#### Abstract

ON Semiconductor and are trademarks of Semiconductor Components Industries, LLC (SCILLC). SCILLC reserves the right to make changes without further notice to any products herein. SCILLC makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does SCILLC assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. "Typical" parameters which may be provided in SCILLC data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. SCILLC does not convey any license under its patent rights nor the rights of others. SCILLC products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the SCILLC product could create a situation where personal injury or death may occur. Should Buyer purchase or use SCILLC products for any such unintended or unauthorized application, Buyer shall indemnify and hold SCILLC and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that SCILLC was negligent regarding the design or manufacture of the part. SCILLC is an Equal Opportunity/Affirmative Action Employer.

## Very High Voltage Off-Line Switching Regulators with On-Chip Power Switch

This monolithic high voltage switching regulator is specifically designed to operate from a rectified ac line voltage source. Included are an on-chip high voltage power switch, active off-line startup circuitry and a full featured PWM controller with fault protection.

## CHAPTER 2 Data Sheets

## LM285

## Micropower Voltage Reference Diodes

The LM285/LM385 series are micropower two-terminal bandgap voltage regulator diodes. Designed to operate over a wide current range of $10 \mu \mathrm{~A}$ to 20 mA , these devices feature exceptionally low dynamic impedance, low noise and stable operation over time and temperature. Tight voltage tolerances are achieved by on-chip trimming. The large dynamic operating range enables these devices to be used in applications with widely varying supplies with excellent regulation. Extremely low operating current make these devices ideal for micropower circuitry like portable instrumentation, regulators and other analog circuitry where extended battery life is required.

The LM285/LM385 series are packaged in a low cost TO-226AA plastic case and are available in two voltage versions of 1.235 and 2.500 V as denoted by the device suffix (see Ordering Information table). The LM285 is specified over a $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range while the LM385 is rated from $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$.

The LM385 is also available in a surface mount plastic package in voltages of 1.235 and 2.500 V .

- Operating Current from $10 \mu \mathrm{~A}$ to 20 mA
- $1.0 \%, 1.5 \%, 2.0 \%$ and $3.0 \%$ Initial Tolerance Grades
- Low Temperature Coefficient
- $1.0 \Omega$ Dynamic Impedance
- Surface Mount Package Available

## NCP100

## Sub 1.0 V Precision Adjustable Shunt Regulator

The NCP100 is a precision low voltage shunt regulator that is programmable over a voltage range of 0.9 V to 6.0 V . This device features a guaranteed reference accuracy of $\pm 1.7 \%$ at $25^{\circ} \mathrm{C}$ and $\pm 2.6 \%$ over the entire temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$. The NCP100 exhibits a sharp low current turn-on characteristic with a low dynamic impedance of $0.20 \Omega$ over an operating current range of $100 \mu \mathrm{~A}$ to 20 mA . These characteristics make this device an ideal replacement for zener diodes in numerous application circuits that require a precise low voltage reference. When combined with an optocoupler, the NCP100 can be used as an error amplifier for controlling the feedback loop in isolated low output voltage ( 2.3 V ) switching power supplies. This device is available in an economical space saving TSOP-5 package.

## Features

- Programmable Output Voltage Range of 0.9 V to 6.0 V
- Voltage Reference Tolerance of $\pm 1.7 \%$
- Sharp Low Current Turn-ON Characteristic
- Low Dynamic Output Impedance of $0.2 \Omega$ from $100 \mu \mathrm{~A}$ to 20 mA
- Wide Operating Current Range of $80 \mu \mathrm{~A}$ to 20 mA
- Space Saving TSOP-5 Package

## Applications

- Reference for Single Cell Alkaline, NiCD and NiMH Applications
- Low Output Voltage (2.3 V) Switching Power Supply Error Amp
- Battery Powered Consumer Products
- Portable Test Equipment and Instrumentation

## APPLICATIONS INFORMATION

The NCP100 is an adjustable shunt regulator similar to the industry standard 431-type regulators. Each device is laser trimmed at wafer probe to allow for tight reference accuracy and low reference voltage shift over the full operating temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ (Figure 7).

The nominal value for the reference is 0.698 V . This lower voltage allows the device to be used in low voltage applications where the traditional 1.25 V and 2.5 V references are not suitable.

Figure 21. Typical Application Circuit
The typical application circuit for this device is shown in Figure 21. The cathode voltage can be programmed between 0.9 V to 6.0 V to allow for proper operation by setting the R1/R2 resistor divider network values. The following equation can be used in calculating the cathode voltage $\left(\mathrm{V}_{\mathrm{KA}}\right)$. Note, if $\mathrm{V}_{\mathrm{KA}}$ is known then the ratio of R 1 and R 2 can be determined from this equation as well.

$$
V_{K A}=V_{\text {ref }}\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right)+I_{\text {ref }} \mathrm{R} 1
$$

The table below shows the required $\mathrm{R} 1 / \mathrm{R} 2$ values using $1.0 \%$ resistors for commonly used voltages.

| $\mathbf{V}_{\mathbf{K A}}$ <br> $(\mathrm{V})$ | $\mathbf{R 1}$ <br> $(\mathbf{k} \Omega)$ | $\mathbf{R 2}$ <br> $(\mathrm{k} \boldsymbol{\Omega})$ |
| :---: | :---: | :---: |
| 0.9 | 30 | 100 |
| 1.0 | 43.2 | 100 |
| 1.8 | 158 | 100 |
| 3.3 | 374 | 100 |
| 5.0 | 619 | 100 |
| 6.0 | 750 | 100 |

Because the error amplifier is a CMOS design the value of $\mathrm{I}_{\text {ref }}$ is extremely low allowing it to be neglected for most applications. The low $\mathrm{I}_{\text {ref }}$ also allows for higher R1 and R2 values keeping current consumption very low.

The NCP100 is especially well suited for lower voltage applications, particularly at $\mathrm{V}_{\mathrm{KA}}=1.0 \mathrm{~V}$. As is seen in Figures 7 and 8, this device exhibits excellent cathode and reference voltage flatness across the $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ temperature range.
In Figure 21, the input resistor $\left(\mathrm{R}_{\text {in }}\right)$ is nominally set to $1.0 \mathrm{k} \Omega$. For proper operation, once $\mathrm{V}_{\mathrm{in}}, \mathrm{R} 1$ and R 2 are set,
the resistance and power value of $\mathrm{R}_{\text {in }}$ can be determined by the following equation.

$$
\mathrm{R}_{\text {in }}=\frac{\mathrm{V}_{\text {in }}-\mathrm{V}_{\mathrm{KA}}}{\mathrm{I}_{\mathrm{K}}+\mathrm{I}_{\mathrm{L}}+\left(\frac{\mathrm{V}_{\mathrm{KA}}}{\mathrm{R}_{1}+\mathrm{R}_{2}}\right)}
$$

The maximum current that will flow through $\mathrm{R}_{\text {in }}$ must be determined. This is the sum of the maximum values of cathode current, resistor divider network current, and load current. With $\mathrm{V}_{\mathrm{in}}$, set, the difference $\left(\mathrm{V}_{\mathrm{in}}-\mathrm{V}_{\mathrm{KA}}\right)$ is now constant. This value is divided by the maximum current calculated above to arrive at the value of $R_{i n}$. Once the value of $R_{\text {in }}$ is calculated, it's minimum power rating is easily derived by:

$$
P_{\text {in }}=\left(l_{\text {in }}\right)^{2} R_{\text {in }}
$$

Once these values are determined, it should be verified that the minimum and maximum values of $\mathrm{I}_{\mathrm{K}}$ are within the recommended range of 0.1 mA to 20 mA under the worst case conditions.
For stability, the NCP100 requires an output capacitor between the cathode and anode. Figure 19 shows the capacitance boundary values required for stable operation across the $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ temperature range. The goal is to remain to the right of the curve for any programmed cathode voltages. For example, if the $\mathrm{V}_{\mathrm{KA}}$ is programmed to 1.0 V , then a load capacitor value of $3.0 \mu \mathrm{~F}$ or greater would be selected. The load capacitor's equivalent series resistance, ESR, should be less than $4.0 \Omega$. Both the capacitance and ESR values should be checked across the anticipated application temperature range to insure that the values meet the requirements stated above.

Figure 22. Negative Dynamic Impedance Circuit
One unique use for the NCP100 is that it can be configured for negative dynamic impedance as shown in Figure 22. This circuit is equivalent to Figure 21 with the addition of a small value resistor $\mathrm{R}_{\text {comp }}$ in the cathode circuit. The regulated voltage output remains across the NCP100 cathode and anode leads. The voltage programming and stability requirements remain the same as in the typical application shown in Figure 21.

## NCP100

The circuit performs the same as the one in Figure 21 with the exception of the effects of $R_{\text {comp }}$. As $I_{K}$ increases, the voltage across $\mathrm{R}_{\text {comp }}$ also increases by:

$$
\mathrm{V}_{\mathrm{comp}}=\mathrm{I}_{\mathrm{KA}} \mathrm{R}_{\mathrm{comp}}
$$

$\mathrm{V}_{\text {comp }}$ effectively adjusts the NCP100 programmed $\mathrm{V}_{\text {KA }}$ voltage slightly down since the R1/R2 voltage divider will try to hold the point it is connected to at the programmed voltage. The regulator $\mathrm{V}_{\mathrm{KA}}$ will now be lowered by the value of the $\mathrm{V}_{\text {comp }}$. This effect can compensate for the NCP100's intrinsic positive impedance versus cathode current ( $\mathrm{I}_{\mathrm{K}}$ ) to allow for $0 \Omega$ or even a negative dynamic impedance.

Figure 23 shows this phenomenon for a program voltage of 1.0 V . The NCP100 intrinsic positive dynamic impedance

Figure 23. Cathode Current vs. Cathode Voltage for Programmed $\mathrm{V}_{\mathrm{KA}}=1.0 \mathrm{~V}$
response is the $\mathrm{R}_{\text {comp }}=0 \Omega$ curve. A $0 \Omega$ dynamic impedance regulator response is realized with $\mathrm{R}_{\text {comp }}=$ $0.15 \Omega$. Negative dynamic impedance responses are achieved with $\mathrm{R}_{\text {comp }}>0.15 \Omega$.

Figure 24 shows the characteristic at a programmed $\mathrm{V}_{\mathrm{KA}}$ of 6.0 V . The $0 \Omega$ dynamic impedance value corresponds to $\mathrm{R}_{\text {comp }}=2.9 \Omega$.
Figure 25 shows the dynamic impedance versus cathode compensation resistance for programmed voltages of 1.0 V , 3.3 V and 6.0 V . It can be seen that any value up to the positive intrinsic dynamic impedance of the NCP100 can be realized. The other limit is that with a high enough negative dynamic impedance, the NCP100 V may drop below the minimum operating $\mathrm{V}_{\mathrm{KA}}$ voltage of 0.9 V , which can result in unpredictable performance.

Figure 24. Cathode Current vs. Cathode Voltage for Programmed $\mathrm{V}_{\mathrm{KA}}=6.0 \mathrm{~V}$

Figure 25. Dynamic Impedance vs. Cathode Compensation Resistance

Figure 26. High Current Shunt Regulator

Figure 27. Low Dropout Series Pass Regulator

Figure 28. Offline Converter with Isolated DC Output

The circuit in Figure 28 uses the NCP100 as a compensated amplifier for controlling the feedback loop of an isolated output line powered converter. This device allows the converter to directly regulate the output voltage at a significantly lower level than obtainable with the
common TL431 device family. The output voltage is programmed by the resistors R1 and R2. The minimum regulated DC output is limited to the sum of the lowest allowable cathode to anode voltage ( 0.9 V ) and the forward drop of the optocoupler light emitting diode (1.4 V).

## INFORMATION FOR USING THE TSOP-5 SURFACE MOUNT PACKAGE <br> MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

TSOP-5

## TLV431A

## Low Voltage Precision Adjustable Shunt Regulator

The TLV431A series are precision low voltage shunt regulators that are programmable over a wide voltage range of 1.24 V to 16 V . These series feature a guaranteed reference accuracy of $\pm 1.0 \%$ at $25^{\circ} \mathrm{C}$ and $\pm 2.0 \%$ over the entire industrial temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$. These devices exhibit a sharp low current turn-on characteristic with a low dynamic impedance of $0.20 \Omega$ over an operating current range of $100 \mu \mathrm{~A}$ to 20 mA . This combination of features makes this series an excellent replacement for zener diodes in numerous applications circuits that require a precise reference voltage. When combined with an optocoupler, the TLV431A can be used as an error amplifier for controlling the feedback loop in isolated low output voltage ( 3.0 V to 3.3 V ) switching power supplies. These devices are available in economical TSOP-5 and TO-92 packages.

## Features

- Programmable Output Voltage Range of 1.24 V to 16 V
- Voltage Reference Tolerance $\pm 1.0 \%$
- Sharp Low Current Turn-On Characteristic
- Low Dynamic Output Impedance of $0.20 \Omega$ from $100 \mu \mathrm{~A}$ to 20 mA
- Wide Operating Current Range of $50 \mu \mathrm{~A}$ to 20 mA
- Micro Miniature TSOP-5 and TO-92 Packages

## Applications

- Low Output Voltage (3.0 V to 3.3 V) Switching Power Supply Error Amplifier
- Adjustable Voltage or Current Linear and Switching Power Supplies
- Voltage Monitoring
- Current Source and Sink Circuits
- Analog and Digital Circuits Requiring Precision References
- Low Voltage Zener Diode Replacements

2. Ambient temperature range: $\mathrm{T}_{\text {low }}=-40^{\circ} \mathrm{C}, \mathrm{T}_{\text {high }}=85^{\circ} \mathrm{C}$.
3. The deviation parameters $\Delta \mathrm{V}_{\text {ref }}$ and $\Delta \mathrm{I}_{\text {ref }}$ are defined as the difference between the maximum value and minimum value obtained over the full operating ambient temperature range that applied.

The average temperature coefficient of the reference input voltage, $\alpha \mathrm{V}_{\text {ref }}$ is defined as:

$$
\alpha \mathrm{V}_{\text {ref }}\left(\frac{\mathrm{ppm}}{{ }^{\circ} \mathrm{C}}\right)=\frac{\left(\frac{\left(\Delta \mathrm{V}_{\text {ref }}\right)}{\mathrm{V}_{\text {ref }}\left(\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}\right)} \times 10^{6}\right)}{\Delta \mathrm{T}_{\mathrm{A}}}
$$

$\alpha \mathrm{V}_{\text {ref }}$ can be positive or negative depending on whether $\mathrm{V}_{\text {ref }}$ Min or $\mathrm{V}_{\text {ref }}$ Max occurs at the lower ambient temperature, refer to Figure 6. Example: $\Delta \mathrm{V}_{\text {ref }}=7.2 \mathrm{mV}$ and the slope is positive,

$$
\begin{aligned}
& \mathrm{V}_{\text {ref }} @ 25^{\circ} \mathrm{C}=1.241 \mathrm{~V} \\
& \Delta \mathrm{~T}_{\mathrm{A}}=125^{\circ} \mathrm{C} \\
& \\
& \qquad \alpha \mathrm{~V}_{\text {ref }}\left(\frac{\mathrm{ppm}}{{ }^{\circ} \mathrm{C}}\right)=\frac{\frac{0.0072}{1.241} \times 10^{6}}{125}=46 \mathrm{ppm} /{ }^{\circ} \mathrm{C}
\end{aligned}
$$

4. The dynamic impedance $Z_{K A}$ is defined as:

$$
\left|Z_{K A}\right|=\frac{\Delta V_{K A}}{\Delta I_{K}}
$$

When the device is operating with two external resistors, R1 and R2, (refer to Figure 2) the total dynamic impedance of the circuit is given by:

$$
\left|Z_{K A^{\prime}}\right|=\left|Z_{K A}\right| \times\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right)
$$

## TLV431A

Figure 32. Isolated Output Line Powered Switching Power Supply
The above circuit shows the TLV431A as a compensated amplifier controlling the feedback loop of an isolated output line powered switching regulator. The output voltage is programmed to 3.3 V by the resistors values selected for R1 and R2. The minimum output voltage that can be programmed with this circuit is 2.64 V , and is limited by the sum of the reference voltage ( 1.24 V ) and the forward drop of the optocoupler light emitting diode ( 1.4 V ). Capacitor C 1 provides loop compensation.

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

TSOP-5
(Footprint Compatible with SOT-23-5)

## Programmable Precision References

The TL431, A, B integrated circuits are three-terminal programmable shunt regulator diodes. These monolithic IC voltage references operate as a low temperature coefficient zener which is programmable from $\mathrm{V}_{\text {ref }}$ to 36 V with two external resistors. These devices exhibit a wide operating current range of 1.0 mA to 100 mA with a typical dynamic impedance of $0.22 \Omega$. The characteristics of these references make them excellent replacements for zener diodes in many applications such as digital voltmeters, power supplies, and op amp circuitry. The 2.5 V reference makes it convenient to obtain a stable reference from 5.0 V logic supplies, and since the TL431, A, B operates as a shunt regulator, it can be used as either a positive or negative voltage reference.

- Programmable Output Voltage to 36 V
- Voltage Reference Tolerance: $\pm 0.4 \%$, Typ @ $25^{\circ} \mathrm{C}$ (TL431B)
- Low Dynamic Output Impedance, $0.22 \Omega$ Typical
- Sink Current Capability of 1.0 mA to 100 mA
- Equivalent Full-Range Temperature Coefficient of $50 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ Typical
- Temperature Compensated for Operation over Full Rated Operating Temperature Range
- Low Output Noise Voltage

NOTES: 1. $\mathrm{T}_{\text {low }}=-40^{\circ} \mathrm{C}$ for TL431AIP TL431AILP, TL431IP, TL431ILP, TL431BID, TL431BIP, TL431BILP, TL431AIDM, TL431IDM, TL431BIDM $=0^{\circ} \mathrm{C}$ for TL431ACP, TL431ACLP, TL431CP, TL431CLP, TL431CD, TL431ACD, TL431BCD, TL431BCP, TL431BCLP, TL431CDM, TL431ACDM, TL431BCDM
$T_{\text {high }}=+85^{\circ} \mathrm{C}$ for TL431AIP, TL431AILP, TL431IP, TL431ILP, TL431BID, TL431BIP, TL431BILP, TL431IDM, TL431AIDM, TL431BIDM $=+70^{\circ} \mathrm{C}$ for TL431ACP, TL431ACLP, TL431CP, TL431ACD, TL431BCD, TL431BCP, TL431BCLP, TL431CDM, TL431ACDM, TL431BCDM 2. The deviation parameter $\Delta \mathrm{V}_{\text {ref }}$ is defined as the difference between the maximum and minimum values obtained over the full operating ambient temperature range that applies.

The average temperature coefficient of the reference input voltage, $\alpha \mathrm{V}_{\text {ref }}$ is defined as:

$$
\mathrm{V}_{\text {ref }} \frac{\mathrm{ppm}}{{ }^{\circ} \mathrm{C}}=\frac{\left(\frac{\Delta \mathrm{V}_{\text {ref }}}{\mathrm{V}_{\text {ref }} @ 25^{\circ} \mathrm{C}}\right) \times 10^{6}}{\Delta \mathrm{~T}_{\mathrm{A}}}=\frac{\Delta \mathrm{V}_{\text {ref }} \times 10^{6}}{\Delta \mathrm{~T}_{\mathrm{A}}\left(\mathrm{~V}_{\text {ref }} @ 25^{\circ} \mathrm{C}\right)}
$$

$\alpha \mathrm{V}_{\text {ref }}$ can be positive or negative depending on whether $\mathrm{V}_{\text {ref }}$ Min or $\mathrm{V}_{\text {ref }}$ Max occurs at the lower ambient temperature. (Refer to Figure 6.)

Example : $\Delta \mathrm{V}_{\text {ref }}=8.0 \mathrm{mV}$ and slope is positive,

$$
\mathrm{V}_{\text {ref }} @ 25^{\circ} \mathrm{C}=2.495 \mathrm{~V}, \Delta \mathrm{~T}_{\mathrm{A}}=70^{\circ} \mathrm{C} \quad \alpha \mathrm{~V}_{\text {ref }}=\frac{0.008 \times 10^{6}}{70(2.495)}=45.8 \mathrm{ppm} /{ }^{\circ} \mathrm{C}
$$

3. The dynamic impedance $Z_{K A}$ is defined as $\left|Z_{K A}\right|=\frac{\Delta V_{K A}}{\Delta I_{K}}$

When the device is programmed with two external resistors, R1 and R2, (refer to Figure 2) the total dynamic impedance of the circuit is defined as:

$$
\left|Z_{K A}{ }^{\prime}\right| \approx\left|Z_{K A}\right|\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right)
$$

$T_{\text {high }}=+85^{\circ} \mathrm{C}$ for TL431AIP, TL431AILP, TL431IP, TL431ILP, TL431BID, TL431BIP, TL431BILP, TL431IDM, TL431AIDM, TL431BIDM
$=+70^{\circ} \mathrm{C}$ for TL431ACP, TL431ACLP, TL431CP, TL431ACD, TL431BCD, TL431BCP, TL431BCLP, TL431CDM, TL431ACDM, TL431BCDM
2. The deviation parameter $\Delta \mathrm{V}_{\text {ref }}$ is defined as the difference between the maximum and minimum values obtained over the full operating ambient temperature range that applies.

The average temperature coefficient of the reference input voltage, $\alpha \mathrm{V}_{\text {ref }}$ is defined as:

$$
\mathrm{V}_{\text {ref }} \frac{\mathrm{ppm}}{{ }^{\circ} \mathrm{C}}=\frac{\left(\frac{\Delta \mathrm{V}_{\text {ref }}}{\mathrm{V}_{\text {ref }} @ 25^{\circ} \mathrm{C}}\right) \times 10^{6}}{\Delta \mathrm{~T}_{\mathrm{A}}}=\frac{\Delta \mathrm{V}_{\text {ref }} \times 10^{6}}{\Delta \mathrm{~T}_{\mathrm{A}}\left(\mathrm{~V}_{\text {ref }} @ 25^{\circ} \mathrm{C}\right)}
$$

$\alpha \mathrm{V}_{\text {ref }}$ can be positive or negative depending on whether $\mathrm{V}_{\text {ref }}$ Min or $\mathrm{V}_{\text {ref }}$ Max occurs at the lower ambient temperature. (Refer to Figure 6.)
Example : $\Delta \mathrm{V}_{\text {ref }}=8.0 \mathrm{mV}$ and slope is positive,

$$
\mathrm{V}_{\text {ref }} @ 25^{\circ} \mathrm{C}=2.495 \mathrm{~V}, \Delta \mathrm{~T}_{\mathrm{A}}=70^{\circ} \mathrm{C} \quad \alpha \mathrm{~V}_{\text {ref }}=\frac{0.008 \times 10^{6}}{70(2.495)}=45.8 \mathrm{ppm} /{ }^{\circ} \mathrm{C}
$$

3. The dynamic impedance $Z_{K A}$ is defined as $\left|Z_{K A}\right|=\frac{\Delta V_{K A}}{\Delta I_{K}}$

When the device is programmed with two external resistors, R1 and R2, (refer to Figure 2) the total dynamic impedance of the circuit is defined as:

$$
\left|Z_{K A^{\prime}}\right| \approx\left|Z_{K A}\right|\left(1+\frac{R 1}{R 2}\right)
$$

## TL431, A, B Series

## APPLICATIONS INFORMATION

The TL431 is a programmable precision reference which is used in a variety of ways. It serves as a reference voltage in circuits where a non-standard reference voltage is needed. Other uses include feedback control for driving an optocoupler in power supplies, voltage monitor, constant current source, constant current sink and series pass regulator. In each of these applications, it is critical to maintain stability of the device at various operating currents and load capacitances. In some cases the circuit designer can estimate the stabilization capacitance from the stability boundary conditions curve provided in Figure 15. However, these typical curves only provide stability information at specific cathode voltages and at a specific load condition. Additional information is needed to determine the capacitance needed to optimize phase margin or allow for process variation.

A simplified model of the TL431 is shown in Figure 31. When tested for stability boundaries, the load resistance is $150 \Omega$. The model reference input consists of an input transistor and a dc emitter resistance connected to the device anode. A dependent current source, Gm, develops a current whose amplitude is determined by the difference between the 1.78 V internal reference voltage source and the input transistor emitter voltage. A portion of Gm flows through compensation capacitance, $\mathrm{C}_{\mathrm{P} 2}$. The voltage across $\mathrm{C}_{\mathrm{P} 2}$ drives the output dependent current source, Go, which is connected across the device cathode and anode.

Model component values are:

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{ref}}=1.78 \mathrm{~V} \\
& \mathrm{Gm}=0.3+2.7 \exp \left(-\mathrm{I}_{\mathrm{C}} / 26 \mathrm{~mA}\right)
\end{aligned}
$$

where $I_{C}$ is the device cathode current and $G m$ is in mhos
$\mathrm{Go}=1.25\left(\mathrm{~V}_{\mathrm{cp}} 2\right) \mu \mathrm{mhos}$.
Resistor and capacitor typical values are shown on the model. Process tolerances are $\pm 20 \%$ for resistors, $\pm 10 \%$ for capacitors, and $\pm 40 \%$ for transconductances.

An examination of the device model reveals the location of circuit poles and zeroes:

$$
\mathrm{P} 1=\frac{1}{2 \pi \mathrm{R}_{\mathrm{GM}} \mathrm{C}_{\mathrm{P} 1}}=\frac{1}{2 \pi * 1.0 \mathrm{M}^{*} 20 \mathrm{pF}}=7.96 \mathrm{kHz}
$$

$$
\begin{aligned}
& \mathrm{P} 2=\frac{1}{2 \pi \mathrm{R}_{\mathrm{P} 2} \mathrm{C}_{\mathrm{P} 2}}=\frac{1}{2 \pi * 10 \mathrm{M} * 0.265 \mathrm{pF}}=60 \mathrm{kHz} \\
& \mathrm{Z} 1=\frac{1}{2 \pi \mathrm{R}_{\mathrm{Z} 1} \mathrm{C}_{\mathrm{P} 1}}=\frac{1}{2 \pi * 15.9 \mathrm{k} * 20 \mathrm{pF}}=500 \mathrm{kHz}
\end{aligned}
$$

In addition, there is an external circuit pole defined by the load:

$$
P_{L}=\frac{1}{2 \pi R_{L} C_{L}}
$$

Also, the transfer dc voltage gain of the TL431 is:

$$
\mathrm{G}=\mathrm{G}_{\mathrm{M}} \mathrm{R}_{\mathrm{GM}} \mathrm{GoR}_{\mathrm{L}}
$$

Example 1:
${ }^{\mathrm{I}} \mathrm{C}=10 \mathrm{~mA}, \mathrm{R}_{\mathrm{L}}=230 \Omega, \mathrm{C}_{\mathrm{L}}=0$. Define the transfer gain.
The DC gain is:

$$
\begin{gathered}
\mathrm{G}=\mathrm{G}_{\mathrm{M}} \mathrm{R}_{\mathrm{GM}} \mathrm{GoR}_{\mathrm{L}}= \\
(2.138)(1.0 \mathrm{M})(1.25 \mu)(230)=615=56 \mathrm{~dB} \\
\text { Loop gain }=\mathrm{G} \frac{8.25 \mathrm{k}}{8.25 \mathrm{k}+15 \mathrm{k}}=218=47 \mathrm{~dB}
\end{gathered}
$$

The resulting transfer function Bode plot is shown in Figure 32. The asymptotic plot may be expressed as the following equation:

$$
A v=615 \frac{\left(\frac{1+j f}{500 \mathrm{kHz}}\right)}{\left(\frac{1+\mathrm{jf}}{8.0 \mathrm{kHz}}\right)\left(\frac{1+\mathrm{jf}}{60 \mathrm{kHz}}\right)}
$$

The Bode plot shows a unity gain crossover frequency of approximately 600 kHz . The phase margin, calculated from the equation, would be 55.9 degrees. This model matches the Open-Loop Bode Plot of Figure 12. The total loop would have a unity gain frequency of about 300 kHz with a phase margin of about 44 degrees.

## TL431, A, B Series

Figure 31. Simplified TL431 Device Model

Figure 32. Example 1 Circuit Open Loop Gain Plot Example 2.
$\mathrm{I}_{\mathrm{C}}=7.5 \mathrm{~mA}, \mathrm{R}_{\mathrm{L}}=2.2 \mathrm{k} \Omega, \mathrm{C}_{\mathrm{L}}=0.01 \mu \mathrm{~F}$. Cathode tied to reference input pin. An examination of the data sheet stability boundary curve (Figure 15) shows that this value of load capacitance and cathode current is on the boundary. Define the transfer gain.

The DC gain is:

$$
\begin{gathered}
\mathrm{G}=\mathrm{G}_{\mathrm{M}} \mathrm{R}_{\mathrm{GM}} \mathrm{GoR}_{\mathrm{L}}= \\
(2.323)(1.0 \mathrm{M})(1.25 \mu)(2200)=6389=76 \mathrm{~dB}
\end{gathered}
$$

The resulting open loop Bode plot is shown in Figure 33. The asymptotic plot may be expressed as the following equation:

$$
A v=615 \frac{\left(\frac{1+\mathrm{jf}}{500 \mathrm{kHz}}\right)}{\left(\frac{1+\mathrm{jf}}{8.0 \mathrm{kHz}}\right)\left(\frac{1+\mathrm{jf}}{60 \mathrm{kHz}}\right)\left(\frac{1+\mathrm{jf}}{7.2 \mathrm{kHz}}\right)}
$$

Note that the transfer function now has an extra pole formed by the load capacitance and load resistance.

Note that the crossover frequency in this case is about 250 kHz , having a phase margin of about -46 degrees. Therefore, instability of this circuit is likely.

Figure 33. Example 2 Circuit Open Loop Gain Plot
With three poles, this system is unstable. The only hope for stabilizing this circuit is to add a zero. However, that can only be done by adding a series resistance to the output capacitance, which will reduce its effectiveness as a noise filter. Therefore, practically, in reference voltage applications, the best solution appears to be to use a smaller value of capacitance in low noise applications or a very large value to provide noise filtering and a dominant pole rolloff of the system.

## CS1009

### 2.5 Volt Reference

The CS1009 is a precision trimmed $2.5 \mathrm{~V} \pm 5.0 \mathrm{mV}$ shunt regulator diode. The low dynamic impedance and wide operating current range enhances its versatility. The tight reference tolerance is achieved by on-chip trimming which minimizes voltage tolerance and temperature drift.

A third terminal allows the reference voltage to be adjusted $\pm 5.0 \%$ to calibrate out system errors. In many applications, the CS1009GZ can be used as a pin-to-pin replacement of the LT1009CZ and the LM136Z-2.5 with the external trim network eliminated.

## Features

- 0.2\% Initial Tolerance Max.
- Guaranteed Temperature Stability
- Maximum $0.6 \Omega$ Dynamic Impedance
- Wide Operating Current Range
- Directly Interchangeable with LT1009 and LM136 for Improved Performance
- No Adjustments Needed for Minimum Temperature Coefficient
- Meets Mil Std 883C ESD Requirements

## MC1403, B

## Low Voltage Reference

A precision band-gap voltage reference designed for critical instrumentation and D/A converter applications. This unit is designed to work with D/A converters, up to 12 bits in accuracy, or as a reference for power supply applications.

- Output Voltage: $2.5 \mathrm{~V} \pm 25 \mathrm{mV}$
- Input Voltage Range: 4.5 V to 40 V
- Quiescent Current: 1.2 mA Typical
- Output Current: 10 mA
- Temperature Coefficient: $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ Typical
- Guaranteed Temperature Drift Specification
- Equivalent to AD580
- Standard 8-Pin DIP, and 8-Pin SOIC Package

## Typical Applications

- Voltage Reference for 8 to 12 Bit D/A Converters
- Low $\mathrm{T}_{\mathrm{C}}$ Zener Replacement
- High Stability Current Reference
- Voltmeter System Reference

Figure 1. A Reference for Monolithic D/A Converters

Providing the Reference Current for ON Semiconductor Monolithic D/A Converters

The MC1403 makes an ideal reference for many monolithic D/A converters, requiring a stable current reference of nominally 2.0 mA . This can be easily obtained from the MC1403 with the addition of a series resistor, R1. A variable resistor, R2, is recommended to provide means for fullscale adjust on the D/A converter.

The resistor R3 improves temperature performance by matching the impedance on both inputs of the $D / A$ reference amplifier. The capacitor decouples any noise present on the reference line. It is essential if the D/A converter is located any appreciable distance from the reference.
A single MC1403 reference can provide the required current input for up to five of the monolithic D/A converters.

## MC1403, B

## 3-1/2-Digit Voltmeter - Common Anode Displays, Flashing Overrange

An example of a 3-1/2-digit voltmeter using the MC14433 is shown in the circuit diagram of Figure 8. The reference voltage for the system uses an MC1403 2.5 V reference IC. The full scale potentiometer can calibrate for a full scale of 199.9 mV or 1.999 V . When switching from 2.0 V to 200 mV operation, $\mathrm{R}_{\mathrm{I}}$ is also changed, as shown on the diagram.

When using $\mathrm{R}_{\mathrm{C}}$ equal to $300 \mathrm{k} \Omega$, the clock frequency for the system is about 66 kHz . The resulting conversion time is approximately 250 ms .

When the input is overrange, the display flashes on and off. The flashing rate is one-half the conversion rate. This
is done by dividing the EOC pulse rate by 2 with $1 / 2$ MC14013B flip-flop and blanking the display using the blanking input of the MC14543B.

The display uses an LED display with common anode digit lines driven with an MC14543B decoder and an MC1413 LED driver. The MC1413 contains 7 Darlington transistor drivers and resistors to drive the segments of the display. The digit drive is provided by four MPS-A12 Darlington transistors operating in an emitter-follower configuration. The MC14543B, MC14013B and LED displays are referenced to $\mathrm{V}_{\mathrm{EE}}$ via Pin 13 of the MC14433. This places the full power supply voltage across the display. The current for the display may be adjusted by the value of the segment resistors shown as $150 \Omega$ in Figure 8 .

Figure 8. 3-1/2-Digit Voltmeter

## MC78L00A Series

## 100 mA Positive Voltage Regulators

The MC78L00A Series of positive voltage regulators are inexpensive, easy-to-use devices suitable for a multitude of applications that require a regulated supply of up to 100 mA . Like their higher powered MC7800 and MC78M00 Series cousins, these regulators feature internal current limiting and thermal shutdown making them remarkably rugged. No external components are required with the MC78L00 devices in many applications.

These devices offer a substantial performance advantage over the traditional zener diode-resistor combination, as output impedance and quiescent current are substantially reduced.

- Wide Range of Available, Fixed Output Voltages
- Low Cost
- Internal Short Circuit Current Limiting
- Internal Thermal Overload Protection
- No External Components Required
- Complementary Negative Regulators Offered (MC79L00A Series)

Figure 1. Representative Schematic Diagram

Figure 2. Standard Application
A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.

## ON Semiconductor ${ }^{\text {w }}$

http://onsemi.com

*SOP-8 is an internally modified SO-8 package. Pins $2,3,6$, and 7 are electrically common to the die attach flag. This internal lead frame modification decreases package thermal resistance and increases power dissipation capability when appropriately mounted on a printed circuit board. SOP-8 conforms to all external dimensions of the standard SO-8 package.

## MC78L00A Series

## APPLICATIONS INFORMATION

## Design Considerations

The MC78L00A Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition. Internal Short Circuit Protection limits the maximum current the circuit will pass.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. The

The MC78L00 regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC78L05C is chosen in this application. Resistor R determines the current as follows:

$$
\mathrm{I}_{0}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{B}}
$$

$I_{I B}=3.8 \mathrm{~mA}$ over line and load changes

For example, a 100 mA current source would require R to be a $50 \Omega, 1 / 2 \mathrm{~W}$ resistor and the output voltage compliance would be the input voltage less 7 V .

Figure 9. Current Regulator
input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

## MC78M00, MC78M00A Series

## 500 mA Positive Voltage Regulators

The MC78M00/MC78M00A Series positive voltage regulators are identical to the popular MC7800 Series devices, except that they are specified for only half the output current. Like the MC7800 devices, the MC78M00 three-terminal regulators are intended for local, on-card voltage regulation.

Internal current limiting, thermal shutdown circuitry and safe-area compensation for the internal pass transistor combine to make these devices remarkably rugged under most operating conditions. Maximum output current, with adequate heatsinking is 500 mA .

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- MC78M00A High Accuracy ( $\pm 2 \%$ ) Available for 5.0 V, 8.0 V, 12 V and 15 V

This device contains 28 active transistors.

## MC78M00, MC78M00A Series

## DEFINITIONS

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current - That part of the input current that is not delivered to the load.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability - Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

## MC78M00, MC78M00A Series

## APPLICATIONS INFORMATION

## Design Considerations

The MC78M00/MC78M00A Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the

The MC78M00 regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC78M05C is chosen in this application. Resistor R determines the current as follows:

$$
\mathrm{I}_{0}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{IB}}
$$

$I_{I B}=1.5 \mathrm{~mA}$ over line and load changes.

For example, a 500 mA current source would require $R$ to be a $5.0 \Omega, 10 \mathrm{~W}$ resistor and the output voltage compliance would be the input voltage less 7.0 V .

Figure 10. Current Regulator

$X X=2$ digits of type number indicating voltage.

The MC78M00 series can be current boosted with a PNP transistor. The MJ2955 provides current to 5.0 A. Resistor R in conjunction with the $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input-output differential voltage minimum is increased by $V_{B E}$ of the pass transistor.

Figure 12. Current Boost Regulator
regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulator's input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 2.0 V greater than the regulator voltage.

Figure 11. Adjustable Output Regulator

$X X=2$ digits of type number indicating voltage.
The circuit of Figure 12 can be modified to provide supply protection against short circuits by adding a short circuit sense resistor, $\mathrm{R}_{\mathrm{sc}}$, and an additional PNP transistor. The current sensing PNP must be able to handle the short circuit current of the three-terminal regulator .Therefore, a 4.0 A plastic power transistor is specified.

## MC7800, MC7800A, LM340, LM340A Series

### 1.0 A Positive Voltage Regulators

These voltage regulators are monolithic integrated circuits designed as fixed-voltage regulators for a wide variety of applications including local, on-card regulation. These regulators employ internal current limiting, thermal shutdown, and safe-area compensation. With adequate heatsinking they can deliver output currents in excess of 1.0 A. Although designed primarily as a fixed voltage regulator, these devices can be used with external components to obtain adjustable voltages and currents.

- Output Current in Excess of 1.0 A
- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Output Voltage Offered in $2 \%$ and $4 \%$ Tolerance
- Available in Surface Mount D²PAK, DPAK and Standard 3-Lead Transistor Packages

MAXIMUM RATINGS ( $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.)

| Rating | Symbol | Value | Unit |
| :--- | :---: | :---: | :---: |
| Input Voltage (5.0-18 V) | $\mathrm{V}_{\mathrm{I}}$ | 35 | Vdc |
| $(24 \mathrm{~V})$ |  |  |  |$)$

NOTE: ESD data available upon request.

## ON Semiconductor ${ }^{\text {w }}$

http://onsemi.com

## STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the input ripple voltage.
XX , These two digits of the type number indicate nominal voltage.

* $\mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter.
${ }^{* *} \mathrm{C}_{0}$ is not needed for stability; however, it does improve transient response. Values of less than $0.1 \mu \mathrm{~F}$ could cause instability.

## ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 167 of this data sheet. section on page 169 of this data sheet.

## APPLICATIONS INFORMATION

## Design Considerations

The MC7800 Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long

The MC7800 regulators can also be used as a current source when connected as above. In order to minimize dissipation the MC7805C is chosen in this application. Resistor R determines the current as follows:

$$
\begin{gathered}
\mathrm{I}_{\mathrm{O}}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{B}} \\
\mathrm{I}_{\mathrm{B}} \cong 3.2 \mathrm{~mA} \text { over line and load changes. }
\end{gathered}
$$

For example, a 1.0 A current source would require R to be a $5.0 \Omega$, 10 W resistor and the output voltage compliance would be the input voltage less 7.0 V .

Figure 8. Current Regulator

$X X=2$ digits of type number indicating voltage.

The MC7800 series can be current boosted with a PNP transistor. The MJ2955 provides current to 5.0 A. Resistor $R$ in conjunction with the $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input/output differential voltage minimum is increased by $\mathrm{V}_{\mathrm{BE}}$ of the pass transistor.
wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 2.0 V greater than the regulator voltage.

Figure 9. Adjustable Output Regulator

The circuit of Figure 10 can be modified to provide supply protection against short circuits by adding a short circuit sense resistor, $\mathrm{R}_{\mathrm{SC}}$, and an additional PNP transistor. The current sensing PNP must be able to handle the short circuit current of the three-terminal regulator. Therefore, a four-ampere plastic power transistor is specified.

## DEFINITIONS

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.

Quiescent Current - That part of the input current that is not delivered to the load.

Output Noise Voltage - The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.
Long Term Stability - Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

### 3.0 A Positive Voltage Regulators

This family of fixed voltage regulators are monolithic integrated circuits capable of driving loads in excess of 3.0 A. These three-terminal regulators employ internal current limiting, thermal shutdown, and safe-area compensation. Devices are available with improved specifications, including a $2 \%$ output voltage tolerance, on AC-suffix 5.0, 12 and 15 V device types.

Although designed primarily as a fixed voltage regulator, these devices can be used with external components to obtain adjustable voltages and currents. This series of devices can be used with a series-pass transistor to supply up to 15 A at the nominal output voltage.

- Output Current in Excess of 3.0 A
- Power Dissipation: 25 W
- No External Components Required
- Output Voltage Offered in $2 \%$ and $4 \%$ Tolerance*
- Thermal Regulation is Specified
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation

XX Indicates nominal voltage.

* $2 \%$ regulators available in 5,12 and 15 V devices.
\# Automotive temperature range selections are available with special test conditions and additional tests. Contact your local ON Semiconductor sales office for information.

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.2 V above the output voltage even during the low point on the input ripple voltage.
XX these two digits of the type number indicate voltage.

* $\mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter. (See Applications Information for details.)
${ }^{* *} \mathrm{C}_{0}$ is not needed for stability; however, it does improve transient response.

2. Line and load regulation are specified at constant junction temperature. Changes in $V_{O}$ due to heating effects must be taken into account separately. Pulse testing with low duty cycle is used.

## VOLTAGE REGULATOR PERFORMANCE

The performance of a voltage regulator is specified by its immunity to changes in load, input voltage, power dissipation, and temperature. Line and load regulation are tested with a pulse of short duration $(<100 \mu \mathrm{~s})$ and are strictly a function of electrical gain. However, pulse widths of longer duration (> 1.0 ms ) are sufficient to affect temperature gradients across the die. These temperature gradients can cause a change in the output voltage, in addition to changes caused by line and load regulation. Longer pulse widths and thermal gradients make it desirable to specify thermal regulation.

Thermal regulation is defined as the change in output voltage caused by a change in dissipated power for a specified time, and is expressed as a percentage output voltage change per watt. The change in dissipated power

\end{array}
$$

Figure 1. MC78T05AC Line and Thermal Regulation
can be caused by a change in either the input voltage or the load current. Thermal regulation is a function of IC layout and die attach techniques, and usually occurs within 10 ms of a change in power dissipation. After 10 ms , additional changes in the output voltage are due to the temperature coefficient of the device.
Figure 1 shows the line and thermal regulation response of a typical MC78T05AC to a 20 W input pulse. The variation of the output voltage due to line regulation is labeled (1) and the thermal regulation component is labeled (2). Figure 2 shows the load and thermal regulation response of a typical MC78T05AC to a 20 W load pulse. The output voltage variation due to load regulation is labeled (1) and the thermal regulation component is labeled (2).

## MC78T00 Series

## APPLICATIONS INFORMATION

## Design Considerations

The MC78T00 Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the
regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulator's input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

The MC78T05 regulator can also be used as a current source when connected as above. In order to minimize dissipation the MC78T05 is chosen in this application. Resistor R determines the current as follows:

$$
\mathrm{I}_{0}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{B}}
$$

$\Delta \mathrm{l}_{\mathrm{B}} \cong 0.7 \mathrm{~mA}$ over line, load and Temperature changes $I_{B} \cong 3.5 \mathrm{~mA}$
For example, a 2.0 A current source would require R to be a $2.5 \Omega$, 10 W resistor and the output voltage compliance would be the input voltage less 7.0 V .

Figure 14. Current Regulator

$X X=2$ digits of type number indicating voltage.
The MC78T00 series can be current boosted with a PNP transistor. The 2N4398 provides current to 15 A . Resistor $R$ in conjunction with the $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input-output differential voltage minimum is increased by the $\mathrm{V}_{\mathrm{BE}}$ of the pass transistor.

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 3.0 V greater than the regulator voltage.

Figure 15. Adjustable Output Regulator

$X X=2$ digits of type number indicating voltage.
The circuit of Figure 17 can be modified to provide supply protection against short circuits by adding a short circuit sense resistor, $\mathrm{R}_{\mathrm{SC}}$, and an additional PNP transistor. The current sensing PNP must be able to handle the short circuit current of the three-terminal regulator. Therefore, an eight-ampere power transistor is specified.

Figure 17. Current Boost With Short Circuit Protection

### 3.0 A Positive Voltage Regulators

The LM323,A are monolithic integrated circuits which supply a fixed positive 5.0 V output with a load driving capability in excess of 3.0 A. These three-terminal regulators employ internal current limiting, thermal shutdown, and safe-area compensation. The A-suffix is an improved device with superior electrical characteristics and a $2 \%$ output voltage tolerance. These regulators are offered with a $0^{\circ}$ to $+125^{\circ} \mathrm{C}$ temperature range in a low cost plastic power package.

Although designed primarily as a fixed voltage regulator, these devices can be used with external components to obtain adjustable voltages and currents. These devices can be used with a series pass transistor to supply up to 15 A at 5.0 V .

- Output Current in Excess of 3.0 A
- Available with $2 \%$ Output Voltage Tolerance
- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Thermal Regulation and Ripple Rejection Have Specified Limits

## Simplified Application

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.5 V above the output voltage even during the low point on the input ripple voltage.

NOTES: 1 . $\mathrm{T}_{\text {low }}$ to $\mathrm{T}_{\text {high }}=0^{\circ}$ to $+125^{\circ} \mathrm{C}$
2. Although power dissipation is internally limited, specifications apply only for $\mathrm{P} \leq \mathrm{P}_{\max }=25 \mathrm{~W}$.
3. Load and line regulation are specified at constant junction temperature. Pulse testing is required with a pulse width $\leq 1.0 \mathrm{~ms}$ and a duty cycle $\leq 5 \%$.
4. Without a heatsink, the thermal resistance $\left(\mathrm{R}_{\theta \mathrm{JA}}\right.$ is $\left.65^{\circ} \mathrm{C} / \mathrm{W}\right)$. With a heatsink, the effective thermal resistance can approach the specified values of $2.0^{\circ} \mathrm{C} / \mathrm{W}$, depending on the efficiency of the heatsink.

Representative Schematic Diagram

## VOLTAGE REGULATOR PERFORMANCE

The performance of a voltage regulator is specified by its immunity to changes in load, input voltage, power dissipation, and temperature. Line and load regulation are tested with a pulse of short duration $(<100 \mu \mathrm{~s})$ and are strictly a function of electrical gain. However, pulse widths of longer duration ( $>1.0 \mathrm{~ms}$ ) are sufficient to affect temperature gradients across the die. These temperature gradients can cause a change in the output voltage, in addition to changes by line and load regulation. Longer pulse widths and thermal gradients make it desirable to specify thermal regulation.

Thermal regulation is defined as the change in output voltage caused by a change in dissipated power for a specified time, and is expressed as a percentage output
voltage change per watt. The change in dissipated power can be caused by a change in either input voltage or the load current. Thermal regulation is a function of IC layout and die attach techniques, and usually occurs within 10 ms of a change in power dissipation. After 10 ms , additional changes in the output voltage are due to the temperature coefficient of the device.

Figure 1 shows the line and thermal regulation response of a typical LM323A to a 20 W input pulse. The variation of the output voltage due to line regulation is labeled $\AA$ and the thermal regulation component is labeled Á. Figure 2 shows the load and thermal regulation response of a typical LM323A to a 20 W load pulse. The output voltage variation due to load regulation is labeled $A$ and the thermal regulation component is labeled Á.

## APPLICATIONS INFORMATION

## Design Considerations

The LM323,A series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the
regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulator's input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

The LM323,A regulator can also be used as a current source when connected as above. Resistor R determines the current as follows:

$$
\mathrm{I}_{0}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{B}}
$$

$\Delta \mathrm{l}_{\mathrm{B}} \cong 0.7 \mathrm{~mA}$ over line, load and temperature changes $\mathrm{I}_{\mathrm{B}} \cong 3.5 \mathrm{~mA}$

For example, a 2.0 A current source would require R to be a $2.5 \Omega$, 15 W resistor and the output voltage compliance would be the input voltage less 7.5 V .

Figure 13. Current Regulator

The LM323, A series can be current boosted with a PNP transistor. The 2N4398 provides current to 15 A . Resistor R in conjunction with the $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input-output differential voltage minimum is increased by the $\mathrm{V}_{\mathrm{BE}}$ of the pass transistor.

Figure 15. Current Boost Regulator

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtainable with this arrangement is 3.0 V greater than the regulator voltage.

Figure 14. Adjustable Output Regulator

The circuit of Figure 16 can be modified to provide supply protection against short circuits by adding a short circuit sense resistor, $\mathrm{R}_{\mathrm{SC}}$, and an additional PNP transistor. The current sensing PNP must be able to handle the short circuit current of the three-terminal regulator. Therefore, an 8.0 A power transistor is specified.

Figure 16. Current Boost with Short Circuit Protection

## 100 mA Negative Voltage Regulators

The MC79L00, A Series negative voltage regulators are inexpensive, easy-to-use devices suitable for numerous applications requiring up to 100 mA . Like the higher powered MC7900 Series negative regulators, this series features thermal shutdown and current limiting, making them remarkably rugged. In most applications, no external components are required for operation.

The MC79L00 devices are useful for on-card regulation or any other application where a regulated negative voltage at a modest current level is needed. These regulators offer substantial advantage over the common resistor/zener diode approach.

- No External Components Required
- Internal Short Circuit Current Limiting
- Internal Thermal Overload Protection
- Low Cost
- Complementary Positive Regulators Offered (MC78L00 Series)
- Available in Either $\pm 5 \%$ (AC) or $\pm 10 \%$ (C) Selections

* Automotive temperature range selections are available with special test conditions and additional tests in 5,12 and 15 V devices. Contact your local ON Semiconductor sales office for information.

## MC79L00, MC79L00A Series

## THREE-TERMINAL LOW CURRENT NEGATIVE FIXED VOLTAGE REGULATORS

SEMICONDUCTOR TECHNICAL DATA

*SOP-8 is an internally modified SO-8 package. Pins $2,3,6$, and 7 are electrically common to the die attach flag. This internal lead frame modification decreases package thermal resistance and increases power dissipation capability when appropriately mounted on a printed circuit board. SOP-8 conforms to all external dimensions of the standard SO-8 package.

## APPLICATIONS INFORMATION

## Design Considerations

The MC79L00, A Series of fixed voltage regulators are designed with Thermal Overload Protections that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire length, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good

Figure 1. Positive and Negative Regulator
high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulator's input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above the output voltage even during the low point on the ripple voltage.
${ }^{*} \mathrm{C}_{\text {I }}$ is required if regulator is located an appreciable distance from the power supply filter
${ }^{* *} \mathrm{C}_{0}$ improves stability and transient response.

## 500 mA Negative Voltage Regulators

The MC79M00 series of fixed output negative voltage regulators are intended as complements to the popular MC78M00 series devices.

Available in fixed output voltage options of $-5.0,-8.0,-12$ and -15 V , these regulators employ current limiting, thermal shutdown, and safe-area compensation - making them remarkably rugged under most operating conditions. With adequate heatsinking they can deliver output currents in excess of 0.5 A .

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Also Available in Surface Mount DPAK (DT) Package

## STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 1.1 V more negative even during the high point of the input ripple voltage.
$X X$, These two digits of the type number indicate nominal voltage.
${ }^{*} \mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter.
** $\mathrm{C}_{\mathrm{O}}$ improve stability and transient response.

## MC7900 Series

### 1.0 A Negative Voltage Regulators

The MC7900 series of fixed output negative voltage regulators are intended as complements to the popular MC7800 series devices. These negative regulators are available in the same seven-voltage options as the MC7800 devices. In addition, one extra voltage option commonly employed in MECL systems is also available in the negative MC7900 series.

Available in fixed output voltage options from -5.0 V to -24 V , these regulators employ current limiting, thermal shutdown, and safe-area compensation - making them remarkably rugged under most operating conditions. With adequate heatsinking they can deliver output currents in excess of 1.0 A .

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Available in 2\% Voltage Tolerance (See Ordering Information)

$D^{2}$ PAK D2T SUFFIX CASE 936

Heatsink surface (shown as terminal 4 in case outline drawing) is connected to Pin 2.

## STANDARD APPLICATION

A common ground is required between the input and the output voltages. The input voltage must remain typically 2.0 V above more negative even during the high point of the input ripple voltage.

XX, These two digits of the type number indicate nominal voltage.

* $\mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter.
${ }^{* *} \mathrm{C}_{\mathrm{O}}$ improve stability and transient response.

## ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 204 of this data sheet.

DEVICE MARKING INFORMATION
See general marking information in the device marking section on page 205 of this data sheet.

## APPLICATIONS INFORMATION

## Design Considerations

The MC7900 Series of fixed voltage regulators are designed with Thermal overload Protection that shuts down the circuit when subjected to an excessive power overload condition. Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high-frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The capacitor chosen should have an equivalent series resistance of less than $0.7 \Omega$. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input terminals. Normally good construction techniques should be

*Mounted on heatsink.
When a boost transistor is used, short circuit currents are equal to the sum of the series pass and regulator limits, which are measured at 3.2 A and 1.8 A respectively in this case. Series pass limiting is approximately equal to $0.6 \mathrm{~V} / \mathrm{R}_{\mathrm{Sc}}$. Operation beyond this point to the peak current capability of the MC7905C is possible if the regulator is mounted on a heatsink; otherwise thermal shutdown will occur when the additional load current is picked up by the regulator.
used to minimize ground loops and lead resistance drops since the regulator has no external sense lead. Bypassing the output is also recommended.

The MC7905, -5.0 V regulator can be used as a constant current source when connected as above. The output current is the sum of resistor R current and quiescent bias current as follows.

$$
\mathrm{I}_{\mathrm{O}}=\frac{5.0 \mathrm{~V}}{\mathrm{R}}+\mathrm{I}_{\mathrm{B}}
$$

The quiescent current for this regulator is typically 4.3 mA . The 5.0 V regulator was chosen to minimize dissipation and to allow the output voltage to operate to within 6.0 V below the input voltage.

Figure 8. Current Regulator

The MC7815 and MC7915 positive and negative regulators may be connected as shown to obtain a dual power supply for operational amplifiers. A clamp diode should be used at the output of the MC7815 to prevent potential latch-up problems whenever the output of the positive regulator (MC7815) is drawn below ground with an output current greater than 200 mA .

## DEFINITIONS

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current - That part of the input current that is not delivered to the load.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long Term Stability - Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

## 100 mA Adjustable Output, Positive Voltage Regulator

The LM317L is an adjustable 3-terminal positive voltage regulator capable of supplying in excess of 100 mA over an output voltage range of 1.2 V to 37 V . This voltage regulator is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, it employs internal current limiting, thermal shutdown and safe area compensation, making them essentially blow-out proof.

The LM317L serves a wide variety of applications including local, on card regulation. This device can also be used to make a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM317L can be used as a precision current regulator.

- Output Current in Excess of 100 mA
- Output Adjustable Between 1.2 V and 37 V
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Floating Operation for High Voltage Applications
- Standard 3-Lead Transistor Package
- Eliminates Stocking Many Fixed Voltages

## Simplified Application

${ }^{*} \mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter.
${ }^{* *} C_{0}$ is not needed for stability, however, it does improve transient response.

$$
V_{\text {out }}=1.25 \mathrm{~V}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since $I_{\text {Adj }}$ is controlled to less than $100 \mu \mathrm{~A}$, the error associated with this term is negligible in most applications.

## APPLICATIONS INFORMATION

## Basic Circuit Operation

The LM317L is a 3-terminal floating regulator. In operation, the LM317L develops and maintains a nominal 1.25 V reference ( $\mathrm{V}_{\text {ref }}$ ) between its output and adjustment terminals. This reference voltage is converted to a programming current ( $\mathrm{I}_{\mathrm{PROG}}$ ) by $\mathrm{R}_{1}$ (see Figure 13), and this constant current flows through $\mathrm{R}_{2}$ to ground. The regulated output voltage is given by:

$$
V_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since the current from the adjustment terminal ( $\mathrm{I}_{\mathrm{Adj}}$ ) represents an error term in the equation, the LM317L was designed to control $\mathrm{I}_{\text {Adj }}$ to less than $100 \mu \mathrm{~A}$ and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM317L is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

Figure 17. Basic Circuit Configuration

## Load Regulation

The LM317L is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor (R1) should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of R2 can be returned near the load ground to provide remote ground sensing and improve load regulation.

## External Capacitors

A $0.1 \mu \mathrm{~F}$ disc or $1.0 \mu \mathrm{~F}$ tantalum input bypass capacitor $\left(\mathrm{C}_{\mathrm{in}}\right)$ is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor ( $\mathrm{C}_{\mathrm{Adj}}$ ) prevents ripple from being amplified as the output voltage is increased. A $10 \mu \mathrm{~F}$ capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.

Although the LM317L is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance $\left(\mathrm{C}_{\mathrm{O}}\right)$ in the form of a $1.0 \mu \mathrm{~F}$ tantalum or $25 \mu \mathrm{~F}$ aluminum electrolytic capacitor on the output swamps this effect and insures stability.

## Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 14 shows the LM317L with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values ( $\mathrm{C}_{\mathrm{O}}>10 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{Adj}}>5.0 \mu \mathrm{~F}$ ). Diode $\mathrm{D}_{1}$ prevents $\mathrm{C}_{\mathrm{O}}$ from discharging thru the IC during an input short circuit. Diode $\mathrm{D}_{2}$ protects against capacitor $\mathrm{C}_{\text {Adj }}$ discharging through the IC during an output short circuit. The combination of diodes $D_{1}$ and $D_{2}$ prevents $C_{\text {Adj }}$ from discharging through the IC during an input short circuit.

## LM317M

## 500 mA Adjustable Output, Positive Voltage Regulator

The LM317M is an adjustable three-terminal positive voltage regulator capable of supplying in excess of 500 mA over an output voltage range of 1.2 V to 37 V . This voltage regulator is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, it employs internal current limiting, thermal shutdown and safe area compensation, making it essentially blow-out proof.

The LM317M serves a wide variety of applications including local, on-card regulation. This device also makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM317M can be used as a precision current regulator.

- Output Current in Excess of 500 mA
- Output Adjustable between 1.2 V and 37 V
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Floating Operation for High Voltage Applications
- Eliminates Stocking Many Fixed Voltages

* $=\mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter. ${ }^{* *}=C_{0}$ is not needed for stability, however, it does improve transient response.

$$
V_{\text {out }}=1.25 \mathrm{~V}\left(1+\frac{\mathrm{R}_{2}}{\mathrm{R}_{1}}\right)+\mathrm{I}_{\mathrm{Adj}} \mathrm{R}_{2}
$$

Since $\mathrm{I}_{\text {Adj }}$ is controlled to less than $100 \mu \mathrm{~A}$, the error associated with this term is negligible in most applications.

## APPLICATIONS INFORMATION

## Basic Circuit Operation

The LM317M is a three-terminal floating regulator. In operation, the LM317M develops and maintains a nominal 1.25 V reference ( $\mathrm{V}_{\mathrm{ref}}$ ) between its output and adjustment terminals. This reference voltage is converted to a programming current ( $\mathrm{I}_{\mathrm{PROG}}$ ) by $\mathrm{R}_{1}$ (see Figure 19), and this constant current flows through $\mathrm{R}_{2}$ to ground. The regulated output voltage is given by:

$$
V_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since the current from the terminal ( $\mathrm{I}_{\text {Adj }}$ ) represents an error term in the equation, the LM317M was designed to control $\mathrm{I}_{\text {Adj }}$ to less than $100 \mu \mathrm{~A}$ and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM317M is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

Figure 19. Basic Circuit Configuration

## Load Regulation

The LM317M is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor $\left(\mathrm{R}_{1}\right)$ should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of $\mathrm{R}_{2}$ can be returned near the load ground to provide remote ground sensing and improve load regulation.

## External Capacitors

A $0.1 \mu \mathrm{~F}$ disc or $1.0 \mu \mathrm{~F}$ tantalum input bypass capacitor $\left(\mathrm{C}_{\mathrm{in}}\right)$ is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor ( $\mathrm{C}_{\mathrm{Adj}}$ ) prevents ripple from being amplified as the output voltage is increased. A $10 \mu \mathrm{~F}$ capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.
Although the LM317M is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance $\left(\mathrm{C}_{\mathrm{O}}\right)$ in the form of a $1.0 \mu \mathrm{~F}$ tantalum or $25 \mu \mathrm{~F}$ aluminum electrolytic capacitor on the output swamps this effect and insures stability.

## Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 20 shows the LM317M with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values ( $\mathrm{C}_{\mathrm{O}}>25 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{Adj}}>5.0 \mu \mathrm{~F}$ ). Diode $\mathrm{D}_{1}$ prevents $\mathrm{C}_{\mathrm{O}}$ from discharging thru the IC during an input short circuit. Diode $\mathrm{D}_{2}$ protects against capacitor $\mathrm{C}_{\text {Adj }}$ discharging through the IC during an output short circuit. The combination of diodes $D_{1}$ and $D_{2}$ prevents $C_{\text {Adj }}$ from discharging through the IC during an input short circuit.

### 1.5 A Adjustable Output, Positive Voltage Regulator

The LM317 is an adjustable 3-terminal positive voltage regulator capable of supplying in excess of 1.5 A over an output voltage range of 1.2 V to 37 V . This voltage regulator is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, it employs internal current limiting, thermal shutdown and safe area compensation, making it essentially blow-out proof.

The LM317 serves a wide variety of applications including local, on card regulation. This device can also be used to make a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM317 can be used as a precision current regulator.

- Output Current in Excess of 1.5 A
- Output Adjustable between 1.2 V and 37 V
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting Constant with Temperature
- Output Transistor Safe-Area Compensation
- Floating Operation for High Voltage Applications
- Available in Surface Mount D²PAK, and Standard 3-Lead Transistor Package
- Eliminates Stocking many Fixed Voltages

## Standard Application

${ }^{*} \mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter. ${ }^{* *} \mathrm{C}_{0}$ is not needed for stability, however, it does improve transient response.

$$
\mathrm{V}_{\text {out }}=1.25 \mathrm{~V}\left(1+\frac{\mathrm{R}_{2}}{\mathrm{R}_{1}}\right)+\mathrm{I}_{\mathrm{Adj}} \mathrm{R}_{2}
$$

Since $I_{\text {Adj }}$ is controlled to less than $100 \mu \mathrm{~A}$, the error associated with this term is negligible in most applications.

## APPLICATIONS INFORMATION

## Basic Circuit Operation

The LM317 is a 3-terminal floating regulator. In operation, the LM317 develops and maintains a nominal 1.25 V reference ( $\mathrm{V}_{\mathrm{ref}}$ ) between its output and adjustment terminals. This reference voltage is converted to a programming current ( $\mathrm{I}_{\mathrm{PROG}}$ ) by $\mathrm{R}_{1}$ (see Figure 17), and this constant current flows through $\mathrm{R}_{2}$ to ground.

The regulated output voltage is given by:

$$
v_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since the current from the adjustment terminal ( $\mathrm{I}_{\text {Adj }}$ ) represents an error term in the equation, the LM317 was designed to control $\mathrm{I}_{\text {Adj }}$ to less than $100 \mu \mathrm{~A}$ and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM317 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

Figure 17. Basic Circuit Configuration

## Load Regulation

The LM317 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor $\left(\mathrm{R}_{1}\right)$ should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of $R_{2}$ can be returned near the load ground to provide remote ground sensing and improve load regulation.

## External Capacitors

A $0.1 \mu \mathrm{~F}$ disc or $1.0 \mu \mathrm{~F}$ tantalum input bypass capacitor $\left(\mathrm{C}_{\mathrm{in}}\right)$ is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor ( $\mathrm{C}_{\mathrm{Adj}}$ ) prevents ripple from being amplified as the output voltage is increased. A $10 \mu \mathrm{~F}$ capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.
Although the LM317 is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance $\left(\mathrm{C}_{\mathrm{O}}\right)$ in the form of a $1.0 \mu \mathrm{~F}$ tantalum or $25 \mu \mathrm{~F}$ aluminum electrolytic capacitor on the output swamps this effect and insures stability.

## Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the LM317 with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values ( $\mathrm{C}_{\mathrm{O}}>25 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{Adj}}>10 \mu \mathrm{~F}$ ). Diode $\mathrm{D}_{1}$ prevents $\mathrm{C}_{\mathrm{O}}$ from discharging thru the IC during an input short circuit. Diode $\mathrm{D}_{2}$ protects against capacitor $\mathrm{C}_{\text {Adj }}$ discharging through the IC during an output short circuit. ### 3.0 A, Adjustable Output, Positive Voltage Regulator

The LM350 is an adjustable three-terminal positive voltage regulator capable of supplying in excess of 3.0 A over an output voltage range of 1.2 V to 33 V . This voltage regulator is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, it employs internal current limiting, thermal shutdown and safe area compensation, making it essentially blow-out proof.

The LM350 serves a wide variety of applications including local, on card regulation. This device also makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM350 can be used as a precision current regulator.

- Guaranteed 3.0 A Output Current
- Output Adjustable between 1.2 V and 33 V
- Load Regulation Typically $0.1 \%$
- Line Regulation Typically 0.005\%/V
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting Constant with Temperature
- Output Transistor Safe Area Compensation
- Floating Operation for High Voltage Applications
- Standard 3-lead Transistor Package
- Eliminates Stocking Many Fixed Voltages

${ }^{*}=\mathrm{C}_{\text {in }}$ is required if regulator is located an appreciable distance from power supply filter. ${ }^{* *}=\mathrm{C}_{0}$ is not needed for stability, however, it does improve transient response.

$$
V_{\text {out }}=1.25 \mathrm{~V}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since $\mathrm{I}_{\text {Adj }}$ is controlled to less than $100 \mu \mathrm{~A}$, the error associated with this term is negligible in most applications.

## APPLICATIONS INFORMATION

## Basic Circuit Operation

The LM350 is a three-terminal floating regulator. In operation, the LM350 develops and maintains a nominal 1.25 V reference ( $\mathrm{V}_{\mathrm{ref}}$ ) between its output and adjustment terminals. This reference voltage is converted to a programming current (IPROG) by $\mathrm{R}_{1}$ (see Figure 17), and this constant current flows through $\mathrm{R}_{2}$ to ground. The regulated output voltage is given by:

$$
V_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since the current from the terminal ( $\mathrm{I}_{\mathrm{Adj}}$ ) represents an error term in the equation, the LM350 was designed to control $\mathrm{I}_{\text {Adj }}$ to less than $100 \mu \mathrm{~A}$ and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM350 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

Figure 17. Basic Circuit Configuration

## Load Regulation

The LM350 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor $\left(\mathrm{R}_{1}\right)$ should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation. The ground end of $\mathrm{R}_{2}$ can be returned near the load ground to provide remote ground sensing and improve load regulation.

## External Capacitors

A $0.1 \mu \mathrm{~F}$ disc or $1 \mu \mathrm{~F}$ tantalum input bypass capacitor $\left(\mathrm{C}_{\mathrm{in}}\right)$ is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor ( $\mathrm{C}_{\mathrm{Adj}}$ ) prevents ripple from being amplified as the output voltage is increased. A $10 \mu \mathrm{~F}$ capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.

Although the LM350 is stable with no output capacitance, like any feedback circuit, certain values of external capacitance can cause excessive ringing. An output capacitance $\left(\mathrm{C}_{\mathrm{O}}\right)$ in the form of a $1 \mu \mathrm{~F}$ tantalum or $25 \mu \mathrm{~F}$ aluminum electrolytic capacitor on the output swamps this effect and insures stability.

## Protection Diodes

When external capacitors are used with any IC regulator, it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the LM350 with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values $\left(\mathrm{C}_{\mathrm{O}}>25 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{Adj}}>10 \mu \mathrm{~F}\right)$. Diode $\mathrm{D}_{1}$ prevents $\mathrm{C}_{\mathrm{O}}$ from discharging thru the IC during an input short circuit. Diode $\mathrm{D}_{2}$ protects against capacitor $\mathrm{C}_{\text {Adj }}$ discharging through the IC during an output short circuit. The combination of diodes $D_{1}$ and $D_{2}$ prevents $C_{\text {Adj }}$ from discharging through the IC during an input short circuit.

2. $I_{\max }=1.5 \mathrm{~A}, \mathrm{P}_{\max }=20 \mathrm{~W}$
3. Load and line regulation are specified at constant junction temperature. Change in $\mathrm{V}_{\mathrm{O}}$ because of heating effects is covered under the Thermal Regulation specification. Pulse testing with a low duty cycle is used.
4. C $_{\text {Adj, }}$, when used, is connected between the adjustment pin and ground.
5. Since Long Term Stability cannot be measured on each device before shipment, this specification is an engineering estimate of average stability from lot to lot.
6. Power dissipation within an IC voltage regulator produces a temperature gradient on the die, affecting individual IC components on the die. These effects can be minimized by proper integrated circuit design and layout techniques. Thermal Regulation is the effect of these temperature gradients on the output voltage and is expressed in percentage of output change per watt of power change in a specified time.

## APPLICATIONS INFORMATION

## Basic Circuit Operation

The LM337 is a 3-terminal floating regulator. In operation, the LM337 develops and maintains a nominal -1.25 V reference ( $\mathrm{V}_{\text {reff }}$ ) between its output and adjustment terminals. This reference voltage is converted to a programming current ( $\mathrm{I}_{\mathrm{PROG}}$ ) by $\mathrm{R}_{1}$ (see Figure 17), and this constant current flows through $\mathrm{R}_{2}$ from ground.

The regulated output voltage is given by:

$$
v_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2}
$$

Since the current into the adjustment terminal ( $\mathrm{I}_{\text {Adj }}$ ) represents an error term in the equation, the LM337 was designed to control $\mathrm{I}_{\text {Adj }}$ to less than $100 \mu \mathrm{~A}$ and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the LM337 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

Figure 17. Basic Circuit Configuration

## Load Regulation

The LM337 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor $\left(\mathrm{R}_{1}\right)$ should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby
degrading regulation. The ground end of $\mathrm{R}_{2}$ can be returned near the load ground to provide remote ground sensing and improve load regulation.

## External Capacitors

A $1.0 \mu \mathrm{~F}$ tantalum input bypass capacitor $\left(\mathrm{C}_{\mathrm{in}}\right)$ is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor ( $\mathrm{C}_{\mathrm{Adj}}$ ) prevents ripple from being amplified as the output voltage is increased. A $10 \mu \mathrm{~F}$ capacitor should improve ripple rejection about 15 dB at 120 Hz in a 10 V application.

An output capacitance $\left(\mathrm{C}_{\mathrm{O}}\right)$ in the form of a $1.0 \mu \mathrm{~F}$ tantalum or $10 \mu \mathrm{~F}$ aluminum electrolytic capacitor is required for stability.

## Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the LM337 with the recommended protection diodes for output voltages in excess of -25 V or high capacitance values ( $\mathrm{C}_{\mathrm{O}}>25 \mu \mathrm{~F}, \mathrm{C}_{\mathrm{Adj}}>10 \mu \mathrm{~F}$ ). Diode $\mathrm{D}_{1}$ prevents $\mathrm{C}_{\mathrm{O}}$ from discharging thru the IC during an input short circuit. Diode $\mathrm{D}_{2}$ protects against capacitor $\mathrm{C}_{\text {Adj }}$ discharging through the IC during an output short circuit. The combination of diodes $D_{1}$ and $D_{2}$ prevents $C_{\text {Adj }}$ from the discharging through the IC during an input short circuit.

## MC78LC00 Series

## Micropower Voltage Regulator

The MC78LC00 series voltage regulators are specifically designed for use as a power source for video instruments, handheld communication equipment, and battery powered equipment.

The MC78LC00 series features an ultra-low quiescent current of $1.1 \mu \mathrm{~A}$ and a high accuracy output voltage. Each device contains a voltage reference, an error amplifier, a driver transistor and resistors for setting the output voltage. These devices are available in either SOT-89, 3 pin, or SOT-23, 5 pin, surface mount packages.

## Features

- Low Quiescent Current of $1.1 \mu \mathrm{~A}$ Typical
- Low Dropout Voltage ( 220 mV at 10 mA )
- Excellent Line Regulation (0.1\%)
- High Accuracy Output Voltage ( $\pm 2.5 \%$ )
- Output Current for Low Power (up to 80 mA )
- Two Surface Mount Packages (SOT-89, 3 Pin, or SOT-23, 5 Pin)

2. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.

## MC78LC00 Series

## DEFINITIONS

Dropout Voltage - The input/output voltage differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.
Line Regulation - The change in output voltage for a change in input voltage. The measurement is made under conditions

Figure 2. Output Voltage versus Input Voltage

Figure 4. Dropout Voltage versus Output Current
of low dissipation or by using pulse techniques such that average chip temperature is not significantly affected.
Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.
Quiescent Bias Current - Current which is used to operate the regulator chip and is not delivered to the load.

## MC78LC00 Series

## APPLICATIONS INFORMATION

## Introduction

The MC78LC00 micropower voltage regulators are specifically designed with high accuracy output voltage and ultra low quiescent current by CMOS process making them ideal for battery powered applications and hand-held communication equipment. An input bypass capacitor is recommended if the regulator is located an appreciable distance ( $\geq 4$ inches) from the input voltage source. These regulators require $\geq 0.1 \mu \mathrm{~F}$ capacitance between the output terminal and ground for stability. Most types of aluminum, tantalum or multilayer ceramic will perform adequately. Solid tantalums or other appropriate capacitors are recommended for operation below $25^{\circ} \mathrm{C}$. The bypass capacitors should be mounted with the shortest possible leads or track lengths directly across the regulator input and output terminals.

With economical electrolytic capacitors, cold temperature operation can pose a serious stability problem. As the
electrolyte freezes, around $-30^{\circ} \mathrm{C}$, the capacitance will decrease and the equivalent series resistance (ESR) will increase drastically, causing the circuit to oscillate. Quality electrolytic capacitors with extended temperature ranges of $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$ are readily available. Solid tantalum capacitors may be the better choice if small size is a requirement. However, a maximum ESR limit of $3.0 \Omega$ must be observed over temperature to maintain stability.

In the Current Boost Circuit, shown in Figures 11 and 13, an output current of up to 600 mA can be delivered by the circuit. The circuit of Figure 11 has no current limit. In each case, the external transistor must be rated for the expected power dissipation. Figure 12 shows how a fixed output may be programmed, using R1 and R2, to provide a higher output voltage.

## MC33761

## Ultra Low-Noise Low Dropout Voltage Regulator with 1.0 V ON/OFF Control

The MC33761 is an Low DropOut (LDO) regulator featuring excellent noise performances. Thanks to its innovative design, the circuit reaches an impressive $40 \mu \mathrm{VRMS}$ noise level without an external bypass capacitor. Housed in a small SOT-23 5 leads-like package, it represents the ideal designer's choice when space and noise are at premium.

The absence of external bandgap capacitor accelerates the response time to a wake-up signal and keeps it within $40 \mu$ s (in repetitive mode), making the MC33761 as a natural candidate for portable applications.

The MC33761 also hosts a novel architecture which prevents excessive undershoots in the presence of fast transient bursts, as in any bursting systems.

Finally, with a static line regulation better than -75 dB , it naturally shields the downstream electronics against choppy lines.

## Features

- Ultra-Low Noise: $150 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ @ $100 \mathrm{~Hz}, 40 \mu \mathrm{VRMS}$ $100 \mathrm{~Hz}-100 \mathrm{kHz}$ Typical, $\mathrm{I}_{\text {out }}=60 \mathrm{~mA}, \mathrm{Co}=1.0 \mu \mathrm{~F}$
- Fast Response Time from OFF to ON: $40 \mu$ s Typical at a 200 Hz Repetition Rate
- Ready for 1.0 V Platforms: ON with a 900 mV High Level
- Nominal Output Current of 80 mA with a 100 mA Peak Capability
- Typical Dropout of 90 mV @ $30 \mathrm{~mA}, 160 \mathrm{mV}$ @ 80 mA
- Ripple Rejection: 70 dB @ 1.0 kHz
- $1.5 \%$ Output Precision @ $25^{\circ} \mathrm{C}$
- Thermal Shutdown
- $\mathrm{V}_{\text {out }}$ Available at $2.5 \mathrm{~V}, 2.8 \mathrm{~V}, 3.0 \mathrm{~V}$
- Operating Range from -40 to $+85^{\circ} \mathrm{C}$
- Dual Version is Available as MC33762

## Applications

- Noise Sensitive Circuits: VCOs RF Stages, etc.
- Bursting Systems (TDMA Phones)
- All Battery Operated Devices

4. $\mathrm{V}_{\text {out }}$ is brought to $\mathrm{V}_{\text {out }}-100 \mathrm{mV}$.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant chip temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential value). The dropout level is affected by the chip temperature, load current and minimum input supply requirements.

## Output Noise Voltage

This is the integrated value of the output noise over a specified frequency range. Input voltage and output current are kept constant during the measurement. Results are expressed in $\mu$ VRMS.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specs.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected. One usually distinguishes static line regulation or DC line regulation (a DC step in the input voltage generates a corresponding step in the output voltage) from ripple rejection or audio susceptibility where the input is combined with a frequency generator to sweep from a few hertz up to a defined boundary while the output amplitude is monitored.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $125^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent catastrophic failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package power dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient temperature, it is possible to calculate the maximum power dissipation and thus the maximum available output current.

## Characterization Curves

All curves taken with $\mathrm{V}_{\text {in }}=\mathrm{V}_{\text {out }}+1.0 \mathrm{~V}, \mathrm{~V}_{\text {out }}=2.8 \mathrm{~V}, \mathrm{C}_{\text {out }}=1.0 \mu \mathrm{~F}$

## APPLICATION HINTS

## Input Decoupling

As with any regulator, it is necessary to reduce the dynamic impedance of the supply rail that feeds the component. A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the MC33761 package. Higher values will correspondingly improve the overall line transient response.

## Output Decoupling

Thanks to a novel concept, the MC33761 is a stable component and does not require any specific Equivalent Series Resistance (ESR) neither a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices.

## Noise Decoupling

Unlike other LDOs, the MC33761 is a true low-noise regulator. Without the need of an external bypass capacitor, it typically reaches the incredible level of $40 \mu \mathrm{VRMS}$ overall noise between 100 Hz and 100 kHz . To give maximum insight on noise specifications, ON Semiconductor includes spectral density graphics. The classical bypass capacitor impacts the start-up phase of standard LDOs. However, thanks to its low-noise architecture, the MC33761 operates without a bypass element and thus offers a typical $40 \mu$ s start-up phase.

## Protections

The MC33761 hosts several protections, giving natural ruggedness and reliability to the products implementing the component. The output current is internally limited to a maximum value of 180 mA typical while temperature shutdown occurs if the die heats up beyond $125^{\circ} \mathrm{C}$. These values let you assess the maximum differential voltage the device can sustain at a given output current before its protections come into play.

The maximum dissipation the package can handle is given by:

$$
P_{\max }=\frac{T_{J \max }-T_{A}}{R_{\theta J A}}
$$

If $\mathrm{T}_{\text {Jmax }}$ is limited to $125^{\circ} \mathrm{C}$, then the MC33761 can dissipate up to $470 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$. The power dissipated by the MC33761 can be calculated from the following formula:

$$
\text { Ptot }=\left(\mathrm{v}_{\text {in }} \times \mathrm{I}_{\text {gnd }}\left(\mathrm{I}_{\text {out }}\right)\right)+\left(\mathrm{v}_{\text {in }}-\mathrm{v}_{\text {out }}\right) \times \mathrm{I}_{\text {out }}
$$

or

$$
\mathrm{Vin}_{\max }=\frac{\text { Ptot }+\mathrm{V}_{\text {out }} \times \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 80 mA output current is needed, the ground current is extracted from the data-sheet curves: $4.0 \mathrm{~mA} @ 80 \mathrm{~mA}$. For a MC33761SNT1-28 (2.8 V) delivering 80 mA and operating at $25^{\circ} \mathrm{C}$, the maximum input voltage will then be 8.3 V .

## Typical Applications

The following picture portrays the typical application of the MC33761.

Figure 7. A Typical Application Schematic

As for any low noise designs, particular care has to be taken when tackling Printed Circuit Board (PCB) layout. The figure below gives an example of a layout where stray inductances/capacitances are minimized. This layout is the

basis for the MC33761 performance evaluation board. The BNC connectors give the user an easy and quick evaluation mean.

## Understanding the Load Transient Improvement

The MC33761 features a novel architecture which allows the user to easily implement the regulator in burst systems where the time between two current shots is kept very small.

The quality of the transient response time is related to many parameters, among which the closed-loop bandwidth with the corresponding phase margin plays an important role. However, other characteristics also come into play like the series pass transistor saturation. When a current perturbation suddenly appears on the output, e.g. a load increase, the error amplifier reacts and actively biases the PNP transistor. During this reaction time, the LDO is in open-loop and the output impedance is rather high. As a result, the voltage brutally drops until the error amplifier effectively closes the loop and corrects the output error. When the load disappears, the opposite phenomenon takes place with a positive overshoot. The problem appears when this overshoot decays down to the LDO steady-state value.

Figure 8. A Standard LDO Behavior when the Load Current Disappears

Figure 10. Without Load Transient Improvement

During this decreasing phase, the LDO stops the PNP bias and one can consider the LDO asleep (Figure 8). If by misfortune a current shot appears, the reaction time is incredibly lengthened and a strong undershoot takes place. This reaction is clearly not acceptable for line sensitive devices, such as VCOs or other Radio-Frequency parts. This problem is dramatically exacerbated when the output current drops to zero rather than a few mA. In this later case, the internal feedback network is the only discharge path, accordingly lengthening the output voltage decay period (Figure 9).
The MC33761 cures this problem by implementing a clever design where the LDO detects the presence of the overshoot and forces the system to go back to steady-state as soon as possible, ready for the next shot. Figure 10 and 11 show how it positively improves the response time and decreases the negative peak voltage.

Figure 9. A Standard LDO Behavior when the Load Current Appears in the Decay Zone

Figure 11. MC33761 with Load Transient Improvement

## MC33761

## MC33761 Has a Fast Start-Up Phase

Thanks to the lack of bypass capacitor the MC33761 is able to supply its downstream circuitry as soon as the OFF to ON signal appears. In a standard LDO, the charging time of the external bypass capacitor hampers the response time. A simple solution consists in suppressing this bypass element but, unfortunately, the noise rises to an
unacceptable level. MC33761 offers the best of both worlds since it no longer includes a bypass capacitor and starts in less than $40 \mu$ s typically (Repetitive at 200 Hz ). It also ensures a low-noise level of $40 \mu$ VRMS $100 \mathrm{~Hz}-100 \mathrm{kHz}$. The following picture details the typical 33761 start-up phase.

## NCP4561

## Ultra Low-Noise Low Dropout Voltage Regulator with 1.0 V ON/OFF Control

The NCP4561 is a Low DropOut (LDO) regulator featuring excellent noise performances. Thanks to its innovative concept, the circuit reaches an incredible $40 \mu$ VRMS noise level without an external bypass capacitor. Housed in a small SOT-23 5 leads-like package, it represents the ideal designer's choice when space and noise are at premium.

The absence of external bandgap capacitor unleashes the response time to a wake-up signal and makes it stay within $40 \mu$ s (in repetitive mode), pushing the NCP4561 as a natural candidate in portable applications.

The NCP4561 also hosts a novel architecture which prevents excessive undershoots when the regulator is the seat of fast transient bursts, as in any bursting systems.

Finally, with a static line regulation better than -75 dB , it naturally shields the downstream electronics against choppy lines.

## Features

- Ultra Low-Noise: $150 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ @ $100 \mathrm{~Hz}, 40 \mu$ VRMS $100 \mathrm{~Hz}-$ 100 kHz Typical, Iout $=60 \mathrm{~mA}, \mathrm{C}_{\mathrm{o}}=1.0 \mu \mathrm{~F}$
- Fast Response Time from OFF to ON: $40 \mu \mathrm{~s}$ Typical at a 200 Hz Repetition Rate
- Ready for 1.0 V Platforms: ON with a 900 mV High Level
- Nominal Output Current of 80 mA with a 100 mA Peak Capability
- Typical Dropout of 90 mV @ $30 \mathrm{~mA}, 160 \mathrm{mV}$ @ 80 mA
- Ripple Rejection: 70 dB @ 1.0 kHz
- $1.5 \%$ Output Precision @ $25^{\circ} \mathrm{C}$
- Thermal Shutdown

## Applications

- Noise Sensitive Circuits: VCOs RF Stages, etc.
- Bursting Systems (TDMA Phones)
- All Battery Operated Devices

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant chip temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential value). The dropout level is affected by the chip temperature, load current and minimum input supply requirements.

## Output Noise Voltage

This is the integrated value of the output noise over a specified frequency range. Input voltage and output current are kept constant during the measurement. Results are expressed in $\mu$ VRMS.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specs.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected. One usually distinguishes static line regulation or DC line regulation (a DC step in the input voltage generates a corresponding step in the output voltage) from ripple rejection or audio susceptibility where the input is combined with a frequency generator to sweep from a few hertz up to a defined boundary while the output amplitude is monitored.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $125^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent catastrophic failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package power dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient temperature, it is possible to calculate the maximum power dissipation and thus the maximum available output current.

## APPLICATION HINTS

## Input Decoupling

As with any regulator, it is necessary to reduce the dynamic impedance of the supply rail that feeds the component. A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP4561 package. Higher values will correspondingly improve the overall line transient response.

## Output Decoupling

Thanks to a novel concept, the NCP4561 is a stable component and does not require any specific Equivalent Series Resistance (ESR) neither a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices.

## Noise Decoupling

Unlike other LDOs, the NCP4561 is a true low-noise regulator. Without the need of an external bypass capacitor, it typically reaches the incredible level of $40 \mu$ VRMS overall noise between 100 Hz and 100 kHz . To give maximum insight on noise specifications, ON Semiconductor includes spectral density graphics. The classical bypass capacitor impacts the start-up phase of standard LDOs. However, thanks to its low-noise architecture, the NCP4561 operates without a bypass element and thus offers a typical $40 \mu \mathrm{~s}$ start-up phase.

## Protections

The NCP4561 hosts several protections, giving natural ruggedness and reliability to the products implementing the component. The output current is internally limited to a maximum value of 180 mA typical while temperature shutdown occurs if the die heats up beyond $125^{\circ} \mathrm{C}$. These values let you assess the maximum differential voltage the device can sustain at a given output current before its protections come into play.
The maximum dissipation the package can handle is given by:

$$
P_{\max }=\frac{T_{J \max }-T_{A}}{R_{\theta J A}}
$$

If $\mathrm{T}_{\mathrm{Jmax}}$ is limited to $125^{\circ} \mathrm{C}$, then the NCP4561 can dissipate up to $470 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$. The power dissipated by the NCP4561 can be calculated from the following formula:

$$
\text { Ptot }=\left(v_{\text {in }} \times I_{\text {gnd }}\left(I_{\text {out }}\right)\right)+\left(v_{\text {in }}-v_{\text {out }}\right) \times I_{\text {out }}
$$

or

$$
\operatorname{Vin}_{\max }=\frac{\text { Ptot }+\mathrm{V}_{\text {out }} \times I_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 80 mA output current is needed, the ground current is extracted from the data-sheet curves: $4.0 \mathrm{~mA} @ 80 \mathrm{~mA}$. For a NCP4561SNT1-28 (2.8 V) delivering 80 mA and operating at $25^{\circ} \mathrm{C}$, the maximum input voltage will then be 8.3 V .

## Typical Applications

The following figure portrays the typical application of the NCP4561.

Figure 10. A Typical Application Schematic

## PCB Layout Considerations

As for any low noise designs, particular care has to be taken when tackling Printed Circuit Board (PCB) layout. The figure below gives an example of a layout where stray

inductances/capacitances are minimized. This layout is the basis for the NCP4561 performance evaluation board. The BNC connectors give the user an easy and quick evaluation mean.

Figure 11. PCB Layout

## Understanding the Load Transient Improvement

The NCP4561 features a novel architecture which allows the user to easily implement the regulator in burst systems where the time between two current shots is kept very small.

The quality of the transient response time is related to many parameters, among which the closed-loop bandwidth with the corresponding phase margin plays an important role. However, other characteristics also come into play like the series pass transistor saturation. When a current perturbation suddenly appears on the output, e.g. a load increase, the error amplifier reacts and actively biases the PNP transistor. During this reaction time, the LDO is in open-loop and the output impedance is rather high. As a result, the voltage brutally drops until the error amplifier effectively closes the loop and corrects the output error. When the load disappears, the opposite phenomenon takes place with a positive overshoot. The problem appears when this overshoot decays down to the LDO steady-state value.

During this decreasing phase, the LDO stops the PNP bias and one can consider the LDO asleep. If by misfortune a current shot appears, the reaction time is incredibly lengthened and a strong undershoot takes place. This reaction is clearly not acceptable for line sensitive devices, such as VCOs or other Radio-Frequency parts. This problem is dramatically exacerbated when the output current drops to zero rather than a few mA. In this later case, the internal feedback network is the only discharge path, accordingly lengthening the output voltage decay period.
The NCP4561 cures this problem by implementing a clever design where the LDO detects the presence of the overshoot and forces the system to go back to steady-state as soon as possible, ready for the next shot, which positively improves the response time and decreases the negative peak voltage.

## NCP4561 has a fast start-up phase

Thanks to the lack of bypass capacitor the NCP4561 is able to supply its downstream circuitry as soon as the OFF to ON signal appears. In a standard LDO, the charging time of the external bypass capacitor hampers the response time. A simple solution consists in suppressing this bypass element but, unfortunately, the noise rises to an
unacceptable level. NCP4561 offers the best of both worlds since it no longer includes a bypass capacitor and starts in less than $40 \mu$ s typically (Repetitive at 200 Hz ). It also ensures a low-noise level of $40 \mu \mathrm{VRMS} 100 \mathrm{~Hz}-100 \mathrm{kHz}$. The following picture details the typical NCP4561 startup phase.

## NCP502

## 80 mA CMOS Low Iq Voltage Regulator in an SC70-5

The NCP502 series of fixed output linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP502 series features an ultra-low quiescent current of $40 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP502 has been designed to be used with low cost ceramic capacitors. The device is housed in the micro-miniature SC70-5 surface mount package. Standard voltage versions are $1.5,1.8,2.5$, $2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $40 \mu \mathrm{~A}$ Typical
- Excellent Line and Load Regulation
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Cellular Phones
- Battery Powered Consumer Products
- Hand-Held Instruments
- Camcorders and Cameras

## PIN CONNECTIONS

(Top View)

ORDERING INFORMATION
See detailed ordering and shipping information in the package dimensions section on page 287 of this data sheet.

NCP502

PIN FUNCTION DESCRIPTION

| Pin No. | Pin Name | Description |
| :---: | :---: | :--- |
| 1 | Gnd | Power supply ground. |
| 2 | Vin | Positive power supply input voltage. |
| 3 | Vout | Regulated output voltage. |
| 4 | N/C | No internal connection. |
| 5 | Enable | This input is used to place the device into low-power standby. When this input is pulled low, the device is <br> disabled. If this function is not used, Enable should be connected to Vin. |

Figure 9. Output Voltage versus Input Voltage

Figure 10. Dropout Voltage versus Temperature

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP502 series is shown in Figure 1, front page.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP502 package. Higher values and lower ESR will improve the overall line transient response. If large line or load transients are not expected, then it is possible to operate the regulator without the use of a capaitor.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP502 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. If load transients are not to be expected, then it is possible for the regulator to operate with no output capacitor. Otherwise, capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $5.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Enable Operation

The enable pin will turn on the regulator when pulled high and turn off the regulator when pulled low. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\mathrm{in}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP502 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP502 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP502 can dissipate up to $250 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$.

The power dissipated by the NCP502 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} l_{\text {gnd }}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right] * l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $40 \mu \mathrm{~A}$. For an NCP502 (3.0 V), the maximum input voltage will then be 6.12 V .

## NCP502

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

SC70-5
(SC-88A/SOT-353)

## NCP512

## Product Preview 80 mA CMOS Low Iq Voltage Regulator in an SC70-5

The NCP512 series of fixed output linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP512 series features an ultra-low quiescent current of $40 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP512 has been designed to be used with low cost ceramic capacitors. The device is housed in the micro-miniature SC70-5 surface mount package. Standard voltage versions are $1.5,1.8,2.5$, $2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $40 \mu \mathrm{~A}$ Typical
- Low Dropout Voltage of 250 mV at 80 mA
- Excellent Line and Load Regulation
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Cellular Phones
- Battery Powered Consumer Products
- Hand-Held Instruments
- Camcorders and Cameras

This device contains \# active transistors

$$

4. Low duty cycle pulse techniques are used during testing to maintain the junction temperature as close to ambient as possible.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP512 series is shown in Figure 1, front page.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP512 package. Higher values and lower ESR will improve the overall line transient response.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP512 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Enable Operation

The enable pin will turn on the regulator when pulled high and turn off the regulator when pulled low. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\mathrm{in}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP512 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP512 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP512 can dissipate up to xxx mW @ $25^{\circ} \mathrm{C}$.

The power dissipated by the NCP512 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} I_{\text {gnd }}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right]^{*} l_{\text {out }}
$$

or

$$
V_{\text {inMAX }}=\frac{P_{\text {tot }}+V_{\text {out }}{ }^{*} I_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $40 \mu \mathrm{~A}$. For an NCP512 (3.0 V), the maximum input voltage will then be $x x \mathrm{~V}$.

## NCP512

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## NCP552

## 80 mA CMOS Low Iq NOCAP ${ }^{T M}$ Voltage Regulator

The NCP552 series of fixed output NOCAP linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP552 series features an ultra-low quiescent current of $2.8 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP552 has been designed to be used with low cost ceramic capacitors. This device has the ability to operate without an output capacitor. The device is housed in the micro-miniature SC82-AB surface mount package. Standard voltage versions are $1.5,1.8,2.5$, $2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $2.8 \mu \mathrm{~A}$ Typical
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Battery Powered Consumer Products
- Hand-Held Instruments
- Camcorders and Cameras

This device contains 32 active transistors

3. Maximum package power dissipation limits must be observed.

$$
P D=\frac{T_{J(\max )}-T_{A}}{R_{\theta J A}}
$$

4. Low duty cycle pulse techniques are used during testing to maintain the junction temperature as close to ambient as possible.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## NCP552

Figure 8. Load Transient Response

Figure 10. Turn-On Response

Figure 11. Output Voltage versus Input Voltage

## APPLICATIONS INFORMATION

A typical application circuit for the NCP552 series is shown in Figure 1, front page.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP552 package. Higher values and lower ESR will improve the overall line transient response. If large line or load transients are not expected, then it is possible to operate the regulator without the use of a capacitor.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP552 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. If load transients are not to be expected, then it is possible for the regulator to operate with no output capacitor. Otherwise, capacitors exhibiting ESRs ranging from a few $m \Omega$ up to $10 \Omega$ can thus safely be used. The minimum decoupling value is $0.1 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Enable Operation

The enable pin will turn on the regulator when pulled high and turn off the regulator when pulled low. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\mathrm{in}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP552 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP552 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP552 can dissipate up to $250 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$.

The power dissipated by the NCP552 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }} * I_{\text {gnd }}\left(l_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right]^{*} l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $2.8 \mu \mathrm{~A}$. For an NCP552 (3.0 V), the maximum input voltage will then be 6.12 V .

## INFORMATION FOR USING THE SC-82AB SURFACE MOUNT PACKAGE

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## NCP553

## 80 mA CMOS Low Iq NOCAP ${ }^{\text {TM }}$ Voltage Regulator

The NCP553 series of fixed output NOCAP linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP553 series features an ultra-low quiescent current of $2.8 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP553 has been designed to be used with low cost ceramic capacitors. This device has the ability to operate without an output capacitor. The device is housed in the micro-miniature SC82-AB surface mount package. Standard voltage versions are $1.5,1.8,2.5$, $2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $2.8 \mu \mathrm{~A}$ Typical
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Battery Powered Consumer Products
- Hand-Held Instruments
- Camcorders and Cameras

This device contains 32 active transistors

3. Maximum package power dissipation limits must be observed.

$$
P D=\frac{T_{J(\max )}-T_{A}}{R_{\theta J A}}
$$

4. Low duty cycle pulse techniques are used during testing to maintain the junction temperature as close to ambient as possible.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

Figure 6. Output Noise Density

Figure 7. Line Transient Response

## NCP553

Figure 8. Load Transient Response

Figure 9. Load Transient Response

Figure 10. Output Voltage vs. Input Voltage

## APPLICATIONS INFORMATION

A typical application circuit for the NCP553 series is shown in Figure 1, front page.

## Input Decoupling (C1)

A $0.1 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP553 package. Higher values and lower ESR will improve the overall line transient response. If large line or load transients are not expected, then it is possible to operate the regulator without the use of a capacitor.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP553 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. If load transients are not to be expected, then it is possible for the regulator to operate with no output capacitor. Otherwise, capacitors exhibiting ESRs ranging from a few $m \Omega$ up to $10 \Omega$ can thus safely be used. The minimum decoupling value is $0.1 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP553 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP553 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP553 can dissipate up to $250 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$.

The power dissipated by the NCP553 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} l_{\text {gnd }}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right] * l_{\text {out }}
$$

or

$$
V_{\text {inMAX }}=\frac{P_{\text {tot }}+V_{\text {out }}{ }^{*} I_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $2.8 \mu \mathrm{~A}$. For an NCP553 $(3.0 \mathrm{~V})$, the maximum input voltage will then be 6.12 V .

## INFORMATION FOR USING THE SC-82AB SURFACE MOUNT PACKAGE

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## NCP562

## 80 mA CMOS Low Iq Low-Dropout Voltage Regulator

The NCP562 series of fixed output low-dropout linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP562 series features an ultra-low quiescent current of $2.5 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP562 has been designed to be used with low cost ceramic capacitors and requires a minimum output capacitor of $0.1 \mu \mathrm{~F}$. The device is housed in the micro-miniature $\mathrm{SC} 82-\mathrm{AB}$ surface mount package. Standard voltage versions are $1.5,1.8,2.5,2.7,2.8,3.0,3.3$, and 5.0 V .

## Features

- Low Quiescent Current of $2.5 \mu \mathrm{~A}$ Typical
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Battery Powered Instruments
- Hand-Held Instruments
- Camcorders and Cameras

This device contains 28 active transistors

Figure 1. Representative Block Diagram

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP562 series is shown in Figure 1.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP562 package. Higher values and lower ESR will improve the overall line transient response.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP562 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $10 \Omega$ can thus safely be used. The minimum decoupling value is $0.1 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Enable Operation

The enable pin will turn on the regulator when pulled high and turn off the regulator when pulled low. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used, then the pin should be connected to $\mathrm{V}_{\mathrm{in}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP562 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP562 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP562 can dissipate up to 250 mW @ $25^{\circ} \mathrm{C}$.
The power dissipated by the NCP562 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} l_{\text {gnd }}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right] * l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $2.5 \mu \mathrm{~A}$. For an NCP562SQ30T1 (3.0 V), the maximum input voltage will then be 6.0 V .

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP563 series is shown in Figure 1.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP563 package. Higher values and lower ESR will improve the overall line transient response.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP563 is a stable regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $10 \Omega$ can thus safely be used. The minimum decoupling value is $0.1 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, C1608X5R1A105K, or C3216X7R1C105K

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP563 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP563 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP563 can dissipate up to 250 mW @ $25^{\circ} \mathrm{C}$.

The power dissipated by the NCP563 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} \operatorname{lgnd}\left(l_{\text {out }}\right)\right]+\left.\left[V_{\text {in }}-V_{\text {out }}\right]^{*}\right|_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If an 80 mA output current is needed then the ground current from the data sheet is $2.5 \mu \mathrm{~A}$. For an NCP563SQ30T1 ( 3.0 V ), the maximum input voltage will then be 6.0 V .

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## NCP563

## LM2931 Series

## 100 mA, Adjustable Output, LDO Voltage Regulator with 60 V Load Dump Protection

The LM2931 series consists of positive fixed and adjustable output voltage regulators that are specifically designed to maintain proper regulation with an extremely low input-to-output voltage differential. These devices are capable of supplying output currents in excess of 100 mA and feature a low bias current of 0.4 mA at 10 mA output.

Designed primarily to survive in the harsh automotive environment, these devices will protect all external load circuitry from input fault conditions caused by reverse battery connection, two battery jump starts, and excessive line transients during load dump. This series also includes internal current limiting, thermal shutdown, and additionally, is able to withstand temporary power-up with mirror-image insertion.

Due to the low dropout voltage and bias current specifications, the LM2931 series is ideally suited for battery powered industrial and consumer equipment where an extension of useful battery life is desirable. The ' C ' suffix adjustable output regulators feature an output inhibit pin which is extremely useful in microprocessor-based systems.

- Input-to-Output Voltage Differential of < 0.6 V @ 100 mA
- Output Current in Excess of 100 mA
- Low Bias Current
- 60 V Load Dump Protection
- -50 V Reverse Transient Protection
- Internal Current Limiting with Thermal Shutdown
- Temporary Mirror-Image Protection
- Ideally Suited for Battery Powered Equipment
- Economical 5-Lead TO-220 Package with Two Optional Leadforms
- Available in Surface Mount SOP-8, D²PAK and DPAK Packages
- High Accuracy ( $\pm 2 \%$ ) Reference (LM2931AC) Available

## APPLICATIONS INFORMATION

The LM2931 series regulators are designed with many protection features making them essentially blow-out proof. These features include internal current limiting, thermal shutdown, overvoltage and reverse polarity input protection, and the capability to withstand temporary power-up with mirror-image insertion. Typical application circuits for the fixed and adjustable output device are shown in Figures 17 and 18.

The input bypass capacitor $\mathrm{C}_{\mathrm{in}}$ is recommended if the regulator is located an appreciable distance ( $\geq 4^{\prime \prime}$ ) from the supply input filter. This will reduce the circuit's sensitivity to the input line impedance at high frequencies.

This regulator series is not internally compensated and thus requires an external output capacitor for stability. The capacitance value required is dependent upon the load current, output voltage for the adjustable regulator, and the type of capacitor selected. The least stable condition is encountered at maximum load current and minimum output voltage. Figure 22 shows that for operation in the "Stable" region, under the conditions specified, the magnitude of the output capacitor impedance $\left|\mathrm{Z}_{\mathrm{O}}\right|$ must not exceed $0.4 \Omega$. This
limit must be observed over the entire operating temperature range of the regulator circuit.

With economical electrolytic capacitors, cold temperature operation can pose a serious stability problem. As the electrolyte freezes, around $-30^{\circ} \mathrm{C}$, the capacitance will decrease and the equivalent series resistance (ESR) will increase drastically, causing the circuit to oscillate. Quality electrolytic capacitors with extended temperature ranges of $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$ and $-55^{\circ}$ to $+105^{\circ} \mathrm{C}$ are readily available. Solid tantalum capacitors may be a better choice if small size is a requirement, however, the maximum $\left|Z_{O}\right|$ limit over temperature must be observed.
Note that in the stable region, the output noise voltage is linearly proportional to $\left|\mathrm{Z}_{\mathrm{O}}\right|$. In effect, $\mathrm{C}_{\mathrm{O}}$ dictates the high frequency roll-off point of the circuit. Operation in the area titled "Marginally Stable" will cause the output of the regulator to exhibit random bursts of oscillation that decay in an under-damped fashion. Continuous oscillation occurs when operating in the area titled "Unstable". It is suggested that oven testing of the entire circuit be performed with maximum load, minimum input voltage, and minimum ambient temperature.

Figure 17. Fixed Output Regulator

The LM2931 series can be current boosted with a PNP transistor. The D45VH7, on a heatsink, will provide an output current of 5.0 A with an input to output voltage differential of approximately 1.0 V . Resistor R in conjunction with the $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting. This circuit is not short circuit proof.

Figure 19. (5.0 A) Low Differential Voltage Regulator

Switch Position $1=$ Output "On", $2=$ Output "Off"

$$
V_{\text {out }}=V_{\text {ref }}\left(1+\frac{R_{2}}{R_{1}}\right)+I_{\text {Adj }} R_{2} \quad 22.5 k \geq \frac{R_{1} R_{2}}{R_{1}+R_{2}}
$$

Figure 18. Adjustable Output Regulator

The circuit of Figure 19 can be modified to provide supply protection against short circuits by adding the current sense resistor $\mathrm{R}_{\mathrm{Sc}}$ and an additional PNP transistor. The current sensing PNP must be capable of handling the short circuit current of the LM2931. Safe operating area of both transistors must be considered under worst case conditions.

## LM2931 Series

## DEFINITIONS

Dropout Voltage - The input/output voltage differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output decreases 100 mV from nominal value at 14 V input, dropout voltage is affected by junction temperature and load current.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.

Bias Current - That part of the input current that is not delivered to the load.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Long-Term Stability - Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices electrical characteristics and maximum power dissipation.

## LP2950, LP2951

## 100 mA, 3.0 V, Low Power Low Dropout Voltage Regulator

The LP2950 and LP2951 are micropower voltage regulators that are specifically designed to maintain proper regulation with an extremely low input-to-output voltage differential. These devices feature a very low quiescent bias current of $75 \mu \mathrm{~A}$ and are capable of supplying output currents in excess of 100 mA . Internal current and thermal limiting protection is provided.

The LP2951 has three additional features. The first is the $\overline{\text { Error }}$ Output that can be used to signal external circuitry of an out of regulation condition, or as a microprocessor power-on reset. The second feature allows the output voltage to be preset to $5.0 \mathrm{~V}, 3.3 \mathrm{~V}$ or 3.0 V output (depending on the version) or programmed from 1.25 V to 29 V . It consists of a pinned out resistor divider along with direct access to the Error Amplifier feedback input. The third feature is a Shutdown input that allows a logic level signal to turn-off or turn-on the regulator output.

Due to the low input-to-output voltage differential and bias current specifications, these devices are ideally suited for battery powered computer, consumer, and industrial equipment where an extension of useful battery life is desirable. The LP2950 is available in the three pin case 29 and DPAK packages, and the LP2951 is available in the eight pin dual-in-line, SO-8 and Micro-8 surface mount packages. The ' $A$ ' suffix devices feature an initial output voltage tolerance $\pm 0.5 \%$.

## LP2950 and LP2951 Features:

- Low Quiescent Bias Current of $75 \mu \mathrm{~A}$
- Low Input-to-Output Voltage Differential of 50 mV at $100 \mu \mathrm{~A}$ and 380 mV at 100 mA
- 5.0 V, 3.3 V or $3.0 \mathrm{~V} \pm 0.5 \%$ Allows Use as a Regulator or Reference
- Extremely Tight Line and Load Regulation
- Requires Only a $1.0 \mu \mathrm{~F}$ Output Capacitor for Stability
- Internal Current and Thermal Limiting

## LP2951 Additional Features:

- Error Output Signals an Out of Regulation Condition
- Output Programmable from 1.25 V to 29 V
- Logic Level Shutdown Input

6. The Junction-to-Ambient Thermal Resistance is determined by PC board copper area per Figure 27.
7. ESD data available upon request.
8. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.
9. $V_{O(n o m)}$ is the part number voltage option.
10. Noise tests on the LP2951 are made with a $0.01 \mu \mathrm{~F}$ capacitor connected across Pins 7 and 1.

## DEFINITIONS

Dropout Voltage - The input/output voltage differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.

Line Regulation - The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.

Bias Current - Current which is used to operate the regulator chip and is not delivered to the load.

Figure 2. Quiescent Current

Figure 4. Input Current

Output Noise Voltage - The rms ac voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Leakage Current - Current drawn through a bipolar transistor collector-base junction, under a specified collector voltage, when the transistor is "off".
Upper Threshold Voltage - Voltage applied to the comparator input terminal, below the reference voltage which is applied to the other comparator input terminal, which causes the comparator output to change state from a logic " 0 " to " 1 ".
Lower Threshold Voltage - Voltage applied to the comparator input terminal, below the reference voltage which is applied to the other comparator input terminal, which causes the comparator output to change state from a logic " 1 " to " 0 ".
Hysteresis - The difference between Lower Threshold voltage and Upper Threshold voltage.

## APPLICATIONS INFORMATION

## Introduction

The LP2950/LP2951 regulators are designed with internal current limiting and thermal shutdown making them user-friendly. Typical application circuits for the LP2950 and LP2951 are shown in Figures 18 through 26.

These regulators are not internally compensated and thus require a $1.0 \mu \mathrm{~F}$ (or greater) capacitance between the LP2950/LP2951 output terminal and ground for stability. Most types of aluminum, tantalum or multilayer ceramic will perform adequately. Solid tantalums or appropriate multilayer ceramic capacitors are recommended for operation below $25^{\circ} \mathrm{C}$.

At lower values of output current, less output capacitance is required for output stability. The capacitor can be reduced to $0.33 \mu \mathrm{~F}$ for currents less than 10 mA , or $0.1 \mu \mathrm{~F}$ for currents below 1.0 mA . Using the 8 -pin versions at voltages less than 5.0 V operates the error amplifier at lower values of gain, so that more output capacitance is needed for stability. For the worst case operating condition of a 100 mA load at 1.23 V output (Output Pin 1 connected to the feedback Pin 7) a minimum capacitance of $3.3 \mu \mathrm{~F}$ is recommended.

The LP2950 will remain stable and in regulation when operated with no output load. When setting the output voltage of the LP2951 with external resistors, the resistance values should be chosen to draw a minimum of $1.0 \mu \mathrm{~A}$.

A bypass capacitor is recommended across the LP2950/LP2951 input to ground if more than 4 inches of wire connects the input to either a battery or power supply filter capacitor

Input capacitance at the LP2951 Feedback Pin 7 can create a pole, causing instability if high value external resistors are used to set the output voltage. Adding a 100 pF capacitor between the Output Pin 1 and the Feedback Pin 7 and increasing the output filter capacitor to at least $3.3 \mu \mathrm{~F}$ will stabilize the feedback loop.

## Error Detection Comparator

The comparator switches to a positive logic low whenever the LP2951 output voltage falls more than approximately $5.0 \%$ out of regulation. This value is the comparator's designed-in offset voltage of 60 mV divided by the 1.235 V internal reference. As shown in the representative block diagram. This trip level remains $5.0 \%$ below normal regardless of the value of regulated output voltage. For example, the error flag trip level is 4.75 V for a normal 5.0 V regulated output, or 9.50 V for a 10 V output voltage.

Figure 2 is a timing diagram which shows the ERROR signal and the regulated output voltage as the input voltage
to the LP2951 is ramped up and down. The $\overline{\mathrm{ERROR}}$ signal becomes valid (low) at about 1.3 V input. It goes high when the input reaches about 5.0 V ( $\mathrm{V}_{\text {out }}$ exceeds about 4.75 V ). Since the LP2951's dropout voltage is dependent upon the load current (refer to the curve in the Typical Performance Characteristics), the input voltage trip point will vary with load current. The output voltage trip point does not vary with load.
The error comparator output is an open collector which requires an external pull-up resistor. This resistor may be returned to the output or some other voltage within the system. The resistance value should be chosen to be consistent with the $400 \mu \mathrm{~A}$ sink capability of the error comparator. A value between 100 k and $1.0 \mathrm{M} \Omega$ is suggested. No pull-up resistance is required if this output is unused.
When operated in the shutdown mode, the error comparator output will go high if it has been pulled up to an external supply. To avoid this invalid response, the error comparator output should be pulled up to $\mathrm{V}_{\text {out }}$ (see Figure 16).

Figure 16. ERROR Output Timing

## Programming the Output Voltage (LP2951)

The LP2951CX may be pin-strapped for the nominal fixed output voltage using its internal voltage divider by tying Pin 1 (output) to Pin 2 (sense) and Pin 7 (feedback) to Pin 6 (5.0 V tap). Alternatively, it may be programmed for any output voltage between its 1.235 reference voltage and its 30 V maximum rating. An external pair of resistors is required, as shown in Figure 17.

Figure 17. Adjustable Regulator
The complete equation for the output voltage is:

$$
v_{\text {out }}=v_{\text {ref }}(1+R 1 / R 2)+I_{F B} R 1
$$

where $\mathrm{V}_{\text {ref }}$ is the nominal 1.235 V reference voltage and $\mathrm{I}_{\mathrm{FB}}$ is the feedback pin bias current, nominally -20 nA . The minimum recommended load current of $1.0 \mu \mathrm{~A}$ forces an upper limit of $1.2 \mathrm{M} \Omega$ on the value of R 2 , if the regulator must work with no load. $\mathrm{I}_{\mathrm{FB}}$ will produce a $2 \%$ typical error in $\mathrm{V}_{\text {out }}$ which may be eliminated at room temperature by adjusting R1. For better accuracy, choosing R2 $=100 \mathrm{k}$ reduces this error to $0.17 \%$ while increasing the resistor program current to $12 \mu \mathrm{~A}$. Since the LP2951 typically draws $75 \mu \mathrm{~A}$ at no load with Pin 2 open circuited, the extra $12 \mu \mathrm{~A}$ of current drawn is often a worthwhile tradeoff for eliminating the need to set output voltage in test.

## Output Noise

In many applications it is desirable to reduce the noise present at the output. Reducing the regulator bandwidth by increasing the size of the output capacitor is the only method
for reducing noise on the 3 lead LP2950. However, increasing the capacitor from $1.0 \mu \mathrm{~F}$ to $220 \mu \mathrm{~F}$ only decreases the noise from $430 \mu \mathrm{~V}$ to $160 \mu \mathrm{Vrms}$ for a 100 kHz bandwidth at the 5.0 V output.
Noise can be reduced fourfold by a bypass capacitor across R1, since it reduces the high frequency gain from 4 to unity. Pick

$$
C_{\text {Bypass }} \approx \frac{1}{2 \pi R 1 \times 200 \mathrm{~Hz}}
$$

or about $0.01 \mu \mathrm{~F}$. When doing this, the output capacitor must be increased to $3.3 \mu \mathrm{~F}$ to maintain stability. These changes reduce the output noise from $430 \mu \mathrm{~V}$ to $126 \mu \mathrm{Vrms}$ for a 100 kHz bandwidth at 5.0 V output. With bypass capacitor added, noise no longer scales with output voltage so that improvements are more dramatic at higher output voltages.

Figure 18. 1.0 A Regulator with 1.2 V Dropout

## TYPICAL APPLICATIONS

Figure 19. Lithium Ion Battery Cell Charger

Figure 20. Low Drift Current Sink

Error flag occurs when $\mathrm{V}_{\text {in }}$ is too low to maintain $\mathrm{V}_{\text {out }}$, or if $\mathrm{V}_{\text {out }}$ is reduced by excessive load current.

Figure 21. Latch Off When Error Flag Occurs

Figure 22. 5.0 V Regulator with 2.5 V Sleep Function

All diodes are 1N4148.
Early Warning flag on low input voltage.
Main output latches off at lower input voltages.
Battery backup on auxiliary output.
Operation: Regulator \#1's $\mathrm{V}_{\text {out }}$ is programmed one diode drop above 5.0 V . Its error flag becomes active when $\mathrm{V}_{\text {in }} \leq 5.7 \mathrm{~V}$. When $\mathrm{V}_{\text {in }}$ drops below 5.3 V , the error flag of regulator \#2 becomes active and via Q1 latches the main output "off". When $\mathrm{V}_{\text {in }}$ again exceeds 5.7 V , regulator \#1 is back in regulation and the early warning signal rises, unlatching regulator \#2 via D3.

Figure 23. Regulator with Early Warning and Auxiliary Output

$\mathrm{V}_{\text {out }}=1.25 \mathrm{~V}(1.0+\mathrm{R} 1 / \mathrm{R} 2)$
For 5.0 V output, use internal resistors. Wire Pin 6 to 7 , and wire Pin 2 to $+V_{\text {out }}$ Bus.

## CS8221

## Micropower 5.0 V, 100 mA Low Dropout Linear Regulator

The CS8221 is a precision $5.0 \mathrm{~V}, 100 \mathrm{~mA}$ micropower voltage regulator with very low quiescent current ( $60 \mu \mathrm{~A}$ typical at $100 \mu \mathrm{~A}$ load). The 5.0 V output is accurate within $\pm 2.0 \%$ and supplies 100 mA of load current with a maximum dropout voltage of only 600 mV .

The regulator is protected against reverse battery, short circuit, overvoltage, and over temperature conditions. The device can withstand 74 V peak transients making it suitable for use in automotive environments. The CS8221 is pin for pin compatible with the LM2931.

## Features

- Low Quiescent Current ( $60 \mu \mathrm{~A}$ @ $100 \mu \mathrm{~A}$ Load)
- $5.0 \mathrm{~V} \pm 2.0 \%$ Output
- 100 mA Output Current Capability
- Internally Fused Leads in SO-8 Package
- Fault Protection
- +74 V Peak Transient Voltage
-     - 15 V Reverse Voltage
- Short Circuit
- Thermal Shutdown

## CIRCUIT DESCRIPTION

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 2).

Figure 2. Typical Circuit Waveforms for Output Stage Protection

If the input voltage rises above 30 V , the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients.

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

Figure 3. Application and Test Diagram

## STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor CouT shown in Figure 3 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for Cout for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Increase the temperature to your highest operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 4) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT }(\mathrm{min})}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J A}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like
$R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS9201

## Micropower 5.0 V, 100 mA <br> Low Dropout Linear Regulator with NOCAPTM

The CS9201 is a precision $5.0 \mathrm{~V}, 100 \mathrm{~mA}$ voltage regulator with low quiescent current ( $450 \mu \mathrm{~A}$ typ. @ $100 \mu \mathrm{~A}$ load). The 5.0 V output is accurate within $\pm 2 \%$ and supplies 100 mA of load current with a maximum dropout voltage of only 600 mV .

The regulator is protected against reverse battery, short circuit, over voltage, and over temperature conditions. The device can withstand 74 V peak transients making it suitable for use in automotive environments. ON's proprietary NOCAP solution is the first technology which allows the output to be stable without the use of an external capacitor. NOCAP is suitable for slow switching or steady loads.

## Features

- NOCAP
- Low Quiescent Current ( $450 \mu \mathrm{~A}$ typ. @ $100 \mu \mathrm{~A}$ load)
- $5.0 \mathrm{~V}, \pm 2 \%$ Output
- 100 mA Output Current Capability
- Fault Protection
- 74 V Peak Transient Voltage
-     - 15 V Reverse Voltage
- Short Circuit
- Thermal Shutdown
- Overvoltage Shutdown
- Internally Fused Leads

(1) Contact factory for optional Sense lead.

## CIRCUIT DESCRIPTION

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 8).

If the input voltage rises above 32 V (typ), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients.

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

Figure 8. Typical Circuit Waveforms for Output Stage Protection

* C 1 is required if regulator is distant from power source filter.

Figure 9. Application and Test Diagram

## APPLICATION NOTES

## STABILITY CONSIDERATIONS / NOCAP

Normally a low dropout or quasi-low dropout regulator (or any type requiring a slow lateral PNP in the control loop) necessitates a large external compensation capacitor at the output of the IC. The external capacitor is also used to curtail overshoot, determine startup delay time and load transient response.

Traditional LDO regulators typically have low unity gain bandwidth, display overshoot and poor ripple rejection. Compensation is also an issue and depends on the external capacitor value, ESR (Equivalent Series Resistance) and board layout parasitics that all can create oscillations if not properly accounted for.

NOCAP is an ON Semiconductor exclusive output stage which internally compensates the LDO regulator over temperature, load and line variations without the need for an expensive external capacitor
NOCAP is ideally suited for slow switching or steady loads. If the load is characterized by transient current events, an output storage capacitor may be needed. If this is the case, the capacitor should be no larger than 100 nF . With loads that require greater transient suppression, a regulator with a traditional output stage (such as the CS8221) may be better suited for proper operation.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 10) is:

$$
\begin{align*}
P_{D(\max )}= & \left\{V_{\operatorname{IN}(\max )}-\mathrm{V}_{\text {OUT }}(\min )\right\} \operatorname{IOUT}(\max ) \\
& +\mathrm{V}_{\operatorname{IN}(\max )} \mathrm{I} \mathrm{Q} \tag{1}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{A}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

Figure 10. Single output regulator with key performance parameters labeled.

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS9202

## Micropower 3.3 V, 100 mA <br> Low Dropout Linear Regulator with NOCAPTM

The CS9202 is a precision $3.3 \mathrm{~V}, 100 \mathrm{~mA}$ voltage regulator with low quiescent current ( $450 \mu \mathrm{~A}$ typ. @ $100 \mu \mathrm{~A}$ load). The 3.3 V output is accurate within $\pm 2 \%$ and supplies 100 mA of load current.

The regulator is protected against reverse battery, short circuit, over voltage, and over temperature conditions. The device can withstand 74 V peak transients making it suitable for use in automotive environments. ON's proprietary NOCAP solution is the first technology which allows the output to be stable without the use of an external capacitor. NOCAP is suitable for slow switching or steady loads.

## APPLICATION NOTES

## STABILITY CONSIDERATIONS / NOCAP

Normally a low dropout or quasi-low dropout regulator (or any type requiring a slow lateral PNP in the control loop) necessitates a large external compensation capacitor at the output of the IC. The external capacitor is also used to curtail offshoot, determine startup delay time and load transient response.

Traditional LDO regulators typically have low unity gain bandwidth, display overshoot and poor ripple rejection. Compensation is also an issue and depends on the external capacitor value, ESR (Equivalent Series Resistance) and board layout parasitics that all can create oscillations if not properly accounted for.

NOCAP is an ON Semiconductor exclusive output stage which internally compensates the LDO regulator over temperature, load and line variations without the need for an expensive external capacitor
NOCAP is ideally suited for slow switching or steady loads. If the load is characterized by transient current events, an output storage capacitor may be needed. If this is the case, the capacitor should be no larger than 100 nF . With loads that require greater transient suppression, a regulator with a traditional output stage (such as the CS8221) may be better suited for proper operation.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 10) is:

$$
\begin{align*}
P_{D(\max )}= & \left\{V_{\operatorname{IN}(\max )}-\mathrm{V}_{\text {OUT }}(\min )\right\} \operatorname{IOUT}(\max ) \\
& +\mathrm{V}_{\operatorname{IN}(\max )} \mathrm{I} \mathrm{Q} \tag{1}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \text { JA }}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{A}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

Figure 10. Single output regulator with key performance parameters labeled.

The value of $\mathrm{R}_{\Theta J A}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta J A}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## 100 mA, 5.0 V, Low Dropout Voltage Regulator with Power-On Reset

The L4949 is a monolithic integrated 5.0 V voltage regulator with a very low dropout and additional functions such as power-on reset and input voltage sense.

It is designed for supplying the micro-computer controlled systems especially in automotive applications.

- Operating DC Supply Voltage Range 5.0 V to 28 V
- Transient Supply Voltage Up to 40 V
- Extremely Low Quiescent Current in Standby Mode
- High Precision Standby Output Voltage $5.0 \mathrm{~V} \pm 1 \%$
- Output Current Capability Up to 100 mA
- Very Low Dropout Voltage Less Than 0.4 V
- Reset Circuit Sensing The Output Voltage
- Programmable Reset Pulse Delay With External Capacitor
- Voltage Sense Comparator
- Thermal Shutdown and Short Circuit Protections

## APPLICATION INFORMATION

## Supply Voltage Transient

High supply voltage transients can cause a reset output signal perturbation. For supply voltages greater than 8.0 V the circuit shows a high immunity of the reset output against supply transients of more than $100 \mathrm{~V} / \mu \mathrm{s}$. For supply voltages
less than 8.0 V supply transients of more than $0.4 \mathrm{~V} / \mu \mathrm{s}$ can cause a reset signal perturbation. To improve the transient behavior for supply voltages less than 8.0 V a capacitor at Pin 3 can be used. A capacitor at Pin $3(\mathrm{C} 3 \leq 1.0 \mu \mathrm{~F})$ reduces also the output noise.

Figure 11. Application Schematic

## OPERATING DESCRIPTION

The L4949 is a monolithic integrated low dropout voltage regulator. Several outstanding features and auxiliary functions are implemented to meet the requirements of supplying microprocessor systems in automotive applications. Nevertheless, it is suitable also in other applications where the present functions are required. The modular approach of this device allows the use of other features and functions independently when required.

## Voltage Regulator

The voltage regulator uses an isolated Collector Vertical PNP transistor as a regulating element. With this structure, very low dropout voltage at currents up to 100 mA is obtained. The dropout operation of the standby regulator is maintained down to 3.0 V input supply voltage. The output voltage is regulated up to the transient input supply voltage of 35 V . With this feature no functional interruption due to overvoltage pulses is generated.

The typical curve showing the standby output voltage as a function of the input supply voltage is shown in Figure 13.

The current consumption of the device (quiescent current) is less than $200 \mu \mathrm{~A}$.

To reduce the quiescent current peak in the undervoltage region and to improve the transient response in this region, the dropout voltage is controlled. The quiescent current as a function of the supply input voltage is shown in Figure 14.

## Short Circuit Protection:

The maximum output current is internally limited. In case of short circuit, the output current is foldback current limited as described in Figure 12.

Figure 12. Foldback Characteristic of $\mathrm{V}_{\text {out }}$

Figure 13. Output Voltage versus Supply Voltage

Figure 14. Quiescent Current versus Supply Voltage

## Preregulator

To improve the transient immunity a preregulator stabilizes the internal supply voltage to 6.0 V . This internal voltage is present at Pin $3\left(\mathrm{~V}_{\mathrm{Z}}\right)$. This voltage should not be used as an output because the output capability is very small $(\leq 100 \mu \mathrm{~A})$.

This output may be used as an option when better transient behavior for supply voltages less than 8.0 V is required. In this case a capacitor $(100 \mathrm{nF}-1.0 \mu \mathrm{~F})$ must be connected between Pin 3 and Gnd. If this feature is not used Pin 3 must be left open.

## Reset Circuit

The block circuit diagram of the reset circuit is shown in Figure 15.

The reset circuit supervises the output voltage. The reset threshold of 4.5 V is defined with the internal reference voltage and standby output divider.

The reset pulse delay time $\mathrm{t}_{\mathrm{RD}}$, is defined with the charge time of an external capacitor $\mathrm{C}_{\mathrm{T}}$ :

$$
\mathrm{t}_{\mathrm{RD}}=\frac{\mathrm{C}_{\mathrm{T}} \times 2.0 \mathrm{~V}}{2.0 \mu \mathrm{~A}}
$$

The reaction time of the reset circuit originates from the discharge time limitation of the reset capacitor $\mathrm{C}_{\mathrm{T}}$ and is proportional to the value of $\mathrm{C}_{\mathrm{T}}$. The reaction time of the reset circuit increases the noise immunity.

Figure 15. Reset Circuit

Standby output voltage drops below the reset threshold only a bit longer than the reaction time results in a shorter reset delay time.

The nominal reset delay time will be generated for standby output voltage drops longer than approximately $50 \mu \mathrm{~s}$. The typical reset output waveforms are shown in Figure 16.

Figure 16. Typical Reset Output Waveforms

## Sense Comparator

The sense comparator compares an input signal with an internal voltage reference of typical 1.23 V . The use of an external voltage divider makes this comparator very flexible in the application.

It can be used to supervise the input voltage either before or after the protection diode and to give additional information to the microprocessor like low voltage warnings.

## CS8311

## Micropower 10 V, 100 mA <br> Low Dropout Linear Regulator with RESET and ENABLE

The CS8311 is a precision 10 V micropower voltage regulator with very low quiescent current ( $100 \mu \mathrm{~A}$ typ at $100 \mu \mathrm{~A}$ load). The 10 V output is accurate within $\pm 4.0 \%$ and supplies 100 mA of load current with a typical dropout voltage of only 400 mV . Microprocessor control logic includes an $\overline{\text { ENABLE }}$ input and an active $\overline{\text { RESET. }}$

The active $\overline{\text { RESET }}$ circuit includes hysteresis, and operates correctly at an output voltage as low as 1.0 V . The $\overline{\text { RESET }}$ function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits by more than 1.0 V typ. The logic level compatible ENABLE input allows the user to put the regulator into a shutdown mode where it draws only $20 \mu \mathrm{~A}$ typical of quiescent current.

The regulator is protected against reverse battery, short circuit, over voltage, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments.

## Features

- $10 \mathrm{~V} \pm 4.0 \%$ Output
- Low $100 \mu \mathrm{~A}$ Quiescent Current
- Active RESET
- ENABLE Input for ON/OFF and Active/Sleep Mode Control
- 100 mA Output Current Capability
- Fault Protection
- +60 V Peak Transient Voltage
-     - 15 V Reverse Voltage Short Circuit Thermal Overload
- Low Reverse Current (Output to Input)

## CIRCUIT DESCRIPTION

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 2).

Figure 2. Typical Circuit Waveforms for Output Stage Protection

If the input voltage rises above 30 V (e.g. load dump), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the load current capability is reduced thereby preventing thermal overload. This thermal management function is an effective means to prevent die overheating since the load current is the principle heat source in the IC.

REGULATOR CONTROL FUNCTIONS
The CS8311 contains two microprocessor compatible control functions: $\overline{\mathrm{ENABLE}}$ and $\overline{\mathrm{RESET}}$ (Figure 3).

(1) $=$ No Reset Delay Capacitor
(2) = With Reset Delay Capacitor

## ENABLE Function

The ENABLE function switches the output transistor ON and OFF. When the voltage on the $\overline{\text { ENABLE }}$ lead exceeds 1.4 V typ, the output pass transistor turns off, leaving a high impedance facing the load. The IC will remain in Sleep mode, drawing only $50 \mu \mathrm{~A}$ (max), until the voltage on this input drops below the $\overline{\mathrm{ENABLE}}$ threshold.

## RESET Function

A $\overline{\mathrm{RESET}}$ signal (low voltage) is generated as the IC powers up until $\mathrm{V}_{\text {OUT }}$ is within 1.0 V of the regulated output voltage, or when $V_{\text {OUT }}$ drops out of regulation, and is lower than 1.1 V below the regulated output voltage. A hysteresis of 50 mV is included in the function to minimize oscillations.
The RESET output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC thereby guaranteeing that the $\overline{\text { RESET }}$ signal is valid for $\mathrm{V}_{\text {OUT }}$ as low as 1.0 V .

Figure 4. RC Network for RESET Delay
An external RC network on the lead (Figure 4) provides a sufficiently long delay for most microprocessor based applications. RC values can be chosen using the following formula:

$$
\text { RTOTCRST }=\left[\frac{t_{\text {Delay }}}{\ln \left(\frac{V_{T}-V_{\text {OUT }}}{V_{\text {RST }}-V_{\text {OUT }}}\right)}\right]
$$

where:
$\mathrm{R}_{\mathrm{RST}}=\overline{\mathrm{RESET}}$ Delay resistor
$\mathrm{R}_{\mathrm{IN}}=\mu \mathrm{P}$ port impedance
$\mathrm{R}_{\mathrm{TOT}}=\mathrm{R}_{\mathrm{RST}}$ in parallel with $\mathrm{R}_{\mathrm{IN}}$
$\mathrm{C}_{\mathrm{RST}}=\overline{\mathrm{RESET}}$ Delay capacitor
$t_{\text {Delay }}=$ desired delay time
$\mathrm{V}_{\mathrm{RST}}=\mathrm{V}_{\mathrm{SAT}}$ of $\overline{\mathrm{RESET}}$ lead ( 0.7 V @ turn -ON )
$\mathrm{V}_{\mathrm{T}}=\overline{\mathrm{RESET}}$ threshold.

Figure 3. Circuit Waveform

## APPLICATION NOTES

Figure 5. Microprocessor Control of CS8311 Using External Switching Transistor Q1

The circuit depicted in Figure 5 lets the system control its power source, the CS8311 regulator. A SWITCH (potentially an I/O port on microprocessor) is used to drive the base of Q1. When Q1 is driven into saturation, the voltage on the $\overline{\text { ENABLE }}$ lead falls below its lower threshold. The regulator's output is enabled. When the drive current is removed, the voltage on the $\overline{\text { ENABLE }}$ lead rises, the output is switched off and the IC moves into Sleep mode where it draws $50 \mu \mathrm{~A}$ (max).

By coupling these two controls with the ENABLE lead, the system has added flexibility. Once the system is running, the state of the SWITCH is irrelevant as long as the I/O port continues to drive Q1. The microprocessor can turn off its own power by withdrawing drive current, once the SWITCH is open. This software control at the I/O port allows the microprocessor to finish key housekeeping functions before power is removed.

The logic options are summarized in Table 1.
Table 1. Logic Control of CS8311 Output

| Microprocessor <br> I/O Drive | Switch | ENABLE | Output |
| :---: | :---: | :---: | :---: |
| ON | Closed | LOW | ON |
|  | Open | LOW | ON |
| OFF | Closed | LOW | ON |
|  | Open | HIGH | OFF |

The I/O port of the microprocessor typically provides $50 \mu \mathrm{~A}$ to Q1. In automotive applications the SWITCH is connected to the ignition switch.

STABILITY CONSIDERATIONS
The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

${ }^{*} \mathrm{C}_{\mathrm{IN}}$ required if regulator is located far from the power supply filter.
*COUT required for stability. Capacitor must operate at minimum temperature expected.

Figure 6. Test and Application Circuit Showing Output Compensation
The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.
The value for the output capacitor Cout shown in Figure 6 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for Cout for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 7) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$\mathrm{I}_{\mathrm{OUT}(\max )}$ is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J A}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 7. Single Output Regulator With Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8101

## Micropower 5.0 V, 100 mA Low Dropout Linear Regulator with RESET and ENABLE

The CS8101 is a precision 5.0 V micropower voltage regulator with very low quiescent current ( $70 \mu \mathrm{~A}$ typ at $100 \mu \mathrm{~A}$ load). The 5.0 V output is accurate within $\pm 2.0 \%$ and supplies 100 mA of load current with a typical dropout voltage of only 400 mV . Microprocessor control logic includes an $\overline{\text { ENABLE }}$ input and an active $\overline{\text { RESET. This }}$ combination of low quiescent current, outstanding regulator performance and control logic makes the CS8101 ideal for any battery operated, microprocessor controlled equipment.

The active $\overline{\text { RESET }}$ circuit includes hysteresis, and operates correctly at an output voltage as low as 1.0 V . The RESET function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits by more than 200 mV typ. The logic level compatible ENABLE input allows the user to put the regulator into a shutdown mode where it draws only $20 \mu \mathrm{~A}$ typical of quiescent current.

The regulator is protected against reverse battery, short circuit, over voltage, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments.

The CS8101 is functionally equivalent to the National Semiconductor LP2951 series low current regulators.

## Features

- $5.0 \mathrm{~V} \pm 2.0 \%$ Output
- Low $70 \mu \mathrm{~A}$ Quiescent Current
- Active RESET
- ENABLE Input for ON/OFF and Active/Sleep Mode Control
- 100 mA Output Current Capability
- Fault Protection
- +60 V Peak Transient Voltage
-     - 15 V Reverse Voltage Short Circuit Thermal Overload
- Low Reverse Current (Output to Input)
- Internally Fused Leads Available in SO-20L Package

## TYPICAL PERFORMANCE CHARACTERISTICS

Figure 2. CS8101 Dropout Voltage vs. Load Over Temperature

## CIRCUIT DESCRIPTION

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 3).

Figure 3. Typical Circuit Waveforms for Output Stage Protection

If the input voltage rises above 30 V (e.g. load dump), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients.

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the load current capability is reduced thereby preventing thermal overload. This thermal management function is an effective means to prevent die overheating since the load current is the principle heat source in the IC.

## REGULATOR CONTROL FUNCTIONS

The CS8101 contains two microprocessor compatible control functions: $\overline{\mathrm{ENABLE}}$ and $\overline{\mathrm{RESET}}$ (Figure 4).

(1) = No Reset Delay Capacitor
(2) $=$ With Reset Delay Capacitor

Figure 4. Circuit Waveform

## ENABLE Function

The $\overline{\text { ENABLE }}$ function switches the output transistor ON and OFF. When the voltage on the ENABLE lead exceeds 1.4 V typ, the output pass transistor turns off, leaving a high impedance facing the load. The IC will remain in Sleep mode, drawing only $50 \mu \mathrm{~A}$, until the voltage on this input drops below the ENABLE threshold.

## RESET Function

A $\overline{\text { RESET }}$ signal (low voltage) is generated as the IC powers up until $\mathrm{V}_{\text {OUT }}$ is within 250 mV of the regulated output voltage, or when $\mathrm{V}_{\text {OUT }}$ drops out of regulation, and is lower than 300 mV below the regulated output voltage. A hysteresis of 50 mV is included in the function to minimize oscillations.

The $\overline{\text { RESET }}$ output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC thereby guaranteeing that the $\overline{\text { RESET }}$ signal is valid for V VUT as low as 1.0 V .

Figure 5. RC Network for RESET Delay
An external RC network on the lead (Figure 5) provides a sufficiently long delay for most microprocessor based applications. RC values can be chosen using the following formula:

$$
\text { RTOTCRST }=\left[\frac{- \text { tDelay }}{\ln \left(\frac{\mathrm{V}_{T}-\mathrm{V}_{\text {OUT }}}{\mathrm{V}_{\text {RST }}-\mathrm{V}_{\text {OUT }}}\right)}\right]
$$

where:
$\mathrm{R}_{\text {RST }}=\overline{\mathrm{RESET}}$ Delay resistor
$\mathrm{R}_{\mathrm{IN}}=\mu \mathrm{P}$ port impedance
$\mathrm{R}_{\mathrm{TOT}}=\mathrm{R}_{\mathrm{RST}}$ in parallel with $\mathrm{R}_{\mathrm{IN}}$
$\mathrm{C}_{\mathrm{RST}}=\overline{\mathrm{RESET}}$ Delay capacitor
$t_{\text {Delay }}=$ desired delay time
$\mathrm{V}_{\mathrm{RST}}=\mathrm{V}_{\mathrm{SAT}}$ of $\overline{\mathrm{RESET}}$ lead ( 0.7 V @ turn -ON )
$\mathrm{V}_{\mathrm{T}}=\overline{\mathrm{RESET}}$ threshold.
The circuit depicted in Figure 6 lets the microprocessor control its power source, the CS8101 regulator. An I/O port on the $\mu \mathrm{P}$ and the SWITCH port are used to drive the base of Q1. When Q1 is driven into saturation, the voltage on the ENABLE lead falls below its lower threshold. The regulator's output is enabled. When the drive current is removed, the voltage on the ENABLE lead rises, the output is switched off and the IC moves into Sleep mode where it draws $50 \mu \mathrm{~A}$ (max).
By coupling these two controls with the ENABLE lead, the system has added flexibility. Once the system is running, the state of the SWITCH is irrelevant as long as the I/O port continues to drive Q1. The microprocessor can turn off its own power by withdrawing drive current, once the SWITCH is open. This software control at the I/O port allows the microprocessor to finish key housekeeping functions before power is removed.

The logic options are summarized in Table 1.
Table 1. Logic Control of CS8101 Output

| Microprocessor <br> I/O Drive | Switch | ENABLE | Output |
| :---: | :---: | :---: | :---: |
| ON | Closed | LOW | ON |
|  | Open | LOW | ON |
| OFF | Closed | LOW | ON |
|  | Open | HIGH | OFF |

The I/O port of the microprocessor typically provides $50 \mu \mathrm{~A}$ to Q1. In automotive applications the SWITCH is connected to the ignition switch.

## APPLICATION NOTES

Figure 6. Microprocessor Control of CS8101 Using External Switching Transistor Q1

## STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

${ }^{*} \mathrm{C}_{\mathrm{IN}}$ required if regulator is located far from the power supply filter.
*Cout required for stability. Capacitor must operate at minimum temperature expected.

Figure 7. Test and Application Circuit Showing Output Compensation

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor Cout shown in Figure 7 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for $\mathrm{C}_{\text {OUT }}$ for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause
the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.
Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 8) is:
$P_{D}($ max $)=\left\{\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{V}_{\mathrm{OUT}(\text { min })} \mathrm{I}^{\mathrm{IOUT}(\text { max })}+\mathrm{V}_{\mathrm{IN}(\text { max })} \mathrm{I}_{\mathrm{Q}}\right.$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 8. Single Output Regulator With Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \text { JA. }}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JJC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it is a function of package type. $\mathrm{R}_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8151

### 5.0 V, 100 mA Low Dropout Linear Regulator with Watchdog, RESET, and Wake Up

The CS8151 is a precision $5.0 \mathrm{~V}, 100 \mathrm{~mA}$ micro-power voltage regulator with very low quiescent current ( $400 \mu \mathrm{~A}$ typical at $200 \mu \mathrm{~A}$ load). The 5.0 V output is accurate within $\pm 2 \%$ and supplies 100 mA of load current with a typical dropout voltage of 400 mV . Microprocessor control logic includes Watchdog, Wake Up and RESET. This unique combination of low quiescent current and full microprocessor control makes the CS8151 ideal for use in battery operated, microprocessor controlled equipment.

The CS8151 Wake Up function brings the microprocessor out of Sleep mode. The microprocessor in turn, signals its Wake Up status back to the CS8151 by issuing a Watchdog signal.

The Watchdog logic function monitors an input signal (WDI) from the microprocessor. The CS8151 responds to the falling edge of the Watchdog signal which it expects at least once during each wake-up period. When the correct Watchdog signal is received, a falling edge is issued on the wake-up signal line.
$\overline{\text { RESET }}$ is independent of $\mathrm{V}_{\text {IN }}$ and operates correctly to an output voltage as low as 1.0 V . A $\overline{\mathrm{RESET}}$ signal is issued in any of three situations. During power up the RESET is held low until the output voltage is in regulation. During operation if the output voltage shifts below the regulation limits, the RESET toggles low and remains low until proper output voltage regulation is restored. And finally, a $\overline{\text { RESET }}$ signal is issued if the regulator does not receive a Watchdog signal within the Wake Up period.

The RESET pulse width, Wake Up signal frequency, and Wake Up delay time are all set by one external capacitor $C_{\text {Delay }}$.

The regulator is protected against short circuit, over voltage, and thermal runaway conditions. The device can withstand 74 volt peak transients, making it suitable for use in automotive environments.

## Features

- $5.0 \mathrm{~V} \pm 2 \% / 100 \mathrm{~mA}$ Output Voltage
- Micropower Compatible Control Functions
- Wake Up
- Watchdog
- $\overline{\text { RESET }}$
- Low Dropout Voltage: 400 mV @ 100 mA
- Low Sleep Mode Quiescent Current ( $400 \mu \mathrm{~A}$ Typ)
- Protection Features
- Thermal Shutdown
- Short Circuit
- 74 V Peak Transient Capability
- Reverse Transient (-50 V)
- Internally Fused Leads in DIP-16 and SO-16L Packages

## DEFINITION OF TERMS

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse
techniques such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.
Quiescent Current: The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.

Ripple Rejection: The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.
Current Limit: Peak current that can be delivered to the output.

## CIRCUIT DESCRIPTION

## Functional Description

To reduce the drain on the battery a system can go into a low current consumption mode when ever its not performing a main routine. The Wake Up signal is generated continuously and is used to interrupt a microcontroller that is in sleep mode. The nominal output is a 5.0 volt square wave with a duty cycle of $50 \%$ at a frequency that is determined by a timing capacitor, $\mathrm{C}_{\text {Delay }}$.

When the microprocessor receives a rising edge from the Wake Up output, it must issue a watchdog pulse and check its inputs to decide if it should resume normal operations or remain in the sleep mode.

Figure 5. Wake Up Response to WDI

Figure 6. Wake Up Response to RESET (Low Voltage)

The first falling edge of the watchdog signal causes the Wake Up to go low within $2.0 \mu \mathrm{~s}$ (typ) and remain low until the next Wake Up cycle (see Figure 5). Other watchdog pulses received within the same cycle are ignored (Figures 2,3 , and 4).

During power up, $\overline{\text { RESET }}$ is held low until the output voltage is in regulation. During operation, if the output voltage shifts below the regulation limits, the RESET toggles low and remains low until proper output voltage regulation is restored. After the $\overline{\text { RESET }}$ delay, $\overline{\mathrm{RESET}}$ returns high.
The Watchdog circuitry continuously monitors the input watchdog signal (WDI) from the microprocessor. The absence of a falling edge on the Watchdog input during one Wake Up cycle will cause a $\overline{\text { RESET }}$ pulse to occur at the end of the Wake Up cycle (see Figure 3).
The Wake Up output is pulled low during a RESET regardless of the cause of the $\overline{\mathrm{RESET}}$. After the $\overline{\mathrm{RESET}}$ returns high, the Wake Up cycle begins again (see Figure 3).
The $\overline{\text { RESET }}$ pulse width, Wake Up signal frequency and RESET high to Wake Up delay time are all set by one external capacitor $C_{\text {Delay. }}$

Wake Up Period $=\left(4 \times 10^{5}\right) \mathrm{C}_{\text {Delay }}$
$\overline{\text { RESET }}$ Delay Time $=\left(5 \times 10^{4}\right) C_{\text {Delay }}$
$\overline{\text { RESET High to Wake Up Delay Time }}=\left(2 \times 10^{5}\right) \mathrm{C}_{\text {Delay }}$
Capacitor temperature coefficient and tolerance as well as the tolerance of the CS8151 must be taken into account in order to get the correct system tolerance for each parameter.

## APPLICATION NOTES

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (see Figure 7).

If the input voltage rises above the overvoltage shutdown threshold (e.g. load dump), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients.

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

Figure 7. Typical Circuit Waveforms for Output Stage Protection

## Stability Considerations

The output or compensation capacitor C 2 (see Figure 8) helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

*C1 required if regulator is located far from the power supply filter.
${ }^{* *} \mathrm{C} 2$ required for stability.
Figure 8. Test and Application Circuit Showing Output Compensation

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or
ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provide this information.
The value for the output capacitor C 2 shown in the test and applications circuit should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for C 2 for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low
temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## Calculating Power Dissipation

 In a Single Output Linear RegulatorThe maximum power dissipation for a single output regulator (Figure 9) is:

$$
\begin{align*}
\mathrm{PD}_{\mathrm{D}}(\max )= & \left(\mathrm{V}_{\mathrm{IN}}(\max )-\mathrm{V}_{\mathrm{OUT}}(\min )\right) \mathrm{IOUT}(\max )  \tag{1}\\
& +\mathrm{VIN}_{\mathrm{IN}(\max ) \mathrm{Q}}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

## Heat Sinks

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heatsink data sheets of heatsink manufacturers.

## Micropower Voltage Regulator

The MC78FC00 series voltage regulators are specifically designed for use as a power source for video instruments, handheld communication equipment, and battery powered equipment.

The MC78FC00 series voltage regulator ICs feature a high accuracy output voltage and ultra-low quiescent current. Each device contains a voltage reference unit, an error amplifier, a driver transistor, and resistors for setting output voltage, and a current limit circuit. These devices are available in SOT-89 surface mount packages, and allow construction of an efficient, constant voltage power supply circuit.

MC78FC00 Series Features:

- Ultra-Low Quiescent Current of $1.1 \mu \mathrm{~A}$ Typical
- Ultra-Low Dropout Voltage ( 100 mV at 10 mA )
- Large Output Current (up to 120 mA )
- Excellent Line Regulation (0.1\%)
- Wide Operating Voltage Range (2.0 V to 10 V )
- High Accuracy Output Voltage ( $\pm 2.5 \%$ )
- Wide Output Voltage Range (2.0 V to 6.0 V)
- Surface Mount Package (SOT-89)

NOTE: 1. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.

## DEFINITIONS

Dropout Voltage - The input/output voltage differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.
Line Regulation - The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques
such that average chip temperature is not significantly affected.
Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.
Quiescent Bias Current - Current which is used to operate the regulator chip and is not delivered to the load.

## APPLICATIONS INFORMATION

## Introduction

The MC78FC00 micropower voltage regulators are specifically designed with internal current limiting and low quiescent current making them ideal for battery powered applications. An input bypass capacitor is recommended if the regulator is located an appreciable distance ( $\geq 4$ inches) from the input voltage source. These regulators require $0.1 \mu \mathrm{~F}$ capacitance between the output terminal and ground for stability. Most types of aluminum, tantalum or multilayer ceramic will perform adequately. Solid tantalums or other appropriate capacitors are recommended for operation below $25^{\circ} \mathrm{C}$. The bypass capacitors should be mounted with the shortest possible leads or track lengths directly across the regulator input and output terminals.

With economical electrolytic capacitors, cold temperature operation can pose a serious stability problem. As the electrolyte freezes, around $-30^{\circ} \mathrm{C}$, the capacitance will decrease and the equivalent series resistance (ESR) will increase drastically, causing the circuit to oscillate. Quality electrolytic capacitors with extended temperature ranges of $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$ are readily available. Solid tantalum capacitors may be the better choice if small size is a requirement. However, a maximum ESR limit of $3.0 \Omega$ must be observed over temperature to maintain stability.

Figure 6 is a typical circuit application. Figure 7 is a current boost circuit which can deliver more than 600 mA . The circuit has no current limiting and the external transistor must be rated for the expected power dissipation.

## CS8321

## Micropower 5.0 V, 150 mA Low Dropout Linear Regulator

The CS8321 is a precision 5.0 V micropower voltage regulator with very low quiescent current ( $140 \mu \mathrm{~A}$ typ at 1.0 mA load). The 5.0 V output is accurate within $\pm 2 \%$ and supplies 150 mA of load current with a typical dropout voltage of only 300 mV .

This combination of low quiescent current and outstanding regulator performance makes the CS8321 ideal for any battery operated equipment.

The regulator is protected against reverse battery and short circuit conditions. The device can withstand 45 V load dump transients making it suitable for use in automotive environments.

## Features

- $5.0 \mathrm{~V} \pm 2 \%$ Output
- Low $140 \mu \mathrm{~A}$ (typ) Quiescent Current
- 150 mA Output Current Capability
- Fault Protection
-     - 15 V Reverse Voltage Output Current Limit
- Low Reverse Current (Output to Input)

*Lead Shorted to $\mathrm{V}_{\text {OUT }}$ in 3-Pin Applications

## CIRCUIT DESCRIPTION AND APPLICATION NOTES

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

The CS8321 is a series pass voltage regulator. It consists of an error amplifier, bandgap voltage reference, PNP pass transistor with antisaturation control, and current limit.

As the voltage at the input, $\mathrm{V}_{\mathrm{IN}}$, is increased (Figure 1), $\mathrm{Q}_{\mathrm{N}}$ is forward biased via $R$. $\mathrm{Q}_{\mathrm{N}}$ provides base drive for $\mathrm{Q}_{\mathrm{P}}$. As $Q_{P}$ becomes forward biased, the output voltage, $V_{\text {OUT }}$, begins to rise as Qp 's output current charges the output capacitor. Once V OUT rises to a certain level, the error amplifier becomes biased and provides the appropriate amount of base current to $Q_{p}$. The error amplifier monitors the scaled output voltage via an internal voltage divider, R1 and R2, and compares it to the bandgap voltage reference. The error amplifier's output is a current which is equal to the error amplifier's differential input voltage times its transconductance. Therefore, the error amplifier varies the base drive current to $\mathrm{Q}_{\mathrm{N}}$, which provides bias to $\mathrm{Q}_{\mathrm{P}}$, based on the difference between the reference voltage and the scaled output voltage, V VUT.

## Antisaturation Protection

An antisaturation control circuit has also been added to prevent the pass transistor from going into deep saturation, which would cause excessive power dissipation due to large bias currents lost to the substrate via a parasitic PNP transistor, as shown in Figure 2.

Figure 2. The Parasitic PNP Transistor Which Is Part of the Pass Transistor ( $\mathbf{Q}_{\mathrm{P}}$ ) Structure

## Current Limit Limit

The output stage is protected against short circuit conditions. As shown in Figure 3, the output current will fold back when the faulted load is continually increased. This technique has been incorporated to limit the total power dissipation across the device during a short circuit condition, since the device does not contain overtemperature shutdown.

## STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

Figure 3. Typical Current Limit and Fold Back Waveform

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.
The value for the output capacitor $\mathrm{C}_{\text {OUT }}$ shown in Figure 4 should work for most applications, however it is not necessarily the best solution.

${ }^{*} \mathrm{C}_{\mathrm{IN}}$ required if regulator is located far from the power supply filter.
${ }^{* *}$ Cout required for stability. Capacitor must operate at $^{\text {ren }}$ minimum temperature expected.
$\dagger$ Pin internally shorted to $\mathrm{V}_{\text {OUT }}$ in 3-pin applications.

Figure 4. Test and Application Circuit Showing Output Compensation

To determine an acceptable value for Cout for a particular application, start with a tantalum capacitor of the
recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 5) is:

$$
\begin{align*}
\mathrm{PD}_{\mathrm{D}}(\max )= & \left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}}(\min )\right) \mathrm{IOUT}(\max )  \tag{1}\\
& +\mathrm{V}_{\mathrm{IN}(\max ) \mathrm{I}_{\mathrm{Q}}}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{A}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\text {©JA }}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 5. Single Output Regulator with Key Performance Parameters Labeled

## HEATSINKS

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like
$R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heatsink data sheets of heatsink manufacturers.

## MC33263

# Ultra Low Noise 150 mA Low Dropout Voltage Regulator with ON/OFF Control 

Housed in a SOT23-L package, the MC33263 delivers up to 150 mA where it exhibits a typical 180 mV dropout. With an incredible noise level of $25 \mu$ VRMS (over 100 Hz to 100 kHz , with a 10 nF bypass capacitor), the MC33263 represents the ideal choice for sensitive circuits, especially in portable applications where noise performance and space are premium. The MC33263 also excels in response time and reacts in less than $25 \mu \mathrm{~s}$ when receiving an OFF to ON signal (with no bypass capacitor).

Thanks to a novel concept, the MC33263 accepts output capacitors without any restrictions regarding their Equivalent Series Resistance (ESR) thus offering an obvious versatility for immediate implementation.

With a typical DC ripple rejection better than $-90 \mathrm{~dB}(-70 \mathrm{~dB}$ @ 1.0 kHz ), it naturally shields the downstream electronics against choppy power lines.

Additionally, thermal shutdown and short-circuit protection provide the final product with a high degree of ruggedness.

## Features:

- Very Low Quiescent Current $170 \mu \mathrm{~A}$ (ON, no load), 100 nA (OFF, no load)
- Very Low Dropout Voltage, Typical Value is 137 mV at an Output Current of 100 mA
- Very Low Noise with External Bypass Capacitor (10 nF),

Typically $25 \mu \mathrm{Vrms}$ over 100 Hz to 100 kHz

- Internal Thermal Shutdown
- Extremely Tight Line Regulation Typically -90 dB
- Ripple Rejection -70 dB @ 1.0 kHz
- Line Transient Response: 1.0 mV for $\Delta \mathrm{V}_{\mathrm{in}}=3.0 \mathrm{~V}$
- Extremely Tight Load Regulation, Typically 20 mV at $\Delta \mathrm{I}_{\mathrm{out}}=150 \mathrm{~mA}$
- Multiple Output Voltages Available
- Logic Level ON/OFF Control (TTL-CMOS Compatible)
- ESR can vary from 0 to $3.0 \Omega$
- Functionally and Pin Compatible with TK112xxA/B Series

## Applications:

- All Portable Systems, Battery Powered Systems, Cellular Telephones, Radio Control Systems, Toys and Low Voltage Systems

## DEFINITIONS

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Dropout Voltage - The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.

Output Noise Voltage - The RMS AC voltage at the output with a constant load and no input ripple, measured over a specified frequency range.

Maximum Power Dissipation - The maximum total dissipation for which the regulator will operate within specifications.

Quiescent Current - Current which is used to operate the regulator chip and is not delivered to the load.

Line Regulation - The change in input voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Line Transient Response - Typical over- and undershoot response when input voltage is excited with a given slope.

Thermal Protection - Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically $150^{\circ} \mathrm{C}$, the regulator turns off.

This feature is provided to prevent catastrophic failures from accidental overheating.

Maximum Package Power Dissipation - The maximum package power dissipation is the power dissipation level at which the junction temperature reaches its maximum value i.e. $125^{\circ} \mathrm{C}$. The junction temperature is rising while the difference between the input power ( $\mathrm{V}_{\mathrm{CC}} \mathrm{X} \mathrm{I}_{\mathrm{CC}}$ ) and the output power $\left(V_{\text {out }} X_{I_{\text {out }}}\right)$ is increasing.

Depending on ambient temperature, it is possible to calculate the maximum power dissipation, maximum load current or maximum input voltage (see Application Hints: Protection).

The maximum power dissipation supported by the device is a lot increased when using appropriate application design. Mounting pad configuration on the PCB, the board material and also the ambient temperature are affected the rate of temperature rise. It means that when the $\mathrm{I}_{\mathrm{C}}$ has good thermal conductivity through PCB, the junction temperature will be "low" even if the power dissipation is great.

The thermal resistance of the whole circuit can be evaluated by deliberately activating the thermal shutdown of the circuit (by increasing the output current or raising the input voltage for example).

Then you can calculate the power dissipation by subtracting the output power from the input power. All variables are then well known: power dissipation, thermal shutdown temperature $\left(150^{\circ} \mathrm{C}\right.$ for MC 33263$)$ and ambient temperature.

## APPLICATION HINTS

Input Decoupling - As with any regulator, it is necessary to reduce the dynamic impedance of the supply rail that feeds the component. A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the MC33263 package. Higher values will correspondingly improve the overall line transient response.

Output Decoupling - Thanks to a novel concept, the MC33263 is a stable component and does not require any Equivalent Series Resistance (ESR) neither a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices.

Noise Performances - Unlike other LDOs, the MC33263 is a true low-noise regulator. With a 10 nF bypass capacitor, it typically reaches the incredible level of $25 \mu \mathrm{VRMS}$ overall noise between 100 Hz and 100 kHz . To give maximum insight on noise specifications, ON Semiconductor includes spectral density graphics as well as noise dependency versus bypass capacitor.

The bypass capacitor impacts the start-up phase of the MC33263 as depicted by the data-sheet curves. A typical 1.0 ms settling time is achieved with a 10 nF bypass capacitor. However, thanks to its low-noise architecture, the MC33263 can operate without bypass and thus offers a typical $20 \mu \mathrm{~s}$ start-up phase. In that case, the typical output noise stays lower than $65 \mu \mathrm{VRMS}$ between $100 \mathrm{~Hz}-$ 100 kHz .

Protections - The MC33263 hosts several protections, conferring natural ruggedness and reliability to the products implementing the component. The output current is internally limited to a minimum of 175 mA while temperature shutdown occurs if the die heats up beyond $150^{\circ} \mathrm{C}$. These value lets you assess the maximum differential voltage the device can sustain at a given output current before its protections come into play.

The maximum dissipation the package can handle is given by:

$$
P_{\max }=\frac{T_{J \max }-T_{A}}{R_{\theta J A}}
$$

If $\mathrm{T}_{\text {Jmax }}$ is internally limited to $150^{\circ} \mathrm{C}$, then the MC33263 can dissipate up to 595 mW @ $25^{\circ} \mathrm{C}$.

The power dissipated by the MC33263 can be calculated from the following formula:

$$
\text { Ptot }=\left\langle\mathrm{V}_{\text {in }} \cdot I_{\text {gnd }}\left(I_{\text {out }}\right)\right\rangle+\left\langle\mathrm{V}_{\text {in }}-\mathrm{V}_{\text {out }}\right\rangle \cdot I_{\text {out }}
$$

or

$$
\operatorname{Vin}_{\max }=\frac{\text { Ptot }+\mathrm{V}_{\text {out }} \cdot I_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 150 mA output current is needed, the ground current is extracted from the data-sheet curves: $6.5 \mathrm{~mA} @ 150 \mathrm{~mA}$. For a MC33263NW28R2 ( 2.8 V ), the maximum input voltage will then be 6.48 V , a rather comfortable margin.

Typical Application - The following figure portraits the typical application for the MC33263 where both input/output decoupling capacitors appear.

Figure 2. A Typical MC33263 Application with Recommended Capacitor Values

As for any low noise designs, particular care has to be taken when tackling Printed Circuit Board (PCB) layout. The following figure gives an example of a layout where stray inductances/capacitances are minimized.

Figure 3. Printed Circuit Board

Figure 4. Copper Side Component Layout
This layout is the basis for an MC33263 performance evaluation board where the BNC connectors give the user an easy and quick evaluation mean.

MC33263 Wake-up Improvement - In portable applications, an immediate response to an enable signal is vital. If noise is not of concern, the MC33263 without a bypass capacitor settles in nearly $20 \mu$ s and typically delivers $65 \mu \mathrm{VRMS}$ between 100 Hz and 100 kHz .

In ultra low-noise systems, the designer needs a 10 nF bypass capacitor to decrease the noise down to $25 \mu$ VRMS between 100 Hz and 100 kHz . With the adjunction of the 10 nF capacitor, the wake-up time expands up to 1.0 ms as shown on the data-sheet curves. If an immediate response is wanted, following figure's circuit gives a solution to
charge the bypass capacitor with the enable signal without degrading the noise response of the MC33263.

At power-on, C 4 is discharged. When the control logic sends its wake-up signal by going to a high level, the PNP base is momentarily tight to ground. The PNP switch closes and immediately charges the bypass capacitor C 1 toward its operating value. After a few $\mu \mathrm{s}$, the PNP opens and becomes totally transparent to the regulator.

This circuit improves the response time of the regulator which drops from 1.0 ms down to $30 \mu \mathrm{~s}$. The value of C 4 needs to be tweaked in order to avoid any bypass capacitor overload during the wake-up transient.

Figure 5. A PNP Transistor Drives the Bypass Pin when Enable Goes High

Figure 6. MC33263 Wake-up Improvement with Small PNP Transistor

The PNP being wired upon the bypass pin, it shall not degrade the noise response of the MC33263. Figure 7 confirms the good behavior of the integrated circuit in this
area which reaches a typical noise level of $26 \mu \mathrm{VRMS}$ $(100 \mathrm{~Hz}$ to 100 kHz$)$ at $\mathrm{I}_{\text {out }}=60 \mathrm{~mA}$.

## MC78PC00 Series

## Low Noise 150 mA <br> Low Drop Out (LDO) Linear Voltage Regulator

The MC78PC00 are a series of CMOS linear voltage regulators with high output voltage accuracy, low supply current, low dropout voltage, and high Ripple Rejection. Each of these voltage regulators consists of an internal voltage reference, an error amplifier, resistors, a current limiting circuit and a chip enable circuit.

The dynamic Response to line and load is fast, which makes these products ideally suited for use in hand-held communication equipment.

The MC78PC00 series are housed in the SOT-23 5 lead package, for maximum board space saving.

## MC78PC00 Features:

- Ultra-Low Supply Current: typical $35 \mu \mathrm{~A}$ in ON mode with no load.
- Standby Mode: typical $0.1 \mu \mathrm{~A}$.
- Low Dropout Voltage: typical 0.2 V @ $\mathrm{I}_{\mathrm{OUT}}=100 \mathrm{~mA}$.
- High Ripple Rejection: typical 70 dB @ $\mathrm{f}=1 \mathrm{kHz}$.
- Low Temperature-Drift Coefficient of Output Voltage: typical $\pm 100 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$.
- Excellent Line Regulation: typical 0.05\%/V.
- High Accuracy Output Voltage: $\pm 2.0 \%$.
- Fast Dynamic Response to Line and Load.
- Small Package: SOT-23 5 leads.
- Built-in Chip Enable circuit (CE input pin).
- Identical Pinout to the LP2980/1/2.

## MC78PC00 Applications:

- Power source for cellular phones (GSM, CDMA, TDMA), Cordless Phones (PHS, DECT) and 2-way radios.
- Power source for domestic appliances such as cameras, VCRs and camcorders.
- Power source for battery-powered equipment.

## MC78PC00 Series

OPERATION

In the MC78PC00, the output voltage $\mathrm{V}_{\text {OUT }}$ is detected by $\mathrm{R} 1, \mathrm{R} 2$. The detected output voltage is then compared to the internal voltage reference by the error amplifier. Both a current limiting circuit for short circuit protection, and a chip enable circuit are included.

## MC78PC00 Series

## APPLICATION HINTS

When using these circuits, please be sure to observe the following points:

- Phase compensation is made for securing stable operation even if the load current varies. For this reason, be sure to use a capacitor Cout with good frequency characteristics and ESR (Equivalent Series Resistance) as described in the graphs on page 434.
On page 434, the relations between IOUT (Output

Current) and ESR of Output Capacitor are shown. The conditions where the white noise level is under $40 \mu \mathrm{~V}$ (Avg.) are marked by the shaded area in the graph. (note: When additional ceramic capacitors are connected to the Output Pin with Output capacitor for phase compensation, there is a possibility that the operation will be unstable. Because of this, test these circuits with as same external components as ones to be used on the PCB).

Figure 46. Measuring Circuit for White Noise: MC78PC30

- Please be sure the $\mathrm{V}_{\mathrm{in}}$ and GND lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or to malfunction.
- Connect the capacitor with a capacitance of $1.0 \mu \mathrm{~F}$ or more between $\mathrm{V}_{\text {in }}$ and GND as close as possible to $\mathrm{V}_{\text {in }}$ or GND.
- Set external components, especially the Output Capacitor, as close as possible to the circuit, and make the wiring as short as possible.

## NCP551

## 150 mA CMOS Low Iq Low-Dropout Voltage Regulator

The NCP551 series of fixed output low dropout linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP551 series features an ultra-low quiescent current of $4.0 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP551 has been designed to be used with low cost ceramic capacitors and requires a minimum output capacitor of $0.1 \mu \mathrm{~F}$. The device is housed in the micro-miniature TSOP-5 surface mount package. Standard voltage versions are $1.5,1.8,2.5,2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $4.0 \mu \mathrm{~A}$ Typical
- Maximum Operating Voltage of 12 V
- Minimum Output Capacitance of $1.0 \mu \mathrm{~F}$
- Low Output Voltage Option
- High Accuracy Output Voltage of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Battery Powered Instruments
- Hand-Held Instruments
- Camcorders and Cameras

3. Maximum package power dissipation limits must be observed.

$$
P D=\frac{T_{J(\max )}-T_{A}}{R_{\theta J A}}
$$

4. Low duty cycle pulse techniques are used during testing to maintain the junction temperature as close to ambient as possible.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP551 series is shown in Figure 20.

## Input Decoupling (C1)

A $0.1 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP551 package. Higher values and lower ESR will improve the overall line transient response.

## Output Decoupling (C2)

The NCP551 is a stable Regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $0.1 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.

## Enable Operation

The enable pin will turn on or off the regulator. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\text {in }}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Thermal

As power across the NCP551 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material, and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP551 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP551 can dissipate up to $400 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$.

The power dissipated by the NCP551 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} l_{\text {gnd }}\left(l_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right]^{*} l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \text { I out }}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 150 mA output current is needed then the ground current from the data sheet is $4.0 \mu \mathrm{~A}$. For an NCP551SN30T1 (3.0 V), the maximum input voltage will then be 5.6 V .

Figure 20. Typical Application Circuit

Figure 21. Current Boost Regulator
The NCP551 series can be current boosted with a PNP transistor. Resistor R in conjunction with $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input/Output differential voltage minimum is increased by $\mathrm{V}_{\mathrm{BE}}$ of the pass resistor.

Figure 23. Delayed Turn-on
If a delayed turn-on is needed during power up of several voltages then the above schematic can be used. Resistor R, and capacitor C , will delay the turn-on of the bottom regulator.

Figure 22. Current Boost Regulator with Short Circuit Limit

Short circuit current limit is essentially set by the $\mathrm{V}_{\mathrm{BE}}$ of Q 2 and $R 1$. $\mathrm{I}_{\mathrm{SC}}=\left(\left(\mathrm{V}_{\mathrm{BEQ} 2}-\mathrm{ib}{ }^{*} \mathrm{R} 2\right) / \mathrm{R} 1\right)+\mathrm{I}_{\mathrm{O}(\max )}$ Regulator

Figure 24. Input Voltages Greater than 12 V
A regulated output can be achieved with input voltages that exceed the 12 V maximum rating of the NCP551 series with the addition of a simple pre-regulator circuit. Care must be taken to prevent Q1 from overheating when the regulated output ( $\mathrm{V}_{\text {out }}$ ) is shorted to $\mathrm{G}_{\text {nd }}$.

## NCP551

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

TSOP-5
(Footprint Compatible with SOT23-5)

## NCP561

## 150 mA CMOS Low Iq Low-Dropout Voltage Regulator

The NCP561 series of fixed output low dropout linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent. The NCP561 series features an ultra-low quiescent current of $3.0 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP561 has been designed to be used with low cost ceramic capacitors and requires a minimum output capacitor of $1.0 \mu \mathrm{~F}$. The device is housed in the micro-miniature TSOP-5 surface mount package. Standard voltage versions are 1.5, 1.8, 2.5, 2.7, 2.8, 3.0, 3.3 and 5.0 V .

## Features

- Low Quiescent Current of $3.0 \mu \mathrm{~A}$ Typical
- Low Dropout Voltage of 170 mV at 150 mA
- Low Output Voltage Option
- Output Voltage Accuracy of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Battery Powered Instruments
- Hand-Held Instruments
- Camcorders and Cameras

This device contains 28 active transistors

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP561 series is shown in Figure 13.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP561 package. Higher values and lower ESR will improve the overall line transient response.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K

## Output Decoupling (C2)

The NCP561 is a stable Regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.
TDK capacitor: C2012X5R1C105K, or C1608X5R1A105K, or C3216X7R1C105K

## Enable Operation

The enable pin will turn on the regulator when pulled high and turn off the regulator when pulled low. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\mathrm{IN}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads a short as possible.

## Thermal

As power across the NCP561 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP561 has good thermal conductivity through the PCB, the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J(\max )}-T_{A}}{R_{\theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP561 can dissipate up to 400 mW @ $25^{\circ} \mathrm{C}$.
The power dissipated by the NCP561 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} \operatorname{lgnd}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right]^{*} l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {INMAX }}=\frac{\mathrm{P}_{\mathrm{TOT}}+\mathrm{V}_{\mathrm{OUT}}{ }^{*} \text { IOUT }}{\mathrm{I}_{\mathrm{GND}}+\mathrm{I}_{\mathrm{OUT}}}
$$

If a 150 mA output current is needed then the ground current from the data sheet is $4.0 \mu \mathrm{~A}$. For an NCP561SN30T1 ( 3.0 V ), the maximum input voltage will then be 5.6 V .

Figure 13. Typical Application Circuit

## APPLICATION CIRCUITS

Figure 14. Current Boost Regulator
The NCP561 series can be current boosted with a PNP transistor. Resistor R in conjunction with $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input/Output differential voltage minimum is increased by $\mathrm{V}_{\mathrm{BE}}$ of the pass resistor.

Figure 16. Delayed Turn-on
If a delayed turn-on is needed during power up of several voltages then the above schematic can be used. Resistor R, and capacitor C , will delay the turn-on of the bottom regulator.

Figure 15. Current Boost Regulator with Short Circuit Limit

Short circuit current limit is essentially set by the $\mathrm{V}_{\mathrm{BE}}$ of Q 2 and R1. $I_{S C}=\left(\left(V_{B E Q 2}-i b * R 2\right) / R 1\right)+I_{(\text {max })}$ Regulator

Figure 17. Input Voltages Greater than 6.0 V
A regulated output can be achieved with input voltages that exceed the 6.0 V maximum rating of the NCP561 series with the addition of a simple pre-regulator circuit. Care must be taken to prevent Q1 from overheating when the regulated output ( $\mathrm{V}_{\text {OUT }}$ ) is shorted to $\mathrm{G}_{\text {nd }}$.

## NCP561

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

TSOP-5
(Footprint Compatible with SOT23-5)

## NCP500

## 150 mA CMOS Low Noise Low-Dropout Voltage Regulator

The NCP500 series of fixed output low dropout linear regulators are designed for portable battery powered applications which require low noise operation, fast enable response time, and low dropout. The device achieves its low noise performance without the need of an external noise bypass capacitor. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, and resistors for setting output voltage, and current limit and temperature limit protection circuits.

The NCP500 has been designed to be used with low cost ceramic capacitors and requires a minimum output capacitor of $1.0 \mu \mathrm{~F}$. Standard voltage versions are $1.8,2.5,2.7,2.8,3.0,3.3$, and 5.0 V .

## Features

- Ultra-Low Dropout Voltage of 170 mV at 150 mA
- Fast Enable Turn-On Time of $20 \mu \mathrm{sec}$
- Wide Operating Voltage Range of 1.8 V to 6.0 V
- Excellent Line and Load Regulation
- High Accuracy Output Voltage of 2.5\%
- Enable Can Be Driven Directly by 1.0 V Logic
- Very Small QFN 2x2 Package

## Typical Applications

- Noise Sensitive Circuits - VCO's, RF Stages, etc.
- SMPS Post-Regulation
- Hand-Held Instrumentation
- Camcorders and Cameras

NOTE: Pin numbers in parenthesis indicate QFN package.

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output load current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $2 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Output Noise Voltage

This is the integrated value of the output noise over a specified frequency range. Input voltage and output load current are kept constant during the measurement. Results are expressed in $\mu \mathrm{VRMS}$ or $\mathrm{n} V \sqrt{\mathrm{~Hz}}$.

## Quiescent Current

The current which flows through the ground pin when the regulator operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$.

## APPLICATIONS INFORMATION

The NCP500 series regulators are protected with internal thermal shutdown and internal current limit. A typical application circuit is shown in Figure 27.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP500 package. Higher values and lower ESR will improve the overall line transient response.

## Output Decoupling (C2)

The NCP500 is a stable component and does not require a minimum Equivalent Series Resistance (ESR) or a minimum output current. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response. Figure 29 shows the stability region for a range of operating conditions and ESR values.

## Noise Decoupling

The NCP500 is a low noise regulator without the need of an external bypass capacitor. It typically reaches a noise level of $50 \mu \mathrm{VRMS}$ overall noise between 10 Hz and 100 kHz . The classical bypass capacitor impacts the start up phase of standard LDOs. However, thanks to its low noise architecture, the NCP500 operates without a bypass element and thus offers a typical $20 \mu$ start up phase.

## Enable Operation

The enable pin will turn on or off the regulator. These limits of threshold are covered in the electrical specification section of this data sheet. The turn-on/turn-off transient voltage being supplied to the enable pin should exceed a slew rate of $10 \mathrm{mV} / \mu \mathrm{s}$ to ensure correct operation. If the enable is not to be used then the pin should be connected to Vin.

## Thermal

As power across the NCP500 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material, and the ambient temperature effect the rate of junction temperature rise for the part. This is stating that when the NCP500 has good thermal conductivity through the PCB, the junction temperature will be relatively low with high power dissipation applications.

The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\Theta J A}}
$$

If $\mathrm{T}_{\mathrm{J}}$ is not recommended to exceed $125^{\circ} \mathrm{C}$, then the NCP500 can dissipate up to $400 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$.

The power dissipated by the NCP500 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} I_{\text {gnd }}\left(l_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right]^{*} l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 150 mA output current is needed the ground current is extracted from the data sheet curves: $200 \mu \mathrm{~A} @ 150 \mathrm{~mA}$. For a NCP500SN18T1 $(1.8 \mathrm{~V})$, the maximum input voltage will then be 4.4 V , good for a 1 Cell Li -ion battery.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.
Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## Package Placement

QFN packages can be placed using standard pick and place equipment with an accuracy of $\pm 0.05 \mathrm{~mm}$. Component pick and place systems are composed of a vision system that recognizes and positions the component and a mechanical system which physically performs the pick and place operation. Two commonly used types of vision systems are: (1) a vision system that locates a package silhouette and (2) a vision system that locates individual bumps on the interconnect pattern. The latter type renders more accurate place but tends to be more expensive and time consuming. Both methods are acceptable since the parts align due to a self-centering feature of the QFN solder joint during solder re-flow.

## Solder Paste

Type 3 or Type 4 solder paste is acceptable.

## Re-flow and Cleaning

The QFN may be assembled using standard IR/IR convection SMT re-flow processes without any special considerations. As with other packages, the thermal profile for specific board locations must be determined. Nitrogen purge is recommended during solder for no-clean fluxes. The QFN is qualified for up to three re-flow cycles at $235^{\circ} \mathrm{C}$ peak (J-STD-020). The actual temperature of the QFN is a function of:

- Component density
- Component location on the board
- Size of surrounding components

Figure 27. Typical Application Circuit

Figure 28. Typical Application Circuit

Figure 29. Stability

Figure 30. Current Boost Regulator

The NCP500 series can be current boosted with a PNP transistor. Resistor R in conjunction with $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input/Output differential voltage minimum is increased by $\mathrm{V}_{\mathrm{BE}}$ of the pass resistor.

Figure 31. Current Boost Regulator with Short Circuit Limit

Short circuit current limit is essentially set by the $V_{B E}$ of $Q 2$ and R1. $I_{S C}=\left(\left(V_{B E Q 2}-i b * R 2\right) / R 1\right)+I_{O(\max )}$ Regulator

Figure 32. Delayed Turn-on
If a delayed turn-on is needed during power up of several voltages then the above schematic can be used. Resistor R, and capacitor C , will delay the turn-on of the bottom regulator. A few values were chosen and the resulting delay can be seen in Figure 33.

Figure 33. Delayed Turn-on
The graph shows the delay between the enable signal and output turn-on for various resistor and capacitor values.

Figure 34. Input Voltages Greater than 6.0 V
A regulated output can be achieved with input voltages that exceed the 6.0 V maximum rating of the NCP500 series with the addition of a simple pre-regulator circuit. Care must be taken to prevent Q1 from overheating when the regulated output $\left(V_{\text {out }}\right)$ is shorted to $G_{\text {nd }}$.

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

## NCP511

## 150 mA CMOS Low Iq Low-Dropout Voltage Regulator

The NCP511 series of fixed output low dropout linear regulators are designed for handheld communication equipment and portable battery powered applications which require low quiescent current. The NCP511 series features an ultra-low quiescent current of $40 \mu \mathrm{~A}$. Each device contains a voltage reference unit, an error amplifier, a PMOS power transistor, resistors for setting output voltage, current limit, and temperature limit protection circuits.

The NCP511 has been designed to be used with low cost ceramic capacitors and requires a minimum output capacitor of $1.0 \mu \mathrm{~F}$. The device is housed in the micro-miniature TSOP-5 surface mount package. Standard voltage versions are $1.5,1.8,2.5,2.7,2.8,3.0,3.3$, and 5.0 V . Other voltages are available in 100 mV steps.

## Features

- Low Quiescent Current of $40 \mu \mathrm{~A}$ Typical
- Low Dropout Voltage of 100 mV at 100 mA
- Excellent Line and Load Regulation
- Maximum Operating Voltage of 6.0 V
- Low Output Voltage Option
- High Accuracy Output Voltage of $2.0 \%$
- Industrial Temperature Range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

## Typical Applications

- Cellular Phones
- Battery Powered Instruments
- Hand-Held Instruments
- Camcorders and Cameras

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $3.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specifications.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient power dissipation and thus the maximum available output current.

## APPLICATIONS INFORMATION

A typical application circuit for the NCP511 series is shown in Figure 16.

## Input Decoupling (C1)

A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the NCP511 package. Higher values and lower ESR will improve the overall line transient response.

## Output Decoupling (C2)

The NCP511 is a stable Regulator and does not require any specific Equivalent Series Resistance (ESR) or a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices. Larger values improve noise rejection and load regulation transient response.

## Enable Operation

The enable pin will turn on or off the regulator. These limits of threshold are covered in the electrical specification section of this data sheet. If the enable is not used then the pin should be connected to $\mathrm{V}_{\mathrm{in}}$.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction.

Set external components, especially the output capacitor, as close as possible to the circuit, and make leads a short as possible.

Figure 16. Typical Application Circuit

## Thermal

As power across the NCP511 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and also the ambient temperature effect the rate of temperature rise for the part. This is stating that when the NCP511 has good thermal conductivity through the PCB , the junction temperature will be relatively low with high power dissipation applications.
The maximum dissipation the package can handle is given by:

$$
\mathrm{PD}=\frac{\mathrm{T}_{\mathrm{J}(\max )}-\mathrm{T}_{A}}{R_{\Theta J A}}
$$

If junction temperature is not allowed above the maximum $125^{\circ} \mathrm{C}$, then the NCP511 can dissipate up to 400 mW @ $25^{\circ} \mathrm{C}$.

The power dissipated by the NCP511 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} \operatorname{lgnd}\left(l_{\text {out }}\right)\right]+\left.\left[V_{\text {in }}-V_{\text {out }}\right]^{*}\right|_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 150 mA output current is needed then the ground current from the data sheet is $40 \mu \mathrm{~A}$. For an NCP511SN30T1 (3.0 V), the maximum input voltage will then be 5.6 V .

Figure 17. Output Capacitor vs. Output Current

## APPLICATION CIRCUITS

Figure 18. Current Boost Regulator
The NCP511 series can be current boosted with a PNP transistor. Resistor R in conjunction with $\mathrm{V}_{\mathrm{BE}}$ of the PNP determines when the pass transistor begins conducting; this circuit is not short circuit proof. Input/Output differential voltage minimum is increased by $\mathrm{V}_{\mathrm{BE}}$ of the pass resistor.

Figure 19. Current Boost Regulator with Short Circuit Limit

Short circuit current limit is essentially set by the $V_{B E}$ of $Q 2$ and R1. $I_{S C}=\left(\left(V_{B E Q 2}-i b * R 2\right) / R 1\right)+I_{(\text {max })}$ Regulator

Figure 21. Delayed Turn-on
The graph shows the delay between the enable signal and output turn-on for various resistor and capacitor values. ages then the above schematic can be used. Resistor R, and capacitor C , will delay the turn-on of the bottom regulator. A few values were chosen and the resulting delay can be seen in Figure 21.

Figure 22. Input Voltages Greater than 6.0 V
A regulated output can be achieved with input voltages that exceed the 6.0 V maximum rating of the NCP511 series with the addition of a simple pre-regulator circuit. Care must be taken to prevent Q1 from overheating when the regulated output ( $\mathrm{V}_{\text {out }}$ ) is shorted to $\mathrm{G}_{\text {nd. }}$.

## NCP511

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to insure proper solder connection
interface between the board and the package. With the correct pad geometry, the packages will self align when subjected to a solder reflow process.

TSOP-5

## NCP5426

## LDO Regulator/Vibration Motor Driver

The NCP5426 series of fixed output, 150 mA low dropout linear regulators are designed to be an economical solution for a variety of applications. Each device contains a voltage reference unit, an error amplifier, a PNP power transistor, resistors for setting output voltage, an under voltage lockout on the input, an enable pin, and current limit and temperature limit protection circuits.

The NCP5426 is designed for driving a vibration motor using ceramic capacitors on the output. The device is housed in the micro-miniature TSOP-5 surface mount package. The NCP5426 is available in output voltages of 1.2 to 2.0 volts in 0.1 volt increments.

## Features

- Wide Operating Voltage Range to 12 Volts
- Internally Set Output Voltages
- Enable Pin for On/Off Control
- UVLO on the Input Voltage with Hysteresis
- Current and Thermal Protection
- Compatible with Ceramic, Tantalum or Aluminum Electrolytic Capacitors

## Typical Applications

- Vibration Motor Driver

This device contains 47 active transistors.

Figure 12. Transient Response for Switching the Enable Pin, Vibration Motor Load

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output load current at a constant temperature and input voltage.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops $2.0 \%$ below its nominal. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

## Output Noise Voltage

This is the integrated value of the output noise over a specified frequency range. Input voltage and output load current are kept constant during the measurement. Results are expressed in $\mu \mathrm{VRMS}$ or $\mathrm{nV} \sqrt{\mathrm{Hz}}$.

## Quiescent Current

The current which flows through the ground pin when the regulator operates without a load on its output: internal IC operation, bias, etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected.

## Line Transient Response

Typical over and undershoot response when input voltage is excited with a given slope.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $150^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

## Maximum Package Power Dissipation

The power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$.

## APPLICATIONS INFORMATION

The following description will assist the system designer to correctly use the NCP5426 in an application. The NCP5426 is designed specifically for use with inductive loads, typically Vibration Motors. The LDO is capable of using ceramic and tantalum capacitors. Please refer to Figure 13 for a typical system schematic.

## Input Decoupling

A capacitor, C 1 , is necessary on the input for normal operation. A ceramic or tantalum capacitor with a minimum value of $1.0 \mu \mathrm{~F}$ is required. Higher values of capacitance and lower ESR will improve the overall line and load transient response.

## Output Decoupling

A capacitor, C2, is required for the NCP5426 to operate normally. A ceramic or tantalum capacitor will suffice. The selection of the output capacitor is dependant upon several factors: output current, power up and down delays, inductive kickback during power up and down. It is recommended the output capacitor be as close to the output pin and ground pin for the best system response.

## Enable Pin

The enable pin will turn on or off the regulator. The enable pin is active high. The internal input resistance of the enable pin is high which will keep the current very low when the pin is pulled high. A low threshold voltage permits the NCP5426 to operate directly from microprocessors or controllers.

## Thermal

As power across the NCP5426 increases, it might become necessary to provide some thermal relief. The maximum power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material and the ambient temperature effect the rate of junction temperature rise for the part. This is stating that when the NCP5426 has good thermal conductivity through the PCB, the junction temperature will be relatively low with high power dissipation applications.

The maximum dissipation the package can handle is given by:

$$
P D=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

$\mathrm{T}_{\mathrm{J}}$ is not recommended to exceed $125^{\circ} \mathrm{C}$. The NCP5426 can dissipate up to $400 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$. The power dissipated by the NCP5426 can be calculated from the following equation:

$$
P_{\text {tot }}=\left[V_{\text {in }}{ }^{*} \operatorname{lgnd}\left(I_{\text {out }}\right)\right]+\left[V_{\text {in }}-V_{\text {out }}\right] * l_{\text {out }}
$$

or

$$
\mathrm{V}_{\text {inMAX }}=\frac{\mathrm{P}_{\text {tot }}+\mathrm{V}_{\text {out }}{ }^{*} \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 150 mA output current is needed then the ground current is extracted from the data sheet curves: $200 \mu \mathrm{~A}$ @ 150 mA . For an NCP5426SN18T1 (1.8 V), the maximum input voltage will then be 4.4 V , good for a 1 Cell Li -ion battery.

## Hints

Please be sure the Vin and Gnd lines are sufficiently wide. When the impedance of these lines is high, there is a chance to pick up noise or cause the regulator to malfunction. Set external components, especially the output capacitor, as close as possible to the circuit, and make leads as short as possible.

## CS8182

## Micropower 200 mA Low Dropout Tracking Regulator/Line Driver

The CS8182 is a monolithic integrated low dropout tracking regulator designed to provide adjustable buffered output voltage that closely tracks ( $\pm 10 \mathrm{mV}$ ) the reference input. The output delivers up to 200 mA while being able to be configured higher, lower or equal to the reference voltages.

The output has been designed to operate over a wide range ( 2.8 V to 45 V ) while still maintaining excellent DC characteristics. The CS8182 is protected from reverse battery, short circuit and thermal runaway conditions. The device also can withstand 45 V load dump transients and -50 V reverse polarity input voltage transients. This makes it suitable for use in automotive environments.

The $\mathrm{V}_{\mathrm{REF}} /$ ENABLE lead serves two purposes. It is used to provide the input voltage as a reference for the output and it also can be pulled low to place the device in sleep mode where it nominally draws less than $30 \mu \mathrm{~A}$ from the supply.

## Features

- 200 mA Source Capability
- Output Tracks within $\pm 10 \mathrm{mV}$ Worst Case
- Low Dropout (0.35 V typ. @ 200 mA )
- Low Quiescent Current
- Thermal Shutdown
- Short Circuit Protection
- Wide Operating Range
- Internally Fused Leads in SO-8 Package

| 4 | 4 | Adj | Adjust lead. |
| 5 | 5 | $\mathrm{~V}_{\text {REF }} /$ ENABLE | Reference voltage and ENABLE input. |

## CIRCUIT DESCRIPTION

## ENABLE Function

By pulling the $\mathrm{V}_{\mathrm{REF}} / \mathrm{ENABLE}$ lead below 2.0 V typically, (see Figure 5 or Figure 6), the IC is disabled and enters a sleep state where the device draws less than $55 \mu \mathrm{~A}$ from supply. When the $\mathrm{V}_{\mathrm{REF}} / E N A B L E$ lead is greater than 2.75 V , $\mathrm{V}_{\text {OUT }}$ tracks the $\mathrm{V}_{\text {REF }} /$ ENABLE lead normally.

Figure 2. Tracking Regulator at the Same Voltage

Figure 4. Tracking Regulator at Lower Voltages

Figure 6. Alternative ENABLE Circuit

[^10]
## Output Voltage

The output is capable of supplying 200 mA to the load while configured as a similiar (Figure 2), lower (Figure 4), or higher (Figure 3) voltage as the reference lead. The Adj lead acts as the inverting terminal of the op amp and the $\mathrm{V}_{\text {REF }}$ lead as the non-inverting.

The device can also be configured as a high-side driver as displayed in Figure 7

Figure 3. Tracking Regulator at Higher Voltages

Figure 5. Tracking Regulator with ENABLE Circuit

Figure 7. High-Side Driver

## APPLICATION NOTES

## Switched Application

The CS8182 has been designed for use in systems where the reference voltage on the $\mathrm{V}_{\mathrm{REF}} / E N A B L E$ pin is continuously on. Typically, the current into the $\mathrm{V}_{\mathrm{REF}} / \mathrm{ENABLE}$ pin will be less than $1.0 \mu \mathrm{~A}$ when the voltage on the $\mathrm{V}_{\text {IN }}$ pin (usually the ignition line) has been switched out ( $\mathrm{V}_{\text {IN }}$ can be at high impedance or at ground.) Reference Figure 8.

Figure 8.

## External Capacitors

The output capacitor for the CS8182 is required for stability. Without it, the regulator output will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability. Worst-case is determined at the minimum ambient temperature and maximum load expected.

The output capacitor can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltage during brief conditions of negative input transients that might be characteristic of a particular system.

The capacitor must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, a capacitor rated at that temperature must be used.

More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 9) is:

$$
\begin{align*}
\operatorname{PD}(\max )= & \left\{\mathrm{V}_{\operatorname{IN}}(\max )-\mathrm{V}_{\text {OUT }}(\min )\right\} \operatorname{IOUT}(\max ) \\
& +\mathrm{V}_{\operatorname{IN}}(\max ) \mathrm{I}_{\mathrm{Q}} \tag{1}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of PD (max) is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta J A}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heat sink will be required.

Figure 9. Single Output Regulator with Key Performance Parameters Labeled

## Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J \mathrm{~J}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it is a function of package type. $\mathrm{R}_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## MC33565

## Smart Voltage Regulator for Peripheral Card Applications

The MC33565 Low Drop Out Voltage Regulator is designed for computer peripheral card applications, allowing glitch-free transitions from "sleep" to "active" system modes. It has internal logic circuitry to detect whether there is a 5 V supply ("active" system mode) or an auxiliary 3.3 V supply ("sleep" system mode). A guaranteed 3.3 V regulated output voltage at 200 mA is always available even if the main 5 V supply drops out.

The regulated 3.3 V output voltage is provided by either an internal dropout 5.0 V-to-3.3 V voltage regulator or an external P-channel MOSFET, depending on the system being in the "active" or "sleep" mode.

## Features

- Glitch-Free Transition from "Sleep" to "Active" Mode
- Compatible with Instantly Available PC Systems
- Output Current up to 200 mA
- Output Regulated to $2 \%$ over Temperature
- Excellent Line and Load Regulation (0.4\%)
- Prevents Reverse Current Flow during Sleep Mode

## Applications

- Computer
- Ethernet
- PCI/NIC Cards

## OPERATING DESCRIPTION

The MC33565 is designed for power managed computer applications such as peripheral card interface (PCI) and network interface cards (NIC) where glitch-free transition between +3.3 V and +5 V is necessary. In this type of application, the presence of a +5 V supply represents the "active" system mode, while the presence of +3.3 V represents the "sleep" system mode. The MC33565 complies with the instantly available requirements as specified by the Advanced Configuration and Power Interface (ACPI) standards set by Intel, Microsoft, and Toshiba. A regulated output voltage of +3.3 V is available even when the +5 V supply has been shut down and only the +3.3 V auxiliary supply is available.

The MC33565 has dual inputs, $+5 \mathrm{~V}_{\text {in }}$ and $+3.3 \mathrm{~V}_{\text {in }}$. It functions as a linear regulator when $\mathrm{V}_{\text {in }}$ is greater than 4.02 V. Below this threshold value, the linear regulator turns off and the auxiliary DRIVE OUT feature allows the use of an external P -channel MOSFET to supply power to the output. The MC33565 connects the $+3.3 \mathrm{~V}_{\text {in }}$ auxiliary power supply directly to the output P -channel MOSFET.

## 5 V Detect

Internal circuitry detects if the system is being powered from a +5 V supply or a 3.3 V auxiliary supply. During normal operating conditions, the MC33565 is powered by the +5 V supply. A regulated output voltage of +3.3 V is provided by an internal low drop out 5.0 V -to- 3.3 V voltage regulator. The gate of the P -channel MOSFET is driven high and therefore disabled.

If the +5 V supply is not available or the supply voltage drops below a typical threshold value of 4.02 V , the DRIVE OUT goes low. This enables the external P -channel MOSFET, connecting the +3.3 V auxiliary supply to the load and allowing the load to remain powered even though the +5 V supply is not available.

As the supply voltage begins to rise, the linear regulator output will be disabled until $\mathrm{V}_{\text {in }}$ reaches a typical threshold voltage of 4.17 V . The load continues to be powered by the auxiliary DRIVE OUT while $\mathrm{V}_{\text {in }}$ reaches the threshold voltage. When $V_{\text {in }}$ reaches the threshold voltage, the gate of the external P-channel MOSFET is driven high and turns off.

The 5 V detect logic is active throughout the entire range of the +5 V supply ramp-up. The DRIVE OUT signal is never turned ON or OFF inappropriately during ramp-up of the $+5 \mathrm{~V}_{\text {in }}$ supply. The +3.3 V output voltage never drops below 3.0 V while the +5 V supply is above the 5 V DETECT minimum threshold of 3.9 V .

## Input Blocking

The internal NPN pass transistor of the low drop out regulator (LDO) ensure that no significant reverse current will flow from $\mathrm{V}_{\text {out }}$ to $\mathrm{V}_{\text {in }}$ or GND when the $+5 \mathrm{~V}_{\text {in }}$ input is not powered and the $+3.3 \mathrm{~V}_{\text {in }}$ supply is present.

## P-Channel MOSFET Polarity

It is imperative that the polarity of the P -channel MOSFET be observed because the P -channel MOSFET body diode will be connected between the auxiliary power supply and the load. The P-channel MOSFET drain is connected to the $+3.3 \mathrm{~V}_{\text {in }}$ auxiliary power supply; source is connected to load; gate is connected to DRIVE OUT. If the polarity is reversed with the drain connected to the load and the source connected to the auxiliary supply, the body diode could be forward biased if the auxiliary supply is not present. Consequently the linear regulator would not turn off and it would supply current to everything on the auxiliary supply rail.

## Hysteresis

The internal 5 V DETECT has a typical high threshold voltage of 4.17 V and a typical low threshold voltage of 4.02 V . This results in a typical hysteresis of 150 mV for noise immunity. The input supply voltage, $\mathrm{V}_{\mathrm{in}}$, must drop 150 mV while the linear regulator is supplying power to the load before the auxiliary DRIVE OUT is enabled.

## External Compensation

An external compensation capacitor with a minimum value of $4.7 \mu \mathrm{~F}$ is required for the linear regulator to be stable. Increasing the capacitance will improve the overall transient response. The equivalent series resistance (ESR) of the capacitor should be less than $1 \Omega$ in order for the output voltage to be maintained within tight tolerance.

## Sense

The SENSE IN pin provides tight regulation of the load voltage while the 5 V supply is present even with varying load current. To take advantage of the SENSE PIN, connect pin 6 as close to the load as possible. Use a separate trace to connect the source of the MOSFET to the load. Refer to Figure 2.

Figure 2.

## Board Layout

The PCB component layout shown in Figure 27 is designed for an input range of 4.3 V to 5.5 V ; an output voltage range of 3.267 V to 3.333 V ; and an output current of 200 mA .

## Current Limit and Thermal Shutdown

Full protection with both current limit and thermal shutdown is provided. Internal thermal limiting circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at $170^{\circ} \mathrm{C}$, the output is disabled. There
is no hysteresis built into the thermal limiting circuit. As a result, if the device is overheating, the output will appear to be oscillating. This feature is provided to prevent catastrophic failures from accidental device overheating. It is not intended to be used as a substitute for proper heatsinking.

## MC33275

## 300 mA, 2.5 V, Low Dropout Voltage Regulator

The MC33275 series are micropower low dropout voltage regulators available in a wide variety of output voltages as well as packages, DPAK, SOT-223, and SOP-8 surface mount packages. These devices feature a very low quiescent current and are capable of supplying output currents up to 300 mA . Internal current and thermal limiting protection are provided by the presence of a short circuit at the output and an internal thermal shutdown circuit.

The MC33275 is available as a MC33375 which includes an On/Off control.

Due to the low input-to-output voltage differential and bias current specifications, these devices are ideally suited for battery powered computer, consumer, and industrial equipment where an extension of useful battery life is desirable.

## Features:

- Low Quiescent Current ( $125 \mu \mathrm{~A}$ )
- Low Input-to-Output Voltage Differential of 25 mV at $\mathrm{I}_{\mathrm{O}}=10 \mathrm{~mA}$, and 260 mV at $\mathrm{I}_{\mathrm{O}}=300 \mathrm{~mA}$
- Extremely Tight Line and Load Regulation
- Stable with Output Capacitance of only $0.33 \mu \mathrm{~F}$ for 2.5 V Output Voltage
- Internal Current and Thermal Limiting

Simplified Block Diagram

This device contains 41 active transistors

NOTE: 1. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.
2. Quiescent Current is measured where the PNP pass transistor is in saturation. $\mathrm{V}_{\mathrm{in}}=\left[\mathrm{V}_{\mathrm{O}}-0.5\right] \mathrm{V}$ guarantees this condition.

## DEFINITIONS

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Dropout Voltage - The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.

Output Noise Voltage - The RMS AC voltage at the output with a constant load and no input ripple, measured over a specified frequency range.

Maximum Power Dissipation - The maximum total dissipation for which the regulator will operate within specifications.

Quiescent Current - Current which is used to operate the regulator chip and is not delivered to the load.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Maximum Package Power Dissipation - The maximum package power dissipation is the power dissipation level at which the junction temperature reaches its maximum value i.e. $150^{\circ} \mathrm{C}$. The junction temperature is rising while the
difference between the input power $\left(\mathrm{V}_{\mathrm{CC}} \mathrm{X} \mathrm{I}_{\mathrm{CC}}\right)$ and the output power $\left(V_{\text {out }} X \mathrm{I}_{\text {out }}\right)$ is increasing.

Depending on ambient temperature, it is possible to calculate the maximum power dissipation and so the maximum current as following:

$$
P d=\frac{T_{J}-T_{A}}{R_{\theta J A}}
$$

The maximum operating junction temperature $\mathrm{T}_{\mathrm{J}}$ is specified at $150^{\circ} \mathrm{C}$, if $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, then $\mathrm{P}_{\mathrm{D}}$ can be found. By neglecting the quiescent current, the maximum power dissipation can be expressed as:

$$
I_{\text {out }}=\frac{P_{D}}{V_{C C}-V_{o u t}}
$$

The thermal resistance of the whole circuit can be evaluated by deliberately activating the thermal shutdown of the circuit (by increasing the output current or raising the input voltage for example).

Then you can calculate the power dissipation by subtracting the output power from the input power. All variables are then well known: power dissipation, thermal shutdown temperature $\left(150^{\circ} \mathrm{C}\right.$ for MC 33275$)$ and ambient temperature.

$$
R_{\theta J A}=\frac{T_{J}-T_{A}}{P_{D}}
$$

## APPLICATIONS INFORMATION

Figure 14. Typical Application Circuit

The MC33275 regulators are designed with internal current limiting and thermal shutdown making them user-friendly. Figure 14 is a typical application circuit. The output capability of the regulator is in excess of 300 mA , with a typical dropout voltage of less than 260 mV . Internal protective features include current and thermal limiting.

## EXTERNAL CAPACITORS

These regulators require only a $0.33 \mu \mathrm{~F}$ (or greater) capacitance between the output and ground for stability for $2.5 \mathrm{~V}, 3.0 \mathrm{~V}$, and 3.3 V output voltage options. Output voltage options of 5.0 V require only $0.22 \mu \mathrm{~F}$ for stability. The output capacitor must be mounted as close as possible to the MC33275. If the output capacitor must be mounted further than two centimeters away from the MC33275, then a larger value of output capacitor may be required for stability. A value of $0.68 \mu \mathrm{~F}$ or larger is recommended. Most type of aluminum, tantalum, or multilayer ceramic will perform adequately. Solid tantalums or appropriate multilayer ceramic capacitors are recommended for operation below $25^{\circ} \mathrm{C}$. An input bypass capacitor is recommended to improve transient response or if the regulator is connected to the supply input filter with long wire lengths, more than 4 inches. This will reduce the circuit's sensitivity to the input line impedance at high frequencies. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, ceramic, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with shortest possible lead or track length directly across the regulator's input terminals. Figure 15 shows the ESR that allows the LDO to remain stable for various load currents.

Figure 15. ESR for $\mathrm{V}_{\text {out }}=3.0 \mathrm{~V}$
Applications should be tested over all operating conditions to insure stability.

## THERMAL PROTECTION

Internal thermal limiting circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at $150^{\circ} \mathrm{C}$, the output is disabled. There is no hysteresis built into the thermal protection. As a result the output will appear to be oscillating during thermal limit. The output will turn off until the temperature drops below the $150^{\circ} \mathrm{C}$ then the output turns on again. The process will repeat if the junction increases above the threshold. This will continue until the existing conditions allow the junction to operate below the temperature threshold.

Thermal limit is not a substitute for proper heatsinking.
The internal current limit will typically limit current to 450 mA . If during current limit the junction exceeds $150^{\circ} \mathrm{C}$, the thermal protection will protect the device also. Current limit is not a substitute for proper heatsinking. OUTPUT NOISE
In many applications it is desirable to reduce the noise present at the output. Reducing the regulator bandwidth by increasing the size of the output capacitor will reduce the noise on the MC33275.

## MC33375

## Advance Information 300 mA, 2.5 V, Low Dropout Voltage Regulator with On/Off Control

The MC33375 series are micropower low dropout voltage regulators available in a wide variety of output voltages as well as packages, SOT-223, and SOP-8 surface mount packages. These devices feature a very low quiescent current and are capable of supplying output currents up to 300 mA . Internal current and thermal limiting protection are provided by the presence of a short circuit at the output and an internal thermal shutdown circuit.

The MC33375 has a control pin that allows a logic level signal to turn-off or turn-on the regulator output.

Due to the low input-to-output voltage differential and bias current specifications, these devices are ideally suited for battery powered computer, consumer, and industrial equipment where an extension of useful battery life is desirable.

## Features:

- Low Quiescent Current ( $0.3 \mu \mathrm{~A}$ in OFF mode; $125 \mu \mathrm{~A}$ in ON mode)
- Low Input-to-Output Voltage Differential of 25 mV at $\mathrm{I}_{\mathrm{O}}=10 \mathrm{~mA}$, and 260 mV at $\mathrm{I}_{\mathrm{O}}=300 \mathrm{~mA}$
- Extremely Tight Line and Load Regulation
- Stable with Output Capacitance of only $0.33 \mu \mathrm{~F}$ for 2.5 V Output Voltage
- Internal Current and Thermal Limiting
- Logic Level ON/OFF Control

This device contains 41 active transistors

## THERMAL SHUTDOWN

| Thermal Shutdown | - | - | 150 | - |
| :--- | :--- | :--- | :--- | :--- |
| ${ }^{\circ} \mathrm{C}$ |  |  |  |  |

NOTE: 1. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.
2. Quiescent Current is measured where the PNP pass transistor is in saturation. $\mathrm{V}_{\mathrm{in}}=\left[\mathrm{V}_{\mathrm{O}}-0.5\right] \mathrm{V}$ guarantees this condition.

## DEFINITIONS

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Dropout Voltage - The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.

Output Noise Voltage - The RMS AC voltage at the output with a constant load and no input ripple, measured over a specified frequency range.

Maximum Power Dissipation - The maximum total dissipation for which the regulator will operate within specifications.

Quiescent Current - Current which is used to operate the regulator chip and is not delivered to the load.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Maximum Package Power Dissipation - The maximum package power dissipation is the power dissipation level at which the junction temperature reaches its maximum value i.e. $150^{\circ} \mathrm{C}$. The junction temperature is rising while the
difference between the input power $\left(\mathrm{V}_{\mathrm{CC}} \mathrm{X} \mathrm{I}_{\mathrm{CC}}\right)$ and the output power $\left(V_{\text {out }} X \mathrm{I}_{\text {out }}\right)$ is increasing.

Depending on ambient temperature, it is possible to calculate the maximum power dissipation and so the maximum current as following:

$$
P d=\frac{T_{J}-T_{A}}{R_{\theta J A}}
$$

The maximum operating junction temperature $\mathrm{T}_{\mathrm{J}}$ is specified at $150^{\circ} \mathrm{C}$, if $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, then $\mathrm{P}_{\mathrm{D}}$ can be found. By neglecting the quiescent current, the maximum power dissipation can be expressed as:

$$
I_{\text {out }}=\frac{P_{D}}{V_{C C}-V_{o u t}}
$$

The thermal resistance of the whole circuit can be evaluated by deliberately activating the thermal shutdown of the circuit (by increasing the output current or raising the input voltage for example).

Then you can calculate the power dissipation by subtracting the output power from the input power. All variables are then well known: power dissipation, thermal shutdown temperature $\left(150^{\circ} \mathrm{C}\right.$ for MC 33375$)$ and ambient temperature.

$$
R_{\theta J A}=\frac{T_{J}-T_{A}}{P_{D}}
$$

Figure 22. Typical Application Circuit

The MC33375 regulators are designed with internal current limiting and thermal shutdown making them user-friendly. Figure 15 is a typical application circuit. The output capability of the regulator is in excess of 300 mA , with a typical dropout voltage of less than 260 mV . Internal protective features include current and thermal limiting.

## EXTERNAL CAPACITORS

These regulators require only a $0.33 \mu \mathrm{~F}$ (or greater) capacitance between the output and ground for stability for $1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3.0 \mathrm{~V}$, and 3.3 V output voltage options. Output voltage options of 5.0 V require only $0.22 \mu \mathrm{~F}$ for stability. The output capacitor must be mounted as close as possible to the MC33375. If the output capacitor must be mounted further than two centimeters away from the MC33375, then a larger value of output capacitor may be required for stability. A value of $0.68 \mu \mathrm{~F}$ or larger is recommended. Most type of aluminum, tantalum, or multilayer ceramic will perform adequately. Solid tantalums or appropriate multilayer ceramic capacitors are recommended for operation below $25^{\circ} \mathrm{C}$. An input bypass capacitor is recommended to improve transient response or if the regulator is connected to the supply input filter with long wire lengths, more than 4 inches. This will reduce the circuit's sensitivity to the input line impedance at high
frequencies. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, ceramic, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with shortest possible lead or track length directly across the regulator's input terminals. Figure 16 shows the ESR that allows the LDO to remain stable for various load currents.

Figure 23. $E S R$ for $V_{\text {out }}=3.0 \mathrm{~V}$
Applications should be tested over all operating conditions to insure stability.

## THERMAL PROTECTION

Internal thermal limiting circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at $150^{\circ} \mathrm{C}$, the output is disabled. There is no hysteresis built into the thermal protection. As a result the output will appear to be oscillating during thermal limit. The output will turn off until the temperature drops below the $150^{\circ} \mathrm{C}$ then the output turns on again. The process will repeat if the junction increases above the threshold. This will continue until the existing conditions allow the junction to operate below the temperature threshold.

Thermal limit is not a substitute for proper heatsinking.

The internal current limit will typically limit current to 450 mA . If during current limit the junction exceeds $150^{\circ} \mathrm{C}$, the thermal protection will protect the device also. Current limit is not a substitute for proper heatsinking.

## OUTPUT NOISE

In many applications it is desirable to reduce the noise present at the output. Reducing the regulator bandwidth by increasing the size of the output capacitor will reduce the noise on the MC33375.

## ON/OFF PIN

When this pin is pulled low, the MC33375 is off. This pin should not be left floating. The pin should be pulled high for the MC33375 to operate.

## CS8120

### 5.0 V, 300 mA Linear Regulator with RESET and ENABLE

The CS8120 is a $5.0 \mathrm{~V}, 300 \mathrm{~mA}$ precision linear regulator with two microprocessor compatible control functions and protection circuitry included on chip. The composite NPN-PNP output pass transistor assures a lower dropout voltage ( 1.0 V @ 200 mA ) without requiring excessive supply current ( 2.5 mA ).

The CS8120's two logic control functions make this regulator well suited to applications requiring microprocessor-based control at the board or module level. ENABLE controls the output stage. A high voltage ( $>2.9 \mathrm{~V}$ ) on the $\overline{\text { ENABLE }}$ lead turns off the regulator's pass transistor and sends the IC into Sleep mode where it draws only $250 \mu \mathrm{~A}$. The $\overline{\text { RESET }}$ function sends a $\overline{\text { RESET }}$ signal when the IC is powering up or whenever the output voltage moves out of regulation. The $\overline{\text { RESET }}$ signal is valid down to $\mathrm{V}_{\text {OUT }}=1.0 \mathrm{~V}$.

The CS8120 design optimizes supply rejection by switching the internal bandgap reference from the supply input to the regulator output as soon as the nominal output voltage is achieved. Additional on chip filtering enhances rejection of high frequency transients on all external leads.

The CS8120 is fault protected against short circuit, over voltage and thermal runaway conditions.

## Features

- $5.0 \mathrm{~V} \pm 4.0 \%$ Output Voltage 300 mA
- Low Dropout Voltage (1.0 V @ 150 mA )
- Low Quiescent Current ( 2.5 mA @ $\mathrm{I}_{\mathrm{OUT}}=150 \mathrm{~mA}$ )
- $\mu \mathrm{P}$ Compatible Control Functions
- $\overline{\text { RESET }}$
- $\overline{\text { ENABLE }}$
- Low Current Sleep Mode
$-\mathrm{I}_{\mathrm{Q}}=250 \mu \mathrm{~A}$
- Fault Protection
- Thermal Shutdown
- Short Circuit
- 60 V Load Dump

Output Voltage

## CIRCUIT DESCRIPTION

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Precision Voltage Reference

The regulated output voltage depends on the precision band gap voltage reference in the IC. By adding an error amplifier into the feedback loop, the output voltage is maintained within $\pm 4.0 \%$ over temperature and supply variation.

## Output Stage

The composite PNP-NPN output structure (Figure 9) provides 300 mA (typ) of output current while maintaining a low drop out voltage ( 1.00 V , typ) and drawing little quiescent current ( 2.5 mA ). The NPN pass device prevents deep saturation of the output stage which in turn improves the IC's efficiency by preventing excess current from being used and dissipated by the IC.

Figure 9. Composite Output Stage of the CS8120

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 10).

Figure 10. Typical Circuit Waveforms for Output Stage Protection

If the input voltage rises above 26 V (e.g. load dump), the output shuts down. This response protects the internal
circuitry and enables the IC to survive unexpected voltage transients.
Using an emitter sense scheme, the amount of current through the NPN pass transistor is monitored. Feedback circuitry insures that the output current never exceeds a preset limit.
Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

## REGULATOR CONTROL FUNCTIONS

The CS8120 contains two microprocessor compatible control functions: $\overline{\text { ENABLE }}$ and $\overline{\text { RESET }}$ (Figure 11).

## ENABLE Function

The ENABLE function switches the output transistor. When the voltage on the ENABLE lead exceeds 2.9 V typ, the output pass transistor turns off, leaving a high impedance facing the load. The IC will remain in Sleep mode, drawing only $250 \mu \mathrm{~A}$, until the voltage on the lead drops below 2.1 V typ. Hysteresis ( 800 mV ) is built into the ENABLE function to provide good noise immunity.

(1) $=$ No Reset Delay Capacitor
(2) = With Reset Delay Capacitor

Figure 11. Circuit Waveform for CS8120

## RESET Function

A $\overline{\mathrm{RESET}}$ signal (low voltage) is generated as the IC powers up ( $\mathrm{V}_{\text {OUT }}>\mathrm{V}_{\text {OUT }}-100 \mathrm{mV}$ ) or when $\mathrm{V}_{\text {OUT }}$ drops out of regulation ( $\mathrm{V}_{\text {OUT }}<\mathrm{V}_{\text {OUT }}-140 \mathrm{mV}$, typ). 40 mV of hysteresis is included in the function to minimize oscillations.
The RESET output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is
functionally independent of the rest of the IC, thereby guaranteeing that the $\overline{\text { RESET }}$ signal is valid for $\mathrm{V}_{\text {OUT }}$ as low as 1.0 V .

Figure 12. RC Network for RESET Delay Circuitry

An external RC network on the $\overline{\text { RESET }}$ lead (Figure 12) provides a sufficiently long delay for most microprocessor based applications. RC values can be chosen using the following formula:
where:
$\mathrm{R}_{\mathrm{TOT}}=\mathrm{R}_{\mathrm{RST}}$ in parallel with $\mathrm{R}_{\mathrm{IN}}$,
$\mathrm{R}_{\mathrm{IN}}=\mu \mathrm{P}$ port impedance,
$\mathrm{C}_{\text {RST }}=\overline{\mathrm{RESET}}$ delay capacitor,
$\mathrm{t}_{\text {Delay }}=$ desired delay time,
$\mathrm{V}_{\mathrm{RST}}=\mathrm{V}_{\text {SAT }}$ of $\overline{\text { RESET }}$ lead ( 0.7 V @ turn -ON ), and
$\mathrm{V}_{\mathrm{T}}=\mu \mathrm{P}$ logic threshold voltage.

## APPLICATION NOTES

The circuit depicted in Figure 13 lets the microprocessor control its power source, the CS8120 regulator. An I/O port on the $\mu \mathrm{P}$ and the SWITCH port are used to drive the base of Q1. When Q1 is driven into saturation, the voltage on the ENABLE lead falls below its lower threshold. The regulator's output is switched out. When the drive current is removed, the voltage on the $\overline{\text { ENABLE }}$ lead rises, the output is switched off and the IC moves into Sleep mode where it draws $250 \mu \mathrm{~A}$.

By coupling these two controls with the ENABLE, the system has added flexibility. Once the system is running, the state of the SWITCH is irrelevant as long as the I/O port continues to drive Q1. The microprocessor can turn off its own power by withdrawing drive current, once the SWITCH is open. This software control at the I/O port
allows the microprocessor to finish key housekeeping functions before power is removed.

The logic options are summarized in Table 1.
Table 1. Logic Control of CS8120 Output

| Microprocessor <br> I/O Drive | SWITCH | ENABLE | Output |
| :---: | :---: | :---: | :---: |
| ON | Closed | LOW | ON |
|  | Open | LOW | ON |
| OFF | Closed | LOW | ON |
|  | Open | HIGH | OFF |

The I/O port of the microprocessor typically provides $50 \mu \mathrm{~A}$ to Q 1 . In automotive applications the SWITCH is connected to the ignition switch.

Figure 13. Microprocessor Control of CS8120 Using External Switching Transistor Q1

## STABILITY CONSIDERATIONS

The output or compensation capacitor, $\mathrm{C}_{2}$, helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor $\mathrm{C}_{2}$ shown in Figure 14 should work for most applications, however it is not necessarily the optimized solution.

${ }^{*} \mathrm{C}_{1}$ is required if regulator is far from the power source filter.
${ }^{* *} \mathrm{C}_{2}$ is required for stability.
Figure 14. Circuit Showing Output Compensation Capacitor

To determine an acceptable value for $\mathrm{C}_{2}$ for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause
the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 15) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $R_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 15. Single Output Regulator With Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS5231-3

## 500 mA , 3.3 V Linear Regulator with Auxiliary Control

The CS5231-3 combines a three-terminal linear regulator with circuitry controlling an external PFET transistor thus managing two input supplies. The part provides a 3.3 V regulated output either from the main 5.0 V supply or a 3.3 V auxiliary that switches on when the 5.0 V supply is not present. This delivers constant, uninterrupted power to the load. The CS5231-3 meets Intel's "Instantly Available" power requirements which follows from the "Advanced Configuration and Power Interface" (ACPI) standards developed by Intel, Microsoft and Toshiba.

The CS5231-3 linear regulator provides a fixed 3.3 V output at 500 mA with an overall accuracy of $\pm 2.0 \%$. The internal NPN-PNP composite pass transistor provides a low dropout voltage and requires less supply current than a straight PNP design. Full protection with both current limit and thermal shutdown is provided.

Designed for low reverse current, the IC prevents excessive current from flowing from $V_{\text {OUT }}$ to either $\mathrm{V}_{\text {IN }}$ or ground when the regulator input voltage is lower than the output voltage.

The CS5231-3 can be used to provide power to an ASIC on a PCI Network Interface Card (NIC). When the system enters a Sleep State and the 5.0 V input drops below 4.4 V , the AuxDrv control signal on the CS5231-3 is activated turning on the external PFET. This switches the supply source from the 5.0 V input to the 3.3 V input through the PFET, guaranteeing a constant 3.3 V output to the ASIC that is "glitch free."

The CS5231-3 is available in two package types: the 5-Lead $\mathrm{D}^{2}$ PAK (TO263) package and the 8-Lead SOIC 4-Lead-fused (DF) package. Other applications include desktop computers, power supplies with multiple input sources and PCMCIA/PCI interface cards.

## Features

- Linear Regulator
$-3.3 \mathrm{~V} \pm 2.0 \%$ Output Voltage
- 3.0 mA Quiescent Current @ 500 mA
- Fast Transient Response
- Current Limit Protection
- Thermal Shutdown with Hysteresis
- $450 \mu \mathrm{~A}$ Reverse Output Current
- System Power Management
- Auxiliary Supply Control
- "Glitch Free" Transition Between Two Supplies
- Internally Fused Leads in SO-8 Package

## APPLICATION INFORMATION

## THEORY OF OPERATION

The CS5231-3 is a fixed 3.3 V linear regulator that contains an auxiliary drive control feature. When $\mathrm{V}_{\text {IN }}$ is greater than the typical 4.5 V threshold, the IC functions as a linear regulator. It provides up to 500 mA of current to a load through a composite PNP-NPN pass transistor. An output capacitor greater than $10 \mu \mathrm{~F}$ with equivalent series resistance less than $1.0 \Omega$ is required for compensation. More information is provided in the Stability Considerations section.

The CS5231-3 provides an auxiliary drive feature that allows a load to remain powered even if the $\mathrm{V}_{\text {IN }}$ supply for the IC is absent. An external p-channel FET is the only additional component required to implement this function if an auxiliary power supply is available. The PFET gate is connected to the AuxDrv lead. The PFET drain is connected to the auxiliary power supply, and the PFET source is connected to the load. The polarity of this connection is very important, since the PFET body diode will be connected between the load and the auxiliary supply. If the PFET is connected with its drain to the load and its source to the supply, the body diode will be forward-biased if the auxiliary supply is turned off. This will result in the linear regulator providing current to everything on the auxiliary supply rail.
The AuxDrv lead is internally connected to a $10 \mathrm{k} \Omega$ resistor and to a saturating NPN transistor that acts as a switch. If the $\mathrm{V}_{\text {IN }}$ supply is off, the AuxDrv output will connect the PFET gate to ground through the $10 \mathrm{k} \Omega$ resistor, and the PFET will conduct current to the load.

As the $\mathrm{V}_{\text {IN }}$ supply begins to rise, the AuxDrv lead will also rise until it reaches a typical voltage of about 650 mV . The NPN transistor connected to the AuxDrv lead will saturate at this point, and the gate of the PFET will be pulled down to a typical voltage of about 100 mV . The PFET will continue to conduct current to the load.

The $\mathrm{V}_{\text {IN }}$ supply voltage will continue to rise, but the linear regulator output is disabled until $\mathrm{V}_{\text {IN }}$ reaches a typical threshold of 4.5 V . During this time, the load continues to be powered by the auxiliary driver. Once the $4.5 \mathrm{~V} \mathrm{~V}_{\text {IN }}$ threshold is reached, the saturating NPN connected to the AuxDrv lead turns off. The on-chip $10 \mathrm{k} \Omega$ pull-up resistor will pull the PFET gate up to $\mathrm{V}_{\mathrm{IN}}$, thus turning the PFET off. The linear regulator turns on at the same time. An external compensation capacitor is required for the linear regulator to be stable, and this capacitance also serves as a charge reservoir to minimize any "glitching" that might result during the supply changeover. Hysteresis is present in the AuxDrv circuitry, requiring $\mathrm{V}_{\text {IN }}$ to drop by 100 mV (typical) after the linear regulator is providing power to the load before the AuxDrv circuitry can be re-enabled.

Figure 13. Initial Power-Up, $\mathrm{V}_{\text {AUX }}$ Not Present $R_{\text {OUT }}=8.8 \Omega$

Figure 14. Power-Up, $V_{A U X}=3.3$ V. Note the "Oscillatory Performance" as the Linear Regulator Changes the $\mathrm{V}_{\text {OUT }}$ Node. $\mathrm{I}_{\text {OUT }} \times \mathrm{R}_{\mathrm{DS}(\mathrm{ON})} \approx \mathbf{1 3 0} \mathbf{~ m V}$

Figure 15. Power-Down, $\mathrm{V}_{\mathrm{AUX}}=3.3 \mathrm{~V}$. Again, Note $\Delta V=I R_{D S(O N)} \approx 130 \mathrm{mV}$

Figure 16. Power-Up, $\mathrm{V}_{\mathrm{A} U \mathrm{X}}=3.135 \mathrm{~V}$. The "Oscillatory Performance" Mode Lasts Longer Because the Difference Between $\mathrm{V}_{\mathrm{AUX}}$ and 3.3 is Greater

$\mathrm{I}_{\mathrm{OUT}}=375 \mathrm{~mA} \quad \mathrm{~V}_{\text {AUX }}=3.135$
Figure 17. Power-Down, $\mathrm{V}_{\mathrm{AUX}}=3.135 \mathrm{~V}$. The Difference in Voltage is Now IOUT $\times \mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ Plus the Difference in Supply Voltages (3.3-V $\mathrm{V}_{\text {AUX }}$ )

Figure 18. Power-Up, $\mathrm{V}_{\mathrm{AUX}}=3.465 \mathrm{~V}$. I IOUT $\times \mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ is Compensated By Higher Value of $\mathrm{V}_{\mathrm{AUX}}$

Figure 19. Power-Down, $\mathrm{V}_{\mathrm{AUX}}=3.465 \mathrm{~V}$

## STABILITY CONSIDERATIONS

The output capacitor helps determine three main characteristics of a linear regulator: startup, transient response and stability.
Startup is affected because the output capacitor must be charged. At initial startup, the $\mathrm{V}_{\text {IN }}$ supply may not be present, and the output capacitor will be charged through the PFET. The PFET will initially provide current to the load through its body diode. The diode will act as a voltage follower until sufficient voltage is present to turn the FET on. Since most commercial power supplies have a fairly low ramp rate, charging through the body diode should effectively limit in-rush current to the capacitor.

During normal operation, transient load current requirements will be satisfied from the charge stored in the output capacitor until either the linear regulator or the auxiliary supply can respond. Larger values of capacitance will improve transient response, but will also cost more. A linear regulator will respond within microseconds, where an external power supply may take milliseconds to react. The output capacitance will provide the difference in current until this occurs. The result will be an instantaneous voltage change at the output. This change is the product of the current change and the capacitor ESR:

$$
\Delta \mathrm{V}_{\mathrm{OUT}}=\Delta \mathrm{I} \mathrm{LOAD} \times \mathrm{ESR}
$$

This limitation directly affects load regulation. Capacitor ESR must be minimized if output voltage must be maintained within tight tolerances. In such a case, it is often advisable to use a parallel network of different types of capacitors. For example, electrolytic capacitors provide high charge storage capacity in a small size, while tantalum capacitors have low ESR. The parallel combination will result in a high capacity, low ESR network. It is also important to physically locate the capacitance network close to the load, and to connect the network to the load with wide PC board traces to minimize the metal resistance.

The CS5231-3 has been carefully designed to be stable for output capacitances greater than $10 \mu \mathrm{~F}$ with equivalent series resistance less than $1.0 \Omega$. While careful board layout is important, the user should have a stable system if these constraints are met. A graph showing the region of stability for the CS5231-3 is included in the "Typical Performance Characteristics" section of this datasheet.

## INPUT CAPACITORS AND THE $V_{\text {IN }}$ THRESHOLDS

A capacitor placed on the $\mathrm{V}_{\text {IN }}$ pin will help to improve transient response. During a load transient, the input capacitor serves as a charge "reservoir," providing the needed extra current until the external power supply can respond. One of the consequences of providing this current is an instantaneous voltage drop at $\mathrm{V}_{\text {IN }}$ due to capacitor ESR. The magnitude of the voltage change is again the product of the current change and the capacitor ESR.

It is very important to consider the maximum current step that can exist in the system. If the change in current is large enough, it is possible that the instantaneous voltage drop on $\mathrm{V}_{\text {IN }}$ will exceed the $\mathrm{V}_{\text {IN }}$ threshold hysteresis, and the IC will enter a mode of operation resembling an oscillation. As the part turns on, the output current $\mathrm{I}_{\text {OUT }}$ will increase, reaching current limit during initial charging. Increasing IOUT results in a drop at $\mathrm{V}_{\text {IN }}$ such that the shutdown threshold is reached. The part will turn off, and the load current will decrease. As IOUT decreases, $\mathrm{V}_{\text {IN }}$ will rise and the part will turn on, starting the cycle all over again. This oscillatory operation is most likely at initial start-up when the output capacitance is not charged, and in cases where the ramp-up of the $\mathrm{V}_{\mathrm{IN}}$ supply is slow. It may also occur during the power transition when the regulator turns on and the PFET turns off. A $15 \mu \mathrm{~s}$ delay exists between turn-on of the regulator and the AuxDrv pin pulling the gate of the PFET high. This delay prevents "chatter" during the power transitions. During this interval, the linear regulator will attempt to regulate the output voltage as 3.3 V . If the output voltage is significantly below 3.3 V , the IC will go into current limit while trying to raise $\mathrm{V}_{\text {OUT }}$. It is a short-lived phenomenon and is mentioned here to alert the user that the condition can exist. It is typically not a problem in applications. Careful choice of the PFET switch with respect to $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ will minimize the voltage drop which the output must charge through to return to a regulated state. More information is provided in the section on choosing the PFET switch.

If required, using a few capacitors in parallel to increase the bulk charge storage and reduce the ESR should give better performance than using a single input capacitor. Short, straight connections between the power supply and $\mathrm{V}_{\text {IN }}$ lead along with careful layout of the PC board ground plane will reduce parasitic inductance effects. Wide $\mathrm{V}_{\text {IN }}$ and $V_{\text {OUT }}$ traces will reduce resistive voltage drops.

## CHOOSING THE PFET SWITCH

The choice of the external PFET switch is based on two main considerations. First, the PFET should have a very low
turn-on threshold. Choosing a switch transistor with $\mathrm{V}_{\mathrm{GS}(\mathrm{ON})} \approx 1.0 \mathrm{~V}$ will ensure the PFET will be fully enhanced with only 3.3 V of gate drive voltage. Second, the switch transistor should be chosen to have a low $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ to minimize the voltage drop due to current flow in the switch. The formula for calculating the maximum allowable on-resistance is

$$
\operatorname{RDS}(\mathrm{ON}) \mathrm{MAX}=\frac{\mathrm{V}_{\mathrm{AUX}}(\mathrm{MIN})-\mathrm{V}_{\mathrm{OUT}}(\mathrm{MIN})}{1.5 \times \operatorname{lOUT}(\mathrm{MAX})}
$$

where $\mathrm{V}_{\mathrm{AUX}(\mathrm{MIN})}$ is the minimum value of the auxiliary supply voltage, $\mathrm{V}_{\text {OUT(MIN) }}$ is the minimum allowable output voltage, IOUT(MAX) is the maximum output current and 1.5 is a "fudge factor" to account for increases in $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ due to temperature.

## OUTPUT VOLTAGE SENSING

It is not possible to remotely sense the output voltage of the CS5231-3 since the feedback path to the error amplifier is not externally available. It is important to minimize voltage drops due to metal resistance of high current PC board traces. Such voltage drops can occur in both the supply traces and the return traces.
The following board layout practices will help to minimize output voltage errors:

- Always place the linear regulator as close to both load and output capacitors as possible.
- Always use the widest possible traces to connect the linear regulator to the capacitor network and to the load.
- Connect the load to ground through the widest possible traces.
- Connect the IC ground to the load ground trace at the point where it connects to the load.

## CURRENT LIMIT

The CS5231-3 has internal current limit protection. Output current is limited to a typical value of 850 mA , even under output short circuit conditions. If the load current drain exceeds the current limit value, the output voltage will be pulled down and will result in an out of regulation condition. The IC does not contain circuitry to report this fault.

## THERMAL SHUTDOWN

The CS5231-3 has internal temperature monitoring circuitry. The output is disabled if junction temperature of the IC reaches $180^{\circ} \mathrm{C}$. Thermal hysteresis is typically $25^{\circ} \mathrm{C}$ and allows the IC to recover from a thermal fault without the need for an external reset signal. The monitoring circuitry is located near the composite PNP-NPN output transistor, since this transistor is responsible for most of the on-chip power dissipation. The combination of current limit and thermal shutdown will protect the IC from nearly any fault condition.

## REVERSE CURRENT PROTECTION

During normal system operation, the auxiliary drive circuitry will maintain voltage on the $\mathrm{V}_{\text {OUT }}$ pin when $\mathrm{V}_{\text {IN }}$ is absent. IC reliability and system efficiency are improved by limiting the amount of reverse current that flows from $\mathrm{V}_{\text {OUT }}$ to ground and from $\mathrm{V}_{\text {OUT }}$ to $\mathrm{V}_{\text {IN }}$. Current flows from $V_{\text {OUT }}$ to ground through the feedback resistor divider that sets up the output voltage This resistor can range in value from $6.0 \mathrm{k} \Omega$ to about $10 \mathrm{k} \Omega$, and roughly $500 \mu \mathrm{~A}$ will flow in the typical case. Current flow from $\mathrm{V}_{\text {OUT }}$ to $\mathrm{V}_{\text {IN }}$ will be limited to leakage current after the IC shuts down. On-chip RC time constants are such that the output transistor should be turned off well before $\mathrm{V}_{\mathrm{IN}}$ drops below the $\mathrm{V}_{\text {OUT }}$ voltage.

## CALCULATING POWER DISSIPATION AND HEATSINK REQUIREMENTS

Most linear regulators operate under conditions that result in high on-chip power dissipation. This results in high junction temperatures. Since the IC has a thermal shutdown feature, ensuring the regulator will operate correctly under normal conditions is an important design consideration. Some heatsinking will usually be required.

Thermal characteristics of an IC depend on four parameters: ambient temperature ( $\mathrm{T}_{\mathrm{A}}$ in ${ }^{\circ} \mathrm{C}$ ), power dissipation ( $\mathrm{P}_{\mathrm{D}}$ in watts), thermal resistance from the die to the ambient air $\left(\theta_{\mathrm{JA}}\right.$ in ${ }^{\circ} \mathrm{C}$ per watt) and junction temperature ( $\mathrm{T}_{\mathrm{J}}$ in ${ }^{\circ} \mathrm{C}$ ). The maximum junction temperature is calculated from the formula below:

$$
\mathrm{T}_{\mathrm{J}(\mathrm{MAX})}=\mathrm{T}_{\mathrm{A}}(\mathrm{MAX})+\left(\theta_{\mathrm{JA}} \times \mathrm{P}_{\mathrm{D}}(\mathrm{MAX})\right)
$$

Maximum ambient temperature and power dissipation are determined by the design, while $\theta_{\mathrm{JA}}$ is dependent on the package manufacturer. The maximum junction temperature for operation of the CS5231-3 within specification is $150^{\circ} \mathrm{C}$. The maximum power dissipation of a linear regulator is given as

$$
\begin{aligned}
\mathrm{PD}_{\mathrm{D}(\mathrm{MAX})}= & \left(\mathrm{V}_{\mathrm{IN}}(\mathrm{MAX})-\mathrm{V}_{\mathrm{OUT}(\mathrm{MIN})}\right) \\
& \times\left(\operatorname{ILOAD}(\mathrm{MAX})+\mathrm{V}_{\mathrm{IN}(\mathrm{MAX})}\right) \\
& \times \operatorname{IGND}(\mathrm{MAX})
\end{aligned}
$$

where $\mathrm{I}_{\mathrm{GND}(\mathrm{MAX})}$ is the IC bias current.
It is possible to change the effective value of $\theta_{\mathrm{JA}}$ by adding a heatsink to the design. A heatsink serves in some manner to raise the effective area of the package, thus improving the flow of heat from the package into the surrounding air. Each material in the path of heat flow has its own characteristic thermal resistance, all measured in ${ }^{\circ} \mathrm{C}$ per watt. The thermal resistances are summed to determine the total thermal resistance between the die junction and air. There are three components of interest: junction-to-case thermal resistance $\left(\theta_{\mathrm{JC}}\right)$, case-to-heatsink thermal resistance $\left(\theta_{\mathrm{CS}}\right)$ and heatsink-to-air thermal resistance $\left(\theta_{\mathrm{SA}}\right)$. The resulting equation for junction-to-air thermal resistance is

$$
\theta \mathrm{JA}=\theta \mathrm{JC}+\theta_{\mathrm{CS}}+\theta \mathrm{SA}
$$

The value of $\theta_{\text {JC }}$ both packages of the CS5231-3 are provided in the Packaging Information section of this data sheet. The value of $\theta_{\mathrm{CS}}$ can be considered zero, since heat is conducted out of the D2 2PAK package by the IC leads and the tab, and out of the SOIC package by its IC leads that are soldered directly to the PC board.
Modification of $\theta_{\mathrm{SA}}$ is the primary means of thermal management. For surface mount components, this means modifying the amount of trace metal that connects to the IC.
The thermal capacity of PC board traces is dependent on how much copper area is used, whether or not the IC is in direct contact with the metal, whether or not the metal surface is coated with some type of sealant, and whether or not there is airflow across the PC board. The chart provided below shows heatsinking capability of a square, single sided copper PC board trace. The area is given in square millimeters, and it is assumed there is no airflow across the PC board.

Figure 20. Thermal Resistance Capability of Copper PC Board Metal Traces

TYPICAL D²PAK PC BOARD HEATSINK DESIGN
A typical design of the PC board surface area needed for the $\mathrm{D}^{2}$ PAK package is shown on page 550. Calculations were made assuming $\mathrm{V}_{\mathrm{IN}(\mathrm{MAX})}=5.25 \mathrm{~V}, \mathrm{~V}_{\text {OUT(MIN) }}=$ $3.266 \mathrm{~V}, \mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})}=500 \mathrm{~mA}, \mathrm{I}_{\mathrm{GND}(\mathrm{MAX})}=5.0 \mathrm{~mA}$ and $\mathrm{T}_{\mathrm{A}}$ $=70^{\circ} \mathrm{C}$.

$$
\begin{aligned}
P D= & (5.25 \mathrm{~V}-3.266 \mathrm{~V}) \times 0.5 \mathrm{~A} \\
& +(5.25 \mathrm{~V})(0.005 \mathrm{~A})=1018 \mathrm{~mW}
\end{aligned}
$$

Maximum temperature rise

$$
\begin{gathered}
\Delta \mathrm{T}=\mathrm{T}(\mathrm{MAX})-\mathrm{T}_{\mathrm{A}}=150^{\circ} \mathrm{C}-70^{\circ} \mathrm{C}=80^{\circ} \mathrm{C} \\
\theta \mathrm{JA}(\text { worst case })=\Delta \mathrm{T} / \mathrm{PD}=80^{\circ} \mathrm{C} / 1.018 \mathrm{~W}=78.56^{\circ} \mathrm{C} / \mathrm{W}
\end{gathered}
$$

First, we determine the need for heatsinking. If we assume the maximum $\theta_{\mathrm{JA}}=50^{\circ} \mathrm{C} / \mathrm{W}$ for the $\mathrm{D}^{2} \mathrm{PAK}$, the maximum temperature rise is found to be

$$
\Delta \mathrm{T}=\mathrm{PD} \times \theta \mathrm{JA}=1.018 \mathrm{~W} \times 50^{\circ} \mathrm{C} / \mathrm{W}=50.9^{\circ} \mathrm{C}
$$

This is less than the maximum specified operating junction temperature of $125^{\circ} \mathrm{C}$, and no heatsinking is required. Since the $D^{2}$ PAK has a large tab, mounting this part to the PC board by soldering both tab and leads will provide superior performance with no PC board area penalty.

## TYPICAL 8 LEAD FUSED LEAD SOIC DESIGN

We first determine the need for a heat sink for the 8 Lead SOIC package at a load of 500 mA . Using the dissipation from the $\mathrm{D}^{2}$ PAK example of 1018 mW and the $\theta_{\mathrm{JA}}$ of the SOIC package of $110^{\circ} \mathrm{C} / \mathrm{W}$ gives a temperature rise of $112^{\circ} \mathrm{C}$. Adding this to an ambient temperature of $70^{\circ} \mathrm{C}$ gives $182^{\circ} \mathrm{C}$ junction temperature. This is an excessive temperature rise but it can be reduced by adding additional cooling in the form of added surface area of copper on the PCB. Using the relationship of maximum temperature rise of

$$
\Delta T_{J A}=T_{J}(\mathrm{MAX})-\mathrm{T}_{\mathrm{A}}=150^{\circ} \mathrm{C}-70^{\circ} \mathrm{C}=80^{\circ} \mathrm{C}
$$

We calculate the thermal resistance allowed from junction to air:
$\theta \mathrm{JA}($ worst case $)=\Delta \mathrm{TJA} / \mathrm{PD}=80^{\circ} \mathrm{C} / 1.018 \mathrm{~W}=79.6^{\circ} \mathrm{C} / \mathrm{W}$
The thermal resistance from the die to the leads (case) is $25^{\circ} \mathrm{C} / \mathrm{W}$. Subtracting these two numbers gives the allowable thermal resistance from case to ambient:
$\theta \mathrm{CA}=\theta \mathrm{JA}-\theta \mathrm{JC}=79.6^{\circ} \mathrm{C} / \mathrm{W}-25^{\circ} \mathrm{C} / \mathrm{W}=54.6^{\circ} \mathrm{C} / \mathrm{W}$
The thermal resistance of this copper area will be $54.6^{\circ} \mathrm{C} / \mathrm{W}$. We now look at Figure 20 and find the PCB trace area that will be less than $54.5^{\circ} \mathrm{C} / \mathrm{W}$. Examination shows that $750 \mathrm{~mm}^{2}$ of copper will provide cooling for this part. This would be the SOIC part with the center 4 ground leads soldered to pads in the center of a copper area about 27 mm $\times 27 \mathrm{~mm}$. A lower dissipation or the addition of air-flow could result in a smaller required surface area.

## DESCRIPTION

The CS5231-3 application circuit has been implemented as shown in the following pages. The schematic, bill of materials and printed circuit board artwork can be used to build the circuit. The design is very simple and consists of two capacitors, a p-channel FET and the CS5231-3. Five turret pins are provided for connection of supplies, meters, oscilloscope probes and loads. The CS5231-3 power supply management solution is implemented in an area less than 1.5 square inches. Due to the simplicity of the design, output current must be derated if the CS5231-3 is operated at $\mathrm{V}_{\text {IN }}$ voltages greater than 7.0 V . Figure 21 provides the derating curve on a maximum power dissipation if heatsink is added.

Operating at higher power dissipation without CS5231-3 heatsink may result in a thermal shutdown condition.

Figure 21. Demo Board Output Current Derating vs. $\mathrm{V}_{\mathbf{I N}}$

## The $\mathrm{V}_{\mathrm{IN}}$ Connection

The $\mathrm{V}_{\text {IN }}$ connection is denoted as such on the PC board. The maximum input voltage to the IC is 14 V before damage to the IC is possible. However, the specification range for the IC is $4.75 \mathrm{~V}<\mathrm{V}_{\text {IN }}<6.0 \mathrm{~V}$.

## The GND Connection

The GND connection ties the IC power return to two turret pins. The extra turret pin provides for connection of multiple instrument grounds to the demonstration board.

## The AuxDrv Connection

The AuxDrv lead of the CS5231-3 is connected to the gate of the external PFET. This connection is also brought to a turret pin to allow easy connection of an oscilloscope probe for viewing the AuxDrv waveforms.

## The $\mathrm{V}_{\text {AUX }}$ Connection

The $\mathrm{V}_{\text {AUX }}$ turret pin provides a connection point between an external 3.3 V supply and the PFET drain.

## The Vout Connection

The $\mathrm{V}_{\text {OUT }}$ connection is tied to the $\mathrm{V}_{\text {OUT }}$ lead of the CS5231-3 and the PFET source. This point provides a convenient point at which some type of lead may be applied.

Figure 22. Application Circuit Schematic

## PC Board Layout Artwork

The PC Board is a single layer copper design. The layout artwork is reproduced at actual size below.

Figure 23. Top Copper Layer

Figure 24. Top Silk Screen Layer

## Test Description

The startup and supply transition waveforms shown in Figures 13 through 19 were obtained using the application circuit board with a resistive load of $8.8 \Omega$. This provides a DC load of 375 mA when the regulated output voltage is 3.3 V. A standard 2.0 A bench supply was used to provide power to the application circuit. The transient response waveforms shown in the Typical Performance Characteristics section were obtained by switching a $6.3 \Omega$ resistor across the output.

Temperature Performance
The graph below shows thermal performance for the CS5231-3 across the normal operating output current range.

## CS5233-3

## 500 mA and 1.5 A, 3.3 V Dual Input Linear Regulator with Auxiliary Control

The CS5233-3 provides a glitch-free 3.3 V output from one of three possible supplies, ( $\mathrm{V}_{\mathrm{IN}}, \mathrm{V}_{\mathrm{SB}}$ and $\left.3.3 \mathrm{~V}_{\mathrm{AUX}}\right)$. An on-chip linear regulator powers the output when either $\mathrm{V}_{\mathrm{IN}}$ or $\mathrm{V}_{\mathrm{SB}}$ is available. Otherwise AuxDrv turns on an external PFET, which connects the $3.3 \mathrm{~V}_{\mathrm{AUX}}$ supply to the output. The CS5233-3 is intended to provide power to an ASIC on a PCI Network Interface Card (NIC), and meets Intel's "Instantly Available" power requirements which follow from the Advanced Configuration and Power Interface (ACPI) standards. Other applications include desktop computers, power supplies with multiple input sources, and PCMCIA interface cards.

The CS5233-3 linear regulator provides a fixed 3.3 V output at up to 1.5 A with an overall accuracy of $\pm 2 \%$. The internal NPN-PNP composite pass transistor provides a low dropout voltage and requires less supply current than a straight PNP design. Full protection with both current limit and thermal shutdown is provided. Designed for low reverse current, the IC prevents excessive current from flowing from $\mathrm{V}_{\text {OUT }}$ to either $\mathrm{V}_{\text {IN }}$ or ground when the regulator input voltage is lower than the output. The auxiliary drive control feature allows the use of an external PFET to supply power to the output when the regulator supplies are off.

The CS5233-3 regulator is available in two package types: the 5 Lead D ${ }^{2}$ PAK package (TO-263) and 8 Lead SOIC with 4 Lead Fused (DF8) package. When powered from the $\mathrm{V}_{\text {IN }}$ source, the $\mathrm{D}^{2}$ PAK is rated for 1.5 A and the 8 Lead SOIC is rated for 500 mA . Both packages are rated for 500 mA when only powered from the $\mathrm{V}_{\mathrm{SB}}$ source.

## Features

- Linear Regulator
- $3.3 \mathrm{~V} \pm 2 \%$ Output Voltage
- Current Limit
- Thermal Shutdown with Hysteresis
- $400 \mu \mathrm{~A}$ Reverse Current
- ESD Protected
- System Power Management
- Auxiliary Supply Control
- "Glitch Free" Transition Between 3 Sources
- Similar to CS5231-3
- High Output Current Capability
$-1.5 \mathrm{~A} \mathrm{D}^{2} \mathrm{PAK}$
- 500 mA 8 Lead SOIC DF8
- Internally Fused Leads in SO-8 Package

## THEORY OF OPERATION

## Linear Regulator

The CS5233-3 is a dual input fixed 3.3 V linear regulator that contains an auxiliary drive control feature. When $\mathrm{V}_{\mathrm{IN}}$ alone is present, or $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {SB }}$ are simultaneously present, the CS5233-3 uses the $\mathrm{V}_{\text {IN }}$ supply to generate the 3.3 V output at currents of up to 1.5 A . When $\mathrm{V}_{\mathrm{SB}}$ alone is present, the CS5233-3 uses the $\mathrm{V}_{\mathrm{SB}}$ supply to generate the 3.3 V output at currents of up to 500 mA . The linear regulator is composed of a composite PNP-NPN pass transistor to provide low-voltage dropout capability. An output capacitor greater than $10 \mu \mathrm{~F}$ with equivalent series resistance (ESR) less than $1.0 \Omega$ is required for compensation. More information is provided in the Stability Considerations section.

## Auxiliary Drive Feature

The CS5233-3 provides an auxiliary drive feature that allows a load to remain powered even if both supplies to the IC are absent. An external p-channel FET is the only additional component required to implement this function when the auxiliary power supply is available. The PFET gate is connected to the IC's AuxDrv output, the PFET drain is connected to the auxiliary power supply, and the PFET source is connected to the load. The polarity of this connection is very important, since the PFET body diode will be connected between the load and the auxiliary supply. If the PFET is connected with its drain to the load and its source to the supply, the body diode could be forward-biased if the auxiliary supply is not present. This would result in the linear regulator providing current to everything on the auxiliary supply rail.

The AuxDrv ( 5.0 V detect) output is pulled up to the input voltage through an internal resistor when $\mathrm{V}_{\text {IN }}$ or $\mathrm{V}_{\mathrm{SB}}$ are available. If $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {SB }}$ are not available or both drop below 4.4 V , the AuxDrv output goes low, turning on an external PFET that connects the 3.3 V auxiliary supply to the
load. The AuxDrv is low only when neither $\mathrm{V}_{\text {IN }}$ nor $\mathrm{V}_{\mathrm{SB}}$ are available.
There is 100 mV of hysteresis (typical) in the circuitry that determines if $\mathrm{V}_{\mathrm{IN}}$ or $\mathrm{V}_{\mathrm{SB}}$ are present.

## STABILITY CONSIDERATIONS

The output capacitor helps determine three main characteristics of a linear regulator: loop stability, load transient response, and start-up delay. The CS5233-3 is designed to be stable with an output capacitor that has a minimum value of $10 \mu \mathrm{~F}$ and an equivalent series resistance less than $1.0 \Omega$. To guarantee loop stability, the output capacitor should be located close to the regulator output and ground pins. The load transient response, during the time it takes the regulator to respond, is also determined by the output capacitor. For large changes in load current, the ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

There is then an additional drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{T} / \mathrm{C}
$$

where T is the time for the regulation loop to begin to respond, (typically $4.0 \mu$ s for the CS5233-3). If tight output regulation is required with fast changing loads, a capacitor network of tantalum and low ESR ceramic capacitors can be added as close to the load as possible, with enough capacitance and a reduced ESR to minimize the voltage change, as determined by the formulas above.

## Input Capacitors and the Vin Thresholds

A capacitor placed on the $\mathrm{V}_{\text {IN }}$ pin will help to improve transient response. During a load transient, the input capacitor serves as a charge "reservoir," providing the needed extra current until the external power supply can
respond. One of the consequences of providing this current is an instantaneous voltage drop at $\mathrm{V}_{\text {IN }}$ due to capacitor ESR. The magnitude of the voltage change is again the product of the current change and the capacitor ESR.

It is very important to consider the maximum current step that can exist in the system. If the change in current is large enough, it is possible that the instantaneous voltage drop on $\mathrm{V}_{\text {IN }}$ will exceed the $\mathrm{V}_{\text {IN }}$ threshold hysteresis, and the IC will enter a mode of operation resembling an oscillation. As the part turns on, the output current IOUT will increase, reaching current limit during initial charging. Increasing IOUT results in a drop at $\mathrm{V}_{\text {IN }}$ such that the shutdown threshold is reached. The part will turn off, and the load current will decrease. As IOUT decreases, $\mathrm{V}_{\text {IN }}$ will rise and the part will turn on, starting the cycle all over again. This oscillatory operation is most likely at initial start-up when the output capacitance is not charged, and in cases where the ramp-up of the $\mathrm{V}_{\mathrm{IN}}$ supply is slow. It may also occur during the power transition when the linear regulator turns on and the PFET turns off. A $20 \mu \mathrm{~s}$ delay exists between turn-on of the regulator and the AuxDrv pin pulling the gate of the PFET high. This delay prevents "chatter" during the power transitions.

If required, using a few capacitors in parallel to increase the bulk charge storage and reduce the ESR should give better performance than using a single input capacitor. Short, straight connections between the power supply and $\mathrm{V}_{\text {IN }}$ lead along with careful layout of the PC board ground plane will reduce parasitic inductance effects. Wide $\mathrm{V}_{\text {IN }}$ and $V_{\text {OUT }}$ traces will reduce resistive voltage drops.

## Choosing the PFET Switch

The choice of the external PFET switch is based on two main considerations. First, the PFET should have a very low turn-on threshold. Choosing a switch transistor with $\mathrm{V}_{\mathrm{GS}(\mathrm{ON})} \approx 1.0 \mathrm{~V}$ will ensure the PFET will be fully enhanced with only 3.3 V of gate drive voltage. Second, the switch transistor should be chosen to have a low $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ to minimize the voltage drop due to current flow in the switch. The formula for calculating the maximum allowable on-resistance is

$$
\operatorname{RDS}(\mathrm{ON}) \mathrm{MAX}=\frac{\mathrm{V}_{\text {AUX }}(\mathrm{MIN})-\mathrm{V}_{\text {OUT }}(\mathrm{MIN})}{1.5 \times \operatorname{lOUT}(\mathrm{MAX})}
$$

$\mathrm{V}_{\text {AUX(MIN) }}$ is the minimum value of the auxiliary supply voltage, $\mathrm{V}_{\mathrm{OUT}(\mathrm{MIN})}$ is the minimum allowable output voltage, $\mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})}$ is the maximum output current and 1.5 is a "fudge factor" to account for increases in $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ due to temperature.

## Output Voltage Sensing

It is not possible to remotely sense the output voltage of the C5233-3 since the feedback path to the error amplifier is not externally available. It is important to minimize voltage drops due to metal resistance of high current PC board traces. Such voltage drops can occur in both the supply traces and the return traces.

The following board layout practices will help to minimize output voltage errors:

- Always place the linear regulator as close to both load and output capacitors as possible.
- Always use the widest possible traces to connect the linear regulator to the capacitor network and to the load.
- Connect the load to ground through the widest possible traces.
- Connect the IC ground to the load ground trace at the point where it connects to the load.

## Current Limit

The CS5233-3 has internal current limit protection. Output current is limited to a typical value of 3.0 A for the $D^{2}$ PAK using $V_{\text {IN }}$ and 800 mA using $\mathrm{V}_{\mathrm{SB}}$, even under output short circuit conditions. If the load current drain exceeds the current limit value, the output voltage will be pulled down and will result in an out of regulation condition.

## Thermal Shutdown

The CS5233-3 has internal temperature monitoring circuitry. The output is disabled if junction temperature of the IC reaches $180^{\circ} \mathrm{C}$. Thermal hysteresis is typically $25^{\circ} \mathrm{C}$ and allows the IC to recover from a thermal fault without the need for an external reset signal. The monitoring circuitry is located near the composite PNP-NPN output transistor, since this transistor is responsible for most of the on-chip power dissipation. The combination of current limit and thermal shutdown will protect the IC from nearly any fault condition.

## Reverse Current Protection

During normal system operation, the auxiliary drive circuitry will maintain voltage on the VOUT pin. IC reliability and system efficiency are improved by limiting the amount of reverse current that flows from $\mathrm{V}_{\text {OUT }}$ to ground and from $\mathrm{V}_{\text {OUT }}$ to $\mathrm{V}_{\text {IN }}$. Current flows from $\mathrm{V}_{\text {OUT }}$ to ground through the feedback resistor divider that sets up the output voltage, typically $400 \mu \mathrm{~A}$. Current flow from V VUT to $\mathrm{V}_{\text {IN }}$ will be limited to leakage current after the IC shuts down. On-chip RC time constants are such that the output transistor should be turned off well before $\mathrm{V}_{\text {IN }}$ drops below the $\mathrm{V}_{\text {OUT }}$ voltage.

## Calculating Power Dissipation and Heatsink Requirements

Most linear regulators operate under conditions that result in high on-chip power dissipation. This results in high junction temperatures. Since the IC has a thermal shutdown feature, ensuring the regulator will operate correctly under normal conditions is an important design consideration. Some heatsinking will usually be required.

Thermal characteristics of an IC depend on four parameters: ambient temperature ( $\mathrm{T}_{\mathrm{A}}$ in ${ }^{\circ} \mathrm{C}$ ), power dissipation ( $\mathrm{P}_{\mathrm{D}}$ in watts), thermal resistance from the die to the ambient air $\left(\theta_{\mathrm{JA}}\right.$ in ${ }^{\circ} \mathrm{C}$ per watt $)$ and junction temperature
( $\mathrm{T}_{\mathrm{J}}$ in ${ }^{\circ} \mathrm{C}$ ). The maximum junction temperature is calculated from the formula below:

$$
\mathrm{T}_{\mathrm{J}(\mathrm{MAX})}=\mathrm{T}_{\mathrm{A}(\mathrm{MAX})}+\theta \mathrm{JA} \times \mathrm{P}_{\mathrm{D}}(\mathrm{MAX})
$$

Maximum ambient temperature and power dissipation are determined by the design, while $\theta_{\mathrm{JA}}$ is dependent on the package manufacturer. The maximum junction temperature for operation of the CS5233-3 within specification is $150^{\circ} \mathrm{C}$. The maximum power dissipation of a linear regulator is given as

$$
\begin{aligned}
\operatorname{PD}(\mathrm{MAX})= & \left(\mathrm{VIN}^{\prime}(\mathrm{MAX})-\mathrm{V}_{\mathrm{OUT}}(\mathrm{MIN})\right) \\
& \times \operatorname{ILOAD}(\mathrm{MAX})+\mathrm{V}_{\mathrm{IN}(\mathrm{MAX})} \\
& \times \operatorname{IGND}(\mathrm{MAX})
\end{aligned}
$$

where $\mathrm{I}_{\mathrm{GND}(\mathrm{MAX})}$ is the IC bias current.
It is possible to change the effective value of $\theta_{\mathrm{JA}}$ by adding a heatsink to the design. A heatsink serves in some manner to raise the effective area of the package, thus improving the flow of heat from the package into the surrounding air. Each material in the path of heat flow has its own characteristic thermal resistance, all measured in ${ }^{\circ} \mathrm{C}$ per watt. The thermal resistances are summed to determine the total thermal resistance between the die junction and air. There are three components of interest: junction-to-case thermal resistance $\left(\theta_{\mathrm{JC}}\right)$, case-to-heatsink thermal resistance $\left(\theta_{\mathrm{CS}}\right)$ and heatsink-to-air thermal resistance $\left(\theta_{\mathrm{SA}}\right)$. The resulting equation for junction-to-air thermal resistance is

$$
\begin{aligned}
& \theta \mathrm{JA}=\theta \mathrm{JC}+\theta \mathrm{CS}+\theta \mathrm{SA}, \text { or } \\
& \theta \mathrm{JA}=\theta \mathrm{JC}+\theta \mathrm{SA} \text { for } \theta \mathrm{CS}=0
\end{aligned}
$$

The value of $\theta_{\mathrm{JC}}$ for the CS5233-3 is provided in the Packaging Information section of this data sheet. $\theta_{\mathrm{CS}}$ can be considered zero, since heat is conducted out of the package by the IC leads and the tab of the $\mathrm{D}^{2}$ PAK package, and since the IC leads and tab are soldered directly to the PC board.

Modification of $\theta_{\mathrm{SA}}$ is the primary means of thermal management. For surface mount components, this means modifying the amount of trace metal that connects to the IC.

The thermal capacity of PC board traces is dependent on how much copper area is used, if the IC is in direct contact with the metal, whether the metal surface is coated with some type of sealant, and whether there is airflow across the PC board. The chart provided below shows heatsinking capability of a square, single sided copper PC board trace. The area is given in square millimeters, and it is assumed there is no airflow across the PC board.

Figure 12. Thermal Resistance Capability of Copper PC Board Metal Traces

## CS8140, CS8141

### 5.0 V, 500 mA Linear Regulator with ENABLE, RESET, and Watchdog

The CS8140 and CS8141 are linear regulators suited for microprocessor applications in automotive environments.

These ON Semiconductor parts provide the power for the microprocessors along with many of the control functions needed in today's computer based systems. Incorporating all of these features saves both cost, and board space.

Packages are available for surface mounting as well as through hole mounting.

The CS8141 has the same feature set as the CS8140 with the exception of the response to the watchdog signals (WDI). The CS8141 only responds to input signals (WDI) which are below the preset watchdog frequency threshold.

## Features

- $5.0 \mathrm{~V} \pm 4.0 \%$, 500 mA Output Voltage
- $\mu \mathrm{P}$ Compatible Control Functions
- Watchdog
- $\overline{\text { RESET }}$
- ENABLE
- Low Dropout Voltage (1.25 V @ 500 mA )
- Low Quiescent Current ( 7.0 mA @ 500 mA )
- Low Noise, Low Drift
- Low Current SLEEP Mode ( $\mathrm{I}_{\mathrm{Q}}=250 \mu \mathrm{~A}$ )
- Fault Protection
- Thermal Shutdown
- Short Circuit
- 60 V Peak Transient Voltage

## DEFINITION OF TERMS

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques
such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.
Quiescent Current: The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.
Ripple Rejection: The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.
Current Limit: Peak current that can be delivered to the output.

## CIRCUIT DESCRIPTION

The CS8140 is a 5.0 V Watchdog Regulator with protection circuitry and three logic control functions that allow a microprocessor to control its own power supply. The CS8140 is designed for use in automotive, switch mode power supply post regulator, and battery powered systems.

Basic regulator performance characteristics include a low noise, low drift, $5.0 \mathrm{~V} \pm 4.0 \%$ precision output voltage with low dropout voltage ( 1.25 V @ $\mathrm{I}_{\mathrm{OUT}}=500 \mathrm{~mA}$ ) and low quiescent current ( 7.0 mA @ $\mathrm{I}_{\text {OUT }}=500 \mathrm{~mA}$ ). On board short circuit, thermal, and overvoltage protection make it possible to use this regulator in particularly harsh operating environments.

The Watchdog logic function monitors an input signal (WDI) from the microprocessor or other signal source. When the signal frequency moves outside externally programmable window limits, a RESET signal is generated ( $\overline{\text { RESET }}$ ). An external capacitor (CDELAY) programs the watchdog window frequency limits as well as the power on reset (POR) and RESET delay.

The $\overline{\text { RESET }}$ function is activated by any of three conditions: the watchdog signal moves outside of its preset limits; the output voltage drops out of regulation by more than $4.5 \%$; or the IC is in its power up sequence. The $\overline{\text { RESET }}$ signal is independent of $\mathrm{V}_{\mathrm{IN}}$ and reliable down to $\mathrm{V}_{\text {OUT }}=$ 1.0 V .

In conjunction with the Watchdog, the ENABLE function controls the regulator's power consumption. The CS8140's output stage and its attendant circuitry are enabled by setting the ENABLE lead high. The regulator goes into sleep mode when the ENABLE lead goes low and the watchdog signal moves outside its preset window limits. This unique combination of control functions in the CS8140 gives the microprocessor control over its own power down sequence: i.e. it gives the microprocessor the flexibility to perform housekeeping functions before it powers down.

The CS8141 has the same features as the CS8140, except that the CS8141 only responds to input signals (WDI) which are below the preset watchdog frequency threshold.

## VOLTAGE REFERENCE AND OUTPUT CIRCUITRY

## Precision Voltage Reference

The regulated output voltage depends on the precision band gap voltage reference in the IC. By adding an error amplifier into the feedback loop, the output voltage is maintained within $\pm 4.0 \%$ over temperature and supply variation.

## Output Stage

The composite PNP-NPN output structure (Figure 14) provides $500 \mathrm{~mA}(\mathrm{~min})$ of output current while maintaining a low drop out voltage ( 1.25 V ) and drawing little quiescent current ( 7.0 mA ).

Figure 14. Composite Output Stage of the CS8140/1
The NPN pass device prevents deep saturation of the output stage which in turn improves the IC's efficiency by preventing excess current from being used and dissipated by the IC.

## Output Stage Protection

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 15).
If the input voltage rises above 30 V (e.g. load dump), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients.
Using an emitter sense scheme, the amount of current through the NPN pass transistor is monitored. Feedback
circuitry insures that the output current never exceeds a preset limit.

Figure 15. Typical Circuit Waveforms for Output Stage Protection

Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ), the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

## REGULATOR CONTROL FUNCTIONS

The CS8140 differs from all other linear regulators in its unique combination of control features.

## Watchdog and ENABLE Function

$V_{\text {OUT }}$ is controlled by the logic functions ENABLE and Watchdog (Table 1).

Table 1. V OUt as a Function of ENABLE and Watchdog

| $\mathrm{V}_{\text {OUT }}$ (V) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | WDI |  |  |  |  |
| ENABLE | Slow | Normal | Fast | High | Low |
| H | 5 | 5 | 5 | 5 | 5 |
| L | 0 | 5 | 0 | 0 | 0 |

As long as ENABLE is high or ENABLE is low and the Watchdog signal is normal, $\mathrm{V}_{\text {OUT }}$ will be at 5.0 V (typ). If ENABLE is low and the Watchdog signal moves outside programmable limits, the output transistor turns off and the IC goes into SLEEP mode. Only the ENABLE circuitry in the IC remains powered up, drawing a quiescent current of $250 \mu \mathrm{~A}$.

The Watchdog monitors the frequency of an incoming WDI signal. If the signal falls outside of the WDI window, a frequency programmable pulse train is generated at the RESET lead (Figure 16) until the correct Watchdog input signal reappears at the lead $(\mathrm{ENABLE}=\mathrm{HIGH})$.

The lower and upper window threshold limits of the watchdog function are set by the value of CDELAY. The limits are determined according to the following equations for the CS8140:
(a) $\operatorname{tWDI}($ LOWER $)=(1.3 \times 105)$ CDELAY or fWDI $($ LOWER $)=\left(7.69 \times 10^{-6}\right)$ CDELAY $^{-1}$
(b) tWDI(UPPER) $=\left(3.82 \times 10^{-4}\right)$ CDELAY or fWDI(UPPER) $=\left(2.62 \times 10^{-5}\right)$ CDELAY $^{-1}$

For the CS8141 the lower limit is determined by the equations in (a) above.
The capacitor CDELAY also determines the frequency of the $\overline{\mathrm{RESET}}$ signal and the POWER-ON- $\overline{\mathrm{RESET}}$ (POR) delay period.

## RESET Function

The RESET function is activated when the Watchdog signal is outside of its preset window (Figure 16), when the regulator is in its power up state (Figure 17) or when $\mathrm{V}_{\text {OUT }}$ drops below $\mathrm{V}_{\text {OUT }}-4.5 \%$ for more than $2.0 \mu \mathrm{~s}$ (Figure 18)
If the Watchdog signal falls outside of the preset voltage and frequency window, a frequency programmable pulse train is generated at the RESET lead (Figure 16) until the correct Watchdog input signal reappears at the lead. The duration of the RESET pulse is determined by CDELAY according to the following equation:

$$
\operatorname{tWDI}(\overline{\mathrm{RESET}})=\left(1.0 \times 10^{4}\right) \mathrm{CDELAY}
$$

## RESET CIRCUIT WAVEFORMS WITH DELAYS INDICATED

If an undervoltage condition exists, the voltage on the $\overline{\text { RESET }}$ lead goes low and the delay capacitor, C DELAY, is discharged. RESET remains low until output is in regulation, the voltage on CDELAY exceeds the upper switching threshold and the Watchdog input signal is within its set window limits (Figures 17 and 18). The delay after the output is in regulation is:

$$
\operatorname{tPOR}(\operatorname{typ})=\left(4.75 \times 10^{5}\right) \text { CDELAY }
$$

The $\overline{\text { RESET }}$ delay circuit is also programmed with the external cap C DELAY.
The output of the reset circuit is an open collector NPN. $\overline{\mathrm{RESET}}$ is operational down to $\mathrm{V}_{\text {OUT }}=1.0 \mathrm{~V}$. Both $\overline{\mathrm{RESET}}$ and its delay are governed by comparators with hysteresis to avoid undesirable oscillations.
$V_{\text {Out }}$ When Watchdog is Held High and ENABLE $=$ HIGH
$V_{\text {Out }}$ When Watchdog is Held Low and ENABLE = HIGH

## APPLICATION NOTES

## CS8140 DESIGN EXAMPLE

The CS8140 with its unique integration of linear regulator and control features: RESET, ENABLE and WATCHDOG, provides a single IC solution for a microprocessor power supply. The reset delay, reset duration and watchdog frequency limits are all determined by a single capacitor. For a particular microprocessor the overriding requirement is usually the reset delay (also known as power on reset). The capacitor is chosen to meet this requirement and the reset duration and watchdog frequency follow.

The reset delay is given by:

$$
\operatorname{tPOR}(\operatorname{typ})=(4.75 \times 105) \text { CDELAY }
$$

Assume that the reset delay must be 200 ms minimum.
From the CS8140 data sheet the reset delay has a $\pm 37 \%$ tolerance due to the regulator.

Assume the capacitor tolerance is $\pm 10 \%$.

$$
\begin{aligned}
\operatorname{tPOR}(\mathrm{min})= & \left(4.75 \times 10^{5} \times 0.63\right) \times \operatorname{CDELAY} \times 0.9 \\
& \operatorname{CDELAY}(\mathrm{~min})=\frac{\mathrm{tPOR}(\mathrm{~min})}{2.69 \times 105} \\
& \operatorname{CDELAY}^{(\mathrm{min})}=0.743 \mu \mathrm{~F}
\end{aligned}
$$

Closest standard value is $0.82 \mu \mathrm{~F}$.
Minimum and maximum delays using $0.82 \mu \mathrm{~F}$ are 220 ms and 586 ms .

The duration of the reset pulse is given by:

$$
\text { TWDI( } \overline{\text { RESET }})(\text { typ })=\left(1.0 \times 10^{4}\right) \times \text { CDELAY }
$$

This has a tolerance of $\pm 50 \%$ due to the IC, and $\pm 10 \%$ due to the capacitor.

The duration of the reset pulse ranges from 3.69 ms to 13.5 ms .

The watchdog signal can be expressed as a frequency or time. From a programmers point of view, time is more useful since they must ensure that a watchdog signal is issued consistently several times per second.

The maximum and minimum watchdog times are given by:

$$
\begin{aligned}
& \operatorname{tWDI(LOWER)}=\left(1.3 \times 10^{5}\right) \text { CDELAY } \\
& \mathrm{tWDI}(\text { UPPER })=\left(3.82 \times 10^{4}\right) \text { CDELAY }
\end{aligned}
$$

There is a tolerance of $\pm 20 \%$ due to the CS8140. With a capacitor tolerance of $\pm 10 \%$ :

$$
\begin{gathered}
\text { tWDI(LOWER) }=\left(1.3 \times 10^{5}\right) \times 1.2 \times 1.1 \times \text { CDelay } \\
\text { tWDI(UPPER) }=\left(3.82 \times 10^{4}\right) \times 0.8 \times 0.9 \times \text { CDelay } \\
\text { tWDI }(\text { LOWER })=141 \mathrm{~ms}(\mathrm{max}) \\
\text { tWDI }(\mathrm{UPPER})=22.5 \mathrm{~ms}(\mathrm{max}) \\
\text { tWDI }(\mathrm{LOWER})=\left(1.3 \times 10^{5}\right) \times 0.8 \times 0.9 \times \text { CDELAY } \\
\text { tWDI }(\text { UPPER })=\left(3.82 \times 10^{4}\right) \times 1.2 \times 1.1 \times \text { CDELAY } \\
\text { tWDI }(\text { LOWER })=76 \mathrm{~ms}(\mathrm{~min}) \\
\text { tWDI }(\text { UPPER })=41 \mathrm{~ms}(\mathrm{~min})
\end{gathered}
$$

The software must be written so that a watchdog signal arrives at least every 76 ms but not faster than every 41 ms (Figure 19).

Figure 19. WDI Signal for $C_{\text {Delay }}=0.82 \mu \mathrm{~F}$ using CS8140
The CS8141 is identical to the CS8140 except that the CS8141 only has a lower watchdog frequency threshold. The designer using this part need only be concerned with $t_{\text {WDI(LOWER) }}$ as shown in Figure 20.

Figure 20. WDI Signal for $C_{\text {Delay }}=0.82 \mu \mathrm{~F}$ using CS8141

## ENERGY CONSERVATION AND SMART FEATURES

Energy conservation is another benefit of using a regulator with integrated microprocessor control features. Using the CS8140 or CS8141 as indicated in Figure 21, the microprocessor can control its own power down sequence. The momentary contact switch quickly charges C1 through R1.

When the voltage across C 1 reaches 3.95 V ( the enable threshold), the output switches on and $\mathrm{V}_{\text {OUT }}$ rises to 5.0 V . After a delay period determined by $\mathrm{C}_{\text {Delay }}$, a frequency programmable reset pulse train is generated at the reset output. The pulse train continues until the correct watchdog signal appears at the WDI lead. C1 is now left to discharge through the input impedance of the enable lead (approximately $150 \mathrm{k} \Omega$ ) and the enable signal disappears. The output voltage remains at 5.0 V as long as the CS8140 continues to receive the correct watchdog signal.
The microprocessor can power itself down by terminating its watchdog signal. When the microprocessor finishes its housekeeping or power down software routine, it stops sending a watchdog signal. In response, the regulator generates a reset signal and goes into a sleep mode where $\mathrm{V}_{\text {OUT }}$ drops to 0 V , shutting down the microprocessor.

Figure 21. Application Diagram for CS8140. The CS8140 Provides a 5.0 V Tightly Regulated Supply and Control Function to the Microprocessor. In this Application, the Microprocessor Controls its own Power Down Sequence (see text).

${ }^{* *} \mathrm{C} 2$ is required for stability.
${ }^{* * *} \mathrm{R} \leq 80 \mathrm{k} \Omega$.
Figure 22. Application Diagram

## STABILITY CONSIDERATIONS

The output or compensation capacitor $\mathrm{C}_{2}$ in Figure 22 helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor $\mathrm{C}_{2}$ shown in Figure 22 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for $\mathrm{C}_{2}$ for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Increase the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.
Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 23) is:
$\mathrm{P}_{\mathrm{D}(\text { max })}=\left\{\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}(\min )}\right)_{\mathrm{IOUT}(\max )}+\mathrm{V}_{\mathrm{IN}(\max )} \mathrm{I}_{\mathrm{Q}}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$\mathrm{I}_{\text {OUT(max) }}$ is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Figure 23. Single Output Regulator With Key Performance Parameters Labeled

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\text {©JA's }}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## Micropower Voltage Regulator

The MC78BC00 voltage regulators are specifically designed to be used with an external power transistor to deliver high current with high voltage accuracy and low quiescent current.

The MC78BC00 series are devices suitable for constructing regulators with ultra-low dropout voltage and output current in the range of several tens of mA to hundreds of mA . These devices have a chip enable function, which minimizes the standby mode current drain. Each of these devices contains a voltage reference unit, an error amplifier, a driver transistor and feedback resistors. These devices are available in the SOT-23, 5 pin surface mount packages.

These devices are ideally suited for battery powered equipment, and power sources for hand-held audio instruments, communication equipment and domestic appliances.

## MC78BC00 Series Features:

- Ultra-Low Supply Current ( $50 \mu \mathrm{~A}$ )
- Standby Mode ( $0.2 \mu \mathrm{~A}$ )
- Ultra-Low Dropout Voltage ( 0.1 V with External Transistor and $\mathrm{I}_{\mathrm{O}}=100 \mathrm{~mA}$ )
- Excellent Line Regulation (Typically 0.1\%/V)
- High Accuracy Output Voltage ( $\pm 2.5 \%$ )

NOTES: 1. Low duty pulse techniques are used during test to maintain junction temperature as close to ambient as possible.
2. The output current depends upon the performance of External PNP Transistor. Use External PNP Transistor of a low saturation type, with an $\mathrm{H}_{\mathrm{FE}}$ of 100 or more.

## MC78BC00 Series

## DEFINITIONS

Dropout Voltage - The input/output voltage differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.
Line Regulation - The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques
such that average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Maximum Power Dissipation - The maximum total device dissipation for which the regulator will operate within specifications.
Supply Current - Current which is used to operate the regulator chip and is not delivered to the load.

## APPLICATIONS INFORMATION

## Introduction

The MC78BC00 series of micropower voltage regulators are specifically designed for ultra-low dropout voltage and an output current which ranges from several tens of mA to several hundreds of mA making them ideal for battery-powered equipment. These regulators also have a chip enable function which minimizes supply current in stand-by mode. An input bypass capacitor is recommended if the regulator is located an appreciable distance ( $\geq 4$ inches) from the input voltage source. These regulators require a $10 \mu \mathrm{~F}$ capacitance between the output terminal and ground for stability. Most types of aluminum, tantalum or multilayer ceramic will perform adequately. Solid tantalums or other appropriate capacitors are recommended for
operation below $25^{\circ} \mathrm{C}$. The bypass capacitors should be mounted with the shortest possible leads or track lengths directly across the regulator input and output terminals.

With economical electrolytic capacitors, cold temperature operation can pose a serious stability problem. As the electrolyte freezes, around $-30^{\circ} \mathrm{C}$, the capacitance will decrease and the equivalent series resistance (ESR) will increase drastically, causing the circuit to oscillate. Quality electrolytic capacitors with extended temperature ranges of $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$ are readily available. Solid tantalum capacitors may be the better choice if small size is a requirement. However, a maximum ESR limit of $3.0 \Omega$ must be observed over temperature to maintain stability.

Figure 9. Typical Operation

## MC78BC00 Series

## External PNP Transistor

The external pin of this IC is protected by a current limit circuit from the destruction caused by excess current. The R2 resistor shown in Figure 10 is used for the protection of
the external transistor, although this circuit can operate without the resistor. Resistor R2 should be determined via the input voltage, output voltage, output current, temperature and the $\mathrm{H}_{\mathrm{FE}}$ of the external pass transistor.

Figure 10. External PNP

Figure 11. Typical Application

## CS403

### 5.0 V, 750 mA Linear Regulator with RESET

The CS403 is a linear regulator specially designed as a post regulator. The CS403 provides low noise, low drift, and high accuracy to improve the performance of a switching power supply. It is ideal for applications requiring a highly efficient and accurate linear regulator. The active RESET makes the device particularly well suited to supply microprocessor based systems. The PNP-NPN output stage assures a low dropout voltage without requiring excessive supply current. Its features include low dropout ( 1.0 V typically) and low supply drain ( 4.0 mA typical with $\mathrm{I}_{\mathrm{OUT}}=500 \mathrm{~mA}$ ).

The CS403 design optimizes supply rejection by switching the internal reference from the supply input to the regulator output as soon as the nominal output voltage is reached.

## Features

- 5.0 V $\pm 3.0 \%$ Output Voltage
- Low Drift
- High Efficiency
- Short Circuit Protection
- Active Delayed Reset
- Noise Immunity on Reset
- 750 mA Output Current

RESET CIRCUIT

Figure 5. Reset Circuit Waveform

## CIRCUIT DESCRIPTION

The CS403 $\overline{\text { RESET }}$ function is very precise, has hysteresis on both the $\overline{\text { RESET }}$ and Delay comparators, a latching Delay capacitor discharge circuit, and operates down to 1.0 V .

The $\overline{\text { RESET }}$ circuit output is an open collector type with ON and OFF parameters as specified. The $\overline{\text { RESET }}$ output NPN transistor is controlled by the two circuits described (see Figure 1).

## Low Voltage Inhibit Circuit

This circuit monitors output voltage, and when output voltage is below the specified minimum, causes the $\overline{\text { RESET }}$ output transistor to be in the ON (saturation) state. When the output voltage is above the specified level, this circuit permits the RESET output transistor to go into the OFF state if allowed by the reset Delay circuit.

## Reset Delay Circuit

This circuit provides a programmable (external capacitor) delay on the $\overline{\text { RESET }}$ output lead. The Delay lead provides source current to the external delay capacitor only when the

Low Voltage Inhibit circuit indicates that output voltage is above $\mathrm{V}_{\mathrm{RT}(\mathrm{ON})}$. Otherwise, the Delay lead sinks current to ground (used to discharge the Delay capacitor). The discharge current is latched ON when the output voltage is below $\mathrm{V}_{\mathrm{RT}(\mathrm{OFF})}$, or when the voltage on the Delay capacitor is above $\mathrm{V}_{\text {DIS }}$. In other words, the Delay capacitor is fully discharged any time the output voltage falls out of regulation, even for a short period of time. This feature ensures a controlled RESET pulse is generated following detection of an error condition. The circuit allows the $\overline{\text { RESET }}$ output transistor to go to the OFF (open) state only when the voltage on the Delay lead is higher than $\mathrm{V}_{\text {DIS }}$.

$$
\mathrm{t}_{\mathrm{d}}=\mathrm{C}_{\mathrm{d}} \times \mathrm{V}_{\mathrm{DTC}} / \mathrm{I}_{\mathrm{CH}}=\text { CDelay } \times 2.105 \text { (typical). }
$$

where:
$\mathrm{t}_{\mathrm{d}}=$ Time delay.
$C_{d}=$ Value of external charging capacitor (see Figure 6).
$\mathrm{V}_{\mathrm{DTC}}=$ Delay Threshold charge.
$\mathrm{I}_{\mathrm{ch}}=$ Reset delay capacitor charging current.

$\mathrm{C}_{1}{ }^{*}$ is required if the regulator is far from the power source filter. $\mathrm{C}_{2}{ }^{* *}$ is required for stability.

Figure 6. Test Circuit

## APPLICATION NOTES

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor Cout shown in the test and applications circuit should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for COUT for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.
Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the
higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.
Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.
Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 7) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$I_{\text {OUT(max) }}$ is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \text { JA }}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\text {©JA }}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 7. Single Output Regulator With Key Performance Parameters Labeled

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JJC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like
$R_{\Theta J A}$, it is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8122

## 2.0\% 5.0 V, 750 mA Low Dropout Linear Regulator with Delayed RESET

The CS8122 is a precision 5.0 V linear regulator capable of sourcing in excess of 750 mA . The $\overline{\mathrm{RESET}}$ 's delay time is externally programmed using a discrete RC network. During power up, or when the output goes out of regulation, the RESET lead remains in the low state for the duration of the delay. This function is independent of the input voltage and will function correctly as long as the output voltage remains at or above 1.0 V . Hysteresis is included in the Delay and the RESET comparators to improve noise immunity. A latching discharge circuit is used to discharge the delay capacitor when it is triggered by a brief fault condition.

The regulator is protected against a variety of fault conditions: i.e. reverse battery, overvoltage, short circuit and thermal runaway conditions. The regulator is protected against voltage transients ranging from -50 V to +40 V . Short circuit current is limited to 1.2 A (typ).

The CS8122 is an improved replacement for the CS8126 and features a tighter tolerance on its output voltage ( $2.0 \%$ vs. $4.0 \%$ ).

The CS8122 is packaged in a 5 lead TO-220 with copper tab. The copper tab can be connected to a heat sink if necessary.

## Features

- 5.0 V $\pm 2.0 \%$ Regulated Output
- Low Dropout Voltage ( 0.6 V @ 0.5 A )
- 750 mA Output Current Capability
- Externally Programmed $\overline{\text { RESET }}$ Delay
- Fault Protection
- Reverse Battery
- 60 V Load Dump
- -50 V Reverse Transient
- Short Circuit
- Thermal Shutdown

## CIRCUIT DESCRIPTION

The CS8122 $\overline{\text { RESET }}$ function, has hysteresis on both the reset and delay comparators, a latching Delay capacitor discharge circuit, and operates down to 1.0 V .

The RESET circuit output is an open collector type with ON and OFF parameters as specified. The RESET output NPN transistor is controlled by the two circuits described (see Block Diagram on page 588).

## Low Voltage Inhibit Circuit

The Low Voltage Inhibit Circuit monitors output voltage, and when output voltage is below the specified minimum, causes the $\overline{\text { RESET }}$ output transistor to be in the ON (saturation) state. When the output voltage is above the specified level, this circuit permits the $\overline{\text { RESET }}$ output transistor to go into the OFF state if allowed by the $\overline{\mathrm{RESET}}$ Delay circuit.

## Reset Delay Circuit

The Reset Delay Circuit provides a programmable (by external capacitor) delay on the $\overline{\text { RESET }}$ output lead. The Delay lead provides source current to the external delay capacitor only when the Low Voltage Inhibit circuit indicates that output voltage is above $\mathrm{V}_{\mathrm{RT}(\mathrm{ON})}$. Otherwise, the Delay lead sinks current to ground (used to discharge the
delay capacitor). The discharge current is latched ON when the output voltage is below $\mathrm{V}_{\mathrm{RT}(\mathrm{OFF})}$. The Delay capacitor is fully discharged anytime the output voltage falls out of regulation, even for a short period of time. This feature ensures that a controlled $\overline{\text { RESET }}$ pulse is generated following detection of an error condition. The circuit allows the RESET output transistor to go to the OFF (open) state only when the voltage on the Delay lead is higher than $\mathrm{V}_{\mathrm{DC}(\mathrm{HI})}$.

${ }^{*} \mathrm{C}_{I N}$ is required if regulator is far from the power source filter.
${ }^{* *} \mathrm{C}_{\text {OUT }}$ is required for stability.
Figure 13. Test Circuit

## APPLICATION NOTES

## STABILITY CONSIDERATIONS

The output or compensation capacitor, Cout, helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor Cout shown in Figure 13 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for COUT for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 14) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$\mathrm{I}_{\mathrm{OUT}(\max )}$ is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at

## IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J A}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 14. Single Output Regulator With Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

PACKAGE THERMAL DATA

| Parameter |  | TO-220 <br> FIVE LEAD | Unit |
| :--- | :---: | :---: | :---: |

| $\mathrm{R}_{\Theta \mathrm{JA}}$ | Typical | 50 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## CS8126

### 5.0 V, 750 mA Low Dropout Linear Regulator with Delayed RESET

The CS8126 is a low dropout, high current 5.0 V linear regulator. It is an improved replacement for the CS8156. Improvements include higher accuracy, tighter saturation control, better supply rejection, and enhanced $\overline{\text { RESET }}$ circuitry. Familiar PNP regulator features such as reverse battery protection, overvoltage shutdown, thermal shutdown, and current limit make the CS8126 suitable for use in automotive and battery operated equipment. Additional on-chip filtering has been included to enhance rejection of high frequency transients on all external leads.

An active microprocessor $\overline{\text { RESET }}$ function is included on-chip with externally programmable delay time. During power-up, or after detection of any error in the regulated output, the RESET lead will remain in the low state for the duration of the delay. Types of errors include short circuit, low input voltage, overvoltage shutdown, thermal shutdown, or others that cause the output to become unregulated. This function is independent of the input voltage and will function correctly with an output voltage as low as 1.0 V . Hysteresis is included in both the reset and Delay comparators for enhanced noise immunity. A latching discharge circuit is used to discharge the Delay capacitor, even when triggered by a relatively short fault condition. This circuit improves upon the commonly used SCR structure by providing full capacitor discharge ( 0.2 V type).

Note: The CS8126 is lead compatible with the LM2927 and LM2926.

## Features

- Low Dropout Voltage ( 0.6 V at 0.5 A )
- 3.0\% Output Accuracy
- Active RESET
- External RESET Delay for Reset
- Protection Circuitry
- Reverse Battery Protection
- +60 V, -50 V Peak Transient Voltage
- Short Circuit Protection
- Internal Thermal Overload Protection

RESET CIRCUIT WAVEFORM

Figure 12. RESET Circuit Waveform

## CIRCUIT DESCRIPTION

The CS8126 $\overline{\text { RESET }}$ function, has hysteresis on both the Reset and Delay comparators, a latching Delay capacitor discharge circuit, and operates down to 1.0 V .

The RESET circuit output is an open collector type with ON and OFF parameters as specified. The $\overline{\text { RESET }}$ output NPN transistor is controlled by the two circuits described (see Block Diagram).

## Low Voltage Inhibit Circuit

This circuit monitors output voltage, and when the output voltage falls below $\mathrm{V}_{\mathrm{RT} \text { (OFF) }}$, causes the $\overline{\mathrm{RESET}}$ output transistor to be in the ON (saturation) state. When the output voltage rises above $\mathrm{V}_{\mathrm{RT}(\mathrm{ON})}$, this circuit permits the $\overline{\mathrm{RESET}}$ output transistor to go into the OFF state if allowed by the RESET Delay circuit.

## RESET Delay Circuit

This circuit provides a programmable (by external capacitor) delay on the $\overline{\text { RESET }}$ output lead. The Delay lead provides source current to the external delay capacitor only when the "Low Voltage Inhibit" circuit indicates that output
voltage is above $\mathrm{V}_{\mathrm{RT}(\mathrm{ON})}$. Otherwise, the Delay lead sinks current to ground (used to discharge the delay capacitor). The discharge current is latched ON when the output voltage falls below $\mathrm{V}_{\mathrm{RT}(\mathrm{OFF})}$. The Delay capacitor is fully discharged anytime the output voltage falls out of regulation, even for a short period of time. This feature ensures a controlled $\overline{\text { RESET }}$ pulse is generated following detection of an error condition. The circuit allows the $\overline{\text { RESET }}$ output transistor to go to the OFF (open) state only when the voltage on the Delay lead is higher than $\mathrm{V}_{\mathrm{DC}(\mathrm{H} 1)}$.
The Delay time for the $\overline{\text { RESET }}$ function is calculated from the formula:

$$
\begin{gathered}
\text { Delay time }=\frac{C_{\text {Delay }} \times V_{\text {Delay }} \text { Threshold }}{} \\
\text { ICharge } \\
\text { Delay time }=\text { CDelay } \times 3.2 \times 10^{5}
\end{gathered}
$$

If $C_{\text {Delay }}=0.1 \mu \mathrm{~F}$, Delay time $(\mathrm{ms})=32 \mathrm{~ms} \pm 50 \%$ : i.e. 16 ms to 48 ms . The tolerance of the capacitor must be taken into account to calculate the total variation in the delay time.

${ }^{*} \mathrm{C}_{1}$ is required if the regulator is far from the power source filter.
${ }^{* *} \mathrm{C}_{2}$ is required for stability.
Figure 13. Application Diagram

## APPLICATION NOTES

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low
temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.
The value for the output capacitor $\mathrm{C}_{2}$ shown in the test and applications circuit should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for $\mathrm{C}_{2}$ for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.
Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.
Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.
Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 14) is:

$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at $I_{\text {OUT (max) }}$.
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PDD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\text {©JA }}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 14. Single Output Regulator With Key Performance Parameters Labeled

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JJC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it is a function of package type. $\mathrm{R}_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## MARKING DIAGRAMS

## CS8129

### 5.0 V, 750 mA Low Dropout Linear Regulator with Lower RESET Threshold

The CS8129 is a precision 5.0 V linear regulator capable of sourcing 750 mA . The $\overline{\mathrm{RESET}}$ threshold voltage has been lowered to 4.2 V so that the regulator can be used with 4.0 V microprocessors. The lower $\overline{\text { RESET }}$ threshold also permits operation under low battery conditions (5.5 V plus a diode). The RESET's delay time is externally programmed using a discrete RC network. During power up, or when the output goes out of regulation, $\overline{\text { RESET }}$ remains in the low state for the duration of the delay. This function is independent of the input voltage and will function correctly as long as the output voltage remains at or above 1.0 V . Hysteresis is included in the Delay and the $\overline{\text { RESET }}$ comparators to improve noise immunity. A latching discharge circuit is used to discharge the delay capacitor when it is triggered by a brief fault condition.

The regulator is protected against a variety of fault conditions: i.e. reverse battery, overvoltage, short circuit and thermal runaway conditions. The regulator is protected against voltage transients ranging from -50 V to +40 V . Short circuit current is limited to 1.2 A (typ).

The CS8129 is packaged in a 5 lead TO-220 and a 16 lead surface mount package.

## Features

- 5.0 V $\pm 3.0 \%$ Regulated Output
- Low Dropout Voltage ( 0.6 V @ 0.5 A )
- 750 mA Output Current Capability
- Reduced $\overline{\text { RESET }}$ Threshold for use with 4.0 V Microprocessors
- Externally Programmed RESET Delay
- Fault Protection
- Reverse Battery
- 60 V, -50 V Peak Transient Voltage
- Short Circuit
- Thermal Shutdown

CIRCUIT DESCRIPTION

The CS8129 $\overline{\text { RESET }}$ function has hysteresis on both the reset and delay comparators, a latching Delay capacitor discharge circuit, and operates down to 1.0 V .
The RESET circuit output is an open collector type with ON and OFF parameters as specified. The $\overline{\text { RESET }}$ output NPN transistor is controlled by the two circuits described (see Block Diagram on page 605).

## Low Voltage Inhibit Circuit

This circuit monitors output voltage, and when output voltage is below the specified minimum causes the RESET output transistor to be in the ON (saturation) state. When the output voltage is above the specified level, this circuit permits the RESET output transistor to go into the OFF state if allowed by the RESET Delay circuit.

## Reset Delay Circuit

This circuit provides a programmable (by external capacitor) delay on the RESET output lead. The Delay lead provides source current to the external delay capacitor only when the "Low Voltage Inhibit" circuit indicates that output voltage is above $\mathrm{V}_{\mathrm{RT}(\mathrm{ON}) \text {. Otherwise, the Delay lead sinks }}$ current to ground (used to discharge the delay capacitor). The discharge current is latched ON when the output voltage is below $\mathrm{V}_{\mathrm{RT}(\mathrm{OFF})}$. The Delay capacitor is fully discharged anytime the output voltage falls out of regulation, even for a short period of time. This feature ensures that a controlled $\overline{\text { RESET }}$ pulse is generated following detection of an error
condition. The circuit allows the RESET output transistor to go to the OFF (open) state only when the voltage on the Delay lead is higher than $\mathrm{V}_{\mathrm{DC}(\mathrm{HI})}$.

Figure 13. Test \& Application Circuit
The Delay time for the $\overline{\text { RESET }}$ function is calculated from the formula:

$$
\begin{gathered}
\text { Delay time }=\frac{C_{\text {Delay }} \times V_{\text {Delay Threshold }}}{I_{\text {Charge }}} \\
\text { Delay time }=\mathrm{C}_{\text {Delay }(\mu \mathrm{F})} \times 3.2 \times 10^{5}
\end{gathered}
$$

If $\mathrm{C}_{\text {Delay }}=0.1 \mu \mathrm{~F}$, Delay time $(\mathrm{ms})=32 \mathrm{~ms} \pm 50 \%$ : i.e. 16 ms to 48 ms . The tolerance of the capacitor must be taken into account to calculate the total variation in the delay time.

## APPLICATION NOTES

## STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor CouT shown in Figure 13 should work for most applications, however it is not necessarily the optimized solution.

To determine an acceptable value for COUT for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 14) is:
$P_{D}($ max $)=\left\{V_{I N}(\text { max })-V_{\text {OUT }}(\text { min }) \mid \operatorname{IOUT}(\text { max })+V_{I N(m a x)}\right)^{Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at

> IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 14. Single Output Regulator With Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$.

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## MC34268

## 800 mA, 2.85 V, SCSI-2 Active Terminator, Low Dropout Voltage Regulator

The MC34268 is a medium current, low dropout positive voltage regulator specifically designed for use in SCSI-2 active termination circuits. This device offers the circuit designer an economical solution for precision voltage regulation, while keeping power losses to a minimum. The regulator consists of a 1.0 V dropout composite PNP/NPN pass transistor, current limiting, and thermal limiting. These devices are packaged in the 8 -pin SOP-8 and 3-pin DPAK and SOT-223 surface mount power packages.

Applications include active SCSI-2 terminators and post regulation of switching power supplies.

- 2.85 V Output Voltage for SCSI-2 Active Termination
- 1.0 V Dropout
- Output Current in Excess of 800 mA
- Thermal Protection
- Short Circuit Protection
- Output Trimmed to $1.4 \%$ Tolerance
- No Minimum Load Required
- Space Saving DPAK, SOT-223 and SOP-8 Surface Mount Power Packages

Figure 1. Dropout Voltage versus Output Load Current

Figure 2. Transient Load Regulation

Figure 3. Typical SCSI Application

Figure 3 is a circuit of a typical SCSI terminator application. The MC34268 is designed specifically to provide 2.85 V required to drive a SCSI-2 bus. The output current capability of the regulator is in excess of 800 mA ; enough to drive standard SCSI-2, fast SCSI-2, and some wide SCSI-2 applications. The typical dropout voltage is less than 1.0 V , allowing the IC to regulate to input voltages less than 4.0 V . Internal protective features include current and thermal limiting.

Figure 4. SOP-8 Thermal Resistance versus P.C.B. Copper Length

The MC34268 requires an external $10 \mu \mathrm{~F}$ capacitor with an ESR of less than $10 \Omega$ for stability over temperature. With economical electrolytic capacitors, cold temperature operation can pose a stability problem. As temperature decreases, the capacitance also decreases and the ESR increases, which could cause the circuit to oscillate. Tantalum capacitors may be a better choice if small size is a requirement. Also, the capacitance and ESR of a tantalum capacitor is more stable over temperature.

## Product Preview

# 1.0 A Low-Dropout Positive Fixed and Adjustable Voltage Regulators 

The NCP1117 series are low dropout positive voltage regulators that are capable of providing an output current that is in excess of 1.0 A with a maximum dropout voltage of 1.2 V at 800 mA over temperature. This series contains eight fixed output voltages of 1.5 V , $1.8 \mathrm{~V}, 2.0 \mathrm{~V}, 2.5 \mathrm{~V}, 2.85 \mathrm{~V}, 3.3 \mathrm{~V}, 5.0 \mathrm{~V}$, and 12 V that have no minimum load requirement to maintain regulation. Also included is an adjustable output version that can be programmed from 1.25 V to 18.8 V with two external resistors. On chip trimming adjusts the reference/output voltage to within $\pm 1.0 \%$ accuracy. Internal protection features consist of output current limiting, safe operating area compensation, and thermal shutdown. The NCP1117 series can operate with up to 20 V input. Devices are available in SOT-223 and DPAK packages.

## Features

- Output Current in Excess of 1.0 A
- 1.2 V Maximum Dropout Voltage at 800 mA Over Temperature
- Fixed Output Voltages of $1.5 \mathrm{~V}, 1.8 \mathrm{~V}, 2.0 \mathrm{~V}, 2.5 \mathrm{~V}, 2.85 \mathrm{~V}, 3.3 \mathrm{~V}$, 5.0 V , and 12 V
- Adjustable Output Voltage Option
- No Minimum Load Requirement for Fixed Voltage Output Devices
- Reference/Output Voltage Trimmed to $\pm 1.0 \%$
- Current Limit, Safe Operating and Thermal Shutdown Protection
- Operation to 20 V Input

Applications

- Consumer and Industrial Equipment Point of Regulation
- Active SCSI Termination for 2.85 V Version
- Switching Power Supply Post Regulation
- Hard Drive Controllers
- Battery Chargers

## ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 625 of this data sheet.

## DEVICE MARKING INFORMATION

See general marking information in the device marking section on page 626 of this data sheet.

## TYPICAL APPLICATIONS

1．This device series contains ESD protection and exceeds the following tests：
Human Body Model 2000 V per MIL－STD－883，Method 3015.
Machine Model Method 200 V ．
2．Internal thermal shutdown protection limits the die temperature to approximately $175^{\circ} \mathrm{C}$ ．Proper heatsinking is required to prevent activation． The maximum package power dissipation is：

$$
P_{D}=\frac{T_{J(\max )}-T_{A}}{R_{\theta J A}}
$$

3．The regulator output current must not exceed 1.0 A with $\mathrm{V}_{\text {in }}$ greater than 12 V ．

## APPLICATIONS INFORMATION

## Introduction

The NCP1117 features a significant reduction in dropout voltage along with enhanced output voltage accuracy and temperature stability when compared to older industry standard three-terminal adjustable regulators. These devices contain output current limiting, safe operating area compensation and thermal shutdown protection making them designer friendly for powering numerous consumer and industrial products. The NCP1117 series is pin compatible with the older LM317 and its derivative device types.

## Output Voltage

The typical application circuits for the fixed and adjustable output regulators are shown in Figures 20 and 21. The adjustable devices are floating voltage regulators. They develop and maintain the nominal 1.25 V reference voltage between the output and adjust pins. The reference voltage is programmed to a constant current source by resistor R1, and this current flows through R2 to ground to set the output voltage. The programmed current level is usually selected to be greater than the specified 5.0 mA minimum that is required for regulation. Since the adjust pin current, $\mathrm{I}_{\mathrm{adj}}$, is significantly lower and constant with respect to the programmed load current, it generates a small output voltage error that can usually be ignored. For the fixed output devices R1 and R2 are included within the device and the ground current $\mathrm{I}_{\mathrm{gnd}}$, ranges from 3.0 mA to 5.0 mA depending upon the output voltage.

## External Capacitors

Input bypass capacitor $\mathrm{C}_{\text {in }}$ may be required for regulator stability if the device is located more than a few inches from the power source. This capacitor will reduce the circuit's sensitivity when powered from a complex source impedance and significantly enhance the output transient response. The input bypass capacitor should be mounted with the shortest possible track length directly across the regulator's input and ground terminals. A $10 \mu \mathrm{~F}$ ceramic or tantalum capacitor should be adequate for most applications.

Figure 20. Fixed Output Regulator

Frequency compensation for the regulator is provided by capacitor $\mathrm{C}_{\text {out }}$ and its use is mandatory to ensure output stability. A minimum capacitance value of $4.7 \mu \mathrm{~F}$ with an equivalent series resistance (ESR) that is within the limits of $0.25 \Omega$ to $2.2 \Omega$ is required. The capacitor type can be ceramic, tantalum, or aluminum electrolytic as long as it meets the minimum capacitance value and ESR limits over the circuit's entire operating temperature range. Higher values of output capacitance can be used to enhance loop stability and transient response with the additional benefit of reducing output noise.

Figure 21. Adjustable Output Regulator
The output ripple will increase linearly for fixed and adjustable devices as the ratio of output voltage to the reference voltage increases. For example, with a 12 V regulator, the output ripple will increase by $12 \mathrm{~V} / 1.25 \mathrm{~V}$ or 9.6 and the ripple rejection will decrease by $20 \log$ of this ratio or 19.6 dB . The loss of ripple rejection can be restored to the values shown with the addition of bypass capacitor $\mathrm{C}_{\mathrm{adj}}$, shown in Figure 21. The reactance of $\mathrm{C}_{\mathrm{adj}}$ at the ripple frequency must be less than the resistance of R1. The value of R1 can be selected to provide the minimum required load current to maintain regulation and is usually in the range of $100 \Omega$ to $200 \Omega$.

$$
\mathrm{C}_{\mathrm{adj}}>\frac{1}{2 \pi \text { fripple }^{\mathrm{R} 1}}
$$

The minimum required capacitance can be calculated from the above formula. When using the device in an application that is powered from the AC line via a transformer and a full wave bridge, the value for $\mathrm{C}_{\text {adj }}$ is:
fripple $=120 \mathrm{~Hz}, \mathrm{R} 1=120 \Omega$, then $\mathrm{C}_{\text {adj }}>11.1 \mu \mathrm{~F}$
The value for $\mathrm{C}_{\text {adj }}$ is significantly reduced in applications where the input ripple frequency is high. If used as a post regulator in a switching converter under the following conditions:
fripple $=50 \mathrm{kHz}, \mathrm{R} 1=120 \Omega$, then $\mathrm{C}_{\text {adj }}>0.027 \mu \mathrm{~F}$
Figures 10 and 11 shows the level of ripple rejection that is obtainable with the adjust pin properly bypassed.

## Protection Diodes

The NCP1117 family has two internal low impedance diode paths that normally do not require protection when used in the typical regulator applications. The first path connects between $\mathrm{V}_{\text {out }}$ and $\mathrm{V}_{\text {in }}$, and it can withstand a peak surge current of about 15 A . Normal cycling of $\mathrm{V}_{\text {in }}$ cannot generate a current surge of this magnitude. Only when $\mathrm{V}_{\text {in }}$ is shorted or crowbarred to ground and $\mathrm{C}_{\text {out }}$ is greater than $50 \mu \mathrm{~F}$, it becomes possible for device damage to occur. Under these conditions, diode D1 is required to protect the device. The second path connects between $\mathrm{C}_{\mathrm{adj}}$ and $\mathrm{V}_{\text {out }}$, and it can withstand a peak surge current of about 150 mA . Protection diode D2 is required if the output is shorted or crowbarred to ground and $\mathrm{C}_{\mathrm{adj}}$ is greater than $1.0 \mu \mathrm{~F}$.

Figure 22. Protection Diode Placement
A combination of protection diodes D1 and D2 may be required in the event that $\mathrm{V}_{\text {in }}$ is shorted to ground and $\mathrm{C}_{\mathrm{adj}}$ is greater than $50 \mu \mathrm{~F}$. The peak current capability stated for the internal diodes are for a time of $100 \mu$ s with a junction temperature of $25^{\circ} \mathrm{C}$. These values may vary and are to be used as a general guide.

## Load Regulation

The NCP1117 series is capable of providing excellent load regulation; but since these are three terminal devices, only partial remote load sensing is possible. There are two conditions that must be met to achieve the maximum available load regulation performance. The first is that the top side of programming resistor R1 should be connected as close to the regulator case as practicable. This will minimize the voltage drop caused by wiring resistance RW + from appearing in series with reference voltage that is across R1.

The second condition is that the ground end of R 2 should be connected directly to the load. This allows true Kelvin sensing where the regulator compensates for the voltage drop caused by wiring resistance RW -.

Figure 23. Load Sensing

## Thermal Considerations

This series contains an internal thermal limiting circuit that is designed to protect the regulator in the event that the maximum junction temperature is exceeded. When activated, typically at $175^{\circ} \mathrm{C}$, the regulator output switches off and then back on as the die cools. As a result, if the device is continuously operated in an overheated condition, the output will appear to be oscillating. This feature provides protection from a catastrophic device failure due to accidental overheating. It is not intended to be used as a substitute for proper heatsinking. The maximum device power dissipation can be calculated by:

$$
P_{D}=\frac{T_{J}(\max )-T_{A}}{R_{\theta J A}}
$$

The devices are available in surface mount SOT-223 and DPAK packages. Each package has an exposed metal tab that is specifically designed to reduce the junction to air thermal resistance, $\mathrm{R}_{\theta J \mathrm{JA}}$, by utilizing the printed circuit board copper as a heat dissipater. Figures 18 and 19 show typical $R_{\theta J A}$ values that can be obtained from a square pattern using economical single sided 2.0 ounce copper board material. The final product thermal limits should be tested and quantified in order to insure acceptable performance and reliability. The actual $\mathrm{R}_{\theta \mathrm{JA}}$ can vary considerably from the graphs shown. This will be due to any changes made in the copper aspect ratio of the final layout, adjacent heat sources, and air flow.

Figure 24. Constant Current Regulator

Figure 26. Regulator with Shutdown

The $50 \Omega$ resistor that is in series with the ground pin of the upper regulator level shifts its output 300 mV higher than the lower regulator. This keeps the lower regulator off until the input source is removed.

Figure 27. Digitally Controlled Regulator

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

The surface mount board layout is a critical portion of the total design. The footprint for the regulator package must be of correct size to insure a proper solder connection of the

SOT-223, Case 318H
package tab and pins to the printed circuit board copper. With proper footprint pad sizes, the packages will self align when subjected to a solder reflow process.

## MC33269

## 800 mA, Adjustable Output, Low Dropout Voltage Regulator

The MC33269 series are low dropout, medium current, fixed and adjustable, positive voltage regulators specifically designed for use in low input voltage applications. These devices offer the circuit designer an economical solution for precision voltage regulation, while keeping power losses to a minimum.

The regulator consists of a 1.0 V dropout composite PNP-NPN pass transistor, current limiting, and thermal shutdown.

- $3.3 \mathrm{~V}, 5.0 \mathrm{~V}, 12 \mathrm{~V}$ and Adjustable Versions.
2.85 V version available as MC34268.
- Space Saving DPAK, SOP-8 and SOT-223 Power Packages
- 1.0 V Dropout
- Output Current in Excess of 800 mA
- Thermal Protection
- Short Circuit Protection
- Output Trimmed to $1.0 \%$ Tolerance

## APPLICATIONS INFORMATION

Figures 11 through 15 are typical application circuits. The output current capability of the regulator is in excess of 800 mA , with a typical dropout voltage of less than 1.0 V . Internal protective features include current and thermal limiting.

* The MC33269 requires an external output capacitor for stability. The capacitor should be at least $10 \mu \mathrm{~F}$ with an equivalent series resistance (ESR) of less than $10 \Omega$ but greater than $0.2 \Omega$ over the anticipated operating temperature range. With economical electrolytic capacitors, cold temperature operation can pose a problem. As temperature decreases, the capacitance also decreases and the ESR increases, which could cause the circuit to oscillate. Also capacitance and ESR of a solid tantalum capacitor is more stable over temperature. The use of a low ESR ceramic capacitor placed within close proximity to the output of the device could cause instability.
** An input bypass capacitor is recommended to improve transient response or if the regulator is connected to the

An input capacitor is not necessary for stability, however it will improve the overall performance.

Figure 11. Typical Fixed Output Application

Figure 13. Current Regulator

The Schottky diode in series with the ground leg of the upper regulator shifts its output voltage higher by the forward voltage drop of the diode. This will cause the lower device to remain off until the input voltage is removed.

Figure 14. Battery Backed-Up Power Supply
supply input filter with long wire lengths. This will reduce the circuit's sensitivity to the input line impedance at high frequencies. A $0.33 \mu \mathrm{~F}$ or larger tantalum, mylar, ceramic, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with shortest possible lead or track length directly across the regulator's input terminals. Applications should be tested over all operating conditions to insure stability.

Internal thermal limiting circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically at $170^{\circ} \mathrm{C}$, the output is disabled. There is no hysteresis built into the thermal limiting circuit. As a result, if the device is overheating, the output will appear to be oscillating. This feature is provided to prevent catastrophic failures from accidental device overheating. It is not intended to be used as a substitute for proper heatsinking.

${ }^{* * *} \mathrm{C}_{\text {Adj }}$ is optional, however it will improve the ripple rejection. The MC34269 develops a 1.25 V reference voltage between the output and the adjust terminal. Resistor R1, operates with constant current to flow through it and resistor R2. This current should be set such that the Adjust Pin current causes negligible drop across resistor R2. The total current with minimum load should be greater than 8.0 mA .

Figure 12. Typical Adjustable Output Application

$\mathrm{R}_{2}$ sets the maximum output voltage. Each transistor reduces the output voltage when turned on.

## CS5201-3

### 1.0 A, 3.3 V Fixed Linear Regulator

The CS5201-3 linear regulator provides 1.0 A @ 3.3 V reference at 1.0 A with an output voltage accuracy of $\pm 1.5 \%$.

This regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages less than 1.2 V at 1.0 A output current.

The maximum quiescent current is only 10 mA at full load. Device protection includes over-current and thermal shutdown.

The CS5201-3 is pin compatible with the LT1086 family of linear regulators.

The regulator is available in TO-220, surface mount $\mathrm{D}^{2}$, and SOT-223 packages.

## Features

- Output Current to 1.0 A
- Output Accuracy to $\pm 1.5 \%$ Over Temperature
- Dropout Voltage (typical) 1.0 V @ 1.0 A
- Fast Transient Response
- Fault Protection

## APPLICATIONS INFORMATION

The CS5201-3 linear regulator provides a fixed 3.3 V output voltage at currents up to 1.0 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS5201-3 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5201-3 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and
ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5201-3 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 9 is recommended.

Figure 9. Protection Diode Scheme for Large Output Capacitors

## Output Voltage Sensing

Since the CS5201-3 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 10.

Figure 10. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme For Fixed Output Regulators

## Calculating Power Dissipation and Heat Sink Requirements

The CS5201-3 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $P_{D}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{4}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta \mathrm{SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{6}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (4).

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5201-3 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta} \mathrm{SA}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5201-1

### 1.0 A Adjustable Linear Regulator

The CS5201-1 linear regulator provides 1.0 A with an output voltage accuracy of $\pm 1.0 \%$. The device uses two external resistors to set the output voltage within a 1.25 V to 5.5 V range.

This regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages less than 1.2 V at 1.0 A output current. Device protection includes overcurrent and thermal shutdown.

The CS5201 is pin compatible with the LT1086 family of linear regulators.

The regulator is available in TO-220, surface mount $\mathrm{D}^{2}$, and SOT-223 packages.

## Features

- Output Current to 1.0 A
- Output Accuracy to $\pm 1.0 \%$ Over Temperature
- Dropout Voltage (typical) 1.0 V @ 1.0 A
- Fast Transient Response
- Fault Protection
- Current Limit
- Thermal Shutdown

## APPLICATIONS INFORMATION

The CS5201-1 linear regulator provides adjustable voltages at currents up to 1.0 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS5201-1 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The CS5201-1 has an output voltage range of 1.25 V to 5.5 V . An external resistor divider sets the output voltage as shown in Figure 11. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 2.0 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. While not required, a bypass capacitor from the adjust pin to ground will improve ripple rejection and transient response. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Type and value may be varied to obtain optimum performance vs. price.

Figure 11. Resistor Divider Scheme

## Short Circuit Protection

The CS5201-1 linear regulator has an absolute maximum specification of 7.0 V for the voltage difference between $\mathrm{V}_{\mathrm{IN}}$ and Vout. However, the IC may be used to regulate voltages in excess of 7.0 V . The main considerations in such a design are power-up and short circuit capability.

In most applications, ramp-up of the power supply to $\mathrm{V}_{\mathrm{IN}}$ is fairly slow, typically on the order of several tens of milliseconds, while the regulator responds in less than one microsecond. In this case, the linear regulator begins charging the load as soon as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential is large enough that the pass transistor conducts current. The load at this point is essentially at ground, and the supply voltage is on the order of several hundred millivolts, with the result that the pass transistor is in dropout. As the supply to $\mathrm{V}_{\text {IN }}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ reaches the point at which the IC is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. The result is that the output voltage follows the power supply ramp-up, staying in dropout until the regulation point is reached. In this manner, any output voltage may be regulated. There is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 7.0 V is not exceeded.

However, the possibility of destroying the IC in a short circuit condition is very real for this type of design. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Over-voltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 7.0 V if failsafe operation is required. One possible clamp circuit is
illustrated in Figure 12; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 12. Short Circuit Protection Circuit for High Voltage Application.

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5201-1 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5201-1 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 13 is recommended.

Figure 13. Protection Diode for Large Output Capacitors

## Output Voltage Sensing

Since the CS5201-1 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.

For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, RC is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes.

$$
\mathrm{R}_{\mathrm{C}} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitic Resistance Effects

## Calculating Power Dissipation and Heat Sink Requirements

The CS5201-1 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.
The case is connected to V Vut on the CS5201-1, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.
The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{7}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$I_{\text {OUT(max) }}$ is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta \mathrm{JA}}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta \mathrm{SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{9}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (7).

The value for $\mathrm{R}_{\Theta J C}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5201-1 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and
thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS52015-3

### 1.5 A, 3.3 V Fixed Linear Regulator

The CS52015-3 linear regulator provides 1.5 A @ 3.3 V reference at 1.0 A with an output voltage accuracy of $\pm 1.5 \%$.

The regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages less than 1.4 V at 1.5 A output current. The maximum quiescent current is only 10 mA at full load. Device protection includes over-current and thermal shutdown.

The CS52015-3 is pin compatible with the LT1086 family of linear regulators but has lower dropout voltage.

The regulator is available in TO-220, surface mount $\mathrm{D}^{2}$, and SOT-223 packages.

## Features

- Output Current to 1.5 A
- Output Accuracy to $\pm 1.5 \%$ Over Temperature
- Dropout Voltage (typical) 1.05 V @ 1.5 A
- Fast Transient Response
- Fault Protection
- Current Limit
- Thermal Shutdown

## APPLICATIONS INFORMATION

The CS52015-3 linear regulator provides a 3.3 V output voltage at currents up to 1.5 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS52015-3 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS52015-3 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS52015-3 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 9 is recommended.

Figure 9. Protection Diode Scheme for Large Output Capacitors

## Output Voltage Sensing

Since the CS52015-3 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 10.

Figure 10. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme For Fixed Output Regulators

## Calculating Power Dissipation and Heat Sink Requirements

The CS52015-3 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V OUT on the CS52015-3, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JJ}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{10}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{~A}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{12}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (10).

The value for $\mathrm{R}_{\Theta J C}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS52015-3 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta} \mathrm{SA}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \text { JA }}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS52015-1

### 1.5 A Adjustable Linear Regulator

The CS52015-1 linear regulator provides 1.5 A with an accuracy of $\pm 1.0 \%$. The device uses two external resistors to set the output voltage within a 1.25 V to 5.5 V range.

The regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages less than 1.4 V at 1.5 A output current. Device protection includes overcurrent and thermal shutdown.

The CS52015-1 is pin compatible with the LT1086 family of linear regulators but has lower dropout voltage.

The regulator is available in TO-220, surface mount $\mathrm{D}^{2}$, and SOT-223 packages.

## APPLICATIONS INFORMATION

The CS52015-1 linear regulator provides adjustable voltages at currents up to 1.5 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS52015-1 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The CS52015-1 has an output voltage range of 1.25 V to 5.5 V . An external resistor divider sets the output voltage as shown in Figure 11. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.
The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R 1 is chosen so that the minimum load current is at least $2.0 \mathrm{~mA} . \mathrm{R} 1$ and R2 should be the same type, e.g. metal film for best tracking over temperature. While not required, a bypass capacitor from the adjust pin to ground will improve ripple rejection and transient response. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Type and value may be varied to obtain optimum performance vs. price.

Figure 11. Resistor Divider Scheme

## Short Circuit Protection

The CS52015-1 linear regulator has an absolute maximum specification of 7.0 V for the voltage difference between $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {OUT }}$. However, the IC may be used to regulate voltages in excess of 7.0 V . The main considerations in such a design are power-up and short circuit capability.

In most applications, ramp-up of the power supply to $\mathrm{V}_{\mathrm{IN}}$ is fairly slow, typically on the order of several tens of milliseconds, while the regulator responds in less than one microsecond. In this case, the linear regulator begins charging the load as soon as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential is large enough that the pass transistor conducts current. The load at this point is essentially at ground, and the supply voltage is on the order of several hundred millivolts, with the result that the pass transistor is in dropout. As the supply to $\mathrm{V}_{\text {IN }}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ reaches the point at which the IC is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. The result is that the output voltage follows the power supply ramp-up, staying in dropout until the regulation point is reached. In this manner, any output voltage may be regulated. There is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 7.0 V is not exceeded.

However, the possibility of destroying the IC in a short circuit condition is very real for this type of design. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Over-voltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 7.0 V if failsafe operation is required. One possible clamp circuit is
illustrated in Figure 12; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 12. Short Circuit Protection Circuit for High Voltage Application.

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS52015-1 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS52015-1 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 13 is recommended.

Figure 13. Protection Diode for Large Output Capacitors

## Output Voltage Sensing

Since the CS52015-1 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.

For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, RC is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes.

$$
\mathrm{R}_{\mathrm{C}} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitic Resistance Effects

## Calculating Power Dissipation and Heat Sink Requirements

The CS52015-1 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.
The case is connected to V Vut on the CS52015-1, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.
The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{13}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$P_{D}($ max $)=\left\{\mathrm{V}_{\operatorname{IN}(\text { max })}-\mathrm{V}_{\mathrm{OUT}(\text { min })}\right\}_{\mathrm{I}} \mathrm{OUT}($ max $)+\mathrm{V}_{\mathrm{IN}(\text { max })} \mathrm{I}_{\mathrm{Q}}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$I_{\text {OUT(max) }}$ is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta \mathrm{JA}}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\text {©SA }}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{15}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (13).

The value for $\mathrm{R}_{\Theta J C}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS52015-1 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and
thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5203-3

### 3.0 A, 3.3 V Fixed Linear Regulator

The CS5203-3 linear regulator provides 3.3 V reference at 3.0 A with an output voltage accuracy of $\pm 1.5 \%$.

This regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to provide 3.0 A of output current with dropout voltages of less than 1.15 V . The maximum quiescent current is only 10 mA at full load. Device protection includes over-current and thermal shutdown.

The CS5203-3 is pin compatible with the LT1085 family of linear regulators.

The regulator is available in a surface mount $\mathrm{D}^{2}$ package.

## Features

- Output Current to 3.0 A
- Output Accuracy to $\pm 1.5 \%$ Over Temperature
- Dropout Voltage (typical) 1.15 V @ 3.0 A
- Fast Transient Response
- Fault Protection
- Current Limit
- Thermal Shutdown

## APPLICATIONS INFORMATION

The CS5203-3 linear regulator provides a fixed 3.3 V output voltage at currents up to 3.0 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS5203-3 has a composite PNP-NPN output transistor and requires an output capacitor for stability.

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5203-3 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5203-3 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 9 is recommended.

Figure 9. Protection Diode Scheme for Large Output Capacitors

## Output Voltage Sensing

Since the CS5203-3 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 10.

Figure 10. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme For Fixed Output Regulators

## Calculating Power Dissipation and Heat Sink Requirements

The CS5203-3 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{16}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{~A}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{18}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J \text { J }}$ is calculated using equation (3) and the result can be substituted in equation (16).

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5203-3 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta} \mathrm{SA}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5203A-1, CS5203A-2, CS5203A-3, CS5203A-5

### 3.0 A Adjustable, and Fixed 1.5 V, 3.3 V and 5.0 V Linear Regulators

The CS5203A series of linear regulators provides 3.0 A at adjustable and fixed voltages with an accuracy of $\pm 1.0 \%$ and $\pm 2.0 \%$ respectively. The adjustable version uses two external resistors to set the output voltage within a 1.25 V to 13 V range.

The regulators are intended for use as post regulators and microprocessor supplies. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulators are fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The CS5203A is pin compatible with the LT1085 family of linear regulators but has lower dropout voltage.

The regulators are available in TO-220 and surface mount $\mathrm{D}^{2} \mathrm{PAK}$ packages.

## Features

## APPLICATIONS INFORMATION

The CS5203A family of linear regulators provides fixed or adjustable voltages at currents up to 3.0 A . The regulators are protected against short circuit, and include thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5203A has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator (CS5203A-1) has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 10. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R 2 that adds to the 1.25 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\mathrm{Adj}} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is bypassed to improve the transient response and ripple rejection of the regulator.

Figure 10. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5203A the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current.

The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under load transient conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5203A-X family of linear regulators, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figures 11 and 12 is recommended.

Figure 11. Protection Diode Scheme for Adjustable Output Regulator

Figure 12. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5203A is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the fixed regulators should be connected as shown in Figure 13.

Figure 13. Conductor Parasitic Resistance can be Minimized with the Above Grounding Scheme for Fixed Output Regulators

For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes

$$
\mathrm{R}_{\mathrm{C}} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5203A series of linear regulators includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V OUT on the CS5203A, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{19}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$P_{D}($ max $)=\left\{V_{I N}(\right.$ max $)-V_{O U T}($ min $\left.)\right\} I_{O U T}($ max $)+V_{I N(m a x)}{ }^{l Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\mathrm{\Theta SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{21}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (19).

The value for $\mathrm{R}_{\Theta J C}$ is normally quoted as a single figure for a given package type based on an average die size. For a high current regulator such as the CS5203A the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $R_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5253B-8

### 3.0 A LDO 5-Pin 2.5 V Fixed Linear Regulator for Remote Sense Applications

This new very low dropout linear regulator reduces total power dissipation in the application. To achieve very low dropout, the internal pass transistor is powered separately from the control circuitry. Furthermore, with the control and power inputs tied together, this device can be used in single supply configuration and still offer a better dropout voltage than conventional PNP-NPN based LDO regulators. In this mode the dropout is determined by the minimum control voltage.

The CS5253B-8 is offered in a five-terminal $\mathrm{D}^{2}$ PAK package, which allows for the implementation of a remote-sense pin permitting very accurate regulation of output voltage directly at the load, where it counts, rather than at the regulator. This remote sensing feature virtually eliminates output voltage variations due to load changes and resistive voltage drops. Typical load regulation measured at the sense pin is less than 1.0 mV for an output voltage of 2.5 V with a load step of 10 mA to 3.0 A .

The CS5253B-8 has a very fast transient loop response.
Internal protection circuitry provides for "bust-proof" operation, similar to three-terminal regulators. This circuitry, which includes overcurrent, short circuit, and overtemperature protection will self protect the regulator under all fault conditions.

The CS5253B-8 is ideal for generating a 2.5 V supply to power graphics controllers used on VGA cards. Its remote sense and low value capacitance requirements make this a low cost high performance solution. The CS5253B-8 is optimized from the CS5253-1 to allow a lower value of output capacitor to be used at the expense of a slower transient response.

## Features

- V ${ }_{\text {OUT }}$ Fixed @ $2.5 \mathrm{~V} \pm 1.5 \%$
- $V_{\text {POWER }}$ Dropout < 0.40 V @ 3.0 A
- $V_{\text {CONTROL }}$ Dropout < 1.05 V @ 3.0 A
- $1.5 \%$ Trimmed Reference
- Fast Transient Response
- Remote Voltage Sensing
- Thermal Shutdown
- Current Limit
- Short Circuit Protection
- Drop-In Replacement for EZ1582
- Backwards Compatible with 3-Pin Regulators
- Very Low Dropout Reduces Total Power Consumption

4. This parameter is guaranteed by design and is not $100 \%$ production tested.
5. Dropout is defined as either the minimum control voltage ( $\mathrm{V}_{\text {CONTROL }}$ ) or minimum power voltage ( $\mathrm{V}_{\text {POWER }}$ ) to output voltage differential required to maintain $1.5 \%$ regulation at a particular load current.
6. This parameter is guaranteed by design, but not parametrically tested in production. However, a $100 \%$ thermal shutdown functional test is performed on each part.

## PACKAGE PIN DESCRIPTION

| PACKAGE PIN \# |  |  |
| :---: | :---: | :---: |
| D2PAK | PIN SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\text {SENSE }}$ | This Kelvin sense pin allows for remote sensing of the output voltage at the load for improved regulation. It is internally connected to the positive input of the voltage sensing error amplifier. |
| 2 | GND | This pin is connected to system ground. |
| 3 | V OUT | This pin is connected to the emitter of the power pass transistor and provides a regulated voltage capable of sourcing 3.0 A of current. |
| 4 | $\mathrm{V}_{\text {CONTROL }}$ | This is the supply voltage for the regulator control circuitry. For the device to regulate, this voltage should be between 0.9 V and 1.3 V (depending on the output current) greater than the output voltage. The control pin current will be about $1.0 \%$ of the output current. |
| 5 | $V_{\text {POWER }}$ | This is the power input voltage. This pin is physically connected to the collector of the power pass transistor. For the device to regulate, this voltage should be between 0.1 V and 0.6 V greater than the output voltage depending on the output current. The output load current of 3.0 A is supplied through this pin. |

## APPLICATIONS NOTES

## THEORY OF OPERATION

The CS5253B-8 linear regulator is fixed at 2.5 V at currents up to 3.0 A . The regulator is protected against short circuits, and includes a thermal shutdown circuit with hysteresis. The output, which is current limited, consists of a PNP-NPN transistor pair and requires an output capacitor for stability.

## $V_{\text {POWER }}$ Function

The CS5253B-8 utilizes a two supply approach to maximize efficiency. The collector of the power device is brought out to the VPOWER pin to minimize internal power dissipation under high current loads. $\mathrm{V}_{\text {CONTROL }}$ provides for the control circuitry and the drive for the output NPN transistor. $\mathrm{V}_{\text {CONTROL }}$ should be at least 1.0 V greater than the output voltage. Special care has been taken to ensure that there are no supply sequencing problems. The output voltage will not turn on until both supplies are operating. If the control voltage comes up first, the output current will be limited to about three milliamperes until the power input voltage comes up. If the power input voltage comes up first, the output will not turn on at all until the control voltage comes up. The output can never come up unregulated.

The CS5253B-8 can also be used as a single supply device with the control and power inputs tied together. In this mode, the dropout will be determined by the minimum control voltage.

## Output Voltage Sensing

The CS5253B-8 five terminal linear regulator includes a dedicated $\mathrm{V}_{\text {SENSE }}$ function. This allows for true Kelvin sensing of the output voltage. This feature can virtually eliminate errors in the output voltage due to load regulation. Regulation will be optimized at the point where the sense pin is tied to the output.

DESIGN GUIDELINES

## Remote Sense

Remote sense operation can be easily obtained with the CS5253B-8 but some care must be paid to the layout and positioning of the filter capacitors around the part. The ground side of the input capacitors on the +5.0 V and +3.3 V lines and the local $\mathrm{V}_{\text {OUT }}$-to-ground output capacitor on the IC must be tied close to the ground pin of the regulator. This will establish the stability of the part. The IC ground may then be connected to ground remotely at the load, giving the ground portion remote sense operation.
The $\mathrm{V}_{\text {SENSE }}$ line can then be tied remotely at the positive load connection, giving the feedback remote sense operation. The remote sense lines should be Kelvin connected so as to eliminate the effect of load current voltage drop. An optional bypass capacitor may be used at the load to reduce the effect of load variations and spikes.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions.

## Short Circuit Protection

The device includes short circuit protection circuitry that clamps the output current at approximately 500 mA less than its current limit value. This provides for a current foldback function, which reduces power dissipation under a direct shorted load.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to activate above a die junction temperature of approximately $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry has $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

Figure 16. Remote Sense

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5253B-8 usually operate at high junction temperatures. Therefore, it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to VOUT on the CS5253B-8, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound in necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit

The thermal characteristics of an IC depend on the following four factors: junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{PD}_{(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:

$$
\begin{aligned}
\mathrm{PD}_{(\max )}= & \left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}(\min )}\right) \operatorname{IOUT}(\max ) \\
& \left.+\mathrm{VIN}_{\text {I }} \text { max }\right) \times \operatorname{IIN}(\max )
\end{aligned}
$$

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance which is measured in degrees per watt. Like series electrical resistances, these thermal resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta J A}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case ( $\mathrm{R}_{\Theta \mathrm{JIC}}$ ), case to heat sink $\left(\mathrm{R}_{\Theta C S}\right)$, and heat sink to ambient air $\left(\mathrm{R}_{\Theta S A}\right)$. The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

The value for $\mathrm{R}_{\Theta J C}$ is $2.5^{\circ} \mathrm{C}$ /watt for the CS5253B-8 in the D2PAK package. For a high current regulator such as the CS5253B-8 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta J \text { J }}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see our application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## CS5203-1

### 3.0 A Adjustable Linear Regulator

The CS5203-1 linear regulator provides 3.0 A at adjustable output voltages with an accuracy of $\pm 1.5 \%$. The device uses two external resistors to set the output voltage within a 1.25 V to 5.5 V range.

The regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages less than 1.4 V at 3.0 A output current. Device protection includes overcurrent and thermal shutdown.

The CS5203-1 is pin compatible with the LT1085 family of linear regulators but has lower dropout voltage.

The regulator is available in TO-220 and surface mount $\mathrm{D}^{2}$ packages.

## Features

- Output Current to 3.0 A
- Output Accuracy to $\pm 1.5 \%$ Over Temperature
- Dropout Voltage (typical) 1.2 V @ 3.0 A
- Fast Transient Response
- Fault Protection
- Current Limit
- Thermal Shutdown

## APPLICATIONS INFORMATION

The CS5203-1 linear regulator provides adjustable voltages at currents up to 3.0 A . The regulator is protected against overcurrent conditions and includes thermal shutdown.

The CS5203-1 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The CS5203-1 has an output voltage range of 1.25 V to 5.5 V . An external resistor divider sets the output voltage as shown in Figure 12. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 2.0 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. While not required, a bypass capacitor from the adjust pin to ground will improve ripple rejection and transient response. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Type and value may be varied to obtain optimum performance vs. price.

Figure 12. Resistor Divider Scheme

The CS5201-1 linear regulator has an absolute maximum specification of 7.0 V for the voltage difference between $\mathrm{V}_{\text {IN }}$ and Vout. However, the IC may be used to regulate voltages in excess of 7.0 V . The main considerations in such a design are power-up and short circuit capability.

In most applications, ramp-up of the power supply to $\mathrm{V}_{\text {IN }}$ is fairly slow, typically on the order of several tens of milliseconds, while the regulator responds in less than one microsecond. In this case, the linear regulator begins charging the load as soon as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential is large enough that the pass transistor conducts current. The load at this point is essentially at ground, and the supply voltage is on the order of several hundred millivolts, with the result that the pass transistor is in dropout. As the supply to $\mathrm{V}_{\mathrm{IN}}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $V_{\text {OUT }}$ reaches the point at which the IC is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. The result is that the output voltage follows the power supply ramp-up, staying in dropout until the regulation point is reached. In this manner, any output voltage may be regulated. There is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 7.0 V is not exceeded.
However, the possibility of destroying the IC in a short circuit condition is very real for this type of design. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Over-voltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 7.0 V if failsafe operation is required. One possible clamp circuit is illustrated in Figure 13; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 13. Short Circuit Protection Circuit for High Voltage Application.

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5203-1 the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5203-1 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 14 is recommended.

Figure 14. Protection Diode Scheme for Large Output Capacitors

## Output Voltage Sensing

Since the CS5203-1 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.
For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 15. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes.

$$
\mathrm{R}_{\mathrm{C}} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 15. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitic Resistance Effects

## Calculating Power Dissipation and Heat Sink Requirements

The CS5203-1 linear regulator includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V Vut on the CS5203-1, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{22}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$P_{D}($ max $)=\left\{V_{I N}(\right.$ max $)-V_{O U T}($ min $\left.)\right\} I_{O U T}($ max $)+V_{I N(m a x)}{ }^{l Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{~A}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{24}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (22).
The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5203-1 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \text { JA }}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5253-1

### 3.0 A LDO 5-Pin Adjustable Linear Regulator

This new very low dropout linear regulator reduces total power dissipation in the application. To achieve very low dropout, the internal pass transistor is powered separately from the control circuitry. Furthermore, with the control and power inputs tied together, this device can be used in single supply configuration and still offer a better dropout voltage than conventional PNP-NPN based LDO regulators. In this mode the dropout is determined by the minimum control voltage.

The CS5253-1 is offered in a five-terminal D ${ }^{2}$ PAK package, which allows for the implementation of a remote-sense pin permitting very accurate regulation of output voltage directly at the load, where it counts, rather than at the regulator. This remote sensing feature virtually eliminates output voltage variations due to load changes and resistive voltage drops. Typical load regulation measured at the sense pin is less than 1.0 mV for an output voltage of 2.5 V with a load step of 10 mA to 3.0 A .

The CS5253-1 has a very fast transient loop response which can be adjusted using a small capacitor on the Adjust pin.

Internal protection circuitry provides for "bust-proof" operation, similar to three-terminal regulators. This circuitry, which includes overcurrent, short circuit, and overtemperature protection will self protect the regulator under all fault conditions.

The CS5253-1 is ideal for generating a 2.5 V supply to power graphics controllers used on VGA cards.

## Features

- V
- $V_{\text {POWER }}$ Dropout < 0.40 V @ 3.0 A
- $\mathrm{V}_{\text {CONTROL }}$ Dropout < 1.05 V @ 3.0 A
- $1.0 \%$ Trimmed Reference
- Fast Transient Response
- Remote Voltage Sensing
- Thermal Shutdown
- Current Limit
- Short Circuit Protection
- Drop-In Replacement for EZ1582
- Backwards Compatible with 3-Pin Regulators
- Very Low Dropout Reduces Total Power Consumption

5. Dropout is defined as either the minimum control voltage ( $\mathrm{V}_{\text {CONTROL }}$ ) or minimum power voltage ( $\mathrm{V}_{\text {POWER }}$ ) to output voltage differential required to maintain $1.0 \%$ regulation at a particular load current.
6. This parameter is guaranteed by design, but not parametrically tested in production. However, a $100 \%$ thermal shutdown functional test is performed on each part.

## PACKAGE PIN DESCRIPTION

| PACKAGE PIN \# |  |  |
| :---: | :---: | :---: |
| D2PAK | PIN SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\text {SENSE }}$ | This Kelvin sense pin allows for remote sensing of the output voltage at the load for improved regulation. It is internally connected to the positive input of the voltage sensing error amplifier. |
| 2 | Adjust | This pin is connected to the low side of the internally trimmed $1.0 \%$ bandgap reference voltage and carries a bias current of about $50 \mu \mathrm{~A}$. A resistor divider from Adjust to $\mathrm{V}_{\text {OUT }}$ and from Adjust to ground sets the output voltage. Also, transient response can be improved by adding a small bypass capacitor from this pin to ground. |
| 3 | $\mathrm{V}_{\text {OUT }}$ | This pin is connected to the emitter of the power pass transistor and provides a regulated voltage capable of sourcing 3.0 A of current. |
| 4 | V ${ }_{\text {CONTROL }}$ | This is the supply voltage for the regulator control circuitry. For the device to regulate, this voltage should be between 0.9 V and 1.3 V (depending on the output current) greater than the output voltage. The control pin current will be about $1.0 \%$ of the output current. |
| 5 | $V_{\text {POWER }}$ | This is the power input voltage. This pin is physically connected to the collector of the power pass transistor. For the device to regulate, this voltage should be between 0.1 V and 0.6 V greater than the output voltage depending on the output current. The output load current of 3.0 A is supplied through this pin. |

## APPLICATIONS NOTES

## THEORY OF OPERATION

The CS5253-1 linear regulator provides adjustable voltages from 1.26 V to 5.0 V at currents up to 3.0 A . The regulator is protected against short circuits, and includes a thermal shutdown circuit with hysteresis. The output, which is current limited, consists of a PNP-NPN transistor pair and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## $V_{\text {Power }}$ Function

The CS5253-1 utilizes a two supply approach to maximize efficiency. The collector of the power device is brought out to the $V_{\text {POWER }}$ pin to minimize internal power dissipation under high current loads. $\mathrm{V}_{\text {CONTROL }}$ provides for the control circuitry and the drive for the output NPN transistor. $\mathrm{V}_{\text {CONTROL }}$ should be at least 1.0 V greater than the output voltage. Special care has been taken to ensure that there are no supply sequencing problems. The output voltage will not turn on until both supplies are operating. If the control voltage comes up first, the output current will be limited to about three milliamperes until the power input voltage comes up. If the power input voltage comes up first, the output will not turn on at all until the control voltage comes up. The output can never come up unregulated.

The CS5253-1 can also be used as a single supply device with the control and power inputs tied together. In this mode, the dropout will be determined by the minimum control voltage.

## Output Voltage Sensing

The CS5253-1 five terminal linear regulator includes a dedicated $\mathrm{V}_{\text {SENSE }}$ function. This allows for true Kelvin sensing of the output voltage. This feature can virtually eliminate errors in the output voltage due to load regulation. Regulation will be optimized at the point where the sense pin is tied to the output.

## DESIGN GUIDELINES

## Adjustable Operation

This LDO adjustable regulator has an output voltage range of 1.26 V to 5.0 V . An external resistor divider sets the output voltage as shown in Figure 19. The regulator's voltage sensing error amplifier maintains a fixed 1.260 V reference between the output pin and the adjust pin.

Figure 19. Typical Application Schematic. The Resistor Divider Sets $\mathrm{V}_{\text {OUT }}$, With the Internal 1.260 V Reference Dropped Across R1.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.260 V across R1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of V VUT is necessary. The output voltage is set according to the formula:

$$
\mathrm{V} \text { OUT }=1.260 \mathrm{~V} \times \frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}+\mathrm{R} 2 \times \mathrm{I} \mathrm{ADJ}
$$

The term $\mathrm{I}_{\mathrm{ADJ}} \times \mathrm{R} 2$ represents the error added by the adjust pin current. R1 is chosen so that the minimum load current is at least $10 \mathrm{~mA} . \mathrm{R} 1$ and R 2 should be of the same composition for best tracking over temperature. The divider resistors should be placed physically as close to the load as possible.

While not required, a bypass capacitor connected between the adjust pin and ground will improve transient response and ripple rejection. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Value and type may be varied to optimize performance vs. price.

## Other Adjustable Operation Considerations

The CS5253-1 linear regulator has an absolute maximum specification of 6.0 V for the voltage difference between $\mathrm{V}_{\text {Power }}$ and $\mathrm{V}_{\text {OUT }}$. However, the IC may be used to regulate voltages in excess of 6.0 V . The two main
considerations in such a design are the sequencing of power supplies and short circuit capability.

Power supply sequencing should be such that the $\mathrm{V}_{\text {CONTROL }}$ supply is brought up coincidentally with or before the $\mathrm{V}_{\text {POWER }}$ supply. This allows the IC to begin charging the output capacitor as soon as the VPOWER to $V_{\text {OUT }}$ differential is large enough that the pass transistor conducts. As VPOWER increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. In this manner, any output voltage less than 13 V may be regulated, provided the $V_{\text {POWER }}$ to $V_{\text {OUT }}$ differential is less than 6.0 V. In the case where $\mathrm{V}_{\text {CONTROL }}$ and $\mathrm{V}_{\text {POWER }}$ are shorted, there is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 6.0 V is not exceeded.

There is a possibility of damaging the IC when VPOWER - V VUT is greater than 6.0 V if a short circuit occurs. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Overvoltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 6.0 V if fail safe operation is required. One possible clamp circuit is illustrated in Figure 20; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 20. This Circuit Is an Example of How the CS5253-1 Can Be Short-Circuit Protected When Operating With $\mathrm{V}_{\mathrm{OUT}}>6.0 \mathrm{~V}$

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: loop stability, start-up delay, and load transient response. Different capacitor types vary widely in tolerance, ESR (equivalent
series resistance), ESL (equivalent series inductance), and variation over temperature. Tantalum and aluminum electrolytic capacitors work best, with electrolytic capacitors being less expensive in general, but varying more in capacitor value and ESR over temperature.
The CS5253-1 requires an output capacitor to guarantee loop stability. The Stability vs ESR graph in the typical performance section shows the minimum ESR needed to guarantee stability, but under ideal conditions. These include: having $\mathrm{V}_{\text {OUT }}$ connected to $\mathrm{V}_{\text {SENSE }}$ directly at the IC pins; the compensation capacitor located right at the pins with a minimum lead length; the adjust feedback resistor divider ground, (bottom of R2 in Figure 19), connected right at the capacitor ground; and with power supply decoupling capacitors located close to the IC pins. The actual performance will vary greatly with board layout for each application. In particular, the use of the remote sensing feature will require a larger capacitor with less ESR. For most applications, a minimum of $33 \mu \mathrm{~F}$ tantalum or $150 \mu \mathrm{~F}$ aluminum electrolytic, with an ESR less than $1.0 \Omega$ over temperature, is recommended. Larger capacitors and lower ESR will improve stability.

The load transient response, during the time it takes the regulator to respond, is also determined by the output capacitor. For large changes in load current, the ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

There is then an additional drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{T} / \mathrm{C}
$$

where T is the time for the regulation loop to begin to respond. The very fast transient response time of the CS5253-1 allows the ESR effect to dominate. For microprocessor applications, it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best transient response.

## Protection Diodes

When large external capacitors are used with a linear regulator, it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage, and the rate at which $\mathrm{V}_{\text {CONTROL }}$ drops. In the CS5253-1 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 21 is recommended.

Figure 21. Diode Protection Circuit
A rule of thumb useful in determining if a protection diode is required is to solve for current:

$$
I=\frac{C \times V}{T}
$$

where:
I is the current flow out of the load capacitance when $\mathrm{V}_{\text {CONTROL }}$ is shorted,
C is the value of load capacitance
V is the output voltage, and
T is the time duration required for $\mathrm{V}_{\mathrm{CONTROL}}$ to transition from high to being shorted.
If the calculated current is greater than or equal to the typical short circuit current value provided in the specifications, serious thought should be given to the use of a protection diode.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions.

## Short Circuit Protection

The device includes short circuit protection circuitry that clamps the output current at approximately 500 mA less than its current limit value. This provides for a current foldback function, which reduces power dissipation under a direct shorted load.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to activate above a die junction temperature of approximately $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry has $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5253-1 usually operate at high junction temperatures. Therefore, it is
important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5253-1, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound in necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit

The thermal characteristics of an IC depend on the following four factors: junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{PD}_{(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:

$$
\begin{aligned}
\mathrm{PD}_{(\max )}= & \left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}(\text { min })}\right) \mathrm{I}_{\mathrm{OUT}}(\text { max }) \\
& +\mathrm{V}_{\mathrm{IN}(\text { max })} \times \mathrm{I}_{\mathrm{IN}(\text { max })}
\end{aligned}
$$

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance which is measured in degrees per watt. Like series electrical resistances, these thermal resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta \mathrm{JA}}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case ( $\mathrm{R}_{\Theta J C}$ ), case to heat $\operatorname{sink}\left(\mathrm{R}_{\Theta C S}\right)$, and heat sink to ambient air $\left(\mathrm{R}_{\Theta S A}\right)$. The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

The value for $\mathrm{R}_{\mathrm{QJC}}$ is $2.5^{\circ} \mathrm{C} /$ watt for the CS5253-1 in the $D^{2}$ PAK package. For a high current regulator such as the CS5253-1 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see our application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## CS5204-2

### 4.0 A, 1.5 V Fixed Linear Regulator

The CS5204-2 linear regulator provides $4.0 \mathrm{~A} @ 1.5 \mathrm{~V}$ with an accuracy of $\pm 2.0 \%$.

The fast loop response and low dropout voltage make this regulator ideal for GTL bus termination where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulator is fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The regulator is available in TO-220 and surface mount $\mathrm{D}^{2}$ packages.

## Features

- Output Current to 4.0 A
- Output Voltage Trimmed to $\pm 2.0 \%$
- Dropout Voltage (typical) 1.10 V @ 4.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

## APPLICATIONS INFORMATION

The CS5204-2 linear regulator provides fixed 1.5 V voltage at currents up to 4.0 A . The regulator is protected against short circuit, and includes thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increase.

The CS5204-2 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5204-2 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5204-2 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 7 is recommended.

Figure 7. Protection Diode Scheme

## Output Voltage Sensing

Since the CS5204-2 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 8.

Figure 8. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme

## Calculating Power Dissipation and Heat Sink Requirements

The CS5204-2 linear regulator includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V VUT on the CS5204-2, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{25}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta \mathrm{SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{27}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (25).
$\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.6^{\circ} \mathrm{C} / \mathrm{Watt}$ for the CS5204-2. For a high current regulator such as the CS5204-2 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5204-1, CS5204-3, CS5204-5

### 4.0 A Adjustable, and 3.3 V and 5.0 V Fixed Linear Regulators

The CS5204-x series of linear regulators provides 4.0 A at adjustable and fixed voltages with an accuracy of $\pm 1.0 \%$ and $\pm 2.0 \%$ respectively. The adjustable version uses two external resistors to set the output voltage within a 1.25 V to 13 V range.

The regulators are intended for use as post regulators and microprocessor supplies. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulators are fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The regulators are available in TO-220 and surface mount $\mathrm{D}^{2} \mathrm{PAK}$ packages.

## APPLICATIONS INFORMATION

The CS5204-x family of linear regulators provides fixed or adjustable voltages at currents up to 4.0 A . The regulators are protected against short circuit, and include thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5204-x has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator (CS5204-1) has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 10. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is bypassed to improve the transient response and ripple rejection of the regulator.

Figure 10. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5204-x the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current.

The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under load transient conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5204-x family of linear regulators, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figures 11 and 12 is recommended.

Figure 11. Protection Diode Scheme for Adjustable Output Regulator

Figure 12. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5204-x is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the fixed regulators should be connected as shown in Figure 13.

Figure 13. Conductor Parasitic Resistance can be Minimized with the Above Grounding Scheme for Fixed Output Regulators

For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes

$$
\mathrm{RC} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5204-x series of linear regulators includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V VUT on the CS5204-x, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{28}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$P_{D}($ max $)=\left\{V_{I N}(\right.$ max $)-V_{O U T}($ min $\left.)\right\} I_{O U T}($ max $)+V_{I N(m a x)}{ }^{l Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{~A}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{30}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (28).

The value for $\mathrm{R}_{\Theta J C}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5204-x the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5205-2

### 5.0 A, 1.5 V Fixed Linear Regulator

The CS5205-2 linear regulator provides 5.0 A @ 1.5 V with an accuracy of $\pm 2.0 \%$.

The regulator is intended for use as an active termination for the GTL bus on Intel based motherboards. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulator is fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The CS5205-2 is available in TO-220 and surface mount $\mathrm{D}^{2}$ packages.

## Features

- Output Current to 5.0 A
- Output Voltage Trimmed to $\pm 2.0 \%$
- Dropout Voltage 1.2 V @ 5.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

## APPLICATIONS INFORMATION

The regulator is protected against short circuit, and includes thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increase.

The CS5205-2 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5205-2 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5205-2 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 7 is recommended.

Figure 7. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5205-2 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 8.

Figure 8. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme for Fixed Output Regulators

## Calculating Power Dissipation and Heat Sink Requirements

The CS5205-2 includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to VOUT on the CS5205-2, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $P_{D}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{31}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta \mathrm{SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{33}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (31).
$\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.6^{\circ} \mathrm{C} /$ Watt for the CS5205-2. For a high current regulator such as the CS5205-2 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5205-1, CS5205-3, CS5205-5

### 5.0 A Adjustable, and 3.3 V and 5.0 V Fixed Linear Regulators

The CS5205-x series of linear regulators provides 5.0 A at adjustable and fixed voltages with an accuracy of $\pm 1.0 \%$ and $\pm 2.0 \%$ respectively. The adjustable version uses two external resistors to set the output voltage within a 1.25 V to 13 V range.

The regulators are intended for use as post regulators and microprocessor supplies. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulators are fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The CS5205-x is pin compatible with the LT1084 family of linear regulators but has lower dropout voltage.

The regulators are available in TO-220 and surface mount $\mathrm{D}^{2} \mathrm{PAK}$ packages.

## APPLICATIONS INFORMATION

The CS5205-x family of linear regulators provide fixed or adjustable voltages at currents up to 5.0 A. The regulators are protected against short circuit, and include thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5205-x has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator (CS5205-1) has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 10. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is bypassed to improve the transient response and ripple rejection of the regulator.

Figure 10. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5205-x the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current.

The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under load transient conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5205-x family of linear regulators, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figures 11 and 12 is recommended.

Figure 11. Protection Diode Scheme for Adjustable Output Regulator

Figure 12. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5205-x is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the fixed regulators should be connected as shown in Figure 13.

Figure 13. Conductor Parasitic Resistance can be Minimized with the Above Grounding Scheme for Fixed Output Regulators

For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes

$$
\mathrm{RC} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5205-x series of linear regulators includes thermal shutdown and current limit circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to VOUT on the CS5205-x, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{34}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$P_{D}($ max $)=\left\{V_{I N}(\right.$ max $)-V_{O U T}($ min $\left.)\right\} I_{O U T}($ max $)+V_{I N(m a x)}{ }^{l} \mathrm{Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{SA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{36}
\end{equation*}
$$

The value for $\mathrm{R}_{\text {©JA }}$ is calculated using equation (3) and the result can be substituted in equation (34).

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $3.5^{\circ} \mathrm{C} / \mathrm{W}$ for a given package type based on an average die size. For a high current regulator such as the CS5205-x the majority of the heat is generated in the power transistor section. The value for $R_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5205A-1

### 5.0 A Adjustable Linear Regulator

The CS5205A-1 linear regulator provides 5.0 A at an adjustable voltage with an accuracy of $\pm 1 \%$. Two external resistors are used to set the output voltage within a 1.25 V to 13 V range.

The regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulator is fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The CS5205A-1 is pin compatible with the LT1084 family of linear regulators but has lower dropout voltage.

The regulator is available in $T O-220$ and surface mount $\mathrm{D}^{2}$ packages.

## Features

- Output Current to 5.0 A
- Output Trimmed to $\pm 1 \%$
- Dropout Voltage 1.15 V @ 5.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

Figure 6. Ripple Rejection vs. Frequency

## APPLICATIONS INFORMATION

The CS5205A-1 linear regulator provides an adjustable voltage at currents up to 5.0 A . The regulator is protected against short circuit, and include thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5205A-1 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator (CS5205A-1) has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 7. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{\text {Adj }} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is bypassed to improve the transient response and ripple rejection of the regulator.

Figure 7. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5205A-1 the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under load transient conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5205A-1 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 8 is recommended.

Figure 8. Protection Diode Scheme for Adjustable Output Regulator

## Output Voltage Sensing

Since the CS5205A-1 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.

Best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 9. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes

$$
\mathrm{R}_{\mathrm{C}} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 9. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5205A-1 linear regulator includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.
The case is connected to $V_{\text {OUT }}$ on the CS5205A-1, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.
The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{37}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$\mathrm{P}_{\mathrm{D}(\text { max })}=\left\{\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{V}_{\mathrm{OUT}(\min )}\right\}_{\mathrm{I}} \mathrm{OUT}(\max )+\mathrm{V}_{\mathrm{IN}(\text { max })} \mathrm{l}_{\mathrm{Q}}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
$I_{\text {OUT(max) }}$ is the maximum output current, for the application $\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\mathrm{ESA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{39}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (37).

The value for $\mathrm{R}_{\Theta J C}$ is normally quoted as a single figure for a given package type based on an average die size. For a high current regulator such as the CS5205A-1 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact
area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5206-1, CS5206-3, CS5206-5

### 6.0 A Adjustable, and Fixed 3.3 V and 5.0 V Linear Regulators

The CS5206-X series of linear regulators provides 6.0 A at adjustable and fixed voltages of 3.3 V and 5.0 V with an accuracy of $\pm 1 \%$ and $\pm 2 \%$ respectively. The adjustable version uses two external resistors to set the output voltage within a 1.25 V to 13 V range.

The regulators are intended for use as post regulators and microprocessor supplies. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulators are fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The regulators are available in TO-220 and surface mount $\mathrm{D}^{2} \mathrm{PAK}$ packages.

## Features

- Output Current to 6.0 A
- Output Trimmed to $\pm 1 \%$
- Dropout Voltage 1.3 V @ 6.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

## APPLICATIONS INFORMATION

The CS5206-X family of linear regulators provide fixed or adjustable voltages at currents up to 6.0 A. The regulators are protected against short circuit, and include thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5206-X has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator (CS5206-1) has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 10. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary.

The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{A d j} \times R 2
$$

The term $\mathrm{I}_{\text {Adj }} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is
bypassed to improve the transient response and ripple rejection of the regulator.

Figure 10. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the

CS5206-X the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under load transient conditions. The output capacitor network should be as close as possible to the load for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5206-X family of linear regulators, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figures 11 and 12 is recommended.

Figure 11. Protection Diode Scheme for Adjustable Output Regulator

Figure 12. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5206-X is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the fixed regulators should be connected as shown in Figure 13.

Figure 13. Conductor Parasitic Resistance can be Minimized with the Above Grounding Scheme for Fixed Output Regulators
For the adjustable regulator, the best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 14. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes

$$
\mathrm{RC} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 14. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5206-X series of linear regulators includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction
temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5206-X, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $P_{D}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{40}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:
$\mathrm{P}_{\mathrm{D}(\text { max })}=\left\{\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{V}_{\mathrm{OUT}(\text { min })}\right\}_{\mathrm{I}} \mathrm{OUT}($ max $)+\mathrm{V}_{\mathrm{IN}(\text { max })}{ }^{\mathrm{l} Q}$
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application $\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S \mathrm{~A}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{42}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (40).

The value for $\mathrm{R}_{\Theta J C}$ is normally quoted as a single figure for a given package type based on an average die size. For a high current regulator such as the CS5206-X the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta \text { JSA }}$ depends on the heat sink type, while $\mathrm{R}_{\Theta \text { JICS }}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $R_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5207-2

### 7.0 A, 1.5 V Fixed Linear Regulator

The CS5207-2 provides 7.0 A at 1.5 V with an accuracy of $\pm 2.0 \%$. The regulator is intended for use as an active termination for the GTL bus on Intel based motherboards. The fast loop response and low dropout voltage make these regulators ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current level. The maximum quiescent current is only 10 mA at full load.

The regulators are fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The CS5207-2 is available in TO-220 packages.

## Features

- Output Current to 7.0 A
- Output Voltage Trimmed to $\pm 2.0 \%$
- Dropout Voltage 1.45 V @ 7.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

## APPLICATIONS INFORMATION

The CS5207-2 linear regulator provides a fixed 1.5 V output at currents up to 7.0 A . The regulator is protected against short circuit, and includes thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increase.

The CS5207-2 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5207-2 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5207-2 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 6 is recommended.

Figure 6. Protection Diode Scheme for Fixed Output Regulators

## Output Voltage Sensing

Since the CS5207-2 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load. For best results the regulator should be connected as shown in Figure 7.

Figure 7. Conductor Parasitic Resistance Effects Can Be Minimized With the Above Grounding Scheme for Fixed Output Regulators

## Calculating Power Dissipation and Heat Sink Requirements

The CS5207-2 includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to VOUT on the CS5207-2, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $P_{D}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{43}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\text {©SA }}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{45}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (43).
$\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.6^{\circ} \mathrm{C} /$ Watt for the CS5207-2. For a high current regulator such as the CS5207-2 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## APPLICATIONS INFORMATION

The CS5207-3 linear regulator provides a fixed 3.3 V output currents up to 7.0 A . The regulator is protected against short circuit, and includes thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increase.

The CS5207-3 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5207-3 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5207-3 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 6 is recommended.

Figure 6. Protection Diode Scheme for Fixed Output Regulator

## Output Voltage Sensing

Since the CS5207-3 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.
Best load regulation occurs when the regulator is connected to the load as shown in Figure 7.

Figure 7. Grounding Scheme for the Output Regulator to Minimize Parasitics

## Calculating Power Dissipation and Heat Sink Requirements

The CS5207-3 linear regulator includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V VUT on the CS5207-3, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $P_{D}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{46}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ $\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S A}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{48}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (46).
$\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.6^{\circ} \mathrm{C} /$ Watt for the CS5207-3. For a high current regulator such as the CS5207-3 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5207-1

### 7.0 A Adjustable Linear Regulator

The CS5207-1 linear regulator provides 7.0 A adjustable voltages with an accuracy of $\pm 1.5 \%$. Two external resistors are used to set the output voltage within a 1.25 V to 13 V range.

The regulator is intended for use as post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V depending on the output current. The maximum quiescent current is only 10 mA at full load.

The regulator is fully protected against overload conditions with protection circuitry for Safe Operating Area (SOA), overcurrent and thermal shutdown.

The regulator is available in TO-220 package. A 3.3 V , fixed version is also available. Please consult your local sales representative for more information.

## Features

- Output Current to 7.0 A
- Output Trimmed to $\pm 1.5 \%$
- Dropout Voltage 1.4 V @ 7.0 A
- Fast Transient Response
- Fault Protection Circuitry
- Thermal Shutdown
- Overcurrent Protection
- Safe Area Protection

## APPLICATIONS INFORMATION

The CS5207-1 linear regulator provides adjustable voltages at currents up to 7.0 A . The regulator is protected against short circuit, and includes thermal shutdown and safe area protection (SOA) circuitry. The SOA protection circuitry decreases the maximum available output current as the input-output differential voltage increases.

The CS5207-1 has a composite PNP-NPN output transistor and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## Adjustable Operation

The adjustable regulator has an output voltage range of 1.25 V to 13 V . An external resistor divider sets the output voltage as shown in Figure 7. The regulator maintains a fixed 1.25 V (typical) reference between the output pin and the adjust pin.

A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.25 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of VOUT is necessary.
The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R 1+R 2}{R 1}\right)+I_{\text {Adj }} \times R 2
$$

The term $\mathrm{I}_{\mathrm{Adj}} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R 1 is chosen so that the minimum load current is at least 10 mA . R1 and R2 should be the same type, e.g. metal film for best tracking over temperature. The adjust pin is bypassed to improve the transient response and ripple rejection of the regulator.

Figure 7. Resistor Divider Scheme for the Adjustable Version

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.
A $22 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5207-1 the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta \mathrm{V}=\Delta \mathrm{I} \times \mathrm{ESR}
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\text {IN }}$ drops. In the CS5207-1 linear regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 8 is recommended.

Figure 8. Protection Diode Scheme for Adjustable Output Regulator

## Output Voltage Sensing

Since the CS5207-1 is a three terminal regulator, it is not possible to provide true remote load sensing. Load regulation is limited by the resistance of the conductors connecting the regulator to the load.

Best load regulation occurs when R1 is connected directly to the output pin of the regulator as shown in Figure 9. If R1 is connected to the load, $\mathrm{R}_{\mathrm{C}}$ is multiplied by the divider ratio and the effective resistance between the regulator and the load becomes.

$$
\mathrm{RC} \times\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

where $\mathrm{R}_{\mathrm{C}}=$ conductor parasitic resistance.

Figure 9. Grounding Scheme for Adjustable Output Regulator to Minimize Parasitic Resistance Effects

## Calculating Power Dissipation and Heat Sink Requirements

The CS5207-1 linear regulator includes thermal shutdown and safe operating area circuitry to protect the device. High power regulators such as these usually operate at high junction temperatures so it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used.

The case is connected to V ${ }_{\text {OUT }}$ on the CS5207-1, electrical isolation may be required for some applications. Thermal compound should always be used with high current regulators such as these.

The thermal characteristics of an IC depend on the following four factors:

1. Maximum Ambient Temperature $\mathrm{T}_{\mathrm{A}}\left({ }^{\circ} \mathrm{C}\right)$
2. Power dissipation $\mathrm{P}_{\mathrm{D}}$ (Watts)
3. Maximum junction temperature $\mathrm{T}_{\mathrm{J}}\left({ }^{\circ} \mathrm{C}\right)$
4. Thermal resistance junction to ambient $\mathrm{R}_{\Theta \mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$

These four are related by the equation

$$
\begin{equation*}
T_{J}=T_{A}+P_{D} \times R_{\Theta J A} \tag{49}
\end{equation*}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type.

The maximum power dissipation for a regulator is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT(min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current, for the application
$\mathrm{I}_{\mathrm{Q}}$ is the maximum quiescent current at $\mathrm{I}_{\mathrm{OUT}(\max )}$.
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine $\mathrm{R}_{\Theta J A}$, the total thermal resistance between the junction and the surrounding air.

1. Thermal Resistance of the junction to case, $\mathrm{R}_{\Theta \mathrm{JC}}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
2. Thermal Resistance of the case to Heat Sink, $\mathrm{R}_{\Theta C S}$ ( ${ }^{\circ} \mathrm{C} / \mathrm{W}$ )
3. Thermal Resistance of the Heat Sink to the ambient air, $\mathrm{R}_{\Theta S A}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$
These are connected by the equation:

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{51}
\end{equation*}
$$

The value for $\mathrm{R}_{\Theta J A}$ is calculated using equation (3) and the result can be substituted in equation (49).

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is normally quoted as a single figure for a given package type based on average die size. For a high current regulator such as the CS5207-1 the majority of the heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $R_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5207A-1

### 7.0 A LDO 3-Pin Adjustable Linear Regulator

The CS5207A-1 linear regulator provides 7.0 A at adjustable voltages from 1.25 V to 5.0 V . This adjustable device requires two external resistors to set the output voltage and provide the minimum load current for proper regulation.

This regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V at 7.0 A .

This regulator is protected against overload conditions with overcurrent and thermal shutdown protection circuitry.

The CS5207A-1 is pin compatible with the LT1584 family of linear regulators but has lower dropout voltage and faster transient response.

This regulator is available in a TO-220 package.

## Features

- 1.25 V to 5.0 V V OUT @ 7.0 A
- Dropout Voltage < 1.0 V @ 7.0 A
- $1.5 \%$ Trimmed Reference
- Fast Transient Response
- Thermal Shutdown
- Current Limit
- Short Circuit Protection
- Drop-In Replacement for LT1584

## APPLICATION NOTES

## THEORY OF OPERATION

The CS5207A-1 linear regulator has a composite PNP-NPN output stage that requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## ADJUSTABLE OPERATION

## Design Guidelines

This LDO adjustable regulator has an output voltage range of 1.25 V to 5.0 V . An external resistor divider sets the output voltage as shown in Figure 11. The regulator's voltage sensing error amplifier maintains a fixed 1.25 V reference between the output pin and the adjust pin.

A resistor divider network $R_{1}$ and $R_{2}$ causes a fixed current to flow to ground. This current creates a voltage across $\mathrm{R}_{2}$ that adds to the 1.25 V across $\mathrm{R}_{1}$ and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through $\mathrm{R}_{2}$ and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary. The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R_{1}+R_{2}}{R_{1}}\right)+R_{2} \times I_{A d j}
$$

The term $\mathrm{I}_{\mathrm{Adj}} \times \mathrm{R}_{2}$ represents the error added by the adjust pin current.
$\mathrm{R}_{1}$ is chosen so that the minimum load current is at least 10 mA . $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ should be of the same composition for best tracking over temperature. For best results, the divider resistor should be placed near the regulator with a seperate metal trace connecting them to output..

Figure 11.
While not required, a bypass capacitor connected between the adjust pin and ground will improve transient response and ripple rejection. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Value and type may be varied to optimize performance vs price.

OTHER ADJUSTABLE OPERATION CONSIDERATIONS
The CS5207A-1 linear regulator has an absolute maximum specification of 6.0 V for the voltage difference between $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {OUT }}$. However, the IC may be used to regulate voltages in excess of 6.0 V . The main considerations in such a design are power-up and short circuit capability.
In most applications, ramp-up of the power supply to $\mathrm{V}_{\text {IN }}$ is fairly slow, typically on the order of several tens of milliseconds, while the regulator responds in less than one microsecond. In this case, the linear regulator begins charging the output capacitor as soon as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential is large enough that the pass transistor conducts current. V ${ }_{\text {OUT }}$ is essentially at ground, and $\mathrm{V}_{\text {IN }}$ is on the order of several hundred millivolts, so the pass transistor is in dropout. As $\mathrm{V}_{\text {IN }}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ is in regulation. Further increase in $\mathrm{V}_{\text {IN }}$ brings the pass transistor out of dropout. The result is that the output voltage follows the power supply ramp-up, staying in dropout until the regulation point is reached. In this manner, any output voltage may be regulated. There is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 6.0 V is not exceeded.

However, maximum ratings of the IC will be exceeded in a short circuit condition. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Over-voltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 6.0 V if failsafe operation is required. One possible clamp circuit is illustrated in Figure 12; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit conditions indefinitely while protecting the IC.

Figure 12.

## STABILITY CONSIDERATIONS

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $300 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5207A-1 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5207A-1 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 13 is recommended.

A rule of thumb useful in determining if a protection diode is required is to solve for current

$$
\mathrm{I}=\frac{\mathrm{C} \times \mathrm{V}}{\mathrm{~T}}
$$

where:
I is the current flow out of the load capacitance when $\mathrm{V}_{\mathrm{IN}}$ is shorted,
C is the value of the load capacitance,
V is the output voltage, and
T is the time duaration required for $\mathrm{V}_{\mathrm{IN}}$ to transition from high to being shorted.

If the calculated current is greater than or equal to the typical short circuit current value provided in the specifications, serious thought should be given to including a protection diode.

Figure 13.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions and protects the regulator.

## Short Circuit Protection

The device includes foldback short circuit current limit that clamps the output current at approximately two amperes less than its current limit value.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to become activated above a die junction temperature of $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry includes a thermal hysteresis circuit with $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5207A-1 usually operate at high junction temperatures. Therefore, it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5207A-1, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound is necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit
The thermal characteristics of an IC depend on the following four factors. Junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{P}_{\mathrm{D}(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:
$\mathrm{P}_{\mathrm{D}(\max )}=\left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}}(\min )\right) \mathrm{IOUT}_{\mathrm{O}}(\max )+\mathrm{V}_{\mathrm{IN}(\text { max }} \times \mathrm{I}_{\mathrm{IN}(\text { max })}$
A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta \mathrm{JC}}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case ( $\mathrm{R}_{\Theta \mathrm{JC}}$ ), case to heat sink ( $\mathrm{R}_{\Theta C S}$ ), and heat sink to ambient air ( $\mathrm{R}_{\Theta S A}$ ). The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

$\mathrm{R}_{\Theta \mathrm{JC}}$ is rated @ $1.4^{\circ} \mathrm{C} / \mathrm{W}$ for the CS5207A-1. For a high current regulator such as the CS5207A-1 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $R_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5257A-1

### 7.0 A LDO 5-Pin Adjustable Linear Regulator

This new very low dropout regulator is designed to power the next generation of advanced microprocessors. To achieve very low dropout, the internal pass transistor is powered separately from the control circuitry. Furthermore, with the control and power inputs tied together, this device can be used in single supply configuration and still offer a better dropout voltage than conventional PNP-NPN based LDO regulators. In this mode the dropout is determined by the minimum control voltage.

It is supplied in five-terminal TO-220 and $\mathrm{D}^{2}$ PAK packages, allowing for the implementation of a remote-sense pin permitting very accurate regulation of output voltage directly at the load, where it counts, rather than at the regulator. This remote sensing feature virtually eliminates output voltage variations due to load changes and resistive voltage drops. Typical load regulation measured at the sense pin is 1.0 mV for an output voltage of 2.5 V with a load step of 10 mA to 7.0 A .

The very fast transient loop response easily meets the needs of the latest microprocessors. In addition, a small capacitor on the Adjust pin will further improve the transient capabilities.

Internal protection circuitry provides for "bust-proof" operation, similar to three-terminal regulators. This circuitry, which includes overcurrent, short circuit, supply sequencing and overtemperature protection will self protect the regulator under all fault conditions.

The CS5257A-1 is ideal for generating a secondary $2.0-2.5 \mathrm{~V}$ low voltage supply on a motherboard where both 5.0 V and 3.3 V are already available.

## Features

- 1.25 V to $5.0 \mathrm{~V} \mathrm{~V}_{\text {OUT }}$ at 7.0 A
- $\mathrm{V}_{\text {POWER }}$ Dropout < 0.35 V @ 7.0 A
- $\mathrm{V}_{\text {CONTROL }}$ Dropout < $1.1 \mathrm{~V} @ 7.0 \mathrm{~A}$
- $1.5 \%$ Trimmed Reference
- Fast Transient Response
- Remote Voltage Sensing
- Thermal Shutdown
- Current Limit
- Short Circuit Protection
- Drop-In Replacement for LT1580
- Backwards Compatible with 3-Pin Regulators

## APPLICATIONS NOTES

## THEORY OF OPERATION

The CS5257A-1 linear regulator provides adjustable voltages from 1.25 V to 5.0 V at currents up to 7.0 A . The regulator is protected against short circuits, and includes a thermal shutdown circuit with hysteresis. The output, which is current limited, consists of a PNP-NPN transistor pair and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## $V_{\text {POWER }}$ Function

The CS5257A-1 utilizes a two supply approach to maximize efficiency. The collector of the power device is brought out to the $\mathrm{V}_{\text {POWER }}$ pin to minimize internal power dissipation under high current loads. $\mathrm{V}_{\text {CONTROL }}$ provides power for the control circuitry and the drive for the output NPN transistor. $\mathrm{V}_{\text {CONTROL }}$ should be at least 1.0 V greater than the output voltage. Special care has been taken to ensure
that there are no supply sequencing problems. The output voltage will not turn on until both supplies are operating. If the control voltage comes up first, the output current will be typically limited to about 3.0 mA until the power input voltage comes up. If the power input voltage comes up first the output will not turn on at all until the control voltage comes up. The output can never come up unregulated.

The CS5257A-1 can also be used as a single supply device with the control and power inputs tied together. In this mode, the dropout will be determined by the minimum control voltage.

## Output Voltage Sensing

The CS5257A-1 five terminal linear regulator includes a dedicated $\mathrm{V}_{\text {SENSE }}$ function. This allows for true Kelvin sensing of the output voltage. This feature can virtually eliminate errors in the output voltage due to load regulation.

Regulation will be optimized at the point where the sense pin is tied to the output.

## DESIGN GUIDELINES

## Adjustable Operation

This LDO adjustable regulator has an output voltage range of 1.25 V to 5.0 V . An external resistor divider sets the output voltage as shown in Figure 16. The regulator's voltage sensing error amplifier maintains a fixed 1.253 V reference between the output pin and the adjust pin.

Figure 16. An External Resistor Divider Sets the Value of $V_{\text {OUt }}$. The 1.253 V Reference Voltage Drops Across R1.
A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.253 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary. The output voltage is set according to the formula:

$$
\mathrm{VOUT}=1.253 \mathrm{~V} \times \frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}+\mathrm{R} 2 \times \mathrm{I}_{\mathrm{AD}} \mathrm{~J}
$$

The term $\mathrm{I}_{\mathrm{ADJ}} \times \mathrm{R} 2$ represents the error added by the adjust pin current. R1 is chosen so that the minimum load current is a least 10 mA . R1 and R2 should be of the same composition for best tracking over temperature. The divider resistors should be placed physically as close to the load as possible.

While not required, a bypass capacitor connected between the adjust pin and ground will improve transient response and ripple rejection. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Value and type may be varied to optimize performance vs. price.

## Other Adjustable Operation Considerations

The CS5257A-1 linear regulator has an absolute maximum specification of 6.0 V for the voltage difference between $V_{\text {IN }}$ and Vout. However, the IC may be used to regulate voltages in excess of 6.0 V . The two main considerations in such a design are the sequencing of power supplies and short circuit capability.

Power supply sequencing should be such that the $\mathrm{V}_{\text {CONTROL }}$ supply is brought up coincidentally with or before the $\mathrm{V}_{\text {POWER }}$ supply. This allows the IC to begin charging the output capacitor as soon as the $\mathrm{V}_{\text {POWER }}$ to $V_{\text {OUT }}$ differential is large enough that the pass transistor conducts. As VPOWER increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. In this manner, any output voltage less than 13 V may be regulated, provided the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential is less than 6.0 V . In the case where $\mathrm{V}_{\text {CONTROL }}$ and $\mathrm{V}_{\text {POWER }}$ are shorted, there is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 6.0 V is not exceeded.
There is a possibility of damaging the IC when $V_{\text {POWER }}$ $-\mathrm{V}_{\text {IN }}$ is greater than 6.0 V if a short circuit occurs. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Overvoltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 6.0 V if fail safe operation is required. One possible clamp circuit is illustrated in Figure 17; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 17. Example Clamp Circuitry for $V_{\text {POWER }}-V_{\text {OUT }}>6.0 \mathrm{~V}$

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The
aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $300 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5257A-1 the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage, and the rate at which $\mathrm{V}_{\text {CONTROL }}$ drops. In the CS5257A-1 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 18 is recommended.

Figure 18. Diode Protection Against $\mathrm{V}_{\text {control }}$ Short Circuit Conditions

Use of the diode has the added benefit of bleeding $\mathrm{V}_{\text {OUT }}$ to ground if $\mathrm{V}_{\text {CONTROL }}$ is shorted. This prevents an unregulated output from causing system damage.

A rule of thumb useful in determining if a protection diode is required is to solve for current

$$
\mathrm{I}=\frac{\mathrm{C} \times \mathrm{V}}{\mathrm{~T}}
$$

where:
I is the current flow out of the load capacitance when $\mathrm{V}_{\text {CONTROL }}$ is shorted,
C is the value of load capacitance,
V is the output voltage, and
T is the time duration required for $\mathrm{V}_{\text {CONTROL }}$ to transition from high to being shorted.
If the calculated current is greater than or equal to the typical short circuit current value provided in the specifications, serious thought should be given to the use of a protection diode.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions.

## Short Circuit Protection

The device includes short circuit protection circuitry that clamps the output current at approximately two amperes less than its current limit value. This provides for a current foldback function, which reduces power dissipation under a direct shorted load.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to activate above a die junction temperature of approximately $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry has $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5257A-1 usually operate at high junction temperatures. Therefore, it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5257A-1, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound in necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit.
The thermal characteristics of an IC depend on the following four factors: junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{PD}_{(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the
maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:

$$
\begin{aligned}
\mathrm{PD}_{(\max )}= & \left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{VOUT}_{\text {(min })}\right) \operatorname{IOUT}(\max ) \\
& +\mathrm{VIN}_{\operatorname{IN}(\max )} \times \operatorname{IIN}(\max )
\end{aligned}
$$

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance which is measured in degrees per watt. Like series electrical resistances, these thermal resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta J A}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case $\left(\mathrm{R}_{\Theta \mathrm{JC}}\right)$, case to heat sink $\left(\mathrm{R}_{\Theta C S}\right)$, and heat sink to ambient air $\left(\mathrm{R}_{\Theta S A}\right)$. The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.4^{\circ} \mathrm{C} /$ watt for the CS5257A-1 in both the TO-220 and D ${ }^{2}$ PAK packages. For a high current regulator such as the CS5257A-1 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see our application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## CS5208-1

### 8.0 A LDO 3-Pin Adjustable Linear Regulator

The CS5208-1 linear regulator provides 8.0 A at adjustable voltages from 1.25 V to 4.5 V . This adjustable device requires two external resistors to set the output voltage and provide the minimum load current for proper regulation.

This regulator is intended for use as a post regulator and microprocessor supply. The fast loop response and low dropout voltage make this regulator ideal for applications where low voltage operation and good transient response are important.

The circuit is designed to operate with dropout voltages as low as 1.0 V at 8.0 A .

The regulator is protected against overload conditions with overcurrent and thermal shutdown protection circuitry.

The regulator is available in a TO-220 package.

## Features

- 1.25 V to $4.5 \mathrm{~V}_{\text {OUT }}$ at 8.0 A
- Dropout Voltage < 1.0 V @ 8.0 A
- $1.5 \%$ Trimmed Reference
- Fast Transient Response
- Thermal Shutdown
- Current Limit
- Short Circuit Protection

## APPLICATION NOTES

## THEORY OF OPERATION

The CS5208-1 linear regulator has a composite PNP-NPN output stage that requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## ADJUSTABLE OPERATION

## Design Guidelines

This LDO adjustable regulator has an output voltage range of 1.25 V to 4.5 V . An external resistor divider sets the output voltage as shown in Figure 11. The regulator's voltage sensing error amplifier maintains a fixed 1.25 V reference between the output pin and the adjust pin.

A resistor divider network $R_{1}$ and $R_{2}$ causes a fixed current to flow to ground. This current creates a voltage across $\mathrm{R}_{2}$ that adds to the 1.25 V across $\mathrm{R}_{1}$ and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through $\mathrm{R}_{2}$ and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary. The output voltage is set according to the formula:

$$
V_{\text {OUT }}=V_{\text {REF }} \times\left(\frac{R_{1}+R_{2}}{R_{1}}\right)+R_{2} \times I_{A d j}
$$

The term $\mathrm{I}_{\mathrm{Adj}} \times \mathrm{R}_{2}$ represents the error added by the adjust pin current.
$\mathrm{R}_{1}$ is chosen so that the minimum load current is at least 10 mA . $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ should be of the same composition for best tracking over temperature. The divider resistors should be placed as close to the IC as possible and connected to the output with a seperate metal trace.

Figure 11.
While not required, a bypass capacitor connected between the adjust pin and ground will improve transient response and ripple rejection. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Value and type may be varied to optimize performance vs price.

OTHER ADJUSTABLE OPERATION CONSIDERATIONS
The CS5208-1 linear regulator has an absolute maximum specification of 6.0 V for the voltage difference between $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {OUT }}$. However, the IC may be used to regulate voltages in excess of 6.0 V . The main considerations in such a design are power-up and short circuit capability.
In most applications, ramp-up of the power supply to $\mathrm{V}_{\text {IN }}$ is fairly slow, typically on the order of several tens of milliseconds, while the regulator responds in less than one microsecond. In this case, the linear regulator begins charging the output capacitor as soon as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential is large enough that the pass transistor conducts current. V ${ }_{\text {OUT }}$ is essentially at ground, and $\mathrm{V}_{\text {IN }}$ is on the order of several hundred millivolts, so the pass transistor is in dropout. As $\mathrm{V}_{\text {IN }}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ is in regulation. Further increase in $\mathrm{V}_{\text {IN }}$ brings the pass transistor out of dropout. The result is that the output voltage follows the power supply ramp-up, staying in dropout until the regulation point is reached. In this manner, any output voltage may be regulated. There is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 6.0 V is not exceeded.

However, the maximum ratings of the IC will be exceeded in a short circuit condition. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Over-voltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp $\mathrm{V}_{\text {IN }}$ to $\mathrm{V}_{\text {OUT }}$ differential to less than 6.0 V if failsafe operation is required. One possible clamp circuit is illustrated in Figure 12; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit conditions indefinitely while protecting the IC.

Figure 12.

## STABILITY CONSIDERATIONS

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.

The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $300 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5208-1 the transient response and stability improve with higher values of capacitance. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage and the rate at which $\mathrm{V}_{\mathrm{IN}}$ drops. In the CS5208-1 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 13 is recommended.

A rule of thumb useful in determining if a protection diode is required is to solve for current

$$
\mathrm{I}=\frac{\mathrm{C} \times \mathrm{V}}{\mathrm{~T}}
$$

where:
I is the current flow out of the load capacitance when $\mathrm{V}_{\mathrm{IN}}$ is shorted,
C is the value of the load capacitance,
V is the output voltage, and
T is the time duaration required for $\mathrm{V}_{\text {IN }}$ to transition from high to being shorted.

If the calculated current is greater than or equal to the typical short circuit current value provided in the specifications, serious thought should be given to including a protection diode.

Figure 13.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions and protects the regulator.

## Short Circuit Protection

The device includes foldback short circuit current limit that clamps the output current at approximately two amperes less than its current limit value.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to become activated above a die junction temperature of $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry includes a thermal hysteresis circuit with $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5208-1 usually operate at high junction temperatures. Therefore, it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5208-1, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound is necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit
The thermal characteristics of an IC depend on the following four factors. Junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{P}_{\mathrm{D}(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:

$$
\mathrm{P}_{\mathrm{D}(\max )}=\left(\mathrm{V}_{\mathrm{IN}(\max )}-\mathrm{V}_{\mathrm{OUT}(\min )}\right) \mathrm{IOUT}_{\mathrm{O}}(\max )+\mathrm{V}_{\mathrm{IN}(\max )} \times \mathrm{I}_{\mathrm{IN}(\max )}
$$

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance. Like series electrical resistances, these resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta \mathrm{JC}}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case ( $\mathrm{R}_{\Theta J C}$ ), case to heat sink ( $\mathrm{R}_{\Theta C S}$ ), and heat sink to ambient air ( $\mathrm{R}_{\Theta S A}$ ). The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

$\mathrm{R}_{\Theta \mathrm{JC}}$ is rated @ $1.4^{\circ} \mathrm{C} / \mathrm{W}$ for the CS5208-1. For a high current regulator such as the CS5208-1 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $\mathrm{R}_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $R_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://onsemi.com.

## CS5258-1

### 8.0 A LDO 5-Pin Adjustable Linear Regulator

This new very low dropout regulator is designed to power the next generation of advanced microprocessors. To achieve very low dropout, the internal pass transistor is powered separately from the control circuitry. Furthermore, with the control and power inputs tied together, this device can be used in single supply configuration and still offer a better dropout voltage than conventional PNP-NPN based LDO regulators. In this mode the dropout is determined by the minimum control voltage.

It is supplied in a five-terminal TO-220 package, which allows for the implementation of a remote-sense pin permitting very accurate regulation of output voltage directly at the load, where it counts, rather than at the regulator. This remote sensing feature virtually eliminates output voltage variations due to load changes and resistive voltage drops. Typical load regulation measured at the sense pin is 1.0 mV for an output voltage of 2.5 V with a load step of 10 mA to 8.0 A .

The very fast transient loop response easily meets the needs of the latest microprocessors. In addition, a small capacitor on the Adjust pin will further improve the transient capabilities.

Internal protection circuitry provides for "bust-proof" operation, similar to three-terminal regulators. This circuitry, which includes overcurrent, short circuit, supply sequencing and overtemperature protection, will self protect the regulator under all fault conditions.

The CS5258-1 is ideal for generating a secondary $2.0-2.5 \mathrm{~V}$ low voltage supply on a motherboard where both 5.0 V and 3.3 V are already available.

## Features

7. This parameter is guaranteed by design, but not parametrically tested in production. However, a $100 \%$ thermal shutdown functional test is performed on each part.

## PACKAGE PIN DESCRIPTION

| PACKAGE PIN \# |  |  |
| :---: | :---: | :---: |
| TO-220 | PIN SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\text {SENSE }}$ | This Kelvin sense pin allows for remote sensing of the output voltage at the load for improved regulation. It is internally connected to the positive input of the voltage sensing error amplifier. |
| 2 | Adjust | This pin is connected to the low side of the internally trimmed $1.5 \%$ bandgap reference voltage and carries a bias current of about $50 \mu \mathrm{~A}$. A resistor divider from Adjust to $\mathrm{V}_{\text {OUT }}$ and from Adjust to ground sets the output voltage. Also, transient response can be improved by adding a small bypass capacitor from this pin to ground. |
| 3 | $\mathrm{V}_{\text {OUT }}$ | This pin is connected to the emitter of the power pass transistor and provides a regulated voltage capable of sourcing 8.0 A of current. |
| 4 | $\mathrm{V}_{\text {CONTROL }}$ | This is the supply voltage for the regulator control circuitry. For the device to regulate, this voltage should be between 1.0 V and 1.3 V (depending on the output current) greater than the output voltage. The control pin current will be about $1.0 \%$ of the power pin output current. |
| 5 | $V_{\text {POWER }}$ | This is the power input voltage. This pin is physically connected to the collector of the power pass transistor. For the device to regulate, this voltage should be between 0.1 V and 0.7 V greater than the output voltage depending on the output current. The output load current of 8.0 A is supplied through this pin. |

## APPLICATIONS NOTES

## THEORY OF OPERATION

The CS5258-1 linear regulator provides adjustable voltages from 1.25 V to 5.0 V at currents up to 8.0 A . The regulator is protected against short circuits, and includes a thermal shutdown circuit with hysteresis. The output, which is current limited, consists of a PNP-NPN transistor pair and requires an output capacitor for stability. A detailed procedure for selecting this capacitor is included in the Stability Considerations section.

## $V_{\text {POWER }}$ Function

The CS5258-1 utilizes a two supply approach to maximize efficiency. The collector of the power device is brought out to the $\mathrm{V}_{\text {POWER }}$ pin to minimize internal power dissipation under high current loads. VCONTROL provides power for the control circuitry and the drive for the output NPN transistor. $\mathrm{V}_{\text {CONTROL }}$ should be at least 1.0 V greater than the output voltage. Special care has been taken to ensure
that there are no supply sequencing problems. The output voltage will not turn on until both supplies are operating. If the control voltage comes up first, the output current will be typically limited to about 3.0 mA until the power input voltage comes up. If the power input voltage comes up first the output will not turn on at all until the control voltage comes up. The output can never come up unregulated.
The CS5258-1 can also be used as a single supply device with the control and power inputs tied together. In this mode, the dropout will be determined by the minimum control voltage.

## Output Voltage Sensing

The CS5258-1 five terminal linear regulator includes a dedicated $\mathrm{V}_{\text {SENSE }}$ function. This allows for true Kelvin sensing of the output voltage. This feature can virtually eliminate errors in the output voltage due to load regulation. Regulation will be optimized at the point where the sense pin is tied to the output.

## DESIGN GUIDELINES

## Adjustable Operation

This LDO adjustable regulator has an output voltage range of 1.25 V to 5.0 V . An external resistor divider sets the output voltage as shown in Figure 16. The regulator's voltage sensing error amplifier maintains a fixed 1.253 V reference between the output pin and the adjust pin.

Figure 16. An External Resistor Divider Sets the Value of $\mathrm{V}_{\text {OUt }}$. The 1.253 V Reference Voltage Drops Across R1.
A resistor divider network R1 and R2 causes a fixed current to flow to ground. This current creates a voltage across R2 that adds to the 1.253 V across R 1 and sets the overall output voltage. The adjust pin current (typically $50 \mu \mathrm{~A}$ ) also flows through R2 and adds a small error that should be taken into account if precise adjustment of $\mathrm{V}_{\text {OUT }}$ is necessary. The output voltage is set according to the formula:

$$
\mathrm{V}_{\mathrm{OUT}}=1.253 \mathrm{~V} \times \frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 1}+\mathrm{R} 2 \times \mathrm{I}_{\mathrm{ADJ}}
$$

The term $\mathrm{I}_{\mathrm{ADJ}} \times \mathrm{R} 2$ represents the error added by the adjust pin current.

R 1 is chosen so that the minimum load current is a least 10 mA . R1 and R2 should be of the same composition for best tracking over temperature. The divider resistors should be located as close to the load as possible.

While not required, a bypass capacitor connected between the adjust pin and ground will improve transient response and ripple rejection. A $0.1 \mu \mathrm{~F}$ tantalum capacitor is recommended for "first cut" design. Value and type may be varied to optimize performance vs. price.

## Other Adjustable Operation Considerations

The CS5258-1 linear regulator has an absolute maximum specification of 6.0 V for the voltage difference between $\mathrm{V}_{\mathrm{IN}}$ and V Vut. However, the IC may be used to regulate voltages in excess of 6.0 V . The two main considerations in such a design are the sequencing of power supplies and short circuit capability.

Power supply sequencing should be such that the $\mathrm{V}_{\text {CONTROL }}$ supply is brought up coincidentally with or
before the $\mathrm{V}_{\text {POWER }}$ supply. This allows the IC to begin charging the output capacitor as soon as the $\mathrm{V}_{\text {POWER }}$ to $V_{\text {OUT }}$ differential is large enough that the pass transistor conducts. As $V_{\text {POWER }}$ increases, the pass transistor will remain in dropout, and current is passed to the load until $\mathrm{V}_{\text {OUT }}$ is in regulation. Further increase in the supply voltage brings the pass transistor out of dropout. In this manner, any output voltage less than 13 V may be regulated, provided the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential is less than 6.0 V . In the case where $\mathrm{V}_{\text {CONTROL }}$ and $\mathrm{V}_{\text {POWER }}$ are shorted, there is no theoretical limit to the regulated voltage as long as the $\mathrm{V}_{\text {POWER }}$ to $\mathrm{V}_{\text {OUT }}$ differential of 6.0 V is not exceeded.

There is a possibility of damaging the IC when $V_{\text {POWER }}$ $-\mathrm{V}_{\text {IN }}$ is greater than 6.0 V if a short circuit occurs. Short circuit conditions will result in the immediate operation of the pass transistor outside of its safe operating area. Overvoltage stresses will then cause destruction of the pass transistor before overcurrent or thermal shutdown circuitry can become active. Additional circuitry may be required to clamp the $V_{\text {POWER }}$ to $V_{\text {OUT }}$ differential to less than 6.0 V if fail safe operation is required. One possible clamp circuit is illustrated in Figure 17; however, the design of clamp circuitry must be done on an application by application basis. Care must be taken to ensure the clamp actually protects the design. Components used in the clamp design must be able to withstand the short circuit condition indefinitely while protecting the IC.

Figure 17. Example Clamp Circuitry for $V_{\text {POWER }}-V_{\text {OUT }}>6.0 \mathrm{~V}$

## Stability Considerations

The output compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response, and loop stability.
The capacitor value and type is based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive
solution. However, when the circuit operates at low temperatures, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet provides this information.

A $300 \mu \mathrm{~F}$ tantalum capacitor will work for most applications, but with high current regulators such as the CS5258-1 the transient response and stability improve with higher values of capacitor. The majority of applications for this regulator involve large changes in load current so the output capacitor must supply the instantaneous load current. The ESR of the output capacitor causes an immediate drop in output voltage given by:

$$
\Delta V=\Delta I \times E S R
$$

For microprocessor applications it is customary to use an output capacitor network consisting of several tantalum and ceramic capacitors in parallel. This reduces the overall ESR and reduces the instantaneous output voltage drop under transient load conditions. The output capacitor network should be as close to the load as possible for the best results.

## Protection Diodes

When large external capacitors are used with a linear regulator it is sometimes necessary to add protection diodes. If the input voltage of the regulator gets shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage, and the rate at which $\mathrm{V}_{\text {CONTROL }}$ drops. In the CS5258-1 regulator, the discharge path is through a large junction and protection diodes are not usually needed. If the regulator is used with large values of output capacitance and the input voltage is instantaneously shorted to ground, damage can occur. In this case, a diode connected as shown in Figure 18 is recommended. Use of the diode has the added benefit of bleeding $\mathrm{V}_{\text {OUT }}$ to ground if $\mathrm{V}_{\text {CONTROL }}$ is shorted. This prevents an unregulated output from causing system damage.

Figure 18. Diode Protection Against $V_{\text {CONTROL }}$ Short Circuit Conditions

A rule of thumb useful in determining if a protection diode is required is to solve for current

$$
\mathrm{I}=\frac{\mathrm{C} \times \mathrm{V}}{\mathrm{~T}}
$$

where:
I is the current flow out of the load capacitance when $\mathrm{V}_{\text {CONTROL }}$ is shorted,
C is the value of load capacitance,
V is the output voltage, and
T is the time duration required for $\mathrm{V}_{\text {CONTROL }}$ to transition from high to being shorted.
If the calculated current is greater than or equal to the typical short circuit current value provided in the specifications, serious thought should be given to the use of a protection diode.

## Current Limit

The internal current limit circuit limits the output current under excessive load conditions.

## Short Circuit Protection

The device includes short circuit protection circuitry that clamps the output current at approximately two amperes less than its current limit value. This provides for a current foldback function, which reduces power dissipation even further under a direct shorted load.

## Thermal Shutdown

The thermal shutdown circuitry is guaranteed by design to activate above a die junction temperature of approximately $150^{\circ} \mathrm{C}$ and to shut down the regulator output. This circuitry has $25^{\circ} \mathrm{C}$ of typical hysteresis, thereby allowing the regulator to recover from a thermal fault automatically.

## Calculating Power Dissipation and Heat Sink Requirements

High power regulators such as the CS5258-1 family usually operate at high junction temperatures. Therefore, it is important to calculate the power dissipation and junction temperatures accurately to ensure that an adequate heat sink is used. Since the package tab is connected to $\mathrm{V}_{\text {OUT }}$ on the CS5258-1, electrical isolation may be required for some applications. Also, as with all high power packages, thermal compound is necessary to ensure proper heat flow. For added safety, this high current LDO includes an internal thermal shutdown circuit.
The thermal characteristics of an IC depend on the following four factors: junction temperature, ambient temperature, die power dissipation, and the thermal resistance from the die junction to ambient air. The maximum junction temperature can be determined by:

$$
\mathrm{T}_{\mathrm{J}(\max )}=\mathrm{T}_{\mathrm{A}(\max )}+\mathrm{PD}_{(\max )} \times \mathrm{R}_{\Theta \mathrm{JA}}
$$

The maximum ambient temperature and the power dissipation are determined by the design while the maximum junction temperature and the thermal resistance depend on the manufacturer and the package type. The maximum power dissipation for a regulator is:

$$
\begin{aligned}
\mathrm{PD}_{(\max )}= & \left(\mathrm{VIN}_{\mathrm{IN}}^{\max )}-\mathrm{VOUT}(\min )\right) \mathrm{IOUT}(\max ) \\
& +\mathrm{VIN}(\max ) \times \operatorname{IIN}(\max )
\end{aligned}
$$

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air. Each material in the heat flow path between the IC and the outside environment has a thermal resistance which is measured in degrees per watt. Like series electrical resistances, these thermal resistances are summed to determine the total thermal resistance between the die junction and the surrounding air, $\mathrm{R}_{\Theta \mathrm{JA}}$. This total thermal resistance is comprised of three components. These resistive terms are measured from junction to case ( $\mathrm{R}_{\Theta \mathrm{JC}}$ ), case to heat sink $\left.\mathrm{R}_{\Theta C S}\right)$, and heat sink to ambient air $\left(\mathrm{R}_{\Theta S A}\right)$. The equation is:

$$
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A}
$$

The value for $\mathrm{R}_{\Theta \mathrm{JC}}$ is $1.4^{\circ} \mathrm{C}$ watt for the CS5258-1 in the TO-220 package. For a high current regulator such as the CS5258-1 the majority of heat is generated in the power transistor section. The value for $\mathrm{R}_{\Theta S A}$ depends on the heat sink type, while the $R_{\Theta C S}$ depends on factors such as package type, heat sink interface (is an insulator and thermal grease used?), and the contact area between the heat sink and the package. Once these calculations are complete, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated and the proper heat sink selected. For further discussion on heat sink selection, see our application note "Thermal Management for Linear Regulators," document number SR006AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## PACKAGE THERMAL DATA

| Parameter |  | TO-220 Five Lead | Unit |

300 mA Very Low Noise, Low
Dropout Linear Regulator
The NCP2860 is a low noise, low dropout linear regulator that has been designed to supply $2.77 \mathrm{~V} / 300 \mathrm{~mA}$ from 3.0 V to 6.0 V input. If wished, the "SET" pin enables to adjust the output voltage level that then depends on the voltage applied to this pin. The excellent performances the NCP2860 features in terms of transient responses, PSRR and noise, make it an ideal solution for audio applications (e.g. audio amplifier drivers).

## Features

- High Output Current (300 mA Max)
- Low Output Voltage Noise: $60 \mu \mathrm{Vrms}$
- Low Dropout ( $150 \mathrm{mV} @ \mathrm{I}_{\text {out }}=300 \mathrm{~mA}$ )
- Thermal Overload and Short Circuit Protections
- Very Low Consumption in Shutdown Mode (10 nA)
- High Power Supply Rejection Ratio ( 60 dB @ 1.0 kHz )
- $\overline{\text { FAULT Indicator }}$
- Programmable Output Voltage
- Soft Start

## Typical Applications

- Cellular Phone
- Handheld Instruments

## ON Semiconductor ${ }^{\text {w }}$

| NCP2860DM277R2 | Micro8 | 4000 Units/Reel |

PIN DESCRIPTION

| Pin | Name | Description |
| :---: | :---: | :--- |
| 1,4 | OUT | "OUT" is the regulator output. A low ESR, bypass capacitor should be connected for stable operation. |
| 2 | IN | "IN" is the supply input that is connected to the power source (up to 6.0 V ). Bypass with a $2.2 \mu \mathrm{~F}$ capacitor. |
| 3 | GND | Ground |
| 5 | SET | Ground the "SET" pin to set the output voltage to 2.77 V. Refer to the "output voltage setting" paragraph if <br> you need to program another value. |
| 6 | N.C. | This pin is non-connected. |
| 7 | STDWN | If the "STDWN" pin is low, the circuit enters the shutdown mode. |
| 8 | FAULT | The "FAULT" terminal is a high impedance, open drain output. If the circuit is out of regulation, the voltage <br> pin goes low. Otherwise (normal operation or shutdown mode), this pin is high impedance. Connect the pin <br> to ground, if unused. |

## MAXIMUM RATINGS

| Rating | Symbol | Value | Unit |
| :---: | :---: | :---: | :---: |

## DETAILED OPERATING DESCRIPTION

## Internal Pass Transistor

The NCP2860 incorporates a $0.5 \Omega$ typical P-channel MOSFET pass transistor. The P -channel MOSFET requires no drive current and then compared to the PNP based regulators, this solution drastically reduces the quiescent current and associated losses.

## Shutdown Block

The circuit turns into shutdown mode when the shutdown pin is in low state. In this mode, the internal biasing current sources are disconnected so that the pass transistor is off and the consumption reduced to a minimum value. Practically, the shutdown consumption is in the range of 10 nA . When this function is unused, "IN" is generally applied to the shutdown pin.

## Current Limitation

The NCP2860 incorporates a short circuit protection that prevents the pass transistor current from exceeding 465 mA typically. The current limit is set to 220 mA during the start-up phase.

## Thermal Protection

The thermal protection protects the die against excessive overheating. Practically, when the junction temperature exceeds $170^{\circ} \mathrm{C}$, an internal thermal sensor sends a logical signal to the shutdown block so that the circuit enters the shutdown mode. Once the die has cooled enough (typically $30^{\circ} \mathrm{C}$ ), the circuit enters a new working phase.

## Output Voltage Setting

The output voltage is set to 2.77 V if the "SET" pin is grounded. It can also be programmed to a different value. To do so, a portion of the output voltage must be applied to the "SET" pin. If a (R1, R2) resistors divider is used, then:

$$
\mathrm{V}_{\text {out }}=(1+\mathrm{R} 1 / \mathrm{R} 2) * \mathrm{~V}_{\text {ref }}
$$

Therefore, as $\mathrm{V}_{\text {ref }}$ typically equals 1.244 V :

$$
\mathrm{V}_{\text {out }}=1.244 *(1+\mathrm{R} 1 / \mathrm{R} 2)
$$

Now if R1 and R2 are high impedance resistors, the leakage current that is absorbed by the "SET" pin, may have to be taken into account as follows:

$$
\mathrm{V}_{\text {out }}=[1.244 *(1+\mathrm{R} 1 / \mathrm{R} 2)]+\left(\mathrm{R} 1 * \mathrm{I}_{\mathrm{lk}}\right) \text { where } \mathrm{I}_{\mathrm{lk}} \text { is the }
$$ "SET" pin leakage current.

If the output voltage is directly applied to the "SET" pin, $\mathrm{V}_{\text {out }}=\mathrm{V}_{\text {ref }}=1.244 \mathrm{~V}$.

## Regulation

The circuit incorporates a transconductance error amplifier. The error amplifier output varies in response to load and input voltage variations to control the pass transistor current so that the "OUT" pin delivers the wished voltage. No compensation capacitor is required.

## Fault Detection Circuitry

The circuit detects when the input-output differential voltage is too low to ensure a correct load and line regulation at the output. The input-output differential threshold scales proportionally with the load current to be always just higher than the dropout.
When the circuit detects a fault condition, an internal switch connects "FAULT" to ground. In normal operation, the "FAULT" terminal is an open-drain-N-channel MOSFET and if a pull-up resistor is connected between "OUT" and "FAULT", "FAULT" goes high. The pull-up resistor is generally selected in the range of $100 \mathrm{k} \Omega$ to minimize the current consumption.

## Application Information

It is recommended to use $2.2 \mu \mathrm{~F}$ capacitors on the input and on the output of the NCP2860. Capacitor type is not very critical. Simply the ESR should be lower than $0.5 \Omega$ to ensure a stable operation over the temperature and output current ranges. It could be convenient to increase the capacitor size and its quality (lower ESR) only if it was necessary to further improve the noise performances, the Power Supply Rejection Ratio or the fast transient response.

Figure 15. With External Output Voltage Adjustment

Figure 16. Application for 2.77 V Output Voltage

# Very Low Dropout/ Ultra Low Noise 5 Outputs Voltage Regulator 

The MC33765 is an ultra low noise, very low dropout voltage regulator with five independent outputs which is available in TSSOP 16 surface mount package.

The MC33765 is available in 2.8 V . The output voltage is the same for all five outputs but each output is capable of supplying different currents up to 150 mA for output 4 . The device features a very low dropout voltage ( 0.11 V typical for maximum output current), very low quiescent current ( $5.0 \mu \mathrm{~A}$ maximum in OFF mode, $130 \mu \mathrm{~A}$ typical in ON mode) and one of the output (output 3) exhibits a very low noise level which allows the driving of noise sensitive circuitry. Internal current and thermal limiting protections are provided.

Additionally, the MC33765 has an independent Enable input pin for each output. It includes also a common Enable pin to shutdown the complete circuit when not used. The Common Enable pin has the highest priority over the five independent Enable input pins.

The voltage regulators VR1, VR2 and VR3 have a common input voltage pin $\mathrm{V}_{\mathrm{CC}} 1$.

The other voltage regulators VR4 and VR5 have a common input voltage pin $\mathrm{V}_{\mathrm{CC}} 2$.

- Five Independent Outputs at 2.8 V Typical, based upon voltage version
- Internal Trimmed Voltage Reference
- $\mathrm{V}_{\text {out }}$ Tolerance $\pm 3.0 \%$ over the Temperature Range $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
- Enable Input Pin (Logic-Controlled Shutdown) for Each of the Five Outputs
- Common Enable Pin to Shutdown the Whole Circuit
- Very Low Dropout Voltage (0.11 V Typical for Output 1, 2, 3 and 5; 0.17 V Typical for Output 4 at Maximum Current)
- Very Low Quiescent Current (Maximum $5.0 \mu \mathrm{~A}$ in OFF Mode, $130 \mu \mathrm{~A}$ Typical in ON Mode)
- Ultra Low Noise for VR3 ( $30 \mu \mathrm{~V}$ RMS Max, $100 \mathrm{~Hz}<\mathrm{f}<100 \mathrm{kHz}$ )
- Internal Current and Thermal Limit
- 100 nF for VR1, VR2, VR4 and VR5 and $1.0 \mu \mathrm{~F}$ for VR3 for Stability
- Supply Voltage Rejection: 60 dB (Typical) @ f $=1.0 \mathrm{kHz}$

| Dynamic CrossTalk Attenuation between the Regulator Outputs $(\mathrm{f}=10 \mathrm{kHz}), \mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}(\text { Note } 6)$ | 30 | 35 | - | dB |

## Thermal Shutdown

| Thermal Shutdown | - | 160 | - | ${ }^{\circ} \mathrm{C}$ |
| :--- | :--- | :--- | :--- | :--- |

4. The Fall time is highly dependent on the load conditions, i.e. load current for a specified value of $\mathrm{C}_{\text {out }}$.
5. Static Crosstalk is a DC shift caused by switching ON one of the outputs through independent enable to all other outputs. This parameter is highly dependent on overall PCB layout and requires the implementation of low-noise GROUND rules (e.g. Ground plane).
6. Dynamic crosstalk is the ratio between a forced output signal to signal transferred to other outputs. This requires special device configuration to be measured.

## DEFINITIONS

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Dropout Voltage - The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential input/output), dropout voltage is affected by junction temperature, load current and minimum input supply requirements.

Output Noise Voltage - The RMS AC voltage at the output with a constant load and no input ripple, measured over a specified frequency range.

Maximum Power Dissipation - The maximum total dissipation for which the regulator will operate within specifications.

Quiescent Current - Current which is used to operate the regulator chip with no load current.

Line Regulation - The change in input voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Thermal Protection - Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated, typically $160^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent catastrophic failures from accidental overheating.

Maximum Package Power Dissipation and RMS Current - The maximum package power dissipation is the power dissipation level at which the junction temperature reaches its maximum value i.e. $125^{\circ} \mathrm{C}$. The junction temperature is rising while the difference between the input power ( $\mathrm{V}_{\mathrm{CC}} \mathrm{X}_{\mathrm{CC}}$ ) and the output power ( $\mathrm{V}_{\text {out }} \mathrm{X} \mathrm{I}_{\text {out }}$ ) is increasing.

As MC33765 device exhibits five independent outputs $\mathrm{I}_{\text {out }}$ is specified as the maximum RMS current combination of the five output currents.

As the device can be switched ON/OFF through independent Enable (ON/OFF pin) or Common Enable, the output signal could be, for example, a square wave. Let's assume that the device is ON during $\mathrm{T}_{\mathrm{ON}}$ on a signal period T. The RMS current will be given by:

$$
{ }^{{ }^{\text {utt }_{\text {RMS }}}}=I_{\mathrm{P}} \times \sqrt{\mathrm{D}}
$$

where $\quad \mathrm{D}=\frac{\mathrm{T}^{\mathrm{O}} \mathrm{ON}}{\mathrm{T}}$

Depending on ambient temperature, it is possible to calculate the maximum power dissipation and so the maximum RMS current as following:

$$
P d=\frac{T_{J}-T_{A}}{R_{\theta J A}}
$$

The maximum operating junction temperature $\mathrm{T}_{\mathrm{J}}$ is specified at $125^{\circ} \mathrm{C}$, if $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, then $\mathrm{P}_{\mathrm{D}}=700 \mathrm{~mW}$. By neglecting the quiescent current, the maximum power dissipation can be expressed as:

$$
I_{\text {out }}=\frac{P_{D}}{V_{C C}-V_{\text {out }}}
$$

So that in the more drastic conditions:
$\mathrm{V}_{\mathrm{CC}}=5.3 \mathrm{~V}, \mathrm{~V}_{\text {out }}=2.7 \mathrm{~V}$ then the maximum RMS value of $\mathrm{I}_{\text {out }}$ is 269 mA .

The maximum power dissipation supported by the device is a lot increased when using appropriate application design. Mounting pad configuration on the PCB, the board material and also the ambient temperature are affected the rate of temperature rise. It means that when the $\mathrm{I}_{\mathrm{C}}$ has good thermal conductivity through PCB, the junction temperature will be "low" even if the power dissipation is great.

The thermal resistance of the whole circuit can be evaluated by deliberately activating the thermal shutdown of the circuit (by increasing the output current or raising the input voltage for example).

Then you can calculate the power dissipation by subtracting the output power from the input power. All variables are then well known: power dissipation, thermal shutdown temperature $\left(160^{\circ} \mathrm{C}\right.$ for MC 33765$)$ and ambient temperature.

$$
R_{\theta J A}=\frac{T_{J}-T_{A}}{P_{D}}
$$

## MC33765

## DESIGN HINTS

## Reducing the cross-talk between the MC33765 outputs

One of the origin of the DC shift finds its seat in the layout surrounding the integrated circuit. Particular care has to be taken when routing the output ground paths. Star grounding

or a ground plane are the absolute conditions to reduce the noise or shift associated to common impedance situations, as depicted by Figure 17.

Figure 17. Star Cabling Avoids Coupling by Common Ground Impedance

The first left cabling will generate a voltage shift which will superimpose on the output voltages, thus creating an undesirable offset. By routing the return grounds to a single
low impedance point, you naturally shield the circuit against common impedance disturbances. Figure 18 portraits the text fixture implemented to test the response of the MC33765.

Figure 18. DC Shift Text Fixture

## DESIGN HINTS (cont.)

Output 4 was banged from 0 to 150 mA via its dedicated control pin, while output 3 fixed at 50 mA was monitored. The circuit has been implemented on a PCB equipped with a
ground plane and routed with short copper traces. The results are shown hereafter, revealing the excellent behavior of the MC33765 when crosstalks outputs is at utmost importance.

Figure 20. Vin $=5 \mathrm{~V}, \mathrm{Y} 1=1 \mathrm{mV} / \mathrm{div}$

## MC33765

## TECHNICAL TERMS

Rise Time - Common Enable being in ON state, the device is switched on by ON/OFF pin control.
Let's call $t_{1}$ the time when ON/OFF signal reaches $1 \%$ of its nominal value.

Let's call $t_{2}$ the time when output signal reaches $99 \%$ of its nominal value.

The rise time for this device is specified as:

$$
\mathrm{t}_{\mathrm{ON}}=\mathrm{t}_{1}-\mathrm{t}_{2}
$$

Fall Time - The fall time is highly dependent on the output capacitor and so device design is not impacting at all this parameter.

Overshoot, Settling Time - As regulators are based on regulation loop through an error amplifier, this type of device requires a certain time to stabilize and reach its nominal value.
The overshoot is defined as the voltage difference between the peak voltage and steady state when switching ON the regulator.
The settling time is equal to the time required by the regulator to stabilize to its nominal value ( $\pm 0.5 \%$ ) after peak value when switching ON the regulator.

## MC33762

## Dual Ultra Low-Noise Low Dropout Voltage Regulator with 1.0 V ON/OFF Control

The MC33762 is a dual Low DropOut (LDO) regulator featuring excellent noise performances. Thanks to its innovative design, the circuit reaches an impressive $40 \mu \mathrm{VRMS}$ noise level without an external bypass capacitor. Housed in a small $\mu 8$ package, it represents the ideal designer's choice when space and noise are at premium.

The absence of external bandgap capacitor accelerates the response time to a wake-up signal and keeps it within $40 \mu \mathrm{~s}$, making the MC33762 as a natural candidate for portable applications.

The MC33762 also hosts a novel architecture which prevents excessive undershoots in the presence of fast transient bursts, as in any bursting systems.

Finally, with a static line regulation better than -75 dB , it naturally shields the downstream electronics from choppy lines.

## Features

- Nominal Output Current of 80 mA with a 100 mA Peak Capability
- Ultra-Low Noise: $150 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ @ $100 \mathrm{~Hz}, 40 \mu \mathrm{VRMS}$ $100 \mathrm{~Hz}-100 \mathrm{kHz}$ Typical, $\mathrm{I}_{\text {out }}=60 \mathrm{~mA}, \mathrm{Co}=1.0 \mu \mathrm{~F}$
- Fast Response Time from OFF to ON: $40 \mu$ s Typical
- Ready for 1.0 V Platforms: ON with a 900 mV High Level
- Typical Dropout of 90 mV @ $30 \mathrm{~mA}, 160 \mathrm{mV}$ @ 80 mA
- Ripple Rejection: 70 dB @ 1.0 kHz
- $1.5 \%$ Output Precision @ $25^{\circ} \mathrm{C}$
- Thermal Shutdown
- $\mathrm{V}_{\text {out }}$ Available at $2.5 \mathrm{~V}, 2.8 \mathrm{~V}$, and 3.0 V
- Separate Dice for Each Regulator Provides Maximum Isolation Between Regulators
- Operating Range from -40 to $+85^{\circ} \mathrm{C}$

## Applications

- Noise Sensitive Circuits: VCOs RF Stages, etc.
- Bursting Systems (TDMA Phones)
- All Battery Operated Devices

## DEFINITIONS

## Load Regulation

The change in output voltage for a change in output current at a constant chip temperature.

## Dropout Voltage

The input/output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. Measured when the output drops 100 mV below its nominal value (which is measured at 1.0 V differential value). The dropout level is affected by the chip temperature, load current and minimum input supply requirements.

## Output Noise Voltage

This is the integrated value of the output noise over a specified frequency range. Input voltage and output current are kept constant during the measurement. Results are expressed in $\mu$ VRMS.

## Maximum Power Dissipation

The maximum total dissipation for which the regulator will operate within its specs.

## Quiescent Current

The quiescent current is the current which flows through the ground when the LDO operates without a load on its output: internal IC operation, bias etc. When the LDO becomes loaded, this term is called the Ground current. It is actually the difference between the input current (measured through the LDO input pin) and the output current.

## Line Regulation

The change in output voltage for a change in input voltage. The measurement is made under conditions of low dissipation or by using pulse technique such that the average chip temperature is not significantly affected. One usually distinguishes static line regulation or DC line regulation (a DC step in the input voltage generates a corresponding step in the output voltage) from ripple rejection or audio susceptibility where the input is combined with a frequency generator to sweep from a few hertz up to a defined boundary while the output amplitude is monitored.

## Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically $125^{\circ} \mathrm{C}$, the regulator turns off. This feature is provided to prevent catastrophic failures from accidental overheating.

## Maximum Package Power Dissipation

The maximum power package power dissipation is the power dissipation level at which the junction temperature reaches its maximum operating value, i.e. $125^{\circ} \mathrm{C}$. Depending on the ambient temperature, it is possible to calculate the maximum power dissipation and thus the maximum available output current.

## APPLICATION HINTS

## Input Decoupling

As with any regulator, it is necessary to reduce the dynamic impedance of the supply rail that feeds the component. A $1.0 \mu \mathrm{~F}$ capacitor either ceramic or tantalum is recommended and should be connected close to the MC33762 package. Higher values will correspondingly improve the overall line transient response.

## Output Decoupling

Thanks to a novel concept, the MC33762 is a stable component and does not require any specific Equivalent Series Resistance (ESR) neither a minimum output current. Capacitors exhibiting ESRs ranging from a few $\mathrm{m} \Omega$ up to $3.0 \Omega$ can thus safely be used. The minimum decoupling value is $1.0 \mu \mathrm{~F}$ and can be augmented to fulfill stringent load transient requirements. The regulator accepts ceramic chip capacitors as well as tantalum devices.

## Noise Performances

Unlike other LDOs, the MC33762 is a true low-noise regulator. Without the need of an external bypass capacitor, it typically reaches the incredible level of $40 \mu \mathrm{VRMS}$ overall noise between 100 Hz and 100 kHz . To give maximum insight on noise specifications, ON Semiconductor includes spectral density graphics. The classical bypass capacitor impacts the start-up phase of standard LDOs. However, thanks to its low-noise architecture, the MC33762 operates without a bypass element and thus offers a typical $40 \mu$ s start-up phase.

## Protections

The MC33762 hosts several protections, giving natural ruggedness and reliability to the products implementing the component. The output current is internally limited to a maximum value of 180 mA typical while temperature shutdown occurs if the die heats up beyond $125^{\circ} \mathrm{C}$. These values let you assess the maximum differential voltage the device can sustain at a given output current before its protections come into play.

The maximum dissipation the package can handle is given by:

$$
P_{\max }=\frac{T_{J \max }-T_{A}}{R_{\theta J A}}
$$

If $\mathrm{T}_{\text {Jmax }}$ is limited to $125^{\circ} \mathrm{C}$, then the MC33762 can dissipate up to $395 \mathrm{~mW} @ 25^{\circ} \mathrm{C}$. The power dissipated by the MC33762 can be calculated from the following formula:

$$
\text { Ptot }=\left(\mathrm{v}_{\text {in }} \times \mathrm{I}_{\text {gnd }}\left(\mathrm{I}_{\text {out }}\right)\right)+\left(\mathrm{v}_{\text {in }}-\mathrm{v}_{\text {out }}\right) \times \mathrm{I}_{\text {out }}
$$

or

$$
\mathrm{Vin}_{\max }=\frac{\text { Ptot }+\mathrm{V}_{\text {out }} \times \mathrm{I}_{\text {out }}}{I_{\text {gnd }}+I_{\text {out }}}
$$

If a 80 mA output current is needed, the ground current is extracted from the data-sheet curves: $4.0 \mathrm{~mA} @ 80 \mathrm{~mA}$. For a half $2.8 \mathrm{~V} \mathrm{MC} 33762(2.8 \mathrm{~V})$ operating at $25^{\circ} \mathrm{C}$, the maximum input voltage will then be 7.3 V .

## Typical Applications

The following picture portrays the typical application of the MC33762.

## MC33762

Figure 7. A Typical Application Schematic

As for any low noise designs, particular care has to be taken when tackling Printed Circuit Board (PCB) layout. Connections shall be kept short and wide. Layout example
as given in the MC33761 application hints can be used as a starting basis.

## Understanding the Load Transient Improvement

The MC33762 features a novel architecture which allows the user to easily implement the regulator in burst systems where the time between two current shots is kept very small.

The quality of the transient response time is related to many parameters, among which the closed-loop bandwidth with the corresponding phase margin plays an important role. However, other characteristics also come into play like the series pass transistor saturation. When a current perturbation suddenly appears on the output, e.g. a load increase, the error amplifier reacts and actively biases the PNP transistor. During this reaction time, the LDO is in open-loop and the output impedance is rather high. As a result, the voltage brutally drops until the error amplifier effectively closes the loop and corrects the output error. When the load disappears, the opposite phenomenon takes place with a positive overshoot. The problem appears when this overshoot decays down to the LDO steady-state value.

Figure 8. A Standard LDO Behavior when the Load Current Disappears

Figure 10. Without Load Transient Improvement

During this decreasing phase, the LDO stops the PNP bias and one can consider the LDO asleep (Figure 8). If by misfortune a current shot appears, the reaction time is incredibly lengthened and a strong undershoot takes place. This reaction is clearly not acceptable for line sensitive devices, such as VCOs or other Radio-Frequency parts. This problem is dramatically exacerbated when the output current drops to zero rather than a few mA. In this later case, the internal feedback network is the only discharge path, accordingly lengthening the output voltage decay period (Figure 9).
The MC33762 cures this problem by implementing a clever design where the LDO detects the presence of the overshoot and forces the system to go back to steady-state as soon as possible, ready for the next shot. Figure 10 and 11 show how it positively improves the response time and decreases the negative peak voltage.

Figure 9. A Standard LDO Behavior when the Load Current Appears in the Decay Zone

Figure 11. MC33762 with Load Transient Improvement

## MC33762

## MC33762 Has a Fast Start-Up Phase

Thanks to the lack of bypass capacitor the MC33762 is able to supply its downstream circuitry as soon as the OFF to ON signal appears. In a standard LDO, the charging time of the external bypass capacitor hampers the response time. A simple solution consists in suppressing this bypass element but, unfortunately, the noise rises to an
unacceptable level. MC33762 offers the best of both worlds since it no longer includes a bypass capacitor and starts in less than $40 \mu$ s typically (Repetitive at 200 Hz ). It also ensures an incredible low-noise level of $40 \mu$ VRMS $100 \mathrm{~Hz}-100 \mathrm{kHz}$. The following picture details the typical 33762 startup phase.

## MC33762

## MINIMUM RECOMMENDED FOOTPRINT FOR SURFACE MOUNTED APPLICATIONS

Surface mount board layout is a critical portion of the total design. The footprint for the semiconductor packages must be the correct size to ensure proper solder connection interface
between the board and the package. With the correct pad geometry, the packages will self-align when subjected to a solder reflow process.

## MC33762

## MC33566

## Smart Voltage Regulator for Peripheral Card Applications

The MC33566 Low Dropout Regulator is designed for computer peripheral card applications complying with the instantly available requirements as specified by ACPI objectives. The MC33566 permits glitch-free transitions from "sleep" to "active" system modes and has internal logic circuitry to detect whether the system is being powered from the motherboard main 5.0 V power supply or the 3.3 V aux supply.

The MC33566 provides a regulated output voltage of 3.3 V via either an internal low dropout 5.0 V-to-3.3 V voltage regulator or an external P-channel MOSFET, depending on the operating status of the system in which the card is installed. During normal operating mode ( 5.0 V main supply available) the 3.3 V output is provided from the internal low dropout regulator at an output current of 0.4 A . When the motherboard enters sleep mode, the MC33566 operates from the 3.3 V aux supply and routes the aux current to the output via the external P-channel MOSFET bypass transistor controlled by the drive out pin. As a result, the output voltage provided to the peripheral card remains constant at 3.3 V even during host systems transitions to and from sleep mode.

## MC33566 Features:

- Output Current up to 0.4 A
- Excellent Line and Load Regulation
- Low Dropout Voltage
- Prevents Reverse Current Flow During Sleep Mode
- Glitch-Free Transfer from Sleep Mode to Active Mode
- Compatible with Instantly Available PC Systems

Figure 2. Functional Block Diagram
FUNCTIONAL DESCRIPTION

Input Blocking - The internal NPN pass transistor of the LDO regulator ensures that no significant reverse current will flow from $+3.3 \mathrm{~V}_{\text {out }}$ back to the $+5.0 \mathrm{~V}_{\text {in }}$ input when the 5.0 V input is not powered and the $3.3 \mathrm{~V}_{\text {in }}$ supply is present.
5.0 Volt Detect - Internal circuitry detects the presence of the 5.0 V input supply. When the 5.0 V supply drops below a given threshold, the $+3.3 \mathrm{~V}_{\mathrm{in}}$ bypass transistor (an external P -channel MOSFET) is enabled. The 5.0 V detect logic is active throughout the entire range of ramp-up from 0 to 5.5 V . Additionally, the drive out signal is never turned ON or OFF inappropriately during ramp-up of the $+5.0 \mathrm{~V}_{\text {in }}$ supply. Also, $+3.3 \mathrm{~V}_{\text {out }}$ never drops below 3.0 V while $+5.0 \mathrm{~V}_{\mathrm{in}}$ is above the 5.0 V detect minimum threshold.

Glitch-free Transfer - The design of the 5.0 V detect circuitry and drive out control circuitry guarantees that the $+3.3 \mathrm{~V}_{\text {out }}$ will not exceed the output voltage specification listed in the table of DC Operating Specifications even with $+5.0 \mathrm{~V}_{\text {in }}$ ramping up and down at the extremes of the slew rates in the table of AC Operating Specifications.
Offset Voltage Performance - To ensure performance when external offsets are present on the $+5.0 \mathrm{~V}_{\text {in }}$ and $+3.3 \mathrm{~V}_{\text {in }}$ power inputs, the device has been designed to be capable of operating with either one or both of these inputs rising from or falling to zero volts, or with offsets of 0.05 V to 0.9 V as the inputs ramp up and down.

## MC33567

## Dual Linear Controller for High Current Voltage Regulation

The MC33567 Dual Linear Power Supply Controller is designed to facilitate power management for motherboard applications where reliable regulation of high current supply planes is required. It provides the Drive, Sense and Control signals to interface two external, N-channel MOSFETs for regulating two different supply planes. Undervoltage, short circuit detection places the operation of the system into a protected mode pending removal of the short.

## Features

- MC33567-1: Two, Independent Regulated Supplies 1.515 V - Supply for GTL and AGP Planes 1.818 V - Supply for I/O Plane and Memory Termination
- MC33567-2: Dual 2.525 V Supplies for Clock and Memory
- Undervoltage Detection and Protection Mode
- Drive Capability for SOT-223, DPAK, and D ${ }^{2}$ PAK MOSFETs
- Bypass Function for 3.3 V AGP Card Detection

## Applications

- Motherboards
- Dual Power Supplies

| 8 | 12 volt input | Supply voltage for operation and gate drive output. |

## OPERATING DESCRIPTION

The MC33567 Dual Linear Controller is designed for power management applications where high current, voltage regulation is needed. Some computer applications include:

- 1.515 V - AGP (Advanced Graphic Port) and GTL+ (Gunning Transistor Logic - Intel's electrical bus technology)
- $1.818 \mathrm{~V}-\mathrm{I} / \mathrm{O}$ planes on motherboard
- 2.525 V - Clock and memory

## Hiccup Mode

If the output drops below $75 \%$ of the regulated threshold for greater than $250 \mu$ s or a short circuit condition exists, that output will go into hiccup mode. This means that the output is turned ON for 1.0 ms and OFF for 40 ms for a duty cycle of 1:40. Please refer to Figure 2. Each transition from low to high of the input restarts the hiccup mode holdoff period. Once the short circuit is removed or the output comes back to the regulated threshold, it will operate under normal operating conditions.

Figure 2. Hiccup Mode Duty Cycle

## Shutdown

The SHUTDOWN pin is connected to the external board (AGP or GTL+). Please refer to Figure 3.

PIN 5 TRUTH TABLE
Pin 5 No connect $=1.515 \mathrm{~V}$ LDO drive out active Pin $5<0.8 \mathrm{~V}=$ shutdown (drive out 0 V ) $1.3 \mathrm{~V}<\operatorname{pin} 5<4.1 \mathrm{~V}=1.515 \mathrm{~V}$ LDO drive out active Pin $5>4.2 \mathrm{~V}=3.3 \mathrm{~V}$ bypass mode (drive out $=\mathrm{V}_{\text {in }}$ for FET )

The way in which the external board is wired to the shutdown pin will determine the output of the MC33567. Listed are the conditions the external board is wired and the corresponding output voltages:

1. If there is no connection on the external board, there is an open and the output will be the regulated output voltage.
2. If there is a ground on the external board which will cause the SHUTDOWN pin to be less than 0.8 V , the MOSFET turns off and there is no output voltage.
3. If there is a resistor on the external board pulling the SHUTDOWN pin above 4.1 V , the output will be in the bypass mode. In this mode, the MOSFET is fully on, or fully enhanced, and the output will be whatever voltage is supplied to the input voltage of the MOSFET, $\mathrm{V}_{\text {in }}$.
4. If the SHUTDOWN pin is between 1.3 V and 4.1 V , the output will be the regulated voltage.
Tables 1 and 2 are the logic tables for the SHUTDOWN pins. Note that the logic tables are not the same for the 1.515 V regulator and the 1.818 V regulator. The MC33567-2 does not have the Full-On Bypass feature.

Table 1. Logic Table for Shutdown (Pin 5) on the 1.515 V Regulator

| $<0.8 \mathrm{~V}$ | Shutdown |
| $>1.3 \mathrm{~V}$ | 1.818 V |

Figure 3. 1.5 V/3.3 V AGP Card Detection

## Sense

The SENSE pins provide tight regulation of the load voltages with varying load currents. When the load is located at a distance, there will be a voltage drop due to the resistance loss of the trace. If the load is not near the MC33567, it is recommended that the SENSE pins be used. Connect the SENSE pins as close to the load as possible. Use a separate trace to connect the source of the N-Channel MOSFET to the load. Refer to Figure 4.

Figure 4.

## Capacitor Selection

Stable operation is achieved by preserving an adequate phase margin. A rule of thumb for preserving an adequate phase margin is:

$$
\begin{aligned}
& C \cdot R \geq 10 \times 10^{-6} \\
& R \geq \frac{10 \times 10^{-6}}{C}
\end{aligned}
$$

Where:

$$
\begin{aligned}
& \mathrm{C}=\text { load capacitance } \\
& \mathrm{R}=\text { equivalent series resistance }(\mathrm{ESR}) \text { of the capacitor }
\end{aligned}
$$

For example, if the load capacitor is $400 \mu \mathrm{~F}$, then the ESR of the capacitor would need to be no less than $25 \mathrm{~m} \Omega$.

$$
25 \mathrm{~m} \Omega \geq \frac{10 \times 10^{-6}}{400 \mu \mathrm{~F}}
$$

This rule of thumb assumes that all capacitors across the load are the same type and value. If different types and values are used in parallel across the load, then each individual capacitor must meet the requirements of the given equation.

## PCB Layout Guidelines

It is recommended that the MC33567 be placed as physically close as possible to the external series pass MOSFET transistors. Use short traces to minimize extraneous signals from being magnetically or electrostatically induced on the sense or drive lines. Place the sense trace and power trace in the same plane and same direction. The power trace is to be placed from the series pass transistor source lead to the load. Avoid routing the sense lead near the load current return path. Also avoid unterminated runs of the sense leads. If it is desired to have options where the sense lead is placed on the board, use $0 \Omega$ resistor jumpers to make the alternate sense lead connection near the sense pin.

## N-Channel MOSFET Selection

The ON Semiconductor MTD3055VL N-Channel MOSFET was used in the characterization of the MC33567. To select a N-Channel MOSFET the drain-source on-resistance, $\mathrm{R}_{\mathrm{DS}(\mathrm{on})}$, must be considered. For best results, $\mathrm{R}_{\mathrm{DS}(\mathrm{on})}$ needs to be low. Below is the calculation for $\mathrm{R}_{\mathrm{DS}(\mathrm{on})}$. The 0.5 in the equation is to prevent saturation and to account for tolerance build-up.

$$
\mathrm{R}_{\mathrm{DS}(\mathrm{on})} \leq 0.5 \frac{\mathrm{~V}_{\text {in }}-\mathrm{V}_{\text {out }}}{\mathrm{I}_{\text {Load }}}
$$

Where:

$$
\begin{aligned}
& \mathrm{V}_{\text {in }}=3.3 \mathrm{~V} \text { typically } \\
& \mathrm{V}_{\text {out }}=1.515 \mathrm{~V}, 1.818 \mathrm{~V} \text {, or } 2.525 \mathrm{~V} \\
& \mathrm{I}_{\text {Load }}=\text { Current at load }
\end{aligned}
$$

## 100 mA, 5.0 V Voltage Regulator and Supervisory Circuit for Microprocessors

The MC34160 Series is a voltage regulator and supervisory circuit containing many of the necessary monitoring functions required in microprocessor based systems. It is specifically designed for appliance and industrial applications, offering the designer a cost effective solution with minimal external components. These integrated circuits feature a $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ regulator with short circuit current limiting, pinned out 2.6 V bandgap reference, low voltage reset comparator, power warning comparator with programmable hysteresis, and an uncommitted comparator ideally suited for microprocessor line synchronization.

Additional features include a chip disable input for low standby current, and internal thermal shutdown for over temperature protection.

These devices are contained in a 16 pin dual-in-line heat tab plastic package for improved thermal conduction.

- 5.0 V Regulator Output Current in Excess of 100 mA
- Internal Short Circuit Current Limiting
- Pinned Out 2.6 V Reference
- Low Voltage Reset Comparator
- Power Warning Comparator with Programmable Hysteresis
- Uncommitted Comparator
- Low Standby Current
- Internal Thermal Shutdown Protection
- Heat Tab Power Package

PIN FUNCTION DESCRIPTION

| Pin | Function | Description |
| :---: | :--- | :--- |
| 1 | Comparator Inverting Input | This is the Uncommitted Comparator Inverting input. It is typically connected to a <br> resistor divider to monitor a voltage. |
| 2 | Comparator Noninverting Input | This is the Uncommitted Comparator Noninverting input. It is typically connected to a <br> reference voltage. |
| 3 | N.C. | No connection. This pin is not internally connected. |
| $4,5,12,13$ | Gnd | These pins are the control circuit grounds and are connected to the source and load <br> ground returns. They are part of the IC lead frame and can be used for heatsinking. |
| 6 | Comparator Output | This is the Uncommitted Comparator output. It is an open collector sink-only output <br> requiring a pull-up resistor. |
| 7 | Reset | This is the Reset Comparator output. It is an open collector sink-only output requiring <br> a pull-up resistor. |
| 8 | Power Warning | This is the Power Warning Comparator output. It is an open collector sink-only output <br> requiring a pull-up resistor. |
| 10 | Hysteresis Adjust | This is the Power Warning Comparator noninverting input. It is typically connected to a <br> resistor divider to monitor the input power source voltage. |
| 11 | Regulator Output | The Power Warning Comparator hysteresis is programmed by a resistor connected <br> from this pin to ground. |
| 14 | VCC | This is the 5.0 V Regulator output. |
| 15 | Chip Disable | This pin is the positive supply input of the control IC. |
| 16 | Vref | This input is used to switch the IC into a standby mode turning off all outputs. |
| 16 | This is the 2.6 V Reference output. It is intended to be used in conjunction with the <br> Power Warning and Uncommitted comparators. |  |

The MC34160 series is a monolithic voltage regulator and supervisory circuit containing many of the necessary monitoring functions required in microprocessor based systems. It is specifically designed for appliance and industrial applications, offering the designer a cost effective solution with minimal external components. These devices are specified for operation over an input voltage of 7.0 V to 40 V , and with a junction temperature of $-40^{\circ}$ to $+150^{\circ} \mathrm{C}$. A typical microprocessor application is shown in Figure 10.

## Regulator

The 5.0 V regulator is designed to source in excess of 100 mA output current and is short circuit protected. The output has a guaranteed tolerance of $\pm 5.0 \%$ over line, load, and temperature. Internal thermal shutdown circuitry is included to limit the maximum junction temperature to a safe level. When activated, typically at $170^{\circ} \mathrm{C}$, the regulator output turns off.

In specific situations a combination of input and output bypass capacitors may be required for regulator stability. If the regulator is located an appreciable distance ( $\geq 4^{\prime \prime}$ ) from the supply filter, an input bypass capacitor ( $\mathrm{C}_{\mathrm{in}}$ ) of $0.33 \mu \mathrm{~F}$ or greater is suggested. Output capacitance values of less than 5.0 nF may cause regulator instability at light load ( $\leq$ 1.0 mA ) and cold temperature. An output bypass capacitor of $0.1 \mu \mathrm{~F}$ or greater is recommended to ensure stability under all load conditions. The capacitors selected must provide good high frequency characteristics.

Good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator does not have external sense inputs.

## Reference

The 2.6 V bandgap reference is short circuit protected and has a guaranteed output tolerance of $\pm 5.0 \%$ over line, load, and temperature. It is intended to be used in conjunction with the Power Warning and Uncommitted comparator. The reference can source in excess of 2.0 mA and sink a maximum of $10 \mu \mathrm{~A}$. For additional current sinking capability, an external load resistor to ground must be used.

Reference biasing is internally derived from either $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{O}}$, allowing proper operation if either drops below nominal.

## Chip Disable

This input is used to switch the IC into a standby mode. When activated, internal biasing for the entire die is removed causing all outputs to turn off. This reduces the power supply current $\left(\mathrm{I}_{\mathrm{CC}}\right)$ to less than 0.3 mA .

## Comparators

Three separate comparators are incorporated for voltage monitoring. Their outputs can provide diagnostic
information to the microprocessor, preventing system malfunctions.
The Reset Comparator Inverting Input is internally connected to the 2.6 V reference while the Noninverting Input monitors $\mathrm{V}_{\mathrm{O}}$. The $\overline{\text { Reset }}$ Output is active low when $\mathrm{V}_{\mathrm{O}}$ falls approximately 180 mV below its regulated voltage. To prevent erratic operation when crossing the comparator threshold, 70 mV of hysteresis is provided.
The Power Warning Comparator is typically used to detect an impending loss of system power. The Inverting Input is internally connected to the reference, fixing the threshold at 2.6 V . The input power source $\mathrm{V}_{\text {in }}$ is monitored by the Noninverting Input through the $\mathrm{R}_{1} / \mathrm{R}_{2}$ divider (Figure 10). This input features an adjustable $10 \mu \mathrm{~A}$ to 50 $\mu \mathrm{A}$ current $\operatorname{sink} \mathrm{I}_{\mathrm{H}}$ that is programmed by the value selected for resistor $\mathrm{R}_{\mathrm{H}}$. A default current of $6.5 \mu \mathrm{~A}$ is provided if $\mathrm{R}_{\mathrm{H}}$ is omitted. When the comparator input falls below 2.6 V , the current sink is activated. This produces hysteresis if $\mathrm{V}_{\text {in }}$ is monitored through a series resistor $\left(\mathrm{R}_{1}\right)$. The comparator thresholds are defined as follows:

$$
\begin{aligned}
& \mathrm{V}_{\text {th }(\text { lower })}=\mathrm{V}_{\text {ref }} \quad\left(1+\frac{\mathrm{R} 1}{\mathrm{R}_{2}}\right)-\mathrm{I}_{\mathrm{IB}} \mathrm{R}_{1} \\
& \mathrm{~V}_{\text {th }(\text { upper) }}=\mathrm{V}_{\text {ref }} \\
& \left(1+\frac{\mathrm{R} 1}{\mathrm{R}_{2}}\right)+\mathrm{I}_{\mathrm{H}} \mathrm{R}_{1}
\end{aligned}
$$

The nominal hysteresis current $\mathrm{I}_{\mathrm{H}}$ equals $1.2 \mathrm{~V} / \mathrm{R}_{\mathrm{H}}$ (Figure 4).

The Uncommitted Comparator can be used to synchronize the microprocessor with the ac line signal for timing functions, or for synchronous load switching. It can also be connected as a line loss detector as shown in Figure 11. The comparator contains 200 mV of hysteresis preventing erratic output behavior when crossing the input threshold.

The Power Warning and Uncommitted Comparators each have a transistor base-emitter connected across their inputs. The base input normally connects to a voltage reference while the emitter input connects to the voltage to be monitored. The transistor limits the negative excursion on the emitter input to -0.7 V below the base input by supply current from $\mathrm{V}_{\mathrm{CC}}$. This clamp current will prevent forward biasing the IC substrate. Zener diodes are connected to the comparator inputs to enhance the ICs electrostatic discharge capability. Resistors $R_{1}$ and $R_{\text {in }}$ must limit the input current to a maximum of $\pm 2.0 \mathrm{~mA}$.

Each comparator output consists of an open collector NPN transistor capable of sinking 2.0 mA with a saturation voltage less than 0.4 V , and standing off 40 V with minimal leakage. Internal bias for the Reset and Power Warning Comparators is derived from either $\mathrm{V}_{\mathrm{CC}}$ or the regulator output to ensure functionality when either is below nominal.

## Heat Tab Package

The MC34160 is contained in a 16 lead plastic dual-in-line package in which the die is mounted on a special Heat Tab copper alloy lead frame. This tab consists of the four center ground pins that are specifically designed to improve thermal conduction from the die to the surrounding air. The pictorial in Figure 8 shows a simple but effective method of utilizing the printed circuit board
medium as a heat dissipator by soldering these tabs to an adequate area of copper foil. This permits the use of standard board layout and mounting practices while having the ability to more than halve the junction to air thermal resistance. The example and graph are for a symmetrical layout on a single sided board with one ounce per square foot copper.

## CS8271

## Adjustable Micropower Low Dropout Linear Regulator with ENABLE

The CS8271 is an adjustable micropower voltage regulator with very low quiescent current ( $60 \mu \mathrm{~A}$ typical at $100 \mu \mathrm{~A}$ load). The output supplies 100 mA of load current with a maximum dropout voltage of only 600 mV . Control logic includes ENABLE. The combination of low quiescent current, outstanding regulator performance and control logic makes the CS8271 ideal for any battery operated equipment.

The logic level ENABLE compatible pin allows the user to put the regulator into a shutdown mode where it draws only $50 \mu \mathrm{~A}$ of quiescent current.

The regulator is protected against reverse battery, short circuit, over voltage, and over temperature conditions. The device can withstand 60 V load dump transients making it suitable for use in automotive environments.

The CS8271 is pin compatible with the National Semiconductor LM2931.

## Features

- Low Quiescent Current
- Adjustable Output: 5.0 V to 12 V
- ENABLE for Sleep Mode Control
- 100 mA Output Current Capability
- Fault Protection
- +60 V Load Dump
-     - 15 V Reverse Voltage Short Circuit
- Thermal Shutdown
- Low Reverse Current (Output to Input)

| 5 | 5 | ENABLE | Logic level switch, when High, regulator is in sleep mode. |
| 8 | 8 | $\mathrm{V}_{\mathrm{IN}}$ | Input voltage. |

## CIRCUIT DESCRIPTION

## OUTPUT VOLTAGE ADJUSTMENT

The output voltage of the CS8271 is adjustable to any value between 5.0 V and the maximum input voltage minus the dropout voltage. To adjust the output voltage, a pair of external resistors R1 and R2 are connected as shown in Figure 2.

The equation for the output voltage is

$$
V_{\text {OUT }}=V_{R E F} \times\left(\frac{R 1+R 2}{R 2}\right)+I_{A d j} \times R 1
$$

where $\mathrm{V}_{\text {REF }}$ is the typical reference voltage and $\mathrm{I}_{\text {Adj }}$ is the adjust pin bias current. This is usually 500 nA maximum.

Figure 2. Output Voltage Adjustment

## OUTPUT STAGE PROTECTION

The output stage is protected against overvoltage, short circuit and thermal runaway conditions (Figure 3).

If the input voltage rises above 30 V (e.g. load dump), the output shuts down. This response protects the internal circuitry and enables the IC to survive unexpected voltage transients up to 60 V in magnitude.

Short circuit protection limits the amount of current the output transistor can supply. In the case of a CS8271 under a short circuit condition, the output transistor current is limited to 100 mA .
Should the junction temperature of the power device exceed $180^{\circ} \mathrm{C}$ (typ) the power transistor is turned off. Thermal shutdown is an effective means to prevent die overheating since the power transistor is the principle heat source in the IC.

Figure 3. Typical Circuit Waveforms for Output Stage Protection

## ENABLE

The ENABLE function switches the output transistor. When the voltage on the $\overline{\text { ENABLE }}$ pin exceeds 2.0 V typ, the output pass transistor turns off, leaving a high impedance facing the load. The IC will remain in Sleep mode, drawing only $20 \mu \mathrm{~A}$ (typ), until the voltage on this input drops below the ENABLE threshold.

## APPLICATION NOTES

## SELECTING THE RIGHT CAPACITOR VALUE

The output compensation capacitor COUT, determines three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The selection of a capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR, can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provide this information.

The value for the output compensation capacitor COUT shown in Figure 4 should work for most applications, but it is not necessarily the least expensive or the optimal solution.

Figure 4. Test and Application Circuit Showing An Output Compensation Capacitor

To determine an acceptable value for $\mathrm{C}_{\text {OUT }}$ for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. (Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible).

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. (A smaller capacitor will usually cost less and occupy less board space.) If the capacitor oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.
Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real work environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitor should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.
Capacitance on the Adjust pin combined with the feedback resistors R1 and R2 can affect loop stability and should also be considered. The CS8271 internal circuitry produces about 5.0 pF to Ground on the Adjust pin. This capacitance, plus any additional external capacitance on the Adjust pin will create a pole when combined with the resistive feedback network. The effect can be significant when using large values for the feedback resistors to minimize quiescent current.
A capacitor connected from the Adjust pin to Ground provides additional means to compensate the regulator by creating a pole. Alternately, a capacitor can be connected from the Adjust pin to V VUT to create a zero.

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 5) is:

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT (min) }}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with
$\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

## CS8183

## Dual Micropower 200 mA Low Dropout Tracking Regulator/Line Driver

The CS8183 is a dual low dropout tracking regulator designed to provide adjustable buffered output voltages that closely track $( \pm 10 \mathrm{mV})$ the reference inputs. The outputs deliver up to 200 mA while being able to be configured higher, lower or equal to the reference voltages.

The outputs have been designed to operate over a wide range ( 2.8 V to 45 V ) while still maintaining excellent DC characteristics. The CS8183 is protected from reverse battery, short circuit and thermal runaway conditions. The device also can withstand 45 V load dump transients and -50 V reverse polarity input voltage transients. This makes it suitable for use in automotive environments.

The $\mathrm{V}_{\text {REF }} / E N A B L E$ leads serve two purposes. They are used to provide the input voltage as a reference for the output and they also can be pulled low to place the device in sleep mode where it nominally draws less than $30 \mu \mathrm{~A}$ from the supply.

## Features

- Two Regulated Outputs $200 \mathrm{~mA}, \pm 10 \mathrm{mV}$ Track Worst Case
- Low Dropout (0.35 V typ. @ 200 mA )
- Low Quiescent Current
- Independent Thermal Shutdown
- Short Circuit Protection
- Wide Operating Range
- Internally Fused Leads in the SO-20L Package

## CIRCUIT DESCRIPTION

## ENABLE Function

By pulling the $\mathrm{V}_{\mathrm{REF}} /$ ENABLE 1, 2 lead below 2.0 V typically, (see Figure 5 or Figure 6), the IC is disabled and enters a sleep state where the device draws less than $30 \mu \mathrm{~A}$ from supply. When the $\mathrm{V}_{\mathrm{REF}} /$ ENABLE lead is greater than $2.75 \mathrm{~V}, \mathrm{~V}_{\mathrm{OUT}}$ tracks the $\mathrm{V}_{\mathrm{REF}} / \mathrm{ENABLE}$ lead normally.

## Output Voltage

Figures 2 through 7 only display one channel of the device for simplicity. The configurations shown apply for both channels.

$$
\text { VOUT }=V_{\text {REF }}
$$

Figure 2. Tracking Regulator at the Same Voltage

Figure 4. Tracking Regulator at Lower Voltages

Figure 6. Alternative ENABLE Circuit

[^14]The outputs are capable of supplying 200 mA to the load while configured as a similiar (Figure 2), lower (Figure 4), or higher (Figure 3) voltage as the reference lead. The Adj lead acts as the inverting terminal of the op amp and the $\mathrm{V}_{\text {REF }}$ lead as the non-inverting.

The device can also be configured as a high-side driver as displayed in Figure 7.

Figure 3. Tracking Regulator at Higher Voltages

Figure 5. Tracking Regulator with ENABLE Circuit

Figure 7. High-Side Driver

## APPLICATION NOTES

## Switched Application

The CS8183 has been designed for use in systems where the reference voltage on the $\mathrm{V}_{\text {REF }} /$ /ENABLE pin is continuously on. Typically, the current into the $\mathrm{V}_{\text {REF/ }}$ /ENABLE pin will be less than $1.0 \mu \mathrm{~A}$ when the voltage on the $\mathrm{V}_{\text {IN }}$ pin (usually the ignition line) has been switched out ( $\mathrm{V}_{\text {IN }}$ can be at high impedance or at ground.) Reference Figure 8.

Figure 8.

## External Capacitors

Output capacitors for the CS8183 are required for stability. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability. Worst-case is determined at the minimum ambient temperature and maximum load expected.

The output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltage during brief conditions of negative input transients that might be characteristic of a particular system.

The capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, a capacitor rated at that temperature must be used.
More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators."

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 9) is:

$$
\begin{align*}
\mathrm{PD}(\max )= & \left\{\mathrm{V}_{\mathrm{IN}}(\max )-\mathrm{V}_{\text {OUT1 }}(\min )\right\} \operatorname{IOUT1}(\max ) \\
& +\left\{\mathrm{V}_{\mathrm{IN}}(\max )-\mathrm{V}_{\text {OUT2 }}(\min )\right\} \operatorname{IOUT2}(\max 2) \\
& +\mathrm{V}_{\mathrm{IN}}(\max ) \mathrm{I} \mathrm{Q} \tag{1}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\text { max })}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$V_{\text {OUT2(min) }}$ is the minimum output voltage from $V_{\text {OUT2 }}$, Iout1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application,
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).
Once the value of $\mathrm{PD}(\max )$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\text {©JA's }}$ less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heat sink will be required.

Figure 9. Dual Output Regulator with Key Performance Parameters Labeled

## Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.
Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©IC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta \mathrm{SA}}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\text {©JC }}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8363

### 3.3 V Dual Micropower Low Dropout Regulator with ENABLE and RESET

The CS8363 is a precision micropower dual voltage regulator with $\overline{\text { ENABLE }}$ and $\overline{\text { RESET. }}$

The 3.3 V standby output is accurate within $\pm 2 \%$ while supplying loads of 100 mA . Quiescent current is low, typically $140 \mu \mathrm{~A}$ with a $300 \mu \mathrm{~A}$ load. The active $\overline{\mathrm{RESET}}$ output monitors the 3.3 V standby output and is low during power-up and regulator dropout conditions. The $\overline{\text { RESET }}$ circuit includes hysteresis and is guaranteed to operate correctly with 1.0 V on the standby output.

The second output tracks the 3.3 V standby output through an external adjust lead, and can supply loads of 250 mA with a typical dropout voltage of 400 mV . The logic level lead ENABLE is used to control this tracking regulator output.

Both outputs are protected against overvoltage, short circuit, reverse battery and overtemperature conditions. The robustness and low quiescent current of the CS8363 makes it not only well suited for automotive microprocessor applications, but for any battery powered microprocessor applications.

## Features

- 2 Regulated Outputs
- Standby Output 3.3 V $\pm 2 \%$; 100 mA
- Adjustable Tracking Output; 250 mA
- Low Dropout Voltage
- RESET for $V_{\text {STBY }}$
- ENABLE for VTRK
- Low Quiescent Current
- Protection Features
- Independent Thermal Shutdown
- Short Circuit
- 60 V Load Dump
- Reverse Battery

PACKAGE PIN DESCRIPTION

| PACKAGE PIN \# |  |  |
| :---: | :---: | :--- |
| D2PAK | PIN SYMBOL |  |
| 1 | $\mathrm{~V}_{\text {STBY }}$ | FUNCTION |

## CIRCUIT DESCRIPTION

## ENABLE Function

The ENABLE function switches the output transistor for $V_{\text {TRK }}$ on and off. When the ENABLE lead voltage exceeds 1.4 V (typ), $\mathrm{V}_{\text {TRK }}$ turns off. This input has several hundred millivolts of hysteresis to prevent spurious output activity during power-up or power-down.

## RESET Function

The $\overline{\text { RESET }}$ is an open collector NPN transistor, controlled by a low voltage detection circuit sensing the $\mathrm{V}_{\text {STBY }}(3.3 \mathrm{~V}$ ) output voltage. This circuit guarantees the RESET output stays below $1.0 \mathrm{~V}\left(0.1 \mathrm{~V}\right.$ typ) when $\mathrm{V}_{\text {STBY }}$ is as low as 1.0 V to ensure reliable operation of microprocessor-based systems.

## $V_{\text {TRK }}$ Output Voltage

This output uses the same type of output device as $\mathrm{V}_{\text {STBY }}$, but is rated for 250 mA . The output is configured as a tracking regulator of the standby output. By using the standby output as a voltage reference, giving the user an external programming lead (Adj lead), output voltages from 3.3 V to 20 V are easily realized. The programming is done with a simple resistor divider, and following the formula:

$$
V_{\mathrm{TRK}}=\mathrm{V}_{\mathrm{STBY}} \times(1+\mathrm{R} 1 / \mathrm{R} 2)+\mathrm{I}_{\mathrm{Adj}} \times \mathrm{R} 1
$$

If another 3.3 V output is needed, simply connect the Adj lead to the $\mathrm{V}_{\text {TRK }}$ output lead.

Figure 2. Test and Application Circuit, 3.3 V, 5.0 V Regulator

*C1 is required if regulator is located far from power supply filter.
${ }^{* *} \mathrm{C} 2$ and C3 are required for stability.
Figure 3. Test and Application Circuit, Dual 3.3 V Regulator

## APPLICATION NOTES

## External Capacitors

Output capacitors for the CS8363 are required for stability. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability. Worst-case is determined at the minimum ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, capacitors rated at that temperature must be used.

More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 4) is
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,

IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at both IOUT1(max) and IOUT2(max).
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\text {©JA }}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 4. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

## CS8363

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

PACKAGE THERMAL DATA

| Parameter |  | D$^{2}$ PAK, 7-Pin | Unit |
| :--- | :---: | :---: | :---: |
| $R_{\text {®JC }}$ | Typical | 3.5 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $R_{\text {®JA }}$ | Typical | $10-50^{\star}$ | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{*}$ Depending on thermal properties of substrate. $R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C A}$.

## CS8361

### 5.0 V Dual Micropower Low Dropout Regulator with ENABLE and RESET

The CS8361 is a precision micropower dual voltage regulator with $\overline{\text { ENABLE }}$ and $\overline{\text { RESET. }}$

The 5.0 V standby output is accurate within $\pm 2 \%$ while supplying loads of 100 mA and has a typical dropout voltage of 400 mV . Quiescent current is low, typically $140 \mu \mathrm{~A}$ with a $300 \mu \mathrm{~A}$ load. The active RESET output monitors the 5.0 V standby output and is low during power-up and regulator dropout conditions. The $\overline{\text { RESET }}$ circuit includes hysteresis and is guaranteed to operate correctly with 1.0 V on the standby output.

The second output tracks the 5.0 V standby output through an external adjust lead, and can supply loads of 250 mA with a typical dropout voltage of 400 mV . The logic level $\overline{\text { ENABLE }}$ lead is used to control this tracking regulator output.

Both outputs are protected against overvoltage, short circuit, reverse battery and overtemperature conditions. The robustness and low quiescent current of the CS8361 makes it not only well suited for automotive microprocessor applications, but for any battery powered microprocessor applications.

## Features

- 2 Regulated Outputs
- Standby Output 5.0 V $\pm 2 \%$; 100 mA
- Tracking Output $5.0 \mathrm{~V} ; 250 \mathrm{~mA}$
- Low Dropout Voltage ( 0.4 V at Rated Current)
- RESET Option
- ENABLE Option
- Low Quiescent Current
- Protection Features
- Independent Thermal Shutdown
- Short Circuit
- 60 V Load Dump
- Reverse Battery
- Internally Fused Leads in SO-16L Package

## CIRCUIT DESCRIPTION

## ENABLE Function

The ENABLE function switches the output transistor for $\mathrm{V}_{\text {TRK }}$ on and off. When the ENABLE lead voltage exceeds 1.4 V (typ), $\mathrm{V}_{\text {TRK }}$ turns off. This input has several hundred millivolts of hysteresis to prevent spurious output activity during power-up or power-down.

## RESET Function

The RESET is an open collector NPN transistor, controlled by a low voltage detection circuit sensing the $\mathrm{V}_{\text {STBY }}(5.0 \mathrm{~V})$ output voltage. This circuit guarantees the RESET output stays below $1.0 \mathrm{~V}\left(0.1 \mathrm{~V}\right.$ typ) when $\mathrm{V}_{\text {STBY }}$ is as low as 1.0 V to ensure reliable operation of microprocessor- based systems.

## $\mathrm{V}_{\text {TRK }}$ Output Voltage

This output uses the same type of output device as $\mathrm{V}_{\mathrm{STBY}}$, but is rated for 250 mA . The output is configured as a tracking regulator of the standby output. By using the standby output as a voltage reference, giving the user an external programming lead (Adj lead), output voltages from 5.0 V to 20 V are easily realized. The programming is done with a simple resistor divider (Figure 2), and following the formula:

$$
V_{\text {TRK }}=V_{\text {STBY }} \times(1+\mathrm{R} 1 / R 2)+I_{\text {Adj }} \times R 1
$$

If another 5.0 V output is needed, simply connect the Adj lead to the $\mathrm{V}_{\text {TRK }}$ output lead.

*C1 is required if regulator is located far from power supply filter.
${ }^{* *} \mathrm{C} 2$ and C3 are required for stability.
Figure 3. Test and Application Circuit, Dual 5.0 V Regulator

## APPLICATION NOTES

## External Capacitors

Output capacitors for the CS8361 are required for stability. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability. Worst-case is determined at the minimum ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, capacitors rated at that temperature must be used.

More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 4) is
where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,

IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at both IOUT1(max) and IOUT2(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\text {©JA }}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 4. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

## CS8361

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

PACKAGE THERMAL DATA

| :--- | :---: | :---: | :---: | :---: |
| $R_{\text {®JC }}$ | Typical | 18 | 3.5 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $R_{\text {®JA }}$ | Typical | 75 | $10-50^{*}$ | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

*Depending on thermal properties of substrate. $R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C A}$.

## CS8147

## 10 V/5.0 V Low Dropout Dual Regulator with ENABLE

The CS8147 is a $10 \mathrm{~V} / 5.0 \mathrm{~V}$ dual output linear regulator. The 10 V $\pm 5.0 \%$ output sources 500 mA and the $5.0 \mathrm{~V} \pm 3 \%$ output sources 70 mA . The secondary output is inherently stable and does not require an external capacitor.

The on board ENABLE function controls the regulator's two outputs. When ENABLE is high, the regulator is placed in SLEEP mode. Both outputs are disabled and the regulator draws only $70 \mu \mathrm{~A}$ of quiescent current.

The regulator is protected against overvoltage conditions. Both outputs are protected against short circuit and thermal runaway conditions.

The CS8147 is packaged in a 5 lead TO-220 with copper tab. The copper tab can be connected to a heat sink if necessary.

## Features

- Two Regulated Outputs
- $10 \mathrm{~V} \pm 5.0 \%$; 500 mA
$-5.0 \mathrm{~V} \pm 3.0 \%$; 70 mA
- $70 \mu \mathrm{~A}$ SLEEP Mode Current
- Inherently Stable Secondary Output (No Output Capacitor Required)
- Fault Protection
- Overvoltage Shutdown
- Reverse Battery
- 60 V Peak Transient
- -50 V Reverse Transient
- Short Circuit
- Thermal Shutdown
- CMOS Compatible ENABLE Input with Low (IOUT(max) Input Current

## DEFINITION OF TERMS

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Current Limit - Peak current that can be delivered to the output.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Quiescent Current - The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.
Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of VOUT - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

${ }^{* *} \mathrm{C}_{2}$ is required for stability.
Figure 15. Test \& Applications Circuit

## APPLICATION NOTES

Since both outputs are controlled by the same ENABLE, the CS8147 is ideal for applications where a sleep mode is required. Using the CS8147, a section of circuitry such as a display and nonessential 5.0 V circuits can be shut down under microprocessor control to conserve energy.

The test applications circuit diagram shows an automotive radio application where the display is powered by 10 V from $\mathrm{V}_{\text {OUT1 }}$ and the Tuner IC is powered by 5.0 V from $\mathrm{V}_{\text {OUT2 }}$. Neither output is required unless both the ignition and the Radio On/OFF switch are on.

## Stability Considerations

The secondary output $\mathrm{V}_{\text {OUT2 }}$ is inherently stable and does not require a compensation capacitor. However a compensation capacitor connected between $V_{\text {OUT1 }}$ and ground is required for stability in most applications.

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor C 2 shown in the test and applications circuit should work for most applications, however it is not necessarily the optimized solution.

To determine acceptable value for C 2 for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.
Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.

Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.
Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found for each output, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitors should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 16) is

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be compared with those in the package section of the data sheet. Those packages with
$\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 16. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta \mathrm{JA}}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $\mathrm{R}_{\Theta J A}$, it too is a function of package type. $\mathrm{R}_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8156

## 12 V, 5.0 V Low Dropout Dual Regulator with ENABLE

The CS8156 is a low dropout $12 \mathrm{~V} / 5.0 \mathrm{~V}$ dual output linear regulator. The $12 \mathrm{~V} \pm 5.0 \%$ output sources 750 mA and the $5.0 \mathrm{~V} \pm 2.0 \%$ output sources 100 mA .

The on board ENABLE function controls the regulator's two outputs. When the ENABLE lead is low, the regulator is placed in SLEEP mode. Both outputs are disabled and the regulator draws only 200 nA of quiescent current.

The regulator is protected against overvoltage conditions. Both outputs are protected against short circuit and thermal runaway conditions.

The CS8156 is packaged in a 5 lead TO-220 with copper tab. The copper tab can be connected to a heat sink if necessary.

## Features

## DEFINITION OF TERMS

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.
Quiescent Current - The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of VOUT - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 19. Typical Circuit Waveform

## APPLICATION NOTES

## Stability Considerations

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the cheapest solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitors C2 and C3 shown in the test and applications circuit should work for most applications, however it is not necessarily the best solution.

To determine acceptable values for C 2 and C 3 for a particular application, start with a tantalum capacitor of the recommended value and work towards a less expensive alternative part for each output.
Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs with an oscilloscope. A decade box connected in series with the capacitor $\mathrm{C}_{2}$ will simulate the higher ESR of an aluminum capacitor. Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible.
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations
are observed, the capacitor is large enough to ensure a stable design under steady state conditions.
Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase. This point represents the worst case input voltage conditions.
Step 5: If the capacitor is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. A smaller capacitor will usually cost less and occupy less board space. If the output oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.
Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real working environment. Vary the ESR to reduce ringing.
Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found for each output, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitors should be less than $50 \%$ of the maximum allowable ESR found in step 3 above.

Repeat steps 1 through 7 with $\mathrm{C}_{3}$, the capacitor on the other output.

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 20) is
where:
$\mathrm{V}_{\mathrm{IN}(\text { max })}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
VOUT2(min) is the minimum output voltage from $V_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,

IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}^{2}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J \text { J }}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\text {©JA }}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 20. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$ where:

$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8156

${ }^{*} \mathrm{C}_{1}$ is required if the regulator is far from power supply filter.
${ }^{* *} \mathrm{C}_{2}, \mathrm{C}_{3}$ required for stability.

## CS8161

## 12 V, 5.0 V Low Dropout Dual Regulator with ENABLE

The CS8161 is a $12 \mathrm{~V} / 5.0 \mathrm{~V}$ dual output linear regulator. The $12 \mathrm{~V} \pm 5.0 \%$ output sources 400 mA and the $5.0 \mathrm{~V} \pm 2.0 \%$ output sources 200 mA .

The on board ENABLE function controls the regulator's two outputs. When the ENABLE pin is low, the regulator is placed in SLEEP mode. Both outputs are disabled and the regulator draws only 200 nA of quiescent current.

The primary output, $V_{\text {OUT1 }}$ is protected against overvoltage conditions. Both outputs are protected against short circuit and thermal runaway conditions.

The CS8161 is packaged in a 5 lead TO-220 with copper tab. The copper tab can be connected to a heat sink if necessary.

## Features

- Two Regulated Outputs
- $12 \mathrm{~V} \pm 5.0 \%$; 400 mA
$-5.0 \mathrm{~V} \pm 2.0 \% ; 200 \mathrm{~mA}$
- Very Low SLEEP Mode Current Drain 200 nA
- Fault Protection
- Reverse Battery (-15 V)
- 74 V Load Dump
- -100 V Reverse Transient
- Short Circuit
- Thermal Shutdown

## DEFINITION OF TERMS

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.
Quiescent Current - The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.
Temperature Stability of VOUT - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 17. Typical Circuit Waveform

${ }^{*} \mathrm{C}_{1}$ required if regulator is located far from power supply filter.
${ }^{* *} \mathrm{C}_{2}, C_{3}$ required for stability, value may be increased. Capacitor must operate at minimum temperature expected.
Figure 18. Application Diagram

## APPLICATION NOTES

Since both outputs are controlled by the same ENABLE, the CS8161 is ideal for applications where a sleep mode is required. Using the CS8161, a section of circuitry such as a display and nonessential 5.0 V circuits can be shut down under microprocessor control to conserve energy.

The example in the Applications Diagram (Figure 18) shows an automotive radio application where the display is powered by the 12 V on $\mathrm{V}_{\text {OUT1 }}$ and the Tuner IC is powered by the 5.0 V on $\mathrm{V}_{\text {OUT2 }}$. Neither output is required unless both the ignition and the Radio On/Off switch are on.

## Stability Considerations

The output or compensation capacitor (Application diagram $\mathrm{C}_{2}$ and $\mathrm{C}_{3}$ ) helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the cheapest solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The values for the output capacitors $\mathrm{C}_{2}$ and $\mathrm{C}_{3}$ shown in the test and applications circuit should work for most applications, however it is not necessarily the best solution.

To determine acceptable values for $\mathrm{C}_{2}$ and $\mathrm{C}_{3}$ for a particular application, start with tantalum capacitors of the recommended value on each output and work towards less expensive alternative parts for each output in turn.
Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs on the oscilloscope. A decade box connected in series with the capacitor $\mathrm{C}_{2}$ will simulate the higher ESR of an aluminum capacitor.(Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible)
Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.
Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.
Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase.

This point represents the worst case input voltage conditions.
Step 5: If the capacitor $\mathrm{C}_{2}$ is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. (A smaller capacitor will usually cost less and occupy less board space.) If the capacitor oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.
Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real work environment. Vary the ESR to reduce ringing.
Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.
Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of $\pm 20 \%$ so the minimum value found should be increased by at least $50 \%$ to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitors should be less than $50 \%$ of the maximum allowable ESR found in step 3 above. Once the value for $\mathrm{C}_{2}$ is determined, repeat the steps to determine the appropriate value for $\mathrm{C}_{3}$.

## Calculating Power Dissipation in a

## Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 19) is

```
\(P_{D}(\) max \()=\left\{V_{I N}(\right.\) max \(\left.)-V_{O U T 1(m i n)}\right){ }^{\text {IOUT1 }}\) (max) \()+\)
    \(\left(\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{V}_{\text {OUT2 }}(\min )\right.\) IIOUT2(max) \(+\mathrm{V}_{\mathrm{IN}(\text { max })} \mathrm{IQ}_{\text {(1) }}\)
```

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
$\mathrm{I}_{\text {OUT2 (max) }}$ is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
R_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \text { JA }}$ can be compared with those in the package section of the data sheet. Those packages with
$\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 19. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $\mathrm{R}_{\Theta J A}$, it too is a function of package type. $\mathrm{R}_{\Theta C S}$ and $\mathrm{R}_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## PACKAGE THERMAL DATA

| $\mathrm{R}_{\Theta J A}$ | Typical | 50 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## CS8281

### 5.0 V/250 mA, $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Micropower Low Dropout Regulator with ENABLE

The CS8281 is a precision, dual 5.0 V micropower linear voltage regulator. The switched primary output ( $\mathrm{V}_{\text {OUT1 }}$ ) supplies up to 250 mA while the secondary ( $\mathrm{V}_{\text {OUT2 }}$ ) is capable of supplying 100 mA . Both outputs have a maximum dropout voltage of 600 mV and low reverse current. Quiescent current drain is typically $150 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from each output.

The ENABLE input provides logic level control of the primary output. With the primary output disabled, quiescent current drain is typically $100 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from the secondary output.

The CS8281 is extremely robust with protection provided for reverse battery, short circuit, overvoltage, and overtemperature on both outputs.

The CS8281 is available in a 5 -lead D ${ }^{2}$ PAK.

## Features

- $5.0 \mathrm{~V} / 250 \mathrm{~mA}$ Primary Output
- $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Secondary Output
- 3.0\% Tolerance, Both Outputs
- ON/OFF Control for Primary Output
- Low Quiescent Current Drain ( $100 \mu \mathrm{~A} \mathrm{~V}_{\mathrm{OUT} 2}$ )
- Low Reverse Current
- Protection Features
- Reverse Battery (-15 V)
- 74 V Load Dump
- Short Circuit
- Overtemperature
- Overvoltage (34 V)

PACKAGE PIN DESCRIPTION

| PACKAGE LEAD \# |  |  |
| :---: | :---: | :---: |
| D2PAK, 5-PIN | LEAD SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\text {IN }}$ | Supply voltage to IC, usually direct from battery. |
| 2 | $\mathrm{V}_{\text {OUT1 }}$ | 5.0 V regulated output which is activated by ENABLE input. |
| 3 | GND | Ground connection. |
| 4 | $\mathrm{V}_{\text {OUT2 }}$ | Standby output 5.0 V, 100 mA capability; always on. |
| 5 | ENABLE | CMOS compatible input lead; switches $\mathrm{V}_{\text {OUt1 }}$. When ENABLE is high, $\mathrm{V}_{\text {OUT1 }}$ is active. |

## DEFINITION OF TERMS

Current Limit - Peak current that can be delivered to the output.

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Quiescent Current - The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Short Circuit Current Limit - Peak current that can be delivered by the outout when forced to 0 V .

Temperature Stability of Vout - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 2. Typical Circuit Waveform

## APPLICATION NOTES

## General

The CS8281 is a micropower dual 5.0 V regulator. All bias required to operate the internal circuitry is derived from the standby output, $V_{\text {OUT2 }}$. If this output experiences an over current situation and collapses, then $\mathrm{V}_{\text {OUT1 }}$ will also collapse (see Figure 2).

If there is critical circuitry that must remain active under most conditions it should be connected to VOUT2. Any circuitry that is likely to be subjected to a short circuit, e.g., circuitry outside the module, should be connected to $V_{\text {OUT1 }}$.

## External Capacitors

Output capacitors are required for stability with the CS8281. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability.

Worst-case is determined at the minimum ambient temperature and maximum load expected.
Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.
Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, capacitors rated at that temperature must be used.
More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## ENABLE

The ENABLE function controls V ${ }_{\text {OUT1 }}$. When ENABLE is high, $V_{\text {OUT1 }}$ is on. When ENABLE is low, $V_{\text {OUT1 }}$ is off.

## Calculating Power Dissipation in a <br> Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 3) is

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at both IOUT1(max) and IOUT2(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 3. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JJC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8371

### 8.0 V/1.0 A, $5.0 \mathrm{~V} / 250 \mathrm{~mA}$ Dual Regulator with Independent Output Enables and NOCAP ${ }^{\text {M }}$

The CS8371 is an $8.0 \mathrm{~V} / 5.0 \mathrm{~V}$ dual output linear regulator. The 8.0 $\mathrm{V} \pm 5.0 \%$ output sources 1.0 A , while the $5.0 \mathrm{~V} \pm 5.0 \%$ output sources 250 mA . Each output is controlled by its own ENABLE lead. Setting the ENABLE input high turns on the associated regulator output. Holding both ENABLE inputs low puts the IC into sleep mode where current consumption is less than $10 \mu \mathrm{~A}$.

The regulator is protected against overvoltage, short-circuit and thermal runaway conditions. The device can withstand 45 V load dump transients making suitable for use in automotive environments. ON's proprietary NOCAP solution is the first technology which allows the output to be stable without the use of an external capacitor.

The CS8371 is available in a 7 lead TO-220 package with copper tab. The tab can be connected to a heatsink if necessary.

## Features

- Two Regulated Outputs
- 8.0 V $\pm 5.0 \%$; 1.0 A
- $5.0 \mathrm{~V} \pm 5.0 \% ; 250 \mathrm{~mA}$
- Independent ENABLE for Each Output
- Seperate Sense Feedback Lead for 8.0 V Output
- < $10 \mu \mathrm{~A}$ Sleep Mode Current
- Fault Protection
- Overvoltage Shutdown
- +45 V Peak Transient Voltage
- Short Circuit
- Thermal Shutdown
- CMOS Compatible, Low Current ENABLE Inputs

## DEFINITION OF TERMS

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Current Limit - Peak current that can be delivered to the output.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage - The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.
Quiescent Current - The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.
Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of Vout - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 23. Applications Circuit

## APPLICATION NOTES

With seperate control of each output channel, the CS8371 is ideal for applications where each load must be switched independently. In an automotive radio, the 8.0 V output drives the displays and tape drive motors while the 5.0 V output supplies the Tuner IC and memory.

## Stability Considerations/NOCAP

Normally a low dropout or quasi-low dropout regulator (or any type requiring a slow lateral PNP in the control loop) necessitates a large external compensation capacitor at the output of the IC. The external capacitor is also used to curtail overshoot, determine startup delay time and load transient response.

Traditional LDO regulators typically have low unity gain bandwidth, display overshoot and poor ripple rejection. Compensation is also an issue because the high frequency
load capacitor value, ESR (Equivalent Series Resistance) and board layout parasitics all can create oscillations if not properly accounted for.
NOCAP is an ON Semiconductor exclusive output stage which internally compensates the LDO regulator over temperature, load and line variations without the need for an expensive external capacitor. It incorporates high gain ( $>80 \mathrm{~dB}$ ) and large unity gain bandwidth ( $>100 \mathrm{kHz}$ ) while maintaining many of the characteristics of a single-pole amplifier (large phase margin and no overshoot).
NOCAP is ideally suited for slow switching or steady loads. If the load displays large transient current requirements, such as with high frequency microprocessors, an output storage capacitor may be needed. Some large capacitor and small capacitor ESR values at the output may
cause small signal oscillations at the output. This will depend on the load conditions. With these types of loads, a traditional output stage may be better suited for proper operation.

Output 1 employs NOCAP. Refer to the plots in the Typical Performance Characteristics section for appropriate output capacitor selections for stability if an external capacitor is required by the switching characteristics of the load. Output 2 has a Darlington NPN-type output structure and is inherently stable with any type of capacitive load or no capacitor at all.

## Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 24) is

$$
\begin{aligned}
& \left.P_{D}(\text { max })=\left\{V_{I N}(\text { max })-V_{O U T 1(m i n)}\right) \text { IOUT1 } \text { max }\right)+
\end{aligned}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at IOUT(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{PD}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \text { JA }}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 24. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8391

## $5.0 \mathrm{~V} / 250 \mathrm{~mA}, 5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Micropower Low Dropout Regulator with ENABLE

The CS8391 is a precision, dual 5.0 V micropower linear voltage regulator. The switched primary output ( $\mathrm{V}_{\text {OUT1 }}$ ) supplies up to 250 mA while the secondary ( $\mathrm{V}_{\text {OUT2 }}$ ) is capable of supplying 100 mA . Both outputs have a maximum dropout voltage of 600 mV and low reverse current. Quiescent current drain is typically $150 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from each output.

The ENABLE input provides logic level control of the primary output. With the primary output disabled, quiescent current drain is typically $100 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from the secondary output.

The CS8391 is extremely robust with protection provided for reverse battery, short circuit, and overtemperature on both outputs

The CS8391 is available in a 5 -lead D ${ }^{2} \mathrm{PAK}$.

## Features

- $5.0 \mathrm{~V} / 250 \mathrm{~mA}$ Primary Output
- $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Secondary Output
- 3.0\% Tolerance, Both Outputs
- ON/OFF Control for Primary Output
- Low Quiescent Current Drain ( $100 \mu \mathrm{~A} \mathrm{~V}_{\mathrm{OUT} 2}$ )
- Low Reverse Current
- Protection Features
- Reverse Battery (-15 V)
- Short Circuit
- Overtemperature

| D2PAK, 5-PIN | LEAD SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\mathrm{IN}}$ | Supply voltage to IC, usually direct from battery. |
| 2 | $V_{\text {OUT1 }}$ | 5.0 V regulated output which is activated by ENABLE input. |
| 3 | GND | Ground connection. |
| 4 | $V_{\text {OUT2 }}$ | Standby output 5.0 V, 100 mA capability; always on. |
| 5 | ENABLE | CMOS compatible input lead; switches $\mathrm{V}_{\text {OUT1 }}$. When ENABLE is high, Vout1 is active. |

## DEFINITION OF TERMS

Current Limit - Peak current that can be delivered to the output.

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.
Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.
Quiescent Current - The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.
Short Circuit Current Limit - Peak current that can be delivered by the outout when forced to 0 V .
Temperature Stability of Vout - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 2. Typical Circuit Waveform

## APPLICATION NOTES

## General

The CS8391 is a micropower dual 5.0 V regulator. All bias required to operate the internal circuitry is derived from the standby output, $V_{\text {OUT2 } 2}$. If this output experiences an over current situation and collapses, then Vout1 will also collapse (see Figure 2).

If there is critical circuitry that must remain active under most conditions it should be connected to $\mathrm{V}_{\text {OUT2 }}$. Any circuitry that is likely to be subjected to a short circuit, e.g., circuitry outside the module, should be connected to $\mathrm{V}_{\text {OUT1 }}$ -

## External Capacitors

Output capacitors are required for stability with the CS8391. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability.

Worst-case is determined at the minimum ambient temperature and maximum load expected.
Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.
Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, capacitors rated at that temperature must be used.
More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## ENABLE

The ENABLE function controls V OUT1. When ENABLE is high, V VUT1 is on. When ENABLE is low, V ${ }_{\text {OUT1 }}$ is off.

## Calculating Power Dissipation in a <br> Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 3) is
$\mathrm{P}_{\mathrm{D}(\text { max })}=\left\{\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{VOUT1}^{(\text {min })}\right)_{\text {IOUT1 }}($ max $)+$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at both IOUT1(max) and IOUT2(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J A}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heat sink will be required.

Figure 3. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\text {©JC }}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heat sink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heat sink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## CS8481

### 3.3 V/250 mA, $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Micropower Low Dropout Regulator with ENABLE

The CS8481 is a precision, dual micropower linear voltage regulator. The switched 3.3 V primary output ( $\mathrm{V}_{\text {OUT1 }}$ ) supplies up to 250 mA while the secondary 5.0 V ( $\mathrm{V}_{\text {OUT2 }}$ ) is capable of supplying 100 mA . Both outputs have a maximum dropout voltage of 600 mV and low reverse current. Quiescent current drain is typically $150 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from each output.

The ENABLE input provides logic level control of the primary output. With the primary output disabled, quiescent current drain is typically $100 \mu \mathrm{~A}$ when supplying $100 \mu \mathrm{~A}$ from the secondary output.

The CS8481 is extremely robust with protection provided for reverse battery, short circuit, overvoltage, and overtemperature on both outputs.

The CS8481 is available in a 5 -lead $\mathrm{D}^{2} \mathrm{PAK}$.

## Features

- $3.3 \mathrm{~V} / 250 \mathrm{~mA}$ Primary Output
- $5.0 \mathrm{~V} / 100 \mathrm{~mA}$ Secondary Output
- 3.0\% Tolerance, Both Outputs
- ON/OFF Control for Primary Output
- Low Quiescent Current Drain ( $100 \mu \mathrm{~A} \mathrm{~V}_{\mathrm{OUT} 2}$ )
- Low Reverse Current
- Protection Features
- Reverse Battery (-15 V)
- 74 V Peak Transient Voltage
- Short Circuit
- Overtemperature
- Overvoltage (34 V)

## PACKAGE PIN DESCRIPTION

| PACKAGE LEAD \# |  |  |
| :---: | :---: | :---: |
| D2PAK, 5-PIN | LEAD SYMBOL | FUNCTION |
| 1 | $\mathrm{V}_{\mathrm{IN}}$ | Supply voltage to IC, usually direct from battery. |
| 2 | $\mathrm{V}_{\text {OUT1 }}$ | 3.3 V regulated output which is activated by ENABLE input. |
| 3 | GND | Ground connection. |
| 4 | $V_{\text {OUT2 }}$ | Standby output 5.0 V, 100 mA capability; always on. |
| 5 | ENABLE | CMOS compatible input lead; switches $\mathrm{V}_{\text {OUT1 }}$. When ENABLE is high, $\mathrm{V}_{\text {OUT } 1}$ is active. |

## DEFINITION OF TERMS

Current Limit - Peak current that can be delivered to the output.

Dropout Voltage - The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Output Differential - The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Input Voltage - The DC voltage applied to the input terminals with respect to ground.

Line Regulation - The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation - The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability - Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Quiescent Current - The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection - The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.
Short Circuit Current Limit - Peak current that can be delivered by the outout when forced to 0 V .

Temperature Stability of Vout - The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Figure 2. Typical Circuit Waveform

## APPLICATION NOTES

## General

The CS8481 is a micropower dual regulator. All bias required to operate the internal circuitry is derived from the standby output, $\mathrm{V}_{\text {OUT2 }}$. If this output experiences an over current situation and collapses, then VOUT1 will also collapse (see Figure 2).

If there is critical circuitry that must remain active under most conditions it should be connected to VOUT2. Any circuitry that is likely to be subjected to a short circuit, e.g., circuitry outside the module, should be connected to $V_{\text {OUT1 }}$.

## External Capacitors

Output capacitors are required for stability with the CS8481. Without them, the regulator outputs will oscillate. Actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) is also a factor in the IC stability.

Worst-case is determined at the minimum ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.
Capacitors must also be rated at all ambient temperatures expected in the system. To maintain regulator stability down to $-40^{\circ} \mathrm{C}$, capacitors rated at that temperature must be used.
More information on capacitor selection for SMART REGULATOR®s is available in the SMART REGULATOR application note, "Compensation for Linear Regulators," document number SR003AN/D, available through the Literature Distribution Center or via our website at http://www.onsemi.com.

## ENABLE

The ENABLE function controls V OUT1. When ENABLE is high, V VUT1 is on. When ENABLE is low, $V_{\text {OUT1 }}$ is off.

## Calculating Power Dissipation in a <br> Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 3) is
$\mathrm{P}_{\mathrm{D}(\text { max })}=\left\{\mathrm{V}_{\mathrm{IN}(\text { max })}-\mathrm{VOUT1}^{(\text {min })}\right)_{\text {IOUT1 }}($ max $)+$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT1(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT1 }}$,
$\mathrm{V}_{\text {OUT2(min) }}$ is the minimum output voltage from $\mathrm{V}_{\text {OUT2 }}$,
IOUT1(max) is the maximum output current, for the application,
IOUT2(max) is the maximum output current, for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at both IOUT1(max) and IOUT2(max).

Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta J A}$ can be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta \mathrm{JA}}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 3. Dual Output Regulator With Key Performance Parameters Labeled.

## Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JIC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

* Depending on thermal properties of substrate. $\mathrm{R}_{\Theta \mathrm{JA}}=\mathrm{R}_{\Theta \mathrm{JC}}+\mathrm{R}_{\Theta \mathrm{CA}}$

## Advance Information <br> Micropower 150 mA LDO Linear Regulators with ENABLE, Delay, RESET, and Monitor Flag

The NCV8501 is a family of precision micropower voltage regulators. Their output current capability is 150 mA . The family has output voltage options for adjustable, $2.5 \mathrm{~V}, 3.3 \mathrm{~V}, 5.0 \mathrm{~V}, 8.0 \mathrm{~V}$, and 10 V .

The output voltage is accurate within $\pm 2.0 \%$ with a maximum dropout voltage of 0.6 V at 150 mA . Low quiescent current is a feature drawing only $70 \mu \mathrm{~A}$ with a $100 \mu \mathrm{~A}$ load. This part is ideal for any and all battery operated microprocessor equipment.

Microprocessor control logic includes an active $\overline{\text { RESET (with }}$ DELAY), and a flag monitor which can be used to provide an early warning signal to the microprocessor of a potential impending $\overline{\text { RESET }}$ signal. The use of the flag monitor allows the microprocessor to finish any signal processing before the $\overline{\text { RESET }}$ shuts the microprocessor down.

The active $\overline{\text { RESET }}$ circuit includes hysteresis, and operates correctly at an output voltage as low as 1.0 V . The RESET function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits.

The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments. The device has also been optimized for EMC conditions.

## Features

- Output Voltage Options: Adjustable, 2.5 V, 3.3 V, 5.0 V, 8.0 V, 10 V
- $\pm 2.0 \%$ Output
- Low $70 \mu \mathrm{~A}$ Quiescent Current
- Fixed or Adjustable Output Voltage
- Active RESET
- ENABLE
- 150 mA Output Current Capability
- Fault Protection
- +60 V Peak Transient Voltage
- -15 V Reverse Voltage
- Short Circuit
- Thermal Overload
- Early Warning through $\overline{\text { FLAG }} /$ MON Leads

Figure 2. Block Diagram

## CIRCUIT DESCRIPTION

## REGULATOR CONTROL FUNCTIONS

The NCV8501 contains the microprocessor compatible control function $\overline{\text { RESET }}$ (Figure 3).

Figure 3. Reset and Delay Circuit Wave Forms

## RESET Function

A $\overline{\text { RESET }}$ signal (low voltage) is generated as the IC powers up until $\mathrm{V}_{\text {OUT }}$ is within $6.0 \%$ of the regulated output voltage, or when V VUT drops out of regulation, and is lower than $8.0 \%$ below the regulated output voltage. Hysteresis is included in the function to minimize oscillations.

The $\overline{\text { RESET }}$ output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC thereby guaranteeing that the $\overline{\text { RESET }}$ signal is valid for $\mathrm{V}_{\text {OUT }}$ as low as 1.0 V .

## ENABLE Function

The part stays in a low $\mathrm{I}_{\mathrm{Q}}$ sleep mode when the ENABLE pin is held low. The part has an internal pull down if the pin is left floating. This is intended for failure modes only. An external connection (active pulldown, resistor, or switch) for normal operation is recommended.

The integrity of the ENABLE pin allows it to be tied directly to the battery line. It will withstand load dump potentials.

Figure 4. ENABLE Function

## Delay Function

The reset delay circuit provides a programmable (by an external capacitor) delay on the RESET output lead. The delay lead provides source current (typically $3.0 \mu \mathrm{~A}$ ) to the external delay capacitor only when the output voltage, $V_{\text {OUT }}$, has dropped below the reset threshold. Otherwise, the delay pin is always grounded through an internal NPN. If reset delay is not needed, this pin should be left open.

## FLAG/Monitor Function

An on-chip comparator is provided to perform an early warning to the microprocessor of a possible reset signal. The reset signal typically turns the microprocessor off instantaneously. This can cause unpredictable results with the microprocessor. The signal received from the FLAG pin
will allow the microprocessor time to complete its present task before shutting down. This function is performed by a comparator referenced to the bandgap reference. The actual trip point can be programmed externally using a resistor divider to the input monitor (MON) (Figure 5).

Figure 5. Flag/Monitor Function

## Voltage Adjust

Figure 6 shows the device setup for a user configurable output voltage. The feedback to the $\mathrm{V}_{\mathrm{ADJ}}$ pin is taken from a voltage divider referenced to the output voltage. The loop is balanced around the SENSE threshold (1.28 V typical).

Figure 6. Adjustable Output Voltage

## APPLICATION NOTES

## FLAG MONITOR

Figure 7 shows the FLAG Monitor waveforms as a result of the circuit depicted in Figure 5. As the input voltage falls $\left(\mathrm{V}_{\mathrm{IN}}\right)$, the Monitor threshold is crossed. This causes the voltage on the FLAG output to go low sending a warning signal to the microprocessor that a RESET signal may occur in a short period of time. TWARNING is the time the microprocessor has to complete the function it is currently working on and get ready for the $\overline{\text { RESET }}$ shutdown signal.

Figure 7. FLAG Monitor Circuit Waveform

## SETTING THE DELAY TIME

The delay time is controlled by the Reset Delay Low Voltage, Delay Switching Threshold, and the Delay Charge Current. The delay follows the equation:

$$
\text { tDELAY }=\frac{\left[\text { CDELAY }\left(\mathrm{V}_{\mathrm{dt}}-\text { Reset Delay Low Voltage }\right)\right]}{\text { Delay Charge Current }}
$$

Example:
Using C $_{\text {DELAY }}=33 \mathrm{nF}$.
Assume reset Delay Low Voltage $=0$.
Use the typical value for $\mathrm{V}_{\mathrm{dt}}=1.8 \mathrm{~V}$.
Use the typical value for Delay Charge Current $=3.0 \mu \mathrm{~A}$.

$$
\text { tDELAY }=\frac{[33 \mathrm{nF}(1.8-0)]}{3.0 \mu \mathrm{~A}}=19.8 \mathrm{~ms}
$$

## STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures $\left(-25^{\circ} \mathrm{C}\right.$ to $\left.-40^{\circ} \mathrm{C}\right)$, both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor Cout shown in Figure 8 should work for most applications, however it is not necessarily the optimized solution.

${ }^{*} \mathrm{C}_{\text {IN }}$ required if regulator is located far from the power supply filter
${ }^{* *}$ Cout required for stability. Capacitor must operate at minimum temperature expected

Figure 8. Test and Application Circuit Showing Output Compensation

## CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 9) is:

$$
\begin{align*}
\mathrm{PD}(\max )= & {\left[V \operatorname{IN}(\max )-\mathrm{VOUT}^{\text {min })}\right] \operatorname{IOUT}(\max ) }  \tag{1}\\
& +\mathrm{V}_{\operatorname{IN}(\max )} \mathrm{I} \mathrm{Q}
\end{align*}
$$

where:
$\mathrm{V}_{\mathrm{IN}(\max )}$ is the maximum input voltage,
$\mathrm{V}_{\text {OUT }(\mathrm{min})}$ is the minimum output voltage,
IOUT(max) is the maximum output current for the application, and
$\mathrm{I}_{\mathrm{Q}}$ is the quiescent current the regulator consumes at
$I_{O U T(m a x)}$.
Once the value of $\mathrm{P}_{\mathrm{D}(\max )}$ is known, the maximum permissible value of $\mathrm{R}_{\Theta J A}$ can be calculated:

$$
\begin{equation*}
\mathrm{R}_{\Theta J A}=\frac{150^{\circ} \mathrm{C}-\mathrm{T}_{\mathrm{A}}}{\mathrm{P}_{\mathrm{D}}} \tag{2}
\end{equation*}
$$

The value of $\mathrm{R}_{\Theta \mathrm{JA}}$ can then be compared with those in the package section of the data sheet. Those packages with $\mathrm{R}_{\Theta J A}$ 's less than the calculated value in equation 2 will keep the die temperature below $150^{\circ} \mathrm{C}$.
In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 9. Single Output Regulator with Key Performance Parameters Labeled

## HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $\mathrm{R}_{\Theta J A}$ :

$$
\begin{equation*}
R_{\Theta J A}=R_{\Theta J C}+R_{\Theta C S}+R_{\Theta S A} \tag{3}
\end{equation*}
$$

where:
$\mathrm{R}_{\Theta \mathrm{JJC}}=$ the junction-to-case thermal resistance,
$\mathrm{R}_{\Theta C S}=$ the case-to-heatsink thermal resistance, and
$\mathrm{R}_{\Theta S A}=$ the heatsink-to-ambient thermal resistance.
$\mathrm{R}_{\Theta \mathrm{JC}}$ appears in the package section of the data sheet. Like $R_{\Theta J A}$, it too is a function of package type. $R_{\Theta C S}$ and $R_{\Theta S A}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.

## NCV8502 Series

## Advance Information Micropower 150 mA LDO Linear Regulators with Delay, Adjustable RESET, and Monitor Flag

The NCV8502 is a family of precision micropower voltage regulators. Their output current capability is 150 mA . The family has output voltage options for adjustable, $2.5 \mathrm{~V}, 3.3 \mathrm{~V}, 5.0 \mathrm{~V}, 8.0 \mathrm{~V}$, and 10 V .

The output voltage is accurate within $\pm 2.0 \%$ with a maximum dropout voltage of 0.6 V at 150 mA . Low quiescent current is a feature drawing only $70 \mu \mathrm{~A}$ with a $100 \mu \mathrm{~A}$ load. This part is ideal for any and all battery operated microprocessor equipment.

Microprocessor control logic includes an active $\overline{\text { RESET (with }}$ DELAY), and a flag monitor which can be used to provide an early warning signal to the microprocessor of a potential impending $\overline{\text { RESET }}$ signal. The use of the flag monitor allows the microprocessor to finish any signal processing before the $\overline{\text { RESET }}$ shuts the microprocessor down.

The active $\overline{\text { RESET }}$ circuit includes hysteresis, and operates correctly at an output voltage as low as 1.0 V . The RESET function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits.

The reset threshold voltage can be decreased by the connection of external resistor divider to $\mathrm{R}_{\mathrm{ADJ}}$ lead.

The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments. The device has also been optimized for EMC conditions.

## Features

- Output Voltage Options: Adjustable, 2.5 V, 3.3 V, 5.0 V, 8.0 V, 10 V
- $\pm 2.0 \%$ Output
- Low $70 \mu \mathrm{~A}$ Quiescent Current
- Fixed or Adjustable Output Voltage
- Active RESET
- Adjustable Reset
- 150 mA Output Current Capability
- Fault Protection
- +60 V Peak Transient Voltage
-     - 15 V Reverse Voltage
- Short Circuit
- Thermal Overload
- Early Warning through $\overline{\text { FLAG/MON Leads }}$

## NCV8502 Series

## PACKAGE PIN DESCRIPTION, ADJUSTABLE OUTPUT

| Package Pin Number |  |  |  |
| :---: | :---: | :---: | :--- |
| SO-8 | SOW-16 <br> E PAD | Pin Symbol |  |
| 1 | 7 |  | Input Voltage. |
| 2 | 15 | MON | Monitor. Input for early warning comparator. If not needed connect to $V_{\text {OUT. }}$ |
| 3,4 | $3-6,8-12$, <br> 14 | NC | No connection. |
| 5 | 13 | GND | Ground. All GND leads must be connected to Ground. |
| 6 | 16 | FLAG | Open collector output from early warning comparator. |
| 7 | 1 | V $_{\text {ADJ }}$ | Voltage Adjust. A resistor divider from $\mathrm{V}_{\text {OUT }}$ to this lead sets the output voltage. |
| 8 | 2 | V OUT | $\pm 2.0 \%, 150 \mathrm{~mA}$ output. |

NOTE: Tentative pinout for SOW-16 E Pad.

## PACKAGE PIN DESCRIPTION, FIXED OUTPUT

| Package Pin Number |  |  |  | Function |
| :---: | :---: | :---: | :---: | :---: |
| SO-8 | SO-14 | SOW-16 <br> E PAD | Pin Symbol |  |
| 1 | 13 | 7 | $\mathrm{V}_{\text {IN }}$ | Input Voltage. |
| 2 | 14 | 8 | MON | Monitor. Input for early warning comparator. If not needed connect to $\mathrm{V}_{\text {OUT }}$. |
| 3 | 1 | 9 | $\mathrm{R}_{\text {ADJ }}$ | Reset Adjust. If not needed connect to ground. |
| 4 | 2 | 10 | DELAY | Timing capacitor for RESET function. |
| 5 | 11 | 13 | GND | Ground. All GND leads must be connected to Ground. |
| 6 | 7 | 16 | RESET | Active reset (accurate to $\mathrm{V}_{\text {OUT }} \geq 1.0 \mathrm{~V}$ ) |
| 7 | 8 | 1 | FLAG | Open collector output from early warning comparator. |
| 8 | 9 | 2 | $\mathrm{V}_{\text {OUT }}$ | $\pm 2.0 \%, 150 \mathrm{~mA}$ output. |
| - | 3-6, 10, 12 | $\begin{gathered} 3-6,11, \\ 12,14,15 \end{gathered}$ | NC | No connection. |

NOTE: Tentative pinouts for SO-14 and SOW-16 E Pad. 5.0 V option only for SO-14.

Figure 2. Block Diagram

## CIRCUIT DESCRIPTION

## REGULATOR CONTROL FUNCTIONS

The NCV8502 contains the microprocessor compatible control function $\overline{\text { RESET }}$ (Figure 3).

Figure 3. Reset and Delay Circuit Wave Forms

## RESET Function

A $\overline{\text { RESET }}$ signal (low voltage) is generated as the IC powers up until $\mathrm{V}_{\text {OUT }}$ is within $6.0 \%$ of the regulated output voltage, or when V VUT drops out of regulation, and is lower than $8.0 \%$ below the regulated output voltage. Hysteresis is included in the function to minimize oscillations.

The $\overline{\text { RESET }}$ output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC thereby guaranteeing that the $\overline{\text { RESET }}$ signal is valid for $\mathrm{V}_{\text {OUT }}$ as low as 1.0 V .

## Adjustable Reset Function

The reset threshold can be made lower by connecting an external resistor divided to the $\mathrm{R}_{\text {ADJ }}$ lead from the $\mathrm{V}_{\text {OUT }}$ lead, as displayed in Figure 4. This lead is grounded to select the default value of 4.6 V .

Figure 4. Adjustable RESET

## Delay Function

The reset delay circuit provides a programmable (by an external capacitor) delay on the RESET output lead. The delay lead provides source current (typically $3.0 \mu \mathrm{~A}$ ) to the external delay capacitor only when the output voltage, $V_{\text {OUT }}$, has dropped below the reset threshold. Otherwise, the delay pin is always grounded through an internal NPN. If reset delay is not needed, this pin should be left open.

## FLAG/Monitor Function

An on-chip comparator is provided to perform an early warning to the microprocessor of a possible reset signal. The reset signal typically turns the microprocessor off instantaneously. This can cause unpredictable results with
the microprocessor. The signal received from the FLAG pin will allow the microprocessor time to complete its present task before shutting down. This function is performed by a comparator referenced to the bandgap reference. The actual trip point can be programmed externally using a resistor divider to the input monitor (MON) (Figure 5).

Figure 5. Flag/Monitor Function

## Voltage Adjust

Figure 6 shows the device setup for a user configurable output voltage. The feedback to the $\mathrm{V}_{\mathrm{ADJ}}$ pin is taken from a voltage divider referenced to the output voltage. The loop is balanced around the SENSE threshold (1.28 V typical).

Figure 6. Adjustable Output Voltage

## APPLICATION NOTES

## FLAG MONITOR

Figure 7 shows the FLAG Monitor waveforms as a result of the circuit depicted in Figure 5. As the input voltage falls $\left(\mathrm{V}_{\mathrm{IN}}\right)$, the Monitor threshold is crossed. This causes the voltage on the $\overline{\text { FLAG }}$ output to go low sending a warning signal to the microprocessor that a $\overline{\text { RESET }}$ signal may occur in a short period of time. T TWARNING is the time the microprocessor has to complete the function it is currently working on and get ready for the $\overline{\text { RESET }}$ shutdown signal.

Figure 7. FLAG Monitor Circuit Waveform

## SETTING THE DELAY TIME
