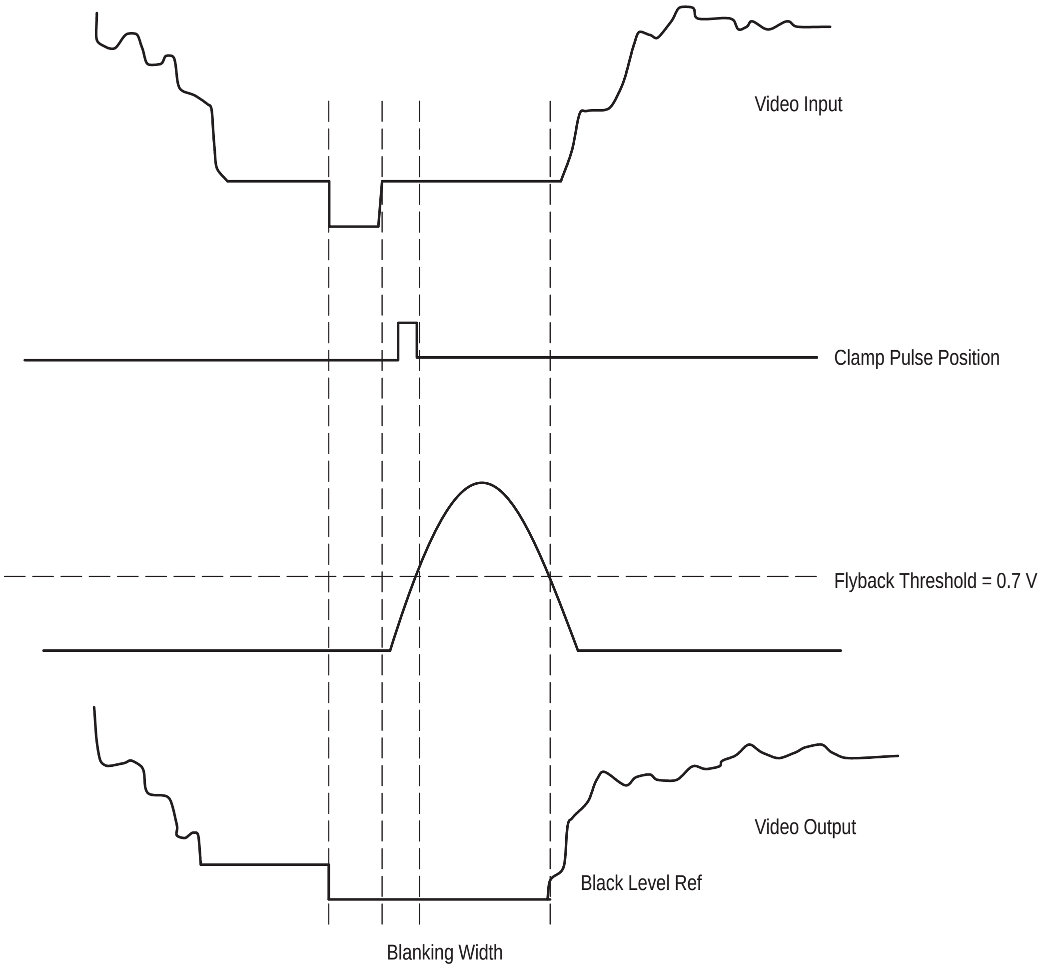


NOTE: Region X will appear as bright vertical stripe.

Figure 8.



In case 2, composite sync is used instead of VTTL and HTTL sync, the clamp pulse is located at the backporch of the video signal, and the width of the clamp pulse is calculated as follows:

$$\text{Clamp Pulse Width} = \frac{1}{64 \text{ x Line Frequency}} \text{ x } 3$$

Blanking Width = Sync Width + Clamp Pulse Width
+ Flyback Threshold (0.7 V) (See Figure 8)

From the above diagram, it can be seen that the horizontal position adjustment is basically the same as case 1 except slightly wider with the addition of clamp pulse blanking.

8. Horizontal Timing Relationship for Phase Detector 2

The following paragraphs explain the PLL2 mechanism. Figure 9 portrays the timing signals of various parts of the IC.

In using the H–Sync pulse, which is generated from PLL1, a horizontal ramp 1 signal is created. H–Ramp1 starts at 1/4th line before H–Sync and the ramping slope is directly proportional to horizontal frequency. The lower tip of this ramp is at approximately 1.2 V, and the amplitude is about 4.2 V. By adjusting the dc bias to the H–Phase control, a pulse waveform is derived from this H–Ramp1.

A phase detector is used to compare the phase between the pulse generated above, and the incoming flyback pulse. An integrating capacitor is applied to generate a dc voltage. This dc voltage, PD2F output, is used to slice the H–Ramp1 signal in order to generate Comp2 output pulse.

A second ramp signal, H–Ramp2, is triggered from this Comp2 output. By applying a dc voltage (H–Width control) to H–Ramp2, the Comp3 output pulses are generated.

The H–Drive output is formed by the rising edge of Comp2 output and the rising edge of Comp3 output.

It can be seen from Figure 9, if the H–Phase control is over or under driven, it will reach the upper/lower tip of H–Ramp1, and thus PLL2 will be disturbed.

Figure 9. Horizontal Timing for PLL2 Internal Sections

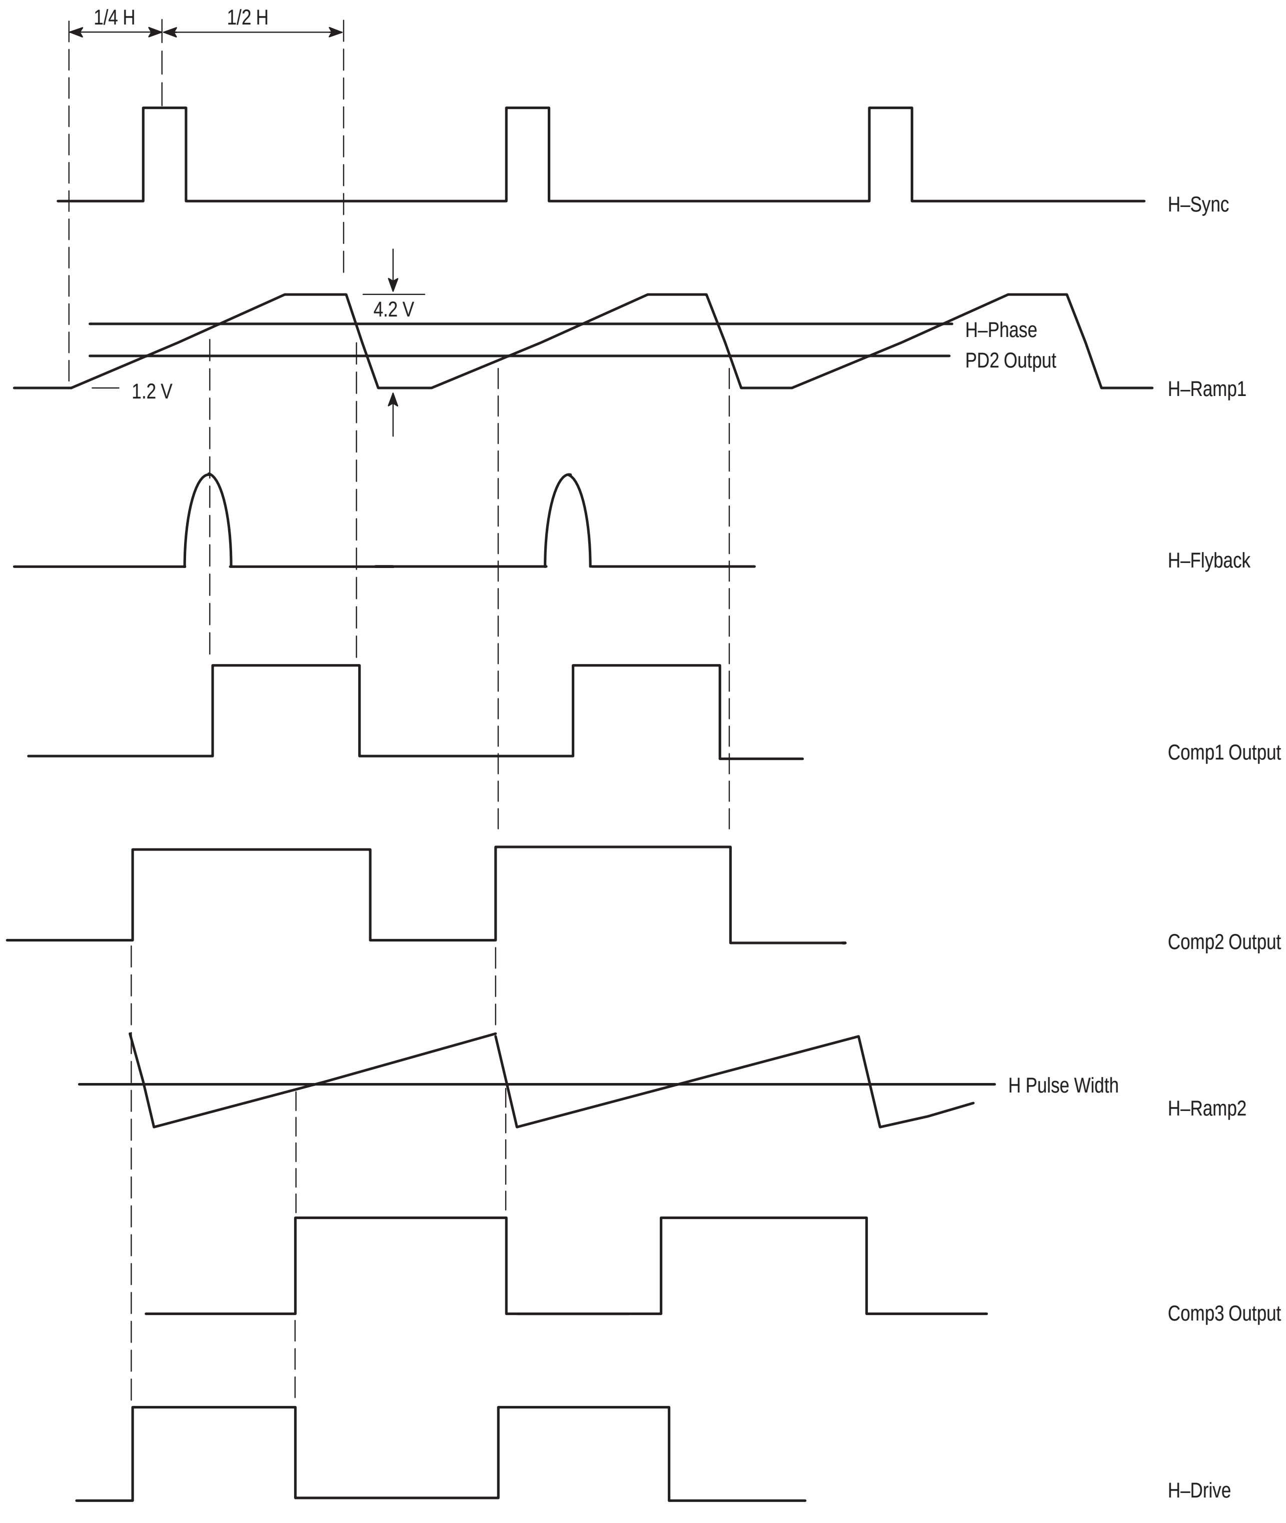


Figure 10. Vertical Section

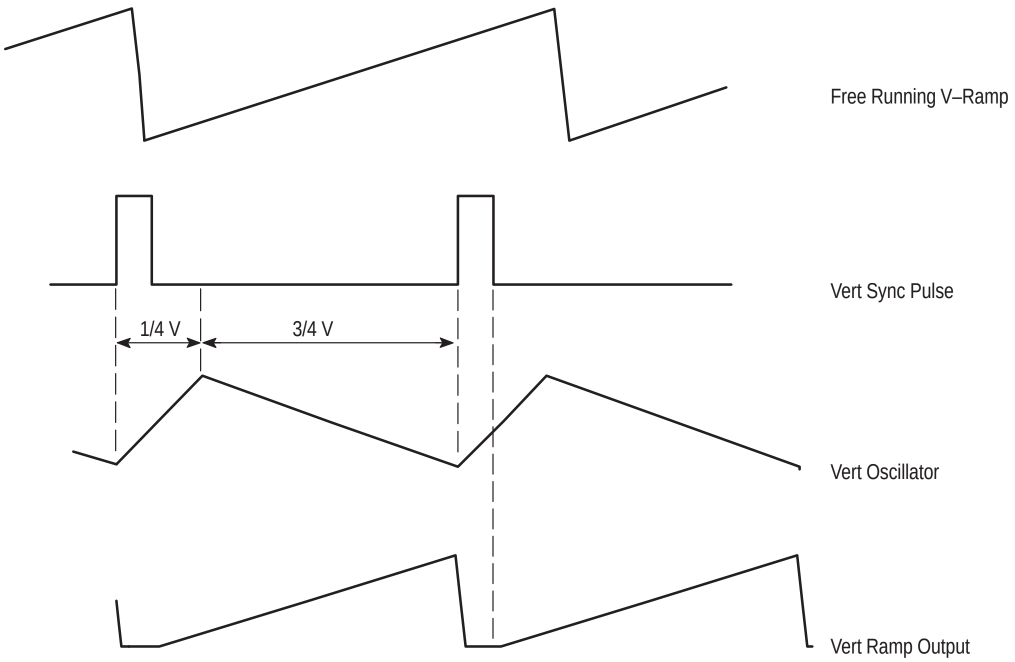


9. Vertical Frequency Range (Pins 48, 51, 52)

The MC13081X vertical oscillator is an injection–lock type. The device can handle vertical frequency from 45 Hz to 100 Hz.

The internal ramp generator will generate a ramp output in the absence of a V–Sync signal. Upon receiving an external vertical sync pulse, the ramp up portion is forced to retrace, and therefore, the vertical ramp output is synchronized with incoming V–Sync.

The slope of the Vertical Ramp output is directly proportional to the current flowing out of Pin 52. Half of this current is used to charge up the Vertical Ramp Capacitor. As the charging current is increased, so does the ramp slope. External feedback can be provided from Pin 48 to Pins 51 and 52 for linearity adjustment.

10. Vertical Free Running Frequency (Pins 1, 2)

The purpose of the vertical oscillator is to maintain a vertical ramp to the deflection circuitry in the event the vertical sync is not present. Because of the injection–lock type, the free running frequency must be lower than the system’s lowest vertical frequency.

While various combinations of C4 and R9 can produce a given frequency, it is recommended C4 be 0.1 µF in order to obtain practical values for R9. The free running frequency should be set at about 10% lower than the minimum operating vertical frequency (54 Hz for a 60 Hz system).

R9 is then calculated from:

$$R9 = \frac{V_{CC} - 1.4}{96 \text{ x } C4 \text{ x } FV} - 2.5 \text{ k}$$

Connecting a potentiometer, (VR2) provides “Vertical Hold” adjustment.

11. X–Ray Shutdown Protection (Pin 41)

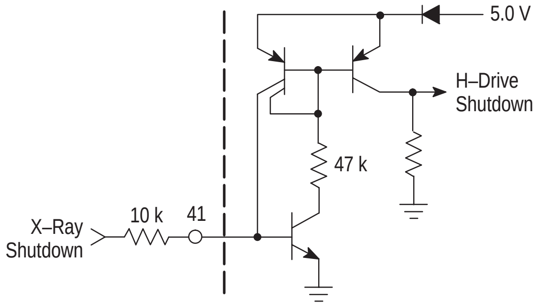
The X–Ray input (Pin 41) permits shutting off the horizontal drive, usually by external circuitry which monitors faults within the high voltage supply, such as excess anode current. This input is activated by taking it above ≈ 0.6 V which causes the drive transistor at Pin 43 to be turned on (low) permanently by an internal latch.

An external resistor must be connected to Pin 41 to limit the input current, and to assist with the latching action (see Figure 11). 10 kΩ is a typical value, but the value can be chosen based on the specifies of the driving circuit. The external resistor reduces the sensitivity of Pin 41 to noise and transients which may otherwise result in false latches.

To resume normal operation (after correction of the fault), lower Pin 41 below 0.4 V. If the external circuit’s normal operation does not take it below 0.4 V, but does take it below 0.6 V, then recycle V_{CC} “off”–“on”. If the pin is not used, it must be connected to ground.

The minimum holding current to keep the latch on is ≈ 70 µA, while the minimum turn–on current is ≈ 0.4 µA.

Figure 11. X–Ray Shutdown Circuit



MOTOROLA

MC13280AY
MC13281A/B

80/100 MHz VIDEO PROCESSOR

Advance Information

80/100 MHz Video Processor

The MC13280AY and MC13281A/B are three channel wideband amplifiers designed for use as a video pre–amplifier in high resolution RGB color monitors.

Features:

- 4.0 Vpp Output Swing
- 3.5 ns Rise/Fall Time, 100 MHz Bandwidth (MC13281A/B)
- 4.3 ns Rise/Fall Time, 80 MHz Bandwidth (MC13280AY)
- Subcontrast Controls for Each Channel
- Main Contrast Control
- Blanking and Clamping Inputs
- Packages: NDIP–24 and NDIP–20
- A Single PC Board Pattern Can Accept the MC13281A and the MC13282A (Video Amplifier with OSD)

PIN FUNCTION DESCRIPTION

MC13280AY MC13281B Pin	MC13281A Pin	Name	Equivalent Internal Circuit	Description
1	1	R Subcontrast Control		These pins provides a maximum of 26 dB attenuation to vary the gain of each video amplifier separately. Input voltage is from 0 to 5.0 V. Increasing the voltage will increase the contrast level.
3	3	G Subcontrast Control		
5	5	B Subcontrast Control		
2	2	R Input		The input coupling capacitor is used for input clamping storage. The maximum source impedance is 100 Ω. Input polarity of the video signal is positive. Nominal 0.7 Vpp input signal is recommended (maximum 1.0 Vpp).
4	4	G Input		
6	6	B Input		
7	7	Ground		Ground pin. Connect to a clean, solid ground.
N/A	8	N/C		Connected to ground.
	10	N/C		
	11	N/C		
	12	N/C		
8	9	V_{CC}		Connect to 8.0 Vdc supply, ±5%. Decoupling is required at this pin.
9	13	Contrast		Overall Contrast Control for the three channels. The input range is 0 V to 5.0 V. An increase of voltage increases the contrast.
10	14	Fast Commutate		Must be connected to ground.
11	15	B Emitter Output		The video outputs are configured as emitter–followers with a driving capability of about 15 mA each. The dc voltage at these three emitters is set to 1.2 V (black level). The dc current through the output stage is determined by the emitter resistors (typically 330 Ω).
15	19	G Emitter Output		
18	22	R Emitter Output		

PIN FUNCTION DESCRIPTION (continued)

MC13280AY MC13281B Pin	MC13281A Pin	Name	Equivalent Internal Circuit	Description
12	16	B Clamp Capacitor		A 100 nF capacitor is connected to each of these pins. The capacitor is used for video output dc restoration.
14	18	G Clamp Capacitor		
17	21	R Clamp Capacitor		
13	17	Video V$_{CC}$		Connect to 8.0 V dc supply, ±5%. The V$_{CC}$ is for the video output stage. It is internally connected to the collectors of the output transistors.
16	20	5.0 V$_{ref}$ (V5)		5.0 V regulator. Minimum 10 µF capacitor is required for noise filtering and compensation. It can source up to 20 mA but not sink current. Output impedance is ≈ 10 Ω. Recommended for use as a voltage reference only.
19	23	Clamp		This pin is used for video clamping. The threshold clamping level is 3.75 V.
20	24	Blank		This pin is used for video blanking. The threshold blanking level is 1.25 V.

FUNCTIONAL DESCRIPTION

The MC13280AY and MC13281A/B are composed of three video amplifiers, clamping and blanking circuitry with contrast and subcontrast controls. Each video amplifier is designed to have a –3.0 dB bandwidth of 100 MHz (MC13281, 80 MHz for the MC13280) with a gain of up to about 5.6 V/V, or 15 dB.

Video Input

The video input stages are high impedance and designed to accept a maximum signal of 1.0 Vpp with 75 Ω termination (typically) provided externally. During the clamping period, a current is provided to the input capacitor by the clamping circuit which brings the input to a proper dc level (nominal 2.0 V). The blanking and clamping signals are to be provided externally, with their thresholds at 1.25 V and 3.75 V, respectively.

Video Output

The video output stages are configured as emitter–followers, with a driving capability of about 15 mA for each channel. The dc voltage at these three emitters is set to 1.2 V (black level). The dc current through each output stage is determined by the emitter resistor (typically 330 Ω).

Contrast Control

The contrast control varies the gain of three video amplifiers from a minimum of 0.3 V/V to a maximum of 5.6 V/V when all subcontrast levels are set to 5.0 V.

Subcontrast Control

Each subcontrast control provides a maximum of 26 dB attenuation on each video amplifier separately.

Clamp Pulse Input

The clamping pulse is provided externally, and the pulse width must be no less than 500 ns.

Blank Pulse Input

The blanking pulse is used to blank the video signal during the horizontal sync period, or used as a control pin for video mute function.

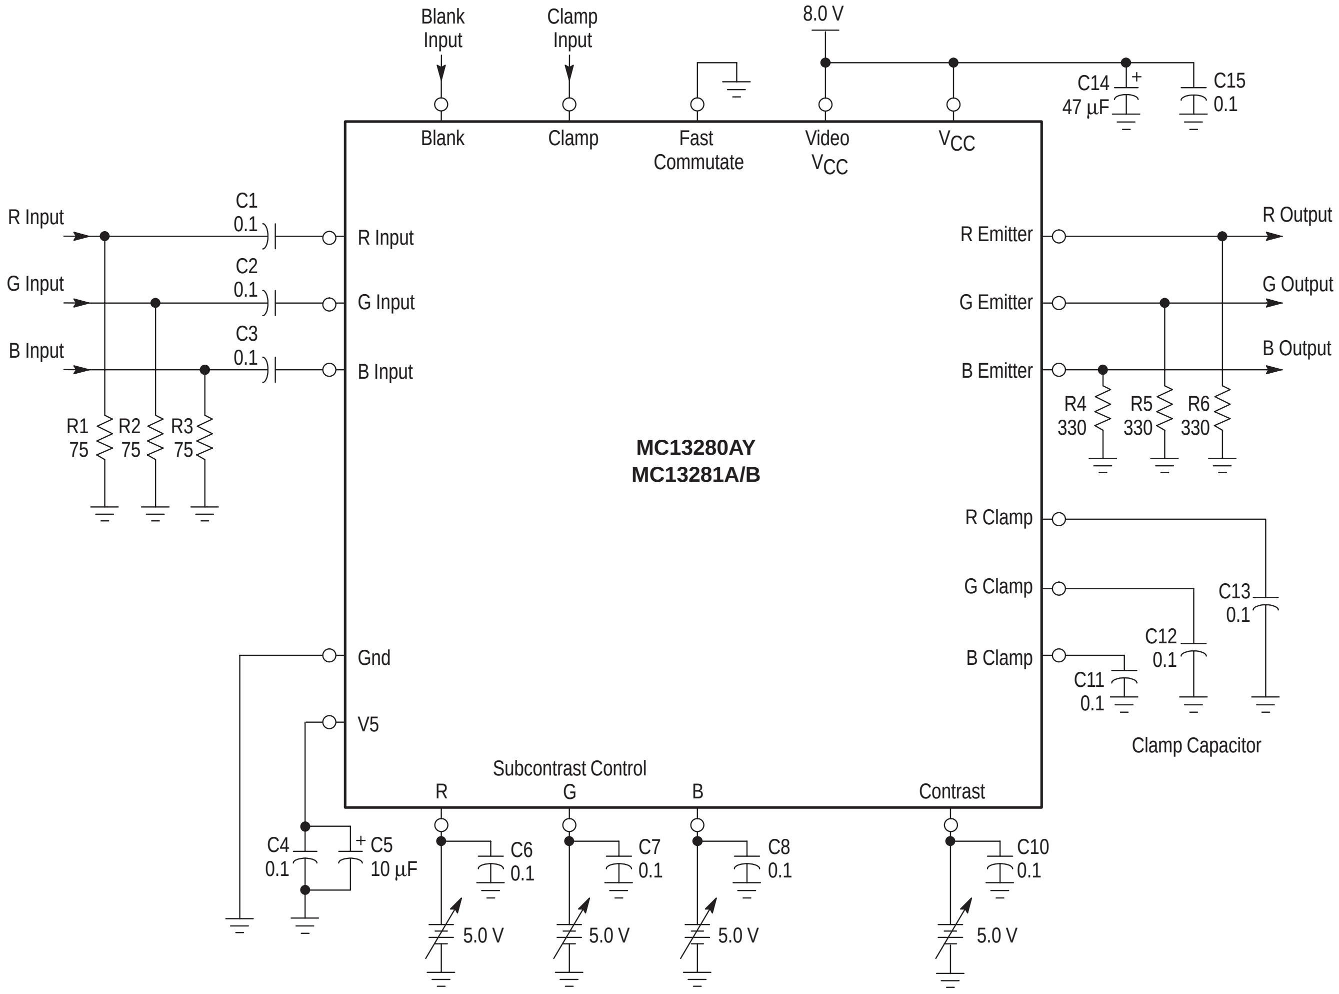
Fast Commutate

This pin should be connected to ground.

Power Supplies

V_{CC} and Video V_{CC} supplies are to be 8.0 V ±5%.

Figure 2. Test Circuit



APPLICATION INFORMATION

PCB Layout

Care should be taken in the PCB layout to minimize the noise effects. The most sensitive pins are V_{CC}, Video V_{CC}, V5 and Clamp. It is strongly recommended to make a ground plane and connect V_{CC}/Video V_{CC} and ground traces, to the power supply directly. Separate power supply traces should be used for V_{CC} and Video V_{CC} and decoupling capacitors should be connected as close as possible to the device. Multi–layer ceramic and tantalum capacitors are recommended. V5 is designed as a 5.0 V voltage reference for contrast, and RGB subcontrast controls, so the same precautions for V_{CC} should also be applied at this pin. The Clamp capacitors should be connected to ground close to IC's ground pin, or power supply ground. The copper trace of video signal inputs and outputs should be as short as possible and separated by ground traces to avoid any RGB cross–interference. A double sided PCB should be used to optimize the device's performance.

RGB Input and Output

The RGB output stages are designed as emitter–followers to drive the CRT driver circuitry directly. The emitter resistors used are 330 Ω (typically) and the driving current is 15 mA maximum for each channel. The loading impedance connected to the output stages should be greater than 330 Ω and less than 5.0 pF for optimum performance (e.g., rise/fall time, bandwidth, etc.). Decreasing the resistive load will reduce the rise/fall time by increasing the driving current, but the output stage may be damaged due to increasing power dissipation at the same time. The frequency response is affected by the loading capacitance. The typical value is 3.0 to 5.0 pF. Figure 3 shows a typical interface with a video output driver. For high resolution color monitor application, it is recommended to use coaxial cable or shielded cable for input signal connections.

Clamp and Blank Input

The clamp input is normally (except for Sync–on–Green) connected to a positive horizontal sync pulse and has a threshold level of 3.75 V. It is used as a timing reference for the dc restoration process, so it cannot be an open circuit. If Sync–on–Green timing mode is used, the clamping pulse should be located at the horizontal back porch period instead of horizontal sync. Otherwise, the black level will be clamped at the wrong dc level.

The blank input is used as a video mute, or horizontal blanking control pin, and is normally connected to a blanking pulse generated from the flyback or MCU. The threshold level is 1.25 V. The blanking pulse width should be equal to the flyback retrace period to make sure that the video signal is blanked properly during retrace. It is necessary to limit the amplitude and avoid any negative undershoot if the flyback pulse is used. The blanking input pin cannot accept a negative voltage. This pin should be grounded if it is not used.

Advance Information

100 MHz Video Processor with OSD Interface

The MC13282A is a three channel wideband amplifier designed for use as a video pre–amp in high resolution RGB color monitors.

Features:

- 4.0 Vpp Output with 100 MHz Bandwidth
- 3.5 ns Rise/Fall Time
- Subcontrast Control for Each Channel
- Blanking and Clamping Inputs
- Contrast Control
- OSD Interface with 50 MHz Bandwidth
- OSD Contrast Control
- Package: NDIP–24

PIN FUNCTION DESCRIPTION

Pin	Name	Equivalent Internal Circuit	Description
1 3 5	R Subcontrast Control G Subcontrast Control B Subcontrast Control		These pin provides a maximum of 26 dB attenuation to vary the gain of each video amplifier separately. Input voltage is from 0 to 5.0 V. Increasing the voltage will increase the contrast level.
2 4 6	R Input G Input B Input		The input coupling capacitor is used for input clamping storage. The maximum source impedance is 100 Ω. Input polarity of the video signal is positive. Nominal 0.7 Vpp input signal is recommended (maximum 1.0 Vpp).
7	Ground		Ground pin. Connect to a clean, solid ground.
8 10 12	R_{OSD} Input G_{OSD} Input B_{OSD} Input		These inputs are standard TTL level.
9	V_{CC}		Connect to 8.0 Vdc supply, ±5%. Decoupling is required at this pin.
11	OSD Contrast		On Screen Display contrast control. Input voltage is from 0 to 5.0 V. Increasing the voltage will increase the contrast of the OSD signal.
13	Contrast		Overall Contrast Control for the three channels. The input range is 0 V to 5.0 V. An increase of voltage increases the contrast.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
14	Fast Commutate		This pin is used in conjunction with the RGB OSD inputs. It is a high speed switch used for overlaying text on picture. A logic low selects Pins 2, 4, 6. A logic high selects Pins 8, 10, 12.
15 19 22	B Emitter Output G Emitter Output R Emitter Output		The video outputs are configured as emitter–followers with a driving capability of about 15 mA each. The dc voltage at these three emitters is set to 1.2 V (black level). The dc current through the output stage is determined by the emitter resistors (typically 330 Ω).
16 18 21	B Clamp Capacitor G Clamp Capacitor R Clamp Capacitor		A 100 nF capacitor is connected to each of these pins. The capacitor is used for video output dc restoration.
17	Video V_{CC}		Connect to 8.0 V dc supply, ±5%. This V_{CC} is for the video output stage. It is internally connected to the collectors of the output transistors.
20	5.0 V_{ref} (V5)		5.0 V regulator. Minimum 10 µF capacitor is required for noise filtering and compensation. It can source up to 20 mA but not sink current. Output impedance is ≈ 10 Ω. Recommended for use as a voltage reference only.

PIN FUNCTION DESCRIPTION (continued)

Pin	Name	Equivalent Internal Circuit	Description
23	Clamp		This pin is used for video clamping. The threshold clamping level is 3.75 V.
24	Blank		This pin is used for video blanking. The threshold blanking level is 1.25 V.

FUNCTIONAL DESCRIPTION

The MC13282A is composed of three video amplifiers, clamping and blanking circuitry with contrast and subcontrast controls and OSD interface. Each video amplifier is designed to have a –3.0 dB bandwidth of 100 MHz with a gain of up to about 5.6 V/V, or 15 dB.

Video Input

The video input stages are high impedance and designed to accept a maximum signal of 1.0 Vpp with 75 Ω termination (typically) provided externally. During the clamping period, a current is provided to the input capacitor by the clamping circuit which brings the input to a proper dc level (nominal 2.0 V). The blanking and clamping signals are to be provided externally, with their thresholds sitting at 1.25 V and 3.75 V, respectively.

Video Output

The video output stages are configured as emitter–followers, with a driving capability of about 15 mA for each channel. The dc voltage at these three emitters is set to 1.2 V (black level). The dc current through each output stage is determined by the emitter resistor (typically 330 Ω).

Contrast Control

The contrast control varies the gain of three video amplifiers from a minimum of 0.3 V/V to a maximum of 5.6 V/V when all subcontrast levels are set to 5.0 V.

Subcontrast Control

Each subcontrast control provides a maximum of 26 dB attenuation on each video amplifier separately.

OSD Interface

The three OSD inputs are TTL compatible and have a typical bandwidth of 50 MHz. A fast commutate pin is provided to select either the video or the OSD inputs as the source for the outputs. OSD contrast control is also provided to set the amount of gain required when OSD inputs are selected.

Clamp Pulse Input

The clamping pulse is provided externally, and the pulse width must be no less than 500 ns.

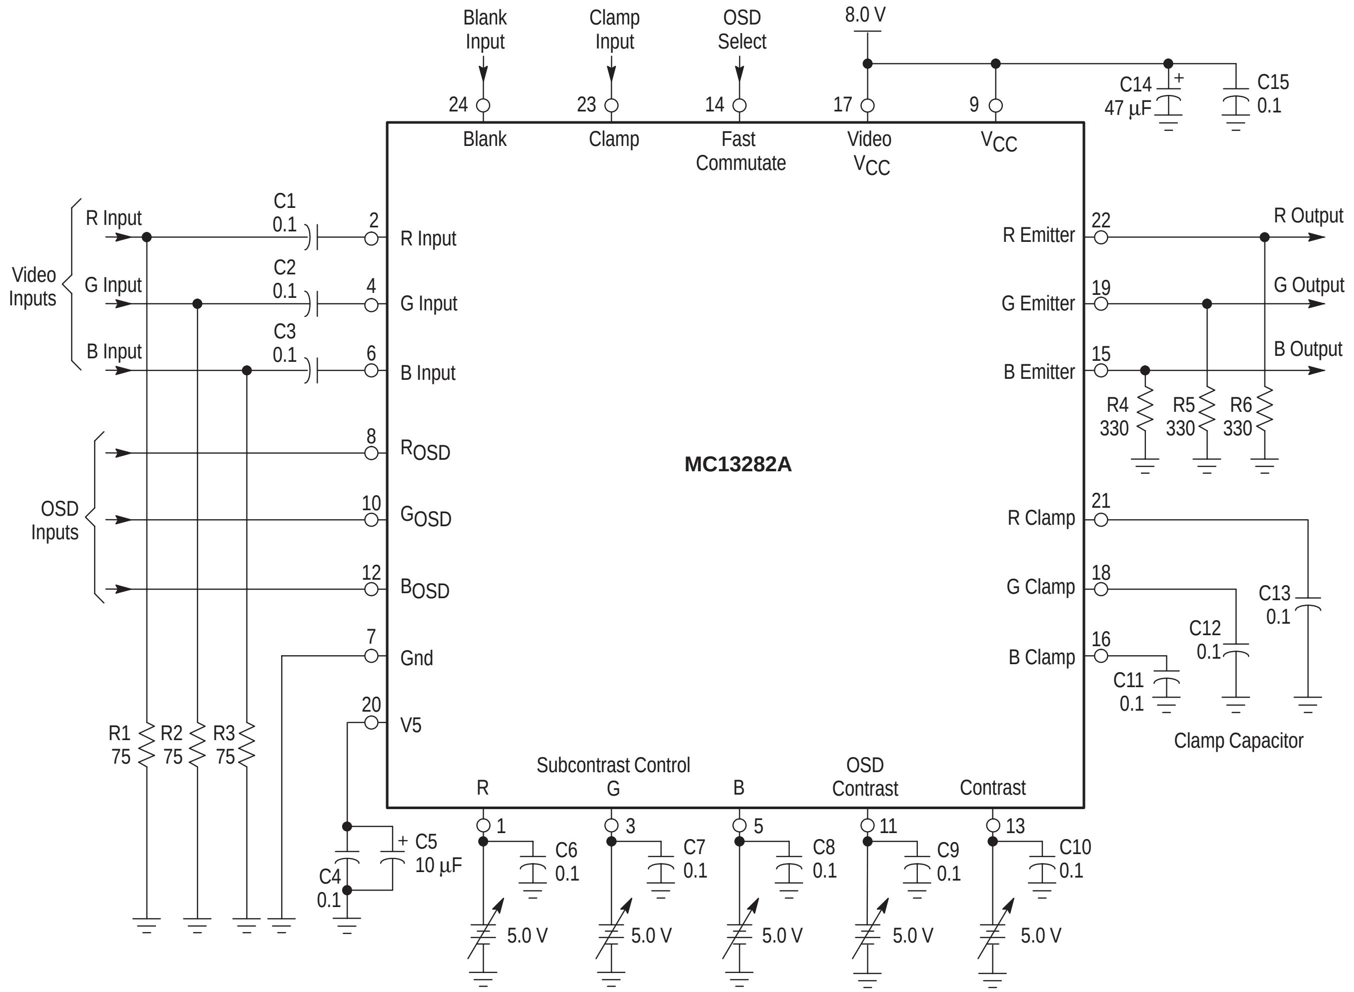
Blank Pulse Input

The blanking pulse is used to blank the video signal during the horizontal sync period, or used as a control pin for video mute function.

Power Supplies

V_{CC} and Video V_{CC} supplies are to be 8.0 V ±5%.

Figure 2. Test Circuit



APPLICATION INFORMATION

PCB Layout

Care should be taken in the PCB layout to minimize the noise effects. The most sensitive pins are V_{CC} (9), Video V_{CC} (17), V5 (20), Clamp (16, 18, 21). It is strongly recommended to make a ground plane and connect V_{CC}/Video V_{CC} and ground traces to the power supply directly. Separate power supply traces, should be used for V_{CC} and Video V_{CC} and decoupling capacitors should be connected as close as possible to the device. Multi–layer ceramic and tantalum capacitors are recommended. Pin 20 (V5) is designed as a 5.0 V voltage reference for contrast, RGB subcontrast and OSD contrast controls, so the same precaution for V_{CC} should be also applied at this pin. The Clamp capacitors at Pins 16,18 and 21 should be connected to ground close to IC's ground Pin 7 or power supply ground. The copper trace of the video signal inputs and outputs should be as short as possible and separated by ground traces to avoid any RGB cross–interference. A double sided PCB should be used to optimize the device's performance.

RGB Input and Output

The RGB output stages are designed as emitter–followers to drive the CRT driver circuitry directly. The emitter resistors used is 330 Ω (typically) and the driving current is 15 mA maximum for each channel. The loading impedance connected to the output stages should be greater than 330 Ω and less than 5.0 pF for optimum performance (e.g., rise/fall time, bandwidth, etc.). Decreasing the resistive load will reduce the rise/fall time by increasing the driving current, but the output stage may be damaged due to increasing power dissipation at the same time. The frequency response is affected by the loading capacitance. The typical value is 3.0 to 5.0 pF. Figure 4 shows a typical interface with a video output driver. For a high resolution color monitor application, it is recommended to use coaxial cable or shielded cable for input signal connections.

Clamp and Blank Input

The clamp input is normally (except for Sync–on–Green) connected to a positive horizontal sync pulse, and has a threshold level of 3.75 V. It is used as a timing reference for the dc restoration process, so it cannot be left open. If Sync–on–Green timing mode is used, the clamping pulse should be located at horizontal back porch period instead of horizontal sync tip. Otherwise, the black level will be clamped at an incorrect voltage.

The blank input is used as a video mute, or horizontal blanking control, and is normally connected to a blanking pulse generated from the flyback or from an MCU. The threshold level of 1.25 V. The blanking pulse width should be equal to the flyback retrace period to make sure that the video signal is blanked properly during retrace. It is necessary to limit the amplitude, and avoid any negative undershoots if the flyback pulse is used. This Blanking input pin cannot accept a negative voltage. This pin should be grounded if it is not used.

OSD interface

Figure 3 show a typical application with an OSD device (MC141540). The MC141540 OSD and FC outputs are TTL compatible, and therefore interface directly with MC13282A. Level shifting circuitry is not needed. The MC141540 is a digital device, controlled by an MCU. Therefore, separate power supply runs to the MC141540 and to the MC13282A are recommended. Care should be taken in the PC board layout to prevent digital noise from entering the analog portions of MC13282A.

Normally the OSD switching is done during the active video time. It is recommended that the Fast Commutate pin not be activated during the horizontal sync time.

MC34119

Low Power Audio Amplifier

The MC34119 is a low power audio amplifier intergrated circuit intended (primarily) for telephone applications, such as in speakerphones. It provides differential speaker outputs to maximize output swing at low supply voltages (2.0 V minimum). Coupling capacitors to the speaker are not required. Open loop gain is 80 dB, and the closed loop gain is set with two external resistors. A Chip Disable pin permits powering down and/or muting the input signal. The MC34119 is available in standard 8–pin DIP, SOIC package, and TSSOP package.

- Wide Operating Supply Voltage Range (2.0 V to 16 V), Allows Telephone Line Powered Applications
- Low Quiescent Supply Current (2.7 mA Typ) for Battery Powered Applications
- Chip Disable Input to Power Down the IC
- Low Power–Down Quiescent Current (65 µA Typ)
- Drives a Wide Range of Speaker Loads (8.0 Ω and Up)
- Output Power Exceeds 250 mW with 32 Ω Speaker
- Low Total Harmonic Distortion (0.5% Typ)
- Gain Adjustable from <0 dB to >46 dB for Voice Band
- Requires Few External Components

MAXIMUM RATINGS

PIN FUNCTION DESCRIPTION

Symbol	Pin	Description
CD	1	Chip Disable – Digital input. A Logic “0” (<0.8 V) sets normal operation. A logic “1” (≥2.0 V) sets the power down mode. Input impedance is nominally 90 kΩ .
FC2	2	A capacitor at this pin increases power supply rejection, and affects turn–on time. This pin can be left open if the capacitor at FC1 is sufficient.
FC1	3	Analog ground for the amplifiers. A 1.0 µF capacitor at this pin (with a 5.0 µF capacitor at Pin 2) provides (typically) 52 dB of power supply rejection. Turn–on time of the circuit is affected by the capacitor on this pin. This pin can be used as an alternate input.
V_{in}	4	Amplifier input. The input capacitor and resistor set low frequency rolloff and input impedance. The feedback resistor is connected to this pin and V_{O1}.
V_{O1}	5	Amplifier Output #1. The dc level is ≈ (V_{CC} – 0.7 V)/2.
V_{CC}	6	DC supply voltage (+2.0 V to +16 V) is applied to this pin.
GND	7	Ground pin for the entire circuit.
V_{O2}	8	Amplifier Output #2. This signal is equal in amplitude, but 180° out–of–phase with that at V_{O1}. The dc level is ≈ (V_{CC} – 0.7 V)/2.

DESIGN GUIDELINES

General

The MC34119 is a low power audio amplifier capable of low voltage operation (V_{CC} = 2.0 V minimum) such as that encountered in line–powered speakerphones. The circuit provides a differential output ($V_{O1}–V_{O2}$) to the speaker to maximize the available voltage swing at low voltages. The differential gain is set by two external resistors. Pins FC1 and FC2 allow controlling the amount of power supply and noise rejection, as well as providing alternate inputs to the amplifiers. The CD pin permits powering down the IC for muting purposes and to conserve power.

Amplifiers

Referring to the block diagram, the internal configuration consists of two identical operational amplifiers. Amplifier #1 has an open loop gain of ≥80 dB (at f ≤ 100 Hz), and the closed loop gain is set by external resistor R_f and R_i. The amplifier is unity gain stable, and has a unity gain frequency of approximately 1.5 MHz. In order to adequately cover the telephone voice band (300 Hz to 3400 Hz), a maximum closed loop gain of 46 is recommended. Amplifier #2 is internally set to a gain of – 1.0 (0 dB).

The outputs of both amplifiers are capable of sourcing and sinking a peak current of 200 mA. The outputs can typically swing to within ≈0.4 V above ground, and to within ≈1.3 V below V_{CC}, at the maximum current. See Figures 18 and 19 for V_{OH} and V_{OL} curves.

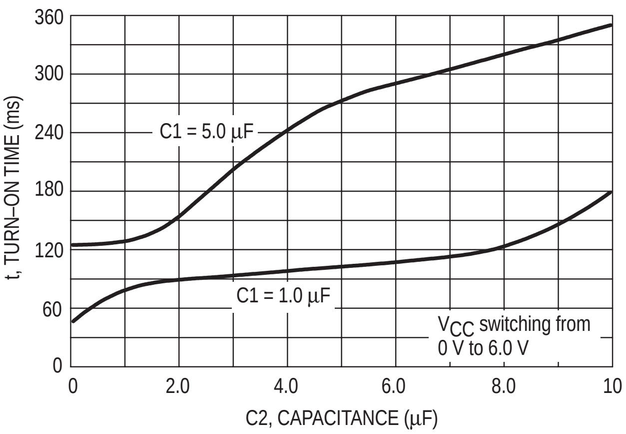
The output dc offset voltage ($V_{O1}–V_{O2}$) is primarily a function of the feedback resistor (R_f), and secondarily due to the amplifiers' input offset voltages. The input offset voltage of the two amplifiers will generally be similar for a particular IC, and therefore nearly cancel each other at the outputs. Amplifier #1's bias current, however, flows out of V_{in} (Pin 4) and through R_f, forcing V_{O1} to shift negative by an amount equal to [$R_f \times I_{IB}$]. V_{O2} is shifted positive an equal amount. The output offset voltage, specified in the Electrical Characteristics, is measured with the feedback resistor shown in the Typical Application Circuit, and therefore takes into account the bias current as well as internal offset voltages of the amplifiers. The bias current is constant with respect to V_{CC}.

FC1 and FC2

Power supply rejection is provided by the capacitors (C1 and C2 in the Typical Application Circuit) at FC1 and FC2. C2 is somewhat dominant at low frequencies, while C1 is dominant at high frequencies, as shown in the graphs of Figures 4 to 7. The required values of C1 and C2 depend on the conditions of each application. A line powered speakerphone, for example, will require more filtering than a circuit powered by a well regulated power supply. The amount of rejection is a function of the capacitors, and the equivalent impedance looking into FC1 and FC2 (listed in the Electrical Characteristics as R_{FC1} and R_{FC2}).

In addition to providing filtering, C1 and C2 also affect the turn–on time of the circuit at power–up, since the two capacitors must charge up through the internal 50 k and 125 kΩ resistors. The graph of Figure 1 indicates the turn–on time upon application of V_{CC} of +6.0 V. The turn–on time is ≈60% longer for V_{CC} = 3.0 V, and ≈20% less for V_{CC} = 9.0 V. Turn–off time is <10 µs upon removal of V_{CC}.

Figure 1. Turn–On Time versus C1, C2 at Power–On



Chip Disable

The Chip Disable (Pin 1) can be used to power down the IC to conserve power, or for muting, or both. When at a Logic "0" (0 V to 0.8 V), the MC34119 is enabled for normal operation. When Pin 1 is at a Logic "1" (2.0 V to V_{CC} V), the IC is disabled. If Pin 1 is open, that is equivalent to a Logic "0," although good design practice dictates that an input should never be left open. Input impedance at Pin 1 is a nominal 90 kΩ. The power supply current (when disabled) is shown in Figure 15.

Muting, defined as the change in differential gain from normal operation to muted operation, is in excess of 70 dB. The turn–off time of the audio output, from the application of the CD signal, is <2.0 µs, and turn on–time is 12 ms–15 ms. Both times are independent of C1, C2, and V_{CC}.

When the MC34119 is disabled, the voltages at FC1 and FC2 do not change as they are powered from V_{CC}. The outputs, V_{O1} and V_{O2}, change to a high impedance condition, removing the signal from the speaker. If signals from other sources are to be applied to the outputs (while disabled), they must be within the range of V_{CC} and Ground.

Power Dissipation

Figures 8 to 10 indicate the device dissipation (within the IC) for various combinations of V_{CC}, R_L, and load power. The maximum power which can safely be dissipated within the MC34119 is found from the following equation:

$$P_D = (140°C – T_A)/\theta_{JA}$$

where T_A is the ambient temperature; and θ_{JA} is the package thermal resistance (100°C/W for the standard DIP package, and 180°C/W for the surface mount package.)

The power dissipated within the MC34119, in a given application, is found from the following equation:

$$P_D = (V_{CC} \times I_{CC}) + (I_{RMS} \times V_{CC}) – (R_L \times I_{RMS}^2)$$

where I_{CC} is obtained from Figure 15; and I_{RMS} is the RMS current at the load; and R_L is the load resistance.

Figures 8 to 10, along with Figures 11 to 13 (distortion curves), and a peak working load current of ±200 mA, define the operating range for the MC34119. The operating range is further defined in terms of allowable load power in Figure 14 for loads of 8.0 Ω, 16 Ω and 32 Ω. The left (ascending) portion of each of the three curves is defined by the power level at which 10% distortion occurs. The center flat portion of each curve is defined by the maximum output current capability of the MC34119. The right (descending) portion of each curve is defined by the maximum internal power dissipation of the IC at 25°C. At higher ambient temperatures, the maximum load power must be reduced according to the above equations. Operating the device beyond the current and junction temperature limits will degrade long term reliability.

Layout Considerations

Normally a snubber is not needed at the output of the MC34119, unlike many other audio amplifiers. However, the PC board layout, stray capacitances, and the manner in which the speaker wires are configured, may dictate otherwise. Generally, the speaker wires should be twisted tightly, and not more than a few inches in length.

NOTE: If V_{CC} and V_{EE} are not symmetrical about ground then FC1 must be connected through a capacitor to ground as shown on the front page.

MOTOROLA

MC44002
MC44007

Advance Information

Chroma 4 Multistandard Video Processor

The MC44002/7 is a highly advanced circuit which performs most of the basic functions required for a color TV. All of its advanced features are under processor control via an I^{2}C bus, enabling potentiometer controls to be removed completely. In this way the component count may be reduced dramatically, allowing significant cost savings together with the possibility of implementing sophisticated automatic test routines. Using the MC44002/7, TV manufacturers will be able to build a standard chassis for anywhere in the world. Additional features include 4 selectable matrix modes (primarily for NTSC), fast beam current limiting and 16:9 display.

- Operation from a Single 5.0 V Supply; Typical Current Consumption Only 120 mA
- Full PAL/SECAM/NTSC Capability (4 Matrix Modes)
- Dual Composite Video or S-VHS Inputs
- All Chroma/Luma Channel Filtering, and Luma Delay Line Are Integrated Using Sampled Data Filters Requiring No External Components
- Filters Automatically Commutate with Change of Standard
- Chroma Delay Line is Realized with a 16 Pin Companion Device, the MC44140
- RGB Drives Incorporate Contrast and Brightness Controls and Auto Gray Scale
- Switched RGB Inputs with Separate Saturation Control
- Auxiliary Y, R-Y, B-Y Inputs
- Line Timebase Featuring H-Phase Control, Time Constant and Switchable Phase Detector Gain
- Vertical Timebase Incorporating Vertical Geometry Corrections
- 16:9 Display Mode Capability
- E-W Parabola Drive Incorporating Horizontal Geometry Corrections
- Beam Current Monitor with Breathing Compensation
- Analog Contrast Control, Allowing Fast Beam Current Limitation
- MC44007 Decoders PAL/NTSC Only

MAXIMUM RATINGS (T_A = 25°C, unless otherwise noted.)

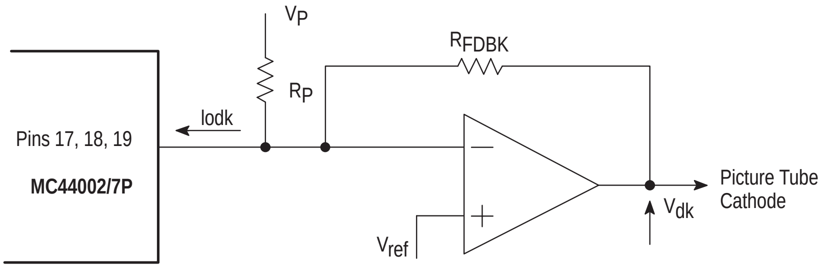
Figure 1. Example of Output Circuitry



V_p, V_{ref}, R_{FDBK} and R_p values will determine the exact operating point.

For example, let us take:
$V_p = 5.0$ V $R_{FDBK} = 39$ kΩ
$V_{ref} = 3.6$ V
$R_p = 6.8$ kΩ

The formula giving the Dark Cathode Voltage with above circuit is: $V_{dk} = V_{ref} + R_{FDBK}*(V_{ref} – V_p + Iodk*R_p) / R_p$

With above application, component values and Iodk specifications, all 3 cathodes on all devices will always have a range of at least 120 V to 150 V.

By changing the values of V_p, V_{ref} and R_p, the cathode voltage range may be shifted up or down as required.

Figure 2. Vertical Waveforms

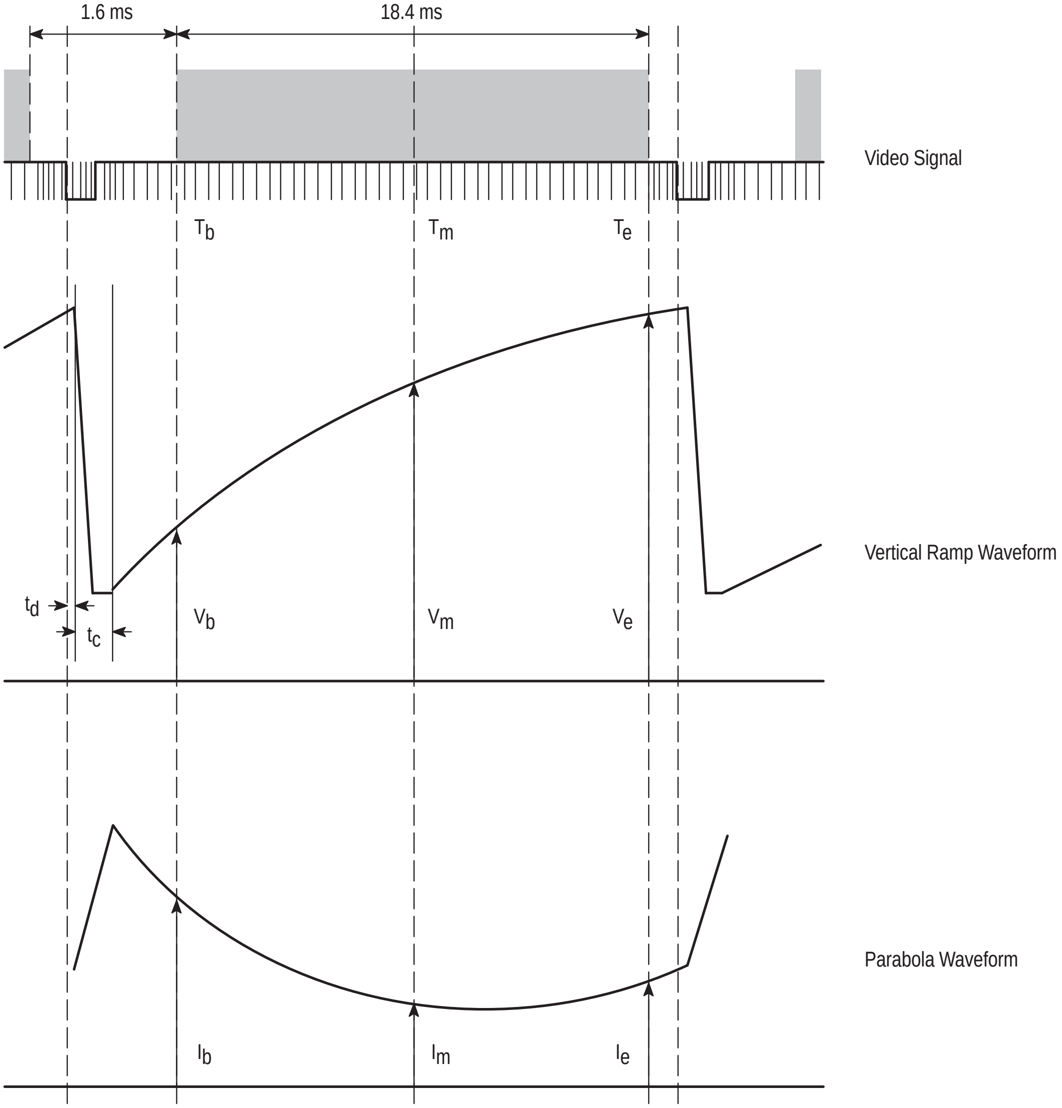


Figure 3. Vertical Ramp Positions (V7 versus V6)

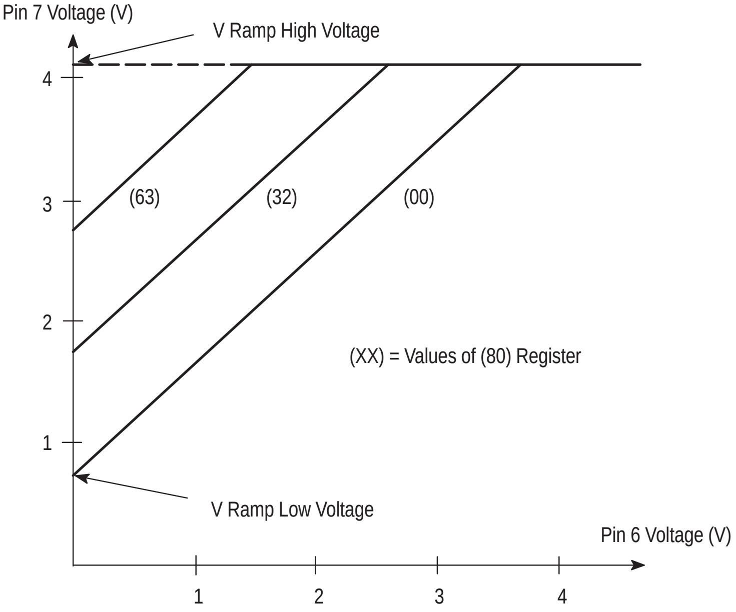


Definitions

$$\text{Parabola Amplitude} = \frac{(i_b + i_e)}{2} - i_m$$

$$\text{Parabola Tilt} = \frac{(i_e - i_b)}{\text{Parabola Amplitude}}$$

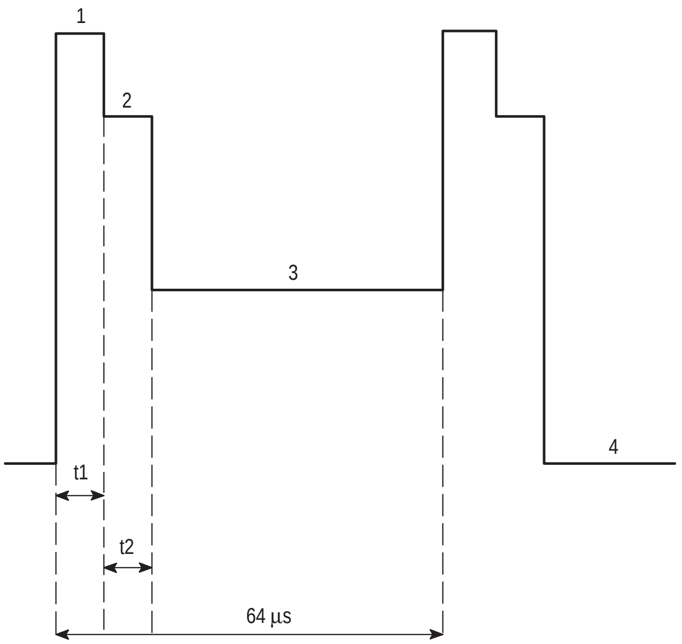
$$\text{Horizontal Amplitude} = i_m$$

$$\text{Vertical Amplitude} = V_e - V_b$$

$$\text{Vertical Linearity} = \frac{(V_e - V_m)}{V_m - V_b}$$

Corner correction is calculated in the same way as Parabola Amplitude.

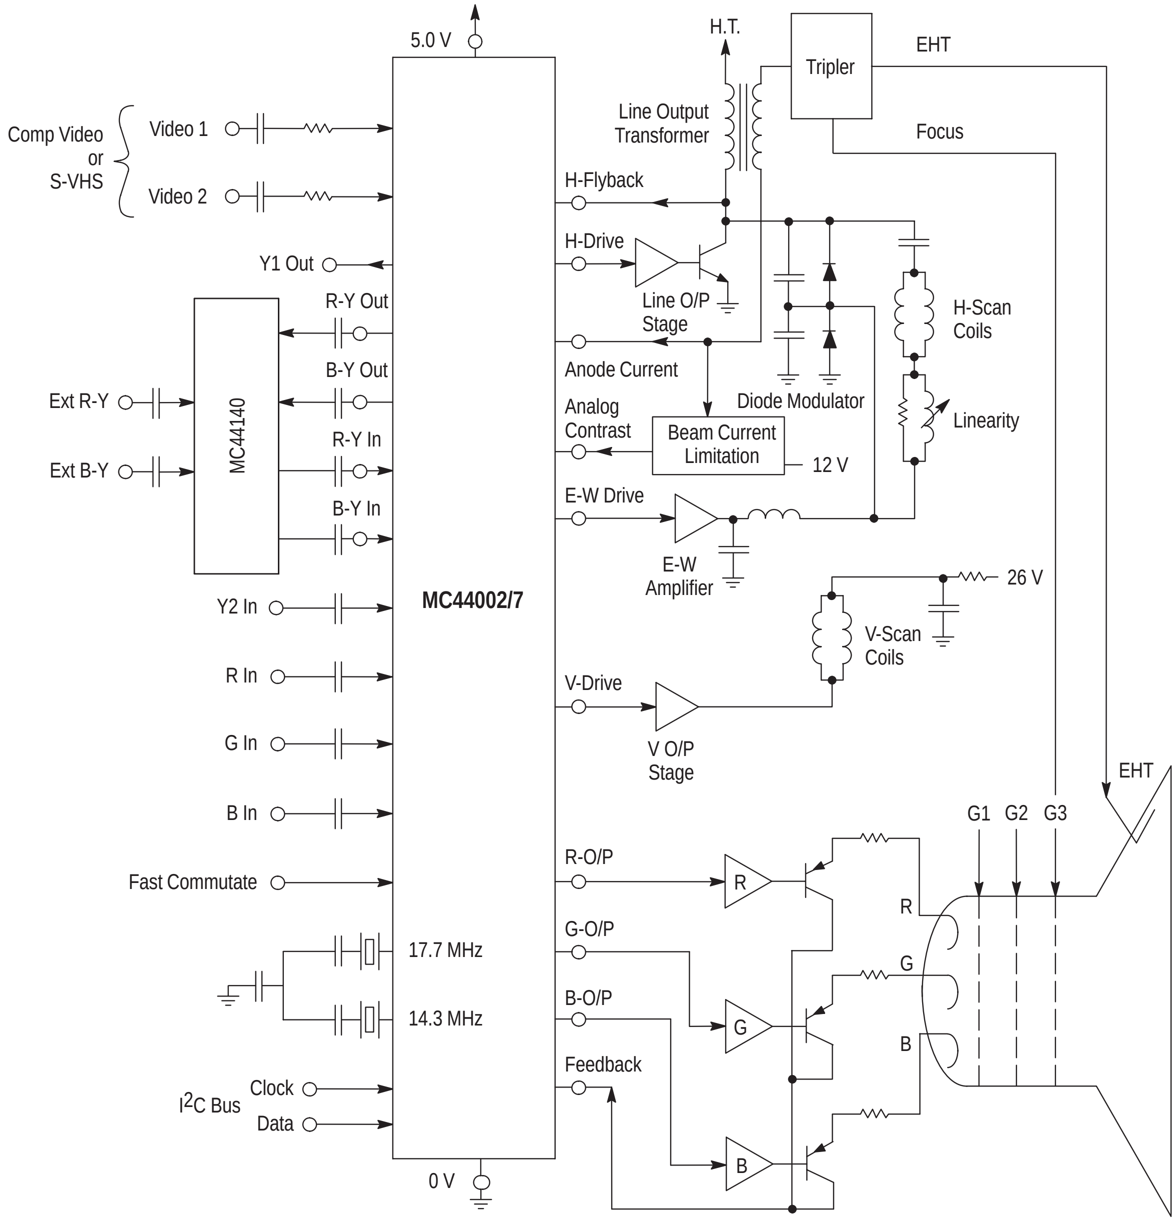
Figure 4. Sandcastle Output (Pin 31)



GENERAL DESCRIPTION OF THE CHROMA 4 SYSTEM

Figure 5 shows a simplified block diagram representation of the basic system using the MC44002/7 and its companion device the MC44140 chroma delay line. The MC44002/7 has been designed to carry out all the processing of video signals, display controls and timebase functions. There are two video inputs which can be used for normal composite video or separate Y and C inputs. In either case, the inputs are interchangeable and selection is made via the I^2C bus. The video is decoded within the MC44002/7 and involves separation, filtering, delay of the luminance part of the signal and demodulation of the chroma into color difference signals. The luminance (called Y1) together with the demodulated R-Y and B-Y are all then brought out from the IC. The color difference signals then enter the MC44140 which performs color correction in PAL and the delay line function in SECAM. Corrected color difference signals then re-enter the MC44002/7.

Figure 5. Connection to TV Chassis



The next stage is called the color difference stage where a number of control functions are carried out together with matrixing of the components to derive RGB signals. At this point a number of auxiliary signals may also be switched in, again all under MCU control. External RGB (text) and Fast Commutate enter here; also an external luminance (Y2) may be used instead of Y1. External R-Y and B-Y are switched in via the delay line circuit to save pins on the main device. The Y2 and External R-Y, B-Y will obviously be of considerable benefit from the system point of view for use with external decoders.

The final stage of video processing is the RGB outputs which drive the high voltage amplifiers connected to the tube cathodes. These outputs are controlled by a sophisticated digital servo-loop which is maintained and stabilized by a sequentially sampled beam current feedback system. Automatic gray scale control is featured as a part of this system.

Both horizontal and vertical timebases are incorporated into the MC44002/7 and control is via the I^{2}C bus. The horizontal timebase employs a dual loop system of a PLL and variable phase shifter, and the vertical uses a countdown system. For the vertical, a field rate sawtooth is available which is used to drive an external power amplifier with flyback generator (usually a single IC). The line output consists of a pulse which drives a conventional line output stage in the normal way. The line flyback pulse is sensed and used by the second loop for horizontal phase shift.

Where E-W correction is required, a parabola waveform is available for this which, with the addition of a power amplifier, can be used with a diode modulator type line output stage for dynamic width and E-W control. The bottom of the EHT overwinding is returned to the MC44002/7 and is used for anode current monitoring.

Fast beam current limitation is also made possible by the use of an analog contrast control.

A much more detailed description of each stage of the MC44002/7 will be found in the next section. Information on the delay line is to be found in its own data sheet.

Introduction

The following information describes the basic operation of the MC44002/7 IC together with the MC44140 chroma delay line. The MC44002/7 is a highly advanced circuit which performs all the video processing, timebase and display functions needed for a modern color TV. The device employs analog circuitry but with the difference that all its advanced features are under processor control, enabling external filtering and potentiometer adjustments to be removed completely. Sophisticated feedback control techniques have been used throughout the design to ensure stable operating conditions and the absence of drift with age.

The IC described herein is one of a new generation of TV circuits, which make use of a serial data bus to carry out control functions. Its revolutionary design concept permits a level of integration and degree of flexibility never achieved before. The MC44002/7 consists of a single bipolar VLSI chip which uses a high density, high frequency, low voltage process called MOSAIC 1.5. Contained within this single 40 pin package is all the circuitry needed for the video signal processing, horizontal and vertical timebases and CRT display control for today's color TV. Furthermore, all the user controls and manufacturer's set-up adjustments are under the control of the processor I^{2}C bus, eliminating the need for potentiometer controls. The MC44002/7 offers an enormous variety of different options configurable in software, to cater to virtually any video standard or circumstance commonly met. The decoder section offers full multistandard capability, able to handle PAL, SECAM (MC44002 only) and NTSC standards with 4 matrix modes available. Practically all the filtering is carried out onboard the IC by means of sampled data filters, and requires no external components or adjustment.

Digital Interface

One of the most important features of MC44002/7 is the use of processor control to replace external potentiometer and filter adjustments. Great flexibility is possible using processor control, as each user can configure the software to suit their individual application. The circuit operates on a bidirectional serial data bus, based on the well known I^{2}C bus. This system is rapidly becoming a world standard for the control of consumer equipment.

I^{2}C Bus

It is not within the scope of this data sheet to describe in detail the functioning of the I^{2}C bus. Basically, the I^{2}C bus is a two-wire bidirectional system consisting of a clock and a serial data stream. The write cycle consists of 3 bytes of data and 3 acknowledge bits. The first byte is the Chip Address, the second the Sub-address to identify the location in the memory, and the third byte is the data. When the address' Read/Write bit is high, the second and third bytes are used to transmit status flags back to the MCU.

Figure 6 shows a block diagram of the MC44002/7 Bus Interface/Decoder. To begin with, the start bit is recognized by means of the data going low during CLK high. This causes the Counter and all the latches to be reset. For a write operation, the Write address ($88) is read into the Shift Register. If the correct address is identified, the Chip Address Latch is set and at CLK 9 an acknowledge is sent.

The second byte is now read into the Shift Register and is used to select the Sub-address. At CLK 18 a Sub-address Enable is sent to the memory to allow the Data in the register to be changed. Also, at CLK 18 another acknowledge is sent.

The third byte is now read into the Shift Register and the Data bussed into the memory. The Data in the Sub-address location already selected is then altered. A third acknowledge is sent at CLK 27 to complete the cycle.

A Read address ($89) indicates that the MCU wants to read the MC44002/7 status flags. In this instance, the Read/Write Latch is set, causing the Memory Enable and Subaddress Enable to be inhibited, and the flags to be written onto the data line. Two of the status flags are permanently wired one-high and one-low (O.K. and Fault), to provide a check on the communication medium between the MC44002/7 and the MCU.

At start-up the Counter is automatically reset and the Data for each Sub-address is read in from the MCU. Only after the entire memory contents have been transmitted, is Data 00 sent to register 00 to start the Horizontal Drive.

The MC44002/7 needs the full 27 clock cycles, or a stop condition, to properly release the I^{2}C bus.

Figure 6. I^{2}C Bus Interface and Decoder

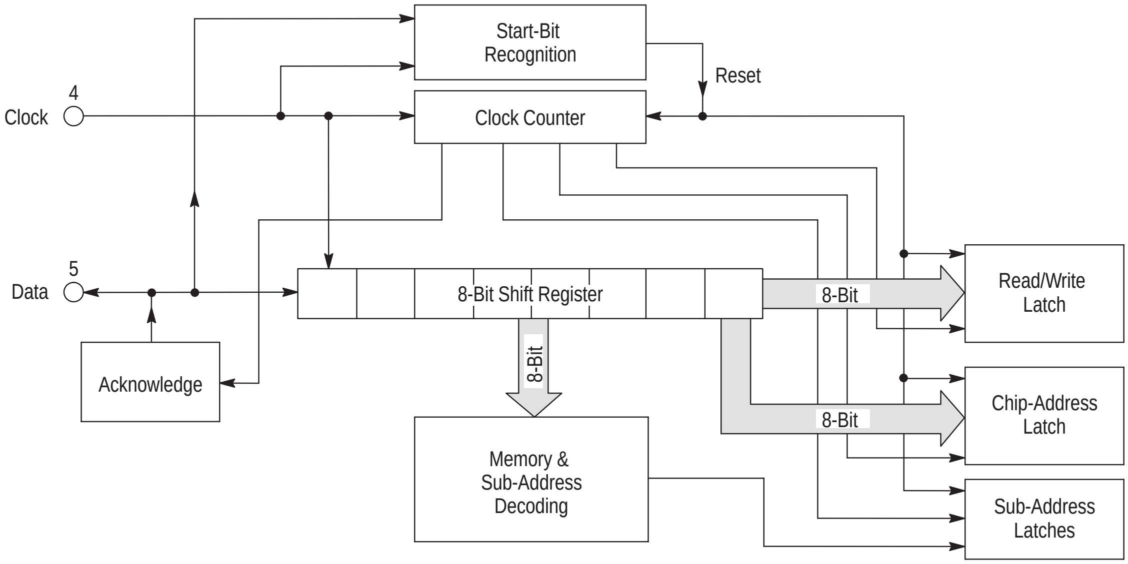


Figure 7. MC44002/7 Memory Map

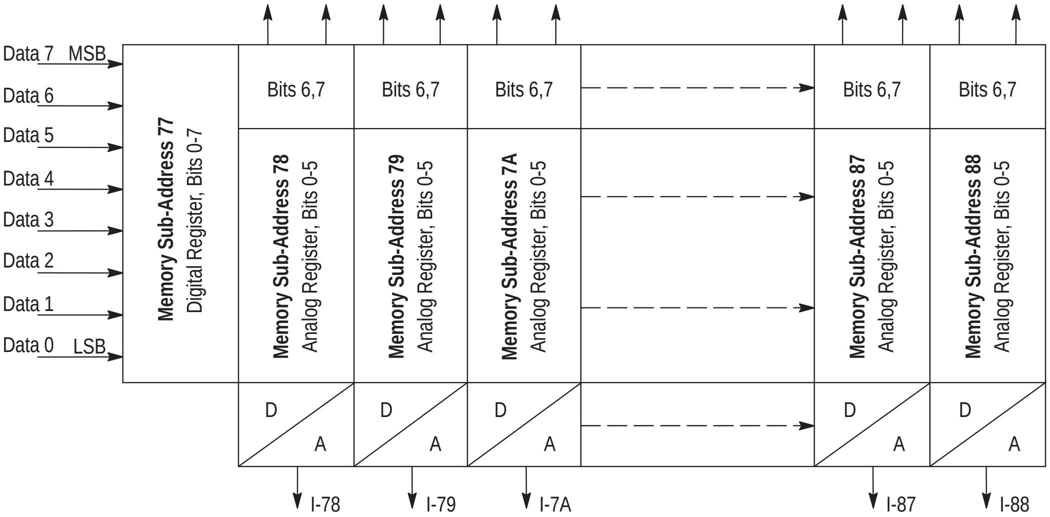


Memory

Figure 7 shows a diagram of the MC44002/7 Memory Map. It has 18 bytes of memory which are located at hex sub-addresses 77 to 88. Sub-address 77 is used to set up the vertical timebase mode of the IC and for S-VHS switching, and consists of 8 separate data bits. The remaining 17 bytes use the least significant 6-bits as an analog control register. The contents of each are D/A converted, providing an analog control current which is distributed to the appropriate part of the circuit. Bits 6 and 7 are used singularly for switching control functions.

Chroma Decoder

The main function of this section is to decode the incoming composite video, which may be in any of the PAL, NTSC or SECAM (MC44002 only) Standards, and to retrieve the luminance and color difference signals. In addition, the signal filtering and luma delay line functions are carried out in this section by means of sampled data filters.

The entire decoder section operates in sampled data mode using clocks generated by external crystals. The oscillator, which is phase-locked in the usual way for PAL/NTSC modes, provides the clock function for the whole circuit. The crystals are selected by the MCU by means of a control bit (XS). Only crystals appropriate to the standards which are going to be received need to be fitted. A 17.7 MHz crystal (4x PAL subcarrier) is used for PAL and SECAM systems (50 Hz, 625 lines); and 14.3 MHz (4x NTSC subcarrier) for the NTSC system (60 Hz, 525 lines). Nearly all the filters, together with the luma delay line and peaking, have been integrated, requiring no external components or any adjustment. The filter characteristics are entirely determined by the clocks and by capacitor ratios, and are thus completely independent of variations in the manufacturing process. The PAL/NTSC subcarrier PLL and ACC loop filters have not been integrated in order to facilitate testing. These filters consist of fixed external components.

Figure 8 is a block diagram of the main features of the chroma decoder. Selection is first made between the Video 1 and Video 2 inputs. These may be either normal composite video or separate luma and chroma which may enter the IC at either pin. Commands from the MCU are used to route the signals through the appropriate delay and filter sections.

In PAL/NTSC, a variable low pass filter, which can be software bypassed (control bit T3), is then used to compensate for IF filtering and the Q of the external sound traps. Filter response is controlled by means of control bits T1 and T2. It is not recommended to use this filter in SECAM or in S–VHS, as luma–chroma delays will not be optimized. Next, the video enters the luma path. The PAL/NTSC or SECAM chroma signals are separated out by transversal high pass filters. In SECAM mode, the chroma trap frequency is dynamically steered to follow the instantaneous frequency of the chroma.

Then, another transversal filter provides luma peaking, which is also active in S–VHS mode. The high frequency luma may be peaked (at about 3.0 MHz with the 17.7 MHz crystal, and 2.4 MHz with the 14.3 MHz crystal) in 7 steps up to a maximum of 8.5 dB, by a control word from the MCU.

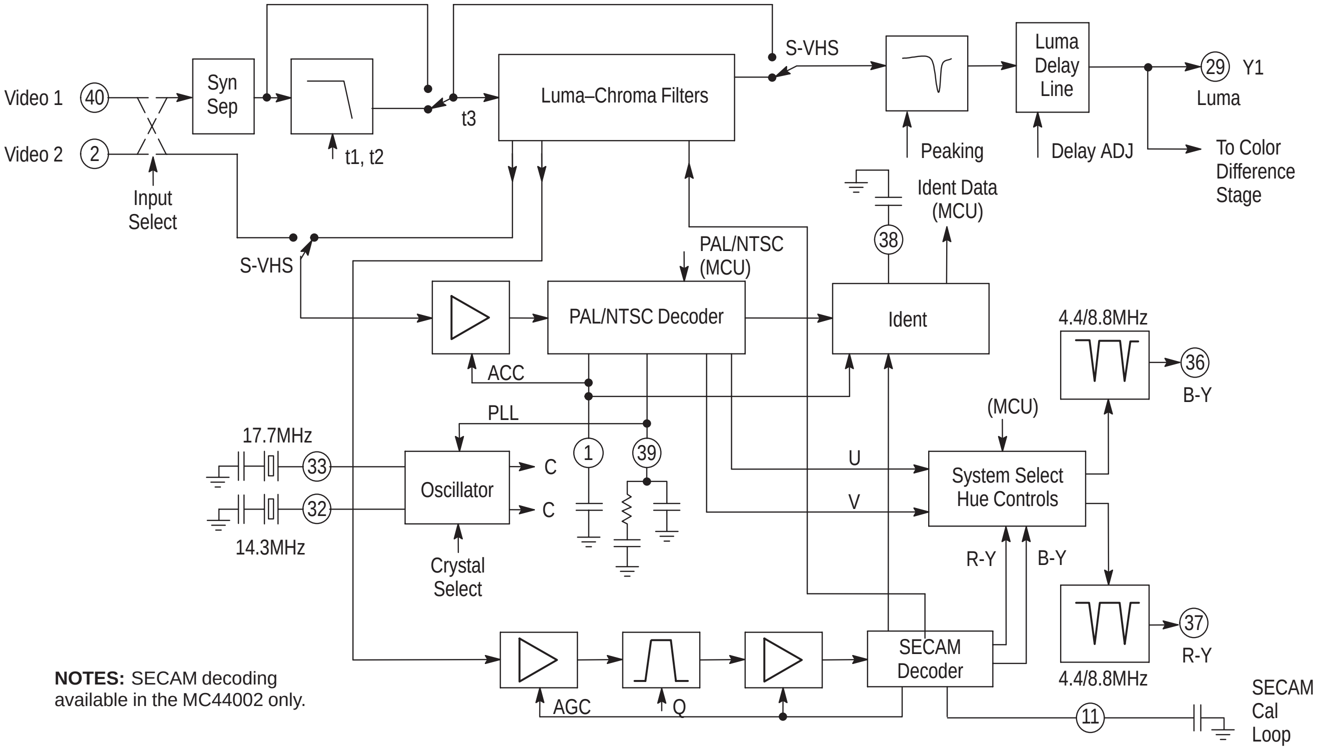
Another control word is used to trim the delay in the luma channel. Five steps of 56 ns (70 ns with the 14.3 MHz crystal) are possible, giving a total programmable delay of 280 ns. Steps 6 and 7 are used in S–VHS mode. The resulting processed luma signal then proceeds to the color difference section after being low–pass filtered by an active filter to remove components of the crystal frequency, and twice that frequency. The luma component (Y1) is made available at Pin 29 for use with auxiliary external functions, as well as testing.

When in the S–VHS mode, the S–VHS control bit controls the signal paths. The luma signal bypasses the first section of the luma channel, which contains the chroma trap. The S–VHS chroma is passed directly to the PAL/NTSC decoder without further filtering.

As all the delay and filter responses are determined by the crystal, they automatically commute to the new standard when the crystal is changed over. Thus, when the 14.3 MHz clock is being used, the chroma trap moves to 3.58 MHz.

The filtered PAL/NTSC and SECAM chroma signals are decoded by their respective circuits. The PAL/NTSC decoder employs a conventional design, using ACC action for gain control and the common double balanced multipliers to retrieve the color difference signals. The SECAM decoder is discussed in a separate subsection.

Figure 8. Chroma Decoder



NOTES: SECAM decoding available in the MC44002 only.

The actual decision as to a signal's identity is made by the MCU based on data provided by 3 flags returned to it, namely: ACC Active, PAL Identified, and SECAM Identified.

Control bits SSA–SSD must be sent to set the decoder to the correct standard.

This allows a maximum of flexibility, since the software may be written to accommodate many different sets of circumstances. For example, channel information could be taken into account if certain channels always carry signals in the same standard. Alternatively, if one standard is never going to be received, the software can be adapted to this circumstance. If none of the flags are on, color killing can be implemented by the MCU. This occurs if the net Ident Signal is too low, or if the ACC circuit is inactive due to too low a signal level.

The demodulated color difference signals now enter the Hue control section, where selection is made between PAL/NTSC and SECAM outputs. The Hue control is simply realized by altering the amplitudes of both color difference signals together. Hue control is only a requirement in NTSC mode and would not normally be used for other standards. The function is usually carried out prior to demodulation of the chroma by shifting the phase of the subcarrier reference, causing decoding to take place along different axes. In the MC44002/7, Hue control is performed on the already demodulated color difference signals. A proportion of the R-Y signal is added or subtracted to the B-Y signal and vice-versa. This has the same effect as altering the reference phase. If desired, the MC44002/7 can apply the Hue control to simple PAL signals.

After manipulation by the Saturation and Hue controls, the color difference signals are finally filtered to reduce any remaining subcarrier and multiplier products. Before leaving the chip at Pins 36 and 37, the signals are blanked during line and frame intervals. The 64 µs chroma delay line is carried out by a companion device, the MC44140.

SECAM Decoder (MC44002 only)

The SECAM signal from the high-pass filter enters tightly controlled AGC amplifiers wrapped around a cloche filter which is a sampled recursive type, with the AGC derived from a signal squarer. Next, the signal is blanked during the calibration gate period and a reference 4.43 MHz is inserted during this time. The SECAM signal is then passed through a limiter.

The frequency demodulator function is carried out by a frequency-locked-loop (F.L.L.). This consists of three components: a tracking filter, a phase detector and a loop filter. The center frequency of the tracking filter depends on three factors: internal R-C product, ADJUST voltage, and TUNING voltage. The tracking filter is dynamically tuned by the TUNING feedback from the loop-filter forming the F.L.L. The ADJUST control calibrates the F.L.L. and compensates for variations in the R-C product. After the F.L.L., the color difference signals are passed to another block where several functions are carried out. The signals are de-emphasized and outputs are provided to the Ident section. Another function of this section is to generate the I_{COMP} signal used for calibrating the F.L.L. This signal is blanked during the H-IG period to ensure that (R-Y) and (B-Y) output signals have a clean dc level for clamping purposes.

In addition, components are added to compensate for the R-C product, and tuning offsets are introduced during the active lines for F0R/F0B.

Calibration of the F.L.L. takes place during every field blanking interval, starting from field retrace and ending just before the SECAM vertical Ident sequence (bottles). The calibration current I_{CAL} is derived from I_{COMP} during the calibration gate (CAL) and integrated by an external capacitor on Pin 11. The resulting voltage V_{EXT} is then transformed to generate the ADJUST control voltage removing from the loop range most of the variations due to internal RC products and temperature.

Color Difference Stages

This stage accepts luminance and color difference signals, together with external R,G,B and Fast Commutation inputs and carries out various functions on them, including clamping, blanking, switching and matrixing. The outputs, consisting of processed R,G,B signals, are then passed to the Auto Gray Scale section.

A block diagram of this stage is shown in Figure 10. The Y2, R-Y, B-Y together with R, G and B are all external inputs to the chip. The Y1 signal comes from the decoder section. Each of the signals is back-porch clamped and then blanked. The Y2 and R,G,B inputs have their own simple sync separators, the output from which may be used as the primary synchronization for the chip by means of commands from the MCU.

The Fast Commutation is an active high input used to drive a high speed switch; for switching between the Y and color difference inputs and the R,G,B (text) inputs.

After blanking, the Y1 and Y2 channels go to the Luma Selector which is controlled by means of 2 bits from the MCU. From here the selected luma signal goes to the RGB matrix. The two color difference signals pass through the saturation control. From here they go to a matrix in which G-Y is generated from the R-Y and B-Y, and lastly, to another matrix where Y is added to the three color difference signals to derive R,G,B.

Control bits (via the I^2C bus) allow the matrix coefficients to be adjusted in order to suit different requirements, particularly in NTSC. Table 1 shows the theoretical demodulation angles and amplitudes and the corresponding matrix coefficient values for each of the 4 selectable modes. (The A mode corresponds to the standard PAL/SECAM/NTSC mode). Although primarily intended for NTSC, this feature can also act on PAL/SECAM or external RGB signals.

The R,G,B inputs may take one of two different paths. They may either go straight to the output without further processing, or via a separate matrix and the saturation control. The path taken is controlled in software. When the latter route is selected, the R,G,B signals undergo a matrix operation to derive Y. From this, R-Y and B-Y are easily derived by subtraction from R and B; the derived color difference signals are then subjected to saturation control. This extra circuitry allows another feature to be added to the TV set, namely the ability to adjust the color saturation of the RGB inputs. After the saturation control the derived signals are processed as before.

Table 1. Matrix Modes Coefficients

	A	B	C	C
RR	1.0	1.577	1.539	1.556
RB	0	–0.156	–0.248	–0.251
GR	–0.513	–0.443	–0.462	–0.504
GB	–0.187	–0.168	–0.150	–0.125
BB	1.0	1.0	1.0	1.0

Gm	0.344	0.3	0.3	0.31
Ra	90	100	106	106
Ga	237	236	240	246

NOTE: BB = Gain of $(B_{out}/(B–Y)_{in})$ = 1 (reference). BR = Gain of $(B_{out}/(R–Y)_{in})$ = 0 (theoretically).

Figure 9. SECAM Decoder (MC44002 only)

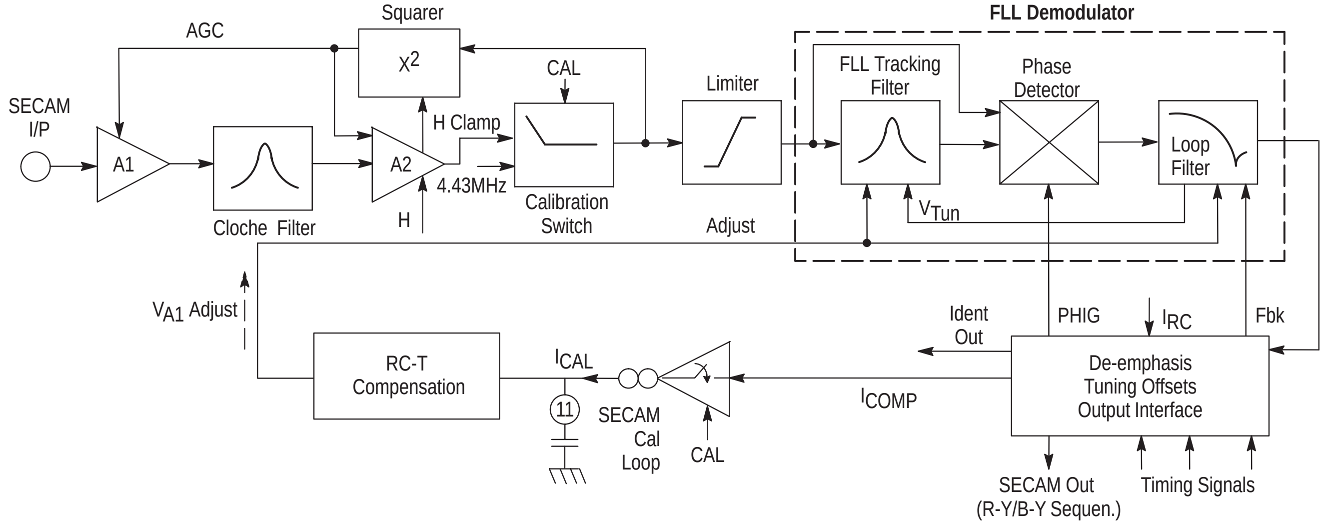

Figure 10. Color Difference Stages

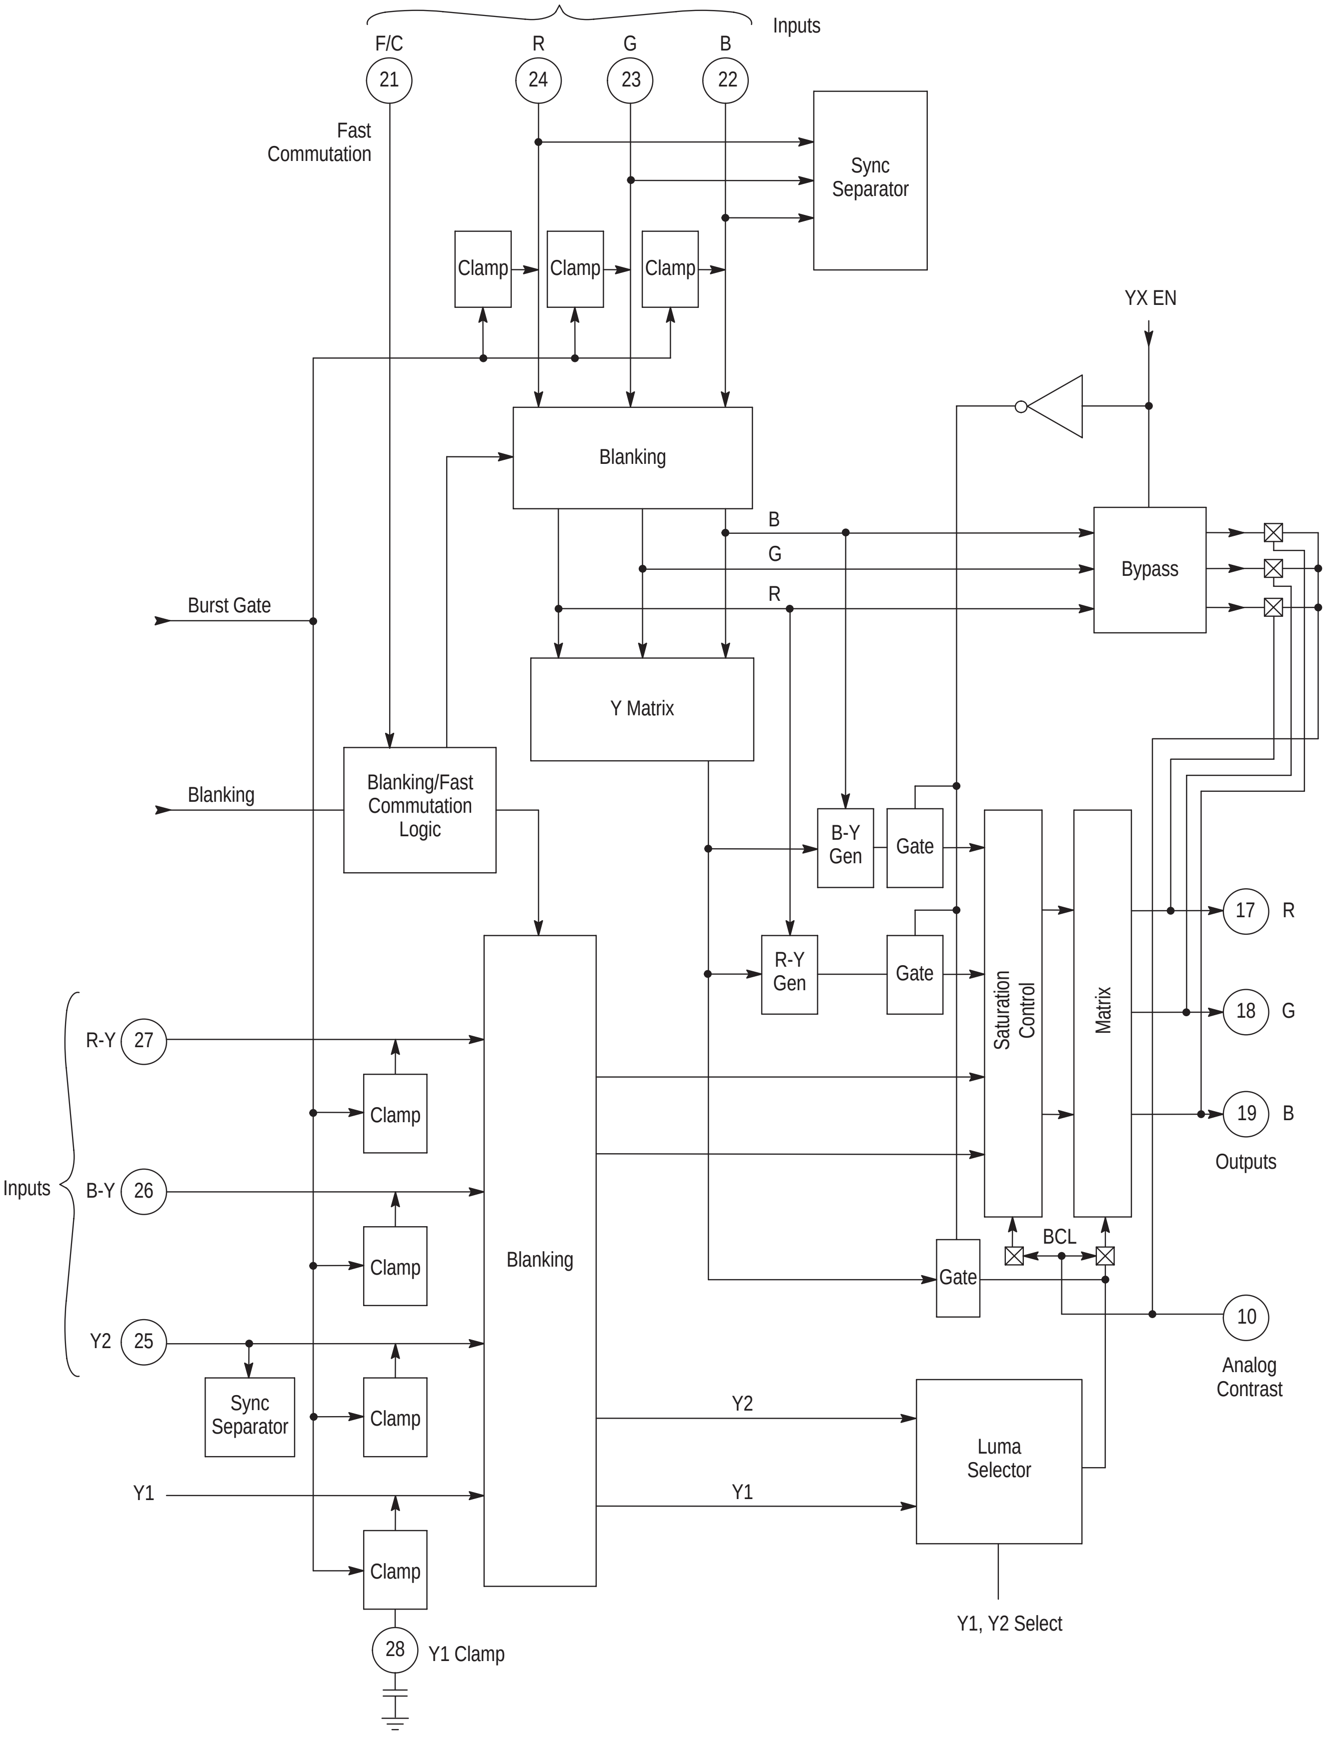

In order to implement automatic beam current limiting (BCL), the possibility of fast contrast reduction has been added. For normal operation, the Contrast control is achieved by auto grey scale output loops and is I^2C bus controlled (see Section 4). In the case of excess beam current, this control is not fast enough to protect the tube and power supply stages. It is now possible, by acting on the Pin 10 voltage, to reduce the contrast about 12 dB by reducing the luma gain and saturation. In the case of direct RGB mode, the RGB gains are also reduced.

Figure 11. Typical Contrast Reduction

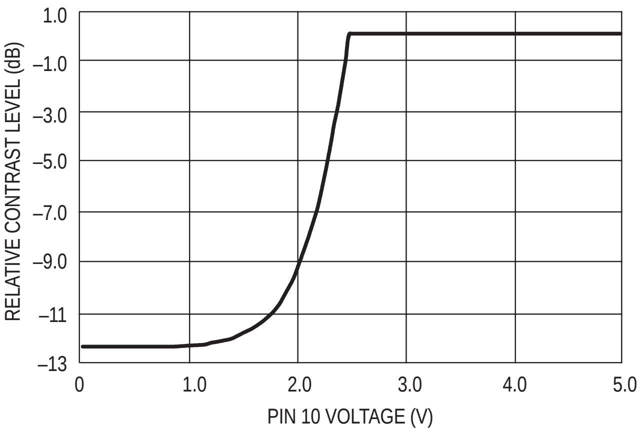

Figure 11 is showing the typical analog CONTRAST reduction possible as a function of the voltage on Pin 10. Two solutions are possible for obtaining the BCL function:

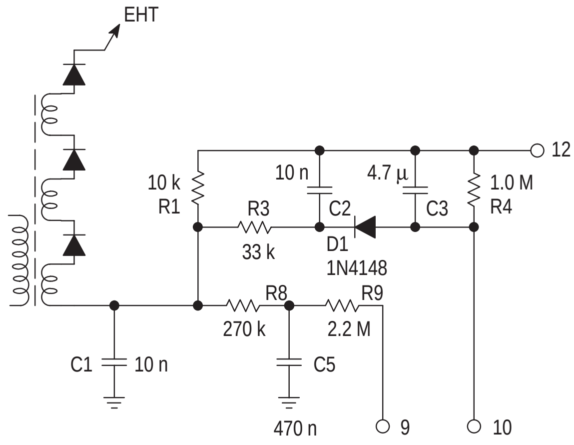
1st solution: A measure of the average and/or peak beam current is applied to Pin 10, which causes a reduction of the RGB drive levels to the high voltage video amplifiers. In this case, no software control is required, but variations in color balance and saturation may be observed. A typical application is shown in Figure 12.

2nd solution: The beam current flags are read and acted on by the MCU, which reduces the I^2C bus CONTRAST control to maintain the average beam current below the desired level. In the case of rapid and extreme beam current changes (black to white picture at high contrast level), the circuit of Figure 12 may be used as a fast aging protection while the MCU is reducing the CONTRAST through I^2C bus. The average of this method is to make any color balance/saturation variation only transient.

Figure 12. Automatic Beam Current Limiter Application

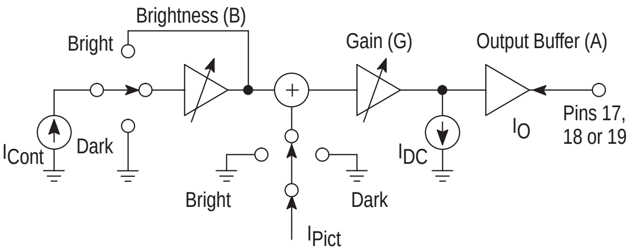


Auto Gray Scale Control Loops

This section supplies current drives to the RGB cathode amplifiers and receives a signal feedback from them, proportional to the combined cathode currents. The current feedback is used to establish a set of feedback loops to control the dc level of the cathode voltage (cut–off), and gain of the signal at the cathode (white balance). There are three loops to control the dark currents dark loops and another three to control the gains bright loops. The system uses 3 lines at the end of the vertical suppression period and just before the beginning of the picture for sampling the cathode current (i.e., one line for red, one for green and one for blue). The first half of reach line is used for adjusting the gain of the channel and is usually called the “bright” adjustment period. The second half of the line is used for adjusting the dc level of the channel and is called the “dark” adjustment.

The theoretical circuit diagram for one channel is shown in Figure 13 along with the basic equations. The dc level (Idc) and gain (G) are both controlled by 7 bit DACs which receive data directly from latches in which the required values are stored between sampling periods.

Figure 13. Bright/Dark Current Control



Picture Output Current: $I_{O(Pict)} = A \times [\, I_{DC} = G \times ((B \times I_{Cont}) + I_{Pict})]$
Dark Sample Output Current: $I_{O(dk)} = A \times I_{DC}$
Bright Sample Output Current: $I_{O(br)} = I_{O(dk)} - A \times G \times I_{Cont}$
Black Level Output Current: $I_{O(bk)} = I_{O(dk)} - B \times A \times G \times I_{Cont}$
$= I_{O(dk)} \times B \times [I_{O(dk)} - I_{O(br)}]$

A block diagram of the complete system is illustrated in Figure 16. Data words from the MCU which represent the RGB color temperatures selected at the factory, are stored in Latches 1,2,3 and D/A converted by DAC1,2,3 to reference currents. During the bright adjustment period, a reference current pulse, whose amplitude depends on the Contrast setting, is output to the cathode of the tube. The gain control is adjusted to bring the feedback current to the same value as the bright reference current, which is defined by the color intensity setting of the output considered. The currents must match each other. If not, a current will flow in resistor R producing an error voltage. This is then buffered into comparators Comp1, 2 and is compared with voltage references V_{ref1} and V_{ref2}. If the error voltage is greater than V_{ref1}, Comp1 causes the counter to count up. If the error voltage is less than V_{ref2}, Comp2 sends a count-down command. In this way, a “deadband” is set up to prevent the outputs from continuously changing. With the color intensity DAC set to about 32_d, the bright cathode current is 100 µA (10 times the dark current).

During Load the contents of the counter are loaded into Latch 6 (for red dc) and then D/A converted. The resulting dc current is then applied as an offset to the red output amplifier, completing the loop. During the dark adjustment period, the same intensity data is used but divided by a common factor (typically 10). A black level reference pulse is applied and the feedback loop adjusts the dc levels of the cathode to obtain a set of cathode currents equal to the dark reference currents

(10 μA). Therefore, the image color will always be adjusted to match the dark level color, i.e. grey scale tracking is ensured.

The Load/Backload sequencer is used to control which latch is being addressed at any given time by means of the timing signals input to it. The backload command sends the data from the appropriate latch to the Up/Down Counter, ready to be modified if necessary.

The Brightness control is affected by simply changing the dc pedestal of all three drives by the same amount, and does not form part of the feedback loop. The Contrast is adjusted to a set of values dependent on the level of the bright pulse applied during the set–up period. This level is set by a control word from the MCU. Once the loops have stabilized under normal working conditions, they may be deactivated by means of a control bit from the MCU. When, however, any change is made to either contrast or RGB intensity, the loops must be reactivated. For normal operation, it is not necessary to deactivate the bright loops.

Increasing the RGB intensity values will cause the Black–to–White cathode voltage amplitude to increase for a given Contrast setting. The White balance can therefore be set by adjusting the relative values of R, G and B intensity. An extra loop has been included via Latch 4 and DAC 4, which operates during the field flyback time to compensate for offsets within the loop. This has the effect of counteracting any input offset from the Buffer/Amp and will also compensate for cathode leakage should this be needed.

A second output of the reference currents from the RGB DACs are used to compare with preset limits, to ensure that the loops are working within their range of control. Should the limits be exceeded in either direction, flags are returned to the MCU to request that the G2 control be adjusted up or down as appropriate. Once set–up, the servo loops maintain the same conditions throughout the life of the TV.

Horizontal Timebase

The horizontal timebase consists of a PLL which locks up to the incoming horizontal sync, and a phase detector and shifter whose purpose is to maintain the H-Drive in phase with the line flyback pulse.

Because of on-chip component tolerances, the free-running oscillator frequency cannot be set more accurately than ± 40%; this range would be too much for the line output stage to cope with. For this reason the free-running frequency is calibrated periodically by other means. During startup and whenever there is a channel change, the phase detector is disconnected from the VCO for 2 lines during the blanking interval. A block diagram of the line timebase is given in Figure 14. The calibration loop consists of a frequency comparator driving an Up/Down Counter. The count is D/A converted to give a dc bias which is used to correct a 1.0 MHz VCO. The 1.0 MHz is divided by 64 to give line frequency and this is returned to the frequency comparator. This compares Fh from the VCO with a reference derived from dividing down the subcarrier frequency. Any difference in frequency will result in an output from the comparator, causing the counter to count up or down; and thus closing the loop. Since the horizontal oscillator is quite stable, this calibration does not need to be carried out very often. After switch–on, the calibration loop need only be enabled when the timebase goes out of lock.

A Coincidence Detector looks at the PLL Fh and compares it with the incoming H-sync. If they are not in lock, a flag is returned to the MCU. To allow for use with VCRs, the gain of the phase detector may be switched by means of commands from the MCU (bits HGAIN1 and HGAIN2). The gain of the phase detector is switched to the maximum value at the end of the vertical sync pulse and then reduced to the selected value after about 11 lines. This allows the horizontal timebase to rapidly compensate any horizontal phase jump (e.g. with a VCR) during the vertical blanking period, thus avoiding bending at the top of the picture.

Twice line frequency is output from the PLL which may be divided by either 1 or 2 depending on the command of the MCU. The x2 Fh will be used with Feature Boxes. The phase of the Fh and flyback pulses are compared in a phase detector, whose output drives a phase shifter. A 6-bit control word and D/A converter are used to apply an offset to the phase detector giving a horizontal phase shift control.

The presence of the horizontal flyback pulse is detected; if it is missing a warning flag is sent back to the MCU which can take appropriate action.

Vertical Timebase

The vertical timebase consists of two sections; a digital section which includes a vertical sync separator and standard recognition; and an analog section which generates a vertical ramp which may be modified under MCU control to allow for geometrical adjustments. A parabola is also generated and may be used for pin-cushion (E-W) correction and width control (see Figure 15).

In the digital section, the MC44002/7 uses a video sync separator which works using feedback, such that the threshold level of a comparator (slice level) is always maintained at the center of the sync pulse. Sync from any of the auxiliary inputs may also be used. The composite sync is fed to a vertical sync separator, where vertical sync is derived. This consists of a comparator, up/down counter and decoder. The counter counts up when sync is high, and down when sync is low. The output of the decoder is compared with a threshold level, the threshold only being reached with a high count during the broad pulses in the field interval.

When “Auto Countdown” is selected, the vertical timebase in fact starts off in the “Injection Lock” mode. This means that the timebase locks immediately to the first signal received, in exactly the same way as an old type injection locked timebase. A coincidence detector looks for counts of the right number (525 e.g.), and causes a 4 bit counter to count up. When there are 8 consecutive coincidences, the vertical countdown is engaged, and the MSB of the counter is brought out to set the flag. Similarly, non–coincidence, which will occur if synchronizing pulses are missing or in the wrong place, or if there is noise on the signals, causes the counter to count down. When the count goes back to zero, after 8 noncoincidences, the timebase automatically reverts to “Injection Lock” mode.

If it is known that lock will be lost (e.g., channel change), it is possible to jump straight into Injection Lock mode and not have to wait for the 8 consecutive non-coincidences. In this way the new channel will be captured rapidly. Once locked on to the new channel, “auto countdown” is then reselected by the MCU.

Under some conditions such as some VCRs in Search mode, it is possible to get signals having an incorrect number of lines, meaning that the countdown flag will go off because of successive non-coincidences. In these circumstances, if “auto countdown” is selected, the timebase will automatically lock to the signal in the Injection Lock mode. The fact that the flag is effectively saying that the vertical timebase is out of lock need not be a cause for major concern, since the horizontal timebase will still be locked to the signal, and has its own flag – "Horizontal out of lock". The vertical countdown and horizontal lock flags both perform an independent test for the presence of a valid signal. A logical OR function can be performed on the two flags, such that if either are present then by definition a valid signal is present.

The vertical oscillator has end-stops set at two line-count decodes as given below:

50 x 625 / 740 = 42.2 Hz (min)
50 x 625 / 448 = 69.8 Hz (max)

These figures assume that the horizontal timebase is running at 15,625 Hz. When the vertical timebase is in Injection Lock mode, the line counter reset is inhibited so that it ignores any sync pulses before a count of 448 is reached. This prevents any possible attempted synchronization in the middle of the picture. If the count reaches 740 lines, then there is an automatic reset which effectively sets the lower frequency limit. The choice of these limits is a compromise between a wide window for rapid signal capture and a narrow window for good noise immunity.

It is also possible to run the timebase in 2.0 V mode as there are decodes for 100 Hz (2 x 50 Hz) operation with upper and lower limits in proportion. This is, of course, intended to be used in conjunction with field and frame memory stores. The similar decodes which would be necessary to allow 120 Hz (2 x 60 Hz) operation have not, for the present, been implemented. Finally, the timebase can be forced into a count of either 625 or 525 by commands from the MCU; in this mode the input signal, if present, is ignored completely. If there is no signal present save for noise, then this feature can be used to obtain a stable raster.

In the analog section, an adjustable current source is used to charge an external capacitor at Pin 6 to generate a vertical ramp. The amplitude of the ramp is varied according to the current source (Height), and is automatically adapted when the 525 standard is recognized by multiplying by 1.2. The Linearity control is achieved by squaring the ramp and either adding or subtracting a portion of it to the main linear current. In addition, a correction current, depending on the level of anode current, is applied in the sense of oppose a change of picture height with EHT (Breathing).

The final ramp with corrections added is then passed to a driver/amplifier and is output at Pin 7. The vertical ramp can be used to drive a separate vertical deflection power circuit with local feedback control. Vertical "S" Correction will then be made using fixed components within the feedback loop of the power op amp. The vertical position can be adjusted under MCU control – this is achieved by varying the dc output level at Pin 7. The vertical amplitude can be reduced to 75% of its original value (bit VDI) to make possible the display of a 16:9 picture on a 4:3 screen.

The reference ramp is squared to provide a pin-cushion correction parabola, developed across an external resistor at Pin 8. The parabola itself is squared, giving an independent fourth order term (Corner Correction) whose level can also be varied; this is then added as a further modifying term to the E-W output. This latter correction is used for obtaining good corner geometry with flat-square tubes. A variable dc current is added to the parabola to effect a width control. Using a suitable power amplifier and a diode-modulator in the line output stage, the parabola may be used for E-W correction and dynamic width control. A further control is provided to shift the center point of the parabola up and down the screen (Parabola Tilt).

All of the vertical and horizontal signals are adjustable via 6-bit words from the MCU, and stored in latches. The adjustment controls available are:

Vertical Amplitude/Linearity/Breathing Correction/Position
Parabola (E-W) Amplitude/Horizontal Amplitude/
Corner Correction, and Parabola Tilt

The Anode Current Sense at Pin 9 is also used as a beam current monitor. Two thresholds may be set, by the manufacturer, using external components. The first threshold sets a flag to the processor if beam current becomes excessive. The MCU could, e.g., reduce brightness and/or contrast to alleviate the condition. The second threshold sets a flag warning of an overload condition where the CRT phosphor could be damaged. If such a condition were to arise, the processor would be programmed to shut down the PSU.

The vertical blanking lines may be selected by means of a bit from the MCU for either the 525 or 625 standard. The interlace may also be suppressed again under the control of the processor (bits ICI, IFI).

PIN FUNCTION AND EXTERNAL CIRCUIT REQUIREMENTS

The following section describes the purpose and function of each of the 40 pins on the MC44002/7. There is also an explanation of the external circuit component requirements for a practical application; a diagram of the small signal circuit will be found in Figure 17. One of the primary design aims for the MC44002/7 was to use the minimum number of external components, and where these are necessary, to employ low cost and easily obtainable standard types. Thus for example, as all the video signal filtering is carried out on the IC, there are no coils required whatsoever. The most common requirement is for ac coupling capacitors which are far too big to be integrated onto the chip. The time constants on certain pins are deliberately determined by external components to facilitate testing and for fine tuning the performance.

PIN FUNCTION DESCRIPTION

Pin	Equivalent Internal Circuit	Description
1		**ACC** External Filter used by ACC section. A single capacitor, that does not have a critical value, typically 0.01 µF, filters the feedback loop of the chroma automatic gain control amplifier.
2 40		**Video Input 1 (Pin 40) and 2 (Pin 2)** Video inputs (Pin 2 = Video 2; Pin 40 = Video1); Intended for a nominal 1.0 Vpp input level of composite video. Separate luma and chroma components may also be used with these input pins for S–VHS. The external circuit requirement is for a coupling capacitor of 0.01 µF and a series resistance not exceeding 1.0 kΩ. The input selection and adaptation for Y and C is carried out in software.
3		**Reference Current** Master reference current used throughout the IC. This is programmed by means of an external pull–up resistor, as on–board resistors are not sufficiently accurate. The designated current is 70 µA. This pin should be very well de–coupled to ground to avoid picking up interference from the nearby I^2C bus inputs. Nominal voltage at the pin is 1.3 V.
4		**I^2C Clock** I^2C bus clock input. This input can be taken straight into the IC, but in a real TV application it may be prudent to fit a series current limiting resistor near the pin in case of flash–over. A single pull–up resistor to 5.0 V is required. Although its value is associated with the µP, taking into account system capacitance at high data rates, a value of 4.7 kΩ, giving optimal performance, is recommended.
5		**I^2C Data** I^2C data input. Comments above for Pin 4 also apply to this pin.
6		**Vertical Ramp** A current is used to charge an external capacitor connected to this pin, developing a voltage sawtooth with a field period. The capacitor value determines the ramp amplitude. 82 nF is the more convenient value for symmetrical, linearity and parabola tilt adjustments.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
7		**Vertical Drive** The sawtooth derived on Pin 6 is used to drive an external power amplifier vertical output stage. The amplitude, linearity and position of the output ramp are adjustable via the MCU.
8		**Parabola (E–W) Drive** An inverted parabolic waveform derived by squaring the vertical ramp is used to drive an external power amplifier. In sets fitted with a diode modulator type line output stage, this provides width control and pin–cushion correction. The parabola is squared again to give a fourth order correction term required for flat square tubes. The E–W amplitude, dc level, tilt and corner correction are all adjustable by means of the MCU. This is a current output and may be used, for example, to drive the virtual ground of an external power amplifier
9		**Anode Current** Used as an anode current monitor whose purpose is to: (1) Provide E.H.T. compensation (anti–breathing) for the vertical ramp; and (2) provide warning of excessive and overload beam current conditions. The pin is connected via about 560 kΩ series resistor to the bottom of the E.H.T. overwinding. Therefore, increasing beam current will pull the voltage on this pin more negative. This change is sensed within the chip and used to apply a correction to the ramp and parabola amplitudes. With large beam currents, thresholds at $+V_{be}$ and $-2.0\ V_{be}$ set off warning flags to the MCU, which then has to take the appropriate action. The anode current levels at which these thresholds are reached are set up using fixed external resistors.
10		**Anode Contrast** This pin is used as an Analog Contrast monitor, allowing fast Beam Current Limiting (BCL). The fast BCL is controlled by Pin 10 voltage, which decreases with the contrast reduction (see typical curve). Above 2.5 V on the pin, the contrast remains maximum. Below 2.5, the contrast is reduced by about 12 dB, which is reached at about 1.0 V.
11		**SECAM Calibration Loop** This pin is used for the storage capacitor of the analog SECAM calibration loop (typically 100 nF). The capacitor is required regardless of whether or not SECAM will be decoded.
12		**Horizontal Drive Output** Horizontal drive pulses having an approximately even mark–to–space ratio emerge from this pin. This is an open–collector output which can sink up to 10 mA. However, taking this much current is not recommended since there is no separate ground pin available which may be connected near the line output stage; noise could be injected into the signal ground on the IC. Therefore, with a transformer driven line output stage, this output has been designed to be used with an extra external transistor inverter between the IC and the line driver. The transistor is open during the period when the line deflection transistor should be conducting.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
13		**Horizontal Flyback Input** Flyback sensing input taken from the line output transformer. These pulses are used by the 2nd horizontal loop for H–Phase control. A positive going pulse from 0 to 5.0 V amplitude is needed for correct operation. The internal impedance of the pin is about 50 kΩ and an external attenuating series resistor of around 120 kΩ will also be needed.
14		**Horizontal Loop 2 Filter** Components at this pin filter the output of the phase detector in the 2nd horizontal loop. A simple external filter consisting of a 0.1 µF capacitor is required.
15		**Horizontal Loop 1 Filter** Horizontal PLL loop time constant. Components at this pin filter the output of the phase detector is in the 1st horizontal loop. The value of RC time constant is selected with external components to give a smooth recovery after the field interval disturbance and to ensure optimum performances in the presence of noise.
17 18 19		**RGB Outputs** The R, G and B drives are current rather than voltage due to the limited headroom available with the 5.0 V supply line. The outputs themselves consist of open–collector transistors and these are used to drive the virtual ground point of the high voltage cathode amplifiers
20		**Feedback** Current feedback sense derived from the video output amplifiers. The currents from all three guns are summed together as each is driven sequentially with know current pulses during the field interval. This feedback is then compared with internally set–up references. A low value ceramic capacitor to ground may be fitted close to this pin to help stabilize the control loops. A secondary function of this pin is for peak beam current limiting. When the feedback voltage during picture time becomes too great (i.e. too high beam current), a threshold at V_{CC} + 3.0 V_{be} is exceeded at which time a flag is sent to the MCU. The MCU then has to carry out the function of peak beam limiter by e.g. reducing contrast until the flag goes off. The threshold current is set externally with a fixed resistor value.
21		**Fast Commutate** A very fast active high switch (transition time 10 ns) used with text on the RGB inputs, for overlaying text on picture. This hardware switch may be enabled and disabled in software.

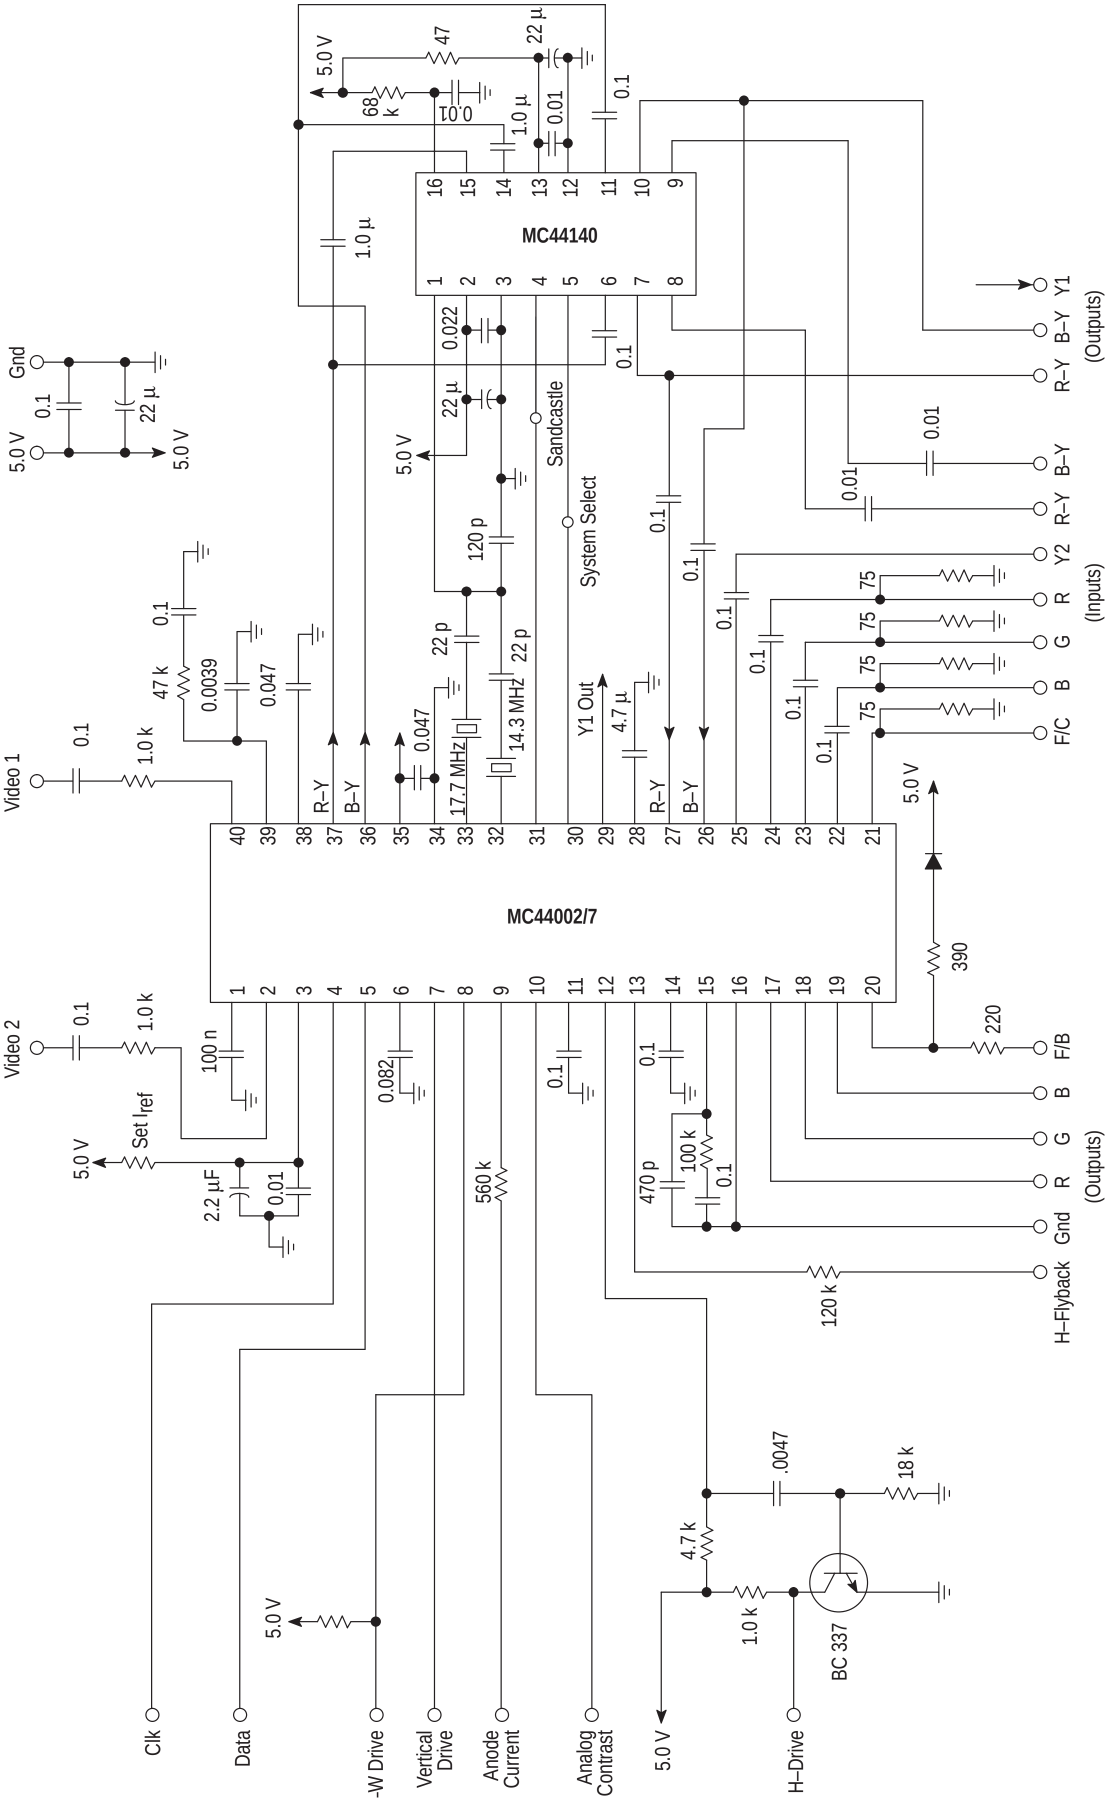
PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
22 23 24		**RGB Inputs** These external input signals to the color difference stages are ac coupled into the IC via 0.1 µF capacitors. They have a clamp and sync separator. The inputs should be driven from a source of less than 1.0 kΩ output impedance with 700 mVpp signal levels.
25		**Y2 Input** Auxiliary external input to MC44002/7 which can be used in conjunction with auxiliary color difference inputs and/or as a sync input. The pin should be driven from a source of less than 1.0 kΩ output impedance with 700 mVpp luminance signal. The signal must be ac coupled via an external 0.1 µF coupling capacitor. Internal clamp and sync separator are provided.
26 27		**B–Y and R–Y Inputs** Corrected color difference inputs from the MC44140. The signals are ac coupled via 0.1 µF capacitors and are clamped internally. The inputs should be driven from a source of less than 1.0 kΩ output impedance.
28		**YI Clamp** External capacitor used by the circuit which clamps the Y1 signal output on Pin 29. A typical value is 4.7 µF.
29		**YI Output** The luminance, after passing through the filter and delay line/peaking sections, is made available on this pin. It is also routed internally to the color difference stages.
30		**System Select** A multilevel dc output controlled in software, which is used by the MC44140 for system selection. Please refer to separate functional description of the MC44140 chroma delay line.
31		**Sandcastle** A special multilevel timing pulse derived in the MC44002/7 for use by the MC44140. Please refer to separate function description of the MC44140 chroma delay line.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
32 33		**Crystals (Respectively 14.3 MHz and 17.7 MHz)** Drive for externally fitted crystal clock reference for PAL, SECAM or NTSC. Four times F_{SC} is used. If the NTSC system is not going to be received, the 14.3 MHz crystal may be omitted. The crystal is parallel driven from a single pin and it requires a series load capacitance of appropriate value (usually 20 to 30 pF). Only crystals intended for VCO use should be fitted. The reference frequency is divided down in a capacitor chain to provide about 50 mV of clock reference for the MC44140. Positions for Pins 32 and 33 are selected by software.
34 35		**5.0 V Supply (35) and Ground (34)** Supply line, nominally 5.0 V, requiring about 120 mA. The actual voltage should be in the range of 4.75 to 5.25 V for usable results. It is recommended to decouple the supply line using a small ceramic capacitor mounted close to the supply and ground pins.
36 37		**B–Y and R–Y Outputs** Demodulated color difference outputs. These signals are ac coupled to the MC44140 for correction and delay with PAL and SECAM respectively. Signal level of about 1.4 Vpp may be expected on B–Y output when using a standard 75% color bars input video signal.
38		**Identification** External filter used by R–Y identification circuit. The filter normally consists of a single capacitor whose value is a compromise between rapid identification and noise rejection. Experience has shown that 0.047 µF is a suitable value.
39		**Oscillator Loop Filter** External time constant for chroma PLL. The crystal reference oscillator is phase locked to the incoming burst in PAL and NTSC. A low value ceramic capacitor, for good noise immunity, is normally placed in parallel with a much longer RC time constant. The PLL pull–in range is reduced when the time constant on the pin is made bigger, allowing this function to be optimized by the user.

Figure 17. Typical Application Circuit



SOFTWARE CONTROL FUNCTIONS

General Description

As already related in the circuit description, the MC44002/7 has a memory of 18 bytes. All, except Sub-address 77 and 7F, use the 6 least significant bits as an analog control register with D/A converters (64 steps) within the memory section. The remaining bits are controlled individually for switching numerous functions. Table 2 gives a listing of all the memory registers and control bits. An explanation of the function of the 16 DACs is given below.

Vertical Amplitude – Changes the amplitude of the vertical ramp available on Pin 7.

Vertical Breathing Correction – A correction is applied to the vertical ramp amplitude in a sense opposite to the picture expansion and contraction produced by changes in beam current. This register alters the sensitivity of the beam current sensing and hence the size of correction applied for a given change in beam current.

Parabola Amplitude – Changes the amplitude of the E-W output parabola developed across an external pull-up resistor at Pin 8.

Parabola Tilt – Shifts the point of inflection of the E-W parabola from side to side along the time axis. Also known as *keystone correction*.

Vertical Linearity – The vertical ramp is multiplied by itself to give a squared term, a part of which is either added or subtracted to the linear ramp as determined by this register.

Corner Correction – An independent 4th order term which is subtracted from the E-W parabola to achieve correct geometry with flat square tubes.

Horizontal Amplitude – A variable dc offset applied to the E-W output parabola on Pin 8.

Vertical Position – Adjust the dc level of the vertical ramp on Pin 7, allowing vertical centering control.

Horizontal Phase Control – Applies a variable phase offset to the horizontal drive pulse at Pin 15 providing for a picture centering control.

B, G, R Intensity – These controls set up the current reference pulses used when sampling the beam current during field interval. The data is fixed by the TV manufacturer when setting up the White balance and the CRT for correct Gray Scale tracking.

(All the above registers are for use during the test and setting up procedures; the remaining 4 registers are also user controls.)

Contrast – During bright sample time during the field interval, this control varies the level of the current pulses injected into the R,G,B channels, so altering the picture contrast.

Brightness – A variable current pedestal which is added to the three drives during active picture time.

Saturation – A variable gain control for the two color difference signals.

Hue – Achieved by mixing a portion of one color difference signal into the other.

Individually Adjustable Control Bits – These consist of bits 7 and 6 of registers 77 through 88, as well as bits 0 to 5 of register 77 and bits 0 to 3 of register 7F. Some of these are used individually to control single functions requiring just on/off switching; and some are arranged into 2 or 3-bit words (e.g., luma peaking). A list of control words and truth tables for these may be found in Table 3.

CA1, CB1 – Used to change the mode of operation of the vertical timebase to either injection lock or auto countdown, or to force it into 525 or 625 lines. Just prior to changing channel, the vertical timebase can be switched to injection lock mode and when a new channel is captured, the timebase is switched back to auto mode. In this way there is no delay in locking onto the new channel and hence no picture roll. If there is no valid signal being received, the display can be stabilized by forcing the timebase into 525 or 625 lines.

IC1, IF1 – These bits are used to suppress the field interlace, which can be scanned in the nearest even or odd half line.

HI, VI – Selects the type of SECAM ident when operating in this mode. Either vertical ident bursts or horizontal ident can be selected individually, or ident can be taken from a combination of the two. In certain transmissions the vertical SECAM identification is not present (and sometimes replaced by other signals), so it is strongly recommended that only the horizontal identification be used. These bits must both be set to 1 when SECAM is not decoded (MC44002 and MC44007).

SSA, SSB, SSC – Used to set the color decoder and the dc level of the System Select output from the MC44002/7, Pin 30. This output is used by the MC44140 delay line in turn for changing between PAL, NTSC, SECAM and external modes of operation. In effect, the MC44140 is being controlled by the I^2C bus via the MC44002/7.

0	1	1	948 ns	1150 ns	1218 ns	N/A
1	0	0	1004 ns	1220 ns	1274 ns	N/A
1	0	1	1060 ns	1290 ns	1330 ns	N/A
1	1	0	N/A	N/A	N/A	480 ns
1	1	1	N/A	N/A	N/A	480 ns

SSE, SS1, SS2 – These 3 bits select the signal input from which the timebase synchronization is taken. The composite video input has a high quality sync separator which has been designed to cope with noise and interference on the video; the RGB and Y2 inputs have simple single sync separators which may also be used for synchronization.

T1, T2 – The bits are used to modify the response of the variable Low Pass Filter placed at the composite video inputs (for PAL/NTSC signals) in order to compensate for IF filtering and the Q of external sound traps.

P1, P2, P3 – These 3 bits are used to adjust the Luma peaking value. The amount of peaking indicated is with respect to the gain at the minimum peaking value (P1, P2, P3 = 111).

D1, D2, D3 – These 3 bits are used to adjust the Luma delay. The indicated delay is that from the video inputs (Pins 2 and 40) to the Y1 output. The amount of delay depends on the composite video standard used if S–VHS is selected.

NT0, NT1, NT2 – These 3 bits are used in conjunction with SSA for the selection of the matrix coefficients mode.

HGAIN1, HGAIN2 – These 2 bits are used to set the gain of the horizontal phase detector. The high gain position is used to acquire lock and for operation with a VCR. Setting HGAIN1 to 0 also enables a horizontal sync window. The low gain position is used for off–the–air signals.

The remaining control bits are used singularly and are listed as follows:

T3 – When high, this bit enables the variable Low Pass Filter at the video inputs. For optimum performance, T3 must be set to 0 in S–VHS and SECAM modes, and to 1 in PAL and NTSC. The filter response is set with bits T1, T2.

S-VHS – Set to 1 for normal composite video input to Pin 2 or 40. In this mode, the luma–chroma separator is active. Set to 0 for S–VHS (Y/C) operation at those pins. In this mode, luma is to be applied to the selected video input (with bit V1/V2), and chroma is to be applied to the other input. The luma–chroma separator is bypassed.

FSI – Selects either 50 Hz or 100 Hz field rate. When bit is low, 50 Hz operation is selected. No usable with NTSC.

BAI – This bit selects the number of blanked lines for either 525 or 625 line standards.

INTSEL – The vertical sync separator operates by starting a counter counting up at the beginning of each sync pulse, a field pulse being recognized only if the counter counts up to a sufficiently high value. The control bit INTSEL is used in taking the decision as to when a vertical sync pulse has been detected. When low, the pulse is detected after 36 µs; when high after 68 µs. This may find application with anti-copy techniques used with some VCRs, which rely on a modified or corrupted field sync to allow a TV with a short time constant to display a stable picture. However, a VCR having a longer time constant will be unable to lock to the vertical.

CALKILL – Enables or disables the horizontal calibration loop. The loop is normally enabled only during startup for some seconds and when there is no signal present. The loop may be disabled so long as the horizontal timebase is locked to an incoming signal.

XS – Is used to change between the two external crystal positions (Pins 32 and 33).

SSD – Forces system select to PAL level. Can be used to override SECAM mode in the delay line. When low, SECAM mode is enabled (MC44002 only).

VDI – Either 4:3 or 16:9 display mode can be chosen using this bit. When low, the 16:9 mode is enabled.

D EN – Enables or disables the RGB Fast Commutation switch for the RGB inputs. When low, RGB inputs are enabled.

Y1 EN – Switches Y1 through to the color difference stage.

Y2 EN – Switches Y2 through to the color difference stage.

Test – When bit is low, enables continuous sampling by the RGB output control loops throughout the entire field period. Used only for testing the IC.

YX EN – Enables the luma matrix allowing saturation control in the color difference stage.

Norm – Alters the division ratio for the reference frequency used by the horizontal calibration loop. Always used when changing between 14.3 MHz and 17.7 MHz crystals.

BRI EN – Used to switch on or off the “bright” sampling pulses used by the RGB output loops. This feature was originally introduced to prevent any backscatter from these three bright lines in the field interval from getting into the picture. Must be enabled when adjusting intensity Contrast or Red, Green and Blue.

2x Fh – Line drive output is either standard 15.625 kHz (15.750 kHz) or at double this rate.

H EN – Control bit enables horizontal drive pulse. This is normally done automatically after the values stored in the MCU nonvolatile memory have been read into the MC44002/7 memory.

V1/V2 – To select between Video Inputs 1 and 2.

Table 4. Control Bit Functions

Bits	Bit Low	Bit High
T3	Variable Input LPF By–Passed	Variable Input LPF Enabled
$\overline{\text{S–VHS}}$	S–VHS Mode Enabled	Composite Video Mode Enabled
FSI	50 Hz Field Rate Selected	100 Hz Field Rate Selected
BAI	Vertical Blanking for 525 Lines	Vertical Blanking for 625 Lines
INTSEL	Short Vertical Time–Constant	Long Vertical Time–Constant
CALKILL	H Calibration Loop Enabled	H Calibration Loop Disabled
XS	17.7 MHz Crystal (Pin 33) Selected	14.3 MHz Crystal (Pin 32) Selected
SSD	System Select Active	System Select Forced to PAL
$\overline{\text{D EN}}$	RGB Inputs Enabled	RGB Inputs Disabled
Y2 EN	External Luma Input Switched “Off”	External Luma Input Switched “On”
Y1 EN	Luma from Filters Switched “Off”	Luma from Filters Switched “On”
$\overline{\text{TEST}}$	Video Outputs Sampled Continuously	Video Outputs Sampled Once per Field
YX EN	Disable Luma Matrix (RGB Saturation Control)	Enable Luma Matrix (RGB Saturation Control)
$\overline{\text{HGAIN1}}$	H–Phase Detector Gain Division by 3 Enabled	H–Phase Detector Gain Division by 3 Disabled
HGAIN2	H–Phase Detector Gain Division by 2 Disabled	H–Phase Detector Gain Division by 2 Enabled
NORM	H–Reference Divider Ratio for 17.7 MHz Crystal	H–Reference Divider Ratio for 14.3 MHz Crystal
BRI EN	“Bright” Sample Switched “Off”	“Bright” Sample Switched “On”
2 x fH	H–Drive : 1 x fH	H–Drive : 2 x fH
H EN	H–Drive Enabled	H–Drive Disabled
VDI	16:9 Display Mode Enabled	4:3 Display Mode Enabled
V1/V2	Video Input 2 (Pin 2) Selected	Video Input 1 (Pin 40) Selected

FLAGS RETURNED BY THE MC44002/7

When the Address Read/Write bit is high the last two bytes of I^2C data are read by the MCU as status flags; a listing of these may be found in Table 5. The MC44002/7 is designed to be part of a closed-loop system with the MCU; these flags are the feedback mechanism which allow the MCU to interact with the MC44002/7.

A brief description of each of the flags, its significance and possible uses are given below.

Table 5. Flags Returned

Clock #	Flag (Bit High)
10	Horizontal Flyback Present
11	Horizontal Drive Enabled
12	Horizontal Out Of Lock
13	Excess Average Beam Current
14	Less Than 576 Lines
15	Vertical Countdown Engaged
16	Overload Average Beam Current
17	Reserved
18	(Acknowledge)
19	Grid 2 Voltage Up Request
20	Grid 2 Voltage Down Request
21	OK
22	Fault
23	ACC Active
24	PAL Identified
25	SECAM Identified (MC44002 only)
26	Excess Peak Beam Current
27	(Acknowledge)

Horizontal Flyback Present – A sense of the horizontal flyback is taken via a current limiting series resistor from one of the flyback transformer secondaries to Pin 13. This is used for the H-phase shift control, but the presence of the pulse is also flagged to the MCU. Should the flag be missing after the chassis has been started up, then the MCU would have to shut down the set immediately.

Horizontal Drive Enabled – Indicates that the horizontal drive pulse output at Pin 15 has been enabled. This occurs after the stored values in the nonvolatile memory have been transferred to the MC44002/7 memory.

Horizontal Out of Lock – This flag is high when no valid signal is being received by the MC44002/7. Possible action in this case would be to change the phase detector gain and time constant bits to ensure rapid capture and locking to a new signal.

Excess Average Beam Current – This is one of two threshold levels which are determined by an external component network connected to the beam current sensing at Pin 9. This flag indicates an excess of beam current. A typical application of this flag in conjunction with “Overload Average Beam Current” flag is for the software controlled Automatic Beam Current Limiting. When this flag is “on”, it is recommended that the software prevent increases to the Contrast setting.

Less Than 576 Lines – Output from the line counter in the vertical timebase. If there is a count of less than 576 this is indicative of a 525 line system being received. If the flag is low then a 625 line system is being received. This information can be used as part of an automatic system selection software.

Vertical Countdown Engaged – The vertical timebase is based on a countdown system. The timebase starts in Injection Lock mode and when vertical retrace is initiated a 4-bit counter is set to zero. A coincidence detector looks for counts of 625 lines. In Auto mode each coincidence causes the counter to count up. When eight consecutive coincidences are detected, the countdown is engaged. The MSB of the counter is used to set this flag to the processor.

Overload Average Beam Current – This is the second threshold level which is set by the external component network on Pin 9. The flag warns of an overload in anode current which should be lowered by reducing the Contrast.

Grid 2 Voltage Up/Down Requests – These flags indicate when the RGB output loops are about to go out of the control range necessary for correct gray scale tracking. These 2 flags are used during factory adjustment.

OK and Fault – These two flags are included as a check on the communication line between the MCU and MC44002/7. The OK flag is permanently wired high and Fault is permanently wired low. The MCU can use these flags to verify that the data received is valid.

ACC Active – This flag is high when there is a sufficient level of burst present in PAL and NTSC modes during the video back porch period. The flag goes low when the level of burst falls below a set threshold or if the signal becomes too noisy. The flag is used to implement a software color killer in PAL and NTSC and is also available for system identification purposes. Since in SECAM there is line carrier present during the gating period, it is quite likely that the ACC will be on, or will flicker on and off in this mode.

*** PAL Identified** – Recognizes the line-by-line swinging phase characteristic of the PAL burst. When this flag is on together with the ACC flag, this is positive identification for a PAL signal.

*** SECAM Identified** – Senses the changing line-by-line reference frequencies (Fo1 and Fo2) present during the back porch period of the SECAM signal. This flag alone provides identification that SECAM is being received (MC44002 only).

Excess Peak Beam Current – A voltage threshold is set on the beam current feedback on Pin 20, which is also used for the RGB output loops for current sampling. When the threshold is reached, the flag is set, indicating too high a peak beam current which may be in only a part of the screen. The response of the MCU might be to reduce the contrast of the picture. This flag, together with the Excess Average Beam Current flag, performs the function of beam limiting. The exact way in which this is handled is left to the discretion of the user who will have their own requirements, which may be incorporated by the way in which the software is written.

---

* These two flags are set in opposition to one another such that they can never both be on at the same time. This has been done to try to prevent misidentification from occurring. Often it is very difficult to distinguish between PAL and SECAM especially when broadcast material has been transcoded, sometimes badly, leaving e.g. large amounts of SECAM carrier in a transcoded PAL signal (also often with noise). With this method the strongest influence will win out making a misidentification much less likely.

APPENDIX A – SYSTEM IDENTIFICATION TABLE

The table below can be used for color standard selection between the normal PAL (I, BG), SECAM (L, BG) and NTSC (3.58 MHz – M) standards. Detecting the hybrid VCR standard (525 lines with 4.4 MHz chrominance) would entail switching back to the 17.7 MHz crystal in the event of there being no flag present with the 14.3 MHz crystal. The MC44002/7 could also be used for the PAL M and N standards that are used in some parts of South America, but because the subcarrier frequencies differ by some kHz from the normal, crystals with a different center frequency would be required.

Table 6. System Identification

Flags from the MC44002/7				Crystal (MHz)	Standard Selected By MCU
<576 Lines	ACC On	PAL	SECAM		
0	0	0	0	17.7	Kill
0	0	0	1	17.7	SECAM
0	0	1	0	17.7	Kill
0	0	1	1	17.7	I^2C Bus Error
0	1	0	0	17.7	Kill
0	1	0	1	17.7	SECAM
0	1	1	0	17.7	PAL
0	1	1	1	17.7	I^2C Bus Error
1	0	0	0	14.3	NTSC Kill
1	0	0	1	14.3	NTSC Kill
1	0	1	0	14.3	NTSC Kill
1	0	1	1	14.3	I^2C Bus Error
1	1	0	0	14.3	NTSC
1	1	0	1	14.3	NTSC
1	1	1	0	14.3	NTSC
1	1	1	1	14.3	I^2C Bus Error

APPENDIX B – I2C BUS AND RGB CONTROL LOOPS WITH MC44002/7

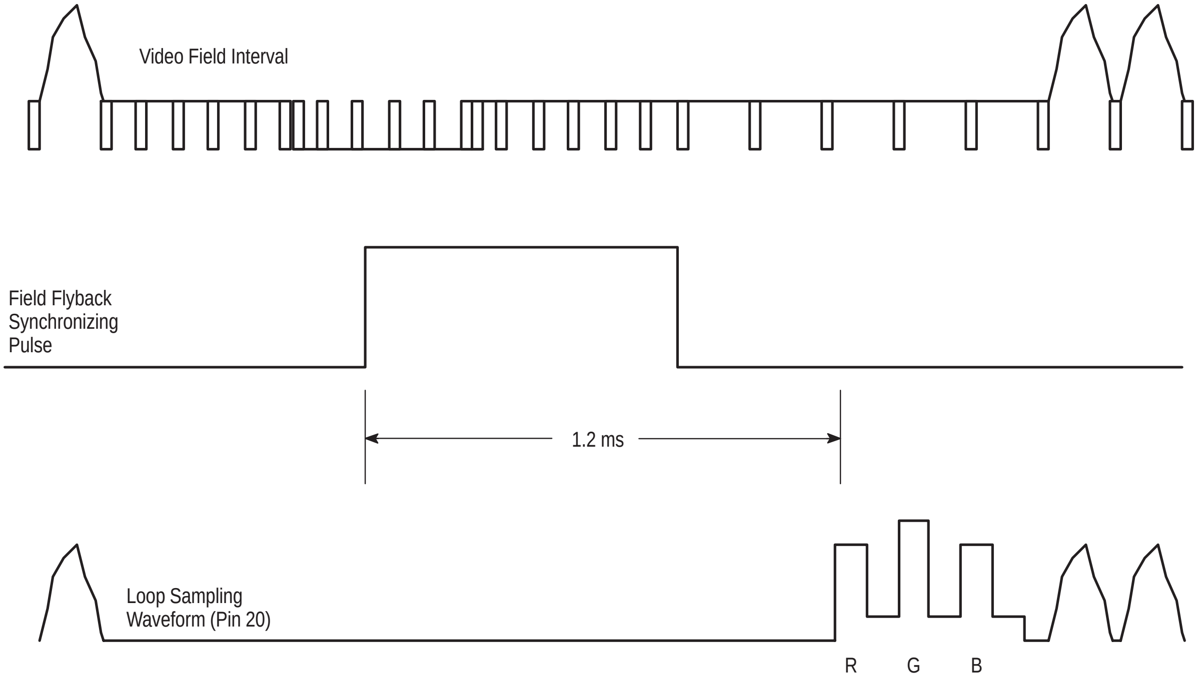
The RGB drive DACs cannot be buffered on account of the chip area that this would take up. This factor has considerable implications on the way that the I2C data is written into the MC44002/7 memory. If the data for Brightness, Contrast, Saturation and Hue are transmitted at just any time, a disturbance will be visible on the screen.

To overcome this difficulty, a method synchronizing the MCU to write data only during the field interval has been developed. This represents something of a limitation, but has to be used only for the 4 user controls.

Another characteristic of the MC44002/7 is that the Contrast control function is carried out within the RGB sampling loops. If data is written into the registers during the time when the RGB loops are taking their samples, then the situation arises where data is being sampled and changed at the same time. Hence, the loops will inevitably go unstable. When this happens, the brightness is seen to vary uncontrollably while the Contrast is changed. The effect has been described as “loop bounce”.

The timing diagram below show the exact situation.

From the start of the field flyback pulse to the beginning of the RGB sampling, approximately 1.2 ms is available to write the I2C data. Therefore, with a reasonable safety margin, the write time should be limited to only about 1.0 ms. This should not present any serious difficulty since only the data byte has to be transmitted during this time, and then only for the 4 user controls.



APPENDIX C – A SUGGESTED METHOD FOR OUTPUT LOOPS ADJUSTMENT

As described in section 4, the MC44002/7 output loops stage automatically adjust the dc level of the cathode voltage (cut–off) and the gain of the signal at the cathode (white balance). These automatic adjustments replace the conventional manual adjustments. The only adjustment that must be carried out, either by hand or automatically using an "intelligent screwdriver", is for the G2 voltage.

As the G2 voltage is varied, the automatic output loops of the MC44002/7 will adjust the cathode voltage of the dark sample level to always obtain the correct dark cathode current. However, if the G2 voltage is adjusted too high or too low, one or more of the DAC's controlling the dc level will reach the end of their range and the cathode voltage on the channel will not be correctly adjusted. In order to inform the operator or machine adjusting the G2 voltage that the control range has been exceeded, the G2–Up Request or G2–Down Request flags will be set. These flags are set when any one of the dc–DAC's approaches the end of its range. The threshold for setting the flags lies typically between 15 and 20% of the range from the actual end. Therefore, when a flag is set, the output loops can still operate correctly. As the gain of the picture tube varies very little with the G2 voltage, flags are not provided for the gain–DAC's.

In order to fix a procedure for setting the G2 voltage it is necessary to consider several points:

– On a given sample, the output currents from the three channels corresponding to the dark level are all different. The range of each DAC is about 2.4 mA and varies little from one channel to another and from one device to another. For reasons of stability and control range we recommend that the feedback resistor of the high–voltage video amplifier be 39 kΩ. this means that the dark cathode voltage range of each channel is about 94 V (i.e. 39 kΩ x 2.4 mA), but the absolute value of the cathode voltage can vary.

– In a typical application the actual cut–off voltage (i.e. zero cathode current) lies about 10–15 V higher than the dark cathode current (10 µA).

– When the beam–current in the picture tube increases, the G2 voltage tends to decrease. With the output loops of the MC44002/7, the cathode voltage is lowered automatically to compensate, but this effect would normally cause the values in the dc–DAC's to fall, using up their useful control range. as high beam current is associated to high contrast, in the MC44002/7 the dc output current (and therefore the cathode voltage) is reduced directly as the contrast setting is increased. In this way as contrast is increased, leading to higher beam current and lower G2 voltage, the dc–DAC's do not move much, thus saving range.

– A picture tube can have a difference in cut–off voltage between guns of up to about 30 V and it is not generally possible to identify in a particular type and make of tube which gun has the lowest and which gun has the highest cut–off voltage. Also, it is generally recommended by the tube manufacturer to set the cut–off voltage of the highest gun to a certain value which gives optimum focus performance.

– As the picture tube ages, the cathode cut–off voltage falls. It is therefore best to set the G2 voltage when the tube is new to give the highest possible cathode cut–off voltage.

Taking into account the above points, it is recommended that the G2 voltage be set up in the following way:

1) Display a black picture with the brightness control to minimum. (This give minimum beam current and no drop in G2 voltage.)

2) Set he contrast to maximum. (This causes the dc output current to be forced to a lower level and the output loops to compensate by moving towards the top of their range.)

3) Now adjust the G2 voltage so that the G2 Down Request flag is just turned off. (All the dc–DAC's are towards the top of their range and the highest one is just at the level to switch on the flag. Lowering the contrast setting, increasing the beam current or aging of the tube will cause the output loops to reduce the values in the dc–DAC's, but the available range will be a maximum.)

4) With a white picture and contrast set to give the maximum allowable beam current, check that the G2 Up Request flag is still off. (This is just to check that the G2 voltage is not falling too much at high beam current, but this step is not absolutely necessary.)

It is not recommended adjusting the G2 voltage to reach a specific value of cathode cut–off or dark voltage. The reason for this is that tolerances of the picture tube, high voltage video amplifier and the MC44002/7 itself will cause the dc–DACs to be set anywhere in their range and perhaps near the bottom end, leaving no margin for aging and G2 voltage drop.

MOTOROLA

MC44011

Advance Information

Bus Controlled Multistandard Video Processor

The Motorola MC44011, a member of the MC44000 Chroma 4 family, is designed to provide RGB or YUV outputs from a variety of inputs. The inputs can be composite video (two inputs), S–VHS, RGB, and color difference (R–Y, B–Y). The composite video can be PAL and/or NTSC as the MC44011 is capable of decoding both systems. Additionally, R–Y and B–Y outputs and inputs are provided for use with a delay line where needed. Sync separators are provided at all video inputs.

In addition, the MC44011 provides a sampling clock output for use by a subsequent triple A/D converter system which digitizes the RGB/YUV outputs. The sampling clock (6.0 to 40 MHz) is phase–locked to the horizontal frequency.

Additional outputs include composite sync, vertical sync, field identification, luma, burst gate, and horizontal frequency.

Control of the MC44011, and reading of status flags, is via an I^2C bus.

- Accepts NTSC and PAL Composite Video, S–VHS, RGB, and R–Y, B–Y
- Includes Luma and Chroma Filters, Luma Delay Lines, and Sound Traps
- Digitally Controlled via I^2C Bus
- R–Y, B–Y Inputs for Alternate Signal Source
- Line–Locked Sampling Clock for A/D Converters
- Burst Gate, Composite Sync, Vertical Sync and Field Identification Outputs
- RGB/YUV Outputs can Provide 3.0 Vpp for A/D Inputs
- Overlay Capability
- Single Power Supply: 5.0 V, ±5%, 550 mW (Typical)
- 44 Pin PLCC and QFP Packages

ELECTRICAL CHARACTERISTICS (The tested electrical characteristics are based on the conditions shown in Table 1 and 2. Composite Video input signal = 1.0 Vpp, composed of: 0.7 Vpp Black–to–White; 0.3 Vpp Sync–to–Black; 0.3 Vpp Color Burst. $V_{CC1} = V_{CC2} = V_{CC3} = 5.0$ V, $I_{ref} = 32$ µA (Pin 9), unless otherwise noted.)

Table 1. Control Bit Test Settings

Control Bit	Name	Value	Function
$77–7	S–VHS–Y	0	Composite Video input selected.
$77–6	S–VHS–C	0	Composite Video input selected.
$77–5	FSI	0	50 Hz Field Rate selected.
$77–4	$\overline{\text{L2 GATE}}$	0	PLL #2 Gating enabled.
$77–3	$\overline{\text{BLCP}}$	0	Clamp Pulse Gating enabled.
$77–2	$\overline{\text{L1 GATE}}$	0	Vertical Gating enabled.
$77–1, 0	CB1, CA1	1,1	Vertical section Auto–Countdown mode
$78–7	36/68 µs	0	Time from beginning of Line 4 to Vertical Sync is 36 µs.
$78–6	CalKill	0	Horizontal Calibration Loop enabled.
$79–7, 6	HI, VI	1,1	Normal
$7A–7	Xtal	–	0 = 17.7 MHz crystal selected, 1 = 14.3 MHz crystal selected.
$7A–6	SSD	0	Normal
$7B–7, 6	T1, T2	1,1	Sound Trap Notch filter set to 5.5 MHz (with 17.7 MHz crystal).
$7C–7	SSC	0	Permits PAL and NTSC selection.
$7C–6, $7D–6	SSA, SSB	–	0, 1 = PAL decoding, 1,0 = NTSC decoding
$7D–7, $7E–7, 6	P1, P3, P2	1, 1, 1	Sets Luma Peaking at 0 dB.
$7F–7, 6, $80–6	D3, D1, D2	0, 0, 0	Set Luma Delay to minimum
$80–7	$\overline{\text{RGB EN}}$	0	Fast Commutate input can enable RGB inputs.
$81–7	Y2 EN	0	Y2 input (Pin 29) deselected
$81–6	Y1 EN	1	Y1 luma path from PAL/NTSC decoder selected.
$82–7	YUV EN	0	RGB output mode selected
$82–6	YX EN	0	Disable luma matrix from RGB inputs.
$83–7	L2 Gain	0	Set PLL #2 Phase/Frequency detector gain high.
$83–6	L1 Gain	1	Set PLL #1 Phase Detector gain high.
$84–7	H Switch	0	Set Horizontal Phase Detector filter switch open.
$84–6	525/625	–	0 = 625 lines (PAL), 1 = 525 lines (NTSC)
$85–7	$F_{osc} \div 2$	0	Select direct VCO output from PLL #2.
$85–6	C_{Sync}	0	16 Fh output selected at Pin 13.
$86–7	V_{in} Sync	1	Composite Video inputs (Pin 1 or 3) Sync Source selected.
$86–6	H EN	0	Enabled Horizontal Timebase.
$87–7	Y2 Sync	0	Y2 sync source not selected.
$88–7	V2/V1	1	Select Video 1 input (Pin 1).
$88–6	RGB Sync	0	RGB inputs Sync Source not selected.

Table 2. DAC Test Settings

DAC	Value	Function	DAC	Value	Function
$78	32	R–Y/B–Y Gain	$82	32	Red Contrast Trim
$79	32	Sub Carrier Phase	$83	32	Blue Brightness Trim
$7D	00	Blue Output DC Bias	$84	32	Main Brightness
$7E	00	Red Output DC Bias	$85	32	Red Brightness Trim
$7F	63	Pixel Clock VCO Gain	$86	32	Saturation (Color Diff.)

PIN FUNCTION DESCRIPTION

FB QFP Pin	FN PLCC Pin	Representative Circuitry (Pin numbers refer to PLCC package)	Description (Pin numbers refer to PLCC package)
39, 41	1, 3		**Video Input 1 & 2** – Video 1 (Pin 1) and Video 2 (Pin 3) are composite video inputs. Either can be NTSC or PAL. Input impedance is high, termination must be external. Also used for the luma and chroma components of an S–VHS signal. Selection of these inputs is done by software. External components protect against ESD and noise.
40	2		**ACC Filter** – A 0.1 µF capacitor at this pin filters the feedback loop of the chroma automatic gain control amplifier. Input chroma burst amplitude can be between 30 and 600 mVpp.
42	4		**Vertical Sync Output** – An open collector output requiring an external pull–up. Output is an active low pulse, 500 µs wide, occurring each field. Timing of this pulse depends on Bit $78–7.
43	5		**SCL** – Clock for the I^2C bus interface. See Appendix C for specifications. Maximum frequency is 100 kHz.
44	6		**SDL** – Bidirectional data line for the I^2C bus interface. As an output, it is an open collector. (Write Address $8A, Read Address $8B)
1	7		**Field ID** – TTL level output indicating Field 1 or Field 2. Polarity depends on state of Bit $78–7 (Vertical Sync Delay). See Table 11 and Figure 33 and 34.
2	8	(Same as Pin 7)	**Burst Gate** – TTL level output used for external clamps, as well as internally. Pulse is active high, ≈ 3.5 µs wide, with the rising edge ≈ 3.0 µs after center of selected incoming sync pulse.
3	9		**Reference Current Input** – Current supplied to this pin, typically 32 µA from 5.0 V through a 110 kΩ resistor, is the reference current for the calibration circuit. Noise filtering should be done at the pin. Voltage at this pin is typically 1.2 V.
4	10	(See power distribution diagram at the end of this section.)	**Quiet Ground** – Ground for the horizontal PLL filter (PLL #1) at Pin 11.

PIN FUNCTION DESCRIPTION (continued)

FB QFP	FN PLCC	Representative Circuitry (Pin numbers refer to PLCC package)	Description (Pin numbers refer to PLCC package)
Pin			
5	11		**H Filter** – Components at this pin filter the output of the phase detector of PLL #1. This PLL becomes phase–locked to the selected incoming horizontal sync. External component values are valid for NTSC and PAL systems.
6	12		**H Filter Switch** – An internal switch–to–ground which permits altering the filtering action of the components at Pin 11.
7	13	(Same as Pin 7)	**16 Fh/C$_{Sync}$** – A TTL level output from PLL #1. This pin provides either a square wave equal to Fh x 16 (≈ 250 kHz), or composite sync, depending on the setting of Bit $85–6.
8	14	(Same as Pin 7)	**Fh Reference** – A TTL square wave output which is phase–locked to the selected incoming horizontal sync. The rising edge occurs ≈ 1.3 µs after sync center.
9	15		**15 kHz Return** – This TTL input receives the output of an external frequency divider which is part of PLL #2 (Pixel Clock PLL). This signal will be phase and frequency–locked to the Fh signal at Pin 14. If PLL #2 is not used, this pin should be connected to a 5.0 V supply.
10	16		**PLL #2 Filter** – Components at this pin filter the output of the phase detector of PLL 2. This PLL becomes phase–locked to the Fh signal at Pin 14. Recommended values for filter components are shown. External components should be connected to ground at Pin 17. If PLL #2 is not used, this pin should be grounded.
11	17	(See power distribution diagram at the end of this section.)	**Gnd3** – Ground for the high frequency PLL #2. Signals at Pins 15 to 19 should be referenced to this ground.
12	18		**Pixel Clock Outpu**t – Sampling clock output (TTL) for external A/D converters, and for the external frequency divider. Frequency range at this pin is 6.0 to 40 MHz.

PIN FUNCTION DESCRIPTION (continued)

FB	FN	Representative Circuitry (Pin numbers refer to PLCC package)	Description (Pin numbers refer to PLCC package)
QFP	PLCC		
Pin			
13	19	(See power distribution diagram at the end of this section.)	**V_{CC3}** – A 5.0 V supply (±5%), for the high frequency PLL #2. Decoupling must be provided from this pin to Pin 17. Ripple on this pin will affect pixel clock jitter.
14	20		**R/V Output** – Red (in RGB mode), or R–Y (in YUV mode), output from the color difference stage. A pull–up (390 Ω) to 5.0 V is required. Blank level is ≈ 1.4 Vdc. Maximum amplitude is ≈ 3.0 Vpp, black–to–white.
15	21	(Same as Pin 20)	**G/Y Output** – Green (in RGB mode), or Y (in YUV mode), output from the color difference stage (same as Pin 20).
16	22	(Same as Pin 20)	**B/U Output** – Blue (in RGB mode), or B–Y (in YUV mode), output from the color difference stage (same as Pin 20).
17	23	(See power distribution diagram at the end of this section.)	**V_{CC2}** – A 5.0 V supply (±5%), for the color difference stage. Decoupling must be provided from this pin to Pin 24.
18	24	(See power distribution diagram at the end of this section.)	**Gnd2** – Ground for the color difference stage. Signals at Pins 20 to 31 should be referenced to this pin.
19	25		**FC** – Fast Commutate switch. Taking this pin high (TTL level) connects the RGB inputs (Pins 26 to 28) to the RGB outputs (Pins 20 to 22), permitting an overlay function. The switch can be disabled in software (Bit $80–7).
20, 21, 22	26, 27, 28		**Blue (26), Green (27), Red (28) Inputs** – Inputs to the color difference stage. Designed to accept standard analog video levels, these input pins have a clamp and sync separator. They are selected with Pin 25 or in software (Bit $80–7).
23	29		**Y2 Input** – Luma #2/Composite sync input. This luma input to the color difference stage is used in conjunction with auxiliary color difference inputs, and/or as a sync input. Clamp and sync separator are provided.
24, 25	30, 31		**B–Y (30), R–Y (31) Inputs** – Inputs to the color difference stage. Designed for standard color difference levels, these inputs can be capacitor coupled from the color difference outputs, from a delay line, or an auxiliary signal source. Input clamp is provided.
26	32		**Y1 Clamp** – A 0.47 µF capacitor at this pin provides clamping for the Luma #1 output.

PIN FUNCTION DESCRIPTION (continued)

FB QFP Pin	FN PLCC Pin	Representative Circuitry (Pin numbers refer to PLCC package)	Description (Pin numbers refer to PLCC package)
27	33		**Y1 Output** – Luma #1 output. This output from the PAL/NTSC/S–VHS decoder is the luma component of the decoded composite video at Pin 1 or 3. It is internally directed to the color difference stage.
28	34		**System Select** – A multi–level dc output which indicates the color decoding system to which the PAL/NTSC detector is set by the software. This output is used by the MC44140 chroma delay line.
29	35		**Sandcastle Pulse** – A multi–level timing pulse output used by the MC44140 chroma delay line. This pulse encompasses the horizontal sync and burst time.
30, 32	36, 38	 R = 400 Ω at Pin 38 R = 300 Ω at Pin 36	**Xtal 2 (36), Xtal 1 (38)** – Designed for connection of 4x subcarrier color crystals. Selection is done in software. The selected frequency is used by the PAL/NTSC detector; system identifier; all notches and traps; delay lines; and the horizontal calibration circuit. The crystal frequency should be: 14.3 MHz at Pin 36 for NTSC, 17.7 MHz at Pin 38 for PAL. (See Table 17 for crystal specifications)
31	37		**No Connect** – This pin is to be left open.
33	39	(See power distribution diagram at the end of this section.)	**Ground 1** – Ground for all sections except PLL #2 and the color difference stage.
34	40	(See power distribution diagram at the end of this section.)	**V_{CC1}** – A 5.0 V (±5%), supply to all sections except PLL #2 and the color difference stage.
35	41		**B–Y Output** – Output from the PAL/NTSC decoder, it is typically capacitor–coupled to a delay line or to the B–Y input. This pin is clamped, and filtered at the color subcarrier frequency, 2x, and 8x that frequency.
36	42	(Same as Pin 41)	**R–Y Output** – Output from the PAL/NTSC decoder.
37	43		**Ident Filter** – A 0.1 µF capacitor filters the system identification circuit in the NTSC/PAL decoder.

PIN FUNCTION DESCRIPTION (continued)

FB	FN	Representative Circuitry (Pin numbers refer to PLCC package)	Description (Pin numbers refer to PLCC package)
QFP	PLCC		
Pin			
38	44		**Crystal PLL Filter** – Components at this pin filter the PLL for the crystal chroma oscillator circuit.
4, 11, 13, 17, 18, 33, 34	10, 17, 19, 23, 24, 39, 40	 (Dashed lines indicate substrate connection.)	**Power Distribution** – The three V_{CC} pins must be externally connected to 5.0 V (±5%) supply. The four grounds must be externally tied together, preferably to a ground plane.

FUNCTIONAL DESCRIPTION

Introduction

The MC44011, a member of the MC44000 Chroma 4 family, is a composite video decoder which has been tailored for applications involving multimedia, picture–in–picture, and frame storage (although not limited to those applications). The first stage of the MC44011 provides color difference signals (R–Y, B–Y, and Y) from one of two (selectable) composite video inputs, which are designed to receive PAL, NTSC, and S–VHS (Y,C) signals. The second stage provides either RGB or YUV outputs from the first stage's signals, or from a separate (internally selectable) set of RGB inputs, permitting an overlay function to be performed. Adjustments can be made to saturation; hue; brightness; contrast; brightness balance; contrast balance; U and V bias; subcarrier phase; and color difference gain ratio.

The above mentioned video decoding sections provide the necessary luma/delay function, as well as all necessary filters for sound traps, luma/chroma separation, luma peaking, and subcarrier rejection. External tank circuits and luma delay lines are not needed. For PAL applications, the MC44140 chroma delay line provides the necessary line–by–line corrections to the color difference signals required by that system.

The MC44011 provides a pixel clock to set the sampling rate of external A/D converters. This pixel clock, and other horizontal frequency related output signals, are phase–locked to the incoming sync. The VCO's gain is adjustable for optimum performance. The MC44011 also provides vertical sync and field identification (Field 1, Field 2) outputs.

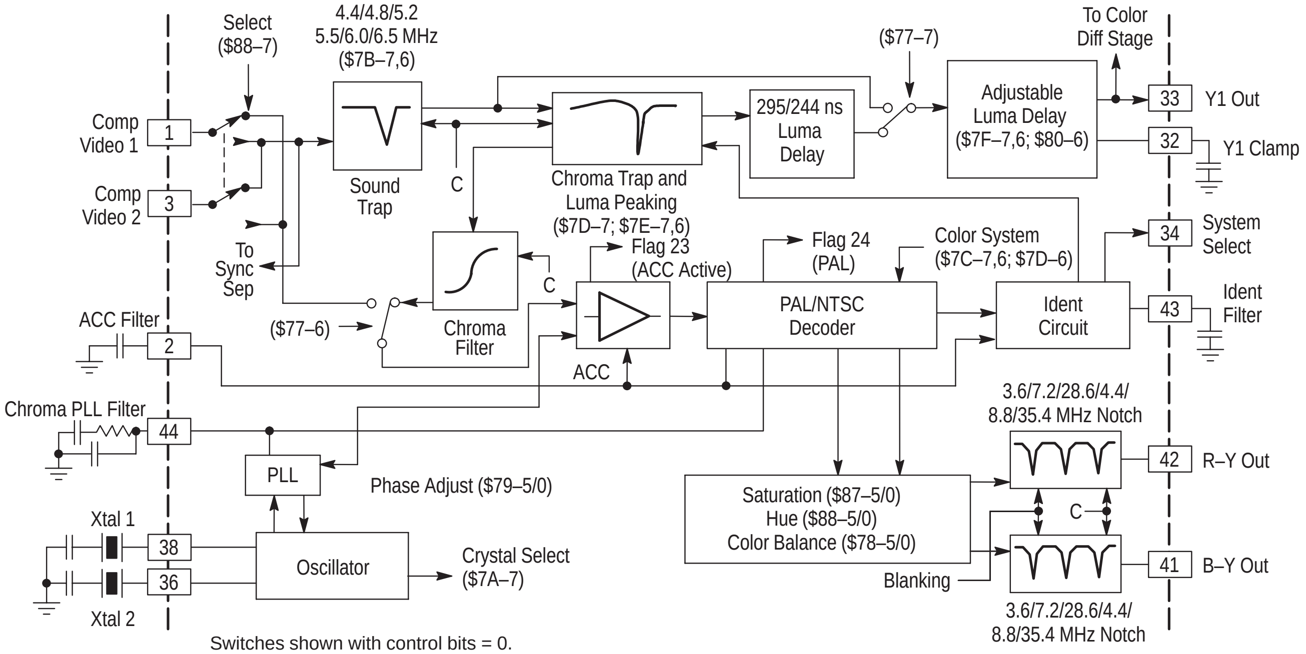
Selection of the various inputs, outputs, and functions, as well as the adjustments, is done by means of a two–wire I^{2}C interface. The basic procedure requires the microprocessor system to read the internal flags of the MC44011, and then set the internal registers appropriately. This I^{2}C interface eliminates the need for manual controls (potentiometers) and external switches. All of the external components for the MC44011, except for the two crystals, are standard value resistors and capacitors, and can be non–precision.

(The DACs mentioned in the following description are 6–bits wide. The settings mentioned for them are given in decimal values of 00 to 63. These are not hex values.)

PAL/NTSC/S–VHS Decoder

A block diagram of this decoder section is shown in Figure 35. This section's function is to take the incoming composite video (at Pins 1 or 3), separate it into luma and chroma information, determine if the signal is PAL or NTSC (for the flags), and then provide color difference and luma signals at the outputs. If the input is S–VHS, the luma/chroma separation is bypassed, but the other functions are still in effect.

Figure 35. PAL/NTSC/S–VHS Decoder Block Diagram



Switches shown with control bits = 0.

Inputs

The inputs at Pins 1 and 3 are high impedance inputs designed to accept standard 1.0 Vpp positive video signals (with negative going sync). The inputs are to be capacitor–coupled so as not to upset the internal dc bias. When normal composite video is applied, the desired input is selected by Bit $88–7. Bits $77–6 and $77–7 must be set to 0 so that their switches are as shown in Figure 35. The selected signal passes through the sound trap, and is then separated by the chroma trap and the chroma (high pass) filter.

When S–VHS signals (Y,C) are applied to the two inputs, Bit $88–7 is used to direct the luma information to the sound trap, and the chroma information to the ACC circuit (Bit $77–6 must be set to a Logic 1). Bit $77–7 is normally set to a Logic 1 in this mode to bypass the first luma delay line and the chroma trap, but it can be left 0 if the additional delay is desired.

Sound Trap

The sound trap will filter out any residual sound subcarrier at the frequency selected by control bits T1 and T2 according to Table 3. The accuracy of the notch frequency is directly related to the selected crystal frequency.

Table 3. Sound Trap Frequency

Crystal Frequency	T1 ($7B–7)	T1 ($7B–6)	Notch Frequency
17.73 MHZ	0	0	6.5 MHz
	0	1	5.5 + 5.75 MHz
	1	0	6.0 MHz
	1	1	5.5 MHz
14.32 MHz	0	0	5.25 MHz
	0	1	4.44 + 4.64 MHz
	1	0	4.84 MHz
	1	1	4.44 MHz

Code 01 (for T1, T2) is used to widen the band rejection where stereo is in use. Typical rejection is 30 dB.

ACC and PAL/NTSC Decoder

The chroma filter bandpass characteristics (3.58 or 4.43 MHz) is determined by the selected crystal. The output of the chroma filter is sent to the ACC circuit which detects the burst signal, and provides automatic gain control once the crystal oscillator has achieved phase lock–up to the burst. The dc voltage at Pin 2 is ≈ 1.5 to 2.0 V. This will occur if the burst amplitude exceeds 30 mVpp, and if the correct crystal is selected (Bit $7A–7). A 17.734472 MHz crystal is required for PAL, and a 14.31818 MHz crystal is required for NTSC. When Flag 23 is high, it indicates that the crystal's PLL has locked up, and the ACC circuit is active, providing automatic gain control. A small amount of phase adjustment (≈ ±5°) of the crystal PLL, for color correction, can be made with control DAC $79–5/0. Pin 2 is the filter for the ACC loop, and Pin 44 is the filter for the crystal oscillator PLL.

The PAL/NTSC decoder then determines if the signal is PAL or NTSC by looking for the alternating phase characteristic of the PAL burst. When Flag 24 is high, PAL has been detected. Bits SSA, SSB, SSC, and SSD (Table 4) must then be sent to the decoder to set the appropriate decoding method.

Table 4. Color System Select

SSA ($7C–6)	SSB ($7D–6)	SSC ($7C–7)	SSD ($7A–6)	Color System
0	0	0	0	Not Used
0	1	0	0	PAL
1	0	0	0	NTSC
1	1	0	0	Color Kill
X	X	1	0	External

Upon receiving the SSA to SSD bits, the decoder provides the correct color difference signals, and with the Identification circuit, provides the correct level at the System Select output (Pin 34). This output is used by the MC44140 delay line.

The color kill setting (SSA = SSB = 1) should be used when the ACC flag is 0, when the color system cannot be properly determined, or when it is desired to have a black–and–white output (the ACC circuit and flag will still function if the input signal has a burst signal). The "External" setting (SSC = 1) is used when an external (alternate) source of color difference signals are applied to the MC44140 delay line. (See Miscellaneous Applications Information for more details.)

Color Difference Controls and Outputs

The color difference signals (R–Y, B–Y) from the PAL/NTSC decoder are directed to the saturation, hue and color balance controls, and then through a series of notch filters before being output at Pins 41 and 42. Blanking and clamping are applied to these outputs.

The saturation control DAC($87–5/0) varies the amplitude of the two signals from 0 Vpp (DAC setting = 00), to a maximum of ≈ 1.8 Vpp (at a DAC setting of 63). The maximum amplitude (without clipping) is ≈ 1.5 Vpp, but a nominal setting is ≈ 1.3 Vpp at a DAC setting of 15.

The hue control ($88–5/0) varies the relative amplitude of the two signals to provide a hue adjustment. The nominal setting for this DAC is 32.

The color balance control ($78–5/0) provides a fine adjustment of the relative amplitude of the two outputs. This provides for a more accurate color setting, particularly when NTSC signals are decoded. The nominal setting for this DAC is 32, and should be adjusted before the hue control is adjusted.

The notch filters provide filtering at the color burst frequency, and at 2x and 8x that frequency. Additionally, blanking and clamping (derived from the horizontal PLL) are applied to the signals at this stage. The nominal output dc level is ≈ 2.0 to 2.5 Vdc, and the load applied to these outputs should be >10 kΩ. Sync is not present on these outputs.

Luma Peaking, Delay Line, and Y1 Output

When composite video is applied, the luma information extracted in the chroma trap is then applied to a stage which allows peaking at ≈ 3.0 MHz with the 17.7 MHz crystal (≈ 2.2 MHz with the 14.3 MHz crystal). The amount of peaking at Y1 is with respect to the gain at the minimum peaking value (P1, P2, P3 = 111), and is adjustable with Bits $7D–7, and $7E–7,6 according to Table 5.

The luma delay lines allow for adjustment of that delay so as to correspond to the chroma delay through this section. Table 6 indicates the amount of delay using the D1–D3 bits ($7F–7,6, and $80–6). The delay indicated is the total delay from Pin 1 or 3 to the Y1 output at Pin 33. The amount of delay depends on whether Composite Video is applied, or YC signals (S–VHS) are applied.

The output impedance at Y1 is ≈ 300 Ω, and the black level clamp is at ≈ 1.1 V. Sync is present on this output. Y1 is also internally routed to the color difference stage.

Table 5. Luma Peaking

P1 ($7D–7)	P2 ($7E–6)	P3 ($7E–7)	Y1 Peaking
0	0	0	9.5 dB
0	0	1	8.5
1	0	0	7.7
1	0	1	6.5
0	1	0	5.3
0	1	1	3.8

Color Difference Stage and RGB/YUV Outputs

A block diagram of this section is shown in Figure 36. This section’s function is to take the color difference input signals (Pins 30, 31), or the RGB inputs (Pins 26 to 28), and output the information at Pins 20 to 22 as either RGB or YUV.

The inputs (on the left side of Figure 36) are analog RGB, or color difference signals (R–Y and B–Y) with Y1 or Y2 as the luma component. Pin 25 (Fast Commutate) is a logic level input, used in conjunction with $\overline{\text{RGB EN}}$ (Bit $80–7), to select the RGB inputs or the color difference inputs. The outputs (Pins 20 to 22) are either RGB or YUV, selected with Bit $82–7. The bit numbers adjacent to the various switches and gates indicate the bits used to control those functions. Table 7 indicates the modes of operation.

Table 7. Color Difference Input/Output Selection

FC	$\overline{\text{RGB EN}}$ $80–7	YX EN $82–6	YUV EN $82–7	Function
1	0	0	0	RGB inputs, RGB outputs, no saturation control
1	0	1	0	RGB inputs, RGB outputs, with saturation control
1	0	1	1	RGB inputs, YUV outputs, with saturation control
1	0	0	1	Not usable
FC Low and/or RGB EN Hi		X	0	R–Y, B–Y inputs, RGB outputs. Y1 or Y2 must be selected
FC Low and/or RGB EN Hi		X	1	R–Y, B–Y inputs, YUV outputs. Y1 or Y2 must be selected

In addition to Table 7, the following guidelines apply:

a. To select the RGB inputs, both FC must be high and RGB EN must be low. Therefore, the RGB inputs can be selected either by the I^2C bus by leaving FC permanently high, or by the FC input by leaving Bit $80–7 permanently low. For overlay functions, where high speed, well controlled switching is necessary, the FC pin must be the controlling input.

b. When the R–Y, B–Y inputs are selected, either Y1 or Y2 must be selected, and the other must be deselected. The YX input is automatically disabled in this mode.

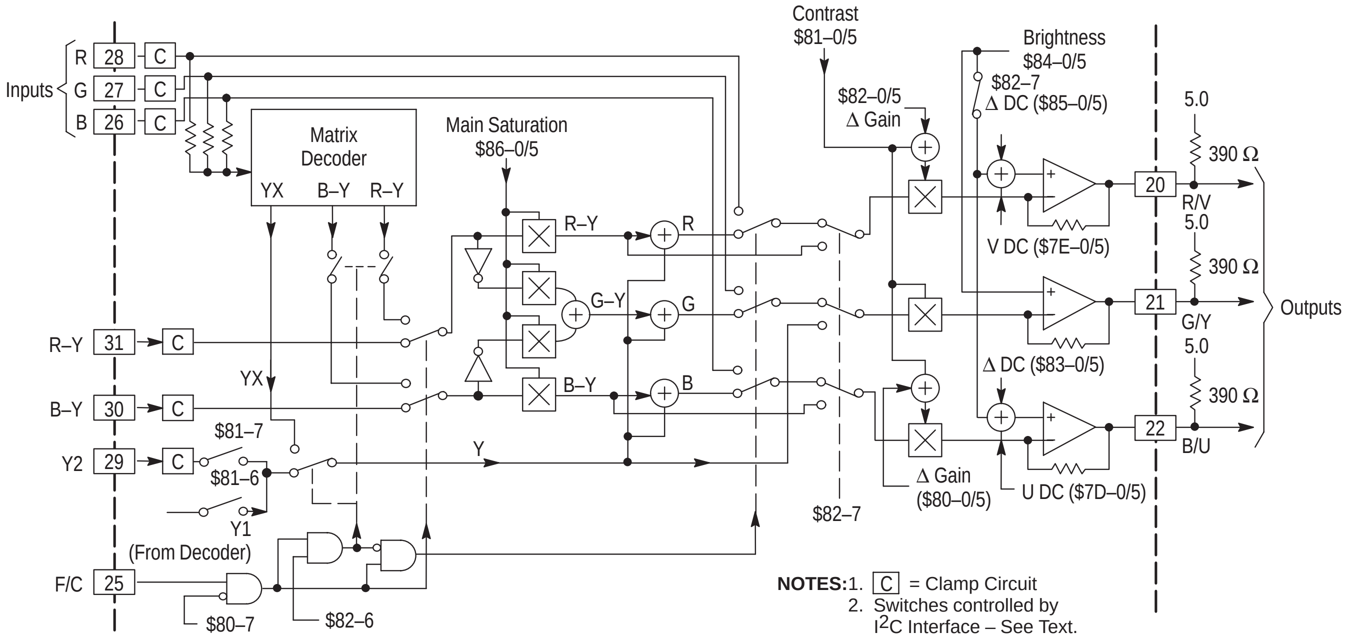
c. In applications where the color difference inputs are obtained from the NTSC/PAL decoder (from a composite video signal), Y1 is used. The Y2 input is normally used where alternately sourced color difference signals are applied, either through the MC44140 delay line, or through other external switching to Pins 30 and 31.

In Figure 36, the bit numbers followed by "–0/5" indicate DAC operated controls (contrast, brightness, etc.), which are controlled by the I^2C bus. The DACs have 6–bit resolution, allowing 64 adjustment steps. Table 8 provides guidelines on the DAC operation.

Table 8. DAC Operation – Color Difference Section

Function	Bits	RGB Outputs ($82–7 = 0)	YUV Outputs ($82–7 = 1)
Brightness	$84–0/5	Affects dc black and maximum levels of the three outputs, but not the clamp level, nor the amplitude.	Affects dc black and white levels of the Y output only, but not the clamp level, nor the amplitude.
Δ DC – Red Δ DC – Blue	$85–0/5 $83–0/5	Fine tune the Red and Blue brightness levels.	Allows a small amount of color tint control (not to be confused with hue).
Contrast	$81–0/5	Provides gain adjustment (black–to–white) of the three outputs.	Provides gain adjustment of the three outputs.
Δ Gain – Red Δ Gain – Blue	$82–0/5 $80–0/5	Fine tune the Red and Blue contrast levels.	Fine tune of the U and V gain levels.
V DC U DC	$7E–0/5 $7D–0/5	Must be set to 00.	Should nominally be set to 32. This sets the dc level of the U and V outputs at ≈ mid–scale.
Main Saturation	$86–0/5	Affects color saturation, except when the RGB inputs bypass this section (YX EN = 0).	Affects color saturation levels of the UV outputs. Does not affect the Y output.

Figure 36. Color Difference Stage and Outputs



NOTES: 1. C = Clamp Circuit
2. Switches controlled by I^2C Interface – See Text.

The RGB and Y2 inputs are designed to accept standard 1.0 Vpp analog video signals. They are not designed for TTL level signals. The color difference inputs are designed to accept signals ranging up to 1.8 Vpp. All signals are to be capacitor–coupled as clamping is provided internally. Input impedance at these six pins is high.

For applications involving externally supplied color difference signals, sync can be supplied on the luma input (Y2), or it can be supplied separately at the RGB inputs. Where the color difference signals are obtained from the NTSC/PAL decoder, sync is provided to this section on the internal Y1 signal. See Sync Separator section for more details on injecting sync into the MC44011.

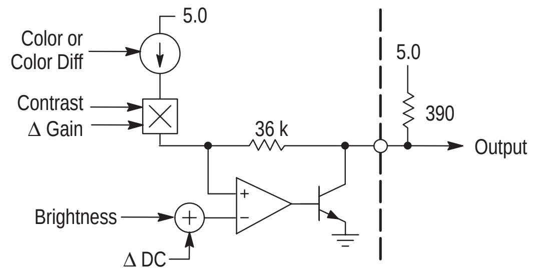
Sync is present on all three outputs in the RGB mode, and on the Y output only (Pin 21) in the YUV mode.

The Fast Commutate input (FC, Pin 25) is a logic level input with a threshold at ≈ 0.5 V. Input impedance is ≈ 67 kΩ, and the graph of Figure 24 shows the input current requirements. Propagation delay from the FC pin to the RGB/YUV outputs is ≈ 50 ns when enabling the RGB inputs, and ≈ 90 ns when disabling the inputs. (See Figure 29 Fast Commutate Timing diagram.) If Pin 25 is open, that is equivalent to a Logic 1, although good design practices dictate that inputs should never be left open. The voltage on this pin should not be allowed to go more than 0.5 V above V_{CC2} or below ground.

The three outputs (Pins 20 to 22) are open–collector, requiring an external pull–up. A representative schematic is shown in Figure 37.

The output amplitude can be varied from 100 mVpp to 3.0 Vpp by use of the contrast and saturation controls. Any output load to ground should be kept larger than 1.0 kΩ. In the RGB mode, DACs $7D and $7E should be set to 00, which results in clamping levels of ≈ 1.4 Vdc. In the YUV mode, DACs $7D and $7E should be set to 00, which results in clamping levels of ≈ 1.4 Vdc. In the YUV mode, the DACs should be set to 32 to bias the U and V outputs to ≈ 2.3 V. The Y output clamp will remain at ≈ 1.4 V in the YUV mode.

Figure 37. Output Stage



Horizontal PLL (PLL1)

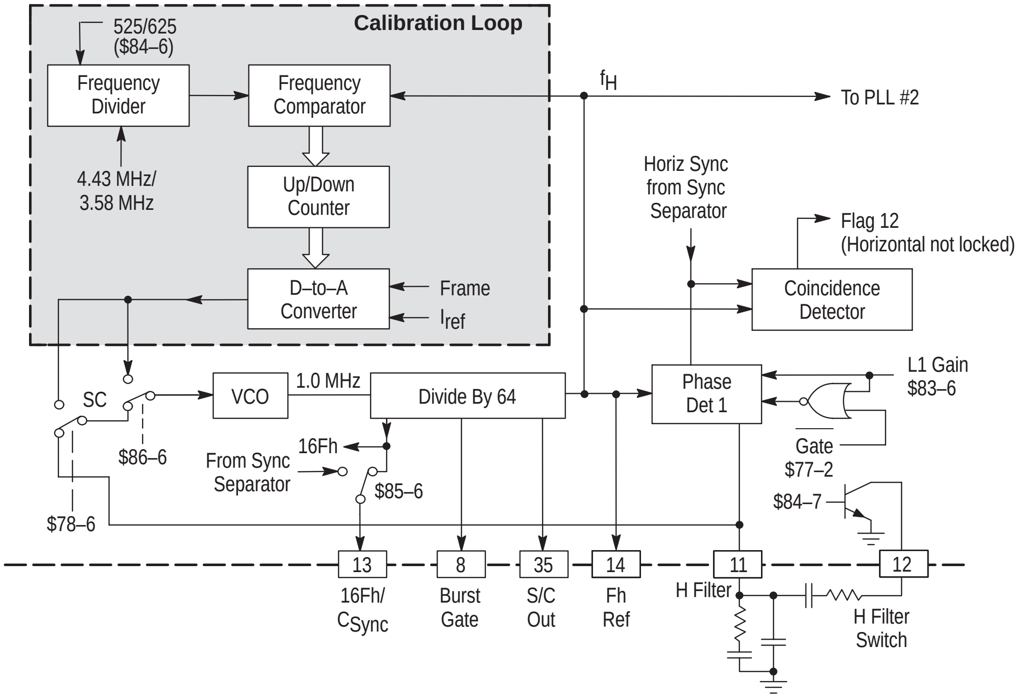
PLL1 (shown in Figure 38) provides several outputs which are phase–locked to the incoming horizontal sync. In normal operation, the two switches at the left side of Figure 38 are as shown, and (usually) the transistor at Pin 12 is off.

The phase detector compares the incoming sync (from the sync separator) to the frequency from the ÷ 64 block. The phase detector's output, filtered at Pin 11, controls the VCO to set the correct frequency (≈ 1.0 MHz) so that the output of the ÷ 64 is equal to the incoming horizontal frequency.

The line–locked outputs are:

1) **Fh Ref** (Pin 14) – A square wave, TTL levels, at the horizontal frequency, and phase–locked to the sync source according to the timing diagram of Figures 25 and 27.
2) **Burst Gate** (Pin 8) – This is a positive going pulse, TTL levels, coincident with the burst signal. See the timing diagram of Figures 25 and 27.

Figure 38. Horizontal PLL (PLL1)



3) **Sandcastle Output** (Pin 35) – This is a multilevel output, at the horizontal frequency, used by the MC44140 delay line. See the timing diagram of Figures 25 and 27.

4) **16Fh/C$_{Sync}$** (Pin 13) – This is a dual purpose output, TTL levels, user selectable. When Bit $85–6 is set to 0, Pin 13 is a square wave at 16x the horizontal frequency (250 kHz for PAL, ≈ 252 kHz for NTSC). When Bit $85–6 is set to 1, Pin 13 is negative composite sync, derived from the internal sync separator. See the timing diagram of Figures 25 and 27.

The first three outputs mentioned above, and Pin 13 when set to 16Fh, are consistent, and do not change duty cycle or wave shape during the vertical sync interval. These four outputs will also be present regardless of the presence of a video signal at the selected input.

When Pin 13 is set to C$_{Sync}$ output, it follows the incoming composite sync format. If there is no video signal present at the selected input, this output will be a steady logic high.

Loading on these pins should not be less than 2.0 kΩ to either ground or 5.0 V.

Pin 11 is the filter for the PLL, and requires the components shown in Figure 38, and with the values shown in the application circuit of Figure 42. Pin 12 is a switch which allows the filtering characteristics at Pin 11 to be changed. Switching in the additional components (set $84–7 = 1) increases the filter time constant, permitting better performance in the presence of noisy signals.

The gain of the phase detector may be set high or low, depending on the jitter content of the incoming horizontal frequency, by using Bit $83–6. Broadcast signals usually have a very stable horizontal frequency, in which case the low gain setting ($83–6 = 0) should be used. When the video source is, for example, a VCR, the high gain setting may be preferable to minimize instability artifacts which may show up on the screen.

The gating function ($77–2) provides additional control where the stability of the incoming horizontal frequency is in question. With this bit set to 0, gating is in effect, causing the phase detector to not respond to the incoming sync pulses during the vertical interval. This reduces disturbances in this PLL due to the half–line pulses and their change in polarity. The gating may be disabled by setting this bit to 1 where the timing of the incoming sync is known to be stable. The gating cannot be enabled if the phase detector gain is set high ($83–6 = 1).

Calibration Loop

The calibration loop (upper left portion of Figure 38) maintains a near correct frequency of this PLL in the absence of incoming sync signals. This feature minimizes re–adjustment and lock time when sync signals are re–applied. The calibration loop is similar to the PLL function, receiving one frequency from the crystal (either 4.43 MHz or 3.58 MHz) divided down to a frequency similar to the standard horizontal frequency. Bit $84–6 is used to set the frequency divider to the correct ratio, depending on which crystal is selected (see Table 9). The output of the frequency comparator operates an up/down counter, which in turn sets the D–to–A converter to drive the VCO through switch Sc. The resulting frequency at the output of the divide–by–64 block is then fed to the frequency comparator to complete the loop.

When a sync signal is not present at Phase Detector #1, and at the Coincidence Detector, as indicated by the coincidence detector’s output (Flag 12), Bit $78–6 should be set to 0. This will cause the switch (Sc) to transfer to the D–to–A converter for two lines (lines 4, 5) in each vertical field, and will maintain the PLL1 at a frequency near the standard horizontal frequency (between 14 to 16 kHz). When lock to an incoming sync is established, Bit $78–6 may be set to 1, disabling the periodic recalibration function, or it may be left set to 0.

If a more accurate horizontal frequency is desired in the absence of an input signal, Bit $86–6. can be set to 1 (and Bit $84–6 set according to Table 9). This holds the horizontal frequency to ≈ 15.7 kHz. In this mode, Flag 12 will stay 0, as the PLL will not be able to lock–up to a newly applied external signal. To reset the system, set $86–6 to 0, write $00 to register $00, and then check Flag 12 to determine when the loop locks to an incoming signal.

Table 9. Calibration Loop

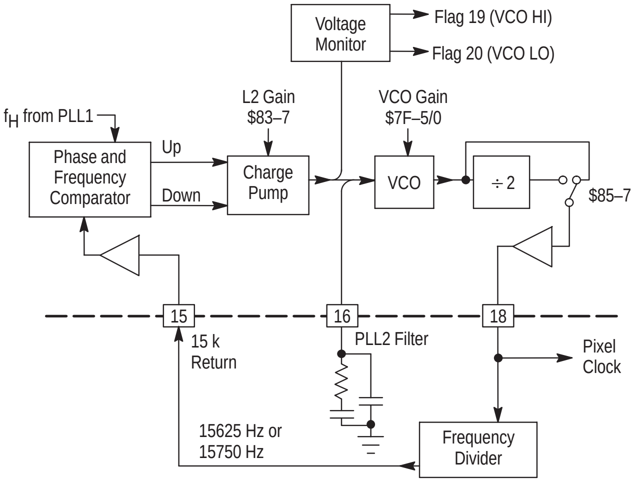
Crystal	Set Bit $84–6 to
14.3 MHz	1
17.7 MHz	0

On initial power up, Bit $86–6 (PLL1 EN) is automatically set to 1, engaging the calibration loop continuously. This condition will remain until this bit is set to 0, and $00 is written to register $00, as part of the initialization routine.

Pixel Clock PLL (PLL2)

The second PLL, depicted in Figure 39, generates a high frequency clock which is phase–locked to the horizontal frequency.

Figure 39. Pixel Clock PLL (PLL2)



The phase and frequency comparator receive inputs from PLL1 (f_H, the horizontal frequency), and the frequency returned from the external divider. Any difference between these two signals causes the Up or Down output to change the charge pump's timing. The charge pump output is composed of two equal current sources which alternately source and sink current to the filter at Pin 16. The voltage at Pin 16 (which is the input to the VCO) is therefore determined by the relative timing of those two current sources, and the filter characteristics. A coarse control of the loop gain is set with Bit $83–7. Low gain is obtained by setting this bit to a 1, which sets the charge pump's output current sources to ≈ ±20 µA. Setting this bit to 0 sets the current sources to ≈ ±50 µA, or high gain.

Depending on the output frequency desired, and whether or not a 50–50 square wave is needed at the pixel clock, the ÷ 2 may be engaged (Bit $85–7). Generally, the ÷ 2 should not be engaged for high frequencies, and should be engaged for low frequencies, so as to keep the VCO's input voltage in a comfortable range (between 1.7 and 3.3 V). If the input voltage is outside this range, Flag 19 or 20 will switch high, indicating the need to fine tune the VCO's gain (control DAC $7F). The usable adjustment range for this DAC is 00 to ≈ 50. Settings of 51 to 62 will generally produce non–square wave outputs, and can be unstable. A setting of 63 will shut off the VCO, which should be done if the pixel clock is not used. When not used, Pin 18 will be at a constant low level.

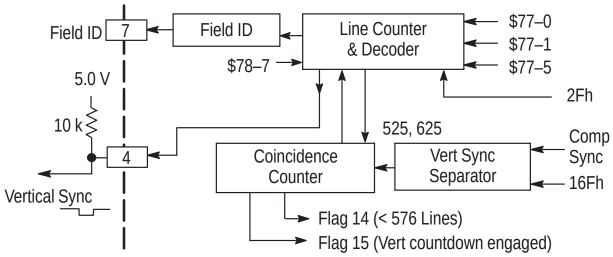
The pixel clock frequency is equal to the horizontal frequency (f_H) x the frequency divider ratio. The frequency divider can be made up of programmable counters (e.g., MC74F161A Applications Information), or it can be integrated into another device (e.g., an ASIC). The returned signal to Pin 15 must be TTL/CMOS logic levels, and must have a low time of > 200 ns. The phase comparator will phase–lock the falling edge of the returned signal with the rising edge of the f_H signal at Pin 14 (see Figure 32).

Vertical Decoder

The vertical decoder section, depicted in Figure 40, provides a vertical sync pulse and a field identification signal, as well as flags which indicate if vertical lockup has occurred, and if the number of horizontal lines per frame is greater or less than 576.

Inputs to this section consists of the composite sync from the sync separator, and horizontal related signals from the horizontal PLL (PLL1).

Figure 40. Vertical Decoder



The sync output (Pin 4) is an active low signal which starts after the horizontal half–line sync pulses change polarity (see Figures 33 and 34). The pulse width is nominally 500 µs for both PAL and NTSC signals. The position of this sync pulse's leading edge can be altered slightly with Bit $78–7, but this does not change the pulse width. Since the pulse width is generated digitally by counters, it will not vary with temperature, supply voltage, or manufacturing distribution. The sync output is an open–collector NPN output, requiring an external pull–up resistor. Minimum value for the pull–up is 1.0 kΩ, with 10 kΩ recommended for most applications.

Flag 14 (< 576 lines) is derived from the counter which compares the number of horizontal lines in each frame with a preset value of 576. This flag can be used externally to help determine whether PAL or NTSC signals are being provided to the MC44011. Flag 15 (Vertical countdown engaged) indicates that the vertical decoder has locked–up to the incoming composite sync information for eight consecutive fields (CB1, CA1 = 11).

The operation of the vertical decoder is controlled by Bits $77–0 and $77–1, according to Table 10.

Table 10. Vertical Decoder Mode

CB1 ($77–1)	CA1 ($77–0)	Vertical Sync Mode
0	0	Force 625
1	0	Force 525
0	1	Injection Lock
1	1	Auto–Count

The Injection Lock mode has a quicker response time, but less noise immunity, than the Auto–Count mode, and is normally used when attempting to lock–up to a new signal (such as when changing video input selection). Flag 15 will not switch high when in this mode. The Auto–Count mode, having a higher noise immunity, should be set once the horizontal PLL is locked–up (by reading Flag 12), and then Flag 15 should be checked after 8 fields for vertical lock–up.

The modes designated Force 525 and Force 625 can be used for those cases where it is desired to force the vertical sync pulse to occur twice every 525 or 625 lines, regardless of the incoming signal. In either of these modes, the MC44011's vertical section will not lock–up to the vertical sync information contained in the incoming composite video signal. If there is no incoming video signal, the vertical sync will still occur every 525 or 625 lines generated by the horizontal PLL. Flag 14 will indicate the number of lines selected, and Flag 15 will be a steady high.

Bit $77–5 (FSI) is used only in the PAL mode to select the vertical sync output rate. With this bit set to 0, the vertical sync pulses will be synchronized with the composite vertical sync input (every 20 ms). With this bit set to 1, the MC44011 will add a second vertical output sync pulse 10 ms after the one occurring at the vertical interval, giving a vertical sync rate of 100 Hz.

The Field ID output (Pin 7) indicates which field is being processed when interlaced signals are applied, but the polarity depends on Bit $78–7. Table 11 indicates Pin 7 output. When non–interlaced signals are being processed, Pin 7 will be a constant high level when $78–7 is set to 1, and will be a constant low level when $78–7 is set to a 0. Loading on Pin 7 should not be less than 2.0 kΩ to either ground or 5.0 V. Figures 33 and 34 indicate the timing.

Table 11. Field ID Output

36/68 μs ($78–7)	Field	Field ID (Pin 7)
1	1	High
1	2	Low
0	1	Low
0	2	High

Sync Separator

The sync separator block provides composite sync information to the horizontal PLL, and to various other blocks within the MC44011 from one of several sources. It also provides composite sync output at Pin 13 when Bit $85–6 = 1. The sync source is selectable via the I^2C bus according to Table 12.

Table 12. Sync Source

V_{in} Sync ($86–7)	Y2 Sync ($87–7)	RGB Sync ($88–6)	Sync Source
0	0	0	None
0	0	1	RGB (Pins 26–28)
0	1	0	Y2 (Pin 29)
1	X	X	Comp. Video (Pins 1, 3)

Setting Bit $86–7 to a 1 overrides the other bits, thereby deriving the sync from the composite video input (either Pin 1 or 3) selected by Bit $88–7.

When RGB is selected, sync information on Pins 26 to 28 is used. Sync may be applied to all three inputs, or to any one with the other two ac grounded. If RGB signals are applied to these pins, sync may be present on any one or all three.

When Y2 is selected, sync information on Pin 29 is used. The sync amplitude applied to any of the above pins must be greater than 100 mV, and it must be capacitor coupled.

This system allows a certain amount of flexibility in using the MC44011, in that if the sync information is not present as part of the applied video signals, sync may be applied to another input. In other words, the input selected for the sync information need not be the same as the input selected for the video information.

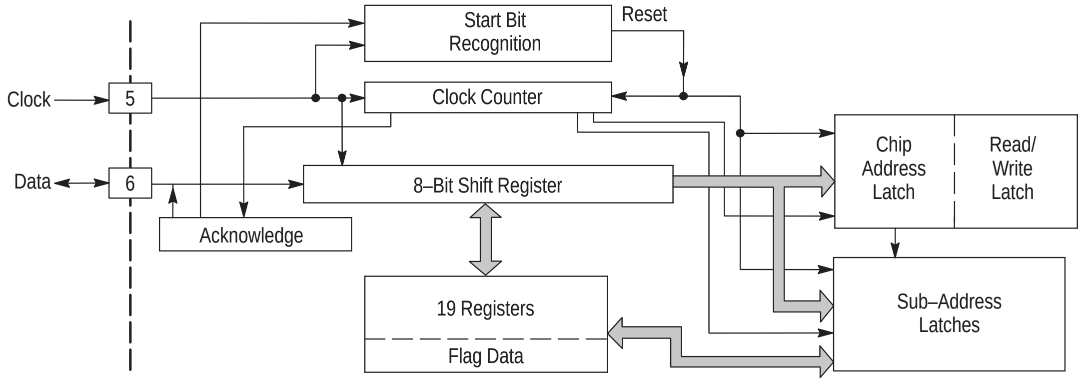
SOFTWARE CONTROL OF THE MC44011

I^2C Interface

Communication to and from the MC44011 follows the I^2C interface arrangement and protocol defined by Philips Corporation. In simple terms, I^2C is a two line, multimaster bidirectional bus for data transfer. See Appendix C for a description of the I^2C requirements and operation. Although an I^2C system can be multimaster, the MC44011 never functions as a master.

The MC44011 has a write address of $8A, and a flag read address of $8B. It requires that an external microprocessor read the internal flags, and then set the appropriate registers. The MC44011 does not do any automatic internal switching when applied video signals are changed. A block diagram of the I^2C interface is shown in Figure 41. Since writing to the MC44011's registers can momentarily create jitter and other undesirable artifacts on the screen, writing should be done only during vertical retrace (before line 20). Reading of flags, however, can be done anytime.

Figure 41. I^2C Bus Interface and Decoder



Write to Control Registers

Writing should be done only during vertical retrace. A write cycle consists of three bytes (with three acknowledge bits):

1) The first byte is always the write address for the MC44011 ($8A).
2) The second byte defines the sub–address register (within the MC44011) to be operated on ($77 through $88, and $00).
3) The third byte is the data for that register.

Communication begins when a start bit (data taken low while clock is high), initiated by the master, is detected, generating an internal reset. The first byte is then entered, and if the address is correct ($8A), an acknowledge is generated by the MC44011, which tells the master to continue the communication. The second byte is then entered, followed by an acknowledge. The third byte is the operative data which is directed to the designated register, followed by a third acknowledge.

Sub–Address Registers

The sub–addresses of the 19 registers are at $77 through $88, and $00. Fourteen of the registers use Bits 0–5 to operate DACs which provide the analog adjustments. Most of the other bits are used to set/reset functions, and to select appropriate inputs/outputs. Table 13 indicates the assignments of the registers.

Table 13. Sub–Address Register Assignments

Sub–Address	7	6	5	4	3	2	1	0
$77	S–VHS Y	S–VHS C	FSI	$\overline{\text{L2 GATE}}$	$\overline{\text{BLCP}}$	$\overline{\text{L1 GATE}}$	CBI	CAI
$78	36/38 μs	Cal Kill	(R–Y)/(B–Y) adjust DAC					
$79	HI	VI	Subcarrier balance DAC					
$7A	Xtal	SSD						
$7B	T1	T2						
$7C	SSC	SSA						
$7D	P1	SSB	Blue bias for YUV operation DAC					
$7E	P3	P2	Red bias for YUV operation DAC					
$7F	D3	D1	Pixel Clock VCO Gain adjust DAC					
$80	$\overline{\text{RGB EN}}$	D2	Blue Contrast trim DAC					
$81	Y2 EN	Y1 EN	Main Contrast DAC					
$82	YUV EN	YX EN	Red Contrast trim DAC					
$83	L2 Gain	L1 Gain	Blue Brightness trim DAC					
$84	H Switch	525/625	Main Brightness DAC					
$85	PClk/2	C Sync	Red Brightness trim DAC					
$86	V_{in} Sync	$\overline{\text{PLL1 En}}$	Main Saturation DAC (Color Difference section)					
$87	Y2 Sync	0	(R–Y)/(B–Y) Saturation balance DAC (Decoder section)					
$88	V2/V1	RGB Sync	Hue DAC					
$00	Set to $00 to start Horizontal Loop if $88–6 = 0							

Table 14 is a brief explanation of the individual control bits. A more detailed explanation of the functions is found in the block diagram description of the text (within the Functional Description section). Table 15 provides an explanation of the DACs. Each DAC is 6 bits wide, allowing 64 adjustment steps. The proper sequence and control of the bits and DACs, to achieve various system functions, is described in the Applications Information section.

Table 14. Control Bit Description

Control Bit	Name	Description
$77–7	S–VHS–Y	Set to 0 for normal Composite Video inputs at V1 and/or V2 (Pins 1, 3). Set to 1 for S–VHS (YC) operation. When 1, the Y–input at the selected video input (V1 or V2, selected by Bit $88–7) bypasses the initial luma delay line, and associated luma/chroma filters and peaking. The signal passes through the second luma delay, adjustable with Bits D1–D3. Luma is output at Pin 33.
$77–6	S–VHS–C	Set to 0 for normal Composite Video inputs at V1 and/or V2 (Pins 1, 3). Set to 1 for S–VHS (YC) operation. When 1, the chroma input at the non–selected video input (V1 or V2 by Bit $88–7) is directed to the ACC loop and PAL/NTSC detector. Color difference signals are then output at Pins 41 and 42.
$77–5	FSI	Set to 0 for a Vertical Sync output rate of 50 Hz. Set to 1 for 100 Hz. Useable in PAL systems only.
$77–4	$\overline{\text{L2 GATE}}$	When set to 0, the pixel clock charge pump (PLL2) operation is inhibited during the Vertical Retrace to minimize momentary instabilities. When set to 1, PLL2 operation is not inhibited.
$77–3	$\overline{\text{BLCP}}$ $\overline{\text{GATE}}$	When 0, Vertical Gating of the black level clamp pulse during the Vertical Retrace occurs to minimize momentary instabilities. The Vertical Gating can be inhibited by setting this bit to 1.
$77–2	$\overline{\text{L1 GATE}}$	When set to 0, the horizontal PLL's phase detector (PLL1) operation is inhibited during the Vertical Retrace to minimize momentary instabilities. When set to 1, the phase detector is not inhibited. If PLL1 gain is high (Bit $83–6 = 1), gating cannot be enabled.
$77–1, 0	CB1, CA1	Sets the Vertical Timebase operating method according to Table 10.
$78–7	36/68 µs	When 0, the time delay from the sync polarity reversal within the Composite Sync to the leading edge of the Vertical Sync output (Pin 4) is 36 µs. When 1, the time delay is 68 µs. (See Figure 33 and 34).
$78–6	CalKill	When 0, the Horizontal Calibration Loop is enabled for two lines (lines 4 and 5) in each field. When 1, the Calibration Loop is not engaged. Upon power–up, this bit is ineffective (Calibration Loop is enabled) until bit $86–6 is set to 0, and register $00 is set to $00.
$79–7	HI	This bit is not used in the MC44011, and must be set to 1.
$79–6	VI	This bit is not used in the MC44011, and must be set to 1.
$7A–7	Xtal	When 0, the crystal at Pin 38 (17.7 MHz) is selected. When 1, the crystal at Pin 36 (14.3 MHz) is selected.
$7A–6	SSD	This bit is not used in the MC44011, and must be set to 0.
$7B–7, 6	T1, T2	Used to set the Sound Trap Notch filter frequency according to Table 3.
$7C–7, 6 $7D–6	SSC, SSA, SSB	Sets the NTSC/PAL decoder to the correct system according to Table 4.
$7D–7 $7E–7, 6	P1, P2, P3	Sets the Luma Peaking in the decoder section according to Table 5. (See text).
$7F–7, 6 $80–6	D3, D1, D2	Sets the Luma Delay in the decoder section according to Table 6. (See text).
$80–7	$\overline{\text{RGB EN}}$	When 0, permits the RGB inputs (Pins 26 to 28) to be selected with the Fast Commutate (FC) input (Pin 25). When 1, the FC input is disabled, preventing the RGB inputs from being selected. When the RGB inputs are selected, the Color Difference inputs (Pins 30, 31) are deselected.
$81–7	Y2 EN	When 1, the Y2 Luma input (Pin 29) is selected. When 0, it is deselected.
$81–6	Y1 EN	When 1, the Y1 Luma Signal (provided by the decoder section to the color difference section) is selected. When 0, it is deselected.
$82–7	YUV EN	When 0, Pins 20 to 22 provide RGB output signals. When 1, those pins provide YUV output signals.
$82–6	YX EN	Effective only when the RGB inputs are selected. When 0, the RGB inputs (Pins 26 to 28) are directed to the RGB outputs (Pins 20 to 22) via the Contrast and Brightness controls. When 1, the RGB inputs are directed through the Color Difference Matrix, allowing Saturation control in addition to the Brightness and Contrast controls. See Figure 36.
$83–7	L2 Gain	When 0, the gain of the pixel clock VCO (PLL2) is high (50 µA). When 1, the gain is low (20 µA).
$83–6	L1 Gain	When 0, the Horizontal Phase Detector Gain (PLL1) is low. When 1, the gain is high.
$84–7	H Switch	When 0, Pin 12 is open. When 1, Pin 12 is internally switched to ground, allowing the PLL1 filter operation to be adjusted for noisy signals.
$85–7	PClk/2	When 0, the PLL2 VCO provides the Pixel Clock at Pin 18 directly. When 1, the VCO output is directed through a ÷ 2 stage, and then to Pin 18.

Table 14. Control Bit Description (continued)

Control Bit	Name	Description
$84–6	525/625	This bit sets the division ratio from the crystal for the reference frequency for the Horizontal Calibration Loop. For NTSC systems, set to 1. For PAL systems, set to 0.
$85–6	C Sync	When 0, Pin 13 will provide a square wave of ≈ 250 kHz (16 x Fh). When 1, Pin 13 provides a negative composite sync signal. See Figures 25, 27, 30, 31.
$86–7	V_{in} Sync	When 1, Composite Sync at the selected Video input (Pin 1 or 3) is used for all internal timing. When 0, the Sync source is selected by Bits $87–7 and $88–6. See Table 12.
$86–6	PLL1 Enable	After power up, this bit must be set to 0, and then register $00 set to $00, to enable the Horizontal Loop (PLL1). Setting this bit to a 1 will disable the Horizontal Loop, and engages the Calibration Loop.
$87–7	Y2 Sync	When 1, and $86–7 = $88–6 = 0, Composite Sync at the Y2 input (Pin 29) is used for all internal timing. When 0, the Sync source is selected by Bits $86–7 or $88–6. See Table 12.
$87–6	0	This bit must always be set to 0.
$88–7	V2/V1	When Composite Video is applied, and this bit is 0, the Video 2 input (Pin 3) is directed to the Sound Trap. When 1, the Video 1 input (Pin 1) is selected. In S–VHS applications, when 0, Pin 3 is the Y (luma) input, and Pin 1 is the chroma input. When this bit is 1, Pin 1 is the luma input, and Pin 3 is the chroma input.
$88–6	RGB Sync	When 1, and $86–7 = $87–7 = 0, Composite Sync at any or all of the RGB inputs (Pin 26 to 28) is used for all internal timing. When 0, the sync source is selected by Bits $86–7 or $87–7. See Table 12.

Table 15. Control DAC Description

Control Bits	Description
$78–5/0	This DAC allows for a relative gain adjustment of the R–Y and B–Y outputs (Pins 41, 42) as a means of adjusting the color decoding accuracy. Nominal setting is 32.
$79–5/0	Used to balance out reference errors of the color subcarrier, primarily for NTSC. Nominal setting is 32. Adjustment range is ≈ ±5°.
$7D–5/0	Used to set the U (Pin 22) dc bias level. When in the YUV mode ($82–7 = 1), this setting should nominally be 32. When in RGB mode, set to 00.
$7E–5/0	Used to set the V (Pin 22) dc bias level. When in the YUV mode ($82–7 = 1), this setting should nominally be 32. When in RGB mode, set to 00.
$7F–5/0	Used to fine tune the gain of the Pixel Clock VCO to obtain optimum performance without instabilities. A setting of 63 will shut off the VCO. Setting 50 to 62 provide non–square wave outputs, and can be unstable. As the setting is increased from 00 to 49, the gain is increased. Changing this register does not change the Pixel Clock frequency.
$80–5/0	Used to fine tune the contrast of the Blue output when in RGB mode. In YUV mode this provides a fine tuning of the color, similar to, but not to be confused with, hue.
$81–5/0	Used to adjust the gain of the three outputs. In RGB mode this is the Contrast control.
$82–5/0	Used to fine tune the contrast of the Red output when in RGB mode. In YUV mode this provides a fine tuning of the color, similar to, but not to be confused with, hue.
$83–5/0	Used to fine tune the brightness of the Blue output when in RGB mode. In YUV mode this provides a fine tuning of the color, similar to, but not to be confused with, hue.
$84–5/0	Used to adjust the brightness of the three RGB outputs. In YUV mode this DAC affects only Y output (Pin 21).
$85–5/0	Used to fine tune the brightness of the Red output when in RGB mode. In YUV mode this provides a fine tuning of the color, similar to, but not to be confused with, hue.
$86–5/0	Used to adjust the saturation of the RGB/YUV outputs of the Color Difference section.
$87–5/0	Used to adjust the saturation of the R–Y, B–Y outputs (Pins 41, 42) of the Decoder section.
$88–5/0	Used to adjust the hue of the R–Y, B–Y outputs (Pins 41, 42). Nominal setting is 32.
$00–7/0	This register must be set to 00, after Bit $86–6 is set to 0, to enable the Horizontal Loop (PLL1) after power up, or anytime when Bit $86–6 is set to 0 after having been a 1.

NOTE: The above DACs are 6–bits wide. The settings mentioned above, and in subsequent paragraphs are given in decimal values of 00 to 63. These are not hex values.

Reading Flags

A read cycle need not be restricted to the vertical interval, but may be done anytime. A flag read cycle consists of three bytes (with three acknowledge bits):

- The first byte is always the Read address for the MC44011 ($8B).
- The second and third bytes are the flag data.

Communication begins when a start bit (data taken low while clock is high), initiated by the master (not the MC44011), is detected, generating an internal reset. The first byte (address) is then entered, and if correct, an acknowledge is generated by the MC44011. The flag bits will then exit the MC44011 as two 8 bit bytes at clock cycles 10–17 and 19–26. The master (receiving the data) is expected to generate the acknowledge bits at clocks 18 and 27. The master must then generate the stop bit.

The MC44011 flags must be read on a regular basis to determine the status of the various circuit blocks. The MC44011 does not generate interrupts. It is recommended the flags be read once per field or frame. See Table 16 for a description of the flags.

Table 16. Flag Description

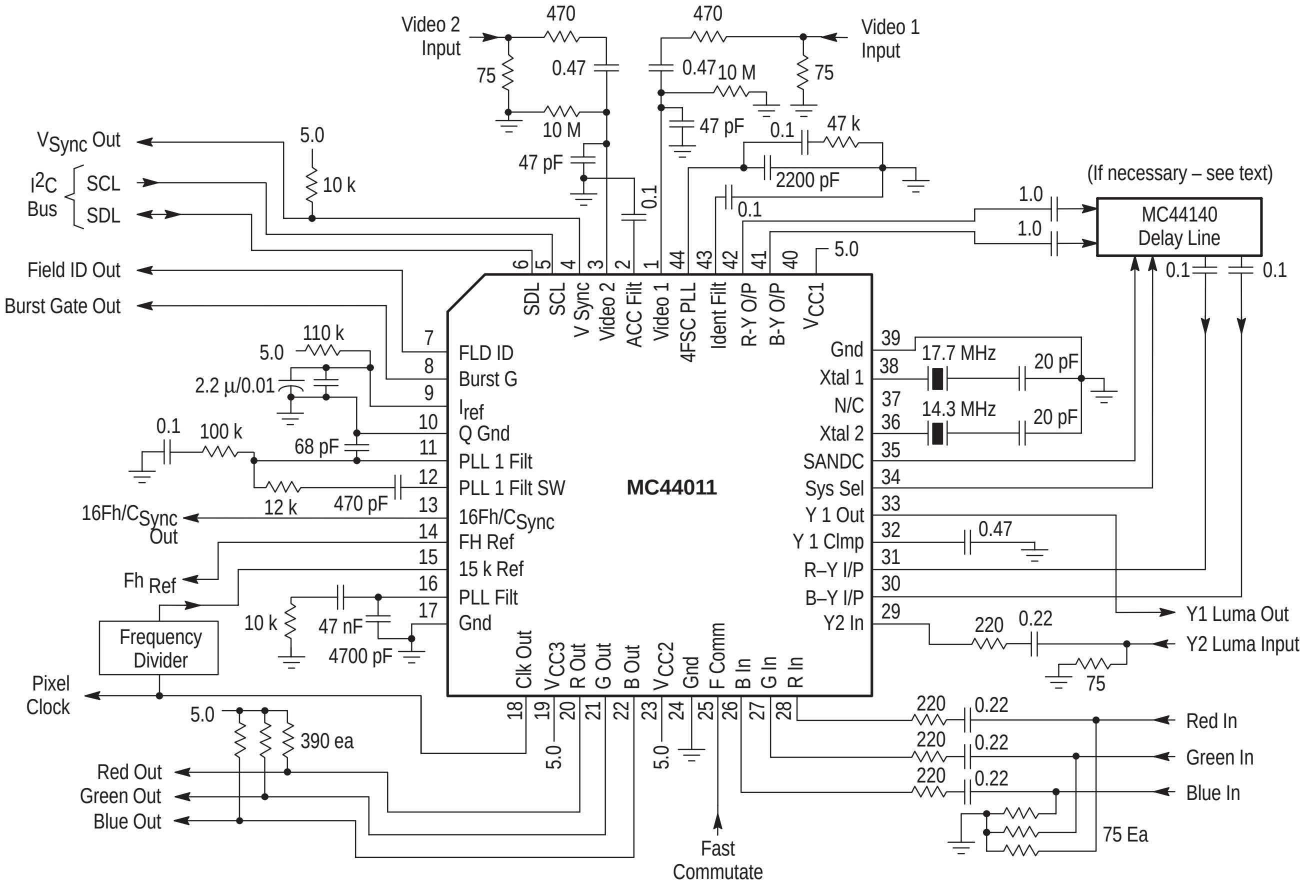
Clock No.	Description (When Flag = 1)
10	Internally set to a Logic 1.
11	Horizontal Loop (PLL1) enabled, indicating the loop can be driven by the incoming sync. This bit will be low upon power up, and will change to a 1 after initialization of control Bit $86–6 and register $00.
12	Horizontal Loop (PLL1) not locked. Lack of incoming sync, or wrong sync source selection, or the wrong horizontal frequency, will cause the Coincidence Detector to indicate a “not locked” condition.
13	Internally set to Logic 0.
14	Less than 576 horizontal lines counted per frame. This flag helps determine the applied video system. When high, a 525 line system (NTSC) is indicated. When low, a 625 line system (PAL) is indicated.
15	Vertical Countdown engaged. When high, this flag indicates the Vertical Countdown section has successfully maintained lock for 8 consecutive fields, indicating therefor a successful vertical lock–up. This flag is low in the Injection Lock mode.
16	Internally set to a Logic 1.
17	Internally set to a Logic 1.
18	(Acknowledge pulse).
19	Pixel clock VCO control voltage too low (< 1.7 V at Pin 16). This indicates the VCO may not function correctly as the control voltage is near one end of its range. The DAC setting at register $7F–5/0 must be increased, and/or the ÷ 2 block must be selected (set $85–7 = 1), to clear this flag.
20	Pixel clock VCO control voltage too high (> 3.3 V at Pin 16). This indicates the VCO may not function correctly as the control voltage is near one end of its range. The DAC setting at register $7F–5/0 must be reduced, and/or the ÷ 2 block must be deselected (set $85–7 = 0) to clear this flag. This flag will be high if the VCO is off (DAC $7F = 63).
21	Internally set to a Logic 1.
22	Internally set to a Logic 0.
23	ACC Loop is active, indicating it is locked up to the color burst signal. The Color Burst amplitude must exceed 30 mVpp, and the correct crystal selected, for lock–up to occur.
24	PAL system identified by the decoder, indicating the decoder recognizes the line–by–line change in the burst phase. When NTSC is applied, this flag is 0.
25	Not used.
26	Internally set to a Logic 0.
27	(Acknowledge pulse).

APPLICATIONS INFORMATION

Design Procedure and PC Board Layout

The external components required by the MC44011 are shown in Figure 42. Except for the crystals, all the components are standard value resistors and capacitors, and can be non–precision. Table 18 describes the external components for each pin.

Figure 42. Basic Functional Circuit



Crystal Specifications and Operation

The crystals used with the MC44011 should comply with Table 17 specifications.

Table 17. Crystal Specifications

Frequency: (4 x Subcarrier)	NTSC (14.31818 MHz) PAL (17.734472 MHz) PAL–M (14.30244 MHz)
Pull–in range:	±1600 Hz (with respect to crystal frequency)
Tolerance:	30 ppm (with fixed load capacitor)
Temperature Coefficient:	50 ppm (with fixed load capacitor)
Operating Mode:	Fundamental series resonance
Load Capacitance:	Nominally 20 pF
Motional Capacitance:	10 to 30 fF
Series Resistance:	< 30 Ω (nominally 10 Ω)

The oscillator output resistance at Pin 36 is nominally 300 Ω for NTSC mode, and 400 Ω at Pin 38 for PAL mode. It is recommended that a stray capacitance (PC board, package pins, etc.) of 4.0 to 5.0 pF be included when selecting a crystal.

The above values for tolerance and temperature coefficent can be increased if a trimmer capacitor is used for the load capacitor.

The crystal PLL filter (Pin 44) voltage is between 1.8 and 3.8 V in normal operation. If the color output of the MC44011 is incorrect, or non–existent (ACC flag off), this voltage should be checked. If it is beyond either of the above limits, the capacitor in series with the crystal should be changed so as to allow the PLL to pull–in the crystal. The capacitor is generally specified by the crystal manufacturer, but should also comply with Table 17 specifications. If no burst is present, Pin 44 voltage will be ≈ 1.3 V.

The selected crystal frequency can be checked by using a scope at the non–selected crystal pin. The signal amplitude is nominally 200 to 400 mVpp. In this way the selected crystal's frequency is not affected by the scope probe.

Table 18. External Components

Pin	Name	Function
1, 3	Video 1, Video 2	Input signals must be capacitor–coupled. The 470 Ω resistors protect the pins from ESD and RFI. The 75 Ω resistors are not required by the MC44011, but depend on the signal source. The 47 pF capacitors filter high frequency noise.
2	ACC Filter	The 0.1 µF ceramic capacitor filters the Automatic Gain circuit.
4	Vert Sync	The pull–up resistor is required for this open–collector output.
5, 6	SCL, SDL	Pull–up resistors are required on each I^2C line since outputs are open–collector. They are typically located at the master device.
7	Field ID	No external components required.
8	Burst Gate	No external components required.
9	I_{ref}	The 110 kΩ resistor provides ≈ 32 µA from the 5.0 V source. This pin must be well filtered to the Quiet Ground (Pin 10).
10	Quiet Gnd	This is the Reference Ground for Pin 9 and the PLL1 Filter.
11	PLL1 Filter	The 100 kΩ resistor, and the 0.1 µF and 68 pF capacitors are the filter network for this PLL. Connect to Pin 10 ground.
12	PLL1 Filt SW	The 12 kΩ resistor and 470 pF capacitor give the filter a longer time constant when Pin 12 is switched in.
13	$16Fh/C_{Sync}$	No external components required.
14	Fh Ref	No external components required.
15	15 k Return	TTL Return signal from external frequency divider.
16	PLL2 Filter	The 10 kΩ resistor and 47 nF and 4.7 nF capacitors are the filter network for this PLL. Connect to Pin 17 ground.
17	Ground	Ground for the Pixel Clock circuit.
18	Clk Out	Pixel Clock output to external frequency divider and triple A/D converter.
19	V_{CC3}	5.0 V supply for the Pixel Clock circuit.
20, 21, 22	R, G, B Out	The 390 Ω pull–up resistors are required for these open–collector outputs. The pull–ups should go to a clean, well filtered 5.0 V supply. These pins cannot drive 75 Ω directly. If required to do so, see text for suggested buffer.
23	V_{CC2}	5.0 V supply for the Color Difference section.
24	Ground	Ground for the Color Difference section.
25	Fast Comm	No external components required. This input *should not* be left open.
26, 27, 28	B, G, R In	Input signals must be capacitor–coupled. The 220 Ω resistors protect the pins from ESD and RFI.
29	Y2 Input	Input signals must be capacitor–coupled. The 220 Ω resistor protects the pin from ESD and RFI. The 75 Ω resistor is not required by the MC44011, but depends on the signal source.
30, 31	B–Y, R–Y In	Input signals must be capacitor–coupled. The MC44140 is required if PAL signals are processed (see text).
32	Y1 Clamp	The 0.1 µF ceramic capacitor provides clamping for the Y1 output.
33	Y1 Out	No external components required. This pin cannot drive 75 Ω directly. If required to do so, see text for suggested buffer.
34, 35	System Sel, Sandcastle	For use by the MC44140 delay line. No other external components required.
36, 38	Xtal 2, Xtal 1	A 17.7 MHz crystal is required (at Pin 38) for PAL signals, and a 14.3 MHz crystal is required (at Pin 36) for NTSC signals. If only one crystal is required, leave the other pin open. The series capacitor depends on the crystal manufacturer. (See Table 17 for crystal specs.)
37	N/C	No external components required.
39	Ground	Ground for Color Decoder section.
40	V_{CC1}	5.0 V supply for the Color Decoder section.
41, 42	B–Y, R–Y Out	The MC44140 is required if PAL signals are processed. Otherwise, capacitor–couple to Pins 30, 31 (see text).
43	Indent Filter	The 0.1 µF ceramic capacitor provides filtering for the Identification circuit.
44	4FSC PLL	The 47 kΩ resistor, and 0.1 µF and 2.2 nF capacitors are the filter network for the crystal PLL. Connect to Pin 39 ground.

Power Supplies and Ground

There are three V_{CC} pins (Pins 19, 23, and 40) which must be connected to a source of 5.0 V, ±5%. Since the three pins are internally connected by diodes, none can be left open, even if a particular section (such as the Pixel Clock Generator) is to be unused. Total current required is ≈ 135 mA (including the RGB output load current). There are four ground pins (Pins 10, 17, 24, and 39) which must be connected together, and preferably connected to a ground plane.

Pins 19 and 17 are the V_{CC} and ground for the Pixel Clock Generator, and the circuitry associated with the Pixel Clock should be referenced to those two pins.

Pins 23 and 24 are the V_{CC} and ground for the Color Difference section, which includes the RGB outputs. The output pull–up resistors should be connected to the V_{CC} at Pin 23.

Pins 40 and 39 are the V_{CC} and ground for the Color Decoder, Sync Separator, Horizontal PLL and the Vertical Decoder. Pin 10 is the Quiet Ground for the horizontal PLL's VCO and filter, and therefore, the components on Pins 9 and 11 should be connected as close as possible to Pin 10.

Bypassing of the power supplies must be done as close as possible to each V_{CC} pin, and at the output pull–up resistors. Recommended bypassing components are a 10 µF tantalum capacitor in parallel with a 0.01 µF ceramic.

Input Signals

The various video inputs, Video 1 and 2, Red In, Green In, Blue In, R–Y, B–Y, and Y2 inputs, are designed to accept standard level analog video waveforms. They are not designed for digital signals. The input impedance of the above pins is high. The need for 75 Ω terminations for those video signals depends on the video source itself. All of the above signals must be capacitor–coupled as clamping is provided internally.

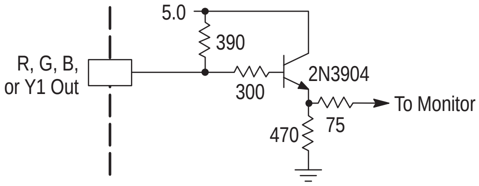
The I^{2}C inputs (SCL, SDL) are designed according to the I^{2}C specifications, which define V_{OL} as between 0 and 1.5 V, and V_{OH} as between 3.0 V to V_{CC}. See Appendix C.

The 15 k Return and Fast Commutate (Pins 15 and 25, respectively) are designed for TTL level signals. If unused, they should not be left open, but connected to 5.0 V, or ground, as appropriate.

Output Signals

The RGB/YUV outputs are open–collector, and require pull–up resistors (typically 390 Ω) to a clean 5.0 V (V_{CC2}). The output impedance is such that the load impedance (to ground) should be >1.5 kΩ. If it is desired to drive a 75 Ω load (e.g., a monitor) from these outputs, a simple buffer (see Figure 43) can be added.

Figure 43. Output Buffer



The Y1 output (Pin 33) has an output impedance of ≈ 300 Ω, and can be used as a monitoring point, or to drive the input of the MC44145 sync separator, or other high impedance loads (minimum load for Y1 is 1.0 kΩ). If it is to be used to drive a 75 Ω load, the buffer shown in Figure 43 can be used, *except the 390 Ω resistor must be deleted*.

The Vertical Sync output (Pin 4) is an open–collector logic level output, and requires a pull–up resistor to 5.0 V. 10 kΩ is recommended, but it can be as low as 1.0 kΩ. The I^{2}C data line (SDL, Pin 6) is also open–collector when it is an output, and can sink a maximum of 3.0 mA. Only one pull–up resistor is required on the SDL line (regardless of the number of devices on that line), and it is typically near the master device. The Field ID, Burst Gate, 16Fh/C_{Sync}, Fh Ref, and Pixel Clock outputs are logic level totem–pole outputs.

PC Board

The PC board layout should be neat and compact, and should preferably have a ground plane. If feasible, a second plane should be provided for the 5.0 V supply, but this is not mandatory. The components at Pins 9 and 11 should be connected to the same ground track which goes to Pin 10. The V_{CC} and ground should be connected as directly as possible to the power supply, and not routed through a maze of digital circuitry before arriving at the MC44011. Since the MC44011 is intended to be used with A/D converters and high speed digital signals, it is expected digital circuitry will be on the same board. Care should be taken in the layout to prevent digital noise from entering the analog portions of the MC44011. The most sensitive pins are Pins 1, 2, 3, 9, 10, 11, 12, 16, and 44, and should be protected from noise.

Initialization and Programming Information

Upon powering up the MC44011, initialization consists of first filling the registers with initial values to set a known condition. Table 19 provides recommended values for the initial settings, although these may be tailored for each application (with the exception of Bits $79–6,7, $7A–6, $86–6, and $87–6). Table 19 settings will set up the MC44011 to the following conditions:

- Composite video input at Video 1 (Pin 1), NTSC, using the crystal at Xtal 2 (Pin 36).
- Y1 enabled, RGB outputs enabled, and Composite Sync at Pin 13
- RGB inputs not enabled (R–Y, B–Y inputs are enabled)
- The Sound Trap at 4.5 MHz
- The Luma Peaking at 0 dB
- The Luma Delay at minimum
- High gain and high noise rejection for the horizontal PLL
- Vertical decoder set to Injection Lock mode
- The Pixel Clock VCO is off

After the registers are initialized, then set Bit $86–6 to 0, and load register $00 with $00. This will enable the horizontal PLL, permitting normal operation.

Table 19. Recommended Initial Settings

Sub–Address	7	6	5	4	3	2	1	0
$77	S–VHS Y = 0	S–VHS C = 0	FSI = 0	$\overline{\text{L2 Gain}}$ = 0	$\overline{\text{BLCP}}$ = 0	$\overline{\text{L1 Gain}}$ = 0	CBI = 0	CAI = 1
$78	36/68 µs = 0	Calkill = 0	(R–Y)/(B–Y) Adjust DAC = 32					
$79	HI = 1	VI = 1	Subcarrier Balance DAC = 32					
$7A	Xtal = 1	SSD = 0	–					
$7B	T1 = 1	T2 = 1	–					
$7C	SSC = 0	SSA = 1	–					
$7D	P1 = 1	SSB = 0	Blue Bias = 00					
$7E	P3 = 1	P2 = 1	Red Bias = 00					
$7F	D3 = 0	D1 = 0	Pixel Clock VCO Gain Adjust = 63					
$80	$\overline{\text{RGB EN}}$ = 1	D2 = 0	Blue Contrast Trim = 32					
$81	Y2 EN = 0	Y1 EN = 1	Main Contrast = 47					
$82	YUV EN = 0	YX EN = 0	Red Contrast Trim = 32					
$83	L2 Gain = 1	L1 Gain = 1	Blue Brightness Trim = 32					
$84	H Switch = 1	525/625 = 1	Main Brightness = 30					
$85	PClk/2 = 1	C_{Sync} = 1	Red Brightness Trim = 32					
$86	V_{in} Sync = 1	$\overline{\text{PLL1 EN}}$ = 1	Main Saturation (Color Difference section) = 32					
$87	Y2 Sync = 0	0	(R–Y)/(B–Y) Saturation Balance (Decoder section) = 15					
$88	V2/V1 = 1	RGB_{Sync} = 0	Hue = 32					

NOTE: These settings are for power–up initialization only. Refer to the text, and Appendix B, for subsequent modifications based on the application.

Then, after selecting the desired input(s) (from Pins 1, 3, or 26 to 31), and based on the applied signals at those inputs, and by reading the flags, the registers are adjusted for the desired and proper mode of operation. A suggested routine for setting modes is given in Appendix B. The “initial values” in the Control DACs table of Appendix B are those in Table 19. The remainder of the flow chart is a recommendation only, and should be tailored for each application.

The monitoring of flags should be done on a regular basis, and it is recommended it be done once per field. See Table 16 (in the Functional Description section) for a summary of the flags. Should any flags change, the following procedures are recommended:

Flag 11 (Horizontal Enabled) – Once enabled by setting Bit $86–6 = 0, this flag should always remain a 1. Should it change to 0, reset $86–6 to 0, and write $00 to register $00 again. If the flag does not return to a 1, this indicates a possible device malfunction.

Flag 12 (Horizontal Out–of–Lock) – When 1, this indicates:

a. the wrong input is selected (Bits $88–7, $81–7, $80–7, and $77–7,6), or;
b. the wrong sync source is selected (Bits $86–7, $87–7, and $88–6), or;
c. the incoming signal is somewhat unstable, as from a VCR tape (change Bit $83–6), and/or;
d. the incoming signal is noisy (change Bit $84–7), or;
e. a loss of the incoming signal with sync.

(It is possible for this flag to flicker when the video signal is from a poor quality tape, or other poor quality source.)

Flag 14 (Less than 576 lines) – This flag, from the vertical decoder, is used to help determine if the signal is PAL or NTSC. Should it change, this indicates the incoming signal has changed format, or possibly one of the items listed under Flag 12 above.

Flag 15 (Vertical Countdown Engaged) – Bits 77–0 and 1 must be set to 1 (after Flag 12 reads 0) for this flag to indicate correctly. Then this flag will change to a 1 after 8 fields of successful synchronization of the internal counters with the incoming signal. To change to a 0 requires 8 consecutive fields of non–synchronization. If this flag changes to 0, this indicates a loss of signal, a change of signal format, or instability in the horizontal PLL.

Flags 19, 20 (VCO Control Voltage Low/High) – These flags are meaningful only if the Pixel Clock Generator is used. If Flag 19 is a 1, the gain of the pixel clock VCO needs to be increased by increasing the value of register $7F, and/or set Bit $85–7 = 1. If Flag 20 is a 1, the value of the register must be decreased, and/or set Bit $85–7 = 0. If the VCO is turned off ($7F = 63), Flag 19 will be 0, and Flag 20 will be 1.

Flag 23 (ACC Active) – If this flag is a 0, it indicates the ACC loop is not active. This will happen if the burst signal is less than 30 mVpp, if the incorrect crystal is selected ($7A–7), if the crystal PLL is not locked, or if the horizontal PLL is not locked.

Flag 24 (PAL Identified) – This flag is a 1 when PAL signals are applied, and a 0 when NTSC signals are applied, or when no burst is present.

It is recommended that the Color Decoder section, and crystal, should be set according to the state of Flags 14, 23, and 24 according to Table 20.

Table 20. Color Standard Selection Table

Flags			Bit Settings				
#14 <576 Lines	#23 ACC Active	#24 PAL Signal	Crystal	SSA ($7C–6)	SSB ($7D–6)	SSC ($7C–7)	System
X	0	X	Either	1	1	0	Color Kill
0	1	0	Either	1	1	0	Color Kill
0	1	1	17.7 MHz	0	1	0	PAL
1	1	0	14.3 MHz	1	0	0	NTSC
1	1	1	(Note 1)	0	1	0	PAL–M

NOTES: 1. PAL–M, used in Brazil and other South American countries, can be decoded by the MC44011, but requires a 14.3024 MHz crystal.
2. SSD ($7A–6) is always set to 0.

MISCELLANEOUS APPLICATIONS INFORMATION

Use of the MC44140 Delay Line

The MC44140 delay line is generally required if PAL signals are to be decoded, so as to average out the line–by–line color information associated with PAL color decoding. If the same single PAL video source is always used in a particular application, the delay line can be eliminated, and any slight phase errors can be corrected with the DAC of register $79–5/0. If, however, various video sources can be used, and/or if the video signal is less than broadcast quality, it is recommended the MC44140 delay line be included.

The MC44140 acts on the color difference signals before they enter the color difference stage of the MC44011. It will, however, pass NTSC signals through without modifications. The MC44011 uses the System Select output (Pin 34) to indicate to the delay line which signals are being processed. The System Select voltage is set when the color decoder is set with Bits SSA, SSB, SSC, SSD. The Sandcastle output (Pin 35) provides the horizontal timing signals to the delay line. In addition, the MC44140 uses the crystal frequency for the internal counters.

The MC44140 is inserted into the circuit between the Color Difference outputs and inputs of the MC44011. In addition, the MC44140 provides pins (Pins 8,9) for inserting an alternate source of color difference signals to the MC44011 by setting the System Select to external (Bit $7C–7 = 1). See Figure 44 for a suggested circuit.

If only NTSC signals are to be processed by the MC44011, the MC44140 is not needed. In this case, connect Pin 42 to Pin 31 with a 0.1 μF capacitor, and similarly connect Pin 41 to Pin 30.

47	2360	340
63	3160	440

Use of the MC44145 Pixel Clock Generator

For most applications the Pixel Clock Generator (PLL2) within the MC44011 will be suitable. In those cases, however, where the pixel clock frequency is set to within ±1.0 MHz of the selected crystal frequency (14.3 MHz or 17.7 MHz), or to within ±1.0 MHz of double the selected crystal frequencies, undesirable noise artifacts may be present on the RGB outputs. In these cases the MC44145 should be used to generate the Pixel Clock. The circuitry within the MC44145 duplicates that of the MC44011, but since it is physically removed from the circuitry within the MC44011, the interfering noise is not generated. If the MC44145 is used, the Pixel Clock Generator within the MC44011 should be shut off by setting the DAC of register $7F to 63, eliminating the components at Pin 16, and grounding Pin 16.

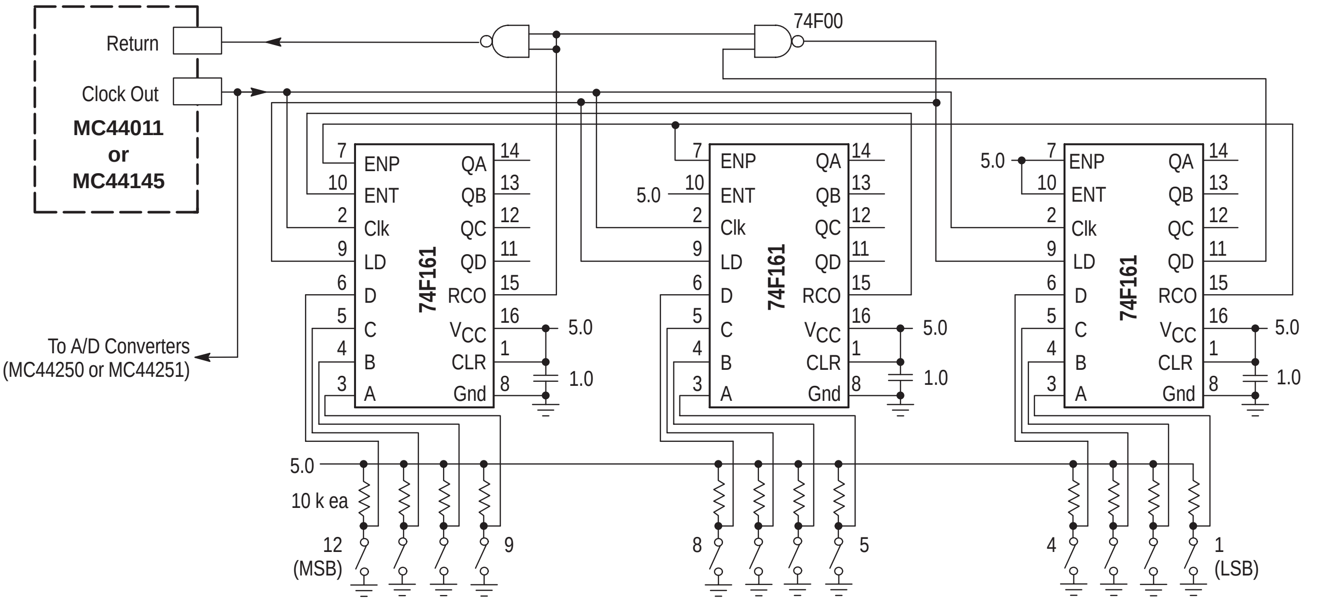
If the desired pixel clock frequency is close to the limits mentioned above, then experimentation may be used to determine the need for the MC44145.

Frequency Divider

The frequency of the Pixel Clock is determined by the horizontal frequency and an external frequency divider. The divider simply divides down the Pixel Clock Frequency so that it equals the horizontal frequency. The PLL within the MC44011 (or the MC44145) compares the horizontal frequency with the returned frequency, and adjusts the internal VCO accordingly, to achieve the proper relationship between the two. The PLL will phase–lock the negative–going edge of the returned signal with the positive–going edge of the Fh signal (Pin 14 of the MC44011). The returned signal must be TTL logic level amplitudes, and have a minimum low time of 200 ns. A suggested circuit for the divider, shown in Figure 46, uses 74F161 programmable binary counters. The 12 switches at the bottom are used to set the division ratio, and hence the Pixel Clock frequency.

The division ratio is determined by dividing the desired clock frequency by the horizontal frequency, and then using the closest whole number. After determining the binary equivalent of that number, close each switch corresponding to a 1, and leave open each switch corresponding to a 0. Alternately, the switches could be deleted, and Pins 3, 4, 5 and 6 of each 74F161 hard–wired to 5.0 V or ground, or controlled by a microprocessor where different pixel clock frequencies are required.

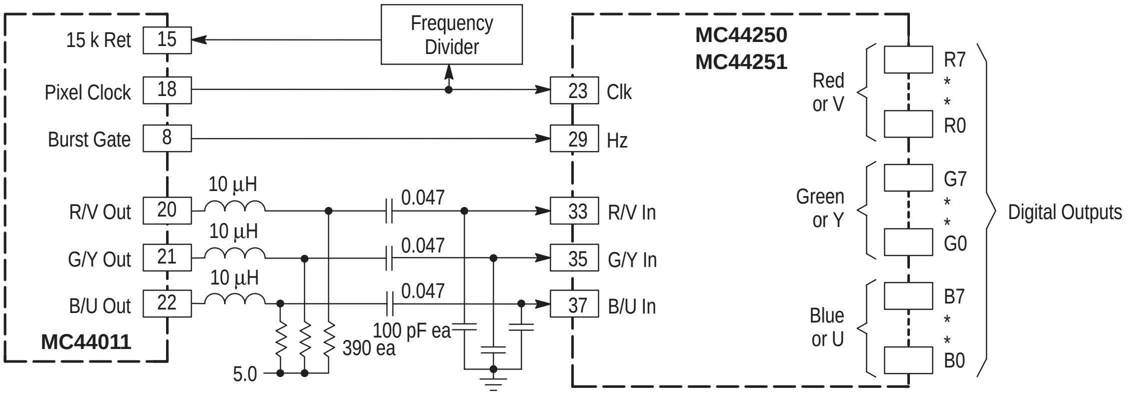
Figure 46. Suggested Frequency Divider



Connecting the MC44011 to the MC44250 or MC44251 A/D Converter

The MC44250 and MC44251 triple A/D converters are designed to accept RGB or YUV inputs, and provide 8–bit equivalents of each. Additionally, the inputs have black level clamps, allowing the input signals to be capacitor–coupled. The simplified schematic of Figure 47 shows the connections between the MC44011 and the MC44250/1, including anti–aliasing filters between the devices. Connection to other A/D converters would be done in a similar manner. Refer to the appropriate data sheet for details.

Figure 47. Connecting to a Triple A/D Converter



Connecting the MC44011 to the MC141621 or MC141625 NTSC Comb Filter

A comb filter can be used ahead of the MC44011 to enhance picture quality by providing a more accurate separation of the luma and chroma components from the composite video, without sacrificing bandwidth. The usual benefits are reduced dot crawl, and increased color purity.

Figure 48 (a simplified schematic) shows the normal mode of implementing the MC141621 (NTSC) or MC141625 (PAL/NTSC) comb filter with the MC44011. The two comb filters can also provide the Y and C signals in digital format. Refer to their data sheets for details. The MC14576A operational amplifiers have an internally set gain of 2.

Figure 48. Implementing the Comb Filter

APPENDIX C

I^{2}C Description

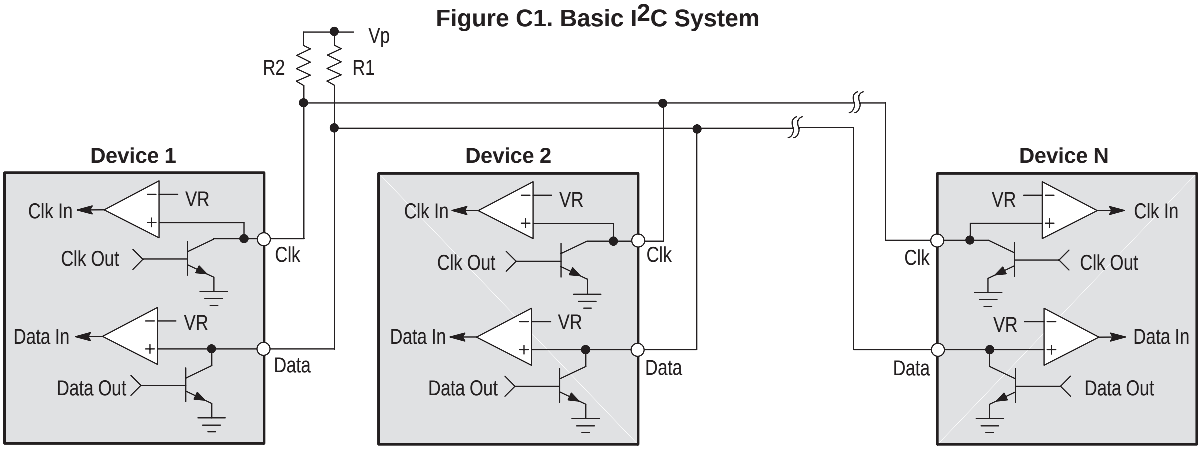
Introduction

The I^{2}C system, a patented and proprietary system developed by Philips Corporation, defines a two–wire communication system. The number of devices in a system is limited only by the system capacitance and data rate. Each device is assigned two unique addresses – one for writing to it, and one for reading from it. Any device may act as a master by initiating a data transfer with any other device (the slave). Data transfer is in 8–bit bytes, and can be in either direction, but not in both directions in one data transfer operation.

Hardware Aspects

The system bus consists of two wires, Clock and Data. All devices must have open–collector (or open–drain) outputs. A single pull–up resistor is required on each line, as shown in Figure C1.

Figure C1. Basic I^{2}C System



Devices such as the MC44011, which never act as a master, need not have the output drive transistor at the Clock pin. Nominal value for R1 and R2 is 10 kΩ, but can be different to account for system capacitance at high data rates. VR is a switching threshold for input signals.

The significant electrical characteristics are as follows:

– Maximum data rate (Clock frequency) is 100 kHz;
– V_{OL} max is 0.4 V when sinking 3.0 mA;
– V_{IL} max is 0.3 x Vp, but at least 1.5 V;
– V_{IH} min is 3.0 V for a 5.0 V system, or 0.7 x Vp for other supply voltages.
– The maximum input current at Clock and Data at V_{OL} max (when they are inputs) is –10 µA;
– The maximum input current at Clock and Data at 0.9 x Vp (when they are inputs) is 10 µA;
– The maximum pin capacitance is 10 pF;
– Maximum bus capacitance is 400 pF.

Data Transfer

Prior to initiating a data transfer, both lines must be high (all drive transistors off). A device which initiates a data transfer assumes the role of the master, and generates a START condition by taking the Data line low while Clock is still high. At this time, all other devices become listeners. The master will supply the clock for the entire sequence.

The master then sends the 8–bit address by operating both the clock and data lines. Data must be stable during the clock's high time, and can change during the clock's low time. The MSB is sent first. The address must end in a 0 if it is a Write operation (data transfer from master–to–slave), and it must end in a 1 if it is a Read operation.

At the 9th Clock Pulse, the master must release the Data line high, and the slave must provide an acknowledge bit by pulling Data low during this clock time. If the master does not receive a proper acknowledge, it can terminate the operation.

After the first acknowledge, the role of the two devices depends on whether it is a Write or a Read operation, but the master always supplies the clock.

– In a Write operation the master is the transmitter, and the slave is the receiver.
– In a Read operation the slave is the transmitter, and the master is the receiver.

The transmitter then sends the next 8–bit byte. At the 18th Clock Pulse (and every 9th clock pulse thereafter), the transmitter releases the Data line, and the receiver acknowledges by pulling Data low. There is no limit to how many bytes may be sent after the address.

When all data is transferred, the Data line must be released by the transmitter so that the master can set the STOP condition. This is done by first pulling Data low (during clock low), then releasing Data high while clock is high. After this, the bus is free for any other device to initiate a new data transfer.

Definitions

Master – The device which initiates a data transfer (regardless of the data direction), generates the clock, and terminates the transfer.

Slave – The device addressed by the master.

Transmitter – The device which supplies data to the bus.

Receiver – The device which receives data from the bus.

Notice that the master is not necessarily the transmitter, and the slave is not necessarily the receiver.

Other

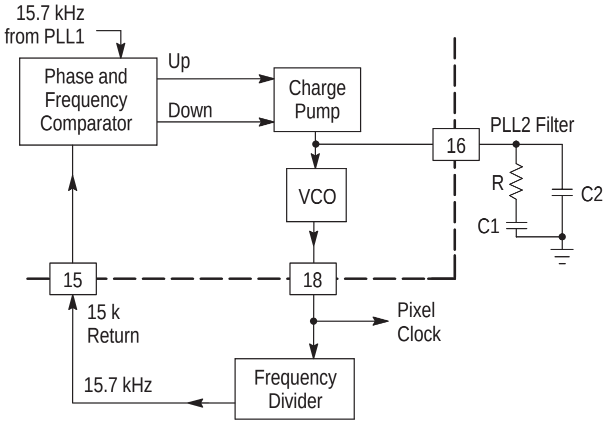
APPENDIX D

PLL Loop Theory

High Frequency Line–Locked Clock Generator

This section is not intended as a complete loop theory, its aim is merely to point out the idiosyncrasies of the loop, and provide the user with enough information for the selection of filter components. For a more in depth explanation, the references at the end of this section may be consulted.

Figure D1. PLL2 Basic Configuration



The following general remarks apply to the loop (PLL2):

- The loop frequency is ≈ 15.7 kHz.
- In spite of the samples nature of the loop, a continuous time approximation is possible if the loop bandwidth is sufficiently small.
- Ripple on V_C (filter pin) is a function of loop bandwidth.
- The loop is a type II, 3rd order. However, since C2 is small, the pole it creates is far removed from the low frequency dominant poles, and the loop can be analyzed as a 2nd order loop.

The following remarks apply to the Phase and Frequency Comparator:

- Phase and frequency sensitive.
- Independent of duty cycle.
- It has 3 allowed states: up, down, and off (high impedance).
- The VCO is always pulled in the right direction during acquisition.
- The Comparator’s gain is higher at or near lock.

The last two remarks imply that only the higher value need be taken into account, as acquisition will be slower but always in the correct direction, whereas the higher gain will come into action as soon as the error reaches 2π.

The following values are selected and defined:
C2 = C1/10 or less, to satisfy the requirement that the effect of C2 on the low frequency response of the loop be minimal, and similar to a 2nd order loop.

ξ = 0.707 (damping factor).
ωi = 15750 x 2p = 98960 rad/sec (input frequency).
τ = RC as the loop filter
K = Ko x Ip x R/(2πN) – the loop gain
K′ = K x τ = $4\xi^2$ (the normalized loop gain)
Ko = 70×10^6 rad/V

Stability analysis with C2 = C1/10 and K′ = 2 (ξ = 0.707) gives a minimum value of 7.5 for the ratio ωi/K. To have some margin, a reasonable value can be 15 to 20 or higher.

Selecting ωi/K = 20 yields,
K = ωi/20 ≈ 5000.

Using the following items:
K′ = 2,
τ = 2/K = 400 µs,
K = Ko x Ip x R/(2πN)
Ip = 20 µA
N = 2000 (average value)

yields a value of 22 kΩ for R. Using a value of 400 µs for τ, C1 calculates to 18 nF, and C2 calculates to 1.8 nF.

With the above values, the loop’s natural frequency (ωn), and loop bandwidth (ω3dB) can be calculated:
$\omega n = \{(Ko/N) \times Ip/(2\pi C)\}^{0.5}$ = 3520 rad/sec.
fn = 3520/2π = 560 Hz.
ω3dB ≈ 2 x ωn = 1120 Hz (valid if ξ = 0.707).

The circuit designer should be cautioned at this point that the above calculated values are not necessarily optimum for every application. Besides the fact that several assumptions were made in the discussion, the equations cannot account for items such as the PC board layout, characteristics of the external divider, and noise from various sources. The above calculated values provide for a functional circuit, which should then be tweaked to obtain minimum jitter at the pixel clock output.

When initially adjusting the filter component values, it is advisable to maintain the same general time constant (400 µs in this example), and the same x10 relationship between C1 and C2.

GLOSSARY

Aspect Ratio – The ratio of the width of a TV screen to the height. In standard TVs, it is 4:3. In HDVT it will likely be 16:9.

Back Porch – The blanking time after the sync signal during which the color burst is inserted.

Blank, Pedestal – The signal level which is either at black, or slightly more negative than black (“blacker–than–black”), and is used to turn off the screen dot during retrace. Also referred to as the *pedestal*.

Brightness – A measure of the dc levels of the luma component. Changing brightness will change the minimum and maximum luma levels together.

Burst – The 8 to 10 cycle sine wave which is inserted in the back porch. It’s frequency is the color subcarrier (3.58 MHz or 4.43 MHz), and is used as a phase reference for the color decoder.

Burst Gate – A signal identifying the time during which the burst signal occurs.

C, Chrominance – The color component of the video signal. The color is determined by the phase of the chrominance component relative to the burst signal.

Clamping – A process which establishes a fixed dc voltage level, usually during the back porch time.

Color Difference Signals – B–Y, R–Y, also designated as U and V.

Color Decoder – A circuit which separates composite video into Red, Blue, and Green, luminance, and sync signals.

Color Encoder – A circuit which combines Red, Blue, and Green, luminance, and sync signals into composite video.

Comb Filter – A multi–bandpass filter which separates the luma and chrominance components from the video signal, without sacrificing bandwidth.

Component Video, YUV – A format whereby the video information is kept as separate luma, R–Y, and B–Y signals *(YUV)*. U is the same as B–Y, and V is the same as R–Y.

Composite Sync – A sync signal which combines horizontal and vertical sync information. The waveform is made up of regularly spaced negative going pulses for the horizontal sync, and then half–line pulses and polarity reversal to indicate the vertical sync and retrace time.

Composite Video – The video signal which consists of sync, back porch, color burst, video information (luma and chroma), and front porch. This is the signal normally broadcast by TV stations.

Contrast – A measure of the difference between minimum and maximum luma amplitudes. Increasing contrast produces a “blacker” black and a “whiter” white.

dB – A power or voltage measurement unit, referred to another power or voltage. It is generally computed as:

10 x log (P1/P2) for power measurements, and
20 x log (V1/V2) for voltage measurements.

Field – One of the two or more equal parts into which a frame is divided in an interlaced system.

Frame – The information which makes up one complete picture. It consists of 525 lines in NTSC systems, and 625 lines in PAL systems. An interlaced system is typically composed of two fields.

Front Porch – The blanking time immediately before the sync signal.

Horizontal Sync – The negative going sync pulses at the beginning of each line. The pulses indicate to the circuit to begin sweeping the dot across the screen.

Hue – A measure of the correctness of the colors on a screen.

Interlaced System – A method of generating a picture on the screen whereby the even number lines are processed, and then the odd number lines are processed, thereby completing a full picture.

IRE – Abbreviation for *International Radio Engineers*, it is the amplitude unit used to define video levels. In standard NTSC signals, blank–to–white is 100 IRE units, and blank–to–sync tip is 40 IRE units. In a 1.0 Vpp signal, one IRE unit is 7.14 mV.

Luma, Y – The brightness component of the video signal. Usually abbreviated “Y”, it defines the shade of gray in a black–and–white TV set. In color systems, it is composed of 0.30 red, 0.59 green and 0.11 blue.

NTSC – *National Television System Committee*. This committee set the color encoding standards and format for television broadcast in the United States.

PAL – *Phase Alternating Line*. A color encoding system in which the burst is alternated 90° each line to help compensate for color errors which may occur during transmission. This system is popular mainly in Europe.

Pixel – The smallest picture element, or dot, on a screen. It is determined by the design of the CRT, as well as the system bandwidth.

R–Y, B–Y – Referred to as *color difference signals*. These are two of the three signals of component video. When combined with Y, the full color and luminance information is available.

Retrace – The rapid movement of the blanked dot from the screen’s right edge to the left edge so it can start scanning a new line. It is also the rapid movement from the lower right corner to the upper left corner during vertical blanking.

RGB – The three main colors *(red, blue, green)* used in the acquiring, and subsequent display of a video signal.

S–VHS – A format whereby the video information is kept as separate luma and chroma signals (Y and C).

Sandcastle – A signal which indicates the horizontal blanking time. It encompasses the front porch, sync, and back porch. Two amplitudes distinguish the front porch + sync time from the back porch.

Saturation – A measure of the intensity of the color on a screen. Also related to its purity.

Sync Separator – A circuit which will detect, and output, the sync signal from a composite video waveform.

Vertical Sync – The synchronizing signal which indicates to the circuitry to drive the dot to the upper left corner of the screen, thereby starting a new field. This signal is derived from the composite sync.

Multistandard Video Signal Processor with Integrated Chroma Delay Line

**MULTISTANDARD
VIDEO SIGNAL PROCESSOR
WITH INTEGRATED
CHROMA DELAY LINE**

**SEMICONDUCTOR
TECHNICAL DATA**

The MC44030/35 is a highly advanced circuit which performs most of the basic functions required for a color TV. All its advanced features are under processor control via I^{2}C bus, enabling potentiometer controls to be removed completely and allowing significant cost savings together with the possibility of implementing sophisticated automatic test routines.

A summary of the features available on the device is given below:

- Operation from a Single 5.0 V Supply; Low Current Consumption (Typically 150 mA)
- PAL/SECAM/NTSC Decoding Capability (4 Matrix Modes Available)
- Integrated Chroma Delay Line
- Dual Composite Video or S–VHS Inputs
- Integrated Luma and Chroma Filters (Including SECAM Cloche Filter)
- Programmable Luma Delay and Peaking
- RGB Drives Including CONTRAST/BRIGHTNESS Controls and Auto Grey–Scale
- External RGB and Fast Commutate Inputs with SATURATION Control Possibility
- Auxiliary Y, R–Y, B–Y Inputs
- Line Timebase Featuring H–PHASE Control and Switchable Phase Detector Gain
- Countdown Type Vertical Timebase Including the Vertical Geometry Corrections
- 16:9 Display Mode Capability
- E–W Parabola Drive Including the Horizontal Geometry Corrections
- Anode Current Monitor with Vertical Breathing Compensation
- Analog Contrast Control, Allowing Fast Beam Current Limitation
- Pin to Pin Compatible with MC44002/7
- MC44035 is the PAL/NTSC Only Version of the MC44030
- Available in DIP and TQFP Packages

MOTOROLA

MC44144

Subcarrier Phase-Locked Loop

SUBCARRIER PHASE–LOCKED LOOP

SEMICONDUCTOR TECHNICAL DATA

The MC44144 is a gated phase–locked loop intended for, but not restricted to, video applications. The integrated circuit contains a gated phase detector, voltage controlled crystal oscillator, divide–by–4 circuitry, and a video clamp. This device provides a 4X reference frequency output, and a 1X reference frequency output.

The MC44144 is manufactured using Motorola's high density, bipolar MOSAIC™ process.

- 8–Pin DIP or Surface Mount Package
- Gated–Phase Detector
- Single Pin Voltage Controlled Crystal Oscillator
- 1X and 4X Subcarrier Output
- Operates Off of a Standard 5.0 V Supply

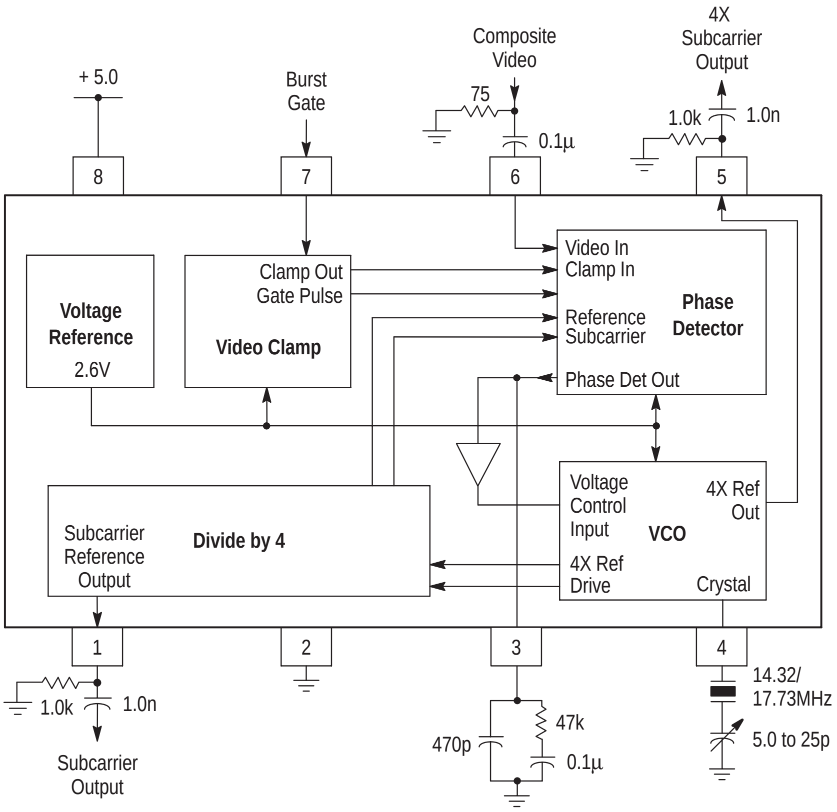
Figure 2. Representative Schematic Diagram



FUNCTIONAL DESCRIPTION

The MC44144 is designed to implement the color sync function in a video system. When provided NTSC/PAL composite video or composite chroma and burst gate inputs, the IC will phase–lock a Voltage Controlled Crystal Oscillator (VCXO) to the color burst. Both 4X and 1X subcarrier frequency outputs are provided by the IC. The VCXO operates off of a 4X subcarrier crystal and The VCXO operates off a 4X subcarrier crystal and is capable of at least ± 600 Hz of pull–in. The tradeoff for such a wide pull–in range is a resultant "soft" lock, or a 3° phase shift per 100 Hz *change* in oscillator free–run or input reference frequency.

In addition to providing the gate pulse for the MC44144 phase detector, the Burst Gate input also initiates a clamp pulse that sets up the level of the composite video at the input to the Phase Detector. The start and duration of the Gate Pulse should be timed so that the pulse envelopes the color burst of the video signal, but not so wide as to gate sync or video into the Phase Detector.

The Phase Detector is enabled when the voltage at the Burst Gate input (Pin 7) is above the nominal 2.2 V threshold. While this makes possible the ability to lock to a color burst, it does not exclude the possibility of lock to a constant reference. If a constant source is to be the reference, the Phase Detector can be permanently enabled by holding the voltage on the Phase Detector input pin higher than the threshold voltage.

The phase detector gain must be specified in two ways, for a constant reference and for a burst–locked application. The gain in a constant reference application is specified by the maximum current output with the maximum phase error. For a maximum phase error of $\pi/2$ radians the maximum current available is approximately 200 μA. So the phase detector gain is defined as,

$$KPD = 200/(\pi/2)(\mu A/rad \bullet sec)$$

For a burst–locked application, the Phase Detector is active for only the duration of the color burst. Therefore the phase detector gain must be specified as an average gain over a line period. In this case the phase detector gain for NTSC and for PAL applications is,

$$KPD_{NTSC} = (8/(\pi/2))(\mu A/rad \bullet sec) \text{ and,}$$

$$KPD_{PAL} = (7/(\pi/2))(\mu A/rad \bullet sec)$$

A suitable filter for both types of applications is shown in the test schematic Figure 2. This same filter also works for both NTSC and PAL applications.

The 4X subcarrier Voltage Controlled Crystal Oscillator (VCXO) uses a design that enables the use of series or parallel resonant types of crystals. Still, layout and crystal positioning are critical as the oscillator frequency is sensitive to shunt capacitance. Care should be taken to keep the crystal close to the IC and crystal switching should be avoided. A suitable parallel type crystal would meet the specifications in Table 1.

A plot showing the VCXO gain is shown in Figure 1. From this plot the gain must be estimated from the operating point. KO_{PAL} is the gain for PAL applications and KO_{NTSC} is the gain for NTSC applications.

PIN FUNCTION DESCRIPTION

Name	Pin	Representative Circuitry	Description	Expected Waveforms
Subcarrier Output	1		Subcarrier Output. A phase–locked reference of the PAL or NTSC color burst is output at this pin.	A 300 mVpp square wave is output. Some high frequency content is present.
Ground	2		Circuit Ground	
Phase Detector Output	3		The error current from the phase detector is output at this pin. A filter circuit should be connected at this pin.	A beat waveform, showing both horizontal period and half the subcarrier period, is present. 4X Sub Xtal	4		Crystal Oscillator Pin. A 4X subcarrier parallel resonant crystal, in series with a 5.0 to 25 pF trimmer capacitor provides the resonant element for the Voltage Controlled Crystal Oscillator (VCXO).	Approximately 40 mVpp. A scope probe will disturb the frequency of oscillation.
4X Subcarrier Output (or Black Burst)	5		Buffered output from the 4X voltage controlled oscillator.	The sinusoidal $4Xf_{SC}$ oscillator output is available at this pin. The output is nominally: 525 mVpp for NTSC, 425 mVpp for PAL.
Composite Video Input (Black Burst, Continuous Wave, or Composite Chroma can also be applied)	6		Composite Video Input. Color burst from the video present at this pin is used as a reference to phase lock the VCXO. Positive or negative video may be used.	Composite video should be applied at this pin. The color burst amplitude of the input video should be at least 50 mV, but no more than 1000 mV. The waveform at this pin should not exceed ground or V_{CC}. Burst Gate Input	7		Input for the phase detector gate pulse. TTL compatible. The threshold is nominally 2.6V.	A positive going gate pulse should be applied at this pin. The Burst Gate input should envelope the color burst. V_{CC}	8		Power Supply Pin. 5.0 Vdc should be applied at this pin.	

Linear and TTL Output Buffers

The output buffers of the MC44144 are not designed to any specific logic family. If it is desired, Linear or TTL buffers can be added externally. Figure 3 shows an example of a Linear buffer using an MC3346 Transistor array; virtually any utility transistor can be used. Figure 4 shows a TTL type buffer using an MC74LS04 buffer.

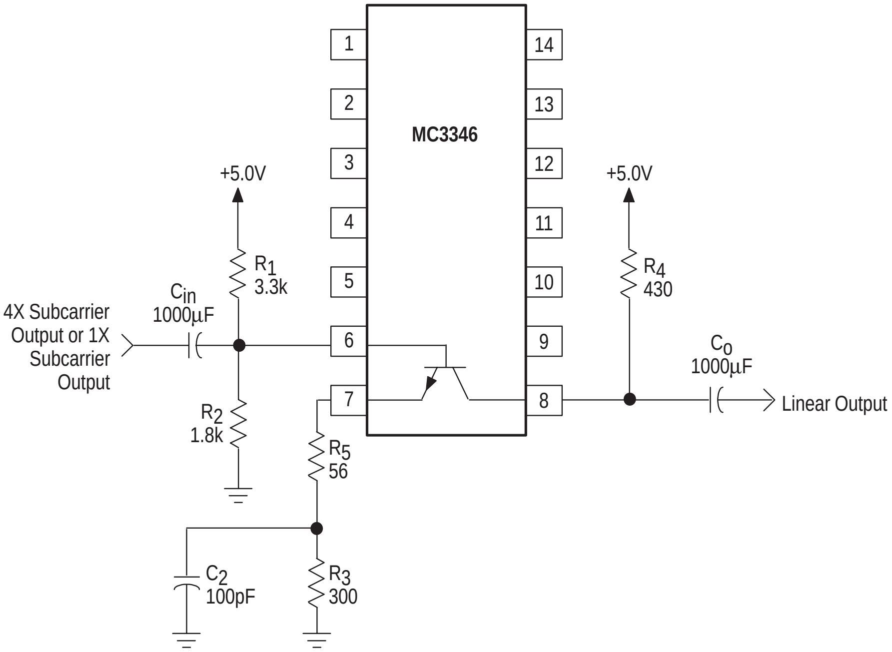

Figure 4. TTL Buffer

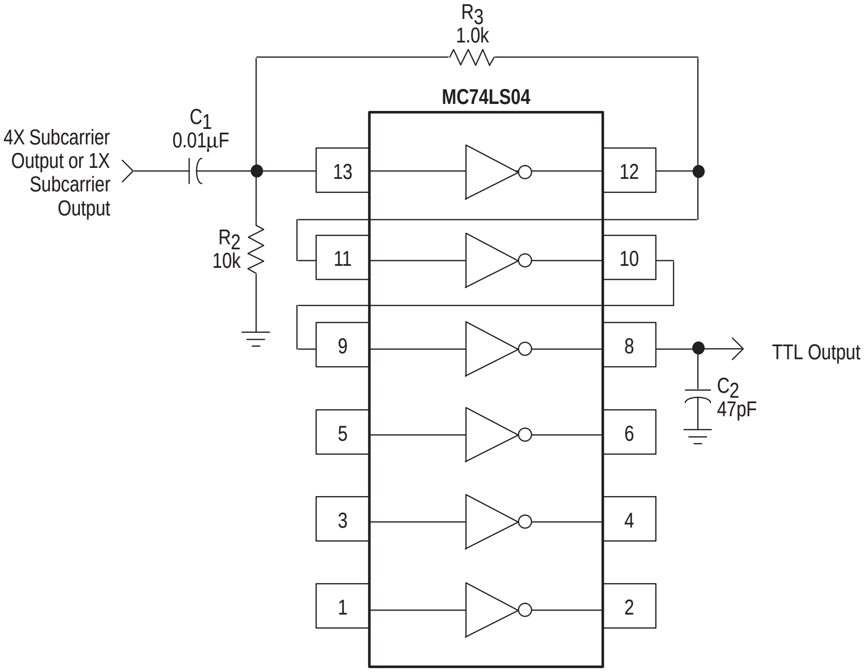

MOTOROLA

MC44145

Pixel Clock Generator/ Sync Separator

The MC44145, Pixel Clock Generator, is a component of the MC44000 family.

The MC44145 contains a sync separator with composite sync and vertical outputs, and clock generation circuitry for the digitization of any video signal along with the necessary circuitry for clock generation, such as a phase comparator and a divide–by–2 to provide a 50% duty cycle.

The MC44145 is available in a SO–14 package and is fabricated in the Motorola high density, high speed, low voltage, process called MOSAIC 1.5®.

CIRCUIT DESCRIPTION

Composite Sync Separator

The composite sync separation section is comprised of two blocks, a sync slicer and a sync amplifier, which can be used to extract the vertical sync and composite sync information from a video signal.

The sync separator is an adaptive slicer in which the video signal is slightly integrated and then sliced at a ratio of 4.7 to 64 which corresponds to the sync to horizontal ratio. Two outputs are given, one of high impedance and the other low impedance.

A slicing sync inverting amplifier is also on–chip, allowing one output to be used for composite sync and the other output to be integrated and then sliced using the slicing amplifier to extract the vertical sync information.

Clock Generation

The clock generation is made up of a wide ranging emitter–coupled VCO followed by a switchable ÷2 to provide a 50% duty cycle wherever required, or twice the set frequency if an external divider is used. The clock generator is a PLL subsection; its function is the generation of a high frequency, line locked clock that is used for video sampling and digitizing.

The clock output is a LSTTL–like buffer which has a limited drive capability of two LSTTL loads.

The VCO is driven from a charge pump with selectable current. The charge pump is driven by the phase comparator.

The phase comparator is a type IV “phase and frequency comparator” sequential circuit.

The clock generator, the heart of a PLL, is to be closed by means of an external divider, thus setting the synthesized frequency. This divider could be implemented in discrete logic or be a part of an ASIC subsystem.

Phase and Frequency Comparator

The phase comparator is fed from two input buffers, F_{ref} which expects a reference frequency at line rate and that is rising edge sensitive, and NBACK which comes from the external divider and is falling edge sensitive.

Charge pump current and output divider action are controlled by applying suitable voltage on the appropriate pins (respectively, NPD Gain and Div 2 EN).

PIN FUNCTION DESCRIPTION

Pin	Function	Description
1	NPD Gain	This pin sets the gain of the phase frequency detector by changing the current of the charge pump output (40 µA or 80 µA). Low current with this pin > 2.0 V, high current for < 0.5 V.
2	Ground	Ground connection common to the PLL and sync separator sections.
3	Sync B	High impedance sync output.
4	Sync Amp In	Sync amplifier input.
5	Sync C	Low impedance sync output.
6	V_{CC}	Power connection to the PLL section.
7	Clock Out	VCO clock output. Capable of limited LSTTL drive. It should not be used to drive high capacitive loads, such as long PCB traces or coaxial lines.
8	Div 2 EN	The divider is switched in with this pin > 2.0 V; switched out for < 0.5 V.
9	F_{ref}	Reference frequency input to the phase and frequency comparator. Typically this will be a 15625 (15750) Hz signal. It is rising edge sensitive. Due to the nature of the phase and frequency comparator, no missing pulses are tolerable on this input. In a typical setup, this signal can be provided by the MC44011.
10	Sync Amp Out	Sync amplifier output.
11	V_{CC2}	Power connection to the sync separator and amplifier.
12	Video In	Video signal input to the sync separator.
13	NBACK	Fed by the external clock divider. Sets the multiplication ratio of the loop in multiples of the F_{ref} frequency. Negative edge sensitive.
14	PLL Loop Filter	See loop filter calculations at the end of this document.

NOTE: The two V_{CC} pins are not independent, as they are internally connected by means of the input protection diodes; they must always be both connected to a suitable V_{CC} line.

CIRCUIT OPERATION

Composite Sync Separator

The sync separator is an adaptive slicer. It will output “raw” sync data. Two outputs are given, thus allowing one output to be used for composite sync and the other output to be integrated and then sliced using the inverting slicing amplifier provided. As the input of the slicing amplifier is external, the amplifier may be driven from either sync output, although normally the high impedance output (Sync B) would be recommended.

The positive video input signal required is nominally 1.0 V sync–to–white, but the circuit supports signals above and below this level and also is resistant to a degree of reflections on the signal. Coupling to the sync separator may be achieved by a simple capacitor of 100 nF, but better results may be obtained with a higher value in series with a resistance of 1.0 kΩ.

Clock Generator

The system is best put to use in a dual loop configuration; a first loop locks to line frequency by means of a type I phase detector (multiplier type) which is insensitive to missing pulses. This PLL is then followed by a second loop using the MC44145, performing frequency multiplication. The phase comparator of the MC44145 is frequency and phase sensitive. It is a type IV (sequential type) phase detector, which does not tolerate missing pulses. The dual loop structure makes up a noise insensitive frequency (and phase) locked loop.

The phase and frequency comparator provides two logical outputs, mutually exclusive – up or down – that are used to source or sink current to and from the loop filter. This current can be user–selected to be 40 µA or 80 µA (typical), thus providing some degree of loop gain control.

The VCO is an emitter–coupled multivibrator type, with an on–chip timing capacitor, and has been designed for low phase noise.

The divide–by–2 is included at the output of the VCO, thus allowing for a precise 50% duty cycle, hence the VCO is operating at twice the required frequency. The divider can be bypassed, bringing the VCO output directly to the output buffer.

The external divider must provide a feedback pulse to close the loop; the falling edge of this pulse will be aligned (when the loop is in lock) with the rising edge of the pulse applied to the F_{ref} input. Operation of the phase comparator is insensitive to the duty cycle of both its inputs. The feedback pulse should have a minimum width of 500 ns. This can be guaranteed if it has a length of at least 16 output clock cycles (highest output frequency with the divider disabled).

APPLICATION INFORMATION

Analog video signals out of the MC44011 are sampled and converted to 8–bits digital in the A/D converter (MC44250 series) by means of the clock provided by the MC44145, pixel clock generator (see Figure 1).

The frame store contains the memory, the necessary logic for the memory addressing, as well as the counter to set the frequency multiplication ratio of the line locked clock generator (H. Count).

Figure 1. Application Block Diagram

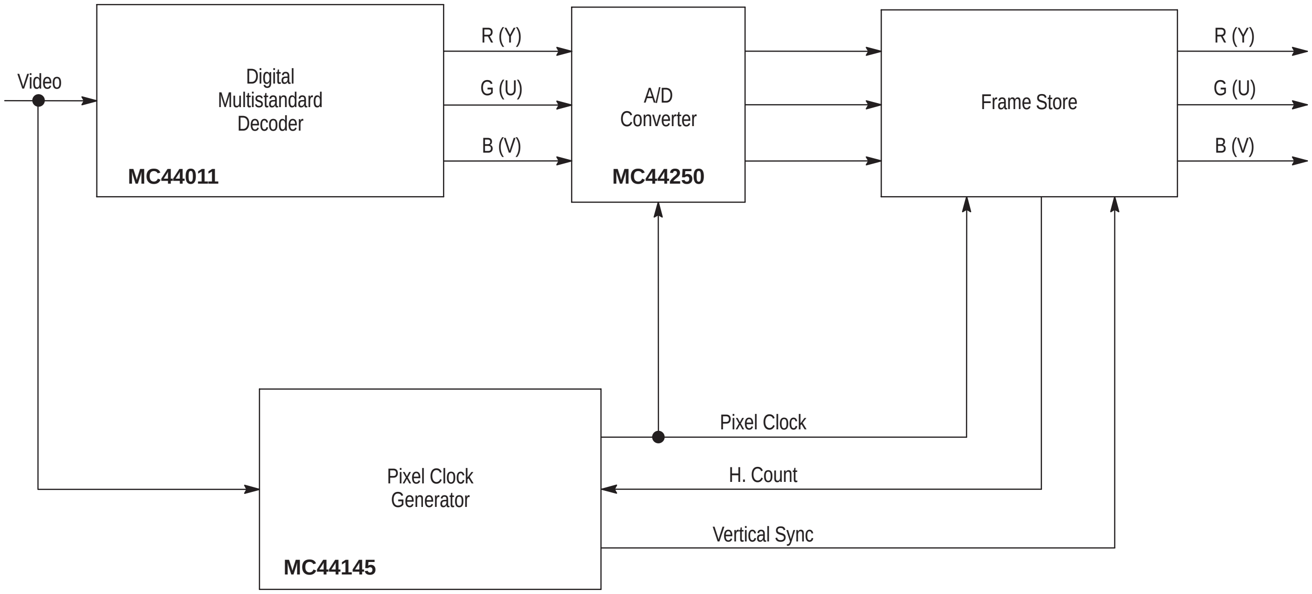

Figure 2.

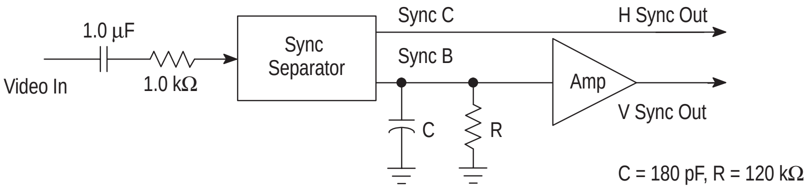

Figure 3. Typical VCO Transfer Characteristics

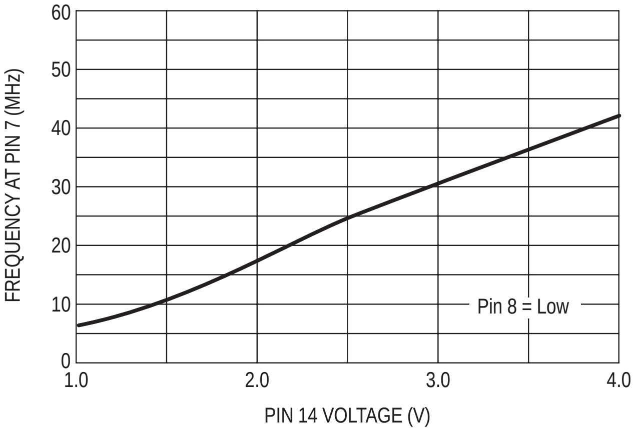

Figure 4. Sync Separator Timing

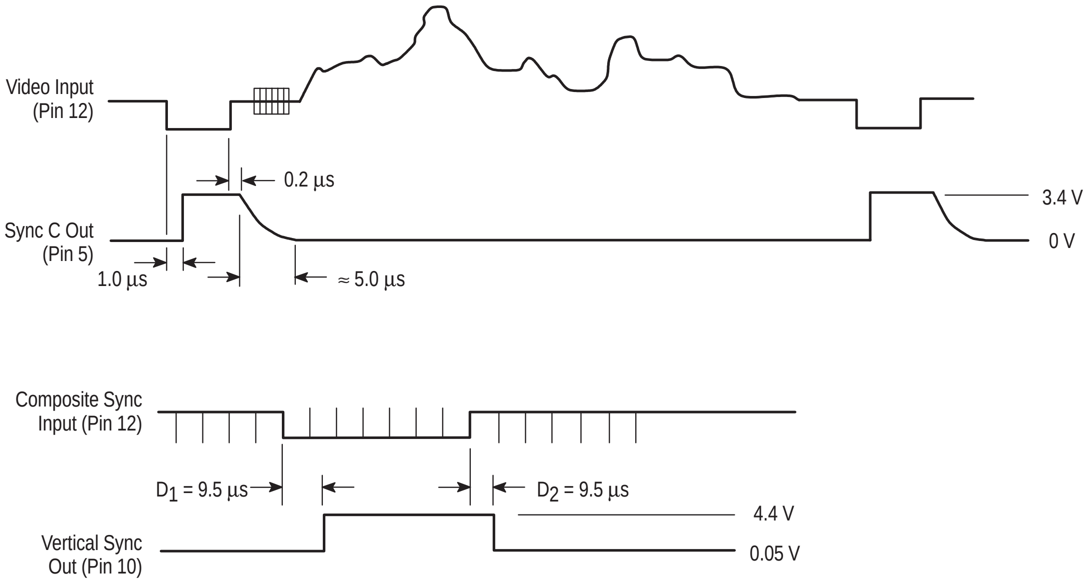

Note: D_1 and D_2 depend on the value of R and C connected to Pin 3. They are specified here for the values: R = 120 kΩ, and C = 180 pF.

LOOP FILTER CALCULATION

This section is not intended as a complete loop theory; its aim is merely to point out the peculiarities of the loop, and provide the user with enough information for the filter components selection. For a more in–depth covering, the cited reference should be consulted, especially [1].

The following remarks apply to the loop:

- The loop frequency is 15 kHz.
- In spite of the sampled nature of the loop, a continuous time approximation is possible if the loop bandwidth is sufficiently small.
- Ripple on V_C is a function of the loop bandwidth
- The loop is a type II, 3rd order; however, since C2 is small, the pole it creates is far removed from the low frequency dominant poles, and the loop can be analyzed as a 2nd order loop.

These remarks apply to the PFD:

- Phase and frequency sensitive.
- Independent of duty cycle.
- PFD has 3 allowed states: up, down, hi–Z
- The VCO is always pulled in the right direction (during acquisition).
- PFD gain is higher near lock.

The last two remarks imply that only the higher value need be taken into account, as acquisition will be slower, but always in the proper direction, whereas the higher gain will enter the action as soon as the error reaches $\pm 2\pi$.

The following values are selected and defined (see Block Diagram):

C2 = C/10 or less, to satisfy the requirement that the effect of C2 on the low frequency response of the loop be minimal, and similar to a second order loop.

$\zeta = 0.707$ for the damping factor.

$\omega i = 15625 \text{ x } 2\pi$ the input pulsation.

$\tau = RC$ as the loop filter.

$K = Ko \text{ x } Ip \text{ x } R/(2 \text{ x } \pi \text{ x } N)$ the loop gain.

$K' = K \text{ x } \tau = 4\zeta^2$ is the “normalized” loop gain.

$Ko = 57 \text{ x } 10^6$ [rad/Vs] (9.0 MHz/V).

Stability analysis, with C2 = C/10 and $K' = 2$ ($\zeta = 0.707$) gives a minimum value of 7.5 for the ratio $\omega i/K$ and to have some margin, a reasonable value can be 15 to 20 or higher [1].

Selecting $\omega i/K = 20$, gives : $K = \omega i/20 \approx 5000$.

With $K' = 2$, $\tau = 2/K = 400$ µs.

Using $K = Ko \text{ x } Ip \text{ x } R/(2 \text{ x } \pi \text{ x } N)$ and setting $Ip = 60$ µA, and N an average value of 1000, we get R = 9.1 kΩ.

Then for $\tau = 400$ µs, C becomes 47 nF and C2, 4.7 nF.

With these values, the loop natural frequency (ωn) and the loop bandwidth ($\omega 3dB$) can be calculated:

$\omega n = [(Ko/N) \text{ x } Ip/(2\pi C)^{1/2} = 3400$ and

$fn = 3400/2\pi = 540$ Hz.

$\omega 3dB = 2 \text{ x } \omega n = 1080$ Hz (valid if ζ is close to 0.707).

PLL Tuned UHF Audio/Video Modulator ICs for PAL, SECAM and NTSC TV Systems

MC44353 – Multi–Standard Modulator IC
MC44354 – PAL/NTSC Modulator IC
MC44355 – PAL/NTSC Modulator IC with Fixed Video Modulation Index

These modulator circuits are intended for use in VCRs, satellite receivers, set–top boxes, video games, etc. An on–chip high speed I^2C compatible bus receiver is included and is used to set the channel, tuned by a PLL over the full range in the UHF bands. The modulator incorporates a sound subcarrier oscillator, using a second PLL to derive 4.5, 5.5, 6.0 and 6.5 MHz carrier frequencies, selectable by the bus.

For the sound, either frequency modulation with pre–emphasis or amplitude modulation (MC44353 only) is possible. A control bit (MC44353 only) is used to select AM sound with positive RF modulation (system L). The level of the sound carrier with respect to the vision carrier and the modulation depth of both sound and vision may be adjusted by means of the bus. In addition, an on–chip video test pattern generator may be switched in with a 1.0 kHz audio test signal.

- UHF Operation (471 MHz to 855 MHz)
- On–Chip Low Power Operational Amplifier for Direct Tuning Voltage Output
- Single–Ended Output for Low Cost and Ease of Interface
- Low External Component Count
- High Speed I^2C Bus Compatible (Min 500 kHz)
- Programmable Video Modulation Depth (8 Steps of 2.5%)
- Programmable Picture/Sound Carriers Ratio and Audio Sensitivity (8 Steps of 1.0 dB)
- Programmable Sound Subcarrier Oscillator (4.5 MHz to 6.5 MHz)
- Video Test Pattern Generator with Sound Test Signal (1.0 kHz)
- V_{CC} Standby Mode (Typ 500 µA)
- Transient Output Inhibit During PLL Lock–Up at Power–On

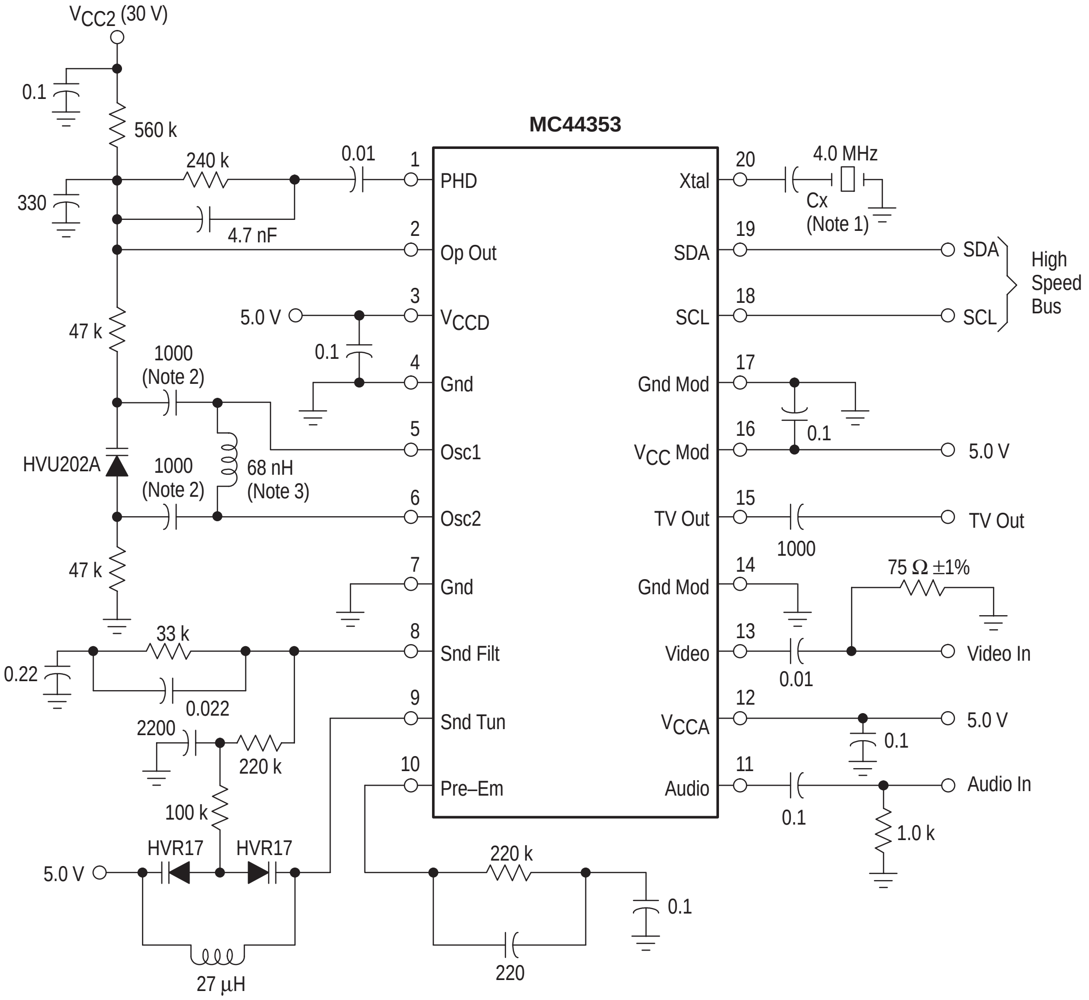
Typical Application



NOTES: 1. Cx depends on Crystal Load Capacitance, Crystal resistance < 200 Ω.
2. Tubular 0603 1000 pF capacitors.
3. UHF Coil is a surface mount 0805 Chip Inductor, REF: AVX/KYOCERA – L0805 6R8 DEW ±0.5 nH (@ 450 MHz Q = 43, @ 900 MHz Q = 62 and L = 7.0 nH)

MODULATOR FUNCTIONAL DESCRIPTION

General

The device has two main sections; a PLL section to synthesize the channel frequency of the UHF output and a modulator section which accepts audio and video inputs and modulates the UHF carrier with them.

The channel frequency, sound and picture modulation index and sound/picture carrier ratio are all programmable by means of a high speed I^2C compatible bus. An on–chip video test pattern generator with an audio test signal is also included.

The MC44353 is designed to operate as a multi–standard modulator and can handle the systems B/G, D/K, H, I, L and N with the same external circuit components.

Advance Information

Picture-in-Picture (PIP) Controller

PICTURE–IN–PICTURE (PIP) CONTROLLER

SEMICONDUCTOR TECHNICAL DATA

The MC44461 Picture–in–Picture (PIP) controller is a member of Motorola's low cost PIP family. It is NTSC compatible and contains all the analog signal processing, control logic and memory necessary to provide for the overlay of a small picture from a second non synchronized source onto the main picture of a television. All control and setup of the MC44461 is via a standard two pin I^{2}C bus interface. The device is fabricated using BICMOS technology. It is available in a 56–pin shrink dip (SDIP) package.

The main features of the MC44461 are:

- Two NTSC CVBS Inputs
- Switchable Main and PIP Video Signals
- Single NTSC CVBS Output Allows Simple TV Chassis Integration
- Two PIP Sizes; 1/16 and 1/9 Screen Area
- Freeze Field Feature
- Variable PIP Position in 64–X by 64–Y Steps
- PIP Border with Programmable Color
- Programmable PIP Tint and Saturation Control
- Automatic Main to PIP Contrast Balance
- Vertical Filter
- Integrated 64 k Bit DRAM Memory Resulting in Minimal RFI
- Minimal RFI Allows Simple Low Cost Application into TV
- I^{2}C Bus Control – No External Variable Adjustments Needed
- Operates from a Single 5.0 V Supply
- Economical 56–Pin Shrink DIP Package

Figure 2. Application Circuit

NOTE: For proper noise isolation, Power Supply Pins 8, 14, 43 and 50 should be bypassed by both high and low frequency capacitors. As a guideline, a 10 µF in parallel with a 0.1 µF at each supply pin is recommended.

PIN FUNCTION DESCRIPTION

Pin	Equivalent Internal Circuit	Description
1		**Horizontal Reference In (H_{in})** CMOS level pulse synchronous with TV horizontal retrace signal. This pulse may be active high or low since there is a polarity selector bit in an internal control register. *This pulse should begin 0.5 to 0.75 µs after the beginning of the main video H sync period.* Its duty cycle should be less than 50%.
2		**Vertical Reference In (V_{in})** CMOS level pulse synchronous with TV vertical retrace signal. This pulse may be active high or low since there is a polarity selector bit in an internal control register. This pulse should begin during the main video vertical interval and have a duration of at least .5H.
3		**Serial Clock (SCL)** CMOS level I^{2}C Compatible slave only clock input. 100 kHz Maximum frequency. 50% duty cycle. See Figure 4 for timing. See I^{2}C Register Description for internal register descriptions and addresses.
4		**Serial Data (SDA)** CMOS level I^{2}C Compatible slave only data input/output. As an output it is open collector. See Figure 4 for timing. See I^{2}C Register Description for internal register descriptions and addresses.
5		**Reset** The active low, Power On Reset initializes all internal registers to zero and resets the I^{2}C interface. Minimum active low time required for Power On Reset reset is 100 ms.
6		**Test Clock**
7		**PLL Filter** Filter for the 16X S/C PLL which is phase locked to the 4X S/C oscillator.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
8 14, 43, 50 9 15, 35, 48		**V_{DD}, V_{SS}** The four V_{DD} pins must be externally connected to a 5.0 V (±5%) supply. The four V_{SS} lines must externally connect to their respective V_{DD} bypass return(s) to ensure that no ground disturbances occur in operation. All supplies must be properly bypassed and isolated for the application. Bypass capacitors of 10 µF in parallel with 0.1 µF for each supply are recommended as a general guideline. The 0.1 µF, high frequency bypass capacitors should be placed as close to the power pins as practical.
10		**Video 1/2 Select Output** High output level indicates that Video 1 is selected to be the main picture video. Low output level indicates Video 2 is selected to be the main picture video.
28		**Sync Out** Outputs the video signal selected as the PIP to be filtered and applied to the H and V timebase through the Sync In pin.
29		**Sync In** PIP sync pulses are externally filtered and applied to the H and V timebase to allow H and V synchronization.
30		**Multi Test** Under control of I^2C bus output signals for test and adjustment are provided through this pin.
31		**H PLL** Connection for horizontal timebase PLL filter.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
33		**Filter PLL** The on board reference filter produces a phase shift which is measured and applied to an internal filter PLL. This capacitor connected to this pin stores the phase correction voltage for the PLL which sets the 90° phase correction reference for the rest of the on chip filters.
36 and 34		**Video Input 1 and 2** Accepts ac coupled 1.0 Vpp composite video input usually from a source generated inside the TV and an external video source. The series coupling capacitor also functions as the storage capacitor for the clamp voltage for the input circuit. It is necessary to return the input of this capacitor to ground through a dc low impedance to enable this clamp function. R = 50 to 100 Ω is acceptable.
37		**Decoder ACC** The Decoder ACC pin provides access to the internal chroma decoder automatic gain control amplifier. The ACC capacitor filters the feedback loop of this amplifier. During PIP burst gate time a voltage proportional to the burst gate magnitude is stored on the capacitor connected to this pin to compensate for input chroma level variation and provide a constant U and V output level to the A/D conversion stage.
38		**Decoder Crystal** 4X Sub–Carrier crystal used to synchronize the decoding of the PIP UV information prior to A/D conversion, sub–sampling and storage in the field memory. The crystal frequency is 14.31818 MHz.
39		**Decoder PLL** Connection for Decoder PLL filter.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
44		**Encoder Phase** Phase difference of the main to encoded burst is sampled and applied to the capacitor connected to this pin to shift the phase of the re–encoded chrominance to match the main.
45		**Encoder ACC** The Encoder ACC pin provides access to the internal chroma reference sample and hold circuit, which stores the sampled value of the main channel chroma burst amplitude on this external ACC capacitor. The ACC amplifier matches the chroma amplitude of the insert picture to that of the main picture.
46		**Encoder PLL** Connection for Encoder PLL filter. See separate discussion for filter values.
47		**Encoder Crystal** 4X Sub–Carrier crystal used to synchronize the encoding of the PIP YUV from the field memory with the main video. The output from this PLL is phase corrected to match the PIP video signal to the main video at the PIP switch. The crystal frequency is 14.31818 MHz.
49		**Video Out** The selected Video 1/2 input is available at the Video Out mixed with the PIP overlay when selected. This signal is a nominal 2.0 V peak–to–peak signal unterminated. This connection is intended to drive an external series 75 Ω load into a 75 Ω termination to ground to provide a 1.0 Vpp signal at the termination.

PIN FUNCTION DESCRIPTION (continued)

Pin	Equivalent Internal Circuit	Description
54, 53, 52, 42, 41, 40		**Encoder and Decoder YUV Caps** During the internal H rate clamping time the YUV reference levels are set by the charge on the capacitors attached to these pins. The nominal value of these capacitors should be 0.01 µF.

SOFTWARE CONTROL OF THE MC44461

Communications to and from the MC44461 follows the I^{2}C interface protocol defined by the Philips Corporation. In simple terms, the I^{2}C is a two line, multi–master, bidirectional bus used for data transfer. Although an I^{2}C system can be multi–master, the MC44461 never functions as a master.

The MC44461 has a write address of $24 and a flag read address of $25. A block diagram of the I^{2}C interface is shown in Figure 3. Writing to the MC44461 registers can cause momentary jitter or other undesirable effects to the TV screen, writing should be done only during the vertical retrace (before line 20).

Write to Control Registers

A write cycle consists of three bytes, with three acknowledge bits.

1) The first byte is always the write address for the MC44461 ($24).

2) The second byte defines the sub–address register, within the MC44461, to be updated; $00 through $0B.

3) The third byte is the data for that register.

The communication begins when a start sequence (data line taken low while the clock line is high) is initiated by the master (MCU) and detected by the MC44461, generating an internal reset. The first byte is then generated, and if the address is correct ($24), an acknowledge is generated by the MC44461, which tells the master to continue to send data. The second byte is then entered, followed by an acknowledge. The third byte is the operative data which is stored in the designated register, followed by the third acknowledge. Writing to multiple registers in a single write operation is permitted in the MC44461. The sub–address is auto–incremented while receiving n – data bytes + Ack, ending with the stop sequence. The sub–address of the 11 registers are at $00 through $0B.

Figure 3. I^{2}C Bus Interface and Decoder

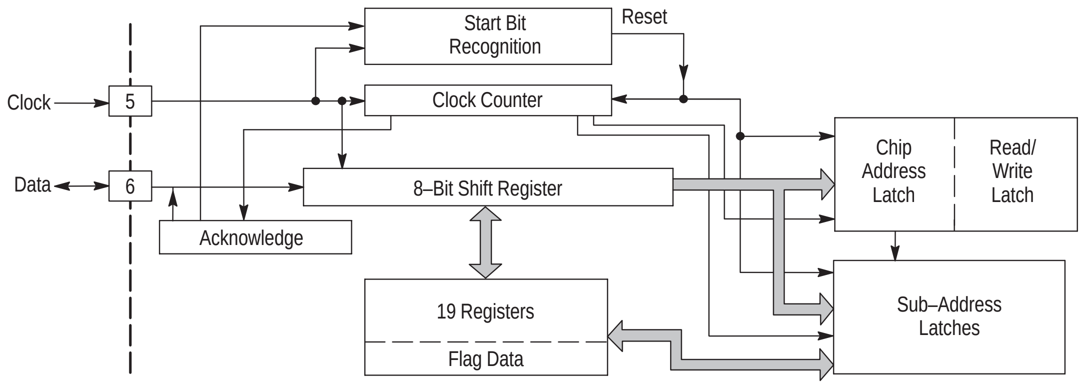

Figure 4. I^{2}C Data Transfer

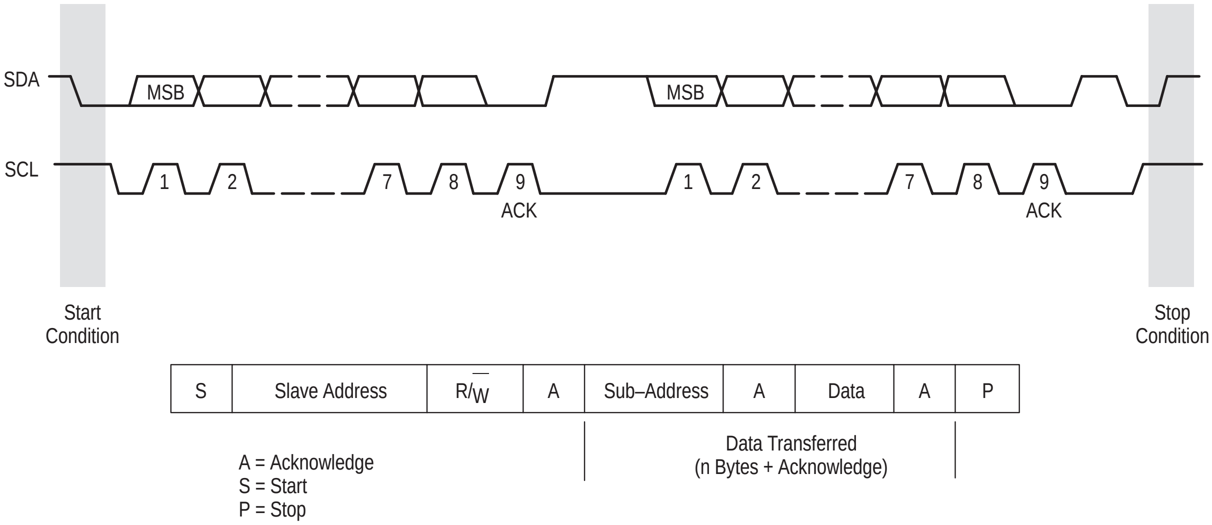

I^{2}C REGISTER DESCRIPTIONS

Base write address = 24h

Base read address = 25h

Read Register

There are two active bits in the single read byte available from the MC44461 as follows:

Write Vertical Indicator (WVI0) – D7

When 0 indicates that the write operation specified by the last I^{2}C command has been completed.

PIP Sync Detect Bit (PSD0) – D1

When 0 indicates that the PIP video H pulses are present and the horizontal timebase oscillator is within acceptable limits.

Write Registers

Read Start Position/Write Start Position Registers

Sub–address = 00h

Write Raster Position Start Bits (WPS0–2) – D0–D2

Establishes the horizontal beginning of the PIP and its black level measurement gate. This beginning may be varied by approximately 3.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Read Raster Position Bits (RPS0–3) – D4–D7

Establishes the clamp gate position for the black level reference for the main picture. This position may be varied by approximately 5.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Pip Switch Delay/Vertical Filter Register

Sub–address = 01h

PIP Switch Delay Bits (PSD0–3) – D0–D3

Delays the start of PIP on time relative to the PIP picture. These bits are used to center the PIP border and PIP picture in the horizontal direction.

Vertical Filter Bit (VFON) – D4

When the filter is activated (VFON = 1) a three line weighted average is taken to provide the data stored in the field memory.

Border Color Register

Sub–address = 02h

Border Color Bits (BC0–2) – D0–D2

These Bits control the color of the border. Note that when using one of the saturated border colors it is possible to get objectionable dot crawl at the edge of the border in some TVs unless appropriate comb filtering is used in the TV circuitry.

BC (2:0)	Border Color
000	Black
001	White 70%
010	No Border (clear)
011	No Border (clear)
100	Blue
101	Green
110	Red
111	White

Test Mode/Main Vertical and Horizontal Polarity Register

Sub–address = 03h

Internal Test Mode Register (ITM0–2) – D0–D2

Sets the Multi Test Pin output to provide one of several internal signals for test and production alignment. Also controls the test memory address counter.

ITM (2:0)	Multi–Test I/O and Function
000	Input – Analog Test mode
001	Input – Digital Test mode
010	Output – Sync Detect
011	Output – PIP Switch
100	Output – PIP H Detect
101	Output – PIP V Detect
110	Output – PIP Clamp
111	Output – Main Clamp

Main vertical polarity select bit (MVP0) – D6

Selects polarity of active level of vertical reference input. 0 = positive going, 1 = negative going.

Main horizontal polarity select bit (MHP0) – D7

Selects polarity of active level of horizontal reference input. 0 = positive going, 1 = negative going.

PIP Freeze/PIP Size/Main and PIP Video Source Register

Sub–address = 04h

PIP Freeze Bit (STIL0) – D4

When set to one, the most recently received field is continuously displayed until the freeze bit is cleared.

PIP Size Bit (PSI90) – D5

Switches the PIP size between 1/16 main size (when 0) and 1/9 main size (when 1).

Main Video Source Select Bit (MSEL0) – D6

Selects which video input will be applied to the PIP switch as the main video out.

PIP Video Source Select Bit (PSEL0) – D7

Selects which video input will be applied to the video decoder to provide the PIP video.

MSEL/PSEL	Function
0	Video 1 Input to Main/ Video 1 Input to PIP
1	Video 2 Input to Main/ Video 2 Input to PIP

PIP On/PIP Blank Register

Sub–address = 05h

PIP On Bit (PON0) – D0

When on (1) turns the PIP on.

PIP Blanking Bit (PBL0) – D4

When on (1) sets the PIP to black. If the PIP is off, then it will be black if it is turned on. Overrides all other settings of the PIP control.

PIP X Position Register

Sub–address = 06h

X Position Bits (XPS0–5) – D0–D5

Moves the PIP start position from the left to the right edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Y Position Register

Sub–address = 07h

Y Position Bits (YPS0–5) – D0–D5

Moves the PIP start position from the top to the bottom edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Chroma Level Register

Sub–address = 08h

Chroma (C0–5) – D0–D5

The color of the PIP can be adjusted to suit viewer preference by setting the value stored in these bits. A total of 64 steps varies the color from no color to maximum. This control acts in conjunction with the auto phase control.

PIP Tint Level Register

Sub–address = 09h

Tint (T0–5) – D0–D5

An auto phase control compares the main color burst to the internally generated pseudo color burst so that the tints are matched. In addition to this, the tint of the PIP can be varied ±10° in a total of 64 steps by changing the value of these bits to suit viewer preference.

PIP Luma Delay Register

Sub–address = 0Ah

Y Delay (YDL0–2) – D0–D2

Since the Chroma passes through a bandpass filter and the color decoder, it is delayed with respect to the Luma signal. Therefore, to time match the Luma and Chroma these bits are set to a single value determined to be correct in the application.

Pip Fill/Test Register

Sub–address = 0Ch

PIP Fill Bits (PIPFILL0–1) – D0–D1

May be used to fill the PIP with one of three selectable solid colors

Test Register Bits (INTC0 and MACR0) – D6–D7

Used for production test only.

Function Control of the MC44461

The registers of the MC44461 may be programmed via the I^{2}C bus. At power up, the registers are in an undefined state. The Setup Value given in the Register Table represents a nominal start point. The setup will put a 1/9 size PIP, with white borders, in the lower right corner of the screen.

I^{2}C REGISTER TABLE

CIRCUIT DESCRIPTION

The MC44461 Picture–in–Picture (PIP) controller is composed of an analog section, logic section and an 8192 x 8–bit DRAM array. A block diagram showing details of all of these sections is shown in the Representative Block Diagram.

The analog section includes an Input Switch, Sync Processor, Filters, PLLs, NTSC Decoder, ADC, DACs, NTSC Encoder and Output Switch. All necessary controls are provided by registers in the logic section. These registers are set by external control through the I^{2}C Bus.

In operation, the MC44461 overlays a single PIP on the main video in either a 1/9th or 1/16th size. In 1/9th, the PIP is 152 samples (114 Y, 19 V, 19 U) by 70 lines and occupies 8094 bytes of the 8192 byte DRAM. The 1/16 size is 112 samples (84 Y, 14 V, 14 U) by 52 lines and occupies 4452 bytes of the DRAM. An extra line of data is stored for each PIP size to allow for interlace disorder correction. The 6:1:1 samples are formatted by the logic section as follows in order to efficiently utilize memory:

Byte 1: Y0(5:0), V(1:0)

Byte 2: Y1(5:0), V(3:2)

Byte 3: Y2(5:0), V(5:4)

Byte 4: Y3(5:0), U(1:0)

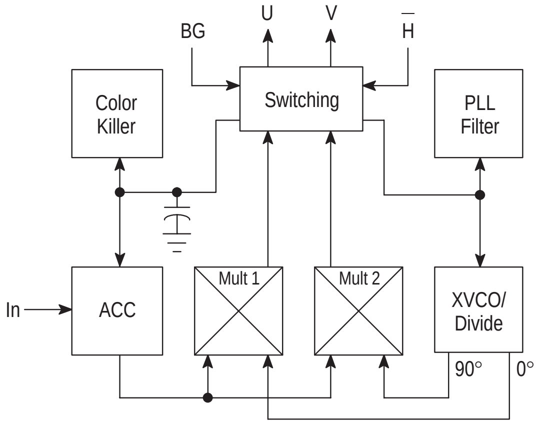
Byte 5: Y4(5:0), U(3:2)

Byte 6: Y5(5:0), U(5:4)

Refer to the block diagram. Both the video inputs are applied to an input switch which is controlled by the I^{2}C bus interface. Either of the inputs is applied to the PIP processing circuitry and either to the main video signal path of the output switch. The signal applied to the PIP processor also provides the vertical sync reference to the PIP processor.

The PIP output from the switch is applied to a 1.0 MHz cutoff low pass GmC biquad filter to extract the luminance signal and a similar bandpass filter to pass chroma to the decoder section. These filters are tracked to a master GmC cell using subcarrier as a reference. A single–ended transconductance stage with relatively large signal handling ability (>2.5 Vpp @ 4.5 V V_{CC}) is used to avoid potential noise problems.

Figure 5. NTSC Decoder



The NTSC Decoder (Figure 5) consists of two multipliers, a voltage controlled 4 X S/C crystal oscillator/divider, Automatic Color Control (ACC) block, Color Kill circuit and necessary switching. During Burst Gate time, the ACC block in the NTSC Decoder is calibrated with respect to burst magnitude by applying the output of multiplier 1 to the reference input of the ACC block. The result is U and V outputs which are 0.6 V ± 0.5 dB for burst amplitudes varying from –12 dB to 3.0 dB. The second multiplier serves as a phase detector during color burst to match the 90 degree output from the XVCO to the 180 degree color burst and feed a correction current to the PLL filter. The phase is correct when the two signals are 90 degrees out of phase.

During the H drive time, the output of the multipliers is fed to the YUV clamp, filtered to 200 KHz and input along with the Y signal to the multiplexer.

The YUV samples are fed through a multiplexer to a single six bit A/D converter. The A/D is a flash type architecture and is capable of digitizing at a 20 MHz sample rate. It is comprised of an internal bandgap source voltage reference, a 64 tap resistor ladder comparator array, a binary encoder and output latches. Once the multiplexer has switched, sufficient time is provided to allow the A/D converter to settle before the reading is latched. The encoder code is determined from the values of any comparators which are not metastable.

The multiplexer and A/D converter receive and convert the YUV data at a $4F_{SC}/3$ rate for a 1/9th size picture or F_{SC} for a 1/16th size picture. The samples are taken in the following way to simplify the control logic:

Y,V,Y,U,Y,V,Y,U

To provide a 6:1:1 format, one of three U and V samples is saved to memory giving a luminance sample rate of $2F_{SC}/3$ for a 1/9th picture and $F_{SC}/2$ for a 1/16 picture. In the vertical direction, one line of every 3 (1/9th picture) or 4 (1/16th picture) are saved. In order to avoid objectionable artifacts, a piece–wise vertical filter is used to take a weighted average on the luminance samples. For three lines (1/9th size) the weight is 1/4 + 1/2 + 1/4 and for four lines (1/16 size) it is 1/4 + 1/4 + 1/4 + 1/4. This filter also delays the luma samples correcting for the longer chroma signal path through the decoder.

Finally the logic incorporates a field generator to determine the current field in order to correct interlace disorders arising from a single field memory.

A separate process runs in the logic section to create the PIP window on the main picture. Control signals are generated and sent to the memory controller to read data from the field memory. Data from the eight bit memory are then de–multiplexed into a six bit YUV format, borders are added, blanking is generated for the video clamps and sent to the Y, U and V DACs. Since the PIP display is based on a data clock, it is important to minimize the main display clock skew on a line by line basis. Skew is minimized in the MC44461 by reclocking the display timebase to the nearest rising or falling edge of a $16F_{SC}$ clock. This produces a maximum line to line skew of approximately 8.0 ns which is not perceptible to the viewer. The PIP write logic also incorporates a field generator for use by the memory controller for interlace disorder correction. Interlace disorder can occur when the line order of the two fields of the PIP image is swapped due to a mismatch with the main picture field or due to an incomplete field being displayed from memory. The main and PIP field generators, along with monitoring, when the PIP read address passes the PIP write address, allows the read address to the memory to be modified to correct for interlace disorder.

The read logic can provide various border colors: black, 75% white (light gray), 50% white (medium gray), red, green, blue or transparent (no border). In a system without an adaptive comb filter, borders which contain no chroma give the best results. Also built into the read logic is a PIP fill mode which allows the PIP window to be filled with either a solid green, blue or red color as an aid in aligning the PIP analog color circuitry.

Because the DAC output video will be referenced during back porch time, the read processor zeroes the luminance value and sets the bipolar U and V values to mid–range during periods outside the PIP window to ensure clamping at correct levels. Since the PIP window is positioned relative to the main picture's vertical and horizontal sync, a safety feature turns off the window if the window encroaches upon the sync period, thus preventing erroneous clamping.

The Y, U and V DACs are all three of the same design. A binary weighted current source is used, split into two, three bit levels. In the three most significant bits, the current sources are cascaded to improve the matching to the three least significant current sources. Analog transmission gates, switched by the bi–phase outputs of the data latches, feed the binary currents to the single ended current mirror. The output current is subsequently clamped and filtered for processing buy the NTSC Encoder.

The outputs of the U and V DACS are buffered and burst flag pulses added to both signals. The U burst flag is fixed to generate a –180° color burst at the modulator output. The V burst flag is variable under the control of an internal register set through the I^2C bus to provide a variable tint. Saturation is controlled by varying a register which sets the reference voltage to the U and V DACs. This is also under I^2C bus control. By oversampling the U and V DACs, it was possible to use identical post–DAC filtering for Y, U and V, thereby reducing the delay inequalities between Y and UV and also simplifying the design. After filtering, the U and V signals are clamped to an internal reference voltage during horizontal blanking periods and fed to the U and V modulators. In the NTSC Decoder, the Y, U and V signals were scaled to use the entire A/D range. Gain through the NTSC Encoder is set to properly match these amplitudes.

The phase of the re–encoded chrominance must match that of the incoming main video signal at the input to the PIP switch, so a separate first order PLL is placed within the loop of the main video signal burst PLL. The first order PLL compares the phase of the main burst with that of the encoded burst and moves the oscillator phase so that they match. A special phase shift circuit allowing a continuous range of 180° was developed to do this.

The amplitude of the re–encoded chrominance signal must also match that of the main video signal. To do this, a synchronous amplitude comparator looks at both burst signals and adjusts the chrominance amplitude in the modulator section of the NTSC encoder. The Y signal from the YDAC is compared to the main video signal at black level during back porch time and clamped to this same black level voltage. The PIP chrominance and luminance are then added together and fed to the PIP output switch through a buffered output.

Y-C Picture-in-Picture (PIP) Controller

The MC44462 Y–C PIP controller is a low cost member of a family of high performance PIP controllers and video signal processors for television. It is a follow–up to the MC44461 PIP and has a modified input selection to allow higher performance in TV systems which have S–Video inputs on the back panel. The S–Video input is separate luma (luminance) and chroma components. It is NTSC compatible and contains all the analog signal processing, control logic and memory necessary to provide for the overlay of a small picture from a second non synchronized source onto the main picture of a television. All control and setup of the MC44462 is via a standard two pin I^2C bus interface. The device is fabricated using BICMOS technology. It is available in a 56–pin shrink dip (SDIP) package.

The main features of the MC44462 are:

- Switchable PIP Composite Video Signals – Video 1 and Video 2
- S–Video Output Allows High Performance in TV
- Two PIP Sizes; 1/16 and 1/9 Screen Area
- Freeze Field Feature
- Variable PIP Position in 64–X by 64–Y Steps
- PIP Border with Programmable Color
- Programmable PIP Tint and Saturation Control
- Automatic Main to PIP Contrast Balance
- Vertical Filter
- Integrated 64 k Bit DRAM Memory Resulting in Minimal RFI
- Minimal RFI Allows Simple Low Cost Application into TV
- I^2C Bus Control – No External Variable Adjustments Needed
- Operates from a Single 5.0 V Supply
- Economical 56–Pin Shrink DIP Package

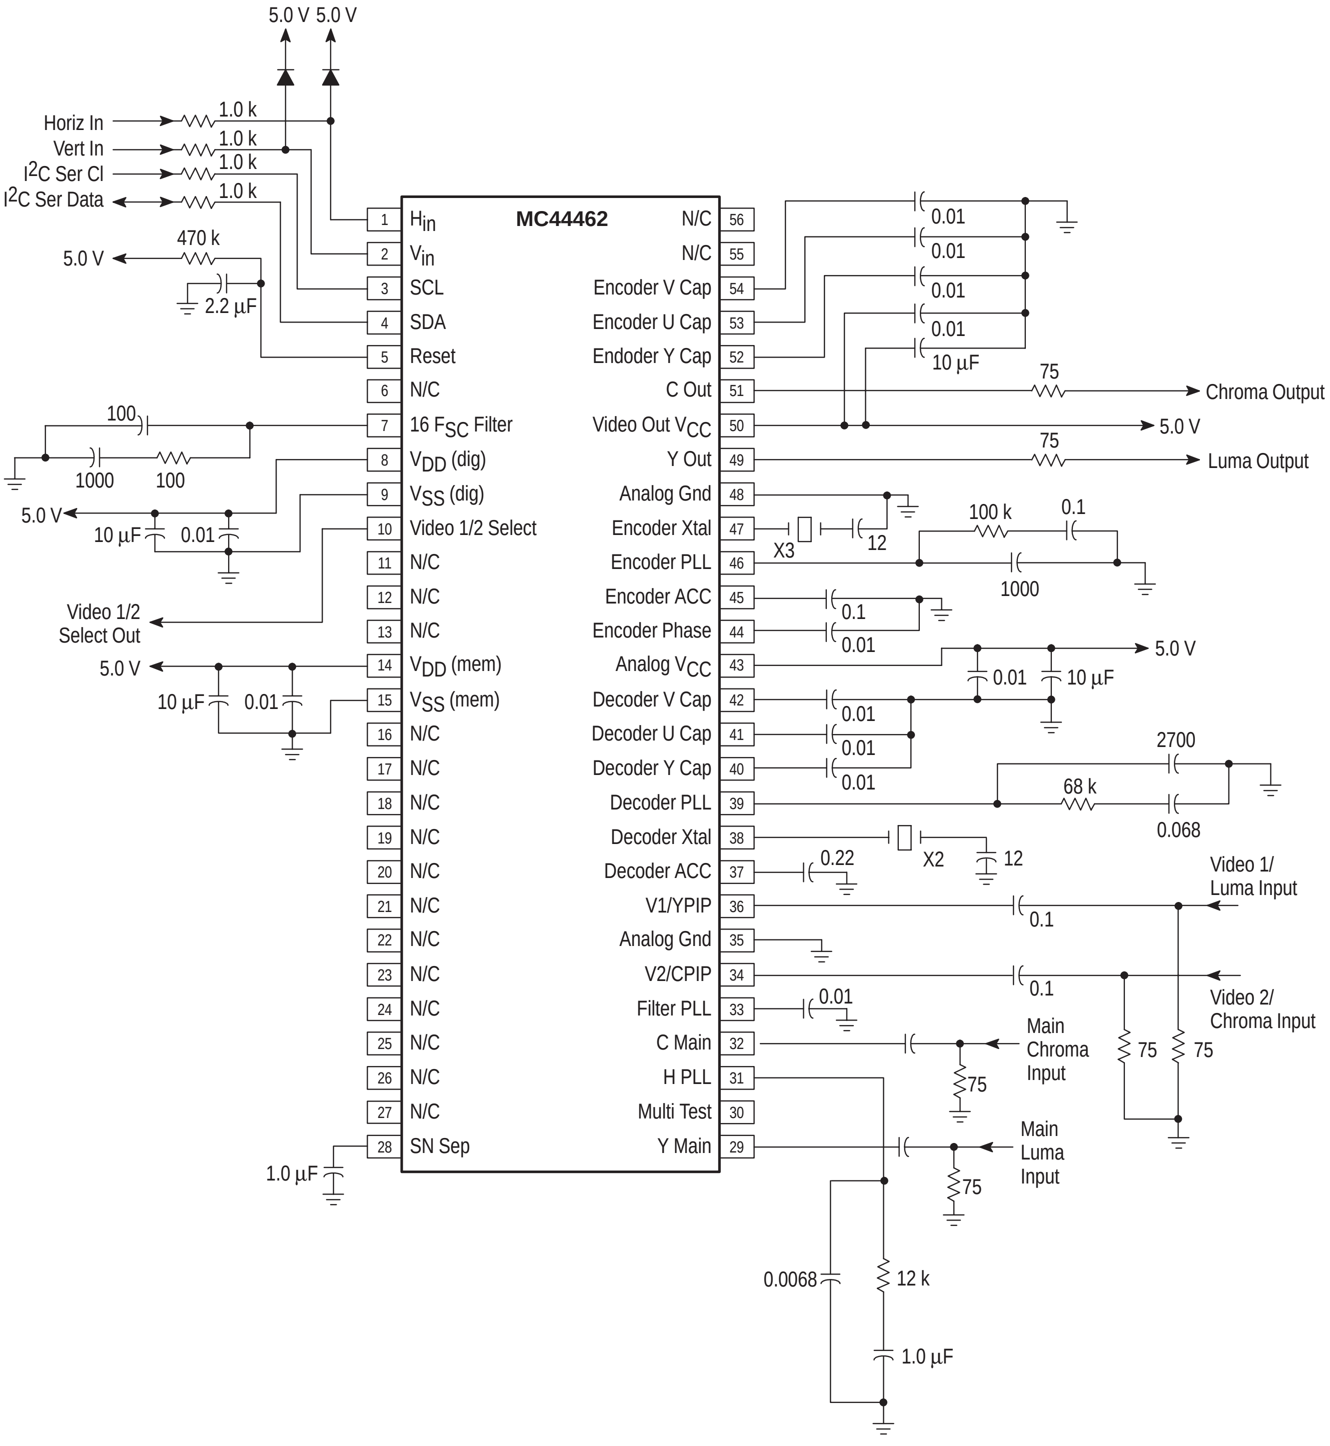
Figure 2. Application Circuit



X2 – 14.31818 MHz – Fox 143–20 or equivalent
X3 – 14.31818 MHz – Fox 143–20 or equivalent

NOTE: For proper noise isolation, Power Supply Pins 8, 14, 43 and 50 should be bypassed by both high and low frequency capacitors. As a guideline, a 10 µF in parallel with a 0.1 µF at each supply pin is recommended.

I^{2}C REGISTER DESCRIPTIONS

Base write address = 24h

Base read address = 25h

Read Register

There are two active bits in the single read byte available from the MC44462 as follows:

Write Vertical Indicator (WVI0) – D7

When 0 indicates that the write operation specified by the last I^{2}C command has been completed.

PIP Sync Detect Bit (PSD0) – D1

When 0 indicates that the PIP video H pulses are present and the horizontal timebase oscillator is within acceptable limits.

Write Registers

Read Start Position/Write Start Position Registers
Sub–address = 00h

Write Raster Position Start Bits (WPS0–2) – D0–D2

Establishes the horizontal beginning of the PIP and its black level measurement gate. This beginning may be varied by approximately 3.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Read Raster Position Bits (RPS0–3) – D4–D7

Establishes the clamp gate position for the black level reference for the main picture. This position may be varied by approximately 5.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Pip Switch Delay/Vertical Filter Register
Sub–address = 01h

PIP Switch Delay Bits (PSD0–3) – D0–D3

Delays the start of PIP on time relative to the PIP picture. These bits are used to center the PIP border and PIP picture in the horizontal direction.

Vertical Filter Bit (VFON) – D4

When the filter is activated (VFON = 1) a three line weighted average is taken to provide the data stored in the field memory.

Border Color Register
Sub–address = 02h

Border Color Bits (BC0–2) – D0–D2

These Bits control the color of the border. Note that when using one of the saturated border colors it is possible to get objectionable dot crawl at the edge of the border in some TVs unless appropriate comb filtering is used in the TV circuitry.

BC (2:0)	Border Color
000	Black
001	White 70%
010	No Border (clear)
011	No Border (clear)
100	Blue
101	Green
110	Red
111	White

Test Mode/Main Vertical and Horizontal Polarity Register
Sub–address = 03h

Internal Test Mode Register (ITM0–2) – D0–D2

Sets the Multi Test Pin output to provide one of several internal signals for test and production alignment. Also controls the test memory address counter.

ITM (2:0)	Multi–Test I/O and Function
000	Input – Analog Test mode
001	Input – Digital Test mode
010	Output – Sync Detect
011	Output – PIP Switch
100	Output – PIP H Detect
101	Output – PIP V Detect
110	Output – PIP Clamp
111	Output – Main Clamp

Main vertical polarity select bit (MVP0) – D6

Selects polarity of active level of vertical reference input. 0 = positive going, 1 = negative going.

Main horizontal polarity select bit (MHP0) – D7

Selects polarity of active level of horizontal reference input. 0 = positive going, 1 = negative going.

PIP Freeze/PIP Size/Main and PIP Video Source Register
Sub–address = 04h

PIP Freeze Bit (STIL0) – D4

When set to one, the most recently received field is continuously displayed until the freeze bit is cleared.

PIP Size Bit (PSI90) – D5

Switches the PIP size between 1/16 main size (when 0) and 1/9 main size (when 1).

Video Type Select Bit (YCPSEL) – D6

Selects which video type will be applied to the PIP input.

PIP Video Source Select Bit (PSEL0) – D7

Selects which composite video input will be applied to the video decoder to provide the PIP video in CV mode.

PSEL	YCPSEL	Function
0	1	YC Input to PIP
0 1	0	CV$_1$ Input to PIP CV$_2$ Input to PIP

PIP On/PIP Blank Register
Sub–address = 05h

PIP On Bit (PON0) – D0

When on (1) turns the PIP on.

PIP Blanking Bit (PBL0) – D4

When on (1) sets the PIP to black. If the PIP is off, then it will be black if it is turned on. Overrides all other settings of the PIP control.

PIP X Position Register
Sub–address = 06h

X Position Bits (XPS0–5) – D0–D5

Moves the PIP start position from the left to the right edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Y Position Register

Sub–address = 07h

Y Position Bits (YPS0–5) – D0–D5

Moves the PIP start position from the top to the bottom edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Chroma Level Register

Sub–address = 08h

Chroma (C0–5) – D0–D5

The color of the PIP can be adjusted to suit viewer preference by setting the value stored in these bits. A total of 64 steps varies the color from no color to maximum. This control acts in conjunction with the auto phase control.

PIP Tint Level Register

Sub–address = 09h

Tint (T0–5) – D0–D5

An auto phase control compares the main color burst to the internally generated pseudo color burst so that the tints are matched. In addition to this, the tint of the PIP can be varied ±10° in a total of 64 steps by changing the value of these bits to suit viewer preference.

PIP Luma Delay Register

Sub–address = 0Ah

Y Delay (YDL0–2) – D0–D2

Since the Chroma passes through a bandpass filter and the color decoder, it is delayed with respect to the Luma signal. Therefore, to time match the Luma and Chroma these bits are set to a single value determined to be correct in the application.

Pip Fill/Test Register

Sub–address = 0Ch

PIP Fill Bits (PIPFILL0–1) – D0–D1

May be used to fill the PIP with one of three selectable solid colors

Test Register Bits (INTC0 and MACR0) – D6–D7

Used for production test only.

Picture-in-Picture (PIP) Controller

The MC44463 Picture–In–Picture (PIP) controller is a low cost member of a family of high performance PIP controllers and video processors for television. It is a follow–up to the MC44461 PIP, in which two additional modes of operation have been added. A replay mode is provided, which captures several seconds of the main picture for replay in four different speeds. The capture time is programmable in four resolutions (ratio of captured fields to total fields), which trade the number of fields captured to the length of replay time. The second additional mode provides for multiple small picture overlays from a second non–synchronized source. The number of PIP images is 3 for the 1/9 screen area and 4 for the 1/16 screen area. Like the MC44461 this is NTSC compatible, I^2C bus controlled and available in the 56–pin shrink dip (SDIP) package.

The main features of the MC44463 are:

- Three PIP Functional Modes: Standard Single Active PIP Mode, Up to 8 Seconds of Capture and Replay Mode, and a 3 or 4 Multiple PIP Mode – Vertical Stacked with 1 Active at Any One Time
- 4 Capture Resolutions – 1 out of 10, 1:8, 1:6, 1:4. 4 Playback Speeds = 1 Times Acquire Speed; 1/2; 1/4; 1/8
- Full 2 Frame Store for the Single PIP Removes the Rolling Store/Playback Memory Interference – “Joint Line”
- External Memory for Replay and Multiple Modes: 4 Meg and 16 Meg
- Two NTSC CVBS Inputs – Switchable Main and PIP Video Signals
- Single NTSC CVBS Output Allows Simple TV Chassis Integration
- Two PIP Sizes; 1/16 and 1/9 Screen Area – Freeze Field Feature
- Variable PIP Position in 64–X by 64–Y Steps
- PIP Border with Programmable Color
- Programmable PIP Tint and Saturation Control
- Automatic Main to PIP Contrast Balance
- Vertical Filter
- I^2C Bus Control – No External Variable Adjustments Needed
- Operates from a Single 5.0 V Supply
- Economical 56–Pin Shrink DIP Package

I²C REGISTER DESCRIPTIONS

Base write address = 26h

Base read address = 27h

Read Register

There are two active bits in the single read byte available from the MC44463 as follows:

Write Vertical Indicator (WVI0) – D7

When 0 indicates that the write operation specified by the last I²C command has been completed.

PIP Sync Detect Bit (PSD0) – D1

When 0 indicates that the PIP video H pulses are present and the horizontal timebase oscillator is within acceptable limits.

Write Registers

Read Start Position/Write Start Position Registers

Sub–address = 00h

Write Raster Position Start Bits (WPS0–2) – D0–D2

Establishes the horizontal beginning of the PIP and its black level measurement gate. This beginning may be varied by approximately 3.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Read Raster Position Bits (RPS0–3) – D4–D7

Establishes the clamp gate position for the black level reference for the main picture. This position may be varied by approximately 5.0 µs. The position of this pulse may be observed through the Multi Test Pin 30 (See Test Mode Register Sub–address 03h).

Pip Switch Delay/Vertical Filter Register

Sub–address = 01h

PIP Switch Delay Bits (PSD0–3) – D0–D3

Delays the start of PIP on time relative to the PIP picture. These bits are used to center the PIP border and PIP picture in the horizontal direction.

Vertical Filter Bit (VFON) – D4

When the filter is activated (VFON = 1) a three line weighted average is taken to provide the data stored in the field memory.

Border Color Register

Sub–address = 02h

Border Color Bits (BC0–2) – D0–D2

These Bits control the color of the border. Note that when using one of the saturated border colors it is possible to get objectionable dot crawl at the edge of the border in some TVs unless appropriate comb filtering is used in the TV circuitry.

BC (2:0)	Border Color
000	Black
001	White 70%
010	No Border (clear)
011	No Border (clear)
100	Blue
101	Green
110	Red
111	White

Test Mode/Main Vertical and Horizontal Polarity Register

Sub–address = 03h

Internal Test Mode Register (ITM0–2) – D0–D2

Sets the Multi Test Pin output to provide one of several internal signals for test and production alignment. Also controls the test memory address counter.

ITM (2:0)	Multi–Test I/O and Function
000	Input – Analog Test mode
001	Input – Digital Test mode
010	Output – Sync Detect
011	Output – PIP Switch
100	Output – PIP H Detect
101	Output – PIP V Detect
110	Output – PIP Clamp
111	Output – Main Clamp

Main vertical polarity select bit (MVP0) – D6

Selects polarity of active level of vertical reference input. 0 = positive going, 1 = negative going.

Main horizontal polarity select bit (MHP0) – D7

Selects polarity of active level of horizontal reference input. 0 = positive going, 1 = negative going.

PIP Freeze/PIP Size/Main and PIP Video Source Register

Sub–address = 04h

LIVE PIP Select Bits (LIVE_P0–1) – D0–D1

Selects which of the mutliple PIP pictures is the active “live” one.

LIVE_P (1:0)	1/16 Size	1/9 Size
00	Top = LIVE	Top = LIVE
01	2nd from Top = LIVE	2nd from Top = LIVE
10	3rd from Top = LIVE	3rd from Top = LIVE
11	4th from Top = LIVE	3rd from Top = LIVE

PIP Freeze Bit (STIL0) – D4

When set to one, the most recently received field is continuously displayed until the freeze bit is cleared.

PIP Size Bit (PSI90) – D5

Switches the PIP size between 1/16 main size (when 0) and 1/9 main size (when 1).

Main Video Source Select Bit (MSEL0) – D6

Selects which video input will be applied to the PIP switch as the main video out.

PIP Video Source Select Bit (PSEL0) – D7

Selects which video input will be applied to the video decoder to provide the PIP video.

MSEL/PSEL	Function
0	Video 1 Input to Main/ Video 1 Input to PIP
1	Video 2 Input to Main/ Video 2 Input to PIP

PIP On/PIP Blank Register

Sub–address = 05h

PIP On Bits (PON0–3) – D4–D3

When on (1) turns the corresponding PIP display on.

PON (3:0)	1/16 Size	1/9 Size
0000	No PIP	No PIP
0001	Top = On	Top = On
0010	2nd from Top = On	2nd from Top = On
0100	3rd from Top = On	3rd from Top = On
1000	4th from Top = On	3rd from Top = On

PIP Blanking Bits (PBL0–3) – D4–D7

When on (1) sets the corresponding PIP to black. If the individual PIP is off, then it will be black when it is turned on.

PBL (7:4)	Function
0000	PIP Picture Normal
0001	Top = Blanked (Set to Black)
0010	2nd from Top = Blanked (Set to Black)
0100	3rd from Top = Blanked (Set to Black)
1000	4th from Top = Blanked (Set to Black)

PIP X Position Register

Sub–address = 06h

X Position Bits (XPS0–5) – D0–D5

Moves the PIP start position from the left to the right edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Y Position Register

Sub–address = 07h

Y Position Bits (YPS0–5) – D0–D5

Moves the PIP start position from the top to the bottom edge of the display in 64 steps. There is protection circuitry to prevent the PIP from interfering with the main picture sync pulses.

PIP Chroma Level Register

Sub–address = 08h

Chroma (C0–5) – D0–D5

The color of the PIP can be adjusted to suit viewer preference by setting the value stored in these bits. A total of 64 steps varies the color from no color to maximum. This control acts in conjunction with the auto phase control.

PIP Tint Level Register

Sub–address = 09h

Tint (T0–5) – D0–D5

An auto phase control compares the main color burst to the internally generated pseudo color burst so that the tints are matched. In addition to this, the tint of the PIP can be varied ±10° in a total of 64 steps by changing the value of these bits to suit viewer preference.

PIP Luma Delay Register

Sub–address = 0Ah

Y Delay (YDL0–2) – D0–D2

Since the Chroma passes through a bandpass filter and the color decoder, it is delayed with respect to the Luma signal. Therefore, to time match the Luma and Chroma these bits are set to a single value determined to be correct in the application.

PIP Acquire/Playback Register

Sub–address = 0Bh

PIP Acquire Speed Bits (ACQ_SP0–1) – D0–D1

These select the speed of the video acquisition. This is only active when RE_AQ = 1.

ACQ_SP (1:0)	Function
00	Acquire 1 Out of Every 4 Fields
01	Acquire 1 Out of Every 6 Fields
10	Acquire 1 Out of Every 8 Fields
11	Acquire 1 Out of Every 10 Fields

PIP Save/Clear Bit (RE_AQ) –D2

This bit controls the save and clear function for the instant replay. The bit value 1 is only effective when PON0–3 = 0000. (No PIP display.)

RE_AQ (2:2)	Function
0	Save Memory
1	Clear Reacquire

PIP Playback Speed Bits (PB_SP0–1) – D4–D5

These bits control the relative playback speed, to the acquired speed.

PB_SP (5:4)	Function
00	Playback at 1 x ACQ_SP Speed
01	Playback at 1/2 x ACQ_SP Speed
10	Playback at 1/4 x ACQ_SP Speed
11	Playback at 1/8 x ACQ_SP Speed

PIP Playback Control Bit (PB) – D6

This bit controls the start/stop of the instant replay function.

PB (6:6)	Function
0	No Action
1	Instant Replay Activated

PIP Fill/Background/Free Run/Test Register

Sub–address = 0Ch

PIP Fill Bits (PIPFILL0–1) – D0–D1

May be used to fill the PIP with one of three selectable solid colors

PIPFILL (1:0)	Function
00	Normal
01	Red
10	Green
11	Blue

Test Register Bits (INTC0 and MACR0) – D6–D7

When the FRUN is set to 1 the circuitry provides a generated sync and displays a flat field that can be either dark blue or gray determined by the BGND bit.

BGND (2:2)	Function
0	Blue
1	50% White

Function Control of the MC44463

There are three modes of operation; Single PIP, Multiple PIP and Replay. These are enabled by setting specific register bits in the I^{2}C register set.

Single PIP (SPIP) Operation

Register 0Bh : D6 –> 0

Register 05h : D0–D7 –> 01h

Multiple PIP (MPIP) Operation

Register 05h : D0–D3 –> 07h or 0Fh

Register 04h : D0–D1 –> 0 to 3

Register 0Bh : D6 –> 0

Register 0Ch : D5 –> 1, D2 –> 0 or 1 (Optional)

Replay PIP (RPIP) Operation

In sequence, the Capture Ready mode must be first activated, allowing up to 8 seconds of fill memory with the desired video stream. Then the Capture mode must be set, disabling further write to memory. The Capture data may be re–displayed at any time afterword.

Capture Ready

Register 05h : D0–D3 –> 0

Register 0Bh : D6 –> 0, D2 –> 1, D0–D1 –> 0 to 3

Capture

Register 0Bh : D6 –> 1, D2 –> 0, D4–D5 –> 0 to 3

Register 05h: D0 –> 1

MOTOROLA

MC44817/17B

PLL Tuning Circuits with 3-Wire Bus

The MC44817/17B are tuning circuits for TV and VCR tuner applications. They contain on one chip all the functions required for PLL control of a VCO. The integrated circuits also contain a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44817 has programmable 512/1024 reference divider while the MC44817B has a fixed reference divider of 1024.

The MC44817/17B are manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (3–Wire Bus). Data and Clock Inputs are IIC Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Reference Divider: Programmable for Division Ratios 512 and 1024. The MC44817B has a Fixed 1024 Reference Divider
- Tri–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Integrated PNP Band Buffers for 40 mA (V_{CC1} to 14.4 V)
- Output Options for the Reference Frequency and the Programmable Divider
- Bus Protocol for 18 or 19 Bit Transmission
- Extra Protocol for 34 Bit for Test and Further Features
- High Sensitivity Preamplifier
- Circuit to Detect Phase Lock
- Fully ESD Protected

MOSAIC is a trademark of Motorola, Inc.

Data Format and Bus Receiver

The circuit is controlled by a 3–wire bus via Data (DA), Clock (CL), and Enable (EN) inputs. The Data and Clock inputs may be shared with other inputs on the IIC–Bus while the Enable is a separate signal. The circuit is compatible with 18 and 19 bit data transmission and also has a mode for 34 bit transmission for test and additional features.

The 3–wire bus receiver receives data for the internal shift register after the positive going edge of the EN–signal. The data is transmitted to the band buffers on the negative going edge of the clock pulse 4 (signal DTB1).

18 and 19 Bit Data Transmission

The programmable divider may receive 14 bit (18 bit transmission) or 15 bit (19 bit transmission). The data is transmitted to the programmable divider (latches A) on the negative going edge of clock pulse 19 or on the negative edge of the EN–signal if EN goes down after the 18th clock pulse (signal DTF). If the programmable divider receives 14 bit, its MSB (bit N_{14}) is internally reset. The reset pulse is generated only if EN goes negative after the 18th clock pulse (signal RL).

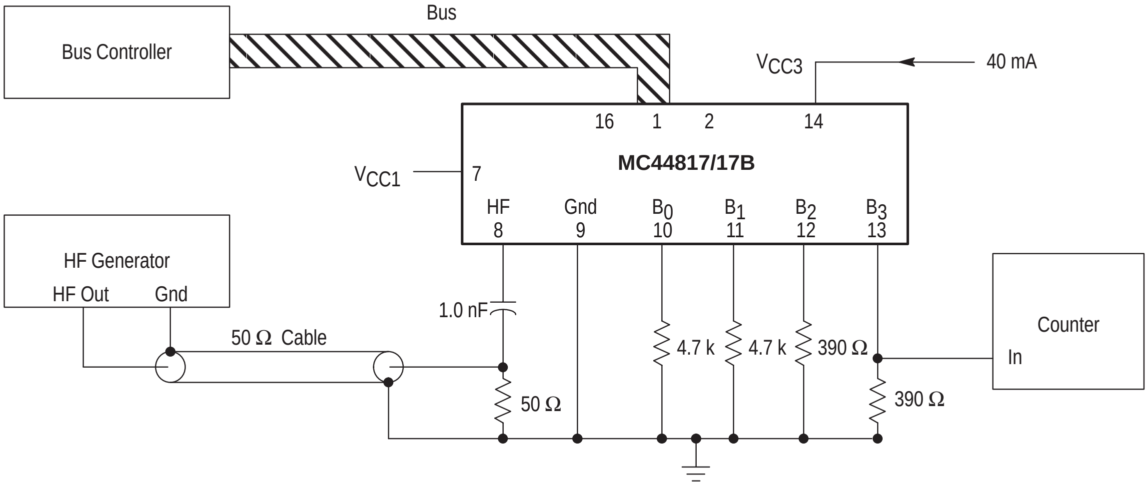
34 Bit Data Transmission
(For Test and Additional Features)

In the test mode, the programmable divider receives 15 bit and the data is transferred to latches A on the negative edge of clock pulse 19 (signal DTF). The information for test is received on clock pulses 20 to 26 and transmitted to the latches on the negative edge of pulse 34 (signal DTB2). These latches have a power–on reset. The power–on reset sets the programmable divider to a counting ratio of 256 or higher and resets the corresponding latches to the test bits T_0 to T_6 (signal POR). The bus receiver is not disturbed if the data format is wrong. Useless bits are ignored. If for example the Enable signal goes low after the clock pulse 9, bits one to four are accepted as valid buffer information and the other bits are ignored. If more than 34 bits are received, bit 35 and the following are ignored.

Lock Detector

The lock–detector output is low in lock. The output goes immediately high when an unlock condition is detected. The output goes low again when the loop is in lock during a complete period of the reference frequency.

Figure 1. HF Sensitivity Test Circuit



Device is in test mode. B_2, B_3 are "On" and B_0, B_1 are "Off".
Sensitivity is level of HF generator on 50 Ω load (without Pin 8 loading).

HF CHARACTERISTICS (See Figure 1)

Characteristic	Pin	Min	Typ	Max	Unit
DC Bias	8	–	1.6	–	V
Input Voltage Range					mVrms
10–80 MHz, Prescaler "Off", $T_6 = 1.0$	8	20	–	315	
80–150 MHz	8	10	–	315	
150–600 MHz	8	5.0	–	315	
600–950 MHz	8	10	–	315	
950–1300 MHz	8	50	–	315

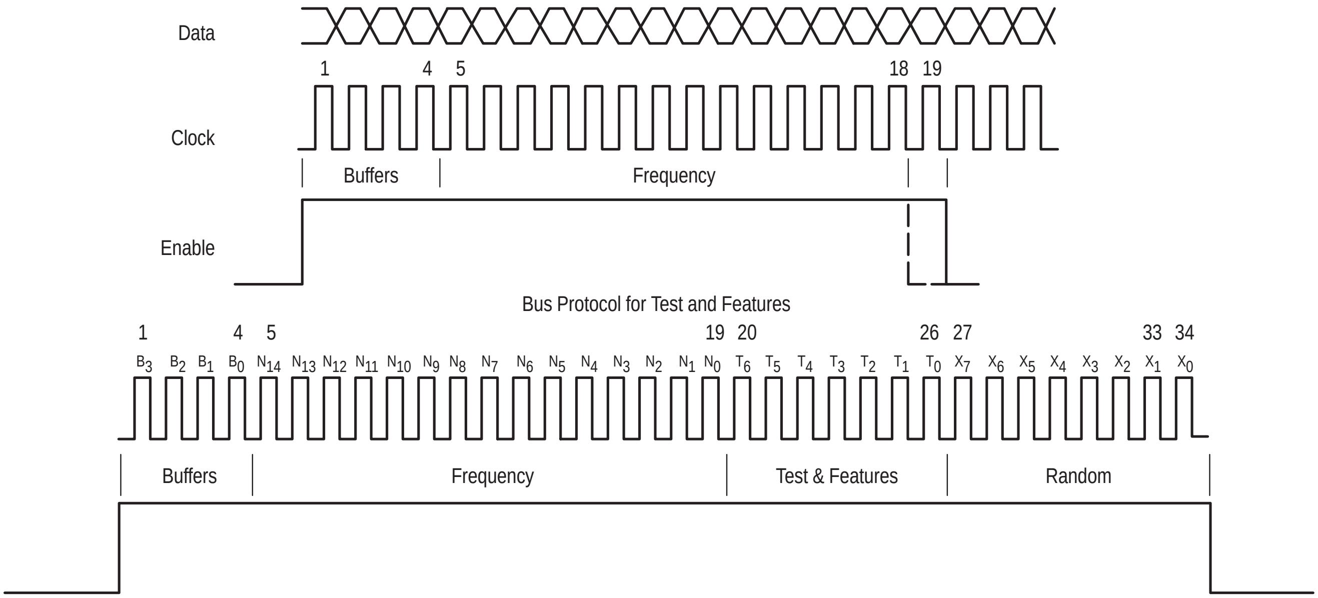
Bus Timing Diagram

Standard Bus Protocol 18 or 19 Bit



Definition of Permissible Bus Protocols

1. Bus Protocol for 18 Bit
   B_3 B_2 B_1 B_0 N_{13} N_{12} N_{11} N_{10} N_9 N_8 N_7 N_6 N_5 N_4 N_3 N_2 N_1 N_0
   Max Counting Ratio 16363
   N_{14} is Reset Internally
2. Bus Protocol for 19 Bit
   B_3 B_2 B_1 B_0 N_{14} N_{13} N_{12} N_{11} N_{10} N_9 N_8 N_7 N_6 N_5 N_4 N_3 N_2 N_1 N_0
   Max Counting Ratio 32767
   - B_0 to B_3: Control of Band Buffers
   - N_0 to N_{14}: Control of Programmable Dividers

   N_{14} = MSB; N_0 = LSB
   Minimum Counting Ratio Always 17
   B_3 = First Shifted Bit
   N_0 = Last Shifted Bit
3. Bus Protocol for Test and Further Features (34 Bit)
   B_3 B_2 B_1 B_0 N_{14}…N_0 T_6 T_5 T_4 T_3 T_2 T_1 T_0 X_7 X_6…X_1 X_0
   - T_0 to T_3: Control the Phase Comparator
   - T_4: Switches Test Signals to the Buffer Outputs
   - T_5: Division Ratio of the Reference Divider
     B Version T_5 = “X”
   - T_6: Bypasses the Prescaler (Note 1)
   - X_0 to X_7: Are Random

   B_3 = First Shifted Bit
   X_0 = Last Shifted Bit

Definition of the Bits for Test and Features

Bit T_0: Defines the Charge Pump Current of the Phase Comparator

T_0 = 0 = 1	Pump Current 50 µA Typical Pump Current 15 µA Typical

Bits T_1 and T_2: Define the Digital Function of the Phase Comparator

T_2	T_1	State	Output Function of Phase Comparator
0	0	1	Normal Operation
0	1	2	High Impedance (Tri–State)
1	0	3	Upper Source “On”, Lower Source “Off”
1	1	4	Lower Source “On”, Upper Source “Off”

NOTE: 1. The phase comparator pulls high if the input frequency is too high and it pulls low when the input frequency is too low. (Inversion by Operational Amplifier) The phase comparator generates a fixed duration offset pulse for each comparison pulse (similar to the MC44802A). This guarantees operation in the linear region. The offset pulse is a positive current pulse (upper source).

Bit T_3: Defines the Offset Pulse of the Phase Comparator

T_3 = 0	Offset Pulse Short (200 ns) Normal Mode
= 1	Offset Pulse Long (350 ns)

Bit T_4: Switches the Internal Frequencies F_{ref} and FBY2 to the Buffer Outputs (B_2, B_3)

T_4 = 0	Normal Operation
= 1	F_{ref} Switched to Buffer Output B_2 FBY2 Switched to Buffer Output B_3

NOTE: Bits B_2 and B_3 have to be one in this case.
F_{ref} is the reference frequency.
FBY2 is the output frequency of the programmable divider, divided by two.

Bit T_5: Defines the Division Ratio of the Reference Divider

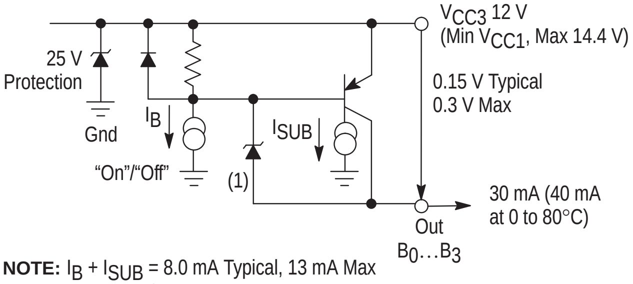
T_5 = 0 = 1	Division Ratio 512 Division Ratio 1024

NOTE: The division ratio of the reference divider can only be programmed in the 34 bit bus protocol.
In the standard bus protocol the division ratio is 512.
(The power–up reset POR sets the division ratio to 512).
On “B–version”, T_5 = “X”. Division ratio 1024 fixed.

Bit T_6: Switches the Prescaler

$T_6 = 0$	Normal Operation, 1.3 GHz
= 1	Low Frequency Operation Preamp. 2 Switched Off, 165 MHz maximum The prescaler is bypassed and the power supply of the prescaler is switched off. Input: 10 MHz minimum, 20 mVrms minimum

Figure 4. Equivalent Circuit of the Integrated Band Buffers



NOTE: $I_B + I_{SUB}$ = 8.0 mA Typical, 13 mA Max
I_B = Base Current
I_{SUB} = Substrate Current of PNP

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider; this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:

$N = 16384 \times N_{14} + 8132 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$

Maximum Ratio 32767
(16363 in case of 18 bit bus protocol)
Minimum Ratio 17
$N_0 \ldots N_{14}$ are the different bits for frequency information.

At power–on the whole bus receiver is reset and the programmable divider is set to a counting ratio of N = 256 or higher.

The Prescaler

The prescaler has a preamplifier which guarantees high input sensitivity.

The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

The Operational Amplifier

The operational amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The operational amplifier needs 28.5 V supply (V_{CC2}) as minimum voltage for a guaranteed maximum tuning voltage of 28 V.

Figure 6 shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

The Oscillator

The oscillator uses a 3.2 to 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in the series resonance mode.

The voltage at Pin 3 has low amplitude and low harmonic distortion.

Figure 5. Equivalent Circuit of the Lock Output

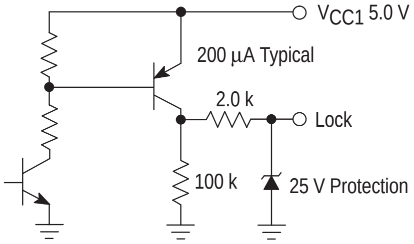


Figure 6. Typical Tuner Application

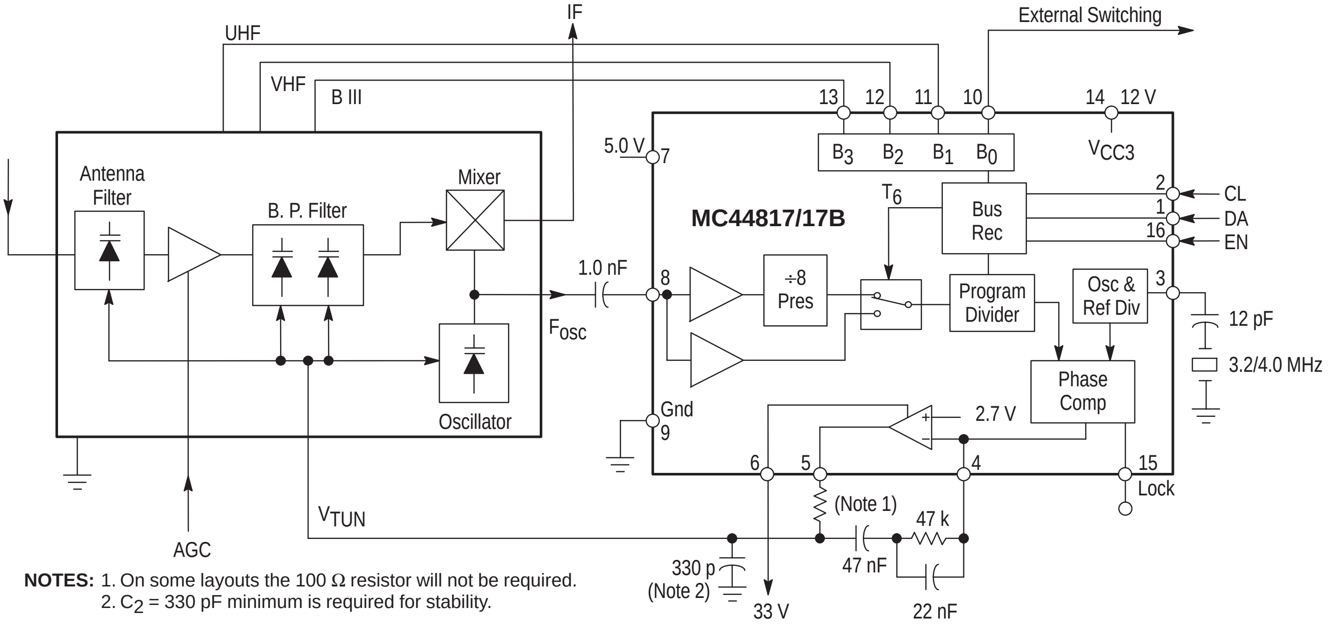

NOTES: 1. On some layouts the 100 Ω resistor will not be required.
2. C_2 = 330 pF minimum is required for stability.

MC44818

PLL Tuning Circuit with I^{2}C Bus

The MC44818 is a tuning circuit for TV and VCR tuner applications. It contains, on one chip, all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz. The MC44818 is a pin compatible drop in replacement for the MC44817, where the only difference is the MC44818 has a fixed divide–by–8 prescaler (cannot be bypassed) and the MC44817 uses the three wire bus.

The MC44818 has a programmable 512/1024 reference divider and is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus). Data and Clock Inputs are 3–Wire Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Reference Divider: Programmable for Division Ratios 512 and 1024.
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Integrated PNP Band Buffers for 40 mA (V_{CC1} to 14.4 V)
- Output Options for the Reference Frequency and the Programmable Divider
- High Sensitivity Preamplifier
- Circuit to Detect Phase Lock
- Fully ESD Protected

MOSAIC is a trademark of Motorola, Inc.

Data Format and Bus Receiver

The circuit receives the information for tuning and control via the I^2C bus. The incoming information, consisting of a chip address byte followed by two or four data bytes, is treated in the I^2C bus receiver. The definition of the permissible bus protocol is shown below:

1_STA CA CO BA STO
2_STA CA FM FL STO
3_STA CA CO BA FM FL STO
4_STA CA FM FL CO BA STO

STA = Start Condition
STO = Stop Condition
CA = Chip Address Byte
CO = Data Byte for Control Information
BA = Band Information
FM = Data Byte for Frequency Information
FL = Data Byte for Frequency Information

Figure 1. Complete Data Transfer Process

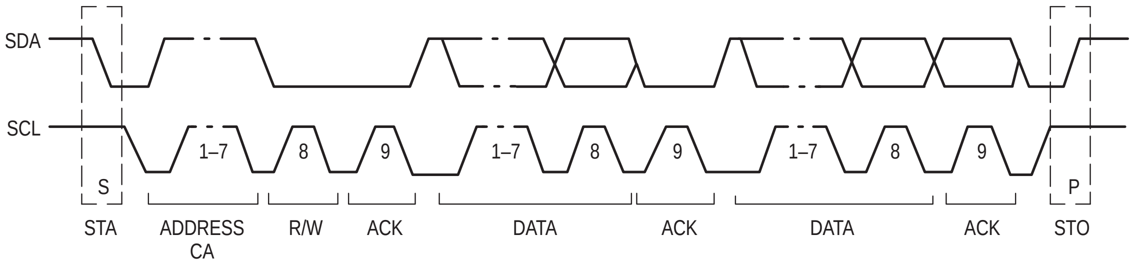

Figure 2 shows the five bytes of information that are needed for circuit operation: there is the chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received the third data byte is ignored.

If five or more data bytes are received the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit which allows the IC to distinguish between frequency information and control plus band information.

Frequency information is preceeded by a Logic “0”. If the function bit is Logic “1” the two following bytes contain control and band information. The first data byte, shifted after the chip address, may be byte CO or byte FM.

The two permissible bus protocols with five bytes are shown in Figure 2.

Figure 2. Definition of Bytes

CA_Chip Address	1	1	0	0	0	0/1	0/1	0	ACK

Chip Address

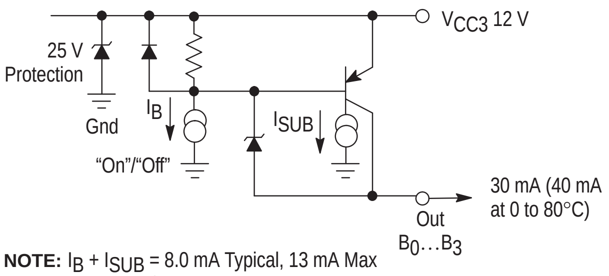
The chip address is programmable by Pin 16 (AS – Address Select).

AS – Pin 16	Address (HEX.)
Gnd to 0.1 V_{CC1}	C0
Open or 0.2 V_{CC1} to 0.3 V_{CC1}	C2
0.4 V_{CC1} to 0.7 V_{CC1}	C4
0.8 V_{CC1} to 1.1 V_{CC1}	C6

Bits B_0, B_1, B_2, B_3: Control the Band Buffers

B_0, B_1, B_2, B_3 = 0 = 1	Buffer “Off” Buffer “On”

Figure 3. Equivalent Circuit of the Integrated Band Buffers



NOTE: $I_B + I_{SUB}$ = 8.0 mA Typical, 13 mA Max
I_B = Base Current
I_{SUB} = Substrate Current of PNP

Bit T_8: Controls the Output of the Operational Amplifier

T_8 = 0	Normal Operation Operational Amplifier Active
= 1	Output State of Operational Amplifier Switched “Off”, Output Pulls High Through 20 k Internal Pull–Up Resistor

Bits T_9, T_{12}: Control the Phase Comparator

T_9	T_{12}	Function
1	0	Normal Operation
1	1	High Impedance
0	0	Upper Source “On” Only
0	1	Lower Source “On” Only

Bits T_{10}, T_{11}: Control the Reference Ratio

T_{10}	T_{11}	Division Ratio
0	0	512
0	1	1024
1	0	1024
1	1	512

Bit T_{13}: Switches the Internal Signals F_{ref} and F_{BY2} to the Band Buffer Outputs (Test)

T_{13} = 0	Normal Operation
= 1	Test Mode F_{ref} Output at B_2 (Pin 12) F_{BY2} Output at B_3 (Pin 13)

Bits B_2 and B_3 have to be “On”, $B_2 = B_3 = 1$ in the test mode.
F_{ref} is the reference frequency.
F_{BY2} is the output frequency of the programmable divider, divided by two.

Bit T_{14}: Controls the Charge Pump Current of the Phase Comparator

$T_{14} = 0$	Pump Current 15 µA Typical
$= 1$	Pump Current 50 µA Typical

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider; this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:

$N = 16384 \times N_{14} + 8192 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$

Maximum Ratio 32767

Minimum Ratio 17

$N_0 \ldots N_{14}$ are the different bits for frequency information.

At power "on" the whole bus receiver is reset and the programmable divider is set to a counting ratio of N = 256 or higher.

The Prescaler

The prescaler has a preamplifier which guarantees high input sensitivity.

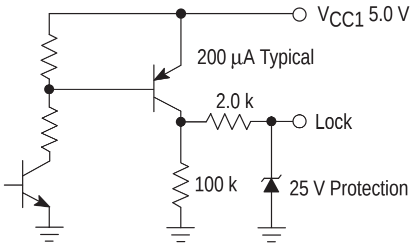
The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

Lock Detector

The lock detector output is low in lock. The output goes immediately high when an unlock condition is detected. The output goes low again when the loop is in lock during a complete period of the reference frequency.

Figure 4. Equivalent Circuit of the Lock Output



The Operational Amplifier

The operational amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The operational amplifier needs 28.5 V supply (V_{CC2}) as minimum voltage for a guaranteed maximum tuning voltage of 28 V.

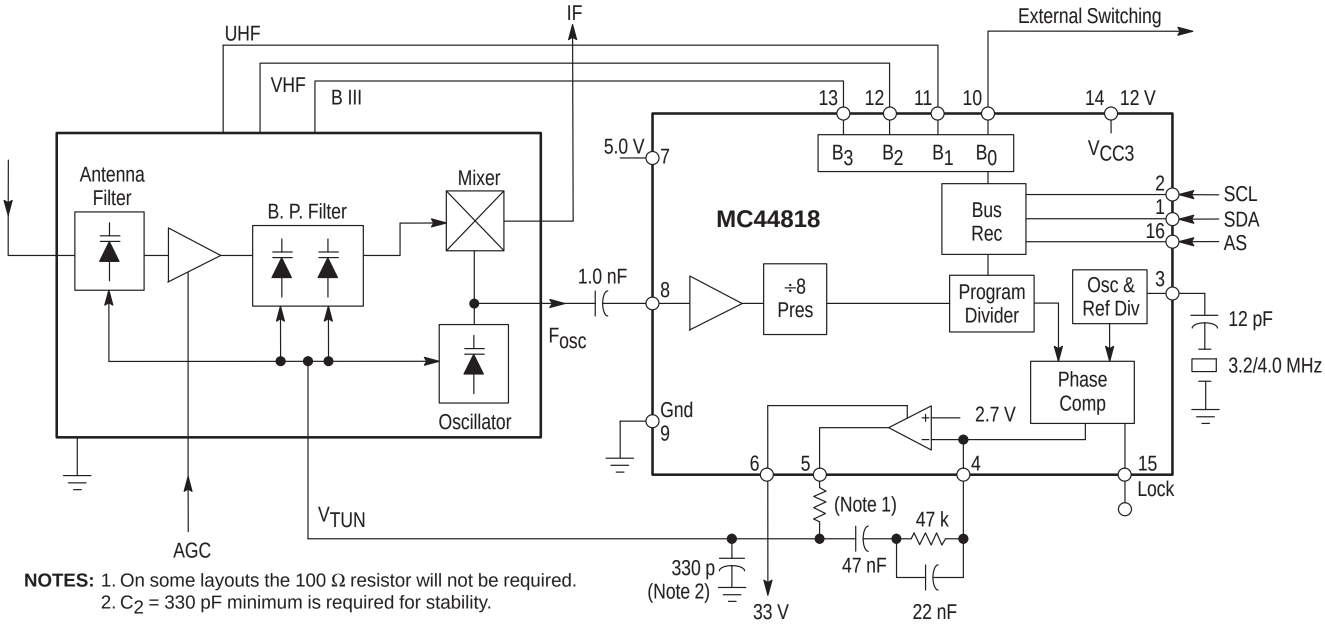
Figure 6 shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

The Oscillator

The oscillator uses a 3.2 to 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in the series resonance mode.

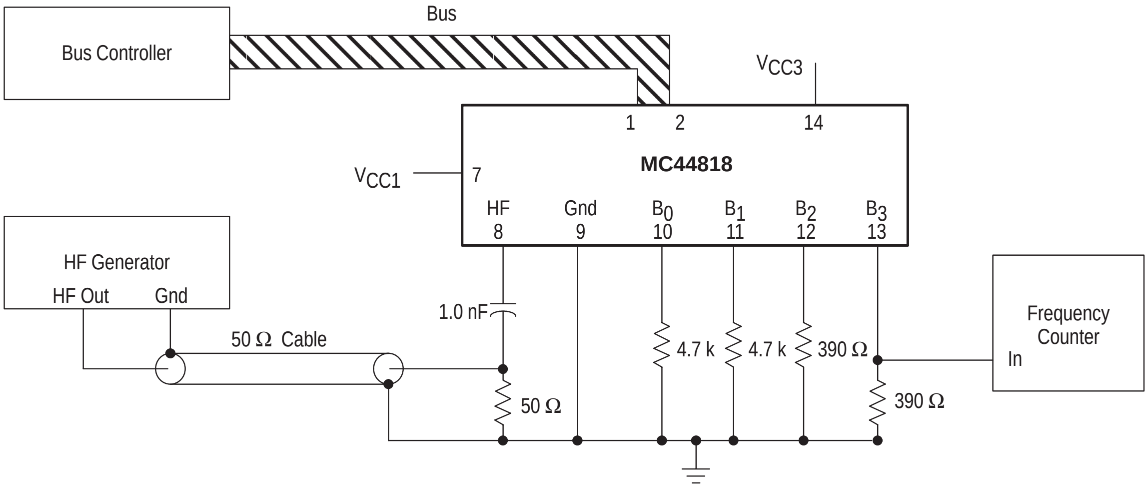
The voltage at Pin 3 has low amplitude and low harmonic distortion.

Figure 5. Typical Tuner Application



NOTES: 1. On some layouts the 100 Ω resistor will not be required.
2. C_2 = 330 pF minimum is required for stability.

Figure 6. HF Sensitivity Test Circuit



Device is in test mode. B_2, B_3 are "On" and B_0, B_1 are "Off".
Sensitivity is level of HF generator on 50 Ω load (without Pin 8 loading).

HF CHARACTERISTICS (See Figure 1)

Characteristic	Pin	Min	Typ	Max	Unit

MC44824/25

PLL Tuning Circuits with I^{2}C Bus

The MC44824/25 are tuning circuits for TV and VCR tuner applications. They contain on one chip all the functions required for PLL control of a VCO. The integrated circuits also contain a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44824/25 are manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus). Data and Clock Inputs are 3–Wire Bus Compatible
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider
- Reference Divider: Programmable for Division Ratios 512 and 1024
- 3–State Phase/Frequency Comparator
- 4 Programmable Chip Addresses
- 3 Output Buffers (MC44824) respectively 5 Output Buffers (MC44825) for 10 mA/15 V
- Operational Amplifier for use with External NPN Transistor
- SO–14 Package for MC44824 and SO–16 for MC44825
- High Sensitivity Preamplifier
- Fully ESD Protected

MOSAIC is a trademark of Motorola, Inc.

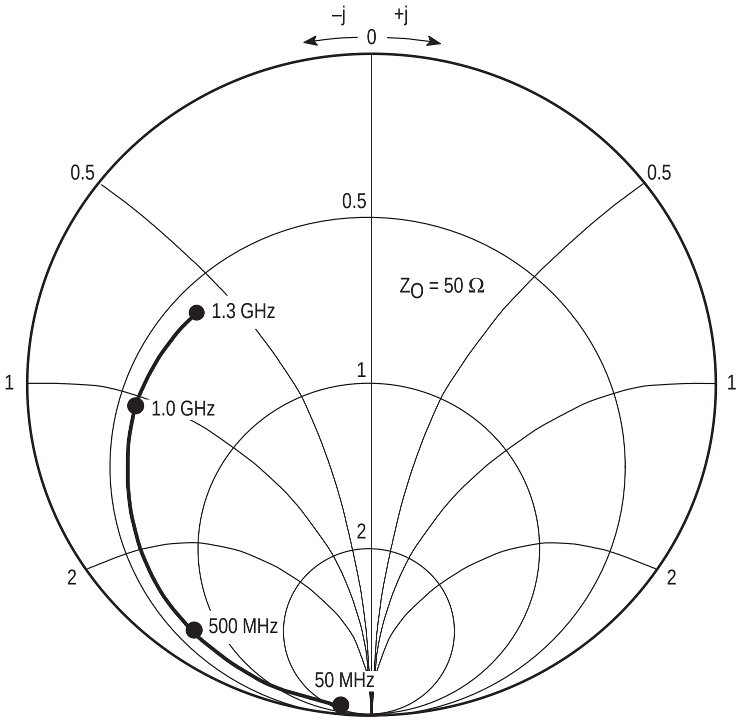
Sensitivity is level of HF generator on 50 Ω load.

Figure 2. Typical HF Input Impedance



Data Format and Bus Receiver

The circuit receives the information for tuning and control via the I^{2}C bus. The incoming information, consisting of a chip address byte followed by two or four data bytes, is treated in the I^{2}C bus receiver. The definition of the permissible bus protocol is shown below:

1_STA CA CO BA STO
2_STA CA FM FL STO
3_STA CA CO BA FM FL STO
4_STA CA FM FL CO BA STO

STA = Start Condition
STO = Stop Condition
CA = Chip Address Byte
CO = Data Byte for Control Information
BA = Band Information
FM = Data Byte for Frequency Information (MSB’s)
FL = Data Byte for Frequency Information (LSB’s)

Figure 3. Complete Data Transfer Process

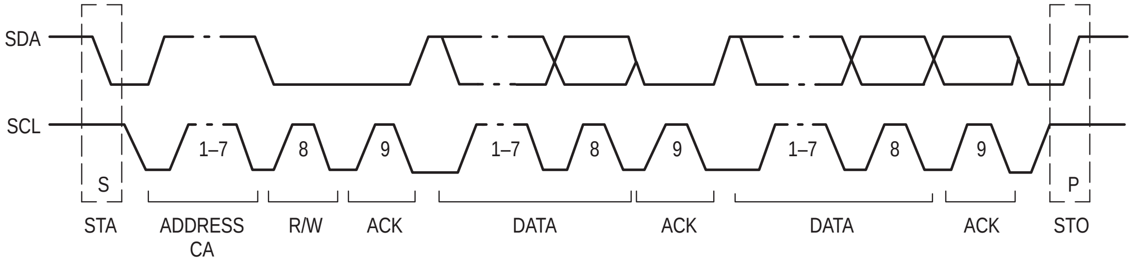


Figure 4 shows the five bytes of information that are needed for circuit operation: there is the chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received, the third data byte is ignored.

If five or more data bytes are received, the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit which allows the IC to distinguish between frequency information and control plus band information.

Frequency information is preceded by a Logic “0”. If the function bit is Logic “1” the two following bytes contain control and band information. The first data byte, shifted after the chip address, may be byte CO or byte FM.

The two permissible bus protocols with five bytes are shown in Figure 4.

0	0	512
0	1	1024
1	0	1024
1	1	512

Bit T_{13}: Switches the Internal Signals F_{ref} and F_{BY2} to the Band Buffer Outputs (Test)

$T_{13} = 0$	Normal Operation
$= 1$	Test Mode F_{ref} Output at B_7 F_{BY2} Output at B_2

Bits B_2 and B_7 have to be “Off”, $B_2 = B_7 = 0$ in the test mode.
F_{ref} is the reference frequency.
F_{BY2} is the output frequency of the programmable divider, divided by two.

Bit T_{14}: Controls the Charge Pump Current of the Phase Comparator

$T_{14} = 0$	Pump Current 40 µA Typical
$= 1$	Pump Current 125 µA Typical

The Band Buffers

BA_Band Information
MC44824 14 Pin version

B_7	X	X	X	X	B_2	B_1	X	ACK

MC44825 16 Pin version

B_7	X	X	B_4	X	B_2	B_1	B_0	ACK

The band buffers are open collector buffers and are active “low” at Bn = 1. They are designed for 10 mA with a typical “On” resistance of 160 Ω. These buffers are designed to withstand relative high output voltage in the “Off” state.

B_2 and B_7 buffers may also be used to output internal IC signals (reference frequency and programmable divider output frequency divided by 2) for test purposes.

The bit B_2 and/or B_7 have to be zero if the buffers are used for these additional functions.

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider, this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:
$N = 16384 \times N_{14} + 8192 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$
Maximum Ratio 32767
Minimum Ratio 17

Where $N_0 \ldots N_{14}$ are the different bits for frequency information.

The counter may be used for any ratio between 17 and 32767 and reloads correctly as long as its output frequency does not exceed 1.0 MHz.

The data transfer between latches A and B (signal TDI) is also initiated by any start condition on the I^2C bus.

At power–on, the whole bus receiver is reset and the programmable divider is set to a counting ration of N = 256 or higher.

The first I^2C message must be sent only when the POWER ON RESET is completed.

The Prescaler

The prescaler has a preamplifier which guarantees high input sensitivity.

The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

The Tuning Voltage Amplifier

The amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The tuning voltage amplifier needs an external NPN with a pull–up resistor to generate the tuning voltage.

The amplifier can be switched “Off” through bit T_8. When bit T_8 is “One”, the amplifier is “Off”. The tuning voltage is then pulled high by the external pull–up resistor.

Figure 5 shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

As a starting point for optimization, the component values in Figure 5 may be used for 7.8125 kHz reference frequency in a multiband TV tuner.

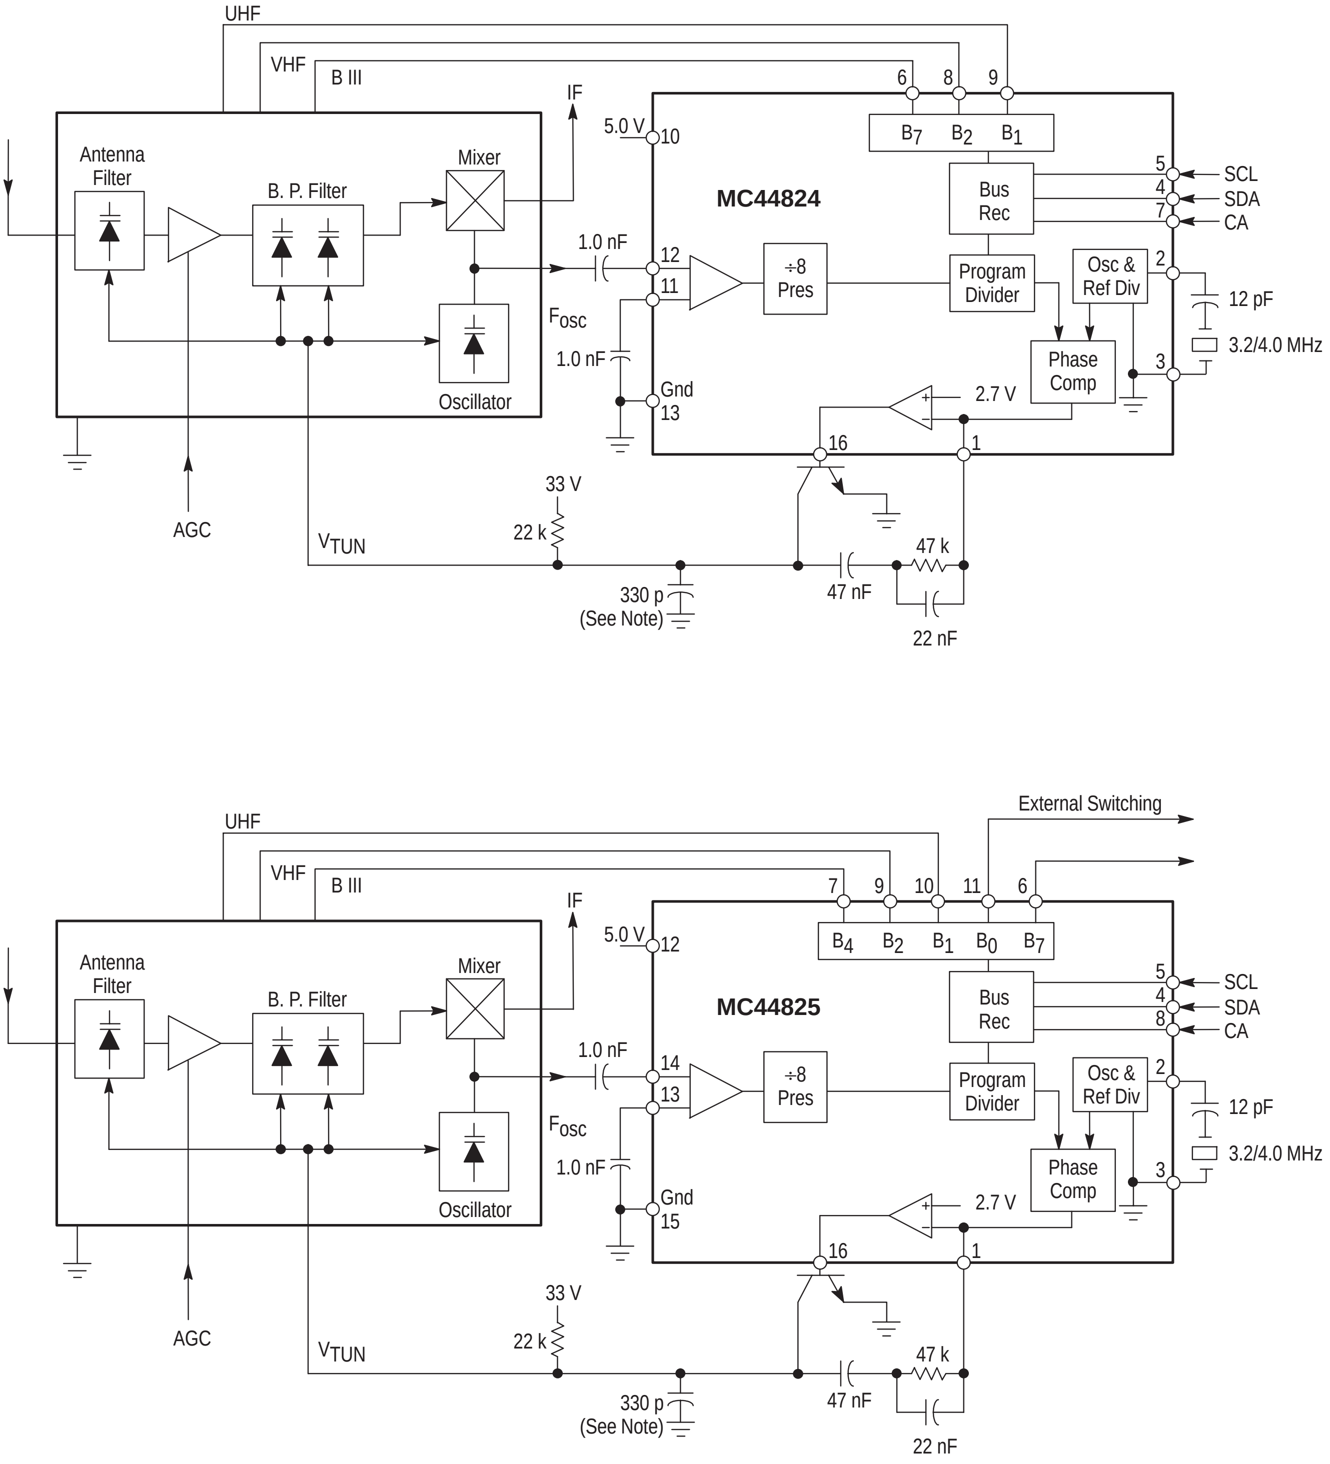
The Oscillator

The oscillator uses a 4.0 MHz crystal tied to ground “or between Pins 2 and 3” through a series capacitor. The crystal oscillates in its series resonance mode.

The voltage at Pin 13 XTAL1, has low amplitude and low harmonic distortion.

Pin XTAL2 is the internal ground of the oscillator; it is connected internally to ground Pin 13 (15).

Figure 5. Typical Tuner Applications



NOTE: C_2 = 330 pF minimum is required for stability.

MOTOROLA

MC44826

PLL Tuning Circuit with I^{2}C Bus

The MC44826 is a tuning circuit for TV and VCR tuner applications. It contains, on one chip, all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz. The circuit has a band decoder that provides the band switching signal for the mixer/oscillator circuit. The decoder is controlled by the buffer bits or independently by extra bits T_6 and T_7.

The MC44826 has a programmable 512/1024 reference divider and is manufactured on a single silicon chip using Motorola’s high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus)
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider
- Reference Divider: Programmable for Division Ratios 512 and 1024
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Programmable Chip Addresses
- Integrated Band Decoder for the Mixer/Oscillator Circuit
- Band Buffers with Low “On” Voltage (0.4 V Maximum at 15 mA)
- Fully ESD Protected to MIL–STD–883C, Method 3015.7 (2000 V, 1.5 kΩ, 150 pF)

MOSAIC is a trademark of Motorola, Inc.

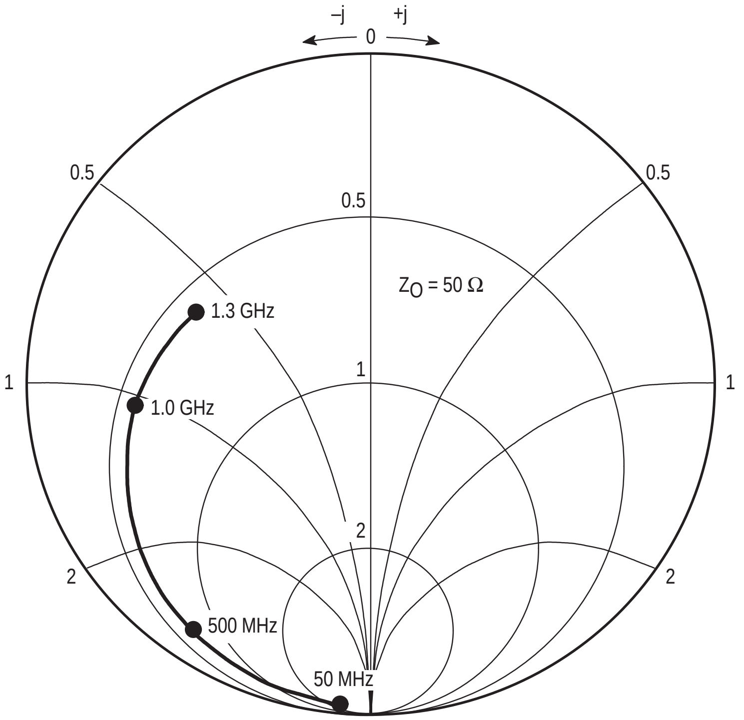

Figure 4. Complete Data Transfer Process

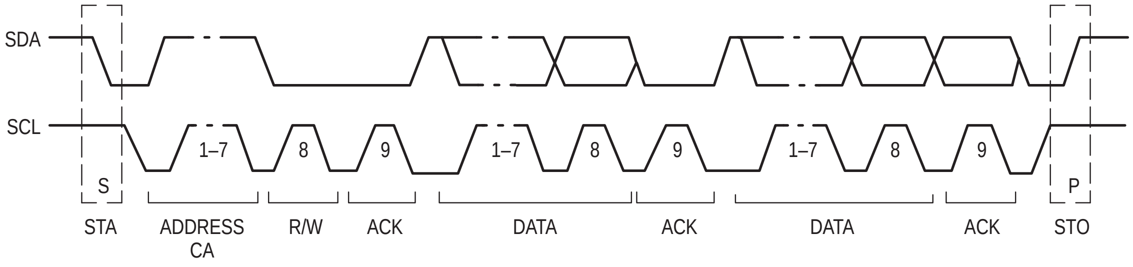

Data Format and Bus Receiver

The circuit receives the information for tuning and control via the I^{2}C bus. The incoming information, consisting of a chip address byte followed by two or four data bytes, is treated in the I^{2}C bus receiver. The definition of the permissible bus protocol is shown below:

1_STA CA CO BA STO
2_STA CA FM FL STO
3_STA CA CO BA FM FL STO
4_STA CA FM FL CO BA STO

STA = Start Condition
STO = Stop Condition
CA = Chip Address Byte
CO = Data Byte for Control Information
BA = Band Information
FM = Data Byte for Frequency Information (MSB's)
FL = Data Byte for Frequency Information (LSB's)

Figure 5 shows the five bytes of information that are needed for circuit operation: there is the chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received the third data byte is ignored.

If five or more data bytes are received the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit which allows the IC to distinguish between frequency information and control plus band information.

Frequency information is preceded by a Logic "0". If the function bit is Logic "1" the two following bytes contain control and band information. The first data byte, shifted after the chip address, may be byte CO or byte FM.

The two permissible bus protocols with five bytes are shown in Figure 5.

The Data and Clock inputs (Pins 10 and 11) are high impedance when the supply voltage V_{CC1} is between 0 and 5.5 V.

Chip Address

The chip address is programmable by Pin 9 (CA – Address Select).

CA – Pin 9	Address (HEX.)

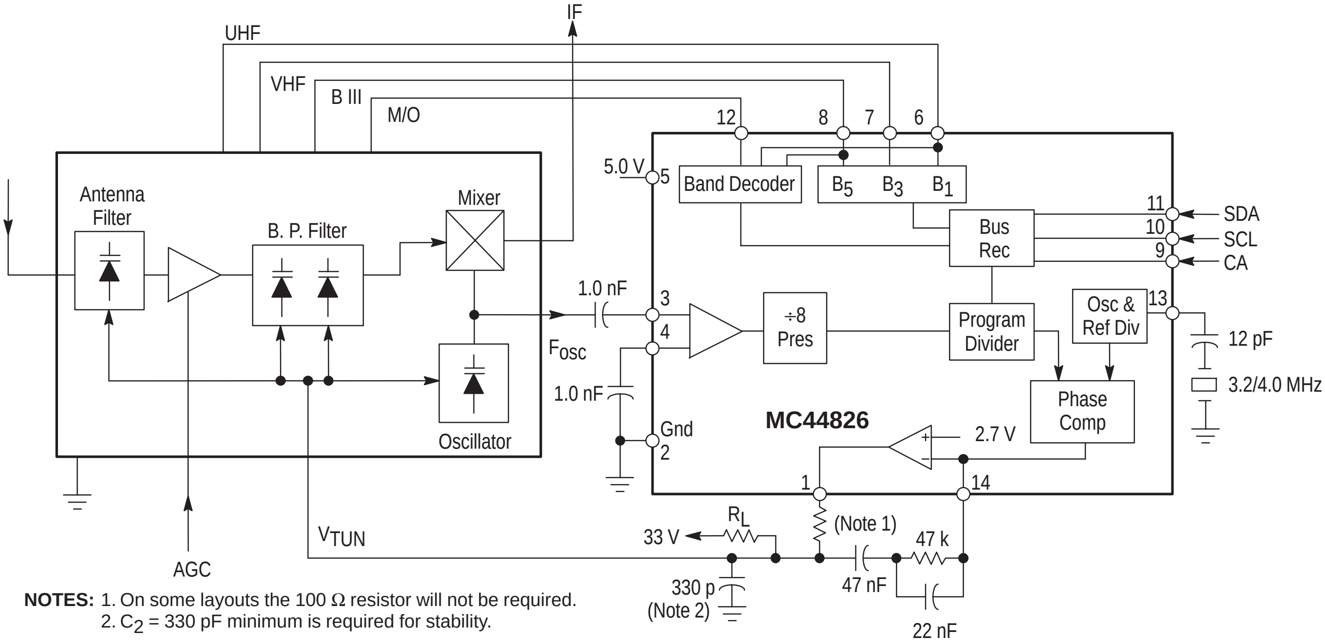
Figure 6. Typical Tuner Application



NOTES: 1. On some layouts the 100 Ω resistor will not be required.
2. C_2 = 330 pF minimum is required for stability.

Bits B_1, B_3, B_5: Control the Band Buffers

B_1, B_3, B_5 = 0 = 1	Buffer "Off" Buffer "On"

Bit T_8: Controls the Output of the Operational Amplifier

T_8 = 0	Normal Operation Operational Amplifier Active
= 1	Output State of Operational Amplifier Switched "Off", Output Pulls High Through the External Pull–Up Resistor R_L

Bits T_9, T_{12}: Control the Phase Comparator

T_9	T_{12}	Function
1	0	Normal Operation
1	1	High Impedance
0	0	Upper Source "On" Only
0	1	Lower Source "On" Only

Bits T_{10}, T_{11}: Control the Reference Divider

T_{10}	T_{11}	Division Ratio
0	0	512
0	1	1024
1	0	1024
1	1	512

Bit T_{13}: Switches the Internal Signals F_{ref} and F_{BY2} to the Band Buffer Outputs (Test)

T_{13} = 0	Normal Operation
= 1	Test Mode F_{ref} Output at B_3 (Pin 7) F_{BY2} Output at B_5 (Pin 8)

Bits B_3 and B_5 have to be "On", $B_3 = B_5 = 1$ in the test mode.
F_{ref} is the reference frequency.
F_{BY2} is the output frequency of the programmable divider, divided by two.

Bit T_{14}: Controls the Charge Pump Current of the Phase Comparator

T_{14} = 0	Pump Current 40 µA Typical
= 1	Normal Operation. Pump Current 125 µA Typical

Bits T_6, T_7: Mixer/Oscillator Band Decoder

The band decoder provides the band switching signal for the mixer/oscillator circuit. The buffer bits control the decoder output. The decoder can be controlled by the buffer bits or independently by the control bits T_6 and T_7 as per the tables below.

T_7	T_6	Decoder Output DEC
0	0	Decoder Output Controlled by Buffer Bits B_1, B_3, B_5
0	1	0 to 0.8 V
1	0	1.8 to 2.1 V
1	1	3.4 V to V_{CC1} (V_{CC1} = 4.5 to 5.5 V)

B_5	B_3	B_1	Decoder Output DEC
0	X	0	1.8 to 2.1 V
0	X	1	0 to 0.8 V
1	X	0	3.4 V to V_{CC1} (V_{CC1} = 4.5 to 5.5 V)
1	X	1	Undefined

BA_Band Information

T_7	T_6	B_5	X	B_3	X	B_1	X	ACK

The band buffers are open collector buffers and are active "low" at Bn = 1. They are designed for 15 mA with a typical "On" voltage of 200 mV. These buffers are designed to withstand relative high output voltage in the "Off" state.

B_3 and B_5 buffers may also be used to output internal IC signals (reference frequency and programmable divider output frequency divided by 2) for test purposes.

The bit B_3 and/or B_5 have to be one if the buffers are used for these additional functions.

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider, this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:

$N = 16384 \times N_{14} + 8192 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$

Maximum Ratio 32767

Minimum Ratio 256

Where $N_0 \ldots N_{14}$ are the different bits for frequency information.

The counter may be used for any ratio between 256 and 32767, and reloads correctly as long as its output frequency does not exceed 1.0 MHz.

The data transfer between latches A and B (signal TDI) is also initiated by any start condition on the I^2C bus.

At power–on the whole bus receiver is reset and the bit N_8 of the programmable divider is set to $N_8 = 1$. Thus the programmable divider starts with a division ratio of 256 or higher.

The first I^2C message must be sent only when the POWER ON RESET is completed. Division ratios of $N < 256$ are not allowed.

The Prescaler

The prescaler has a preamplifier which guarantees high input sensitivity.

The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

The Tuning Voltage Amplifier

The amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The tuning voltage amplifier needs an external pull–up resistor to generate the tuning voltage.

The amplifier can be switched "Off" through bit T_8. When bit T_8 is "One", the amplifier is "Off". The tuning voltage is then pulled high by the external pull–up resistor.

Figure 6 shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

The Oscillator

The oscillator uses a 3.2 or 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in its series resonance mode.

The voltage at Pin 13, has low amplitude and low harmonic distortion.

The negative impedance of the crystal input (Pin 13) is about 3.0 kΩ.

PLL Tuning Circuit with 3-Wire Bus

The MC44827 is a tuning circuit for TV and VCR tuner applications. This device contains on one chip all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz.

The MC44827 is controlled by a 3–wire bus. It has the same function as the MC44828 which is I^{2}C bus controlled. The MC44827 and MC44828 can replace each other to allow conversion between 3–wire bus and I^{2}C bus control.

The MC44827 is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

The MC44827 has the same features as MC44817 with the following differences:

- Lower Power Consumption, 200 mW Typical
- Improved Prescaler with Higher Margins for Sensitivity and Temperature Range. (A typical device is functional in a temperature range greater than –40 to 100°C.)
- Lock Detector with Push–Pull Output
- No Bypass of Divide–by–8 Prescaler
- TSSOP Package

MC44829

PLL Tuning Circuit with I^{2}C Bus

The MC44829 is a tuning circuit for TV and VCR tuner applications. It contains, on one chip, all the functions required for PLL control of a VCO. This integrated circuit also contains a high frequency prescaler and thus can handle frequencies up to 1.3 GHz. The circuit has a band decoder that provides the band switching signal for the mixer/oscillator circuit. The decoder is controlled by the buffer bits.

The MC44829 has programmable 512/1024 reference dividers and is manufactured on a single silicon chip using Motorola’s high density bipolar process, MOSAIC™ (Motorola Oxide Self Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control (I^{2}C Bus)
- Divide–by–8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider
- Reference Divider: Programmable for Division Ratios 512 and 1024
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Tuning Voltage Output (30 V)
- Four Programmable Chip Addresses
- Integrated Band Decoder for the Mixer/Oscillator Circuit
- Band Buffers with Low “On” Voltage (0.4 V Maximum at 5.0 mA)
- Fully ESD Protected to MIL–STD–883C, Method 3015.7 (2000 V, 1.5 kΩ, 150 pF)

MOSAIC is a trademark of Motorola, Inc.

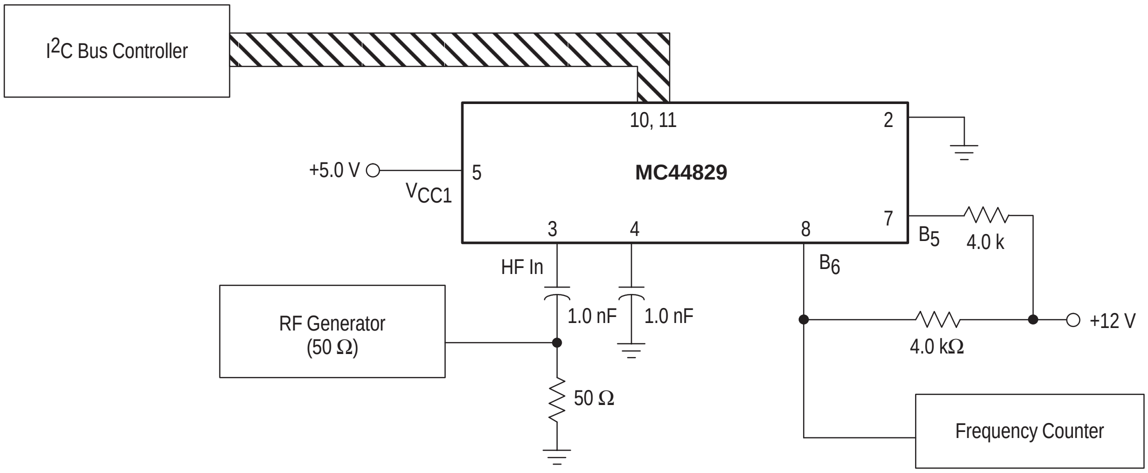
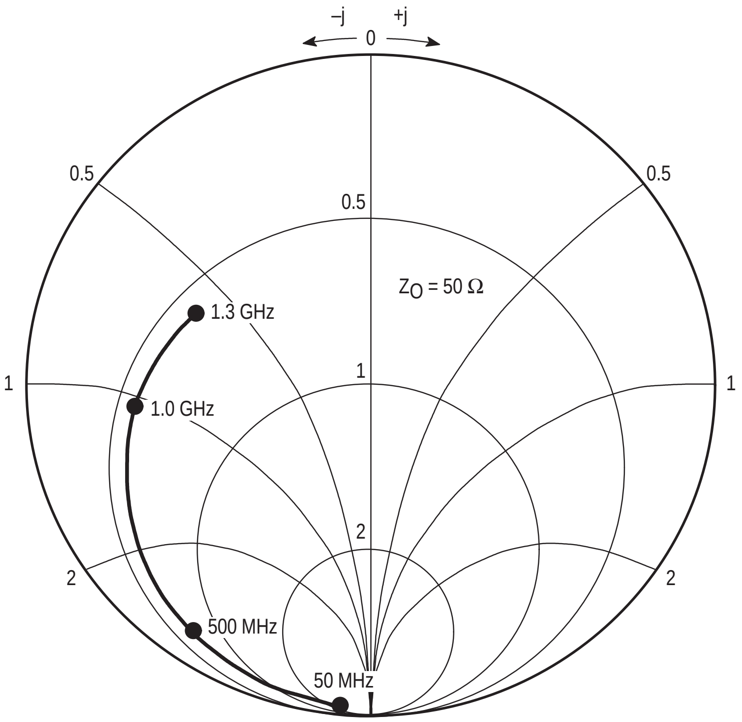
50–950 MHz	3, 4	10	–	315	
950–1300 MHz	3, 4	50	–	315	

Figure 2. RF Sensitivity Test Circuit



Device is in test mode, B_5 and B_6 are "On", B_4 is "Off".
Sensitivity is the level of the HF generator of 50 Ω load.

Figure 3. Typical HF Input Impedance



Data Format and Bus Receiver

The circuit receives the information for tuning and control via the I^2C bus. The incoming information, consisting of a chip address byte followed by two or four data bytes, is treated in the I^2C bus receiver. The definition of the permissible bus protocol is shown below:

1_STA CA CO BA STO
2_STA CA FM FL STO
3_STA CA CO BA FM FL STO
4_STA CA FM FL CO BA STO

STA = Start Condition
STO = Stop Condition
CA = Chip Address Byte
CO = Data Byte for Control Information
BA = Band Information
FM = Data Byte for Frequency Information (MSB’s)
FL = Data Byte for Frequency Information (LSB’s)

Figure 4. Complete Data Transfer Process

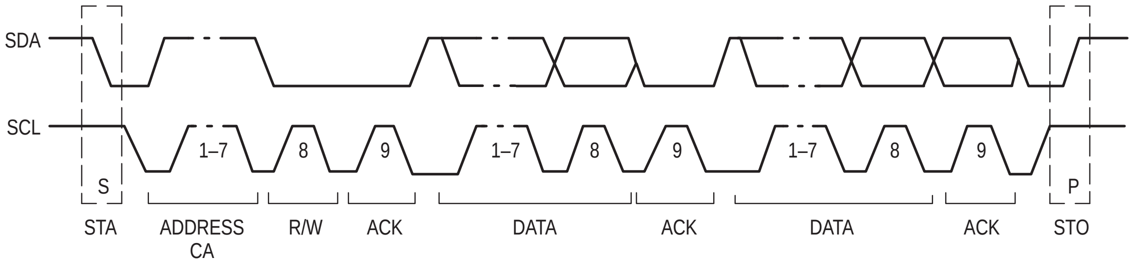


Figure 5 shows the five bytes of information that are needed for circuit operation: there is the chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received the third data byte is ignored.

If five or more data bytes are received the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit which allows the IC to distinguish between frequency information and control plus band information.

Frequency information is preceded by a Logic “0”. If the function bit is Logic “1” the two following bytes contain control and band information. The first data byte, shifted after the chip address, may be byte CO or byte FM.

The two permissible bus protocols with five bytes are shown in Figure 5.

The Data and Clock inputs (Pins 10 and 11) are high impedance when the supply voltage V_{CC1} is between 0 and 5.5 V.

Chip Address

The chip address is programmable by Pin 9 (CA – Address Select).

CA – Pin 9	Address (HEX.)
–0.04 V_{CC1} to 0.1 V_{CC1}	C_0
Open or 0.2 V_{CC1} to 0.3 V_{CC1}	C_2
0.42 V_{CC1} to 0.75 V_{CC1}	C_4
0.9 V_{CC1} to 1.2 V_{CC1}	C_6

T_{13} = 0	Normal Operation
= 1	Test Mode F_{ref} Output at B_5 (Pin 7) F_{BY2} Output at B_6 (Pin 8)

Bits B_5 and B_6 have to be “On”, $B_5 = B_6 = 1$ in the test mode.
F_{ref} is the reference frequency.
F_{BY2} is the output frequency of the programmable divider, divided by two.

Bit T_{14}: Controls the Charge Pump Current of the Phase Comparator

T_{14} = 0	Pump Current 40 µA Typical
= 1	Normal Operation. Pump Current 125 µA Typical

Mixer/Oscillator Band Decoder

The band decoder provides the band switching signal for the mixer/oscillator circuit. The buffer bits B_4 and B_6 control the decoder output. B_5 is not decoded. The decoder is controlled by the buffer bits as per the table below.

B_6	B_5	B_4	Decoder Output DEC
0	X	0	Undefined
0	X	1	3.4 V to V_{CC1} (V_{CC1} = 4.5 to 5.5 V)
1	X	0	0 to 0.8 V
1	X	1	1.8 to 2.1 V

BA_Band Information

X	B_6	B_5	B_4	X	X	X	X	ACK

The band buffers are open collector buffers and are active “low” at Bn = 1. They are designed for 5.0 mA with a typical “on” voltage of 160 mV. These buffers are designed to withstand relative high output voltage in the “off” state.

B_5 and B_6 buffers may also be used to output internal IC signals (reference frequency and programmable divider output frequency divided by 2) for test purposes.

The bit B_5 and/or B_6 have to be one if the buffers are used for these additional functions.

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider, this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:

$N = 16384 \times N_{14} + 8132 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$

Maximum Ratio 32767

Minimum Ratio 256

Where $N_0 \ldots N_{14}$ are the different bits for frequency information.

The counter may be used for any ratio between 256 and 32767 and reloads correctly as long as its output frequency does not exceed 1.0 MHz.

The data transfer between latches A and B (signal TDI) is also initiated by any start condition on the I^2C bus.

At power "on" the whole bus receiver is reset and the bit N_8 of the programmable divider is set to $N_8 = 1$. Thus the programmable divider starts with a division ratio of 256 or higher.

The first I^2C message must be sent only when the POWER ON RESET is completed. Division ratios of $N < 256$ are not allowed.

The Prescaler

The prescaler has a preamplifier which guarantees high input sensitivity.

The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

The Tuning Voltage Amplifier

The amplifier is designed for very low noise, low input bias current and high power supply rejection. The positive input is biased internally. The tuning voltage amplifier needs an external pull–up resistor to generate the tuning voltage.

The amplifier can be switched "off" through bit T_8. When bit T_8 is "One", the amplifier is "Off". The tuning voltage is then pulled high by the external pull–up resistor.

Figure 6 shows a possible filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

The Oscillator

The oscillator uses a 3.2 or 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in its series resonance mode.

The voltage at Pin 13, has low amplitude and low harmonic distortion.

The negative impedance of the crystal input (Pin 13) is about 3.0 kΩ.

MOTOROLA

Advance Information

PLL Tuning Circuit with 1.3 GHz Prescaler and D/A Converters for Automatic Tuner Alignment

The MC44864 is a tuning circuit for TV applications. This device contains a PLL section and a DAC section and is MCU controlled through an I^2C Bus.

The PLL section contains all the functions required to control the VCO of a TV tuner. The IC generates the tuning voltage and the additional control signals, such as band switching voltages.

The D/A section generates three additional varactor voltages to feed all of the varactors of the tuner with individually optimized control voltages (automatic tuner adjustment). The MC44864 is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSIAC™ (Motorola Oxide Self–Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control
- Selectable ÷8 Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Programmable Reference Divider
- 3–State Phase/Frequency Comparator
- Operational Amplifier for Direct Varactor Control with Low Saturation Voltage
- Four Output Buffers (15 mA)
- Output Options for 62.5 kHz, Reference Frequency and the Programmable Divider
- The HF Input is Symmetrical
- Three 6 Bit DACs for Automatic Tuner Adjustment Allowing Use of Non–Matched Varactors
- Better Tuner Performances Through Optimum Filter Response
- I^2C Bus Controlled
- Four Chip Addresses for the PLL Section
- Four Chip Addresses for the D/A Section
- ESD Protected to MIL–STD–883C, Method 3015.7 (2,000 V, 1.5 kΩ, 150 pF)

MAXIMUM RATINGS (T_A = 25°C, unless otherwise noted.)

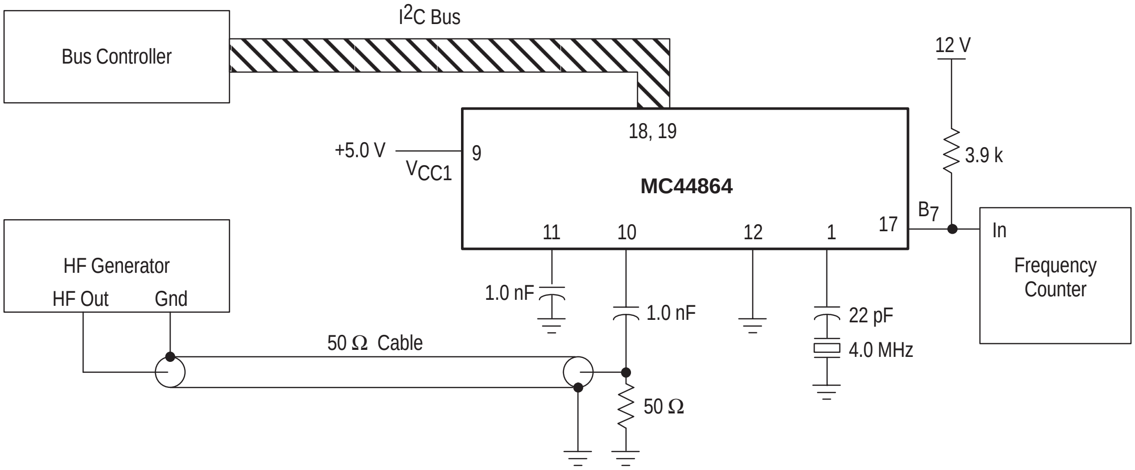
V_{CC1} Supply Current (V_{CC1} = 5.0 V)(1)(2)	9	–	50	70	mA
V_{CC2} Supply Voltage Range	4	25	30	35	V
V_{CC2} Supply Current (Output Open)	4	–	1.3	2.5(4)	mA
Band Buffer Leakage Current when “Off” at 12 V	14 – 17	–	0.01	1.0	µA
Band Buffer Saturation Voltage when “On” at 15 mA	14 – 17	–	1.8	2.0	V
Data/Clock Current at 0 V	18, 19	–10	–	0	µA
Clock Current at 5.0 V	18	0	–	1.0	µA
Data Current at 5.0 V Acknowledge “Off”	19	0	–	1.0	µA
Data Saturation Voltage at 15 mA Acknowledge “On”	19	–	1.2	–	V
Data/Clock Input Voltage Low	18, 19	–	–	1.5	V
Data/Clock Input Voltage High	18, 19	3.0	–	–	V
Clock Frequency Range	18	–	–	100	kHz
Phase Detector Current in High Impedance State	2	–15	–	15	nA
Oscillator Frequency Range	1, 2	3.5	4.0	4.1	MHz
Phase Detector High–State Source Current (@ 1.5 V)	2	–2.5	–	–0.5	mA
Phase Detector Low–State Sink Current (@ 4.0 V)	2	0.5	–	2.5	mA
Operational Amplifier Internal Reference Voltage	–	2.0	2.5	3.0	V
Operational Amplifier Input Current	3	–15	–	15	nA
DC Open Loop Gain	–	2000	–	–	V/V
Gain Bandwidth Product	–	–	0.2	–	MHz
Phase Margin	–	–	50	–	Deg.
V_{out} Low, Sinking 50 µA	6 – 8	–	0.2	0.5	V
V_{out} High, Sourcing 50 µA (V_{CC2} – V_{out} High)	6 – 8	–	–	1.5	V
Tuning Voltage (DC)	5 – 8	–	–	30	V
D/A Converters Step Size(3)	6 – 8	0.5	–	1.5	LSB
D/A Converters Temperature Drift	6 – 8	–	1.0	–	LSB
DAC Offset at V_{TUN} = 2.5 V	–	–50	–	50	mV
DAC Offset at V_{TUN} = 25 V	–	–700	–	700	mV
DAC Voltages (DC)	6 – 8	–	–	33	V

NOTES:
1. When prescaler “Off”, typical supply current is decreased by 10 mA.
2. Band Buffers “Off”, 2.4 mA more when one buffer is on.
3. For definition of the LSB, see Figure 9 in the D/A section.
4. 2.5 mA as long as the analog outputs are not in saturation high, which means V_{TUN}, V_{DAC} (Pins 5, 6, 7, 8) lower than V_{CC2} – 1.5 V. When all outputs are in saturation high the maximum V_{CC2} current is 5.0 mA.

HF CHARACTERISTICS (See Figure 1)

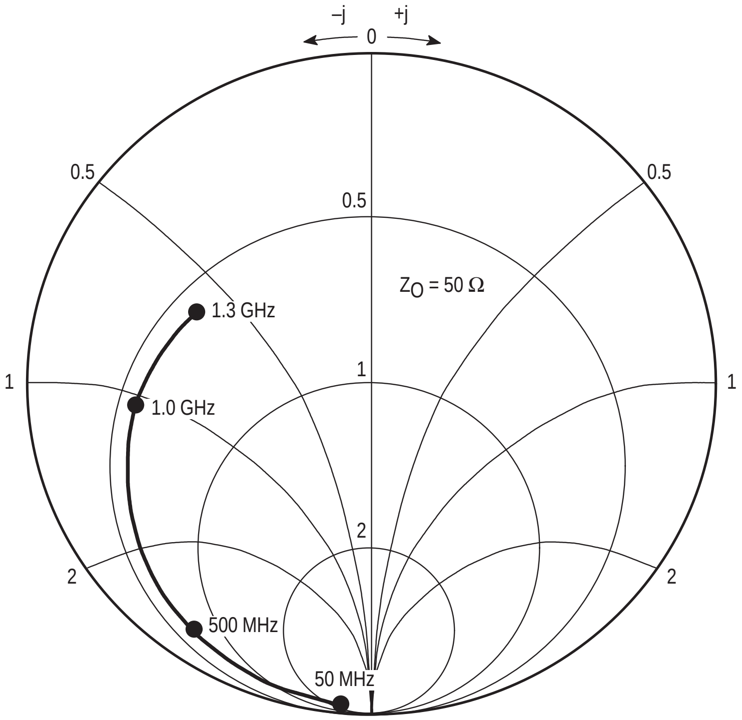
Characteristic	Pin	Min	Typ	Max	Unit
DC Bias	10, 11	–	1.55	–	V
Input Voltage Range					mVrms
10–150 MHz (Prescaler "Off")	10, 11	20	–	315	
80–1000 MHz	10, 11	20	–	315	
1000–1300 MHz	10, 11	50	–	315	

Figure 1. HF Sensitivity Test Circuit



Device is in test mode: B_7 is "On", R_2 = 1 and R_3 = 0 (see Bus section).
Sensitivity is the level of the HF generator on 50 Ω load (without MC44864 load).

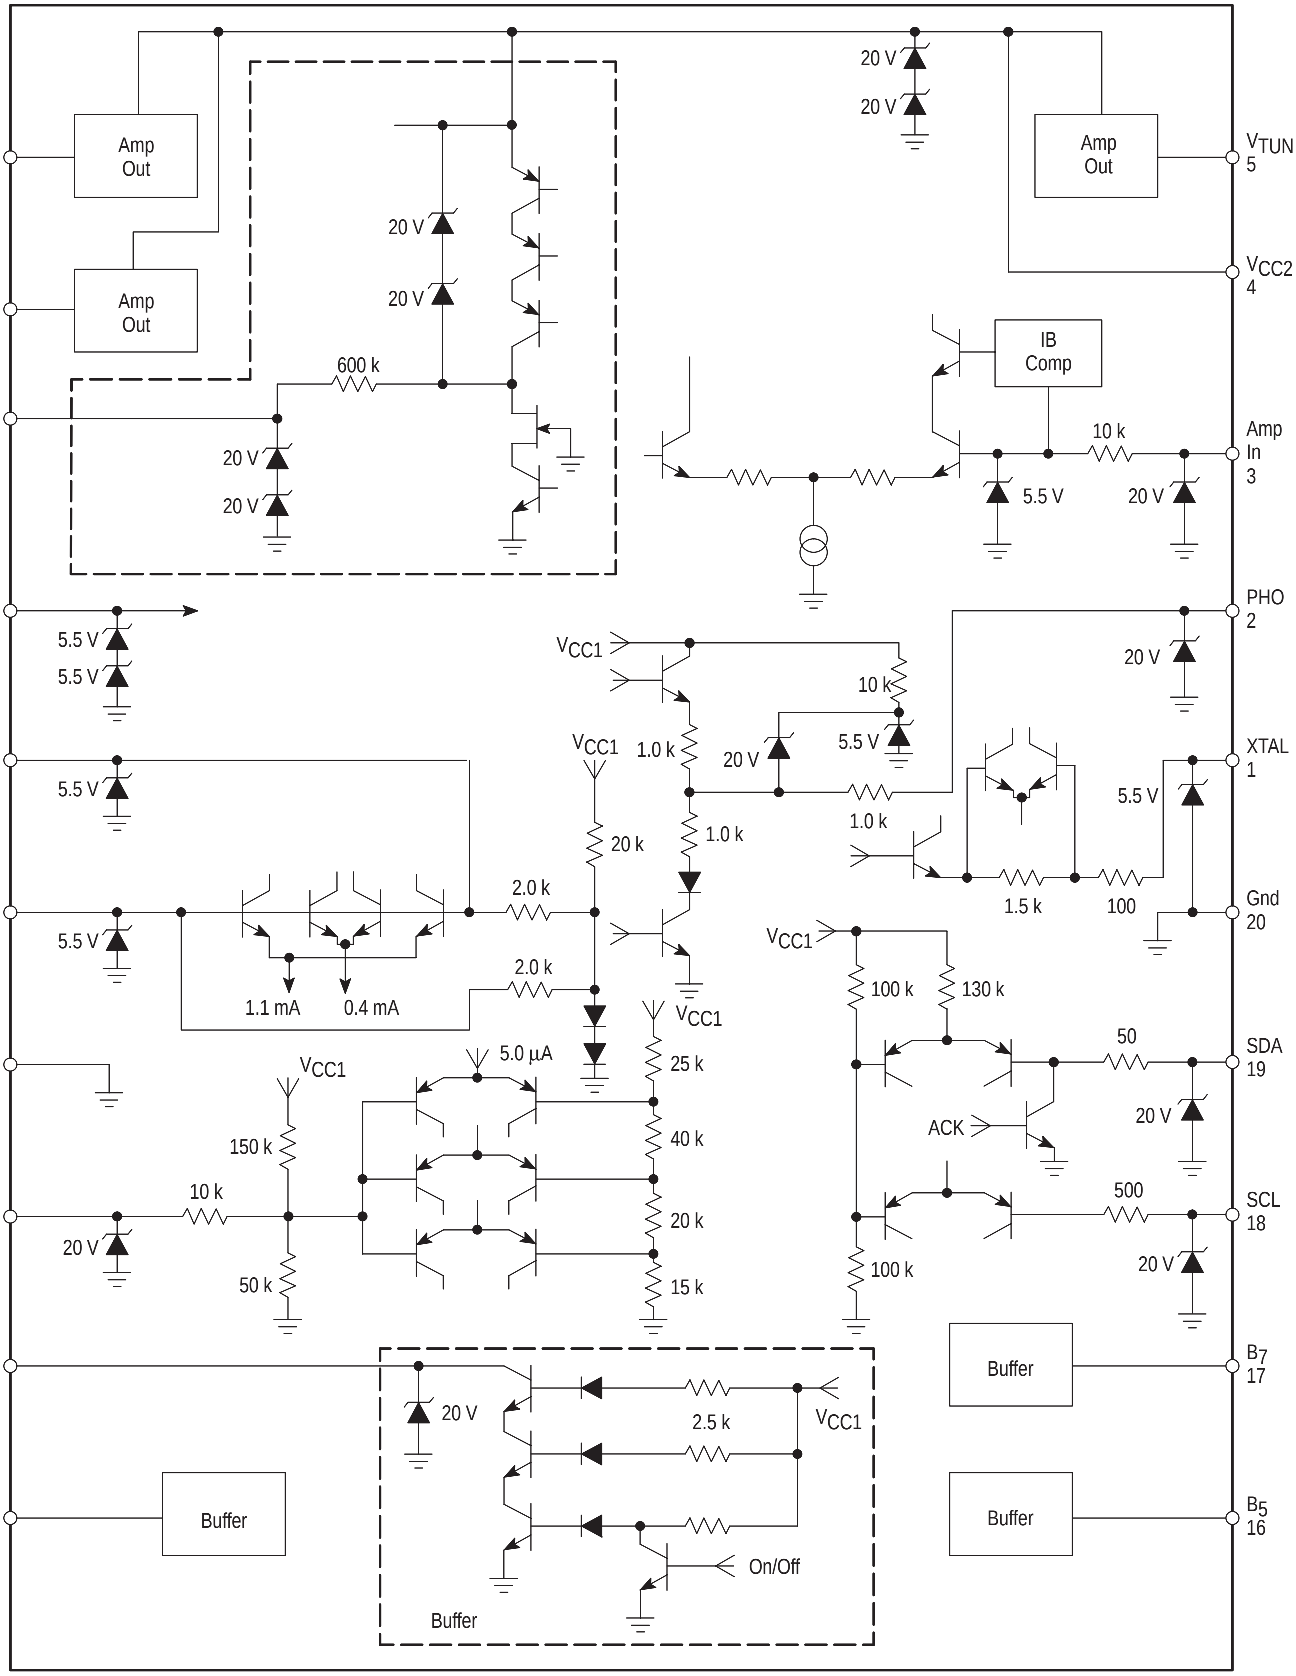
Figure 2. Typical HF Input Impedance



PIN FUNCTION DESCRIPTION

Pin	Symbol	Description
6, 7, 8	DA1, DA2, DA3	D/A output control voltages
9	V_{CC1}	Positive supply of the circuit (except DACs)
10, 11	HF_1, HF_2	HF input from local oscillator
12, 20	Gnd	Ground
13	CA	Chip Address
14, 15, 16, 17	B_1, B_3, B_5, B_7	Band buffer output can drive 15 mA
18	SCL	Clock input (supplied by the microprocessor via Bus)
19	SDA	Data input (bus)
1	XTAL	Crystal oscillator (typically 4.0 MHz)
2	PHO	Phase comparator output
3	Amp In	Negative operational amplifier input
4	V_{CC2}	Operational amplifier positive supply
5	V_{TUN}	Operational amplifier output which provides the tuning voltage

Figure 3. Pin Circuit Schematic



FUNCTIONAL DESCRIPTION

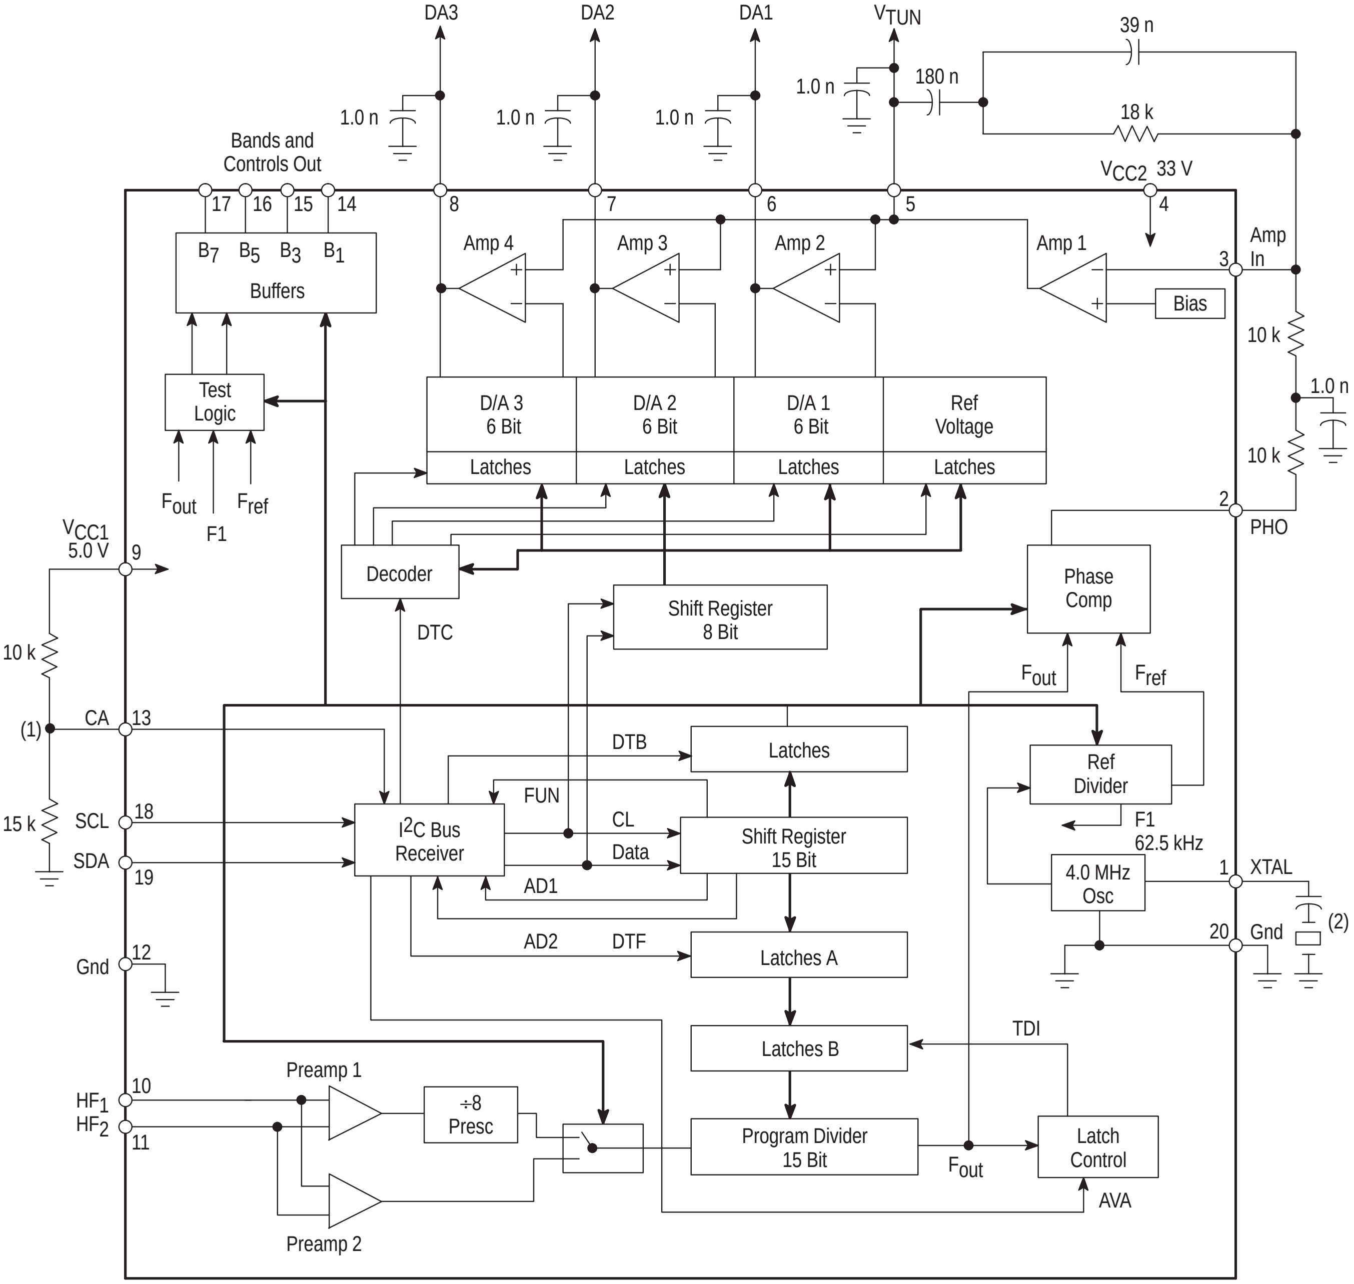
A representative block diagram and a typical system application are shown in Figures 4 and 5. A discussion of the features and function of the internal blocks is given below.

Automatic Tuner Alignment

The circuit generates the tuning voltage through the PLL. The output voltages of the D/A converters are equal to the tuning voltage plus a positive or negative offset of up to 31 steps. During the automatic alignment one first lets the PLL lock to the appropriate frequency and then searches for the optimum value of the other varactor voltages. The digital word for each voltage value is stored in a nonvolatile memory (NVM). Hence, for each frequency point to be adjusted, three times 6 bits of information have to be stored (plus 2 bits for the DAC range).

The information stored in the NVM reflects the characteristic of the individual tuner. For this reason, the NVM is preferably situated inside the tuner and is also controlled by the I^2C Bus.

Figure 4. Block Diagram



NOTES: 1. Pin 13:

Short to V_{CC}	for addresses CC, CE
Resistors ±10%	for addresses C8, CA (values 10 k and 15 k) for test only
Open or 1.0 nF to Gnd	for addresses C4, C6
Short to Gnd	for addresses C0, C2

2. The crystal may be connected to Pin 20 with no connection to external Gnd.

Chip Addresses

The chip address is programmable by Pin CA.

The PLL addresses C0, C2, C4, C6 are officially allocated to PLL–IC's.

The addresses C8, CA, CC, CE are not officially allocated. Care has to be taken in the application that no conflict occurs with other devices on the same I^2C Bus when using the addresses C8 to CE.

CA Pin (13)	A_3	A_2	A_1	A_0	Address	Function
–0.04 V_{CC1} to 0.1 V_{CC1}	0	0	0	0	C0	1st PLL

PLL SECTION

Data Format and Bus Receiver

The circuit receives the information for tuning and control via I^2C Bus. The incoming information is treated in the bus receiver. The definition of the permissible bus protocol is shown in the four examples below:

Ex. 1	STA	CA1	CO	BA	STO		
Ex. 2	STA	CA1	FM	FL	STO		
Ex. 3	STA	CA1	CO	BA	FM	FL	STO
Ex. 4	STA	CA1	FM	FL	CO	BA	STO

STA = Start Condition
STO = Stop Condition
CA1 = Chip Address Byte of the PLL Section
CO = Data Byte for Control Information
BA = Band Information
FM = Data Byte for Frequency Information (MSB's)
FL = Data Byte for Frequency Information (LSB's)

Figure 6 shows the five bytes of information that are needed for circuit operation: there is a chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received, the third data byte is ignored. If five or more data bytes are received, the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit F. If the function bit F= 0, frequency information is acknowledged and if F = 1, control/band information is acknowledged.

If the address is correct (signal AD1) the information is loaded into latches.

A function bit in the first and third data byte is used to pass this data either into the latches of the programmable divider (signal DTF) or into the latches for band and control information (signal DTB). The data transfer to the latches (signals DTF and DTB) is initiated after the 2nd and 4th data bytes.

A second string of latches is used for the data transfer into the programmable divider to inhibit the transfer during the preset operation (signal TDI, signal AVA is an internal “address valid” command).

The switching levels of clock and data (Pins 18 and 19) are 0.5 x V_{CC1}.

The control and band information bits have the following functions.

Bits R_0, R_1: Controls Reference Divider Division Ratio

R_0	R_1	Division Ratio
0	0	2048
1	0	1024
0	1	512
1	1	256

Bits R_2, R_3: Switches Internal Signals to the Buffer Outputs

R_2	R_3	Pin 16	Pin 17
0	0	–	–
0	1	62.5 kHz	–
1	0	F_{ref}	F_{BY2}
1	1	–	–

Bit B_5 has to be “one” when Pin 16 is used to output 62.5 kHz. Bits B_5 and B_7 have to be “one” to output F_{ref} and F_{BY2}. F_{BY2} is the programmable divider output frequency divided by two.

Bits R_2, R_6, T: Controls the Phase Comparator Output Stage

R_2	R_6	T	Output State
0	0	0	Normal Operation
0	0	1	“Off” (High Impedance)
0	1	0	High
0	1	1	Low
1	0	0	Normal Operation
1	0	1	“Off”
1	1	0	Normal Operation
1	1	1	“Off”

The Band Buffers

The band buffers are open collector transistors and are active “low” at Bn = 1. They are designed for 15 mA with typical on–voltage of 1.8 V. These buffers are designed to withstand relative high output voltage in the off–state (15 V).

B_5 and B_7 buffers (Pins 16 and 17) may also be used to output internal IC signals (reference frequency and programmable divider output frequency divided by 2) for test purposes.

Buffer B_5 may also be used to output a 62.5 kHz frequency from an intermediate stage of the reference divider. The bits B_5 and B_7 have to be “one” if the buffers are used for these additional functions.

The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider, this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:

$N = 16384 \times N_{14} + 8192 \times N_{13} + \ldots + 4 \times N_2 + 2 \times N_1 + N_0$

Maximum Ratio 32767

Minimum Ratio 256

where $N_0 \ldots N_{14}$ are the different bits for frequency information.

The counter reloads correctly as long as its output frequency does not exceed 1.0 MHz.

Division ratios of < 256 are not allowed. At power–up the counter bit N8 is preset to “1”. All other bits are undetermined. In this way, the counter always starts with a division ratio of 256 or higher.

The data transfer between latches A and B (signal TDI) is also initiated by any start condition on the bus.

At power–on the whole bus receiver is reset and the programmable divider is set to a counting ratio of N = 256 or higher.

The Prescaler

The prescaler has a preamplifier and may be bypassed (Bit P). The signal then passes through preamplifier 2.

The table on the following page shows the frequency ranges which may be synthesized with and without prescaler.

The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

The Operational Amplifier

The operational amplifier for the tuning voltage is designed for low noise, low input bias current and high power supply rejection. The positive input is biased internally. The operational amplifier needs 30 V supply (V_{CC2}) as minimum voltage for a guaranteed maximum tuning voltage of 28.5 V.

Figure 4 shows the usual filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

As a starting point for optimization, the component values in Figure 4 may be used for 7.8125 kHz reference frequency in a multiband TV tuner.

The Oscillator

The oscillator uses a 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in the series resonance mode.

The crystal is driven through a 1.6 kΩ resistor on chip.

The voltage at Pin 16 “crystal”, has low amplitude and low harmonic distortion.

The negative resistance of the oscillator at Pin 1 (XTAL) is about 3.0 kΩ.

Input Data		Ref. Divider Div. Ratio	Ref. Freq. Hz(1)	With Int. Prescaler P = 0		Without Prescaler P = 1	
R_0	R_1			Frequency Steps kHz	Max. Input Freq. MHz	Frequency Steps kHz	Max. Imput Freq. MHz
0	0	2048	1953.125	15.625	512	1.953125	64
1	0	1024	3906.25	31.25	1024	3.90625	128
0	1	512	7812.5	62.5	1300(2)	7.8125	165(3)
1	1	256	15625.0	125.0	1300(2)	15.625	165(3)

NOTES: 1. With 4.0 MHz Crystal
2. Limit of Prescaler
3. Limit of Programmable Divider

For satellite tuner applications the circuit may be used with an external /4 prescaler and a reference divider ration of 1024 (R_0 = 1, R_1 = 0). In this way, frequencies up to 4.0 GHz can be synthesized with 125 kHz resolution (4.0 MHz crystal).

The same result can be achieved with an external /32 prescaler when the internal prescaler is bypassed (P = 1).

The Reference Divider

The reference divider of the MC44864 is programmable (Bits R_0 and R_1) for ratios of 2048, 1024, 512 and 256. This feature makes the circuit versatile.

Bit P: Controls the Prescaler

P	Prescaler Function
0	Prescaler Active
1	Prescaler Bypassed Prescaler Power Supply “Off”

Bits B_1, B_3, B_5, B_7: Controls the Band Buffers

B_1, B_3, B_5, B_7 = 0	Buffer “Off”
= 1	Buffer “On”

D/A SECTION

Basic Function

The D/A section has four separate chip addresses from the PLL section. Three D–to–A converters that have a resolution of 6 bits (5 bits plus sign) are on chip. The analog output voltages are dc. The converters are buffered to the analog outputs DA1, DA2 and DA3 by operational amplifiers with an output voltage range that is equal to the tuning voltage range (about 0 to 30 V). The operational amplifiers are arranged such that a positive or negative offset can be generated from the tuning voltage.

Data Format and Bus Protocols

The D–to–A information consists of the D/A chip address (CA2) and four data bytes. The first two bits of the data bytes are used as the function address. Thus the bytes C_1, C_2 and C_3 contain the address for the individual converter and the 6 bits to be converted. Bit D_5 is the sign (log “1” for positive offset, log “0” for negative offset) and the bits D_0 to D_4 determine the number of steps to be made as an offset from the tuning voltage. The bits S_0 and S_1 in the data byte RA define the step size (V_{step}) and the range of the converters (see Figures 8 and 9). The range is the same for all converters.

After the chip address (CA2) is acknowledged, up to four data bytes may be received by the IC. If more than four bytes are received, the fifth and following bytes are ignored and the last acknowledge pulse is sent after the fourth data byte. The data transfer to the converters (signal DTC) is initiated each time a complete data byte is received.

The following shows some examples of the permissible bus protocols of the D–to–A section. The data bytes may be sent to the IC in random order with up to four in one sequence. The same converter may be loaded up to four times as shown in example 6. Below are 6 examples of permissible bus protocols.

Ex. 1	STA	CA2	C1	STO			
Ex. 2	STA	CA2	C1	C2	STO		
Ex. 3	STA	CA2	C1	C2	C3	STO	
Ex. 4	STA	CA2	C1	C2	C3	RA	STO
Ex. 5	STA	CA2	RA	C1	C2	C3	STO
Ex. 6	STA	CA2	C1	C1	C1	C1	STO

STA = Start Condition
STO = Stop Condition
CA2 = Chip Address Byte for D/A Section
C1, C2, C3 = Data Bytes for D/A Converters
RA = Data Byte for Range

Figure 7. Definition of Bytes

CA2_D/A Chip Address	1	1	0	0	A_2	A_1	$A_0 = 0$		ACK

Figure 8. Output Voltage (D/A Converters)

$$V_{DA} = V_{TUN} \pm V_{step}\,(D_0 + 2\,D_1 + 4\,D_2 + 8\,D_3 + 16\,D_4)$$

D_5 = 1 positive sign; D_5 = 0 negative sign

V_{TUN}: Tuning Voltage set by PLL
V_{step}: Voltage Step (LSB) of the D/A Converters

Figure 9. Range Selection of the D/A Converters

Input Data		Typ. Step Size V_{step}	Guaranteed Range 31 Steps
S_0	S_1		
0	0	225 mV	6.25 V
1	0	125 mV	3.40 V
0	1	70 mV	1.90 V
1	1	40 mV	1.05 V

The D/A Converters

The D/A converters convert 5 bit into analog current of which the polarity is switched by the sixth bit. The reference voltage of the converters is programmed by two bits (S_0, S_1 of the RA–byte) to determine the scaling factor. The analog currents are then converted into voltages and added to their respective operational amplifier nominal bias. The resulting voltages at Pins 6, 7 and 8 are the tuning voltages (V_{TUN}, see Figure 4) at Pin 5 plus any offset provided by information in the D/A converters.

If the data bits D_0 to D_4 are all “0”, the three D/A output voltages on Pins 6, 7 and 8 are equal to the tuning voltage (Pin 5) within the DAC offset voltages.

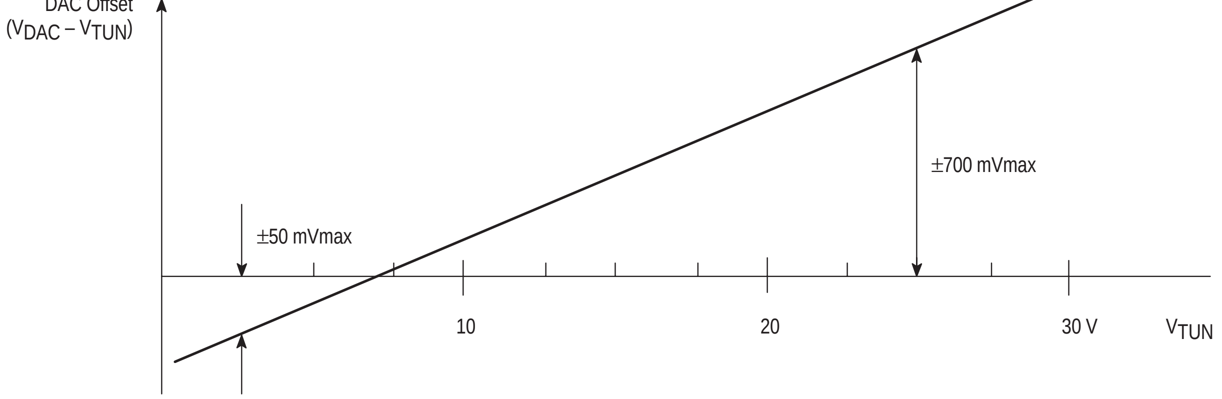
The four amplifiers have the same output characteristics with the maximum output voltage being 1.5 V lower than V_{CC2} in the worst case. The four analog outputs are short–circuit protected. At power–up, the D/A outputs are undetermined.

The D/A converters are guaranteed to be monotonic with a voltage step variation of ±0.5 LSB.

The D/A converters work correctly as long as the PLL loop is active. V_{TUN} is then between 0.3 V and V_{CC2} – 1.5 V. If the loop saturates, the DACs do not work.

The DAC–OFFSET is defined as the difference between the DAC output voltage (with bits D_0 to D_4 = 0) and the tuning voltage (PLL active). The DAC operation is guaranteed from 0.3 V to V_{CC2} – 1.5 V. On typical samples, the DACs will operate down to 0.2 V.

Figure 10. Definition of DAC Offset



Automotive Electronic Circuits

In Brief . . .

Motorola Analog has established itself as a global leader in custom integrated circuits for the automotive market. With multiple design centers located on four continents, global process and assembly sites, and strategically located supply centers, Motorola serves the global automotive market needs. These products are key elements in the rapidly growing engine control, body, navigation, entertainment, and communication electronics portions of modern automobiles. Though Motorola is most active in supplying automotive custom designs, many of yesterday's proprietary custom devices have become standard products of today, available to the broad base manufacturers who support this industry. Today, based on new technologies, Motorola offers a wide array of standard products ranging from rugged high current ''smart'' fuel injector drivers which control and protect the fuel management system through the rigors of the underhood environment, to the latest SMARTMOS™ switches and series transient protectors. Several devices are targeted to support microprocessor housekeeping and data line protection. A wide range of packaging is available including die, flip–chip, and SOICs for high density layouts, to low thermal resistance multi–pin, single–in–line types for high power control ICs.

Automotive Electronic Circuits

Table 1. Voltage Regulators

Function	Features	Suffix/ Package	Device
Low Dropout Voltage Regulator	Positive fixed and adjustable output voltage regulators which maintain regulation with very low input to output voltage differential.	Z/29, T/221A, T/314D, TH/314A, TV/314B, DT/369A, DT–1/369, D2T/936, D2T/936A, D/751	LM2931, C
Low Dropout Dual Regulator	Positive low voltage differential regulator which features dual 5.0 V outputs, with currents in excess of 750 mA (switched) and 10 mA standby, and quiescent current less than 3.0 mA.	T/314D, TH/314A, TV/314B, D2T/936A	LM2935
Automotive Voltage Regulator	Provides load response control, duty cycle limiting, under/overvoltage and phase detection, high side MOSFET field control, voltage regulation in 12 V alternator systems.	DW/751D	MC33092
Low Dropout Voltage Regulator	Positive 5.0 V, 500 mA regulator having on–chip power–up–reset circuit with programmable delay, current limit, and thermal shutdown.	T/314D, TV/314B	MC33267
Low Dropout Voltage Regulator	Positive 3.3 V, 5.0 V, 12 V, 800 mA regulator.	D/751, DT/369A	MC33269

Table 2. Electronic Ignition

Function	Features	Suffix/ Package	Device
Electronic Ignition Circuit	Used in high energy variable dwell electronic ignition systems with variable reluctance sensors. Dwell and spark energy are externally adjustable. “Bumped” die for inverted mounting to substrate.	P/626, D/751, Flip–Chip	MC3334, MCCF3334
Electronic Ignition Circuit	Used in high energy electronic ignition systems requiring differential Hall Sensor control. ‘‘Bumped” die for inverted mounting to substrate.	DW/751G, Flip–Chip	MC33093, MCCF33093
Electronic Ignition Circuit	Used in high energy electronic ignition systems requiring single Hall Sensor control. ‘‘Bumped” die for inverted mounting to substrate.	DW/751G, Flip–Chip	MC33094, MCCF33094
Electronic Ignition Circuit	Used in high energy electronic ignition systems requiring single Hall Sensor control. Dwell feedback for coil variation. ‘‘Bumped” die for inverted mounting to substrate.	DW/751G, Flip–Chip	MC79076, MCCF79076

Table 3. Special Functions

Function	Features	Suffix/ Package	Device
Low Side Protected Switch	Single automotive low side switch having CMOS compatible input, 1.0 A maximum rating, with overcurrent, overvoltage and thermal protection.	T/221A, T–1/314D, DW/751G	MC3392
Low Current High–Side Switch	Drives loads from positive side of power supply and protects against high–voltage transients.	T/314D, DW/751G	MC3399
High–Side TMOS Driver	Designed to drive and protect N–channel power MOSFETs used in high side switching applications. Has internal charge pump, externally programmed timer and fault reporting.	P/626, D/751	MC33091A
MI–Bus Interface Stepper Motor Controller	High noise immunity serial communication using MI–Bus protocol to control relay drivers and motors in harsh environments. Four phase signals drive two phase motors in either half or full–step modes.	DW/751G	MC33192
Quad Fuel Injector Driver	Four low side switches with parallel CMOS compatible input control, $\leq$ 7.0 mA quiescent current, 0.25 Ω $r_{DS(on)}$ at 25°C independent outputs with 3.0 A current limiting and internal 65 V clamps.	T/821D, TV/821C	MC33293A
Octal Serial Output Switch	Eight low side switches having 8–bit serial CMOS compatible input control, serial fault reporting, $\leq$ 4.0 mA quiescent current, independent 0.45 Ω $r_{DS(on)}$ at 25°C outputs with 3.0 A minimum current limiting and internal 55 V clamps.	P/738, DW/751E	MC33298
Integral Alternator Regulator	Control device used in conjunction with a Darlington device to monitor and control the field current in alternator charging systems. ‘‘Bumped” die for inverted mounting to substrate.	D/751A, Flip–Chip	MC33095 MCCF33095
Peripheral Clamping Array	Protects up to six MPU I/O lines against voltage transients.	*/626, D/751	TCF6000
Automotive Direction Indicator	Detects defective lamps and protects against overvoltage in automotive turn–signal applications. Replaces UAA1041B in most applications.	D/751, P/626	MC33193
Automotive Wash Wiper Timer	Standard wiper timer control device that drives a wiper motor relay and can perform the intermittent, afterwash and continuous wiper timer functions.	D/751, P/626	MC33197A
Automotive ISO 9141 Serial Link Driver	Interface between the two–wire asynchronous serial communication interface (SCI) of a microcontroller and a special one–wire care diagnosis system (DIA).	D/751A	MC33199

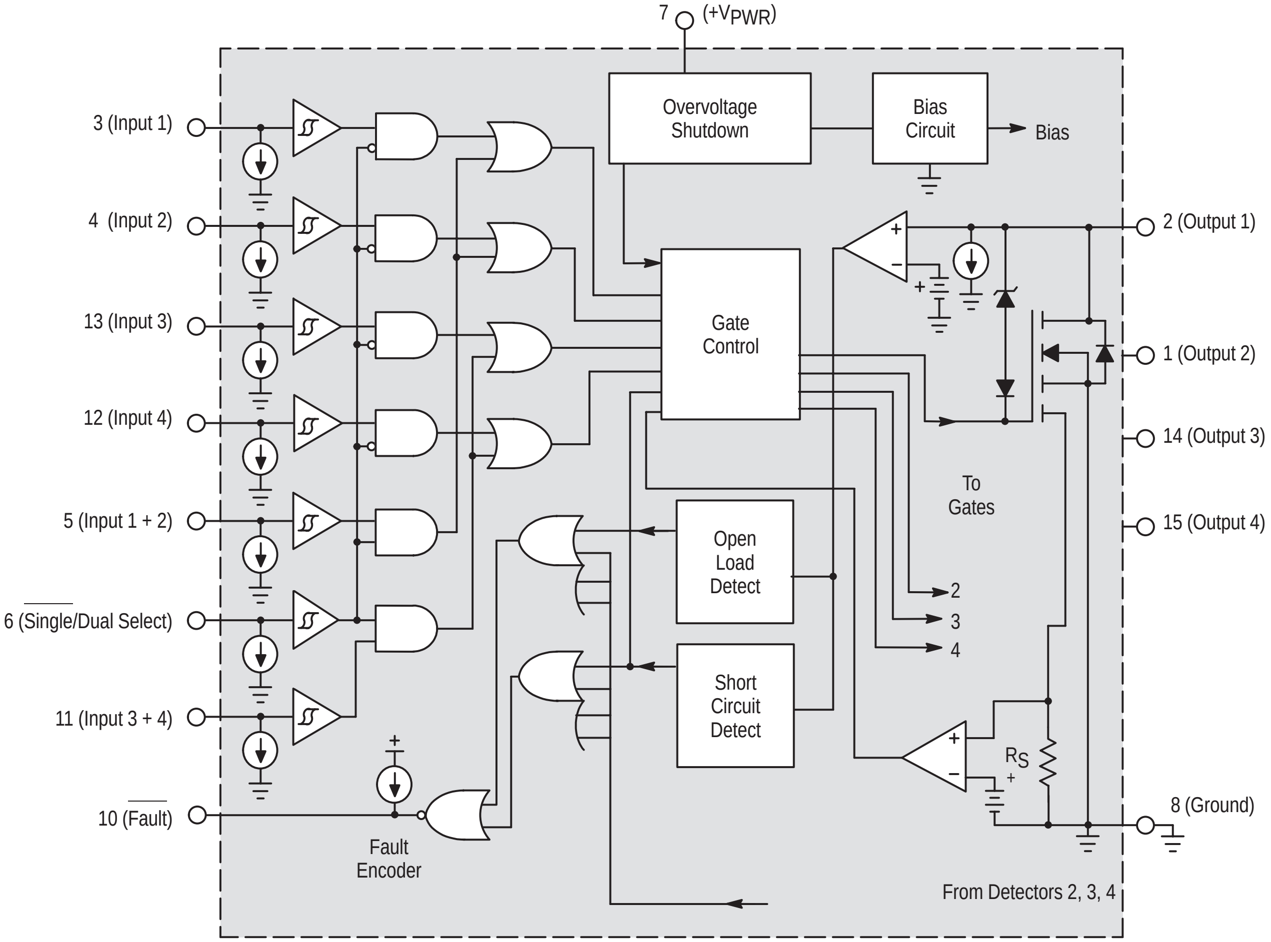
* No Suffix

Quad Fuel Injector Driver

MC33293AT, MC33293ATV

T_J = –40° to +150°C, Case 821D, C

The MC33293AT is a monolithic quad low–side switching device having CMOS logic, bipolar/ CMOS analog circuitry, and DMOS power FETs. All inputs are CMOS compatible. Each independent output is internally clamped to 65 V, current limited to ≥ 3.0 A, and has an $r_{DS(on)}$ of ≤ 0.25 Ω with V_{PWR} ≥ 9.0 V and may be paralleled to lower $r_{DS(on)}$. Fault output reports existence of open loads (outputs “On” or “Off”), shorted loads, and over temperature condition of outputs. A shorted load condition will shut off only the specific output involved while allowing other outputs to operate normally. An overvoltage condition will shut off all outputs for the overvoltage duration. A single/dual mode select pin allows either independent input/output operation or paired output operation.

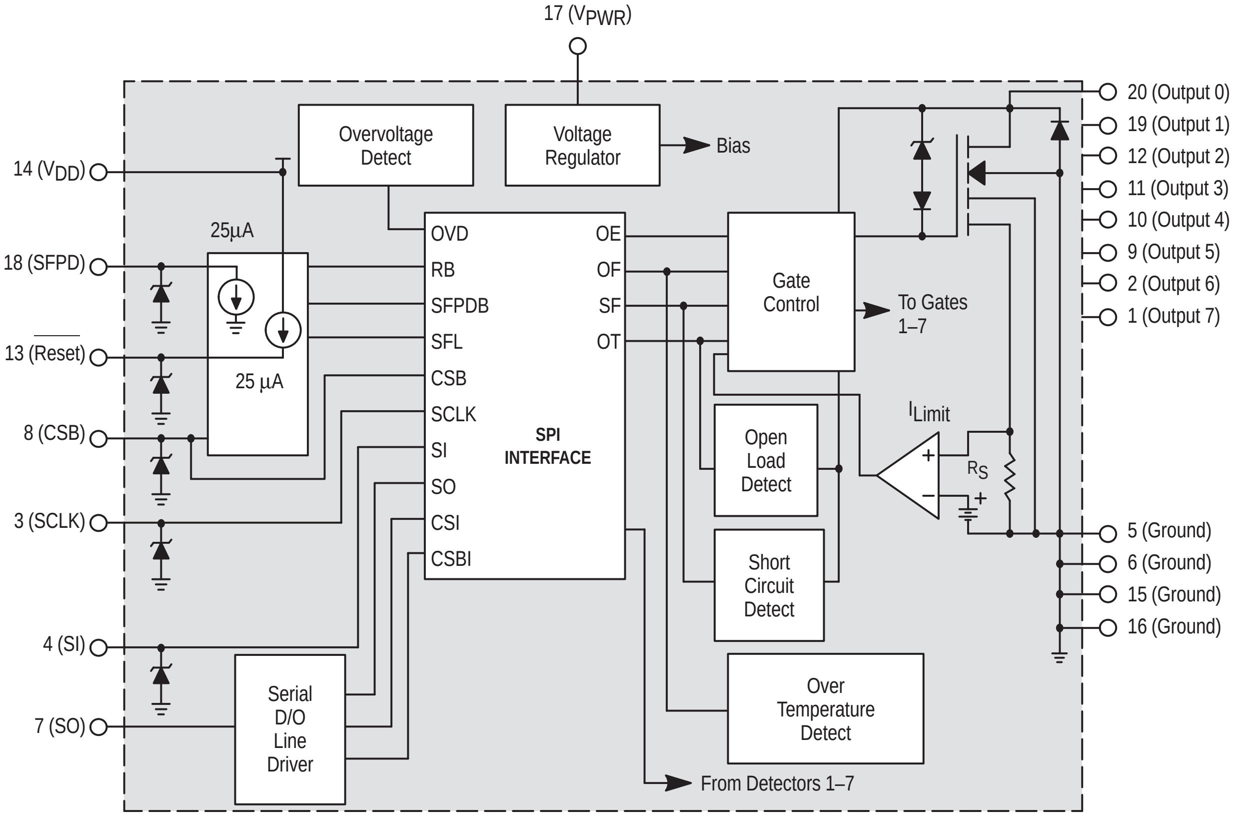


Octal Serial Switch

MC33298P, MC33298DW

T_J = –40° to +150°C, Case 738, 751E

The MC33298 is a monolithic eight output low–side switch with 8–bit serial input control. Incorporates CMOS logic, bipolar/CMOS analog circuitry, and DMOS power FETs. All inputs are CMOS compatible. It is designed to interface to a microcontroller and switch inductive or incandescent loads. Each independent output is internally clamped to 55 V, current limited to ≥ 3.0 A, and has an $r_{DS(on)}$ of ≤ 0.45 Ω with V_{PWR} ≥ 9.0 V. This device has low standby current, cascadable fault status reporting, output diagnostics, and shutdown for each output.



Dual High–Side Switch

MC33143DW

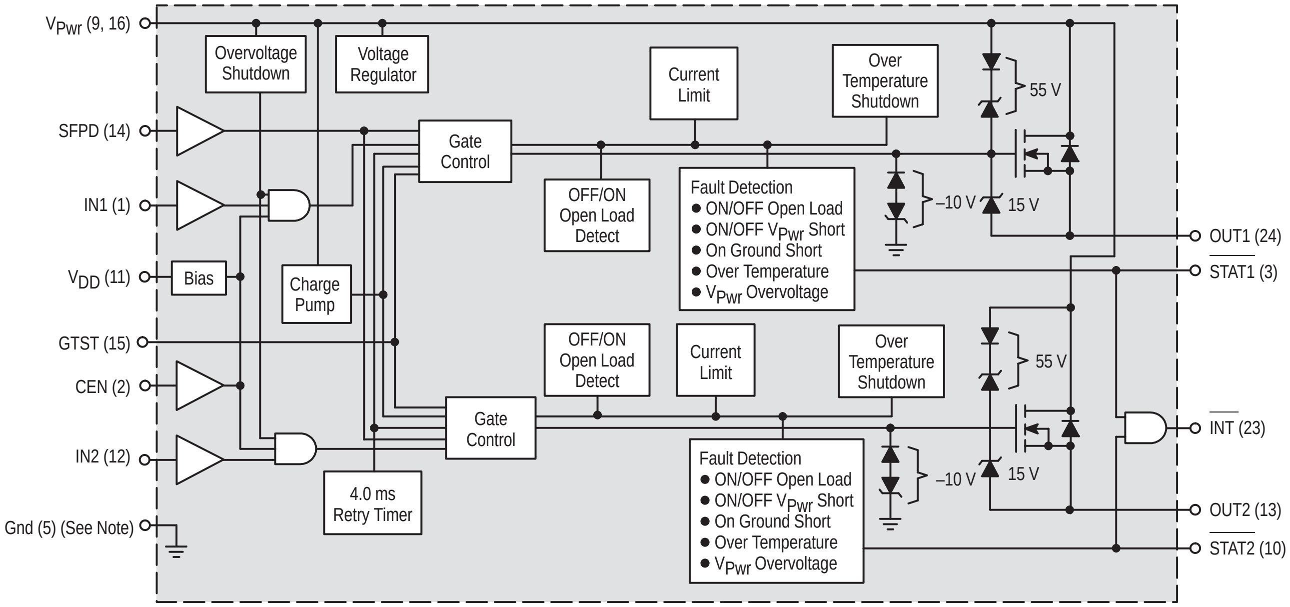
T_A = –40° to +125°C, Case 751E

The MC33143 is a dual high–side switch designed for solenoid control in harsh automotive applications, but is well suited for other environments. The device can also be used to control small motors and relays as well as solenoids. The MC33143 incorporates SMARTMOS™ technology, with CMOS logic, bipolar/MOS analog circuitry, and DMOS power outputs. An internal charge pump is incorporated for efficient gate enhancement of the internal high–side power output devices. The outputs are designed to provide current to low impedance solenoids. The MC33143 provides individual output fault status reporting along with internal Overcurrent and Over Temperature protection. The device also has Overvoltage protection, with automatic recovery, which “globally” disables both outputs for the duration of an Overvoltage condition. Each output has individual Overcurrent and Over Temperature shutdown with automatic retry recovery. Outputs are enabled with a CMOS logic high signal applied to an input to providing true logic control. The outputs, when turned on, provide full supply (battery) voltage across the solenoid coil.

The MC33143 is packaged in an economical 24 pin surface mount power package and specified over an operating voltage of 5.5 V ≤ V_{Pwr} < 26 V for –40°C ≤ T_A ≤ 125°C.

- Designed to Operate Over Wide Supply Voltages of 5.5 V to 26 V
- Dual High–Side Outputs Clamped to –10 V for Driving Inductive Loads
- Internal Charge Pump for Enhanced Gate Drive
- Interfaces Directly to a Microcontroller with Parallel Input Control
- Outputs Current Limited to 3.0 A to 6.0 A for Driving Incandescent Loads
- Chip Enable “Sleep Mode” for Power Conservation
- Individual Output Status Reporting
- Fault Interrupt Output for System Interrupt Use
- Output ON or OFF Open Load Detection
- Overvoltage Detection and Shutdown
- Output Over Temperature Detection and Shutdown with Automatic Retry
- Sustained Current Limit or Immediate Overcurrent Shutdown Output Modes
- Output Short to Ground Detection and Shutdown with Automatic Retry
- Output Short to V_{Pwr} Detection

Simplified Internal Block Diagram



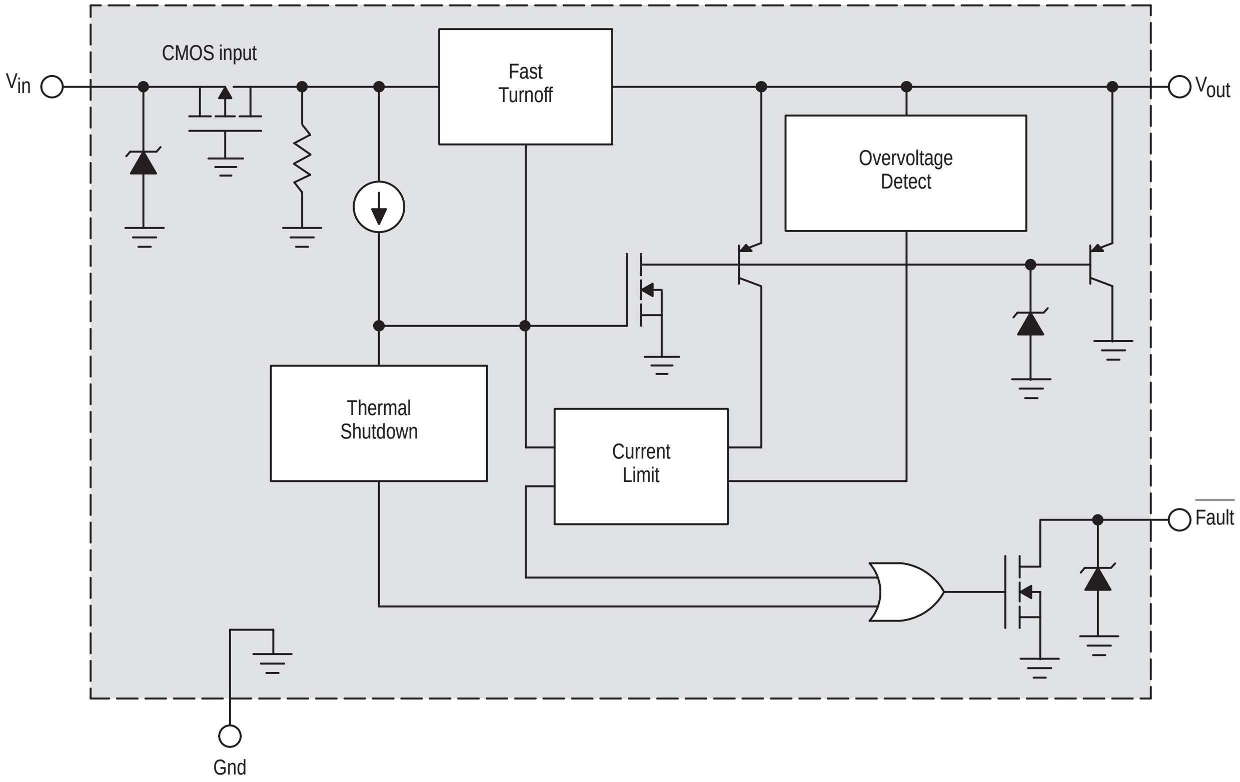
NOTE: Pins 5, 6, 7, 8, 17, 18, 19 and 20 should all be grounded so as to provide electrical as well as thermal heatsinking of the device.

Low Side Protected Switch

MC3392T, T–1, DW

T_J = –40° to +150°C,
Case 221A, 314D, 751G

Single low side protected switch with fault reporting capability. Input is CMOS compatible. Output is short circuit protected to 1.0 A minimum with a unique current fold–back feature. Device has internal output clamp for driving inductive loads with overcurrent, overvoltage, and thermal protection. When driving a moderate load, the MC3392 performs as an extremely high gain, low saturation Darlington transistor having a CMOS input characteristic with added protection features. In some applications, the three terminal version can replace industry standard TIP100/101 NPN power Darlington transistors.

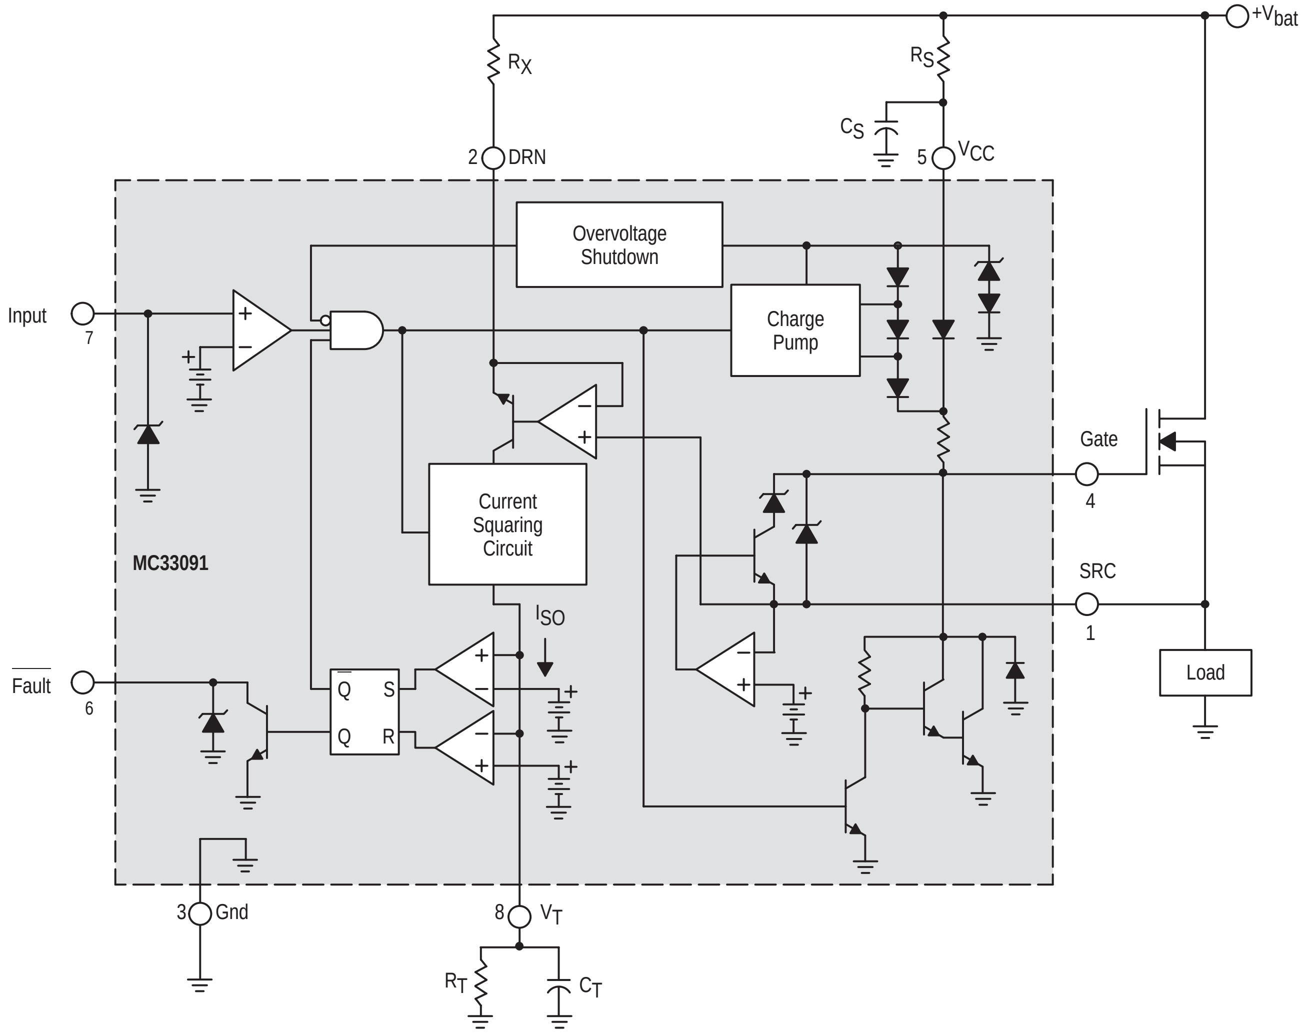


High Side TMOS Driver

MC33091AP, AD

T_J = –40° to +150°C, Case 626, 751

Offers an economical solution to drive and protect N–channel power TMOS devices used in high side switching configurations. Unique device monitors load resulting V_{DS}. TMOS voltage to produce a proportional current used to drive an externally programmed over current timer circuit to protect the TMOS device from shorted load conditions. Timer can be programmed to accommodate driving incandescent loads. Few external components required to drive a wide variety of N–channel TMOS devices. A Fault output is made available through the use of an open collector NPN transistor requiring a single pull–up resistor for operation. Input is CMOS compatible. Device uses ≤ 3.0 µA standby current and has an internal charge pump requiring no external components for operation.

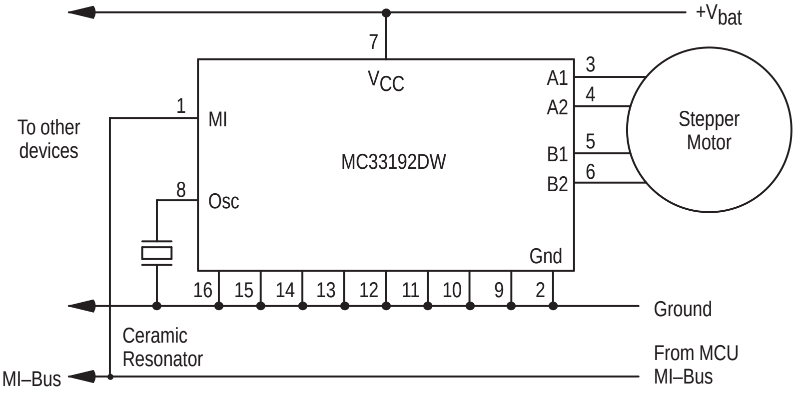


MI–Bus Interface Stepper Motor Controller

MC33192DW

T_J = –40° to +100°C, Case 751G

Intended to control loads in harsh automotive environments using a serial communication bus. Can provide satisfactory real time control of up to eight stepper motors using MI–Bus protocol. Use of MI–Bus offers a noise immune system solution for difficult applications involving relays and motors. The stepper motor controller provides four phase signals to drive two phase motors in either half of full–step modes. Designed to interface to a microprocessor with minimal amount of wiring, affording an economical and versatile system.



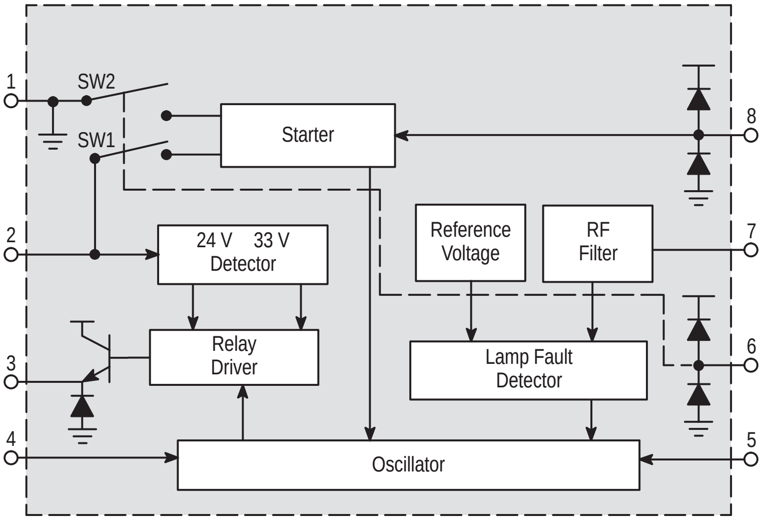
Automotive Direction Indicator

MC33193P, D

T_A = –40° to +125°C, Case 626, 751

The MC33193 is a new generation industry standard UAA1041 “Flasher”. It has been developed for enhanced EMI sensitivity, system reliability, and improved wiring simplification. The MC33193 is pin compatible with the UAA1041 and UAA1041B in the standard application configuration as shown in Figure 9, without lamp short circuit detection and using a 20 mΩ shunt resistor. The MC33193 has a standby mode of operation requiring very low standby supply current and can be directly connected to the vehicle’s battery. It includes a RF filter on the Fault detection pin (Pin 7) for EMI purposes. Fault detection thresholds are reduced relative to those of the UAA1041 allowing a lower shunt resistance value (20 mΩ) to be use.

- Pin Compatible with the UAA1041
- Defective Lamp Detection Threshold
- RF Filter for EMI Purposes
- Load Dump Protection
- Double Battery Capability for Jump Start Protection
- Internal Free Wheeling Diode Protection
- Low Standby Current Mode



Automotive Wash Wiper Timer

MC33197AD

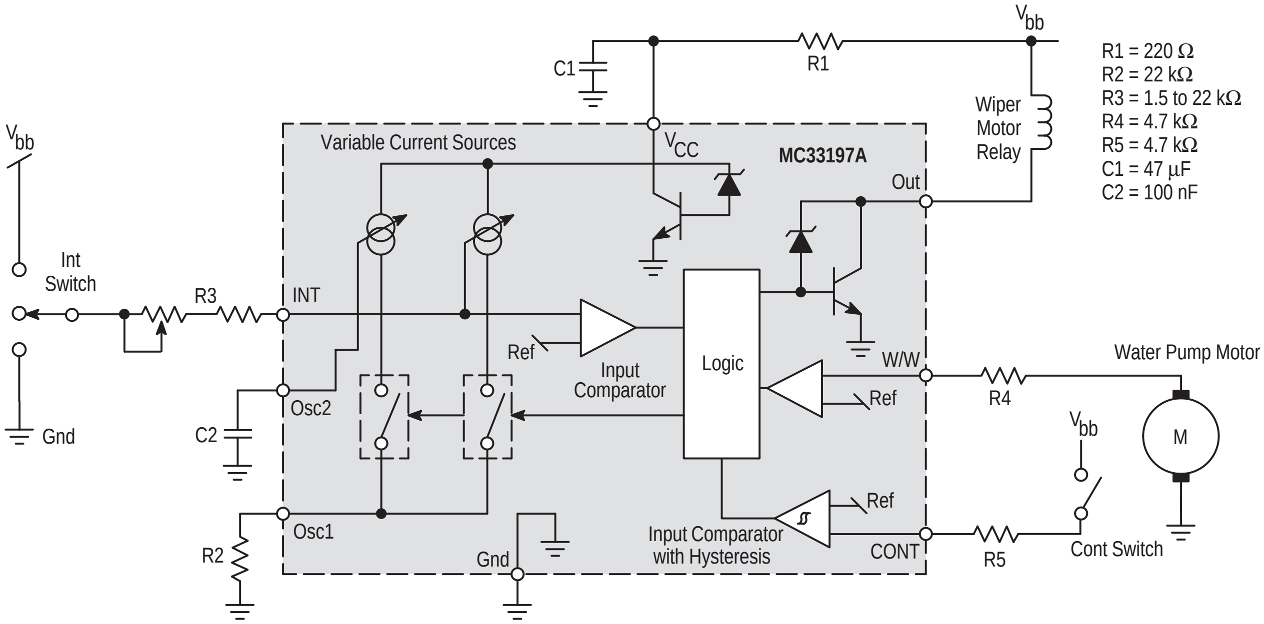
T_A = –40° to +105°C, Case 751

MC33197AP

T_A = –40° to +125°C, Case 626

The MC33197A is a standard wiper timer control device designed for harsh automotive applications. The device can perform the intermittent, after wash, and continuous wiper timer functions. It is designed to directly drive a wiper motor relay. The MC33197A requires very few external components for full system implementation. The intermittent control pin can be switched to ground or V_{bat} to meet a large variety of possible applications. The intermittent timing can be fixed or adjustable via an external resistor. The MC33197A is built using bipolar technology and parametrically specified over the automotive ambient temperature range and 8.0 to 16 V supply voltage. The MC33197A can operate in both front and rear wiper applications.

- Adjustable Time Interval of Less Than 500 ms to More Than 30 s
- Intermittent Control Pin Can Be Switched to Ground or V_{bat}
- Adjustable After Wipe Time
- Priority to Continuous Wipe
- Minimum Number of Timing Components
- Integrated Relay Driver With Free Wheeling Protection Diode
- Operating Voltage Range From 8.0 to 16 V
- For Front Wiper and Rear Wiper Window Applications



Automotive ISO 9141 Serial Link Driver

MC33199D

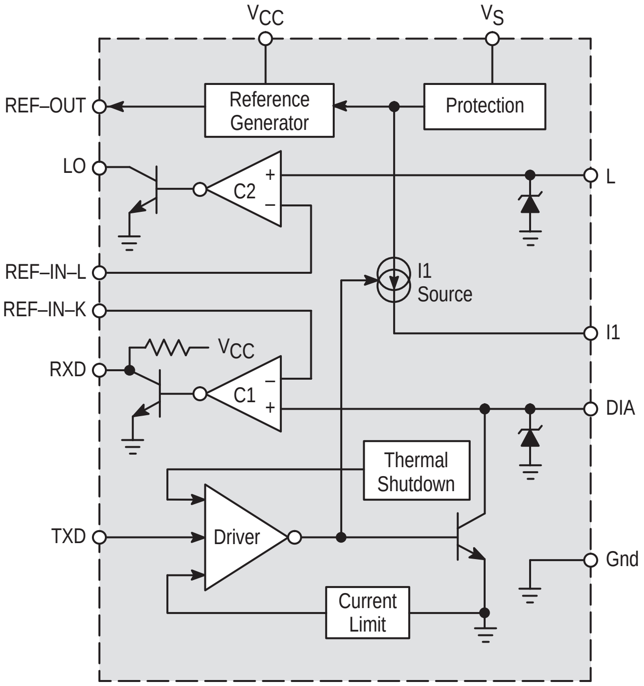
T_A = –40° to +125°C, Case 751A

The MC33199D is a serial interface circuit used in diagnostic applications. It is the interface between the microcontroller and the special K and L Lines of the ISO diagnostic port. The MC33199D has been designed to meet the "Diagnosis System ISO 9141" specification.

The device has a bi–directional bus K Line driver, fully protected against short circuits and over temperature. It also includes the L Line receiver, used during the wake up sequence in the ISO transmission.

The MC33199 has a unique feature which allows transmission baud rate up to 200 k baud.

- Electrically Compatible with Specification "Diagnosis System ISO 9141"
- Transmission Speed Up to 200 k Baud
- Internal Voltage Reference Generator for Line Comparator Thresholds
- TXD, RXD and LO Pins are 5.0 V CMOS Compatible
- High Current Capability of DIA Pin (K Line)
- Short Circuit Protection for the K Line Input
- Over Temperature Shutdown with Hysteresis
- Large Operating Range of Driver Supply Voltage
- Full Operating Temperature Range
- ESD Protected Pins



Alternator Voltage Regulator

MC33092DW

T_J = –40° to +125°C, Case 751D

Provides voltage regulation and load response control in diode rectified 12 V alternator charging systems. Provides externally programmed load response control of the alternator output current to eliminate engine speed hunting and vibration due to sudden electrical loads. Monitors and compares the system battery voltage to an externally programmed set point value and pulse width modulates an N–channel MOSFET transistor to control the average alternator field current. In addition, has duty cycle limiting, under/overvoltage and phase detection (broken belt) protective features.

CIRCUIT DESCRIPTION

The MC3334 high energy ignition circuit was designed to serve aftermarket Delco five–terminal ignition applications. This device, driving a high voltage Darlington transistor, offers an ignition system which optimizes spark energy at minimum power dissipation. The IC is pinned–out to permit thick film or printed circuit module design without any crossovers.

The basic function of an ignition circuit is to permit build–up of current in the primary of a spark coil, and then to interrupt the flow at the proper firing time. The resulting flyback action in the ignition coil induces the required high secondary voltage needed for the spark. In the simplest systems, fixed dwell angle produces a fixed duty cycle, which can result in too little stored energy at high RPM, and/or wasted power at low RPM. The MC3334 uses a variable DC voltage reference, stored on C_{Dwell}, and buffered to the bottom end of the reluctor pickup (S1) to vary the duty cycle at the spark coil. At high RPM, the MC3334 holds the output “off” for approximately 1.0 ms to permit full energy discharge from the previous spark; then it switches the output Darlington transistor into full saturation. The current ramps up at a slope dictated by V_{bat} and the coil L. At very high RPM the peak current may be less than desired, but it is limited by the coil itself.

As the RPM decreases, the ignition coil current builds up and would be limited only by series resistance losses. The MC3334 provides adjustable peak current regulation sensed by R_S and set by R_{D1}, in this case at 5.5 A, as shown in Figure 2. As the RPM decreases further, the coil current is held at 5.5 A for a short period. This provides a reserve for sudden acceleration, when discharge may suddenly occur earlier than expected. The peak hold period is about 20% at medium RPM, decreasing to about 10% at very low RPM. (Note: 333 Hz = 5000 RPM for an eight cylinder four stroke engine.) At lower V_{bat}, the “on” period automatically stretches to accommodate the slower current build–up. At very low V_{bat} and low RPM, a common condition during cold starting, the “on” period is nearly the full cycle to permit as much coil current as possible.

The output stage of the IC is designed with an OVP circuit which turns it on at $V_{bat} \approx 30$ V ($V_{CC} \approx 22$ V), holding the output Darlington off. This protects the IC and the Darlington from damage due to load dump or other causes of excessive V_{bat}.

Component Values

Pickup – series resistance = 800 Ω ± 10% @ 25°C
inductance = 1.35 H @ 1.0 kHz @ 15 Vrms

Coil – leakage L = 0.6 mH
primary R = 0.43 Ω ± 5% @ 25°C
primary L = 7.5 mH to 8.5 mH @ 5.0 A

R_L – load resistor for pickup = 10 kΩ ± 20%

R_A, R_B – input buffer resistors provide additional transient protection to the already clamped inputs = 20 k ± 20%

C1, C2 – for reduction of high frequency noise and spark transients induced in pick–up and leads; optional and non–critical

R_{bat} – provides load dump protection (but small enough to allow operation at V_{bat} = 4.0 V) = 300 Ω ± 20%

C_{Filter} – transient filter on V_{CC}, non–critical

C_{Dwell} – stores reference, circuit designed for 0.1 µF ± 20%

R_{Gain} – R_{Gain}/R_{D1} sets the DC gain of the current regulator = 5.0 k ± 20%

R_{D2} – R_{D2}/R_{D1} set up voltage feedback from R_S

R_S – sense resistor (PdAg in thick film techniques) = 0.075 Ω ± 30%

R_{Drive} – low enough to supply drive to the output Darlington, high enough to keep $V_{CE(sat)}$ of the IC below Darlington turn–on during load dump = 100 Ω ± 20%, 5.0 W

R_{D1} – starting with 35 Ω assures less than 5.5 A, increasing as required to set 5.5 A

$$R_{D1} = \frac{I_{O(pk)}\,R_S - V_{ref}}{\dfrac{V_{ref}}{R_{D2}} - \dfrac{1.4}{R_{Gain}}} - (\approx 100\ \Omega)$$

General Layout Notes

The major concern in the substrate design should be to reduce ground resistance problems. The first area of concern is the metallization resistance in the power ground to module ground and the output to the R_{drive} resistor. This resistance directly adds to the $V_{CE(sat)}$ of the IC power device and if not minimized could cause failure in load dump. The second concern is to reference the sense ground as close to the ground end of the sense resistor as possible in order to further remove the sensitivity of ignition coil current to ground I.R. drops.

All versions were designed to provide the same pin–out order viewed from the top (component side) of the board or substrate. This was done to eliminate conductor cross–overs. The standard MC3334 plastic device is numbered in the industry convention, counter–clockwise viewed from the top, or bonding pad side. The MCCF3334 “flip” or “bump” chip is made from reversed artwork, so it is numbered clockwise viewed from its bump side. Since this chip is mounted face down, the resulting assembly still has the same counter–clockwise order viewed from above the component surface. All chips have the same size and bonding pad spacing. See Figure 4 for dimensions.

MOTOROLA

MC3392

Low Side Protected Switch

The MC3392 is a low side protected switch designed for use in harsh automotive applications which require the capability of handling high voltages attributed to load and field dump transients, in addition to reverse and double battery conditions. The three terminal TO–220 is intended to replace power Darlington transistors in new and existing switching applications when taking into account the CMOS input levels required by the MC3392. It offers improved functionality and ruggedness over power Darlingtons while retaining the same package and pin configuration, and can be used as a replacement in many applications using the industry standard TIP100/101 NPN power Darlington transistor.

The five–terminal TO–220 has the added feature of having a $\overline{\text{Fault}}$ output (active low) which will indicate the existence of an over temperature, over–voltage or current limit condition, including an output short to ground.

When driving a moderate load, the MC3392 performs as an extremely high gain, low saturation Darlington transistor having CMOS input levels. The primary advantage of the MC3392 over a Darlington transistor is the additional protection afforded the device and load when driving difficult or faulty loads. This device incorporates unique internal current limit and thermal protection circuitry to safeguard itself and the associated load from catastrophic failure.

The MC3392 is available in a three and five–lead TO–220 package; the five–lead having the added diagnostic feature. The full featured MC3392 is also available in a 16 pin wide body SOIC plastic power package.

- Designed for Automotive Applications
- Can Be Used as a Replacement for TIP100/101 NPN Power Darlingtons
- Drives Inductive Loads without External Clamp Circuitry
- Withstands Negative and Positive Transient Voltages
- Low ON Voltage
- CMOS Logic Compatible Input
- Over Current, Overvoltage, and Thermal Protection
- Extended Operating Temperature Range
- $\overline{\text{Fault}}$ Output

TECHNICAL DISCUSSION

Introduction

The MC3392 is a low side protected switch incorporating many features making it ideal for use in harsh automotive applications. The protection circuitry of the MC3392 protects not only itself but also the associated load from destructive voltage transients attributed to load and field dump, as well as reverse and double battery conditions found in automotive applications. The MC3392 is unique in that the protection circuitry is internal and does not require additional external protection components for its operation. This makes the device very cost effective because its application utilizes few external components, thus reducing cost and space requirements needed for the system. The MC3392 is extremely effective when used to drive solenoids, as well as incandescent lamp loads. The following description of the device's operation is in reference to the functional blocks of the Representative Block Diagram shown in Figure 1.

CMOS Input

The input of the MC3392 is CMOS compatible. Input control performs as true logic. When the input (V_{in}) is less than 1.0 V the MC3392 switch is in a high impedance or OFF state. When V_{in} is greater than 4.0 V, is in a low impedance or ON state. The switching threshold of the input is approximately 2.0 V and is graphed in Figure 7. With the input at 4.0 V, the input sink current will be approximately 250 µA. In the ON state, the internal protection circuitry is activated and all of the protection features are available for use. In the OFF state, however, it is important to note that none of the protection features are available, with the exception of the internal inductive load clamp. The input pin is afforded a minimum of 2000 V ESD protection (Human Body Model) by virtue of the 7.2 V zener diode.

Over Temperature Shutdown

Internal Thermal Shutdown Circuitry is provided to protect the MC3392 in the event the Operating Junction Temperature (T_J) exceeds 150°C. Typically, Thermal Shutdown will occur at 160° to 170°C. The thermal shutdown sense element is embedded within the output PNP (Q4) in order to afford very fast thermal coupling of Q4 to the sense element. Any rise in temperature due to the ambient is translated directly to Q4 and the sense element. If the junction temperature rises excessively above 150°C, the Thermal Shutdown circuit will turn ON, quickly pulling the gate of Q2 to ground, which pulls the base of Q4 to ground, turning it OFF. In addition, the Thermal Shutdown circuit simultaneously turns Q5 ON and with a suitable pull–up resistor at the Fault pin reports the presence of a fault (logic low). The output PNP will remain OFF until the junction temperature decreases to within the operating range at which time Thermal Shutdown turns OFF, ceasing to hold the gate of Q2 low, turning Q4 back ON. This process will repeat as long as the thermal over load exists. This mode of operation is a nondestructive safety feature of the device and will correct itself real time when the cause of over temperature is removed. A continued over temperature condition will thermally Pulse Width Modulate (PWM) the output and Fault and may be incorrectly interpreted as an oscillating load if one does not consider the simultaneous performance of the Fault pin.

Current Limit

The MC3392 protects itself against V_{out} to $+V_S$ hard shorts as well as any over current conditions by reducing the magnitude of output current (I_O) to that of the short circuit current limit value (I_{SC}). When the output current monitored by Q3 tries to exceed I_{SC}, the Current Limit circuit lowers the gate voltage of Q2, lowering the base of Q4, causing the load current through Q4 to diminish. Simultaneously, when the load current exceeds I_{SC}, Q5 will turn ON reporting a fault condition. If the output current is allowed to remain excessively high for the degree of heatsinking incorporated, and the junction temperature of the device is allowed to heat beyond 150°C, the Thermal Shutdown circuit will activate and the output will thermally PWM. Again, these modes of operation are safety features of the MC3392 and are not destructive.

Overvoltage Detect

This circuitry protects the MC3392 from V_{out} voltages in excess of 16 V by lowering the output current to a nondestructive value. With increasing V_{out} voltage ($16\ V < V_{out} < 45\ V$) the load current is reduced to below that of I_{SC} and produces a fold back current effect. As V_{out} increases in excess of 16 V, the output current decreases linearly until V_{out} exceeds 45 V. With an infinite heatsink and $V_{out} > 45$ V, I_O will be less than 100 mA. For the other extreme, no heatsink and $V_{out} > 45$ V, I_O can be expected to be less than about 400 mA. This behavior of I_O in relation to V_{out} is shown in Figure 13.

For the infinite heatsink case, the output current initially increases with increased voltage until V_{out} exceeds 16 V, thereafter the behavior is expressed as,

$$I_O = I_{SC}\ [1 – (V_{out} – 16\ V) / 30\ V]$$

Beyond 45 V, I_O is limited to less than 100 mA. Anytime the Overvoltage Detect circuit is activated, the gate of Q5 is pulled low causing Q5 to turn ON to report the fault at the Fault pin.

Inductive Load Clamp

The MC3392 has an internal inductive load clamp for protection against flyback voltages imposed on the output pin in excess of 70 V. The incorporated zener clamp can quickly dissipate up to 60 milli–Joules of inductive flyback energy. Figure 14 shows the maximum inductive load versus load current that the clamp can handle safely. As an example (using Figure 14), if operating the MC3392 to drive a 0.33 H inductor, the maximum load current should be adjusted to 600 mA or less. If the load current is too high for the inductor used, some series resistance can be added to the load to limit the current. If this is not possible, an external clamp must be used to facilitate handling the higher energy. When using an external clamp, the external clamp voltage must be less than 60 V so as to override the internal clamp. The output clamp offers protection for the output when the MC3392 is in the OFF state. During the ON state, other protection features (Overvoltage, Current, and Temperature) are available to protect the output.

Fault Logic

The Fault is comprised of an internal open drain FET requiring an external pull–up resistor. Typically, a 5.0 k pull–up resistor to a +5.0 V supply is satisfactory. The Fault pin is afforded a minimum of 2000 V ESD protection (Human Body Model) by virtue of the 7.2 V zener diode. The Fault will report a fault (logic low state) whenever the MC3392 experiences a fault condition. Conditions producing a fault are: $I_O > 1.3$ A (over current/shorted load); $T_J > 150$°C (over temperature); and $V_{out} > 16$ V (overvoltage).

If the device goes into Thermal Shutdown, caused by environmental overheating (not resulting from another fault condition), the Fault and V_{out} will thermally PWM as the MC3392 repeatedly heats to shut off, cools, and again turns on. If a current limit fault causes the device to go into Thermal Shutdown, the output will oscillate while the Fault remains pulled low. There is no thermal hysteresis designed in to control the PWM effect and this fault mode of operation is not destructive.

Fast Turn–Off

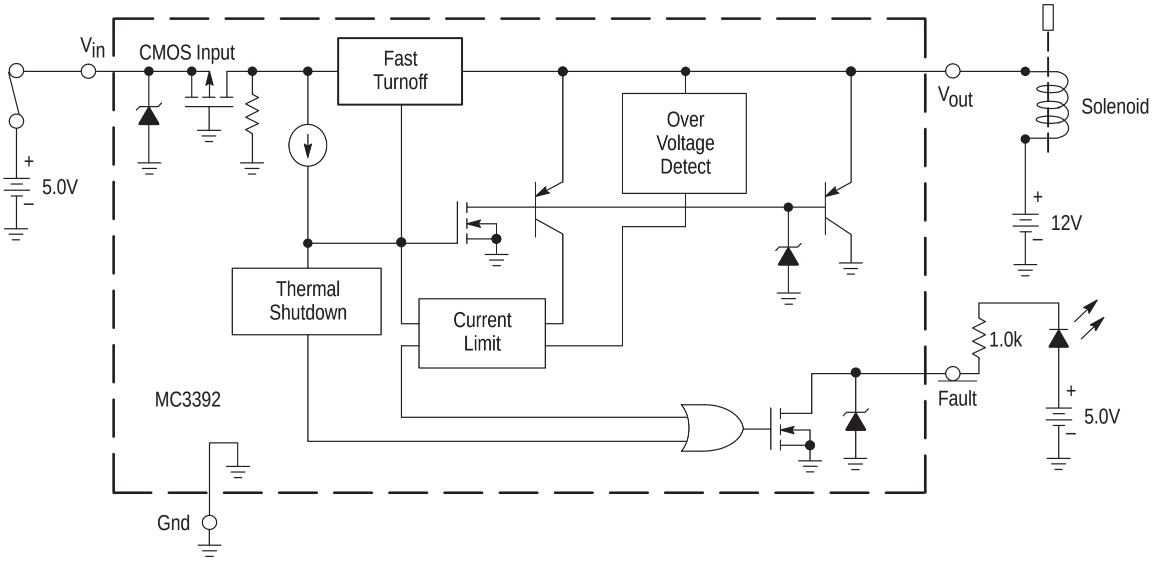
This circuitry enhances the MC3392 turn–off performance. Whenever V_{in} goes to a logic low state, V_{out} is held in an OFF state for approximately 15 µs. During fast turn–off, less than 30 mA of current is allowed to flow producing an abrupt turn–off. This turn–off characteristic can be seen in Figure 12, a photograph of the typical turn–off waveform.

APPLICATIONS INFORMATION

Solenoid Driver

The MC3392 can be used to drive a variety of solenoid applications similar to that of Figure 15. For example; driving a solenoid having an inductance of 73.8 mH and a resistance of 95 Ω from a 12 V supply will cause 240 mA of sink current to flow with the MC3392 in the ON state. The resulting current value is within the normal load current operating region and will not produce a fault. Load current is paramount in any design using the MC3392 and must be less than I_{SC} for acceptable operation. If the load current is greater than I_{SC}, a current limit fault state will exist. Operation in this state is not destructive as the device will turn off if the Junction Temperature (T_J) rises above 150°C. When the Junction Temperature cools below 150°C the device will again turn–on, with a repeat of the cycle. Careful design to acceptable load current limits should be insured for satisfactory operation of an application.

Figure 15. Solenoid Driver



Instrument Panel Lamp Dimmer Control

The MC3392 can be used to control the dimming function associated with instrument panel lamps. The brightness of incandescent lamps can be varied by pulse width modulating the input of the MC3392. The modulating signal for the MC3392 can be obtained directly from a microprocessor or, as in Figure 16, from an MC1455 timer. The MC1455 timer is configured as a free–running clock having both frequency and duty cycle control. The typical timer frequency is approximately 80 Hz when the frequency potentiometer is adjusted to 1.0 k. This frequency was chosen so as to avoid any perceptible lamp flicker. The duty cycle potentiometer controls the duty cycle over a range of approximately 3.0% to 97%; When at 3.0% duty cycle, the lamps are essentially off; When at 97% duty cycle, the lamps are essentially full lit. Six incandescent lamps are shown in this application drawing 720 mA total current. Similar applications can be used to drive a variety of lamp loads. The total load current is the primary factor of consideration when driving lamp loads. The total value of I_O must be less than I_{SC}.

Another convenient aspect of this application is the LED. The LED can be used to denote the existence of a system fault (overvoltage, current limiting, or thermal shutdown).

MOTOROLA

MC3399

Automotive Half-Amp High-Side Switch

The MC3399 is a High–Side Switch designed to drive loads from the positive side of the power supply. The output is controlled by a TTL compatible input Enable pin. In the “on” state, the device exhibits very low saturation voltages for load currents in excess of 750 mA. The device isolates the load from positive or negative going high voltage transients by abruptly “opening” thus protecting the load from the transient voltage for the duration of the transient. The device automatically re–establishes its original operating state following the transient condition.

The MC3399 is fabricated on a power BIMOS process which combines the best features of Bipolar and MOS technologies. The mixed technology provides higher gain PNP output devices and results in Power Integrated Circuits having substantially reduced quiescent currents.

The device operates over a wide power supply voltage range and can withstand voltage transients (positive or negative) of ±100 V. A rugged PNP output stage along with active clamp circuitry, output current limit and thermal shutdown permit the driving of all types of loads, including inductive. The MC3399 is offered in 5–lead TO–220 and 16–lead SOIC plastic packages to facilitate either “thru–hole” or surface mount use. In addition, it is specified over a wide ambient operating temperature of –40°C to +125°C and is ideally suited for industrial and automotive applications where harsh environments exist.

- Low Switch Voltage Drop
- Load Currents in Excess of 750 mA
- Low Quiescent Current
- Transient Protection Up to ± 100 V
- TTL Compatible Enable Input
- On–Chip Current Limit and Thermal Shutdown Circuitry

MOTOROLA

MC33091A

High-Side TMOS Driver

The MC33091A is a High–Side TMOS Driver designed for use in harsh automotive switching applications requiring the capability of handling high voltages attributed to load and field dump transients, as well as reverse and double battery conditions. Few external components are required to drive a wide variety of N–Channel TMOS devices. The MC33091A, driving an appropriate TMOS device, offers economical system solutions for high–side switching large currents. The MC33091A has CMOS compatible input control, charge pump to drive the TMOS power transistor, basic fault detection circuit, V_{DS} monitoring circuit used to detect a shorted TMOS load, and overcurrent protection timer with associated current squaring circuitry.

Short circuit protection is made possible by having a unique V_{DS} voltage to current converter drive an externally programmable integrator circuit. This circuit affords fast detection of a shorted load while allowing difficult loads, such as lamps having high in–rush currents, additional time to turn on.

The Fault output is comprised of an open collector NPN transistor requiring a single pull–up resistor for operation. A fault is reported whenever the MOSFET on–current exceeds an externally programmed set level.

The MC33091A is available in the plastic 8–Pin DIP package as well as the plastic 8–Pin surface mount package.

- Designed for Automotive High–Side Driver Applications
- Works with a Wide Variety of N–Channel Power MOSFETs
- Drives Inductive Loads with No External Clamp Circuitry Required
- CMOS Logic Compatible Input Control
- On–Board Charge Pump with No External Components Required
- Shorted Load Detection and Protection
- Forward Overvoltage and Reverse Battery Protection
- Load and Field Dump Protection
- Extended Operating Temperature Range
- Fault Output to Report a MOSFET Overcurrent Condition

FUNCTIONAL DESCRIPTION

Introduction

The MC33091A is designed to drive a wide variety of N–channel TMOS transistors in high–side configured, low frequency switching applications. The MC33091A has an internal charge pump to fully enhance the on–state of the TMOS device. The MC33091A protects the TMOS device from shorts to ground and provides a Fault output to report the presence of an overcurrent condition. The few additional external components required allow tailoring of the application's protection level. The protection scheme of the MC33091A uses an externally programmable, nonlinear timer that disables the TMOS device in the event the drain to source voltage exceeds a specified value for a specified duration. Both the value and duration are externally programmable allowing for flexibility in applications.

Description of Pins

Figure 1 shows a typical application as well as the internal functional blocks of the MC33091A. The discussion to follow references this figure.

Input (Pin 7): The logic levels of the Input are compatible with CMOS logic families. The Input enables the protection and charge pump circuitry. With the Input in a logic low state the MC33091A draws only leakage current of less than 300 µA and in this condition the associated TMOS device will be in the "off" state. When the Input is in a logic high state, the Gate voltage (Pin 4) rise is limited to a maximum of 14 V above SRC (Pin 1), due to an internal clamp diode being used and the TMOS device is enhanced full on.

Fault (Pin 6): The Fault output is comprised of an open collector NPN transistor capable of sinking at least 500 µA when the TMOS gate is disabled due to an overcurrent condition. When the TMOS device experiences an overcurrent condition, the Fault pin is pulled low.

SRC (Pin 1): The SRC pin senses the TMOS source voltage and is the input to the V_{DS} buffer used in conjunction with the DRN pin in monitoring the drain to source voltage developed across the TMOS device. The purpose of the 1.0 k resistor connected to this pin is to protect the SRC input from overvoltage as a result of flyback voltage produced when the TMOS device is used to switch large inductive loads. This resistor can be eliminated when switching noninductive loads.

DRN (Pin 2): The DRN is used in conjunction with the SRC pin and together constitute a V_{DS} monitor of the TMOS drain to source voltage. Feedback from the SRC pin will maintain a voltage across the resistor, R_X, equal to the V_{DS} voltage developed across the TMOS device. The series resistor, R_X, connected between the drain of the TMOS device and DRN of the MC33091A is used in conjunction with the feedback buffer and associated PNP transistor to establish a current proportional to the drain to source voltage, V_{DS}, of the TMOS device. This proportional current, acted upon by the current squaring circuit of the MC33091A, is an important part of the TMOS protection scheme.

V_{CC} (Pin 5): The V_{CC} pin supplies operational power to the MC33091A. An internal 30 V zener clamp connected to this pin provides overvoltage protection of the MC33091A. When the zener is activated, the MC33091A disables the TMOS device only for the duration of the overvoltage but the Fault output (Pin 6) does not change logic states. The Fault pin does not go to a logic low state during the overvoltage duration since this is not an MC33091A device fault, but an external system fault.

Gate (Pin 4): The Gate pin of the MC33091A is the output of the internal charge pump which controls the TMOS device. The charge pump is a voltage tripler and requires no additional external components for operation. When the Input is at a logic low state, the charge pump will be turned off. When the Input is pulled to a logic high state, with no load fault existing, the charge pump turns on and pumps the TMOS gate voltage to at least 8.0 V, typically 10 to 14 V, above V_{CC}. An internal zener clamp is incorporated to limit the Gate to approximately 14 V above the source and prevent rupture of the TMOS gate.

V_T (Pin 8): The Timer pin (V_T) is both an input to the timer window comparators and an output of the current squaring circuit. An external resistor (R_T) and capacitor (C_T) are tied to this node so as to afford programing the characteristics necessary for protection of the TMOS device.

Overcurrent Protection Timer

The MC33091A protection scheme is based on the ability of the MC33091A to constantly sense the voltage drop developed across the TMOS device. A low voltage drop is indicative of normal TMOS "on" operation while a large voltage drop represents the existence of an overcurrent condition. By monitoring the TMOS drain to source voltage (V_{DS}) the MC33091A is able to detect a shorted load and react to disable the TMOS device. The circuit protection scheme is essentially based on a timer whose rate is dependent on the magnitude of V_{DS}. If the drain to source voltage is large (i.e. $V_{DS} = V_{CC}$), the timer will disable the gate drive very quickly. If V_{DS} is only slightly above the normal operating level, the timer will take much longer to disable the gate drive.

Since the power dissipated in the TMOS device is proportional to V_{DS}^2, low V_{DS} conditions can be tolerated for a longer time than high V_{DS} conditions. To enhance the system application, the timer time–out of the MC33091A is inversely proportional to V_{DS}^2. This approach maximizes the TMOS operating range. The timer parameters are completely user programmable through the use of external components affording application usage of a wide variety of TMOS devices. This is intended to model the generation and dissipation of heat within the TMOS device.

The external components R_X, R_T and C_T determine the timer characteristics. Once enabled, the MC33091A will source a current, I_{SQ}, from the timer pin that is proportional to V_{DS}^2 such that:

$$I_{SQ} = KV_{DS}^2 \qquad (1)$$

where: $K = 1/(R_X^2 I_Q)$

I_Q is an internal current source parameter of the MC33091A that has a nominal value of 100 µA and R_X is the external resistor in series with the drain of the TMOS device that establishes the value of the voltage to current proportionality constant. Since the parallel combination of R_T and C_T appear at the timer pin (V_T), the timer pin voltage, V_T, can be written as:

$$V_T(t) = I_{SQ}R_T[1–e^{–t/(R_TC_T)}] \qquad (2)$$

With the Input (Pin 7) in a logic high state and no overcurrent condition exists, the TMOS device will be in the "on" state. If the TMOS device experiences an overcurrent condition, I_{SQ} flowing through R_T will increase causing C_T to charge up, in turn causing the timer voltage, V_T, to exceed the threshold, V_{TH}, of the upper comparator. This sets the latch causing the Q output of the latch to go high (and the Q output to go low), causing the TMOS gate and Fault output (Pin 6) to be pulled low, disabling the TMOS device. Both the current squaring circuit (I_{SQ}) and the charge pump are disabled whenever the Q output of the latch goes low. Using Equation 2, the fault time response for an overcurrent condition can be written as:

$$t = –R_TC_T \ln(1–V_{TH}/I_{SQ}R_T) \qquad (3)$$

Using Equation 1 and substituting for I_{SQ} in Equation 3:

$$t = –R_TC_T \ln[1–(V_{TH}R_X{}^2I_Q)/(V_{DS}{}^2R_T)] \qquad (4)$$

When the timer current (I_{SQ}) is disabled, the attained V_{TH} voltage at Pin 8 decays according to the R_TC_T time constant until the V_{TL} threshold of the lower comparator is reached. At this point the latch is reset and the TMOS gate, charge pump and the current squaring circuit are again enabled, again turning on the TMOS device. The MC33091A will repeatedly duty cycle the TMOS gate in this manner so long as the overcurrent condition exists and the input control signal remains in a high logic state. The Fault output (Pin 6) will likewise duty cycle.

Consider the case where in Equation 4 the term $(V_{TH}R_X{}^2I_Q)$ / $(V_{DS}{}^2R_T) \geq 1$ such that the time period is undefined. Solving for V_{DS} for this case yields the *minimum* drain to source voltage necessary which will *not* allow V_T to charge to the V_{TH} threshold of the upper comparator. In other words, whenever the TMOS on–time period is infinite, *no* TMOS overcurrent condition exists. The minimum drain to source voltage required for uninterrupted continuous TMOS operation is:

$$V_{DS(min)} = [(V_{TH}R_X{}^2I_Q)/R_T]^{1/2} = (V_{TH}/KR_T)^{1/2} \qquad (5)$$

Under *normal* operating steady state TMOS "on" conditions; the values chosen for R_X and R_T should be such that the upper comparator threshold voltage is *never* reached. This insures the TMOS device will always be in operation so long as the $V_{DS(min)}$ is not exceeded.

The minimum time required for the capacitor C_T to charge up to upper comparator threshold voltage occurs when the TMOS device experiences maximum current (I_{max}). This will occur when the load, and in turn the source, are shorted to ground resulting in the full battery voltage (V_S) to appear directly across the TMOS device. This condition causes maximum I_{SQ} current to be produced by the current squaring circuit. The maximum I_{SQ} current experienced is:

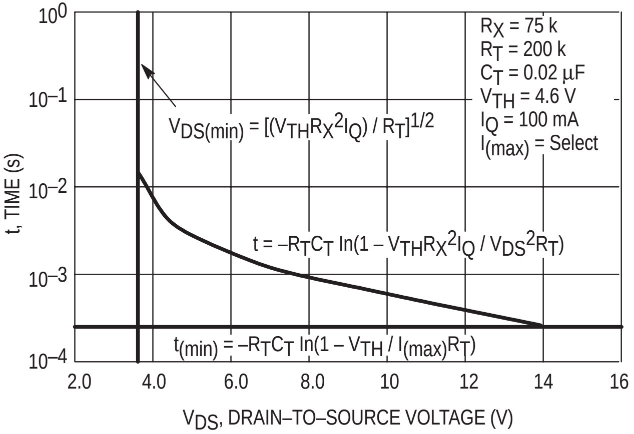
$$I_{SQ(max)} = KV_S{}^2 = (V_S/R_X)^2/I_Q \qquad (6)$$

An expression for the minimum time–out is obtained by substituting I_Q of Equation 6 into Equation 3:

$$t_{(min)} = –R_TC_T \ln[1–V_{TH}/(I_{SQ(max)}R_T)] \qquad (7)$$

Equation 4 is shown graphically along with the asymptotic limits imposed by Equations 5 and 7 in Figure 29.

Figure 29. Theoretical Fault Time versus V_{DS}



When driving incandescent lamp loads, the minimum timer time–out (time required for the V_T voltage to reach V_{TH} threshold of the upper comparator) should be set long enough so as to *not* allow the in–rush current of incandescent lamp to cause a false trigger, yet short enough to afford the TMOS device survival protection against direct shorts under worst case supply and temperature conditions.

TMOS Driver Power Dissipation

Under load short conditions, the MC33091A will duty cycle the TMOS gate. The power dissipation in this mode can be significant. For this reason proper heatsinking of the TMOS device is essential as is the selection of compatible external components so as to protect the TMOS device from destruction. In most cases, the heatsink required to handle the TMOS power dissipation under normal operating conditions will be adequate to insure the device survives a short circuit for an indefinite time under worst case conditions.

The MC33091A can protect the TMOS device under a direct load short condition. If the source voltage is less than about 1.5 V above ground, which will normally be the case in the event of a dead short, the MC33091A will clamp the gate to source voltage at 7.0 V. This action will limit the TMOS current and power dissipated under a direct load short condition.

The data sheet for the particular TMOS device being used will normally reveal the current value, $I_{DS(max)}$, to be expected under a dead short condition. TMOS data sheets normally depict graphs of drain current versus drain to source voltage for various gate to source voltages from which the drain current at 7.0 V V_{GS}, $I_{DS(max)}$, can reasonably be approximated. Using this information, the peak TMOS power dissipation under a dead short condition is approximated to be:

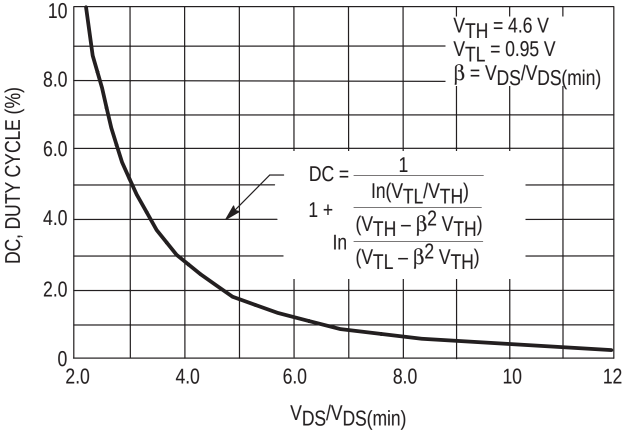
$$P_{D(peak)} = V_{S(max)} I_{DS(max)} \tag{8}$$

The average power is equal to the peak power dissipation multiplied by the duty cycle (DC):

$$P_{D(avg)} = P_{D(peak)} DC \tag{9}$$

As long as the average power, in Equation 9, is less than the maximum power dissipation of the TMOS device under normal conditions, the short circuit protection scheme of the MC33091A will adequately protect the TMOS device. The duty cycle at which the MC33091A controls the gate can be determined by using Figure 30.

Figure 30. MC33091A Duty Cycle versus V_{DS} / $V_{DS(min)}$



As previously discussed, I_{SQ} is externally dependant on the sensed V_{DS} voltage developed across the TMOS device and R_X in accordance with Equations 1 and 2. At the onset of an overload condition, the voltage across C_T will be less than the V_{TH} threshold voltage of the upper comparator with the TMOS device in an "on" state. I_{SQ} current will increase dramatically and the timing capacitor C_T charges toward V_{TH}. When the voltage on C_T reaches the V_{TH} threshold voltage of the upper comparator, the upper comparator output goes high setting the latch output (Q) high, turning on the open collector NPN transistor and pulling the Fault output low. At the same time, I_{SQ} is switched off, allowing C_T to discharge through resistor R_T to V_{TL}, at which time the TMOS device is again switched on. This action is repeated so long as the overload condition exists. The V_{TL} and V_{TH} thresholds are internally set to approximately 0.95 V and 4.6 V respectively.

The charge time (t_c) of C_T can be shown as:

$$t_c = -R_T C_T \ln[1-(V_{TH}-V_{TL})/(I_{SQ} R_T - V_{TL})] \tag{10}$$

The discharge time (t_d) of C_T can be shown as:

$$t_d = -R_T C_T \ln(V_{TL}/V_{TH}) \tag{11}$$

The duty cycle is defined as charge time divided by the charge plus discharge time and represented by:

$$DC = t_c/(t_c+t_d) \tag{12}$$

Substituting Equations 10 and 11 into 12:

$$DC = 1/1+\ln(V_{TL}/V_{TH})/\ln\{(V_{TH}-\beta^2 V_{TH})/(V_{TL}-\beta^2 V_{TH})\} \tag{13}$$

$$\text{where: } \beta = V_{DS}/V_{DS(min)}$$

Notice the duty cycle is dependent *only* on the ratio of the drain to source voltage, V_{DS}, of the TMOS device to the minimum drain to source voltage, $V_{DS(min)}$, allowing uninterrupted continuous TMOS operation as calculated in Equation 5. A graph of Equation 13 is shown in Figure 30 and is valid for any ratio of V_{DS} to $V_{DS(min)}$. Knowing this ratio, the duty cycle can be determined by using Figure 30 or Equation 13 and knowing the duty cycle, the average power dissipation can be calculated by using Equation 9.

If the TMOS device experiences a hard load short to ground a minimum duty cycle will be experienced which can be calculated. When this condition exists, the TMOS device experiences a V_{DS} voltage of V_S which is sensed by the MC33091A. The MC33091A very rapidly charges the timing capacitor C_T to V_{TH} shutting down the TMOS device. This condition produces the minimum duty cycle for the specific system conditions. The minimum duty cycle can be calculated for any valid V_S voltage by substituting the value of V_S used for V_{DS} in Equation 13 and solving for the duty cycle.

Knowing the duty cycle and peak power allows determination of the average power as was pointed out in Equation 9. TMOS data sheets specify the maximum allowable junction temperature and thermal resistance, junction–to–case, at which the device may be operated. Knowing the average power and the device thermal information, proper heatsinking of the TMOS device can be determined.

The duty cycle graph (Figure 30) reveals lower values of $V_{DS(min)}$ produce shorter duty cycles, for given V_{DS} voltages. The minimum duty cycle, being limited to the case where $V_{DS} = V_S$, increases as higher values of V_S are used.

APPLICATION

The following design approach will simplify application of the MC33091A and will insure the components chosen to be optimal for a specific application.

1. Characterize the load impedance and determine the maximum load current possible for the load supply voltage used.

2. Select a TMOS device capable of handling the maximum load current. Though the MC33091A will equally drive our competitors products, it is hoped you will select one of the many TMOS devices listed in Motorola's *Power MOSFET Transistor Data Book*.

3. Determine the maximum steady state V_{DS} voltage the TMOS device will experience under *normal* operating conditions. Typically, this is the maximum load current multiplied by the specified $R_{DS(on)}$ of the TMOS device. Junction temperature considerations should be taken into account for the $R_{DS(on)}$ value since it is significantly temperature dependent. Normally, TMOS data sheets depict the effect of junction temperature on $R_{DS(on)}$ and an $R_{DS(on)}$ value at some considered maximum junction temperature should be used. Various graphs relating to $R_{DS(on)}$ are depicted in Motorola TMOS data sheets. Though Motorola TMOS devices typically specify a maximum allowable junction temperature of 150°C, in a practical sense, the user should strive to keep junction temperature as low as possible so as to enhance the applications long term reliability. The maximum steady state V_{DS} voltage the TMOS device will experience under *normal* operating conditions is thus:

$$V_{DS(norm)} = I_{L(max)}R_{DS(on)} \tag{14}$$

4. Calculate the maximum power dissipation of the TMOS device under *normal* operating conditions:

$$P_{D(max)} = V_{DS(on)}I_{L(max)} \tag{15}$$

5. The calculated maximum power dissipation of the TMOS device dictates the required thermal impedance for the application. Knowing this, the selection of an appropriate heatsink to maintain the junction temperature below the maximum specified by the TMOS manufacture for operation can be made. The required overall thermal impedance is:

$$TR_{JA} = (T_{J(max)} - T_{A(max)})/P_{D(max)} \tag{16}$$

Where $T_{J(max)}$, the maximum allowable junction temperature, is found on the TMOS data sheet and $T_{A(max)}$, the maximum ambient temperature, is dictated by the application itself.

6. The thermal resistance, TR_{JA}, represents the maximum overall or total thermal resistance, from junction to the surrounding ambient, allowable to insure the TMOS manufactures maximum junction temperature will not be exceeded. In general, this overall thermal resistance can be considered as being made up of several separate minor thermal resistance interfaces comprised of TR_{JC}, TR_{CS} and TR_{SA} such that:

$$TR_{JA} = TR_{JC} + TR_{CS} + TR_{SA} \tag{17}$$

Where TR_{JC}, TR_{CS} and TR_{SA} represent the junction–to–case, case–to–heatsink and heatsink–to–ambient thermal resistances respectively. TR_{CS} and TR_{SA} are the only parameters the device user can influence.

The case–to–heatsink thermal resistance, TR_{CS}, is material dependent and can be expressed as:

$$TR_{CS} = \rho \times t/A \tag{18}$$

Where "ρ" is the thermal resistivity of the heatsink material (expressed in °C/Watt/Unit Thickness), "t" is the thickness of heatsink material, and "A" is the contact area of the case–to–heatsink. Heatsink manufactures specify the value of TR_{CS} for standard heatsinks. For nonstandard heatsinks, the user is required to calculate TR_{CS} using some form of the basic Equation 18.

The required heatsink–to–ambient thermal resistance, TR_{SA}, can easily be calculated once the terms of Equation 17 are known. Substituting TR_{JA} of Equation 16 into Equation 17 and solving for TR_{SA} produces:

$$TR_{SA} = (T_{J(max)}–T_{A(max)})/P_{D(max)}–(TR_{JC}+TR_{CS}) \tag{19}$$

Consulting the heatsink manufactures catalog will provide TR_{CS} information for various heatsinks under various mounting conditions so as to allow easy calculation of TR_{SA} in units of °C/W (or when multiplied by the power dissipation produces the heatsink mounting surface temperature rise). Furthermore, heatsink manufactures typically specify for various heatsinks, heatsink efficiency in the form of mounting surface temperature rise above the ambient conditions for various power dissipation levels. The user should insure that the heatsink selected will provide a surface temperature rise somewhat less than the maximum capability of the heatsink so that the device junction temperature will not be exceeded. The user should consult the heatsink manufacturers catalog for this information.

7. Set the value of $V_{DS(min)}$ to something greater than the *normal operating* drain to source voltage, $V_{DS(norm)}$, the TMOS device will experience as calculated in Step 3 above (Equation 14). From a practical standpoint, a value two or three times $V_{DS(norm)}$ expected under normal operation will prove to be a good starting point for $V_{DS(min)}$.

8. Select a value of R_T less than 1.0 MΩ for minimal timing error whose value is compatible with R_X (R_X will be selected in Step 9 below). A recommended starting value to use for R_T would be 470 k. The consideration here is that the input impedance of the threshold comparators are approximately 10 MΩ and if R_T values greater than 1.0 MΩ are used, significant timing errors may be experienced as a result of input bias current variations of the threshold comparators.

9. Select a value of R_X which is compatible with R_T. The value of R_X should be between 50 k and 100 k. Recall in Equation 5 that $V_{DS(min)}$ was determined by the combined selection of R_X and R_T. Low values of R_X will give large values for K ($K = 4.0\ \mu A/V^2$ for $R_X = 50$ k) causing I_{SQ} to be very sensitive to V_{DS} variations (see Equation 1). This is desirable if a minimum V_{DS} trip point is needed in the 1.0 V range since small V_{DS} values will generate measurable currents. However, at high V_{DS} values, TMOS device currents become excessively large and the current squaring function begins to deviate slightly from the predicted value due to high level injection effects occurring in the output PNP of the current squaring circuit. These effects can be seen when I_{SQ} exceeds several hundred microamps. See Figure 22 for graphical aid in the selection of R_T and R_X.

10. Calculate the shorted load average power dissipation for the application using Equations 8 and 9. This involves determining the peak shorted load power dissipation of the TMOS device and gate duty cycle. The duty cycle is based on $V_{DS(min)}$, the value of V_{DS} under shorted conditions (i.e. $V_{S(max)}$).

11. The calculated shorted load average power dissipation of Step 10 should be less than the maximum power dissipation under *normal* operating conditions calculated in Step 4. If this is not the case, there are two options.

Option one is to reduce the thermal resistance of the TMOS device heatsink, in other words, use a larger or better heatsink. This though, is not always practical to do particularly if restricted by size.

Option two is to set $V_{DS(min)}$ to the lowest practical value. If for instance $V_{DS(min)}$ is set to 4.0 V when only 2.0 V are needed, the short circuit duty cycle will be over twice as large, resulting in double the TMOS device power dissipated. Keeping $V_{DS(min)}$ to a minimum, reduces the shorted load average power.

12. Choose a value of C_T. The value of C_T can be determined either by trial and error or by characterizing the V_{DS} waveform for the load and selecting a capacitor value that generates a minimum fault time curve (see Equation 4) that encompasses the V_{DS} versus time waveform. The value of C_T has *no* effect on the duty cycle itself as was pointed out earlier. See Figure 23 for a graphical selection of C_T.

Inductive Loads

The TMOS device is turned off by pulling the gate to near ground potential. Turning off an inductive load will cause the source of the TMOS device to go below ground due to flyback voltage to the point where the TMOS device may become biased on again allowing the inductive energy to be dissipated through the load. An internal 14 V zener diode clamp from the gate to source pin limits how far the source pin can be pulled below ground. For high inductive loads, it may be necessary to have an external 10 k current limiting resistor in series with the source pin to limit the clamp current in the event the source pin is pulled more than 14 V below ground.

Transient Faults

The MC33091A is not able to withstand automotive voltage transients directly. By correctly sizing resistor R_S and capacitor C_S, the MC33091A can withstand load dump and other automotive type transients. The V_{CC} voltage is clamped at approximately 30 V through the use of an internal zener diode.

Under reverse battery conditions, the load will be energized in reverse due to the parasitic body diode inherent in the TMOS device. Under this condition, the drain is grounded and the MC33091A clamps the gate at 0.7 V below the battery potential. This turns the TMOS device on in reverse and minimizes the voltage across the TMOS device resulting in minimal power dissipation. Neither the MC33091A nor the TMOS device will be damaged under such a condition. In addition, if the load can tolerate a reverse polarity, the load will not be damaged. Caution; some sensitive applications may not tolerate a reverse polarity load condition with reverse battery polarity.

There is no protection of the TMOS device during a reverse battery condition if the load itself is already shorted to ground. The MC33091A will not incur damage under this specialized reverse battery condition but the TMOS device may be damaged since there could be significant energy available from the battery to be dissipated in the TMOS device.

The MC33091A will withstand a maximum V_{CC} voltage of 28 V and with the proper TMOS device used, the system can withstand a double battery condition.

Figure 36 depicts a method of protecting the FET from positive transient voltages in excess of the rated FET breakdown voltage. The zener voltage, in this case, should be less than the FET breakdown voltage. The diode, D, is necessary where reverse battery protection of the gate of the FET is required.

EMI Concern

The gate capacitance and thus the size of the TMOS device used will determine the turn–on and turn–off times experienced. In a practical sense, smaller TMOS devices have smaller gate capacitances and give rise to higher slew rates. By way of example, the turn–on of an MPT50N06 TMOS device might be of the order of 80 µs while that of an MPT8N10 might be 10 µs (see Figure 25). The speed of turn–on or turn–off can be calculated by assuming the charge pump to supply approximately 100 µA over the time the gate capacitance will transition a V_{GS} voltage of 0 V to 10 V. In reality, the V_{GS} voltage will be greater than 10 V, but the additional increase in TMOS drain current will be minimal for V_{GS} voltages greater than 10 V.

The charge pump current is sized so that turn–on time need not be of concern in all but the most critical of applications. Where limiting of EMI is of concern, the charge pump of the MC33091A may be slew rate limited by adding an external feedback capacitor from the gate–to–source of the TMOS device for slow down adjustment of both turn–on and turn–off times (see Figure 33). Figures 31 through 35 depict various methods of modifying the turn–on or turn–off times.

Figure 35 depicts a method of using only six external components to decrease turn–off time and clamp the flyback voltage associated with switching inductive loads. $V_{GS(th)}$ used in the critical component selection criteria refers to the gate–to–source threshold voltage of the FET used in the application.

Caution should be exercised when slowing down the switching transition time since doing so can greatly increase the average power dissipation of the TMOS device. The resulting increase in power dissipation should be taken into account when selecting the R_TC_T time constant values in order to protect the TMOS device from any overcurrent condition.

MC33092

Alternator Voltage Regulator

ALTERNATOR VOLTAGE REGULATOR

SEMICONDUCTOR
TECHNICAL DATA

The MC33092 is specifically designed for voltage regulation and Load Response Control (LRC) of diode rectified alternator charging systems, as commonly found in automotive applications. The MC33092 provides load response control of the alternator output current to eliminate engine speed hunting and vibration due to sudden electrical loads which cause abrupt torque loading of the engine at low RPM. Two load response rates are selectable using Pin 11. The timing of the response rates is dependent on the oscillator frequency.

In maintaining system voltage, the MC33092 monitors and compares the system battery voltage to an externally programmed set point value and pulse width modulates an N–channel MOSFET transistor to control the average alternator field current.

- Forced Load Response Control (LRC) with Heavy Load Transitions at Low RPM
- Capable of Regulating Voltage to ± 0.1 V @ 25°C
- Operating Frequency Selectable with One External Resistor
- < 0.1 V Variation over Speed Range of 2000 to 10,000 RPM
- < 0.4 V Variation over 10% to 95% of Maximum Alternator Output
- Maintains Regulation with External Loads as Low as 1.0 A
- Load Dump Protection of Lamp, Field Control Devices, and Loads
- Duty Cycle Limit Protection
- Provides High Side MOSFET Control of a Ground Referenced Field Winding
- Controlled MOSFET and Flyback Diode Recovery Characteristics for Minimum RFI
- < 2.0 mA Standby Current from Battery @ 25°C
- < 3.0 mA Standby Current from Battery Over Temperature Range
- Optional 2.5 or 10 sec. LRC Rate Control (Osc. Freq. = 280 kHz)
- Undervoltage, Overvoltage and Phase Fault (Broken Belt) Detection

PIN FUNCTION DESCRIPTION

Pin No.	Function	Description
1	FB	This pin provides a filtered result of the Sense input (if the Sense input is used) or the Supply Regulation input (if the Sense input is not used).
2	Sense	The Sense input is a remote (Kelvin), low current battery voltage reference input used to give an accurate representation of the true battery voltage. This input is also used to monitor overvoltage or load dump conditions.
3	Lamp Collector and Power–Up/Down	This pin connects to the collector of the transistor (Q2) used to drive the fault lamp. It is also used to sense a closed ignition switch (voltage sense) which then turns power on to the IC.
4	Lamp Base	The Lamp Base pin provides base current to the fault lamp drive transistor (Q2).
5	Ground	Grounded to provide a ground return for the fault lamp control logic circuit.
6, 15	Ground	IC ground reference pins.
7	Oscillator Adjust	A resistor to ground on this pin adjusts the internal oscillator frequency (see Figure 6).
8	* $V_{ref\emptyset}$	This is a test point for the 1.1 V to 1.4 V reference voltage. It has a zero temperature coefficient. The reference is used internally for phase signal and undervoltage detection.
9	* Oscillator	Test point for checking the operation of the internal oscillator.
10	Phase	The Phase input detects the existence of a magnetic field rotating within the alternator.
11	Rate	The Rate pin is used to select a slow mode (floating) or fast mode (ground) Load Response Control recovery rate.
12	Supply Regulation	The voltage on the Supply Regulation pin is used as a representation of the alternator output voltage. This input also used to monitor overvoltage or load dump conditions.
13	$V_{CC}3$	Positive supply for the internal Charge Pump.
14	$V_{CC}1$	Positive supply for the entire IC except for the Charge Pump.
15, 6	Ground	Ground reference for the IC.
16	N/C	No connection.
17	Gate	Controls the Gate of the MOSFET used to energize the field winding.
18	Source	Field winding control MOSFET source reference.
19	Undervoltage	If the voltage at this pin goes below 1.0 V, the fault lamp is guaranteed to turn on. The IC will continue to function, but with limited performance.
20	* V_{ref}	Test point for the 1.7 V to 2.3 V Bandgap reference voltage. This voltage has a negative temperature coefficient of approximately –11 mV/°C.

***NOTE:** Pins 8, 9 and 20 are test points only.

APPLICATION CIRCUIT DESCRIPTION

Introduction

The MC33092, designed to operate in a 12 V system, is intended to control the voltage in an automotive system that uses a 3 phase alternator with a rotating field winding. The system shown in Figure 1 includes an alternator with its associated field coil, stator coils and rectifiers, a battery, a lamp and an ignition switch. A tap is connected to one corner of the stator windings and provides an AC signal for rotation (phase) detection.

A unique feature of the MC33092 is the Load Response Control (LRC) circuitry. The LRC circuitry is active when the stator winding AC signal frequency (phase buffer input signal, Pin 10) is lower than the Low/High RPM transition frequency. When active, the LRC circuitry dominates the basic analog control circuitry and slows the alternator response time to sudden increases in load current. This prevents the alternator from placing a sudden, high torque load on the automobile engine when a high current accessory is switched on.

The LRC circuitry is inactive when the stator winding AC signal frequency is higher than the Low/High RPM transition frequency. When the LRC circuitry is inactive, the basic analog control circuitry controls the alternator so it will supply a constant voltage that is independent of the load current.

Both the LRC and analog control circuits control the system voltage by switching ON and OFF the alternator field current using Pulse Width Modulation (PWM). The PWM approach controls the duty cycle and therefore the average field current. The field current is switched ON and OFF at a fixed frequency by a MOSFET (Q1) which is driven directly by the IC. The MC33092 uses a charge pump to drive the MOSFET in a high side configuration for alternators having a grounded field winding.

A fault detector is featured which detects overvoltage, undervoltage, slow rotation or non–rotation (broken alternator belt) conditions and indicates them through a fault lamp drive output (Pin 4).

A Load Dump protection circuit is included. During a load dump condition, the MOSFET gate drive (Pin 17) and the fault lamp drive output are disabled to protect the MOSFET, field winding and lamp.

Power–Up/Down

Power is continuously applied to the MC33092 through $V_{CC}1$ and $V_{CC}3$. A power–up/down condition is determined by the voltage on the Lamp Collector pin (Pin 3). When this voltage is below 0.5 V the IC is guaranteed to be in a low current standby mode. When the voltage at Pin 3 is above 2.0 V, the IC is guaranteed to be fully operational. The power–up voltage is applied to Pin 3 via the ignition switch and fault lamp. In case the fault lamp opens, a 500 Ω bypass resistor should be used to ensure regulator IC power–up.

A power–up reset circuit provides a reset or set condition for all digital counter circuitry. There is also a built–in power–up delay circuit that protects against erratic power–up signals.

Battery and Alternator Output Voltage Sensing

The battery and the alternator output voltage are sensed by the remote (Sense, Pin 2), and the local (Supply Regulator, Pin 12) input buffer pins, respectively, by way of external voltage dividers. The regulated system voltage is determined by the voltage divider resistor values.

Normally the remote pin voltage determines the value at which the battery voltage is regulated. In some cases the remote pin is not used. When this condition ($V_{Pin\ 2} < 0.6$ V typically) exists, a sense loss function allows the local pin voltage to determine the regulated battery voltage with no attenuation of signal. If, however, when the remote pin is used, and the voltage at this pin is approximately 25% less than the voltage at the local sense pin (but greater than 0.6 V, typically), the value at which the battery voltage is regulated is switched to the local sense pin voltage (minus the 25%). The signal combiner/switch controls this transfer function.

Low Pass Filter, DAC & Regulator Comparator

The output of the combiner/switch buffer feeds a low pass filter block to remove high frequency system noise. The filter output is buffered and compared by the regulator comparator to a descending ramp waveform generated by an internal DAC. When the two voltages are approximately equal, the output of the regulator comparator changes state and the gate of the MOSFET is pulled low (turned OFF) by the output control logic for the duration of the output frequency clock cycle. At the beginning of the next output clock cycle, the DAC begins its descending ramp waveform and the MOSFET is turned ON until the regulator comparator output again changes state. This ongoing cycle constitutes the PWM technique used to control the system voltage.

Oscillator

The oscillator block provides the clock pulses for the prescaler–counter chain and the charge control for the charge pump circuit. The oscillator frequency is set by an external resistor from Pin 7 to ground as presented in Figure 6.

The prescaler–counter divides the oscillator frequency by 2^{12} (4096) and feeds it to the output control logic and divider–up/down counter chain. The output control logic uses it as the fundamental regulation output frequency (Pin 17).

Load Response Control

The Load Response Control (LRC) circuit generates a digital control of the regulation function and is active when the stator output AC signal (Pin 10) frequency is lower than the Low/High RPM transition frequency. The LRC circuit takes the output signal of the prescaler–counter chain and with a subsequent divider and up/down counter to provide delay, controls the alternator response time to load increases on the system. The response time is pin programmable to two rates. Pin 11 programs the divider to divide by 12 or divide by 48. If Pin 11 is grounded, the signal fed to the up/down counter is divided by 12 and the response time is 12 times slower than the basic analog response time. If Pin 11 is left floating, the signal to the up/down counter is divided by 48 and the response time is 48 times slower.

The basic analog (LRC not active) and digital duty cycle control (LRC active) are OR'd such that either function will terminate drive to the gate of the MOSFET device with the shortest ON–time, i.e., lower duty cycle dominating.

The digital ON–time is determined by comparing the output of the up/down counter to a continuous counter and decoding when they are equal. This event will terminate drive to the MOSFET. A count direction shift register requires three consecutive clock pulses with a state change on the data input of the register to result in an up/down count direction change. The count will increase for increasing system load up to 100% duty cycle and count down for decreased loading to a minimum of 29% duty cycle. The analog control can provide a minimum duty cycle of 4 to 5%. The initial power–up duty cycle is 29% until the phase comparator input exceeds its input threshold voltage. Also, the IC powers up with the LRC circuit active, i.e., when the Lamp Collector pin exceeds the power–up threshold voltage.

Fault Lamp Indicator

Pins 3 and 4 control the external Darlington transistor (Q2) that drives the fault indicator lamp. A 10 Ω resistor should be placed in series with the transistor’s emitter for current limiting purposes. The fault lamp is energized during any of the following fault conditions: 1) No Phase buffer (Pin 10) input due to slow or no alternator rotation, shorted phase winding, etc.; 2) Phase buffer input AC voltage less than the phase detect threshold; 3) Overvoltage on Pin 2, or Pin 12 if Pin 2 is not used, or 4) Undervoltage on Pin 19 with the phase buffer input signal higher than the Low/High RPM transition frequency.

Phase Buffer Input

A tap is normally connected to one corner of the alternator’s stator winding to provide an AC voltage for rotation detection. This AC signal is fed into the phase buffer input (Pin 10) through a voltage divider. If the frequency of this signal is less than the phase rotation detect frequency (36 Hz, typically), the fault lamp is lit indicating an insufficient alternator rotation and the MOSFET drive (Pin 17) output duty cycle is restricted to approximately 29% maximum. Also, if the peak voltage of the AC signal is less than the phase detect threshold, the fault lamp is lit indicating an insufficient amount of field current and again the MOSFET drive (Pin 17) output duty cycle is restricted to approximately 29% maximum.

Undervoltage, Overvoltage and Load Dump

The low pass filter output feeds an undervoltage comparator through an external voltage divider. The voltage divider can be used to adjust the undervoltage detection level. During an undervoltage condition, the fault lamp will light only if the phase buffer input signal frequency is higher than the Low/High RPM transition frequency. This is to ensure that the undervoltage condition is caused by a true fault and not just by low alternator rotation. To help maintain system voltage regulation during an undervoltage condition, the output duty cycle is automatically increased to 100%. Even though the fault lamp may be energized for an undervoltage condition, the MC33092 will continue to operate but with limited performance.

Through an internal voltage divider, the low pass filter feeds an overvoltage comparator which monitors this output for an overvoltage condition. If the overvoltage threshold is exceeded, the fault lamp is lit and the MOSFET drive (Pin 17) output duty cycle is restricted to approximately 4% maximum.

The internal voltage divider on the input to the load dump comparator has a different ratio than the divider used on the overvoltage comparator. This allows the load dump detect threshold to be higher than the overvoltage threshold even though both comparators are monitoring the same low pass filter output. If the load dump detect threshold is exceeded, the fault lamp and MOSFET drive outputs are disabled to protect the MOSFET, field winding and lamp.

MOTOROLA

MC33143

Advance Information

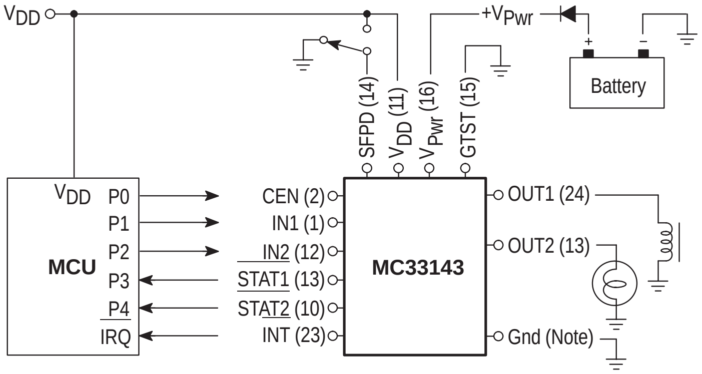
Dual High-Side Switch

The MC33143 is a dual high–side switch designed for solenoid control in harsh automotive applications, but is well suited for other environments. The device can also be used to control small motors and relays as well as solenoids. The MC33143 incorporates SMARTMOS™ technology, with CMOS logic, bipolar/MOS analog circuitry, and DMOS power outputs. An internal charge pump is incorporated for efficient gate enhancement of the internal high–side power output devices. The outputs are designed to provide current to low impedance solenoids. The MC33143 provides individual output fault status reporting along with internal Overcurrent and Over Temperature protection. The device also has Overvoltage protection, with automatic recovery, which “globally” disables both outputs for the duration of an Overvoltage condition. Each output has individual Overcurrent and Over Temperature shutdown with automatic retry recovery. Outputs are enabled with a CMOS logic high signal applied to an input to providing true logic control. The outputs, when turned on, provide full supply (battery) voltage across the solenoid coil.

The MC33143 is packaged in an economical 24 pin surface mount power package and specified over an operating voltage of $5.5\ V \le V_{Pwr} < 26\ V$ for $-40°C \le T_A \le 125°C$.

- Designed to Operate Over Wide Supply Voltages of 5.5 V to 26 V
- Dual High–Side Outputs Clamped to –10 V for Driving Inductive Loads
- Internal Charge Pump for Enhanced Gate Drive
- Interfaces Directly to a Microcontroller with Parallel Input Control
- Outputs Current Limited to 3.0 A to 6.0 A for Driving Incandescent Loads
- Chip Enable “Sleep Mode” for Power Conservation
- Individual Output Status Reporting
- Fault Interrupt Output for System Interrupt Use
- Output ON or OFF Open Load Detection
- Overvoltage Detection and Shutdown
- Output Over Temperature Detection and Shutdown with Automatic Retry
- Sustained Current Limit or Immediate Overcurrent Shutdown Output Modes
- Output Short to Ground Detection and Shutdown with Automatic Retry
- Output Short to V_{Pwr} Detection

Simplified Application



NOTE: Pins 5, 6, 7, 8, 17, 18, 19 and 20 provide electrical ground and heatsinking.

This device contains 889 active transistors.

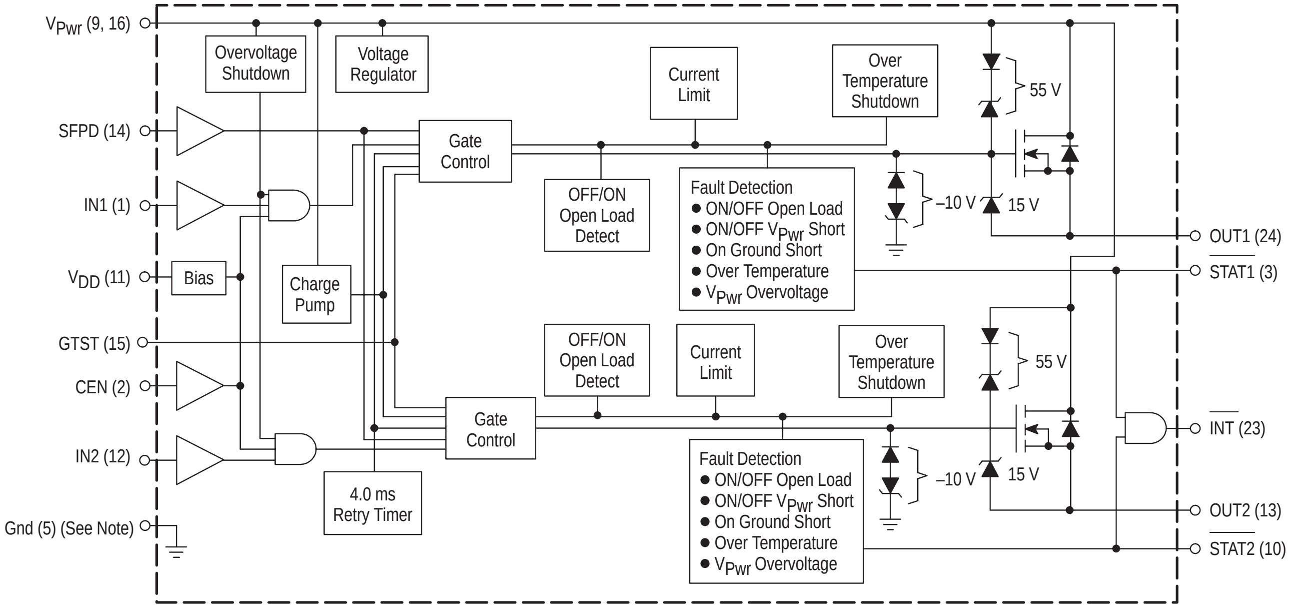
ORDERING INFORMATION

Device	Operating Temperature Range	Package
MC33143DW	T_A = – 40° to +125°C	SOP–24L

Figure 1. Simplified Internal Block Diagram



NOTE: Pins 5, 6, 7, 8, 17, 18, 19 and 20 should all be grounded so as to provide electrical as well as thermal heatsinking of the device.

MAXIMUM RATINGS (All voltages are with respect to ground, unless otherwise noted.)

Rating	Symbol	Value	Unit
Power Supply Voltage	V_{Pwr}		V
Steady State Continuous Operation		26	
Negative Transient (Note 1)		–1.5	
Positive Load Dump Transient (Note 2)		60	
Logic Supply Voltage Range	V_{DD}	–0.3 to 7.0	V
Logic Supply Current	I_{DD}	5.0	mA
Input Voltage (Note 3)	V_{in}	–0.3 to 7.0	V
Output Clamp Voltage	V_{Clamp}		V
I_O = –20 mA		–3.0 to –20	
I_O = –200 mA		–5.5 to –20	
Output Current Limit (Note 4)	$I_{O(Lim)}$	–3.0 to –6.0	A
Output Clamp Energy (I_O = –1.0 A)	E_{Clamp}		mJ
T_J = 25°C		300	
T_J = 125°C		100	
ESD (Minimum)			V
Human Body Model (Note 5)	HBM	2000	
Machine Model (Note 6)	MM	200	
Power Dissipation (T_A = 25°C) (Note 7)	P_D	4.2	W
Operating Temperature (Note 8)	T_A	–40 to +125	°C
Operating Junction Temperature	T_J	–40 to +150	°C
Storage Temperature	T_{stg}	–55 to +150	°C
Soldering Temperature (for 10 Seconds)	T_{solder}	270	°C
Thermal Resistance			°C/W
Junction–to–Lead	$R_{\theta JL}$	15	
Junction–to–Ambient	$R_{\theta JA}$	30	

NOTES:
1. Negative transient survival capability for 100 ms time duration.
2. Positive transient survival capability with typical automotive load dump condition; 400 ms time constant decay.
3. All input pins (IN1–2, CEN and SFPD).
4. Each output has independent current limiting.
5. Performed in accordance to HBM; C_{Zap} = 100 pF, R_{Zap} = 1500 Ω.
6. Performed in accordance to MM; C_{Zap} = 100 pF, R_{Zap} = 0 Ω.
7. Derate Power Dissipation 33 mW/°C for temperatures above 25°C.
8. Ambient temperature is given as a practical reference; Maximum junction temperature is the limiting factor.
9. ESD data available upon request.

DC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions 9.0 V ≤ V_{Pwr} ≤ 17 V, 4.5 V ≤ V_{DD} 5.5 V, –40°C ≤ T_L ≤ 125°C, unless otherwise noted, typical values represent approximate mean at T_L = 25°C.)

Characteristic	Symbol	Min	Typ	Max	Unit
POWER INPUT					
Supply Voltage Range (Operational)	V_{Pwr}	9.0	–	17	V
Supply Current (Note 1)					
Both Outputs ON					
(CEN = IN1 = IN2 = 0.7 x V_{DD}, I_{O1} = I_{O2} = –1.0 A)	I_{Pwr}	0.1	4.2	7.0	mA
Standby (CEN = 0.7 x V_{DD}, IN1 = IN2 = 0.3 x V_{DD}, R_L = 12 Ω)	$I_{Pwr(sby)}$	–	3.9	7.0	mA
“Sleep State” (CEN = IN1 = IN2 = 0.3 x V_{DD}, R_L = 12 Ω)	$I_{Pwr(sleep)}$	–	0.2	300	µA
Logic Supply Voltage Range	V_{DD}	4.5	–	5.5	V
Logic Supply Current	I_{DD}	–	0.43	5.0	
Both Outputs ON (IN1 = IN2 = 0.7 x V_{DD}, I_{O1} = I_{O2} = –1.0 A)					mA
Overvoltage Shutdown (Note 2)	$V_{Pwr(ovsd)}$	30	33.2	38	V
Overvoltage Shutdown Hysteresis	$V_{Pwr(hys)}$	0.3	0.5	1.5	V

NOTES: 1. Supply current when both outputs are ON and during standby are measured in the Ground pin while during “sleep state” is measured in the V_{Pwr} pin.

2. Overvoltage Shutdown causes enabled outputs to be forced OFF; Overvoltage fault is immediately reported.

DC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions 9.0 V ≤ V_{Pwr} ≤ 17 V, 4.5 V ≤ V_{DD} 5.5 V, –40°C ≤ T_L ≤ 125°C, unless otherwise noted, typical values represent approximate mean at T_L = 25°C.)

Characteristic	Symbol	Min	Typ	Max	Unit

I_O = –20 mA		–9.0	–13.2	–20	
I_O = –200 mA		–9.0	–13.5	–20	
Over Temperature Shutdown Range (Note 5)	T_{Lim}	155	–	185	°C
(CEN = IN1 = IN2 = SFPD = 0.7 x V_{DD})					
Over Temperature Shutdown Hysteresis (Note 6)	$T_{Lim(hys)}$	–	–	15	°C

NOTES: 1. $R_{DS(on)}$ applies to OUT1, OUT2 and is independent of output current.

2. Applies to each output; each output has independent self–limiting source current feature; Over Current and Short–to–Ground defined as condition when output source current exceeds $I_{O(Lim)}$; Device ignores Over Current and Short–to–Ground faults from 0 to t_{ss}.

3. Applies to each output; tested for by ramping I_O from 0 until $\overline{\text{STAT}}$ ≤ 0.7 x V_{DD}; defined as the condition when I_O is outside of $I_{O(on)}$ current window.

4. Applies to each output; each output has independent dynamic output voltage clamping feature.

5. Applies to each output; each output has independent thermal shutdown; parameter is measured by ramping temperature until enabled output is disabled; parameter is established by design but is not production tested; thermal fault is immediately reported.

6. Parameter is established by design but is not production tested.

DC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions 9.0 V ≤ V_{Pwr} ≤ 17 V, 4.5 V ≤ V_{DD} 5.5 V, –40°C ≤ T_L ≤ 125°C, unless otherwise noted, typical values represent approximate mean at T_L = 25°C.)

Characteristic	Symbol	Min	Typ	Max	Unit
CONTROL INTERFACE					
Input Control					V_{DD}
Logic High (I_O = –0.1 A) (Note 1)	V_{IH}	0.7	0.56	–	
Logic Low (I_O = 0) (Note 2)	V_{IL}	–	0.52	0.3	
Input Logic Voltage Hysteresis (V_{IH} – V_{IL})	V_{hys}	50	250	500	mV
Input Pull–Down Current (0.3 x V_{DD} ≤ V_{in} < 0.7 x V_{DD}) (Note 3)	$I_{in(pd)}$	20	44	100	µA
Chip–Enable Threshold					V_{DD}
Logic Low (Note 4)	$V_{CEN(IL)}$	–	0.5	0.3	
Logic High (Note 5)	$V_{CEN(IH)}$	0.7	0.5	–	
Chip–Enable Hysteresis ($V_{CEN(IH)}$ – $V_{CEN(IL)}$)	$V_{CEN(hys)}$	50	150	500	mV
Chip–Enable Pull–Up Current (CEN = 0.7 x V_{DD})	$I_{\overline{CEN}(pu)}$	–2.0	–16.8	–40	µA
Status Low Voltage (I_{in} = 600 µA) (Note 6)	$V_{\overline{STAT}(low)}$	–	0.07	0.2	V_{DD}
Status Pull–Up Current (Note 7)	$I_{STAT(pu)}$	–20	–44	–100	µA
Interrupt (Note 8)					V_{DD}
Logic High	$\overline{INT}_h$	0.7	–	–	
Logic Low	INT_l	–	–	0.3	

NOTES: 1. Upper logic threshold voltage applies to IN1, IN2, and SFPD and expressed in V_{DD} units
2. Lower logic threshold voltage applies to IN1, IN2, and SFPD and expressed in V_{DD} units.
3. Applies to IN1, IN2, and SFPD.
4. Initially have CEN = 0.7 x V_{DD}, Ramp CEN down from V_{DD} until I_O = 0 and note disabling point.
5. Initially have V_{in} = 0.7 x V_{DD}, Ramp CEN up from ground until I_O = 0.1 A and note enabling point.
6. Applies equally to $\overline{\text{STAT1–2}}$ and INT outputs; Measured threshold voltage by applying an "open" fault to OUT1 or OUT2 while forcing 600 µA of current into STAT1–2 or INT.
7. Measured with no faults on OUT1–2, $V_{\overline{STAT}}$ = $V_{\overline{INT}}$ = 0.8 x V_{DD}.
8. The Interrupt output has an internal active current pull–up.

DC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions 9.0 V ≤ V_{Pwr} ≤ 17 V, 4.5 V ≤ V_{DD} 5.5 V, –40°C ≤ T_L ≤ 125°C, unless otherwise noted, typical values represent approximate mean at T_L = 25°C.)

NOTES: 1. CEN = 0.7 x V_{DD}, SFPD = 0.3 x V_{DD}, R_L = 0, Step V_{in} from 0.3 x V_{DD} to 0.7 x V_{DD}; Sense time measured from step until $\overline{\text{STAT}}$ = 0.2 x V_{DD}.
2. CEN = IN1 = IN2 = 0.7 x V_{DD}, R_L = 0; Refresh time measured from output disable until output is re–enabled.
3. R_L = "open", Step V_{in} from ground to 0.7 x V_{DD}, Open sense time measured from step until V_{STAT} ≤ 0.2 x V_{DD}.
4. R_L = 12 Ω, C_L = 0.01 µF, step V_{in} from V_{IL} to V_{IH}; Turn–On propagation measured from V_{in} = 0.5 x V_{DD} until V_{out} = 2.0 V (see Figure 2).
5. R_L = 12 Ω, C_L = 0.01 µF, step V_{in} from V_{IH} to V_{IL}; Turn–Off propagation measured from V_{out} = V_{Pwr} –3.0 V until V_{out} = 2.0 V (see Figure 2).
6. R_L = 12 Ω, C_L = 0.01 µF, step V_{in} from V_{IL} to V_{IH}; Output Slew Rate measured from 2.0 V to V_{Pwr} – 3.0 V (see Figure 2).
7. R_L = 12 Ω, C_L = 0.01 µF, step V_{in} from V_{IH} to V_{IL}; Output Slew Rate measured from V_{Pwr} – 3.0 V to 2.0 V (see Figure 2).

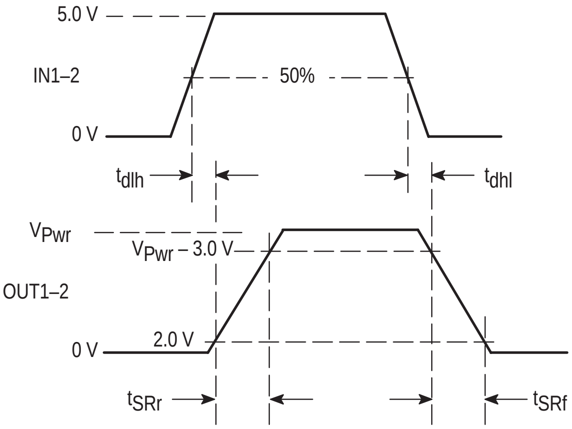

Figure 2. Output Response Waveform

PIN FUNCTION DESCRIPTION

Pin	Symbol	Description
1, 12	IN1, IN2	INput 1 and INput 2 (IN1 and IN2) respectively determine the state of the corresponding output drivers (OUT1 and OUT2) under normal operating conditions. When an input is high, it's corresponding output is active ON, and when low is disabled OFF. IN1 and IN2 have internal active pull–downs which allow a floating input pin to be conservatively interpreted as a logic low, turning Off the output. An unused input should be connected to ground.
2	CEN	Chip Enable (CEN) input pin, when low, disables both outputs (OUT1 and OUT2) and places the device in a "sleep mode" reducing the bias current required from V_{DD} and V_{Pwr}. A falling edge of CEN causes OUT1 and OUT2 to rapidly turn OFF. A falling edge of CEN should precede any V_{DD} shutdown to allow time OUT1 and OUT2 to be disabled. When CEN is low, INTerrupt (INT) and STATus 1 and 2 (STAT1–2) will be tri–stated (high impedance). The CEN pin can also be used for power–on reset and under voltage lockout to disable the outputs for power supply voltages less than 4.5 V. CEN is a dependent input from the system microcontroller unit (MCU) or some other integrated circuit. It has an internal pull–up resistor to V_{DD} affording a floating pin to be interpreted as a logic high. $R_{pull–up}$ is greater than 50 kΩ. If used externally, this pin should be connected to V_{DD}.
3, 10	$\overline{\text{STAT1}}$. $\overline{\text{STAT2}}$	The STATus pins ($\overline{\text{STAT1–2}}$) respectively indicate the presence of faults on OUT1–2. $\overline{\text{STAT1–2}}$ will be logic high during normal operation. A logic low will occur whenever an Open Load, Short–to–Ground, Short–to–Supply (Battery), Thermal Limit, or Overvoltage Shutdown fault condition is experienced on a corresponding output. STAT1–2 are both active low digital drivers. A 10 kΩ resistor between STAT1–2 and the system CPU may improve a Failure Mode Evaluation Analysis (FMEA) score if STAT1–2 are externally shorted to V_{Pwr}. If unused, this pin should be left connected.
4, 9, 16, 21	V_{Pwr}	These pins are connected to the supply and provide load current to the DMOS outputs, are used pumping the DMOS gates, and for Overvoltage shutdown detection of the DMOS. The DMOS outputs will turn ON with 5.5 to 24 V applied to V_{Pwr}. V_{Pwr} is limited to –1.5 V for a maximum duration of 250 ms. A 10 nF de–coupling cap is recommended to be used from V_{Pwr} to Ground.
5, 6, 7, 8, 17, 18, 19, 20	Gnd	These eight pins constitute the circuits ground (Gnd) and also provide heatsinking for the DMOS output transistors. Ground continuity is required for the outputs2 to turn ON.
11	V_{DD}	This pin is to be connected to the 5.0 V logic supply of the system. A 10 nF de–coupling capacitor is recommended from V_{DD} to Gnd.
13, 24	OUT1, OUT2	These pins are connected internally to the DMOS output transistors which source current into the corresponding load. Each output incorporates dynamic clamping to accommodate inductive loads. In addition, each output has independent short to ground detection and protection, current limit detection and protection, thermal limit detection and protection, ON open load and or short to supply (battery) detection. Neither output will turn ON if CEN is logic low. An unused output should be connected to a 10 kΩ load to prevent false fault reporting. A 1.0 nF filter capacitor may be used from OUT to Gnd to provide dV/dt noise filtering.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Description
14	SFPD	This is a Short Fault Protect Disable (SFPD) input; which when logic high disables the internal current limit timer preventing OUT1–2 from latching OFF when confronted with an overcurrent condition. The condition of SFPD does not affect fault reporting. Current and thermal limit remain active when the SFPD pin is logic high. Having the SFPD pin logic high facilitates the device to drive incandescent lamp loads with peak in–rush currents in excess of three amperes. When SFPD is logic low, an overcurrent demand will latch OFF only the output affected. The device will then automatically begin active re–enabling of the corresponding output affected for the duration of the overcurrent condition. SFPD has an internal active pull–down which affords a floating input pin condition to be conservatively interpreted as a logic low. A 10 kΩ resistor between SFPD and the system CPU may improve the FMEA score if SFPD is externally shorted to OUT2. SFPD should be connected to Gnd or V_{DD} for the desired operating mode and not be left “floating”.
15	GTST	The Gate TeST (GTST) pin is used to stress the devices DMOS gates during testing operations. This pin should normally be connected to ground in the application.
23	$\overline{\text{INT}}$	The INTerrupt pin $\overline{\text{INT}}$ is active logic low and indicates the presence of a fault on either the output. $\overline{\text{INT}}$ can be paralleled with additional fault pins and used as a system CPU interrupt to indicate the presence of a fault. The system CPU can then read STAT1–2 to determine the specific type of fault occurring. INT will be logic high during normal operation. A logic low will result if a fault occurs on either OUT1 or OUT2. INT has an internal active pull–up and requires no external pull–up resistor to be used. The INT output has sufficient current drive capability to afford paralleling of up to five INT pins. A 10 kΩ resistor between INT and the system CPU may improve the FMEA score if INT is externally shorted to OUT1. This pin should be left unconnected if the feature is not used.

	High	Low	High–Z	Output disabled.	STAT tri–stated, no faults reported.

FUNCTIONAL DESCRIPTION

General

The MC33143 is designed as an interface device; between system's electronic control unit and the actuators. It is designed to withstand several abnormal operating conditions, with the capability of reporting it's operating status back to the control unit. The MC33143 will resume normal operation after having experienced 60 V transients on the V_{Pwr} line, output shorts to V_{Pwr}, open loads, output shorts to ground, over current, over temperature, or overvoltage conditions. Status information is available when ever a load experiences any of the faults. In addition, the MC33143 device incorporates internal output transient clamps allowing it to control inductive loads and survive negative voltage spikes without the need of external components.

Power Supply Voltage Requirements

The MC33143 is designed to operate with 5.5 V to 26 V applied to the power supply pin (V_{Pwr}) and 4.5 V to 5.5 V applied to the logic supply pin (V_{DD}). If V_{Pwr} is above the specified Overvoltage Shutdown voltage limit ($V_{Pwr(ovsd)}$) the outputs will be disabled and the status line voltage will transition to a low logic state indicating a fault.

When the CEN voltage is at a low logic state, OUT1 and OUT2 will turn OFF. This provides an under voltage shutdown for V_{Pwr} in the 0 to 4.5 V range. The active low under voltage must be externally provided to the CEN pin.

The MC33143 is designed to survive the loss of V_{Pwr}.

Normal Operations

The MC33143 is considered to be operating normal when the following conditions are met:

8) $5.5\ V \le V_{Pwr} \le 26\ V$.
9) $-40°C \le TJ \le 150°C$.
10) When load currents (I_O) exceed the Output Open "ON" detection current ($I_{O(on)}$) and occur within the Open Sense "ON" time ($t_{os(on)}$) window.
11) When load currents (I_O) are less than the Output Limit Current ($I_{O(Lim)}$) for durations in excess of the Short Sense time (t_{SS}).
12) So long as the output of the device is able to clamp negative voltages produced when switching inductive loads to the specified clamp voltage (V_{Clamp}).

Fault Conditions

Anytime the MC33143 is not operating normal it is said to be operating in a "faulted condition". Fault conditions will result in level changes of the status outputs (STAT1–2) and disable the affected faulted output.

Output Over Current/Short to Ground Faults

For an enabled input, the status line voltage will transition to a low logic level if the output current equals or exceeds the Output Limit current ($I_{O(Lim)}$) for a period of time in excess of the Short Sense time (t_{SS}). Only the affected output will turn off; independent of the corresponding input's condition. The device incorporates an internal short duration Refresh timer (t_{ref}) to mask edge transients due to switching noise. The output will remain off for the short t_{ref} duration and then attempt to re–energize the shorted load. The internal protection circuitry continues to be active during this process. If the short is not removed; the circuitry will sequence and the output will remain off for a another t_{ref} time. This process will continue so long as the output remains shorted and the input remains in a logic high state. If the short is removed from the output, while the input is ON, the MC33143 will return to normal operation and the status line will go to a logic high state after the t_{ref} time–out. The status line will also go to a logic high state on the falling edge of the corresponding input.

Open Load/Short to V_{Pwr} Fault

This condition is commonly referred to as an "ON" open fault. For this fault to be present, the output current of the driver must be at or near zero. Since the MC33143 is a "high–side switch"; It is for this reason a Short to V_{Pwr} fault resembles an Open Load fault, in so far as the MC33143 is concerned. When this fault is present the status line voltage will transition to a low logic level so long as the output current does not exceed the specified Open ON detection current ($I_{O(on)}$) for a duration in excess of the specified Open Sense ON time ($t_{os(on)}$). If the open load or output short to V_{Pwr} condition is removed, and the corresponding input is at a logic high state, the status line voltage will go to a logic high state after the drain current has exceeded $I_{O(on)}$. The ON open fault detection circuit incorporates a voltage comparator which monitors the voltage difference from V_{Pwr} to OUT. When ever the V_{Pwr} to OUT voltage difference falls below 10 mV an ON Open fault is reported. A Short to V_{Pwr} external to any module the MC33143 is in will not be detected as an ON Open fault if the voltage difference from V_{Pwr} to OUT is greater than 10 mV. V_{Pwr} line voltage drops directly impact this detection ability.

Overvoltage Fault

When this fault is present the status line voltage will transition to a logic low state when V_{Pwr} exceeds the specified Overvoltage Shutdown threshold $V_{Pwr(ovsd)}$. This fault produces a "global" response on the part of the MC33143 by turning OFF both outputs independent of input conditions. The outputs will resume normal operation when V_{Pwr} drops the specified Overvoltage Hysteresis $V_{Pwr(hys)}$ value.

Over Temperature Fault

When this fault is present the status line voltage transitions to a low logic level when the junction temperature of either output exceeds the specified Thermal Limit threshold (T_{Lim}). Only the specific faulted output will shutdown independent of the input condition. The other output will continue to operate in a normal fashion unless it also becomes faulted. The thermally faulted output will resume normal operation when the junction temperature drops the specified Over Temperature Shutdown Hysteresis ($T_{Lim(hys)}$) amount.

MOTOROLA

MC33192

MI-Bus Interface Stepper Motor Controller

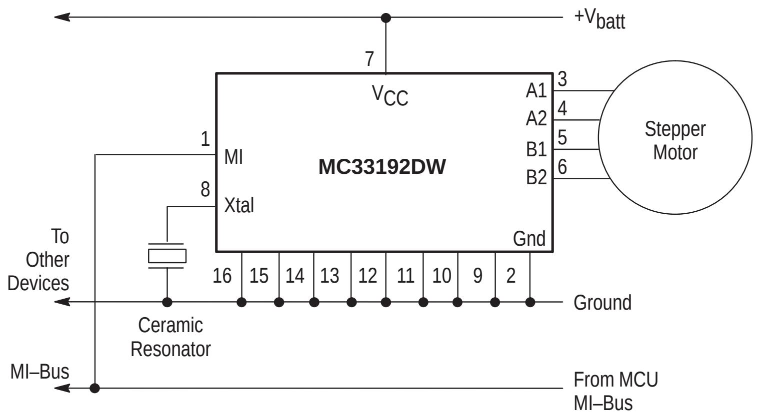
The MC33192 Stepper Motor Controller is intended to control loads in harsh automotive environments using a serial communication bus. The MI–Bus can provide satisfactory real time control of up to eight stepper motors. MI–Bus technology offers a noise immune system solution for difficult control applications involving relay drivers, motor controllers, etc.

The MC33192 stepper motor controller provides four phase signals to drive two phase motors in either half or full step modes. When used with an appropriate Motorola HCMOS microprocessor it provides an economical solution for applications requiring a minimum amount of wiring and optimized system versatility.

The MC33192 is packaged in an economical 16 pin surface mount package and specified at an operating voltage 12 V for – 40°C $\leq T_A \leq$ 100°C.

- Single Wire Open Bus Capability Up to 10 Meters in Length
- Programmable Address Bus System
- Fault Detection of Half–Bridge Drivers and Motor Windings
- Ceramic Resonator For Accurate and Reliable Transmission of Data
- Sub–Multiple of Oscillator End–of–Frame Signal
- MI–Bus Signal Slew Rate Limited to 1.0 V/µs for Minimum RFI
- MI–Bus Error Diagnostics
- Non–Functioning Device Diagnotics
- Over Temperature Detection
- Address Programming Sequence Status
- Load and Double Battery (Jump Start) Protection

Simplified Application



This device contains 1,528 active transistors.

NOTES:
1. Transient capability is defined as the positive overvoltage transient with 250 ms decay time constant. The detection on an overvoltage condition causes all H–Bridges to be latched "off".
2. Ambient temperature is given as a convience; Maximum junction temperature is the limiting factor.
3. Load Dump is the inductive transient voltage imposed on an automotive battery line as a result of opening the battery connection while the alternator system is producing charge current. The detection on an overvoltage condition causes all H–Bridges to be latched "off".
4. Standby Current is with both H–Bridges "off" (Inh1 = Inh2 = 0).
5. H–Bridge Saturation Voltage is referenced to the positive supply or ground respective of the H–Bridge output being High or Low. Saturation voltage is the voltage drop from the output to the positive supply (with output High) and the voltage drop to ground (with output Low).
6. Address Programming Current is the current encountered when the bus is at 12 V during address programming.
7. A typical application uses an external ceramic resonator crystal having a frequency of 644 kHz. An internal capacitor in parallel with ceramic resonator is used to shift the frequency to the working frequency of 640 kHz. The frequency accuracy of the oscillator is dependant on the capacitor and ceramic resonator tolerance (usually ±1.0%).
8. The Message Time Slot is the time required for one complete device message transfer. The message time is equivalent to a total of 16 periods of the oscillator frequency used.
9. If the MI–Bus becomes shorted to ground, all MC33192 outputs will be disabled after a period of nine time slots ($9t_s$).
10. MI–Bus voltage required for address programming.

GENERAL DESCRIPTION

The MC33192 is a serial stepper motor controller for use in harsh automotive applications using multiplex wiring. The MC33192 provides all the necessary four phase drive signals to control two phase bipolar stepper motors operated in either half or full step modes. Multiple stepper motor controllers can be operated on a real time basis at step frequencies up to 200 Hz using a single microcontroller (MCU). A primary attribute of operation is the utilization of the MI–Bus message media to provide high noise immunity communication ensuring very high operating reliability of motor stepping.

The MC33192 is designed to drive bipolar stepper motors having a winding resistance of 80 Ω at 20°C with a supply voltage of 12 V. It is supplied in a SO–16L plastic package having eight pins, on one side, connected directly to the lead frame thus enhancing the thermal performance to allow a power dissipation of 0.5 W at 120°C ambient temperature.

Multiple Simultaneous Motor Operation

Several motors can be controlled in a serial fashion, one after the other, using the same software time base. The time base determines the step frequency of the motors. A single motor can be operated at a maximum speed of 200 Hz pull–in with a duration of 5.0 ms per step. Three motors can be operated simultaneously using a 68HC05B6 MCU at the same time base (200 Hz) with about 1.7 ms per step. A 68HC11 MCU can control 4 stepper motors with adequate program step time. The step frequency must be decreased to control additional motors. To control eight motors simultaneously would require the motor speed to be decreased to 100 Hz producing about 2.0 ms time duration per step with adequate program time.

MI–Bus General Description

The Motorola Interconnect Bus (MI–Bus) is a serial push–pull communications protocol which efficiently supports distributed real time control while exhibiting a high level of noise immunity.

Under the SAE Vehicle Network categories, the MI–Bus is a Class A bus with a data stream transfer bit rate in excess of 20 kHz and thus inaudible to the human ear. It requires a single wire to carry the control data between the master MCU and its slave devices. The bus can be operated at lengths up to 15 meters.

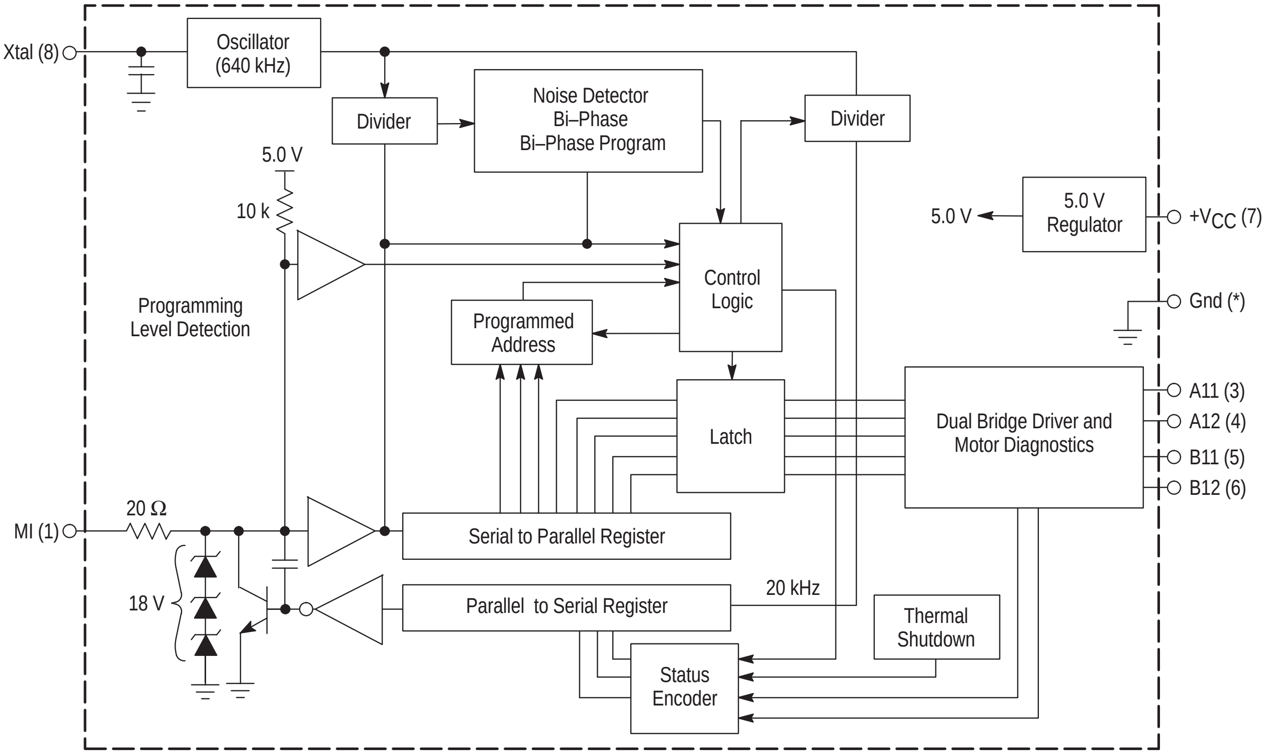
At 20 kHz the time slot used to construct the message (25 µs) can be handled by software using many MCUs available on the market.

The MI–Bus is suitable for medium speed networks requiring very low cost multiplex wiring. Aside from ground, the MI–Bus requires only one signal wire connecting the MCU to multiple slave MC33192 devices with individual control.

A single MI–Bus can accomplish simultaneous automotive system control of Air Conditioning, Head Lamp Levellers, Window Lifts, Sensors, Intelligent Coil Drivers, etc. The MI–Bus has been found to be cost effective in vehicle body electronics by replacing the conventional wiring harness.

Figure 1 shows the internal block diagram of the MC33192 Stepper Motor Controller.

Figure 1. MC33192 Stepper Motor Conroller Block Diagram



NOTE: (*) Pins 2, 9, 10, 11, 12, 13, 14, 15 and 16 are common electrical and heatsink ground pins for the device.

MI–Bus Access Method

The information on the MI–Bus is sent in a fixed message frame format (See Figure 4). The system MCU can take control of the MI–Bus at any time with a start bit which violates the law of Manchester Bi–Phase code by having three consecutive Time Slots ($3t_S$) held constantly at a Logic "0" state.

Push–Pull Communication Sequence

Communication between the system MCU and slave MC33192 devices always use the same message frame organization. The MCU first sends eight serial data bits over the MI–Bus comprised of five control bits followed by three address bits. This communication sequence is called a "Push Field" since it represents command information sent from the MCU. The sequence of the five control data bits follow the order D0, D1, D2, D3 and D4. The three address bits are sent in sequential order A0, A1 and A2 defining a binary address code. The condition of MI–Bus during any of the control bit time windows defines a specific control function as shown in Figure 2. A "Pull Sync" bit is sent at the end of the Push Field, the positive edge of which causes all data sent to the selected device to be latched into the output circuit.

Figure 2. Push Field Data Bits

Bit	Name	Control Function
D4	Inh2	Inhibits H–Bridge 2
D3	Dir2	Establishes Direction of H–Bridge 2 Current
D2	E	Energizes Bridge Coils 1 and 2
D1	Dir1	Establishes Direction of H–Bridge 1 Current
D0	Inh1	Inhibits H–Bridge 1

After the Pull Sync bit is sent, following the Push Field, the MCU listens on the MI–Bus for serial data bits sent back from the previously addressed MC33192 device. This portion of the communication sequence starts the "Pull Field Data" since it represents information pulled from the addressed MC33192 and received by the MCU.

The address selected MC33192 device sends data, in the form of status bits, back to the MCU reporting the devices condition. At the end of the Push Field the MCU outputs a Pull Sync bit which signals the start of the Pull Field. In the Pull Field are three bits (S2, S1 and S0) which report the status of the previously addressed MC33192 according to Figure 3.

Figure 3. Pull Field Status Bits

S2	S1	S0	Status	Comments
0	0	0	Not used	
0	0	1	Free	
0	1	0	No Back EMF	Drivers and/or coils failed
0	1	1	Free	
1	0	0	Normal/OK	
1	0	1	Thermal	Chip temperature > 150°C
1	1	0	Programming	PROM energized
1	1	1	Selection failed	Noise on MI–Bus, failed or disconnected module

The positive edge of the Pull Sync pulse (set by the MCU) causes all Push Field Data sent to the selected MC33192 to be stored in the output latch circuit in time with the strobe pulse. This means the data bits are emitted in real time synchronization with the MCU's machine cycle. The strobe pulse occurs only after the Push Field sequence is validated by the address selected device.

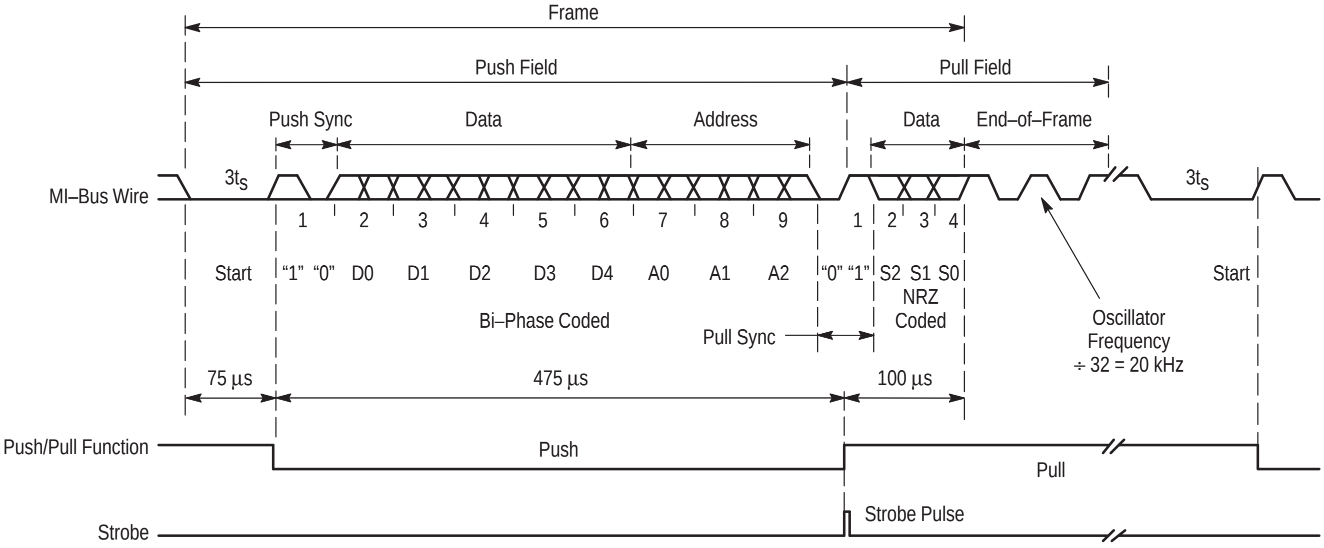
Message Validation

The communication between the MCU and the selected MC33192 device is valid only when the MCU reads (receives) the Pull Field Data having the correct codes (excluding the code "1–1–1" and "0–0–0") followed by an End–of–Frame signal. The frequency of the End–of–Frame signal may be a sub–multiple of the selected devices local oscillator or related to an internal or external analog parameter using a Voltage to Frequency Converter.

Error Detection

An error is detected when the Pull Field contains the code "1–1–1" followed by the End–of–Frame permanently tied to a logic "1" state (internally from 5.0 V through a pull–up resistor). This means the communication between the MCU and the selected device was not obtained.

Figure 4. MI–Bus Timing Diagram



There are four types of system error detections which are not mutually exclusive; These are:

1) Noise Detection

The system MC33192 slave devices receive the Push Field message from the MCU twice for each Time Slot (t_S) of the Bi–Phase Code. A receive error occurs when the two message samples fail to “logic wise” match. Noise and Bi–Phase detection are discussed further under Message Coding.

2) Bi–Phase Detection

The system slave devices receiving the Push Field message from the MCU detect the Bi–Phase Code. A detector error occurs when the two time slots of the Bi–Phase Code do not contain an Exclusive–OR logic function.

3) Field Check

A field error is detected when a fixed–form bit field contains an improper number of bits. A bit error can also be detected by the MCU during the Push Field. The MCU can simultaneously monitor the MI–Bus at the time it is sending data. A bit error is detected if the sent bit value does not match the value which was monitored.

4) Urgent Output Disable

If the MI–Bus becomes shorted to ground, the slave device outputs will be disabled after a period of $9t_S$. The MCU itself can take advantage of this feature to “globally” disable the outputs of all system slave devices by keeping the MI–Bus at a logic “0” level for a duration of $9t_S$ or more. Normal operation is resumed when the MCU sends a “standard” instruction over the MI–Bus.

Basic Stepper Motor Construction and Operation

Stepper motors are constructed with a permanent magnet rotor magnetized with the same number of pole pairs as contained in one stator coil section. Operationally, stepper motors rotate at constant incremental angles by stepping one step every time the current switches discretely in one stator field coil causing the North–South stator field to rotate either clockwise or counter–clockwise causing the permanent magnet rotor to follow (see Figure 5). For simplicity, assume the starting condition of the A1 to A2 stator field to be top to bottom polarized N to S and the B1 to B2 stator field to be left to right polarized N to S. The resulting stator field will produce a vector which points in the direction of position 3. The rotor will, in this case, be in the position shown in Figure 5 (pointing to position 1). This initial condition corresponds to that of step 1 in Figure 6. As the direction of current flow in the B1 to B2 stator field is reversed, the field polarity of the B1 to B2 also reverses and is left to right polarized S to N. This causes the resulting stator field vector to point in the direction of position 4. This in turn causes the N–S rotor to follow and rotate 90° in a clockwise direction and point in the direction of position 2. This condition corresponds to step 2 of Figure 6. Continued clockwise rotor steps will be experienced as the stator field continues to be incrementally rotated as shown in steps 3, 4, 5, etc. of Figure 6. The 90° steps in this simplistic example constitute “full steps”. It is to be noticed that both coils, in the foregoing full step example, were simultaneously energized in one of two directions. It is possible to increment the rotor in 45° “intermediate steps” or “half steps” by alternately energizing only one stator coil at a time in the appropriate direction while turning the other stator coil off. The drive signals for Half Step operation are shown in Figure 7. The Power output stages of the MC33192 consist of two H–Bridges capable of driving two–phase bi–polar permanent magnet motors in either half or full step increment.

Figure 5. Permanent Magnet Stepper Motor

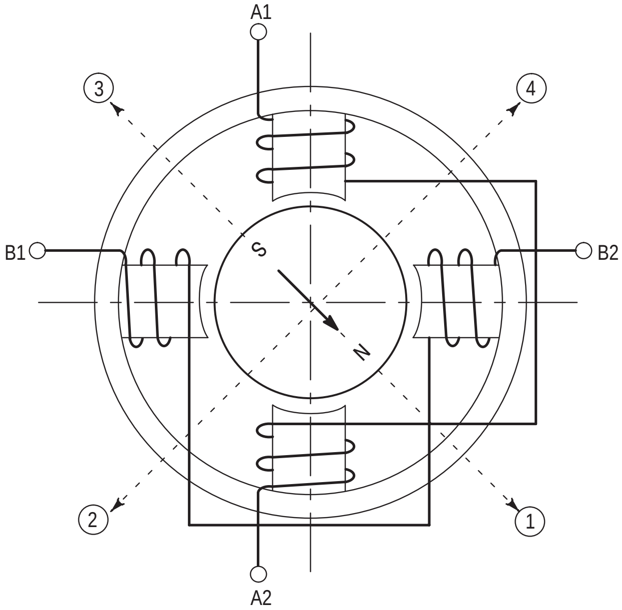


Figure 6. 4–Step “Full Step” Operation

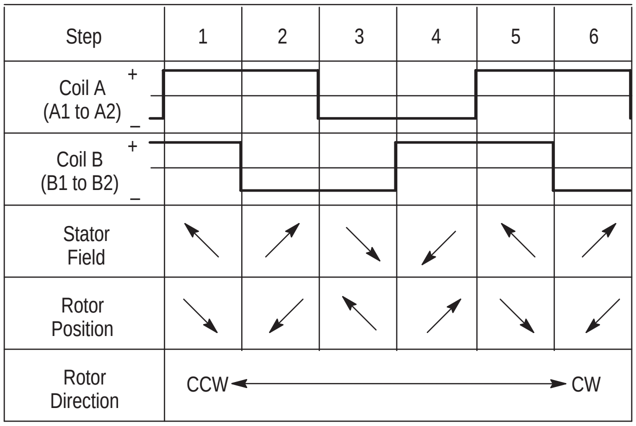

Figure 7. 8–Step “Half Step” Operation

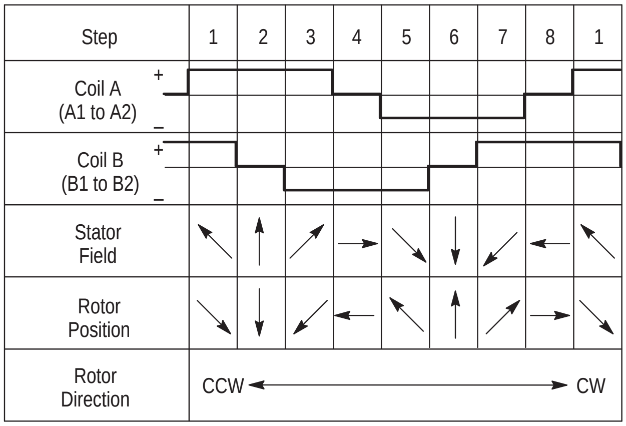

Permanent magnetic stepping motors exhibit the characteristic ability to hold a shaft rotor position with or without a stator coil being energized. Normally the shaft holding ability of the motor with a stator coil energized is referred to as “Holding Torque” while “Residual Torque” or “Detent Torque” refers to the shaft holding ability when a stator coil is not energized. The Holding Torque value is dependent on the interactive magnetic force created by the resulting energized stator fields with that of the permanent magnet rotor. The Residual Torque is a function of the physical size and composition of the permanent magnet rotor material coupled with its intrinsic magnetic attraction for the un–energized stator core material and as a result, the weaker of the two torques.

It is to be noted when using half step operation, only one coil is energized during alternate step periods which produces a somewhat weaker Holding Torque. Holding Torque is maximized when both coils are simultaneously energized. In addition, since each winding and resulting flux conditions are not perfectly matched for each half step, incremental accuracy is not as good as when full stepping.

Two Phase Drive Signals

The DIR1 and DIR2 bits in the Data Frame of the Push Field determine the direction of H–Bridge current flow, and thus the magnetic field polarization of the stator coils, for H–Bridge outputs “A” and “B” respectively. The directional signals DIR1 and DIR2, generated by the MCU, communicate over the MI–Bus to control the two H–Bridge power output stages of the MC33192 to drive two phase bipolar permanent magnet motors. Figure 8 shows the MC33192 truth table to accomplish incremental stepping of the motor in a clockwise or counter–clockwise direction in either half or full step modes. The stator field polarization and rotor position are also shown for reference relative to the basic stepper motor of Figure 5.

Figure 8. Truth Table and Serial Push Field Data Bits For Sequential Stepping

		Push Field Bits

		0	0	0	1	1	Z	Z	Z	1			

NOTES: 1. X = Don’t care; Z = High impedance; 1 = High (active “on”) state; 0 = Low (inactive “off”) state.
2. The stator field direction and position of the rotor are shown for explanation purposes and relative to the basic stepper motor shown in Figure 3.
3. DIR1 establishes the direction of current flow in H–Bridge “A”.
4. DIR2 establishes the direction of current flow in H–Bridge “B”.

MI–Bus Interface Description

The MI–Bus Interface shown in Figure 9 is made up of a single NPN transistor (Q1). The two main functions of this NPN transistor are:

1) To drive the MI–Bus during the Push Field with approximately 20 mA of current while also exhibiting low saturation characteristics ($V_{CE(sat)}$).

2) To protect the Input/Output (I/O) pin of the MCU against any Electro–Magnetic Interference (EMI) captured on the bus wire.

Without the NPN transistor, the MCU could be destroyed as a result of receiving excessive EMI energy present on the bus. In addition, the transistor blocks the MCU from receiving EMI signals which could erroneously change the data direction register of the MCU I/O.

The MCU input pin (P_{in}), used to read the Pull Field of the MI–Bus, is protected by two diodes (D2 and D3) and two resistors (R5 and R6). Any transient EMI generated voltage present on the bus is clamped by the two diodes to a windowed voltage value not to be greater than the V_{DD} or less than the V_{SS} supply voltages of the MCU.

MI–Bus Levels

The MI–Bus can have one of two valid logic states, recessive or dominant. The recessive state corresponds to a Logic “1” and is obtained through use of a 10 kΩ pull–up resistor (R9) to 5.0 V. The dominant state corresponds to a Logic “0” which represents a voltage less than 0.3 V and created by the $V_{CE(sat)}$ of Q1.

MI–Bus Overvoltage Protection

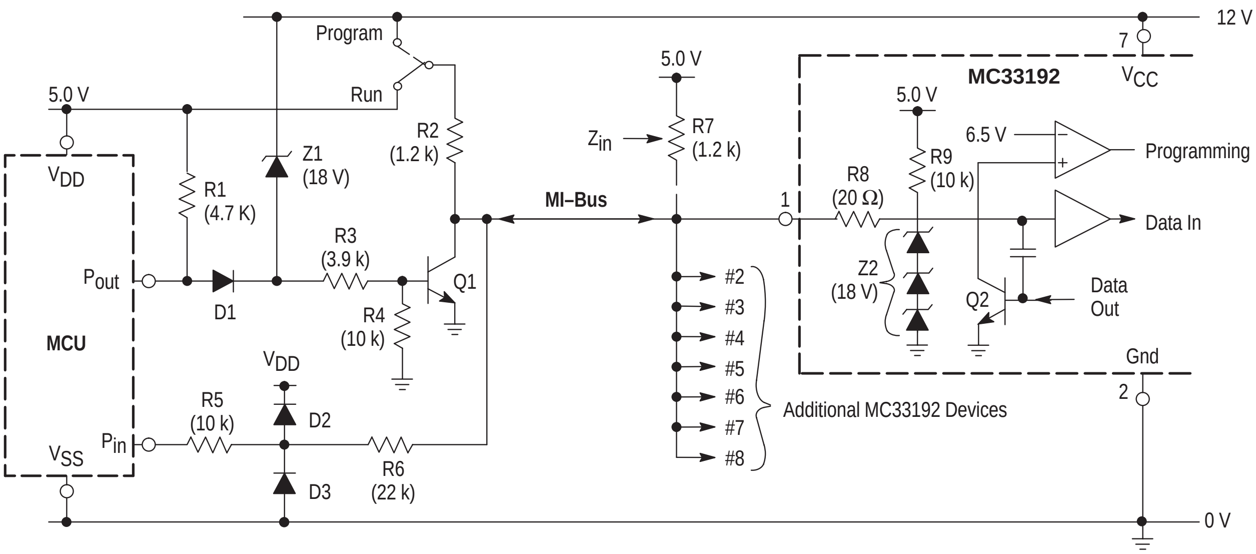
An external zener diode (Z1) is incorporated in the interface circuit so as to protect the MCU output pin (P_{out}) from overvoltages commonly encountered in automotive applications as a result of “Load Dump” and “Jump Start” conditions. Load Dump is defined as the inductive transient generated on the battery line as a result of opening the battery connection while the alternator system is producing charge current. Jump Start overvoltages are the result of paralleling the installed automotive battery, through the use of “jumper cables”, to an external voltage source in excess of the vehicles nominal system voltage. For 12 V automotive systems, it is common for 24 V “jump start” voltages to be used.

When an overvoltage situation (>18 V) exists, due to a load dump or jump start condition, the zener diode (Z1) is activated and supplies base current to turn on the NPN transistor Q1 causing the bus to be pulled to less than 0.3 V producing a Logic “0” on the MI–Bus. After a duration corresponding to $8t_S$ (200 µs) of continuous Logic “0” on the bus all MC33192 devices will disable their outputs. Normal operation is resumed, following the overvoltage, by the MCU sending out a “standard” message instruction.

MI–Bus Termination Network

The MI–Bus is resistively loaded according to the number of MC33192 devices installed on the bus. Each MC33192 has an internal 10 kΩ pull–up resistor to 5.0 V. An external pull–up resistor (R7) is recommended to be used to optimally adjust termination of the bus for a load resistance of 600 Ω.

Figure 9. MI–Bus MCU Interface



MESSAGE CODING

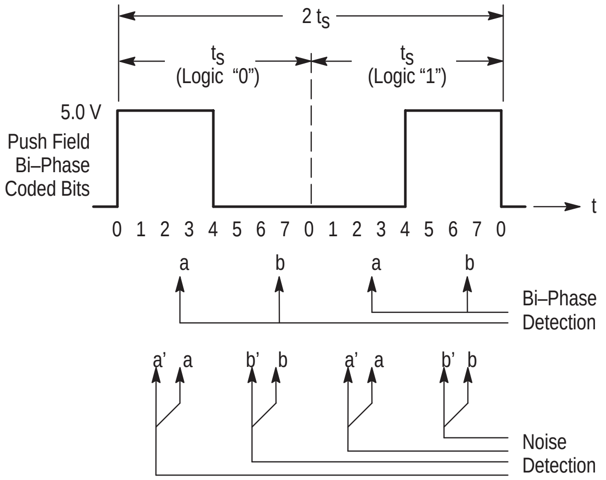
Bi–Phase Coding and Detection

The Manchester Bi–Phase code shown in Figure 10 requires two time slots ($2t_S$) to encode a single data bit. This allows detection of a single error at the time slot level. The logic levels "1" or "0" are determined by the organization of the two time slots. These always have complementary logic levels of either zero volts or plus five volts, which are detected using an Exclusive OR detection circuit during the Push Field sequence. A "1" bit is detected when the first time slot is set to a zero logic state (0 V) followed by the second time slot set to a logic state one (5.0 V). Conversely, a "0" bit is detected when the first time slot is set to the logic state "one" (5.0 V) followed by a second time slot set to a "zero" logic state (0 V). For these two bits are Exclusive–ORs of each other.

The addressed devices receiving the Push Field detect the Bi–Phase code. Bi–Phase detection involves the sampling of the Push Field Bi–Phase code twice (a and b) for each time slot. A code error occurs when the two time slots of the Bi–Phase do not follow a logical Exclusive–OR function (see Figure 10).

Noise monitoring is accomplished by sampling the Push Field Bi–Phase code twice (a and a') and (b and b') during each time slot. A noise error is detected if the two sample values do not have the same logical level.

Figure 10. Noise/Bi–Phase Detection



Each message frame consists of two fields: The Push Field, in which data and addresses are transferred by the MCU to the slave device; and the Pull Field, in which serial data is transferred back to the MCU from the address selected slave device. The message frame is broken down into seven individual field segments as indicated in Figure 4 (Start, Push Field Sync, Push Field Data, Push Field Address, Pull Field Sync, Pull Field Data, and End–of–Frame). The following lists the bit size and function of each of these segments:

1) **Start** is the start of message and consists of three time slots ($3t_S$) having the dominant Logic "0" state of less than 0.3 V. Holding the MI–Bus at ground for three time slots ($3t_S$) marks the beginning of the message frame by violating the law of the Manchester Code.

2) **Push Field Sync** is a single bit which establishes initial timing for the Push Field Data to follow.

3) **Push Field Data** is comprised of five serial data bit fields (D0, D1, D2, D3 and D4) which comprise the instruction set defining the configuration and condition of the two H–Bridge output stages.

4) **Push Field Address** is comprised of three serial data bit fields (A0, A1 and A2) which define the address or name of a MC33192 on the MI–Bus.

5) **Pull Field Sync** is a single bit which establishes the end of the Push Field and the initial start timing for the Pull Field Data to follow.

6) **Pull Field Data** is made up of three serial data bit fields (S2, S1 and S0) which contain the existing status information of an addressed MC33192.

7) **End–of–Frame** field is a signal which communicates to the MCU that the status information sent by the MC33192 is complete.

The Push Field Sync bit, Push Field Data bits, Push Field Address bits, Pull Field Sync bit are all coded by the Manchester Bi–Phase L Code. The Pull Field Data bits are Non–Return to Zero (NRZ) coded. The End–of Frame field is a square wave signal with a frequency of 20 kHz or higher so as to avoid a condition which causes a bus violation.

The Manchester Bi–Phase L code requires two time slots ($2t_S$) to encode a single bit. This allows a single error to be detected during the time slot.

Address Programming involves the use of three instructions. Refer to Figure10.

First Instruction Set the MI–Bus continuously at 12 V. This places the MC33192 in the programming mode. Programming is possible only when the MI–Bus is at 12 V.

Next, the MCU serially enters "Logic Zeros" in all five Push Field Data bit positions (D0, D1, D2, D3 and D4) followed by the designated address value in the Push Field Address positions (A0, A1, & A2).

The MCU now waits 275 µs before starting the second instruction. The total of the Pull time, Delay time, and Bus Violation time (V) of the second instruction (150 µs, 275 µs and 75 µs respectively) will cause the memory cell to be energized for 500 µs. During the first 150 µs of this time, the MCU is checking the Pull Field Data Bits S2, S1 and S0 looking for the **programming code "110"** to indicate complete activation of the memory cell.

Second Instruction (MI–Bus voltage remaining at 12 V)

The MCU repeats the same Push Field instruction as previously sent in the First Instruction; entering all "Logic Zeros" in the Push Field Data positions followed by the designated Push Field Address value in the address positions.

Again, the MCU waits for the Pull, Delay, and Bus violation time while checking the Pull Field Data bits looking for the **programming code "110"** code. The MCU must repeat the initial Push Field Address instruction until a "110" code is received before advancing to the Third Instruction.

Third Instruction The MI–Bus voltage is lowered to 5.0 V.

The MCU serially loads "Logic Zeros" in all five Push Field Data bit positions followed by the programmed address in the Push Field Address positions. The MCU then checks the Pull Field Address status bits looking this time for the

programming OK code "100" indicating the address programming to be executed.

The First and Second Instructions must be repeated until the MCU successfully receives the programming code "100". Address programming is not complete until a "100" OK status is received by the MCU with the MI–Bus voltage at 5.0 V.

Overwrite–Bit Programming involves the use of two instructions. See Figure 11.

First Instruction Have the MI–Bus continuously set at 12 V so as to have the MC33192 in the programming mode. Programming can only be accomplished with the MI–Bus at 12 V.

The MCU serially enters "Logic Zeros" for the Push Field Data bits D0, D1, D2 and D3 and a Logic "1" for D4 bit followed by the programmed address bits A0, A1 and A2.

The MCU now waits 275 µs before starting the second instruction. The total of the Pull time, Delay time, and Bus Violation time (V) of the second instruction (150 µs, 275 µs and 75 µs respectively) will cause the memory cell to be energized for 500 µs. During the first 150 µs of this time, the MCU is checking the Pull Field Data Bits for the status of bits S2, S1 and S0 looking for the **programming code "110"** to indicate complete activation of the memory cell.

Second Instruction (MI–Bus remaining at 12 V)

The MCU repeats the first instruction outlined above until the **programming OK code "100"** is sent back to the MCU from the selected MC33192 indicating the overwrite–bit protection to be programmed. If after eight repeat instructions, the programming code "110" or the OK code "100" is not generated four times in succession, programming of the MC33192 has failed. If this occurs, the Overwrite–Bit Programming sequence should be reviewed and re–started from the beginning.

H–Bridge Output

The H–Bridge output drive circuit and associated diagnostic encoder are shown in Figure 12. The H–Bridge output uses internal diode clamps (D1, D2, D3, D4) to provide transient protection of the output transistors necessary when switching inductive loads associated with stepper motors.

Back EMF Detection

Three different Back EMF currents can occur depending on whether the motor is running or manner in which it is being stopped. Referring to Figure 12; When the Dir1 bit is set to logic 0, the direction of current flow will be from V_{CC} through transistor Q2, Coil A (A1 to A2), and transistor Q4 to ground.

1) **Fast Decay** (when transistors Q1, Q2, Q3 and Q4 are switched off).

When the current flowing in the coil is stopped by setting the Inh1 bit to logic 0, the back EMF current will circulate through the voltage supply (V_{CC}) and diodes D1 and D3. At that time, the voltage developed across the diode D1 is detected by transistor Q6. The generated voltage pulse of Q6 is then encoded and sent, in the Pull–Field, to the microprocessor.

2) **Slow Decay** (Q3 and Q4 are switched off)

When the current flowing in the coil is stopped by setting the E bit to logic 0, the back EMF current will circulate through the diode D1 and transistor Q2 which is already switched on.

3) **When Motor is Running**

The rotational direction of the motor changes whenever the Dir bit state is changed. When the Dir bit is changed from a logic 0 to a logic 1, transistors Q2 and Q4 are switched off and transistors Q1 and Q3 are switched on. At this time, the back EMF current will circulate from ground through diodes D1 and D3 to the voltage supply (V_{CC}). In all cases, the back EMF currents will be detected by transistors Q5 and Q6.

MOTOROLA

MC33193

Advance Information

Automotive Direction Indicator

The MC33193 is a new generation industry standard UAA1041 “Flasher”. It has been developed for enhanced EMI sensitivity, system reliability, and improved wiring simplification. The MC33193 is pin compatible with the UAA1041 and UAA1041B in the standard application configuration as shown in Figure 9, without lamp short circuit detection and using a 20 mΩ shunt resistor. The MC33193 has a standby mode of operation requiring very low standby supply current and can be directly connected to the vehicle’s battery. It includes an RF filter on the Fault detection pin (Pin 7) for EMI purposes. Fault detection thresholds are reduced relative to those of the UAA1041, allowing a lower shunt resistance value (20 mΩ) to be used.

- Pin Compatible with the UAA1041
- Defective Lamp Detection Threshold
- RF Filter for EMI Purposes
- Load Dump Protection
- Double Battery Capability for Jump Start Protection
- Internal Free Wheeling Diode Protection
- Low Standby Current Mode

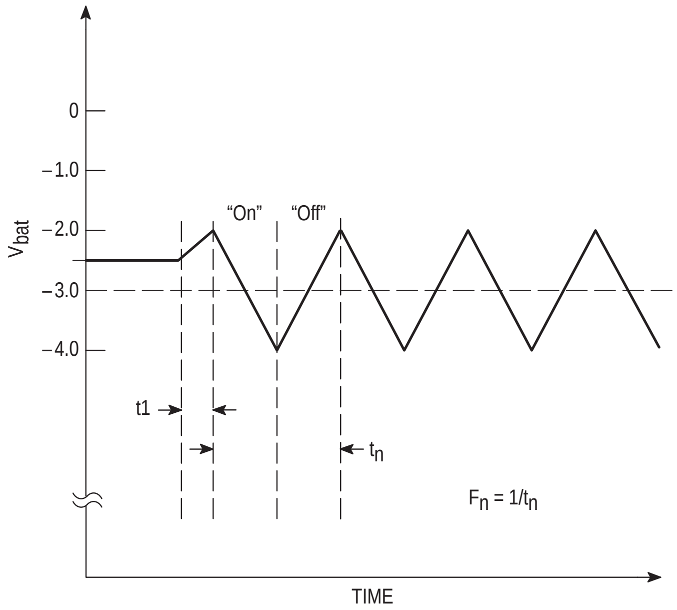

Figure 2. One Defective Lamp Oscillator Timing Diagram

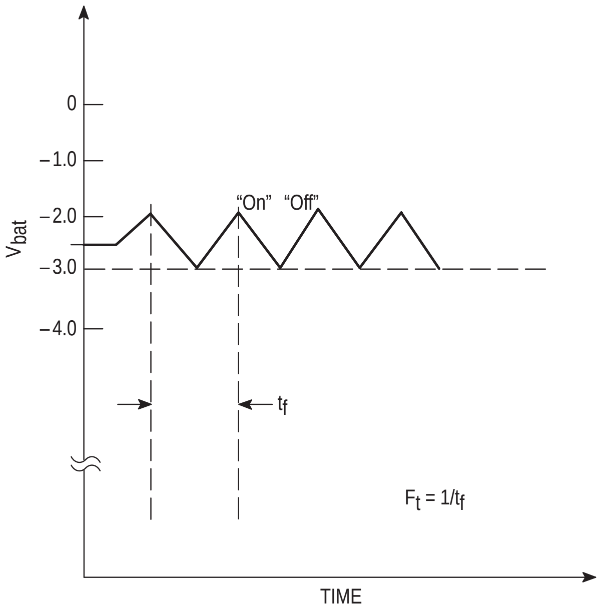

INTRODUCTION

The MC33193 is designed to drive the direction indicator flasher relay. It is a new generation industry standard UAA1041 "Flasher". It consists of the following functions:

- Supply and Protections
- On–Chip Relay Driver
- Oscillator
- Starter Functions
- Lamp Fault Detector with Internal RF Filter
- Standby Mode

Supply and Protection Systems

Pin 1 is connected to ground via resistor R3 which limits the current in the event of any high voltage transients. Pin 2 (V_{CC}) is the positive supply and may be connected directly to the vehicle's battery voltage.

Overvoltage and Double Battery Protection: When the applied V_{CC} to V_{SS} voltage is greater than 22 V, the overvoltage detector circuit turns the relay driver off. Both the device and the lamps are protected if two 12 V batteries are connected in series and used to jump start the vehicle.

Load Dump Overvoltage Protection: A 29 V overvoltage detector protects the circuits against high voltage transients due to load dumps and other low energy spikes. The relay driver is automatically turned on whenever the V_{CC} to V_{SS} voltage is greater than 34 V.

Overvoltage Protection, High Voltage Transients: The Enable and the Starter pins are protected against positive and negative transients by internal on–chip diodes.

On–Chip Relay Driver

The device directly drives the flasher relay. The output structure is an Emitter of an NPN transistor. It contains the free wheeling diode circuitry necessary to protect the device whenever the relay is switched off.

Oscillator

The device uses a sawtooth oscillator (Figure 1).

The frequency is determined by the external components C1 and R1. In the normal operating mode, the flashing frequency is: $F_n = 1/R1*C1*K_n$. With a defective (open) 21 W lamp (Figure 2), the flashing frequency changes to: $F_n = 2.2*F_n$.

The typical first flash delay (the time between the moment when the indicator switch is closed and the first lamp flash occurs) is: t1 = K1*R1*C1

The fault detection delay is from the time relay R1 is on and fault detection is enabled. Where a 21 W lamp opens, the delay is expressed as: t2 = K2*R1*C1

Starter

Pin 8 is connected through a 3.3 kΩ resistor to the flashing lamp. Pin 8 is the input to the Starter function and senses the use of S1 by sensing ground through the lamp (Figures 9 and 10).

Lamp Fault Detector with Internal RF Filter

A Lamp defect is sensed by the lamp fault detector's monitoring of the voltage developed across the external shunt resistor R_S via the RF filter. The R_S voltage drop is compared to a V_{bat} dependent internal reference voltage (V_{ref}) to validate the comparison over the full battery voltage range. A detected fault causes the oscillator to change frequency (Figure 2).

Standby Mode

When the ignition key and warning switches are open; Enable is in a low state and the internal switches, SW1 and SW2, are open and no current passes through the circuit. In this condition, the device's current consumption is zero (I_{CC} = 0). When ignition key and warning switches are closed; Enable is in a high state with SW1 and SW2 being closed and the circuit is powered on.

MAIN DIFFERENCES BETWEEN UAA1041B & MC33193

The MC33193 is pin compatible with the UAA1041.

Supply Current

Supply current is more stable on the MC33193 when the device is in “on” or “off” state. In “on” state the supply current is only 40% higher than when in the “off” state, as compared to a ratio of 3 times for the UAA1041. This results in a lower voltage drop across the ground resistor R3 (see On–Chip Relay Driver).

Short Circuit Detection

The MC33193 has no short circuit detection.

Standby Mode (Pin 6)

The UAA1041 has no standby mode. Pin 6 is used as an Enable/Disable for the short circuit detection.

The MC33193 uses Pin 6 to set the device in standby mode. If Pin 6 is connected to ground, the MC33193 is in the standby mode. In this mode, standby current is very low and Pin 8’s starter resistor R2 and a 2.0 kΩ internal resistor are switched off. As soon as Pin 6 is at a high level (typical threshold = $2V_{be}$) the device becomes active. In the application, the MC33193 can be connected directly to the battery and awakened whenever Pin 6 is connected to the vehicle’s battery by way of a protection resistor and the ignition key switch.

Lamp Defect Detection (Pin 7)

The UAA1041 operates with a 30 mΩ shunt resistor to sense the lamp current. It’s lamp defect detection threshold of Pin 7 is typically 85 mV.

The MC33193 is designed to operate with 20 mΩ shunt resistor and at a reduced threshold of 50 mV. This reduces power generation in the flasher module. In addition, the MC33193 incorporates an RF filter to enhance RFI immunity.

Load Dump and Overvoltage Behavior

The UAA1041 and MC33193 both behave the same in this regard. Both have double battery detection and lamp turn–off protection in the event of a jump start. During load dump, both devices are protected by an internal 30 V zener diode with the relay activated during a load dump.

Relay Driver

Drive capability of both devices is the same. Free wheeling diode protection is internal to both devices. The free wheeling voltage is $2V_{be}$ for the UAA1041 and $3V_{be}$ for the MC33193. This results in a higher clamp voltage across the relay and thus in a faster turn–off. In addition, the lower “on” state supply current is lower on the MC33193 and thus the voltage drop across the ground resistor R3 is reduced. This results in an even higher clamp voltage across the relay.

Oscillator Phase

The oscillator phase is opposite on the MC33193 as compared to the UAA1041. The Oscillator voltage is falling during “on” state and rising during “off” state for the MC33193.

Figure 3. Clamping Voltage versus Temperature

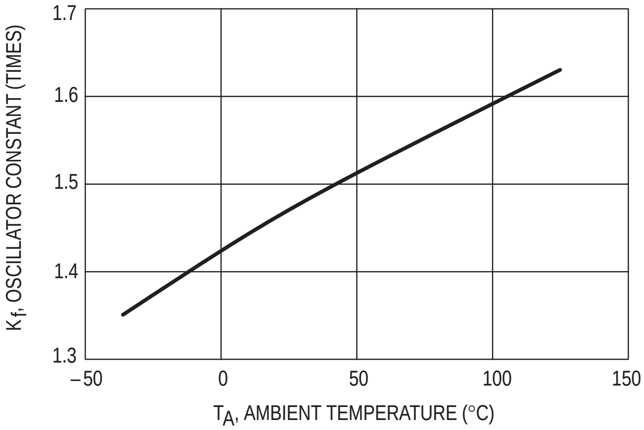

Figure 9. MC33193 Typical Application

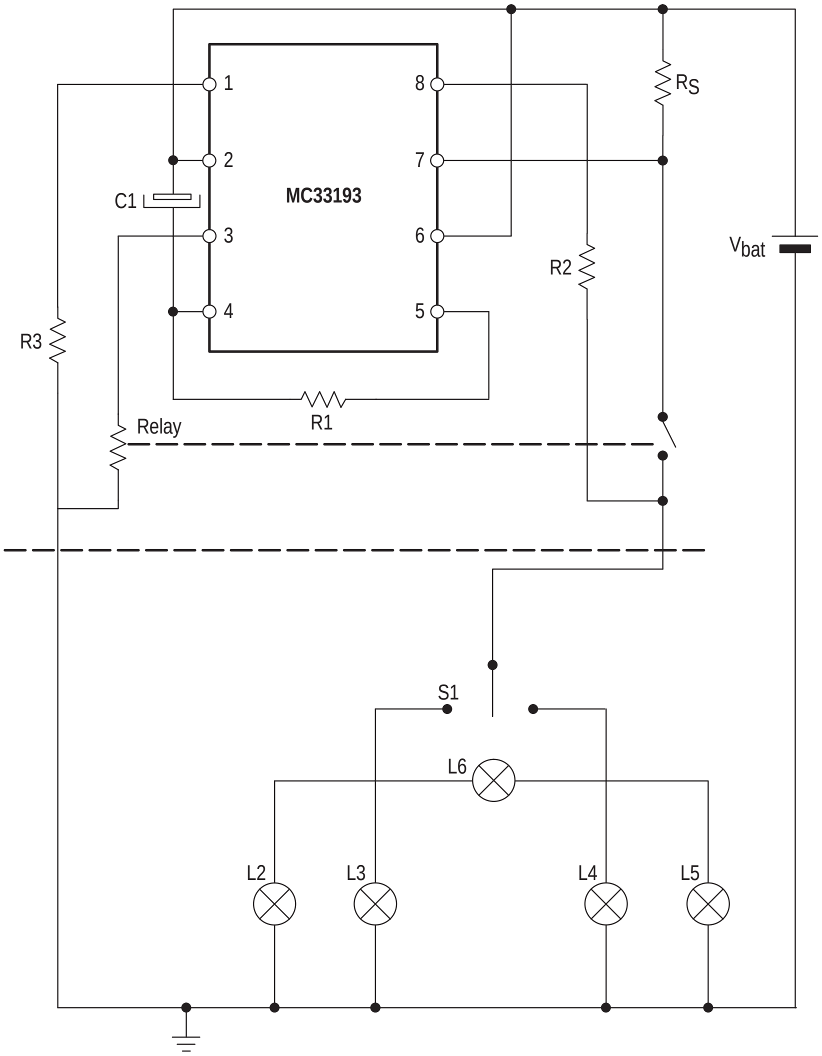
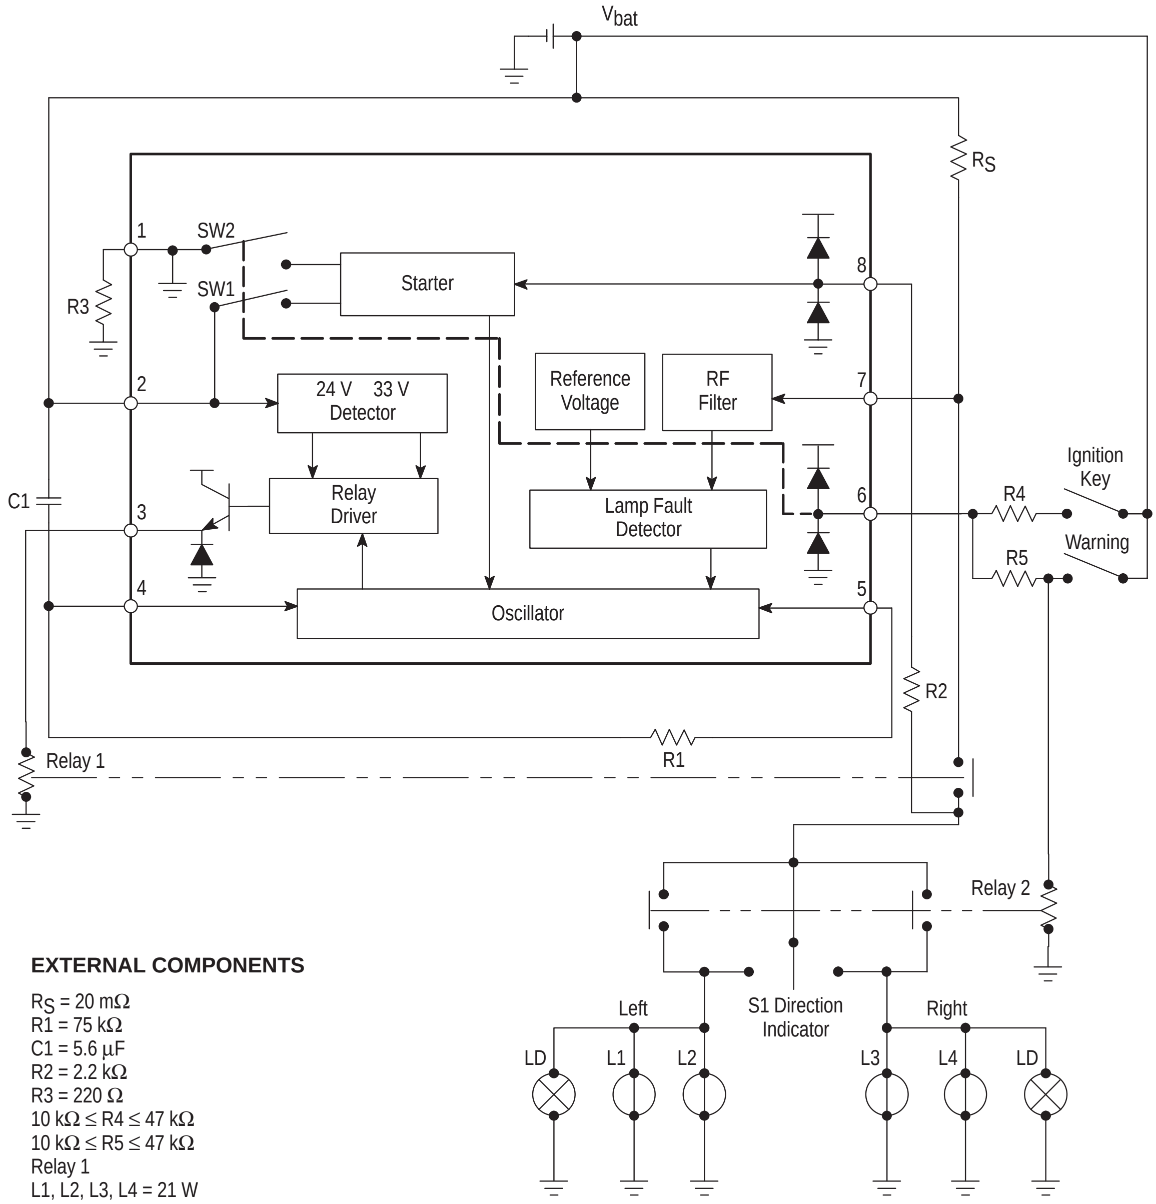


R_S = 20 mΩ
R1 = 75 kΩ
C1 = 5.6 µF
R2 = 3.3 kΩ
R3 = 200 Ω
L2, L3, L4, L5 = 21 W Turn Signal Lamps

Application Information

NOTES:
1. In the above application, the MC33193 is compatible with the UAA1041 and UAA1041B except for the shunt resistor value (R_S = 20 mΩ).
2. The flashing cycle is started by the closing of switch S1.
3. The position of switch S1 is sensed across resistor R2 and R_{Lamp} by the input, Pin 8.

Figure 10. Typical MC33193 Application



EXTERNAL COMPONENTS

R_S = 20 mΩ
R1 = 75 kΩ
C1 = 5.6 µF
R2 = 2.2 kΩ
R3 = 220 Ω
10 kΩ ≤ R4 ≤ 47 kΩ
10 kΩ ≤ R5 ≤ 47 kΩ
Relay 1
L1, L2, L3, L4 = 21 W
L_D = Dashboard Indicator

Application Information

NOTES: 1. The flashing cycle is started by the closing of switch S1.
2. The S1 switch position is sensed across the resistor R2 and R_{Lamp} by the input (Pin 8).
3. If the logic state at Pin 6 is [0], the current through R2 is off.

MOTOROLA

MC33197A

Advance Information

Automotive Wash Wiper Timer

The MC33197A is a standard wiper timer control device designed for harsh automotive applications. The device can perform the intermittent, after wash, and continuous wiper timer functions. It is designed to directly drive a wiper motor relay. The MC33197A requires very few external components for full system implementation. The intermittent control pin can be switched to ground or V_{bat} to meet a large variety of possible applications. The intermittent timing can be fixed or adjustable via an external resistor. The MC33197A is built using bipolar technology and parametrically specified over the automotive ambient temperature range and 8.0 to 16 V supply voltage. The MC33197A can operate in both front and rear wiper applications.

- Adjustable Time Interval of Less Than 500 ms to More Than 30 s
- Intermittent Control Pin Can Be Switched to Ground or V_{bat}
- Adjustable After Wipe Time
- Priority to Continuous Wipe
- Minimum Number of Timing Components
- Integrated Relay Driver With Free Wheeling Protection Diode
- Operating Voltage Range From 8.0 to 16 V
- For Front Wiper and Rear Wiper Window Applications

CONT Threshold (V_{CC} = 16 V)	V_{ih}	–	$V_{CC}/2$	–	V

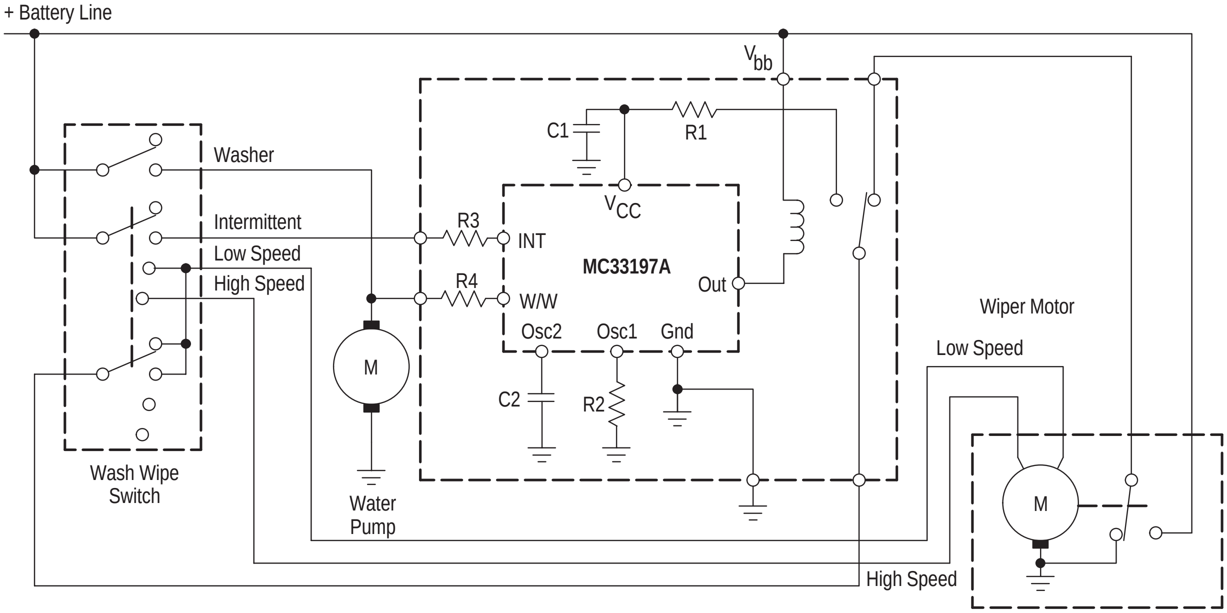
NOTES: 1. The oscillator frequency is defined by the current flowing through the external resistor R2. The voltage at the INT pin is ($V_{CC}/2 – V_{be}$) and hence the current flowing through R3 is different if R3 is connected to V_{bb} or to Gnd because of the voltage drop across resistor R1. This voltage drop causes the oscillator coefficient for t_{b2} to be different for the two cases of INT terminated to Gnd or to V_{bb}. Because of this, the oscillator coefficient is specified with a specific value of R1 whenever INT is connected to V_{bb}. If R1 is changed, the coefficient will change. Also, any extra current through the resistor R1 other than the current used by the device will cause timing deviations in t_{b2} timings (as in the case where two devices are sharing a common R1 resistor).

2. The oscillator stability with temperature is dependent on the temperature coefficients of the external components. If the capacitance value of the external capacitor varies more than 5% over the parametric temperature range, the figures quoted for oscillator variation are not valid.

3. The t_{b1} duration is given by coefficient 4 x R2 x C2 (t_{b1} duration = t_{b1} x 4 x R2 x C2).

4. The t_{b2} duration is given by coefficient x R3 x C2 (t_{b2} duration = t_{b2} x R3 x C2).

Figure 1. Intermittent Wash Wiper Typical Application



This application shows the MC33197A with the external wirings and two speed wiper motor. This application has the Intermittent and Wash Wiper functions.

INTRODUCTION

The MC33197A is a wiper timer control device designed for use in harsh automotive applications. The device can perform the intermittent, after wash, and continuous wiper timer functions.

The MC33197A is designed to directly drive a wiper motor relay. The MC33197A is suitable for both front and rear wiper applications. The MC33197A connects directly to the vehicle's battery voltage (V_{bat}) through a 220 Ω resistor used with a 47 µF de–coupling filter capacitor. The device has an internal oscillator controlled by one of two external resistors (R2 and R3) in addition to one external capacitor (C2), dependent on the application function required. The values of C2 and R2 determine the t_{b1} time base. T_{b1} is used to generate the relay wiper activation during the INT function (T3) and the after wash timing (T2) during the wash wipe mode. The values C2 and R3 determine the t_{b2} time base. The t_{b2} time base is used to generate the pause or intermittent time (T4).

The intermittent wiper function can generate intermittent timing (T4) from less than 500 ms to more than 30 seconds. The intermittent function of the device can be activated by the INT input connected to either ground or V_{bat}. The intermittent timing is externally adjustable by changing the value of resistor R3.

The wash wiper timer function detects the water pump motor's operation. When the pump motor activation is detected, the MC33197A turns the wiper on for the entire duration of the pump motor's activation. When the motor is turned off, it generates an after wash timing (T2) to maintain the wiping action. The W/W pin is connected to the water pump motor through a protection resistor (R4).

The MC33197A also has a continuous function, which activates the wiper relay whenever the CONT input is activated. The CONT input is connected to a switch through a protection resistor (R5). The CONT input comparator has an input threshold of $V_{bb}/2$ with hysteresis.

The device has internal debounce circuitry, based on the oscillator period. This provides filtering of the intermittent (INT) and wash wipe (W/W) input signals (see T1 Debounce Timing paragraph that follows). The device directly drives the wiper motor relay. It internally incorporates a 20 V free wheeling zener diode to protect the device against overvoltage spikes produced when relay is switched off.

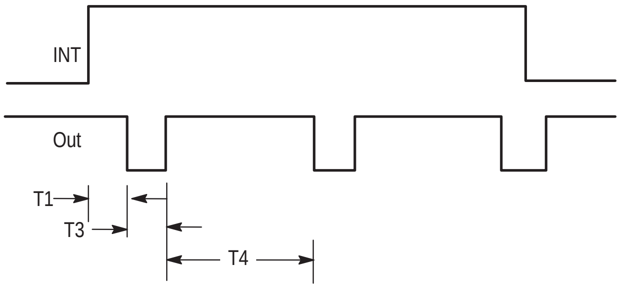
Intermittent Operation

Conditions:

- W/W not connected or connected to ground.
- CONT not connected or connected to ground.
- INT connected to V_{bb} or to ground.

In this configuration, the circuit will respond to the switching of INT to either V_{bb} or ground after a time T1 (see T1 Debounce Timing). If INT is disconnected before the end of T1; no action will be taken. After a time T1, the output will be switched on for a duration, T3 = 16 x 4 x t_{b1} and then switched off for a duration, T4 = 144 x 4 x t_{b2}. This sequence will continue to repeat so long as INT is disconnected from V_{bb} or ground for a time duration greater than T1. If INT is disconnected during the time T3; the output will remain on for the remainder of T3. This is illustrated in the diagram on Figure 2.

Figure 2. Switching Waveform INT Timing



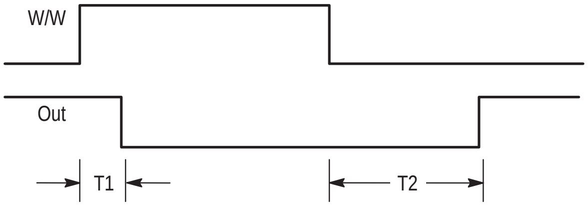
Wash Wipe Operation

Conditions:

- INT disconnected.
- CONT disconnected or connected to ground.

In this condition, the circuit will respond to the switching of W/W to V_{bb} after a time T1 (see T1 Debounce Timing). If W/W is disconnected or connected to ground before the end of T1; no action will be taken. After a time T1; the circuit will perform as shown on Figure 3. The output will turn on and remain on for the duration of W/W. When W/W becomes inactive, the output will remain on for T2 = 96 x 4 x t_{b1}.

Figure 3. Switching Waveform W/W Timing



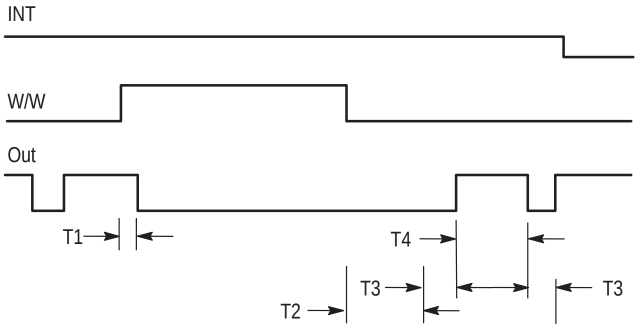
Continuous Operation

In this condition, the circuit responds to the switching of CONT to V_{bb}. If CONT is connected to V_{bb}, the output will turn on regardless of the state of any other input and remain on so long as CONT is active. This command operates directly on the relay output and does not interfere with any other timing. Therefore, the circuit will not be reset to a defined state.

Wash Wiper and Intermittent Operation

If W/W is activated during the time INT is also activated, the circuit will respond to W/W after a time T1 (see T1 Debounce Timing). The output will turn on after T1, and stay on for a time T2 + T3 after W/W is deactivated. Following this, normal operation of INT will occur. This is shown on Figure 4.

Figure 4. Switching Waveform W/W and INT Active



T1 Debounce Timing

The criteria for an input signal to be detected is that it should be active at two successive negative internal clock edges. The inputs are sampled on the negative edge of the internal clock. If two consecutive samples are the same, the input is detected as being in that state. Hence the time T1 from a signal becoming active to the time that the circuit responds can be anytime from 4 x t_{b1} to 2 x 4 x t_{b1} (due to synchronizing the input to the oscillator period) when the oscillator is oscillating with a time base of t_{b1} and 4 x t_{b2} to 2 x 4 x t_{b2}, when the oscillator is oscillating with a time base of t_{b2}.

The following table summarizes all T1 debounce timings:

Condition	Debounce Time
INT Active	4 x t_{b1} to 2 x 4 x t_{b1}
INT Inactive	4 x t_{b1} to 2 x 4 x t_{b1}
W/W Active When INT Inactive	4 x t_{b1} to 2 x 4 x t_{b1}
W/W Active When INT Active During T3	4 x t_{b1} to 2 x 4 x t_{b1}
W/W Active When INT Active During T4	4 x t_{b2} to 2 x 4 x t_{b2}

Two MC33197A Devices Using One Decoupling Resistor and Capacitor

Two devices may be connected to the power source using a common R1 resistor for protection against overvoltages. If this is done it should be noted that the current flowing through R1 is increased and hence the voltage drop across R1 is increased.

Overvoltage Protection

In reference to the Block Diagram and Typical Application, all of the foregoing operational cases require:

R1 ≥ 100 Ω, C1 ≥ 47 µF

R3 ≥ 1.0 kΩ, R4 ≥ 4.7 kΩ, R5 ≥ 4.7 kΩ

The circuit will not operate during the transient conditions. By using the above component values, the circuit will be able to sustain the following overvoltages on V_{bb} without permanent damage:

1. +28 V for 5 minutes
2. –15 V for 5 minutes
3. –16 V cycled off for 1.0 minute
4. +80 V pulse decaying exponentially to 8.0 V in 400 ms repeated 3 times at 1.0 minute intervals.
5. ± 300 V pulse decaying exponentially to 30 V in 300 ms with a maximum energy of 1.0 Joule.
6. ±100 V pulse decaying exponentially to 10 V in 2 ms.

Recommended External Component Values

Below are the recommended component values to ensure the device will operate properly, and that all specified parameters will stay within their tolerances.

R1 should be greater than 100 Ω; recommended value of 220 Ω. R1 can be up to 500 Ω, but in this case the t_{b2v} parameter could be out of it's specified value (see Electrical Characteristics and Note 1). Also, the minimum operating voltage range should be greater than 8.0 V. The following values should be adhered to:

10 kΩ ≤ R2 ≤ 68 kΩ

1.5 kΩ ≤ R3 ≤ 47 kΩ

R4 ≥ 4.7 kΩ

R5 ≥ 4.7 kΩ

C1 ≥ 47 uF

47 nF ≤ C2 ≤ 470 nF

Application Information

The following is an example of timing calculations using the following external components values:

R2 = 22 kΩ, R3 = 2.2 kΩ, C2 = 100 nF (Referring to Block Diagram and Typical Application).

Oscillator Time Base Calculation:

t_{b1} duration = t_{b1} x 4 x R2 x C2 = 1 x 4 x 27e3 x 100e–9 = 10.8 ms

t_{b2} duration_g (INT to Gnd) = t_{b2g} x R3 x C2 = 15.5 x 2.2e3 x 100e–9 = 3.41 ms

t_{b2} duration_v (INT to V_{bb}) = t_{b2v} x R3 x C2 = 12.1 x 2.2e3 x 100e–9 = 2.66 ms

Intermittent timing calculation:

T3 = 16 x 4 x t_{b1} duration = 16 x 4 x 10.8 ms = 691 ms

T4 = 144 x 4 x t_{b2} duration_g = 144 x 4 x 3.41 ms = 1.96 s (INT connected to Gnd)

T4 = 144 x 4 x t_{b2} duration_v = 144 x 4 x 2.66 ms = 1.53 s (INT connected to V_{bb})

Wash wipe timing calculation:

T2 = 96 x 4 x t_{b1} = 96 x 4 x 10.8 ms = 4.15 s

T1 Debounce Time Calculation (see T1 Debounce Timing)

When oscillator is oscillating at t_{b1}:

T1 minimum = 4 x t_{b1} = 4 x 10.8 ms = 43.2 ms

T1 maximum = 2 x 4 x t_{b1} = 2 x 4 x 10.8 ms = 86.4 ms

When oscillator is oscillating at t_{b2}:

T1 minimum (INT connected to Gnd, t_{b2g}) = 4 x t_{b2} = 4 x 3.41 ms = 13.6 ms

T1 maximum (INT connected to Gnd, t_{b2g}) = 2 x 4 x t_{b2} = 2 x 4 x 3.41 ms = 27.3 ms

MC33199

Automotive ISO 9141 Serial Link Driver

ISO 9141
SERIAL LINK DRIVER

SEMICONDUCTOR
TECHNICAL DATA

The MC33199D is a serial interface circuit used in diagnostic applications. It is the interface between the microcontroller and the special K and L Lines of the ISO diagnostic port. The MC33199D has been designed to meet the “Diagnosis System ISO 9141” specification.

The device has a bi–directional bus K Line driver, fully protected against short circuits and over temperature. It also includes the L Line receiver, used during the wake up sequence in the ISO transmission.

The MC33199 has a unique feature which allows transmission baud rate up to 200 k baud.

- Electrically Compatible with Specification “Diagnosis System ISO 9141”
- Transmission Speed Up to 200 k Baud
- Internal Voltage Reference Generator for Line Comparator Thresholds
- TXD, RXD and LO Pins are 5.0 V CMOS Compatible
- High Current Capability of DIA Pin (K Line)
- Short Circuit Protection for the K Line Input
- Over Temperature Shutdown with Hysteresis
- Large Operating Range of Driver Supply Voltage
- Full Operating Temperature Range
- ESD Protected Pins

Test pulses are directly applied to V_S and via a capacitor of 1.0 nF to DIA and L. The voltage V_S is limited to – 2.0 V/40 V by the transient suppressor diode D1. Pulses can occur simultaneously or separately.

INTRODUCTION

The MC33199 is a serial interface circuit used in diagnostic applications. It is the interface between the microcontroller and the special K and L Lines of the ISO diagnostic port. The MC33199 has been designed to meet the “Diagnosis System ISO 9141” specification.

This product description will detail the functionality of the device (see simplified application). The power supply and reference voltage generator will be discussed followed by the path functions between MCU, K and L Lines. A dedicated paragraph will discuss the special functionality of the I1 pin in it’s ability to accommodate high baud rate transmissions.

Power Supplies and Reference Voltage

The device requires two power supplies to be used; a 5.0 V supply, V_{CC}, which is normally connected to the MCU supply. The device V_{CC} pin is capable of sinking typically 1.0 mA during normal operation. A V_{bat} supply voltage, V_S, is normally tied to the car’s battery voltage. The V_{bat} pin can sustain up to 40 V dc. Care should be taken to provide any additional reverse battery and transient voltage protection in excess of 40 V.

The voltage reference generator is supplied from both V_{CC} and V_{bat} pins. The voltage reference generator provides a reference voltage for the K and L Line comparator thresholds. The reference voltage is dependant on the V_{bat} voltage; it is linear in relation to the V_{bat} voltage for all V_{bat} voltages between 5.6 V and 18 V. Below 5.6 V and over 18 V the reference voltage is clamped (see Figure 11). The REF–OUT pin connects the reference voltage out externally making it available for other application needs. The REF–OUT pin is capable of supplying a current of 50 µA (see Figure 12).

Path Functions Between MCU, K and L Lines

The path function from the MCU to the K Line uses a driver to interface directly with the MCU through the TXD pin. The TXD pin is CMOS compatible. This driver controls the On–Off conduction of the power transistor. When the power transistor is On, it pulls the DIA pin low. This pin is known as K Line in the ISO 9141 specification. The DIA pin structure is open collector and requires an external pull–up resistor for use. Having an open collector without an internal pull–up resistor allows several MC33199 to be connected to the K Line while using a single pull–up resistor for the system (see Figure 6). In order to protect the DIA pin against short circuits to V_{bat}, the MC33199 incorporates an internal current limit (see Figure 16) and thermal shutdown circuit. The current limit feature makes it possible for the device to drive a K Line bus having a large parasitic capacitor value (see Special Functionality of I1 pin below).

The path from the DIA pin, or K Line, to the MCU is done through a comparator. The comparator threshold voltage is connected to REF–IN–K pin. It can be tied to the REF–OUT voltage if a V_{bat} dependant threshold is required in the application. The second input of this comparator is connected internally to DIA pin. The output of this comparator is available at the RXD output pin and normally connects to an MCU I/O port. RXD pin has a 2.0 kΩ internal pull–up resistor.

The path from the L Line, used during a wake–up sequence of the transmission, to the MCU is done through a second comparator. The comparator threshold voltage is connected to REF–IN–L pin. The REF–IN–K pin can be tied to the REF–OUT voltage if a V_{bat} dependant threshold is required in the application. The second input of this comparator is internally connected to L pin. The output of this comparator is available on LO output pin, which is also an open collector structure. The LO pin is normally connected to an MCU I/O port.

The DIA and L pins can sustain up to 40 V dc. Care should be taken to protect these pins from reverse battery and transient voltages exceeding 40 V.

The DIA and L pins both have internal pull–down current sources of typically 7.5 µA (see Figure 14). The L Line exhibits a 10 µA pull–down current. The DIA pin has the same behavior when it is in “off” state, that is when TXD is at logic high level.

Special Functionality of I1 Pin

The MC33199 has a unique feature which accommodates transmission baud rates of up to 200 k baud. In practice, the K Line can be several meters long and have a large parasitic capacitance value. Large parasitic capacitance values will slow down the low to high transition of the K Line and limit the baud rate transmission. For the K Line to go from low to high level, the parasitic capacitor must first be charged, and can only be charged through the pull–up resistor. A low pull–up resistor value would result in fast charge time of the capacitor but also large output currents to be supplied causing a high power dissipation in the driver.

To avoid this problem, the MC33199 incorporates a dynamic current source which is temporarily activated at the low to high transition of the TXD pin when the DIA pin or K Line switches from a low to high level (see Figures 3 and 4).

This current source is available at the I1 pin. The I1 pin has a typical current capability of 80 mA. It is activated for 4.0 µs (see Figures 21 and 22) and is automatically disabled after this time. During this time it will charge the K Line parasitic capacitor. This extra current will quickly increase the K Line voltage up to V_{bat}, resulting in a reduced rise time of the K Line. With this feature, the MC33199 ensures baud rate transmission of up to 200 k baud.

During high to low transitions of the K Line, the parasitic capacitor of the line will be discharged by the output transistor of the DIA pin. In this case, the total current may exceed the internal current limitation of the DIA pin. If so, the current limit circuit will activate, limiting the discharge current to typically 60 mA (see Figures 4 and 16).

If a high baud rate is necessary, the I1 pin should be connected to the DIA as shown in the typical application circuit shown in Figure 5. The I1 pin can be left open, if the I1 functionality and high baud rate are not required for the application.

PIN DESCRIPTION

Pin 1: V_{CC}

Power Supply pin; typically 5.0 V and requiring less than 1.5 mA.

Pin 2: REF–IN–L

Input reference for C2 comparator. This input can be connected directly to REF–OUT with or without a resistor network or to an external reference.

Pin 3: REF–IN–K

Input reference for C1 comparator. This input can be connected directly to REF–OUT with or without a resistor network or to an external reference.

Pin 4: LO

Output of C2 comparator and normally connected to a microcontroller I/O. If L input > (REF–IN–L + Hyst/2); output LO is in high state. If L< (REF–IN–L – Hyst/2); output LO is in low state and the output transistor is "on". This pin is an open collector structure and requires a pull–up resistor to be connected to V_{CC}. Output drive capability of this output is 5.0 mA.

Pin 5: RXD

Receive output normally connected to a microcontroller I/O. If DIA input > (REF–IN–L + Hyst/2); output LO is in high state. If DIA < (REF–IN–L – Hyst/2); output LO is in low state and the output transistor is "on". This pin has an internal pull–up resistor (typically 2.0 kΩ) connected to V_{CC}. Drive capability of this output is 5.0 mA.

Pin 6: TXD

Transmission input normally connected to a microcontroller I/O. This pin controls the DIA output. If TXD is high, the output DIA transistor is in the "off" state. If TXD is low, the DIA output transistor is "on".

Pin 9: DIA

Input/Output Diagnosis Bus line pin. This pin is an open collector structure and is protected against overcurrent and circuit shorts to V_{bat} and V_S. Whenever the open collector transistor turns "on" (TXD low), the Bus line is pulled to ground and the DIA pin current is internally limited to nominal value of 60 mA. The internal power transistor incorporates a thermal shutdown circuit which forces the DIA output "off" in the event of an over temperature condition. The DIA pin is also the C1 comparator input. It is protected against both positive and negative overvoltages by an internal 40 V zener diode. This pin exhibits a constant input current of 7.5 μA.

Pin 10: Gnd

Ground reference for the entire device.

Pin 11: I1

Bus source current pin. It is normally tied to DIA pin and to the Bus line. The current source I1 delivers a nominal current of 3.0 mA at static "High" or "Low" levels of TXD. Only during "Low" to "High" transitions, does this current increase to a higher value so as to charge the key line capacitor (Cl < 4.0 nF) in a short time (see Figures 3 and 4).

Pin 12: L

Input for C2 comparator. This pin is protected against both positive and negative overvoltage by a 40 V zener diode. This L Line is a second independent input. It can be used for wake up sequence in ISO diagnosis or as an additional input bus line. This pin exhibits a constant input current of 7.5 μA.

Pin 13: V_S

12 V typical, or V_{bat} supply pin for the device. This pin is protected against overvoltage transients.

Pin 14: REF–OUT

Internal reference voltage generator output pin. Its value depends on V_S (V_{bat}) values. This output can be directly connected to REF–IN–L and REF–IN–K, or through a resistor network. Maximum current capability is 50 μA.

MOTOROLA

MC33293A

Advance Information

Quad Low Side Switch

The MC33293A is a single monolithic integrated circuit designed for quad low side switching applications. This device was initially conceived as a quad injector driver for use in the harsh automotive environment but is well suited for many other applications. The MC33293A incorporates *SMARTMOS*™ technology having CMOS logic, bipolar and CMOS analog circuitry and DMOS power MOSFETs. All of the device inputs are CMOS compatible. The four output devices are N-channel power MOSFETs. A Fault detect output is provided to flag the existence of open loads (outputs ON or OFF) or shorted loads. If a short circuit is detected, the fault detect circuitry turns off the shorted output, but allows the others to function normally. An overvoltage (V_{PWR}) condition will turn off all outputs for the overvoltage duration. Each output functions independently and has a drain-to-gate diode clamp for inductive flyback voltage protection. A Single/Dual select pin is incorporated to allow either individual output control or control of a pair of outputs from one input.

The MC33293A is parametrically specified over $-40°C \le T_A \le 125°C$ ambient temperature and a $9.0\ V \le V_{PWR} \le 14.5\ V$ supply.

- Designed to Operate with Supply Voltages of 5.5 V to 30 V
- CMOS Compatible Inputs with Active Pull-Downs
- Maximum 5.0 mA Quiescent Current
- $R_{DS(on)}$ of 0.25 Ω Maximum at 25°C, with $V_{PWR} \ge 9.0$ V
- Each Output Clamped to 65 V for Driving Inductive Loads
- Each Output Current Limited at 3.0 A to handle Incandescent Lamp Loads
- Active Low Output Fault Status with Interrogation Capability
- Open Load Detection (Output ON or OFF)
- Capable of Withstanding Reverse Battery
- Overvoltage Shutdown
- Short Circuit Detection and Shutdown with Automatic Retry

PIN DESCRIPTION

Pin	Function	Description
1	Output 2	This is one of four open drain power MOSFET output connections. The load is connected from this pin to the positive voltage supply.
2	Output 1	This is one of four open drain power MOSFET output connections. The load is connected from this pin to the positive voltage supply.
3	Input 1	This input controls the turn ON and turn OFF of Output 1 when the $\overline{\text{Single}}$/Dual pin is at a logic low level. It is a CMOS input with an internal active pull-down employed for noise immunity.
4	Input 2	This input controls the turn ON and turn OFF of Output 2 when the $\overline{\text{Single}}$/Dual pin is at a logic low level. It is a CMOS input with an internal active pull-down employed for noise immunity.
5	Input 1 & 2	This input controls the turn ON and turn OFF of Output 1 and Output 2 when the $\overline{\text{Single}}$/Dual select pin is at a logic high level. It is a CMOS input with an internal active pull-down employed for noise immunity.
6	$\overline{\text{Single}}$/Dual Select	This input selects between the single (one input controls one output) mode and the dual (one input controls two outputs) mode of operation.
7	V_{PWR}	The power (voltage and current) to operate the IC is supplied through this pin. The MC33293A is designed to operate over a voltage range of 5.5 V to 30 V.
8	Ground	IC ground reference pin.
9	N/C	No connection.
10	$\overline{\text{Fault}}$	One of three fault conditions, Output-On Open-Load, Output-Off Open-Load or Over-Current are reported at this output. A logic low state signals the existence of a fault condition. This output has an internal active pull-up and does not require an external pull-up resistor.
11	Input 3 & 4	This input controls the turn ON and turn OFF of Output 3 and Output 4 when the $\overline{\text{Single}}$/Dual select pin is at a logic high level. It is a CMOS input with an internal active pull-down employed for noise immunity.
12	Input 4	This input controls the turn ON and turn OFF of Output 4 when the $\overline{\text{Single}}$/Dual pin is at a logic low level. It is a CMOS input with an internal active pull-down employed for noise immunity.
13	Input 3	This input controls the turn ON and turn OFF of Output 3 when the $\overline{\text{Single}}$/Dual pin is at a logic low level. It is a CMOS input with an internal active pull-down employed for noise immunity.
14	Output 3	This is one of four open-drain power MOSFET output connections. The load is connected from this pin to the positive voltage supply.
15	Output 4	This is one of four open-drain power MOSFET output connections. The load is connected from this pin to the positive voltage supply.

CIRCUIT DESCRIPTION

Introduction

The MC33293A is a four output low side switch originally intended for use in automotive applications as a fuel injection driver. This circuit can be used in a variety of applications. It is parametrically specified over a battery voltage range of 9.0 V to 14.5 V, but is designed to operate over a considerably wider range of 5.5 V to 30 V. The design incorporates the use of logic level MOSFETs as output devices which are fully enhanced at a gate voltage of 5.0 V, eliminating the need for internal charge pumps. Each output is identically sized and is *independent* in operation. The efficiency of each output device is such that with as little as 9.0 V of V_{PWR} applied, the $R_{DS(on)}$ is 0.18 Ω typically, at room temperature and increases to only 0.22 Ω as V_{PWR} decreases to 5.5 V.

All inputs of the MC33293A are CMOS and have individual 11 μA internal active pull-downs. This eliminates the need for external pull-down resistors to prevent false switching due to noise on the input control lines. This also ensures that at power-up, no load is turned on before a logic high appears on an input pin. Fault reporting is through the use of an open-drain MOSFET having a 100 μA internal active pull-up.

All inputs incorporate *true logic* (or positive logic). This means that whenever an input is in a logic low state (< 0.8 V) the corresponding output will be in an OFF state. Conversely, whenever an input is in a logic high state (> 3.0 V), the corresponding output will be in an ON state.

$\overline{\text{Single}}$/Dual Select

The $\overline{\text{Single}}$/Dual Select pin can be used to switch between completely independent control and control of the outputs in pairs. Whenever the $\overline{\text{Single}}$/Dual Select pin is in a logic low state, Inputs 1, 2, 3 and 4 control Outputs 1, 2, 3 and 4, respectively. In this mode, only Inputs 1, 2, 3 and 4 can exercise individual control over their respective output. Hence the term “single select” mode of operation. Input 1 & 2 (Pin 5) and Input 3 & 4 (Pin 11) have *no* control whenever the $\overline{\text{Single}}$/Dual Select pin is in a logic low state.

When the Single/Dual Select pin is held at a logic high state, Control Inputs 1, 2, 3 and 4 are turned OFF and can *not* exercise any control over the outputs. In this mode, input control transfers from a single to a dual mode of operation, wherein only Input 1 & 2 and Input 3 & 4 have control of Output 1 plus Output 2, and Output 3 plus Output 4, respectively. Hence the term “Dual Select” mode of operation.

Paralleling Outputs

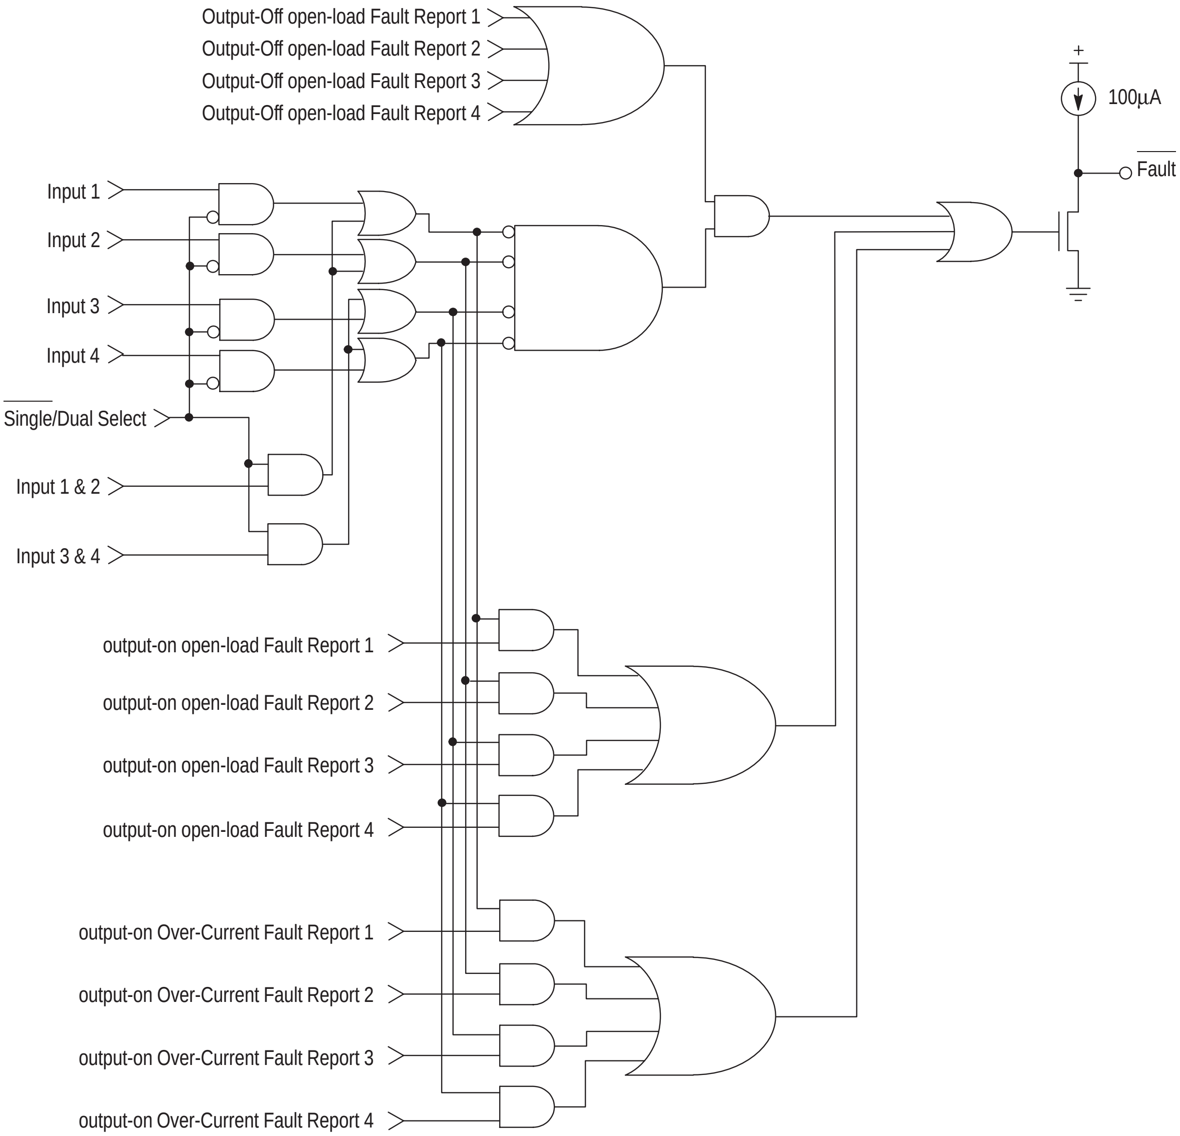
Paralleling outputs may be desirable in the event the application requires a lower $R_{DS(on)}$ or higher current switching capability than a single output. The MC33293A can be operated with all outputs (and therefore all inputs) tied together but modified operation is to be expected. With all inputs tied together and depending on the dual or single select mode used, the paralleled input control current will either be twice (with the dual mode selected) or four times (with the single mode selected) that of any single input. Other expected differences are: $R_{DS(on)}$ will decrease by a factor of four while the Output-On Open-Load Detect current and the Output Limiting current will increase by a factor of four. There will be no change in the Over-Voltage Shutdown Range or the Output-Off Output-On Open-Load Detect Threshold Voltage Range. As always, system level thermal design and verification are important when outputs are paralleled.

FAULT LOGIC OPERATION

General

The Fault Status output (Pin 10) on the MC33293A reports any one of three possible faults from any one of the four outputs. The three possible faults are output-on open-load Fault, output-off open-load Fault and over-current Fault. All faults from any of the four outputs are OR’d together and reported by the single Fault Status output-on Pin 10 (Figure 13).

Figure 13. MC33293A Fault Logic Diagram



Output-On open-load Fault

The MC33293A always checks for an open-load on the outputs whether the outputs are ON or OFF. An output-on open-load Fault is detected if an open-load exists when the output is ON (corresponding input at a logic high state). The output-on open-load Fault detection occurs when the load current is less than the minimum Output-On Open-Load Detect current ($I_{Oon(th)}$), specified in this data sheet. The value of $I_{Oon(th)}$ is, typically, 75 mA at room temperature. See Figure 3.

The minimum load resistance value that the MC33293A will interpret as an output-on open-load ($R_{open(on)}$) is a function of; the Output-On Open-Load Detect current ($I_{Oon(th)}$); the load supply voltage (V_{load}); and the resistance of the output ($R_{DS(on)}$), as shown below.

$$R_{open(on)} = [V_{load} / I_{Oon(th)}] - R_{DS(on)} \approx V_{load} / I_{Oon(th)} \tag{1}$$

Using Equation 1 for the steady state case,

when: $V_{load} = 14\ V$
$R_{DS(on)} = 0.3\ \Omega$
$I_{Oon(th)} = 75\ mA$

an output-on open-load Fault will be detected and reported whenever $R_{load} \geq 187\ \Omega$.

Each output has an output-on open-load fault detect circuit that performs real time load current monitoring. Load current is monitored immediately after any output is turned ON. Since it takes a finite amount of time for load current to begin, the MC33293A detects an output-on open-load Fault from the time the output is turned ON until the load current exceeds the Output-On Open-Load Detect current ($I_{Oon(th)}$). It is important to note that a fault will *not* be reported at the Fault Status output during this short period of time. This is due to the built-in output-on open-load Fault Status Delay Time (t_{oson}), see Figure 3. This delay time is incorporated in the MC33293A to mask the reporting of a false output-on open-load Fault at the Fault Status output. The delay is typically 2.2 ms.

The purpose for the $t_{os(on)}$ delay is to prevent false fault reporting, especially when driving inductive loads. The load inductance causes a current lag when the load is turned ON. The normal current lag of an inductive load could be misinterpreted as an open-load if it weren't for the built-in delay. This delay or masking is accomplished internally with a single timer which resets every time any input switches from a low-to-high logic state. An output-on open-load Fault will be reported by the Fault Status output as a result of turning ON an output having an open-load Fault and the most recent $t_{os(on)}$ is allowed to lapse after switching ON any input.

The time it takes the load current to reach $I_{Oon(th)}$ is a function of the load resistance (R_{load}); load inductance (L_{load}); output on resistance ($R_{DS(on)}$); load supply voltage (V_{load}); and the turn-on time (t_{on}) as shown below. The value of t_{on} is comprised of the low-to-high V_{in} propagation delay time ($t_{on(dly)}$), and the output voltage rise time (t_r). See Figure 2.

$$t_{on(false\ fault)} = -\tau\ \ln [(I_{Oon(th)} - I_{load})/(-I_{load})] + t_{on} \tag{2}$$

where: $\tau = L_{load} / R_{load}$ = time constant (3)

$$I_{load} = V_{load} / [R_{load} + R_{DS(on)}] \tag{4}$$

$$t_{on} = t_{on(dly)} + t_r \tag{5}$$

Using Equation 2 for the transient case,

when: $V_{load} = 14\ V$
$R_{DS(on)} = 0.3\ \Omega$
$L_{load} = 10\ mH$
$R_{load} = 14\ \Omega$
$I_{Oon(th)} = 75\ mA$

an output-on open-load Fault will be detected, but not reported after initial turn ON for a duration of 57 µs + t_{on}.

Output-Off open-load Fault

The MC33293A checks for open-loads on the outputs regardless of an output being on or off. An output-off open-load Fault is detected if an open-load exists when the output is turned OFF (corresponding input at a logic low state). When any one of the four outputs are turned OFF, an independent internal current source tied to each output tries to pull a small amount of zero input voltage drain current ($I_{DS(off)}$, typically 23 µA), through the load. If, while this zero input voltage drain current is being pulled through the load, the output voltage is less than the output-off open-load Detect Threshold Voltage ($V_{Ooff(th)}$, typically 3.7 V), an output-off open-load Fault will be detected.

The zero input voltage drain current could be provided by a large external resistor connected from the output to ground. However, if an external resistor were used to provide this zero input voltage drain current, only "opens" resulting from open-loads or output to ground shorts could be detected. The external resistor could *not* guarantee detection of an open resulting from an output wire bond failure internal to the MC33293A. Because the current source is provided internally, open loads, output to ground shorts, and loss of output wire bonds will all be detected.

The value of load resistance that will be detected as an output-off open-load ($R_{open(off)}$), is a function of the zero input voltage drain current ($I_{DS(off)}$); the load supply voltage (V_{load}); and the output-off open-load Detect Threshold Voltage ($V_{Ooff(th)}$), as shown next by:

$$R_{open(off)} = \frac{[V_{load} - V_{Ooff(th)}]}{I_{DS(off)}} \tag{6}$$

Using Equation 6 for the steady state case,

when: $V_{load} = 14\ V$
$I_{DS(off)} = 23\ \mu A$
$V_{Ooff(th)} = 3.7\ V$

an output-off open-load Fault will be detected and reported whenever $R_L \geq 448\ k\Omega$.

Each output has an output-off open-load fault detect circuit that performs real time output voltage monitoring. Output voltage is monitored immediately after any output is turned off. A finite amount of time is required for output voltage to rise. The MC33293A detects an output-off open-load Fault from when an output is turned off until the output voltage exceeds the output-off open-load Detect Threshold Voltage ($V_{Ooff(th)}$). It is important to note a fault will *not* be reported at the Fault Status output during this rise time. This is due to the built-in output-off open-load Fault Status Delay Time, $t_{os(off)}$, see Figure 4. This delay time is incorporated in the MC33293A to delay the reporting of an output-off open-load Fault at the Fault Status Output. The delay is typically 19 µs.

The purpose for the $t_{os(off)}$ delay is to prevent false fault reporting experienced with capacitance type loads. The load capacitance causes the rise in output voltage to lag even after the load has been turned OFF. The normal voltage lag caused by load capacitance could be misinterpreted as an open-load if it weren't for the built-in delay. This delay, or masking, is accomplished with four separate timers that reset independent of each other when the corresponding input is switched from a high to a low logic state. Internal logic prevents an output-off open-load Fault from being reported at the Fault pin when any input is high. An output-off open-load Fault will be reported at the Fault Status pin after an open load occurs, all inputs not corresponding to the faulted output are low and a time in excess of $t_{os(off)}$ is exceeded after switching OFF the input corresponding to the faulted output.

An important note that bears repeating is that an output-off open-load Fault will not be reported at the Fault Status pin unless all input pins are at a logic low state (Figure 13). This is a Fault Status interrogation feature. It helps in distinguishing between an output-on open-load Fault and an output-on over-current Fault. (Fault Status interrogation is explained in greater detail in a later section).

The time the output voltage takes to reach $V_{Ooff(th)}$ after being turned OFF is $t_{off\ false\ fault}$. It is a function of the load resistance (R_{load}); load inductance (L_{load}); load current (I_{load}); output-on resistance ($R_{DS(on)}$), output capacitance (C_O); load supply voltage (V_{load}); and the turn OFF time (t_{off}). The value of t_{off} is comprised of the V_{in} high-to-low propagation delay time ($t_{off(dly)}$), and the output voltage fall time (t_f).

For the case when:

$$1/2\ L_{load}\ (I_{load})^2 >> 1/2\ C_O\ (V_{Ooff(th)})^2 \qquad (7)$$

$$t_{off\ false\ fault} = [(C_O\ \Delta V)\ /\ I_{load}] + t_{off} \qquad (8)$$

where: $$I_{load} = V_{load}\ /\ [R_{load} + R_{DS(on)}] \qquad (9)$$

$$\Delta V = V_{Ooff(th)} - [I_{load}\ R_{DS(on)}] \qquad (10)$$

$$t_{off} = t_{off(dly)} + t_f \qquad (11)$$

Using Equation 7 for the transient case,

when: $V_{load} = 14$ V
$R_{DS(on)} = 0.3\ \Omega$
$L_{load} = 10$ mH
$R_{load} = 14\ \Omega$
$C_O = 0.001\ \mu F$
$V_{Ooff(th)} = 3.7$ V

an Output-Off open-load Fault will be detected but not reported after initial turn OFF for a duration of 3.5 ns + t_{off}. From Equation 7, the energy stored in the load inductor will be 4.8 mJ. This is much greater than the 68 nJ needed to charge the output capacitance. This allows the use of Equation 8 in determining the false output-off open-load Fault duration following turn OFF because it assures that the output capacitance will be charged by the energy stored in the load inductance.

Over-Current Fault

An over-current (short circuit or current limit) Fault is the detection and reporting of any output over-current condition. An over-current condition is defined as a condition where load current exceeds the internal current limit value (typically 4.0 A). An over-current condition activates the current limit circuit. This circuit then sends an analog signal to the gate control circuit, lowering the voltage on the output transistor's gate. Lowering the gate voltage forces the output transistor to transition from the resistive (fully enhanced) mode of operation to the current limit (between fully enhanced and fully OFF) mode.

The actual detection of an over-current condition does not occur at the initial onset of current limit. The onset of current limit causes the voltage on the affected output to increase. The actual Over-Current detection occurs when the output voltage increases and exceeds the over-current Detect Voltage Threshold ($V_{OC(limit)}$, typically 3.7 V), while the corresponding input signal is in a logic high state.

After detection, the reporting of an over-current Fault at the Fault Status output is delayed by a time equal to the over-current Sense Time (t_{oc}), see Figures 5 and 6. This delay time is typically 55 µs. If the over-current condition no longer exists after the over-current Sense Time has passed, then no fault is reported. The purpose of the Fault reporting delay is to blank any false faults that might be reported due to high inrush current loads such as incandescent lamps. If the over-current condition still exists after the delay time has passed, then a fault will be reported at the Fault Status output and the affected output is turned OFF.

The Over-Current Sense Time is accomplished internally with four separate timers that reset and start independent of each other whenever a corresponding output is turned ON, either due to the corresponding input turning ON or the completion of the over-current Refresh Time (t_{ref}) explained in the next paragraph, (see Figures 5 and 6). An over-current Fault will be reported at the Fault Status output when an over-current condition is detected and a lapse time in excess of t_{oc} is exceeded after turning ON the affected output.

At the same time the over-current Fault is reported, a single internal over-current refresh timer resets, causing *any* over-current outputs to be turned OFF for a duration of t_{ref}, typically 3.6 ms. After a time t_{ref}, the faulted output(s) will be turned ON again to check if the over-current condition still exists. If the over-current condition still exists, the output(s) will be turned OFF again after a time t_{oc}. This periodic retry continues turning ON and OFF over-current loads at a duty cycle of $t_{oc}\ /(t_{oc} + t_{ref})$ with a period of $t_{oc} + t_{ref}$ until either the input is turned OFF or the over-current condition is removed. Any subsequent over-current conditions will reset and restart the t_{ref} timer.

Detection of an over-current condition coincides with, but does not occur until after the onset of current limit. This allows a specific but small current limit range to go undetected. The factors that determine the value of load resistance causing an over-current condition to be detected are: the Output-Load Current Limit [$I_{DS(limit)}$]; load voltage (V_{load}); and the Over-Current Detect Threshold Voltage [$V_{OC(limit)}$] as shown below:

$$R_{load(detect)} = \frac{[V_{load} - V_{OC(limit)}]}{I_{DS(limit)}} \qquad (12)$$

The factors that determine the value of load resistance that will cause the onset of current limit are: $I_{DS(limit)}$, V_{load}, and $R_{DS(on)}$, as shown below.

$$R_{load(limit)} = [V_{load} / I_{DS(limit)}] – R_{DS(on)} \quad (13)$$

For the case when: $V_{load} = 14\ V$
$V_{OC(limit)} = 3.7\ V$
$R_{DS(on)} = 0.3\ \Omega$
$I_{DS(limit)} = 4.0\ A$

an over-current condition will be detected for any load resistance such that $R_{load} \le 2.6\ \Omega$. An undetected current limit condition will occur any time $2.6\ \Omega \le R_{load} \le 3.2\ \Omega$. Notice that the undetected current limit range is quite small.

Fault Interrogation

Even though the MC33293A incorporates a single Fault Status Output pin for reporting three different fault conditions, a real time interrogation routine can be used to determine which one of the three Fault conditions is being reported and which single output is affected.

An important point to note about Fault interrogation is that only one fault on a single output can be interpreted. In other woRDS, if more than one over-current or open-load Fault exists among the four outputs, it is *not* possible to distinguish which outputs have a fault and which do not. It is very unlikely, however, that more than one output will be faulted at the same time.

When a Fault is reported, the first step is to determine if it is an over-current or open-load Fault ($R_{load} \ge 447\ k\Omega$, typical). This is done by taking all the inputs (single or dual) to a logic low state. If the Fault Status resets (changes to a logic high state) after the Fault Status Reset Delay Time ($t_{s(reset)}$, see Figure 4) has lapsed, then an over-current Fault is being reported. If the Fault Status does not reset (remains at a logic low state) after $t_{s(reset)}$ has lapsed, then an open-load Fault ($R_{load} \ge 447\ k\Omega$, typical) is being reported. This type of interrogation is possible because an output-off open-load Fault can only be reported when all the inputs are in a logic low state.

For an over-current Fault, the next step is to determine which single output is affected. After all inputs are turned OFF and the fault status resets, each input is then turned ON then OFF sequentially. A Fault will again be reported when the input to the corresponding Over-Current output is turned ON and $t_{os(on)}$ has lapsed. If the dual input mode is being used, an over-current Fault can only be interrogated down to the two outputs being driven together.

For an open-load Fault ($R_{load} \ge 447\ k\Omega$, typical) interrogation, all inputs are turned OFF and the fault status remains set. Each input is then turned ON and OFF sequentially. The Fault status will remain set when the input to the corresponding faulted output is turned ON and $t_{os(on)}$ has lapsed. If the dual input mode is used, an open-load Fault can only be interrogated down to the two outputs driven together.

From the example following Equation 1, the typical value of $R_{open(on)}$ is 187 Ω. From the example following Equation 6, the typical value of $R_{open(off)}$ is 447 kΩ. Therefore, if the load resistance is between 187 Ω and 447 kΩ typically, an output-on open-load Fault will be reported at the Fault Status output but an output-off open-load Fault will not. This condition is referred to as a *soft open fault*. If a soft open fault exists, it is reported at the Fault Status output the same as an over-current Fault except for the reporting delay time. A soft open fault has a reporting delay time of 2.2 ms typically, and an over-current Fault has a reporting delay time of only 55 µs typically, after the input to the faulted output is turned ON.

***NOTE:** All inputs must be a logic low state for an Output-Off open-load Fault to be reported.

MC33298

Octal Serial Switch with Serial Peripheral Interface I/O

OCTAL SERIAL SWITCH (SPI Input/Output)

SEMICONDUCTOR TECHNICAL DATA

The MC33298 is an eight output low side power switch with 8 bit serial input control. The MC33298 is a versatile circuit designed for automotive applications, but is well suited for other environments. The MC33298 incorporates SMARTMOS™ technology, with CMOS logic, bipolar/MOS analog circuitry, and DMOS power MOSFETs. The MC33298 interfaces directly with a microcontroller to control various inductive or incandescent loads. The circuit's innovative monitoring and protection features are: very low standby current, cascadable fault reporting, internal 65 V clamp on each output, output specific diagnostics, and independent shutdown of outputs. The MC33298 is parametrically specified over a temperature range of $-40°C \le T_A \le +125°C$ ambient temperature and $9.0\ V \le V_{PWR} \le 16\ V$ supply. The economical 20 pin DIP and SO–24 wide body surface mount plastic packages make the MC33298 very cost effective.

- Designed to Operate Over Wide Supply Voltages of 5.5 V to 26.5 V
- Interfaces Directly to Microprocessor Using SPI Protocol
- SPI Communication for Control and Fault Reporting
- 8–Bit Serial I/O is CMOS Compatible
- 3.0 A Peak Current Outputs with Maximum $R_{DS(on)}$ of 0.45 Ω at 25°C
- Outputs are Current Limited to 3.0 A to 6.0 A for Driving Incandescent Lamp Loads
- Output Voltages Clamped to 65 V During Inductive Switching
- Maximum Sleep Current (I_{PWR}) of 50 µA with $V_{DD} \le 2.0$ V
- Maximum of 4.0 mA I_{DD} During Operation
- Maximum of 2.0 mA I_{PWR} During Operation with All Outputs "On"
- Open Load Detection (Outputs "Off")
- Overvoltage Detection and Shutdown
- Each Output has Independent Over Temperature Detection and Shutdown
- Output Mode Programmable for Sustained Current Limit or Shutdown
- Short Circuit Detect and Shutdown with Automatic Retry for Every Write Cycle
- Serial Operation Guaranteed to 2.0 MHz

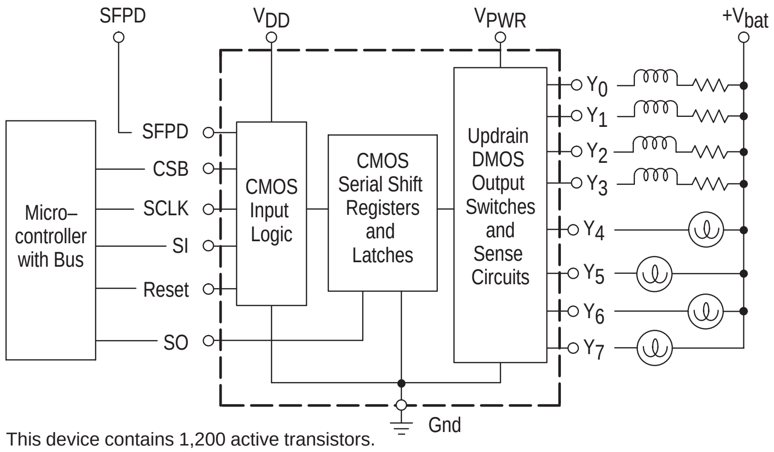
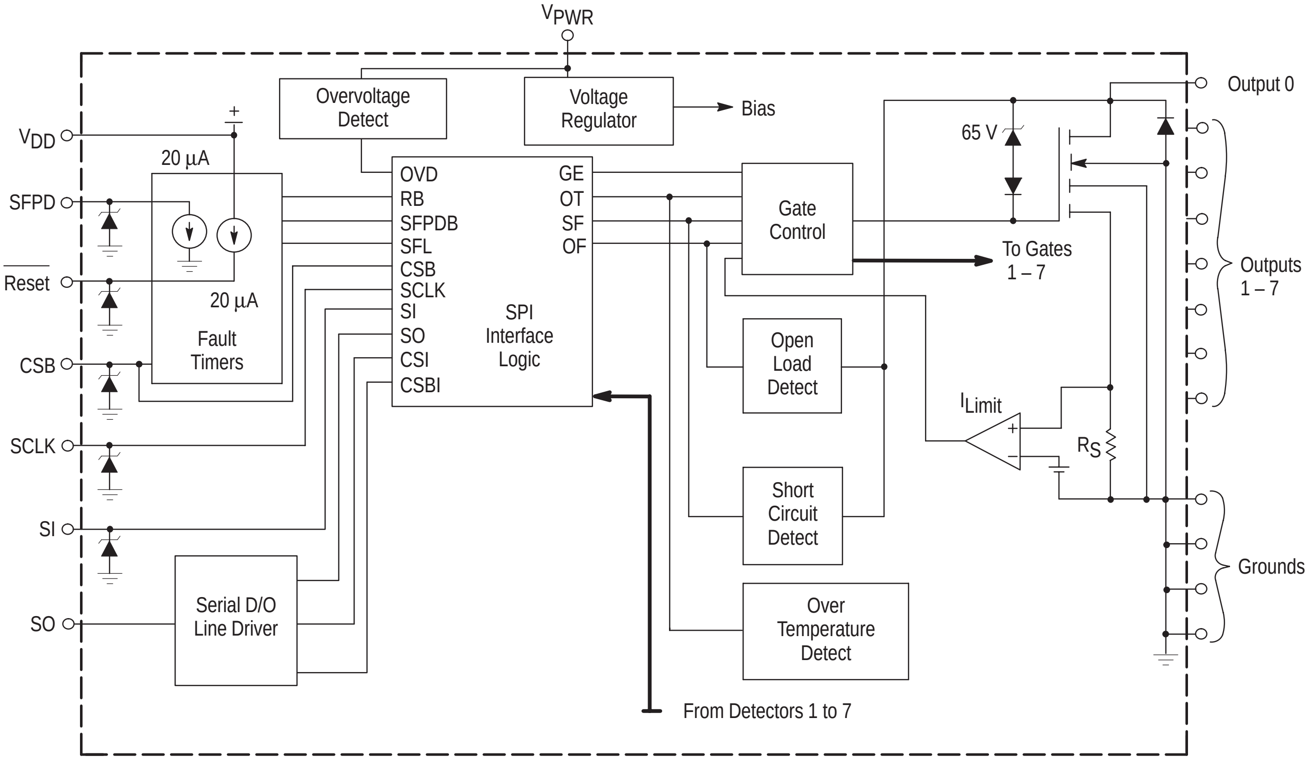
MC33298DW		SOP–24L

Simplified Application



This device contains 1,200 active transistors.

Figure 1. Simplified Block Diagram



FAULT OPERATION

SERIAL OUTPUT (SO) PIN REPORTS

Overvoltage	Overvoltage condition reported.
Over Temperature	Fault reported by Serial Output (SO) pin.
Over Current	SO pin reports short to battery/supply or over current condition.
Output “On,” Open Load Fault	Not reported.
Output “Off,” Open Load Fault	SO pin reports output “off” open load condition.

DEVICE SHUTDOWNS

Overvoltage	Total device shutdown at V_{PWR} = 28–36 V. Re–operates when overvoltage is removed with all outputs assuming an off state upon recovery from overvoltage. All device registers are automatically reset (cleared) during shutdown.
Over Temperature	Only the output experiencing an over temperature shuts down.
Over Current	Only the output experiencing an over current condition shuts down at 3.0 A to 6.0 A after a 25 µs to 100 µs delay, with SFPD pin grounded. All outputs will continue to operate in a current limit mode, with no shutdown, if the SPFD pin is at 5.0 V.

MAXIMUM RATINGS (All voltages are with respect to ground, unless otherwise noted.)

Rating	Symbol	Value	Unit
Power Supply Voltage			
Steady–State	$V_{PWR(sus)}$	–1.5 to 26.5	V
Transient Conditions (Note1)	$V_{PWR(pk)}$	–13 to 60	V
Logic Supply Voltage (Note 2)	V_{DD}	– 0.3 to 7.0	V
Input Pin Voltage (Note 3)	V_{IN}	– 0.3 to 7.0	V
Output Clamp Voltage (Note 4)	$V_{OUT(off)}$		V
(2.0 mA ≤ I_{out} ≤ 0.5 A)		50 to 75	
Output Self–Limit Current	$I_{OUT(lim)}$	3.0 to 6.0	A
Continuous Per Output Current (Note 5)	$I_{OUT(cont)}$	1.0	A
ESD Voltage			
Human Body Model (Note 6)	V_{ESD1}	2000	V
Machine Model (Note 7)	V_{ESD2}	200	V
Output Clamp Energy (Note 8)	E_{clamp}		
Repetitive:			
T_J = 25°C		100	mJ
T_J = 125°C		30	mJ
Non–Repetitive:			
T_J = 25°C		2.0	J
T_J = 125°C		0.5	J
Recommended Frequency of SPI Operation (Note 9)	f_{SPI}	2.0	MHz
Storage Temperature	T_{stg}	– 55 to +150	°C
Operating Case Temperature	T_C	– 40 to +125	°C
Operating Junction Temperature	T_J	– 40 to +150	°C
Power Dissipation (T_A = 25°C) (Note 10)	P_D	3.0	W
Soldering Temperature (for 10 seconds)	T_{solder}	260	°C

SOP–24 Package, Case 751E:			
All Outputs “On” (Note 12)		34	
Single Output (Note 13)		40	

NOTES:
1. Transient capability with external 100 Ω resistor connected in series with V_{PWR} pin and supply.
2. Exceeding these limits may cause a malfunction or permanent damage to the device.
3. Exceeding voltage limits on SCLK, SI, CSB, SFPD, or Reset pins may cause permanent damage to the device.
4. With output “off.”
5. Continuous output rating so long as maximum junction temperature is not exceeded. (See Figure 21 and 22 for more details).
6. ESD1 testing is performed in accordance with the Human Body Model (C_{Zap} = 100 pF, R_{Zap} = 1500 Ω).
7. ESD2 testing is performed in accordance with the Machine Model (C_{Zap} = 100 pF, R_{Zap} = 0 Ω).
8. Maximum output clamp energy capability at indicated Junction Temperature using single pulse method. See Figure 19 for more details.
9. Guaranteed and production tested for 2.0 MHz SPI operation but has been demonstrated to operate to 8.5 MHz @ 25°C.
10. Maximum power dissipation at indicated junction temperature with no heat sink used. See Figures 20, 21, and 22 for more details.
11. See Figure 20 for Thermal Model.
12. Thermal resistance from Junction–to–Ambient with all outputs “on” and dissipating equal power.
13. Thermal resistance from Junction–to–Ambient with a single output “on.”

STATIC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions of 4.5 V ≤ V_{DD} ≤ 5.5 V, 9.0 V ≤V_{PWR} ≤ 16 V, – 40°C ≤ T_C ≤ 125°C, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
POWER INPUT					
Supply Voltage Range Quasi–Functional (Note 1) Full Operational	 $V_{PWR(qf)}$ $V_{PWR(fo)}$	 5.5 9.0	 – –	 9.0 26.5	V
Supply Current (all Outputs “On,” I_{out} = 0.5 A) (Note 2)	$I_{PWR(on)}$	–	1.0	2.0	mA
Sleep State Supply Current (V_{DD} = 0.5 V)	$I_{PWR(ss)}$	–	1.0	50	µA
Sleep State Output Leakage Current (per Output, V_{DD} = 0.5 V)	$I_{OUT(ss)}$	–	–	50	µA
Overvoltage Shutdown	V_{OV}	28	–	36	V

Over Temperature Shutdown (Outputs “Off”) (Note 7)	T_{LIM}	155	170	185	°C
Over Temperature Shutdown Hysteresis (Note 7)	$T_{LIM(hys)}$	–	10	20	°C

NOTES:
1. SPI inputs and outputs operational; Fault reporting may not be fully operational within this voltage range.
2. Value reflects normal operation (no faults) with all outputs “on.” Each “on” output contributes approximately 20 µA to I_{PWR}. Each output experiencing a “soft short” condition contributes approximately 0.5 mA to I_{PWR}. A “soft short” is defined as any load current causing the output source current to self–limit. A “hard” output short is a very low impedance short to supply.
3. For V_{DD} less than the Undervoltage Lockout Threshold voltage, all data registers are reset and all outputs are disabled.
4. Output fault detect threshold with outputs programmed “off.” Output fault detect thresholds are the same for output opens and shorts.
5. Output “Off” Open Load Detect Current is the current required to flow through the load for the purpose of detecting the existence of an open condition when the specific output is commanded to be “off.”
6. Output leakage current measured with output “off” and at 16 V.
7. This parameter is guaranteed by design but is not production tested.

STATIC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions of 4.5 V ≤ V_{DD} ≤ 5.5 V, 9.0 V ≤ V_{PWR} ≤ 16 V, – 40°C ≤ T_C ≤ 125°C, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
DIGITAL INTERFACE					
Input Logic High Voltage (Note 1)	V_{IH}	0.7	–	1.0	V_{DD}
Input Logic Low Voltage (Note 2)	V_{IL}	0.0	–	0.2	V_{DD}
Input Logic Voltage Hysteresis (Note 3)	$V_{I(hys)}$	50	100	500	mV
Input Logic Current (Note 4)	I_{IN}	–10	0	10	µA
Reset Pull–Up Current (Reset = 0.7 V_{DD})	I_{RSTB}	10	22	50	µA
SFPD Pull–Down Current (SFPD = 0.2 V_{DD})	I_{SFPD}	10	22	50	µA
SO High State Output Voltage (I_{OH} = 1.0 mA)	V_{SOH}	V_{DD} –1.0 V	V_{DD} – 0.6 V	–	V

NOTES:
1. Output Rise and Fall time respectively measured across a 26 Ω resistive load at 10% to 90% and 90% to 10% voltage points.
2. Output Turn “On” Delay time measured from rising edge of CSB to 50% of output “off” V_{out} voltage with R_L = 26 Ω resistive load (see Figure 7 and 9).
3. Output Turn “Off” Delay time measured from rising edge of CSB to 50% of output “off” V_{out} voltage with R_L = 26 Ω resistive load (see Figure 7 and 9).
4. Output Short Fault Disable Report Delay measured from rising edge of CSB to I_{out} = 2.0 A point with output “on,” V_{out} = 5.0 V, and SFPD = 0.2 x V_{DD} (see Figure 8 and 10).
5. Output “Off” Fault Report Delay measured from 50% points of rising edge of CSB to rising edge of output (see Figure 9).

DYNAMIC ELECTRICAL CHARACTERISTICS (Characteristics noted under conditions of 4.5 V ≤ V_{DD} ≤ 5.5 V, 9.0 V ≤ V_{PWR} ≤ 16 V, – 40°C ≤ T_C ≤ 125°C, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
DIGITAL INTERFACE TIMING					
SCLK Clock Period (Note 6)	t_{pSCLK}	500	–	–	ns
SCLK Clock High Time	t_{wSCLKH}	175	–	–	ns
SCLK Clock Low Time	t_{wSCLKL}	175	–	–	ns
Required Low State Duration for Reset (V_{IL} ≤ 0.2 V_{DD}) (Note 1)	t_{wRSTB}	250	50	–	ns
Falling Edge of CSB to Rising Edge of SCLK (Required Setup Time)	t_{lead}	250	50	–	ns
Falling Edge of SCLK to Rising Edge of CSB (Required Setup Time)	t_{lag}	250	50	–	ns
SI to Falling Edge of SCLK (Required Setup Time)	t_{SISU}	125	25	–	ns
Falling Edge of SCLK to SI (Required Hold Time)	$t_{SI(hold)}$	125	25	–	ns
SO Rise Time (C_L = 200 pF)	t_{rSO}	–	25	75	ns
SO Fall Time (C_L = 200 pF)	t_{fSO}	–	25	75	ns
SI, CSB, SCLK Incoming Signal Rise Time (Note 2)	t_{rSI}	–	–	200	ns
SI, CSB, SCLK Incoming Signal Fall TIme (Note 2)	t_{fSI}	–	–	200	ns
Time from Falling Edge of CSB to SO					ns
Low Impedance (Note 3)	$t_{SO(en)}$	–	–	200	
HIgh Impedance (Note 4)	$t_{SO(dis)}$	–	–	200	
Time from Rising Edge of SCLK to SO Data Valid (Note 5) 0.2 V_{DD} ≤ SO ≥ 0.8 V_{DD}, C_L = 200 pF	t_{valid}	–	50	125	ns

NOTES:
1. Reset Low duration measured with outputs enabled and going to “off” or disabled condition.
2. Rise and Fall time of incoming SI, CSB, and SCLK signals suggested for design consideration to prevent the occurrence of double pulsing.
3. Time required for output status data to be available for use at SO.
4. Time required for output status data to be terminated at SO.
5. Time required to obtain valid data out from SO following the rise of SCLK.
6. Clock period includes 75 ns rise plus 75 ns fall transition time in addition to clock high and low time.

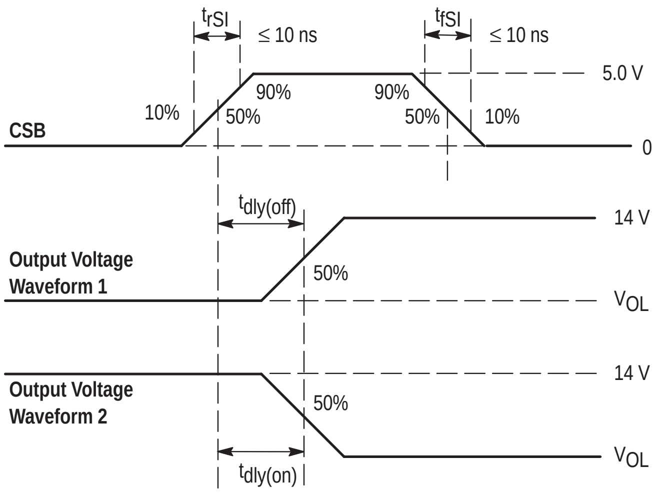
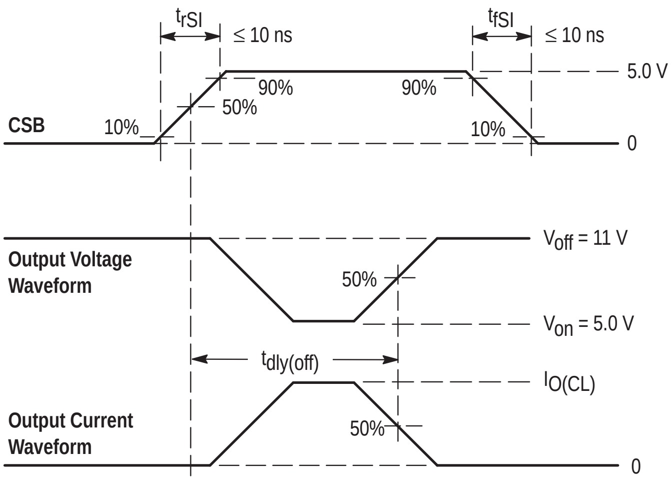
Figure 9. Turn–On/Off Waveforms



NOTES: 1. $t_{dly(on)}$ and $t_{dly(off)}$ are turn–on and turn–off propagation delay times.
2. Waveform 1 is an output programmed from an “on” to an “off” state.
3. Waveform 2 is an output programmed from an “off” to an “on” state.

Figure 10. Output Fault Unlatch Disable Delay Waveforms



NOTES: 1. $t_{pdly(off)}$ is the output fault unlatch disable propagation delay time required to correctly report an output fault after CSB rises. Represents an output commanded “on” while having an existing output short (overcurrent) to supply.
2. SFPD pin ≤ 0.2 V.

CIRCUIT DESCRIPTION

Introduction

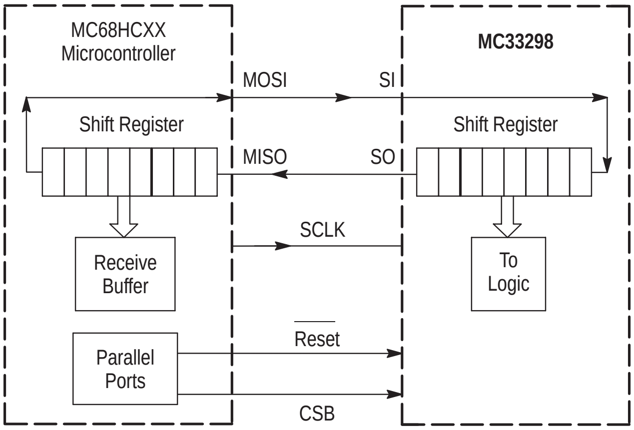
The MC33298 was conceived, specified, designed, and developed for automotive applications. It is an eight output low side power switch having 8–bit serial control. The MC33298 incorporates SMARTMOS™ technology having effective 2.0 µ CMOS logic, bipolar/MOS analog circuitry, and independent state of the art double diffused MOS (DMOS) power output transistors. Many benefits are realized as a direct result of using this mixed technology. A simplified block diagram of the MC33298 is shown in Figure 1.

Where bipolar devices require considerable control current for their operation, structured MOS devices, since they are voltage controlled, require only transient gate charging current affording a significant decrease in power consumption. The CMOS capability of the SMARTMOS™ process allows significant amounts of logic to be economically incorporated into the monolithic design. In addition, bipolar/MOS analog circuits embedded within the updrain power DMOS output transistors monitor and provide fast, independent protection control functions for each individual output. All outputs have internal 65 V at 0.5 A independent output voltage clamps to provide fast inductive turn–off and transient protection.

The MC33298 uses high efficiency updrain power DMOS output transistors exhibiting very low drain to source “on” resistance values ($R_{DS(on)} \leq 0.45\ \Omega$) and dense CMOS control logic. Operational bias currents of less than 4.0 mA (1.0 mA typical) with any combination of outputs “on” are the result of using this mixed technology and would not be possible with bipolar structures. To accomplish a comparable functional feature set using a bipolar structure approach would result in a device requiring hundreds of milliamperes of internal bias and control current. This would represent a very large amount of power to be consumed by the device itself and not available for load use.

In operation the MC33298 functions as an eight output serial switch serving as a microcontroller (MCU) bus expander and buffer with fault management and fault reporting features. In doing so, the device directly relieves the MCU of the fault management functions. The MC33298 directly interfaces to an MCU and operates at system clock serial frequencies in excess of 2.0 MHz using a Synchronous Peripheral Interface (SPI) for control and diagnostic readout. Figure 11 shows the basic SPI configuration between an MCU and one MC33298.

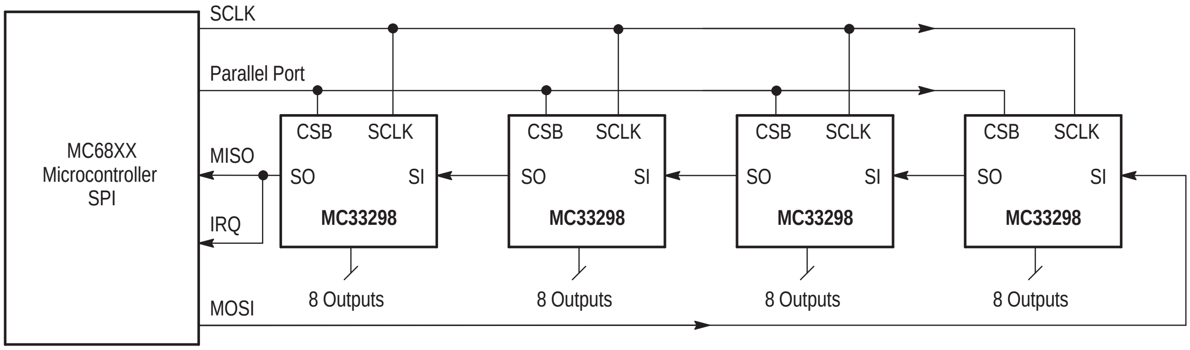
Figure 11. SPI Interface with Microcontroller



The circuit can also be used in a variety of other applications in the computer, telecommunications, and industrial fields. It is parametrically specified over an input “battery”/supply range of 9.0 V to 16 V but is designed to operate over a considerably wider range of 5.5 V to 26.5 V. The design incorporates the use of Logic Level MOSFETs as output devices. These MOSFETs are sufficiently turned “on” with a gate voltage of less than 5.0 V thus eliminating the need for an internal charge pump. Each output is identically sized and independent in operation. The efficiency of each output transistor is such that with as little as 9.0 V supply (V_{PWR}), the maximum $R_{DS(on)}$ of an output at room temperature is 0.45 Ω (0.35 Ω typical) and increases to only 1.0 Ω (0.5 Ω typical) as V_{PWR} is decreased to 5.5 V.

All inputs are compatible with 5.0 V CMOS logic levels and incorporate negative or inverted logic. Whenever an input is programmed to a logic low state (< 1.0 V) the corresponding low side switched output being controlled will be active low and turned “on.” Conversely, whenever an input is programmed to a logic high state (> 3.0 V), the output being controlled will be high and turned “off.”

Figure 12. MC33298 SPI System Daisy Chain



One main advantage of the MC33298 is the serial port which when coupled to an MCU, receives “on”/“off” commands from the MCU and in return transmits the drain status of the device’s output switches. Many devices can be “daisy–chained” together to form a larger system (see Figure 12). Note in this example that only one dedicated MCU parallel port (aside from the required SPI) is needed for chip select to control 32 possible loads.

Multiple MC33298 devices can also be controlled in a parallel input fashion using SPI (see Figure 13). This figure shows a possible 24 loads being controlled by only three dedicated parallel MCU ports used for chip select.

Figure 13. Parallel Input SPI Control

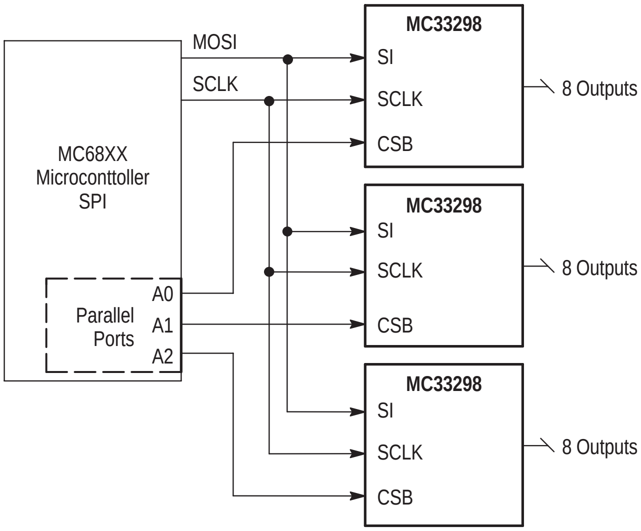


Figure 14 shows a basic method of controlling multiple MC33298 devices using two MCUs. A system can have only one master MCU at any given instant of time and one or more slave MCUs. The master MCU supplies the system clock signal (top MCU designated the master); the lower MCU being the slave. It is possible to have a system with more than one master but not at the same time. Only when the master is not communicating can a slave communicate. MCU master control is switched through the use of the slave select (SS) pin of the MCUs. A master will become a slave when it detects a logic low state on its SS pin.

These basic examples make the MC33298 very attractive for applications where a large number of loads need be controlled efficiently. The popular Synchronous Serial Peripheral Interface (SPI) protocol is incorporated, to this end, to communicate efficiently with the MCU.

SPI System Attributes

The SPI system is flexible enough to communicate directly with numerous standard peripherals and MCUs available from Motorola and other semiconductor manufacturers. SPI reduces the number of pins necessary for input/output (I/O) on the MC33298. It also offers an easy means of expanding the I/O function using few MCU pins. The SPI system of communication consists of the MCU transmitting, and in return, receiving one databit of information per clock cycle.

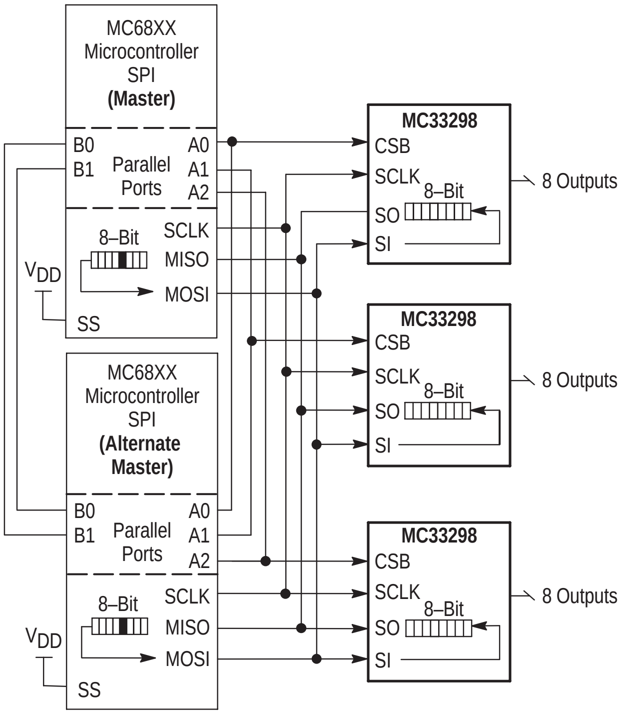
Databits of information are simultaneously transmitted by one pin, Microcontroller Out Serial In (MOSI), and received by another pin, Microcontroller In Serial Out (MISO), of the MCU.

Some features of SPI are:

- Full Duplex, Three–Wire Synchronous Data Transfer
- Each Microcontroller can be a Master or a Slave
- Provides Write Collision Flag Protection
- Provides End of Message Interrupt Flag
- Four I/Os associated with SPI (MOSI, MISO, SCLK, SS)

The only drawbacks to SPI are that an MCU is required for efficient operational control and, in contrast to parallel input control, is slower at performing pulse width modulating (PWM) functions.

Figure 14. Multiple MCU SPI Control



PIN FUNCTION DESCRIPTION

CSB Pin

The system MCU selects the MC33298 to be communicated with through the use of the CSB pin. Whenever the pin is in a logic low state, data can be transferred from the MCU to the MC33298 and vise versa. Clocked–in data from the MCU is transferred from the MC33298 shift register and latched into the power outputs on the rising edge of the CSB signal. On the falling edge of the CSB signal, drain status information is transferred from the power outputs and loaded into the device's shift register. The CSB pin also controls the output driver of the serial output pin. Whenever the CSB pin goes to a logic low state, the SO pin output driver is enabled allowing information to be transferred from the MC33298 to the MCU. To avoid any spurious data, it is essential that the high–to–low transition of the CSB signal occur only when SCLK is in a logic low state.

SCLK Pin

The system clock pin (SCLK) clocks the internal shift registers of the MC33298. The serial input pin (SI) accepts data into the input shift register on the falling edge of the SCLK signal while the serial output pin (SO) shifts data information out of the shift register on the rising edge of the SCLK signal. False clocking of the shift register must be avoided to guarantee validity of data. It is essential that the SCLK pin be in a logic low state whenever chip select bar pin (CSB) makes any transition. For this reason, it is recommended though not necessary, that the SCLK pin be kept in a low logic state as long as the device is not accessed (CSB in logic high state). When CSB is in a logic high state, any signal at the SCLK and SI pin is ignored and SO is tristated (high impedance). See the Data Transfer Timing diagram of Figure 16.

SI Pin

This pin is for the input of serial instruction data. SI information is read in on the falling edge of SCLK. A logic high state present on this pin when the SCLK signal rises will program a specific output "off," and in turn, turns "off" the specific output on the rising edge of the CSB signal. Conversely, a logic low state present on the SI pin will program the output "on," and in turn, turns "on" the specific output on the rising edge of the CSB signal. To program the eight outputs of the MC33298 "on" or "off," an eight bit serial stream of data is required to be entered into the SI pin starting with Output 7, followed by Output 6, Output 5, etc., to Output 0. For each rise of the SCLK signal, with CSB held in a logic low state, a databit instruction ("on" or "off") is loaded into the shift register per the databit SI state. The shift register is full after eight bits of information have been entered. To preserve data integrity, care should be taken to not transition SI as SCLK transitions from a low to high logic state.

SO Pin

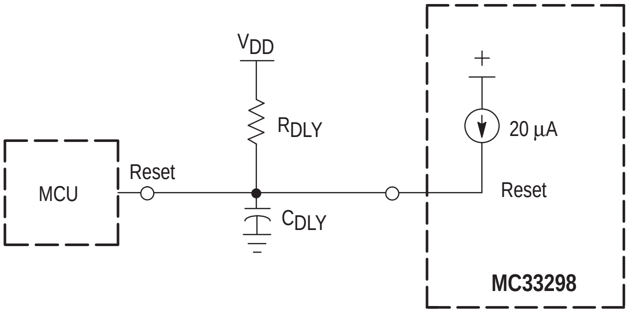
The serial output (SO) pin is the tri–stateable output from the shift register. The SO pin remains in a high impedance state until the CSB pin goes to a logic low state. The SO data reports the drain status, either high or low. The SO pin changes state on the rising edge of SCLK and reads out on the falling edge of SCLK. When an output is "off" and not faulted, the corresponding SO databit is a high state. When an output is "on," and there is no fault, the corresponding databit on the SO pin will be a low logic state. The SI/SO shifting of data follows a first–in–first–out protocol with both input and output words transferring the Most Significant Bit (MSB) first. The SO pin is not affected by the status of the Reset pin.

Reset Pin

The MC33298 Reset pin is active low and used to clear the SPI shift register and in doing so sets all output switches "off." With the device in a system with an MCU; upon initial system power up, the MCU holds the Reset pin of the device in a logic low state ensuring all outputs to be "off" until both the V_{DD} and V_{PWR} pin voltages are adequate for predictable operation. After the MC33298 is reset, the MCU is ready to assert system control with all output switches initially "off." If the V_{PWR} pin of the MC33298 experiences a low voltage, following normal operation, the MCU should pull the Reset pin low so as to shutdown the outputs and clear the input data register. The Reset pin is active low and has an internal pull–up incorporated to ensure operational predictability should the external pull–up of the MCU open circuit. The internal pull–up is only 20 µA to afford safe and easy interfacing to the MCU. The Reset pin of the MC33298 should be pulled to a logic low state for a duration of at least 250 ns to ensure reliable reset.

A simple power "on" reset delay of the system can be programmed through the use of an RC network comprised of a shunt capacitor from the Reset pin to Ground and a resistor to V_{DD} (See Figure 15). Care should be exercised to ensure proper discharge of the capacitor so as to not adversely delay the reset nor damage the MCU should the MCU pull the Reset line low and yet accomplish initialization for turn "on" delay. It may be easier to incorporate delay into the software program and use a parallel port pin of the MCU to control the MC33298 Reset pin.

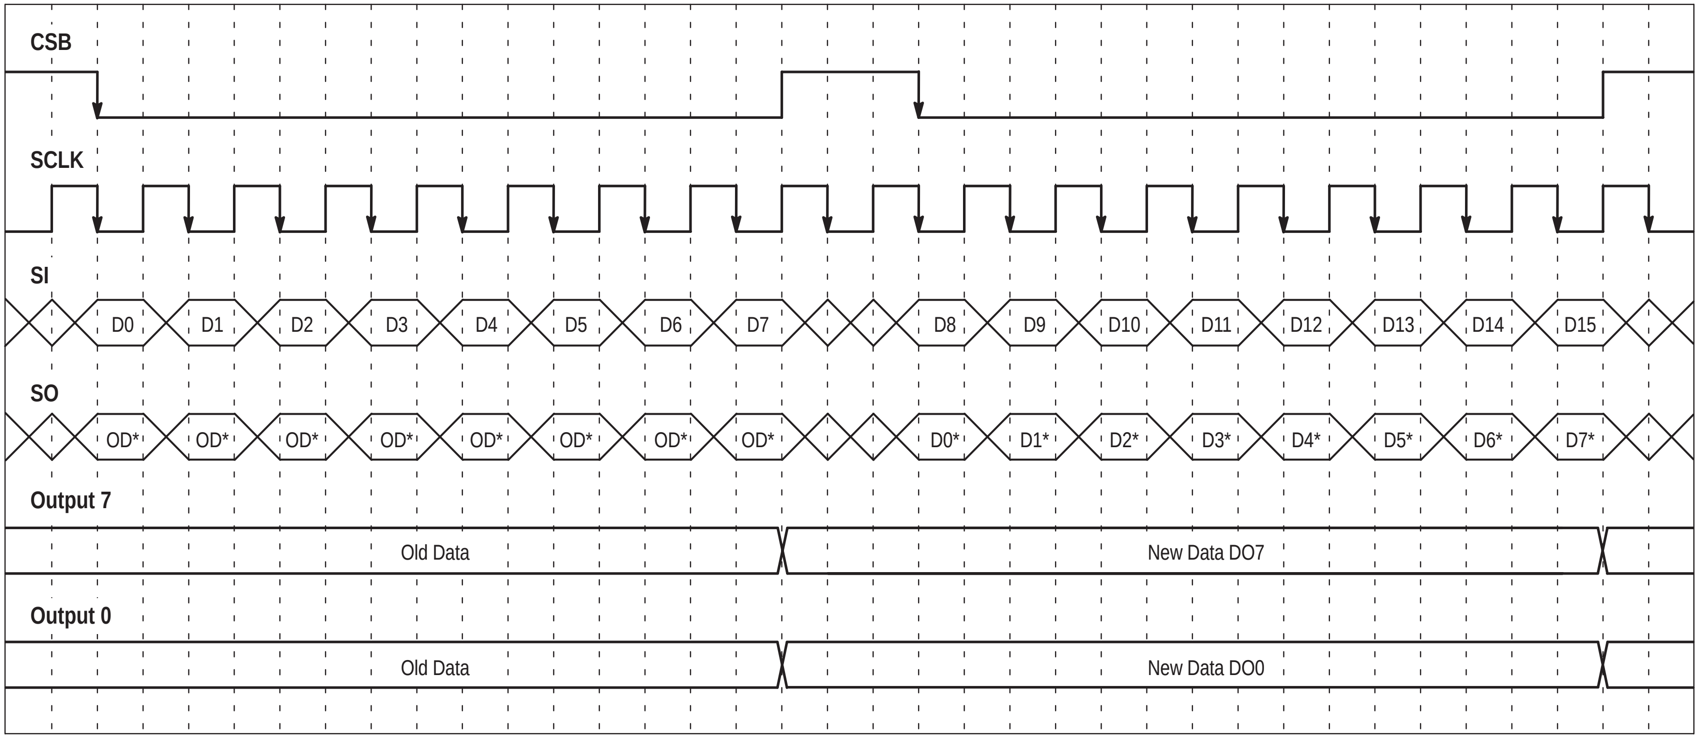
Figure 15. Power "On" Reset



SFPD Pin

The Short Fault Protect Disable (SFPD) pin is used to disable the over current latch–off. This feature allows control of incandescent loads where in–rush currents exceed the device's analog current limits. Essentially the SFPD pin determines whether the MC33298 output(s) will instantly shut down upon sensing an output short or remain "on" in a current limiting mode of operation until the output short is removed or thermal shutdown is reached. If the SFPD pin is tied to V_{DD} = 5.0 V the MC33298 output(s) will remain "on" in a current limited mode of operation upon encountering a load short to supply. If the SFPD pin is grounded, a short circuit will immediately shut down only the output affected. Other outputs not having a fault condition will operate normally. The short circuit operation is addressed in more detail later.

Figure 16. Data Transfer Timing



NOTES: 1. Reset pin is in a logic high state during the above operation.
2. D0, D1, D2, ..., and D15 relate to the ordered entry of program data into the MC33298 with D0/D8 bits (MSB) corresponding to Output 7 and D7/D15 corresponding to Output 0.
3. D0*, D1*, D2*, ..., and D7* relate to the ordered data out of the MC33298 with D0* bit (MSB) corresponding to Output 7.
4. OD* corresponds to Old Databits.
5. For brevity, only DO7 and DO0 are shown which respectively correspond to Output 7 and Output 0.

Data Transfer Timing (General)

CSB High–to–Low	SO pin is enabled. Output Status information transferred to Output Shift Register.
CSB Low–to–High	Data from the Shift Register is transferred to the Output Power Switches.
SO	Will change state on the rising edge of the SCLK pin signal.
SI	Will accept data on the falling edge of the SCLK pin signal.

Power Consumption

The MC33298P has extremely low power consumption in both the operating and standby modes. In the standby or “sleep” mode, with $V_{DD} \le 2.0$ V, the current consumed by the V_{PWR} pin is less than 50 µA. In the operating mode, the current drawn by the V_{DD} pin is less than 4.0 mA (1.0 mA typical) while the current drawn at the V_{PWR} pin is 2.0 mA maximum (1.0 mA typical). During normal operation, turning outputs “on” increases I_{PWR} by only 20 µA per output. Each output experiencing a “soft short” (overcurrent conditions just under the current limit), adds 0.5 mA to the I_{PWR} current.

Paralleling of Outputs

Using MOSFETs as output switches allows the connection of any combination of outputs together. MOSFETs have an inherent positive temperature coefficient thermal feedback which modulates $R_{DS(on)}$ providing balanced current sharing between outputs without destructive operation (bipolar outputs could not be paralleled in this fashion as thermal run–away would likely occur). The device can even be operated with all outputs tied together. This mode of operation may be desirable in the event the application requires lower power dissipation or the added capability of switching higher currents. Performance of parallel operation results in a corresponding decrease in $R_{DS(on)}$ while the Output Off Open Load Detect Currents and the Output Current Limits increase correspondingly (by a factor of eight if all outputs are paralleled). Less than 56 mΩ $R_{DS(on)}$ with current limiting of 24 to 48 A will result if all outputs are paralleled together. There will be no change in the Overvoltage detect or the “Off” Output Threshold Voltage Range. The advantage of paralleling outputs within the same MC33298 affords the existence of minimal $R_{DS(on)}$ and output clamp voltage variation between outputs. Typically, the variation of $R_{DS(on)}$ between outputs of the same device is less than is 0.5%. The variation in clamp voltages (which could affect dynamic current sharing) is less than 5%. Paralleling outputs from two or more devices is possible but not recommended. This is because there is no guarantee that the $R_{DS(on)}$ and clamp voltage of the two devices will match. System level thermal design analysis and verification should be conducted whenever paralleling outputs.

FAULT LOGIC OPERATION

General

The MCU can perform a parity check of the fault logic operation by comparing the command 8–bit word to the status 8–bit word. Assume that after system reset, the MCU first sends an 8–bit command word, Command Word 1, to the MC33298. Each output that is to be turned “on” will have its corresponding databit low. Refer to the Data Transfer Timing diagram of Figure 16. As this word, Command Word 1, is being written into the shift register of the MC33298, a status word is being simultaneously written out and received by the MCU. However, the word being received by the MCU is the status of the previous write word to the MC33298, Status Word 0. If the command word of the MCU is written a second time (Command Word 2 = Command Word 1), the word received by the MCU, Status Word 2, is the status of Command Word 1. The timing diagram shown in Figure 16 depicts this operation. Status Word 2 is then compared with Command Word 1. The MCU will Exclusive OR Status Word 2 with Command Word 1 to determine if the two words are identical. If the two words are identical, no faults exist. The timing between the two write words must be greater than 100 µs to receive proper drain status. The system databus integrity may be tested by writing two like words to the MC33298 within a few microseconds of each other.

Initial System Setup Timing

The MCU can monitor two kinds of faults:

(1) Communication errors on the data bus and

(2) Actual faults of the output loads.

After initial system start up or reset, the MCU will write one word to the MC33298. If the word is repeated within a few microseconds (say 5) of the first word, the word received by the MCU, at the end of the repeated word, serves as a confirmation of data bus integrity (1). At startup, the MC33298 will take 25 to 100 µs before a repeat of the first word can give the actual status of the outputs. Therefore, the first word should be repeated at least 100 µs later to verify the status of the outputs.

The SO of the MC33298 will indicate any one of four faults. The four possible faults are Over Temperature, Output Off Open Fault, Short Fault (overcurrent), and V_{PWR} Overvoltage Fault. All of these faults, with the exception of the Overvoltage Fault, are output specific. Over Temperature Detect, Output Off Open Detect, and Output Short Detect are dedicated to each output separately such that the outputs are independent in operation. A V_{PWR} Overvoltage Detect is of a “global” nature causing all outputs to be turned “off.”

Over Temperature Fault

Patent pending Over Temperature Detect and shutdown circuits are specifically incorporated for each individual output. The shutdown that follows an Over Temperature condition is independent of the system clock or any other logic signal. Each independent output shuts down at 155°C to 185°C. When an output shuts down due to an Over Temperature Fault, no other outputs are affected. The MCU recognizes the fault since the output was commanded to be “on” and the status word indicates that it is “off.” A maximum hysteresis of 20°C ensures an adequate time delay between output turn “off” and recovery. This avoids a very rapid turn “on” and turn “off” of the device around the Over Temperature threshold. When the temperature falls below the recovery level for the Over Temperature Fault, the device will turn “on” only if the Command Word during the next write cycle indicates the output should be turned “on.”

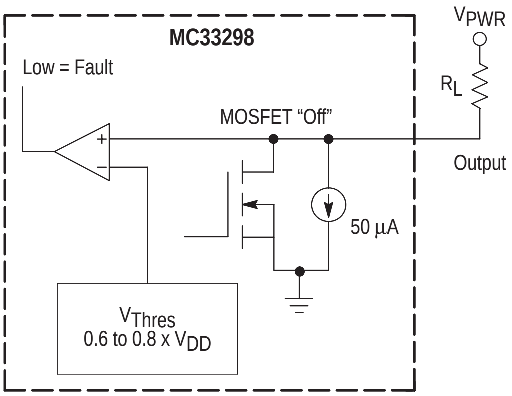
Overvoltage Fault

An Overvoltage condition on the V_{PWR} pin will cause the MC33298 to shut down all outputs until the overvoltage condition is removed and the device is re–programmed by the SPI. The overvoltage threshold on the V_{PWR} pin is specified as 28 V to 36 V with 1.0 V typical hysteresis. Following the overvoltage condition, the next write cycle sends the SO pin the hexadecimal word $FF (all ones) indicating all outputs are turned “off.” In this way, potentially dangerous timing problems are avoided and the MCU reset routine ensures an orderly startup of the loads. The MC33298 does not detect an overvoltage on the V_{DD} pin. Other external circuitry, such as the Motorola MC33161 Universal Voltage Monitor, is necessary to accomplish this function.

Output Off Open Load Fault

An Output Off Open Load Fault is the detection and reporting of an "open" load when the corresponding output is disabled (input in a logic high state). To understand the operation of the Open Load Fault detect circuit, see Figure 17. The Output Off Open Load Fault is detected by comparing the drain voltage of the specific MOSFET output to an internally generated reference. Each output has one dedicated comparator for this purpose.

Figure 17. Output "Off" Open Load Detect



An Output Off Open Load Fault is indicated when the output voltage is less than the Output Threshold Voltage (V_{Thres}) of 0.6 to 0.8 x V_{DD}. Since the MC33298 outputs function as switches, during normal operation, each MOSFET output should either be completely turned "on" or "off." By design the threshold voltage was selected to be between the "on" and "off" voltage of the MOSFET. During normal operation, the "on" state V_{DS} voltage of the MOSFET is less than the threshold voltage and the "off" state V_{DS} voltage is greater than the threshold voltage. This design approach affords using the same threshold comparator for Output Open Load Detect in the "off" state and Short Circuit Detect in the "on" state. See Figure 18 for an understanding of the Short Circuit Detect circuit. With V_{DD} = 5.0 V, an "off" state output voltage of less than 3.0 V will be detected as an Output Off Open Load Fault while voltages greater than 4.0 V will not be detected as a fault.

The MC33298 has an internal pull–down current source of 50 µA, as shown in Figure 17, between the MOSFET drain and ground. This prevents the output from floating up to V_{PWR} if there is an open load or internal wirebond failure. The internal comparator compares the drain voltage with a reference voltage, V_{Thres} (0.6 to 0.8 x V_{DD}). If the output voltage is less than this reference voltage, the MC33298 will declare the condition to be an open load fault.

During steady–state operation, the minimum load resistance (R_L) needed to prevent false fault reporting during normal operation can be found as follows:

$$V_{PWR} = 9.0\text{ V (min)}$$
$$I_{LCO} = 50\ \mu\text{A}$$
$$V_{Thres}\text{ (max)} = (0.8 \times 5.5)\text{V} = 4.4\text{ V}$$

Therefore, the load resistance necessary to prevent false open load fault reporting is (using Ohm's Law) equal to 92 kΩ or less.

During output switching, especially with capacitive loads, a false Output Off Open Load Fault may be triggered. To prevent this false fault from being reported an internal fault filter of 25 to 100 µs is incorporated. The duration for which a false fault may be reported is a function of the load impedance (R_L, C_L, L_L), $R_{DS(on)}$, and C_{out} of the MOSFET as well as the supply voltage, V_{PWR}. The rising edge of CSB triggers a built in fault delay timer which must time out (25 to 100 µs) before the fault comparator is enabled to detect a faulted threshold. The circuit automatically returns to normal operation once the condition causing the Open Load Fault is removed.

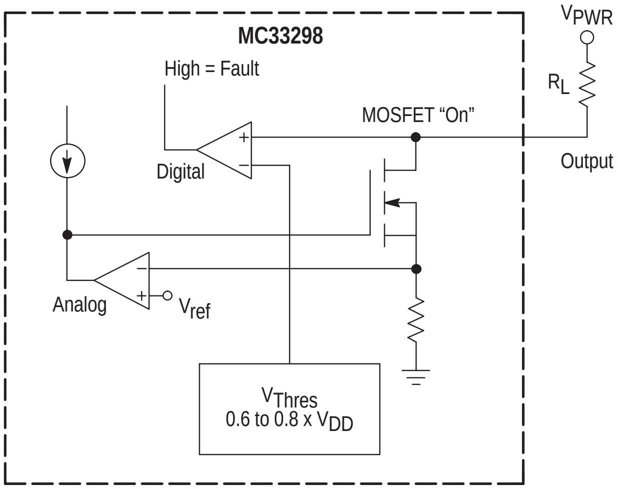
Shorted Load Fault

A shorted load (overcurrent) fault can be caused by any output being shorted directly to supply, or an output experiencing a current greater than the current limit.

There are three safety circuits progressively in operation during load short conditions which afford system protection: 1) The device's output current is monitored in an analog fashion using a SENSEFET™ approach and limited; 2) The device's output current limit threshold is sensed by monitoring the MOSFET drain voltage; and 3) The device's output thermal limit is sensed and when attained causes only the specific faulted output to be latched "off," allowing remaining outputs to operate normally. All three protection mechanisms are incorporated in each output affording robust independent output operation.

The analog current limit circuit is always active and monitors the output drain current. An overcurrent condition causes the gate control circuitry to reduce the gate to source voltage imposed on the output MOSFET which re–establishes the load current in compliance with current limit (3.0 to 6.0 A) range. The time required for the current limit circuitry to act is less than 20 µs. Therefore, currents higher than 3.0 to 6.0 A will never be seen for more than 20 µs (a typical duration is 10 µs). If the current of an output attempts to exceed the predetermined limit of 3.0 to 6.0 A (4.0 A nominal), the V_{DS} voltage will exceed the V_{Thres} voltage and the overcurrent comparator will be tripped as shown in Figure 18.

Figure 18. Short Circuit Detect and Analog Current Limiting Circuit



The status of SFPD will determine whether the MC33298 will shut down or continue to operate in an analog current limited mode until either the short circuit is removed or thermal shutdown is reached.

Grounding the SFPD pin will enable the short fault protection shutdown circuitry. Consider a load short (output short to supply) occurring on an output before, during, and after output turn "on." When the CSB signal rises to the high logic state, the corresponding output is turned "on" and a delay timer activated. The duration of the delay timer is 25 to 100 µs. If the short circuit takes place before the output is turned "on," the delay experienced is the entire 25 to 100 µs followed by shutdown. If the short occurs during the delay time, the shutdown still occurs after the delay time has elapsed. If the short circuit occurs after the delay time, shut– down is immediate (within 20 µs after sensing). The purpose of the delay timer is to prevent false faults from being reported when switching capacitive loads.

If the SFPD pin is at 5.0 V (or V_{DD}), an output will not be disabled when overcurrent is detected. The specific output will, within 5.0 to 10 µs of encountering the short circuit, go into an analog current limited mode. This feature is especially useful when switching incandescent lamp loads, where high in–rush currents experienced during startup last for 10 to 20 ms.

Each output of the MC33298 has its own overcurrent shutdown circuitry. Over temperature faults and the overvoltage faults are not affected by the SFPD pin.

Both load current sensing and output voltage sensing are incorporated for Short Fault detection with actual detection occurring slightly after the onset of current limit. The current limit circuitry incorporates a SENSEFET™ approach to measure the total drain current. This calls for the current through a small number of cells in the power MOSFET to be measured and the result multiplied by a constant to give the total current. Whereas output shutdown circuitry measures the drain to source voltage and shuts down if a threshold (V_{Thres}) is exceeded.

Short Fault detection is accomplished by sensing the output voltage and comparing it to V_{Thres}. The lowest V_{Thres} requires a voltage of 0.6 times 4.5 V (the minimum V_{DD} voltage) or 2.7 V to be sensed. For an enabled output, with $V_{DD} = 5.0 \pm 0.5$ V, an output voltage in excess of 4.4 V will be detected as a "short" while voltages less than 2.7 V will not be detected as "shorts."

Over Current Recovery

If the SFPD pin is in a high logic state, the circuit returns to normal operation automatically after the short circuit is removed (unless thermal shutdown has occurred).

If the SFPD pin is grounded and overcurrent shutdown occurs; removal of the short circuit will result in the output remaining "off" until the next write cycle. If the short circuit is not removed, the output will turn "on" for the delay time (25 to 100 µs) and then turn "off" for every write cycle commanding a turn "on."

SFPD Pin Voltage Selection

Since the voltage condition of the SFPD pin controls the activation of the short fault protection (i.e. shutdown) mode equally for all eight outputs, the load having the longest duration of in–rush current determines what voltage (state) the SFPD pin should be at. Usually if at least one load is, say an incandescent lamp, the in–rush current on that input will be milliseconds in duration. Therefore, setting SFPD at 5.0 V will prevent shutdown of the output due to the in–rush current. The system relies only on the Over Temperature Shutdown to protect the outputs and the loads. The MC33298 was designed to switch GE194 incandescent lamps with the SFPD pin in a grounded state. Considerably larger lamps can be switched with the SFPD pin held in a high logic state.

Sometimes both a delay period greater than 25 to 100 µs (current limiting of the output) followed by an immediate over current shutdown is necessary. This can be accomplished by programming the SFPD pin to 5.0 V for the extended delay period to afford the outputs to remain "on" in a current limited mode and then grounding it to accomplish the immediate shutdown after some period of time. Additional external circuitry is required to implement this type of function. An MCU parallel output port can be devoted to controlling the SFPD voltage during and after the delay period, is often a much better method. In either case, care should be taken to execute the SFPD start–up routine every time start–up or reset occurs.

Undervoltage Shutdown

An undervoltage V_{DD} condition will result in the global shutdown of all outputs. The undervoltage threshold is between 2.5 V and 4.5 V. When V_{DD} goes below the threshold, all outputs are turned "off" and the SO register is reset to indicate the same.

An undervoltage condition at the V_{PWR} pin will not cause output shutdown and reset. When V_{PWR} is between 5.5 V and 9.0 V, the outputs will operate per the command word. However, the status as reported by the serial output (SO) pin may not be accurate. Proper operation at V_{PWR} voltages below 5.5 V cannot be guaranteed.

Deciphering Fault Type

The MC33298 SO pin can be used to understand what kind of system fault has occurred. With eight outputs having open load, over current and over temperature faults, a total of 25 different faults are possible. The SO status word received by the MCU will be compared with the word sent to the MC33298 during the previous write cycle. If the two words are not the same, then the MCU should be programmed to determine which output or outputs are indicating faults. If the command bit for any of the output switches indicating a fault is high, the fault is an open load.

The eight open load faults are therefore the ones most easily detected. Over current and over temperature faults are often related. Turning the affected output switches "off" and waiting for some time should make these faults go away. Over current and over temperature faults can not be differentiated in normal application usage.

One advantage of the synchronous serial output is that multiple faults can be detected with only one pin (SO) being used for fault status indication.

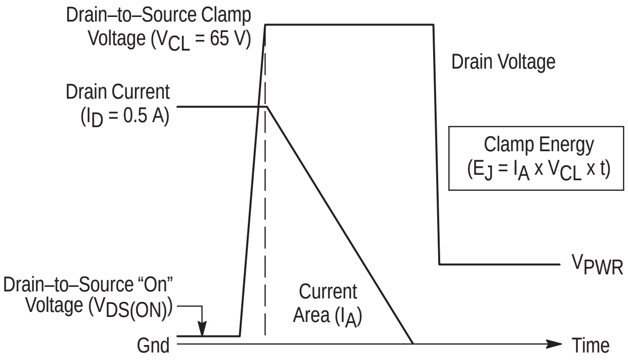
If V_{PWR} experiences an overvoltage condition, all outputs will immediately be turned "off" and remain latched "off." A new command word is required to turn the outputs back "on" following an overvoltage condition.

Output Voltage Clamping

Each output of the MC33298 incorporates an internal voltage clamp to provide fast turn–off and transient protection of the output. Each clamp independently limits the drain to source voltage to 65 V at drain currents of 0.5 A and keeps the output transistors from avalanching by causing the transient energy to be dissipated in the linear mode (see Figure 19). The total energy (E_J) can be calculated by multiplying the current area under the current curve (I_A) during the time the clamp is active and the clamp voltage (V_{CL}).

Characterization of the output clamps, using a single pulse repetitive method at 0.5 A, indicate the maximum energy to be 100 mJ at 25°C and 25 mJ at 125°C per output. Using a single pulse non–repetitive method at 0.5 A the clamps are capable of 2.0 Joules at 25°C and 0.5 Joules at 125°C.

Figure 19. Output Voltage Clamping



THERMAL CHARACTERIZATION

Thermal Model

Logic functions take up a very small area of the die and generate negligible power. In contrast, the output transistors take up most of the die area and are the primary contributors of power generation. The thermal model shown in Figure 20 was developed for the MC33298 mounted on a typical PC board. The model is accurate for both steady state and transient thermal conditions. The components R_{d0}, R_{d1}, R_{d2}, ..., and R_{d7} represent the steady state thermal resistance of the silicon die for transistor outputs 0, 1, 2, ..., and 7, while C_{d0}, C_{d1}, C_{d2}, ..., and C_{d7} represent the corresponding thermal capacitance of the silicon die transistor outputs and plastic. The device area and die thickness determine the values of these specific components.

The thermal impedance of the package from the internal mounting flag to the outside environment is represented by the terms R_{pkg} and C_{pkg}. The steady state thermal resistance of leads and the PC board make up the steady state package thermal resistance, R_{pkg}. The thermal capacitance of the package is made up of the combined capacitance of the flag and the PC board. The mold compound was not modeled as a specific component but is factored into the other overall component values.

The battery voltage in the thermal model represents the ambient temperature the device and PC board are subjected to. The I_{PWR} current source represents the total power dissipation and is calculated by adding up the power dissipation of each individual output transistor. This is easily done by knowing $R_{DS(on)}$ and load current of the individual outputs.

Very satisfactory steady state and transient results have been experienced with this thermal model. Tests indicate the model accuracy to have less than 10% error. Output interaction with an adjacent output is thought to be the main contributor to the thermal inaccuracy. Tests indicate little or no detectable thermal affects caused by distant output transistors which are isolated by one or more other outputs. Tests were conducted with the device mounted on a typical PC board placed horizontally in a 33 cubic inch still air enclosure. The PC board was made of FR4 material measuring 2.5″ by 2.5″, having double–sided circuit traces of 1.0 oz. copper soldered to each device pin. The board temperature was measured with thermal couple soldered to the board surface one inch away from the center of the device. The ambient temperature of the enclosure was measured with a second thermal couple located over the center and one inch distant from device.

Thermal Performance

Figure 20 shows the worst case thermal component parameters values for the MC33298 in the 20 pin plastic power DIP and the SOP–24 wide body surface mount package. The power DIP package has Pins 5, 6, 15, and 16 connected directly to the lead frame flag. The parameter values indicated take into account adjacent output cell thermal pulling effects as well as different output combinations. The characterization was conducted over power dissipation levels of 0.7 to 17 W. The junction–to–ambient temperature thermal resistance was found to be 37°C/W with a single output active (31°C/W with all outputs dissipating equal power) and in conjunction with this, the thermal resistance from junction to PC board ($R_{junction–board}$) was found to be 27°C/W (board temperature, measured 1″ from device center). In addition, the thermal resistance from junction–to–heatsink lead was found to approximate 10°C/W. Devoting additional PC board metal around the heatsinking pins improved R_{pkg} from 30° to 28°C/W.

The SOP–24 package has Pins 5, 6, 7, 8, 17, 18, 19, and 20 of the package connected directly to the lead frame flag. Characterization was conducted in the same manner as for the DIP package. The junction–to–ambient temperature resistance was found to be 40°C/W with a single output active (34°C/W with all outputs dissipating equal power) and the thermal resistance from junction–to–PC board ($R_{junction–board}$) to be 30°C/W (board temperature, measured 1″ from device center). The junction–to–heatsink lead resistance was found again to approximate 10°C/W. Devoting additional PC board metal around the heatsinking pins for this package improved the R_{pkg} from 33° to 31°C/W.

The total power dissipation available is dependent on the number of outputs enabled at any one time. At 25°C the $R_{DS(on)}$ is 450 mΩ with a coefficient of 6500 ppm/°C. For the junction temperature to remain below 150°C, the maximum available power dissipation must decrease as the ambient temperature increases. Figures 21 and 22 depict the per output limit of current at ambient temperatures necessary for the plastic DIP and SOP packages respectively when one, four, or eight outputs are enabled "on." Figure 23 depicts how the $R_{DS(on)}$ output value is affected by junction temperature.

Figure 20. Thermal Model (Electrical Equivalent)

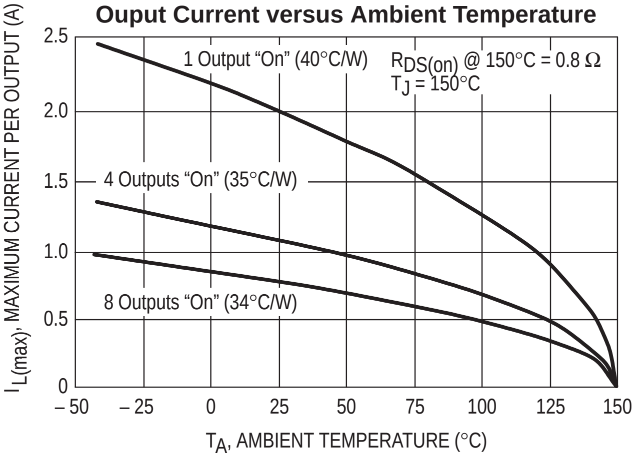

Figure 23. Maximum Output "On" Resistance versus Junction Temperature

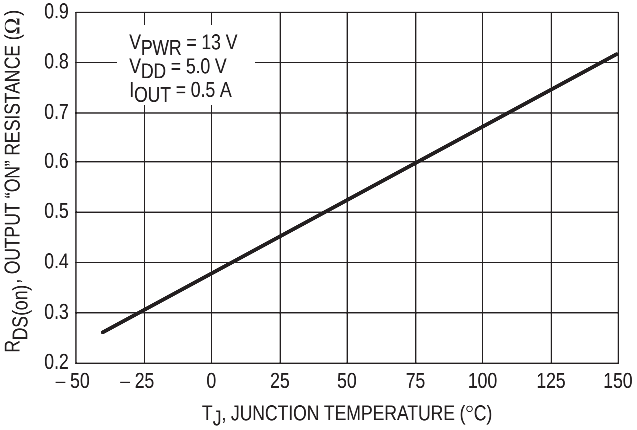


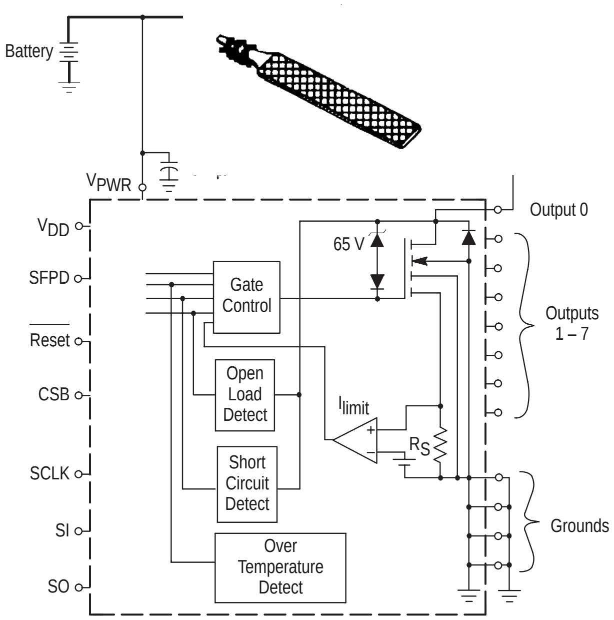
Latch–Up Immunity

Device latch–up caused by substrate injection has been characterized. Latch–up immunity has both a dc and a transient immunity component. DC latch–up immunity results indicate the device to be capable of withstanding in excess of four amps of reverse current out of any of the output transistors while the control logic continues to function normally. The logic control current (I_{DD}) was found to increase by only 0.6 mA with four amps of current being pulled out of an output. Additionally, the I_{PWR} current was found to increase by only 0.15 mA under the same condition. These increases are a result of minority carriers being injected into substrate and subsequently being collected.

The following procedure has been developed to test for transient latch–up immunity and has been applied to this automotive circuit design. Results of transient testing indicate the device to operate properly at output currents greater than 1.5 A. The procedure tests for the device's immunity to intermittent load to battery current connection with the device controlling an inductive load. Appropriately termed "the file test," the battery is connected to a shop file while the lead to the inductive load is dragged across the files surface causing intermittent load opens producing lots of arcs, sparks, and smoke, plus severe transients (see Figure 24). It is during these severe transients that latch–up most likely could occur. The battery voltage used for this test was 18 V and the inductive load was 2.0 mH. These values were found to produce severe transient stresses of the device outputs. All outputs must maintain operation and input control during transient generation to pass "the file test."

The device's input control currents were found to remain stable and were not affected by dc or transient latch–up immunity testing.

Figure 24. Transient Latch–Up Immunity File Test



APPLICATIONS INFORMATION

SIOP Communication

Two common communication protocols used in Motorola's microprocessors are the Serial Peripheral Interface (SPI) and Synchronous Input Output Port (SIOP). SIOP is a subset of the more flexible SPI and the simpler of the two protocols. SIOP is used on many of the MC68HC05 family of microcontrollers. Restrictions of the SIOP protocol include: 1) the SCLK frequency is fixed at one–fourth the internal clock rate and 2) the polarity of the SCLK signal is fixed.

By way of example, the MC68HC05P9 utilizes SIOP protocol and is not directly compatible with the serial input requirements of the MC33298. Specifically, the MC33298 accepts data on the falling edge of SCLK whereas its rising edge triggers data transfer in the SIOP protocol. SCLK is high during SIOP transmissions, which is the opposite of what the MC33298 requires.

Though designed specifically for SPI communication protocol, the MC33298 can easily be adapted to communicate with SIOP protocol through the use of software. The amount of code required to implement SPI in software is relatively small, so the only major drawback is a slower transfer of data. The software routine shown in Table 1 completes a transfer in about 100 µs.

Cost

The bottom line relates to cost. The MC33298 is a very cost effective octal output serial switch for applications typically encountered in the automotive and industrial market segments. To accomplish only the most basic serial switch function the MC33298 offers, using a discrete semiconductor approach, would require the use of at least eight logic level power MOSFETs for the outputs and two shift registers for the I/O plus other miscellaneous "glue" components. Additional circuitry would have to be incorporated to accomplish the protection features offered by the MC33298. Other noteworthy advantages the MC33298 offers are conservation of power and board space, requirement of fewer application components, and enhanced application reliability. The MC33298 is available at a fraction of the cost required for discrete component implementation and represents true value.

The MC33298 represents a cost effective device having advanced performance and features and worthy of consideration.

Electronic Ignition Control Circuit

The MCCF79076, in conjunction with an appropriate Motorola Power Darlington Transistor, provides an economical solution for automotive ignition applications. The MCCF79076 offers optimum performance by providing closed loop operation of the Power Darlington in controlling the ignition coil current.

The MCCF79076 incorporates Flip–Chip Technology which involves the formation of solder bumps, rather than traditional wire bonds, to establish mechanical and electrical contact to the semiconductor chip. This process affords a unique device having improved reliability at elevated operating temperatures.

- Solder Bumped for Flip–Chip Assembly
- Ignition Coil Voltage Internally Limited to 375 V
- Coil Current Limiting to 7.5 A
- Output On–Time (Dwell) Control
- Dwell Feedback Control to Sense Coil Variation
- Hall Sensor Input
- – 30°C ≤ T_A ≤ +140°C Ambient Operating Temperature

Integral Alternator Regulator

The MCCF33095 (Flip–Chip) and MC33095 (Surface Mount) are regulator control integrated circuits designed for use in automotive 12 V alternator charging systems. Few external components are required for full system implementation. These devices provide control for a broad range of 12 V alternator charging systems when used in conjunction with the appropriate Motorola Power Darlington transistor to control the field current of the specific alternator.

Both versions have internal detection and protection features to withstand extreme electrical variations encountered in harsh automotive environments. Flip–Chip Technology allows the MCCF33095 to operate at higher ambient temperatures than the surface mount version in addition to withstanding severe vibration and thermal shock with a high degree of reliability.

- Constant Frequency with Variable Duty Cycle Operation
- Adjusts System Charging to Compensate for Changes in Ambient Temperature
- Slew Rate Control to Reduce EMI
- Lamp Pin to Indicate Abnormal Operating Conditions
- Shorted Field Protection
- Resumes Normal Operation Once Fault Condition Ceases
- Operation from –40°C to 170°C for Flip–Chip and –40°C to 125°C for SO–14
- Surface Mount or Solder Bump Processed Flip–Chip Assembly Versions

FUNCTIONAL DESCRIPTION

Introduction

This ignition control circuit was originally designed and offered as an MCCF33095 Flip–Chip for use in 12 V automotive alternator charging systems. The MCCF33095 consists of many protection features which are entailed in a ten pin flip–chip package. The device was subsequently made available in a 14 pin surface mount version (MC33095D). Both versions perform in a similar manner. The Flip–Chip version has an advantage over the surface mount version where minimized space and higher operating ambient temperatures are of major concern. Device operation and application suggestions for both versions are given below.

Oscillator

The oscillator frequency is determined by the value of an external capacitor from the Oscillator pin to ground (see applications circuit). The oscillator frequency in a typical application is approximately 175 Hz, but a range of 50 Hz to 500 Hz can reasonably be used. The waveform generated consists of a positive linear slope followed by relatively fast negative fall (sawtooth). The flip–flops are reset by the falling edge of the sawtooth signal as shown on the logic diagram. The oscillator signal peaks at approximately 3.0 V and provides the timing required for the device.

Ignition

The Ignition input signal enables the device turn–on when the Ignition pin voltage is greater than 1.4 V. This signal normally originates from the ignition switch of automotive systems.

Sense

The Sense pin functions as a voltage sensor. It proportionally senses the battery voltage and determines the amount of time the Darlington transistor is high over the next cycle. A low voltage at the Sense pin will result in a long duty cycle for the Darlington while a high voltage produces a short duty cycle. In the application, proportional control is used to determine the duty cycle. Proportional control is defined as the sense ratio of battery voltage, present on the Sense pin, required to obtain a 20% to 95% duty cycle range in the application. The 20% duty cycle value will correlate to the maximum battery in the application. Normally the sense ratio of battery voltage is an end product trim adjustment.

Lamp

The Lamp output pin functions as a warning indicator for overvoltage and stopped engine or broken belt conditions existing in the system.

Stator

The Stator pin senses the voltage from the stator in the application circuit, and keeps the device powered up while the stator voltage is high. Furthermore, it acts as a sense for a stopped engine or broken belt condition. If this condition is detected, the Stator turns “on” the Lamp.

Power Supply, V_{CC}

The V_{CC} pin powers the entire device and disables all outputs during any overvoltage condition.

Roll–Off

The Roll–Off pin provides thermal protection for the circuit. This capability exists, but has not been characterized and is not tested for at this time. Therefore, it is recommended that this pin be connected to ground. The surface mount version has this pin internally connected to ground.

Darlington Drive

The purpose of the Darlington Drive output pin is to turn on an external power Darlington transistor. The Sense pin voltage determines the duty cycle of the Darlington. The oscillator is set to maintain a minimum duty cycle, except during overvoltage and short circuit conditions.

Short Circuit

The Short Circuit pin monitors the field voltage. When the Darlington Drive and Short Circuit pins are simultaneously high for a duration greater than the slew rate period, a short circuit condition is noted. The detection time required prevents the device from reacting to false shorts. As a result of short circuit detection, the output is disabled. During a short circuit condition, the device automatically retries with a 2% duty cycle (Darlington “on” time). Once the short circuit condition ceases, normal device operation resumes.

Application Notes

A capacitor should be used in parallel with the V_{CC} pin to filter out noise transients on the supply or battery line. Likewise, a capacitor should be used in parallel with the Sense pin to create a dominant closed loop pole. Resistors connected to inputs, as mentioned in Notes 1 through 5 of the Electrical Characteristic table, should be used.

FLIP–CHIP APPLICATION INFORMATION

Introduction

Although the packaging technology known as “flip–chip” has been available for some time, it has seen few applications outside the automotive and computer industries. Present microelectronic trends are demanding smaller chip sizes, reduced manufacturing costs, and improved reliability. Flip–chip technology satisfies all of these needs.

Conventional assembly techniques involve bonding wires to metal pads to make electrical contact to the integrated circuit. Flip–chip assembly requires further processing of the integrated circuit after final nitride deposition to establish robust solder bumps with which to make electrical contact to the circuit. A spatially identical solderable solder bump pattern, normally formed on ceramic material, serves as a substrate host for the flip–chip. The “bumped” flip–chip is aligned to, and temporarily held in place through the use of soldering paste. The aligned flip–chip and substrate host are placed into an oven and the solder reflowed to establish both electrical and mechanical bonding of the flip–chip to the substrate circuit. Use of solder paste not only holds the chip in temporary placement for reflow but also enhances the reflow process to produce highly reliable bonds.

Flip–Chip Benefits

Some of the benefits of flip–chip assembly are:

1) Higher circuit density resulting in approximately one–tenth the footprint required of a conventional plastic encapsulated device.
2) Improved reliability, especially in high temperature applications. This is due, in part, to the absence of wires to corrode or fatigue from extensive thermal cycling.
3) No bond wires are required that might possibly become damaged during assembly.
4) Adaptable for simultaneous assembly of multiple flip–chips, in a hybrid fashion, onto a single ceramic substrate.

The following discussion covers the flip–chip process steps performed by Motorola, and the assembly processing required by the customer, in order to attach the flip–chip onto a ceramic substrate.

MOTOROLA’S FLIP–CHIP PROCESS

Overview

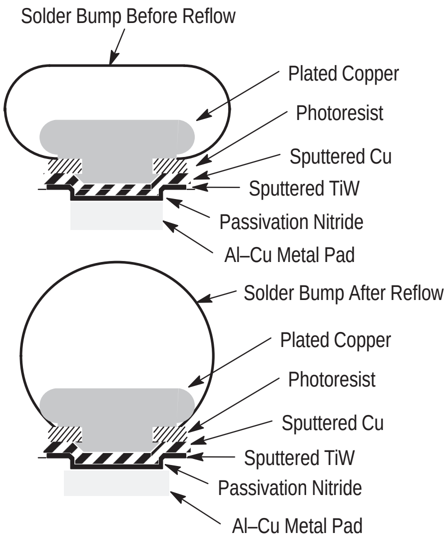
The process steps to develop an integrated circuit flip–chip are identical to that of conventional integrated circuits up to and including the deposition of the final nitride passivation layer on the front surface (circuit side). At this stage all device metal interconnects are present.

The process sequence is as follows:

1) Passivation–nitride photoresist and etch
2) Bimetal sputter (titanium (Ti) and tungsten (W) followed by copper (Cu))
3) Photo mask to define the bump area
4) Copper plate
5) Lead plate
6) Tin plate
7) Photoresist clean to remove all photoresist material
8) Bimetal etchback
9) Reflow for bump formation
10) Final inspection

The diagram below depicts the various layers involved in the bump process.

Figure 9. Plated Bump Structure and Process Flow



Initially, photoresist techniques are used to create openings in the nitride passivation layer exposing the metal pad bias. Ti/W, followed by Cu, are sputtered across the entire wafer surface. The surface is then photo patterned to define the bump areas. The sputtered metals together constitute a base metal for the next two metal depositions.

The Ti/W layer provides excellent intermetallic adhesion between the metal pads and the sputtered copper. In addition, the Ti/W provides a highly reliable interface to absorb mechanical shock and vibrations frequently encountered in automotive applications. The sputtered copper layer creates a platform onto which an electroplated copper layer can be built–up. Layers of Cu, Pb, and Sn are applied by plating onto the void areas of the photoresist material. The photoresist is then removed and the earlier sputtered materials are etched away. The flip–chip wafer is then put into an oven exposing it to a specific ambient temperature which causes the lead and tin to ball–up and form a solder alloy.

IC Solder Bumps

The solder consists of approximately 93% lead and 7% tin. The alloying of lead with tin provides a bump with good ductility and joint adhesion properties. Precise amounts of tin are used in conjunction with lead. Too much tin in relation to lead can cause the solder joints to become brittle and subject to fatigue failure. Motorola has established what it believes to be the optimum material composition necessary in order to achieve high bump reliability.

In the make–up of the flip–chip design, bumps are ideally spaced evenly and symmetrically along each edge of the chip allowing for stress experienced during thermal expansion and vibration to be distributed evenly from bump to bump. The bump dimensions and center–to–center spacing (pitch) are specified by the chip layout and the specific application. The nominal diameter of the bumps is 6.5 mils and the minimum center–to–center pitch is roughly 8.0 mils.

Reflow

The reflow process creates a thermally induced amalgam of the lead and tin. In the melting process, the surface tension is equalized causing the melted solder to uniformly ball up as mentioned earlier.

The ideal reflow oven profile gradually ramps up in temperature to an initial plateau. The purpose of the plateau is to establish a near equilibrium temperature just below that of the solder's melting temperature. Following the preheat, a short time and higher temperature excursion is necessary. This is to ensure adequate melting of the solder materials. The temperature is then ramped down to room temperature.

An atmosphere of hydrogen is used during the reflow heat cycle. The hydrogen provides a reducing atmosphere for the removal of any surface oxides present. The formation or presence of oxides can cause degradation in the bond reliability of the product.

During the flip–chip attachment reflow onto the ceramic substrate host, the created surface tension of the molten solder aids in the alignment of the chip onto the ceramic substrate.

Reliability

Motorola is determined to bring high quality and reliable products to its customers. This is being brought about by increased automation, in–line Statistical Process Control (SPC), bump shear strength testing, thermocycling from – 40° to +140°C, process improvements such as backside laser marking of the silicon chip, and improved copper plating techniques.

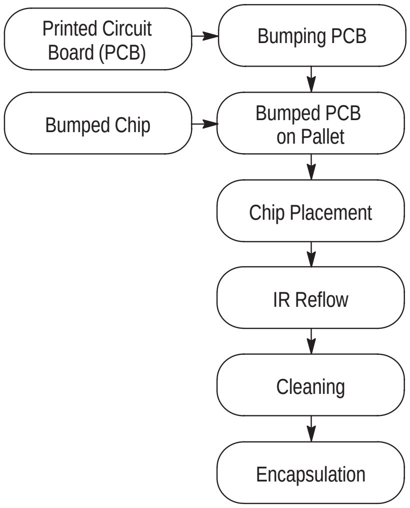
ATTACHING FLIP–CHIPS ONTO CERAMIC SUBSTRATES

Overview

The assembly or process of attaching the flip–chip onto a ceramic substrate is performed by the module fabricator. Prior to actual assembly, the ceramic substrate should undergo several process steps. Care should be exercised to properly orient the flip–chip onto the substrate host in order to accommodate the appropriate solder bumps. Ideally, the flip–chip should be removed from the waffle pack with a pick and place machine utilizing a vacuum pick–up to move the die onto the ceramic substrate. Any other components to be reflow soldered onto the substrate can be placed onto the substrate in a similar manner. Flip–chip assembly onto a ceramic substrate allows for some passive components, such as resistors, to be formed directly into the ceramic substrate circuit pattern itself. With all surface components to be mounted in place on the ceramic substrate, the assembly is moved into the furnace where it undergoes a specified temperature variation to solder all the components onto the ceramic substrate. This is accomplished by melting (reflowing) the substrate solder bumps. The resulting assembly should, after being cooled, be cleaned to remove any flux residues. If the substrate assembly is to be mounted into a module, it is recommended that the cavity of the module be filled with an appropriate silicon gel. The use of a gel coating helps to seal the individual components on the substrate from external moisture. A commonly used gel for this purpose is Dow Corning 562. As a final module assembly step, a cover is recommended to be placed over the ceramic assembly for further protection of the circuit.

It should be pointed out that the commonly used ceramic substrate material, though more expensive than other substrate materials, offers significantly superior thermal properties. By comparison, the use of ceramic material offers 33 times the thermal advantage of the second best material, Ceracom. The common FR–4 epoxy material is 100 times less thermally conductive than ceramic. For applications where dielectric constants are important and/or heat dissipation is not of real importance, other less costly materials can be used. The basic concept of the process is identical for all flip–chip substrates used.

Figure 10. Process Flow Diagram



Ceramic Substrate Preparation

The recommended ceramic substrate is aluminum oxide. These substrates come connected in what is referred to as a card. This is identical to the concept of die or chips on a wafer. Each card usually contains 8 to 16 substrates.

Initially, the ceramic should be precleaned with isopropyl alcohol, followed by freon. The bump pattern is then transferred onto the substrate using a metal stencil technique using a palladium silver conducting paste, such as DuPont 9476, through a #325 mesh. Once the pattern is applied, the substrate is dried for ten minutes at 150°C and then fired for 60 minutes at a temperature increasing to a peak of 850°C for ten additional minutes. Solder paste is then stenciled onto the pads.

A metal etched stencil defining the contact areas is recommended. The use of an etched stencil affords better solder paste control than does a silk screen. The metal stencil affords a deposition of a known amount of solder paste, thereby preventing bridging caused by excess solder usage.

Solder Paste Content

It is recommended that the solder paste consist of 10% tin, 88% lead, and 2% silver alloy. However, 95/3/2 compositions have had successful results.

A rosin based flux, such as RMA (Rosin Mildly Activated) manufactured by Dupont and having spherical particles of 45 to 75 microns, should be used. The tackiness of the solder paste at room temperature helps to hold the flip–chip in place during the pick and place operation. The use of flux:

1) Prevents excess oxidation during reflow.
2) Optimizes the flow of liquid solder through the stencil.
3) Smooths the surface by reducing surface tension, and
4) Enhances the normalization of surface tension upon reflow causing the flip–chip bumps to effectively auto–align themselves to substrate bump pads.

A solder mask can be used for applications requiring high precision as shown in Figures 11a and 11b.

Figure 11a. Before Reflow

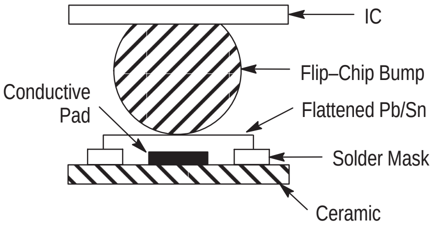


Figure 11b. After Reflow

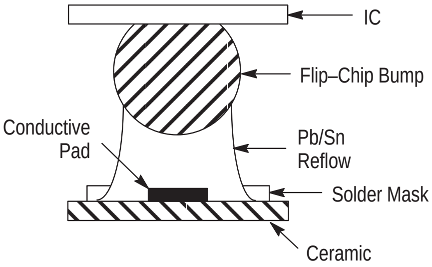
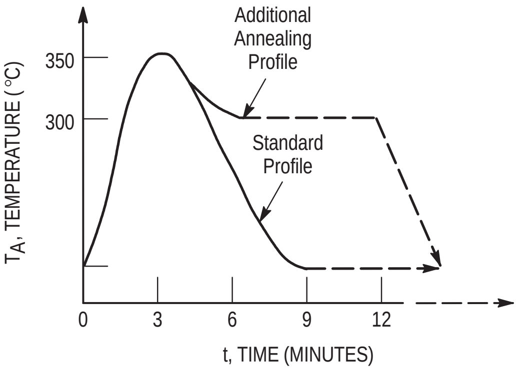


Oven Profile

After the flip–chip is placed onto the bumped substrate, the substrate and flip–chip are ready for reflow. Initially, the flip–chip is heated to a peak temperature of around 300° to 350°C for five minutes. It is to be noted that the flip–chip bumps have a higher melting temperature than the bumps on the substrate. During assembly reflow, the substrate bumps melt and create a substrate to flip–chip bump bond. After reflow, the assembled part is cooled to room temperature or to some intermediate temperature point for annealing purposes.

Figure 12. Reflow Oven Profile



The oven temperature profile is established primarily to melt the solder while minimizing the alloying of the materials and keeping the flux from boiling away. It should be noted that when the flip–chip is placed onto the substrate, the material is stressed in one direction or another. The use of flux helps to reduce any surface stresses present. A reduction in the surface stress enhances solder wetting which in turn aids in the alignment of the flip–chip to the substrate. Poor solder wetting will produce misalignment as well as inferior bond strengths and reliability.

It is recommended that an inert atmosphere such as nitrogen be used during the reflow process to prevent oxidation.

Final Cleaning

The final cleaning involves removing the remaining flux from the flip–chip assembly. Three possible methods of removing flux are: ultrasonic cleaner, Terpene solvent and DI water, or vapor degreaser. The flux manufacturer should be able to recommend the proper type of vapor degreaser to be used.

Test and Reliability

Both visual inspection and shear strength testing should be performed on packaged flip–chip assemblies.

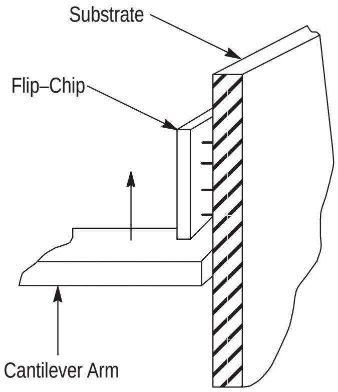
Solder reflow results that exhibit a grainy and dull appearance produce inferior bond shear strengths. Inferior bond shear strengths are visually recognizable by:

1) The presence of old or badly oxidized solder paste.
2) Insufficient amount of solderable material.
3) The contamination of bond pads with grease, oil, etc.

It should be mentioned that many contaminants are transparent and not easily detectable by visual means.

Shear strength testing should meet a 0.8 Newtons/Bump criteria. Shear strength testing should follow thermocycling of the chip from – 40° to +140°C to insure the stability of shear strength over temperature. Figure 13 depicts a test set–up which might possibly be used.

Figure 13. Shear Test Fixture



Aside from physical contamination, flip–chips, like any other chips, should not be handled directly due to the fact that electrostatic discharges can cause permanent damage to the electronic circuit. Flip–chips which do survive an electrostatic discharge can be left in a weakened condition resulting in reduced reliability of the end product. To avoid electrostatic damage of the circuit, assembly personnel should make use of a wrist strap or some other device to provide electrostatic grounding of their body. For the same reason, machinery used to assemble semiconductor circuits should be electrostaticly grounded.

Flip–chips rely primarily on the thermal path established by the bumps to remove heat from the chip as a result of internal circuit operation. Standard Motorola flip–chips have a thermal resistance of approximately 290°C/W/Bump. This figure can be used to estimate the allowed maximum power dissipation of the chip.

Cost and Equipment Manufacturers

The cost of implementing a flip–chip assembly process depends on the specific production requirements and as a result will vary over a broad range. It is possible to implement a small volume laboratory set–up for a few hundred dollars using manual operations. At the other end of the scale one could spend millions setting up a fully automated line incorporating pattern recognization, chip and substrate orientation, reflow, cleaning, and test. The module fabricator will have to make this assessment.

An assembly operator can manually accomplish the pick and place operation using a vacuum probe to pick–up and orient the flip–chip onto the substrate. Furthermore, it is possible to perform the reflow assembly operation using a simple batch process oven fabricated from a laboratory hot plate. However, the use of such process techniques will have questionable impact on the final product's reliability and quality. For this reason, it is highly recommended that the module fabricator seriously consider two major pieces of equipment; a pick and place machine and an infrared solder reflow oven. Both pieces of equipment can vary over a wide cost range depending on the production requirements. A partial list of manufacturers for this equipment is given below.

Pick and Place Machine:
- Universal Instruments Corp.
  Dover Technologies, Inc.
  Binghamton, NY 13902
  (607) 772–7522
- Seiko
  Torrance, CA 90505
  (310) 517–7850
- Laurier Inc.
  Hudson, NH 03051
  (603) 889–8800

Infrared Reflow Oven:
- BTU
  Bellerica, MA 01862
  (508) 667–4111
- Vitronics
  Newmarket, NH 03857
  (603) 659–6550

Additional Applications

Completed ceramic flip–chip sub–assemblies can be stacked one on top of another to produce an overall assembly by making contact connections through bumps. This technology is beginning to emerge in the computer industry where physical module size is of significant importance. Furthermore, this assembly technology, though more complex, is undergoing serious consideration within the automotive industry as well.

Applications requiring small size and high reliability at high ambient temperatures can benefit considerably through the implementation of flip–chip assembly techniques.

TCF6000

Peripheral Clamping Array

The TCF6000 was designed to protect input/output lines of microprocessor systems against voltage transients.

- Optimized for HMOS System
- Minimal Component Count
- Low Board Space Requirement
- No P.C.B. Track Crossovers Required
- Applications Areas Include Automotive, Industrial, Telecommunications and Consumer Goods

CIRCUIT DESCRIPTION

To ensure the reliable operation of any integrated circuit based electronics system, care has been taken that voltage transients do not reach the device I/O pins. Most NMOS, HMOS and Bipolar integrated circuits are particularly sensitive to negative voltage peaks which can provoke latch–up or otherwise disturb the normal functioning of the circuit, and in extreme cases may destroy the device.

Generally the maximum rating for a negative voltage transients on integral circuits is –0.3 V over the whole temperature range. Classical protection units have consisted of diode/resistor networks as shown in Figures 2a and 2b.

The arrangement in Figure 2a does not, in general, meet the specification and is therefore inadequate.

The problem with the solution shown if Figure 2b lies mainly with the high current drain through the biassing devices R_1 and D_3. A second problem exists if the input line carries an analog signal. When V_{in} is close to the ground potential, currents arising from leakage and mismatch between D_3 and D_2 can be sourced into the input line, thus disturbing the reading.

Figure 2. Classical Protection Circuits

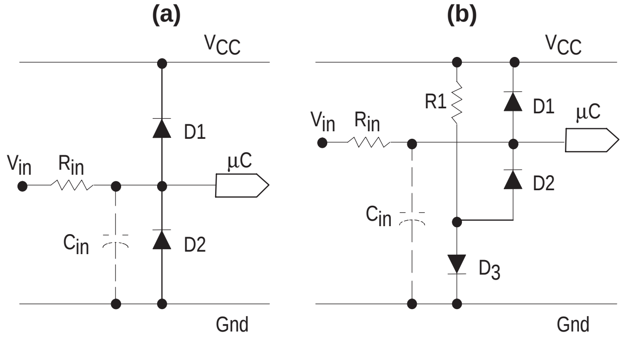

Figure 3 shows the clamping characteristics which are common to each of the six cells in the Peripheral Clamping Array.

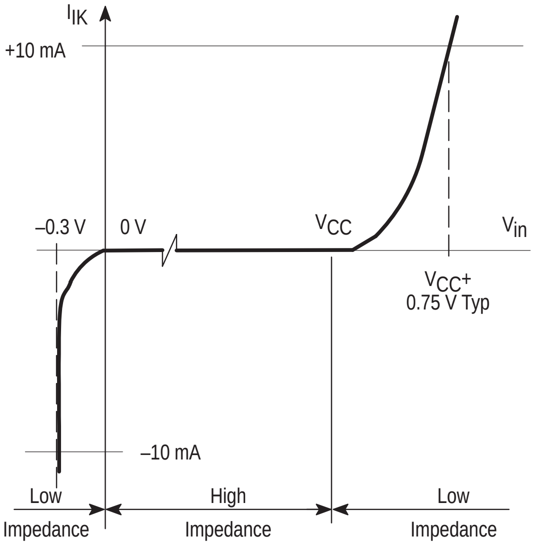
As with the classical protection circuits, positive voltage transients are clamped by means of a fast diode to the V_{CC} supply line.

Figure 3. Clamping Characteristics



APPLICATIONS INFORMATION

Figure 4 depicts a typical application in a microcomputer based automotive ignition system.

The TCF6000 is being used not only to protect the system's normal inputs but also the (bidirectional) serial diagnostics port.

The value of the input resistors, R_{in}, is determined by the clamping current and the anticipated value of the spikes.

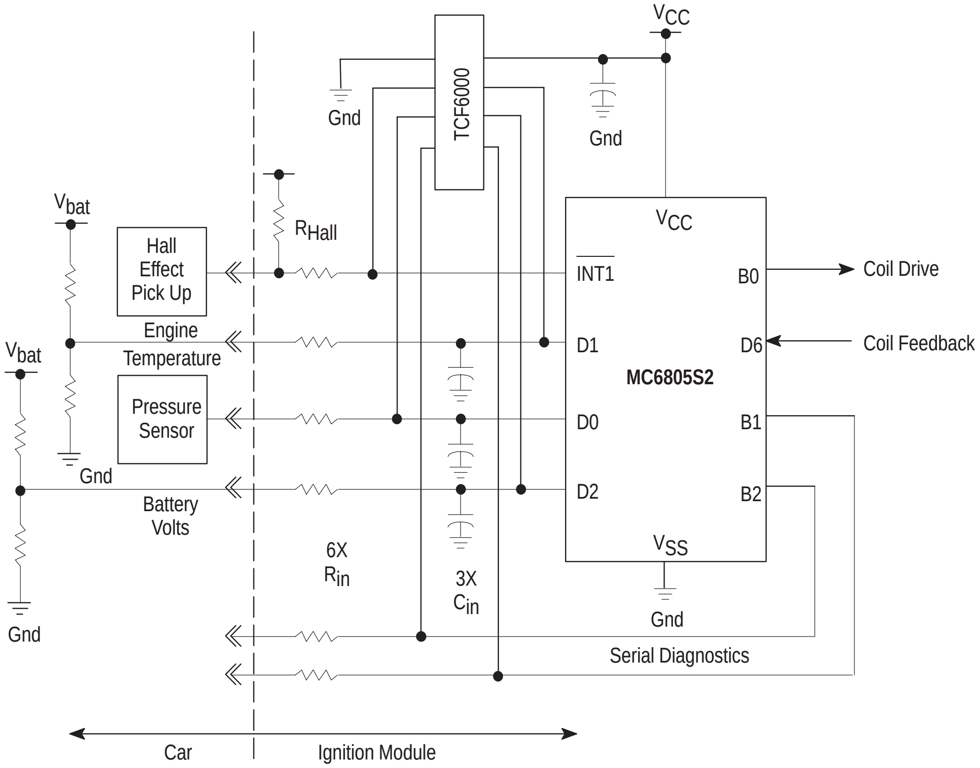
Thus:

$$R_{in} = \frac{V}{I_{IK}}\ \Omega$$

where: V = Peak Volts (V)
I_{IK} = Clamping current (A)
So, taking, V = 300 V typically (SAE J1211)
I_{IK} = 10 mA (recommended)
gives, R_{in} = 30 k

Resistors of this value will not usually cause any problems in MOS systems, but their presence needs to be taken into account by the designer. Their effect will normally need to be compensated for Bipolar systems.

Figure 4. Typical Automotive Application



The use of C_{in} is not mandatory, and is not recommended where the lines to be protected are used for output or for both input and output. For digital input lines, the use of a small capacitor in the range of 50 pF to 220 pF is recommended as this will reduce the rate of rise of voltage seen by the TCF6000 and hence the possibility of overshoot.

In the case of the analog inputs, such as that from the pressure sensor, the capacitor C_{in} is necessary for devices such as the MC6805S2 shown, which present a low impedance during the sampling period. The maximum value for C_{in} is determined by the accuracy required, the time taken to sample the input and the input impedance during that time, while the maximum value is determined by the required frequency response and the value of R_{in}.

Thus for a resistive input A/D connector where:

T_S = Sample time (seconds)
R_D = Device input resistance (Ω)
V_{in} = Input voltage (V)
k = Required accuracy (%)
Q_1 = Charge on capacitor before sampling
Q_2 = Charge on capacitor after sampling
I_D = Device input current (A)

Thus: $Q_1 – Q_2 = \frac{k \times Q_1}{100}$

but, $Q_1 = C_{in} V_{in}$
and, $Q_1 – Q_2 = I_D \bullet T_S$

so that, $I_D T_S = \frac{k \bullet C_{in} – V_{in}}{100}$

and, $C_{in} \text{ (min)} = \frac{I_D \bullet T_S}{V_{in} \bullet k}$ Farad

so, $C_{in} \text{ (min)} = \frac{100 \bullet T_S}{k \bullet R_D}$ Farad

The calculation for a sample and hold type converter is even simpler:

k = Required accuracy (%)
C_H = Hold capacitor (Farad)

$C_{in} \text{ (min)} = \frac{100 \bullet C_H}{k}$ Farad

For the MC6805S2 this comes out at:

$C_{in} \text{ (min)} = \frac{100.25 \text{ pF}}{0.25}$ = 10 nF for 1/4% accuracy

MOTOROLA

UAA1041B

Automotive Direction Indicator

This device was designed for use in conjunction with a relay in automotive applications. It is also applicable for other warning lamps such as “handbrake ON,” etc.

- Defective Lamp Detection
- Overvoltage Protection
- Short Circuit Detection and Relay Shutdown to Prevent Risk of Fire
- Reverse Battery Connection Protection
- Integrated Suppression Clamp Diode

CIRCUIT DESCRIPTION

The circuit is designed to drive the direction indicator flasher relay. Figure 2 shows the typical system configuration with the external components. It consists of a network (R1, C1) to determine the oscillator frequency, shunt resistor (R_S) to detect defective bulbs and short circuits in the system, and two current limiting resistors (R_2/R_3) to protect the IC against load dump transients. The circuit can be used either with or without short circuit detection, and features overvoltage, defective lamp and short circuit detection.

The lightbulbs L2, L3, L4, L5 are the turn signal indicators with the dashboard–light L6. When switch S1 is closed, after a time delay of t_1 (in our example t_1 = 75 ms), the relay will be actuated. The corresponding lightbulbs (L2, L3 or L4, L5) will flash at the oscillator frequency, independent of the battery voltage of 8.0 V to 18 V. The flashing cycle stops and the circuit is reset to the initial position when switch S1 is open.

Overvoltage Detection

Senses the battery voltage. When this voltage exceeds 20.2 V (this is the case when two batteries are connected in series), the relay will be turned off to protect the lightbulbs.

Lightbulb Defect Detector

Senses the current through the shunt resistor R_S. When one of the lightbulbs is defective, the failure is indicated by doubling the flashing frequency.

Short Circuit Detector

Detects excessive current (I_{sh} > 25 A) flowing in the shunt resistor R_S. The detection takes place after a time delay of t_3 (t_3 = 55 ms). In this case, the relay will be turned off. The circuit is reset by switching S1 to the off position.

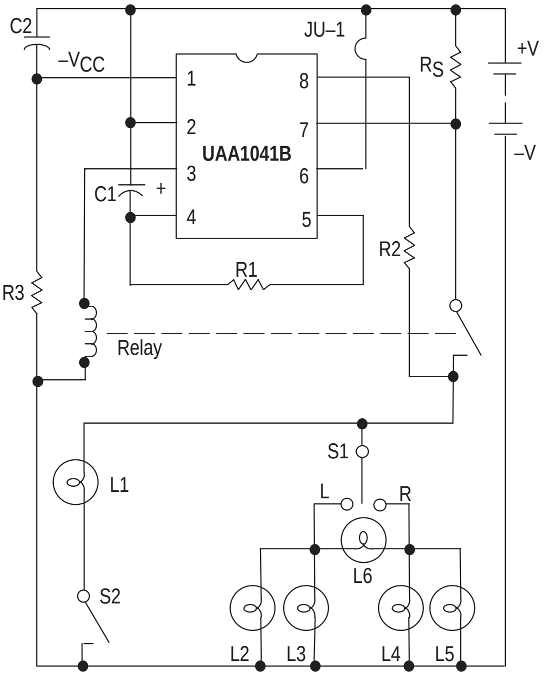
Operation with Short Circuit Detection

Pin 6 has to be left open and a capacitor C_2 has to be connected between Pin 1 and Pin 2.

Operation without Short Circuit Detection

Pin 6 has to be connected to Pin 2, and the use of capacitor C_2 is not necessary. The circuit can also be used for other warning flashers. In this example, when the handbrake is engaged, it is signaled by the light (L1).

Figure 2. Typical System Configuration



PARTS LIST

R1 = 75 kΩ
R2 = 3.3 kΩ
R3 = 220 Ω
R_S = 30 mΩ
Wire Resistor
C1 = 5.6 µF
C2 = 0.047 µF

Relay–Coil Resistance
Range 60 Ω to 800 Ω

Note: Per text connect
jumper JU–1 bypass
short circuit detector
C2 may be deleted also.

APPLICATION INFORMATION

1. The flashing cycle is started by closing S1. The switch position is sensed across resistor R_2 and R_{Lamp} by Input 8.

   $$R_{st} = R_2 + R_{Lamp}.$$

   The condition for the start is: R_{st} < 3.6 kΩ.
   For correct operation, leakage resistance from Pin 8 to ground must be greater than 5.6 kΩ.

2. Flashing frequency: $f_n = \dfrac{1}{R_1C_1K_n}$

3. Flashing frequency in the case of one defective lightbulb of 21 W:

   $$f_F = \frac{1}{R_1C_1K_F} \quad K_n = 2{,}2K_F$$

4. t_1: delay at the moment when S1 is closed and first flash
   $t_1 = K_1R_1C$
5. t_2: defective lightbulb detection delay $t_2 = K_2R_1C_1$
6. t_3: short circuit detection delay $t_3 = K_1R_1C_1$
   In the case of short circuit – it is assumed that the voltage (V_{Pin2}–V_{Pin1}) ≥ 8.0 V. The relay will be turned off after delay t_3. The circuit is reset by switching S1 to the off position.
7. The capacitor C2 is not obligatory when the short circuit detector is not used. In this case Pin 6 has to be connected to Pin 2.
8. When overvoltage is sensed (V_{Pin2} – V_{Pin1}) the relay is turned off to protect the relay and the lightbulbs against excessive currents.

Other Analog Circuits

In Brief . . .

Other analog circuits are provided for special applications with both bipolar and CMOS technologies. These circuits range from the industry standard analog timing circuits and multipliers to specialized CMOS smoke detectors. These products provide key functions in a wide range of applications, including data transmission, commercial smoke detectors, and various industrial controls.

Timing Circuits

These highly stable timers are capable of producing accurate time delays or oscillation. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor. For a stable operation as an oscillator, the free–running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor. The output structure can source or sink up to 200 mA or drive TTL circuits. Timing intervals from microseconds through hours can be obtained. Additional terminals are provided for triggering or resetting if desired.

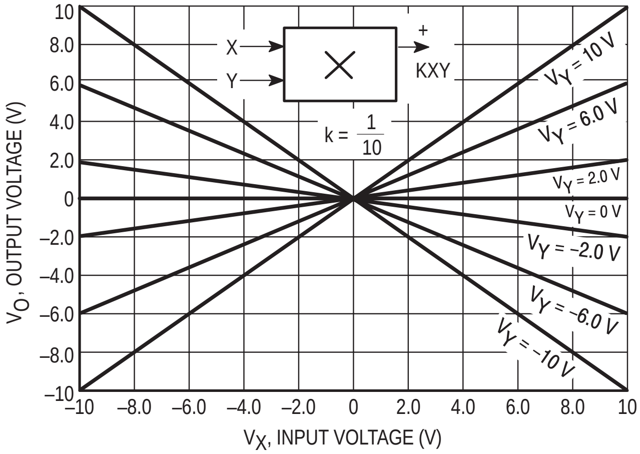
Multipliers

Linear Four–Quadrant Multipliers

Multipliers are designed for use where the output voltage is a linear product of two input voltages. Typical applications include: multiply, divide, square, root–mean–square, phase detector, frequency doubler, balanced modulator/demodulator, electronic gain control.

Multiplier Transfer Characteristics



MC1494P

T_A = 0° to +70°C, Case 648

This device has all the necessary internal regulation and references. The single–ended output is referenced to ground.

MC1495D, P

T_A = 0° to +70°C, Case 751A, 646

Maximum versatility is assured by allowing the user to select the level shift method.

MC1495BP

T_A = –40° to +125°C, Case 646

Linearity and offset are actually tested over temperature. This is an improved specification over previous versions.

Smoke Detectors (CMOS)

These smoke detector ICs require a minimum number of external components. When smoke is sensed, or a low battery voltage is detected, an alarm is sounded via an external piezoelectric transducer. All devices are designed to comply with UL specifications.

GENERAL OPERATION

The MC1455 is a monolithic timing circuit which uses an external resistor – capacitor network as its timing element. It can be used in both the monostable (one–shot) and astable modes with frequency and duty cycle controlled by the capacitor and resistor values. While the timing is dependent upon the external passive components, the monolithic circuit provides the starting circuit, voltage comparison and other functions needed for a complete timing circuit. Internal to the integrated circuit are two comparators, one for the input signal and the other for capacitor voltage; also a flip–flop and digital output are included. The comparator reference voltages are always a fixed ratio of the supply voltage thus providing output timing independent of supply voltage.

Monostable Mode

In the monostable mode, a capacitor and a single resistor are used for the timing network. Both the threshold terminal and the discharge transistor terminal are connected together in this mode (refer to circuit in Figure 14). When the input voltage to the trigger comparator falls below 1/3 V_{CC}, the comparator output triggers the flip–flop so that its output sets low. This turns the capacitor discharge transistor “off” and drives the digital output to the high state. This condition allows the capacitor to charge at an exponential rate which is set by the RC time constant. When the capacitor voltage reaches 2/3 V_{CC}, the threshold comparator resets the flip–flop. This action discharges the timing capacitor and returns the digital output to the low state. Once the flip–flop has been triggered by an input signal, it cannot be retriggered until the present timing period has been completed. The time that the output is high is given by the equation $t = 1.1\ R_A\ C$. Various combinations of R and C and their associated times are shown in Figure 16. The trigger pulse width must be less than the timing period.

A reset pin is provided to discharge the capacitor, thus interrupting the timing cycle. As long as the reset pin is low, the capacitor discharge transistor is turned “on” and prevents the capacitor from charging. While the reset voltage is applied the digital output will remain the same. The reset pin should be tied to the supply voltage when not in use.

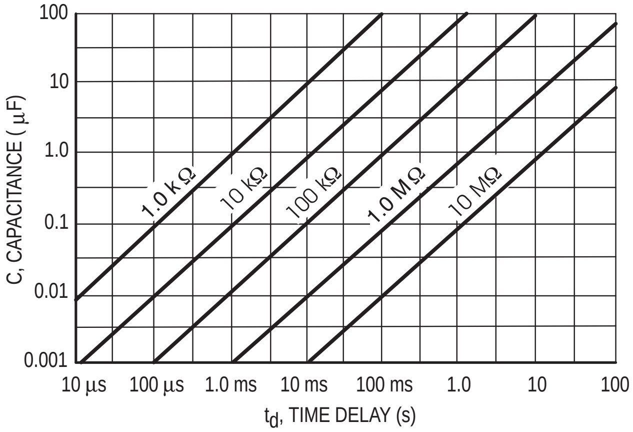

Figure 17. Astable Circuit

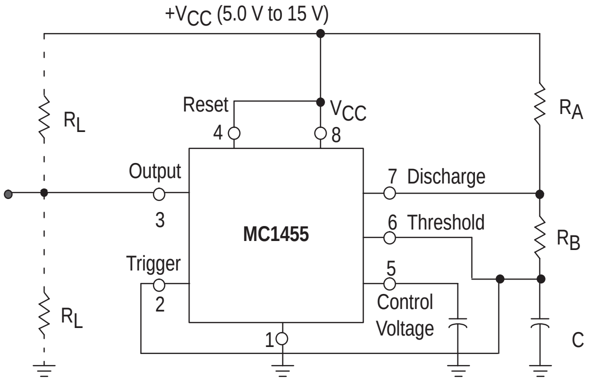

Figure 18. Astable Waveforms

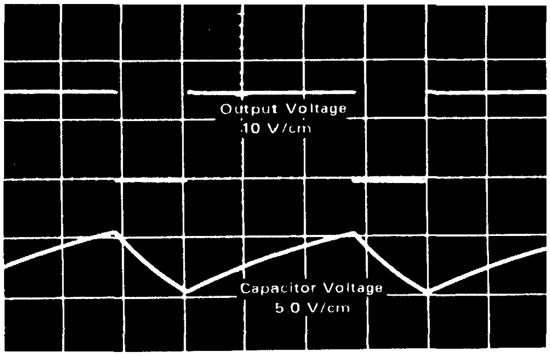


t = 20 µs/cm
(R_A = 5.1 kΩ, C = 0.01 µF, R_L = 1.0 kΩ; R_B = 3.9 kΩ, V_{CC} = 15 V)

Astable Mode

In the astable mode the timer is connected so that it will retrigger itself and cause the capacitor voltage to oscillate between 1/3 V_{CC} and 2/3 V_{CC}. See Figure 17.

The external capacitor changes to 2/3 V_{CC} through R_A and R_B and discharges to 1/3 V_{CC} through R_B. By varying the ratio of these resistors the duty cycle can be varied. The charge and discharge times are independent of the supply voltage.

The charge time (output high) is given by:

$$t_1 = 0.695\ (R_A + R_B)\ C$$

The discharge time (output low) is given by:

$$t_2 = 0.695\ (R_B)\ C$$

Thus the total period is given by:

$$T = t_1 + t_2 = 0.695\ (R_A + 2R_B)\ C$$

The frequency of oscillation is then: $f = \frac{1}{T} = \frac{1.44}{(R_A + 2R_B)\ C}$

and may be easily found as shown in Figure 19.

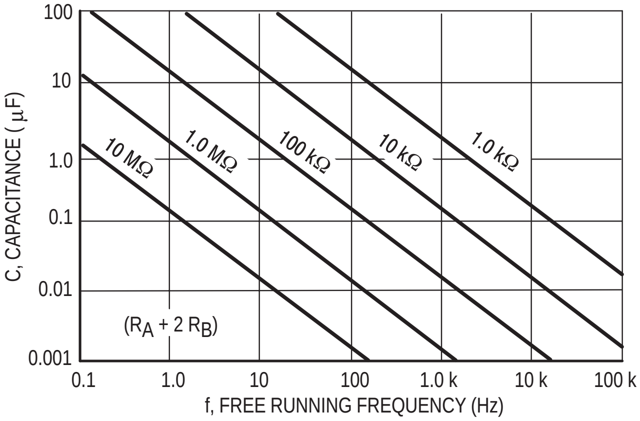
The duty cycle is given by: $DC = \frac{R_B}{R_A + 2R_B}$

To obtain the maximum duty cycle R_A must be as small as possible; but it must also be large enough to limit the discharge current (Pin 7 current) within the maximum rating of the discharge transistor (200 mA).

The minimum value of R_A is given by:

$$R_A \geq \frac{V_{CC}\ (\text{Vdc})}{I7\ (\text{A})} \geq \frac{V_{CC}\ (\text{Vdc})}{0.2}$$

Figure 19. Free Running Frequency



APPLICATIONS INFORMATION

Linear Voltage Ramp

In the monostable mode, the resistor can be replaced by a constant current source to provide a linear ramp voltage. The capacitor still charges from 0 V_{CC} to 2/3 V_{CC}. The linear ramp time is given by:

$$t = \frac{2}{3}\,\frac{V_{CC}}{1}, \quad \text{where } I = \frac{V_{CC} - V_B - V_{BE}}{R_E}$$

If V_B is much larger than V_{BE}, then t can be made independent of V_{CC}.

Missing Pulse Detector

The timer can be used to produce an output when an input pulse fails to occur within the delay of the timer. To accomplish this, set the time delay to be slightly longer than the time between successive input pulses. The timing cycle is then continuously reset by the input pulse train until a change in frequency or a missing pulse allows completion of the timing cycle, causing a change in the output level.

Figure 20. Linear Voltage Sweep Circuit

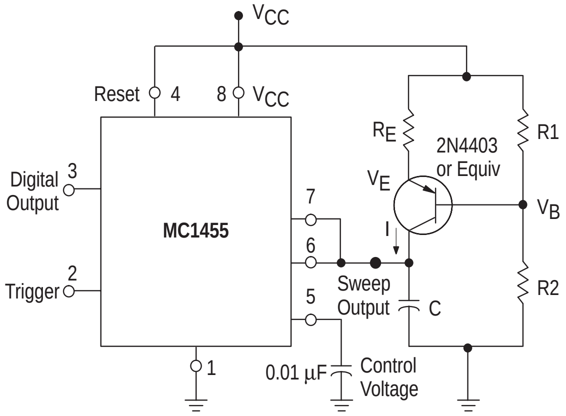


Figure 21. Missing Pulse Detector

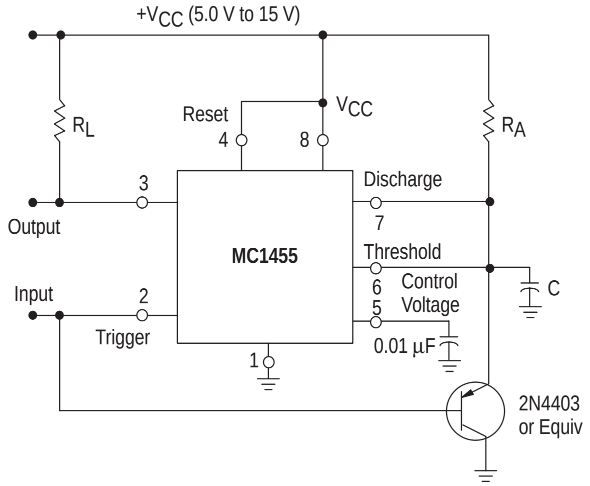

Figure 22. Linear Voltage Ramp Waveforms

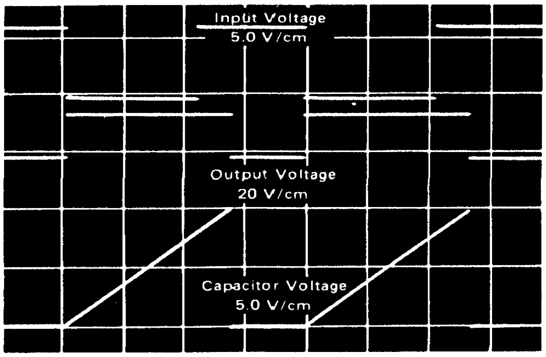
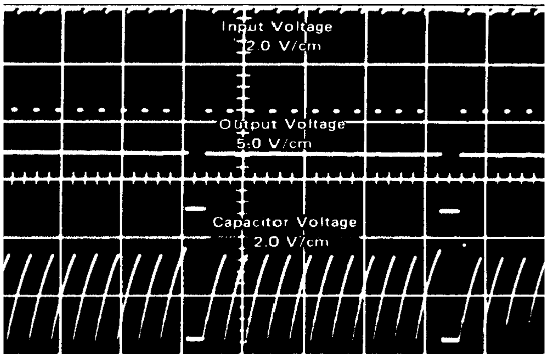


t = 100 µs/cm

(R_E = 10 kΩ, R2 = 100 kΩ, R1 = 39 kΩ, C = 0.01 µF, V_{CC} = 15 V)

Figure 23. Missing Pulse Detector Waveforms



t = 500 µs/cm

(R_A = 2.0 kΩ, R_L = 1.0 kΩ, C = 0.01 µF, V_{CC} = 15 V)

Pulse Width Modulation

If the timer is triggered with a continuous pulse train in the monstable mode of operation, the charge time of the capacitor can be varied by changing the control voltage at Pin 5. In this manner, the output pulse width can be modulated by applying a modulating signal that controls the threshold voltage.

Figure 24. Pulse Width Modulator

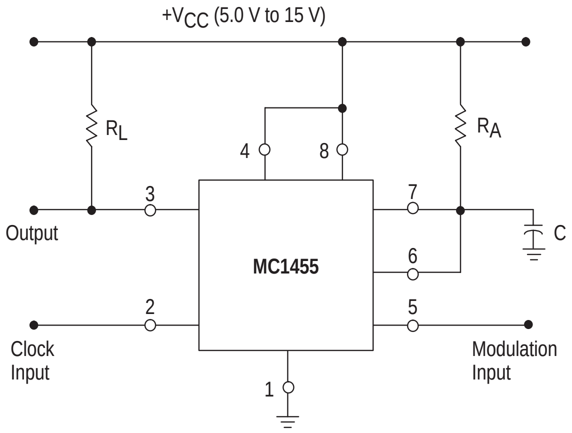


Figure 25. Pulse Width Modulation Waveforms

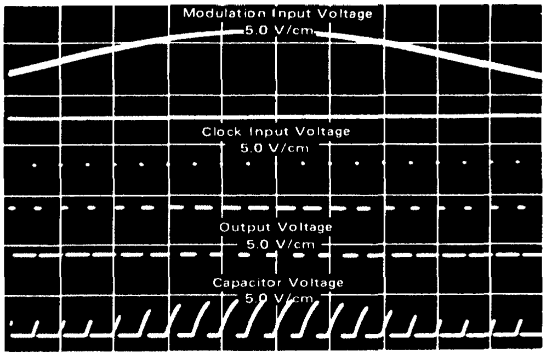
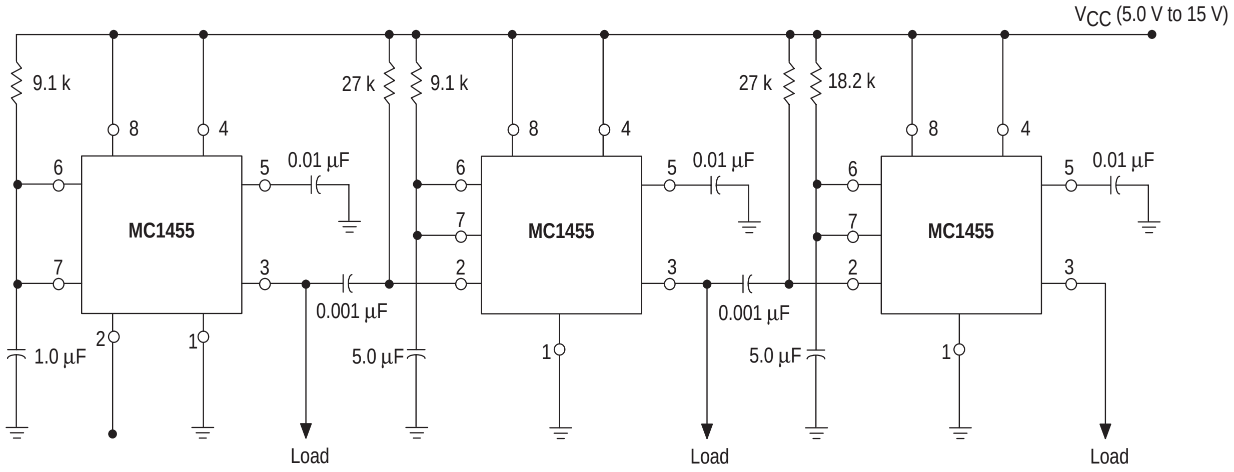


t = 0.5 ms/cm
(R_A = 10 kΩ, C = 0.02 µF, V_{CC} = 15 V)

Test Sequences

Several timers can be connected to drive each other for sequential timing. An example is shown in Figure 26 where the sequence is started by triggering the first timer which runs for 10 ms. The output then switches low momentarily and starts the second timer which runs for 50 ms and so forth.

Figure 26. Sequential Timer



MOTOROLA

MC1494

Linear Four-Quadrant Multiplier

The MC1494 is designed for use where the output voltage is a linear product of two input voltages. Typical applications include: multiply, divide, square root, mean square, phase detector, frequency doubler, balanced modulator/ demodulator, electronic gain control.

The MC1494 is a variable transconductance multiplier with internal level–shift circuitry and voltage regulator. Scale factor, input offsets and output offset are completely adjustable with the use of four external potentiometers. Two complementary regulated voltages are provided to simplify offset adjustment and improve power supply rejection.

- Operates with ±15 V Supplies
- Excellent Linearity: Maximum Error (X or Y) ±1.0 %
- Wide Input Voltage Range: ±10 V
- Adjustable Scale Factor, K (0.1 nominal)
- Single–Ended Output Referenced to Ground
- Simplified Offset Adjust Circuitry
- Frequency Response (3.0 dB Small–Signal): 1.0 MHz
- Power Supply Sensitivity: 30 mV/V typical

CIRCUIT DESCRIPTION

Introduction

The MC1494 is a monolithic, four–quadrant multiplier that operates on the principle of variable transconductance. It features a single–ended current output referenced to ground and provides two complementary regulated voltages for use with the offset adjust circuits to virtually eliminate sensitivity of the offset voltage nulls to changes in supply voltages.

As shown in Figure 17, the MC1494 consists of a multiplier proper and associated peripheral circuitry to provide these features.

Regulator

The regulator biases the entire MC1494 circuit making it essentially independent of supply variation. It also provides two convenient regulated supply voltages which can be used in the offset adjust circuitry. The regulated output voltage at Pin 2 is approximately + 4.3 V, while the regulated voltage at Pin 4 is approximately – 4.3 V. For optimum temperature stability of these regulated voltages, it is recommended that $|I_2| = |I_4| = 1.0$ mA (equivalent load of 8.6 kΩ). As will be shown later, there will normally be two 20 kΩ potentiometers and one 50 kΩ potentiometer connected between Pins 2 and 4.

The regulator also establishes a constant current reference that controls all of the constant current sources in the MC1494. Note that all current sources are related to current I_1 which is determined by R1. For best temperatures performance, R1 should be 16 kΩ so that $I_1 \approx 0.5$ mA for all applications.

Multiplier

The multiplier section of the MC1494 (center section of Figure 17) is nearly identical to the MC1495 and is discussed in detail in Application Note AN489, *Analysis and Basic Operation of the MC1495*. The result of this analysis is that the differential output current of the multiplier is given by:

$$I_A - I_B = \Delta I \approx \frac{2V_X\,V_Y}{R_X R_Y I_1}$$

Therefore, the output is proportional to the product of the two input voltages.

Differential Current Converter

This portion of the circuitry converts the differential output current ($I_A - I_B$) of the multiplier to a single–ended output current (I_O); $I_O = I_A - I_B$

$$\text{or} \quad I_O = \frac{2V_X\,V_Y}{R_X R_Y I_1}$$

The output current can be easily converted to an output voltage by placing a load resistor R_L from the output (Pin 14) to ground (Figure 19) or by using an op amp as a current–to–voltage converter (Figure 18). The result in both circuits is that the output voltage is given by:

$$V_O = \frac{2R_L\,V_X\,V_Y}{R_X R_Y I_1} = KV_X V_Y$$

$$\text{where, K (scale factor)} = \frac{2R_L}{R_X R_Y I_1}$$

DC OPERATION

Selection of External Components

For low frequency operation the circuit of Figure 18 is recommended. For this circuit, $R_X = 30$ kΩ, $R_Y = 62$ kΩ, R1 = 16 kΩ and, hence, $I_1 \approx 0.5$ mA. Therefore, to set the scale factor (K) equal to 1/10, the value of R_L can be calculated to be:

$$K = \frac{1}{10} = \frac{2R_L}{R_X R_Y I_1}$$

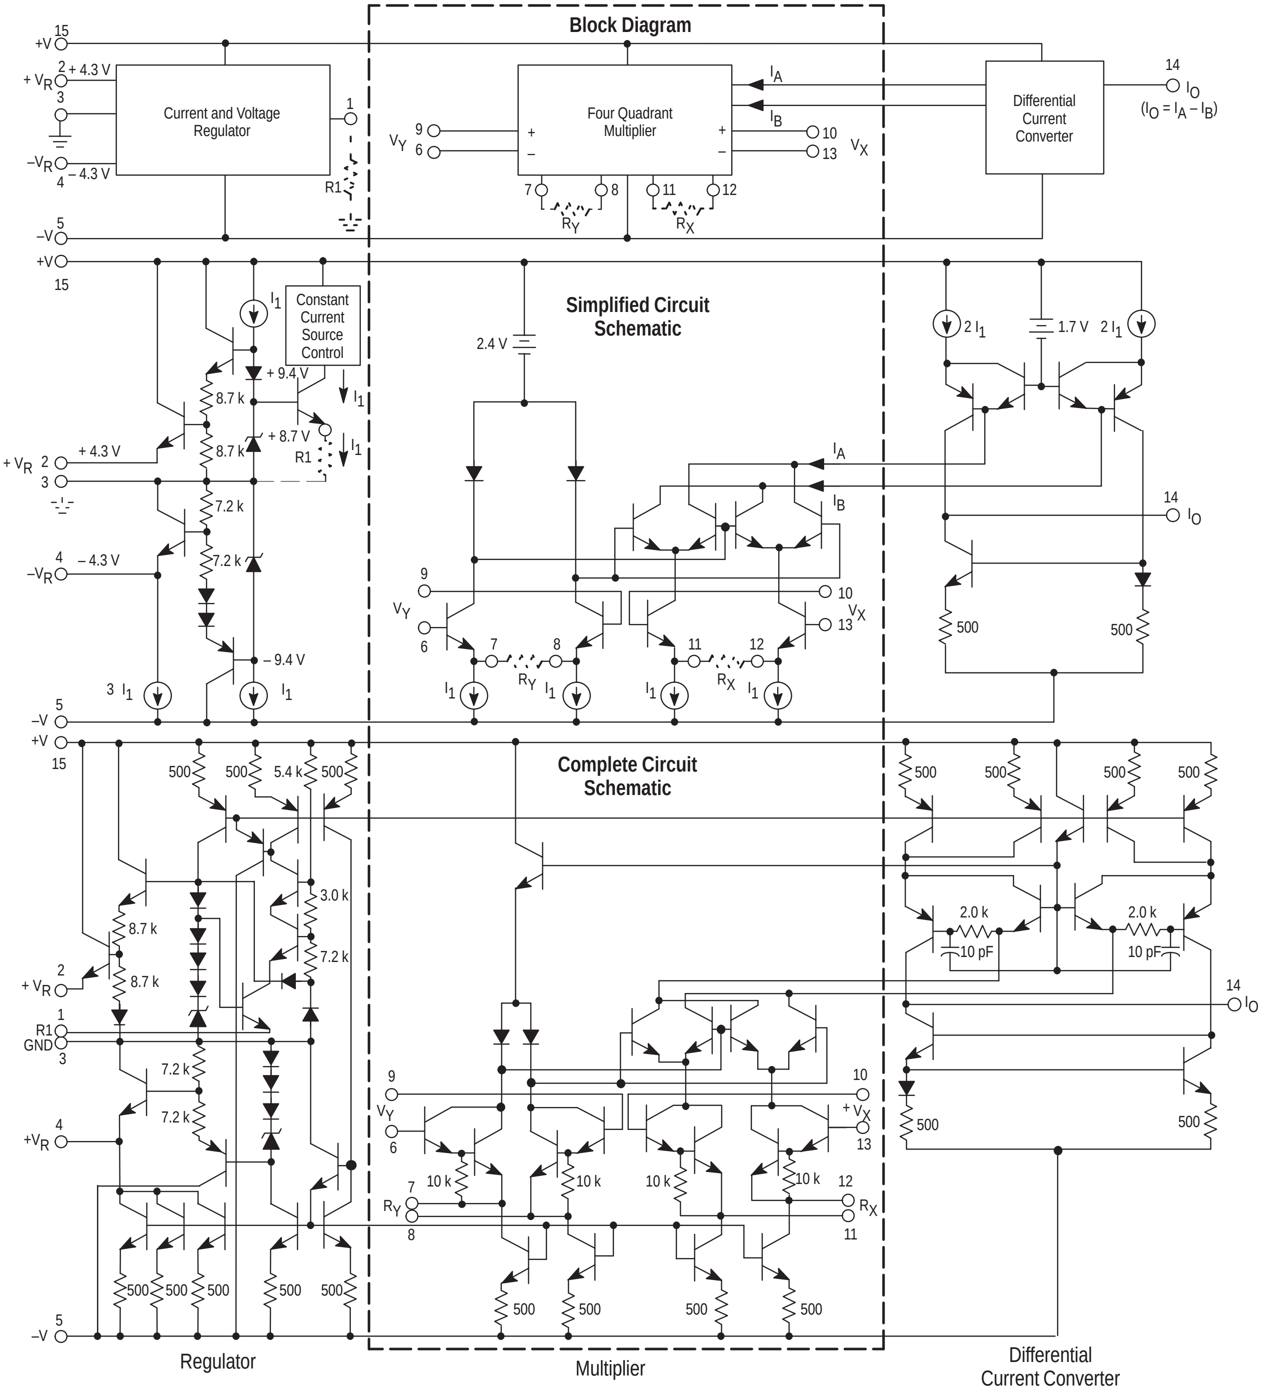
$$\text{or} \quad R_L = \frac{R_X R_Y I_1}{(2)\,(10)} = \frac{(30\text{ k})\,(62\text{ k})\,(0.5\text{ mA})}{20}$$

$$R_L = 46.5\text{ k}$$

Thus, a reasonable accuracy in scale factor can be achieved by making R_L a fixed 47 kΩ resistor. However, if it is desired that the scale factor be exact, R_L can be comprised of a fixed resistor and a potentiometer as shown in Figure 18.

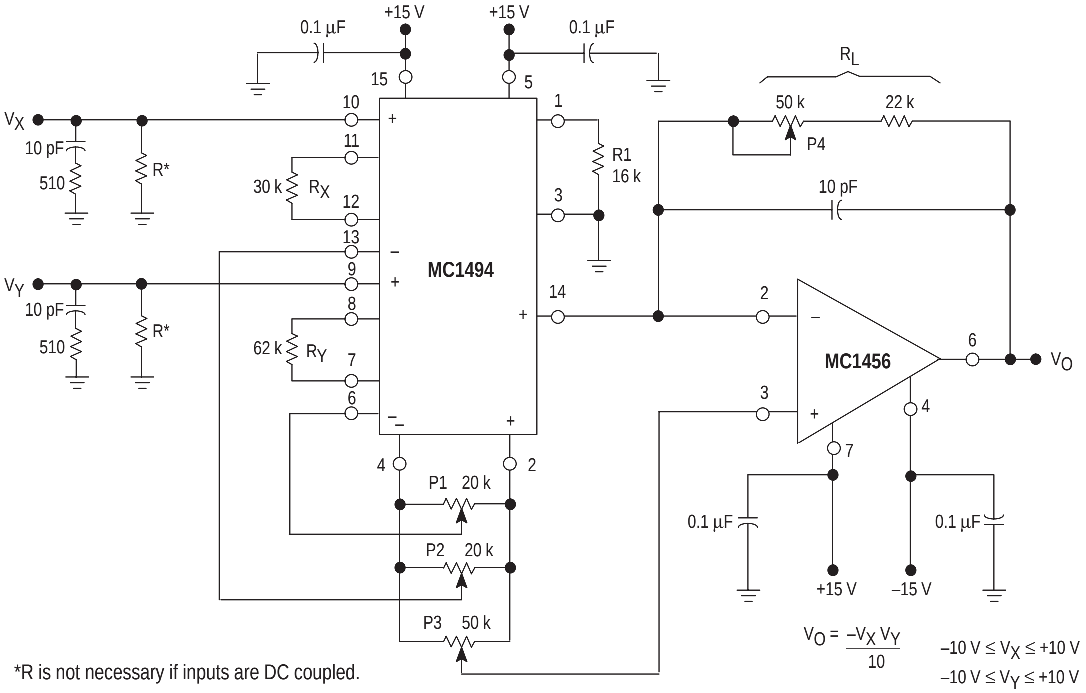
Figure 17. Internal Schematic

(Recommended External Circuitry is Depicted within Dotted Lines)



This device contains 44 active transistors.

Figure 18. Typical Multiplier Connection



*R is not necessary if inputs are DC coupled.

It should be pointed out that there is nothing magic about setting the scale factor to 1/10. This is merely a convenient factor to use if the V_X and V_Y input voltages are expected to be large, say ±10 V. Obviously with $V_X = V_Y = 10$ V and a scale factor of unity, the device could not hope to provide a 100 V output, so the scale factor is set to 1/10 and provides an output scaled down by a factor of ten. For many applications it may be desirable to set K = 1/2 or K = 1 or even K = 100. This can be accomplished by adjusting R_X, R_Y and R_L appropriately.

The selection of R_L is arbitrary and can be chosen after resistors R_X and R_Y are found. Note in Figure 18 that R_Y is 62 kΩ while R_X is 30 kΩ. The reason for this is that the “Y” side of the multiplier exhibits a second order nonlinearity whereas the “X” side exhibits a simple nonlinearity. By making the R_Y resistor approximately twice the value of the R_X resistor, the linearity on both the “X” and “Y” sides are made equal. The selection of the R_X and R_Y resistor values is dependent upon the expected amplitude of V_X and V_Y inputs. To maintain a specified linearity, resistors R_X and R_Y should be selected according to the following equations:

$R_X \ge 3\ V_X$ (max) in kΩ when V_X is in Volts,
$R_Y \ge 6\ V_Y$ (max) in kΩ when V_Y is in Volts.

For example, if the maximum input on the “X” side is ±1.0 V, resistor R_X can be selected to be 3.0 kΩ. If the maximum input on the “Y” side is also ±1.0 V, then resistor R_Y can be selected to be 6.0 kΩ (6.2 kΩ nominal value). If a scale factor of K = 10 is desired, the load resistor is found to be 47 kΩ. In this example, the multiplier provides a gain of 20 dB.

Operational Amplifier Selection

The operational amplifier connection in Figure 18 is a simple but extremely accurate current–to–voltage converter. The output current of the multiplier flows through the feedback resistor R_L to provide a low impedance output voltage from the op amp. Since the offset current and bias currents of the op amp will cause errors in the output voltage, particularly with temperature, one with very low bias and offset currents is recommended. The MC1456 or MC1741 are excellent choices for this application.

Since the MC1494 is capable of operation at much higher frequencies than the op amp, the frequency characteristics of the circuit in Figure 18 will be primarily dependent upon the operational amplifier.

Stability

The current–to–voltage converter mode is a most demanding application for an operational amplifier. Loop gain is at its maximum and the feedback resistor in conjunction with stray or input capacitance at the multiplier output adds additional phase shift. It may therefore be necessary to add (particularly in the case of internally compensated op amps) a small feedback capacitor to reduce loop gain at the higher frequencies. A value of 10 pF in parallel with R_L should be adequate to insure stability over production and temperature variations, etc.

An externally compensated op amp might be employed using slightly heavier compensation than that recommended for unity–gain operation.

Offset Adjustment

The noninverting input of the op amp provides a convenient point to adjust the output offset voltage. By connecting this point to the wiper arm of a potentiometer (P3), the output offset voltage can be adjusted to zero (see Offset and Scale Factor Adjustment Procedure).

The input offset adjustment potentiometers, P1 and P2 will be necessary for most applications where it is desirable to take advantage of the multiplier’s excellent linearity characteristics. Depending upon the particular application, some of the potentiometers can be omitted (see Figures 19, 21, 24, 26 and 27).

Offset and Scale Factor Adjustment Procedure

The adjustment procedure for the circuit of Figure 18 is:

A. X Input Offset
   1. Connect oscillator (1.0 kHz, 5.0 Vpp sinewave) to the ‘‘Y’’ input (Pin 9).
   2. Connect ‘‘X’’ input (Pin 10) to ground.
   3. Adjust X–offset potentiometer, P2 for an AC null at the output.

B. Y Input Offset
   1. Connect oscillator (1.0 kHz, 5.0 Vpp sinewave) to the ‘‘X’’ input (Pin 10).
   2. Connect ‘‘Y’’ input (Pin 9) to ground.
   3. Adjust Y–offset potentiometer, P1 for an AC null at the output.

C. Output Offset
   1. Connect both ‘‘X’’ and ‘‘Y’’ inputs to ground.
   2. Adjust output offset potentiometer, P3 until the output voltage V_O is 0 Vdc.

D. Scale Factor
   1. Apply +10 Vdc to both the ‘‘X’’ and ‘‘Y’’ inputs.
   2. Adjust P4 to achieve –10 V at the output.
   3. Apply –10 Vdc to both ‘‘X’’ and ‘‘Y’’ inputs and check for V_O = –10 V.

E. Repeat steps A through D as necessary.

The ability to accurately adjust the MC1494 is dependent on the offset adjust potentiometers. Potentiometers should be of the “infinite” resolution type rather than wirewound. Fine adjustments in balanced–modulator applications may require two potentiometers to provide “coarse” and “fine” adjustment. Potentiometers should have low temperature coefficients and be free from backlash.

Temperature Stability

While the MC1494 provides excellent performance in itself, overall performance depends to a large degree on the quality of the external components. Previous discussion shows the direct dependence on R_X, R_Y and R_L and indirect dependence on R1 (through I_1). *Any circuit subjected to temperature variations should be evaluated with these effects in mind.*

Bias Currents

The MC1494 multiplier, like most linear ICs, requires a DC bias current into its input terminals. The device cannot be capacitively coupled at the input without regard for this bias current. If inputs V_X and V_Y are able to supply the small bias current (≈ 0.5 µA) resistors R can be omitted (see Figure 18). If the MC1494 is used in an AC mode of operation and capacitive coupling is used the value of resistor R can be any reasonable value up to 100 kΩ. For minimum noise and optimum temperature performance, the value of resistor R should be as low as practical.

Parasitic Oscillation

When long leads are used on the inputs, oscillation may occur. In this event, an RC parasitic suppression network similar to the ones shown in Figure 18 should be connected directly to each input using short leads. The purpose of the network is to reduce the “Q” of the source–tuned circuits which cause the oscillation.

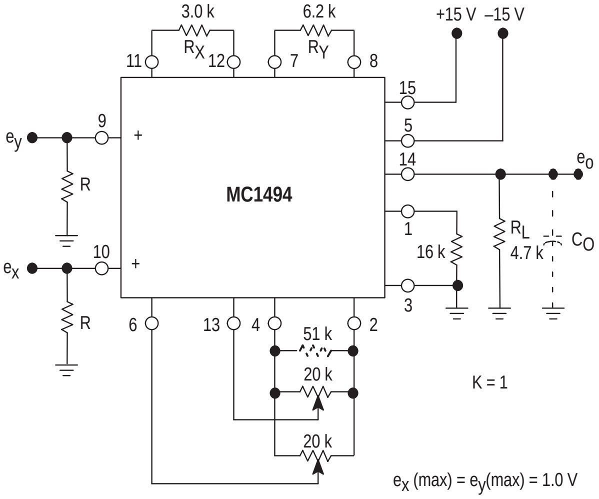
Inability to adjust the circuit to within the specified accuracy may be an indication of oscillation.

AC OPERATION

General

For AC operation, such as balanced modulation, frequency doubler, AGC, etc., the op amp will usually be omitted as well as the output offset adjust potentiometer. The output offset adjust potentiometer is omitted since the output will normally be AC coupled and the DC voltage at the output is of no concern providing it is close enough to zero volts that it will not cause clipping in the output waveform. Figure 19 shows a typical AC multiplier circuit with a scale factor K ≈ 1. Again, resistor R_X and R_Y are chosen as outlined in the previous section, with R_L chosen to provide the required scale factor.

Figure 19. Wideband Multiplier



The offset voltage then existing at the output will be equal to the offset current times the load resistance. The output offset current of the MC1494 is typically 17 µA and 35 µA maximum. Thus, the maximum output offset would be about 160 mV.

Bandwidth

The bandwidth of the MC1494 is primarily determined by two factors. First, the dominant pole will be determined by the load resistor and the stray capacitance at the output terminal. For the circuit shown in Figure 19, assuming a total output capacitance (C_O) of 10 pF, the 3.0 dB bandwidth would be approximately 3.4 MHz. If the load resistor were 47 kΩ, the bandwidth would be approximately 340 kHz.

Secondly, a “zero” is present in the frequency response characteristic for both the “X” and “Y” inputs which causes the output signal to rise in amplitude at a 6.0 dB/octave slope at frequencies beyond the breakpoint of the “zero”. The “zero” is caused by the parasitic and substrate capacitance which is related to resistors R_X and R_Y and the transistors associated with them. The effect of these transmission “zeros” is seen in Figures 11 and 12. The reason for this increase in gain is due to the bypassing of R_X and R_Y at high frequencies. Since the R_Y resistor is approximately twice the value of the R_X resistor, the zero associated with the “Y” input will occur at approximately one octave below the zero associated with “X” input. For R_X = 30 kΩ and R_Y = 62 kΩ, the zeros occur at 1.5 MHz for the “X” input and 700 kHz for the “Y” input. These two measured breakpoints correspond to a shunt capacitance of about 3.5 pF. Thus, for the circuit of

Figure 19, the “X” input zero and “Y” input zero will be at approximately 15 MHz and 7.0 MHz respectively.

It should be noted that the MC1494 multiplies in the time domain, hence, its frequency response is found by means of complex convolution in the frequency (Laplace) domain. This means that if the “X” input does not involve a frequency, it is not necessary to consider the “X” side frequency response in the output product. Likewise, for the “Y” side. Thus, for applications such as a wideband linear AGC amplifier which has a DC voltage as one input, the multiplier frequency response has one zero and one pole. For applications which involve an AC voltage on both the “X” and “Y” side such as a balanced modulator, the product voltage response will have two zeros and one pole, hence, peaking may be present in the output.

From this brief discussion, it is evident that for AC applications; (1) the value of resistors R_X, R_Y and R_L should be kept as small as possible to achieve maximum frequency response, and (2) it is possible to select a load resistor R_L such that the dominant pole (R_L, C_O) cancels the input zero (R_X, 3.5 pF or R_Y, 3.5 pF) to give a flat amplitude characteristic with frequency. This is shown in Figures 11 and 12. Examination of the frequency characteristics of the “X” and “Y” inputs will demonstrate that for wideband amplifier applications, the best tradeoff with frequency response and gain is achieved by using the “Y” input for the AC signal.

For AC applications requiring bandwidths greater than those specified for the MC1494, two other devices are recommended. For modulator–demodulator applications, the MC1496 may be used up to 100 MHz. For wideband multiplier applications, the MC1495 (using small collector loads and AC coupling) can be used.

Slew–Rate

The MC1494 multiplier is not slew–rate limited in the ordinary sense that an op amp is. Since all the signals in the multiplier are currents and not voltages, there is no charging and discharging of stray capacitors and thus no limitations beyond the normal device limitataions. However, it should be noted that the quiescent current in the output transistors is 0.5 mA and thus the maximum rate of change of the output voltage is limited by the output load capacitance by the simple equation:

$$\text{Slew Rate } \frac{\Delta V_O}{\Delta T} = \frac{I_O}{C}$$

Thus, if C_O is 10 pF, the maximum slew rate would be:

$$\frac{\Delta V_O}{\Delta T} = \frac{0.5 \times 10^{-3}}{10 \times 10^{-12}} = 50\ \text{V}/\mu\text{s}$$

This can be improved, if necessary, by the addition of an emitter–follower or other type of buffer.

Phase Vector Error

All multipliers are subject to an error which is known as the phase vector error. This error is a phase error only and does not contribute an amplitude error per se. The phase vector error is best explained by an example. If the “X” input is described in vector notation as;

$$X = A \measuredangle 0^\circ$$

and the “Y” input is described as;

$$Y = B \measuredangle 0^\circ$$

then the output product would be expected to be;

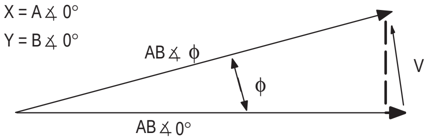
$$V_O = AB \measuredangle 0^\circ \text{ (see Figure 20)}$$

However, due to a relative phase shift between the ‘‘X’’ and ‘‘Y’’ channels, the output product will be given by:

$$V_O = AB \measuredangle \phi$$

Notice that the magnitude is correct but the phase angle of the product is in error. The vector (V) associated with this error is the ‘‘phase vector error’’. The startling fact about the phase vector error is that it occurs and accumulates much more rapidly than the amplitude error associated with frequency response. In fact, a relative phase shift of only 0.57° will result in a 1% phase vector error. For most applications, this error is meaningless. If phase of the output product is not important, then neither is the phase vector error. If phase is important, such as in the case of double sideband modulation or demodulation, then a 1% phase vector error will represent a 1% amplitude error a the phase angle of interest.

Figure 20. Phase Vector Error



Circuit Layout

If wideband operation is desired, careful circuit layout must be observed. Stray capacitance across R_X and R_Y should be avoided to minimize peaking (caused by a zero created by the parallel RC circuit).

DC APPLICATIONS

Squaring Circuit

If the two inputs are connected together, the resultant function is squaring:

$$V_O = KV^2$$

where K is the scale factor (see Figure 21).

However, a more careful look at the multiplier’s defining equation will provide some useful information. The output voltage, without initial offset adjustments is given by:

$$V_O = K(V_X + V_{iox} - V_{X\ off})\ (V_Y + V_{ioy} - V_{Y\ off}) + V_{OO}$$

(Refer to “Definitions” section for an explanation of terms.)

With $V_X = V_Y = V$ (squaring) and defining;

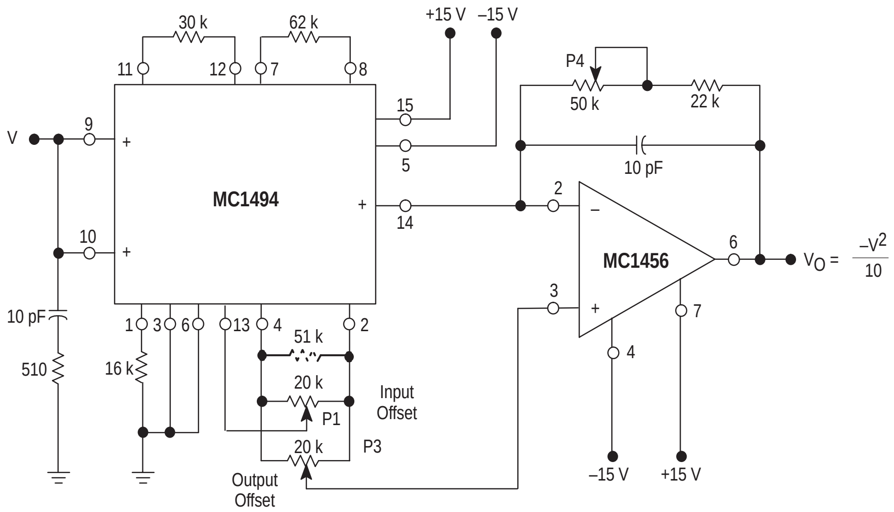
$$\in_x = V_{iox} - V_x \text{ (off)}$$

$$\in_y = V_{ioy} - V_y \text{ (off)}$$

The output voltage equation becomes:

$$V_O = KV_x^2 + KV_x\ (\in_x + \in_y) + K\in_x \in_y + V_{OO}$$

Figure 21. MC1494 Squaring Circuit



This shows that all error terms can be eliminated with only three adjustment potentiometers, eliminating one of the input offset adjustments. For instance, if the "X" input offset adjustment is eliminated, $\in_X$ is determined by the internal offset (V_{ioX}) but $\in_Y$ is adjustable to the extent that the ($\in_X + \in_Y$) term can be zeroed. Then the output offset adjustment is used to adjust the V_{OO} term and thus zero the remaining error terms. An AC procedure for nulling with three adjustments is:

A. AC Procedure:
   1. Connect oscillator (1.0 kHz, 15 Vpp) to input.
   2. Monitor output at 2.0 kHz with tuned voltmeter and adjust P4 for desired gain (Be sure to peak response of voltmeter).
   3. Tune voltmeter to 1.0 kHz and adjust P1 for a minimum output voltage.
   4. Ground input and adjust P3 (output offset) for 0 Vdc out.
   5. Repeat steps 1 through 4 as necessary.

B. DC Procedure:
   1. Set $V_X = V_Y = 0$ V and adjust P3 (output offset potentiometer) such that $V_O = 0$ Vdc.
   2. Set $V_X = V_Y = 1.0$ V and adjust P1 (Y input offset potentiometer) such that the output voltage is – 0.100 V.
   3. Set $V_X = V_Y = 10$ Vdc and adjust P4 (load resistor) such that the output voltage is –10 V.
   4. Set $V_X = V_Y = -10$ Vdc and check that $V_O = -10$ V.
   5. Repeat steps 1 through 4 as necessary.

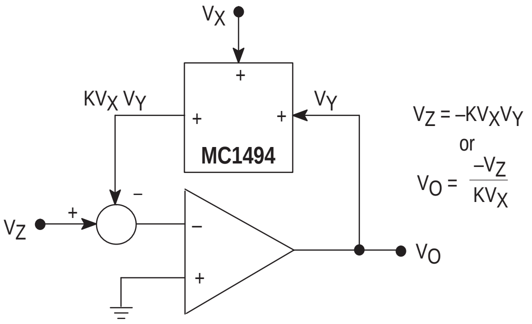
Divide

Divide circuits warrant a special discussion as a result of their special problems. Classic feedback theory teaches that if a multiplier is used as a feedback element in an operational amplifier circuit, the divide function results. Figure 22 illustrates the theoretical simplicity of such an approach and a practical realization is shown in Figure 23.

The characteristic "failure" mode of the divide circuit is latch–up. One way it can occur is if V_X is allowed to go negative, or in some cases, if V_X approaches zero.

Figure 22 illustrates why this is so. For $V_X > 0$ the transfer function through the multiplier is noninverting. Its output is fed to the inverting input of the op amp Thus, operation is in the negative feedback mode and the circuit is DC stable.

Figure 22. Basic Divide Circuit Using Multiplier

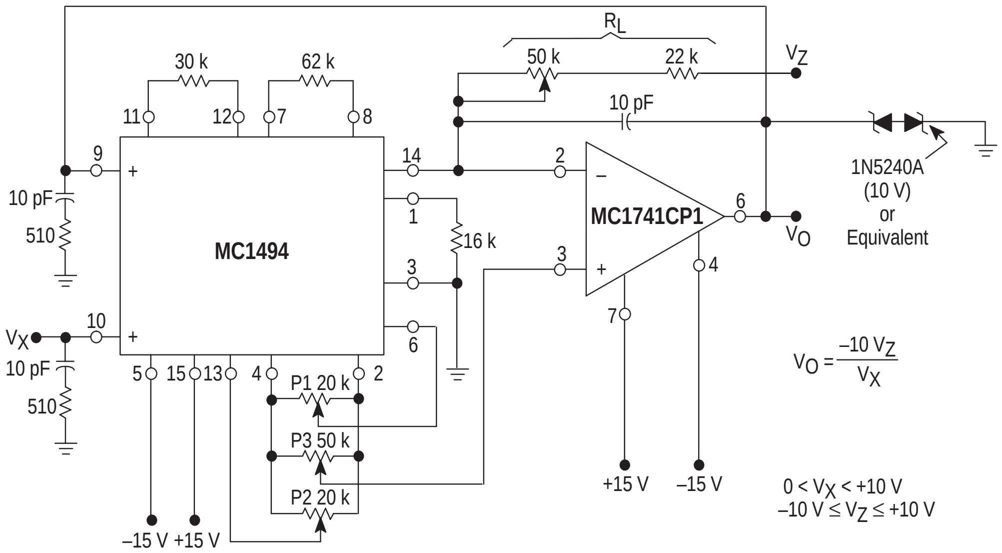


Should V_X change polarity, the transfer function through the multiplier becomes inverting, the amplifier has positive feedback and latch–up results. The problem resulting from V_X being near zero is a result of the transfer through the multiplier being near zero. The op amp is then operating with a very high closed–loop gain and error voltages can thus become effective in causing latch–up.

The other mode of latch–up results from the output voltage of the op amp exceeding the rated common mode input voltage of the multiplier. The input stage of the multiplier becomes saturated, phase reversal results, and the circuit is latched up. The circuit of Figure 23 protects against this happening by clamping the output swing of the op amp to approximately ± 10.7 V. Five percent tolerance, 10 V zeners are used to assure adequate output swing but still limit the output voltage of the op amp from exceeding the common mode input range of the MC1494.

Setting up the divide circuit for reasonably accurate operation is somewhat different from the procedure for the multiplier itself. One approach, however, is to break the feedback loop, null out the multiplier circuit, and then close the loop.

Figure 23. Practical Divide Circuit



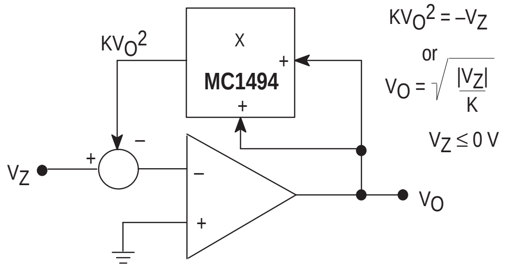
A simpler approach, since it does not involve breaking the loop (thus making it more practical on a production basis), is:

1. Set V_Z = 0 V and adjust the output offset potentiometer (P3) until the output voltage (V_O) remains at some (not necessarily zero) constant value as V_X is varied between +1.0 V and +10 V.
2. Maintain V_Z at 0 V, set V_X at +10 V and adjust the Y input offset potentiometer (P1) until V_O = 0 V.
3. With $V_X = V_Z$, adjust the X input offset potentiometer (P2) until the output voltage remains at some (not necessarily –10 V) constant value as $V_Z = V_X$ is varied between +1.0 V and +10 V.
4. Maintain $V_X = V_Z$ and adjust the scale factor potentiometer (R_L) until the average value of V_O is –10 V as $V_Z = V_X$ is varied between +1.0 V and +10 V.
5. Repeat steps 1 through 4 as necessary to achieve optimum performance.

Users of the divide circuit should be aware that the accuracy to be expected decreases in direct proportion to the denominator voltage. As a result, if V_X is set to 10 V and 0.5% accuracy is available, then 5% accuracy can be expected when V_X is only 1.0 V.

In accordance with an earlier statement, V_X may have only one polarity (positive) while V_Z may be either polarity.

Figure 24. Basic Square Root Circuit



Square Root

A special case of the divide circuit in which the two inputs to the multiplier are connected together results in the square root function as indicated in Figure 24. This circuit too may suffer from latch–up problems similar to those of the divide circuit. Note that only one polarity of input is allowed and diode clamping (see Figure 25) protects against accidental latch–up.

This circuit too, may be adjusted in the closed–loop mode:

1. Set V_Z = –0.01 Vdc and adjust P3 (output offset) for V_O = 0.316 Vdc.
2. Set V_Z to –0.9 Vdc and adjust P2 (“X” adjust) for V_O = +3.0 Vdc.
3. Set V_Z to –10 Vdc and adjust P4 (gain adjust) for V_O = +10 Vdc.
4. Steps 1 through 3 may be repeated as necessary to achieve desired accuracy.

NOTE: Operation near 0 V input may prove very inaccurate, hence, it may not be possible to adjust V_O to zero but rather only to within 100 mV to 400 mV of zero.

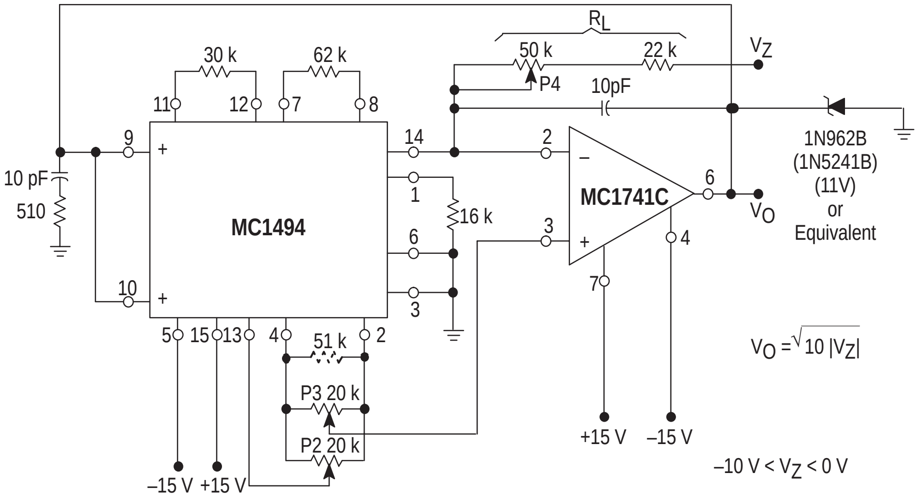
AC APPLICATIONS

Wideband Amplifier with Linear AGC

If one input to the MC1494 is a DC voltage and a signal voltage is applied to the other input, the amplitude of the output signal can be controlled in a linear fashion by varying the DC voltage. Hence, the multiplier can function as a DC coupled, wideband amplifier with linear AGC control.

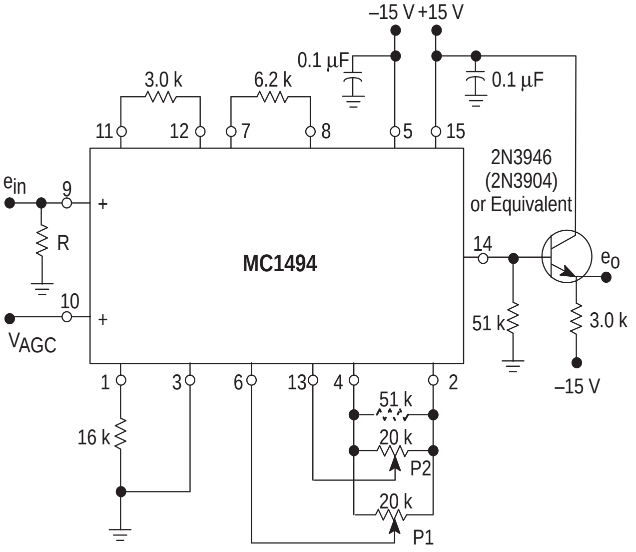
In addition to the advantage of linear AGC control, the multiplier has three other distinct advantages over most other types of AGC systems. First, the AGC dynamic range is theoretically infinite. This stems from the basic fact that with 0 Vdc applied to the AGC, the output will be zero regardless of the input. In practice, the dynamic range is limited by the ability to adjust the input offset adjust potentiometers. By using cermet multi–turn potentiometers, a dynamic range of 80 dB can be obtained. The second advantage of the multiplier is that variation of the AGC voltage has no effect on the signal handling capability of the signal port, nor does it alter the input impedance of the signal port. This feature is particularly important in AGC systems which are phase sensitive. A third advantage of the multiplier is that the output voltage swing capability and output impedance are unchanged with variations in AGC voltage.

Figure 25. Square Root Circuit



The circuit of Figure 26 demonstrates the linear AGC amplifier. The amplifier can handle 1.0 Vrms and exhibits a gain of approximately 20 dB. It is AGC'd through a 60 dB dynamic range with the application of an AGC voltage from 0 Vdc to 1.0 Vdc. The bandwidth of the amplifier is determined by the load resistor and output stray capacitance. For this reason, an emitter–follower buffer has been added to extend the bandwidth in excess of 1.0 MHz.

Figure 26. Wideband Amplifier with Linear AGC



Balanced Modulator

When two–time variant signals are used as inputs, the resulting output is suppressed–carrier double–sideband modulation. In terms of sinusoidal inputs, this can be seen in the following equation:

$$V_O = K(e_1 \cos\omega_m t)\,(e_2 \cos\omega_c t)$$

where ω_m is the modulation frequency and ω_c is the carrier frequency. This equation can be expanded to show the suppressed carrier or balanced modulation:

$$V_O = \frac{Ke_1e_2}{2}\,[\cos(\omega_c+\omega_m)\,t + \cos(\omega_c \pm \omega_m)t]$$

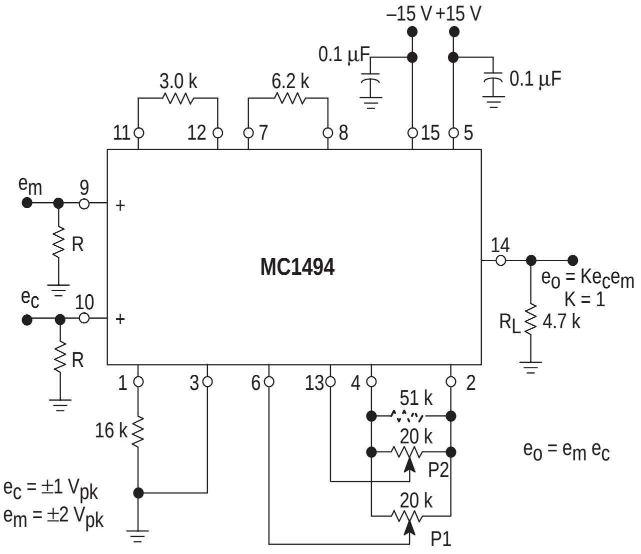
Unlike many modulation schemes, which are nonlinear in nature, the modulation which takes place when using the MC1494 is linear. This means that for two sinusoidal inputs, the output will contain only two frequencies, the sum and difference, as seen in the above equation. There will be no spectrum centered about the second harmonic of the carrier, or any multiple of the carrier. For this reason, the filter requirements of a modulation system are reduced to the minimum. Figure 27 shows the MC1494 configuration to perform this function.

Notice that the resistor values for R_X, R_Y and R_L have been modified. This has been done primarily to increase the bandwidth by lowering the output impedance of the MC1494 and then lowering R_X and R_Y to achieve a gain of 1. The e_c can be as large as 1.0 V peak and e_m as high as 2.0 V peak. No output offset adjust is employed since we are interested only in the AC output components.

The input reisstors (R) are used to supply bias current to the multiplier inputs as well as provide matching input impedance. The output frequency range of this configuration is determined by the 4.7 kΩ output impedance and capacitive loading. Assuming a 6.0 pF load, the small–signal bandwidth is 5.5 MHz.

The circuit of Figure 27 will provide at typical carrier rejection of ≥ 70 dB from 10 kHz to 1.5 MHz.

Figure 27. Balanced Modulator



The adjustment procedure for this circuit is quite simple.

1. Place the carrier signal at Pin 10. With no signal applied to Pin 9, adjust potentiometer P1 such that an AC null is obtained at the output.
2. Place a modulation signal at Pin 9. With no signal applied to Pin 10, adjust potentiometer P2 such that an AC null is obtained at the output.

Again, the ability to make careful adjustment of these offsets will be a function of the type of potentiometers used for P1 and P2. Multiple turn cermet type potentiometers are recommended.

Frequency Doubler

If for Figure 27 both inputs are identical:

$$e_m = e_c = E \cos\omega t$$

then the output is given by,

$$e_o = e_m e_c = E^2 \cos^2 \omega t$$

which reduces to,

$$e_o = \frac{E^2}{2}\,(1 + \cos 2\omega t)$$

This equation states that the output will consist of a DC term equal to one half the peak voltage squared and the second harmonic of the input frequency. Thus, the circuit acts as a frequency doubler. Two facts about this circuit are worthy of note. First, the second harmonic of the input frequency is the only frequency appearing at the output. The fundamental does not appear. Second, if the input is sinusoidal, the output will be sinusoidal and requires *no* filtering.

The circuit of Figure 27 can be used as a frequency doubler with input frequencies in excess of 2.0 MHz.

Amplitude Modulator

The circuit of Figure 27 is also easily used as an amplitude modulator. This is accomplished by simply varying the input offset adjust potentiometer (P1) associated with the mudulation input. This procedure places a DC offset on the modulation input of the multiplier such that the carrier still passes through the multiplier when the modulating signal is zero. The result is amplitude modulation. This is easily seen by examining the basic mathematical expression for amplitude modulation given below. For the case under discussion, with K = 1,

$$e_o = (E + E_m \cos\omega_m t)\,(E_c \cos\omega_c t)$$

where E is the DC input offset adjust voltage. This expression can be written as:

$$e_o = E_o\,[1 + M \cos\omega_c t] \cos\omega_c t$$

where, $E_o = EE_c$

$$\text{and,}\quad M = \frac{E_m}{E} = \text{modulation index.}$$

This is the standard equation for amplitude modulation. From this, it is easy to see that 100% modulation can be achieved by adjusting the input offset adjust voltage to be exactly equal to the peak value of the modulation (E_m). This is done by observing the output waveform and adjusting the input offset potentiometer (P1) until the output exhibits the familiar amplitude modulation waveform.

Phase Detector

If the circuit of Figure 27 has as its inputs two signals of identical frequency, but having a relative phase shift, the output will be a DC signal which is directly proportional to the cosine of phase difference as well as the double frequency term.

$$e_c = E_c \cos\omega_c t$$

$$e_m = E_m \cos(\omega_c t + \phi)$$

$$e_o = e_c e_m = E_c E_m \cos\omega_c t \cos(\omega_c t + \phi)$$

$$\text{or,}\quad e_o = \frac{E_c E_m}{2}\,[\cos\phi + \cos(2\omega_c t + \phi)]$$

The addition of a simple low pass filter to the output (which eliminates the second cosine term) and return of R_L to an offset adjustment potentiometer will result in a DC output voltage which is proportional to the cosine of the phase difference. Hence, the circuit functions as a synchronous detector.

DEFINITION OF SPECIFICATIONS

Because of the unique nature of a multiplier, i.e., two inputs and one output, operating specifications are difficult to define and interpret. Indeed the same specification may be defined in several completely different ways depending upon which manufacturer is doing the defining. In order to clear up some of the mystery, the following definitions and examples are presented.

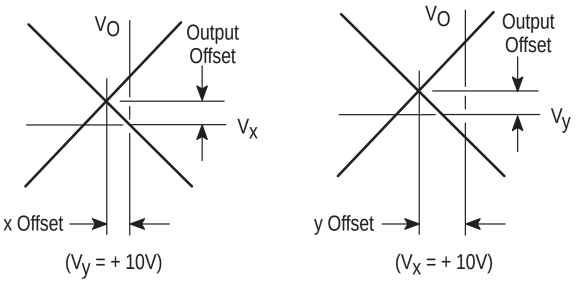
Multiplier Transfer Function – The output of the multiplier may be expressed by the following equation:

$$V_O = K[V_x \pm V_{iox} - V_{x(off)}]\ [V_y \pm V_{ioy} - V_{y(off)}] \pm V_{OO} \quad (1)$$

where, K = scale factor
V_x = “x” input voltage
V_y = “y” input voltage
V_{iox} = “x” input offset voltage
V_{ioy} = “y” input offset voltage
$V_{x(off)}$ = “x” input offset adjust voltage
$V_{y(off)}$ = “y” input offset adjust voltage
V_{OO} = output offset voltage

The voltage transfer characteristic below indicates x, y and output offset voltages.

Figure 28. Offset Voltages



Linearity – Linearity is defined to be the maximum deviation of output voltage from a straight line transfer function. It is expressed as a percentage of full–scale output and is measured for V_x and V_y separately, either using an X–Y plotter (and checking the deviation from a straight line) or by using the method shown in Figure 3. The latter method nulls the output signal with the input signal, resulting in distortion components proportional to the linearity.

Example: 0.35% linearity means

$$V_O = \frac{V_x\,V_y}{10} \pm (0.0035)(10\ V)$$

Input Offset Voltage – The input offset voltage is defined from Equation (1). It is measured for V_x and V_y separately and is defined to be that DC input offset adjust voltage (x or y) that will result in minimum AC output when AC (5.0 Vpp, 1.0 kHz) is applied to the other input (y or x, respectively). From Equation (1) we have:

$$V_O(AC) = K\,[0 \pm V_{iox} - V_{x(off)}]\ [\sin\omega t]$$

adjust $V_{x(off)}$ so that $[\pm V_{iox} - V_{x(off)}] = 0$.

Output Offset Current and Voltage – Output offset current (I_{OO}) is the DC current flowing in the output lead when $V_x = V_y = 0$ and X and Y offset voltages are adjusted to zero.

Output offset voltage (V_{OO}) is:

$$V_{OO} = I_{OO}\,R_L$$

where R_L is the load resistance.

NOTE: Output offset voltage is defined by many manufacturers with all inputs at zero but without adjusting X and Y offset voltages to zero. Thus, it includes input offset terms, an output offset term and a scale factor term.

Scale Factor – Scale factor is the K term in Equation (1). It determines the gain of the multiplier and is expressed approximately by the following equation.

$$K = \frac{2R_L}{R_x R_y I_1}\ \text{, where } R_x \text{ and } R_y >> \frac{kT}{qI_1}$$

and I_1 is the current out of Pin 1.

Total DC Accuracy – The total DC accuracy of a multiplier is defined as error in multiplier output with DC (± 10 Vdc) applied to both inputs. It is expressed as a percent of full scale. Accuracy is not specified for the MC1494 because error terms can be nulled by the user.

Temperature Stability (Drift) – Each term defined above will have a finite drift with temperature. The temperature specifications are obtained by readjusting the multiplier offsets and scale factor at each new temperature (see previous definitions and the adjustment procedure) and noting the change.

Assume inputs are grounded and initial offset voltages have been adjusted to zero. Then output voltage drift is given by:

$$\Delta V_O = \pm\ [K \pm K\,(TCK)\,(\Delta T)]\ [(TCV_{iox})\,(\Delta T)]$$
$$[(TCV_{ioy})\,(\Delta T)] \pm (TCV_{OO})\,(\Delta T)$$

Total DC Accuracy Drift – This is the temperature drift in output voltage with 10 V applied to each input. The output is adjusted to 10 V at T_A = + 25°C. Assuming initial offset voltages have been adjusted to zero at T_A = +25°C, then:

$$V_O = [\,K \pm K\,(TCK)\,(\Delta T)]\ [10 \pm (TCV_{iox})\,(\Delta T)]$$
$$[10 \pm (TCV_{ioy})\,(\Delta T)] \pm (TCV_{OO})\,(\Delta T)$$

Power Supply Rejection – Variation in power supply voltages will cause undesired variation of the output voltage. It is measured by superimposing a 1.0 V, 100 Hz signal on each supply (±15 V) with each input grounded. The resulting change in the output is expressed in mV/V.

Output Voltage Swing – Output voltage swing capability is the maximum output voltage swing (without clipping) into a resistive load. (Note, output offset is adjusted to zero).

If an op amp is used, the multiplier output becomes a virtual ground – the swing is then determined by the scale factor and the op amp selected.

MOTOROLA

MC1495

Wideband Linear Four-Quadrant Multiplier

The MC1495 is designed for use where the output is a linear product of two input voltages. Maximum versatility is assured by allowing the user to select the level shift method. Typical applications include: multiply, divide*, square root*, mean square*, phase detector, frequency doubler, balanced modulator/demodulator, and electronic gain control.

- Wide Bandwidth
- Excellent Linearity:
  2% max Error on X Input, 4% max Error on Y Input Over Temperature
  1% max Error on X Input, 2% max Error on Y Input at + 25°C
- Adjustable Scale Factor, K
- Excellent Temperature Stability
- Wide Input Voltage Range: ± 10 V
- ±15 V Operation

*When used with an operational amplifier.

OPERATION AND APPLICATIONS INFORMATION

Theory of Operation

The MC1495 is a monolithic, four-quadrant multiplier which operates on the principle of variable transconductance. A detailed theory of operation is covered in Application Note AN489, *Analysis and Basic Operation of the MC1595*. The result of this analysis is that the differential output current of the multiplier is given by:

$$I_A - I_B = \Delta I = \frac{2V_X V_Y}{R_X R_Y I_3}$$

where, I_A and I_B are the currents into Pins 14 and 2, respectively, and V_X and V_Y are the X and Y input voltages at the multiplier input terminals.

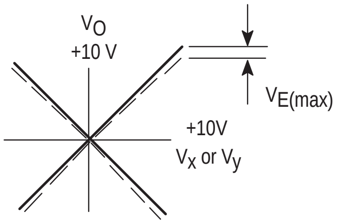
DESIGN CONSIDERATIONS

General

The MC1495 permits the designer to tailor the multiplier to a specific application by proper selection of external components. External components may be selected to optimize a given parameter (e.g. bandwidth) which may in turn restrict another parameter (e.g. maximum output voltage swing). Each important parameter is discussed in detail in the following paragraphs.

Linearity, Output Error, E_{RX} or E_{RY}

Linearity error is defined as the maximum deviation of output voltage from a straight line transfer function. It is expressed as error in percent of full scale (see figure below).



For example, if the maximum deviation, $V_{E(max)}$, is ±100 mV and the full scale output is 10 V, then the percentage error is:

$$E_R = \frac{V_E(max)}{V_O(max)} \times 100 = \frac{100 \times 10^{-3}}{10} \times 100 = \pm 1.0\%.$$

Linearity error may be measured by either of the following methods:

1. Using an X-Y plotter with the circuit shown in Figure 5, obtain plots for X and Y similar to the one shown above.
2. Use the circuit of Figure 4. This method nulls the level shifted output of the multiplier with the original input.The peak output of the null operational amplifier will be equal to the error voltage, $V_{E\ (max)}$.

One source of linearity error can arise from large signal nonlinearity in the X and Y input differential amplifiers. To avoid introducing error from this source, the emitter degeneration resistors R_X and R_Y must be chosen large enough so that nonlinear base-emitter voltage variation can be ignored. Figures 17 and 18 show the error expected from this source as a function of the values of R_X and R_Y with an operating current of 1.0 mA in each side of the differential amplifiers (i.e., $I_3 = I_{13} = 1.0$ mA).

3 dB Bandwidth and Phase Shift

Bandwidth is primarily determined by the load resistors and the stray multiplier output capacitance and/or the operational amplifier used to level shift the output. If wideband operation is desired, low value load resistors and/or a wideband operational amplifier should be used. Stray output capacitance will depend to a large extent on circuit layout.

Phase shift in the multiplier circuit results from two sources: phase shift common to both X and Y channels (due to the load resistor-output capacitance pole mentioned above) and relative phase shift between X and Y channels (due to differences in transadmittance in the X and Y channels). If the input to output phase shift is only 0.6°, the output product of two sine waves will exhibit a vector error of 1%. A 3° relative phase shift between V_X and V_Y results in a vector error of 5%.

Maximum Input Voltage

$V_{X(max)}$, $V_{Y(max)}$ input voltages must be such that:

$$V_{X(max)} < I_{13} R_Y$$

$$V_{Y(max)} < I_3 R_Y$$

Exceeding this value will drive one side of the input amplifier to “cutoff” and cause nonlinear operation.

Current I_3 and I_{13} are chosen at a convenient value (observing power dissipation limitation) between 0.5 mA and 2.0 mA, approximately 1.0 mA. Then R_X and R_Y can be determined by considering the input signal handling requirements.

For $V_{X(max)} = V_{Y(max)} = 10$ V;

$$R_X = R_Y > \frac{10\ \text{V}}{1.0\ \text{mA}} = 10\ \text{k}\Omega.$$

The equation $I_A - I_B = \dfrac{2V_X V_Y}{R_X R_Y I_3}$

is derived from $I_A - I_B = \dfrac{2V_X V_Y}{\left(R_X + \dfrac{2kT}{qI_{13}}\right)\left(R_Y + \dfrac{2kT}{qI_3}\right) I_3}$

with the assumption $R_X \gg \dfrac{2kT}{qI_{13}}$ and $R_Y \gg \dfrac{2kT}{qI_3}$.

At $T_A = +25°C$ and $I_{13} = I_3 = 1.0$ mA,

$$\frac{2kT}{qI_{13}} = \frac{2kT}{qI_3} = 52\ \Omega.$$

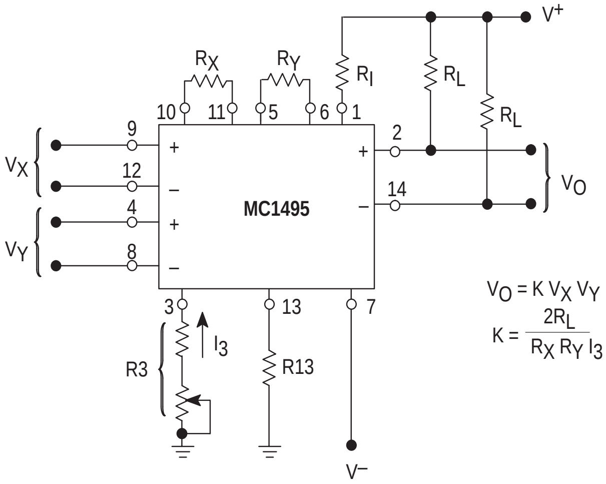
Therefore, with $R_X = R_Y = 10$ kΩ the above assumption is valid. Reference to Figure 19 will indicate limitations of $V_{X(max)}$ or $V_{Y(max)}$ due to V_1 and V_7. Exceeding these limits will cause saturation or “cutoff” of the input transistors. See Step 4 of General Design Procedure for further details.

Maximum Output Voltage Swing

The maximum output voltage swing is dependent upon the factors mentioned below and upon the particular circuit being considered.

For Figure 20 the maximum output swing is dependent upon V^+ for positive swing and upon the voltage at Pin 1 for negative swing. The potential at Pin 1 determines the quiescent level for transistors Q_5, Q_6, Q_7 and Q_8. This potential should be related so that negative swing at Pins 2 or 14 does not saturate those transistors. See General Design Procedure for further information regarding selection of these potentials.

Figure 20. Basic Multiplier



If an operational amplifier is used for level shift, as shown in Figure 21, the output swing (of the multiplier) is greatly reduced. See Section 3 for further details.

GENERAL DESIGN PROCEDURE

Selection of component values is best demonstrated by the following example. Assume resistive dividers are used at the X and Y-inputs to limit the maximum multiplier input to ± 5.0 V [$V_X = V_{Y(max)}$] for a ± 10 V input [$V_{X'} = V_{Y'(max)}$] (see Figure 21). If an overall scale factor of 1/10 is desired,

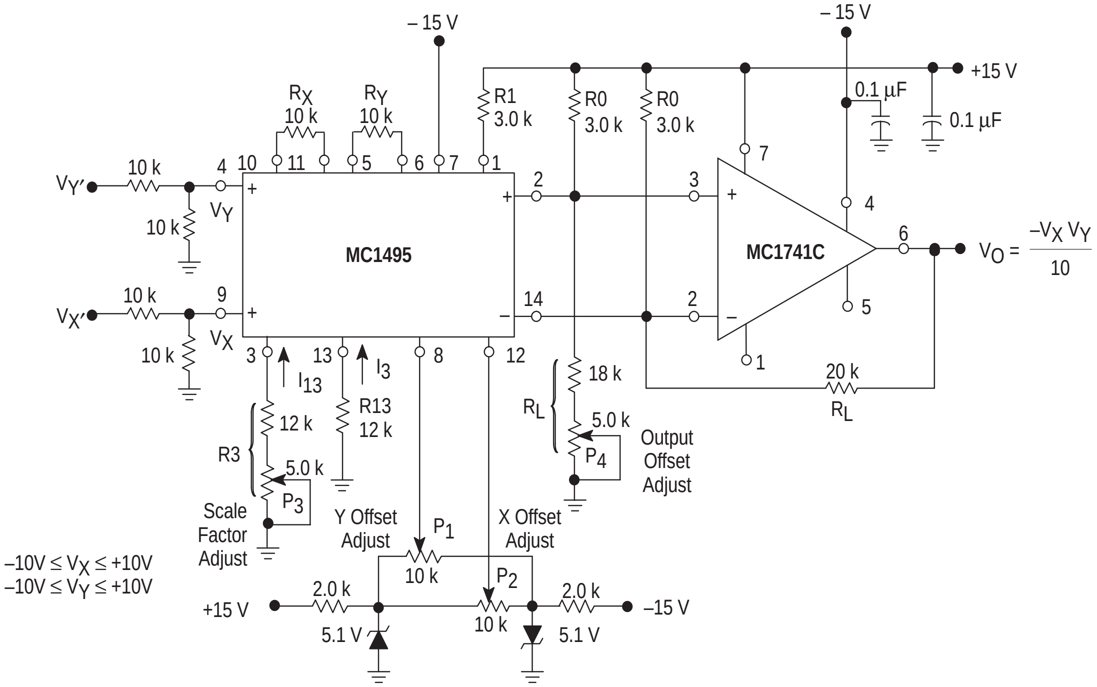
$$\text{then, } V_O = \frac{V_{X'}\,V_{Y'}}{10} = \frac{(2V_X)\,(2V_Y)}{10} = 4/10\ V_X\,V_Y$$

Therefore, K = 4/10 for the multiplier (excluding the divider network).

Step 1. The fist step is to select current I_3 and current I_{13}. There are no restrictions on the selection of either of these currents except the power dissipation of the device. I_3 and I_{13} will normally be 1.0 mA or 2.0 mA. Further, I_3 does not have to be equal to I_{13}, and there is normally no need to make them different. For this example, let

$$I_3 = I_{13} = 1.0\text{ mA.}$$

Figure 21. Multiplier with Operational Amplifier Level Shift



To set currents I_3 and I_{13} to the desired value, it is only necessary to connect a resistor between Pin 13 and ground, and between Pin 3 and ground. From the schematic shown in Figure 3, it can be seen that the resistor values necessary are given by:

$$R13 + 500\ \Omega = \frac{|V-| - 0.7\ V}{I_{13}}$$

$$R3 + 500\ \Omega = \frac{|V-| - 0.7\ V}{I_3}$$

$$\text{Let } V- = -15\ V\text{, then } R13 + 500 = \frac{14.3\ V}{1.0\ mA} \text{ or } R13 = 13.8\ k\Omega$$

Let $R_{13} = 12\ k\Omega$. Similarly, $R_3 = 13.8\ k\Omega$, let $R_3 = 15\ k\Omega$

However, for applications which require an accurate scale factor, the adjustment of R_3 and consequently, I_3, offers a convenient method of making a final trim of the scale factor. For this reason, as shown in Figure 21, resistor R_3 is shown as a fixed resistor in series with a potentiometer.

For applications not requiring an exact scale factor (balanced modulator, frequency doubler, AGC amplifier, etc.) Pins 3 and 13 can be connected together and a single resistor from Pin 3 to ground can be used. In this case, the single resistor would have a value of 1/2 the above calculated value for R_{13}.

Step 2. The next step is to select R_X and R_Y. To insure that the input transistors will always be active, the following conditions should be met:

$$\frac{V_X}{R_X} < I_{13}, \qquad \frac{V_Y}{R_Y} < I_3$$

A good rule of thumb is to make $I_3R_Y \geq 1.5\ V_{Y(max)}$ and $I_{13}R_X \geq 1.5\,V_{X(max)}$. The larger the I_3R_Y and $I_{13}R_X$ product in relation to V_Y and V_X respectively, the more accurate the multiplier will be (see Figures 17 and 18).

Let $R_X = R_Y = 10\ k\Omega$,
then $I_3R_Y = 10\ V$
$I_{13}R_X = 10\ V$

since $V_{X(max)} = V_{Y(max)} = 5.0\ V$, the value of $R_X = R_Y = 10\ k\Omega$ is sufficient.

Step 3. Now that R_X, R_Y and I_3 have been chosen, R_L can be determined:

$$K = \frac{2R_L}{R_X\ R_Y\ I_3} = \frac{4}{10}\ \text{, or } \frac{(2)\ (R_L)}{(10\ k)\ (10\ k)\ (1.0\ mA)} = \frac{4}{10}$$

Thus $R_L = 20\ k\Omega$.

Step 4. To determine what power supply voltage is necessary for this application, attention must be given to the circuit schematic shown in Figure 3. From the circuit schematic it can be seen that in order to maintain transistors Q_1, Q_2, Q_3 and Q_4 in an active region when the maximum input voltages are applied ($V_{X'} = V_{Y'} = 10$ V or $V_X = 5.0$ V, $V_Y = 5.0$ V), their respective collector voltage should be at least a few tenths of a volt higher than the maximum input voltage. It should also be noticed that the collector voltage of transistors Q_3 and Q_4 is at a potential which is two diode-drops below the voltage at Pin 1. Thus, the voltage at Pin 1 should be about 2.0 V higher than the maximum input voltage. Therefore, to handle +5.0 V at the inputs, the voltage at Pin 1 must be at least +7.0 V. Let $V_1 = 9.0$ Vdc.

Since the current flowing into Pin 1 is always equal to $2I_3$, the voltage at Pin 1 can be set by placing a resistor (R_1) from Pin 1 to the positive supply:

$$R_1 = \frac{V^+ - V_1}{2I_3}$$

$$\text{Let } V+ = 15\ V\text{, then } R_1 = \frac{15\ V - 9.0\ V}{(2)\ (1.0\ mA)}$$

$$R_1 = 3.0\ k\Omega.$$

Note that the voltage at the base of transistors Q_5, Q_6, Q_7 and Q_8 is one diode-drop below the voltage at Pin 1. Thus, in order that these transistors stay active, the voltage at Pins 2 and 14 should be approximately halfway between the voltage at Pin 1 and the positive supply voltage. For this example, the voltage at Pins 2 and 14 should be approximately 11 V.

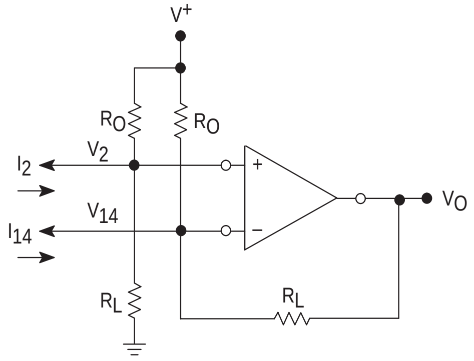
Step 5. For dc applications, such as the multiply, divide and square-root functions, it is usually desirable to convert the differential output to a single-ended output voltage referenced to ground. The circuit shown in Figure 22 performs this function. It can be shown that the output voltage of this circuit is given by:

$$V_O = (I_2 - I_{14})\ R_L$$

$$\text{And since } I_A - I_B = I_2 - I_{14} = \frac{2I_X\ I_Y}{I_3} = \frac{2V_XV_Y}{I_3R_XR_Y}$$

then $V_O = \dfrac{2R_L\ V_X'\ V_Y'}{4R_X\ R_X\ I_3}$ where, $V_X'\ V_Y'$ is the voltage at the input to the voltage dividers.

Figure 22. Level Shift Circuit



The choice of an operational amplifier for this application should have low bias currents, low offset current, and a high common mode input voltage range as well as a high common mode rejection ratio. The MC1456, and MC1741C operational amplifiers meet these requirements.

Referring to Figure 21, the level shift components will be determined. When $V_X = V_Y = 0$, the currents I_2 and I_{14} will be equal to I_{13}. In Step 3, R_L was found to be 20 kΩ and in Step 4, V_2 and V_{14} were found to be approximately 11 V. From this information R_O can be found easily from the following equation (neglecting the operational amplifiers bias current):

$$\frac{V2}{R_L} + I_{13} = \frac{V^+ - V_2}{R_O}$$

And for this example, $\frac{11\ V}{20\ k\Omega} + 1.0\ mA = \frac{15\ V - 11\ V}{R_O}$

Solving for R_O: $R_O = 2.6\ k\Omega$, thus, select $R_O = 3.0\ k\Omega$

For $R_O = 3.0\ k\Omega$, the voltage at Pins 2 and 14 is calculated to be:

$$V_2 = V_{14} = 10.4\ V.$$

The linearity of this circuit (Figure 21) is likely to be as good or better than the circuit of Figure 5. Further improvements are possible as shown in Figure 23 where R_Y has been increased substantially to improve the Y linearity, and R_X decreased somewhat so as not to materially affect the X linearity. This avoids increasing R_L significantly in order to maintain a K of 0.1.

The versatility of the MC1495 allows the user to to optimize its performance for various input and output signal levels.

OFFSET AND SCALE FACTOR ADJUSTMENT

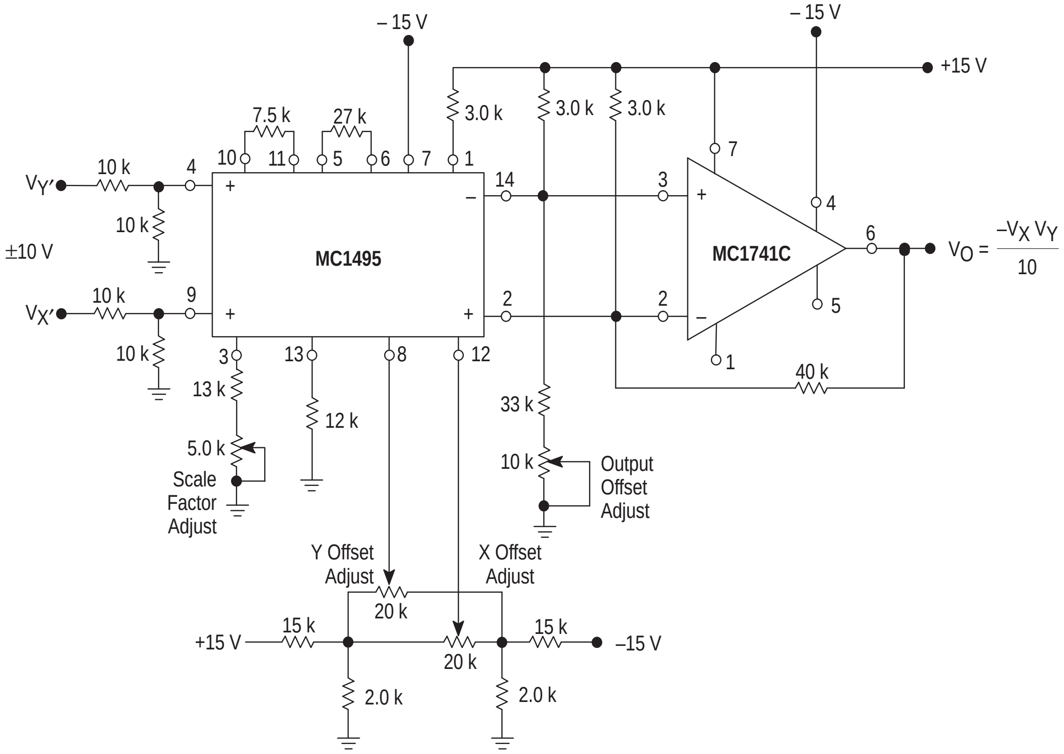
Offset Voltages

Within the monolithic multiplier (Figure 3) transistor base-emitter junctions are typically matched within 1.0 mV and resistors are typically matched within 2%. Even with this careful matching, an output error can occur. This output error is comprised of X-input offset voltage, Y-input offset voltage, and output offset voltage. These errors can be adjusted to zero with the techniques shown in Figure 21. Offset terms can be shown analytically by the transfer function:

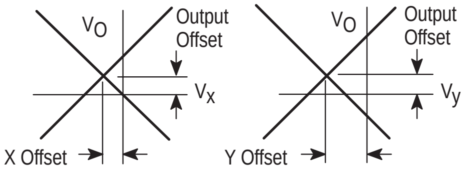
$$V_O = K[V_x \pm V_{iox} \pm V_{x(off)}]\ [V_y \pm V_{ioy} \pm V_{y(off)}] \pm V_{OO} \quad (1)$$

Where:
K = scale factor
V_x = “x” input voltage
V_y = “y” input voltage
V_{iox} = “x” input offset voltage
V_{ioy} = “y” input offset voltage
$V_{x(off)}$ = “x” input offset adjust voltage
$V_{y(off)}$ = “y” input offset adjust voltage
V_{OO} = output offset voltage.

Figure 23. Multiplier with Improved Linearity



X, Y and Output Offset Voltages



For most dc applications, all three offset adjust potentiometers (P_1, P_2, P_4) will be necessary. One or more offset adjust potentiometers can be eliminated for ac applications (see Figures 28, 29, 30, 31).

If well regulated supply voltages are available, the offset adjust circuit of Figure 13 is recommended. Otherwise, the circuit of Figure 14 will greatly reduce the sensitivity to power supply changes.

Scale Factor

The scale factor K is set by P_3 (Figure 21). P_3 varies I_3 which inversely controls the scale factor K. It should be noted that current I_3 is one-half the current through R_1. R_1 sets the bias level for Q_5, Q_6, Q_7, and Q_8 (see Figure 3). Therefore, to be sure that these devices remain active under all conditions of input and output swing, care should be exercised in adjusting P_3 over wide voltage ranges (see General Design Procedure).

Adjustment Procedures

The following adjustment procedure should be used to null the offsets and set the scale factor for the multiply mode of operation, (see Figure 21).

1. X-Input Offset
   (a) Connect oscillator (1.0 kHz, 5.0 V_{pp} sinewave) to the Y-input (Pin 4).
   (b) Connect X-input (Pin 9) to ground.
   (c) Adjust X offset potentiometer (P_2) for an ac null at the output.
2. Y-Input Offset
   (a) Connect oscillator (1.0 kHz, 5.0 V_{pp} sinewave) to the X-input (Pin 9).
   (b) Connect Y-input (Pin 4) to ground.
   (c) Adjust Y offset potentiometer (P_1) for an ac null at the output.
3. Output Offset
   (a) Connect both X and Y-inputs to ground.
   (b) Adjust output offset potentiometer (P_4) until the output voltage (V_O) is 0 Vdc.
4. Scale Factor
   (a) Apply +10 Vdc to both the X and Y-inputs.
   (b) Adjust P_3 to achieve + 10 V at the output.
5. Repeat steps 1 through 4 as necessary.

The ability to accurately adjust the MC1495 depends upon the characteristics of potentiometers P_1 through P_4. Multi-turn, infinite resolution potentiometers with low temperature coefficients are recommended.

DC APPLICATIONS

Multiply

The circuit shown in Figure 21 may be used to multiply signals from dc to 100 kHz. Input levels to the actual multiplier are 5.0 V (max). With resistive voltage dividers the maximum could be very large however, for this application two-to-one dividers have been used so that the maximum input level is 10 V. The maximum output level has also been designed for 10 V (max).

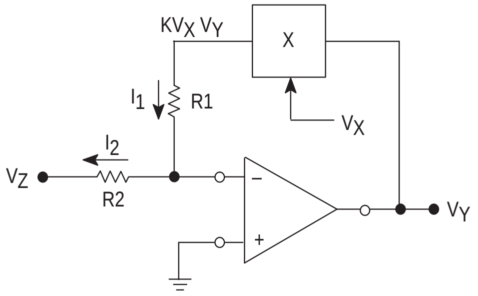
Squaring Circuit

If the two inputs are tied together, the resultant function is squaring; that is $V_O = KV^2$ where K is the scale factor. Note that all error terms can be eliminated with only three adjustment potentiometers, thus eliminating one of the input offset adjustments. Procedures for nulling with adjustments are given as follows:

A. AC Procedure:
   1. Connect oscillator (1.0 kHz, 15 V_{pp}) to input.
   2. Monitor output at 2.0 kHz with tuned voltmeter and adjust P_3 for desired gain. (Be sure to peak response of the voltmeter.)
   3. Tune voltmeter to 1.0 kHz and adjust P_1 for a minimum output voltage.
   4. Ground input and adjust P_4 (output offset) for 0 Vdc output.
   5. Repeat steps 1 through 4 as necessary.

B. DC Procedure:
   1. Set $V_X = V_Y = 0$ V and adjust P_4 (output offset potentiometer) such that $V_O = 0$ Vdc
   2. Set $V_X = V_Y = 1.0$ V and adjust P_1 (Y-input offset potentiometer) such that the output voltage is + 0.100 V.
   3. Set $V_X = V_Y = 10$ Vdc and adjust P_3 such that the output voltage is + 10 V.
   4. Set $V_X = V_Y = –10$ Vdc. Repeat steps 1 through 3 as necessary.

Figure 24. Basic Divide Circuit



Divide Circuit

Consider the circuit shown in Figure 24 in which the multiplier is placed in the feedback path of an operational amplifier. For this configuration, the operational amplifier will maintain a “virtual ground” at the inverting (–) input. Assuming that the bias current of the operational amplifier is negligible, then $I_1 = I_2$ and,

$$\frac{KV_XV_Y}{R1} = \frac{-V_Z}{R2} \tag{1}$$

$$\text{Solving for } V_Y, \quad V_Y = \frac{-R1}{R2\,K}\,\frac{V_Z}{V_X} \tag{2}$$

$$\text{If R1=R2,} \quad V_Y = \frac{-V_Z}{KV_X} \tag{3}$$

$$\text{If R1= KR2,} \quad V_Y = \frac{-V_Z}{V_X} \tag{4}$$

Hence, the output voltage is the ratio of V_Z to V_X and provides a divide function. This analysis is, of course, the ideal condition. If the multiplier error is taken into account, the output voltage is found to be:

$$V_Y = -\left[\frac{R1}{R2\,K}\right]\frac{V_Z}{V_X} + \frac{\Delta E}{KV_X} \tag{5}$$

where ΔE is the error voltage at the output of the multiplier. From this equation, it is seen that divide accuracy is strongly dependent upon the accuracy at which the multiplier can be set, particularly at small values of V_Y. For example, assume that R1 = R2, and K = 1/10. For these conditions the output of the divide circuit is given by:

$$V_Y = \frac{-10\,V_Z}{V_X} + \frac{10\,\Delta E}{V_X} \tag{6}$$

From Equation 6, it is seen that only when $V_X = 10$ V is the error voltage of the divide circuit as low as the error of the multiply circuit. For example, when V_X is small, (0.1 V) the error voltage of the divide circuit can be expected to be a hundred times the error of the basic multiplier circuit.

In terms of percentage error,

$$\text{percentage error} = \frac{\text{error}}{\text{actual}} \times 100\%$$

or from Equation (5),

$$PE_D = \frac{\dfrac{\Delta E}{KV_X}}{\left[\dfrac{R1}{R2\,K}\right]\dfrac{V_Z}{V_X}} = \left[\frac{R2}{R1}\right]\frac{\Delta E}{V_Z} \tag{7}$$

From Equation 7, the percentage error is inversely related to voltage V_Z (i.e., for increasing values of V_Z, the percentage error decreases).

A circuit that performs the divide function is shown in Figure 25.

Two things should be emphasized concerning Figure 25.

1. The input voltage ($V_{X'}$) must be greater than zero and must be positive. This insures that the current out of Pin 2 of the multiplier will always be in a direction compatible with the polarity of V_Z.
2. Pin 2 and 14 of the multiplier have been interchanged in respect to the operational amplifiers input terminals. In this instance, Figure 25 differs from the circuit connection shown in Figure 21; necessitated to insure negative feedback around the loop.

A suggested adjustment procedure for the divide circuit.

1. Set $V_Z = 0$ V and adjust the output offset potentiometer (P_4) until the output voltage (V_O) remains at some (not necessarily zero) constant value as $V_{X'}$ is varied between +1.0 V and +10 V.
2. Keep V_Z at 0 V, set $V_{X'}$ at +10 V and adjust the Y input offset potentiometer (P_1) until $V_O = 0$ V.
3. Let $V_{X'} = V_Z$ and adjust the X-input offset potentiometer (P_2) until the output voltage remains at some (not necessarily – 10 V) constant value as $V_Z = V_{X'}$ is varied between +1.0 and +10 V.
4. Keep $V_{X'} = V_Z$ and adjust the scale factor potentiometer (P_3) until the average value of V_O is –10 V as $V_Z = V_{X'}$ is varied between +1.0 V and +10 V.
5. Repeat steps 1 through 4 as necessary to achieve optimum performance.

Figure 25. Divide Circuit

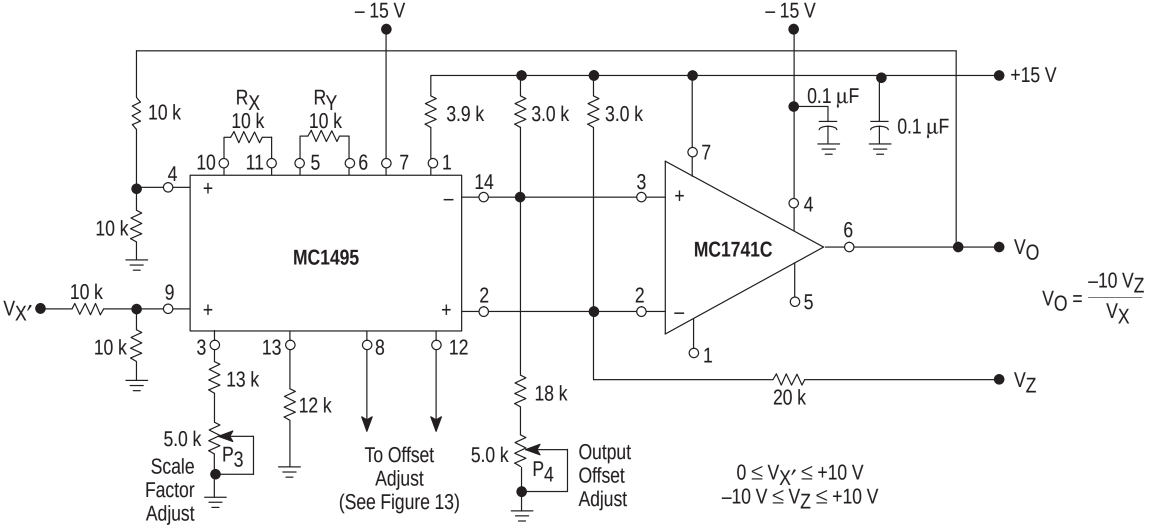


Figure 26. Basic Square Root Circuit

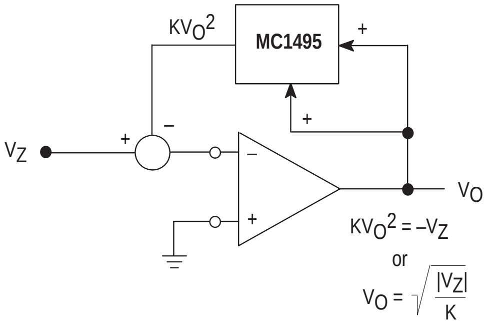

Square Root

A special case of the divide circuit in which the two inputs to the multiplier are connected together is the square root function as indicated in Figure 26. This circuit may suffer from latch-up problems similar to those of the divide circuit. Note that only one polarity of input is allowed and diode clamping (see Figure 27) protects against accidental latch-up.

This circuit also may be adjusted in the closed-loop mode as follows:

1. Set V_Z to –0.01 V and adjust P_4 (output offset) for V_O = +0.316 V, being careful to approach the output from the positive side to preclude the effect of the output diode clamping.
2. Set V_Z to –0.9 V and adjust P_2 (X adjust) for V_O = +3.0 V.
3. Set V_Z to –10 V and adjust P_3 (scale factor adjust) for V_O = +10 V.
4. Steps 1 through 3 may be repeated as necessary to achieve desired accuracy.

AC APPLICATIONS

The applications that follow demonstrate the versatility of the monolithic multiplier. If a potted multiplier is used for these cases, the results generally would not be as good because the potted units have circuits that, although they optimize dc multiplication operation, can hinder ac applications.

Frequency doubling often is done with a diode where the fundamental plus a series of harmonics are generated. However, extensive filtering is required to obtain the desired harmonic, and the second harmonic obtained under this technique usually is small in magnitude and requires amplification.

When a multiplier is used to double frequency the second harmonic is obtained directly, except for a dc term, which can be removed with ac coupling.

$$e_O = KE^2 \cos^2 \omega t$$

$$e_O = \frac{KE^2}{2} (1 + \cos 2\omega t).$$

A potted multiplier can be used to obtain the double frequency component, but frequency would be limited by its internal level-shift amplififer. In the monolithic units, the amplifier is omitted.

In a typical doubler circuit, conventional ± 15 V supplies are used. An input dynamic range of 5.0 V peak-to-peak is allowed. The circuit generates wave-forms that are double frequency; less than 1% distortion is encountered without filtering. The configuration has been successfully used in excess of 200 kHz; reducing the scale factor by decreasing the load resistors can further expand the bandwidth.

Figure 29 represents an application for the monolithic multiplier as a balanced modulator. Here, the audio input signal is 1.6 kHz and the carrier is 40 kHz.

Figure 27. Square Root Circuit

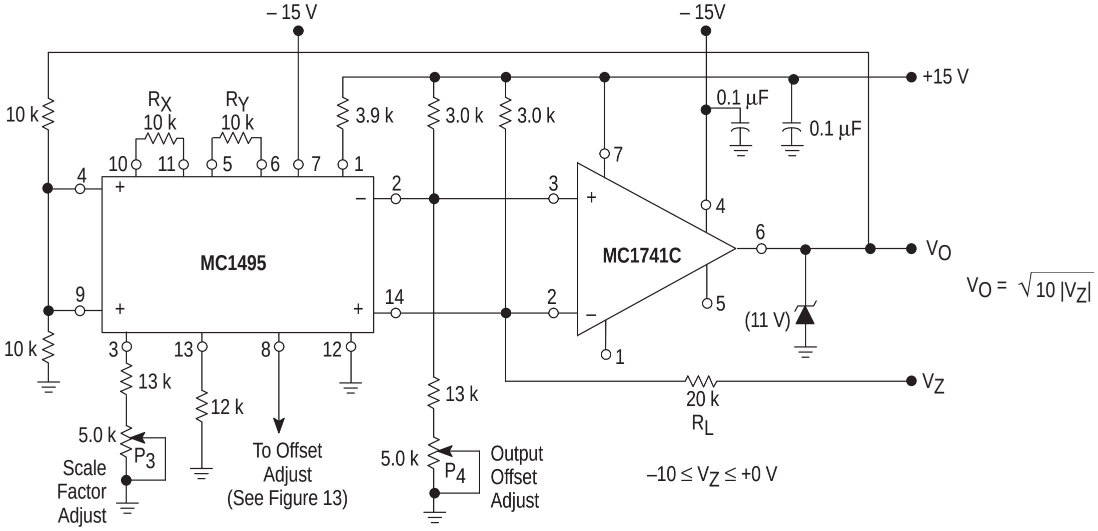

Figure 28. Frequency Doubler

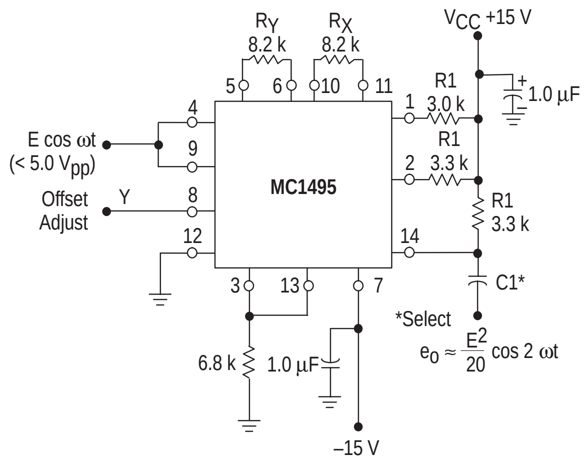
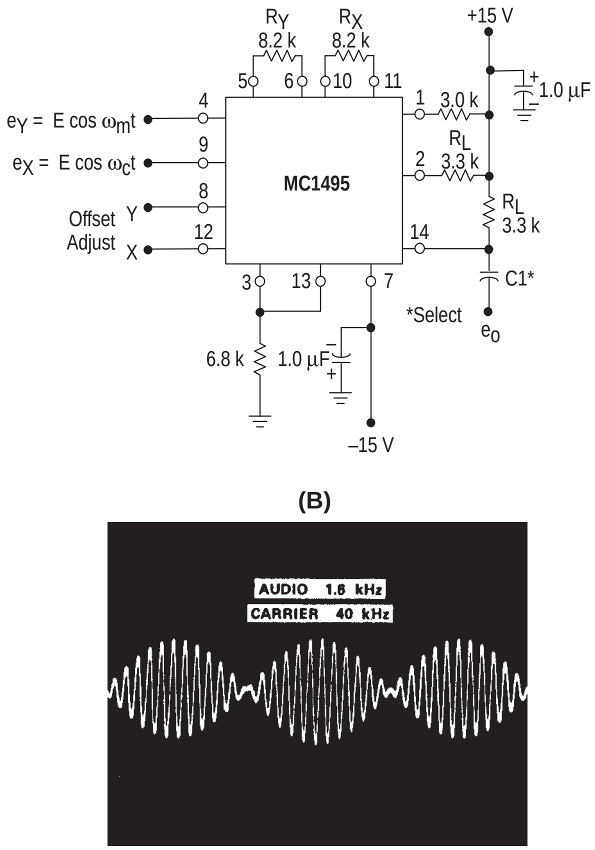


When two equal cosine waves are applied to X and Y, the result is a wave shape of twice the input frequency. For this example the input was a 10 kHz signal, output was 20 kHz.

Figure 29. Balanced Modulator



(A)

(B)

The defining equation for balanced modulation is

$$K(E_m \cos \omega_m t)\,(E_c \cos \omega_c t) =$$

$$\frac{KE_c\,E_m}{2}\,[\,\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)\,t\,]$$

where ω_c is the carrier frequency, ω_m is the modulator frequency and K is the multiplier gain constant.

AC coupling at the output eliminates the need for level translation or an operational amplifier; a higher operating frequency results.

A problem common to communications is to extract the intelligence from single-sideband received signal. The ssb signal is of the form:

$$e_{ssb} = A \cos(\omega_c + \omega_m)\,t$$

and if multiplied by the appropriate carrier waveform, cos ω_ct,

$$e_{ssb}e_{carrier} = \frac{AK}{2}\,[\cos(2\omega_c + \omega_m)t + \cos(\omega_c)\,t\,].$$

If the frequency of the band-limited carrier signal (ω_c) is ascertained in advance, the designer can insert a low pass filter and obtain the (AK/2) (cosω_ct) term with ease. He/she also can use an operational amplifier for a combination level shift-active filter, as an external component. But in potted multipliers, even if the frequency range can be covered, the operational amplifier is inside and not accessible, so the user must accept the level shifting provided, and still add a low pass filter.

Amplitude Modulation

The multiplier performs amplitude modulation, similar to balanced modulation, when a dc term is added to the modulating signal with the Y-offset adjust potentiometer (see Figure 30).

Here, the identity is:

$$E_m(1 + m \cos \omega_m t)\,E_c \cos \omega_c t = KE_mE_c \cos \omega_c t +$$

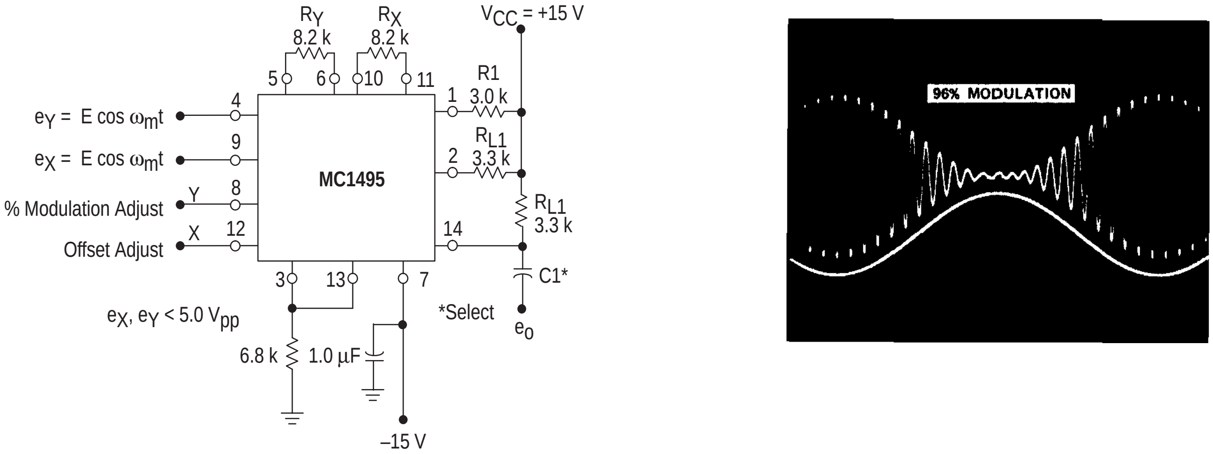
$$\frac{KE_mE_cm}{2}\,[\,\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)\,t\,]$$

where m indicates the degrees of modulation. Since m is adjustable, via potentiometer P_1, 100% modulation is possible. Without extensive tweaking, 96% modulation may be obtained where ω_c and ω_m are the same as in the balanced modulator example.

Linear Gain Control

To obtain linear gain control, the designer can feed to one of the two MC1495 inputs a signal that will vary the unit's gain. The following example demonstrates the feasibility of this application. Suppose a 200 kHz sinewave, 1.0 V peak-to-peak, is the signal to which a gain control will be added. The dynamic range of the control voltage V_C is 0 V to +1.0 V. These must be ascertained and the proper values of R_X and R_Y can be selected for optimum performance. For the 200 kHz operating frequency, load resistors of 100 Ω were chosen to broaden the operating bandwidth of the multiplier, but gain was sacrificed. It may be made up with an amplifier operating at the appropriate frequency (see Figure 31).

Figure 30. Amplitude Modulation



The signal is applied to the unit's Y-input. Since the total input range is limited to 1.0 V_{pp}, a 2.0 V swing, a current source of 2.0 mA and an R_Y value of 1.0 kΩ is chosen. This takes best advantage of the dynamic range and insures linear operation in the Y-channel.

Since the X-input varies between 0 and +1.0 V, the current source selected was 1.0 mA, and the R_X value chosen was 2.0 kΩ. This also insures linear operation over the X-input dynamic range. Choosing R_L = 100 assures wide bandwidth operation.

Hence, the scale factor for this configuration is:

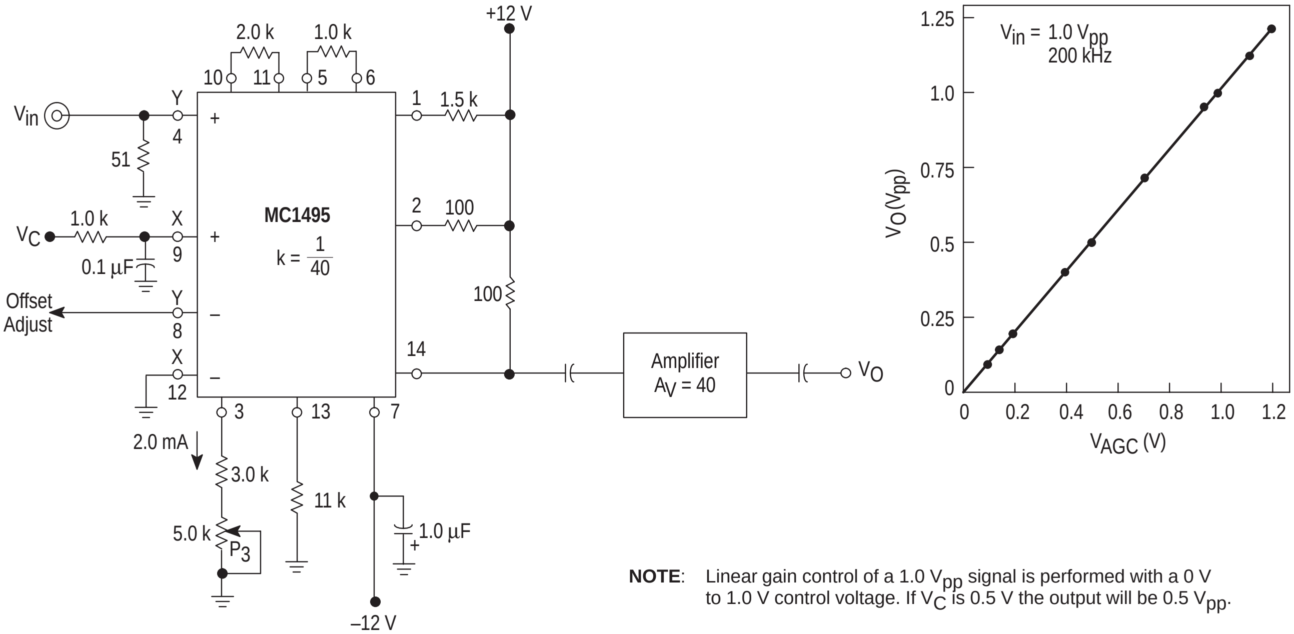
$$K = \frac{R_L}{R_X\, R_Y\, I_3}$$

$$= \frac{100}{(2\ k)\ (1\ k)\ (2 \times 10^3)}\ V^{-1}$$

$$= \frac{1}{40}\ V^{-1}$$

The 2 in the numerator of the equation is missing in this scale factor expression because the output is single-ended and ac coupled.

Figure 31. Linear Gain Control



NOTE: Linear gain control of a 1.0 V_{pp} signal is performed with a 0 V to 1.0 V control voltage. If V_C is 0.5 V the output will be 0.5 V_{pp}.

MOTOROLA

MC3456

Dual Timing Circuit

The MC3456 dual timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. Additional terminals are provided for triggering or resetting if desired. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor per timer. For astable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor per timer. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200 mA or drive MTTL circuits.

- Direct Replacement for NE556/SE556 Timers
- Timing from Microseconds through Hours
- Operates in Both Astable and Monostable Modes
- Adjustable Duty Cycle
- High Current Output can Source or Sink 200 mA
- Output can Drive MTTL
- Temperature Stability of 0.005% per °C
- Normally “On” or Normally “Off” Output
- Dual Version of the Popular MC1455 Timer

GENERAL OPERATION

The MC3456 is a dual timing circuit which uses as its timing elements an external resistor/capacitor network. It can be used in both the monostable (one shot) and astable modes with frequency and duty cycle, controlled by the capacitor and resistor values. While the timing is dependent upon the external passive components, the monolithic circuit provides the starting circuit, voltage comparison and other functions needed for a complete timing circuit. Internal to the integrated circuit are two comparators, one for the input signal and the other for capacitor voltage; also a flip–flop and digital output are included. The comparator reference voltages are always a fixed ratio of the supply voltage thus providing output timing independent of supply voltage.

Monostable Mode

In the monostable mode, a capacitor and a single resistor are used for the timing network. Both the threshold terminal and the discharge transistor terminal are connected together in this mode (refer to circuit Figure 15). When the input voltage to the trigger comparator falls below 1/3 V_{CC} the comparator output triggers the flip–flop so that it's output sets low. This turns the capacitor discharge transistor "off" and drives the digital output to the high state. This condition allows the capacitor to charge at an exponential rate which is set by the RC time constant. When the capacitor voltage reaches 2/3 V_{CC} the threshold comparator resets the flip–flop. This action discharges the timing capacitor and returns the digital output to the low state. Once the flip–flop has been triggered by an input signal, it cannot be retriggered until the present timing period has been completed. The time that the output is high is given by the equation $t = 1.1\ R_A\ C$. Various combinations of R and C and their associated times are shown in Figure 14. The trigger pulse width must be less than the timing period.

A reset pin is provided to discharge the capacitor thus interrupting the timing cycle. As long as the reset pin is low, the capacitor discharge transistor is turned "on" and prevents the capacitor from charging. While the reset voltage is applied the digital output will remain the same. The reset pin should be tied to the supply voltage when not in use.

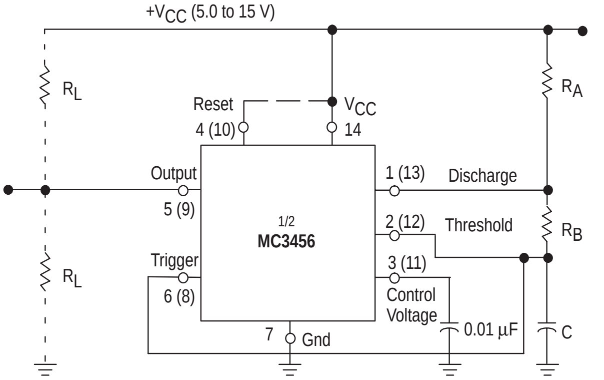

Figure 18. Astable Waveforms

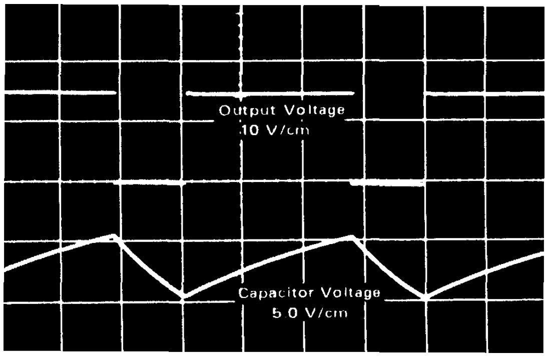


t = 20 µs/cm
(R_A = 5.1 kΩ, C = 0.0 1 µF, R_L = 1.0 kΩ, R_B = 3.9 kΩ, V_{CC} = 15 V)

Astable Mode

In the astable mode the timer is connected so that it will retrigger itself and cause the capacitor voltage to oscillate between 1/3 V_{CC} and 2/3 V_{CC} (see Figure 17).

The external capacitor charges to 2/3 V_{CC} through R_A and R_B and discharges to 1/3 V_{CC} through R_B. By varying the ratio of these resistors the duty cycle can be varied. The charge and discharge times are independent of the supply voltage.

The charge time (output high) is given by:

$$t_1 = 0.695\,(R_A + R_B)\,C$$

The discharge time (output low) by:

$$t_2 = 0.695\,(R_B)\,C$$

Thus the total period is given by:

$$T = t_1 + t_2 = 0.695\,(R_A + 2R_B)\,C$$

The frequency of oscillation is then: $f = \frac{1}{T} = \frac{1.44}{(R_A + 2R_B)\,C}$

and may be easily found as shown in Figure 19.

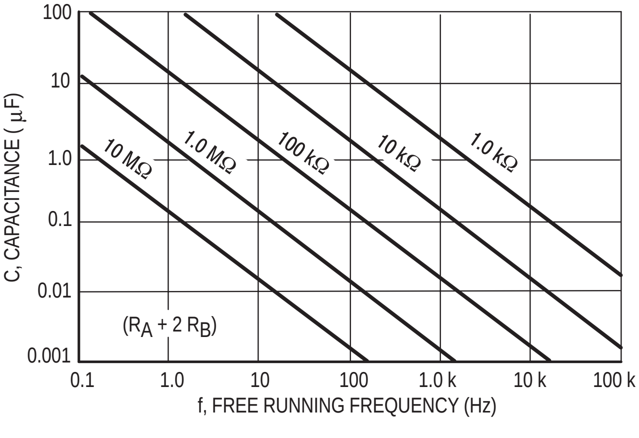
The duty cycle is given by: $DC = \frac{R_B}{R_A + 2R_B}$

To obtain the maximum duty cycle, R_A must be as small as possible; but it must also be large enough to limit the discharge current (Pin 7 current) within the maximum rating of the discharge transistor (200 mA).

The minimum value of R_A is given by:

$$R_A \geq \frac{V_{CC}\,(Vdc)}{I_7\,(A)} \geq \frac{V_{CC}\,(Vdc)}{0.2}$$

Figure 19. Free Running Frequency



APPLICATIONS INFORMATION

Tone Burst Generator

For a tone burst generator, the first timer is used as a monostable and determines the tone duration when triggered by a positive pulse at Pin 6. The second timer is enabled by the high output of the monostable. It is connected as an astable and determines the frequency of the tone.

Dual Astable Multivibrator

This dual astable multivibrator provides versatility not available with single timer circuits. The duty cycle can be adjusted from 5% to 95%. The two outputs provide two phase clock signals often required in digital systems. It can also be inhibited by use of either reset terminal.

Figure 20. Tone Burst Generator

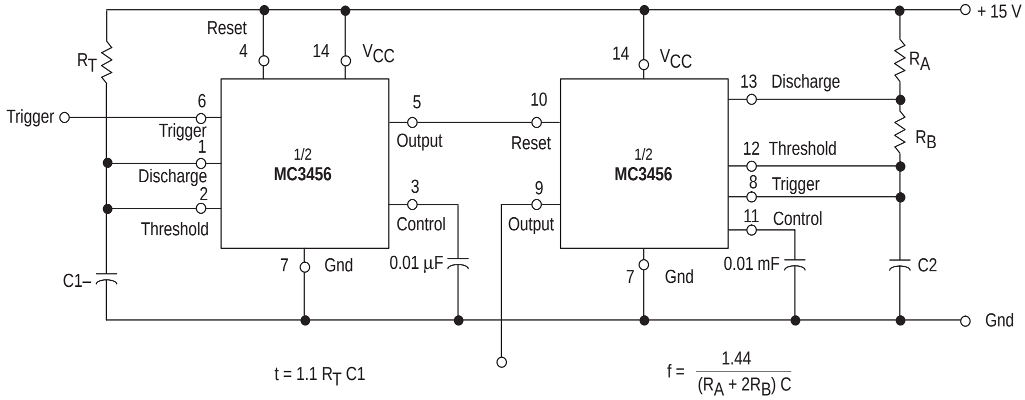


Figure 21. Dual Astable Multivibrator

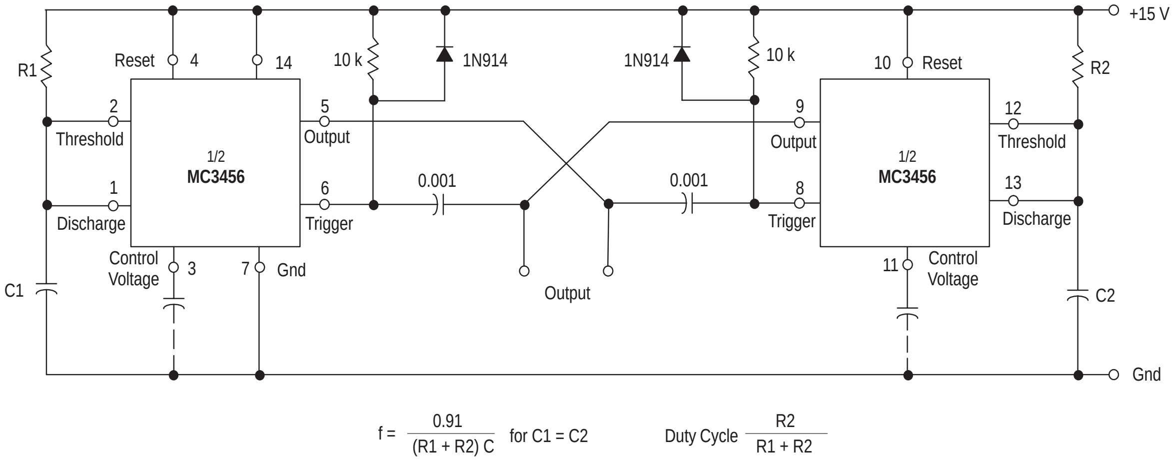

Pulse Width Modulation

If the timer is triggered with a continuous pulse train in the monostable mode of operation, the charge time of the capacitor can be varied by changing the control voltage at Pin 3. In this manner, the output pulse width can be modulated by applying a modulating signal that controls the threshold voltage.

Test Sequences

Several timers can be connected to drive each other for sequential timing. An example is shown in Figure 24 where the sequence is started by triggering the first timer which runs for 10 ms. The output then switches low momentarily and starts the second timer which runs for 50 ms and so forth.

Tape and Reel Options

In Brief . . .

Motorola offers the convenience of Tape and Reel packaging for our growing family of standard integrated circuit products. Reels are available to support the requirements of both first and second generation pick–and–place equipment. The packaging fully conforms to the latest EIA–481A specification. The antistatic embossed tape provides a secure cavity, sealed with a peel–back cover tape.

SOT–89 (3/5 Pin)	12	1,000	7	T1

(1) Minimum order quantity is 1 reel. Distributors/OEM customers may break lots or reels at their option, however broken reels may not be returned.

(2) Integrated circuits in TO–226AA packages are available in Styes A and E only, with optional “Ammo Pack” (Suffix RP or RM). The RA and RP configurations are preferred. For ordering information please contact your local Motorola Semiconductor Sales Office.

Packaging Information

In Brief . . .

The packaging availability for each device type is indicated on the individual data sheets and the Selector Guide. All of the outline dimensions for the packages are given in this section.

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature can be found from the equation:

$$P_{D(TA)} = \frac{T_{J(max)} - T_A}{R_{\theta JA(Typ)}}$$

where:

$P_{D(TA)}$ = *Power Dissipation allowable at a given operating ambient temperature. This must be greater than the sum of the products of the supply voltages and supply currents at the worst case operating condition.*

$T_{J(max)}$ = *Maximum operating Junction Temperature as listed in the Maximum Ratings Section. See individual data sheets for $T_{J(max)}$ information.*

T_A = *Maximum desired operating Ambient Temperature*

$R_{\theta JA(Typ)}$ = *Typical Thermal Resistance Junction-to-Ambient*

Quality and Reliability Assurance

In Brief . . .

The word quality has been used to describe many things, such as fitness for use, customer satisfaction, customer enthusiasm, what the customer says quality is, etc. These descriptions convey important truths, however, quality should be described in a way that precipitates immediate action. With that in mind, quality can be described as reduction of variability around a target, so that conformance to customer requirements and possibly expectations can be achieved in a cost effective way. This definition provides direction and potential for immediate action for a person desiring to improve quality.

The definition of quality as described above can be applied to a task, process or a whole company. If we are to reap the benefits of quality and obtain a competitive advantage, quality must be applied to the whole company.

Implementation of quality ideas company wide requires a quality plan showing: a philosophy (belief) of operation, measurable goals, training of individuals and methods of communicating this philosophy of operation to the whole organization.

Motorola, for example, believes that quality and reliability are the responsibility of every person. Participative Management is the process by which problem solving and quality improvement are facilitated at all levels of the organization through crossfunctional teams. Continuous improvement for the individual is facilitated by a broad educational program covering onsite, university and college courses. Motorola University provides leadership and administers this educational effort on a company wide basis.

Another key belief is that quality excellence is accomplished by people doing things right the first time and committed to never ending improvement. The Six Sigma (6σ) challenge is designed to convey and facilitate the idea of continuous improvement at all levels.

Page

Quality Concepts

Quality improvement for a task or a process can be quickly described in terms of the target, current status with respect to target (variability), reduction of variability (commitment to never ending improvement), customer requirements (who receives output, what are a person's requirements/ expectations) and economics (cost of nonconformance, loss function, etc.).

Application of quality to the whole company has come to be known by such names as **"Total Quality Control" (TQC); "Company Wide Quality Control" (CWQC); "Total Quality Excellence" or "Total Quality Engineering" (TQE); "Total Quality Involvement" (TQI).** These names attempt to convey the idea that quality is a process (a way of acting continuously) rather than a program (implying a beginning and an end). Nevertheless for this process to be successful it must be able to show measurable results.

"**Six Sigma** is the required capability level to approach the standard. The **standard** is **zero defects**. Our goal is to be Best-in-Class in product, sales and service." (For a more detailed explanation, contact your Motorola Representative for a pamphlet of the Six Sigma Challenge.)

Quick insight into six sigma is obtained if we realize that a six sigma process has variability which is one half of the variation allowed (tolerance, spread) by the customer requirements (i.e. natural variation is one half of the customer specification range for a given characteristic). When six sigma is achieved, virtually zero defects are observed in the output of a process/product even allowing for potential process shifts (Figure 1).

Policies, objectives and five year plans are the mechanisms for communicating the key beliefs and measurable goals to all personnel and continuously keeping them in focus. This is done at the corporate, sector, group, division, and department levels.

The Analog Division, for example, evaluates performance to the corporate goals of **10 fold improvement by 1989; 100 fold improvement by 1991** and achievement of **six sigma capability by 1992** by utilizing indices such as Outgoing Electrical and Visual Mechanical Quality **(AOQ)** in terms of PPM (parts per million or sometimes given in parts per billion); **% of devices with zero PPM ; product quality returns** (RMR); number of processes/products with specified **capability indices (cp, cpk); six sigma capability roadmaps; failure rates for various reliability tests** (operating life, temperature humidity bias, hast, temperature cycling, etc.); **on-time delivery; customer product evaluation and failure analysis turnaround; cost of nonconformance; productivity improvement and personnel development**.

Figure 2 shows the improvement in electrical outgoing quality for analog products over recent years in a normalized form. Figure 3 shows the number of parts with zero PPM over a period of time.

Documentation control is an important part of **statistical process control. Process mapping** (flow charting etc.) with documentation identified allows visualization and therefore optimization of the process. Figure 4 shows a portion of a flow chart for wafer fabrication. **Control plans** are an important part of Statistical Process Control, these plans identify in detail critical points where data for process control is taken, parameters measured, frequency of measurements, type of control device used, measuring equipment, responsibilities and reaction plans. Figure 5 shows a portion of a control plan for wafer fabrication. Six sigma progress is tracked by roadmaps based on the six sigma process, a portion of which is shown on Figure 6.

On-time delivery is of great importance, with the current emphasis on **just-in-time** systems. Tracking is done on an overall basis, and at the device levels.

STEP	±6σ Summary
1. Identify critical characteristics	• Product Description • Marketing • Industrial Design • R&D/Developmental Engineering • Actual or Potential Customers
2. Determine specified product elements contributing to critical characteristics	• Critical Characteristics Matrix • Cause-and-Effect and Ishikawa Diagrams • Success Tree/Fault Tree Analysis • Component Search or Other Forms of Planned Experimentation • FMECA (Failure Mode Effects and Critical Analysis)
3. For each product element, determine the process step or process choice that affects or controls required performance	• Planned Experiments • Computer-Aided Simulation • TOP/Process Engineering Studies • Multi-Vari Analysis • Comparative Experiments
4. Determine maximum (real) allowable tolerance for each and process	• Graphing Techniques • Engineering Handbooks • Planned Experiments • Optimization, Especially Response Surface Methodology

Reliability Concepts

Reliability is the probability that an analog integrated circuit will succesfully perform its specified function in a given environment for a specified period of time. This is the classical definition of reliability applied to analog integrated circuits.

Another way of thinking about reliability is in relationship to quality. While **quality** is a measure of variability (extending to potential nonconformances-rejects) in the population domain, **reliability** is a measure of variability (extending to potential nonconformances-failures) in the population, time and environmental conditions domain. In brief, **reliability** can be thought of as **quality over time** and **environmental conditions**.

Ultimately, **product reliability** is a function of proper **understanding** of **customer requirements** and **communicating** them throughout design, product/process development, manufacturing and final product use. **Quality Function Deployment (QFD)** is a technique which may be used to facilitate identification of customer quality and reliability requirements and communicating them throughout an organization.

The most frequently used reliability measure for integrated circuits is the **failure rate expressed** in percent per thousand device hours (%/1000 hrs.). If the time interval is small the failure rate is called **Instantaneous Failure Rate** [λ (t)] or ‘‘Hazard Rate.” If the time interval is long (for example total operational time) the failure rate is called **Cumulative Failure Rate**.

The number of failures observed, taken over the number of device hours accumulated at the end of the observation period and expressed as a percent is called the point estimate failure rate. This however, is a number obtained from observations from a sample of all integrated circuits. If we are to use this number to estimate the failure rate of all integrated circuits (total population), we need to say something about the risk we are taking by using this estimate. A **risk** statement is provided by the **confidence level** expressed together with the failure rate. Mathematically, the failure rate at a given confidence level is obtained from the point estimate and the **CHI square** (X^2) distribution. (The X^2 is a statistical distribution used to relate the observed and expected frequencies of an event.) In practice, a reliability calculator rule is used which gives the failure rate at the confidence level desired for the number of failures and device hours under question.

As the number of device hours increases, our confidence in the estimate increases. In integrated circuits, it is preferred to make estimates on the basis of failures per 1,000,000,000 (10^9) device hours **(FITS)** or more. If such large numbers of device hours are not available for a particular device, then the point estimate is obtained by pooling the data from devices that are similar in process, voltage, construction, design, etc., and for which we expect to see the same failure modes in the field.

The environment is specified in terms of the temperature, electric field, relative humidity, etc., by an **Eyring** type equation of the form:

$$\lambda = Ae - \frac{\phi}{KT}\ \ldots e - \frac{B}{RH}\ \ldots e - \frac{C}{E}$$

where A, B, C, ϕ & K are constants, T is temperature, RH is relative humidity, E is the electric field, etc.

The most familiar form of this equation deals with the first exponential which shows an **Arrhenius type** relationship of the **failure rate** versus the **junction temperature** of integrated circuits, while the causes of failure generally remain the same. Thus we can test devices near their maximum junction temperatures, analyze the failures to assure that they are the types that are accelerated by temperature and then applying known acceleration factors, estimate the failure rates for lower junction temperatures. The Eyring or Arrhenius relationships should be used for failure rate projections in conjunction with proper understanding of failure modes, mechanisms and patterns such as infant mortality, constant failure rate (useful region) and wearout. For example if by design and proper process control infant mortality and useful period failures have been brought to zero and wearout failures do not start until, let us say, 30,000 hours at 125°C then failure rate projections at lower temperatures must account for these facts and whether the observed wearout failures occur at lower temperatures.

Figure 7 shows an example of a curve which gives estimates of failure rates versus temperature for an integrated circuit case study.

$$\text{Arrhenius type of equation:}\quad \lambda = Ae - \frac{\phi}{KT}$$

where: λ = Failure Rate
A = Constant
e = 2.72
ϕ = Activation Energy
K = Botzman’s Constant
T = Temperature in Degrees Kelvin

$$T_J = T_A + \theta_{JA} P_D \text{ or } T_J = T_C + \theta_{JC} P_D$$

where: T_J = Junction Temperature
T_A = Ambient Temperature
T_C = Case Temperature
θ_{JA} = Junction to Ambient Thermal Resistance
θ_{JC} = Junction to Case Thermal Resistance
P_D = Power Dissipation

Life patterns (failure rate curves) for equipment and devices can be represented by an idealized graph called the **Bathtub Curve** (Figure 8).

There are three important regions identified on this curve. In Region A, the failure rate decreases with time and it is generally called **infant mortality** or early life failure region. In Region B, the failure rate has reached a relatively constant level and it is called **constant failure rate** or useful life region**.** In the third region, the failure rate increases again and it is called **wearout region**. Modern integrated circuits generally do not reach the wearout portion of the curve when operating under normal use conditions.

Figure 7. Example of a Failure Rate versus Junction Temperature Curve

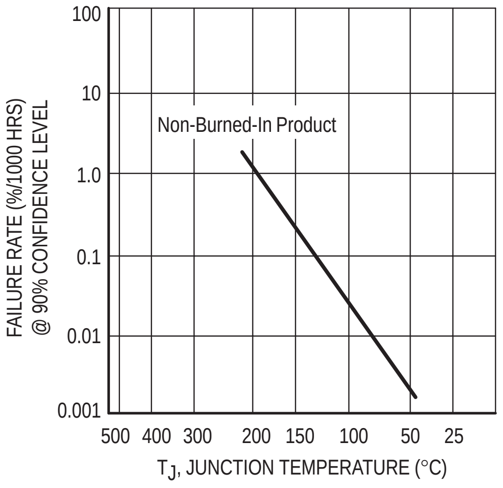

Figure 8. A Model for Failure Distribution in Time Domain Bathtub Curve Model

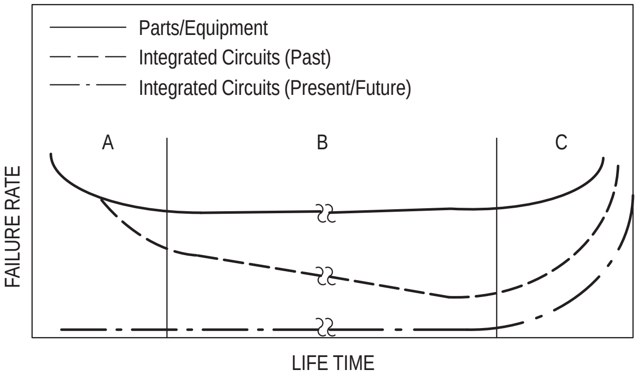

Decreasing Failure Rate	Constant Failure Rate	Increasing Failure Rate
Infant Mortality Burn-In	Useful Life	Wearout
Manufacturing Variations Workmanship Defects	Random (Chance) Defects (No Pattern; Occur Regularly)	Material, Design, Process Limitations
Weibull Log Normal Gamma Distribution	Weibull Exponential for Equipment Log Normal for ICs	Weibull Normal (Gaussian)

The wearout portion of the curve can usually be identified by using highly accelerated test conditions. For modern integrated circuits, even the useful life portion of the curve may be characterized by few or no failures. As a result the bathtub curve looks like continuously declining (few failures, Figure 8, Curve B) or zero infant and useful period failures (constant failure rate until wearout, Curve C).

The **infant mortality** portion of the curve is of most interest to equipment manufacturers because of its impact on customer perception and potential warranty costs. In recent years the infant mortality portion of the curve for integrated circuits, and even equipment, has been drastically reduced

(Figure 8, Curve C). The reduction was accomplished by improvements in technology, emphasis on statistical process control, reliability modeling in design and reliability in manufacturing (wafer level reliability, assembly level reliability, etc.). In this respect many integrated circuit families have zero or near zero failure patterns until wearout starts.

Does a user still need to consider burn-in? For this question to be answered properly the IC user must consider the **target failure rate** of the equipment, **apportioned** to the components used, application environment, maturity of equipment and components (new versus mature technology), the impact of a failure (i.e. safety versus casual loss of entertainment), maintenance costs, etc. Therefore, if the IC user is going through these considerations for the first time, the question of burn-in at the component level should be discussed during a user-vendor interface meeting.

A frequently asked question is about the reliability differences between **plastic** and **hermetic** packaged integrated circuits. In general, for all integrated circuits including analog, the field removal rates are the same for normal use environments, with many claims of plastic being better because of its ‘‘solid block” structure.

The tremendous decrease of failure rates of plastic packages has been accomplished by **continuous improvements** in piece parts, materials and processes. Nevertheless, differences can still be observed under highly accelerated environmental stress conditions. For example, if a bimetallic (gold wire and aluminum metallization) system is used in plastic packages and they are placed on a high temperature operating life test (125°C) then failures in the form of opens, at the gold to aluminum interface, may not be observed until 30,000 hours of continuous operating life. Packages, whether plastic or hermetic, with a monometallic system (aluminum wire to aluminum metallization) will have no opens because of the absence of the gold to aluminum interface. As a result, a difference in failure rates will be observable.

Differences in failure rates between plastics and hermetics may also be observed if devices from both packaging systems are placed in a moist environment such as 85°C, 85% RH with bias applied. At some point in time plastic encapsulated ICs should fail since they are considered pervious by moisture, (the failure mechanism being corrosion of the aluminum metallization) while hermetic packages should not fail since they are considered impervious by moisture. The reason the word ‘‘should” was used is because advances in plastic compounds, package piece parts, encapsulation processes and final chip passivation have made plastic integrated circuits capable of operating more than 5000 hours without failures in an 85°C, 85% RH environment. Differences in failure rates due to internal corrosion between plastic and hermetic packages may not be observable until well after 5000 operating hours.

The aforementioned two examples had environments substantially more accelerated than normal life so the two issues discussed are not even a factor under normal use conditions. In addition, mechanisms inherent in hermetic packages but absent in plastics were not even considered here. Improved reliability of plastic encapsulated ICs has decreased demand of hermetic packages to the point where many devices are offered only in plastic packages. The user then should feel comfortable in using the present plastic packaging systems.

A final question that is asked by the IC user is, how can one be assured that the reliability of standard product does not degrade over time? This is accomplished by our emphasis on **statistical process control, in-line reliability** assessment and **reliability auditing** by periodic and strategic sampling and accelerated testing of the various integrated circuit device packaging systems. A description of these audit programs follows.

Analog Reliability Audit Program

The reliability of a product is a function of proper understanding of the application and environmental conditions that the product will encounter during its life as well as design, manufacturing process and final use conditions. **Inherent reliability** is the reliability which a product would have if there were no imperfections in the materials, piece parts and manufacturing processes of the product. The presence of imperfections gives rise to reliability risks. **Failure Mode and Effects Analysis (FMEA)** is a technique for identifying, controlling and eliminating potential failures from the design and manufacture of the product.

Motorola uses **on-line** and **off-line** reliability monitoring in an attempt to prevent situations which could degrade reliability. **On-line** reliability monitoring is at the **wafer and assembly levels** while **off-line** reliability monitoring involves reliability assessment of the **finished product** through the use of **accelerated** environmental tests.

Continuous monitoring of the reliability of analog integrated circuits is accomplished by the **Analog Reliability Audit Program**, which is designed to compare the actual reliability to that specified. This objective is accomplished by periodic and strategic sampling of the various integrated circuit device packaging systems. The samples are tested by subjecting them to accelerated environmental conditions and the results are reviewed for unfavorable trends that would indicate a degradation of the reliability or quality of a particular packaging system. This provides the trigger mechanism for initiating an investigation for **root cause** and **corrective action**. Concurrently, in order to provide a minimum of interruption of product flow and assure that the product is fit for use, a lot by lot sampling or a non-destructive type 100% screen may be used to assure that a particular packaging system released for shipment does have the expected reliability. This rigorous surveillance is continued until there is sufficient proof (many consecutive lots) that the problem has been corrected.

The **Logic and Analog Technologies Group** has used reliability audits since the late sixties. Such programs have been identified by acronyms such as CRP (Consumer Reliability Program), EPIIC (Environmental Package Indicators for Integrated Circuits), LAPP (Linear Accelerated Punishment Program), and RAP (Reliability Audit Program).

Currently, the Analog Reliability Audit Program consists of a **Weekly Reliability Audit** and a **Quarterly Reliability Audit**. The Weekly Reliability Audit consists of rapid (short time) types of tests used to monitor the production lines on a real time basis. This type of testing is performed at the assembly/test sites worldwide. It provides data for use as an **early warning system** for identifying negative trends and triggering investigations for root cause and corrective actions.

The Quarterly Reliability Audit consists of long term types of tests and is performed at th U.S. Bipolar Analog Division Center. The data obtained from the Quarterly Reliability Audit is used to assure that the correlation between the short term weekly tests and long term quarterly tests has not changed and a new failure mechanism has not appeared.

A large data base is established by combining the results from the Weekly Reliability Audit with the results from the Quarterly Reliability Audit. Such a data base is necessary for estimating long term failure rates and evaluating potential process improvement changes. Also, after a process improvement change has been implemented, the Analog Reliability Audit Program provides a system for monitoring the change and the past history data base for evaluating the affect of the change.

Weekly Reliability Audit

The Weekly Reliability Audit is performed by each assembly/test site worldwide. The site must have capability for final electrical and quality assurance testing, reliability testing and first level of failure analysis. The results are reviewed on a continuous basis and corrective action is taken when appropriate. The results are accumulated on a monthly basis and published.

The Reliability Audit test plan is as follows:

Electrical Measurements: Performed initially and after each reliability test, consist of critical parameters and functional testing at 25°C on a go-no-go basis.

High Temperature Operating Life: Performed to detect failure mechanisms that are accelerated by a combination of temperature and electric fields. Procedure and conditions are per MIL-STD-883, Method 1015 with an ambient temperature of 145°C for 40 hours or equivalent based on a 1.0 eV activation energy and the Arrhenius equation.

Approximate Accelerated Factors

	125°C	50°C
145°C	4	4000
125°C	1	1000

Temperature Cycling/Thermal Shock: Performed to detect mechanisms related to thermal expansion and contraction of dissimilar materials, etc. Procedures and conditions are per MIL-STD-883, Methods 1010 or 1011, with ambient temperatures of –65° to +150°C or –40° to +125°C (JEDEC-STD-22-A104), for a minimum of 100 cycles.

Pressure Temperature Humidity (Autoclave): Performed to measure the moisture resistance of plastic encapsulated packages. It detects corrosion type failure mechanisms due to free ionic contaminants that may have entered the package during the manufacturing processes. Conditions are per JEDEC-STD-22, Method 102, a temperature of 121°C, steam environment and 15 psig. The duration of the test is 96 hours (minimum).

Analysis Procedure: Devices failing to meet the electrical criteria after being subjected to an accelerated environment type test are verified and characterized electrically, then submitted for failure analysis.

Quarterly Reliability Audit

The Quarterly Analog Reliability Audit Program is performed at the U.S. Bipolar Analog Division Center. This testing is designed to assure that the correlation between the short term weekly tests and the longer quarterly tests has not changed and that no new failure mechanisms have appeared. It also provides additional long term information for a data base for estimating failure rates and evaluation of potential process improvement changes.

Electrical Measurements: Performed initially and at interim readouts, consist of all standard DC and functional parameters at 25°C, measured on a go-no-go basis.

High Temperature Operating Life Test: Performed to detect failure mechanisms that are accelerated by a combination of temperature and electric fields. Procedure and conditions are per MIL-STD-883, Method 1015, with an ambient temperature of 145°C for 40 and 250 hours or equivalent, based on 1.0 eV activation energy and the Arrhenius equation.

Approximate Accelerated Factors

	125°C	50°C
145°C	4	4000
125°C	1	1000

Temperature Cycling/Thermal Shock: Performed to detect mechanisms related to thermal expansion and contraction, mismatch effects, etc. Procedure and conditions are per MIL-STD-883, Methods 1010 or 1011, with ambient temperatures of –65° to +150°C or –40° to +125°C (JEDEC-STD-22-A104) for 100, 500 and 1000 or more cycles, depending on the temperature range used. Temperature Cycling is used more frequently than Thermal Shock.

Pressure Temperature Humidity (Autoclave): Performed to measure the moisture resistance of plastic encapsulated packages. It detects corrosion type failure mechanisms due to free ionic contaminants that may have entered the package during the manufacturing processes. Conditions are per JEDEC-STD-22, Method 102, a temperature of 121°C, steam environment and 15 psig. The duration of the test is for 96 hours (minimum), with a 48 hour interim readout.

Pressure Temperature Humidity Bias (PTHB; Biased Autoclaved): This test measures the moisture resistance of plastic encapsulated packages. It detects corrosion type failure mechanisms due to free and bounded ionic contaminants that may have entered the package during the manufacturing processes, or they may be bound in the materials of the integrated circuit packaging system and activated by the moisture and the applied electrical fields. Conditions are per JEDEC-STD-22, Method 102, with bias applied, a temperature of 121°C, steam environment and 15 psig. This test detects the same type of failures as the Temperature Humidity Bias (85°C, 85% RH, with bias) test, only faster. The acceleration factor between PTHB and THB is between 20 and 40 times, depending on the type of corrosion mechanism, electrical field and packaging system.

Highly Accelerated Stress Test (HAST) is increasingly replacing the aforementioned **PTHB** test. The reason is that the **HAST** test allows control of pressure, temperature and humidity independently of each other, thus we are able to set different combinations of temperature and relative humidity. The most frequently used combination is **130°C with 85% RH**. This has been related to THB (85°C, 85% RH) by an **acceleration factor of 20** (minimum). The ability to keep the relative humidity variable constant for different temperatures is the most appealing factor of the HAST test because it reduces the determination of the acceleration factor to a single Arrhenius type of relationship. Motorola has been phasing over to HAST testing since 1985.

Temperature, Humidity and Bias (THB): This test measures the moisture resistance of plastic encapsulated packages. It detects corrosion type failure mechanisms due to free and bounded ionic contaminants that may have entered the package during the manufacturing processes, or they may be bound in the materials of the integrated circuit packaging system and activated by moisture and the applied electrical fields. Conditions are per JEDEC-STD-22, Method 102 (85°C, 85% RH), with bias applied. The duration is for 1008 hours, with a 504 hour interim readout. The acceleration factor between THB (85°C, 85% RH with bias) and the 30°C, 90% RH is typically 40 to 50 times, depending on the type of corrosion mechanism, electrical field and packaging system.

Analysis Procedure: Devices failing to meet the electrical criteria after being subjected to an accelerated environment type test(s) are verified and characterized electrically, then they are submitted for root cause failure analysis and corrective action for continuous improvement.

Applications and Product Literature

In Brief . . .

Motorola's Applications Literature provides guidance to the effective use of its semiconductor families across a broad range of practical applications. Many different topics are discussed — in a way that is not possible in a device data sheet — from detailed circuit designs complete with PCB layouts, through matters to consider when embarking on a design, to complete overviews of product families and their design philosophies.

Information is presented in the form of Application Notes, Article Reprints and detailed Engineering Bulletins.

Abstracts of all the applications documents are provided as a guide to their content; each abstract also shows the number of pages in the document, plus the origin of the article in the case of Article Reprints. Documents new to this issue are highlighted throughout.

Applications and Product Literature

*Indicates New Document

The application literature listed in this section has been prepared to acquaint the circuits and systems engineer with Motorola Linear integrated circuits and their applications. To obtain copies of the notes, simply list the publications number or numbers and send your request on your company letterhead to: Literature Distribution Center, Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix, Arizona 85036.

Application Note Abstracts

AN004E *Semiconductor Consideration for DC Power Supply Voltage Protector Circuits*

This paper addresses the requirements for the semiconductor sensing circuitry and SCR crowbar devices used in DC power supply over/under voltage protection schemes. (8pp)

AN428 *Automotive Direction Indicator with Short Circuit Detection Using the UAA1041*

Cold lamps and faulty wiring can cause false operation when using the UAA1041 Automotive Direction Indicator IC. This note provides simple solutions. (3pp)

AN531 *MC1596 Balanced Modulator*

The MC1596 Monolithic Balanced Modulator is a versatile HF communications building block. It functions as a broadband, double-sideband suppressed-carrier balanced modulator without the need for transformers or tuned circuits. This article describes device operation and biasing, and gives circuit details for typical modulator/demodulator applications in AM, SSB and suppressed-carrier AM. Additional uses as an SSB Product Detector, AM Modulator/Detector, Mixer, Frequency Doubler, Phase Detector and others are also illustrated. An appendix gives detailed AC and DC analysis. (13pp)

AN535 *Phase-Locked-Loop Design Fundamentals*

The fundamental design concepts for phase-locked-loops implemented with integrated circuits are outlined. The necessary equations required to evaluate the basic loop performance are given in conjunction with a brief design example. (12pp)

AN545A *Television Video IF Amplifier Using Integrated Circuits*

This applications note considers the requirements of the video IF amplifier section of a television receiver, and gives working circuit schematics using integrated circuits which have been specifically designed for consumer oriented products. The integrated circuits used are the MC1350, MC1352, and the MC1330. (12pp)

AN559 *A Single Ramp Analog-to-Digital Converter*

A simple single ramp A/D converter which incorporates a calibration cycle to ensure an accuracy of 12 bits is discussed. The circuit uses standard ICs and requires only one precision part — the reference voltage used in the calibration. This converter is useful in a number of instrumentation and measurement applications. (10pp)

AN569 *Transient Thermal Resistance — General Data and its Use*

Data illustrating the thermal response of a number of semiconductor die and package combinations are given. Its use, employing the concepts of transient thermal resistance and superposition, permit the circuit designer to predict semiconductor junction temperature at any point in time during application of a complex power pulse train. (16pp)

AN587 *Analysis and Design of the Op Amp Current Source*

Voltage-controlled current sources based on operational amplifiers are both versatile and accurate, yet the quality of op amps required is unimportant. This note develops general expressions for basic transfer function and output impedance, and shows that simplified equations give a very accurate description of actual circuit performance. Includes a section on analysis of the errors that result from changes in circuit parameters and temperature. (7pp)

AN703 *Designing Digitally-Controlled Power Supplies*

This application note shows two design approaches; a basic low voltage supply using an inexpensive MC1723 voltage regulator and a high current, high voltage, supply using the MC1466 floating regulator with optoelectronic isolation. Various circuit options are shown to allow the designer maximum flexibility in an application. (9pp)

AN708A *Line Driver and Receiver Considerations*

This report discusses many line driver and receiver design considerations such as system description, definition of terms, important parameter measurements, design procedures and application examples. An extensive line of devices is available from Motorola to provide the designer with the tools to implement the data transmission requirements necessary for almost every type of transmission system. (18pp)

AN719 *A New Approach To Switching Regulators*

This article describes a 24 V, 3.0 A switching mode supply. It operates at 20 kHz from a 120 V AC line with an overall efficiency of 70%. New techniques are used to shape the load line. The control circuit uses a quad comparator and an opto-coupler and features short circuit protection. (12pp)

AN740 ***The Design of an N-Channel 16k x 16 Bit Memory System for the PDP-11***

This application note describes the design and construction of a mainframe memory system with MCM6605 N-channel MOS memories. Topics included are: the interface to the PDP-11, refresh control and bookkeeping, timing control logic for the memories, memory system considerations and organization. The memory also features new integrated circuits that reduce package count and enhance memory system performance. (16pp)

AN781A ***Revised Data Interface Standards***

Revised data interface standards allow higher data rates and longer cables. This note provides an overview and comparison of the electrical and performance characteristics of RS232-C, RS422, RS423, RS449 and RS485. Includes a list of appropriate Motorola drivers and receivers with performance summaries. (6pp)

AN829 ***Application of the MC1374 TV Modulator***

The MC1374 was designed for use in applications where separate audio and composite video signals are available, which need converting to a high quality VHF television signal. It’s ideally suited as an output device for subscription TV decoders, video disk and video tape players. (12pp)

AN879 ***Monomax: Application of the MC13001 Monochrome Television Integrated Circuit***

This application note presents a complete 12″ black and white line-operated television receiver, including artwork for the printed circuit board. It is intended to provide a good starting point for the first-time user. Some of the most common pitfalls are overcome, and the significance of component selections and locations are discussed. (12pp)

AN917 ***Reading and Writing in Floppy Disk Systems Using Motorola Integrated Circuits***

The floppy disk system has become a widely used means for storing and retrieving both programs and data. A floppy disk drive requires precision controls to position and load the head as will as defined read/write signals in order to be a viable system. This application note describes the use of the MC3469 and MC3471 Write Control ICs and the MC3470 Read Amplifier which provide the necessary head and erase control, timing functions, and filtering. (16pp)

AN920 ***Theory and Applications of the MC34063 and µA78S40 Switching Regular Control Circuits***

This paper describes in detail the principle of operation of the MC34063 and µA78S40 switching regulator subsystems. Several converter design examples and numerous applications circuits with test data are included. (38pp)

AN921 ***Horizontal APC/AFC Loops***

The most popular method used in modern television receivers to synchronize the line frequency oscillator is the phase locked loop. The operating characteristics and parameters of the loops are discussed. (19pp)

AN932 ***Application of the MC1377 Color Encoder***

The MC1377 is an economical, high quality, RGB encoder for NTSC or PAL applications. It accepts RGB and composite sync inputs, and delivers a 1.0 Vp-p composite NTSC or PAL video output into a 75 Ω load. It can provide its own color oscillator and burst gating, or it can easily be driven from external sources. Performance virtually equal to high-cost studio equipment is possible with common color receiver components. (12pp)

AN954** ***A Unique Converter Configuration Provides Step–Up/Down Functions

The use of switching regulators in new portable equipment designs is becoming more pronounced over that of linear regulators. This is primarily due to the need for reductions in size and weight which dictate an ever increasing demand for higher power conversion efficiency from a battery pack. When designing at the board level it sometimes becomes necessary to generate a constant output voltage that is less than that of the battery. The step–down circuit is presented that will perform this function efficiently. However, as the battery discharges, its terminal voltage will eventually fall down below the desired output, and in order to utilize the remaining battery energy a step–up circuit is also presented.

AN957 ***Interfacing the Speakerphone to the MC34010/11/13 Speech Networks***

Interfacing the MC34018 speakerphone circuit to the MC34010 series of telephone circuits is described in this application note. The series includes the MC34010, MC34011, MC34013, and the new ‘‘A’’ version of each of those. The interface is applicable to existing designs, as well as to new designs. (12pp)

AN958 ***Transmit Gain Adjustments for the MC34014 Speech Network***

The MC34014 telephone speech network provides for direct connection to an electret microphone and to Tip and Ring. In between, the circuit provides gain, drive capability, and determination of the ac impedance for compatibility with the telephone lines. Since different microphones have different sensitivity levels, different gain levels are required from the microphone to the Tip and Ring lines. This application note will discuss how to change the gain level to suit a particular microphone while not affecting the other circuit parameters. (2pp)

AN959 ***A Speakerphone with Receive Idle Mode***

The MC34018 speakerphone system operates on the principle of comparing the transmit and receive signals to determine which is stronger, and then switching the circuit into that mode. (2pp)

AN960 ***Equalization of DTMF Signals Using the MC34014***

This application note will describe how to obtain equalization (line length compensation) of the DTMF dialing tones using the MC34014 speech network. (2pp)

AN968 ***A Digital Voice/Data Telephone Set***

This design provides standard analog telephone functions while simultaneously transmitting 9600 baud asynchronous data. It is based on Motorola's MC145422/26 UDLT family of voice/data ICs which provide 80 kbps full-duplex synchronous communication over distances up to 2 km. The circuit includes a Codec/filter, Data Set Interface and pulse/tone dialer. (7pp)

AN976 ***A New High Performance Current Mode Controller Teams Up with Current Sensing Power MOSFETs***

A new current mode control IC that interfaces directly with current sensing power MOSFETs is described. Its second generation architecture is shown to provide a variety of advantages in current mode power supplies. The most notable of these advantages is a ‘‘lossless’’ current sensing capability that is provided when used with current sensing MOSFETs. The discussion includes subtle factors to watch out for in practical designs, and an applications example. (8pp)

AN980 ***VHF Narrowband FM Receiver Design Using the MC3362 and the MC3363 Dual Conversion Receivers***

The MC3362 and MC3363 narrowband FM dual conversion receivers feature excellent VHF performance with low power drain, making them ideal for cordless telephones, narrowband voice and data receivers and RF security devices. This note provides a detailed description of the operation of the two devices, plus circuits and descriptions for four applications: a Single Channel VHF FM Narrowband Receiver; a Ten Channel Frequency Synthesized Cordless Telephone Receiver; a 256 Channel Frequency Synthesized Two-Meter Amateur Band Receiver; and a Single Chip Weather Band Receiver. (14pp)

AN983 ***A Simplified Power Supply Design Using the TL494 Control Circuit***

This application note describes the operation and characteristics of the TL494 Switchmode™ Voltage Regulator and shows its application of a 400 W offline power supply.

The TL494 is a fixed-frequency pulse width modulation control circuit, incorporating the primary building blocks required for the control of a switching power supply. (5pp)

AN1002 ***A Handsfree Featurephone Design Using the MC34114 Speech Network and the MC34018 Speakerphone ICs***

A comprehensive application note which develops a full featurephone circuit using the MC34114 Speech Network, the MC34018 Speakerphone IC and the MC145412 Dialer. Functions include 10 number memory pulse/tone dialer, tone ringer, mike mute and line length compensation for both handset and speakerphone operation. Options include line-powered circuit, line-powered circuit with booster for long lines, and external supply-powered. Includes glossary of telephone terms. (18pp)

AN1003 ***A Featurephone Design, with Tone Ringer and Dialer, Using the MC34118 Speakerphone IC***

This application note describes how to add a handset, dialer and tone ringer to the MC34118 speakerphone circuit. Although any one of several speech networks could be used as an interface between the MC34118 and the phone line this application note covers the case where simplicity and low cost are paramount. Two circuits are developed in this discussion: line-powered and supply-powered versions. (13pp)

AN1004 ***A Handsfree Featurephone Design Using the MC34114 Speech Network and the MC34118 Speakerphone ICs***

Complete designs for a featurephone providing 10 number memory, pulse or tone dialling, tone ringer, microphone muting, and line length compensation for both handset and speakerphone operation. Includes line-powered, line-powered plus long-line booster, and supply-powered versions. The MC34114 interfaces with tip and ring and provides 2-to-4 wire conversion. (18pp)

AN1006 ***Linearize the Volume Control of the MC34118 Speakerphone***

A single resistor added to the volume control potentiometer in an MC34118 speakerphone application will almost perfectly linearize the control law. (1pp)

AN1016 ***Infrared Sensing and Data Transmission Fundamentals***

Many applications need electrical isolation, remote control or position sensing. Infrared light provides an excellent solution due to its low cost, ease of use, availability of components, and freedom from the licensing and interference concerns of RF techniques. This note is a brief but informative reference on the design principles for IR systems, including a selection of receiver circuits. (6pp)

AN1019 ***NTSC Decoding Using the TDA3330, with Emphasis on Cable In/Cable Out Operation***

The TDA3330 is a Composite Video to RGB Color Decoder originally intended for PAL and NTSC color TV receivers and monitors — so its data sheet concentrates on picture tube drive. This practical application note supplements the data sheet by providing circuits for video cable drive as used in video processing, frame store and other specialized applications, and expands on TDA3330 functional details. Includes PCB artwork and layout of an evaluation board. (8pp)

AN1040 ***Mounting Considerations for Power Semiconductors***

The operating environment is a vital factor in setting current and power ratings of a semiconductor device. Reliability is increased considerably for relatively small reductions in junction temperature. Faulty mounting not only increases the thermal gradient between the device and its heatsink, but can also cause mechanical damage. This comprehensive note shows correct and incorrect methods of mounting all types of discrete packages, and discusses methods of thermal system evaluation. (20pp)

AN1044 ***The MC1378 — A Monolithic Composite Video Synchronizer***

The MC1378 provides an interface between a remote composite color video source and local RGB. On-chip circuitry can lock a local computer to the remote source, switching between local and remote signals to generate composite video overlays. This detailed note describes local and remote operation; picture-in-picture applications and the design of test fixtures to help system development. Printed circuit artwork for an evaluation board is provided. The NTSC/PAL color encoder is similar to the MC1377, discussed in detail in AN932. (13pp)

AN1046 ***Three Piece Solution for Brushless Motor Control Design (Rev. 1)***

Until recently, the design of compact but comprehensive circuits taking full advantage of the unique attributes of brushless DC motors has been difficult, while available power transistors have not always performed as well as is necessary for the application. This high-performance three-chip solution couples the rugged MPM3003 three phase MOSFET bridge (in a 12-pin power package) with the MC33035 Brushless DC Motor Adapter. Design is simplified, board area reduced. Full circuit, parts list, and discussion of practical considerations. (10pp)

AN1065** ***Use of the MC68HC68T1 Real–Time Clock with Multiple Time Bases

While this Application Note is primarily about the MC68HC68T1 clock/calendar device, it also provides an example of the application of two Motorola Analog ICs: the MC34160 Microporcessor Voltage Regulator and Supervisory Circuit and the MC34164 Undervoltage Sensing Circuit. The MC34160 provides a regulated 5.0 V supply, plus power warning and reset outputs to the MCU. The MC34164 assures that the MCU is held in reset when the supply voltage is too low for the MC34160 to operate correctly.

AN1077 ***Adding Digital Volume Control To Speakerphone Circuits***

Describes how to control speakerphone volume from UP and DOWN switches in place of the more usual potentiometer. Includes a fully annotated circuit using only three standard CMOS ICs and no critical components. (4pp)

AN1078 ***New Components Simplify Brush DC Motor Drives***

A variety of new components simplify the design of brush motor drives. One is a brushless motor control IC which is easily adapted to brush motors. Others include multiple Power MOSFETs in H-Bridge configuration, a new MOS turn-off device, and gain-stable opto level shifters. Several circuits illustrate how the new devices can be used in practical motor drives, in particular to control speed in both directions and operate from a single power supply. (6pp)

AN1080 ***External-Sync Power Supply with Universal Input Voltage Range for Monitors***

As the resolution of color monitors increases, the performance and features of their power supplies becomes more critical. EMI/RFI generated by switching power supplies can adversely affect resolution if switching frequency is not synchronized to horizontal scanning frequency. This 90 W flyback switching supply demonstrates the use of new high performance devices in a low cost design, and includes a new universal input voltage adapter. (20pp)

AN1081 ***Minimize the "pop" in the MC34119 Low Power Audio Amplifier***

Sometimes a "pop" is heard in the loudspeaker when the MC34119 audio amplifier is re-enabled. There are several possible causes, but this note offers a simple and low cost remedy to satisfy the most demanding user. (3pp)

AN1101 ***One-Horsepower Off-Line Brushless Permanent Magnet Motor Drive***

Brushless Permanent Magnet (BPM) motors (brushless DC motors) using MOSFET inverters are common in low voltage, variable speed applications such as disk drives. Higher voltage off-line applications can also use the same technology, but there have been problems in designing a reliable, low cost high side driver and understanding the more subtle effects of diode snap and PCB layout. This one-horsepower off-line BPM motor drive board uses opto-isolators and a special MOSFET turn-off IC for level translation. Includes PCB artwork and parts list, and a discussion of the theory. (10pp)

AN1108 ***Design Considerations for a Two Transistor, Current Mode Forward Converter***

This design for a 150 W, 150 kHz, two transistor, current mode forward converter illustrates solutions for noise control, feedback circuit analysis and magnetic component design — topics that often create the most problems for designers. Improved Schottky rectifiers, power MOSFETs and optocouplers — and their effects on switchmode power supply design — are also considered. Includes circuit, analysis, parts list and theoretical discussion. (11pp)

AN1122 ***Running the MC44802A PLL Circuit***

The MC44802A provides the Phase-Locked-Loop (PLL) portion of a tuning circuit intended for TV, FM radio and set-top converter applications up to 1.3 GHz; a complete tuning circuit is formed by adding a Voltage Controlled Oscillator (VCO) and mixer. The data sheet recommends use of an MCU for sending the control bytes that set the tuning frequency. This note describes a serial (I^2C) interface with an MC68HC11E9 in a tuner design — the information is sufficiently general to allow almost any MCU to be used. Includes M68HC11 program listing. (12pp)

AN1126 ***Evaluation Systems for Remote Control Devices on an Infrared Link***

The availability at low cost of remote control devices and infrared communication links provides opportunities in many application areas. This note gives information for constructing the basic building blocks to evaluate both IR links and the most popular remote control devices. Schematics and single-side PCB layouts are presented that should enable the designer quickly to put together a basic control link and evaluate its suitability for a given application in terms of data rate, effective distance, error rate and cost. Sources for special parts are also given. (10pp)

AN1203 ***A Software Method for Decoding the Output from the MC14497/MC3373 Combination***

Infrared communication is now widely used as a simple and effective means of remote control over short distances. A variety of encoding methods is used, including the biphase scheme implemented by the MC14497, a complete building block for IR data transmission. The MC3373 is a companion receiver chip to the MC14497, providing front-end processing to interface a photo detector to a TTL level. This note describes the decoding of the data at the output of the MC3373, along with software listings for the MC68HC11 and the MC68HC05. (5pp)

AN1300 ***Interfacing Microcomputers to Fractional Horsepower Motors***

In fractional horsepower motion control systems, command signals are usually now generated by a microprocessor or digital signal processor, while power is applied with MOSFETs. The interface between the two can still present difficulties; for small motors it will be, typically, 5.0 V logic to complementary P-Channel/N-Channel MOSFET H-bridges. A number of factors need to be considered, including diode snap, group bounce, noise suppression and locking out invalid inputs. The design discussed here is embodied in evaluation board DEVB103. (8pp)

AN1301 ***Interfacing Analog Inputs to Fractional Horsepower Motors***

In many types of systems it is desirable to control motor speed with an analog signal. Even in digital systems, it is often cost effective to generate an analog signal from static speed control bits or a lower frequency PWM signal than to use a more expensive MCU capable of generating a 20 kHz+ PWM signal directly. Although recent developments have simplified analog input conversion and power MOSFET outputs, the interface between signal processing circuits and power outputs is still far from simple. This note discusses the issues using the DEVB118 evaluation board as an example design. (9pp)

AN1306 ***Thermal Distortion in Video Amplifiers***

Thermal distortion is a problem in many high resolution video amplifiers. It occurs when there are instantaneous power changes in the transistor stages, and if the problem remains uncompensated, this leads to the visual effect known as smearing. This note discusses what smearing is, what causes thermal distortion, how to measure it, and how to compensate for it. (5pp)

AN1307 ***A Simple Pressure Regulator Using Semiconductor Pressure Transducers***

Semiconductor pressure transducers offer an economical means of achieving high reliability and performance in pressure sensing applications. The completely integrated MPX5100 (0 psi to 15 psi) series provides a temperature compensated, high level linear output suitable for interfacing directly with many linear control systems. This circuit illustrates how the MPX5100 can be used with a simple pressure feedback system based on the MC33033 Brushless Motor Controller to establish pressure regulation. Includes circuit diagram and PCB artwork. (7pp)

AN1315** ***An Evaluation System Interfacing the MPX2000 Series Pressure Sensors to a Microprocessor

Outputs from compensated and calibrated semiconductor pressure sensors such as the MPX2000 series devices are easily amplified and interfaced to a microprocessor. Design considerations and the description of an evaluation board using a simple analog interface connected to a microprocessor is presented here. (21pp)

AN1510 ***A Mode Indicator for the MC34118 Speakerphone Circuit***

Within the MC34118 are two comparators driven by the level detectors which are sensing the speech signals (see MC34118/D Data Sheet, Figure 24). The comparators' outputs drive the attenuator control block which sets the operating mode. (2pp)

AN1539** ***An IF Communication Circuit Tutorial

This article is intended to be a tutorial on the use of IF communication integrated circuits. The ISM band channel bandwidths and the Motorola MC13156 are used within this article as a platform for discussion. An examination of the devices topology is provided along with a discussion of the classical parameters critical to the proper operation of any typical IF device. The parameters reviewed are impedance matching the mixer, selecting the quad tank and filters and concluding with a overview of bit error rate testing for digital applications. Upon completion, the reader will have a better understanding of IF communications basics and will be able to specify the support components necessary for proper operation of these devices. (8pp)

AN1544** ***Design of Continuously Variable Slope Delta Modulation Communication Systems

Delta modulation is a simple and robust method of A/D conversion in systems requiring serial digital communications of analog signals. Delta modulation is limited by the anlaog input frequency and amplitude processed with any given circuit configuration; *i.e.*, the higher the clock frequency, the better the modulation quality (the clock frequency should be typically 9.6 kHz to 64 kHz for voice applications). Delta modulaton has the advantage that signal to noise ratios do not vary with distance in digital transmission and multiplexing, and the switching and repeating hardware is more economical than with purely analog systems. This paper is intended to give practical guidance in designing an optimum deltamod configuration for the most common voice applications using a Continuously Variable Slope Delta Modulator/Demodulator, MC34115 or MC3418, and provide some useful SNR performance information. (20pp)

AN1548** ***Guidelines for Debugging the MC44011 Video Decoder

Normally, the implementation of the MC44011 Multistandard video decoder is fairly simple in that there are no external adjustments, or critical components, to deal with. However, since this IC contains several interrelated functions and a substantial amount of programmability, debugging an improperly working circuit can sometimes be daunting. The purpose of this document is to provide a procedure for debugging and checking the operation of this IC, and an indication of what to expect at some of the various pins. (8pp)

AN1575** ***Worldwide Cordless Telephone Frequencies

This application note contains a listing of the worldwide cordless telephone frequencies by country. These tables reference application information provided in the MC13109, MC13110, and MC13111 Universal Cordless Telephone Subsystem Integrated Circuit Technical Data Sheets. Channel number, T_X channel frequency, 1st LO frequency, and T_X and R_X divider values are listed in this application note. (8pp)

ANE424 ***50 W Current Mode Controlled Offline Switch Mode Power Supply Working over 50% Duty Cycle using the UC3842A***

Switchmode power supplies based on flyback architecture and voltage-controlled PWM techniques are well established. This note describes a way of improving their dynamic characteristics using a Current Controlled PWM technique. A dedicated bipolar IC, the UC3842A Off-Line Current Mode PWM Controller, performs the current control, regulation and safety features. Full analysis of transformer and other components, plus discussion of the instability inherent in the current control mode. (27pp)

ANHK02 ***Low Power FM Transmitter System MC2831A***

This application note provides information concerning the MC2831A, a one-chip low-power FM transmitter system designed for FM communication equipment such as FM transceivers, cordless telephones, remote control and RF data link. (16pp)

Article Reprint Abstracts

AR301 ***Solid State Devices Ease Task of Designing Brushless DC Motors***

Brushless fractional-horsepower DC motors are gaining in popularity over brush type motors. Their characteristics are similar but they avoid the practical problems associated with brushes. In the past control complexity has made them less attractive, but dedicated control ICs like the MC33034, plus current-sensing power MOSFETs, mean that much of the control and protection electronics is available off the shelf. (*EDN*, 3 September 1987) (7pp)

AR323 ***Managing Heat Dissipation in DPAK Surface Mount Power Packages***

Physically smaller than a lead-formed TO-220, the DPAK was introduced to accommodate larger die than in previously available SM packages like the SOT-89. But larger die implies increased heat dissipation. New board materials and good circuit design ensure that DPAK Power MOSFETs can readily switch at their full pulse current ratings.
(*Powertechnics*, December 1988) (4pp)

AR340 ***The Low Forward Voltage Schottky***

As feature sizes are scaled down in very high density circuits, it will be necessary for the standard power supply voltage to be reduced from 5.0 V to 3.3 V within the next few years to avoid degrading performance in the new devices. Also, greater power supply efficiency will be required if the power supply is not to occupy a disproportionate amount of the total system volume. Since the major power loss in switching power supplies is in the output rectification circuits, more efficient rectifiers are needed. Schottky rectifier technology shows the greatest potential. (*Powertechnics*, May 1990) (3pp)

Engineering Bulletin Abstracts

EB27A ***Get 300 Watts EPE Linear Across 2 to 30 MHz from this Push-Pull Amplifier***

Includes circuit, PCB artwork and layout for a 300 W push-pull linear amplifier based on two MRF422s, designed to operate over the 2.0 MHz to 30 MHz band. An MC1723 voltage regulator is used as a bias supply. (4pp)

EB85A ***Full-Bridge Switching Power Supplies***

A useful selection chart presenting preferred Bipolar, power MOSFET, Rectifier and Control devices for various areas of typical 500 W to 1000 W full-bridge switching power supplies. (1p)

EB112 ***The Application of a Telephone Tone Ringer as a Ring Detector***

Telephone ringers are driven by high voltage, low frequency AC signals which are superimposed on the 48 V DC Tip-Ring feed voltage. An electronic ring detector must sense the presence of an AC signal on the line and produce a dielectrically isolated logic level to the system processor. (2pp)

EB123 ***A Simple Brush Type DC Motor Controller***

A simple and cost effective way to drive brush type DC motors is to use power MOSFETs with a Brushless DC Motor Control IC. The low cost MC33033 controller and integrated 8.0 A/100 V MPM3002 H-bridge combine to give a minimum parts count brush motor drive. (2pp)

EB124 ***MOSFETs Compete with Bipolars in Flyback Power Supplies***

Power MOSFETs with 400 V to 500 V breakdown ratings are widely used in multiple-transistor off-line power supplies. Now they can be used in flyback supplies as well, as breakdown voltages are extended to 1000 V. A discussion of the advantages and disadvantages, illustrated with typical 100 W MOSFET and Bipolar designs. (2pp)

EB126 ***Ultra-Rapid Nickel-Cadmium Battery Charger***

Charging NiCad batteries is a particular problem when their voltage exceeds the voltage of the available charging source. The ultra-fast charger presented here is capable of charging eight to twelve 1.5 V batteries at 1.2 A to 1.8 A in 30 to 45 minutes from a 10 V to 14 V source — a feat made possible by the use of new sintered electrode technology by battery manufacturers. Includes PC artwork and layout. (3pp)

EB128 ***Simple, Low-Cost Motor Controller***

This low cost DC motor controller uses the cost effective MPM3002 SENSEFET-based H-Bridge, plus the MC34060 PWM IC. It is capable of driving a 1/3 HP, permanent magnet 90 V DC motor, and includes dynamic braking and Soft-Start. (2pp)

EB142 ***The MOSFET Turn-Off Device — A New Circuit Building Block***

Technical developments have lead to a variety of discrete devices using circuit integration to reduce system cost and board space, while offering some performance improvement over conventional solutions. The first of these new components — dubbed SMALLBLOCK™ — is a building block that simplifies and reduces the component cost of an active gate-turn-off network for current-source driven MOSFETs. It is available in TO-92, SOT-23 and SOT-223 packages. (8pp)
