MC34166
MC33166

Power Switching Regulators

The MC34166, MC33166 series are high performance fixed frequency power switching regulators that contain the primary functions required for dc–to–dc converters. This series was specifically designed to be incorporated in step–down and voltage–inverting configurations with a minimum number of external components and can also be used cost effectively in step–up applications.

These devices consist of an internal temperature compensated reference, fixed frequency oscillator with on–chip timing components, latching pulse width modulator for single pulse metering, high gain error amplifier, and a high current output switch.

Protective features consist of cycle–by–cycle current limiting, undervoltage lockout, and thermal shutdown. Also included is a low power standby mode that reduces power supply current to 36 µA.

- Output Switch Current in Excess of 3.0 A
- Fixed Frequency Oscillator (72 kHz) with On–Chip Timing
- Provides 5.05 V Output without External Resistor Divider
- Precision 2% Reference
- 0% to 95% Output Duty Cycle
- Cycle–by–Cycle Current Limiting
- Undervoltage Lockout with Hysteresis
- Internal Thermal Shutdown
- Operation from 7.5 V to 40 V
- Standby Mode Reduces Power Supply Current to 36 µA
- Economical 5–Lead TO–220 Package with Two Optional Leadforms
- Also Available in Surface Mount D^2PAK Package

INTRODUCTION

The MC34166, MC33166 series are monolithic power switching regulators that are optimized for dc–to–dc converter applications. These devices operate as fixed frequency, voltage mode regulators containing all the active functions required to directly implement step–down and voltage–inverting converters with a minimum number of external components. They can also be used cost effectively in step–up converter applications. Potential markets include automotive, computer, industrial, and cost sensitive consumer products. A description of each section of the device is given below with the representative block diagram shown in Figure 13.

Oscillator

The oscillator frequency is internally programmed to 72 kHz by capacitor C_T and a trimmed current source. The charge to discharge ratio is controlled to yield a 95% maximum duty cycle at the Switch Output. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds the inverting input of the AND gate high, disabling the output switch transistor. The nominal oscillator peak and valley thresholds are 4.1 V and 2.3 V respectively.

Pulse Width Modulator

The Pulse Width Modulator consists of a comparator with the oscillator ramp voltage applied to the noninverting input, while the error amplifier output is applied into the inverting input. Output switch conduction is initiated when C_T is discharged to the oscillator valley voltage. As C_T charges to a voltage that exceeds the error amplifier output, the latch resets, terminating output transistor conduction for the duration of the oscillator ramp–up period. This PWM/Latch combination prevents multiple output pulses during a given oscillator clock cycle. Figures 6 and 14 illustrate the switch output duty cycle versus the compensation voltage.

Current Sense

The MC34166 series utilizes cycle–by–cycle current limiting as a means of protecting the output switch transistor from overstress. Each on–cycle is treated as a separate situation. Current limiting is implemented by monitoring the output switch transistor current buildup during conduction, and upon sensing an overcurrent condition, immediately turning off the switch for the duration of the oscillator ramp–up period.

The collector current is converted to a voltage by an internal trimmed resistor and compared against a reference by the Current Sense comparator. When the current limit threshold is reached, the comparator resets the PWM latch. The current limit threshold is typically set at 4.3 A. Figure 9 illustrates switch output current limit threshold versus temperature.

Error Amplifier and Reference

A high gain Error Amplifier is provided with access to the inverting input and output. This amplifier features a typical dc voltage gain of 80 dB, and a unity gain bandwidth of 600 kHz with 70 degrees of phase margin (Figure 3). The noninverting input is biased to the internal 5.05 V reference and is not pinned out. The reference has an accuracy of ± 2.0% at room temperature. To provide 5.0 V at the load, the reference is programmed 50 mV above 5.0 V to compensate for a 1.0% voltage drop in the cable and connector from the converter output. If the converter design requires an output voltage greater than 5.05 V, resistor R_1 must be added to form a divider network at the feedback input as shown in Figures 13 and 18. The equation for determining the output voltage with the divider network is:

$$V_{out} = 5.05 \left(\frac{R_2}{R_1} + 1\right)$$

External loop compensation is required for converter stability. A simple low–pass filter is formed by connecting a resistor (R_2) from the regulated output to the inverting input, and a series resistor–capacitor (R_F, C_F) between Pins 1 and 5. The compensation network component values shown in each of the applications circuits were selected to provide stability over the tested operating conditions. The step–down converter (Figure 18) is the easiest to compensate for stability. The step–up (Figure 20) and voltage–inverting (Figure 22) configurations operate as continuous conduction flyback converters, and are more difficult to compensate. The simplest way to optimize the compensation network is to observe the response of the output voltage to a step load change, while adjusting R_F and C_F for critical damping. The final circuit should be verified for stability under four boundary conditions. These conditions are minimum and maximum input voltages, with minimum and maximum loads.

By clamping the voltage on the error amplifier output (Pin 5) to less than 150 mV, the internal circuitry will be placed into a low power standby mode, reducing the power supply current to 36 µA with a 12 V supply voltage. Figure 10 illustrates the standby supply current versus supply voltage.

The Error Amplifier output has a 100 µA current source pull–up that can be used to implement soft–start. Figure 17 shows the current source charging capacitor C_{SS} through a series diode. The diode disconnects C_{SS} from the feedback loop when the 1.0 M resistor charges it above the operating range of Pin 5.

Switch Output

The output transistor is designed to switch a maximum of 40 V, with a minimum peak collector current of 3.3 A. When configured for step–down or voltage–inverting applications, as in Figures 18 and 22, the inductor will forward bias the output rectifier when the switch turns off. Rectifiers with a high forward voltage drop or long turn–on delay time should not be used. If the emitter is allowed to go sufficiently negative, collector current will flow, causing additional device heating and reduced conversion efficiency. Figure 8 shows that by clamping the emitter to 0.5 V, the collector current will be in the range of 100 µA over temperature. A 1N5822 or equivalent Schottky barrier rectifier is recommended to fulfill these requirements.

Undervoltage Lockout

An Undervoltage Lockout comparator has been incorporated to guarantee that the integrated circuit is fully functional before the output stage is enabled. The internal 5.05 V reference is monitored by the comparator which enables the output stage when V_{CC} exceeds 5.9 V. To prevent erratic output switching as the threshold is crossed, 0.9 V of hysteresis is provided.

Thermal Protection

Internal Thermal Shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at 170°C, the latch is forced into a ‘reset’ state, disabling the output switch. This feature is provided to prevent catastrophic failures from accidental device overheating. **It is not intended to be used as a substitute for proper heatsinking.** The MC34166 is contained in a 5–lead TO–220 type package. The tab of the package is common with the center pin (Pin 3) and is normally connected to ground.

DESIGN CONSIDERATIONS

Do not attempt to construct a converter on wire–wrap or plug–in prototype boards. Special care should be taken to separate ground paths from signal currents and ground paths from load currents. All high current loops should be kept as short as possible using heavy copper runs to minimize ringing and radiated EMI. For best operation, a tight component layout is recommended. Capacitors C_{IN}, C_O, and all feedback components should be placed as close to the IC as physically possible. It is also imperative that the Schottky diode connected to the Switch Output be located as close to the IC as possible.

The Step–Down Converter application is shown in Figure 18. The output switch transistor Q_1 interrupts the input voltage, generating a squarewave at the LC_O filter input. The filter averages the squarewaves, producing a dc output voltage that can be set to any level between V_{in} and V_{ref} by controlling the percent conduction time of Q_1 to that of the total oscillator cycle time. If the converter design requires an output voltage greater than 5.05 V, resistor R_1 must be added to form a divider network at the feedback input.

Figure 20 shows that the MC34166 can be configured as a step–up/down converter with the addition of an external power MOSFET. Energy is stored in the inductor during the on–time of transistors Q_1 and Q_2. During the off–time, the energy is transferred, with respect to ground, to the output filter capacitor and load. This circuit configuration has two significant advantages over the basic step–up converter circuit. The first advantage is that output short–circuit protection is provided by the MC34166, since Q_1 is directly in series with V_{in} and the load. Second, the output voltage can be programmed to be less than V_{in}. Notice that during the off–time, the inductor forward biases diodes D_1 and D_2, transferring its energy with respect to ground rather than with respect to V_{in}. When operating with V_{in} greater than 20 V, a gate protection network is required for the MOSFET. The network consists of components R_G, D_3, and D_4.

Two potential problems arise when designing the standard voltage–inverting converter with the MC34166. First, the Switch Output emitter is limited to –1.5 V with respect to the ground pin and second, the Error Amplifier's noninverting input is internally committed to the reference and is not pinned out. Both of these problems are resolved by connecting the IC ground pin to the converter's negative output as shown in Figure 22. This keeps the emitter of Q_1 positive with respect to the ground pin and has the effect of reversing the Error Amplifier inputs. Note that the voltage drop across R_1 is equal to 5.05 V when the output is in regulation.

Multiple auxiliary outputs can easily be derived by winding secondaries on the main output inductor to form a transformer. The secondaries must be connected so that the energy is delivered to the auxiliary outputs when the Switch Output turns off. During the OFF time, the voltage across the primary winding is regulated by the feedback loop, yielding a constant Volts/Turn ratio. The number of turns for any given secondary voltage can be calculated by the following equation:

$$\#\ \text{TURNS}_{(SEC)} = \frac{V_{O(SEC)} + V_{F(SEC)}}{\left(\dfrac{V_{O(PRI)} + V_{F(PRI)}}{\#\text{TURNS}_{(PRI)}}\right)}$$

Note that the 12 V winding is stacked on top of the 5.0 V output. This reduces the number of secondary turns and improves lead regulation. For best auxiliary regulation, the auxiliary outputs should be less than 33% of the total output power.

MBR20100CT – 5925B

The MC34166 can be used cost effectively in off–line applications even though it is limited to a maximum input voltage of 40 V. Figure 27 shows a simple and efficient method for converting the AC line voltage down to 24 V. This preconverter has a total power rating of 125 W with a conversion efficiency of 90%. Transformer T_1 provides output isolation from the AC line and isolation between each of the secondaries. The circuit self–oscillates at 50 kHz and is controlled by the saturation characteristics of T_2. Multiple MC34166 post regulators can be used to provide accurate independently regulated outputs for a distributed power system.

NOTES: 1. V_{sat} – Switch Output source saturation voltage, refer to Figure 7.
2. V_F – Output rectifier forward voltage drop. Typical value for 1N5822 Schottky barrier rectifier is 0.5 V.
3. Duty cycle is calculated at the minimum operating input voltage and must not exceed the guaranteed minimum $DC_{(max)}$ specification of 0.92.

The following converter characteristics must be chosen:

V_{out} – Desired output voltage.
I_{out} – Desired output current.
ΔI_L – Desired peak–to–peak inductor ripple current. For maximum output current especially when the duty cycle is greater than 0.5, it is suggested that ΔI_L be chosen to be less than 10% of the average inductor current $I_{L\ avg}$. This will help prevent $I_{pk(switch)}$ from reaching the guaranteed minimum current limit threshold of 3.3 A. If the design goal is to use a minimum inductance value, let $\Delta I_L = 2\ (I_{L\ avg})$. This will proportionally reduce the converter’s output current capability.
$V_{ripple(pp)}$ – Desired peak–to–peak output ripple voltage. For best performance, the ripple voltage should be kept to less than 2% of V_{out}. Capacitor C_O should be a low equivalent series resistance (ESR) electrolytic designed for switching regulator applications.

MOTOROLA

MC34167
MC33167

Power Switching Regulators

The MC34167, MC33167 series are high performance fixed frequency power switching regulators that contain the primary functions required for dc–to–dc converters. This series was specifically designed to be incorporated in step–down and voltage–inverting configurations with a minimum number of external components and can also be used cost effectively in step–up applications.

These devices consist of an internal temperature compensated reference, fixed frequency oscillator with on–chip timing components, latching pulse width modulator for single pulse metering, high gain error amplifier, and a high current output switch.

Protective features consist of cycle–by–cycle current limiting, undervoltage lockout, and thermal shutdown. Also included is a low power standby mode that reduces power supply current to 36 µA.

- Output Switch Current in Excess of 5.0 A
- Fixed Frequency Oscillator (72 kHz) with On–Chip Timing
- Provides 5.05 V Output without External Resistor Divider
- Precision 2% Reference
- 0% to 95% Output Duty Cycle
- Cycle–by–Cycle Current Limiting
- Undervoltage Lockout with Hysteresis
- Internal Thermal Shutdown
- Operation from 7.5 V to 40 V
- Standby Mode Reduces Power Supply Current to 36 µA
- Economical 5–Lead TO–220 Package with Two Optional Leadforms
- Also Available in Surface Mount D^{2}PAK Package

INTRODUCTION

The MC34167, MC33167 series are monolithic power switching regulators that are optimized for dc–to–dc converter applications. These devices operate as fixed frequency, voltage mode regulators containing all the active functions required to directly implement step–down and voltage–inverting converters with a minimum number of external components. They can also be used cost effectively in step–up converter applications. Potential markets include automotive, computer, industrial, and cost sensitive consumer products. A description of each section of the device is given below with the representative block diagram shown in Figure 13.

Oscillator

The oscillator frequency is internally programmed to 72 kHz by capacitor C_T and a trimmed current source. The charge to discharge ratio is controlled to yield a 95% maximum duty cycle at the Switch Output. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds the inverting input of the AND gate high, disabling the output switch transistor. The nominal oscillator peak and valley thresholds are 4.1 V and 2.3 V respectively.

Pulse Width Modulator

The Pulse Width Modulator consists of a comparator with the oscillator ramp voltage applied to the noninverting input, while the error amplifier output is applied into the inverting input. Output switch conduction is initiated when C_T is discharged to the oscillator valley voltage. As C_T charges to a voltage that exceeds the error amplifier output, the latch resets, terminating output transistor conduction for the duration of the oscillator ramp–up period. This PWM/Latch combination prevents multiple output pulses during a given oscillator clock cycle. Figures 6 and 14 illustrate the switch output duty cycle versus the compensation voltage.

Current Sense

The MC34167 series utilizes cycle–by–cycle current limiting as a means of protecting the output switch transistor from overstress. Each on cycle is treated as a separate situation. Current limiting is implemented by monitoring the output switch transistor current buildup during conduction, and upon sensing an overcurrent condition, immediately turning off the switch for the duration of the oscillator ramp–up period.

The collector current is converted to a voltage by an internal trimmed resistor and compared against a reference by the Current Sense comparator. When the current limit threshold is reached, the comparator resets the PWM latch. The current limit threshold is typically set at 6.5 A. Figure 9 illustrates switch output current limit threshold versus temperature.

Error Amplifier and Reference

A high gain Error Amplifier is provided with access to the inverting input and output. This amplifier features a typical dc voltage gain of 80 dB, and a unity gain bandwidth of 600 kHz with 70 degrees of phase margin (Figure 3). The noninverting input is biased to the internal 5.05 V reference and is not pinned out. The reference has an accuracy of ± 2.0% at room temperature. To provide 5.0 V at the load, the reference is programmed 50 mV above 5.0 V to compensate for a 1.0% voltage drop in the cable and connector from the converter output. If the converter design requires an output voltage greater than 5.05 V, resistor R_1 must be added to form a divider network at the feedback input as shown in Figures 13 and 18. The equation for determining the output voltage with the divider network is:

$$V_{out} = 5.05\left(\frac{R_2}{R_1} + 1\right)$$

External loop compensation is required for converter stability. A simple low–pass filter is formed by connecting a resistor (R_2) from the regulated output to the inverting input, and a series resistor–capacitor (R_F, C_F) between Pins 1 and 5. The compensation network component values shown in each of the applications circuits were selected to provide stability over the tested operating conditions. The step–down converter (Figure 18) is the easiest to compensate for stability. The step–up (Figure 20) and voltage–inverting (Figure 22) configurations operate as continuous conduction flyback converters, and are more difficult to compensate. The simplest way to optimize the compensation network is to observe the response of the output voltage to a step load change, while adjusting R_F and C_F for critical damping. The final circuit should be verified for stability under four boundary conditions. These conditions are minimum and maximum input voltages, with minimum and maximum loads.

By clamping the voltage on the error amplifier output (Pin 5) to less than 150 mV, the internal circuitry will be placed into a low power standby mode, reducing the power supply current to 36 µA with a 12 V supply voltage. Figure 10 illustrates the standby supply current versus supply voltage.

The Error Amplifier output has a 100 µA current source pull–up that can be used to implement soft–start. Figure 17 shows the current source charging capacitor C_{SS} through a series diode. The diode disconnects C_{SS} from the feedback loop when the 1.0 M resistor charges it above the operating range of Pin 5.

Switch Output

The output transistor is designed to switch a maximum of 40 V, with a minimum peak collector current of 5.5 A. When configured for step–down or voltage–inverting applications, as in Figures 18 and 22, the inductor will forward bias the output rectifier when the switch turns off. Rectifiers with a high forward voltage drop or long turn on delay time should not be used. If the emitter is allowed to go sufficiently negative, collector current will flow, causing additional device heating and reduced conversion efficiency. Figure 8 shows that by clamping the emitter to 0.5 V, the collector current will be in the range of 100 µA over temperature. A 1N5825 or equivalent Schottky barrier rectifier is recommended to fulfill these requirements.

Undervoltage Lockout

An Undervoltage Lockout comparator has been incorporated to guarantee that the integrated circuit is fully functional before the output stage is enabled. The internal reference voltage is monitored by the comparator which enables the output stage when V_{CC} exceeds 5.9 V. To prevent erratic output switching as the threshold is crossed, 0.9 V of hysteresis is provided.

Thermal Protection

Internal Thermal Shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at 170°C, the latch is forced into a ‘reset’ state, disabling the output switch. This feature is provided to prevent catastrophic failures from accidental device overheating. **It is not intended to be used as a substitute for proper heatsinking.** The MC34167 is contained in a 5–lead TO–220 type package. The tab of the package is common with the center pin (Pin 3) and is normally connected to ground.

DESIGN CONSIDERATIONS

Do not attempt to construct a converter on wire–wrap or plug–in prototype boards. Special care should be taken to separate ground paths from signal currents and ground paths from load currents. All high current loops should be kept as short as possible using heavy copper runs to minimize ringing and radiated EMI. For best operation, a tight component layout is recommended. Capacitors C_{in}, C_O, and all feedback components should be placed as close to the IC as physically possible. It is also imperative that the Schottky diode connected to the Switch Output be located as close to the IC as possible.

The Step–Down Converter application is shown in Figure 18. The output switch transistor Q_1 interrupts the input voltage, generating a squarewave at the LC_O filter input. The filter averages the squarewaves, producing a dc output voltage that can be set to any level between V_{in} and V_{ref} by controlling the percent conduction time of Q_1 to that of the total oscillator cycle time. If the converter design requires an output voltage greater than 5.05 V, resistor R_1 must be added to form a divider network at the feedback input.

Figure 20 shows that the MC34167 can be configured as a step–up/down converter with the addition of an external power MOSFET. Energy is stored in the inductor during the ON time of transistors Q_1 and Q_2. During the OFF time, the energy is transferred, with respect to ground, to the output filter capacitor and load. This circuit configuration has two significant advantages over the basic step–up converter circuit. The first advantage is that output short circuit protection is provided by the MC34167, since Q_1 is directly in series with V_{in} and the load. Second, the output voltage can be programmed to be less than V_{in}. Notice that during the OFF time, the inductor forward biases diodes D_1 and D_2, transferring its energy with respect to ground rather than with respect to V_{in}. When operating with V_{in} greater than 20 V, a gate protection network is required for the MOSFET. The network consists of components R_G, D_3, and D_4.

Two potential problems arise when designing the standard voltage–inverting converter with the MC34167. First, the Switch Output emitter is limited to –1.5 V with respect to the ground pin and second, the Error Amplifier's noninverting input is internally committed to the reference and is not pinned out. Both of these problems are resolved by connecting the IC ground pin to the converter's negative output as shown in Figure 22. This keeps the emitter of Q_1 positive with respect to the ground pin and has the effect of reversing the Error Amplifier inputs. Note that the voltage drop across R_1 is equal to 5.05 V when the output is in regulation.

Multiple auxiliary outputs can easily be derived by winding secondaries on the main output inductor to form a transformer. The secondaries must be connected so that the energy is delivered to the auxiliary outputs when the Switch Output turns off. During the OFF time, the voltage across the primary winding is regulated by the feedback loop, yielding a constant Volts/Turn ratio. The number of turns for any given secondary voltage can be calculated by the following equation:

$$\#\ \text{TURNS}_{(SEC)} = \frac{V_{O(SEC)} + V_{F(SEC)}}{\left(\dfrac{V_{O(PRI)} + V_{F(PRI)}}{\#\text{TURNS}_{(PRI)}}\right)}$$

Note that the 12 V winding is stacked on top of the 5.0 V output. This reduces the number of secondary turns and improves lead regulation. For best auxiliary regulation, the auxiliary outputs should be less than 33% of the total output power.

MBR20100CT – 5925B

The MC34167 can be used cost effectively in off–line applications even though it is limited to a maximum input voltage of 40 V. Figure 27 shows a simple and efficient method for converting the AC line voltage down to 24 V. This preconverter has a total power rating of 125 W with a conversion efficiency of 90%. Transformer T_1 provides output isolation from the AC line and isolation between each of the secondaries. The circuit self–oscillates at 50 kHz and is controlled by the saturation characteristics of T_2. Multiple MC34167 post regulators can be used to provide accurate independently regulated outputs for a distributed power system.

V_{out}	$V_{ref}\left(\frac{R_2}{R_1} + 1\right)$	$V_{ref}\left(\frac{R_2}{R_1} + 1\right)$	$V_{ref}\left(\frac{R_2}{R_1} + 1\right)$

NOTES: 1. V_{sat} – Switch Output source saturation voltage, refer to Figure 7.
2. V_F – Output rectifier forward voltage drop. Typical value for 1N5822 Schottky barrier rectifier is 0.35 V.
3. Duty cycle is calculated at the minimum operating input voltage and must not exceed the guaranteed minimum $DC_{(max)}$ specification of 0.92.

The following converter characteristics must be chosen:

V_{out} – Desired output voltage.
I_{out} – Desired output current.
ΔI_L – Desired peak–to–peak inductor ripple current. For maximum output current especially when the duty cycle is greater than 0.5, it is suggested that ΔI_L be chosen minimum current limit threshold of 5.5 A. If the design goal is to use a minimum inductance value, let $\Delta I_L = 2\ (I_{L\ avg})$. This will proportionally reduce the converter’s output current capability.
$V_{ripple(pp)}$ – Desired peak–to–peak output ripple voltage. For best performance, the ripple voltage should be kept to less than 2% of V_{out}. Capacitor C_O should be a low equivalent series resistance (ESR) electrolytic designed for switching regulator applications.

MOTOROLA

MC34261
MC33261

Power Factor Controllers

The MC34261/MC33261 are active power factor controllers specifically designed for use as a preconverter in electronic ballast and in off–line power converter applications. These integrated circuits feature an internal startup timer, a one quadrant multiplier for near unity power factor, zero current detector to ensure critical conduction operation, high gain error amplifier, trimmed internal bandgap reference, current sensing comparator, and a totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of input undervoltage lockout with hysteresis, cycle–by–cycle current limiting, and a latch for single pulse metering. These devices are available in dual–in–line and surface mount plastic packages.

- Internal Startup Timer
- One Quadrant Multiplier
- Zero Current Detector
- Trimmed 2% Internal Bandgap Reference
- Totem Pole Output
- Undervoltage Lockout with Hysteresis
- Low Startup and Operating Current
- Pinout Equivalent to the SG3561
- Functional Equivalent to the TDA4817

FUNCTIONAL DESCRIPTION

Introduction

Most electronic ballasts and switching power supplies use a bridge rectifier and a filter capacitor to derive raw dc voltage from the utility ac line. This simple rectifying circuit draws power from the line when the instantaneous ac voltage exceeds the capacitor's voltage. This occurs near the line voltage peak and results in a high charge current spike. Since power is only taken near the line voltage peaks, the resulting spikes of current are extremely nonsinusoidal with a high content of harmonics. This results in a poor power factor condition where the apparent input power is much higher than the real power.

The MC34261, MC33261 are high performance, critical conduction, current mode power factor controllers specifically designed for use in off–line active preconverters. These devices provide the necessary features required to significantly enhance poor power factor loads by keeping the ac line current sinusoidal and in phase with the line voltage. With proper control of the preconverter, almost any complex load can be made to appear resistive to the ac line, thus significantly reducing the harmonic current content.

Operating Description

The MC34261, MC33261 contains many of the building blocks and protection features that are employed in modern high performance current mode power supply controllers. There are, however, two areas where there is a major difference when compared to popular devices such as the UC3842 series. Referring to the block diagram in Figure 15, note that a multiplier has been added to the current sense loop and that this device does not contain an oscillator. A description of each of the functional blocks is given below.

Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 85 dB, and a unity gain bandwidth of 1.0 MHz with 58° of phase margin (Figure 4). The noninverting input is internally biased at 2.5 V ±2.0% and is not pinned out. The output voltage of the power factor converter is typically divided down and monitored by the inverting input. The maximum input bias current is –1.0 µA which can cause an output voltage error that is equal to the product of the input bias current and the value of the upper divider resistor R_2. The Error Amp Output is internally connected to the Multiplier and is pinned out (Pin 2) for external loop compensation. Typically, the bandwidth is set below 20 Hz, so that the Error Amp output voltage is relatively constant over a given ac line cycle. The output stage consists of a 500 µA current source pull–up with a Darlington transistor pull–down. It is capable of swinging from 2.1 V to 5.7 V, assuring that the Multiplier can be driven over its entire dynamic range.

Multiplier

A single quadrant, two input multiplier is the critical element that enables this device to control power factor. The ac haversines are monitored at Pin 3 with respect to ground while the Error Amp output at Pin 2 is monitored with respect to the Voltage Feedback Input threshold. A graph of the Multiplier transfer curve is shown in Figure 1. Note that both inputs are extremely linear over a wide dynamic range, 0 V to 3.2 V for the Multiplier input (Pin 3), and 2.5 V to 4.0 V for the Error Amp output (Pin 2). The Multiplier output controls the Current Sense Comparator threshold (Pin 4) as the ac voltage traverses sinusoidally from zero to peak line. This has the effect of forcing the MOSFET peak current to track the input line voltage, thus making the preconverter load appear to be resistive.

$$\text{Pin 4 Threshold} \approx 0.62(V_{\text{Pin 2}} - V_{FB})V_{\text{Pin 3}}$$

Zero Current Detector

The MC34261 operates as a critical conduction current mode controller, whereby output switch conduction is initiated by the Zero Current Detector and terminated when the peak inductor current reaches the threshold level established by the Multiplier output. The Zero Current Detector initiates the next on–time by setting the RS Latch at the instant the inductor current reaches zero. This critical conduction mode of operation has two significant benefits. First, since the MOSFET cannot turn on until the inductor current reaches zero, the output rectifier's reverse recovery time becomes less critical allowing the use of an inexpensive rectifier. Second, since there are no deadtime gaps between cycles, the ac line current is continuous thus limiting the peak switch to twice the average input current.

The Zero Current Detector indirectly senses the inductor current by monitoring when the auxiliary winding voltage falls below 1.6 V. To prevent false tripping, 110 mV of hysteresis is provided. The Zero Current Detector input is internally protected by two clamps. The upper 6.7 V clamp prevents input overvoltage breakdown while the lower 0.7 V clamp prevents substrate injection. Device destruction can result if this input is shorted to ground. An external resistor must be used in series with the auxiliary winding to limit the current through the clamps.

Current Sense Comparator and RS Latch

The Current Sense Comparator RS Latch configuration ensures that only a single pulse appears at the Drive Output during a given cycle. The inductor current is converted to a voltage by inserting a ground referenced sense resistor R_9 in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input and compared to the Multiplier output voltage. The peak inductor current is controlled by the threshold voltage of Pin 4 where:

$$I_{pk} = \frac{\text{Pin 4 Threshold}}{R_9}$$

With the component values shown in Figure 16, the Current Sense Comparator threshold, at the peak of the haversine varies from 1.1 V at 90 Vac to 100 mV at 268 Vac. The Current Sense Input to Drive Output propagation delay is typically 200 ns.

Timer

A watchdog timer function was added to the IC to eliminate the need for an external oscillator when used in stand alone applications. The Timer provides a means to automatically start or restart the preconverter if the Drive Output has been off for more than 400 µs after the inductor current reaches zero.

Undervoltage Lockout

An Undervoltage Lockout comparator guarantees that the IC is fully functional before enabling the output stage. The positive power supply terminal (V_{CC}) is monitored by the UVLO comparator with the upper threshold set at 10 V and the lower threshold at 8.0 V (Figure 14). In the standby mode, with V_{CC} at 7.0 V, the required supply current is less than 0.5 mA (Figure 13). This hysteresis and low startup current allow the implementation of efficient bootstrap startup techniques, making these devices ideally suited for wide input range off line preconverter applications. An internal 36 V clamp has been added from V_{CC} to ground to protect the IC and capacitor C_5 from an overvoltage condition. This feature is desirable if external circuitry is used to delay the startup of the preconverter.

Output

The MC34261/MC33261 contain a single totem pole output stage specifically designed for direct drive of power MOSFETs. The Drive Output is capable of up to ±500 mA peak current with a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Drive Output in a sinking mode whenever the Undervoltage Lockout is active. This characteristic eliminates the need for an external gate pull–down resistor. The totem pole output has been optimized to minimize cross conduction current during high speed operation. The addition of two 10 Ω resistors, one in series with the source output transistor and one in series with the sink output transistor, reduces the cross conduction current, as shown in Figure 12. A 16 V clamp has been incorporated into the output stage to limit the high state V_{OH}. This prevents rupture of the MOSFET gate when V_{CC} exceeds 20 V.

Table 1. Design Equations

Notes	Calculation	Formula
Calculate the maximum required output power.	Required Converter Output Power	$P_O = V_O I_O$
Calculated at the minimum required ac line for regulation. Let the efficiency n = 0.95.	Peak Inductor Current	$I_{L(pk)} = \frac{2\sqrt{2}\,P_O}{\eta Vac_{(LL)}}$
Let the switching cycle t = 20 µs.	Inductance	$L = \frac{2t\left(\frac{V_O}{\sqrt{2}} - Vac\right)Vac^2}{V_O\,Vac_{(LL)}\,I_{L(pk)}}$
In theory the on–time t_{on} is constant. In practice t_{on} tends to increase at the ac line zero crossings due to the charge on capacitor C_6.	Switch On–Time	$t_{on} = \frac{2\,P_O\,L}{\eta\,Vac^2}$
The off–time t_{off} is greatest at peak ac line and approaches zero at the ac line zero crossings. Theta (θ) represents the angle of the ac line voltage.	Switch Off–Time	$t_{off} = \frac{t_{on}}{\frac{V_O}{\sqrt{2}\,Vac\,\lvert\sin\theta\rvert} - 1}$
The minimum switching frequency occurs at peak ac line and increases as t_{off} decreases.	Switching Frequency	$f = \frac{1}{t_{on} + t_{off}}$
Set the current sense threshold V_{CS} to 1.0 V for universal input (85 Vac to 265 Vac) operation and to 0.5 V for fixed input (92 Vac to 138 Vac, or 184 to 276 Vac) operation.	Peak Switch Current	$R_9 = \frac{V_{CS}}{I_{L(pk)}}$
Set the multiplier input voltage V_M to 3.0 V at high line. Empirically adjust V_M for the lowest distortion over the ac line range while guaranteeing startup at minimum line.	Multiplier Input Voltage	$V_M = \frac{Vac\,\sqrt{2}}{\left(\frac{R_7}{R_3} + 1\right)}$
The I_{IB} R_1 error term can be minimized with a divider current in excess of 100 µA.	Converter Output Voltage	$V_O = V_{ref}\left(\frac{R_2}{R_1} + 1\right) - I_{IB}\,R_2$
The bandwidth is typically set to 20 Hz for minimum output ripple over the ac line haversine.	Error Amplifier Bandwidth	$BW = \frac{1}{2\pi\,\frac{R_1 R_2}{R_1 + R_2}\,C_1}$

The following converter characteristics must be chosen:

V_O – Desired output voltage	Vac – AC RMS line voltage
I_O – Desired output current	$Vac_{(LL)}$ – AC RMS low line voltage

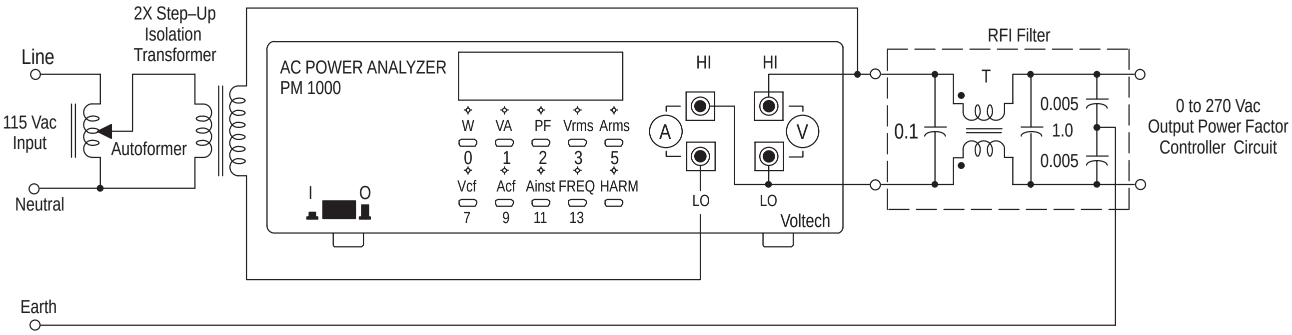
Figure 17. Power Factor Test Set–Up



An RFI filter is required for best performance when connecting the preconverter directly to the AC line. Commercially available two stage filters such as the Delta Electronics 03DPCG5 work excellent. The simple single stage test filter shown above can easily be constructed with a common mode transformer. Transformer (T) is a Coilcraft CMT3–28–2 with 28 mH minimum inductance and a 2.0 A maximum current rating.

Power Factor Controllers

The MC34262/MC33262 are active power factor controllers specifically designed for use as a preconverter in electronic ballast and in off–line power converter applications. These integrated circuits feature an internal startup timer for stand–alone applications, a one quadrant multiplier for near unity power factor, zero current detector to ensure critical conduction operation, transconductance error amplifier, quickstart circuit for enhanced startup, trimmed internal bandgap reference, current sensing comparator, and a totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of an overvoltage comparator to eliminate runaway output voltage due to load removal, input undervoltage lockout with hysteresis, cycle–by–cycle current limiting, multiplier output clamp that limits maximum peak switch current, an RS latch for single pulse metering, and a drive output high state clamp for MOSFET gate protection. These devices are available in dual–in–line and surface mount plastic packages.

- Overvoltage Comparator Eliminates Runaway Output Voltage
- Internal Startup Timer
- One Quadrant Multiplier
- Zero Current Detector
- Trimmed 2% Internal Bandgap Reference
- Totem Pole Output with High State Clamp
- Undervoltage Lockout with 6.0 V of Hysteresis
- Low Startup and Operating Current
- Supersedes Functionality of SG3561 and TDA4817

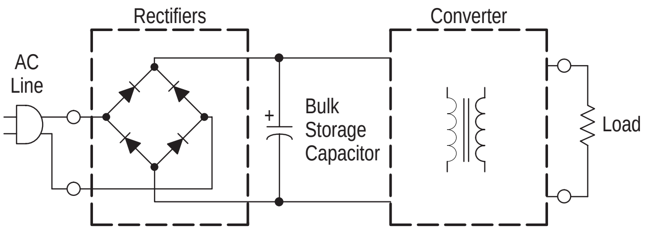
FUNCTIONAL DESCRIPTION

Introduction

With the goal of exceeding the requirements of legislation on line–current harmonic content, there is an ever increasing demand for an economical method of obtaining a unity power factor. This data sheet describes a monolithic control IC that was specifically designed for power factor control with minimal external components. It offers the designer a simple, cost–effective solution to obtain the benefits of active power factor correction.

Most electronic ballasts and switching power supplies use a bridge rectifier and a bulk storage capacitor to derive raw dc voltage from the utility ac line, Figure 15.

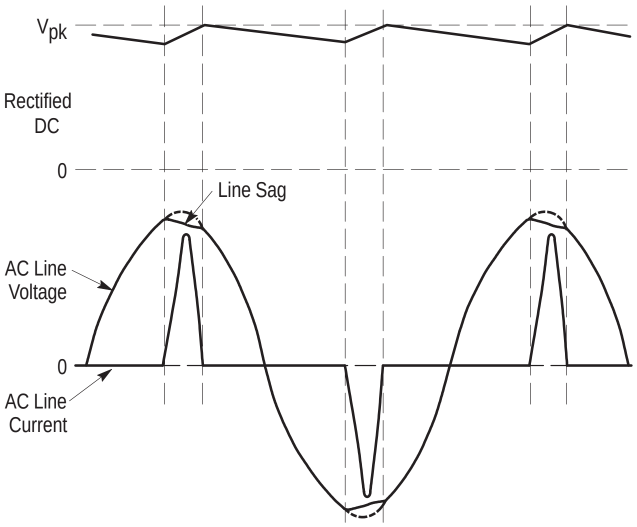
Figure 15. Uncorrected Power Factor Circuit



This simple rectifying circuit draws power from the line when the instantaneous ac voltage exceeds the capacitor voltage. This occurs near the line voltage peak and results in a high charge current spike, Figure 16. Since power is only taken near the line voltage peaks, the resulting spikes of current are extremely nonsinusoidal with a high content of harmonics. This results in a poor power factor condition where the apparent input power is much higher than the real power. Power factor ratios of 0.5 to 0.7 are common.

Power factor correction can be achieved with the use of either a passive or an active input circuit. Passive circuits usually contain a combination of large capacitors, inductors, and rectifiers that operate at the ac line frequency. Active circuits incorporate some form of a high frequency switching converter for the power processing, with the boost converter being the most popular topology, Figure 17. Since active input circuits operate at a frequency much higher than that of the ac line, they are smaller, lighter in weight, and more efficient than a passive circuit that yields similar results. With proper control of the preconverter, almost any complex load can be made to appear resistive to the ac line, thus significantly reducing the harmonic current content.

Figure 16. Uncorrected Power Factor Input Waveforms

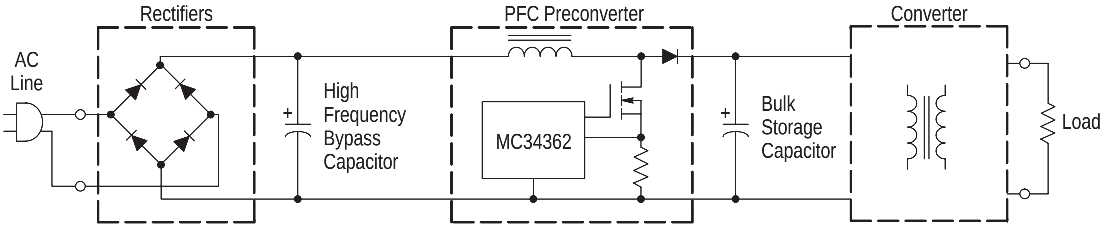


The MC34262, MC33262 are high performance, critical conduction, current–mode power factor controllers specifically designed for use in off–line active preconverters. These devices provide the necessary features required to significantly enhance poor power factor loads by keeping the ac line current sinusoidal and in phase with the line voltage.

Operating Description

The MC34262, MC33262 contain many of the building blocks and protection features that are employed in modern high performance current mode power supply controllers. There are, however, two areas where there is a major difference when compared to popular devices such as the UC3842 series. Referring to the block diagram in Figure 19, note that a multiplier has been added to the current sense loop and that this device does not contain an oscillator. The reasons for these differences will become apparent in the following discussion. A description of each of the functional blocks is given below.

Figure 17. Active Power Factor Correction Preconverter



Error Amplifier

An Error Amplifier with access to the inverting input and output is provided. The amplifier is a transconductance type, meaning that it has high output impedance with controlled voltage–to–current gain. The amplifier features a typical gm of 100 µmhos (Figure 5). The noninverting input is internally biased at 2.5 V ± 2.0% and is not pinned out. The output voltage of the power factor converter is typically divided down and monitored by the inverting input. The maximum input bias current is – 0.5 µA, which can cause an output voltage error that is equal to the product of the input bias current and the value of the upper divider resistor R_2. The Error Amp output is internally connected to the Multiplier and is pinned out (Pin 2) for external loop compensation. Typically, the bandwidth is set below 20 Hz, so that the amplifier's output voltage is relatively constant over a given ac line cycle. In effect, the error amp monitors the average output voltage of the converter over several line cycles. The Error Amp output stage was designed to have a relatively constant transconductance over temperature. This allows the designer to define the compensated bandwidth over the intended operating temperature range. The output stage can sink and source 10 µA of current and is capable of swinging from 1.7 V to 6.4 V, assuring that the Multiplier can be driven over its entire dynamic range.

A key feature to using a transconductance type amplifier, is that the input is allowed to move independently with respect to the output, since the compensation capacitor is connected to ground. This allows dual usage of of the Voltage Feedback Input pin by the Error Amplifier and by the Overvoltage Comparator.

Overvoltage Comparator

An Overvoltage Comparator is incorporated to eliminate the possibility of runaway output voltage. This condition can occur during initial startup, sudden load removal, or during output arcing and is the result of the low bandwidth that must be used in the Error Amplifier control loop. The Overvoltage Comparator monitors the peak output voltage of the converter, and when exceeded, immediately terminates MOSFET switching. The comparator threshold is internally set to 1.08 V_{ref}. In order to prevent false tripping during normal operation, the value of the output filter capacitor C_3 must be large enough to keep the peak–to–peak ripple less than 16% of the average dc output. The Overvoltage Comparator input to Drive Output turn–off propagation delay is typically 400 ns. A comparison of startup overshoot without and with the Overvoltage Comparator circuit is shown in Figure 23.

Multiplier

A single quadrant, two input multiplier is the critical element that enables this device to control power factor. The ac full wave rectified haversines are monitored at Pin 3 with respect to ground while the Error Amp output at Pin 2 is monitored with respect to the Voltage Feedback Input threshold. The Multiplier is designed to have an extremely linear transfer curve over a wide dynamic range, 0 V to 3.2 V for Pin 3, and 2.0 V to 3.75 V for Pin 2, Figure 1. The Multiplier output controls the Current Sense Comparator threshold as the ac voltage traverses sinusoidally from zero to peak line, Figure 18. This has the effect of forcing the MOSFET on–time to track the input line voltage, resulting in a fixed Drive Output on–time, thus making the preconverter load appear to be resistive to the ac line. An approximation of the Current Sense Comparator threshold can be calculated from the following equation. This equation is accurate only under the given test condition stated in the electrical table.

$$V_{CS}\text{, Pin 4 Threshold} \approx 0.65\,(V_{Pin\ 2} - V_{th(M)})\,V_{Pin\ 3}$$

A significant reduction in line current distortion can be attained by forcing the preconverter to switch as the ac line voltage crosses through zero. The forced switching is achieved by adding a controlled amount of offset to the Multiplier and Current Sense Comparator circuits. The equation shown below accounts for the built–in offsets and is accurate to within ten percent. Let $V_{th(M)} = 1.991$ V

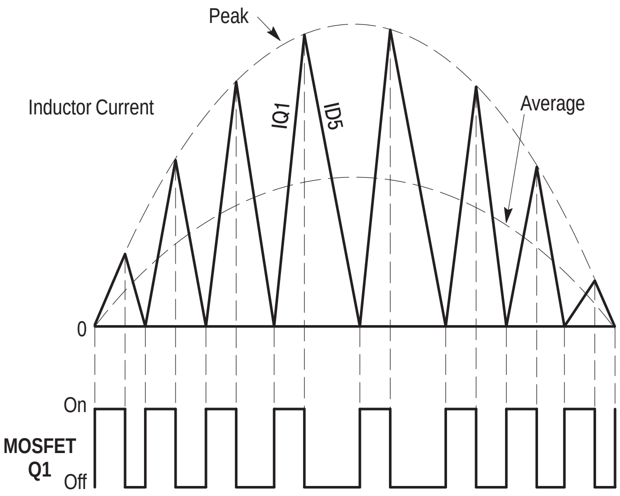
$$V_{CS}\text{, Pin 4 Threshold} = 0.544\,(V_{Pin\ 2} - V_{th(M)})\,V_{Pin\ 3} + 0.0417\,(V_{Pin\ 2} - V_{th(M)})$$

Zero Current Detector

The MC34262 operates as a critical conduction current mode controller, whereby output switch conduction is initiated by the Zero Current Detector and terminated when the peak inductor current reaches the threshold level established by the Multiplier output. The Zero Current Detector initiates the next on–time by setting the RS Latch at the instant the inductor current reaches zero. This critical conduction mode of operation has two significant benefits. First, since the MOSFET cannot turn–on until the inductor current reaches zero, the output rectifier reverse recovery time becomes less critical, allowing the use of an inexpensive rectifier. Second, since there are no deadtime gaps between cycles, the ac line current is continuous, thus limiting the peak switch to twice the average input current.

The Zero Current Detector indirectly senses the inductor current by monitoring when the auxiliary winding voltage falls below 1.4 V. To prevent false tripping, 200 mV of hysteresis is provided. Figure 9 shows that the thresholds are well–defined over temperature. The Zero Current Detector input is internally protected by two clamps. The upper 6.7 V clamp prevents input overvoltage breakdown while the lower 0.7 V clamp prevents substrate injection. Current limit protection of the lower clamp transistor is provided in the event that the input pin is accidentally shorted to ground. The Zero Current Detector input to Drive Output turn–on propagation delay is typically 320 ns.

Figure 18. Inductor Current and MOSFET Gate Voltage Waveforms



Current Sense Comparator and RS Latch

The Current Sense Comparator RS Latch configuration used ensures that only a single pulse appears at the Drive Output during a given cycle. The inductor current is converted to a voltage by inserting a ground–referenced sense resistor R_7 in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input and compared to a level derived from the Multiplier output. The peak inductor current under normal operating conditions is controlled by the threshold voltage of Pin 4 where:

$$I_{L(pk)} = \frac{\text{Pin 4 Threshold}}{R_7}$$

Abnormal operating conditions occur during preconverter startup at extremely high line or if output voltage sensing is lost. Under these conditions, the Multiplier output and Current Sense threshold will be internally clamped to 1.5 V. Therefore, the maximum peak switch current is limited to:

$$I_{pk(max)} = \frac{1.5\text{ V}}{R_7}$$

An internal RC filter has been included to attenuate any high frequency noise that may be present on the current waveform. This filter helps reduce the ac line current distortion especially near the zero crossings. With the component values shown in Figure 20, the Current Sense Comparator threshold, at the peak of the haversine varies from 1.1 V at 90 Vac to 100 mV at 268 Vac. The Current Sense Input to Drive Output turn–off propagation delay is typically less than 200 ns.

Timer

A watchdog timer function was added to the IC to eliminate the need for an external oscillator when used in stand–alone applications. The Timer provides a means to automatically start or restart the preconverter if the Drive Output has been off for more than 620 μs after the inductor current reaches zero. The restart time delay versus temperature is shown in Figure 8.

Undervoltage Lockout and Quickstart

An Undervoltage Lockout comparator has been incorporated to guarantee that the IC is fully functional before enabling the output stage. The positive power supply terminal (V_{CC}) is monitored by the UVLO comparator with the upper threshold set at 13 V and the lower threshold at 8.0 V. In the stand–by mode, with V_{CC} at 7.0 V, the required supply current is less than 0.4 mA. This large hysteresis and low startup current allow the implementation of efficient bootstrap startup techniques, making these devices ideally suited for wide input range off–line preconverter applications. An internal 36 V clamp has been added from V_{CC} to ground to protect the IC and capacitor C_4 from an overvoltage condition. This feature is desirable if external circuitry is used to delay the startup of the preconverter. The supply current, startup, and operating voltage characteristics are shown in Figures 13 and 14.

A Quickstart circuit has been incorporated to optimize converter startup. During initial startup, compensation capacitor C_1 will be discharged, holding the error amp output below the Multiplier threshold. This will prevent Drive Output switching and delay bootstrapping of capacitor C_4 by diode D_6. If Pin 2 does not reach the multiplier threshold before C_4 discharges below the lower UVLO threshold, the converter will “hiccup” and experience a significant startup delay. The Quickstart circuit is designed to precharge C_1 to 1.7 V, Figure 7. This level is slightly below the Pin 2 Multiplier threshold, allowing immediate Drive Output switching and bootstrap operation when C_4 crosses the upper UVLO threshold.

Drive Output

The MC34262/MC33262 contain a single totem–pole output stage specifically designed for direct drive of power MOSFETs. The Drive Output is capable of up to ± 500 mA peak current with a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Drive Output in a sinking mode whenever the Undervoltage Lockout is active. This characteristic eliminates the need for an external gate pull–down resistor. The totem–pole output has been optimized to minimize cross–conduction current during high speed operation. The addition of two 10 Ω resistors, one in series with the source output transistor and one in series with the sink output transistor, helps to reduce the cross–conduction current and radiated noise by limiting the output rise and fall time. A 16 V clamp has been incorporated into the output stage to limit the high state V_{OH}. This prevents rupture of the MOSFET gate when V_{CC} exceeds 20 V.

APPLICATIONS INFORMATION

The application circuits shown in Figures 19, 20 and 21 reveal that few external components are required for a complete power factor preconverter. Each circuit is a peak detecting current–mode boost converter that operates in critical conduction mode with a fixed on–time and variable off–time. A major benefit of critical conduction operation is that the current loop is inherently stable, thus eliminating the need for ramp compensation. The application in Figure 19 operates over an input voltage range of 90 Vac to 138 Vac and provides an output power of 80 W (230 V at 350 mA) with an associated power factor of approximately 0.998 at nominal line. Figures 20 and 21 are universal input preconverter examples that operate over a continuous input voltage range of 90 Vac to 268 Vac. Figure 20 provides an output power of 175 W (400 V at 440 mA) while Figure 21 provides 450 W (400 V at 1.125 A). Both circuits have an observed worst–case power factor of approximately 0.989. The input current and voltage waveforms of Figure 20 are shown in Figure 22 with operation at 115 Vac and 230 Vac. The data for each of the applications was generated with the test set–up shown in Figure 24.

Table 1. Design Equations

Notes	Calculation	Formula
Calculate the maximum required output power.	Required Converter Output Power	$P_O = V_O I_O$
Calculated at the minimum required ac line voltage for output regulation. Let the efficiency η = 0.92 for low line operation.	Peak Inductor Current	$I_{L(pk)} = \frac{2\sqrt{2}\,P_O}{\eta Vac_{(LL)}}$
Let the switching cycle t = 40 µs for universal input (85 to 265 Vac) operation and 20 µs for fixed input (92 to 138 Vac, or 184 to 276 Vac) operation.	Inductance	$L_P = \frac{t\left(\frac{V_O}{\sqrt{2}} - Vac_{(LL)}\right)\eta\, Vac_{(LL)}^2}{\sqrt{2}\,V_O P_O}$
In theory the on–time t_{on} is constant. In practice t_{on} tends to increase at the ac line zero crossings due to the charge on capacitor C_5. Let Vac = $Vac_{(LL)}$ for initial t_{on} and t_{off} calculations.	Switch On–Time	$t_{on} = \frac{2 P_O L_P}{\eta\, Vac^2}$
The off–time t_{off} is greatest at the peak of the ac line voltage and approaches zero at the ac line zero crossings. Theta (θ) represents the angle of the ac line voltage.	Switch Off–Time	$t_{off} = \frac{t_{on}}{\frac{V_O}{\sqrt{2}\,Vac\,\lvert \sin\theta \rvert} - 1}$
The minimum switching frequency occurs at the peak of the ac line voltage. As the ac line voltage traverses from peak to zero, t_{off} approaches zero producing an increase in switching frequency.	Switching Frequency	$f = \frac{1}{t_{on} + t_{off}}$
Set the current sense threshold V_{CS} to 1.0 V for universal input (85 Vac to 265 Vac) operation and to 0.5 V for fixed input (92 Vac to 138 Vac, or 184 Vac to 276 Vac) operation. Note that V_{CS} must be <1.4 V.	Peak Switch Current	$R_7 = \frac{V_{CS}}{I_{L(pk)}}$
Set the multiplier input voltage V_M to 3.0 V at high line. Empirically adjust V_M for the lowest distortion over the ac line voltage range while guaranteeing startup at minimum line.	Multiplier Input Voltage	$V_M = \frac{Vac\,\sqrt{2}}{\left(\frac{R_5}{R_3} + 1\right)}$
The I_{IB} R_1 error term can be minimized with a divider current in excess of 50 µA.	Converter Output Voltage	$V_O = V_{ref}\left(\frac{R_2}{R_1} + 1\right) - I_{IB} R_2$
The calculated peak–to–peak ripple must be less than 16% of the average dc output voltage to prevent false tripping of the Overvoltage Comparator. Refer to the Overvoltage Comparator text. ESR is the equivalent series resistance of C_3	Converter Output Peak to Peak Ripple Voltage	$\Delta V_{O(pp)} = I_O \sqrt{\left(\frac{1}{2\pi f_{ac} C_3}\right)^2 + ESR^2}$
The bandwidth is typically set to 20 Hz. When operating at high ac line, the value of C_1 may need to be increased. (See Figure 25)	Error Amplifier Bandwidth	$BW = \frac{gm}{2\pi C_1}$

The following converter characteristics must be chosen:

V_O — Desired output voltage
I_O — Desired output current
ΔV_O — Converter output peak–to–peak ripple voltage
Vac — AC RMS line voltage
$Vac_{(LL)}$ — AC RMS low line voltage

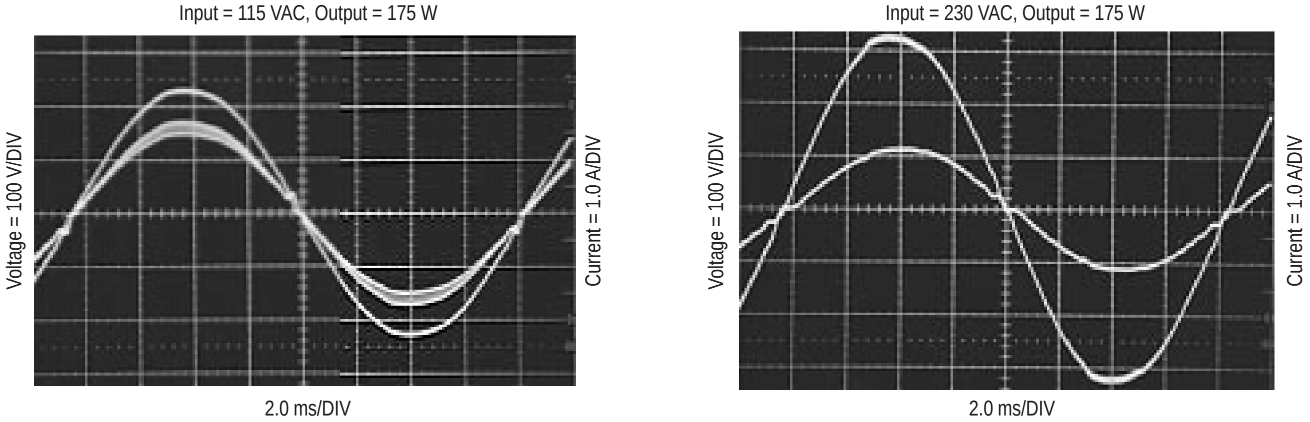

Figure 23. Output Voltage Startup Overshoot
(Figure 20 Circuit)

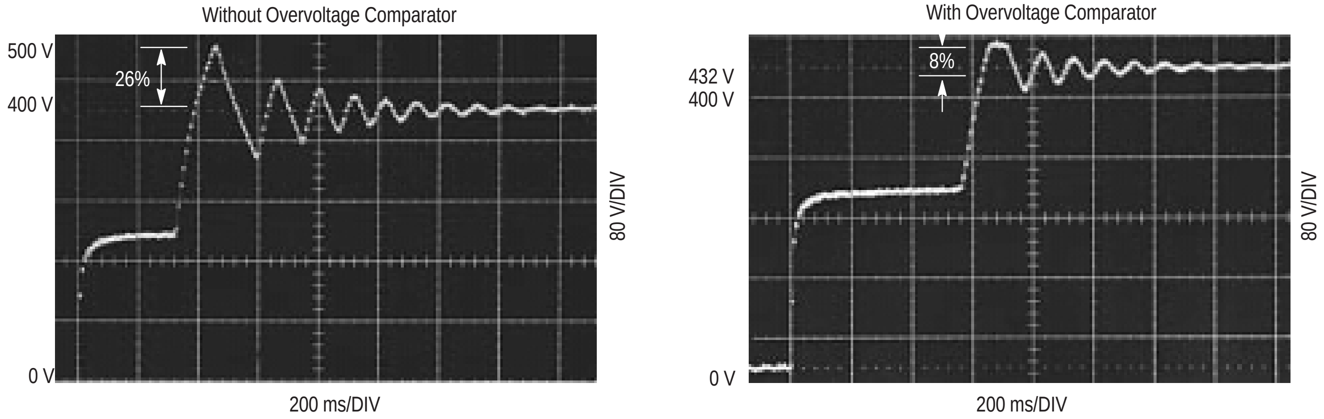

Figure 24. Power Factor Test Set–Up

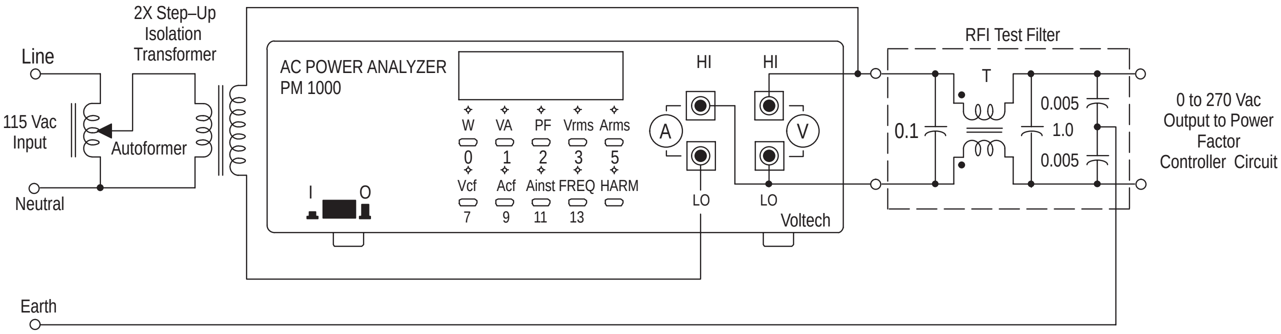
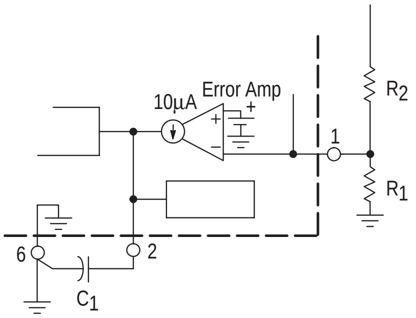


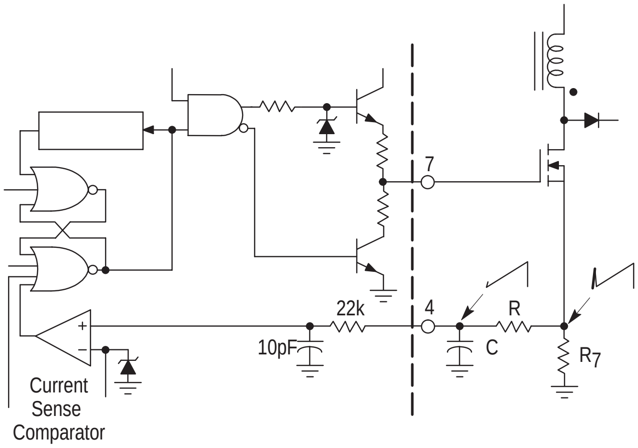
An RFI filter is required for best performance when connecting the preconverter directly to the ac line. The filter attenuates the level of high frequency switching that appears on the ac line current waveform. Figures 19 and 20 work well with commercially available two stage filters such as the Delta Electronics 03DPCG5. Shown above is a single stage test filter that can easily be constructed with four ac line rated capacitors and a common–mode transformer. Coilcraft CMT3–28–2 was used to test Figures 19 and 20. It has a minimum inductance of 28 mH and a maximum current rating of 2.0 A. Coilcraft CMT4–17–9 was used to test Figure 21. It has a minimum inductance of 17 mH and a maximum current rating of 9.0 A. Circuit conversion efficiency η (%) was calculated without the power loss of the RFI filter.

Figure 25. Error Amp Compensation



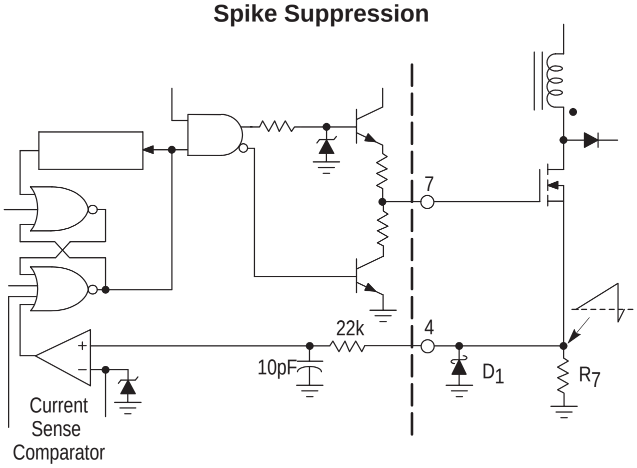
The Error Amp output is a high impedance node and is susceptible to noise pickup. To minimize pickup, compensation capacitor C_1 must be connected as close to Pin 2 as possible with a short, heavy ground returning directly to Pin 6. When operating at high ac line, the voltage at Pin 2 may approach the lower threshold of the Multiplier, ≈ 2.0 V. If there is excessive ripple on Pin 2, the Multiplier will be driven into cut–off causing circuit instability, high distortion and poor power factor. This problem can be eliminated by increasing the value of C_1.

Figure 26. Current Waveform Spike Suppression



A narrow turn–on spike is usually present on the leading edge of the current waveform and can cause circuit instability. The MC34262 provides an internal RC filter with a time constant of 220 ns. An additional external RC filter may be required in universal input applications that are above 200 W. It is suggested that the external filter be placed directly at the Current Sense Input and have a time constant that approximates the spike duration.

Figure 27. Negative Current Waveform Spike Suppression



A negative turn–off spike can be observed on the trailing edge of the current waveform. This spike is due to the parasitic inductance of resistor R_7, and if it is excessive, it can cause circuit instability. The addition of Shottky diode D_1 can effectively clamp the negative spike. The addition of the external RC filter shown in Figure 26 may provide sufficient spike attenuation.

NOTE: Use 2 oz. copper laminate for optimum circuit performance.

MOTOROLA

MC34268

SCSI-2 Active Terminator Regulator

The MC34268 is a medium current, low dropout positive voltage regulator specifically designed for use in SCSI–2 active termination circuits. This device offers the circuit designer an economical solution for precision voltage regulation, while keeping power losses to a minimum. The regulator consists of a 1.0 V dropout composite PNP/NPN pass transistor, current limiting, and thermal limiting. These devices are packaged in the 8–pin SOP–8 and 3–pin DPAK surface mount power packages.

Applications include active SCSI–2 terminators and post regulation of switching power supplies.

- 2.85 V Output Voltage for SCSI–2 Active Termination
- 1.0 V Dropout
- Output Current in Excess of 800 mA
- Thermal Protection
- Short Circuit Protection
- Output Trimmed to 1.4% Tolerance
- No Minimum Load Required
- Space Saving DPAK and SOP–8 Surface Mount Power Packages

Figure 1. Dropout Voltage versus Output Load Current

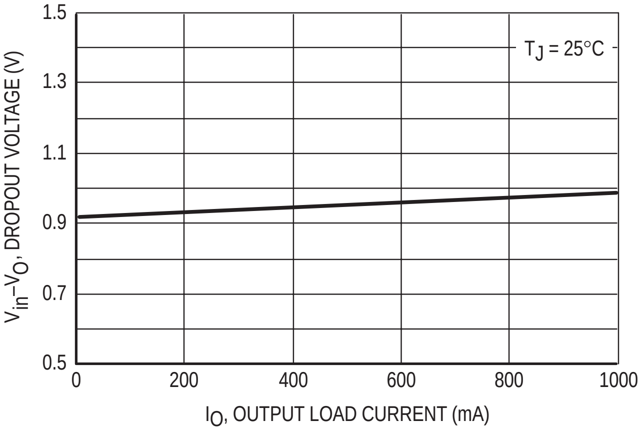

Figure 2. Transient Load Regulation

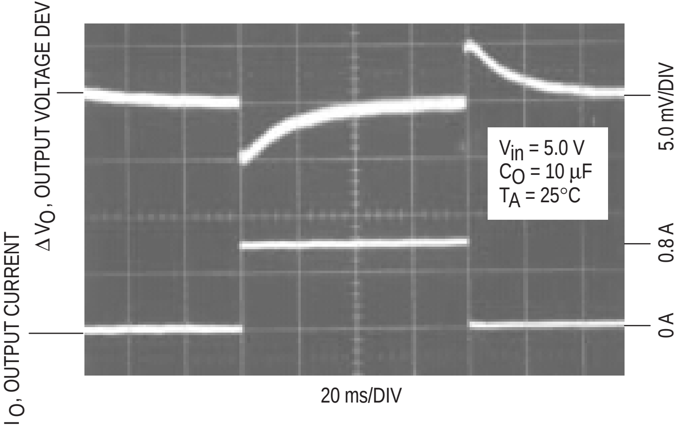

Figure 3. Typical SCSI Application

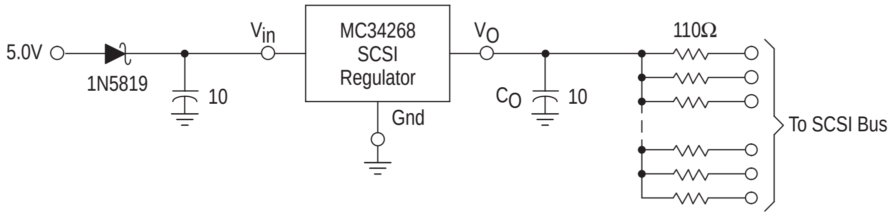

Figure 3 is a circuit of a typical SCSI terminator application. The MC34268 is designed specifically to provide 2.85 V required to drive a SCSI–2 bus. The output current capability of the regulator is in excess of 800 mA; enough to drive standard SCSI–2, fast SCSI–2, and some wide SCSI–2 applications. The typical dropout voltage is less than 1.0 V, allowing the IC to regulate to input voltages less than 4.0 V. Internal protective features include current and thermal limiting.

The MC34268 requires an external 10 μF capacitor with an ESR of less than 10 Ω for stability over temperature. With economical electrolytic capacitors, cold temperature operation can pose a stability problem. As temperature decreases, the capacitance also decreases and the ESR increases, which could cause the circuit to oscillate. Tantalum capacitors may be a better choice if small size is a requirement. Also, the capacitance and ESR of a tantalum capacitor is more stable over temperature.

MOTOROLA

MC34270
MC34271

Liquid Crystal Display and Backlight Integrated Controller

The MC34270 and MC34271 are low power dual switching voltage regulators, specifically designed for handheld and laptop applications, to provide several regulated output voltages using a minimum of external parts. Two uncommitted switching regulators feature a very low standby bias current of 5.0 µA, and an operating current of 7.0 mA capable of supplying output currents in excess of 200 mA.

Both devices have three additional features. The first is an ELD Output that can be used to drive a backlight or a liquid crystal display. The ELD output frequency is the clock divided by 256. The second feature allows four additional output bias voltages, in specific proportions to V_B, one of the switching regulated output voltages. It allows use of mixed logic circuitry and provides a voltage bias for N–Channel load control MOSFETs™. The third feature is an Enable input that allows a logic level signal to turn–“off” or turn–“on” both switching regulators.

Due to the low bias current specifications, these devices are ideally suited for battery powered computer, consumer, and industrial equipment where an extension of useful battery life is desirable.

MC34270 and MC34271 Features:

- Low Standby Bias Current of 5.0 µA
- Uncommitted Switching Regulators Allow Both Positive and Negative Supply Voltages
- Logic Enable Allows Microprocessor Control of All Outputs
- Synchronizable to External Clock
- Mode Commandable for ELD and LCD Interface
- Frequency Synchronizable
- Auxiliary Output Bias Voltages Enable Load Control via N–Channel FETs

MOSFET is a trademark of Motorola, Inc.

OPERATING DESCRIPTION

The MC34270 and MC34271 series are monolithic, fixed frequency power switching regulators specifically designed for dc to dc converter and battery powered applications. These devices operate as fixed frequency, voltage mode regulators containing all the active functions required to directly implement step–up, step–down and voltage inverting converters with a minimum number of external components. Potential markets include battery powered, handheld, automotive, computer, industrial and cost sensitive consumer products. A description of each section is given below with the representative block diagram shown in Figure 9.

Oscillator

The oscillator frequency is programmed by resistor R_T. The charge to discharge ratio is controlled to yield a 95% maximum duty cycle at the switch outputs. During the fall time of the internal sawtooth waveform, the oscillator generates an internal blanking pulse that holds the inverting input of the AND gates high, disabling the output switching MOSFETs. The internal sawtooth waveform has a nominal peak voltage of 3.3 V and a valley voltage of 1.7 V.

Pulse Width Modulators

Both pulse width modulators consist of a comparator with the oscillator ramp voltage applied to the noninverting input, while the error amplifier output is applied to the inverting input. A third input to the comparator has a 0.5 mA typical current source that can be used to implement soft start. Output switch conduction is initiated when the ramp waveform is discharged to the valley voltage. As the ramp voltage increases to a voltage that exceeds the error amplifier output, the latch resets, terminating output MOSFET conduction for the duration of the oscillator ramp. This PWM/latch combination prevents multiple output pulses during a given oscillator cycle.

Each PWM circuit is enabled by a logic input. When disabled, the entire block is turned off, drawing only leakage current from the power source. Shared circuits, like the reference and oscillator, can be activated by either EN_1 or EN_2.

Circuit #1 has an ELD output which may be used to drive an LCD or backlight. Its output frequency is the oscillator frequency divided by 1024.

Error Amplifiers and Reference

Each error amplifier is provided with access to both inverting and noninverting inputs, and the output. The Error Amplifiers’ Common Mode Input Range is 0 to 2.5 V. The amplifiers have a minimum dc voltage gain of 60 dB. The 1.25 V reference has an accuracy of ±4.0% at room temperature.

External loop compensation is required for converter stability. A simple low–pass filter is formed by connecting a resistive divider from the output to the error amplifier inverting input, and a series resistor–capacitor from the error amplifier output also to the to the inverting input. The step down converter is easiest to compensate for stability. The step–up and voltage inverting configurations, when operated as continuous conduction boost or flyback converters, are more difficult to compensate, and may require a lower loop design bandwidth.

MOSFET Switch Outputs

The output MOSFETs are designed to switch a maximum of 60 V, with a peak drain current capability of 500 mA. In circuit #1 an additional DRV_1 output is provided for interfacing with an external MOSFET.The gates of the MOSFETs are held low when the circuit is disabled.

Auxiliary Output Voltages

Output voltages V_0 through V_4 are provided for use as references or bias voltages. V_0 is the circuit #2 output voltage, when an internal FET switch is activated. The other auxiliary output voltages are proportional to V_B. The amplifiers for V_1 and V_2 are powered from V_0, while the amplifiers for V_3 and V_4 are powered from V_{DD}.

MOTOROLA

MC44602

High Performance Current Mode Controller

The MC44602 is an enhanced high performance fixed frequency current mode controller that is specifically designed for off–line and high voltage dc–to–dc converter applications. This device has the unique ability of changing operating modes if the converter output is overloaded or shorted, offering the designer additional protection for increased system reliability. The MC44602 has several distinguishing features when compared to conventional current mode controllers. These features consist of a foldback amplifier for overload detection, valid load and demag comparators with a fault latch for short circuit detection, thermal shutdown, and separate high current source and sink outputs that are ideally suited for driving a high voltage bipolar power transistor, such as the MJE18002, MJE18004, or MJE18006.

Standard features include an oscillator with a sync input, a temperature compensated reference, high gain error amplifier, and a current sensing comparator. Protective features consist of input and reference undervoltage lockouts each with hysteresis, cycle–by–cycle current limiting, a latch for single pulse metering, and a flip–flop which blanks the output off every other oscillator cycle, allowing output deadtimes to be programmed from 50% to 70%. This device is manufactured in a 16 pin dual–in–line heat tab package for improved thermal conduction.

- Separate High Current Source and Sink Outputs Ideally Suited for Driving Bipolar Power Transistors: 1.0 A Source, 1.5 A Sink
- Unique Overload and Short Circuit Protection
- Thermal Protection
- Oscillator with Sync Input
- Current Mode Operation to 500 kHz Output Switching Frequency
- Output Deadtime Adjustable from 50% to 70%
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Input and Reference Undervoltage Lockouts with Hysteresis
- Low Startup and Operating Current

OPERATING DESCRIPTION

The MC44602 is a high performance, fixed frequency, current mode controller specifically designed to directly drive a bipolar power switch in off–line and high voltage dc–to–dc converter applications. This device offers the designer a cost effective solution with minimal external components. The representative block and timing diagrams are shown in Figures 27 and 28.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T. Capacitor C_T is charged from the 5.0 V reference through resistor R_T to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds one of the inputs of the NOR gate high. This causes the Source and Sink outputs to be in a low state, thus producing a controlled amount of output deadtime. An internal toggle flip–flop has been incorporated in the MC44602 which blanks the output off every other clock cycle by holding one of the inputs of the NOR gate high. This in combination with the C_T discharge period yields output deadtimes programmable from 50% to 70%. Figure 1 shows R_T versus Oscillator Frequency and Figure 2, Output Deadtime versus Frequency, both for a given value of C_T. Note that many values of R_T and C_T will give the same oscillator frequency but only one combination will yield a specific output deadtime at a given frequency.

In many noise sensitive applications it may be desirable to frequency–lock the converter to an external system clock. This can be accomplished by applying a narrow rectangular clock signal with an amplitude of 3.2 V to 5.5 V to the Sync Input (Pin 7). For reliable locking, the free–running oscillator frequency should be set about 10% less than the clock frequency. If the clock signal is ac coupled through a capacitor, an external clamp diode may be required if the negative sync input current is greater than –5.0 mA. Connecting Pin 7 to V_{ref} will cause C_T to discharge to 0 V, inhibiting the Oscillator and conduction of the Source Output. Multi–unit synchronization can be accomplished by connecting the C_T pin of each IC to a single MC1455 timer.

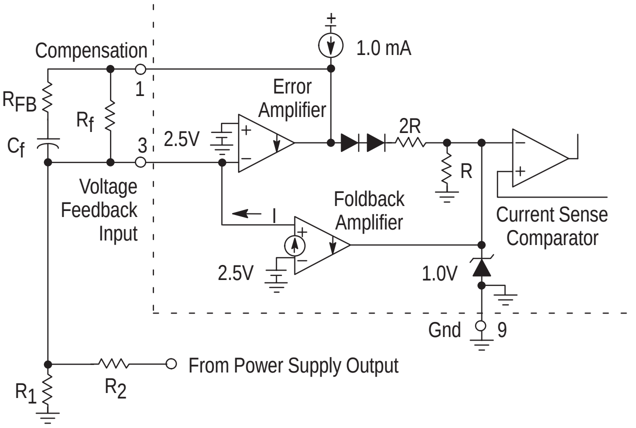
Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 90 dB, and a unity gain bandwith of 1.0 MHz with 57 degrees of phase margin (Figure 7). The noninverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current with the inverting input at 2.5 V is –2.0 µA. This can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp Output (Pin 1) is provided for external loop compensation (Figure 29). The output voltage is offset by two diodes drops (≈1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Source Output (Pin 11) when Pin 1 is at its lowest state (V_{OL}). This occurs when the power supply is operating and the load is removed, or at the beginning of a soft–start interval. The Error Amp minimum feedback resistance is limited by the amplifier's minimum source current (0.5 mA) and the required output voltage (V_{OH}) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\ (1.0\ V)\ +\ 1.4\ V}{0.5 mA}\ =\ 8800\ \Omega$$

Figure 29. Error Amplifier Compensation



Current Sense Comparator and PWM Latch

The MC44602 operates as a current mode controller, where output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier output (Pin 1). Thus the error signal controls the peak inductor current on a cycle–by–cycle basis. The Current Sense Comparator PWM Latch configuration used ensures that only a single pulse appears at the Source Output during the appropriate oscillator cycle. The inductor current is converted to a voltage by inserting the ground referenced sense resistor R_S in series with the emitter of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 6) and compared to a level derived from the Error Amp output. The peak inductor current under normal operating conditions is controlled by the voltage at Pin 1 where:

$$I_{pk} \approx \frac{V\ (Pin1)\ -\ 1.4V}{3\ R_S}$$

Abnormal operating conditions occur when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the Current Sense Comparator threshold will be internally clamped to 1.0 V. Therefore the maximum peak switch current is:

$$I_{pk(max)} \approx \frac{1.0\ V}{R_S}$$

A narrow spike on the leading edge of the current waveform can usually be observed and may cause the power supply to exhibit an instability when the output is lightly loaded. This spike is due to the power transformer interwinding capacitance and the output rectifier recovery time. The addition of an RC filter on the Current Sense Input with a time constant that approximates the spike duration will usually eliminate the instability; refer to Figure 30.

Undervoltage Lockout

Two undervoltage lockout comparators have been incorporated to guarantee that the IC is fully functional before the output stage is enabled. The positive power supply terminal (V_{CC}) and the reference output (V_{ref}) are each monitored by separate comparators. Each has built–in hysteresis to prevent erratic output behavior as their respective thresholds are crossed. The V_{CC} comparator upper and lower thresholds are 14.1 V/10.2 V. The V_{ref} comparator upper and lower thresholds are 3.6 V/3.3 V. The large hysteresis and low startup current of the MC44602 make it ideally suited for off–line converter applications (Figures 33, 34) where efficient bootstrap startup techniques are required.

A 20 V zener is connected as a shunt regulator from V_{CC} to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The upper limit for the minimum operating voltage of the MC44602 is 11V.

Outputs

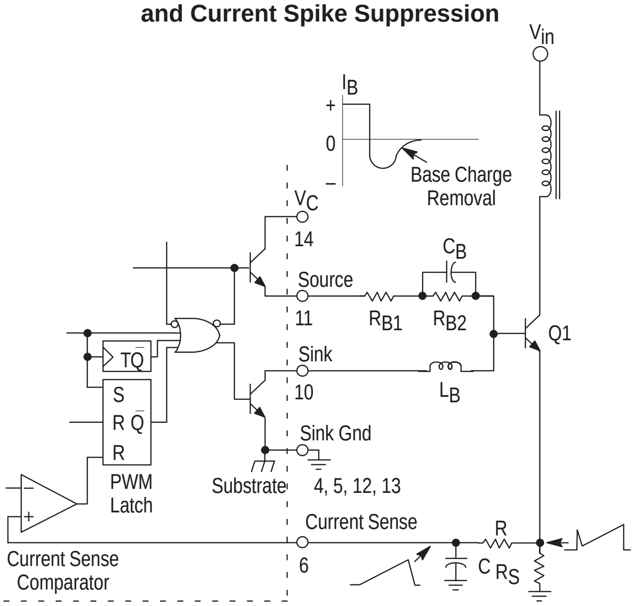
The MC44602 contains a high current split totem pole output that was specifically designed for direct drive of Bipolar Power Transistors. By splitting the totem pole into separate source and sink outputs, the power supply designer has the ability to independently adjust the turn–on and turn–off base drive to the external power transistor for optimal switching. The Source and Sink outputs are capable of up to 1.0 A and 1.5 A respectively and feature 50 ns switching times with a 1.0 nF load. Additional internal circuitry has been added to keep the Source Output “Off” and the Sink Output “On” whenever an undervoltage lockout is active. This feature eliminates the need for an external pull–down resistor and guarantees that the power transistor will be held in the “Off” state.

Separate output stage power and ground pins are provided to give the designer added flexibility in tailoring the base drive circuitry for a specific application. The Source Output high–state is controlled by applying a positive voltage to V_C (Pin 14) and is independent of V_{CC}. A zener clamp is typically connected to this input when driving power MOSFETs in systems where V_{CC} is greater than 20V. The Sink Output low–state is controlled by applying a negative voltage to the Sink Ground (Pins 4, 5, 12, 13). The Sink Ground can be biased as much as 5.0 V negative with respect to Ground (Pin 7). Proper implementation of the V_C and Sink Ground pins will significantly reduce the level of switching transient noise imposed on the control circuitry. This becomes particularly useful when reducing the $I_{pk(max)}$ clamp level.

Reference

The 5.0 V bandgap reference has a tolerance of ±6.0% over a junction temperature range of –25°C to 85°C. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short circuit protection and is capable of providing in excess of 20 mA for powering additional control system circuitry.

Figure 30. Bipolar Transistor Drive and Current Spike Suppression



Thermal Protection and Package

Internal Thermal Shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at 160°C, the PWM Latch is held in the “reset” state, forcing the Source Output “Off” and the Sink Output “On”. This feature is provided to prevent catastrophic failures from accidental device overheating. It is not intended to be used as a substitute for proper heatsinking.

The MC44602 is contained in a heatsinkable 16–lead plastic dual–in–line package in which the die is mounted on a special heat tab copper alloy lead frame. This tab consists of the four center Sink Ground pins that are specifically designed to improve the thermal conduction from the die to the circuit board. Figure 14 shows a simple and effective method of utilizing the printed circuit medium as a heat dissipater by soldering these pins to an adequate area of copper foil. This permits the use of standard layout and mounting practices while having the ability to halve the junction to air thermal resistance. This example is for a symmetrical layout on a single–sided board with two ounce per square foot of copper.

Design Considerations

Do not attempt to construct the converter on wire–wrap or plug–in prototype boards. High frequency circuit layout techniques are imperative to prevent pulse–width jitter. This is usually caused by excessive noise pick–up imposed on the Current Sense or Voltage Feedback inputs. Noise immunity can be improved by lowering circuit impedances at these points. The printed circuit layout should contain a ground plane with low–current signal, and high current switch and output grounds returning on separate paths back to the input filter capacitor. Ceramic bypass capacitors (0.1 µF) connected directly to V_{CC}, V_C, and V_{ref} may be required depending upon circuit layout. This provides a low impedance path for filtering the high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be located close to the IC and as far as possible from the power switch and other noise generating components.

PROTECTION MODES

The MC44602 operates as a conventional fixed frequency current mode controller when the power supply output load is less than the design limit. For enhanced system reliability, this device has the unique ability of changing operating modes if the power supply output is overloaded or shorted.

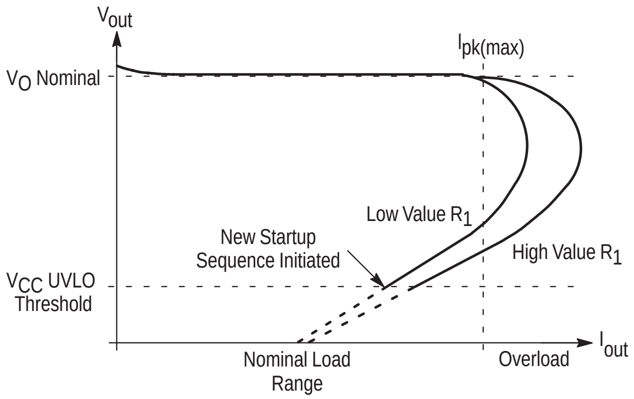
Overload Protection

Power supply overload protection is provided by the Foldback Amplifier. As the output load gradually increases, the Error Amplifier senses that the voltage at Pin 3 is less than the 2.5 V threshold. This causes the voltage at Pin 1 to rise, increasing the Current Sense Comparator threshold in order to maintain output regulation. As the load further increases, the inverting input of the Current Sense Comparator reaches the internal 1.0 V clamp level, limiting the switch current to the calculated $I_{pk(max)}$. At this point any further increase in load will cause the power supply output to fall out of regulation. As the voltage at Pin 3 falls below 2.5 V, current will flow out of the Foldback Amplifier input, and the internal clamp level will be proportionally reduced (Figures 9, 10). The increase in current flowing out of the Foldback Amplifier input in conjunction with the reduced clamp level, causes the power supply output voltage to fall at a faster rate than the voltage at Pin 3. This results in the output foldback characteristic shown in Figure 31. The shape of the current limit “knee” can be modified by the value of resistor R_1 in the feedback divider. Lower values of R_1 will reduce the $I_{pk(max)}$ clamp level at a faster rate.

Improper operation of the Foldback Amp can be encountered when the Error Amp compensation capacitor C_f exceeds 2.0 nF. The problem appears at Startup when the output voltage of the power supply is below nominal, causing the Error Amp output to rise quickly. The rapid change in output voltage will be coupled through C_f to the Inverting Input (Pin 3), keeping it at its 2.5 V threshold as the 1.0 mA Error Amp current source charges C_f. This has the effect of disabling the Foldback Amp by preventing Pin 3 and the clamp level at the inverting input of the Current Sense Comparator, from rising in proportion to the power supply output voltage. By adding resistor R_{FB} in series with C_f, the voltage at Pin 3 can be held to 1.0 V, corresponding to a Current Sense clamp level of 0.08 V (Figure 10), while allowing the Error Amp output to reach its high state V_{OH} of 7.0 V. The required resistor to keep Pin 3 below 1.0 V during initial Startup is:

$$\frac{R_{FB}\,R_f}{R_{FB} + R_f} \geq 6\left(\frac{R_1\,R_2}{R_1 + R_2}\right)$$

Figure 31. Output Foldback Characteristic



Short Circuit Protection

Short circuit protection for the power supply is provided by the Valid Load Comparator, Fault Latch, and Demag Comparator. Figure 32 shows the logic truth table of the functional blocks. When operating the power supply with nominal output loading, the Fault Latch is “Set” by the NOR gate driver during the Power Transistor “On” time and “Reset” by the Fault Comparator during the “Off” time. When a severe overload or short circuit occurs on any output, the voltage during the “Off” time (flyback voltage) at the Load Detect Input, is unable to reach the 2.5 V threshold of the Valid Load Comparator. This causes the Fault Latch to remain in the “Set” state with output Q “Low”. During the “Off” time the Demag Comparator output will also be “Low”. This causes the NOR gate to internally hold the Sync Input “High”, inhibiting the next fixed frequency Oscillator cycle and switching of the Power Transistor. As the load dissipates the stored transformer energy, the voltage at the Load Detect Input will fall. When this voltage reaches 85 mV, the Demag Comparator output goes “High”, allowing the Sync Input to go “Low”, and the Power Transistor to turn “On”.

Note that as long as there is an output short, the switching frequency will shift to a much lower frequency than that set by R_T/C_T. The frequency shift has the effect of lowering the duty cycle, resulting in a significant reduction in Power Transistor and Output Rectifier heating when compared to conventional current mode controllers. The extended “On” time is the result of C_T charging from 0 V to 2.8 V instead of 1.2 V to 2.8 V. The extended “Off” time is the result of the output short time constant. The time constant consists of the output filter capacitance, and the equivalent series resistance (ESR) of the capacitor plus the associated wire resistance.

Figure 32. Logic Truth Table of Functional Blocks

Output Load	Power Transistor	Demag		Fault Latch			Sync	Operating Comments
		Input	Out	S	R	$\overline{Q}$	Input	
Nominal	On	<85mV	1	1	0	0	0	NOR gate driver sets Fault Latch.
	At Turn–Off	>85 mV, <2.5 V	0	0	0	0		Narrow spike at Sync Input (<2.5 V) as transformer voltage rises quickly, Oscillator is not affected.
	Off	>2.5 V	0	0	1	1	0	Valid Load Comparator resets Fault Latch.
Short	On	<85 mV	1	1	0	0	0	Short is not detected until transistor turn–off.
	At Turn–Off	>85 mV, <2.5 V	0	0	0	0	1	Valid Load Comparator fails to reset Fault Latch, Pulse at Sync Input exceeds 2.5 V, Oscillator is disabled.
	Off	<85 mV	1	0	0	0	0	Load dissipates transformer energy, Oscillator enabled.

During the initial power supply startup the controller sequences through the Short Circuit and Overload Protection modes as the output filter capacitors charge–up. If an output is shorted and the auxiliary feedback winding is used to power the control IC as in Figure 33, the V_{CC} UVLO lower threshold level will be reached after several cycles, disabling the IC and initiating a new startup sequence. The Short Circuit Protection mode can be disabled by grounding the Sync Input. Narrow switching spikes are present on this pin during normal operation. These spikes are caused by the rise time of the flyback voltage from the 85 mV Demag Comparator threshold to the 2.5 V Valid Load Comparator threshold. In high power applications, the increased negative current at the Load Detect Input can extend the switching spikes to the point where they exceed the Sync Input threshold. This problem can be eliminated by placing an external small signal clamp diode at the Load Detect Input. The diode is connected with the cathode at Pin 2 and the anode at ground.

The divide–by–two toggle flip–flop will appear not to function properly during power supply startup without foldback, or operation with an overloaded output. This phenomena appears at the end of the oscillator cycle if there was not a current sense comparison, and after the flyback voltage at the Load Detect Input failed to exceed 2.5 V. Under these conditions, the Sync input will go high approximately 1.0 µs after the Load Detect Input exceeds the 85 mV Demag Comparator threshold. This causes C_T to discharge down towards ground, generating a second negative going edge on the oscillator waveform. This second edge results in the divide–by–two flip–flop being clocked twice for each “On” time of the switch transistor. During initial startup, this effect can be eliminated by insuring that the Foldback Amplifier is fully active with the addition of resistor R_{FB}. With the Foldback Amplifier active, the clamp level at the inverting input of the Current Sense Comparator will be low, allowing a comparison to take place during the switch transistor “On” time. When the Load Detect Input exceeds 85 mV, the Sync Input will go high, discharging C_T to ground after 1.0 µs, thus eliminating the second negative edge. Operation with the output overloaded will cause the toggle flip–flop to be clocked twice for each “On” time. This should not be a problem since the next “On” time is delayed by the Demag Comparator until the load dissipates the transformers energy.

The point where the IC detects that there is a severe output overload, or that the transformer has reached zero current, is controlled by the voltage of the auxiliary winding and a resistor divider. The divider consists of an external series resistor and an internal shunt resistor. The shunt resistor is nominally 18 kΩ but can range from 12 kΩ to 30 kΩ due to process variations. If more precise overload and zero current detection is required, the internal resistor variations can be swamped out by connecting a low value external resistor (≤2.7 kΩ) from Pin 2 to ground.

PIN FUNCTION DESCRIPTION

Pin	Function	Description
1	Compensation	This pin is the Error Amplifier output and is made available for loop compensation.
2	Load Detect Input	A voltage indicating a severe overload or short circuit condition at any output of the switching power supply is connected to this input. The Oscillator is controlled by this information making the power supply short circuit proof.
3	Voltage Feedback Input	This is the inverting input of the Error Amplifier and the noninverting input of the Foldback Amplifier. It is normally connected to the switching power supply output through a resistor divider.
4, 5, 12, 13	Sink Ground	The Sink Ground pins form a single power return that is typically connected back to the power source on a separate path from Pin 9 Ground, to reduce the effects of switching transient noise on the control circuitry. These pins can be used to enhance the package power capabilities (Figure 14). The Sink Output low state (V_{OL}) can be modified by applying a negative voltage to these pins with respect to Ground (Pin 9) to optimize turn–off of a bipolar junction transistor.
6	Current Sense Input	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate conduction of the output switch transistor.
7	Sync Input	A narrow rectangular waveform applied to this input will synchronize the Oscillator. A dc voltage within the range of 3.2 V to 5.5 V will inhibit the Oscillator.
8	R_T/C_T	The Oscillator frequency and maximum Output duty cycle are programmed at this pin by connecting resistor R_T to V_{ref} and capacitor C_T to ground.
9	Ground	This pin is the control circuitry ground and is typically connected back to the power source on a separate path from the Sink Ground (Pins 4, 5, 12, 13).
10	Sink Output	Peak currents up to 1.5 A are sunk by this output suiting it ideally for turning–off a bipolar junction transistor. The output switches at one–half the oscillator frequency.
11	Source Output	Peak currents up to 1.0 A are sourced by this output suiting it ideally for turning–on a bipolar junction transistor. The output switches at one–half the oscillator frequency.
14	V_C	The Output high state (V_{OH}) is set by the voltage applied to this pin. With a separate connection to the power source, it can reduce the effects of switching transient noise on the control circuitry.
15	V_{CC}	This pin is the positive supply of the control IC. The minimum operating voltage range after startup is 11 V to 18 V.
16	V_{ref}	This is the 5.0 V reference output. It provides charging current for capacitor C_T through resistor R_T and can be used to bias any additional system circuitry.

MOTOROLA

MC44603

Advance Information

Mixed Frequency Mode GreenLine™ PWM Controller:

Fixed Frequency, Variable Frequency, Standby Mode

The MC44603 is an enhanced high performance controller that is specifically designed for off–line and dc–to–dc converter applications. This device has the unique ability of automatically changing operating modes if the converter output is overloaded, unloaded, or shorted, offering the designer additional protection for increased system reliability. The MC44603 has several distinguishing features when compared to conventional SMPS controllers. These features consist of a foldback facility for overload protection, a standby mode when the converter output is slightly loaded, a demagnetization detection for reduced switching stresses on transistor and diodes, and a high current totem pole output ideally suited for driving a power MOSFET. It can also be used for driving a bipolar transistor in low power converters (< 150 W). It is optimized to operate in discontinuous mode but can also operate in continuous mode. Its advanced design allows use in current mode or voltage mode control applications.

Current or Voltage Mode Controller

- Operation up to 250 kHz Output Switching Frequency
- Inherent Feed Forward Compensation
- Latching PWM for Cycle–by–Cycle Current Limiting
- Oscillator with Precise Frequency Control

High Flexibility

- Externally Programmable Reference Current
- Secondary or Primary Sensing
- Synchronization Facility
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis

Safety/Protection Features

- Overvoltage Protection Against Open Current and Open Voltage Loop
- Protection Against Short Circuit on Oscillator Pin
- Fully Programmable Foldback
- Soft–Start Feature
- Accurate Maximum Duty Cycle Setting
- Demagnetization (Zero Current Detection) Protection
- Internally Trimmed Reference

GreenLine Controller: Low Power Consumption in Standby Mode

- Low Startup and Operating Current
- Fully Programmable Standby Mode
- Controlled Frequency Reduction in Standby Mode
- Low dV/dT for Low EMI Radiations

MIXED FREQUENCY MODE GREENLINE PWM* CONTROLLER:

VARIABLE FREQUENCY, FIXED FREQUENCY, STANDBY MODE

* PWM = Pulse Width Modulation

ORDERING INFORMATION

Device	Operating Temperature Range	Package
MC44603P	T_A = –25° to +85°C	Plastic DIP–16
MC44603DW		SOP–16L

MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Total Power Supply and Zener Current	$(I_{CC} + I_Z)$	30	mA
Supply Voltage with Respect to Ground (Pin 4)	V_C V_{CC}	18	V
Output Current (Note 1)			mA
Source	$I_{O(Source)}$	–750	
Sink	$I_{O(Sink)}$	750	
Output Energy (Capacitive Load per Cycle)	W	5.0	µJ
$R_{F\ Stby}$, C_T, Soft–Start, R_{ref}, $R_{P\ Stby}$ Inputs	V_{in}	–0.3 to 5.5	V
Foldback Input, Current Sense Input, E/A Output, Voltage Feedback Input, Overvoltage Protection, Synchronization Input	V_{in}	–0.3 to V_{CC} + 0.3	V
Synchronization Input			
High State Voltage	V_{IH}	V_{CC} + 0.3	V
Low State Reverse Current	V_{IL}	–20	mA
Demagnetization Detection Input Current			mA
Source	$I_{demag–ib\ (Source)}$	–4.0	
Sink	$I_{demag–ib\ (Sink)}$	10	
Error Amplifier Output Sink Current	$I_{E/A\ (Sink)}$	20	mA
Power Dissipation and Thermal Characteristics			
P Suffix, Dual–In–Line, Case 648			
Maximum Power Dissipation at T_A = 85°C	P_D	0.6	W
Thermal Resistance, Junction–to–Air	$R_{\theta JA}$	100	°C/W
DW Suffix, Surface Mount, Case 751G			
Maximum Power Dissipation at T_A = 85°C	P_D	0.45	W
Thermal Resistance, Junction–to–Air	$R_{\theta JA}$	145	°C/W
Operating Junction Temperature	T_J	150	°C
Operating Ambient Temperature	T_A	–25 to +85	°C

NOTES: 1. Maximum package power dissipation limits must be observed.
2. ESD data available upon request.

ELECTRICAL CHARACTERISTICS (V_{CC} and V_C = 12 V, [Note 3], R_{ref} = 10 kΩ, C_T = 820 pF, for typical values T_A = 25°C, for min/max values T_A = –25° to +85°C [Note 4], unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
OUTPUT SECTION					
Output Voltage (Note 5)					V
Low State (I_{Sink} = 100 mA)	V_{OL}	–	1.0	1.2	
(I_{Sink} = 500 mA)		–	1.4	2.0	
High State (I_{Source} = 200 mA)	V_{OH}	–	1.5	2.0	
(I_{Source} = 500 mA)		–	2.0	2.7	
Output Voltage During Initialization Phase	V_{OL}				V
V_{CC} = 0 to 1.0 V, I_{Sink} = 10 µA		–	–	1.0	
V_{CC} = 1.0 to 5.0 V, I_{Sink} = 100 µA		–	0.1	1.0	
V_{CC} = 5.0 to 13 V, I_{Sink} = 1.0 mA		–	0.1	1.0

PIN FUNCTION DESCRIPTION

Pin	Name	Description
1	V_{CC}	This pin is the positive supply of the IC. The operating voltage range after startup is 9.0 to 14.5 V.
2	V_C	The output high state (V_{OH}) is set by the voltage applied to this pin. With a separate connection to the power source, it can reduce the effects of switching noise on the control circuitry.
3	Output	Peak currents up to 750 mA can be sourced or sunk, suitable for driving either MOSFET or Bipolar transistors. This output pin must be shunted by a Schottky diode, 1N5819 or equivalent.
4	Gnd	The ground pin is a single return, typically connected back to the power source; it is used as control and power ground.
5	Foldback Input	The foldback function provides overload protection. Feeding the foldback input with a portion of the V_{CC} voltage (1.0 V max) establishes on the system control loop a foldback characteristic allowing a smoother startup and sharper overload protection. Above 1.0 V the foldback input is inactive.
6	Overvoltage Protection	When the overvoltage protection pin receives a voltage greater than 17 V, the device is disabled and requires a complete restart sequence. The overvoltage level is programmable.
7	Current Sense Input	A voltage proportional to the current flowing into the power switch is connected to this input. The PWM latch uses this information to terminate the conduction of the output buffer when working in a current mode of operation. A maximum level of 1.0 V allows either current or voltage mode operation.
8	Demagnetization Detection	A voltage delivered by an auxiliary transformer winding provides to the demagnetization pin an indication of the magnetization state of the flyback transformer. A zero voltage detection corresponds to complete core saturation. The demagnetization detection ensures a discontinuous mode of operation. This function can be inhibited by connecting Pin 8 to Gnd.
9	Synchronization Input	The synchronization input pin can be activated with either a negative pulse going from a level between 0.7 V and 3.7 V to Gnd or a positive pulse going from a level between 0.7 V and 3.7 V up to a level higher than 3.7 V. The oscillator runs free when Pin 9 is connected to Gnd.
10	C_T	The normal mode oscillator frequency is programmed by the capacitor C_T choice together with the R_{ref} resistance value. C_T, connected between Pin 10 and Gnd, generates the oscillator sawtooth.
11	Soft–Start/D_{max}/ Voltage–Mode	A capacitor, resistor or a voltage source connected to this pin limits the switching duty–cycle. This pin can be used as a voltage mode control input. By connecting Pin 11 to Ground, the MC44603 can be shut down.
12	$R_{P\ Standby}$	A voltage level applied to the $R_{P\ Standby}$ pin determines the output power level at which the oscillator will turn into the reduced frequency mode of operation (i.e. standby mode). An internal hysteresis comparator allows to return in the normal mode at a higher output power level.
13	E/A Out	The error amplifier output is made available for loop compensation.
14	Voltage Feedback	This is the inverting input of the Error Amplifier. It can be connected to the switching power supply output through an optical (or other) feedback loop.
15	$R_{F\ Standby}$	The reduced frequency or standby frequency programming is made by the $R_{F\ Standby}$ resistance choice.
16	R_{ref}	R_{ref} sets the internal reference current. The internal reference current ranges from 100 µA to 500 µA. This requires that 5.0 kΩ ≤ R_{ref} ≤ 25 kΩ.

OPERATING DESCRIPTION

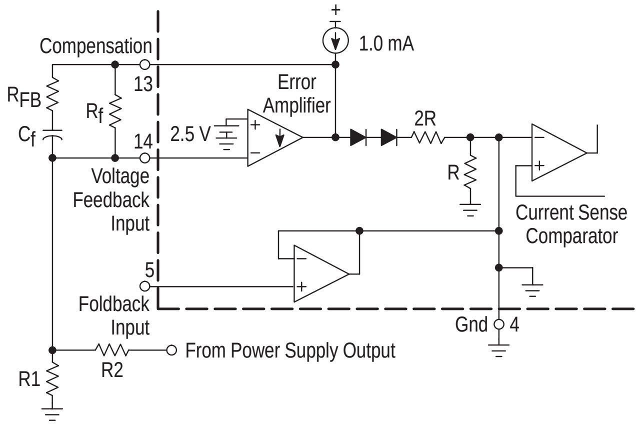
Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 70 dB. The noninverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current with the inverting input at 2.5 V is –2.0 µA. This can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp output (Pin 13) is provided for external loop compensation. The output voltage is offset by two diode drops (≈ 1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Output (Pin 3) when Pin 13 is at its lowest state (V_{OL}). The Error Amp minimum feedback resistance is limited by the amplifier's minimum source current (0.2 mA) and the required output voltage (V_{OH}) to reach the current sense comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\ (1.0\ V) + 1.4\ V}{0.2\ mA} = 22\ k\Omega$$

Figure 32. Error Amplifier Compensation



Current Sense Comparator and PWM Latch

The MC44603 can operate as a current mode controller or as a voltage mode controller. In current mode operation, the MC44603 uses the current sense comparator. The output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier output (Pin 13). Thus, the error signal controls the peak inductor current on a cycle–by–cycle basis. The Current Sense Comparator PWM Latch ensures that only a single pulse appears at the Source Output during the appropriate oscillator cycle.

The inductor current is converted to a voltage by inserting the ground referenced sense resistor R_S in series with the power switch Q1.

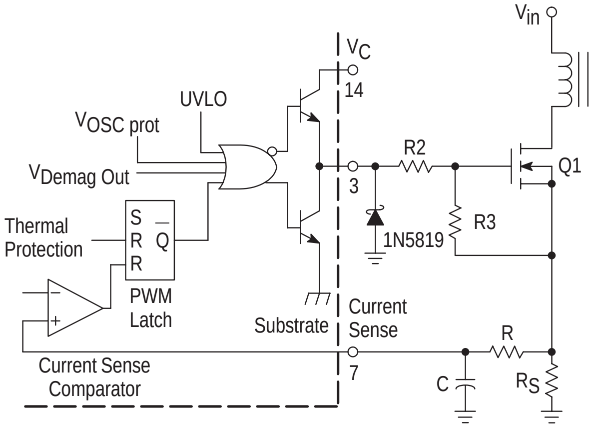
This voltage is monitored by the Current Sense Input (Pin 7) and compared to a level derived from the Error Amp output. The peak inductor current under normal operating conditions is controlled by the voltage at Pin 13 where:

$$I_{pk} \approx \frac{V_{(Pin\ 13)} - 1.4\ V}{3\ R_S}$$

The Current Sense Comparator threshold is internally clamped to 1.0 V. Therefore, the maximum peak switch current is:

$$I_{pk(max)} \approx \frac{1.0\ V}{R_S}$$

Figure 33. Output Totem Pole



Oscillator

The oscillator is a very accurate sawtooth generator that can work either in free mode or in synchronization mode. In this second mode, the oscillator stops in the low state and waits for a demagnetization or a synchronization pulse to start a new charging cycle.

- **The Sawtooth Generation:**

In the steady state, the oscillator voltage varies between about 1.6 V and 3.6 V.

The sawtooth is obtained by charging and discharging an external capacitor C_T (Pin 10), using two distinct current sources = I_{charge} and $I_{discharge}$. In fact, C_T is permanently connected to the charging current source (0.4 I_{ref}) and so, the discharge current source has to be higher than the charge current to be able to decrease the C_T voltage (refer to Figure 35).

This condition is performed, its value being (2.0 I_{ref}) in normal working and (0.4 I_{ref} + 0.5 $I_{F\ Stby}$ in standby mode).

Figure 34. Oscillator

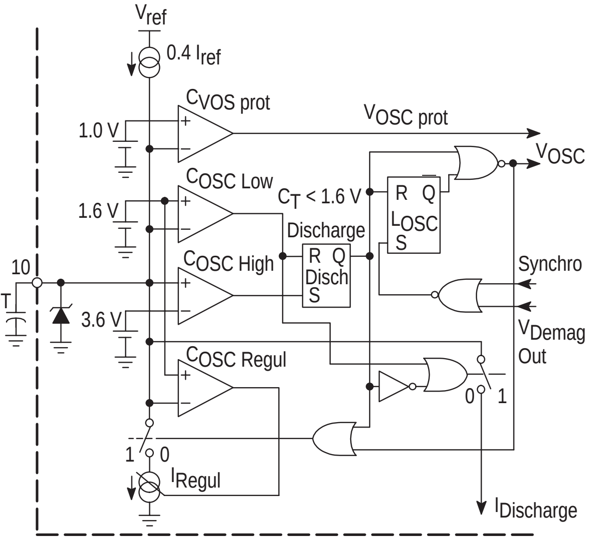


Figure 35. Simplified Block Oscillator

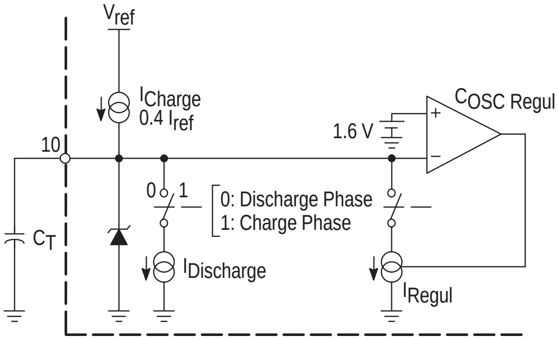


Two comparators are used to generate the sawtooth. They compare the C_T voltage to the oscillator valley (1.6 V) and peak reference (3.6 V) values. A latch (L_{disch}) memorizes the oscillator state.

In addition to the charge and discharge cycles, a third state can exist. This phase can be produced when, at the end of the discharge phase, the oscillator has to wait for a synchronization or demagnetization pulse before restarting. During this delay, the C_T voltage must remain equal to the oscillator valley value (≃1.6 V). So, a third regulated current source I_{Regul} controlled by $C_{OSC\ Regul}$, is connected to C_T in order to perfectly compensate the (0.4 I_{ref}) current source that permanently supplies C_T.

The maximum duty cycle is 80%. Indeed, the on–time is allowed only during the oscillator capacitor charge.

Consequently:

$T_{charge} = C_T \times \Delta V / I_{charge}$
$T_{discharge} = C_T \times \Delta V / I_{discharge}$

where:

T_{charge} is the oscillator charge time
ΔV is the oscillator peak–to–peak value
I_{charge} is the oscillator charge current

and

$T_{discharge}$ is the oscillator discharge time
$I_{discharge}$ is the oscillator discharge current

So, as $f_S = 1 / (T_{charge} + T_{discharge})$ when the Regul arrangement is not activated, the operating frequency can be obtained from the graph in Figure 1.

NOTE: The output is disabled by the signal $V_{OSC\ prot}$ when V_{CT} is lower than 1.0 V (refer to Figure 30).

Synchronization and Demagnetization Blocks

To enable the output, the L_{OSC} latch complementary output must be low. Reset is activated by the L_{disch} output during the discharge phase. To restart, the L_{OSC} has to be set (refer to Figure 34). To perform this, the demagnetization signal and the synchronization must be low.

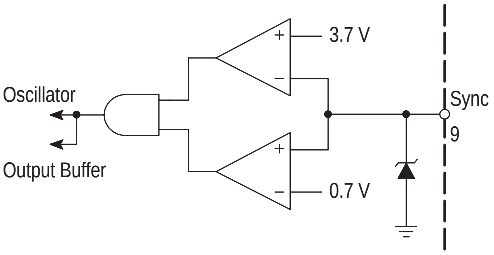
- **Synchronization:**

The synchronization block consists of two comparators that compare the synchronization signal (external) to 0.7 and 3.7 V (typical values). The comparators' outputs are connected to the input of an AND gate so that the final output of the block should be :

– high when 0.7 < SYNC < 3.7 V
– low in the other cases.

As a low level is necessary to enable the output, synchronized low level pulses have to be generated on the output of the synchronization block. If synchronization is not required, the Pin 9 must be connected to the ground.

Figure 36. Synchronization



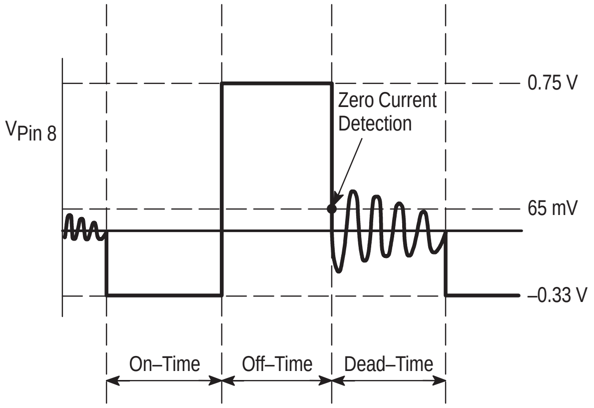
- **Demagnetization:**

In flyback applications, a good means to detect magnetic saturation of the transformer core, or demagnetization, consists in using the auxiliary winding voltage. This voltage is:

– negative during the on–time,
– positive during the off–time,
– equal to zero for the dead–time with generally some ringing (refer to Figure 37).

That is why, the MC44603 demagnetization detection consists of a comparator that can compare the auxiliary winding voltage to a reference that is typically equal to 65 mV.

Figure 37. Demagnetization Detection



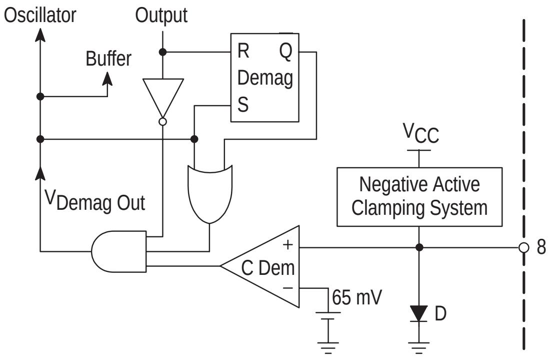
A diode D has been incorporated to clamp the positive applied voltages while an active clamping system limits the negative voltages to typically –0.33 V. This negative clamp level is sufficient to avoid the substrate diode switching on.

In addition to the comparator, a latch system has been incorporated in order to keep the demagnetization block output level low as soon as a voltage lower than 65 mV is detected and as long as a new restart is produced (high level on the output) (refer to Figure 38). This process prevents ringing on the signal at Pin 8 from disrupting the demagnetization detection. This results in a very accurate demagnetization detection.

The demagnetization block output is also directly connected to the output, disabling it during the demagnetization phase (refer to Figure 33).

NOTE: The demagnetization detection can be inhibited by connecting Pin 8 to the ground.

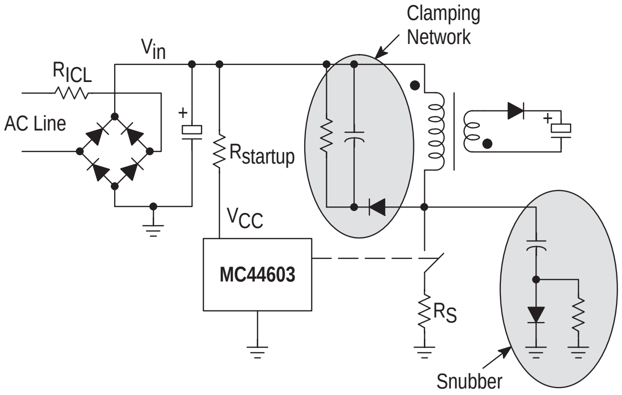
Figure 38. Demagnetization Block



Standby

- **Power Losses in a Classical Flyback Structure**

Figure 39. Power Losses in a Classical Flyback Structure



In a classical flyback (as depicted in Figure 39), the standby losses mainly consist of the energy waste due to:

– the startup resistor $R_{startup}$ → $P_{startup}$
– the consumption of the IC and the power switch control → $P_{control}$
– the inrush current limitation resistor R_{ICL} → P_{ICL}
– the switching losses in the power switch → P_{SW}
– the snubber and clamping network → $P_{SN–CLN}$

$P_{startup}$ is nearly constant and is equal to:

$$\left((V_{in} - V_{CC})^2 / R_{startup}\right)$$

P_{ICL} only depends on the current drawn from the mains. Losses can be considered constant. This waste of energy decreases when the standby losses are reduced.

$P_{control}$ increases when the oscillator frequency is increased (each switching requires some energy to turn on the power switch).

P_{SW} and $P_{SN–CLN}$ are proportional to the switching frequency.

Consequently, standby losses can be minimized by decreasing the switching frequency as much as possible.

The MC44603 was designed to operate at a standby frequency lower than the normal working one.

- **Standby Power Calculations with MC44603**

During a switching period, the energy drawn by the transformer during the on–time to be transferred to the output during the off–time, is equal to:

$$E = \frac{1}{2} \times L \times I_{pk}^2$$

where:

– L is the transformer primary inductor,
– I_{pk} is the inductor peak current.

Input power is labelled P_{in}:

$$P_{in} = 0.5 \times L \times I_{pk}^2 \times f_S$$

where f_S is the normal working switching frequency.

Also,

$$I_{pk} = \frac{V_{CS}}{R_S}$$

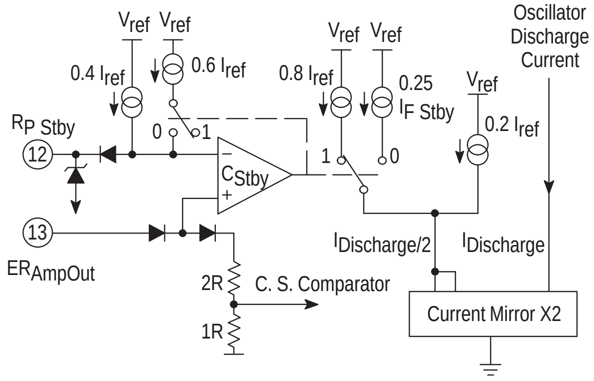
where R_S is the resistor used to measure the power switch current.

Thus, the input power is proportional to V_{CS}^2 (V_{CS} being the internal current sense comparator input).

That is why the standby detection is performed by creating a V_{CS} threshold. An internal current source (0.4 x I_{ref}) sets the threshold level by connecting a resistor to Pin 12.

As depicted in Figure 40, the standby comparator noninverting input voltage is typically equal to (3.0 x V_{CS} + V_F) while the inverter input value is ($V_{R\ P\ Stby}$ + V_F).

Figure 40. Standby



The V_{CS} threshold level is typically equal to [($V_{R\ P\ Stby}$)/3] and if the corresponding power threshold is labelled P_{thL}:

$$P_{thL} = 0.5 \times L \times \left(\frac{V_{R\ P\ Stby}}{3.0\ R_S}\right)^2 \times f_S$$

And as:

$$V_{R\ P\ Stby} = R_{P\ Stby} \times 0.4 \times I_{ref}$$

$$= R_{R\ P\ Stby} \times 0.4 \times \frac{V_{ref}}{R_{ref}}$$

$$R_{P\ Stby} = \frac{10.6 \times R_S \times R_{ref}}{V_{ref}} \times \sqrt{\frac{P_{thL}}{L \times f_S}}$$

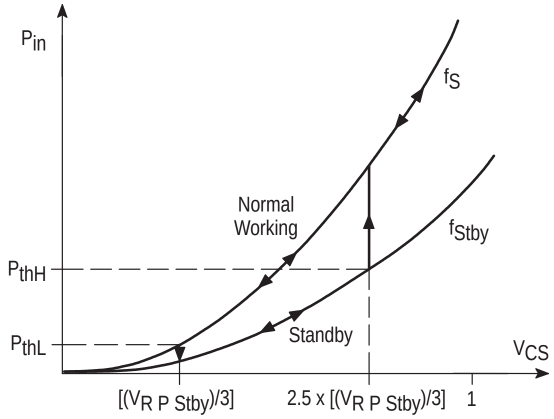
Thus, when the power drawn by the converter decreases, V_{CS} decreases and when V_{CS} becomes lower than [$V_{CS–th}$ x ($V_{R\ P\ Stby}$)/3], the standby mode is activated. This results in an oscillator discharge current reduction in order to increase the oscillator period and to diminish the switching frequency. As it is represented in Figure 40, the (0.8 x I_{ref}) current source is disconnected and is replaced by a lower value one (0.25 x $I_{F\ Stby}$).

Where: $I_{F\ Stby} = V_{ref}/R_{F\ Stby}$

In order to prevent undesired mode switching when power is close to the threshold value, a hysteresis that is proportional to $V_{R\ P\ Stby}$ is incorporated creating a second V_{CS} threshold level that is equal to [2.5 x ($V_{R\ P\ Stby}$)/3]. When the standby comparator output is high, a second current source (0.6 x I_{ref}) is connected to Pin 12.

Finally, the standby mode function can be shown graphically in Figure 41.

Figure 41. Dynamic Mode Change



This curve shows that there are two power threshold levels:

– the low one:

P_{thL} fixed by $V_{R\ P\ Stby}$

– the high one:

$$P_{thH} = (2.5)^2 \times P_{thL} \times \frac{f_{Stby}}{f_S}$$

$$P_{thH} = 6.25 \times P_{thL} \times \frac{f_{Stby}}{f_S}$$

Maximum Duty Cycle and Soft–Start Control

Maximum duty cycle can be limited to values less than 80% by utilizing the D_{max} and soft–start control. As depicted in Figure 42, the Pin 11 voltage is compared to the oscillator sawtooth.

Figure 42. D_{max} and Soft–Start

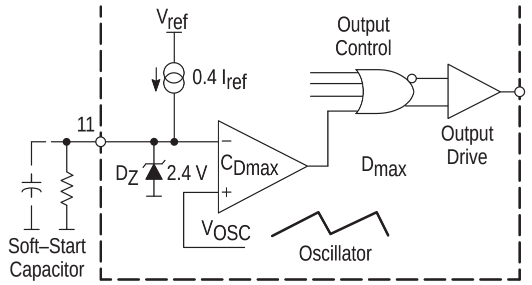


Figure 43. Maximum Duty Cycle Control

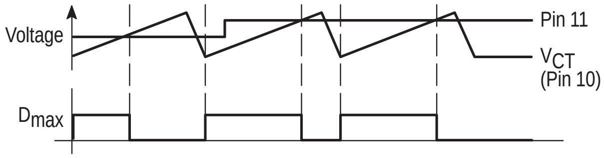
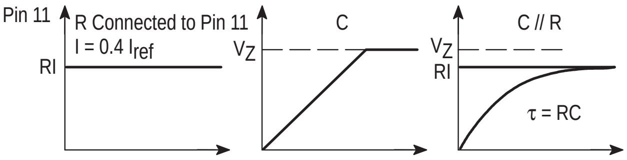


Using the internal current source (0.4 I_{ref}), the Pin 11 voltage can easily be set by connecting a resistor to this pin.

If a capacitor is connected to Pin 11, the voltage increases from 0 to its maximum value progressively (refer to Figure 44), thereby, implementing a soft–start. The soft–start capacitor is discharged internally when the V_{CC} (Pin 1) voltage drops below 9.0 V.

Figure 44. Different Possible Uses of Pin 11



If no external component is connected to Pin 11, an internal zener diode clamps the Pin 11 voltage to a value V_Z that is higher than the oscillator peak value, disabling soft–start and maximum duty cycle limitation.

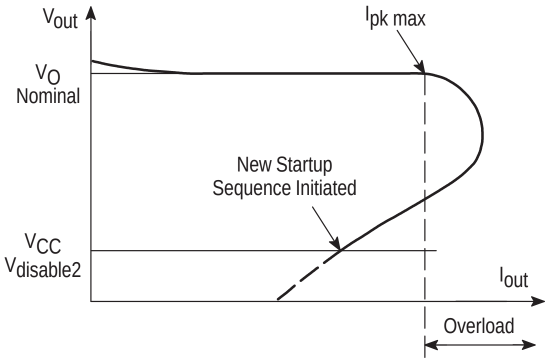
Foldback

As depicted in Fgure 32, the foldback input (Pin 5) can be used to reduce the maximum V_{CS} value, providing foldback protection. The foldback arrangement is a programmable peak current limitation.

If the output load is increased, the required converter peak current becomes higher and V_{CS} increases until it reaches its maximum value (normally, $V_{CS\ max} = 1.0$ V).

Then, if the output load keeps on increasing, the system is unable to supply enough energy to maintain the output voltages in regulation. Consequently, the decreasing output can be applied to Pin 5, in order to limit the maximum peak current. In this way, the well known foldback characteristic can be obtained (refer to Figure 45).

Figure 45. Foldback Characteristic



NOTE: Foldback is disabled by connecting Pin 5 to V_{CC}.

Overvoltage Protection

The overvoltage arrangement consists of a comparator that compares the Pin 6 voltage to V_{ref} (2.5 V) (refer to Figure 46).

If no external component is connected to Pin 6, the comparator noninverting input voltage is nearly equal to:

$$\left(\frac{2.0\ \text{k}\Omega}{11.6\ \text{k}\Omega + 2.0\ \text{k}\Omega}\right) \text{x}\ V_{CC}$$

The comparator output is high when:

$$\left(\frac{2.0\ \text{k}\Omega}{11.6\ \text{k}\Omega + 2.0\ \text{k}\Omega}\right) \text{x}\ V_{CC} \geq 2.5\ \text{V}$$

$$\Leftrightarrow V_{CC} \geq 17\ \text{V}$$

A delay latch (2.0 µs) is incorporated in order to sense overvoltages that last at least 2.0 µs.

If this condition is achieved, $V_{OVP\ out}$, the delay latch output, becomes high. As this level is brought back to the input through an OR gate, $V_{OVP\ out}$ remains high (disabling the IC output) until V_{ref} is disabled.

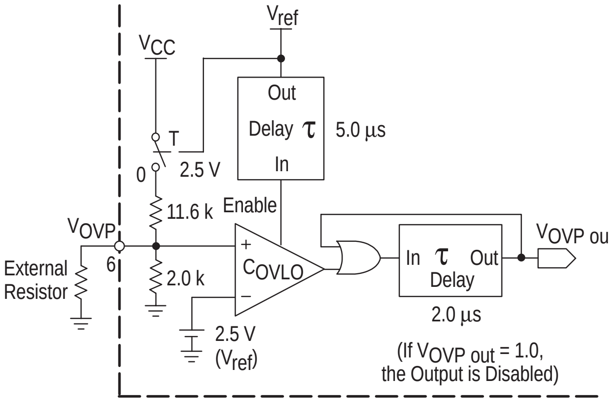
Consequently, when an overvoltage longer than 2.0 µs is detected, the output is disabled until V_{CC} is removed and then re–applied.

The V_{CC} is connected after V_{ref} has reached steady state in order to limit the circuit startup consumption.

The overvoltage section is enabled 5.0 µs after the regulator has started to allow the reference V_{ref} to stabilize.

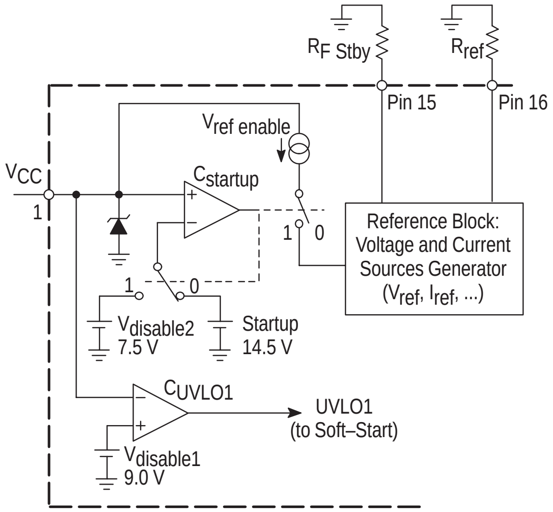
By connecting an external resistor to Pin 6, the threshold V_{CC} level can be changed.

Figure 46. Overvoltage Protection



Undervoltage Lockout Section

Figure 47. V_{CC} Management



As depicted in Figure 47, an undervoltage lockout has been incorporated to garantee that the IC is fully functional before allowing system operation.

This block particularly, produces V_{ref} (Pin 16 voltage) and I_{ref} that is determined by the resistor R_{ref} connected between Pin 16 and the ground:

$$I_{ref} = \frac{V_{ref}}{R_{ref}} \text{ where } V_{ref} = 2.5 \text{ V (typically)}$$

Another resistor is connected to the Reference Block: $R_{F\ Stby}$ that is used to fix the standby frequency.

In addition to this, V_{CC} is compared to a second threshold level that is nearly equal to 9.0 V ($V_{disable1}$). UVLO1 is generated to reset the maximum duty cycle and soft–start block disabling the output stage as soon as V_{CC} becomes lower than $V_{disable1}$. In this way, the circuit is reset and made ready for the next startup, before the reference block is disabled (refer to Figure 29). Finally, the upper limit for the minimum normal operating voltage is 9.4 V (maximum value of $V_{disable1}$) and so the minimum hysteresis is 4.2 V. ($(V_{stup–th})_{min} = 13.6$ V).

The large hysteresis and the low startup current of the MC44603 make it ideally suited for off–line converter applications where efficient bootstrap startup techniques are required.

MC44604

Product Preview

High Safety Standby Ladder Mode GreenLine™ PWM Controller

The MC44604 is an enhanced high performance controller that is specifically designed for off–line and dc–to–dc converter applications.

The MC44604 is a modification of the MC44603. The MC44604 offers enhanced safety and reliable power management in its protection features (foldback, overvoltage detection, soft–start, accurate demagnetization detection). Its high current totem pole output is also ideally suited for driving a power MOSFET but can also be used for driving a bipolar transistor in low power converters (< 150 W).

In addition, the MC44604 offers a new efficient way to reduce the standby operating power by means of a patented standby ladder mode operation of the converter significantly reducing the converter consumption in standby mode.

Current or Voltage Mode Controller

- Operation Up to 250 kHz Output Switching Frequency
- Inherent Feed Forward Compensation
- Latching PWM for Cycle–by–Cycle Current Limiting
- Oscillator with Precise Frequency Control

High Flexibility

- Externally Programmable Reference Current
- Secondary or Primary Sensing
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis

Safety/Protection Features

- Overvoltage Protection Facility Against Open Loop
- Protection Against Short Circuit on Oscillator Pin
- Fully Programmable Foldback
- Soft–Start Feature
- Accurate Maximum Duty Cycle Setting
- Demagnetization (Zero Current Detection) Protection
- Internally Trimmed Reference

GreenLine™ Controller:

- Low Startup and Operating Current
- Patented Standby Ladder Mode for Low Standby Losses
- Low dV/dT for Low EMI

High Safety Latched Mode GreenLine™ PWM Controller for (Multi)Synchronized Applications

The MC44605 is a high performance current mode controller that is specifically designed for off–line converters. The MC44605 has several distinguishing features that make it particularly suitable for multisynchronized monitor applications.

The MC44605 synchronization arrangement enables operation from 16 kHz up to 130 kHz. This product was optimized to operate with universal ac mains voltage from 80 V to 280 V, and its high current totem pole output makes it ideally suited for driving a power MOSFET.

The MC44605 protections provide well controlled, safe power management. Safety enhancements detect four different fault conditions and provide protection through a disabling latch.

Current or Voltage Mode Controller

- Current Mode Operation Up to 250 kHz Output Switching Frequency
- Inherent Feed Forward Compensation
- Latching PWM for Cycle–by–Cycle Current Limiting
- Oscillator with Precise Frequency Control
- Externally Programmable Reference Current
- Secondary or Primary Sensing (Availability of Error Amplifier Output)
- Synchronization Facility
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis
- Low Output dV/dT for Low EMI
- Low Startup and Operating Current

Safety/Protection Features

- Soft–Start Feature
- Demagnetization (Zero Current Detection) Protection
- Overvoltage Protection Facility Against Open Loop
- EHT Overvoltage Protection (E.H.T.OVP): Protection Against Excessive Amplitude Synchronization Pulses
- Winding Short Circuit Detection (W.S.C.D.)
- Limitation of the Maximum Input Power (M.P.L.): Calculation of Input Power for Overload Protection
- Over Heating Detection (O.H.D.): to Prevent the Power Switch from Excessive Heating

Latched Disabling Mode

- When one of the following faults is detected: EHT overvoltage, Winding Short Circuit (WSCD), excessive input power (M.P.L.), power switch over heating (O.H.D.), a counter is activated
- If the counter is activated for a time that is long enough, the circuit gets definitively disabled. The latch can only be reset by removing and then re–applying power

SG3525A
SG3527A

Pulse Width Modulator Control Circuits

The SG3525A, SG3527A pulse width modulator control circuits offer improved performance and lower external parts count when implemented for controlling all types of switching power supplies. The on–chip +5.1 V reference is trimmed to ±1% and the error amplifier has an input common–mode voltage range that includes the reference voltage, thus eliminating the need for external divider resistors. A sync input to the oscillator enables multiple units to be slaved or a single unit to be synchronized to an external system clock. A wide range of deadtime can be programmed by a single resistor connected between the C_T and Discharge pins. These devices also feature built–in soft–start circuitry, requiring only an external timing capacitor. A shutdown pin controls both the soft–start circuitry and the output stages, providing instantaneous turn off through the PWM latch with pulsed shutdown, as well as soft–start recycle with longer shutdown commands. The under voltage lockout inhibits the outputs and the changing of the soft–start capacitor when V_{CC} is below nominal. The output stages are totem–pole design capable of sinking and sourcing in excess of 200 mA. The output stage of the SG3525A features NOR logic resulting in a low output for an off–state while the SG3527A utilized OR logic which gives a high output when off.

- 8.0 V to 35 V Operation
- 5.1 V ± 1.0% Trimmed Reference
- 100 Hz to 400 kHz Oscillator Range
- Separate Oscillator Sync Pin
- Adjustable Deadtime Control
- Input Undervoltage Lockout
- Latching PWM to Prevent Multiple Pulses
- Pulse–by–Pulse Shutdown
- Dual Source/Sink Outputs: ±400 mA Peak

APPLICATION INFORMATION

Shutdown Options (See Block diagram, front page)

Since both the compensation and soft–start terminals (Pins 9 and 8) have current source pull–ups, either can readily accept a pull–down signal which only has to sink a maximum of 100 µA to turn off the outputs. This is subject to the added requirement of discharging whatever external capacitance may be attached to these pins.

An alternate approach is the use of the shutdown circuitry of Pin 10 which has been improved to enhance the available shutdown options. Activating this circuit by applying a positive signal on Pin 10 performs two functions: the PWM latch is immediately set providing the fastest turn–off signal to the outputs; and a 150 µA current sink begins to discharge the external soft–start capacitor. If the shutdown command is short, the PWM signal is terminated without significant discharge of the soft–start capacitor, thus, allowing, for example, a convenient implementation of pulse–by–pulse current limiting. Holding Pin 10 high for a longer duration, however, will ultimately discharge this external capacitor, recycling slow turn–on upon release.

Pin 10 should not be left floating as noise pickup could conceivably interrupt normal operation.

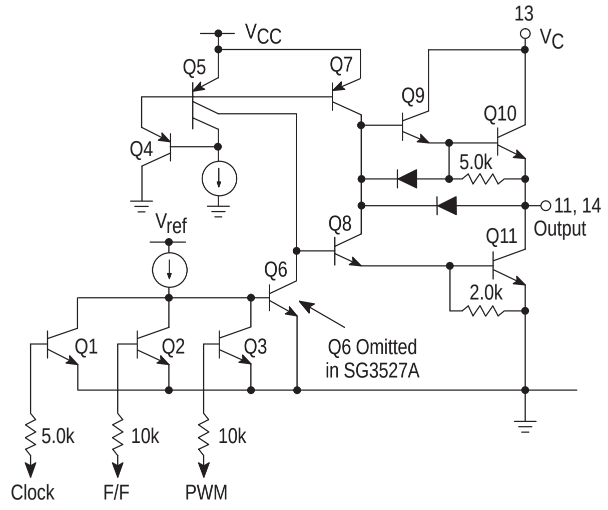

Figure 8. Single–Ended Supply

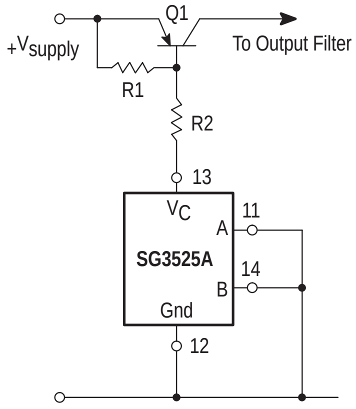
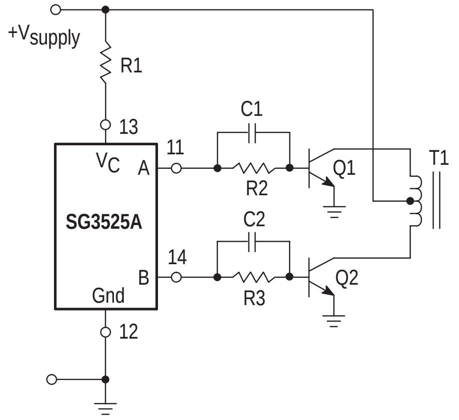


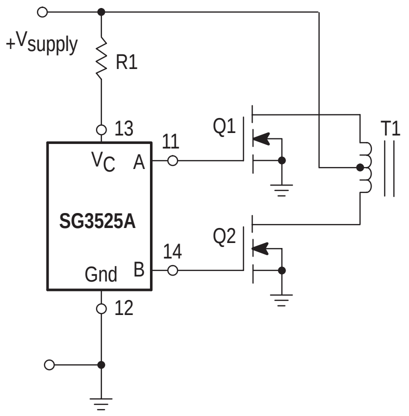
For single–ended supplies, the driver outputs are grounded. The V_C terminal is switched to ground by the totem–pole source transistors on alternate oscillator cycles.

Figure 9. Push–Pull Configuration



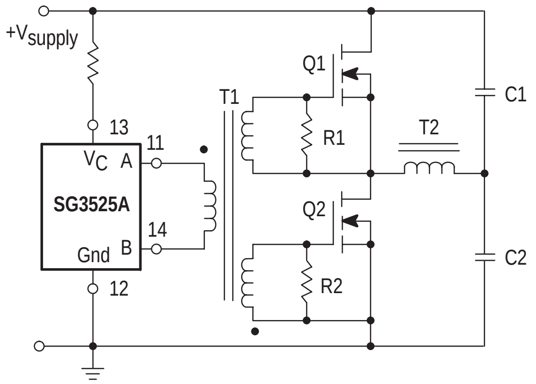
In conventional push–pull bipolar designs, forward base drive is controlled by R1–R3. Rapid turn–off times for the power devices are achieved with speed–up capacitors C1 and C2.

Figure 10. Driving Power FETS



The low source impedance of the output drivers provides rapid charging of power FET input capacitance while minimizing external components.

Figure 11. Driving Transformers in a Half–Bridge Configuration



Low power transformers can be driven directly by the SG3525A. Automatic reset occurs during deadtime, when both ends of the primary winding are switched to ground.

MOTOROLA

SG3526

Pulse Width Modulation Control Circuit

The SG3526 is a high performance pulse width modulator integrated circuit intended for fixed frequency switching regulators and other power control applications.

Functions included in this IC are a temperature compensated voltage reference, sawtooth oscillator, error amplifier, pulse width modulator, pulse metering and steering logic, and two high current totem pole outputs ideally suited for driving the capacitance of power FETs at high speeds.

Additional protective features include soft start and undervoltage lockout, digital current limiting, double pulse inhibit, adjustable dead time and a data latch for single pulse metering. All digital control ports are TTL and B–series CMOS compatible. Active low logic design allows easy wired–OR connections for maximum flexibility. The versatility of this device enables implementation in single–ended or push–pull switching regulators that are transformerless or transformer coupled. The SG3526 is specified over a junction temperature range of 0° to +125°C.

- 8.0 V to 35 V Operation
- 5.0 V ±1% Trimmed Reference
- 1.0 Hz to 400 kHz Oscillator Range
- Dual Source/Sink Current Outputs: ±100 mA
- Digital Current Limiting
- Programmable Dead Time
- Undervoltage Lockout
- Single Pulse Metering
- Programmable Soft–Start
- Wide Current Limit Common Mode Range
- Guaranteed 6 Unit Synchronization

The metering Flip–Flop is an asynchronous data latch which suppresses high frequency oscillations by allowing only one PWM pulse per oscillator cycle.

The memory Flip–Flop prevents double pulsing in a push–pull configuration by remembering which output produced the last pulse.

TCA5600
TCF5600

Universal Microprocessor Power Supply/Controllers

The TCA5600, TCF5600 are versatile power supply control circuits for microprocessor based systems and are mainly intended for automotive applications and battery powered instruments. To cover a wide range of applications, the devices offer high circuit flexibility with a minimum of external components.

Functions included in this IC are a temperature compensated voltage reference, on–chip dc/dc converter, programmable and remote controlled voltage regulator, fixed 5.0 V supply voltage regulator with external PNP power device, undervoltage detection circuit, power–on RESET delay and watchdog feature for safe and hazard free microprocessor operations.

- 6.0 V to 30 V Operation Range
- 2.5 V Reference Voltage Accessible for Other Tasks
- Fixed 5.0 V ± 4% Microprocessor Supply Regulator Including Current Limitation, Overvoltage Protection and Undervoltage Monitor.
- Programmable 6.0 V to 30 V Voltage Regulator Exhibiting High Peak Current (150mA), Current Limiting and Thermal Protection.
- Two Remote Inputs to Select the Regulator’s Operation Mode:
  - OFF = 5.0 V, 5.0 V Standby
  - Programmable Output Voltage
- Self–Contained dc/dc Converter Fully Controlled by the Programmable Regulator to Guarantee Safe Operation Under All Working Conditions
- Programmable Power–On RESET Delay
- Watchdog Select Input
- Negative Edge Triggered Watchdog Input
- Low Current Consumption in the V_{CC1} Standby Mode
- All Digital Control Ports are TTL and MOS–Compatible

Applications Include:

- Microprocessor Systems with E^2PROMs
- High Voltage Crystal and Plasma Displays
- Decentralized Power Supplies in Computer Telecom Systems

APPLICATIONS INFORMATION

(See Figure 18)

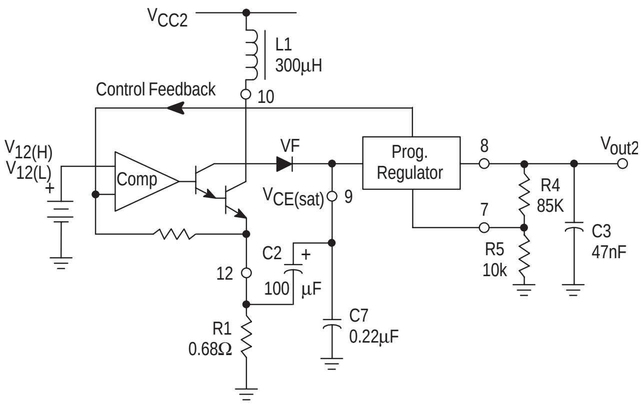
Voltage Reference (V_{ref})

The voltage reference V_{ref} is based upon a highly stable bandgap voltage reference and is accessible on Pin 5 for additional tasks. This circuit part has its own supply connection on Pin 3 and is, therefore, able to operate in standby mode. The RC network R3, C6 improves the ripple rejection on both regulators.

DC/DC Converter

The dc/dc converter performs according to the flyback principle and does not need a time base circuit. The maximum coil current is well defined by means of the current sensing resistor R1 under all working conditions (startup phase, circuit overload, wide supply voltage range and extreme load current change). Figure 13 shows the Simplified Converter Schematic.

Figure 13. Simplified Converter Schematic



A simplified method on “how to calculate the coil inductance” is given below. The operation point at minimum supply voltage (V_{CC2}) and max. output current (I_{out2}) for a fixed output voltage (V_{out2}) determines the coil data. Figure 14 shows the typical voltage and current waveforms on the coil L1 (coil losses neglected).

Equations (1) and (2) yield the respective coil voltage V_L – and V_L + (see Figure 14):

$$V_L+ = V_{out2} + \Delta V_{(Pin\ 9\ -\ Pin\ 8)} + V_F - V_{CC2} \quad (1)$$
$$V_L- = V_{CC2} - V_{CE(sat)} - V_{12(H)} \quad (2)$$

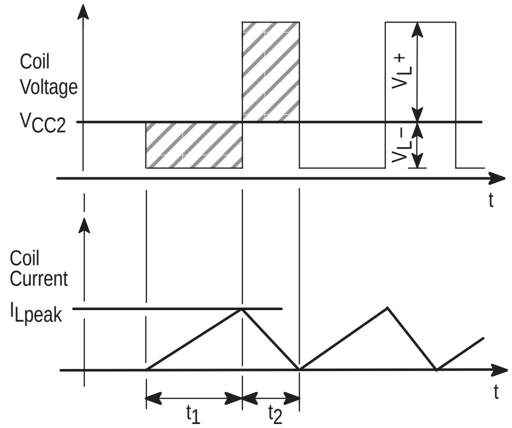
[$\Delta V_{(Pin\ 9\ –\ Pin\ 8)}$: input/output voltage drop of the regulator, 2.5 V typical]

[V_F, $V_{CE(sat)}$, $V_{12(H)}$: see Electrical Characteristics Table]

The time ratio α for the charging time to dumping time is defined by Equation (3):

$$\alpha = \frac{t_1}{t_2} = \frac{V_L+}{V_L-} \quad (3)$$

Figure 14. Voltage and Current Waveform on the Coil (not to scale)



The coil charging time t_1 is found using Equation (4):

$$t_1 = \frac{1}{(1 + \frac{1}{\alpha}) \cdot f} \quad (4)$$

[f : minimum oscillation frequency which should be chosen above the audio frequency band (e.g. 20 kHz)]

Knowing the dc output current I_{out2} of the programmable regulator, the peak coil current $I_{L(peak)}$ can now be calculated:

$$I_{L(peak)} = 2 \cdot (I_{out2}) (1 + \alpha) \quad (5)$$

The coil inductance L1 of the nonsaturated coil is given by Equation (6):

$$L1 = \frac{t_1}{I_{L(peak)}} (V_L-) \quad (6)$$

The formula (6a) yields the current sensing resistor R1 for a defined peak coil current $I_{L(peak)}$:

$$R1 = \frac{V_{12(H)}}{I_{L(peak)}} \quad (6a)$$

In order to limit the by–pass current through capacitor C7 during the energy dumping phase the value C2>>C7 should be implemented.

For all other operation conditions, the feedback signal from the programmable voltage regulator controls the activity of the converter.

Programmable Voltage Regulator

This series voltage regulator is programmable by the voltage divider R4, R5 for a nominal output voltage of $6.0\ V \leq V_{out2} \leq 30\ V$.

$$R4 = \frac{(V_{out2} - V_{ref\ nom}) \bullet R5}{V_{ref\ nom}} \qquad (7)$$

$$[R5 = 10\ k,\ V_{ref\ nom} = 2.5\ V]$$

Current limitation and thermal shutdown capability are standard features of this regulator. The voltage drop $\Delta V_{(Pin\ 9 - Pin\ 8)}$ across the series pass transistor generates the feedback signal to control the dc/dc converter (see Figure 13).

Control Inputs INH1, INH2

The dc/dc converter and/or the regulator V_{out2} are remote controllable through the TTL, MOS compatible inhibit inputs INH1 and INH2 where the latter is a three–level detector (Logic "0", High Impedance "Z", Logic "1"). Both inputs are set–up to provide the following truth table:

Figure 15. INH1, INH2 TruthTable

Mode	INH1	INH2	V_{out2}	DC/DC
1	0	0	OFF	INT
2	0	High "Z"	V_{out2}	ON
3	0	1	V_{out2}	INT
4	1	0	OFF	INT
5	1	High "Z"	5.0 V	ON
6	1	1	5.0 V	INT

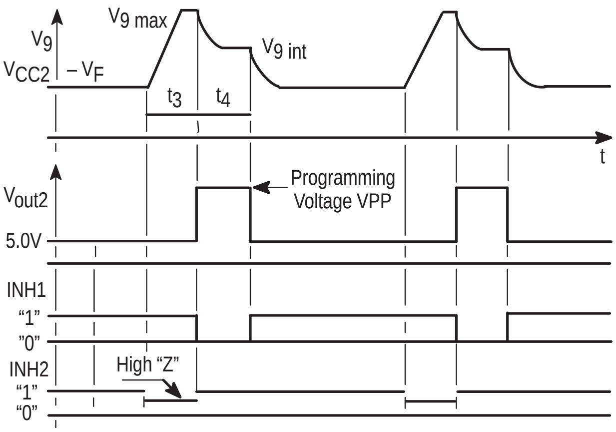
INT: Intermittent operation of the converter means that the converter operates only if $V_{CC2} < V_{out2}$.

ON: The converter loads the storage capacitor C2 to its full charge (V_9 = 33 V), allowing fast response time of the regulator V_{out2} when addressed by the control software.

OFF: High impedance (internal resistor 10 k to ground)

Figure 16 represents a typical timing diagram for an E^2PROM programming sequence in a microprocessor based system. The High "Z" state enables the dc/dc converter to ramp during t_3 to the voltage V_9 at Pin 9 to a high level before the write cycle takes place in the memory.

Figure 16. Typical E^2PROM Programming Sequence
(not to scale)



Microprocessor Supply Regulator

Together with an external PNP power transistor (Q1), a 5.0 V supply exhibiting low voltage drop is obtained to power microprocessor systems and auxiliary circuits. Using a power Darlington with adequate heat sink in the output stage boosts the output current I_{out1} above 1.0 A.

The current limitation circuit measures the emitter current of Q1 by means of the sensing resistor, R_{SC}:

$$R_{SC} = \frac{V_{RSC}}{I_E} \qquad (8)$$

[I_E: emitter current of Q1]

[V_{RSC}: threshold voltage (see Electrical Characteristics Table)]

The voltage protection circuit performs a foldback characteristic above a nominal operating voltage, $V_{CC2} \geq 18\ V$.

Delay and Watchdog Circuit

The undervoltage monitor supervises the power supply V_{out1} and releases the delay circuit RESET as soon as the regulator output reaches the microprocessor operating a range [e.g., $V_{low} \geq 0.93 \bullet V_{out1(nom)}$]. The RESET output has an open–collector and may be connected in a "wired–OR" configuration.

The watchdog circuit consists of a retriggerable monostable with a negative edge sensitive control input WDI. The watchdog feature may be disabled by means of the watchdog select input WDS driven to a "1". Figure 17 displays the Typical RESET Timing Diagram.

The commuted current source I_{C5} on Pin 17, threshold voltage $V_{C5(L)}$, $V_{C5(H)}$ and an external capacitor C5 define the RESET delay and the watchdog timing. The relationship of the timing signals are indicated by the Equations (9) to (11).

$$\overline{\text{RESET}}\ \text{delay:}\quad t_d = \frac{C5 \bullet V_{C5(H)}}{|I_{C5}|} \qquad (9)$$

$$\text{Watchdog timeout:}\quad t_{wd} = \frac{C5 \bullet (V_{C5(H)} - V_{C5(L)})}{5 \bullet I_{C5}} \qquad (10)$$

$$\text{Watchdog}\ \overline{\text{RESET}}\text{:}\quad t_r = \frac{C5 \bullet (V_{C5(H)} - V_{C5(L)})}{50 \bullet |I_{C5}|} \qquad (11)$$

[I_{C5}, $V_{C5(H)}$, $V_{C5(L)}$: see Electrical Characteristics Table]

APPLICATIONS INFORMATION

Description

The TL494 is a fixed–frequency pulse width modulation control circuit, incorporating the primary building blocks required for the control of a switching power supply. (See Figure 1.) An internal–linear sawtooth oscillator is frequency–programmable by two external components, R_T and C_T. The approximate oscillator frequency is determined by:

$$f_{OSC} \approx \frac{1.1}{R_T \bullet C_T}$$

For more information refer to Figure 3.

Output pulse width modulation is accomplished by comparison of the positive sawtooth waveform across capacitor C_T to either of two control signals. The NOR gates, which drive output transistors Q1 and Q2, are enabled only when the flip–flop clock–input line is in its low state. This happens only during that portion of time when the sawtooth voltage is greater than the control signals. Therefore, an increase in control–signal amplitude causes a corresponding linear decrease of output pulse width. (Refer to the Timing Diagram shown in Figure 2.)

The control signals are external inputs that can be fed into the deadtime control, the error amplifier inputs, or the feedback input. The deadtime control comparator has an effective 120 mV input offset which limits the minimum output deadtime to approximately the first 4% of the sawtooth–cycle time. This would result in a maximum duty cycle on a given output of 96% with the output control grounded, and 48% with it connected to the reference line. Additional deadtime may be imposed on the output by setting the deadtime–control input to a fixed voltage, ranging between 0 V to 3.3 V.

Functional Table

Input/Output Controls	Output Function	$\frac{f_{out}}{f_{osc}} =$
Grounded	Single–ended PWM @ Q1 and Q2	1.0
@ V_{ref}	Push–pull Operation	0.5

The pulse width modulator comparator provides a means for the error amplifiers to adjust the output pulse width from the maximum percent on–time, established by the deadtime control input, down to zero, as the voltage at the feedback pin varies from 0.5 V to 3.5 V. Both error amplifiers have a common mode input range from –0.3 V to (V_{CC} – 2V), and may be used to sense power–supply output voltage and current. The error–amplifier outputs are active high and are ORed together at the noninverting input of the pulse–width modulator comparator. With this configuration, the amplifier that demands minimum output on time, dominates control of the loop.

When capacitor C_T is discharged, a positive pulse is generated on the output of the deadtime comparator, which clocks the pulse–steering flip–flop and inhibits the output transistors, Q1 and Q2. With the output–control connected to the reference line, the pulse–steering flip–flop directs the modulated pulses to each of the two output transistors alternately for push–pull operation. The output frequency is equal to half that of the oscillator. Output drive can also be taken from Q1 or Q2, when single–ended operation with a maximum on–time of less than 50% is required. This is desirable when the output transformer has a ringback winding with a catch diode used for snubbing. When higher output–drive currents are required for single–ended operation, Q1 and Q2 may be connected in parallel, and the output–mode pin must be tied to ground to disable the flip–flop. The output frequency will now be equal to that of the oscillator.

The TL494 has an internal 5.0 V reference capable of sourcing up to 10 mA of load current for external bias circuits. The reference has an internal accuracy of ±5.0% with a typical thermal drift of less than 50 mV over an operating temperature range of 0° to 70°C.

APPLICATIONS INFORMATION

Description

The TL594 is a fixed–frequency pulse width modulation control circuit, incorporating the primary building blocks required for the control of a switching power supply. (See Figure 1.) An internal–linear sawtooth oscillator is frequency–programmable by two external components, R_T and C_T. The approximate oscillator frequency is determined by:

$$f_{osc} \approx \frac{1.1}{R_T \bullet C_T}$$

For more information refer to Figure 3.

Output pulse width modulation is accomplished by comparison of the positive sawtooth waveform across capacitor C_T to either of two control signals. The NOR gates, which drive output transistors Q1 and Q2, are enabled only when the flip–flop clock–input line is in its low state. This happens only during that portion of time when the sawtooth voltage is greater than the control signals. Therefore, an increase in control–signal amplitude causes a corresponding linear decrease of output pulse width. (Refer to the Timing Diagram shown in Figure 2.)

The control signals are external inputs that can be fed into the deadtime control, the error amplifier inputs, or the feedback input. The deadtime control comparator has an effective 120 mV input offset which limits the minimum output deadtime to approximately the first 4% of the sawtooth–cycle time. This would result in a maximum duty cycle on a given output of 96% with the output control grounded, and 48% with it connected to the reference line. Additional deadtime may be imposed on the output by setting the deadtime–control input to a fixed voltage, ranging between 0 V to 3.3 V.

The pulse width modulator comparator provides a means for the error amplifiers to adjust the output pulse width from the maximum percent on–time, established by the deadtime control input, down to zero, as the voltage at the feedback pin varies from 0.5 V to 3.5 V. Both error amplifiers have a common–mode input range from –0.3 V to (V_{CC} – 2 V), and may be used to sense power–supply output voltage and current. The error–amplifier outputs are active high and are ORed together at the noninverting input of the pulse–width modulator comparator. With this configuration, the amplifier that demands minimum output on time, dominates control of the loop.

Functional Table

Input/Output Controls	Output Function	$\frac{f_{out}}{f_{osc}}$ =
Grounded	Single–ended PWM @ Q1 and Q2	1.0
@ V_{ref}	Push–pull Operation	0.5

When capacitor C_T is discharged, a positive pulse is generated on the output of the deadtime comparator, which clocks the pulse–steering flip–flop and inhibits the output transistors, Q1 and Q2. With the output–control connected to the reference line, the pulse–steering flip–flop directs the modulated pulses to each of the two output transistors alternately for push–pull operation. The output frequency is equal to half that of the oscillator. Output drive can also be taken from Q1 or Q2, when single–ended operation with a maximum on–time of less than 50% is required. This is desirable when the output transformer has a ringback winding with a catch diode used for snubbing. When higher output–drive currents are required for single–ended operation, Q1 and Q2 may be connected in parallel, and the output–mode pin must be tied to ground to disable the flip–flop. The output frequency will now be equal to that of the oscillator.

The TL594 has an internal 5.0 V reference capable of sourcing up to 10 mA of load current for external bias circuits. The reference has an internal accuracy of ±1.5% with a typical thermal drift of less than 50 mV over an operating temperature range of 0° to 70°C.

MOTOROLA

TL780 Series

Three-Terminal Positive Fixed Voltage Regulators

This family of precision fixed voltage regulators are monolithic integrated circuits capable of driving loads in excess of 1.5 A. Innovative design concepts, coupled with advanced thermal layout techniques have resulted in improved accuracy and excellent load, line and thermal regulation characteristics. Internal current limiting, thermal shutdown and safe–area compensation are employed, making these devices extremely rugged and virtually immune to overload.

- ±1% Output Voltage Tolerance @ 25°C
- ±2% Output Voltage Tolerance over Full Operating Temperature Range
- Internal Short Circuit Current Limiting
- Internal Thermal Overload Protection
- Output Transistor Safe–Area Compensation
- No External Components Required
- Pinout Compatible with MC7800 Series

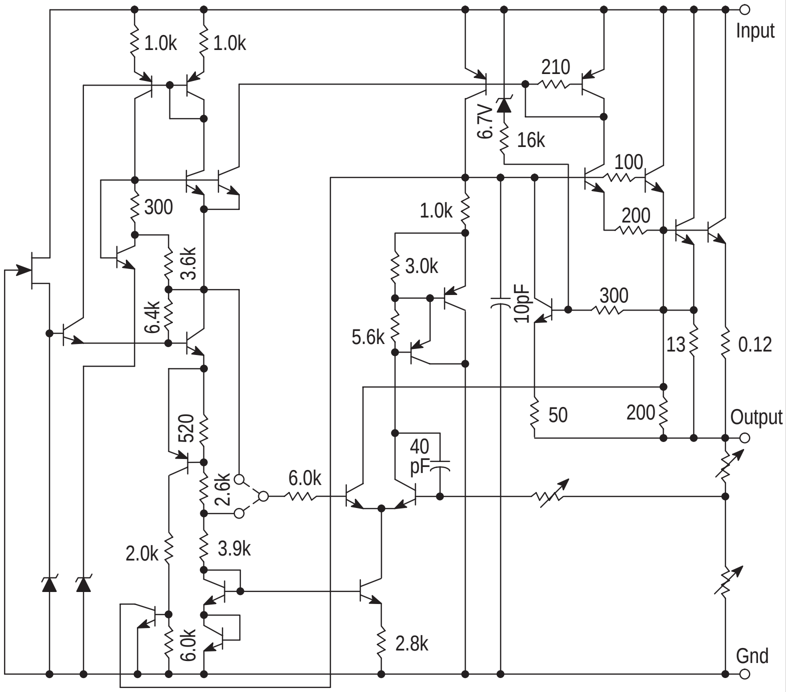
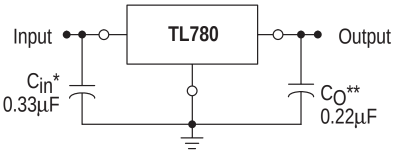
Representative Schematic Diagram



STANDARD APPLICATION



A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

(XX), these two digits of the type number indicate voltage.

* C_{in} is required if regulator is located an appreciable distance from power supply filter.
** C_O is not needed for stability; however, it does improve transient response.

VOLTAGE REGULATOR PERFORMANCE

The performance of a voltage regulator is specified by its immunity to changes in load, input voltage, power dissipation, and temperature. Line and load regulation are tested with a pulse of short duration (< 100 µs) and are strictly a function of electrical gain. However, pulse widths of longer duration (> 1.0 ms) are sufficient to affect temperature gradients across the die. These temperature gradients can cause a change in the output voltage, in addition to changes by line and load regulation. Longer pulse widths and thermal gradients make it desirable to specify thermal regulation.

Thermal regulation is defined as the change in output voltage caused by a change in dissipated power for a specified time, and is expressed as a percentage output voltage change per watt. The change in dissipated power can be caused by a change in either the input voltage or the load current. Thermal regulation is a function of IC layout and die attach techniques, and usually occurs within 10 ms of a change in power dissipation. After 10 ms, additional changes in the output voltage are due to the temperature coefficient of the device.

Figure 1 shows the line and thermal regulation response of a typical TL780–05C to a 10 W input pulse. The variation of the output voltage due to line regulation is labeled ① and the thermal regulation component is labeled ②. Figure 2 shows the load and thermal regulation response of a typical TL780–05C to a 15 W load pulse. The output voltage variation due to load regulation is labeled ① and the thermal regulation component is labeled ②.

High Performance Current Mode Controllers

The UC3842A, UC3843A series of high performance fixed frequency current mode controllers are specifically designed for off–line and dc–to–dc converter applications offering the designer a cost effective solution with minimal external components. These integrated circuits feature a trimmed oscillator for precise duty cycle control, a temperature compensated reference, high gain error amplifier, current sensing comparator, and a high current totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of input and reference undervoltage lockouts each with hysteresis, cycle–by–cycle current limiting, programmable output deadtime, and a latch for single pulse metering.

These devices are available in an 8–pin dual–in–line plastic package as well as the 14–pin plastic surface mount (SO–14). The SO–14 package has separate power and ground pins for the totem pole output stage.

The UCX842A has UYLO thresholds of 16 V (on) and 10 V (off), ideally suited for off–line converters. The UCX843A is tailored for lower voltage applications having UVLO thresholds of 8.5 V (on) and 7.6 V (off).

- Trimmed Oscillator Discharge Current for Precise Duty Cycle Control
- Current Mode Operation to 500 kHz
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Internally Trimmed Reference with Undervoltage Lockout
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis
- Low Startup and Operating Current
- Direct Interface with Motorola SENSEFET Products

OPERATING DESCRIPTION

The UC3842A, UC3843A series are high performance, fixed frequency, current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost effective solution with minimal external components. A representative block diagram is shown in Figure 17.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T. Capacitor C_T is charged from the 5.0 V reference through resistor R_T to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the discharge of C_T, the oscillator generates and internal blanking pulse that holds the center input of the NOR gate high. This causes the Output to be in a low state, thus producing a controlled amount of output deadtime. Figure 1 shows R_T versus Oscillator Frequency and Figure 2, Output Deadtime versus Frequency, both for given values of C_T. Note that many values of R_T and C_T will give the same oscillator frequency but only one combination will yield a specific output deadtime at a given frequency. The oscillator thresholds are temperature compensated, and the discharge current is trimmed and guaranteed to within ± 10% at T_J = 25°C. These internal circuit refinements minimize variations of oscillator frequency and maximum output duty cycle. The results are shown in Figures 3 and 4.

In many noise sensitive applications it may be desirable to frequency–lock the converter to an external system clock. This can be accomplished by applying a clock signal to the circuit shown in Figure 20. For reliable locking, the free–running oscillator frequency should be set about 10% less than the clock frequency. A method for multi unit synchronization is shown in Figure 21. By tailoring the clock waveform, accurate Output duty cycle clamping can be achieved.

Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 90 dB, and a unity gain bandwidth of 1.0 MHz with 57 degrees of phase margin (Figure 7). The noninverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current is –2.0 µA which can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp Output (Pin 1) is provide for external loop compensation (Figure 30). The output voltage is offset by two diode drops (≈ 1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Output (Pin 6) when Pin 1 is at its lowest state (V_{OL}). This occurs when the power supply is operating and the load is removed, or at the beginning of a soft–start interval (Figures 23, 24). The Error Amp minimum feedback resistance is limited by the amplifier's source current (0.5 mA) and the required output voltage (V_{OH}) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\ (1.0\ V) + 1.4\ V}{0.5\ mA} = 8800\ \Omega$$

Current Sense Comparator and PWM Latch

The UC3842A, UC3843A operate as a current mode controller, whereby output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier Output/Compensation (Pin1). Thus the error signal controls the peak inductor current on a cycle–by–cycle basis. The current Sense Comparator PWM Latch configuration used ensures that only a single pulse appears at the Output during any given oscillator cycle. The inductor current is converted to a voltage by inserting the ground referenced sense resistor R_S in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 3) and compared a level derived from the Error Amp Output. The peak inductor current under normal operating conditions is controlled by the voltage at pin 1 where:

$$I_{pk} = \frac{V_{(Pin\ 1)} - 1.4\ V}{3\ R_S}$$

Abnormal operating conditions occur when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the Current Sense Comparator threshold will be internally clamped to 1.0 V. Therefore the maximum peak switch current is:

$$I_{pk(max)} = \frac{1.0\ V}{R_S}$$

When designing a high power switching regulator it becomes desirable to reduce the internal clamp voltage in order to keep the power dissipation of R_S to a reasonable level. A simple method to adjust this voltage is shown in Figure 22. The two external diodes are used to compensate the internal diodes yielding a constant clamp voltage over temperature. Erratic operation due to noise pickup can result if there is an excessive reduction of the $I_{pk(max)}$ clamp voltage.

A narrow spike on the leading edge of the current waveform can usually be observed and may cause the power supply to exhibit an instability when the output is lightly loaded. This spike is due to the power transformer interwinding capacitance and output rectifier recovery time. The addition of an RC filter on the Current Sense Input with a time constant that approximates the spike duration will usually eliminate the instability; refer to Figure 26.

PIN FUNCTION DESCRIPTION

Pin		Function	Description
8–Pin	14–Pin		
1	1	Compensation	This pin is Error Amplifier output and is made available for loop compensation.
2	3	Voltage Feedback	This is the inverting input of the Error Amplifier. It is normally connected to the switching power supply output through a resistor divider.
3	5	Current Sense	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate the output switch conduction.
4	7	R_T/C_T	The Oscillator frequency and maximum Output duty cycle are programmed by connecting resistor R_T to V_{ref} and capacitor C_T to ground. Operation to 500 kHz is possible.
5	–	Gnd	This pin is the combined control circuitry and power ground (8–pin package only).
6	10	Output	This output directly drives the gate of a power MOSFET. Peak currents up to 1.0 A are sourced and sunk by this pin.
7	12	V_{CC}	This pin is the positive supply of the control IC.
8	14	V_{ref}	This is the reference output. It provides charging current for capacitor C_T through resistor R_T.
–	8	Power Ground	This pin is a separate power ground return (14–pin package only) that is connected back to the power source. It is used to reduce the effects of switching transient noise on the control circuitry.
–	11	V_C	The Output high state (V_{OH}) is set by the voltage applied to this pin (14–pin package only). With a separate power source connection, it can reduce the effects of switching transient noise on the control circuitry.
–	9	Gnd	This pin is the control circuitry ground return (14–pin package only) and is connected back to the power source ground.
–	2,4,6,13	NC	No connection (14–pin package only). These pins are not internally connected.

Undervoltage Lockout

Two undervoltage lockout comparators have been incorporated to guarantee that the IC is fully functional before the output stage is enabled. The positive power supply terminal (V_{CC}) and the reference output (V_{ref}) are each monitored by separate comparators. Each has built–in hysteresis to prevent erratic output behavior as their respective thresholds are crossed. The V_{CC} comparator upper and lower thresholds are 16 V/10 V for the UCX842A, and 8.4 V/7.6 V for the UCX843A. The V_{ref} comparator upper and lower thresholds are 3.6V/3.4 V. The large hysteresis and low startup current of the UCX842A makes it ideally suited in off–line converter applications where efficient bootstrap startup techniques are required (Figure 33). The UCX843A is intended for lower voltage dc to dc converter applications. A 36 V zener is connected as a shunt regulator form V_{CC} to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The minimum operating voltage for the UCX842A is 11 V and 8.2 V for the UCX843A.

Output

These devices contain a single totem pole output stage that was specifically designed for direct drive of power MOSFETs. It is capable of up to ±1.0 A peak drive current and has a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Output in a sinking mode whenever an undervoltage lockout is active. This characteristic eliminates the need for an external pull–down resistor.

The SO–14 surface mount package provides separate pins for V_C (output supply) and Power Ground. Proper implementation will significantly reduce the level of switching transient noise imposed on the control circuitry. This becomes particularly useful when reducing the $I_{pk(max)}$ clamp level. The separate V_C supply input allows the designer added flexibility in tailoring the drive voltage independent of V_{CC}. A zener clamp is typically connected to this input when driving power MOSFETs in systems where V_{CC} is greater that 20 V. Figure 25 shows proper power and control ground connections in a current sensing power MOSFET application.

Reference

The 5.0 V bandgap reference is trimmed to ±1.0% tolerance at T_J = 25°C on the UC284XA, and ± 2.0% on the UC384XA. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short circuit protection and is capable of providing in excess of 20 mA for powering additional control system circuitry.

DESIGN CONSIDERATIONS

Do not attempt to construct the converter on wire–wrap or plug–in prototype boards. High Frequency circuit layout techniques are imperative to prevent pulsewidth jitter. This is usually caused by excessive noise pick–up imposed on the Current Sense or Voltage Feedback inputs. Noise immunity can be improved by lowering circuit impedances at these points. The printed circuit layout should contain a ground plane with low–current signal and high–current switch and output grounds returning on separate paths back to the input filter capacitor. Ceramic bypass capacitors (0.1 μF) connected directly to V_{CC}, V_C, and V_{ref} may be required depending upon circuit layout. This provides a low impedance path for filtering the high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be located close to the IC and as far as possible from the power switch and other noise generating components.

Current mode converters can exhibit subharmonic oscillations when operating at a duty cycle greater than 50% with continuous inductor current. This instability is independent of the regulators closed–loop characteristics and is caused by the simultaneous operating conditions of fixed frequency and peak current detecting. Figure 19A shows the phenomenon graphically. At t_0, switch conduction begins, causing the inductor current to rise at a slope of m_1. This slope is a function of the input voltage divided by the inductance. At t_1, the Current Sense Input reaches the threshold established by the control voltage. This causes the switch to turn off and the current to decay at a slope of m_2 until the next oscillator cycle. The unstable condition can be shown if a pertubation is added to the control voltage, resulting in a small ΔI (dashed line). With a fixed oscillator period, the current decay time is reduced, and the minimum current at switch turn–on (t_2) is increased by ΔI + ΔI m2/m1. The minimum current at the next cycle (t_3) decreases to $(\Delta I + \Delta I\, m_2/m_1)\,(m_2/m_1)$. This pertubation is multiplied by $m_2.m_1$ on each succeeding cycle, alternately increasing and decreasing the inductor current at switch turn–on. Several oscillator cycles may be required before the inductor current reaches zero causing the process to commence again. If m_2/m_1 is greater than 1, the converter will be unstable. Figure 19B shows that by adding an artificial ramp that is synchronized with the PWM clock to the control voltage, the ΔI pertubation will decrease to zero on succeeding cycles. This compensation ramp (m_3) must have a slope equal to or slightly greater than $m_2/2$ for stability. With $m_2/2$ slope compensation, the average inductor current follows the control voltage yielding true current mode operation. The compensating ramp can be derived from the oscillator and added to either the Voltage Feedback or Current Sense inputs (Figure 32).

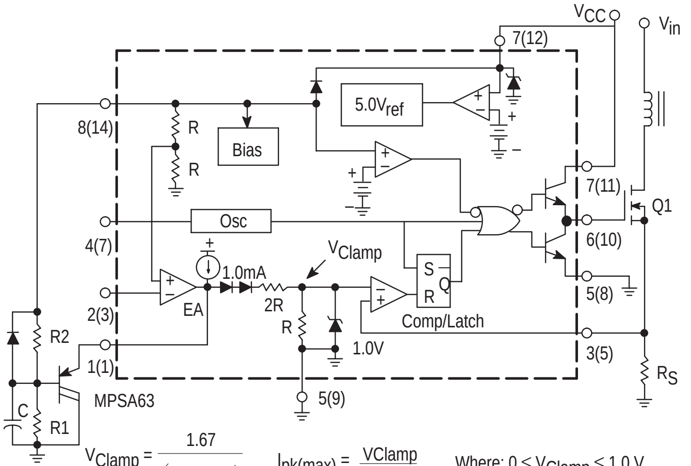
$t_{Soft–Start} \approx 3600C$ in µF

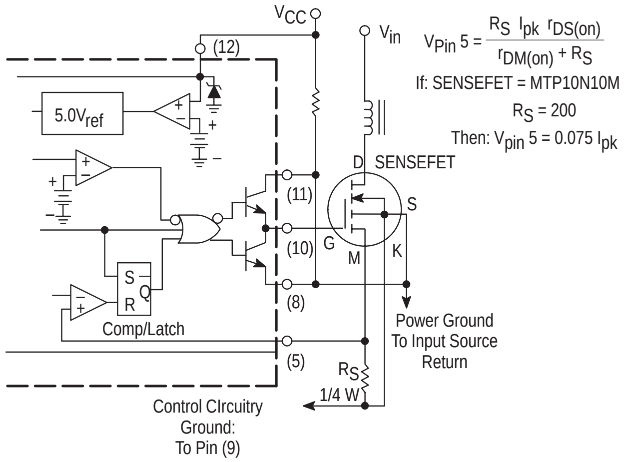
Figure 24. Adjustable Buffered Reduction of Clamp Level with Soft–Start



$V_{Clamp} = \frac{1.67}{\left(\frac{R_2}{R_1} + 1\right)}$ $I_{pk(max)} = \frac{V_{Clamp}}{RS}$ Where: $0 \le V_{Clamp} \le 1.0$ V

$t_{Softstart} = -\ln\left[1 - \frac{V_C}{3V_{Clamp}}\right] C \left(\frac{R_1 R_2}{R_1 + R_2}\right)$

Figure 25. Current Sensing Power MOSFET



$V_{Pin\,5} = \frac{R_S\; I_{pk}\; r_{DS(on)}}{r_{DM(on)} + R_S}$

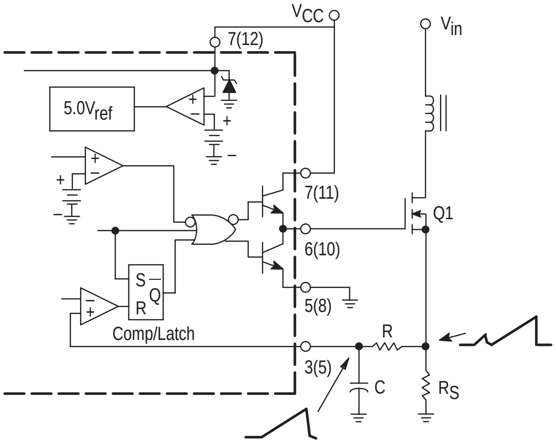
If: SENSEFET = MTP10N10M

$R_S = 200$

Then: $V_{pin\,5} = 0.075\; I_{pk}$

Virtually lossless current sensing can be achieved with the implementation of a SENSEFET power switch. For proper operation during over current conditions, a reduction of the $I_{pk(max)}$ clamp level must be implemented. Refer to Figures 22 and 24.

Figure 26. Current Waveform Spike Suppression



The addition of the RC filter will eliminate instability caused by the leading edge spike on the current waveform.

UC2842B, 43B

High Performance Current Mode Controllers

The UC3842B, UC3843B series are high performance fixed frequency current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost–effective solution with minimal external components. These integrated circuits feature a trimmed oscillator for precise duty cycle control, a temperature compensated reference, high gain error amplifier, current sensing comparator, and a high current totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of input and reference undervoltage lockouts each with hysteresis, cycle–by–cycle current limiting, programmable output deadtime, and a latch for single pulse metering.

These devices are available in an 8–pin dual–in–line and surface mount (SO–8) plastic package as well as the 14–pin plastic surface mount (SO–14). The SO–14 package has separate power and ground pins for the totem pole output stage.

The UCX842B has UVLO thresholds of 16 V (on) and 10 V (off), ideally suited for off–line converters. The UCX843B is tailored for lower voltage applications having UVLO thresholds of 8.5 V (on) and 7.6 V (off).

- Trimmed Oscillator for Precise Frequency Control
- Oscillator Frequency Guaranteed at 250 kHz
- Current Mode Operation to 500 kHz
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Internally Trimmed Reference with Undervoltage Lockout
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis
- Low Startup and Operating Current

PIN FUNCTION DESCRIPTION

Pin		Function	Description
8–Pin	14–Pin		
1	1	Compensation	This pin is the Error Amplifier output and is made available for loop compensation.
2	3	Voltage Feedback	This is the inverting input of the Error Amplifier. It is normally connected to the switching power supply output through a resistor divider.
3	5	Current Sense	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate the output switch conduction.
4	7	R_T/C_T	The Oscillator frequency and maximum Output duty cycle are programmed by connecting resistor R_T to V_{ref} and capacitor C_T to ground. Operation to 500 kHz is possible.
5		Gnd	This pin is the combined control circuitry and power ground.
6	10	Output	This output directly drives the gate of a power MOSFET. Peak currents up to 1.0 A are sourced and sunk by this pin.
7	12	V_{CC}	This pin is the positive supply of the control IC.
8	14	V_{ref}	This is the reference output. It provides charging current for capacitor C_T through resistor R_T.
	8	Power Ground	This pin is a separate power ground return that is connected back to the power source. It is used to reduce the effects of switching transient noise on the control circuitry.
	11	V_C	The Output high state (V_{OH}) is set by the voltage applied to this pin. With a separate power source connection, it can reduce the effects of switching transient noise on the control circuitry.
	9	Gnd	This pin is the control circuitry ground return and is connected back to the power source ground.
	2,4,6,13	NC	No connection. These pins are not internally connected.

OPERATING DESCRIPTION

The UC3842B, UC3843B series are high performance, fixed frequency, current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost–effective solution with minimal external components. A representative block diagram is shown in Figure 17.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T. Capacitor C_T is charged from the 5.0 V reference through resistor R_T to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds the center input of the NOR gate high. This causes the Output to be in a low state, thus producing a controlled amount of output deadtime. Figure 1 shows R_T versus Oscillator Frequency and Figure 2, Output Deadtime versus Frequency, both for given values of C_T. Note that many values of R_T and C_T will give the same oscillator frequency but only one combination will yield a specific output deadtime at a given frequency. The oscillator thresholds are temperature compensated to within ±6% at 50 kHz. Also because of industry trends moving the UC384X into higher and higher frequency applications, the UC384XB is guaranteed to within ±10% at 250 kHz. These internal circuit refinements minimize variations of oscillator frequency and maximum output duty cycle. The results are shown in Figures 3 and 4.

In many noise–sensitive applications it may be desirable to frequency–lock the converter to an external system clock. This can be accomplished by applying a clock signal to the circuit shown in Figure 20. For reliable locking, the free–running oscillator frequency should be set about 10% less than the clock frequency. A method for multi–unit synchronization is shown in Figure 21. By tailoring the clock waveform, accurate Output duty cycle clamping can be achieved.

Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 90 dB, and a unity gain bandwidth of 1.0 MHz with 57 degrees of phase margin (Figure 7). The non–inverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current is –2.0 µA which can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp Output (Pin 1) is provided for external loop compensation (Figure 31). The output voltage is offset by two diode drops (≈1.4 V) and divided by three before it connects to the non–inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Output (Pin 6) when pin 1 is at its lowest state (V_{OL}). This occurs when the power supply is operating and the load is removed, or at the beginning of a soft–start interval (Figures 23, 24). The Error Amp minimum feedback resistance is limited by the amplifier's source current (0.5 mA) and the required output voltage (V_{OH}) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\ (1.0\ V) + 1.4\ V}{0.5\ mA} = 8800\ \Omega$$

Current Sense Comparator and PWM Latch

The UC3842B, UC3843B operate as a current mode controller, whereby output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier Output/Compensation (Pin 1). Thus the error signal controls the peak inductor current on a cycle–by–cycle basis. The Current Sense Comparator PWM Latch configuration used ensures that only a single pulse appears at the Output during any given oscillator cycle. The inductor current is converted to a voltage by inserting the ground–referenced sense resistor R_S in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 3) and compared to a level derived from the Error Amp Output. The peak inductor current under normal operating conditions is controlled by the voltage at pin 1 where:

$$I_{pk} = \frac{V_{(Pin\ 1)} - 1.4\ V}{3\ R_S}$$

Abnormal operating conditions occur when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the Current Sense Comparator threshold will be internally clamped to 1.0 V. Therefore the maximum peak switch current is:

$$I_{pk(max)} = \frac{1.0\ V}{R_S}$$

When designing a high power switching regulator it becomes desirable to reduce the internal clamp voltage in order to keep the power dissipation of R_S to a reasonable level. A simple method to adjust this voltage is shown in Figure 22. The two external diodes are used to compensate the internal diodes, yielding a constant clamp voltage over temperature. Erratic operation due to noise pickup can result if there is an excessive reduction of the $I_{pk(max)}$ clamp voltage.

A narrow spike on the leading edge of the current waveform can usually be observed and may cause the power supply to exhibit an instability when the output is lightly loaded. This spike is due to the power transformer interwinding capacitance and output rectifier recovery time. The addition of an RC filter on the Current Sense Input with a time constant that approximates the spike duration will usually eliminate the instability (refer to Figure 26).

Figure 17. Representative Block Diagram

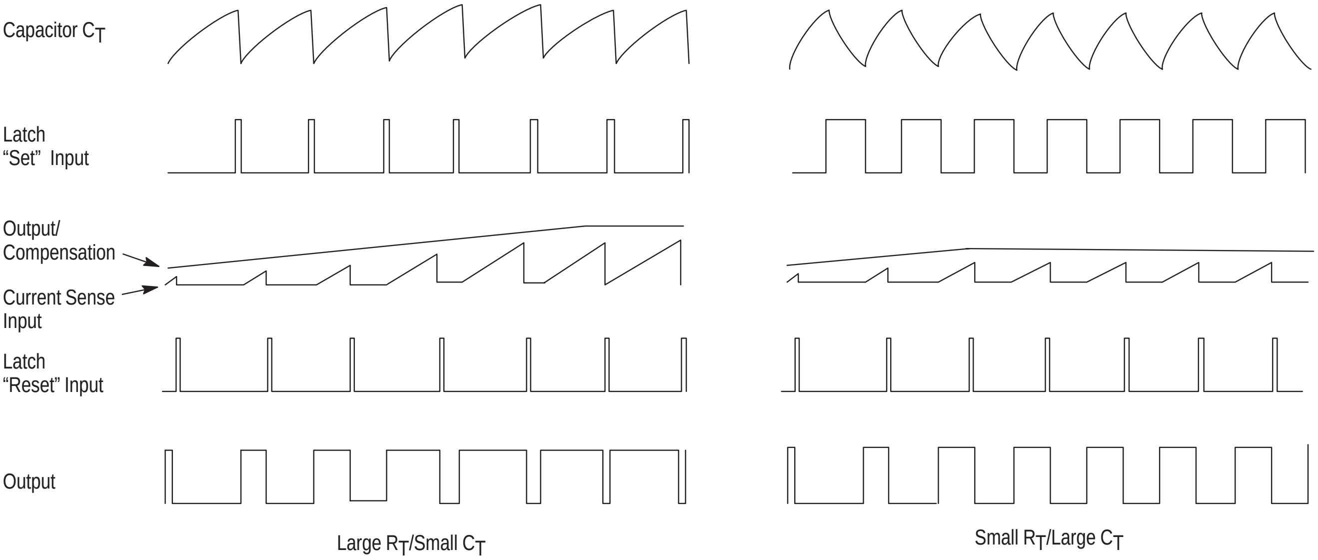
Figure 18. Timing Diagram



Undervoltage Lockout

Two undervoltage lockout comparators have been incorporated to guarantee that the IC is fully functional before the output stage is enabled. The positive power supply terminal (V_{CC}) and the reference output (V_{ref}) are each monitored by separate comparators. Each has built–in hysteresis to prevent erratic output behavior as their respective thresholds are crossed. The V_{CC} comparator upper and lower thresholds are 16 V/10 V for the UCX842B, and 8.4 V/7.6 V for the UCX843B. The V_{ref} comparator upper and lower thresholds are 3.6 V/3.4 V. The large hysteresis and low startup current of the UCX842B makes it ideally suited in off–line converter applications where efficient bootstrap startup techniques are required (Figure 33). The UCX843B is intended for lower voltage dc–to–dc converter applications. A 36 V zener is connected as a shunt regulator from V_{CC} to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The minimum operating voltage (V_{CC}) for the UCX842B is 11 V and 8.2 V for the UCX843B.

These devices contain a single totem pole output stage that was specifically designed for direct drive of power MOSFETs. It is capable of up to ±1.0 A peak drive current and has a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Output in a sinking mode whenever an undervoltage lockout is active. This characteristic eliminates the need for an external pull–down resistor.

The SO–14 surface mount package provides separate pins for V_C (output supply) and Power Ground. Proper implementation will significantly reduce the level of switching transient noise imposed on the control circuitry. This becomes particularly useful when reducing the $I_{pk(max)}$ clamp level. The separate V_C supply input allows the designer added flexibility in tailoring the drive voltage independent of V_{CC}. A zener clamp is typically connected to this input when driving power MOSFETs in systems where V_{CC} is greater than 20 V. Figure 25 shows proper power and control ground connections in a current–sensing power MOSFET application.

Reference

The 5.0 V bandgap reference is trimmed to ±1.0% tolerance at $T_J = 25°C$ on the UC284XB, and ±2.0% on the UC384XB. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short–circuit protection and is capable of providing in excess of 20 mA for powering additional control system circuitry.

Design Considerations

Do not attempt to construct the converter on wire–wrap or plug–in prototype boards. High frequency circuit layout techniques are imperative to prevent pulse–width jitter. This is usually caused by excessive noise pick–up imposed on the Current Sense or Voltage Feedback inputs. Noise immunity can be improved by lowering circuit impedances at these points. The printed circuit layout should contain a ground plane with low–current signal and high–current switch and output grounds returning on separate paths back to the input filter capacitor. Ceramic bypass capacitors (0.1 μF) connected directly to V_{CC}, V_C, and V_{ref} may be required depending upon circuit layout. This provides a low impedance path for filtering the high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be located close to the IC and as far as possible from the power switch and other noise–generating components.

Current mode converters can exhibit subharmonic oscillations when operating at a duty cycle greater than 50% with continuous inductor current. This instability is independent of the regulator's closed loop characteristics and is caused by the simultaneous operating conditions of fixed frequency and peak current detecting. Figure 19A shows the phenomenon graphically. At t_0, switch conduction begins, causing the inductor current to rise at a slope of m_1. This slope is a function of the input voltage divided by the inductance. At t_1, the Current Sense Input reaches the threshold established by the control voltage. This causes the switch to turn off and the current to decay at a slope of m_2, until the next oscillator cycle. The unstable condition can be shown if a perturbation is added to the control voltage, resulting in a small ΔI (dashed line). With a fixed oscillator period, the current decay time is reduced, and the minimum current at switch turn–on (t_2) is increased by $\Delta I + \Delta I\, m_2/m_1$. The minimum current at the next cycle (t_3) decreases to $(\Delta I + \Delta I\, m_2/m_1)\,(m_2/m_1)$. This perturbation is multiplied by m_2/m_1 on each succeeding cycle, alternately increasing and decreasing the inductor current at switch turn–on. Several oscillator cycles may be required before the inductor current reaches zero causing the process to commence again. If m_2/m_1 is greater than 1, the converter will be unstable. Figure 19B shows that by adding an artificial ramp that is synchronized with the PWM clock to the control voltage, the ΔI perturbation will decrease to zero on succeeding cycles. This compensating ramp (m_3) must have a slope equal to or slightly greater than $m_2/2$ for stability. With $m_2/2$ slope compensation, the average inductor current follows the control voltage, yielding true current mode operation. The compensating ramp can be derived from the oscillator and added to either the Voltage Feedback or Current Sense inputs (Figure 32).

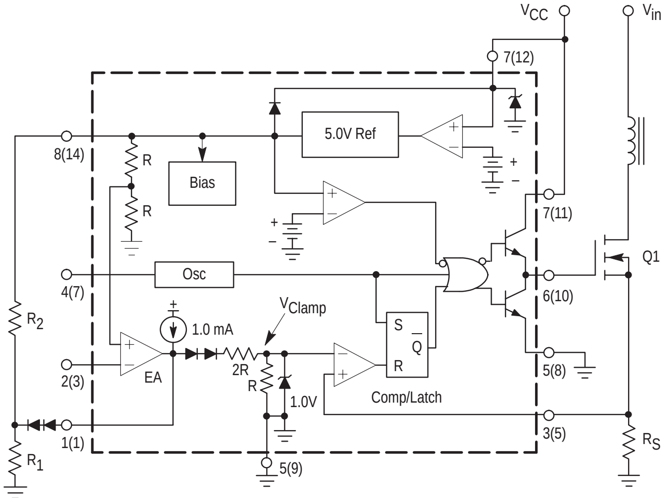
Figure 22. Adjustable Reduction of Clamp Level

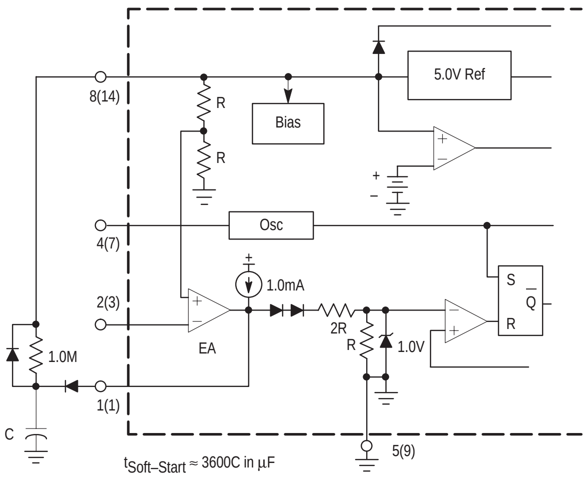


$$V_{Clamp} \approx \frac{1.67}{\left(\frac{R_2}{R_1} + 1\right)} + 0.33\text{x}10^{-3} \left(\frac{R_1 R_2}{R_1 + R_2}\right)$$

Where: $0 \leq V_{Clamp} \leq 1.0$ V

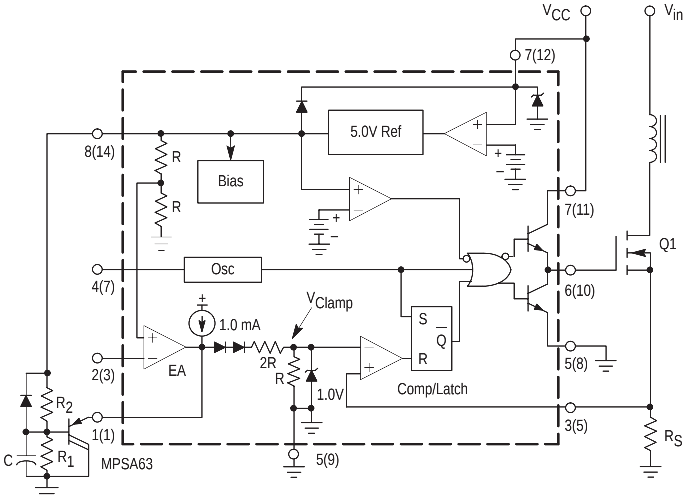
$$I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$$

Figure 23. Soft–Start Circuit



$t_{Soft–Start} \approx 3600C$ in µF

Figure 24. Adjustable Buffered Reduction of Clamp Level with Soft–Start



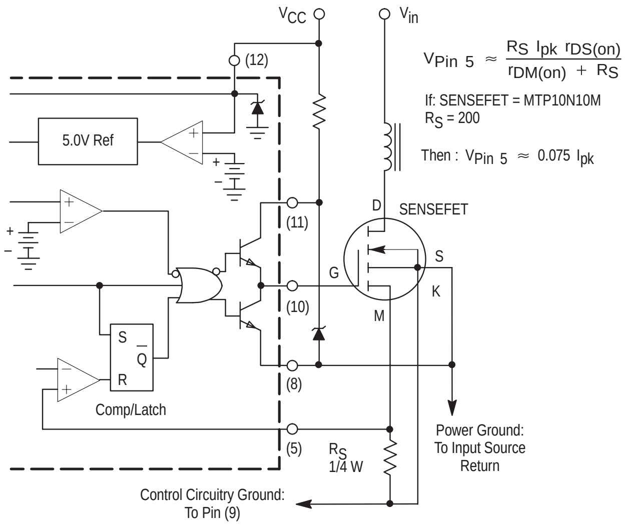
$$V_{Clamp} \approx \frac{1.67}{\left(\frac{R_2}{R_1} + 1\right)}$$

Where: $0 \leq V_{Clamp} \leq 1.0\ V$

$$t_{Soft\text{-}Start} = -\ln\left[1 - \frac{V_C}{3\ V_{Clamp}}\right] C \frac{R_1\ R_2}{R_1 + R_2}$$

$$I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$$

Figure 25. Current Sensing Power MOSFET



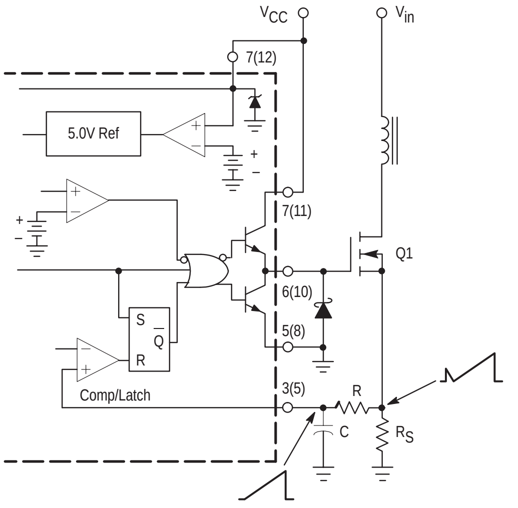
$$V_{Pin\ 5} \approx \frac{R_S\ I_{pk}\ r_{DS(on)}}{r_{DM(on)} + R_S}$$

If: SENSEFET = MTP10N10M
$R_S = 200$

Then : $V_{Pin\ 5} \approx 0.075\ I_{pk}$

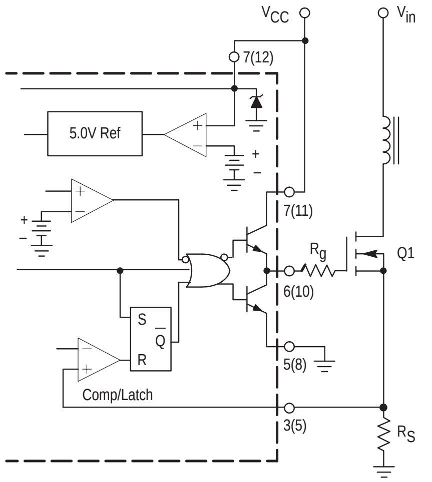
Virtually lossless current sensing can be achieved with the implementation of a SENSEFET power switch. For proper operation during over–current conditions, a reduction of the $I_{pk(max)}$ clamp level must be implemented. Refer to Figures 22 and 24.

Figure 26. Current Waveform Spike Suppression



The addition of the RC filter will eliminate instability caused by the leading edge spike on the current waveform.

Figure 27. MOSFET Parasitic Oscillations



Series gate resistor R_g will damp any high frequency parasitic oscillations caused by the MOSFET input capacitance and any series wiring inductance in the gate–source circuit.

HIGH PERFORMANCE CURRENT MODE CONTROLLERS

High Performance Current Mode Controllers

The UC3844, UC3845 series are high performance fixed frequency current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost effective solution with minimal external components. These integrated circuits feature an oscillator, a temperature compensated reference, high gain error amplifier, current sensing comparator, and a high current totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of input and reference undervoltage lockouts each with hysteresis, cycle–by–cycle current limiting, a latch for single pulse metering, and a flip–flop which blanks the output off every other oscillator cycle, allowing output deadtimes to be programmed for 50% to 70%.

These devices are available in an 8–pin dual–in–line plastic package as well as the 14–pin plastic surface mount (SO–14). The SO–14 package has separate power and ground pins for the totem pole output stage.

The UCX844 has UVLO thresholds of 16 V (on) and 10 V (off), ideally suited for off–line converters. The UCX845 is tailored for lower voltage applications having UVLO thresholds of 8.5 V (on) and 7.6 V (off).

- Current Mode Operation to 500 kHz Output Switching Frequency
- Output Deadtime Adjustable from 50% to 70%
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Internally Trimmed Reference with Undervoltage Lockout
- High Current Totem Pole Output
- Input Undervoltage Lockout with Hysteresis
- Low Startup and Operating Current
- Direct Interface with Motorola SENSEFET Products

PIN FUNCTION DESCRIPTION

Pin		Function	Description
8–Pin	14–Pin		
1	1	Compensation	This pin is Error Amplifier output and is made available for loop compensation.
2	3	Voltage Feedback	This is the inverting input of the Error Amplifier. It is normally connected to the switching power supply output through a resistor divider.
3	5	Current Sense	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate the output switch conduction.
4	7	R_T/C_T	The Oscillator frequency and maximum Output duty cycle are programmed by connecting resistor R_T to V_{ref} and capacitor C_T to ground. Operation to 1.0 MHz is possible.
5	–	Gnd	This pin is combined control circuitry and power ground (8–pin package only).
6	10	Output	This output directly drives the gate of a power MOSFET. Peak currents up to 1.0 A are sourced and sunk by this pin. The output switches at one–half the oscillator frequency.
7	12	V_{CC}	This pin is the positive supply of the control IC.
8	14	V_{ref}	This is the reference output. It provides charging current for capacitor C_T through resistor R_T.
–	8	Power Ground	This pin is a separate power ground return (14–pin package only) that is connected back to the power source. It is used to reduce the effects of switching transient noise on the control circuitry.
–	11	V_C	The Output high state (V_{OH}) is set by the voltage applied to this pin (14–pin package only). With a separate power source connection, it can reduce the effects of switching transient noise on the control circuitry.
–	9	Gnd	This pin is the control circuitry ground return (14–pin package only) and is connected to back to the power source ground.
–	2,4,6,13	NC	No connection (14–pin package only). These pins are not internally connected.

OPERATING DESCRIPTION

The UC3844, UC3845 series are high performance, fixed frequency, current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost effective solution with minimal external components. A representative block diagram is shown in Figure 15.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T. Capacitor C_T is charged from the 5.0 V reference through resistor R_T to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds the center input of the NOR gate high. This causes the Output to be in a low state, thus producing a controlled amount of output deadtime. An internal flip–flop has been incorporated in the UCX844/5 which blanks the output off every other clock cycle by holding one of the inputs of the NOR gate high. This in combination with the C_T discharge period yields output deadtimes programmable from 50% to 70%. Figure 1 shows R_T versus Oscillator Frequency and figure 2, Output Deadtime versus Frequency, both for given values of C_T. Note that many values of R_T and C_T will give the same oscillator frequency but only one combination will yield a specific output deadtime at a given frequency.

In many noise sensitive applications it may be desirable to frequency–lock the converter to an external system clock. This can be accomplished by applying a clock signal to the circuit shown in Figure 17. For reliable locking, the free–running oscillator frequency should be set about 10% less than the clock frequency. A method for multi unit synchronization is shown in Figure 18. By tailoring the clock waveform, accurate Output duty cycle clamping can be achieved to realize output deadtimes of greater than 70%

Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 90 dB, and a unity gain bandwidth of 1.0 MHz with 57 degrees of phase margin (Figure 5). The noninverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current is –2.0 µA which can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp Output (Pin 1) is provide for external loop compensation (Figure 28). The output voltage is offset by two diode drops (≈ 1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Output (Pin 6) when Pin 1 is at its lowest state (V_{OL}). This occurs when the power supply is operating and the load is removed, or at the beginning of a soft–start interval (Figures 20, 21). The Error Amp minimum feedback resistance is limited by the amplifier's source current (0.5 mA) and the required output voltage (V_{OH}) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\ (1.0\ V) + 1.4\ V}{0.5\ mA} = 8800\ \Omega$$

Current Sense Comparator and PWM Latch

The UC3844, UC3845 operate as a current mode controller, whereby output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier Output/Compensation (Pin1). Thus the error signal controls the inductor current on a cycle–by–cycle basis. The current Sense Comparator PWM Latch configuration used ensures that only a single pulse appears at the Output during any given oscillator cycle. The inductor current is converted to a voltage by inserting the ground referenced sense resistor R_S in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 3) and compared a level derived from the Error Amp Output. The peak inductor current under normal operating conditions is controlled by the voltage at pin 1 where:

$$I_{pk} = \frac{V_{(Pin\ 1)} - 1.4\ V}{3\ R_S}$$

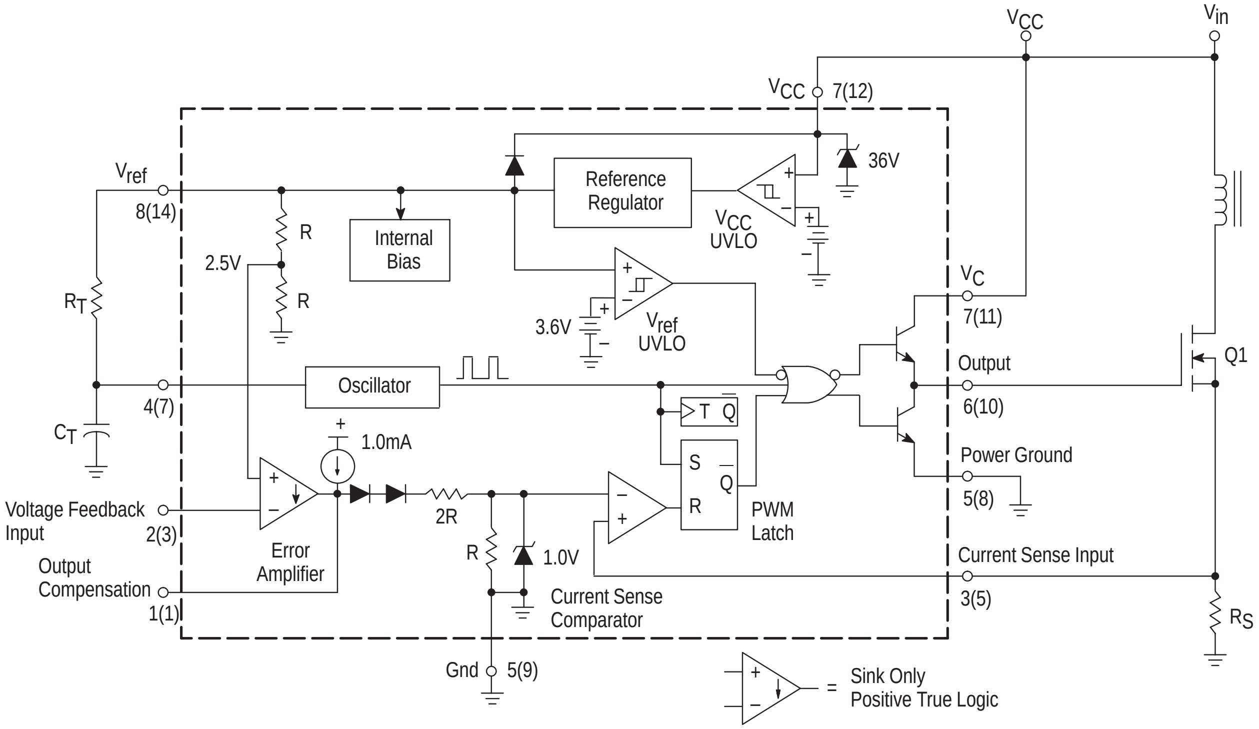
Abnormal operating conditions occur when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the Current Sense Comparator threshold will be internally clamped to 1.0 V. Therefore the maximum peak switch current is:

$$I_{pk(max)} = \frac{1.0\ V}{R_S}$$

When designing a high power switching regulator it becomes desirable to reduce the internal clamp voltage in order to keep the power dissipation of R_S to a reasonable level. A simple method to adjust this voltage is shown in Figure 19. The two external diodes are used to compensate the internal diodes yielding a constant clamp voltage over temperature. Erratic operation due to noise pickup can result if there is an excessive reduction of the $I_{pk(max)}$ clamp voltage.

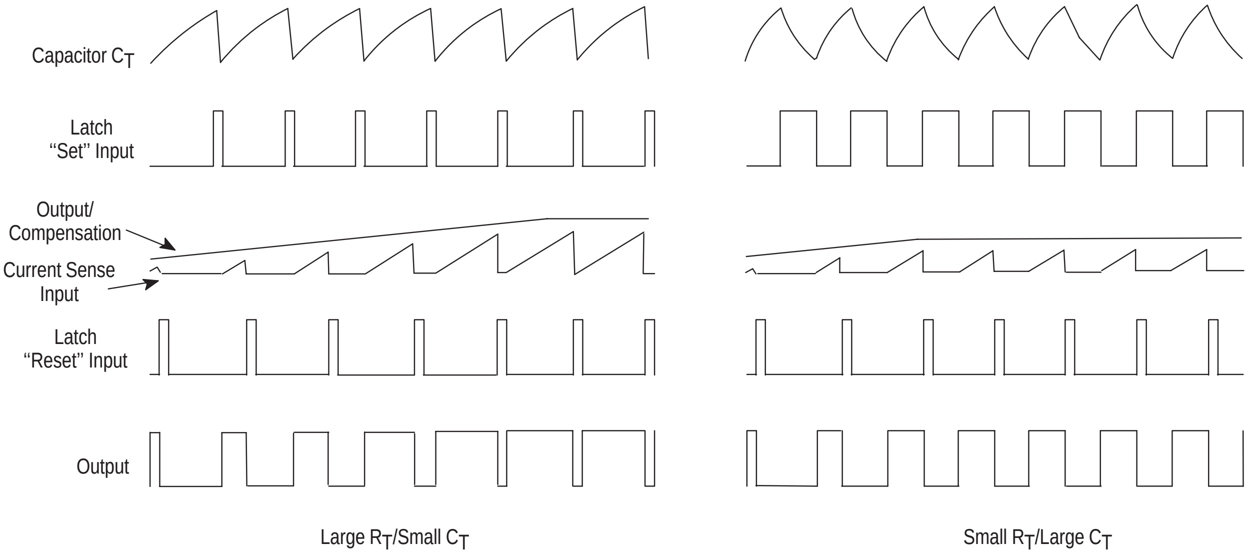
A narrow spike on the leading edge of the current waveform can usually be observed and may cause the power supply to exhibit an instability when the output is lightly loaded. This spike is due to the power transformer interwinding capacitance and output rectifier recovery time. The addition of an RC filter on the Current Sense Input with a time constant that approximates the spike duration will usually eliminate the instability; refer to Figure 23.

Figure 15. Representative Block Diagram



Pin numbers in parenthesis are for the D suffix SO–14 package.

Figure 16. Timing Diagram



Undervoltage Lockout

Two undervoltage lockout comparators have been incorporated to guarantee that the IC is fully functional before the output stage is enabled. The positive power supply terminal (V_{CC} and the reference output (V_{ref}) are each monitored by separate comparators. Each has built–in hysteresis to prevent erratic output behavior as their respective thresholds are crossed. The V_{CC} comparator upper and lower thresholds are 16 V/10 V for the UCX844, and 8.4 V/7.6 V for the UCX845. The V_{ref} comparator upper and lower thresholds are 3.6 V/3/4 V. The large hysteresis and low startup current of the UCX844 makes it ideally suited in off–line converter applications where efficient bootstrap startup techniques later required (Figure 29). The UCX845 is intended for lower voltage dc–to–dc converter applications. A 36 V zener is connected as a shunt regulator from V_{CC} to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The minimum operating voltage for the UCX844 is 11 V and 8.2 V for the UCX845.

Output

These devices contain a single totem pole output stage that was specifically designed for direct drive of power MOSFETs. It is capable of up to ± 1.0 A peak drive current and has a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Output in a sinking mode whenever and undervoltage lockout is active. This characteristic eliminates the need for an external pull–down resistor.

The SO–14 surface mount package provides separate pins for V_C (output supply) and Power Ground. Proper implementation will significantly reduce the level of switching transient noise imposed on the control circuitry. This becomes particularly useful when reducing the $I_{pk(max)}$ clamp level. The separate V_C supply input allows the designer added flexibility in tailoring the drive voltage independent of V_{CC}. A zener clamp is typically connected to this input when driving power MOSFETs in systems where V_{CC} is greater the 20 V. Figure 22 shows proper power and control ground connections in a current sensing power MOSFET application.

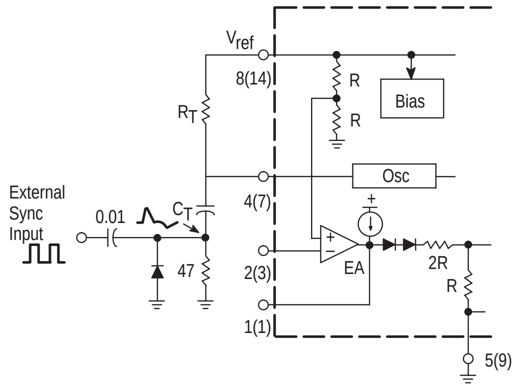
Reference

The 5.0 V bandgap reference is trimmed to ± 1.0% tolerance at T_J = 25°C on the UC284X, and ± 2.0% on the UC384X. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short circuit protection and is capable of providing in excess of 20 mA for powering additional control system circuitry.

Design Considerations

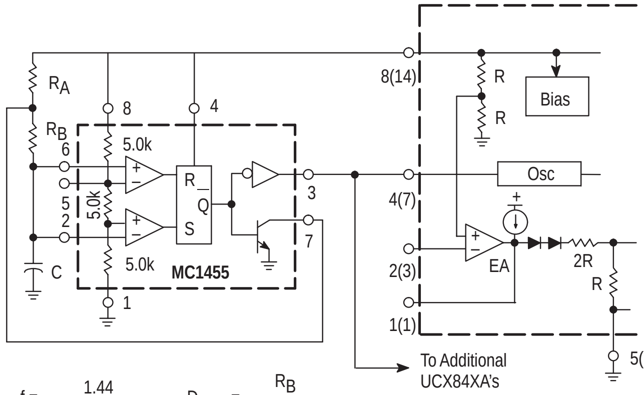
Do not attempt to construct the converter on wire–wrap or plug–in prototype boards. High frequency circuit layout techniques are imperative to prevent pulsewidth jitter. This is usually caused by excessive noise pick–up imposed on the Current Sense or Voltage Feedback inputs. Noise immunity can be improved by lowering circuit impedances at these points. The printed circuit layout should contain a ground plane with low–current signal and high–current switch and output grounds returning on separate paths back to the input filter capacitor. Ceramic bypass capacitors (0.1 µF) connected directly to V_{CC}, V_C, and V_{ref} may be required depending upon circuit layout. This provides a low impedance path for filtering the high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be located close to the IC and as far as possible from the power switch and other noise generating components.

Figure 17. External Clock Synchronization



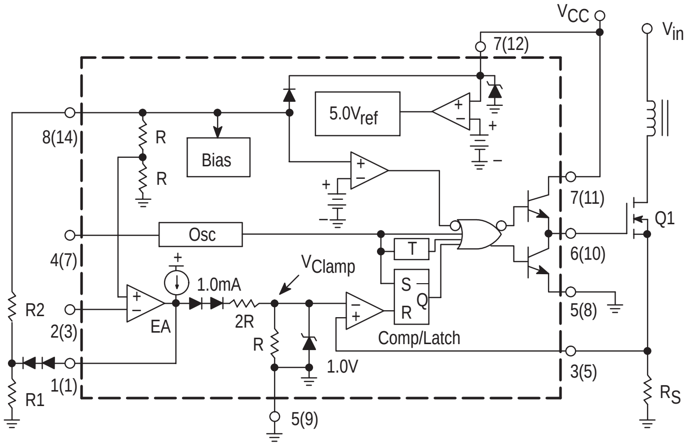
The diode clamp is required if the Sync amplitude is large enough to cause the bottom side of CT to go more than 300 mV below ground.

Figure 18. External Duty Cycle Clamp and Multi–Unit Synchronization



$f = \frac{1.44}{(R_A + 2R_B)C}$ $D_{max} = \frac{R_B}{R_A + 2R_B}$

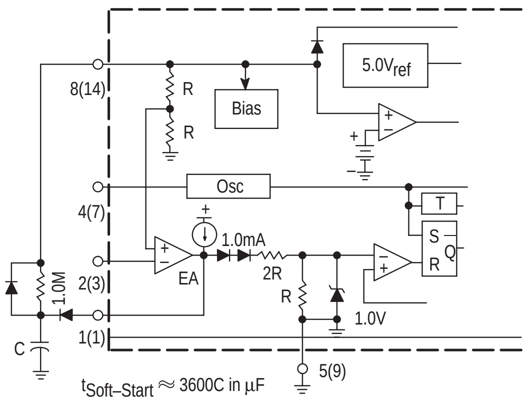
Figure 19. Adjustable Reduction of Clamp Level



$$V_{Clamp}\ \frac{1.67}{\left(\frac{R_2}{R_1}+1\right)} + 0.33 \times 10^{-3}\left(\frac{R_1\ R_2}{R_1+R_2}\right) \qquad I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$$

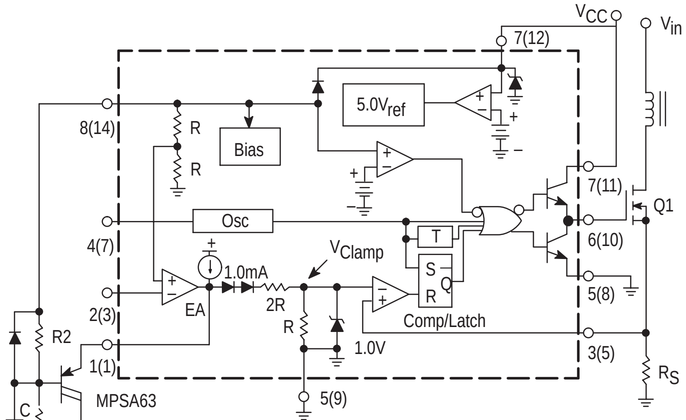
Where: $0 \le V_{Clamp} \le 1.0$ V

Figure 20. Soft–Start Circuit



$t_{Soft-Start} \approx 3600C$ in µF

Figure 21. Adjustable Buffered Reduction of Clamp Level with Soft–Start

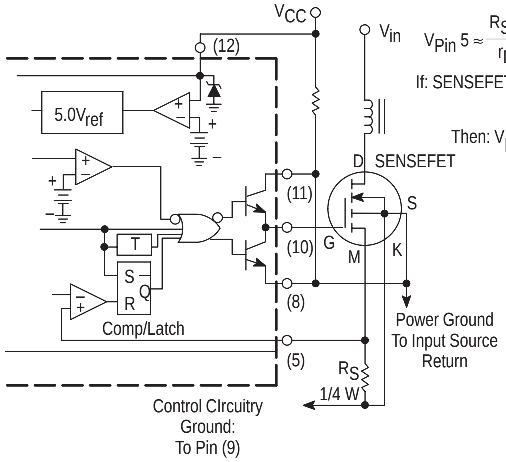


$$V_{Clamp}\ \frac{1.67}{\left(\frac{R_2}{R_1}+1\right)} + 0.33 \times 10^{-3}\ \frac{R_1\ R_2}{R_1+R_2}$$

$I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$ Where: $0 \le V_{Clamp} \le 1.0$ V

$$t_{Softstart} = -\ln\left[1 - \frac{V_C}{3V_{Clamp}}\right] C\ \frac{R_1\ R_2}{R_1 + R_2}$$

Figure 22. Current Sensing Power MOSFET



$$V_{Pin\ 5} \approx \frac{R_S\ I_{pk}\ r_{DS(on)}}{r_{DM(on)} + R_S}$$

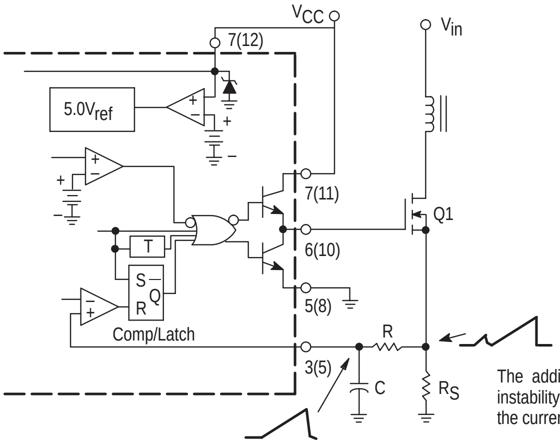
If: SENSEFET = MTP10N10M

$R_S = 200$

Then: $V_{pin\ 5} = 0.075\ I_{pk}$

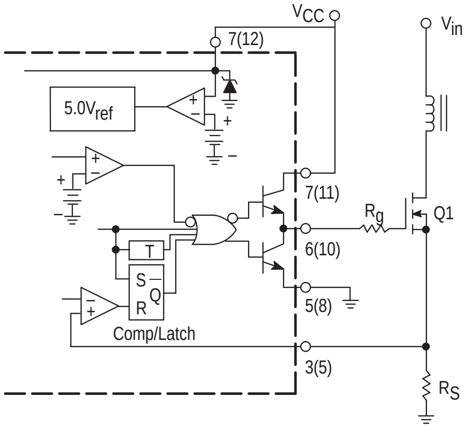
Virtually lossless current sensing can be achieved with the implement of a SENSEFET power switch. For proper operation during over current conditions, a reduction of the $I_{pk(max)}$ clamp level must be implemented. Refer to Figures 19 and 21.

Figure 23. Current Waveform Spike Suppression



The addition of the RC filter will eliminate instability caused by the leading edge spike on the current waveform.

Figure 24. MOSFET Parasitic Oscillations



Series gate resistor R_g will damp any high frequency parasitic oscillations caused by the MOSFET input capacitance and any series wiring inductance in the gate–source circuit.

An additional series resistor may be required when using tantalum or other low ESR capacitors.

MOTOROLA

UC3844B, 45B
UC2844B, 45B

High Performance Current Mode Controllers

The UC3844B, UC3845B series are high performance fixed frequency current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost–effective solution with minimal external components. These integrated circuits feature an oscillator, a temperature compensated reference, high gain error amplifier, current sensing comparator, and a high current totem pole output ideally suited for driving a power MOSFET.

Also included are protective features consisting of input and reference undervoltage lockouts each with hysteresis, cycle–by–cycle current limiting, a latch for single pulse metering, and a flip–flop which blanks the output off every other oscillator cycle, allowing output deadtimes to be programmed from 50% to 70%.

These devices are available in an 8–pin dual–in–line and surface mount (SO–8) plastic package as well as the 14–pin plastic surface mount (SO–14). The SO–14 package has separate power and ground pins for the totem pole output stage.

The UCX844B has UVLO thresholds of 16 V (on) and 10 V (off), ideally suited for off–line converters. The UCX845B is tailored for lower voltage applications having UVLO thresholds of 8.5 V (on) and 7.6 V (off).

- Trimmed Oscillator for Precise Frequency Control
- Oscillator Frequency Guaranteed at 250 kHz
- Current Mode Operation to 500 kHz Output Switching Frequency
- Output Deadtime Adjustable from 50% to 70%
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Internally Trimmed Reference with Undervoltage Lockout
- High Current Totem Pole Output
- Undervoltage Lockout with Hysteresis
- Low Startup and Operating Current

PIN FUNCTION DESCRIPTION

Pin		Function	Description
8–Pin	14–Pin		
1	1	Compensation	This pin is the Error Amplifier output and is made available for loop compensation.
2	3	Voltage Feedback	This is the inverting input of the Error Amplifier. It is normally connected to the switching power supply output through a resistor divider.
3	5	Current Sense	A voltage proportional to inductor current is connected to this input. The PWM uses this information to terminate the output switch conduction.
4	7	R_T/C_T	The Oscillator frequency and maximum Output duty cycle are programmed by connecting resistor R_T to V_{ref} and capacitor C_T to ground. Oscillator operation to 1.0 kHz is possible.
5		Gnd	This pin is the combined control circuitry and power ground.
6	10	Output	This output directly drives the gate of a power MOSFET. Peak currents up to 1.0 A are sourced and sunk by this pin. The output switches at one–half the oscillator frequency.
7	12	V_{CC}	This pin is the positive supply of the control IC.
8	14	V_{ref}	This is the reference output. It provides charging current for capacitor C_T through resistor R_T.
	8	Power Ground	This pin is a separate power ground return that is connected back to the power source. It is used to reduce the effects of switching transient noise on the control circuitry.
	11	V_C	The Output high state (V_{OH}) is set by the voltage applied to this pin. With a separate power source connection, it can reduce the effects of switching transient noise on the control circuitry.
	9	Gnd	This pin is the control circuitry ground return and is connected back to the power source ground.
	2,4,6,13	NC	No connection. These pins are not internally connected.

OPERATING DESCRIPTION

The UC3844B, UC3845B series are high performance, fixed frequency, current mode controllers. They are specifically designed for Off–Line and dc–to–dc converter applications offering the designer a cost–effective solution with minimal external components. A representative block diagram is shown in Figure 15.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T. Capacitor C_T is charged from the 5.0 V reference through resistor R_T to approximately 2.8 V and discharged to 1.2 V by an internal current sink. During the discharge of C_T, the oscillator generates an internal blanking pulse that holds the center input of the NOR gate high. This causes the Output to be in a low state, thus producing a controlled amount of output deadtime. An internal flip–flop has been incorporated in the UCX844/5B which blanks the output off every other clock cycle by holding one of the inputs of the NOR gate high. This in combination with the C_T discharge period yields output deadtimes programmable from 50% to 70%. Figure 1 shows R_T versus Oscillator Frequency and Figure 2, Output Deadtime versus Frequency, both for given values of C_T. Note that many values of R_T and C_T will give the same oscillator frequency but only one combination will yield a specific output deadtime at a given frequency. The oscillator thresholds are temperature compensated to within ±6% at 50 kHz. Also, because of industry trends moving the UC384X into higher and higher frequency applications, the UC384XB is guaranteed to within ±10% at 250 kHz.

In many noise–sensitive applications it may be desirable to frequency–lock the converter to an external system clock. This can be accomplished by applying a clock signal to the circuit shown in Figure 17. For reliable locking, the free–running oscillator frequency should be set about 10% less than the clock frequency. A method for multi–unit synchronization is shown in Figure 18. By tailoring the clock waveform, accurate Output duty cycle clamping can be achieved to realize output deadtimes of greater than 70%.

Error Amplifier

A fully compensated Error Amplifier with access to the inverting input and output is provided. It features a typical dc voltage gain of 90 dB, and a unity gain bandwidth of 1.0 MHz with 57 degrees of phase margin (Figure 5). The non–inverting input is internally biased at 2.5 V and is not pinned out. The converter output voltage is typically divided down and monitored by the inverting input. The maximum input bias current is –2.0 µA which can cause an output voltage error that is equal to the product of the input bias current and the equivalent input divider source resistance.

The Error Amp Output (Pin 1) is provided for external loop compensation (Figure 28). The output voltage is offset by two diode drops (≈1.4 V) and divided by three before it connects to the inverting input of the Current Sense Comparator. This guarantees that no drive pulses appear at the Output (Pin 6) when Pin 1 is at its lowest state (V_{OL}). This occurs when the power supply is operating and the load is removed, or at the beginning of a soft–start interval (Figures 20, 21). The Error Amp minimum feedback resistance is limited by the amplifier's source current (0.5 mA) and the required output voltage (V_{OH}) to reach the comparator's 1.0 V clamp level:

$$R_{f(min)} \approx \frac{3.0\,(1.0\text{ V}) + 1.4\text{ V}}{0.5\text{ mA}} = 8800\ \Omega$$

Current Sense Comparator and PWM Latch

The UC3844B, UC3845B operate as a current mode controller, whereby output switch conduction is initiated by the oscillator and terminated when the peak inductor current reaches the threshold level established by the Error Amplifier Output/Compensation (Pin 1). Thus the error signal controls the peak inductor current on a cycle–by–cycle basis. The Current Sense Comparator PWM Latch configuration used ensures that only a single pulse appears at the Output during any given oscillator cycle. The inductor current is converted to a voltage by inserting the ground–referenced sense resistor R_S in series with the source of output switch Q1. This voltage is monitored by the Current Sense Input (Pin 3) and compared to a level derived from the Error Amp Output. The peak inductor current under normal operating conditions is controlled by the voltage at Pin 1 where:

$$I_{pk} = \frac{V_{(Pin\ 1)} - 1.4\text{ V}}{3\,R_S}$$

Abnormal operating conditions occur when the power supply output is overloaded or if output voltage sensing is lost. Under these conditions, the Current Sense Comparator threshold will be internally clamped to 1.0 V. Therefore the maximum peak switch current is:

$$I_{pk(max)} = \frac{1.0\text{ V}}{R_S}$$

When designing a high power switching regulator it becomes desirable to reduce the internal clamp voltage in order to keep the power dissipation of R_S to a reasonable level. A simple method to adjust this voltage is shown in Figure 19. The two external diodes are used to compensate the internal diodes, yielding a constant clamp voltage over temperature. Erratic operation due to noise pickup can result if there is an excessive reduction of the $I_{pk(max)}$ clamp voltage.

A narrow spike on the leading edge of the current waveform can usually be observed and may cause the power supply to exhibit an instability when the output is lightly loaded. This spike is due to the power transformer interwinding capacitance and output rectifier recovery time. The addition of an RC filter on the Current Sense Input with a time constant that approximates the spike duration will usually eliminate the instability (refer to Figure 23).

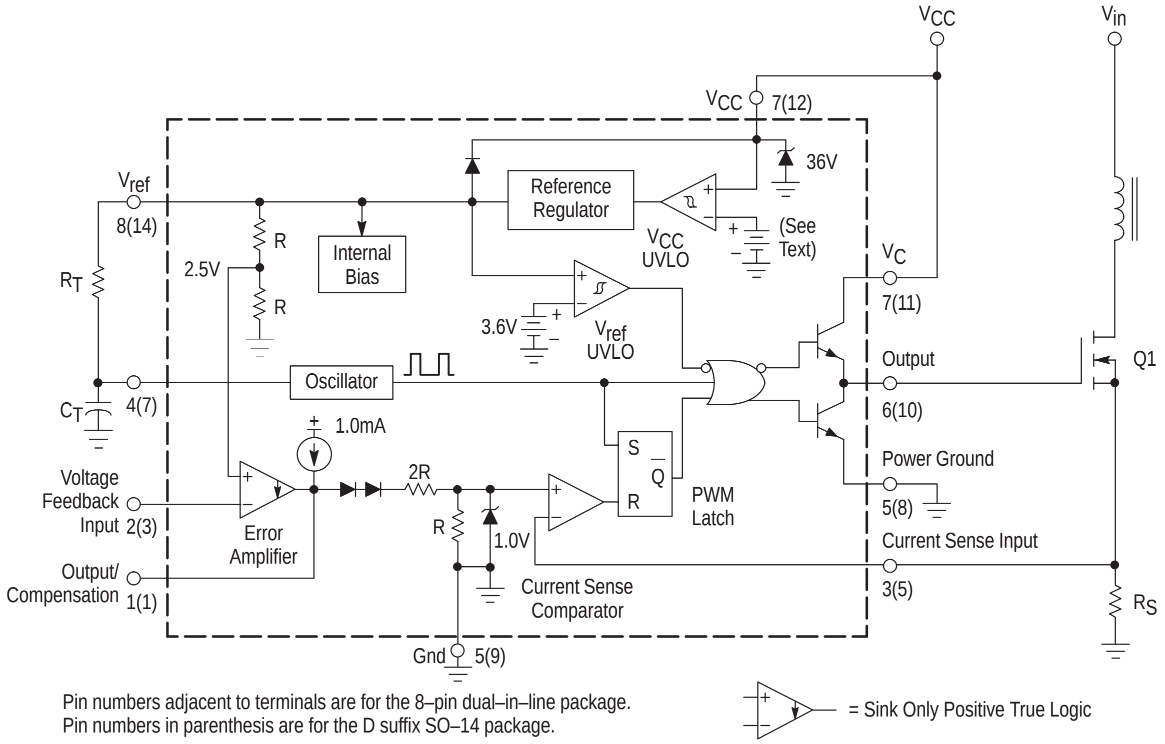

Figure 15. Representative Block Diagram

Pin numbers adjacent to terminals are for the 8–pin dual–in–line package.
Pin numbers in parenthesis are for the D suffix SO–14 package.

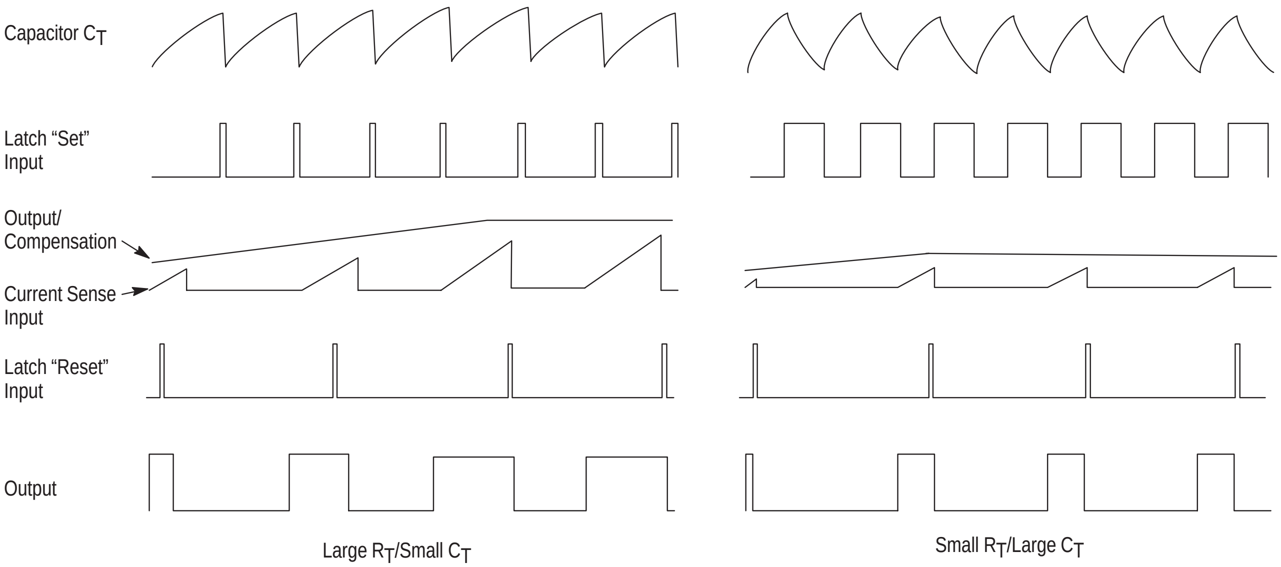

Figure 16. Timing Diagram

Undervoltage Lockout

Two undervoltage lockout comparators have been incorporated to guarantee that the IC is fully functional before the output stage is enabled. The positive power supply terminal (V_{CC}) and the reference output (V_{ref}) are each monitored by separate comparators. Each has built–in hysteresis to prevent erratic output behavior as their respective thresholds are crossed. The V_{CC} comparator upper and lower thresholds are 16 V/10 V for the UCX844B, and 8.4 V/7.6 V for the UCX845B. The V_{ref} comparator upper and lower thresholds are 3.6 V/3.4 V. The large hysteresis and low startup current of the UCX844B makes it ideally suited in off–line converter applications where efficient bootstrap startup techniques are required (Figure 29). The UCX845B is intended for lower voltage dc–to–dc converter applications. A 36 V zener is connected as a shunt regulator from V_{CC} to ground. Its purpose is to protect the IC from excessive voltage that can occur during system startup. The minimum operating voltage for the UCX844B is 11 V and 8.2 V for the UCX845B.

Output

These devices contain a single totem pole output stage that was specifically designed for direct drive of power MOSFETs. It is capable of up to ±1.0 A peak drive current and has a typical rise and fall time of 50 ns with a 1.0 nF load. Additional internal circuitry has been added to keep the Output in a sinking mode whenever an undervoltage lockout is active. This characteristic eliminates the need for an external pull–down resistor.

The SO–14 surface mount package provides separate pins for V_C (output supply) and Power Ground. Proper implementation will significantly reduce the level of switching transient noise imposed on the control circuitry. This becomes particularly useful when reducing the $I_{pk(max)}$ clamp level. The separate V_C supply input allows the designer added flexibility in tailoring the drive voltage independent of V_{CC}. A zener clamp is typically connected to this input when driving power MOSFETs in systems where V_{CC} is greater than 20 V. Figure 22 shows proper power and control ground connections in a current–sensing power MOSFET application.

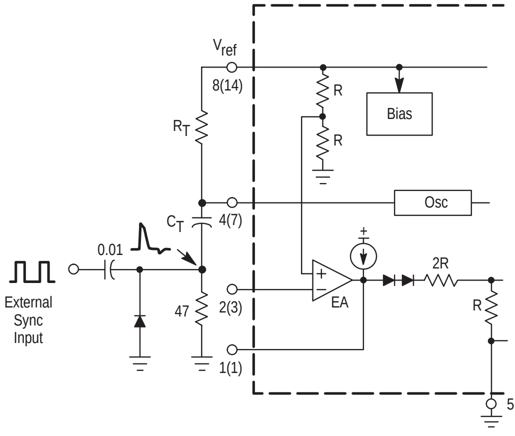
Reference

The 5.0 V bandgap reference is trimmed to ±1.0% tolerance at T_J = 25°C on the UC284XB, and ±2.0% on the UC384XB. Its primary purpose is to supply charging current to the oscillator timing capacitor. The reference has short–circuit protection and is capable of providing in excess of 20 mA for powering additional control system circuitry.

Design Considerations

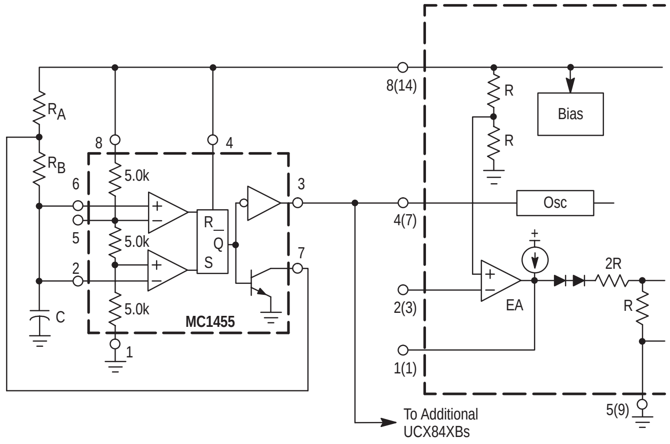
Do not attempt to construct the converter on wire–wrap or plug–in prototype boards. High frequency circuit layout techniques are imperative to prevent pulse–width jitter. This is usually caused by excessive noise pick–up imposed on the Current Sense or Voltage Feedback inputs. Noise immunity can be improved by lowering circuit impedances at these points. The printed circuit layout should contain a ground plane with low–current signal and high–current switch and output grounds returning on separate paths back to the input filter capacitor. Ceramic bypass capacitors (0.1 µF) connected directly to V_{CC}, V_C, and V_{ref} may be required depending upon circuit layout. This provides a low impedance path for filtering the high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI. The Error Amp compensation circuitry and the converter output voltage divider should be located close to the IC and as far as possible from the power switch and other noise–generating components.

Figure 17. External Clock Synchronization



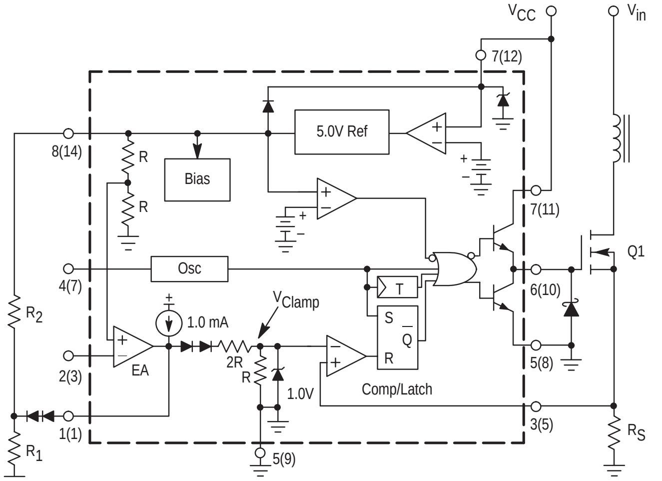
The diode clamp is required if the Sync amplitude is large enough to cause the bottom side of C_T to go more than 300 mV below ground.

Figure 18. External Duty Cycle Clamp and Multi–Unit Synchronization



$$f = \frac{1.44}{(R_A + 2R_B)C} \qquad D_{(max)} = \frac{R_A}{R_A + 2R_B}$$

Figure 19. Adjustable Reduction of Clamp Level

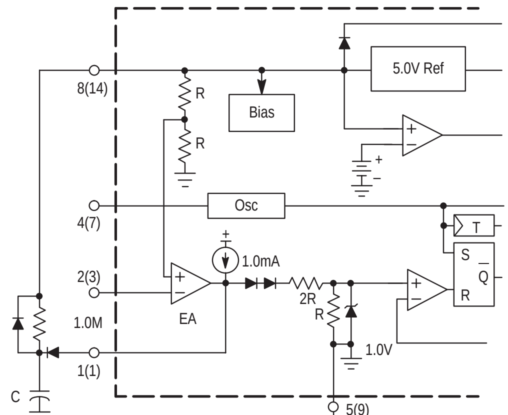


$$V_{Clamp} \approx \frac{1.67}{\left(\frac{R_2}{R_1}+1\right)} + 0.33\text{x}10^{-3}\left(\frac{R_1R_2}{R_1+R_2}\right)$$

Where: $0 \le V_{Clamp} \le 1.0$ V

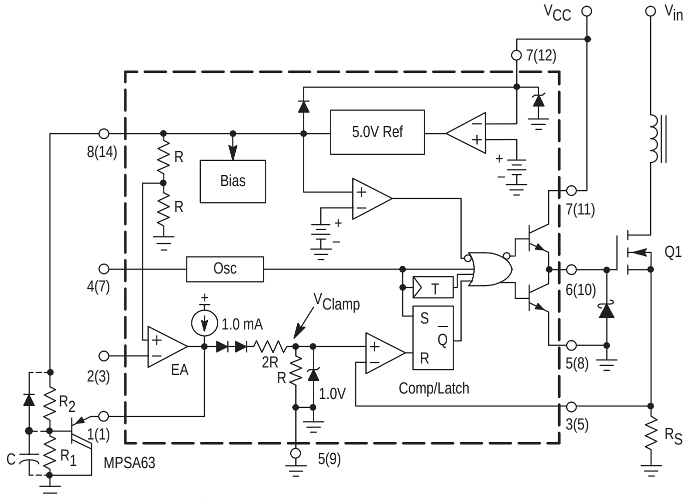
$$I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$$

Figure 20. Soft–Start Circuit



$t_{Soft–Start} \approx 3600C$ in µF

Figure 21. Adjustable Buffered Reduction of Clamp Level with Soft–Start

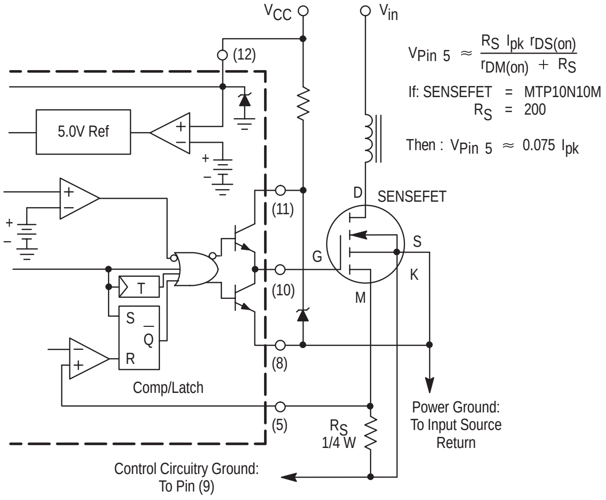


$$V_{Clamp} \approx \frac{1.67}{\left(\frac{R_2}{R_1}+1\right)}$$

Where: $0 \le V_{Clamp} \le 1.0$ V

$$t_{Soft\text{-}Start} = -\ln\left[1 - \frac{V_C}{3V_{Clamp}}\right] C\frac{R_1\ R_2}{R_1 + R_2} \qquad I_{pk(max)} \approx \frac{V_{Clamp}}{R_S}$$

Figure 22. Current Sensing Power MOSFET



$$V_{Pin\ 5} \approx \frac{R_S\ I_{pk}\ r_{DS(on)}}{r_{DM(on)} + R_S}$$

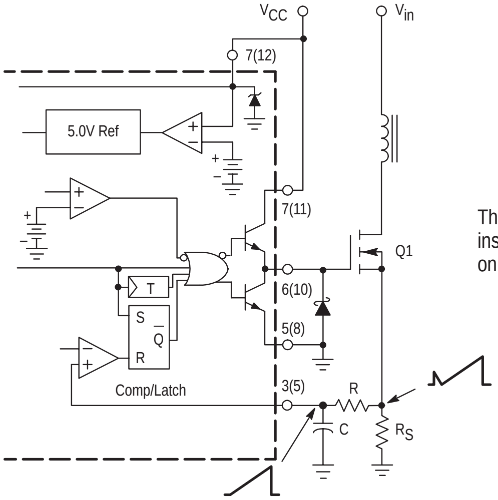
If: SENSEFET = MTP10N10M

$R_S = 200$

Then : $V_{Pin\ 5} \approx 0.075\ I_{pk}$

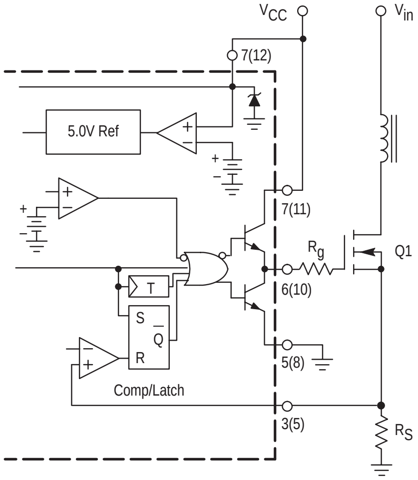
Virtually lossless current sensing can be achieved with the implementation of a SENSEFET power switch. For proper operation during over–current conditions, a reduction of the $I_{pk(max)}$ clamp level must be implemented. Refer to Figures 19 and 21.

Figure 23. Current Waveform Spike Suppression



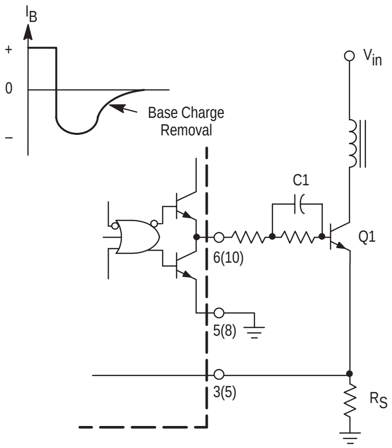
The addition of the RC filter will eliminate instability caused by the leading edge spike on the current waveform.

Figure 24. MOSFET Parasitic Oscillations



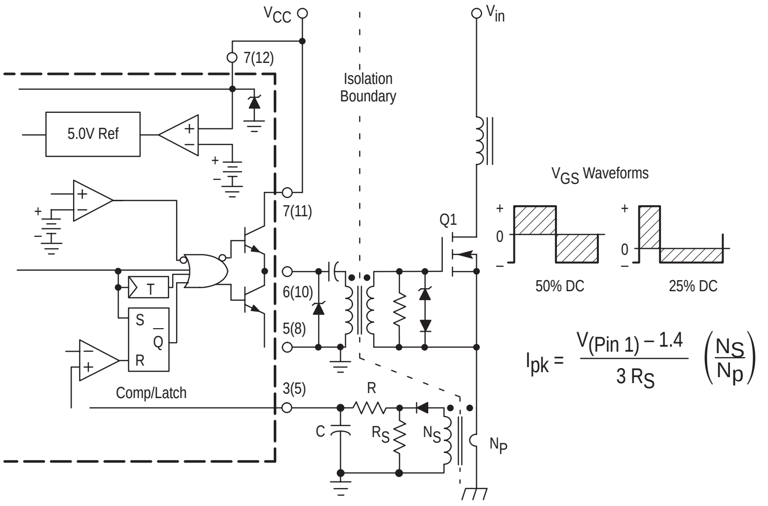
Series gate resistor R_g will damp any high frequency parasitic oscillations caused by the MOSFET input capacitance and any series wiring inductance in the gate–source circuit.

Figure 25. Bipolar Transistor Drive



The totem pole output can furnish negative base current for enhanced transistor turn–off, with the addition of capacitor C_1.

Figure 26. Isolated MOSFET Drive



$$I_{pk} = \frac{V_{(Pin\ 1)} - 1.4}{3\ R_S} \left(\frac{N_S}{N_p}\right)$$

Figure 27. Latched Shutdown

An additional series resistor may be required when using tantalum or other low ESR capacitors.

MOTOROLA

μA78S40

Universal Switching Regulator Subsystem

UNIVERSAL SWITCHING REGULATOR SUBSYSTEM

SEMICONDUCTOR TECHNICAL DATA

The μA78S40 is a switching regulator subsystem, consisting of a temperature compensated voltage reference, controlled–duty cycle oscillator with an active current limit circuit, comparator, high–current and high–voltage output switch, capable of 1.5 A and 40 V, pinned–out power diode and an uncommitted operational amplifier, which can be powered up or down independent of the IC supply. The switching output can drive external NPN or PNP transistors when voltages greater the 40 V, or currents in excess of 1.5 A, are required. Some of the features are wide–supply voltage range, low standby current, high efficiency and low drift. The μA78S40 is available in commercial (0° to + 70°C), and automotive (–40° to + 85°C) temperature ranges.

Some of the applications include use in step–up, step–down, and inverting regulators, with extremely good results obtained in battery–operated systems.

- Output Adjustable from 1.25 V to 40 V
- Peak Output Current of 1.5 A Without External Transistor
- 80 dB Line and Load Regulation
- Operation from 2.5 V to 40 V Supply
- Low Standby Current Drain
- High Gain, High Output Current, Uncommitted Op Amp

Design Formula Table

Calculation	Step–Down	Step–Up	Inverting
$\frac{t_{on}}{t_{off}}$	$\frac{V_{out} + V_F}{V_{in(min)} - V_{sat} - V_{out}}$	$\frac{V_{out} - V_F \quad V_{in(min)}}{V_{in(min)} \quad V_{sat}}$	$\frac{V_{out} + V_F}{V_{in(min)} - V_{sat}}$
$(t_{on} + t_{off})$ max	$\frac{I}{f_{min}}$	$\frac{I}{f_{min}}$	$\frac{I}{f_{min}}$
C_T	$4 \times 10^{5}\, t_{on}$	$4 \times 10^{5}\, t_{on}$	$4 \times 10^{5}\, t_{on}$
$I_{pk(switch)}$	$2\, I_{out(max)}$	$2\, I_{out(max)} \left(\frac{t_{on} - t_{off}}{t_{off}}\right)$	$2\, I_{out(max)} \left(\frac{t_{on} + t_{off}}{t_{off}}\right)$
R_{SC}	$\frac{0.33}{I_{pk(switch)}}$	$\frac{0.33}{I_{pk(switch)}}$	$\frac{0.33}{I_{pk(switch)}}$
$L_{(min)}$	$\left(\frac{V_{in(min)} - V_{sat} - V_{out}}{I_{pk(switch)}}\right) t_{on(max)}$	$\left(\frac{V_{in(min)} - V_{sat}}{I_{pk(switch)}}\right) t_{on(max)}$	$\left(\frac{V_{in(min)} - V_{sat}}{I_{pk(switch)}}\right) t_{on(max)}$
C_O	$\frac{I_{pk(switch)}\,(t_{on} + t_{off})}{8\, V_{ripple(pp)}}$	$\approx \frac{I_{out}\, t_{on}}{V_{ripple}}$	$\approx \frac{I_{out}\, t_{on}}{V_{ripple}}$

V_{sat} = Saturation voltage of the output switch. V_F = Forward voltage drop of the ringback rectifier.

The following power supply characteristics must be chosen:

V_{in} – Nominal input voltage. If this voltage is not constant, then use $V_{in(max)}$ for step–down and $V_{in(min)}$ for step–up and inverting convertor.

V_{out} – Desired output voltage: $V_{out} = 1.25 \left(1 + \frac{R_2}{R_1}\right)$ for step–down and step–up: $V_{out} = \frac{1.25\ R_2}{R_1}$ for inverting.

I_{out} – Desired output current.

f_{min} – Minimum desired output switching frequency at the selected values for V_{in} and I_O.

$V_{ripple(pp)}$ – Desired peak–to–peak output ripple voltage. In practice, the calculated value will need to be increased due to the capacitor's equivalent series resistance and board layout. The ripple voltage should be kept to a low value since it will directly effect the line and load regulation.

See Application Note AN920 for further information

Addendum
Linear & Switching Voltage Regulator Applications Information

In Brief . . .

In most electronic systems, voltage regulation is required for various functions. Today's complex electronic systems are requiring greater regulating performance, higher efficiency and lower parts count. Present integrated circuit and power package technology has produced IC voltage regulators which can ease the task of regulated power supply design, provide the performance required and remain cost effective. Available in a growing variety, Motorola offers a wide range of regulator products from fixed and adjustable voltage types to special–function and switching regulator control ICs.

This handbook describes Motorola's voltage regulator products and provides information on applying these products. Basic Linear regulator theory and switching regulator topologies have been included along with practical design examples. Other relevant topics include trade–offs of Linear versus switching regulators, series pass elements for Linear regulators, switching regulator component design considerations, heatsinking, construction and layout, power supply supervision and protection, and reliability.

TABLE OF CONTENTS

TABLE OF CONTENTS (Continued)

SECTION 1

BASIC LINEAR REGULATOR THEORY

A. IC Voltage Regulator

The basic functional block diagram of an integrated circuit voltage regulator is shown in Figure 1–1. It consists of a stable reference, whose output voltage is V_{ref}, and a high gain error amplifier. The output voltage (V_O), is equal to or a multiple of V_{ref}. The regulator will tend to keep V_O constant by sensing any changes in V_O and trying to return it to its original value. Therefore, the ideal voltage regulator could be considered a voltage source with a constant output voltage. However, in practice the IC regulator is better represented by the model shown in Figure 1–2.

In this figure, the regulator is modeled as a voltage source with a positive output impedance (Z_O). The value of the voltage source (V) is not constant; instead it varies with changes in supply voltage (V_{CC}) and with changes in IC junction temperature (T_J) induced by changes in ambient temperature and power dissipation. Also, the regulator output voltage (V_O) is affected by the voltage drop across Z_O, caused by the output current (I_O). In the following text, the reference and amplifier sections will be described, and their contributions to the changes in the output voltage analyzed.

B. Voltage Reference

Naturally, the major requirement for the reference is that it be stable; variations in supply voltage or junction temperature should have little or no effect on the value of the reference voltage (V_{ref}).

1. Zener Diode Reference

The simplest form of a voltage reference is shown in Figure 1–3a. It consists of a resistor and a zener diode. The zener voltage (V_Z) is used as the reference voltage. In order to determine V_Z, consider Figure 1–3b. The zener diode (VR1) of Figure 1–3a has been replaced with its equivalent circuit model and the value of V_Z is therefore given by (at a constant junction temperature):

$$V_Z = V_{BZ} + I_Z Z_Z = V_{BZ} + \left(\frac{V_{CC} - V_{BZ}}{R + Z_Z}\right) Z_Z \qquad (1)$$

where: V_{BZ} = zener breakdown voltage
I_Z = zener current
Z_Z = zener impedance at I_Z.

Note that changes in the supply voltage give rise to changes in the zener current, thereby changing the value of the reference voltage (V_Z).

Figure 1–1. Voltage Regulator Functional Block Diagram

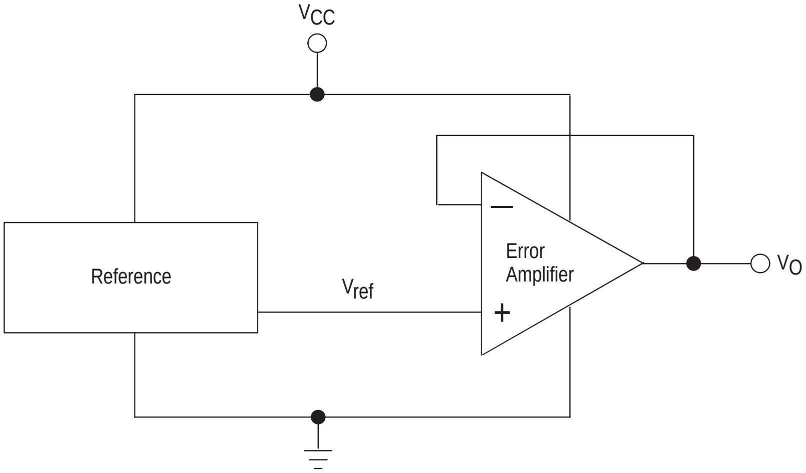

Figure 1–2. Voltage Regulator Equivalent Circuit Model

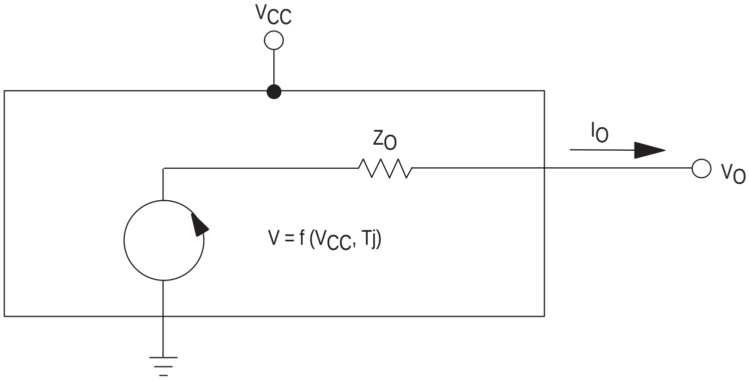

Figure 1–3. Zener Diode Reference

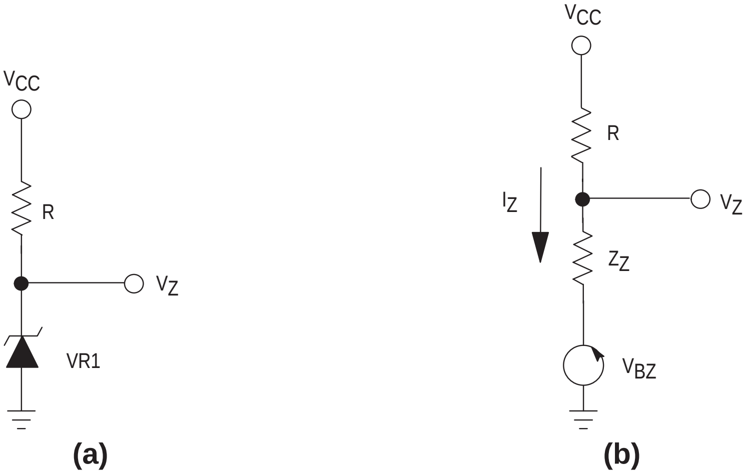


2. Constant Current — Zener Reference

The effect of zener impedance can be minimized by driving the zener diode with a constant current as shown in Figure 1–4. The value of the zener current is largely independent of V_{CC} and is given by:

$$I_Z = \frac{V_{BEQ1}}{R_{SC}} \tag{2}$$

where: V_{BEQ1} = base–emitter voltage of Q1.

This gives a reference voltage of:

$$V_{ref} = V_Z + V_{BEQ1} = V_{BZ} + I_Z Z_Z + V_{BEQ1} \tag{3}$$

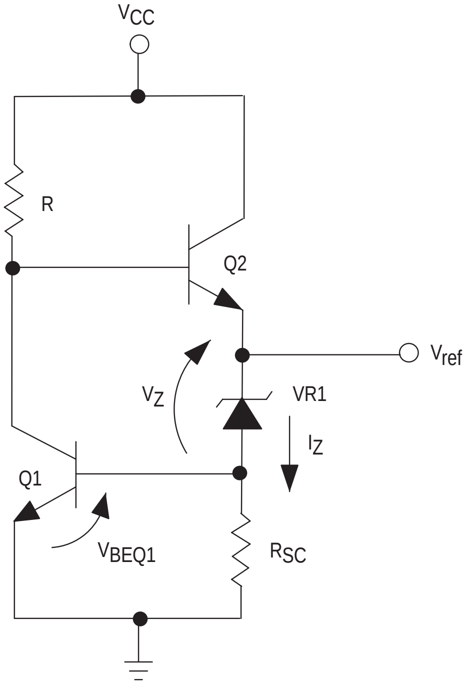
where I_Z is constant and given by Equation 2.

The reference voltage (about 7.0 V) of this configuration is therefore largely independent of supply voltage variations. This configuration has the additional benefit of better temperature stability than that of a simple resistor–zener reference.

Referring back to Figure 1–3a, it can be seen that the reference voltage temperature stability is equal to that of the zener diode, VR1. The stability of zener diodes used in most integrated circuitry is about + 2.2 mV/°C or $\simeq$ 0.04%/°C (for a 6.2 V zener). If the junction temperature varies 100°C, the zener or reference voltage would vary 4%. A variation this large is usually unacceptable.

However, the circuit of Figure 1–4 does not have this drawback. Here the positive 2.2 mV/°C temperature coefficient (TC) of the zener diode is offset by the negative 2.2 mV/°C TC of the V_{BE} of Q1. This results in a reference voltage with very stable temperature characteristics.

Figure 1–4. Constant Current (Zener Reference)



3. Bandgap Reference

Although very stable, the circuit of Figure 1–4 does have a disadvantage in that it requires a supply voltage of 9.0 V or more. Another type of stable reference which requires only a few volts to operate was described by Widlar(1) and is shown in Figure 1–5. In this circuit V_{ref} is given by:

$$V_{ref} = V_{BEQ3} + I_2R_2 \tag{4}$$

where: $I_2 = \dfrac{V_{BEQ1} - V_{BEQ2}}{R_1}$ (neglecting base currents)

The change in V_{ref} with junction temperature is given by:

$$\Delta V_{ref} = \Delta V_{BE3} + \left\{\frac{\Delta V_{BEQ1} - \Delta V_{BEQ2}}{R_1}\right\} R_2 \tag{5}$$

It can be shown that,

$$\Delta V_{BEQ1} = \Delta T_JK \ln I_1 \tag{6}$$

and, $$\Delta V_{BEQ2} = \Delta T_JK \ln I_2 \tag{7}$$

where: K = a constant

ΔT_J = change in junction temperature

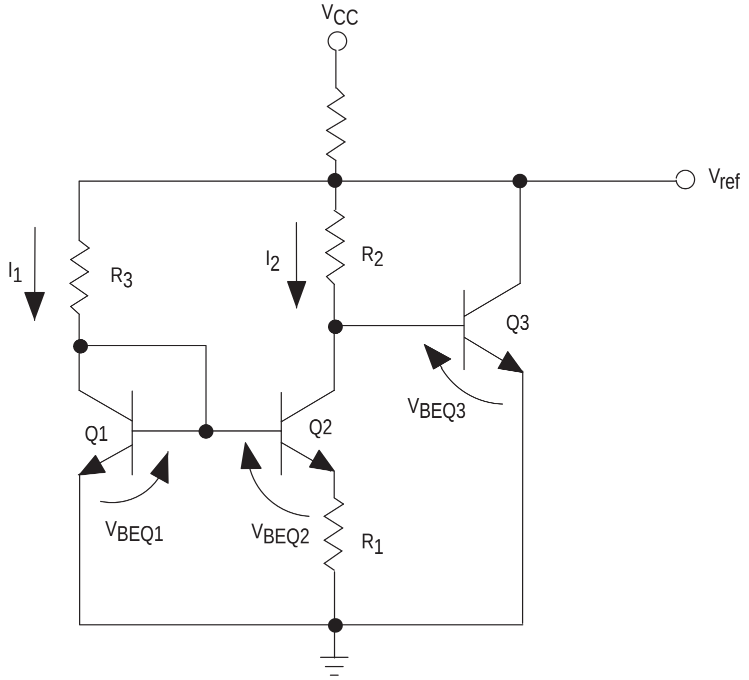
and, $I_1 > I_2$

Combining (5), (6), and (7)

$$\Delta V_{ref} = \Delta V_{BEQ3} + \Delta T_JK\left(\frac{R_2}{R_1}\right) \ln \frac{I_1}{I_2} \tag{8}$$

Since ΔV_{BEQ3} is negative, and with $I_1 > I_2$, $\ln I_1/I_2$ is positive, the net change in V_{ref} with temperature variations can be made to equal zero by appropriately selecting the values of I_1, R_1, and R_2.

Figure 1–5. Bandgap Reference



C. The Error Amplifier

Given a stable reference, the error amplifier becomes the determining factor in integrated circuit voltage regulator performance. Figure 1–6 shows a typical differential error amplifier in a voltage regulator configuration. With a constant supply voltage (V_{CC}) and junction temperature, the output voltage is given by:

$$V_O = A_{VOL}\,\upsilon_i - Z_{OL}\,I_O = A_{VOL}\,\{(V_{ref} \pm V_{IO}) - V_O\,\beta\} - Z_{OL}\,I_O \qquad (9)$$

where: A_{VOL} = amplifier open loop gain

V_{IO} = input offset voltage

Z_{OL} = open loop output impedance

$\beta = \dfrac{R_1}{R_1 + R_2}$ = feedback ratio (β is always ≤ 1)

I_O = output current

υ_i = true differential input voltage

Manipulating Equation 9:

$$V_O = \frac{(V_{ref} \pm V_{IO}) - \dfrac{Z_{OL}}{A_{VOL}}\,I_O}{\beta + \dfrac{1}{A_{VOL}}} \qquad (10)$$

Note that if the amplifier open loop gain is infinite, this expression reduces to:

$$V_O = \frac{1}{\beta}\,(V_{ref} \pm V_{IO}) = (V_{ref} \pm V_{IO})\left(1 + \frac{R_2}{R_1}\right) \qquad (11)$$

The output voltage can thus be set any value equal to or greater than ($V_{ref} \pm V_{IO}$). Note also that if A_{VOL} is not infinite, with constant output current (a non–varying output load), the output voltage can still be "tweaked–in" by varying R_1 and R_2, even though V_O will not exactly equal that given by Equation 11.

Assuming a stable reference and a finite value of A_{VOL}, inaccuracy of the output voltage can be traced to the following amplifier characteristics:

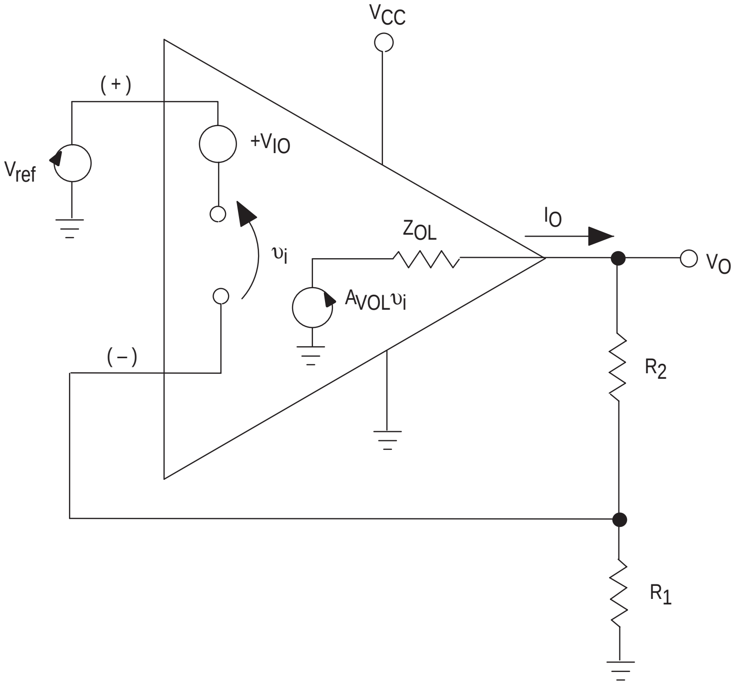
1. Amplifier Input Offset Voltage Drift

The input transistors of integrated circuit amplifiers are usually not perfectly matched. As in operational amplifiers, this is expressed in terms of an input offset voltage (V_{IO}). At a given temperature, this effect can be nulled out of the desired output voltage by adjusting V_{ref} or $1/\beta$. However, V_{IO} drifts with temperature, typically ± 5.0 μV/°C to +15 μV/°C, causing a proportional change in the output voltage. Closer matching of the internal amplifier input transistors minimizes this effect, as does selecting a feedback ratio (β) to be close to unity.

2. Amplifier Power Supply Sensitivity

Changes in regulator output voltage due to power supply voltage variations can be attributed to two amplifier performance parameters: power supply rejection ratio (PSRR) and common mode rejection ratio (CMRR). In modern integrated circuit regulator amplifiers, the utilization of constant current sources gives such large values of PSRR that this effect on V_O can usually be neglected. However, supply voltage changes can affect the output voltage since these changes appear as common mode voltage changes, and they are best measured by the CMRR.

Figure 1–6. Typical Voltage Regulator Configuration

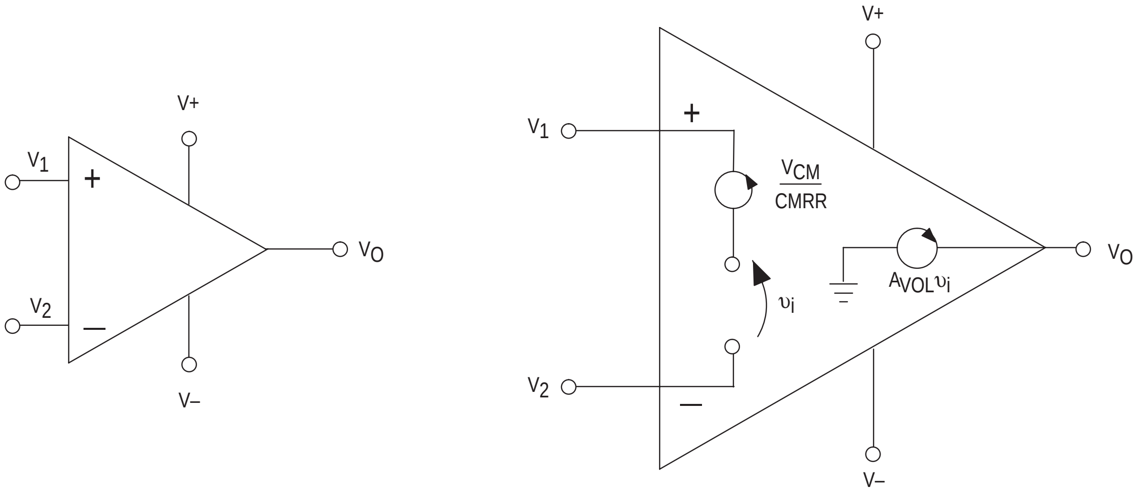


The definition of common mode voltage (V_{CM}), illustrated by Figure 1–7a, is:

$$V_{CM} = \left[\frac{V_1 + V_2}{2}\right] - \left[\frac{(V+) + (V-)}{2}\right] \quad (12)$$

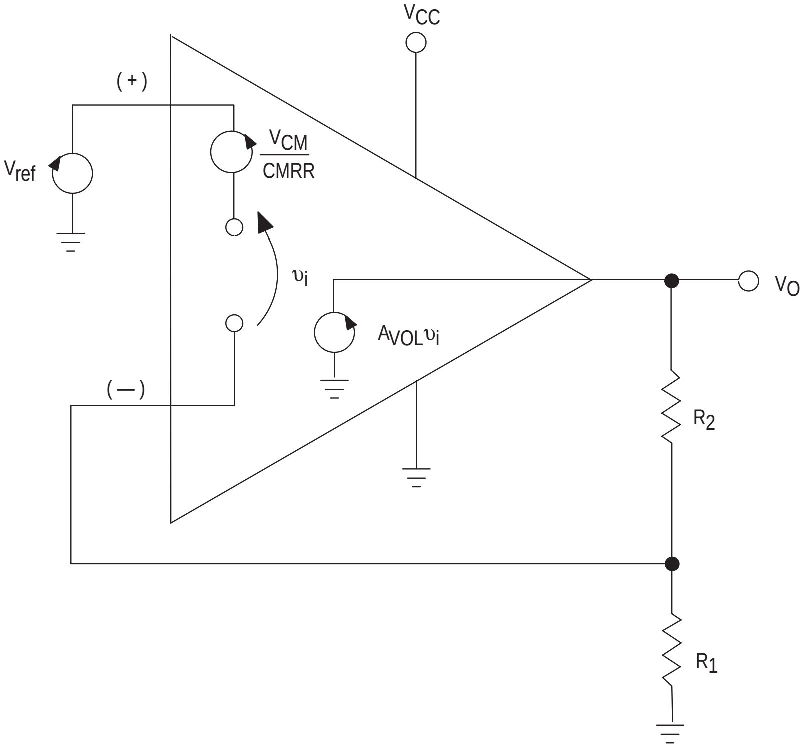
where: V_1 = voltage on amplifier noninverting input
V_2 = voltage on amplifier inverting input
V+ = positive supply voltage
V– = negative supply voltage

Figure 1–7. Definition of Common Mode Voltage Error



(a) **(b)**

Figure 1–8. Common Mode Regulator Effects



In an ideal amplifier, only the differential input voltage ($V_1 – V_2$) has any effect on the output voltage; the value of V_{CM} would not effect the output. In fact, V_{CM} does influence the amplifier output voltage. This effect can be modeled as an additional voltage offset at the amplifier input equal to V_{CM}/CMRR as shown in Figures 1–7b and 1–8. The latter figure is the same configuration as Figure 1–6, with amplifier input offset voltage and output impedance deleted for clarity and common mode voltage effects added. The output voltage of this configuration is given by:

$$V_O = A_{VOL}\,\upsilon_i = A_{VOL}\left(V_{ref} - \frac{V_{CM}}{CMRR} - \beta V_O\right) \tag{13}$$

Manipulating,

$$V_O = \frac{\left(V_{ref} - \frac{V_{CM}}{CMRR}\right)}{\beta + \frac{1}{A_{VOL}}} \tag{14}$$

where: $V_{CM} = V_{ref} - \frac{V_{CC}}{2}$ (15)

and, CMRR = common mode rejection ratio

It can be seen from Equations (14) and (15) that the output can vary when V_{CC} varies. This can be reduced by designing the amplifier to have a high A_{VOL}, a high CMRR, and by choosing the feedback ratio (β) to be unity.

3. Amplifier Output Impedance

Referring back to Equation (9), it can be seen that the equivalent regulator output impedance (Z_O) is given by:

$$Z_O = \frac{\Delta V_O}{\Delta I_O} \simeq \frac{Z_{OL}}{\beta A_{VOL}} \qquad (16)$$

This impedance must be as low as possible, in order to minimize load current effects on the output voltage. This can be accomplished by lowering Z_{OL}, choosing an amplifier with high A_{VOL}, and by selecting the feedback ratio (β) to be unity.

A simple way of lowering the effective value of Z_{OL} is to make an impedance transformation with an emitter follower, as shown in Figure 1–9. Given a change in output current (ΔI_O) the amplifier will see a change of only $\Delta I_O/h_{FEQ1}$ in its output current (I_O'). Therefore, (Z_{OL}) in Equation (16) has been effectively reduced to Z_{OL}/h_{FEQ1}, reducing the overall regulator output impedance (Z_O).

D. The Regulator within a Regulator Approach

In the preceding text, we have analyzed the sections of an integrated circuit voltage regulator and determined how they contribute to its non–ideal performance characteristics. These are shown in Table 1–1 along with procedures which minimize their effects.

It can be seen that in all cases regulator performance can be improved by selecting A_{VOL} as high as possible and $\beta = 1$. Since a limit is soon approached in how much A_{VOL} can be practically obtained in an integrated circuit amplifier, selecting a feedback ratio (β) equal to unity is the only viable way of improving total regulator performance, especially in reducing regulator output impedance. However, this method presents a basic problem to the regulator designer. If the configuration of Figure 1–6 is used, the output voltage cannot be adjusted to a value other than V_{ref}. The solution is to utilize a different regulator configuration known as the *regulator within a regulator* approach.(2) Its greatest benefit is in reducing total regulator output impedance.

Figure 1–9. Emitter Follower Output

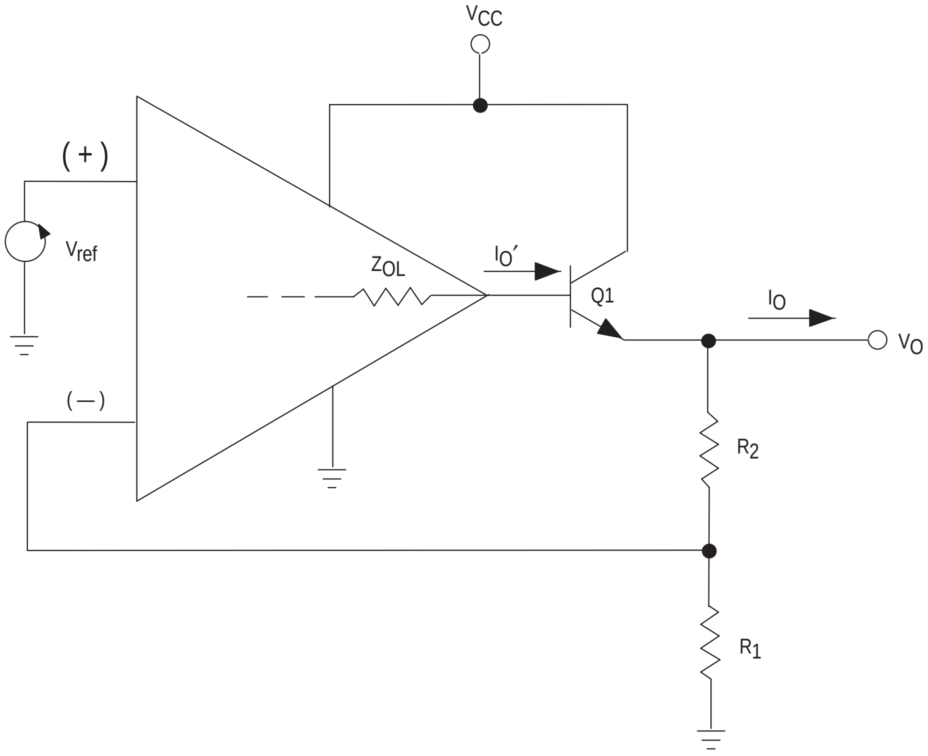


Table 1–1

V_O Changes Section	Effect Can Be Induced By:	Minimized By Selecting:
Reference	V_{CC}	• Constant current–zener method • Bandgap reference
	T_J	• Bandgap reference • TC compensated zener method
Amplifier	V_{CC}	• High CMRR amplifier • High A_{VOL} amplifier • $\beta = 1$
	T_J	• Low V_{IO} drift amplifier • High A_{VOL} amplifier • $\beta = 1$
	I_O	• Low Z_{OL} amplifier • High A_{VOL} amplifier • Additional emitter follower output • $\beta = 1$

As shown in Figure 1–10, amplifier A1 sets up a voltage (V_1) given by:

$$V_1 \simeq V_{ref}\left(1 + \frac{R_2}{R_1}\right) \tag{17}$$

V_1 now serves as the reference voltage for amplifier A2, whose output voltage (V_O) is given by:

$$V_O \simeq V_1 \simeq V_{ref}\left(1 + \frac{R_2}{R_1}\right) \tag{18}$$

Note that the output impedance of A2, and therefore the regulator output impedance, has been minimized by selecting A2's feedback factor to be unity; and that output voltage can still be set at voltages greater than V_{ref} by adjusting R_1 and R_2.

SECTION 2

SELECTING A LINEAR IC VOLTAGE REGULATOR

A. Selecting the Type of Regulator

There are five basic linear regulator types; positive, negative, fixed output, tracking and floating regulators. Each has its own particular characteristics and best uses, and selection depends on the designer's needs and trade–offs in performance and cost.

1. Positive Versus Negative Regulators

In most cases, a positive regulator is used to regulate positive voltages and a negative regulator negative voltages. However, depending on the system's grounding requirements, each regulator type may be used to regulate the "opposite" voltage.

Figures 2–1a and 2–1b show the regulators used in the conventional and obvious mode. Note that the ground reference for each (indicated by the heavy line) is continuous. Several positive regulators could be used with the same input supply to deliver several voltages with common grounds; negative regulators may be utilized in a similar manner.

If no other common supplies or system components operate off the input supply to the regulator, the circuits of Figures 2–1c and 2–1d may be used to regulate positive voltages with a negative regulator and vice versa. In these configurations, the input supply is essentially floated, i.e., neither side of the input is tied to the system ground.

There are methods of utilizing positive regulators to obtain negative output voltages without sacrificing ground bus continuity. However, these methods are only possible at the expense of increased circuit complexity and cost. An example of this technique is shown in Section 3.

2. Three–Terminal, Fixed Output Regulators

These regulators offer the designer a simple, inexpensive way to obtain a source of regulated voltage. They are available in a variety of positive or negative output voltages and current ranges.

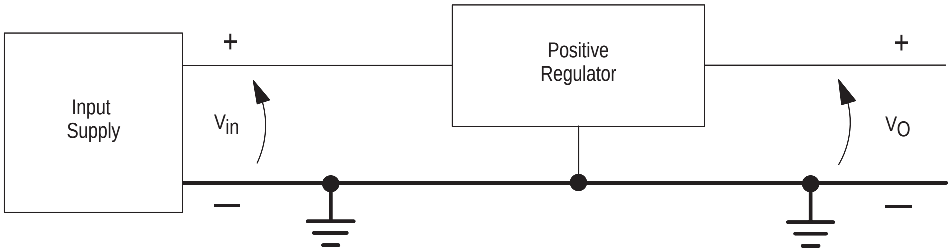
The advantages of these regulators are:

a) Easy to use.
b) Internal overcurrent and thermal protection.
c) No circuit adjustments necessary.
d) Low cost.

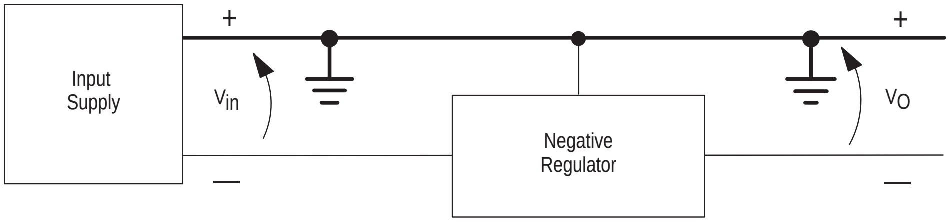
Their disadvantages are:

a) Output voltage cannot be precisely adjusted. (Methods for obtaining adjustable outputs are shown in Section 3).
b) Available only in certain output voltages and currents.
c) Obtaining greater current capability is more difficult than with other regulators. (Methods for obtaining greater output currents are shown in Section 3.)

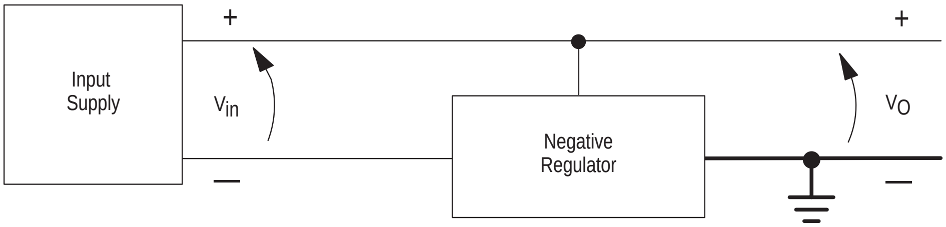
Figure 2–1. Regulator Configurations



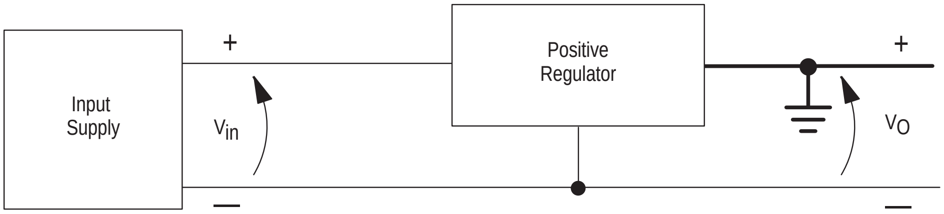
(a) Positive Output Using Positive Regulator



(b) Negative Output Using Negative Regulator



(c) Positive Output Using Negative Regulator



(d) Negative Output Using Positive Regulator

3. Three–Terminal, Adjustable Output Regulators

Like the three–terminal fixed regulators, the three–terminal adjustable regulators are easy and inexpensive to use. These devices provide added flexibility with output voltage adjustable over a wide range, from 1.2 V to nearly 40 V, by means of an external, two–resistor voltage divider. A variety of current ranges from 100 mA to 3.0 A are available.

B. Selecting an IC Regulator

Once the type of regulator is decided upon, the next step is to choose a specific device. To provide higher currents than are available from monolithic technologies, an IC regulator will often be used as a driver to a boost transistor. This complicates the selection and design task, as there are now several overlapping solutions to many of the design problems.

Unfortunately, there is no exact step–by–step procedure that can be followed which will lead to the ideal regulator and circuit configuration for a specific application. The regulating circuit that is finally accepted will be a compromise between such factors as performance, cost, size and complexity. Because of this, the following general design procedure is suggested:

1. Select the regulators which meet or exceed the requirements for line regulation, load regulation, TC of the output voltage and operating ambient temperature range. At this point, do not be overly concerned with the regulator capabilities in terms of output voltage, output current, SOA and special features.

2. Next, select application circuits from Section 3 which meet the requirements for output current, output voltage, special features, etc. Preliminary designs using the chosen regulators and circuit configurations are then possible. From these designs a judgement can be made by the designer as to which regulator circuit configuration combination best meets his or her requirements in terms of cost, size and complexity.

SECTION 3

LINEAR REGULATOR CIRCUIT CONFIGURATION AND DESIGN CONSIDERATIONS

Once the IC regulators, which meet the designer's performance requirements, have been selected, the next step is to determine suitable circuit configurations. Initial designs are devised and compared to determine the IC regulator/circuit configuration that best meets the designer's requirements. In this section, several circuit configurations and design equations are given for the various regulator ICs. Additional circuit configurations can be found on the device data sheets. Organization is first by regulator type and then by variants, such as current boost. Each circuit diagram has component values for a particular voltage and current regulator design.

It should be noted that all circuit configurations shown have constant current limiting. If foldback limiting is desired, see Section 4C for techniques and design equations.

A. Positive, Adjustable Output IC Regulator Configurations

1. Basic Regulator Configurations

Positive Three–Terminal Adjustables

These adjustables, comprised of the LM317L, LM317, and LM350 series devices range in output currents of 100 mA, 500 mA, 1.5 A, and 3.0 A respectively. All of these devices utilize the same basic circuit configuration as shown in Figure 3–1A.

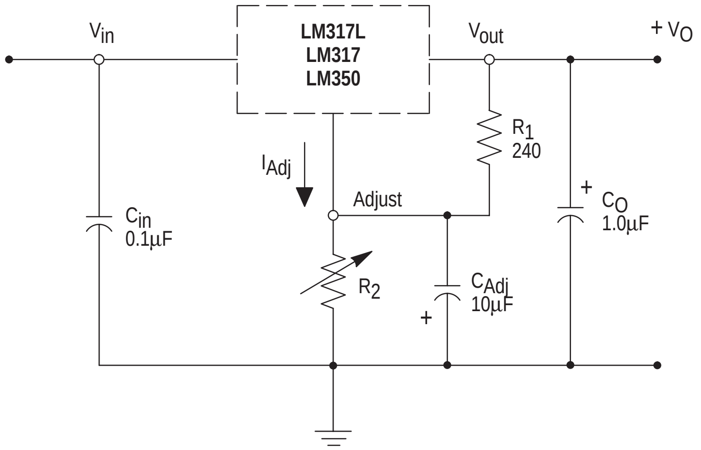
MC1723C

The basic circuit configurations for the MC1723C regulator are shown in Figures 3–2A and 3–3A. For output voltages from $\simeq$ 7.0 V to 37 V the configuration of Figure 3–2A can be used, while Figure 3–3A can be used to obtain output voltages from 2.0 V to $\simeq$ 7.0 V.

2. Output Current Boosting

If output currents greater than those available from the basic circuit configurations are desired, the current boost circuits shown in this section can be used. The output currents which can be obtained with this configurations are limited only by capabilities of the external pass element(s).

Figure 3–1A. Basic Configuration for Positive, Adjustable Output Three–Terminal Regulators



C_{in}: required if regulator is located an appreciable distance from power supply filter.

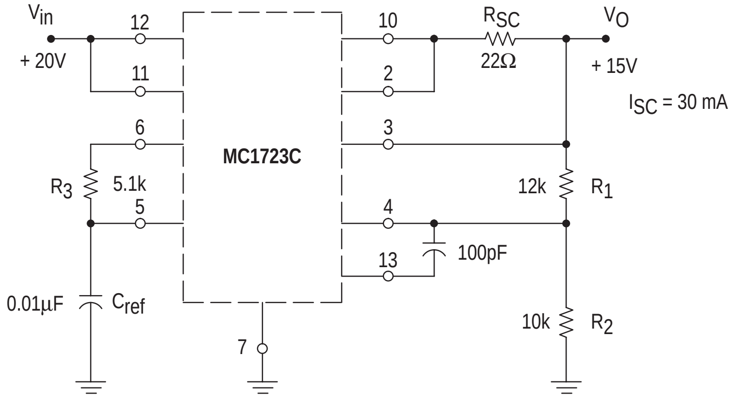
C_O: improves transient response.

C_{Adj}: improves Ripple Rejection.

$$V_{out} = 1.25\ V\ \ 1 + \left(\frac{R_2}{R_1}\right) + I_{Adj}\,R_2$$

Since I_{Adj} is controlled to less than 100 µA, the error associated with this term is negligible in most applications.

Figure 3–2A. MC1723C Basic Circuit Configuration for $V_{ref} \le V_O \le 37$ V



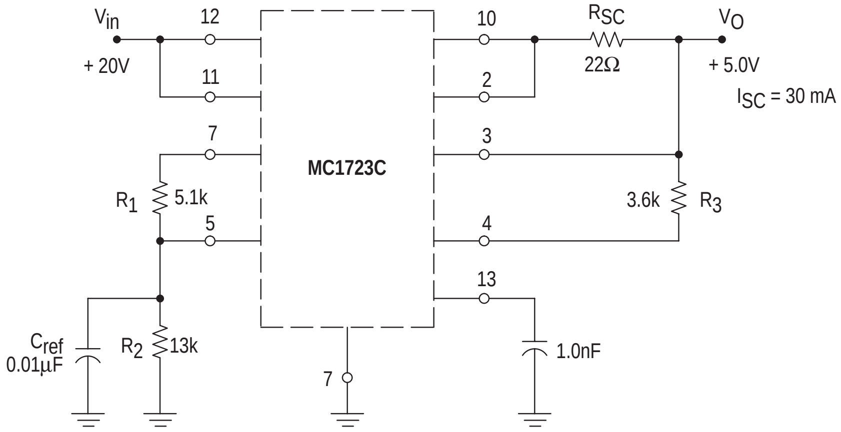
$R_{SC} \cong \frac{0.66\ V}{I_{SC}}$; $10\ k\Omega < R_1 + R_2 < 100\ k\Omega$

$R_3 \cong R_1 \parallel R_2$; $0 \le C_{ref} \le 0.1\ \mu F$

$$R_2 = \frac{V_{ref}}{V_O}\ (R_1 + R_2) \approx \frac{7.0\ V}{V_O}\ (R_1 + R_2)$$

Values shown are for a 15 V, 30 mA regulator using an MC1723CP for a $T_{A(max)}$ = 25°C.

Figure 3–3A. MC1723C Basic Circuit Configuration for 2.0 V ≤ V_O ≤ V_{ref}



$$R_{SC} \simeq \frac{0.66V}{I_{SC}}\ ;\ 10\ k\Omega < R_1 + R_2 < 100\ k\Omega$$

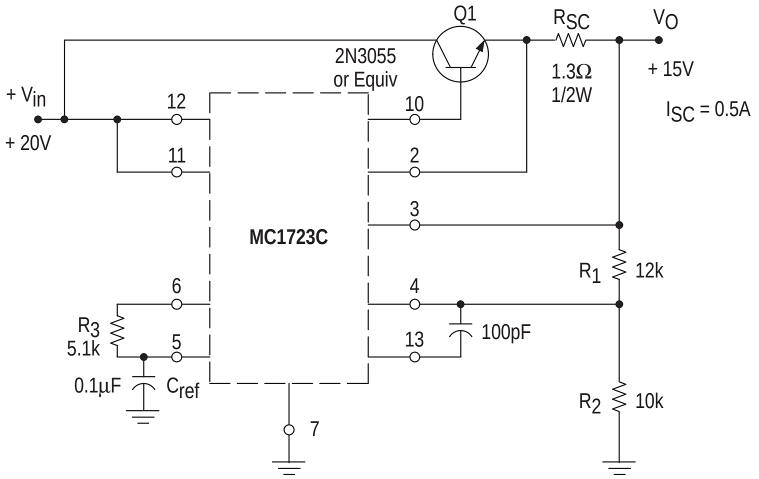
$$R_2 = \frac{V_O}{V_{ref}}\ (R_1 + R_2) \simeq \frac{V_O}{7.0\ V}\ (R_1 + R_2)$$

$$R_3 = R_1 \parallel R_2;\ 0 \le C_{ref} \le 0.1\ \mu F$$

Values shown are for a 5.0 V, 30 mA regulator using an MC1723CP for a $T_{A(max)}$ = 70°C.

To obtain greater output currents with the MC1723C the configurations shown in Figures 3–4A and 3–5A can be used. Figure 3–4A uses an NPN external pass element, while a PNP is used in Figure 3–5A.

Figure 3–4A. MC1723C NPN Boost Configuration



$$R_{SC} \cong \frac{0.66\ V}{I_{SC}}\ ;\ 10\ k\Omega < R_1 + R_2 < 100\ k\Omega$$

$$R_2 = \frac{V_{ref}}{V_O}\ (R_1 + R_2) \cong \frac{7.0\ V}{V_O}\ (R_1 + R_2)$$

$$0 \le C_{ref} \le 0.1\ \mu F\ ;\ R_3 \cong R_1 \parallel R_2$$

Selection of Q1 based on considerations of Section 4.

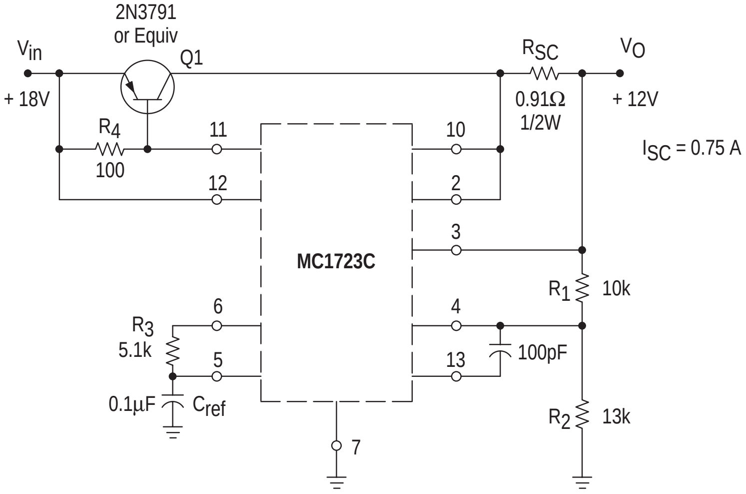
Figure 3–5A. MC1723C PNP Boost Configuration



$R_{SC} \cong \frac{0.66\ V}{I_{SC}}$; $10\ k\Omega < R_1 + R_2 < 100\ k\Omega$; $0 \le C_{ref} \le 0.1\ \mu F$

$R_2 = \frac{V_{ref}}{V_O}(R_1 + R_2) \cong \frac{7.0\ V}{V_O}(R_1 + R_2)$

$R_3 = R_1 \parallel R_2$

$0 < R_4 \le V_{BE_{on\ (Q1)}} / 5.0\ mA$

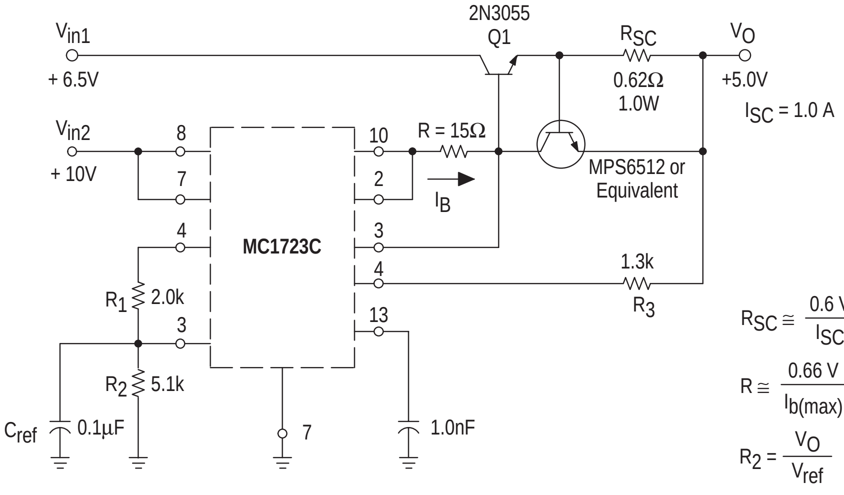
Selection of Q1 based on considerations of Section 4.

Values shown are for a 12 V, 750 mA regulator using an unheatsinked MC1723CP and a 2N3791 on a 4°C/W heatsink for T_A up to + 70°C.

3. High Efficiency Regulator Configurations

When large output currents at voltages under approximately 9.0 V are desired, the configuration of Figure 3–6A can be utilized to obtain increased operating efficiency. This is accomplished by providing a separate low voltage input supply for the pass element. This method, however, usually necessitates that separate short circuit protection be provided for the IC regulator and external pass element. Figure 3–6A shows a high efficiency regulator configuration for the MC1723C.

Figure 3–6A. MC1723C High Efficiency Regulator Configuration



$R_{SC} \cong \frac{0.6\ V}{I_{SC}}$

$R \cong \frac{0.66\ V}{I_{b(max)}}$; $10\ k\Omega < R_1 + R_2 < 100\ k\Omega$

$R_2 = \frac{V_O}{V_{ref}}(R_1 + R_2) \cong \frac{V_O}{7.0\ V}(R_1 + R_2)$

$0 \le C_{ref} \le 0.1\ \mu F$

$R_3 \cong R_1 \parallel R_2$

See Section 3F for general design considerations.
Selection of Q1 based on considerations of Section 4.

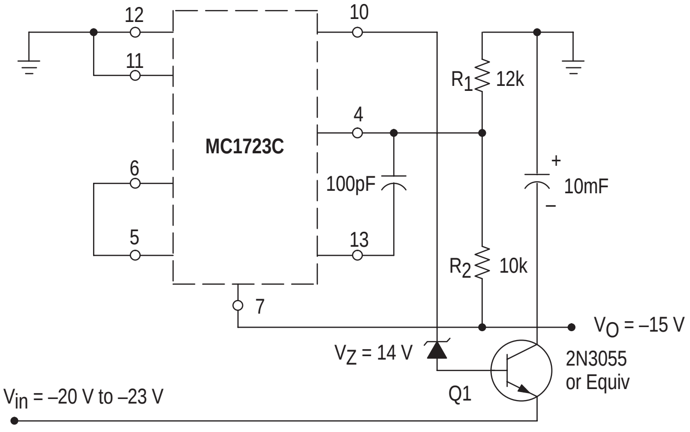
Values shown for a 5.0 V, 1.0 A regulator using an unheatsinked MC1723CP and a 2N3055 on a 10°C/W heatsink for T_A up to + 70°C.

B. Negative, Adjustable Output IC Regulator Configurations

1. Basic Regulator Configurations (MC1723C)

Although a positive regulator, the MC1723C can be used in a negative regulator circuit configuration. This is done by using an external pass element and a zener level shifter as shown in Figure 3–1B. It should be noted that for proper operation, the input supply must not vary over a wide range, since the correct value for V_Z depends directly on this voltage. In addition, it should be noted that this circuit will not operate with a shorted output.

Figure 3–1B. MC1723C Negative Regulator Configuration



$|V_O| \geq 10\ V;\ 10\ k\Omega \leq R_1 + R_2 \leq 100\ k\Omega$

$$R_2 = \frac{V_{ref}}{|V_O|}\ (R_1 + R_2) \cong \frac{7.0\ V}{|V_O|}\ (R_1 + R_2)$$

$V_Z \leq |V_{in}| - V_{BE(Q1)} - 3.0\ V;\ V_Z \geq |V_{in}| - |V_O| - V_{BE(Q1)} + 6.0\ V$

Selection of Q1 based on considerations of Section 4.

Values shown are for a –15 V, 750 mA regulator using the MC1723CP with Q1 mounted on a 20°C/W heatsink at T_A up to +70°C. **Do not short circuit output.**

C. Positive, Fixed Output IC Regulator Configurations

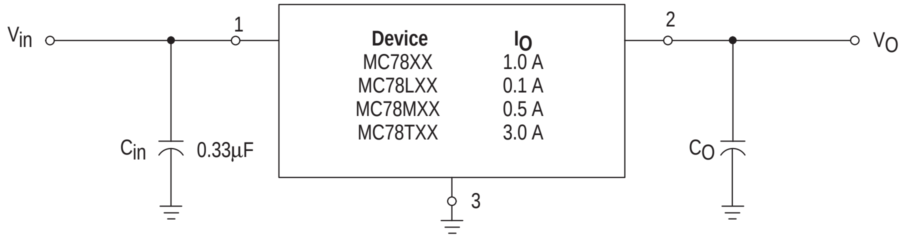
1. Basic Regulator Configuration

The basic current configuration for the positive three–terminal regulators is shown in Figure 3–1C. Depending on which regulator type is used, this configuration can provide output currents in excess of 3.0 A.

2. Output Current Boosting

Figure 3–2C illustrates a method for obtaining greater output currents with the three–terminal positive regulators. Although any of these regulators may be used, usually it is most economical to use the 1.0 A MC7800C in this configuration.

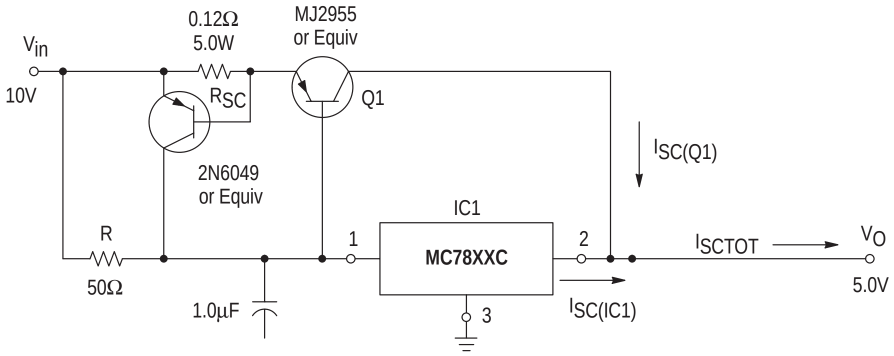
Figure 3–1C. Basic Circuit Configuration for Positive, Fixed Output, Three–Terminal Regulators



C_{in}: required if regulator is located more than a few (≈2 to 4) inches away from input supply capacitor; for long input leads to regulator, up to 1.0 µF may be needed for C_{in}. (C_{in} should be a high frequency type capacitor.)
C_O: improves transient response.
XX: two digits of type number indicating nominal output voltage.

See Section 15 for heatsinking.

Figure 3–2C. Current Boost Configuration for Positive Three–Terminal Regulators



XX: two digits of type number indicating nominal output voltage.
R: used to divert IC regulator bias current and determines at what output current level Q1 begins conducting.

$$0 < R \leq \frac{V_{BE\ on(Q1)}}{I_{Bias\ (IC1)}}\ ;\ R_{SC} \approx \frac{0.6\ V}{I_{SC(Q1)}}\ ;\ I_{SCTOT} = I_{SC(Q1)} + I_{SC(IC1)}$$

Selection of Q1 based on considerations of Section 4.

Values shown are for a 5.0 V, 5.0 A regulator using an MC7805CT on a 2.5°C/W heatsink and Q1 on a 1°C/W heatsink for T_A up to 70°C.

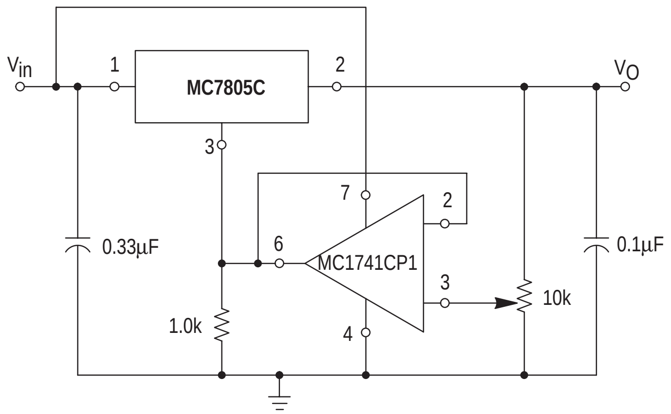
3. Obtaining an Adjustable Output Voltage

With the addition of an op amp, an adjustable output voltage supply can be obtained with the MC7805C. Regulation characteristics of the three–terminal regulators are retained in this configuration, shown in Figure 3–3C. If lower output currents are required, then an MC78M05C (0.5 A) could be used in place of the MC7805C.

4. Current Regulator

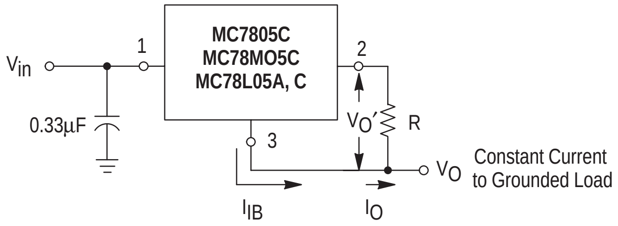
In addition to providing voltage regulation, the three–terminal positive regulators can also be used as current regulators to provide a constant current source. Figure 3–4C shows this configuration. The output current can be adjusted to any value from ≈ 8.0 mA (I_Q, the regulator bias current) up to the available output current of the regulator. Five–volt regulators should be used to obtain the greatest output voltage compliance range for a given input voltage.

Figure 3–3C. Adjustable Output Voltage Configuration Using a Three–Terminal Positive Regulator



V_O = 7.0 V to 33 V
$V_{in} - V_O \geq 2.0$ V
$V_{in} \geq 35$ V

Figure 3–4C. Current Regulator Configuration



$$I_O = \frac{V_O'}{R} + I_{IB}$$

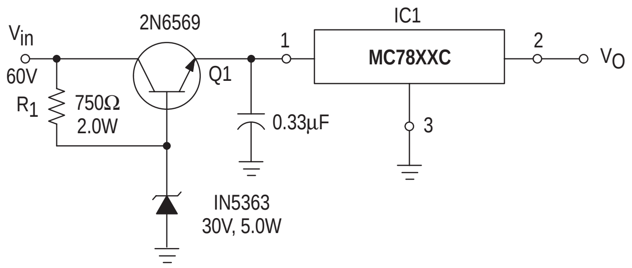
$$\text{Current Reg } \Delta I_O = \frac{\Delta V_O'}{R} + \Delta I_{IB}$$

$$V_O + V_O' + 2.0\text{ V} \leq V_{in} \leq 35\text{ V}$$

5. High Input Voltage

Occasionally, it may be necessary to power a three–terminal regulator from a supply voltage greater than $V_{in(max)}$, 35 V or 40 V. In these cases a preregulator circuit, as shown in Figure 3–5C, may be used.

Figure 3–5C. Preregulator for Input Voltages Above $V_{in(max)}$



$$R_1 = \left(\frac{V_{in} - 30}{1.5}\right) \bullet h_{fe(Q1)}$$

$$V_{CEO(Q1)} \leq V_{in}$$

XX: two digits of type number indicating nominal output voltage.

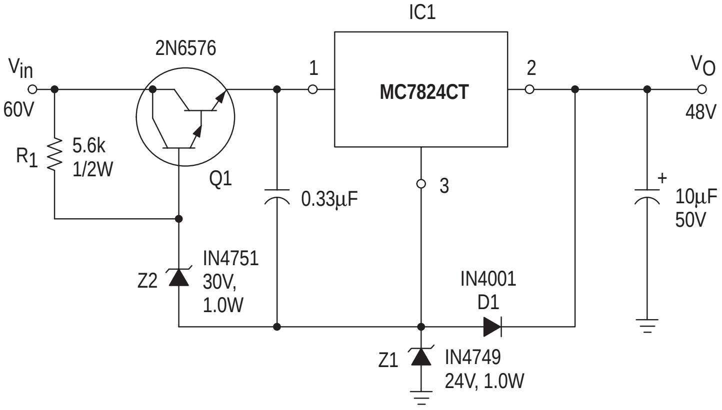
Values shown for V_{in} = 60 V

Q1 should be mounted on a 2°C/W heatsink for operation at T_A up to +70°C. IC1 should be appropriately heatsinked for the package type used.

6. High Output Voltage

If output voltages above 24 V are desired, the circuit configuration of Figure 3–6C may be used. Zener diode (Z1) sets the output voltage, while Q1, Z2, and D1 assure that the MC7824C does not have more than 30 V across it during short circuit conditions.

Figure 3–6C. High Output Voltage Configuration for Three–Terminal Positive Regulators



$$V_O = V_{Z1} + 24;\ R_1 = \left(\frac{V_{in} - (V_{Z1} + V_{Z2})}{1.5}\right) \bullet h_{fe(Q2)}$$

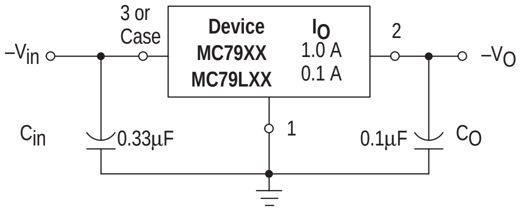
Values shown are for a 48 V, 1.0 A regulator
Q1 mounted on a 10°C/W heatsink
and IC1 mounted on a 2°C/W heatsink for T_A up to +70°C.

D. Negative, Fixed Output IC Regulator Configurations

1. Basic Regulator Configurations

Figure 3–1D gives the basic circuit configuration for the MC79XX and MC79LXX three–terminal negative regulators.

Figure 3–1D. Basic Circuit Configuration for Negative Three–Terminal Regulators



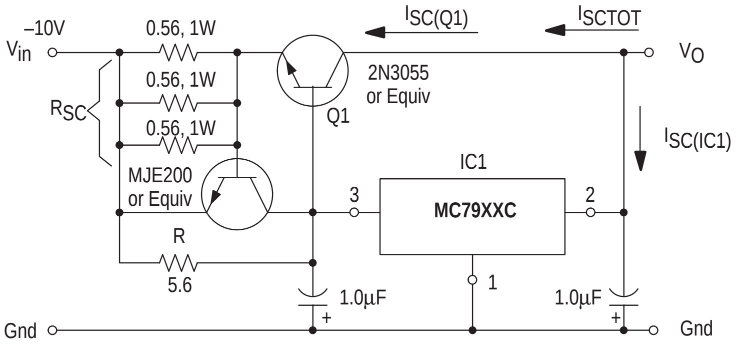
C_{in}: required if regulator is located more than a few (≈ 2 to 4) inches away from input supply capacitor; for long input leads to regulator, up to 1.0 µF may be required. C_{in} should be a high frequency type capacitor.
C_O: improves stability and transient response.
XX: two digits of type number indicating nominal output voltage.

See Section 15 for heatsinking.

Output Current Boosting

In order to obtain increased output current capability from the negative three–terminal regulators, the current boost configuration of Figure 3–2D may be used. Currents which can be obtained with this configuration are limited only by the capabilities of the external pass transistor(s).

Figure 3–2D. Output Current Boost Configuration for Three–Terminal Negative Regulators



XX: two digits of type number indicating output voltage. See Section 2 for available voltages.
R: used to divert regulator bias current and determine at what output current level Q1 begins conducting.

$$O < R \le \frac{V_{BE\ on(Q1)}}{I_{Bias(IC1)}}$$

$$I_{SCTOT} = I_{SC(Q1)} + I_{SC(IC1)}$$

$$R_{SC} \approx \frac{0.6\ V}{I_{SC(Q1)}}$$

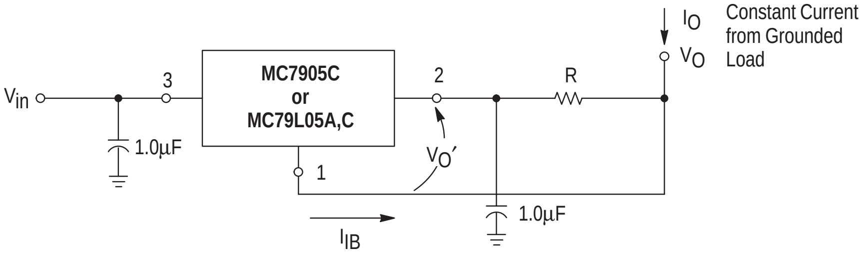
Selection of Q1 based on considerations of Section 4.

Values shown are for a –5.0 V, +4.0 A regulator; using an MC7905CT on a 1.5°C/W heatsink with Q1 mounted on a 1°C/W heatsink for T_A up to +70°C.

2. Current Regulator

The three–terminal negative regulators may also be used to provide a constant current sink, as shown in Figure 3–3D. In order to obtain the greatest output voltage compliance range at a given input voltage, the MC7905C or MC79L05C should be used in this configuration.

Figure 3–3D. Current Regulator Configuration for the Three–Terminal Negative Regulators



$V_{in} \ge -35$ V for MC7905C
$V_{in} \ge -30$ V for MC79L05C
$V_{in} \le V_O + V_O - 2.0$ V

$$I_O = \frac{V_O'}{R} + I_{IB}$$

Current regulation: $\Delta I_O = \dfrac{\Delta V_O'}{R} + \Delta I_{IB}$

F. General Design Considerations

In addition to the design equations given in the regulator circuit configuration panels of Sections 3A–E, there are a few general design considerations which apply to all regulator circuits. These considerations are given below.

1. Regulator Voltages

For any circuit configuration, the worse–case voltages present on each pin of the IC regulator must be within the maximum and/or minimum limits specified on the device data sheets. These limits are instantaneous values, not averages.

They include:
a. $V_{in(min)}$
b. $V_{in(max)}$
c. $(V_{in} - V_{out})$ min
d. $V_{out(min)}$
e. $V_{out(max)}$

For example, the voltage between Pins 12 and 7 (V_{in}) of an MC1723CP must never fall below 9.5 V, even instantaneously, or the regulator will not function properly, (see Figure 3–1B).

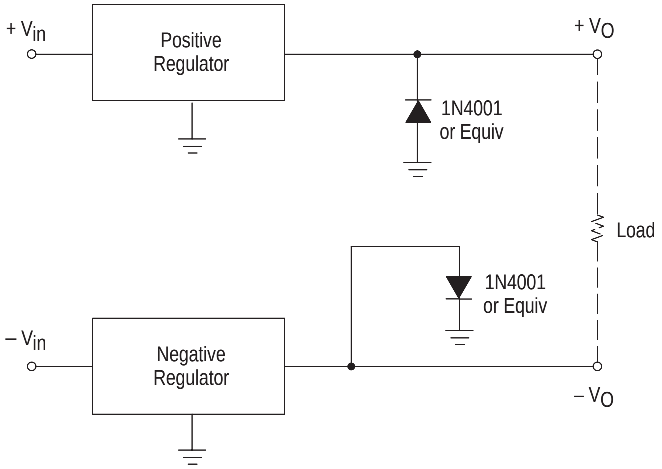
2. Regulator Power Dissipation, Junction Temperature and Safe Operating Area

The junction temperature, power dissipation output current or safe operating area limits of the IC regulator *must never be exceeded*.

3. Operation with a Load Common to a Voltage of Opposite Polarity

In many cases, a regulator powers a load which is not connected to ground but instead is connected to a voltage source of opposite polarity (e.g. op amps, level shifting circuits, etc.). In these cases, a clamp diode should be connected to the regulator output as shown in Figure 3–1F. This protects the regulator, during startup and short circuit operation, from output polarity reversals.

Figure 3–1F. Output Polarity Reversal Protection



4. Reverse Bias Protection

Occasionally, there exists the possibility that the input voltage to the regulator can collapse faster than the output voltage. This could occur, for example, if the input supply is “crowbarred” during an output overvoltage condition. If the output voltage is greater ≈ 7.0 V, the emitter–base junction of the series pass element (internal or external) could break down and be damaged. To prevent this, a diode shunt can be employed, as shown in Figure 3–2F.

Figure 3–3F shows a three–terminal positive–adjustable regulator with the recommended protection diodes for output voltages in excess of 25 V, or high output capacitance values ($C_O > 25\ \mu F$, $C_{Adj} > 10\ \mu F$). Diode D1 prevents C_O from discharging through the regulator during an input short circuit. Diode D2 protects against capacitor C_{Adj} from discharging through the regulator during an output short circuit. The combination of diodes D1 and D2 prevents C_{Adj} from discharging through the regulator during an input short circuit.

Figure 3–2F. Reverse Bias Protection

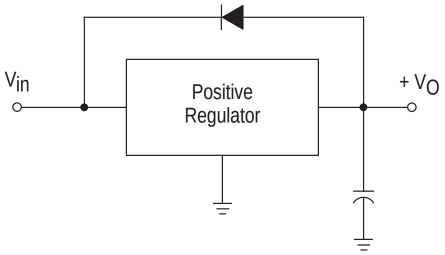


Figure 3–3F. Reverse Bias Protection for Three–Terminal Adjustable Regulators

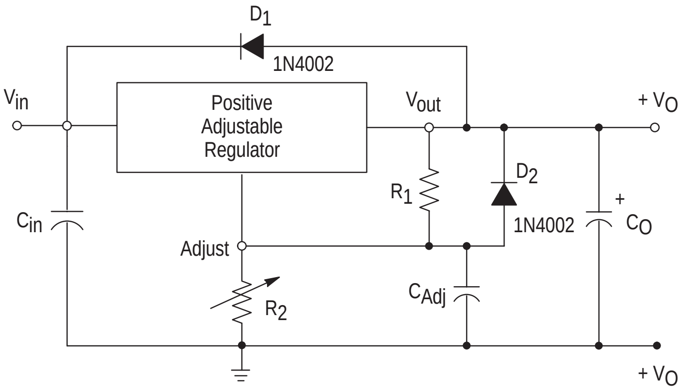


SECTION 4

SERIES PASS ELEMENT CONSIDERATIONS FOR LINEAR REGULATORS

Presently, most monolithic IC voltage regulators that are available have output current capabilities from 100 mA to 3.0 A. If greater current capability is required, or if the IC regulator does not possess sufficient safe–operating–area (SOA), the addition of an external series pass element is necessary.

In this section, configurations, specifications and current limit techniques for external series pass elements will be considered. For illustrative purposes, pass elements for only positive regulator types will be discussed. However, the same considerations apply for pass elements used with negative regulators.

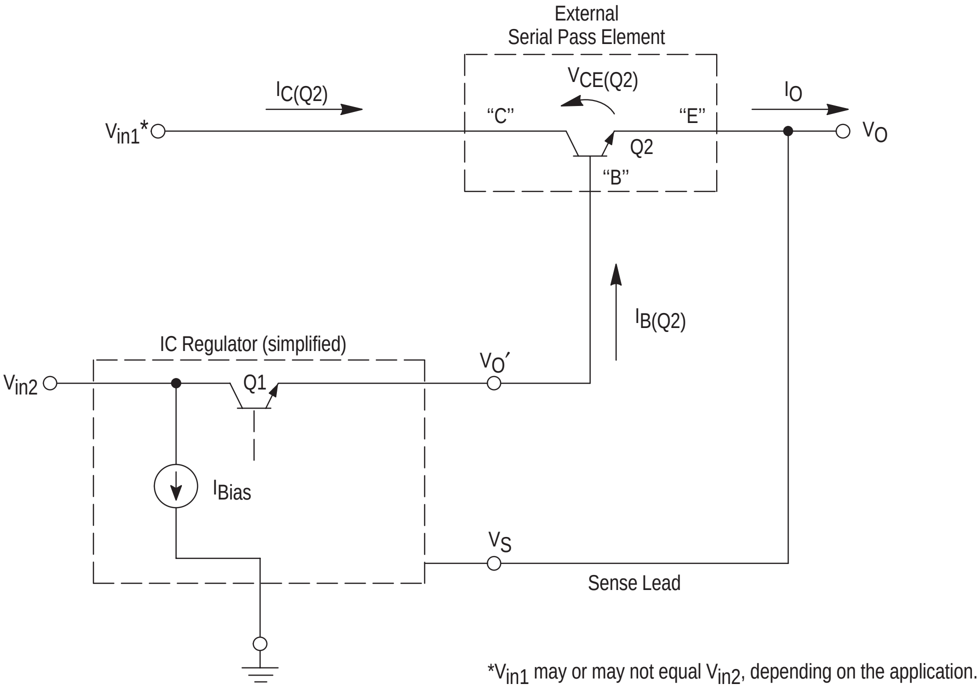
A. Series Pass Element Configurations

Using an NPN Type Transistor

If the IC regulator has an external sense lead, an NPN type series pass element may be used, as shown in Figure 4–1 A. This pass element could be a single transistor or multiple transistors arranged in Darlington and/or paralleled configurations.

In this configuration, the IC regulator supplies the base current (I_B) to the pass element (Q2) which acts as a current amplifier and provides the increased output current (I_O) capability.

Figure 4–1A. NPN Type Series Pass Element Configuration

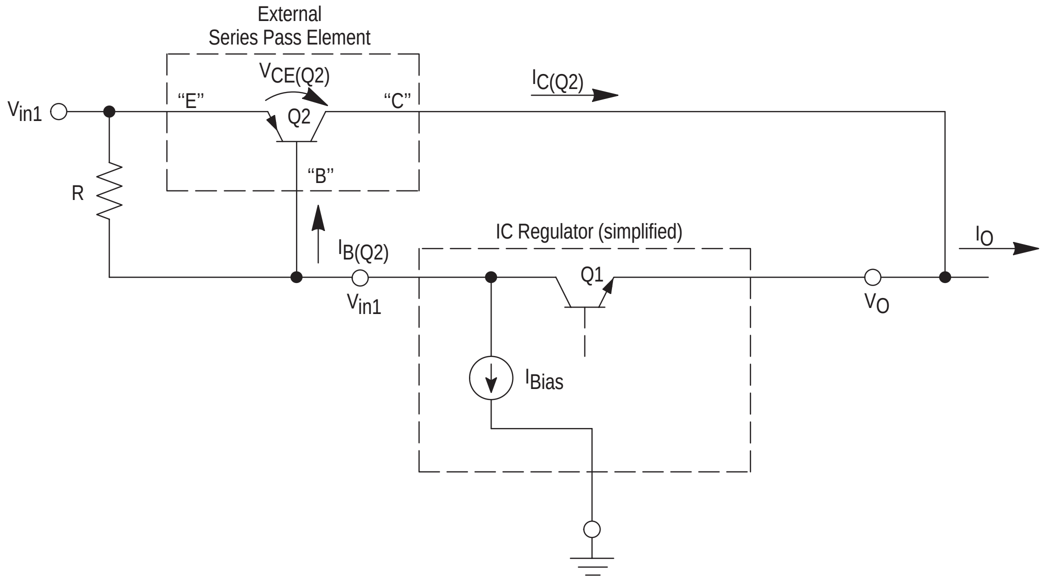


*V_{in1} may or may not equal V_{in2}, depending on the application.

Using a PNP Type Transistor

If the IC regulator does not have an external sense lead, as in the case of the three–terminal fixed output regulators, the configuration of Figure 4–1B can be used. (Regulators which possess an external sense lead may also be used with this configuration.) As before, the PNP type pass element can be a single transistor or multiple transistors.

Figure 4–1B. PNP Type Series Pass Element Configuration



This configuration functions in a similar manner to that of Figure 4–1A, in that the regulator supplies base current to pass element. The resistor (R) serves to route the IC regulator bias current (I_{Bias}) away from the base of Q2. If not included, regulation would be lost at low output currents. The value of R is low enough to prevent Q2 from turning on when I_{Bias} flows through this resistor, and is given by:

$$0 < R \le \frac{V_{BEon}(Q2\ )}{I_{Bias}} \tag{4.0}$$

B. Series Pass Element Specifications

Independent of which configuration is utilized, the transistor or transistors that compose the pass element must have adequate ratings for $I_{C(max)}$, V_{CEO}, h_{fe}, power dissipation, and safe operating area.

1. $I_{C(max)}$ — for the pass element of Figure 4–1A, $I_{C(max)}$ is given by:

$$I_{C(max)(Q2)} \ge I_{O(max)} - I_{B(max)(Q2)} = I_{O(max)} - \frac{I_{C(max)(Q2)}}{h_{fe(Q2)}} \tag{4.1}$$

$$\ge I_{O(max)} \tag{4.2}$$

For the configuration of Figure 4–1B:

$$I_{C(max)(Q2)} \ge I_{O(max)} + I_{B(max)(Q2)} \tag{4.3}$$

$$\ge I_{O(max)} \tag{4.4}$$

2. **V_{CEO} —** since $V_{CE(Q2)}$ is equal to $V_{in1(max)}$ when the output is shorted or during start up:

$$V_{CEO(Q2)} \leq V_{in1(max)} \tag{4.5}$$

3. **h_{fe} —** the minimum DC current gain for Q2 in Figures 4–1A and 4–1B is given by:

$$h_{fe(min)(Q2)} \geq \frac{I_{C(max)(Q2)}}{I_{B(max)(Q2)}} \ @\ V_{CE} = (V_{in1(min)} - V_O) \tag{4.6}$$

4. Maximum Power Dissipation $P_{D(max)}$, and Safe Operating Area (SOA)

For any transistor there are certain combinations of I_C and V_{CE} at which it may safely be operated. When plotted on a graph, whose axes are V_{CE} and I_C, a safe–operating region is formed.

As an example, the safe–operating–area (SOA) curve for the well known 2N3055 NPN silicon power transistor is shown in Figure 4–2. The boundaries of the SOA curve are formed by $I_{C(max)}$, power dissipation, second breakdown and V_{CEO} ratings of the transistor. Notice that the power dissipation and second breakdown ratings are given for a case temperature of +25°C and must be derated at higher case temperatures. (Derating factors may be found in the transistors' data sheets.) These boundaries must never be exceeded during operation, or destruction of the transistor(s) which constitute the pass element may result. (In addition, the maximum operating junction temperature *must not be exceeded*, see Section 15.)

C. Current Limiting Techniques

In order to select a transistor or transistors with adequate SOA, the locus of pass element I_C and V_{CE} operating points must be known. This locus of points is determined by the input voltage (V_{in1}, output voltage (V_O), output current (I_O) and the type of output current limiting technique employed.

In most cases, V_{in1}, V_O, and the required output current are already known. All that is left to determine is how the chosen current limit scheme affects required pass element SOA.

Note, since the external pass element is merely an extension of the IC regulator, the following discussions apply equally well to IC regulators not using an external pass element.

1. Constant Current Limiting

This method is the simplest to implement and is extensively used, especially at the lower output current levels. The basic circuit configuration is shown in Figure 4–3A, and operates in the following manner.

As the output current increases, the voltage drop across R_{SC} increases, proportionately. When the output current has increased to the point that the voltage drop across R_{SC} is equal to the base–emitter ON voltage of Q3 (V_{BEon}(Q3)), Q3 conducts. This diverts base current (I_{Drive}) away from Q1, the IC regulator's internal series pass element. Base drive ($I_{B(Q2)}$) of Q2 is therefore reduced and its collector–emitter voltage increases, thereby reducing the output voltage below its regulated value, V_{out}. The resulting output voltage–current characteristic is shown in Figure 4–3B.

The value of I_{SC} is given by:

$$I_{SC} = \frac{V_{BEon(Q3)}}{R_{SC}} \tag{4.7}$$

Figure 4–2. 2N3055 Safe Operating Area (SOA)

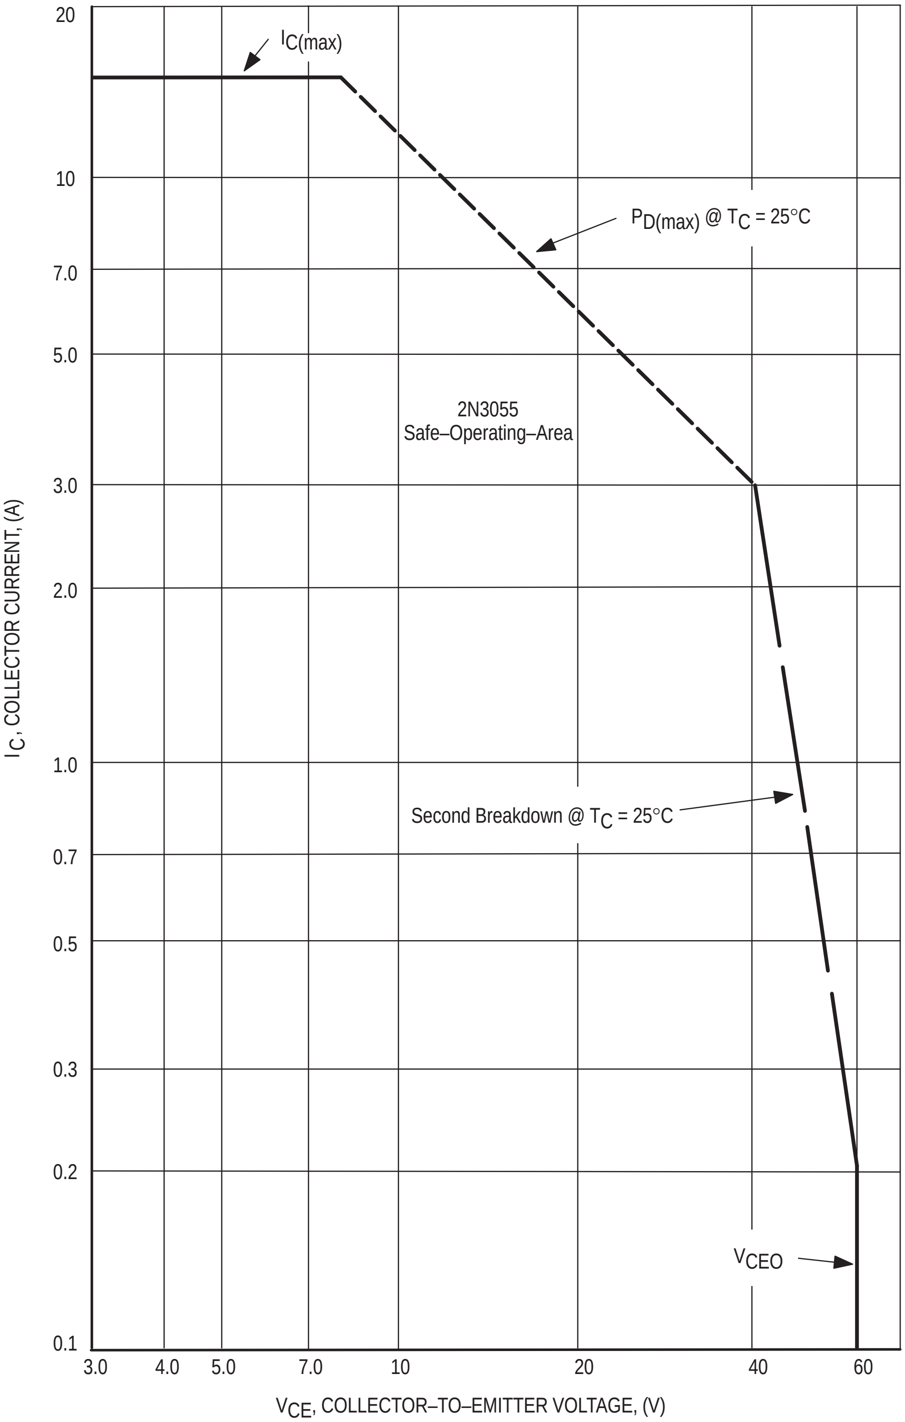


Figure 4–3. Constant Current Limiting

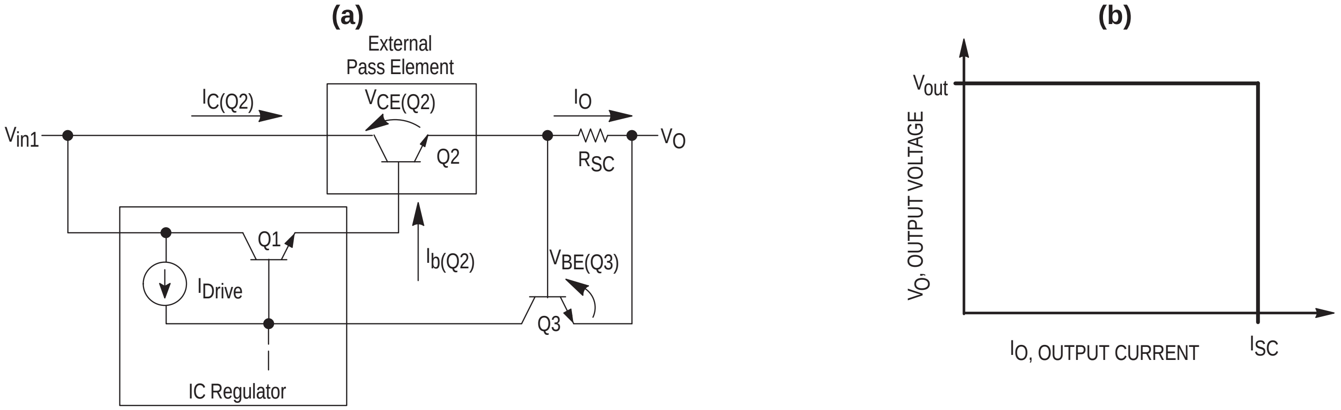


By using the base of Q1 in the IC regulator as a control point, this configuration has the added benefit of limiting the IC regulator output current ($I_{B(Q2)}$) to Isc/$h_{fe(Q2)}$, as well as limiting the collector current of Q2 to I_{SC}. Of course, access to this point is necessary. Fortunately, it is usually available in the form of a separate pin or as the regulator's compensation terminal.(1)

The required safe–operating–area for Q2 can be obtained by plotting the V_{CE} and I_C of Q2 given by:

$$V_{CE(Q2)} = V_{in1} - V_O - I_O R_{SC} \simeq V_{in1} - V_O \tag{4.8}$$

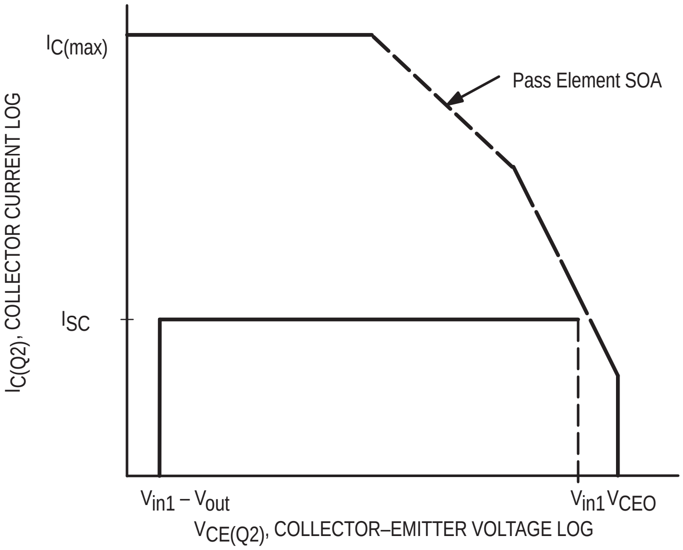
$$I_{C(Q2)} \simeq I_O \tag{4.9}$$

$$\text{where, } V_O = V_{out} \text{ for } 0 \le I_O \le I_{SC} \tag{4.10}$$

$$\text{and, } I_O = I_{SC} \text{ for } 0 \le V_O \le V_{out} \tag{4.11}$$

The resulting plot is shown in Figure 4–4. The transistor chosen for Q2 must have an SOA which encloses this plot, see Figure 4–4. Note that the greatest demand on the transistor's SOA capability occurs when the output of the regulator is short circuited and the pass element must support the full input voltage and short circuit current simultaneously.

Figure 4–4. Constant Current Limit SOA Requirements
(See Section 3 for Circuit Techniques)



---

(1) The three–terminal regulators have internal current limiting and therefore do not provide access to this point. If an external pass element is used with these regulators, constant current limiting can still be accomplished by diverting pass element drive.

2. Foldback Current Limiting

A disadvantage of the constant current limit technique is that in order to obtain sufficient SOA the pass element must have a much greater collector current capability than is actually needed. If the short circuit current could be reduced, while still allowing full output current to be obtained during normal regulator operation, more efficient utilization of the pass elements SOA capability would result. This can be done by using a “foldback” current limiting technique instead of constant current limiting.

The basic circuit configuration for this method is shown in Figure 4–5(A). The circuit operates in a manner similar to that of the constant current limiting circuit, in that output current control is obtained by diverting base drive away from Q1 with Q3.

At low output currents, V_A approximately equals V_O and V_{R2} is less than than V_O. Q3 is therefore non–conducting and the output voltage remains constant. As the output current increases, the voltage drop across R_{SC} increases until V_A and V_{R2} are great enough to bias Q3 on. The output current at which this occurs is I_K, the “knee” current.

Figure 4–5. Foldback Current Limiting

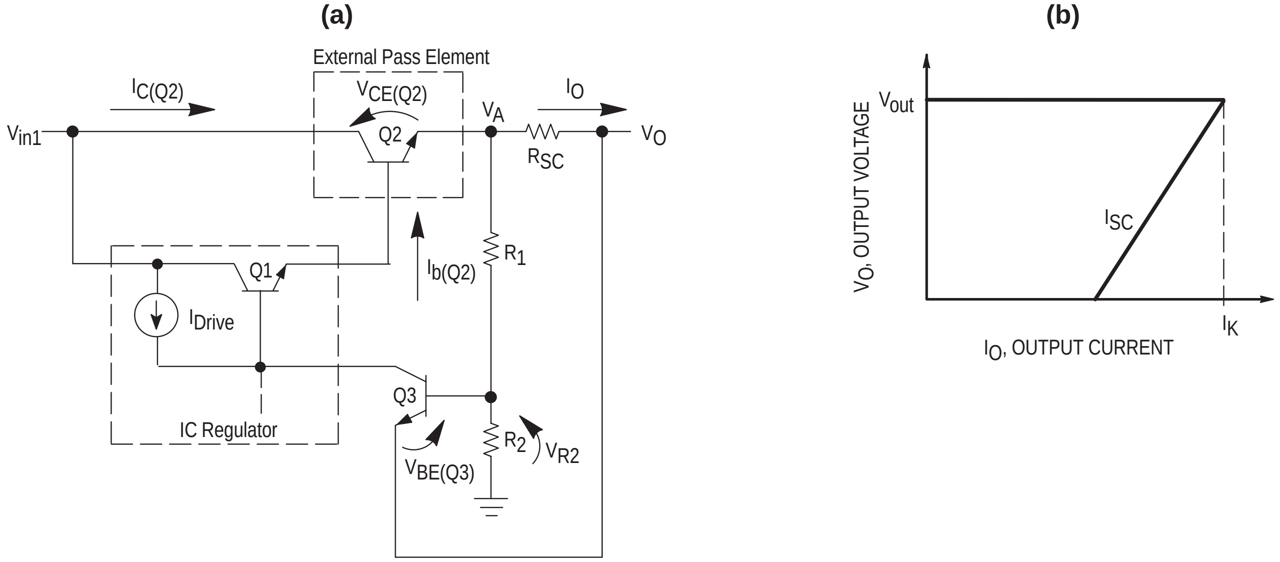


Figure 4–6. Foldback Current Limit SOA Requirements

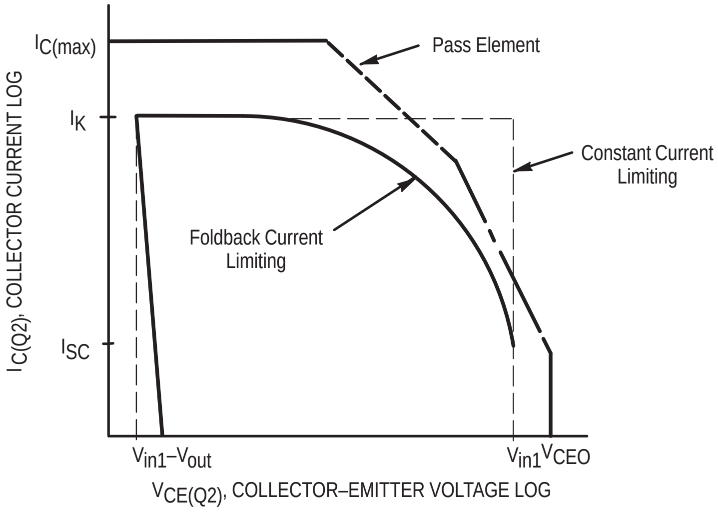


The output voltage will now decrease. Less output current is now required to keep V_A and V_{R2} at a level sufficient to bias Q3 on since the voltage at its emitter has the tendency to decrease faster than that at its base. The output current will continue to “foldback” as the output voltage decreases, until an output short circuit current level (I_{SC}) is reached when the output voltage is zero. The resulting output current–voltage characteristic is shown in Figure 4–5B. The values for R_1, R_2, and R_{SC} (neglecting base current of Q3) are given by:

$$R_{SC} = \frac{V_{out}/I_{SC}}{\left(1 + \frac{V_{out}}{V_{BEon(Q3)}}\right) - \frac{I_K}{I_{SC}}} \tag{4.12}$$

$$\frac{R_2}{R_1 + R_2} = \frac{V_{BEon(Q3)}}{I_{SC}\,R_{SC}} \tag{4.13}$$

$$\text{and, } R_1 + R_2 \leq \frac{V_{out}}{I_{Drive}} \tag{4.14}$$

where: V_{out} = normal regulator output voltage
I_K = knee current
I_{SC} = short circuit current
I_{Drive} = base drive to regulator’s internal pass element(s)

A plot of Q2 operating points, which result when using this technique, is shown in Figure 4–6. Note that the pass element is required to operate with a collector current of only I_{SC} during short circuit conditions, not the full output current, I_K. This results in a more efficient utilization of the SOA of Q2 allowing the use of a smaller transistor than if constant current limiting were used. Although foldback current limiting allows use of smaller pass element transistors for a given regulator output current than does constant current limiting, it does have a few disadvantages.

Referring to Equation (4.12), as the foldback ratio (I_K/I_{SC}) is increased, the required value of R_{SC} increases. This results in a greater input voltage at higher foldback ratios. In addition, it can be seen for Equation (4.12) that there exists an absolute limit to the foldback ratio equal to:

$$\left(\frac{I_K}{I_{SC(max)}}\right) = 1 + \frac{V_{out}}{V_{BEon(Q3)}} \text{ for } R_{SC} = \infty \tag{4.15}$$

For these reasons, foldback ratios greater than 2:1 or 3:1 are not usually practical for the lower output voltage regulators.

D. Paralleling Pass Element Transistors

Occasionally, it will not be possible to obtain a transistor with sufficient safe–operating–area. In these cases it is necessary to parallel two or more transistors. Even if a single transistor with sufficient capability is available, it is possible that paralleling two smaller transistors is more economical.

In order to insure that the collector currents of the paralleled transistors are approximately equal, the configuration of Figure 4–7 can be used. Emitter–ballasting resistors are used to force collector–current sharing between Q1 and Q2. The collector–current mismatch can be determined by considering the following, from Figure 4–7,

$$V_{BE1} + V_1 = V_{BE2} + V_2 \qquad (4.16)$$

$$\text{and, } \Delta V_{BE} = \Delta V \qquad (4.17)$$

where: $V_{BE} = V_{BE1} - V_{BE2}$ and, $\Delta V = V_2 - V_1$

Assuming $I_{E1} \simeq I_{C1}$ and $I_{E2} \simeq O_{C2}$, the collector–current mismatch is given by,

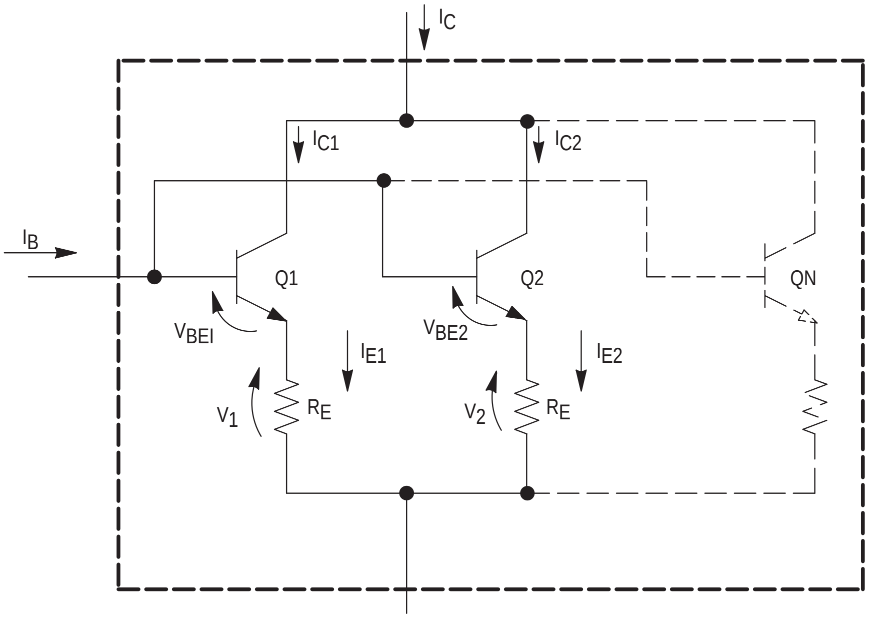
$$\frac{I_{C2} - I_{C1}}{I_{C2}} = \frac{\left(\frac{V_2}{R_E}\right) - \left(\frac{V_1}{R_E}\right)}{\left(\frac{V_2}{R_E}\right)} = \frac{V_2 - V_1}{V_2} = \frac{\Delta V}{V_2} = \frac{\Delta V_{BE}}{V_2} \qquad \begin{matrix}(4.18)\\(4.19)\end{matrix}$$

$$\text{and, percent collector–current mismatch} = \frac{\Delta V_{BE}}{V_2} \times 100\% \qquad (4.20)$$

From Equation (4.20), the collector–current mismatch is dependent on ΔV_{BE} and V_2. Since ΔV_{BE} is usually acceptable, V_2 should be 1.0 V to 0.5 V, respectively. R_E is therefore given by:

$$R_E = \frac{0.5\text{ V to }1.0\text{ V}}{I_{C1}} = \frac{0.5\text{ V to }1.0\text{ V}}{I_{C2}} = \frac{0.5\text{ V to }1.0\text{ V}}{I_C/2} \qquad (4.21)$$

Figure 4–7. Paralleling Pass Element Transistors



SECTION 5

LINEAR REGULATOR CONSTRUCTION AND LAYOUT

An important, and often neglected, aspect of the total regulator circuit design is the actual layout and component placement of the circuit. In order to obtain excellent transient response performance, high frequency transistors are used in modern integrated circuit voltage regulators. Proper attention to circuit layout is therefore necessary to prevent regulator instability or oscillations, or degraded performance.

In this section, guidelines will be given on proper regulator layout and placement of circuit components. In addition, topics such as remote voltage sensing, semiconductor mounting techniques, and thermal system evaluations will also be discussed.

1. General Layout and Component Placement Considerations

As mentioned previously, modern integrated circuit regulators are necessarily high bandwidth devices in order to obtain good transient response characteristics. To insure stable closed–loop operation, all these devices are frequency compensated, either internally or externally. This compensation can easily be upset by unwanted stray circuit capacitances and lead inductances, resulting in spurious oscillations. Therefore, it is important that the circuit lead lengths be short and the layout as tight as possible. Particular attention should be paid to locating the compensation and bypass capacitors as close to the IC as possible. Lead lengths associated with the external pass element(s), if used, should also be minimized.

Often overlooked is the stray inductance associated with the input leads to the regulator circuit. If the lead length from the input supply filter capacitor to the regulator input is more than a couple of inches, a 0.01 μF to 1.0 μF high frequency type capacitor (tantalum, ceramic, etc.) should be used to bypass the supply leads close to the regulator input pins.

2. Ground Loops and Remote Voltage Sensing

Ground Loops — Regulator performance can also suffer if ground loops in the circuit wiring are not avoided. The most common ground loop problem occurs when the return lead of the input supply filter capacitor is improperly located, as shown in Figure 5–1. If this return lead is physically connected between the load return and the regulator circuit ground point (“B”), a ripple voltage component (60 Hz or 120 Hz) can be induced on the load voltage (V_L). This is due to the high peaks of the filter capacitor ripple current (I_{ripple}) flowing through the lead resistance between the load and regulator. These peaks can be 5 to 15 times the value of load current. Since the regulator will only keep constant the voltage between its sense lead and ground point, points “A” and “B” in Figure 5–1, this additional ripple voltage (V_{lead}), will appear at the load.

This problem can be avoided by proper placement and connection of the filter capacitor return load as shown in Figure 5–2.

Remote Voltage Sensing — Closely related to the above ground loop problem is resistance in the current carrying leads to the load. This can cause poorer than expected load regulation in cases where the load currents are large or where the load is located some distance from the regulator. This is illustrated in Figure 5–3. As stated previously, the regulator circuit will keep the voltage present between its sense and ground pins constant. From Figure 5–3 we can see that any lead resistance between these points and the load will cause the load voltage (V_L) to vary with varying load current, I_L. This effectively lowers the load regulation of the circuit.

Figure 5–1. Filter Capacitor Ground Loop — WRONG!

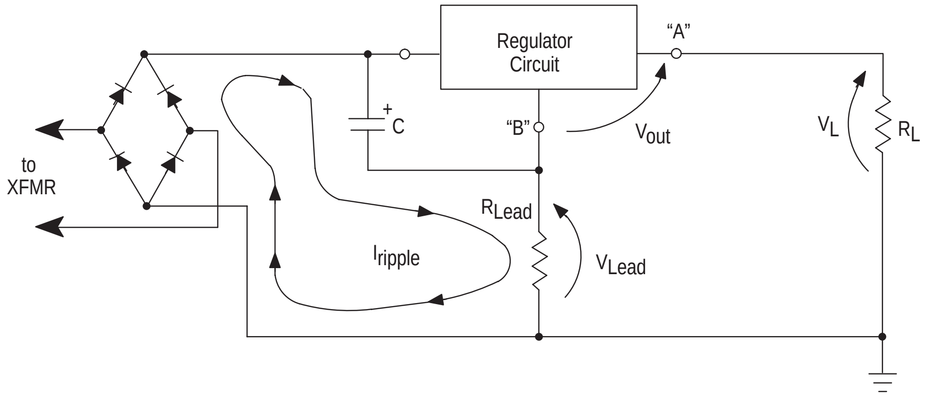


Figure 5–2. Filter Capacitor Ground Loop — RIGHT!

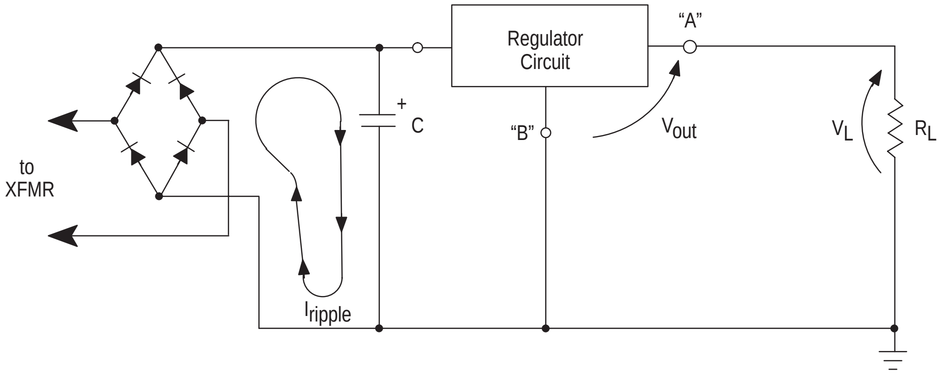

This problem can be avoided by the use of remote Sense leads, as shown in Figure 5–4. The voltage drops in the high current carrying leads now have no effect on the load voltage (V_L). However, since the Sense and Ground leads are usually rather long, care must be exercised that their associated lead inductance is minimized, or loop instability may result. The Ground and Sense leads should be formed into a twisted pair lead to minimize their lead inductance and noise pickup.

Figure 5–3. Effects of Resistance In Output Leads

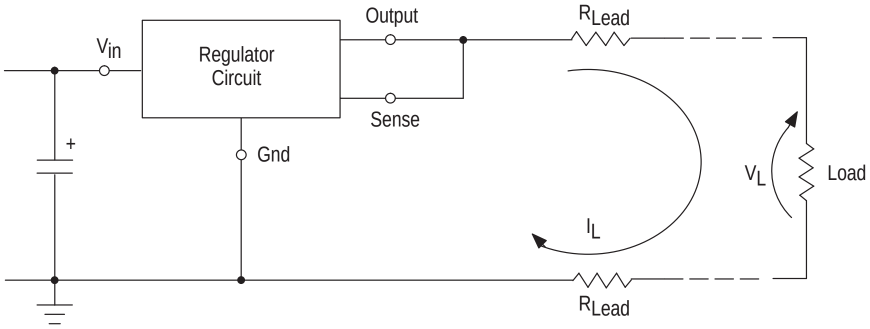

Figure 5–4. Remote Voltage Sensing

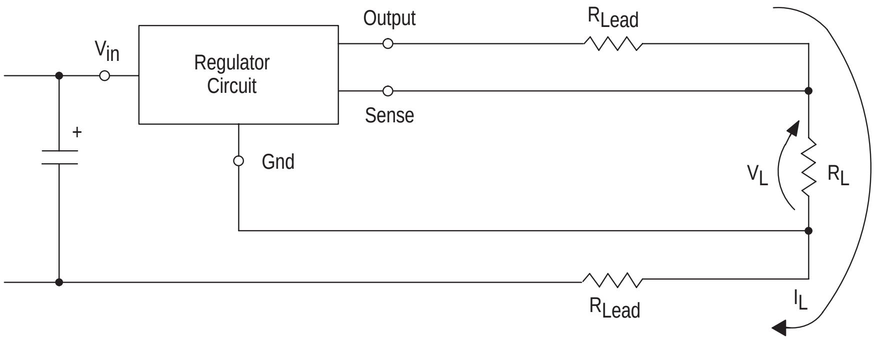

3. Mounting Considerations for Power Semiconductors

Current and power ratings of semiconductors are inseparably linked to their thermal environment. Except for lead–mounted parts used at low currents, a heat exchanger is required to prevent the junction temperature from exceeding its rated limit, thereby running the risk of a high failure rate. Furthermore, the semiconductor industry's field history indicated that the failure rate of most silicon semiconductors decreases approximately by one–half for a decrease in junction temperature from 160° to 135°C.(1) Guidelines for designers of military power supplies impose a 110°C limit upon junction temperature.(2) Proper mounting minimizes the temperature gradient between the semiconductor case and the heat exchanger.

Most early life field failures of power semiconductors can be traced to faulty mounting procedures. With metal packaged devices, faulty mounting generally causes unnecessarily high junction temperature, resulting in reduced component lifetime, although mechanical damage has occurred on occasion from improperly mounting to a warped surface. With the widespread use of various plastic packaged semiconductors, the prospect of mechanical damage is very significant. Mechanical damage can impair the case moisture resistance or crack the semiconductor die.

Figure 5–5 shows an example of doing nearly everything wrong. A tab mount TO–220 package is shown being used as a replacement for a TO–213AA (TO–66) part which was socket mounted. To use the socket, the leads are bent — an operation which, if not properly done, can crack the package, break the internal bonding wires, or crack the die. The package is fastened with a sheet metal screw through a 1/4″ hole containing a fiber–insulating sleeve. The force used to tighten the screw tends to pull the package into the hole, possibly causing enough distortion to crack the die. In addition the contact area is small because of the area consumed by the large hole and the bowing of the package, the result is a much higher junction temperature than expected. If a rough heatsink surface and/or burrs around the hole were displayed in the illustration, most but not all poor mounting practices would be covered.

In many situations the case of the semiconductor must be electrically isolated from its mounting surface. The isolation material is, to some extent, a thermal isolator as well, which raises junction operating temperatures. In addition, the possibility of arc–over problems is introduced if high voltages are present. Various regulating agencies also impose creepage distance specifications which further complicates design. Electrical isolation thus places additional demands upon the mounting procedure.

Proper mounting procedures usually necessitate orderly attention to the following:

1. Preparing the mounting surface
2. Applying a thermal grease (if required)
3. Installing the insulator (if electrical isolation is desired)
4. Fastening the assembly
5. Connecting the terminals to the circuit

In this note, mounting procedures are discussed in general terms for several generic classes of packages. As newer packages are developed, it is probable that they will fit into the generic classes discussed in this note. Unique requirements are given on data sheets pertaining to the particular package. The following classes are defined:

Flange Mount	Tab Mount
Plastic Body Mount	Surface Mount

Appendix A contains a brief review of thermal resistance concepts.

Appendix B discusses measurement difficulties with interface thermal resistance tests.

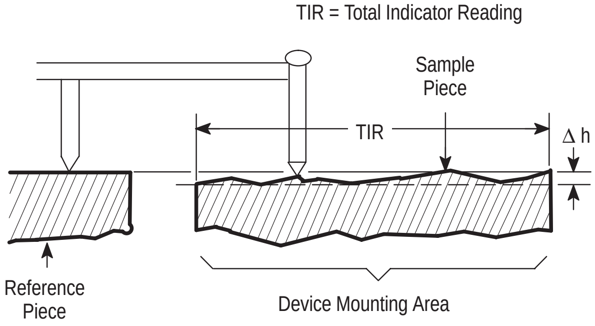
Mounting Surface Preparation

In general, the heatsink mounting surface should have a flatness and finish comparable to that of the semiconductor package. In lower power applications, the heatsink surface is satisfactory if it appears flat against a straight edge and is free from deep scratches. In high power applications, a more detailed examination of the surface is required. Mounting holes and surface treatment must also be considered.

Surface Flatness

Surface flatness is determined by comparing the variance in height (Δh) of the test specimen to that of a reference standard as indicated in Figure 5–6. Flatness is normally specified as a fraction of the Total Indicator Reading (TIR). The mounting surface flatness (i.e, Δh/TIR) if less than 4 mils per inch, normal for extruded aluminum, is satisfactory in most cases.

Figure 5–6. Surface Flatness Measurement



Surface Finish

Surface finish is the average of the deviations both above and below the mean value of surface height. For minimum interface resistance, a finish in the range of 50 µin. to 60 µin. is satisfactory. A finer finish is costly to achieve and does not significantly lower contact resistance. Tests conducted by Thermalloy using a copper TO–204 (TO–3) package with a typical 32 µin. finish, showed that heatsink finishes between 16 µin. and 64 µin. caused less than ±2.5% difference in interface thermal resistance when the voids and scratches were filled with a thermal joint compound.(3) Most commercially available cast or extruded heatsinks will require spotfacing when used in high power applications. In general, milled or machined surfaces are satisfactory if prepared with tools in good working condition.

Mounting Holes

Mounting holes generally should only be large enough to allow clearance of the fastener. The larger thick flange type packages having mounting holes removed from the semiconductor die location, such as the TO–204AA, may successfully be used with larger holes to accommodate an insulating bushing, but many plastic encapsulated packages are intolerant of this condition. For these packages, a smaller screw size must be used such that the hole for the bushing does not exceed the hole in the package.

Punched mounting holes have been a source of trouble because if not properly done, the area around a punched hole is depressed in the process. This "crater" in the heatsink around the mounting hole can cause two problems. The device can be damaged by distortion of the package as the mounting pressure attempts to conform it to the shape of the heatsink indentation, or the device may only bridge the crater and leave a significant percentage of its heat–dissipating surface out of contact with the heatsink. The first effect may often be detected immediately by visual cracks in the package (if plastic), but usually an unnatural stress is imposed, which results in an early–life failure. The second effect results in hotter operation and is not manifested until much later.

Although punched holes are seldom acceptable in the relatively thick material used for extruded aluminum heatsinks, several manufacturers are capable of properly utilizing the capabilities inherent in both fine–edge blanking or sheared–through holes when applied to sheet metal as commonly used for stamped heatsinks. The holes are pierced using Class A progressive dies mounted on four–post die sets equipped with proper pressure pads and holding fixtures.

When mounting holes are drilled, a general practice with extruded aluminum, surface cleanup is important. Chamfers must be avoided because they reduce heat transfer surface and increase mounting stress. However, the edges must be broken to remove burrs which cause poor contact between device and heatsink and may puncture isolation material.

Surface Treatment

Many aluminum heatsinks are black–anodized to improve radiation ability and prevent corrosion. Anodizing results in significant electrical but negligible thermal insulation. It need only be removed from the mounting area when electrical contact is required. Heatsinks are also available which have a nickel plated copper insert under the semiconductor mounting area. No treatment of this surface is necessary.

Another treated aluminum finish is iridite, or chromate–acid dip, which offers low resistance because of its thin surface, yet has good electrical properties because it resists oxidation. It need only be cleaned of the oils and films that collect in the manufacture and storage of the sinks, a practice which should be applied to all heatsinks.

For economy, paint is sometimes used for sinks; removal of the paint where the semiconductor is attached is usually required because of the paint's high thermal resistance. However, when it is necessary to insulate the semiconductor package from the heatsink, hard anodized or painted surfaces allow an easy installation for low voltage applications. Some manufacturers will provide anodized or painted surfaces meeting specific insulation voltage requirements, usually up to 400 V.

It is also necessary that the surface be free from all foreign material, film, and oxide (freshly bared aluminum forms an oxide layer in a few seconds). Immediately prior to assembly, it is a good practice to polish the mounting area with No. 000 steel wool, followed by an acetone or alcohol rinse.

Interface Decisions

When any significant amount of power is being dissipated, something must be done to fill the air voids between mating surfaces in the thermal path. Otherwise, the interface thermal resistance will be unnecessarily high and quite dependent upon the surface finishes.

For several years, thermal joint compounds, often called grease, have been used in the interface. They have a resistivity of approximately 60°C/W/in whereas air has 1200°C/W/in. Since surfaces are highly pockmarked with minute voids, use of a compound makes a significant reduction in the interface thermal resistance of the joint. However, the grease causes a number of problems, as discussed in the following section. To avoid using grease, manufacturers have developed dry conductive and insulating pads to replace the more traditional materials. These pads are conformal and therefore partially fill voids when under pressure.

Thermal Compounds (Grease)

Joint compounds are a formulation of fine zinc or other conductive particles in a silicone oil or other synthetic base fluid which maintains a grease–like consistency with time and temperature. Since some of these compounds do not spread well, they should be evenly applied in a very thin layer using a spatula or lintless brush, and wiped lightly to remove excess material. Some cyclic rotation of the package will help the compound spread evenly over the entire contact area. Some experimentation is necessary to determine the correct quantity; too little will not fill all the voids, while too much may permit some compound to remain between well mated metal surfaces where it will substantially increase the thermal resistance of the joint.

To determine the correct amount, several semiconductor samples and heatsinks should be assembled with different amounts of grease applied evenly to one side of each mating surface. When the amount is correct, a very small amount of grease should appear around the perimeter of each mating surface as the assembly is slowly torqued to the recommended value. Examination of a dismantled assembly should reveal even wetting across each mating surface. In production, assemblers should be trained to slowly apply the specified torque even though an excessive amount of grease appears at the edges of mating surfaces. Insufficient torque causes a significant increase in the thermal resistance of the interface.

To prevent accumulation of airborne particulate matter, excess compound should be wiped away using a cloth moistened with acetone or alcohol. These solvents should not contact plastic–encapsulated devices, as they may enter the package and cause a leakage path or carry in substances which might attack the semiconductor chip.

Data showing the effect of compounds on several package types under different mounting conditions is shown in Table 5–1. The rougher the surface, the more valuable the grease becomes in lowering contact resistance; therefore, when mica insulating washers are used, use of grease is generally mandatory. The joint compound also improves the breakdown rating of the insulator.

Table 5–1. Approximate Values for Interface Thermal Resistance Data from Measurements Performed In Motorola Applications Engineering Laboratory

Dry interface values are subject to wide variation because of extreme dependence upon surface conditions. Unless otherwise noted the case temperature is monitored by a thermocouple located directly under the die reached through a hole in the heatsink. (See Appendix B for a discussion of Interface Thermal Resistance Measurements.)

Package Type and Data		Interface Thermal Resistance (°C/W)						
			Metal–to–Metal		With Insulator			
JEDEC Outlines	Description	Test Torque In–Lb	Dry	Lubed	Dry	Lubed	Type	See Note
TO–204AA (TO–3)	Diamond Flange	6	0.5	0.1	1.3	0.36	3 mil Mica	1
TO–220AB	Thermowatt	8	1.2	1.0	3.4	1.6	2 mil Mica	1, 2

NOTES: 1. See Figures 5–7 and 5–8 for additional data on TO–204AA and TO–220 packages.
2. Screw not insulated (see Figure 5–12).

Conductive Pads

Because of the difficulty of assembly using grease and the evaporation problem, some equipment manufacturers will not, or cannot, use grease. To minimize the need for grease, several vendors offer dry conductive pads which approximate performance obtained with grease. Data for a greased bare joint and a joint using Grafoil, a dry graphite compound, is shown in the data of Figure 5–7. Grafoil is claimed to be a replacement for grease when no electrical isolation is required; the data indicates it does indeed perform as well as grease. Another conductive pad available from AAVID is called KON–DUX. It is made with a unique, grain oriented, flake–like structure (patent pending). Highly compressible, it becomes formed to the surface roughness of both the heatsink and semiconductor. Manufacturer's data shows it to provide an interface thermal resistance better than a metal interface with filled silicone grease. Similar dry conductive pads are available from other manufacturers. They are a fairly recent development; long term problems, if they exist, have not yet become evident.

Insulation Considerations

Since most power semiconductors use are vertical device construction it is common to manufacture power semiconductors with the output electrode (anode, collector or drain) electrically common to the case; the problem of isolating this terminal from ground is a common one. For lowest overall thermal resistance, which is quite important when high power must be dissipated, it is best to isolate the entire heatsink/semiconductor structure from ground, rather than to use an insulator between the semiconductor and the heatsink. Heatsink isolation is not always possible, however, because of EMI requirements, safety reasons, instances where a chassis serves as a heatsink or where a heatsink is common to several non–isolated packages. In these situations insulators are used to isolate the individual components from the heatsink. Newer packages, such as the Motorola Full Pak and EMS modules, contain the electrical isolation material within, thereby saving the equipment manufacturer the burden of addressing the isolation problem.

Insulator Thermal Resistance

When an insulator is used, thermal grease is of greater importance than with a metal–to–metal contact, because two interfaces exist instead of one and some materials, such as mica, have a hard, markedly uneven surface. With many isolation materials reduction of interface thermal resistance of between 2 to 1 and 3 to 1 are typical when grease is used.

Data obtained by Thermalloy, showing interface resistance for different insulators and torques applied to TO–204 (TO–3) and TO–220 packages, is shown in Figure 5–7, for bare and greased surfaces. Similar materials to those shown are available from several manufacturers. It is obvious that with some arrangements, the interface thermal resistance exceeds that of the semiconductor (junction–to–case).

Referring to Figure 5–7, one may conclude that when high power is handled, beryllium oxide is unquestionably the best. However, it is an expensive choice. (It should not be cut or abraided, as the dust is highly toxic.) Thermafilm is a filled polyimide material which is used for isolation (variation of Kapton). It is a popular material for low power applications because of its low cost ability to withstand high temperatures, and ease of handling in contrast to mica which chips and flakes easily.

A number of other insulating materials are also shown. They cover a wide range of insulation resistance, thermal resistance and ease of handling. Mica has been widely used in the past because it offers high break down voltage and fairly low thermal resistance at a low cost but it certainly should be used with grease.

Silicone rubber insulators have gained favor because they are somewhat conformal under pressure. Their ability to fill in most of the metal voids at the interface reduces the need for thermal grease. When first introduced, they suffered from cut–through after a few years in service. The ones presently available have solved this problem by having imbedded pads of Kapton or fiberglass. By comparing Figures 5–7(c) and 5–7(d), it can be noted that Thermasil, a filled silicone rubber without grease, has about the same interface thermal resistance as greased mica for the TO–220 package.

Figure 5–7. Interface Thermal Resistance Using Different Insulating Materials as a Function of Mounting Screw Torque

A number of manufacturers offer silicone rubber insulators. Table 5–2 shows measured performance of a number of these insulators under carefully controlled, nearly identical conditions. The interface thermal resistance extremes are over 2:1 for the various materials. It is also clear that some of the insulators are much more tolerant than others of out–of–flat surfaces. Since the tests were performed, newer products have been introduced. The Bergquist K–10 pad, for example, is described as having about 2/3 the interface resistance of the Sil Pad 1000 which would place its performance close to the Chomerics 1671 pad. AAVID also offers an isolated pad called Rubber–Duc, however it is only available vulcanized to a heatsink and therefore was not included in the comparison. Published data from AAVID shows $R\theta_{CS}$ below 0.3°C/W for pressures above 500 psi. However, surface flatness and other details are not specified so a comparison cannot be made with other data in this note.

Table 5–2. Thermal Resistance of Silicone Rubber Pads

Manufacturer	Product	$R_{\theta CS}$ @ 3 Mils*	$R_{\theta CS}$ @ 7.5 Mils*
Wakefield	Delta Pad 173–7	0.790	1.175
Bergquist	Sil Pad K–4	0.752	1.470
Stockwell Rubber	1867	0.742	1.015

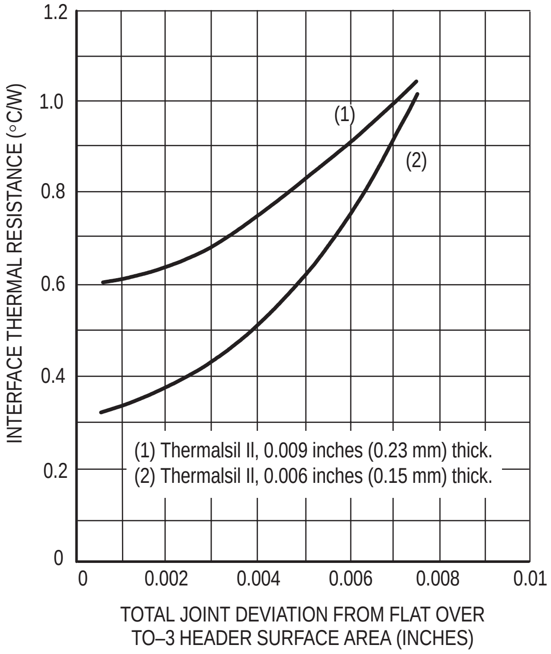
Ablestik	Thermal Wafers	0.500	0.990
Thermalloy	Thermalsil III	0.440	1.035
Chomerics	1671	0.367	0.655

*Test Fixture Deviation from flat Thermalloy EIR86–1010.

The thermal resistance of some silicone rubber insulators is sensitive to surface flatness when used under a fairly rigid base package. Data for a TO–204AA (TO–3) package insulated with Thermasil is shown on Figure 5–8. Observe that the "worst case" encountered (7.5 mils) yields results having about twice the thermal resistance of the "typical case" (3 mils), for the more conductive insulator. In order for Thermasil III to exceed the performance of greased mica, total surface flatness must be under 2 mils, a situation that requires spot finishing.

Figure 5–8. Effect of Total Surface Flatness on Interface Resistance Using Silicon Rubber Insulators



Data Courtesy of Thermalloy

Silicon rubber insulators have a number of unusual characteristics. Besides being affected by surface flatness and initial contact pressure, time is a factor. For example, in a study of the Cho–Therm 1688 pad thermal interface impedance dropped from 0.90°C/W to 0.70°C/W at the end of 1000 hours. Most of the change occurred during the first 200 hours where $R\theta_{CS}$ measured 0.74°C/W. The torque on the conventional mounting hardware had decreased to 3 in–lb from an initial 6 in–lb. With non–conformal materials, a reduction in torque would have increased the interface thermal resistance.

Because of the difficulties in controlling all variables affecting tests of interface thermal resistance, data from different manufacturers is not in good agreement. Table 5–3 shows data obtained from two sources. The relative performance is the same, except for mica which varies widely in thickness. Appendix B discusses the variables which need to be controlled. At the time of this writing ASTM Committee D9 is developing a standard for interface measurements.

The conclusions to be drawn from all this data is that some types of silicon rubber pads, mounted dry, will out perform the commonly used mica with grease. Cost may be a determining factor in making a selection.

Table 5–3. Performance of Silicon Rubber Insulators Tested per MIL–I–49456

	Measured Thermal Resistance (°C/W)	
Material	**Thermalloy Data**(1)	**Bergquist Data**(2)
Bare Joint, greased	0.033	0.008
BeO, greased	0.082	—
Cho–Therm, 1617	0.233	—
Q Pad (non–insulated)	—	0.009
Sil–Pad, K–10	0.263	0.200
Thermasil III	0.267	—
Mica, greased	0.329	0.400
Sil–Pad 1000	0.400	0.300

Insulation Resistance

When using insulators, care must be taken to keep the mating surfaces clean. Small particles of foreign matter can puncture the insulation, rendering it useless or seriously lowering its dielectric strength. In addition, particularly when voltages higher than 300 V are encountered, problems with creepage may occur. Dust and other foreign material can shorten creepage distances significantly, so having a clean assembly area is important. Surface roughness and humidity also lower insulation resistance. Use of thermal grease usually raises the withstand voltage of the insulation system but excess must be removed to avoid collecting dust. Because of these factors, which are not amenable to analysis, hi–pot testing should be done on prototypes and a large margin of safety employed.

Insulated Electrode Packages

Because of the nuisance of handling and installing the accessories needed for an insulated semiconductor mounting, equipment manufacturers have longed for cost–effective insulated packages since the 1950s. The first to appear were stud mount types which usually have a layer of beryllium oxide between the stud hex and the can. Although effective, the assembly is costly and requires manual mounting and lead wire soldering to terminals on top of the case. In the late eighties, a number of electrically isolated parts became available from various semiconductor manufacturers. These offerings presently consist of multiple chips and integrated circuits as well as the more conventional single chip devices.

The newer insulated packages can be grouped into two categories. The first has insulation between the semiconductor chips and the mounting base; an exposed area of the mounting base is used to secure the part. The second category contains parts which have a plastic overmold covering the metal mounting base. The Full Pak (Case 221C) illustrated in Figure 5–13, is an example of parts in the second category.

Parts in the first category — those with an exposed metal flange or tab — are mounted the same as their non–insulated counterparts. However, as with any mounting system where pressure is bearing on plastic, the overmolded type should be used with a conical compression washer, described later in this note.

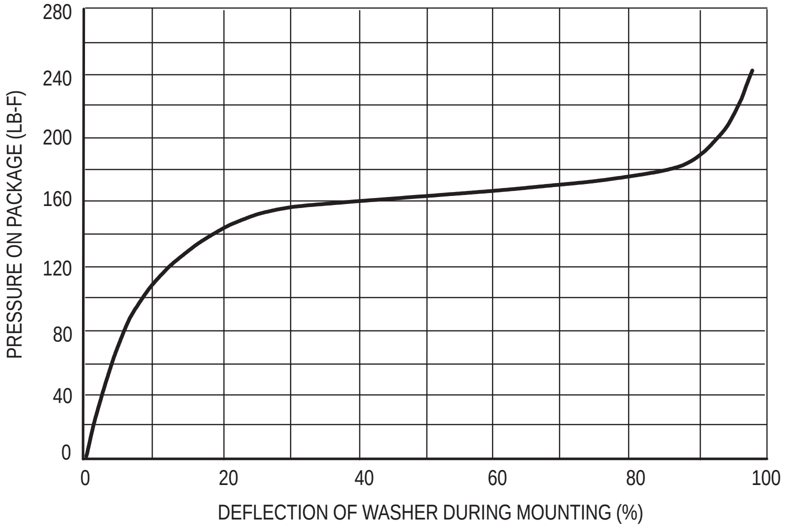
Fastener and Hardware Characteristics

Characteristics of fasteners, associated hardware, and the tools to secure them determine their suitability for use in mounting the various packages. Since many problems have arisen because of improper choices, the basic characteristics of several types of hardware are discussed next.

Compression Hardware

Normal split ring lock washers are not the best choice for mounting power semiconductors. A typical #6 washer flattens at about 50 pounds, whereas 150 to 300 pounds is needed for good heat transfer at the interface. A very useful piece of hardware is the conical, sometimes called a Belleville washer, compression washer. As shown in Figure 5–9, it has the ability to maintain a fairly constant pressure over a wide range of its physical deflection — generally 20% to 80%. When installing, the assembler applies torque until the washer depresses to half its original height. (Tests should be run prior to setting up the assembly line to determine the proper torque for the fastener used to achieve 50% deflection.) The washer will absorb any cyclic expansion of the package, insulating washer or other materials caused by temperature changes. Conical washers are the key to successful mounting of devices requiring strict control of the mounting force or when plastic hardware is used in the mounting scheme. They are used with the large face contacting the packages. A new variation of the conical washer includes it as part of a nut assembly. Called a Sync Nut, the patented device can be soldered to a PC board and the semiconductor mounted with a 6–32 machine screw.(4)

Figure 5–9. Characteristics of the Conical Compression Washers Designed for Use with Plastic Body Mounted Semiconductors



---

(4) ITW Shakeproof, St. Charles Road, Elgin, IL 60120.

Clips

Fast assembly is accomplished with clips. When only a few watts are being dissipated, the small board–mounted or free–standing heat dissipators with an integral clip, offered by several manufacturers, result in a low cost assembly. When higher power is being handled, a separate clip may be used with larger heatsinks. In order to provide proper pressure, the clip must be specially designed for a particular heatsink thickness and semiconductor package.

Clips are especially popular with plastic packages such as the TO–220 and TO–126. In addition to fast assembly, the clip provides lower interface thermal resistance than other assembly methods when it is designed for proper pressure to bear on the top of the plastic over the die. The TO–220 package usually is lifted up under the die location when mounted with a single fastener through the hole in the tab because of the high pressure at one end.

Machine Screws

Machine screws, conical washers, and nuts (or Sync Nut) can form a trouble–free fastener system for all types of packages which have mounting holes. However, proper torque is necessary. Torque ratings apply when dry; therefore, care must be exercised when using thermal grease to prevent it from getting on the threads as inconsistent torque readings result. Machine screw heads should not directly contact the surface of plastic packages types as the screw heads are not sufficiently flat to provide properly distributed force. Without a washer, cracking of the plastic case may occur.

Self–Tapping Screws

Under carefully controlled conditions, sheet metal screws are acceptable. However, during the tapping process with a standard screw, a volcano–like protrusion will develop in the metal being threaded; an unacceptable surface that could increase the thermal resistance may result. When standard sheet metal screws are used, they must be used in a clearance hole to engage a speed nut. If a self–tapping process is desired, the screw type must be used which roll–forms machine screw threads.

Rivets

Rivets are not recommended fasteners for any of the plastic packages. When a rugged metal flange–mount package is being mounted directly to a heatsink, rivets can be used provided press–riveting is used. Crimping force must be applied slowly and evenly. Pop–riveting should never be used because the high crimping force could cause deformation of most semiconductor packages. Aluminum rivets are much preferred over steel because less pressure is required to set the rivet and thermal conductivity is improved.

The hollow rivet, or eyelet, is preferred over solid rivets. An adjustable, regulated pressure press is used such that a gradually increasing pressure is used to pan the eyelet. Use of sharp blows could damage the semiconductor die.

Solder

Until the advent of the surface mount assembly technique, solder was not considered a suitable fastener for power semiconductors. However, user demand has led to the development of new packages for this application. Acceptable soldering methods include conventional belt–furnace, irons, vapor–phase reflow, and infrared reflow. It is important that the semiconductor temperature not exceed the specified maximum (usually 260°C) or the die bond to the case could be damaged. A degraded die bond has excessive thermal resistance which often leads to a failure under power cycling.

Adhesives

Adhesives are available which have coefficients of expansion compatible with copper and aluminum.(5) Highly conductive types are available; a 10 mil layer has approximately 0.3°C/W interface thermal resistance. Different types are offered: high strength types for non–field–serviceable systems or low strength types for field–serviceable systems. Adhesive bonding is attractive when case mounted parts are used in wave soldering assembly because thermal greases are not compatible with the conformal coatings used and the greases foul the solder process.

Plastic Hardware

Most plastic materials will flow, but differ widely in this characteristic. When plastic materials form parts of the fastening system, compression washers are highly valuable to assure that the assembly will not loosen with time and temperature cycling. As previously discussed, loss of contact pressure will increase interface thermal resistance.

Fastening Techniques

Each of the various classes of packages in use requires different fastening techniques. Details pertaining to each type are discussed in following sections. Some general considerations follow.

To prevent galvanic action from occurring when devices are used on aluminum heatsinks in a corrosive atmosphere, many devices are nickel or gold–plated. Consequently, precautions must be taken not to mar the finish.

Another factor to be considered is that when a copper based part is rigidly mounted to an aluminum heatsink, a bimetallic system results which will bend with temperature changes. Not only is the thermal coefficient of expansion different for copper and aluminum, but the temperature gradient through each metal also causes each component to bend. If bending is excessive and the package is mounted by two or more screws the semiconductor chip could be damaged. Bending can be minimized by:

1. Mounting the component parallel to the heatsink fins to provide increased stiffness.
2. Allowing the heatsink holes to be a bit oversized so that some slip between surfaces can occur as temperature changes.
3. Using a highly conductive thermal grease or mounting pad between the heatsink and semiconductor to minimize the temperature gradient and allow for movement.

Flange Mount

Few known mounting difficulties exist with the smaller flange mount packages, such as the TO–204 (TO–3). The rugged base and distance between die and mounting hose combine to make it extremely difficult to cause any warpage unless mounted on a surface which is badly bowed or unless one side is tightened excessively before the other screw is started. It is therefore good practice to alternate tightening of the screws so that pressure is evenly applied. After the screws are finger–tight the hardware should be torqued to its final specification in at least two sequential steps. A typical mounting installation for a popular flange type part is shown in Figure 5–10. Machine screws (preferred), self–tapping screws, islets or rivets may be used to secure the package using guidelines in the previous section, **Fastener and Hardware Characteristics**.

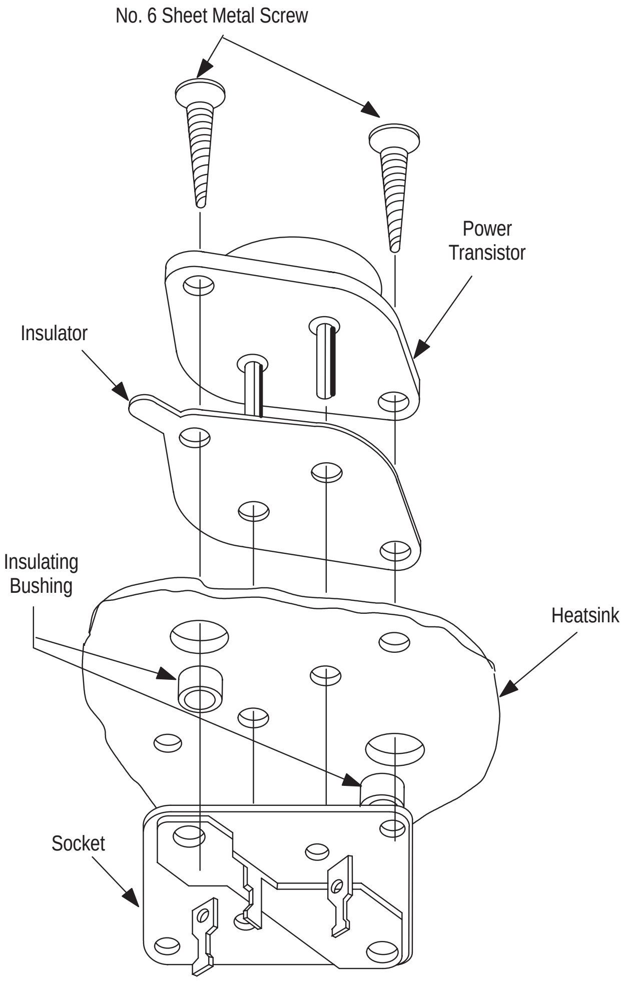
Figure 5–10. Hardware Used for a TO–204AA (TO–3) Flange Mount Part



Tab Mount

The tab mount class is composed of a wide array of packages as illustrated in Figure 5–11. Mounting considerations for all varieties are similar to that for the popular TO–220 package, whose suggested mounting arrangements and hardware are shown in Figure 5–12. The rectangular washer shown in Figure 5–12a is used to minimize distortion of the mounting flange; excessive distortion could cause damage to the semiconductor chip. Use of the washer is only important when the size of the mounting hole exceeds 0.140 inch (6–32 clearance). Larger holes are needed to accommodate the lower insulating bushing when the screw is electrically connected to the case; however, the holes should not be larger than necessary to provide hardware clearance and should never exceed a diameter of 0.250 inch. Flange distortion is also possible if excessive torque is used during mounting. A maximum torque of 8 inch–pounds is suggested when using a 6–32 screw.

Care should be exercised to assure that the tool used to drive the mounting screw never comes in contact with the plastic body during the driving operation. Such contact can result in damage to the plastic body and internal device connections. To minimize this problem, Motorola TO–220 packages have a chamfer on one end. TO–220 packages of other manufacturers may need a spacer or combination spacer and isolation bushing to raise the screw head above the top surface of the plastic.

The popular TO–220 package and others of similar construction lift off the mounting surface as pressure is applied to one end. (See Appendix B, Figure B1.) To counter this tendency, at least one hardware manufacturer offers a hard plastic cantilever beam which applies more even pressure on the tab.(6) In addition, it separates the mounting screw from the metal tab. Tab mount parts may also be effectively mounted with clips as shown in Figure 5–14(c). To obtain high pressure without cracking the case, a pressure spreader bar should be used under the clip. Interface thermal resistance with the cantilever beam or clips can be lower than with screw mounting.

Plastic Body Mount

The Full Pak plastic power packages shown in Figure 5–13 are typical of packages in this group. They have been designed to feature minimum size with no compromise in thermal resistance.

The Full Pak (Case 221C) is similar to a TO–220 except that the tab is encased in plastic. Because the mounting force is applied to plastic, the mounting procedure differs from a standard TO–220 and is similar to that of the Thermopad.

Several types of fasteners may be used to secure these packages; machine screws, eyelets, or clips are preferred. With screws or eyelets, a conical washer should be used which applies the proper force to the package over a fairly wide range of deflection and distributes the force over a fairly large surface area. Screws should not be tightened with any type of air–driven torque gun or equipment which may cause high impact. Characteristics of a suitable conical washer is shown in Figure 5–9.

The Full Pak (Case 221C, 221D and 340B) permits the mounting procedure to be greatly simplified over that of a standard TO–220. As shown in Figure 5–14(c), one properly chosen clip, inserted into two slotted holes in the heatsink, is all the hardware needed. Even though clip pressure is much lower than obtained with a screw, the thermal resistance is about the same for either method. This occurs because the clip bears directly on top of the die and holds the package flat while the screw causes the package to lift up somewhat under the die. (See Figure B1 of Appendix B.) The interface should consist of a layer of thermal grease or a highly conductive thermal pad. Of course, screw mounting shown in Figure 5–14(b) may also be used but a conical compression washer should be included. Both methods afford a major reduction in hardware as compared to the conventional mounting method with a TO–220 package which is shown in Figure 5–14(a).

Surface Mount

Although many of the tab mount parts have been surface mounted, special small footprint packages for mounting power semiconductors using surface mount assembly techniques have been developed. The DPAK, shown in Figure 5–15, for example, will accommodate a die up to 112 mils × 112 mils, and has a typical thermal resistance around 2°C/W junction to case. The thermal resistance values of the solder interface is well under 1°C/W. The printed circuit board also serves as the heatsink.

Standard glass–epoxy 2 oz. boards do not make very good heatsinks because the thin foil has a high thermal resistance. As Figure 5–16 shows, thermal resistance assymtotes to about 20°C/W at 10 square inches of board area, although a point of diminishing returns occurs at about 3 square inches.

Boards are offered that have thick aluminum or copper substrates. A dielectric coating designed for low thermal resistance is overlayed with one or two ounce copper foil for the preparation of printed conductor traces. Tests run on such a product indicate that case to substrate thermal resistance is in the vicinity of 1°C/W, exact values depending upon board type.(7) The substrate may be an effective heatsink itself, or it can be attached to a conventional finned heatsink for improved performance.

Since DPAK and other surface mount packages are designed to be compatible with surface mount assembly techniques, no special precautions are needed other than to insure that maximum temperature/time profiles are not exceeded.

Free Air and Socket Mounting

In applications where average power dissipation is on the order of a watt or so, most power semiconductors may be mounted with little or no heatsinking. The leads of the various metal power packages are not designed to support the packages; their cases must be firmly supported to avoid the possibility of cracked seals around the leads. Many plastic packages may be supported by their leads in applications where high shock and vibration stresses are not encountered and where no heatsink is used. The leads should be as short as possible to increase vibration resistance and reduce thermal resistance. As a general practice however, it is better to support the package. A plastic support for the TO–220 Package and other similar types is offered by heatsink accessory vendors.

In certain situations, in particular where semiconductor testing is required or prototypes are being developed, sockets are desirable. Manufacturers have provided sockets for many of the packages available from Motorola. The user is urged to consult manufacturers' catalogs for specific details. Sockets with Kelvin connections are necessary to obtain accurate voltage readings across semiconductor terminals.

Connecting and Handling Terminals

Pins, leads, and tabs must be handled and connected properly to avoid undue mechanical stress which could cause semiconductor failure. Change in mechanical dimensions as a result of thermal cycling over operating temperature extremes must be considered. Standard metal, plastic, and RF stripline packages each have some special considerations.

Metal Packages

The pins of metal packaged devices using glass to metal seals are not designed to handle any significant bending or stress. If abused, the seals could crack. Wires may be attached using sockets, crimp connectors or solder, provided the data sheet ratings are observed. When wires are attached directly to the pins, flexible or braided leads are recommended in order to provide strain relief.

Plastic Packages

The leads of the plastic packages are somewhat flexible and can be reshaped although this is not a recommended procedure. In many cases, a heatsink can be chosen which makes lead–bending unnecessary. Numerous lead and tab–forming options are available from Motorola on large quantity orders. Preformed leads remove the users risk of device damage caused by bending.

If, however, lead–bending is done by the user, several basic considerations should be observed. When bending the lead, support must be placed between the point of bending and the package. For forming small quantities of units, a pair of pliers may be used to clamp the leads at the case, while bending with the fingers or another pair of pliers. For production quantities, a suitable fixture should be made.

The following rules should be observed to avoid damage to the package.

1. A leadbend radius greater than 1/32 inch for TO–220.
2. No twisting of leads should be done at the case.
3. No axial motion of the lead should be allowed with respect to the case.

The leads of plastic packages are not designed to withstand excessive axial pull. Force in this direction greater than 4 pounds may result in permanent damage to the device. If the mounting arrangement imposes axial stress on the leads, a condition which may be caused by thermal cycling, some method of strain relief should be devised. When wires are used for connections, care should be exercised to assure that movement of the wire does not cause movement of the lead at the lead–to–plastic junctions. Highly flexible or braided wires are good for providing strain relief.

Wire wrapping of the leads is permissible, provided that the lead is restrained between the plastic case and the point of the wrapping. The leads may be soldered; the maximum soldering temperature, however, must not exceed 260°C and must be applied for not more than 5 seconds at a distance greater than 1/8 inch from the plastic case.

Cleaning Circuit Boards

It is important that any solvents or cleaning chemicals used in the process of degreasing or flux removal do not affect the reliability of the devices. Alcohol and unchlorinated freon solvents are generally satisfactory for use with plastic devices, since they do not damage the package. Hydrocarbons such as gasoline and chlorinated freon may cause the encapsulant to swell, possibly damaging the transistor die.

When using an ultrasonic cleaner for cleaning circuit boards, care should be taken with regard to ultrasonic energy and time of application. This is particularly true if any packages are free–standing without support.

Thermal System Evaluation

Assuming that a suitable method of mounting the semiconductor without incurring damage has been achieved, it is important to ascertain whether the junction temperature is within bounds.

In applications where the power dissipated in the semiconductor consists of pulses at a low duty cycle, the instantaneous or peak junction temperature, not average temperature, may be the limiting condition. In this case, use must be made of transient thermal resistance data. For a full explanation of its use, see Motorola Application Note, AN569.

Other applications, notably switches driving highly reactive loads, may create severe current crowding conditions which render the traditional concepts of thermal resistance or transient thermal impedance invalid. In this case, transistor safe operating area, thyristor di/dt limits, or equivalent ratings as applicable, must be observed.

Fortunately, in many applications, a calculation of the average junction temperature is sufficient. It is based on the concept of thermal resistance between the junction and a temperature reference point on the case. (See Appendix A.) A fine wire thermocouple should be used, such as #36 AWG, to determine case temperature. Average operating junction temperature can be computed from the following equation:

$$T_J = T_C + R_{\theta JC} \times P_D$$

where, T_J = junction temperature (°C),
T_C = case temperature (°C),
$R_{\theta JC}$ = thermal resistance junction–to–case as specified on the data sheet (°C/W),
P_D = power dissipated in the device (W).

The difficulty in applying the equation often lies in determining the power dissipation. Two commonly used empirical methods are graphical integration and substitution.

Graphical Integration

Graphical integration may be performed by taking oscilloscope pictures of a complete cycle of the voltage and current waveforms, using a limit device. The pictures should be taken with the temperature stabilized. Corresponding points are then read from each photo at a suitable number of time increments. Each pair of voltage and current values are multiplied together to give instantaneous values of power. The results are plotted on linear graph paper, the number of squares within the curve counted, and the total divided by the number of squares along the time axis. The quotient is the average power dissipation. Oscilloscopes are available to perform these measurements and make the necessary calculations.

Substitution

This method is based upon substituting an easily measurable, smooth dc source for a complex waveform. A switching arrangement is provided which allows operating the load with the device under test, until it stabilizes in temperature. Case temperature is monitored. By throwing the switch to the “test” position, the device under test is connected to a dc power supply, while another pole of the switch supplies the normal power to the load to keep it operating at full power level. The dc supply is adjusted so that the semiconductor case temperature remains approximately constant when the switch is thrown to each position for about 10 seconds. The dc voltage and current values are multiplied together to obtain average power. It is generally necessary that a Kelvin connection be used for the device voltage measurement.

Appendix A
Thermal Resistance Concepts

The basic equation for heat transfer under steady–state conditions is generally written as:

$$q = hA\Delta T \qquad (1)$$

where, q = rate of heat transfer or power dissipation (P_D),

h = heat transfer coefficient,

A = area involved in heat transfer,

ΔT = temperature difference between regions of heat transfer.

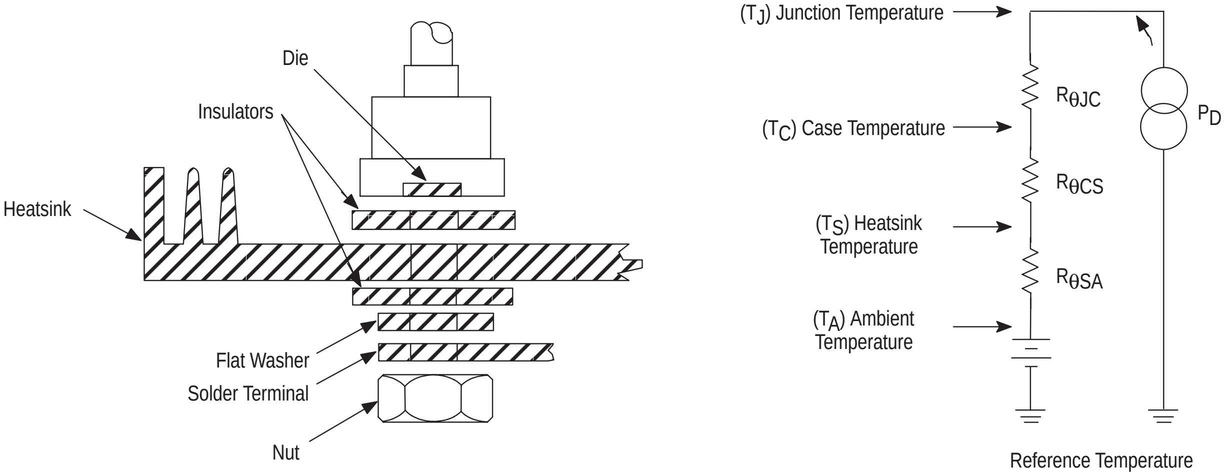
However, electrical engineers generally find it easier to work in terms of thermal resistance, defined as the ratio of temperature to power. From Equation 1, thermal resistance (R_θ) is

$$R_\theta = \Delta T/q = 1/hA \qquad (2)$$

The coefficient (h) depends upon the heat transfer mechanism used and various factors involved in that particular mechanism.

An analogy between Equation 2 and Ohm's Law is often made to form models of heat flow. Note that T could be thought of as a voltage thermal resistance corresponds to electrical resistance (R); and, power (q) is analogous to current (I). This gives rise to a basic thermal resistance model for a semiconductor as indicated by Figure A–1.

Figure A–1. Basic Thermal Resistance Model Showing Thermal to Electrical Analogy for a Semiconductor



The equivalent electrical circuit may be analyzed by using Kirchoff's Law and the following equation results:

$$T_J = P_D(R_{\theta JC} + R_{\theta CS} + R_{\theta SA}) + T_A \qquad (3)$$

where, T_J = junction temperature,

P_D = power dissipation,

$R_{\theta JC}$ = semiconductor thermal resistance (junction–to–case),

$R_{\theta CS}$ = interface thermal resistance (case–to–heatsink),

$R_{\theta SA}$ = heatsink thermal resistance (heatsink–to–ambient),

T_A = ambient temperature.

The thermal resistance junction–to–ambient is the sum of the individual components. Each component must be minimized if the lowest junction temperature is to result.

The value for the interface thermal resistance ($R_{\theta CS}$) may be significant compared to the other thermal resistance terms. A proper mounting procedure can minimize $R_{\theta CS}$.

The thermal resistance of the heatsink is not absolutely constant; its thermal efficiency increases as ambient temperature increases and it is also affected by orientation of the sink. The thermal resistance of the semiconductor is also variable; it is a function of biasing and temperature. Semiconductor thermal resistance specifications are normally at conditions where current density is fairly uniform. In some applications such as in RF power amplifiers and short–pulse applications, current density is not uniform and localized heating in the semiconductor chip will be the controlling factor in determining power handling ability.

Appendix B
Measurement of Interface Thermal Resistance

Measuring the interface thermal resistance $R_{\theta CS}$ appears deceptively simple. All that's apparently needed is a thermocouple on the semiconductor case, a thermocouple on the heatsink, and a means of applying and measuring dc power. However, $R_{\theta CS}$ is proportional to the amount of contact area between the surfaces and consequently is affected by surface flatness and finish and the amount of pressure on the surfaces. The fastening method may also be a factor. In addition, placement of the thermocouples can have a significant influence upon the results. Consequently, values for interface thermal resistance presented by different manufacturers are not in good agreement. Fastening methods and thermocouple locations are considered in this Appendix.

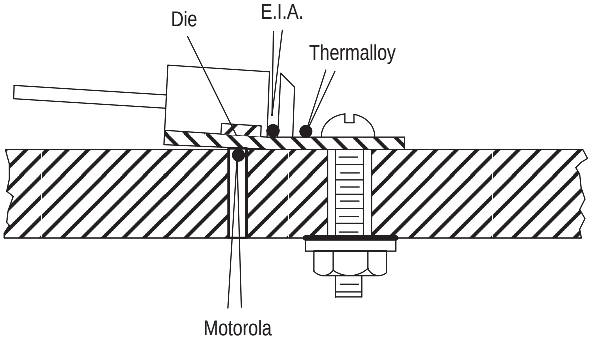
When fastening the test package in place with screws, thermal conduction may take place through the screws, for example, from the flange ear on a TO–204AA package directly to the heatsink. This shunt path yields values which are artificially low for the insulation material and dependent upon screw head contact area and screw material. MIL–I–49456 allows screws to be used in tests for interface thermal resistance probably because it can be argued that this is "application oriented".

Thermalloy takes pains to insulate all possible shunt conduction paths in order to more accurately evaluate insulation materials. The Motorola fixture uses an insulated clamp arrangement to secure the package which also does not provide a conduction path.

As described previously, some packages, such as a TO–220, may be mounted with either a screw through the tab or a clip bearing on the plastic body. These two methods often yield different values for interface thermal resistance. Another discrepancy can occur if the top of the package is exposed to the ambient air where radiation and convection can take place. To avoid this, the package should be covered with insulating foam. It has been estimated that a 15% to 20% error in $R_{\theta CS}$ can be incurred from this source.

Another significant cause for measurement discrepancies is the placement of the thermocouple to measure the semiconductor case temperature. Consider the TO–220 package shown in Figure B–1. The mounting pressure at one end causes the other end — where the die is located — to lift off the mounting surface slightly. To improve contact, Motorola TO–220 Packages are slightly concave. Use of a spreader bar under the screw lessens the lifting, but some is inevitable with a package of this structure.

B–1. JEDEC TO–220 Package Mounted to Heatsink Showing Various Thermocouple Locations and Lifting Caused by Pressure at One End



Three thermocouple locations are shown.

a) The Motorola location is directly under the die reached through a hole in the heatsink. The thermocouple is held in place by a spring which forces the thermocouple into intimate contact with the bottom of the semi's case.

b) The JEDEC location is close to the die on the top surface of the package base reached through a blind hole drilled through the molded body. The thermocouple is swaged in place.

c) The Thermalloy location is on the top portion of the tab between the molded body and the mounting screw. The thermocouple is soldered into position.

Temperatures at the three locations are generally not the same. Consider the situation depicted in Figure B–1. Because the only area of direct contact is around the mounting screw, nearly all the heat travels horizontally along the tab from the die to the contact area. Consequently, the temperature at the JEDEC location is hotter than at the Thermalloy location and the Motorola location is even hotter. Since junction–to–sink thermal resistance must be constant for a given test setup, the calculated junction–to–case thermal resistance values decrease and case–to–sink values increase as the case temperature thermocouple readings become warmer. Thus the choice of reference point for the case temperature is quite important.

There are examples where the relationship between the thermocouple temperatures are different from the previous situation. If a mica washer with grease is installed between the semiconductor package and the heatsink, tightening the screw will not bow the package; instead, the mica will be deformed. The primary heat conduction path is from the die through the mica to the heatsink. In this case, a small temperature drop will exist across the vertical dimension of the package mounting base so that the thermocouple at the EIA location will be the hottest. The thermocouple temperature at the Thermalloy location will be lower but close to the temperature at the EIA location as the lateral heat flow is generally small. The Motorola location will be coolest.

The EIA location is chosen to obtain the highest temperature on the case. It is of significance because power ratings are supposed to be based on this reference point. Unfortunately, the placement of the thermocouple is tedious and leaves the semiconductor in a condition unfit for sale.

The Motorola location is chosen to obtain the highest temperature of the case at a point where, hopefully, the case is making contact to the heatsink. Once the special heatsink to accommodate the thermocouple has been fabricated, this method lends itself to production testing and does not mark the device. However, this location is not easily accessible to the user.

The Thermalloy location is convenient and is often chosen by equipment manufacturers. However, it also blemishes the case and may yield results differing up to 1°C/W for a TO–220 package mounted to a heatsink without thermal grease and no insulator. This error is small when compared to the thermal resistance of heat dissipaters often used with this package, since power dissipation is usually a few watts. When compared to the specified junction–to–case values of some of the higher power semiconductors becoming available, however, the difference becomes significant and it is important that the semiconductor manufacturer and equipment manufacturer use the same reference point.

Another EIA method of establishing reference temperatures utilizes a soft copper washer (thermal grease is used) between the semiconductor package and the heatsink. The washer is flat to within 1.0 mil/inch, has a finish better than 63 µin., and has an imbedded thermocouple near its center. This reference includes the interface resistance under nearly ideal conditions and is therefore application–oriented. It is also easy to use but has not become widely accepted.

A good way to improve confidence in the choice of case reference point is to also test for junction–to–case thermal resistance while testing for interface thermal resistance. If the junction–to–case values remain relatively constant as insulators are changed, torque varied, etc., then the case reference point is satisfactory.

SECTION 6

LINEAR REGULATOR DESIGN EXAMPLE

As an illustration of the use of the material contained in the preceding sections, the following regulator design example is given.

Regulator Performance Requirements:

Output Voltage, $V_O = +10\text{ V} \pm 0.1\text{ V}$
Output Current, $I_O = 1.0\text{ A}$, current limited
Load Regulation, $\leq 0.1\%$ for $I_O = 10\text{ mA}$ to 750 mA
Line Regulation, $\leq 0.1\%$
Output ripple, ≤ 2.0 mVpp
Max Ambient Temperature, $T_A \leq +70°\text{C}$
Supply will have common loads to a negative supply.

1. IC Regulator Selection

Study of the available regulators given in the selection guide reveals that the MC1723C would meet the regulation performance requirements. This regulator must be current boosted to obtain the required 1.0 A output current. A rough cost estimate shows that an MC1723C series pass element combination is the most economical approach.

2. Circuit Configuration

In Section 3, an appropriate circuit configuration is found. This is the MC1723C NPN boost configuration of Figure 3–4A.

3. Determination of Component Values

Using the equations given in Figure 3–4A, the values of C_{ref}, R_1, R_2, R_3 and R_{SC} are determined.

a) C_{ref} is chosen to be 0.1 µF for low noise operation.

b) $R_1 + R_2$ is chosen to be ≈ 10 k.

c) R_2 is then given by: $R_2 \approx \frac{7.0\text{ V}}{V_O}(R_1 + R_2) = 0.7\ (10\text{ k}) = 7.0\text{ k}$

d) Since V_{ref} can vary by as much as ± 5% for the MC1723C, R_2 should be made variable by at least that much, so that V_O can be set to the required value of +10 V ± 0.1 V. R_2 is therefore chosen to consist of a 62 k resistor and a 2.0 k trimpot.

e) $R_1 = 10\text{ k} - R_2 = 10\text{ k} - 7.0\text{ k} = 3.0\text{ k}$

f) $R_{SC} \approx \frac{0.6\text{ V}}{I_{SC}} = \frac{0.6\text{ V}}{1.0\text{ A}} = 0.6\ \Omega$; $0.56\ \Omega$, 1.0 W chosen for R_{SC}.

g) $R_3 = R_1 \,||\, R_2 \cong 2.2\text{ k}$

4. Determination of Input Voltage (V_{in})

There are two basic constraints on the input voltage: 1) the device limits for minimum and maximum V_{in} and, 2) the minimum input–output voltage differential. These limits are found on the device data sheet to be:

$$9.5\text{ V} \le V_{in} \le 40\text{ V and } (V_{in} - V_O) \ge 3.0\text{ V}$$

For the configuration of Figure 3–5A, (V_{in} – V_O) is given by:

$$(V_{in} - V_O) = [V_{in} - (V_O + 2\phi)] \ge 3.0\text{ V, where } \phi = V_{BEon} \approx 0.6\text{ V}$$

Note that (V_{in} – V_O) is defined on the device data sheet to be the differential between the input and output pins. Since the base–emitter junction drops of Q1 and R_{SC} have been added to the circuit, they must be added to the minimum value of (V_{in} – V_O). Therefore,

$$V_{in} \ge V_O + 2\phi + 3.0\text{ V} = 10 + 1.2 + 3$$

$$V_{in} \ge 14.2\text{ V}$$

This condition also satisfies the requirement for a minimum V_{in} of 9.5 V.

In order to simplify the design of the input supply (see Section 8), V_{in} is chosen to be 16 V average with a 3.0 Vpp ripple at full load and up to 25 V at no load. This assures that the input voltage is always above the required minimum value of 14.2 V. Now, the output ripple can be determined. The MC1723C has a typical ripple rejection ratio of –74 db, as given on its data sheet. With an input ripple of 3.0 Vpp, the output ripple would be less than 1.0 mVpp, which meets the regulator output ripple requirements.

5. Selection of the Series Pass Element (Q1)

The transistor type chosen for Q1 must have the following characteristics (see Section 4):

a) $V_{CEO} \ge V_{in(max)}$

b) $I_{C(max)} \ge I_{SC}$

c) $h_{fe} \ge \frac{I_{SC}}{I_O}$ @ $V_{CE} = V_{in} - V_O - \phi$, where $\phi = V_{BEon} \approx 0.6$ V

d) $P_{D(max)} \ge V_{in}, \times I_{SC}$

e) θ_{JC} such to allow practical heatsinking

f) SOA such that it can withstand $V_{CE} = V_{in}$ @ $I_C = I_{SC}$

For this example: $V_{CEO} \ge 25$ V
$I_{C(max)} \ge 1.0$ A
$h_{fe} \ge 25$ @ $V_{CE} = 5.0$ V @ $I_C = 1.0$ A
$P_{D(max)} \ge 16$ W
$\theta_{JC} = 1.52°$C/W
SOA = 1.0 A @ 16 V

A 2N3055 transistor is chosen as a suitable device for Q1 using the selection guide of Section 4 and the transistor data sheets (available from the device manufacturer).

6. Q1 Heatsink Calculation

$$T_J = T_A + P_D\,\theta_{JA} \quad \text{(Equation 15.1 from Section 15)}$$

where, $P_D = V_{in} \times I_{SC}$

$$\theta_{JA} = \theta_{JC} + \theta_{CS} + \theta_{SA} \quad \text{(Equation 6.2)}$$

Solving for θ_{SA}:

$$\theta_{SA} = \left[\frac{T_J - T_A}{P_D}\right] - (\theta_{JC} + \theta_{CS}) \qquad (6.2)$$

From the 2N3055 data sheet, $T_J = 200°C$ and $\theta_{JC} = 1.52°C/W$. The transistor will be mounted with thermal grease directly to the heatsink. Therefore, θ_{CS} is found to be 0.1°C/W from Table 15–1.
Solving for Equation 6.2:

$$\theta_{SA} = \left[\frac{200°C - 70°C}{16\ V \times 1.0\ A}\right] - (1.52 + 0.1)\ °C/W$$

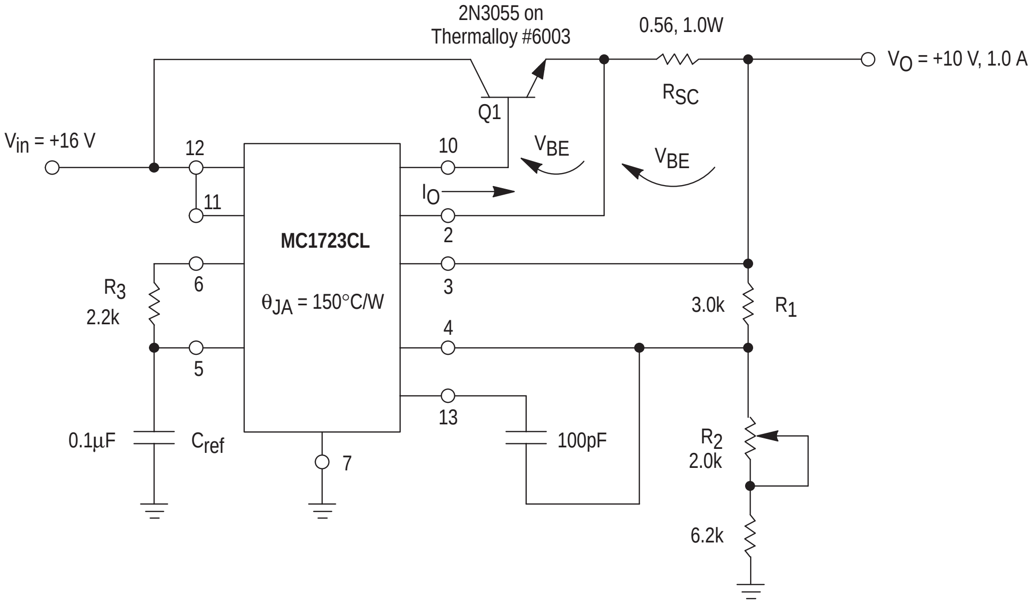
$$\leq 6.6°C/W$$

A commercial heatsink is now chosen from Table 15–2 or one custom designed using the methods given in Section 15. For this example, a Thermalloy #6003 heatsink, having a θ_{CS} of 6.2°C/W, was used.

7. Clamp Diode

Since the regulator can power a load which is also connected to a negative supply, a 1N4001 diode is connected to the output for protection. The complete circuit schematic is shown in Figure 6–1.

Figure 6–1. 10 V, 1.0 A Design Example



8. Construction Input Supply Design

The input supply is now designed using the information contained in Section 8 and the regulator circuit is constructed using the guidelines given in Section 5.

SECTION 7

LINEAR REGULATOR CIRCUIT TROUBLESHOOTING CHECKLIST

Occasionally, the designer's prototype regulator circuit will not operate properly. If problems do occur, the trouble can be traced to a design error in 99.9% of the cases. As a troubleshooting aid to the designer, the following guide is presented.

Of course, it would be difficult, if not impossible, to devise a troubleshooting guide which would cover all possible situations. However, the checklist provided will help the designer pinpoint the problem in the majority of cases. To use the guide, first locate the problem's symptom(s) and then carefully recheck the regulator design in the area indicated using the information contained in the referenced handbook section.

If, after carefully rechecking the circuit, the designer is not successful in resolving the problem, seek assistance from the factory by contacting the nearest Motorola Sales office.

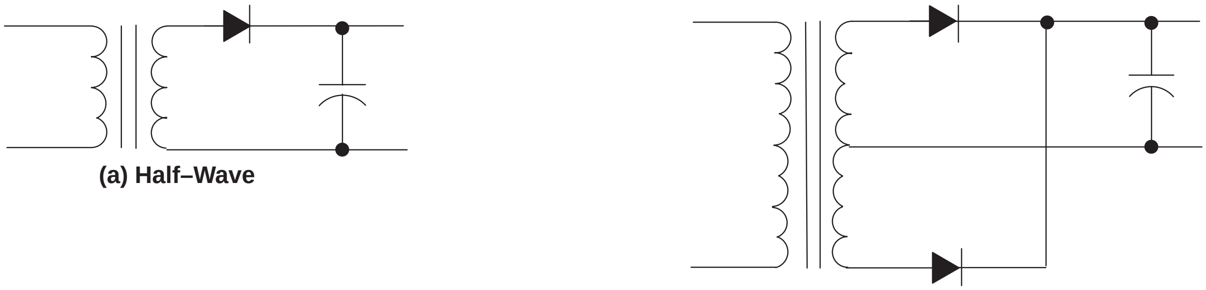
Symptoms	Design Area to Check	Section
Regulator oscillates	1. Layout 2. Compensation capacitor too small 3. Input leads not bypassed 4. External pass element parasitically oscillating	5 3 5 5
Loss of regulation at light loads	1. Emitter–base resistor in "PNP" type boost configuration too large 2. Absence of 1.0 mA ''minimum'' load. (See load regulation test spec on device data sheet) 3. Improper circuit configuration	4 3
Loss of regulation at heavy loads	1. Input voltage too low [$V_{in(min)}$, $\lvert V_{in} - V_O \rvert_{min}$] 2. External pass element gain too low 3. Current limit too low 4. Line resistance between sense points and load 5. Inadequate heatsinking	2, 3 4 3 5 15
IC regulator or pass element fails after warm–up or at high T_A.	1. Inadequate heatsinking 2. Input Voltage Transient $V_{in(max)}$, V_{CEO}	15 2, 4, 5
Pass element fails during short circuit.	1. Insufficient pass element ratings SOA, $I_{C(max)}$ 2. Inadequate heatsinking	4 15
IC regulator fails during short circuit.	1. IC current or SOA capability exceeded 2. Inadequate heatsinking	2
IC regulator fails during power–up	1. Input voltage transient $V_{in(max)}$ 2. IC current or SOA capability exceeded as load (capacitor) is charged up.	2 2
IC regulator fails during power–down.	1. Regulator reverse biased	3
Output voltage does not come up during power–up or after short circuit	1. Out polarity reversal 2. Load has ''latched–up'' in some manner. (Usually seen with op amps, current sources, etc.)	3
Excessive 60 Hz or 120 Hz output ripple	1. Input supply filter capacitor ground loop	5

SECTION 8

DESIGNING THE INPUT SUPPLY

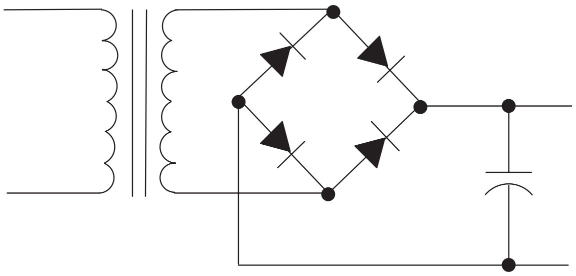
Most input supplies used to power series pass regulator circuits consist of a 60 Hz, single phase step–down transformer followed by a rectifier circuit whose output is smoothed by a choke or capacitor input filter. The type of rectifier circuit used can be either a half–wave, full–wave, or full–wave bridge type, as shown in Figure 8–1. The half–wave circuit is used in low current applications, while the full–wave is preferable in high–current, low output voltage cases. The full–wave bridge is usually used in all other high–current applications.

Figure 8–1. Rectification Schemes



(a) Half–Wave

(b) Full–Wave or Full–Wave Center Tap



(c) Full–Wave Bridge

In this section, specification of the filter capacitor, rectifier and transformer ratings will be discussed. The specifications for the choke input filter will not be considered since the simpler capacitor input type is more commonly used in series regulated circuits. A detailed description of this type of filter can be found in the reference listed at the end of this section.

1. Design of Capacitor–Input Filters

The best practical procedure for the design of capacitor–input filters still remains based on the graphical data presented by Schade(1) in 1943. The curves shown in Figures 8–2 through 8–5 give all the required design information for half–wave and full–wave rectifier circuits. Whereas Schade originally also gave curves for the impedance of vacuum–tube rectifiers, the equivalent values for semiconductor diodes must be substituted. However, the rectifier forward drop often assumes more significance than the dynamic resistance in low–voltage supply applications, as the dynamic resistance can generally be neglected when compared with the sum of the transformer secondary–winding resistance plus the reflected primary–winding resistance. The forward drop may be of considerable importance, however, since it is about 1.0 V, which clearly cannot be ignored in supplies of 12 V or less.

C in Farads
R_L in Ohms
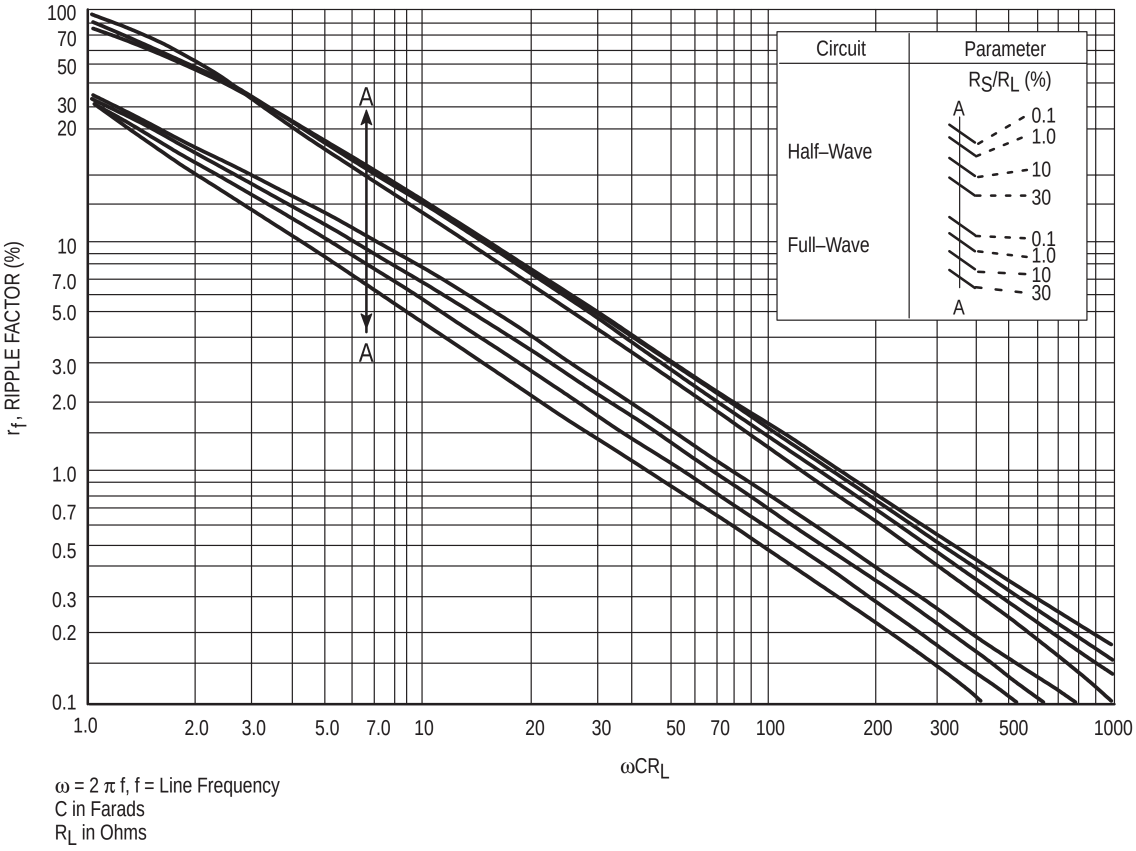
R_S = RMS Equivalent Source Resistance

Figure 8–5. Root–Mean–Square Ripple Voltage for Capacitor–Input Circuits



Returning to the above curves, the full–wave circuit will be considered. Figure 8–3 shows that a circuit must operate with $\omega CR_L \geq 10$ in order to hold the voltage reduction to less than 10% and $\omega CR_L \geq 40$ to obtain less than 2.0% reduction. However, it will also be seen that these voltage reduction figures require R_S/R_L, where R_S is now the total series resistance, to be about 0.1% which, if attainable, causes repetitive peak–to–average current ratios from 10 to 17 respectively, as can be seen from Figure 8–4. These ratios can be satisfied by many diodes; however, they may not be able to tolerate the turn–on surge current generated when the input–filter capacitor is discharged and the transformer primary is energized at the peak of the input waveform. The rectifier is then required to pass a surge current determined by the peak secondary voltage less the rectifier forward drop and limited only by the series resistance R_S. In order to control this turn–on surge, additional resistance must often be provided in series with each rectifier. It becomes evident, then, that a compromise must be made between voltage reduction on the one hand and diode surge rating and hence average current–carrying capacity on the other hand. If small voltage reduction, that is good voltage regulation, is required, a much larger diode is necessary than that demanded by the average current rating.

Surge Current

The capacitor–input filter allows a large surge to develop, because the reactance of the transformer leakage inductance is rather small. The maximum instantaneous surge current is approximately V_M/R_S and the capacitor charges with a time constant $\tau \approx R_S C_1$. As a rough — but conservative — check, the surge will not damage the diode if V_M/R_S is less than the diode I_{FSM} rating and τ is less than 8.3 ms. It is wise to make R_S as large as possible and not pursue tight voltage regulation; therefore, not only will the surge be reduced but rectifier and transformer ratings will more nearly approach the DC power requirements of the supply.

2. Design Procedure

A) From the regulator circuit design (see Section 6), we know:

$V_{C(DC)}$ = the required full load average dc output voltage of the capacitor input filter
$V_{Ripple(pp)}$ = the maximum no load peak–to–peak ripple voltage
V_m = the maximum no load output voltage
I_O = the full–load filter output current
f = the input ac line frequency

B) From Figure 8–5, we can determine a range of minimum capacitor values to obtain sufficient ripple attenuation. First determine r_f:

$$r_f = \frac{V_{Ripple(pp)}}{2\sqrt{2}\,V_{C(DC)}} \times 100\% \qquad (8.1)$$

A range for ωCR_L can now be found from Figure 8–5.

C) Next, determine the range of R_S/R_L from Figure 8–2 or 8–3 using $V_{C(DC)}$ and the values for ωCR_L found in part B. If the range of ωCR_L values initially determined from Figure 8–5 is above $\simeq 10$, R_S/R_L can be found from Figures 8–2 and 8–3 using the lowest ωCR_L value. Otherwise, several iterations between Figures 8–2 or 8–3 and 8–5 may be necessary before an exact solution for R_S/R_L and ωCR_L for a given r_f and $V_{C(DC)}/V_m$ can be found.

D) Once ωCR_L is found, the value of the filter capacitor (C) can be determined from:

$$C = \frac{\omega CR_L}{2\pi f\left(\dfrac{V_{C(DC)}}{I_O}\right)} \qquad (8.2)$$

E) The rectifier requirements may now be determined:

1. Average current per diode;

$I_{F(avg)}$ = I_O for half–wave rectification (8.3)
= $I_O/2$ for full–wave rectification

2. RMS and Peak repetitive rectifier current ratings can be determined from Figure 8–4.
3. The rectifier PIV rating is 2 V_m for the half–wave and full–wave circuits, V_m for the full wave bridge circuit. In addition, a minimum safety margin of 20% to 50% is advisable due to the possibility of line transients.
4. Maximum surge current, $I_{surge} = V_m/(R_S + ESR)$ (8.4)
where, ESR = minimum equivalent series resistance of filter capacitor from its data sheet.

F) Transformer Specification

1. Secondary leg RMS voltage, $V_S = \{V_m + (n)\ 1.0\}/\sqrt{2}$ (8.5)
where; n = 1 for half–wave and full–wave
n = 2 for full–wave bridge
2. Total resistance of secondary and any external resistors to be equal to R_S found from Figures 8–2, 8–3, and 8–4 (see Part C).
3. Secondary RMS current; half–wave = I_{rms}
full–wave = I_{rms} (8.6)
full–wave bridge = $\sqrt{2}\ I_{rms}$
where, I_{rms} = rms rectifier current (from part E.1 and E.2).
4. Transformer VA rating; half–wave = $V_S\ I_{rms}$
full–wave = $2\ V_S\ I_{rms}$ (8.7)
full–wave bridge = $V_S\ I_{rms}(\sqrt{2})$
where, I_{rms} = rms rectifier current (from part E.1 and E.2) and,
V_S = secondary leg RMS voltage.

3. Design Example

A) Find the values for the filter capacitor, transformer rectifier ratings, given Full–Wave Bridge Rectification;

$$\begin{aligned} V_{C(DC)} &= 16\text{ V} \\ V_{Ripple(pp)} &= 3.0\text{ V} \\ V_M &= 25\text{ V} \\ I_O &= 1.0\text{ A} \\ f &= 60\text{ Hz} \end{aligned}$$

B) Using Equation (8.1),

$$r_f = \frac{3}{2\sqrt{2}\,(16)} \times 100\% = 6.6\%$$

from Figure 8.5, $\omega CR_L \simeq 7$ to 15

C) Using $\omega CR_L = 10$, R_S/R_L is found from Figure 8–3 using,

$$\frac{V_{C(DC)}}{V_M} = \frac{16}{25} = 0.64 = 64\%$$

$$R_S/R_L = 20\% \text{ or } R_S = 0.2 \times R_L = 0.2\left(\frac{V_{C(DC)}}{I_O}\right) = 0.2\,(16)$$

$$R_S = 3.2\ \Omega$$

D) From Equation (8.2), the filter capacitor size is found:

$$C = \frac{\omega CR_L}{2\pi f\left(\frac{V_{C(DC)}}{I_O}\right)} = \frac{10}{2\pi f(60)16} = 1658\ \mu\text{F}$$

E) The rectifier ratings are now specified:

1. $I_{F(avg)} = I_O/2 = 0.5$ A from Equation (8.3)
2. $I_{F(rms)} = 2 \times I_{F(AVG)} = 1.0$ A from Figure 8–4
3. $I_{F(Peak)} = 5.2 \times I_{F(AVG)} = 2.6$ A from Figure 8–4
4. PIV = V_M = 25 V (use 50 V for safety margin)
5. $I_{surge} = V_M/(R_S + ESR) \simeq 25/3.2 = 7.8$ A from Equation (8.4), neglecting capacitor ESR.

F) The transformer should have the following ratings:

1. $V_S = \{V_M + n(1.0)\}/\sqrt{2} = (25 + 2)/\sqrt{2} = 19$ VRMS {from Equation (8.5)}
2. Secondary Resistance should be 3.2 Ω
3. Secondary RMS current rating should be 1.4 A, (from Equation (8.6)).
4. From Equation (8.7), the transformer should have a 27 VA rating.

It should be noted that, in order to simplify the procedure, the above design does not allow for line voltage variations or component tolerances. The designer should take these factors into account when designing his input supply. Typical tolerances would be: line voltage = +10% to –15% and filter capacitors = +75% to –10%.

SECTION 9

AN INTRODUCTION TO SWITCHING POWER SUPPLIES

The Switching Power Supply continues to increase in popularity and is one of the fastest growing markets in the world of power conversion. Its performance and size advantages meet the needs of today's modern and compact electronic equipment and the increasing variety of components directed at these applications makes new designs even more practical.

This guide is intended to provide the designer with an overview of the more popular inverter circuits, their basic theory of operation, and some of the subtle characteristics involved in selecting a circuit and the appropriate components. Also included are valuable design tips on both the major passive and active components needed for a successful design. Finally, a complete set of selector guides to Motorola's Switchmode components is provided which gives a detailed listing of the industry's most comprehensive line of semiconductor products for switching power supplies.

Comparison with Linear Regulators

The primary advantages of a switching power supply are efficiency, size,and weight. It is also a more complex design, cannot meet some of the performance capabilities of linear supplies and generates a considerable amount of electrical noise. However switchers are being accepted in the industry, particularly where size and efficiency are of prime importance. Performance continues to improve and for most applications they are usually cost competitive down to the 20 W power level.

In the past the switcher's advantage versus the linear regulator was in the high power arena where passive components such as transformers and filters were small compared to the linear regulator at the same power level. However, active component count was high and tended to make the switcher less cost effective at low power levels. In recent years, Switchers have been significantly cost reduced because designers have been able to simplify the control circuits with new, cost effective integrated circuits and have found even lower cost alternatives in the passive component area.

A performance comparison chart of switching versus linear supplies is shown in Table 9–1. Switcher efficiencies run from 70% to 80% but occasionally fall to (60% to 65%) when linear post regulators are used for the auxiliary outputs. Some linear power supplies on the other hand, are operated with up to 50% efficiency but these are areas where line variations or hold–up time problems are minimal. Most linears operate with typical efficiencies of only 30%. The overall size reduction of a 20 kHz switcher is about 4:1 and newer designs in the 100 kHz to 200 kHz region end up at about 8:1 (versus a linear). Other characteristics such as static regulation specs are comparable, while ripple and load transient response are usually worse. Output noise specs can be somewhat misleading. Very often a 500 mV switching spike at the output may be attenuated considerably at the load itself due to the series inductance of the connecting cables and the additional filter capacitors found in many logic circuits. In the future, the noise generated at higher switching frequencies (100 kHz to 500 kHz) will probably be easier to filter and the transient response will be faster. Hold–up time is greater for switchers because it is easier to store energy in high voltage capacitors (200 V to 400 V) than in the lower voltage (20 V to 50 V) filter capacitors common to linear power supplies. This is due to the fact that the physical size of a capacitor is dependent on its CV product while energy storage is proportional to CV^2.

Table 9–1. 20 kHz Switcher versus Linear Performance

Parameter	Switcher	Linear
Efficiency	75%	30%
Size	2.0 W/in^3	0.5 W/in^3
Weight	40 W/lb	10 W/lb
Line and Load Regulation	0.1%	0.1%
Output Ripple V_{pp}	50 mV	5.0 mV
Noise V_{pp}	50 mV to 200 mV	—
Transient Response	1.0 ms	20 µs
Hold–Up Time	20 ms to 30 ms	1.0 ms to 2.0 ms

Basic Configurations

A switching power supply is a relatively complex circuit as is shown by the four basic building blocks of Figure 9–1. It is apparent here that the heart of the supply is really the high frequency inverter. It is here that the work of chopping the rectified line at a high frequency (20 kHz to 200 kHz) is done. It is here also that the line voltage is transformed down to the correct output level for use by logic or other electronic circuits. The remaining blocks support this basic function. The 60 Hz input line is rectified and filtered by one block and after the inverter steps this voltage down, the output is again rectified and filtered by another. The task of regulating the output voltage is left to the control circuit which closes the loop from the output to the inverter. Most control circuits generate a fixed frequency internally and utilize pulse width modulation techniques to implement the desired regulation. Basically, the on–time of the square wave drive to the inverter is controlled by the output voltage. As load is removed or input voltage increases,the slight rise in output voltage will signal the control circuit to deliver shorter pulses to the inverter and conversely as the load is increased or input voltage decreases, wider pulses will be fed to the inverter.

The inverter configurations used in today's switchers actually evolved from the buck and boost circuits shown in Figures 9–2a and 9–2b. In each case the regulating means and loop analysis will remain the same but a transformer is added in order to provide electrical isolation between the line and load. The forward converter family which includes the push–pull and half bridge circuits evolved from the buck regulator (Figure 9–2a). And the newest switcher, the flyback converter, actually evolved from the boost regulator. The buck circuit interrupts the line and provides a variable pulse width square wave to a simple averaging LC filter. In this case, the first order approximation of the output voltage is $V_{out} = V_{in} \times$ duty cycle and regulation is accomplished by simply varying the duty cycle. This is satisfactory for most analysis work and only the transformer turns ratio will have to be adjusted slightly to compensate for IR drops, diode drops, and transistor saturation voltages.

Operation of the boost circuit is more subtle in that it first stores energy in a choke and then delivers this energy plus the input line to the load. However, the flyback regulators which evolved from this configuration delivers only the energy stored in the choke to the load. This method of operation is actually based on the buck boost model shown in Figure 9–2c. Here, when the switch is opened, only the stored inductive energy is delivered to the load. The true boost circuit can also regulate by stepping up (or boosting) the input voltage whereas the buck–boost or flyback regulator can step the input voltage up or down. Analysis of the boost regulator begins by dealing with the choke as an energy storage element which delivers a fixed amount of power to the load: $P_O = 1/2\ L\ If_O$ where, I = the peak choke current; $f_O =$ the operating frequency; and, L = the inductance.

Because it delivers a fixed amount of power to the load regardless of load impedance (except for short circuits), the boost regulator is the designer's first choice in photoflash and capacitive–discharge (CD) automotive ignition circuits to recharge the capacitive load. It also makes a good battery charger. For an electronic circuit load, however, the load resistance must be known in order to determine the output voltage:

$$V_O = \sqrt{P_O R_L} = I \sqrt{\frac{L f_O R_L}{2}} \quad \text{where, } R_L = \text{the load resistance.}$$

In this case, the choke current is proportional to the on–time or duty cycle of the switch and regulation for fixed loads simply involves varying the duty cycle as before. However, the output also depends on the load which was not the case with buck regulators and results in a variation of loop gain with load.

Figure 9–1. Functional Block Diagram — Switching Power Supply

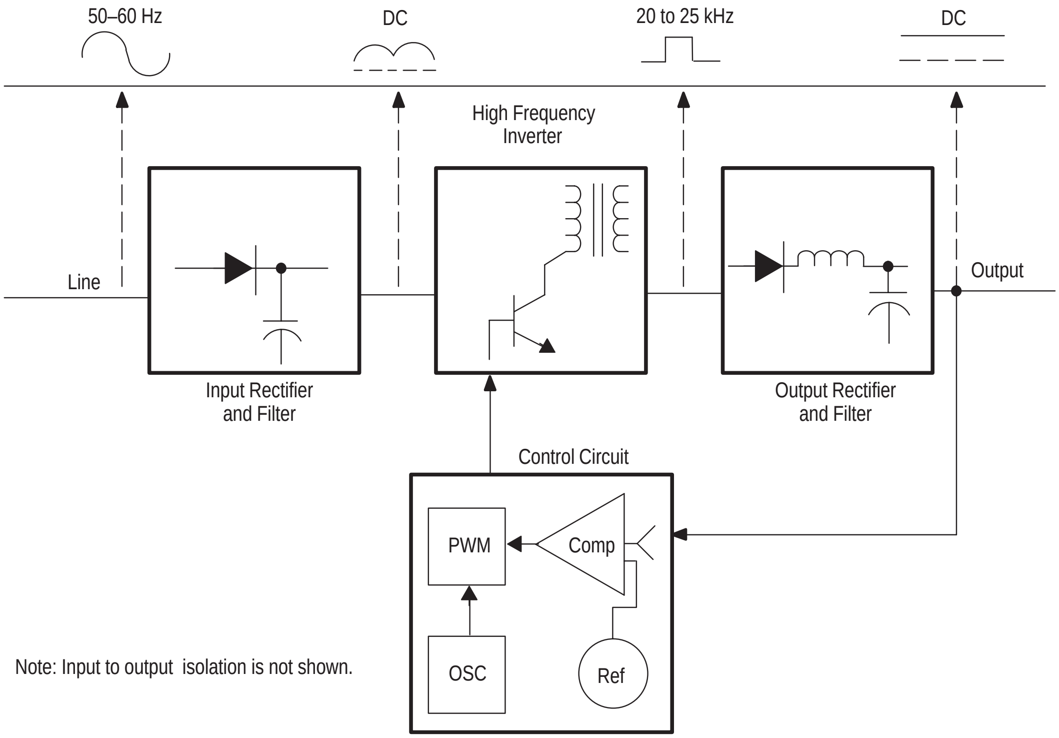

Figure 9–2. Nonisolated DC–DC Converters

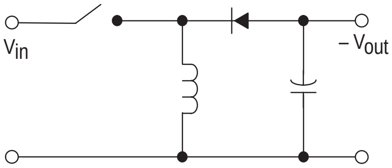
(a) Buck (Step–Down)

(b) Boost (Step–Up)



(c) Buck–Boost Regulator
which Resembles the Flyback Regulator
(Step–Up or Down)

For both regulators, transient response or responses to step changes in load are very difficult to analyze. They lead to what is termed a “load dump” problem. This requires that energy already stored in the choke or filter be provided with a place to go when load is abruptly removed. Practical solutions to this problem include limiting the minimum load and using the right amount of filter capacitance to give the regulator time to respond to this change.

The Future

The future offers a lot of growth potential for switchers in general and low power switchers (20 W to 100 W) in particular. The latter are responding to the growth in microprocessor based equipment as well as computer peripherals. Today’s configurations have already been challenged by the sine wave inverter which reduces noise and improves transistor reliability but does effect a cost penalty. Also, a trend to higher switching frequencies to reduce size and cost even further has begun. The latest bipolar designs operate efficiently up to 100 kHz and the FET seems destined to own the 200 kHz to 500 kHz range.

At this time there are a lot of safety and noise specifications. Originally governed only by MIL specs and the VDE in Europe, now both UL and the FCC have released a set of specifications that apply to electronic systems which often include switchers (see Table 9–2). It seems probable, however, that system engineers or power supply designers will be able to add the necessary line filters and EMI shields without evoking a significant cost penalty in the design.

The most optimistic note concerning switchers is in the component area. Switching power supply components have actually evolved from components used in similar applications. And it is very likely that newer and more mature products specifically for switchers will continue to appear over the next several years. The ultimate effect of this evolution will be to further simplify, cost reduce and increase the reliability of these designs.

Table 9–2. SMPS Specifications

Specification	Area
UL 478, VDE 0730, VDE 0806	Safety
VDE 0871, VDE 0875	EMI
MIL–STD–217D	Reliability
MIL–STD–461A	EMI
DOD–STD–1399	Harmonic Content
FCC Class A & B	EMI
CSA C22.2, IEC 380	Safety

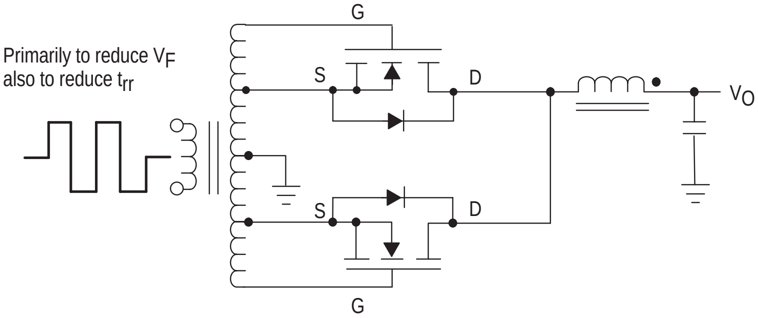
The synchronous rectifier is one example of a new component developed specifically for low voltage switchers. As requirements for 2.0 V and 3.0 V supplies emerge for use by fine geometry VLSI chips, the only way to maintain decent conversion efficiency is to develop lower forward drop rectifiers. The differences in 3.0 V and 5.0 V rectifier requirements are shown in Table 9–3. At this time, Motorola offers low V_F Schottky and area efficient TMOS III FETs for this task and is considering a variety of additional technology options. The direct approach involves using low V_F Schottkys or pinch rectifiers which will feature V_Fs of 0.3 V to 0.4 V. The indirect approach involves using FETs or bipolar transistors and slightly more complex circuitry like that shown in Figure 9–3. Both transistors will feature V_Fs of 0.2 V and, in addition, the bipolar will have high EBOs (30 V) and high gain (100) with a recovery time of 100 ns.

And for designers who are not satisfied with the relatively low frequency limitations of square wave switchers, there is the SRPS. The series resonant power supply topology seems to offer the possibility of working in the 1.0 MHz region. If components like the relatively exotic power transformer can be cost reduced, then it will be possible for this topology to become dominant in the market. The features generally associated with this type of power supply are listed in Table 9–4 and a typical half bridge circuit is shown in Figure 9–4. In a design now being studied in Motorola’s advanced products laboratory, standard FETs, Schottkys and ultrafast rectifiers all appear to work very well at 1.0 MHz.

Table 9–3. Synchronous Rectifier Requirements

Output Voltage	Rectifier Characteristics	
	V_F	V_R
5.0 V	0.5 V–1.0 V	30 V–60 V
3.0 V	0.3 V–0.6 V	20 V–40 V

Figure 9–3. Synchronous Rectifiers for 3.0 V Power Supplies

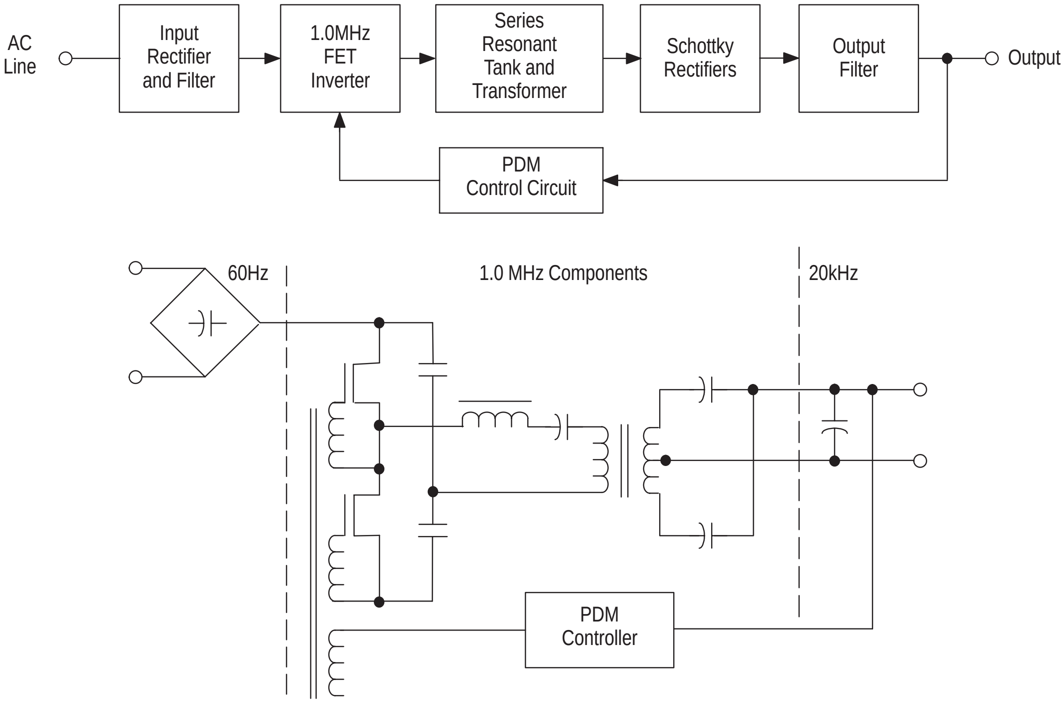


Note: The FET must be operated below V_F of the diode in order to gain the t_{rr} advantage.

Table 9–4. SRPS Features

Feature	Description
High Frequency	Today's line operated designs use sine waves in the 500 kHz to 1.0 MHz range.
Small Size	The ferrite transformer and polypropylene coupling capacitor are smaller than those found in lower frequency square wave designs.
Low Noise	Switching occurs at zero crossings which reduces component stress and lowers EMI.
Efficient	Because switching losses are reduced, efficiency is high (typically 80%).
High Peak to Average Current Ratios	Current ratings of the transistors and rectifiers are twice as high as similar flyback designs.
Special Control Circuit	PDM (density) rather than PWM (width) control is used and requires a control IC with a programmable VCO.
Market	The SRPS is expected to own 15% of the power supply market by 1990.

Figure 9–4. SRPS Block Diagram



SECTION 10

SWITCHING REGULATOR TOPOLOGIES

FET and Bipolar Drive Considerations

There are probably as many base drive circuits for bipolars as there are designers. Ideally, the transistor would like just enough forward drive (current) to stay in or near saturation and reverse drive that varies with the amount of stored base charge such as a low impedance reverse voltage. Many of today's common drive circuits are shown in Figure 10–1. The fixed drive circuits of Figure 10(a), (b) and (c) tend to emphasize economy, while the Baker clamp and proportional drive circuits of Figure 10(d) and (e) emphasize performance over cost.

FET drive circuits are another alternative. The standard that has evolved at this time is shown in Figure 10–2A. This transformer coupled circuit will produce forward and reverse voltages applied to the FET gate which vary with the duty cycle as shown. For this example, a V_{GS} rating of 20 V would be adequate for the worst case condition of high logic supply (12 V) and minimum duty cycle. And yet, minimum gate drive levels of 10 V are still available with duty cycles up to 50%. If wide variations in duty cycle are anticipated, it might be wise to consider using a semi–regulated logic supply for these situations. Finally, one point that is not obvious when looking at the circuit is that FETs can be directly coupled to many ICs with only 100 mA of sink and source capability and still switch efficiently at 20 kHz. However, to achieve switching efficiently at higher frequencies, 1.0 A to 2.0 A of drive may be required on a pulsed basis in order to quickly charge and discharge the gate capacitances. A simple example will serve to illustrate this point and also show that the Miller effect, produced by C_{DG}, is the predominant speed limitation when switching high voltages (see Figure 10–2B). A FET responds instantaneously to changes in gate voltage and will begin to conduct when the threshold is reached (V_{GS} = 2.0 V to 3.0 V) and be fully on with V_{GS} = 7.0 V to 8.0 V. Gate waveforms will show a porch at a point just above the threshold voltage which varies in duration depending on the amount of drive current available and this determines both the rise and fall times for the drain current.

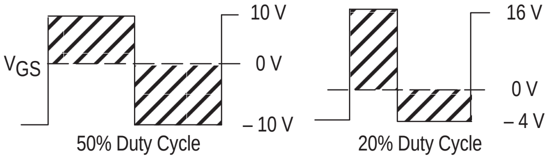
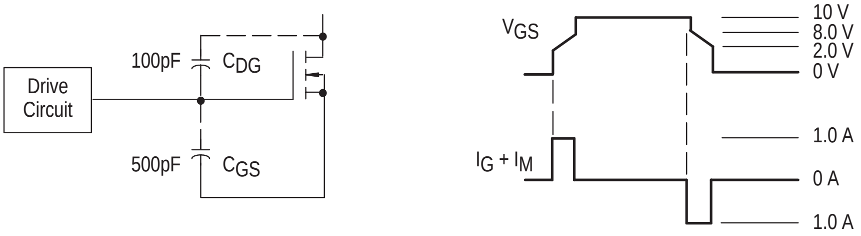
Wave Forms



V_{GS} Wave Forms

Figure 10–2B. FET Drive Current Requirements



1. Miller Current for 30 ns:
$I_M = C_{DG}\ dv/dt$
$= 100\ pF \times \frac{300\ V}{30\ ns} = 1.0\ A$

2. Gate Cap Current for 30 ns:
$I_G = C_{GS}\ dv/dt$
$= 500\ pF \times \frac{6.0\ V}{30\ ns} = 0.1\ A$

To estimate drive current requirements, two simple calculations with gate capacitances can be made:

1. $I_M = C_{DG} dv/dt$ and,
2. $I_G = C_{GS} dv/dt$

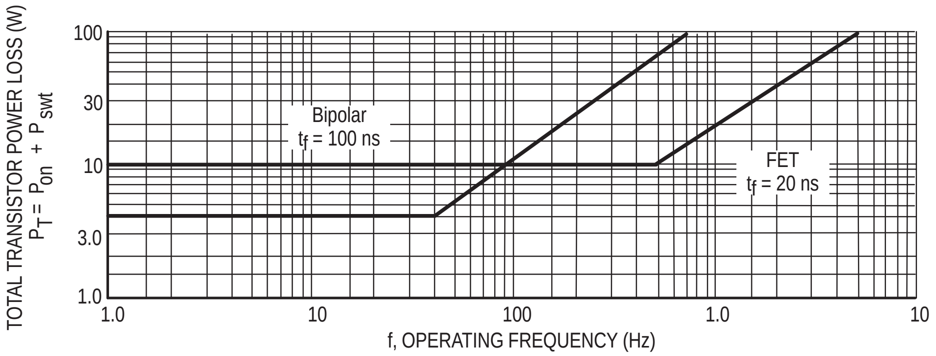
I_M is the current required by the Miller Effect to charge the drain–to–gate capacitance at the rate it is desired to move the drain voltage (and current). And I_G is usually the lesser amount of current required to charge the gate–to–source capacitance through the linear region (2.0 V to 8.0 V). As an example, if 30 ns switching times are desired at 300 V, where C_{DG} = 100 pF and C_{GS} = 500 pF, then:

1. I_M = 100 pF × 300 V/30 ns = 1.0 A and,
2. I_G = 500 pF × 6.0 V/30 ns = 0.1 A

This example shows the direct proportion of drive current capability to speed and also illustrates that for most devices, C_{DG} will have the greatest effect on switching speed and that C_{GS} is important only in estimating turn–on and turn–off delays.

Aside from its unique drive requirements, a FET is very similar to a bipolar transistor. Today’s 400 V FETs compete with bipolar transistors in many switching applications. They are faster and easier to drive, but do cost more and have higher saturation, or more accurately, “on” voltages. The performance or efficiency tradeoffs are analyzed using Figure 10–3, where typical power losses for switching transistors versus frequency are shown. The FET (and bipolar) losses were calculated at 100°C rather than 25°C because on resistance and switching times are highest here and 100°C is typical of many applications. These curves are asymptotes of the actual device performance, but are useful in establishing the “breakpoint” of various devices, which is the point where saturation and switching losses are equal.

Figure 10–3. Typical Switching Losses at 300 V and 5.0 A (T_J = 100°C)



Control Circuits

Over the years, a variety of control ICs for SMPS have been introduced. The voltage mode controllers diagramed in Table 10–1 still dominate this market. The basic regulating function is performed in the pulse width modulator (PWM) section. Here, the dc feedback signal is compared to a fixed frequency sawtooth waveform. The result is a variable duty cycle pulse train which, with suitable buffer or interface circuits, can be used to drive the power switching transistor. Some ICs provide only a single output while others provide a phase splitter or flip–flop to alternately pulse two output channels. Additionally, most ICs provide an error amplifier and reference section shown as a means to process, compare and amplify the feedback signal.

Features required by a control IC vary to some extent because of the particular needs of a designer and on the circuit configuration chosen. However, most of today's current generation ICs have evolved with the following capabilities or features:

- Programmable (to 500 kHz) Fixed Frequency Oscillator
- Linear PWM Section with Duty Cycle from 0% to 100%
- On Board Error Amplifiers
- On Board Reference Regulator
- Adjustable Deadtime
- Under Voltage (low V_{CC}) Inhibit
- Good Output Drive (100 mA to 200 mA)
- Option of Single or Dual Channel Output
- Uncommitted Output Collector and Emitter or Totem Pole Drive Configuration
- Soft–Start
- Digital Current Limiting
- Oscillator Sync Capability

It is primarily the cost differences in these parts that determine whether all or only part of these features will be incorporated. Most of these are evident to the designer who has already started comparing competitive device data sheets.

In addition to the control circuits listed in Table 10–2, Motorola also has two dc converter control chips, the µA78S40 and the MC34063A. These chips feature an on–board 40 V, 2.0 A switching transistor and operate by dropping pulses from a fixed frequency, fixed duty cycle oscillator depending on load demand.

Today there is a demand for simple, low cost, single control ICs. These ICs, like Motorola's MC34060A and MC34063A components, are used to run the low–power flyback type configurations and are usually part of a three chip rather than a single chip system. The differences in these two approaches are illustrated in Figure 10–6.

When it is necessary to drive two or more power transistors, drive transformers are a practical interface element and are driven by the conventional dual channel ICs. In the case of a single transistor converter, however, it is usually more cost effective to directly drive the transistor from the IC. In this situation, an optocoupler is commonly used to couple the feedback signal from the output back to this control IC. And the error amplifier in this case is nothing more than a programmable zener like Motorola's TL431.

Overvoltage Protection

Linear and switching power supplies can be protected from overvoltage with a crowbar circuit. For linear supplies, the pass transistor can fail shorted, allowing high line transformer voltage to the load. For switching power supplies, a loose or disconnected remote sense lead can allow high voltage to the load.

Table 10–1. Basic SM Control ICs

Control Technique	Type A Voltage Mode	Type B Voltage Mode w/Latch	Type C Current Mode
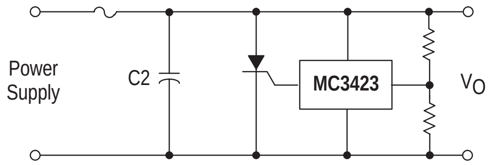
Schematic			Single Channel Parts	MC34060A	—	UC3842 MC34129
Dual Channel Parts	TL494/594	SG3525A/27A SG3526	—
Features	Low Cost	Digital Current Limiting, Good Noise Immunity	Designed for Flyback, Inherent Feed Forward
PWM Waveforms **Output**			
Table 10–2. Control Circuits

Overvoltage Protection (OVP)		Over/Undervoltage Protection (O/UVP)	Undervoltage Sense MPU/MCU Reset
Standard	**High Performance**		
TL431	MC3423 TL431A	MC3425 MC34161	MC34064–5 MC34164–3 MC34164–5

The list of available circuits is shown in Table 10–2 and a typical 0 V application is shown in Figure 10–4. This crowbar circuit ignores noise spikes but will fire the SCR when a valid overvoltage condition is detected. The SCR will discharge C2 and either blow the fuse or cause the power supply to shut down.

Figure 10–4. Crowbar Circuit



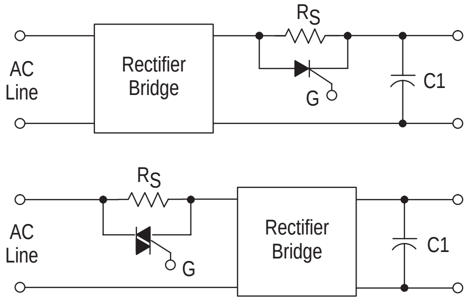
For further information, see the MC3423 data sheet.

Surge Current Protection

Many high current PWM switching supplies operate directly off the ac line. They have very large capacitive input filters with high inrush surge currents. The line circuit breaker and the rectifier bridge must be protected during turn–on.

Surge current limiting can be accomplished by adding R_S and an SCR short after charging C1, as shown in Figure 10–5, or by phase controlling the line voltage with a Triac.

Figure 10–5. Surge Current Limiting for a Switching Power Supply



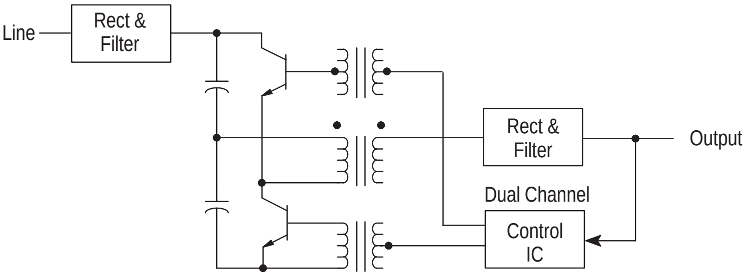
Transformer Design

With respect to transformer design, many of today’s designers would say don’t try it. They’d advise using a consultant or winding house to perform this task and with good reason. It takes quite a bit of time to develop a feel for this craft and be able to use both experience and intuition to find solutions to second and third order problems. Because of these subtle problems, most designers find that after the first paper design is done, as many as four or five lab iterations may be necessary before the transformer meets the design goals. However, there is a considerable design challenge in this area and a great deal of satisfaction can be obtained by mastering it.

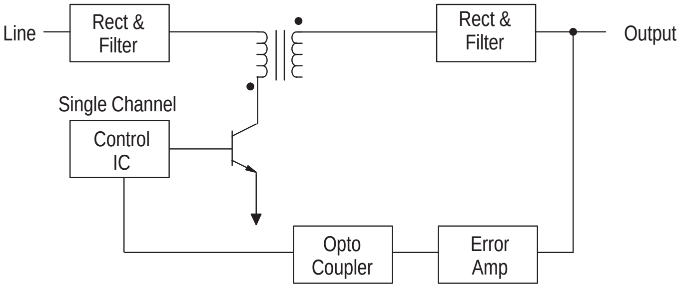
This component design, as do all others, begins by requesting all available literature from the appropriate manufacturers and then following this up with phone calls when specific questions arise. A partial list of companies is shown in Table 10–3. Designs below 20 W generally use pot cores, but for 20 W and above, E cores are preferred. E cores expose the windings to air so that heat is not trapped inside and make it easier to bring out connections for several windings. Remember that flyback designs require lower permeability cores than the others. The classic approach is to consult manufacturers charts like the one shown in Figure 10–8 and then to pick a core with the required power handling ability. Both E and EC (E cores with a round center leg) are popular now and they are available from several manufacturers. EC cores offer a performance advantage (better coupling) but standard E cores cost less and are also used in these applications. Another approach that seems to work equally well is to do a paper design of the estimated windings and turns required. Size the wire for 500 circular mils (CM) per amp and then find a core that has the required window area for this design. Now, before the windings are put on, it is a good idea to modify the turns so that they fit on one layer or an integral number of layers on that bobbin. This involves checking the turns per inch of the wire against the bobbin length. The primary generally goes on first and then the secondaries. If the primary hangs over an extra half layer, try reducing the turns or the wire size. Conversely, if the secondary does not take up a full layer, try bifilar winding (parallel) using wire half the size originally chosen (i.e., 3 wire sizes smaller, like 23 versus 20). This technique ultimately results in the use of foil for the higher current (20 A) low voltage windings. Most windings can be separated with 3 mil mylar (yellow) tape but for good isolation, cloth is recommended between primary and secondary.

Finally, once a mechanical fit has been obtained, it is time for the circuit tests. The isolation voltage rating is strictly a mechanical problem and is one of the reasons why cloth is preferred over tape between the primary and secondary. The inductance and saturating current level of the primary are inherent to the design, and should be checked in the circuit or other suitable test fixture. Such a fixture is shown in Figure 10–7 where the transistor and diode are sized to handle the anticipated currents. The pulse generator is run at a low enough duty cycle to allow the core to reset. Pulse width is increased until the start of saturation is observed (I_{sat}). Inductance is found using $L = E/(di/dt)$.

Figure 10–6. Control Circuit Topologies



(a) Single Chip System — Drive Transformer Isolation



(b) Three Chip System — Opto Coupler Isolation

In forward converters, the transformer generally has no gap in order to minimize the magnetizing current (I_M). For these applications the core should be chosen large enough so that the resulting LI product insures that I_M at operating voltages is less than I_{sat}. For flyback designs, a gap is necessary and the test circuit is useful again to evaluate the effect of the gap. The gap will normally be quite large, Lg > > L_m/u,

where, Lg = gap length
L_m = magnetic path length, and
u = permeability.

Under this stipulation, the gap directly controls the LI parameters and doubling it will decrease L by two and increase I_{sat} by two until fringing effects occur. Gaps of 5 mils to 20 mils are common. Again, the anticipated switching currents must be less than I_{sat} when the core is gapped for the correct inductance.

Table 10–3. Partial List of Core (C) and Transformer (T) Manufacturers

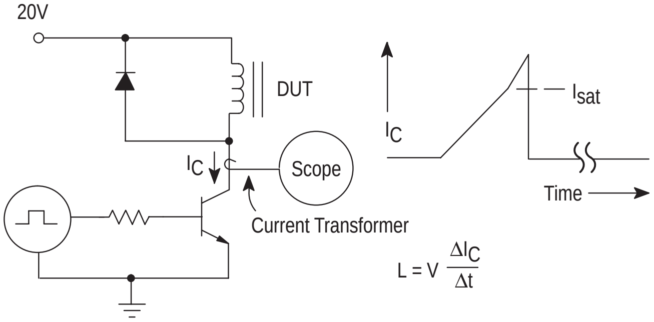
Company	Location	Code
Ferroxcube Inc.	Sauggerties, NY	C
Indiana General	Keasby, NJ	C
Stackpole	St. Marys, PA	C
TDK	El Segundo, CA	C
Pulse Engineering	San Diego, CA	T
Coilcraft	Cary, IL	T

Transformer tests in the actual supply are usually done with a high voltage dc power supply on the primary and with a pulse generator or other manual control for the pulse width (such as using the control IC in the open loop configuration). Here the designer must recheck three areas:

1. Core saturation
2. Correct amount of secondary voltage
3. Transformer heat rise

If problems are detected in any of these areas, the ultimate fix may be to redesign using the next larger core size. However, if problems are minimal, or none exist, it is possible to stay with the same core or even consider using the next smaller size.

Figure 10–7. Simple Coil Tester



Filter Capacitor Considerations

In today’s 20 kHz switchers, aluminum electrolytics still predominate. The good news is that most have been characterized, improved, and cost reduced for this application. The input filter requires a voltage rating that depends on the peak line voltage; i.e., 400 V to 450 V for a 220 V switcher. If voltage is increased beyond this point, the capacitor will begin to act like a zener and be thermally destroyed from high leakage currents if the rating is exceeded for enough time. In doubler circuits, voltage sharing of the two capacitors in series can be a problem. Here extra voltage capability may be needed to make up for the imbalances caused by different values of capacitance and leakage current. A bleeder resistor is normally used here not only for safety but to mask the differences in leakage current. The RMS current rating is also an important consideration for input capacitors and is an example of improvements offered by today’s manufacturers. Earlier “lytics” usually lacked this rating and often overheated. Large capacitors that were not needed for performance were used just to reduce this heating. However, today’s devices offer lower thermal resistance, improved connection to the foil and good RMS ratings. A partial list of manufacturers that supply both high voltage input and the lower voltage output capacitors for switchers is shown in Table 10–4. Most of the companies offer not only the standard 85°C components, but devices with up to 125°C ratings which are required because of the high ambient temperatures (55° to 85°C) that many switchers have to operate in, many times without the benefit of fans.

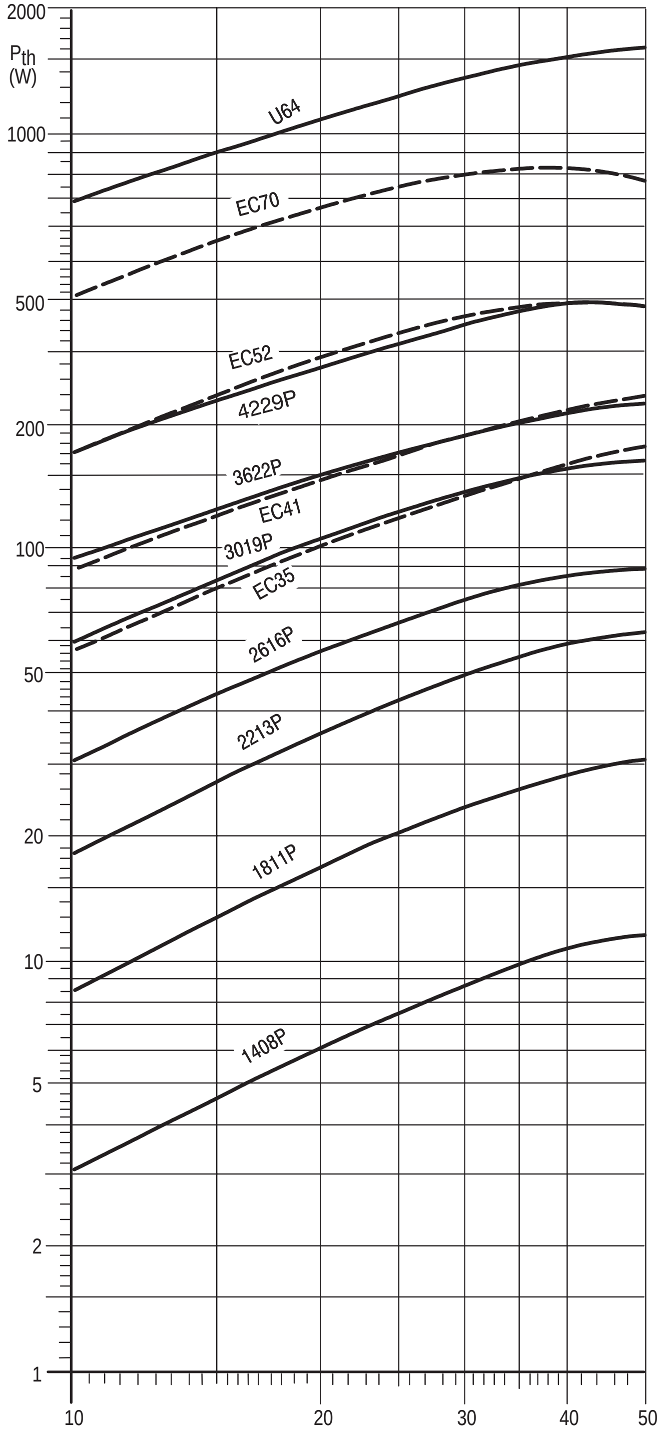
Table 10–4. Partial List of Capacitor Companies

Company (U.S.)	Location
MEPCO/Electra	Columbia, SC
Cornell–Dublier	Sanford, NC
Sangamo	Pickens, SC
Mallory	Indianapolis, IN

For output capacitors the buzz word is low ESR (equivalent series resistance). It turns out that for most capacitors even in the so–called “low ESR” series, the output ripple depends more on this resistance than on the capacitor value itself. Although typical and maximum ESR ratings are now available on most capacitors designed for switchers, the lead inductance generally is not specified except for the ultra–high frequency four terminal capacitors from some vendors. This parameter is responsible for the relatively high switching spikes that appear at the output. However, at this point in time, most designers find it less costly and more effective to add a high frequency noise filter rather than use a relatively expensive capacitor with low equivalent series inductance (ESL).

These LC noise or spike filters are made using small powdered iron toroids (1/2″ to 1″ OD) with distributed windings to minimize interwinding capacitance. And the output is bypassed using a small 0.1 µF ceramic or a 10 µF to 50 µF tantalum or both. Larger powered iron toroids are often used in the main LC output filter although the higher permeability ferrite EC and E cores with relatively large gaps can also be used. Calculations for the size of this component should take into account the minimum load so that the choke will not run “dry” as stated earlier.

Figure 10–8. Core Selection for Bridge Configurations (Reprinted from Ferroxcube Design Manual)



Note: Power handling decreases by a factor of 2 in forward and by 4 in flyback configurations.

SECTION 11

SWITCHING REGULATOR COMPONENT DESIGN TIPS

Transistors

The initial selection of a transistor for a switcher is basically a problem of finding the one with voltage and current capabilities that are compatible with the application. For the final choice performance and cost tradeoffs among devices from the same or several manufacturers have to be weighed. Before these devices can be put in the circuit, both protective and drive circuits will have to be designed.

Motorola's first line of devices for switchers were trademarked “Switchmode” transistors and introduced in the early 70's with data sheets that provided all the information that a designer would need including reverse bias safe operating area (RBSOA) and performance at elevated temperature (100°C). The first series was the 2N6542 through 2N6547, TO–204 (TO–3) and was followed by the MJE13002 through MJE13009 series in a plastic TO–220 package. Finally, high voltage (1.0 kV) requirements were met by the metal MJ8500 thru MJ8505 series and the plastic MJE8500 series. The Switchmode II series is an advanced version of Switchmode I that features faster switching. Switchmode III is a state of the art bipolar with exceptional speed, RBSOA, and up to 1.5 kV blocking capacity. Here, device cost is somewhat higher, but system costs may be lowered because of reduced snubber requirements and higher operating frequencies. A similar argument applies to Motorola TMOS Power FETs. These devices make it possible to switch efficiently at higher frequencies (200 kHz to 500 kHz) but the main selling point is that they are easier to drive. This latter point is the one most often made to show that systems savings are again quite possible even though the initial device cost is higher.

Table 11–1. Motorola High Voltage Switching Transistor Technologies

Family	Typical Device	Typical Fall Time	Approximate Switching Frequency
SWITCHMODE I	2N6545 MJE13005 MJE12007	200 ns to 500 ns	20 k
SWITCHMODE II	MJ13081	100 ns	100 k
SWITCHMODE III	MJ16010	50 ns	200 k
TMOS	MTP5N40	20 ns	500 k

Table 11–2 is a chart of the transistor voltage requirements for the various off–line converter circuits. As illustrated, the most stringent requirement for single transistor circuits (flyback and forward) is the blocking or V_{CEV} rating. Bridge circuits, on the other hand, turn on and off from the dc bus and their most critical voltage is the turn–on or $V_{CEO(sus)}$ rating.

Table 11–2. Power Transistor Voltage Chart

Line Voltage	Circuit			
	Flyback, Forward or Push–Pull		Half or Full–Bridge	
	V_{CEV}	$V_{CEO(sus)}$	$V_{CEO(sus)}$	V_{CEV}
220 120	850 kV to 1.0 kV 450	450 250	450 250	450 250

Most switchmode transistor load lines are inductive during turn–on and turn–off. Turn–on is generally inductive because the short circuit created by output rectifier reverse recovery times is isolated by leakage inductance in the transformer. This inductance effectively snubs most turn–on load lines so that the rectifier recovery (or short circuit) current and the input voltage are not applied simultaneously to the transistor. Sometimes primary interwinding capacitance presents a small current spike but usually turn–on transients are not a problem. Turn–off transients due to this same leakage inductance, however, are almost always a problem. In bridge circuits, clamp diodes can be used to limit these voltage spikes. If the resulting inductive load line exceeds the transistor's reverse bias switching capability (RBSOA) then an RC network may also be added across the primary to absorb some of this transient energy. The time constant of this network should equal the anticipated switching time of the transistor (50 ns to 500 ns). Resistance values of 100 Ω to 1000 Ω in this RC network are generally appropriate. Trial and error will indicate how low the resistor has to be to provide the correct amount of snubbing. For single transistor converters, the circuits shown in Figure 11–1 are generally used.

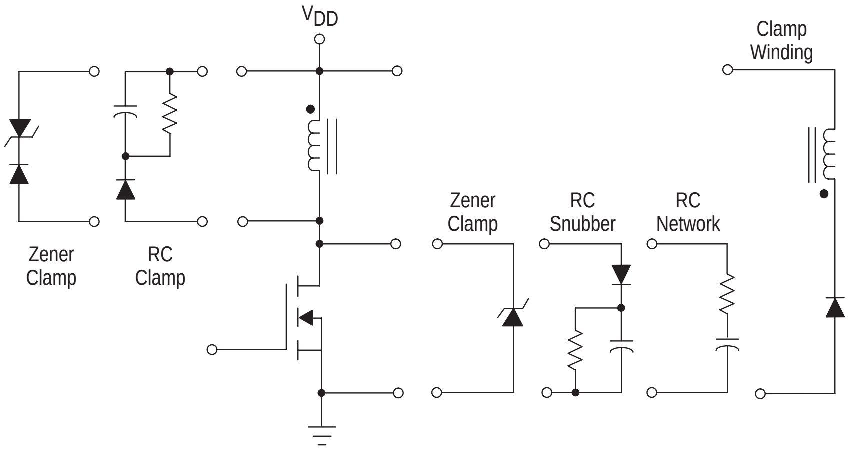
Here slightly different criteria are used to define the R and C snubber values:

$$C = \frac{I\,t_f}{V}$$

where; I = the peak switching current
t_f = the transistor fall time
V = the peak switching voltage (Approximately twice the DC bus)
also, R = t_{on}/C (it is not necessary to completely discharge this capacitor in order to obtain the desired effects of this circuit)
where, t_{on} = the minimum on–time or pulse width
and, $P_R = \dfrac{CV^2f}{2}$
where, P_R = the power rating of the resistor
and, f = the operating frequency.

In most of today's designs snubber elements are small or nonexistent and voltage spikes from energy left in the leakage inductance a more critical problem depending on how good the coupling is between the primary and clamp windings and how fast the clamp diode turns on. FETs often have to be slowed down to prevent self destruction from this spike.

Figure 11–1. Protection Circuits for Switching Transistors



Zener and Mosorb Transient Suppressors

If necessary, protection from voltage spikes may be obtained by adding a zener and rectifier across the primary as shown in Figure 11–1. Here Motorola's 5.0 W zener lines with ratings up to 200 V, and 10 W TO–220 Mosorbs with ratings up to 250 V can provide the clamping or spike limiting function. If the zener must handle most of the power, its size can be estimated using:

$$PZ = \frac{L_L I^2 f}{2}$$

where, P_Z = the zener power rating
and, L_L = the leakage inductance (measured with the clamp winding or secondary shorted)
I = peak collector current
f = operating frequency

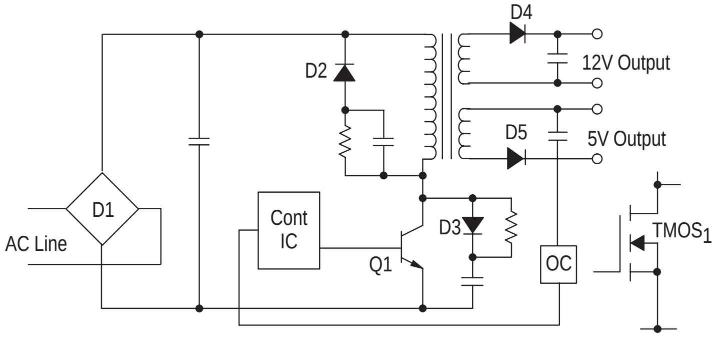
Distinction is sometimes made between devices trademarked Mosorb (by Motorola, Inc.), and standard zener/avalanche diodes used for reference, low–level regulation and low–level protection purposes. It must be emphasized that Mosorb devices are, in fact, zener diodes. The basic semiconductor technology and processing are identical. The primary difference is in the applications for which they are designed. Mosorb devices are intended specifically for transient protection purposes and are designed, therefore, with a large effective junction area that provides high pulse power capability while minimizing the total silicon use. Thus, Mosorb pulse power ratings begin at 600 W — well in excess of low power conventional zener diodes which in many cases do not even include pulse power ratings among their specifications.

MOVs, like Mosorbs, do have the pulse power capabilities for transient suppression. They are metal oxide varistors (not semiconductors) that exhibit bidirectional avalanche characteristics, similar to those of back–to–back connected zeners. The main attributes of such devices are low manufacturing cost, the ability to absorb high energy surges (up to 600 joules) and symmetrical bidirectional "breakdown" characteristics. Major disadvantages are: high clamping factor, an internal wear–out mechanism and an absence of low–end voltage capability. These limitations restrict the use of MOVs primarily to the protection of insensitive electronic components against high energy transients in applications above 20 V, whereas, Mosorbs are best suited for precise protection of sensitive equipment even in the low voltage range the same range covered by conventional zener diodes.

Rectifiers

Once components for the inverter section of a switcher have been chosen, it is time to determine how to get power into and out of this section. This is where the all–important rectifier comes into play. (See Figure 11–2.) The input rectifier is generally a standard recovery bridge that operates off the ac line and into a capacitive filter. For the output section, most designers use Schottkys for efficient rectification of the low voltage, 5.0 V output windings and for the higher voltage, 12 V to 15 V outputs, the more economical fast recovery or ultrafast diodes are used.

Figure 11–2. Switchmode Power Supply Flyback or Boost Design



D1 — Bridge Rectifier — Line Voltage
D2 — Clamp Diode — HV/Fast–Ultrafast
D3 — Snubber Diode — HV/Fast–Ultrafast
D4 — Output Rectifier — Fast/Ultrafast
D5 — Output Rectifier — Schottky

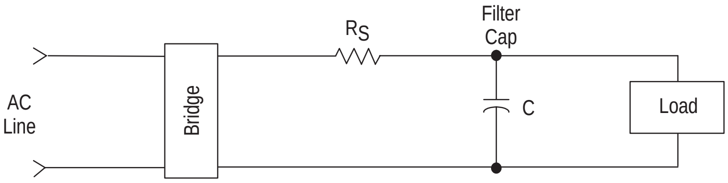
For the process of choosing an input rectifier, it is useful to visualize the circuit shown in Figure 11–3. To reduce cost, most earlier approaches of using choke input filters, soft start relays (Triacs), or SCRs to bypass a large limiting resistor have been abandoned in favor of using small limiting resistors or thermistors and a large bridge. The bridge must be able to withstand the surge currents that exist from repetitive starts at peak line. The procedure for finding the right component and checking its fit is as follows:

1. Choose a rectifier with 2 to 5 times the average I_O required.
2. Estimate the peak surge current (I_P) and time (t) using:

$$I_P = \frac{1.4\ V_{in}}{R_S} \qquad t = R_S C$$

Where V_{in} is the RMS input voltage; R_S is the total series resistance; and C is the filter capacitor size.

Figure 11–3. Choosing Input Rectifiers



3. Compare this current pulse to the sub cycle surge current rating (I_S) of the diode itself. If the curve of I_S versus time is not given on the data sheet, the approximate value for I_S at a particular pulse width (t) may be calculated knowing:
   - I_{FSM} — the single cycle (8.3 ms) surge current rating and using.
   - $I^2 \sqrt{t} = K$, which applies when the diode temperature rise is controlled by its thermal response as well as power (i.e., $T = K'P \sqrt{t}$ for t < 8.0 ms).

   This gives:

$$I_S{}^2 \sqrt{t} = I^2{}_{FSM} \sqrt{8.3\ ms} \quad \text{or,} \quad I_S = I_{FSM} \left(\frac{8.3\ ms}{t}\right)^{1/4} \text{, t is in milliseconds.}$$

4. If $I_S < I_P$, consider either increasing the limiting resistor (R_S) or utilizing a larger diode.

In the output section where high frequency rectifiers are needed, there are several types available to the designer. In addition to the Schottky (SBR) and fast recovery (FR), there is also an ultrafast recovery (UFR). Comparative performance for devices with similar current ratings is shown in Table 11–3. The obvious point here is that lower forward voltage improves efficiency and lower recovery times reduce turn–on losses in the switching transistors, but the tradeoff is higher cost. As stated earlier, Schottkys are generally used for 5.0 V outputs and fast recovery and ultrafast devices for 12 V outputs and greater. The ultrafast is competing both with the Schottky where higher breakdown is needed and with the fast recovery in those applications where performance is more important than cost. Ten years ago Schottkys were very fragile and could fail short from either excessive dv/dt (1.0 V to 5.0 V per nanosecond) or reverse avalanche. Since that time, Motorola has incorporated a “guard ring” or internal zener which minimizes these earlier problems and reduces the need for RC snubbers and other external protective networks.

Table 11–3. Motorola Rectifier Product Portfolio

Parameter	Schottky	Ultrafast	Fast Recovery	Standard Recovery
Forward Voltage (V_F)	0.5 V to 0.6 V	0.9 V to 1.0 V	1.2 V to 1.4 V	1.2 V to 1.4 V
Reverse Recovery Time (t_{rr})	<10 ns	25 ns to 100 ns	150 ns	1.0 μs
t_{rr} Form	Soft	Soft	Soft	Soft
DC Blocking Voltage (V_R)	20 V to 60 V	50 V to 1000 V	50 V to 1000 V	50 V to 1000 V
Cost Ratio	3:1	3:1	2:1	1:1

SECTION 12

BASIC SWITCHING POWER SUPPLY CONFIGURATIONS

The implementation of switching power supplies by the non–specialist is becoming increasingly easy due to the availability of power devices and control ICs especially developed for this purpose by the semiconductor manufacturer.

This section is meant to help in the preliminary selection of the devices required for the implementation of the listed switching power supplies.

Flyback and Forward Converter Switching Power Supplies (50 W to 250 W)

- Input line variation: V_{in} + 10%, – 20%
- Converter efficiency: $\eta = 80\%$
- Output regulation by duty cycle (δ variation: $\delta_{(max)} = 0.4$)
- Maximum Transistor working current:

$$I_W = \frac{2.0\ P_{out}}{\eta \times \delta_{(max)} \times V_{in(min)} \times \sqrt{2}} = \frac{5.5\ P_{out}}{V_{in}} \quad \text{(Flyback)}$$

$$= \frac{P_{out}}{\eta \times \delta_{(max)} \times V_{in(min)} \times \sqrt{2}} = \frac{2.25\ P_{out}}{V_{in}} \quad \text{(Forward)}$$

- Maximum transistor working voltage: $V_W = 2 \times V_{in(max)} \times \sqrt{2}$ + guardband
- Working frequency: f = 20 kHz to 200 kHz

Basic Flyback Configuration

Flyback and Forward Converters

To take advantage of the regulating techniques discussed earlier and also provide isolation, a total of seven popular configurations have evolved and are listed below. Each circuit has a practical power range or capability associated with it as follows:

Circuit	Power Range	Parts Cost
DC Converter	5.0 W	$ 4.00
Converter w/30 V Transformer	10 W	7.00
Blocking OSC	20 W	10.00
Flyback	50 W	15.00
Forward	100 W	20.00
Half–Bridge	200 W	30.00
Full–Bridge	500 W	75.00

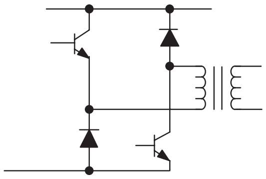
First to be discussed will be the low power (20 W to 200 W) converters which are dominated by the single transistor circuits shown in Figure 12–1. All of these circuits operate the magnetic element in the unipolar rather than bipolar mode. This means that transformer size is sacrificed for circuit simplicity.

The flyback (alternately known as the “ringing choke”) regulator stores energy in the primary winding and dumps it into the secondary windings, see Figure 12–1(a). A clamp winding is usually present to allow energy stored in the leakage reactance to return safely to the line instead of avalanching the switching transistor. The operating model for this circuit is the buck–boost discussed earlier. The flyback is the lowest cost regulator because output filter chokes are not required since the output capacitors feed from a current source rather than a voltage source. It does have higher output ripple than the forward converters because of this. However, it is an excellent choice when multiple output voltages are required and does tend to provide better cross regulation than the other types. In other words changing the load on one winding will have little effect on the output voltage of the others.

Figure 12–1. Low Power Popular (20 to 200 W) Converter Configurations

(a) Flyback (Clamp Winding is Optional)

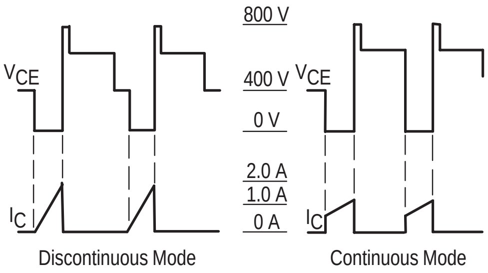
(b) Forward (Clamp Winding is Necessary)



(c) Two Transistor Forward or Flyback
(Clamp Winding is not Needed)

A 120/220 Vac flyback design requires transistors that block twice the peak line plus transients or about 1.0 kV. Motorola’s MJE13000 and 16000A series with ratings of 750 V to 1000 V are normally used here. These bipolar devices are relatively fast (100 ns) and are typically used in the 20 kHz to 50 kHz operating frequency range. The recent availability of 900 V and 1000 V TMOS FETs allows designers to operate in the next higher range (50 kHz to 80 kHz) and some have even gone as high as 300 kHz with square wave designs and FETs. Faster 1.0 kV bipolar transistors are also planned in the future and will provide another design alternative. The two transistor variations of this circuit, Figure 12–1(c), eliminate the clamp winding and add a transistor and diode to effectively clamp peak transistor voltages to the line. With this circuit a designer can use the faster 400 V to 500 V FET transistors and push operating frequencies considerably higher. There is a cost penalty here over the single transistor circuit due to the extra transistor, diodes and gate drive circuitry.

Figure 12–2. Flyback Transistor Waveforms

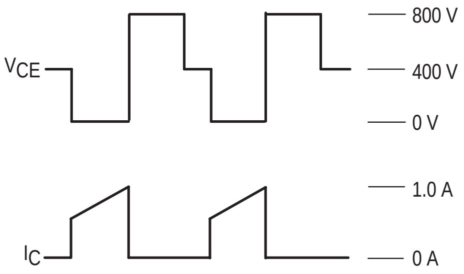


A subtle variation in the method of operation can be applied to the flyback regulator. The difference is referred to as operation in the discontinuous or continuous mode and the waveform diagrams are shown in Figure 12–2. The analysis given in the earlier section on boost regulators dealt strictly with the discontinuous mode where all the energy is dumped from the choke before the transistor turns on again. If the transistor is turned on while energy is still being dumped into the load, the circuit is operating in the continuous mode. This is generally an advantage for the transistor in that it needs to switch only half as much peak current in order to deliver the same power to the load. In many instances, the same transformer transformer may be used with only the gap reduced to provide more inductance. Sometimes the core size will need to be increased to support the higher LI product (2 to 4 times) now required because the inductance must increase by almost 10 times to effectively reduce the peak current by two. In dealing with the continuous mode, it should also be noted that the transistor must now turn on from 500 V to 600 V rather than 400 V level because there no longer is any deadtime to allow the flyback voltage to settle back down in the input voltage level. Generally, it is advisable to have $V_{CEO(sus)}$ ratings comparable to the turn–on requirements except for SMIII where turn–on up to V_{CEV} is permitted.

The flyback converter stands out from the others in its need for a low inductance, high current primary. Conventional E and pot core ferrites are difficult to work with because their permeability is too high even with relatively large gaps (50 to 100 milli–inches). The industry needs something better that will provide permeabilities of 60 to 120 instead of 2000 to 3000 for this application.

The single transistor forward converter is shown in Figure 12–1(b). Although it initially appears very similar to the flyback, it is not. The operating model for this circuit is actually the buck regulator discussed earlier. Instead of storing energy in the transformer and then delivering it to the load, this circuit uses the transformer in the active or forward mode and delivers power to the load while the transistor is on. The additional output rectifier is used as a freewheeling diode for the LC filter and the third winding is actually a reset winding. It generally has the same turns as the primary, (is usually bifilar wound) and does clamp the reset voltage to twice the line. However, its main function is to return energy stored in the magnetizing inductance to the line and thereby reset the core after each cycle of operation. Because it takes the same time to set and reset the core, the duty cycle of this circuit cannot exceed 50%. This also is a very popular low power converter and like the flyback is practically immune from transformer saturation problems. Transistor waveforms shown in Figure 12–3 illustrate that the voltage requirements are identical to the flyback. For the single transistor versions, 400 V turn–on and 1.0 kV blocking devices like the MJE13000 and MJE16000 transistors are required. The two transistor circuit variations shown in Figure 12–1(b) again adds a cost penalty but allows a designer to use the faster 400 V to 500 V devices. With this circuit, operation in the discontinuous mode refers to the time when the load is reduced to a point where the filter choke runs “dry.” This means that choke current starts at and returns to zero during each cycle of operation. Most designers prefer to avoid this type of mode because of higher ripple and noise even though there are no adverse effects on the components themselves. Standard ferrite cores work fine here and in the high power converters as well. In these applications, no gap is used as the high permeability (3000) results in the desirable effect of very low magnetizing current levels. And, zeners or RC clamps may be used to reset the core in lieu of the clamp winding to lower the voltage stress on the switching transistors.

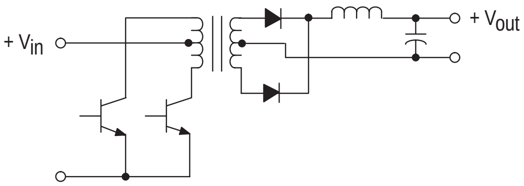
Figure 12–3. Forward Converter Transistor Waveforms



Push–Pull and Bridge Converters

The high power circuits shown in Figures 12–4 to 12–7 all operate the magnetic element in the bipolar or push–pull mode and require 2 to 4 inverter transistors. Because the transformers operate in this mode they tend to be almost half the size of the equivalent single transistor converters and thereby provide a cost advantage over their counterparts at power levels of 200 kW to 1.0 kW.

Figure 12–4. Push–Pull Converter (200 W to 1.0 kW)



The push–pull converter shown in Figure 12–4 is one of the oldest converter circuits around. Its early use was in low voltage inverters such as the 12 Vdc to 120 Vdc power source for recreational vehicles and in dc to dc converters. Because these converters are free running rather than driven and operate from low voltages, transformer saturation problems are minimal. In the high voltage off–line switchers, saturation problems are common and were difficult to solve. The transistors are also subjected to twice the peak line voltage which requires the use of high voltage (1.0 kV) transistors. Both of these drawbacks have tended to discourage designers of off–line switchers from using this configuration until current mode control ICs were introduced. Now these circuits are being looked at with renewed interest.

Push–Pull Switching Power Supplies (100 W to 500 W)

- Input line variation: V_{in} + 10%, – 20%
- Converter efficiency: η = 80%
- Output regulation by duty cycle (δ) variation: $\delta_{(max)} = 0.8$
- Maximum transistor working current:

$$I_W = \frac{P_{out}}{\eta \times \delta_{(max)} \times V_{in(min)} \times \sqrt{2}} = \frac{1.4\ P_{out}}{V_{in}}$$

- Maximum transistor working voltage: $V_W = 2 \times V_{in(max)} \times \sqrt{2}$ + guardband
- Working frequency: f = 20 kHz to 200 kHz

Basic Push–Pull Configuration

Half and Full–Bridge

The most popular high power converter is the half–bridge (Figure 12–6). It has two clear advantages over the push–pull and became the favorite rather quickly. First, the transistors never see more than the peak line voltage and the standard 400 V fast switchmode transistors that are readily available may be used. And second, and probably even more important, transformer saturation problems are easily minimized by use of a small coupling capacitor (about 2.0 µF to 5.0 µF) as shown above. Because the primary winding is driven in both directions, a full–wave output filter, rather than half, is now used and the core is actually utilized more effectively. Another more subtle advantage of this circuit is that the input filter capacitors are placed in series across the rectified 220 V line which allows them to be used as the voltage doubler elements on a 120 V line. This still allows the inverter transformer to operate from a nominal 320 V bus when the circuit is connected to either 120 V or 220 V. Finally, this topology allows diode clamps across each transistor to contain destructive switching transients. The designer's dream, of course, is for fast transistors that can handle a clamped inductive load line at rated current. And a few (like the MJE16000 series from Motorola) are beginning to appear on the market. With the improved RBSOA that these transistors feature, less snubbing is required and this improves both the cost and efficiency of these designs.

*More than one device per leg, matched.

The effective current limit of today's low cost TO–218 discrete transistors (250 mil die) is somewhere in the 10 A to 20 A area. Once this limit is reached, the designer generally changes to the full–bridge configurations shown in Figure 12–7. Because full line rather than half is applied to the primary winding, the power out can be almost double that of the half–bridge with the same switching transistors. Power Darlington transistors are a logical choice for higher power control with current, voltage and speed capabilities allowing very high performance and cost effective designs. Another variation of the half–bridge is the split winding circuit, shown in Figure 12–5. A diode clamp can protect the lower transistor but a snubber or zener clamp must still be used to protect the top transistor from switching transients. Because both emitters are at an ac ground point, expensive drive transformers can now be replaced by lower cost capacitively–coupled drive circuits.

SECTION 13

SWITCHING REGULATOR DESIGN EXAMPLES

In addition to the application materials in this data book, Motorola publishes several application notes which contain basic information on the design of power supplies using a variety of Motorola Analog ICs. AN920 describes in detail the principles of operation of the MC34063A and µA78S40 Switching Regulator Subsystems. Several converter design examples and numerous applications circuits with test data are included in this application note. The circuit techniques described in this note are also applicable to the MC34163 and MC34165 Power Switching Regulators.

Operating details of the MC34129 Current Mode Switching Regulator Controller, and examples of its use with Motorola SENSEFET™ products, are provided in AN976. The application note AN983 focuses on a 400 W half-bridge power supply design which uses the TL494 PWM control circuit. The TL594 can be used in this same application.

Essentially all of the data sheets for newer power supply control and supervisory circuits include extensive applications information with test conditions and performance results. Many data sheets also include printed circuit board layouts for some key applications so that the designer can evaluate the integrated circuits in an actual power supply. This data book presents all data sheets in their entirety so that the applications information is readily available for each device.

SECTION 14

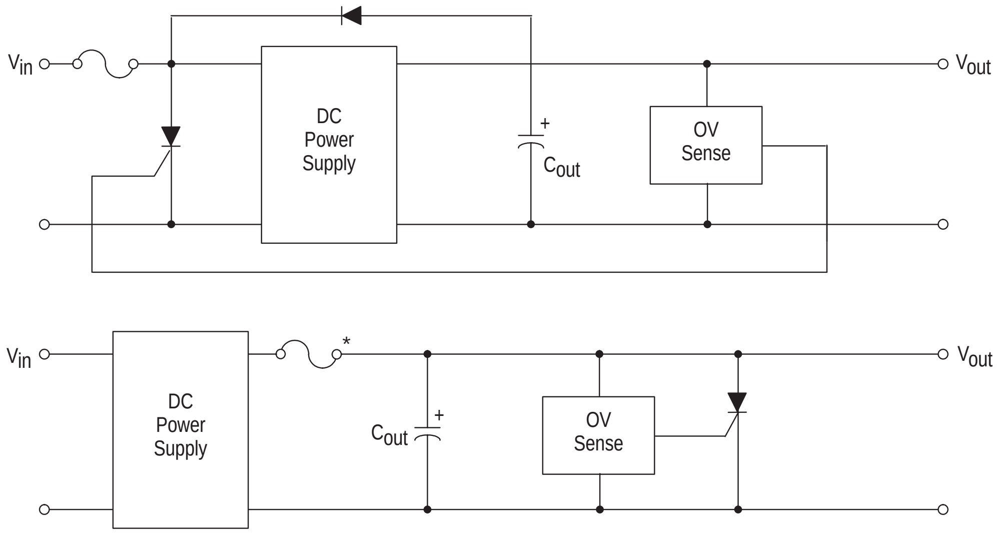
POWER SUPPLY SUPERVISORY AND PROTECTION CONSIDERATIONS

The use of SCR crowbar overvoltage protection (OVP) circuits has been, for many years, a popular method of providing protection from accidental overvoltage stress for the load. In light of the recent advances in LSI circuitry, this technique has taken on added importance. It is not uncommon to have several hundred dollars worth of electronics supplied from a single low voltage supply. If this supply were to fail due to component failure or other accidental shorting of higher voltage supply busses to the low voltage bus, several hundred dollars worth of circuitry could literally go up in smoke. The small additional investment in protection circuitry can easily be justified in such applications.

A. The Crowbar Technique

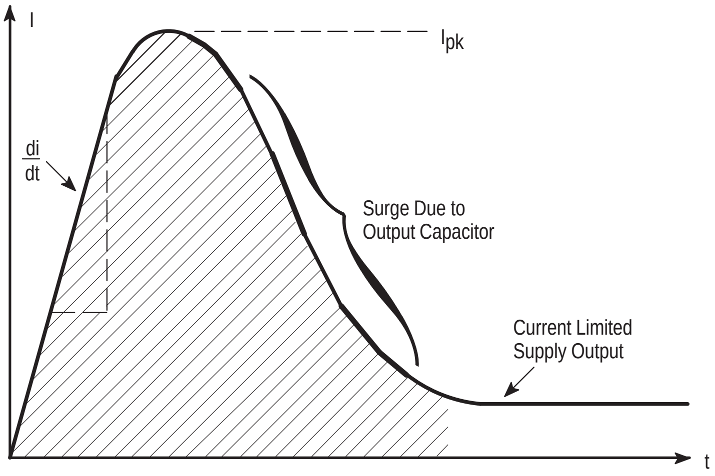
One of the simplest and most effective methods of obtaining overvoltage protection is to use a “crowbar” SCR placed across the equipment’s dc power supply bus. As the name implies, the SCR is used much like a crowbar would be, to short the dc supply when an overvoltage condition is detected. Typical circuit configurations for this circuit are shown on Figure 14–1. This method is very effective in eliminating the destructive overvoltage condition. However, the effectiveness is lost if the OVP circuitry is not reliable.

Figure 14–1. Typical Crowbar OVP Circuit Configurations



*Needed if supply not current–limited.

Figure 14–2. Crowbar SCR Surge Current Waveform



B. SCR Considerations

Referring to Figure 14–1, it can easily be seen that, when activated, the crowbar SCR is subjected to a large current surge from the filter and output capacitors. This large current surge, illustrated in Figure 14–2, can cause SCR failure or degradation by any one of three mechanisms: di/dt, peak surge current, or I2 t. In many instances the designer must empirically determine the SCR and circuit elements which will result in reliable and effective OVP operation. To aid in the selection of devices for this application, Motorola has characterized several devices specifically for crowbar applications. A summary of these specifications and a selection guide for this application is shown in Table 14–1. This significantly reduces the amount of empirical testing that must be done by the designer. A good understanding of the factors that influence the SCR's di/dt and surge current capability will greatly simplify the total circuit design task.

Table 14–1. Crowbar SCRs

Device Type**	Peak Discharge Current*	di/dt*
MCR67	300 A	75 A/µs
MCR68	300 A	75 A/µs
MCR69	750 A	100 A/µs
MCR70	850 A	100 A/µs
MCR71	1700 A	200 A/µs

* tw = 1.0 µs, exponentially decaying

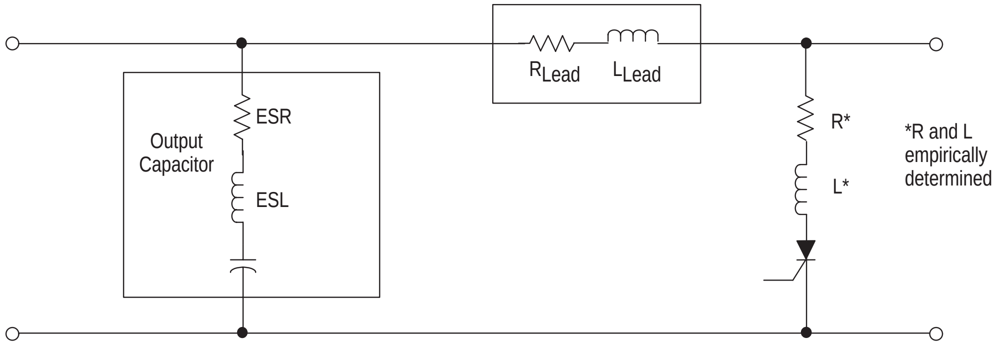
** All devices available with 25, 50, and 100 V ratings

1. di/dt — As the gate region of the SCR is driven on, its area of conduction takes a finite amount of time to grow, starting as a very small region and gradually spreading. Since the anode current flows through this turned–on gate region, very high current densities can occur in the gate region if high anode currents appear quickly (di/dt). This can result in immediate destruction of the SCR or gradual degradation of its forward blocking voltage capabilities, depending upon the severity of the occasion.

The value of di/dt that an SCR can safely handle is influenced by its construction and the characteristics of the gate drive signal. A center–gate–fire SCR has more di/dt capability than a corner–gate–fire type, and heavily overdriving (3 to 5 times I_{GT}) the SCR gate with a fast <1.0 µs rise time signal will maximize its di/dt capability. A typical maximum di/dt in phase control SCRs of less than 50 A rms rating might be 200 A/µs, assuming a gate current of five times IGT and <1.0 µs rise time. If having done this, a di/dt problem still exists, the designer can also decrease the di/dt of the current saveform by adding inductance in series with the SCR, as shown in Figure 14–3. Of course, this reduces the circuit's ability to rapidly reduce the dc bus voltage, and a tradeoff must be made between speedy voltage reduction and di/dt.

2. Surge Current — If the peak current and/or the duration of the surge is excessive, immediate destruction due to device overheating will result. The surge capability of the SCR is directly proportional to its die area. If the surge current cannot be reduced (by adding series resistance, see Figure 14–3) to a safe level which is consistent with the system's requirements for speedy bus voltage reduction, the designer must use a higher current SCR. This may result in the average current capability of the SCR exceeding the steady state current requirements imposed by the dc power supply.

Figure 14–3. Circuit Elements Affecting SCR Surge & di/dt



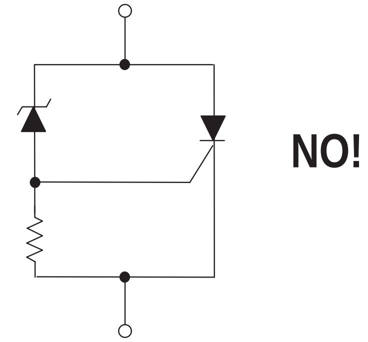
(For additional information on SCRs in crowbar applications refer to *Characterizing the SCR for Crowbar Applications*, Al Pshaenich, Motorola AN789).

C. The Sense and Drive Circuit

In order to maximize the crowbar SCR's di/dt capability, it should receive a fast rise time high–amplitude gate–drive signal. This must be one of the primary factors considered when selecting the sensing and drive circuitry. Also important is the sense circuitry's noise immunity.

Noise immunity can be a major factor in the selection of the sense circuitry employed. If the sensing circuit has low immunity and is operated in a noisy environment, nuisance tripping of the OVP circuit can occur on short localized noise spikes, which would not normally damage the load. This results in excessive system down time. There are several types of sense circuits presently being used in OVP applications. These can be classified into three types: zener, discrete, and “723.”

Figure 14–4. The Zener Sense Circuit



1. The Zener Sense Circuit — Figure 14–4 shows the use of a zener to trigger the crowbar SCR. This method is NOT recommended since it provides very poor gate drive and greatly decreases the SCR's di/dt handling capability, especially since the SCR steals its own very necessary gate drive as it turns on. Additionally, this method does not allow the trip point to be adjusted except by zener replacement.

2. The Discrete Sense Circuit — A technique which can provide adequate gate drive and an adjustable, low temperature coefficient trip point is shown in Figure 14–5. While overcoming the disadvantages of the zener sense circuit, this technique requires many components and is more costly. In addition, this method is not particularly noise immune and often suffers from nuisance tripping.

3. The “723” Sense Circuit — By using an integrated circuit voltage regulator, such as the industry standard “723” type, a considerable reduction in component count can be achieved. This is illustrated in Figure 14–6. Unfortunately, this technique is not noise immune, and suffers an additional disadvantage in that it must be operated at voltages above 9.5 V.

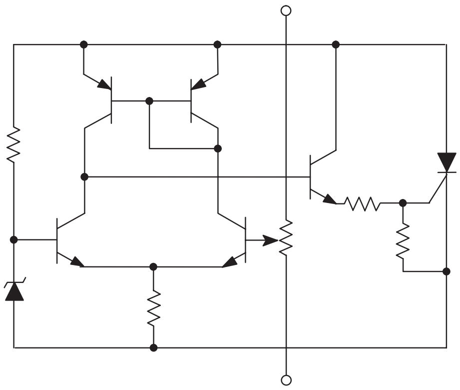


Figure 14–5. The Discrete Sense Circuit

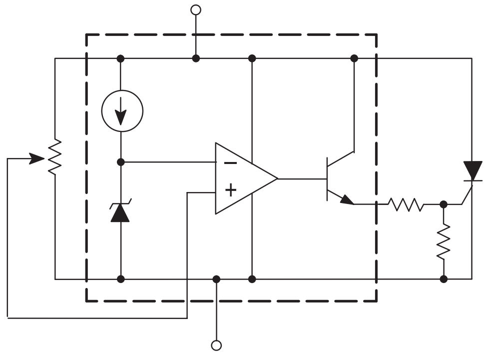

Figure 14–6. The “723” Sense Circuit

4. The MC3423 — To fill the need for a low cost, low complexity method of implementing crowbar overvoltage protection which does not suffer the disadvantages of previous techniques, an IC has been developed for use as an OVP sense and drive circuit, the MC3423.

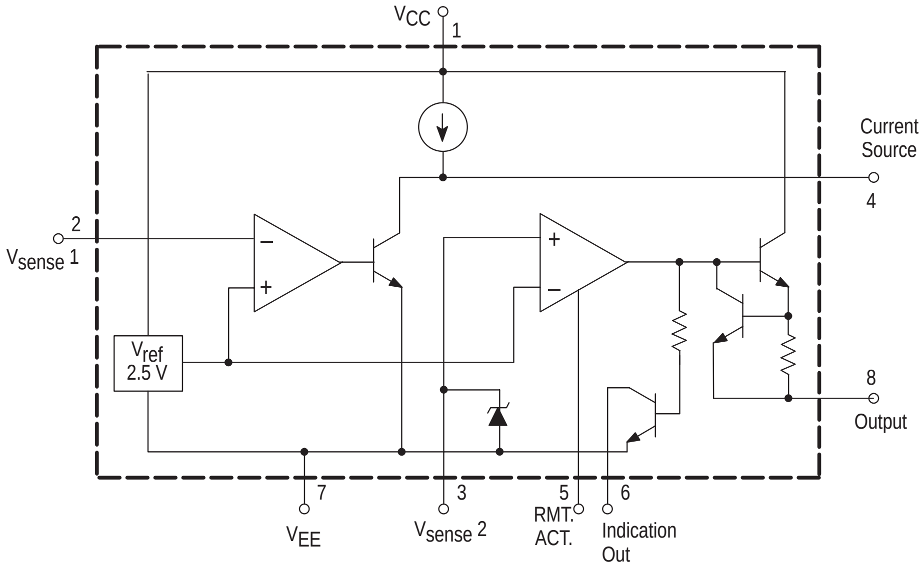
The MC3423 was designed to provide output currents of up to 300 mA with a 400 mA/µs rise time in order to maximize the di/dt capabilities of the crowbar SCR. In addition, its features include:

1. Operation off 4.5 V to 40 V supply voltages.
2. Adjustable low temperature coefficient trip point.
3. Adjustable minimum overvoltage duration before actuation to reduce nuisance tripping in noisy environments.
4. Remote activation input.
5. Indication output.

5. Block Diagram — The block diagram of the MC3423 is shown in Figure 14–7. It consists of a stable 2.6 V reference, two comparators and a high current output. This output, together with the indication output transistor, is activated either by a voltage greater than 2.6 V on Pin 3 or by a TTL/5.0 V CMOS high logic level on the remote activation input, Pin 5.

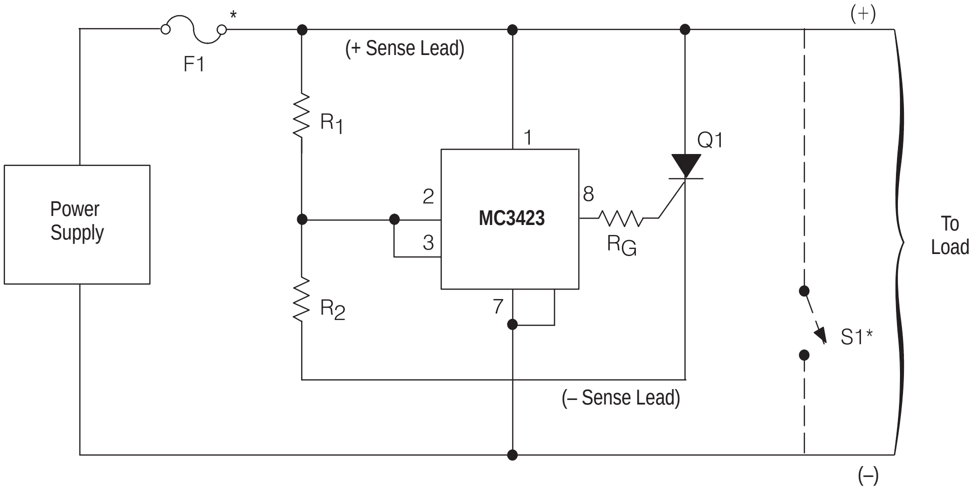
The circuit also has a comparator–controlled current source which can be used in conjunction with and external timing capacitor to set a minimum overvoltage duration (0.5 µs to 1.0 ms) before actuation occurs. This feature allows the OVP circuit to operate in noisy environments without nuisance tripping.

Figure 14–7. MC3423 Block Diagram



6. Basic Circuit Configuration — The basic circuit configuration of the MC3423 OVP is shown in Figure 14–8. In this circuit the voltage sensing inputs of both the internal amplifiers are tied together for sensing the overvoltage condition. The shortest possible propagation delay is thus obtained. The threshold or trip voltage at which the MC3423 will trigger and supply gate drive to the crowbar SCR, Q1, is determined by the selection of R_1 and R_2. Their values can be determined by the equations given in Figure 14–8 or by the graph shown in Figure 14–9. The switch (S1) shown in Figure 14–8 may be used to reset the SCR crowbar. Otherwise, the power supply, across which the SCR is connected, must be shut down to reset the crowbar. If a non current–limited supply is used a fuse or circuit breaker, F1, should be used to protect the SCR and/or the load.

Figure 14–8. MC3423 Basic Circuit Configuration



$$V_{trip} = V_{ref}\left(1 + \frac{R_1}{R_2}\right) \approx 2.6\ V\left(1 + \frac{R_1}{R_2}\right)$$

$R_2 \le 10\ k\Omega$ for minimum drift

*Needed if supply is not current–limited

7. MC3423 Programmable Configuration — In many instances, MC3423 OVP will be used in a noisy environment. To prevent false tripping of the OVP circuit by noise which would not normally harm the load, MC3423 has a programmable delay feature. To implement this feature, the circuit configuration of Figure 14–10 is used.

Here a capacitor is connected from Pin 3 and Pin 4 to V_{EE}. The value of this capacitor determines the minimum duration of the overvoltage condition (t_D) which is necessary to trip the OVP. The value of C_D can be found from Figure 14–11. The circuit operates in the following manner: when V_{CC} rises above the trip point set by R_1 and R_2, the internal current source begins charging the capacitor, C_D, connected to Pins 3 and 4. If the overvoltage condition remains present long enough for the capacitor voltage, V_{CD} to reach V_{ref}, the output is activated. If the overvoltage condition disappears before this occurs, the capacitor is discharged at a rate 10 times faster than the charging rate, resetting the timing feature until the next overvoltage condition occurs.

8. Indication Output — An additional output for use as an indicator of OVP activation is provided by the MC3423. This output (Pin 6) is an open–collector transistor which saturates when the MC3423 OVP is activated. It will remain in a saturated state until the SCR crowbar pulls the supply voltage, V_{CC}, below 4.5 V as in Figure 14–10. This output can be used to clock an edge triggered flip–flop whose output inhibits or shuts down the power supply when the OVP trips. This reduces or eliminates the heatsinking requirements for the crowbar SCR.

Figure 14–9. R_1 versus Trip Voltage for the MC3423 OVP

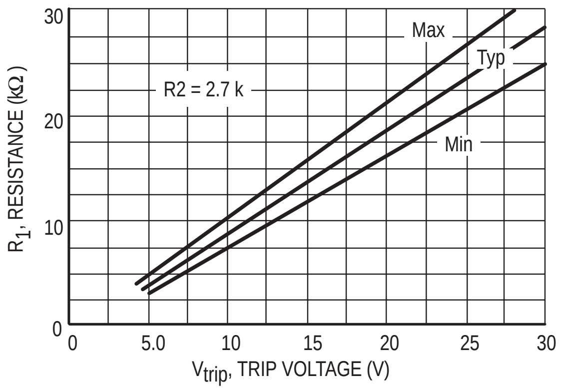


Figure 14–10. MC3423 Configuration for Programmable Minimum Duration of Overvoltage Condition Before Tripping

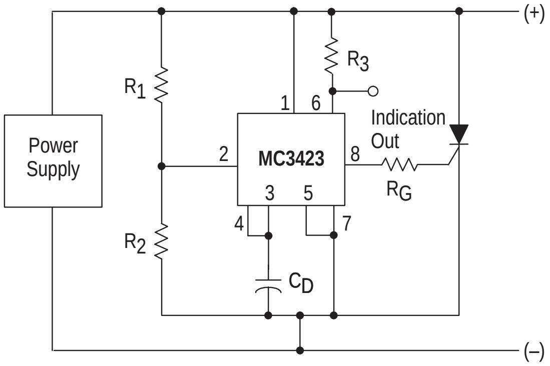


$$R_3 \geq \frac{V_{trip}}{10\ mA}$$

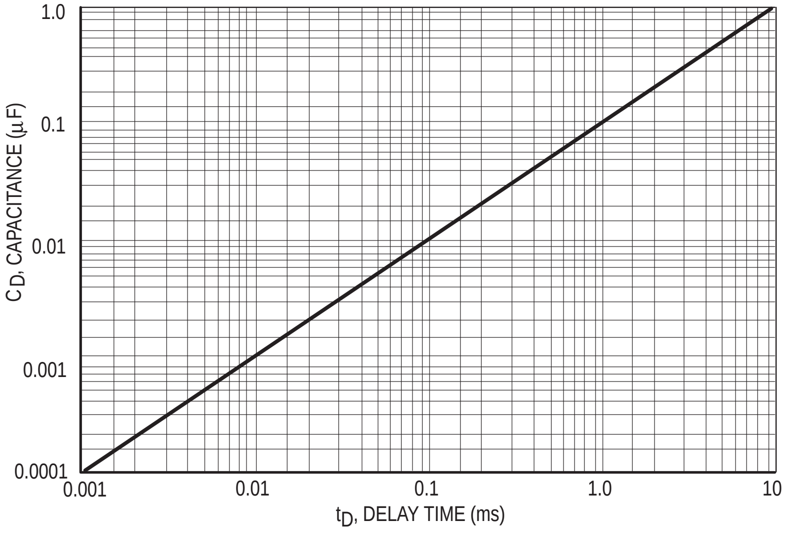
9. Remote Activation Input — Another feature of the MC3423 is its Remote Activation Input, Pin 5. If the voltage on this CMOS/TTL compatible input is held below 0.7 V, the MC3423 operates normally. However, if it is raised to a voltage above 2.0 V, the OVP output is activated independent of whether or not an overvoltage condition is present.

This feature can be used to accomplish an orderly and sequenced shutdown of system power supplies during a system fault condition. In addition, the Indication Output of one MC3423 can be used to activate another MC3423, if a single transistor inverter is used to interface the former's Indication Output to the latter's Remote Activation Input.

D. MC3425 Power Supply Supervisory Circuit

In addition to the MC3423 a second IC, the MC3425 has been developed. Similar in many respects to the MC3423, the MC3425 is a power supply supervisory circuit containing all the necessary functions required to monitor over and undervoltage fault conditions. The block diagram is shown below in Figure 14–12. The Overvoltage (OV) and Undervoltage (UV) Input Comparators are both referenced to an internal 2.5 V regulator. The UV Input Comparator has a feedback activated 12.5 µA current sink (I_H) which is used for programming the input hysteresis voltage (V_H). The source resistance feeding this input (R_H) determines the amount of hysteresis voltage by $V_H = I_H R_H = 12.5 \times 10^{-6}\ R_H$.

Figure 14–11. C_D versus Minimum Overvoltage Duration, t_D for The MC3423 OVP



Separate Delay pins (OV DLY, UV DLY) are provided for each channel to independently delay the Drive and Indicator outputs, thus providing greater input noise immunity. The two Delay pins are essentially the outputs of the respective input comparators, and provide a constant current source, $I_{DLY(source)}$, of typically 200 µA when the noninverting input voltage is greater than the inverting input level. A capacitor connected from these Delay pins to ground, will establish a predictable delay time (t_{DLY}) for the Drive and Indicator outputs. The Delay pins are internally connected to the non–inverting inputs of the OV and UV Output Comparators, which are referenced to the internal 2.5 V regulator. Therefore, delay time (t_{DLY}) is based on the constant current source, $I_{DLY(source)}$, charging the external delay capacitor (C_{DLY}) to 2.5 V.

$$t_{DLY} = \frac{V_{ref}\,C_{DLY}}{I_{DLY(source)}} = \frac{2.5\,C_{DLY}}{200\ \mu A} = 12500\,C_{DLY}$$

Figure 14–13 provides C_{DLY} values for a wide range of time delays. The Delay pins are pulled low when the respective input comparator's non–inverting input is less than the inverting input. The sink current $I_{DLY(sink)}$ capability of the Delay pins is ≥1.8 mA and is much greater than the typical 200 µA source current, thus enabling a relatively fast delay capacitor discharge time.

The Overvoltage Drive Output is a current–limited emitter–follower capable of sourcing 300 mA at a turn–on slew rate of 2.0 A/µs, ideal for driving crowbar SCRs. The Undervoltage Indicator Output is an open–collector NPN transistor, capable of sinking 30 mA to provide sufficient drive for LEDs, small relays or shutdown circuitry. These current capabilities apply to both channels operating simultaneously, providing device power dissipation limits are not exceeded. The MC3425 has an internal 2.5 V bandgap reference regulator with an accuracy of ± 4.0% for the basic devices.

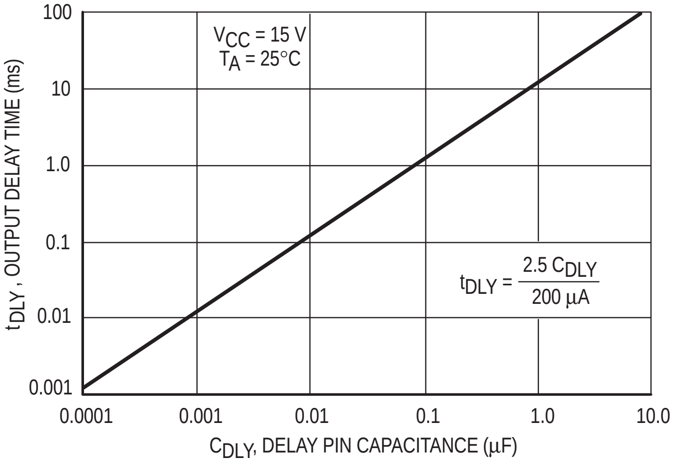
Note: All voltages and currents are nominal.

Figure 14–13. Output Delay Time versus Delay Capacitance



E. MC34064 and MC34164 Series

The MC34064 and MC34164 series are two families of undervoltage sensing circuits specifically designed for use as reset controllers in microprocessor–based systems. They offer the designer an economical solution for low voltage detection with a single external resistor. Both parts feature a trimmed bandgap reference, and a comparator with precise thresholds and built–in hysteresis to prevent erratic reset operation.

The two families of undervoltage sensing circuits, taken together, cover the needs of the most commonly specified power supplies used in MCU/MPU systems. Key parameter specifications of the MC34164 family were chosen to complement the MC34064 series. The table summarizes critical parameters of both families. The MC34064 fulfills the needs of a 5.0 V ± 5% system and features a tighter hysteresis specification. The MC34164 series covers 5.0 V ± 10% and 3.0 V ± 5% power supplies with significantly lower power consumption, making them ideal for applications where extended battery life is required such as consumer products or hand held equipment.

Applications include direct monitoring of the 5.0 V MPU/logic power supply used in appliance, automotive, consumer, and industrial equipment. The MC34164 is specifically designed for battery powered applications where low bias current (1/25th of the MC34064's) is an important characteristic.

SECTION 15

HEATSINKING

A. The Thermal Equation

A necessary and primary requirement for the safe operation of any semiconductor device, whether it be an IC or a transistor, is that its junction temperature be kept below the specified maximum value given on its data sheet. The operating junction temperature is given by:

$$T_J = T_A + P_D\ \theta_{JA} \qquad (15.1)$$

where: T_J = junction temperature (°C)
T_A = ambient air temperature (°C)
P_D = power dissipated by device (W)
θ_{JA} = thermal resistance from junction–to–ambient air (°C/W)

The junction–to–ambient thermal resistance (θ_{JA}) in Equation (15.1), can be expressed as a sum of thermal resistances as shown below:

$$\theta_{JA} = \theta_{JC} + \theta_{CS} + \theta_{SA} \qquad (15.2)$$

where: θ_{JC} = junction–to–case thermal resistance
θ_{CS} = case–to–heatsink thermal resistance
θ_{SA} = heatsink–to–ambient thermal resistance

Equation (15.2) applies only when an external heatsink is used. If no heatsink is used, θ_{JA} is equal to the device package θ_{JA} given on the data sheet.

θ_{JC} depends on the device and its package (case) type, while θ_{SA} is a property of the heatsink and θ_{CS} depends on the type of package/heatsink interface employed. Values for θ_{JC} and θ_{SA} are found on the device and heatsink data sheets, while θ_{CS} is given in Table 15–1.

Table 15–1. θ_{CS} For Various Packages & Mounting Arrangements

	θ_{CS}			
	Metal–to–Metal*		**Using an Insulator***	
Case	**Dry**	**With Heatsink Compound**	**With Heatsink Compound**	**Type**
TO–204	0.5°C/W	0.1°C/W	0.36°C/W 0.28°C/W	3 mil MICA Anodized Aluminum
TO–220	1.2°C/W	1.0°C/W	1.6°C/W	2 mil MICA

*Typical values; heatsink surface should be free of oxidation, paint, and anodization

Examples showing the use of Equations (15.1) and (15.2) in thermal calculations are as follows:

Example 1: Find required heatsink θ_{SA} for an MC7805CT, given:

$$T_{J(max)}\ \text{(desired)} = +125°C$$
$$T_{A(max)} = +70°C$$
$$P_D = 2.0\ W$$

Mounted directly to heatsink with silicon thermal grease at interface:

1. From MC7805CT data sheet, θ_{JC} = 5°C/W
2. From Table 15–1. θ_{CS} = 1.6°C/W
3. Using Equation (15.1) and (15.2), solve for θ_{SA}:

$$\theta_{SA} = \frac{(T_J - T_A)}{P_D} - \theta_{CS} - \theta_{JC}$$

$$\theta_{SA} = \frac{(125 - 70)}{2} - 5.0 - 1.6 \; (\leq 20.9°\text{C/W required})$$

Example 2: Find the maximum allowable T_A for an unheatsinked MC78L15CT, given:

$T_{J(max)}$ (desired) = +125°C
P_D = 0.25 W

1. From MC78L15CT data sheet, θ_{JA} = 200°C/W
2. Using Equation (15.1), find T_A:

$$\begin{aligned} T_A &= T_j - P_D\,\theta_{JA} \\ &= 125 - 0.25\,(200) \\ &= +75°\text{C} \end{aligned}$$

B. Selecting a Heatsink

Usually, the maximum ambient temperature, power being dissipated, the $T_{J(max)}$, and θ_{JC} for the device being used are known. The required θ_{SA} for the heatsink is then determined using Equations (15.1) and (15.2), as in Example 1. The designer may elect to use a commercially available heatsink, or if packaging or economy demands it, design his own.

1. Commercial Heatsinks

As an aid in selecting a heatsink, a representative listing is shown in Table 15–2. This listing is by no means complete and is only included to give the designer an idea of what is available.

2. Custom Heatsink Design

Custom heatsinks are usually either forced air cooled or convection cooled. The design of forced air cooled heatsinks is usually done empirically, since it is difficult to obtain accurate air flow measurements. On the other hand, convection cooled heatsinks can be designed with fairly predictable characteristics. It must be emphasized, however, that any custom heatsink design should be thoroughly tested in the actual equipment configuration to be certain of its performance. In the following sections, a design procedure for convection cooled heatsinks is given.

Obviously, the basic goal of any heatsink design is to produce a heatsink with an adequately low thermal resistance, θ_{SA}. Therefore, a means of determining θ_{SA} is necessary in the design. Unfortunately, a precise calculation method for θ_{SA} is beyond the scope of this book.* However, a first order approximation can be calculated for a convection cooled heatsink if the following conditions are met:

1. The heatsink is a flat rectangular or circular plate whose thickness is smaller than its length or width.
2. The heatsink will not be located near other heat radiating surfaces.
3. The aspect ratio of a rectangular heatsink (length:width) is not greater than 2:1.
4. Unrestricted convective air flow.

For the above conditions, the heatsink thermal resistance can be approximated by:

$$\theta_{SA} \simeq \frac{1}{A\eta\,(F_c h_c + \in H_r)} \quad (^\circ C/W) \tag{15.3}$$

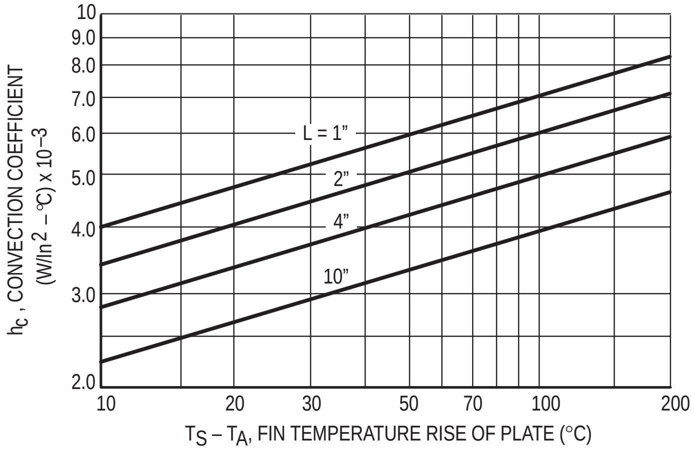
where: A = area of the heatsink surface
η = heatsink effectiveness
F_c = convective correction factor
h_c = convection heat transfer coefficient
$\in$ = emissivity
H_r = normalized radiation heat transfer coefficient

The convective heat transfer coefficient, h_c, can be found from Figure 15–1. Note that it is a function of the heatsink fin temperature rise ($T_S - T_A$) and the heatsink significant dimension (L). The fin temperature rise ($T_S - T_A$) is given by:

$$T_S - T_A = \theta_{SA} P_D \tag{15.4}$$

where: T_S = heatsink temperature
T_A = ambient temperature
θ_{SA} = heatsink–to–ambient thermal resistance
P_D = power dissipated

Figure 15–1. Convection Coefficient (h_c)



---

*If greater precision is desired, or more information on heat flow and heatsinking is sought, consult the references list at the end of this section.

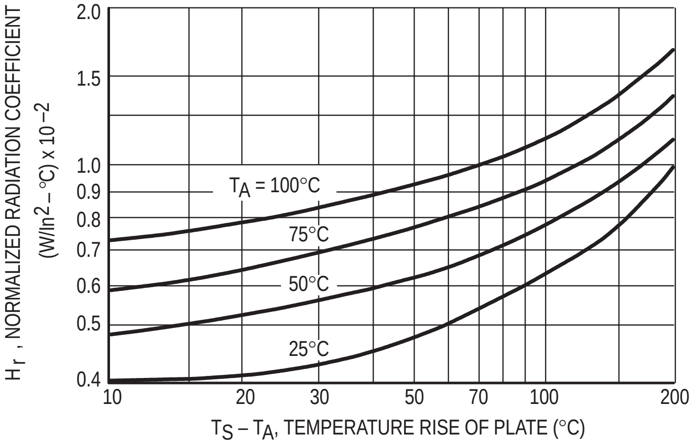
The significant heatsink dimension (L) is dependent on the heatsink shape and mounting place and is given in Table 15–3. The convective correction factor (F_C) is likewise dependent on shape and mounting plane of the heatsink and is also given in Table 15–3.

Table 15–3. Significant Dimension (L) and Correction Factor (F_C) for Convection Thermal Resistance

Surface	Significant Dimension L		Correction Factor F_C	
	Position	**L**	**Position**	**F_C**
Rectangular Plane	Vertical	Height (max 2 ft)	Vertical Plane	1.0
	Horizontal	$\frac{\text{length} \times \text{width}}{\text{length} + \text{width}}$	Horizontal Plane both surfaces exposed	1.35
Circular Plane	Vertical	$\pi / 1 \times$ diameter	Top only exposed	0.9

The normalized radiation heat transfer coefficient (H_r) is dependent on the ambient temperature (T_A) and the heatsink temperature rise ($T_S - T_A$) given by Equation (15.4). H_r can be determined from Figure 15–2.

Figure 15–2. Normalized Radiation Coefficient (H_r)



The emissivity (∈) can be found in Table 15–4 for various heatsink surfaces.

Table 15–4. Typical Emissivities of Common Surfaces

Surface	Emissivity (∈)
Alodine on Aluminum	0.15
Aluminum, Anodized	0.7 to 0.9
Aluminum, Polished	0.05
Copper, Polished	0.07
Copper, Oxidized	0.70
Rolled Sheet Steel	0.66
Air Drying Enamel (any color)	0.85 to 0.91
Oil Paints (any color)	0.92 to 0.96
Varnish	0.89 to 0.93

Finally, the heatsink efficient (η) can be found from the nomograph of Figure 15–3. Use of the nomograph is as follows:

a) Find $h_T = Fchc + \in H_r$ from Figures 15–1, 15–2 and Tables 15–3 and 15–4, and locate this point on the nomograph.

b) Draw a line from h_T through chosen heatsink fin thickness (x) to find α.

c) Determine D for the heatsink shape as given in Figure 15–4 and draw a line from this point through α, which was found in (b), to determine η.

d) If power dissipating element is not located at heatsink's center of symmetry, multiply η by 0.7 (for vertically mounted plates only).

Note that in order to calculate θ_{SA} from Equation (15.3), it is necessary to know the heatsink size. Therefore, in order to arrive at a suitable heatsink design, a trial size is selected, its θ_{SA} evaluated, and the original size reduced or enlarged as necessary. This process is iterated until the smallest heatsink is obtained that has the required θ_{SA}. The following design example is given to illustrate this procedure.

Figure 15–3. Fin Effectiveness Nomogram for Symmetrical Flat, Uniformly Thick Fins

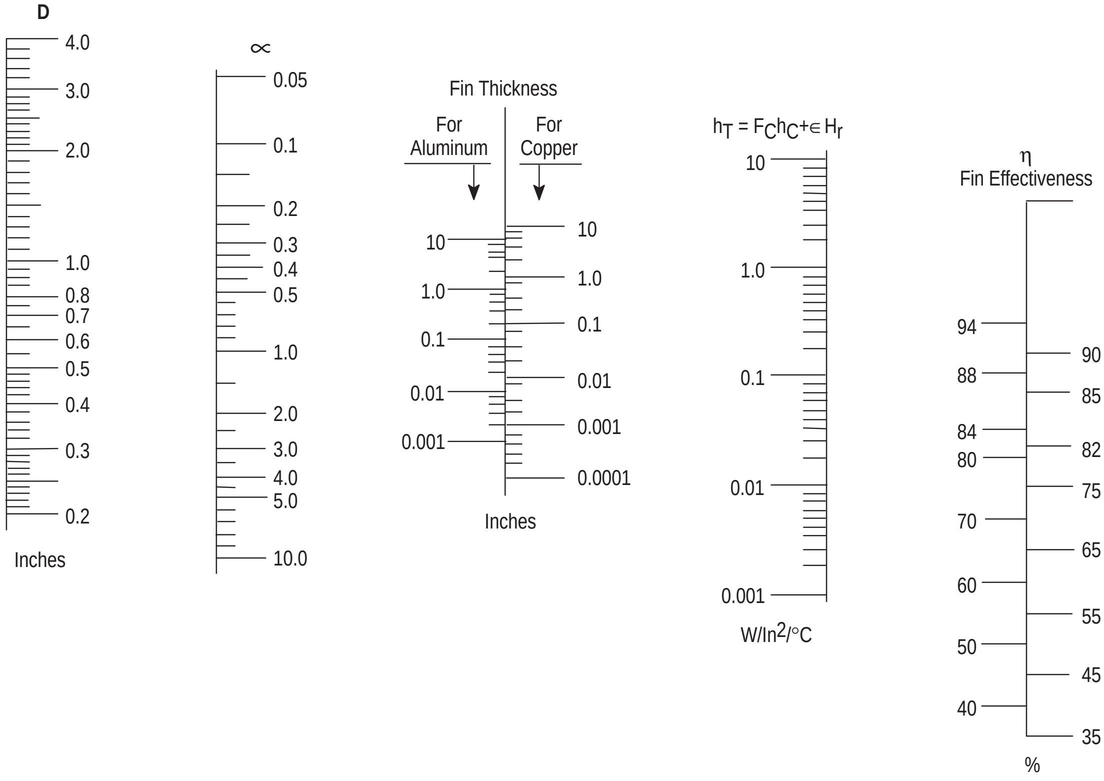


Figure 15–4. Determination of D for Use in η Nomograph of Figure 15–3

$D \cong \sqrt{\frac{ab}{\pi}}$, if $a,b \gg S$ & $b \le 2a$

$D \simeq \frac{d}{2}$, if $d \gg s$

Heatsink Design Example

Design a flat rectangular heatsink for use with a horizontally mounted power device on a PC board, given the following:

1. Heatsink $\theta_{SA} = 25°C/W$
2. Power to be dissipated, $P_D = 2.0$ W
3. Maximum ambient temperature, $T_A = 50°C$
4. Heatsink to be constructed from 1/8″ (0.125″) thick anodized aluminum.
   a) First, a trial heatsink is chosen: 2″ × 3″ (experience will simplify this selection and reduce the number of necessary iterations.)
   b) The factors in Equation (15.3) are evaluated by using the Figures and Tables given:

$$\begin{aligned}
A &= 2'' \times 3'' = 6 \text{ sq. in.}\\
L &= 6/5'' = 1.2 \text{ in. (from Table 15–3)}\\
T_S - T_A &= 50°C \text{ (from Figure 15–4)}\\
h_c &= 5.8 \times 10^{-3} \text{ W/in}^2 - °C \text{ (from Figure 15–1)}\\
F_c &= 0.9 \text{ (from Table 15–3)}\\
H_r &= 6.1 \times 10^{-3} \text{ W/in}^2 - °C \text{ (from Figure 15–2)}\\
\in &= 0.9 \text{ (from Table 15–4)}\\
h_T &= Fchc + H_{r\in} = 10.7 \times 10^{-3} \text{ W/in}^2 - °C\\
\alpha &= 0.13 \text{ (from Figure 15–3)}\\
D &= 1.77 \text{ (from Figure 15–4)}\\
\eta &> 0.94 \simeq 1 \text{ (from Figure 15–3)}
\end{aligned}$$

   c) Using Equation (15.3), find θ_{SA}:

$$\theta_{SA} \simeq \frac{1}{A\eta\ (Fchc + \in H_r)} = 16.66°C/W < 25°C/W$$

   d) Since 2″ × 3″ is too large, try 2″ × 2″. Following the same procedure, θ_{SA} is found to be 25°C/W, which exactly meets the design requirements.

SOIC MINIATURE IC PLASTIC PACKAGE

Thermal Information

The maximum power consumption an integrated circuit can tolerate at a given operating ambient temperature, can be found from the equation:

$$P_{D(T_A)} = \frac{T_{J(max)} - T_A}{R_{\theta JA}\ (typ)}$$

where: $P_{D(T_A)}$ = power dissipation allowable at a given operating ambient temperature,

$T_{J(max)}$ = maximum operating junction temperature as listed in the maximum ratings section,

T_A = desired operating ambient temperature,

$R_{\theta JA}$ (typ) = typical thermal resistance junction–to–ambient.

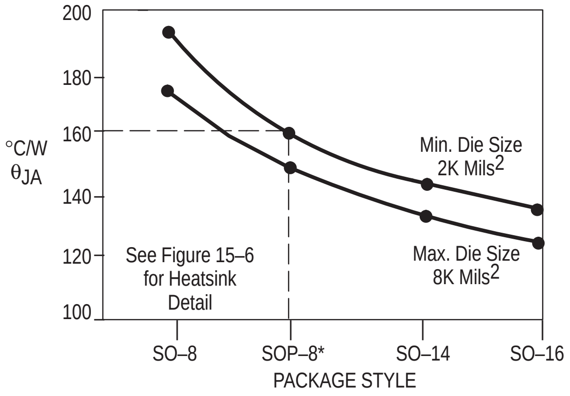
Maximum Ratings

Rating	Symbol	Value	Unit
Operating Ambient Temperature Range	T_A	0 to +70 – 40 to +85	°C
Operating Junction Temperature	T_J	150	°C
Storage Temperature Range	T_{stg}	– 55 to +150	°C

THERMAL CHARACTERISTICS OF SOIC PACKAGES

Measurement specimens are solder mounted on a Philips SO test board #7322–078, 80873 in still air. No auxiliary thermal conduction aids are used. As thermal resistance varies inversely with die area, a given package takes thermal resistance values between the max and min curves shown. These curves represent the smallest (2000 square mils) and largest (8000 square mils) die areas expected to be assembled in the SOIC package.

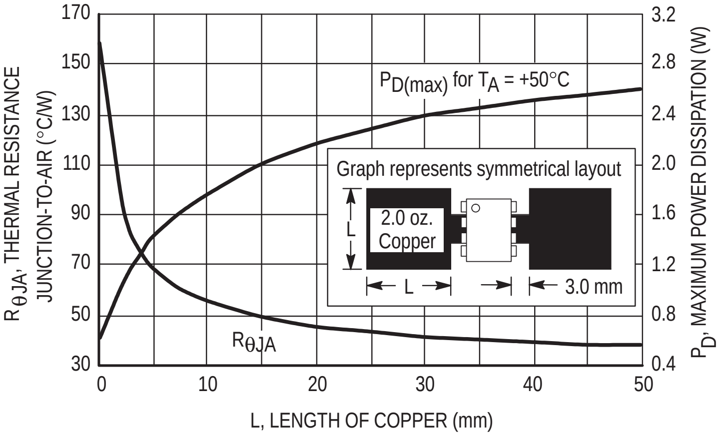
Figure 15–5. Thermal Resistance, Junction–to–Ambient (°C/W)



Data taken using Philips SO test board #7322–078, 80873

*SOP–8 using standard SO–8 footprint — minimum pad size

Figure 15–6. SOP–8 Thermal Resistance and Maximum Power Dissipation versus P.C.B. Copper Length



SOP–8 and SOP–16L Packaged Devices

Several families of voltage regulators and power control ICs have been introduced in surface mounted packages which were developed by the Analog IC Division. The SOP–8 and SOP–16L packages have external dimensions which are identical to the standard SO–8 and SO–16L surface mount devices, but the center four leads of the packages are all connected to the leadframe die flag. This internal modification decreases the package thermal resistance and therefore increases its power dissipation capability. This advantage is fully realized when the package is mounted on a printed circuit board with a single pad for the four center leads. This large area of copper then acts as an external heat spreader, efficiently conducting heat away from the package.

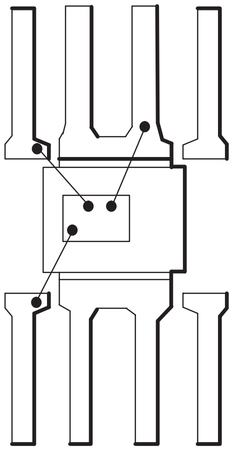


Figure 15–7. SOP–16L Thermal Resistance and Maximum Power Dissipation versus P.C.B. Copper Length

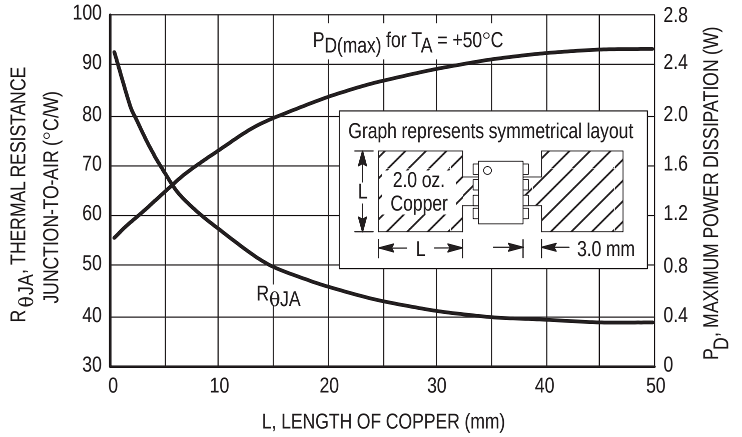
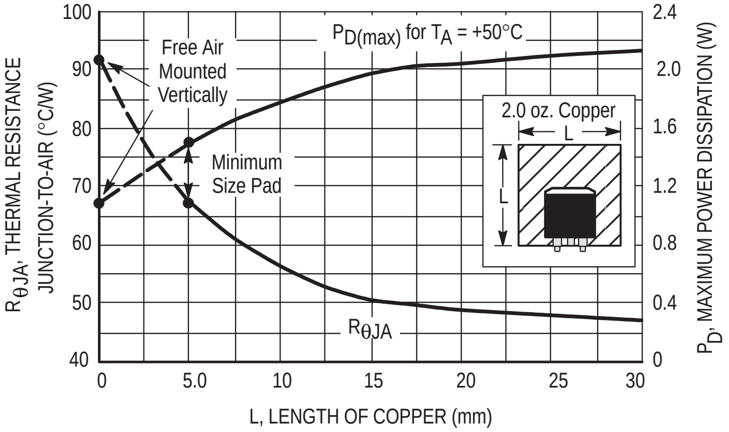


THERMAL CHARACTERISTICS OF DPAK AND D^{2}PAK PACKAGE

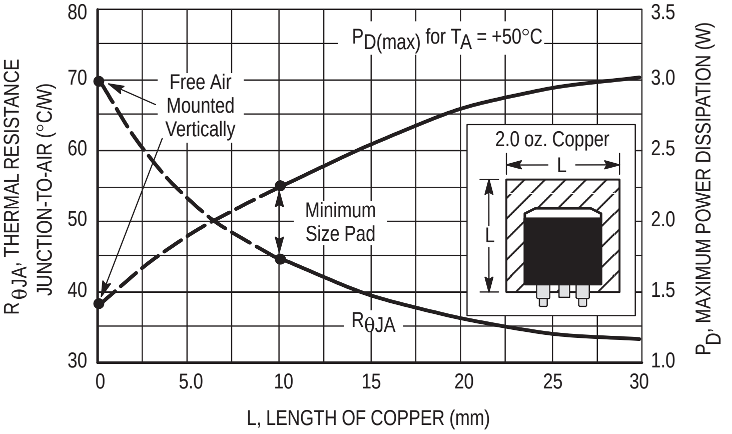
The evaluation was performed using an active device (4900 square mils) mounted on 2.0 ounce copper foil epoxied to a GIO type printed circuit board. Measurements were made in still air and no auxiliary thermal conduction aids were used. The size of a square copper pad was varied, and all measurements were made with the unit mounted as shown in Figure 15–8. The curve shown in Figure 15–8 is a plot of junction–to–air thermal resistance versus the length of the square copper pad in millimeters. This shows that when the DPAK is mounted on a 10 mm × 10 mm square pad of 2.0 ounce copper it has a thermal resistance which is comparable to a TO–220 device mounted vertically without additional heatsinking.

Figure 15–8. DPAK Thermal Resistance and Maximum Power Dissipation versus P.C.B. Copper Length



The thermal characteristics of the D^{2}PAK are shown in Figure 15–9. The device was mounted on 2.0 oz. copper on an FR4–type P.C. board. The maximum power dissipation was measured with a junction temperature of 150°C.

Figure 15–9. 3–Pin and 5–Pin D^{2}PAK Thermal Resistance and Maximum Power Dissipation versus P.C.B. Copper Length



Power/Motor Control Circuits

In Brief . . .

With the expansion of electronics into more and more mechanical systems, there comes an increasing demand for simple but intelligent circuits that can blend these two technologies. In the past, the task of power/motor control was once accomplished with discrete devices. But today this task is being performed by bipolar IC technology due to cost, size, and reliability constraints. Motorola offers integrated circuits designed to anticipate the requirements for both simple and sophisticated control systems, while providing cost effective solutions to meet the needs of the applications.

Power Controllers

An assortment of battery and ac line–operated control ICs for specific applications are shown. They are designed to enhance system performance and reduce complexity in a wide variety of control applications.

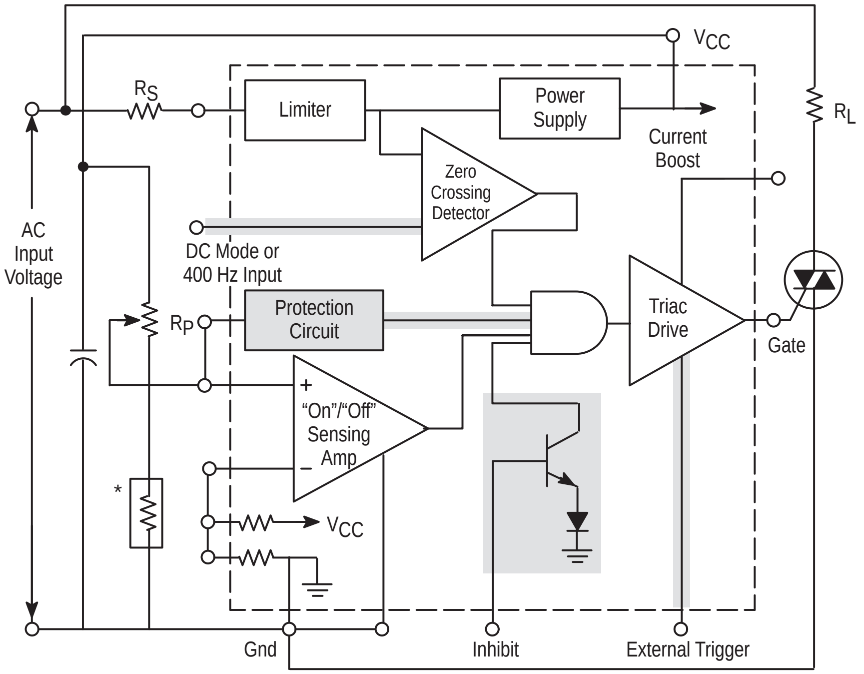
Zero Voltage Switch

CA3059

T_A = –40° to +85°C, Case 646

This device is designed for thyristor control in a variety of ac power switching applications for ac input voltages of 24 V, 120 V, 208/230 V, and 227 V @ 50/60 Hz.

- **Limiter–Power Supply** – Allows operation directly from an ac line.
- **Differential "On"/"Off" Sensing Amplifier** – Tests for condition of external sensors or input command signals. Proportional control capability or hysteresis may be implemented.
- **Zero–Crossing Detector** – Synchronizes the output pulses to the zero voltage point of the ac cycle. Eliminates RFI when used with resistive loads.
- **Triac Drive** – Supplies high current pulses to the external power controlling thyristor.
- **Protection Circuit** (CA3059 only) – A built–in circuit may be actuated, if the sensor opens or shorts, to remove the drive circuit from the external triac.
- **Inhibit Capability** (CA3059 only) – Thyristor firing may be inhibited by the action of an internal diode gate.
- **High Power DC Comparator Operation** (CA3059 only) – Operation in this mode is accomplished by connecting Pin 7 to 12 (thus overriding the action of the zero–crossing detector).



*NTC Sensor
NOTE: Shaded Area Not Included with CA3079.

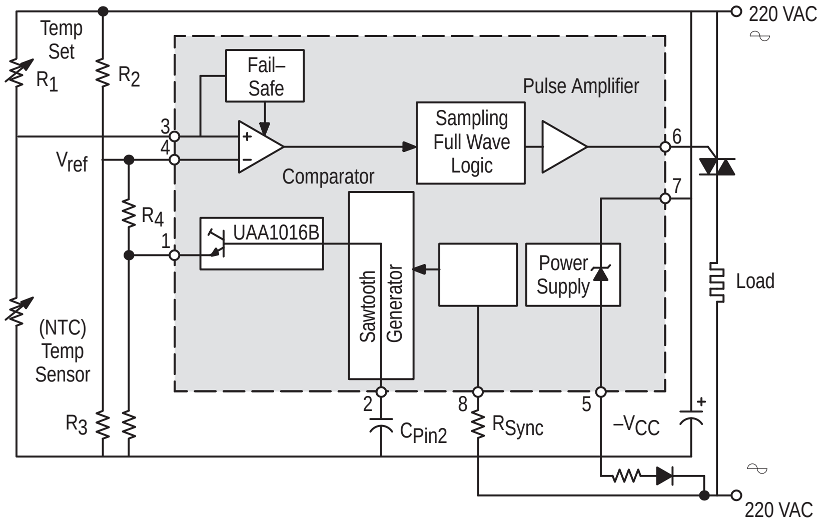
Zero Voltage Controller

UAA1016B

T_A = –20° to +100°C, Case 626

The UAA1016B is designed to drive triacs with the Zero voltage technique which allows RFI free power regulation of resistive loads. It provides the following features:

- Proportional Temperature Control Over an Adjustable Band
- Adjustable Burst Frequency (to Comply with Standards)
- No DC Current Component Through the Main Line (to Comply with Standards)
- Negative Output Current Pulses (Triac Quadrants 2 and 3)
- Direct AC Line Operation
- Low External Components Count



Zero Voltage Controller

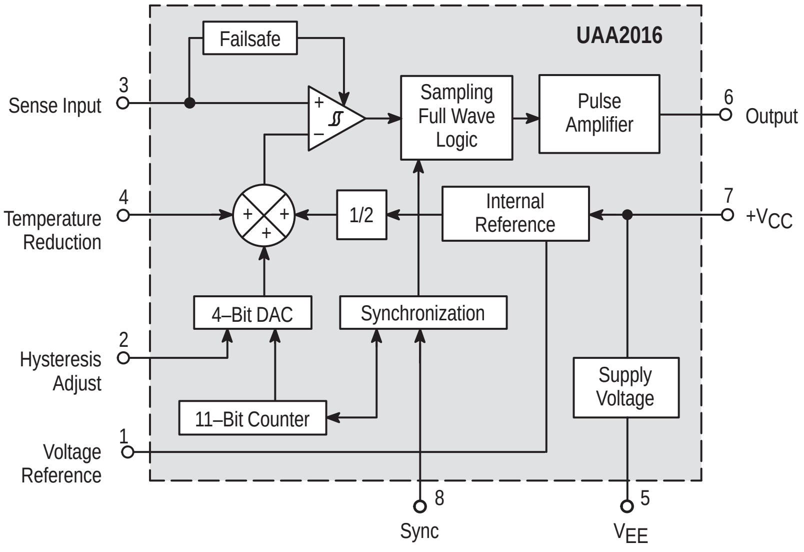
UAA2016P, D

T_A = –20° to +85°C, Case 626, 751

The UAA2016 is designed to drive triacs with the Zero Voltage technique which allows RFI free power regulation of resistive loads. Operating directly on the ac power line, its main application is the precision regulation of electrical heating systems such as panel heaters or irons.

A built–in digital sawtooth waveform permits proportional temperature regulation action over a ±1°C band around the set point. For energy savings there is a programmable temperature reduction function, and for security, a sensor failsafe inhibits output pulses when the sensor connection is broken. Preset temperature (i.e., defrost) application is also possible. In applications where high hysteresis is needed, its value can be adjusted up to 5°C around the set point. All these features are implemented with a very low external component count.

- Zero Voltage Switch for Triacs, up to 2.0 kW (MAC212A8)
- Direct AC Line Operation
- Proportional Regulation of Temperature over a 1°C Band
- Programmable Temperature Reduction
- Preset Temperature (i.e., Defrost)
- Sensor Failsafe
- Adjustable Hysteresis
- Low External Component Count



Power Controllers (continued)

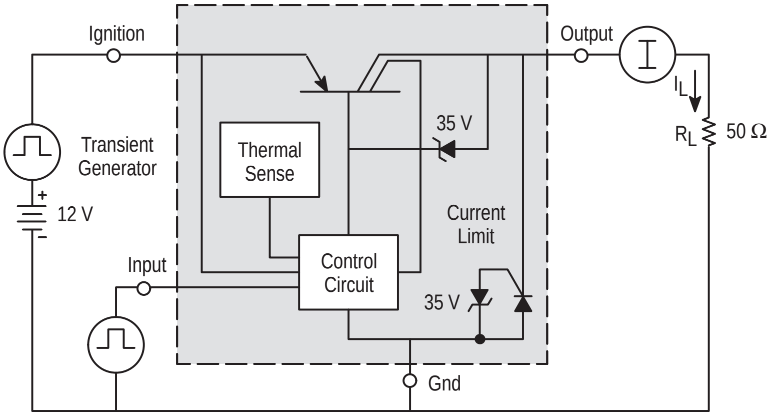
High–Side Driver Switch

MC3399T, DW

T_J = –40° to +150°C, Case 314D, 751G

The MC3399T is a high side driver switch that is designed to drive loads from the positive side of the power supply. The output is controlled by a TTL compatible Enable pin. In the “on” state, the device exhibits very low saturation voltages for load currents in excess of 750 mA. The device also protects the load from positive or negative–going high voltage transients by becoming an open circuit and isolating the transient for its duration from the load.

The MC3399T is fabricated on a Power BiMOS process which combines the best features of Bipolar and MOS technologies. The mixed technology provides higher gain PNP output devices and results in Power Integrated Circuits with reduced quiescent current.



Motor Controllers

This section contains integrated circuits designed for cost effective control of specific motor families. Included are controllers for brushless, dc servo, stepper, and universal type motors.

Brushless DC Motor Controllers

Advances in magnetic materials technology and integrated circuits have contributed to the unprecedented rise in popularity of brushless dc motors. Analog control ICs are making the many features and advantages of brushless motors available at a much more economical price. Motorola offers a family of monolithic integrated brushless dc motor controllers. These ICs provide a choice of control functions which allow many system features to be easily implemented at a fraction of the cost of discrete solutions. The following table summarizes and compares the features of Motorola’s brushless motor controllers.

1Features Summary for Motorola Brushless DC Motor Controllers

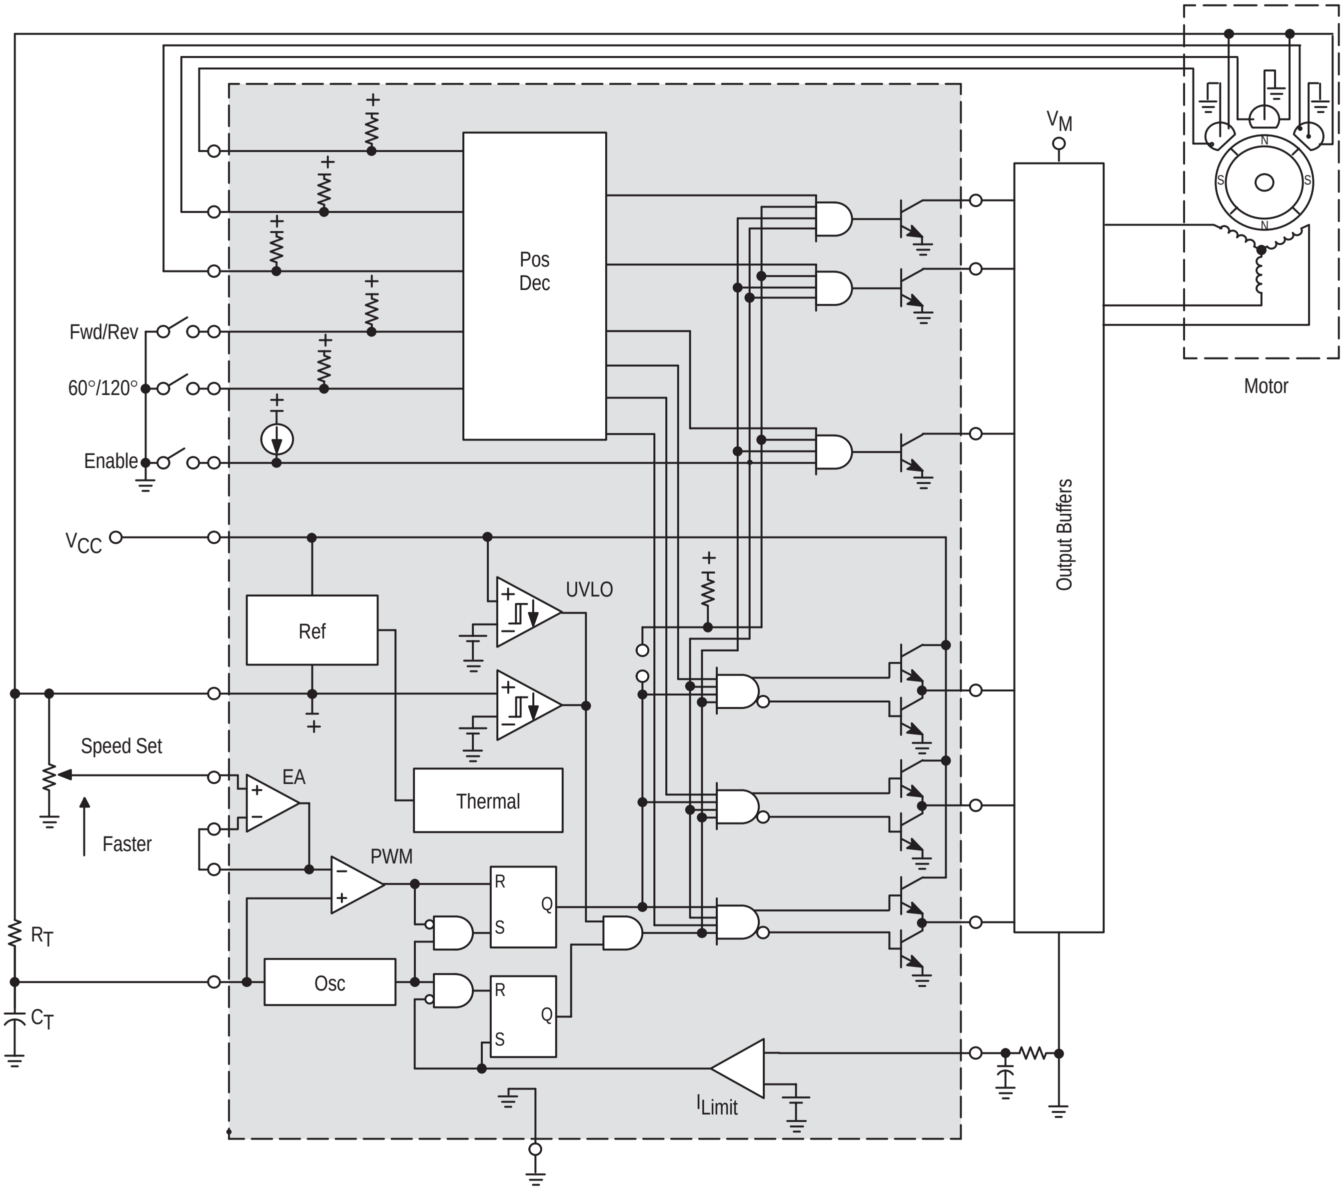
Device	Operating Voltage Range (V)		Undervoltage Lockout	Internal Thermal Shutdown	Fwd/Rev Control	Sensor Electrical Phasing	Output Enable	Output Drivers		6.25 V Reference Output	Current Sense Comparator Input(s)	Error Amplifier	$\overline{\text{FAULT}}$ Output	Separate Drive V_C	Brake Input	Suffix/ Package
	V_{CC}	V_C						Totem Pole (Bottom)	Open Collector (Top)							
MC33033	10–30	–	✓	✓	✓	60°/300° and 120°/240°	✓	✓	✓	✓	Noninv. Only	✓	–	–	–	P/738, DW/751D
MC33035	10–40	10–30	✓	✓	✓		✓	✓	✓	✓	Noninv. and Inv.	✓	✓	✓	✓	P/724, DW/751E

MC33033P, DW

T_A = –40° to +85°C, Case 738, 751D

The MC33033 is a lower cost second generation brushless dc motor controller which has evolved from the full featured MC33034 and MC33035 controllers. The MC33033 contains all of the active functions needed to implement a low cost open loop motor control system. This IC has all of the key control and protection functions of the two full featured devices with the following secondary features deleted: separate drive–circuit supply and ground pins, the brake input, and the fault output signal. Like its MC33035 predecessor, the MC33033 has a control pin which allows the user to select 60°/300° or 120°/240° sensor electrical phasings.

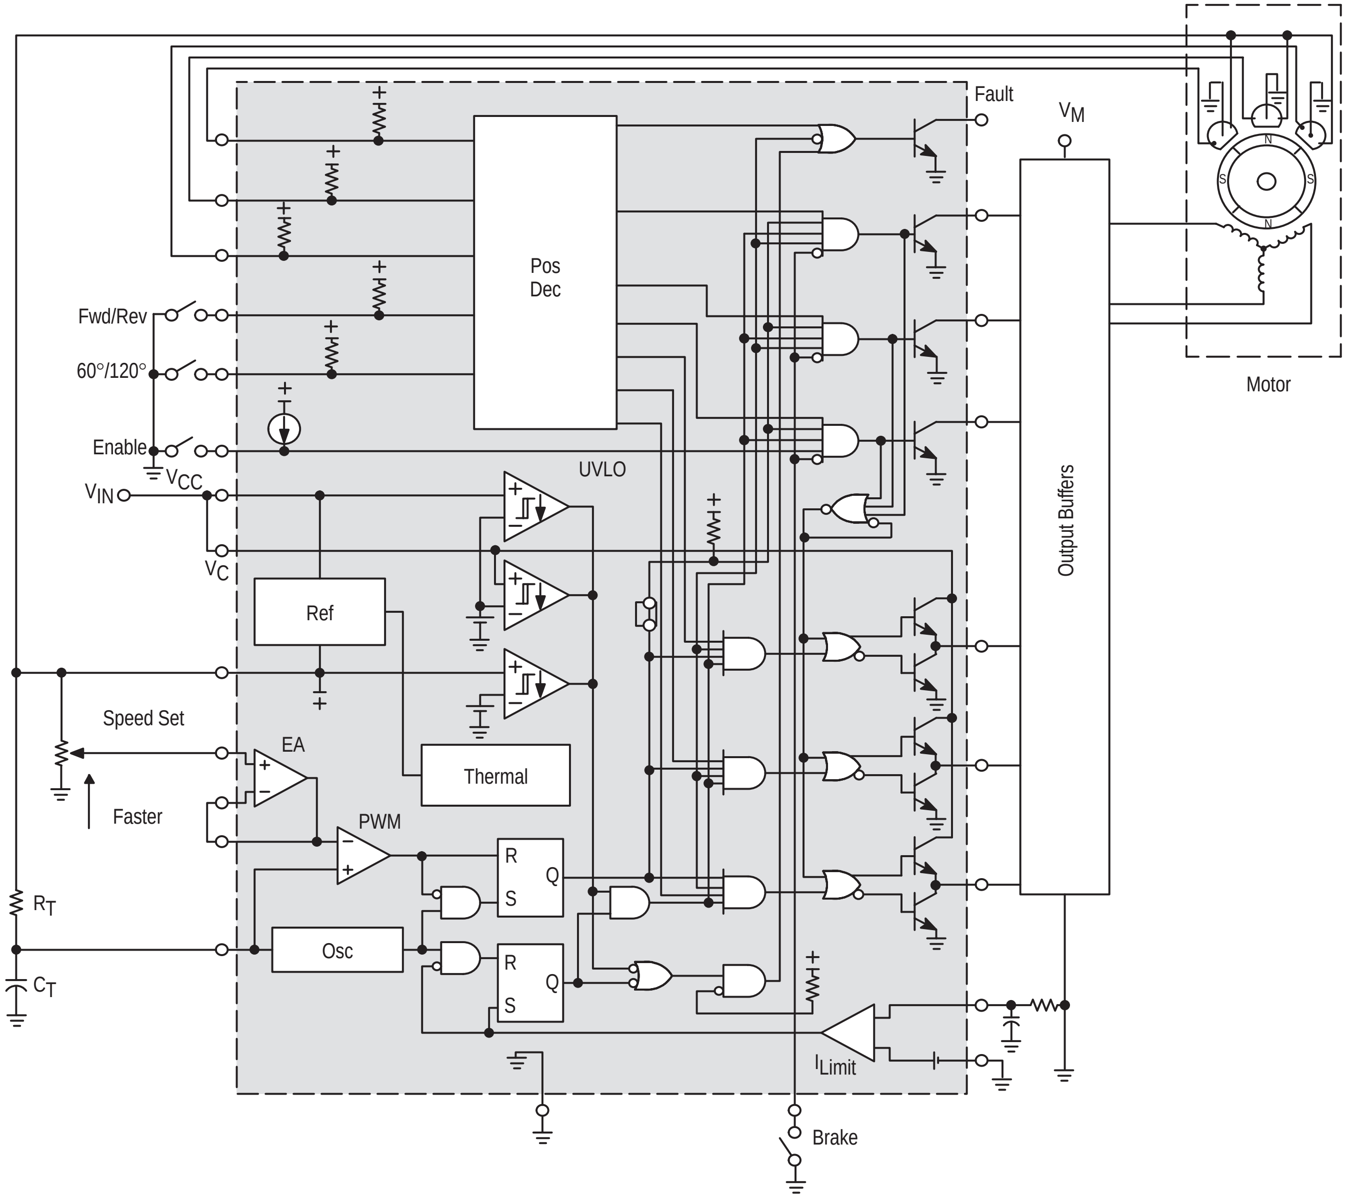
Because of its low cost, the MC33033 can efficiently be used to control brush dc motors as well as brushless. A brush dc motor can be driven using two of the three drive output phases provided in the MC33033, while the Hall sensor input pins are selectively tied to V_{ref} or ground. Other features such as forward/reverse, output enable, speed control, current limiting, undervoltage lockout and internal thermal shutdown will still remain functional.



MC33035P, DW

T_A = –40° to +85°C, Case 724, 751E

The MC33035 is a second generation high performance brushless dc motor controller which contains all of the active functions required to implement a full featured open loop motor control system. While being pin–compatible with its MC33034 predecessor, the MC33035 offers additional features at a lower price. The two additional features provided by the MC33035 are a pin which allows the user to select 60°/300° or 120°/240° sensor electrical phasings, and access to both inverting and noninverting inputs of the current sense comparator. The earlier devices had two part numbers which were needed to support the different sensor phasings, and the inverting input to the current sense comparator was internally grounded. All of the control and protection features of the MC33034 are also provided in the MC33035.

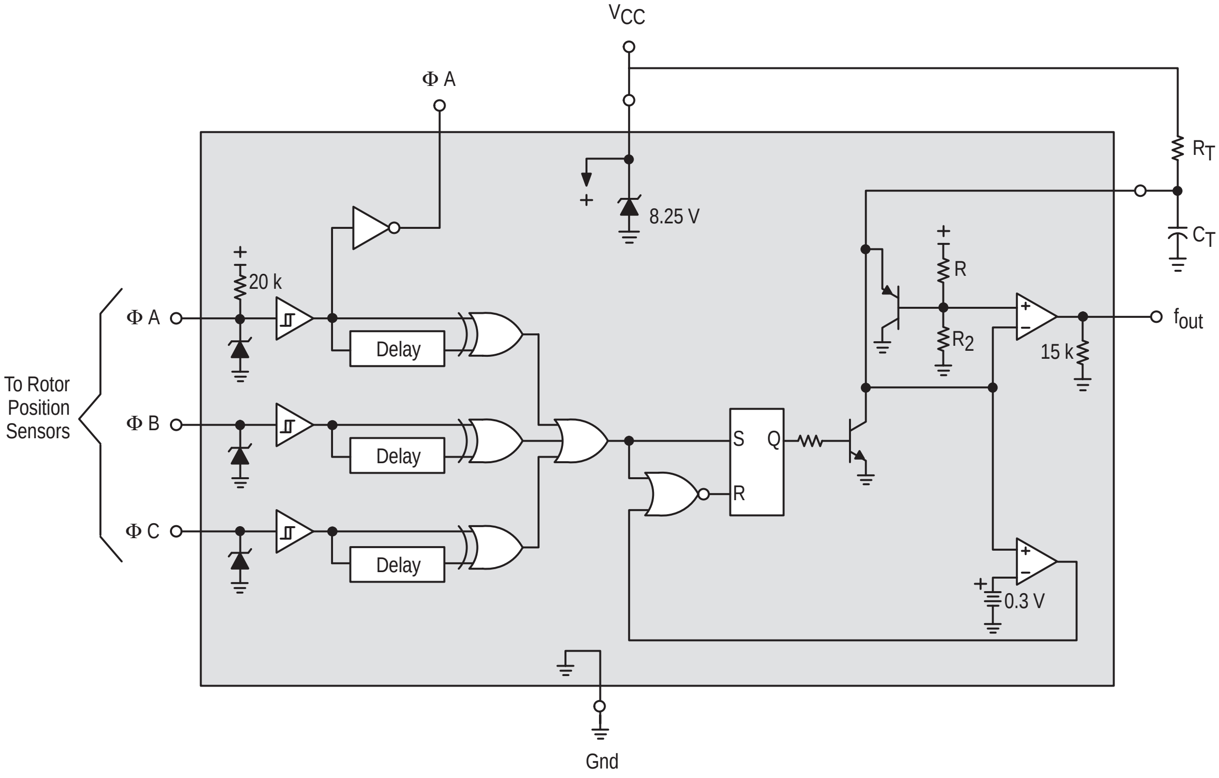


Closed Loop Brushless Motor Adapter

MC33039P, D

T_A = –40° to +85°C, Case 626, 751

The MC33039 is a high performance close loop speed control adapter specifically designed for use in brushless dc motor control systems. Implementation will allow precise speed regulation without the need for a magnetic or optical tachometer. These devices contain three input buffers each with hysteresis for noise immunity, three digital edge detectors, a programmable monostable, and an internal shunt regulator. Also included is an inverter output for use in systems that require conversion of sensor phasing. Although this device is primarily intended for use with the MC33033/35 brushless motor controllers, it can be used cost effectively in many other closed loop speed control applications.

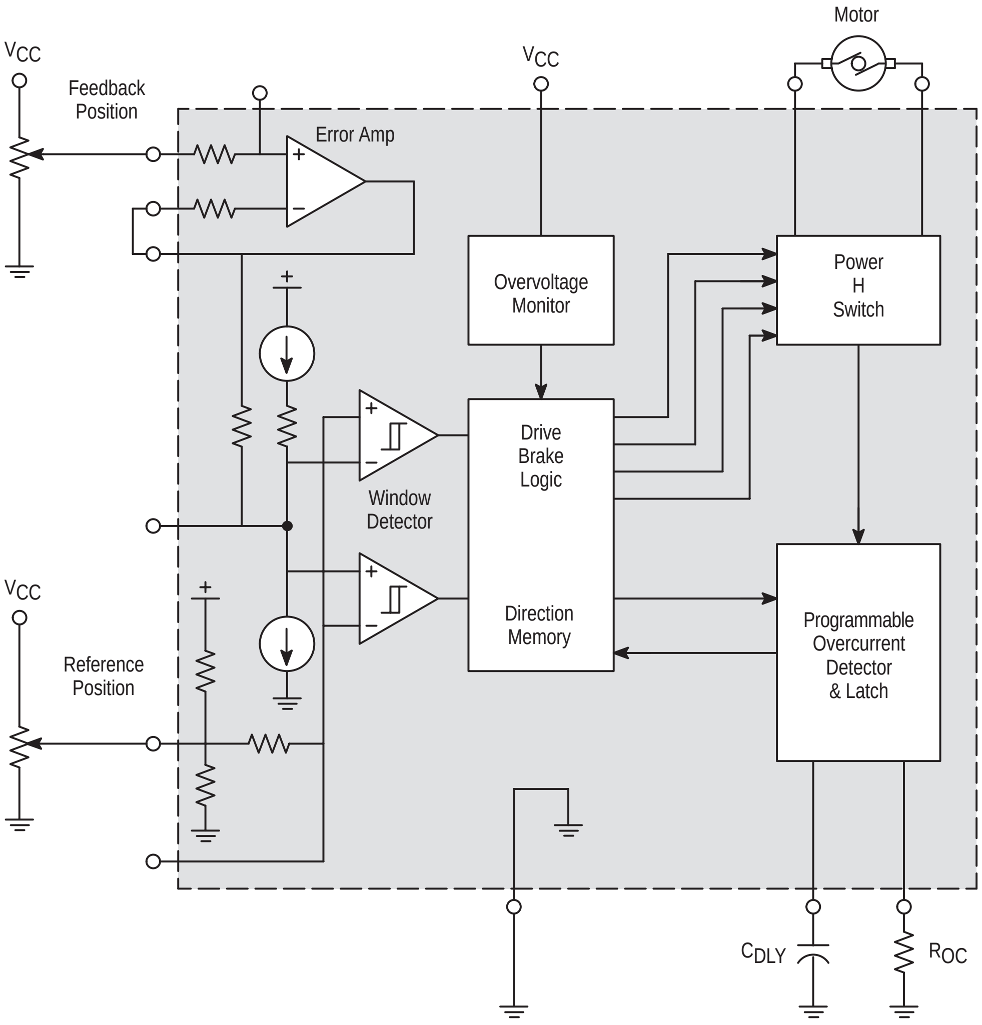


DC Servo Motor Controller/Driver

MC33030P, DW

T_A = –40° to +85°C, Case 648C, 751G

A monolithic dc servo motor controller providing all active functions necessary for a complete closed loop system. This device consists of an on–chip op amp and window comparator with wide input common mode range, drive and brake logic with direction memory, a power H switch driver capable of 1.0 A, independently programmable over current monitor and shutdown delay, and over voltage monitor. This part is ideally suited for almost any servo positioning application that requires sensing of temperature, pressure, light, magnetic flux, or any other means that can be converted to a voltage.



Stepper Motor Driver

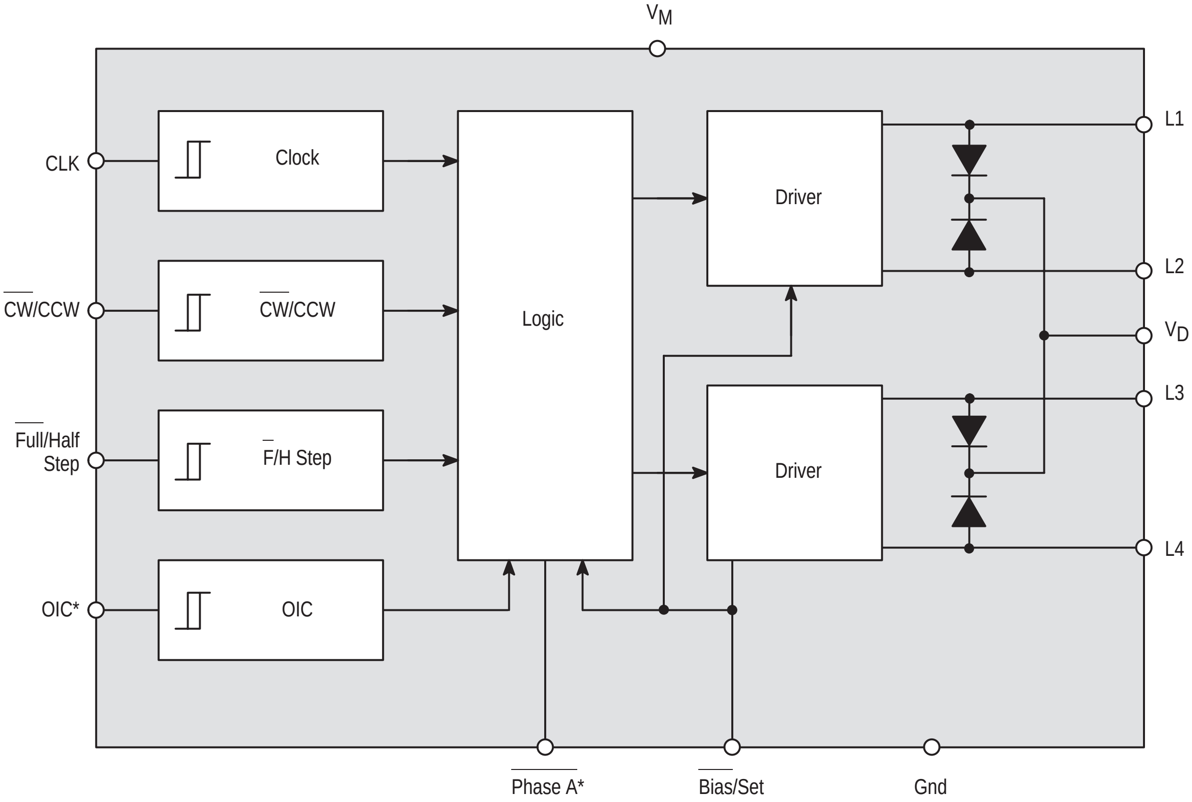
MC3479P, FN

T_A = 0° to +70°C, Case 648C, 775

SAA1042V

T_A = –30° to +125°C, Case 648C

These Stepper Motor Drivers provide up to 500 mA of drive per coil for two phase 6.0 V to 24 V stepper motors. Control logic is provided to accept commands for clockwise, counter clockwise and half or full step operation. The MC3479 has an added Output Impedance Control (OIC) and a Phase A drive state indicator (not available on SAA1042 devices).



* MC3479 Only

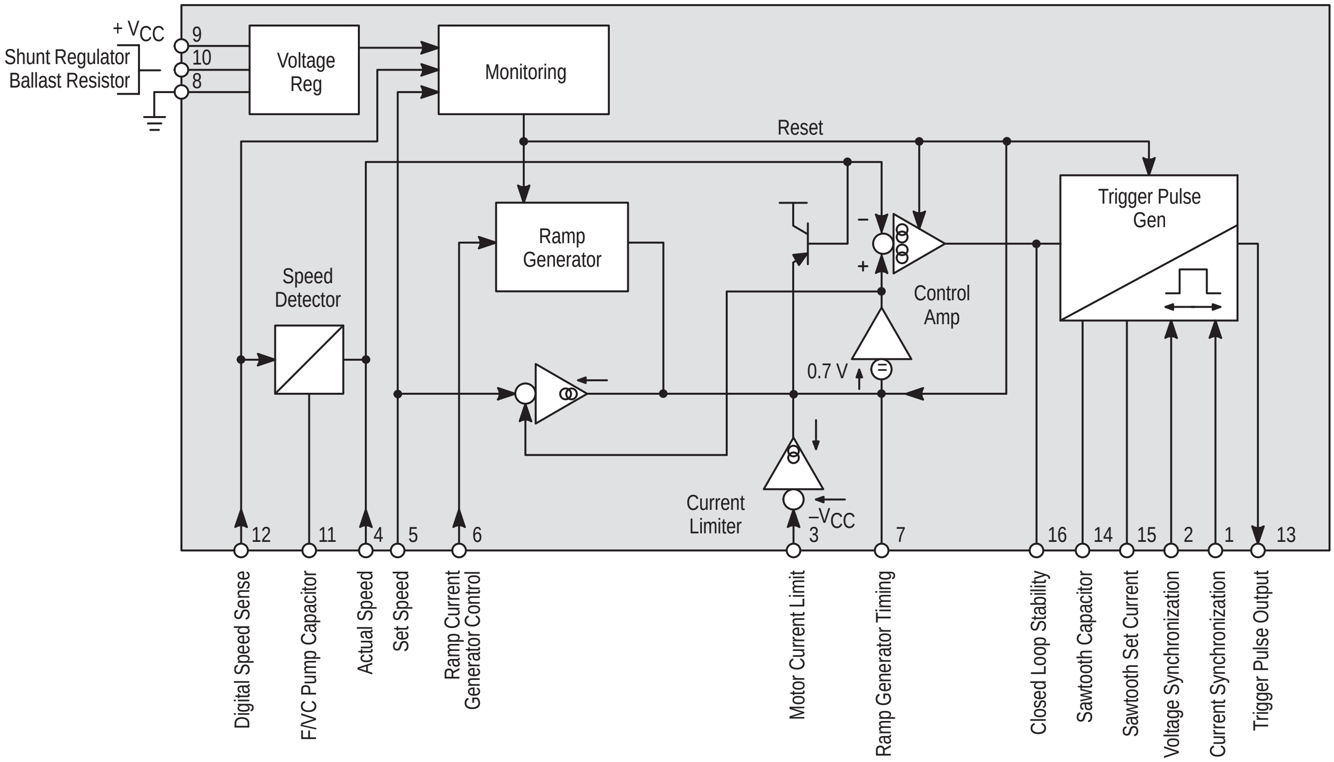
Universal Motor Speed Controller

TDA1085C, CD

T_A = –10° to +120°C, Case 648, 751B

The TDA1085C is a phase angle triac controller having all the necessary functions for universal motor speed control in washing machines. It operates in closed loop configuration and provides two ramp possibilities.

- On-Chip Frequency to Voltage Converter
- On-Chip Ramps Generator
- Soft Start
- Load Current Limitation
- Tachogenerator Circuit Sensing
- Direct Supply from AC Line
- Security Functions Peformed by Monitor



Triac Phase Angle Controller

TDA1185A

T_A = 0° to +70°C, Case 646

This device generates controlled triac triggering pulses and allows tachless speed stabilization of universal motors by an integrated positive feedback function.

- Low Cost External Components Count
- Optimum Triac Firing (2nd and 3rd Quadrants)
- Repetitive Trigger Pulses when Triac Current is Interrupted by Motor Brush Bounce
- Triac Current Sensed to Allow Inductive Loads
- Soft–Start
- Power Failure Detection and General Circuit Reset
- Low Power Consumption: 1.0 mA

ORDERING INFORMATION

Device	Operating Temperature Range	Package
CA3059	T_A = – 40° to +85°C	Plastic DIP

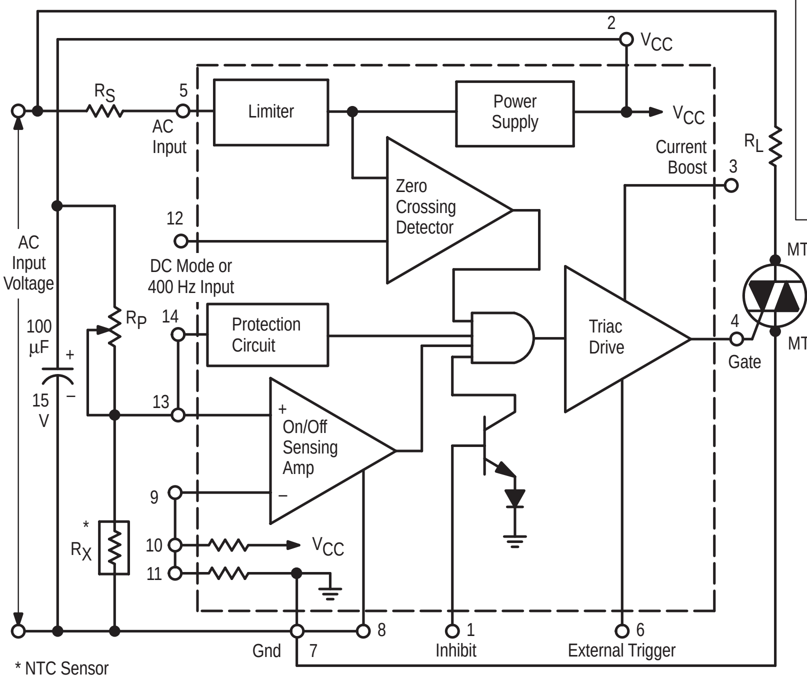
Zero Voltage Switch

This series is designed for thyristor control in a variety of AC power switching applications for AC input voltages of 24 V, 120 V, 208/230 V, and 277 V @ 50/60 Hz.

Applications:

- Relay Control
- Heater Control
- Valve Control
- Lamp Control
- On–Off Motor Switching
- Differential Comparator with Self–Contained Power Supply for Industrial Applications
- Synchronous Switching of Flashing Lights

Figure 1. Representative Block Diagram



AC Input Voltage (50/60 Hz) Vac	Input Series Resistor (R_S) kΩ	Dissipation Rating for R_S W
24	2.0	0.5
120	10	2.0
208/230	20	4.0
277	25	5.0

FUNCTIONAL BLOCK DESCRIPTION

1. **Limiter–Power Supply** — Allows operation of the CA3059 directly from an AC line. Suggested dropping resistor (R_S) values are given in the table below.
2. **Differential On/Off Sensing Amplifier** — Tests for condition of external sensors or input command signals. Proportional control capability or hysteresis may be implemented using this block.
3. **Zero–Crossing Detector** — Synchronizes the output pulses to the zero voltage point of the AC cycle. This synchronization eliminates RFI when used with resistive loads.
4. **Triac Drive** — Supplies high–current pulses to the external power controlling thyristor.
5. **Protection Circuit** — A built–in circuit may be actuated, if the sensor opens or shorts, to remove the drive current from the external triac.
6. **Inhibit Capability** — Thyristor firing may be inhibited by the action of an internal diode gate at Pin 1.
7. **High Power DC Comparator Operation** — Operation in this mode is accomplished by connecting Pin 7 to Pin 12 (thus overriding the action of the zero–crossing detector). When Pin 13 is positive with respect to Pin 9, current to the thyristor is continuous.

APPLICATION INFORMATION

Power Supply

The CA3059 is a self–powered circuit, powered from the AC line through an appropriate dropping resistor (see Table A). The internal supply is designed to power the auxiliary power circuits.

In applications where more output current from the internal supply is required, an external power supply of higher voltage should be used. To use an external power supply, connect Pin 5 and Pin 7 together and apply the synchronizing voltage to Pin 12 and the DC supply voltage to Pin 2 as shown in Figure 4.

Operation of Protection Circuit

The protection circuit, when connected, will remove current drive from the triac if an open or shorted sensor is detected. This circuit is activated by connecting Pin 13 to Pin 14 (see Figure 1).

The following conditions should be observed when the protection circuit is utilized:

a. The internal supply should be used and the external load current must be limited to 2 mA with a 5 kΩ dropping resistor.

b. Sensor Resistance (R_X) and R_P values should be between 2 kΩ and 100 kΩ.

c. The relationship $0.33 < R_X/R_P < 3$ must be met over the anticipated temperature range to prevent undesired activation of the circuit. A shunt or series resistor may have to be added.

External Inhibit Function

A priority inhibit command applied to Pin 1 will remove current drive from the thyristor. A command of at least +1.2 V @ 10 µA is required. A DTL or TTL logic 1 applied to Pin 1 will activate the inhibit function.

DC Gate Current Mode

When comparator operation is desired or inductive loads are being switched, Pins 7 and 12 should be connected. This connection disables the zero–crossing detector to permit the flow of gate current from the differential sensing amplifier on demand. Care should be exercised to avoid possible overloading of the internal power supply when operating the device in this mode. A resistor should be inserted between Pin 4 and the thyristor gate in order to limit the current.

MOTOROLA

MC3479

Stepper Motor Driver

STEPPER MOTOR DRIVER

SEMICONDUCTOR TECHNICAL DATA

The MC3479 is designed to drive a two–phase stepper motor in the bipolar mode. The circuit consists of four input sections, a logic decoding/sequencing section, two driver–stages for the motor coils, and an output to indicate the Phase A drive state.

- Single Supply Operation: 7.2 to 16.5 V
- 350 mA/Coil Drive Capability
- Clamp Diodes Provided for Back–EMF Suppression
- Selectable CW/CCW and Full/Half Step Operation
- Selectable High/Low Output Impedance (Half Step Mode)
- TTL/CMOS Compatible Inputs
- Input Hysteresis: 400 mV Minimum
- Phase Logic Can Be Initialized to Phase A
- Phase A Output Drive State Indication (Open–Collector)
- Available in Standard DIP and Surface Mount

PIN FUNCTION DESCRIPTION

Pin No.		Function	Symbol	Description
20–Pin	16–Pin			
20	16	Power Supply	V_M	Power supply pin for both the logic circuit and the motor coil current. Voltage range is + 7.2 to + 16.5 volts.
4, 5, 6, 7, 14, 15, 16, 17	4, 5, 12, 13	Ground	Gnd	Ground pins for the logic circuit and the motor coil current. The physical configuration of the pins aids in dissipating heat from within the IC package.
1	1	Clamp Diode Voltage	V_D	This pin is used to protect the outputs where large voltage spikes may occur as the motor coils are switched. Typically a diode is connected between this pin and Pin 16. See Figure 11.
2, 3, 18, 19	2, 3, 14, 15	Driver Outputs	L1, L2 L3, L4	High current outputs for the motor coils. L1 and L2 are connected to one coil, and L3 and L4 to the other coil.
8	6	Bias/Set	B/S	This pin is typically 0.7 volts below V_M. The current out of this pin (through a resistor to ground) determines the maximum output sink current. If the pin is opened (I_{BS} < 5.0 µA) the outputs assume a high impedance condition, while the internal logic presets to a Phase A condition.
9	7	Clock	Clk	The positive edge of the clock input switches the outputs to the next position. This input has no effect if Pin 6 is open.
11	9	Full/Half Step	F/HS	When low (Logic “0”), each clock input pulse will cause the motor to rotate one full step. When high, each clock pulse will cause the motor to rotate one–half step. See Figure 7 for sequence.
12	10	Clockwise/ Counterclockwise	CW/CCW	This input allows reversing the rotation of the motor. See Figure 7 for sequence.
10	8	Output Impedance Control	OIC	This input is relevant only in the half step mode (Pin 9 > 2.0 V). When low (Logic “0”), the two driver outputs of the non–energized coil will be in a high impedance condition. When high the same driver outputs will be at a low impedance referenced to V_M. See Figure 7.
13	11	Phase A	Ph A	This open–collector output indicates (when low) that the driver outputs are in the Phase A condition (L1 = L3 = V_{OHD}, L2 = L4 = V_{OLD}).

APPLICATION INFORMATION

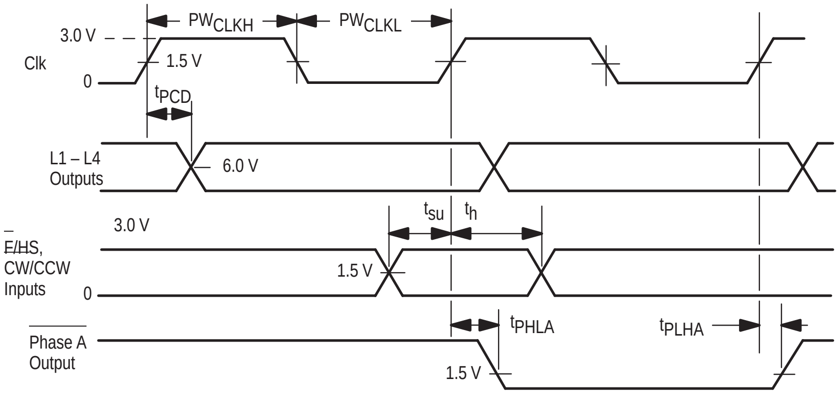
General

The MC3479 integrated circuit is designed to drive a stepper positioning motor in applications such as disk drives and robotics. The outputs can provide up to 350 mA to each of two coils of a two–phase motor. The outputs change state with each low–to–high transition of the clock input, with the new output state depending on the previous state, as well as the input conditions at the logic controls.

Outputs

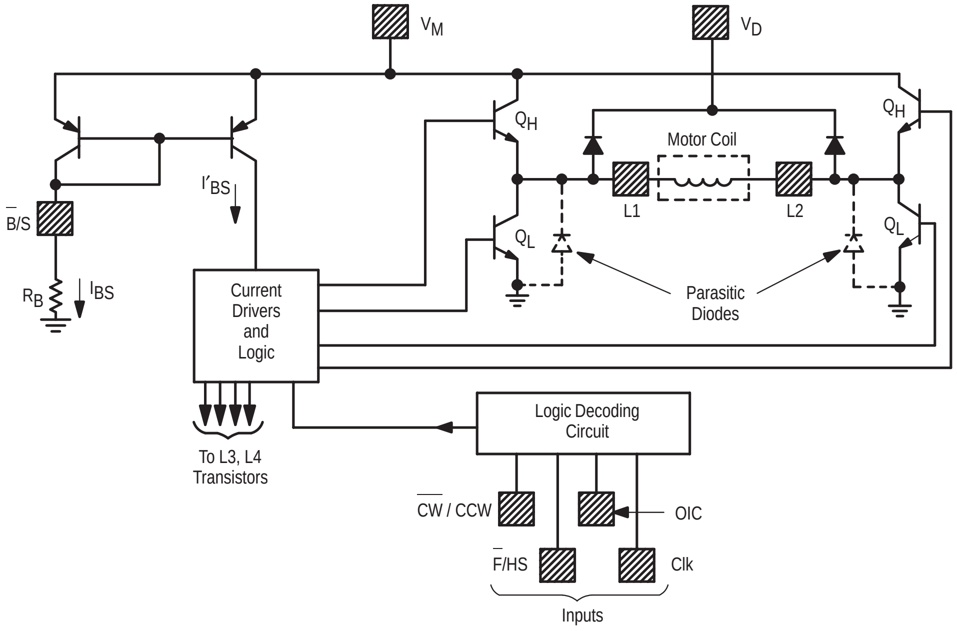
The outputs (L1–L4) are high current outputs (see Figure 5), which when connected to a two–phase motor, provide two full–bridge configurations (L3 and L4 are not shown in Figure 5). The polarities applied to the motor coils depend on which transistor (Q_H or Q_L) of each output is on, which in turn depends on the inputs and the decoding circuitry.

Figure 4. Clock Timing
(Refer to Figure 2)



Note: t_r, t_f (10% to 90%) for input signals are ≤ 10 ns.

Figure 5. Output Stages

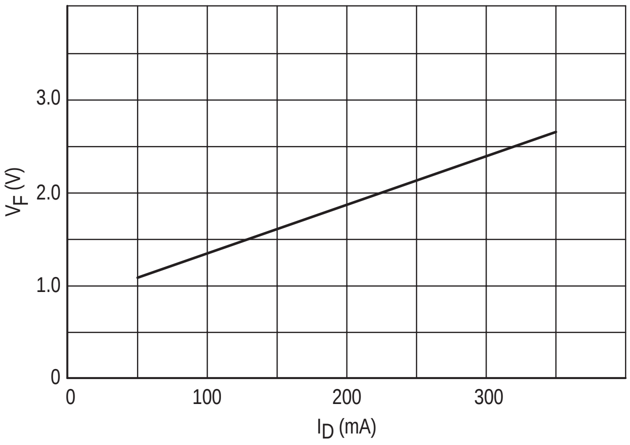


The maximum sink current available at the outputs is a function of the resistor connected between Pin 6 and ground (see section on Bias/Set operation). Whenever the outputs are to be in a high impedance state, both transistors (Q_H and Q_L of Figure 5) of each output are off.

V_D

This pin allows for provision of a current path for the motor coil current during switching, in order to suppress back–EMF voltage spikes. V_D is normally connected to V_M (Pin 16) through a diode (zener or regular), a resistor, or directly. The peaks instantaneous voltage at the outputs must not exceed V_M by more than 6.0 V. The voltage drop across the internal clamping diodes must be included in this portion of the design (see Figure 6). Note the parasitic diodes (Figure 5) across each Q_L of each output provide for a complete circuit path for the switched current.

Figure 6. Clamp Diode Characteristics



$\overline{\text{Full}}$/Half Step

When this input is at a Logic “0” (<0.8 V), the outputs change a full step with each clock cycle, with the sequence direction depending on the CW/CCW input. There are four steps (Phase A, B, C, D) for each complete cycle of the sequencing logic. Current flows through both motor coils during each step, as shown in Figure 7.

When taken to a Logic “1” (>2.0 V), the outputs change a half step with each clock cycle, with the sequence direction depending on the CW/CCW input. Eight steps (Phase A to H) result for each complete cycle of the sequencing logic. Phase A, C, E and G correspond (in polarity) to Phase A, B, C, and D, respectively, of the full step sequence. Phase B, D, F and H provide current to one motor coil, while de–energizing the other coil. The condition of the outputs of the de–energized coil depends on the OIC input, see Figure 7 timing diagram.

OIC

The output impedance control input determines the output impedance to the de–energized coil when operating in the half–step mode. When the outputs are in Phase B, D, F or H (Figure 7) and this input is at a Logic “0” (<0.8 V), the two outputs to the de–energized coil are in a high impedance condition — Q_L and Q_H of both outputs (Figure 5) are off. When this input is at a Logic “1” (>2.0 V), a low impedance output is provided to the de–energized coil as both outputs have Q_H on (Q_L off). To complete the low impedance path requires connecting V_D to V_M as described elsewhere in this data sheet.

$\overline{\text{Bias}}$/Set

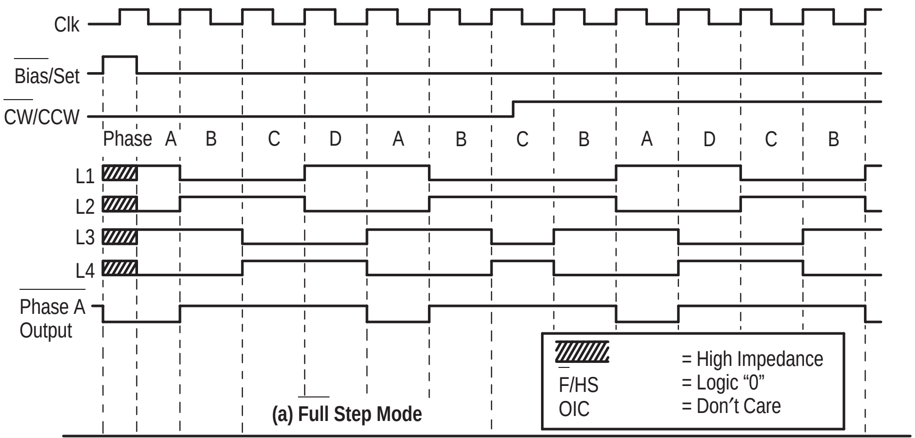
This pin can be used for three functions: a) determining the maximum output sink current; b) setting the internal logic to a known state; and c) reducing power consumption.

a) The maximum output sink current is determined by the base drive current supplied to the lower transistors (Q_Ls of Figure 5) of each output, which in turn, is a function of I_{BS}. The appropriate value of I_{BS} is determined by:

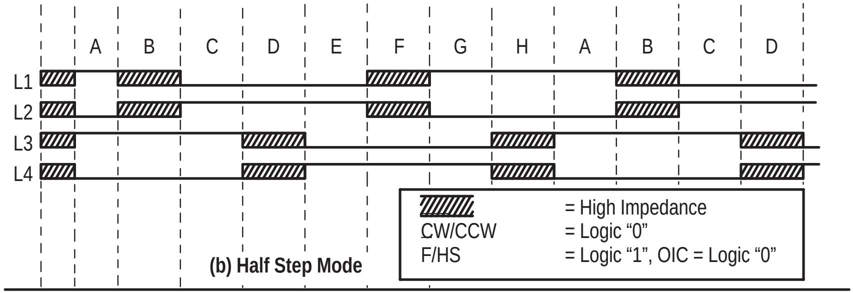
$$I_{BS} = I_{OD} \times 0.86$$

where I_{BS} is in microamps, and I_{OD} is the motor current/coil in milliamps.

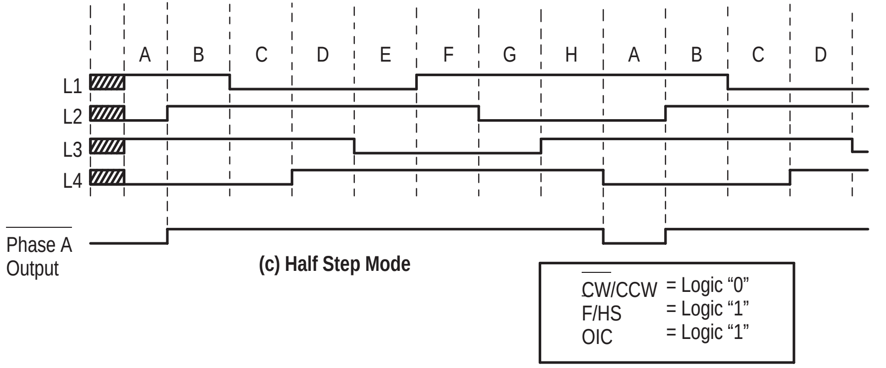
Figure 7. Output Sequence



(a) Full Step Mode



(b) Half Step Mode



(c) Half Step Mode

The value of R_B (between this pin and ground) is then determined by:

$$R_B = \frac{V_M - 0.7\ V}{I_{BS}}$$

b) When this pin is opened (raised to V_M) such that I_{BS} is <5.0 µA, the internal logic is set to the Phase A condition, and the four driver outputs are put into a high impedance state. The Phase A output (Pin 11) goes active (low), and input signals at the controls are ignored during this time. Upon re–establishing I_{BS}, the driver outputs become active, and will be in the Phase A position ($L1 = L3 = V_{OHD}$, $L2 = L4 = V_{OLD}$). The circuit will then respond to the inputs at the controls.

The Set function (opening this pin) can be used as a power–up reset while supply voltages are settling. A CMOS logic gate (powered by V_M) can be used to control this pin as shown in Figure 11.

c) Whenever the motor is not being stepped, power dissipation in the IC and in the motor may be lowered by reducing I_{BS}, so as to reduce the output (motor) current. Setting I_{BS} to 75 µA will reduce the motor current, but will not reset the internal logic as described above. See Figure 12 for a suggested circuit.

Power Dissipation

The power dissipated by the MC3479 must be such that the junction temperature (T_J) does not exceed 150°C. The power dissipated can be expressed as:

$$P = (V_M \times I_M) + (2 \times I_{OD}) [(V_M - V_{OHD}) + V_{OLD}]$$

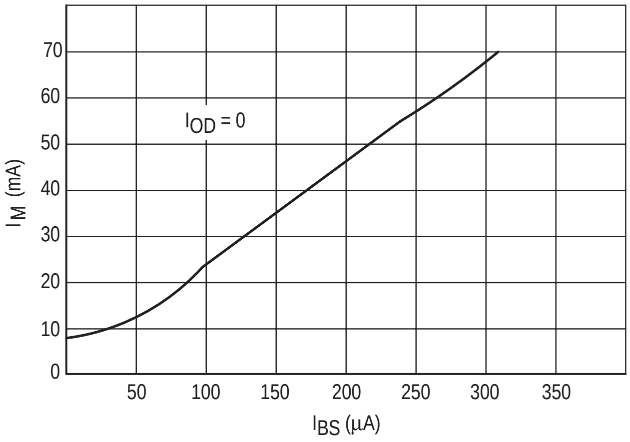
where V_M = Supply voltage;
I_M = Supply current other than I_{OD};
I_{OD} = Output current to each motor coil;
V_{OHD} = Driver output high voltage;
V_{OLD} = Driver output low voltage.

The power supply current (I_M) is obtained from Figure 8. After the power dissipation is calculated, the junction temperature can be calculated using:

$$T_J = (P \times R_{\theta JA}) + T_A$$

where $R_{\theta JA}$ = Junction–to–ambient thermal resistance (52°C/W for the DIP, 72°C/W for the FN Package);
T_A = Ambient Temperature.

Figure 8. Power Supply Current



For example, assume an application where V_M = 12 V, the motor requires 200 mA/coil, operating at room temperature with no heatsink on the IC. I_{BS} is calculated:

$$I_{BS} = 200 \times 0.86$$
$$I_{BS} = 172\ \mu A$$

R_B is calculated:

$$R_B = (12 - 0.7)\ V/172\ \mu A$$
$$R_B = 65.7\ k\Omega$$

From Figure 8, I_M (max) is determined to be 40 mA. From Figure 9, V_{OLD} is 0.46 volts, and from Figure 10, ($V_M - V_{OHD}$) is 1.4 volts.

$$P = (12 \times 0.040) + (2 \times 0.2)(1.4 + 0.46)$$
$$P = 1.22\ W$$
$$T_J = (1.22\ W \times 52°C/W) + 25°C$$
$$T_J = 88°C$$

This temperature is well below the maximum limit. If the calculated T_J had been higher than 150°C, a heatsink such as the Staver Co. V–7 Series, Aavid #5802, or Thermalloy #6012 could be used to reduce $R_{\theta JA}$. In extreme cases, forced air cooling should be considered.

The above calculation, and $R_{\theta JA}$, assumes that a ground plane is provided under the MC3479 (either or both sides of the PC board) to aid in the heat dissipation. Single nominal width traces leading from the four ground pins should be avoided as this will increase T_J, as well as provide potentially disruptive ground noise and IR drops when switching the motor current.

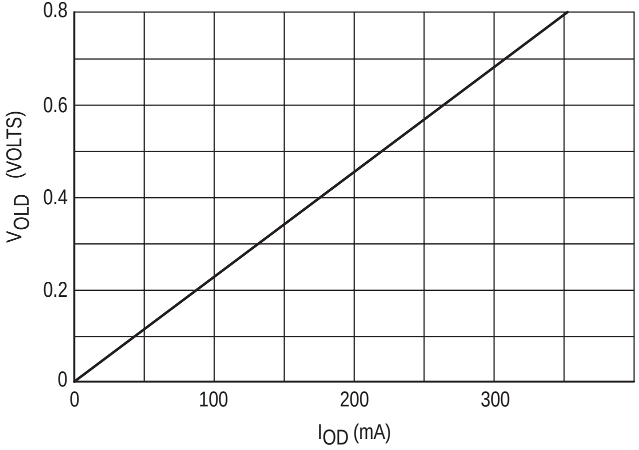

Figure 10. Maximum Saturation Voltage — Driver Output High

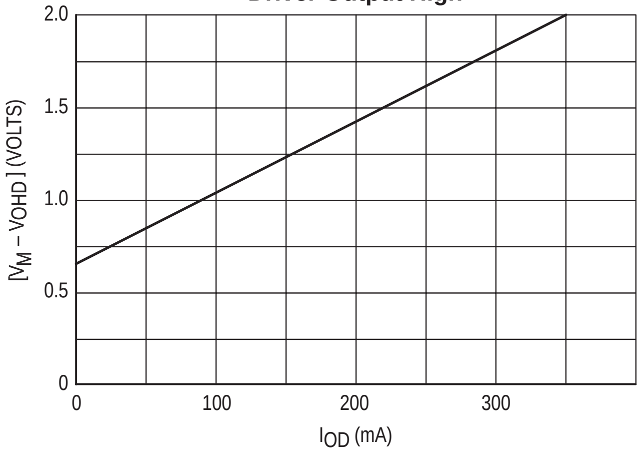

Figure 11. Typical Applications Circuit

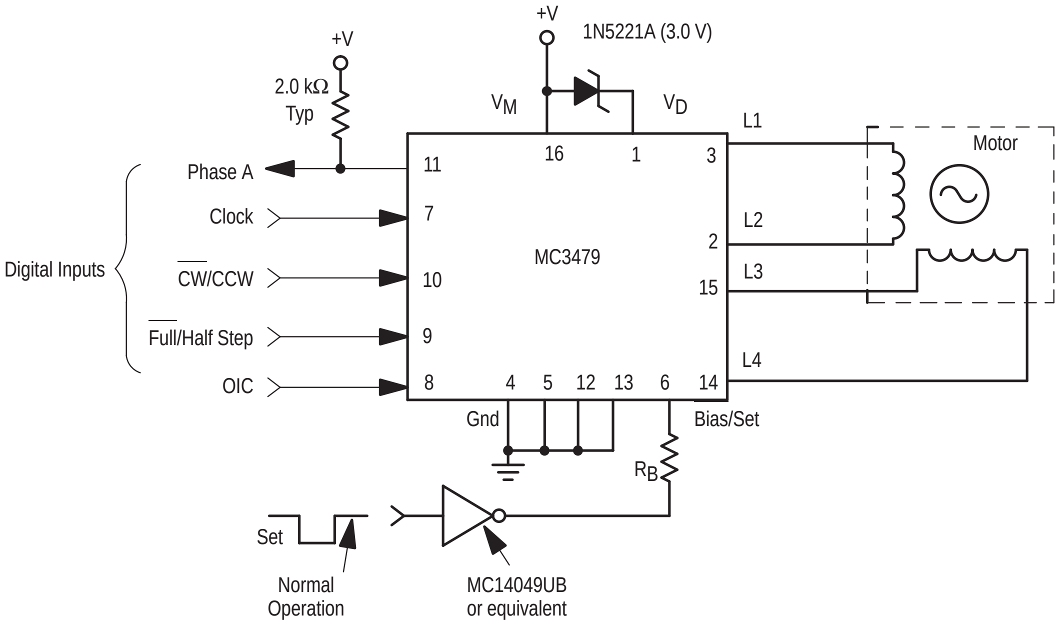

Figure 12. Power Reduction

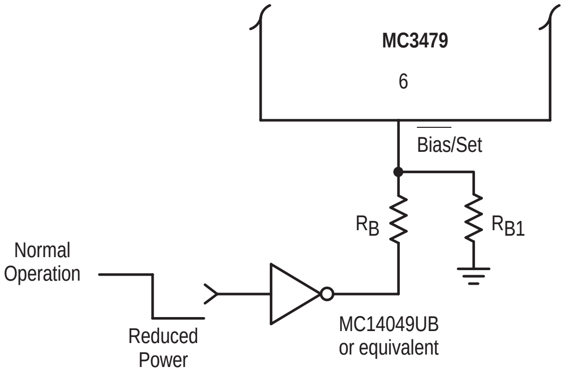

— Suggested value for R_{B1} (V_M = 12 V) is 150 kΩ.
— R_B calculation (see text) must take into account
the current through R_{B1}.

MOTOROLA

MC33030

DC Servo Motor Controller/Driver

DC SERVO MOTOR CONTROLLER/DRIVER

SEMICONDUCTOR TECHNICAL DATA

The MC33030 is a monolithic DC servo motor controller providing all active functions necessary for a complete closed loop system. This device consists of an on–chip op amp and window comparator with wide input common–mode range, drive and brake logic with direction memory, Power H–Switch driver capable of 1.0 A, independently programmable over–current monitor and shutdown delay, and over–voltage monitor. This part is ideally suited for almost any servo positioning application that requires sensing of temperature, pressure, light, magnetic flux, or any other means that can be converted to a voltage.

Although this device is primarily intended for servo applications, it can be used as a switchmode motor controller.

- On–Chip Error Amp for Feedback Monitoring
- Window Detector with Deadband and Self Centering Reference Input
- Drive/Brake Logic with Direction Memory
- 1.0 A Power H–Switch
- Programmable Over–Current Detector
- Programmable Over–Current Shutdown Delay
- Over–Voltage Shutdown

OPERATING DESCRIPTION

The MC33030 was designed to drive fractional horsepower DC motors and sense actuator position by voltage feedback. A typical servo application and representative internal block diagram are shown in Figure 17. The system operates by setting a voltage on the reference input of the Window Dectector (Pin 1) which appears on (Pin 2). A DC motor then drives a position sensor, usually a potentiometer driven by a gear box, in a corrective fashion so that a voltage proportional to position is present at Pin 3. The servo motor will continue to run until the voltage at Pin 3 falls within the dead zone, which is centered about the reference voltage.

The Window Detector is composed of two comparators, A and B, each containing hysteresis. The reference input, common to both comparators, is pre–biased at 1/2 V_{CC} for simple two position servo systems and can easily be overriden by an external voltage divider. The feedback voltage present at Pin 3 is connected to the center of two resistors that are driven by an equal magnitude current source and sink. This generates an offset voltage at the input of each comparator which is centered about Pin 3 that can float virtually from V_{CC} to ground. The sum of the upper and lower offset voltages is defined as the window detector input dead zone range.

To increase system flexibility, an on–chip Error Amp is provided. It can be used to buffer and/or gain–up the actuator position voltage which has the effect of narrowing the dead zone range. A PNP differential input stage is provided so that the input common–mode voltage range will include ground. The main design goal of the error amp output stage was to be able to drive the window detector input. It typically can source 1.8 mA and sink 250 µA. Special design considerations must be made if it is to be used for other applications.

The Power H–Switch provides a direct means for motor drive and braking with a maximum source, sink, and brake current of 1.0 A continuous. Maximum package power dissipation limits must be observed. Refer to Figure 15 for thermal information. For greater drive current requirements, a method for buffering that maintains all the system features is shown in Figure 30.

The Over–Current Monitor is designed to distinguish between motor start–up or locked rotor conditions that can occur when the actuator has reached its travel limit. A fraction of the Power H–Switch source current is internally fed into one of the two inverting inputs of the current comparator, while the non–inverting input is driven by a programmable current reference. This reference level is controlled by the resistance value selected for R_{OC}, and must be greater than the required motor run–current with its mechanical load over temperature; refer to Figure 8. During an over–current condition, the comparator will turn off and allow the current source to charge the delay capacitor, C_{DLY}. When C_{DLY} charges to a level of 7.5 V, the set input of the over–current latch will go high, disabling the drive and brake functions of the Power H–Switch. The programmable time delay is determined by the capacitance value–selected for C_{DLY}.

$$t_{DLY} = \frac{V_{ref}\ C_{DLY}}{I_{DLY(source)}} = \frac{7.5\ C_{DLY}}{5.5\ \mu A} = 1.36\ C_{DLY}\quad \text{in } \mu F$$

This system allows the Power H–Switch to supply motor start–up current for a predetermined amount of time. If the rotor is locked, the system will time–out and shut–down. This feature eliminates the need for servo end–of–travel or limit switches. Care must be taken so as not to select too large of a capacitance value for C_{DLY}. An over–current condition for an excessively long time–out period can cause the integrated circuit to overheat and eventually fail. Again, the maximum package power dissipation limits must be observed. The over–current latch is reset upon power–up or by readjusting $V_{Pin\ 2}$ as to cause $V_{Pin\ 3}$ to enter or pass through the dead zone. This can be achieved by requesting the motor to reverse direction.

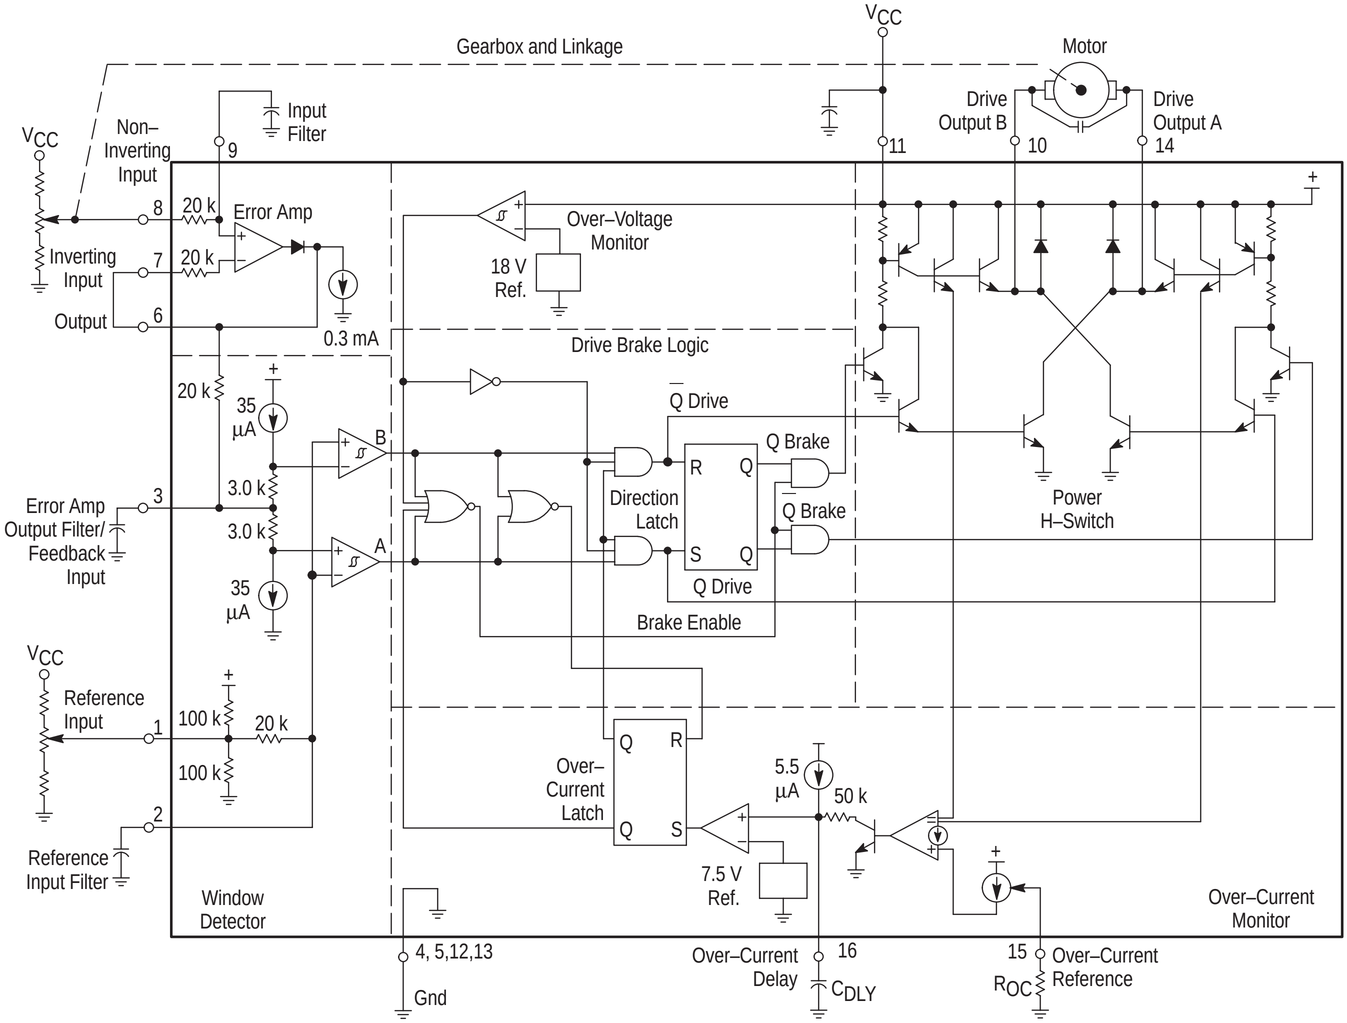
An Over–Voltage Monitor circuit provides protection for the integrated circuit and motor by disabling the Power H–Switch functions if V_{CC} should exceed 18 V. Resumption of normal operation will commence when V_{CC} falls below 17.4 V.

A timing diagram that depicts the operation of the Drive/Brake Logic section is shown in Figure 18. The waveforms grouped in [1] show a reference voltage that was preset, appearing on Pin 2, which corresponds to the desired actuator position. The true actuator position is represented by the voltage on Pin 3. The points V_1 through V_4 represent the input voltage thresholds of comparators A and B that cause a change in their respective output state. They are defined as follows:

V_1 = Comparator B turn–off threshold
V_2 = Comparator A turn–on threshold
V_3 = Comparator A turn–off threshold
V_4 = Comparator B turn–on threshold
V_1–V_4 = Comparator B input hysteresis voltage
V_2–V_3 = Comparator A input hysteresis voltage
V_2–V_4 = Window detector input dead zone range
$|(V_2 - V_{Pin2}) - (V_{Pin2} - V_4)|$ = Window detector input voltage

It must be remembered that points V_1 through V_4 always try to follow and center about the reference voltage setting if it is within the input common–mode voltage range of Pin 3; Figures 4 and 5. Initially consider that the feedback input voltage level is somewhere on the dashed line between V_2 and V_4 in [1]. This is within the dead zone range as defined above and the motor will be off. Now if the reference voltage is raised so that $V_{Pin\ 3}$ is less than V_4, comparator B will turn–on [3] enabling $\overline{Q}$ Drive, causing Drive Output A to sink and B to source motor current [8]. The actuator will move in Direction B until $V_{Pin\ 3}$ becomes greater than V_1. Comparator B will turn–off, activating the brake enable [4] and $\overline{Q}$ Brake [6] causing Drive Output A to go high and B to go into a high impedance state. The inertia of the mechanical system will drive the motor as a generator creating a positive voltage on Pin 10 with respect to Pin 14. The servo system can be stopped quickly, so as not to over–shoot through the dead zone range, by braking. This is accomplished by shorting the motor/generator terminals together. Brake current will flow into the diode at Drive Output B, through the internal V_{CC} rail, and out the emitter of the sourcing transistor at Drive Output A. The end of the solid line and beginning of the dashed for $V_{Pin\ 3}$ [1] indicates the possible resting position of the actuator after braking.

Figure 17. Representative Block Diagram and Typical Servo Application



If $V_{Pin\ 3}$ should continue to rise and become greater than V_2, the actuator will have over shot the dead zone range and cause the motor to run in Direction A until $V_{Pin\ 3}$ is equal to V_3. The Drive/Brake behavior for Direction A is identical to that of B. Overshooting the dead zone range in both directions can cause the servo system to continuously hunt or oscillate. Notice that the last motor run–direction is stored in the direction latch. This information is needed to determine whether Q or Q Brake is to be enabled when $V_{Pin\ 3}$ enters the dead zone range. The dashed lines in [8,9] indicate the resulting waveforms of an over–current condition that has exceeded the programmed time delay. Notice that both Drive Outputs go into a high impedance state until $V_{Pin\ 2}$ is readjusted so that $V_{Pin\ 3}$ enters or crosses through the dead zone [7, 4].

The inputs of the Error Amp and Window Detector can be susceptible to the noise created by the brushes of the DC motor and cause the servo to hunt. Therefore, each of these inputs are provided with an internal series resistor and are pinned out for an external bypass capacitor. It has been found that placing a capacitor with *short leads* directly across the brushes will significantly reduce noise problems. Good quality RF bypass capacitors in the range of 0.001 to 0.1 µF may be required. Many of the more economical motors will generate significant levels of RF energy over a spectrum that extends from DC to beyond 200 MHz. The capacitance value and method of noise filtering must be determined on a system by system basis.

Thus far, the operating description has been limited to servo systems in which the motor mechanically drives a potentiometer for position sensing. Figures 19, 20, 27, and 31 show examples that use light, magnetic flux, temperature, and pressure as a means to drive the feedback element. Figures 21, 22 and 23 are examples of two position, open loop servo systems. In these systems, the motor runs the actuator to each end of its travel limit where the Over–Current Monitor detects a locked rotor condition and shuts down the drive. Figures 32 and 33 show two possible methods of using the MC33030 as a switching motor controller. In each example a fixed reference voltage is applied to Pin 2. This causes $V_{pin\ 3}$ to be less than V_4 and Drive Output A, Pin 14, to be in a low state saturating the TIP42 transistor. In Figure 32, the motor drives a tachometer that generates an ac voltage proportional to RPM. This voltage is rectified, filtered, divided down by the speed set potentiometer, and applied to Pin. 8. The motor will accelerate until $V_{Pin\ 3}$ is equal to V_1 at which time Pin 14 will go to a high state and terminate the motor drive. The motor will now coast until $V_{Pin\ 3}$ is less than V_4 where upon drive is then reapplied. The system operation of Figure 31 is identical to that of 32 except the signal at Pin 3 is an amplified average of the motors drive and back EMF voltages. Both systems exhibit excellent control of RPM with variations of V_{CC}; however, Figure 32 has somewhat better torque characteristics at low RPM.

MOTOROLA

MC33033

Brushless DC Motor Controller

The MC33033 is a high performance second generation, limited feature, monolithic brushless dc motor controller which has evolved from Motorola′s full featured MC33034 and MC33035 controllers. It contains all of the active functions required for the implementation of open loop, three or four phase motor control. The device consists of a rotor position decoder for proper commutation sequencing, temperature compensated reference capable of supplying sensor power, frequency programmable sawtooth oscillator, fully accessible error amplifier, pulse width modulator comparator, three open collector top drivers, and three high current totem pole bottom drivers ideally suited for driving power MOSFETs. Unlike its predessors, it does not feature separate drive circuit supply and ground pins, brake input, or fault output signal.

Included in the MC33033 are protective features consisting of undervoltage lockout, cycle–by–cycle current limiting with a selectable time delayed latched shutdown mode, and internal thermal shutdown.

Typical motor control functions include open loop speed, forward or reverse direction, and run enable.The MC33033 is designed to operate brushless motors with electrical sensor phasings of 60°/300° or 120°/240°, and can also efficiently control brush dc motors.

- 10 to 30 V Operation
- Undervoltage Lockout
- 6.25 V Reference Capable of Supplying Sensor Power
- Fully Accessible Error Amplifier for Closed Loop Servo Applications
- High Current Drivers Can Control External 3–Phase MOSFET Bridge
- Cycle–By–Cycle Current Limiting
- Internal Thermal Shutdown
- Selectable 60°/300° or 120°/240° Sensor Phasings
- Also Efficiently Control Brush DC Motors with External MOSFET H–Bridge

PIN FUNCTION DESCRIPTION

Pin	Symbol	Description
1, 2, 20	B_T, A_T, C_T	These three open collector Top Drive Outputs are designed to drive the external upper power switch transistors.
3	Fwd//Rev	The Forward/Reverse Input is used to change the direction of motor rotation.
4, 5, 6	S_A, S_B, S_C	These three Sensor Inputs control the commutation sequence.
7	Reference Output	This output provides charging current for the oscillator timing capacitor C_T and a reference for the Error Amplifier. It may also serve to furnish sensor power.
8	Oscillator	The Oscillator frequency is programmed by the values selected for the timing components, R_T and C_T.
9	Error Amp Noninverting Input	This input is normally connected to the speed set potentiometer.
10	Error Amp Inverting Input	This input is normally connected to the Error Amp Output in open loop applications.
11	Error Amp Out/PWM Input	This pin is available for compensation in closed loop applications.
12	Current Sense Noninverting Input	A 100 mV signal, with respect to Pin 13, at this input terminates output switch conduction during a given oscillator cycle. This pin normally connects to the top side of the current sense resistor.
13	Gnd	This pin supplies a separate ground return for the control circuit and should be referenced back to the power source ground.
14	V_{CC}	This pin is the positive supply of the control IC. The controller is functional over a V_{CC} range of 10 to 30 V.
15, 16, 17	C_B, B_B, A_B	These three totem pole Bottom Drive Outputs are designed for direct drive of the external bottom power switch transistors.
18	60°/$\overline{120^\circ}$ Select	The electrical state of this pin configures the control circuit operation for either 60° (high state) or 120° (low state) sensor electrical phasing inputs.
19	Output Enable	A logic high at this input causes the motor to run, while a low causes it to coast.

INTRODUCTION

The MC33033 is one of a series of high performance monolithic dc brushless motor controllers produced by Motorola. It contains all of the functions required to implement a limited–feature, open loop, three or four phase motor control system. Constructed with Bipolar Analog technology, it offers a high degree of performance and ruggedness in hostile industrial environments.The MC33033 contains a rotor position decoder for proper commutation sequencing, a temperature compensated reference capable of supplying sensor power, a frequency programmable sawtooth oscillator, a fully accessible error amplifier, a pulse width modulator comparator, three open collector top drive outputs, and three high current totem pole bottom driver outputs ideally suited for driving power MOSFETs.

Included in the MC33033 are protective features consisting of undervoltage lockout, cycle–by–cycle current limiting with a latched shutdown mode, and internal thermal shutdown.

Typical motor control functions include open loop speed control, forward or reverse rotation, and run enable. In addition, the MC33033 has a 60°/120° select pin which configures the rotor position decoder for either 60° or 120° sensor electrical phasing inputs.

FUNCTIONAL DESCRIPTION

A representative internal block diagram is shown in Figure 18, with various applications shown in Figures 34, 36, 37, 41, 43, and 44. A discussion of the features and function of each of the internal blocks given below and referenced to Figures 18 and 36.

Rotor Position Decoder

An internal rotor position decoder monitors the three sensor inputs (Pins 4, 5, 6) to provide the proper sequencing of the top and bottom drive outputs. The Sensor Inputs are designed to interface directly with open collector type Hall Effect switches or opto slotted couplers. Internal pull–up resistors are included to minimize the required number of external components. The inputs are TTL compatible, with their thresholds typically at 2.2 V. The MC33033 series is designed to control three phase motors and operate with four of the most common conventions of sensor phasing. A 60°/120° Select (Pin 18) is conveniently provided which affords the MC33033 to configure itself to control motors having either 60°, 120°, 240° or 300° electrical sensor phasing. With three Sensor Inputs there are eight possible input code combinations, six of which are valid rotor positions. The remaining two codes are invalid and are usually caused by an open or shorted sensor line. With six valid input codes, the decoder can resolve the motor rotor position to within a window of 60 electrical degrees.

The Forward/Reverse input (Pin 3) is used to change the direction of motor rotation by reversing the voltage across the stator winding. When the input changes state, from high to low with a given sensor input code (for example 100), the enabled top and bottom drive outputs with the same alpha designation are exchanged (A_T to A_B, B_T to B_B, C_T to C_B). In effect the commutation sequence is reversed and the motor changes directional rotation.

Motor on/off control is accomplished by the Output Enable (Pin19). When left disconnected, an internal pull–up resistor to a positive source enables sequencing of the top and bottom drive outputs. When grounded, the Top Drive Outputs turn off and the bottom drives are forced low, causing the motor to coast.

The commutation logic truth table is shown in Figure 19. In half wave motor drive applications, the Top Drive Outputs are not required and are typically left disconnected.

Error Amplifier

A high performance, fully compensated Error Amplifier with access to both inputs and output (Pins 9, 10, 11) is provided to facilitate the implementation of closed loop motor speed control. The amplifier features a typical dc voltage gain of 80 dB, 0.6 MHz gain bandwidth, and a wide input common mode voltage range that extends from ground to V_{ref}. In most open loop speed control applications, the amplifier is configured as a unity gain voltage follower with the Noninverting Input connected to the speed set voltage source. Additional configurations are shown in Figures 29 through 33.

Oscillator

The frequency of the internal ramp oscillator is programmed by the values selected for timing components R_T and C_T. Capacitor C_T is charged from the Reference Output (Pin 7) through resistor R_T and discharged by an internal discharge transistor. The ramp peak and valley voltages are typically 4.1 V and 1.5 V respectively. To provide a good compromise between audible noise and output switching efficiency, an oscillator frequency in the range of 20 to 30 kHz is recommended. Refer to Figure 1 for component selection.

Pulse Width Modulator

The use of pulse width modulation provides an energy efficient method of controlling the motor speed by varying the average voltage applied to each stator winding during the commutation sequence. As C_T discharges, the oscillator sets both latches, allowing conduction of the Top and Bottom Drive Outputs. The PWM comparator resets the upper latch, terminating the Bottom Drive Output conduction when the positive–going ramp of C_T becomes greater than the Error Amplifier output. The pulse width modulator timing diagram is shown in Figure 20. Pulse width modulation for speed control appears only at the Bottom Drive Outputs.

Current Limit

Continuous operation of a motor that is severely over–loaded results in overheating and eventual failure. This destructive condition can best be prevented with the use of cycle–by–cycle current limiting. That is, each on–cycle is treated as a separate event. Cycle–by–cycle current limiting is accomplished by monitoring the stator current build–up each time an output switch conducts, and upon sensing an over current condition, immediately turning off the switch and holding it off for the remaining duration of

NOTES:
1. V = Any one of six valid sensor or drive combinations.
   X = Don't care.
2. The digital inputs (Pins 3, 4, 5, 6, 18, 19) are all TTL compatible. The current sense input (Pin 12) has a 100 mV threshold with respect to Pin 13. A logic 0 for this input is defined as < 85 mV, and a logic 1 is > 115 mV.
3. The top drive outputs are open collector design and active in the low (0) state.
4. With 60°/120° (Pin 18) in the high (1) state, configuration is for 60° sensor electrical phasing inputs. With Pin 18 in the low (0) state, configuration is for 120° sensor electrical phasing inputs.
5. Valid 60° or 120° sensor combinations for corresponding valid top and bottom drive outputs.
6. Invalid sensor inputs; All top and bottom drives are off.
7. Valid sensor inputs with enable = 0; All top and bottom drives are off.
8. Valid sensor inputs with enable and current sense = 1; All top and bottom drives are off.

oscillator ramp–up period. The stator current is converted to a voltage by inserting a ground–referenced sense resistor R_S (Figure 34) in series with the three bottom switch transistors (Q_4, Q_5, Q_6). The voltage developed across the sense resistor is monitored by the current sense input (Pin 12), and compared to the internal 100 mV reference. If the current sense threshold is exceeded, the comparator resets the lower latch and terminates output switch conduction. The value for the sense resistor is:

$$R_S = \frac{0.1}{I_{stator(max)}}$$

The dual–latch PWM configuration ensures that only one single output conduction pulse occurs during any given oscillator cycle, whether terminated by the output of the Error Amplifier or the current limit comparator.

Reference

The on–chip 6.25 V regulator (Pin 7) provides charging current for the oscillator timing capacitor, a reference for the Error Amplifier, and can supply 20 mA of current suitable for directly powering sensors in low voltage applications. In higher voltage applications it may become necessary to transfer the power dissipated by the regulator off the IC. This is easily accomplished with the addition of an external pass transistor as shown in Figure 21. A 6.25 V reference level was chosen to allow implementation of the simpler NPN circuit, where $V_{ref} – V_{BE}$ exceeds the minimum voltage required by Hall Effect sensors over temperature. With proper transistor selection, and adequate heatsinking, up to one amp of load current can be obtained.

Undervoltage Lockout

A dual Undervoltage Lockout has been incorporated to prevent damage to the IC and the external power switch transistors. Under low power supply conditions, it guarantees that the IC and sensors are fully functional, and that there is sufficient Bottom Drive Output voltage. The positive power supply to the IC (V_{CC}) is monitored to a threshold of 8.9 V. This level ensures sufficient gate drive necessary to attain low $R_{DS(on)}$ when interfacing with standard power MOSFET devices. When directly powering the Hall sensors from the reference, improper sensor operation can result if the reference output voltage should fall below 4.5 V. If one or both of the comparators detects an undervoltage condition, the top drives are turned off and the Bottom Drive Outputs are held in a low state. Each of the comparators contain hysteresis to prevent oscillations when crossing their respective thresholds.

Figure 20. PWM Timing Diagram

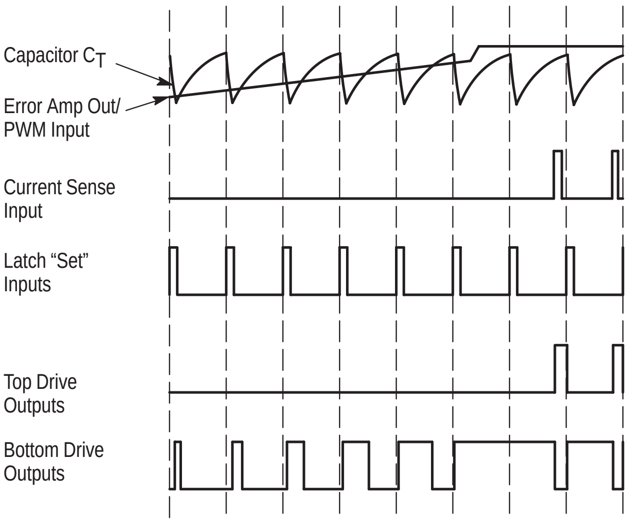

Figure 21. Reference Output Buffers

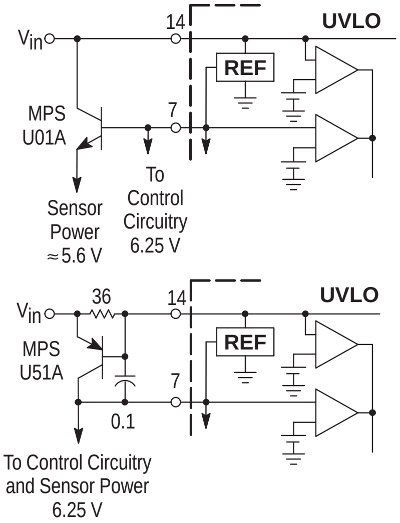
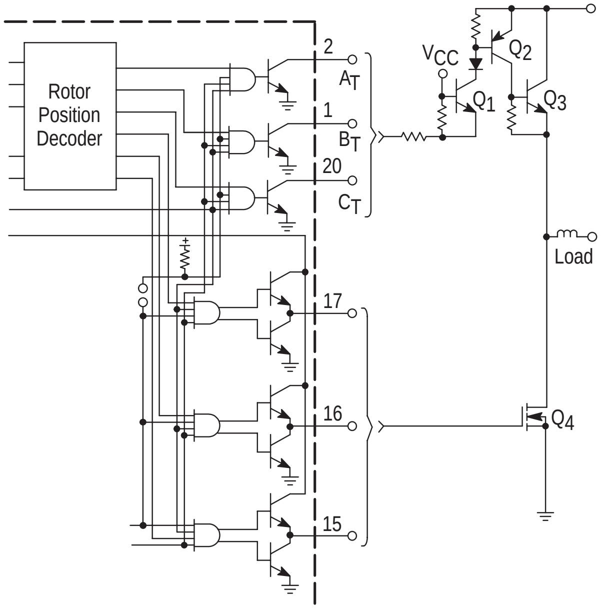


The NPN circuit is recommended for powering Hall or opto sensors, where the output voltage temperature coefficient is not critical. The PNP circuit is slightly more complex, but also more accurate. Neither circuit has current limiting.

Figure 22. High Voltage Interface with NPN Power Transistors



Transistor Q_1 is a common base stage used to level shift from V_{CC} to the high motor voltage, V_M. The collector diode is required if V_{CC} is present while V_M is low.

Figure 23. High Voltage Interface with N–Channel Power MOSFETs

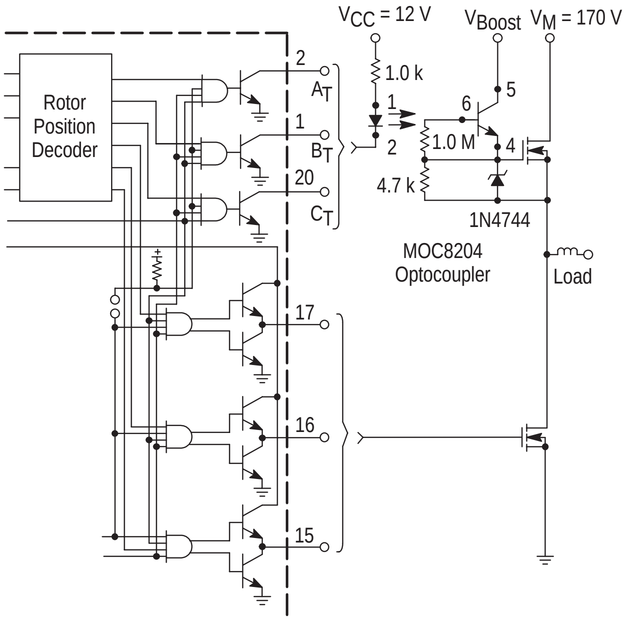


Figure 24. Current Waveform Spike Suppression

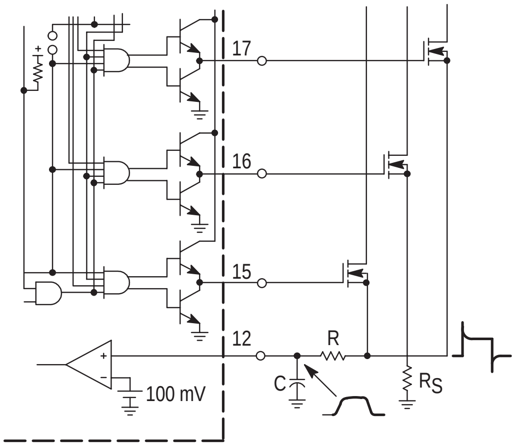
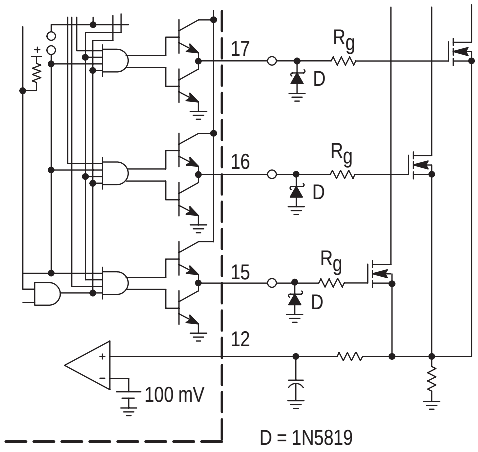


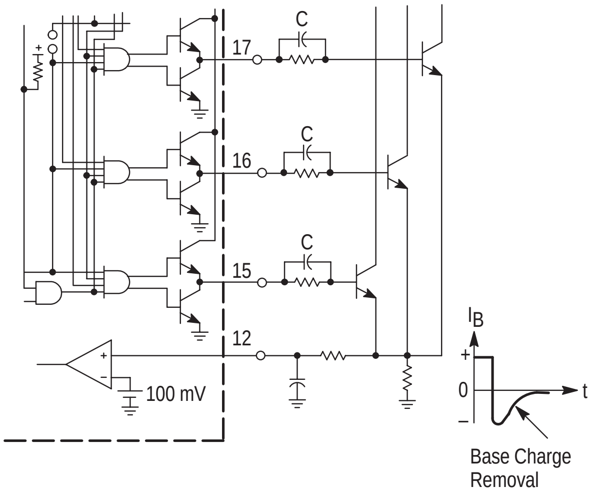
The addition of the RC filter will eliminate current–limit instability caused by the leading edge spike on the current waveform. Resistor R_S should be a low inductance type.

Figure 25. MOSFET Drive Precautions



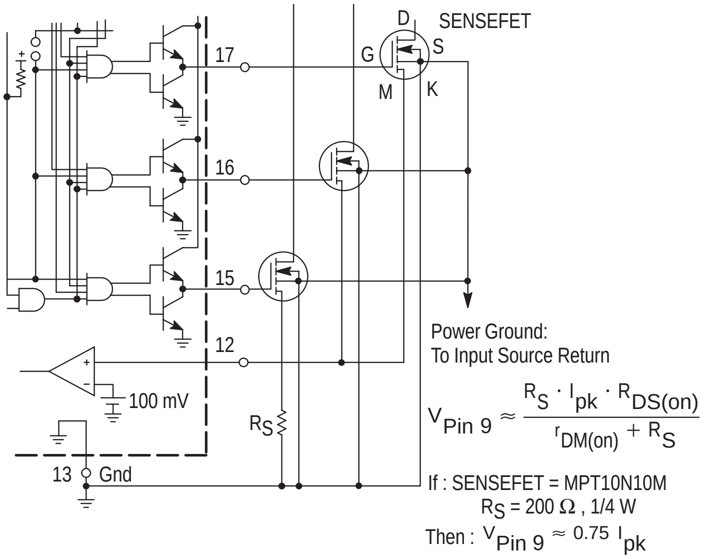
Series gate resistor R_g will damp any high frequency oscillations caused by the MOSFET input capacitance and any series wiring induction in the gate–source circuit. Diode D is required if the negative current into the Bottom Drive Outputs exceeds 50 mA.

Figure 26. Bipolar Transistor Drive



The totem pole output can furnish negative base current for enhanced transistor turn–off, with the addition of capacitor C.

Figure 27. Current Sensing Power MOSFETs

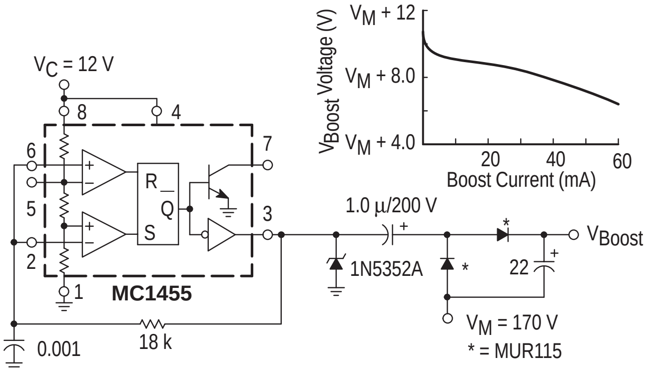


$$V_{Pin\ 9} \approx \frac{R_S \cdot I_{pk} \cdot R_{DS(on)}}{r_{DM(on)} + R_S}$$

If : SENSEFET = MPT10N10M
$R_S = 200\ \Omega$, 1/4 W
Then : $V_{Pin\ 9} \approx 0.75\ I_{pk}$

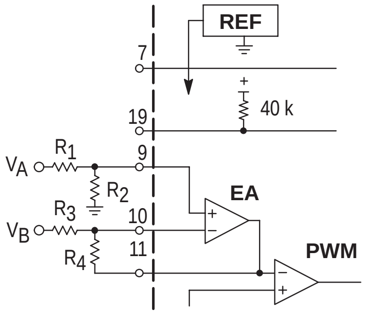
Virtually lossless current sensing can be achieved with the implementation of SENSEFET power switches.

Figure 28. High Voltage Boost Supply



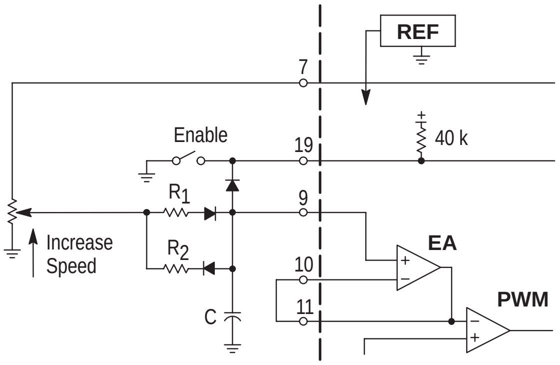
This circuit generates V_{Boost} for Figure 23.

Figure 29. Differential Input Speed Controller



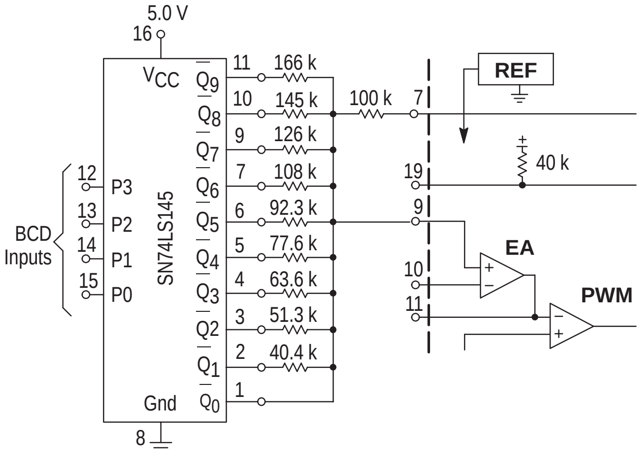
$$V_{Pin\ 11} = V_A \left(\frac{R_3 + R_4}{R_1 + R_2}\right) \frac{R_2}{R_3} - \left(\frac{R_4}{R_3}\ V_B\right)$$

Figure 30. Controlled Acceleration/Deceleration



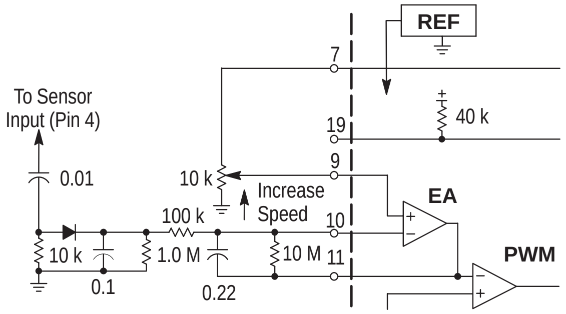
Resistor R_1 with capacitor C sets the acceleration time constant while R_2 controls the deceleration. The values of R_1 and R_2 should be at least ten times greater than the speed set potentiometer to minimize time constant variations with different speed settings.

Figure 31. Digital Speed Controller



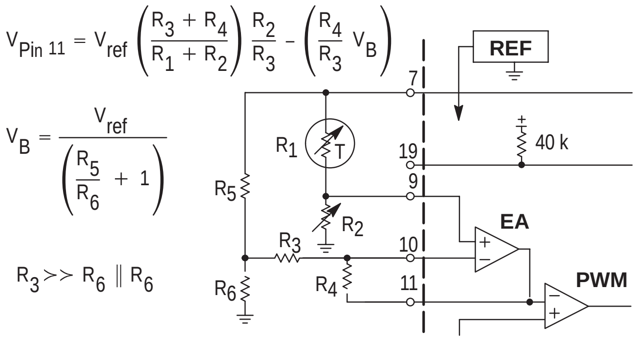
The SN74LS145 is an open collector BCD to One of Ten decoder. When connected as shown, input codes 0000 through 1001 steps the PWM in increments of approximately 10% from 0 to 90% on–time. Input codes 1010 through 1111 will produce 100% on–time or full motor speed.

Figure 32. Closed Loop Speed Control



The rotor position sensors can be used as a tachometer. By differentiating the positive–going edges and then integrating them over time, a voltage proportional to speed can be generated. The error amp compares this voltage to that of the speed set to control the PWM.

Figure 33. Closed Loop Temperature Control



$$V_{Pin\ 11} = V_{ref}\left(\frac{R_3 + R_4}{R_1 + R_2}\right)\frac{R_2}{R_3} - \left(\frac{R_4}{R_3}\,V_B\right)$$

$$V_B = \frac{V_{ref}}{\left(\frac{R_5}{R_6} + 1\right)}$$

$$R_3 >> R_6 \parallel R_6$$

This circuit can control the speed of a cooling fan proportional to the difference between the sensor and set temperatures. The control loop is closed as the forced air cools the NTC thermistor. For controlled heating applications, exchange the positions of R_1 and R_2.

Drive Outputs

The three Top Drive Outputs (Pins 1, 2, 20) are open collector NPN transistors capable of sinking 50 mA with a minimum breakdown of 30 V. Interfacing into higher voltage applications is easily accomplished with the circuits shown in Figures 22 and 23.

The three totem pole Bottom Drive Outputs (Pins 15, 16, 17) are particularly suited for direct drive of N–Channel MOSFETs or NPN bipolar transistors (Figures 24, 25, 26, and 27). Each output is capable of sourcing and sinking up to 100 mA.

Thermal Shutdown

Internal thermal shutdown circuity is provided to protect the IC in the event the maximum junction temperature is exceeded. When activated, typically at 170°C, the IC acts as though the regulator was disabled, in turn shutting down the IC.

SYSTEM APPLICATIONS

Three Phase Motor Commutation

The three phase application shown in Figure 34 is an open loop motor controller with full wave, six step drive. The upper power switch transistors are Darlington PNPs while the lower switches are N–Channel power MOSFETs. Each of these devices contains an internal parasitic catch diode that is used to return the stator inductive energy back to the power supply. The outputs are capable of driving a delta or wye connected stator, and a grounded neutral wye if split supplies are used. At any given rotor position, only one top and one bottom power switch (of different totem poles) is enabled. This configuration switches both ends of the stator winding from supply to ground which causes the current flow to be bidirectional or full wave. A leading edge spike is usually present on the current waveform and can cause a current–limit error. The spike can be eliminated by adding an RC filter in series with the Current Sense Input. Using a low inductance type resistor for R_S will also aid in spike reduction. Figure 35 shows the commutation waveforms over two electrical cycles. The first cycle (0° to 360°) depicts motor operation at full speed while the second cycle (360° to 720°) shows a reduced speed with about 50% pulse width modulation. The current waveforms reflect a constant torque load and are shown synchronous to the commutation frequency for clarity.

Figure 34. Three Phase, Six Step, Full Wave Motor Controller

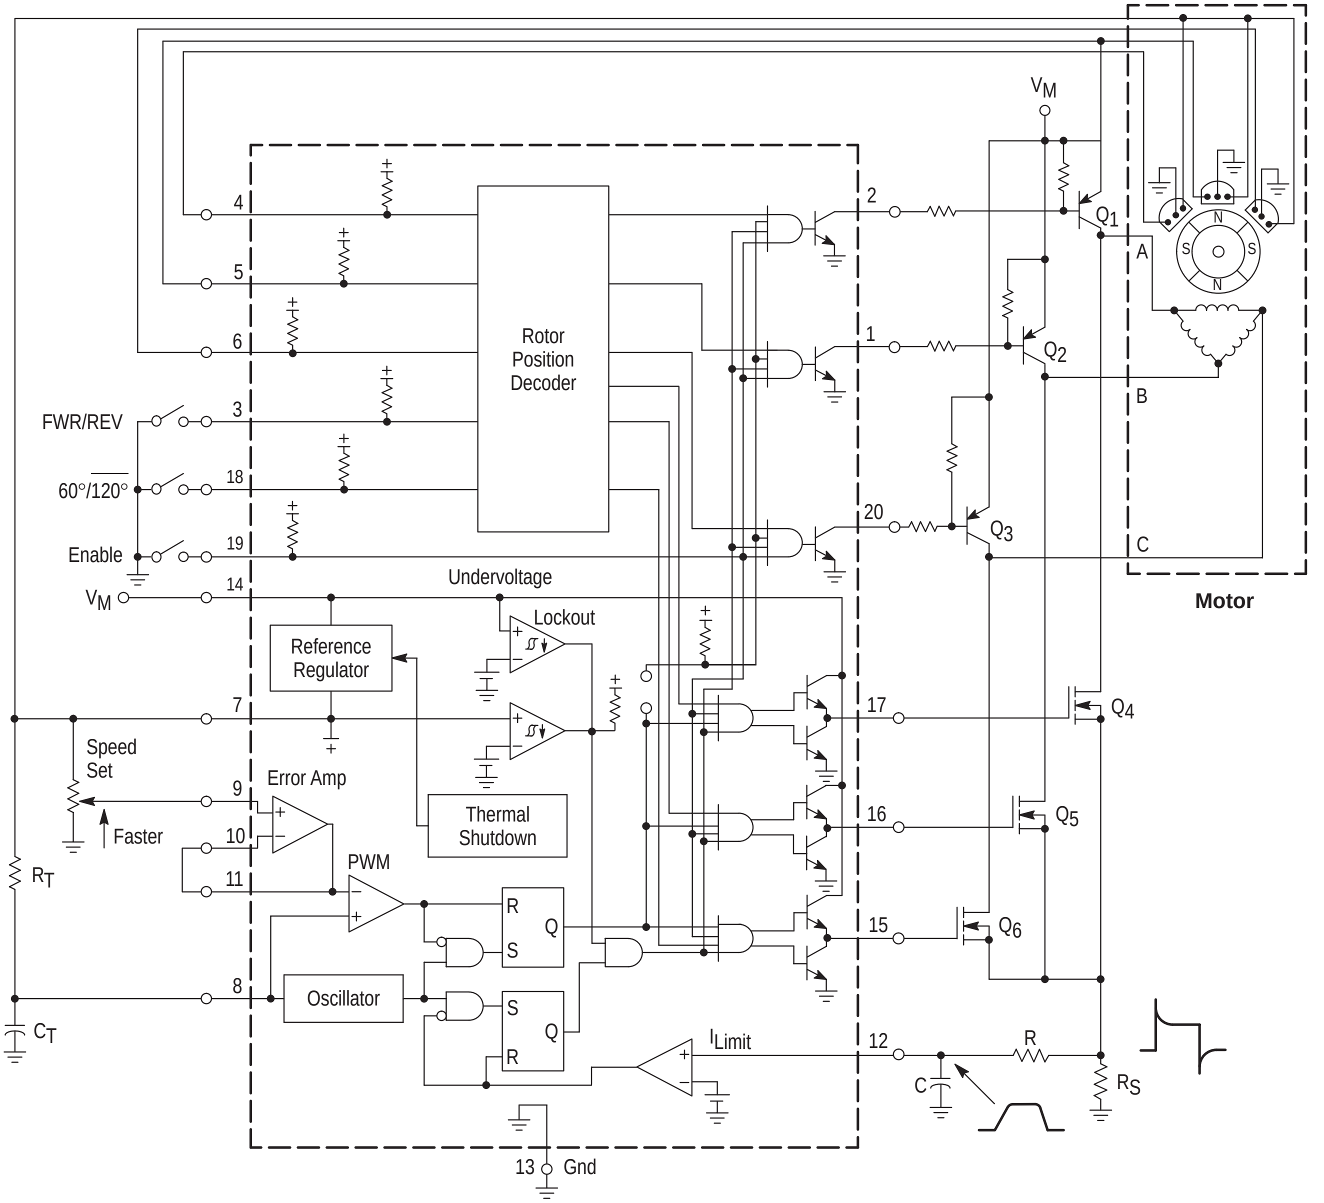


Figure 35. Three Phase, Six Step, Full Wave Commutation Waveforms

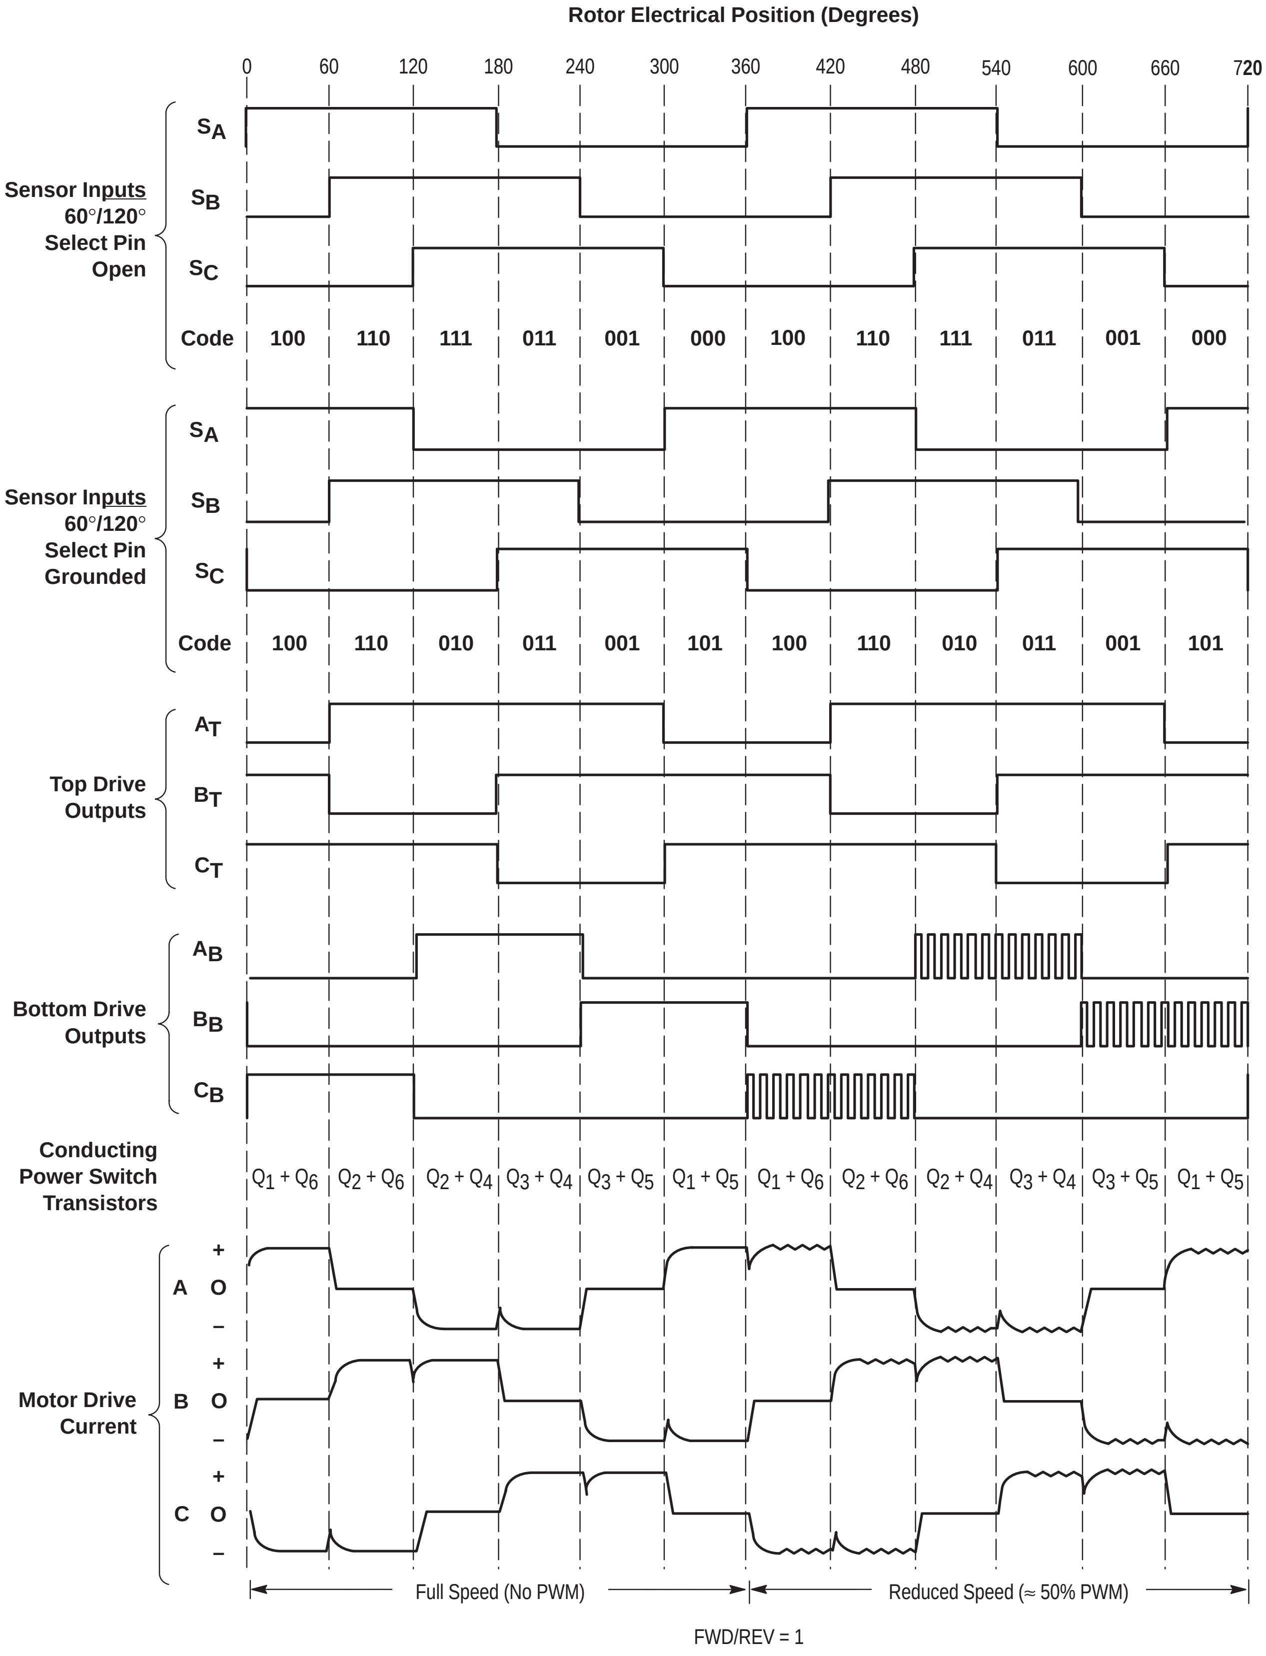

Figure 36 shows a three phase, three step, half wave motor controller. This configuration is ideally suited for automobile and other low voltage applications since there is only one power switch voltage drop in series with a given stator winding. Current flow is unidirectional or half wave because only one end of each winding is switched. The stator flyback voltage is clamped by a single zener and three diodes.

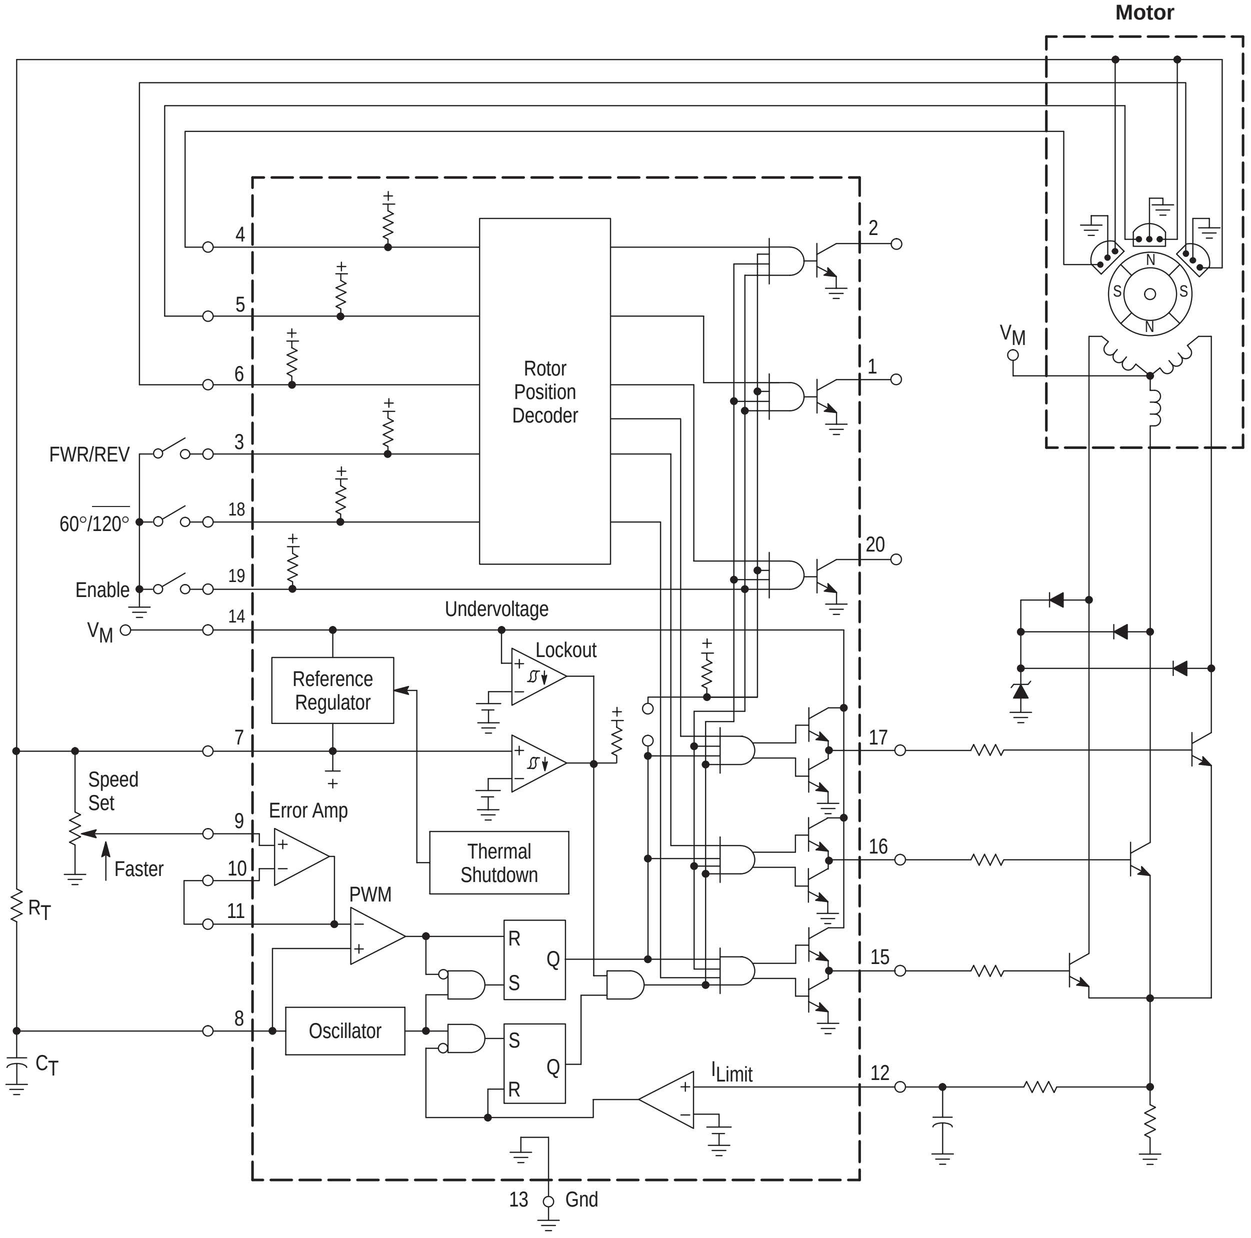
Figure 36. Three Phase, Three Step, Half Wave Motor Controller

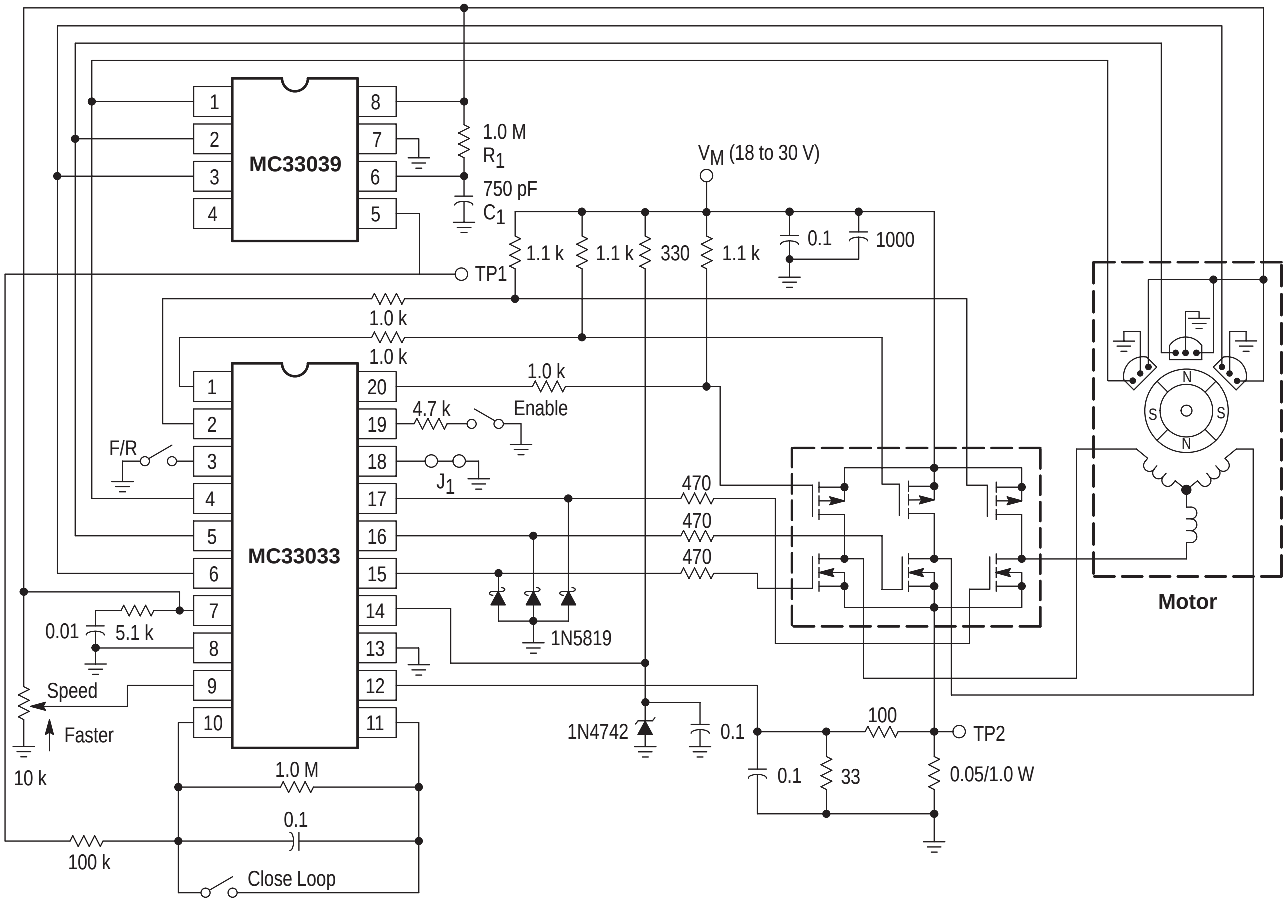


Three Phase Closed Loop Controller

The MC33033, by itself, is capable of open loop motor speed control. For closed loop speed control, the MC33033 requires an input voltage proportional to the motor speed. Traditionally this has been accomplished by means of a tachometer to generate the motor speed feedback voltage. Figure 37 shows an application whereby an MC33039, powered from the 6.25 V reference (Pin 7) of the MC33033, is used to generate the required feedback voltage without the need of a costly tachometer. The same Hall sensor signals used by the MC33033 for rotor position decoding are utilized by the MC33039. Every positive or negative going transition of the Hall sensor signals on any of the sensor lines causes the MC33039 to produce an output pulse of defined amplitude and time duration, as determined by the external resistor R_1 and capacitor C_1. The resulting output train of pulses present at Pin 5 of the MC33039 are integrated by the Error Amplifier of the MC33033 configured as an integrator, to produce a dc voltage level which is proportional to the motor speed. This speed proportional voltage establishes the PWM reference level at Pin 11 of the MC33033 motor controller and completes or closes the feedback loop. The MC33033 ouputs drive a TMOS power MOSFET 3–phase bridge. High current can be expected during conditions of start–up and when changing direction of the motor.

The system shown in Figure 37 is designed for a motor having 120/240 degrees Hall sensor electrical phasing. The system can easily be modified to accommodate 60/300 degree Hall sensor electrical phasing by removing the jumper (J_1) at Pin 18 of the MC33033.

Figure 37. Closed Loop Brushless DC Motor Control With the MC33033 Using the MC33039



Sensor Phasing Comparison

There are four conventions used to establish the relative phasing of the sensor signals in three phase motors. With six step drive, an input signal change must occur every 60 electrical degrees, however, the relative signal phasing is dependent upon the mechanical sensor placement. A comparison of the conventions in electrical degrees is shown in Figure 38. From the sensor phasing table (Figure 39), note that the order of input codes for 60° phasing is the reverse of 300°. This means the MC33033, when the 60°/120° select (Pin 18) and the FWD/REV (Pin 3) both in the high state (open), is configured to operate a 60° sensor phasing motor in the forward direction. Under the same conditions a 300° sensor phasing motor would operate equally well but in the reverse direction. One would simply have to reverse the FWD/REV switch (FWD/REV closed) in order to cause the 300° motor to also operate in the same direction. The same difference exists between the 120° and 240° conventions.

Figure 38. Sensor Phasing Comparison

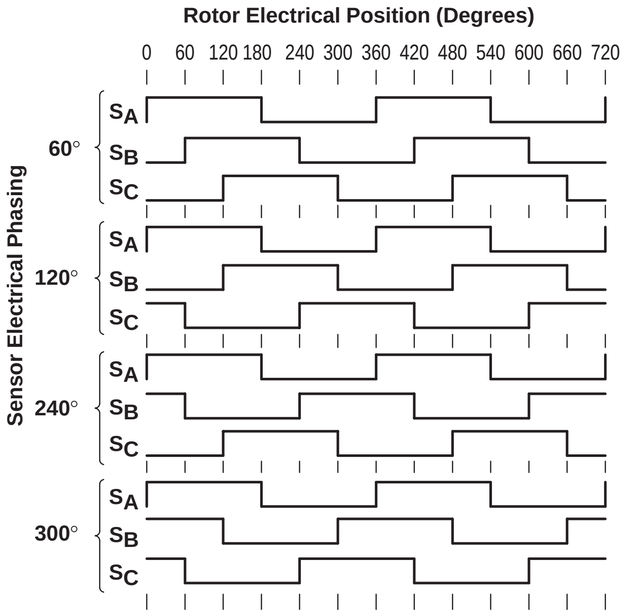


Figure 39. Sensor Phasing Table

Sensor Electrical Phasing (Degrees)											
60°			120°			240°			300°		
S_A	S_B	S_C	S_A	S_B	S_C	S_A	S_B	S_C	S_A	S_B	S_C
1	**0**	**0**	1	0	1	1	1	0	1	**1**	1
1	**1**	0	1	0	0	1	0	0	1	**1**	0
1	**1**	1	1	1	0	1	0	1	**1**	**0**	**0**
0	1	1	0	1	0	0	0	1	0	0	0
0	0	1	0	1	1	0	1	1	0	0	1
0	0	0	0	0	1	0	1	0	0	1	1

In this data sheet, the rotor position has always been given in electrical degrees since the mechanical position is a function of the number of rotating magnetic poles. The relationship between the electrical and mechanical position is:

$$\text{Electrical Degrees} = \text{Mechanical Degrees}\left(\frac{\#\text{Rotor Poles}}{2}\right)$$

An increase in the number of magnetic poles causes more electrical revolutions for a given mechanical revolution. General purpose three phase motors typically contain a four pole rotor which yields two electrical revolutions for one mechanical.

Two and Four Phase Motor Commutation

The MC33033 configured for 60° sensor inputs is capable of providing a four step output that can be used to drive two or four phase motors. The truth table in Figure 40 shows that by connecting sensor inputs S_B and S_C together, it is possible to truncate the number of drive output states from six to four. The output power switches are connected to B_T, C_T, B_B, and C_B. Figure 41 shows a four phase, four step, full wave motor control application. Power switch transistors Q_1 through Q_8 are Darlington type, each with an internal parasitic catch diode. With four step drive, only two rotor position sensors spaced at 90 electrical degrees are required. The commutation waveforms are shown in Figure 42.

Figure 43 shows a four phase, four step, half wave motor controller. It has the same features as the circuit in Figure 36, except for the deletion of speed adjust.

Brush Motor Control

Though the MC33033 was designed to control brushless dc motors, it may also be used to control dc brush–type motors. Figure 44 shows an application of the MC33033 driving a H–bridge affording minimal parts count to operate a brush–type motor. Key to the operation is the input sensor code [100] which produces a top–left (Q_1) and a bottom–right (Q_3) drive when the controller's Forward/Reverse pin is at logic [1]; top–right (Q_4), bottom–left (Q_2) drive is realized when the Forward/Reverse pin is at logic [0]. This code supports the requirements necessary for H–bridge drive accomplishing both direction and speed control.

The controller functions in a normal manner with a pulse width modulated frequency of approximately 25 kHz. Motor speed is controlled by adjusting the voltage presented to the noninverting input of the Error Amplifier establishing the PWM′s slice or reference level. Cycle–by–cycle current limiting of the motor current is accomplished by sensing the voltage (100 mV threshold) across the R_S resistor to ground of the H–bridge motor current. The over current sense circuit makes it possible to reverse the direction of the motor, on the fly, using the normal Forward/Reverse switch, and not have to completely stop before reversing.

LAYOUT CONSIDERATIONS

Do not attempt to construct any of the motor control circuits on wire–wrap or plug–in prototype boards. High frequency printed circuit layout techniques are imperative to prevent pulse jitter. This is usually caused by excessive noise pick–up imposed on the current sense or error amp inputs. The printed circuit layout should contain a ground plane with low current signal and high drive and output buffer grounds returning on separate paths back to the power supply input filter capacitor V_M. Ceramic bypass capacitors (0.01 µF) connected close to the integrated circuit at V_{CC}, V_{ref} and error ampliflier noninverting input may be required depending upon circuit layout. This provides a low impedance path for filtering any high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI.

MOTOROLA

MC33035

Brushless DC Motor Controller

The MC33035 is a high performance second generation monolithic brushless DC motor controller containing all of the active functions required to implement a full featured open loop, three or four phase motor control system. This device consists of a rotor position decoder for proper commutation sequencing, temperature compensated reference capable of supplying sensor power, frequency programmable sawtooth oscillator, three open collector top drivers, and three high current totem pole bottom drivers ideally suited for driving power MOSFETs.

Also included are protective features consisting of undervoltage lockout, cycle–by–cycle current limiting with a selectable time delayed latched shutdown mode, internal thermal shutdown, and a unique fault output that can be interfaced into microprocessor controlled systems.

Typical motor control functions include open loop speed, forward or reverse direction, run enable, and dynamic braking. The MC33035 is designed to operate with electrical sensor phasings of 60°/300° or 120°/240°, and can also efficiently control brush DC motors.

- 10 to 30 V Operation
- Undervoltage Lockout
- 6.25 V Reference Capable of Supplying Sensor Power
- Fully Accessible Error Amplifier for Closed Loop Servo Applications
- High Current Drivers Can Control External 3–Phase MOSFET Bridge
- Cycle–By–Cycle Current Limiting
- Pinned–Out Current Sense Reference
- Internal Thermal Shutdown
- Selectable 60°/300° or 120°/240° Sensor Phasings
- Can Efficiently Control Brush DC Motors with External MOSFET H–Bridge

PIN FUNCTION DESCRIPTION

Pin	Symbol	Description
1, 2, 24	B_T, A_T, C_T	These three open collector Top Drive outputs are designed to drive the external upper power switch transistors.
3	Fwd/Rev	The Forward/Reverse Input is used to change the direction of motor rotation.
4, 5, 6	S_A, S_B, S_C	These three Sensor Inputs control the commutation sequence.
7	Output Enable	A logic high at this input causes the motor to run, while a low causes it to coast.
8	Reference Output	This output provides charging current for the oscillator timing capacitor C_T and a reference for the error amplifier. It may also serve to furnish sensor power.
9	Current Sense Noninverting Input	A 100 mV signal, with respect to Pin 15, at this input terminates output switch conduction during a given oscillator cycle. This pin normally connects to the top side of the current sense resistor.
10	Oscillator	The Oscillator frequency is programmed by the values selected for the timing components, R_T and C_T.
11	Error Amp Noninverting Input	This input is normally connected to the speed set potentiometer.
12	Error Amp Inverting Input	This input is normally connected to the Error Amp Output in open loop applications.
13	Error Amp Out/PWM Input	This pin is available for compensation in closed loop applications.
14	Fault Output	This open collector output is active low during one or more of the following conditions: Invalid Sensor Input code, Enable Input at logic 0, Current Sense Input greater than 100 mV (Pin 9 with respect to Pin 15), Undervoltage Lockout activation, and Thermal Shutdown.
15	Current Sense Inverting Input	Reference pin for internal 100 mV threshold. This pin is normally connected to the bottom side of the current sense resistor.
16	Gnd	This pin supplies a ground for the control circuit and should be referenced back to the power source ground.
17	V_{CC}	This pin is the positive supply of the control IC. The controller is functional over a minimum V_{CC} range of 10 to 30 V.
18	V_C	The high state (V_{OH}) of the Bottom Drive Outputs is set by the voltage applied to this pin. The controller is operational over a minimum V_C range of 10 to 30 V.
19, 20, 21	C_B, B_B, A_B	These three totem pole Bottom Drive Outputs are designed for direct drive of the external bottom power switch transistors.
22	60°/120° Select	The electrical state of this pin configures the control circuit operation for either 60° (high state) or 120° (low state) sensor electrical phasing inputs.
23	Brake	A logic low state at this input allows the motor to run, while a high state does not allow motor operation and if operating causes rapid deceleration.

INTRODUCTION

The MC33035 is one of a series of high performance monolithic DC brushless motor controllers produced by Motorola. It contains all of the functions required to implement a full–featured, open loop, three or four phase motor control system. In addition, the controller can be made to operate DC brush motors. Constructed with Bipolar Analog technology, it offers a high degree of performance and ruggedness in hostile industrial environments. The MC33035 contains a rotor position decoder for proper commutation sequencing, a temperature compensated reference capable of supplying a sensor power, a frequency programmable sawtooth oscillator, a fully accessible error amplifier, a pulse width modulator comparator, three open collector top drive outputs, and three high current totem pole bottom driver outputs ideally suited for driving power MOSFETs.

Included in the MC33035 are protective features consisting of undervoltage lockout, cycle–by–cycle current limiting with a selectable time delayed latched shutdown mode, internal thermal shutdown, and a unique fault output that can easily be interfaced to a microprocessor controller.

Typical motor control functions include open loop speed control, forward or reverse rotation, run enable, and dynamic braking. In addition, the MC33035 has a 60°/120° select pin which configures the rotor position decoder for either 60° or 120° sensor electrical phasing inputs.

FUNCTIONAL DESCRIPTION

A representative internal block diagram is shown in Figure 19 with various applications shown in Figures 36, 38, 39, 43, 45, and 46. A discussion of the features and function of each of the internal blocks given below is referenced to Figures 19 and 36.

Rotor Position Decoder

An internal rotor position decoder monitors the three sensor inputs (Pins 4, 5, 6) to provide the proper sequencing of the top and bottom drive outputs. The sensor inputs are designed to interface directly with open collector type Hall Effect switches or opto slotted couplers. Internal pull–up resistors are included to minimize the required number of external components. The inputs are TTL compatible, with their thresholds typically at 2.2 V. The MC33035 series is designed to control three phase motors and operate with four of the most common conventions of sensor phasing. A 60°/120° Select (Pin 22) is conveniently provided and affords the MC33035 to configure itself to control motors having either 60°, 120°, 240° or 300° electrical sensor phasing. With three sensor inputs there are eight possible input code combinations, six of which are valid rotor positions. The remaining two codes are invalid and are usually caused by an open or shorted sensor line. With six valid input codes, the decoder can resolve the motor rotor position to within a window of 60 electrical degrees.

The Forward/Reverse input (Pin 3) is used to change the direction of motor rotation by reversing the voltage across the stator winding. When the input changes state, from high to low with a given sensor input code (for example 100), the enabled top and bottom drive outputs with the same alpha designation are exchanged (A_T to A_B, B_T to B_B, C_T to C_B). In effect, the commutation sequence is reversed and the motor changes directional rotation.

Motor on/off control is accomplished by the Output Enable (Pin 7). When left disconnected, an internal 25 µA current source enables sequencing of the top and bottom drive outputs. When grounded, the top drive outputs turn off and the bottom drives are forced low, causing the motor to coast and the Fault output to activate.

Dynamic motor braking allows an additional margin of safety to be designed into the final product. Braking is accomplished by placing the Brake Input (Pin 23) in a high state. This causes the top drive outputs to turn off and the bottom drives to turn on, shorting the motor–generated back EMF. The brake input has unconditional priority over all other inputs. The internal 40 kΩ pull–up resistor simplifies interfacing with the system safety–switch by insuring brake activation if opened or disconnected. The commutation logic truth table is shown in Figure 20. A four input NOR gate is used to monitor the brake input and the inputs to the three top drive output transistors. Its purpose is to disable braking until the top drive outputs attain a high state. This helps to prevent simultaneous conduction of the the top and bottom power switches. In half wave motor drive applications, the top drive outputs are not required and are normally left disconnected. Under these conditions braking will still be accomplished since the NOR gate senses the base voltage to the top drive output transistors.

Error Amplifier

A high performance, fully compensated error amplifier with access to both inputs and output (Pins 11, 12, 13) is provided to facilitate the implementation of closed loop motor speed control. The amplifier features a typical DC voltage gain of 80 dB, 0.6 MHz gain bandwidth, and a wide input common mode voltage range that extends from ground to V_{ref}. In most open loop speed control applications, the amplifier is configured as a unity gain voltage follower with the noninverting input connected to the speed set voltage source. Additional configurations are shown in Figures 31 through 35.

Oscillator

The frequency of the internal ramp oscillator is programmed by the values selected for timing components R_T and C_T. Capacitor C_T is charged from the Reference Output (Pin 8) through resistor R_T and discharged by an internal discharge transistor. The ramp peak and valley voltages are typically 4.1 V and 1.5 V respectively. To provide a good compromise between audible noise and output switching efficiency, an oscillator frequency in the range of 20 to 30 kHz is recommended. Refer to Figure 1 for component selection.

NOTES:
1. V = Any one of six valid sensor or drive combinations X = Don’t care.
2. The digital inputs (Pins 3, 4, 5, 6, 7, 22, 23) are all TTL compatible. The current sense input (Pin 9) has a 100 mV threshold with respect to Pin 15. A logic 0 for this input is defined as < 85 mV, and a logic 1 is > 115 mV.
3. The fault and top drive outputs are open collector design and active in the low (0) state.
4. With 60°/120° select (Pin 22) in the high (1) state, configuration is for 60° sensor electrical phasing inputs. With Pin 22 in low (0) state, configuration is for 120° sensor electrical phasing inputs.
5. Valid 60° or 120° sensor combinations for corresponding valid top and bottom drive outputs.
6. Invalid sensor inputs with brake = 0; All top and bottom drives off, Fault low.
7. Invalid sensor inputs with brake = 1; All top drives off, all bottom drives on, Fault low.
8. Valid 60° or 120° sensor inputs with brake = 1; All top drives off, all bottom drives on, Fault high.
9. Valid sensor inputs with brake = 1 and enable = 0; All top drives off, all bottom drives on, Fault low.
10. Valid sensor inputs with brake = 0 and enable = 0; All top and bottom drives off, Fault low.
11. All bottom drives off, Fault low.

Pulse Width Modulator

The use of pulse width modulation provides an energy efficient method of controlling the motor speed by varying the average voltage applied to each stator winding during the commutation sequence. As C_T discharges, the oscillator sets both latches, allowing conduction of the top and bottom drive outputs. The PWM comparator resets the upper latch, terminating the bottom drive output conduction when the positive–going ramp of C_T becomes greater than the error amplifier output. The pulse width modulator timing diagram is shown in Figure 21. Pulse width modulation for speed control appears only at the bottom drive outputs.

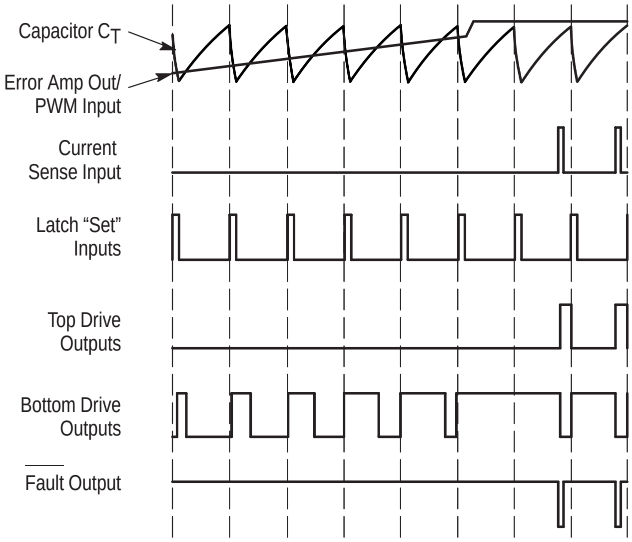
Current Limit

Continuous operation of a motor that is severely over–loaded results in overheating and eventual failure. This destructive condition can best be prevented with the use of cycle–by–cycle current limiting. That is, each on–cycle is treated as a separate event. Cycle–by–cycle current limiting is accomplished by monitoring the stator current build–up each time an output switch conducts, and upon sensing an over current condition, immediately turning off the switch and holding it off for the remaining duration of oscillator ramp–up period. The stator current is converted to a voltage by inserting a ground–referenced sense resistor R_S (Figure 36) in series with the three bottom switch transistors (Q_4, Q_5, Q_6). The voltage developed across the sense resistor is monitored by the Current Sense Input (Pins 9 and 15), and compared to the internal 100 mV reference. The current sense comparator inputs have an input common mode range of approximately 3.0 V. If the 100 mV current sense threshold is exceeded, the comparator resets the lower sense latch and terminates output switch conduction. The value for the current sense resistor is:

$$R_S = \frac{0.1}{I_{stator(max)}}$$

The $\overline{\text{Fault}}$ output activates during an over current condition. The dual–latch PWM configuration ensures that only one single output conduction pulse occurs during any given oscillator cycle, whether terminated by the output of the error amp or the current limit comparator.

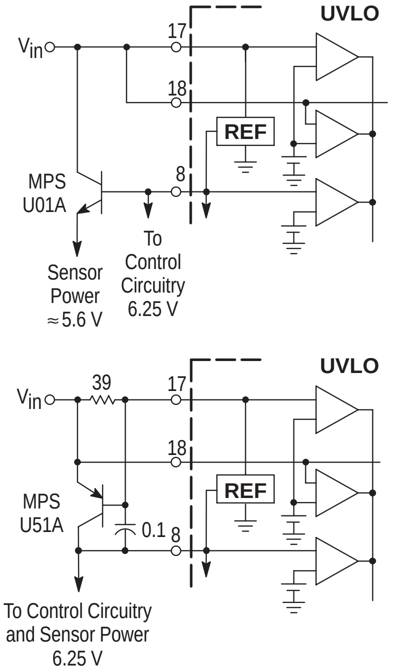
Figure 21. Pulse Width Modulator Timing Diagram



Reference

The on–chip 6.25 V regulator (Pin 8) provides charging current for the oscillator timing capacitor, a reference for the error amplifier, and can supply 20 mA of current suitable for directly powering sensors in low voltage applications. In higher voltage applications, it may become necessary to transfer the power dissipated by the regulator off the IC. This is easily accomplished with the addition of an external pass transistor as shown in Figure 22. A 6.25 V reference level was chosen to allow implementation of the simpler NPN circuit, where $V_{ref} – V_{BE}$ exceeds the minimum voltage required by Hall Effect sensors over temperature. With proper transistor selection and adequate heatsinking, up to one amp of load current can be obtained.

Figure 22. Reference Output Buffers



The NPN circuit is recommended for powering Hall or opto sensors, where the output voltage temperature coefficient is not critical. The PNP circuit is slightly more complex, but is also more accurate over temperature. Neither circuit has current limiting.

Undervoltage Lockout

A triple Undervoltage Lockout has been incorporated to prevent damage to the IC and the external power switch transistors. Under low power supply conditions, it guarantees that the IC and sensors are fully functional, and that there is sufficient bottom drive output voltage. The positive power supplies to the IC (V_{CC}) and the bottom drives (V_C) are each monitored by separate comparators that have their thresholds at 9.1 V. This level ensures sufficient gate drive necessary to attain low $R_{DS(on)}$ when driving standard power MOSFET devices. When directly powering the Hall sensors from the reference, improper sensor operation can result if the reference output voltage falls below 4.5 V. A third comparator is used to detect this condition. If one or more of the comparators detects an undervoltage condition, the Fault Output is activated, the top drives are turned off and the bottom drive outputs are held in a low state. Each of the comparators contain hysteresis to prevent oscillations when crossing their respective thresholds.

Fault Output

The open collector Fault Output (Pin 14) was designed to provide diagnostic information in the event of a system malfunction. It has a sink current capability of 16 mA and can directly drive a light emitting diode for visual indication. Additionally, it is easily interfaced with TTL/CMOS logic for use in a microprocessor controlled system. The Fault Output is active low when one or more of the following conditions occur:

1) Invalid Sensor Input code
2) Output Enable at logic [0]
3) Current Sense Input greater than 100 mV
4) Undervoltage Lockout, activation of one or more of the comparators
5) Thermal Shutdown, maximum junction temperature being exceeded

This unique output can also be used to distinguish between motor start–up or sustained operation in an overloaded condition. With the addition of an RC network between the Fault Output and the enable input, it is possible to create a time–delayed latched shutdown for overcurrent. The added circuitry shown in Figure 23 makes easy starting of motor systems which have high inertial loads by providing additional starting torque, while still preserving overcurrent protection. This task is accomplished by setting the current limit to a higher than nominal value for a predetermined time. During an excessively long overcurrent condition, capacitor C_{DLY} will charge, causing the enable input to cross its threshold to a low state. A latch is then formed by the positive feedback loop from the Fault Output to the Output Enable. Once set, by the Current Sense Input, it can only be reset by shorting C_{DLY} or cycling the power supplies.

Drive Outputs

The three top drive outputs (Pins 1, 2, 24) are open collector NPN transistors capable of sinking 50 mA with a minimum breakdown of 30 V. Interfacing into higher voltage applications is easily accomplished with the circuits shown in Figures 24 and 25.

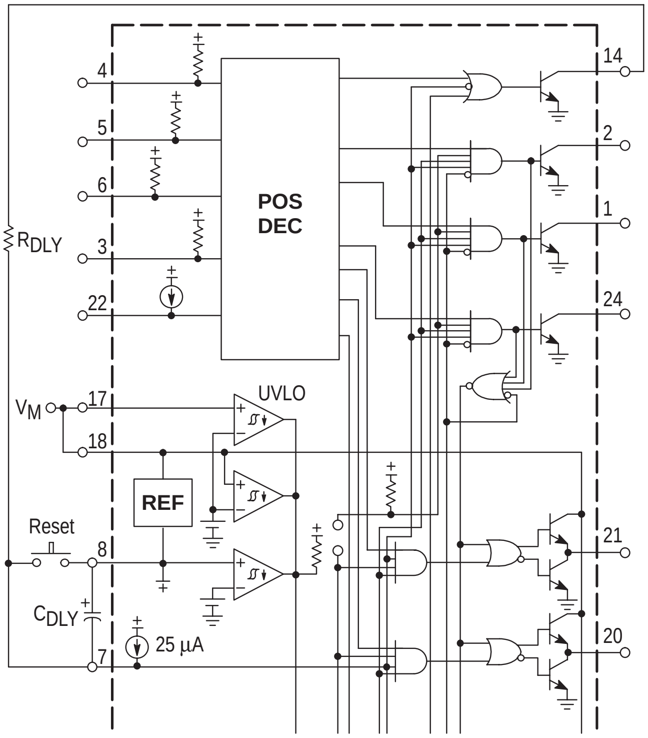
The three totem pole bottom drive outputs (Pins 19, 20, 21) are particularly suited for direct drive of N–Channel MOSFETs or NPN bipolar transistors (Figures 26, 27, 28 and 29). Each output is capable of sourcing and sinking up to 100 mA. Power for the bottom drives is supplied from V_C (Pin 18). This separate supply input allows the designer added flexibility in tailoring the drive voltage, independent of V_{CC}. A zener clamp should be connected to this input when driving power MOSFETs in systems where V_{CC} is greater than 20 V so as to prevent rupture of the MOSFET gates.

The control circuitry ground (Pin 16) and current sense inverting input (Pin 15) must return on separate paths to the central input source ground.

Thermal Shutdown

Internal thermal shutdown circuitry is provided to protect the IC in the event the maximum junction temperature is exceeded. When activated, typically at 170°C, the IC acts as though the Output Enable was grounded.

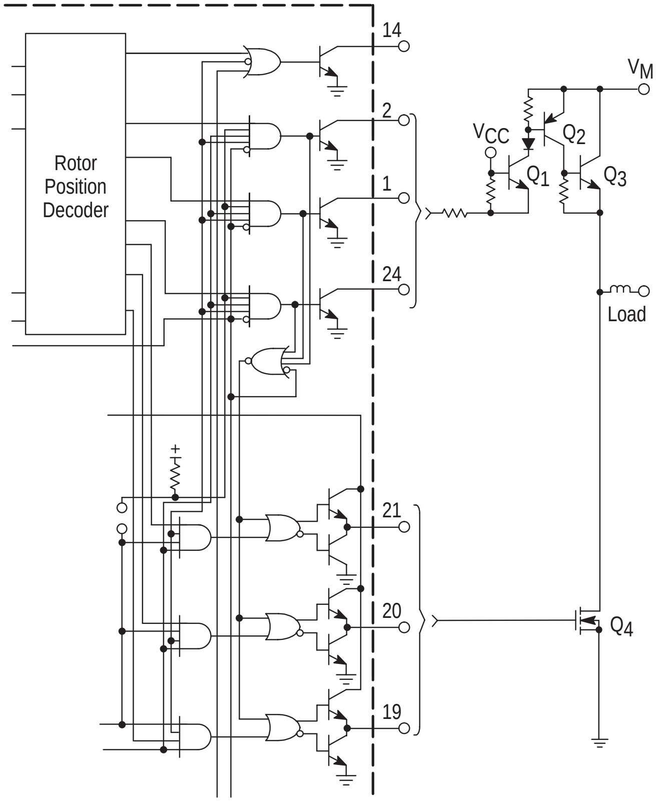
Figure 23. Timed Delayed Latched Over Current Shutdown



$$t_{DLY} \approx R_{DLY}\ C_{DLY}\ \ln\left(\frac{V_{ref} - (I_{IL}\ \text{enable}\ R_{DLY})}{V_{th}\ \text{enable} - (I_{IL}\ \text{enable}\ R_{DLY})}\right)$$

$$\approx R_{DLY}\ C_{DLY}\ \ln\left(\frac{6.25 - (20 \times 10^{-6}\ R_{DLY})}{1.4 - (20 \times 10^{-6}\ R_{DLY})}\right)$$

Figure 24. High Voltage Interface with NPN Power Transistors



Transistor Q_1 is a common base stage used to level shift from V_{CC} to the high motor voltage, V_M. The collector diode is required if V_{CC} is present while V_M is low.

Figure 25. High Voltage Interface with N–Channel Power MOSFETs

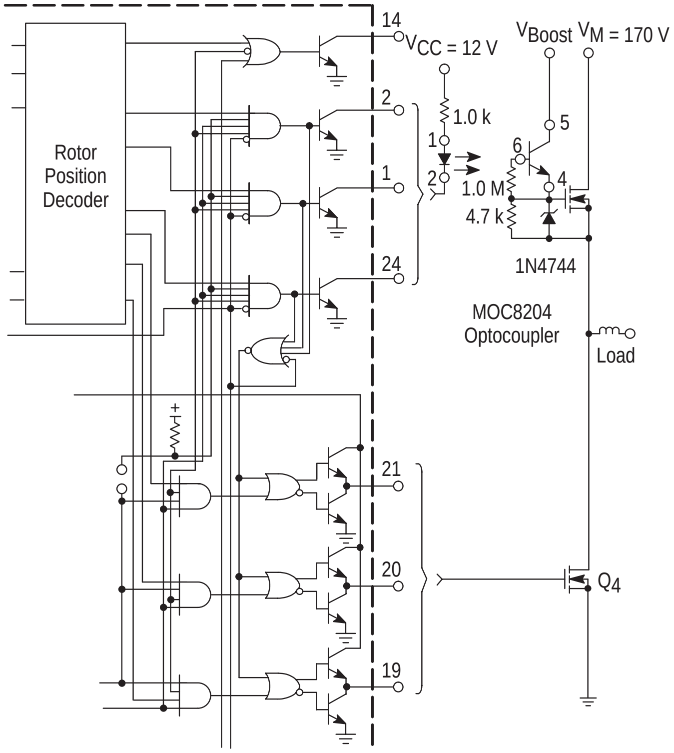


Figure 26. Current Waveform Spike Suppression

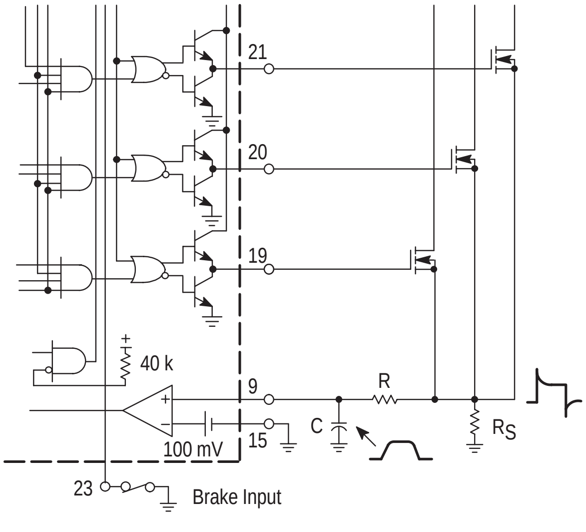
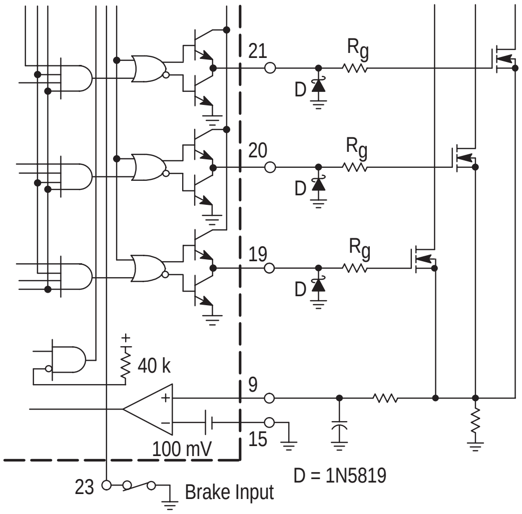


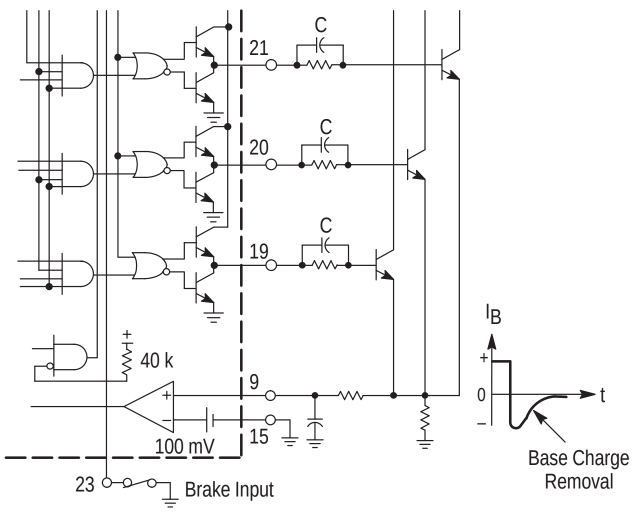
The addition of the RC filter will eliminate current–limit instability caused by the leading edge spike on the current waveform. Resistor R_S should be a low inductance type.

Figure 27. MOSFET Drive Precautions



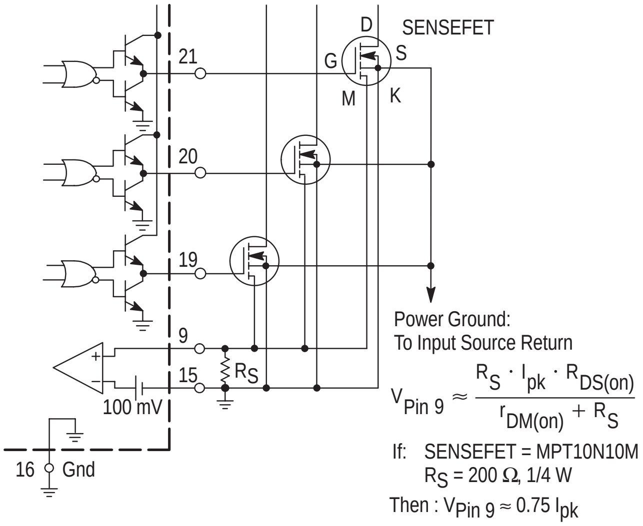
Series gate resistor R_g will dampen any high frequency oscillations caused by the MOSFET input capacitance and any series wiring induction in the gate–source circuit. Diode D is required if the negative current into the Bottom Drive Outputs exceeds 50 mA.

Figure 28. Bipolar Transistor Drive



The totem–pole output can furnish negative base current for enhanced transistor turn–off, with the addition of capacitor C.

Figure 29. Current Sensing Power MOSFETs



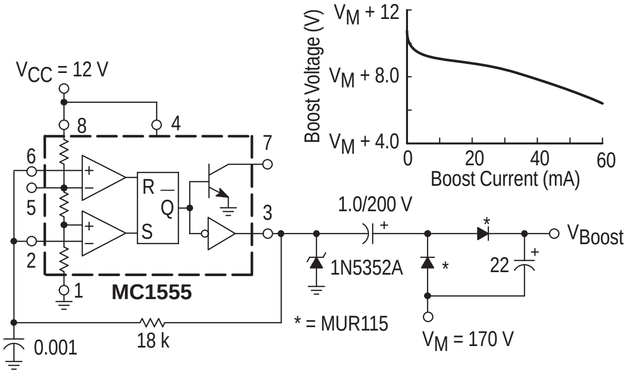
$$V_{Pin\ 9} \approx \frac{R_S \cdot I_{pk} \cdot R_{DS(on)}}{r_{DM(on)} + R_S}$$

If: SENSEFET = MPT10N10M
R_S = 200 Ω, 1/4 W
Then : $V_{Pin\ 9} \approx 0.75\ I_{pk}$

Control Circuitry Ground (Pin 16) and Current Sense Inverting Input (Pin 15) must return on separate paths to the Central Input Source Ground.

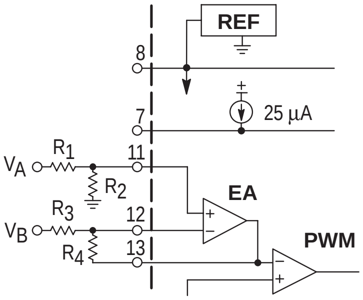
Virtually lossless current sensing can be achieved with the implementation of SENSEFET power switches.

Figure 30. High Voltage Boost Supply



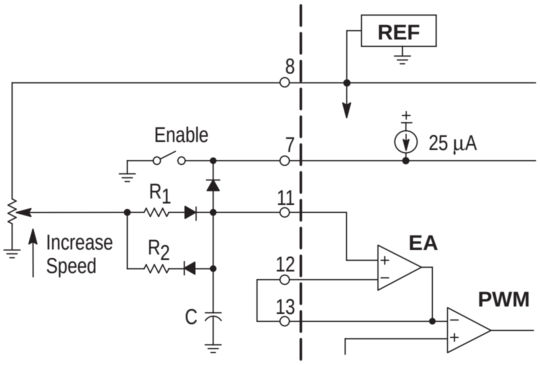
This circuit generates V_{Boost} for Figure 25.

Figure 31. Differential Input Speed Controller



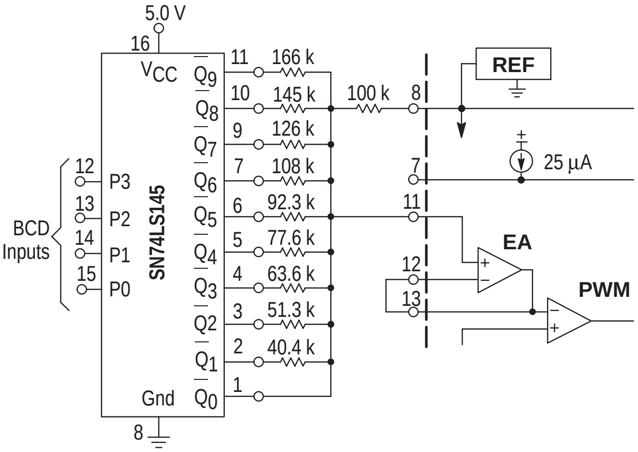
$$V_{Pin\ 13} = V_A \left(\frac{R_3 + R_4}{R_1 + R_2}\right) \frac{R_2}{R_3} - \left(\frac{R_4}{R_3} V_B\right)$$

Figure 32. Controlled Acceleration/Deceleration



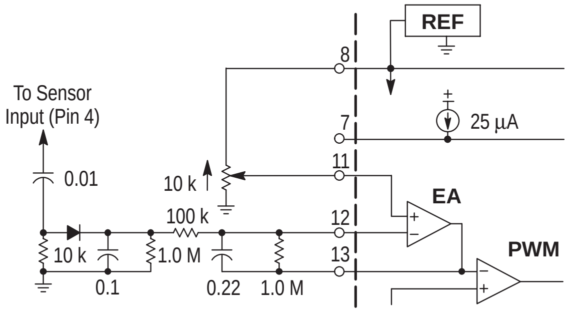
Resistor R_1 with capacitor C sets the acceleration time constant while R_2 controls the deceleration. The values of R_1 and R_2 should be at least ten times greater than the speed set potentiometer to minimize time constant variations with different speed settings.

Figure 33. Digital Speed Controller



The SN74LS145 is an open collector BCD to One of Ten decoder. When connected as shown, input codes 0000 through 1001 steps the PWM in increments of approximately 10% from 0 to 90% on–time. Input codes 1010 through 1111 will produce 100% on–time or full motor speed.

Figure 34. Closed Loop Speed Control



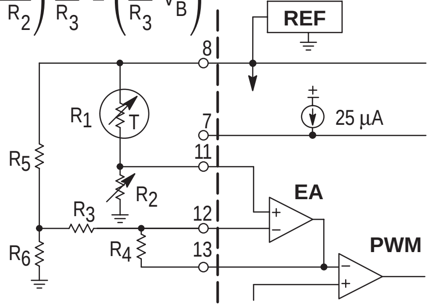
The rotor position sensors can be used as a tachometer. By differentiating the positive–going edges and then integrating them over time, a voltage proportional to speed can be generated. The error amp compares this voltage to that of the speed set to control the PWM.

Figure 35. Closed Loop Temperature Control

$$V_{Pin\ 3} = V_{ref} \left(\frac{R_3 + R_4}{R_1 + R_2}\right) \frac{R_2}{R_3} - \left(\frac{R_4}{R_3} V_B\right)$$

$$V_B = \frac{V_{ref}}{\left(\frac{R_5}{R_6} + 1\right)}$$

$$R_3 >> R_5 \parallel R_6$$



This circuit can control the speed of a cooling fan proportional to the difference between the sensor and set temperatures. The control loop is closed as the forced air cools the NTC thermistor. For controlled heating applications, exchange the positions of R_1 and R_2.

SYSTEM APPLICATIONS

Three Phase Motor Commutation

The three phase application shown in Figure 36 is a full–featured open loop motor controller with full wave, six step drive. The upper power switch transistors are Darlingtons while the lower devices are power MOSFETs. Each of these devices contains an internal parasitic catch diode that is used to return the stator inductive energy back to the power supply. The outputs are capable of driving a delta or wye connected stator, and a grounded neutral wye if split supplies are used. At any given rotor position, only one top and one bottom power switch (of different totem poles) is enabled. This configuration switches both ends of the stator winding from supply to ground which causes the current flow to be bidirectional or full wave. A leading edge spike is usually present on the current waveform and can cause a current–limit instability. The spike can be eliminated by adding an RC filter in series with the Current Sense Input. Using a low inductance type resistor for R_S will also aid in spike reduction. Care must be taken in the selection of the bottom power switch transistors so that the current during braking does not exceed the device rating. During braking, the peak current generated is limited only by the series resistance of the conducting bottom switch and winding.

$$I_{peak} = \frac{V_M + EMF}{R_{switch} + R_{winding}}$$

If the motor is running at maximum speed with no load, the generated back EMF can be as high as the supply voltage, and at the onset of braking, the peak current may approach twice the motor stall current. Figure 37 shows the commutation waveforms over two electrical cycles. The first cycle (0° to 360°) depicts motor operation at full speed while the second cycle (360° to 720°) shows a reduced speed with about 50% pulse width modulation. The current waveforms reflect a constant torque load and are shown synchronous to the commutation frequency for clarity.

Figure 36. Three Phase, Six Step, Full Wave Motor Controller

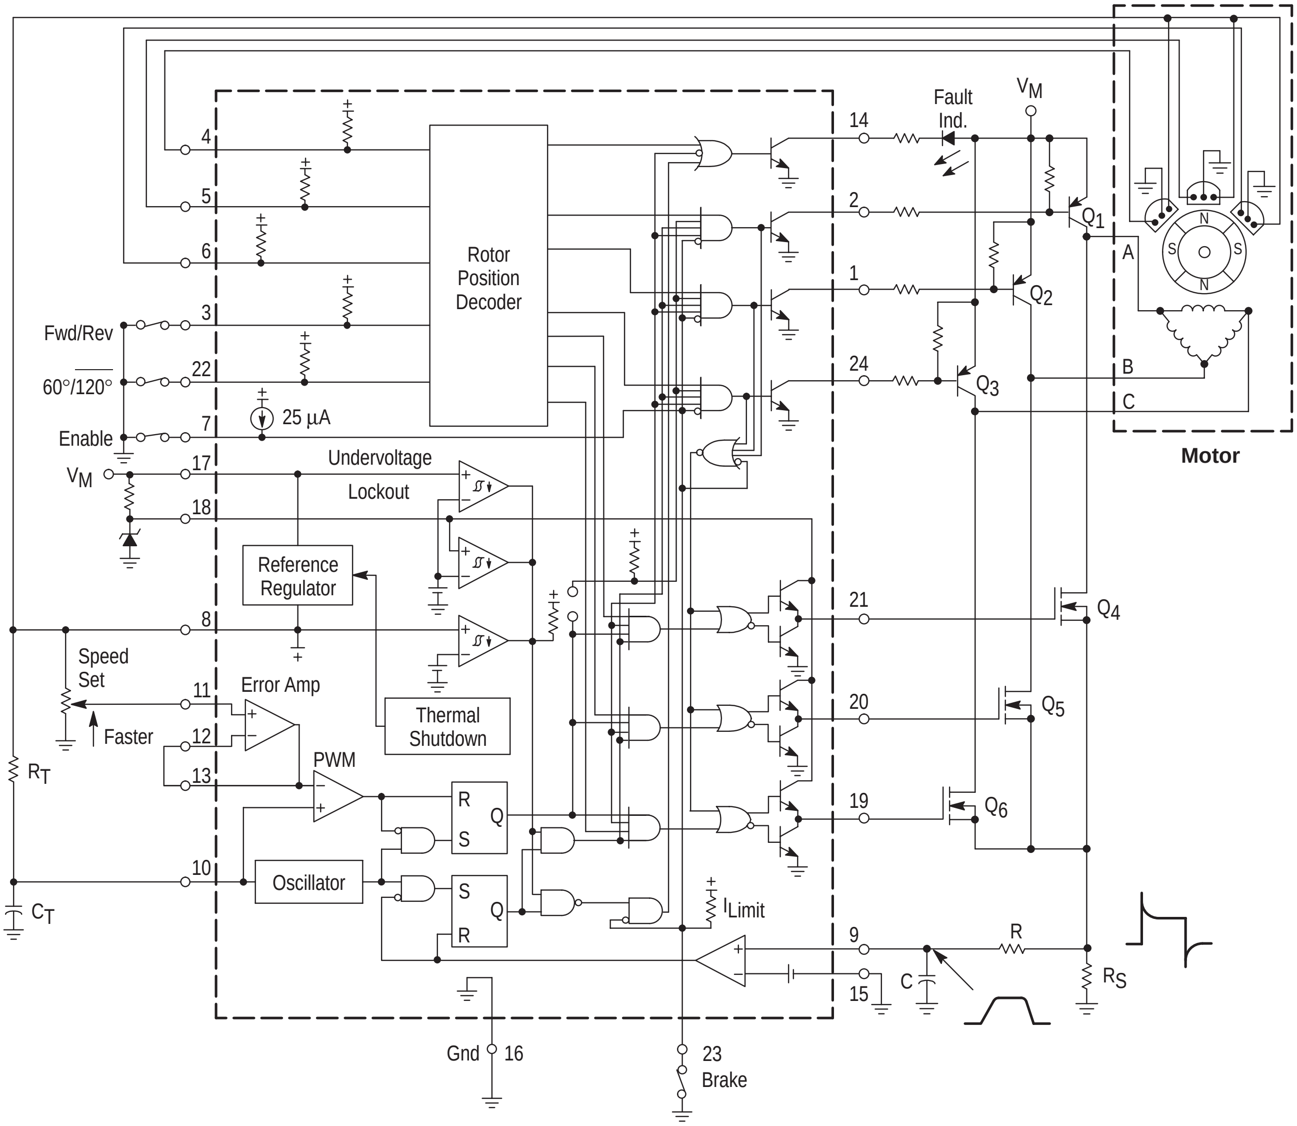


Figure 37. Three Phase, Six Step, Full Wave Commutation Waveforms

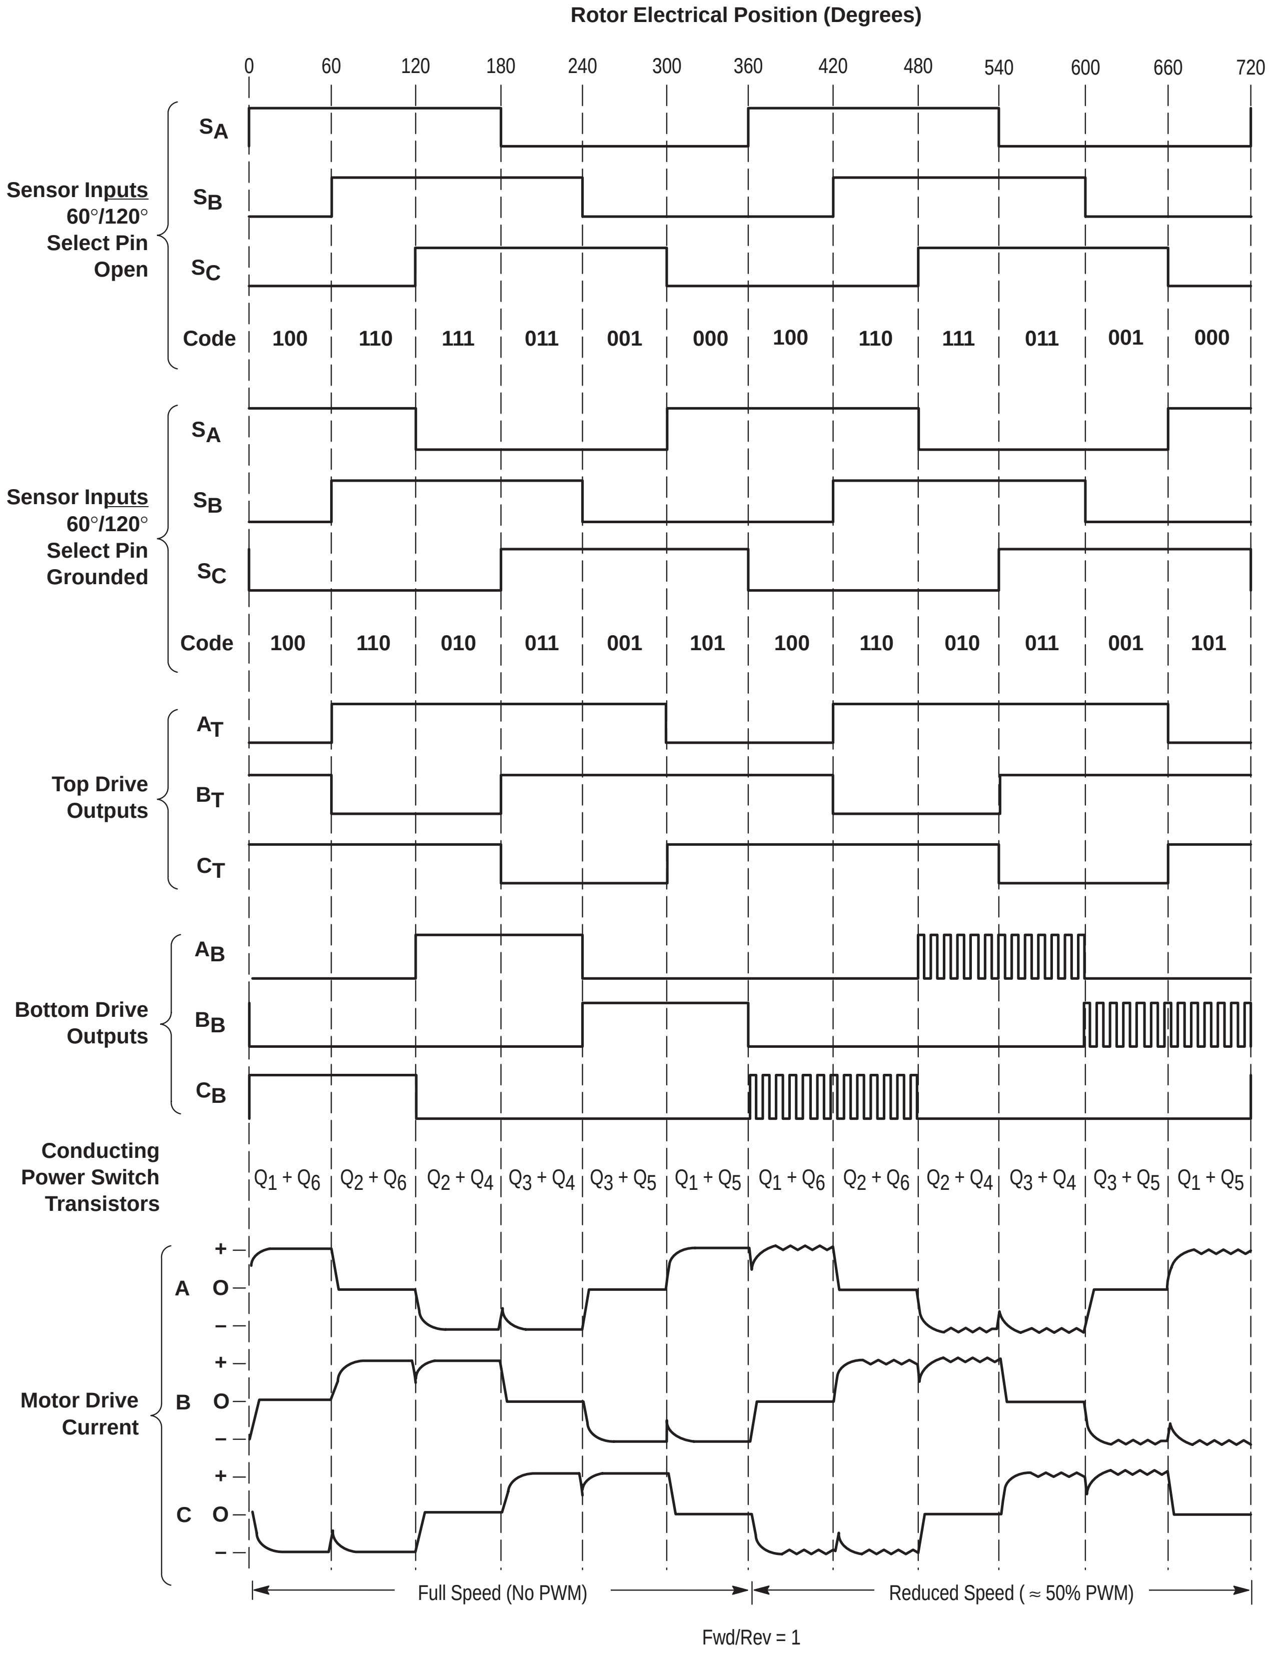

Figure 38 shows a three phase, three step, half wave motor controller. This configuration is ideally suited for automotive and other low voltage applications since there is only one power switch voltage drop in series with a given stator winding. Current flow is unidirectional or half wave because only one end of each winding is switched. Continuous braking with the typical half wave arrangement presents a motor overheating problem since stator current is limited only by the winding resistance. This is due to the lack of upper power switch transistors, as in the full wave circuit, used to disconnect the windings from the supply voltage V_M. A unique solution is to provide braking until the motor stops and then turn off the bottom drives. This can be accomplished by using the Fault Output in conjunction with the Output Enable as an over current timer. Components R_{DLY} and C_{DLY} are selected to give the motor sufficient time to stop before latching the Output Enable and the top drive AND gates low. When enabling the motor, the brake switch is closed and the PNP transistor (along with resistors R_1 and R_{DLY}) are used to reset the latch by discharging C_{DLY}. The stator flyback voltage is clamped by a single zener and three diodes.

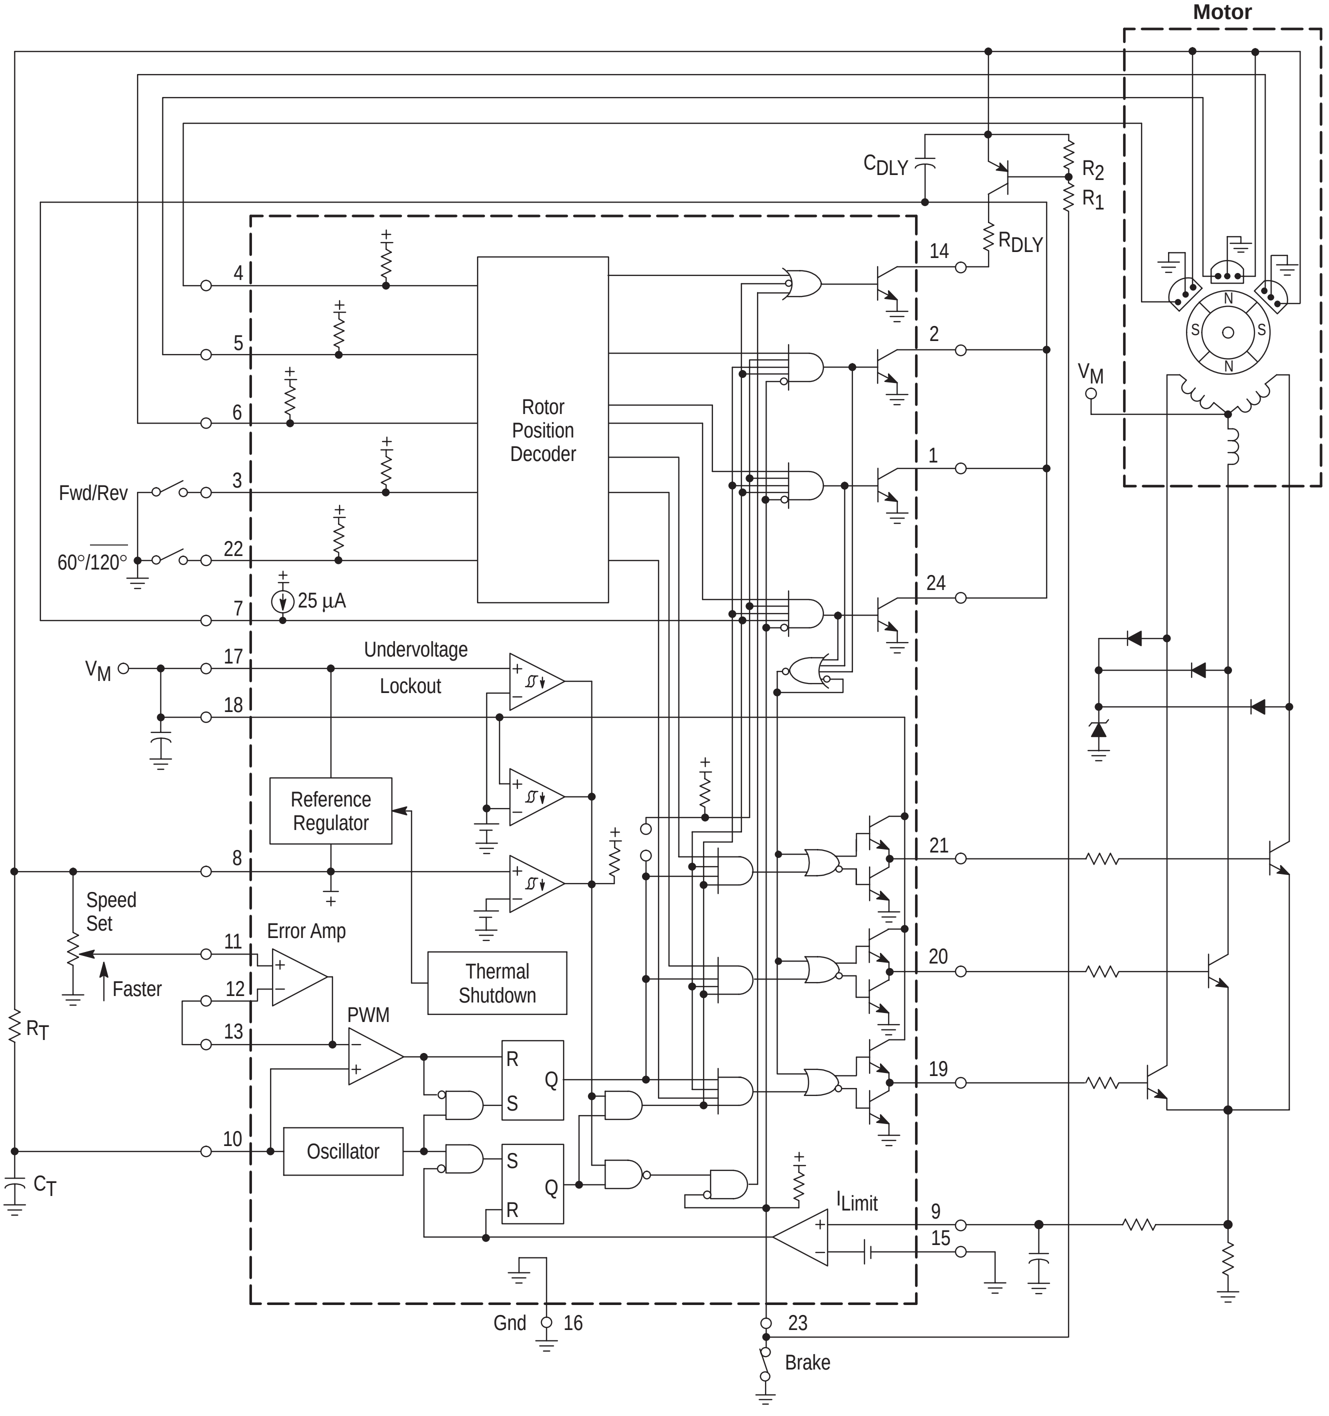
Figure 38. Three Phase, Three Step, Half Wave Motor Controller

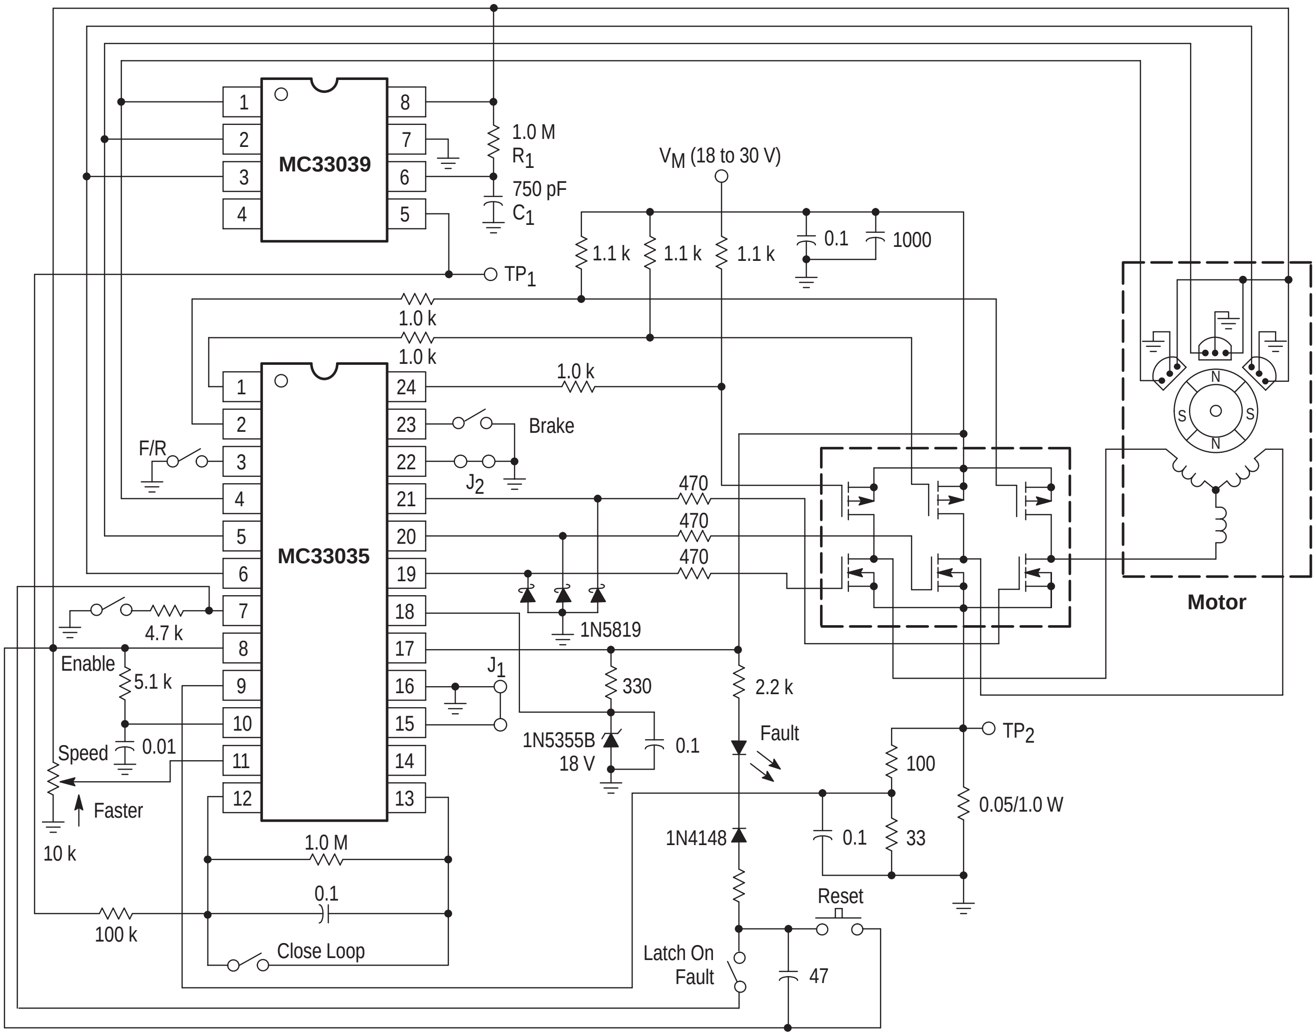


Three Phase Closed Loop Controller

The MC33035, by itself, is only capable of open loop motor speed control. For closed loop motor speed control, the MC33035 requires an input voltage proportional to the motor speed. Traditionally, this has been accomplished by means of a tachometer to generate the motor speed feedback voltage. Figure 39 shows an application whereby an MC33039, powered from the 6.25 V reference (Pin 8) of the MC33035, is used to generate the required feedback voltage without the need of a costly tachometer. The same Hall sensor signals used by the MC33035 for rotor position decoding are utilized by the MC33039. Every positive or negative going transition of the Hall sensor signals on any of the sensor lines causes the MC33039 to produce an output pulse of defined amplitude and time duration, as determined by the external resistor R_1 and capacitor C_1. The output train of pulses at Pin 5 of the MC33039 are integrated by the error amplifier of the MC33035 configured as an integrator to produce a DC voltage level which is proportional to the motor speed. This speed proportional voltage establishes the PWM reference level at Pin 13 of the MC33035 motor controller and closes the feedback loop. The MC33035 outputs drive a TMOS power MOSFET 3–phase bridge. High currents can be expected during conditions of start–up, breaking, and change of direction of the motor.

The system shown in Figure 39 is designed for a motor having 120/240 degrees Hall sensor electrical phasing. The system can easily be modified to accommodate 60/300 degree Hall sensor electrical phasing by removing the jumper (J_2) at Pin 22 of the MC33035.

Figure 39. Closed Loop Brushless DC Motor Control Using The MC33035 and MC33039



Sensor Phasing Comparison

There are four conventions used to establish the relative phasing of the sensor signals in three phase motors. With six step drive, an input signal change must occur every 60 electrical degrees; however, the relative signal phasing is dependent upon the mechanical sensor placement. A comparison of the conventions in electrical degrees is shown in Figure 40. From the sensor phasing table in Figure 41, note that the order of input codes for 60° phasing is the reverse of 300°. This means the MC33035, when configured for 60° sensor electrical phasing, will operate a motor with either 60° or 300° sensor electrical phasing, but resulting in opposite directions of rotation. The same is true for the part when it is configured for 120° sensor electrical phasing; the motor will operate equally, but will result in opposite directions of rotation for 120° for 240° conventions.

Figure 40. Sensor Phasing Comparison

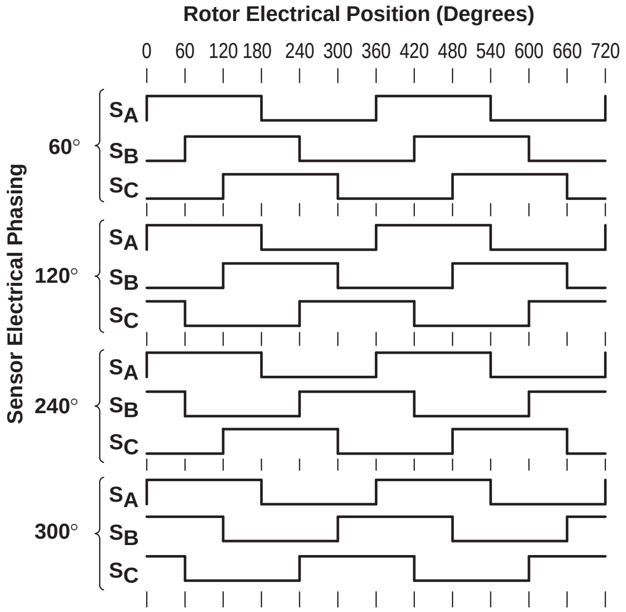


Figure 41. Sensor Phasing Table

Sensor Electrical Phasing (Degrees)											
60°			120°			240°			300°		
S_A	S_B	S_C	S_A	S_B	S_C	S_A	S_B	S_C	S_A	S_B	S_C
1	**0**	**0**	1	0	1	1	1	0	1	**1**	1
1	**1**	0	1	0	0	1	0	0	1	**1**	0
1	**1**	1	1	1	0	1	0	1	**1**	**0**	**0**
0	1	1	0	1	0	0	0	1	0	0	0
0	0	1	0	1	1	0	1	1	0	0	1
0	0	0	0	0	1	0	1	0	0	1	1

In this data sheet, the rotor position is always given in electrical degrees since the mechanical position is a function of the number of rotating magnetic poles. The relationship between the electrical and mechanical position is:

$$\text{Electrical Degrees} = \text{Mechanical Degrees}\left(\frac{\text{\#Rotor Poles}}{2}\right)$$

An increase in the number of magnetic poles causes more electrical revolutions for a given mechanical revolution. General purpose three phase motors typically contain a four pole rotor which yields two electrical revolutions for one mechanical.

Two and Four Phase Motor Commutation

The MC33035 is also capable of providing a four step output that can be used to drive two or four phase motors. The truth table in Figure 42 shows that by connecting sensor inputs S_B and S_C together, it is possible to truncate the number of drive output states from six to four. The output power switches are connected to B_T, C_T, B_B, and C_B. Figure 43 shows a four phase, four step, full wave motor control application. Power switch transistors Q_1 through Q_8 are Darlington type, each with an internal parasitic catch diode. With four step drive, only two rotor position sensors spaced at 90 electrical degrees are required. The commutation waveforms are shown in Figure 44.

Figure 45 shows a four phase, four step, half wave motor controller. It has the same features as the circuit in Figure 38, except for the deletion of speed control and braking.

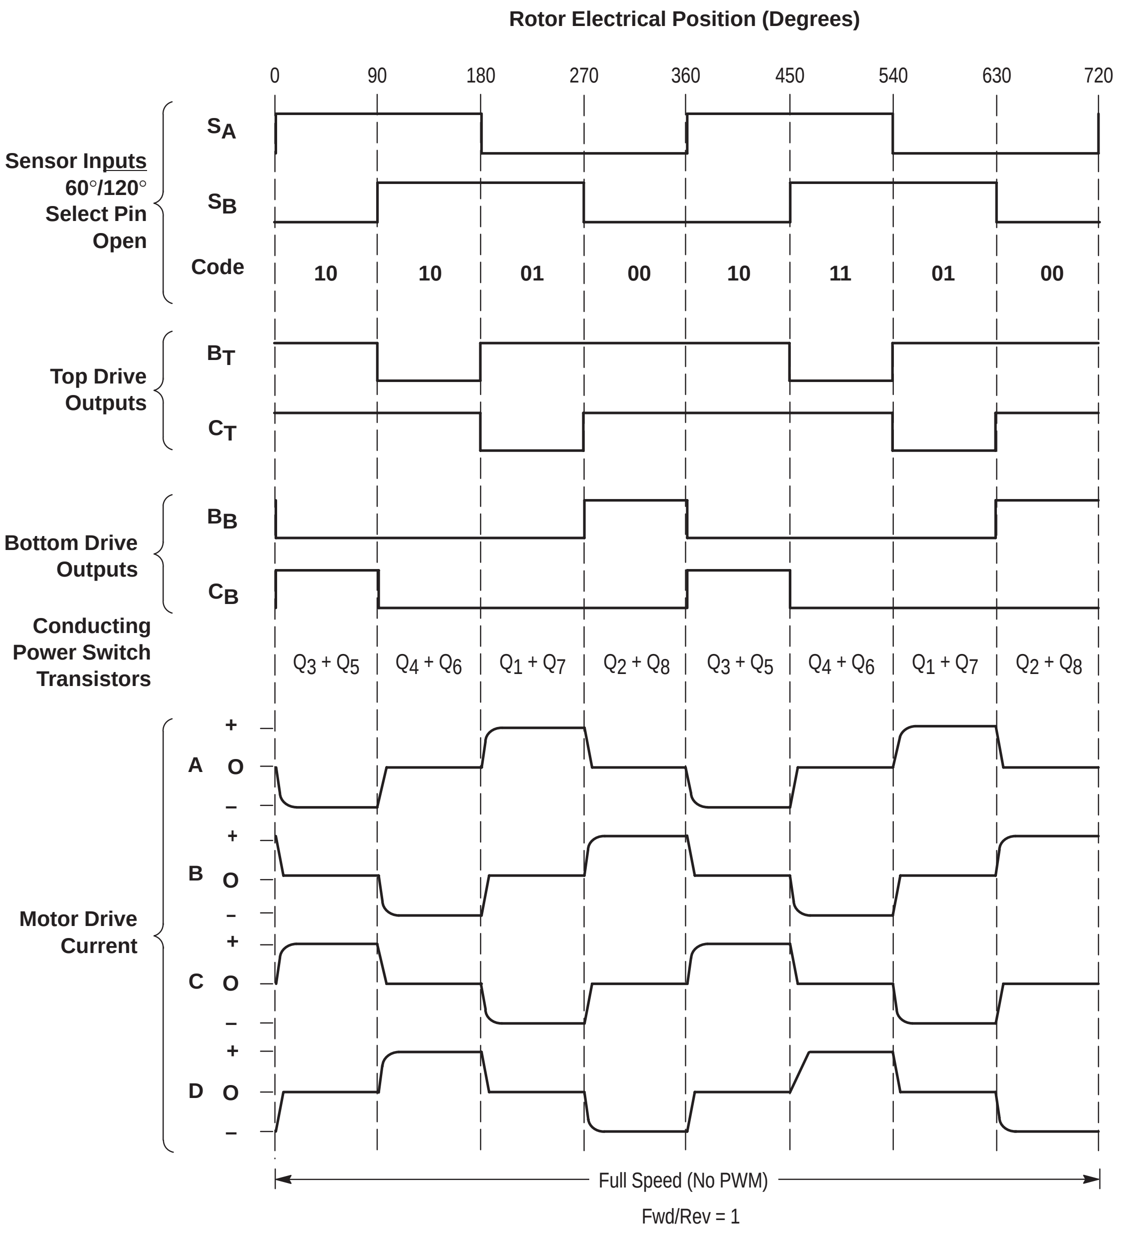

Figure 45. Four Phase, Four Step, Half Wave Motor Controller

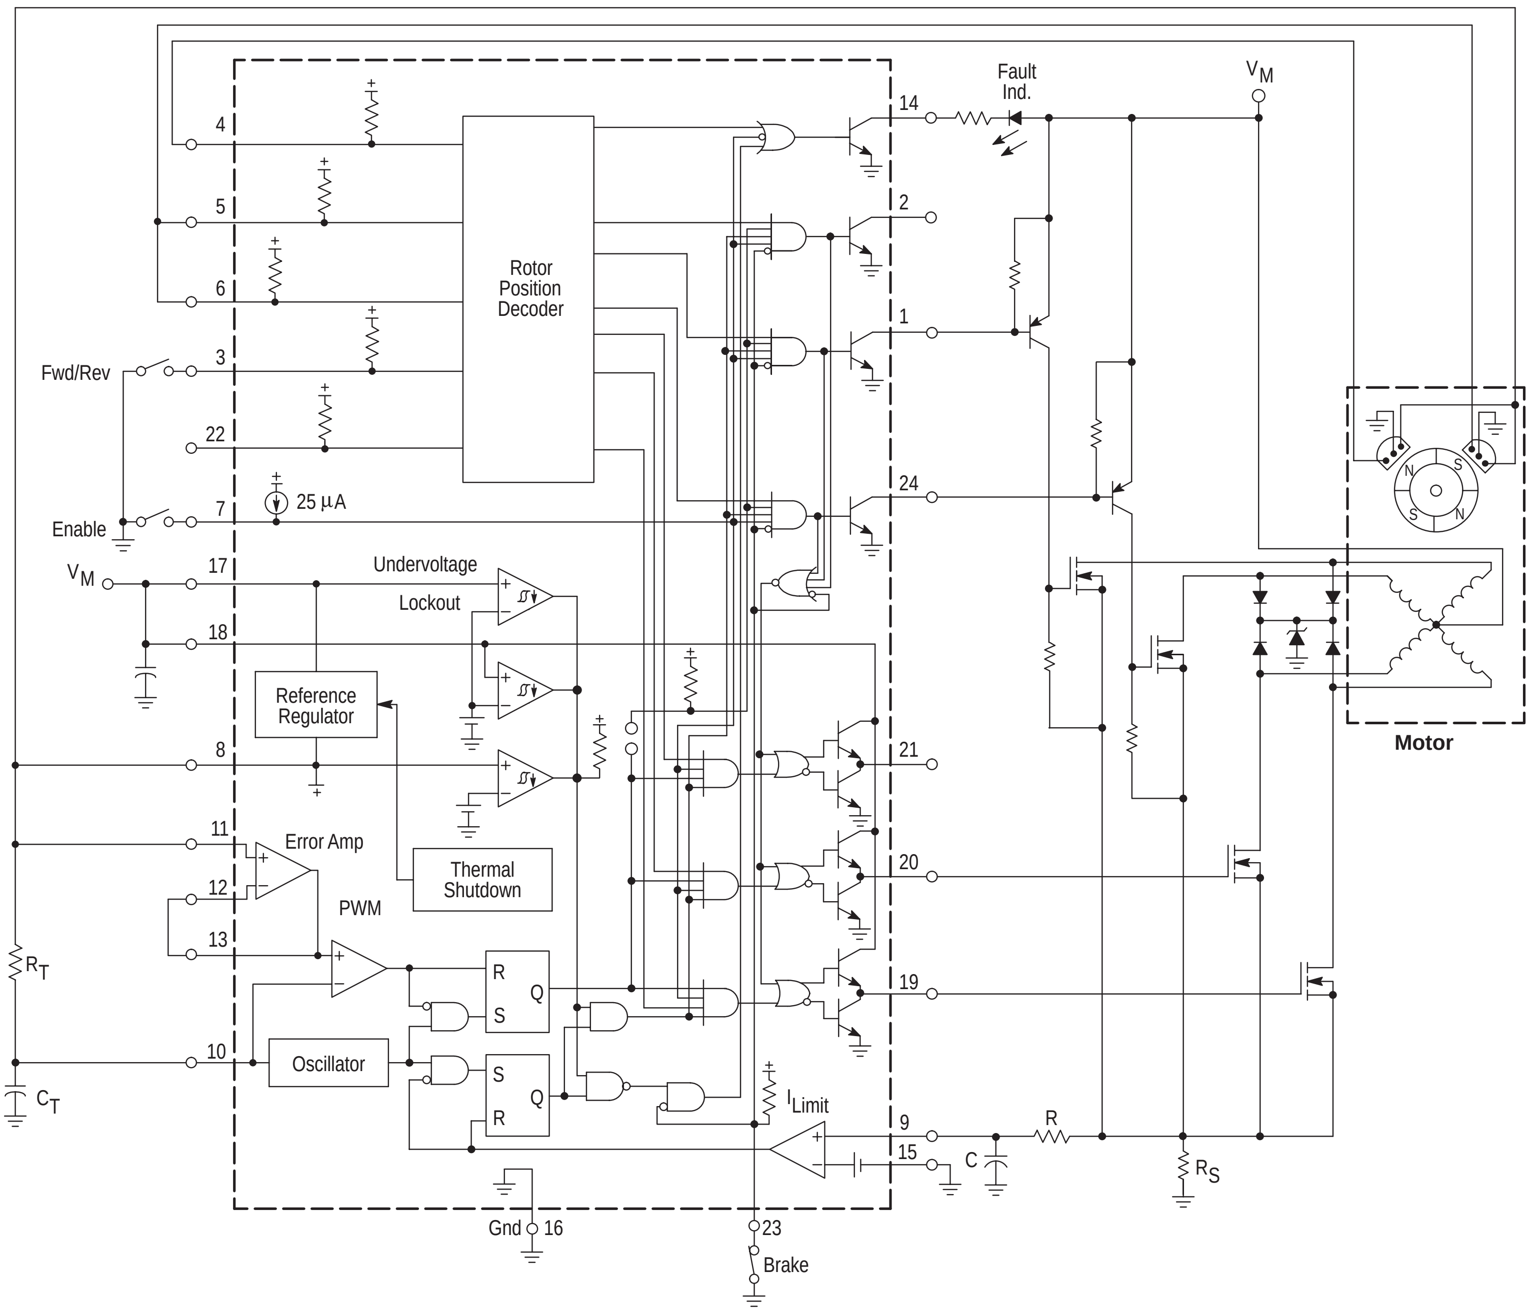


Brush Motor Control

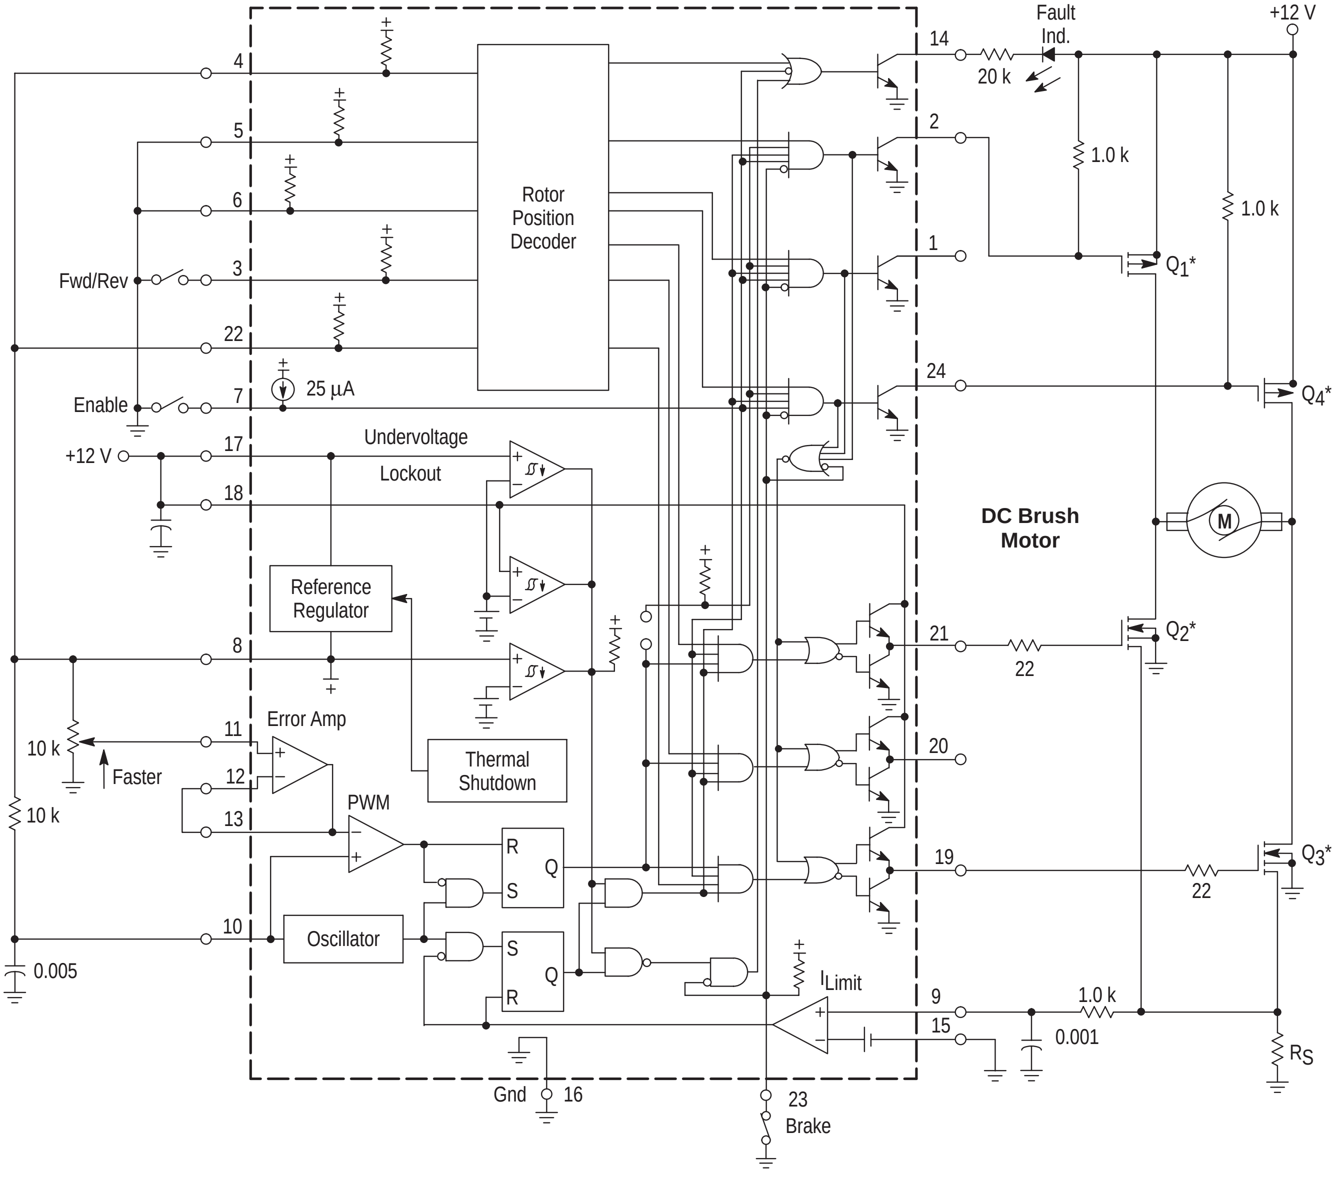
Though the MC33035 was designed to control brushless DC motors, it may also be used to control DC brush type motors. Figure 46 shows an application of the MC33035 driving a MOSFET H–bridge affording minimal parts count to operate a brush–type motor. Key to the operation is the input sensor code [100] which produces a top–left (Q_1) and a bottom–right (Q_3) drive when the controller's forward/reverse pin is at logic [1]; top–right (Q_4), bottom–left (Q_2) drive is realized when the Forward/Reverse pin is at logic [0]. This code supports the requirements necessary for H–bridge drive accomplishing both direction and speed control.

The controller functions in a normal manner with a pulse width modulated frequency of approximately 25 kHz. Motor speed is controlled by adjusting the voltage presented to the noninverting input of the error amplifier establishing the PWM's slice or reference level. Cycle–by–cycle current limiting of the motor current is accomplished by sensing the voltage (100 mV) across the R_S resistor to ground of the H–bridge motor current. The over current sense circuit makes it possible to reverse the direction of the motor, using the normal forward/reverse switch, on the fly and not have to completely stop before reversing.

LAYOUT CONSIDERATIONS

Do not attempt to construct any of the brushless motor control circuits on wire–wrap or plug–in prototype boards. High frequency printed circuit layout techniques are imperative to prevent pulse jitter. This is usually caused by excessive noise pick–up imposed on the current sense or error amp inputs. The printed circuit layout should contain a ground plane with low current signal and high drive and output buffer grounds returning on separate paths back to the power supply input filter capacitor V_M. Ceramic bypass capacitors (0.1 µF) connected close to the integrated circuit at V_{CC}, V_C, V_{ref} and the error amp noninverting input may be required depending upon circuit layout. This provides a low impedance path for filtering any high frequency noise. All high current loops should be kept as short as possible using heavy copper runs to minimize radiated EMI.

Figure 46. H–Bridge Brush–Type Controller



MOTOROLA

MC33039

Closed Loop Brushless Motor Adapter

The MC33039 is a high performance closed–loop speed control adapter specifically designed for use in brushless DC motor control systems. Implementation will allow precise speed regulation without the need for a magnetic or optical tachometer. This device contains three input buffers each with hysteresis for noise immunity, three digital edge detectors, a programmable monostable, and an internal shunt regulator. Also included is an inverter output for use in systems that require conversion of sensor phasing. Although this device is primarily intended for use with the MC33035 brushless motor controller, it can be used cost effectively in many other closed–loop speed control applications.

- Digital Detection of Each Input Transition for Improved Low Speed Motor Operation
- TTL Compatible Inputs With Hysteresis
- Operation Down to 5.5 V for Direct Powering from MC33035 Reference
- Internal Shunt Regulator Allows Operation from a Non–Regulated Voltage Source
- Inverter Output for Easy Conversion between 60°/300° and 120°/240° Sensor Phasing Conventions

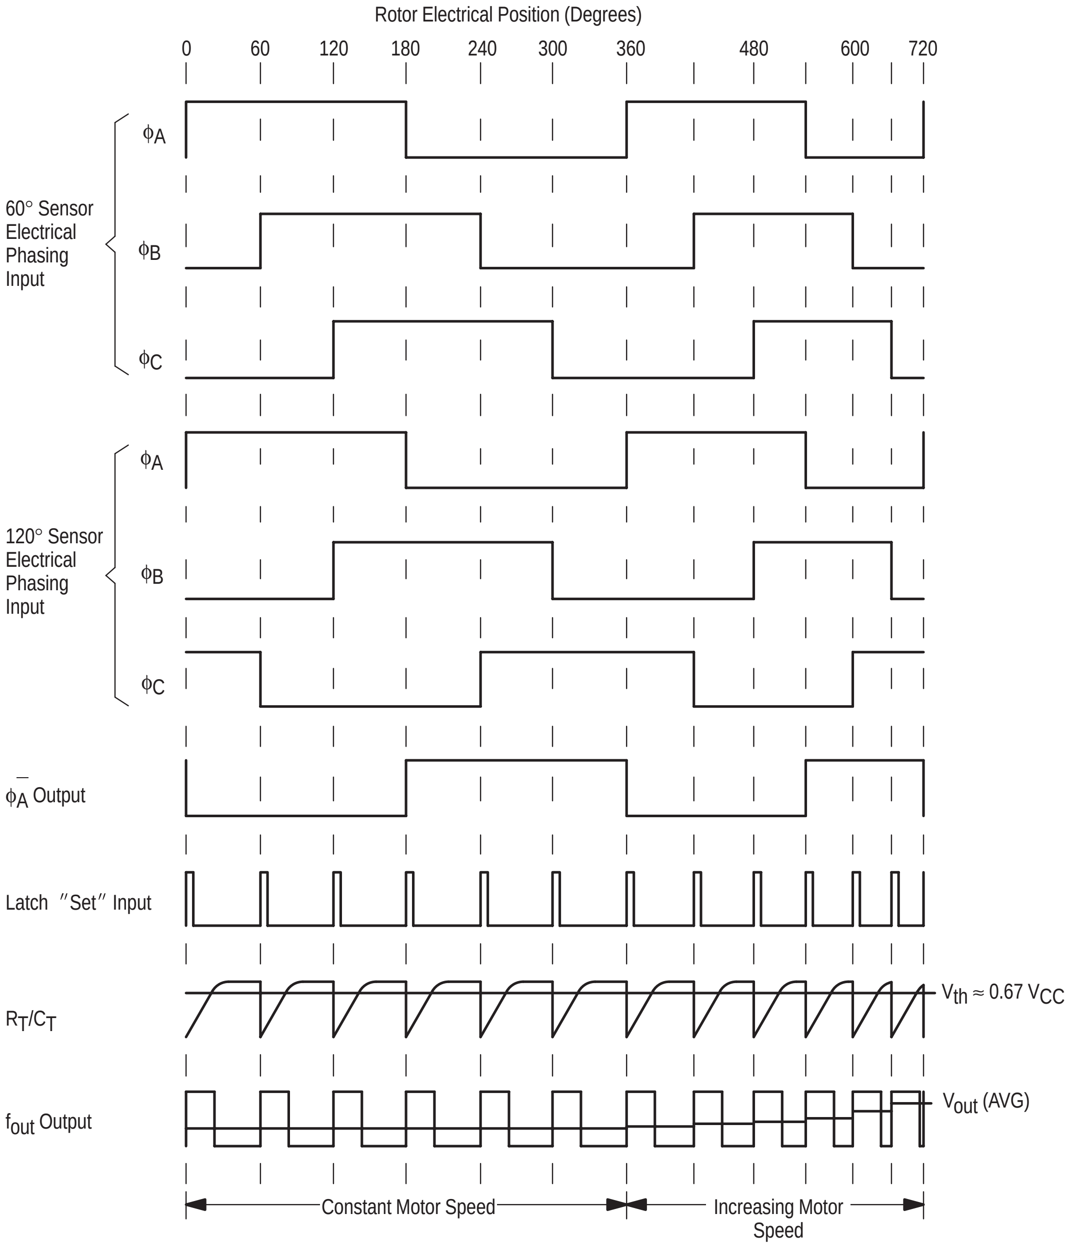
Figure 1. Typical Three Phase, Six Step Motor Application



OPERATING DESCRIPTION

The MC33039 provides an economical method of implementing closed–loop speed control of brushless DC motors by eliminating the need for a magnetic or optical tachometer. Shown in the timing diagram of Figure 1, the three inputs (Pins 1, 2, 3) monitor the brushless motor rotor position sensors. Each sensor signal transition is digitally detected, OR′ed at the Latch ′Set′ Input, and causes C_T to discharge. A corresponding output pulse is generated at f_{out} (Pin 5) of a defined amplitude, and programmable width determined by the values selected for R_T and C_T (Pin 6). The average voltage of the output pulse train increases with motor speed. When fed through a low pass filter or integrator, a DC voltage proportional to speed is generated. Figure 2 shows the proper connections for a typical closed loop application using the MC33035 brushless motor controller. Constant speed operation down to 100 RPM is possible with economical three phase four pole motors.

The $\overline{\phi_A}$ inverter output (Pin 4) is used in systems where the controller and motor sensor phasing conventions are not compatible. A method of converting from either convention to the other is shown in Figure 3. For a more detailed explanation of this subject, refer to the text above Figure 39 on the MC33035 data sheet.

The output pulse amplitude V_{OH} is constant with temperature and controlled by the supply voltage on V_{CC} (Pin 8). Operation down to 5.5 V is guaranteed over temperature. For systems without a regulated power supply, an internal 8.25 V shunt regulator is provided.

MOTOROLA

SAA1042

Stepper Motor Driver

The SAA1042 drives a two–phase stepper motor in the bipolar mode. The device contains three input stages, a logic section and two output stages. The IC is contained in a 16 pin dual–in–line heat tab plastic package for improved heatsinking capability. The center four ground pins are connected to the copper alloy heat tab and improve thermal conduction from the die to the circuit board.

- Drive Stages Designed for Motors: 6.0 V and 12 V: SAA1042V
- 500 mA/Coil Drive Capability
- Built–In Clamp Diodes for Overvoltage Suppression
- Wide Logic Supply Voltage Range
- Accepts Commands for CW/CCW and Half/Full Step Operation
- Inputs Compatible with Popular Logic Families: MOS, TTL, DTL
- Set Input Defined Output State
- Drive Stage Bias Adaptable to Motor Power Dissipation for Optimum Efficiency

INPUT/OUTPUT FUNCTIONS

Clock — (Pin 7) This input is active on the positive edge of the clock pulse and accepts Logic ‘1’ input levels dependent on the supply voltage and includes hysteresis for noise immunity.

CW/CCW — (Pin 10) This input determines the motor’s rotational direction. When the input is held low, (OV, see the electrical characteristics) the motor’s direction is nominally clockwise (CW). When the input is in the high state, Logic ‘1’, the motor direction is nominally counter clockwise (CCW), depending on the motor connections.

Full/Half Step — (Pin 8) This input determines the angular rotation of the motor for each clock pulse. In the low state, the motor will make a full step for each applied clock pulse, while in the high state, the motor will make half a step.

V_D — (Pin 2) This pin is used to protect the outputs (1, 3,14, 16) where large positive spikes occur due to switching the motor coils. The maximum allowable voltage on these pins is the clamp voltage (V_{clamp}). Motor performance is improved if a zener diode is connected between Pin 2 and 15, as shown in Figure 1.

The following conditions have to be considered when selecting the zener diode:

$$V_{clamp} = V_M + 6.0\text{ V}$$
$$V_Z = V_{clamp} - V_M - V_F$$

where: V_F = clamp diodes forward voltage drop (see Figure 4)

V_{clamp}: ≤ 20 V for SAA1042V ≤ 30 V for SAA1042AV

Pins 2 and 15 can be linked, in this case $V_Z = 0$ V.

Set/Bias Input — (Pin 6) This input has two functions:

1) The resistor R_B adapts the drivers to the motor current.
2) A pulse via the resistor R_B sets the outputs (1, 3, 14, 16) to a defined state.

The resistor R_B can be determined from the graph of Figure 2 according to the motor current and voltage. Smaller values of R_B will increase the power dissipation of the circuit and larger values of R_B may increase the saturation voltage of the driver transistors.

When the “set” function is not used, terminal A of the resistor R_B must be grounded. When the set function is used, terminal A has to be connected to an open–collector (buffer) circuit. Figure 7 shows this configuration. The buffer circuit (off–state) has to sustain the motor voltage (V_M). When a pulse is applied via the buffer and the bias resistor (R_B), the motor driver transistors are turned off during the pulse and after the pulse has ended, the outputs will be in defined states. Figure 6 shows the Timing Diagram.

Figure 7 illustrates a typical application in which the SAA1042 drives a 12 V stepper motor with a current consumption of 200 mA/coil. A bias resistor (R_B) of 56 kΩ is chosen according to Figure 2.

The maximum voltage permitted at the output pin is V_M + 6.0 V (see Maximum Ratings table), in this application V_M = 12 V, therefore the maximum voltage is 18 V. The outputs are protected by the internal diodes and an external zener connected between Pins 2 and 15.

From Figure 4, it can be seen that the voltage drop across the internal diodes is about 1.7 V at 200 mA. This results in a zener voltage between Pins 2 and 15 of:

$$V_Z = 6.0\text{ V} - 1.7\text{ V} = 4.3\text{ V.}$$

To allow for production tolerances and a safety margin, a 3.9 V zener has been chosen for this example.

The clock is derived from the line frequency which is phase–locked by the MC14046B and the MC14024. The voltage on the clock input is normally low (Logic ‘0’). The motor steps on the positive going transition of the clock pulse.

The Logic ‘0’ applied to the Full/Half input (Pin 8) operates the motor in Full Step mode. A Logic ‘1’ at this input will result in Half Step mode. The logic level state on the CW/CCW input (Pin 10), and the connection of the motor coils to the outputs determines the rotational direction of the motor.

These two inputs should be biased to a Logic ‘0’ or ‘1’ and not left floating. In the event of non–use, they should be tied to ground or the logic supply line, V_{CC}.

The output drivers can be set to a fixed operating point by use of the Set input and a bias resistor, R_B. A positive pulse to this input turns the drivers off and sets the logic state of the outputs.

After the negative going transition of the Set pulse, and until the first positive going transition of the clock, the outputs will be:

L1 = L3 = high and L2 = L4 = low, (see Figure 6).

The Set input can be driven by a MC14007B or a transistor whose collector resistor is R_B. **If the input is not used, the bottom of R_B must be grounded.**

The total power dissipation of the circuit can be determined from Figures 3 and 5:

$$P_D = 0.9\text{ W} + 0.08\text{ W} = 0.98\text{ W.}$$

The junction temperature can then be computed using Figure 8.

GENERAL DESCRIPTION

The TDA 1085C triggers a triac accordingly to the speed regulation requirements. Motor speed is digitally sensed by a tachogenerator and then converted into an analog voltage.

The speed set is externally fixed and is applied to the internal linear regulation input after having been submitted to programmable acceleration ramps. The overall result consists in a full motor speed range with two acceleration ramps which allow efficient washing machine control (Distribute function).

Additionally, the TDA 1085C protects the whole system against AC line stop or variations, overcurrent in the motor and tachogenerator failure.

INPUT/OUTPUT FUNCTIONS
(Refer to Figures 1 and 8)

Voltage Regulator – (Pins 9 and 10) This is a parallel type regulator able to sink a large amount of current and offering good characteristics. Current flow is provided from AC line by external dropping resistors R1, R2, and rectifier: This half wave current is used to feed a smoothering capacitor, the voltage of which is checked by the IC.

When V_{CC} is reached, the excess of current is derived by another dropping resistor R10 and by Pin 10. These three resistors must be determined in order:

- To let 1.0 mA flow through Pin 10 when AC line is minimum and V_{CC} consumption is maximum (fast ramps and pulses present).
- To let V_{10} reach 3.0 V when AC line provides maximum current and V_{CC} consumption is minimum (no ramps and no pulses).
- All along the main line cycle, the Pin 10 dynamic range must not be exceeded unless loss of regulation.

An AC line supply failure would cause shut down.

The double capacitive filter built with R1 and R2 gives an efficient V_{CC} smoothing and helps to remove noise from set speeds.

Speed Sensing – (Pins 4, 11, 12) The IC is compatible with an external analog speed sensing: its output must be applied to Pin 4, and Pin 12 connected to Pin 8.

In most of the applications it is more convenient to use a digital speed sensing with an unexpensive tachogenerator which doesn′t need any tuning. During every positive cycle at Pin 12, the capacitor $C_{Pin\ 11}$ is charged to almost V_{CC} and during this time, Pin 4 delivers a current which is 10 times the one charging $C_{Pin\ 11}$. The current source gain is called G and is tightly specified, but nevertheless requires an adjustment on $R_{Pin\ 4}$. The current into this resistor is proportional to $C_{Pin\ 11}$ and to the motor speed; being filtered by a capacitor, $V_{Pin\ 4}$ becomes smothered and represents the “true actual motor speed”.

To maintain linearity into the high speed range, it is important to verify that $C_{Pin\ 11}$ is fully charged: the internal source on Pin 11 has 100 KΩ impedance. Nevertheless $C_{Pin\ 11}$ has to be as high as possible as it has a large influence on FV/C temperature factor. A 470 KΩ resistor between Pins 11 and 9 reduces leakage currents and temperature factor as well, down to neglectable effects.

Pin 12 also has a monitoring function: when its voltage is above 5.0 V, the trigger pulses are inhibited and the IC is reset. It also senses the tachogenerator continuity, and in case of any circuit aperture, it inhibits pulse, avoiding the motor to run out of control. In the TDA 1085C, Pin 12 is negatively clamped by an internal diode which removes the necessity of the external one used in the former circuit.

Ramp Generator – (Pins 5, 6, 7) The true Set Speed value taken in consideration by the regulation is the output of the ramp generator (Pin 7). With a given value of speed set input (Pin 5), the ramp generator charges an external capacitor $C_{Pin\ 7}$ up to the moment $V_{Pin\ 5}$ (set speed) equals $V_{Pin\ 4}$ (true speed), see Figure 2. The IC has an internal charging current source of 1.2mA and delivers it from 0 to 12 V at Pin 7. It is the high acceleration ramp (5.0 s typical) which allows rapid motor speed changes without excessive strains on the mechanics. In addition, the TDA 1085C offers the possibility to break this high acceleration with the introduction of a low acceleration ramp (called Distribution) by reducing the Pin 7 source current down to 5.0 µA under Pin 6 full control, as shown by following conditions:

- Presence of high acceleration ramp $V_{Pin\ 5} > V_{Pin\ 4}$
- Distribution occurs in the $V_{Pin\ 4}$ range (true motor speed) defined by $V_{Pin\ 6} \leqq V_{Pin\ 4} \leqq 2.0\ V_{Pin\ 6}$

For two fixed values of $V_{Pin\ 5}$ and $V_{Pin\ 6}$, the motor speed will have high acceleration, excluding the time for $V_{Pin\ 4}$ to go from $V_{Pin\ 6}$ to two times this value, high acceleration again, up to the moment the motor has reached the set speed value, at which it will stay, see Figure 3.

Should a reset happen (whatever the cause would be), the above mentioned successive ramps will be fully reprocessed from 0 to the maximum speed. If $V_{Pin\ 6} = 0$, only the high acceleration ramp occurs.

To get a real zero speed position, Pin 5 has been designed in such a way that its voltage from 0 to 80 mV is interpreted as a true zero. As a consequence, when changing the speed set position, the designer must be sure that any transient zero would not occur: if any, the entire circuit will be reset.

As the voltages applied by Pins 5 and 6 are derived from the internal voltage regulator supply and Pin 4 voltage is also derived from the same source, motor speed (which is determined by the ratios between above mentioned voltages) is totally independent from V_{CC} variations and temperature factor.

Control Amplifier – (Pin 16) It amplifies the difference between true speed (Pin 4) and set speed (Pin 5), through the ramp generator. Its output available at Pin 16 is a double sense current source with a maximum capability of ± 100 µA and a specified transconductance (340 µA/V typical). Pin 16 drives directly the trigger pulse generator, and must be loaded by an electrical network which compensates the mechanical characteristics of the motor and its load, in order to provide stability in any condition and shortest transient response; see Figure 4.

This network must be adjusted experimentally.

In case of a periodic torque variations, Pin 16 directly provides the phase angle oscillations.

Trigger Pulse Generator – **(Pins 1, 2, 5, 13, 14, 15)**
This circuit performs four functions:

- The conversion of the control amplifier DC output level to a proportional firing angle at every main line half cycle.
- The calibration of pulse duration.
- The repetition of the pulse if the triac fails to latch on if the current has been interrupted by brush bounce.
- The delay of firing pulse until the current crosses zero at wide firing angles and inductive loads.

$R_{Pin\ 15}$ programs the Pin 14 discharging current. Saw tooth signal is then fully determined by R15 and C14 (usually 47 nF). Firing pulse duration and repetition period are in inverse ratio to the saw tooth slope. Pin 13 is the pulse output and an external limiting resistor is mandatory. Maximum current capability is 200 mA.

Current Limiter – (Pin 3) Safe operation of the motor and triac under all conditions is ensured by limiting the peak current. The motor current develops an alternative voltage in the shunt resistor (0.05 Ω in Figure 4). The negative half waves are transferred to Pin 3 which is positively preset at a voltage determined by resistors R3 and R4. As motor current increases, the dynamical voltage range of Pin 3 increases and when Pin 3 becomes slightly negative in respect to Pin 8, a current starts to circulate in it. This current, amplified typically 180 times, is then used to discharge Pin 7 capacitor and, as a result, reduces firing angle down to a value where an equilibrium is reached. The choice of resistors R3, R4 and shunt determines the magnitude of the discharge current signals on $C_{Pin\ 7}$.

Notice that the current limiter acts only on peak triac current.

APPLICATION NOTES
(Refer to Figure 4)

Printed Circuit Layout Rules
In the common applications, where TDA 1085C is used, there is on the same board, presence of high voltage, high currents as well as low voltage signals where millivolts count. It is of first magnitude importance to separate them from each other and to respect the following rules:

- Capacitor decoupling pins, which are the inputs of the same comparator, must be physically close to the IC, close to each other and grounded in the same point.
- Ground connection for tachogenerator must be directly connected to Pin 8 and should ground only the tacho. In effect, the latter is a first magnitude noise generator due to its proximity to the motor which induces high dϕ/dt signals.
- The ground pattern must be in the “star style” in order to fully eliminate power currents flowing in the ground network devoted to capacitors decoupling sensitive Pins: 4, 5, 7, 11, 12, 14, 16.

As an example, Figure 5 presents a PC board pattern which concerns the group of sensitive Pins and their associated capacitors into which the a.m. rules have been implemented. Notice the full separation of “Signal World” from “Power”, one by line AB and their communication by a unique strip.

These rules will lead to much satisfactory volume production in the sense that speed adjustment will stay valid in the entire speed range.

Power Supply
As dropping resistor dissipates noticeable power, it is necessary to reduce the I_{CC} needs down to a minimum. Triggering pulses, if a certain number of repetitions are kept in reserve to cope with motor brush wearing at the end of its life, are the largest I_{CC} user. Classical worst case configuration has to be considered to select dropping resistor. In addition, the parallel regulator must be always into its dynamic range, i.e., $I_{Pin\ 10}$ over 1.0 mA and $V_{Pin\ 10}$ over 3.0 V in any extreme configuration. The double filtering cell is mandatory.

Tachogenerator Circuit
The tacho signal voltage is proportional to the motor speed. Stablility considerations, in addition, require an RC filter, the pole of which must be looked at. The combination of both elements yield a constant amplitude signal on Pin 12 in most of the speed range. It is recommended to verify this maximum amplitude to be within 1.0 V peak in order to have the largest signal/noise ratio without resetting the integrated circuit (which occurs if $V_{Pin\ 12}$ reaches 5.5 V). It must be also verified that the Pin 12 signal is approximately balanced between “high” (over 300 mV) and “low”. An 8–poles tacho is a minimum for low speed stability and a 16–poles is even better.

The RC pole of the tacho circuit should be chosen within 30 Hz in order to be as far as possible from the 150 Hz which corresponds to the AC line 3rd harmonic generated by the motor during starting procedure. In addition, a high value resistor coming from V_{CC} introduces a positive offset at Pin 12, removes noise to be interpreted as a tacho signal. This offset should be designed in order to let Pin 12 reach at least – 200 mV (negative voltage) at the lowest motor speed. We remember the necessity of an individual tacho ground connection.

Frequency to Voltage Converter – F V/C
$C_{Pin\ 11}$ has a recommended value of 820 pF for 8–poles tachos and maximum motor rpm of 15000, and $R_{Pin\ 11}$ must be always 470 K.

$R_{Pin\ 4}$ should be choosen to deliver within 12 V at maximum motor speed in order to maximize signal/noise ratio. As the FV/C ratio as well as the $C_{Pin\ 11}$ value are dispersed, $R_{Pin\ 4}$ must be adjustable and should be made of a fixed resistor in serice with a trimmer representing 25% of the total. Adjustment would become easier.

Once adjusted, for instance at maximum motor speed, the FV/C presents a residual non linearity; the conversion factor (mV per RPM) increases by within 7.7% as speed draws to zero. The guaranteed dispersion of the latter being very narrow, a maximum 1% speed error is guaranteed if during Pin 5 network design the small set values are modified, once forever, according this increase.

The following formulas give $V_{Pin\ 4}$:

$$V_{Pin\ 4} = G.0 \cdot (V_{CC} – V_a) \cdot C_{Pin\ 11} \cdot R_4 \cdot f \cdot \frac{1}{\left(1 + \frac{120k}{R_{Pin11}}\right)} \text{ In volts.}$$

$G.0 \cdot (V_{CC} – V_a) \simeq 140$
$V_a = 2.0\ V_{BE}$
$120\ k = R_{int}$, on Pin 11

Speed Set – (Pin 5) Upon designer choice, a set of external resistors apply a series of various voltages corresponding to the various motor speeds. When switching external resistors, verify that no voltage below 80 mV is ever applied to Pin 5. If so, a full circuit reset will occur.

Ramps Generator – (Pin 6) If only a high acceleration ramp is needed, connect Pin 6 to ground.

When a Distribute ramp should occur, preset a voltage on Pin 6 which corresponds to the motor speed starting ramp point. Distribution (or low ramp) will continue up to the moment the motor speed would have reached twice the starting value.

The ratio of two is imposed by the IC. Nevertheless, it could be externally changed downwards (Figure 6) or upwards (Figure 7).

The distribution ramp can be shortened by an external resistor from V_{CC} charging $C_{Pin\ 7}$, adding its current to the internal 5.0 µA generator.

Power Circuits
Triac Triggering pulse amplitude must be determined by Pin 13 resistor according to the needs in Quadrant IV. Trigger pulse duration can be disturbed by noise signals generated by the triac itself, which interfere within Pins 14 and 16, precisely those which determine it. While easily visible, this effect is harmless.

The triac must be protected from high AC line dV/dt during external disturbances by 100 nF x 100 Ω network.

Shunt resistor must be as non–inductive as possible. It can be made locally by using constantan alloy wire.

When the load is a DC fed universal motor through a rectifier bridge, the triac must be protected from commutating dV/dt by a 1.0 to 2.0 mH coil in series with MT_2.

Synchronization functions are performed by resistors sensing AC line and triac conduction. 820 k values are normal but could be reduced down to 330 k in order to detect the “zeros” with accuracy and to reduce the residual DC line component below 20 mA.

Current Limitation
The current limiter starts to discharge Pin 7 capacitor (reference speed) as the motor current reaches the designed threshold level. The loop gain is determined by the resistor connecting Pin 3 to the series shunt. Experience has shown that its optimal value for a 10 Arms limitation is within 2.0 kΩ. Pin 3 input has a sensitivity in current which is limited to reasonable values and should not react to spikes.

If not used, Pin 3 must be connected to a maximum positive voltage of 5.0 V rather than be left open.

Loop Stability
The Pin 16 network is predominant and must be adjusted experimentally during module development. The values indicated in Figure 4 are typical for washing machine applications but accept large modifications from one model to another. R16 (the sole restriction) should not go below 33 k, otherwise slew rate limitation will cause large transient errors for load steps.

MOTOROLA

TDA1185A

Triac Phase Angle Controller

TRIAC PHASE ANGLE CONTROLLER

SEMICONDUCTOR TECHNICAL DATA

The TDA1185A generates controlled triac triggering pulses and allows tachless speed stabilization of universal motors by an integrated positive feedback function. Typical applications are power hand tools, vacuum cleaners, mixers, light dimmer and other small appliances.

- Supply Power Obtained from AC Line
- Can be used with 220 V/50 Hz or 110 V/60 Hz
- Low Count/Cost External Components
- Optimum Triac Firing (2nd and 3rd Quadrants)
- Repetitive Trigger Pulses when Triac Current is Interrupted by Motor Brush Bounce
- Triac Current Sensing to Allow Inductive Loads
- Programmable Soft–Start
- Power Failure Detection and General Circuit Reset
- Low Power Consumption: 6.0 mA

PIN FUNCTION DESCRIPTION

Pin No.	Function	Description
1	V_{EE}	This pin is the negative supply for the chip and is clamped at – 8.6 V by an internal zener.
2	Gate Trigger Pulse	This pin supplies – 1.0 V triac trigger pulse at twice the line frequency.
3	NC	Not connected.
4	Ramp Generator	The value of the capacitor at this pin determines the slope of the ramp.
5	NC	Not connected.
6	Current Sense	This pin senses if the triac is on, and if so, will disable the gate trigger pulse.
7	Voltage Sense	The internal timing of the chip is set by the frequency of the voltage at this pin.
8	Integration Capacitor	This pin is the output of the feedback and the variation in voltage is averaged out by the capacitor.
9	Feedback Input	The change in load current is detected by the change in voltage across R9.
10	Current Program	The bias current for the circuit is determined by the resistor value at this pin.
11	NC	Not connected.
12	Phase Angle Set	The voltage at this pin sets the no–load firing angle.
13	Soft–Start	The firing angle is slowly increased from 180° to the set value of Pin 12.
14	V_{CC}	Ground

Introduction

The Motorola TDA1185A generates trigger pulses (Pin 2) for triac control of power into an AC load. The triac trigger pulse is determined by generating a ramp voltage (Pin 4) synchronized to twice the AC line frequency and compared to an external set voltage (Pin 12) representing the conduction angle. Gate pulses are negative (sink current) and thus the triac is driven into its most effective quadrants (Q2 to Q3).

If the load is a Universal motor (the speed of which decreases as torque increases), the TDA1185A allows to increase the conduction angle proportionally to the motor current, sensed (Pin 9) by a low value resistor in series with the load.

FUNCTIONAL DESCRIPTION

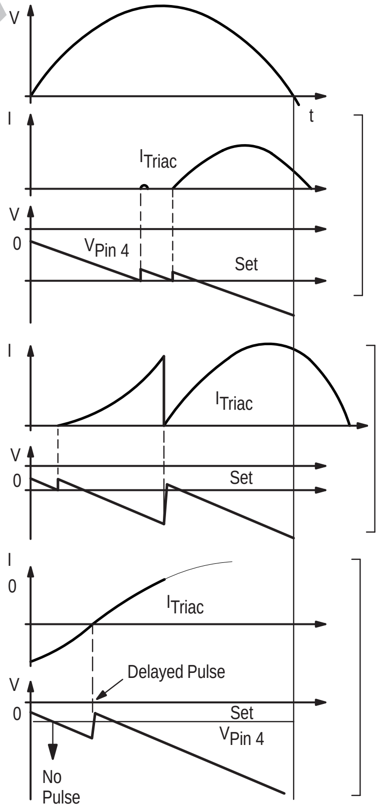
DC Power Supply

DC power is directly derived from the AC line through a 2.0 W resistor, half–wave rectifier and filtering capacitor circuit. The V_{EE} voltage is internally regulated by an integrated zener. Referenced to ground (Pin 14), the power supply voltage is – 8.6 V. The TDA1185A internal consumption is 6.0 mA.

Trigger Pulse Generator

It delivers a 60 mA minimum sink current pulse (Pin 2) through an internally short circuit protected output. Pulse width is roughly proportional to R_{10} x C_4 and is repeated every 420 µs if triac fails to latch or is switched off by brush bounce. With inductive loads, the current lags in respect to the voltage. Pin 6 delays the triggering pulse up to the moment the triac is off, in order to prevent erratic power control (see Figure 2).

Figure 2. Multipulse Generation Delayed Pulse



The triac failed to latch at the first pulse. Successive pulses are generated up to the moment latching occurs.

The triac turned off due to brush bounce, a new pulse is immediately delivered.

Approaching full conduc–tion, a pulse would occur when the triac still carries current; the pulse is delaye until the triac turns off.

Ramp Generator

A constant current sink discharges capacitor C_4 producing a negative voltage ramp synchronized with the main line. Pin 4 voltage is reset to – 1.6 V at every AC line zero crossing (see Figure 3) and ramps down to – 7.1 V. The constant current sink is externally programmable by R_{10} using the equation below.

$$I_4 = I_{10} \pm 5\%$$

$$I_{10} = \frac{|V_{EE} + 1.25|}{R_{10}}$$

Main Comparator

Its role is to determine the trigger pulse which occurs when the ramp voltage equals the phase angle set voltage at Pin 12. Fixed phase angle set voltage values lead to a constant TRIAC conduction angle unless positive current feedback (Pin 9) is connected or the Soft–Start capacitor (Pin 13) is not charged.

Soft–Start

The TDA1185A allows the user to avoid any abrupt inrush of current into the load. This provides protection for fragile loads, light bulbs or tubes. Another advantage is that the AC line disturbance is minimized.

The conduction angle is established from zero to the set value at Pin 12 according to a voltage ramp generated by a constant current delivered to C_{13}. The value of current I_{13} can be expressed by the following equation:

$$I_{13} = 0.2 \times I_{10} \pm 10\%$$

The voltage ramp lasts as long as V_{13} is lower than the set voltage V_{12}. Upon reset, V_{13} is forced to V_{EE} as shown in Figure 4. If the load is a universal motor, it will not turn until a minimum conduction angle is achieved to overcome friction. The time the voltage ramp requires to reach its threshold value is considered deadtime, and can be eliminated by an appropriate series resistor at Pin 13. The voltage drop developed by I_{13} thru the resistor causes the conduction angle to immediately reach the threshold value and have the Soft–Start function without dead time (see Figure 5).

Figure 3. Triggering Pulse Timing

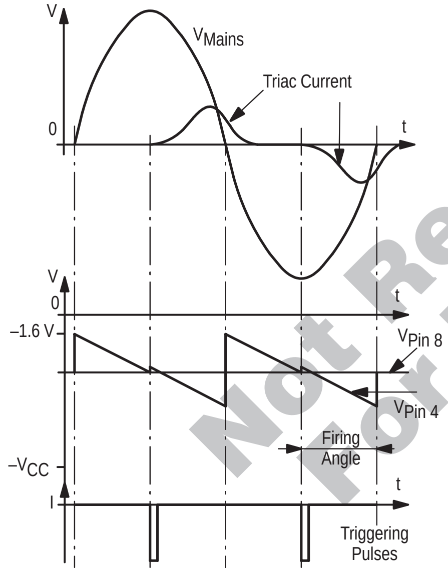


Figure 4. Soft–Start

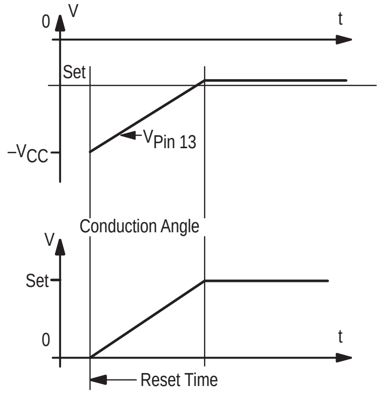

Figure 5. Soft–Start without Deadtime

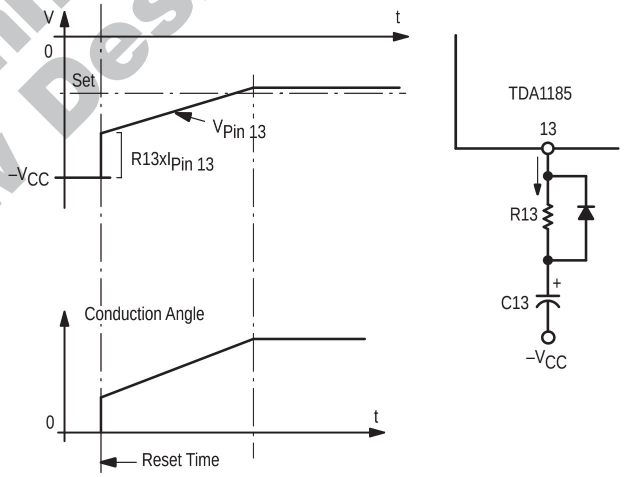

Figure 6. Transfer Function

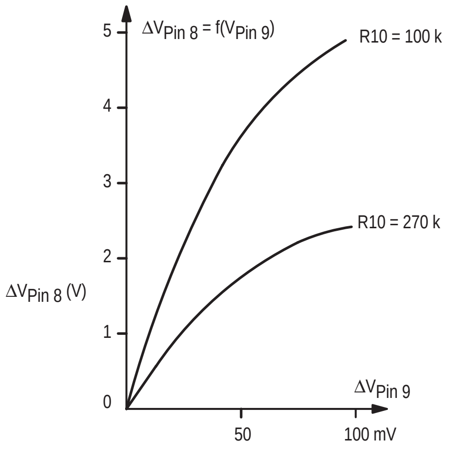

Positive Current Feedback

The Universal motor speed drops as load increases. To maintain the speed, the triac conduction angle must be increased. For this purpose, Pin 9 senses the motor current as a **voltage** developed in a low value resistor, R_9, amplifies, rectifies and adds it internally to the set voltage at Pin 12. Any voltage variation at the output of the feedback, Pin 8, is smoothed out by capacitor C_8. The transfer function, $\Delta V_8 = f(\Delta V_9)$, is shown in Figure 6.

The gain in the linear region is dependent on R_{10}. The voltage transferred to Pin 8 is proportional to the current RMS value, as motor current is not far from a sine wave. This averaging effect is shown in Figure 7.

With large amplitude signals at Pin 9, the change in voltage at Pin 8 reaches a maximum value. This saturation effect limits the maximum conduction angle increase. This effect is illustrated in Figure 8 where the total Pin 8 voltage can be written as follows:

$$V_8 = V_{12} + f(|V_9|, R_{10}) + 1.25$$

The effect of the feedback is illustrated in Figure 9.

Monitoring

A central logic block performs the ENABLE/DISABLE function of the IC with respect to power supply voltage. Under DISABLE conditions, Pin 4, 8, 12 and 13 are forced to appropriate voltages to prepare for the next reset. Refer to the block diagram in Figure 10.

APPLICATION CONSIDERATIONS

Component Selection

To regulate the speed of a universal motor, it is necessary to determine how much gain in the feedback is needed. A change in motor current (due to load increase) causes the conduction angle to change by the appropriate amount to keep the speed constant. This entails, through trial and error, choosing an appropriate resistor value for R_{10}, since the gain of the feedback is determined by value of R_{10} as shown in Figure 8.

Figure 7. Averaging Effect of Transfer Function

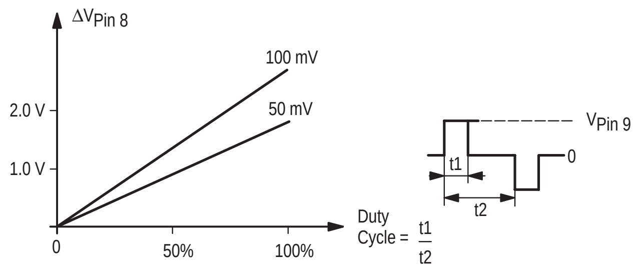

Figure 8. Transfer Function (Pin 8/Pin 9)

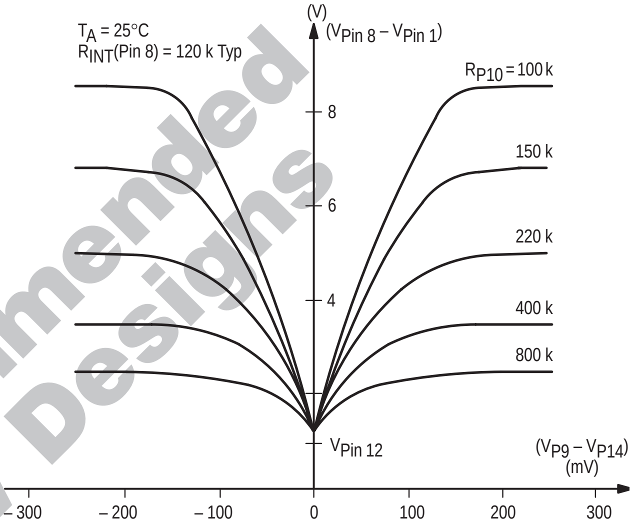

Once R_{10} is picked, C_4 can be calculated from the following equation:

$$C_4 \approx \frac{.672}{f_{line} \times R_{10}}$$

where f_{line} is the line frequency.

Figure 9. Positive Feedback Effect (Offset voltages have been neglected)

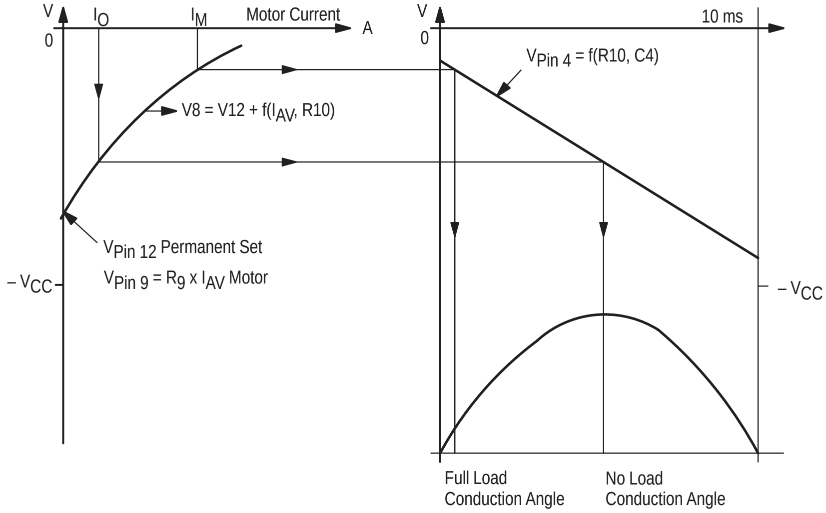

Figure 10. Internal Block Diagram

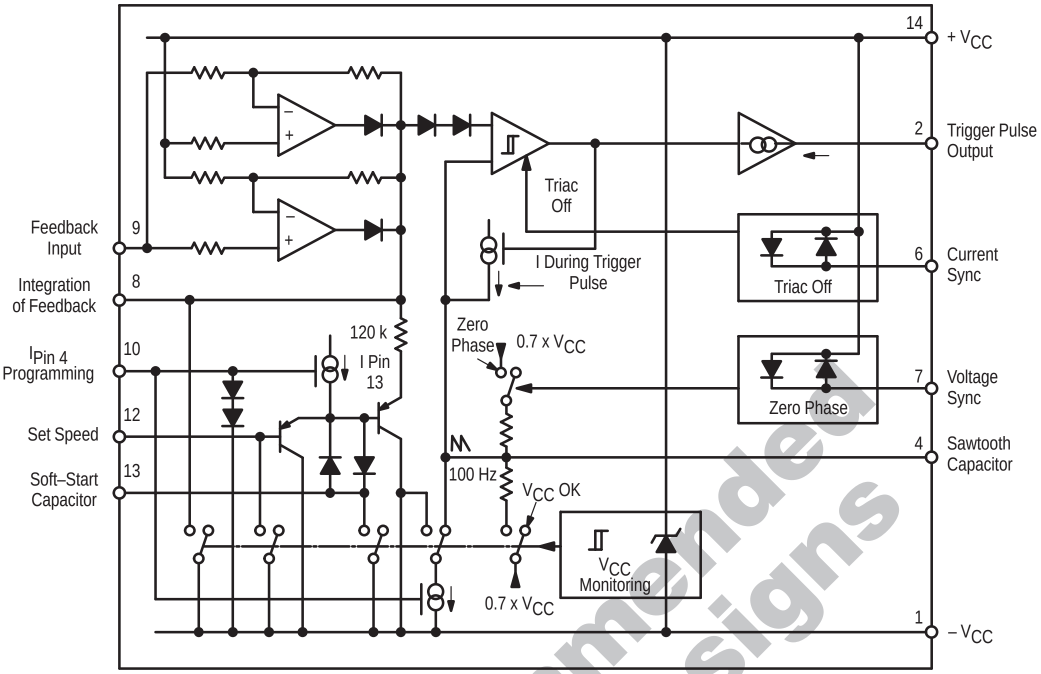

Capacitor C_8 is an integration cap used to smooth out the voltage at Pin 8. The value should be large enough to accomplish this task yet not too large to slow the response of the system.

Capacitor C_{13} determines how fast the conduction angle reaches the set value programmed at Pin 12. To achieve a desired delay, the value for C_{13} can be calculated by the following equation:

$$C_{13} \approx \frac{8 \times t_d}{|8.6 - V_{12}| \times R_{10}}$$

The remaining component values have experimentally been determined and are constant, regardless of application. The following table lists typical values for 110 V application.

Component	Value	Units
R_S	10/2.0 W	kΩ
R_{P1}	100	kΩ
R_{P2}	100	Ω
R_6	330/0.5 W	kΩ
R_7	330/0.5 W	kΩ
R_9	0.05/5.0 W	Ω
R_{10}	100	kΩ
C_4	0.1	µF
C_8	0.22	µF
C_{13}	10	µF

Using an oscilloscope, it should be verified that the ramp generator is ramping down from – 1.6 to – 7.1 V. The slope of the ramp can be changed by C_4 and the DC level of the waveform can be adjusted by R_7.

Pin 9 has a low internal impedance and requires R_{P2} to adjust the feedback level. Pin 8 must always be connected to V_{EE} through a filtering capacitor. For values of R_{10} less than 100 kΩ, the circuit becomes sensitive and could become unstable. Figures 11 and 12 show typical waveforms. As shown, the increase in motor current has resulted in the firing angle to decrease. This translates to an increase in the average power delivered to the load.

Figure 11. No Load Applied

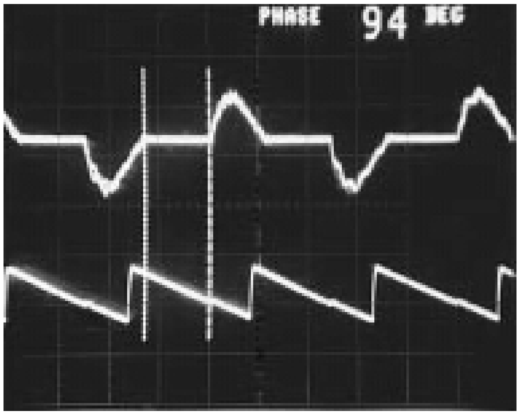

Figure 12. Load Applied

Temperature Effects

The TDA1185A has a very efficient internal temperature compensation. If the current feedback is not connected, the RMS power delivered to the load is stabilized within ± 0.2% over a temperature range of 20 to 70°C. The feedback introduces, in the same temperature range, a drift of 250 mV on the voltage of Pin 8; this slight increase in conduction angle may be successfully used to compensate a motor ohmic resistance increase with temperature.

Main Line Voltage Compensation

As the conduction angle is independent of main line voltage, any change in the latter induces a power variation to the load. A resistor connected to the rectifier anode and to Pin 12 with a capacitor to V_{EE} will introduce a decrease in voltage at Pin 12 as the line voltage is increasing. The values of the RC network can experimentally be determined.

Firing Angle Dynamics

With purely resistive loads, the effective RMS applied voltage to the load is directly proportional to the firing angle (Figure 13). With inductive loads, since the current lags with respect to voltage, 100% power corresponds to a firing angle which is less than 180°.

APPLICATION IDEAS

Soft–Start

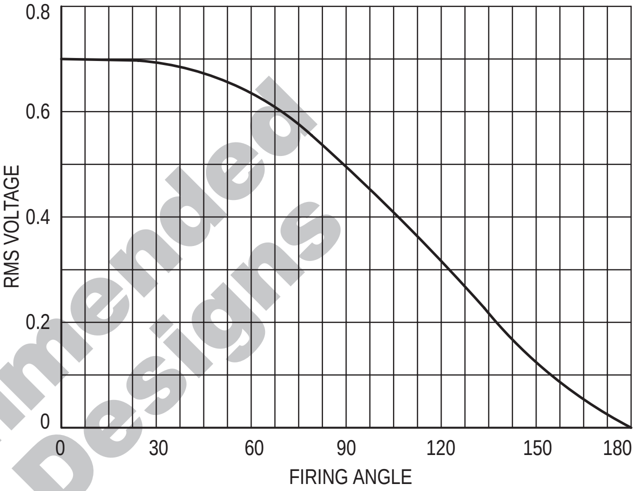
The Soft–Start feature of the TDA1185A in itself opens the door to a lot of interesting applications. For example, the TDA1185A can be used to bring up fragile loads slowly. Expensive and sensitive tubes can be turned on slowly, thus eliminating the inrush of current that could lead to burn out. In this application, R_{P1} is replaced with a resistor divider such that the voltage at Pin 12 results in a conduction angle of 180°. Pin 9 should be grounded, since the feedback portion of the TDA1185A is not necessary (see Figure 14). The time to achieve full conduction is found by the equation below:

$$\Delta t \approx 8.71 \times R_{10} \times C_{13}$$

Light Dimmer

With practically no modification the TDA1185A can be used in a light dimmer application. All that is required is to ground the input to the feedback Pin 9. By grounding Pin 9, we have disconnected the feedback loop and the conduction angle is controlled solely by R_{P1}. Further, since the feedback is disconnected, R_9 and R_{P2} are no longer necessary. The Soft–Start feature can still be used to protect the bulb from an inrush of current. This setup can be used in any application that requires manual control of the power delivered to the load (see Figure 15).

Figure 13. RMS Voltage versus Firing Angle



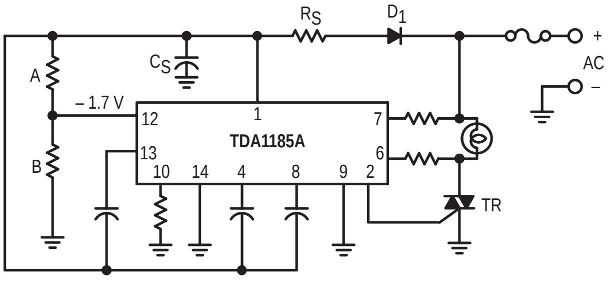
Soft Shut–Off

Once again with little modification, the TDA1185A can be used to turnoff the load slowly. An example of this is in automatic garage lighting. Typically, lights that are on a timer go off without a warning, usually in the most inopportune time (like when you're about to step over the dog). With a soft shut–off, the light dims out slowly, alerting you that it is about to go off. As in the previous case, the feedback is disconnected and R_{P1} is replaced with capacitor C_{12} and a switch (see Figure 16). The turn–off time can be calculated by the following equation:

$$\Delta t \approx R_{12} \times C_{12}$$

R_{12} is the sum of the two resistors on both sides of C_{12}.

Figure 14. Soft–Start Circuit



R_S = 10 kΩ 2 W
R_6 = 470 kΩ. 1/2 W
R_7 = 470 kΩ 1/2 W
R_{10} = 200 kΩ
R_{12A} = 4 x R_{12B}

C_4 = 44 nF
C_{13} = 10 µF
C_S = 100 µF
Turn–off time = 8.71 x R_{10} x C_{13}

PC Board

The printed circuit board in Figure 17 is included for the designer's convenience to evaluate the TDA1185A. The size of the board is intentionally small to show the compactness that can be achieved. Figure 18 shows the component layout for the PC board. R_{P1} has one of the outer leads connected to V_{EE} and the other to R_{12}. The center lead of R_{P1} is connected to Pin 12.

Warning Shock Hazard: It is highly recommended that an isolation transformer be used. Remove the chassis ground for all test equipment.

UAA1016B

Zero Voltage Controller

The UAA1016B is designed to drive triacs with the Zero Voltage technique which allows RFI free power regulation of resistive loads. It provides the following features:

- Proportional Temperature Control Over an Adjustable Band
- Adjustable Burst Frequency (to Comply with Standards)
- No DC Current Component Through the Main Line (to Comply with Standards)
- Negative Output Current Pulses (Triac Quadrants 2 and 3)
- Direct AC Line Operation
- Low External Components Count

CIRCUIT DESCRIPTION

The circuit delivers current pulses to the triac at zero crossings of the main line sensed by Pin 8 through R_{sync}. An internal full wave logic allows the triac to latch during full wave periods in order to avoid any dc component in the main line, in compliance with European regulations. Trigger pulses are generated when the comparator detects $V_{Pin\ 3}$ is above $V_{Pin\ 4}$ (or $V_{reference}$) as sensed temperature through the NTC is then lower than the set value (V_{ref} corresponding to the external Wheatstone bridge equilibrium).

In order to comply with norms limiting the frequency at which a kW sized load, or above, may be connected to the main line (fluorescent tubes “flickering”), the UAA1016B has an internal time base providing (power is delivered by bursts to the load) a proportional temperature band control. In fact, most of the heating regulation systems require low temperature overshoot for more precision and stability which cannot be accomplished by direct on/off regulation (see Figure 1). An internal low frequency sawtooth generator whose output is available at Pin 1, allows the designer to introduce a periodic linear change of V_{ref}. This deviation defines the temperature band allowing proportional power control (see Figure 2).

The IC is directly powered from the mains by a dropping resistor, a diode and a filter capacitor.

KEY CIRCUIT FUNCTIONS DESCRIPTION

Power Supply

The rectified supply current is Zener regulated to 8.6 V. Current consumption of the UAA1016B is typically less than 1.0 mA. The major part of the current fed by the dropping resistor is used for the sensor bridge and triac gate pulses. Any excess of supply current is excess power dissipation into the integrated Zener. Current consumption of the triac pulses may be derived from Figure 3 and 4 (Igt maximum and pulse duration). Usually an 18 kΩ, 2.0 W dropping resistor is convenient to feed the UAA1016.

Comparator

When $V_{Pin\ 3}$ is higher than $V_{Pin\ 4}$ (V_{ref}), the comparator allows the triggering logic to deliver pulses to the triac (Figure 2). The offset hysteresis input voltage has been designed to be as low as possible (±10 mV maximum) in order to minimize the uncontrollable temperature band (proportional to the hysteresis) as per Figure 5. Noise rejection is performed by a synchronous sampling of the comparator output during very short times (typical less than 100 ns).

Sawtooth Generator

A sawtooth voltage signal is generated by a constant current source (typical 7.5 µA), charging an external capacitor $C_{Pin\ 2}$ between two threshold levels, V_{TH1} and V_{TH2}, which are respectively:

$V_{TH1} = –1.0\ V$
$V_{TH2} = –V_{CC} + 1.25\ V$

Charging and discharging currents occur only with negative halfcycles of the line. In the UAA1016B, the sawtooth signal is available at Pin 1 as a voltage source $V_{Pin\ 1} = V_{Pin\ 2} – 0.75\ V$. Maximum source current is 1.0 mA, but to keep good linearity of sawtooth signal, a source current of 40 µA is recommended (see Figure 6).

Sampling Full Wave Logic

Two consecutive zero–crossing trigger pulses are generated at every positive mains half–cycle of the line to minimize generation of noise (as per Figure 7). Within every zero–crossing the pulses are positioned as per Figure 3. Pulse length is also adjustable by R_{sync} on Pin 8 to allow positive triggering of the triac at this critical moment (firing with low voltage between main terminals requires long pulses).

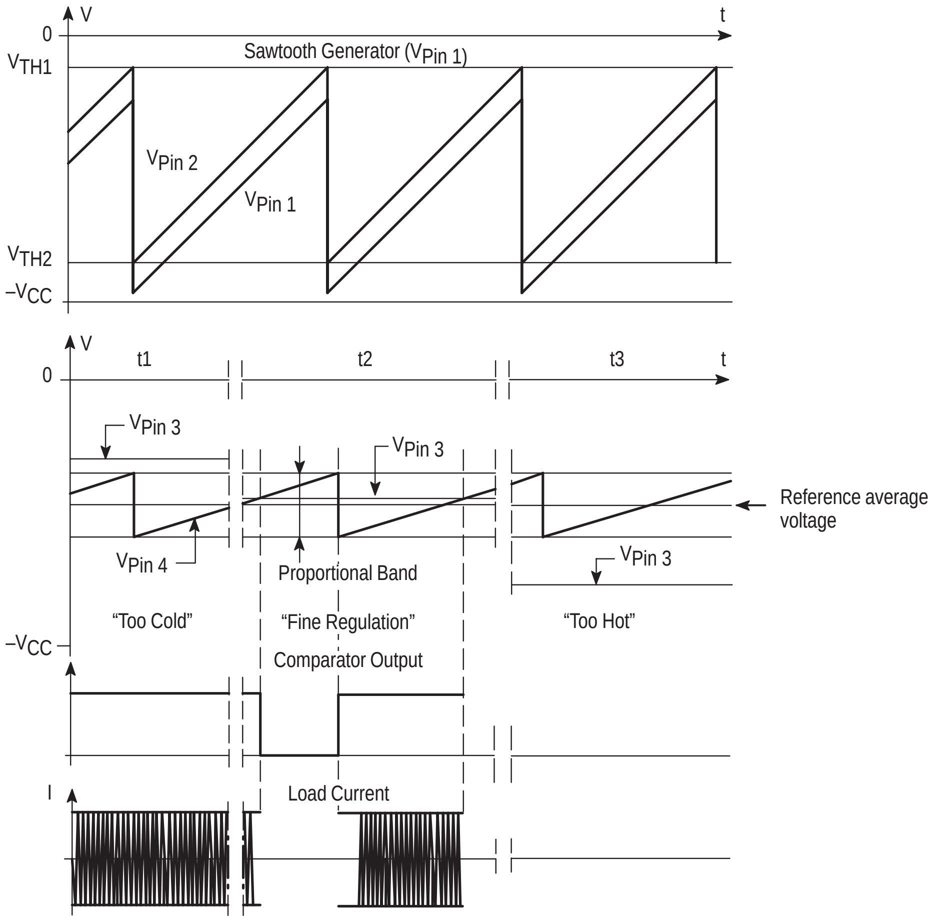
Pulse Amplifier

The pulse amplifier circuit delivers minimum current pulses of 60 mA (sink). The triac is triggered in quadrants II and III.

Synchronization Circuit

This circuit detects mains zero–crossings through R_{sync} and the value selected determines the trigger pulse length. A zero crossing current detector is employed with typical thresholds of ± 27 µA to ± 98 µA (see Figures 3 and 4).

Figure 2. Sawtooth Generator and Proportional Band



COMMENTS TO FIGURE 2

Referring to Figure 1, the average value of V_{ref} is set by R2 and R3. R4 defines the amplitude of the sawtooth signal superimposed on V_{ref}, defining the Proportional Band.

Figure 2 shows three conditions:

1) During time t1 we always have $V_{Pin\ 3} > V_{ref}$, and as a result, the comparator is always "on" and the triac fired (100% maximum power)

2) During time t2, $V_{Pin\ 3}$ is in the proportional band, and the average power delivered to the load is a fraction of maximum power.

3) During time t3, $V_{Pin\ 3} < V_{ref}$, and the triac is always "off."

When the sensor temperature is above the set value and is slowly decreasing as no heating occurs, $V_{Pin\ 3} – V_{Pin\ 4}$ must exceed half the hysteresis value before power is applied again (1). A similar effect occurs in the opposite direction when temperature sensor is below the set value and can remain stable as position (2). This defines the "uncontrollable temperature band" which will be very small if hysteresis is also very small.

SUGGESTIONS FOR USE

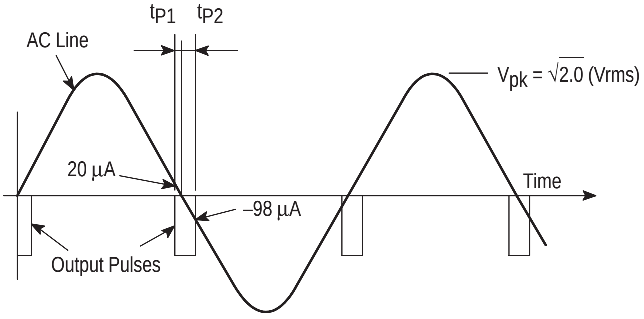
The temperature sensor circuit is a Wheatstone bridge including the sensor element. Comparator inputs may be free from power line noise only if the sensor element is purely resistive (NTC resistor). Usage of any P–N junction sensor would drastically reduce noise rejection.

Fixed phase sensing of the internal comparator output eliminates parasitic signals.

Some loads, even designed to be resistive, have in fact a slight inductive component. A phase shift at Pin 8 can be achieved with external capacitor C3 connected to Pin 8 network (see Figure 8).

Suggested maximum source current at Pin 1 is 40 µA, in order to have acceptable sawtooth signal linearity.

Figure 3. Output Pulse Width Definitions



$$t_{P2} = \frac{\sin^{-1}\left(\frac{98\times10^{-6}}{Vrms \cdot \sqrt{2.0}}\right)}{360f_{AC}} \qquad t_{P1} = \frac{\sin^{-1}\left(\frac{27\times10^{-6}}{Vrms \cdot \sqrt{2.0}}\right)}{360f_{AC}}$$

UAA2016

Product Preview

Zero Voltage Switch Power Controller

The UAA2016 is designed to drive triacs with the Zero Voltage technique which allows RFI–free power regulation of resistive loads. Operating directly on the AC power line, its main application is the precision regulation of electrical heating systems such as panel heaters or irons.

A built–in digital sawtooth waveform permits proportional temperature regulation action over a ±1°C band around the set point. For energy savings there is a programmable temperature reduction function, and for security a sensor failsafe inhibits output pulses when the sensor connection is broken. Preset temperature (i.e. defrost) application is also possible. In applications where high hysteresis is needed, its value can be adjusted up to 5°C around the set point. All these features are implemented with a very low external component count.

- Zero Voltage Switch for Triacs, up to 2.0 kW (MAC212A8)
- Direct AC Line Operation
- Proportional Regulation of Temperature over a 1°C Band
- Programmable Temperature Reduction
- Preset Temperature (i.e. Defrost)
- Sensor Failsafe
- Adjustable Hysteresis
- Low External Component Count

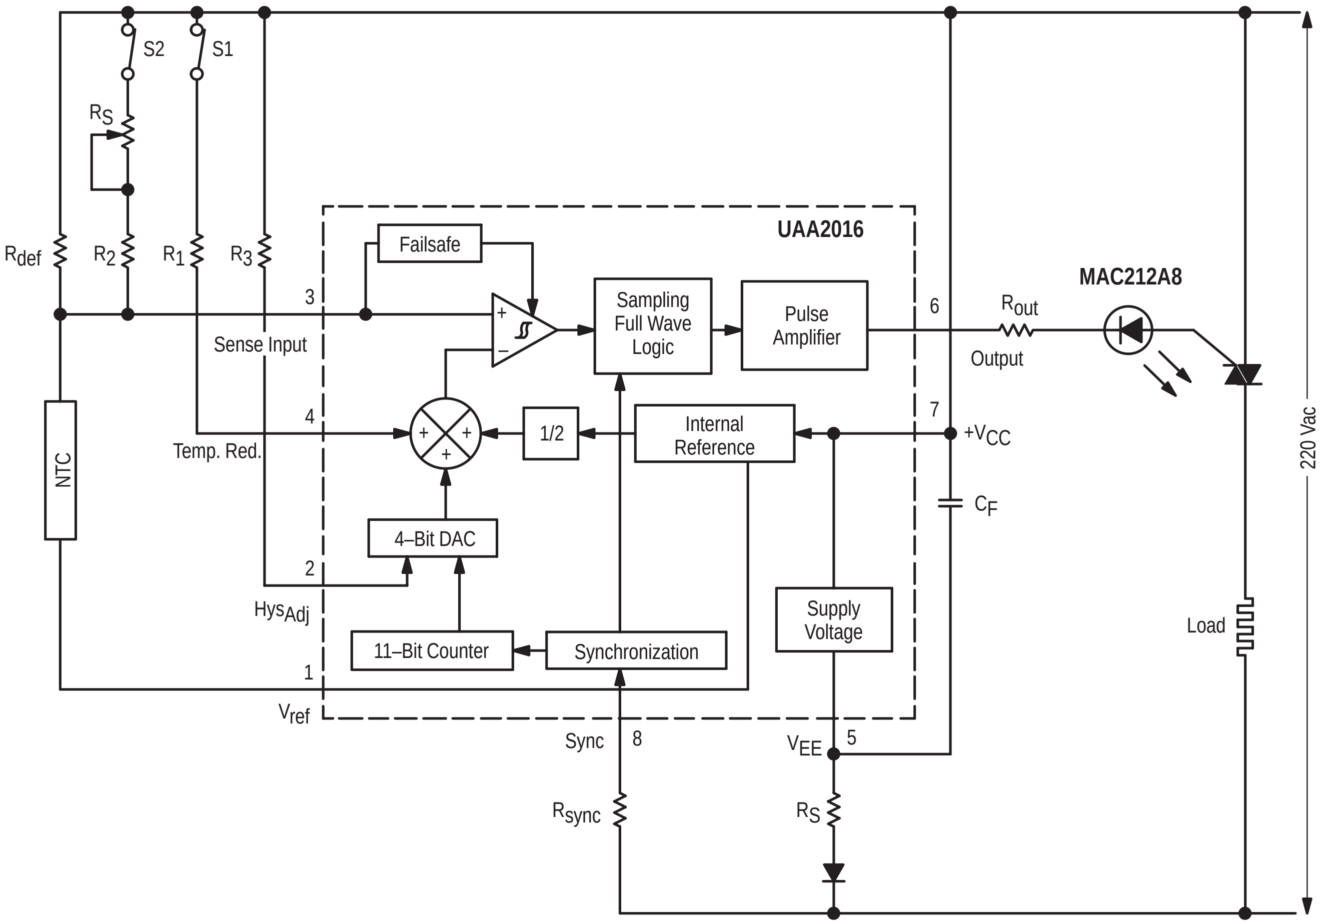
ELECTRICAL CHARACTERISTICS (T_A = 25°C, V_{EE} = –7.0 V, voltages referred to Pin 7, unless otherwise noted.)

Characteristic	Symbol	Min	Typ	Max	Unit
Supply Current (Pins 6, 8 not connected) (T_A = – 20° to + 85°C)	I_{CC}	—	0.9	1.5	mA
Stabilized Supply Voltage (Pin 5) (I_{CC} = 2.0 mA)	V_{EE}	–10	– 9.0	– 8.0	V
Reference Voltage (Pin 1)	V_{ref}	– 6.5	– 5.5	– 4.5	V
Output Pulse Current (T_A = – 20° to + 85°C) (R_{out} = 60 W, V_{EE} = – 8.0 V)	I_O	90	100	130	mA
Output Leakage Current (V_{out} = 0 V)	I_{OL}	—	—	10	µA
Output Pulse Width (T_A = – 20° to + 85°C) (Note 1) (Mains = 220 Vrms, R_{sync} = 220 kΩ)	T_P	50	—	100	µs
Comparator Offset (Note 5)	V_{off}	–10	—	+10	mV
Sensor Input Bias Current	I_{IB}	—	—	0.1	µA
Sawtooth Period (Note 2)	T_S	—	40.96	—	sec
Sawtooth Amplitude (Note 6)	A_S	50	70	90	mV
Temperature Reduction Voltage (Note 3) (Pin 4 Connected to V_{CC})	V_{TR}	280	350	420	mV
Internal Hysteresis Voltage (Pin 2 Not Connected)	V_{IH}	—	10	—	mV
Additional Hysteresis (Note 4) (Pin 2 Connected to V_{CC})	V_H	280	350	420	mV
Failsafe Threshold (T_A = – 20° to + 85°C) (Note 7)	V_{FSth}	180	—	300	mV

NOTES:
1. Output pulses are centered with respect to zero crossing point. Pulse width is adjusted by the value of R_{sync}. Refer to application curves.
2. The actual sawtooth period depends on the AC power line frequency. It is exactly 2048 times the corresponding period. For the 50 Hz case it is 40.96 sec. For the 60 Hz case it is 34.13 sec. This is to comply with the European standard, namely that 2.0 kW loads cannot be connected or removed from the line more than once every 30 sec.
3. 350 mV corresponds to 5°C temperature reduction. This is tested at probe using internal test pad. Smaller temperature reduction can be obtained by adding an external resistor between Pin 4 and V_{CC}. Refer to application curves.
4. 350 mV corresponds to a hysteresis of 5°C. This is tested at probe using internal test pad. Smaller additional hysteresis can be obtained by adding an external resistor between Pin 2 and V_{CC}. Refer to application curves.
5. Parameter guaranteed but not tested. Worst case 10 mV corresponds to 0.15°C shift on set point.
6. Measured at probe by internal test pad. 70 mV corresponds to 1°C. Note that the proportional band is independent of the NTC value.
7. At very low temperature the NTC resistor increases quickly. This can cause the sensor input voltage to reach the failsafe threshold, thus inhibiting output pulses; refer to application schematics. The corresponding temperature is the limit at which the circuit works in the typical application. By setting this threshold at 0.05 V_{ref}, the NTC value can increase up to 20 times its nominal value, thus the application works below – 20°C.

Figure 1. Application Schematic



APPLICATION INFORMATION

(For simplicity, the LED in series with R_{out} is omitted in the following calculations.)

Triac Choice and R_{out} Determination

Depending on the power in the load, choose the triac that has the lowest peak gate trigger current. This will limit the output current of the UAA2016 and thus its power consumption. Use Figure 4 to determine R_{out} according to the triac maximum gate current (I_{GT}) and the application low temperature limit. For a 2.0 kW load at 220 Vrms, a good triac choice is the Motorola MAC212A8. Its maximum peak gate trigger current at 25°C is 50 mA.

For an application to work down to – 20°C, R_{out} should be 60 Ω. It is assumed that: $I_{GT}(T) = I_{GT}(25°C) \times \exp(–T/125)$ with T in °C, which applies to the MAC212A8.

Output Pulse Width, R_{sync}

The pulse with T_P is determined by the triac's I_{Hold}, I_{Latch} together with the load value and working conditions (frequency and voltage):

Given the RMS AC voltage and the load power, the load value is:

$$R_L = V^2\text{rms/POWER}$$

The load current is then:

$$I_{Load} = (\text{Vrms} \times \sqrt{2} \times \sin(2\pi ft) – V_{TM})/R_L$$

where V_{TM} is the maximum on state voltage of the triac, f is the line frequency.

Set $I_{Load} = I_{Latch}$ for $t = T_P/2$ to calculate T_P.

Figures 6 and 7 give the value of T_P which corresponds to the higher of the values of I_{Hold} and I_{Latch}, assuming that V_{TM} = 1.6 V. Figure 8 gives the R_{sync} that produces the corresponding T_P.

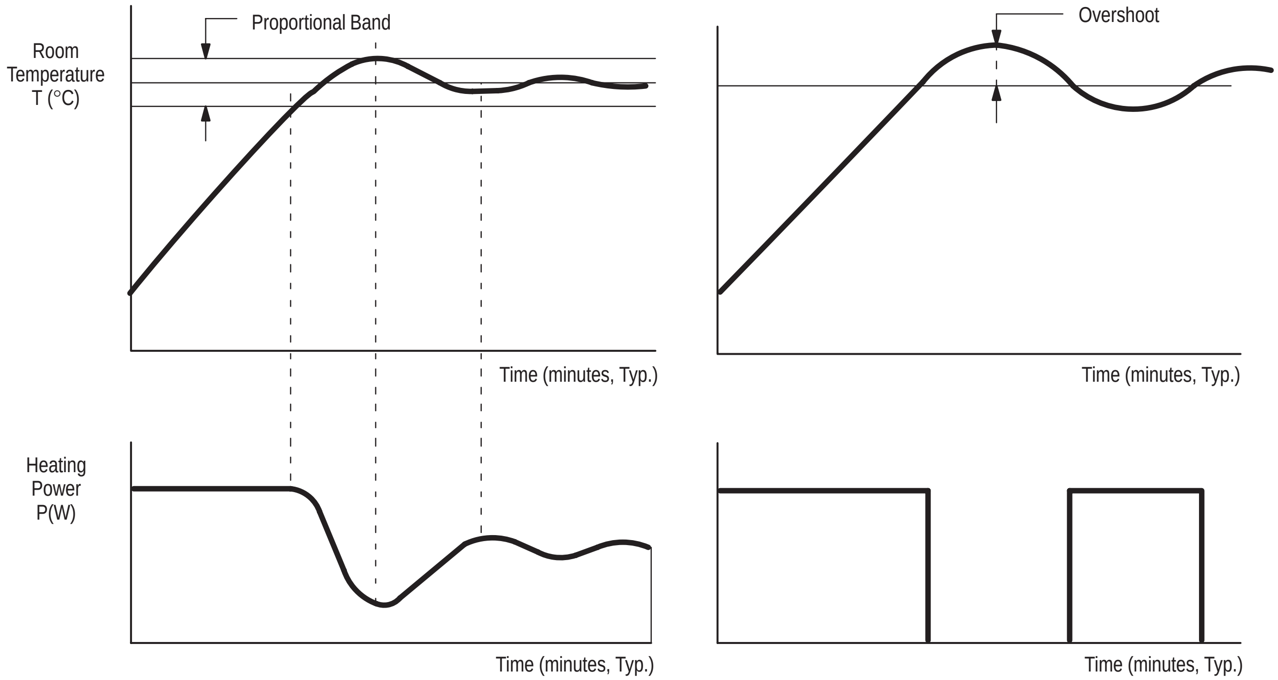
R_{Supply} and Filter Capacitor

With the output current and the pulse width determined as above, use Figures 9 and 10 to determine R_{Supply}, assuming that the sinking current at V_{ref} pin (including NTC bridge current) is less than 0.5 mA. Then use Figure 11 and 12 to determine the filter capacitor (C_F) according to the ripple desired on supply voltage. The maximum ripple allowed is 1.0 V.

Temperature Reduction Determined by R_1

(Refer to Figures 13 and 14.)

Figure 2. Comparison Between Proportional Control and ON/OFF Control



Proportional Temperature Control

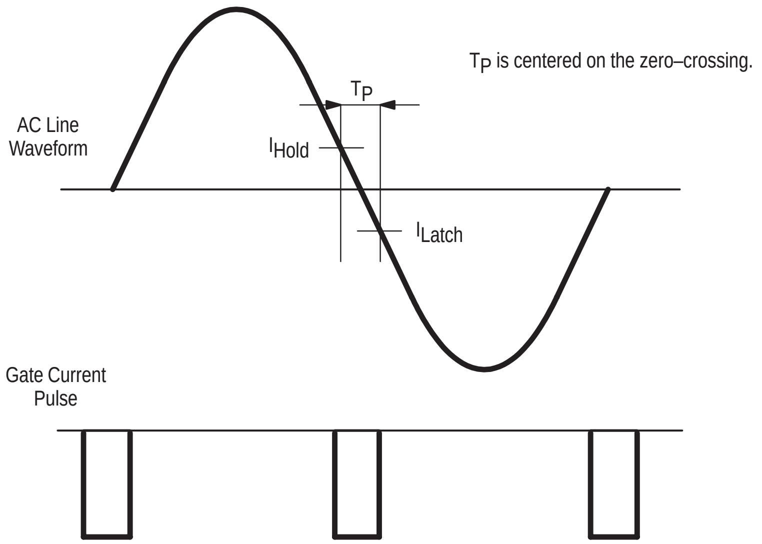
Figure 3. Zero Voltage Technique



T_P is centered on the zero–crossing.

$$T_P = \frac{14 \times R_{sync} + 7 \times 10^5}{Vrms \times \sqrt{2} \times \pi f} (\mu s)$$

f = AC Line Frequency (Hz)
Vrms = AC Line RMS Voltage (V)
R_{sync} = Synchronization Resistor (Ω)

CIRCUIT FUNCTIONAL DESCRIPTION

Power Supply (Pin 5 and Pin 7)

The application uses a current source supplied by a single high voltage rectifier in series with a power dropping resistor. An integrated shunt regulator delivers a V_{EE} voltage of – 8.6 V with respect to Pin 7. The current used by the total regulating system can be shared in four functional blocks: IC supply, sensing bridge, triac gate firing pulses and zener current. The integrated zener, as in any shunt regulator, absorbs the excess supply current. The 50 Hz pulsed supply current is smoothed by the large value capacitor connected between Pins 5 and 7.

Temperature Sensing (Pin 3)

The actual temperature is sensed by a negative temperature coefficient element connected in a resistor divider fashion. This two element network is connected between the ground terminal Pin 5 and the reference voltage – 5.5 V available on Pin 1. The resulting voltage, a function of the measured temperature, is applied to Pin 3 and internally compared to a control voltage whose value depends on several elements: Sawtooth, Temperature Reduction and Hysteresis Adjust. (Refer to Application Information.)

Temperature Reduction

For energy saving, a remotely programmable temperature reduction is available on Pin 4. The choice of resistor R_1 connected between Pin 4 and V_{CC} sets the temperature reduction level.

Comparator

When the positive input (Pin 3) receives a voltage greater than the internal reference value, the comparator allows the triggering logic to deliver pulses to the triac gate. To improve the noise immunity, the comparator has an adjustable hysteresis. The external resistor R_3 connected to Pin 2 sets the hysteresis level. Setting Pin 2 open makes a 10 mV hysteresis level, corresponding to 0.15°C. Maximum hysteresis is obtained by connecting Pin 2 to V_{CC}. In that case the level is set at 5°C. This configuration can be useful for low temperature inertia systems.

Sawtooth Generator

In order to comply with European norms, the ON/OFF period on the load must exceed 30 seconds. This is achieved by an internal digital sawtooth which performs the proportional regulation without any additional component. The sawtooth signal is added to the reference applied to the comparator negative input. Figure 2 shows the regulation improvement using the proportional band action.

Noise Immunity

The noisy environment requires good immunity. Both the voltage reference and the comparator hysteresis minimize the noise effect on the comparator input. In addition the effective triac triggering is enabled every 1/3 sec.

Failsafe

Output pulses are inhibited by the “failsafe” circuit if the comparator input voltage exceeds the specified threshold voltage. This would occur if the temperature sensor circuit is open.

Sampling Full Wave Logic

Two consecutive zero–crossing trigger pulses are generated at every positive mains half–cycle. This ensures that the number of delivered pulses is even in every case. The pulse length is selectable by R_{sync} connected on Pin 8. The pulse is centered on the zero–crossing mains waveform.

Pulse Amplifier

The pulse amplifier circuit sinks current pulses from Pin 6 to V_{EE}. The minimum amplitude is 70 mA. The triac is then triggered in quadrants II and III. The effective output current amplitude is given by the external resistor R_{out}. Eventually, an LED can be inserted in series with the Triac gate (see Figure 1).

Voltage References

In Brief . . .

Motorola's line of precision voltage references is designed for applications requiring high initial accuracy, low temperature drift, and long term stability. Initial accuracies of ±1.0%, and ±2.0% mean production line adjustments can be eliminated. Temperature coefficients of 25 ppm/°C max (typically 10 ppm/°C) provide excellent stability. Uses for the references include D/A converters, A/D converters, precision power supplies, voltmeter systems, temperature monitors, and many others.

Precision Low Voltage References

A family of precision low voltage bandgap reference devices designed for applications requiring low temperature drift.

Micropower Voltage Reference Diodes

MICROPOWER VOLTAGE REFERENCE DIODES

SEMICONDUCTOR TECHNICAL DATA

The LM285/LM385 series are micropower two–terminal bandgap voltage regulator diodes. Designed to operate over a wide current range of 10 µA to 20 mA, these devices feature exceptionally low dynamic impedance, low noise and stable operation over time and temperature. Tight voltage tolerances are achieved by on–chip trimming. The large dynamic operating range enables these devices to be used in applications with widely varying supplies with excellent regulation. Extremely low operating current make these devices ideal for micropower circuitry like portable instrumentation, regulators and other analog circuitry where extended battery life is required.

The LM285/LM385 series are packaged in a low cost TO–226AA plastic case and are available in two voltage versions of 1.235 and 2.500 V as denoted by the device suffix (see Ordering Information table). The LM285 is specified over a –40°C to +85°C temperature range while the LM385 is rated from 0°C to +70°C.

The LM385 is also available in a surface mount plastic package in voltages of 1.235 and 2.500 V.

Low Voltage Reference

A precision band–gap voltage reference designed for critical instrumentation and D/A converter applications. This unit is designed to work with D/A converters, up to 12 bits in accuracy, or as a reference for power supply applications.

- Output Voltage: 2.5 V ± 25 mV
- Input Voltage Range: 4.5 V to 40 V
- Quiescent Current: 1.2 mA Typical
- Output Current: 10 mA
- Temperature Coefficient: 10 ppm/°C Typical
- Guaranteed Temperature Drift Specification
- Equivalent to AD580
- Standard 8–Pin DIP, and 8–Pin SOIC Package

Typical Applications

- Voltage Reference for 8 to 12 Bit D/A Converters
- Low T_C Zener Replacement
- High Stability Current Reference
- Voltmeter System Reference

Providing the Reference Current for Motorola Monolithic D/A Converters

The MC1403 makes an ideal reference for many monolithic D/A converters, requiring a stable current reference of nominally 2.0 mA. This can be easily obtained from the MC1403 with the addition of a series resistor, R1. A variable resistor, R2, is recommended to provide means for full–scale adjust on the D/A converter.

The resistor R3 improves temperature performance by matching the impedance on both inputs of the D/A reference amplifier. The capacitor decouples any noise present on the reference line. It is essential if the D/A converter is located any appreciable distance from the reference.

A single MC1403 reference can provide the required current input for up to five of the monolithic D/A converters.

ELECTRICAL CHARACTERISTICS (V_{in} = 15 V, T_A = 25°C, unless otherwise noted.)

3–1/2–Digit Voltmeter – Common Anode Displays, Flashing Overrange

An example of a 3–1/2–digit voltmeter using the MC14433 is shown in the circuit diagram of Figure 8. The reference voltage for the system uses an MC1403 2.5 V reference IC. The full scale potentiometer can calibrate for a full scale of 199.9 mV or 1.999 V. When switching from 2.0 V to 200 mV operation, R_I is also changed, as shown on the diagram.

When using R_C equal to 300 kΩ, the clock frequency for the system is about 66 kHz. The resulting conversion time is approximately 250 ms.

When the input is overrange, the display flashes on and off. The flashing rate is one–half the conversion rate. This is done by dividing the EOC pulse rate by 2 with 1/2 MC14013B flip–flop and blanking the display using the blanking input of the MC14543B.

The display uses an LED display with common anode digit lines driven with an MC14543B decoder and an MC1413 LED driver. The MC1413 contains 7 Darlington transistor drivers and resistors to drive the segments of the display. The digit drive is provided by four MPS–A12 Darlington transistors operating in an emitter–follower configuration. The MC14543B, MC14013B and LED displays are referenced to V_{EE} via Pin 13 of the MC14433. This places the full power supply voltage across the display. The current for the display may be adjusted by the value of the segment resistors shown as 150 Ω in Figure 8.

MC1404

Voltage Reference Family

The MC1404 of ICs is a family of temperature–compensated voltage references for precision data conversion applications, such as A/D, D/A, V/F, and F/V. Advances in laser–trimming and ion–implanted devices, as well as monolithic fabrication techniques, make these devices stable and accurate to 12 bits over both military and commercial temperature ranges. In addition to excellent temperature stability, these parts offer excellent long–term stability and low noise.

- Output Voltages: Standard, 5.0 V, 6.25 V, 10 V
- Trimmable Output: > ± 6%
- Wide Input Voltage Range: V_{ref} + 2.5 V to 40 V
- Low Quiescent Current: 1.25 mA Typical
- Temperature Coefficient: 10 ppm/°C Typical
- Low Output Noise: 12 µV p–p Typical
- Excellent Ripple Rejection: > 80 dB Typical

Typical Applications

- Voltage Reference for 8 to 12 Bit D/A Converters
- Low T_C Zener Replacement
- High Stability Current Reference
- MPU D/A and A/D Applications

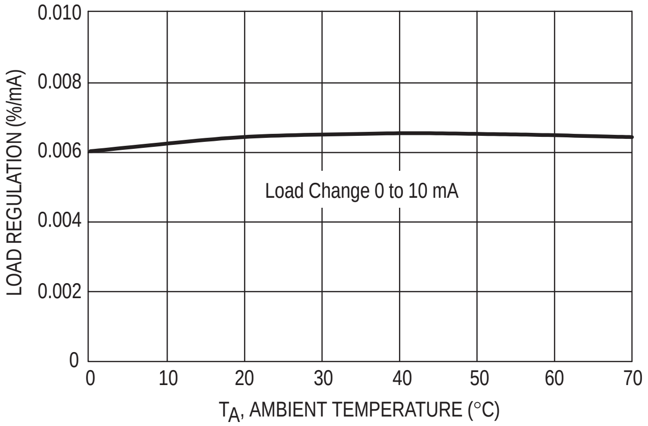

Figure 6. Power Supply Rejection Ratio versus Frequency

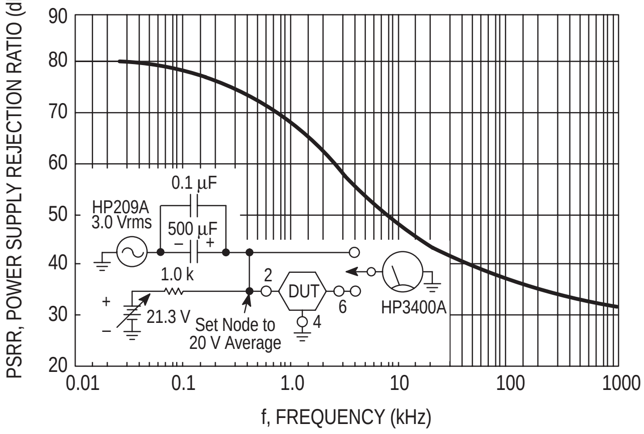

Figure 7. Quiescent Current versus Temperature

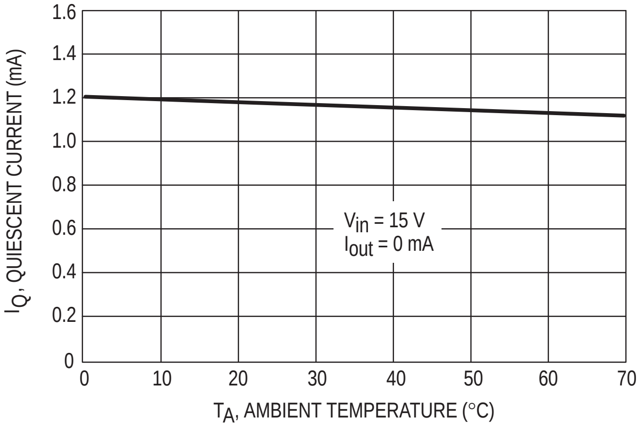

Figure 8. Short Circuit Current versus Temperature

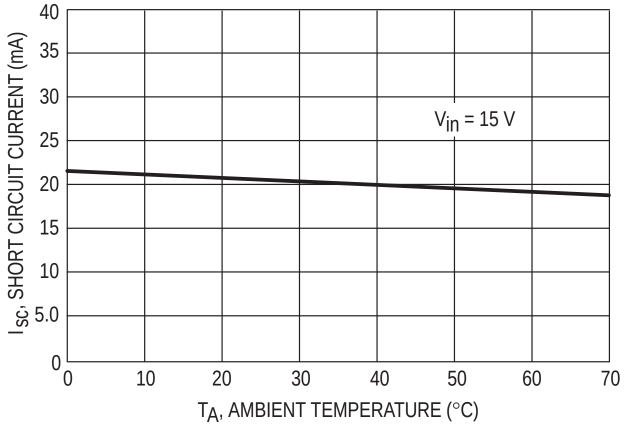

Figure 9. V_{TEMP} Output versus Temperature

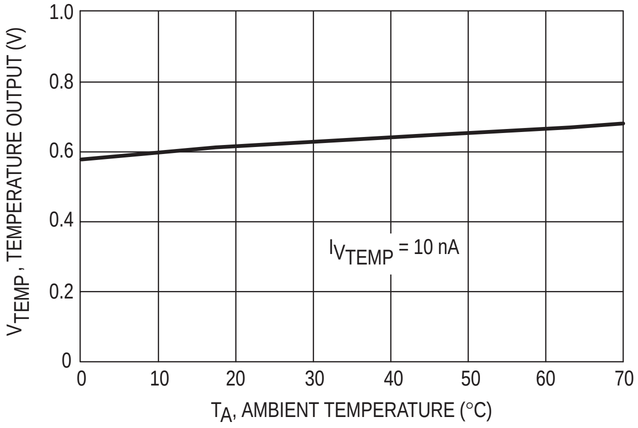

Figure 10. Output Trim Configuration

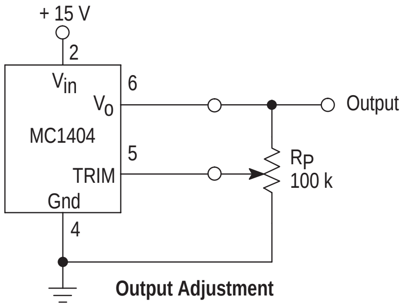
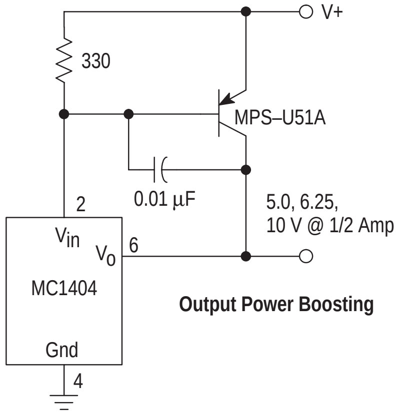


The MC1404 trim terminal can be used to adjust the output voltage over a ± 6.0% range. For example, the output can be set to 10.000 V or to 10.240 V for binary applications. For trimming, Bourns type 3059, 100 kΩ or 200 kΩ trimpot is recommended.

Although Figure 10 illustrates a wide trim range, temperature coefficients may become unpredictable for trim > ± 6.0%.

Figure 11. Precision Supply Using MC1404



The addition of a power transistor, a resistor, and a capacitor converts the MC1404 into a precision supply with one ampere current capability. At V+ = 15 V, the MC1404 can carry in excess of 14 mA of load current with good regulation. If the power transistor current gain exceeds 75, a one ampere supply can be realized.

MOTOROLA

TL431, A, B
Series

Programmable Precision References

The TL431, A, B integrated circuits are three–terminal programmable shunt regulator diodes. These monolithic IC voltage references operate as a low temperature coefficient zener which is programmable from V_{ref} to 36 V with two external resistors. These devices exhibit a wide operating current range of 1.0 mA to 100 mA with a typical dynamic impedance of 0.22 Ω. The characteristics of these references make them excellent replacements for zener diodes in many applications such as digital voltmeters, power supplies, and op amp circuitry. The 2.5 V reference makes it convenient to obtain a stable reference from 5.0 V logic supplies, and since the TL431, A, B operates as a shunt regulator, it can be used as either a positive or negative voltage reference.

- Programmable Output Voltage to 36 V
- Voltage Reference Tolerance: ±0.4%, Typ @ 25°C (TL431B)
- Low Dynamic Output Impedance, 0.22 Ω Typical
- Sink Current Capability of 1.0 mA to 100 mA
- Equivalent Full–Range Temperature Coefficient of 50 ppm/°C Typical
- Temperature Compensated for Operation over Full Rated Operating Temperature Range
- Low Output Noise Voltage

SOP–8 is an internally modified SO–8 package. Pins 2, 3, 6 and 7 are electrically common to the die attach flag. This internal lead frame modification decreases power dissipation capability when appropriately mounted on a printed circuit board. SOP–8 conforms to all external dimensions of the standard SO–8 package.

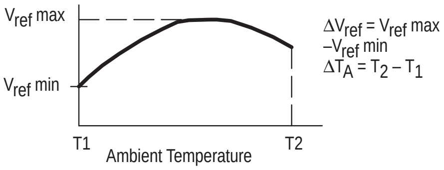
NOTE 2: The deviation parameter ΔV_{ref} is defined as the difference between the maximum and minimum values obtained over the full operating ambient temperature range that applies.



The average temperature coefficient of the reference input voltage, αV_{ref} is defined as:

$$V_{ref}\,\frac{ppm}{°C} = \frac{\left(\frac{\Delta V_{ref}}{V_{ref}\ @\ 25°C}\right) X\ 10^6}{\Delta T_A} = \frac{\Delta V_{ref} \times 10^6}{\Delta T_A (V_{ref}\ @\ 25°C)}$$

αV_{ref} can be positive or negative depending on whether V_{ref} Min or V_{ref} Max occurs at the lower ambient temperature. (Refer to Figure 6.)

Example : ΔV_{ref} = 8.0 mV and slope is positive,

V_{ref} @ 25°C = 2.495 V, ΔT_A = 70°C $\qquad \alpha V_{ref} = \frac{0.008 \times 10^6}{70\ (2.495)} = 45.8$ ppm/°C

NOTE 3 : The dynamic impedance Z_{KA} is defined as $\lvert Z_{KA}\rvert = \frac{\Delta V_{KA}}{\Delta I_K}$

When the device is programmed with two external resistors, R1 and R2, (refer to Figure 2) the total dynamic impedance of the circuit is defined as:

$$\lvert Z_{KA}'\rvert \approx \lvert Z_{KA}\rvert \left(1 + \frac{R1}{R2}\right)$$

ELECTRICAL CHARACTERISTICS (T_A = 25°C, unless otherwise noted.)

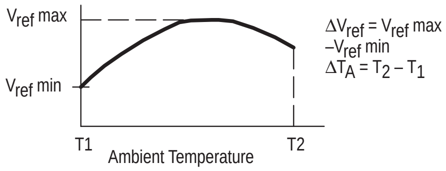
NOTE 1: T_{low} = –40°C for TL431AIP TL431AILP, TL431IP, TL431ILP, TL431BID, TL431BIP, TL431BILP, TL431AIDM, TL431IDM, TL431BIDM
= 0°C for TL431ACP, TL431ACLP, TL431CP, TL431CLP, TL431CD, TL431ACD, TL431BCD, TL431BCP, TL431BCLP, TL431CDM, TL431ACDM, TL431BCDM
T_{high} = +85°C for TL431AIP, TL431AILP, TL431IP, TL431ILP, TL431BID, TL431BIP, TL431BILP, TL431IDM, TL431AIDM, TL431BIDM
= +70°C for TL431ACP, TL431ACLP, TL431CP, TL431ACD, TL431BCD, TL431BCP, TL431BCLP, TL431CDM, TL431ACDM, TL431BCDM

NOTE 2: The deviation parameter ΔV_{ref} is defined as the difference between the maximum and minimum values obtained over the full operating ambient temperature range that applies.



The average temperature coefficient of the reference input voltage, αV_{ref} is defined as:

$$V_{ref}\ \frac{ppm}{°C} = \frac{\left(\dfrac{\Delta V_{ref}}{V_{ref}\ @\ 25°C}\right) \times 10^6}{\Delta T_A} = \frac{\Delta V_{ref} \times 10^6}{\Delta T_A\ (V_{ref}\ @\ 25°C)}$$

αV_{ref} can be positive or negative depending on whether V_{ref} Min or V_{ref} Max occurs at the lower ambient temperature. (Refer to Figure 6.)

Example : ΔV_{ref} = 8.0 mV and slope is positive,

V_{ref} @ 25°C = 2.495 V, ΔT_A = 70°C $\qquad \alpha V_{ref} = \frac{0.008 \times 10^6}{70\ (2.495)} = 45.8$ ppm/°C

NOTE 3 : The dynamic impedance Z_{KA} is defined as $|Z_{KA}| = \frac{\Delta V_{KA}}{\Delta I_K}$

When the device is programmed with two external resistors, R1 and R2, (refer to Figure 2) the total dynamic impedance of the circuit is defined as:

$$|Z_{KA}'| \approx |Z_{KA}| \left(1 + \frac{R1}{R2}\right)$$

NOTE 4: This test is not applicable to surface mount (D and DM suffix) devices.

Data Conversion

In Brief . . .

Motorola's line of digital–to–analog and analog–to–digital converters include several varieties to suit a number of applications.

The A/D converters include an 8–bit flash converter suitable for NTSC and PAL systems. CMOS devices include 8 to 10–bit converters, as well as other high speed digitizers.

The D/A converters have 6 and 8–bit devices, and video speed (for NTSC and PAL) devices.

Data Conversion

The line of data conversion products which Motorola offers spans a wide spectrum of speed and resolution/accuracy. Features, including bus compatibility, minimize external parts count and provide easy interface to microprocessor systems. Various technologies, such as Bipolar and CMOS, are utilized to achieve functional capability, accuracy and production repeatability. Bipolar technology generally results in higher speed, while CMOS devices offer greatly reduced power consumption.

MC10319

High Speed 8-Bit Analog-to-Digital Converter

The MC10319 is an 8–bit high speed parallel flash A/D converter. The device employs an internal Grey Code structure to eliminate large output errors on fast slewing input signals. It is fully TTL compatible, requiring a + 5.0 V supply and a wide tolerance negative supply of – 3.0 to – 6.0 V. Three–state TTL outputs allow direct drive of a data bus or common I/O memory.

The MC10319 contains 256 parallel comparators across a precision input reference network. The comparator outputs are fed to latches and then to an encoder network, to produce an 8–bit data byte plus an overrange bit. The data is latched and converted to 3–state LS–TTL outputs. The overrange bit is always active to allow for either sensing of the overrange condition or ease of interconnecting a pair of devices to produce a 9–bit A/D converter.

Applications include video display and radar processing, high speed instrumentation and TV broadcast encoding.

- Internal Grey Code for Speed and Accuracy, Binary Outputs
- 8–Bit Resolution/9–Bit Typical Accuracy
- Easily Interconnected for 9–Bit Conversion
- 3–State LS–TTL Outputs with True/Complement Enable Inputs
- 25 MHz Sampling Rate
- Wide Input Range: 1.0 to 2.0 V_{pp}, between ± 2.0 V
- Low Input Capacitance: 50 pF
- Low Power Dissipation: 618 mW
- No Sample/Hold Required for Video Bandwidth Signals
- Single Clock Cycle Conversion

PIN FUNCTION DESCRIPTION

Function	Pin		Description
	P Suffix	DW Suffix	
V_{RM}	1	1	The midpoint of the reference resistor ladder. Bypassing can be done at this point to improve performance at high frequencies.
GND	2, 12 16, 22	2, 13, 17 18, 25, 26	Digital ground. The pins should be connected directly together, and through a low impedance path to the power supply.
OVR	3	3	Overrange output. Indicates V_{in} is more positive than V_{RT} 1/2 LSB. This output does not have 3–state capability.
D7–D0	4 to 10, 21	4 to 10, 24	Digital Outputs. D7 (Pin 4) is the MSB. D0 (Pin 21 or 24) is the LSB. LS–TTL compatible with 3–state capability.
$V_{CC(D)}$	11, 17	11, 12 19, 20	Power supply for the digital section. +5.0 V, ±10% required. Reference to digital ground.
V_{EE}	13	14	Negative power supply. Nominally – 5.2 V, it can range from – 3.0 to – 6.0 V, and must be more negative than V_{RB} by $>$ 1.3 V. Reference to analog ground.
V_{in}	14	15	Signal voltage input. This voltage is compared to the reference to generate a digital equivalent. Input impedance is nominally 16 to 33K in parallel with 36 pF.
$V_{CC(A)}$	15	16	Power supply for the analog section. +5.0 V, ±10% required. Reference to analog ground.
CLK	18	21	Clock input. TTL compatible.
EN	19	22	Enable input. TTL compatible, a logic 1 (and $\overline{\text{EN}}$ at a logic 0) enables the data outputs. A logic 0 puts the outputs in a 3–state mode.
EN	20	23	$\overline{\text{Enable}}$ input. TTL compatible, a logic 0 (and EN at a logic 1) enables the data outputs. A logic 1 puts the outputs in a 3–state mode.
V_{RB}	23	27	The bottom (most negative point) of the internal reference resistor ladder.
V_{RT}	24	28	The top (most positive point) of the internal reference resistor ladder.

DESIGN GUIDELINES

Introduction

The MC10319 is a high speed, 8–bit, parallel (“flash”) type analog–to–digital converter containing 256 comparators at the front end. See Figure 17 for a block diagram. The comparators are arranged such that one input of each is referenced to evenly spaced voltages, derived from the reference resistor ladder. The other input of the comparators is connected to the input signal (V_{in}). Some of the comparator′s differential outputs will be “true,” while other comparators will have “not true” outputs, depending on their relative position. Their outputs are then latched, and converted to an 8–bit Grey code by the Differential Latch Array. The Grey code ensures that any input errors due to cross talk, feed–thru, or timing disparities result in glitches at the output of only a few LSBs, rather than the more traditional 1/2 scale and 1/4 scale glitches.

The Grey code is then translated to an 8–bit binary code, and the differential levels are translated to TTL levels before being applied to the output latches. Enable inputs at this final stage permit the TTL outputs (except overrange) to be put into a high impedance (3–state) condition.

ANALOG SECTION

Signal Input

The signal voltage to be digitized (V_{in}) is applied simultaneously to one input of each of the 256 comparators through Pin 14. The other inputs of the comparators are connected to 256 evenly spaced voltages derived from the reference ladder. The output code depends on the relative position of the input signal and the reference voltages. The comparators have a bandwidth of > 50 MHz, which is more than sufficient for the allowable (Nyquist Theorem) input frequency of 12.5 MHz.

The current into Pin 14 varies linearly from 0 (when $V_{in} = V_{RB}$) to ≈60 µA (when $V_{in} = V_{RT}$). If V_{in} is taken below V_{RB} or above V_{RT}, the input current will remain at the value corresponding to V_{RB} and V_{RT} respectively (see Figure 5). However, V_{in} must be maintained within the absolute range of ±2.5 V (with respect to ground) – otherwise excessive currents will result at Pin 14, due to internal clamps.

The input capacitance at Pin 14 is typically 36 pF if $[V_{RT} – V_{RB}]$ is 2.0 V, and increases to 55 pF if $[V_{RT} – V_{RB}]$ is reduced to 1.0 V (see Figure 4). The capacitance is constant as V_{in} varies from V_{RT} down to ≈0.1 V above V_{RB}. Taking V_{in} to V_{RB} will show an increase in the capacitance of ≈50%. If V_{in} is taken above V_{RT}, or below V_{RB}, the capacitance will stay at the values corresponding to V_{RT} and V_{RB}, respectively.

The source impedance of the signal voltage should be maintained below 100 Ω (at the frequencies of interest) in order to avoid sampling errors.

Reference

The reference resistor ladder is composed of a string of equal value resistors to provide 256 equally spaced voltages for the comparators (see Figure 17 for the actual configuration). The voltage difference between adjacent comparators corresponds to 1 LSB of the input range. The first comparator (closest to V_{RB}) is referenced 1/2 LSB above V_{RB}, and 256th comparator (for the overrange) is referenced 1/2 LSB below V_{RT}. The total resistance of the ladder is nominally 130 Ω, ±20%, requiring 15.4 mA @ 2.0 V, and 7.7 mA @ 1.0 V. There is a nominal warm–up change of ≈ +9.0% in the ladder resistance due to the +0.29%/°C temperature coefficient.

The minimum recommended span $[V_{RT} – V_{RB}]$ is 1.0 V. A lower span will allow offsets and nonlinearities to become significant. The maximum recommended span is 2.1 V due to power limitations of the resistor ladder. The span may be anywhere within the range of – 2.1 to + 2.1 V with respect to ground, and V_{RB} must be at least 1.3 V more positive than V_{EE}. The reference voltages must be stable and free of noise and spikes, since the accuracy of a conversion is directly related to the quality of the reference.

In most applications, the reference voltages will remain fixed. In applications involving a varying reference for modulation or signal scrambling, the modulating signal may be applied to V_{RT}, or V_{RB}, or both. The output will vary inversly with the reference signal, introducing a nonlinearity into the transfer function. The addition of the modulating signal and the dc level applied to the reference must be such that the absolute voltage at V_{RT} and V_{RB} is maintained within the values listed in the Recommended Operating Limits. The RMS value of the span must be maintained ≤ 2.1 V.

V_{RM} (Pin 1) is the midpoint of the resistor ladder, excluding the Overrange comparator. The voltage at V_{RM} is:

$$\frac{V_{RT} + V_{RB}}{2.0} - 1/2 \text{ LSB}$$

In most applications, bypassing this pin to ground (0.1 µF) is sufficient to maintain accuracy. In applications involving very high frequencies, and where linearity is critical, it may be necessary to trim the voltage at the midpoint. A means for accomplishing this is indicated in Figure 18.

Power Supplies

$V_{CC(A)}$ is the positive power supply for the comparators, and $V_{CC(D)}$ is the positive power supply for the digital portion. Both are to be +5.0 V, ±10%, and the two are to be within 100 mV of each other. There is indirect internal coupling between $V_{CC(D)}$ and $V_{CC(A)}$. If they are powered separately, and one supply fails, there will be current flow through the MC10319 to the failed supply.

$I_{CC(A)}$ is nominally 17 mA, and does not vary with clock frequency or with V_{in}. It does vary linearly with $V_{CC(A)}$. $I_{CC(D)}$ is nominally 90 mA, and is independent of clock frequency. It does vary, however, by 6 to 7 mA as V_{in} is changed, with the lowest current occurring when V_{in} = V_{RT}. It varies linearly with $V_{CC(D)}$.

V_{EE} is the negative power supply for the comparators, and is to be within the range – 3.0 to – 6.0 V. Additionally, V_{EE} must be at least 1.3 V more negative than V_{RB}. I_{EE} is a nominal – 10 mA, and is independent of clock frequency, V_{in}, and V_{EE}.

For proper operation, the supplies **must** be bypassed **at the IC**. A 10 μF tantalum, in parallel with a 0.1 μF ceramic is recommended for each supply to ground.

DIGITAL SECTION

Clock

The Clock input is TTL compatible with a typical frequency range of 0 to 30 MHz. There is no duty cycle limitations, but the minimum low and high times must be adhered to. See Figure 7 for the input current requirements.

The conversion sequence is shown in Figure 19, and is as follows:

- On the rising edge, the data output latches are latched with old data, and the comparator output latches are released to follow the input signal (V_{in}).
- During the high time, the comparators track the input signal. The data output latches retain the old data.
- On the falling edge, the comparator outputs are latched with the data immediately prior to this edge. The conversion to digital occurs within the device, and the data output latches are released to indicate the new data within 20 ns.
- During the clock low time, the comparator outputs remain latched, and the data output latches remain transparent.

A summary of the sequence is that data present at V_{in} just prior to the Clock falling edge is digitized and available at the data outputs immediately after that same falling edge.

The comparator output latches provide the circuit with an effective sample–and–hold function, eliminating the need for an external sample–and–hold.

Enable Inputs

The two Enable inputs are TTL compatible, and are used to change the data outputs (D7–D0) from active to 3–state. This capability allows cascading two MC10319s into a 9–bit configuration, flip–flopping two MC10319s into a 50 MHz configuration, connecting the outputs directly to a data bus, multiplexing multiple converters, etc. See the Applications Information section for more details. For the outputs to be active, Pin 19 must be a Logic “1”, and Pin 20 must be a Logic “0”. Changing either input will put the outputs into the high impedance mode. The Enable inputs affect **only** the state of the outputs – they do not inhibit a conversion. The input current into Pins 19 and 20 is shown in Figure 6, and the input/output timing is shown in Figure 1 and 20. Leaving either pin open is equivalent to a Logic “1”, although good design practice dictates that an input should never be left open.

The Overrange output (Pin 3) is not affected by the Enable inputs as it does not have 3–state capability.

Outputs

The Data outputs are TTL level outputs with high impedance capability. Pin 4 is the MSB (D7), and Pin 21 is the LSB (D0). The eight outputs are active as long as the Enable inputs are true (Pin 19 = high, Pin 20 = low). The timing of the outputs relative to the Clock input and the Enable inputs is shown in Figures 1 and 20. Figures 8 and 9 indicate the output voltage versus load current, while Figure 3 indicates the leakage current when in the high impedance mode.

The output code is natural binary, depicted in the table below.

The Overrange output (Pin 3) goes high when the input, V_{in}, is more positive than V_{RT} – 1/2 LSB. This output is always active – it does not have high impedance capability. Besides being used to indicate an input overrange, it is additionally used for cascading two MC10319s to form a 9–bit A/D converter (see Figure 27).

Table 1. Output Code

Input	V_{RT}, V_{RB} (V)			Output Code	Overrange
	2.048 V, 0 V	+ 1.0 V, – 1.0 V	+ 1.0 V, 0 V		
$> V_{RT}$ – 1/2 LSB	> 2.044V	> 0.9961 V	> 0.9980 V	FF_H	1
V_{RT} – 1/2 LSB	2.044 V	0.9961 V	0.9980 V	FF_H	0 ↔ 1
V_{RT} – 1 LSB	2.040 V	0.992 V	0.9961 V	FF_H	0
V_{RT} – 1–1/2 LSB	2.036 V	0.988 V	0.9941 V	FE_H ↔ FF_H	0
Midpoint	1.024 V	0.000 V	0.5000 V	80_H	0
V_{RB} + 1/2 LSB	4.0 mV	– 0.9961 V	1.95 mV	00_H ↔ 01_H	0
$< V_{RB}$	< 0 V	< – 1.0 V	< 0 V	00_H	0

APPLICATIONS INFORMATION

Power Supplies, Grounding

The PC board layout, and the quality of the power supplies and the ground system **at the IC** are very important in order to obtain proper operation. Noise, from any source, coming into the device on V_{CC}, V_{EE}, or ground can cause an incorrect output code due to interaction with the analog portion of the circuit. At the same time, noise generated within the MC10319 can cause incorrect operation if that noise does not have a clear path to ac ground.

Both the V_{CC} and V_{EE} power supplies must be decoupled to ground **at the IC** (within 1″ max) with a 10 µF tantalum and a 0.1 µF ceramic. Tantalum capacitors are recommended since electrolytic capacitors simply have too much inductance at the frequencies of interest. The quality of the V_{CC} and V_{EE} supplies should then be checked at the IC with a high frequency scope. Noise spikes (always present when digital circuits are present) can easily exceed 400 mV peak, and if they get into the analog portion of the IC, the operation can be disrupted. Noise can be reduced by inserting resistors and/or inductors between the supplies and the IC.

If switching power supplies are used, there will usually be spikes of 0.5 V or greater at frequencies of 50 to 200 kHz. These spikes are generally more difficult to reduce because of their greater energy content. In extreme cases, 3–terminal regulators (MC78L05ACP, MC7905.2CT), with appropriate high frequency filtering, should be used and dedicated to the MC10319.

The ripple content of the supplies should not allow their magnitude to exceed the values in the Recommended Operating Limits table.

The PC board tracks supplying V_{CC} and V_{EE} to the MC10319 should preferably not be at the tail end of the bus distribution, after passing through a maze of digital circuitry. The MC10319 should be close to the power supply, or the connector where the supply voltages enter the board. If the V_{CC} and V_{EE} lines are supplying considerable current to other parts of the boards, then it is preferable to have dedicated lines from the supply or connector directly to the MC10319.

The four ground pins (2, 12, 16, and 22) must be connected directly together. Any long path between them can cause stability problems due to the inductance (at 25 MHz) of the PC tracks. The ground return for the signal source must be noise free.

Reference Voltage Circuits

Since the accuracy of the conversion is directly related to the quality of the references, it is imperative that accurate and stable voltages be provided to V_{RT} and V_{RB}. If the reference span is 2.0 V, then 1/2 LSB is only 3.9 mV, and it is desireable that V_{RT} and V_{RB} be accurate to within this amount, and furthermore, that they do not drift more than this amount once set. Over the temperature range of 0° to 70°C, a maximum temperature coefficient of 28 ppm/°C is required.

The voltage supplies used for digital circuits should preferably **not** be used as a source for generating V_{RT} and V_{RB}, due to the noise spikes (50 to 400 mV) present on the supplies and on their ground lines. Generally ±15 V, or ±12 V, are available for analog circuits, and are usually clean compared to supplies used for digital circuits, although ripple may be present in varying amounts. Ripple is easier to filter out than spikes, however, and so these supplies are preferred.

Figure 21 depicts a circuit which can provide an extremely stable voltage to V_{RT} **at the current required** (the maximum reference current is 19.2 mA @ 2.0 V). The MC1403 series of reference sources has very low temperature coefficients, good noise rejection, and a high initial accuracy, allowing the circuit to be built without an adjustment pot if the V_{RT} voltage is to remain fixed at one value. Using 0.1% wirewound resistors for the divider provides sufficient accuracy and stability in many cases. Alternately, resistor networks provide high ratio accuracies, and close temperature tracking. If the application requires V_{RT} to be changed periodically, the two resistors can be replaced with a 20 turn, cermet potentiometer. Wirewound potentiometers should not be used for this type of application since the pot's slider jumps from winding to winding, and an exact setting can be difficult to obtain. Cermet pots allow for a smooth continuous adjustment.

In Figure 21, R1 reduces the power dissipation in the transistor, and can be carbon composition. The 0.1 µF capacitor in the feedback path provides stability in the unity gain configuration. Recommended op amps are: LM358, MC34001 series, LM308A, LM324, and LM11C. Offset drift is the key parameter to consider in choosing an op amp, and the LM308A has the lowest drift of those mentioned. Bypass capacitors are not shown in Figure 21, but should always be provided at the input to the 2.5 V reference, and at the power supply pins of the op amp.

Figure 22 shows a simpler and more economical circuit, using the LM317LZ regulator, but with lower initial accuracy and temperature stability. The op amp/current booster is not needed since the LM317LZ can supply the current directly. In a well controlled environment, this circuit will suffice for many applications. Because of the lower initial accuracy, an adjustment pot is a necessity.

Figure 23 shows two circuits for providing the voltage to V_{RB}. The circuits are similar to those of Figures 21 and 22, and have similar accuracy and stability. The output transistor is a PNP in this case since the circuit must sink the reference current.

VIDEO APPLICATIONS

The MC10319 is suitable for digitizing video signals directly without signal conditioning, although the standard 1.0 V_{pp} video signal can be amplified to a 2.0 V_{pp} signal for slightly better accuracy. Figure 24 shows the input (top trace) and reconstructed output of a standard NTSC test signal, sampled at 25 MSPS, consisting of a sync pulse, 3.58 MHz color burst, a 3.58 MHz signal in a Sin^2x envelope, a pulse, a white level signal, and a black level signal. Figure 25 shows a Sin^2x pulse that has been digitized and reconstructed at 25 MSPS. The width of the pulse is ≈450 ns at the base. Figure 26 shows an application circuit for digitizing video.

9–Bit A/D Converter

Figure 27 shows how two MC10319s can be connected to form a 9–bit converter. In this configuration, the outputs (D7 to D0) of the two 8–bit converters are paralleled. The outputs of one device are active, while the outputs of the other are in the 3–state mode. The selection is made by the Overrange output of the lower MC10319, which controls Enable inputs on the two devices. Additionally, this output provides the 9th bit.

The reference ladders are connected in series, providing the 512 steps required for 9 bits. The input voltage range is determined by V_{RT} of the upper MC10319, and V_{RB} of the lower device. A minimum of 1.0 volt is required across each converter. The 500 Ω pot (20 turn cermet) allows for adjustment of the midpoint since the reference resistors of the two MC10319s may not be identical in value. Without the adjustment, a non–equal voltage division would occur, resulting in a nonlinear conversion. If the references are to be symmetrical about ground (e.g., ± 1.0 V), the adjustment can be eliminated, and the midpoint connected to ground. The use of latches on the outputs is optional, depending on the application.

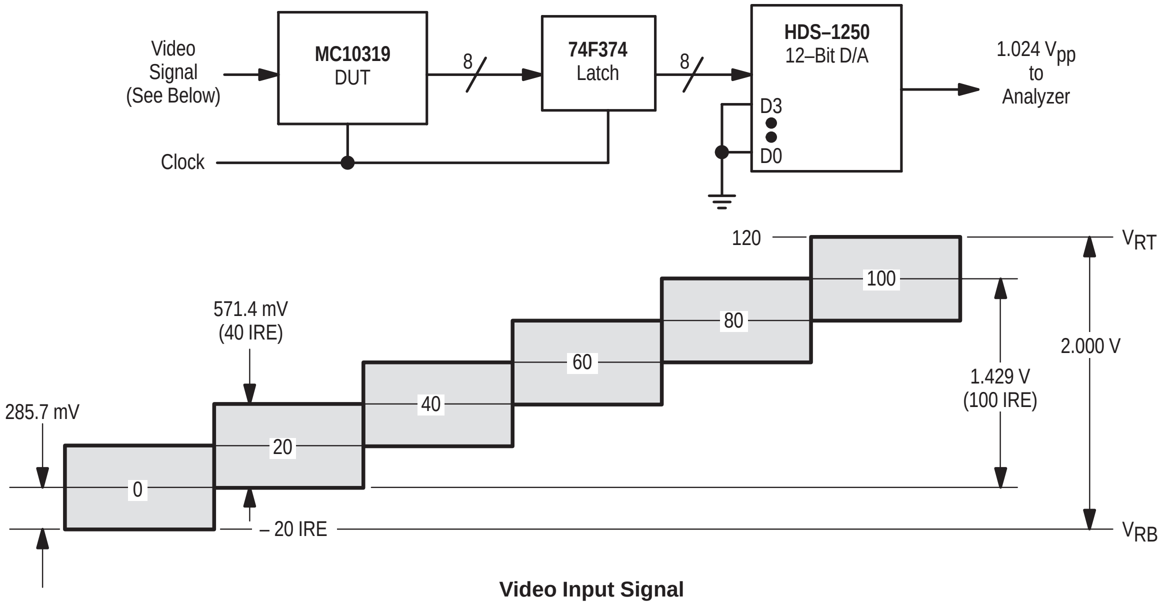
50 MHz, 8–Bit A/D Converter

Figure 28 shows how two MC10319s can be connected together in a flip–flop arrangement in order to have an effective conversion speed of 50 MHz. The 74F74 D–type flip–flop provides a 25 MHz clock to each converter, and at the same time, controls the Enables so as to alternately enable and disable the outputs. The Overranges do not have 3–state capability, and so cannot be paralleled. Instead they are OR'd together. The use of latches is optional, and depends on the application. Data should be latched, or written to RAM (in a DMA operation), on the high–to–low transition of the 50 MHz clock.

Negative Voltage Regulator

In the cases where a negative power supply is not available (neither the – 3.0 to – 6.0 V, nor a higher negative voltage from which to derive it), the circuit of Figure 29 can be used to generate – 5.0 V from the + 5.0 V supply. The PC board space required is small (≈ 2.0 in^2), and it can be located physically close to the MC10319. The MC34063A is a switching regulator, and in Figure 29 is configured in an inverting mode of operation. The regulator operating specifications are also given.

Figure 16. Differential Phase and Gain Test



Video Input Signal

1. Input waveform: 571.4 mV_{pp}, sine wave @ 3.579545 MHz, dc levels as shown above.
2. MC10319 clock at 14.31818 MHz (4x) asynchronous to input.
3. Differential gain: peak–to–peak output @ each IRE level compared to that at 0 IRE.
4. Differential phase: Phase @ each IRE level compared to that @ 0 IRE.

GLOSSARY

Aperture Delay – The time difference between the sampling signal (typically a clock edge) and the actual analog signal converted. The actual signal converted may occur before or after the sampling signal, depending on the internal configuration of the converter.

Bipolar Input – A mode of operation whereby the analog input (of an A/D), or output (of a DAC), includes both negative and positive values. Examples are – 1.0 to + 1.0 V, – 5.0 to + 5.0 V, – 2.0 to + 8.0 V, etc.

Bipolar Offset Error – The difference between the actual and ideal locations of the 00_H to 01_H transition, where the ideal location is 1/2 LSB above the most negative reference voltage.

Bipolar Zero Error – The error (usually expressed in LSBs) of the input voltage location (of an A/D) of the 80_H to 81_H transition. The ideal location is 1/2 LSB above zero volts in the case of an A/D setup for a symmetrical bipolar input (e.g., – 1.0 to + 1.0 V).

Differential Nonlinearity – The maximum deviation in the actual step size (one transition level to another) from the ideal step size. The ideal step size is defined as the Full Scale Range divided by 2^n (n = number of bits). This error must be within ± 1 LSB for proper operation.

ECL – Emitter coupled logic.

Full Scale Range (Actual) – The difference between the actual minimum and maximum end points of the analog input (of an A/D).

Full Scale Range (Ideal) – The difference between the actual minimum and maximum end points of the analog input (of an A/D), plus one LSB.

Gain Error – The difference between the actual and expected gain (end point to end point), with respect to the reference, of a data converter. The gain error is usually expressed in LSBs.

Grey Code – Also known as *reflected binary code*, it is a digital code such that each code differs from adjacent codes by only one bit. Since more than one bit is never changed at each transition, race condition errors are eliminated.

Integral Nonlinearity – The maximum error of an A/D, or DAC, transfer function from the ideal straight line connecting the analog end points. This parameter is sensitive to dynamics, and test conditions must be specified in order to be meaningful. This parameter is the best overall indicator of the device′s performance.

Line Regulation – The ability of a voltage regulator to maintain a certain output voltage as the input to the regulator is varied. The error is typically expressed as a percent of the nominal output voltage.

Load Regulation – The ability of a voltage regulator to maintain a certain output voltage as the load current is varied. The error is typically expressed as a percent of the nominal output voltage.

LSB – Least Significant Bit. It is the lowest order bit of a binary code.

Monotonicity – The characteristic of the transfer function whereby increasing the input code (of a DAC), or the input signal (of an A/D), results in the output never decreasing.

MSB – Most Significant Bit. It is the highest order bit of a binary code.

Natural Binary Code – A binary code defined by:

$$N = A_n 2^n + \ldots + A_3 2^3 + A_2 2^2 + A_1 2^1 + A_0 2^0$$

where each “A” coefficient has a value of 1 or 0. Typically, all zeroes correspond to a zero input voltage of an A/D, and all ones correspond to the most positive input voltage.

Nyquist Theorem – See Sampling Theorem.

Offset Binary Code – Applicable only to bipolar input (or output) data converters, it is the same as Natural Binary, except that all zeros correspond to the most negative input voltage (of an A/D), while all ones correspond to the most positive input.

Power Supply Sensitivity – The change in a data converter′s performance with changes in the power supply voltage(s). This parameter is usually expressed in percent of full scale versus ΔV.

Quantitization Error – Also known as *digitization error* or uncertainty. It is the inherent error involved in digitizing an analog signal due to the finite number of steps at the digital output versus the infinite number of values at the analog input. This error is a minimum of ± 1/2 LSB.

Resolution – The smallest change which can be discerned by an A/D converter, or produced by a DAC. It is usually expressed as the number of bits (n), where the converter has 2^n possible states.

Sampling Theorem – Also known as the *Nyquist Theorem.* It states that the sampling frequency of an A/D must be no less that 2x the highest frequency (of interest) of the analog signal to be digitized in order to preserve the information of that analog signal.

Unipolar Input – A mode of operation whereby the analog input range (of an A/D), or output range (of a DAC), includes values of a signal polarity. Examples are 0 to + 2.0 V, 0 to – 5.0 V, 2.0 to 8.0 V, etc.

Unipolar Offset Error – The difference between the actual and ideal locations of the 00_H to 01_H transition, where the ideal location is 1/2 LSB above the most negative input voltage.

Interface Circuits

In Brief . . .

Described in this section is Motorola's line of interface circuits, which provide the means for interfacing with microprocessor or digital systems and the external world, or to other systems.

Also included are devices which allow a microprocessor to communicate with its own array of memory and peripheral I/O circuits.

The line drivers, receivers, and transceivers permit communication between systems over cables of several thousand feet in length, and at data rates of up to several megahertz. The common EIA data transmission standards, several European standards, and IEEE–488 are addressed by these devices.

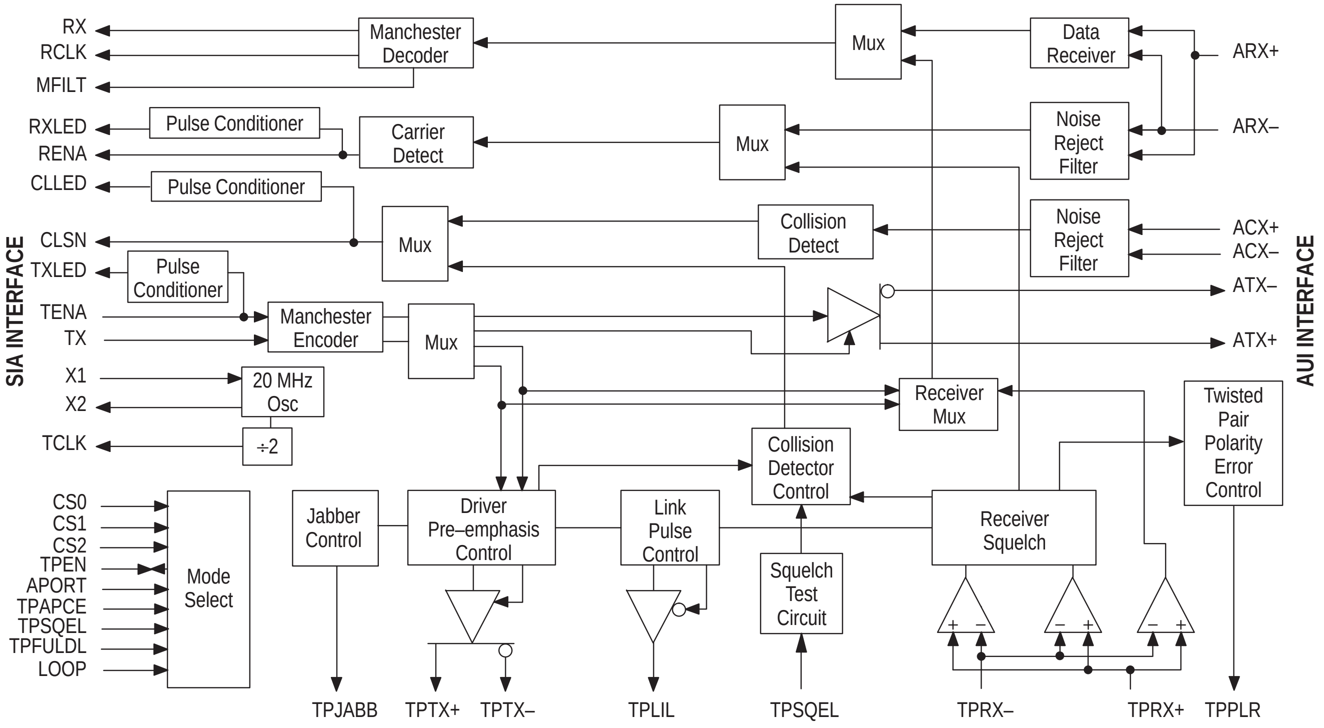
The peripheral drivers are designed to handle high current loads such as relay coils, lamps, stepper motors, and others. Input levels to these drivers can be TTL, CMOS, high voltage MOS, or other user defined levels. The display drivers are designed for LCD or LED displays, and provide various forms of decoding.

Enhanced Ethernet Transceiver

MC68160FB

T_A = 0° to +70°C, Case 848D

The MC68160 Enhanced Ethernet Interface Circuit is a BiCMOS device which supports both IEEE 802.3 Access Unit Interface (AUI) and 10BASE–T Twisted Pair (TP) Interface media connections through external isolation transformers. It encodes NRZ data to Manchester data and supplies the signals which are required for data communication via 10BASE–T or AUI interfaces. The MC68160 gluelessly interfaces to the Ethernet controller contained in the MC68360 Quad Integrated Communications Controller (QUICC) device. The MC68160 also interfaces easily to most other industry–standard IEEE 802.3 LAN controllers. Prior to twisted pair data reception, Smart Squelch circuitry qualifies input signals for correct amplitude, pulse width, and sequence requirements.

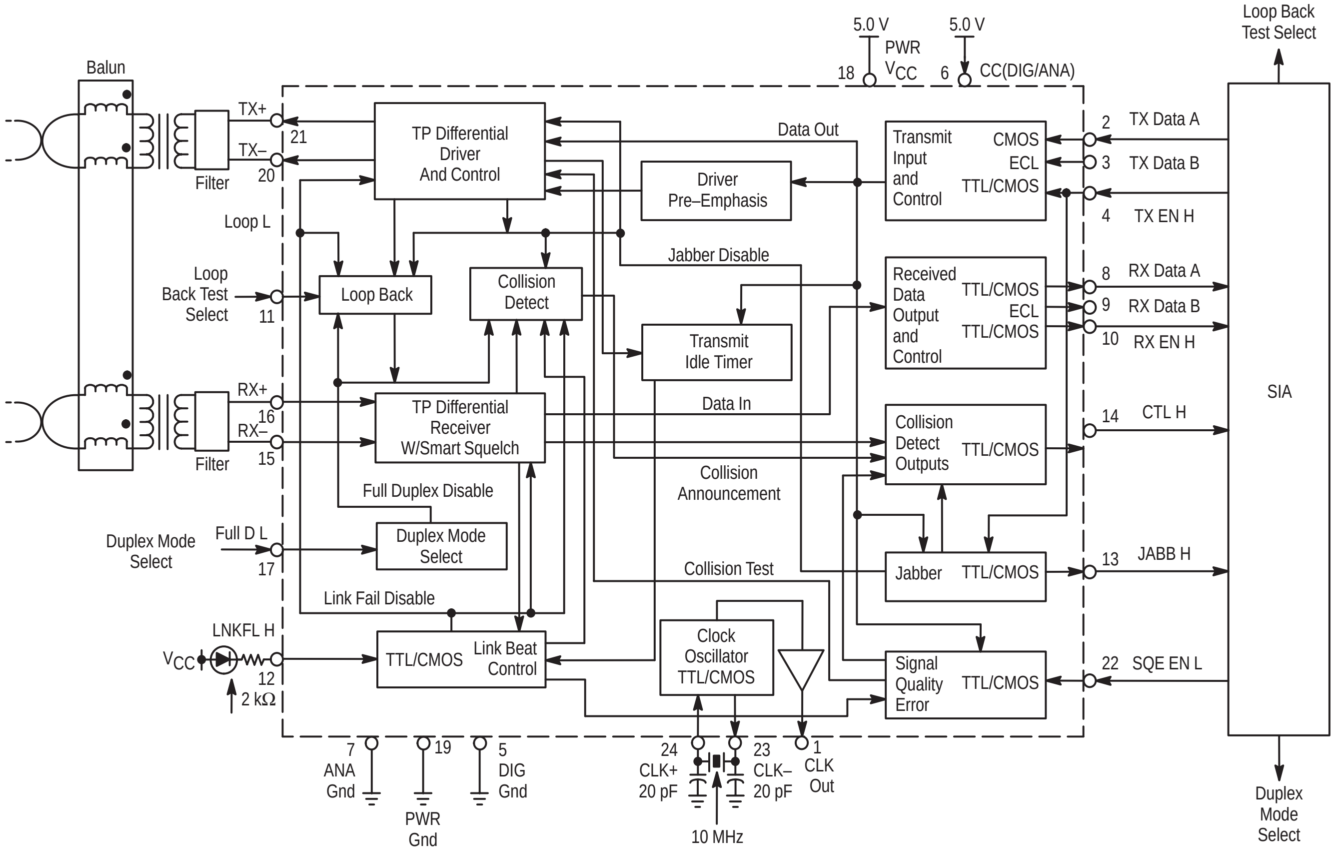


ISO 8802–3[IEEE 802.3] 10BASE–T Transceiver

MC34055DW

T_A = 0° to +70°C, Case 751E

The Motorola 10BASE–T transceiver, designed to comply with the ISO 8802–3[IEEE 802.3] 10BASE–T specification, will support a Medium Dependent Interface (MDI) in an embedded Media Attachment Unit (MAU). The interface supporting the Data Terminal Equipment (DTE) is TTL, CMOS, and raised ECL compatible, and the interface to the Twisted Pair (TP) media is supported through standard 10BASE–T filters and transformers. Differential data intended for the TP media is provided a 50 ns pre–emphasis and data at the TP receiver, is screened by Smart Squelch circuitry for specific threshold, pulse width, and sequence requirements.



Hex EIA–485 Transceiver with Three–State Outputs

MC34058/59FTA

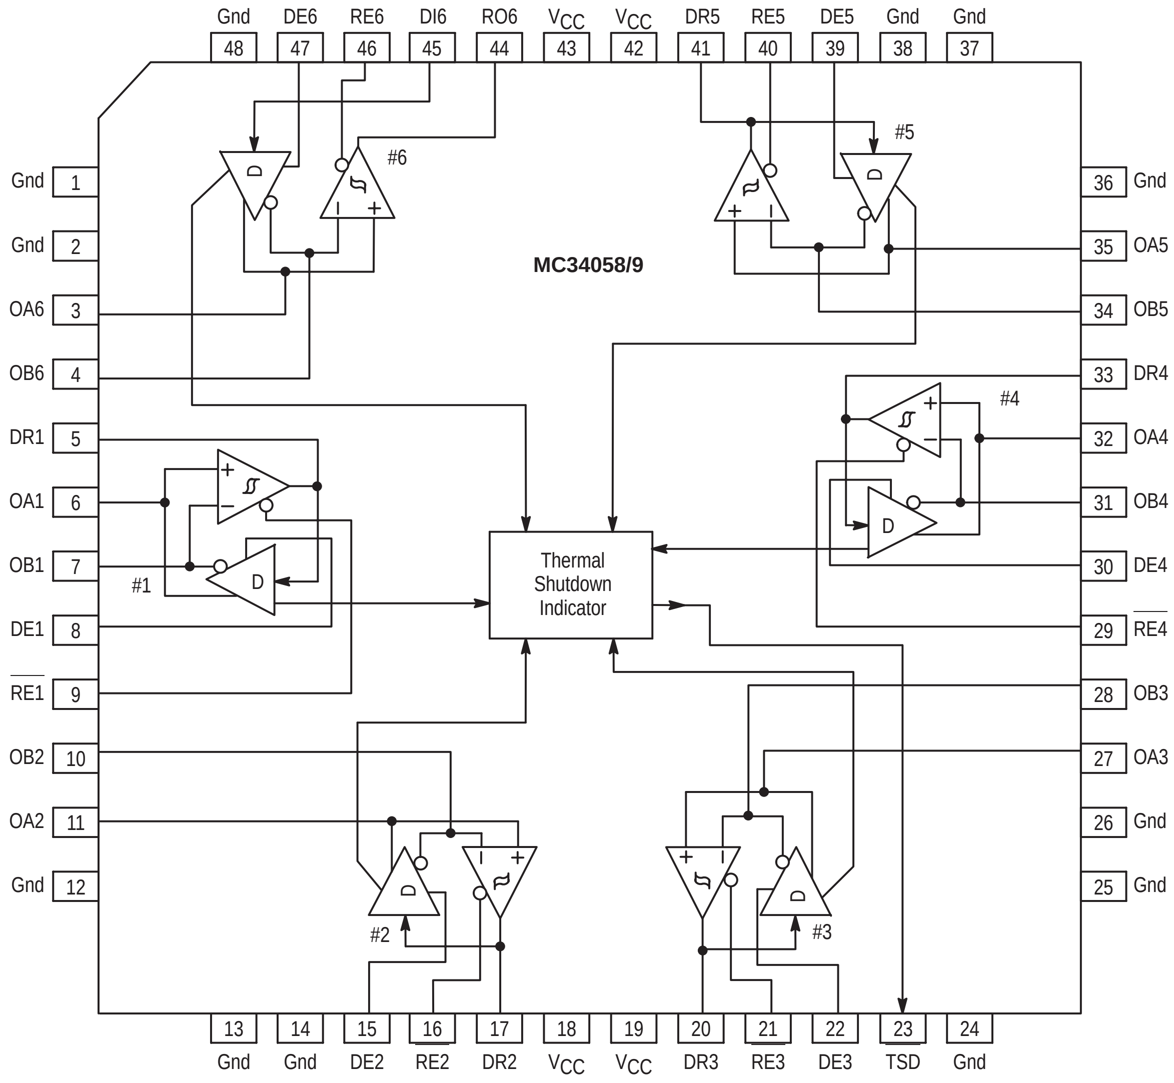
T_A = 0° to +70°C, Case 932

The Motorola MC34058/9 Hex Transceiver is composed of six driver/receiver combinations designed to comply with the EIA–485 standard. Features include three–state outputs, thermal shutdown for each driver, and current limiting in both directions. This device also complies with EIA–422 and CCITT Recommendations V.11 and X.27.

The devices are optimized for balanced multipoint bus transmission at rates to 20 MBPS (MC34059). The driver outputs/receiver inputs feature a wide common mode voltage range, allowing for their use in noisy environments. The current limit and thermal shutdown features protect the devices from line fault conditions.

The MC34058/9 is available in a space saving 7.0 mm 48 lead surface mount quad package designed for optimal heat dissipation.

- Meets EIA–485 Standard for Party Line Operation
- Meets EIA–422A and CCITT Recommendations V.11 and X.27
- Operating Ambient Temperature: 0°C to +70°C
- Common Mode Driver Output/Receiver Input Range: –7.0 to +12 V
- Positive and Negative Current Limiting
- Transmission Rates to 14 MBPS (MC34058) and 20 MBPS (MC34059)
- Driver Thermal Shutdown at 150°C Junction Temperature
- Thermal Shutdown Active Low Output
- Single +5.0 V Supply, ±10%
- Low Supply Current
- Compact 7.0 mm 48 Lead TQFP Plastic Package
- Skew Specified for MC34059



5.0 V, 200 M–Bit/Sec PR–IV Hard Disk Drive Read Channel

MC34250FTA

T_A = 0° to +70°C, Case 840F

The Motorola MC34250 is a fully integrated partial response maximum likelihood disk drive read/write channel for use in zoned recording applications. This device integrates the AGC, active filter, 7 tap equalizer, Viterbi detector, frequency synthesizer, servo demodulator, 8/9 rate (0,4/4) Encoder/Decoder with write precompensation and power management in a single 64 pin 10 mm x 10 mm TQFP package.

FEATURES:

- 50 to 200 MBPS Programmable Data Rate
- 800 mW at 200 MBPS and 5.0 V
- Channel Monitor Output
- Programmable AGC Charge Pump Currents with Different Values for Data and Servo Envelope Modes and Gain Gradient Mode
- Programmable AGC Peak Detector Droop Currents with Different Values for Data and Servo Envelope Modes
- Separate AGC Charge Pump Outputs for Data and Servo Modes
- Programmable Dual Threshold Qualifier or Hysteresis Comparator Type Pulse Detector for Servo Data Detection.
- ERD and Polarity Outputs for Servo Timing and Raw Encoded Data
- Integrated 7 pole 0.05° Equiripple Linear Phase Filter with Programmable Bandwidth from 5.0 MHz to 80 MHz and Different Values for Both Data and Servo Modes
- Programmable Symmetrical Boost from 0 to 10 dB and Different Values for Data and Servo Modes
- Programmable Asymmetrical Boost of Up to ±40% of Nominal Filter Group Delay in Both Data and Servo Modes
- 7 Tap Continuous Time Transversal Equalizer with 8 Bit Programmable Tap Weights and Integrated Decision Directed Sign–Sign Least Mean Squared Adaptation
- Internal Offset Cancellation Loops
- Fast Acquisition Data Phase Locked Loop with Zero Phase Restart
- Programmable Data Phase Locked Loop Charge Pump Current
- Integrated Soft Decision Viterbi Detectors with Programmable Merge References
- Integrated 8/9 Rate (0,4/4) Encoder and Decoder with Code Scrambler and Descrambler
- Programmable 2/4/8 Bit NRZ Data Interface
- Programmable Write Precompensation Delays Locked to the Frequency Synthesizer
- Differential PECL Write Data Outputs
- External Write Data Path for DC Erase or Other Non–Encoded Data
- Integrated Write Current DAC
- Programmable Power Management
- Bi–Directional Serial Microprocessor Interface
- Various Test Modes Controlled Via the Serial Microprocessor Interface

Microprocessor Bus Interface

Motorola offers a spectrum of line drivers and receivers which provide interfaces to many industry standard specifications. Many of the devices add key operational features, such as hysteresis, short circuit protection, clamp diode protection, or special control functions.

Device	Power Supply	Comments	T_A (°C)	Suffix/ Package
MC34250	5.0 V	200 Mbps fully integrated partial response maximum likelihood hard disk drive read/write channel which equalizes to a PR–IV shape and uses 8/9 rate (0, 4/4) coding.	0 to +70	FTA/840F

Inkjet Drivers

Table 12. 28–Channel Inkjet Driver

Device	Power Supply	Comments	T_A (°C)	Suffix/ Package
MC34156	5.0 V	A 4 to 14 line decoder determines the selected output driver in each of two 14 driver banks. Two independent output enable lines permit 1 or 2 of 28 outputs. Outputs are open collector 30 V Darlington drivers capable of sinking 500 mA.	0 to +70	FN/777

CMOS Display Drivers

These CMOS devices include digit as well as matrix drivers for LEDs, LCDs, and VFDs. They find applications over a wide range of end equipment such as instruments, automotive dashboards, home computers, appliances, radios and clocks.

Table 13. Display Drivers

Display Type	Input Format	Drive Capability Per Package	On–Chip Latch	Display Control	Segment Drive Current	Device
LCD (Direct Drive)	Parallel BCD	7 Segments	✓	Blank	≈ 1.0 mA	MC14543B
				Blank, Ripple Blank		MC14544B
	Serial Binary [Compatible with the Serial Peripheral Interface (SPI) on CMOS MCUs]	33 Segments or Dots			20 µA	MC145453
Muxed LCD (1/4 Mux)		48 Segments or Dots			≈ 200 µA	MC145000
		44 Segments or Dots				MC145001
LED, Incandescent, Fluorescent(1)	Parallel BCD	7 Segments		Blank, Lamp Test	25 mA	MC14511B
				Blank, Ripple Blank, Lamp Test		MC14513B
			–	Blank	65 mA	MC14547B
Muxed LED (1/4 Mux)	Serial Binary [Compatible with the Serial Peripheral Interface (SPI) on CMOS MCUs]	4 Digits + Decimals	✓	Oscillator (Scanner)	50 mA (Peak)	MC14499
Muxed LED (1/5 Mux)		5 Characters + Decimals or 25 Lamps		Oscillator (Scanner), Low Power Mode, Dimming	0 to 35 mA (Peak) Adjustable	MC14489
LED (Direct Drive)	Parallel Hex	7 Segments + A thru F Indicator			10 mA(2)	MC14495–1
(Interfaces to Display Drivers)	Parallel BCD	7 Segments	–	Ripple Blank, Enable	–	MC14558B

(1) Absolute maximum working voltage = 18 V.
(2) On–chip current–limiting resistor.

Table 14. Functions

Device	Function	Package
MC14489	Multi–Character LED Display/Lamp Driver	738, 751D
MC14495–1	Hexadecimal–to–7 Segment Latch/Decoder ROM/Driver	648, 751G
MC14499	4–Digit 7–Segment LED Display Decoder/Driver with Serial Interface	707, 751D
MC14511B	BCD–to–7–Segment Latch/Decoder/Driver	648, 751G
MC14513B	BCD–to–7–Segment Latch/Decoder/Driver with Ripple Blanking	726, 707
MC14543B	BCD–to–7–Segment Latch/Decoder/Driver for Liquid Crystals	620, 648
MC14544B	BCD–to–7–Segment Latch/Decoder/Driver with Ripple Blanking	726, 707
MC14547B	High–Current BCD–to–7–Segment Decoder/Driver	620, 648
MC14558B	BCD–to–7–Segment Decoder	620, 648
MC145000	48–Segment Serial Input Multiplexed LCD Driver (Master)	709, 776
MC145001	44–Segment Serial Input Multiplexed LCD Driver (Slave)	707, 776
MC145453	33–Segment, Non–Multiplexed LCD Driver with Serial Interface	711, 777

MOTOROLA

AM26LS30

Dual Differential (EIA-422-A)/ Quad Single-Ended (EIA-423-A) Line Drivers

The AM26LS30 is a low power Schottky set of line drivers which can be configured as two differential drivers which comply with EIA–422–A standards, or as four single–ended drivers which comply with EIA–423–A standards. A mode select pin and appropriate choice of power supplies determine the mode. Each driver can source and sink currents in excess of 50 mA.

In the differential mode (EIA–422–A), the drivers can be used up to 10 Mbaud. A disable pin for each driver permits setting the outputs into a high impedance mode within a ±10 V common mode range.

In the single–ended mode (EIA–423–A), each driver has a slew rate control pin which permits setting the slew rate of the output signal so as to comply with EIA–423–A and FCC requirements and to reduce crosstalk. When operated from symmetrical supplies (±5.0 V), the outputs exhibit zero imbalance.

The AM26LS30 is available in a 16–pin plastic DIP and surface mount package. Operating temperature range is –40° to +85°C.

- Operates as Two Differential EIA–422–A Drivers, or Four Single–Ended EIA–423–A Drivers
- High Impedance Outputs in Differential Mode
- Short Circuit Current Limit In Both Source and Sink Modes
- ± 10 V Common Mode Range on High Impedance Outputs
- ± 15 V Range on Inputs
- Low Current PNP Inputs Compatible with TTL, CMOS, and MOS Outputs
- Individual Output Slew Rate Control in Single–Ended Mode
- Replacement for the AMD AM25LS30 and National Semiconductor DS3691

APPLICATIONS INFORMATION

(Pin numbers refer to DIP and SO–16 packages only.)

Description

The AM26LS30 is a dual function line driver – it can be configured as two differential output drivers which comply with EIA–422–A Standard, or as four single–ended drivers which comply with EIA–423–A Standard. The mode of operation is selected with the Mode pin (Pin 4) and appropriate power supplies (see Table 1). Each of the four outputs is capable of sourcing and sinking 60 to 70 mA while providing sufficient voltage to ensure proper data transmission.

As differential drivers, data rates to 10 Mbaud can be transmitted over a twisted pair for a distance determined by the cable characteristics. EIA–422–A Standard provides guidelines for cable length versus data rate. The advantage of a differential (balanced) system over a single–ended system is greater noise immunity, common mode rejection, and higher data rates.

Where extraneous noise sources are not a problem, the AM26LS30 may be configured as four single–ended drivers transmitting data rates to 100 Kbaud. Crosstalk among wires within a cable is controlled by the use of the slew rate control pins on the AM26LS30.

Mode Selection

(Differential Mode)

In this mode (Pins 4 and 8 at ground), only a +5.0 V supply ±5% is required at V_{CC}. Pins 2 and 7 are the driver inputs, while Pins 10, 11, 14 and 15 are the outputs (see Block Diagram on page 1). The two outputs of a driver are always complementary and the differential voltage available at each pair of outputs is shown in Figure 6 for V_{CC} = 5.0 V. The differential output voltage will vary directly with V_{CC}. A “high” output can only source current, while a “low” output can only sink current (except for short circuit current – see Figure 8).

The two outputs will be in a high impedance mode when the respective Enable input (Pin 3 or 6) is high, or if $V_{CC} \leqslant$ 1.1 V. Output leakage current over a common mode range of ± 10 V is typically less than 1.0 µA.

The outputs have short circuit current limiting, typically, less than 100 mA over a voltage range of 0 to +6.0 V (see Figure 8). Short circuits should not be allowed to last indefinitely as the IC may be damaged.

Pins 9, 12, 13 and 16 are not normally used when in this mode, and should be left open.

(Single–Ended Mode)

In this mode (Pin 4 ≥ 2.0 V) V_{CC} requires +5.0 V, and V_{EE} requires –5.0 V, both ±5.0%. Pins 2, 3, 6, and 7 are inputs for the four drivers, and Pins 15, 14, 11, and 10 (respectively) are the outputs. The four drivers are independent of each other, and each output will be at a positive or a negative voltage depending on its input state, the load current, and the supply voltage. Figures 10 & 11 indicate the high and low output voltages for V_{CC} = 5.0 V, and V_{EE} = –5.0 V. The graph of Figure 10 will vary directly with V_{CC}, and the graph of Figure 11 will vary directly with V_{EE}. A “high” output can only source current, while a “low” output can only sink current (except short circuit current – see Figure 14).

The outputs will be in a high impedance mode only if $V_{CC} \leqslant$ 1.1 V. Changing V_{EE} to 0 V does not set the outputs to a high impedance mode. Leakage current over a common mode range of ±10 V is typically less than 1.0 µA.

The outputs have short circuit current limiting, typically less than 100 mA over a voltage range of ±6.0 V (see Figure 14). Short circuits should not be allowed to last indefinitely as the IC may be damaged.

Capacitors connected between Pins 9, 12, 13, and 16 and their respective outputs will provide slew rate limiting of the output transition. Figure 16 indicates the required capacitor value to obtain a desired rise or fall time (measured between the 10% and 90% points). The positive and negative transition times will be within ≈ ±5% of each other. Each output may be set to a different slew rate if desired.

Inputs

The five inputs determine the state of the outputs in accordance with Table 1. All inputs (regardless of the operating mode) have a nominal threshold of +1.3 V, and their voltage must be kept within a range of 0 V to +15 V for proper operation. If an input is taken more than 0.3 V below ground, excessive currents will flow, and the proper operation of the drivers will be affected. An open pin is equivalent to a logic high, but good design practices dictate that inputs should never be left open. Unused inputs should be connected to ground. The characteristics of the inputs are shown in Figure 9.

Power Supplies

V_{CC} requires +5.0 V, ±5%, regardless of the mode of operation. The supply current is determined by the IC’s internal bias requirements and the total load current. The internally required current is a function of the load current and is shown in Figure 7 for the differential mode.

In the single–ended mode, V_{EE} must be –5.0 V, ±5% in order to comply with EIA–423–A standards. Figures 12 and 13 indicate the internally required bias currents as a function of total load current (the sum of the four output loads). The discontinuity at 0 load current exists due to a change in bias current when the inputs are switched. The supply currents vary ≈ ± 2.0 mA as V_{CC} and V_{EE} are varied from $|4.75\ V|$ to $|5.25\ V|$.

Sequencing of the supplies during power–up/power–down is not required.

Bypass capacitors (0.1 µF minimum on each supply pin) are recommended to ensure proper operation. Capacitors reduce noise induced onto the supply lines by the switching action of the drivers, particularly where long P.C. board tracks are involved. Additionally, the capacitors help absorb transients induced onto the drivers’ outputs from the external cable (from ESD, motor noise, nearby computers, etc.).

Operating Temperature Range

The maximum ambient operating temperature, listed as +85°C, is actually a function of the system use (i.e., specifically how many drivers within a package are used) and at what current levels they are operating. The maximum power which may be dissipated within the package is determined by:

$$P_{Dmax} = \frac{T_{Jmax} - T_A}{R_{\theta JA}}$$

where $R_{\theta JA}$ = package thermal resistance which is typically:
67°C/W for the DIP (PC) package,
120°C/W for the SOIC (D) package,
T_{Jmax} = max. allowable junction temperature (150°C)
T_A = ambient air temperature near the IC package.

1) Differential Mode Power Dissipation

For the differential mode, the power dissipated within the package is calculated from:

$P_D = [(V_{CC} - V_{OD}) \times I_O]$ (each driver) + $(V_{CC} \times I_B)$

where: V_{CC} = the supply voltage
V_{OD} = is taken from Figure 6 for the known value of I_O
I_B = the internal bias current (Figure 7)

As indicated in the equation, the first term (in brackets) must be calculated and summed for each of the two drivers, while the last term is common to the entire package. Note that the term $(V_{CC} - V_{OD})$ is constant for a given value of I_O and does not vary with V_{CC}. For an application involving the following conditions:

T_A = +85°C, I_O = –60 mA (each driver), V_{CC} = 5.25 V, the suitability of the package types is calculated as follows.

The power dissipated is:

P_D = [3.0 V × 60 mA × 2] + (5.25 V × 18 mA)
P_D = 454 mW

The junction temperature calculates to:

T_J = 85°C + (0.454 W × 67°C/W) = 115°C for the DIP package,
T_J = 85°C + (0.454 W × 120°C/W) = 139°C for the
T_J = SOIC package.

Since the maximum allowable junction temperature is not exceeded in any of the above cases, either package can be used in this application.

2) Single–Ended Mode Power Dissipation

For the single–ended mode, the power dissipated within the package is calculated from:

$$P_D = (I_{B+} \times V_{CC}) + (I_{B-} \times V_{EE}) + [(I_O \times (V_{CC} - V_{OH})]\text{(each driver)}$$

The above equation assumes I_O has the same magnitude for both output states, and makes use of the fact that the absolute value of the graphs of Figures 10 and 11 are nearly identical. I_B+ and I_B– are obtained from the right half of Figures 12 and 13, and $(V_{CC} - V_{OH})$ can be obtained from Figure 10. Note that the term $(V_{CC} - V_{OH})$ is constant for a given value of I_O and does not vary with V_{CC}. For an application involving the following conditions:

T_A = +85°C, I_O = –60 mA (each driver), V_{CC} = 5.25 V, V_{EE} = –5.25 V, the suitability of the package types is calculated as follows.

The power dissipated is:

P_D = (24 mA × 5.25 V) + (–3.0 mA × –5.25 V) + [60 mA × 1.45 V × 4.0]
P_D = 490 mW

The junction temperature calculates to:

T_J = 85°C + (0.490 W × 67°C/W) = 118°C for the DIP package,
T_J = 85°C + (0.490 W × 120°C/W) = 144°C for the SOIC package.

Since the maximum allowable junction temperature is not exceeded in any of the above cases, either package can be used in this application.

SYSTEM EXAMPLES

(Pin numbers refer to DIP and SO–16 packages only.)

Differential System

An example of a typical EIA–422–A system is shown in Figure 17. Although EIA–422–A does not specifically address multiple driver situations, the AM26LS30 can be used in this manner since the outputs can be put into a high impedance mode. It is, however, the system designer's responsibility to ensure the Enable pins are properly controlled so as to prevent two drivers on the same cable from being "on" at the same time.

The limit on the number of receivers and drivers which may be connected on one system is determined by the input current of each receiver, the maximum leakage current of each "off" driver, and the DC current through each terminating resistor. The sum of these currents must not exceed the capability of the "on" driver (≈60 mA). If the cable is of any significant length, with receivers at various points along its length, the common mode voltage may vary along its length, and this parameter must be considered when calculating the maximum driver current.

The cable requirements are defined not only by the AC characteristics and the data rate, but also by the DC resistance. The maximum resistance must be such that the minimum voltage across any receiver inputs is never less than 200 mV.

The ground terminals of each driver and receiver in Figure 17 must be connected together by a dedicated wire (or the shield) in the cable to provide a common reference. Chassis grounds or power line grounds should not be relied on for this common connection as they may generate significant common mode differences. Additionally, they usually do not provide a sufficiently low impedance at the frequencies of interest.

Single–Ended System

An example of a typical EIA–423–A system is shown in Figure 18. Multiple drivers on a single data line are not possible since the drivers cannot be put into a high impedance mode. Although each driver is shown connected to a single receiver, multiple receivers can be driven from a single driver as long as the total load current of the receivers and the terminating resistor does not exceed the capability of the driver (≈60 mA). If the cable is of any significant length, with receivers at various points along its length, the common mode voltage may vary along its length, and this parameter must be considered when calculating the maximum driver current.

The cable requirements are defined not only by the AC characteristics and the data rate, but also by the DC resistance. The maximum resistance must be such that the minimum voltage across any receiver inputs is never less than 200 mV.

The ground terminals of each driver and receiver in Figure 18 must be connected together by a dedicated wire (or the shield) in the cable so as to provide a common reference. Chassis grounds or power line grounds should not be relied on for this common connection as they may generate significant common mode differences. Additionally, they usually do not provide a sufficiently low impedance at the frequencies of interest.

Additional Modes of Operation

If compliance with EIA–422–A or EIA–423–A Standard is not required in a particular application, the AM26LS30 can be operated in two other modes.

1) The device may be operated in the differential mode (Pin 4 = 0) with V_{EE} connected to any voltage between ground and –5.25 V. Outputs in the low state will be referenced to V_{EE}, resulting in a differential output voltage greater than that shown in Figure 6. The Enable pins will operate the same as previously described.

2) The device may be operated in the single–ended mode (Pin 4 = 1) with V_{EE} connected to any voltage between ground and –5.25 V. Outputs in the high state will be at a voltage as shown in Figure 10, while outputs in a low state will be referenced to V_{EE}.

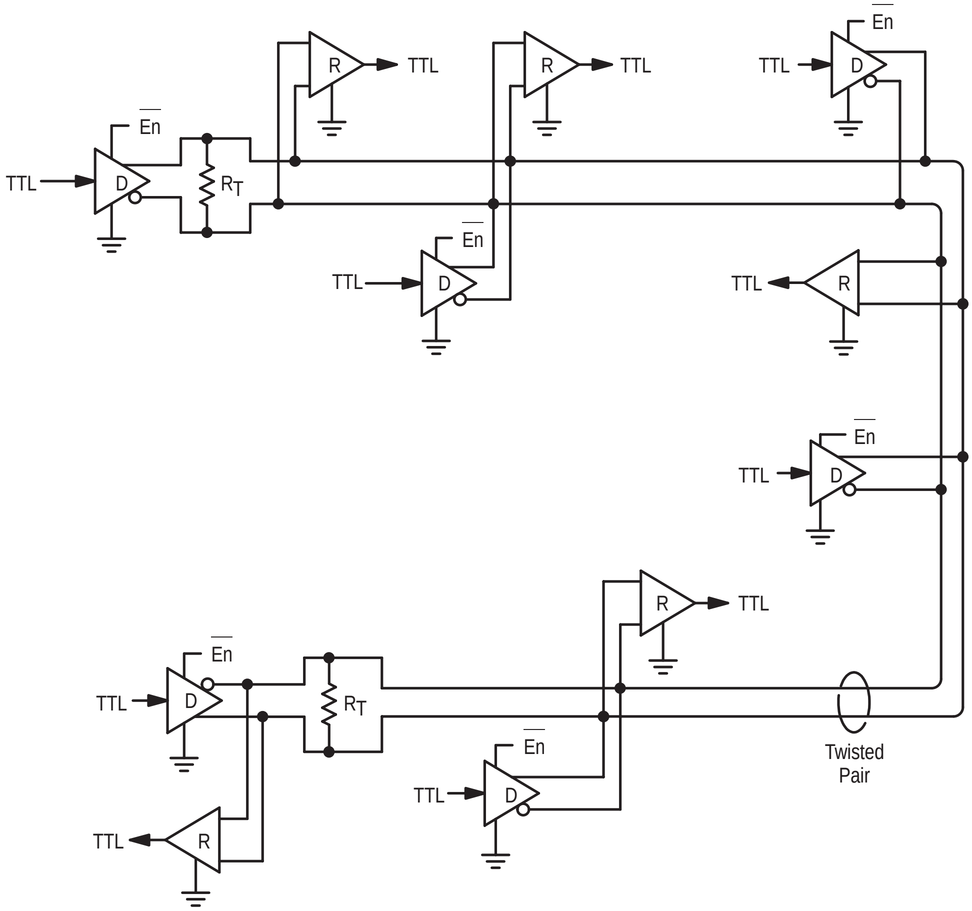
Termination Resistors

Transmission line theory states that, in order to preserve the shape and integrity of a waveform traveling along a cable, the cable must be terminated in an impedance equal to its characteristic impedance. In a system such as that depicted in Figure 17, in which data can travel in both directions, both physical ends of the cable must be terminated. Stubs leading to each receiver and driver should be as short as possible.

In a system such as that depicted in Figure 18, in which data normally travels in one direction only, a terminator is theoretically required only at the receiving end of the cable. However, if the cable is in a location where noise spikes of several volts can be induced onto it, then a terminator (preferably a series resistor) should be placed at the driver end to prevent damage to the driver.

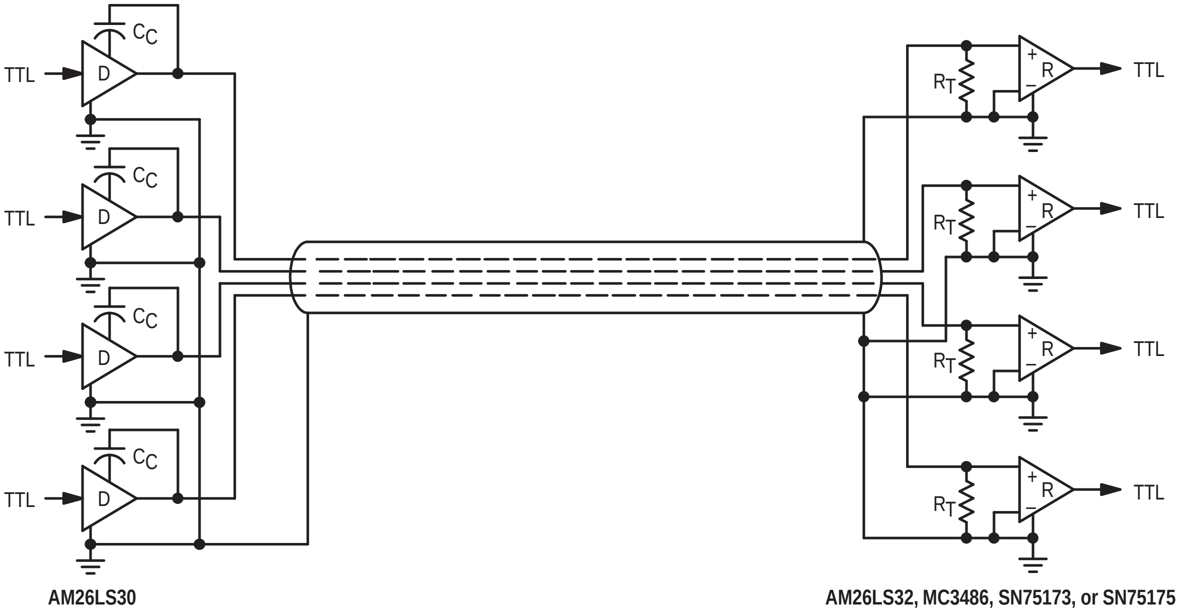
Leaving off the terminations will generally result in reflections which can have amplitudes of several volts above V_{CC} or several volts below ground or V_{EE}. These overshoots/undershoots can disrupt the driver and/or receiver, create false data, and in some cases, damage components on the bus.

Figure 17. EIA–422–A Example



NOTES: 1. Terminating resistors R_T should be located at the physical ends of the cable.
2. Stubs should be as short as possible.
3. Receivers = AM26LS32, MC3486, SN75173 or SN75175.
4. Circuit grounds must be connected together through a dedicated wire.

Figure 18. EIA–423–A Example



MOTOROLA

AM26LS31

Quad Line Driver with NAND Enabled Three-State Outputs

QUAD EIA–422 LINE DRIVER WITH THREE–STATE OUTPUTS

SEMICONDUCTOR TECHNICAL DATA

The Motorola AM26LS31 is a quad differential line driver intended for digital data transmission over balanced lines. It meets all the requirements of EIA–422 Standard and Federal Standard 1020.

The AM26LS31 provides an enable/disable function common to all four drivers as opposed to the split enables on the MC3487 EIA–422 driver.

The high impedance output state is assured during power down.

- Full EIA–422 Standard Compliance
- Single +5.0 V Supply
- Meets Full $V_O = 6.0$ V, $V_{CC} = 0$ V, $I_O < 100\ \mu A$ Requirement
- Output Short Circuit Protection
- Complementary Outputs for Balanced Line Operation
- High Output Drive Capability
- Advanced LS Processing
- PNP Inputs for MOS Compatibility

MOTOROLA

QUAD EIA-422/423 Line Receiver with Three-State Outputs

Motorola's Quad EIA–422/3 Receiver features four independent receiver chains which comply with EIA Standards for the Electrical Characteristics of Balanced/Unbalanced Voltage Digital Interface Circuits. Receiver outputs are 74LS compatible, three–state structures which are forced to a high impedance state when Pin 4 is a Logic "0" and Pin 12 is a Logic "1." A PNP device buffers each output control pin to assure minimum loading for either Logic "1" or Logic "0" inputs. In addition, each receiver chain has internal hysteresis circuitry to improve noise margin and discourage output instability for slowly changing input waveforms. A summary of AM26LS32 features include:

- Four Independent Receiver Chains
- Three–State Outputs
- High Impedance Output Control Inputs (PIA Compatible)
- Internal Hysteresis – 30 mV (Typical) @ Zero Volts Common Mode
- Fast Propagation Times – 25 ns (Typical)
- TTL Compatible
- Single 5.0 V Supply Voltage
- Fail–Safe Input–Output Relationship. Output Always High When Inputs Are Open, Terminated or Shorted
- 6.0 k Minimum Input Impedance

MOTOROLA

MC1413, B
MC1416, B

High Voltage, High Current Darlington Transistor Arrays

The seven NPN Darlington connected transistors in these arrays are well suited for driving lamps, relays, or printer hammers in a variety of industrial and consumer applications. Their high breakdown voltage and internal suppression diodes insure freedom from problems associated with inductive loads. Peak inrush currents to 500 mA permit them to drive incandescent lamps.

The MC1413, B with a 2.7 kΩ series input resistor is well suited for systems utilizing a 5.0 V TTL or CMOS Logic. The MC1416, B uses a series 10.5 kΩ resistor and is useful in 8.0 to 18 V MOS systems.

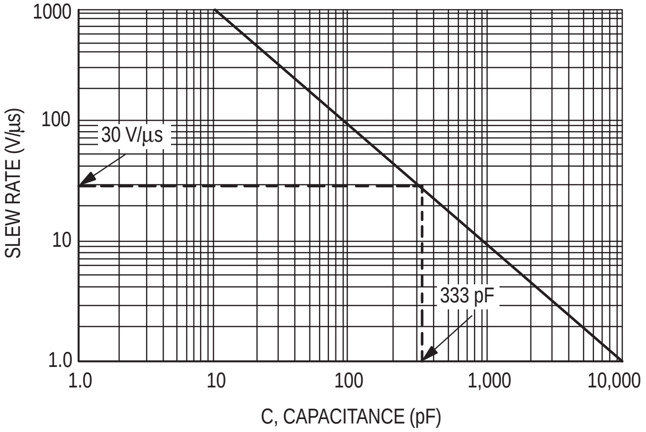
APPLICATIONS INFORMATION

The Electronic Industries Association EIA–232D specification details the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The MC1488 quad driver and its companion circuit, the MC1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the EIA–232D defined levels. The EIA–232D requirements as applied to drivers are discussed herein.

The required driver voltages are defined as between 5.0 and 15 V in magnitude and are positive for a Logic “0” and negative for a Logic “1.” These voltages are so defined when the drivers are terminated with a 3000 to 7000 Ω resistor. The MC1488 meets this voltage requirement by converting a DTL/TTL logic level into EIA–232D levels with one stage of inversion.

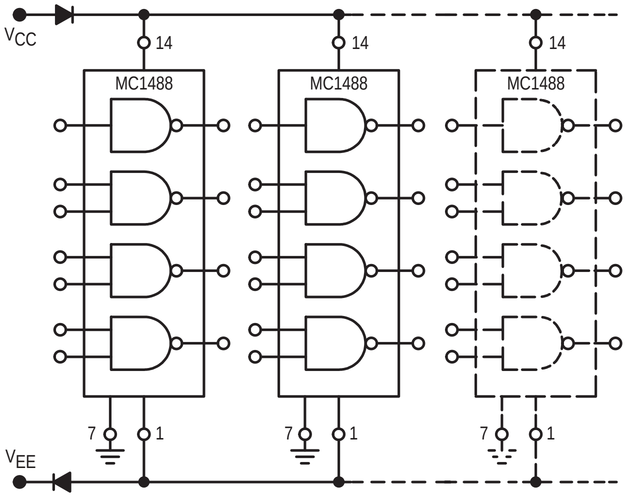
The EIA–232D specification further requires that during transitions, the driver output slew rate must not exceed 30 V per microsecond. The inherent slew rate of the MC1488 is much too fast for this requirement. The current limited output of the device can be used to control this slew rate by connecting a capacitor to each driver output. The required capacitor can be easily determined by using the relationship $C = I_{OS} \times \Delta T/\Delta V$ from which Figure 12 is derived. Accordingly, a 330 pF capacitor on each output will guarantee a worst case slew rate of 30 V per microsecond.

Figure 12. Slew Rate versus Capacitance for I_{SC} = 10 mA



The interface driver is also required to withstand an accidental short to any other conductor in an interconnecting cable. The worst possible signal on any conductor would be another driver using a plus or minus 15 V, 500 mA source. The MC1488 is designed to indefinitely withstand such a short to all four outputs in a package as long as the power supply voltages are greater than 9.0 V (i.e., $V_{CC} \geqslant 9.0$ V; $V_{EE} \leqslant -9.0$ V). In some power supply designs, a loss of system power causes a low impedance on the power supply outputs. When this occurs, a low impedance to ground would exist at the power inputs to the MC1488 effectively shorting the 300 Ω output resistors to ground. If all four outputs were then shorted to plus or minus 15 V, the power dissipation in these resistors would be excessive. Therefore, if the system is designed to permit low impedances to ground at the power supplies of the drivers, a diode should be placed in each power supply lead to prevent overheating in this fault condition. These two diodes, as shown in Figure 13, could be used to decouple all the driver packages in a system. (These same diodes will allow the MC1488 to withstand momentary shorts to the ± 25 V limits specified in the earlier Standard EIA–232B.) The addition of the diodes also permits the MC1488 to withstand faults with power supplies of less than the 9.0 V stated above.

Figure 13. Power Supply Protection to Meet Power Off Fault Conditions



The maximum short circuit current allowable under fault conditions is more than guaranteed by the previously mentioned 10 mA output current limiting.

Other Applications

The MC1488 is an extremely versatile line driver with a myriad of possible applications. Several features of the drivers enhance this versatility:

1. Output Current Limiting – this enables the circuit designer to define the output voltage levels independent of power supplies and can be accomplished by diode clamping of the output pins. Figure 14 shows the MC1488 used as a DTL to MOS translator where the high level voltage output is clamped one diode above ground. The resistor divider shown is used to reduce the output voltage below the 300 mV above ground MOS input level limit.

2. Power Supply Range – as can be seen from the schematic drawing of the drivers, the positive and negative driving elements of the device are essentially independent and do not require matching power supplies. In fact, the positive supply can vary from a minimum 7.0 V (required for driving the negative pulldown section) to the maximum specified 15 V. The negative supply can vary from approximately – 2.5 V to the minimum specified – 15 V. The MC1488 will drive the output to within 2.0 V of the positive or negative supplies as long as the current output limits are not exceeded. The combination of the current limiting and supply voltage features allow a wide combination of possible outputs within the same quad package. Thus if only a portion of the four drivers are used for driving EIA–232D lines, the remainder could be used for DTL to MOS or even DTL to DTL translation. Figure 15 shows one such combination.

APPLICATIONS INFORMATION

General Information

The Electronic Industries Association (EIA) has released the EIA–232D specification detailing the requirements for the interface between data processing equipment and data communications equipment. This standard specifies not only the number and type of interface leads, but also the voltage levels to be used. The MC1488 quad driver and its companion circuit, the MC1489 quad receiver, provide a complete interface system between DTL or TTL logic levels and the EIA–232D defined levels. The EIA–232D requirements as applied to receivers are discussed herein.

The required input impedance is defined as between 3000 Ω and 7000 Ω for input voltages between 3.0 and 25 V in magnitude; and any voltage on the receiver input in an open circuit condition must be less than 2.0 V in magnitude. The MC1489 circuits meet these requirements with a maximum open circuit voltage of one V_{BE}.

The receiver shall detect a voltage between – 3.0 and – 25 V as a Logic “1” and inputs between 3.0 and 25 V as a Logic “0.” On some interchange leads, an open circuit of power “OFF” condition (300 Ω or more to ground) shall be decoded as an “OFF” condition or Logic “1.” For this reason, the input hysteresis thresholds of the MC1489 circuits are all above ground. Thus an open or grounded input will cause the same output as a negative or Logic “1” input.

Device Characteristics

The MC1489 interface receivers have internal feedback from the second stage to the input stage providing input hysteresis for noise rejection. The MC1489 input has typical turn–on voltage of 1.25 V and turn–off of 1.0 V for a typical hysteresis of 250 mV. The MC1489A has typical turn–on of 1.95 V and turn–off of 0.8 V for typically 1.15 V of hysteresis.

Each receiver section has an external response control node in addition to the input and output pins, thereby allowing the designer to vary the input threshold voltage levels. A resistor can be connected between this node and an external power supply. Figures 2, 4 and 5 illustrate the input threshold voltage shift possible through this technique.

This response node can also be used for the filtering of high frequency, high energy noise pulses. Figures 8 and 9 show typical noise pulse rejection for external capacitors of various sizes.

These two operations on the response node can be combined or used individually for many combinations of interfacing applications. The MC1489 circuits are particularly useful for interfacing between MOS circuits and MDTL/MTTL logic systems. In this application, the input threshold voltages are adjusted (with the appropriate supply and resistor values) to fall in the center of the MOS voltage logic levels (see Figure 10).

The response node may also be used as the receiver input as long as the designer realizes that he may not drive this node with a low impedance source to a voltage greater than one diode above ground or less than one diode below ground. This feature is demonstrated in Figure 11 where two receivers are slaved to the same line that must still meet the EIA–232D impedance requirement.

MOTOROLA

MC14C88B

Quad Low Power Line Driver

The MC14C88B is a low power monolithic quad line driver, using BiMOS technology, which conforms to EIA–232–D, EIA–562, and CCITT V.28. The inputs feature TTL and CMOS compatibility with minimal loading. The outputs feature internally controlled slew rate limiting, eliminating the need for external capacitors. Power off output impedance exceeds 300 Ω, and current limiting protects the outputs in the event of short circuits.

Power supply current is less than 160 μA over the supply voltage range of ±4.5 to ±15 V. EIA–232–D performance is guaranteed with a minimum supply voltage of ±6.5 V.

The MC14C88B is pin compatible with the MC1488, SN75188, SN75C188, DS1488, and DS14C88. This device is available in 14 pin plastic DIP, and surface mount packaging.

Features:

- BiMOS Technology for Low Power Operation (< 5.0 mW)
- Meets Requirements of EIA–232–D, EIA–562, and CCITT V.28
- Quiescent Current Less Than 160 μA
- TTL/CMOS Compatible Inputs
- Minimum 300 Ω Output Impedance when Powered Off
- Supply Voltage Range: ±4.5 to ±15 V
- Pin Equivalent to MC1488
- Current Limited Output: 10 mA Minimum
- Operating Ambient Temperature: –40° to 85°C

STANDARDS COMPLIANCE

The MC14C88 is designed to comply with EIA–232–D (formerly RS–232), the newer EIA–562 (which is a higher speed version of the EIA–232), and CCITT's V.28. EIA–562 was written around modern integrated circuit technology, whereas EIA–232 retains many of the specs written around the electro–mechanical circuitry in use at the time of its creation. Yet the user will find enough similarities to allow a certain amount of compatibility among equipment built to the two standards. Following is a summary of the key specifications relating to the systems and the drivers.

Parameter	EIA–232–D	EIA–562
Maximum Data Rate	20 kbaud	38.4 kbaud Asynchronous 64 kbaud Synchronous
Maximum Cable Length	50 feet	Based on cable capacitance/data rate
Maximum Slew Rate	⩽ 30 V/µs anywhere on the waveform	⩽ 30 V/µs anywhere on the waveform ⩾ 4.0 V/µs between +3.0 and –3.0 V
Transition Region	–3.0 to +3.0 V	–3.3 to +3.3 V
Transition Time	For UI ⩾ 25 ms, t_R ⩽1.0 ms For 25 ms > UI > 125 µs, t_R ⩽ 4% UI For UI < 125 µs, t_R ⩽ 5.0 µs	For UI ⩾ 50 µs, 220 ns < t_R ⩽ 3.1 µs For UI < 50 µs, 220 ns < t_R ⩽ 2.1 µs (within the transition region)
MARK (one, off)	More negative than –3.0 V	More negative than –3.3 V
Space (zero, on)	More positive than +3.0 V	More positive than +3.3 V
Short Circuit Proof ?	Yes, to any system voltage	Yes, to ground
Short Circuit Current	⩽ 500 mA to any system voltage	⩽ 60 mA to ground
Open Circuit Voltage	$\lvert V_{OC} \rvert$ ⩽ 25 V	$\lvert V_{OC} \rvert$ < 13.2 V
Loaded Output Voltage	5.0 V ⩽ $\lvert V_O \rvert$ ⩽15 V for loads between 3.0 kΩ and 7.0 kΩ	$\lvert V_O \rvert$ ⩾ 3.7 V for a load of 3.0 kΩ
Power Off Input Source Impedance	⩾ 300 Ω for $\lvert V_O \rvert$ ⩽ 2.0 V	⩾ 300 Ω for $\lvert V_O \rvert$ ⩽ 2.0 V

NOTE: UI = Unit Interval, or bit time.
V.28 standard has the same specifications as EIA–232, with the exception of transition time which is listed as "less than 1.0 ms, or 3% of the UI, whichever is less".

APPLICATIONS INFORMATION

Description

The MC14C88 was designed to be a direct replacement for the MC1488 in that it meets all EIA–232 specifications. However, use is extended as the MC14C88 also meets the faster EIA–562 and CCITT V.28 specifications. Slew rate limited outputs conform to the mentioned specifications and eliminate the need for external output capacitors. Low power consumption is made possible by BiMOS technology. Power supply current is limited to less than 160 μA, plus load currents over the supply voltage range of ±4.5 V to ±15 V (see Figure 2).

Outputs

The output low or high voltage depends on the state of the inputs, the load current, and the supply voltage (see Table 1 and Figure 3). The graphs apply to each driver regardless of how many other drivers within the package are supplying load current.

Table 1. Function Tables

Driver 1

Input A	Output A
H	L
L	H

Drivers 2 through 4

Input *1	Input *2	Output*
H	H	L
L	X	H
X	L	H

H = High level, L = Low level, X = Don't care.

Driver Inputs

The driver inputs determine the state of the outputs in accordance with Table 1. The nominal threshold voltage for the inputs is 1.4 Vdc, and for proper operation, the input voltages should be restricted to the range Gnd to V_{CC}. Should the input voltage drop below V_{EE} by more than 0.3 V or rise above V_{EE} by more than 39 V, excessive currents will flow at the input pin. Open input pins are equivalent to logic high, but good design practices dictate that inputs should never be left open.

Operating Temperature Range

The ambient operating temperature range is listed at –40° to +85°C and meets EIA–232–D, EIA–562 and CCITT V.28 specifications over this temperature range. The maximum ambient temperature is listed as +85°C. However, a lower ambient may be required depending on system use, i.e. specifically how many drivers within a package are used, and at what current levels they are operating. The maximum power which may be dissipated within the package is determined by:

$$P_{Dmax} = \frac{T_{Jmax} - T_A}{R_{\theta JA}}$$

where: $R_{\theta JA}$ = the package thermal resistance (typically, 100°C/W for the DIP package, 125°C/W for the SOIC package);
T_{Jmax} = the maximum operating junction temperature (150°C); and
T_A = the ambient temperature.

$$P_D = \{ [(V_{CC} - V_{OH}) \times |I_{OH}|] \text{ or } [(V_{OL} - V_{EE}) \times |I_{OL}|] \}_{\text{each driver}} + (V_{CC} \times I_{CC}) + (V_{EE} \times I_{EE})$$

where: V_{CC} and V_{EE} are the positive and negative supply voltages;
V_{OH} and V_{OL} are measured or estimated from Figure 3;
I_{CC} and I_{EE} are the quiescent supply currents measured or estimated from Figure 2.

As indicated, the first term (in brackets) must be calculated and summed for each of the four drivers, while the last terms are common to the entire package.

MC14C89B, AB

Quad Low Power Line Receivers

The MC14C89B and MC14C89AB are low monolithic quad line receivers using bipolar technology, which conform to the EIA–232–E, EIA–562 and CCITT V.28 Recommendations. The outputs feature LSTTL and CMOS compatibility for easy interface to +5.0 V digital systems. Internal time–domain filtering eliminates the need for external filter capacitors in most cases.

The MC14C89B has an input hysteresis of 0.35 V, while the MC14C89AB hysteresis is 0.95 V. The response control pins allow adjustment of the threshold level if desired. Additionally, an external capacitor may be added for additional noise filtering.

The MC14C89B and MC14C89AB are available in both a 14 pin dual–in–line plastic DIP and SOIC package.

Features:

- Low Power Consumption
- Meets EIA–232–E, EIA–562, and CCITT V.28 Recommendations
- TTL/CMOS Compatible Outputs
- Standard Power Supply: + 5.0 V ±10%
- Pin Equivalent to MC1489, MC1489A, TI’s SN75C189/A, SN75189/A and National Semiconductor’s DS14C89/A
- External Filtering Not Required in Most Cases
- Threshold Level Externally Adjustable
- Hysteresis: 0.35 V for MC14C89B, 0.95 V for MC14C89AB
- Available in Plastic DIP, and Surface Mount Packaging
- Operating Ambient Temperature: –40° to +85°C

STANDARDS COMPLIANCE

The MC14C89B and MC14C89AB are designed to comply with EIA–232–E (formerly RS–232), the newer EIA–562 (which is a higher speed version of the EIA–232), and CCITT V.28 Recommendations. EIA–562 was written around modern integrated circuit technology, whereas EIA–232 retains many of the specifications written around the electro–mechanical circuitry in use at the time of its creation. Yet the user will find enough similarities to allow a certain amount of compatibility among equipment built to the two standards. Following is a summary of the key specifications relating to the systems and the receivers.

Parameter	EIA–232–E	EIA–562
Max Data Rate	20 kBaud	38.4 kBaud Asynchronous 64 kBaud Synchronous
Max Cable Length	50 feet	Based on cable capacitance/data rate
Transition Region	–3.0 V to +3.0 V	–3.0 V to +3.0 V
MARK (one, off)	More negative than –3.0 V	More negative than –3.3 V
SPACE (zero, on)	More positive than +3.0 V	More positive than +3.3 V
Fail Safe	Output = Binary 1	Output = Binary 1
Open Circuit Input Voltage	$< \lvert 2.0 \rvert$ V	Not Specified
Slew Rate (at the driver)	$\leqslant$30 V/µs anywhere on the waveform	$\leqslant$30 V/µs anywhere on the waveform, $\geqslant$4.0 V/µs between +3.0 V and –3.0 V
Loaded Output Voltage (at the driver)	5.0 V $\leqslant \lvert V_O \rvert \leqslant$ 15 V for loads between 3.0 kΩ and 7.0 kΩ	$\lvert V_O \rvert \geqslant$ 3.7 V for a load of 3.0 kΩ

APPLICATIONS INFORMATION

Description

The MC14C89AB and MC14C89B are designed to be direct replacements for the MC1489A and MC1489. Both devices meet all EIA–232 specifications and also the faster EIA–562 and CCITT V.28 specifications. Noise pulse rejection circuitry eliminates the need for most response control filter capacitors but does not exclude the possibility as filtering is still possible at the Response Control (RC) pins. Also, the Response Control pins allow for a user defined selection of the threshold voltages. The MC14C89AB and MC14C89B are manufactured with a bipolar technology using low power techniques and consume at most 700 µA, plus load currents with a +5.0 V supply.

Outputs

The output low or high voltage depends on the state of the inputs, the load current, the bias of the Response Control pins, and the supply voltage. Table 1 applies to each receiver, regardless of how many other receivers within the package are supplying load current.

Table 1. Function Table

Receivers

Input*	Output*
H	L
L	H

*The asterisk denotes A, B, C, or D.

Receiver Inputs and Response Control

The receiver inputs determine the state of the outputs in accordance with Table 1. The nominal V_{IL} and V_{IH} thresholds are 0.95 V and 1.90 V respectively for the MC14C89AB. For the MC14C89B, the nominal V_{IL} and V_{IH} thresholds are 0.95 and 1.30, respectively. The inputs are able to withstand ±30 V referenced to ground. Should the input voltage exceed ground by more than ±30 V, excessive currents will flow at the input pin. Open input pins will generate a logic high output, but good design practices dictate that inputs should never be left open.

The Response Control (RC) pins are coupled to the inputs through a resistor string. The RC pins provide for adjustment of the threshold voltages of the IC while preserving the amount of hysteresis. Figure 10 shows a typical application to adjust the threshold voltages. The RC pins also provide access to an internal resistor string which permits low pass filtering of the input signal within the IC. Like the input pins, the RC pins should not be taken above or below ground by more than ±30 V or excessive currents will flow at these pins. The dependence of the low level threshold voltage (V_{IL}) upon R_{RC} and V_{bat} can be described by the following equation:

$$V_{IL} \simeq \left\{ V_{0.09} - V_{bat}\left[\frac{505\ \Omega}{R_{RC}\ (1.6)\ +\ 2.02\ k\Omega}\right]\right\}\left(\frac{5.32\ k\Omega + \dfrac{6.67 \times 10^{6}\ \Omega^{2}}{R_{RC}}}{505\ \Omega}\right) \qquad (1)$$

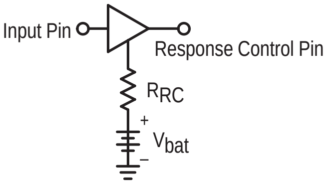
V_{IH} can be found by calculating for V_{IL} using equation (1) then adding the hysteresis for each device (0.35 for the MC14C89B or 0.95 V for the MC14C89AB). Figure 7 plots equation (1) for two values of V_{bat} and a range of R_{RC}.

If an RC pin is to be used for low pass filtering, the capacitor chosen can be calculated by the equation,

$$C_{RC} \simeq \frac{1}{2.02\ k\Omega\ 2\pi\ f_{-3dB}} \qquad (2)$$

where $f_{-3\,dB}$ represents the desired –3 dB role–off frequency of the low pass filter.

Figure 9. Application to Adjust Thresholds



Another feature of the MC14C89AB and MC14C89B is input noise rejection. The inputs have the ability to ignore pulses which exceed the V_{IH} and V_{IL} thresholds but are less than 1.0 µs in duration. As the duration of the pulse exceeds 1.0 µs, the noise pulse may still be ignored depending on its amplitude. Figure 8 is a graph showing typical input noise rejection as a function of pulse amplitude and pulse duration. Figure 8 reflects data taken for an input with an unconnected RC pin and applied to the MC14C89AB and MC14C89B.

Operating Temperature Range

The ambient operating temperature range is listed as –40°C to +85°C, and the devices are designed to meet the EIA–232–E, EIA–562 and CCITT V.28 specifications over this temperature range. The timing characteristics are guaranteed to meet the specifications at +25°C. The maximum ambient operating temperature is listed as +85°C. However, a lower ambient may be required depending on system use (i.e., specifically how many receivers within a package are used), and at what current levels they are operating. The maximum power which may be dissipated within the package is determined by:

$$P_{D(max)} = \frac{T_{J(max)} - T_{A}}{R_{\theta JA}}$$

where: $R_{\theta JA}$ = thermal resistance (typ., 100°C/W for the DIP and 125°C/W for the SOIC packages);
$T_{J(max)}$ = maximum operating junction temperature (150°C); and
T_{A} = ambient temperature.
$P_{D} = \{[(V_{CC} - V_{OH}) \times |I_{OH}|]$ or $[(V_{OL}) \times |I_{OL}|]\}_{\text{each receiver}} + (V_{CC} \times I_{CC})$

where: V_{CC} = positive supply voltage;
V_{OH}, V_{OL} = measured or estimated from Figure 2 and 3;
I_{CC} = measured quiescent supply current.

As indicated, the first term (in brackets) must be calculated and summed for each of the four receivers, while the last term is common to the entire package.

MOTOROLA

Quad Open-Collector Bus Transceiver

This quad transceiver is designed to mate Schottky TTL or NMOS logic to a low impedance bus. The Enable and Driver inputs are PNP buffered to ensure low input loading. The Driver (Bus) output is open–collector and can sink up to 100 mA at 0.8 V, thus the bus can drive impedances as low as 100 Ω. The receiver output is active pull–up and can drive ten Schottky TTL loads.

An active–low $\overline{\text{Enable}}$ controls all four drivers allowing the outputs of different device drivers to be connected together for party–line operation. The line can be terminated at both ends and still give considerable noise margin at the receiver. Typical receiver threshold is 2.0 V.

Advanced Schottky processing is utilized to assure fast propagation delay times. Two ground pins are provided to improve ground current handling and allow close decoupling between V_{CC} and ground at the package. Both ground pins should be tied to the ground bus external to the package.

- Driver Can Sink 100 mA at 0.8 V (Maximum)
- PNP Inputs for Low–Logic Loading
- Typical Driver Delay = 10 ns
- Typical Receiver Delay = 10 ns
- Schottky Processing for High Speed
- Inverting Driver

MC3448A

Quad Bidirectional Instrumentation Bus (GPIB) Transceiver

This bidirectional bus transceiver is intended as the interface between TTL or MOS logic and the IEEE Standard Instrumentation Bus (488–1978, often referred to as GPIB). The required bus termination is internally provided.

Each driver/receiver pair forms the complete interface between the bus and an instrument. Either the driver or the receiver of each channel is enabled by its corresponding Send/Receive input with the disabled output of the pair forced to a high impedance state. An additional option allows the driver outputs to be operated in an open collector* or active pull–up configuration. The receivers have input hysteresis to improve noise margin, and their input loading follows the bus standard specifications.

- Four Independent Driver/Receiver Pairs
- Three–State Outputs
- High Impedance Inputs
- Receiver Hysteresis – 600 mV (Typical)
- Fast Propagation Times – 15 to 20 ns (Typical)
- TTL Compatible Receiver Outputs
- Single 5.0 V Supply
- Open Collector Driver Output Option*
- Power Up/Power Down Protection (No Invalid Information Transmitted to Bus)
- No Bus Loading When Power Is Removed From Device
- Terminations Provided: Termination Removed When Device is Unpowered

* Selection of the “Open Collector” configuration, in fact, selects an open collector device with a passive pull–up load/termination which conforms to Figure 7, IEEE 488–1978 Bus Standard.

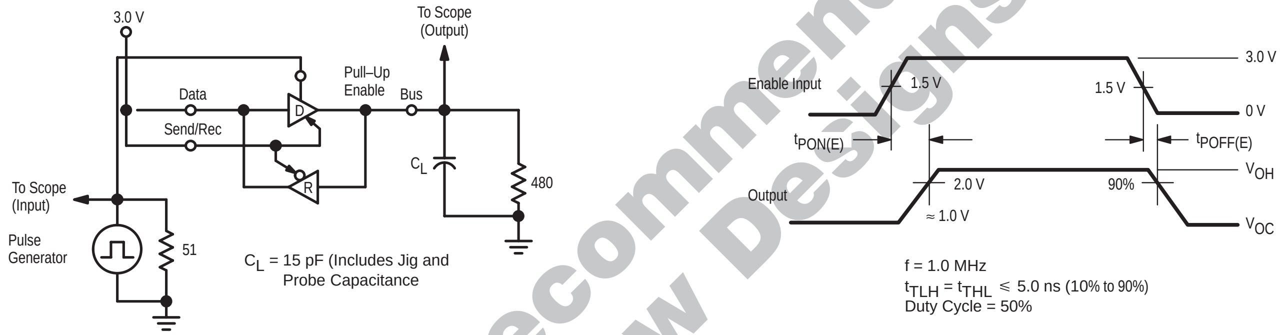

Figure 6. Typical Receiver Hysteresis Characteristics

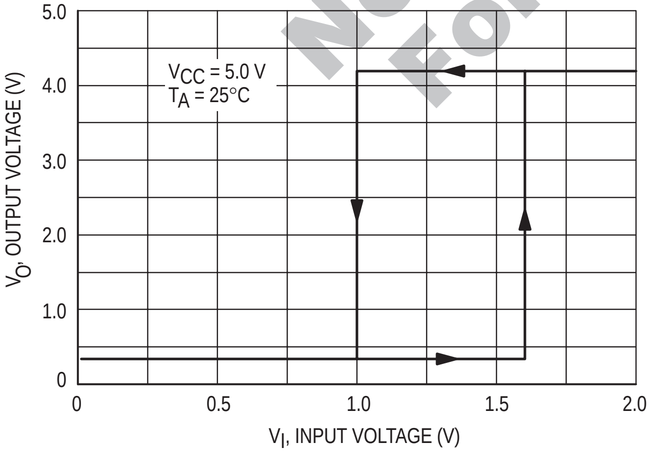

Figure 7. Typical Bus Load Line

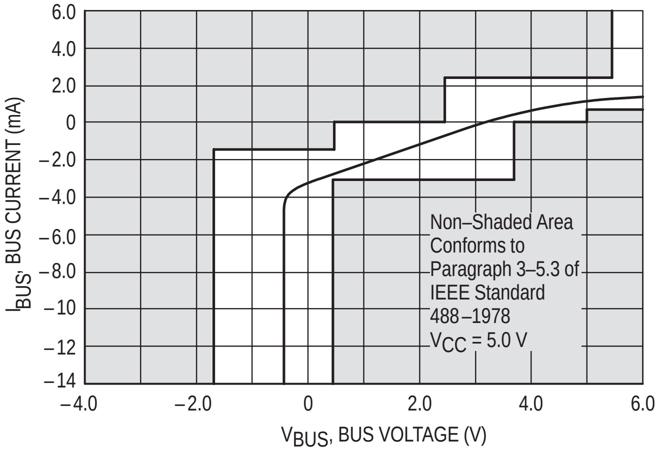

Figure 8. Simple System Configuration

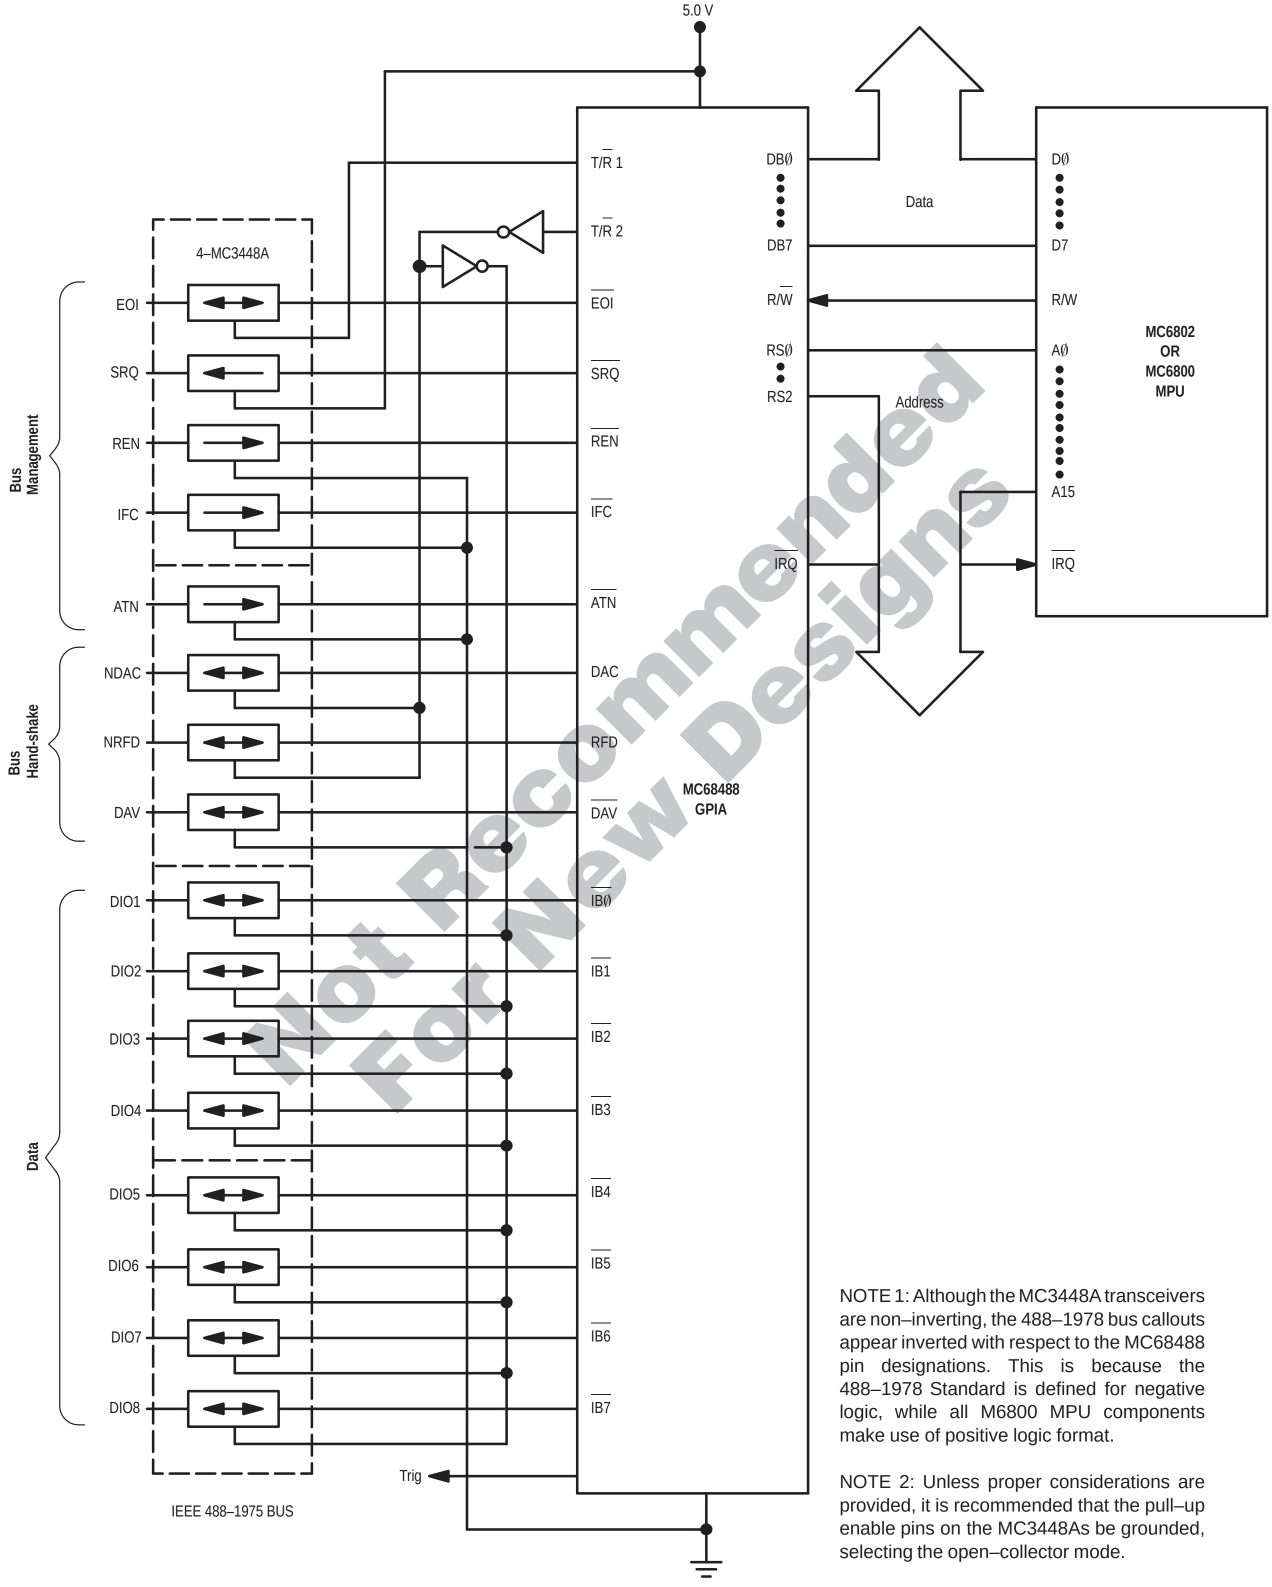

NOTE 1: Although the MC3448A transceivers are non–inverting, the 488–1978 bus callouts appear inverted with respect to the MC68488 pin designations. This is because the 488–1978 Standard is defined for negative logic, while all M6800 MPU components make use of positive logic format.

NOTE 2: Unless proper considerations are provided, it is recommended that the pull–up enable pins on the MC3448As be grounded, selecting the open–collector mode.

MOTOROLA

Quad MTTL Compatible Line Receivers

MC3450

QUAD LINE RECEIVERS WITH COMMON THREE–STATE STROBE INPUT

SEMICONDUCTOR TECHNICAL DATA

The MC3450 features four MC75107 type active pullup line receivers with the addition of a common three–state strobe input. When the strobe input is at a logic zero, each receiver output state is determined by the differential voltage across its respective inputs. With the strobe high, the receiver outputs are in the high impedance state.

The strobe input on both devices is buffered to present a strobe loading factor of only one for all four receivers and inverted to provide best compatability with standard decoder devices.

- Receiver Performance Identical to the Popular MC75107/MC75108 Series
- Four Independent Receivers with Common Strobe Input
- Implied “AND” Capability with Open Collector Outputs
- Useful as a Quad 1103 type Memory Sense Amplifier

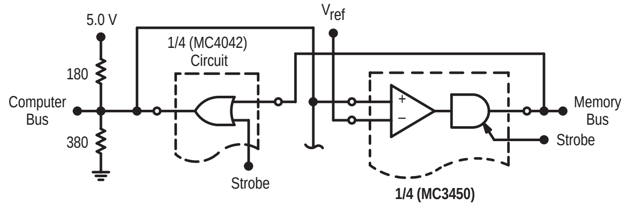
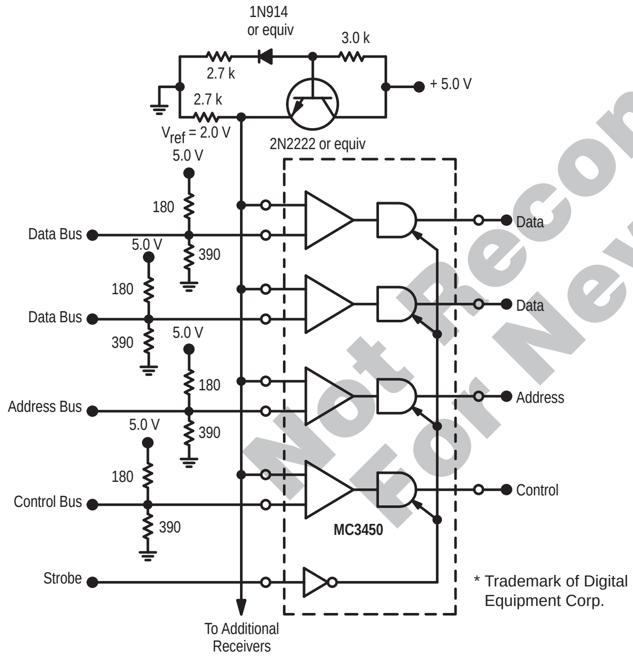
APPLICATIONS INFORMATION

Figure 12. Bidirectional Data Transmission



The three–state capability of the MC3450 permits bidirectional data transmission as illustrated.

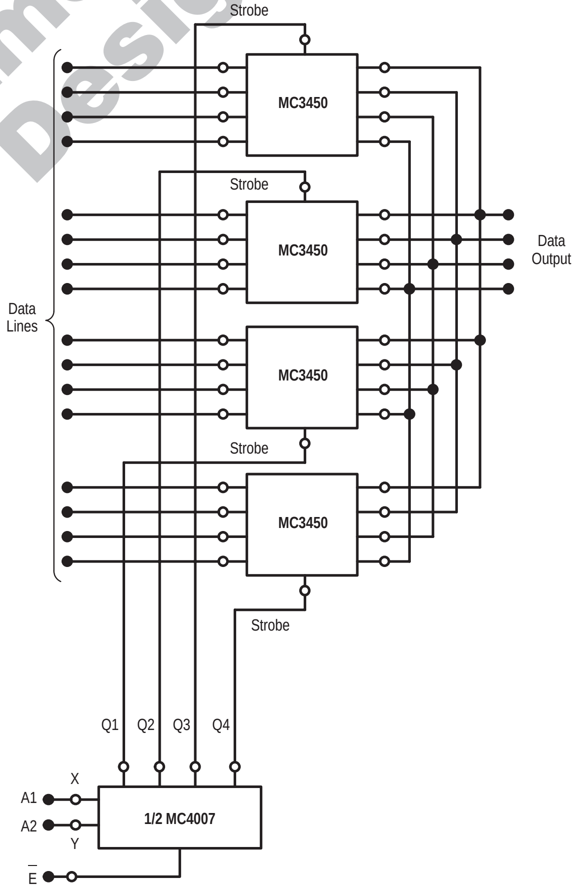
Figure 13. Single–Ended Uni–Bus™ Line Receiver Application for Minicomputer



* Trademark of Digital Equipment Corp.

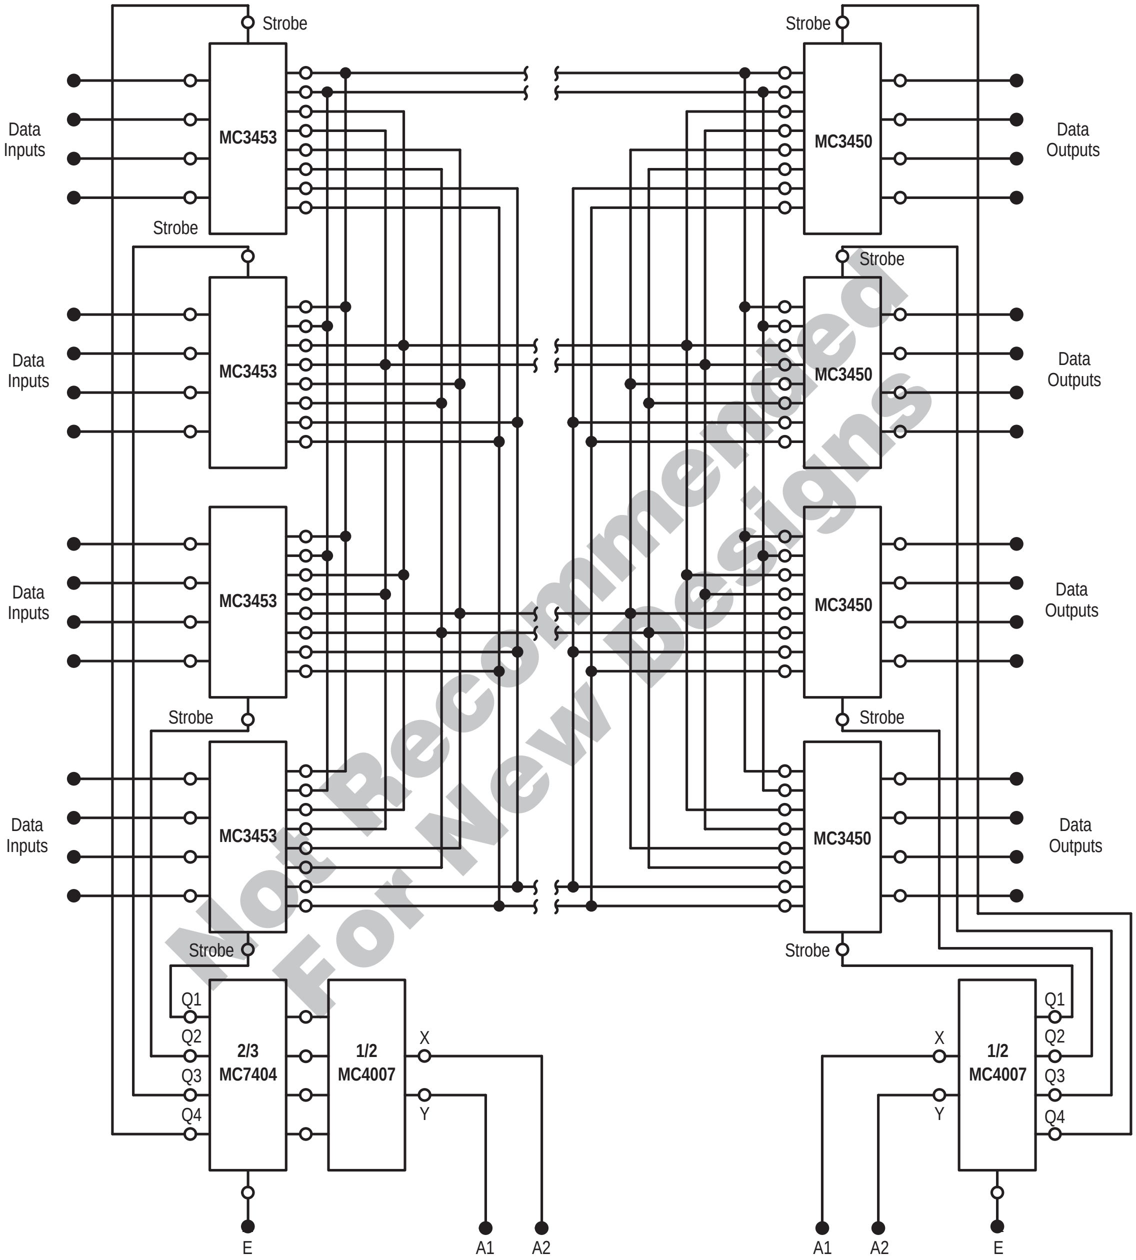
The MC3450 can be used for single–ended as well as differential line receiving. For single–ended line receiver applications, such as are encountered in minicomputers, the configuration shown in Figure 15 can be used. The voltage source, which generates V_{ref}, should be designed so that the V_{ref} voltage is halfway between V_{OH}(min) and V_{OL}(max). The maximum input overdrive required to guarantee a given logic state is extremely small, 25 mV maximum. This low–input overdrive enhances differential noise immunity. Also the high–input impedance of the line receiver permits many receivers to be placed on a single line with minimum load effects.

Figure 14. Wired “OR” Data Selection Using Three–State Logic



APPLICATIONS INFORMATION (continued)

Figure 15. Party–Line Data Transmission System with Multiplex Decoding



MOTOROLA

MC3453

MTTL Compatible Quad Line Driver

The MC3453 features four SN75110 type line drivers with a common inhibit input. When the inhibit input is high, a constant output current is switched between each pair of output terminals in response to the logic level at that channel′s input. When the inhibit is low, all channel outputs are nonconductive (transistors biased to cut–off). This minimizes loading in party–line systems where a large number of drivers share the same line.

- Four Independent Drivers with Common Inhibit Input
- – 3.0 V Output Common–Mode Voltage Over Entire Operating Range
- Improved Driver Design Exceeds Performance of Popular SN75110

MC3467

Triple Wideband Preamplifier with Electronic Gain Control (EGC)

TRIPLE MAGNETIC TAPE MEMORY PREAMPLIFIER

SEMICONDUCTOR TECHNICAL DATA

The MC3467 provides three independent preamplifiers with individual electronic gain control in a single 18–pin package. Each preamplifier has differential inputs and outputs allowing operation in completely balanced systems. The device is optimized for use in 9–track magnetic tape memory systems where low noise and low distortion are paramount objectives.

The electronic gain control allows each amplifier′s gain to be set anywhere from essentially zero to a maximum of approximately 100 V/V.

- Wide Bandwidth – 15 MHz (Typical)
- Individual Electronic Gain Control
- Differential Input/Output

MOTOROLA

MC3481
MC3485

Quad Single-Ended Line Drivers

IBM 360/370 QUAD LINE DRIVERS

SEMICONDUCTOR TECHNICAL DATA

The MC3481 and MC3485 are quad single–ended line drivers specifically designed to meet the IBM 360/370 I/O specification (GA22–6974–3).

Output levels are guaranteed over the full range of output load and fault conditions. Compliance with the IBM requirements for fault protection, flagging, and power up/power down protection for the bus make this an ideal line driver for party line operations.

- Separate Enable and Fault Flags – MC3481
- Common Enable and Fault Flag – MC3485
- Power Up/Down Does Not Disturb Bus
- Schottky Circuitry for High–Speed – PNP Inputs
- Internal Bootstraps for Faster Rise Times
- Driver Output Current Foldback Protection
- MC3485 has LS Totem Pole Driver Output

Ratio of Propagation Delay Times As I/O Driver	$\frac{t_{PLH(D)}}{t_{PHL(D)}}$	–	1.0	–	

NOTES: 1. Reference IBM specification GA22–6974–3 for test terminology.
2. The fault protection circuitry of the MC3481 and MC3485 requires relatively clean input voltage waveforms for current operation. Noise pulses which enter the threshold region (0.8 to 2.0 V) may cause the output to enter the fault protect mode. To exit the protect mode, it is necessary to gate an input of the effected driver to the low logic state.

MOTOROLA

MC3488A

Dual EIA-423/EIA-232D Line Driver

The MC3488A dual is single–ended line driver has been designed to satisfy the requirements of EIA standards EIA–423 and EIA–232D, as well as CCITT X.26, X.28 and Federal Standard FIDS1030. It is suitable for use where signal wave shaping is desired and the output load resistance is greater than 450 ohms. Output slew rates are adjustable from 1.0 µs to 100 µs by a single external resistor. Output level and slew rate are insensitive to power supply variations. Input undershoot diodes limit transients below ground and output current limiting is provided in both output states.

The MC3488A has a standard 1.5 V input logic threshold for TTL or NMOS compatibility.

- PNP Buffered Inputs to Minimize Input Loading
- Short Circuit Protection
- Adjustable Slew Rate Limiting
- MC3488A Equivalent to 9636A
- Output Levels and Slew Rates are Insensitive to Power Supply Voltages
- No External Blocking Diode Required for V_{EE} Supply
- Second Source µA9636A

MOTOROLA

IEEE 802.3 10BASE-T Transceiver

The Motorola 10BASE–T transceiver, designed to comply with the ISO 8802–3 [IEEE 802.3] 10BASE–T specification, will support a Medium Dependent Interface (MDI) in an embedded Media Attachment Unit (MAU)*. The interface supporting the Data Terminal Equipment (DTE) is TTL, CMOS, and raised ECL compatible, and the interface to the Twisted Pair (TP) media is supported through standard 10BASE–T filters and transformers. Differential data intended for the TP media is provided a 50 ns pre–emphasis and data at the TP receiver is screened by Smart Squelch circuitry for specific threshold, pulse width, and sequence requirements.

Other features of the MC34055 include: Collision and Jabber detection status outputs, select mode pins for forcing Loop Back and Full–Duplex operation, a Signal Quality Error pin for testing the collision detect circuitry without affecting the TP output, and a LED driver for Link Integrity status. An on–chip oscillator, capable of receiving a clock input or operating under crystal control, is also provided for internal timing and driving a buffered clock output.

The MC34055 is manufactured on a BiCMOS process and is packaged in a 24 pin SOIC.

- BiCMOS Technology for Low Power Operation
- Standard 5.0 V, ± 5% Voltage Supply
- Smart Squelch Enforcement of Threshold, Pulse Width, and Sequence Requirements
- Driver Pre–Emphasis for Output Data
- TTL, CMOS and Raised ECL Compatible
- Interfaces to TP Media with Standard 10BASE–T Filters and Transformers
- LED Capable Status Outputs for Collision, Jabber Detection, and Link Integrity
- Directly Driven or Crystal Controlled Clock Oscillator
- Selectable Full–Duplex Operation
- Signal Quality Error Test Pin
- Selectable Loop Back

MAXIMUM RATINGS (T_A = 25°C, unless otherwise noted.)

Rating	Symbol	Value	Unit
Power Supply Voltage	V_{CC}	– 0.5 to 7.0	Vdc
Differential Voltage at RX+/RX–	V_{ID}	– 5.25 to 5.25	Vdc
Voltage Applied to Logic and Mode/Test Select Inputs		– 0.5 to 5.5	Vdc
Voltage Applied to Logic Outputs and Output Status Pins		– 0.5 to 7.0	Vdc
Ambient Operating Temperature Range	T_A	0 to 70	°C
Junction Temperature	T_J	– 65 to 150	°C

NOTE: Devices should not be operated at these limits. The “Recommended Operating Conditions” table provides for actual device operation.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Description
1	Clk Out	TTL/CMOS buffered 10 MHz clock output. This pin will source 400 µA and sink 16 mA.
2	TX Data A	CMOS transmit input pin. Data input at this pin is output to the TP media. The input will source less than 175 µA and sink less than 20 µA.
3	TX Data B	Raised ECL transmit input pin. Data input at this pin is output to the TP media. The input can source 40 µA for a high level input or 70 µA for a low level input.
4	TX EN H	TTL/CMOS transmit enable pin. Transmit is enabled when asserted high. The input will source less than 175 µA and sink less than 20 µA.
5	Dig. Gnd	Digital ground
6	V_{CC}(Dig/Ana)	Digital and analog V_{CC}. With the current consumed at this pin and Pin 18, the device will consume less than 180 mA at 5.0 Vdc.
7	Ana. Gnd	Analog ground
8	RX Data A	TTL/CMOS received data output pin. Data from the TP media is output at this pin. The output will source 12 mA and sink 16 mA.
9	RX Data B	Raised ECL received data output pin. Data from the TP media is output at this pin.
10	RX EN H	TTL/CMOS received data output enable pin. This pin is asserted after the Smart Squelch circuitry determines that there is valid data at the TP input pins and also when internal loop–back is occurring. The output will source 12 mA and sink 16 mA. The receive data outputs are forced high when this pin is low.
11	Loop L	TTL/CMOS Loopback test select. Asserting this pin causes the transmit data to be looped to the receive circuit while the TP transmit driver sends a link pulse. The input will source less than 175 µA and sink less than 20 µA.
12	LNKFL H	This pin is driven high to indicate a link fail state. When low, the pin will sink 20 mA to light an LED. An usquelched condition due to valid data on the receive circuit will cause the pin to transition high and low in 100 ms intervals.
13	JABB H	TTL/CMOS Jabber status pin. This pin is asserted when a Jabber condition is detected and will source 12 mA and sink 16 mA.
14	CTL H	TTL/CMOS status pin. This pin pulled high when Jabber or Collision conditions are detected. Also high for a time interval when a Signal Quality Error test is being performed. The pin will source 12 mA and sink 16 mA.
15	RX–	The inverting terminal of the TP differential receiver.
16	RX+	The noninverting terminal of the TP differential receiver.
17	FULLD L	TTL/CMOS duplex mode select. When low, this pin forces the device to operate in full–duplex mode. The input will source less than 175 µA and sink less than 20 µA.
18	Pwr V_{CC}	Power supply pin. With the current consumed at this pin and Pin 6, the device will consume less than 180 mA at 5.0 Vdc.
19	Pwr Gnd	Power ground pin.
20	TX–	The inverting terminal of the TP differential driver.
21	TX+	The noninverting terminal of the TP differential driver.
22	SQE EN L	TTL/CMOS Signal Quality Error test enable pin. Pulling this pin low allows test of the collision detect circuitry without affecting the twisted pair channel. The input will source less than 175 µA and sink less than 20 µA.
23	Clk–	TTL/CMOS clock oscillator pin. See Pin 24.
24	Clk+	TTL/CMOS clock oscillator pin. This pin is used with Pin 23 if the internal oscillator is to be free run with a crystal. The oscillator can also be directly driven with a TTL/CMOS clock signal at this pin. The oscillator frequency should be 10 MHz with a duty cycle of 50 ± 20%.

FUNCTIONAL DESCRIPTION

Introduction

The Motorola 10BASE–T transceiver, designed to comply with the ISO 8802–3[IEEE 802.3] 10BASE–T specification, will support one Medium Dependent Interface (MDI) through standard 10BASE–T filters and transformers. Although the device is capable of being used in embedded or external Medium Attachment Units (MAU), it was primarily designed for use in repeater or hub applications. For this reason a digital interface is provided rather than an AUI interface. This interface is TTL, CMOS, and raised ECL compatible and allows for easy connection in hub applications.

Other features of the MC34055 include: select mode pins of forcing Loop–Back and Full–Duplex operation; a Signal Quality Error pin for testing the collision detect circuitry without affecting the twisted pair output; and LED drivers for Link Integrity status; Collision detection; and Jabber detection. An on chip oscillator, capable of receiving a clock input or operating under crystal control, is also provided for internal timing and driving a buffered clock output.

Data Transmission

For data intended for the twisted pair, the MC34055 has two data inputs, TX Data A and TX Data B. TX Data A is CMOS compatible and TX Data B is raised ECL compatible. The inputs were not intended to be used simultaneously in a single application and are internally logically combined. The unused input should be disabled by connection to V_{CC}.

When data transmission is intended, the MC34055 detects the first falling edge of the Manchester encoded frame at the input being used, synchronizes the on chip oscillator (Pins 23 and 24) and asserts the twisted pair driver output to full differential amplitude within 25 ns if the driver enable pin (TX EN H) is previously asserted. Also, since twisted pair attenuates a 10 MHz signal more than a 5.0 MHz signal the 10BASE–T standard requires that data applied to the twisted pair receive pre–equalization. To fulfill this requirement the MC34055 provides an additional 730 mV for approximately 50 ns to output data. This is accomplished over the single pair of differential driver pins. TX+ and TX–, and effectively equalizes the power of all data components at the receiver. Figure 7A shows a 10 MHz waveform. Figure 7B shows the effect of pre–emphasis on a 5.0 MHz waveform. Manchester encoded data with the pattern shown in Figure 7A would represent a repeating pattern of zeros (000000...). Figure 7B would represent an alternating pattern of ones and zeros (0101010...).

Figure 7A. 10 MHz Waveform on Differential Outputs

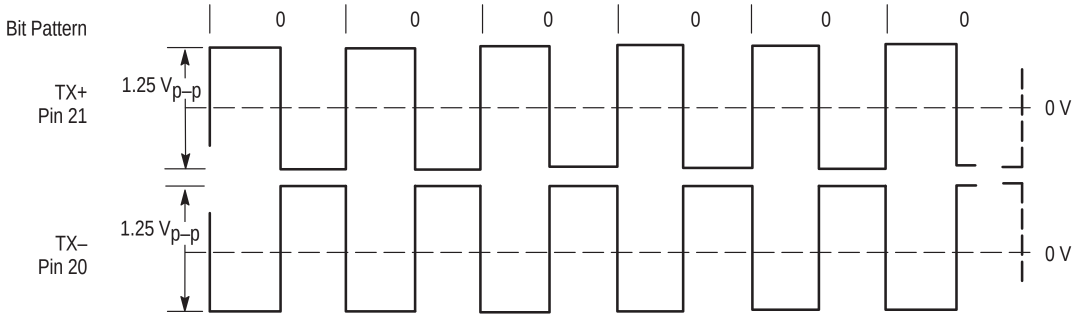

Figure 7B. 5.0 MHz Waveform on Differential Outputs

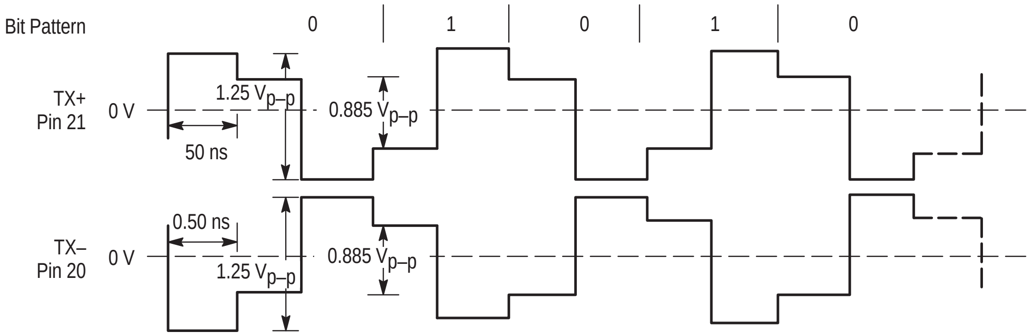


The figures show the voltage waveforms on the differential driver output pins. To actually meet the 10BASE–T specification requires bandpass filtering and a pulse transformer.

The output voltage waveform specifications of the IEEE 802.3 standard require that voltages impressed on the twisted pair meet a voltage template. The MC34055 can meet the voltage template for all the 10BASE–T applications by choosing the appropriate low pass filter and external components in the driver output circuitry. When the differential transmit driver output pins are configured to drive the bandpass filters and pulse transformer as shown in Figure 8, the resultant waveform is capable of meeting the voltage template.

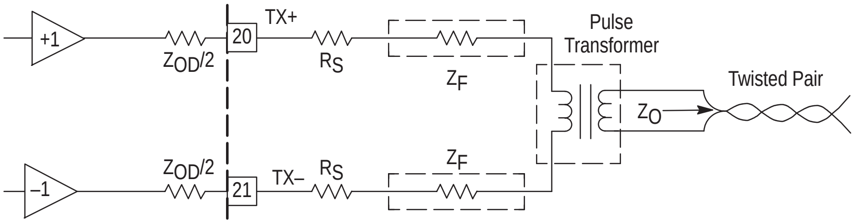
Following the end–of–frame activity, an internal pull–up resistor pulls TX Data A/B high and causes the differential driver to maintain full differential output voltage for approximately 250 ns. The differential driver interprets the lack of transition activity as an end of frame and starts an idle timer. Should another frame intended for the twisted pair arrive before the idle timer expires(~250 ns), the idle timer will be reset, if not, the transmit driver function will begin the decay to idle process. During idle periods the differential driver must force the media to a minimal differential voltage unless a link beat is being produced. The transition to minimal voltage is subject to performance requirements in the IEEE specification and is met by the MC34055 when the appropriate filters and transformers are used to interface to the media.

The MC34055 differential driver generates link pulses (beats) during idle periods. The link pulses produced are singular positive (TX+ positive with respect to TX–) pulses applied to the media at 16 ms intervals and last approximately 100 ns. The link pulses allow the receiver at the other end of the link to verify the validity of the segment. There is the possibility, due to the two asynchronous sources, that one of the two input pins (TX Data A or TX Data B) will receive frame activity immediately after a link pulse is initiated. In this event, the transmit differential driver will remain active for the entire frame interval and the link pulse will not affect more than one bit interval.

The MC34055 also has Jabber circuitry to detect and disable the twisted pair driver in the event that a serial controller fails constantly transmitting. Should any data source try to transmit longer than 20 ms minimum, the Jabber function will disable the differential driver outputs, the collision presence detector and the internal loopback function. Also, two status indicator pins, CTL H and JABB H are asserted. The MC34055 will remain in the jabber state until the TX EN H pin is pulled low or the jabbering input ceases to toggle for a minimum of 500 ms. The status indicator pins, CTL H and JABB H will also sink up to 20 mA and can therefore support external LEDs.

The driver also works with the receiver to provide loop–back. Under normal operating conditions (Loop L= “1”), the data applied to the TX Data A/B pins is looped back internally to the RX Data A/B pins. This function is disabled when there is a collision condition or FULLD L is low.

Figure 8. Differential Driver Media Interface Circuitry

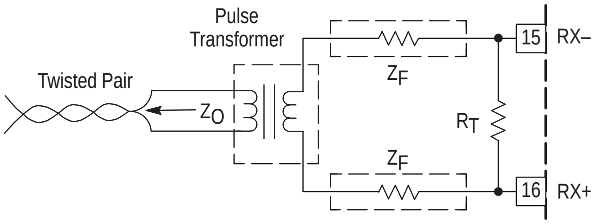


Where: Z_{OD} is the transmitters differential output impedance (~20 Ω),
R_S is a 1% series resistor,
Z_F is the filters impedance, and Z_O is the characteristic impedance of the twisted pair (100 Ω).

Data Reception

Data intended for the DTE proceeds from the twisted pair to the isolation transformer and bandpass filters before reaching the differential receiver terminals. Figure 9 shows the configuration of the external media receive circuitry. Once transitions at the receiver terminals (RX+ and RX–) are detected, the on–chip oscillator is synchronized and the received data is screened by smart squelch circuitry for validity. This qualification requires incoming data to meet amplitude and sequence requirements. If the data meets the Smart Squelch requirements, the receiver enters the unsquelch state and the data is forwarded to the RX Data A/B output pins provided Loop L is not low. Two data outputs are provided to increase design flexibility, RX Data A and RX Data B. RX Data A is CMOS/TTL compatible and RX Data B is raised ECL compatible.

Figure 9. Differential Receiver Media Interface Circuitry



Where: R_T is a terminating resistor (100 Ω), Z_F is the filters impedance, and Z_O is the characteristic impedance of the twisted pair (100 Ω).

The MC34055 powers up in a squelched and “link OK” state, after which minimum and maximum link test and maximum link fail timers are started. If valid data or a link pulse is received after the link test minimum timer but before the link fail maximum timer times out, the timers are reset and begin counting again. In the event of missing or incorrect link pulses, the MC34055 enters the link fail state whereby the LNKFL H status pin is asserted until valid data or link pulse activity appears at the receiver terminals.

Powering up in the squelched state assures that the data path to the data output pin (RX Data A/B) is disabled, and prevents noise at the receiver terminals (RX+/RX–), from being interpreted as valid input data. Once transitions appear at the receiver terminals, the smart squelch circuitry checks for the smart squelch requirements to unsquelch; an alternating sequence (1010... or 0101...) of pulses with amplitude of at least 525 mV. This requirement is met by the preamble of an IEEE 802.3 frame with good signal to noise ratio.

After a pulse is received and checked for proper polarity and amplitude, the pulse width is checked for proper duration. If the duration is to short or too long the smart squelch circuitry resets and begins to look again for a proper sequence. By requiring the differential pulses to meet amplitude and sequence requirements, it is unlikely that pulses due to crosstalk from coresident twisted pairs are capable of causing the receiver to unsquelch. If a positive pulse is received first and the differential driver is not transmitting, the receiver should unsquelch after three alternating pulses. If a negative pulse is received first, one additional pulse is required before unsquelch. If the differential driver is transmitting, three additional pulses are required to unsquelch.

After meeting the smart squelch requirements, the MC34055 will pull high the RX EN H pin and enable the path to the receive data pin (RX Data A/B) provided the MC34055 is not in the loop back test mode (Loop L low). If the receiver unsquelches, the receive enable pin remains high and the data path to the receive data pin remains enabled until transitions cease to exist at the receiver terminals. Valid data reception is also indicated by high/low transitions of the LNKFL H pin at 100 ms intervals. When transitions at the differential terminals cease, marking the end of frame activity, the receiver re–enters the squelch state, pulls low on the RX EN H pin, and begins accepting valid link pulses until the start of the next 802.3 frame.

If the MC34055 is requested to begin transmitting (TX EN H is asserted), and the receiver unsquelches simultaneously, there is a collision. Also, if the MC34055 driver enable pin is previously asserted and the receiver detects valid transition activity, the receiver Smart Squelch circuitry verifies the possibility of collision by requiring three extra transitions at the differential receiver before the unsquelch condition is reached. If unsquelch occurs, a collision condition exists. During all collision conditions the MC34055 asserts the CTL H status pin for the duration of the condition and for a time after the end of collision.

During a collision condition the receive and transmit paths are still both enabled allowing transparency to the media. Either the presence of simultaneous transmit and receive activity or the condition of the CTL H status pin can be used by the communications controller to acknowledge and react to the collision. In applications where a 10 MHz collision signal is required by an SIA, the combination of this status pin and the clock oscillator output can be logically combined to provide a 10 MHz output. If the DTE reacts to the collision and ceases transmitting, the MC34055 will decay to idle until a re–transmit is attempted.

Crystal Oscillator

The MC34055 has an on–chip clock oscillator used to provide a reliable and accurate time reference to all the internal timers. The oscillator can be run with a crystal or driven at Pin 24 from an external clock source. Also provided is a buffered clock output which is useful if the MC34055 is to be used in a repeater or concentrator application.

Table 1. The crystal used in the oscillator is subject to the following specifications.

Crystal Operating Mode	Fundamental
Crystal Cut Type	AT
Crystal External Shunt Capacitance	7.0 pF Max
Crystal Resonant Mode	Series
Crystal Accuracy	± 0.01% @ 25°C
Crystal Temperature Variance	0.005% from 0° to 70°C
Crystal Series Resistance	25 Ω Max, 17 Ω Typical
Crystal Operating Temperature Range	0° to 70°C

LOOP L Test Mode

If the Loop L pin is low, the MC34055 is in a test mode whereby the data at the input pin (TX Data A/B) is being looped back internally to the receive data pin(RX Data A/B). In this mode the data path from the differential receiver terminals to the receive data output pins (RX Data A/B) is disconnected while the Smart Squelch functionality of the differential receiver is still operational. This test mode allows the DTE to test the MC34055 internal loop back circuitry since the data is looped back to the receive circuitry as close to the twisted pair interface as possible.

Signal Quality Error Test

The MC34055 also provides the ability to test the collision detect circuitry without disabling either of the data paths. By pulling the SQE EN L pin low, a collision test is provided to the collision detect circuitry immediately following the last edge of a transmitted 802.3 frame. The test verifies the operability of the collision detect circuitry, operability is announced by the assertion of the CTL H pin for a period following a valid data transmission.

Jabber Detection

The transmit circuitry of the MC34055 has the ability to monitor and shut down the differential driver in the event of a jabber condition. If transmission activity ever exceeds 20 ms minimum, the differential driver, the collision detect, and internal loop back circuits are disabled. To announce the presence of a jabber condition, both the CTL H and the JABB H status output pins are asserted. In order to end the jabber condition, the TX Data A/B input must stop toggling, or the TX EN H pin must be pulled low for a minimum of 500 ms. The status output pins have the ability to drive an external led and were added to facilitize network manageability. The jabber status outputs will not assert during power up or power down.

Full Duplex Mode

The MC34055 can be operated in a full–duplex mode if required. When the FULLD L pin is pulled low the device will enter the full duplex mode. This mode allows the transmitter and driver to operate independently. Collision will not be announced and the internal loop back operation is disabled. The Signal Quality Error test, however, is still operational if enabled.

Status Pins

The MC34055 has three status indicator pins capable of sourcing or sinking enough current to support an external LED. Status pin levels (“1” or “0”) report the condition of the transceiver. Table 2 shows the combinations and significance.

Table 2

Status Pin			Condition
JABB H	**CTL H**	**LNKFL H**	
“0”	“1”	X	Collision condition or Signal Quality Error test.
“1”	“1”	X	Jabber condition
X	X	“0”	Link Failure. Incorrect or nonexistent link pulses, or lack of data at the receiver terminals.
X	X	“1”	Link “OK”. Receiving link pulses.
X	X	“0101…”	Link “OK”. Receiving valid data.

Test Select Pins

The MC34055 has three operation mode test select pins, Loop L, SQE EN L and FULLD L. The level of the pin determines the mode of operation. Table 3 shows the levels and corresponding conditions of the status pins.

Table 3

Pin	Status	Condition
Loop L	“1”	Normal operating mode. Loop back occurs when the transmitter initiates and the receiver is receiving link pulses. The RX EN H pin follows the TX EN H pin and the transmit data appears on the RX Data A/B output pin being used.
	“0”	Loop back test mode. The transmit circuit is looped back internally as close to the differential receive circuit as possible. In this mode the RX EN H pin follows the TX EN H pin and the transmit data appears on the RX Data A/B output pin being used. Any received data other than link pulses are ignored and the receiver will not unsquelch or announce collision.
SQE EN L	“0”	Normal operating mode. Concurrent transmit and receive activity results in a collision condition.
	“1”	Test enabled. An internal test is run on the collision circuitry and the CTL H pin is asserted for a time window following the last positive packet edge. Data transmission and reception is undisturbed.
FULLD L	“1”	Normal operating mode. Internal loop–back is operable and collision is announced.
	“0”	Internal loop–back is disabled and collision will not be announced. Signal Quality Error test is still operable.

APPLICATIONS INFORMATION

The MC34055 implements the physical layer of a 10BASE–T application of IEEE 802.3. It provides the physical connection to the media (twisted pair) and the services required by the MAC sublayer of the Data Link Layer. Two interfaces are defined in the IEEE 802.3 specification of the physical layer; one is the MDI providing connection to the twisted pair; and the other is the AUI providing connection to the encoder/decoder function of the Data Link Layer. While the MC34055 provides the connection to the twisted pair, a CMOS and raised ECL interface is provided instead of an AUI.

The MC34055 implements the twisted pair interface of the physical layer in a 802.3 10BASE–T application but circuitry must be added if an AUI is desired, (see Figure 10 for suggested schematic). For example, an external MAU application requires the AUI and a twisted pair interface. A chip capable of realizing the AUI interface is the Texas Instruments SN75ALS085. This IC has an AUI interface and another interface which is compatible with the MC34055. The differential input of the 75ALS085 can be used for the TX+/TX– terminals of the AUI. The differential drivers of the 75ASL085 can be used as the RX+/RX– and the COL+/COL– terminals of the AUI. The other interface of the 75ALS085 then will interface to the MC34055 by three paths shown in the application suggestion. The application accounts for all the inputs/outputs of an external MAU.

Embedded applications do not require a full AUI and a MC10116 can be used to interface between the raised ECL interfaces of the MC34055 and the AUI of existing encoder/decoder chips. The MC10116 is a MECL 10k Triple Line Receiver with typical propagation delay and rise and fall times (20% to 80%) of 2.0 ns. Figure 11 shows the use of the MC10116 with the MC34055 and the AMD 7992 SIA.

In a multi–port repeater, or hub, a port is required for each DTE connected to the IEEE 802.3 network. This port consists of two connections, one for the TX+/TX– pair and another for the RX+/RX– pair. The repeater unit then multiplexes these lines so that all of the stations are capable of transmitting to or receiving from all the other stations on the network. This establishes the need for a transceiver without an AUI interface. If an AUI is present with each 10BASE–T transceiver, chip count is increased because there is a requirement to convert from balanced to unbalanced lines before multiplexing.

An application suggestion for the use of the MC34055 used in a multiport repeater is shown in Figure 6. Here the receive and transmit lines for the 10BASE–T transceivers are multiplexed by the hub hardware.

MOTOROLA

MC34058
MC34059

Hex EIA-485 Transceiver with Three-State Outputs

HEX EIA–485 TRANSCEIVER with THREE–STATE OUTPUTS

SEMICONDUCTOR TECHNICAL DATA

The Motorola MC34058/9 Hex Transceiver is composed of six driver/receiver combinations designed to comply with the EIA–485 standard. Features include three–state outputs, thermal shutdown for each driver, and current limiting in both directions. This device also complies with EIA–422 and CCITT Recommendations V.11 and X.27.

The devices are optimized for balanced multipoint bus transmission at rates to 20 MBPS (MC34059). The driver outputs/receiver inputs feature a wide common mode voltage range, allowing for their use in noisy environments. The current limit and thermal shutdown features protect the devices from line fault conditions.

The MC34058/9 is available in a space saving 7.0 mm 48 lead surface mount quad package designed for optimal heat dissipation.

- Meets EIA–485 Standard for Party Line Operation
- Meets EIA–422A and CCITT Recommendations V.11 and X.27
- Operating Ambient Temperature: 0°C to +70°C
- Common Mode Driver Output/Receiver Input Range: –7.0 to +12 V
- Positive and Negative Current Limiting
- Transmission Rates to 14 MBPS (MC34058) and 20 MBPS (MC34059)
- Driver Thermal Shutdown at 150°C Junction Temperature
- Thermal Shutdown Active Low Output
- Single +5.0 V Supply, ±10%
- Low Supply Current
- Compact 7.0 mm 48 Lead TQFP Plastic Package

Description

The MC34058/9 is a differential line driver designed to comply with EIA–485 Standard for use in balanced digital multipoint systems containing multiple drivers. The drivers also comply with EIA–422–A and CCITT Recommendations V.11 and X.27. Positive and negative current limiting of the drivers meet the EIA–485 requirement for protection from damage in the event that two or more drivers try to transmit simultaneously on the same cable. Data rates in excess of 10 MBPS are possible, depending on the cable length and cable characteristics. Only a single power supply, 5.0 V ±10% is required.

Driver Inputs

The driver inputs and enable logic determine the state of the outputs in accordance with Table 1. The driver inputs have a nominal threshold of 1.2 V, and the voltage must be kept within the range of 0 V to V_{CC} for proper operation. If the voltage is taken more than 0.5 V below ground or above V_{CC}, excessive currents will flow and proper operation of the drivers will be affected. An open Pin is equivalent to a logic high, but good design practices dictate that inputs should never be left open. The inputs are TTL type and their characteristics are unchanged by the state of the enable pins.

Driver Outputs

Each output (when active) will be a low or a high voltage, depending on the input state and the load current (see Tables 1, 2 and Figures 2 and 3). The graphs apply to each driver, regardless of how many other drivers within the package are supplying load current.

Table 1. Driver Truth Table

Driver Data Inputs	Enables		Outputs	
	DEX	**REX**	**OAX**	**OBX**
H	H	H	H	L
L	H	H	L	H
X	L	H	Z	Z
X	H	L	Not Defined	Not Defined

The outputs will be in a high impedance state when:
a) The Enable inputs are set according to Table 1;
b) The junction temperature exceeds the trip point of the thermal shutdown circuit. When in this condition, the output's source and sink capability are shut off, and a leakage current of less than 20 µA will flow. Disabled outputs may be taken to any voltage between –7.0 V and 12 V without damage to internal circuitry.

The drivers are protected from short circuits by two methods:
a) Current limiting is provided at each output, in both the source and sink direction, for shorts to any voltage within the 12 V to –7.0 V range, with respect to circuit ground. The short circuit current will flow until the fault is removed, or until the thermal shutdown activates. The current limiting circuit has a negative temperature coefficient and requires no resetting upon removal of the fault condition.
b) A thermal shutdown circuit disables the outputs when the junction temperature reaches +150°C, ± 20°C. The thermal shutdown circuit has a hysteresis of ~ 12°C to prevent oscillations. When this circuit activates, the output stage of each driver is put into the high impedance mode, thereby shutting off the output currents. However, the remainder of the internal circuitry remains biased and the outputs will become active once again as the IC cools down.

Receiver Inputs

The receiver inputs and enable logic determine the state of the receiver outputs in accordance with Table 2. Each receiver input pair has a nominal differential threshold of at most 200 mV (Pin OAX with respect to OBX) and a common mode voltage range of –7.0 V and 12 V must be maintained for proper operation. A nominal hysteresis of 100 mV is typical. The receiver input characteristics are shown in Figure 8. When the inputs are in the high impedance state, they remain capable of the common mode voltage range of –7.0 V to 12 V.

Receiver Outputs

The receiver outputs are TTL type outputs and act in accordance with Table 2.

Enable Logic

Each driver output is active when the Driver Enable input is true according to Table 1. Each receiver output is active when the Receiver Enable input is true according to Table 2.

The Enable inputs have a nominal threshold of 1.2 V and their voltage must be kept within the range of 0 V and V_{CC} for proper operation. If the voltage is taken more than 0.5 V below ground or above V_{CC}, excessive currents will flow and proper operation of the drivers will be affected. An open pin is equivalent to a logic high, but good design practices dictate that inputs should never be left open. The enable inputs are TTL compatible. Since the same pins are used for driver input and receiver output, care must be taken to make sure that DEX and $\overline{\text{REX}}$ are not both enabled. This may result in corruption of both the transmitted and received data.

Table 2. Receiver Truth Table

Receiver Data Inputs	Enables		Outputs
OAX–OBX	**DEX**	**$\overline{\text{REX}}$**	**DRX**
≥ +200 mV	L	L	H
≤ –200 mV	L	L	L
X	L	H	Z
X	H	L	Not Defined

APPLICATIONS

The MC34058/9 was designed to meet EIA/TIA–422 and EIA/TIA–485 standards. EIA/TIA–422 specifies balanced point–to–point transmission with the provision for multiple receivers on the line. EIA/TIA–485 specifies balanced point–to–point transmission and allows for multiple drivers and receivers on the line. Refer to EIA/TIA documents for more details. Figure 9 shows a typical EIA/TIA–422 example. Figure 10 shows a typical EIA/TIA–485 example.

Figure 9. Typical EIA/TIA–422 Application

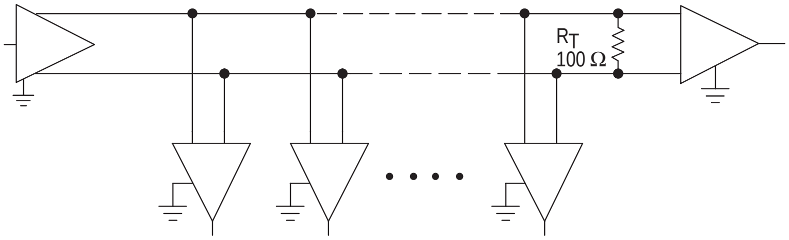

Figure 10. Typical EIA/TIA–485 Application

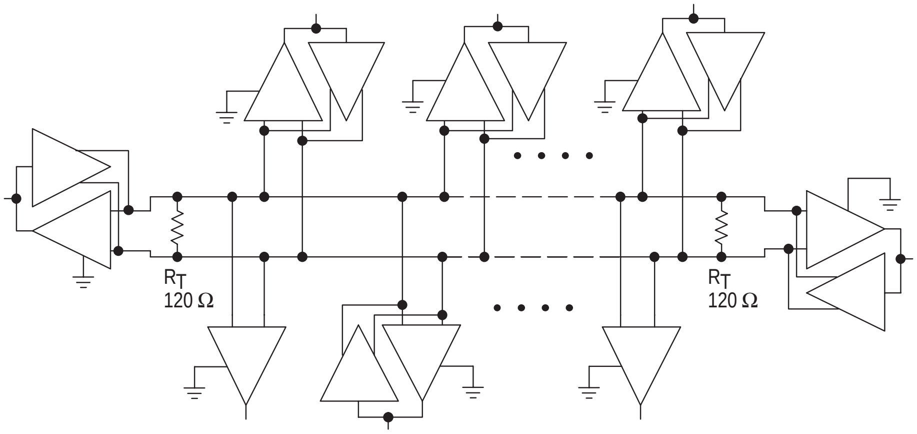
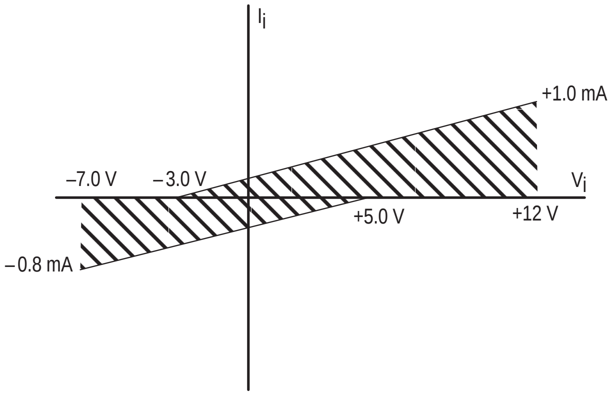


EIA/TIA–422 specifications require the ability to drive at least 10 receivers of input impedance of greater than or equal to 4.0 KΩ plus the 100 Ω termination resistor. This protocol was intended for unidirectional transmission. EIA/TIA–485 is capable of bidirectional transmission by allowing multiple drivers and receivers on the same twisted pair segment. The loading of the twisted pair segment can be up to 32 Unit Loads (U.L.) plus the two 120 Ω terminating resistors. The U.L. definition is shown in Figure 11.

Figure 11. TIA/EIA–485 Unit Load Definition



Calculating Power Dissipation for the MC34058/9 Hex–Transceiver.

The operational temperature range is listed as 0°C to 70°C to satisfy both EIA/TIA–485 and EIA/TIA–422 specifications. However, a lower ambient temperature may be required depending on the specific board layout and/or application.

Using a first order approximation for heat transfer, the maximum power which may be dissipated by the package is determined by (see Appendix A for more details);

$$P_{Dmax} = \frac{T_{Jmax} - T_A}{\theta ja} \qquad [1]$$

where:

θja = package thermal resistance (see Appendix A)

T_{Jmax} = Maximum Junction Temperature. Since the thermal shutdown feature has a trip point of 150°C ± 20°, T_{Jmax} is selected to be +130°C.

T_A = Ambient Operating Temperature.

The power generated within the package is then;

$$PD = \left\{\left[\left(V_{CC} - V_{OH_1}\right) \cdot I_{OH_1}\right] + V_{OL_1} \cdot I_{OL_1}\right\} + ..$$

$$\text{(each\_driver)..} + \left\{\left[\left(V_{CC} - V_{OH_6}\right) \cdot I_{OH_6}\right] + \right.$$

$$\left. V_{OL_6} \cdot I_{OL_6}\right\} + V_{CC} \cdot I_{CCQ} \qquad [2]$$

As indicated in the equation, the part of Equation 2 consisting of I_{OH}, V_{OH}, I_{OL} and V_{OL} must be calculated for each of the drivers and summed for the total power dissipation estimate. The last term can be considered the quiescent power required to keep the IC operational and is measured with the drivers idle and unloaded. The V_{OH} and V_{OL} terms can be determined from the output current versus output voltage curves which provide driver output characteristics.

Example 1 estimates thermal performance based on current requirements.

Example 1. Balanced and Unbalanced Operation

I_{OL} = 50 mA and I_{OH} = ±50 mA for each driver. V_{CC} = 5.0 V.
How many drivers can be used? (Typical power supply current I_{CCQ} = 18 mA.)

Solution:

I_{CCQ} = 0.018 A
The quiescent power is given by: $PQ = I_{CCQ} \cdot V_{CC}$, and is equal to $PQ = 0.09$ W.

Balanced Operation:

To determine the amount of power dissipated by each output stage we need to know the differential output voltage for the output current required. Figure 7 shows that for I_{OH} and I_{OL} differential of 50 mA, V_{ODH} and V_{ODL} are:

$$V_{OD} = |3.0|, \text{ and } I_{OL} = |I_{OH}| = I_{Out} = 0.050 \text{ A.}$$

And the power dissipated by each driver is given by;

$$P_{DrvB} = I_{Out} \cdot \left(V_{CC} - V_{OD}\right) \text{ and equal to}$$

$$P_{DrvB} = 0.10 \text{ W.}$$

Unbalanced Operation:

To determine the amount of power dissipated by each output stage we need to know the single–ended output voltage for the output current required. Figures 5 and 6 shows that for an I_{OH} and I_{OL} of ±50 mA,

$$V_{OH} = 3.9 \text{ V} \quad V_{OL} = 0.895 \text{ V}$$

And the power dissipated by each driver is calculated by;

$$P_{DrvU} = \left(V_{CC} - V_{OH}\right) \cdot |I_{OH}| + V_{OL} \cdot I_{OL}$$

and equal to

$$P_{DrvU} = 0.10 \text{ W.}$$

(For this example, balanced operation is assumed.)

Summing the quiescent and driver power for 6 transceivers operating in a package produces;

$$P_{DTotal} = PQ + 6 \cdot P_{DrvB}, \text{ and equal to } P_{DTotal} = 0.69 \text{ W.}$$

For the MC34058/9, the thermal resistance is capable of a wide range. The ability of the package to dissipate power depends on board type and temperature, layout and ambient temperature (see Appendix A). For the purposes of this example the thermal resistance can range from 40°C/W to 100°C/W;

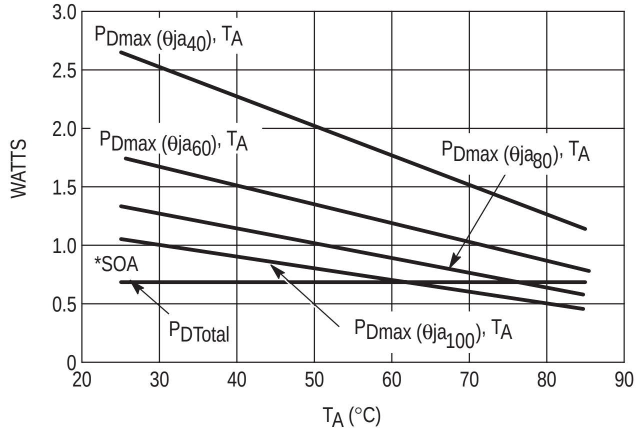
$$\theta ja = j, \ j = 40, 60, .. 100°C/W.$$

Varying the ambient operating temperature T_A = 25, 30, .. 85°C; specifying a maximum junction temperature to avoid thermal shutdown T_{Jmax} = 130°C; and using the first order approximation for maximum power dissipation;

$$P_{Dmax\left(\theta ja\right)}, \ T_A = \frac{T_{Jmax} - T_A}{\theta ja}$$

produces a set curves that can be used to determine a Safe Operating Area for the specific application. P_{DTotal} is graphed with P_{Dmax} to provide a reference.

Graph of Maximum Power Dissipation Possible for a Particular θja and Ambient Temperature

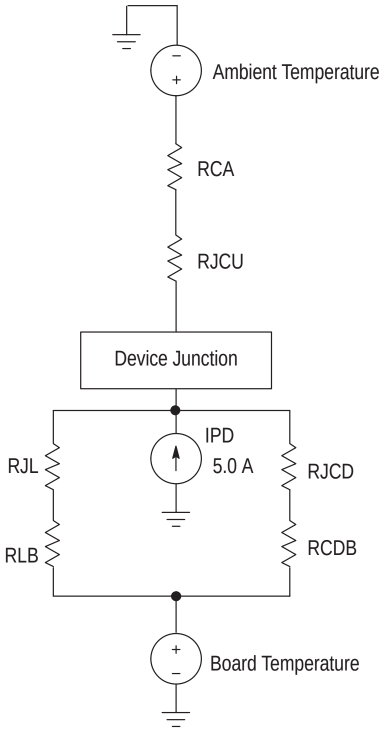


* Safe Operating Area (SOA), is an operating power, P_{DTotal}, less than P_{Dmax}.

So all the drivers in the package can be used if the thermal resistance and/or the ambient temperature is low enough.

Appendix A. Optimizing the Thermal Performance of the MC34058/9

Figure 12. Electrical Model of Package Heat Transfer



An equivalent electrical circuit for the thermal model for the MC34058/9 package is shown in Figure 12. It is a simplified model that shows the dominant means of heat transfer from the thermally enhanced 48–ld package used for the MC34058/9. The model is a first order approximation and is intended to emphasize the need to consider thermal issues when designing the IC into any system. It is however customary to use similar models and Equation 1 to estimate device junction temperatures.

Equation 1 is the common means of using the thermal resistance of a package to estimate junction temperature in a particular system.

$$T_J = \left(P_D \cdot \theta jx\right) + T_A \qquad [1]$$

The term θjx in Equation 1 is usually quoted as a øja value in °C/Watt. However, since the 48–ld package for the MC34058/9 has been thermally enhanced to take advantage of other heat sinking potentials, it must be modified. θjx must actually be considered a composite of all the heat transfer paths from the chip. That is, the three dominant and parallel paths shown in Figure 12. Of those three paths, potentially the most effective is the corner package leads. This is because these corner leads have been attached to the flag on which the silicon die is situated. These pins can be connected to circuit board ground to provide a more efficient conduction path for internal package heat. This path is modeled as the Rjl (junction–to–leads) and Rlb (leads–to–board) combination in Figure 12. This path provides the most effective way of removing heat from the device provided that there is a viable temperature potential (i.e. heat sinking source) to conduct towards. However, if it is not properly considered in the system design, the other paths, (Rjcd + Rcdb) and (Rjcu + Rca) attain greater importance and must be more carefully considered.

So Equation 1, modified to reflect a more complete heat transfer model becomes;

$$T_J = T_A \cdot \frac{\left(\dfrac{1}{\dfrac{1}{Rjcd} + \dfrac{1}{Rjlb}}\right)}{\left(\dfrac{1}{\dfrac{1}{Rjcd} + \dfrac{1}{Rjlb}}\right) + Rjca} + \ldots \qquad [2]$$

$$\ldots\ T_B \cdot \frac{Rjca}{\left(\dfrac{1}{\dfrac{1}{Rjcd} + \dfrac{1}{Rjlb}}\right) + Rjca} + PDISS \cdot \theta ja$$

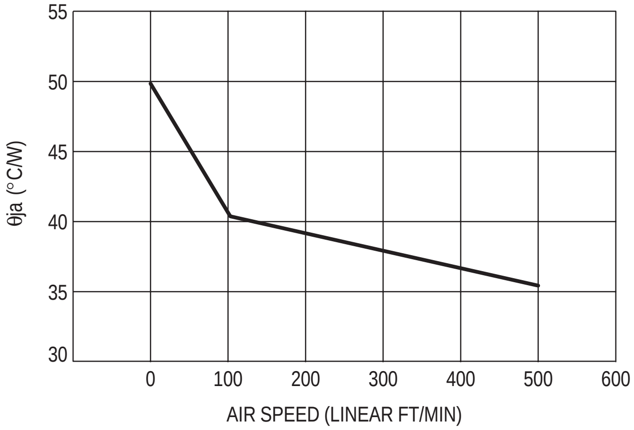
where;

T_J= Junction Temperature
T_A = Ambient Temperature
T_B = Board Temperature
P_{DISS} = Device Power
and θja = Total Thermal Resistance and is composed the parallel combination of all the heat transfer paths from the package.

While Equation 2 is still only a first order approximation of the heat transfer paths of the MC34058/9, at least now it includes consideration for the most effective heat transfer path for the MC34058/9; the board to which the device is soldered. The modified equation also better serves to explain how external variables, namely the board and ambient temperatures, affect the thermal performance of the MC34058/9.

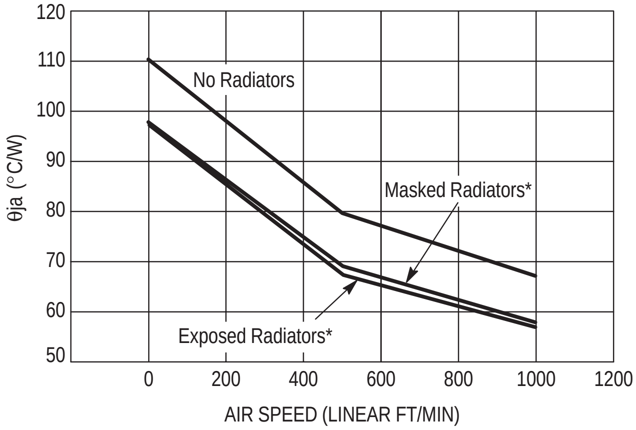
Methods of removing heat via the flag connected pins can be classified into two means; conduction and convection. Radiation is omitted as the contribution is small compared to the other means. Conduction is by far the best method to draw heat away from the MC34058/9 package. This is best accomplished by using a multilayer board with generous ground plane. In this case, the flag connected pins can be connected directly to the ground plane to maximize the heat transfer from the package. Figure 13 shows the results of thermal measurements of a board with an external ground plane (the actual ground area was approximately 6 1/4 in^2). The thermal leads are connected to the board ground plane per the recommended strategy.

Figure 13. Thermal Resistance (θja) for Board with Large External Ground Plane



θjc for the package on this board is 25 ± 20% depending on the location of the package on the board.

Figure 14A. Thermal Resistance (θja) for Board Without Ground Plane



* Masked radiators were covered by a solder mask. Exposed radiators were bare copper.

Figure 14B. Layout Used for Thermal Resistance Measurements in Figure 14A

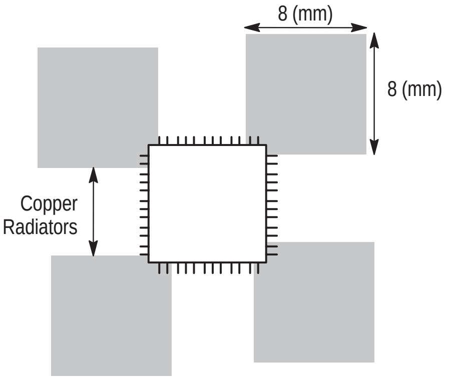


Figure 15. Placement of Thermal Vias to Enhance Heat Transfer to Ground Plane

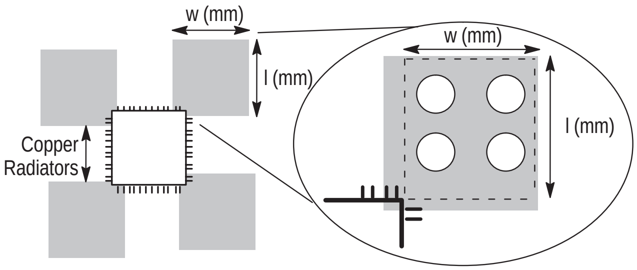

Figure 14A on the other hand shows the result of a single layer board without an internal ground plane. The graphs show that even though there are radiators of substantial area surrounding the package, substantial degredation of thermal performance is evident (Figure 14B shows the layout used for the measurements in Figure 14A). Comparing Figures 13 and 14A shows almost a 2:1 improvement for the strategy involving the external ground plane.

It is clear from Figures 13, 14A and Example 1, that if an application is to use all the device drivers, preparations to assure adequate thermal performance of the system must be taken.

If an extensive external ground plane is unavailable, and only an internal ground plane is available, the thermal performance of the device can still be improved by providing thermal vias to connect the radiators to the internal ground plane. Figure 15 shows a proposed scheme for thermal vias (contact board manufactures for specifics about the thermal performance of their products and possible enhancements).

The thermal resistance for this structure on 1.0 oz. Copper connecting each of the four radiators to an internal ground plane and provide an estimated thermal resistance of approximately 5.0°C/W. The vias used in the estimate had 80 mil diameters, on 100 mil centers and a 1.0 mil copper thickness.

28-Channel Inkjet Driver

28–CHANNEL INKJET DRIVER
(SMARTMOS™ Technology)

SEMICONDUCTOR TECHNICAL DATA

The MC34156 is a 28–Channel Decoder/Driver intended to be used in inkjet printer applications. By using sophisticated SMARTMOS™ technology, it has been possible to combine low power CMOS inputs and logic and high current, high voltage bipolar outputs capable of sustaining a maximum of 30 V.

A 4–to–14 line decoder determines the selected output driver (n) in each 14–driver bank. Two independent output enable inputs (active low) then provide the final decoding to activate 1– or 2–of–28 outputs (OUT_{An} and/or OUT_{Bn}). The ac electrical characteristics of the drivers are tightly controlled and thereby the energy of the device delivers to the inkjet print head. A Chip Enable function is provided to lock out the drivers during system power up. The 28 bipolar power outputs are open collector 30 V Darlington drivers capable of sinking 500 mA at ambient temperatures up to 70°C. All driver outputs are capable of withstanding a contact discharge of ±8.0 kV with the IC biased.

- ESD Output Protection with Clamping Diodes
- Addressable Data Entry
- Tightly Controlled AC and Electrical Characteristics for Inkjet Printers
- CMOS, TTL Compatible Inputs
- Low Power CMOS Logic

MC34250

Product Preview

5.0 V, 200 M-Bit/Sec PR-IV Hard Disk Drive Read Channel

The Motorola MC34250 is a fully integrated partial response maximum likelihood disk drive read/write channel for use in zoned recording applications. This device integrates the AGC, active filter, 7 tap equalizer, Viterbi detector, frequency synthesizer, servo demodulator, 8/9 rate (0,4/4) Encoder/Decoder with write precompensation and power management in a single 64 pin 10 mm x 10 mm TQFP package.

FEATURES:

- 50 to 200 MBPS Programmable Data Rate
- 800 mW at 200 MBPS and 5.0 V
- Channel Monitor Output
- Programmable AGC Charge Pump Currents with Different Values for Data and Servo Envelope Modes and Gain Gradient Mode
- Programmable AGC Peak Detector Droop Currents with Different Values for Data and Servo Envelope Modes
- Separate AGC Charge Pump Outputs for Data and Servo Modes
- Programmable Dual Threshold Qualifier or Hysteresis Comparator Type Pulse Detector for Servo Data Detection.
- ERD and Polarity Outputs for Servo Timing and Raw Encoded Data
- Integrated 7 pole 0.05° Equiripple Linear Phase Filter with Programmable Bandwidth from 5.0 MHz to 80 MHz and Different Values for Both Data and Servo Modes
- Programmable Symmetrical Boost from 0 to 10 dB and Different Values for Data and Servo Modes
- Programmable Asymmetrical Boost of Up to ±40% of Nominal Filter Group Delay in Both Data and Servo Modes
- 7 Tap Continuous Time Transversal Equalizer with 8 Bit Programmable Tap Weights and Integrated Decision Directed Sign–Sign Least Mean Squared Adaptation
- Internal Offset Cancellation Loops
- Fast Acquisition Data Phase Locked Loop with Zero Phase Restart
- Programmable Data Phase Locked Loop Charge Pump Current
- Integrated Soft Decision Viterbi Detectors with Programmable Merge References
- Integrated 8/9 Rate (0,4/4) Encoder and Decoder with Code Scrambler and Descrambler
- Programmable 2/4/8 Bit NRZ Data Interface
- Programmable Write Precompensation Delays Locked to the Frequency Synthesizer
- Differential PECL Write Data Outputs
- External Write Data Path for DC Erase or Other Non–Encoded Data
- Integrated Write Current DAC
- Programmable Power Management
- Bi–Directional Serial Microprocessor Interface
- Various Test Modes Controlled Via the Serial Microprocessor Interface

MC68160

Enhanced Ethernet Transceiver

ENHANCED ETHERNET INTERFACE TRANSCEIVER

SEMICONDUCTOR TECHNICAL DATA

The MC68160 Enhanced Ethernet Interface Circuit is a BiCMOS device which supports both IEEE 802.3 Access Unit Interface (AUI) and 10BASE–T Twisted Pair (TP) Interface media connections through external isolation transformers. It encodes NRZ data to Manchester data and supplies the signals which are required for data communication via 10BASE–T or AUI interfaces. The MC68160 gluelessly interfaces to the Ethernet controller contained in the MC68360 Quad Integrated Communications Controller (QUICC) device. The MC68160 also interfaces easily to most other industry–standard IEEE 802.3 LAN controllers. Prior to twisted pair data reception, Smart Squelch circuitry qualifies input signals for correct amplitude, pulse width, and sequence requirements.

- Interfaces with AMD, National, Intel and Fujitsu IEEE 802.3 LAN Controllers
- Automatic Twisted Pair Wiring Polarity Fault Detection and Correction Option
- Automatic Port Selection Option with Status Output
- Driver Pre–emphasis for Twisted Pair Output Data
- Crystal Controlled Clock Oscillator or External Clock Generator Option
- Digital Phase–Locked–Loop (DPLL) Timing Recovery and Data Decoding
- Standby Mode with Reduced Power Consumption
- Twisted Pair Signal Quality Error (Heartbeat) Test Option
- Diagnostic Local Loop Back Option
- Transmit, Receive and Collision Detection Status Output
- Full–Duplex Operation Option on Twisted Pair Port
- Twisted Pair Jabber Detection and Status Output
- Link Integrity Testing and Status Output

MC68160

Enhanced Ethernet Serial Transceiver

Table 1. Pin Function Description

Pin(s)	Symbol	Type	Name/Function
CONTROLLER INTERFACE			
1	RENA	O TTL/CMO	**Receive Enable Output:** Indication of the presence of network activity, synchronous to RCLK. In the standby mode, RENA is driven to the high impedance state.
2	RX	O TTL/CMOS	**Receive Data Output:** Recovered data, synchronous to RCLK. Following a reset operation, 100 ms should be allowed before attempting to read data processed by the MC68160. This delay is needed to insure that the receive phase locked loop is properly synchronized with incoming data. In the standby mode, RX is driven to the high impedance state.
48	TCLK	O TTL/CMOS	**Transmit Clock Output CMOS/TTL Output:** TCLK provides a symmetrical clock signal at 10 MHz for reference timing of data to be encoded. In the standby mode, TCLK is driven to the high impedance state.
49	TENA	I TTL	**Transmit Enable Input:** Input signal synchronous to TCLK which enables data transmission on the active port. An internal pull–down resistor is provided so that the input is low under no connect conditions. (This resistor is removed in the standby mode). If TENA is asserted at the conclusion of a reset operation, it must first be deasserted and then reasserted before data transmission can occur. In the standby mode, TENA is driven to the high impedance state.
50	RCLK	O TTL/CMOS	**Receive Clock Output:** Recovered clock. In the standby mode, RCLK is driven to the high impedance state.
51	CLSN	O TTL/CMOS	**Collision Output:** In the AUI mode, indicates the presence of signals at the ACX+ and ACX– terminals which meet threshold and pulse width requirements. In the TP mode, indicates simultaneous transmit and receive activity, a heartbeat (SQE Test) signal was generated, or the jabber timer has expired. In the standby mode, CLSN is driven to the high impedance state.
52	TX	I TTL	**Transmit Data Input:** Input signal synchronous to TCLK which provides NRZ serial data to be Manchester encoded. In the standby mode, TX is driven to the high impedance state.
AUI INTERFACE			
21 22	ACX– ACX+	I	**AUI Differential Collision Inputs:** These inputs are connected to a pair of internally biased line receivers consisting of a carrier detect receiver with offset threshold and noise filtering to detect the line activity. Signals at ACX+/– have no effect on data path functions.
23 24	ARX– ARX+	I	**AUI Differential Receiver Inputs:** These inputs are connected to a pair of internally biased line receivers consisting of a carrier detect receiver with offset threshold and noise filtering to detect the line activity, and a data receiver with no offset for Manchester Data reception.
25 26	ATX– ATX+	O	**AUI Differential Transmit Outputs :** This line pair is intended to operate into terminated transmission lines. For TX signals meeting setup and hold time to TCLK when TENA is previously asserted, Manchester encoded data is outputted at ATX+/–. When operating into a 78 Ω terminated transmission line, signaling meets the required output levels and skew for IEEE–802.3 drop cables. When the 10BASE–T port is automatically or manually selected, the AUI outputs are driven to a low power standby state in which the outputs deliver a balanced high state voltage.
TWISTED PAIR INTERFACE			
31 32	TPRX– TPRX+	I	**Twisted Pair Differential Receiver Inputs:** These inputs are connected to a receiver with Smart Squelch capability which only allows differential receive data to pass as long as the input amplitude is greater than a minimum signal threshold level and a specific pulse sequence is received. This assures a good signal to noise ratio while the signal pair is active by preventing crosstalk and impulse noise conditions from activating the receive function.
36 37	TPTX– TPTX+	O	**Twisted Pair Differential Transmitter Outputs:** These lines have pre–distortion drive capability and are intended to drive terminated twisted pair transmission lines. When the AUI port is manually selected, the 10BASE–T outputs are driven to a low power standby state in which the outputs deliver a balanced high state voltage. However, when the AUI port is automatically selected, the 10BASE–T outputs remain active.

NOTE: The sense of the controller interface pins will change, depending on the controller selected.

Table 1. Pin Function Description (continued)

Pin(s)	Symbol	Type	Name/Function
OSCILLATOR AND FREQUENCY MULTIPLIER			
12	MFILT	C	**Frequency Multiplier Filter Connection Point:** An external resistor capacitor filter must be attached to this pin.
16	X1	I/C CMOS	**Oscillator Inverter Input and Crystal Connection Point:** When connected for crystal oscillator operation, the frequency of the clock which appears at TCLK is half that of the crystal oscillator. As an option, instead of connecting to a crystal, X1 may be driven from an external 20 MHz CMOS compatible clock generator.
17	X2	O/C CMOS	**Oscillator Inverter Output and Crystal Connection Point:** This pin is used only for the connection of an external crystal and capacitor. It must be left unconnected if X1 is driven by an external CMOS Clock generator.
MODE SELECT			
3 4 5	CS0 CS1 CS2	I TTL	**Mode Select:** The logic states applied to these pins select the appropriate interface for the desired IEEE–802.3 controller or enable the standby mode. When the standby mode is selected, the MC68160 power supply current is greatly reduced. Additionally, in the standby mode, all of the controller inputs and outputs are driven to the high impedance state.
6	LOOP	I TTL	**Diagnostic Loopback:** Asserting this function causes serial NRZ data at the TX input to be Manchester encoded and then looped back through the Manchester decoder, appearing at the RX output. This diagnostic loopback function operates independent of Twisted Pair (TP) or Access Unit Interface (AUI) port connectivity or activity. Neither the TP port nor the AUI port transmits data from the controller while diagnostic loopback is selected. Likewise, the controller interface receives data neither from the TP nor the AUI receivers while in this mode. The polarity fault detection and link integrity functions are not inhibited by the diagnostic loopback mode. If otherwise enabled, they continue to function. If the twisted pair port is selected, and TPSQEL is driven to the low logic state, a collision detect pulse is delivered following each transmission to simulate the twisted pair SQE test.
9	APORT	I TTL	**Automatic Port Selection Enable:** When high, MC68160 will automatically select the TP or AUI port based on the presence or absence of valid link beats or frames at the TP receive input. If the AUI port is automatically selected, the MC68160 will continue to produce link pulses for the TP port. Changing ports requires approximately 1.0 ms to allow the circuitry for the new port to resume normal operation. The power consumption is minimized in the circuitry associated with the unselected port.
27	TPSQEL	I TTL	**Twisted Pair Signal Quality Error Test Enable:** Forcing this pin low enables testing of the internal TP collision detect circuitry after each transmit operation to the TP media. This function provides a simulated collision to as much of the MC68160 collision detect circuitry as possible without affecting the attached twisted pair channel. A normal SQE test results in a high logic state at the CLSN controller interface pin which begins 6 to 16–bit times after the last transition of a transmitted signal and continues for 5 to 15–bit times. (When the AUI port is selected, SQE test signals are generated by the coaxial cable transceiver and delivered to the controller via the MC68160 ACX+/– receive inputs)
28	TPFULDL	I TTL	**Twisted Pair Full Duplex Mode Select:** Forcing this pin low allows simultaneous transmit and receive operation on the twisted pair port without an indicated collision. This pin is not to be asserted with LOOP as a test mode is enabled that disrupts normal operation.
29	TPAPCE	I TTL	**Twisted Pair Automatic Polarity Correction Enable:** When TPAPCE is high, automatic polarity correction is enabled, and MC68160 will internally correct for a polarity fault on the receive circuit. Additionally, when TPAPCE is high, the presence of a polarity fault is indicated on TPPLR.
46	TPEN	I/O TTL (TTL/CMOS)	**Twisted Pair Port Enable:** If APORT is low, TPEN is an input which determines whether the AUI port (TPEN low) or TP port (TPEN high) will be manually selected. If the AUI port is manually selected, the MC68160 will not produce link pulses for the TP port. If APORT is high, TPEN is an output which will indicate which port has been automatically selected by driving TPEN low (for AUI) or high (for TP). In its output mode TPEN can sink 10 mA in the low output state and source 10 mA in the high output state. (See Pin 9 Description.) Changing ports requires approximately 1.0 ms to allow the circuitry for the new port to resume normal operation. The power consumption is minimized in the circuitry associated with the unselected port. In the standby mode, this pin is driven to the high impedance state.

Table 1. Pin Function Description (continued)

Pin(s)	Symbol	Type	Name/Function
STATUS INDICATOR			
40	TXLED	O TTL/CMOS	**Transmit Status LED Driver Output:** This pin indicates the transmit status of the currently selected TP or AUI port. When there is no transmit activity detected, an internal pull–up takes this pin to its normal off (high) state. When transmit activity is detected, the LED driver turns on. In its on state, TXLED flashes the LED by driving low at approximately 10 Hz at a 50% duty cycle. In the standby mode, this output is driven to the high impedance state.
41	RXLED	O TTL/CMOS	**Receive Status LED Driver Output:** This pin indicates the receive status of the currently selected TP or AUI port. When there is no receive activity detected, an internal pull–up takes this pin to its normal off (high) state. When receive activity is detected, the LED driver turns on. In its on state, RXLED flashes the LED by driving low at approximately 10 Hz at a 50% duty cycle. In the standby mode, this output is driven to the high impedance state.
42	CLLED	O TTL/CMOS	**Collision Status LED Driver Output:** This pin indicates the collision status of the currently selected TP or AUI port. When there is no collision activity detected, an internal pull–up takes this pin to its normal off (high) state. When collision activity is detected, the LED driver turns on. In its on state, CLLED flashes the LED by driving low at approximately 10 Hz at a 50% duty cycle. In the standby mode, this output is driven to the high impedance state.
43	TPLIL	O TTL/CMOS	**Twisted Pair Link Integrity Output:** This output is driven to the low output state to indicate good link integrity on the TP port during TP mode. It is deasserted (high) when link integrity fails in TP mode. The TPLIL output is driven to the high impedance state when the AUI port is selected. In the standby mode, this output is also driven to the high impedance state.
44	TPPLR	O TTL/CMOS	**Twisted Pair Polarity Error Output:** If TPAPCE is high and the wires connected to the Twisted Pair Receiver Inputs (TPRX+, TPRX–) are reversed, TPPLR will be driven to the low logic state to indicate the fault. TPPLR remains low when the MC68160 has automatically corrected for the reversed wires. If the twisted pair link integrity tests fail, this output will be driven to the high logic state. When the AUI mode is selected this output is driven to the high impedance state. In the standby mode, this output is also driven to the high impedance state.
45	TPJABB	O TTL/CMOS	**Twisted Pair Jabber Output:** This pin is driven high to indicate a jabber condition at the TPTX+/– outputs. (Jabber condition also causes CLLED to be driven alternately to the high and low output levels). TPJABB is driven to the low output state when no jabber condition is present. When the AUI mode is selected this output is driven to the high impedance state. In the standby mode, this output is also driven to the high impedance state.
POWER SUPPLY AND GROUND			
10	VDDDIV		**Frequency Divider Supply Pin**
11 13	VDDFM GNDFM		**Frequency Multiplier Supply and Ground Pins**
14 15	GNDVCO VDDVCO		**Voltage Controlled Oscillator Ground and Supply Pins**
20	GNDSUB		**Substrate Ground Pin**
7 8 18 19	VDDDIG GNDDIG VDDDIG GNDDIG		**Digital Supply and Ground Pins**
30 33	VDDANA GNDANA		**Analog Supply and Ground Pins**
34 35 38 39	GNDPWR VDDPWR VDDPWR GNDPWR		**Power Supply and Ground Pins**
47	GNDCTL		**Controller Interface Ground Pin**

NOTE: Power and ground pins are not connected internally. Failure to connect externally may cause malfunction or damage to the IC.

Table 2. Controller Interface Selection

Motorola Transceiver MC68160 (EEST™)	Motorola Controller[2] MC68360 (QUICC™)		Intel Controllers 82586, 82590, 82593, 82596		Fujitsu Controllers 86950 (Etherstar™) 86960 (NICE™)		National Controllers 8390, 83C690, 83932B (SONIC™)

RX	RX	High	RXD	High	RXD	High	RXD	High
RENA	RENA	High	$\overline{\text{CRS}}$	Low	XCD	High	CRS	High
CLSN	CLSN	High	$\overline{\text{CDT}}$	Low	XCOL	Low	COL	High
LOOP[1]	N.A.	High	$\overline{\text{LPBK}}$	Low	LBC	High	LPBK	High

NOTES: 1. Although LOOP input is not ordinarily classifed as a controller pin, it is included in this table because its sense varies according to the controller used.
2. The Motorola controller interface contained in the MC68360 (QUICC™) is compatible with the AMD 7990 (LANCE™) and 79C900 (ILACC™) controllers.
3. The pin sense is shown from the perspective of the identified controller pin.

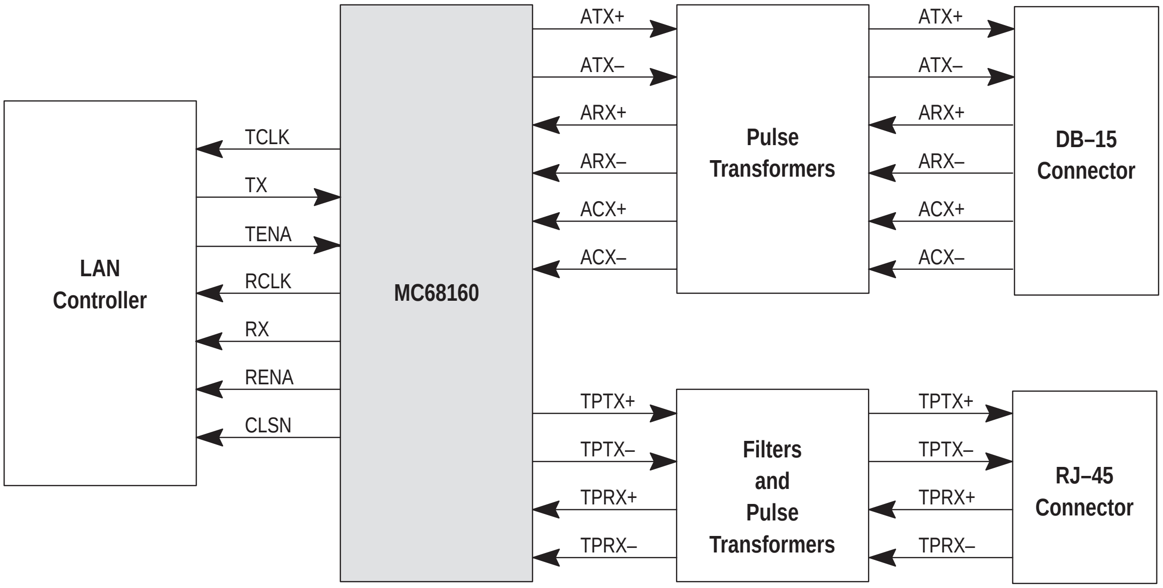
Table 3. Controller Independent Mode Selection

Pin	Standby Mode	Reserved	Reserved	Reserved
CS0 CS1 CS2	1 1 1	0 1 1	1 0 1	0 0 1

NOTE: In standby mode, the MC68160 consumes less power supply current than in any other mode. Additionally, in the standby mode, all of the controller inputs and outputs are driven to the high impedance state. When the standby mode is deasserted, an internal reset pulse of approximately 6.0 µs duration is generated.

Following a period of operation in the standby mode, the time required to insure stable data reception is approximately 100 ms.

Figure 2. Applications Block Diagram



ELECTRICAL CHARACTERISTICS

MAXIMUM RATINGS

Characteristic	Symbol	Min	Max	Unit
Storage Temperature Range	T_{stg}	–65	150	°C
Power Supply Voltage Range Analog Digital	 V_{DDA} V_{DDD}	 – –	 7.0 7.0	V
Voltage on any TTL compatible input pin with respect to Ground Voltage on TPRX, ARX, or ACX input pins with respect to Ground	V	–0.5 –0.5	V_{DD} + 0.5 6.0	V
Differential Voltage on TPRX, ARX, or ACX Input Pins	V_{DIFF}	–6.0	6.0	V

NOTE: Stresses in excess of the Absolute Maximum Ratings can cause permanent damage to the device. Functional operation of the device is not implied at these or any other conditions in excess of those indicated in the operation sections of this data sheet. Exposure to Absolute Maximum Ratings conditions for extended periods can adversely affect device reliability.

RECOMMENDED OPERATING CONDITIONS

Characteristic	Symbol	Min	Max	Unit
Power Supply Voltage Range	V_{DD}	4.75	5.25	V
Power Supply Ripple (20 kHz to 100 kHz)	–	–	50	mV
Power Supply Impulse Noise (Either Polarity)	–	–	100	mV
Ambient Operating Temperature Range	T_A	0	70	°C
ARX/ACX Input Differential Rise and Fall Time (see Figure 39)	t_{260}	2.0	10	ns
ARX Pair Idle Time after Transmission (see Figure 39)	t_{265}	8.0	–	µs

ESD

Although protection circuitry has been designed into this device, proper precautions should be taken to avoid exposure to electrostatic discharge (ESD) during handling and mounting. Motorola employs a Human Body Model (HBM) and a Charged Device Model (CDM) for ESD–susceptibility testing and protection design evaluation. ESD has been adopted for the CDM, however, a standard HBM (resistance = 1500 Ω capacitance – 100 pF) is widely used and, therefore, can be used for comparison purposes. The HBM ESD threshold presented here was obtained by using the circuit parameters contained in this specification. ESD threshold voltage is designed to 1.0 kV Human Body Model.

NOTES:
1. Measured differentially across the output of Test Load A which is connected directly to the TPTX+/– pins of the device.
2. Measured differentially across the output of Test Load D shown in Figure 23 which is connected directly to the TPTX+/– pins of the device.
3. Measured across the output of Test Load C which is connected directly to the TPTX+/– pins of the device.
4. Same as t_{137} except the logic states for TENA and RENA are inverted.
5. Measured across the output of Test Load B shown in Figure 21.
6. Measured at the +/–90% points of the precompensation voltage feature of the waveform. (The 0% reference is 0 V differential.)
7. Load on specified output is 20 pF to ground.

RENA Assertion Delay RENA Deassertion Delay	t_{266} t_{267}	– –	100 450	ns

Squelching Characteristics

The receive data pairs and the collision pairs should have the following squelch characteristics:

1. The squelch circuits are on at idle (with input voltage at approximately 0 V differential).
2. If an input is in squelch, pulse is rejected if the peak differential voltage is more positive than –175 mV, regardless of pulse width.
3. A pulse is considered valid if its peak differential voltage is more negative than –300 mV and its width, measured at –285 mV, is > 25 ns.
4. The squelch circuits are disabled by the first valid negative differential pulse on either the AUI receive data or collision pair.
5. If a positive differential pulse occurs on either the AUI receive data or collision pair > 175 ns, end of frame is assumed and squelch circuitry is turned on.

Figure 39. ARX/ACX Timing

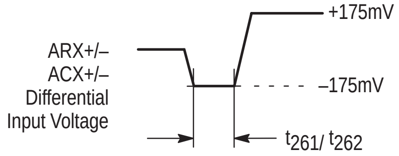

Figure 40. ARX/ACX Timing

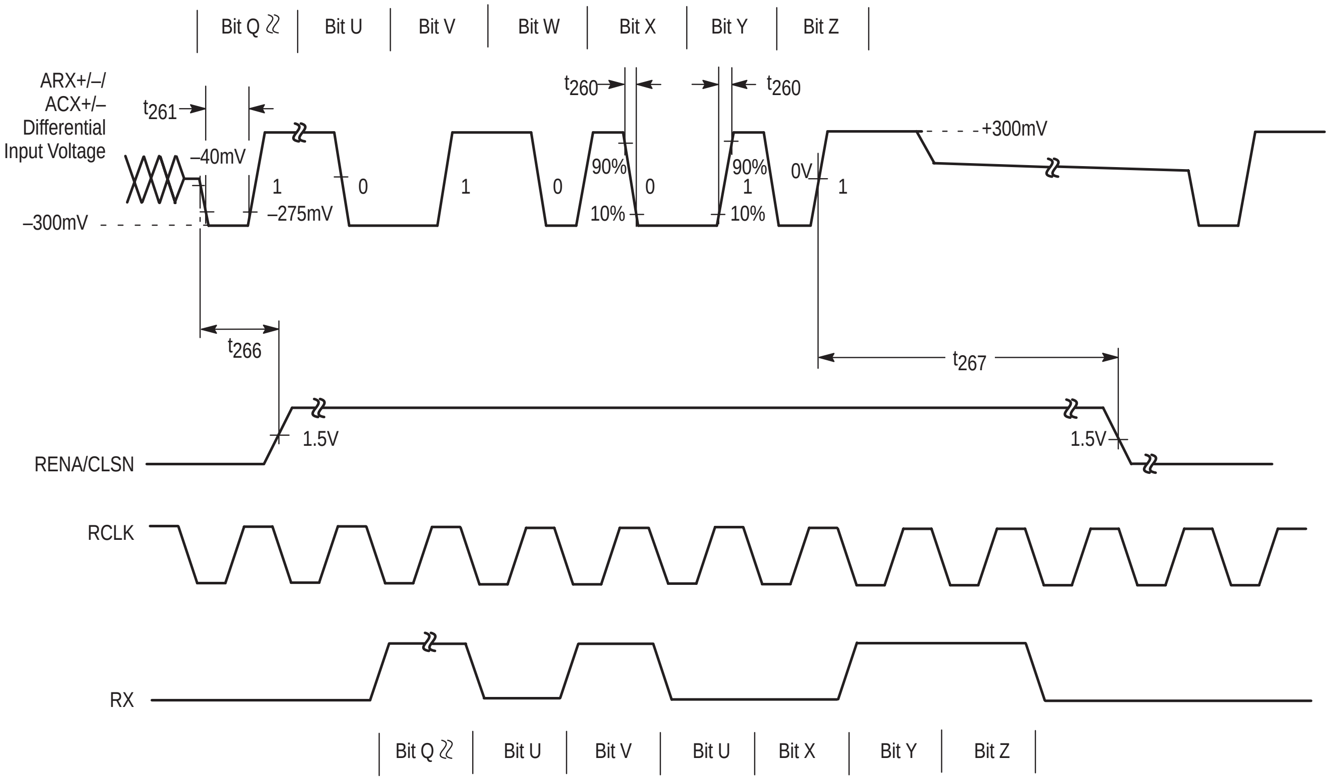


FUNCTIONAL DESCRIPTION

Introduction

The MC68160(EEST) was designed to perform the physical connection to the Ethernet media. This is done through two separate media dependent interfaces and a SIA interface. The media dependent interfaces are the Attachment Unit Interface(AUI) and the 10BASE–T Twisted Pair(TP) port. The SIA interface is compatible with most industry controllers and selected by three mode control pins. Chip status is indicated by the condition of 6 status indicator pins. All but one are open collector outputs.

If the EEST isn't receiving data, the controller may initiate transmission. NRZ data from the communications controller SIA interface is encoded by the MC68160 into Manchester Code in preparation for transmission on the media. The data is then applied to either the AUI or TP port. If the data was transmitted using the 10BASE–T port, this data is also looped back to the receive data interface SIA pins connected to the controller. This allows detection of a collision condition in the event that another station on the media attempted transmission at the same time. After the entire data frame has been transmitted, the EEST must force the media idle signal. The idle signal frees the media for other stations that have deferred transmission. If no other transmissions are required the link enters an idle state. During this idle state the 10BASE–T transmitter issues idle pulses which communicates to the receiver connected to the other side that the link is valid. If the transmitter connected at the other end begins transmission, the EEST will assert a receive enable signal, and forward the received data to the controller.

Upon reception of data at the 10BASE–T port, the data is screened for proper sequence and pulse width requirements. If the preamble of the received frame meets the requirements, the PLL locks onto the 64–bit preamble and begins to decode the Manchester Code to NRZ code. This code is then presented to the communications controller at the receive data pins at the SIA interface. If data is received at the AUI port, it is sent directly to the communications controller via the SIA interface.

Data Transmission

To have properly encoded transmit data, the communications controller must be synchronized to TCLK. Transmission to the 10BASE–T or AUI media occurs when TENA is asserted and data is applied to the TX pin. Finally, to signify transmission, the TXLED in will cycle on and off at a 100 ms period. Data transmission for EEST is accomplished either over the 10BASE–T port or the AUI port. Both connections to the media are made with industry standard media interface components. The 10BASE–T interface requires a filter and transformer, the AUI interface requires only a transformer. The filter for the 10BASE–T transmit circuit will have to be chosen for each application.

If after approximately 40 ms after a TP or AUI transmission has begun, the EEST is still transmitting, the TPJABB pin will assert to signify a jabber condition. Also, the CLLED pin will transition high and low alternately with a 100 ms period. The transmit circuitry is, however, unaffected by the jabber condition, so the communications controller has the responsibility of monitoring and stopping transmission.

When transmission is complete, the transmit circuitry will begin the end of transmit and decay to idle responses necessary to meet requirements of the 802.3 standard for the TP and AUI port.

Data Reception

Other than the case of being in Loop Back mode, data reception to the RX pin of the EEST is initiated by signaling at the RX+/– or AUI ARX+/– pins. If at the TP port, the data is screened for validity by checking for sequence and pulse width requirements, then passed to the decode and receive circuitry. The RENA pin asserts and the data and corresponding clock is passed to the communications controller. After the frame has been transmitted, the MC68160 detects the ending transmission and negates RENA. If at the AUI port, the data is checked for proper pulse width requirements before being passed to the decode circuitry. If the data pulses are longer than at least 20 ns, RENA gets asserted and the frame is decoded to RX with and accompanying RCLK output.

Collision

Collision is the occurrence of simultaneous transmit activity by two or more stations on the network. In the event of collision, the data transfer paths are unaffected. If the MC68160 is in the twisted pair mode, collision is detect by simultaneous receive and transmit activity. If in the AUI mode, collision is detected by activity on the ACX+/– pins. In either case, if collision is detected, the CLSN pin will assert to notify the communications controller.

Jabber

The EEST has a jabber timer to detect the jabber condition. In the event that the transmitting station continues to transmit beyond the allowable transmit time, a jabber timer (40 ms) will expire and assert the TPJABB pin to alert the communications controller of the situation. The TPJABB pin can source or sink up to 10 mA, and so, is capable of driving a status LED. In the AUI mode, the pin is driven to high impedance since the transceiver connected to the AUI port must alert the communications controller of the jabber condition.

Full Duplex

A feature unique to the MC68160 is the Full Duplex mode. In this mode the EEST is capable of transmitting and receiving simultaneously. Collision conditions are not announced and internal loop back is disabled. The remainder of the EEST functionality remains unchanged from the non–Full Duplex mode. Full Duplex mode is enabled by asserting the TPFULDL pin.

Auto Port Selection

If the APORT pin is asserted, the MC68160 will automatically select the TP or AUI port depending on the presence of valid link beats or frames at the TP RX+/– pins. If the AUI port is automatically selected by another transmitting station or by setting TPEN low, the TP transmit port of the EEST continues to transmit link beats to keep the link active.

Auto Polarity Selection

If the RX+ and the RX– wires happen to get reversed, the MC68160 has the ability to automatically reverse the pins internally so that the received data is valid. In addition, an open collector status pin (TPPLR) is driven low to indicate the fault. In the AUI or reset mode this pin presents a high impedance.

Loop Back Mode

To test the transmit and receive circuitry without disturbing the connected network, the EEST has a Loop Back mode. Loop Back mode routes transmit data and clock to the receive data and clock pins using as much of the transmit and receive circuitry as possible. This gives a test of the MC68160 Manchester encode and decode function.

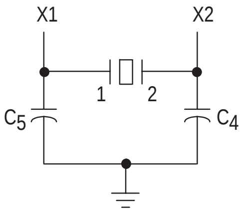
APPLICATIONS INFORMATION

Selection of Crystal and External Components

Accuracy of frequency and stability over temperature are the main determinants of crystal choice. Specifications for a suitable crystal are tabulated below.

Frequency	20.000 MHz
Mode	Fundamental
Tolerance	± 100 ppm
Stability	± 100 ppm
Aging	± 5 ppm/yr
Shunt Capacitance	7.0 pF
Load Capacitance	18–20 pF
Series Fundamental Resistance (ESR)	25 Ω
Drive Level	500 μW

A suitable crystal is the MTRON HC49 MP–1, 20.000 MHz crystal. 20 pF for C4 and C5 have been shown to work reliably.



PLL Filter Components

The filter components at Pin 12 were chosen to assure adequate pull–range but with a emphasis on stability. It is not foreseeable that a design would need to change the components, but for the sake of completeness, relevant values are provided here.

$$\text{VCO Gain} = 24 \left(\frac{\text{MHz}}{\text{Volt} \bullet \text{sec}}\right) \text{ and,}$$

$$\text{Phase Detector Gain} = \frac{100}{\pi/2} \left(\frac{\mu\text{A}}{\text{rad}}\right) \text{ and the}$$

filter impedance function is;

$$Z(j\omega) \approx \frac{(j\omega + 1/C6)}{j\omega \bullet C5 \bullet (j\omega + 1/C5)} \quad (\text{for } C6 >> C5)$$

10BASE–T Filter and Transformer Choice

The MC68160 differential outputs are low impedance voltage sources. Therefore, external series resistors must be used in order to match the characteristic impedance of twisted pair. Since the output resistance of each leg of the transmitter is about 10 Ω, a 39 Ω resistor is used in series as shown in the applications schematic. So the impedance presented from the source to the isolation transformer is then very nearly 100 Ω. The following is a list of some 10BASE–T filter module vendors and their products.

Vendor	**Part #**
FEE Fil–Mag	78Z1120B–01, 78Z1122B/D–01, 78Z1122 F–01
Valor Electronics	PT3877, FL1012, FL1066
Pulse Engineering	PE–65434, PE65424, PE65433
TOKO	PM01–00, PM02–00, PM05–00

AUI Transformer Choice

Like the 10BASE–T outputs, the AUI differential outputs are low impedance sources and capable of meeting the IEEE 802.3 waveform requirements when a coupling transformer is used. Some AUI transformer vendors and their products are provided below.

Vendor	**Part #**
Coilcraft	LAX–ET304
FEE Fil–Mag	23Z90, 23Z91/ 23Z92
Valor Electronics	LT6032, LT6033
Pulse Engineering	PE64502, PE6103
TOKO	Q30ALQ8–1AA3, Q30ALQ9–1AA3

MC75174B

Quad EIA-485 Line Drivers with Three-State Outputs

QUAD EIA–485 LINE DRIVERS

SEMICONDUCTOR TECHNICAL DATA

The Motorola MC75172B/174B Quad Line drivers are differential high speed drivers designed to comply with the EIA–485 Standard. Features include three–state outputs, thermal shutdown, and output current limiting in both directions. These devices also comply with EIA–422–A, and CCITT Recommendations V.11 and X.27.

The MC75172B/174B are optimized for balanced multipoint bus transmission at rates in excess of 10 MBPS. The outputs feature wide common mode voltage range, making them suitable for party line applications in noisy environments. The current limit and thermal shutdown features protect the devices from line fault conditions. These devices offer optimum performance when used with the MC75173 and MC75175 line receivers.

Both devices are available in 16–pin plastic DIP and 20–pin wide body surface mount packages.

- Meets EIA–485 Standard for Party Line Operation
- Meets EIA–422–A and CCITT Recommendations V.11 and X.27
- Operating Ambient Temperature: –40°C to +85°C
- High Impedance Outputs
- Common Mode Output Voltage Range: –7 to 12 V
- Positive and Negative Current Limiting
- Transmission Rates in Excess of 10 MBPS
- Thermal Shutdown at 150°C Junction Temperature, (±20°C)
- Single 5.0 V Supply
- Pin Compatible with TI SN75172/4 and NS µA96172/4
- Interchangeable with MC3487 and AM26LS31 for EIA–422–A Applications

APPLICATIONS INFORMATION

Description

The MC75172B and MC75174B are differential line drivers designed to comply with EIA–485 Standard (April 1983) for use in balanced digital multipoint systems containing multiple drivers. The drivers also comply with EIA–422–A and CCITT Recommendations V.11 and X.27. The drivers meet the EIA–485 requirement for protection from damage in the event that two or more drivers attempt to transmit data simultaneoulsy on the same cable. Data rates in excess of 10 MBPS are possible, depending on the cable length and cable characteristics. A single power supply, 5.0 V, ±5%, is required at a nominal current of 60 mA, plus load currents.

Outputs

Each output (when active) will be a low or a high voltage, which depends on the input state and the load current (see Table 1, 2 and Figures 7 to 10). The graphs apply to each driver, regardless of how many other drivers within the package are supplying load current.

Table 1. MC75172B Truth Table

Data Input	Enables		Outputs	
	EN	EN	Y	Z
H	H	X	H	L
L	H	X	L	H
H	X	L	H	L
L	X	L	L	H
X	L	H	Z	Z

Table 2. MC75174B Truth Table

Data Input	Enable	Outputs	
		Y	Z
H	H	H	L
L	H	L	H
X	L	Z	Z

H = Logic high, L = Logic low, X = Irrelevant, Z = High impedance

The two outputs of a driver are always complementary. A “high” output can only source current out, while a “low” output can only sink current (except for short circuit current – see Figure 16).

The outputs will be in the high impedance mode when:

a) the Enable inputs are set according to Table 1 or 2;

b) V_{CC} is less than 1.5 V;

c) the junction temperature exceeds the trip point of the thermal shutdown circuit (see below). When in this condition, the output’s source and sink capability are shut off, and only leakage currents will flow (see Figures 13, 14). Disabled outputs may be taken to any voltage between –7.0 V and 12 V without damage.

The drivers are protected from short circuits by two methods:

a) Current limiting is provided at each output, in both the source and sink direction, for shorts to any voltage within the range of 12 V to –7.0 V, with respect to circuit ground (see Figure 16). The short circuit current will flow until the fault is removed, or until the thermal shutdown circuit activates (see below). The current limiting circuit has a negative temperature coefficient and requires no resetting upon removal of the fault condition.

b) A thermal shutdown circuit disables the outputs when the junction temperature reaches 150°C, ±20°C. The thermal shutdown circuit has a hysteresis of ≈ 12°C to prevent oscillations. When this circuit activates, the output stage of each driver is put into the high impedance mode, thereby shutting off the output currents. The remainder of the internal circuitry remains biased. The outputs will become active once again as the IC cools down.

Driver Inputs

The driver inputs determine the state of the outputs in accordance with Tables 1 and 2. The driver inputs have a nominal threshold of 1.2 V, and their voltage must be kept within the range of 0 V to V_{CC} for proper operation. If the voltage is taken more than 0.5 V below ground, excessive currents will flow, and proper operation of the drivers will be affected. An open pin is equivalent to a logic high, but good design practices dictate that inputs should never be left open. The characteristics of the driver inputs are shown in Figure 15. This graph is not affected by the state of the Enable pins.

Enable Logic

Each driver’s outputs are active when the Enable inputs (Pins 4 and 12) are true according to Tables 1 and 2.

The Enable inputs have a nominal threshold of 1.2 V and their voltage must be kept within the range of 0 V to V_{CC} for proper operation. If the voltage is taken more than 0.5 V below ground, excessive currents will flow, and proper operation of the drivers will be affected. An open pin is equivalent to a logic high, but good design practices dictate that inputs should never be left open. The Enable input characteristics are shown in Figure 15.

Operating Temperature Range

The minimum ambient operating temperature is listed as –40°C to meet EIA–485 specifications, and 0°C to meet EIA–422–A specifications. The higher V_{OD} required by EIA–422–A is the reason for the narrower temperature range.

The maximum ambient operating temperature (applicable to both EIA–485 and EIA–422–A) is listed as 85°C. However, a lower ambient may be required depending on system use (i.e. specifically how many drivers within a package are used) and at what current levels they are operating. The maximum power which may be dissipated within the package is determined by:

$$PD_{max} = \frac{T_{Jmax} - T_A}{R_{\theta JA}}$$

where: $R_{\theta JA}$ = package thermal resistance (typical 70°C/W for the DIP package, 85°C/W for SOIC package);
T_{Jmax} = max. operating junction temperature, and
T_A = ambient temperature.

Since the thermal shutdown feature has a trip point of 150°C, ±20°C, T_{Jmax} is selected to be 130°C. The power dissipated within the package is calculated from:

$$PD = \{[(V_{CC} - V_{OH}) \bullet I_{OH}] + V_{OL} \bullet I_{OL})\} \text{ each driver } + (V_{CC} \bullet I_{CC})$$

where: V_{CC} = the supply voltage;
V_{OH}, V_{OL} are measured or estimated from Figures 7 to 10;
I_{CC} = the quiescent power supply current (typical 60 mA).

As indicated in the equation, the first term (in brackets) must be calculated and summed for each of the four drivers, while the last term is common to the entire package.

Example 1: T_A = 25°C, $I_{OL} = I_{OH}$ = 55 mA for each driver, V_{CC} = 5.0 V, DIP package. How many drivers per package can be used?

Maximum allowable power dissipation is:

$$PD_{max} = \frac{130°C - 25°C}{70°C/W} = 1.5 \text{ W}$$

Since the power supply current of 60 mA dissipates 300 mW, that leaves 1.2 W (1.5 W – 0.3 W) for the drivers. From Figures 7 and 9, $V_{OL} \approx 1.75$ V, and $V_{OH} \approx 3.85$ V. The power dissipated in each driver is:

$$\{(5.0 - 3.85) \bullet 0.055\} + (1.75 \bullet 0.055) = 160 \text{ mW}.$$

Since each driver dissipates 160 mW, the four drivers per package could be used in this application

Example 2: T_A = 85°C, I_{OL} = 27.8 mA, I_{OH} = 20 mA for each driver, V_{CC} = 5.0 V, SOIC package. How many drivers per package can be used?

Maximum allowable power dissipation is:

$$PD_{max} = \frac{130°C - 85°C}{85°C/W} = 0.53 \text{ W}$$

Since the power supply current of 60 mA dissipates 300 mW, that leaves 230 mW (530 mW – 300 mW) for the drivers. From Figures 8 and 10 (adjusted for V_{CC} = 5.0 V), $V_{OL} \approx 1.38$ V, and $V_{OH} \approx 4.27$ V. The power dissipated in each driver is:

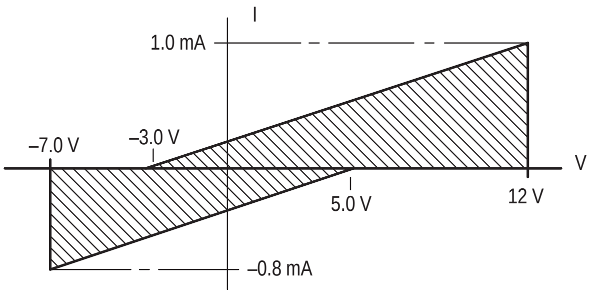
$$\{(5.0 - 4.27) \bullet 0.020\} + (1.38 \bullet 0.0278) = 53 \text{ mW}$$

Since each driver dissipates 53 mW, the use of all four drivers in a package would be marginal. Options include reducing the load current, reducing the ambient temperature, and/or providing a heat sink.

System Requirements

EIA–485 requires each driver to be capable of transmitting data differentially to at least 32 unit loads, plus an equivalent DC termination resistance of 60Ω, over a common mode voltage of –7.0 to 12 V. A unit load (U.L.), as defined by EIA–485, is shown in Figure 17.

Figure 17. Unit Load Definition



Reprinted from EIA–485, Electronic Industries Association, Washington,DC.

A load current within the shaded regions represents an impedance of less than one U.L., while a load current of a magnitude outside the shaded area is greater than one U.L. A system's total load is the sum of the unit load equivalents of each receiver's input current, and each disabled driver's output leakage current. The 60Ω termination resistance mentioned above allows for two 120Ω terminating resistors.

Using the EIA–485 requirements (worst case limits), and the graphs of Figures 7 and 9, it can be determined that the maximum current an MC75172B or MC75174B driver will source or sink is ≈65 mA.

System Example

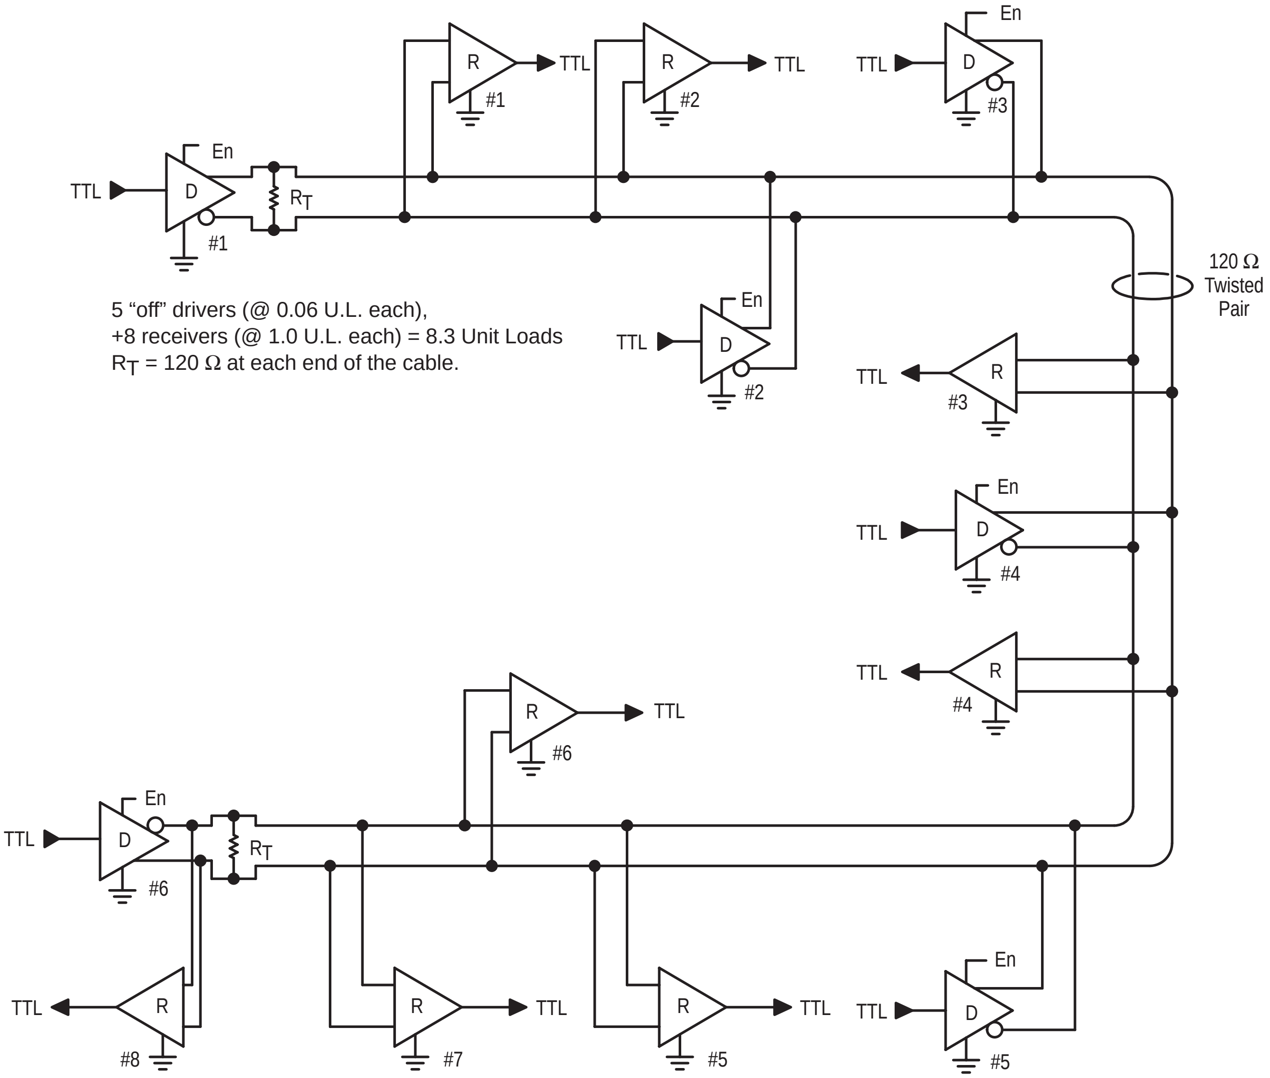
An example of a typical EIA–485 system is shown in Figure 18. In this example, it is assumed each receiver's input characteristics correspond to 1.0 U.L. as defined in Figure 17. Each "off" driver, with a maximum leakage of ±50 µA over the common mode range, presents a load of ≈0.06 U.L. The total load for the active driver is therefore 8.3 unit loads, plus the parallel combination of the two terminating resistors (60Ω). It is up to the system software to control the driver Enable pins to ensure that only one driver is active at any time.

Termination Resistors

Transmission line theory states that, in order to preserve the shape and integrity of a waveform traveling along a cable, the cable must be terminated in an impedance equal to its characteristic impedance. In a system such as that depicted in Figure 18, in which data can travel in both directions, both physical ends of the cable must be terminated. Stubs, leading to each receiver and driver, should be as short as possible.

Leaving off the terminations will generally result in reflections which can have amplitudes of several volts above V_{CC} or below ground. These overshoots and undershoots can disrupt the driver and/or receiver operation, create false data, and in some cases damage components on the bus.

Figure 18. Typical EIA–485 System



5 “off” drivers (@ 0.06 U.L. each),
+8 receivers (@ 1.0 U.L. each) = 8.3 Unit Loads
R_T = 120 Ω at each end of the cable.

NOTES: 1. Terminating resistors R_T must be located at the physical ends of the cable.
2. Stubs should be as short as possible.
3. Circuit ground of all drivers and receivers must be connected via a dedicated wire within the cable. Do not rely on chassis ground or power line ground.

Comparing System Requirements

Characteristic	Symbol	EIA–485	EIA–422–A	V.11 and X.27
GENERATOR (DRIVER)				
Output Impedance (Note 1)	Z_{out}	Not Specified	< 100 Ω	50 10 100 Ω
Open Circuit Voltage				
Differential	V_{OCD}	1.5 to 6.0 V	≤ 6.0 V	≤ 6.0 V, w/3.9 kΩ, Load
Single–Ended	V_{OCS}	< 6.0 V	≤ 6.0 V	≤ 6.0 V, w/3.9 kΩ, Load
Loaded Differential Voltage	V_{OD}	1.5 to 5.0 V, w/54 Ω load	≥ 2.0 V or ≥ 0.5 V_{OCD}, w/100 Ω load	≥ 2.0 V or ≥ 0.5 V_{OCD}, w/100 Ω load
Differential Voltage Balance	ΔV_{OD}	< 200 mV	≤ 400 mV	< 400 mV
Output Common Mode Range	V_{CM}	–7.0 to +12 V	Not Specified	Not Specified
Offset Voltage	V_{OS}	$-1.0 < V_{OS} < 3.0$ V	≤ 3.0 V	≤ 3.0 V
Offset Voltage Balance	ΔV_{OS}	< 200 mV	≤ 400 mV	< 400 mV
Short Circuit Current	I_{OS}	≤ 250 mA for –7.0 to 12 V	≤ 150 mA to ground	≤ 150 mA to ground
Leakage Current (V_{CC} = 0)	I_{OLK}	Not Specified	≤ 100 µA to –0.25 V thru 6.0 V	≤ 100 µA to ± 0.25 V
Output Rise/Fall Time (Note 2)	t_r, t_f	≤ 0.3 T_B, w/54 Ω/1150 pF load	≤ 0.1 T_B or ≤ 20 ns, w/100 Ω load	≤ 0.1 T_B or ≤ 20 ns, w/100 Ω load
RECEIVER				
Input Sensitivity	V_{th}	± 200 mV	± 200 mV	± 300 mV
Input Bias Voltage	V_{bias}	≤ 3.0 V	≤ 3.0 V	≤ 3.0 V
Input Common Mode Range	V_{cm}	–7.0 to 12 V	–7.0 to 7.0 V	–7.0 to 7.0 V
Dynamic Input Impedance	R_{in}	Spec number of U.L.	≥ 4 kΩ	≥ 4 kΩ

NOTES: 1. Compliance with V.11 and X.27 (Blue book) output impedance requires external resistors in series with the outputs of the MC75172B and MC75174B.
2. T_B = Bit time.

Additional Information

Copies of the EIA Recommendations (EIA–485 and EIA–422–A) can be obtained from the Electronics Industries Association, Washington, D.C. (202–457–4966). Copies of the CCITT Recommendations (V.11 and X.27) can be obtained from the United States Department of Commerce, Springfield, VA (703–487–4600).

MOTOROLA

SN75175

Quad EIA-485 Line Receiver

The Motorola SN75175 is a monolithic quad differential line receiver with three–state outputs. It is designed specifically to meet the requirements of EIA–485, EIA–422A/23A Standards and CCITT recommendations.

The device is optimized for balanced multipoint bus transmission at rates up to 10 megabits per second. It also features high input impedance, input hysteresis for increased noise immunity, and input sensitivity of ±200 mV over a common mode input voltage range of –12 V to 12 V. The SN75175 is designed for optimum performance when used with the SN75172 or SN75174 quad differential line drivers.

- Meets EIA Standards EIA–422A and EIA–423A, EIA–485
- Meets CCITT Recommendations V.10, V.11, X.26, and X.27
- Designed for Multipoint Transmission on Long Bus Lines in Noisy Environments
- 3–State Outputs
- Common–Mode Input Voltage Range . . . –12 V to 12 V
- Input Sensitivity . . . ±200 mV
- Input Hysteresis . . . 50 mV Typ
- High Input Impedance . . . 1 EIA–485 Unit Load
- Operates from Single 5.0 V Supply
- Lower Power Requirements
- Plug–In Replacement for MC3486

This device contains 174 active transistors.

MOTOROLA

ULN2068

Quad 1.5 A Sinking High Current Switch

The ULN2068 is a high–voltage, high–current quad Darlington switch array designed for high current loads, both resistive and reactive, up to 300 W.

It is intended for interfacing between low level (TTL, DTL, LS and 5.0 V CMOS) logic families and peripheral loads such as relays, solenoids, dc and stepping motors, multiplexer LED and incandescent displays, heaters, or other high voltage, high current loads.

The Motorola ULN2068 is specified with minimum guaranteed breakdown of 50 V and is 100% tested for safe area using an inductive load. It includes integral transient suppression diodes. Use of a predriver stage reduces input current while still allowing the device to switch 1.5 Amps.

It is supplied in an improved 16–Pin plastic DIP package with heat sink contact tabs (Pins 4, 5, 12 and 13). A copper alloy lead frame allows maximum power dissipation using standard cooling techniques. The use of the contact tab lead frame facilitates attachment of a DIP heat sink while permitting the use of standard layout and mounting practices.

- TTL, DTL, LS, CMOS Compatible Inputs
- 1.5 A Maximum Output Current
- Low Input Current
- Internal Freewheeling Clamp Diodes
- 100% Inductive Load Tested
- Heat Tab Copper Alloy Lead Frame for Increased Dissipation

MAXIMUM RATINGS (T_A = 25°C and ratings apply to any one device in the package, unless otherwise noted)

Rating	Symbol	Value	Unit

ULN2803
ULN2804

Octal High Voltage, High Current Darlington Transistor Arrays

The eight NPN Darlington connected transistors in this family of arrays are ideally suited for interfacing between low logic level digital circuitry (such as TTL, CMOS or PMOS/NMOS) and the higher current/voltage requirements of lamps, relays, printer hammers or other similar loads for a broad range of computer, industrial, and consumer applications. All devices feature open–collector outputs and free wheeling clamp diodes for transient suppression.

The ULN2803 is designed to be compatible with standard TTL families while the ULN2804 is optimized for 6 to 15 volt high level CMOS or PMOS.

Communication Circuits

In Brief . . .

RF

Radio communication has greatly expanded its scope in the past several years. Once dominated by public safety radio, the 30 to 1000 MHz spectrum is now packed with personal and low cost business radio systems. The vast majority of this equipment uses FM or FSK modulation and is targeted at short range applications. From mobile phones and VHF marine radios to garage door openers and radio controlled toys, these new systems have become a part of our lifestyle. Motorola Analog has focused on this technology, adding a wide array of new products including complete receivers processed in our exclusive 3.0 GHz MOSAIC® 1.5 process. New surface mount packages for high density assembly are available for all of these products, as well as a growing family of supporting application notes and development kits.

Telephone & Voice/Data

Traditionally, an office environment has utilized two distinctly separate wired communications systems: telecommunications and data communications. Each had its individual hardware components complement, and each required its own independent transmission line system: twisted wire pairs for Telecom and relatively high priced coaxial cable for Datacom. But times have changed. Today, Telecom and Datacom coexist comfortably on inexpensive twisted wire pairs and use a significant number of components in common. This has led to the development and enhancement of PBX (Private Branch Exchanges) to the point where the long heralded "office of the future," with simultaneous voice and data communications capability at each station, is no longer of the future at all. The capability is here today!

Motorola Semiconductor serves a wide range of requirements for the voice/data marketplace. We offer both CMOS and Analog technologies, each to its best advantage, to upgrade the conventional analog voice systems and establish new capabilities in digital communications. Early products, such as the solid–state single–chip crosspoint switch, the more recent monolithic Subscriber–Loop–Interface Circuit (SLIC), a single–chip Codec/Filter (Mono–Circuit), the Universal Digital Loop Transceivers (UDLT), basic rate ISDN (Integrated Services Digital Network), and single–chip telephone circuits are just a few examples of Motorola leadership in the voice/data area.

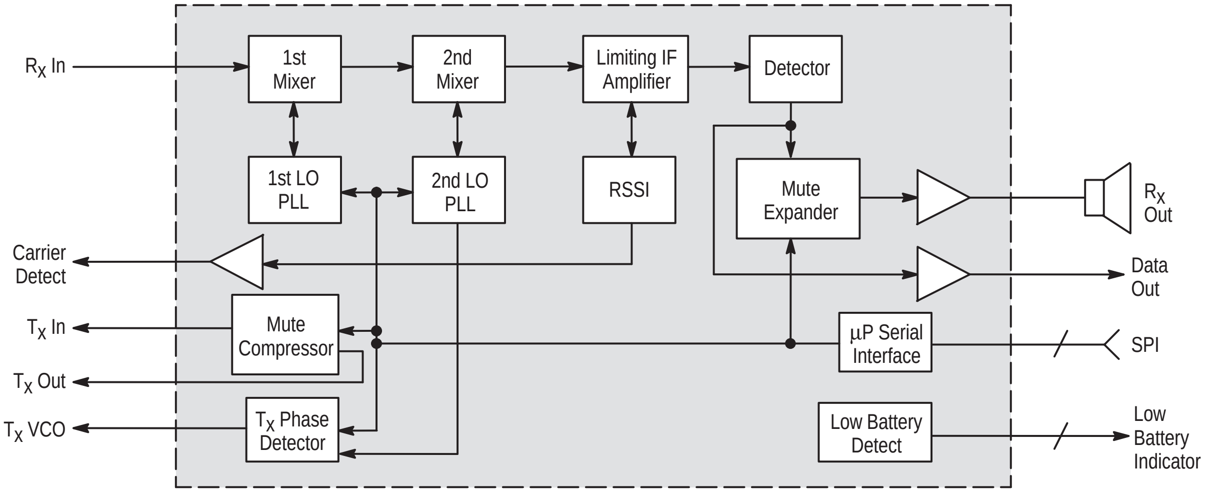
Universal Cordless Telephone Subsystem IC

MC13109FB, FTA

T_A = –20° to +85°C, Case 848B, 932

The MC13109 integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, and external adjustments. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna Input to Audio Output 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expandor Includes Mute, Digital Volume Control and Speaker Driver
  - Compressor Includes Mute, ALC and Limiter
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with No External Switches
  - Universal Design for Domestic and Foreign CT–1 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Output Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Externally Adjustable Trip Point
- 2.0 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices



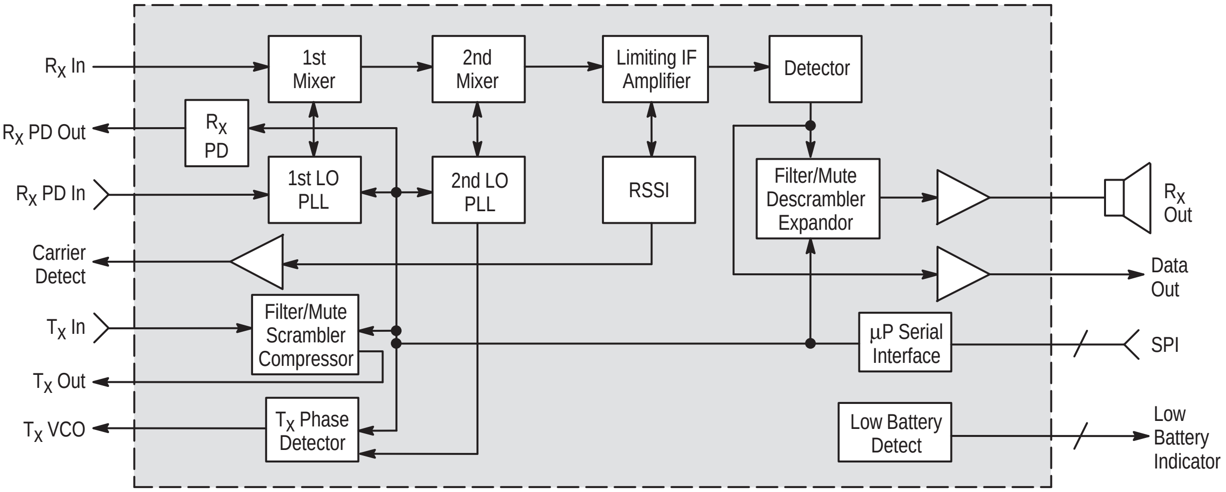
Universal Cordless Telephone Subsystem IC with Scrambler

MC13110FB

T_A = –40° to +85°C, Case 848B

The MC13110 integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, and external adjustments. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna In to Audio Out 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expandor Includes Mute, Digital Volume Control, Speaker Driver, 3.5 kHz Low Pass Filter, and Programmable Gain Block
  - Compressor Includes Mute, 3.5 kHz Low Pass Filter, Limiter, and Programmable Gain Block
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with New External Switches
  - Universal Design for Domestic and Foreign CT–1 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Outputs Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Provides Two Levels of Monitoring with Separate Outputs
  - Separate, Adjustable Trip Points
- Frequency Inversion Scrambler/Descrambler
  - Can Be Enabled/Disabled Via MPU Interface
  - Programmable Carrier Modulation Frequency
- 2.7 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices



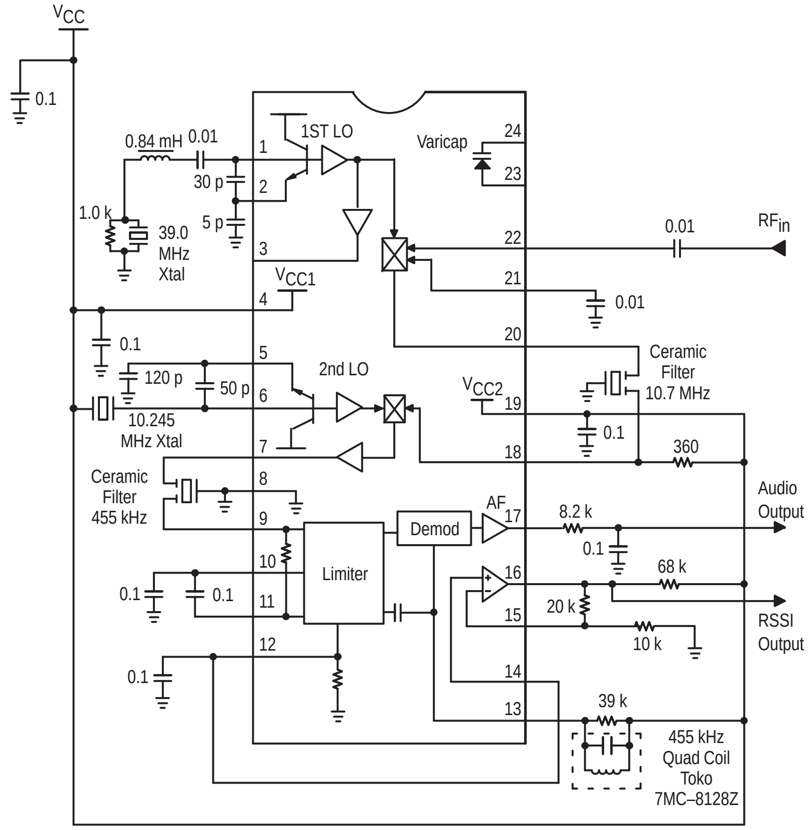
Narrowband FM Receiver

MC13135/136P, DW

T_A = –40° to +85°C, Case 724, 751E

The MC13135 is a full dual conversion receiver with oscillators, mixers, Limiting IF Amplifier, Quadrature Discriminator, and RSSI circuitry. It is designed for use in security systems, cordless phones, and VHF mobile and portable radios. Its wide operating supply voltage range and low current make it ideal for battery applications. The Received Signal Strength Indicator (RSSI) has 65 dB of dynamic range with a voltage output, and an operational amplifier is included for a dc buffered output. Also, an improved mixer third order intercept enables the MC13135 to accommodate larger input signal levels.

- Complete Dual Conversion Circuitry
- Low Voltage: 2.0 to 6.0 Vdc
- RSSI with Op Amp: 65 dB Range
- Low Drain Current: 3.5 mA Typical
- Improved First and Second Mixer 3rd Order Intercept
- Detector Output Impedance: 25 Ω Typically



Narrowband FM Coilless Detector IF Subsystem

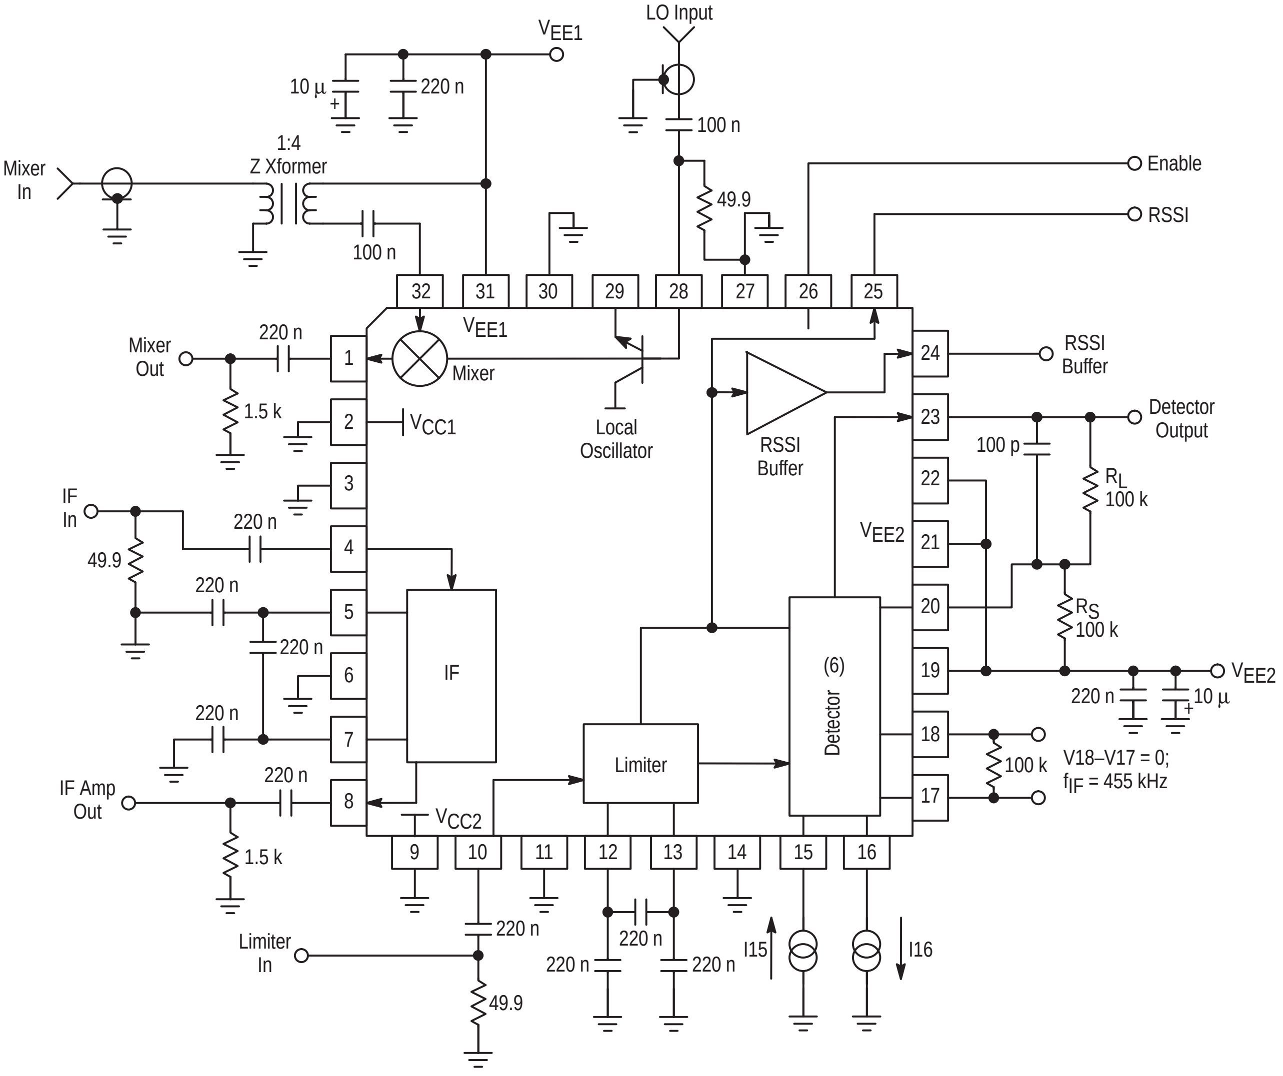
MC13150FTA, FTB

T_A = –40° to +85°C, Case 977, 873

The MC13150 is a narrowband FM IF subsystem targeted at cellular and other analog applications. Excellent high frequency performance is achieved, with low cost, through use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13150 has an onboard Colpitts VCO for Crystal controlled second LO in dual conversion receivers. The mixer is a double balanced configuration with excellent third order intercept. It is useful to beyond 200 MHz. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. The quadrature detector is a unique design eliminating the conventional tunable quadrature coil.

Applications for the MC13150 include cellular, CT–1 900 MHz cordless telephone, data links and other radio systems utilizing narrowband FM modulation.

- Linear Coilless Detector
- Adjustable Demodulator Bandwidth
- 2.5 to 6.0 Vdc Operation
- Low Drain Current: < 2.0 mA
- Typical Sensitivity of 2.0 µV for 12 dB SINAD
- IIP3, Input Third Order Intercept Point of 0 dBm
- RSSI Range of Greater Than 100 dB
- Internal 1.4 kΩ Terminations for 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range



Wideband FM IF System

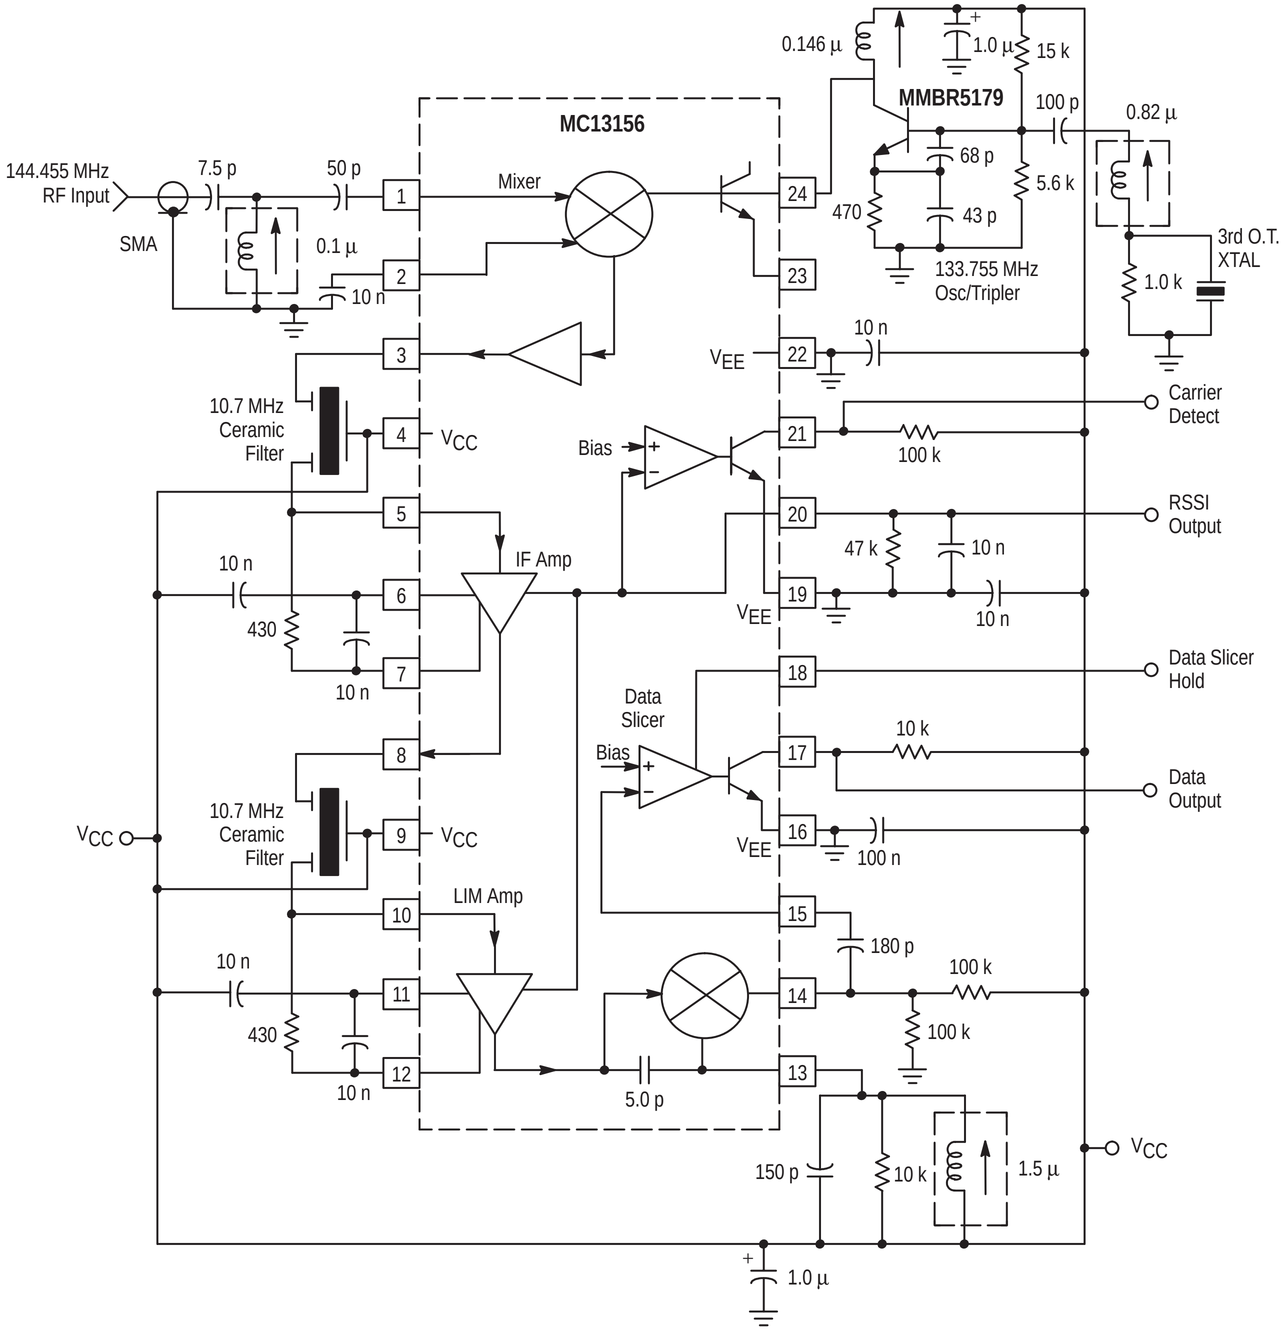
MC13156DW, FB

$T_A = –40°$ to $+85°C$, Case 751E, 873

The MC13156 is a wideband FM IF subsystem targeted at high performance data and analog applications. Excellent high frequency performance is achieved, with low cost, through use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13156 has an onboard Colpitts VCO for PLL controlled multichannel operation. The mixer is useful to beyond 200 MHz and may be used in a differential, balanced, or single–ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has a hold function to preset the shaper for fast recovery of new data.

Applications for the MC13156 include CT–2, wideband data links, and other radio systems utilizing GMSK, FSK or FM modulation.

- 2.0 to 6.0 Vdc Operation
- Typical Sensitivity of 6.0 µV for 12 dB SINAD
- RSSI Dynamic Range Typically 80 dB
- High Performance Data Shaper for Enhanced CT–2 Operation
- Internal 300 Ω and 1.4 kΩ Terminations for 10.7 MHz and 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range



Wideband FM IF Subsystem

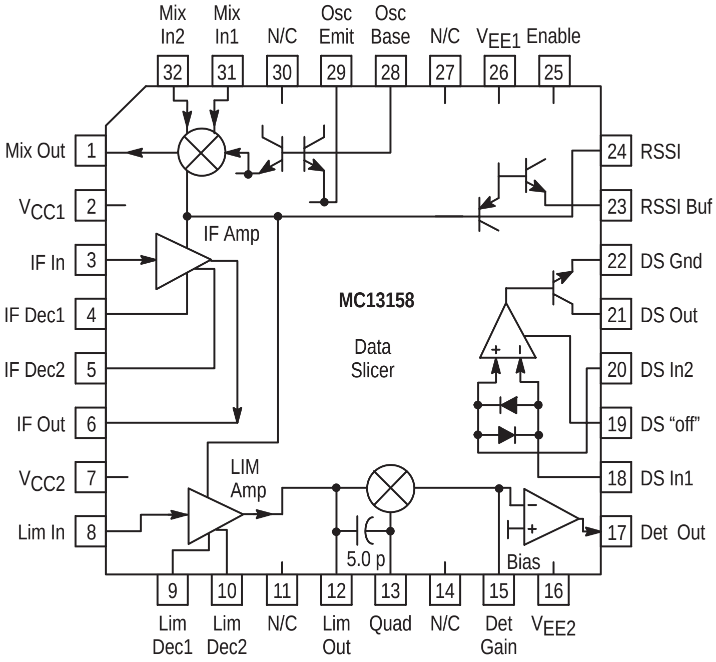
MC13158FTB

T_A = –40° to +85°C, Case 873

The MC13158 is a wideband IF subsystem that is designed for high performance data and analog applications. Excellent high frequency performance is achieved, with low cost, through the use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13158 has an on–board grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multi–channel operation. The mixer is useful to 500 MHz and may be used in a balanced differential or single ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has an Off function to shut the output "off" to save current. An enable control is provided to power down the IC for power management in battery operated applications.

Applications include DECT, wideband wireless data links for personal and portable laptop computers and other battery operated radio systems which utilize GFSK, FSK or FM modulation.

- Designed for DECT Applications
- 1.8 to 6.0 Vdc Operating Voltage
- Low Power Consumption in Active and Standby Mode
- Greater than 600 kHz Detector Bandwidth
- Data Slicer with Special Off Function
- Enable Function for Power Down of Battery Operated Systems
- RSSI Dynamic Range of 80 dB Minimum
- Low External Component Count



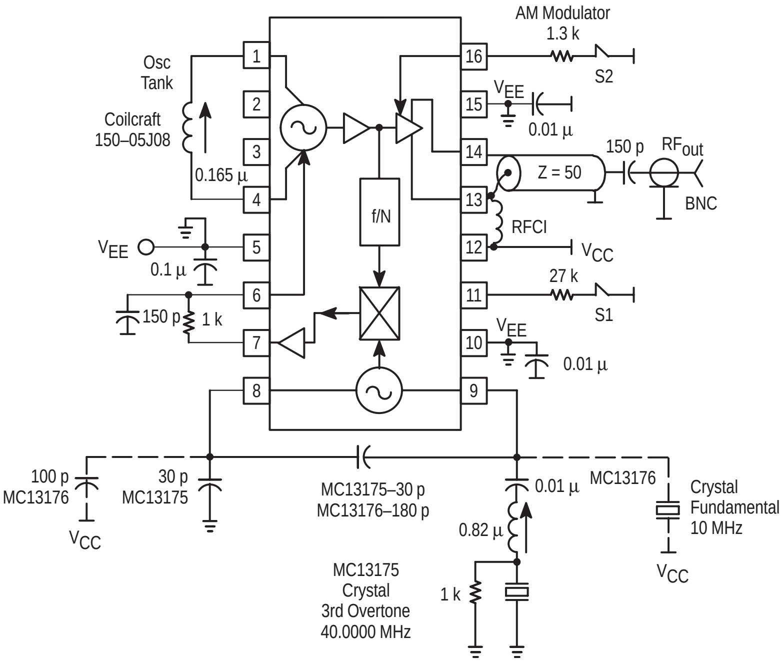
UHF, FM/AM Transmitter

MC13175/176D

T_A = 0° to +70°C, Case 751B

The MC13175 and MC13176 are one chip FM/AM transmitter subsystems designed for AM/FM communication systems operating in the 260 to 470 MHz band covered by FCC Title 47; Part 15. They include a Colpitts crystal reference oscillator, UHF oscillator, ÷8 (MC13175) or ÷32 (MC13176) prescaler, and phase detector forming a versatile PLL system. Another application is as a local oscillator in a UHF or 900 MHz receiver. MC13175/176 offer the following features:

- UHF Current Controlled Oscillator
- Use Easily Available 3rd Overtone or Fundamental Crystals for Reference
- Low Number of External Parts Required
- Low Operating Supply Voltage (1.8 – 5 Vdc)
- Low Supply Drain Currents
- Power Output Adjustable (Up to +10 dBm)
- Differential Output for Loop Antenna or Balun Transformer Networks
- Power Down Feature
- ASK Modulated by Switching Output “On”/“Off”
- MC13175 – $f_o = 8 \times f_{ref}$
- MC13176 – $f_o = 32 \times f_{ref}$



Telecommunications

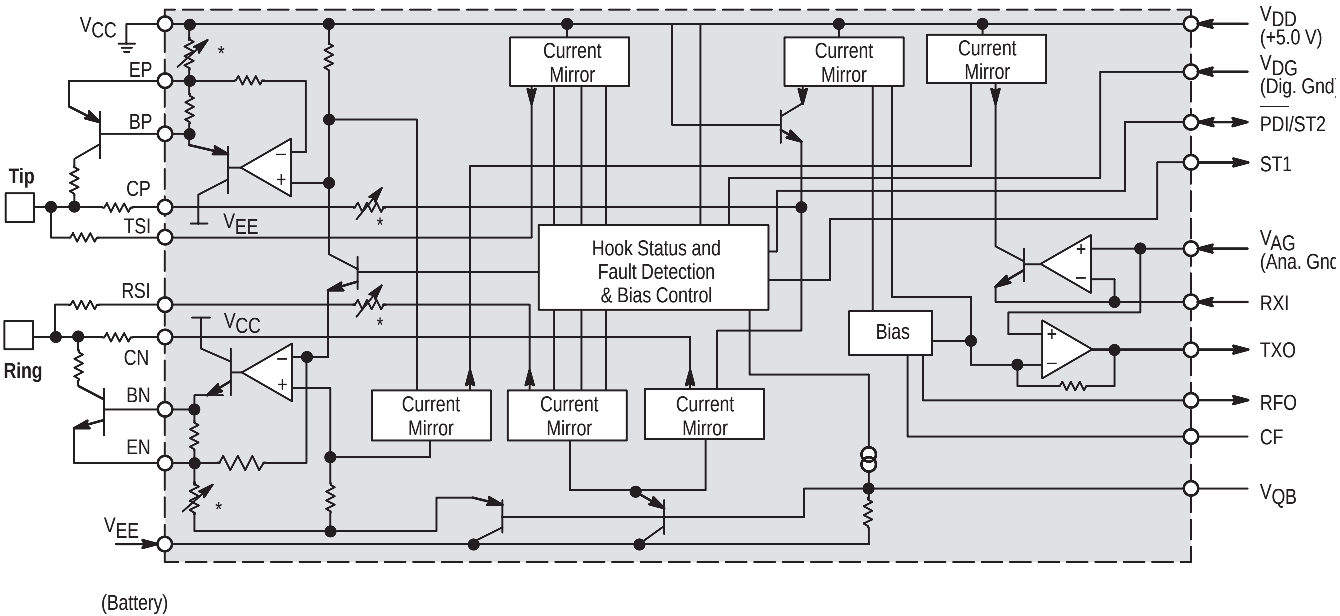
Subscriber Loop Interface Circuit (SLIC)

MC33120/1P, FN

T_A = –40° to +85°C, Case 738, 776

With a guaranteed minimum longitudinal balance of 58 dB, the MC33120/1 is ideally suited for Central Office applications, as well as PBXs, and other related equipment. Protection and sensing components on the two–wire side can be non–precision while achieving required system performance. Most BORSHT functions are provided while maintaining low power consumption, and a cost effective design. Size and weight reduction over conventional transformer designs permit a higher density system.

- All Key Parameters Externally Programmable with Resistors:
  - Transmit and Receive Gains
  - Transhybrid Loss
  - Return Loss
  - DC Loop Current Limit and Battery Feed Resistance
  - Longitudinal Impedance
- Single and Double Fault Sensing and Protection
- Minimum 58 dB Longitudinal Balance (2–wire and 4–wire) Guaranteed
- Digital Hook Status and Fault Outputs
- Power Down Input
- Loop Start or Ground Start Operation
- Size & Weight Reduction Over Conventional Approaches
- Available in 20 Pin DIP and 28 Pin PLCC Packages
- Battery Voltage: –42 to –58 V (for MC33120),
  –21.6 to –42 V (for MC33121)



* Indicates Trimmed Resistor

PBX Architecture (Analog Transmission)

PCM Mono–Circuits Codec–Filters (CMOS LSI)

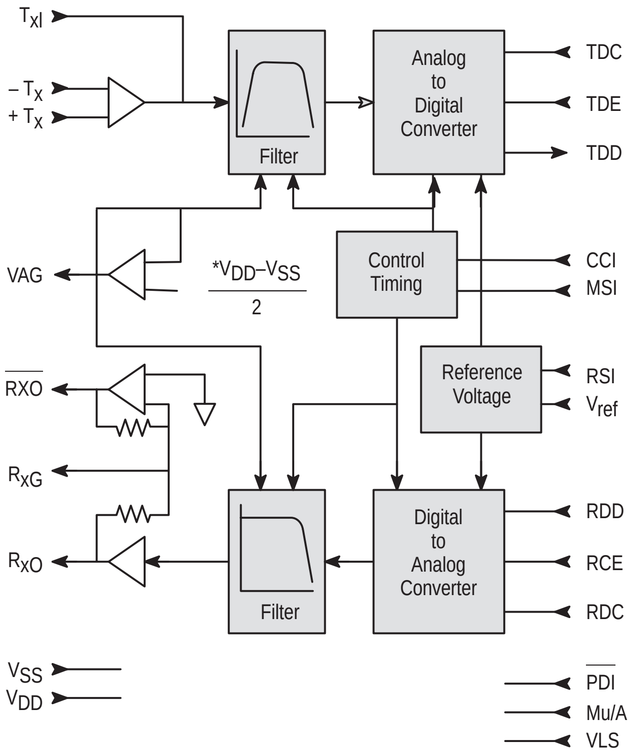
MC145500 Series

Case 648, 708, 751G, 776

The Mono–circuits perform the digitizing and restoration of the analog signals. In addition to these important functions, Motorola's family of pulse–code modulation mono–circuits also provides the band–limiting filter functions – all on a single monolithic CMOS chip with extremely low power dissipation.

The Mono–circuits require no external components. They incorporate the bandpass filter required for antialiasing and 60 Hz rejection, the A/D–D/A conversion functions for either U.S. Mu–Law or European A–Law companding formats, the low–pass filter required for reconstruction smoothing, an on–board precision voltage reference, and a variety of options that lend flexibility to circuit implementations. Unique features of Motorola's Mono–circuit family include wide power supply range (6.0 to 13 V), selectable on–board voltage reference (2.5, 3.1, or 3.8 V), and TTL or CMOS I/O interface.

Motorola supplies three versions in this series. The MC145503 and MC145505 are general–purpose devices in 16 pin packages designed to operate in digital telephone or line card applications. The MC145502 is the full–feature device that presents all of the options available on the chip. This device is packaged in a 22 pin DIP and 28 pin chip carrier package.



MC145554/57/64/67

Case 648, 751D, 751G, 738

These per channel PCM Codec–Filters perform the voice digitization and reconstruction as well as the band limiting and smoothing required for PCM systems. They are designed to operate in both synchronous and asynchronous applications and contain an on–chip precision voltage reference. The MC145554 (Mu–Law) and MC145557 (A–Law) are general purpose devices that are offered in 16 pin packages. The MC145564 (Mu–Law) and MC145567 (A–Law), offered in 20 pin packages, add the capability of analog loop–back and push–pull power amplifiers with adjustable gain.

All four devices include the transmit bandpass and receive lowpass filters on–chip, as well as active RC pre–filtering and post–filtering. Fully differential analog circuit design assures lowest noise. Performance is specified over the extended temperature range of –40° to +85°C.

These PCM Codec–Filters accept both industry standard clock formats. They also maintain compatibility with Motorola's family of MC3419/MC33120 SLIC products.

MC14LC5480P, DW, SD

Case 738, 751D, 940C–02

This 5.0 V, general purpose per channel PCM Codec–Filter offers selectable Mu–Law or A–Law companding in 20 pin DIP, SOG and SSOP packages. It performs the voice digitization and reconstruction as well as the band limiting and smoothing required for PCM systems. It is designed to operate in both synchronous and asynchronous applications and contains an on–chip precision reference voltage (1.575 V).

The transmit bandpass and receive lowpass filters, and the active RC pre–filtering and post–filtering are incorporated, as well as fully differential analog circuit design for lowest noise. Push–pull 300 Ω power drivers with external gain adjust are also included.

The MC14LC5480 PCM Codec–Filter accepts a variety of clock formats, including short–frame sync, long–frame sync, IDL, and GCI timing environments. This device also maintains compatibility with Motorola's family of Telecom products, including the MC145472 U–Interface Transceiver, MC145474/75 S/T–Interface Transceiver, MC145532 ADPCM Transcoder, MC145422/26 UDLT–I, MC145421/25 UDLT–II, and MC3419/MC33120 SLIC.

Replaces the MC145480P, DW, SD.

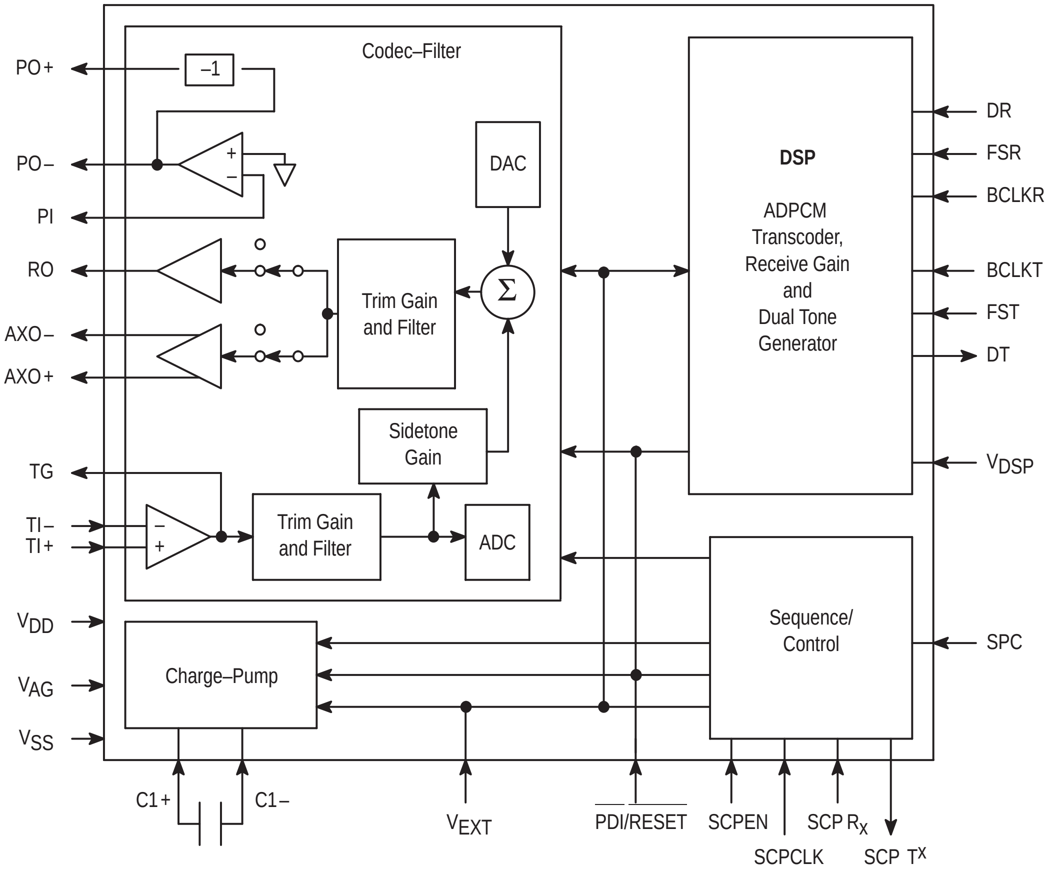
MC14LC5540P, DW, FU

Case 710, 751F, 873

The MC14LC5540 ADPCM Codec is a single chip implementation of a PCM Codec–Filter and an ADPCM encoder/decoder, and therefore provides an efficient solution for applications requiring the digitization and compression of voiceband signals. This device is designed to operate over a wide voltage range, 2.7 V to 5.25 V, and as such is ideal for battery powered as well as ac powered applications. The MC14LC5540 ADPCM Codec also includes a serial control port and internal control and status registers that permit a microcomputer to exercise many built–in features.

The ADPCM Codec is designed to meet the 32 kbps ADPCM conformance requirements of CCITT Recommendation G.721 (1988) and ANSI T1.301 (1987). It also meets ANSI T1.303 and CCITT Recommendation G.723 for 24 kbps ADPCM operation, and the 16 kbps ADPCM standard, CCITT Recommendation G.726. This device also meets the PCM conformance specification of the CCITT G.714 Recommendation.

Figure 1. MC14LC5540 ADPCM Codec Block Diagram



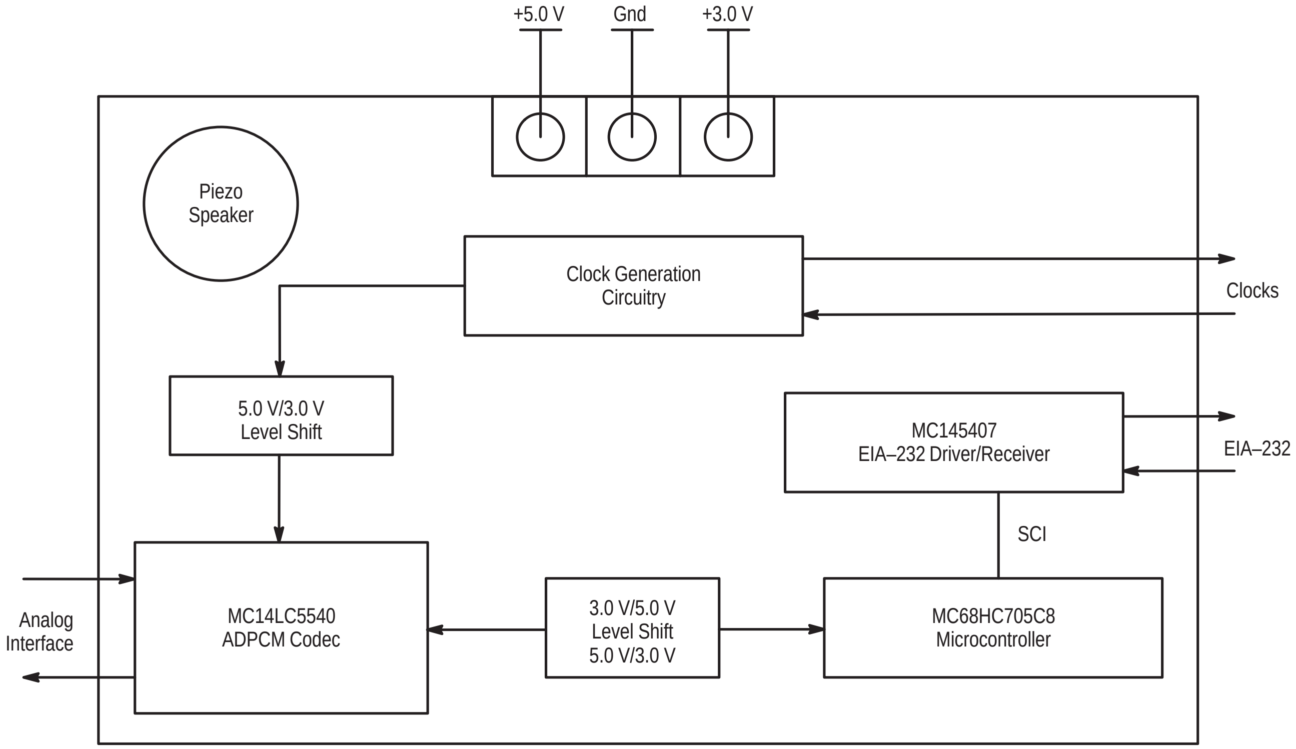
MC145537EVK

ADPCM Codec Evaluation Kit

The MC145537EVK is the primary tool for evaluation and demonstration of the MC14LC5540 ADPCM Codec. It provides the necessary hardware and software interface to access the many features and operational modes of the MC14LC5540 ADPCM Codec.

- Provides Stand Alone Evaluation on Single Board
- The kit provides Analog–to–Analog, Analog–to–Digital or Digital–to–Analog Connections – with Digital Connections being 64 kbps PCM, 32 or 24 kbps ADPCM, or 16 kbps CCITT G.726 or Motorola Proprietary ADPCM
- +5.0 V Only Power Supply, or 5.0 V Plus 2.7 to 5.25 V Supply
- Easily Interfaced to Test Equipment, Customer System, Second MC145537EVK or MC145536EVK (5.0 V Only) for Full Duplex Operation
- Convenient Access to Key Signals
- Piezo Loudspeaker
- EIA–232 Serial Computer Terminal Interface for Control of the MC14LC5540 ADPCM Codec Features
- Compatible Handset Provided
- Schematics, Data Sheets, and User’s Manual Included

Figure 2. MC145537EVK Block Diagram

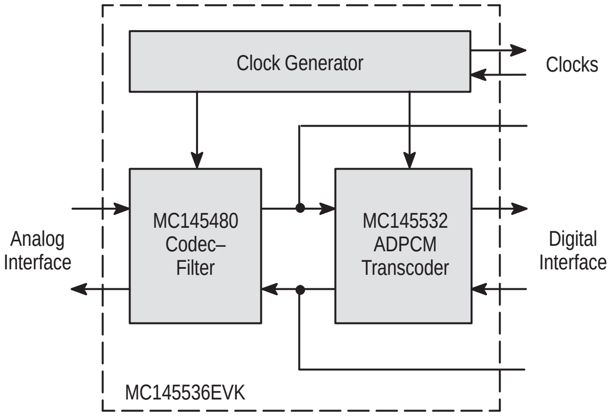


MC145536EVK

Codec–Filter/ADPCM Transcoder Evaluation Kit

The MC145536EVK is the primary tool for evaluation and demonstration of the MC14LC5480 Single +5.0 V supply PCM Codec–Filter and the MC145532 ADPCM Transcoder (see ‘‘Telephone Accessory Circuits’’). The MC145536EVK provides the necessary hardware needed to evaluate the many separate operating modes under which the MC14LC5480 and MC145532 are intended to operate.

- Provides Stand Alone Evaluation on a Single Board
- Easily Interfaced to Test Equipment, Customer System, or Second MC145536EVK
- Convenient Access to Key Signals
- Generous Wire–Wrap Area for Application Development
- The kit provides Analog–to–Analog, Analog–to–Digital, or Digital–to–Analog Connections – with Digital Connections Being 64 kbps PCM; 32, 24, or 16 kbps Motorola Proprietary ADPCM
- Compatible Handset Included
- Schematics, Data Sheets, and User’s Manual included



Dual Tone Multiple Frequency Receiver

MC145436AP, DW

Case 646, 751G

This device contains the filter and decoder for detection of a pair of tones conforming to the DTMF standard with outputs in hexadecimal. Switched capacitor filter technology is used together with digital circuitry for the timing control and output circuits. The MC145436A provides excellent power–line noise and dial tone rejection.

Replaces MC145436P, DW.

ISDN Voice/Data Circuits

Integrated Services Digital Network

ISDN is the revolutionary concept of converting the present analog telephone networks to an end–to–end global digital network. ISDN standards make possible a wide variety of services and capabilities that are revolutionizing communications in virtually every industry.

Motorola’s ISDN product family includes the MC14LC5472 and MC145572 U–Interface Transceivers, the MC145474/75 and MC145574 S/T–Interface Transceivers, MC145488 Dual Data Link Controller, and the MC68302 Integrated Multi–Protocol Processor. These are supported by a host of related devices including the MC14LC5480 +5.0 V PCM Codec–Filter, MC145532 ADPCM Transcoder, MC14LC5540 ADPCM Codec, MC145500 family of single–chip codec/filters, MC145436A DTMF Decoder, MC33120 Subscriber Loop Interface Circuit, MC34129 Switching Power Supply Controller, and the MC145406/07 CMOS EIA 232–E Driver/ Receiver family.

Motorola’s key ISDN devices fit into four ISDN network applications: a digital subscriber line card, an NT1 network termination, an ISDN terminal adapter, and an ISDN terminal. Digital subscriber line cards are used in central offices, remote concentrators, channel banks, T1 multiplexers, and other switching equipment. The NT1 network termination block illustrates the simplicity of remote U– to S/T–interface conversion. The ISDN terminal adapter and ISDN terminal block show how Motorola ICs are used to combine voice and data in PC compatible boards, digital telephones, and other terminal equipment. Expanded applications such as a PBX may include these and other Motorola ISDN circuits. Many “non–ISDN” uses, such as pairgain applications, are appropriate for Motorola’s ISDN devices as well.

Second Generation U–Interface Transceivers

MC145572PB

Case 842D

MC145572FN

Case 777

The MC145572 fully conforms to ANSI T1.601–1992, the North American standard for ISDN Basic Access on a single twisted–wire pair. The transceiver achieves a remarkable 10^{-7} bit error rate performance on all ANSI specified test loops with worst–case impairments present. The state–of–the–art 0.65 micron single–chip solution uses advanced design techniques to combine precision analog signal processing elements with three digital signal coprocessors to build an adaptively equalized echo cancelling receiver.

Two modes of handling U–interface maintenance functions are provided on the MC145572. In the automatic maintenance mode the U–interface transceiver handles all ANSI specified maintenance and channel procedures internally to minimize your software development effort. Automatic procedures include generating and monitoring the cyclic redundancy check, reporting and counting far end block errors (near end block errors too), handling the ACT and DEA bits, as well as monitoring and appropriately responding to embedded operations channel messages.

The MC145572 has 275 mW maximum power dissipation. It also has an enhanced TDM interface that supports an on–chip timeslot assigner, GCI and IDL modes of operation.

The optional manual maintenance mode lets you choose an inexpensive microcontroller, such as a member of Motorola's MC68HC05 family, to control and augment the standard maintenance channel functions. This flexible feature also allows for easy implementation of proprietary maintenance functions.

Second Generation S/T–Interface Transceivers

MC145574PB

Case 873A

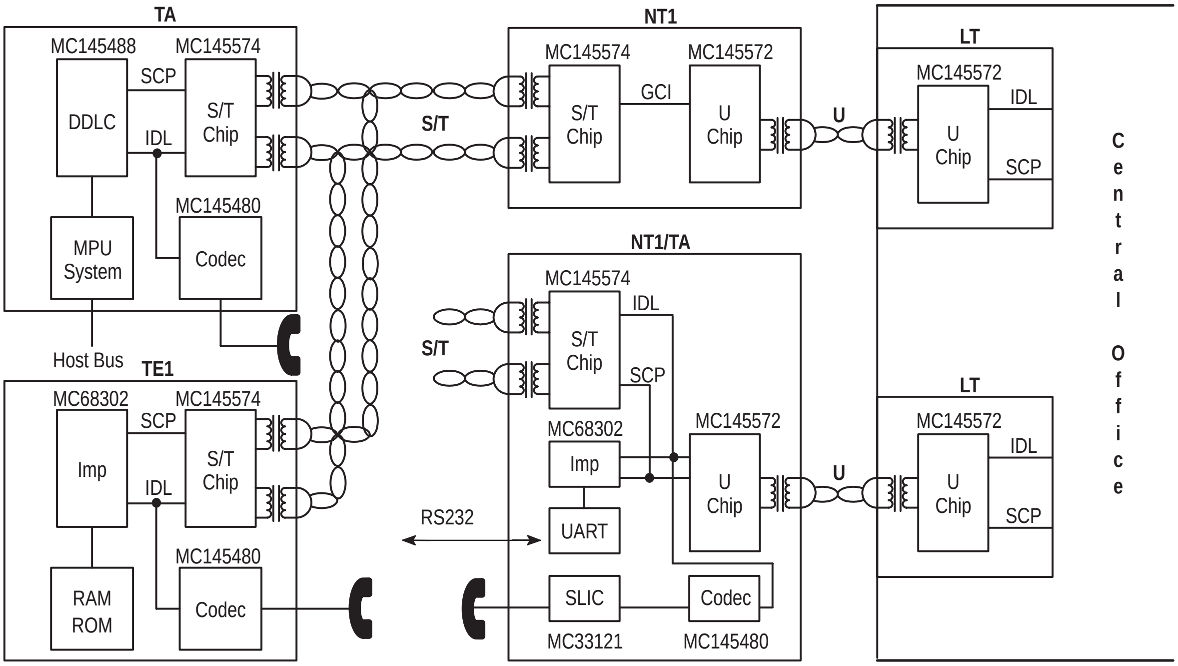
MC145574DW

Case 751F

The MC145574 S/T–Interface Transceivers provide a CCITT I.430 compatible interface for use in line card, network termination, and ISDN terminal equipment applications. Manufactured with Motorola's advanced 0.65 micron CMOS mixed analog and digital process technology, the MC145574 is a physical layer device capable of operating in point–to–point or point–to–multipoint passive bus arrangements. In addition, the MC145574 implements the optional NT1 Star topology, NT terminal mode and TE slave mode.

This device features outstanding transmission performance. It reliably transmits over 1 kilometer in a point–to–point application. Comparable performance is achieved in all other topologies as well. Other features include pin selectable terminal or network operating modes, industry standard microprocessor serial control port, full support of the multiframing S and Q channels, a full range of loopbacks, and low power CMOS operation, with a maximum power consumption of 90 mW.

The MC145574 has an enhanced TDM interface that supports GCI, IDL and an on–chip timeslot assigner.



Dual Data Link Controller

MC145488FN
Case 779

The MC145488 features two full–duplex serial HDLC channels with an on–chip Direct Memory Access (DMA) controller. The DMA controller minimizes the number of microprocessor interrupts from the communications channels, freeing the microprocessor’s resources for other tasks. The DMA controller can access up to 64 kbytes of memory, and transfers either 8–bit bytes or 16–bit words to or from memory. The MC145488 DDLC is compatible with Motorola’s MC68000 and other microprocessors.

In a typical ISDN terminal application, one DDLC communications channel supports the D–channel (LAPD) while the other supports the B–channel (LAPB). While the DDLC is ideally suited for ISDN applications, it can support many other HDLC protocol applications as well.

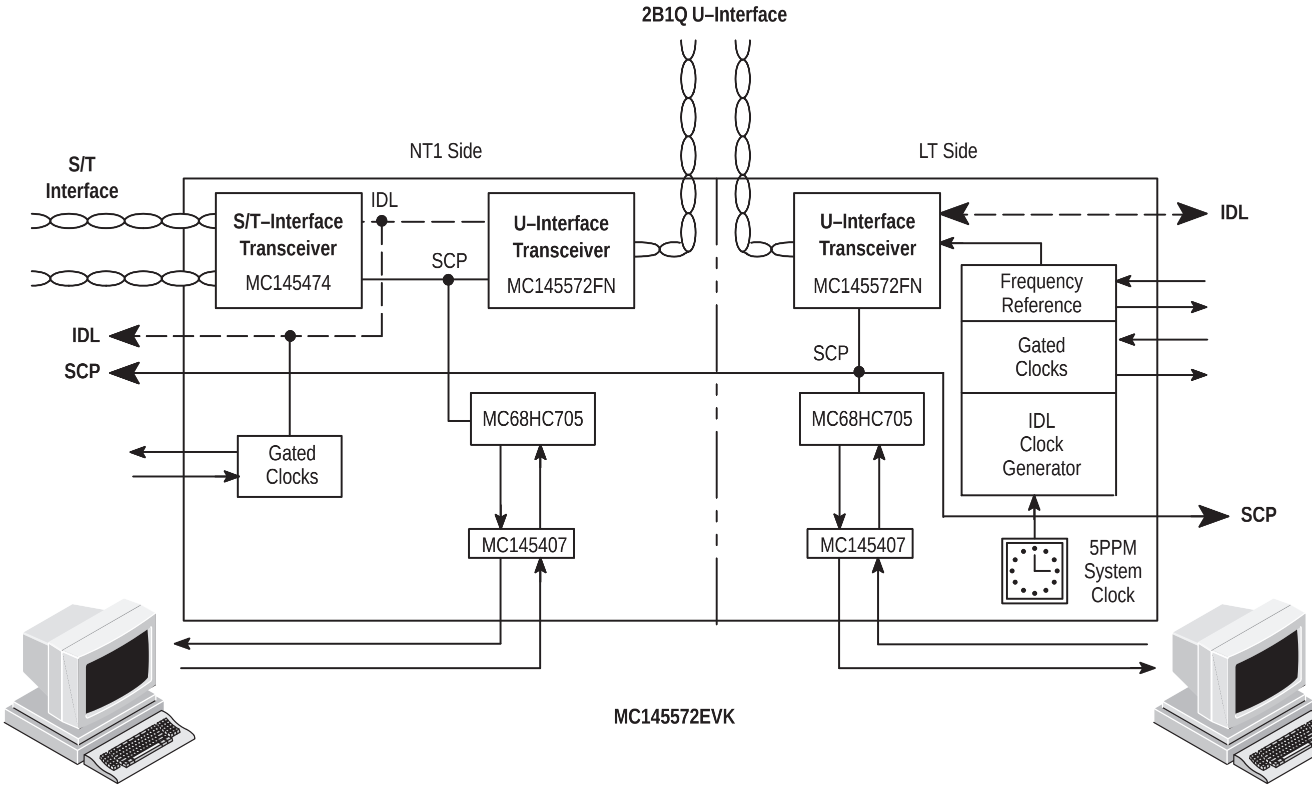
Some of the powerful extras found on the DDLC include automatic abort and retransmit of D–channel collisions in S/T–interface applications, address recognition, automatic recovery mechanisms for faulty frame correction, and several system test modes. Address recognition provides a reduction in the host microprocessor load by filtering data frames not addressed to the host. The DDLC can compare either SAPI or TEI fields of LAPD frames. For LAPD (Q.921) applications, both A and B addresses may be checked.

MC14LC5494EVK
U–Interface Transceiver Evaluation Kit discontinued

MC145572EVK
U–Interface Transceiver Evaluation Kit

This kit provides the hardware and software to evaluate the many configurations under which the MC145572EVK is able to operate. Used as a whole, it operates as both ends of the two–wire U interface that extends from the customer premises (NT1) to the switch line card (LT). The two halves of the board can be physically and functionally separated, providing independent NT1 and LT evaluation capability.

The kit provides the ability to interactively manipulate status registers in the MC145572EVK U–Interface transceiver or in the MC145474/75 S/T–Interface transceiver with the aid of an external terminal. The device can also be controlled using the MC68302 Integrated Multiprotocol Processor application development system to complete a total Basic Rate ISDN evaluation solution.



Voice/Data Communication (Digital Transmission)

2–Wire Universal Digital Loop Transceiver (UDLT)

MC145422P, DW Master Station

Case 708, 751E

MC145426P, DW Slave Station

Case 708, 751E

The UDLT family of transceivers allows the use of existing twisted–pair telephone lines (between conventional telephones and a PBX) for the transmission of digital data. With the UDLT, every voice–only telephone station in a PBX system can be upgraded to a digital telephone station that handles the complex voice/data communications with no increase in cabling costs.

In implementing a UDLT–based system the A/D to D/A conversion function associated with each telset is relocated from the PBX directly to the telset. The SLIC (or its equivalent circuit) is eliminated since its signaling information is transmitted digitally between two UDLTs.

The UDLT master–slave system incorporates the modulation/demodulation functions that permit data communications over a distance up to 2 kilometers. It also provides the sequence control that governs the exchange of information between master and slave. Specifically, the master resides on the PBX line card where it transmits and receives data over the wire pair to the telset. The slave is located in the telset and interfaces the mono–circuit to the wire pair. Data transfer occurs in 10–bit bursts (8 bits of data and 2 signaling bits), with the master transmitting first, and the slave responding in a synchronized half–duplex transmission format.

UDLTs utilize a 256 kilobaud Modified Differential Phase Shift Keyed (MDPSK) burst modulation technique for transmission to minimize radio frequency, electromagnetic, and crosstalk interference. Implementation through CMOS technology takes advantage of low–power operation, increased reliability, and the proven capabilities to perform complex telecommunications functions.

Functional Features

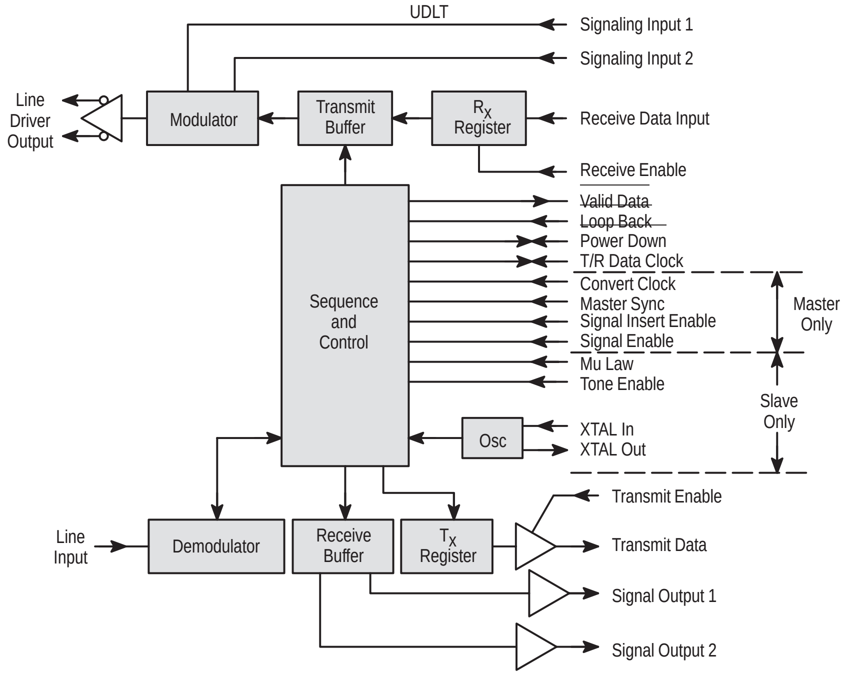
- Provides Synchronous Duplex 64 kbits/Second Voice/Data Channel and Two 8 kbits/Second Signaling Data Channels Over One 26 AWG Wire Pair Up to 2 km.
- Compatible with Existing and Evolving Telephone Switch Architectures and Call Signaling Schemes
- Automatic Detection Threshold Adjustment for Optimum Performance Over Varying Signal Attenuations
- Protocol Independent
- Single 5.0 V to 8.0 V Power Supply

MC145422 Master UDLT

- 2.048 MHz Master Clock
- Pin Controlled Power–Down and Loop–Back Features
- Variable Data Clock – 64 kHz to 2.56 MHz
- Pin Controlled Insertion/Extraction of 8 kbits/Seconds Channel into LSB of 64 kbits/Second Channel for Simultaneous Routing of Voice and Data Through PCM Voice Path of Telephone Switch

MC145426 Slave UDLT

- Compatible with MC145500 Series and Later PCM Mono–Circuits
- Automatic Power–Up/Down Feature
- On–Chip Data Clock Recovery and Generation
- Pin Controlled 500 Hz D3 or CCITT Format PCM Tone Generator for Audible Feedback Applications



2–Wire ISDN Universal Digital Loop Transceiver II (UDLT II)

MC145421P, DW Master

Case 709, 751E

MC145425P, DW Slave

Case 709, 751E

Similar to the MC145422/26 UDLT, but provide synchronous full duplex 160 kbps voice and data communication in a 2B + 2D format for ISDN compatibility on a single twisted pair up to 1 km. Single 5.0 V power supply, protocol independent.

Electronic Telephone

The Complete Electronic Telephone Circuit

MC34010P, FN

T_A = –20° to +60°C, Case 711, 777

The conventional transformer–driven telephone handset is undergoing major innovations. The bulky transformer is disappearing. So are many of its discrete components, including the familiar telephone bell. They are being replaced with integrated circuits that perform all the major handset functions simply, reliably and inexpensively . . . functions such as 2–to–4 wire conversion, DTMF dialing, tone ringing, and a variety of related activities.

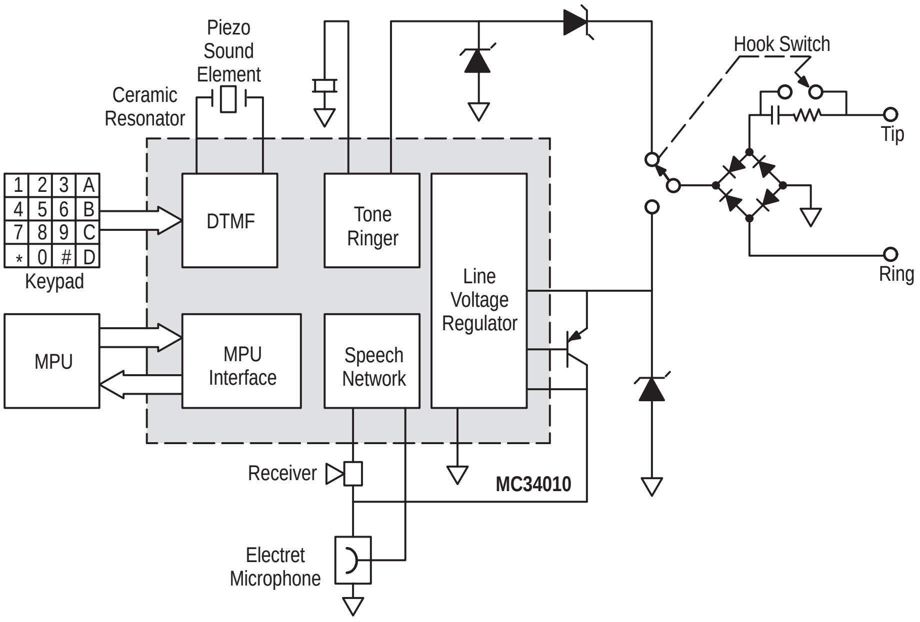
The culmination of these capabilities is the Electronic Telephone Circuit, the MC34010. These ICs place all of the above mentioned functions on a single monolithic chip.

These telephone circuits utilize advanced bipolar analog (I^2L) technology and provide all the necessary elements of a modern tone–dialing telephone. The MC34010 even incorporates an MPU interface circuit for the inclusion of automatic dialing in the final system.

- Provides all basic telephone functions, including DTMF dialer, tone ringer, speech network and line voltage regulator
- DTMF generator uses low cost ceramic resonator with accurate frequency synthesis technique
- Tone ringer drives piezoelectric transducer and satisfies EIA–470 requirements
- Speech network provides 2–to–4 wire conversion with adjustable sidetone utilizing an electret transmitter
- On–chip regulator insures stable operation over wide range of loop lengths
- I^2L technology provides low 1.4 V operation and high static discharge immunity
- Microprocessor interface port for automatic dialing features

Also Available

A broad line of additional telephone components for customizing systems design.



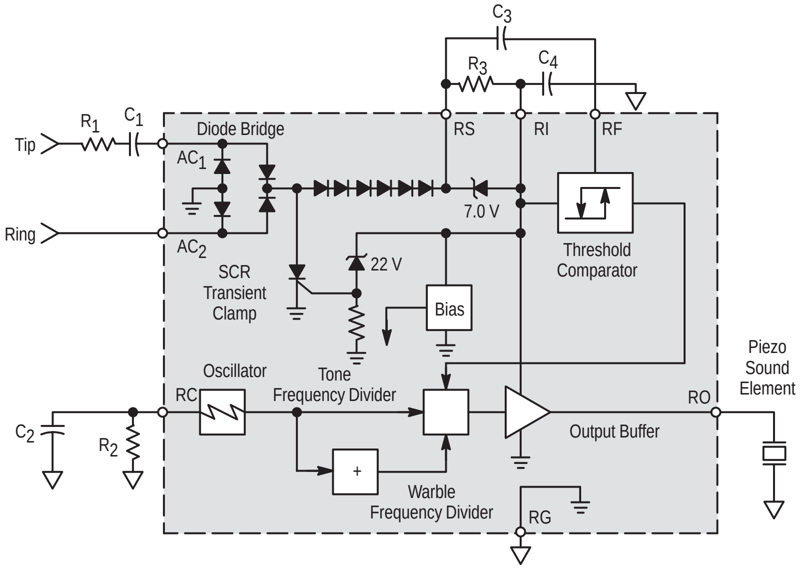
Tone Ringers

The MC34012, MC34017, and MC34117 Tone Ringers are designed to replace the bulky bell assembly of a telephone, while providing the same function and performance under a variety of conditions. The operational requirements spelled out by the FCC and EIA–470, simply stated, are that a ringer circuit MUST function when a ringing signal is provided, and MUST NOT ring when other signals (speech, dialing, noise) are on the line. The tone ringers described below were designed to meet those requirements with a minimum of external components.

MC34012P, D

T_A = –20° to +60°C, Case 626, 751

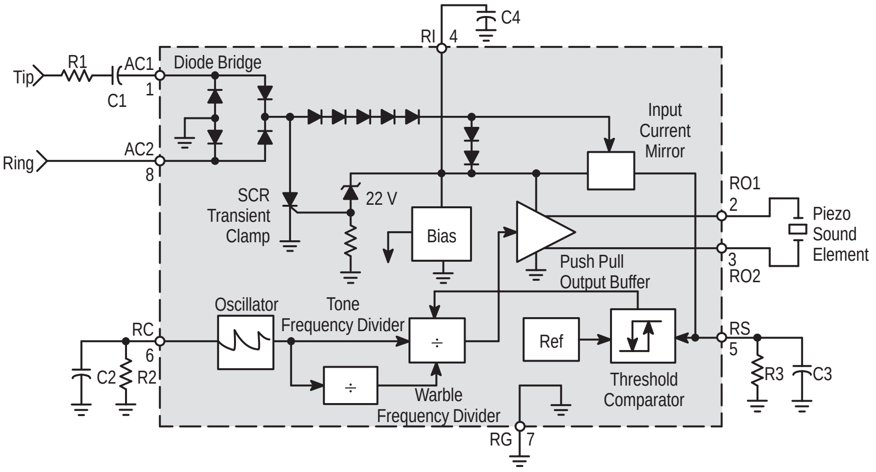
- Complete Telephone Bell Replacement
- On–Chip Diode Bridge and Transient Protection
- Single–Ended Output to Piezo Transducer
- Input Impedance Signature Meets Bell and EIA Standards
- Rejects Rotary Dial and Hook Switch Transients
- Adjustable Base Frequencies
- Output Frequency to Warble Ratio –
    - MC34012–1:80
    - MC34012–2:160
    - MC34012–3:40



MC34017P, D

T_A = –20° to +60°C, Case 626, 751

- Complete Telephone Bell Replacement Circuit with Minimum External Components
- On–Chip Diode Bridge and Transient Protection
- Direct Drive for Piezoelectric Transducers
- Push Pull Output Stage for Greater Output Power Capability
- Base Frequency Options
    - – MC34017–1: 1.0 kHz
    - – MC34017–2: 2.0 kHz
    - – MC34017–3: 500 Hz
- Input Impedance Signature Meets Bell and EIA Standards
- Rejects Rotary Dial Transients

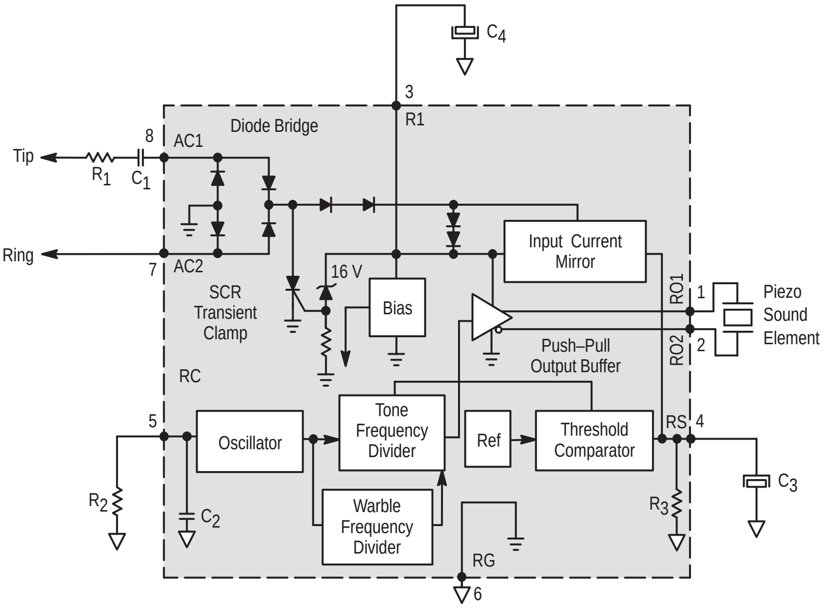


Tone Ringers **(continued)**

MC34217P, D

T_A = –20° to +60°C, Case 626, 751

- Complete Telephone Bell Replacement
- On–Chip Diode Bridge
- Internal Transient Protection
- Differential Output to Piezo Transducer for Louder Sound
- Input Impedance Signature Meets Bell and EIA Standards
- Rejects Rotary Dial and Hook Switch Transients
- Base Frequency and Warble Frequencies are Independently Adjustable
- Adjustable Base Frequency
- Reduced Number of Externals



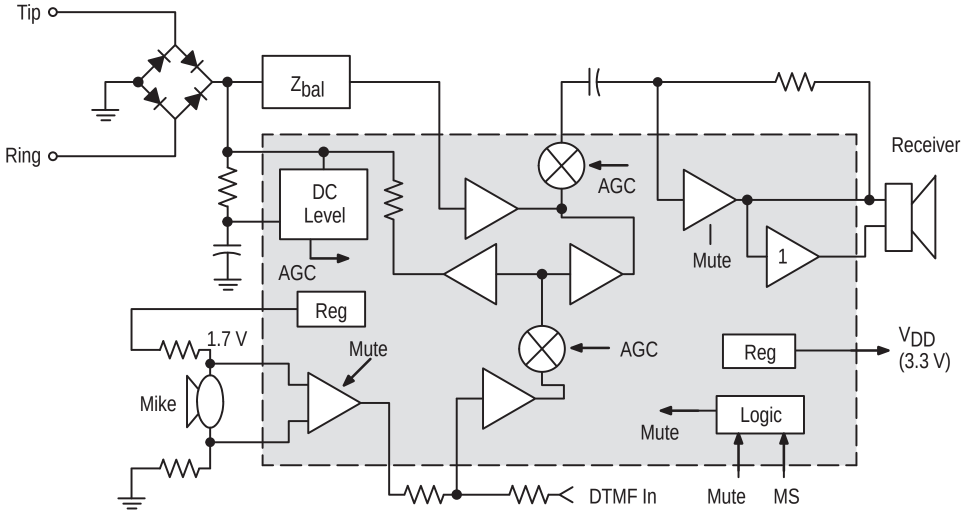
Speech Networks

Telephone Speech Network with Dialer Interface

MC34114P, DW

T_A = –20° to +70°C, Case 707, 751D

- Operation Down to 1.2 V
- Adjustable Transmit, Receive, and Sidetone Gains by External Resistors
- Differential Microphone Amplifier Input Minimizes RFI
- Transmit, Receive, and Sidetone Equalization on both Voice and DTMF Signals
- Regulated 1.7 V Output for Biasing Microphone
- Regulated 3.3 V Output for Powering External Dialer
- Microphone and Receive Amplifiers Muted During Dialing
- Differential Receive Amplifier Output Eliminates Coupling Capacitor
- Operates with Receiver Impedances of 150 Ω and Higher



Cordless Universal Telephone Interface

MC34016DW, P

T_A = –20° to +70°C, Case 751D, 738

The MC34016 is a telephone line interface meant for use in cordless telephone base stations for CT0, CT1, CT2 and DECT. The circuit forms the interface towards the telephone line and performs all speech and line interface functions like dc and ac line termination, 2–4 wire conversion, automatic gain control and hookswitch control. Adjustment of transmission parameters is accomplished by two 8 bit registers accessible via the integrated serial bus interface and by external components.

- DC Masks for Voltage and Current Regulation
- Supports Passive or Active AC Set Impedance Applications
- Double Wheatstone Bridge Sidetone Architecture
- Symmetrical Inputs and Outputs with Large Signal Swing Capability
- Gain Setting and Mute Function for T_X and R_X Amplifiers
- Very Low Noise Performance
- Serial Bus Interface SPI Compatible
- Operation from 3.0 to 5.5 V

FEATURES

Line Driver Architecture

- Two DC Masks for Voltage Regulation
- Two DC Masks for Current Regulation
- Passive or Active Set Impedance Adjustment
- Double Wheatstone Bridge Architecture
- Automatic Gain Control Function

Transmit Channel

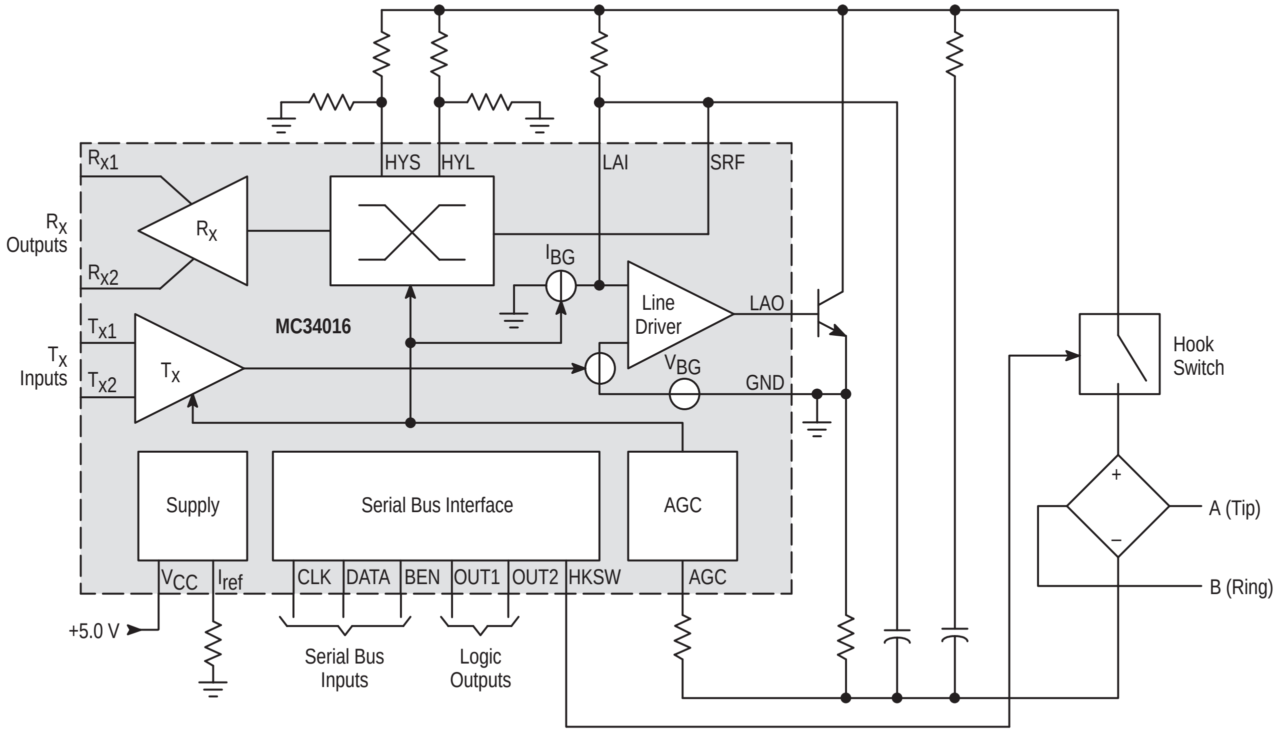
- Symmetrical Inputs Capable of Handling Large Voltage Swing
- Gain Select Option via Serial Bus Interface
- Transmit Mute Function, Programmable via Bus
- Large Voltage Swing Capability at the Telephone Line

Receive Channel

- Double Sidetone Architecture for Optimum Line Matching
- Symmetrical Outputs Capable of Producing High Voltage Swing
- Gain Select Option via Serial Bus Interface
- Receive Mute Function, Programmable via Serial Bus

Serial Bus Interface

- 3–Wire Connection to Microcontroller
- One Programmable Output Meant for Driving a Hookswitch
- Two Programmable Outputs Capable of Driving Low Ohmic Loads
- Two 8–Bit Registers for Parameter Adjustment



Programmable Telephone Line Interface Circuit with Loudspeaker Amplifier

MC34216DW

T_A = 0° to +70°C, Case 751F

The MC34216 is developed for use in telephone applications where besides the standard telephone functions also the group listening–in feature is required. In cooperation with a microcontroller, the circuit performs all basic telephone functions including DTMF generation and pulse–dialing. The listening–in part includes a loudspeaker amplifier, an anti–howling circuit and a strong supply. In combination with the TCA3385, the ringing is performed via the loudspeaker.

FEATURES

Line Driver and Supply

- DC and AC Termination of the Line
- Selectable Masks: France, U.K., Low Voltage
- Current Protection
- Adjustable Set Impedance for Resistive and Complex Termination
- Efficient Supply Point for Loudspeaker Amplifier and Peripherals

Handset Operation

- Transmit and Receive Amplifiers
- Adjustable Sidetone Network
- Line Length AGC
- Microphone and Earpiece Mute
- Earpiece Gain Increase Switch
- Microphone Squelch Function
- Transmit Amplifier Soft Clipping

Dialing and Ringing

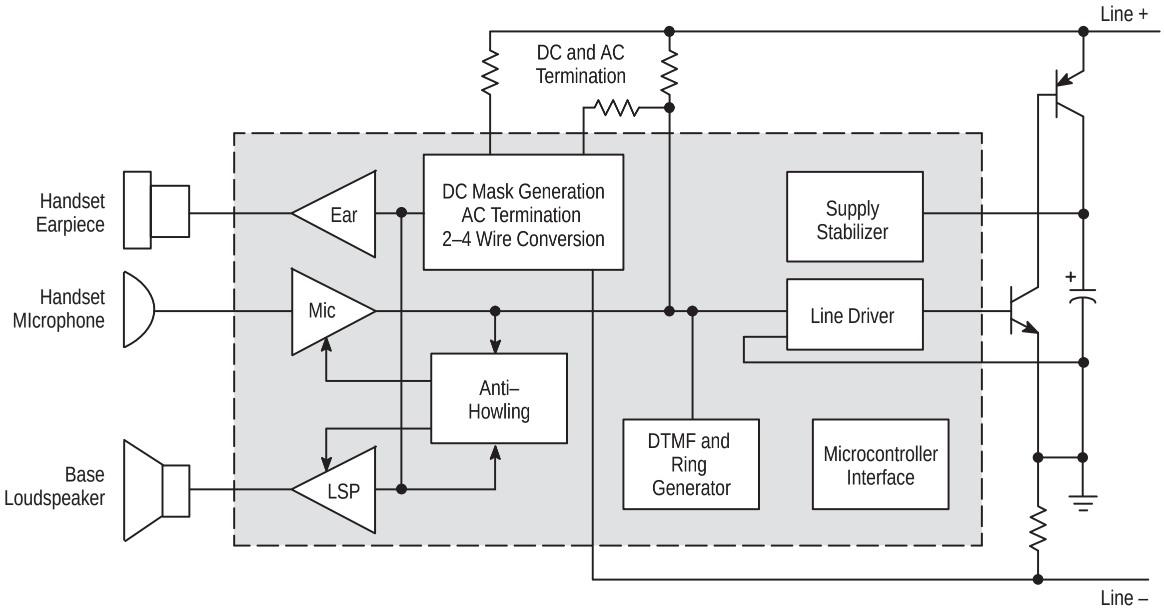
- Generates DTMF, Pilot Tones and Ring Signal
- Interrupter Driver for Pulse–Dialing
- Low Current While Pulse–Dialing
- Optimized for Ringing via Loudspeaker
- Programmable Ring Melodies
- Uses Inexpensive 500 kHz Resonator

Loudspeaking Facility

- Integrated Loudspeaker Amplifier
- Peak–to–Peak Limiter Prevents Distortion
- Programmable Volume
- Anti–Howling Circuitry for Group Listening–In
- Interfacing for Handsfree Conversation

Application Areas

- Corded Telephony with Group Listening–In
- Cordless Telephony Base Station with Group Listening–In
- Telephones with Answering Machines
- Fax, Intercom, Modem



Telephone Line Interface

TCA3388DP, FP

T_A = 0° to +70°C, Case 738, 751D

The TCA3388 is a telephone line interface circuit which performs the basic functions of a telephone set in combination with a microcontroller and a ringer. It includes dc and ac line termination, the hybrid function with 2 adjustable sidetone networks, handset connections and an efficient supply point.

FEATURES

Line Driver and Supply

- DC and AC Termination of the Telephone Line
- Selectable DC Mask: France, U.K., Low Voltage
- Current Protection
- Adjustable Set Impedance for Resistive and Complex Termination
- Efficient Supply Point for Peripherals
- Hook Status Detection

Handset Operation

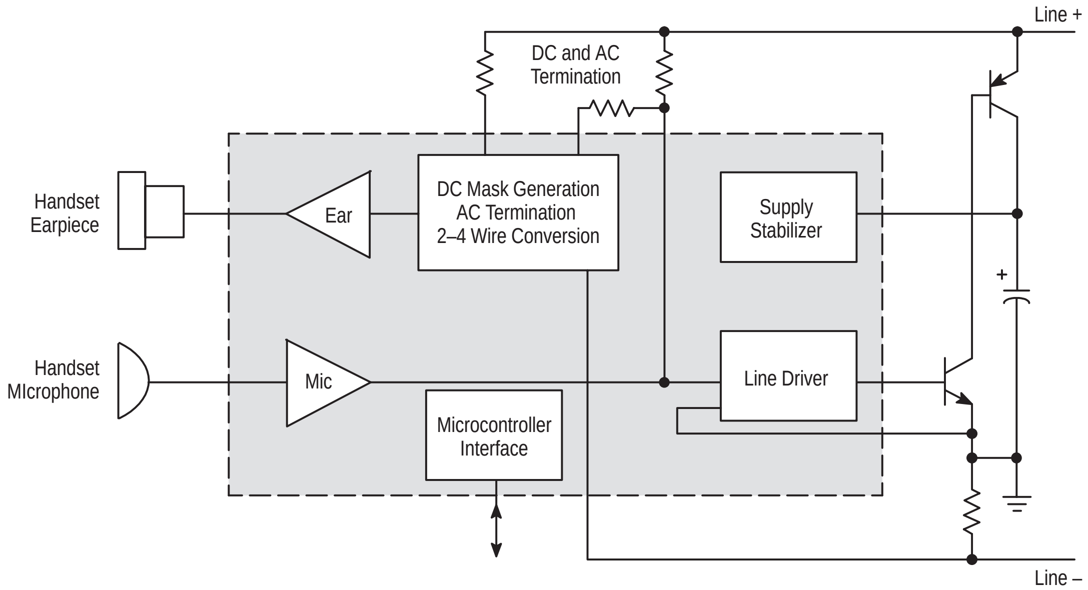
- Transmit and Receive Amplifiers
- Double Anti–Sidetone Network
- Line Length AGC
- Microphone and Earpiece Mute
- Transmit Amplifier Soft Clipping

Dialing and Ringing

- Interrupter Driver for Pulse–Dialing
- Reduced Current Consumption During Pulse–Dialing
- DTMF Interfacing
- Ringing via External Ringer

Application Areas

- Corded Telephony
- Cordless Telephony Base Station
- Answering Machines
- Fax
- Intercom
- Modem



Speakerphones

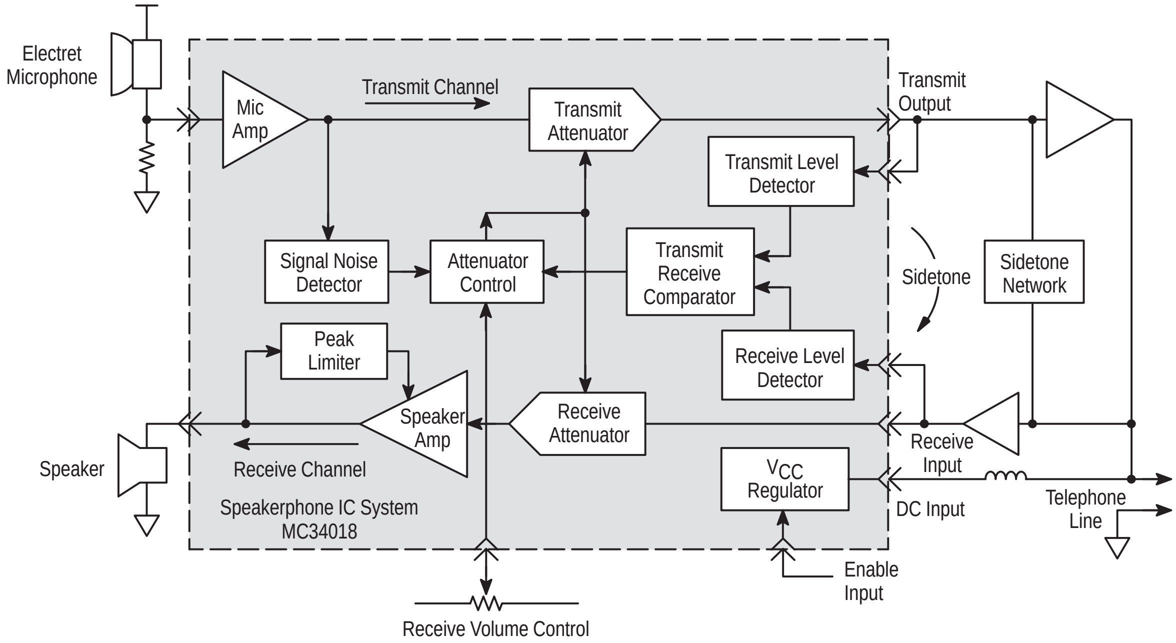
Voice Switched Speakerphone Circuit

MC34018P, DW

T_A = –20° to +60°C, Case 710, 751F

The MC34018 Speakerphone integrated circuit incorporates the necessary amplifiers, attenuators, and control functions to produce a high quality hands–free speakerphone system. Included are a microphone amplifier, a power audio amplifier for the speaker, transmit and receive attenuators, a monitoring system for background sound level, and an attenuation control system which responds to the relative transmit and receive levels as well as the background level. Also included are all necessary regulated voltages for both internal and external circuitry, allowing line–powered operation (no additional power supplies required). A Chip Select pin allows the chip to be powered down when not in use. A volume control function may be implemented with an external potentiometer. MC34018 applications include speakerphones for household and business uses, intercom systems, automotive telephones, and others.

- All Necessary Level Detection and Attenuation Controls for a Hands–Free Telephone in a Single Integrated Circuit
- Background Noise Level Monitoring with Long Time Constant
- Wide Operating Dynamic Range Through Signal Compression
- On–Chip Supply and Reference Voltage Regulation
- Typical 100 mW Output Power (into 25 Ω) with Peak Limiting to Minimize Distortion
- Chip Select Pin for Active/Standby Operation
- Linear Volume Control Function



Voice Switched Speakerphone Circuit

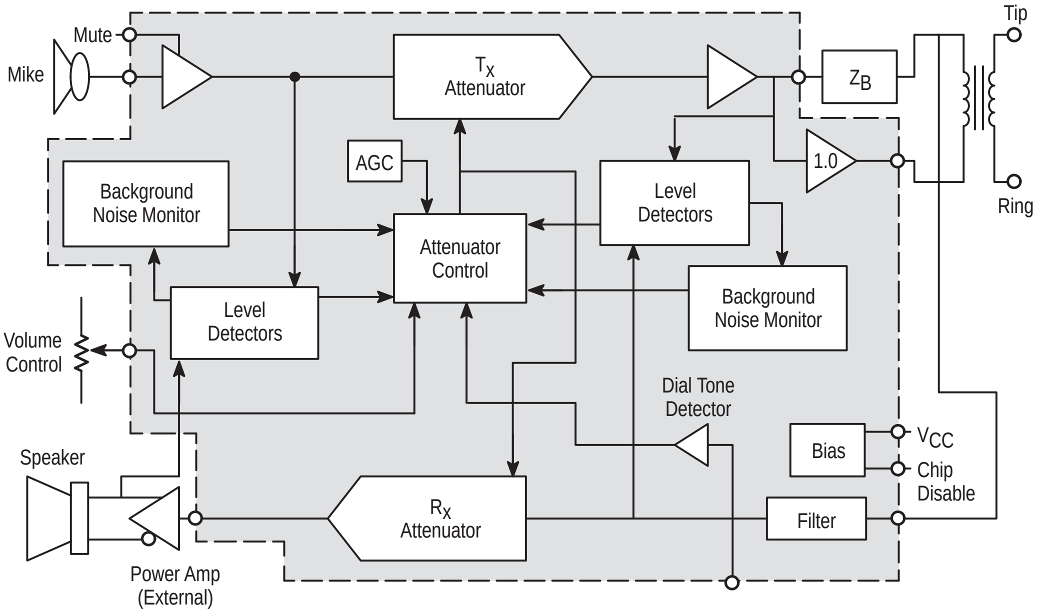
MC34118P, DW

T_A = –20° to +60°C, Case 710, 751F

The MC34118 Voice Switched Speakerphone circuit incorporates the necessary amplifiers, attenuators, level detectors, and control algorithm to form the heart of a high quality hands–free speakerphone system. Included are a microphone amplifier with adjustable gain and mute control, Transmit and Receive attenuators which operate in a complementary manner, level detectors at input and output of both attenuators,and background noise monitors for both the transmit and receive channels. A dial tone detector prevents the dial tone from being attenuated by the Receive background noise monitor circuit. Also included are two line driver amplifiers which can be used to form a hybrid network in conjunction with an external coupling transformer. A high–pass filter can be used to filter out 60 Hz noise in the receive channel, or for other filtering functions. A Chip Disable pin permits powering down the entire circuit to conserve power on long loops where loop current is at a minimum.

The MC34118 may be operated from a power supply, or it can be powered from the telephone line, requiring typically 5.0 mA. The MC34118 can be interfaced directly to Tip and Ring (through a coupling transformer) for stand–alone operation, or it can be used in conjunction with a handset speech network and/or other features of a featurephone.

- Improved Attenuator Gain Range: 52 dB Between Transmit and Receive
- Low Voltage Operation for Line–Powered Applications (3.0 to 6.5 V)
- 4–Point Signal Sensing for Improved Sensitivity
- Background Noise Monitors for Both Transmit and Receive Paths
- Microphone Amplifier Gain Set by External Resistors – Mute Function Included
- Chip Disable for Active/Standby Operation
- On Board Filter Pinned–Out for User Defined Function
- Dial Tone Detector Inhibits Receive Idle Mode During Dial Tone Presence
- Compatible with MC34119 Speaker Amplifier



Voice Switched Speakerphone with µProcessor Interface

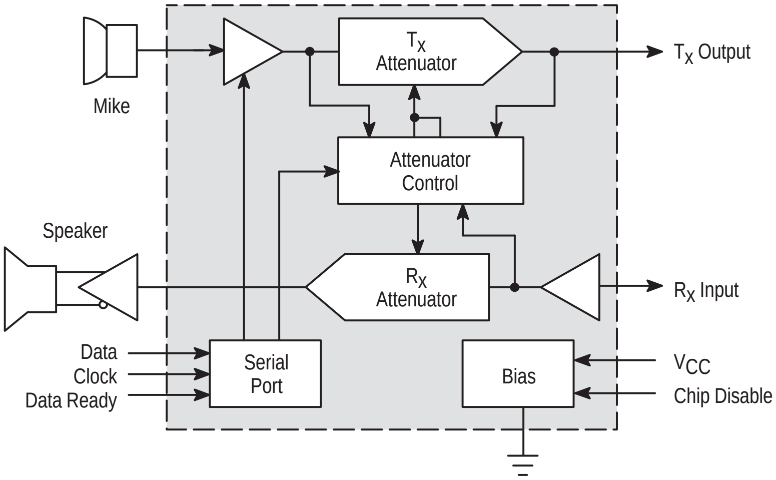
MC33218AP, DW

T_A = –40° to +85°C, Case 724, 751E

The MC33218A, Voice Switched Speakerphone circuit incorporates the necessary amplifiers, attenuators, level detectors, and control algorithm to form the heart of a high quality hands–free speakerphone system. Included are a microphone amplifier with adjustable gain, and mute control, transmit and receive attenuators which operate in a complementary manner, and level detectors and background noise monitors for both paths. A dial tone detector prevents dial tone from being attenuated by the receive background noise monitor. A Chip Disable pin permits powering down the entire circuit to conserve power.

Also included is an 8–bit serial µprocessor port for controlling the receive volume, microphone mute, attenuator gain, and operation mode (force to transmit, force to receive, etc.). Data rate can be up to 1.0 MHz. The MC33218A can be operated from a power supply, or from the telephone line, requiring typically 3.8 mA. It can also be used in intercoms and other voice–activated applications.

- Low Voltage Operation: 2.5 to 6.0 V
- 2–Point Sensing, Background Noise Monitor in Each Path
- Chip Disable Pin for Active/Standby Operation
- Microphone Amplifier Gain Set by External Resistors – Mute Function Included
- Dial Tone Detector to Inhibit Receive Idle Mode During Dial Tone Presence
- Microprocessor port for controlling:
  - Receive Volume Level (16 Steps)
  - Attenuator Range (26 or 52 dB, Selectable)
  - Microphone Mute
  - Force to Transmit, Receive, Idle or Normal Voice Switched Operation
- Compatible with MC34119 Speaker Amplifier



Voice Switched Speakerphone Circuit

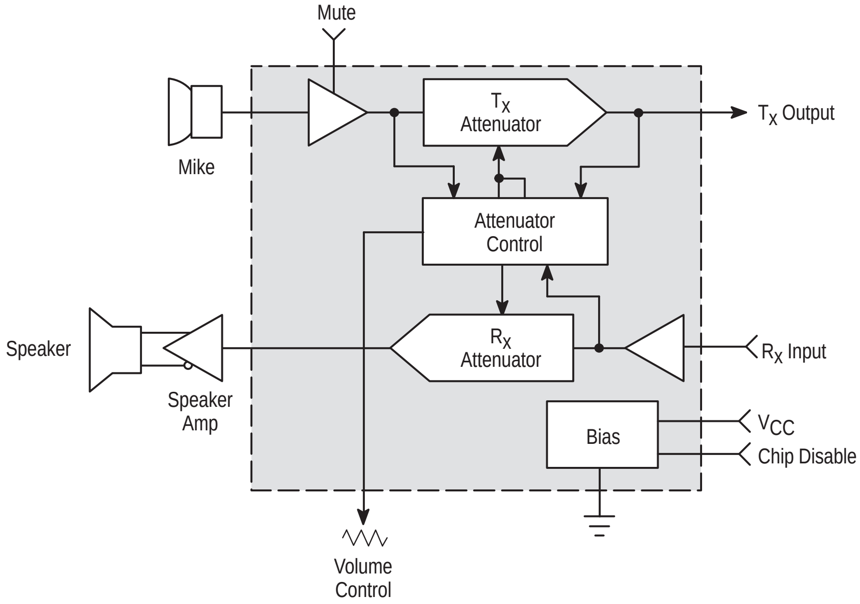
MC33219AP, ADW

T_A = –40° to +85°C, Case 724, 751E

The MC33219A Voice Switched Speakerphone Circuit incorporates the necessary amplifiers, attenuators, level detectors, and control algorithm to form the heart of a high quality hands–free speakerphone system. Included are a microphone amplifier with adjustable gain, and mute control, transmit and receive attenuators which operate in a complementary manner, and level detectors and background noise monitors. A dial tone detector prevents dial tone from being attenuated by the receive background noise monitor. A Chip Disable pin permits powering down the entire circuit to conserve power.

The MC33219A may be operated from a power supply, or it can be powered from the telephone line requiring typically 4.0 mA. The MC33219A can be interfaced directly to Tip and Ring (through a coupling transformer for stand–alone operation, or it can be used in conjuction with a handset speech network and/or other features of a featurephone.

- Low Voltage Operation: 2.7 to 6.0 V
- 2–Point Sensing, Background Noise Monitor in Each Path
- Chip Disable Pin for Active/Standby Operation
- Microphone Amplifier Gain Set by External Resistors – Mute Function Included
- Dial Tone Detector to Inhibit Receive Idle Mode During Dial Tone Presence
- Volume Control Range: 34 dB
- Compatible with MC34119 Speaker Amplifier



Telephone Line Interface and Speakerphone Circuit

MC33215B, FB

T_A = 0° to +70°C, Case 858, 848B

The MC33215 is a combination speech network/ speakerphone developed for use in fully electronic telephone sets with a speakerphone function. The circuit performs the ac and dc line terminations, 2–4 wire conversion, line length AGC and DTMF transmission. The speakerphone part includes a half duplex controller with signal and noise monitoring, base microphone and loudspeaker amplifiers, and an efficient supply. The circuit is designed to operate at low line currents down to 4.0 mA enabling parallel operation with a classical telephone set.

FEATURES

Line Driver and Supply

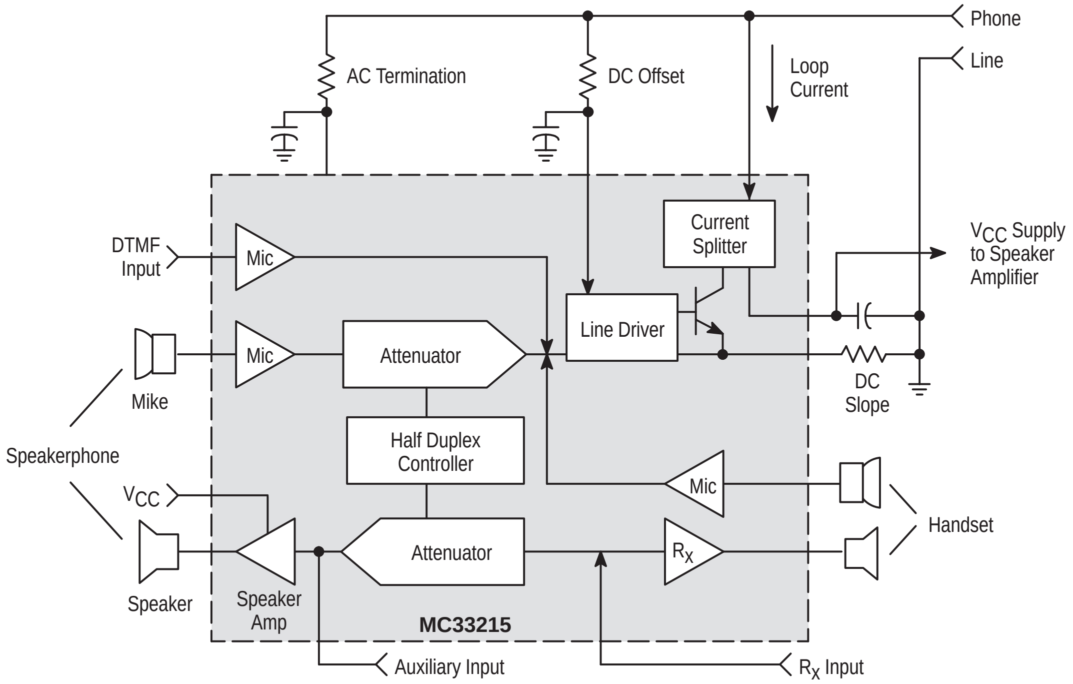
- AC and DC Termination of Telephone Line
- Adjustable Set Impedance for Real and Complex Termination
- Efficient Supply for Speaker Amplifier and Peripherals
- Two Supplies for Handset and Base Microphones
- Separate Supply Arrangement for Handset and Speakerphone Operation

Handset Operation

- Transmit and Receive Amplifiers
- Differential Microphone Inputs
- Sidetone Cancellation Network
- Line Length AGC
- Microphone and Earpiece Mute
- Separate Input for DTMF and Auxiliary Signals
- Parallel Operation Down to 4.0 mA of Line Current

Speakerphone Operation

- Integrated Microphone and Loudspeaker Amplifiers
- Differential Microphone Inputs
- Loudspeaker Amplifier can be Powered and Used Separately from the Rest of the Circuit
- Integrated Switches for Smooth Switch Over from Handset to Speakerphone Mode
- Signal and Background Noise Monitoring in Both Channels
- Adjustable Switching Depth for Handsfree Operation
- Adjustable Switch Over and Idle Mode Timing
- Dial Tone Detector in the Receive Channel
- Handsfree Operation via Loudspeaker and Base Microphone



Speakerphones (continued)

Telephone Accessory Circuits

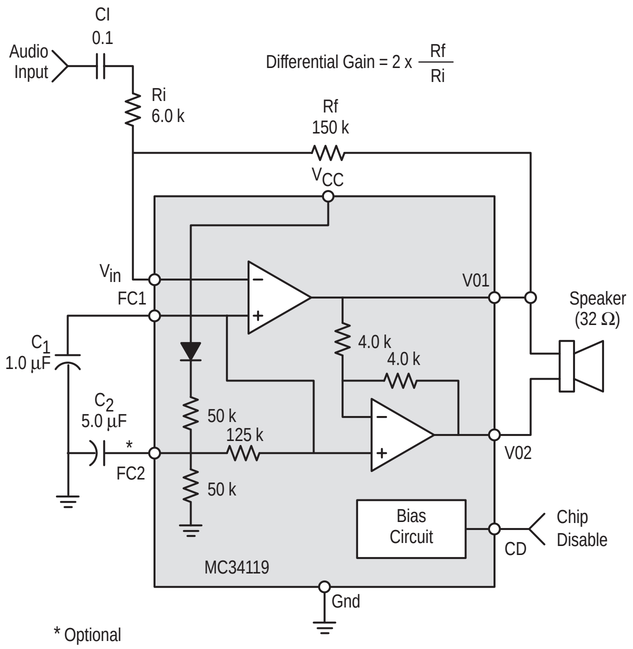
Audio Amplifier

MC34119P, D

T_A = 0° to +70°C, Case 626, 751

A low power audio amplifier circuit intended (primarily) for telephone applications, such as speakerphones. Provides differential speaker outputs to maximize output swing at low supply voltages (2.0 V min.). Coupling capacitors to the speaker, and snubbers, are not required. Overall gain is externally adjustable from 0 to 46 dB. A Chip Disable pin permits powering–down to mute the audio signal and reduce power consumption.

- Drives a Wide Range of Speaker Loads (16 to 100 Ω)
- Output Power Exceeds 250 mW with 32 Ω Speaker
- Low Distortion (THD = 0.4% Typical)
- Wide Operating Supply Voltage (2.0 V to 16 V) – Allows Telephone Line Powered Applications.
- Low Quiescent Supply Current (2.5 mA Typical)
- Low Power–Down Quiescent Current (60 µA Typical)



Current Mode Switching Regulator

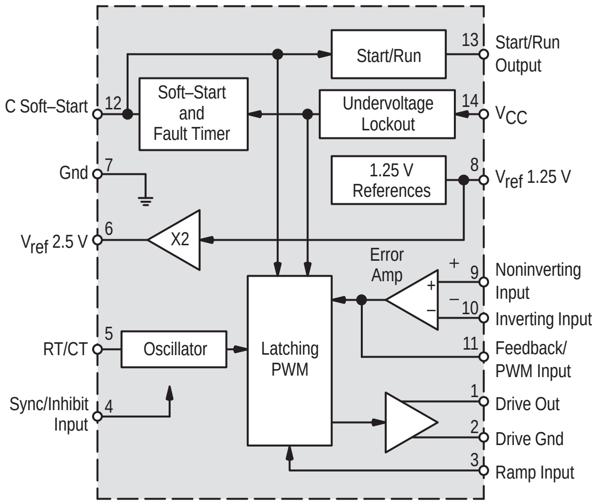
MC34129P, D

T_A = 0° to +70°C, Case 646, 751A

High performance current mode switching regulator for low–power digital telephones. Unique internal fault timer provides automatic restart for overload recovery. A start/run comparator is included to implement bootstrapped operation of V_{CC}.

Although primarily intended for digital telephone systems, these devices can be used cost effectively in many other applications. On–chip functions and features include:

- Current Mode Operation to 300 kHz
- Automatic Feed Forward Compensation
- Latching PWM for Cycle–By–Cycle Current Limiting
- Latched–Off or Continuous Retry after Fault Timeout
- Soft–Start with Maximum Peak Switch Current Clamp
- Internally Trimmed 2% Bandgap Reference
- Input Undervoltage Lockout



300 Baud FSK Modems

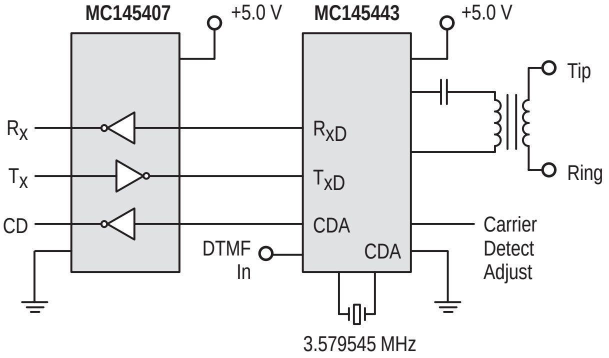
MC145442P, DW Modem – CCITT V.21
Case 738, 751D

MC145443P, DW Modem – Bell 103
Case 738, 751D

This powerful modem combines a complete FSK modulator/demodulator and an accompanying transmit/receive filter system on a single silicon chip. Designed for bidirectional transmission over the telephone network, the modem operates at 300 baud and can be obtained for compatibility with CCITT V.21 and Bell 103 specifications.

The modem contains an on–board carrier–detect circuit that allows direct operation on a telephone line (through a simple transformer), providing simplex, half–duplex, and full–duplex data communications. A built–in power amplifier is capable of driving –9.0 dBm onto a 600 Ω line in the transmit mode.

CMOS processing keeps power dissipation to a very low 45 mW, with a power–down dissipation of only 1.0 mW . . . from a single 5.0 V power supply. Available in a 20 pin dual–in–line P suffix, and a wide body surface mount DW suffix.



MC145444H, DW – CCITT V.21
Case 804, 751D

MC145446AFW – CCITT V.21
Case 751M

This device includes the DTMF generator and call progress tone detector (CPTD) as well as the other circuitry needed for full–duplex, half–duplex, or simplex 300 baud data communication over a pair of telephone lines. It is intended for use with telemeter system or remote control system applications.

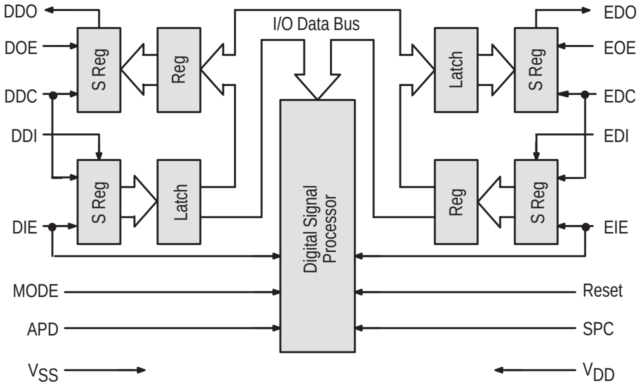
The differential line driver is capable of driving 0 dBm into a 600 Ω load. The transmit attenuator is programmable in 1.0 dB steps.

ADPCM Transcoder

MC145532DW, L
Case 751G, 620

The MC145532 Adaptive Differential Pulse Code Modulation (ADPCM) Transcoder provides a low cost, full–duplex, single–channel transcoder to (from) a 64 kbps PCM channel from (to) either a 16 kbps, 24 kbps, 32 kbps, or 64 kbps channel.

- Complies with CCITT Recommendation G.721 (1988)
- Complies with the American National Standard (T1.301–1987)
- Full–Duplex, Single–Channel Operation
- Mu–Law or A–Law Coding is Pin Selectable
- Synchronous or Asynchronous Operation
- Easily Interfaces with any Member of Motorola’s PCM Codec–Filter Mono–Circuit Family or Other Industry Standard Codecs
- Serial PCM and ADPCM Data Transfer Rate from 64 kbps to 5.12 Mbps
- Power Down Capability for Low Cost Consumption
- The Reset State is Automatically Initiated when the Reset Pin is Released.
- Simple Time Slot Assignment Timing for Transcoder Applications
- Single 5.0 V Power Supply
- Evaluation Kit MC145536 EVK Supports the MC145532 as well as the MC14LC5480 PCM Codec–Filter. (See PBX Architecture Pages for More Information.)



Calling Line Identification (CLID) Receiver with Ring Detector

MC14LC5447P, DW

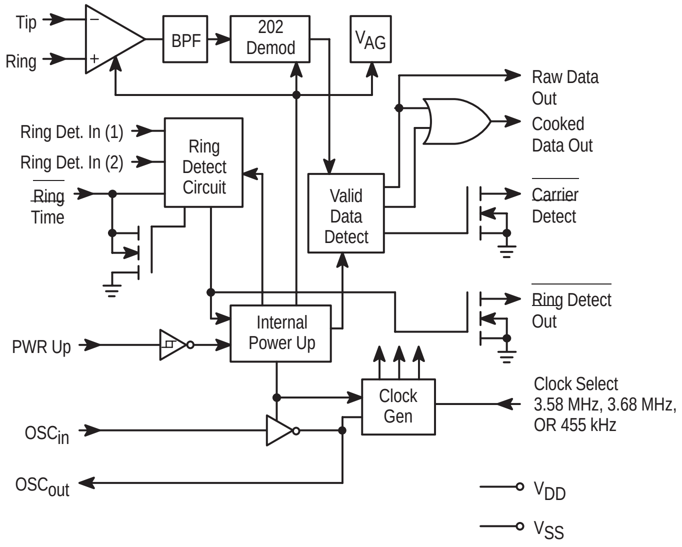
Case 648, 751G

The MC14LC5447 is designed to demodulate Bell 202 1200 baud FSK asynchronous data. Its primary application is in products that will be used to receive and display the calling number, or the message waiting indicator sent to subscribers from participating central office facilities of the public switched telephone network. The device also contains a carrier detect circuit and telephone ring detector which may be used to power up the device.

Applications include adjunct boxes, answering machines, feature phones, fax machines, and computer interface products.

Replaces MC145447P, DW.

- Ring Detector On–Chip
- Ring Detect Output for MCU Interrupt
- Power–Down Mode Less Than 1.0 µA
- Single Supply: 3.5 V to 6.0 V
- Pin Selectable Clock Frequencies: 3.68 MHz, 3.58 MHz, or 455 kHz
- Two–Stage Power–Up for Power Management Control

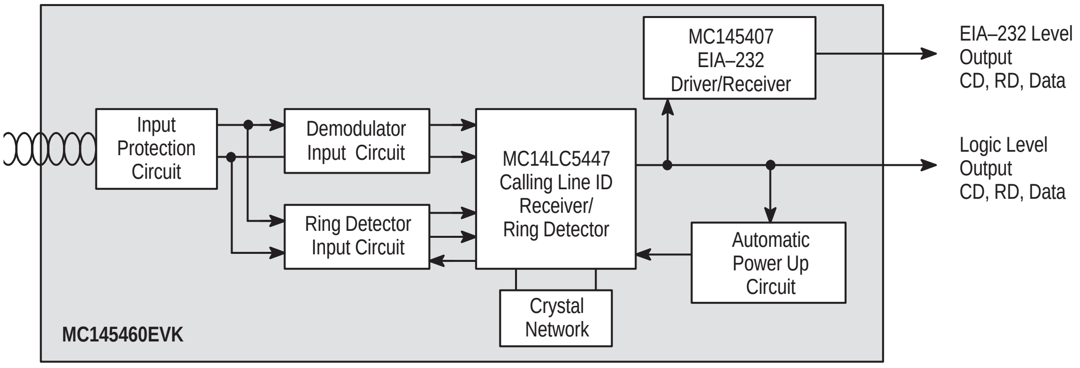


Calling Line ID Receiver Evaluation Kit

MC145460EVK

The MC145460EVK is a low cost evaluation platform for the MC14LC5447. The MC145460EVK facilitates development and testing of products that support the Bellcore customer premises equipment (CPE) data interface, which enables services such as Calling Number Delivery (CND). The MC14LC5447 can be easily incorporated into any telephone, FAX, PBX, key system, answering machine, CND adjunct box or other telephone equipment with the help of the MC145460EVK development kit.

- Easy Clip–On Access to Key MC14LC5447 Signals
- Generous Prototype Area
- Configurable for MC14LC5447 Automatic or External Power Up Control
- EIA–232 and Logic Level Ports for Connection to any PC or MCU Development Platform
- Carrier Detect, Ring Detect and Data Status LEDs
- Optional Tip and Ring Input Protection Network
- MC145460EVK User Guide, MC14LC5447 Data Sheet, and Additional MC14LC5447 Sample Included



Continuously Variable Slope Delta (CVSD) Modulator/Demodulator

MC34115P, DW
T_A = 0° to +70°C, Case 648, 751G

MC3418P, DW
T_A = 0° to +70°C, Case 648, 751G

Provides the A/D–D/A function of voice communications by digital transmission. Designed for speech synthesis and commercial telephone applications. A single IC provides both encoding and decoding.

- Encode and Decode Functions on the Same Chip with a Digital Input
- CMOS Compatible Digital Output
- Digital Input Threshold Selectable (V_{CC}/2 reference provided on Chip)
- MC34115 Has a 3–Bit Algorithm (General Communications)
- MC3418 Has a 4–Bit Algorithm (Commercial Telephone)

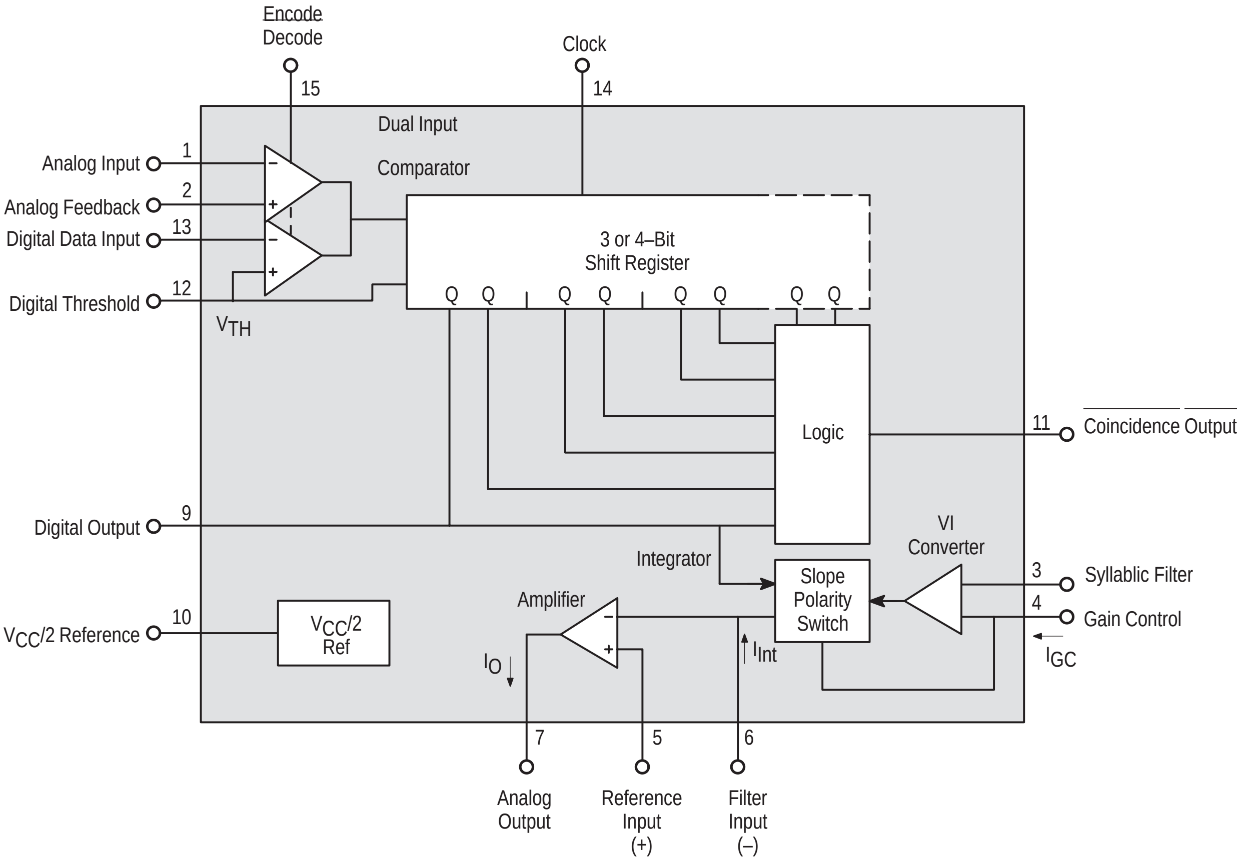


Table 11. Summary of Bipolar Telecommunication Circuits

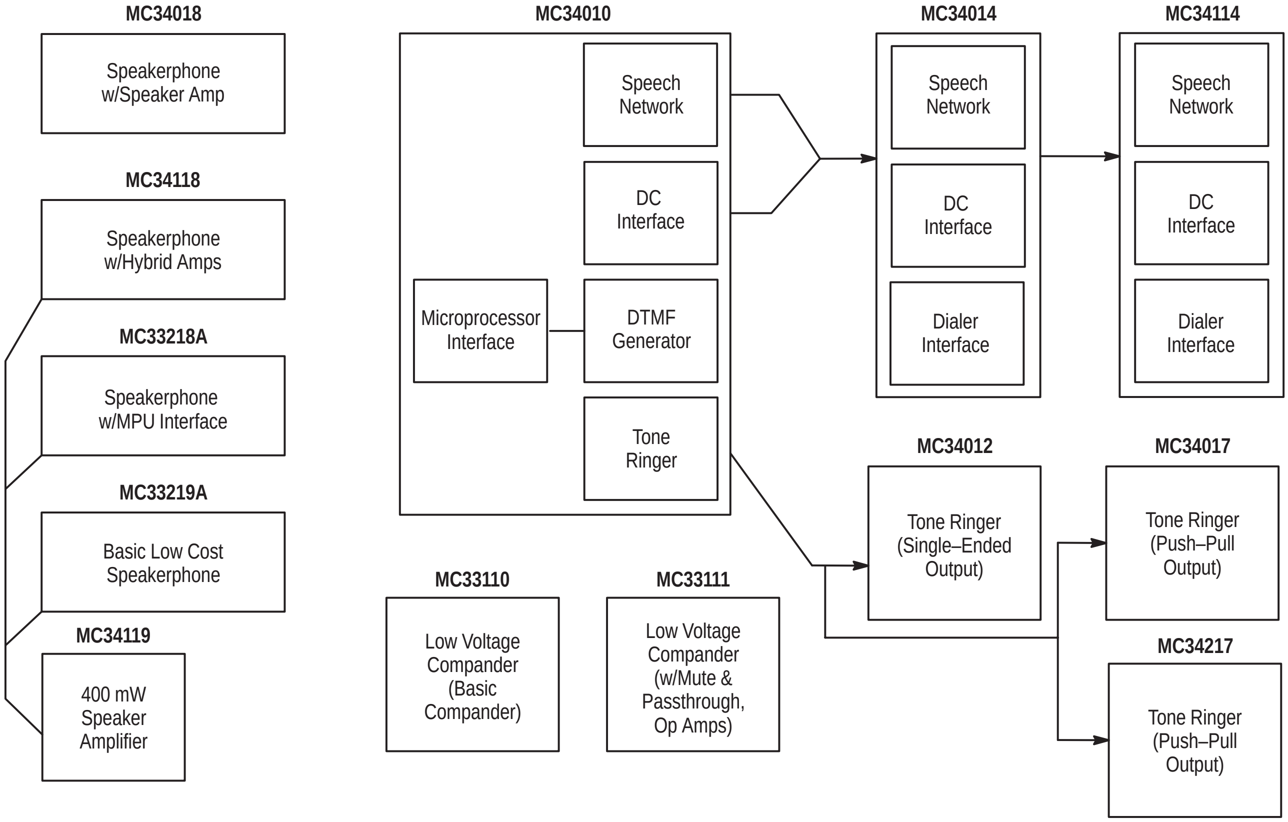
Function	Features	Suffix/ Package	Device
Subscriber Loop Interface Circuits (SLICs)			
Central Office, Remote Terminals, PBX Applications	All gains externally programmable, most BORSHT functions, current limit adjustable to 50 mA, 58 dB Longitudinal Balance, –21.6 V to –42 V.	P/738, FN/776	MC33121
Central Office, Remote Terminals, PBX Applications	All gains externally programmable, most BORSHT functions, current limit adjustable to 50 mA, 58 dB Longitudinal Balance, –42 V to –58 V.	P/738, FN/776	MC33120
Complete Telephone Circuit			
POTS Circuit + MPU Dialing	Speech network, tone ringer, dc loop current interface, DTMF dialer with serial port control.	P/711, FN/777	MC34010
Tone Ringers			
Adjustable Tone Ringer	Single–ended output, meets FCC requirements, adjustable REN, different warble rates.	P/626, D/751	MC34012–1, 2, 3
Adjustable Tone Ringer	Differential output, meets FCC requirements, adjustable REN, different warble rates.	P/626, D/751	MC34017–1, 2, 3
Adjustable Tone Ringer	Differential output, meets FCC requirements, adjustable REN, single warble rates.	P/626, D/751	MC34217
Ring Signal Converter	Switching regulator to convert ringing voltage to regulated dc output. Provides ring detect output.	DP/626, FP/751	TCA3385
Speech Networks			
Speech Network + Speakerphone	Line powered IC provides handset and speakerphone modes, dialer interface, ac/dc terminations, and AGC. Efficient supply design provides 90% of loop current to the speaker amplifier. Speaker amplifier may be used independently. Handset operation to 4.0 mA.	B/858, FB/848B	MC33215
Basic Phone Line Interface	Loop current interface, speech network, line length compensation, speech/dialing modes, Bell System compliant.	P/707, DW/751D	MC34014
Cordless Universal Telephone Interface	For cordless telephone base for CT0, CT1, CT2 and DECT. European dc masks, double wheatstone bridge sidetone circuit. SPI port for masks, AGC hookswitch, mute and gain settings. Requires 5.0 V and µP.	P/738, DW/751D	MC34016
Basic Phone Line Interface	Loop current interface, speech network, line length compensation, speech/dialing modes, Bell System and foreign countries.	P/707, DW/751D	MC34114
Programmable Telephone Line Interface Circuit with Loudspeaker Amplifier	Group listening–in, DTMF and tones generator, ring generator, country programmable, SPI interface.	DW/751F	MC34216
European Speech Network, Programmable Speaker Amplifier	Line powered. European dc masks, DTMF and pilot tone generator, listening–in mode with anti–howling. 2–wire bus control masks, DTMF tones, speaker gain, pulse dialing, mute, AGC. Requires MCU.	DW/751	MC34216A
European Speech Network	Loop current interface, speech network, line length compensation, speech/dialing modes, programmable masks for French, U.K., low voltage and PABX systems.	DP/738, FP/751	TCA3388

Summary of Bipolar Telecommunications Circuits (continued)

Function	Features	Suffix/ Package	Device
Speakerphone Circuits			
Speech Network + Speakerphone	Line powered IC provides handset and speakerphone modes, dialer interface, ac/dc terminations, and AGC. Efficient supply design provides 90% of loop current to the speaker amplifier. Speaker amplifier may be used independently. Handset operation to 4.0 mA.	B/858, FB/848B	MC33215
Complete Speaker Phone with Speaker Amplifier	All level detection (2 pt.), attenuators, and switching controls, mike and speaker amp.	P/710, DW/751F	MC34018
Complete Speaker Phone with Hybrid, Filter	All level detection (4 pt.), attenuators, and switching controls, mike amp with mute, hybrid, and filter.	P/710, DW/751F	MC34118
Complete Speaker Phone with MPU Interface	All level detection, attenuators, and switching controls, mike amp, MPU interface for: volume control, mode selection, mike mute.	P/724, DW/751E	MC33218A
Basic Low Cost Speakerphone	All level detection, attenuators and switching controls, Mike amplifier with Mute, low voltage operation.	P/724, DW/751E	MC33219A
Audio Amplifiers			
1 Watt Audio Amp	1.0 W output power into 16 Ω, 35 V maximum.	D/751	MC13060
Low Voltage Audio Amp	400 mW, 8.0 to 100 Ω, 2.0 to 16 V, differential outputs, chip–disable input pin.	P/626, D/751	MC34119
Companders			
Basic Compander	2.1 V to 7.0 V, no precision externals, 80 dB range, –40° to +85°C, independent compressor and expander.	P/646, D/751A	MC33110
Compander with Features	3.0 V to 7.0 V, no precision externals, 80 dB range, –40° to +85°C, independent compressor and expander, pass through and mute functions, two op amps.	P/648, D/751B	MC33111
Switching Regulator			
Current Mode Regulator	For phone line power applications, soft–start, current limiting, 2% accuracy.	P/646, D/751A	MC34129
Voice Encoder/Decoders			
Continuously Variable Slope Modulator/Demodulator (CVSD)	Telephone quality voice encoding/decoding, variable clock rate, 3–bit coding, for secure communications, voice storage/retrieval, answering machines, 0° to 70°C.	P/738, DW/751G	MC34115
	Same as above except 4–bit coding.	P/738, DW751G	MC3418

Figure 3. The Motorola Family of Handset Telecom Integrated Circuits



Phase–Locked Loop Components

Motorola offers a choice of phase–locked loop components ranging from complete functional frequency synthesizers for dedicated applications to a wide selection of general purpose PLL circuit elements. Technologies include CMOS for lowest power consumption and bipolar for high speed operation. Typical applications include TV, CATV, radios, scanners, cordless telephones plus home and personal computers.

Table 12. PLL Frequency Synthesizers

Frequency (MHz)	Supply Voltage (V)	Nominal Supply Current (mA)	Phase Detector	Standby	Interface	Device	Suffix/ Case
4.0 @ 5.0 V	4.5 to 12	6.0 @ 5.0 V	Single–ended 3–state	No	Parallel	MC145106	P/707, DW/751D

Balanced Modulators/ Demodulators

These devices were designed for use where the output voltage is a product of an input voltage (signal) and a switching function (carrier). Typical applications include suppressed carrier and amplitude modulation, synchronous detection, FM detection, phase detection, and chopper applications. See Motorola Application Note AN531 for additional design information.

- Excellent Carrier Suppression –65 dB typ @ 0.5 MHz
  –50 dB typ @ 10 MHz
- Adjustable Gain and Signal Handling
- Balanced Inputs and Outputs
- High Common Mode Rejection –85 dB typical

This device contains 8 active transistors.

GENERAL OPERATING INFORMATION

Carrier Feedthrough

Carrier feedthrough is defined as the output voltage at carrier frequency with only the carrier applied (signal voltage = 0).

Carrier null is achieved by balancing the currents in the differential amplifier by means of a bias trim potentiometer (R1 of Figure 5).

Carrier Suppression

Carrier suppression is defined as the ratio of each sideband output to carrier output for the carrier and signal voltage levels specified.

Carrier suppression is very dependent on carrier input level, as shown in Figure 22. A low value of the carrier does not fully switch the upper switching devices, and results in lower signal gain, hence lower carrier suppression. A higher than optimum carrier level results in unnecessary device and circuit carrier feedthrough, which again degenerates the suppression figure. The MC1496 has been characterized with a 60 mVrms sinewave carrier input signal. This level provides optimum carrier suppression at carrier frequencies in the vicinity of 500 kHz, and is generally recommended for balanced modulator applications.

Carrier feedthrough is independent of signal level, V_S. Thus carrier suppression can be maximized by operating with large signal levels. However, a linear operating mode must be maintained in the signal–input transistor pair – or harmonics of the modulating signal will be generated and appear in the device output as spurious sidebands of the suppressed carrier. This requirement places an upper limit on input–signal amplitude (see Figure 20). Note also that an optimum carrier level is recommended in Figure 22 for good carrier suppression and minimum spurious sideband generation.

At higher frequencies circuit layout is very important in order to minimize carrier feedthrough. Shielding may be necessary in order to prevent capacitive coupling between the carrier input leads and the output leads.

Signal Gain and Maximum Input Level

Signal gain (single–ended) at low frequencies is defined as the voltage gain,

$$A_{VS} = \frac{V_o}{V_S} = \frac{R_L}{R_e + 2r_e} \quad \text{where } r_e = \frac{26\ \text{mV}}{I5(\text{mA})}$$

A constant dc potential is applied to the carrier input terminals to fully switch two of the upper transistors “on” and two transistors “off” ($V_C = 0.5$ Vdc). This in effect forms a cascode differential amplifier.

Linear operation requires that the signal input be below a critical value determined by R_E and the bias current I5.

$$V_S \leqslant I5\ R_E \text{ (Volts peak)}$$

Note that in the test circuit of Figure 10, V_S corresponds to a maximum value of 1.0 V peak.

Common Mode Swing

The common–mode swing is the voltage which may be applied to both bases of the signal differential amplifier, without saturating the current sources or without saturating the differential amplifier itself by swinging it into the upper switching devices. This swing is variable depending on the particular circuit and biasing conditions chosen.

Power Dissipation

Power dissipation, P_D, within the integrated circuit package should be calculated as the summation of the voltage–current products at each port, i.e. assuming V12 = V6, I5 = I6 = I12 and ignoring base current, $P_D = 2\ I5\ (V6 - V14) + I5)\ V5 - V14$ where subscripts refer to pin numbers.

Design Equations

The following is a partial list of design equations needed to operate the circuit with other supply voltages and input conditions.

A. Operating Current

The internal bias currents are set by the conditions at Pin 5. Assume:

$$I5 = I6 = I12,$$
$$I_B << I_C \text{ for all transistors}$$

then :

$$R5 = \frac{V - -\phi}{I5} - 500\ \Omega$$

where: R5 is the resistor between
Pin 5 and ground
$\phi = 0.75$ at $T_A = +25°C$

The MC1496 has been characterized for the condition $I_5 = 1.0$ mA and is the generally recommended value.

B. Common–Mode Quiescent Output Voltage

$$V6 = V12 = V+ - I5\ R_L$$

Biasing

The MC1496 requires three dc bias voltage levels which must be set externally. Guidelines for setting up these three levels include maintaining at least 2.0 V collector–base bias on all transistors while not exceeding the voltages given in the absolute maximum rating table;

$$30 \text{ Vdc} \geq [(V6, V12) - (V8, V10)] \geq 2 \text{ Vdc}$$
$$30 \text{ Vdc} \geq [(V8, V10) - (V1, V4)] \geq 2.7 \text{ Vdc}$$
$$30 \text{ Vdc} \geq [(V1, V4) - (V5)] \geq 2.7 \text{ Vdc}$$

The foregoing conditions are based on the following approximations:

$$V6 = V12, V8 = V10, V1 = V4$$

Bias currents flowing into Pins 1, 4, 8 and 10 are transistor base currents and can normally be neglected if external bias dividers are designed to carry 1.0 mA or more.

Transadmittance Bandwidth

Carrier transadmittance bandwidth is the 3.0 dB bandwidth of the device forward transadmittance as defined by:

$$\gamma 21C = \frac{i_o \text{ (each sideband)}}{v_s \text{ (signal)}} \Bigg|\, V_o = 0$$

Signal transadmittance bandwidth is the 3.0 dB bandwidth of the device forward transadmittance as defined by:

$$\gamma 21S = \frac{i_o \text{ (signal)}}{v_s \text{ (signal)}} \Bigg|\, V_c = 0.5 \text{ Vdc},\ V_o = 0$$

Coupling and Bypass Capacitors

Capacitors C1 and C2 (Figure 5) should be selected for a reactance of less than 5.0 Ω at the carrier frequency.

Output Signal

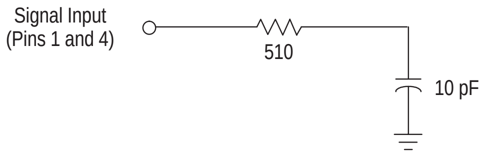
The output signal is taken from Pins 6 and 12 either balanced or single–ended. Figure 11 shows the output levels of each of the two output sidebands resulting from variations in both the carrier and modulating signal inputs with a single–ended output connection.

Negative Supply

V_{EE} should be dc only. The insertion of an RF choke in series with V_{EE} can enhance the stability of the internal current sources.

Signal Port Stability

Under certain values of driving source impedance, oscillation may occur. In this event, an RC suppression network should be connected directly to each input using short leads. This will reduce the Q of the source–tuned circuits that cause the oscillation.



An alternate method for low–frequency applications is to insert a 1.0 kΩ resistor in series with the input (Pins 1, 4). In this case input current drift may cause serious degradation of carrier suppression.

OPERATIONS INFORMATION

The MC1496, a monolithic balanced modulator circuit, is shown in Figure 23.

This circuit consists of an upper quad differential amplifier driven by a standard differential amplifier with dual current sources. The output collectors are cross–coupled so that full–wave balanced multiplication of the two input voltages occurs. That is, the output signal is a constant times the product of the two input signals.

Mathematical analysis of linear ac signal multiplication indicates that the output spectrum will consist of only the sum and difference of the two input frequencies. Thus, the device may be used as a balanced modulator, doubly balanced mixer, product detector, frequency doubler, and other applications requiring these particular output signal characteristics.

The lower differential amplifier has its emitters connected to the package pins so that an external emitter resistance may be used. Also, external load resistors are employed at the device output.

Signal Levels

The upper quad differential amplifier may be operated either in a linear or a saturated mode. The lower differential amplifier is operated in a linear mode for most applications.

For low–level operation at both input ports, the output signal will contain sum and difference frequency components and have an amplitude which is a function of the product of the input signal amplitudes.

For high–level operation at the carrier input port and linear operation at the modulating signal port, the output signal will contain sum and difference frequency components of the modulating signal frequency and the fundamental and odd harmonics of the carrier frequency. The output amplitude will be a constant times the modulating signal amplitude. Any amplitude variations in the carrier signal will not appear in the output.

The linear signal handling capabilities of a differential amplifier are well defined. With no emitter degeneration, the maximum input voltage for linear operation is approximately 25 mV peak. Since the upper differential amplifier has its emitters internally connected, this voltage applies to the carrier input port for all conditions.

Since the lower differential amplifier has provisions for an external emitter resistance, its linear signal handling range may be adjusted by the user. The maximum input voltage for linear operation may be approximated from the following expression:

$$V = (I5)\ (R_E) \text{ volts peak.}$$

This expression may be used to compute the minimum value of R_E for a given input voltage amplitude.

Figure 23. Circuit Schematic

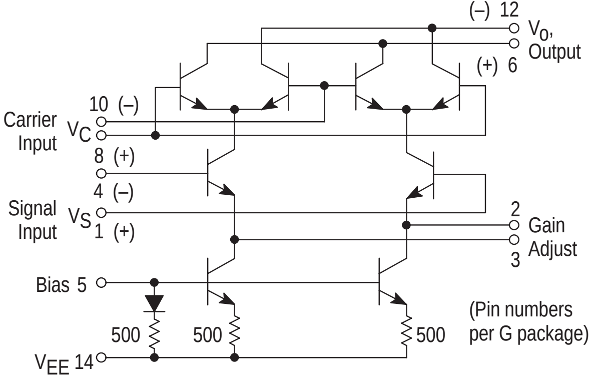

Figure 24. Typical Modulator Circuit

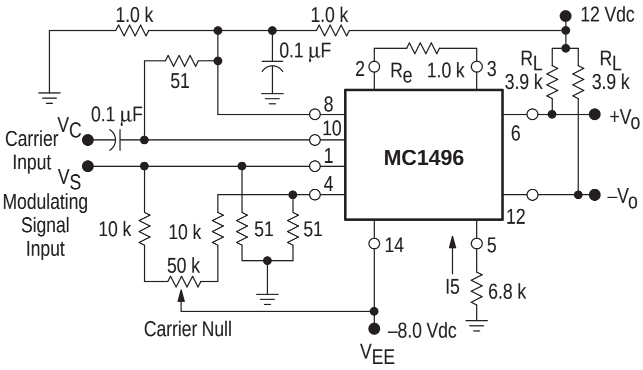

Figure 25. Voltage Gain and Output Frequencies

Carrier Input Signal (V_C)	Approximate Voltage Gain	Output Signal Frequency(s)
Low–level dc	$\frac{R_L \; V_C}{2(R_E + 2r_e)\left(\frac{KT}{q}\right)}$	f_M
High–level dc	$\frac{R_L}{R_E + 2r_e}$	f_M
Low–level ac	$\frac{R_L \; V_C(rms)}{2\sqrt{2}\left(\frac{KT}{q}\right)(R_E + 2r_e)}$	$f_C \pm f_M$
High–level ac	$\frac{0.637 \; R_L}{R_E + 2r_e}$	$f_C \pm f_M, 3f_C \pm f_M, 5f_C \pm f_M, \; . \; . \; .$

NOTES: 1. Low–level Modulating Signal, V_M, assumed in all cases. V_C is Carrier Input Voltage.
2. When the output signal contains multiple frequencies, the gain expression given is for the output amplitude of each of the two desired outputs, $f_C + f_M$ and $f_C - f_M$.
3. All gain expressions are for a single–ended output. For a differential output connection, multiply each expression by two.
4. R_L = Load resistance.
5. R_E = Emitter resistance between Pins 2 and 3.
6. r_e = Transistor dynamic emitter resistance, at 25°C;

$$re \approx \frac{26 \text{ mV}}{I_5 \text{ (mA)}}$$

7. K = Boltzmann's Constant, T = temperature in degrees Kelvin, q = the charge on an electron.

$$\frac{KT}{q} \approx 26 \text{ mV at room temperature}$$

The gain from the modulating signal input port to the output is the MC1496 gain parameter which is most often of interest to the designer. This gain has significance only when the lower differential amplifier is operated in a linear mode, but this includes most applications of the device.

As previously mentioned, the upper quad differential amplifier may be operated either in a linear or a saturated mode. Approximate gain expressions have been developed for the MC1496 for a low–level modulating signal input and the following carrier input conditions:

1) Low–level dc
2) High–level dc
3) Low–level ac
4) High–level ac

These gains are summarized in Figure 25, along with the frequency components contained in the output signal.

APPLICATIONS INFORMATION

Double sideband suppressed carrier modulation is the basic application of the MC1496. The suggested circuit for this application is shown on the front page of this data sheet.

In some applications, it may be necessary to operate the MC1496 with a single dc supply voltage instead of dual supplies. Figure 26 shows a balanced modulator designed for operation with a single 12 Vdc supply. Performance of this circuit is similar to that of the dual supply modulator.

AM Modulator

The circuit shown in Figure 27 may be used as an amplitude modulator with a minor modification.

All that is required to shift from suppressed carrier to AM operation is to adjust the carrier null potentiometer for the proper amount of carrier insertion in the output signal.

However, the suppressed carrier null circuitry as shown in Figure 27 does not have sufficient adjustment range. Therefore, the modulator may be modified for AM operation by changing two resistor values in the null circuit as shown in Figure 28.

Product Detector

The MC1496 makes an excellent SSB product detector (see Figure 29).

This product detector has a sensitivity of 3.0 microvolts and a dynamic range of 90 dB when operating at an intermediate frequency of 9.0 MHz.

The detector is broadband for the entire high frequency range. For operation at very low intermediate frequencies down to 50 kHz the 0.1 μF capacitors on Pins 8 and 10 should be increased to 1.0 μF. Also, the output filter at Pin 12 can be tailored to a specific intermediate frequency and audio amplifier input impedance.

As in all applications of the MC1496, the emitter resistance between Pins 2 and 3 may be increased or decreased to adjust circuit gain, sensitivity, and dynamic range.

This circuit may also be used as an AM detector by introducing carrier signal at the carrier input and an AM signal at the SSB input.

The carrier signal may be derived from the intermediate frequency signal or generated locally. The carrier signal may be introduced with or without modulation, provided its level is sufficiently high to saturate the upper quad differential amplifier. If the carrier signal is modulated, a 300 mVrms input level is recommended.

Doubly Balanced Mixer

The MC1496 may be used as a doubly balanced mixer with either broadband or tuned narrow band input and output networks.

The local oscillator signal is introduced at the carrier input port with a recommended amplitude of 100 mVrms.

Figure 30 shows a mixer with a broadband input and a tuned output.

Frequency Doubler

The MC1496 will operate as a frequency doubler by introducing the same frequency at both input ports.

Figures 31 and 32 show a broadband frequency doubler and a tuned output very high frequency (VHF) doubler, respectively.

Phase Detection and FM Detection

The MC1496 will function as a phase detector. High–level input signals are introduced at both inputs. When both inputs are at the same frequency the MC1496 will deliver an output which is a function of the phase difference between the two input signals.

An FM detector may be constructed by using the phase detector principle. A tuned circuit is added at one of the inputs to cause the two input signals to vary in phase as a function of frequency. The MC1496 will then provide an output which is a function of the input signal frequency.

MC2833

Low Power FM Transmitter System

MC2833 is a one–chip FM transmitter subsystem designed for cordless telephone and FM communication equipment. It includes a microphone amplifier, voltage controlled oscillator and two auxiliary transistors.

- Wide Range of Operating Supply Voltage (2.8–9.0 V)
- Low Drain Current (I_{CC} = 2.9 mA Typ)
- Low Number of External Parts Required
- – 30 dBm Power Output to 60 MHz Using Direct RF Output
- +10 dBm Power Output Attainable Using On–Chip Transistor Amplifiers
- Users Must Comply with Local Regulations on R.F. Transmission (FCC, DOT, P.T.T., etc)

CIRCUIT DESCRIPTION

The MC3335 is a complete FM narrowband receiver from antenna input to audio preamp output. The low voltage dual conversion design yields low power drain, excellent sensitivity and good image rejection in narrowband voice and data link applications.

In the typical application diagram, the first mixer amplifies the signal and converts the RF input to 10.7 MHz. This IF signal is filtered externally and fed into the second mixer, which further amplifies the signal and converts it to a 455 kHz IF signal. After external bandpass filtering, the low IF is fed into the limiting amplifier and detection circuitry. The audio is recovered using a conventional quadrature detector. Twice–IF filtering is provided internally.

The input signal level is monitored by meter drive circuitry which detects the amount of limiting in the limiting amplifier. The voltage at the meter drive pin determines the state of the carrier detect output which is active low.

APPLICATIONS INFORMATION

The first local oscillator can be run using a free running LC tank, as a VCO using PLL synthesis, or driven from an external crystal oscillator. At higher V_{CC} values (6.0 to 7.0 V), it has been run to 170 MHz. The second local oscillator is a common base Colpitts type which is typically run at 10.245 MHz under crystal control.

The mixers are doubly balanced to reduce spurious responses. The first and second mixers have conversion gains of 18 dB and 22 dB (typical), respectively. Mixer gain is stable with respect to supply voltage. For both conversions, the mixer impedances and pin layout are designed to allow the user to employ low cost, readily available ceramic filters. Overall sensitivity is shown in Figure 5. The input level for 20 dB (S + N)/N is 1.3 µV using the two–pole post–detection filter as demonstrated.

Following the first mixer, a 10.7 MHz ceramic bandpass filter is recommended. The 10.7 MHz filtered signal is then fed into one second mixer input pin, the other input pin being connected to V_{CC}. Pin 5 (V_{CC}) is treated as a common point for emitter–driven signals.

The 455 kHz IF is typically filtered using a ceramic bandpass filter, then fed into the limiter input pin. The limiter has 10 µV sensitivity for – 3.0 dB limiting, flat to 1.0 MHz.

The output of the limiter is internally connected to the quadrature detector, including a quadrature capacitor. A parallel LC tank is needed externally from Pin 11 to VCC. A 39 kΩ shunt resistance is included which determines the peak separation of the quadrature detector; a smaller value will increase the spacing and linearity but decrease recovered audio and sensitivity.

A data shaping circuit is available and can be coupled to the recovered audio output of Pin 12. The circuit is a comparator which is designed to detect zero crossings of FSK modulation. Data rates of up to 35000 baud are detectable using the typical application. Hysteresis is available by connecting a high–valued resistor from Pin 13 to Pin 14. Values below 120 kΩ are not recommended as the input signal cannot overcome the hysteresis.

The meter drive circuitry detects input signal level by monitoring the limiting of the limiting amplifier stages. Figure 2 shows the unloaded current at Pin 9 versus input power. The meter drive current can be used directly (RSSI) or can be used to trip the carrier detect circuit at a specified input power. To do this, pick an RF trip level in dBm. Read the corresponding current from Figure 2 and pick a resistor such that:

$$R9 = 0.64\ \text{Vdc} / I9$$

Hysteresis is available by connecting a high–valued resistor RH between Pin 9 and 10. The formula is:

$$\text{Hysteresis} = V_{CC}/(RH \times 10^{-7})\ \text{dB}$$

GENERAL DESCRIPTION

This device is intended for single and double conversion VHF receiver systems, primarily for FSK data transmission up to 500 K baud (250 kHz). It contains an oscillator, mixer, limiting IF, quadrature detector, signal strength meter drive, and data shaping amplifier.

The oscillator is a common base Colpitts type which can be crystal controlled, as shown in Figure 1, or L–C controlled as shown in the other figures. At higher V_{CC}, it has been operated as high as 200 MHz. A mixer/oscillator voltage gain of 2 up to approximately 150 MHz, is readily achievable.

The mixer functions well from an input signal of 10 µVrms, below which the squelch is unpredictable, up to about 10 mVrms, before any evidence of overload. Operation up to 1.0 Vrms input is permitted, but non–linearity of the meter output is incurred, and some oscillator pulling is suspected. The AM rejection above 10 mVrms is degraded.

The limiting IF is a high frequency type, capable of being operated up to 50 MHz. It is expected to be used at 10.7 MHz in most cases, due to the availability of standard ceramic resonators. The quadrature detector is internally coupled to the IF, and a 5.0 pF quadrature capacitor is internally provided. The –3dB limiting sensitivity of the IF itself is approximately 50 µV (at Pin 7), and the IF can accept signals up to 1.0 Vrms without distortion or change of detector quiescent dc level.

The IF is unusual in that each of the last 5 stages of the 6 state limiter contains a signal strength sensitive, current sinking device. These are parallel connected and buffered to produce a signal strength meter drive which is fairly linear for IF input signals of 10 µV to 100 mVrms (see Figure 4).

A simple squelch arrangement is provided whereby the meter current flowing through the meter load resistance flips a comparator at about 0.8 Vdc above ground. The signal strength at which this occurs can be adjusted by changing the meter load resistor. The comparator (+) input and output are available to permit control of hysteresis. Good positive action can be obtained for IF input signals of above 30 µVrms. The 130 kΩ resistor shown in the test circuit provides a small amount of hysteresis. Its connection between the 3.3 k resistor to ground and the 3.0 k pot, permits adjustment of squelch level without changing the amount of hysteresis.

The squelch is internally connected to both the quadrature detector and the data shaper. The quadrature detector output, when squelched, goes to a dc level approximately equal to the zero signal level unsquelched. The squelch causes the data shaper to produce a high (V_{CC}) output.

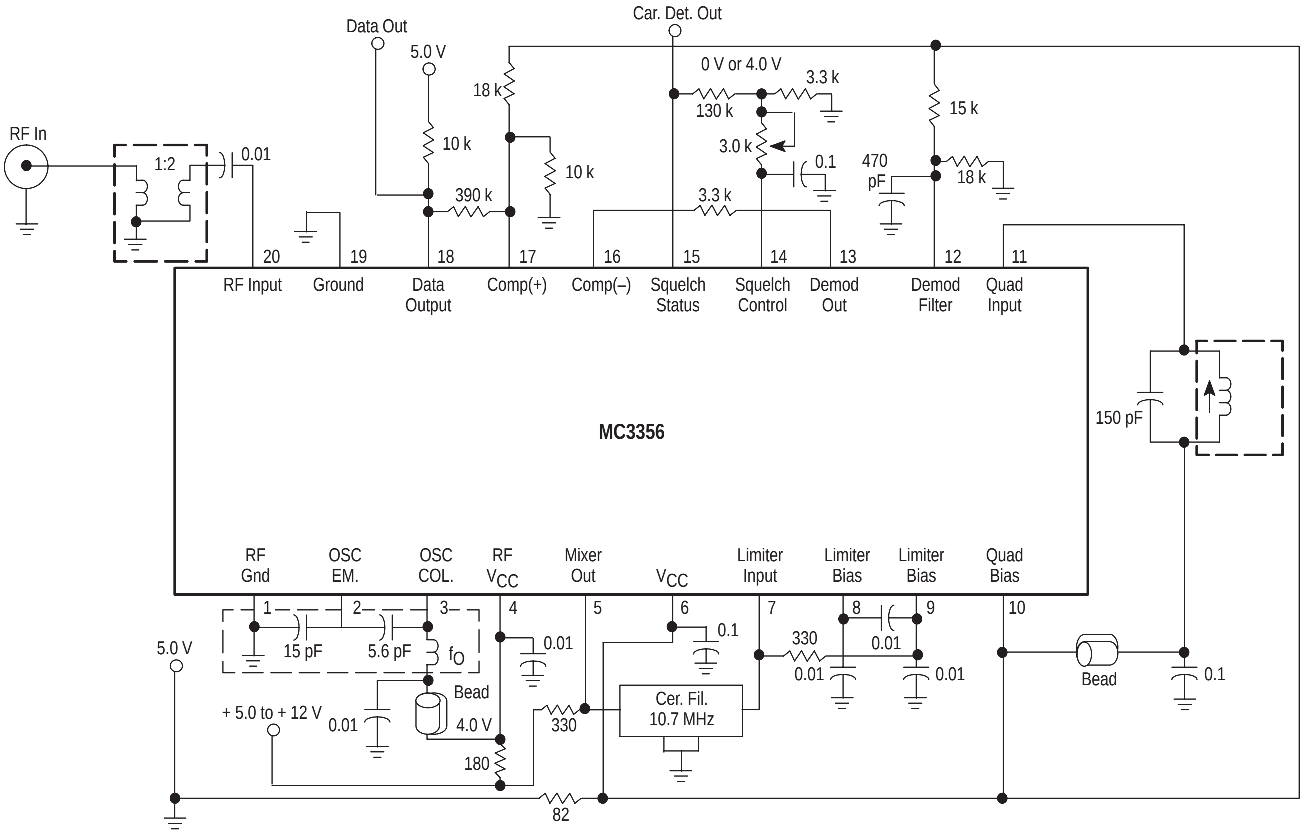
The data shaper is a complete ‘‘floating’’ comparator, with back to back diodes across its inputs. The output of the quadrature detector can be fed directly to either input of this amplifier to produce an output that is either at V_{CC} or V_{EE}, depending upon the received frequency. The impedance of the biasing can be varied to produce an amplifier which “follows” frequency detuning to some degree, to prevent data pulse width changes.

When the data shaper is driven directly from the demodulator output, Pin 13, there may be distortion at Pin 13 due to the diodes, but this is not important in the data application. A useful note in relating high/low input frequency to logic state: low IF frequency corresponds to low demodulator output. If the oscillator is above the incoming RF frequency, then high RF frequency will produce a logic low (input to (+) input of Data Shaper as shown in Figures 1 and 2).

APPLICATION NOTES

The MC3356 is a high frequency/high gain receiver that requires following certain layout techniques in designing a stable circuit configuration. The objective is to minimize or eliminate, if possible, any unwanted feedback.

Figure 5. Application with Fixed Bias on Data Shaper



APPLICATION NOTES (continued)

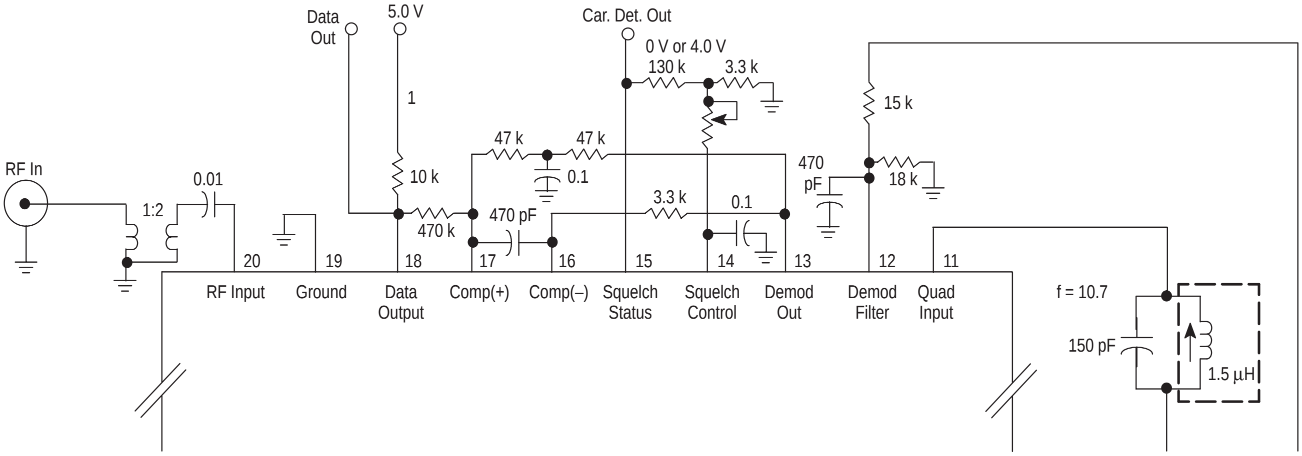
Shielding, which includes the placement of input and output components, is important in minimizing electrostatic or electromagnetic coupling. The MC3356 has its pin connections such that the circuit designer can place the critical input and output circuits on opposite ends of the chip. Shielding is normally required for inductors in tuned circuits.

The MC3356 has a separate V_{CC} and ground for the RF and IF sections which allows good external circuit isolation by minimizing common ground paths.

Note that the circuits of Figures 1 and 2 have RF, Oscillator, and IF circuits predominantly referenced to the plus supply rails. Figure 5, on the other hand, shows a suitable means of ground referencing. The two methods produce identical results when carefully executed. It is important to treat Pin 19 as a ground node for either approach. The RF input should be “grounded” to Pin 1 and then the input and the mixer/oscillator grounds (or RF V_{CC} bypasses) should be connected by a low inductance path to Pin 19. IF and detector sections should also have their bypasses returned by a **separate** path to Pin 19. V_{CC} and RF V_{CC} can be decoupled to minimize feedback, although the configuration of Figure 2 shows a successful implementation on a common 5.0 V supply. Once again, the message is: define a supply node and a ground node and return each section to those nodes by separate, low impedance paths.

The test circuit of Figure 2 has a 3 dB limiting level of 30 µV which can be lowered 6 db by a 1:2 untuned transformer at the input as shown in Figures 5 and 6. For applications that require additional sensitivity, an RF amplifier can be added, but with no greater than 20 db gain. This will give a 2.0 to 2.5 µV sensitivity and any additional gain will reduce receiver dynamic range without improving its sensitivity. Although the test circuit operates at 5.0 V, the mixer/oscillator optimum performance is at 8.0 V to 12 V. A minimum of 8.0 V is recommended in high frequency applications (above 150 MHz), or in PLL applications where the oscillator drives a prescaler.

Figure 6. Application with Self–Adjusting Bias on Data Shaper



APPLICATION NOTES (continued)

Depending on the external circuit, inverted or noninverted data is available at Pin 18. Inverted data makes the higher frequency in the FSK signal a "one" when the local oscillator is above the incoming RF. Figure 5 schematic shows the comparator with hysteresis. In this circuit the dc reference voltage at Pin 17 is about the same as the demodulated output voltage (Pin 13) when no signal is present. This type circuit is preferred for systems where the data rates can drop to zero. Some systems have a low frequency limit on the data rate, such as systems using the MC3850 ACIA that has a start or stop bit. This defines the low frequency limit that can appear in the data stream. Figure 5 circuit can then be changed to a circuit configuration as shown in Figure 6. In Figure 6 the reference voltage for the comparator is derived from the demodulator output through a low pass circuit where τ is much lower than the lowest frequency data rate. This and similar circuits will compensate for small tuning changes (or drift) in the quadrature detector.

Squelch status (Pin 15) goes high (squelch off) when the input signal becomes greater than some preset level set by the resistance between Pin 14 and ground. Hysteresis is added to the circuit externally by the resistance from Pin 14 to Pin 15.

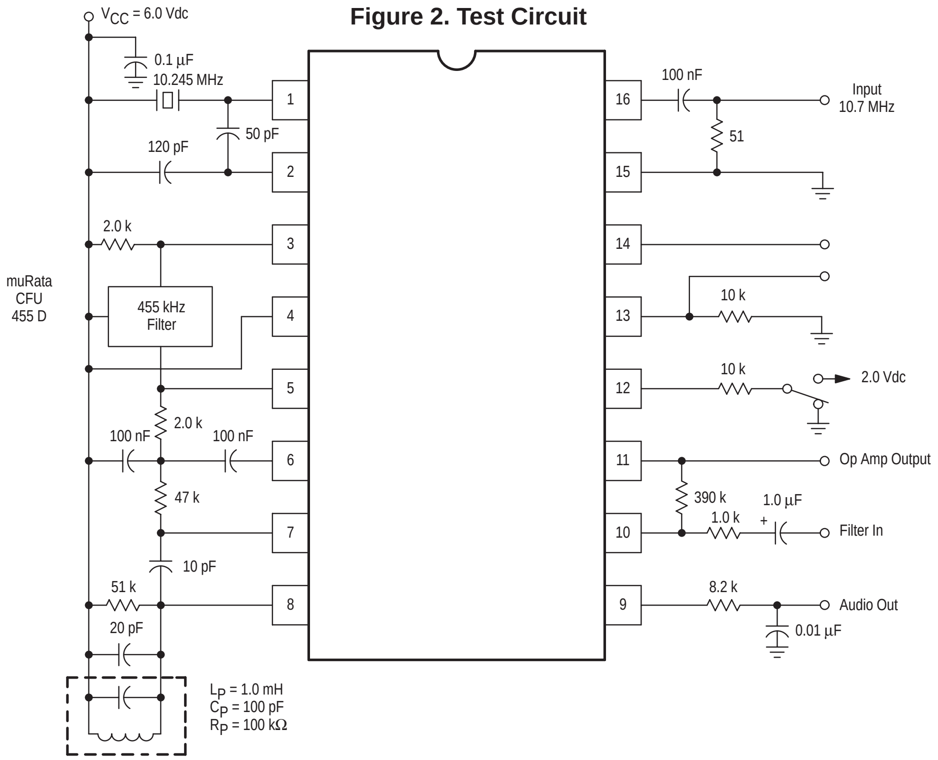
Figure 2. Test Circuit



CIRCUIT DESCRIPTION

The MC3357 is a low power FM IF circuit designed primarily for use in voice communication scanning receivers.

The mixer–oscillator combination converts the input frequency (e.g., 10.7 MHz) down to 455 kHz, where, after external bandpass filtering, most of the amplification is done. The audio is recovered using a conventional quadrature FM detector. The absence of an input signal is indicated by the presence of noise above the desired audio frequencies. This “noise band” is monitored by an active filter and a detector. A squelch trigger circuit indicates the presence of a noise (or a tone) by an output which can be used to control scanning. At the same time, an internal switch is operated which can be used to mute the audio.

The oscillator is an internally–biased Colpitts type with the collector, base, and emitter connections at Pins 4, 1, and 2 respectively. A crystal can be used in place of the usual coil.

The mixer is doubly–balanced to reduce spurious responses. The input impedance at Pin 16 is set by a 3.0 kΩ internal biasing resistor and has low capacitance, allowing the circuit to be preceded by a crystal filter. The collector output at Pin 3 must be dc connected to B +, below which it can swing 0.5 V.

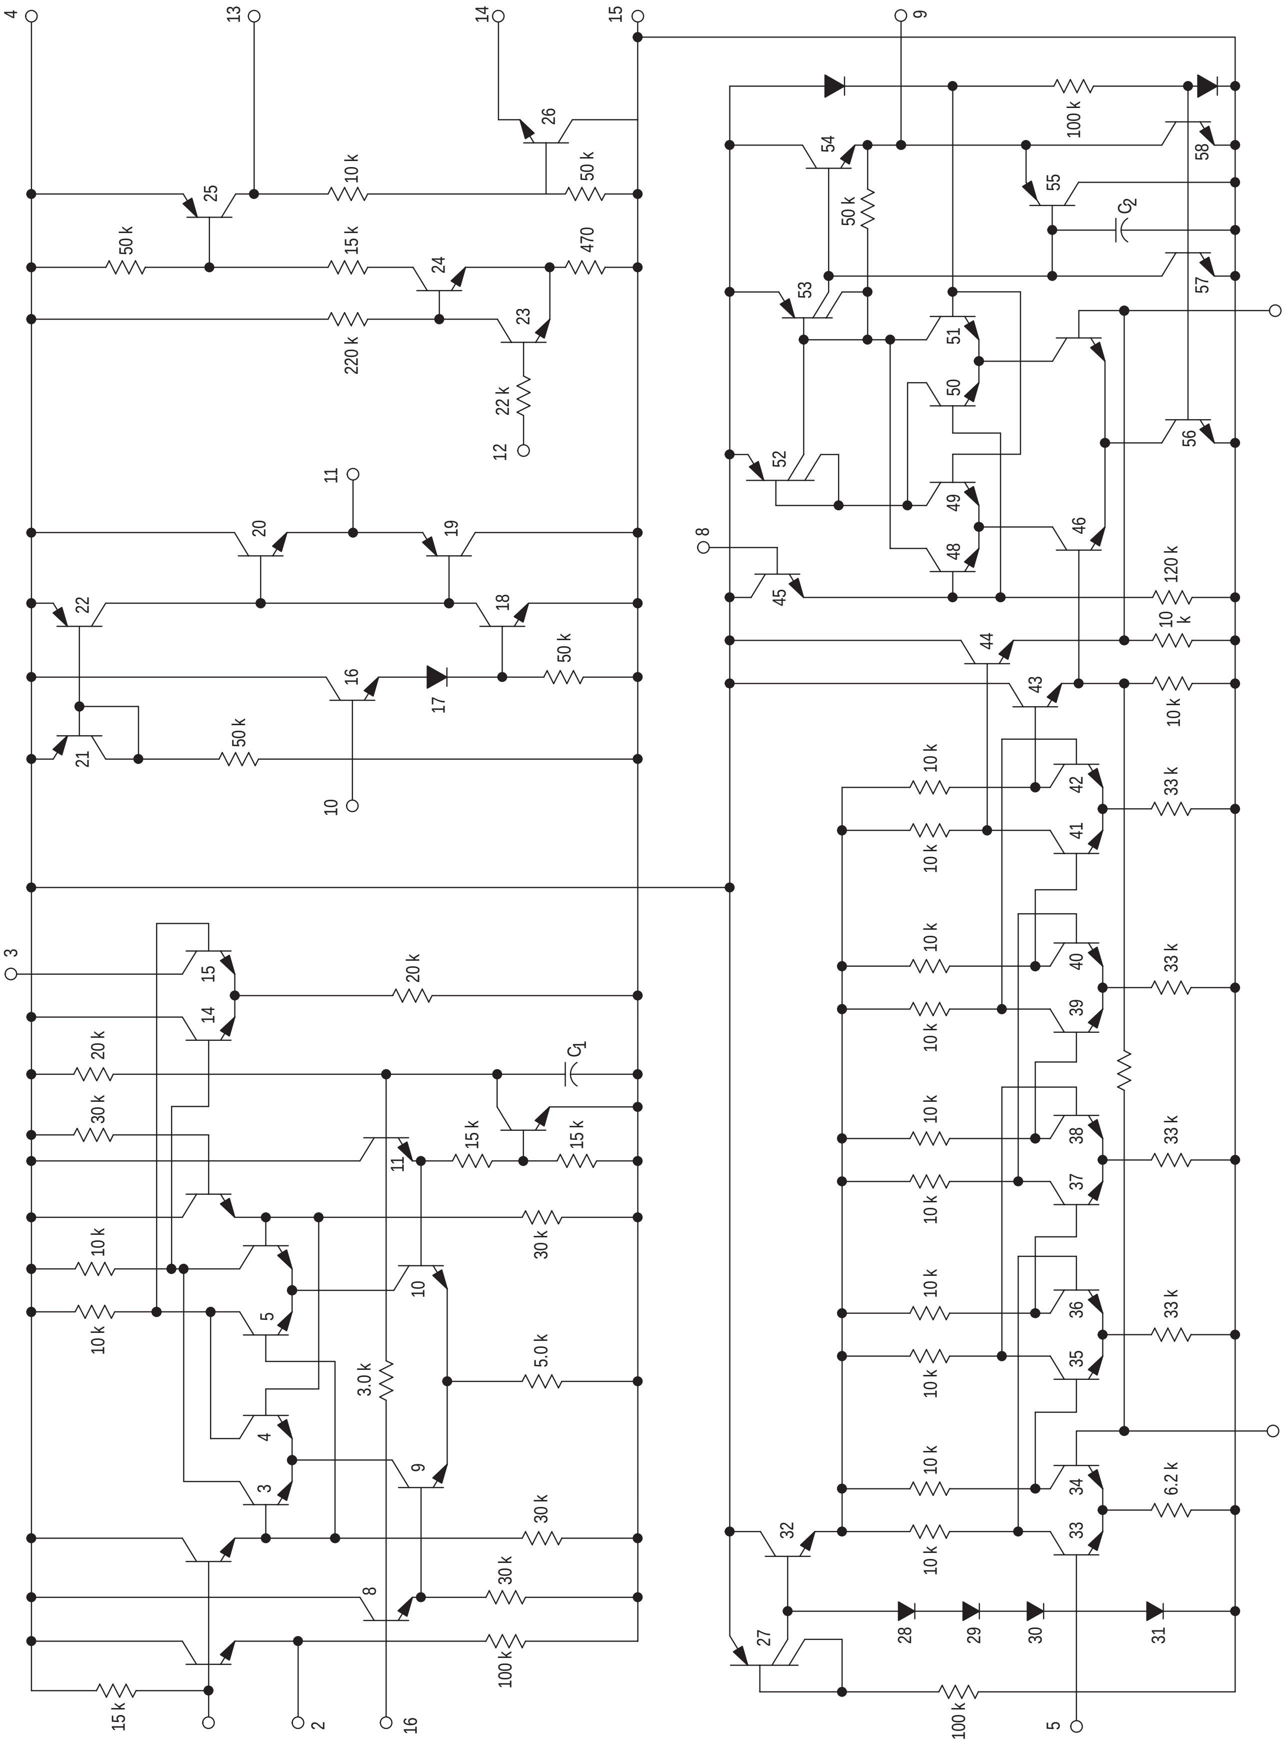
After suitable bandpass filtering (ceramic or LC), the signal goes to the input of a five–stage limiter at Pin 5. The output of the limiter at Pin 7 drives a multiplier, both internally directly, and externally through a quadrature coil, to detect the FM. The output at Pin 7 is also used to supply dc feedback to Pin 5. The other side of the first limiter stage is decoupled at Pin 6.

The recovered audio is partially filtered, then buffered, giving an impedance of around 400 Ω at Pin 9. The signal still requires de–emphasis, volume control and further amplification before driving a loudspeaker.

A simple inverting op amp is provided with an output at Pin 11 providing dc bias (externally) to the input at Pin 10 which is referred internally to 2.0 V. A filter can be made with external impedance elements to discriminate between frequencies. With an external AM detector, the filtered audio signal can be checked for the presence of noise above the normal audio band, or a tone signal. This information is applied to Pin 12.

An external positive bias to Pin 12 sets up the squelch trigger circuit such that Pin 13 is low at an impedance level of around 60 kΩ, and the audio mute (Pin 14) is open circuit. If Pin 12 is pulled down to 0.7 V by the noise or tone detector, Pin 13 will rise to approximately 0.5 Vdc below supply where it can support a load current of around 500 µA and Pin 14 is internally short–circuited to ground. There is 100 mV of hysteresis at Pin 12 to prevent jitter. Audio muting is accomplished by connecting Pin 14 to a high–impedance ground–reference point in the audio path between Pin 9 and the audio amplifier.

Figure 3. Circuit Schematic



MOTOROLA

MC3359

Low Power Narrowband FM IF

. . . includes oscillator, mixer, limiting amplifier, AFC, quadrature discriminator, op/amp, squelch, scan control, and mute switch. The MC3359 is designed to detect narrowband FM signals using a 455 kHz ceramic filter for use in FM dual conversion communications equipment. The MC3359 is similar to the MC3357 except that the MC3359 has an additional limiting IF stage, an AFC output, and an opposite polarity Broadcast Detector. The MC3359 also requires fewer external parts. For low cost applications requiring V_{CC} below 6.0 V, the MC3361BP,BD are recommended. For applications requiring a fixed, tuned, ceramic quadrature resonator, use the MC3357. For applications requiring dual conversion and RSSI, refer to these devices; MC3335, MC3362 and MC3363.

- Low Drain Current: 3.6 mA (Typical) @ V_{CC} = 6.0 Vdc
- Excellent Sensitivity: Input Limiting Voltage –
  – 3.0 dB = 2.0 µV (Typical)

CIRCUIT DESCRIPTION

The MC3359 is a low–power FM IF circuit designed primarily for use in voice–communication scanning receivers. It is also finding a place in narrowband data links.

In the typical application (Figure 1), the mixer–oscillator combination converts the input frequency (10.7 MHz) down to 455 kHz, where, after external bandpass filtering, most of the amplification is done. The audio is recovered using a conventional quadrature FM detector. The absence of an input signal is indicated by the presence of noise above the desired audio frequencies. This “noise band” is monitored by an active filter and a detector. A squelch–trigger circuit indicates the presence of noise (or a tone) by an output which can be used to control scanning. At the same time, an internal switch is operated which can be used to mute the audio.

APPLICATIONS INFORMATION

The oscillator is an internally biased Colpitts type with the collector, base, and emitter connections at Pin 4, 1 and 2, respectively. The crystal is used in fundamental mode, calibrated for parallel resonance at 32 pF load capacitance. In theory this means that the two capacitors in series should be 32 pF, but in fact much larger values do not significantly affect the oscillator frequency, and provide higher oscillator output.

The oscillator can also be used in the conventional L/C Colpitts configuration without loss of mixer conversion gain. This oscillator is, of course, much more sensitive to voltage and temperature as shown in Figure 12. Guidelines for choosing L and C values are given in Figure 14.

The mixer is doubly balanced to reduce spurious responses. The mixer measurements of Figure 4 and 6 were made using an external 50 Ω source and the internal 1.8 k at Pin 3. Voltage gain curves at several V_{CC} voltages are shown in Figure 4. The Third Order Intercept curves of Figure 6 are shown using the conventional dBm scales. Measured power gain (with the 50 Ω input) is approximately 18 dB but the useful gain is much higher because the mixer input impedance is over 3 kΩ. Most applications will use a 330 Ω 10.7 MHz crystal filter ahead of the mixer. For higher frequencies, the relative mixer gain is given in Figure 8.

Following the mixer, a ceramic bandpass filter is recommended. The 455 kHz types come in bandwidths from ± 2 kHz to ± 15 kHz and have input and output impedances of 1.5 k to 2.0 k. For this reason, the Pin 5 input to the 6 stage limiting IF has an internal 1.8 k resistor. The IF has a 3 dB limiting sensitivity of approximately 100 µV at Pin 5 and a useful frequency range of about 5 MHz as shown in Figure 5. The frequency limitation is due to the high resistance values in the IF, which were necessary to meet the low power requirement. The output of the limiter is internally connected to the quadrature detector, including the 10 pF quadrature capacitor. Only a parallel L/C is needed externally from Pin 8 to V_{CC}. A shunt resistance can be added to widen the peak separation of the quadrature detector.

The detector output is amplified and buffered to the audio output, Pin 10, which has an output impedance of approximately 300 Ω. Pin 9 provides a high impedance (50 k) point in the output amplifier for application of a filter or de–emphasis capacitor. Pin 11 is the AFC output, with high gain and high output impedance (1 M). If not needed, it should be grounded, or it can be connected to Pin 9 to double the recovered audio. The detector and AFC responses are shown in Figure 7.

Overall performance of the MC3359 from mixer input to audio output is shown in Figure 9 and 10. The MC3359 can also be operated in “single conversion” equipment; i.e., the mixer can be used as a 455 kHz amplifier. The oscillator is disabled by connecting Pin 1 to Pin 2. In this mode, the overall performance is identical to the 10.7 MHz results of Figure 9.

A simple inverting op amp is provided with an output at Pin 13 providing dc bias (externally) to the input at Pin 12, which is referred internally to 2.0 V. A filter can be made with external impedance elements to discriminate between frequencies. With an external AM detector, the filtered audio signal can be checked for the presence of either noise above the normal audio, or a tone signal.

The open loop response of this op amp is given in Figure13. Bandpass filter design information is provided in Figure 15.

A low bias to Pin 14 sets up the squelch–trigger circuit so that Pin 15 is high, a source of at least 2.0 mA, and the audio mute (Pin 16) is open–circuit. If Pin 14 is raised to 0.7 V by the noise or tone detector, Pin 15 becomes open circuit and Pin 16 is internally short circuited to ground. There is no hysteresis. Audio muting is accomplished by connecting Pin 16 to a high–impedance ground–reference point in the audio path between Pin 10 and the audio amplifier. No dc voltage is needed, in fact it is not desirable because audio “thump” would result during the muting function. Signal swing greater than 0.7 V below ground on Pin 16 should be avoided.

MOTOROLA

MC3362

Low-Power Narrowband FM Receiver

. . . includes dual FM conversion with oscillators, mixers, quadrature discriminator, and meter drive/carrier detect circuitry. The MC3362 also has buffered first and second local oscillator outputs and a comparator circuit for FSK detection.

- Complete Dual Conversion Circuitry
- Low Voltage: V_{CC} = 2.0 to 6.0 Vdc
- Low Drain Current (3.6 mA (Typical) @ V_{CC} = 3.0 Vdc)
- Excellent Sensitivity: Input Voltage 0.6 µVrms (Typical) for 12 dB SINAD
- Externally Adjustable Carrier Detect Function
- Low Number of External Parts Required
- Manufactured Using Motorola′s MOSAIC® Process Technology
- MC13135 is Preferred for New Designs

CIRCUIT DESCRIPTION

The MC3362 is a complete FM narrowband receiver from antenna input to audio preamp output. The low voltage dual conversion design yields low power drain, excellent sensitivity and good image rejection in narrowband voice and data link applications.

In the typical application (Figure 1), the first mixer amplifies the signal and converts the RF input to 10.7 MHz. This IF signal is filtered externally and fed into the second mixer, which further amplifies the signal and converts it to a 455 kHz IF signal. After external bandpass filtering, the low IF is fed into the limiting amplifier and detection circuitry. The audio is recovered using a conventional quadrature detector. Twice–IF filtering is provided internally.

The input signal level is monitored by meter drive circuitry which detects the amount of limiting in the limiting amplifier. The voltage at the meter drive pin determines the state of the carrier detect output, which is active low.

APPLICATIONS INFORMATION

The first local oscillator can be run using a free–running LC tank, as a VCO using PLL synthesis, or driven from an external crystal oscillator. It has been run to 190 MHz.* A buffered output is available at Pin 20. The second local oscillator is a common base Colpitts type which is typically run at 10.245 MHz under crystal control. A buffered output is available at Pin 2. Pins 2 and 3 are interchangeable.

The mixers are doubly balanced to reduce spurious responses. The first and second mixers have conversion gains of 18 dB and 22 dB (typical), respectively, as seen in Figure 6. Mixer gain is stable with respect to supply voltage. For both conversions, the mixer impedances and pin layout are designed to allow the user to employ low cost, readily available ceramic filters. Overall sensitivity and AM rejection are shown in Figure 7. The input level for 20 dB (S + N)/N is 0.7 µV using the two–pole post–detection filter pictured.

---

* If the first local oscillator (Pins 21 and/or 22) is driven from a strong external source (100 mVrms), the mixer can be used to over 450 MHz.

Following the first mixer, a 10.7 MHz ceramic band–pass filter is recommended. The 10.7 MHz filtered signal is then fed into one second mixer input pin, the other input pin being connected to V_{CC}. Pin 6 (V_{CC}) is treated as a common point for emitter–driven signals.

The 455 kHz IF is typically filtered using a ceramic bandpass filter then fed into the limiter input pin. The limiter has 10 µV sensitivity for – 3.0 dB limiting, flat to 1.0 MHz.

The output of the limiter is internally connected to the quadrature detector, including a quadrature capacitor. A parallel LC tank is needed externally from Pin 12 to V_{CC}. A 39 kΩ shunt resistance is included which determines the peak separation of the quadrature detector; a smaller value will increase the spacing and linearity but decrease recovered audio and sensitivity.

A data shaping circuit is available and can be coupled to the recovered audio output of Pin 13. The circuit is a comparator which is designed to detect zero crossings of FSK modulation. Data rates are typically limited to 1200 baud to ensure data integrity and avoid adjacent channel “splatter.” Hysteresis is available by connecting a high valued resistor from Pin 15 to Pin 14. Values below 120 kΩ are not recommended as the input signal cannot overcome the hysteresis.

The meter drive circuitry detects input signal level by monitoring the limiting amplifier stages. Figure 4 shows the unloaded current at Pin 10 versus input power. The meter drive current can be used directly (RSSI) or can be used to trip the carrier detect circuit at a specified input power. To do this, pick an RF trip level in dBm. Read the corresponding current from Figure 4 and pick a resistor such that:

$$R_{10} \simeq 0.64 \text{ Vdc} / I_{10}$$

Hysteresis is available by connecting a high valued resistor R_H between Pins 10 and 11. The formula is:

$$\text{Hysteresis} = V_{CC}/(R_H \times 10^{-7}) \text{ dB}$$

MOTOROLA

Low Voltage FM Narrowband Receiver

. . . with single conversion circuitry including oscillator, mixer, IF amplifiers, limiting IF circuitry, and quadrature discriminator. The MC3374 is perfect for narrowband audio and data applications up to 75 MHz which require extremely low power consumption. Battery powered applications down to V_{CC} = 1.1 V are possible. The MC3374 also includes an on–board voltage regulator, low battery detection circuitry, a receiver enable allowing a power down Sleep–Mode™, two undedicated buffer amplifiers to allow simultaneous audio and data reception, and a comparator for enhancing FSK (Frequency Shift Keyed) data reception to 1200 baud.

- Low Supply Voltage: V_{CC} = 1.1 to 3.0 Vdc
- Low Power Consumption: P_D = 1.5 to 5.0 mW
- Input Bandwidth 75 MHz
- Excellent Sensitivity: 0.5 µVrms for 12 dB SINAD
- Voltage Regulator Available (Source Capability 3.0 mA)
- Receiver Enable to Allow Active/Standby Operation
- Low Battery Detection Circuitry
- Self Biasing Audio Buffer
- Data Buffer
- FSK Data Shaping Comparator
- Standard 32–Lead QFP Surface Mount Package

NOTES:

1. FL1 and FL2 are 455 kHz ceramic bandpass filters, which should have input and output impedances of 1.5 kΩ to 2.0 kΩ. Suggested part numbers are MuRata CFU455X or CFW455x – the ‘X’ suffix denotes bandwidth.
2. LC1 is a 455 kHz LC resonator. Recommended part numbers are Toko America RMC2A6597HM or 5SVLC–0637BGT (smaller). The evaluation board layout shown provides for use of either resonator. Ceramic discriminator elements cannot be used with the MC3374 due to their low input impedance. The damping resistor value can be raised to increase the recovered audio or lowered to increase the quadrature detector’s bandwidth and linearity – practical limits are approximately 27 kΩ to 75 kΩ. Typically the quadrature detector’s bandwidth should match the low IF filter’s bandwidth.
3. The data buffer is set up as a low–pass filter with a corner frequency of approximately 200 Hz. The audio buffer is a bandpass filter with corner frequencies of 300 Hz and 3.0 kHz. The audio amplifier provides bass suppression.
4. C_{C1} and C_{C3} are RF coupling capacitors and should have ≤ 20 Ω impedance at the desired input and oscillator frequencies.
5. C_{C2} provides “light coupling” of the oscillator signal into the mixer, and should have a 3.0 kΩ to 5.0 kΩ impedance at the desired local oscillator frequency.
6. Capacitors labelled C_B are bypass capacitors and should have 20 Ω impedance at the desired RF and local oscillator frequencies.
7. The network of L1, C1 and C2 provides impedance matching of the mixer input (nominally 3.0 kΩ shunted by 9.0 pF) to 50 Ω at the desired RF/IF input frequency. This will allow for bench testing of the receiver from typical RF signal generators or radio service monitors, but additional or different matching will be required to maximize receiver sensitivity when used in conjunction with an antenna, RF preamplifier or mixer.

In. Freq.	L1	L2	C1	C2	C3	C4	C_{C1}/C_{C3}	C_{C2}	C_B	RD
10.7 MHz	6.8 µH	Short	2–82 pF	10 pF	120 pF	50 pF	1.0 nF	5.0 pF	0.1 µF	Open
45 MHz	0.68 µH	1.2 µH	5–25 pF	Open	30 pF	5.0 pF	1.0 nF	1.0 pF	1.0 nF	1.0 k

CIRCUIT DESCRIPTION

The MC3374 is an FM narrowband receiver capable of operation to 75 MHz. The low voltage design yields low power drain and excellent sensitivity in narrowband voice and data link applications. In the typical application the mixer amplifies the incoming RF or IF signal and converts this frequency to 455 kHz. The signal is then filtered by a 455 kHz ceramic filter and applied to the first intermediate frequency (IF) amplifier input, before passing through a second ceramic filter. The modulated IF signal is then applied to the limiting IF amplifier and detector circuitry. Modulation is recovered by a conventional quadrature detector. The typical modulation bandwidth available is 3.0 to 5.0 kHz.

Features available include buffers for audio/data amplification and active filtering, on board voltage regulator, low battery detection circuitry with programmable level, and receiver disable circuitry. The MC3374 is an FM utility receiver to be used for voice and/or narrowband data reception. It is especially suitable where extremely low power consumption and high design flexibility are required.

APPLICATION

The MC3374 can be used as a high performance FM IF for the use in low power dual conversion receivers. Because of the MC3374's extremely good sensitivity (0.6 μV for 20 dB (S+N/N, see Figure 3)), it can also be used as a stand alone single conversion narrowband receiver to 75 MHz for applications not sensitive to image frequency interference. An RF preamplifier will likely be needed to overcome preselector losses.

The oscillator is a Colpitts type which must be run under crystal control. For fundamental mode crystals choose resonators, parallel resonant, for a 32 pF load. For higher frequencies, use a 3rd overtone series mode type. The coil L2 and RD resistor are needed to ensure proper operation.

The best adjacent channel and sensitivity response occur when two 455 kHz ceramic filters are used, as shown in Figure 1. Either can be replaced by a 0.1 μF coupling capacitor to reduce cost, but some degradation in sensitivity and/or stability is suspected.

The detector is a quadrature type, with the connection from the limiter output to the detector input provided internally. A 455 kHz LC tank circuit must be provided externally. One of the tank pins (Pin 8) must be decoupled using a 0.1 μF capacitor. The 56 kΩ damping resistor (see Figure 1), determines the peak separation of the detector (and thus its bandwidth). Smaller values will increase the separation and bandwidth but decrease recovered audio and sensitivity.

The data buffer is a noninverting amplifier with a nominal voltage gain of 2.7 V/V. This buffer needs its dc bias (approximately 250 mV) provided externally or else debiasing will occur. A 2nd order Sallen–Key low pass filter, as shown in Figure 1, connecting the recovered audio output to the data buffer input provides the necessary dc bias and some post detection filtering. The buffer can also be used as an active filter.

The audio buffer is a noninverting amplifier with a nominal voltage gain of 4.0 V/V. This buffer is self–biasing so its input should be ac coupled. The two buffers, when applied as active filters, can be used together to allow simultaneous audio and very low speed data reception. Another possible configuration is to receive audio only and include a noise–triggered squelch.

The comparator is a noninverting type with an open collector output. Typically, the pull–up resistor used between Pin 14 and V_{CC} is 100 kΩ. With R_L = 100 kΩ the comparator is capable of operation up to 25 kHz. The circuit is self–biasing, so its input should be ac coupled.

The regulator is a 1.07 V reference capable of sourcing 3.0 mA. This pin (Pin 17) needs to be decoupled using a 1.0 – 10 μF capacitor to maintain stability of the MC3374.

All three V_{CC}s on the MC3374 (V_{CC}, V_{CC2}, V_{CC3}) run on the same supply voltage. V_{CC} is typically decoupled using capacitors only. V_{CC2} and V_{CC3} should be bypassed using the RC bypasses shown in Figure 1. Eliminating the resistors on the V_{CC2} and V_{CC3} bypasses may be possible in some applications, but a reduction in sensitivity and quieting will likely occur.

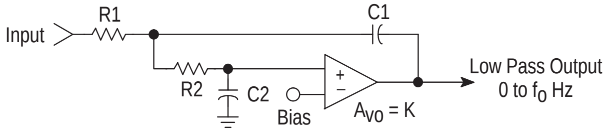
The low battery detection circuit gives an NPN open collector output at Pin 20 which drops low when the MC3374 supply voltage drops below 1.2 V. Typically it would be pulled up via a 100 kΩ resistor to supply.

The 1.2 V Select pin, when connected to the MC3374 supply, programs the low battery detector to trip at V_{CC} < 1.1 V. Leaving this pin open raises the trip voltage on the low battery detector.

Pin 15 is a receiver enable which is connected to V_{CC} for normal operation. Connecting this pin to ground shuts off receiver and reduces current drain to I_{CC} < 0.5 μA.

APPENDIX

Design of 2nd Order Sallen–Key Low Pass Filters



The audio and data buffers can easily be configured as active low pass filters using the circuit configuration shown above. The circuit has a center frequency (f_o) and quality factor (Q) given by the following:

$$f_o = \frac{1}{2\pi\sqrt{R1R2C1C2}}$$

$$Q = \frac{1}{\sqrt{\frac{R2C2}{R1C1}} + \sqrt{\frac{R1C2}{R2C1}} + (1–K)\sqrt{\frac{R1C1}{R2C2}}}$$

If possible, let R1 = R2 or C1 = C2 to simplify the above equations. Be sure to avoid a negative Q value to prevent instability. Setting $Q = 1/\sqrt{2} = 0.707$ yields a maximally flat filter response.

Data Buffer Design

The data buffer is designed as follows:

f_O = 200 Hz
C1 = C2 = 0.01 µF
Q = 0.707 (target)

K = 2.7 (data buffer open loop voltage gain)

Setting C1 = C2 yields:

$$fo = \frac{1}{2\pi C1\sqrt{R1R2}}$$

$$Q = \frac{1}{\sqrt{\frac{R2}{R1}} + (2–K)\sqrt{\frac{R1}{R2}}}$$

Iteration yields R2 = 4.2 (R1) to make Q = 0.707.
Substitution into the equation for f_O yields:
R1 = 38 kΩ (use 39 kΩ)
R2 = 4.2(R1) = 180 kΩ
C1 = C2 = 0.01 µF

Audio Buffer Design

The audio buffer is designed as follows:

f_O = 3000 Hz
R1 = R2 = 8.2 kΩ
Q = 0.707 (target)

K = 3.9 (audio buffer open loop voltage gain)

Setting C1 = C2 yields:

$$fo = \frac{1}{2\pi R1\sqrt{C1C2}}$$

$$Q = \frac{1}{\sqrt{\frac{C2}{C1}} + (1–K)\sqrt{\frac{C1}{C2}}}$$

Iteration yields C2 = 2.65 (C1) to make Q = 0.707.
Substitution into the equation for f_O yields:
C1 = 3900 pF
C2 = 2.65(C1) = 0.01 µF
R1 = R2 = 8.2 kΩ

MOTOROLA

MC3371
MC3372

Low Power Narrowband FM IF

The MC3371 and MC3372 perform single conversion FM reception and consist of an oscillator, mixer, limiting IF amplifier, quadrature discriminator, active filter, squelch switch, and meter drive circuitry. These devices are designed for use in FM dual conversion communication equipment. The MC3371/MC3372 are similar to the MC3361/MC3357 FM IFs, except that a signal strength indicator replaces the scan function controlling driver which is in the MC3361/MC3357. The MC3371 is designed for the use of parallel LC components, while the MC3372 is designed for use with either a 455 kHz ceramic discriminator, or parallel LC components.

These devices also require fewer external parts than earlier products. The MC3371 and MC3372 are available in dual–in–line and surface mount packaging.

- Wide Operating Supply Voltage Range: V_{CC} = 2.0 to 9.0 V
- Input Limiting Voltage Sensitivity of –3.0 dB
- Low Drain Current: I_{CC} = 3.2 mA, @ V_{CC} = 4.0 V, Squelch Off
- Minimal Drain Current Increase When Squelched
- Signal Strength Indicator: 60 dB Dynamic Range
- Mixer Operating Frequency Up to 100 MHz
- Fewer External Parts Required than Earlier Devices

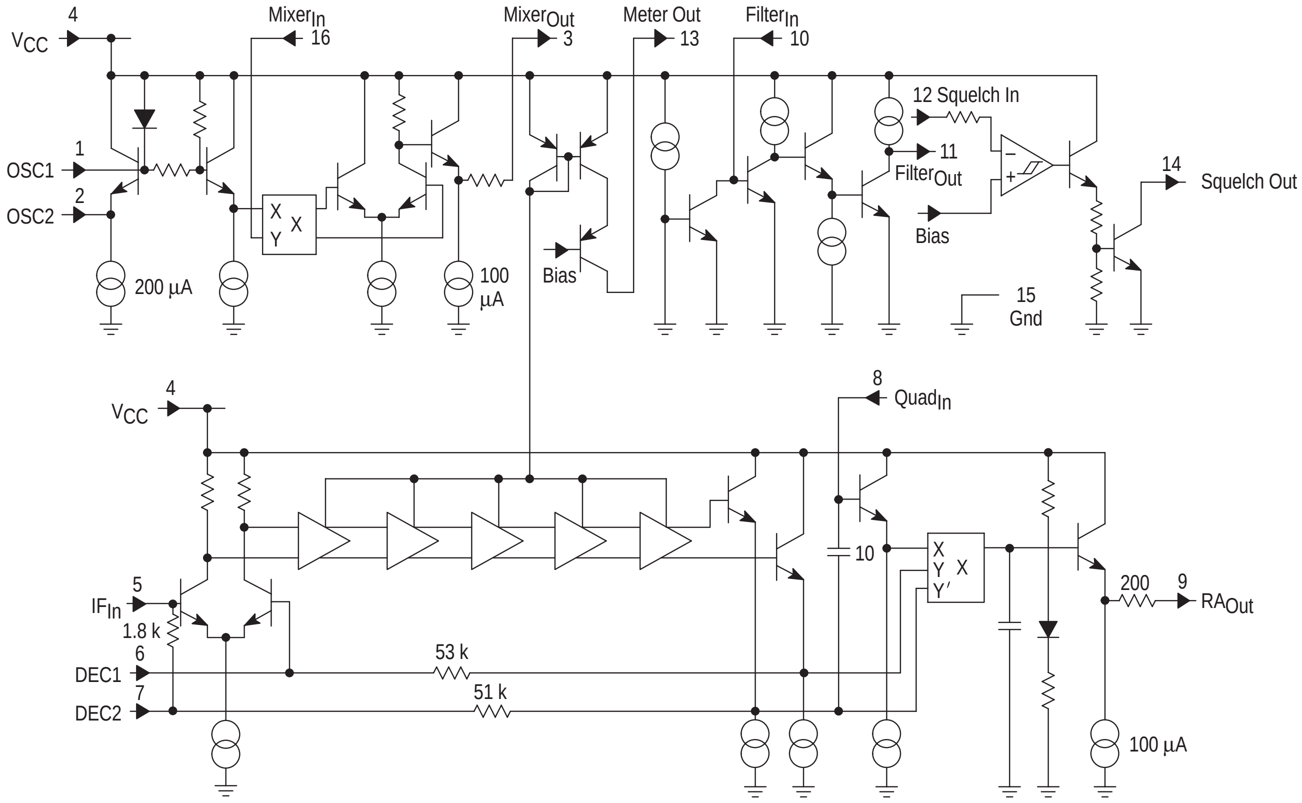

Figure 10. MC3372 Circuit Schematic

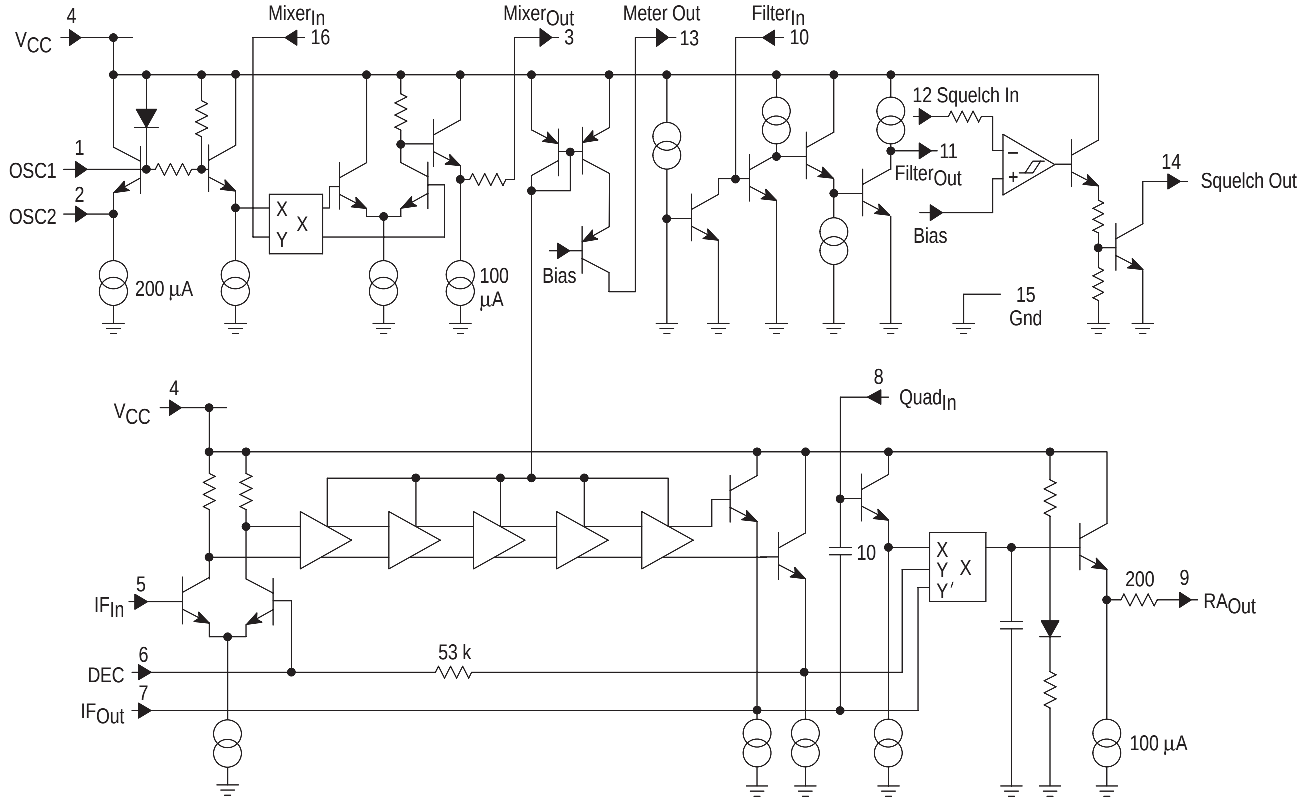

CIRCUIT DESCRIPTION

The MC3371 and MC3372 are low power narrowband FM receivers with an operating frequency of up to 60 MHz. Its low voltage design provides low power drain, excellent sensitivity, and good image rejection in narrowband voice and data link applications.

This part combines a mixer, an IF (intermediate frequency) limiter with a logarithmic response signal strength indicator, a quadrature detector, an active filter and a squelch trigger circuit. In a typical application, the mixer amplifier converts an RF input signal to a 455 kHz IF signal. Passing through an external bandpass filter, the IF signal is fed into a limiting amplifier and detection circuit where the audio signal is recovered. A conventional quadrature detector is used.

The absence of an input signal is indicated by the presence of noise above the desired audio frequencies. This “noise band” is monitored by an active filter and a detector. A squelch switch is used to mute the audio when noise or a tone is present. The input signal level is monitored by a meter drive circuit which detects the amount of IF signal in the limiting amplifier.

APPLICATIONS INFORMATION

The oscillator is an internally biased Colpitts type with the collector, base, and emitter connections at Pins 4, 1 and 2 respectively. This oscillator can be run under crystal control. For fundamental mode crystals use crystal characterized parallel resonant for 32 pF load. For higher frequencies, use 3rd overtone series mode type crystals. The coil (L2) and resistor RD (R13) are needed to ensure proper and stable operation at the LO frequency (see Figure 13, 45 MHz application circuit).

The mixer is doubly balanced to reduce spurious radiation. Conversion gain stated in the AC Electrical Characteristics table is typically 20 dB. This power gain measurement was made under stable conditions using a 50 Ω source at the input and an external load provided by a 455 kHz ceramic filter at the mixer output which is connected to the V_{CC} (Pin 4) and IF input (Pin 5). The filter impedance closely matches the 1.8 kΩ internal load resistance at Pin 3 (mixer output). Since the input impedance at Pin 16 is strongly influenced by a 3.3 kΩ internal biasing resistor and has a low capacitance, the useful gain is actually much higher than shown by the standard power gain measurement. The Smith Chart plot in Figure 17 shows the measured mixer input impedance versus input frequency with the mixer input matched to a 50 Ω source impedance at the given frequencies. In order to assure stable operation under matched conditions, it is necessary to provide a shunt resistor to ground. Figures 11, 12 and 13 show the input networks used to derive the mixer input impedance data.

Following the mixer, a ceramic bandpass filter is recommended for IF filtering (i.e. 455 kHz types having a bandwidth of ±2.0 kHz to ±15 kHz with an input and output impedance from 1.5 kΩ to 2.0 kΩ). The 6 stage limiting IF amplifier has approximately 92 dB of gain. The MC3371 and MC3372 are different in the limiter and quadrature detector circuits. The MC3371 has a 1.8 kΩ and a 51 kΩ resistor providing internal dc biasing and the output of the limiter is internally connected, both directly and through a 10 pF capacitor to the quadrature detector; whereas, in the MC3372 these components are not provided internally. Thus, in the MC3371, no external components are necessary to match the 455 kHz ceramic filter, while in the MC3372, external 1.8 kΩ and 51 kΩ biasing resistors are needed between Pins 5 and 7, respectively (see Figures 12 and 13).

In the MC3371, a parallel LCR quadrature tank circuit is connected externally from Pin 8 to V_{CC} (similar to the MC3361). In the MC3372, a quadrature capacitor is needed externally from Pin 7 to Pin 8 and a parallel LC or a ceramic discriminator with a damping resistor is also needed from Pin 8 to V_{CC} (similar to the MC3357). The above external quadrature circuitry provides 90° phase shift at the IF center frequency and enables recovered audio.

The damping resistor determines the peak separation of the detector and is somewhat critical. As the resistor is decreased, the separation and the bandwidth is increased but the recovered audio is decreased. Receiver sensitivity is dependent on the value of this resistor and the bandwidth of the 455 kHz ceramic filter.

On the chip the composite recovered audio, consisting of carrier component and modulating signal, is passed through a low pass filter amplifier to reduce the carrier component and then is fed to Pin 9 which has an output impedance of 450 Ω. The signal still requires further filtering to eliminate the carrier component, deemphasis, volume control, and further amplification before driving a loudspeaker. The relative level of the composite recovered audio signal at Pin 9 should be considered for proper interaction with an audio post amplifier and a given load element. The MC13060 is recommended as a low power audio amplifier.

The meter output indicates the strength of the IF level and the output current is proportional to the logarithm of the IF input signal amplitude. A maximum source current of 60 µA is available and can be used to drive a meter and to detect a carrier presence. This is referred to as a Received Strength Signal Indicator (RSSI). The output at Pin 13 provides a current source. Thus, a resistor to ground yields a voltage proportional to the input carrier signal level. The value of this resistor is estimated by (V_{CC}(Vdc) – 1.0 V)/60 µA; so for V_{CC} = 4.0 Vdc, the resistor is approximately 50 kΩ and provides a maximum voltage swing of about 3.0 V.

A simple inverting op amp has an output at Pin 11 and the inverting input at Pin 10. The noninverting input is connected to 2.5 V. The op amp may be used as a noise triggered squelch or as an active noise filter. The bandpass filter is designed with external impedance elements to discriminate between frequencies. With an external AM detector, the filtered audio signal is checked for a tone signal or for the presence of noise above the normal audio band. This information is applied to Pin 12.

An external positive bias to Pin 12 sets up the squelch trigger circuit such that the audio mute (Pin 14) is open or connected to ground. If Pin 12 is pulled down to 0.9 V or below by the noise or tone detector, Pin 14 is internally shorted to ground. There is about 57 mV of hyteresis at Pin 12 to prevent jitter. Audio muting is accomplished by connecting Pin 14 to the appropriate point in the audio path between Pin 9 and an audio amplifier. The voltage at Pin 14 should not be lower than –0.7 V; this can be assured by connecting Pin 14 to the point that has no dc component.

Another possible application of the squelch switch may be as a carrier level triggered squelch circuit, similar to the MC3362/MC3363 FM receivers. In this case the meter output can be used directly to trigger the squelch switch when the RF input at the input frequency falls below the desired level. The level at which this occurs is determined by the resistor placed between the meter drive output (Pin 13) and ground (Pin 15).

MOTOROLA

MC3363

Low Power Dual Conversion FM Receiver

The MC3363 is a single chip narrowband VHF FM radio receiver. It is a dual conversion receiver with RF amplifier transistor, oscillators, mixers, quadrature detector, meter drive/carrier detect and mute circuitry. The MC3363 also has a buffered first local oscillator output for use with frequency synthesizers, and a data slicing comparator for FSK detection.

- Wide Input Bandwidth – 200 MHz Using Internal Local Oscillator
  – 450 MHz Using External Local Oscillator
- RF Amplifier Transistor
- Muting Operational Amplifier
- Complete Dual Conversion
- Low Voltage: V_{CC} = 2.0 V to 6.0 Vdc
- Low Drain Current: I_{CC} = 3.6 mA (Typical) at V_{CC} = 3.0 V, Excluding RF Amplifier Transistor
- Excellent Sensitivity: Input 0.3 µV (Typical) for 12 dB SINAD Using Internal RF Amplifier Transistor
- Data Shaping Comparator
- Received Signal Strength Indicator (RSSI) with 60 dB Dynamic Range
- Low Number of External Parts Required
- Manufactured in Motorola's MOSAIC® Process Technology

CIRCUIT DESCRIPTION

The MC3363 is a complete FM narrowband receiver from RF amplifier to audio preamp output. The low voltage dual conversion design yields low power drain, excellent sensitivity and good image rejection in narrowband voice and data link applications.

In the typical application, the input RF signal is amplified by the RF transistor and then the first mixer amplifies the signal and converts the RF input to 10.7 MHz. This IF signal is filtered externally and fed into the second mixer, which further amplifies the signal and converts it to a 455 kHz IF signal. After external bandpass filtering, the low IF is fed into the limiting amplifier and detection circuitry. The audio is recovered using a conventional quadrature detector. Twice-IF filtering is provided internally.

The input signal level is monitored by meter drive circuitry which detects the amount of limiting in the limiting amplifier. The voltage at the meter drive pin determines the state of the carrier detect output, which is active low.

APPLICATIONS INFORMATION

The first local oscillator is designed to serve as the VCO in a PLL frequency synthesized receiver. The MC3363 can operate together with the MC145166/7 to provide a two-chip ten–channel frequency synthesized receiver in the 46/49 cordless telephone band. The MC3363 can also be used with the MC14515X series of CMOS PLL synthesizers and MC120XX series of ECL prescalers in VHF frequency synthesized applications to 200 MHz.

For single channel applications the first local oscillator can be crystal controlled. The circuit of Figure 4 has been used successfully up to 60 MHz. For higher frequencies an external oscillator signal can be injected into Pins 25 and/or 26 — a level of approximately 100 mVrms is recommended. The first mixer′s transfer characteristic is essentially flat to 450 MHz when this approach is used (keeping a constant 10.7 MHz IF frequency). The second local oscillator is a Colpitts type which is typically run at 10.245 MHz under crystal control.

The mixers are doubly balanced to reduce spurious responses. The first and second mixers have conversion gains of 18 dB and 21 dB (typical), respectively. Mixer gain is stable with respect to supply voltage. For both conversions, the mixer impedances and pin layout are designed to allow the user to employ low cost, readily available ceramic filters.

Following the first mixer, a 10.7 MHz ceramic bandpass filter is recommended. The 10.7 MHz filtered signal is then fed into the second mixer input Pin 21, the other input Pin 22 being connected to V_{CC}.

The 455 kHz IF is filtered by a ceramic narrow bandpass filter then fed into the limiter input Pin 9. The limiter has 10 μV sensitivity for –3.0 dB limiting, flat to 1.0 MHz.

The output of the limiter is internally connected to the quadrature detector, including a quadrature capacitor. A parallel LC tank is needed externally from Pin 14 to V_{CC}. A 68 kΩ shunt resistance is included which determines the peak separation of the quadrature detector; a smaller value will lower the Q and expand the deviation range and linearity, but decrease recovered audio and sensitivity.

A data shaping circuit is available and can be coupled to the recovered audio output of Pin 16. The circuit is a comparator which is designed to detect zero crossings of FSK modulation. Data rates of up to 35000 baud are detectable using the comparator. Best sensitivity is obtained when data rates are limited to 1200 baud maximum. Hysteresis is available by connecting a high-valued resistor from Pin 17 to Pin 18. Values below 120 kΩ are not recommended as the input signal cannot overcome the hysteresis.

The meter drive circuitry detects input signal level by monitoring the limiting of the limiting amplifier stages. Figure 5 shows the unloaded current at Pin 12 versus input power. The meter drive current can used directly (RSSI) or can be used to trip the carrier detect circuit at a specified input power.

A muting op amp is provided and can be triggered by the carrier detect output (Pin 13). This provides a carrier level triggered squelch circuit which is activated when the RF input at the desired input frequency falls below a present level. The level at which this occurs is determined by the resistor placed between the meter drive output (Pin 12) and V_{CC}. Values between 80 – 130 kΩ are recommended. This type of squelch is pictured in Figures 3 and 4.

Hysteresis is available by connecting a high-valued resistor Rh between Pins 12 and 13. The formula is:

$$\text{Hyst} = V_{CC} / (\text{Rh} \times 10^{-7})\ \text{dB}$$

The meter drive can also be used directly to drive a meter or to provide AGC. A current to voltage converter or other linear buffer will be needed for this application.

A second possible application of the op amp would be in a noise triggered squelch circuit, similar to that used with the MC3357/MC3359/MC3361B FM IFs. In this case the op amp would serve as an active noise filter, the output of which would be rectified and compared to a reference on a squelch gate. The MC3363 does not have a dedicated squelch gate, but the NPN RF input stage or data shaping comparator might be used to provide this function if available. The op amp is a basic type with the inverting input and the output available. This application frees the meter drive to allow it to be used as a linear signal strength monitor.

The circuit of Figure 4 is a complete 50 MHz receiver from antenna input to audio preamp output. It uses few components and has good performance. The receiver operates on a single channel and has input sensitivity of < 0.3 μV for 12 dB SINAD.

NOTE: For further application and design information, refer to AN980.

MC13055

Wideband FSK Receiver

The MC13055 is intended fo RF data link systems using carrier frequencies up to 40 MHz and FSK (frequency shift keying) data rates up to 2.0 M Baud (1.0 MHz). This design is similar to the MC3356, except that it does not include the oscillator/mixer. The IF bandwidth has been increased and the detector output has been revised to a balanced configuration. The received signal strength metering circuit has been retained, as has the versatile data slicer/comparator.

- Input Sensitivity 20 µV @ 40 MHz
- Signal Strength Indicator Linear Over 3 Decades
- Available in Surface Mount Package
- Easy Application, Few Peripheral Components

GENERAL DESCRIPTION

The MC13055 is an extended frequency range FM IF, quadrature detector, signal strength detector and data shaper. It is intended primarily for FSK data systems. The design is very similar to MC3356 except that the oscillator/mixer has been removed, and the frequency capability of the IF has been raised about 2:1. The detector output configuration has been changed to a balanced, open–collector type to permit symmetrical drive of the data shaper (comparator). Meter drive and squelch features have been retained.

The limiting IF is a high frequency type, capable of being operated up to 100 MHz. It is expected to be used at 40 MHz in most cases. The quadrature detector is internally coupled to the IF, and a 2.0 pF quadrature capacitor is internally provided. The 20 dB quieting sensitivity is approximately 20 μV, tuned input, and the IF can accept signals up to 220 mVrms without distortion or change of detector quiescent DC level.

The IF is unusual in that each of the last 5 stages of the 6 stage limiter contains a signal strength sensitive, current sinking device. These are parallel connected and buffered to produce a signal strength meter drive which is fairly linear for IF input signals of 20 μV to 20 mVrms (see Figure 4).

A simple squelch arrangement is provided whereby the meter current flowing through the meter load resistance flips a comparator at about 0.8 Vdc above ground. The signal strength at which this occurs can be adjusted by changing the meter load resistor. The comparator (+) input and output are available to permit control of hysteresis. Good positive action can be obtained for IF input signals of above 20 μVrms. A resistor (R) from Pin 13 to Pin 12 will provide V_{CC}/R of feedback current. This current can be correlated to an amount of signal strength hysteresis by using Figure 4.

The squelch is internally connected to the data shaper. Squelch causes the data shaper to produce a high (V_{CC}) output.

The data shaper is a complete “floating” comparator, with diodes across its inputs. The outputs of the quadrature detector can be fed directly to either or preferably both inputs of the comparator to produce a squared output swinging from V_{CC} to ground in inverted or noninverted form.

MOTOROLA

MC13109

Universal Cordless Telephone Subsystem IC

The MC13109 integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, and external adjustments. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna Input to Audio Output 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expandor Includes Mute, Digital Volume Control and Speaker Driver
  - Compressor Includes Mute, ALC and Limiter
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with No External Switches
  - Universal Design for Domestic and Foreign CT–1 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Output Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Externally Adjustable Trip Point
- 2.0 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices
- AN1575: Refer to Application Note for a List of “Worldwide Cordless Telephone Frequencies” (Chapter 8 Addendum of DL128 Data Book)

ELECTRICAL CHARACTERISTICS (continued)

RSSI/Carrier Detect

Connect 0.01 µF to Gnd from "RSSI" output pin to form the carrier detect filter. "CD Out" is an open collector output which requires an external 100 kΩ pull–up resistor to V_{CC}. The carrier detect threshold is programmable through the MPU interface.

(R_L = 100 kΩ, V_{CC} = 2.6 V, T_A = 25°C.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
RSSI Output Current Dynamic Range	–	Mix_1 In	RSSI	RSSI	–	65	–	dB

Output Low Voltage	V_{in} = V_{CC} – 0.4 V, I_{OL} = 0 mA	DA In	DA Out	V_{OL}	–	0.03	0.4	V

ELECTRICAL CHARACTERISTICS (continued)

Pre–Amplifier/Expander/R_X Mute/Volume Control (See Figure 4)

The Pre–Amplifier is an inverting rail–to–rail output swing operational amplifier with the non–inverting input terminal connected to the internal V_B half supply reference. External resistors and capacitors can be connected to set the gain and frequency response. The expander analog ground is set to the half supply reference so the input and output swing capability will increase as the supply voltage increases. The volume control can be adjusted through the MPU interface. The "R_X Audio In" input signal is ac coupled.

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C, f_{in} = 1.0 kHz, Set External Pre–Amplifier R's for Gain of 1, Volume Control = (0111).)

ELECTRICAL CHARACTERISTICS (continued)

Speaker Amplifier/SP Mute

The Speaker Amplifier is an inverting rail–to–rail operational amplifier. The non–inverting input terminal is connected to the internal V_B half supply reference. External resistors and capacitors are used to set the gain and frequency response. The “SA In” input is ac coupled.

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C, f_{in} = 1.0 kHz, External Resistors Set for Gain of 1.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
Maximum Output Swing	V_{CC} = 2.3 V, R_L = 130 Ω V_{CC} = 2.3 V, R_L = 600 Ω V_{CC} = 3.4 V, R_L = 600 Ω	SA In	SA Out	V_{Omax}	– – –	0.8 2.0 3.0	– – –	V_{pp}
SP Mute	V_{in} = –20 dBV R_L = 130 Ω No popping detectable during SP Mute transitions	SA In	SA Out	M_{sp}	–	–70	–	dB

Mic Amplifier (See Figure 6)

The Mic Amplifier is an inverting rail–to–rail output operational amplifier with the non–inverting input terminal connected to the internal V_B half supply reference. External resistors and capacitors are connected to set the gain and frequency response. The “T_X In” input is ac coupled.

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C, f_{in} = 1.0 kHz, External Resistors Set for Gain of 1.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit

ELECTRICAL CHARACTERISTICS (continued)

Compressor/ALC/T_X Mute/Limiter (See Figure 5)

The compressor analog gound is set to the half supply reference so the input and output swing capability will increase as the supply voltage increases. The “C In” input is ac coupled. The ALC (Automatic Level Control) provides a soft limit to the output signal swing as the input voltage increases slowly (i.e., a sine wave is maintained). The Limiter circuit limits rapidly changing signal levels by clipping the signal peaks. The ALC and/or Limiter can be disabled through the MPU serial interface.

(Test Conditions: V_{CC} = 2.6 V, f_{in} = 1.0 kHz, T_A = 25°C.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit

ELECTRICAL CHARACTERISTICS (continued)

Splatter Amplifier (see Figure 7)

The Splatter Amplifier is an inverting rail–to–rail output operational amplifier with the non–inverting input terminal connected to the internal V_B half supply reference. External resistors and capacitors can be connected to set the gain and frequency response. The “Spl Amp In” input is ac coupled.

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C, f_{in} = 1.0 kHz, External resistors Set for Gain of 1.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
Open Loop Gain	–	Spl Amp In	T_X Out	A_{VOL}	–	60	–	dB
Gain Bandwidth	–	Spl Amp In	T_X Out	GBW	–	100	–	kHz
Maximum Output Swing	R_L = 10 kΩ	Spl Amp In	T_X Out	V_{Omax}	–	V_{CC} – 0.3	–	V_{pp}

T_X Audio Path Recommendation

The recommended configuration for the T_X Audio path includes setting the Microphone Amplifier gain to 16 dB using the external gain setting resistors and setting the Splatter Amplifier gain to 9.0 dB using the external gain setting resistors. With these gain values, the total T_X Path transfer characteristic is shown in Figure 7.

PLL Voltage Regulator

The PLL supply voltage is regulated to a nominal of 2.2 V. The “V_{CC} Audio” pin is the supply voltage for the internal voltage regulator. The “PLL V_{ref}” pin is the 2.2 V regulated output voltage. Two capacitors with 10 μF and 0.01 μF values must be connected to the “PLL V_{ref}” pin to filter and stabilize this regulated voltage. The voltage regulator provides power for the 2nd LO, R_X and T_X PLL’s, and MPU Interface. The voltage regulator can also be used to provide a regulated supply voltage for external IC’s. R_X and T_X PLL loop performance are independent of the power supply voltage when the voltage regulator is used. The voltage regulator requires about 200 mV of “headroom”. When the power supply decreases to within about 200 mV of the output voltage, the regulator will go out of regulation but the output voltage will not turn off. Instead, the output voltage will maintain about a 200 mV delta to the power supply voltage as the power supply voltage continues to decrease. The “PLL V_{ref}” pin can be connected to “V_{CC} Audio” by the external wiring if voltage higher than 2.2 V is required. But it should not be connected to other supply except “V_{CC} Audio”. The voltage regulator is “on” in the Active and R_X modes. In the Standby and Inactive modes, the voltage regulator is turned off to reduce current drain and the “PLL V_{ref}” pin is internally connected to “V_{CC} Audio” (i.e., the supply voltage is maintained but is now unregulated).

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit
Output Voltge Level	V_{CC} = 2.6 V, O_L= 0 mA	–	V_{CC} PLL	V_{out}	1.9	2.2	2.5	V

Load Regulation	V_{CC} = 2.6 V, I_L = 0 to 1.0 mA	V_{CC}	V_{CC} PLL	Reg_{load}	–	–1.86	40	mV
Drop–Out Voltage	I_L = 0 mA	–	–	DO	–	–	V_{out} + 200	mV

ELECTRICAL CHARACTERISTICS (continued)

Low Battery Detect

An external resistor divider is connected to the “Ref” input pin to set the threshold for the low battery detect. The voltage at the “Ref” input pin is compared to an internal 1.23 V Bandgap reference voltage. The “BD Out” pin is open collector and requires and external pull–up resistor to V_{CC}.

(Test Conditions: V_{CC} = 2.6 V, T_A = 25°C.)

Characteristic	Condition	Input Pin	Measure Pin	Symbol	Min	Typ	Max	Unit

PIN FUNCTION DESCRIPTION

48–TQFP Pin	52–QFP Pin	Symbol	Type	Description
1 2	1 2	LO_2 In LO2 Out	–	These pins form the PLL reference oscillator when connected to an external parallel–resonant crystal (10.24 MHz typical). The reference oscillator is also the second Local Oscillator (LO_2) for the RF receiver.
3	3	PLL V_{ref}	Supply	Voltage Regulator output pin. The internal voltage regulator provides a stable power supply voltage for the R_X and T_X PLL's and can also be used as a regulated supply voltage for the other IC's.
4	4	R_X PD	Output	Three state voltage output of the R_X Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external R_X PLL loop filter. It is important to minimize the line length and capacitance of this pin.
5	5	Gnd PLL	Gnd	Ground pin for PLL section of IC.
6	6	T_X PD	Output	Three state voltage output of the T_X Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external T_X PLL loop filter. It is important to minimize the line length and capacitance on this pin.
7	7	E Cap	–	Expander rectifier filter capacitor pin. Connect capacitor to V_{CC}.
8	8	T_X VCO	Input	Transmit divide counter input which is driven by an ac coupled external transmit loop VCO. The minimum signal level is 200 mV_{pp} @ 80.0 MHz. This pin also functions as the test mode input for the counter tests.
9 10 11	9 10 11	Data EN Clk	Input	Microprocessor serial interface input pins for programming various counters and control functions.
12	12	Clk Out	Output	Microprocesor Clock Output which is derived from the 2nd LO crystal oscillator and a programmable divider. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output whch can be combined with an external capacitor to form a low pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes.
N/A	14	Status Out	Output	This pin indicates when the internal latches may have lost memory due to a power glitch.
13	15	CD Out/ Hardware Interrupt	Output/ Input	Dual function pin; 1) Carrier detect output (open collector with external 100 kΩ pull–up resistor. 2) Hardware interrupt input which can be used to "wake–up" from Inactive Mode.
14	16	BD Out	Output	Low battery detect output (open collector with external pull–up resistor).
15	17	DA Out	Output	Data amplifier output (open collector with internal 100 kΩ pull–up resistor).
16	18	SA Out	Output	Speaker amplifier output.
17	19	SA In	Input	Speaker amplifier input (ac coupled).
18	20	E Out	Output	Expander output.
19	21	V_{CC} Audio	Supply	V_{CC} supply for audio section.
20	22	DA In	Input	Data amplifier input (ac coupled).
21	23	Pre–Amp Out	Output	Pre–amplifier output for connection of pre–amplifier feedback resistor.
22	24	R_X Audio In	Input	R_X audio input to pre–amplifier (ac coupled).
23	25	Det Out	Output	Audio output from FM detector.
24	26	RSSI	–	Receive signal strength indicator filter capacitor.
N/A	27	N/A	–	Note used.
25	28	Q Coil	–	A quad coil or ceramic discriminator are connected to this pin.
26	29	V_{CC} RF	Supply	V_{CC} supply for RF receiver section.
27 28	30 31	Lim C2 Lim C1	–	IF amplifier/limiter capacitor pins.

PIN FUNCTION DESCRIPTION (continued)

48–TQFP Pin	52–QFP Pin	Symbol	Type	Description
29	32	Lim In	Input	Signal input for IF amplifier/limiter.
30	33	Gnd RF	Gnd	Ground pin for RF section of the IC.
31	34	Mix_2 Out	Output	Second mixer output.
32	35	Mix_2 In	Input	Second mixer input.
33	36	V_B	–	Internal half supply analog ground reference.
34	37	Mix_1 Out	Output	First mixer output.
35	38	Mix_1 In_2	Input	Negative polarity first mixer input.
36	39	Mix_1 In_1	Input	Positive polarity first mixer input.
37 38	40 41	LO_1 In LO_1 Out	–	Tank elements for 1st LO multivibrator oscillator are connected to these pins.
39	42	V_{cap} Ctrl	–	1st LO varactor control pin.
40	43	Gnd Audio	Gnd	Ground for audio section of the IC.
41	44	T_x In	Input	T_x path input to Microphone Amplifier (ac coupled).
42	45	Amp Out	Output	Microphone amplifier output.
43	46	C In	Input	Compressor input (ac coupled).
44	47	C Cap	–	Compressor rectifier filter capacitor pin. Connect capacitor to V_{CC}.
45	48	Lim Out	Output	T_x path limiter output.
46	49	Spl Amp In	Input	Splatter amplifier input (ac coupled).
47	50	T_x Out	Output	T_x path audio output.
48	51	Ref	Input	Reference voltage input for low battery detect.
N/A	52	N/A	–	Not used.

Power Supply Voltage

This circuit is used in a cordless telephone handset and base unit. The handset is battery powered and can operate on two ro three NiCad cells or on 5.0 V power.

PLL Frequency Synthesizer General Description

Figure 8 shows a simplified block diagram of the programmable universal dual phase locked loop (PLL). This dual PLL is fully programmable thorugh the MCU serial interface and supports most country channel frequencies including USA (25 ch), France, Spain, Australia, Korea, New Zealand, U.K., Netherlands and China (see channel frequency tables in Appendix A).

The 2nd local oscillator and reference divider provide the reference frequency for the R_x and T_x PLL loops. The programmed divider value for the reference divider is selected based on the crystal frequency and the desired R_x and T_x reference frequency values. Additional divide by 25 and divide by 4 blocks are provided to allow for generation of the 1.0 kHz and 6.25 kHz reference frequencies required for the U.K. The 14–bit T_x counter is programmed for the desired transmit channel frequency. The 14–bit R_x counter is programmed for the desired first local oscillator frequency. All counters power up in the proper default state for USA channel #6 and for a 10.24 MHz reference frequency crystal. Internal fixed capacitors can be connected to the tank circuit of the 1st LO through microprocessor control to extend the sensitivity of the 1st LO for U.S. 25 channel operation.

PLL I/O Pin Specifications

The 2nd LO, R_x and T_x PLL’s and MPU serial interface are normally powered by the internal voltage regulator at the “PLL V_{ref}” pin. The “PLL V_{ref}” pin is the output of a voltage regulator which is powered from the “V_{CC} Audio” power supply pin. Therefore, the maximum input and output levels for most PLL I/O pins (LO_2 In, LO_2 Out, R_x PD, T_x PD, T_x VCO) is the regulated voltage at the “PLL V_{ref}” pin. The ESD protection diodes on these pins are also connected to “PLL V_{ref}”. Internal level shift buffers are provided for the pins (Data, Clk, EN, Clk Out) which connect directly to the microprocessor. The maximum input and output levels for these pins is V_{CC}. Figure 9 shows a simplified schematic of the PLL I/O pins.

Figure 9. PLL I/O Pin Simplified Schematics

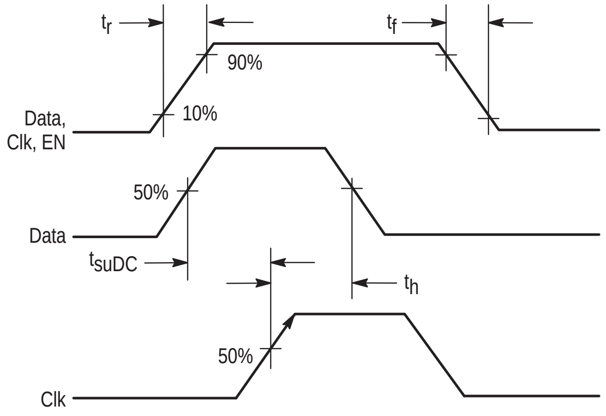
Data, Clk, and EN Pins

Clk Out Pin

Microprocessor Serial Interface

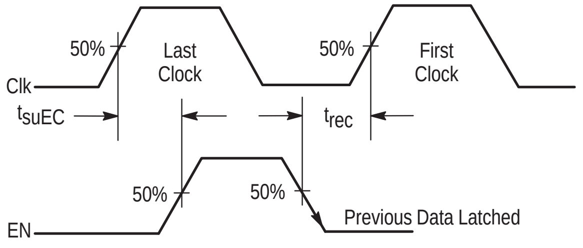
The “Data”, “Clk”, and “EN” pins provide an MPU serial interface for programming the reference counters, the transmit and receive channel divider counter and various control functions. The “Data” and “Clk” pins are used to load data into the shift register. Figure 10 shows “Data” and “Clk” pin timing. Data is clocked on positive clock transitions.

Figure 10. Data and Clock Timing Requirement



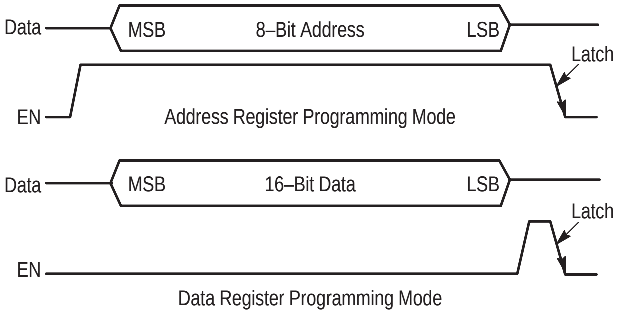
After data is loaded into the shift register, the data is latched into the appropriate latch register using the “EN” pin. This is done in two steps. First, an 8–bit address is loaded into the shift register and latched into the 8–bit address latch register. Then, up to 16–bits of data is loaded into the shift register and latched into the data latch register specified by the address that was previously loaded. Figure 11 shows the timing required on the EN pin. Latching occurs on the negative EN transition.

Figure 11. Enable Timing Requirement



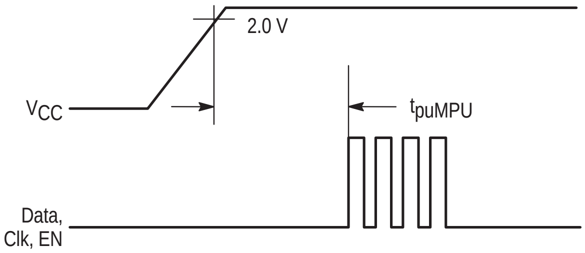
The state of the EN pin when clocking data into the shift register determines whether the data is latched into the address register or a data register. Figure 12 shows the address and data programming diagrams. In the data programming mode, there must not be any clock transitions when “EN” is high. The clock can be in a high state (default high) or a low state (default low) but must not have any transitions during the “EN” high state. The convention in these figures is that latch bits to the left are loaded into the shift register first.

Figure 12. Microprocessor Interface Programming Mode Diagrams



The MPU serial interface is fully operational within 100 µs after the power supply has reached its minimum level during power–up (See Figure 13). The MPU Interface shift registers and data latches are operational in all four power saving modes; Inactive, Standby, R_X, and Active Modes. Data can be loaded into the shift registers and latched into the latch registers in any of the operating modes.

Figure 13. Microprocessor Serial Interface Power–Up Delay



Status Out

This is a digital output which indicates whether the latch registers have been reset to their power–up default values. Latch power–up default values are given in Figure 32. If there is a power glitch or ESD event which causes the latch registers to be reset to their default values, the “Status Out” pin will indicate this to the MPU so it can reload the correct information into the latch registers.

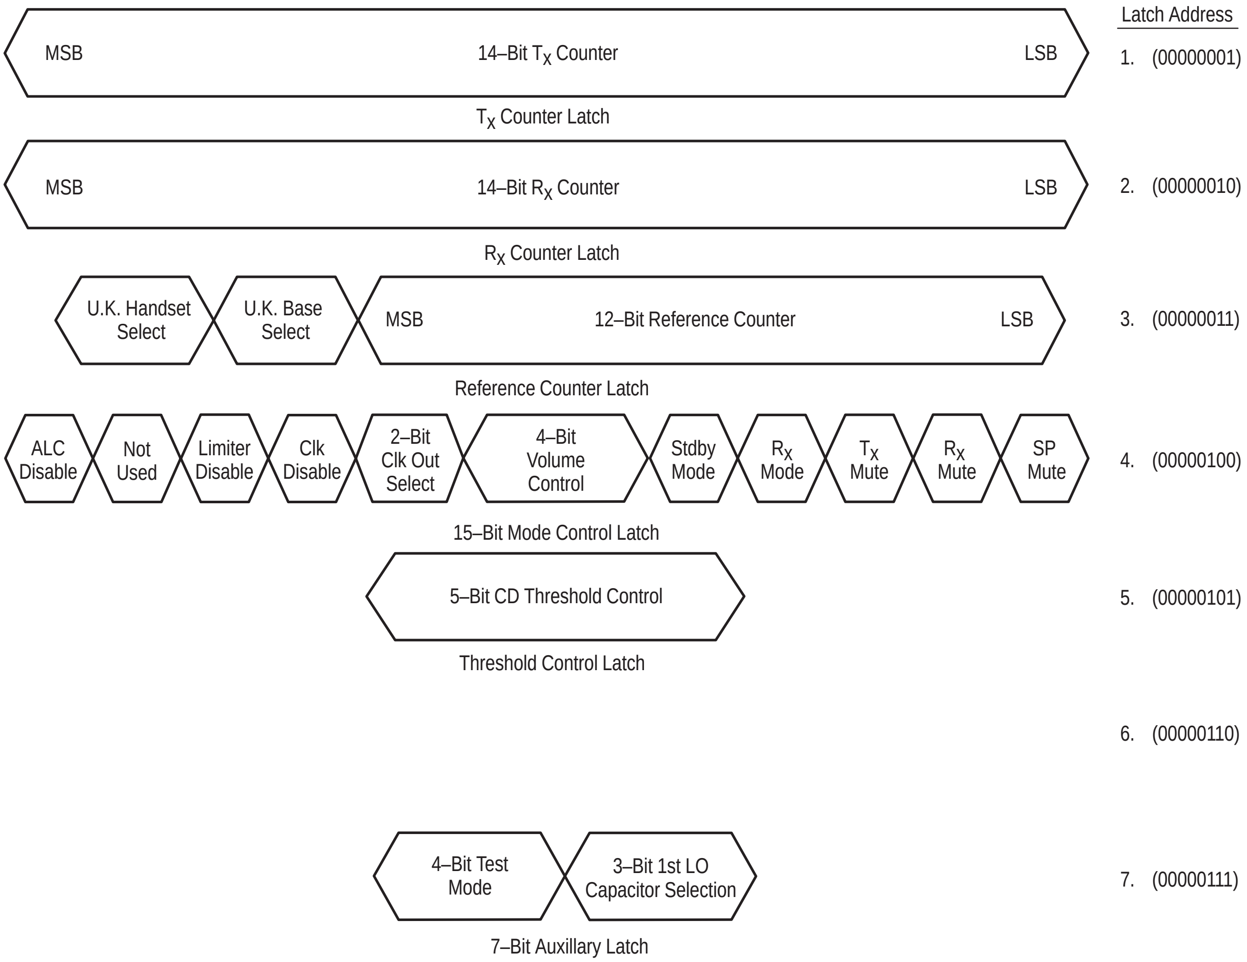
Figure 14. Status Out Operation

Status Latch Register Bits	Status Out Logic Level
Latch bits not at power–up default value	0
Latch bits at power–up default value	1

Data Registers

Figure 15 shows the data latch registers and addresses which are used to select each of these registers. Latch bits to the left (MSB) are loaded into the shift register first. The LSB bit must always be the last bit loaded into the shift register. “Don’t care” bits can be loaded into the shift register first if 8–bit bytes of data are loaded.

Figure 15. Microprocessor Interface Data Latch Registers



Reference Frequency Selection

The “LO_2 In” and “LO_2 Out” pins form a reference oscillator when connected to an external parallel–resonant crystal. The reference oscillator is also the second local oscillator for the RF Receiver. Figure 16 shows the relationship between different crystal frequencies and reference frequencies for cordless phone applications in various countries.

Figure 16. Reference Frequency and Reference Divider Values

Crystal Frequency	Reference Divider Value	U.K. Base/ Handset Divider	Reference Frequency
10.24 MHz	2048	1	5.0 kHz
10.24 MHz	1024	4	2.5 kHz
11.15 MHz	2230	1	5.0 kHz
12.00 MHz	2400	1	5.0 kHz
11.15 MHz	1784	1	6.25 kHz
11.15 MHz	446	4	6.25 kHz
11.15 MHz	446	25	1.0 kHz

Reference Counter

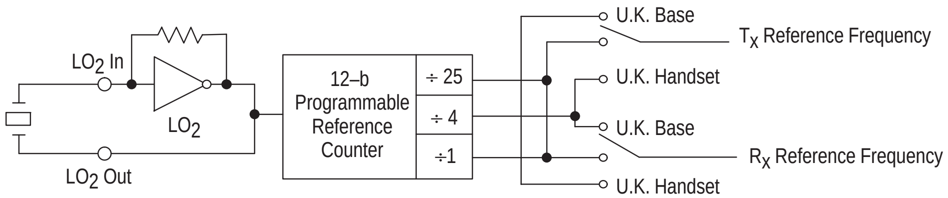
Figure 17 shows how the reference frequencies for the R_X and T_X loops are generated. All countries except U.K. require that the T_X and R_X reference frequencies be identical. In this case, set “U.K. Base Select” and “U.K. Handset Select” bits to “0”. Then the fixed divider is set to “1” and the T_X and R_X reference frequencies will be equal to the crystal oscillator frequency divided by the programmable reference counter value. The U.K. is a special case which requires a different reference frequency value fo T_X and R_X.

For U.K. base operation, set “U.K. Base Select” to “1”. For U.K. handset operation, set “U.K. Handset Select” to “1”. The Netherlands is also a special case since a 2.5 kHz reference frequency is used for both the T_X and R_X reference and the total divider value required is 4096 which is larger than the maximum divide value available from the 12–bit reference divider (4095). In this case, set “U.K. Base Select” to “1” and set “U.K. Handset Select” to “1”. This will give a fixed divide by 4 for both the T_X and R_X reference. Then set the reference divider to 1024 to get a total divider of 4096.

Mode Control Register

Power saving modes, mutes, disables, volume control, and microprocessor clock output frequency are all set by the Control Register. Operation of the Control Register is explained in Figures 18 through 25.

Figure 17. Reference Register Programming Mode



U.K. Handset Select	U.K. Base Select	T_X Divider Value	R_X Divider Value	Application
0	0	1	1	All but U.K. and Netherlands

Power Saving Operating Modes

When the MC13109 is used in a handset, it is important to conserve power in order to prolong battery life. There are five modes of operation; Active, R_X, Standby, Interrupt and Inactive. In Active Mode, all circuit blocks are powered. In R_X mode, all circuitry is powered down exept for those circuit sections needed to receive a transmission from the base. In the Standby and Interrupt Modes, all circuitry is powered down except for the circuitry needed to provide the clock output for the microprocessor. In Inactive Mode, all circuitry is powered down except the MPU interface. Latch memory is maintained in all modes. Figure 20 shows the control register bit values for selection of each power saving mode and Figure 21 show the circuit blocks which are powered in each of these operating mode.

Figure 20. Power Saving Mode Selection

Stdby Mode Bit	R_X Mode Bit	"CD Out/Hardware Interrupt" Pin	Power Saving Mode
0	0	X	Active
0	1	X	R_X
1	0	X	Standby
1	1	1 or High Impedance	Inactive
1	1	0	Inactive

Figure 21. Circuit Blocks Powered During Power Saving Modes

Circuit Blocks	Active	R_X	Standby	Inactive
“PLL V_{ref}” Regulated Voltage	X	X	X[1]	X[1]
MPU Interface	X	X	X	X
2nd LO Oscillator	X	X	X

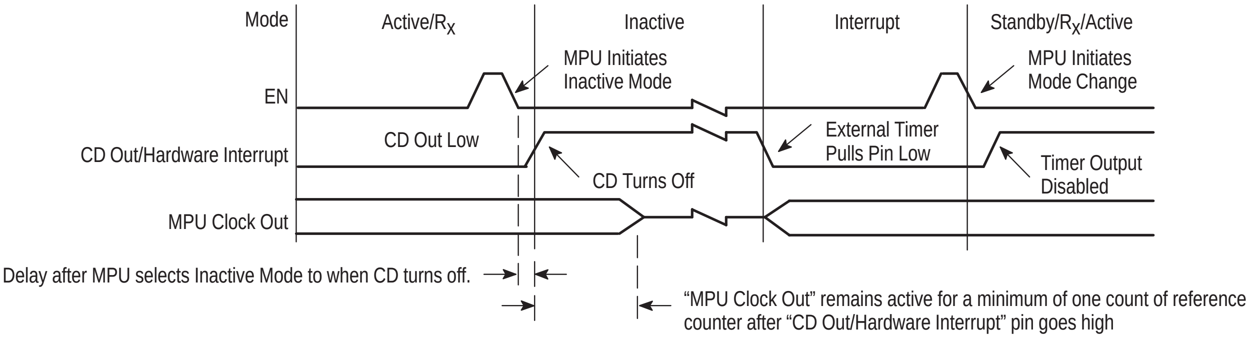
Data Amp	X	X		
Low Battery Detect	X	X		
T_X PLL	X			
R_X Audio Path	X			
T_X Audio Path	X			

NOTE: 1. In Standby and Inactive Modes, “PLL V_{ref}” remains powered but is not regulated. It will fluctuate with V_{CC}.

Inactive Mode Operation and Hardware Interrupt

In some handset applications it may be desirable to power down all circuitry including the microprocessor (MPU). First put the MC13109 into the Inactive mode, which turns off the MPU Clock Output (see Figure 22), and then disable the microprocessor. In order to give the MPU adequate time to power down, the MPU Clock output remains active for a minimum of one reference counter cycle (about 200 µs) after the command is given to switch into the “Inactive” mode. An external timing circuit should be used to initiate the turn–on sequence. The “CD Out” pin has a dual function. In the Active and R_X modes it performs the carrier detect function. In the Standby and Inactive modes the carrier detect circuit is disabled and the “CD Out” pin is in a “High” state due to the external pull–up resistor. In the Inactive mode the “CD Out” pin is the input for the hardware interrupt function. When the “CD Out” pin is pulled “low” by the external timing circuit, the MC13109 swtiches from the Inactive to the Interrupt mode thereby turning on the MPU Clock Output. The MPU can then resume control of the combo IC. The “CD Out” pin must remain low until the MPU changes the operating mode from Interrupt to Standby, Active or R_X modes.

Figure 22. Hardware Interrupt Operation



“Clk Out” Divider Programming

The “Clk Out” pin is derived from the 2nd local oscillator and can be used to drive a microprocessor, thereby reducing the number of crystals required. Figure 23 shows the relationship between the crystal frequency and the clock output for different divider values. Figure 24 shows the “Clk Out” register bit values.

Figure 23. Clock Output Values

Crystal Frequency	Clock Output Divider			
	2	3	5	10
10.24 MHz	5.120 MHz	3.413 MHz	2.560 MHz	2.048 MHz
11.15 MHz	5.575 MHz	3.717 MHz	2.788 MHz	2.230 MHz
12.00 MHz	6.000 MHz	4.000 MHz	3.000 MHz	2.400 MHz

Figure 24. Clock Output Divider

Clk Out Bit #1	Clk Out Bit #0	Clk Out Divider Value
0	0	2
0	1	3
1	0	5
1	1	10

MPU “Clk Out“ Power–Up Default Divider Value

The power–up default divider value is “divide by 10”. This provides an MPU clock of about 1.0 MHz after initial power–up. The reason for choosing this relatively low clock frequency after intial power–up is that some microprocessors that operate down to a 2.0 V power supply have a maximum clock frequency fo 1.0 MHz. After initial power–up, the MPU can change the clock divider value to set the clock to the desired operating frequency. Special care has been taken in the design of the clock divider to ensure that the transition between one clock divider value and another is “smooth” (i.e., there will be no narrow clock pulses to disturb the MPU).

MPU “Clk Out” Radiated Noise on Circuit Board

The clock line running between the MC13109 and the microprocessor has the potential to radiate noise which can cause problems in the system especially if the clock is a square wave digital signal with large high frequency harmonics. In order to minimize radiated noise, a 1.0 kΩ resistor is included on–chip in–series with the “Clk Out” output driver. A small capacitor can be connected to the “Clk Out” line on the PCB to form a single pole low pass filter. This filter will significantly reduce noise radiated from the “Clk Out” line.

Volume Control

The volume control can be programmed in 2.0 dB gain steps from –14 dB to +16 dB. The power–up default value is 0 dB.

Figure 25. Volume Control

Volume Control Bit #3	Volume Control Bit #2	Volume Control Bit #1	Volume Control Bit #0	Volume Control #	Gain/Attenuation Amount
0	0	0	0	0	–14 dB
0	0	0	1	1	–12 dB

1	1	0	1	13	12 dB
1	1	1	0	14	14 dB
1	1	1	1	15	16 dB

Gain Control Register

The gain control register contains bits which control the Carrier Detect threshold. Operation of these latch bits are explained in Figures 26 and 27.

Figure 26. Gain Control Latch Bits

Carrier Detect Threshold Programming

Th "CD Out" pin will give an indication to the microprocessor if a carier signal is present on the selected channel. The nominal value and tolerance of the carrier detect threshold is given in the carrier detect specification section of this document. If a different carrier detect threshold value is desired, it can be set through the MPU interface as shown in Figure 27 below.

Figure 27. Carrier Detect Threshold Control

CD Bit #4	CD Bit #3	CD Bit #2	CD Bit #1	CD Bit #0	CD Control #	Carrier Detect Threshold
0	0	0	0	0	0	–20 dB
0	0	0	0	1	1	–19 dB

Auxiliary Register

The auxiliary register contains a 3–bit 1st LO Capacitor Selection latch and a 4–bit Test Mode latch. Operation of these latch bits are explained in Figures 28, 29 and 30.

Figure 28. Auxiliary Register Latch Bits

First Local Oscillator Capacitor Selection for 25 Channel U.S. Operation

There is a very large frequency difference between the minimum and maximum channel frequencies in the proposed 25 Channel U.S. standard. The sensitivity of the 1st LO is not large enough to accommodate this large frequency variation. Fixed capacitors can be connected across the 1st LO tank circuit to change the 1st LO sensitivity. Internal switches and capacitors are provided to enable microprocessor control over internal fixed capacitor values. Figure 29 shows the schematic of the 1st LO tank circuit. Figure 30 shows the latch control bit values.

The internal varactor temperature coefficient is 1800 ppm/°C (C_O = 8.9 pF at 25°C, V_{cap} control voltage = 1.2 V, F_{req} = 36 MHz). Customer is suggested to use a negative temperature coefficient capacitor in 1st LO tank circuit when the whole operating temperature range of –40 to +85°C is considered.

Figure 29. 1st LO Schematic

Figure 31. Test Mode Description

TM #	TM 3	TM 2	TM 1	TM 0	Counter Under Test or Test Mode Option	"T_X V_{CO}" Input Signal	"Clk Out" Output Expected
0	0	0	0	0	Normal Operation	>200 mV_{pp}	–
1	0	0	0	1	R_X Counter, upper 6	0 to 2.2 V	Input Frequency/64
2	0	0	1	0	R_X Counter, lower 8	0 to 2.2 V	See Note Below
3	0	0	1	1	R_X Prescaler	0 to 2.2 V	Input Frequency/4
4	0	1	0	0	T_X Counter, upper 6	0 to 2.2 V	Input Frequency/64
5	0	1	0	1	T_X Counter, lower 8	0 to 2.2 V	See Note Below
6	0	1	1	0	T_X Prescaler	>200 mV_{pp}	Input Frequency/4
7	0	1	1	1	Reference Counter	0 to 2.2 V	Input Frequency/Reference Counter Value
8	1	0	0	0	Divide by 4, 25	0 to 2.2 V	Input Frequency/100
9	1	0	0	1	AGC Gain = 10 Option	N/A	–
10	1	0	1	0	AGC Gain = 25 Option	N/A	–

NOTE: To determine the correct output, look at the lower 8 bits in the R_X or T_X register (Divisor (7;0). If the value of the divisor is > 16, then the output divisor value is Divisor (7;2) (the upper 6 bits of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) > = 2, then output divisor value is Divisor (3;2) (bits 2 and 3 of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) < 2, then output divisor value is (Divisor (3;2) + 60).

Test Modes

Test Mode Control latch bits enable independent testing of internal counters and set AGC Gain Options. In test mode, the "T_X VCO" input pin is multiplexed to the input of the counter under test and the output of the counter under test is multiplexed to the "Clk Out" output pin so that each counter can be individually tested. Make sure test mode bits are set to "0" for normal operation. Test mode operation is described in Figure 31. During normal operation and when testing the T_X Prescaler, the "T_X VCO" input can be a minimum of 200 mV_{pp} at 80 MHz and should be ac coupled. For other test modes, input signals should be standard logic levels of 0 to 2.2 V and a maximum frequency of 16 MHz.

Power–Up Defaults for Control and Counter Registers

When the IC is first powered up, all latch registers are initialized to a defined state. The MC13109 is initially placed in the Rx mode with all mutes active and nothing disabled. The reference counter is set to generate a 5.0 kHz reference frequency from a 10.24 MHz crystal. The MPU clock output divider is set to 10 to give the minimum clock output frequency. The T_X and R_X latch registers are set for USA Channel Frequency #21. Figure 32 shows the initial power–up states for all latch registers.

APPENDIX A – MEASUREMENT OF COMPANDOR ATTACK/DECAY TIME

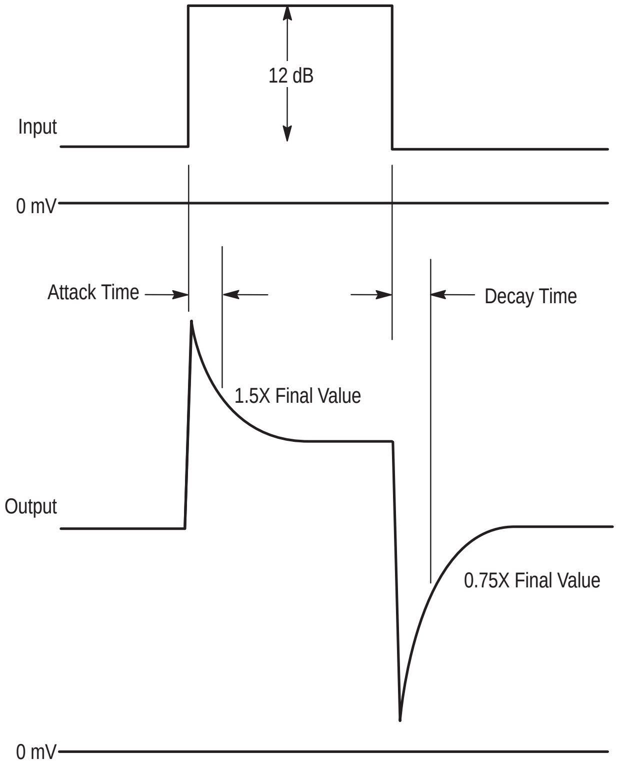
This measurement definition is based on EIA/CCITT recommendations.

Compressor Attack Time

For a 12 dB step up at the input, attack time is defined as the time for the output to settle to 1.5X of the final steady state value.

Compressor Decay Time

For a 12 dB step down at the input, decay time is defined as the time for the input to settle to 0.75X of the final steady state value.

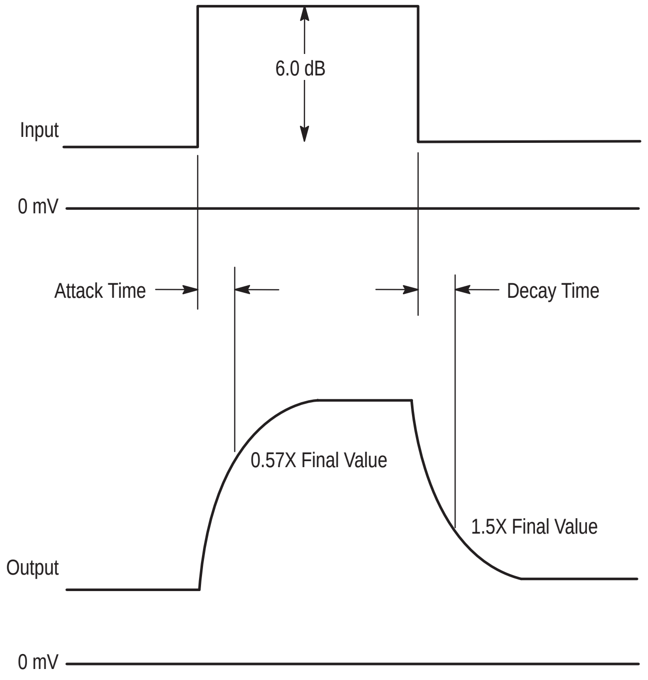


Expander Attack

For a 6.0 dB step up at the input, attack time is defined as the time for the output to settle to 0.57X of the final steady state value.

Expander Decay

For a 6.0 dB step down at the input, decay time is defined as the time for the output to settle to 1.5X of the final steady state value.



MOTOROLA

Universal Cordless Telephone Subsystem IC with Scrambler

The MC13110 integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, and external adjustments. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna In to Audio Out 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expandor Includes Mute, Digital Volume Control, Speaker Driver, 3.5 kHz Low Pass Filter, and Programmable Gain Block
  - Compressor Includes Mute, 3.5 kHz Low Pass Filter, Limiter, and Programmable Gain Block
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with New External Switches
  - Universal Design for Domestic and Foreign CT–1 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Outputs Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Provides Two Levels of Monitoring with Separate Outputs
  - Separate, Adjustable Trip Points
- Frequency Inversion Scrambler/Descrambler
  - Can Be Enabled/Disabled Via MPU Interface
  - Programmable Carrier Modulation Frequency
- 2.7 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices
- AN1575: Refer to this Application Note for a List of the “Worldwide Cordless Telephone Frequencies” (List can also be found in Chapter 8 Addendum of DL128 Data Book)

PIN FUNCTION DESCRIPTION

Pin	Symbol	Type	Description
1 2	LO_2 In LO2 Out	–	These pins form the PLL reference oscillator when connected to an external parallel–resonant crystal (10.24 MHz typical). The reference oscillator is also the second Local Oscillator (LO_2) for the RF receiver. "LO_2 In" may also serve as an input for an externally generated reference signal which is typically ac–coupled.
3	V_{ag}	–	Internal reference voltage for switched capacitor filter section.
4	R_x PD	Output	Three state voltage output of the R_x Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external R_x PLL loop filter. It is important to minimize the line length and parasitic capacitance of this pin.
5	PLL V_{ref}	–	PLL voltage regulator output pin. An internal voltage regulator provides a stable power supply voltage for the R_x and T_x PLL's and can also be used as a regulated supply voltage for other IC's.
6	T_x PD	Output	Three state voltage output of the T_x Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external T_x PLL loop filter. It is important to minimize the line length and parasitic capacitance of this pin.
7	Gnd PLL	Gnd	Ground pin for PLL section of IC.
8	T_x VCO	Input	Transmit divide counter input which is driven by an ac–coupled external transmit loop VCO. The minimum signal level is 200 mVpp @ 60.0 MHz. This pin also functions as the test mode input for the counter tests.
9 10 11	Data EN Clk	Input	Microprocessor serial interface input pins for programming various counters and control functions.
12	Clk Out	Output	Microprocessor Clock Output which is derived from the 2nd LO crystal oscillator and a programmable divider. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output which can be combined with an external capacitor to form a low pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes.
13	CD Out	I/O	Dual function pin; 1) Carrier detect output (open collector with external 100 kΩ pull–up resistor. 2) Hardware interrupt input which can be used to "wake–up" from Inactive Mode.
14	BD_1 Out	Output	Low battery detect output #1 (open collector with external pull–up resistor).
15	DA Out	Output	Data amplifier output (open collector with internal 100 kΩ pull–up resistor).
16	BD_2 Out	Output	Low battery detect output #2 (open collector with external pull–up resistor).
17	T_x Out	Output	T_x path audio output.
18	C Cap	–	Compressor rectifier filter capacitor pin. Pull pin high through a capacitor.
19	C In	Input	Compressor input (ac–coupled).
20	Amp Out	Output	Microphone amplifier output.
21	T_x In	Input	T_x path input to microphone amplifier (Mic Amp) (ac–coupled).
22	DA In	Input	Data amplifier input (ac–coupled).
23	V_{CC} Audio	Supply	V_{CC} supply for audio section.
24	R_x Audio In	Input	R_x audio input (ac–coupled).
25	Det Out	Output	Audio output from FM detector.
26	RSSI	Output	Receive Signal Strength Indicator filter capacitor.
27 28	Q Coil Lim Out	–	A quad coil or ceramic discriminator connected to these pins as part of the FM demodulator circuit.
29	V_{CC} RF	Supply	V_{CC} supply for RF receiver section.
30 31	Lim C_2 Lim C_1	–	IF amplifier/limiter capacitor pins.
32	Lim In	Input	Signal input for IF amplifier/limiter.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Type	Description
33	SGND RF	Gnd	Ground pin for RF section of the IC.
34	Mix_2 In	Input	Second mixer input.
35	Mix_2 Out	Output	Second mixer output.
36	Gnd RF	Gnd	Ground pin for RF section of the IC.
37	Mix_1 Out	Output	First mixer output.
38	Mix_1 In_2	Input	Negative phase first mixer input.
39	Mix_1 In_1	Input	Positive phase first mixer input.
40 41	LO_1 In LO_1 Out	–	Tank Elements for 1st LO Multivibrator Oscillator are connected to these pins.
42	V_{cap} Ctrl	–	1st LO Varactor Control Pin.
43	Gnd Audio	Gnd	Ground for audio section of the IC.
44	SA Out	Output	Speaker amplifier output.
45	SA In	Input	Speaker amplifier input (ac–coupled).
46	E Out	Output	Expandor output.
47	E_{cap}	–	Expandor rectifier filter capacitor pin. Pull pin high through a capacitor.
48	E In	Input	Expandor Input.
49	Scr Out	Output	R_x Scrambler Output.
50	Ref_2	–	Reference voltage input for Low Battery Detect #2.
51	Ref_1	–	Reference voltage input for Low Battery Detect #1.
52	V_B	–	Internal half supply analog ground reference.

FM Receiver

The FM receiver can be used with either a quad coil or a ceramic resonator. The FM receiver and 1st LO have been designed to work for all country channels, including 25 channel U.S., without the need for any external switching circuitry (see Figure 29).

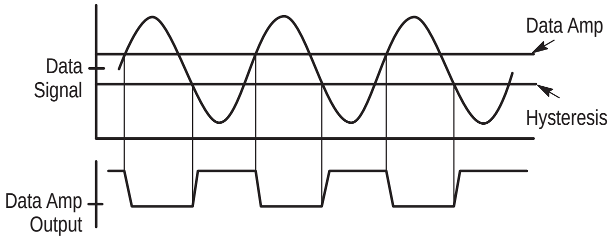
RSSI/Carrier Detect

Connect 0.01 µF to Gnd from “RSSI” output pin to form the carrier detect filter. “CD Out” is an open collector output which requires an external 100 kΩ pull–up resistor to V_{CC}. The carrier detect threshold is programmable through the MPU interface.

Data Amp Comparator

The data amp comparator is an inverting hysteresis comparator. Its open collector output has an internal 100 kΩ pull–up resistor. A band pass filter is connected between the “Det Out” pin and the “DA In” pin with component values as shown in Figure 1 (Test Circuit). The “DA In” input signal is ac–coupled.

Figure 2. Data Amp Operation



Expandor/ Compressor

In Appendix B, the EIA/CCITT recommendations for measurement of the attack and decay times are defined. The curves in Figures 3 and 4 show the typical expandor and compressor output versus input responses.

Figure 3. Expandor Typical Response

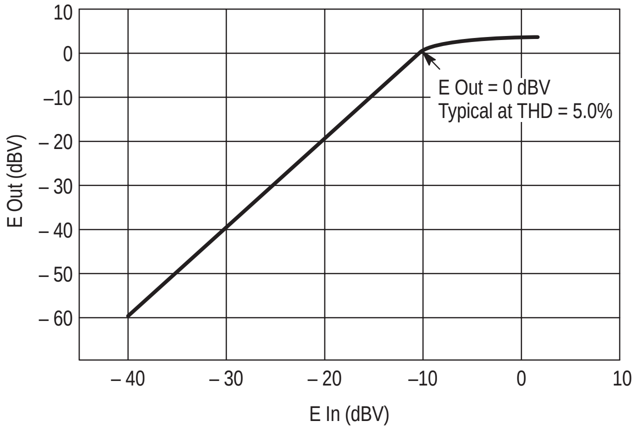


Figure 4. Compressor Typical Response

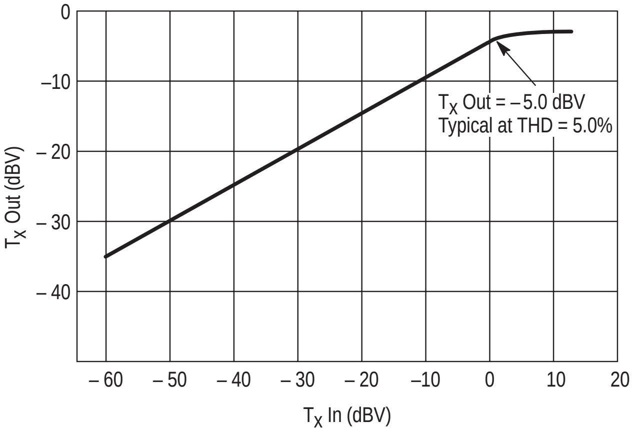

R_X Audio Path (LPF/R_X Gain Adjust/ R_X Mute/Expandor/Volume Control)

The R_X Audio signal path goes from “R_X Audio In” (Pin 24) to “E Out” (Pin 46). The “R_X Audio In” input signal is ac coupled. AC couple between “Scr Out” and “E In” (see Figure 3).

Speaker Amp/SP Mute

The Speaker Amp is an inverting rail–to–rail operational amplifier. The noninverting input is connected to the internal V_B reference. External resistors and capacitors are used to set the gain and frequency response. The “SA In” Input is ac coupled.

Mic Amp

The Mic Amp is an inverting rail–to–rail operational amplifier with noninverting input terminal connected to internal V_B reference. External resistors and capacitors are set to the gain and frequency response. The “T_X In” input is ac coupled.

T_X Audio Path (Compressor/ALC/T_X Mute/ Limiter/LPF/T_X Gain Adjust)

The T_X Audio signal path goes from “C In” (Pin 19) to “T_X Out” (Pin 17). The “C In” input signal is ac coupled. The ALC (Automatic Level Control) provides a “soft” limit to the output signal swing as the input voltage increases slowly (i.e., a sine wave is maintained). The Limiter circuit limits rapidly changing signal levels by clipping the signal peaks. The ALC and/or Limiter can be disabled through the MPU serial interface (see Figure 4).

T_X and R_X Scrambler

The T_X and R_X signal paths each contain a frequency inversion scrambler in the MC13110. Each scrambler contains a pre–mixer low pass switched capacitor filter (SCF), a double balanced mixer and a post–mixer low pass switched capacitor filter. The scrambler function can be defeated by setting the T_X or R_X Scrambler Bypass bits in the control register to “1” through the MPU interface. In this mode, the mixer and the post–mixer LPF are bypassed and only the pre–mixer LPF remains in the signal path. The SCF corner frequencies are proportional to the SCF clock. The SCF Clock Divider is programmable through the MPU interface, (SCF Clock) = F(2nd LO)/(SCF Divider Value*2). The scrambler modulation frequency is (SCF Clock)/40. Four scrambler modulation frequencies may be selected (see Figures 28 and 29).

PLL Voltage Regulator

The “PLL V_{ref}” pin is the internal supply voltage for the R_X and T_X PLL’s. It is regulated to a nominal 2.5 V. The “V_{CC} Audio” pin is the supply voltage for the internal voltage regulator. Two capacitors with 10 μF and 0.1 μF values must be connected to the “PLL V_{ref}” pin to filter and stabilize this regulated voltage. The “PLL V_{ref}” pin may be used to power other IC’s as long as the total external load current does not exceed 1.0 mA. The tolerance of the regulated voltage is initially ±8.0%, but is improved to ±4.0% after the internal Bandgap voltage reference is adjusted electronically through the MPU serial interface. The voltage regulator is turned off in the Standby and Inactive modes to reduce current drain. In these modes, the “PLL V_{ref}” pin is internally connected to the “V_{CC} Audio” pin (i.e., the power supply voltage is maintained but is now unregulated).

Low Battery Detect

Two external precision resistor dividers are used to set independent thresholds for two battery detect hysteresis comparators. The voltages on “Ref_1” and “Ref_2” are compared to an internally generated 1.5 V reference voltage. The tolerance of the internal reference voltage is initially ±6.0%. The Low Battery Detect threshold tolerance can be improved by adjusting a trim–pot in the external resistor divider. Alternately, the tolerance of the internal reference voltage can be improved to ±1.5% through MPU serial interface programming. The internal reference can be measured directly at the “V_B” pin. During final test of the telephone, the V_B internal reference voltage is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the MC13110 IC is powered up. Low Battery Detect outputs are open collector.

Power Supply Voltage

This circuit is used in a cordless telephone handset and base unit. The handset is battery powered and can operate on three NiCad cells or on 5.0 V supply.

PLL Frequency Synthesizer General Description

Figure 5 shows a simplified block diagram of the programmable universal dual phase locked loop (PLL). This dual PLL is fully programmable through the MCU serial interface and supports most country channel frequencies including USA (25 ch), Spain, Australia, Korea, New Zealand, U. K., Netherlands, France, and China.

The 2nd local oscillator and reference divider provide the reference frequency for the receive (R_X) and transmit (T_X) PLL loops. The programmed divider value for the reference divider is selected based on the crystal frequency and the desired R_X and T_X reference frequency values. Additional divide by 25 and divide by 4 blocks are provided to allow for generation of the 1.0 kHz and 6.25 kHz reference frequencies required for the U. K. The 14–bit T_X counter is programmed for the desired transmit channel frequency. The 14–bit R_X counter is programmed for the desired first local oscillator frequency. All counters power up in the proper default state for USA channel #21 (channel #6 for FCC 10 channel band) and for a 10.24 MHz reference frequency crystal. Internal fixed capacitors can be connected to the tank circuit of the 1st LO through microprocessor control to extend the sensitivity of the 1st LO for U.S. 25 channel operation.

PLL I/O Pin Specifications

The 2nd LO, R_X and T_X PLL’s, and MPU serial interface are powered by the internal voltage regulator at the “PLL V_{ref}” pin. The “PLL V_{ref}” pin is the output of a voltage regulator which is powered from the “V_{CC} Audio” power supply pin and is regulated by an internal bandgap voltage reference. Therefore, the maximum input and output levels for most PLL I/O pins (LO_2 In, LO_2 Out, R_X PD, T_X PD, T_X VCO) is the regulated voltage at the “PLL V_{ref}” pin. The ESD protection diodes on these pins are also connected to “PLL V_{ref}”. Internal level shift buffers are provided for the pins (Data, Clk, EN, Clk Out) which connect directly to the microprocessor. The maximum input and output levels for these pins is V_{CC}. Figure 6 shows a simplified schematic of the I/O pins.

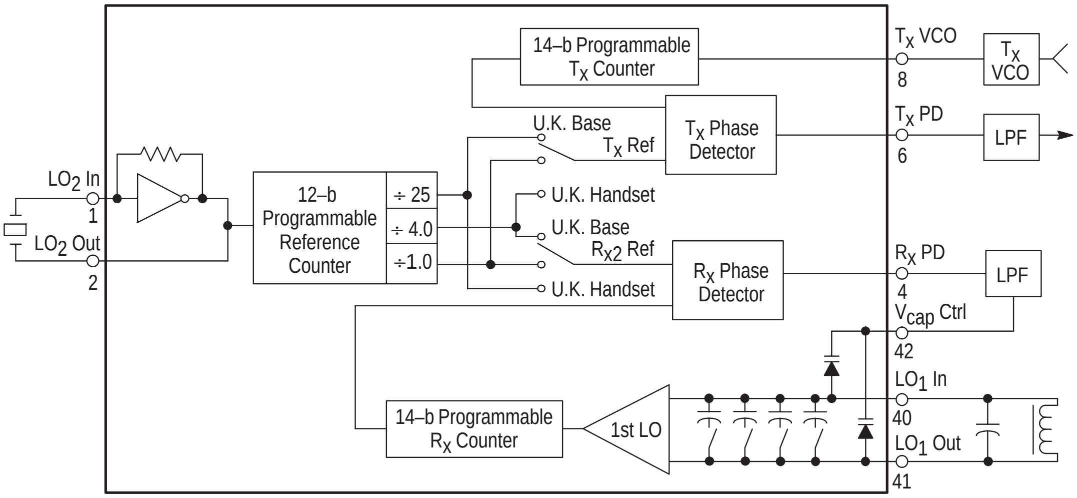

Figure 6. PLL I/O Pin Simplified Schematics

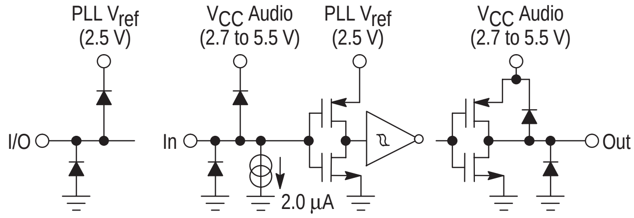


LO_2 In, LO_2 Out, R_X PD, T_X PD and T_X VCO Pins

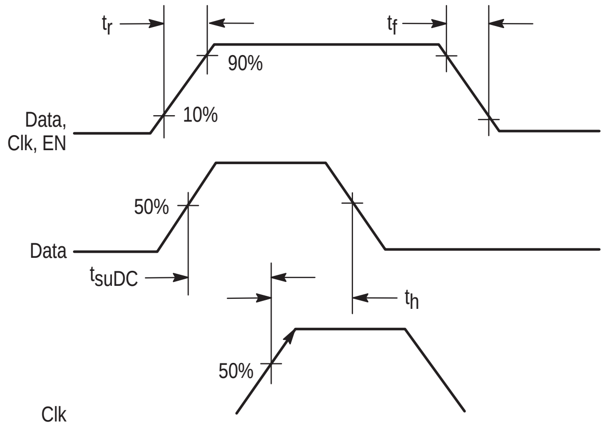
Data, Clk and EN Pins

Clk Out Pin

Microprocessor Serial Interface

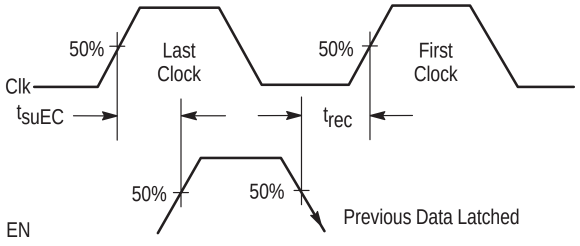
The “Data”, “Clk”, and “EN” pins provide an MPU serial interface for programming the reference counters, the transmit and receive channel divider counters, the switched capacitor filter clock counter, and various control functions. The “Data” and “Clk” pins are used to load data into the shift register. Figure 7 shows the timing required on the “Data” and “Clk” pins. Data is clocked into the shift register on positive clock transitions.

Figure 7. Data and Clock Timing Requirement



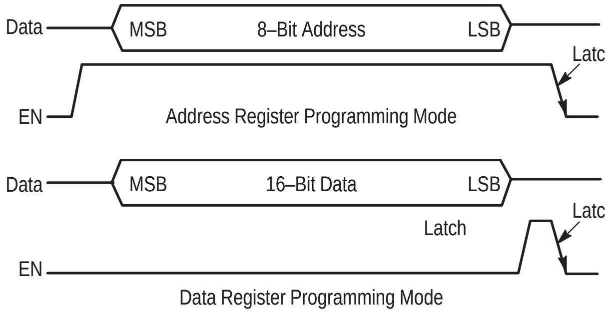
After data is loaded into the shift register, the data is latched into the appropriate latch register using the “EN” pin. This is done in two steps. First, an 8–bit address is loaded into the shift register and latched into the 8–bit address latch register. Then, up to 16–bits of data is loaded into the shift register and latched into the data latch register specified by the address that was previously loaded. Figure 5 shows the timing required on the EN pin. Latching occurs on the negative EN transition.

Figure 8. Enable Timing Requirement



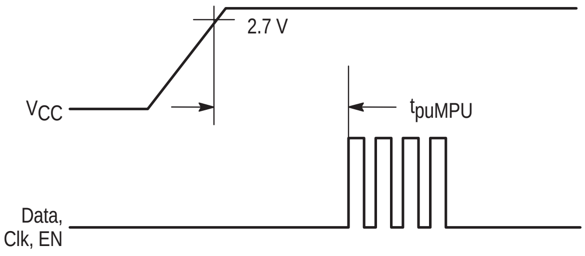
The state of the EN pin when clocking data into the shift register determines whether the data is latched into the address register or a data register. Figure 9 shows the address and data programming diagrams. In the data programming mode, there must not be any clock transitions when “EN” is high. The clock can be in a high state (default high) or a low state (default low) but must not have any transitions during the “EN” high state. The convention in these figures is that latch bits to the left are loaded into the shift register first.

Figure 9. Microprocessor Interface Programming Mode Diagrams



The MPU serial interface is fully operational within 100 µs after the power supply has reached its minimum level during power–up (see Figure 10). The MPU Interface shift registers and data latches are operational in all four power saving modes; Inactive, Standby, R_X, and Active Modes. Data can be loaded into the shift registers and latched into the latch registers in any of the operating modes.

Figure 10. Microprocessor Serial Interface Power–Up Delay



Data Registers

Figure 11 shows shows the data latch registers and addresses which are used to select each of these registers. Latch bits to the left (MSB) are loaded into the shift register first. The LSB bit must always be the last bit loaded into the shift register. Bits preceeding the register must be “0’s” as shown in Figure 11.

Figure 11. Microprocessor Interface Data Latch Registers

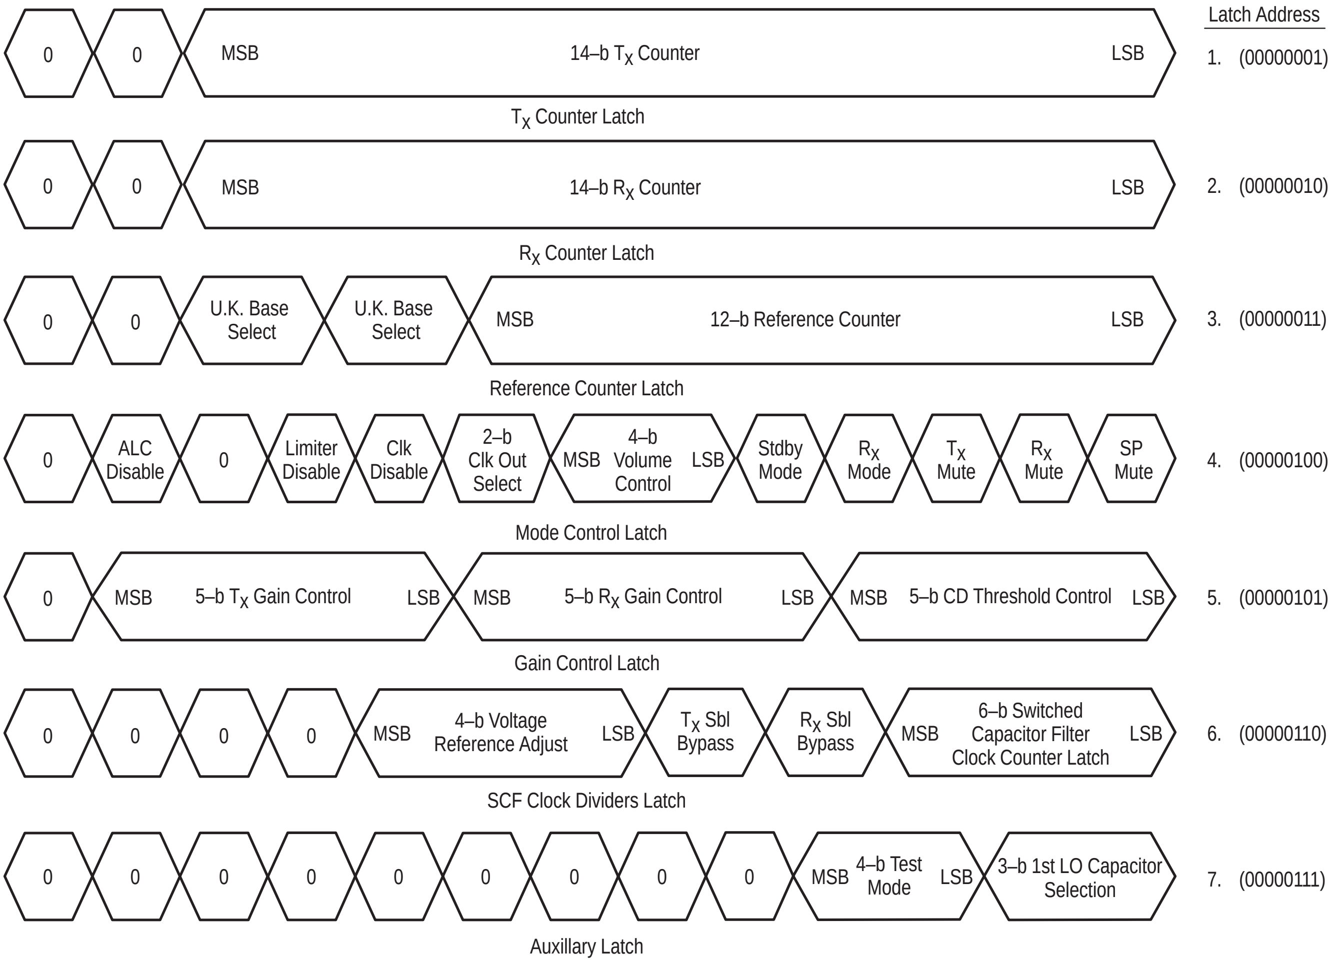


Figure 12. Reference Frequency and Reference Divider Values

Crystal Frequency	Reference Divider Value	U.K. Base/ Handset Divider	Reference Frequency	SC Filter Clock Divider	SC Filter Clock Frequency	Scrambler Modulation Divider	Scrambler Modulation Frequency
10.24 MHz	2048	1.0	5.0 kHz	31	165.16 kHz	40	4.129 kHz
10.24 MHz	1024	4.0	2.5 kHz	31	165.16 kHz	40	4.129 kHz

12.00 MHz	2400	1.0	5.0 kHz	36	166.67 kHz	40	4.167 kHz
11.15 MHz	1784	1.0	6.25 kHz	34	163.97 kHz	40	4.099 kHz
11.15 MHz	446	4.0	6.25 kHz	34	163.97 kHz	40	4.099 kHz
11.15 MHz	446	25	1.0 kHz	34	163.97 kHz	40	4.099 kHz

Reference Frequency Selection

The “LO_2 In” and “LO_2 Out” pins form a reference oscillator when connected to an external parallel–resonant crystal. The reference oscillator is also the second local oscillator for the RF Receiver. Figure 12 shows the relationship between different crystal frequencies and reference frequencies for cordless phone applications in various countries. “LO_2 In” may also serve as an input for an externally generated reference signal which is ac–coupled. The switched capacitor filter 6–bit programmable counter must be programmed for the crystal frequency that is selected since this clock is derived from the crystal frequency and must be held constant regardless of the crystal that is selected. The actual switched capacitor clock divider ratio is twice the programmed divider ratio since there is a fixed divide by 2.0 after the programmable counter. The scrambler mixer modulation frequency is the switched capacitor clock divided by 40.

Reference Counter

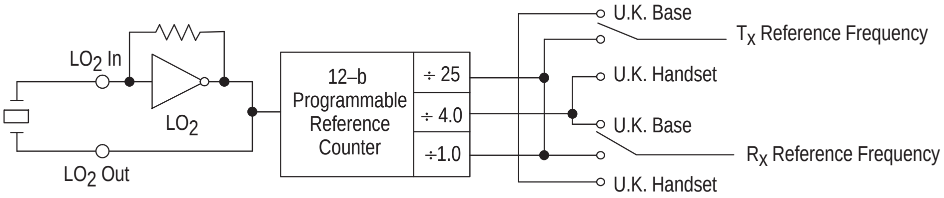
Figure 13 shows how the reference frequencies for the R_X and T_X loops are generated. All countries except the U.K.

require that the T_X and R_X reference frequencies be identical. In this case, set “U.K. Base Select” and “U.K. Handset Select” bits to “0”. Then the fixed divider is set to “1” and the T_X and R_X reference frequencies will be equal to the crystal oscillator frequency divided by the programmable reference counter value. The U.K. is a special case which requires a different reference frequency value for T_X and R_X. For U.K. base operation, set “U.K. Base Select” to “1”. For U.K. handset operation, set “U.K. Handset Select” to “1”.The Netherlands is also a special case since a 2.5 kHz reference frequency is used for both the T_X and R_X reference and the total divider value required is 4096 which is larger than the maximum divide value available from the 12–bit reference divider (4095). In this case, set “U.K. Base Select” to “1” and set “U.K. Handset Select” to “1”. This will give a fixed divide by 4 for both the T_X and R_X reference. Then set the reference divider to 1024 to get a total divider of 4096.

Mode Control Register

Power saving modes, mutes, disables, volume control, and microprocessor clock output frequency are all set by the Mode Control Register. Operation of the Mode Control Register is explained in Figures 14 through 21.

Figure 13. Reference Register Programming Mode



U.K. Handset Select	U.K. Base Select	T_X Divider Value	R_X Divider Value	Application
0	0	1.0	1.0	All but U.K. and Netherlands

SP Mute	1 0	Speaker Amp Muted Normal Operation

Power Saving Operating Modes

When the MC13110 is used in a handset, it is important to conserve power in order to prolong battery life. There are five modes of operation; Active, R_X, Standby, Interrupt, and Inactive. In Active mode, all circuit blocks are powered. In R_X mode, all circuitry is powered down except for those circuit sections needed to receive a transmission from the base. In the Standby and Interrupt Modes, all circuitry is powered down except for the circuitry needed to provide the clock output for the microprocessor. In Inactive Mode, all circuitry is powered down except the MPU interface. Latch memory is maintained in all modes. Figure 16 shows the control register bit values for selection of each power saving mode and Figure 17 shows the circuit blocks which are powered in each of these operating modes.

Figure 16. Power Saving Mode Selection

Stdby Mode Bit	R_X Mode Bit	“CD Out/ Hardware Interrupt” Pin	Mode
0	0	X	Active
0	1	X	R_X
1	0	X	Standby
1	1	1 or High Impedance	Inactive
1	1	0	Interrupt

Figure 17. Power Saving Modes

Circuit Blocks	Active	R_X	Standby	Inactive
“PLL V_{ref}” Regulated Voltage	X	X	X[1]	X[1]
MPU Interface	X	X	X	X
2nd LO Oscillator	X	X	X

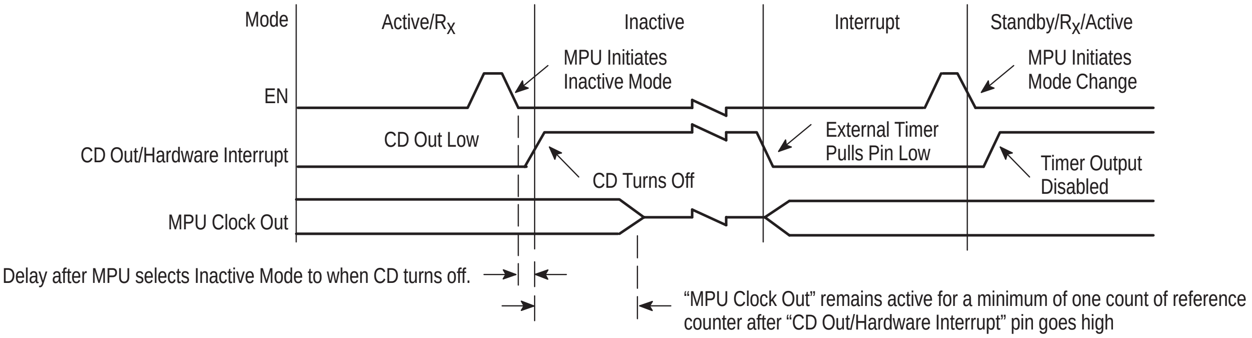
Carrier Detect	X	X		
Data Amp	X	X		
Low Battery Detect	X	X		
T_X PLL	X			
R_X and T_X Audio Paths	X			

NOTE: In Standby and Inactive Modes, “PLL V_{ref}” remains powered but is not regulated. It will fluctuate with V_{CC}.

Inactive Mode Operation and Hardware Interrupt

In some handset applications it may be desirable to power down all circuitry including the microprocessor (MPU). First put the combo IC into the Inactive mode, which turns off the MPU Clock Output (see Figure 18), and then disable the microprocessor. In order to give the MPU adequate time to power down, the MPU Clock output remains active for a minimum of one reference counter cycle (about 200 µs) after the command is given to switch into the “Inactive” mode. An external timing circuit should be used to initiate the turn–on sequence. The “CD Out” pin has a dual function. In the Active and R_X modes it performs the carrier detect function. In the Standby and Inactive modes the carrier detect circuit is disabled and the “CD Out” pin is in a “High” state due to the external pull–up resistor. In the Inactive mode, the “CD Out” pin is the input for the hardware interrupt function. When the “CD Out” pin is pulled “low” by the external timing circuit, the combo IC switches from the Inactive to the Interrupt mode thereby turning on the MPU Clock Output. The MPU can then resume control of the combo IC. The “CD Out” pin must remain low until the MPU changes the operating mode from Interrupt to Standby, Active or R_X modes.

Figure 18. Hardware Interrupt Operation



MPU "Clk Out" Divider Programming

This pin is a clock output which is derived from the crystal oscillator (2nd local oscillator). It can be used to drive a microprocessor and thereby reduce the number of crystals required. Figure 19 shows the relationship between the crystal frequency and the clock output for different divider values. Figure 20 shows the "Clk Out" register bit values.

Figure 19. Clock Output Values

Crystal Frequency	Clock Output Divider			
	2	3	4	5
10.24 MHz	5.120 MHz	3.413 MHz	2.560 MHz	2.048 MHz
11.15 MHz	5.575 MHz	3.717 MHz	2.788 MHz	2.230 MHz
12.00 MHz	6.000 MHz	4.000 MHz	3.000 MHz	2.400 MHz

MPU "Clk Out" Radiated Noise on Circuit Board

The clock line running between the MC13110 and the microprocessor has the potential to radiate noise which can cause problems in the system especially if the clock is a square wave digital signal with large high frequency harmonics. In order to minimize radiated noise, a 1.0 kΩ resistor is included on–chip in series with the "Clk Out" output driver. A small capacitor can be connected to the "Clk Out" line on the PCB to form a single pole low pass filter. This filter will significantly reduce noise radiated from the "Clk Out" line.

Volume Control Programming

The volume control adjustable gain block can be programmed in 2.0 dB gain steps from –14 dB to +16 dB. The power–up default value is 0 dB. (See Figure 21.)

Figure 20. Clock Output Divider

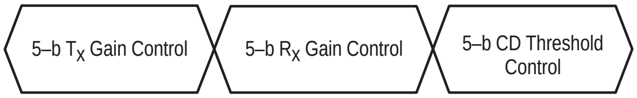
Gain Control Register

The gain control register contains bits which control the T_X Voltage Gain, R_X Voltage Gain, and Carrier Detect threshold. Operation of these latch bits are explained in Figures 22, 23 and 24.

Figure 22. Gain Control Latch Bits



T_X and R_X Gain Programming

The T_X and R_X audio signal paths each have a programmable gain block. If a T_X or R_X voltage gain other than the nominal power–up default is desired, it can be programmed through the MPU interface. Alternately, these programmable gain blocks can be used during final test of the telephone to electronically adjust for gain tolerances in the telephone system as shown in Figure 23. In this case, the T_X and R_X gain register values should be stored in ROM during final test so that they can be reloaded each time the combo IC is powered up.

Carrier Detect Threshold Programming

The “CD Out” pin gives an indication to the microprocessor if a carrier signal is present on the selected channel. The nominal value and tolerance of the carrier detect threshold is given in the carrier detect specification section of this document. If a different carrier detect threshold value is desired, it can be programmed through the MPU interface as shown in Figure 24. Alternately, the carrier detect threshold can be electronically adjusted during final test of the telephone to reduce the tolerance of the carrier detect threshold. This is done by measuring the threshold and then by adjusting the threshold through the MPU interface. In this case, it is necessary to store the carrier detect register value in ROM so that the CD register can be reloaded each time the combo IC is powered up.

Switched Capacitor Filter Clock Programming

A block diagram of the switched capacitor filter and scrambler modulation clock dividers is shown in Figure 27. There is a fixed divide by 2 after the programmable divider. The switched capacitor filter clock value is given by the following equation;

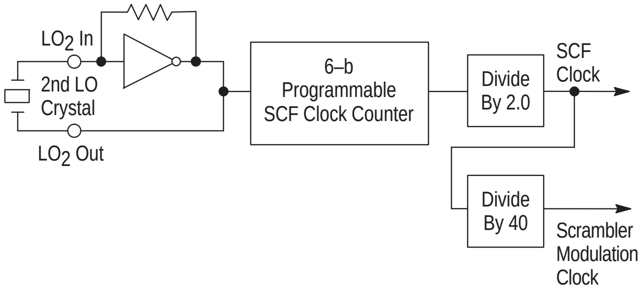
(SCF Clock) = F(2nd LO)/(SCF Divider Value * 2)

The scrambler modulation clock frequency (SMCF) is proportional to the SCF clock and is given by the following equation;

SMCF = (SCF Clock Frequency)/40

The SCF divider should be set to a value which gives a SCF Clock as close to 165.16 kHz as possible based on the 2nd LO frequency which is chosen (see Figure 12).

Figure 27. SCF Clock and Scrambler Carrier Circuit



Scrambler Modulation Frequency Programming

Four different scrambler modulation frequencies may be selected by programming the SCF Clock divider as shown in Figures 28 and 29. Note that all filter corner frequencies will change proportionately with the SCF Clock and Scrambler Modulation Frequency. The power–up default SCF Clock divider value is 31.

Voltage Reference Adjustment

The internal 1.5 V Bandgap voltage reference provides the voltage reference for the “BD1 Out” and “BD2 Out” low battery detect circuits, the “PLL V_{ref}” voltage regulator, the “V_B” reference, and all internal analog ground references. The initial tolerance of the Bandgap voltage reference is ±6%. The tolerance of the internal reference voltage can be improved to ±1.5% through MPU serial interface programming.

During final test of the telephone, the battery detect threshold is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the MC13110 is powered up (see Figure 30).

Auxiliary Register

The auxiliary register contains a 3–bit 1st LO Capacitor Selection latch and a 4–bit Test Mode latch. Operation of these latch bits are explained in Figures 31, 32 and 34.

Figure 31. Auxiliary Register Latch Bits

First Local Oscillator Programmable Selection (U.S. Applications)

There is a very large frequency difference between the minimum and maximum channel frequencies in the 25 Channel U.S. Standard.The sensitivity of the 1st LO may not be large enough to accommodate this large frequency variation. Fixed capacitors can be connected across the 1st LO tank circuit to change the 1st LO sensitivity. Internal switches and capacitors are provided to enable microprocessor control over internal fixed capacitor values. Figures 32 and 33 show the schematic representation of the 1st LO and the tank circuit. Figure 34 shows the latch control bit values for microprocessor control.

Figure 35. Digital Test Mode Description

TM #	TM 3	TM 2	TM 1	TM 0	Counter Under Test or Test Mode Option	"T_X V_{CO}" Input Signal	"Clk Out" Output Expected
0	0	0	0	0	Normal Operation	>200 mVpp	–
1	0	0	0	1	R_X Counter, upper 6	0 to 2.5 V	Input Frequency/64
2	0	0	1	0	R_X Counter, lower 8	0 to 2.5 V	See Note Below
3	0	0	1	1	R_X Prescaler	0 to 2.5 V	Input Frequency/4
4	0	1	0	0	T_X Counter, upper 6	0 to 2.5 V	Input Frequency/64
5	0	1	0	1	T_X Counter, lower 8	0 to 2.5 V	See Note Below
6	0	1	1	0	T_X Prescaler	>200 mVpp	Input Frequency/4
7	0	1	1	1	Reference Counter	0 to 2.5 V	Input Frequency/Reference Counter Value
8	1	0	0	0	Divide by 4, 25	0 to 2.5 V	Input Frequency/100
9	1	0	0	1	SC Counter	0 to 2.5 V	Input Frequency/SC Counter Value
10	1	0	1	0	Scrambler Modulation Counter	0 to 2.5 V	Input Frequency/40

NOTE: To determine the correct output, look at the lower 8–bits in the R_X or T_X register (Divisor (7;0). If the value of the divisor is > 16, then the output divisor value is Divisor (7;2) (the upper 6–bits of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) > = 2, then output divisor value is Divisor (3;2) (bits 2 and 3 of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) < 2, then output divisor value is (Divisor (3;2) + 60).

Figure 36. Analog Test Mode Description

Test Modes

Digital and analog test modes can be selected through the 4–bit Test Mode Register. In digital test mode, the "T_X V_{CO}" input pin is multiplexed to the input of the counter under test and the output of the counter under test is multiplexed to the "Clk Out" output pin so that each counter can be individually tested. Make sure test mode bits are set to "0's" for normal operation. Digital test mode operation is described in Figure 35. During normal operation and when testing the T_X Prescaler, the "T_X VCO" input can be a minimum of 200 mVpp at 80 MHz and should be ac–coupled. For other test modes, input signals should be standard logic levels of 0 to 2.5 V and a maximum frequency of 16 MHz.

The analog test modes enable separate testing of the Compressor and T_X Scrambler blocks as shown in Figure 36. Also, ALC Gain options can be selected through analog test modes.

Power–Up Defaults for Control and Counter Registers

When the IC is first powered up, all latch registers are initialized to a defined state. The device is initially placed in the Rx mode with all mutes active. The reference counter is set to generate a 5.0 kHz reference frequency from a 10.24 MHz crystal. The switched capacitor filter clock counter is set properly for operation with a 10.24 MHz crystal. The scrambler bypass mode control are set for normal operation of scrambler. The T_X and R_X latch registers are set for USA Channel Frequency 21 (Channel 6 for previous FCC 10 Channel Band). Figure 37 shows the initial power–up states for all latch registers.

Figure 37. Latch Register Power–Up Defaults

APPLICATIONS INFORMATION

Evaluation PC Board

The PCB should be double sided with a full ground plane on one side; any leaded components are inserted on the ground plane side. This affords shielding and isolation from the circuit side of the PCB. The other side is the circuit side which has the interconnect traces and the surface mount components. In cases where cost allows, it may be benificial to use multi layer boards.

The placement of certain components specified in the application circuits is very critical. These components should be placed first and the other less critical components are fitted in last. In general, all RF paths should be kept as short as possible, ground pins should be grounded at the pins and V_{CC} pins should have adequate decoupling to ground at the pins. In mixed mode systems where digital and RF/Analog circuitry are present, the V_{EE} and V_{CC} busses are isolated ac–wise from each other.

Component Selection

The evaluation PC board is designed to accommodate specific components, while in some cases it is versatile enough to use components from various manufacturers and coil types. The application circuit schematics specify particular components that were used to achieve the results shown in the typical curves and tables, but alternate components should give similar results.

The MC13110 IC is capable of matching the sensitivity, IMD, adjacent channel rejection, and other performance criteria of a multi–chip analog cordless telephone system. For the most part, the same external components are used as in the multi–chip solution. In the following discussion, various parts of the system are analyzed for best peformance and cost tradeoffs. Specific recommendations are made where certain components or circuit designs offer superior performance. The system analyzed is the USA “CT–1” cordless phone.

Input Matching/Sensitivity

The sensitivity of the IC is typically 0.56 µVrms matched with no preamp. To achieve suitable system performance, a preamp and passive duplexer must be used. In production final test, each section of the IC is separately tested to guarantee its system performance in the specific application. The preamp and duplexer yields typically –114 dBm 12 dB SINAD sensitivity performance under full duplex operation.

The duplexer is important to achieve full duplex operation without significant “de–sensing” of the receiver by the transmitter. The combination of the duplexer and preamp circuit have to attenuate the transmitter power to the receiver by over 60 dB to be effective. They do this while improving the receiver system noise figure and without giving up too much IMD intermodulation performance.

The duplexer may be a single piece unit offered by Shimida and Sansui products (designed for 10 channel CT–1 cordless phone) or a two piece solution offered by Toko (designed for 25 channel operation). The duplexer frequency response at the receiver port has a notch at the transmitter frequency band of about 35 to 40 dB with a 2.0 to 3.0 dB insertion loss at the receiver frequency band.

The preamp circuit utilizes a tuned transformer at the output side of the amplifier; this transformer is designed to bandpass filter the receiver input frequency while rejecting the transmitter frequency. The tuned preamp also improves the noise performance by reducing the bandwidth of the pass band and reducing the second stage contribution of the 1st mixer. The preamp is biased at about 1.0 mA and 3.0 Vdc which yields suitable noise figure and gain.

Mixers

The 1st and 2nd mixers are similar in design. Both are double balanced to suppress the LO and the input frequencies to give only the sum and difference frequencies out. Typically the LO is suppressed about 40 to 60 dB. The 1st mixer may be driven either differentially or single ended. The gain of the 1st mixer has a 3.0 dB corner at 20 MHz and is used at a 10.7 MHz IF. It has an output impedance of 330 Ω and matches to a typical 10.7 MHz ceramic filter with a source and load impedance of 330 Ω. A series resistor may be used to raise the impedance for use with crystal filters which typically have an input impedance much greater than 330 Ω. The 2nd mixer input impedance is typically 3.0 kΩ; it requires an external 360 Ω parallel resistor for use with a standard 330 Ω 10.7 MHz ceramic filter. The second mixer output impedance is 1.5 kΩ making it suitable to match 455 kHz ceramic filters.

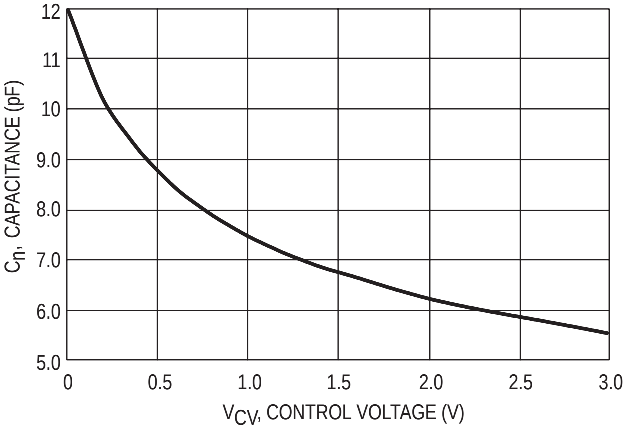
The following table is a list of typical input impedances over frequency for the 1st Mixer. R_P and C_P are represented in parallel form.

Frequency (MHz)	R_P (Ω)	C_P (pF)
20	977.7	2.44
25	944.3	2.60
30	948.8	2.65
35	928	2.55
40	900	2.51
45	873.4	2.65
50	859.3	2.72
55	821	2.72
60	795	2.74

First Local Oscillator

The 1st LO is a multi–vibrator oscillator that takes an external capacitance and inductance. It is voltage controlled to an internal varactor from an external loop filter and an on–board phase–lock loop (PLL). The schematic in Figure 33 shows all the basic parasitic elements of the internal circuitry. The 1st LO internal component values have a tolerance of 15%. A typical dc bias level on the LO Input and LO Output is 0.47 Vdc. The curve in Figure 38 is the varactor control voltage range as it relates to capacitance. It represents the expected capacitance for a given control voltage of the MC13110.

Figure 38. First Local Oscillator Varacter versus Control Voltage



Second Local Oscillator

The 2nd LO is a CMOS oscillator similar to that used in the MC145162. The 2nd LO is also used as the PLL reference oscillator. It is designed to utilize an external parallel resonant crystal.

PLL Design

The 1st LO level is important, as well as the choice of the crystal for the PLL clock reference and 2nd LO. A fundamental, parallel resonant crystal specified with 7.0 to 12 pF load calibration capacitance is recommended. With load calibration capacitance too high, the crystal locks up very slowly. If the LO power is less than –10 dBm, a pull–down resistor at the 1st LO emitter (Pin 41) will increase its drive level. The LO level is primarily a function of the Colpitts capacitive voltage divider formed by the capacitors between the base to emitter and the emitter to ground.

The VCO gain factor expressed in MHz/V is indeed critical to the phase noise performance. If this curve is too steep or too sensitive to changes in control voltage, it may degrade the phase noise performance. The external VCO circuit design needs to consider the typical swing of the control voltage and the corresponding linearity of the transfer function, $\Delta f_{osc}/\Delta V_{control}$. In general, the higher the Q of the VCO circuit inductor, the better phase noise performance.

Adjacent channel rejection and isolation between the 1st and 2nd mixers may be adversely affected due to layout problems and difficulty in getting close to the package pins with the grounds and decoupling capacitors on the RF V_{CC}. These system parameters must be evaluated for sensitivity to layout and external component placement.

Intermodulation and adjacent channel performance problems may also result from spurs around the 1st LO which may be caused by harmonics from the switched capacitor clock driver and too low 1st LO drive level. The clock driver operates at a frequency which is f(2nd LO)/(2 * (SCF Divider)). The harmonics are n * (f(2nd LO)), where n can be any positive integer. The current spikes of the SCF on the supply lines cause the disturbance of the 1st LO. This may be verified by observing the spurs on a spectrum analyzer while changing the clock divider value. The spur frequencies will change when the divider value is changed. The spurious sideband problem may be avoided by changing the clock divider value via software for each channel where it is a problem. Certain channels are worse than others.

The PLL alignment procedure for the application circuit is detailed in Appendix C. Refer to the MC145162 data sheet for PLL design example.

Limiting IF Amplifiers

The limiting IF amplifier typically has about 110 dB of gain; the frequency response starts rolling off at 1.0 MHz. Decoupling capacitors should be placed close to the decoupling Pins 31 and 32 to ensure low noise and stable operation. The IF input impedance is 1.5 kΩ for a suitable match to 455 kHz ceramic filters.

RSSI/Carrier Detect

The Received Signal Strength Indicator (RSSI) indicates the strength of the IF level and the output is proportional to the logarithm of the IF input signal magnitude. The RSSI dynamic range is typically 80 dB. Connect 0.01 µF to GND from “RSSI” output pin to form the carrier detect filter. A resistor needed to convert the RSSI current to voltage is included in the internal circuit. An internal temperature compensated reference current also improves the RSSI accuracy over temperature.

“CD Out” is an open collector output; thus, an external 100 kΩ pull–up resistor to V_{CC} is recommended. The carrier detect threshold is programmable through the MPU interface.

Quadrature Detector

The quadrature detector is coupled to the IF with an external capacitor between Pins 27 and 28; thus, the recovered signal level output is increased for a given bandwidth by increasing the capacitor. The external quadrature component may be either a LCR resonant circuit, which may be adjustable, or a ceramic resonator which is usually fixed tuned.

The bandwidth performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit’s bandwidth:

$$R_T = Q\,X_L \quad (1)$$

where R_T is the equivalent shunt resistance across the LC Tank. X_L is the reactance of the quadrature inductor at the IF frequency ($X_L = 2\pi fL$).

Specific 455 kHz quadrature LC components are manufactured by Toko in various 5 mm, 7 mm and 10 mm shielded cans in surface mount or leaded packages. Recommended components such as, the 7 mm Toko, is used in the application circuit. When minaturization is a key constraint, a surface mount inductor and capacitor may be chosen to form a resonant LC tank with the PCB and parasitic device capacitance. The 455 kHz IF center frequency is calculated by

(2) $f_c = [2\pi\,(LC_p)^{1/2}]-1$

where L is the parallel tank inductor. C_p is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a detector at 455 kHz and a specific loaded Q. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 455 kHz and an IF bandpass of 20 kHz, the IF bandpass Q is approximately 23; the loaded Q of the quadrature tank is chosen at 15.

Example:

Let the total external C = 180 pF. Note: the capacitance may be split between a 150 pF chip capacitor and a 5.0 to 25 pF variable capacitor; this allows for tuning to compensate for component tolerance. Since the external capacitance is much greater than the internal device and PCB parasitic capacitance, the parasitic capacitance may be neglected.

Rewrite equation (2) and solve for L:

$L = (0.159)^2/(C\,fc^2)$
L = 678 μH ; Thus, a standard value is chosen:
L = 680 μH (surface mount inductor)

The value of the total damping resistor to obtain the required loaded Q of 15 can be calculated from equation (1):

$R_T = Q(2\pi fL)$
$R_T = 15\,(2\pi)(0.455)(680) = 29.5\ k\Omega$

The internal resistance, R_{int} at the quadrature tank Pin 27 is approximately 100 kΩ and is considered in determining the external resistance, R_{ext} which is calculated from

$R_{ext} = ((R_T)(R_{int}))/(R_{int} - R_T)$
$R_{ext} = 41.8\ k\Omega$; Thus, choose the standard value:
$R_{ext} = 39\ k\Omega$

A ceramic discriminator is recommended for the quadrature circuit in applications where fixed tuning is desired. The ceramic discriminator and a 22 k resistor are placed from Pin 27 to V_{CC}. A 10 pF capacitor is placed from Pin 28 to 27 to properly drive the discriminator.

MuRata Erie has designed a resonator that is compatible with the IC. For US applications the part number is CDBM455C48. For Europe the part number is CDBM450C48. Contact Motorola Analog Marketing for performance data using muRata's parts.

APPENDIX C – MEASUREMENT OF COMPANDOR ATTACK/DECAY TIME

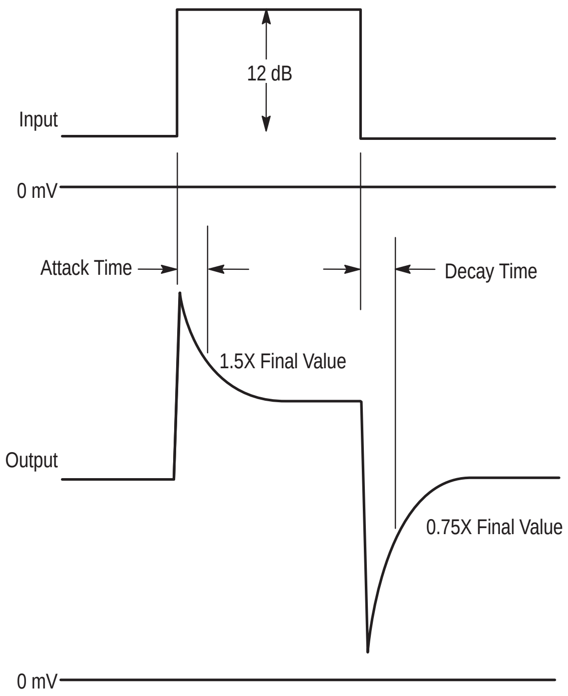
This measurement definition is based on EIA/CCITT recommendations.

Compressor Attack Time

For a 12 dB step up at the input, attack time is defined as the time for the output to settle to 1.5X of the final steady state value.

Compressor Decay Time

For a 12 dB step down at the input, decay time is defined as the time for the input to settle to 0.75X of the final steady state value.

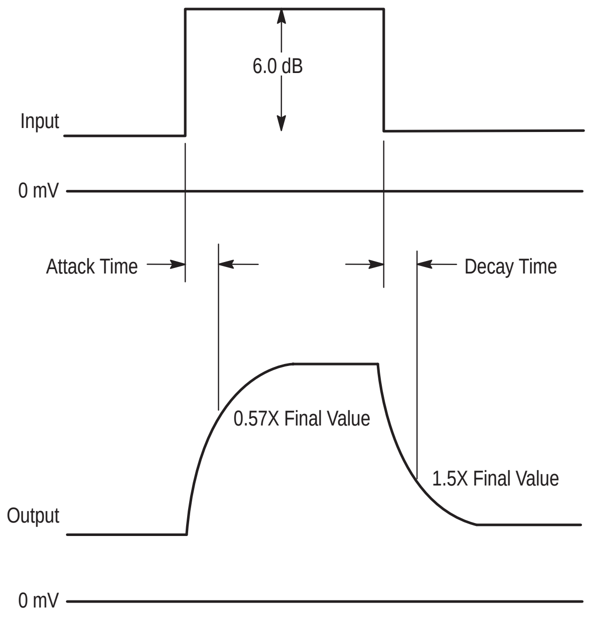


Expandor Attack

For a 6.0 dB step up at the input, attack time is defined as the time for the output to settle to 0.57X of the final steady state value.

Expandor Decay

For a 6.0 dB step down at the input, decay time is defined as the time for the output to settle to 1.5X of the final steady state value.



MOTOROLA

Universal Cordless Telephone Subsystem IC

MC13111

**UNIVERSAL CT–1
SUBSYSTEM
INTEGRATED CIRCUIT**

**SEMICONDUCTOR
TECHNICAL DATA**

The MC13111 integrates several of the functions required for a cordless telephone into a single integrated circuit. This significantly reduces component count, board space requirements, external adjustments, and lowers overall costs. It is designed for use in both the handset and the base.

- Dual Conversion FM Receiver
  - Complete Dual Conversion Receiver – Antenna In to Audio Out 80 MHz Maximum Carrier Frequency
  - RSSI Output
  - Carrier Detect Output with Programmable Threshold
  - Comparator for Data Recovery
  - Operates with Either a Quad Coil or Ceramic Discriminator
- Compander
  - Expandor Includes Mute, Digital Volume Control, Speaker Driver, 3.5 kHz Low Pass Filter, and Programmable Gain Block
  - Compressor Includes Mute, 3.5 kHz Low Pass Filter, Limiter, and Programmable Gain Block
- Dual Universal Programmable PLL
  - Supports New 25 Channel U.S. Standard with No External Switches
  - Universal Design for Domestic and Foreign CT–1 Standards
  - Digitally Controlled Via a Serial Interface Port
  - Receive Side Includes 1st LO VCO, Phase Detector, and 14–Bit Programmable Counter and 2nd LO with 12–Bit Counter
  - Transmit Section Contains Phase Detector and 14–Bit Counter
  - MPU Clock Outputs Eliminates Need for MPU Crystal
- Supply Voltage Monitor
  - Provides Two Levels of Monitoring with Separate Outputs
  - Separate, Adjustable Trip Points
- Programmable Corner Frequency Selection
- MC13111 is Pin–for–Pin Compatible with MC13110
- 2.7 to 5.5 V Operation with One–Third the Power Consumption of Competing Devices
- AN1575: Refer to this Application Note for a List of the “Worldwide Cordless Telephone Frequencies” (List can also be found in Chapter 8 Addendum of DL128 Data Book)

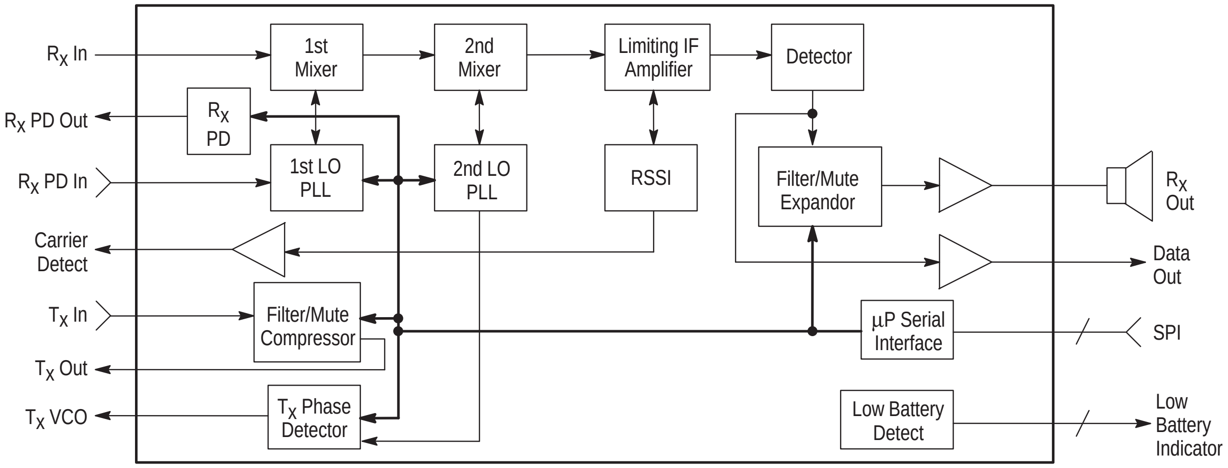
ORDERING INFORMATION

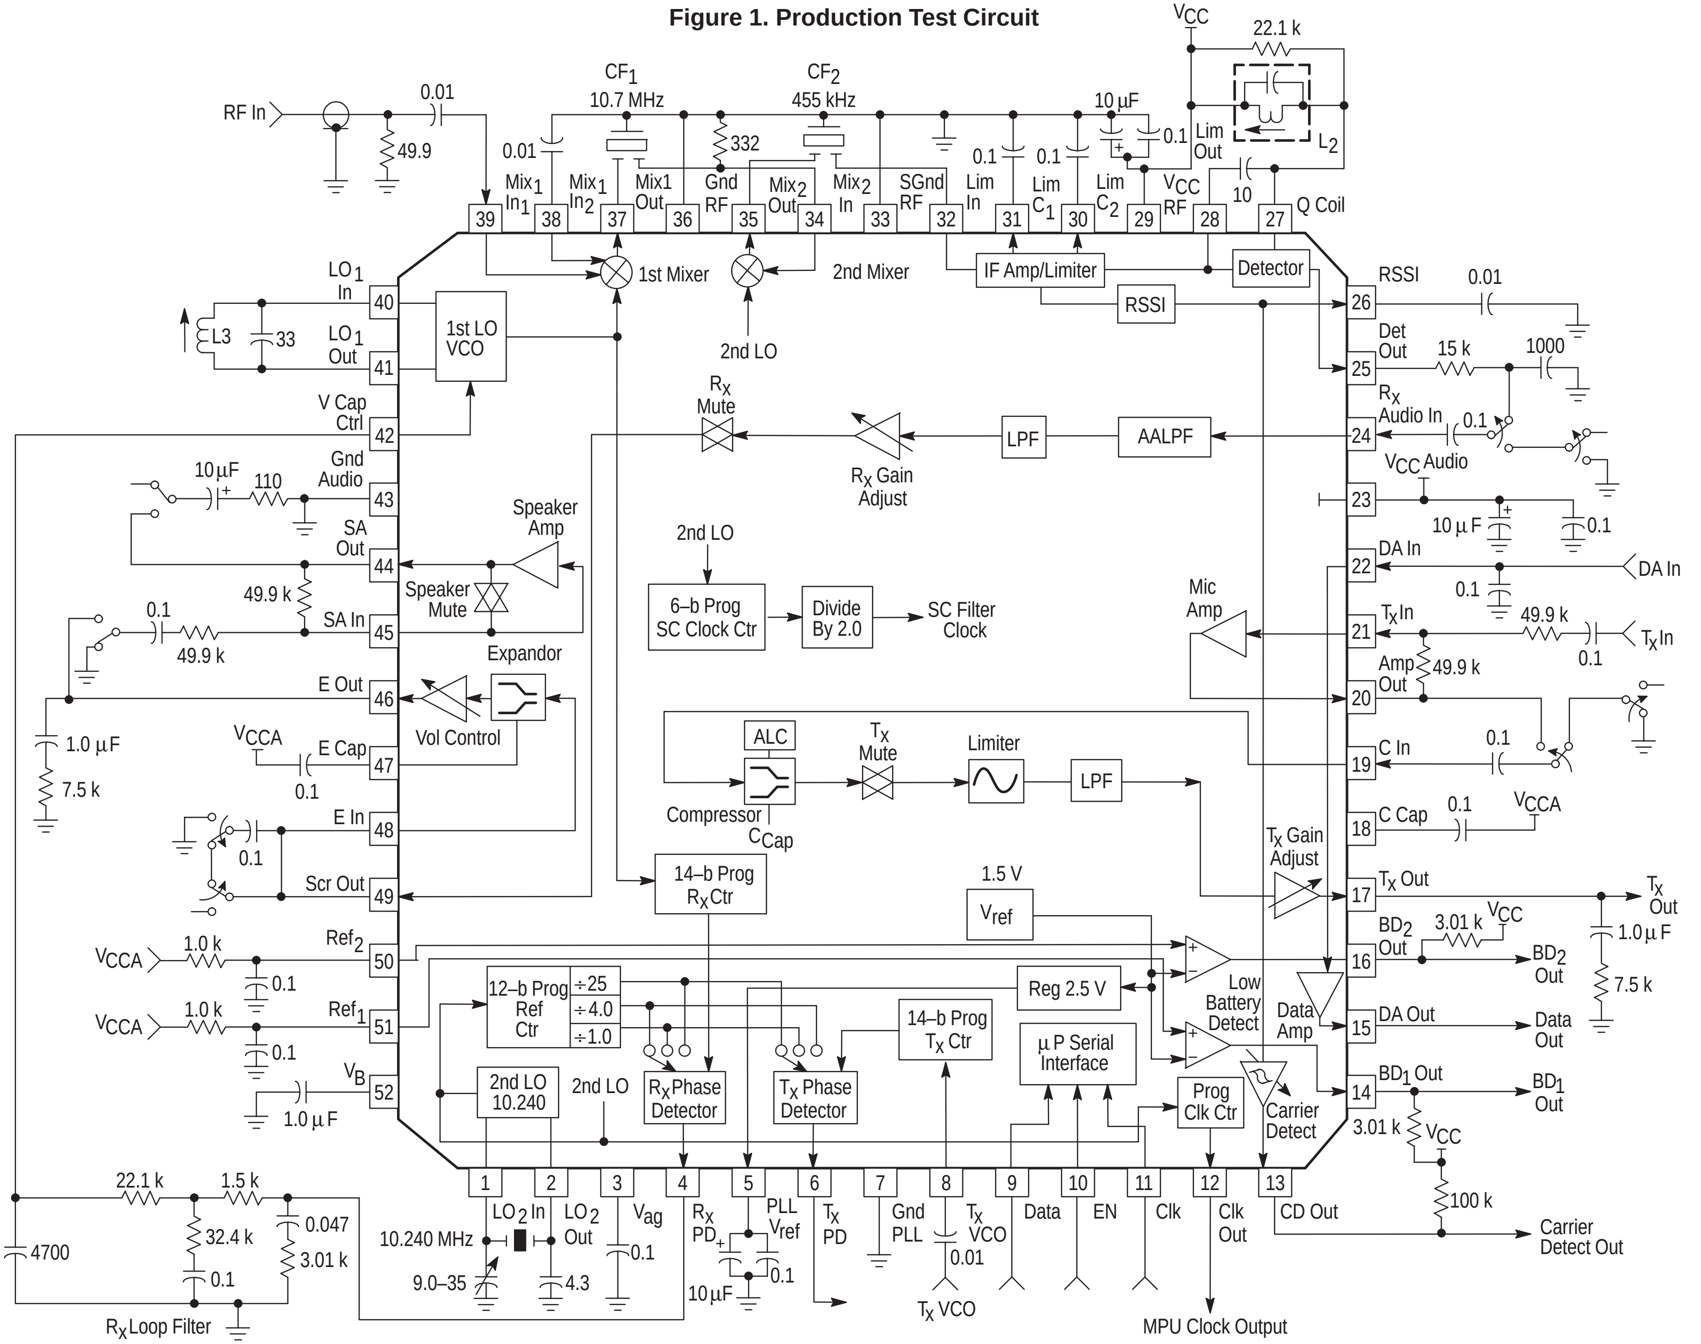
Device	Tested Operating Temperature Range	Package
MC13111FB	T_A = – 40° to +85°C	QFP–52

Simplified Application



This device contains 8,262 active transistors.

Figure 1. Production Test Circuit



NOTE: This schematic is only a representation of the actual production test circuit.

MAXIMUM RATINGS

Characteristic	Symbol	Value	Unit
Power Supply Voltage	V_{CC}	–0.5 to +6.0	Vdc
Junction Temperature	T_J	–65 to +150	°C

NOTES: 1. Devices should not be operated at these limits. The "Recommended Operating Conditions" provide for actual device operation.

2. ESD data available upon request.

RECOMMENDED OPERATING CONDITIONS

Characteristic	Symbol	Min	Typ	Max	Unit
Supply Voltage	V_{CC}	2.7	3.6	5.5	Vdc
Operating Ambient Temperature	T_A	–40	–	85	°C
Input Voltage Low (Data, Clk, EN)	V_{IL}	–	–	0.3	V
Input Voltage High (Data, Clk, EN)	V_{IH}	2.5	–	–	V
Output Current (R_X PD, T_X PD)					mA
High	I_{OH}	–	–	–0.7	
Low	I_{OL}	0.7	–	–	

NOTE: All limits are not necessarily functional concurrently.

DC ELECTRICAL CHARACTERISTICS (V_{CC} = 3.6 V, T_A = 25°C, unless otherwise specified; Test Circuit Figure 1.)

NOTE: 1. The filter specification is based on a 10.24 MHz 2nd LO, and a switched–capacitor (SC) filter counter divider ratio of 31. If other 2nd LO frequencies and/or SC filter counter divider ratios are used, the filter corner frequency will be proportional to the resulting SC filter clock frequency.

PIN FUNCTION DESCRIPTION

Pin	Symbol	Type	Description
1 2	LO_2 In LO2 Out	–	These pins form the PLL reference oscillator when connected to an external parallel–resonant crystal (10.24 MHz typical). The reference oscillator is also the second Local Oscillator (LO_2) for the RF receiver. "LO_2 In" may also serve as an input for an externally generated reference signal which is typically ac–coupled.
3	V_{ag}	–	Internal reference voltage for switched capacitor filter section.
4	R_x PD	Output	Three state voltage output of the R_x Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external R_x PLL loop filter. It is important to minimize the line length and parasitic capacitance of this pin.
5	PLL V_{ref}	–	PLL voltage regulator output pin. An internal voltage regulator provides a stable power supply voltage for the R_x and T_x PLL's and can also be used as a regulated supply voltage for other IC's.
6	T_x PD	Output	Three state voltage output of the T_x Phase Detector. This pin is either "high", "low", or "high impedance" depending on the phase difference of the phase detector input signals. During lock, very narrow pulses with a frequency equal to the reference frequency are present. This pin drives the external T_x PLL loop filter. It is important to minimize the line length and parasitic capacitance of this pin.
7	Gnd PLL	Gnd	Ground pin for PLL section of IC.
8	T_x VCO	Input	Transmit divide counter input which is driven by an ac–coupled external transmit loop VCO. The minimum signal level is 200 mVpp @ 60.0 MHz. This pin also functions as the test mode input for the counter tests.
9 10 11	Data EN Clk	Input	Microprocessor serial interface input pins for programming various counters and control functions.
12	Clk Out	Output	Microprocessor Clock Output which is derived from the 2nd LO crystal oscillator and a programmable divider. It can be used to drive a microprocessor and thereby reduce the number of crystals required in the system design. The driver has an internal resistor in series with the output which can be combined with an external capacitor to form a low pass filter to reduce radiated noise on the PCB. This output also functions as the output for the counter test modes.
13	CD Out	I/O	Dual function pin; 1) Carrier detect output (open collector with external 100 kΩ pull–up resistor. 2) Hardware interrupt input which can be used to "wake–up" from Inactive Mode.
14	BD_1 Out	Output	Low battery detect output #1 (open collector with external pull–up resistor).
15	DA Out	Output	Data amplifier output (open collector with internal 100 kΩ pull–up resistor).
16	BD_2 Out	Output	Low battery detect output #2 (open collector with external pull–up resistor).
17	T_x Out	Output	T_x path audio output.
18	C Cap	–	Compressor rectifier filter capacitor pin. Pull pin high through a capacitor.
19	C In	Input	Compressor input (ac–coupled).
20	Amp Out	Output	Microphone amplifier output.
21	T_x In	Input	T_x path input to microphone amplifier (Mic Amp) (ac–coupled).
22	DA In	Input	Data amplifier input (ac–coupled).
23	V_{CC} Audio	Supply	V_{CC} supply for audio section.
24	R_x Audio In	Input	R_x audio input (ac–coupled).
25	Det Out	Output	Audio output from FM detector.
26	RSSI	Output	Receive Signal Strength Indicator filter capacitor.
27 28	Q Coil Lim Out	–	A quad coil or ceramic discriminator connected to these pins as part of the FM demodulator circuit.
29	V_{CC} RF	Supply	V_{CC} supply for RF receiver section.
30 31	Lim C_2 Lim C_1	–	IF amplifier/limiter capacitor pins.
32	Lim In	Input	Signal input for IF amplifier/limiter.

PIN FUNCTION DESCRIPTION (continued)

Pin	Symbol	Type	Description
33	SGND RF	Gnd	Ground pin for RF section of the IC.
34	Mix_2 In	Input	Second mixer input.
35	Mix_2 Out	Output	Second mixer output.
36	Gnd RF	Gnd	Ground pin for RF section of the IC.
37	Mix_1 Out	Output	First mixer output.
38	Mix_1 In_2	Input	Negative phase first mixer input.
39	Mix_1 In_1	Input	Positive phase first mixer input.
40 41	LO_1 In LO_1 Out	–	Tank Elements for 1st LO Multivibrator Oscillator are connected to these pins.
42	V_{cap} Ctrl	–	1st LO Varactor Control Pin.
43	Gnd Audio	Gnd	Ground for audio section of the IC.
44	SA Out	Output	Speaker amplifier output.
45	SA In	Input	Speaker amplifier input (ac–coupled).
46	E Out	Output	Expandor output.
47	E_{cap}	–	Expandor rectifier filter capacitor pin. Pull pin high through a capacitor.
48	E In	Input	Expandor Input.
49	Scr Out	Output	R_x Audio Output.
50	Ref_2	–	Reference voltage input for Low Battery Detect #2.
51	Ref_1	–	Reference voltage input for Low Battery Detect #1.
52	V_B	–	Internal half supply analog ground reference.

FM Receiver

The FM receiver can be used with either a quad coil or a ceramic resonator. The FM receiver and 1st LO have been designed to work for all country channels, including 25 channel U.S., without the need for any external switching circuitry (see Figure 32).

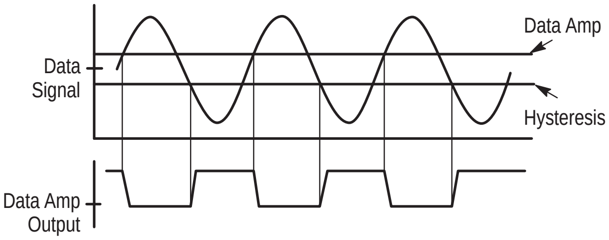
RSSI/Carrier Detect

Connect 0.01 µF to Gnd from “RSSI” output pin to form the carrier detect filter. “CD Out” is an open collector output which requires an external 100 kΩ pull–up resistor to V_{CC}. The carrier detect threshold is programmable through the MPU interface.

Data Amp Comparator

The data amp comparator is an inverting hysteresis comparator. Its open collector output has an internal 100 kΩ pull–up resistor. A band pass filter is connected between the “Det Out” pin and the “DA In” pin with component values as shown in Figure 1 (Test Circuit). The “DA In” input signal is ac–coupled.

Figure 2. Data Amp Operation



Expandor/ Compressor

In Appendix B, the EIA/CCITT recommendations for measurement of the attack and decay times are defined. The curves in Figures 3 and 4 show the typical expandor and compressor output versus input responses.

Figure 3. Expandor Typical Response

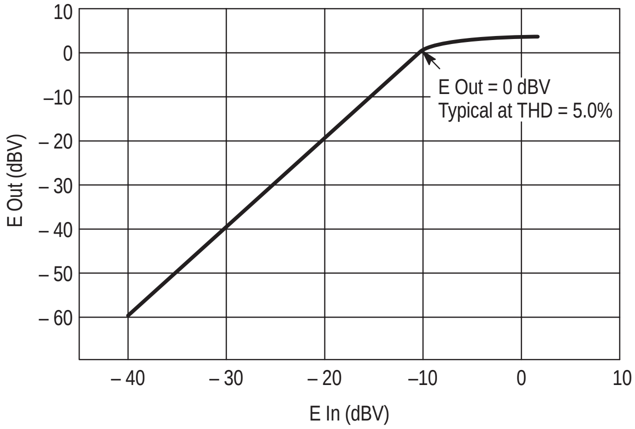


Figure 4. Compressor Typical Response

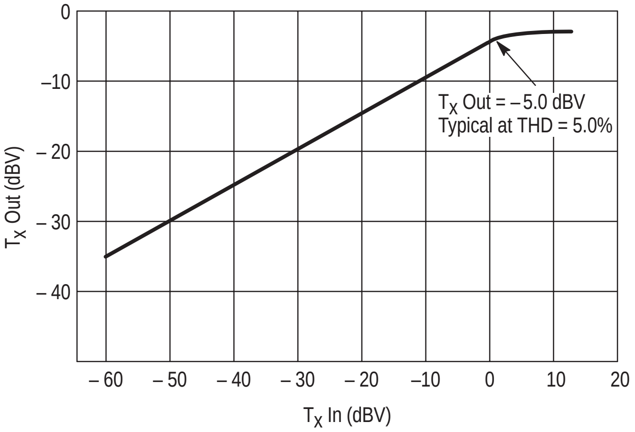


R_X Audio Path (LPF/R_X Gain Adjust/ R_X Mute/Expandor/Volume Control)

The R_X Audio signal path goes from “R_X Audio In” (Pin 24) to “E Out” (Pin 46). The “R_X Audio In” input signal is ac coupled. AC couple between “Scr Out” and “E In” (see Figure 3).

Speaker Amp/SP Mute

The Speaker Amp is an inverting rail–to–rail operational amplifier. The noninverting input is connected to the internal V_B reference. External resistors and capacitors are used to set the gain and frequency response. The “SA In” Input is ac coupled.

Mic Amp

The Mic Amp is an inverting rail–to–rail operational amplifier with noninverting input terminal connected to internal V_B reference. External resistors and capacitors are set to the gain and frequency response. The “T_X In” input is ac coupled.

T_X Audio Path (Compressor/ALC/T_X Mute/ Limiter/LPF/T_X Gain Adjust)

The T_X Audio signal path goes from “T_X In” (Pin 19) to “T_X Out” (Pin 17). The “C In” input signal is ac coupled from “Amp Out”. The ALC (Automatic Level Control) provides a “soft” limit to the output signal swing as the input voltage increases slowly (i.e., a sine wave is maintained). The Limiter circuit limits rapidly changing signal levels by clipping the signal peaks. The ALC and/or Limiter can be disabled through the MPU serial interface (see Figure 4).

T_X and R_X Audio

Each audio path contains a low–pass switched capacitor filter (SCF). The control register must be set through the MPU interface (Figure 11) for proper operation (T_X and R_X bits must be set to “1”). The SCF corner frequencies are proportional to the SCF Clock. The SCF Clock Divider is programmable through the MPU interface as follows: (SCF) = F(2nd LO) / (SCF Divider Value * 2). The LPF corner frequencies can be selected in from the table in Figures 28 and 29 relative to the 2nd LO operating frequency.

PLL Voltage Regulator

The “PLL V_{ref}” pin is the internal supply voltage for the R_X and T_X PLL’s. It is regulated to a nominal 2.5 V. The “V_{CC} Audio” pin is the supply voltage for the internal voltage regulator. Two capacitors with 10 µF and 0.1 µF values must be connected to the “PLL V_{ref}” pin to filter and stabilize this regulated voltage. The “PLL V_{ref}” pin may be used to power other IC’s as long as the total external load current does not exceed 1.0 mA. The tolerance of the regulated voltage is initially ±8.0%, but is improved to ±4.0% after the internal Bandgap voltage reference is adjusted electronically through the MPU serial interface. The voltage regulator is turned off in the Standby and Inactive modes to reduce current drain. In these modes, the “PLL V_{ref}” pin is internally connected to the “V_{CC} Audio” pin (i.e., the power supply voltage is maintained but is now unregulated).

Low Battery Detect

Two external precision resistor dividers are used to set independent thresholds for two battery detect hysteresis comparators. The voltages on “Ref_1” and “Ref_2” are compared to an internally generated 1.5 V reference voltage. The tolerance of the internal reference voltage is initially ±6.0%. The Low Battery Detect threshold tolerance can be improved by adjusting a trim–pot in the external resistor divider. Alternately, the tolerance of the internal reference voltage can be improved to ±1.5% through MPU serial interface programming. The internal reference can be measured directly at the “V_B” pin. During final test of the telephone, the V_B internal reference voltage is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the MC13111 IC is powered up. Low Battery Detect outputs are open collector.

Power Supply Voltage

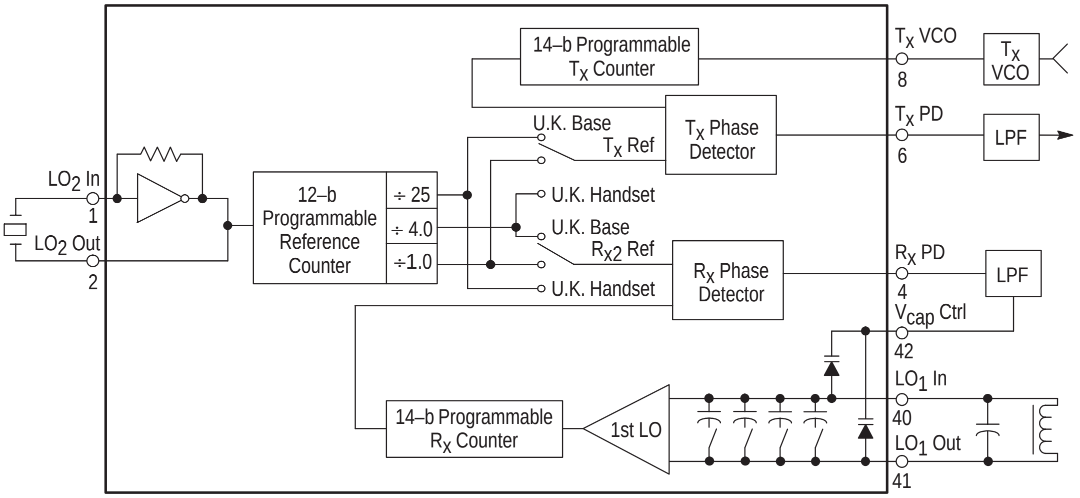
This circuit is used in a cordless telephone handset and base unit. The handset is battery powered and can operate on three NiCad cells or on 5.0 V supply.

PLL Frequency Synthesizer General Description

Figure 5 shows a simplified block diagram of the programmable universal dual phase locked loop (PLL). This dual PLL is fully programmable through the MCU serial interface and supports most country channel frequencies including USA (25 ch), Spain, Australia, Korea, New Zealand, U. K., Netherlands, France, and China.

The 2nd local oscillator and reference divider provide the reference frequency for the receive (R_X) and transmit (T_X) PLL loops. The programmed divider value for the reference divider is selected based on the crystal frequency and the desired R_X and T_X reference frequency values. Additional divide by 25 and divide by 4 blocks are provided to allow for generation of the 1.0 kHz and 6.25 kHz reference frequencies required for the U. K. The 14–bit T_X counter is programmed for the desired transmit channel frequency. The 14–bit R_X counter is programmed for the desired first local oscillator frequency. All counters power up in the proper default state for USA channel #21 (channel #6 for FCC 10 channel band) and for a 10.24 MHz reference frequency crystal. Internal fixed capacitors can be connected to the tank circuit of the 1st LO through microprocessor control to extend the sensitivity of the 1st LO for U.S. 25 channel operation.

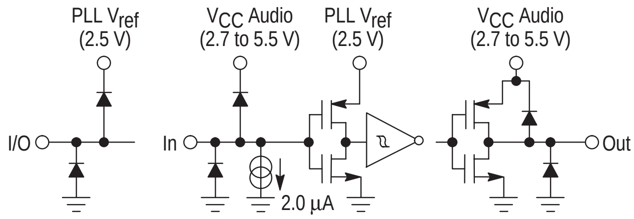
Figure 5. Dual PLL Simplified Block Diagram



PLL I/O Pin Specifications

The 2nd LO, R_X and T_X PLL's, and MPU serial interface are powered by the internal voltage regulator at the "PLL V_{ref}" pin. The "PLL V_{ref}" pin is the output of a voltage regulator which is powered from the "V_{CC} Audio" power supply pin and is regulated by an internal bandgap voltage reference. Therefore, the maximum input and output levels for most PLL I/O pins (LO_2 In, LO_2 Out, R_X PD, T_X PD, T_X VCO) is the regulated voltage at the "PLL V_{ref}" pin. The ESD protection diodes on these pins are also connected to "PLL V_{ref}". Internal level shift buffers are provided for the pins (Data, Clk, EN, Clk Out) which connect directly to the microprocessor. The maximum input and output levels for these pins is V_{CC}. Figure 6 shows a simplified schematic of the I/O pins.

Figure 6. PLL I/O Pin Simplified Schematics



LO_2 In, LO_2 Out, R_X PD, T_X PD and T_X VCO Pins

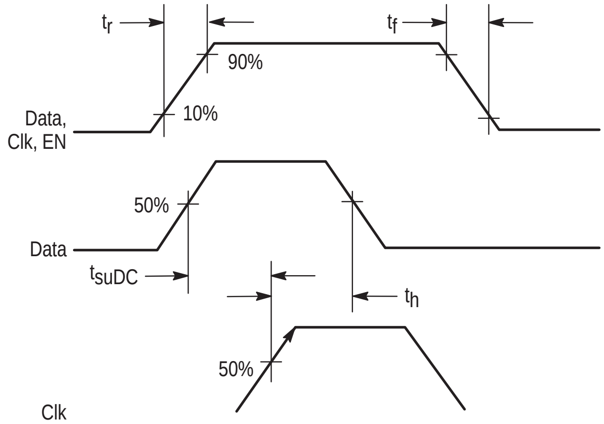
Data, Clk and EN Pins

Clk Out Pin

Microprocessor Serial Interface

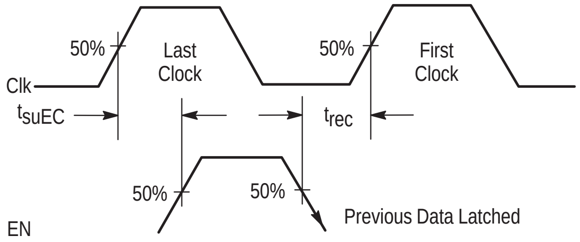
The "Data", "Clk", and "EN" pins provide an MPU serial interface for programming the reference counters, the transmit and receive channel divider counters, the switched capacitor filter clock counter, and various control functions. The "Data" and "Clk" pins are used to load data into the shift register. Figure 7 shows the timing required on the "Data" and "Clk" pins. Data is clocked into the shift register on positive clock transitions.

Figure 7. Data and Clock Timing Requirement



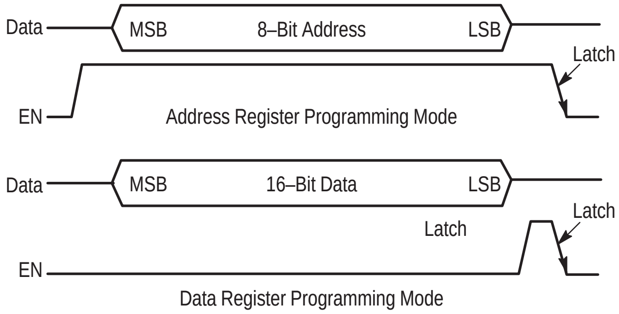
After data is loaded into the shift register, the data is latched into the appropriate latch register using the "EN" pin. This is done in two steps. First, an 8–bit address is loaded into the shift register and latched into the 8–bit address latch register. Then, up to 16–bits of data is loaded into the shift register and latched into the data latch register specified by the address that was previously loaded. Figure 5 shows the timing required on the EN pin. Latching occurs on the negative EN transition.

Figure 8. Enable Timing Requirement



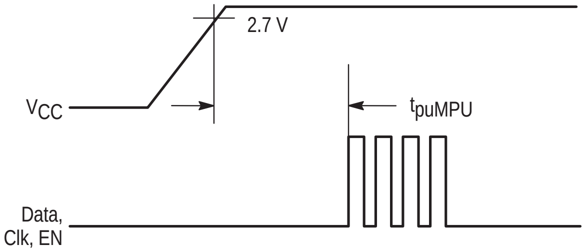
The state of the EN pin when clocking data into the shift register determines whether the data is latched into the address register or a data register. Figure 9 shows the address and data programming diagrams. In the data programming mode, there must not be any clock transitions when "EN" is high. The clock can be in a high state (default high) or a low state (default low) but must not have any transitions during the "EN" high state. The convention in these figures is that latch bits to the left are loaded into the shift register first.

Figure 9. Microprocessor Interface Programming Mode Diagrams



The MPU serial interface is fully operational within 100 µs after the power supply has reached its minimum level during power–up (see Figure 10). The MPU Interface shift registers and data latches are operational in all four power saving modes; Inactive, Standby, R_X, and Active Modes. Data can be loaded into the shift registers and latched into the latch registers in any of the operating modes.

Figure 10. Microprocessor Serial Interface Power–Up Delay



Data Registers

Figure 11 shows shows the data latch registers and addresses which are used to select each of these registers. Latch bits to the left (MSB) are loaded into the shift register first. The LSB bit must always be the last bit loaded into the shift register. Bits preceeding the register must be "0's" as shown in Figure 11.

Figure 11. Microprocessor Interface Data Latch Registers

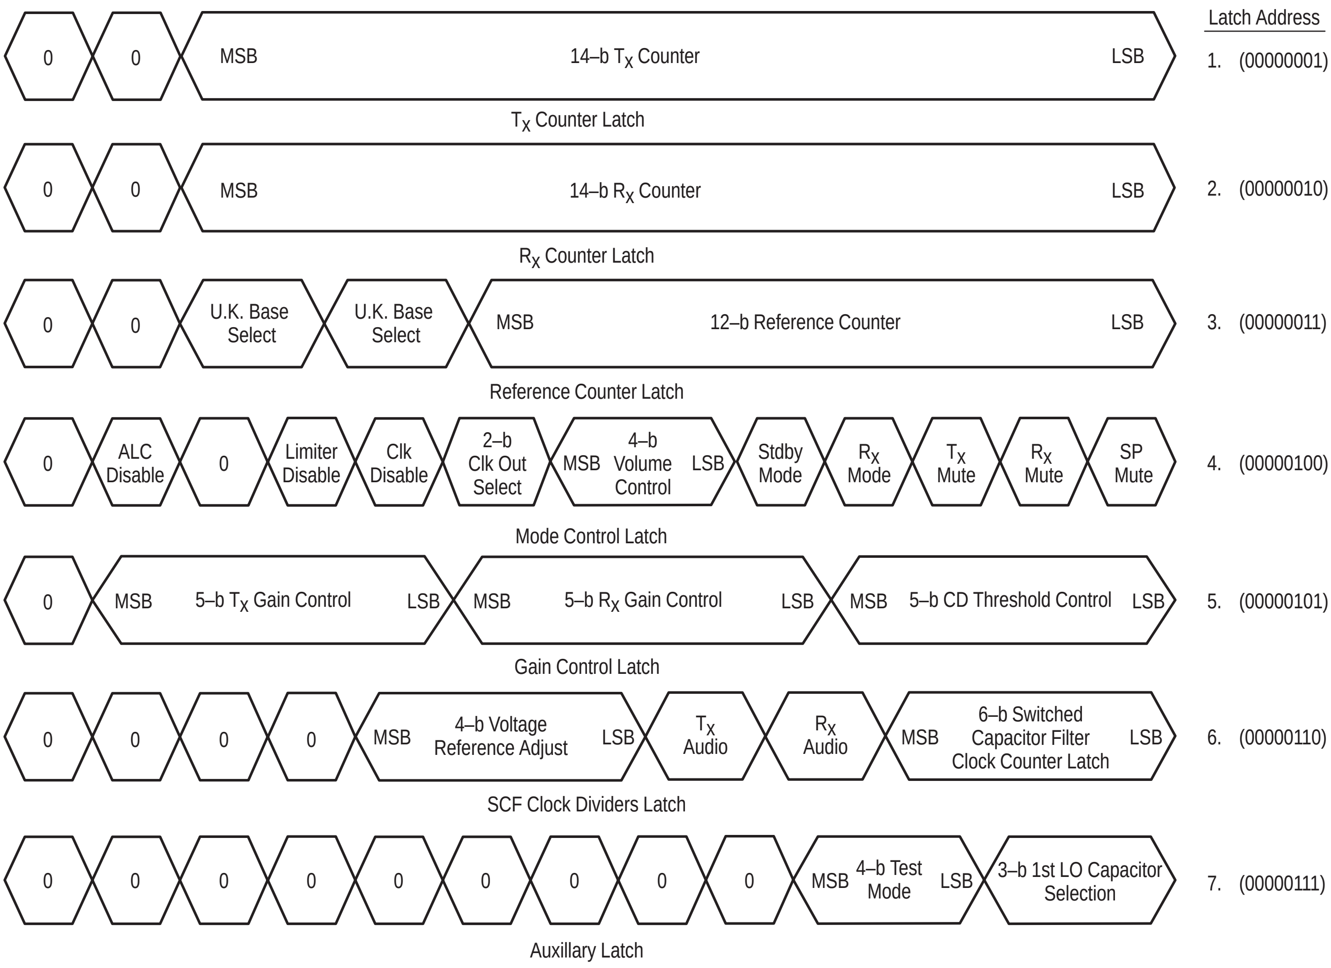


Figure 12. Reference Frequency and Reference Divider Values

Crystal Frequency	Reference Divider Value	U.K. Base/ Handset Divider	Reference Frequency	SC Filter Clock Divider	SC Filter Clock Frequency
10.24 MHz	2048	1.0	5.0 kHz	31	165.16 kHz
10.24 MHz	1024	4.0	2.5 kHz	31	165.16 kHz
11.15 MHz	2230	1.0	5.0 kHz	34	163.97 kHz
12.00 MHz	2400	1.0	5.0 kHz	36	166.67 kHz
11.15 MHz	1784	1.0	6.25 kHz	34	163.97 kHz
11.15 MHz	446	4.0	6.25 kHz	34	163.97 kHz
11.15 MHz	446	25	1.0 kHz	34	163.97 kHz

Reference Frequency Selection

The "LO$_2$ In" and "LO$_2$ Out" pins form a reference oscillator when connected to an external parallel–resonant crystal. The reference oscillator is also the second local oscillator for the RF Receiver. Figure 12 shows the relationship between different crystal frequencies and reference frequencies for cordless phone applications in various countries. "LO$_2$ In" may also serve as an input for an externally generated reference signal which is ac–coupled. The switched capacitor filter 6–bit programmable counter must be programmed for the crystal frequency that is selected since this clock is derived from the crystal frequency and must be held constant regardless of the crystal that is selected. The actual switched capacitor clock divider ratio is twice the programmed divider ratio since there is a fixed divide by 2.0 after the programmable counter.

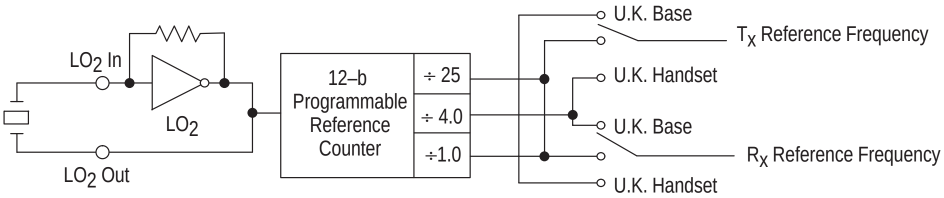
Reference Counter

Figure 13 shows how the reference frequencies for the R_X and T_X loops are generated. All countries except the U.K. require that the T_X and R_X reference frequencies be identical. In this case, set "U.K. Base Select" and "U.K. Handset Select" bits to "0". Then the fixed divider is set to "1" and the T_X and R_X reference frequencies will be equal to the crystal oscillator frequency divided by the programmable reference counter value. The U.K. is a special case which requires a different reference frequency value for T_X and R_X. For U.K. base operation, set "U.K. Base Select" to "1". For U.K. handset operation, set "U.K. Handset Select" to "1".The Netherlands is also a special case since a 2.5 kHz reference frequency is used for both the T_X and R_X reference and the total divider value required is 4096 which is larger than the maximum divide value available from the 12–bit reference divider (4095). In this case, set "U.K. Base Select" to "1" and set "U.K. Handset Select" to "1". This will give a fixed divide by 4 for both the T_X and R_X reference. Then set the reference divider to 1024 to get a total divider of 4096.

Mode Control Register

Power saving modes, mutes, disables, volume control, and microprocessor clock output frequency are all set by the Mode Control Register. Operation of the Mode Control Register is explained in Figures 14 through 21.

Figure 13. Reference Counter Register Programming Mode



U.K. Handset Select	U.K. Base Select	T_X Divider Value	R_X Divider Value	Application
0	0	1.0	1.0	All but U.K. and Netherlands
0	1	25	4.0	U.K. Base Set
1	0	4.0	25	U.K. Hand Set
1	1	4.0	4.0	Netherlands Base and Hand Set

SP Mute	1 0	Speaker Amp Muted Normal Operation

Power Saving Operating Modes

When the MC13111 is used in a handset, it is important to conserve power in order to prolong battery life. There are five modes of operation; Active, R_X, Standby, Interrupt, and Inactive. In Active mode, all circuit blocks are powered. In R_X mode, all circuitry is powered down except for those circuit sections needed to receive a transmission from the base. In the Standby and Interrupt Modes, all circuitry is powered down except for the circuitry needed to provide the clock output for the microprocessor. In Inactive Mode, all circuitry is powered down except the MPU interface. Latch memory is maintained in all modes. Figure 16 shows the control register bit values for selection of each power saving mode and Figure 17 shows the circuit blocks which are powered in each of these operating modes.

Figure 16. Power Saving Mode Selection

Stdby Mode Bit	R_X Mode Bit	"CD Out/ Hardware Interrupt" Pin	Mode
0	0	X	Active
0	1	X	R_X
1	0	X	Standby
1	1	1 or High Impedance	Inactive
1	1	0	Interrupt

Figure 17. Power Saving Modes

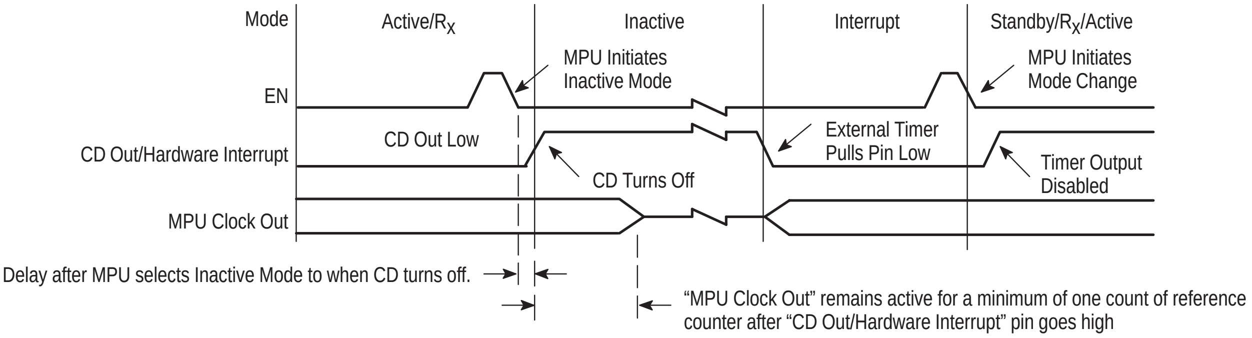
Circuit Blocks	Active	R_X	Standby	Inactive
"PLL V_{ref}" Regulated Voltage	X	X	X[1]	X[1]
MPU Interface	X	X	X	X
2nd LO Oscillator	X	X	X	
MPU Clock Output	X	X	X	
RF Receiver and 1st LO VCO	X	X		
R_X PLL	X	X		
Carrier Detect	X	X		
Data Amp	X	X		
Low Battery Detect	X	X		
T_X PLL	X			
R_X and T_X Audio Paths	X			

NOTE: In Standby and Inactive Modes, "PLL V_{ref}" remains powered but is not regulated. It will fluctuate with V_{CC}.

Inactive Mode Operation and Hardware Interrupt

In some handset applications it may be desirable to power down all circuitry including the microprocessor (MPU). First put the combo IC into the Inactive mode, which turns off the MPU Clock Output (see Figure 18), and then disable the microprocessor. In order to give the MPU adequate time to power down, the MPU Clock output remains active for a minimum of one reference counter cycle (about 200 µs) after the command is given to switch into the "Inactive" mode. An external timing circuit should be used to initiate the turn–on sequence. The "CD Out" pin has a dual function. In the Active and R_X modes it performs the carrier detect function. In the Standby and Inactive modes the carrier detect circuit is disabled and the "CD Out" pin is in a "High" state due to the external pull–up resistor. In the Inactive mode, the "CD Out" pin is the input for the hardware interrupt function. When the "CD Out" pin is pulled "low" by the external timing circuit, the combo IC switches from the Inactive to the Interrupt mode thereby turning on the MPU Clock Output. The MPU can then resume control of the combo IC. The "CD Out" pin must remain low until the MPU changes the operating mode from Interrupt to Standby, Active or R_X modes.

Figure 18. Hardware Interrupt Operation



MPU “Clk Out” Divider Programming

This pin is a clock output which is derived from the crystal oscillator (2nd local oscillator). It can be used to drive a microprocessor and thereby reduce the number of crystals required. Figure 19 shows the relationship between the crystal frequency and the clock output for different divider values. Figure 20 shows the “Clk Out” register bit values.

Figure 19. Clock Output Values

Crystal Frequency	Clock Output Divider			
	2	**3**	**4**	**5**
10.24 MHz	5.120 MHz	3.413 MHz	2.560 MHz	2.048 MHz
11.15 MHz	5.575 MHz	3.717 MHz	2.788 MHz	2.230 MHz
12.00 MHz	6.000 MHz	4.000 MHz	3.000 MHz	2.400 MHz

MPU “Clk Out” Radiated Noise on Circuit Board

The clock line running between the MC13111 and the microprocessor has the potential to radiate noise which can cause problems in the system especially if the clock is a square wave digital signal with large high frequency harmonics. In order to minimize radiated noise, a 1.0 kΩ resistor is included on–chip in series with the “Clk Out” output driver. A small capacitor can be connected to the “Clk Out” line on the PCB to form a single pole low pass filter. This filter will significantly reduce noise radiated from the “Clk Out” line.

Volume Control Programming

The volume control adjustable gain block can be programmed in 2.0 dB gain steps from –14 dB to +16 dB. The power–up default value is 0 dB. (See Figure 21.)

Figure 20. Clock Output Divider

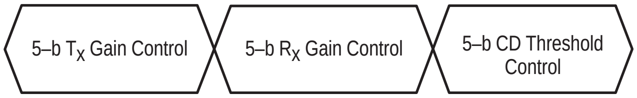
1	1	0	1	13	12 dB
1	1	1	0	14	14 dB
1	1	1	1	15	16 dB

Gain Control Register

The gain control register contains bits which control the T_X Voltage Gain, R_X Voltage Gain, and Carrier Detect threshold. Operation of these latch bits are explained in Figures 22, 23 and 24.

Figure 22. Gain Control Latch Bits



T_X and R_X Gain Programming

The T_X and R_X audio signal paths each have a programmable gain block. If a T_X or R_X voltage gain other than the nominal power–up default is desired, it can be programmed through the MPU interface. Alternately, these programmable gain blocks can be used during final test of the telephone to electronically adjust for gain tolerances in the telephone system as shown in Figure 23. In this case, the T_X and R_X gain register values should be stored in ROM during final test so that they can be reloaded each time the combo IC is powered up.

Figure 23. T_X and R_X Gain Control

1	1	1	1	1	31	16 dB

Carrier Detect Threshold Programming

The “CD Out” pin gives an indication to the microprocessor if a carrier signal is present on the selected channel. The nominal value and tolerance of the carrier detect threshold is given in the carrier detect specification section of this document. If a different carrier detect threshold value is desired, it can be programmed through the MPU interface as shown in Figure 24. Alternately, the carrier detect threshold can be electronically adjusted during final test of the telephone to reduce the tolerance of the carrier detect threshold. This is done by measuring the threshold and then by adjusting the threshold through the MPU interface. In this case, it is necessary to store the carrier detect register value in ROM so that the CD register can be reloaded each time the combo IC is powered up.

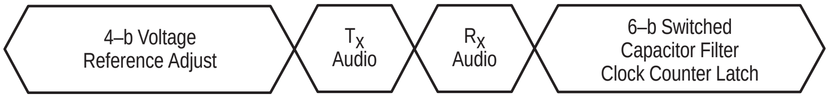
Figure 25. SCF Clock Divider Latch Bits



SCF Clock Divider

This register controls the divider value for the programmable switched capacitor filter clock divider and the voltage reference adjust. Operation is explained in Figures 25 through 30.

Figure 26. Audio Mode Bit Description

T_X Mode	1 0	Normal T_X Path Operation Undefined State
R_X Mode	1 0	Normal R_X Path Operation Undefined State

NOTES: Power–up bit default mode is “0”. Must change bit to “1” for proper operation.

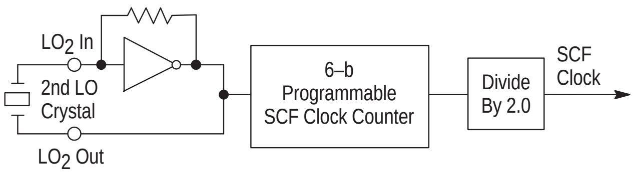
Switched Capacitor Filter Clock Programming

A block diagram of the switched capacitor filter clock dividers is shown in Figure 27. There is a fixed divide by 2 after the programmable divider. The switched capacitor filter clock value is given by the following equation;

$$(\text{SCF Clock}) = F(\text{2nd LO})/(\text{SCF Divider Value} * 2)$$

The SCF divider should be set to a value which gives a SCF Clock as close to 165.16 kHz as possible based on the 2nd LO frequency which is chosen (see Figure 12).

Figure 27. SCF Clock Circuit



Corner Frequency Programming

Four different corner frequencies may be selected by programming the SCF Clock divider as shown in Figures 28 and 29. Note that all filter corner frequencies change proportionately with the SCF Clock Frequency. The power–up default SCF Clock divider is 31.

Figure 28. Corner Frequency Programming for a 10.240 MHz 2nd LO

SCF Clock Divider	Total Divide Value	SCF Clock Freq. (kHz)	R_X Upper Corner Frequency (kHz)	T_X Upper Corner Frequency (kHz)
29	58	176.55	4.147	3.955
30	60	170.67	4.008	3.823
31	62	165.16	3.879	3.700
32	64	160.00	3.758	3.584

NOTE: All filter corner frequencies have a tolerance of ±3%.

35	70	159.29	3.741	3.568

NOTE: All filter corner frequencies have a tolerance of ±3%.

Voltage Reference Adjustment

The internal 1.5 V Bandgap voltage reference provides the voltage reference for the “BD1 Out” and “BD2 Out” low battery detect circuits, the “PLL V_{ref}” voltage regulator, the “V_B” reference, and all internal analog ground references. The initial tolerance of the Bandgap voltage reference is ±6%. The tolerance of the internal reference voltage can be improved to ±1.5% through MPU serial interface programming.

During final test of the telephone, the battery detect threshold is measured. Then, the internal reference voltage value is adjusted electronically through the MPU serial interface to achieve the desired accuracy level. The voltage reference register value should be stored in ROM during final test so that it can be reloaded each time the MC13111 is powered up (see Figure 30).

Figure 30. Bandgap Voltage Reference Adjustment

Auxiliary Register

The auxiliary register contains a 3–bit 1st LO Capacitor Selection latch and a 4–bit Test Mode latch. Operation of these latch bits are explained in Figures 31, 32 and 34.

Figure 31. Auxiliary Register Latch Bits

First Local Oscillator Programmable Selection (U.S. Applications)

There is a very large frequency difference between the minimum and maximum channel frequencies in the 25 Channel U.S. Standard.The sensitivity of the 1st LO may not be large enough to accommodate this large frequency variation. Fixed capacitors can be connected across the 1st LO tank circuit to change the 1st LO sensitivity. Internal switches and capacitors are provided to enable microprocessor control over internal fixed capacitor values. Figures 32 and 33 show the schematic representation of the 1st LO and the tank circuit. Figure 34 shows the latch control bit values for microprocessor control.

8	1	0	0	0	Divide by 4, 25	0 to 2.5 V	Input Frequency/100
9	1	0	0	1	SC Counter	0 to 2.5 V	Input Frequency/SC Counter Value
10	1	0	1	0	Not Used	N/A	–

NOTE: To determine the correct output, look at the lower 8–bits in the R_X or T_X register (Divisor (7;0). If the value of the divisor is > 16, then the output divisor value is Divisor (7;2) (the upper 6–bits of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) > = 2, then output divisor value is Divisor (3;2) (bits 2 and 3 of the divisor). If Divisor (7;0) < 16 and Divisor (3;2) < 2, then output divisor value is (Divisor (3;2) + 60).

15	1	1	1	1	Not Used	N/A	N/A

Test Modes

Digital and analog test modes can be selected through the 4–bit Test Mode Register. In digital test mode, the “T_X V_{CO}” input pin is multiplexed to the input of the counter under test and the output of the counter under test is multiplexed to the “Clk Out” output pin so that each counter can be individually tested. Make sure test mode bits are set to “0’s” for normal operation. Digital test mode operation is described in Figure 35. During normal operation and when testing the T_X Prescaler, the “T_X VCO” input can be a minimum of 200 mVpp at 80 MHz and should be ac–coupled. For other test modes, input signals should be standard logic levels of 0 to 2.5 V and a maximum frequency of 16 MHz.

The analog test modes enable separate testing of the Compressor blocks as shown in Figure 36. Also, ALC Gain options can be selected through analog test modes.

Power–Up Defaults for Control and Counter Registers

When the IC is first powered up, all latch registers are initialized to a defined state. The device is initially placed in the Rx mode with all mutes active. The reference counter is set to generate a 5.0 kHz reference frequency from a 10.24 MHz crystal. The switched capacitor filter clock counter is set properly for operation with a 10.24 MHz crystal. The audio mode will come up in an undefined state and must be set to a bit format shown in Figure 26 for proper operation. The T_X and R_X latch registers are set for USA Channel Frequency 21 (Channel 6 for previous FCC 10 Channel Band). Figure 37 shows the initial power–up states for all latch registers.

Figure 37. Latch Register Power–Up Defaults

Register	Count	MSB								LSB							
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

NOTE: Bits 6 and 7 in the SC latch register must be set to “1” after power–up for proper operation.

APPLICATIONS INFORMATION

Evaluation PC Board

The PCB should be double sided with a full ground plane on one side; any leaded components are inserted on the ground plane side. This affords shielding and isolation from the circuit side of the PCB. The other side is the circuit side which has the interconnect traces and the surface mount components. In cases where cost allows, it may be benificial to use multi layer boards.

The placement of certain components specified in the application circuits is very critical. These components should be placed first and the other less critical components are fitted in last. In general, all RF paths should be kept as short as possible, ground pins should be grounded at the pins and V_{CC} pins should have adequate decoupling to ground at the pins. In mixed mode systems where digital and RF/Analog circuitry are present, the V_{EE} and V_{CC} busses are isolated ac –wise from each other.

Component Selection

The evaluation PC board is designed to accommodate specific components, while in some cases it is versatile enough to use components from various manufacturers and coil types. The application circuit schematics specify particular components that were used to achieve the results shown in the typical curves and tables, but alternate components should give similar results.

The MC13111 IC is capable of matching the sensitivity, IMD, adjacent channel rejection, and other performance criteria of a multi–chip analog cordless telephone system. For the most part, the same external components are used as in the multi–chip solution. In the following discussion, various parts of the system are analyzed for best peformance and cost tradeoffs. Specific recommendations are made where certain components or circuit designs offer superior performance. The system analyzed is the USA “CT–1” cordless phone. (CT–0 is a similar cordless application in Europe.)

Input Matching/Sensitivity

The sensitivity of the IC is typically 0.56 µVrms matched with no preamp. To achieve suitable system performance, a preamp and passive duplexer must be used. In production final test, each section of the IC is separately tested to guarantee its system performance in the specific application. The preamp and duplexer (differential, matched input) yields typically –114 dBm 12 dB SINAD sensitivity performance under full duplex operation.

The duplexer is important to achieve full duplex operation without significant “de–sensing” of the receiver by the transmitter. The combination of the duplexer and preamp circuit will attenuate the transmitter power to the receiver by over 60 dB. This will improve the receiver system noise figure without giving up too much IMD intermodulation performance.

The duplexer may be a single piece unit offered by Shimida and Sansui products (designed for 10 channel CT–1 cordless phone) or a two piece solution offered by Toko (designed for 25 channel operation). The duplexer frequency response at the receiver port has a notch at the transmitter frequency band of about 35 to 40 dB with a 2.0 to 3.0 dB insertion loss at the receiver frequency band.

The preamp circuit utilizes a tuned transformer at the output side of the amplifier. This transformer is designed to bandpass filter at the receiver input frequency while rejecting the transmitter frequency. The tuned preamp also improves the noise performance by reducing the bandwidth of the pass band and reducing the second stage contribution of the 1st mixer. The preamp is biased at about 1.0 mA and 3.0 Vdc which yields suitable noise figure and gain.

Mixers

The 1st and 2nd mixers are similar in design. Both are double balanced to suppress the LO and the input frequencies to give only the sum and difference frequencies out. Typically the LO is suppressed about 40 to 60 dB. The 1st mixer may be driven either differentially or single ended. The gain of the 1st mixer has a 3.0 dB corner at 20 MHz and is used at a 10.7 MHz IF. It has an output impedance of 330 Ω and matches to a typical 10.7 MHz ceramic filter with a source and load impedance of 330 Ω. A series resistor may be used to raise the impedance for use with crystal filters which typically have an input impedance much greater than 330 Ω. The 2nd mixer input impedance is typically 3.0 kΩ; it requires an external 360 Ω parallel resistor for use with a standard 330 Ω 10.7 MHz ceramic filter. The second mixer output impedance is 1.5 kΩ making it suitable to match 455 kHz ceramic filters.

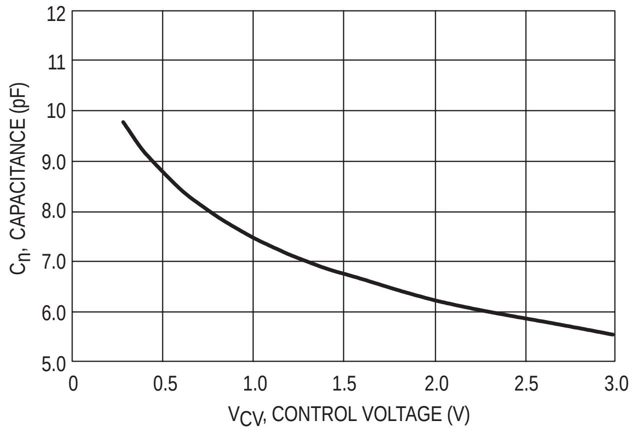
The following table is a list of typical input impedances over frequency for the 1st Mixer. R_P and C_P are represented in parallel form.

Frequency (MHz)	R_P (Ω)	C_P (pF)
20	977.7	2.44
25	944.3	2.60
30	948.8	2.65
35	928	2.55
40	900	2.51
45	873.4	2.65
50	859.3	2.72
55	821	2.72
60	795	2.74

First Local Oscillator

The 1st LO is a multi–vibrator oscillator that takes an external capacitance and inductance. It is voltage controlled to an internal varactor from an external loop filter and an on–board phase–lock loop (PLL). The schematic in Figure 33 shows all the basic parasitic elements of the internal circuitry. The 1st LO internal component values have a tolerance of 15%. A typical dc bias level on the LO Input and LO Output is 0.45 Vdc. The temperature coefficient of the varactor is +0.09%/°C. The curve in Figure 38 is the varactor control voltage range as it relates to capacitance. It represents the expected capacitance for a given control voltage of the MC13111.

Figure 38. First Local Oscillator Varacter versus Control Voltage



Second Local Oscillator

The 2nd LO is a CMOS oscillator similar to that used in the MC145162. The 2nd LO is also used as the PLL reference oscillator. It is designed to utilize an external parallel resonant crystal.

PLL Design

The 1st LO level is important, as well as the choice of the crystal for the PLL clock reference and 2nd LO. A fundamental, parallel resonant crystal specified with 7.0 to 12 pF load calibration capacitance is recommended. If the load calibration capacitance is too high, the crystal locks up very slowly. If the LO power is less than –10 dBm, a pull–down resistor at the 1st LO emitter (Pin 41) will increase its drive level. The LO level is primarily a function of the Colpitts capacitive voltage divider formed by the capacitors between the base to emitter and the emitter to ground.

The VCO gain factor expressed in MHz/V is indeed critical to the phase noise performance. If this curve is too steep or too sensitive to changes in control voltage, it may degrade the phase noise performance. The external VCO circuit design needs to consider the typical swing of the control voltage and the corresponding linearity of the transfer function, $\Delta f_{osc}/\Delta V_{control}$. In general, the higher the Q of the VCO circuit inductor, the better phase noise performance.

Adjacent channel rejection and isolation between the 1st and 2nd mixers may be adversely affected due to layout problems and difficulty in getting up close to the package pins with the grounds and decoupling capacitors on the RF V_{CC}. These system parameters must be evaluated for sensitivity to layout and external component placement.

Intermodulation and adjacent channel performance problems may also result from spurs around the 1st LO. This may be caused by harmonics from the switched capacitor clock driver and too low 1st LO drive level. The clock driver operates at a frequency which is f(2nd LO)/(2 * (SCF Divider)). The harmonics are n * (f(2nd LO)), where n can be any positive integer. The current spikes of the SCF on the supply lines cause the disturbance of the 1st LO. This may be verified by observing the spurs on a spectrum analyzer while changing the clock divider value. The spur frequencies will change when the divider value is changed. The spurious sideband problem may be avoided by changing the clock divider value via software for each channel where it is a problem. Certain channels are worse than others. Refer to the MC145162 data sheet for PLL design example.

Limiting IF Amplifiers

The limiting IF amplifier typically has about 110 dB of gain; the frequency response starts rolling off at 1.0 MHz. Decoupling capacitors should be placed close to Pins 31 and 32 to ensure low noise and stable operation. The IF input impedance is 1.5 kΩ for a suitable match to 455 kHz ceramic filters.

RSSI/Carrier Detect

The Received Signal Strength Indicator (RSSI) indicates the strength of the IF level and the output is proportional to the logarithm of the IF input signal magnitude. The RSSI dynamic range is typically 80 dB. Connect 0.01 µF to GND from “RSSI” output pin to form the carrier detect filter. A resistor needed to convert the RSSI current to voltage is included in the internal circuit. An internal temperature compensated reference current also improves the RSSI accuracy over temperature.

“CD Out” is an open collector output; thus, an external 100 kΩ pull–up resistor to V_{CC} is recommended. The carrier detect threshold is programmable through the MPU interface.

Quadrature Detector

The quadrature detector is coupled to the IF with an external capacitor between Pins 27 and 28; thus, the recovered signal level output is increased for a given bandwidth by increasing the capacitor. The external quadrature component may be either a LCR resonant circuit, which may be adjustable, or a ceramic resonator which is usually fixed tuned.

The bandwidth performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

(1) $R_T = Q\,X_L$

where R_T is the equivalent shunt resistance across the LC Tank. X_L is the reactance of the quadrature inductor at the IF frequency ($X_L = 2\pi fL$).

Specific 455 kHz quadrature LC components are manufactured by Toko in various 5 mm, 7 mm and 10 mm shielded cans in surface mount or leaded packages. Recommended components such as, the 7 mm Toko, is used in the application circuit. When minaturization is a key constraint, a surface mount inductor and capacitor may be chosen to form a resonant LC tank with the PCB and parasitic device capacitance. The 455 kHz IF center frequency is calculated by

(2) $f_c = [2\pi\,(LC_p)^{1/2}] - 1$

where L is the parallel tank inductor. C_p is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a detector at 455 kHz and a specific loaded Q. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 455 kHz and an IF bandpass of 20 kHz, the IF bandpass Q is approximately 23; the loaded Q of the quadrature tank is chosen at 15.

Example:

Let the total external C = 180 pF. Note: the capacitance may be split between a 150 pF chip capacitor and a 5.0 to 25 pF variable capacitor; this allows for tuning to compensate for component tolerance. Since the external capacitance is much greater than the internal device and PCB parasitic capacitance, the parasitic capacitance may be neglected.

Rewrite equation (2) and solve for L:

$L = (0.159)^2/(C\,fc^2)$
$L = 678\ \mu H$; Thus, a standard value is chosen:
$L = 680\ \mu H$ (surface mount inductor)

The value of the total damping resistor to obtain the required loaded Q of 15 can be calculated from equation (1):

$R_T = Q(2\pi fL)$
$R_T = 15\ (2\pi)(0.455)(680) = 29.5\ k\Omega$

The internal resistance, R_{int} at the quadrature tank Pin 27 is approximately 100 kΩ and is considered in determining the external resistance, R_{ext} which is calculated from

$R_{ext} = ((R_T)(R_{int}))/(R_{int} - R_T)$
$R_{ext} = 41.8\ k\Omega$; Thus, choose the standard value:
$R_{ext} = 39\ k\Omega$

A ceramic discriminator is recommended for the quadrature circuit in applications where fixed tuning is desired. The ceramic discriminator and a 22 k resistor are placed from Pin 27 to V_{CC}. A 10 pF capacitor is placed from Pin 28 to 27 to properly drive the discriminator.

MuRata Erie has designed a resonator that is compatible with the IC. For US applications the part number is CDBM455C48. For Europe the part number is CDBM450C48. Contact Motorola Analog Marketing for performance data using muRata's parts.

APPENDIX C – MEASUREMENT OF COMPANDOR ATTACK/DECAY TIME

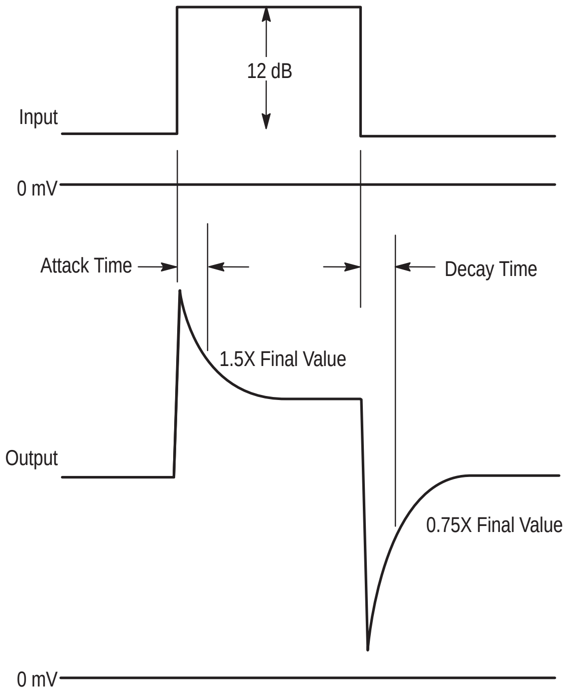
This measurement definition is based on EIA/CCITT recommendations.

Compressor Attack Time

For a 12 dB step up at the input, attack time is defined as the time for the output to settle to 1.5X of the final steady state value.

Compressor Decay Time

For a 12 dB step down at the input, decay time is defined as the time for the input to settle to 0.75X of the final steady state value.

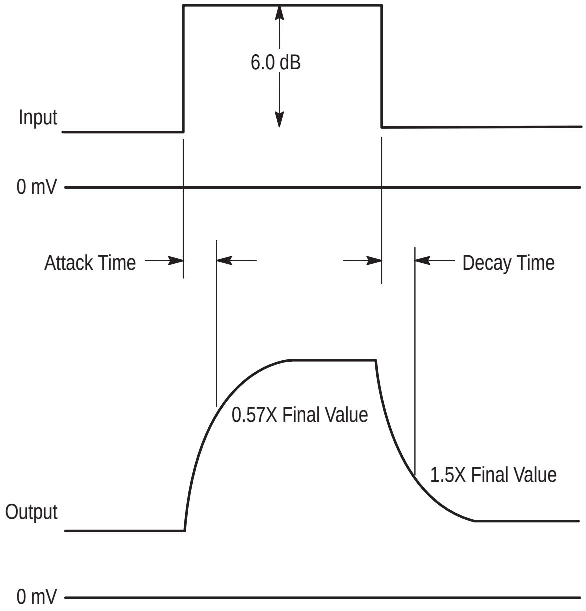


Expandor Attack

For a 6.0 dB step up at the input, attack time is defined as the time for the output to settle to 0.57X of the final steady state value.

Expandor Decay

For a 6.0 dB step down at the input, decay time is defined as the time for the output to settle to 1.5X of the final steady state value.



MOTOROLA

FM Communications Receivers

MC13135
MC13136

The MC13135/MC13136 are the second generation of single chip, dual conversion FM communications receivers developed by Motorola. Major improvements in signal handling, RSSI and first oscillator operation have been made. In addition, recovered audio distortion and audio drive have improved. Using Motorola's MOSAIC™ 1.5 process, these receivers offer low noise, high gain and stability over a wide operating voltage range.

Both the MC13135 and MC13136 include a Colpitts oscillator, VCO tuning diode, low noise first and second mixer and LO, high gain limiting IF, and RSSI. The MC13135 is designed for use with an LC quadrature detector and has an uncommitted op amp that can be used either for an RSSI buffer or as a data comparator. The MC13136 can be used with either a ceramic discriminator or an LC quad coil and the op amp is internally connected for a voltage buffered RSSI output.

These devices can be used as stand–alone VHF receivers or as the lower IF of a triple conversion system. Applications include cordless telephones, short range data links, walkie–talkies, low cost land mobile, amateur radio receivers, baby monitors and scanners.

- Complete Dual Conversion FM Receiver – Antenna to Audio Output
- Input Frequency Range – 200 MHz
- Voltage Buffered RSSI with 70 dB of Usable Range
- Low Voltage Operation – 2.0 to 6.0 Vdc (2 Cell NiCad Supply)
- Low Current Drain – 3.5 mA Typ
- Low Impedance Audio Output < 25 Ω
- VHF Colpitts First LO for Crystal or VCO Operation
- Isolated Tuning Diode
- Buffered First LO Output to Drive CMOS PLL Synthesizer

TEST CIRCUIT INFORMATION

Although the MC13136 can be operated with a ceramic discriminator, the recovered audio measurements for both the MC13135 and MC13136 are made with an LC quadrature detector. The typical recovered audio will depend on the external circuit; either the Q of the quad coil, or the RC matching network for the ceramic discriminator. On the MC13136, an external capacitor between Pins 13 and 14 can be used with a quad coil for slightly higher recovered audio. See Figures 10 through 13 for additional information.

Since adding a matching circuit to the RF input increases the signal level to the mixer, the third order intercept (TOI) point is better with an unmatched input (50 Ω from Pin 21 to Pin 22). Typical values for both have been included in the Electrical Characterization Table. TOI measurements were taken at the pins with a high impedance probe/spectrum analyzer system. The first mixer input impedance was measured at the pin with a network analyzer.

CIRCUIT DESCRIPTION

The MC13135/13136 are complete dual conversion receivers. They include two local oscillators, two mixers, a limiting IF amplifier and detector, and an op amp. Both provide a voltage buffered RSSI with 70 dB of usable range, isolated tuning diode and buffered LO output for PLL operation, and a separate V_{CC} pin for the first mixer and LO. Improvements have been made in the temperature performance of both the recovered audio and the RSSI.

V_{CC}

Two separate V_{CC} lines enable the first LO and mixer to continue running while the rest of the circuit is powered down. They also isolate the RF from the rest of the internal circuit.

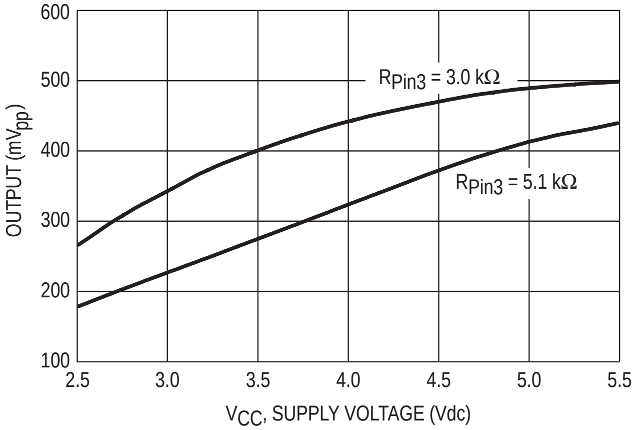
Local Oscillators

The local oscillators are grounded collector Colpitts, which can be easily crystal–controlled or VCO controlled with the on–board varactor and external PLL. The first LO transistor is internally biased, but the emitter is pinned–out and I_Q can be increased for high frequency or VCO operation. The collector is not pinned out, so for crystal operation, the LO is generally limited to 3rd overtone crystal frequencies; typically around 60 MHz. For higher frequency operation, the LO can be provided externally as shown in Figure 16.

Buffer

An amplifier on the 1st LO output converts the single–ended LO output to a differential signal to drive the mixer. Capacitive coupling between the LO and the amplifier minimizes the effects of the change in oscillator current on the mixer. Buffered LO output is pinned–out at Pin 3 for use with a PLL, with a typical output voltage of 320 mV_{pp} at V_{CC} = 4.0 V and with a 5.1 k resistor from Pin 3 to ground. As seen in Figure 14, the buffered LO output varies with the supply voltage and a smaller external resistor may be needed for low voltage operation. The LO buffer operates up to 60 MHz, typically. Above 60 MHz, the output at Pin 3 rolls off at approximately 6.0 dB per octave. Since most PLLs require about 200 mV_{pp} drive, an external amplifier may be required.

Figure 14. Buffered LO Output Voltage versus Supply Voltage



Mixers

The first and second mixer are of similar design. Both are double balanced to suppress the LO and input frequencies to give only the sum and difference frequencies out. This configuration typically provides 40 to 60 dB of LO suppression. New design techniques provide improved mixer linearity and third order intercept without increased noise. The gain on the output of the 1st mixer starts to roll off at about 20 MHz, so this receiver could be used with a 21 MHz first IF. It is designed for use with a ceramic filter, with an output impedance of 330 Ω. A series resistor can be used to raise the impedance for use with a crystal filter, which typically has an input impedance of 4.0 kΩ. The second mixer input impedance is approximately 4.0 kΩ; it requires an external 360 Ω parallel resistor for use with a standard ceramic filter.

Limiting IF Amplifier and Detector

The limiter has approximately 110 dB of gain, which starts rolling off at 2.0 MHz. Although not designed for wideband operation, the bandwidth of the audio frequency amplifier has been widened to 50 kHz, which gives less phase shift and enables the receiver to run at higher data rates. However, care should be taken not to exceed the bandwidth allowed by local regulations.

The MC13135 is designed for use with an LC quadrature detector, and does not have sufficient drive to be used with a ceramic discriminator. The MC13136 was designed to use a ceramic discriminator, but can also be run with an LC quad coil, as mentioned in the Test Circuit Information section. The data shown in Figures 12 and 13 was taken using a muRata CDB455C34 ceramic discriminator which has been specially matched to the MC13136. Both the choice of discriminators and the external matching circuit will affect the distortion and recovered audio.

RSSI/Op Amp

The Received Signal Strength Indicator (RSSI) on the MC13135/13136 has about 70 dB of range. The resistor needed to translate the RSSI current to a voltage output has been included on the internal circuit, which gives it a tighter tolerance. A temperature compensated reference current also improves the RSSI accuracy over temperature. On the MC13136, the op amp on board is connected to the output to provide a voltage buffered RSSI. On the MC13135, the op amp is not connected internally and can be used for the RSSI or as a data slicer (see Figure 17c).

Low Power DC - 1.8 GHz LNA and Mixer

LOW POWER DC – 1.8 GHz LNA AND MIXER

SEMICONDUCTOR TECHNICAL DATA

The MC13141 is intended to be used as a first amplifier and down converter for RF applications. It features wide band operation, low noise, high gain and high linearity while maintaining low current consumption. The circuit consists of a Low Noise Amplifier (LNA), a Local Oscillator amplifier (LO_{amp}), a mixer, an Intermediate Frequency amplifier (IF_{amp}) and a dc control section.

- Wide RF Bandwidth: DC–1.8 GHz
- Wide Mixer Bandwidth: DC–1.8 GHz
- Wide IF Bandwidth: DC–100 MHz
- Low Power: 7.7 mA @ V_{CC} = 2.7–6.5 V
- High Mixer Linearity: $P_{i1.0\ dB}$ = –2.0 dBm, IP_{3in} = 3.0 dBm
- Linearity Adjustment Increases IP_{3in} (Not Available in SOIC8) Up to +20 dBm
- Single–Ended 50 Ω Mixer Input
- Double Balanced Mixer Operation
- Single–Ended 800 Ω Mixer Output
- Single–Ended 50 Ω LO Input

CIRCUIT DESCRIPTION

General

The MC13141 is a low power LNA, double–balanced mixer. This device is designated for use as the front–end section in analog and digital FM systems such as Digital European Cordless Telephone (DECT), PHS, PCS, Cellular, UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services and 902 to 928 MHz cordless telephones. It features a mixer linearity control to preset or auto preset or auto program the mixer dynamic range, an enable function and buffered IF output for increased overall gain. Further details are covered in the Pin Function Description which shows the equivalent internal circuit and external circuit requirements.

Current Regulation/Enable

Temperature compensating voltage independent current regulators are controlled by the the enable function in which “high” powers up the IC.

Low Noise Amplifier (LNA)

The LNA is internally biased at low supply current (approximately 2.0 mA emitter current) for optimal noise figure and gain. Input and output matching may be achieved at various frequencies using few external components (see Application Circuit). Matching the LNA for maximum stable gain (MSG) yields noise performance within a few tenths of a dB of the minimum noise figure. Typical performance at 1.0 GHz is 17 dB gain and 1.8 dB noise figure for Vcc at 3.0 to 5.0 Vdc.

Mixer

The mixer is a double–balanced four quadrant multiplier biased class AB allowing for programmable linearity control via an external current source. An input third order intercept point of 20 dBm may be achieved. All 3 ports of the mixer are designed to work up to 1.8 GHz. The mixer has a 50 Ω single–ended RF input and IF output buffer amplifier. The linear gain of the mixer is approximately 7.0 dB with a SSB noise figure of 16 dB.

Local Oscillator

It requires an external local oscillator source at –10 dBm input level to maximize the mixer gain.

PIN FUNCTION DESCRIPTION

14 Pin SOIC	20 Pin TQFP	Symbol	Equivalent Internal Circuit (20 Pin TQFP)	Functional Description/External Circuit Requirements
4	6	RF_{in}	 	**RF Input** The input is the base of an NPN low noise amplifier. Minimum external matching is required to optimize the input return loss and gain.
2, 3	4, 5	V_{CC}		**V_{CC} – Positive Supply Voltage** Two V_{CC} pins are provided for the Local Oscillator and LO Buffer Amplifier. The operating supply voltage range is from 2.7 Vdc to 6.5 Vdc. In the PCB layout, the V_{CC} trace must be kept as wide as feasible to minimize inductive reactances along the trace. V_{CC} should be decoupled to V_{EE} at the IC pin as shown in the component placement view.
1, 5	2, 3, 7 and 8	V_{EE}		**V_{EE} – Negative Supply** V_{EE} pin is taken to an ample dc ground plane through a low impedance path. The path should be kept as short as possible. A two sided PCB is implemented so that ground returns can be easily made through via holes.
14	1	RF_{out}		**RF Output** The output is from the collector of the LNA. As shown in the 926 MHz application receiver the output is conjugately matched with a shunt L, and series L and C network.
7	11	LO		**Local Oscillator Input** 50 Ω single–ended buffered LO input.

PIN FUNCTION DESCRIPTION (continued)

14 Pin SOIC	20 Pin TQFP	Symbol	Equivalent Internal Circuit (20 Pin TQFP)	Functional Description/External Circuit Requirements
5, 6	9, 10, 12, 14	V_{EE}		**V_{EE} – Negative Supply** These pins are V_{EE} supply for the IF and LO. In the application PC board these pins are tied to a common V_{EE} trace with other V_{EE} pins.
8	13	IF		**IF Output** The IF is a 800 Ω single–ended output which must be externally matched to 50 Ω for optimal performance.
10	16	RF_m		**Mixer RF Input** The mixer input impedance is broadband 50 Ω for applications up to 1.8 GHz. It easily interfaces with a RF ceramic filter as shown in the application schematic. The pin dc bias is set at 1.0 Vbe.
11	17	Mix Lin Cont		**Mixer Linearity Control** The mixer linearity control circuit accepts approximately 0 to 2.3 mA control current to set the dynamic range of the mixer. An Input Third Order Intercept Point, IIP3 of 20 dBm may be achieved at 2.3 mA of control current (approximately 7.0 mA of additional supply current). The pin dc bias is set at 2.0 Vbe.
12	18, 19	V_{EE}		**V_{EE} – Negative Supply** These pins are V_{EE} supply for the mixer input.
13	20	EN		**Enable** The device is enabled by pulling up to V_{CC} or greater than 2.0 Vbe.

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board accommodates all SMT components on the circuit side (see Circuit Side Component Placement View). This evaluation board will be discussed and referenced in this section.

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. The circuit side placement view is illustrated for the components specified in the application circuit. The application circuit schematic specifies particular components that were used to achieve the results given and specified in the tables but alternate components of the same Q and value should give similar results.

Capacitors should be 0805 size; the 6.8 nH inductor is a Toko type LL2012.

Input Matching/Components

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. The PC board layout accommodates both ceramic and SAW RF filters which are offered by various suppliers such as Siemens, Toko and Murata. Interface matching between the LNA, RF filter and the mixer will be required. The interface matching networks shown in the application circuit are designed for 50 Ω interfaces.

The LNA is conjugately matched to 50 Ω input and output at 3.0 Vdc V_{CC}. 17 dB gain and 1.8 dB noise figure is typical at 881.5 MHz. The mixer measures 7.0 dB gain and 16 dB noise figure as shown in the application circuit. Typical insertion loss of the Siemens SAW filter is 3.0 dB.

System Noise Considerations

The block diagram shows the cascaded noise stages of the MC13141 in the front–end receiver subsystem; it represents the application circuit. In the cascaded noise analysis the system noise equation is:

$$F_{system} = F1 + \left[(F2 - 1)/G1\right] + \left[(F3 - 1)\right] / \left[(G1)(G2)\right]$$

where:

F1 = the Noise Factor of the MC13142 LNA
G1 = the Gain of the LNA
F2 = the Noise factor of the RF Ceramic Filter
G2 = the Gain of the Ceramic Filter
F3 = the Noise factor of the Mixer

Note: the above terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

$F = \text{Log}^{-1}\left[(\text{NF in dB})/10\right]$ and similarly
$G = \text{Log}^{-1}\left[(\text{Gain in dB})/10\right]$

Calculating in terms of gain and noise factor yields the following:

F1 = 1.51 ; G1 = 50.11
F2 = 1.99 ; G2 = 0.5
F3 = 39.8

Thus, substituting in the equation for subsystem noise factor:

$F_{subsystem} = 3.08$; $NF_{subsystem} = 4.9$ dB
Overall Subsystem Gain = 21 dB

Current Regulation/Enable

Temperature compensating voltage independent current regulators are controlled by the enable function in which “high” powers up the IC.

Low Noise Amplifier (LNA)

The LNA is internally biased at low supply current (approximately 2.0 mA emitter current) for optimal noise figure and gain. The LNA output is biased internally with a 600 Ω resistor to V_{CC}. Input and output matching may be achieved at various frequencies using few external components. Matching the LNA for Maximum stable gain (MSG) yields noise performance within a few tenths of a dB of the minimum noise figure.

Mixer

The mixer is a double–balanced four quadrant multiplier biased class AB allowing for programmable linearity control via an external current source. An input third order intercept point of 20 dBm may be achieved. All 3 ports of the mixer are designed to work up to 1.8 GHz. The mixer has a 50 Ω single–ended RF input and open collector differential IF outputs. An on–board Local Oscillator transistor has the emitter, base and collector pinned out to implement a low phase noise VCO in various configurations. Additionally, a buffered LO output is provided for operation with a frequency synthesizer. The linear gain of the mixer is approximately 0 dB with a SSB noise figure of 12 dB in the IF output circuit configuration shown in the application example.

Local Oscillator

The on–chip transistor operates with coaxial transmission line or LC resonant elements to over 2.0 GHz. Biasing is done with a temperature compensated current source in the emitter and a collector to base internal resistor of 7.6 kΩ; however, an RFC from V_{CC} to base is recommended. The application circuit shows a voltage controlled Clapp oscillator operating at center frequency of 975 MHz.

PIN FUNCTION DESCRIPTION

Pin 16 Pin SOIC	 20 Pin TQFP	Symbol	Equivalent Internal Circuit (20 Pin TQFP)	Description
1	4 5	EN E Osc		**Enable, E Osc** In SO–16, both enables, (for the Oscillator/LO Buffer and LNA/Mixer) are bonded to Pin 1. In the TQFP, two pins are provided, Pin 5, E Osc enables the oscillator and buffer while Pin 4, EN enables the LNA/Mixer. Enable by pulling up to V_{CC} or to greater than 2.0 V_{BE}.
2	6	RF_{in}		**RF Input** The input is the base of an NPN low noise amplifier. Minimum external matching is required to optimize the input return loss and gain.
3	7, 8	V_{EE}		**V_{EE} – Negative Supply** V_{EE} pin is taken to an ample dc ground plane through a low impedance path. The path should be kept as short as possible. A two sided PCB is implemented so that ground returns can be easily made through via holes.
16	3	RF_{out}		**RF Output** The output is from the collector of the LNA; it is internally biased with a 600 Ω resistor to V_{CC}. As shown in the 926 MHz application receiver the output is conjugately matched with a shunt L, and series L and C network.
4 5 6	9 10 11	Osc E Osc B Osc C		**On–Board VCO Transistor** The transistor has the emitter, base and collector + V_{CC} pins available. Internal biasing which is compensated for stability over temperature is provided. It is recommended that the base pin is pulled up to V_{CC} through an RFC chosen for the particular oscillator center frequency. The application circuit shows a modified Colpitts or Clapp oscillator configuration and its design is discussed in detail in the application section.
6 8	12 14	V_{CC} V_{CC}		**Supply Voltage (V_{CC})** Two V_{CC} pins are provided for the Local Oscillator and LO Buffer Amplifier. The operating supply voltage range is from 2.7 Vdc to 6.5 Vdc. In the PCB layout, the V_{CC} trace must be kept as wide as feasible to minimize inductive reactances along the trace. V_{CC} should be decoupled to V_{EE} at the IC pin as shown in the component placement view.
7	13	LO Buff		**Local Oscillator Buffer** This is a buffered output providing –16 dBm (50 Ω termination) to drive the f_{in} pin of a PLL synthesizer. Impedance matching to the synthesizer may be necessary to deliver the optimal signal and to improve the phase noise performance of the VCO.

PIN FUNCTION DESCRIPTION (continued)

Pin		Symbol	Equivalent Internal Circuit (20 Pin TQFP)	Description
16 Pin SOIC	20 Pin TQFP			
9, 12	15, 18, 19	V_{EE}		**V_{EE}, Negative Supply** These pins are V_{EE} supply for the mixer IF output. In the application PC board these pins are tied to a common V_{EE} trace with other V_{EE} pins.
10, 11	16, 17	IF–, IF+		**IF Output** The IF is a differential open collector configuration which designed to use over a wide frequency range for up conversion as well as down conversion. Differential to single–ended circuit configuration and matching options are discussed in the application section. 6.0 dB of additional Mixer gain can be achieved by conjugately matching at the desired IF frequency.
13	20	RF_m		**Mixer RF Input** The mixer input impedance is broadband 50 Ω for applications up to 1.8 GHz. It easily interfaces with a RF ceramic filter as shown in the application schematic.
14	1	Mix Lin Cont		**Mixer Linearity Control** The mixer linearity control circuit accepts approximately 0 to 2.3 mA control current to set the dynamic range of the mixer. An Input Third Order Intercept Point, IIP3 of 20 dBm may be achieved at 2.3 mA of control current (approximately 7.0 mA of additional supply current).

APPLICATIONS INFORMATION

Evaluation PC Board

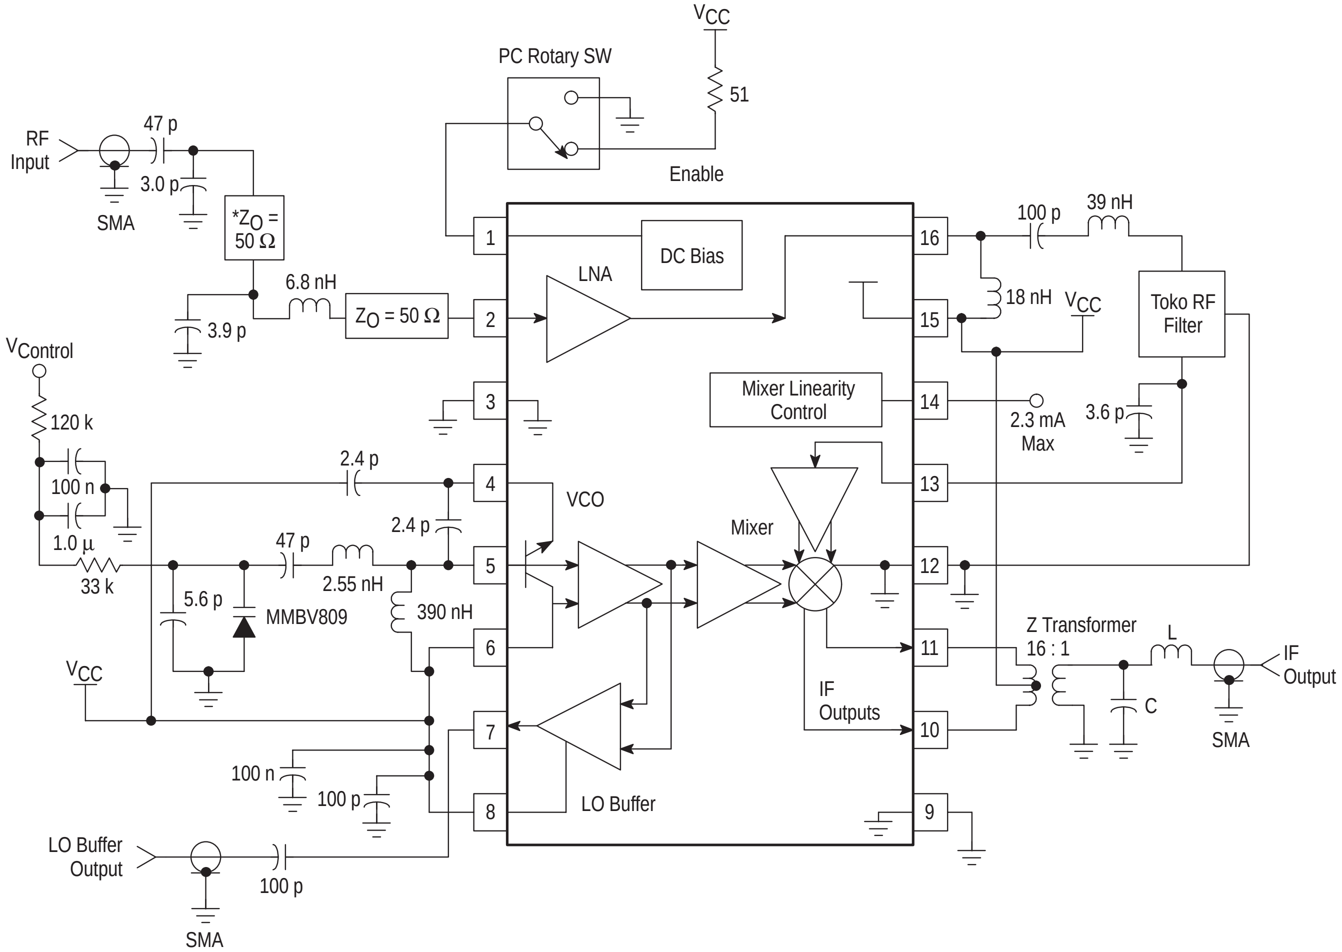
The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board accommodates all SMT components on the circuit side (see Circuit Side Component Placement View). This evaluation board will be discussed and referenced in this section.

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers. The circuit side placement view is illustrated for the components specified in the application circuit. The application circuit schematic specifies particular components that were used to achieve the results given and specified in the tables but alternate components of the same Q and value should give equivalent results.

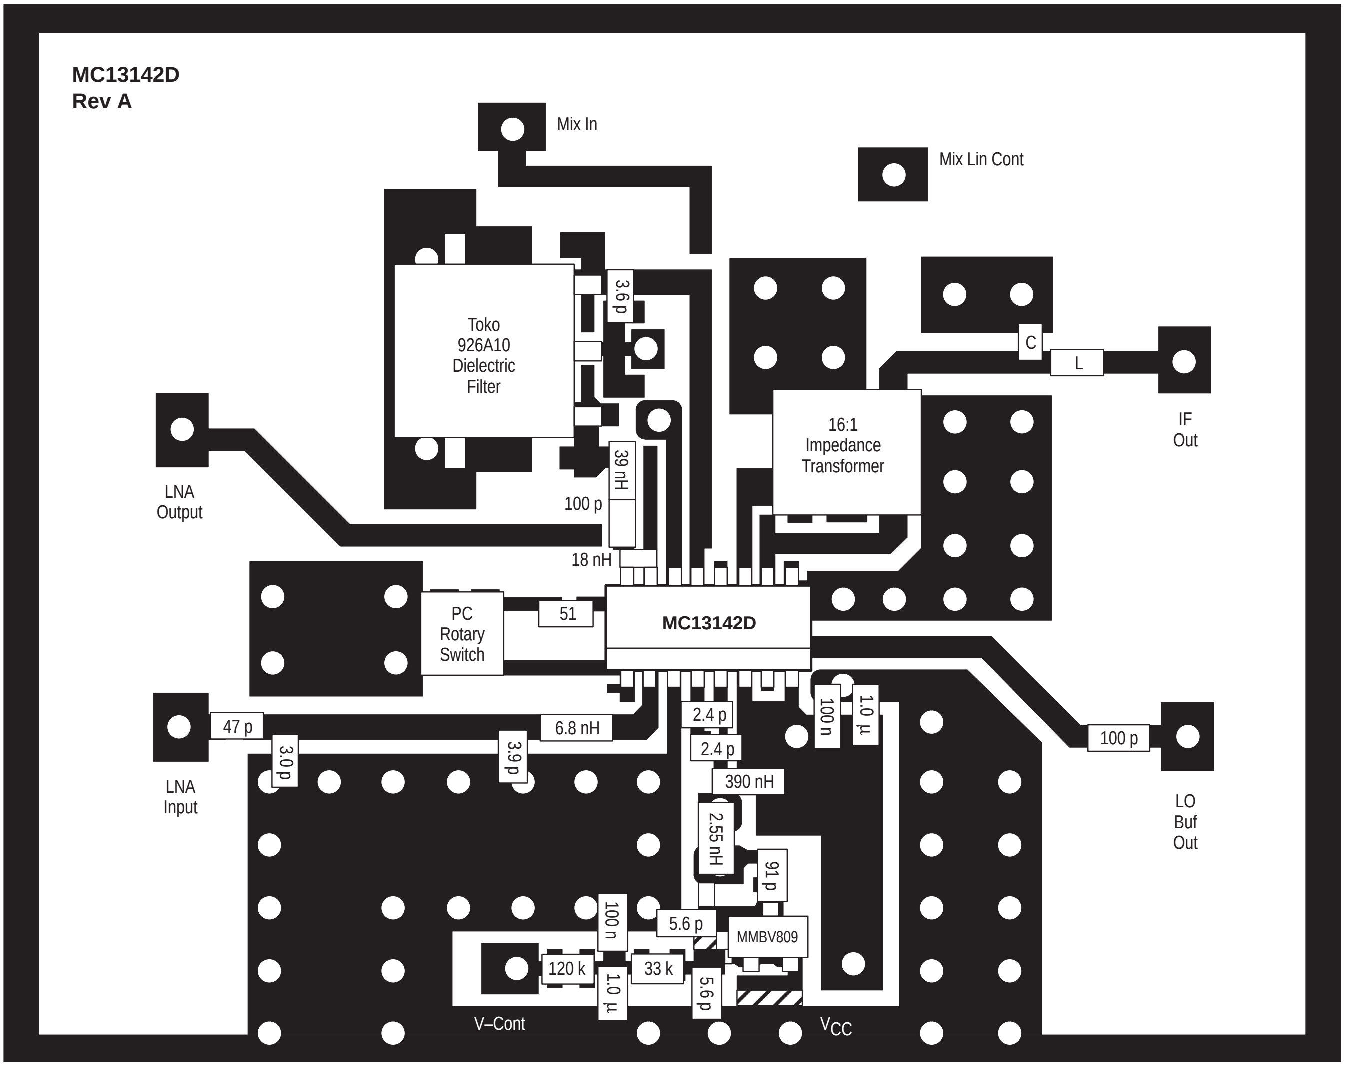
Figure 1. Application Circuit

(926.5 MHz)



NOTE: *50 Ω Microstrip Transmission Line; length shown in Figure 2.

Figure 2. Circuit Side Component Placement View



NOTES: The PCB is laidout for the 4DFA (2 pole SMD type) and 4DFB (3 pole SMD type) filters which are available for applications in cellular and GSM,GPS (1.2–1.5 GHz), DECT, PHS and PCS (1.8–2.0 GHz) and ISM Bands (902–928 MHz and 2.4–2.5 GHz). In the component placement shown above, the 926.5 MHz dielectric type image filter is used (Toko Part # 4DFA–926A10).

The PCB also accommodates a surface mount SAW filter in an eight or six pin ceramic package for the cellular base and handset frequencies. Recommended manufacturers are Siemens and Murata.

Traces are provided on the PCB to evaluate the LNA and mixer separately. The component placement view shows external circuit components used for the 926.5 MHz application circuit. Note: some traces must be cut to accommodate placement of components; likewise some traces must be shorted. The voltage controlled oscillator is shown with the varactor referenced to V_{EE} ground. The PCB is modified as shown to do this.

16:1 broadband impedance transformer is mini circuits part #TX16–R3T; it is in the leadless surface mount “TX” package. Components L and C comprise a low pass filter used to provide narrowband matching at a given IF frequency. For example at 49 MHz C = 36 p and L = 330 nH.
The microstrip trace on the ground side of the PCB is intended for a microstrip resonator; it is cut free when using a lump inductor as done above.

Input Matching/Components

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. The PC board layout accommodates both ceramic and SAW RF filters which are offered by various suppliers such as Siemens, Toko and Murata.

Interface matching between the LNA, RF filter and the mixer will be required. The interface matching networks shown in the application circuit are designed for 50 Ω interfaces.

In the application circuit, the LNA is conjugately matched to 50 Ω input and output for 3.0 to 5.0 Vdc V_{CC}. 17 dB gain and 1.8 dB noise figure is typical at 926 MHz. The mixer measures 0 dB gain and 12 dB noise figure as shown in the application circuit. Typical insertion loss of the Toko ceramic filter is 3.0 dB. Thus, the overall gain of the frontend receiver is 14 dB with a 3.3 dB noise figure.

System Noise Considerations

The block diagram shows the cascaded noise stages of the MC13142 in the frontend receiver subsystem; it represents the application circuit. In the cascaded noise analysis the system noise equation is:

Fsystem = F1 + [(F2 –1)/G1] + [(F3–1)]/[(G1)(G2)]

where:

F1 = the Noise Factor of the MC13142 LNA
G1 = the Gain of the LNA
F2 = the Noise factor of the RF Ceramic Filter
G2 = the Gain of the Ceramic Filter
F3 = the Noise factor of the Mixer

Note: the above terms are defined as linear relationships and are related to the log form for gain and noise figure by the following:

F = Log $^{-1}$ [(NF in dB)/10] and similarly
G = Log $^{-1}$ [(Gain in dB)/10].

Calculating in terms of gain and noise factor yields the following:

F1 = 1.51; G1 = 50.11
F2 = 1.99; G2 = 0.5
F3 = 15.85

Thus, substituting in the equation for system noise factor:

Fsystem = 2.12; NFsystem = 3.3 dB

MC13143

Product Preview

Ultra Low Power DC - 2.4 GHz Linear Mixer

The MC13143 is a high compression linear mixer with single–ended RF input, differential IF output and differential LO inputs which consumes as little as 1.8 mW. A new circuit topology is used to achieve a high third order intermodulation intercept point, high linearity and high 1.0 dB output compression point while maintaining a linear 50 Ω input impedance. It is designed for Up or Down conversion anywhere from dc to 2.4 GHz.

Ultra Low Power: 1.0 mA @ V_{CC} = 1.8–6.5 V

- Wide Input Bandwidth: DC–2.4 GHz
- Wide Output Bandwidth: DC–2.4 GHz
- Wide LO Bandwidth: DC–2.4 GHz
- High Mixer Linearity: $P_{i1.0\ dB}$ = + 3.0 dBm

Linearity Adjustment of up to IP_{3in} = +20 dBm

- 50 Ω Mixer Input
- Single–Ended Mixer Input
- Double Balanced Mixer Operation
- Differential Open Collector Mixer Output

CIRCUIT DESCRIPTION

General

The MC13143 is a double–balanced Mixer. This device is designated for use as the frontend section in analog and digital FM systems such as Wireless Local Area Network (LAN), Digital European Cordless Telephone (DECT), PHS, PCS, GPS, Cellular, UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services and 902 to 928 MHz cordless telephones. It features a mixer linearity control to preset or auto program the mixer dynamic range, an enable function and a wideband IF so the IC may be used either as a down converter or an up converter.

Current Regulation

Temperature compensating voltage independent current regulators provide typical supply current at 1.0 mA with no mixer linearity control current.

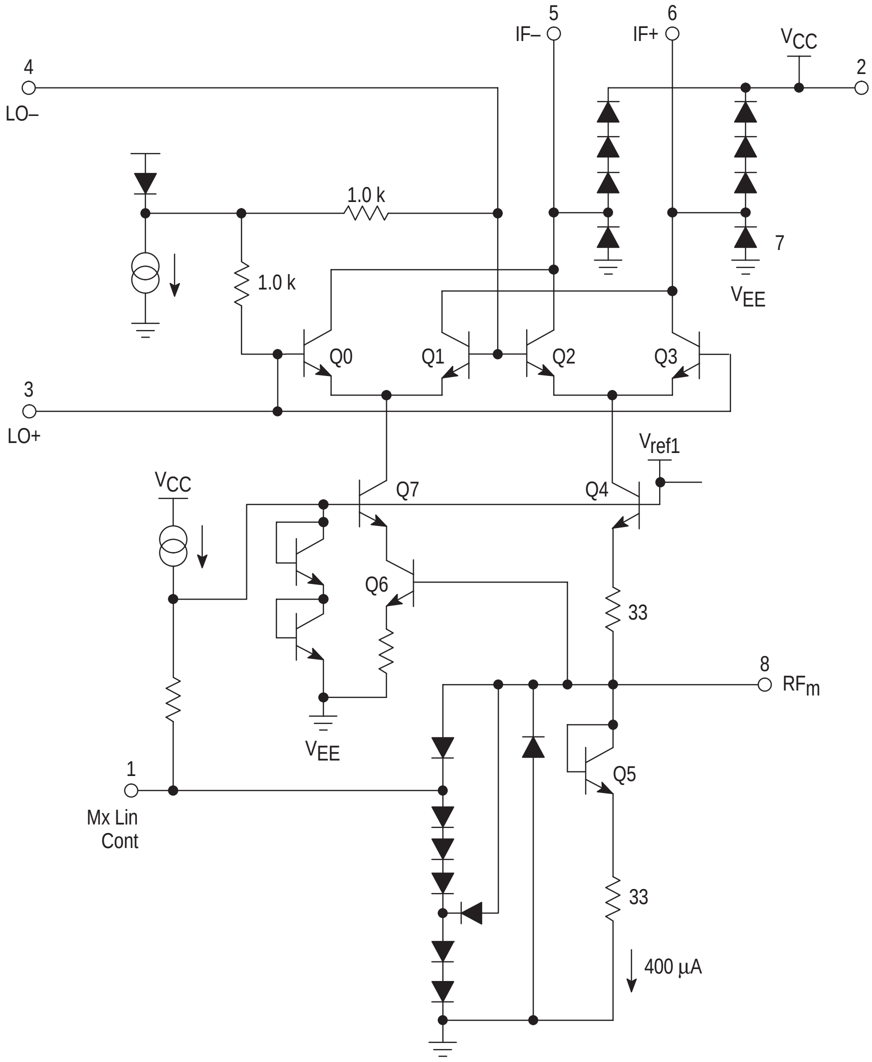
Mixer

The mixer is a unique and patented double–balanced four quadrant multiplier biased class AB allowing for programmable linearity control via an external current source. An input third order intercept point of 20 dBm may be achieved. All 3 ports of the mixer are designed to work up to 2.4 GHz. The mixer has a 50 Ω single–ended RF input and open collector differential IF outputs (see Internal Circuit Schematic for details). The linear gain of the mixer is approximately –5.0 dB with a SSB noise figure of 12 dB.

Local Oscillator

The local oscillator has differential input configuration that requires typically –10 dBm input from an external source to achieve the optimal mixer gain.

Figure 8. MC13143 Internal Circuit*



NOTE: * The MC13143 uses a unique and patented circuit topology.

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board is laid out to accommodate all SMT components on the circuit side (see Circuit Side Component Placement View).

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers. The circuit side placement view is illustrated for the components specified in the application circuit. The Component Placement View specifies particular components that were used to achieve the results shown in the typical curves and tables.

Mixer Input

The mixer input impedance is broadband 50 Ω for applications up to 2.4 GHz. It easily interfaces with a RF ceramic filter as shown in the application schematic.

Mixer Linearity Control

The mixer linearity control circuit accepts approximately 0 to 2.3 mA control current. An Input Third Order Intercept Point, IIP3 of 20 dBm may be achieved at 2.3 mA of control current (approximately 7.0 mA of additional supply current).

Local Oscillator Inputs

The differential LO inputs are internally biased at V_{CC} – 1.0 V_{BE}; this is suitable for high voltage and high gain operation.

For low voltage operation, the inputs are taken to V_{CC} through 51 Ω.

IF Output

The IF is a differential open collector configuration which is designed to use over a wide frequency range for up conversion as well as down conversion.

Input/Output Matching

It is desirable to use a RF ceramic or SAW filter before the mixer to provide image frequency rejection. The filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. The PC board layout accommodates both ceramic and SAW RF filters which are offered by various suppliers such as Siemens, Toko and Murata.

Interface matching between the RF input, RF filter and the mixer will be required. The interface matching networks shown in the application circuit are designed for 50 Ω interfaces.

Differential to single–ended circuit configuration is shown in the test circuit. 6.0 dB of additional mixer gain can be achieved by conjugately matching the output of the MiniCircuits transformer to 50 Ω at the desired IF frequency. With narrowband IF output matching the mixer performance is 3.0 dB gain and 12 dB noise figure (see Narrowband 49 and 83 MHz IF Output Matching Options). Typical insertion loss of the Toko ceramic filter is 3.0 dB. Thus, the overall gain of the circuit is 0 dB with a 15 dB noise figure.

Figure 9. Narrowband IF Output Matching with 16:1 Z Transformer and LC Network

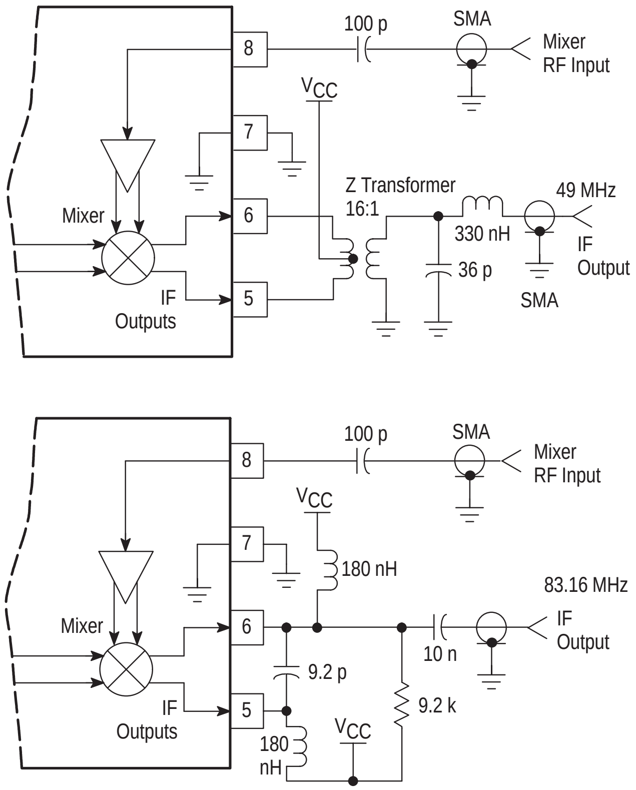


Figure 10. Circuit Side Component Placement View

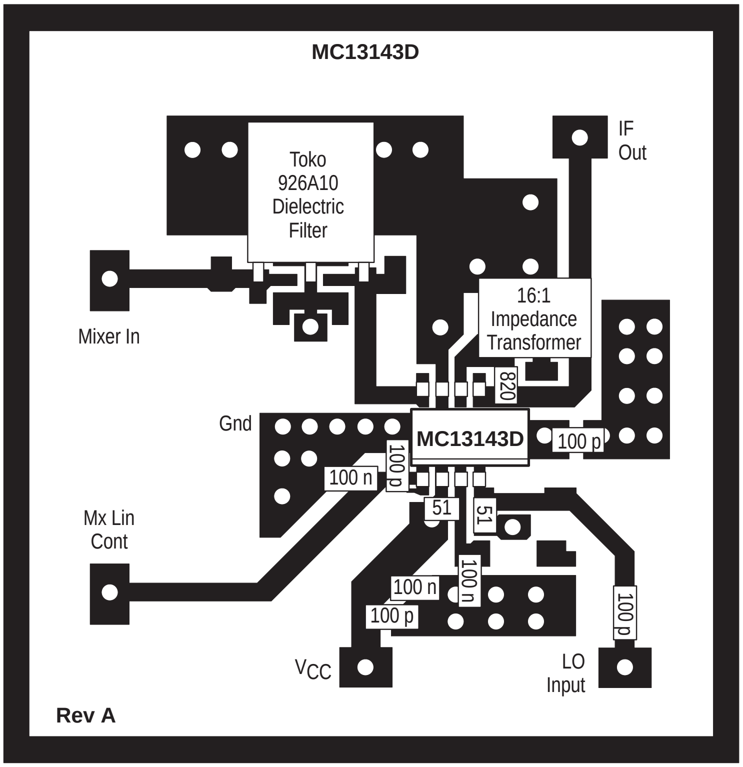

NOTES: 926.5 MHz preselect dielectric filter is Toko part # 4DFA–926A10; the 4DFA (2 and 3 pole SMD type) filters are available for applications in cellular and GSM, GPS, DECT, PHS, PCS and ISM bands at 902–928 MHz, 1.8–1.9 GHz at 2.4–2.5 GHz.

The PCB also accommodates a surface mount RF SAW filter in an eight or six pin ceramic package for the cellular base and handset frequencies. Recommended manufacturers are Siemens and Murata.

The PCB may also be used without a preselector filter; AC coupled to the mixer as shown in the test circuit schematic. All other external circuit components shown in the PCB layout above are the same as used in the test circuit schematic.

16:1 broadband impedance transformer is mini circuits part #TX16–R3T; it is in the leadless surface mount “TX” package. For a more selective narrowband match, a lowpass filter may be used after the transformer. The PCB is designed to accommodate lump inductors and capacitors in more selective narrowband matching of the mixer differential outputs to a single–ended output at a given IF frequency.

. The local oscillator may also be driven in a differential configuration using a coaxial transformer. Recommended sources are the Toko Balun transformers type B4F, B5FL and B5F (SMD component).

MC13144

Product Preview

VHF - 2.0 GHz Low Noise Amplifier with Programmable Bias

The MC13144 is designed in the Motorola High Frequency Bipolar MOSIAC V™ wafer process to provide excellent performance in analog and digital communication systems. It includes a cascoded LNA usable up to 2.0 GHz and at 1.8 Vdc, with 2 bit digital programming of the LNA bias. Targeted applications are in the UHF Family Radio Services, UHF and 800 MHz Special Mobile Radio, 800 MHz Cellular and GSM, PCS, DECT and PHS at 1.8 to 2.0 GHz and Cordless Telephones in the 902 to 928 MHz band covered by FCC Title 47; Part 15. The MC13144 offers the following features:

- 17 dB Gain at 900 MHz
- 1.4 dB Noise Figure at 900 MHz
- 1.0 dB Compression Point of –7.0 dBm; Input Third Order Intercept Point of –5.0 dBm
- Low Operating Supply Voltage (1.8 to 6.0 Vdc)
- Programmable Bias with Enable 1 and Enable 2
- Enable 1 and Enable 2 Programmed High for Optimal Noise Figure and Gain Associated with NF
- Can Override Enable and Externally Program In Up to 15 mA

CIRCUIT DESCRIPTION

General

The MC13144 is a low noise amplifier with programmable bias. This device is designated for use in the front end section in analog and digital FM systems such as Wireless Local Area Network (LAN), Digital European Cordless Telephone (DECT), PHS, PCS, GPS, Cellular, UHF and 800 MHz Special Mobile Radio (SMR), UHF Family Radio Services and 902 to 928 MHz cordless telephones.

Current Regulation/Enable

Temperature compensating voltage independent current regulation is digitally controlled by a 2 bit programmable bias/enable circuit.

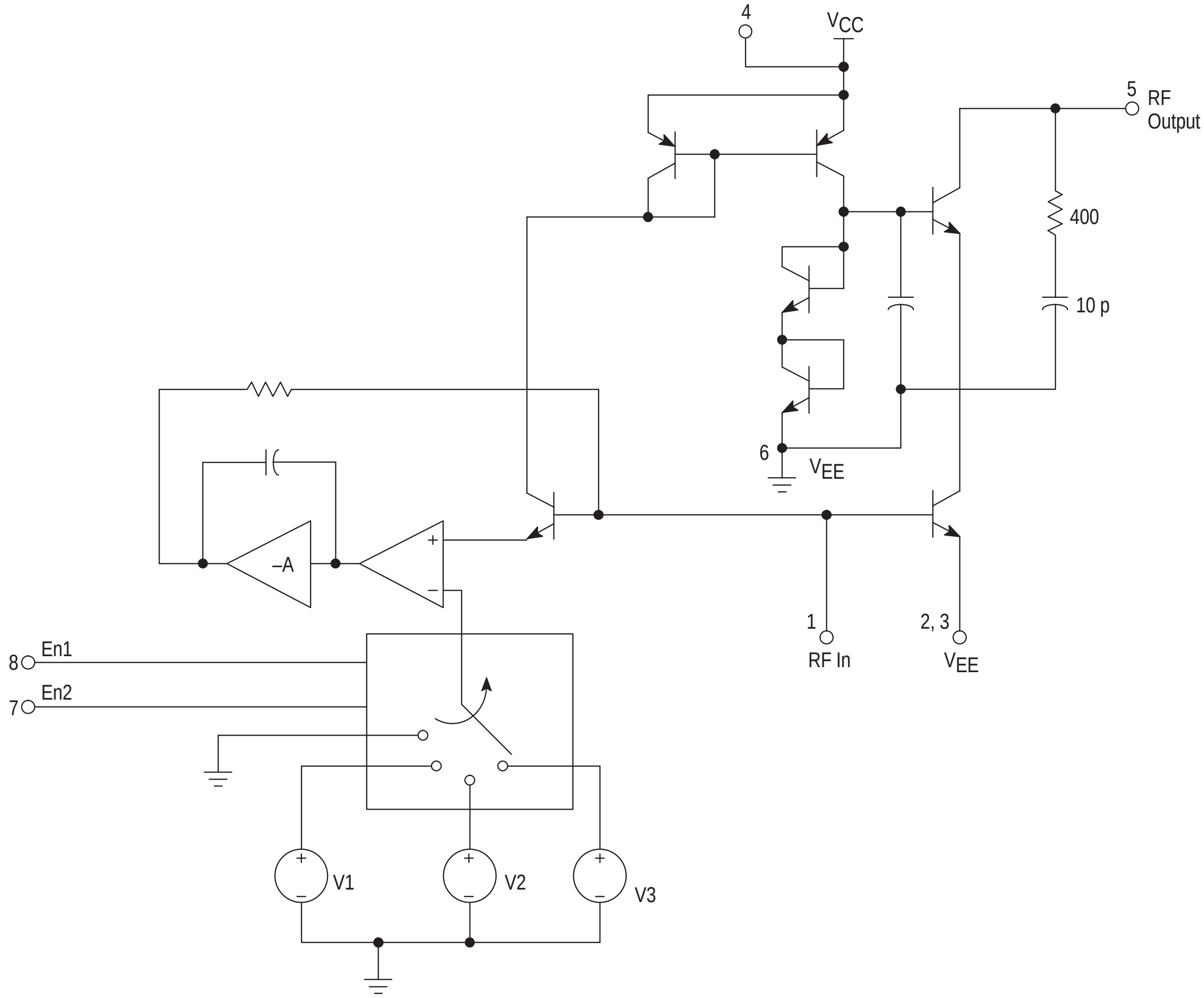
LNA

The LNA is a unique and patented cascode amplifier with digitally (2 bit) programmable bias (see Internal Circuit Schematic). Typical gain of the LNA is 17 dB for minimum noise figure of 1.4 dB at 900 MHz.

Programmable Bias/Enable Circuit

This unique circuit allows for 3 bias levels and a standby mode in which the LNA can be externally biased as desired.

Figure 1. MC13144 Internal Circuit*



NOTE: * The MC13144 uses a unique and patent pending circuit topology.

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The PC board layout accommodates all SMT components on the circuit side (see Circuit Side Component Placement View).

Component Selection

The evaluation PC board is laid out for the 4DFA (2 pole SMD Type) and 4DFB (3 pole SMD Type) filters which are available for applications in Cellular and GSM, GPS (1.2 to 1.5 GHz), DECT, PHS and PCS (1.8 to 2.0 GHz) and ISM Bands (902 to 928 MHz and 2.4 to 2.5 GHz). In the 926.5 MHz Application Circuit, a ceramic deielectric filter is used (Toko part # 4DFA–926A10).

LNA Input/Output

The LNA input impedance is the base of a common emitter cascode amplifier. The LNA output is the collector of the cascode stage and it is loaded with a series resistor of 400 Ω and a capacitor of 10 pF to provide stability.

Digitally Programmable Bias/Enable

The LNA is enabled by a 2 bit (En1 and En2) programmable bias circuit. The internal circuit shows the comparator circuit which programs the internal regulator. The logic table below shows the bias and typical performance.

I_{CC}/Gain	En2 Low	En2 High
En1 Low	0 mA/0 dB	2.0 mA/13 dB
En1 High	4.2 mA/17.0 dB	9.4 mA/18 dB

Input/Output Matching

A typical application at 900 MHz yields 17 dB gain and 1.4 dB noise figure. In this circuit a series inductor of 5.6 nH is used to match the input and a shunt inductor of 8.2 nH which also serves as an RFC and a series capacitor of 0.9 p is used to match the LNA output to 50 Ω load impedance.

It may be desirable to use a RF ceramic or SAW filter after the LNA when driving a mixer to provide image frequency rejection. The image filter is selected based on cost, size and performance tradeoffs. Typical RF filters have 3.0 to 5.0 dB insertion loss. Interface matching between the RF input, RF filter and the mixer is shown in Application Circuit and the Component Placement View.

MOTOROLA

MC13150

Narrowband FM Coilless Detector IF Subsystem

The MC13150 is a narrowband FM IF subsystem targeted at cellular and other analog applications. Excellent high frequency performance is achieved, with low cost, through use of Motorola's MOSAIC 1.5™ RF bipolar process. The MC13150 has an onboard Colpitts VCO for Crystal controlled second LO in dual conversion receivers. The mixer is a double balanced configuration with excellent third order intercept. It is useful to beyond 200 MHz. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. The quadrature detector is a unique design eliminating the conventional tunable quadrature coil.

Applications for the MC13150 include cellular, CT–1 900 MHz cordless telephone, data links and other radio systems utilizing narrowband FM modulation.

- Linear Coilless Detector
- Adjustable Demodulator Bandwidth
- 2.5 to 6.0 Vdc Operation
- Low Drain Current: < 2.0 mA
- Typical Sensitivity of 2.0 µV for 12 dB SINAD
- IIP3, Input Third Order Intercept Point of 0 dBm
- RSSI Range of Greater Than 100 dB
- Internal 1.4 kΩ Terminations for 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range

MC13150 CIRCUIT DESCRIPTION

General

The MC13150 is a very low power single conversion narrowband FM receiver incorporating a split IF. This device is designated for use as the backend in analog narrowband FM systems such as cellular, 900 MHz cordless phones and narrowband data links with data rates up to 9.6 k baud. It contains a mixer, oscillator, extended range received signal strength indicator (RSSI), RSSI buffer, IF amplifier, limiting IF, a unique coilless quadrature detector and a device enable function (see Package Pin Outs/Block Diagram).

Low Current Operation

The MC13150 is designed for battery and portable applications. Supply current is typically 1.7 mAdc at 3.0 Vdc. Figure 2 shows the supply current versus supply voltage.

Enable

The enable function is provided for battery powered operation. The enabled pin is pulled down to enable the regulators. Figure 3 shows the supply current versus enable voltage, V_{enable} (relative to V_{CC}) needed to enable the device. Note that the device is fully enabled at V_{CC} – 1.3 Vdc. Figure 4 shows the relationship of enable current, I_{enable} to enable voltage, V_{enable}.

Mixer

The mixer is a double–balanced four quadrant multiplier and is designed to work up to 500 MHz. It has a single ended input. Figure 5 shows the mixer gain and saturated output response as a function of input signal drive and for –10 dBm LO drive level. This is measured in the application circuit shown in Figure 15 in which a single LC matching network is used. Since the single–ended input impedance of the mixer is 200 Ω, an alternate solution uses a 1:4 impedance transformer to match the mixer to 50 Ω input impedance. The linear voltage gain of the mixer alone is approximately 4.0 dB (plus an additional 6.0 dB for the transformer). Figure 6 shows the mixer gain versus the LO input level for various mixer input levels at 50 MHz RF input.

The buffered output of the mixer is internally loaded, resulting in an output impedance of 1.5 kΩ.

Local Oscillator

The on–chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. 3rd overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 200 MHz is feasible using the on–chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor's bias is increased by adding an external resistor from Pin 29 (in 32 pin QFP package) to V_{EE} to keep the oscillator on continuously or it may be taken to the enable pin to shut it off when the receiver is disabled. –10 dBm of local oscillator drive is needed to adequately drive the mixer (Figure 6). The oscillator configurations specified above are described in the application section.

RSSI

The received signal strength indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the IF and limiting amplifier stages. An external resistor at Pin 25 (in 32 pin QFP package) sets the voltage range or swing of the RSSI output voltage. Linearity of the RSSI is optimized by using external ceramic bandpass filters which have an insertion loss of 4.0 dB. The RSSI circuit is designed to provide 100+ dB of dynamic range with temperature compensation (see Figures 7 and 23 which show the RSSI response of the applications circuit).

RSSI Buffer

The RSSI buffer has limitations in what loads it can drive. It can pull loads well towards the positive and negative supplies, but has problems pulling the load away from the supplies. The load should be biased at half supply to overcome this limitation.

Figure 2. Supply Current versus Supply Voltage

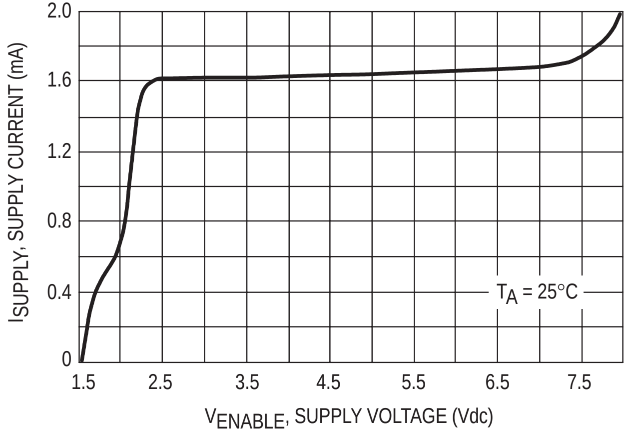

Figure 3. Supply Current versus Enable Voltage

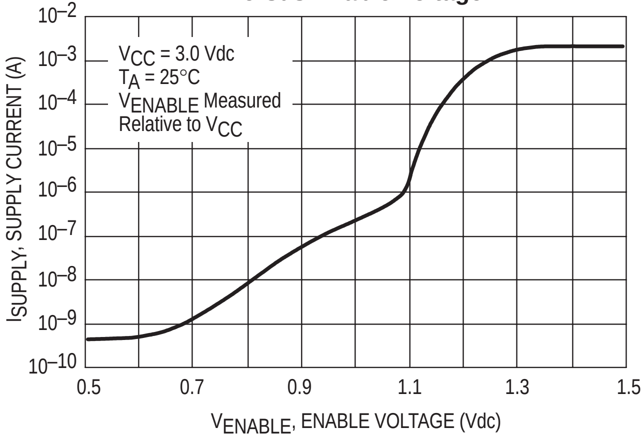

Figure 4. Enable Current versus Enable Voltage

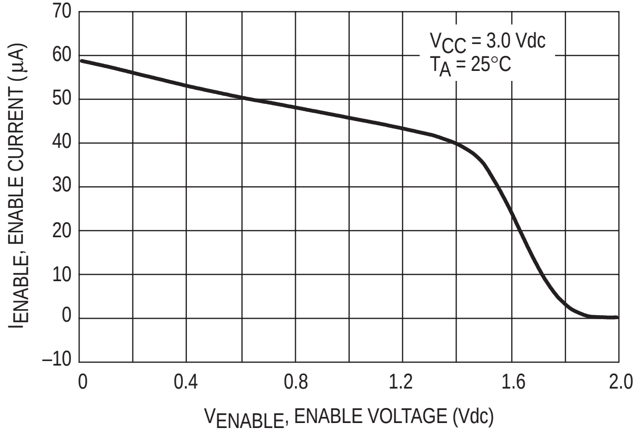

Figure 5. Mixer IF Output Level versus RF Input Level

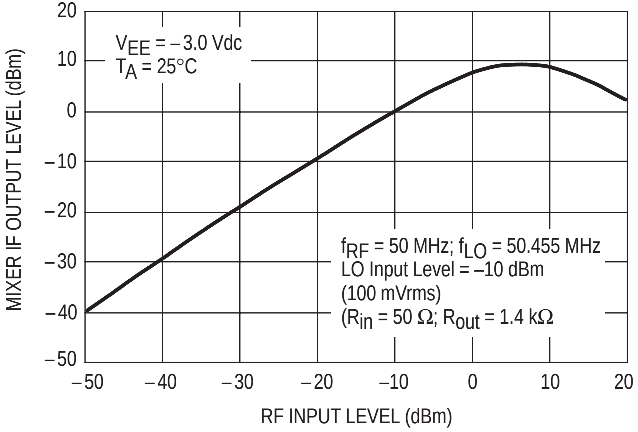

Figure 6. Mixer IF Output Level versus Local Oscillator Input Level

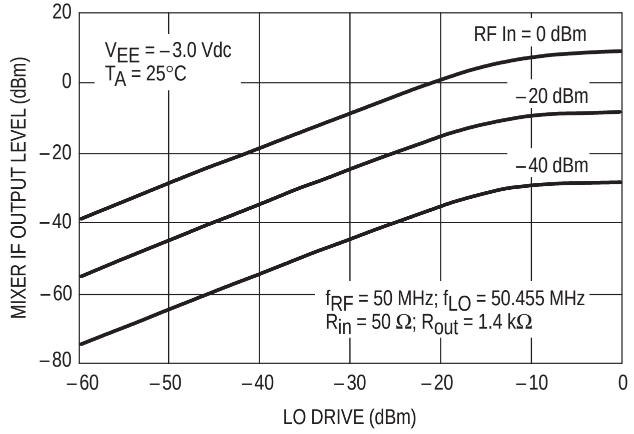

Figure 7. RSSI Output Current versus Input Signal Level

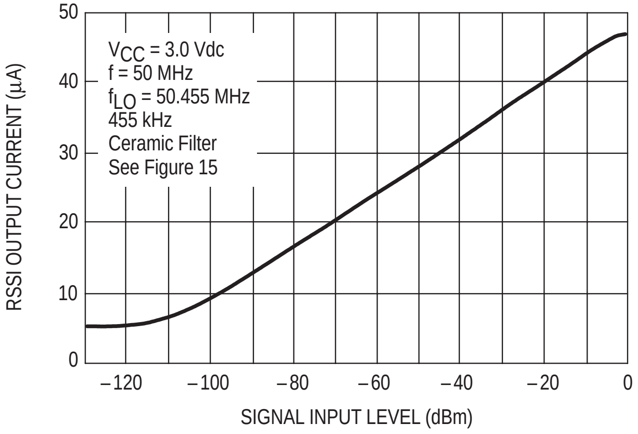

IF Amplifier

The first IF amplifier section is composed of three differential stages. This section has internal dc feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 42 dB at 455 kHz. Figure 8 shows the gain of the IF amplifier as a function of the IF frequency.

The fixed internal input impedance is 1.5 kΩ; it is designed for applications where a 455 kHz ceramic filter is used and no external output matching is necessary since the filter requires a 1.5 kΩ source and load impedance.

Overall RSSI linearity is dependent on having total midband attenuation of 10 dB (4.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 1.5 kΩ.

Limiter

The limiter section is similar to the IF amplifier section except that six stages are used. The fixed internal input impedance is 1.5 kΩ. The total gain of the limiting amplifier section is approximately 96 dB. This IF limiting amplifier section internally drives the quadrature detector section.

Figure 8. IF Amplifier Gain versus IF Frequency

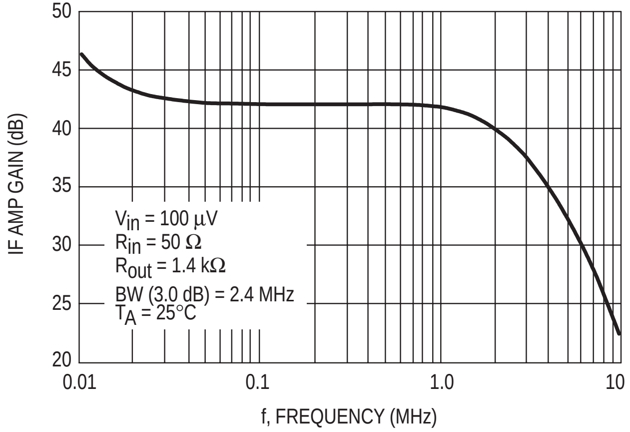

Figure 9. F_{adj} Current versus IF Frequency

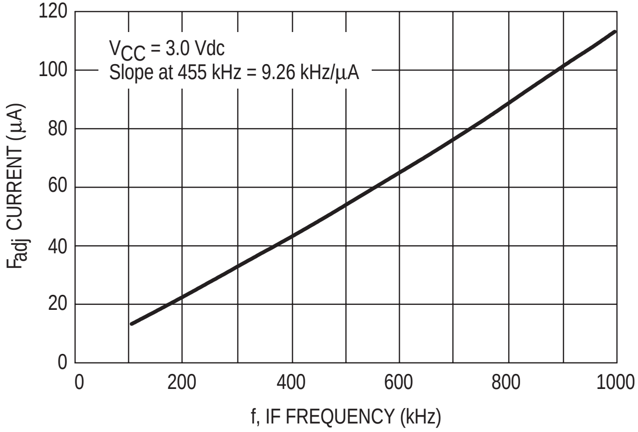

Figure 10. F_{adj} Voltage versus F_{adj} Current

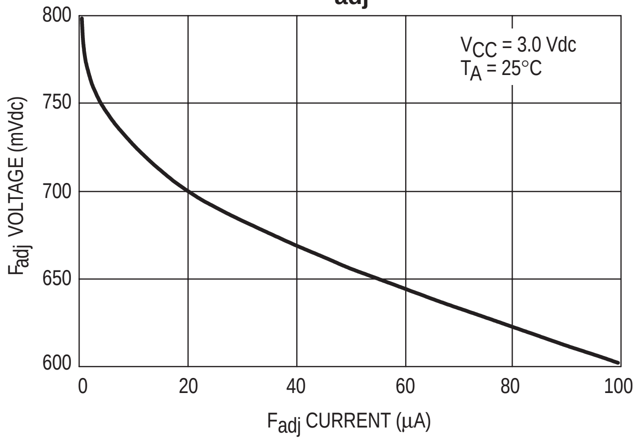

Figure 11. BW_{adj} Current versus IF Frequency

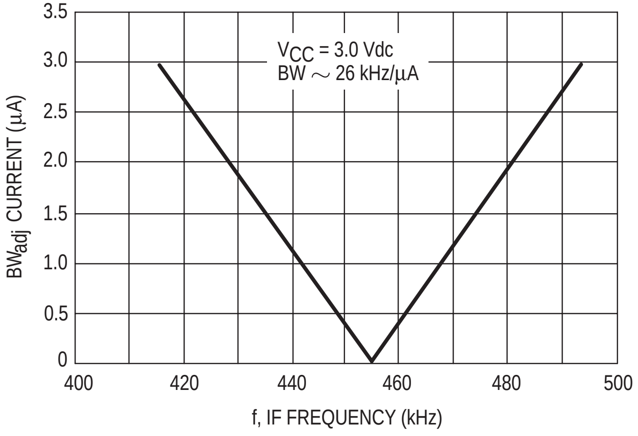

Coilless Detector

The quadrature detector is similar to a PLL. There is an internal oscillator running at the IF frequency and two detector outputs. One is used to deliver the audio signal and the other one is filtered and used to tune the oscillator.

The oscillator frequency is set by an external resistor at the F_{adj} pin. Figure 9 shows the control current required for a particular frequency; Figure 10 shows the pin voltage at that current. From this the value of R_F is chosen. For example, 455 kHz would require a current of around 50 µA. The pin voltage (Pin 16 in the 32 pin QFP package) is around 655mV giving a resistor of 13.1 kΩ. Choosing 12 kΩ as the nearest standard value gives a current of approximately 55 µA. The 5.0 µA difference can be taken up by the tuning resistor, R_T.

The best nominal frequency for the AFT_{out} pin (Pin 17) would be half supply. A supply voltage of 3.0 Vdc suggests a resistor value of (1.5 – 0.655)V/5µA = 169 kΩ. Choosing 150 kΩ would give a tuning current of 3/150 k = 20 µA. From Figure 9 this would give a tuning range of roughly 10 kHz/µA or ± 100 kHz which should be adequate.

The bandwidth can be adjusted with the help of Figure 11. For example, 1.0 µA would give a bandwidth of ± 13 kHz. The voltage across the bandwidth resistor, R_B from Figure 12 is V_{CC} – 2.44 Vdc = 0.56 Vdc for V_{CC} = 3.0 Vdc., so R_B = 0.56V/1.0 µA = 560 kΩ. Actually the locking range will be ±13 kHz while the audio bandwidth will be approximately ±8.4 kHz due to an internal filter capacitor. This is verified in Figure 13. For some applications it may be desirable that the audio bandwidth is increased; this is done by reducing R_B. Reducing R_B widens the detector bandwidth and improves the distortion at high input levels at the expense of 12 dB SINAD sensitivity. The low frequency 3.0dB point is set by the tuning circuit such that the product

$$R_T C_T = 0.68/f3dB.$$

So, for example, 150 k and 1.0 µF give a 3.0 dB point of 4.5 Hz. The recovered audio is set by R_L to give roughly 50mV per kHz deviation per 100 k of resistance. The dc level can be shifted by R_S from the nominal 0.68 V by the following equation:

$$\text{Detector DC Output} = ((R_L + R_S)/R_S)\ 0.68\ \text{Vdc}$$

Thus, $R_S = R_L$ sets the output at 2 x 0.68 = 1.36 V; $R_L = 2R_S$ sets the output at 3 x 0.68 = 2.0 V.

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB is very versatile and is intended to be used across the entire useful frequency range of this device. The center section of the board provides an area for attaching all SMT components to the circuit side and radial leaded components to the component ground side (see Figures 29 and 30). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. There is an area dedicated for a LNA preamp. This evaluation board will be discussed and referenced in this section.

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. The applications circuit schematic (Figure 15) specifies particular components that were used to achieve the results shown in the typical curves but equivalent components should give similar results. Component placement views are shown in Figures 27 and 28 for the application circuit in Figure 15 and for the 83.616 MHz crystal oscillator circuit in Figure 16.

Input Matching Components

The input matching circuit shown in the application circuit schematic (Figure 15) is a series L, shunt C single L section which is used to match the mixer input to 50 Ω. An alternative input network may use 1:4 surface mount transformers or BALUNs. The 12 dB SINAD sensitivity using the 1:4 impedance transformer is typically –100 dBm for f_{mod} = 1.0 kHz and f_{dev} = ±5.0 kHz at f_{in} = 50 MHz and f_{LO} = 50.455 MHz (see Figure 14).

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection and improved sensitivity. SAW filters sourced from Toko (Part # SWS083GBWA) and Murata (Part # SAF83.16MA51X) are excellent choices to easily interface with the MC13150 mixer. They are packaged in a 12 pin low profile surface mount ceramic package. The center frequency is 83.161 MHz and the 3.0 dB bandwidth is 30 kHz.

Figure 14. S+N+D, N+D, N, 30% AMR versus Input Signal Level

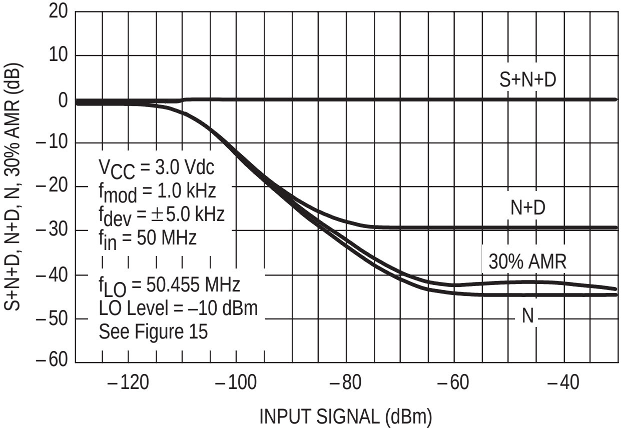

Figure 15. Application Circuit

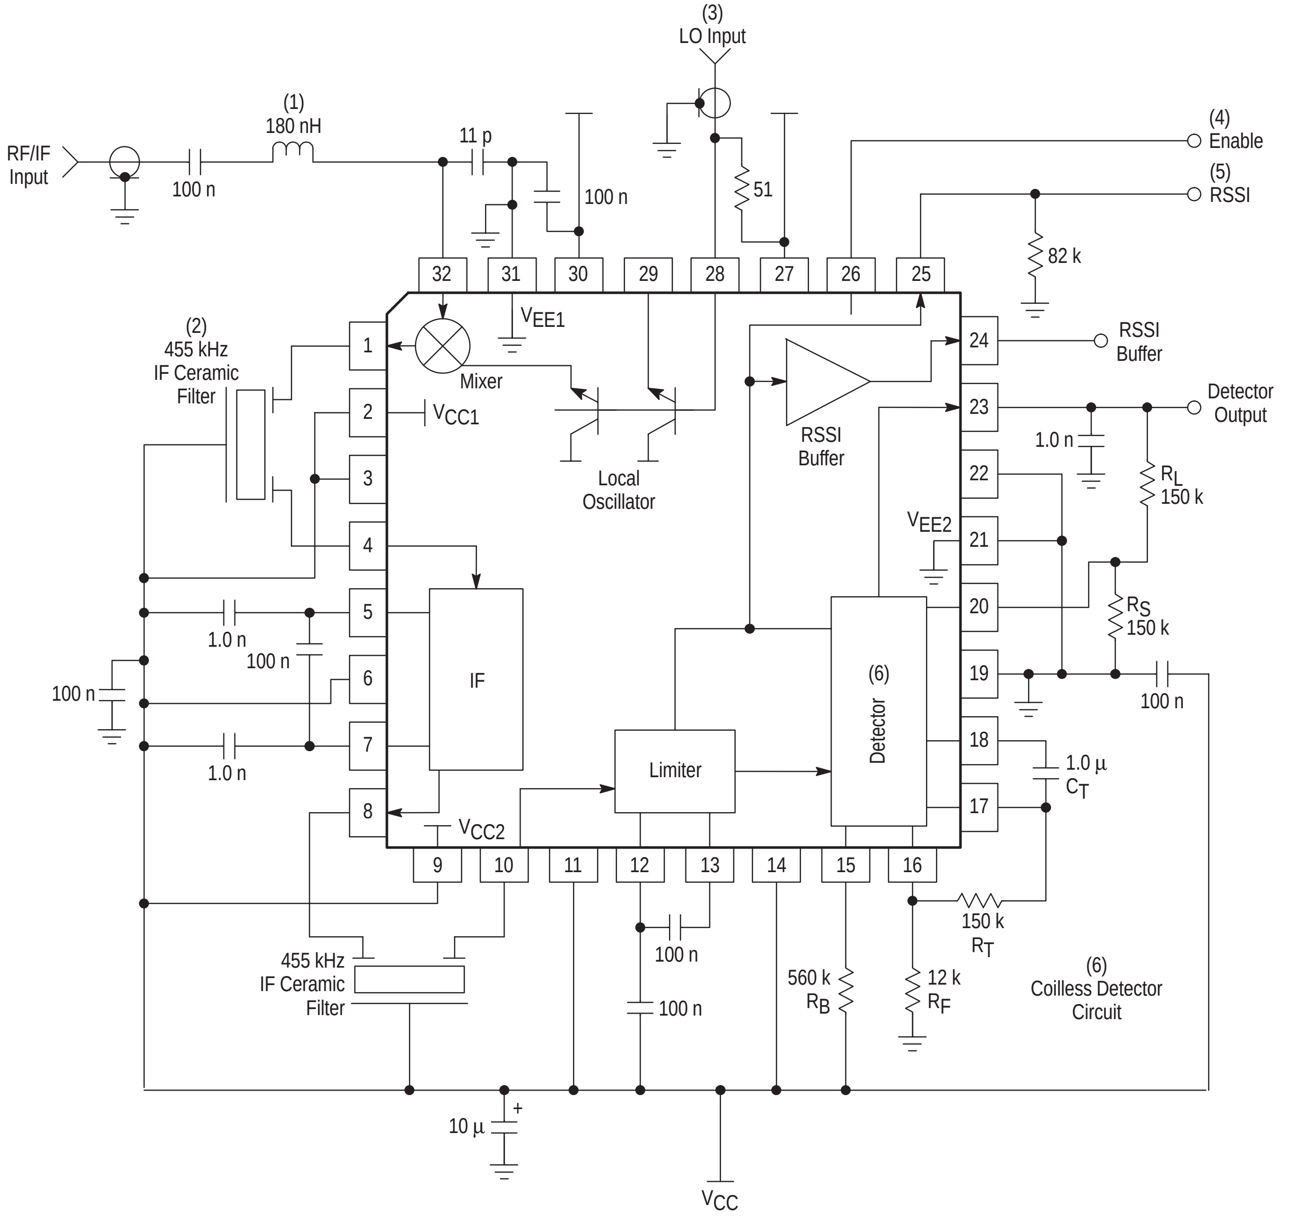

NOTES: 1. Alternate solution is 1:4 impedance transformer (sources include Mini Circuits, Coilcraft and Toko).
2. 455 kHz ceramic filters (source Murata CFU455 series which are selected for various bandwidths).
3. For external LO source, a 51 Ω pull–up resistor is used to bias the base of the on–board transistor as shown in Figure 15. Designer may provide local oscillator with 3rd, 5th, or 7th overtone crystal oscillator circuit. The PC board is laid out to accommodate external components needed for a Butler emitter coupled crystal oscillator (see Figure 16).
4. Enable IC by switching the pin to V_{EE}.
5. The resistor is chosen to set the range of RSSI voltage output swing.
6. Details regarding the external components to setup the coilless detector are provided in the application section.

Local Oscillators

HF & VHF Applications

In the application schematic, an external sourced local oscillator is utilized in which the base is biased via a 51 Ω resistor to V_{CC}. However, the on–chip grounded collector transistor may be used for HF and VHF local oscillators with higher order overtone crystals. Figure 16 shows a 5th overtone oscillator at 83.616 MHz. The circuit uses a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on–chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have tight enough tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and start–up of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high the performance of oscillator may be impacted by lower gain margins.

A series LC network to ac ground (which is V_{CC}) is comprised of the inductance of the base lead of the on–chip transistor and PC board traces and tap capacitors. Parasitic oscillations often occur in the 200 to 800 MHz range. A small resistor is placed in series with the base (Pin 28) to cancel the negative resistance associated with this undesired mode of oscillation. Since the base input impedance is so large, a small resistor in the range of 27 to 68 Ω has very little effect on the desired Butler mode of oscillation.

The crystal parallel capacitance, C_o, provides a feedback path that is low enough in reactance at frequencies of 5th overtones or higher to cause trouble. C_o has little effect near resonance because of the low impedance of the crystal motional arm (R_m–L_m–C_m). As the tunable inductor, which forms the resonant tank with the tap capacitors, is tuned off the crystal resonant frequency, it may be difficult to tell if the oscillation is under crystal control. Frequency jumps may occur as the inductor is tuned. In order to eliminate this behavior an inductor, L_o, is placed in parallel with the crystal. L_o is chosen to resonant with the crystal parallel capacitance, C_o, at the desired operation frequency. The inductor provides a feedback path at frequencies well below resonance; however, the parallel tank network of the tap capacitors and tunable inductor prevent oscillation at these frequencies.

Receiver Design Considerations

The curves of signal levels at various portions of the application receiver with respect to RF input level are shown in Figure 17. This information helps determine the network topology and gain blocks required ahead of the MC13150 to achieve the desired sensitivity and dynamic range of the receiver system. The PCB is laid out to accommodate a low noise preamp followed by the 83.16 MHz SAW filter. In the application circuit (Figure 15), the input 1.0 dB compression point is –10 dBm and the input third order intercept (IP3) performance of the system is approximately 0 dBm (see Figure 18).

Wideband FM IF

The MC13155 is a complete wideband FM detector designed for satellite TV and other wideband data and analog FM applications. This device may be cascaded for higher IF gain and extended Receive Signal Strength Indicator (RSSI) range.

- 12 MHz Video/Baseband Demodulator
- Ideal for Wideband Data and Analog FM Systems
- Limiter Output for Cascade Operation
- Low Drain Current: 7.0 mA
- Low Supply Voltage: 3.0 to 6.0 V
- Operates to 300 MHz

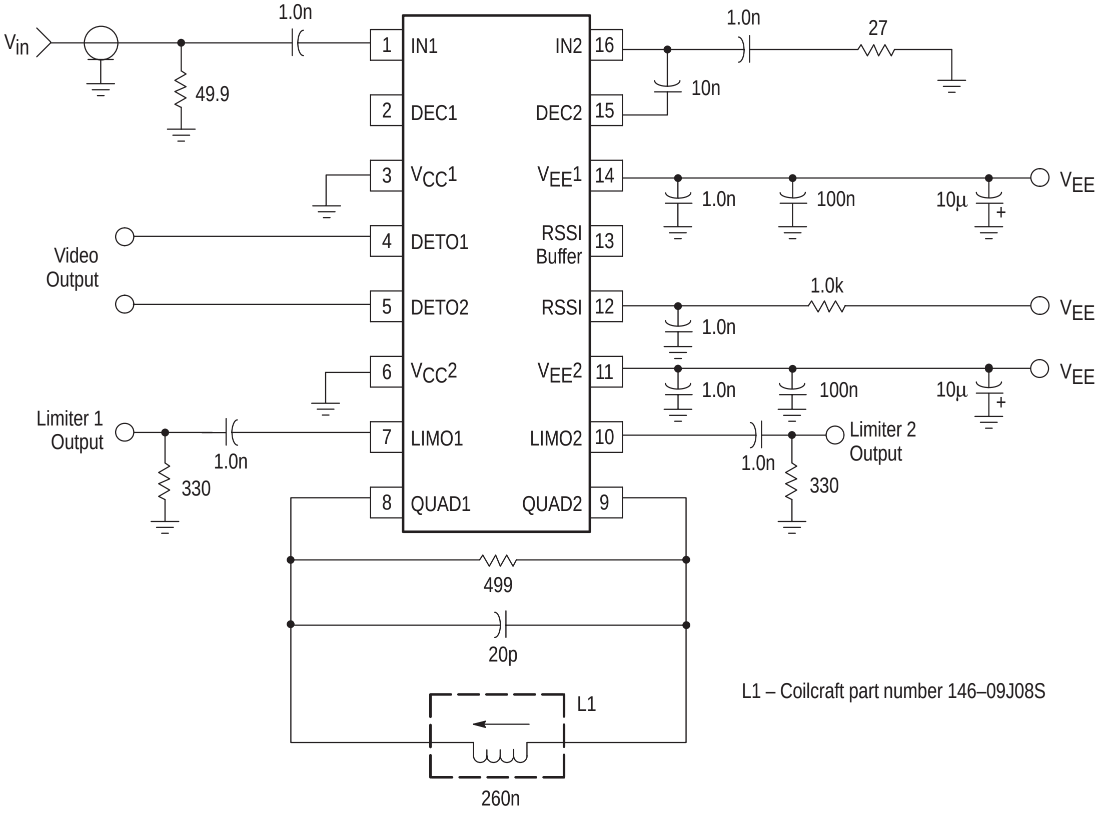
CIRCUIT DESCRIPTION

The MC13155 consists of a wideband three–stage limiting amplifier, a wideband quadrature detector which may be operated up to 200 MHz, and a received signal strength indicator (RSSI) circuit which provides a current output linearly proportional to the IF input signal level for approximately 35 dB range of input level.

Figure 2. Test Circuit



L1 – Coilcraft part number 146–09J08S

APPLICATIONS INFORMATION

Evaluation PC Board

The evaluation PCB shown in Figures 19 and 20 is very versatile and is designed to cascade two ICs. The center section of the board provides an area for attaching all surface mount components to the circuit side and radial leaded components to the component ground side of the PCB (see Figures 17 and 18). Additionally, the peripheral area surrounding the RF core provides pads to add supporting and interface circuitry as a particular application dictates. This evaluation board will be discussed and referenced in this section.

Limiting Amplifier

Differential input and output ports interfacing the three stage limiting amplifier provide a differential power gain of typically 46 dB and useable frequency range of 300 MHz. The IF gain flatness may be controlled by decoupling of the internal feedback network at Pins 2 and 15.

Scattering parameter (S–parameter) characterization of the IF as a two port linear amplifier is useful to implement maximum stable power gain, input matching, and stability over a desired bandpass response and to ensure stable operation outside the bandpass as well. The MC13155 is unconditionally stable over most of its useful operating frequency range; however, it can be made unconditionally stable over its entire operating range with the proper decoupling of Pins 2 and 15. Relatively small decoupling capacitors of about 100 pF have a significant effect on the wideband response and stability. This is shown in the scattering parameter tables where S–parameters are shown for various values of C2 and C15 and at V_{EE} of – 3.0 and – 5.0 Vdc.

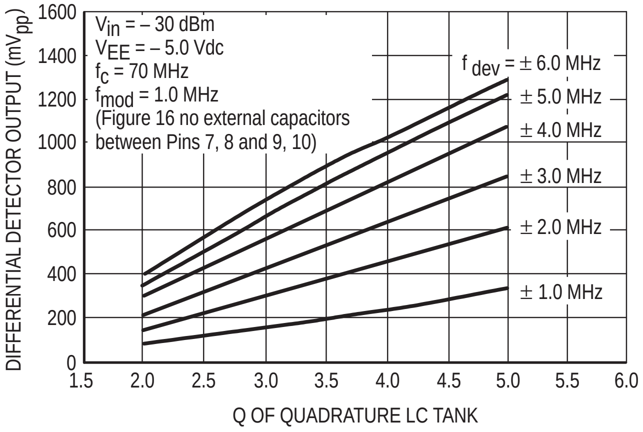

Figure 11B. Differential Detector Output Voltage versus Q of Quadrature LC Tank

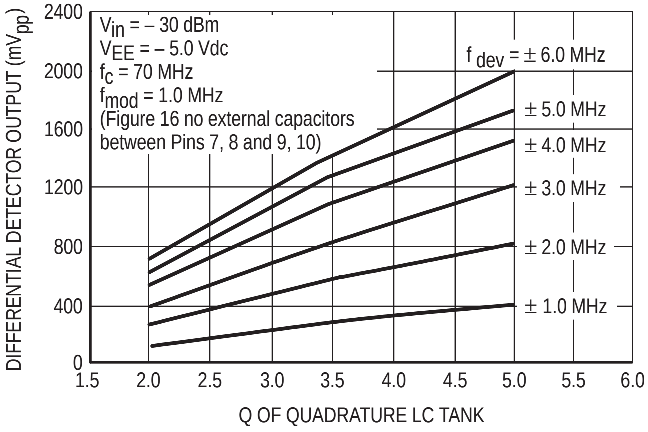

Figure 12. RSSI Output Voltage versus IF Input

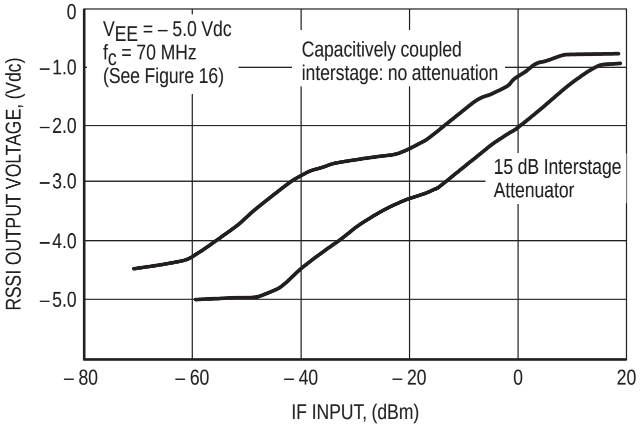

Figure 13. – S+N, N versus IF Input

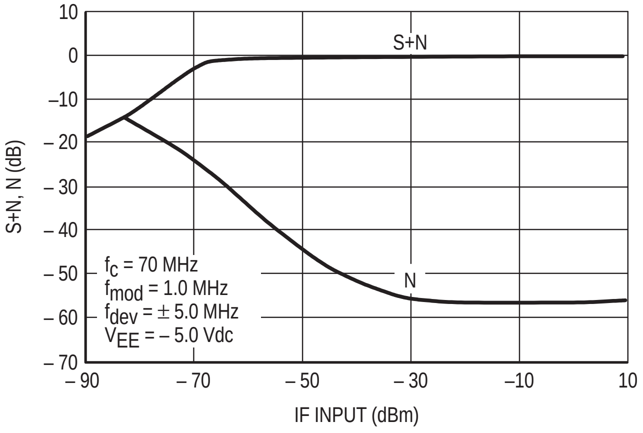

In the S–parameters measurements, the IF is treated as a two–port linear class A amplifier. The IF amplifier is measured with a single–ended input and output configuration in which the Pins 16 and 7 are terminated in the series combination of a 47 Ω resistor and a 10 nF capacitor to V_{CC} ground (see Figure 14. S–Parameter Test Circuit).

The S–parameters are in polar form as the magnitude (MAG) and angle (ANG). Also listed in the tables are the calculated values for the stability factor (K) and the Maximum Available Gain (MAG). These terms are related in the following equations:

$$K = (1 - |S_{11}|^2 - |S_{22}|^2 + |\Delta|^2) / (2 |S_{12} S_{21}|)$$

where: $|\Delta| = |S_{11} S_{22} - S_{12} S_{21}|$.

$$MAG = 10 \log |S_{21}| / |S_{12}| + 10 \log |K - (K^2 - 1)^{1/2}|$$

where: K > 1. The necessary and sufficient conditions for unconditional stability are given as K > 1:

$$B1 = 1 + |S_{11}|^2 - |S_{22}|^2 - |\Delta|^2 > 0$$

DC Biasing Considerations

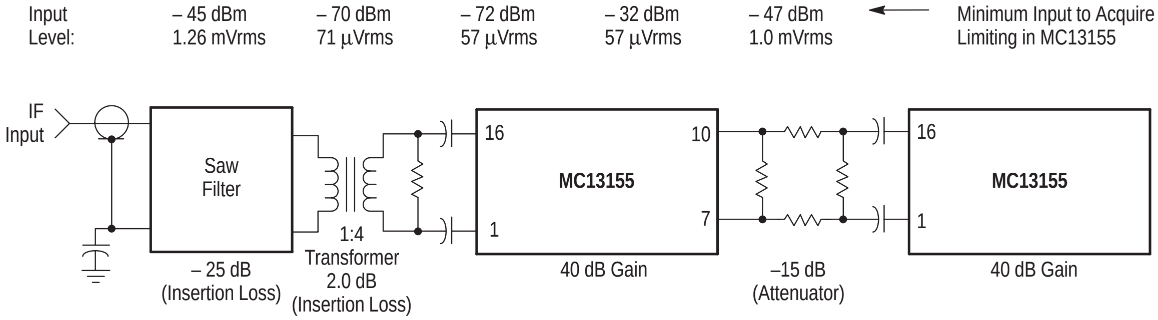
The DC biasing scheme utilizes two V_{CC} connections (Pins 3 and 6) and two V_{EE} connections (Pins 14 and 11). $V_{EE}1$ (Pin 14) is connected internally to the IF and RSSI circuits' negative supply bus while $V_{EE}2$ (Pin 11) is connected internally to the quadrature detector's negative bus. Under positive ground operation, this unique configuration offers the ability to bias the RSSI and IF separately from the quadrature detector. When two ICs are cascaded as shown in the 70 MHz application circuit and provided by the PCB (see Figures 17 and 18), the first MC13155 is used without biasing its quadrature detector, thereby saving approximately 3.0 mA. A total current of 7.0 mA is used to fully bias each IC, thus the total current in the application circuit is approximately 11 mA. Both V_{CC} pins are biased by the same supply. $V_{CC}1$ (Pin 3) is connected internally to the positive bus of the first half of the IF limiting amplifier, while $V_{CC}2$ is internally connected to the positive bus of the RSSI, the quadrature detector circuit, and the second half of the IF limiting amplifier (see Figure 15). This distribution of the V_{CC} enhances the stability of the IC.

RSSI Circuitry

The RSSI circuitry provides typically 35 dB of linear dynamic range and its output voltage swing is adjusted by selection of the resistor from Pin 12 to V_{EE}. The RSSI slope is typically 2.1 µA/dB ; thus, for a dynamic range of 35 dB, the current output is approximately 74 µA. A 47 k resistor will yield an RSSI output voltage swing of 3.5 Vdc. The RSSI buffer output at Pin 13 is an emitter–follower and needs an external emitter resistor of 10 k to V_{EE}.

In a cascaded configuration (see circuit application in Figure 16), only one of the RSSI Buffer outputs (Pin 13) is used; the RSSI outputs (Pin 12 of each IC) are tied together and the one closest to the V_{EE} supply trace is decoupled to V_{CC} ground. The two pins are connected to V_{EE} through a 47 k resistor. This resistor sources a RSSI current which is proportional to the signal level at the IF input; typically, 1.0 mVrms (– 47 dBm) is required to place the MC13155 into limiting. The measured RSSI output voltage response of the application circuit is shown in Figure 12. Since the RSSI current output is dependent upon the input signal level at the IF input, a careful accounting of filter losses, matching and other losses and gains must be made in the entire receiver system. In the block diagram of the application circuit shown below, an accounting of the signal levels at points throughout the system shows how the RSSI response in Figure 12 is justified.

Block Diagram of 70 MHz Video Receiver Application Circuit

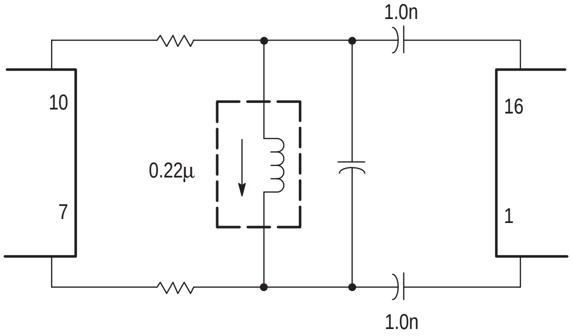


Cascading Stages

The limiting IF output is pinned–out differentially, cascading is easily achieved by AC coupling stage to stage. In the evaluation PCB, AC coupling is shown, however, interstage filtering may be desirable in some applications. In which case, the S–parameters provide a means to implement a low loss interstage match and better receiver sensitivity.

Where a linear response of the RSSI output is desired when cascading the ICs, it is necessary to provide at least 10 dB of interstage loss. Figure 12 shows the RSSI response with and without interstage loss. A 15 dB resistive attenuator is an inexpensive way to linearize the RSSI response. This has its drawbacks since it is a wideband noise source that is dependent upon the source and load impedance and the amount of attenuation that it provides. A better, although more costly, solution would be a bandpass filter designed to the desired center frequency and bandpass response while carefully selecting the insertion loss. A network topology shown below may be used to provide a bandpass response with the desired insertion loss.

Network Topology



Quadrature Detector

The quadrature detector is coupled to the IF with internal 2.0 pF capacitors between Pins 7 and 8 and Pins 9 and 10. For wideband data applications, such as FM video and satellite receivers, the drive to the detector can be increased with additional external capacitors between these pins, thus, the recovered video signal level output is increased for a given bandwidth (see Figure 11A and Figure 11B).

The wideband performance of the detector is controlled by the loaded Q of the LC tank circuit. The following equation defines the components which set the detector circuit's bandwidth:

$$Q = R_T/X_L \qquad (1)$$

where: R_T is the equivalent shunt resistance across the LC Tank and X_L is the reactance of the quadrature inductor at the IF frequency ($X_L = 2\pi fL$).

The inductor and capacitor are chosen to form a resonant LC Tank with the PCB and parasitic device capacitance at the desired IF center frequency as predicted by:

$$fc = (2\pi \sqrt{(LC_p)})^{-1} \qquad (2)$$

where: L is the parallel tank inductor and C_p is the equivalent parallel capacitance of the parallel resonant tank circuit.

The following is a design example for a wideband detector at 70 MHz and a loaded Q of 5. The loaded Q of the quadrature detector is chosen somewhat less than the Q of the IF bandpass. For an IF frequency of 70 MHz and an IF bandpass of 10.9 MHz, the IF bandpass Q is approximately 6.4.

Example:

Let the external Cext = 20 pF. (The minimum value here should be greater than 15 pF making it greater than the internal device and PCB parasitic capacitance, Cint ≈ 3.0 pF).

$$C_p = Cint + Cext = 23 \text{ pF}$$

Rewrite Equation 2 and solve for L:

$L = (0.159)^2 / (C_p\, fc^2)$

L = 198 nH, thus, a standard value is chosen.

L = 0.22 µH (tunable shielded inductor).

The value of the total damping resistor to obtain the required loaded Q of 5 can be calculated by rearranging Equation 1:

$$R_T = Q(2\pi fL)$$

$$R_T = 5\,(2\pi)(70)(0.22) = 483.8\ \Omega.$$

The internal resistance, Rint between the quadrature tank Pins 8 and 9 is approximately 3200 Ω and is considered in determining the external resistance, Rext which is calculated from:

Rext = $((R_T)(Rint))/ (Rint – R_T)$

Rext = 570, thus, choose the standard value.

Rext = 560 Ω.

SAW Filter

In wideband video data applications, the IF occupied bandwidth may be several MHz wide. A good rule of thumb is to choose the IF frequency about 10 or more times greater than the IF occupied bandwidth. The IF bandpass filter is a SAW filter in video data applications where a very selective response is needed (i.e., very sharp bandpass response). The evaluation PCB is laid out to accommodate two SAW filter package types: 1) A five–leaded plastic SIP package. Recommended part numbers are Siemens X6950M which operates at 70 MHz; 10.4 MHz 3 dB passband, X6951M (X252.8) which operates at 70 MHz; 9.2 MHz 3 dB passband; and X6958M which operates at 70 MHz, 6.3 MHz 3 dB passband, and 2) A four–leaded TO–39 metal can package. Typical insertion loss in a wide bandpass SAW filter is 25 dB.

The above SAW filters require source and load impedances of 50 Ω to assure stable operation. On the PC board layout, space is provided to add a matching network, such as a 1:4 surface mount transformer between the SAW filter output and the input to the MC13155. A 1:4 transformer, made by Coilcraft and Mini Circuits, provides a suitable interface (see Figures 16, 17 and 18). In the circuit and layout, the SAW filter and the MC13155 are differentially configured with interconnect traces which are equal in length and symmetrical. This balanced feed enhances RF stability, phase linearity, and noise performance.

MC13156

Wideband FM IF System

The MC13156 is a wideband FM IF subsystem targeted at high performance data and analog applications. Excellent high frequency performance is achieved at low cost using Motorola's MOSAIC 1.5™ bipolar process. The MC13156 has an onboard grounded collector VCO transistor that may be used with a fundamental or overtone crystal in single channel operation or with a PLL in multichannel operation. The mixer is useful to 500 MHz and may be used in a balanced–differential, or single–ended configuration. The IF amplifier is split to accommodate two low cost cascaded filters. RSSI output is derived by summing the output of both IF sections. A precision data shaper has a hold function to preset the shaper for fast recovery of new data.

Applications for the MC13156 include CT–2, wideband data links and other radio systems utilizing GMSK, FSK or FM modulation.

- 2.0 to 6.0 Vdc Operation
- Typical Sensitivity at 200 MHz of 2.0 μV for 12 dB SINAD
- RSSI Dynamic Range Typically 80 dB
- High Performance Data Shaper for Enhanced CT–2 Operation
- Internal 330 Ω and 1.4 kΩ Terminations for 10.7 MHz and 455 kHz Filters
- Split IF for Improved Filtering and Extended RSSI Range
- 3rd Order Intercept (Input) of –25 dBm (Input Matched)

CIRCUIT DESCRIPTION

General

The MC13156 is a low power single conversion wideband FM receiver incorporating a split IF. This device is designated for use as the backend in digital FM systems such as CT–2 and wideband data links with data rates up to 500 kbaud. It contains a mixer, oscillator, signal strength meter drive, IF amplifier, limiting IF, quadrature detector and a data slicer with a hold function (refer to Figure 8, Simplified Internal Circuit Schematic).

Current Regulation

Temperature compensating voltage independent current regulators are used throughout.

Mixer

The mixer is a double–balanced four quadrant multiplier and is designed to work up to 500 MHz. It can be used in differential or in single–ended mode by connecting the other input to the positive supply rail.

Figure 4 shows the mixer gain and saturated output response as a function of input signal drive. The circuit used to measure this is shown in Figure 1. The linear gain of the mixer is approximately 22 dB. Figure 9 shows the mixer gain versus the IF output frequency with the local oscillator of 150 MHz at 100 mVrms LO drive level. The RF frequency is swept. The sensitivity of the IF output of the mixer is shown in Figure 10 for an RF input drive of 10 mVrms at 140 MHz and IF at 10 MHz.

The single–ended parallel equivalent input impedance of the mixer is Rp ~ 1.0 kΩ and Cp ~ 4.0 pF (see Table 1 for details). The buffered output of the mixer is internally loaded resulting in an output impedance of 330 Ω.

Local Oscillator

The on–chip transistor operates with crystal and LC resonant elements up to 220 MHz. Series resonant, overtone crystals are used to achieve excellent local oscillator stability. 3rd overtone crystals are used through about 65 to 70 MHz. Operation from 70 MHz up to 180 MHz is feasible using the on–chip transistor with a 5th or 7th overtone crystal. To enhance operation using an overtone crystal, the internal transistor’s bias is increased by adding an external resistor from Pin 23 to V_{EE}. –10 dBm of local oscillator drive is needed to adequately drive the mixer (Figure 10).

The oscillator configurations specified above, and two others using an external transistor, are described in the application section:

1) A 133 MHz oscillator multiplier using a 3rd overtone crystal, and
2) A 307.8 to 309.3 MHz manually tuned, varactor controlled local oscillator.

RSSI

The Received Signal Strength Indicator (RSSI) output is a current proportional to the log of the received signal amplitude. The RSSI current output is derived by summing the currents from the IF and limiting amplifier stages. An external resistor at Pin 20 sets the voltage range or swing of the RSSI output voltage. Linearity of the RSSI is optimized by using external ceramic or crystal bandpass filters which have an insertion loss of 8.0 dB. The RSSI circuit is designed to provide 70+ dB of dynamic range with temperature compensation (see Figures 6 and 7 which show RSSI responses of the IF and Limiter amplifiers). Variation in the RSSI output current with supply voltage is small (see Figure 11).

Carrier Detect

When the meter current flowing through the meter load resistance reaches 1.2 Vdc above ground, the comparator flips, causing the carrier detect output to go high. Hysteresis can be accomplished by adding a very large resistor for positive feedback between the output and the input of the comparator.

IF Amplifier

The first IF amplifier section is composed of three differential stages with the second and third stages contributing to the RSSI. This section has internal dc feedback and external input decoupling for improved symmetry and stability. The total gain of the IF amplifier block is approximately 39 dB at 10.7 MHz. Figure 5 shows the gain and saturated output response of the IF amplifier over temperature, while Figure 12 shows the IF amplifier gain as a function of the IF frequency.

The fixed internal input impedance is 1.4 kΩ. It is designed for applications where a 455 kHz ceramic filter is used and no external output matching is necessary since the filter requires a 1.4 kΩ source and load impedance.

For 10.7 MHz ceramic filter applications, an external 430 Ω resistor must be added in parallel to provide the equivalent load impedance of 330 Ω that is required by the filter; however, no external matching is necessary at the input since the mixer output matches the 330 Ω source impedance of the filter. For 455 kHz applications, an external 1.1 kΩ resistor must be added in series with the mixer output to obtain the required matching impedance of 1.4 kΩ of the filter input resistance. Overall RSSI linearity is dependent on having total midband attenuation of 12 dB (6.0 dB insertion loss plus 6.0 dB impedance matching loss) for the filter. The output of the IF amplifier is buffered and the impedance is 290 Ω.

Limiter

The limiter section is similar to the IF amplifier section except that four stages are used with the last three contributing to the RSSI. The fixed internal input impedance is 1.4 kΩ. The total gain of the limiting amplifier section is approximately 55 dB. This IF limiting amplifier section internally drives the quadrature detector section.

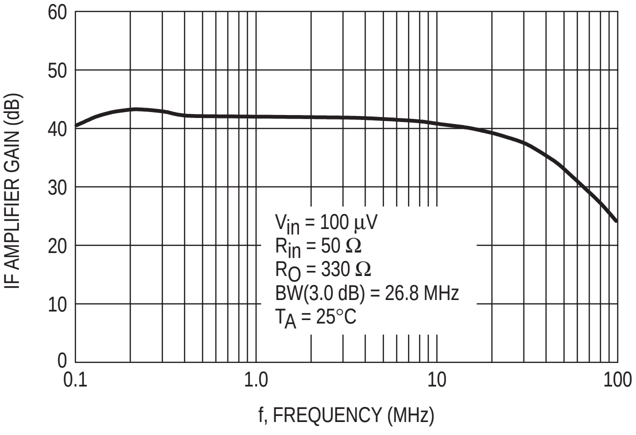

Figure 12. IF Amplifier Gain versus IF Frequency

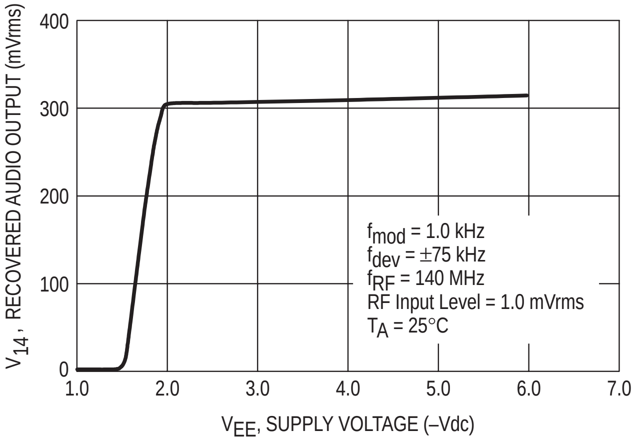

Figure 13. Recovered Audio Output Voltage versus Supply Voltage

Quadrature Detector

The quadrature detector is a doubly balanced four quadrant multiplier with an internal 5.0 pF quadrature capacitor to couple the IF signal to the external parallel RLC resonant circuit that provides the 90 degree phase shift and drives the quadrature detector. A single pin (Pin 13) provides for the external LC parallel resonant network and the internal connection to the quadrature detector.

The bandwidth of the detector allows for recovery of relatively high data rate modulation. The recovered signal is converted from differential to single ended through a push–pull NPN/PNP output stage. Variation in recovered audio output voltage with supply voltage is very small (see Figure 13). The output drive capability is approximately ±9.0 µA for a frequency deviation of ±75 kHz and 1.0 kHz modulating frequency (see Application Circuit).

Data Slicer

The data slicer input (Pin 15) is self centering around 1.1 V with clamping occurring at 1.1 ± 0.5 V_{be} Vdc. It is designed to square up the data signal. Figure 14 shows a detailed schematic of the data slicer.

The Voltage Regulator sets up 1.1 Vdc on the base of Q12, the Differential Input Amplifier. There is a potential of 1.0 V_{be} on the base–collector of transistor diode Q11 and 2.0 V_{be} on the base–collector of Q10. This sets up a 1.5 V_{be} (~ 1.1 Vdc) on the node between the 36 kΩ resistors which is connected to the base of Q12. The differential output of the data slicer Q12 and Q13 is converted to a single–ended output by the Driver Circuit. Additional circuitry, not shown in Figure 14, tends to keep the data slicer input centered at 1.1 Vdc as input signal levels vary.

The Input Diode Clamp Circuit provides the clamping at 1.0 V_{be} (0.75 Vdc) and 2.0 V_{be} (1.45 Vdc). Transistor diodes Q7 and Q8 are on, thus, providing a 2.0 V_{be} potential at the base of Q1. Also, the voltage regulator circuit provides a potential of 2.0 Vbe on the base of Q3 and 1.0 V_{be} on the emitter of Q3 and Q2. When the data slicer input (Pin 15) is pulled up, Q1 turns off; Q2 turns on, thereby clamping the input at 2.0 V_{be}. On the other hand, when Pin 15 is pulled down, Q1 turns on; Q2 turns off, thereby clamping the input at 1.0 V_{be}.

The recovered data signal from the quadrature detector is ac coupled to the data slicer via an input coupling capacitor. The size of this capacitor and the nature of the data signal determine how faithfully the data slicer shapes up the recovered signal. The time constant is short for large peak to peak voltage swings or when there is a change in dc level at the detector output. For small signal or for continuous bits of the same polarity which drift close to the threshold voltage, the time constant is longer. When centered there is no input current allowed, which is to say, that the input looks high in impedance.

Another unique feature of the data slicer is that it responds to various logic levels applied to the Data Slicer Hold Control pin (Pin 18). Figure 15 illustrates how the input and output currents under “no hold” condition relate to the input voltage. Figure 16 shows how the input current and input voltage relate for both the “no hold” and “hold” condition.

The hold control (Pin18) does three separate tasks:

1) With Pin 18 at 1.0 V_{be} or greater, the output is shut off (sets high). Q19 turns on which shunts the base drive from Q20, thereby turning the output off.

2) With Pin 18 at 2.0 V_{be} or greater, internal clamping diodes are open circuited and the comparator input is shut off and effectively open circuited. This is accomplished by turning off the current source to emitters of the input differential amplifier, thus, the input differential amplifier is shut off.

3) When the input is shut off, it allows the input capacitor to hold its charge during transmit to improve recovery at the beginning of the next receive period. When it is turned on, it allows for very fast charging of the input capacitor for quick recovery of new tuning or data average. The above features are very desirable in a TDD digital FM system.

APPLICATIONS INFORMATION

Component Selection

The evaluation PC board is designed to accommodate specific components, while also being versatile enough to use components from various manufacturers and coil types. Figures 18 and 19 show the placement for the components specified in the application circuit (Figure 17). The applications circuit schematic specifies particular components that were used to achieve the results shown in the typical curves and tables but equivalent components should give similar results.

Input Matching Networks/Components

The input matching circuit shown in the application circuit schematic is passive high pass network which offers effective image rejection when the local oscillator is below the RF input frequency. Silver mica capacitors are used for their high Q and tight tolerance. The PC board is not dedicated to any particular input matching network topology; space is provided for the designer to breadboard as desired.

Alternate matching networks using 4:1 surface mount transformers or BALUNs provide satisfactory performance. The 12 dB SINAD sensitivity using the above matching networks is typically –100 dBm for f_{mod} = 1.0 kHz and f_{dev} = ±75 kHz at f_{IN} = 144.45 MHz and f_{OSC} = 133.75 MHz (see Figure 25).

It is desirable to use a SAW filter before the mixer to provide additional selectivity and adjacent channel rejection and improved sensitivity. The SAW filter should be designed to interface with the mixer input impedance of approximately 1.0 kΩ. Table 1 displays the series equivalent single–ended mixer input impedance.

Local Oscillators

VHF Applications – The local oscillator circuit shown in the application schematic utilizes a third overtone crystal and an RF transistor. Selecting a transistor having good phase noise performance is important; a mandatory criteria is for the device to have good linearity of beta over several decades of collector current. In other words, if the low current beta is suppressed, it will not offer good 1/f noise performance. A third overtone series resonant crystal having at least 25 ppm tolerance over the operating temperature is recommended. The local oscillator is an impedance inversion third overtone Colpitts network and harmonic generator. In this circuit a 560 to 1.0 kΩ resistor shunts the crystal to ensure that it operates in its overtone mode; thus, a blocking capacitor is needed to eliminate the dc path to ground. The resulting parallel LC network should “free–run” near the crystal frequency if a short to ground is placed across the crystal. To provide sufficient output loading at the collector, a high Q variable inductor is used that is tuned to self resonate at the 3rd harmonic of the overtone crystal frequency.

The on–chip grounded collector transistor may be used for HF and VHF local oscillator with higher order overtone crystals. Figure 20 shows a 5th overtone oscillator at 93.3 MHz and Figure 21 shows a 7th overtone oscillator at 148.3 MHz. Both circuits use a Butler overtone oscillator configuration. The amplifier is an emitter follower. The crystal is driven from the emitter and is coupled to the high impedance base through a capacitive tap network. Operation at the desired overtone frequency is ensured by the parallel resonant circuit formed by the variable inductor and the tap capacitors and parasitic capacitances of the on–chip transistor and PC board. The variable inductor specified in the schematic could be replaced with a high tolerance, high Q ceramic or air wound surface mount component if the other components have good tolerances. A variable inductor provides an adjustment for gain and frequency of the resonant tank ensuring lock up and startup of the crystal oscillator. The overtone crystal is chosen with ESR of typically 80 Ω and 120 Ω maximum; if the resistive loss in the crystal is too high, the performance of the oscillator may be impacted by lower gain margins.
