

Application Notes and Development Tools for 80C51 Microcontrollers

1997

Data Handbook

QUALITY ASSURED

Our quality system focuses on the continuing high quality of our components and the best possible service for our customers. We have a three-sided quality strategy: we apply a system of total quality control and assurance; we operate customer-oriented dynamic improvement programmes; and we promote a partnering relationship with our customers and suppliers.

PRODUCT SAFETY

In striving for state-of-the-art perfection, we continuously improve components and processes with respect to environmental demands. Our components offer no hazard to the environment in normal use when operated or stored within the limits specified in the data sheet.

Some components unavoidably contain substances that, if exposed by accident or misuse, are potentially hazardous to health. Users of these components are informed of the danger by warning notices in the data sheets supporting the components. Where necessary the warning notices also indicate safety precautions to be taken and disposal instructions to be followed. Obviously users of these components, in general the set-making industry, assume responsibility towards the consumer with respect to safety matters and environmental demands.

All used or obsolete components should be disposed of according to the regulations applying at the disposal location. Depending on the location, electronic components are considered to be 'chemical', 'special' or sometimes 'industrial' waste. Disposal as domestic waste is usually not permitted.

Philips Semiconductors and Philips Electronics North America Corporation reserve the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified. Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

LIFE SUPPORT APPLICATIONS

Philips Semiconductors and Philips Electronics North America Corporation Products are not designed for use in life support appliances, devices, or systems where malfunction of a Philips Semiconductors and Philips Electronics North America Corporation Product can reasonably be expected to result in a personal injury. Philips Semiconductors and Philips Electronics North America Corporation customers using or selling Philips Semiconductors and Philips Electronics North America Corporation Products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors and Philips Electronics North America Corporation for any damages resulting from such improper use or sale.

Philips Semiconductors and Philips Electronics North America Corporation register eligible circuits under the Semiconductor Chip Protection Act.

PRODUCT STATUS

DEFINITIONS		
DATA SHEET IDENTIFICATION	PRODUCT STATUS	DEFINITION
<i>Objective Specification</i>	Formative or in Design	This data sheet contains the design target or goal specifications for product development. Specifications may change in any manner without notice.
<i>Preliminary Specification</i>	Preproduction Product	This data sheet contains preliminary data, and supplementary data will be published at a later date. Philips Semiconductors reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.
<i>Product Specification</i>	Full Production	This data sheet contains Final Specifications. Philips Semiconductors reserves the right to make changes at any time without notice, in order to improve design and supply the best possible product.

Purchase of Philips I²C components conveys a license under the Philips' I²C patent to use the components in the I²C system provided the system conforms to the I²C specifications defined by Philips. This specification can be ordered using the code 9398 393 40011.

Application Notes and Development Tools for 80C51 Microcontrollers

Microcontrollers from Philips Semiconductors

Philips Semiconductors 8 and 16-bit microcontrollers are based on the widely-accepted 8048, 8051 and XA architectures. We offer most of the 'industry standard' products in these architectures as well as a large selection of powerful derivative products. These derivatives offer a wide assortment of features, including: additional memory, A/D, PWM, additional timers, DTMF, OSD, OTP, EMC and EMI, plus many others. The variety of product derivatives allows Philips Semiconductors to support a broad range of functions in consumer, telecom, EDP, multi media, automotive and industrial applications.

For details, see:

- 8048 'industry standard' architecture types (PCF84CXXX family) in "*Data Handbook IC14*".
The PCD33XX family covers telecom terminal family devices based on the 8048 core and instruction set, in "*Data Handbook IC03*".
- 8051 'industry standard' architecture types in "*Data Handbook IC20*".
- XA types in "*Data Handbook IC25*".

The Low Power 80CL51 family of derivatives can be found in "*Data Handbook IC20*". These devices operate over the wide voltage range of 1.8 to 6.0V and are ideal for portable and battery operations.

Many of Philips Semiconductors ICs offer on-board UART serial ports and I²C-bus. The I²C-bus allows easy connection to over 100 other devices, thereby increasing system capabilities even further. For automotive and industrial applications, we also offer the CAN and the VAN serial bus. The CAN standard, developed by Bosch, and VAN concepts offer high noise immunity and error correction.

Philips Semiconductors 16-bit microcontroller family is based on the XA architecture. The XA is upwards compatible with the 80C51 and offers users an easy migration path to higher performance. While compatible with the 80C51, this compatibility has in no way limited the performance of the XA, which is one of the highest performance 16-bit microcontrollers available.

Philips Semiconductors is developing a family of 32-bit microcontrollers that will be based on the MIPS core. This family of microcontrollers will offer advanced performance for those applications that are computation and memory intensive in an embedded control environment.

Section 5 – Package Outlines

Soldering	Package information		5-2
Plastic Dual In-Line Package			
DIP8:	plastic dual in-line package; 8 leads (300 mil)	SOT97-1	5-4
DIP24:	plastic dual in-line package; 24 leads (300 mil)	SOT222-1	5-5
DIP28:	plastic dual in-line package; 28 leads (600 mil); long body	SOT117-2	5-6
DIP40:	plastic dual in-line package; 40 leads (600 mil)	SOT129-1	5-7
Plastic Shrink Dual In-Line Package			
SDIP42:	plastic shrink dual in-line package; 42 leads (600 mil)	SOT270-1	5-8
SDIP64:	plastic shrink dual in-line package; 64 leads (750 mil)	SOT274-1	5-9
Ceramic Dual In-Line Package			
	24-Pin (300 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	0586B	5-10
	28-Pin (600 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	0589B	5-11
	40-Pin (600 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	0590B	5-12
Plastic Leaded Chip Carrier			
PLCC28:	plastic leaded chip carrier; 28 leads; pedestal	SOT261-3	5-13
PLCC44:	plastic leaded chip carrier; 44 leads	SOT187-2	5-14
PLCC68:	plastic leaded chip carrier; 68 leads	SOT188-2	5-15
PLCC68:	plastic leaded chip carrier; 68 leads; pedestal	SOT188-3	5-16
Ceramic Leaded Chip Carrier			
	68-Pin Chip Carrier, J-Bend (L) Package	1240C	5-17
	Ceramic leaded chip carrier (window); 68 leads	NO330	5-18
Plastic Quad Flat Package			
QFP44:	plastic quad flat package; 44 leads (lead length 1.3 mm); body 10 x 10 x 1.75 mm	SOT307-2	5-19
QFP44:	plastic quad flat package; 44 leads (lead length 2.35 mm); body 14 x 14 x 2.2 mm	SOT205-1	5-20
LQFP44:	plastic low profile quad flat package; 44 leads; body 10 x 10 x 1.4 mm	SOT389-1	5-21
QFP64:	plastic quad flat package; 64 leads (lead length 2.35 mm); body 14 x 20 x 2.75 mm	SOT208-1	5-22
QFP64:	plastic quad flat package; 64 leads (lead length 1.95mm); body 14 x 20 x 2.8 mm	SOT319-2	5-23
QFP80:	plastic quad flat package; 80 leads (lead length 1.6 mm); body 14 x 20 x 3.0 mm	SOT310-1	5-24
QFP80:	plastic quad flat package; 80 leads (lead length 1.95 mm); body 14 x 20 x 2.7 mm; high stand-off height	SOT318-1	5-25
QFP80:	plastic quad flat package; 80 leads (lead length 1.95 mm); body 14 x 20 x 2.8 mm	SOT318-2	5-26
Ceramic Quad Flat Package			
	44-pin CerQuad J-Bend (K) Package	1472A	5-27
	68-pin CerQuad J-Bend (K) Package	1473A	5-28
Plastic Small Outline Package			
SO8:	plastic small outline package; 8 leads; body width 3.9mm	SOT96-1	5-29
SO28:	plastic small outline package; 28 leads; body width 7.5mm	SOT136-1	5-30
VSO40:	plastic very small outline package; 40 leads	SOT158-1	5-31
VSO56:	plastic very small outline package; 56 leads	SOT190-1	5-32
Plastic Shrink Small Outline Package			
SSOP24:	plastic shrink small outline package; 24 leads; body width 5.3 mm	SOT340-1	5-33

TOTAL QUALITY MANAGEMENT

Philips Semiconductors is a Quality Company, renowned for the high quality of our products and service. We keep alive this tradition by constantly aiming towards one ultimate standard, that of zero defects. This aim is guided by our Total Quality Management (TQM) system, the basis of which is described in the following paragraphs.

Quality assurance

Based on ISO 9000 standards, customer standards such as Ford TQE and IBM MDQ. Our factories are certified to ISO 9000 by external inspectorates.

Partnerships with customers

PPM co-operations, design-in agreements, ship-to-stock, just-in-time and self-qualification programmes, and application support.

Partnerships with suppliers

Ship-to-stock, statistical process control and ISO 9000 audits.

Quality improvement programme

Continuous process and system improvement, design improvement, complete use of statistical process control, realization of our final objective of zero defects, and logistics improvement by ship-to-stock and just-in-time agreements.

ADVANCED QUALITY PLANNING

During the design and development of new products and processes, quality is built-in by advanced quality planning. Through failure-mode-and-effect analysis the critical parameters are detected and measures taken to ensure good performance on these parameters. The capability of process steps is also planned in this phase.

PRODUCT CONFORMANCE

The assurance of product conformance is an integral part of our quality assurance (QA) practice. This is achieved by:

- Incoming material management through partnerships with suppliers.
- In-line quality assurance to monitor process reproducibility during manufacture and initiate any necessary corrective action. Critical process steps are 100% under statistical process control.
- Acceptance tests on finished products to verify conformance with the device specification. The test results are used for quality feedback and corrective actions. The inspection and test requirements are detailed in the general quality specifications.
- Periodic inspections to monitor and measure the conformance of products.

PRODUCT RELIABILITY

With the increasing complexity of Original Equipment Manufacturer (OEM) equipment, components reliability must be extremely high. Our research laboratories and development departments study the failure mechanisms of semiconductors. Their studies result in design rules and process optimization for the highest built-in product reliability. Highly accelerated tests are applied to the product reliability evaluation. Rejects from reliability tests and from customer complaints are submitted to failure analysis, to result in corrective action.

CUSTOMER RESPONSES

Our quality improvement depends on joint action with our customer. We need our customer's inputs and we invite constructive comments on all aspects of our performance. Please contact our local sales representative.

RECOGNITION

The high quality of our products and services is demonstrated by many Quality Awards granted by major customers and international organizations.

Notes: Production Centers are indicated in the second column: H – Hamburg, S – Sunnyvale, Z – Zurich.

All combinations of part type, speed, temperature and package may not be available.

1) Oscillator options start from 32kHz.

2) Also available in VSO40 package.

3) Also available in VSO56 Package.

4) Not recommended for new design.

5) Package available up to 16 MHz only.

FAX-on-DEMAND System

What is it?

The FAX-on-DEMAND system is a computer facsimile system that allows customers to receive selected documents by fax automatically.

How does it work?

To order a document, you simply enter the document number. This number can be obtained by asking for an index of available documents to be faxed to you the first time you call the system.

Our system has a selection of the latest product data sheets from Philips with varying page counts. As you know, it takes approximately one minute to FAX one page. This isn't bad if the number of pages is less than 10. But if the document is 37 pages long, be ready for a long transmission!

Philips Semiconductors also maintains product information on the World-Wide Web. Our home page can be located at:

<http://www.semiconductors.philips.com>

Who do I contact if I have a question about FAX-on-DEMAND?

Contact your local Philips sales office.

FAX-on-DEMAND phone numbers:

England (United Kingdom, Ireland)	44-181-730-5020
France	33-1-40-99-60-60
Germany (Austria, Switzerland)	49-40-23536-357
Italy	39-167-295502
North America	1-800-282-200

Locations soon to be in operation:

- Hong Kong
- Japan
- The Netherlands

Microcontroller internet and bulletin board access

BULLETIN BOARDS

To better serve our customers, Philips maintains two microcontroller bulletin boards. These computer bulletin board systems feature microcontroller newsletters, application and demonstration programs for download, and the ability to send messages to microcontroller application engineers.

The telephone numbers are:

North American Bulletin Board

**MAX 14.400 baud 8-N-1
(800) 451-6644 (in the U.S.)**

or

(408) 991-2406

European Bulletin Board

**MAX 14.400 baud
Standards V32/V42/V42.bis/HST
+31 40 2721102**

Sunnyvale ROMcode Bulletin Board

We also have a ROM code bulletin board through which you can submit ROM codes. This is a closed bulletin board for security reasons. To get an ID, contact your local sales office. The system can be accessed with a 2400, 1200, or 300 baud modem, and is available 24 hours a day.

The telephone number is:

(408) 991-3459

All code for application notes in this databook are available on the Philips BBS, as well as on the world-wide web.

CONTENTS

PCF1252-X family	Threshold detector and reset generator	2-3
------------------	--	-----

Threshold detector and reset generator

PCF1252-X family

FEATURES

- Very low current consumption, typically 10 μ A
- 10 factory programmed threshold voltages available covering trip voltages from 4.75 to 2.55 V
- ± 50 mV trip point accuracy over full temperature range
- Variable RESET delay
- RESET pulse polarity selection
- Defined outputs at 0.6 V (typ.)
- Comparator for second level detection (e.g. overvoltage detection)
- Advance warning of power fail
- Operating temperature range -40 to $+85$ $^{\circ}$ C.

GENERAL DESCRIPTION

The PCF1252-Xs are low-power CMOS voltage threshold detectors designed especially for supervision of microcontroller/microprocessor systems for detection of power-on/off conditions and generation of a system reset pulse. The PCF1252-X also provides a $\overline{\text{POWF}}$ (power fail) output which is activated at a precise factory-programmed trip point. A system RESET output has a built-in delay with duration determined by an external capacitor (C_{CT}).

A second comparator (comparator 2) has been included to enable the possibility of a second monitoring point in the system.

ORDERING INFORMATION

TYPE NUMBER	PACKAGE		
	NAME	DESCRIPTION	VERSION
PCF1252-XP ⁽¹⁾	DIP8	plastic dual in-line package; 8 leads (300 mil)	SOT97-1
PCF1252-XT ⁽¹⁾	SO8	plastic small outline package; 8 leads; body width 3.9 mm	SOT96-1

Note

1. X = 0 to 9; depending on threshold voltage.

BLOCK DIAGRAM

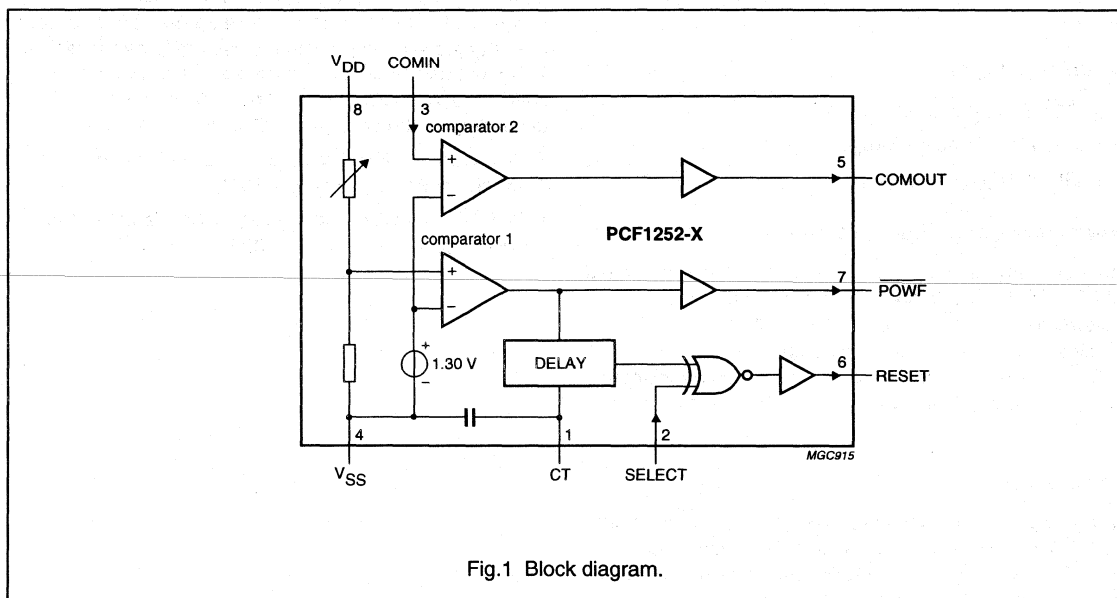

Fig.1 Block diagram.

PINNING

SYMBOL	PIN	DESCRIPTION
CT	1	connection for the external capacitor
SELECT	2	select polarity or external reset input
COMIN	3	comparator input
V _{SS}	4	ground (0 V)
COMOUT	5	comparator output
RESET	6	reset output
POWF	7	power failure signal output
V _{DD}	8	supply voltage

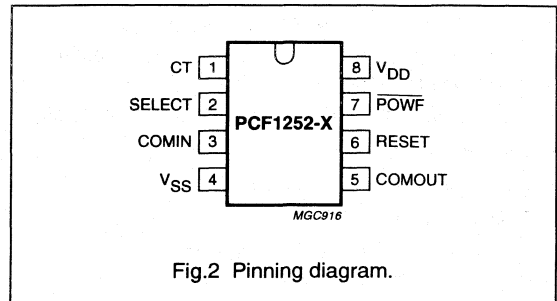

Fig.2 Pinning diagram.

FUNCTIONAL DESCRIPTION (see Fig.1)

The PCF1252-X contains:

- A precise factory-programmed voltage reference
- Two comparators
- A delay circuit.

The PCF1252-X family is comprised of 10 versions with different factory-programmed voltage trip-points (V_{TRIP}), see Chapter "Characteristics".

Supply

The supply voltage (V_{DD}) is internally divided before being compared, via comparator 1, with the internal reference voltage.

 \overline{POWF} (see Fig.3)

The \overline{POWF} output is:

- LOW, if V_{DD} is below V_{TRIP}
- HIGH, if V_{DD} is above V_{TRIP} .

Power-on reset (SELECT = LOW)

As V_{DD} rises past V_{TRIP} , a positive reset pulse is generated at RESET. The duration of the reset pulse (t_R) is determined by the value of the external capacitor (C_{CT} ; maximum 1 μ F, see Fig.8) connected to CT. With no external capacitor connected, C_{CT} assumes a minimum value of 100 pF. If SELECT is HIGH, the reset pulse is inverted.

Power failure

During a power-off condition ($V_{DD} < V_{TRIP}$), \overline{POWF} goes LOW. After a time delay (t_S), also determined by C_{CT} , RESET goes HIGH. Any \overline{POWF} assertion ($V_{DD} < V_{TRIP}$) will result in a subsequent RESET pulse.

Voltage trip-point

By selecting the voltage trip-point slightly higher than the minimum operating voltage of the microcontroller/microprocessor, there is sufficient time for data storage before the power actually fails.

In order to prevent oscillations around the voltage trip-point, a small hysteresis has been included, resulting in a power-on switching point that is higher than the voltage trip-point (minimum of 15 mV). The voltage trip-point refers to the value at which power-off is signalled.

COMIN

Input to the second comparator (comparator 2).

When used in conjunction with an external voltage divider, this allows a second point in the system to be monitored. This input has no built-in hysteresis. When not in use connect to V_{DD} . COMOUT will be LOW or HIGH depending on the voltage at COMIN:

- COMOUT = HIGH, if voltage at COMIN is above the switch point V_{SP} (typically 1.30 V).
- COMOUT = LOW, if voltage at COMIN is below the switch point V_{SP} (typically 1.30 V).

Threshold detector and reset generator

PCF1252-X family

LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT
V_{DD}	supply voltage		-0.5	+7.0	V
V_I	input voltage		-0.5	$V_{DD} + 0.5$	V
I_I	DC clamp-diode current	all pins: $V_I < -0.5$ V or $V_I > V_{DD} + 0.5$ V	-	20	mA
I_O	output current		-	20	mA
P_{tot}	total power dissipation		-	150	mW
T_{stg}	storage temperature		-65	+100	°C
T_{amb}	operating ambient temperature		-40	+85	°C

HANDLING

Inputs and outputs are protected against electrostatic discharge in normal handling. However, to be totally safe, it is desirable to take normal handling precautions appropriate to handling MOS devices (see "Handling MOS Devices").

CHARACTERISTICS

$V_{DD} = 2.4$ to 6.0 V; $V_{SS} = 0$ V; $T_{amb} = -40$ to $+85$ °C; (see Fig.3); unless otherwise specified.

1995 update

1.0 THE I²C-BUS BENEFITS DESIGNERS AND MANUFACTURERS

In consumer electronics, telecommunications and industrial electronics, there are often many similarities between seemingly unrelated designs. For example, nearly every system includes:

- Some intelligent control, usually a single-chip microcontroller
- General-purpose circuits like LCD drivers, remote I/O ports, RAM, EEPROM, or data converters
- Application-oriented circuits such as digital tuning and signal processing circuits for radio and video systems, or DTMF generators for telephones with tone dialling.

To exploit these similarities to the benefit of both systems designers and equipment manufacturers, as well as to maximize hardware efficiency and circuit simplicity, Philips developed a simple bidirectional 2-wire bus for efficient inter-IC control. This bus is called the Inter IC or I²C-bus. At present, Philips' IC range includes more than 150 CMOS and bipolar I²C-bus compatible types for performing functions in all three of the previously mentioned categories. All I²C-bus compatible devices incorporate an on-chip interface which allows them to communicate directly with each other via the I²C-bus. This design concept solves the many interfacing problems encountered when designing digital control circuits.

Here are some of the features of the I²C-bus:

- Only two bus lines are required; a serial data line (SDA) and a serial clock line (SCL)
- Each device connected to the bus is software addressable by a unique address and simple master/slave relationships exist at all times; masters can operate as master-transmitters or as master-receivers
- It's a true multi-master bus including collision detection and arbitration to prevent data corruption if two or more masters simultaneously initiate data transfer
- Serial, 8-bit oriented, bidirectional data transfers can be made at up to 100 kbit/s in the standard mode or up to 400 kbit/s in the fast mode
- On-chip filtering rejects spikes on the bus data line to preserve data integrity
- The number of ICs that can be connected to the same bus is limited only by a maximum bus capacitance of 400 pF.

1.1 Designer benefits

I²C-bus compatible ICs allow a system design to rapidly progress directly from a functional block diagram to a prototype. Moreover, since they 'clip' directly onto the I²C-bus without any additional external interfacing, they allow a prototype system to be modified or upgraded simply by 'clipping' or 'unclipping' ICs to or from the bus.

Here are some of the features of I²C-bus compatible ICs which are particularly attractive to designers:

- Functional blocks on the block diagram correspond with the actual ICs; designs proceed rapidly from block diagram to final schematic
- No need to design bus interfaces because the I²C-bus interface is already integrated on-chip
- Integrated addressing and data-transfer protocol allow systems to be completely software-defined
- The same IC types can often be used in many different applications
- Design-time reduces as designers quickly become familiar with the frequently used functional blocks represented by I²C-bus compatible ICs
- ICs can be added to or removed from a system without affecting any other circuits on the bus
- Fault diagnosis and debugging are simple; malfunctions can be immediately traced
- Software development time can be reduced by assembling a library of reusable software modules.

In addition to these advantages, the CMOS ICs in the I²C-bus compatible range offer designers special features which are particularly attractive for portable equipment and battery-backed systems.

They all have:

- Extremely low current consumption
- High noise immunity
- Wide supply voltage range
- Wide operating temperature range.

Figure 1 shows two examples of I²C-bus applications.

The I²C-bus and how to use it (including specifications)

1.2 Manufacturer benefits

I²C-bus compatible ICs don't only assist designers, they also give a wide range of benefits to equipment manufacturers because:

- The simple 2-wire serial I²C-bus minimizes interconnections so ICs have fewer pins and there are not so many PCB tracks; result — smaller and less expensive PCBs
- The completely integrated I²C-bus protocol eliminates the need for address decoders and other 'glue logic'
- The multi-master capability of the I²C-bus allows rapid testing and alignment of end-user equipment via external connections to an assembly-line computer
- The availability of I²C-bus compatible ICs in SO (small outline), VSO (very small outline) as well as DIL packages reduces space requirements even more.

These are just some of the benefits. In addition, I²C-bus compatible ICs increase system design flexibility by allowing simple

construction of equipment variants and easy upgrading to keep designs up-to-date. In this way, an entire family of equipment can be developed around a basic model. Upgrades for new equipment, or enhanced-feature models (i.e. extended memory, remote control, etc.) can then be produced simply by clipping the appropriate ICs onto the bus. If a larger ROM is needed, it's simply a matter of selecting a microcontroller with a larger ROM from our comprehensive range. As new ICs supersede older ones, it's easy to add new features to equipment or to increase its performance by simply unclipping the outdated IC from the bus and clipping on its successor.

1.3 The ACCESS.bus

Another attractive feature of the I²C-bus for designers and manufacturers is that its simple 2-wire nature and capability of software addressing make it an ideal platform for the ACCESS.bus (Figure 2). This is a lower-cost alternative for an RS-232C interface for connecting peripherals to a host computer via a simple 4-pin connector (see Section 19.0).

The I²C-bus and how to use it (including specifications)

2.0 INTRODUCTION TO THE I²C-BUS SPECIFICATION

For 8-bit digital control applications, such as those requiring microcontrollers, certain design criteria can be established:

- A complete system usually consists of at least one microcontroller and other peripheral devices such as memories and I/O expanders
- The cost of connecting the various devices within the system must be minimized
- A system that performs a control function doesn't require high-speed data transfer
- Overall efficiency depends on the devices chosen and the nature of the interconnecting bus structure.

In order to produce a system to satisfy these criteria, a serial bus structure is needed. Although serial buses don't have the throughput capability of parallel buses, they do require less wiring and fewer IC connecting pins. However, a bus is not merely an interconnecting wire, it embodies all the formats and procedures for communication within the system.

Devices communicating with each other on a serial bus must have some form of protocol which avoids all possibilities of confusion,

data loss and blockage of information. Fast devices must be able to communicate with slow devices. The system must not be dependent on the devices connected to it, otherwise modifications or improvements would be impossible. A procedure has also to be devised to decide which device will be in control of the bus and when. And, if different devices with different clock speeds are connected to the bus, the bus clock source must be defined. All these criteria are involved in the specification of the I²C-bus.

3.0 THE I²C-BUS CONCEPT

The I²C-bus supports any IC fabrication process (NMOS, CMOS, bipolar). Two wires, serial data (SDA) and serial clock (SCL), carry information between the devices connected to the bus. Each device is recognised by a unique address — whether it's a microcontroller, LCD driver, memory or keyboard interface — and can operate as either a transmitter or receiver, depending on the function of the device. Obviously an LCD driver is only a receiver, whereas a memory can both receive and transmit data. In addition to transmitters and receivers, devices can also be considered as masters or slaves when performing data transfers (see Table 1). A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

Table 1. Definition of I²C-bus terminology

TERM	DESCRIPTION
Transmitter	The device which sends the data to the bus
Receiver	The device which receives the data from the bus
Master	The device which initiates a transfer, generates clock signals and terminates a transfer
Slave	The device addressed by a master
Multi-master	More than one master can attempt to control the bus at the same time without corrupting the message
Arbitration	Procedure to ensure that, if more than one master simultaneously tries to control the bus, only one is allowed to do so and the message is not corrupted
Synchronization	Procedure to synchronize the clock signals of two or more devices

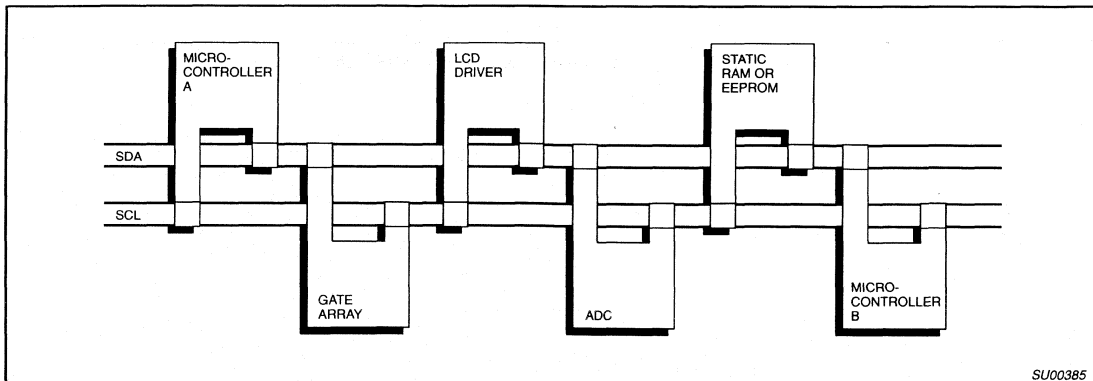

Figure 3. Example of an I²C-bus configuration using two microcontrollers

SU00385

The I²C-bus and how to use it (including specifications)

The I²C-bus is a multi-master bus. This means that more than one device capable of controlling the bus can be connected to it. As masters are usually micro-controllers, let's consider the case of a data transfer between two microcontrollers connected to the I²C-bus (Figure 3). This highlights the master-slave and receiver-transmitter relationships to be found on the I²C-bus. It should be noted that these relationships are not permanent, but only depend on the direction of data transfer at that time. The transfer of data would proceed as follows:

1. Suppose microcontroller A wants to send information to microcontroller B:
 - microcontroller A (master), addresses microcontroller B (slave)
 - microcontroller A (master-transmitter), sends data to microcontroller B (slave-receiver)
 - microcontroller A terminates the transfer.
2. If microcontroller A wants to receive information from microcontroller B:
 - microcontroller A (master) addresses microcontroller B (slave)
 - microcontroller A (master-receiver) receives data from microcontroller B (slave-transmitter)
 - microcontroller A terminates the transfer.

Even in this case, the master (microcontroller A) generates the timing and terminates the transfer.

The possibility of connecting more than one microcontroller to the I²C-bus means that more than one master could try to initiate a data

transfer at the same time. To avoid the chaos that might ensue from such an event — an arbitration procedure has been developed. This procedure relies on the wired-AND connection of all I²C interfaces to the I²C-bus.

If two or more masters try to put information onto the bus, the first to produce a 'one' when the other produces a 'zero' will lose the arbitration. The clock signals during arbitration are a synchronized combination of the clocks generated by the masters using the wired-AND connection to the SCL line (for more detailed information concerning arbitration see Section 7.0).

Generation of clock signals on the I²C-bus is always the responsibility of master devices; each master generates its own clock signals when transferring data on the bus. Bus clock signals from a master can only be altered when they are stretched by a slow-slave device holding-down the clock line, or by another master when arbitration occurs.

4.0 GENERAL CHARACTERISTICS

Both SDA and SCL are bidirectional lines, connected to a positive supply voltage via a pull-up resistor (see Figure 4). When the bus is free, both lines are HIGH. The output stages of devices connected to the bus must have an open-drain or open-collector in order to perform the wired-AND function. Data on the I²C-bus can be transferred at a rate up to 100 kbit/s in the standard-mode, or up to 400 kbit/s in the fast-mode. The number of interfaces connected to the bus is solely dependent on the bus capacitance limit of 400pF.

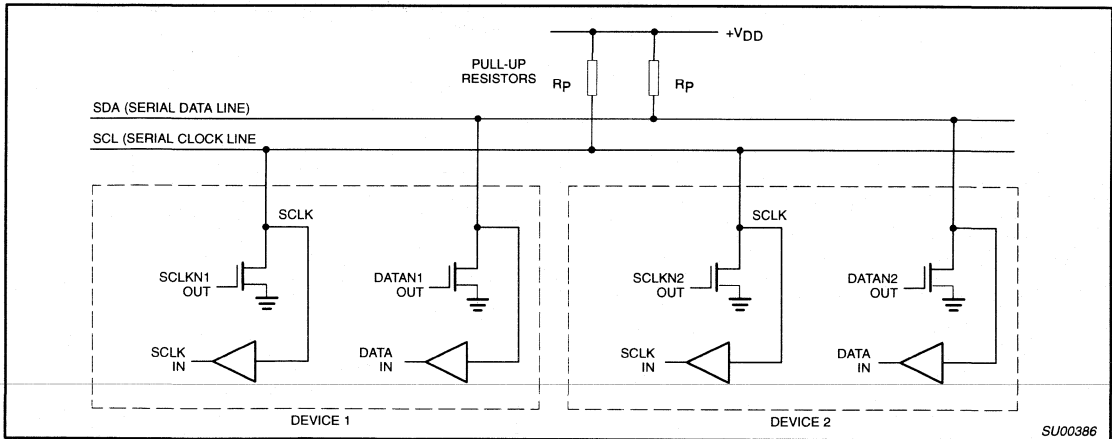

Figure 4. Connection of I²C-bus devices to the I²C-bus

The I²C-bus and how to use it (including specifications)

Figure 5. Bit transfer on the I²C-bus

Figure 6. START and STOP conditions

5.0 BIT TRANSFER

Due to the variety of different technology devices (CMOS, NMOS, bipolar) which can be connected to the I²C-bus, the levels of the logical '0' (LOW) and '1' (HIGH) are not fixed and depend on the associated level of V_{DD} (see Section 15.0 for Electrical Specifications). One clock pulse is generated for each data bit transferred.

5.1 Data validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW (see Figure 5).

5.2 START and STOP conditions

Within the procedure of the I²C-bus, unique situations arise which are defined as START and STOP conditions (see Figure 6).

A HIGH to LOW transition on the SDA line while SCL is HIGH is one such unique case. This situation indicates a START condition.

A LOW to HIGH transition on the SDA line while SCL is HIGH defines a STOP condition.

START and STOP conditions are always generated by the master. The bus is considered to be busy after the START condition. The bus is considered to be free again a certain time after the STOP condition. This bus free situation is specified in Section 15.0.

Detection of START and STOP conditions by devices connected to the bus is easy if they incorporate the necessary interfacing hardware. However, microcontrollers with no such interface have to sample the SDA line at least twice per clock period in order to sense the transition.

The I²C-bus and how to use it (including specifications)

6.0 TRANSFERRING DATA

6.1 Byte format

Every byte put on the SDA line must be 8-bits long. The number of bytes that can be transmitted per transfer is unrestricted. Each byte has to be followed by an acknowledge bit. Data is transferred with the most significant bit (MSB) first (Figure 7). If a receiver can't receive another complete byte of data until it has performed some other function, for example servicing an internal interrupt, it can hold the clock line SCL LOW to force the transmitter into a wait state. Data transfer then continues when the receiver is ready for another byte of data and releases clock line SCL.

In some cases, it's permitted to use a different format from the I²C-bus format (for CBUS compatible devices for example). A message which starts with such an address can be terminated by generation of a STOP condition, even during the transmission of a byte. In this case, no acknowledge is generated (see Section 9.1.3).

6.2 Acknowledge

Data transfer with acknowledge is obligatory. The acknowledge-related clock pulse is generated by the master. The transmitter releases the SDA line (HIGH) during the acknowledge clock pulse.

The receiver must pull down the SDA line during the acknowledge clock pulse so that it remains stable LOW during the HIGH period of this clock pulse (Figure 8). Of course, set-up and hold times (specified in Section 15.0) must also be taken into account.

Usually, a receiver which has been addressed is obliged to generate an acknowledge after each byte has been received, except when the message starts with a CBUS address (see Section 9.1.3).

When a slave-receiver doesn't acknowledge the slave address (for example, it's unable to receive because it's performing some real-time function), the data line must be left HIGH by the slave. The master can then generate a STOP condition to abort the transfer.

If a slave-receiver does acknowledge the slave address but, some time later in the transfer cannot receive any more data bytes, the master must again abort the transfer. This is indicated by the slave generating the not acknowledge on the first byte to follow. The slave leaves the data line HIGH and the master generates the STOP condition.

If a master-receiver is involved in a transfer, it must signal the end of data to the slave-transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave-transmitter must release the data line to allow the master to generate a STOP or repeated START condition.

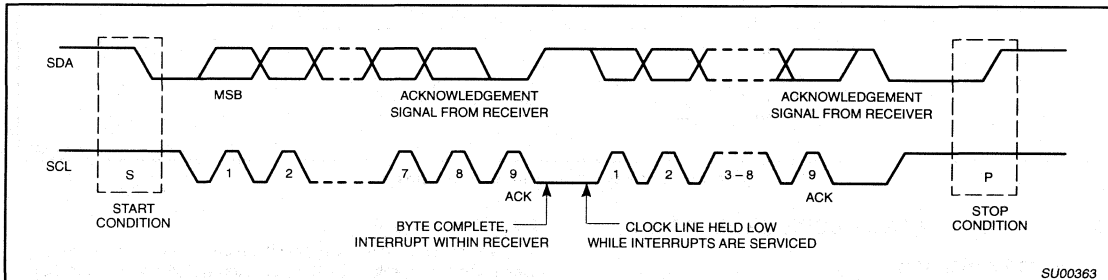

Figure 7. Data transfer on the I²C-bus

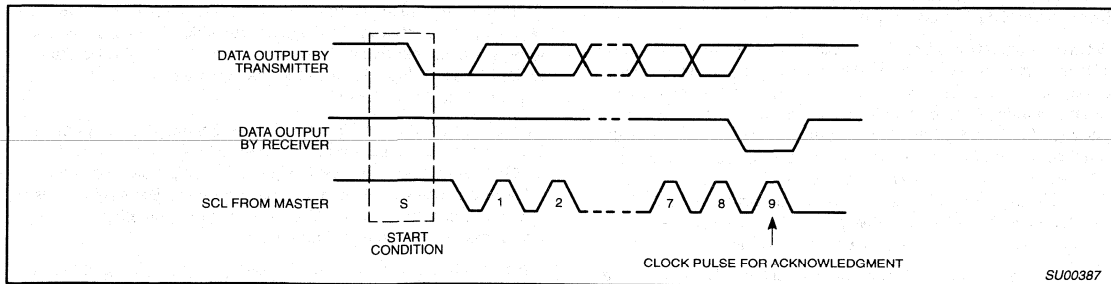

Figure 8. Acknowledge on the I²C-bus

The I²C-bus and how to use it (including specifications)

Figure 9. Clock synchronization during the arbitration procedure

Figure 10. Arbitration procedure of two masters

7.0 ARBITRATION AND CLOCK GENERATION

7.1 Synchronization

All masters generate their own clock on the SCL line to transfer messages on the I²C-bus. Data is only valid during the HIGH period of the clock. A defined clock is therefore needed for the bit-by-bit arbitration procedure to take place.

Clock synchronization is performed using the wired-AND connection of I²C interfaces to the SCL line. This means that a HIGH to LOW transition on the SCL line will cause the devices concerned to start counting off their LOW period and, once a device clock has gone LOW, it will hold the SCL line in that state until the clock HIGH state is reached (Figure 9). However, the LOW to HIGH transition of this clock may not change the state of the SCL line if another clock is still within its LOW period. The SCL line will therefore be held LOW by the device with the longest LOW period. Devices with shorter LOW periods enter a HIGH wait-state during this time.

When all devices concerned have counted off their LOW period, the clock line will be released and go HIGH. There will then be no difference between the device clocks and the state of the SCL line, and all the devices will start counting their HIGH periods. The first device to complete its HIGH period will again pull the SCL line LOW.

In this way, a synchronized SCL clock is generated with its LOW period determined by the device with the longest clock LOW period, and its HIGH period determined by the one with the shortest clock HIGH period.

7.2 Arbitration

A master may start a transfer only if the bus is free. Two or more masters may generate a START condition within the minimum hold time ($t_{HD,STA}$) of the START condition which results in a defined START condition to the bus.

Arbitration takes place on the SDA line, while the SCL line is at the HIGH level, in such a way that the master which transmits a HIGH level, while another master is transmitting a LOW level will switch off its DATA output stage because the level on the bus doesn't correspond to its own level.

Arbitration can continue for many bits. Its first stage is comparison of the address bits (addressing information is in Sections 9.0 and 13.0). If the masters are each trying to address the same device, arbitration continues with comparison of the data. Because address and data information on the I²C-bus is used for arbitration, no information is lost during this process.

A master which loses the arbitration can generate clock pulses until the end of the byte in which it loses the arbitration.

If a master also incorporates a slave function and it loses arbitration during the addressing stage, it's possible that the winning master is trying to address it. The losing master must therefore switch over immediately to its slave-receiver mode.

Figure 10 shows the arbitration procedure for two masters. Of course, more may be involved (depending on how many masters are connected to the bus). The moment there is a difference

The I²C-bus and how to use it (including specifications)

between the internal data level of the master generating DATA 1 and the actual level on the SDA line, its data output is switched off, which means that a HIGH output level is then connected to the bus. This will not affect the data transfer initiated by the winning master.

Since control of the I²C-bus is decided solely on the address and data sent by competing masters, there is no central master, nor any order of priority on the bus.

Special attention must be paid if, during a serial transfer, the arbitration procedure is still in progress at the moment when a repeated START condition or a STOP condition is transmitted to the I²C-bus. If it's possible for such a situation to occur, the masters involved must send this repeated START condition or STOP condition at the same position in the format frame. In other words, arbitration isn't allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition.

7.3 Use of the clock synchronizing mechanism as a handshake

In addition to being used during the arbitration procedure, the clock synchronization mechanism can be used to enable receivers to cope with fast data transfers, on either a byte level or a bit level.

On the byte level, a device may be able to receive bytes of data at a fast rate, but needs more time to store a received byte or prepare another byte to be transmitted. Slaves can then hold the SCL line LOW after reception and acknowledgement of a byte to force the master into a wait state until the slave is ready for the next byte transfer in a type of handshake procedure.

On the bit level, a device such as a microcontroller without, or with only a limited hardware I²C interface on-chip can slow down the bus clock by extending each clock LOW period. The speed of any master is thereby adapted to the internal operating rate of this device.

8.0 FORMATS WITH 7-BIT ADDRESSES

Data transfers follow the format shown in Figure 11. After the START condition (S), a slave address is sent. This address is 7 bits long followed by an eighth bit which is a data direction bit (R/W) — a 'zero' indicates a transmission (WRITE), a 'one' indicates a request for data (READ). A data transfer is always terminated by a STOP condition (P) generated by the master. However, if a master still wishes to communicate on the bus, it can generate a repeated START condition (Sr) and address another slave without first generating a STOP condition. Various combinations of read/write formats are then possible within such a transfer.

Possible data transfer formats are:

- **Master-transmitter transmits to slave-receiver. The transfer direction is not changed (Figure 12)**
- **Master reads slave immediately after first byte (Figure 13).** At the moment of the first acknowledge, the master-transmitter becomes a master-receiver and the slave-receiver becomes a slave-transmitter. This acknowledge is still generated by the slave. The STOP condition is generated by the master
- **Combined format (Figure 14).** During a change of direction within a transfer, the START condition and the slave address are both repeated, but with the R/W bit reversed. If a master receiver sends a repeated START condition, it has previously sent a not acknowledge (\bar{A}).

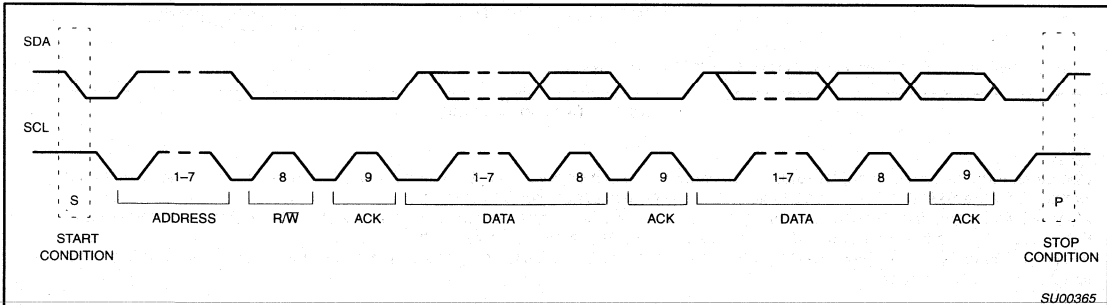

Figure 11. A complete data transfer

The I²C-bus and how to use it (including specifications)

Figure 12. A master-transmitter addresses a slave receiver with a 7-bit address. The transfer direction is not changed

Figure 13. A master reads a slave immediately after the first byte

Figure 14. Combined format

NOTES:

1. Combined formats can be used, for example, to control a serial memory. During the first data byte, the internal memory location has to be written. After the START and slave address is repeated, data can be transferred.
2. All decisions on auto-increment or decrement of previously accessed memory locations etc. are taken by the designer of the device.
3. Each byte is followed by an acknowledgement bit as indicated by the A or A-bar blocks in the sequence.
4. I²C-bus compatible devices must reset their bus logic on receipt of a START or repeated START condition such that they all anticipate the sending of a slave address.

The I²C-bus and how to use it (including specifications)

9.0 7-BIT ADDRESSING

(SEE SECTION 13.0 FOR 10-BIT ADDRESSING)

The addressing procedure for the I²C-bus is such that the first byte after the START condition usually determines which slave will be selected by the master. The exception is the 'general call' address which can address all devices. When this address is used, all devices should, in theory, respond with an acknowledge. However, devices can be made to ignore this address. The second byte of the general call address then defines the action to be taken. This procedure is explained in more detail in Section 9.1.1.

9.1 Definition of bits in the first byte

The first seven bits of the first byte make up the slave address (Figure 15). The eighth bit is the LSB (least significant bit). It determines the direction of the message. A 'zero' in the least significant position of the first byte means that the master will write information to a selected slave. A 'one' in this position means that the master will read information from the slave.

Figure 15. The first byte after the START procedure

When an address is sent, each device in a system compares the first seven bits after the START condition with its address. If they match, the device considers itself addressed by the master as a slave-receiver or slave-transmitter, depending on the R/W bit.

A slave address can be made-up of a fixed and a programmable part. Since it's likely that there will be several identical devices in a system, the programmable part of the slave address enables the maximum possible number of such devices to be connected to the I²C-bus. The number of programmable address bits of a device depends on the number of pins available. For example, if a device has 4 fixed and 3 programmable address bits, a total of 8 identical devices can be connected to the same bus.

The I²C-bus committee coordinates allocation of I²C addresses. Further information can be obtained from the Philips representatives listed on the back cover. Two groups of eight addresses (0000XXX and 1111XXX) are reserved for the purposes shown in Table 2. The bit combination 11110XX of the slave address is reserved for 10-bit addressing (see Section 13.0).

Table 2. Definition of bits in the first byte

SLAVE ADDRESS	R/ bit	DESCRIPTION
0000 000	0	General call address
0000 000	1	START byte
0000 001	X	CBUS address
0000 010	X	Address reserved for different bus format
0000 011	X	Reserved for future purposes
0000 1XX	X	
1111 1XX	X	
1111 0XX	X	10-bit slave addressing

NOTES:

- No device is allowed to acknowledge at the reception of the START byte.
- The CBUS address has been reserved to enable the inter-mixing of CBUS compatible and I²C-bus compatible devices in the same system. I²C-bus compatible devices are not allowed to respond on reception of this address.
- The address reserved for a different bus format is included to enable I²C and other protocols to be mixed. Only I²C-bus compatible devices that can work with such formats and protocols are allowed to respond to this address.

9.1.1 General call address

The general call address is for addressing every device connected to the I²C-bus. However, if a device doesn't need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgement. If a device does require data from a general call address, it will acknowledge this address and behave as a slave-receiver. The second and following bytes will be acknowledged by every slave-receiver capable of handling this data. A slave which cannot process one of these bytes must ignore it by not acknowledging. The meaning of the general call address is always specified in the second byte (Figure 16).

There are two cases to consider:

- When the least significant bit B is a 'zero'
- When the least significant bit B is a 'one'.

When bit B is a 'zero'; the second byte has the following definition:

- 00000110 (H'06'). Reset and write programmable part of slave address by hardware. On receiving this 2-byte sequence, all devices designed to respond to the general call address will reset and take in the programmable part of their address. Precautions have to be taken to ensure that a device is not pulling down the SDA or SCL line after applying the supply voltage, since these low levels would block the bus
- 00000100 (H'04'). Write programmable part of slave address by hardware. All devices which define the programmable part of their address by hardware (and which respond to the general call address) will latch this programmable part at the reception of this two byte sequence. The device will not reset.
- 00000000 (H'00'). This code is not allowed to be used as the second byte.

Sequences of programming procedure are published in the appropriate device data sheets.

The remaining codes have not been fixed and devices must ignore them.

The I²C-bus and how to use it (including specifications)

When bit B is a 'one'; the 2-byte sequence is a 'hardware general call'. This means that the sequence is transmitted by a hardware master device, such as a keyboard scanner, which cannot be programmed to transmit a desired slave address. Since a hardware master doesn't know in advance to which device the message has to be transferred, it can only generate this hardware general call and its own address — identifying itself to the system (Figure 17).

The seven bits remaining in the second byte contain the address of the hardware master. This address is recognised by an intelligent device (e.g. a microcontroller) connected to the bus which will then

direct the information from the hardware master. If the hardware master can also act as a slave, the slave address is identical to the master address.

In some systems, an alternative could be that the hardware master transmitter is set in the slave-receiver mode after the system reset. In this way, a system configuring master can tell the hardware master-transmitter (which is now in slave-receiver mode) to which address data must be sent (Figure 18). After this programming procedure, the hardware master remains in the master-transmitter mode.

The I²C-bus and how to use it (including specifications)

9.1.2 START byte

Microcontrollers can be connected to the I²C-bus in two ways. A microcontroller with an on-chip hardware I²C-bus interface can be programmed to be only interrupted by requests from the bus. When the device doesn't have such an interface, it must constantly monitor the bus via software. Obviously, the more times the microcontroller monitors, or polls the bus, the less time it can spend carrying out its intended function. There is therefore a speed difference between fast hardware devices and a relatively slow microcontroller which relies on software polling.

In this case, data transfer can be preceded by a start procedure which is much longer than normal (Figure 19). The start procedure consists of:

- A START condition (S)
- A START byte (00000001)
- An acknowledge clock pulse (ACK)
- A repeated START condition (Sr).

After the START condition S has been transmitted by a master which requires bus access, the START byte (00000001) is transmitted. Another microcontroller can therefore sample the SDA line at a low sampling rate until one of the seven zeros in the START byte is detected. After detection of this LOW level on the SDA line, the microcontroller can switch to a higher sampling rate to find the repeated START condition Sr which is then used for synchronization.

A hardware receiver will reset on receipt of the repeated START condition Sr and will therefore ignore the START byte.

An acknowledge-related clock pulse is generated after the START byte. This is present only to conform with the byte handling format used on the bus. No device is allowed to acknowledge the START byte.

9.1.3 CBUS compatibility

CBUS receivers can be connected to the I²C-bus. However, a third bus line called DLEN must then be connected and the acknowledge bit omitted. Normally, I²C transmissions are sequences of 8-bit bytes; CBUS compatible devices have different formats.

In a mixed bus structure, I²C-bus devices must not respond to the CBUS message. For this reason, a special CBUS address (0000001X) to which no I²C-bus compatible device will respond, has been reserved. After transmission of the CBUS address, the DLEN line can be made active and a CBUS-format transmission (Figure 20) sent. After the STOP condition, all devices are again ready to accept data.

Master-transmitters can send CBUS formats after sending the CBUS address. The transmission is ended by a STOP condition, recognised by all devices.

NOTE: If the CBUS configuration is known, and expansion with CBUS compatible devices isn't foreseen, the designer is allowed to adapt the hold time to the specific requirements of the device(s) used.

The I²C-bus and how to use it (including specifications)

10.0 ELECTRICAL CHARACTERISTICS FOR I²C-BUS DEVICES

The electrical specifications for the I/Os of I²C-bus devices and the characteristics of the bus lines connected to them are given in Tables 3 and 4 in Section 15.0.

I²C-bus devices with fixed input levels of 1.5 V and 3 V can each have their own appropriate supply voltage. Pull-up resistors must be connected to a 5V ± 10% supply (Figure 21). I²C-bus devices with input levels related to V_{DD} must have one common supply line to which the pull-up resistor is also connected (Figure 22).

When devices with fixed input levels are mixed with devices with input levels related to V_{DD}, the latter devices must be connected to one common supply line of 5 V ± 10% and must have pull-up resistors connected to their SDA and SCL pins as shown in Figure 23.

Input levels are defined in such a way that:

- The noise margin on the LOW level is 0.1 V_{DD}
- The noise margin on the HIGH level is 0.2 V_{DD}
- As shown in Figure 24, series resistors (R_S) of, e.g., 300Ω can be used for protection against high-voltage spikes on the SDA and SCL lines (due to flash-over of a TV picture tube, for example).

Figure 21. Fixed input level devices connected to the I²C-bus

Figure 24. Series resistors (R_S) for protection against high-voltage spikes

The I²C-bus and how to use it (including specifications)

10.1 Maximum and minimum values of resistors R_p and R_s

For standard-mode I²C-bus devices, the values of resistors R_p and R_s in Figure 24 depend on the following parameters:

- Supply voltage
- Bus capacitance
- Number of connected devices (input current + leakage current).

The supply voltage limits the minimum value of resistor R_p due to the specified minimum sink current of 3 mA at V_{OLmax} = 0.4 V for the output stages. V_{DD} as a function of R_{p min} is shown in Figure 25. The desired noise margin of 0.1V_{DD} for the LOW level,

limits the maximum value of R_s. R_{s max} as a function of R_p is shown in Figure 26.

The bus capacitance is the total capacitance of wire, connections and pins. This capacitance limits the maximum value of R_p due to the specified rise time. Figure 27 shows R_{p max} as a function of bus capacitance.

The maximum HIGH level input current of each input/output connection has a specified maximum value of 10 μA. Due to the desired noise margin of 0.2V_{DD} for the HIGH level, this input current limits the maximum value of R_p. This limit depends on V_{DD}. The total HIGH level input current is shown as a function of R_{p max} in Figure 28.

11.0 EXTENSIONS TO THE I²C-BUS SPECIFICATION

The I²C-bus with a data transfer rate of up to 100 kbit/s and 7-bit addressing has now been in existence for more than ten years with an unchanged specification. The concept is accepted world-wide as a de facto standard and hundreds of different types of I²C-bus compatible ICs are available from Philips and other suppliers. The I²C-bus specification is now extended with the following two features:

- A **fast-mode** which allows a fourfold increase of the bit rate to 0 to 400 kbit/s
- **10-bit addressing** which allows the use of up to 1024 additional addresses.

There are two reasons for these extensions to the I²C-bus specification:

- New applications will need to transfer a larger amount of serial data and will therefore demand a higher bit rate than 100 kbit/s. Improved IC manufacturing technology now allows a fourfold speed increase without increasing the manufacturing cost of the interface circuitry
- Most of the 112 addresses available with the 7-bit addressing scheme have been issued more than once. To prevent problems with the allocation of slave addresses for new devices, it is desirable to have more address combinations. About a tenfold increase of the number of available addresses is obtained with the new 10-bit addressing.

All new devices with an I²C-bus interface are provided with the fast-mode. Preferably, they should be able to receive and/or transmit at 400 kbit/s. The minimum requirement is that they can synchronize with a 400 kbit/s transfer; they can then prolong the LOW period of the SCL signal to slow down the transfer. Fast-mode devices must be downward-compatible which means that they must still be able to communicate with 0 to 100 kbit/s devices in a 0 to 100 kbit/s I²C-bus system.

Obviously, devices with a 0 to 100 kbit/s I²C-bus interface cannot be incorporated in a fast-mode I²C-bus system because, since they cannot follow the higher transfer rate, unpredictable states of these devices would occur.

Slave devices with a fast-mode I²C-bus interface can have a 7-bit or a 10-bit slave address. However, a 7-bit address is preferred because it is the cheapest solution in hardware and it results in the shortest message length. Devices with 7-bit and 10-bit addresses can be mixed in the same I²C-bus system regardless of whether it is a 0 to 100 kbit/s standard-mode system or a 0 to 400 kbit/s fast-mode system. Both existing and future masters can generate either 7-bit or 10-bit addresses.

12.0 FAST-MODE

In the fast-mode of the I²C-bus, the protocol, format, logic levels and maximum capacitive load for the SDA and SCL lines quoted in the

previous I²C-bus specification are unchanged. Changes to the previous I²C-bus specification are:

- The maximum bit rate is increased to 400 kbit/s
- Timing of the serial data (SDA) and serial clock (SCL) signals has been adapted. There is no need for compatibility with other bus systems such as CBUS because they cannot operate at the increased bit rate
- The inputs of fast-mode devices must incorporate spike suppression and a Schmitt trigger at the SDA and SCL inputs
- The output buffers of fast-mode devices must incorporate slope control of the falling edges of the SDA and SCL signals
- If the power supply to a fast-mode device is switched off, the SDA and SCL I/O pins must be floating so that they don't obstruct the bus lines
- The external pull-up devices connected to the bus lines must be adapted to accommodate the shorter maximum permissible rise time for the fast-mode I²C-bus. For bus loads up to 200pF, the pull-up device for each bus line can be a resistor; for bus loads between 200pF and 400pF, the pull-up device can be a current source (3mA max.) or a switched resistor circuit as shown in Figure 37.

13.0 10-BIT ADDRESSING

The 10-bit addressing does not change the format in the I²C-bus specification. Using 10 bits for addressing exploits the reserved combination 1111XXX for the first seven bits of the first byte following a START (S) or repeated START (Sr) condition as explained in Section 9.1. The 10-bit addressing does not affect the existing 7-bit addressing. Devices with 7-bit and 10-bit addresses can be connected to the same I²C-bus, and both 7-bit and 10-bit addressing can be used in a standard-mode system (up to 100 kbit/s) or a fast-mode system (up to 400 kbit/s).

Although there are eight possible combinations of the reserved address bits 1111XXX, only the four combinations 11110XX are used for 10-bit addressing. The remaining four combinations 11111XX are reserved for future I²C-bus enhancements.

13.1 Definition of bits in the first two bytes

The 10-bit slave address is formed from the first two bytes following a START condition (S) or a repeated START condition (Sr).

The first seven bits of the first byte are the combination 11110XX of which the last two bits (XX) are the two most-significant bits (MSBs) of the 10-bit address; the eighth bit of the first byte is the R/W bit that determines the direction of the message. A 'zero' in the least significant position of the first byte means that the master will write information to a selected slave. A 'one' in this position means that the master will read information from the slave.

If the R/W bit is 'zero', then the second byte contains the remaining 8 bits (XXXXXXXX) of the 10-bit address. If the R/W bit is 'one', then the next byte contains data transmitted from a slave to a master.

The I²C-bus and how to use it (including specifications)

13.2 Formats with 10-bit addresses

Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing. Possible data transfer formats are:

- **Master-transmitter transmits to slave-receiver with a 10-bit slave address. The transfer direction is not changed (Figure 29).** When a 10-bit address follows a START condition, each slave compares the first seven bits of the first byte of the slave address (11110XX) with its own address and tests if the eighth bit (R/W direction bit) is 0. It is possible that more than one device will find a match and generate an acknowledge (A1). All slaves that found a match will compare the eight bits of the second byte of the slave address (XXXXXXXX) with their own addresses, but only one slave will find a match and generate an acknowledge (A2). The matching slave will remain addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address
- **Master-receiver reads slave-transmitter with a 10-bit slave address. The transfer direction is changed after the second R/W bit (Figure 30).** Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks if the first seven bits of the slave address following Sr are the same as they were after the START condition (S), and tests if the eighth (R/W) bit is 1. If there

is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3.

The slave-transmitter remains addressed until it receives a STOP condition (P) or until it receives another repeated START condition (Sr) followed by a different slave address. After a repeated START condition (Sr), all the other slave devices will also compare the first seven bits of the first byte of the slave address (11110XX) with their own addresses and test the eighth (R/W) bit. However, none of them will be addressed because R/W = 1 (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match)

- **Combined format. A master transmits data to a slave and then reads data from the same slave (Figure 31).** The same master occupies the bus all the time. The transfer direction is changed after the second R/W bit
- **Combined format. A master transmits data to one slave and then transmits data to another slave (Figure 32).** The same master occupies the bus all the time
- **Combined format. 10-bit and 7-bit addressing combined in one serial transfer (Figure 33).** After each START condition (S), or each repeated START condition (Sr), a 10-bit or 7-bit slave address can be transmitted. Figure 33 shows how a master-transmits data to a slave with a 7-bit address and then transmits data to a second slave with a 10-bit address. The same master occupies the bus all the time.

Figure 29. A master-transmitter addresses a slave-receiver with a 10-bit address

Figure 30. A master-receiver addresses a slave-transmitter with a 10-bit address

Figure 31. Combined format. A master addresses a slave with a 10-bit address, then transmits data to this slave and reads data from this slave

The I²C-bus and how to use it (including specifications)

Figure 32. Combined format. A master transmits data to two slaves, both with 10-bit addresses

Figure 33. Combined format. A master transmits data to two slaves, one with a 7-bit address, and one with a 10-bit address

NOTES:

1. Combined formats can be used, for example, to control a serial memory. During the first data byte, the internal memory location has to be written. After the START condition and slave address is repeated, data can be transferred.
2. All decisions on auto-increment or decrement of previously accessed memory locations etc. are taken by the designer of the device.
3. Each byte is followed by an acknowledgement bit as indicated by the A or \bar{A} blocks in the sequence.
4. I²C-bus compatible devices must reset their bus logic on receipt of a START or repeated START condition such that they all anticipate the sending of a slave address.

14.0 GENERAL CALL ADDRESS AND START BYTE

The 10-bit addressing procedure for the I²C-bus is such that the first two bytes after the START condition (S) usually determine which slave will be selected by the master. The exception is the 'general call' address 00000000 (H'00'). Slave devices with 10-bit addressing will react to a 'general call' in the same way as slave devices with 7-bit addressing (see Section 9.1.1).

Hardware masters can transmit their 10-bit address after a 'general call'. In this case, the 'general call' address byte is followed by two successive bytes containing the 10-bit address of the master-transmitter. The format is as shown in Figure 17 where the first DATA byte contains the eight least-significant bits of the master address.

The START byte 00000001 (H'01') can precede the 10-bit addressing in the same way as for 7-bit addressing (see Section 9.1.2).

The I²C-bus and how to use it (including specifications)

15.0 ELECTRICAL SPECIFICATIONS AND TIMING FOR I/O STAGES AND BUS LINES

The I/O levels, I/O current, spike suppression, output slope control and pin capacitance for I²C-bus devices are given in Table 3. The I²C-bus timing is given in Table 4. Figure 34 shows the timing definitions for the I²C-bus.

The noise margin for HIGH and LOW levels on the bus lines for fast-mode devices are the same as those specified in Section 10.0 for standard-mode I²C-bus devices.

The minimum HIGH and LOW periods of the SCL clock specified in Table 4 determine the maximum bit transfer rates of 100 kbit/s for standard-mode devices and 400 kbit/s for fast mode devices. Standard-mode and fast-mode I²C-bus devices must be able to follow transfers at their own maximum bit rates, either by being able to transmit or receive at that speed or by applying the clock synchronization procedure described in Section 7.0 which will force the master into a wait state and stretch the LOW period of the SCL signal. Of course, in the latter case the bit transfer rate is reduced.

Table 3. Characteristics of the SDA and SCL I/O stages for I²C-bus devices

PARAMETER	SYMBOL	STANDARD-MODE DEVICES		FAST-MODE DEVICES		UNIT

Pulse width of spikes which must be suppressed by the input filter	t _{SP}	n/a	n/a	0	50	ns
LOW level output voltage (open drain or open collector): at 3 mA sink current at 6 mA sink current	V _{OL1} V _{OL2}	0 n/a	0.4 n/a	0 0	0.4 0.6	V
Output fall time from V _{IHmin} to V _{ILmax} with a bus capacitance from 10 pF to 400 pF: with up to 3 mA sink current at V _{OL1} with up to 6 mA sink current at V _{OL2}	t _{of}	- n/a	250 ³⁾ n/a	20 + 0.1C _b ²⁾ 20 + 0.1C _b ²⁾	250 250 ³⁾	ns
Input current each I/O pin with an input voltage between 0.4 V and 0.9V _{DDmax}	I _i	-10	10	-10 ⁴⁾	10 ⁴⁾	μA
Capacitance for each I/O pin	C _i	-	10	-	10	pF

n/a = not applicable

1. Maximum V_{IH} = V_{DDmax} + 0.5 V
2. C_b = capacitance of one bus line in pF.
3. The maximum t_f for the SDA and SCL bus lines quoted in Table 4 (300 ns) is longer than the specified maximum t_{of} for the output stages (250 ns). This allows series protection resistors (R_s) to be connected between the SDA/SCL pins and the SDA/SCL bus lines as shown in Figure 37 without exceeding the maximum specified t_f.
4. I/O pins of fast-mode devices must not obstruct the SDA and SCL lines if V_{DD} is switched off.

The I²C-bus and how to use it (including specifications)

Table 4. Characteristics of the SDA and SCL bus lines for I²C-bus devices

PARAMETER	SYMBOL	STANDARD-MODE I ² C-BUS		FAST-MODE I ² C-BUS		UNIT
		Min.	Max.	Min.	Max.	
SCL clock frequency	f _{SCL}	0	100	0	400	kHz
Bus free time between a STOP and START condition	t _{BUF}	4.7	–	1.3	–	µs
Hold time (repeated) START condition. After this period, the first clock pulse is generated	t _{HD,STA}	4.0	–	0.6	–	µs
LOW period of the SCL clock	t _{LOW}	4.7	–	1.3	–	µs
HIGH period of the SCL clock	t _{HIGH}	4.0	–	0.6	–	µs
Set-up time for a repeated START condition	t _{SU,STA}	4.7	–	0.6	–	µs
Data hold time: for CBUS compatible masters (see NOTE, Section 9.1.3) for I ² C-bus devices	t _{HD,DAT}	5.0 0 ¹⁾	–	– 0 ¹⁾	– 0.9 ²⁾	µs µs
Data set-up time	t _{SU,DAT}	250	–	100 ³⁾	–	ns
Rise time of both SDA and SCL signals	t _r	–	1000	20 + 0.1C _b ⁴⁾	300	ns
Fall time of both SDA and SCL signals	t _f	–	300	20 + 0.1C _b ⁴⁾	300	ns
Set-up time for STOP condition	t _{SU,STO}	4.0	–	0.6	–	µs
Capacitive load for each bus line	C _b	–	400	–	400	pF

All values referred to V_{IHmin} and V_{ILmax} levels (see Table 3).

1. A device must internally provide a hold time of at least 300 ns for the SDA signal (referred to the V_{IHmin} of the SCL signal) in order to bridge the undefined region of the falling edge of SCL.
2. The maximum t_{HD,DAT} has only to be met if the device does not stretch the LOW period (t_{LOW}) of the SCL signal.
3. A fast-mode I²C-bus device can be used in a standard-mode I²C-bus system, but the requirement t_{SU,DAT} ≥ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line t_{r max} + t_{SU,DAT} = 1000 + 250 = 1250 ns (according to the standard-mode I²C-bus specification) before the SCL line is released.
4. C_b = total capacitance of one bus line in pF.

SU00645

The I²C-bus and how to use it (including specifications)

16.0 APPLICATION INFORMATION

16.1 Slope-controlled output stages of fast-mode I²C-bus devices

The electrical specifications for the I/Os of I²C-bus devices and the characteristics of the bus lines connected to them are given in Tables 3 and 4 in Section 15.0.

Figures 35 and 36 show examples of output stages with slope control in CMOS and bipolar technology. The slope of the falling edge is defined by a Miller capacitor (C1) and a resistor (R1). The typical values for C1 and R1 are indicated on the diagrams. The wide tolerance for output fall time t_{of} given in Table 3 means that the design is not critical. The fall time is only slightly influenced by the external bus load (C_b) and external pull-up resistor (R_p). However, the rise time (t_r) specified in Table 4 is mainly determined by the bus load capacitance and the value of the pull-up resistor.

16.2 Switched pull-up circuit for fast-mode I²C-bus devices

The supply voltage (V_{DD}) and the maximum output LOW level determine the minimum value of pull-up resistor R_p (see Section 10.1). For example, with a supply voltage of V_{DD} = 5V ± 10% and V_{OLmax} = 0.4V at 3mA, R_{p min} = (5.5 - 0.4)/0.003 = 1.7 kΩ. As shown in Figure 38, this value of R_p limits the maximum bus capacitance to about 200pF to meet the maximum t_r requirement of 300 ns. If the bus has a higher capacitance than this, a switched pull-up circuit as shown in Figure 37 can be used.

The switched pull-up circuit in Figure 37 is for a supply voltage of V_{DD} = 5V ± 10% and a maximum capacitive load of 400pF. Since it is controlled by the bus levels, it needs no additional switching control signals. During the rising/falling edges, the bilateral switch in the HCT4066 switches pull-up resistor R_{p2} on/off at bus levels between 0.8 V and 2.0 V. Combined resistors R_{p1} and R_{p2} can pull-up the bus line within the maximum specified rise time (t_r) of 300 ns. The maximum sink current for the driving I²C-bus device will not exceed 6 mA at V_{OL2} = 0.6 V, or 3 mA at V_{OL1} = 0.4 V.

Series resistors R_s are optional. They protect the I/O stages of the I²C-bus devices from high-voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus line signals. The maximum value of R_s is determined by the maximum permitted voltage drop across this resistor when the bus line is switched to the LOW level in order to switch off R_{p2}.

The I²C-bus and how to use it (including specifications)

16.3 Wiring pattern of the bus lines

In general, the wiring must be so chosen that crosstalk and interference to/from the bus lines is minimized. The bus lines are most susceptible to crosstalk and interference at the HIGH level because of the relatively high impedance of the pull-up devices.

If the length of the bus lines on a PCB or ribbon cable exceeds 10cm and includes the V_{DD} and V_{SS} lines, the wiring pattern must be:

SDA _____

V_{DD} _____

V_{SS} _____

SCL _____

If only the V_{SS} line is included, the wiring pattern must be:

SDA _____

V_{SS} _____

SCL _____

These wiring patterns also result in identical capacitive loads for the SDA and SCL lines. The V_{SS} and V_{DD} lines can be omitted if a PCB with a V_{SS} and/or V_{DD} layer is used.

If the bus lines are twisted-pairs, each bus line must be twisted with a V_{SS} return. Alternatively, the SCL line can be twisted with a V_{SS} return, and the SDA line twisted with a V_{DD} return. In the latter case, capacitors must be used to decouple the V_{DD} line to the V_{SS} line at both ends of the twisted pairs.

If the bus lines are shielded (shield connected to V_{SS}), interference will be minimized. However, the shielded cable must have low capacitive coupling between the SDA and SCL lines to minimize crosstalk.

16.4 Maximum and minimum values of resistors R_p and R_s for fast-mode I²C-bus devices

The maximum and minimum values for resistors R_p and R_s connected to a fast-mode I²C-bus can be determined from Figure 25, 26 and 28 in Section 10.1. Because a fast-mode I²C-bus has faster rise times (t_r) the maximum value of R_p as a function of bus capacitance is less than that shown in Figure 27. The replacement graph for Figure 27 showing the maximum value of R_p as a function of bus capacitance (C_b) for a fast mode I²C-bus is given in Figure 38.

17.0 DEVELOPMENT TOOLS

17.1 Development tools for 8048 and 8051-based systems

PRODUCT	DESCRIPTION
OM1016	I ² C-bus demonstration board with microcontroller, LCD, LED, Par. I/O, SRAM, EEPROM, Clock, DTMF generator, AD/DA conversion, infrared link.
OM1018	manual for OM1016
OM1020	LCD and driver demonstration board

19.0 APPLICATION OF THE I²C-BUS IN THE ACCESS.bus SYSTEM

The ACCESS.bus (bus for connecting ACCESSory devices to a host system) is an I²C-bus based open-standard serial interconnect system jointly developed and defined by Philips and Digital Equipment Corporation. It is a lower-cost alternative to an RS-232C interface for connecting up to 14 inputs/outputs from peripheral equipment to a desk-top computer or workstation over a distance of up to eight metres. The peripheral equipment can be relatively low speed items such as keyboards, hand-held image scanners, cursor positioners, bar-code readers, digitizing tablets, card readers or modems.

All that's required to implement an ACCESS.bus is an 8051-family microcontroller with an I²C-bus interface, and a 4-wire cable carrying a serial data (SDA) line, a serial clock (SCL) line, a ground wire and a 12V supply line (500mA max.) for powering the peripherals.

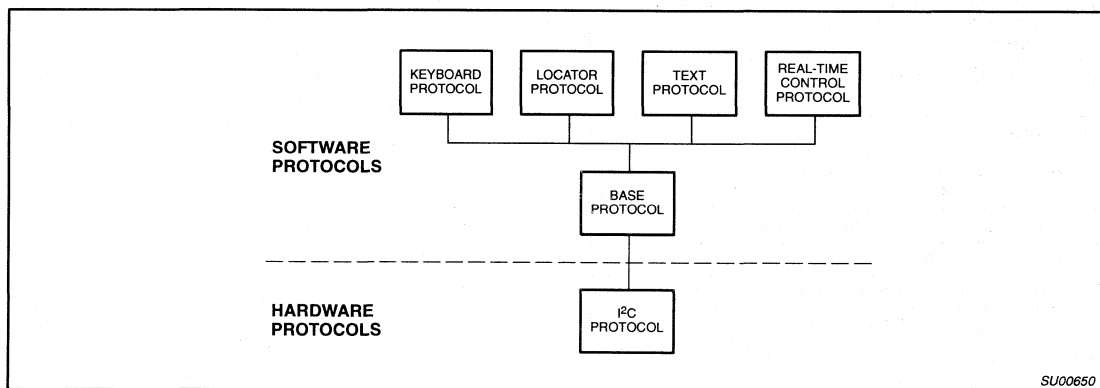

Important features of the ACCESS.bus are that the bit rate is only about 20% less than the maximum bit rate of the I²C-bus, and the peripherals don't need separate device drivers. Also, the protocol allows the peripherals to be changed by 'hot-plugging' without re-booting.

As shown in Figure 39, the ACCESS.bus protocol comprises three levels: the I²C-bus protocol, the base protocol, and the application protocol.

The base protocol is common to all ACCESS.bus devices and defines the format of the ACCESS.bus message. Unlike the I²C-bus protocol, it restricts masters to sending and slaves to receiving data. One item of appended information is a checksum for reliability control. The base protocol also specifies seven types of control and status messages which are used in the system configuration which assigns unique addresses to the peripherals without the need for setting jumpers or switches on the devices.

The application protocol defines the message semantics that are specific to the three categories of peripheral device (keyboards, cursor locators, and text devices which generate character streams, e.g., card readers) which are at present envisaged.

Philips offers computer peripheral equipment manufacturers technical support, a wide range of I²C-bus devices and development kits for the ACCESS.bus. Hardware, software and marketing support is also offered by DEC.

I²C bus extender**82B715****DESCRIPTION**

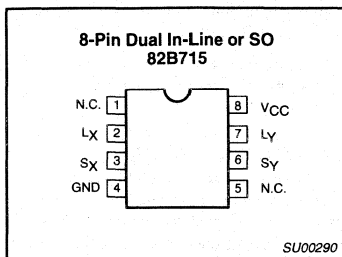

The 82B715 is a bipolar integrated circuit intended for application in I²C bus systems.

While retaining all the operating modes and features of the I²C system it permits extension of the practical separation distance between components on the I²C bus by buffering both the data (SDA) and the clock (SCL) lines.

The I²C bus capacitance limit of 400pF restricts practical communication distances to a few meters. Using one 82B715 at each end of longer cables reduces the cable loading capacitance on the I²C bus by a factor of 10 times and may allow the use of low cost general purpose wiring to extend bus lengths.

FEATURES

- Dual, bi-directional, unity voltage gain buffer
- I²C bus compatible
- Logic signal levels may include both supply and ground
- X10 impedance transformation
- Wide supply voltage range

I²C bus extender

82B715

FUNCTIONAL DESCRIPTION

The 82B715 bipolar integrated circuit contains two identical buffer circuits which enable I²C and similar bus systems to be extended over long distances without degradation of system performance or requiring the use of special cables.

The buffer has an effective current gain of ten from I²C bus to Buffered bus. Whatever current is flowing out of the I²C bus side, ten times that current will be flowing into the Buffered bus side (see Figure 2).

As a consequence of this amplification the system is able to drive capacitive loads up to ten times the standard limit on the Buffered bus side. This current based buffering

approach preserves the bi-directional, open-collector/open-drain characteristic of the I²C SDA/SCL lines.

To minimize interference and ensure stability, current rise and fall rates are internally controlled.

APPLICATION NOTES

By using two (or more) 82B715 ICs, a sub-system can be built which retains the interface characteristics of an I²C device so that it may be included in, or optionally added to, any I²C or related system.

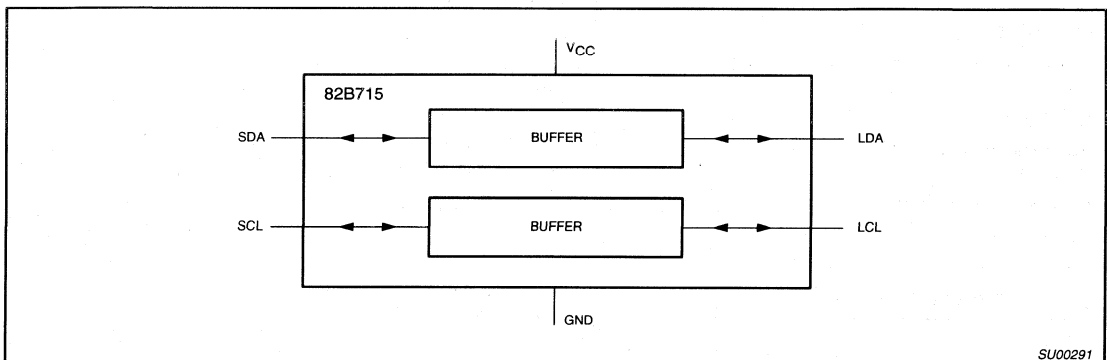

The sub-system features a low impedance or "Buffered" bus, capable of driving large wiring capacities (see Figure 3).

I²C Systems

As with the standard I²C system, pull-up resistors are required to provide the logic HIGH levels on the Buffered bus. (Standard open-collector configuration of the I²C bus). The size and number of these pull-up resistors depends on the system.

If the buffer is to be permanently connected into the system, the circuit should be configured with only one pull-up resistor on the Buffered bus and none on the I²C bus.

Alternatively a buffer may be connected to an existing I²C system. In this case the Buffered bus pull-up will act in parallel with the I²C bus pull-up.

82B715

Pull-Up Resistance Calculation

In calculating the pull-up resistance values, the gain of the buffer introduces scaling factors which must be applied to the system components. Viewing the system from the Buffered bus, all I²C bus capacitances have effectively 10 times their I²C bus value.

In practical systems the pull-up resistance is determined by the rise time limit for I²C systems. As an approximation this limit will be satisfied if the time constant (product of the net resistance and net capacitance) of the total system is set to 1 microsecond.

The total time constant may either be set by considering each bus node individually (i.e., the I²C nodes, and the Buffered bus node) and choosing pull-up resistors to give time constants of 1 microsecond for each node; or by combining the capacitances into an equivalent capacitive loading on the Buffered bus, and calculating the Buffered bus pull-up resistor required by this equivalent capacitance.

For each separate bus the pull-up resistor may be calculated as follows:

$$R = \frac{1 \mu \text{sec}}{C_{\text{device}} + C_{\text{wiring}}}$$

Where: C_{device} = sum of device capacitances connected to each bus,

and C_{wiring} = total wiring and stray capacitance on each bus.

If these capacitances are not known then a good approximation is to assume that each device presents 10pF of load capacitance and 10pF of wiring capacitance.

The capacitance figures for one or more individual I²C bus nodes should be multiplied by a factor of 10 times, and then added to the Buffered bus capacitance. Calculation of a new Buffered bus pull-up resistor will allow this single pull-up resistor to act for both the included I²C bus nodes and the Buffered bus. Thus it is possible to combine some or all of these separate pull-up resistors into a single resistor on the Buffered bus (the value of which is calculated from the sum of the scaled capacitances on the Buffered bus). If the buffer is to be permanently connected into the system then all the separate pull-up resistors should be combined. But if it is to be connected by adding it onto an existing system, then only those on the additional I²C bus system can be combined onto the Buffered bus if the original system is required to be able to still operate on a stand-alone basis.

A further restriction is that the maximum pull-up current, with the bus LOW, should not exceed the I²C bus specification maximum of

3mA, or 30mA on the Buffered bus. The following formula applies:

$$30\text{mA} > \frac{V_{\text{CC}} - 0.4}{R_{\text{P}}}$$

Where: R_P = scaled parallel combination of all pull-up resistors.

If this condition is met, the fall time specifications will also be met.

Figure 4 shows typical loading calculations for the expanded I²C bus.

Sx, Sy, I²C Bus, SDA or SCL

Because the two buffer circuits in the 82B715 are identical either input pin can be used as the I²C Bus SDA data line, or the SCL clock line.

Lx, Ly, Buffered Bus, LDA or LCL

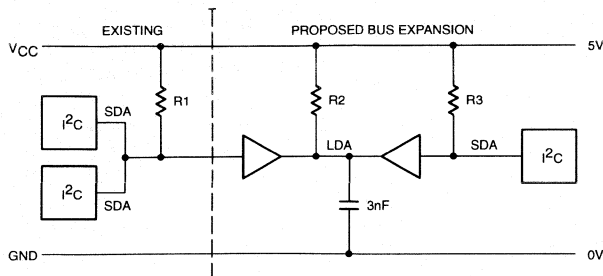

On the buffered low impedance line side, the corresponding output becomes LDA and LCL.

V_{CC}, GND — Positive and Negative Supply Pins

In normal use the power supply voltages at each end of the low impedance line should be comparable. If these differ by a significant amount, noise margin is sacrificed.

Strays	10pF
82B715 Buffer	10pF
TOTAL CAP.	30pF

I²C pull-up

$$R3 = \frac{1\mu\text{sec}}{30\text{pF}} = 33\text{K}\Omega$$

AS AN ADDITION TO AN EXISTING SYSTEM * :

R1 = 20KΩ

$$R2' = \frac{R2 \times 0.1R3}{R2 + 0.1R3} = 300\Omega$$

R3 not required since buffer always connected

FOR A PERMANENT SYSTEM * :

R1 not required since buffer always connected

$$R2' = \frac{0.1R1 \times R2 \times 0.1R3}{0.1R1 + R2 + 0.1R3} = 260\Omega$$

R3 not required since buffer always connected

*** NOTE:**

R1, R2 and R3 are calculated from the capacitive loading and a 1μsec time constant on each bus node. For an addition to an existing system, R2' (the new value for R2) is shown as being calculated from the parallel combination of R2 and the scaled value of R3; while for a permanent system R2, and scaled values of R1 and R3 have been used. Note that this example has used scaled resistor values and combined the node and cable capacitances.

CHECK FOR MAXIMUM PULL-UP CURRENT:

$$\frac{(5 - 0.4)V}{260\Omega} = 17.6\text{mA} < 30\text{mA}$$

AN422

DESCRIPTION

The 83C751/87C751 Microcontroller offers the advantages of the 80C51 architecture in a small package and at a low cost. It combines the benefits of a high-performance microcontroller with on-board hardware supporting the Inter-Integrated Circuit (I²C) bus interface.

The I²C bus, developed and patented by Philips, allows integrated circuits to communicate directly with each other via a simple bidirectional 2-wire bus. The comprehensive family of CMOS and bipolar ICs incorporating the on-chip I²C interface offers many advantages to designers of digital control for industrial, consumer and telecommunications equipment. A typical system configuration is shown in Figure 1.

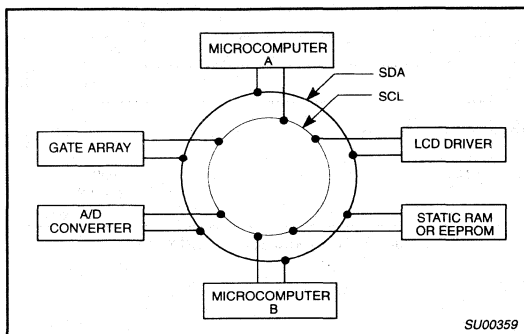

Figure 1. Typical I²C Bus Configuration

Interfacing the devices in an I²C based system is very simple because they connect directly to the two bus lines: a serial data line (SDA) and a serial clock line (SCL). System design can rapidly progress from block diagram to final schematic, as there is no need to design bus interfaces, and functional blocks on a block diagram correspond to actual ICs. A prototype system or a final product version can easily be modified or upgraded by 'clipping' or 'unclipping' ICs to or from the bus. The simplicity of designing with the I²C bus does not reduce its effectiveness; it is a reliable, multimaster bus with integrated addressing and data-transfer protocols (see Figure 2). In addition, the I²C-bus compatible ICs provide cost reduction benefits to equipment manufacturers, some of which are smaller IC packages and a minimization of PCB traces and glue logic.

The availability of microcontrollers like the 83C751, with on-board I²C interface, is a very powerful tool for system designers. The integrated protocols allow systems to be completely software defined. Software development time of different products can be reduced by assembling a library of reusable software modules. In addition, the multimaster capability allows rapid testing and alignment of end-products via external connections to an assembly-line computer.

The mask programmable 83C751 and its EPROM version, the 87C751, can operate as a master or a slave device on the I²C small area network. In addition to the efficient interface to the dedicated function ICs in the I²C family, the on-board interface facilities I/O and RAM expansion, access to EEPROM and processor-to-processor communications.

The multimaster capability of the I²C is very important but many designs do not require it. For many systems, it is sufficient that all communications between devices are initiated by a single, master processor. In this application note, use of the 8XC751 as an I²C bus master is described. Some of the technical features of the bus and the 83C751's special hardware associated with the I²C are discussed. Also included is a software example demonstrating I²C single master communications. Note that the sample routines are quite general, and therefore may be transferred easily to many applications.

The discussion of the I²C bus characteristics in this application note is by no means complete. Additional information for the I²C bus and the S83C751 Microcontroller can be found in the Microcontroller Users' Guide.

THE I²C BUS

The two lines of the I²C-bus are a serial data line (SDA) and a serial clock line (SCL). Both lines are connected to a positive supply via a pull-up resistor, and remain HIGH when the bus is not busy. Each device is recognized by a unique address—whether it is a microcomputer, LCD driver, memory or keyboard interface—and can operate as either a transmitter or receiver, depending on the function of the device. A device generating a message or data is a transmitter, and a device receiving the message or data is a receiver. Obviously, a passive function like an LCD driver could only be a receiver, while a microcontroller or a memory can both transmit and receive data.

Masters and Slaves

When a data transfer takes place on the bus, a device can either be a master or a slave. The device which initiates the transfer, and generates the clock signals for this transfer, is the master. At that time any device addressed is considered a slave. It is important to note that a master could either be a transmitter or a receiver; a master microcontroller may send data to a RAM acting as a transmitter, and then interrogate the RAM for its contents acting as a receiver—in both cases performing as the master initiating the transfer. In the same manner, a slave could be both a receiver and a transmitter.

The I²C is a multimaster bus. It is possible to have, in one system, more than one device capable of initiating transfers and controlling the bus (Figure 2). A microcontroller may act as a master for one transfer, and then be the slave for another transfer, initiated by another processor on the network. The master/slave relationships on the bus are not permanent, and may change on each transfer.

Figure 2. I²C Bus Connection

Using the 8XC751 microcontroller as an I²C bus master

AN422

As more than one master may be connected to the bus, it is possible that two devices will try to initiate a transfer at the same time. Obviously, in order to eliminate bus collisions and communications chaos, an arbitration procedure is necessary. The I²C design has an inherent arbitration and clock synchronization procedure relying on the wired-AND connection of the devices on the bus. In a typical multimaster system, a microcontroller program should allow it to gracefully switch between master and slave modes and preserve data integrity upon loss of arbitration. In this note, a simple case is presented describing the S83C751 operating as a single master on the bus.

Data Transfers

One data bit is transferred during each clock pulse (see Figure 3). The data on the SDA line must remain stable during the HIGH period of the clock pulse in order to be valid. Changes in the data line at this time will be interpreted as control signals. A HIGH-to-LOW transition of the data line (SDA) while the clock signal (SCL) is HIGH indicates a Start condition, and a LOW-to-HIGH transition of the SDA while SCL is HIGH defines a Stop condition (see Figure 4). The bus is considered to be busy after the Start condition and free again at a certain time interval after the Stop condition. The Start and Stop conditions are always generated by the master.

The number of data bytes transferred between the Start and Stop condition from transmitter to receiver is not limited. Each byte, which must be eight bits long, is transferred serially with the most significant bit first, and is followed by an acknowledge bit. (see Figure 5). The clock pulse related to the acknowledge bit is generated by the master. The device that acknowledges has to pull down the SDA line during the acknowledge clock pulse, while the transmitting device releases the SDA line (HIGH) during this pulse (see Figure 6).

Figure 3. Bit Transfer on the I²C Bus

Figure 4. Start and Stop Conditions

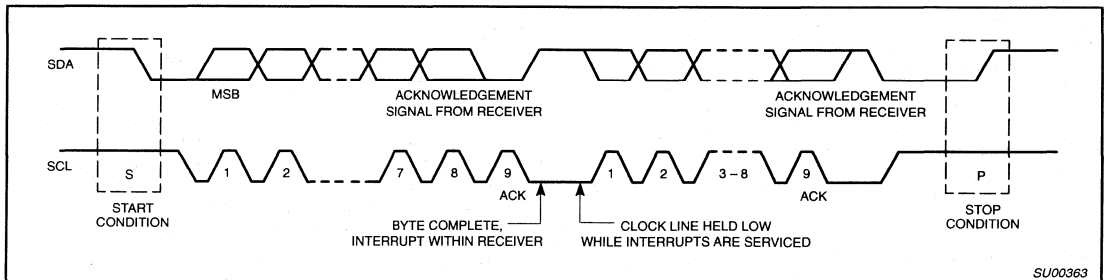

Figure 5. Data Transfer on the I²C Bus

Figure 6. Acknowledge on the I²C Bus

Using the 8XC751 microcontroller as an I²C bus master

AN422

A slave receiver must generate an acknowledge after the reception of each byte, and a master must generate one after the reception of each byte clocked out of the slave transmitter. If a receiving device cannot receive the data byte immediately, it can force the transmitter into a wait state by holding the clock line (SCL) LOW. When designing a system, it is necessary to take into account cases when acknowledge is not received. This happens, for example, when the addressed device is busy in a real time operation. In such a case the master, after an appropriate "time-out", should abort the transfer by generating a Stop condition, allowing other transfers to take place. These "other transfers" could be initiated by other masters in a multimaster system, or by this same master.

There are two exceptions to the "acknowledge after every byte" rule. The first occurs when a master is a receiver: it must signal an end of data to the transmitter by NOT signalling an acknowledge on the last byte that has been clocked out of the slave. The acknowledge related clock, generated by the master should still take place, but the SDA line will not be pulled down. In order to indicate that this is an active and intentional lack of acknowledgement, we shall term this special condition as a "negative acknowledge".

The second exception is that a slave will send a negative acknowledge when it can no longer accept additional data bytes. This occurs after an attempted transfer that cannot be accepted.

The bus design includes special provisions for interfacing to microprocessors which implement all of the I²C communications in software only—it is called "Slow Mode". When all of the devices on the network have built-in I²C hardware support, the Slow Mode is irrelevant.

Addressing and Transfer Formats

Each device on the bus has its own unique address. Before any data is transmitted on the bus, the master transmits on the bus the address of the slave to be accessed for this transaction. A well-behaved slave with a matching address, if it exists on the network, should of course acknowledge the master's addressing. The addressing is done by the first byte transmitted by the master after the Start condition.

An address on the network is seven bits long, appearing as the most significant bits of the address byte. The last bit is a direction (R/W) bit. A zero indicates that the master is transmitting (WRITE) and a one indicates that the master requests data (READ). A complete data

transfer, comprised of an address byte indicating a WRITE and two data bytes is shown in Figure 7.

When an address is sent, each device in the system compares the first seven bits after the Start with its own address. If there is a match, the device will consider itself addressed by the master, and will send an acknowledge. The device could also determine if in this transaction it is assigned the role of a slave receiver or slave transmitter, depending on the R/W bit.

Each node of the I²C network has a unique seven bit address. The address of a microcontroller is of course fully programmable, while peripheral devices usually have fixed and programmable address portions. In addition to the "standard" addressing discussed here, the I²C bus protocol allows for "general call" addressing and interfacing to CBUS devices.

When the master is communicating with one device only, data transfers follow the format of Figure 7, where the R/W bit could indicate either direction. After completing the transfer and issuing a Stop condition, if a master would like to address some other device on the network, it could of course start another transaction, issuing a new Start.

Another way for a master to communicate with several different devices would be by using a "repeated start". After the last byte of the transaction was transferred, including its acknowledge (or negative acknowledge), the master issues another Start, followed by address byte and data—without effecting a Stop. The master may communicate with a number of different devices, combining READS and WRITES. After the last transfer takes place, the master issues a Stop and releases the bus. Possible data formats are demonstrated in Figure 8. Note that the repeated start allows for both change of a slave and a change of direction, without releasing the bus. We shall see later on that the change of direction feature can come in handy even when dealing with a single device.

In a single master system, the repeated start mechanism may be more efficient than terminating each transfer with a Stop and starting again. In a multimaster environment, the determination of which format is more efficient could be more complicated, as when a master is using repeated starts it occupies the bus for a long time and thus preventing other devices from initiating transfers.

AN422

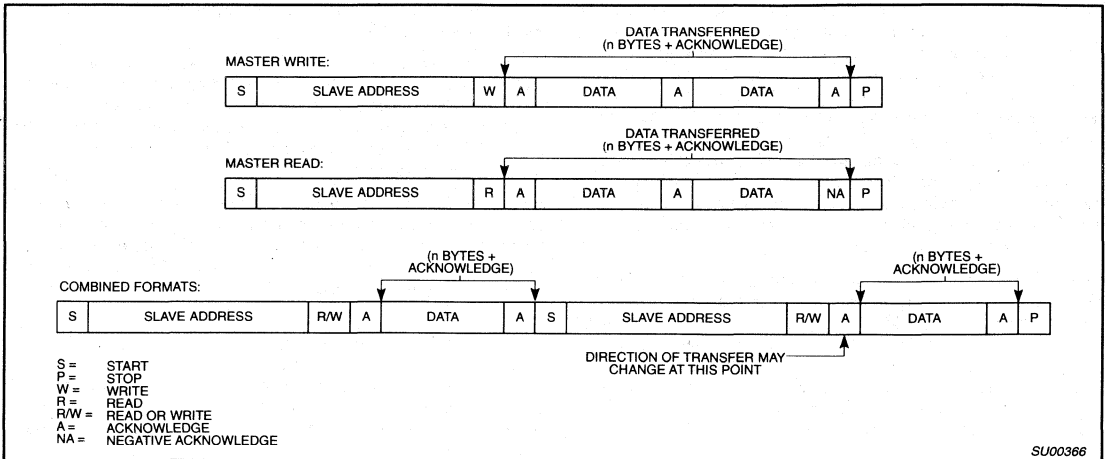

Figure 8. I²C Data Formats

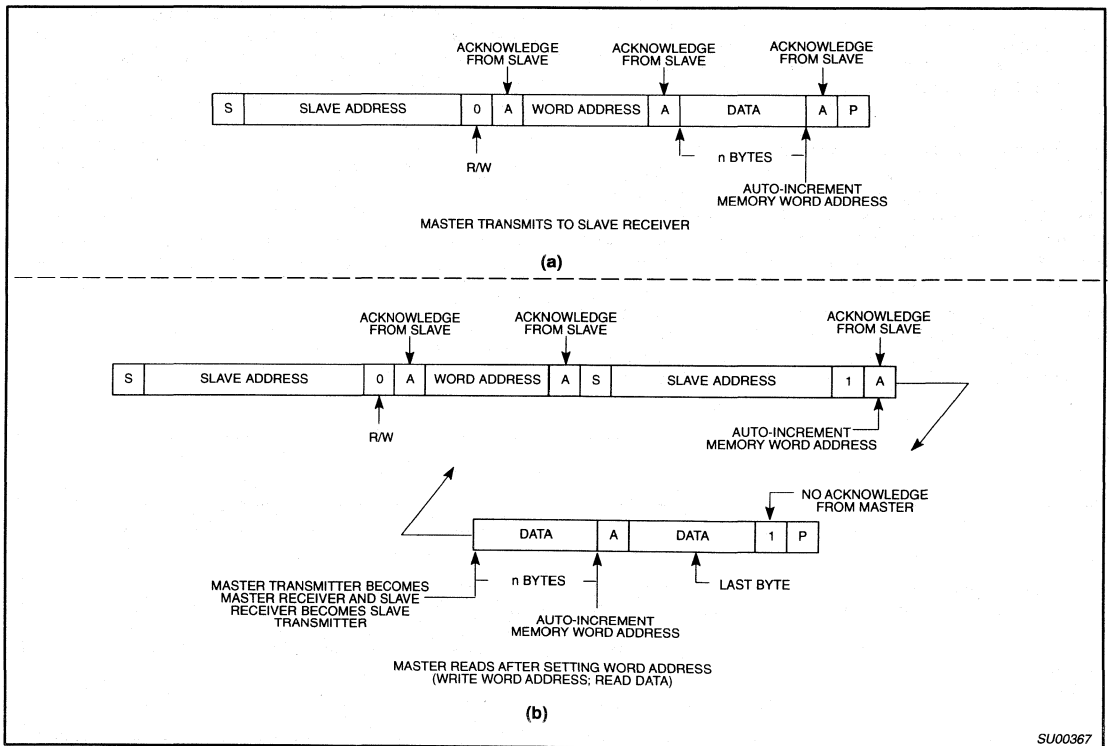

Figure 9. I²C Sub-Address Usage

Using the 8XC751 microcontroller as an I²C bus master

AN422

Use of Sub-Addresses

For some ICs on the I²C bus, the device address alone is not sufficient for effective communications, and a mechanism for addressing the internals of the device is necessary. A typical example when we want to access a specific word inside the device is addressing memories, or a sequence of memory locations starting at a specific internal address.

A typical I²C memory device like the PCF8570 RAM contains a built-in word address register that is incremented automatically after each data byte which is a read or written data byte. When a master communicates with the PCF8570 it must send a sub-address in the byte following the slave address byte. This sub-address is the internal address of the word the master wants to access for a single byte transfer, or the beginning of a sequence of locations for a multi-byte transfer. A sub-address is an 8-bit byte, unlike the device address, it does not contain a direction (R/W) bit, and like any byte transferred on the bus it must be followed by an acknowledge.

A memory write cycle is shown in Figure 9(a). The Start is followed by a slave byte with the direction bit set to WRITE, a sub-address byte, a number of data bytes and a Stop signal. The sub-address is loaded into the word address memory, and the data bytes which follow will be written one after the other starting with the sub-address location, as the register is incremented automatically.

The memory read cycle (see Figure 9(b)) commences in a similar manner, with the master sending a slave address with the direction bit set to WRITE with a following sub-address. Then, in order to reverse the direction of the transfer, the master issues a repeated Start followed again by the memory device address, but this time with the direction bit set to READ. The data bytes starting at the internal sub-address will be clocked out of the device, each followed by a master-generated acknowledge. The last byte of the read cycle will be followed by a negative acknowledge, signalling the end of transfer. The cycle is terminated by a Stop signal.

8XC751 I²C HARDWARE

The on-chip I²C bus hardware support of the 8XC751 allows operation on the bus at full speed, and simplifies the software needed for effective communications on the network. The hardware activates and monitors the SDA and SCL lines, performs the necessary arbitration and framing errors checks, and takes care of clock stretching and synchronization. The hardware support includes a bus time-out timer, called Timer I. The hardware is synchronized to the software either through polled loops or interrupts.

Two of the port 0 pins are multi-functional. When the I²C is active, the pin associated with P0.0 functions as SCL, and the pin associated with P0.1 functions as SDA. These pins have an open drain output.

Two of the five 8XC751 interrupt sources may be used for I²C support. The I²C interrupt is enabled by the EI2 flag of the interrupt enable register, and its service routine should start at address 023h. An I²C interrupt is usually requested (if enabled) when a rising edge of SCL indicates a new data bit on the bus, or a special condition occurs: Start, Stop or arbitration loss. The interrupt is induced by the ATN flag—see below for the conditions for setting this flag. The Timer I overflow interrupt is enabled by the ETI flag, and the service routine starts at 01Bh.

The I²C port is controlled through three special function registers: I²C Control (I2CON), I²C Configuration (I2CFG), and I²C Data (I2DAT). The register addresses are shown in Table 1.

Although the following discussion of the hardware and register details is not complete, it should give a better understanding of the programming examples.

Timer I

In I²C applications, Timer I is dedicated to the port timing generation and bus monitoring. In non-I²C applications, it is available for use as a fixed time base.

In its port timing generation function, Timer I is used to generate SCL, the I²C clock. Timer I is clocked once per machine cycle ($osc/12$), so that the toggle rate of SCL will be some multiple of that rate. Because the 83C751 can be run over a wide range of oscillator frequencies, it is necessary to adjust SCL for the part's oscillator frequency. This allows the I²C bus to be used at its highest transfer rates independent of the oscillator frequency. SCL is adjusted by writing to two bits (CT0 and CT1) in the I2CFG special function register (see Table 2). The inverse of the values in CT0 and CT1 are loaded into the least significant two bit locations of Timer I every time the fourth bit of the timer is toggled. (A value is actually loaded into the least significant three bits, the third bit being 0 unless both CT0 and CT1 are programmed high and in that case the third bit is 1). SCL is then toggled every time the fourth bit of Timer I is toggled. For example: if CT1 = 0 and CT0 = 1 then the least significant three bits of Timer I would be preloaded with 2 (010 binary). Timer I would then count 3, 4, 5, 6, 7, 8 (6 counts or machine cycles). On 8, the fourth bit of Timer I will toggle, SCL will toggle and the 3 least significant bits will again be preloaded with the value 2 (010).

Table 1. I²C Special Function Register Addresses

REGISTER			BIT ADDRESS							
Name	Symbol	Address	MSB						LSB	
I ² C Control	I2CON	98	9F	9E	9D	9C	9B	9A	99	98
I ² C Data	I2DAT	99	-	-	-	-	-	-	-	-
I ² C Configuration	I2CFG	D8	DF	DE	DD	DC	DB	DA	D9	D8

Table 2. CT0, CT1 Timer I Settings

CT1 Values	CT0 Values	Timer I Counts	Oscillator Freq (MHz)
1	0	7	16
0	1	6	15, 14, 13
0	0	5	12, 11
1	1	4	10 or less

Timer I counts = f_{OSC} (MHz) x 0.39 (rounded up to next integer).

Using the 8XC751 microcontroller as an I²C bus master

AN422

For the bus monitoring function, Timer I is used as a "watchdog timer" for bus hang-ups. It creates an interrupt when the SCL line stays in one state for an extended period of time while the bus is active (between a Start condition and a following Stop condition). SCL "stuck low" indicates a faulty master or slave. SCL "stuck high" may mean a faulty device, or that noise induced onto the I²C caused all masters to withdraw from the I²C arbitration.

The time-out interval of Timer I is fixed (cannot be set): it carries out and interrupts (if enabled) when about 1024 machine cycles have elapsed since a change on SCL within a frame. In other words, whenever I²C is active and Timer I is enabled, the falling edge of SCL will reset Timer I. If SCL is not toggled low for 1024 machine cycles, Timer I will overflow and cause an interrupt. (Note: we wrote "about 1024 machine cycles" although for the sake of accuracy—this number is affected by the setting of the CT0 and CT1 bits mentioned above and may vary by up to three machine cycles) The exact number of cycles for a time-out is not critical; what is important is that it indicates SCL is stuck.

In addition to the interrupt, upon Timer I overflow the I²C port hardware is reset. This is useful for multiple master systems in situations where a bus fault might cause the bus to hang-up due to a lack of software response. When this happens, SCL will be released, and I²C operation between other devices can continue.

I²CON Register

The I²C control register (I2CON) can be written to (see Figure 10). When writing to the I2CON register, one should use bit masks as demonstrated in the example program. Trying to clear or set the bits in the register using the bit addressing capabilities of the 8XC751 may lead to undesirable results. The reason is that a command like CLR reads the register, sets the bit and writes it back, and the write-back may affect other bits.

I2CFG Register

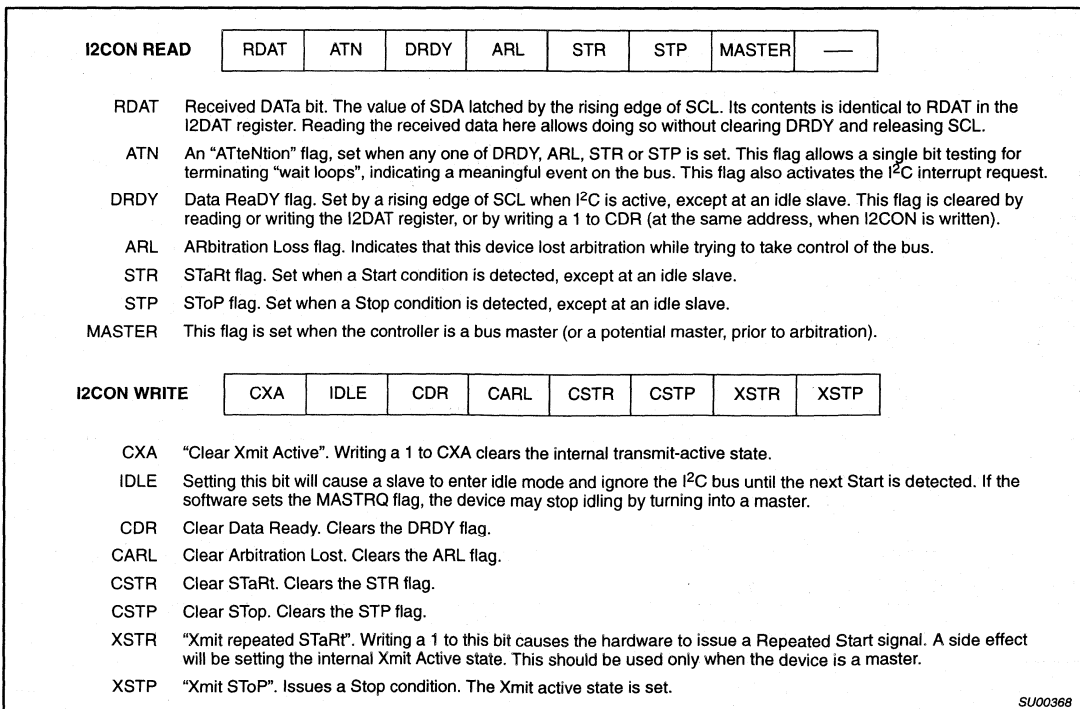

The configuration register (I2CFG) is a read/write register (see Figure 11).

I2DAT Register

The I²C data register (I2DAT) is a read/write register, where the MSB represents the data received or data to be sent. The other seven bits are read as 0 (see Figure 12).

Transmit Active State

The transmit active state—Xmit Active—is an internal state in the I²C interface that is affected by the I²C registers as explained above. The I²C interface will only drive the SDA line low when Xmit Active is set. Xmit Active is set by writing the I2DAT register, or by writing I2CON with XSTR = 1 or XSTP = 1. The ARL bit will be set to 1 only when Xmit Active is set—in such a case Xmit Active will be automatically reset upon arbitration loss. Xmit Active is cleared by writing 1 to CXA at I2CON register or by reading the I2DAT register.

PROGRAMMING EXAMPLE

The listing demonstrates communications routines for the 8XC751 as an I²C bus master in a single-master system.

The single-master system is less complicated than a multimaster environment. The programmer does not have to worry about switching between master and slave roles, or the consequences of an arbitration loss.

The I²C interrupt is not used, and therefore disabled. There is no need for frame Start interrupts, as this processor is the only bus master and all data transfers are initiated by it when the appropriate routines are called by the application. No one else generates frame Starts which could be an interrupt source in a multimaster system. Within the frames we monitor bus activity with a wait-loop which polls the ATN flag. As we expect the bus to operate in its full-speed mode, we can assume that only a small amount of time will be wasted in those loops, and the use of interrupts would be less efficient.

The 8XC751 has single-bit I²C hardware interface, where the registers may directly affect the levels on the bus and the software interacting with the register takes part in the protocol implementation. The hardware and the low-level routines dealing with the registers are tightly coupled. Therefore, one should take extra care if trying to modify these lower level routines.

The beginning of the program, at address 0, contains the reset vector, where the microcontroller begins executing code after a hardware reset. In this case, the code simply jumps to the main part of the program, which begins at the label 'Reset' near the end of the listing.

The main program is a simple demonstration of the I²C routines which comprise the balance of the listing. It first enables the Timer 1 interrupt, and sets up some sample data to be transmitted. Beginning at the label MainLoop, the program then proceeds to transmit one byte of data to a slave device at address 48 hexadecimal, using the routine titled 'SendData'. In our demonstration hardware, this address corresponds to an 8-bit I/O port that drives eight monitor LEDs. The program then reads back one byte of data from the same port using the routine 'RcvData'. The SendData and RcvData routines can send or receive multiple bytes of data, the number of which is determined by the variable 'ByteCnt'.

Upon return from both SendData and RcvData, the program checks the system flag named 'Retry' to see if the transfer was completed correctly. If not, it loops back and attempts the same transfer again.

Next, the program sends four bytes of data to a 256-byte EEPROM device, an 8-pin part called the PCF8582. The routine 'SendSub' is used for this purpose. The EEPROM was located at address A0 hexadecimal on our board. This device uses the sub-addressing feature to select a starting location to address in the EEPROM array. When data is written to the EEPROM, the address is automatically incremented so that the data bytes are stored in consecutive locations.

Finally the program reads back four bytes of data from the EEPROM using the routine 'RcvSub'. Calls to SendSub and RcvSub should also be followed by a test of the Retry flag to insure that all went according to plan.

Using the 8XC751 microcontroller as an I²C bus master

AN422

This entire process is repeated indefinitely by jumping back to MainLoop.

Back at the beginning of the program, the next location after the reset vector is the Timer 1 interrupt service routine. The microcontroller will go to address 1B hexadecimal if Timer 1 overflows. This routine stops the timer, clears the timer interrupt, clears the pending interrupt so that other interrupts will be enabled, restores the stack pointer, and jumps to the 'Recover' routine to try to correct whatever stopped the I²C bus and allowed Timer 1 to overflow.

Next in the listing come the main I²C service routines. These are the routines SendData, RcvData, SendSub, and RcvSub that were called from the main program. Both of the send routines use the data area labeled 'XmtDat' as the transmit data buffer. In this sample program, four bytes were reserved for this area, but it could be larger or smaller depending on the application. The two receive routines use another four byte buffer labeled 'RcvDat' to store received data. All of these routines use the variables 'SlvAdr' and 'ByteCnt' to determine the slave address and the number of bytes to be sent or received, respectively. The SendSub and RcvSub routines use the variable 'SubAdr' as the sub-address to send to the slave device.

Following the main I²C service routines in the listing are the subroutines that are called by the main routines to deal intimately with the I²C hardware.

The 'SendAddr' subroutine requests mastership of the I²C bus and calls the routine 'XmitAddr' to complete sending the slave address. The bulk of the XmitAddr routine is shared with the 'XmitByte' subroutine which sends data bytes on the I²C bus. XmitByte is also used to send I²C sub-addresses. Both subroutines check for an acknowledge from the slave device after every byte is sent on the I²C bus.

The next subroutine 'RDACK' calls the 'RcvByte' routine to read in a byte of data. It then sends an acknowledge to the slave device. RDACK is used to receive all data except for the last byte of a receive data frame, where the acknowledge is omitted by the bus master. The RcvByte subroutine is called directly for the last byte of a frame.

The 'SendStop' subroutine causes a stop condition on the I²C, thus ending a frame. The 'RepStart' subroutine sends a repeated start condition on the I²C bus, to allow the master to start a new frame without first having to send an intervening stop.

The lower level subroutines deal directly with the hardware. The tight coupling between hardware and software is best demonstrated by the

following explanations, relating to two cases in which the code is not self evident.

Sending the Address

When sending the address byte in the Send Addr subroutine, the first bit is written to I2DAT prior to the loop where the other seven bits are sent (SendAd2). The reason is that we need to clear the Start condition in order to release the SCL line, and this is done explicitly by the subsequent command. When SCL is released, the correct bit (MSB of address) must already be in I2DAT.

Capturing the Received Data

Typically, a program receiving data waits in a loop for ATN, and when detected, checks DRDY. If DRDY = 1 then there was a rising SCL, and the new data can be read from RDAT in I2CON or I2DAT. Reading or writing I2DAT clears DRDY, thus releasing SCL.

When reading the last bit in a byte, it should be read from I2CON, and not I2DAT (see the end of the RcvByte routine). This way the Data Ready (DRDY) flag is not cleared, and the low period on SCL is stretched. The reason for doing so is that upon reception of the last bit of a received byte the master must react with an acknowledge. In order to ensure that we "wait" with the acknowledge clock (release of SCL) until the acknowledge level is issued on SDA, the last bit is read out of I2CON and not I2DAT. SCL is stretched low until the acknowledge level is written into I2DAT by the software.

Bus Faults and Other Exceptions

Bus exceptions are detected either by Timer 1 time-out, or "illegal" logic states tested for and detected by the software. Upon Timer 1 time-out, a bus recovery is attempted by the Recover routine. The final section of the listing is this 'Recover' routine. Its job is to try to restore control of the I²C bus to the main program. First, the subroutine 'FixBus' is called. It checks to see if only the SDA line is 'stuck', and if so, tries to correct it by sending some extra clocks on the SCL line, and forcing a stop condition on the bus. If this does not work, another subroutine 'BusReset' is called. This generally happens when a severe bus error occurs, such as a shorted clock line. The philosophy used in this code is that the only chance of recovering from a severe error is to cause a reset of the I²C hardware by deliberately forcing Timer 1 to time out. This method allows recovery from a temporary short or other serious condition on the I²C bus.

Interfacing the PCF8584 I²C-bus controller to 80C51 family microcontrollers

AN425

DESCRIPTION

This application note shows how to use the PCF8584 I²C-bus controller with 80C51 family microcontrollers. One typical way of connecting the PCF8584 to an 80C31 is shown. Some basic software routines are described showing how to transmit and receive bytes in a single master system. An example is given of how to use these routines in an application that makes use of the I²C circuits on an I²C demonstration board.

The PCF8584 is used to interface between parallel microprocessor or microcontroller buses and the serial I²C bus. For a description of the I²C bus protocol refer to the I²C bus specification which is printed in the microcontroller user guide.

The PCF8584 controls the transmission and reception of data on the I²C bus, arbitration, clock speeds and transmission and reception of data on the parallel bus. The parallel bus is compatible with 80C51, 68000, 8085 and Z80 buses. Communication with the I²C-bus can be done on an interrupt or polled basis. This application note focuses on interfacing with 8051 microcontrollers in single master systems.

PCF8584

In Figure 1, a block diagram is shown of the PCF8584. Basically it consists of an I²C-interface similar to the one used in 84Cxx family microcontrollers, and a control block for interfacing to the microcontroller.

The control block can automatically determine whether the control signals are from 80xx or 68xxx type of microcontrollers.

This is determined after the first write action from the microcontroller to the PCF8584. The control block also contains a programmable divider which allows the selection of different PCF8584 and I²C clocks.

The I²C interface contains several registers which can be written and read by the microcontroller.

S1 is the control/status register. This register is accessed while the A0 input is 1. The meaning of the bits depends on whether the register is written to or read from. When used as a single master system the following bits are important:

PIN: Interrupt bit. This bit is made active when a byte is sent/received to/from the I²C-bus. When ENI is made active, PIN also controls the external INT line to interrupt the microcontroller.

ES0-ES2: These bits are used as pointer for addressing S0, S0', S2 and S3. Setting ES0 also enables the Serial I/O.

ENI: Enable Interrupt bit. Setting this bit enables the generation of interrupts on the INT line.

STA, STO: These bits allow the generation of START or STOP conditions.

ACK: With this bit set and the PCF8584 is in master/receiver mode, no acknowledge is generated by the PCF8584. The slave/transmitter now knows that no more data must be sent to the I²C-bus.

BER: This bit may be read to check if bus errors have occurred.

BB: This bit may be read to check whether the bus is free for I²C-bus transmission.

S2 is the clock register. It is addressed when A0 = 0 and ES0-ES2 = 010 in the previous write cycle to S1. With the bits S24-S20 it is possible to select 5 input clock frequencies and 4 I²C clock frequencies.

S3 is the interrupt vector register. It is addressed when A0 = 0 and ES0-ES2 = 001 in the previous write cycle to S1. This register is not used when an 80C51 family microcontroller is used. An 80C51 microcontroller has fixed interrupt vector addresses.

S0' is the own address register. It is addressed when A0 = 0 and ES0-ES2 = 000. This register contains the slave address of the PCF8584. In the single master system described here, this register has no functional use. However, by writing a value to S0', the PCF8584 determines whether an 80Cxx or 68xxx type microcontroller is the controlling microcontroller by looking at the CS and WR lines. So independent of whether the PCF8584 is used as master or slave, the microcontroller should always first write a value to S0' after reset.

S0 is the I²C data register. It is addressed when A0 = 0 and ES0-ES2 = 1x0. Transmission of a byte on the I²C bus is done by writing this byte to S0. When the transmission is finished, the PIN bit in S1 is reset and if ENI is set, an interrupt will be generated. Reception of a byte is signaled by resetting PIN and by generating an interrupt if ENI is set. The received byte can be read from S0.

The SDA and SCL lines have no protection diodes to V_{DD}. This is important for multimaster systems. A system with a PCF8584 can now be switched off without causing the I²C-bus to hang-up. Other masters still can use the bus.

For more information of the PCF8584 refer to the data sheet.

PCF8584/8031 Hardware Interface

Figure 2 shows a minimum system with an 8051 family controller and a PCF8584. In this example, an 80C31 is used. However any 80C51 family controller with external addressing capability can be used.

The software resides in EPROM U3. For addressing this device, latch U2 is necessary to demultiplex the lower address bits from the data bits. The PCF8584 is mapped in the external data memory area. It is selected when A1 = 0. Because in this example no external RAM or other mapped peripherals are used, no extra address decoding components are necessary. A0 is used by the PCF8584 for proper register selection in the PCF8584.

U5A is an inverter with Schmitt trigger input and is used to buffer the oscillator signal of the microcontroller. Without buffering, the rise and fall time specifications of the CLK signal are not met. It is also important that the CLK signal has a duty cycle of 50%. If this is not possible with certain resonators or microcontrollers, then an extra flip-flop may be necessary to obtain the correct duty cycle.

U5C and U5D are used to generate the proper reset signals for the microcontroller and the PCF8584.

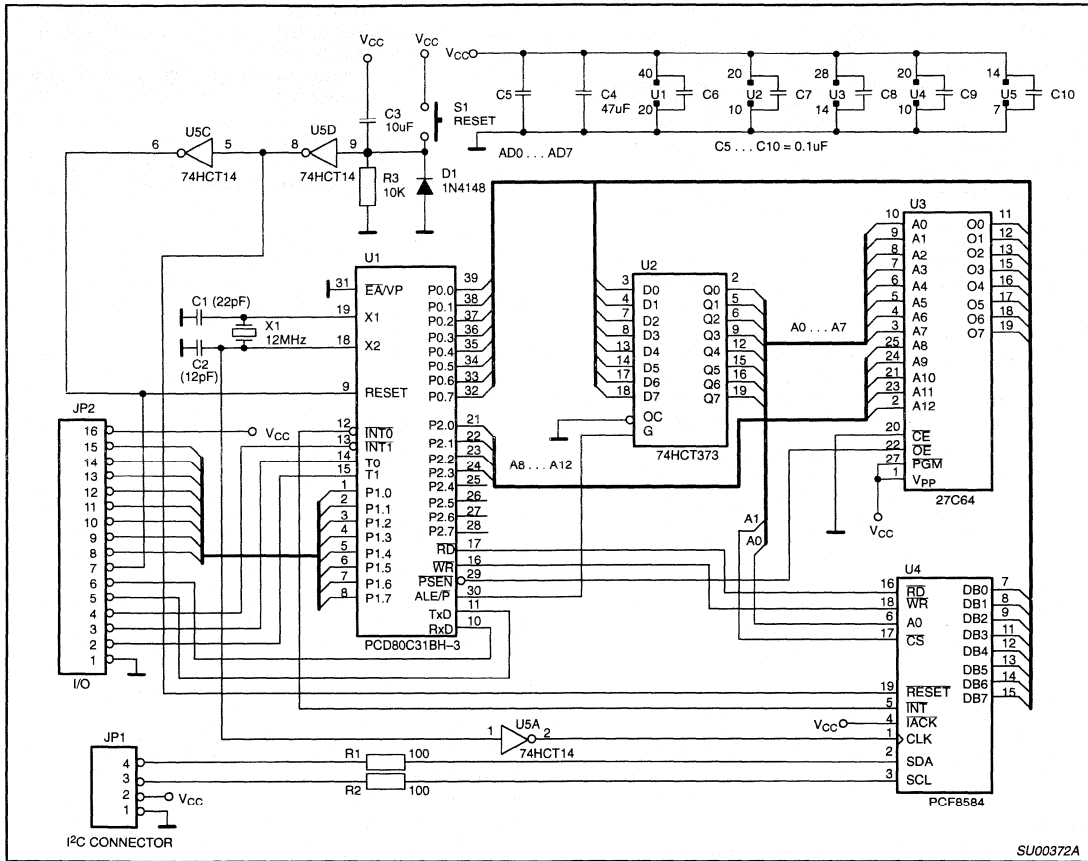

Figure 2. PCF8584 to 80C31 Interface

Basic PCF8584/8031 Driver Routines

In the listing section (page 4-25), some basic routines are shown. The routines are divided in two modules. The module ROUTINE contains the driver routines and initialization of the PCF8584. The module INTERR contains the interrupt handler. These modules may be linked to a module with the user program that uses the routines in INTERR and ROUTINE. In this application note, this module will be called USER. A description of ROUTINE and INTERR follows.

Module ROUTINE

Routine Sendbyte (Lines 17-20)—

This routine sends the contents of the accumulator to the PCF8584. The address is such that A0 = 0. Which register is accessed depends on the contents of ES0-ES2 of the control register. The address of the PCF8584 is in variable 'PCF8584'. This must have been previously defined in the user program. The DPTR is used as a pointer for addressing the peripheral. If the address is less than 255, then R0 or R1 may be used as the address pointer.

Routine Sendcontr (Lines 25, 26)—

This routine is similar to Sendbyte, except that now A0 = 1. This

means that the contents of the accumulator are sent to the control register S1 in the PCF8584.

Routine Readbyte (Lines 30-33)—

This routine reads a register in the PCF8584 with A0 = 0. Which register depends on ES0-ES2 of the control register. The result of the read operation is returned in the accumulator.

Routine Readcontr (Lines 37-39)—

This routine is similar to Readbyte, except that now A0 = 1. This means that the accumulator will contain the value of status register S1 of the PCF8584.

Routine Start Lines (44-56)—

This routine generates a START-condition and the slave address with a R/W bit. In line 44, the variable IIC_CNT is reset. This variable is used as a byte counter to keep track of the number of bytes that are received or transmitted. IIC_CNT is defined in module INTERR.

Lines 45-46 increment the variable NR_BYTES if the PCF8584 must receive data. NR_BYTES is a variable that indicates how many bytes have to be received or transmitted. It must be given the correct value in the USER module. Receiving or transmitting is

Interfacing the PCF8584 I²C-bus controller to 80C51 family microcontrollers

AN425

distinguished by the value of the DIR bit. This must also be given the correct value in the USER module.

Then the status register of PCF8584 must be read to check if the I²C bus is free. First the status register must be addressed by giving ES0-ES2 of the control register the correct value (lines 47-48). Then the Bus Busy bit is tested until the bus is free (lines 49-50). If this is the case, the slave address is sent to data register S0 and the I²C_END bit is cleared (lines 51-53). The slave address is set by the user program in variable USER. The LSB of the slave address is the R/W bit. I²C_END can be tested by the user program whether an I²C reception/transmission is in progress or not.

Next the START condition will be generated and interrupt generation enabled by setting the appropriate bits in control register S1 (lines 54-55).

Now the routine will return back to the user program and other tasks may be performed. When the START condition, slave address and R/W bit are sent, and the ACK is received, the PCF8584 will generate an interrupt. The interrupt routine will determine if more bytes have to be received or transmitted.

Routine Stop (Lines 59-62) —

Calling this routine, a STOP condition will be sent to the I²C bus. This is done by sending the correct value to control register S1 (lines 59-61). After this the I²C_END bit is set, to indicate to the user program that a complete I²C sequence has been received or transmitted.

Routine I²C_Init (Lines 65-76)—

This routine initializes the PCF8584. This must be done directly after reset. Lines 67-70 write data to 'own address' register S0'. First the correct address of S0' is set in control register S1 (lines 67-68), then the correct value is written to it (lines 69-70). The value for S0' is in variable SLAVE_ADR and set by the user program. As noted previously, register S0' must always be the first register to be accessed after reset, because the PCF8584 now determines whether an 80Cxxx or 68xxx microcontroller is connected. Lines 72-76 set the clock register S2. The variable I²C_CLOCK is also set by the user program.

Module INTERR

This module contains the I²C interrupt routine. This routine is called every time a byte is received or transmitted on the I²C bus. In lines 12-15 RAM space for variables is reserved.

BASE is the start address in the internal 80C51 RAM where the data is stored that is received, or where the data is stored that has to be transmitted.

NR_BYTES, IIC_CNT and SLAVE were explained earlier. I²C_END and DIR are flags that are used in the program. I²C_END indicates whether an I²C transmission or reception is in progress. DIR indicates whether the PCF8584 has to receive or transmit bytes. The interrupt routine makes use of register bank 1.

The transmission part of the routine starts at line 42. In lines 42-43, a check is made whether IIC_CNT = NR_BYTES. If true, all bytes are sent and a STOP condition may be generated (lines 44-45).

Next the pointer for the internal RAM is restored (line 46) and the byte to be transmitted is fetched from the internal RAM (line 47). Then this byte is sent to the PCF8584 and the variables are updated (lines 47-49). The interrupt routine is left and the user program may proceed. The receive part starts from line 55. First a check is made if the next byte to be received is the last byte (lines 56-59). If true the ACK must be disabled when the last byte is received. This is accomplished by resetting the ACK bit in the control register S1 (lines 60-61).

Next the received byte may be read (line 62) from data register S0. The byte will be temporary stored in R4 (line 63). Then a check is made if this interrupt was the first after a START condition. If so, the byte read has no meaning and the interrupt routine will be left (lines 68-70). However by reading the data register S0 the next read cycle is started.

If valid data is received, it will be stored in the internal RAM addressed by the value of BASE (lines 71-73). Finally a check is made if all bytes are received. If true, a STOP condition will be sent (lines 75-78).

EXAMPLES

In the listing section (starting on page 4-29), some examples are shown that make use of the routines described before. The examples are transmission of a sequence, reception of I²C data and an example that combines both.

The first example sends bytes to the PCD8577 LCD driver on the OM1016 demonstration board. Lines 7 to 10 define the interface with the other modules and should be included in every user program. Lines 14 to 16 define the segments in the user module. It is completely up to the user how to organize this.

Lines 24 and 28 are the reset and interrupt vectors. The actual user program starts at line 33. Here three variables are defined that are used in the I²C driver routines. Note that PCF8584 must be an even address, otherwise the wrong internal registers will be accessed! Lines 37-42 initialize the interrupt logic of the microcontroller. Next the PCF8584 will be initialized (line 45).

The PCF8584 is now ready to transmit data. A table is made in the routine at line 61. For the PCD8577, the data is a control byte and the segment data. Note that the table does not contain the slave address of the LCD driver. In lines 51-54, variables are made ready to start the transmission. This consists of defining the direction of the transmission (DIR), the address where the data table starts (BASE), the number of bytes to transmit (NR_BYTES, without slave address!) and the slave address (SLAVE) of the I²C peripheral that has to be accessed.

In line 55 the transmission is started. Once the I²C transmission is started, the user program can do other tasks because the transmission works on interrupts. In this example a loop is performed (line 58). The user can check the end of the transmission during the other tasks, by testing the I²C_END bit regularly.

The second example program receives 2 bytes from the PCF8574P I/O expander on the OM1016 demonstration board. Until line 45 the program is identical to the transmit routine because it consists of initialization and variable definition. From line 48, the variables are set for I²C reception. The received bytes are stored in RAM area from label TABLE. During reception, the user program can do other tasks. By testing the I²C_END bit the user can determine when to start processing the data in the TABLE.

The third example program displays time from the PCF8583P clock/calendar/RAM on the LCD display driven by the PCD8577. The LED display (driven by SAA1064) shows the value of the analog inputs of the A/D converter PCF8591. The four analog inputs are scanned consecutively.

In this example, both transmit and receive sequences are implemented as shown in the previous examples. The main clock part is from lines 62-128. This contains the calls to the I²C routines. From lines 135-160, routines are shown that prepare the data to be transmitted. Lines 171 to 232 are the main program for the A/D converter and LED display. Lines 239 to 340 contain routines used by the main program. This demo program can also be used with the I²C peripherals on the OM1016 demonstration board.

Using the 8XC751/752 in multimaster I²C applications

AN430

INTRODUCTION

The Philips Semiconductors 83C751/87C751 offers the advantages of the 80C51 architecture in a small package and at a low cost. It combines the benefits of a high performance microcontroller with on-board hardware supporting the Inter Integrated Circuit (I²C) bus interface.

The Inter IC (I²C) bus developed by Philips allows integrated circuits to communicate directly with each other via a simple bidirectional 2-wire bus. The comprehensive family of CMOS and bipolar ICs incorporating the on-chip I²C interface offers many advantages to designers of digital control for industrial, consumer and telecommunications equipment.

Interfacing the devices in an I²C based system is very simple as they connect directly to the two bus lines: a serial data line (SDA) and a serial clock line (SCL). System design can rapidly progress from block diagram to final schematics, as there is no need to design bus interfaces. In addition, functional blocks on the block diagram correspond to actual ICs. A prototype system or a final product version can be easily modified or upgraded by 'clipping' or 'unclipping' ICs to or from the bus. The simplicity of designing with the I²C bus does not reduce its effectiveness: it is a reliable, multimaster bus with integrated addressing and data-transfer protocols. The I²C-bus compatible ICs give cost reduction benefits through smaller IC packages and a minimization of PCB traces and glue logic.

The availability of microcontrollers, like the 83C751, with on-board I²C interface is a very powerful tool for system designers. The integrated protocols allow systems to be completely software defined. Software development time of different products can be reduced by assembling a library of re-usable software modules. In addition, the multimaster capability allows rapid testing and alignment of end-products via external connections to an assembly-line computer.

The mask programmable 83C751 and its EPROM version, 87C751, can operate as a master or a slave device on the I²C small area network. In addition to the efficient interface to the dedicated

function ICs in the I²C family the on-board interface facilitates I/O and RAM expansion, access to EEPROM, and processor-to-processor communications.

The 83C752 and its EPROM version, 87C752, are essentially the 83C751/87C751 with the addition of a five channel multiplexed 8-bit A/D converter and an 8-bit PWM output. As the I²C bus interface is identical, the programming example and the discussion relates to both processors. The multimaster capability of the I²C bus allows easy integration and expansion of relatively complex systems, in which different devices can independently initiate data transfers. Integration of a multimaster system is easy as a Master on the bus does not have to coordinate its data transfer with other potential Master devices—arbitration and synchronization are taken care of by the hardware and bus protocols. Expanding a system with a new device is trivial—it is "clipped" onto the two serial bus lines, and the new device may act as a Master without any modification to the other devices (see Figure 1). Microcontrollers like the 8XC751/752 on the I²C bus are extremely powerful, as they can be programmed to be both Masters and Slaves in the same system. This way the microcontroller may initiate communication on the bus, and when requested, will respond to a data transfer request by another device.

In this Application Note we shall discuss the most important technical features of the I²C bus and describe the special I²C hardware interface of the 8XC751/752. We shall demonstrate with an example how the microcontroller can be programmed for a multimaster environment. The communications routines of the example are quite general, and can be ported to many applications—so we shall discuss in detail the software interface to these routines.

The description of the 8XC751 I²C interface hardware and part of the general discussion of the I²C bus is similar to Application Note AN422 which dealt with the microcontroller in a single-master environment. Most of the added discussions relate to the multimaster aspects of the bus. Additional information for the I²C bus and the 83C751/752 Microcontroller can be found in the Philips Semiconductors Microcontroller Data Handbook (IC20).

SU00386

THE I²C BUS

The two lines of the I²C bus are a serial data line (SDA) and a serial clock line (SCL). A typical system configuration is shown in Figure 2. Each device is recognized by a unique address—whether it is a microcomputer, LCD driver, memory or keyboard interface—and can operate as either a transmitter or a receiver, depending on the function of the device. A device generating a message or data is a transmitter, and a device receiving the message or data is a receiver. Obviously, a passive function like an LCD driver could only be a receiver, while a microcontroller or a memory can both transmit and receive data.

Every device connected to the bus must have an open-drain or an open-collector output for both the data (SDA) and the clock (SCL) lines. Each one of the lines is connected to the positive supply via a common pull-up resistor (see Figure 2). This implements a wired-AND function, and each of the bus lines which will have the HIGH level only if all the output transistors tied to it are switched off.

Data on the I²C bus can be transferred at a rate up to 100kbit/s. The number of devices connected to the bus is limited only by the maximum bus capacitance of 400pF. As different technology devices can be connected to the I²C bus, the levels of the logical 0 (Low) and logical 1 (High) are not fixed and depend on the appropriate level of V_{DD}.

MASTERS AND SLAVES

When a data transfer takes place on the bus, a device can be either a master or a slave. The device which initiates the transfer, and generates the clock signals for this transfer is the master. At that time any device addressed is considered a slave. It is important to note that a master could be either a transmitter or a receiver: a master microcontroller may send data to a RAM acting as a transmitter, and then interrogate the RAM for its contents acting as a receiver—in both cases being the master initiating the transfer. In the same manner, a slave could be both a receiver and a transmitter.

The I²C is a multimaster bus. It is possible to have in one system more than one device capable of initiating transfers and controlling the bus. A microcontroller may act as a master for one transfer, and

then be the slave for another transfer, initiated by another processor on the network. The master/slave relationships on the bus are not permanent, and exist per transfer.

As more than one master may be connected to the bus it is possible that two devices will try to initiate transfer at the same time. Obviously, in order to eliminate bus collisions and communications chaos, an arbitration procedure is necessary. The I²C design has an inherent arbitration and clock synchronization procedure relying on the wired-AND connection of the devices on the bus. In a typical multimaster system, a microcontroller program should allow it to gracefully switch between master and slave modes and preserve data integrity upon loss of arbitration.

DATA TRANSFERS

One data bit is transferred during each clock pulse (Figure 3). The data on the SDA line must remain stable during the HIGH period of the clock pulse in order to be valid. Changes in the data line at this time will be interpreted as control signals. A HIGH-to-LOW transition of the data line (SDA) while the clock signal (SCL) is HIGH indicates a Start condition, and a LOW-to-HIGH transition of the SDA while SCL is HIGH defines a Stop condition (Figure 4). The bus is considered to be busy after the Start condition and free again a certain time after the Stop condition. The Start and Stop conditions are always generated by the master.

The number of data bytes transferred between the Start and Stop condition from transmitter to receiver is not limited. Each byte, which must be eight bits long, is transferred serially with the most significant bit first, and is followed by an acknowledge bit (Figure 5). The clock pulse related to the acknowledge bit is generated by the master. The device that acknowledges has to pull down the SDA line during the acknowledge clock pulse, while the transmitting device releases the SDA line (HIGH) during this pulse (Figure 6).

A slave receiver must generate an acknowledge after the reception of each byte, and a master must generate one after the reception of each byte clocked out of the slave transmitter. If a receiving device cannot receive the data byte immediately, it can force the transmitter into a wait state by holding the clock line (SCL) LOW. When designing a system it is necessary to take into account cases when

Using the 8XC751/752 in multimaster I²C applications

AN430

acknowledge is not received. This happens, for example, when the addressed device is busy in a real time operation. In such a case the master, after an appropriate "time-out", should abort the transfer by generating a Stop condition, allowing other transfers to take place. These "other transfers" could be initiated by other masters in a multimaster system or by this same master.

An exception to the "acknowledge after every byte" rule occurs when a master is a receiver: it must signal an end of data to the transmitter by NOT signalling an acknowledge on the last byte that has been clocked out of the slave. The acknowledge related clock, generated by the master, should still take place but the SDA line will not be pulled down. In order to indicate that this is an active and intentional lack of acknowledgement, we shall term this special condition as a "Negative ACK".

The bus design includes special provisions for interfacing to microprocessors which implement all the I²C communications in software only—it is called "Slow Mode". When all the devices on the network have built-in I²C hardware support the Slow Mode is irrelevant.

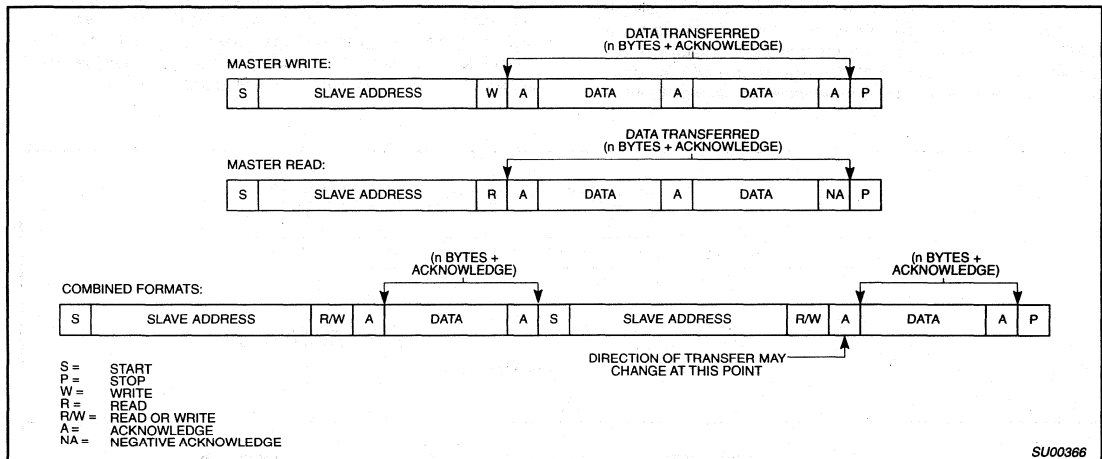

Figure 8. I²C Data Formats

ADDRESSING AND TRANSFER FORMATS

Each device on the bus has its own unique address. Before any data is transmitted on the bus, the master transmits on the bus the address of the slave of this transaction. A well-behaved slave, if it exists on the network, should of course acknowledge the master's addressing. The addressing is done with the first byte transmitted by the master after the Start condition.

An address on the network is seven bits long, appearing as the most significant bits of the address byte. The last bit is a direction (R/W) bit. A zero indicates that the master is transmitting (WRITE) and a one indicates that the master requests data (READ). A complete data transfer, comprised of an address byte indicating a WRITE and two data bytes is shown in Figure 7.

When an address is sent, each device in the system compares the first seven bits after the Start with its own address. If there is a match, the device will consider itself addressed by the master and will send an acknowledge. The device could also determine if in this transaction it is assigned the role of a slave receiver or slave transmitter, depending on the R/W bit.

Each node of the I²C network has a unique seven bit address. The address of a microcontroller is, of course, fully programmable, while peripheral devices usually have fixed and programmable address

portions. In addition to the "standard" addressing discussed here, the I²C bus protocol allows for "general call" addressing and interfacing to CBUS devices.

When the master is communicating with one device only, data transfers follow the format of Figure 8 where the R/W bit could indicate either direction. After completing the transfer and issuing a Stop condition, if a master would like to address some other device on the network, it could start another transaction by issuing a new Start.

Another way for a master to communicate with several different devices would be by using a "repeated start". After the last byte of the transaction was transferred, including its acknowledge (or Negative ACK), the master issues again a Start, followed by address byte and data, without effecting a Stop. The master may communicate with a number of different devices, combining READS and WRITES. Only after the transfer with the last slave took place, the master issues a Stop and releases the bus. Possible data formats are demonstrated in Figure 8. Note that the repeated start allows for both change of a slave and a change of direction, without releasing the bus. We shall see later on that the change of direction feature can come in handy even when dealing with a single device.

Using the 8XC751/752 in multimaster I²C applications

AN430

In a single master system the repeated start mechanism is more efficient than terminating each transfer with a Stop and starting again. In a multimaster environment the determination of which format is more efficient could be more complicated, as when a master is using repeated starts it occupies the bus for a long time and prevents other devices from initiating transfers.

USE OF SUB-ADDRESSES

For some ICs on the I²C bus the device address alone is not sufficient for effective communications and a mechanism for addressing the internals of the device is necessary. A typical example is addressing memories, when we want to access a specific word inside the device or a sequence of memory locations starting at a specific internal address.

A typical I²C memory device like the PCF8570 RAM contains a built-in word address register that is incremented automatically after each read or written data byte. When a master communicates with the PCF8570 it must send a sub-address in the byte following the slave address byte. This sub-address is the internal address of the word the master wants to access for a single byte transfer or the

beginning of a sequence of locations for a multi-byte transfer. A sub-address is an eight bit byte, unlike the device address it does not contain a direction (R/W) bit, and like any byte transferred on the bus it must be followed by an acknowledge.

A memory write cycle is shown in Figure 9(a). The Start is followed by a slave byte with the direction bit set to WRITE, a sub-address byte, a number of data bytes and a Stop signal. The sub-address is loaded into the word address memory. The data bytes which follow will be written one after the other starting with the sub-address location and the register is incremented automatically.

The memory read cycle (Figure 9(b)) commences in a similar manner with the master sending a slave address with the direction bit set to WRITE with a following sub-address. Then, in order to reverse the direction of the transfer, the master issues a repeated Start followed again by the memory device address, but this time with the direction bit set to READ. The data bytes starting at the internal sub-address will be clocked out of the device with each followed by a master-generated acknowledge. The last byte of the read cycle will be followed by a Negative ACK, signalling the end of transfer. The cycle is terminated by a Stop signal.

Figure 10. Clock Synchronization During the Arbitration Procedure

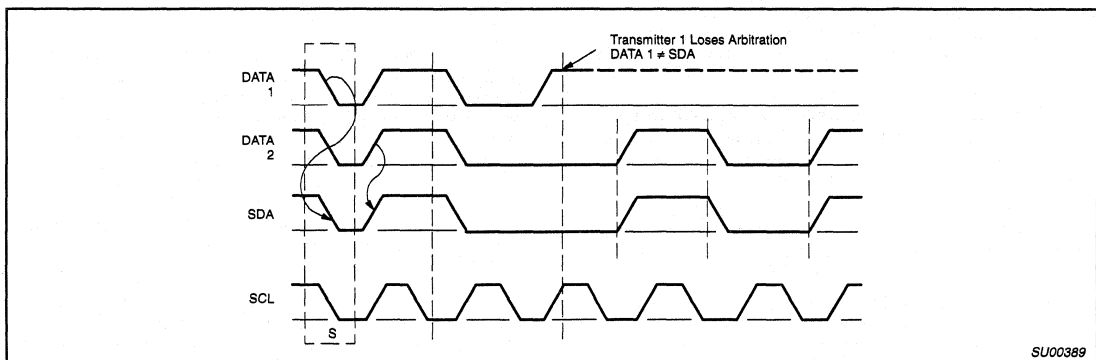

Figure 11. Arbitration Procedure of Two Masters

ARBITRATION IN A MULTIMASTER SYSTEM

The decision about which master has control over the I²C bus is based solely on the address and data sent by competing masters, and there is no central master or any order of device priority on the bus. Any device connected to the I²C bus is allowed to become a master, but devices are not supposed to "steal" the bus from other devices when a transfer is in process. If a device wishing to be a Master is aware that a transaction (initiated by another master) is taking place, it will wait until the transfer is concluded with a Stop condition on the bus—and only then try to seize it by sending its own Start. It is possible, however, that two or more masters may want to start a transfer at exactly the same moment. A scenario that may happen quite frequently in a loaded system: two devices are waiting for a long transaction to be completed, and simultaneously try to get the bus when detecting the Stop condition. An arbitration procedure synchronizes the different clocks, ensuring that the data is not corrupted, and causes all masters except one to withdraw from the bus, so only one master will control the transfer. This procedure applies only when masters initiate transfers simultaneously.

The clock synchronization, illustrated in Figure 10, ensures that only one defined clock is generated on the bus. It occurs naturally, as a result of the wired-AND property of the SCL line. Suppose two masters want to initiate a transfer on the bus. Clk1 and Clk2 in Figure 10 illustrate the desired clock outputs of each device, which would actually occur on the bus if each were the only master. The SCL waveform is the resulting wired-AND of the two clocks. The device that pulls the SCL down first will succeed. The other masters

continuously monitor the clock line, and reset their internal clock counter to start counting their own Low clock period. This way, the first falling edge will synchronize all clock generators to the beginning of the Low time.

Once a device clock has gone Low it will hold the SCL line in this state until its internal clock High state is reached, and then will release the line. The Low to High change in this device will not change the state of the SCL line if another device, which is still within its Low period, is pulling down the line. This way, SCL will be held Low by the device with the longest Low period. A master that has finished its Low time earlier will enter a wait state until SCL is released by the slowest master and goes high. Upon the rising edge of SCL all masters start counting their High period, the first device to complete its High period will pull the SCL Low. In this way a single, synchronized clock is generated on the bus where the rising edge is being defined by the slowest master and the falling edge by the fastest master.

Arbitration between masters takes place on the SDA line. A master which tries to transmit a High while another device transmits a Low will withdraw, shutting off its data output stage and not interfering with the transfer until a Stop condition is detected. Due to the wired-AND property of the SDA line, a device "knows" that it lost arbitration by the fact that the Low SDA is different than its desired High output. Arbitration starts by comparing the address bits. When masters transmit different addresses the one transmitting the address with the lowest binary value wins. If all masters in arbitration transmit to the same address, arbitration continues into

Using the 8XC751/752 in multimaster I²C applications

AN430

the comparison of data. Figure 11 illustrates the arbitration process between two masters.

By definition, the transfer that forces the wired-AND result is the one that wins the arbitration, so the address and data of a winning device are not corrupted and no information is lost in the arbitration process. A master losing arbitration may generate clock pulses until the end of the byte. Thus it may affect the clock speed, but not the data on the bus.

If a master loses arbitration during the addressing stage it is possible that the winning master is trying to address it. In an efficient design, the losing master should switch immediately to its slave receiver mode, receive the data transmitted and acknowledge it—otherwise the message will have to be re-transmitted or is lost. A well designed master will take into account “illegal” protocol situations and will determine that it lost arbitration when it detects a Stop or a Start which are not synchronized with its own transmission. Electrical interference or a malfunctioning device may cause such a situation which actually corrupts the message transfer.

HANDSHAKE BY CLOCK SYNCHRONIZATION

The clock synchronization mechanism as described above actually implements a handshake mechanism, enabling receiving devices to “slow down” fast transfers when necessary.

On the bit level, a slow slave device like a microcontroller that does not have hardware I²C interface port, can extend each clock period and slow down the bus clock. The speed of any master is adapted to the operating rate of this device as long as it is active on the bus.

On the byte level the synchronization mechanism takes effect as a “handshake” mechanism when a slave device that was fast enough to receive or transmit a byte still needs extra time to store the received byte or prepare the next byte for transmission. The slave can hold the SCL line low after the reception and acknowledge of a byte, thus forcing the Master into a wait state—until the slave is ready for the next transfer.

8XC751 I²C HARDWARE

The on-chip I²C bus hardware support of the 8XC751 allows operation on the bus at full speed and simplifies the software needed for effective communications on the network. The hardware activates and monitors the SDA and SCL lines, performs the necessary arbitration and framing error checks, and takes care of clock stretching and synchronization. The hardware support includes a bus timeout timer, called Timer I. The hardware is synchronized to the software either through polled loops or interrupts.

Two of the port 0 pins are multi-functional. When the I²C is active, the pin associated with P0.0 functions as SCL, and the pin associated with P0.1 functions as SDA. These pins have an open drain output.

Two of the five interrupt sources may be used for I²C support. The I²C interrupt is enabled by the EI2 flag of the interrupt enable register, and its service routine should start at address 023h. An I²C interrupt is usually requested (if enabled) when a rising edge of SCL indicates new data on the bus or a special condition occurs: Start, Stop or arbitration loss. The interrupt is induced by the ATN flag, (see below for the conditions for setting this flag). The Timer I overflow interrupt is enabled by the ETI flag, and the service routine starts at 01Bh.

The I²C port is controlled through four special function registers: I²C Control (I2CON), I²C Configuration (I2CFG), I²C Data (I2DAT) and

I²C Status (I2STA). The register addresses are shown in the 8XC751 section of the Philips Semiconductors Microcontroller Data Handbook (IC20). Although the following discussion of the hardware and register details is not complete, it should give a better understanding of the programming examples.

Timer I

In I²C applications, Timer I is dedicated to the port timing generation and bus monitoring. In non-I²C applications, it is available for use as a fixed rate timer.

For the bus monitoring function, Timer I is being used as a “watchdog timer” for bus hang-ups. It creates an interrupt when the SCL line stays in one state for an extended period of time between a Start condition and a following Stop condition. SCL “stuck low” indicates a faulty master or slave. SCL “stuck high” may mean a faulty device or that noise induced into the I²C caused all masters to withdraw from the I²C arbitration.

The time-out interval of Timer I is fixed: it carries out and interrupts (if enabled) when about 1024 machine cycles have elapsed since a change on SCL within a frame. In other words, whenever I²C is active we let Timer I run, but clear it whenever a frame is not in progress (reset or Stop occurred more recently than the last Start condition) or SCL changes within a frame. (Note: we wrote “about 1024 machine cycles” for the sake of accuracy—this number may slightly change according to the setting of the CT0 and CT1 bits mentioned below. In any case, the exact number of cycles for a time out does not have any practical significance).

In addition to the interrupt upon Timer I overflow, the I²C port hardware is reset. This is useful for multiple master systems in situations where this same 8XC751 caused the bus hang-up due to a lack of software response. SCL will be released and I²C operation between other devices could continue.

I2CON Register

The I²C Control register can be read or written to (see Figure 12).

When writing to the I2CON register one should use bit masks as demonstrated in the examples. Trying to clear or set the bits in the register using the bit addressing capabilities of the 8XC751 may lead to undesirable results. The reason is that a command like CLRFB reads the register, sets the bit and writes it back—and the write-back may affect other bits.

I2CFG Register

The configuration register is a read/write register (see Figure 13).

I2DAT Register

The I²C data register is a read/write register, where the msb represents the data received or data to be sent. The other seven bits are read as 0 (see Figure 14).

I2CSTA Register

The I²C STATUS Register is a read-only register reflecting the internal status of the I²C interface hardware (see Figure 15).

Transmit Active State

The transmit active state—Xmit Active—is an internal state in the I²C interface that is affected by the I²C registers as explained above. The I²C interface will only drive the SDA line low when Xmit Active is set. Xmit Active is set by writing the I2DAT register or by writing I2CON with XSTR = 1 or XSTP = 1. The ARL bit will be set to 1 only when Xmit Active is set—in such a case Xmit Active will be automatically reset upon ARL. Xmit Active is cleared by writing 1 to CXA at I2CON register or by reading the I2DAT register.

Using the 8XC751/752 in multimaster I²C applications

AN430

I2CON READ	RDAT	ATN	DRDY	ARL	STR	STP	MASTER	—
RDAT	Received DATA bit. The value of SDA latched by the rising edge of SCL. Its contents is identical to RDAT in the I2DAT register. Reading the received data here allows doing so without clearing DRDY and releasing SCL.							
ATN	An "ATteNtion" flag, set when any one of DRDY, ARL, STR or STP is set. This flag allows a single bit testing for terminating "wait loops", indicating a meaningful event on the bus. This flag also activates the I ² C interrupt request.							
DRDY	Data ReaDY flag. Set by a rising edge of SCL when I ² C is active, except at an idle slave. This flag is cleared by reading or writing the I2DAT register, or by writing a 1 to CDR (at the same address, when I2CON is written).							
ARL	ARbitration Loss flag. Indicates that this device lost arbitration while trying to take control of the bus.							
STR	STaRt flag. Set when a Start condition is detected, except at an idle slave.							
STP	SToP flag. Set when a Stop condition is detected, except at an idle slave.							
MASTER	This flag is set when the controller is a bus master (or a potential master, prior to arbitration).							
I2CON WRITE	CXA	IDLE	CDR	CARL	CSTR	CSTP	XSTR	XSTP
CXA	"Clear Xmit Active". Writing a 1 to CXA clears the internal transmit-active state.							
IDLE	Setting this bit will cause a slave to enter idle mode and ignore the I ² C bus until the next Start is detected. If the software sets the MASTRQ flag, the device may stop idling by turning into a master.							
CDR	Clear Data Ready. Clears the DRDY flag.							
CARL	Clear ARbitration Lost. Clears the ARL flag.							
CSTR	Clear STaRt. Clears the STR flag.							
CSTP	Clear SToP. Clears the STP flag.							
XSTR	"Xmit repeated STaRt". Writing a 1 to this bit causes the hardware to issue a Repeated Start signal. A side effect will be setting the internal Xmit Active state. This should be used only when the device is a master.							
XSTP	"Xmit SToP". Issues a Stop condition. The Xmit active state is set.

I²C COMMUNICATIONS SOFTWARE

The software listing demonstrates programming the 8XC751/752 for a multimaster I²C environment where the device can be both a Master or a Slave responding to other Masters on the I²C network. The bulk of the software is communications routines which are not only for demonstration but could be ported to other user programs with minimal or no modifications. The routines are quite general and could be useful in most applications. We have tried to design a well-defined software interface, enabling most users to copy the routines as they are, and modifying only the pre-defined interface elements to fit the specific applications. We encourage users to use the routines without modifications whenever possible, as the lower levels of the hardware-software integration could be quite involved.

The rest of this application note will relate to the programming example. We shall discuss the general operation of the routines and how they are integrated into an application. Then we shall describe in detail all the software interface elements and how to use them.

I²C COMMUNICATIONS ROUTINES—OVERVIEW

In order to function well in a multimaster environment the microcontroller must be able to take control of the I²C bus as a Master, "tolerate" message transactions between other Masters and other devices, and respond efficiently as a Slave to other bus Masters. The communications routines should allow a Master "graceful" recovery from an arbitration loss and other situations when a message transaction is not completed, allowing for communication re-tries.

For Slave operation the microcontroller must be interrupt driven relative to an I²C frame Start, as any Master on the bus could request a transaction at any moment, not synchronized to the application program executing on the controller. An interrupt service routine monitors the address transmitted on the bus. When the microcontroller is addressed it takes care to either read the data from the bus into a buffer or write buffer data onto the bus. When such a transaction is successfully completed, one of several "Slave Event Routines" is called prior to returning to the main application program. Such an "Event Routine" is a part of the application, allowing an immediate response to the data received, or the fact that data was transmitted to a requesting Master. This allows "synchronization" of the application to a "slave" bus transaction. Typical uses of the Event Routine mechanism will be a computation based on new data, or re-loading the transmit buffer with new data getting ready for the next random request. The actual Event Routines will be programmed differently for different applications, but the names and the calls will remain the same as long as the communications routines are left unmodified.

A transaction as a Master is initiated by the application program. Our implementation uses the interrupt mechanism for the Master communications as well. The application issues a request for the bus by setting the MASTRQ bit of the I²C port control, and when the bus is available an interrupt occurs. This way, if the bus is free there will be an immediate response. If the bus is busy, the application may go on executing (if so programmed) until this controller can get control of the bus. When the microcontroller gets mastership of the bus it initiates a bus transaction according to "directives" set by the

Using the 8XC751/752 in multimaster I²C applications

AN430

application program. The most important directives are the address (and subaddress if relevant) of the slave device addressed, and the length of the message to be transmitted or received.

When a Master transaction is concluded, a Master Event Routine (called MastNext) is called to perform whatever task the application demands. As with the Slave Event Routines it will typically respond to a successful transmission or reception of data. In addition, it could handle situations where a slave does not respond at all, or does not acknowledge a data byte (thus causing data transfer to terminate). A program might react to the fact that a slave does not respond by re-trying to communicate at a later time, by issuing a message to another peripheral device or just ignoring it. The handling of such cases is application dependent, and should be programmed into the routine called "MastNext". The MastNext routine is invoked when the Master terminates the transaction "willingly", but not upon arbitration loss.

The microcontroller operating as a bus Master may lose arbitration to another Master which happens when two Masters transmit in synchronization, commencing with the same Start signal. If arbitration is lost while transmitting or receiving data, our processor withdraws from the bus and turns itself into a slave—an active Slave upon a Start, or returning to the calling program as an idle slave. When the arbitration loss occurs while transmitting an address, our processor turns itself immediately into an active slave, "listening" to the rest of the address transmitted by the new Master. If our processor reads its own address from the bus (as transmitted by the new Master) our processor responds as a willful slave. If this mechanism would not have been implemented, there could be potential inefficiency when a device that happened to be synchronized to another Master loses arbitration, but is not able to respond to the winning device.

Another situation for arbitration loss could be a bus exception resulting from a device operating not according to the bus protocol or interference on the bus lines. In addition to "regular" arbitration loss detected with the ARL hardware flag, such a situation may occur with detecting a Start or a Stop in the middle of transmitting an address or data byte. In such a situation the microcontroller withdraws from the bus as well—active Slave upon a Start detection, or returning as an idle slave in other cases.

When a Master transaction is terminated by an arbitration loss, the Master Request flag (MASTRQ) of the hardware I²C port remains in effect. As a result when the bus gets free, our device will take control, issue a Start, and the transaction that was cut will start again. This restart will happen automatically, without any application involvement (unlike non-acknowledgement, where the MastNext routine determines what shall be done).

The I²C communications routines are structured as an interrupt service routine responding to an I²C port interrupt upon a frame Start. Within a frame the I²C processing is continuous, where the I²C port is polled for hardware response, and the I²C interrupts are disabled. Other interrupts are enabled during the service routine. The set-up requirements from the mainline program are minimal, and interfacing is done via RAM buffers and some pre defined RAM locations. The lower level interface with the hardware is done inside the service routine, and can typically be ignored by the application programmer.

BUS WATCHDOG AND ERROR RECOVERY

A malfunctioning device (in hardware or software) may hold the SCL line low, thus causing the bus to be "stuck". It might even be possible that a transient protocol violation (due to hardware interference, such as a device turning on) may cause some devices (non programmable, or even microcontrollers which were not carefully programmed) to hold the bus. Since within a frame the bus is software-polled, a "stuck" bus might cause the application software to "hang forever". Here the TIMER1 watchdog comes to the rescue, interrupting when there is no bus activity for a long period of time.

When the I²C service routine is interrupted by the watchdog timer, the processing of the current frame is not completed and the event routines are not called. The software returns to execute the mainline application, and will be interrupted again for the next frame (next Start, received as a slave or induced as a Master). A status flag and a counter report on the watchdog interrupt, so the application program can be made to inhibit the I²C port if there are too many occurrences of a "hanging" bus.

Bus protocol errors and "hangups" might be an issue in systems which are susceptible to noise, temporary bus line shorts, "hot plug in" of devices or even erroneously programmed devices—and a "fail safe" controller program should be able to detect bus problems and possibly assist in resolving them. The RECOVER routine resets the I²C interface of the microcontroller, and attempts to release some other devices on the bus by toggling the clock line. The I²C interface of the 8XC751 is reset by letting Timer1 run and expire, since this circuitry does not feature a software controlled reset. This "extreme" measure is needed in some cases of bus protocol violation.

The bus and interface circuit recovery routine can be automatically invoked whenever Timer1 detects a timeout. In addition, for systems where potential bus failures are a concern and reliability is an issue, one may implement mechanisms to invoke bus and interface recovery from the application code. This may help in cases where the bus gets "stuck" when there is no I²C frame in progress. In such an instance the watchdog timer will not give any timeout indications, as it has not been activated. Another case emanates from a design peculiarity of the interface circuitry on the 8XC751: if the SCL line is externally grounded when there is a Start condition, this Start might be ignored, and the watchdog may not be activated. Our programming example deals with potential failures by testing for transaction completion and retrying transmissions when necessary (these are explicit retries, in addition to an "automatic" retry after a Master's arbitration loss, invoked by the MASTRQ bit). Too many transmission failures activate the RECOVER routine.

Using the 8XC751/752 in multimaster I²C applications

AN430

I²C COMMUNICATIONS ROUTINES—INTERFACE

The I²C service routine deals with the transmission and reception of messages, without any concern for the contents of the message. In order to provide a general interface for different applications the data is transferred via buffers. The service routine does not have to "know" where the data goes to or comes from—as long as the application program specifies the required pointers for these buffers. The interface to the actual application (which "cares" about message contents, timing, addressing and so forth) is done in a well defined manner, allowing usage of the same service routine with different application programs.

The interface is carried out with the use of buffers, pre-defined names for Application Event Routines, interface RAM locations for transferring parameters, pointers and flags, and constants. A more detailed discussion of the interface follows.

Buffers

There are three buffers for data transfers between the I²C bus and the application program.

MasBuf is used for Master transmission and reception. The number of data bytes for each Master message—reception or transmission, is specified by the memory location MASTCNT. The value in MASTCNT should be less than the length of MasBuf. For Master transmission the message is placed in MasBuf before the transmission is initiated. In Master reception, the received message will be contained in the same buffer. There is only one Master message transaction occurring at the same time, so we may use the same buffer both for transmission and reception.

For Slave operation we must accommodate data transfers which may come randomly, asynchronous to each other or to possible operation of the same device as a Master. Therefore it is necessary to allocate additional RAM area as buffers dedicated to Slave operation: SRcvBuf for receiving data, STxBuf for transmission.

The length of the Slave receive buffer is defined by the symbol RBufLen. It is used by the code for protection, avoiding overwriting RAM beyond the allocated buffer size in case a Master sends a message which is too long. There is no need for RAM protection for transmission, but the Master should not request more data than STxBuf can supply.

Interface RAM Locations

RAM location MyAddr contains the address of this processor.

Status flag MSGSTAT is used for reporting to the application on I²C communications status—mainly on the successful, or unsuccessful, completion of a message transaction. The contents of MSGSTAT may be used by the mainline application code or by the Event Routines. The different codes that could be placed by the I²C service routine are described later in the text. When the message processing commences, a code indicating Slave or Master processing is inserted to MSGSTAT, and is updated as we go along.

There could be many applications that will not need to use MSGSTAT contents, as the very fact of calling a certain event routine implies completion of a processing stage.

For Master transactions, in addition to the data buffer MasBuf, there are several RAM locations into which the application inserts Master message "directives". These directives provide the service routine with the information necessary to carry out the next Master transaction. The one byte RAM locations used for directives are DESTADRW, DESSUBAD, MASTCNT and MASCMD.

DESTADRW contains the destination slave address in bits 7-1, while bit 0 is the R/W bit. Bit 0 contains 0 for a Write operation (the message is to be transmitted to the slave) and 1 for a Read operation (message is being read from the slave and received by this Master).

DESSUBAD contains the 8 bit sub-address of the slave, if necessary. For transactions without a sub-address, the contents of DESSUBAD is ignored.

MASTCNT contains the number of data bytes in the message to be sent from or received into MasBuf. This number should not be bigger than the length of MasBuf.

MASCMD byte contains the bit flags SUBADD, RPSTRT and SETMRQ. SUBADD is 0 (cleared) for a message with a regular address, and 1 (set) when a subaddress is required. When SUBADD is set, the service routine takes care of all the protocol required for sub-addressing, which includes a Repeated Start for Read operations. A message with a subaddress is considered to be a single message, even if it includes a Repeated Start.

The RPSTRT and SETMRQ are kept cleared in regular applications, and will be used only for "tailoring" the bus transfers in special cases. When RPSTRT is cleared the message will terminate, as usually required, with a Stop. When RPSTRT is set a Repeated Start will be sent on the bus, and Master operation will resume. The RPSTRT directive relates to terminating the message after all the data was transferred, and not to the mandatory Repeated Start in the middle of sub-addressed Read operation. A single message with a subaddress will typically have RPSTRT cleared. SETMRQ indicates what will be loaded into the MASTRQ flag of the hardware when Stop is transmitted. Typically it will be cleared. When SETMRQ is 1, MASTRQ will be set, thus trying to issue a new Start immediately following the Stop. In such a case the service routine will not return upon Stop, but will continue as a Master.

TITOCNT is used to count time-outs of the watchdog timer. Whenever such a timeout invokes the TIMER interrupt service routine the contents of the location TITOCNT are incremented, and the timeout is reported in MSGSTAT. The count is saturated at 0FFh. This mechanism may be used in an application that is very much "concerned" with potential bus failures, allowing some type of "failure monitoring" by the application even for Slave transactions.

Using the 8XC751/752 in multimaster I²C applications

AN430

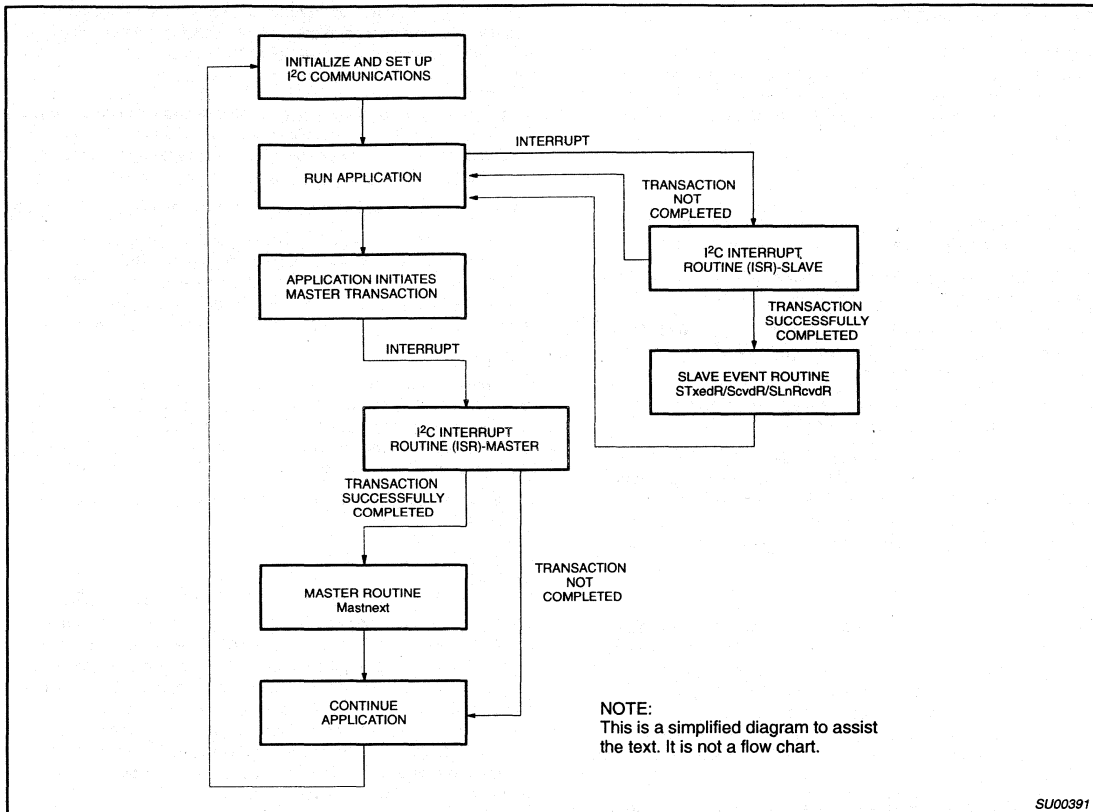

Figure 16. Typical Communications Scenario—A Simplified Diagram

APPLICATION EVENT ROUTINES

The service routine calls Event Routines with pre-defined names (Figure 16), and these routines must be provided by the application program. The actual code of the routines will differ from application to application, but the routine names are being kept the same.

These routines are being called when successful processing of a message (send or receive) is completed. The routines may perform whatever action the application was designed for, which is not necessarily related to the I²C communications mechanism. In addition, the routines may perform the data interface tasks for the I²C port, like emptying buffers from received data or preparing the next message by setting up the buffers.

The mechanism of calling the event routines out of the service routine allows an immediate reaction to the event of message processing completion, before any new activity happens on the bus. In some simple applications this may not be necessary. For example, one may have a main program for a slave which is just a wait loop monitoring a flag set by the service routine when a message transfer, initiated by some master, is completed. In such a case the application could react to the message completion after the interrupt service routine returns. However, in the general case this will not be sufficient. An example could be a slave with an

application which is constantly busy doing another task, in an environment where the communication requests on the I²C bus are frequent. If there is a new message request shortly after the current message is completed, having to wait for the application until it "has time" may result in not reacting, or sending the same data again, or overwriting the received data in the buffer. Another obvious case demanding event routine calls is a Master sending different messages with a Repeated Start—the new data for the following message must be prepared in the interrupt service routine as the current message is completed (there is no return from interrupt prior to the new data transmission).

The programmer has the flexibility to decide where to prepare the next message according to the requirements of the application. This can be done after return from the event routine, in the application code after the return from interrupt, or a combination of both, where the time critical events are performed in the event routines. The application may monitor the MSGSTAT flag for message processing completion. If the event routines are not used, it is recommended to simply code them as a "RET" instruction, thus turning them into dummy routines (this an easier and better practice than changing the service routine itself, eliminating the calls).

Using the 8XC751/752 in multimaster I²C applications

AN430

Master Event Routine:**MastNext**

This routine is called by the service routine when the processing of the current Master message is completed. For an indication on the type of message processing completion, MastNext may inspect the contents of MSGSTAT RAM location.

When MastNext is called, MSGSTAT will contain one of the following codes for message processing completion:

MRCVED (= 21h)—a complete message (with number of data bytes indicated by MASTCNT) was received from the slave.

MTXED (= 22h)—the number of data bytes indicated by MASTCNT were successfully sent and acknowledged by the slave.

MTXNAK (= 23h)—the slave did not acknowledge a data byte of the message, even though it had acknowledged its address. The message transmission was terminated upon the NAK.

MTXNOSLV (= 24h)—no slave acknowledged the address indicated by memory location DESTADDR.

The MastNext routine may perform any task(s) necessary for the application. Data handling tasks will typically be dependent on the MSGSTAT indication. One possible task could be setting the directives for the next message. The necessity for executing this task here (versus the main-line code initiating the transfer) is of course application dependent.

Slave Event Routines:

These routines are called when a message transaction as a slave has been completed. In many cases it could be important to utilize the calls to such routines as the requests for message transactions as a slave can come randomly, asynchronous to the application program. The application may demand that new data coming in should immediately initiate some tasks (e.g. control an output port)—and the event routine can be used to process the result of the slave interrupt.

In most cases it will be necessary for a slave to react immediately to a message received simply in order not to lose the data. As a new message may come randomly, it may overwrite the reception buffer before the data has been transferred out of it or acted upon.

For applications in which the reaction for slave events is performed after the return from the service routine, the event is reported by placing an appropriate code in the MSGSTAT flag. The programmer may use event routines, other mainline routines inspecting MSGSTAT, or both. If the event routines are not used, it is recommended to code them as a "RET" instruction.

SRcvdR:

Called by the service routine when a new, complete message has been received into SRcVBuf. When SRcVdR is called, R1 points to the address of the last byte received into the buffer. In a typical application SRcVdR will transfer the new data out of SRcVBuf, so it will not be written over by a subsequent slave reception.

The equivalent MSGSTAT indication for this event is SRCVD (= 11h).

SLnRcvdR:

Called when a slave message has been received into SRcVBuf, but the message was longer than the SRcVBuf buffer (as specified by RBufLen).

The equivalent MSGSTAT indication for this event is SRLNG (= 12h).

If the program is supposed to react to a too long a message the same way as to a message that can be contained in the buffer, one may code SLnRcvdR simply as a call to SRcVdR.

STXedR:

Called by the service routine when data has been transmitted out of the slave STxBuf buffer according to a master's request. This routine may insert new data into the buffer, preparing it for the next slave transmission.

The equivalent MSGSTAT indication for this event is STXED (= 13h).

Note that we do not have a separate routine for the case that the master requested too many bytes—more than STxBuf length—and we sent out meaningless bytes. It is the master's responsibility to specify the message length, and it should be able to request messages with the appropriate length from each slave on the bus.

SRErrR:

This routine relates more to bus communications than to the application itself. It can be called when we positively detect a bus error upon reception as a slave, in case the application is supposed to know about it. In most cases this call will not be used, as dealing with bus communications difficulties is usually left to the Master.

Just prior to calling SRErrR, the code SRERR (= 14h) is placed in MSGSTAT.

0Completion Routine:**I2CDONE**

This routine is called every time, before returning from the I²C interrupt service routine, whether the transaction was successful or not. It can be used to "safely" monitor MSGSTAT without any risk of a new interrupt modifying the current indication. Simple application programs will not make use of this routine. A more sophisticated application implementing a fail-safe communications protocol may use it to count errors of a certain type in order to determine a recovery scheme. In our programming example, I2CDONE inhibits I²C interrupts when it is evident that as a result of protocol errors interrupts are not caused by legitimate Starts.

CONSTANTS

RBufLen—the length of SRcVBuf, the slave receive buffer. This constant may be used both by the I²C routines and the application program, and it is the responsibility of the application programmer to define the correct buffer length.

MYNUM—This ROM constant is dependent on the application environment. It is a small integer defining a "serial number" of the node, out of all the processors running the same code. This constant is used only when recovering from a timeout, in order to "de-synchronize" masters from each other when trying to recover the bus.

CTVAL1 is a constant defined in ROM. It is used by the application code portion which initializes the I²C, for loading CT0 and CT1 with a value appropriate for the crystal being used.

MYADDR1 is a ROM constant containing the address of the processor's I²C node. This value is used by the application demo to load the RAM location MyAddr.

Using the 8XC751/752 in multimaster I²C applications

AN430

USING THE COMMUNICATIONS SUBROUTINES

In order to use the I²C Communications Routines an application program should take care of the following:

- Upon initialization, load bits CT1, CT0 of I2CFG register according to the clock crystal used (refer to the table of CT1, CT0 values in the 8XC751 section of the Philips Semiconductors Microcontroller Data Handbook (IC20)).
- Load MyAddr RAM location with the address of this node.
- For Slave operation, load STxBuf with the initial data to be transmitted.
- For slave operation, set the SLAVEN bit in the I2CFG register.
- Enable I²C and watchdog interrupts by setting the ET1, EI2 and EA bits of the interrupt enable register.
- For Master operation, set up the next transaction by loading the appropriate directives into MASCMD, DESTADRW, DESSUBAD (if applicable) and MASTCNT, and load MasBuf with the appropriate data if it is a Write message.
- For Master operation, initiate the next transaction by setting MASTRQ bit in I2CFG.
- For both Master and Slave operation, handle data transmission and reception via the buffers in main-line code or the Event Routines.

PROGRAMMING EXAMPLE

The assembler listing includes the I²C Communications Routines and a demo application exercising these routines. In most real-life applications the code of the routines could be used without modifications. For those who follow the coding of the routines, one should note that in many instances code speed and program space have been slightly compromised in order to improve readability. The almost "general purpose" interface to the routines affects efficiency as well, and it is possible to write more compact and somewhat faster code for specific applications. The reader is encouraged, though, to use the code "as is" whenever possible.

The "application" demo is simple—two microcontrollers exchange messages in a "ping-pong" game. In addition to trivial message exchange, the code demonstrates recovery mechanisms from communications errors and bus "hangups". We tried this code with two pairs of controllers exchanging messages on the same bus. The message exchange could repeatedly recover and restart when the SCL and SDA lines were temporarily shorted to ground or between themselves. Simpler versions, without the "protection" mechanisms, could "hang up" under such conditions.

Source Code Available On BBS

The source code file for this program is available for download from the Philips computer bulletin board system. This system is open to all callers, operates 24 hours a day, and can be accessed with modems at 2400, 1200, and 300 baud. The telephone numbers for the BBS are: (800) 451-6644 (in the U.S. only) or (408) 991-2406.

```

679 ;*****
680 ;
681 ;           Main Program
682 ;
683 ;*****
684
685 ; Message ping pong game. Each message is transmitted by
686 ; a processor that is a master on the I2C bus, and it contains one byte
687 ; of data. A processor that receives this data byte as a slave increments
688 ; the data by one and transmits it back as a master. The data received is
689 ; confirmed to be a one increment of the data formerly sent, unless
690 ; it is a "reset" value, chosen to be 00h.
691 ; The two participating processors have similar code, where the node
692 ; address of the second processor is the destination address of this
693 ; one, and vice versa.
694 ; The first data byte each processor tries to send is 00h. One of the
695 ; processors will acquire the bus first, and the second processor that will
696 ; receive this "resetting" 00h will not attempt to confirm it against an
697 ; expected value. It will simply increment and transmit it. Subsequent
698 ; receptions will be confirmed against the expected value, until 0ffh data
699 ; bytes are sent and the game is effectively reset by the 00h resulting from
700 ; the next increment.
701 ; A toggling output (TogLED) tells the outer world that the "ping pong"
702 ; proceeds well. If something unexpected happens we temporarily activate
703 ; another output, ErrLED.
704 ; The different tasks of the code are performed in a combination of main-
705 ; line program and event routines called from the I2C interrupt service
706 ; routine.
707
708
709 ; Initial set-ups:
710 ; Load CT1,CT0 bits of I2CFG register, according to the clock
711 ; crystal used.
712 ; Load RAM location MYADDR with the I2C address of this processor.
713 ; We load these values out of ROM table locations (R_CTVAL and R_MYADDR).
714 ; One may, instead, load with a MOV <immediate> command.
715

I²C slave routines for the 83C751

AN433

Author: Greg Goodhue

The S83C751/S87C751 Microcontroller combines in a small package the benefits of a high-performance microcontroller with on-board hardware supporting the Inter-Integrated Circuit (I²C) bus interface.

The 8XC751 can be programmed both as an I²C bus master, a slave, or both. An overview of the I²C bus and description of the bus support hardware in the 8XC751 microcontrollers appears in application note AN422, "Using the 8XC751 Microcontroller as an I²C Bus Master." That application note includes a programming example, demonstrating a bus-master code. Here we show an example of programming the microcontroller as an I²C slave.

The code listing demonstrates communications routines for the 8XC751 as a slave on the I²C bus. It compliments the program in AN422 which demonstrates the 8XC752 as an I²C bus master. One may demonstrate two 8XC751 devices communicating with each other on the I²C bus, using the AN422 code in one, and the program presented here in the other. The examples presented here and in AN422 allow the 751 to be either a master or a slave, but not both. Switching between master and slave roles in a multimaster environment is described in application note AN435.

The software for a slave on the bus is relatively simple, as the processor plays a relatively passive role. It does not initiate bus transfers on its own, but responds to a master initiating the communications. This is true whether the slave receives or transmits data—transmission takes place only as a response to a bus master's request. The slave does not have to worry about arbitration or about devices which do not acknowledge their address. As the slave is not supposed to take control of the bus, we do not demand it to resolve bus exceptions or "hangups". If the bus becomes inactive the processor simply withdraws, not interfering with the master (or masters) on the bus which should (hopefully) try to resolve the situation.

The 8XC751 has a single bit I²C hardware interface where the registers may directly affect the levels on the bus, and the software interacting with the hardware registers takes part in the protocol implementation. The hardware and the low level routines dealing with the registers are tightly coupled. We repeat here the warning from the 751 bus-master application note: one should take extra care if trying to modify these lower level routines.

The service routine for the I²C slave is interrupt driven per message. This allows for master communication requests which are not synchronized with the application program running on the slave. It is possible to write simple slave application programs which will not be interrupt driven, taking care not to lose master transmissions while doing something else, but the user should be discouraged from doing so. As the slave should respond to asynchronous requests of masters on the bus, an interrupt driven service routine makes sense—and, as the code demonstrates, is simple to implement.

DEMONSTRATION CODE

The main program operation, intended for demonstration only, is simple. There are two data buffers, one for data reception and one for data transmission. When new data has been received from the I²C bus into the receive buffer, the program writes it into the transmit buffer. The first and second bytes of received data are also copied to Port 1 and Port 3, respectively. When a bus master requests to read data, Port 1 and Port 3 will be returned for the first two bytes of requested data, while the remaining bytes will come from the transmit buffer. This allows for simple testing of a master and slave system by having the master compare data received to data sent. This scheme also allows the 8XC751 to be used as a two-byte I²C I/O port.

The program begins at address 0, where the microprocessor begins execution after a hardware reset. This location contains a jump instruction to the main program, which starts at the label `Reset` (towards the end of the listing). Upon reset, the program initializes the stack pointer, the I²C address of the slave processor (`MyAddr`) and clears the data buffers and software flags. In this program the receive and transmit buffers are each eight bytes long—the maximum number of bytes is defined by the label `MaxBytes`. One may easily change the program to handle longer messages by changing the value of `MaxBytes` and allocating more data memory to the buffers.

The I²C interface is configured to operate as a slave by setting the msb of register `I2CFG`. This is done simultaneously with loading the appropriate value of `CTVAL`—bits `CT0` and `CT1`, which are determined by the frequency of the microprocessor's crystal. The interface hardware is explicitly instructed to get into the slave idle mode by setting the appropriate bit in the `I2CON` register. Timer 1, which operates as a "watchdog" timer detecting bus hangups, is activated and its interrupts are enabled.

After the initialization, the program gets to the label `MainLoop`. Most of the time the program will "hang" in a wait loop at this label, simply waiting for an I²C interrupt to occur. When there is an I²C bus request there will be an interrupt, the service routine will be executed and we shall return to the `MainLoop` label. If the service routine receives new data, it sets a flag, `DatFlag`, signalling that data has been updated. This flag will allow us to leave the `MainLoop` label, and execute a short routine copying the updated input buffer to the output (transmit) buffer.

If a new bus interrupt comes before overwriting of the old read buffer data is completed, and an undesirable "mix" of old and new data might occur. This type of situation is avoided by disabling the I²C interrupts (clearing the `IE2` bit in the Interrupt Enable Register) just before copying the data to the transmit buffer, and re-enabling the interrupts when the copy operation is completed.

When the copy routine is completed the `DatFlag` is cleared and we jump back to `MainLoop`, waiting for the next interrupt to occur. If the interrupt is for data transmission the service routine will not set `DatFlag`, and upon return we shall remain at the `MainLoop` label.

I²C slave routines for the 83C751

AN433

THE INTERRUPT SERVICE ROUTINE

The service routine is interrupt driven with respect to the start of each I²C frame, but within each frame the interaction with the hardware is based on polling. An occurrence of a Start on the bus will cause an interrupt that will initiate the service routine which starts at address 23H. After saving registers, all interrupts except the I²C interrupt itself are enabled, as we want to allow response to other interrupts during the routine. The philosophy behind this is that the I²C may be a lower priority than some other operations in the system. Since the I²C hardware will stretch the clock until the program responds, an interrupt of reasonable duration will not have a harmful effect on the data transfer.

Since we intend to react to the I²C hardware by polling the ATN flag in wait loops, we do not want the expected changes on the bus to take us again to the beginning of the routine. Therefore, the EI2 flag is cleared, masking further I²C interrupts even when interrupts are re-enabled (by the ACALL to a RETI instruction).

At the label Slave, the routine starts receiving the address on the bus. Each new address bit is read after a software wait loop detects that the ATN flag is set by the hardware. Note that with the single bit implementation of the I²C port on the 8XC751 the software must closely support the hardware: for example, we need to explicitly clear the Start status before we enter a wait loop for the next bit. If the software does not clear the Start flag, the hardware will stretch the low period of the clock (SCL line) on the bus—and the first address bit will simply not occur. (Such a state will not go on forever—eventually the processor will release the bus as a result of a Timer 1 timeout.)

Reception of the eight bits of Address + R/W is completed using part of the receive byte subroutines. The address received is compared to MyAddr, the address of this specific slave. If the address is different the processor goes idle and leaves the service routine. If the message is intended for this processor (received address matches MyAddr) the Read/Write bit is tested, and the program jumps to the appropriate labels. When the R/W bit is low the master requests a Write—and this slave should receive the data written into it. When the R/W bit is high the master is requesting a Read and this slave should transmit the data (at code label Read).

For "Master Write" we send an acknowledge for the address byte and proceed with receiving the data bytes, responding with an acknowledge for each and transferring them into the receive buffer. For long messages, when the buffer is full (we have received MaxByte bytes) we read from the bus one additional byte and then send a negative acknowledge, letting the master know it should stop sending us data. Then we set DatFlag to signal the mainline program that new data has been received, and jump to MsgEnd. At

the MsgEnd label we wait for the next Stop or Repeated Start. On a Stop we resume the idle mode (Goldie) and return from the service routine. On a Restart the slave process starts again with reception of the new address at the label Slave.

If the message is short enough so that the receive buffer is not filled up, the RcvByte subroutine (called after WrtLoop) will return due to the Stop condition, DRDY will not be set, and we shall exit the loop via label WLEx—setting the DatFlag and proceeding to MsgEnd.

For "Master Read" the transmit buffer is sent on the bus byte by byte in the RdLoop, using the XmitByte subroutine. We exit the loop when all the buffer is transmitted, or the Master does not respond with an acknowledge. Note that lack of acknowledgement for slave transmission does not necessarily indicate a problem or that the receiving master is busy. This could very well be a normal operation of the protocol, which defines that a receiving master signals the transmitting slave to end its message by explicitly transmitting a negative acknowledge as a response to the last byte the master is interested in. The protocol does not include inherent means for specifying in advance the length of a requested message.

SUBROUTINES

The lower level subroutines closely interact with the hardware and the activity on the bus. The XmitByte subroutine transmits one byte and receives the acknowledge bit that comes in response. The byte receive routine, which one may use from different entry points, receives a data or an address byte, and takes care of acknowledgements. When a Start or Stop is detected the subroutine returns immediately—the calling routine is expected to check the flags to determine whether a whole byte has been received (DRDY will be set), or a Start or a Stop condition has occurred.

Close inspection of RcvByte code shows that a total of nine bits are being read off the bus. The first bit does not belong to the received byte, but is the acknowledge this processor sent in response of the former byte or address. Reading the Ack bit from the I2DAT register clears the Transmit Active state and DRDY, thus releasing SCL and allowing the bus activity to proceed to the next data bit. Upon return the Ack bit is left in the Carry flag, and the actual data byte received is returned in the Acc register.

Upon Timer 1 interrupt code execution commences at address 1BH, where there is a jump to the service routine Timer1. This interrupt is caused by the watchdog timer, as a result of an I²C bus that is "hanging" without activity in the middle of a transmission for too long a period of time. The slave simply clears the bus interface, and starts all over again at the label Reset.

I²C slave routines for the 83C751

AN433

```

;*****
;
;       Sample I2C Slave Routines for the 8XC751 and 8XC752
;
; This program demonstrates I2C slave functions for the 8XC751 and 8XC752
; microcontrollers. The program uses separate transmit and receive data
; buffers that are each eight bytes deep. The sample main program
; copies received data to the transmit buffer such that transmitted data can
; be read back by a bus master. Buffer addresses 0 and 1 are mapped to port 1
; and 3 respectively, such that an I2C write will affect the port outputs, and
; an I2C read will return port pin data. The 751 will accept only eight data
; bytes in any one I2C transmission, additional bytes will not be
; acknowledged. Similarly, only eight data bytes may be read from the 751 in
; any one I2C transmission. This program does not support subaddressing for
; buffer access.

Connecting a PC keyboard to the I²C-bus

AN434

CONNECTING A PC KEYBOARD TO THE I²C BUS

This application note illustrates the use of a low-cost 8-bit microcontroller—the 8XC751—to interface a standard PC/AT keyboard to the I²C bus. The 8XC751 (83C751 = ROM-version, 87C751 = EPROM-version) is ideally suited for the task thanks to its built-in I²C interface, small form-factor (24-pin DIP or 28-pin PLCC) and low power consumption (11mA typical @ 12 MHz; see Figure 1). The application software easily fits within the 2K bytes code and 64 bytes data memory provided on the 8XC751.

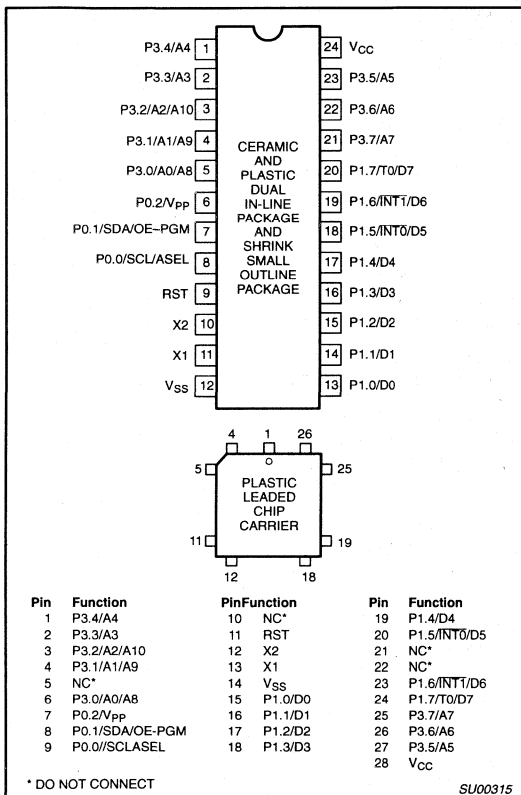

Figure 1. Pin Configuration

The PC/AT Keyboard

The PC/AT keyboard transmits data in a clocked serial format consisting of a start bit, 8 data bits (LSB first), an odd parity bit and a stop bit as shown in Figure 2. Besides clock and data, the 5-pin connector (Figure 3) also includes power, ground and a no connect. Note that the PS/2 keyboard interface is logically equivalent, though it uses a different connector. (A sixth pin provides an additional no connect).

When a key is pressed, the PC/AT keyboard transmits a 'make' code and, when the key is released, a 'break' code. The make code consists of an 8-bit 'scan' code denoting the key pressed. The 'break' code (key released) consists of the same 8-bit scan code preceded by a special code—0F0H.

A notable difference from a regular ASCII keyboard is the way SHIFT, CTRL, ALT, etc. control keys work. For an ASCII keyboard, the control keys directly modify the code output. For example, a 61H (ASCII code for 'a') is output if the 'A' key is pressed by itself, while a 41H (ASCII code for 'A') is output if the SHIFT and 'A' keys are pressed simultaneously.

The PC/AT keyboard handles such a key combination as two separate key presses, i.e., SHIFT-MAKE, 'A'-MAKE, SHIFT-BREAK, 'A'-BREAK. The 'A' scan code (1CH) is the same for both the shifted and unshifted state. To determine whether the 'A' scan code is interpreted as 'A' or 'a' the PC must keep track of the presence or absence of a prior SHIFT-MAKE.

Keyboard-to-I²C Hardware (Figure 4)

The 8XC751 on-chip I²C interface allows direct connection of the SDA (Serial Data) and SCL (Serial Clock) pins to the corresponding I²C bus lines. Since the I²C bus is open collector (allowing multimasters), 10K resistors are used to pull the lines to the idle state between keypresses.

The PC/AT keyboard interface is equally simple. The CLK output from the keyboard is used to generate an interrupt (INT0). In response, the 8XC751 interrupt service routine samples the keyboard serial DATA connected to port 0 bit 2 (P0.2).

When used with a PC, the keyboard implements a bidirectional communication protocol by exploiting the fact that both the keyboard and PC can drive the open collector CLK and DATA lines. However, bidirectional communication is not required for basic keyboard operation and in this application, the keyboard is treated as an 'input-only' device.

Keyboard-to-I²C Software

The keyboard-to-I²C software performs three major functions:

- Capture the clocked serial data from the keyboard
- Translate the keyboard data to the corresponding ASCII code
- Send the ASCII code as an I²C message.

When a key is pressed, the CLK output from the keyboard generates an interrupt via INT0. The 8XC751 shifts in the DATA from the keyboard on P0.2 (port 0, bit 2) and extracts the 8-bit scan code from the 11-bit packet.

Next, the scan code is interpreted and converted to the corresponding ASCII code using a look-up table. Keyboard multi-code outputs are converted to single ASCII codes by tracking the state (i.e. shifted vs. unshifted) of the keyboard and using separate look-up tables for each. For example, a keyboard SHIFT-MAKE, 'A'-MAKE, SHIFT-BREAK, 'A'-BREAK sequence is converted to the ASCII code for uppercase 'A' (41H). The flowchart in Figure 5 depicts the keyboard data capture and code conversion process.

The 8XC751 operates as an I²C slave. When the master issues a read command, the 8XC751 returns the converted ASCII character. The seven least significant bits are used for the ASCII code, while the most significant bit is used as a NEW flag (0 = new, 1 = old). The key code remains marked as new until the master issues a write to the 8XC751 at which point it is marked as old and will be overwritten by the next key processed.

The keyboard-to-I²C software is shown immediately following Figure 5. Less than half the code space available on the 8XC751 is used, leaving room for extra features such as parity checking and more complete keyboard control state mapping using additional look-up tables.

I²C routines for 8XC528

AN438

Philips Semiconductors Application Note EIE/AN90015

Summary

This application note presents a set of software routines to drive the I²C interface in 8xC528 type of microcontrollers. A description of the I²C interface is given. Examples show how to use these routines in PL/M-51, C and assembly source code.

1.0 INTRODUCTION

This application note describes the I²C interface of the 8xC528 microcontroller and gives a set of routines in application programs to drive this interface.

Chapter 2.0 gives a hardware description of the bit level I²C. It gives an overview of what functions are done in hardware by the interface and the functions that should be implemented by software. The registers described are accessible with software and control the I²C interface.

Chapter 3.0 gives a description of the routines that may be used by the application program. The routines are written in such a way that the I²C interface becomes transparent to the user. the slave program is described in more detail, because this routine may be adapted by the user for his specific application.

Chapter 4.0 gives simple example programs that show how to use the routines in assemble, PL/M and C application programs.

2.0 THE I²C INTERFACE

2.1 Characteristics of I²C Interface

The Block diagram of the bit-level I²C interface is shown on page 4-101. P1.6/SCL and P1.7/SDA are the serial I/O pins. These two pins meet the I²C specification concerning the input levels and output drive capability. Consequently, these pins have an open drain configuration. All four modes of the I²C bus can be used:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

The advantages of using the bit-level I²C hardware compared with a full software implementation are:

- Higher bit rate
- No critical software timing requirements
- Less software overhead
- More reliable data transfer

The bit-level I²C hardware can perform the following functions:

- Filtering the incoming serial data and clock signals. Glitches shorter than 4 XTAL periods are rejected.
- Recognition of a START or STOP condition.
- Generating an interrupt request after reception of a START condition.
- Setting the Bus Busy flag when a START condition is detected.
- Clearing the Bus Busy flag when a STOP condition is detected.
- Recognition of a serial clock pulse on the SCL line.
- Latching the serial data bit on the SDA line at every rising edge on the SCL line.
- Stretching the LOW period of the serial clock SCL to synchronizer with external master devices.
- Setting the Read Bit Finished (RBF) or Write Bit Finished (WBF) flag is an error free bit transfer has occurred.
- Setting a Clock LOW-to-HIGH (CLH) flag when a leading edge is detected on the SCL line.
- Generation of serial clock pulse on SCL in master mode.

The following functions must be done with software:

- Handling the I²C interrupt caused by a detected START condition.
- Conversion of serial to parallel data when receiving.
- Conversion of parallel to serial data when transmitting.
- Comparing received slave address with own slave address.
- Interpretation of acknowledge information.
- Guarding the I²C status if the RBF and WBF flags indicate a not regular bit transfer.
- Generating START/STOP conditions when in master mode.
- Handling bus arbitration when in master mode.

2.2 Control and Status Registers

Control of the I²C bus hardware is done via 3 Special Function Registers:

S1INT

This register contains the serial interrupt flag SI.

S1BIT

For read, this register contains the received bit SDI.

For write, this register contains bit SDO to be transmitted.

S1SCS

For read, this register contains status information.

For write, this register is used as control register.

2.2.1 S1INT: I²C Interrupt Register

- **S1INT.7** is the Serial Interrupt request flag (SI).

If the serial I/O is enabled (ENS = 1), then a START condition will be detected and the SI flag is set on the falling edge of the filtered SCL signal.

Provided that EA (global enable) and ES1 (enable I²C interrupt) are set (in the interrupt enable IE register), SI generates an interrupt that will start the slave address receive routine.

SI is cleared by accessing the S1BIT register or by writing '00H' to S1INT. SI cannot be set by software.

After reception of a START condition, the LOW period of the SCL pulse is stretched, suspending serial transfer to allow the software to take appropriate action. This clock stretching is ended by accessing the S1BIT register.

2.2.2 S1BIT: Single Bit Data Register

- **S1BIT.7** contains two physical latches: the Serial Data Output (SDO) latch for a write operation, and the filtered Serial Data Input (SDI) latch for a read operation. SDI data is latched on the rising edge of the filtered SCL pulse. S1BIT.7 accesses the same physical latches as S1SCS.7, but S1BIT.7 is not bit addressable.

Reading or writing S1BIT register starts the next additional actions:

- SI, CLH, RBF and WBF flags are cleared.
- Stretching the LOW period of the SCL clock is finished.
- Auto-clock pulse is started if enabled.

The auto-lock is an active HIGH SCL pulse that starts 28 Xtal periods after an access to S1BIT. SCL remains high for 100 Xtal periods. If the SCL line is kept LOW by any device that wants to hold up the bus transfer, the auto-clock counter still runs for 20 Xtal periods to try to make SCL high and then go into a wait-state. This will result in a minimum SCL HIGH time of 80 Xtal periods (5 μ s at $f_{\text{Xtal}} = 16$ MHz).

The auto-clock signal will be inhibited if the SCO flag in the S1SCS register is set to '1'. SCL pulses must then be generated by software. In this situation, access to S1BIT may be used to clear the SI, CLH, RBF and WBF flags.

A quick check on a successful bit transfer from/to SDO/SDI is carried out by testing only the RBF or WBF flag (see 2.2.3).

2.2.3 S1SCS: Control and Status Register

- **S1SCS.7** represents two physical latches, the Serial Data Output (SDO) latch for write operations and the Serial Data Input (SDI) latch for read operations. S1SCS.7 accesses the same physical latches as S1BIT.7, but S1SCS.7 is bit addressable. However, a

read or write operation of S1SCS.7 does not start an auto-lock pulse, with not finish clock stretching, and will not clear flags.

- **S1SCS.6** represents two physical latches, the Serial Clock Output (SCO) latch for write operations and the Serial Clock Input (SCI) latch for read operations. The output of SCO is "OR-ed" with the auto-clock pulse. If SCO = '1' the auto-clock generation is disabled and its output is LOW. Internal clock stretching logic and external devices can then pull the SCL line LOW.

If the auto-clock is not used, the SCL line has to be controlled by setting SCO = '1', waiting for CLH to become '1' and setting SCO = '0' after the specified SCL HIGH time. Data access should be done via S1SCS.7.

- **S1SCS.5** is the serial Clock LOW-to-HIGH transition flag (CLH). This flag is set by a rising edge of the filtered serial clock. CLH = '1' indicates that no devices are stretching SCL LOW, and since the last CLH reset, a new valid data bit has been latched in SDI.

CLH can be cleared by writing '0' to S1SCS.5 or by a read or write operation to the S1BIT register. Clearing CLH also clears RBF and WBF. Writing a '1' to S1SCS.5 will not affect CLH.

- **S1SCS.4** is the Bus Busy flag (BB). BB is set or cleared by hardware only. If set, it indicates that a START condition has been detected on the I²C bus. A STOP condition clears the BB flag.
- **S1SCS.3** is the Read Bit Finished flag (RBF). If RBF = 1, it indicates that a serial bit has been received and latched into SDI successfully. If during a bit transfer RBF is '0', the cause is indicated as follows:

SCI = '1' and CLH = '1'	The SCL pulse is not finished and still HIGH.
CLH = '0'	A bus device is delaying the transfer by stretching the LOW level on the SCL line.
BB = '0'	A STOP-condition has been detected during the bit transfer. This should be considered as a bus-error.
SI = '1'	A START-condition has been detected during the bit transfer. This should be considered as a bus-error.

RBF can be cleared by clearing CLH or by a read or write operation to the S1BIT register.

- **S1SCS.2** is the Write Bit Finished flag (WBF). If set, it indicates that a serial bit in SDO has been transmitted successfully. If during bit transfer WBF is '0', the following conditions may be the cause:

SCI = '1' and CLH = '1'	The SCL pulse is not finished and still HIGH.
CLH = '0'	A bus device is delaying the transfer by stretching the LOW level on the SCL line.
BB = '0'	A STOP-condition has been detected during the bit transfer. This should be considered as a bus-error.
SI = '1'	A START-condition has been detected during the bit transfer. This should be considered as a bus-error.

WBF can be cleared by clearing CLH or access to the S1BIT register.

I²C routines for 8XC528

AN438

- **S1SCS.1** is the STRetch control flag (STR). STR can be set or cleared by software only. Setting STR enables the stretching of SCL LOW periods. Stretching will occur after a falling edge on the filtered serial clock. This allows synchronization with the SCL clock signal of an external master device.

If STR is cleared, no stretching of the SCL LOW period will occur after the transfer of a serial bit.

The LOW level on the SCL line is also stretched after a START condition is received, regardless of the STR contents. The stretching of the SCL LOW period is finished by a read or write operation of the S1BIT register.

- **S1SCS.0** is the ENable Serial I/O flag (ENS).

ENS can be set or cleared by software only.

ENS = '0' disables the serial I/O. The I/O signals P1.6/SCL and P1.7/SDA are determined by the port latches of P1.6 and P1.7 (open drain). If P1.6 and P1.7 are connected to an I²C bus, then the flags SDI, SCI, CLH, and BB still monitor the I²C bus status, but will not influence the I/O lines, nor will they request an interrupt.

ENS = '1' enables the START detection and clock stretching logic. Note that the P1.6 and P1.7 latches and the SDO and SCO control flags must be set to '1' before ENS is set to avoid SCL and/or SDA to pull the lines LOW.

I²C routines for 8XC528

AN438

3.0 I²C ROUTINES

3.1 Introduction

A set of routines is written for the I²C interface that supports multi-master and slave operation. The routines are placed in a library I2C_DR.LIB. If I2C_DR.LIB is linked to an application program, only the needed object modules are linked in the output file.

The routines can be used as device driver for PL/M-51, C and 8051-assembly code. By using these routines the bit-level I²C interface is fully transparent for the user.

The routines use the following 8xC528 resources:

- Exclusive use of Register_Bank_1. Only R7 of this register bank contains static data (Own Slave Address). R0..R6 may be used by the application program when the I²C routine is finished.
- 7 bytes DATA used for parameter passing.
- 1 byte Bit-Addressable DATA for status flags.

When using routines from this library DPH, DPL, PSW (except CY) and B are not altered.

An n-bytes data buffer is used as destination or source buffer for the bytes to be received/transmitted and reside in DATA or IDATA memory space.

The code is written to generate the highest transfer rate on the I²C bus. At $f_{\text{tal}} = 16\text{MHz}$ this will result in a bit rate of 87.5kbit/sec.

The following software tools from BSO/Tasking are used for program development:

- OM4142 Cross Assembler 8051 for DOS: V3.0b
- OM4144 PL/M 8051 Compiler for DOS: V3.0a
- OM4136 C8051 Compiler for DOS: V1.1a
- OM4129 XRAY51 debugger: V1.4c

3.2 Functional Description

When using these routines in a PL/M application program, they must be declared EXTERNAL. In this declaration the user can specify the type returned by each procedure. All procedures (except Init_IIC and Dis_IIC) can return a BIT or BYTE, depending on the chosen EXTERNAL declaration. The BIT or BYTE returned is '0' if the I²C was successful. If a BYTE is returned, the following check bits are available for the user:

BYTE.0	An I ² C error has been detected.
BYTE.1	No ACK received.
BYTE.2	Arbitration lost.
BYTE.3	Time out error. This may be caused by an external device pulling SCL LOW.
BYTE.4	A bus error has occurred. This may be a spurious START/STOP during a bit transfer.
BYTE.5	No access to I ² C bus.
BYTE.6	0
BYTE.7	0

Note that typed procedures must be called using an expression. If the result of an I²C procedure is to be ignored, a dummy assignment must be done for a typed procedure. The examples in the following section assume that the procedures are called from a PL/M program. Examples will be given later how to use these routines with C and assembly application programs.

3.2.1 Init_IIC

Declaration

```
Init_IIC:
    PROCEDURE (Own_Slave_Address, Slave_Sub_Address)
        EXTERNAL;
    DECLARE (Own_Slave_Address, Slave_Sub_Address) BYTE;
    END;
```

Description

Init_IIC must be called after RESET, before any procedure is called. The I²C interface and I²C interrupt will be enabled. The global enable interrupt flag, however, will not be affected. This should be done afterwards. Own_Slave_Address is passed to Init_IIC for use as slave. Slave_Sub_Address is the pointer to a DATA buffer that is used for data transfer in slave mode. When used as master in a single master system, these parameters are not used.

Example

```
CALL Init_IIC (54h, Slave_Data_Buffer);
ENABLE; /* Enable Interrupts; EA=1 */
```

3.2.2 Dis_IIC

Declaration

```
Dis_IIC:
    PROCEDURE EXTERNAL;
```

Description

Dis_IIC will disable the I²C-interface and the I²C-interrupt. The I²C interface will still monitor the bus, but will not influence the SDA and SCL lines.

Example

```
CALL Dis_IIC;
```

3.2.3 IIC_Test_Device

Declaration

```
IIC_Test_Device:
    PROCEDURE (Slave_Address) [BIT|BYTE] EXTERNAL;
    DECLARE (Slave_Address) BYTE;
    END;
```

Description

IIC_Test_Device just sends the slave address to the I²C bus. It can be used to check the presence of a device on the I²C bus.

I²C Protocol

```
S-SlW-A-P : Device is present, IIC_Error=0
S-SlW-N-P : Device is not present, IIC_Error=1
```

Example

```
DECLARE IIC_Error BIT;
.....
IIC_Error=IIC_Test_Device(8Ch);
IF (IIC_Error) THEN
    "Device not acknowledging on slave address"
ELSE
    "Device acknowledges on slave address"
```

I²C routines for 8XC528

AN438

3.2.4 IIC_Write

Declaration

```
IIC_Write:
  PROCEDURE (Slave_Address, Count, Source_Ptr)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Source_Ptr) BYTE;
  END;
```

Description

IIC_Write is the most basic procedure to write a message to a slave device.

I²C Protocol

```
L           =Count
D1[0..L-1]  BASED by Source_Ptr
```

```
S-SlW-A-D1[0]-A...A-D1[L-1]-A-P
```

Example

```
DECLARE Data_Buffer(4) BYTE;
.....
CALL IIC_Write(02Ch, LENGTH(Data_Buffer),Data_Buffer);
```

3.2.5 IIC_Write_Sub

Declaration

```
IIC_Write_Sub:
  PROCEDURE (Slave_Address, Count, Source_Ptr,
    Sub_Address) [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Source_Ptr, Sub_Address)
    BYTE;
  END;
```

Description

IIC_Write_Sub writes a message preceded by a sub-address to a slave device.

I²C Protocol

```
L           =Count
Sub         =Sub_Address
D1[0..L-1]  BASED by Source_Ptr
```

```
S-SlW-A-Sub-A-D1[0]-A-D1[1]-A...A-D1[L-1]-A-P
```

Example

```
DECLARE Data_Buffer(8) BYTE;
.....
CALL IIC_Write_Sub (48h,LENGTH(Data_Buffer),Data_Buffer,2);
```

3.2.6 IIC_Write_Sub_SWInc

Declaration

```
IIC_Write_Sub_SWInc:
  PROCEDURE (Slave_Address, Count, Source_Ptr,
    Sub_Address) [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Source_Ptr, Sub_Address)
    BYTE;
  END;
```

Description

Some I²C devices addressed with a sub-address do not automatically increment the sub-address after reception of each byte. IIC_Write_Sub_SWInc can be used for such devices the same way as IIC_Write_Sub is used. IIC_Write_Sub_SWInc splits up the message in smaller messages and increments the sub-address itself.

I²C Protocol

```
L           =Count
Sub         =Sub_Address
D1[0..L-1]  BASED by Source_Ptr
```

```
S-SlW-A- (Sub+0) - A-D1[0] - A-P
```

```
S-SlW-A- (Sub+1) - A-D1[1] - A-P
```

```
.....
```

```
S-SlW-A- (Sub+L-1)-A-D1[L-1]-A-P
```

Example

```
DECLARE Data_Buffer(6) BYTE;
.....
CALL IIC_Write_Sub_SWInc(80h,LENGTH
(Data_Buffer),Data_Buffer,2);
```

3.2.7 IIC_Write_Memory

Declaration

```
IIC_Write_Memory:
  PROCEDURE (Slave_Address, Count, Source_Ptr,
    Sub_Address) [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Source_Ptr, Sub_Address)
    BYTE;
  END;
```

Description

I²C Non-Volatile Memory devices (such as PCF8582) need an additional delay after writing a byte to it. IIC_Write_Memory can be used to write to such devices the same way IIC_Write_Sub is used. IIC_Write_Memory splits up the message in smaller messages and increments the sub-address itself. After transmission of each message a delay of 40 milliseconds ($f_{Xtal} = 16$ MHz) is inserted.

I²C Protocol

```
L           =Count
Sub         =Sub_Address
D1[0..L-1]  BASED by Source_Ptr
```

```
S-SlW-A- (Sub+0) - A-D1[0] - A-P
```

```
  Delay 40ms
```

```
S-SlW-A- (Sub+1) - A-D1[1] - A-P
```

```
  Delay 40ms
```

```
.....
```

```
S-SlW-A- (Sub+L-1)-A-D1[L-1]-A-P
```

```
  Delay 40ms
```

Example

```
DECLARE Data_Buffer(10) BYTE;
.....
CALL IIC_Write_Memory(0A0h,LENGTH
(Data_Buffer),Data_Buffer,0F0h);
```

I²C routines for 8XC528

AN438

3.2.8 IIC_Write_Sub_Write

Declaration

```
IIC_Write_Sub_Write:
  PROCEDURE (Slave_Address, Count1, Source_Ptr1,
    Sub_Address, Count2, Source_Ptr2)
    [BIT|BYTE] EXTERNAL;
  DECLARE (Slave_Address, Count1, Source_Ptr1,
    Sub_Address, Count2, Source_Ptr2) BYTE;
  END;
```

Description

IIC_Write_Sub_Write writes 2 data blocks preceded by a sub-address in one message to a slave device. This procedure can be used for devices that need an extended addressing method, without the need to put all data into one large buffer. Such a device is the ECCT (I²C controlled teletext device; see example).

I²C Protocol

```
L           =Count1
M           =Count2
Sub         =Sub_Address
D1[0..L-1]   BASED by Source_Ptr1
D2[0..M-1]   BASED by Source_Ptr2
```

```
S-SlvW-A-Sub-A-D1[0]-A-D1[1]-A-....
-A-D1[L-1]-A-D2[0]-A-D2[1]-A-....
-A-D2[M-1]-A-P
```

Example

```
PROCEDURE Write_CCT_Memory
  (Chapter, Row, Column, Data_Buf, Data_Count);
DECLARE (Chapter, Row, Column, Data_Buf, Data_Count) BYTE;
```

```
/*
  The extended address (CCT-Cursor) is formed by Chapter, Row
  and Column. These three bytes are written after the sub-address
  (=8) followed by the actual data that will be stored relative to the
  extended address.
*/
```

```
CALL IIC_Write_Sub_Write (22h, 3, .Chapter, 8, Data_Buf,
  Data_Count);
END Write_CCT_Memory;
```

3.2.9 IIC_Write_Sub_Read

Declaration

```
IIC_Write_Sub_Read:
  PROCEDURE (Slave_Address, Count1, Source_Ptr1,
    Sub_Address, Count2, Dest_Ptr2)
    [BIT|BYTE] EXTERNAL;
  DECLARE (Slave_Address, Count1, Source_Ptr1,
    Sub_Address, Count2, Dest_Ptr2) BYTE;
  END;
```

Description

IIC_Write_Sub_Read writes a data block preceded by a sub-address, generates an I²C restart condition, and reads a data block. This procedure can be used for devices that need an extended addressing method. Such a device is the ECCT.

I²C Protocol

```
L           =Count1
M           =Count2
Sub         =Sub_Address
D1[0..L-1]   BASED by Source_Ptr1
D2[0..M-1]   BASED by Source_Ptr2
```

```
S-SlvW-A-Sub-A-D1[0]-A-D1[1]-A-....
-A-D1[L-1]-A-S-SlvR-A-D2[0]-A-D2[1]-A-....
-A-D2[M-1]-N-P
```

Example

```
PROCEDURE Read_CCT_Memory
  (Chapter, Row, Column, Data_Buf, Data_Count);
DECLARE (Chapter, Row, Column, Data_Buf, Data_Count) BYTE;
```

```
/*
  The extended address (CCT-Cursor) is formed by Chapter, Row
  and Column. These three bytes are written after the sub-address
  (8). After that the actual data will be read relative to the extended
  address.
*/
```

```
CALL IIC_Write_Sub_Write (22h, 3, .Chapter, 8, Data_Buf,
  Data_Count);
END Read_CCT_Memory;
```

I²C routines for 8XC528

AN438

3.2.10 IIC_Write_Com_Write**Declaration**

```
IIC_Write_Com_Write:
  PROCEDURE (Slave_Address, Count1, Source_Ptr1, Count2,
    Source_Ptr2) [BIT|BYTE] EXTERNAL;
  DECLARE (Slave_Address, Count1, Source_Ptr1, Count2,
    Source_Ptr2) BYTE;
  END;
```

Description

IIC_Write_Com_Write writes two data blocks from different data buffers in one message to a slave receiver. This procedure can be used for devices where the message consists of 2 different data blocks. Such devices are, for instance, LCD-drivers, where the first part of the message consists of addressing and control information, and the second part is the data string to be displayed.

I²C Protocol

```
L           =Count1
M           =Count2
D1[0..L-1]   BASED by Source_Ptr1
D2[0..M-1]   BASED by Source_Ptr2
```

```
S-SlvW-A-D1[0]-A-D1[1]-A-....
  -A-D1[L-1]-A-D2[0]-A-D2[1]-A-....
  -A-D2[M-1]-A-P
```

Example

```
DECLARE Control_Buffer(2) BYTE;
DECLARE Data_Buffer(20) BYTE;
.....
CALL IIC_Write_Com_Write(74h, LENGTH(Control_Buffer),
  .Control_Buffer, LENGTH(Data_Buffer), .Data_Buffer);
```

3.2.11 IIC_Write_Rep_Write**Declaration**

```
IIC_Write_Rep_Write:
  PROCEDURE (Slave_Address1, Count1, Source_Ptr1,
    Slave_Address2, Count2, Source_Ptr2)
    [BIT|BYTE] EXTERNAL;
  DECLARE (Slave_Address1, Count1, Source_Ptr1,
    Slave_Address2, Count2, Source_Ptr2) BYTE;
  END;
```

Description

Two data strings are sent to separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

```
L           =Count1
M           =Count2
SlvW1       =Slave_Address1
SlvW2       =Slave_Address2
D1[0..L-1]   BASED by Source_Ptr1
D2[0..M-1]   BASED by Source_Ptr2
```

```
S-SlvW-A-D1[0]-A-D1[1]-....
  -A-D1[L-1]-A-S-SlvW-A-D2[0]-A-D2[1]-....
  -A-D2[M-1]-A-P
```

Example

```
DECLARE Data_Buffer_1(10) BYTE;
DECLARE Data_Buffer_2(4) BYTE;
.....
CALL IIC_Write_Rep_Write (48h, LENGTH(Data_Buffer_1),
  .Data_Buffer_1, 50h, LENGTH(Data_Buffer_2), .Data_Buffer_2);
```

I²C routines for 8XC528

AN438

3.2.12 IIC_Write_Rep_Read**Declaration**

```
IIC_Write_Rep_Read:
  PROCEDURE (Slave_Address1, Count1, Source_Ptr1,
    Slave_Address2, Count2, Dest_Ptr2)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address1, Count1, Source_Ptr1,
    Slave_Address2, Count2, Dest_Ptr2) BYTE;
  END;
```

Description

A data string is sent and received to/from two separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

```
L           =Count1
M           =Count2
SlvW1      =Slave_Address1
SlvW2      =Slave_Address2
D1[0..L-1]   BASED by Source_Ptr1
D2[0..M-1]   BASED by Dest_Ptr2
```

```
S-SlvW-A-D1[0]-A-D1[1]-....
-A-D1[L-1]-A-S-SlvR-A-D2[0]-A-D2[1]-....
-A-D2[M-1]-N-P
```

Example

```
DECLARE Data_Buffer_1(10) BYTE;
DECLARE Data_Buffer_2(4) BYTE;
.....
CALL IIC_Write_Rep_Read (48h, LENGTH(Data_Buffer_1),
  .Data_Buffer_1, 57h, LENGTH(Data_Buffer_2), .Data_Buffer_2);
```

3.2.13 IIC_Read**Declaration**

```
IIC_Read:
  PROCEDURE (Slave_Address, Count, Dest_Ptr)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Dest_Ptr) BYTE;
  END;
```

Description

IIC_Read is the most basic procedure to read a message from a slave device.

I²C Protocol

```
M           =Count
D2[0..M-1]   BASED by Dest_Ptr
```

```
S-SlvR-A-D2[0]-A-D2[1]-A.....A-D2[M-1]-N-P
```

Example

```
DECLARE Data_Buffer(4) BYTE;
.....
CALL IIC_Read (0B5, LENGTH(Data_Buffer), .Data_Buffer);
```

3.2.14 IIC_Read_Status**Declaration**

```
IIC_Read_Status:
  PROCEDURE (Slave_Address, Dest_Ptr)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Dest_Ptr) BYTE;
  END;
```

Description

Several I²C devices can send a one byte status-word via the bus. IIC_Read_Status can be used for this purpose. IIC_Read_Status works the same way as IIC_Read but the user does not have to pass a count parameter.

I²C Protocol

```
Status      BASED by Dest_Ptr
```

```
S-SlvR-A-Status-N-P
```

Example

```
DECLARE Status_Byte BYTE;
.....
CALL IIC_Read_Status (84h, .Status_Byte);
```

3.2.15 IIC_Read_Sub**Declaration**

```
IIC_Read_Sub:
  PROCEDURE (Slave_Address, Count, Dest_Ptr, Sub_Address)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address, Count, Dest_Ptr, Sub_Address)
    BYTE;
  END;
```

Description

IIC_Read_Sub reads a message from a slave device, preceded by a write of the sub-address. Between writing the sub-address and reading the message, an I²C restart condition is generated without releasing the bus. This prevents other masters from accessing the slave device in between and overwriting the sub-address.

I²C Protocol

```
M           =Count
Sub         =Sub_Address
D2[0..M-1]   BASED by Dest_Ptr
```

```
S-SlvW-A-Sub-A-S-SlvR-D2[0]-A-D2[1]-A.....A-D2[M-1]-N-P
```

Example

```
DECLARE Data_Buffer(5) BYTE;
.....
CALL IIC_Read_Sub (0A3h, LENGTH(Data_Buffer), .Data_Buffer, 2);
```

I²C routines for 8XC528

AN438

3.2.16 IIC_Read_Rep_Read**Declaration**

```
IIC_Read_Rep_Read:
  PROCEDURE (Slave_Address1, Count1, Dest_Ptr1,
    Slave_Address2, Count2, Dest_Ptr2)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address1, Count1, Dest_Ptr1,
    Slave_Address2, Count2, Dest_Ptr2) BYTE;
  END;
```

Description

Two data strings are read from separate slave device, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

```
L           =Count1
M           =Count2
SivW1      =Slave_Address1
SivW2      =Slave_Address2
D1[0..L-1] BASED by Dest_Ptr1
D2[0..M-1] BASED by Dest_Ptr2
```

```
S-SivR-A-D1[0]-A-D1[1]-.....
  -A-D1[L-1]-N-S-SivR-A-D2[0]-A-D2[1]-.....
  -A-D2[M-1]-N-P
```

Example

```
DECLARE Data_Buffer_1(10) BYTE;
DECLARE Data_Buffer_2(4) BYTE;
.....
CALL IIC_Read_Rep_Read (49h, LENGTH(Data_Buffer_1),
  .Data_Buffer_1, 51h,
  LENGTH(Data_Buffer_2), .Data_Buffer_2);
```

3.2.17 IIC_Read_Rep_Write**Declaration**

```
IIC_Read_Rep_Write:
  PROCEDURE (Slave_Address1, Count1, Dest_Ptr1,
    Slave_Address2, Count2, Source_Ptr2)
    [BITIBYTE] EXTERNAL;
  DECLARE (Slave_Address1, Count1, Dest_Ptr1,
    Slave_Address2, Count2, Source_Ptr2) BYTE;
  END;
```

Description

A data string is received and sent from/to two separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

```
L           =Count1
M           =Count2
SivW1      =Slave_Address1
SivW2      =Slave_Address2
D1[0..L-1] BASED by Dest_Ptr1
D2[0..M-1] BASED by Source_Ptr2
```

```
S-SivR-A-D1[0]-A-D1[1]-.....
  -A-D1[L-1]-N-S-SivW-A-D2[0]-A-D2[1]-.....
  -A-D2[M-1]-A-P
```

Example

```
DECLARE Data_Buffer_1(10) BYTE;
DECLARE Data_Buffer_2(4) BYTE;
.....
CALL IIC_Read_Rep_Write(49h, LENGTH(Data_Buffer_1),
  .Data_Buffer_1, 58h,
  LENGTH(Data_Buffer_2), .Data_Buffer_2);
```

I²C routines for 8XC528

AN438

3.2.18 Slave Mode Routines

There are two ways for the I²C interface to enter the slave-mode:

- After an I²C interrupt the software must enter the slave-receiver mode to receive the slave address. This address will then be compared with its own address. If there is a match either slave-transmitter or slave-receiver mode will be entered. If no match occurs, the interrupted program will be continued.
- During transmission of a slave-address in master-mode, arbitration is lost to another master. The interface must then switch to slave-receiver mode to check if this other master wants to address the 8xC528 interface.

The slave-mode protocol is very application dependent. In this note the basic slave-receive and slave-transmit routines are given and should be considered as examples. The user may for instance send NO_ACK after receiving a number of bytes to signal to the master-transmitter that a data buffer is full. A description of the code will be given later.

Slave parameters are given with the Init_IIC procedure. The passed parameters are the own-slave-address and a source/destination-pointer to a data buffer.

The slave-routine will be suspended at the following conditions:

- Interrupts with higher priority. Slave-routine will be resumed again after interrupt is handled.
- If a NO_ACKNOWLEDGE is received from a master-receiver.
- If a STOP condition is detected from a master transmitter.

Constraints for user software.

- The user must control the global enable (EA) bit.
- The user must control the priority level of the I²C interrupt. If the slave routine is interrupted by a higher priority interrupt, the SCL line will be stretched to postpone bus transfer until the higher interrupt is finished.

3.3 The Slave Routine: SLAVE.ASM

The listing of the slave routine can be seen on page 4-111. The routine is written in such a way that stretching of SCL is minimized. Application code can be inserted in this routine and this will increase stretching time.

The routine has 2 entry points.

Entry via MST_ENTRY happens when an arbitration error has occurred when transmitting a slave address in master mode.

Auto-clock generation will be disabled and SCL stretching enabled. The byte will be continued to be received and can later be compared with the own slave address.

The second entry point is via an interrupt when a START condition is detected. At _PIPOA the context of the interrupted program is stored. Next Auto-clock generation is disabled and SCL stretching enabled. Reception of the slave address can now begin by calling RCV_SL_BY. When the received slave-address is compared with the own-slave-address the R/W-bit is ignored. If there is no match between the 2 addresses, a negative ACK bit is sent and the slave routine is left via EXIT. If there was a match the R/W bit is checked to enter the slave-receiver or slave-transmitter mode.

The slave-transmitter mode starts at NXT_TRX. After getting the byte from the data buffer via BUF_POINT and initializing the bit counter BIT_CNT the transmission loop is entered. A bit is written via access to S1BIT because this will automatically reset the CLH and WBF status flags, and also SCL stretching. Now WBF must be tested until the transmission is successful. When WBF becomes true, SCL will be stretched again. When 8 bits are sent, the SDA line is released and RBF is tested until the ACK bit is received. The ACK bit is read by reading SDI instead of S1BIT to maintain SCL stretching. If ACK was false, no more bytes have to be sent and the routine is left. If another byte has to be transmitted, BUF_POINT is updated and transmission will continue.

The slave-receiver mode starts at RCV_SLAVE. A byte is received by calling RCV_SL_BY. This routine will clear the CY-flag when a STOP condition has been received. This means that the master will send no more bytes to this slave and the slave routine will be left. When no STOP condition was detected, the received byte will be stored @BUF_POINT and an ACK bit will be sent. After this, a new byte can be received.

When calling RCV_SL_BY the bit counter BIT_CNT will be initialized and the SCL stretching stopped by a dummy access to S1BIT. In the receive loop both BB and RBF will be checked. When BB is cleared, a STOP condition is detected and the routine will be left with CY=0.

The first 7 bits are received via S1BIT because this will release stretching. The 8th bit is accessed via SDI because stretching must be maintained.

If the slave routine is left via EXIT, the STR bit is cleared (to disable stretching on SCL edges when the 8xC528 is not addressed as slave) and a dummy access to S1BIT is done to finish current SCL stretching. If the slave routine was entered via an interrupt the previous context is restored.

4.0 EXAMPLES

4.1 Introduction

Some examples are given how to use the I²C routines in an application program. Examples are given for assembly, PL/M and C program.

The program displays time from the PCF8583P clock/calendar/RAM on an LCD display driven by the PCF8577.

The example can be executed on the OM4151 I²C evaluation board.

4.2 Using the Routines with Assembly Sources

The listing of the example program is shown on page 4-116. The most important aspect when using the I²C routines is preparing the input parameters before the sub-routine call. When, for example, the IIC_Write routine must be called, the parameters must be called in the following order:

```
MOV _IIC_READ_BYTE,#SLAVE_ADR
MOV _IIC_READ_BYTE+1,#COUNT_1
MOV _IIC_READ_BYTE+2,#SOURCE_PTR_1
CALL _IIC_READ
```

Note that the order of defining the parameters is the same as in a PL/M-call. An easier way to call the routines is making a macro that includes the initializing of the parameters. The example program makes use of macros.

IIC_Read is then called in the following way:

```
%IIC_Read(Slave_Adr,Count_1,Source_Ptr_1);
```

Note that in the listing the contents of the macro are shown, instead of the call.

The macro must be written as follows:

```
;%* DEFINE
(IIC_Read(SLAVE_ADR,COUNT_1,SOURCE_PTR_1))
(MOV _IIC_READ_BYTE,#%SLAVE_ADR
MOV _IIC_READ_BYTE+1,#%COUNT_1
MOV _IIC_READ_BYTE+2,#%SOURCE_PTR_1
LCALL _IIC_READ)
```

Macros for the I²C CALLs are found in I2C.MAC. This file should be included in all modules making use of the macros. One of the modules should also include the variable definitions needed by the I²C routines. These are found in file VAR_DEF.ASM. If the program consists of more than 1 module, then these modules should also include EXT_VAR.ASM. This file contains the EXTRN- definitions of the I²C routines.

When an I²C routine is called, the accumulator contains status information and the CY-bit is set if an error has occurred. The contents of the accumulator are the same as the returned byte when using PL/M.

4.4 Using the Routines with C Sources

An example of a C program using the I²C routines follows. Function prototypes are found in header file "i2c.h". In this example the function prototypes are written in such a way that not value is returned by the function. If the STATUS byte is needed, the header file may be changed to return a byte. Note that the function calls are written in upper-case. This is due to the fact that the used version of the assembler/linker is case sensitive.

```
#include <C:\USER\i2c.h>

rom char          LCD_Tab[]={0xFC,0x60,0xDA,0xF2,0x66,0xB6,0x3E,
                             0xE0,0xFE,0xE6};

void main()
{
    #define Clock_Adr      0xA2
    #define LCD_Adr       0x74
    #define Cl_Sub_Adr    0x01

    rom char          * Tab_Ptr;
    data char         Time_Buffer[4];
    data char         * Time_Ptr;
    data char         LCD_Buffer[5];
    data char         * LCD_Ptr;

    INIT_IIC(0x22,&Time_Buffer);
    LCD_Buffer[0]=0; /* LCD control word */
    Time_Buffer[0]=0;
    Time_Buffer[1]=0;
    IIC_WRITE(Clock_Adr,2,&Time_Buffer); /* Initialize clock */

    while (1) /* Program loop */
    {
        IIC_READ_SUB(Clock_Adr,4,&Time_Buffer,Cl_Sub_Adr);
        /* Get time */
        LCD_Ptr = &LCD_Buffer[1]; /* Initialize pointers */
        Time_Ptr = &Time_Buffer[3];
        Tab_Ptr = (LCD_Tab+(*Time_Ptr >> 4)); /* 10-HR's */
        *(LCD_Ptr++) = *Tab_Ptr;
        Tab_Ptr = (LCD_Tab+(*Time_Ptr-- & 0x0F)); /* HR's */
        *(LCD_Ptr++) = *Tab_Ptr;
        Tab_Ptr = (LCD_Tab+(*Time_Ptr >> 4)); /* 10-MIN's */
        *(LCD_Ptr++) = (*Tab_Ptr | 0x01); /* dp */
        Tab_Ptr = (LCD_Tab+(*Time_Ptr & 0x0F)); /* MIN's */
        *LCD_Ptr = *Tab_Ptr;
        Time_Ptr = &Time_Buffer[1]; /* Check sec's for blinking */
        LCD_Ptr = &LCD_Buffer[1];
        if ((*Time_Ptr & 0x01)>0)
            *LCD_Ptr = (*LCD_Ptr | 0x01);
        IIC_WRITE(LCD_Adr,5,&LCD_Buffer); /* Display time */
    }
}
```

5.0 CONTENTS OF DISK

A disk contains the following 3 directories:

1: \USER

This director contains the files that may be used in the user program.

I2C_DR.LIB	Library with I ² C routines.
I2C.H	Header file for C applications.
I2C.MAC	Macro's for the I ² C routine calls in assembly programs.
VAR_DEF.ASM	Include file with variable definitions for assembly programs.
EXT_VAR.ASM	Include file with external definitions for assembly programs.
LIB.BAT	Example batch file to create I2C_DR.LIB.
ASM.BAT	Example batch file to assemble source modules for library.

2: \EXAMPLE

This directory contains the source files of the examples described in chapter 4.0.

DEMO_ASM.*	Assembly example.
DEMO_PLM.*	PL/M example.
HEAD_51.SRC	Example of environment file for PL/M example.
DEMO_C.*	C example.
CSTART.ASM	Example of environment file for C example.

3: \SOURCE

This directory contains the source files of the modules in the library.

Using the P82B715 I²C extender on long cables

AN444

Author: Don Sherman, Sunnyvale

The P82B715 I²C Buffer was designed to extend the range of the local I²C bus out to 50 Meters. This application note describes the results of testing the buffer on several different types of cables to determine the maximum operating distances possible. The results are summarized in a table for easy reference.

The I²C bus was originally conceived as a convenient 2 wire communication method between Integrated Circuits located within a common chassis, such as inside a TV set or inside a VCR. The serial protocol contains an address, or identifying code, for each type of device and additional internal addresses, if needed within the addressed device. Each device has its own decoding circuitry to allow it to recognize its own unique address or identifying code. To communicate, a device watches the bus activity and jumps in when it sees a stop. Once a Master gets control of the bus, it sends the address of the particular device with which it wants to communicate. Communication will then transpire between the Master and the Slave device. The existence of many types of ICs which have built-in I²C interface capabilities makes system design almost as easy as drawing a block diagram. Real-time clocks, RAM, A/D converters, EEPROMs, Microcontrollers, Keyboard encoders, LCD display drivers, and many other I²C supported chips all communicate over two wires rather than needing 16 Address lines, 8 data lines and Address decoders along with handshake signals, which more conventional designs would require to be routed all over the Printed Circuit board.

Now, with the introduction of the I²C buffer chip, it is easy to branch out beyond the single chassis mode and use this convenient local area network to tie together whole systems without the need to convert from the "internal" I²C protocol to an external communication medium such as RS-232 and then RS-485. By using the new Philips I²C buffer, the external systems' components can be accessed as easily as the internal I²C connected components.

The P82B715 is an 8 pin IC which contains 2 identical amplifier sections to allow for the current amplification and buffering of both the SDA and the SCL signals on the I²C bus. Each section in the P82B715 contains a bipolar times 10 current amplifier which senses the direction of current flow through an internal 30 ohm series resistor in the I²C line. The P82B715 then boosts the current, while keeping the voltage gain at unity, and continues to maintain the voltage drop direction across the resistor. This configuration results in different waveforms as the P82B715 starts to do its job. If the driving source has a strong current sink capability, then it will start to drive the buffered I²C line immediately through the 30 ohm resistor. A microsecond later the P82B715's amplified pull down current kicks in and pulls the line down even harder. If the driving IC is only capable of the I²C specified 3 milliamp pull down current, the buffered bus will fall a little and then just wait at that voltage level for the propagation delay of the amplifier to finally turn on and bring the buffered bus down to a logic low. Thus, there will always be some form of a step in the falling edge of the buffered output waveform, see Figure 1. A weak source will have a step (plateau) up near 4 volts and a strong source, such as the Philips Semiconductors 87C751 microcontroller, will have the step occur below 2 volts. The position of the step will be determined by the current sink capability of the I²C bus driver versus the value of the pull-up resistor which is used on the buffered I²C bus, $V_{step} = 5V - (I_{sink} \times R_{buf})$. For example: $V_{step} = 5V - (3mA \times .165 k \text{ ohms}) = 5 - .495 = 4.5Volts$; another example: $V_{step} = 5V - (20mA \times .165 k \text{ ohms}) = 5 - 3.3 = 1.7Volts$.

Running the I²C signals over long distances poses several problems. The I²C SDA and SCL lines are monitored by all of the

ICs connected on the I²C bus. These ICs each have their own circuitry to decipher the information on the bus. In normal operation, a Start occurs when there is a high to low transition on the SDA line while SCL is high. Obviously, if any external noise is coupled into the SDA line, it could be mistakenly perceived as a Start. Because of this, some form of shielding will be preferred to protect the two I²C signals from external noise sources. During the transmission of data there are signals which are active on both SDA and SCL. If these normal signals are cross-coupled, then data can be corrupted. Thus, although the standard telephone twisted pair cable is the most commonly available built in cable, it is not recommended for long I²C runs. This cable maximizes crosstalk, due to the twisted pair configuration and, since there is no shielding, is very vulnerable to adjacent wire telephone signal coupling and to any stray external electromagnetic interference. This effect can be somewhat reduced by running a signal wire and a grounded wire as adjacent pairs.

Long distance cables present capacitive loading which must be overcome with the driver chips. The limiting factor is the amount of pull-up current which is available to charge the line capacitance. With the simple resistor pull-up recommended by I²C standards, three milliamps is available for charging this line capacitance. The rise time of the signal will increase linearly with the increase in capacitive loading and the specified maximum capacitive loading is only 400 Pico Farads for guaranteed 100kHz communication rates. The P82B715 current buffer allows for 30 milliamps of pull-up current, with a resulting maximum capacitive loading of 4,000 Pico Farads (4 Nano Farads).

The I²C hardware inputs look at the I²C signals and act when those signals pass through the active linear region at about 1.2 to 1.4 volts, and are detected as digital levels. Thus, there is a delay between when an output transistor turns off and when the rising signal is detected as a logic one at the receiver. This time depends on the value of the pull-up resistor, the perceived capacitance at the transmitting end, the delay through the cable, and finally the delay through the receiver's amplifier to its output stage. The maximum allowable time is limited by the characteristic that the I²C master provides the clock signal which must travel down the cable and be received by the slave. This slave must act on the clock signal and produce data information which is sent back to the master with an additional set of delays. Upon reception the data must be put in its proper place before the master starts its next clock signal, or an error will occur.

Different types of cable were tested and the results are shown in Table 1. Keep in mind that the results are based on cable runs in a low electrical noise environment. If reliable operation is desired in a high electrical noise environment, shielded cable must be used. For "short" runs, flat cable with every other conductor grounded, seems to provide a good, low capacitance medium for I²C transmission, otherwise, the shielded audio cable seemed to provide the best price/performance. Note that for long runs, it is desirable to have a separate power supply at each end of the cable, and the shield or ground wire will provide a common reference between the two supplies. The voltage drop due to the resistance of the wire usually is the limiting factor for very long runs of cable where the power to the remote system must also come through the cable. Table 1 shows the results of testing with longer and longer cable lengths until failures were detected. The values in the table represent the maximum cable lengths which still provided error free code from a modified version of the Ping-pong program which is listed in Application Note AN430.

Using the P82B715 I²C extender on long cables

AN444

Figure 1. P82B715 Output Waveform on Long Cable

Table 1. Test Results with P82B715 Over Long Cables

CABLE TYPE	Ohms/m	pF/m	Total Length	Total Ohms	Total Cap.
Belden 8723 45 Ohm Audio 2 each 2—24AWG wire stranded Beldfoil Aluminum-polyester shielded with common drain wire SDA & ground on one pair; SCL & ground on other pair	.049	115	305M (1000')	11.5	48.2nF
Belden 8723 45 Ohm Audio using 1 shielded pair, SDA on Red, SCL on Black	.049	115	330M (1100')	12.7	53nF
RG-174/U 50 Ohm Video Cable SDA and grounded shield in one cable SCL and grounded shield in one cable	.318	101	150M (500')	47.7	15.2nF
"Telephone Cable" 22&24 AWG Solid Copper Twisted Pair, Level 3 LAN & Medium Speed Data SDA and ground in one twisted pair SCL and ground in one twisted pair	.0286	66	95M (310')	2.7	6.4nF
Flat "Ribbon" Cable, every other conductor grounded	.20	52	400M (1320')	80.5	21nF

In all of the tests, the power supply voltage was 4.5 volts. The ground for the remote test fixture was through the long cable. Since 4.5 volts is the recommended minimum voltage for both the 87C751 and the P82B715, it was not possible to operate the remote unit on power supplied through the long cable, since any ohmic drop would place the ICs out of their specified range. However, it is necessary to connect the grounds between the two units for the best noise immunity.

The P82B715 is designed to drive a 4 nF capacitive load at 100kHz. However, the actual total capacitances of the long cables which worked were substantially greater than this. The loading did effect the software driven hardware part of the 87C751. To achieve a true 100kHz data rate, it was necessary to shorten the '751 Timer values for the I²C drivers. This resulted in an asymmetrical waveform, but did achieve a 10 microsecond period (100kHz). This asymmetry in duty cycle can be easily seen in the Figure 1 waveform.

The test with the Belden 8723 Audio Cable worked if one of the shielded pair was connected to a signal and the other was connected to ground or +5volts. When both wires were connected in parallel as signal wires, the capacitance to ground doubled and the test failed. Also note that the adjacent wire mutual inductive coupling of the SDA and SCL signals did not seem to cause any problems

even out to 1000 feet. This indicated that possibly the Belden 9452 45 ohm beldfoil shielded audio cable with a single set of twisted pair wires would be a good candidate to also try.

Flat ribbon cable provided a good compromise between shielding and reasonable capacitance. It is possible to increase the shielding effect by using flat cable with an etched copper foil layer on the back side of the cable. Noise can be induced into the cable by folding it back over itself for mutual induction effects, and also by operating a noise source close to the cable. A transformer type of soldering iron and florescent light transformers seemed to be good noise sources.

The P82B715 can drive multiple P82B715 remote units. The line should have some form of pull-up resistor at each driver. If only two drivers are used, as shown in Figure 2, the load should be split between the two drivers. For example, if the pull-up current is to be 30 milliamps and the voltage is 5 volts, the pull-up resistance should be: $5V/.030 \text{ amps} = 165 \text{ ohms}$. This should be implemented by placing a 330 ohm resistor at each end of the cable so that the parallel resistance is 165 ohms and each end of the line is terminated. Remembering that the current gain can be as low as 8 and that most runs will not be to the maximum possible distance, lower values of pull-up current can be used with the appropriate modifications to the above equations.

Using the P82B715 I²C extender on long cables

AN444

For larger fan-out with fixed locations, the load resistance should also be evenly divided so that the parallel combination of all of the pull-up resistors will provide the desired D.C. pull-up current.

If some of the remote units will be pluggable, it will be necessary to divide the pull-up load to accommodate all of the possible combinations of possible fanout. Figure 3 shows an example of driving up to 30 remote, pluggable peripherals. On the 3 milliamp side of the P82B715 a complete I²C system may exist. In Figure 3, a local I²C network cluster could be joined to other local network clusters through the P82B715 buffered bus so that hundreds of I²C devices could potentially be interconnected.

The ease of connecting I²C clusters into a complete LAN opens the door for many new uses of components which have an I²C bus connection. Now an electronic instrument can have access to remote keyboards and remote sensors by using the I²C bus. The instrument's output can easily be shown on multiple remote displays all connected with the I²C bus. Multiple instruments can also pass data back and forth over the I²C bus. Thus, we see that the I²C bus can become an effective and inexpensive Local Area Network by using the P82B715 I²C bus extender.

THE TEST SETUP

These tests were run on two identical test boards which each use a Philips Semiconductors 87C751 microcontroller that drives the I²C buffer which has a 330 ohm pull-up resistor. The schematic is shown in Figure 4. The software is a modified version of the "Ping-Pong" program which is described in the Philips Semiconductors Application Note, AN430, "Using the 8XC751/752 in Multimaster applications". This program sends a number down the I²C line and, when received, the receiving unit becomes a master and increments the number and sends it back to the first unit where it is checked and then the process repeats itself. The software has extensive error detection capability and monitors for corruption of data, false starts, over run of data, stuck lines and about anything else which might indicate a problem. If any errors did occur, a software counter was incremented. In this setup, the counter was stopped at Hex 07F to prevent wrap around and the contents of the counter are displayed on a bank of 8 LEDs. The MSB of the counter register was used as an indicator that the unit was working. The MSB LED flashes at about a 1 Hz rate when the unit is operating normally. When a cable length was reached which was too long, the MSB LED would stop flashing and the counter would rapidly fill up and stop with all 7 LEDs on (LED on indicates a logic "1" in this application).

THE TEST HARDWARE

A general purpose test rig was designed so that future needs of a general I²C platform could also be met. All of the port pins on the '751 were used. The inputs to the system were a toggle switch with a pull-up resistor connected to P0.2 (because this pin is Open Drain)

and an octal DIP switch connected to port 1 (the internal pull ups of the port were used, so no external pull-up resistors were needed). The output is displayed through an octal buffer connected to port 3. A logical "1" on the pin will light up the LED. The I²C signals, SDA and SCL, are connected to the I²C buffer chip and the outputs of the buffer are pulled up by 330 ohm resistors. The parallel combination of the buffered transmitting end pull-up and the receiving end pull-up resistors is 330/2 ohms, which results in a pull-up load current of 30 milliamps. This current from the two pull-up resistors must be sunk by the single driving transistor of the acting sender. The effective loading seen by the '751 is the I²C buffer's load divided by 10. Thus, the '751's I²C outputs will sink 3 milliamps when driving the I²C buffer which is sinking 30 milliamps on the buffered bus.

The software monitor routine allows the user to monitor any internal '751 RAM location and display the contents on the LEDs. The monitor routine also allows the user to modify the contents of any RAM location including SFR space. The Ping-Pong program needed the first 8 locations in RAM, so the stack pointer for this application was changed from the default location of 07H to location 09H. This starts the stack at 0AH.

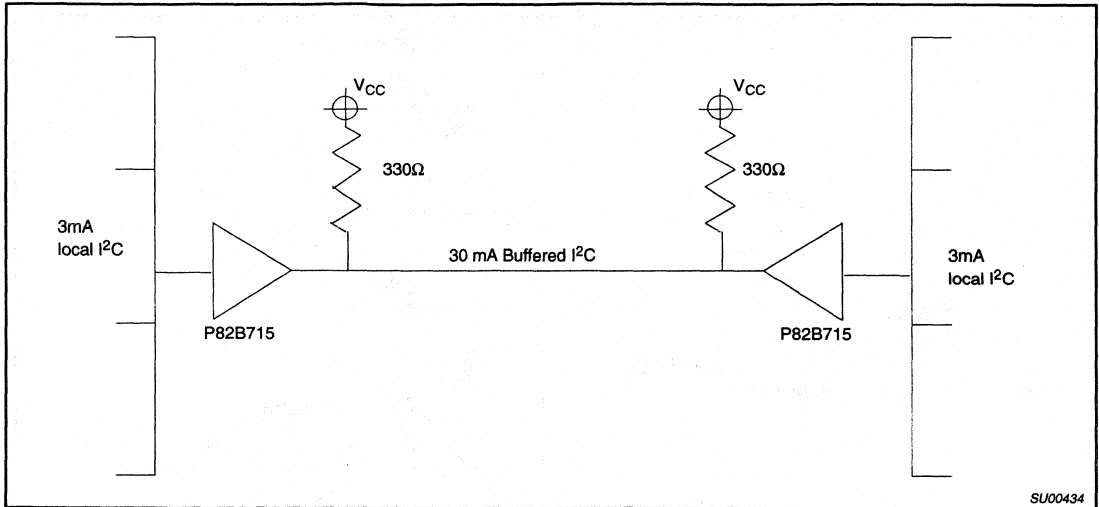

To read the contents of RAM, set the DIP switches to the desired RAM address. The toggle switch is set to a "1". Pressing the Reset switch causes the microprocessor to reset and then enter the monitor program where the program then waits until the toggle switch is changed. Upon closing the toggle switch (a "1" to "0" transition) the program loads the DIP switch selection into R0 of bank 1 (RAM location 08H). The program then loads the contents of the RAM location pointed to by R0 (bank 1) and copies it into port 3, where it is displayed on the 8 LEDs. Thus, the Address is seen by looking at the DIP switches and the contents pointed to are displayed on the LEDs. Note that this indirect Address latch location (R0, bank 1) would have been the normal beginning of the stack, had it not been changed.

The contents of an internal RAM location can also be modified with this program. First, set the DIP switches to the desired Address and set the toggle switch to "0". Reset the processor and then set the toggle switch to "1". This transfers the address to R0 (bank 1). Next, load the desired new data, which is to be stored in RAM, into the DIP switches, and then set the toggle switch to "0". At this time the LEDs will now show the Address of RAM and the DIP switches show what was written into the selected RAM location. To verify that the data was actually written into the RAM, follow the read RAM sequence.

Although this may seem to be a bit cumbersome, it is a workable way to see what is happening inside of the '751. Remember that it is necessary to re-enter the monitor program, or at least to duplicate the read RAM of R0 (bank 1) and output to port 3, to see the latest version of the contents of the RAM location. Since this experiment only looked at the contents of one RAM location, the above method was easy to use and the display always showed the current status of the desired RAM location because it is updated often by the software.

Figure 2. P82B715 Driving Long Line

Using the P82B715 I²C extender on long cables

AN444

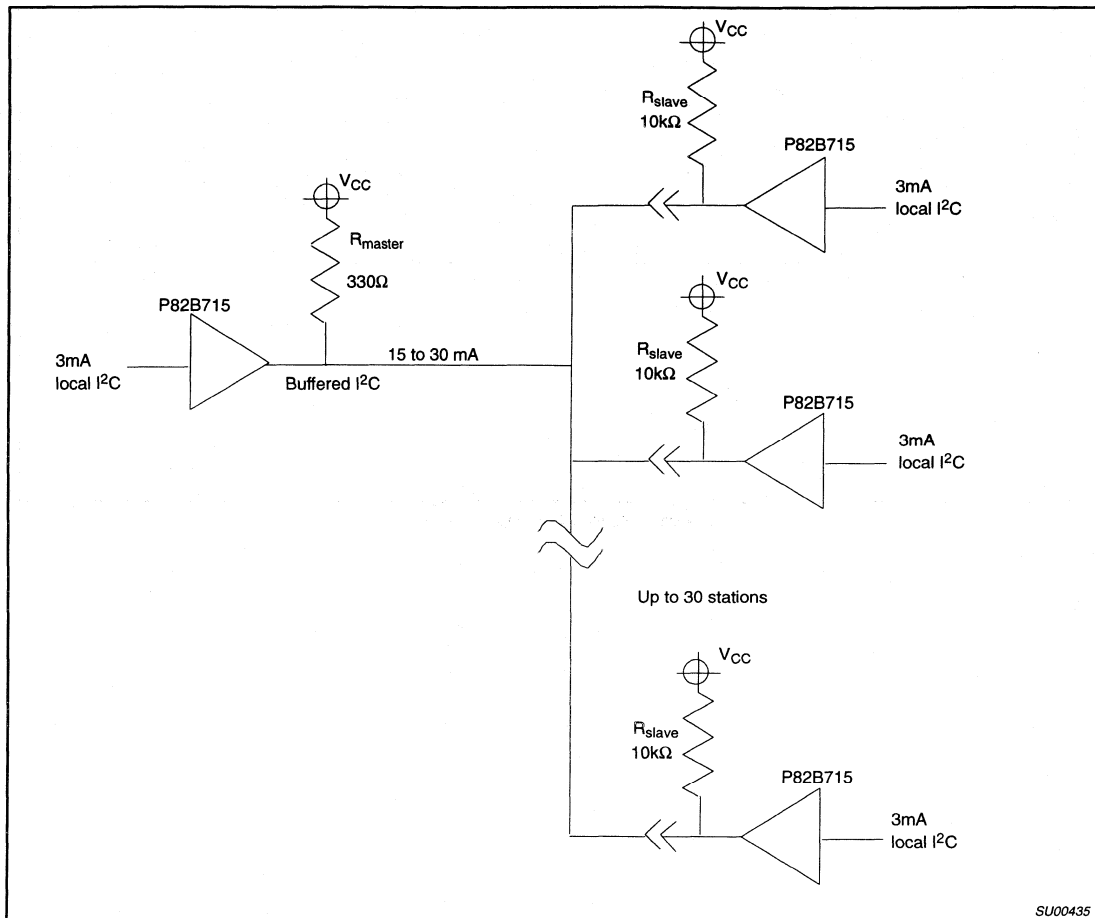

Figure 3. Large Fan-Out Configuration for P82B715

Note that V_{CC} is 5 volts for these values of load resistors. If a different voltage is desired, the calculations are as follows:

$$R_{\text{master}} = \frac{V_{\text{CC}}}{15\text{mA}} \quad \text{example: } R_{\text{master}} = \frac{5\text{V}}{15\text{mA}} = 0.33\text{k} = 330\Omega$$

The pluggable units would be calculated as follows:

Parallel combination of R_{slave} = R_{master}

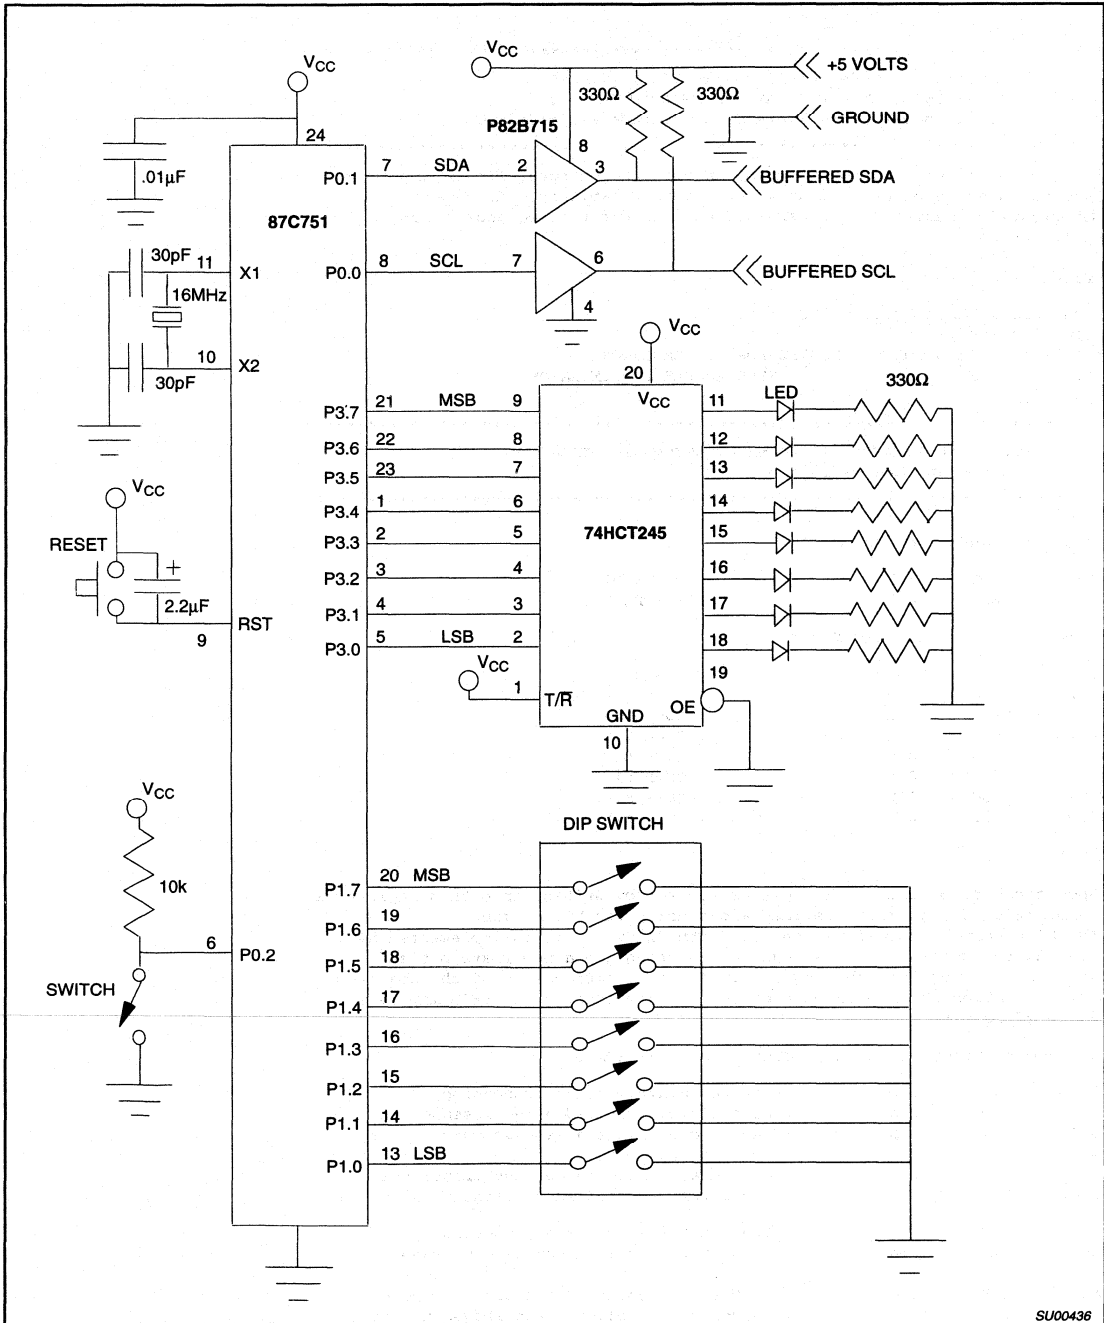

R_{slave} = R_{master} × Fan out

$$\text{example: } R_{\text{slave}} = 330\Omega \times 30 = 9900\Omega = 10\text{k}$$

; Message ping pong game. Each message is transmitted by
; a processor that is a master on the I2C bus, and it contains one byte
; of data. A processor that receives this data byte as a slave increments
; the data by one and transmits it back as a master. The data received is
; confirmed to be a one increment of the data formerly sent, unless
; it is a "reset" value, chosen to be 00h.
; The two participating processors have similar code, where the node
; address of the second processor is the destination address of this
; one, and vice versa.
; The first data byte each processor tries to send is 00h. One of the
; processors will acquire the bus first, and the second processor that will
; receive this "resetting" 00h will not attempt to confirm it against an
; expected value. It will simply increment and transmit it. Subsequent
; receptions will be confirmed against the expected value, until 0ffh data
; bytes are sent and the game is effectively reset by the 00h resulting from
; the next increment.
; A toggling output (TogLED) tells the outer world that the "ping pong"
; proceeds well. If something unexpected happens we temporarily activate
; another output, ErrLED.
; The different tasks of the code are performed in a combination of main-
; line program and event routines called from the I2C interrupt service
; routine.

; Initial set-ups:
; Load CT1,CT0 bits of I2CFG register, according to the clock
; crystal used.
; Load RAM location MYADDR with the I2C address of this processor.
; We load these values out of ROM table locations (R_CTVAL and R_MYADDR).
; One may, instead, load with a MOV <immediate> command.

One mile long I²C communication using the P82B715

AN452

Author: Don Sherman, Applications Engineer

LONG DISTANCE I²C DESIGN CONSIDERATIONS

Summary

I²C communication is possible over very long distances, but at greatly reduced data rates. Tests were made and results shown for cable lengths exceeding one mile. This report explores the design considerations and trade-off needed to implement a successful long distance I²C communication system.

In Application Note AN444 I described how the introduction of the I²C extender chip, the Philips P82B715, allowed I²C to be taken out of the TV set environment and be used to interconnect many nodes, separated by hundreds of feet of distance, and still allow operation at the full 100Kbps data rate. The large addressing range of the I²C protocol makes the large number of stations possible and the P82B715 enables the long distance communication to take place. There are, obviously, limitations and constraints which must be observed, but the ability to take an existing I²C system and to now connect it to other systems without the need for intermediate protocol translators, different power supplies, and expensive interface chips, can be very useful. Needless to say, the user, whose confidence is bolstered by the newly expanded boundaries, wants to know the new rules and the new limits so that he can plan. At 100Kbps the limiting effects eventually boil down to the time that it takes to charge up the cable capacitance through the pull-up resistors. Since the I²C is a two-wire system, there is no common mode noise rejection, so it is inferior to RS422, RS423 and RS485 systems which do use differential drivers and receivers. Since the I²C protocol requires that the Master generate the clock signal which is used by the Slave, it is not tolerant of long phase delays. The Slave must receive the clock and output its data and this data must be received by the Master before the Master starts the next clock cycle. So I²C is inferior to RS232 which, because of its self-clocking, can actually tolerate minutes of phase delay and still deliver the

message at 115 Kbps. Thus, I²C requires at least some form of shielded cable because of its poor tolerance of noise injection, and this shielded cable brings with it the capacitance which ultimately limits the slew rate of the signal.

AN444 showed that shielded audio cable could be used to communicate up to 1000 feet at a 100Kbps data rate. What if the user wants to go farther? The answer is that you can, but you have to do it at a slower data rate. In this Application Note tests were run up to a distance of 6,000 feet, and the effect on the data rate was noted. The results are shown in Figure 1. The tests were run with the I²C hardware on the 87C751. Since there is not a great deal of flexibility in the timing from Timer 1, the only way to reduce the data rate is to reduce the crystal frequency or use software "bit banging". This Application Note used the on-board I²C with the reduced crystal frequency technique. The results are shown in Figure 2.

The reduction in the I²C data communication rate for long distances, produces a dilemma for the user. Is the advantage of being able to directly address every user in the loop worth the trade-off of overall communication (and processing) speed reduction within the local nodes? For those who need the full 100Kbps speed in the local node, it will be necessary to use some form of mail box to store messages and then some other method will be used to forward these mail packets to the far away nodes. This secondary method could be I²C, but it will require a completely separate system from the high speed one. If I²C is chosen, the slow version should probably be just "bit banded". One such program for doing this is available on the Philips Microcontroller BBS entitled I2CBITS.ZIP. There are also several programs on the BBS to "bit bang" RS232, if a UART is not available.

The rest of this Application Note is devoted to the user who can tolerate the overall system speed reduction and wants to use the slow I²C protocol throughout his system.

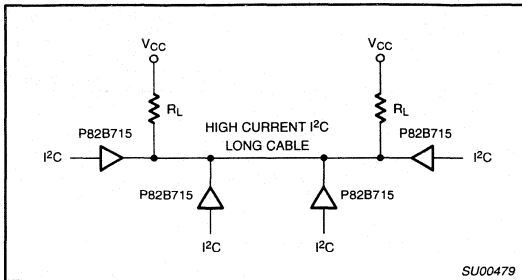

Figure 3.

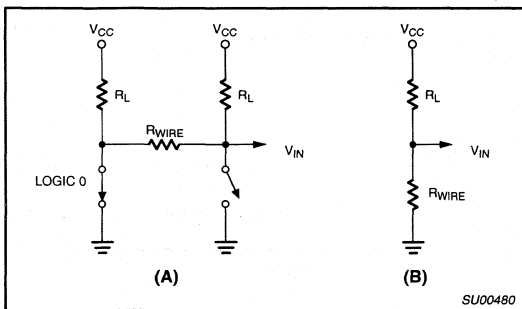

Figure 4.

Figure 5.

The high speed, long distance I²C system was made possible by the introduction of the P82B715 I²C extender chip. This IC consists of two identical X10 current amplifiers. The overall system is shown in Figure 3. The value of the pull-up resistor, R_L, determines the rise time of the signals. Current flows through R_L to charge up the capacitance of the long cable. This requires that a non-standard, intermediate, I²C bus be created which must be de-buffered with another P82B715 at the other end of the line. The local I²C nodes require a 3 mA pull-up current, and the buffered I²C line uses a 30 mA total pull-up current. Note that there are pull-up resistors at each end of the buffered I²C line, so that each end will have drive capability.

As the cable length becomes longer than 1000 feet, the effect of the cable wire resistance starts to become a limiting factor. Figure 4(A) shows a typical system and Figure 4(B) represents the case of detecting a remote logic low signal. Figure 4(B) shows that eventually the resistance of the wire will drop so much voltage that the minimum V_{IN} will be greater than the maximum allowable V_{IL} of the receiving buffer. Thus, it is necessary to increase the value of R_L to keep V_{IN} within reasonable bounds. Note that the wire resistance is fixed and determined by the AWG of the wire and the length. The increase in R_L reduces the available charging current, while at the same time, the increased wire length proportionally increases the capacitive load which must be charged. The propagation time for the signal to go down and return also increases with cable length. This multi-fold effect produces the non-linear curve shown earlier in Figure 1. The increase in load resistance required for the buffered system is shown in Figure 5.

The forced increase in the allowable value of the pull-up resistor, R_L, reduces the need for a powerful bus extender. Experiments were conducted where the microcontroller's I²C outputs were directly connected to the long distance cable. The model for the voltage divider is shown in Figure 6. Note that the R_{DS(ON)} of the output NMOS transistor must sink the sum of all of the pull-up currents, whereas the voltage drop in the cable is only from one pull-up resistor. The values of the pull-up resistor driven directly by the 87C751 microcontroller are shown in Figure 7. The interesting conclusion of testing these two versions, with and without the P82B715 bus extender, was a communication rate vs. distance graph which was virtually identical, thus Figure 1 holds for both methods. The reason for the good performance of the Philips Semiconductors 87C751 microcontroller in these experiments can be seen by examining Table 2.

The tests for this Application Note were run using 1000 foot coils of shielded Belden miniature sound and control Cable, Belden 9452, each roll which has a ground wire of 19.0Ω and a twisted pair of 24AWG wires each with 25.4Ω resistance/1000'. The measured capacitance was signal to ground of 60nF/1K' and with a signal to signal wire capacitance of 32nF/1K'. All of the nodes were powered by floating, transformer isolated power supplies, with only one tied to ground. Large voltage spikes are generated in the ground wire when the outputs are driven to ground. The effect is shown in Figure 8 and discussed later in this Application Note.

One mile long I²C communication using the P82B715

AN452

Tests were run with four independent units operating in a multi-Master configuration. Figure 3 shows the set-up. Note that pull-up resistors were used at the far ends of the network, and that taps along the cable did not require any pull-ups. My test boards used two pairs of the same boards which were described in AN444. The same "Ping-Pong" program, written by Yoram Arbel and available on the Philips BBS, was used with slight modifications. The second pair of boards had different addresses than the end pair. The Ping-Pong program consists of one unit taking mastership and writing a number on the I²C bus to the other unit. The other unit increments the number and sends it back. The new value is checked and if not one count higher than what was sent, an error is detected and a red LED comes on. This program has each unit fighting to gain mastership of the bus. Thus, I noticed that the pair separated by a shorter distance tended to hog the line and got on about twice as often as the two end units.

The system did not operate if there were long, unterminated "stubs" hanging on the line. Thus, if there is to be a stub, it must have its own pull-up resistor. Figure 9 shows one example of a system with terminated stubs. The parallel value of all of the pull-up resistors in the network should add up to one half of the R_L, shown in Figures 5 or 7, for the total length of cable used in the system. Note that the overall capacitance of the system is the sum of all of the cable capacitance. However, the IR drop is dependent on the path that the current must travel from the driving source to each receiver with its associated pull-up resistor.

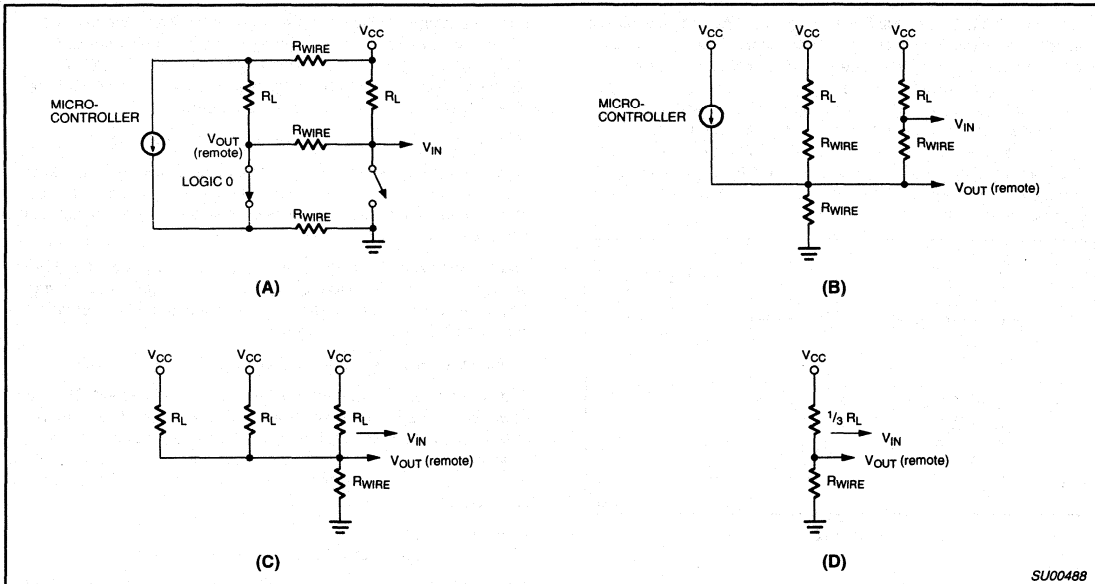

Figure 12.

The effect of the voltage drop in the wire can be seen in Figure 10. Since the microcontroller has TTL translators on the inputs, the actual crossover point is around 1.2 volts. Notice that there is no noise margin left in the scope picture, as the low levels are virtually at the crossover point of the microcontroller's input. Coupling this low, to almost non-existent, noise margin with the horrible ground noise spikes, shown in Figure 8, make the more cautious engineer wonder how the thing works at all.

The noise spikes can be better understood by looking at the AC model for the network as shown in Figure 11. When the remote unit switches to ground, the transition occurs quite rapidly compared to the slow rise time. The closest capacitance (1/2 CCABLE) is quickly discharged by the switch, whereas the receiving side's cable capacitance must complete the current discharge path shown in Figure 11(A). Notice that from the simplified model, Figure 11(B), the instantaneous voltage between the source ground and the remote ground will be 2.5 volts (1/2 VCC) if the cable had been charged all of the way to the 5 volt rail before being driven to ground by the remote unit. The Ground Noise shown on trace 3 of Figure 8 is the difference between the two grounds.

Sending Power Through the Cable

It would be desirable if the remote units in the system could receive their power through the cable. Figure 12(A) shows a model for such a system. The current source is a representation of the current actually consumed by the microprocessor while it is sending a logic 0 to the power sourced unit's VIN pin. The problems with voltage drop in the VCC line can be overcome by sending a higher power supply voltage than needed and then using a voltage regulator at the remote micro's location to provide the regulated local power. The voltage drop in the ground line is the most critical and the model in Figure 12(B) is modified to simplify the ground voltage drop calculations. This figure transposes RL and RWIRE and ignores the VCC supply drop. Figure 12(C) further simplifies the circuit since RL is usually 10 times RWIRE. It also replaces the

approximately 5mA current drawn by the microcontroller at the lowered clock rate, required for the slow I²C configuration, with a resistor equal to the load resistor, i.e., 5mA at 5 volts is equivalent to a 1KΩ resistor and this happens to be the value of the RL used in this example. Finally, Figure 12(D) shows a very simplified model for ground wire and RL calculations. VOUT(remote), the output voltage at the remote sender, will be the largest contributor to the VIN. For RL = 10 RWIRE, VOUT becomes approximately 1/4 of the VCC supply voltage.

$$\begin{aligned} V_{out} &= V_{cc} [R_{wire}/(R_{wire} + 1/3R_L)] \\ &= V_{cc} [R_{wire}/(R_{wire} + 1/3(10R_{wire}))] \\ &= V_{cc} [1/(1+10/3)] \\ &= V_{cc} [1/(13/3)] \\ &= 5V (3/13) \\ V_{out} &= 1.15\text{Volts} \end{aligned}$$

From Figure 12(B), VIN is about 1/10 of the supply voltage, (0.1 VCC). Thus, from Figure 12(D), VIN = VOUT + 0.1VCC. For the case described above, this becomes:

$$\begin{aligned} V_{in} &= 1/4 V_{cc} + 1/10 V_{cc} \\ &= V_{cc} (2.5 + 1)/10 \\ &= 5V 3.5/10 \\ &= 0.35(5V) \\ V_{in} &= 1.75 \text{ volts} \end{aligned}$$

Since the crossover from a logic 0 to a logic 1 is at around 1.2 volts, it is obvious that even one remote unit cannot be supported with this cable for RL = 10 RWIRE.

Conclusion

The additional voltage drop caused by running DC power through the common ground line only serves to reduce the already small noise margin. To compensate for this, the user must either reduce the AWG of the wire to provide a lower IR drop, and/or increase the value of the pull-up resistor, which will slow down the communication rate.

One mile long I²C communication using the P82B715

AN452

Another possibility for providing power down the cable to the remote units consists of alternately charging a capacitor at each node and then using the current stored there to temporarily power the slave micro for a long enough time to get data out of it (see Figure 13). Thus, no communication is attempted during the capacitor charge cycle, so the high voltage drop along the ground line has no deleterious consequences. During the playback time, the individual nodes will have their own local power supplied through its storage capacitor, so that no ground current is needed to power the microprocessor.

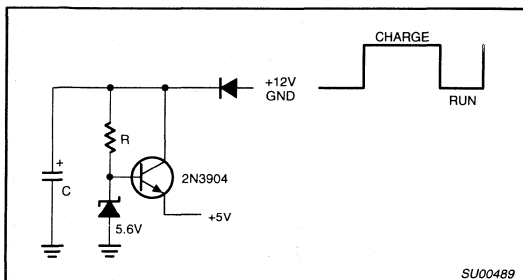

Figure 13.

As an example, twelve volts would be sent down a fourth wire, the "power line", for a sufficient amount of time to charge all of the capacitors. Each capacitor is connected to the power line through a diode. Once the capacitors are fully charged, the power line is taken to ground. The master would then have to interrogate each of the slaves before their power capacitor dropped below the dropout voltage of its regulator. Let us consider two possible scenarios:

In the first example, five remote slaves will be distributed along a 2000 foot cable. From Figure 1, the maximum data rate is 20Kbps. If each slave delivered 2 bytes of response to its one byte address, the total number of bits of data passed to talk to all five units would be:

$$5 \text{ units} \times 3 \text{ bytes of information} \times 8 \text{ bits/byte} = 120 \text{ bits}$$

$$\text{Time to transmit 120 bits} = 120\text{bits}/20\text{Kbits/sec} = 0.006 \text{ sec}$$

Thus, the power supply capacitor must be able to provide current for at least six milli-seconds. To be safe, let's assume a factor of three margin. This results in a time constant of 18mSec. Assuming that the time to discharge the capacitor to the dropout voltage of the regulator is one RC, and that the current per microcontroller plus the SDA pull-up resistor current (remember that the master drives SCL) will be about:

$$10\text{mA micro } I_{CC} + 5\text{V} / 0.5\text{k}\Omega = 10\text{mA} + 10\text{mA} = 20\text{mA}.$$

The 20mA load can be approximated by a resistor which will deliver 20mA at the five volt V_{CC} supply:

$$R = V_{CC}/I_{LOAD} = 5\text{V}/20\text{mA} = 250\Omega$$

$$RC = 18\text{mSec}$$

$$C = 0.018\text{sec}/250\Omega = 72 \mu\text{F}$$

Let's use 100 μF to give us some elbow room. Each node will need a 100 μF capacitor to provide power for 18mSec. The worst case charging time would be if all of the units were at the full 2000' distance. To insure 99% charging, three RC time constants will be used. The R is the resistance of 2000' of cable:

$$RC = (2 \times 25\Omega/1\text{K}') \times (5 \text{ nodes} \times 100\mu\text{F}) = 0.025 \text{ sec}$$

Thus, the master can interrogate each node for two bytes of data every 31 mSec. Twenty five mSec will be used to pump up the storage capacitor and it then takes six milli-seconds to transfer 120 bits of information at 20Kbps.

The second example would be a 64 remote unit system driven by one master over a 4000 foot cable. If each slave delivered 2 bytes of response to its one byte address, the total number of bits of data passed to talk to all 64 units would be:

$$64 \text{ units} \times 3 \text{ bytes of information} \times 8 \text{ bits/byte} = 1536 \text{ bits}$$

At a data rate of 3Kbps, this would take about 1/2 second. Thus, the power supply capacitor must be able to provide current for around one second to be safe. Assuming that the time to discharge the capacitor is one RC, and that the current per microcontroller plus the SDA pull-up resistor current will be about 5 mA, this load can be approximated by a 1 K Ω resistor:

$$RC = 1 \text{ second}$$

$$C = 1/R = 1/1000\Omega\text{s} = 1000\mu\text{F}$$

This is probably too small, but for the sake of calculating, let's use it. Now the total number of capacitors to be charged is equal to the number of nodes, which in this case is 64. So, the time to charge $64 \times 1000\mu\text{F}$ will be determined by the resistance of the wire that the current is flowing through. Four thousand feet of 24AWG wire has about a 100 Ω of resistance, therefore the time to charge up all of the capacitors will be approximately:

$$\begin{aligned} \text{Time to charge to 98\%} &= 3 RC = 3 \times 100\Omega \times 64,000 \mu\text{F} \\ &= 19,200,000 \text{ micro seconds} \\ &= 19.2 \text{ SECONDS} \end{aligned}$$

Now if additional capacitance is added for some elbow room, this system could only deliver 2 bytes of data from each unit every 30 seconds.

Note that only the units at the far end of the cable will see the full 100 Ω of wire resistance. If the master is told which units are farthest away, it could shorten the charging cycle, realizing that the farthest units are not fully charged. If they are addressed first, it might be possible to shorten the total capacitor charge cycle time.

CONCLUSION

By using a local storage capacitor at each node, it is possible to alternately charge the capacitor and then use this charge to power the remote units long enough for the master to interrogate each of the remotes. This system eliminates the problems caused by the reduction in voltage margin caused by passing the microcontrollers' I_{CC} through the signal ground line.

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

Author: R.C.J. Brink, Eindhoven

1. INTRODUCTION

1.1. Purpose

This document is a user manual for the I²C software module IIC51. It is intended for Intel PLM51 users who need to control an I²C bus. This document assumes some basic knowledge about I²C and Intel PLM51.

1.2. Scope

IIC51 is a software module to provide an Intel PLM51 user with a set of procedures to control a bi-directional I²C bus. These procedures have been coded in Intel ASM51 and have been optimized for speed. IIC51 supports all common used I²C master transmitter and master receiver protocols. Each different protocol corresponds to one of the procedures in IIC51. IIC51 is available in two different versions:

IIC51S:

IIC51S is a module for singlemaster I²C to be used on microcontrollers of the 8XC51 family. It directly controls the microcontroller I/O pins by software without the need of any specific hardware. No other I²C masters are allowed on the bus. Note that the electrical characteristics of this microcontroller family are not conform the I²C specifications.

IIC51M:

IIC51M is a module for multimaster I²C to be used on microcontrollers of the PCB8XC552/C652 family. It makes use of the built-in I²C interface hardware (SIO1) of these microcontrollers. Since this hardware is a multimaster interface, other I²C masters are allowed on the bus.

All I²C transfer procedures in IIC51S are fully software interface compatible with IIC51M. This allows a single PLM51 program using I²C to be written for both mentioned microcontroller families.

1.3. Definitions, Acronyms and Abbreviations

I ² C	Inter-IC bus
PLM51	High level Program Language for 8051 family Microcontrollers

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

2. GENERAL DESCRIPTION

2.1. Perspective

IIC51 is designed for use in stand-alone microcontroller I²C systems. It is mainly written to provide a standard set of procedures for computer controlled television/teletext concepts based on 8051 family microcontrollers.

2.2. Functions

IIC51 contains the following functions:

- Initialisation of the I²C interface (software and hardware)
- Transfer of I²C messages to and from an I²C slave device
- Error detection
- Automatic retrying if an error occurs during a transfer (up to 5 attempts)
- Error recovery if the bus is held by a slave device that is out of bit-sync
- Optional slave receiver/transmitter function (IIC51M only)

2.3. User Characteristics

IIC51 is designed to be an easy to use package. All needed code and data is defined in a single object module (IIC51M.OBJ or IIC51S.OBJ). The PLM51 user needs only to link this module to his own application object modules, using Intel's RL51. Procedures and data of concern to the user can be declared EXTERNAL by including the file IIC51.DCL.

2.4. General Constraints

IIC51 is coded for and translated by the Intel MSC-51 Macro Assembler. It is tested together with Intel PLM51 modules. Intel utilities used for testing:

- MSC-51 Macro Assembler, ASM51.EXE, Version V2.3
- PL/M-51 Compiler, PLM51.EXE, Version V1.2 and V1.3
- MSC-51 Relocator and Linker, RL51.EXE, Version V3.1

Development is done on an IBM-PC/AT running DOS.

IIC51S needs:

- 350 Bytes CODE (approx.)
- 6 Bytes DATA
- 1 Byte Bit-Addressable DATA
- 1 Bit

IIC5MS needs:

- 400 Bytes CODE (approx.)
- 6 Bytes DATA
- 1 Byte Bit-Addressable DATA
- 1 Bit
- Exclusive use of Register Bank 1

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

3. FUNCTIONAL DESCRIPTION

3.1. Master Mode Functions

This section describes the available functions in IIC51 on a procedure by procedure basis.

Each procedure must be declared EXTERNAL by the PLM51 user. In this declaration the user can specify the type returned by each procedure. All procedures (except Init_IIC) can return a BIT or a BYTE (depending on the chosen EXTERNAL declaration). The BIT or BYTE returned is 0 if the I²C transmission was successful. If the user decides to declare a procedure untyped, the result of the previous I²C transmission can always be checked by examining the static BIT variable IIC_Error. Note that typed procedures must be called using an expression. If the result of an I²C procedure is to be ignored, a dummy assignment must be done for a typed procedure. An untyped procedure can be called by the PLM51 CALL statement, without any additional overhead. The examples in the following section assume the procedures to be declared untyped.

Note that the least significant bit of all slaveaddresses passed to the I²C procedures must be 0.

3.1.1. Init_IIC

Declaration:

```
Init_IIC:
  PROCEDURE ( Own_Slave_Address ) EXTERNAL ;
  DECLARE ( Own_Slave_Address ) BYTE ;
  END ;
```

Description:

Init_IIC must be called once after reset, before any other procedure is used. It initialises all I²C internal static data and hardware. The Own_Slave_Address is passed to Init_IIC for the optional slave function in a multimaster I²C system (IIC51M). In a singlemaster I²C system (IIC51S), the Own_Slave_Address is ignored. Note that Init_IIC does not effect the global interrupt enable flag (EA). IIC51M requires the user to enable interrupts afterwards (see example).

Example:

```
CALL Init_IIC ( 54h ) ;
ENABLE ; /*Enable Interrupts; EA = 1 */
```

3.1.2. IIC_Test_Device

Declaration:

```
IIC_Test_Device:
  PROCEDURE ( Slave_Address ) [ BIT | BYTE ] EXTERNAL ;
```

Description:

IIC_Test_Device just sends the slaveaddress on the I²C bus. It can be used to check the presence of a device on the I²C bus.

I²C Protocol:

OR

Example:

```
DECLARE IIC_Error BIT EXTERNAL ;
.....
CALL IIC_Test_Device ( 8Ch ) ;
IF ( IIC_Error ) THEN
  "Device is Not Present Handling"
ELSE
  "Device is Present Handling"
```

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

3.1.3. IIC_WriteDeclaration:

```
IIC_Write:
  PROCEDURE ( Slave_Address, Count, Source_Ptr ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Source_Ptr ) BYTE ;
  END ;
```

Description:

IIC_Write is the most basic procedure to write a message to a slave device.

I²C Protocol:

```
L = Count
D1[0..L-1] BASED by Source_Ptr
```

Example:

```
DECLARE Data_Buffer ( 4 ) BYTE ;
.....
CALL IIC_Write ( 0C2h, LENGTH ( Data_Buffer ), .Date_Buffer ) ;
```

3.1.4. IIC_Write_SubDeclaration:

```
IIC_Write_Sub:
  PROCEDURE ( Slave_Address, Count, Source_Ptr, Sub_Address ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Source_Ptr, Sub_Address ) BYTE ;
  END ;
```

Description:

IIC_Write_Sub writes a message preceded by a subaddress to a slave device.

I²C Protocol:

```
L = Count
Sub = Sub_Address
D1[0..L-1] BASED by Source_Ptr
```

Example:

```
DECLARE Data_Buffer ( 8 ) BYTE ;
.....
CALL IIC_Write_Sub ( 48h, LENGTH ( Data_Buffer ), .Date_Buffer, 2 ) ;
```

3.1.5. IIC_Write_Sub_SWIncDeclaration:

```
IIC_Write_Sub_SWInc:
  PROCEDURE ( Slave_Address, Count, Source_Ptr, Sub_Address ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Source_Ptr, Sub_Address ) BYTE ;
  END ;
```

Description:

Some I²C devices addressed with a subaddress do not automatically increment the subaddress after reception of each byte. IIC_Write_Sub_SWInc can be used for such devices the same way IIC_Write_Sub is used. IIC_Write_Sub_SWInc splits up the message in smaller messages and increments the subaddress itself.

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

I²C Protocol:

L = Count
 Sub = Sub_Address
 D1[0..L-1] BASED by Source_Ptr

S	SlvW	A	Sub	A	D1[0]	A	P
---	------	---	-----	---	-------	---	---

S	SlvW	A	Sub+1	A	D1[1]	A	P
---	------	---	-------	---	-------	---	---

.....

S	SlvW	A	Sub+L-1	A	D1[L-1]	A	P
---	------	---	---------	---	---------	---	---

Example:

```
DECLARE Data_Buffer ( 6 ) BYTE ;
.....
CALL IIC_Write_Sub_SWInc ( 80h, LENGTH ( Data_Buffer ), .Date_Buffer, 0 ) ;
```

3.1.6. IIC_Write_MemoryDeclaration:

```
IIC_Write_Memory:
  PROCEDURE ( Slave_Address, Count, Source_Ptr, Sub_Address ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Source_Ptr, Sub_Address ) BYTE ;
  END ;
```

Description:

I²C Non-Volatile Memory devices (such as PCF8582) need an additional delay after writing a byte to it. IIC_Write_Memory can be used to write to such devices the same way IIC_Write_Sub is used. IIC_Write_Memory splits up the message in smaller messages and increments the subaddress itself. After transmission of each small message a delay of 40 milliseconds is inserted.

I²C Protocol:

L = Count
 Sub = Sub_Address
 D1[0..L-1] BASED by Source_Ptr

S	SlvW	A	Sub	A	D1[0]	A	P	< Delay 40 ms >
---	------	---	-----	---	-------	---	---	-----------------

S	SlvW	A	Sub+1	A	D1[1]	A	P	< Delay 40 ms >
---	------	---	-------	---	-------	---	---	-----------------

.....

S	SlvW	A	Sub+L-1	A	D1[L-1]	A	P	< Delay 40 ms >
---	------	---	---------	---	---------	---	---	-----------------

Example:

```
DECLARE Data_Buffer ( 10 ) BYTE ;
.....
CALL IIC_Memory ( 0A0h, LENGTH ( Data_Buffer ), .Date_Buffer, 0F0h ) ;
```

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

3.1.7. IIC_Write_Sub_Write**Declaration:**

```

IIC_Write_Sub_Write:
  PROCEDURE ( Slave_Address, Count1, Source_Ptr1, Sub_Address, Count2, Source_Ptr2 )
    [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count1, Source_Ptr1, Sub_Address, Count2, Source_Ptr2 ) BYTE ;
  END ;

```

Description:

IIC_Write_Sub_Write write 2 data blocks preceded by a subaddress in one message to a slave device. This procedure can be used for devices that need an extended addressing method, without the need to put all data into one large buffer. Such a device is the ECCT (I²C controlled teletext device; see example).

I²C Protocol:

```

L           = Count1
M           = Count2
Sub         = Sub_Address
D1[0..L-1] BASED by Source_Ptr1
D2[0..M-1] BASED by Source_Ptr2

```

**Example:**

```

PROCEDURE Write_CCT_Memory ( Chapter, Row, Column, Data_Buf, Data_Count ) ;
DECLARE ( Chapter, Row, Column, Data_Buf, Data_Count ) BYTE;

/*
  The extended address (CCT-Cursor) is formed by Chapter, Row and Column. These
  three bytes are written after the subaddress (8) followed by the actual data which
  will be stored relative to the extended address.
*/
CALL IIC_Write_Sub_Write ( 22h, 3, .Chapter, 8, Data_Buf, Data_Count ) ;

END Write_CCT_Memory ;

```

3.1.8. IIC_Read**Declaration:**

```

IIC_Read:
  PROCEDURE ( Slave_Address, Count, Dest_Ptr ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Dest_Ptr ) BYTE ;
  END ;

```

Description:

IIC_Read is the most basic procedure to read a message from a slave device.

I²C Protocol:

```

M           = Count
D2[0..M-1] BASED by Dest_Ptr

```

**Example:**

```

DECLARE Data_Buffer ( 4 ) BYTE ;
.....
CALL IIC_Read ( 0B4h, LENGTH ( Data_Buffer ), .Data_Buffer ) ;

```

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

3.1.9. IIC_Read_Status

Declaration:

```
IIC_Read_Status:
  PROCEDURE ( Slave_Address, Dest_Ptr ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Dest_Ptr ) BYTE ;
  END ;
```

Description:

A lot of I²C devices have only a one status byte that can be read via I²C. IIC_Read_Status can be used for this purpose. IIC_Read_Status works the same as IIC_Read but the user does not have to pass a count parameter.

I²C Protocol:

```
M           = Count
Status      BASED by Dest_Ptr
```

Example:

```
DECLARE Status_Byte BYTE ;
.....
CALL IIC_Read_Status ( 84h, .Status_Byte ) ;
```

3.1.10. IIC_Read_Sub

Declaration:

```
IIC_Read_Sub:
  PROCEDURE ( Slave_Address, Count, Dest_Ptr, Sub_Address ) [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count, Dest_Ptr, Sub_Address ) BYTE ;
  END ;
```

Description:

IIC_Read_Sub reads a message from a slave device preceded by a write of the subaddress. Between writing the subaddress and reading the message, an I²C restart condition is generated without surrendering the bus. This prevents other masters from accessing the slave device in between and overwriting the subaddress.

I²C Protocol:

```
M           = Count
Sub         = Sub_Address
D2[0..M-1] BASED by Dest_Ptr
```

Example:

```
DECLARE Data_Buffer ( 5 ) BYTE ;
.....
CALL IIC_Write_Sub ( 0A2h, LENGTH ( Data_Buffer ), .Data_Buffer, 2 ) ;
```

3.1.11. IIC_Write_Sub_Read

Declaration:

```
IIC_Write_Sub_Read:
  PROCEDURE ( Slave_Address, Count1, Source_Ptr1, Sub_Address, Count2, Dest_Ptr2 )
  [ BIT | BYTE ] EXTERNAL ;
  DECLARE ( Slave_Address, Count1, Source_Ptr1, Sub_Address, Count2, Dest_Ptr2 ) BYTE ;
  END ;
```

Description:

IIC_Write_Sub_Read writes a data block preceded by a subaddress, generates an I²C restart condition, and reads a data block. This procedure can be used for devices that need an extended addressing method. Such a device is the ECCT (I²C controlled teletext device; see example).

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

I²C Protocol:

```

L           = Count1
M           = Count2
Sub         = Sub_Address
D1[0..L-1] BASED by Source_Ptr1
D2[0..M-1] BASED by Dest_Ptr2

```

Example:

```

PROCEDURE Read_CCT_Memory ( Chapter,Row, Column, Data_Buf, Data_Count );
DECLARE ( Chapter, Row, Column, Data_Buf, Data_Count ) BYTE ;

/*
The extended address (CCT-Cursor) is formed by Chapter, Row and Column. These
three bytes are written after the subaddress (8). After that the actual data will be
read relative to the extended address.
*/
CALL IIC_Write_Sub_Read ( 22h, 3, .Chapter, 8, Data_Buf, Data_Count ) ;

END Read_CCT_Memory ;

```

3.2. Slave Mode Functions

I²C slave mode is provided by IIC51M only. All slave mode actions (except initialisation) take place in the SIO1 interrupt procedure. Slave mode I²C protocol is very application dependent. If a specific slave mode is required, the user have to modify three procedures in IIC51M at source level. The following sections describe these procedures. The program examples of the procedures implement an I²C slave protocol to read and write the microcontroller's on chip RAM via I²C. This can be a useful feature during program development and debugging.

3.2.1. Init_Slave

This procedure is called from IIC_Init. In this procedure the user can initialise all static data concerning slave mode functions (if any).

Example:

```

Slave_Sub_Address: db 1
....
Init_Slave:      mov Slave_Sub_Address,#0 ; Initialise Sub Address
                ret

```

3.2.2. Receive_Slave

Receive_Slave is a procedure called from the SIO1 interrupt procedure each time a byte is received from another I²C master. The procedure can make use of the bit "IICntrl.BYTE1EXPECTED", as defined in IIC51M. This bit is set to logic 1, every time the first data byte of an I²C message is about to be received. Receive_Slave can use this bit to detect the start of a new message.

Normally all bytes received from the other master will be acknowledged (i.e., SIO1 control bit Assert Acknowledge is set, AA = 1). If AA is cleared by Receive_Slave subsequent bytes in the message will be ignored and a negative acknowledge will be transmitted after reception of each byte. Note that the example does not make use of this feature.

Constraints:

- Receive_Slave must read the S1DAT register.
- Receive_Slave may clear the SIO1 control bit AA, to stop acknowledging data.
- Receive_Slave may not effect any other SIO1 hardware registers/bits.
- Receive_Slave is only allowed to use the accumulator and register R0 in the current registerbank.

Example:

```

Receive_Slave:  mov a,S1DAT                ; Pick up data
                mov r0,#Slave_Sub_Address ; Prepare for 1st byte
                jbc IICntrl.BYTE1EXPECTED,Save_Byte ; Jump if 1st byte
                mov r0,Slave_Sub_Address ; Else data byte
                inc Slave_Sub_Address     ; Postincrement Sub.
Save_Byte:     mov @r0,a                  ; Save Data
                ret                       ; Exit

```

PLM51 I²C software interface IIC51 (version 0.5)

ETV/AN89004

3.2.3. Send_Slave

Send_Slave is a procedure called during the SIO1 interrupt procedure each time a byte has to be transmitted to another I²C master. This occurs after reception of I²C startcondition followed by the microcontroller's own slaveaddress (as passed to Init_IIC) with read-bit. Send_Slave will be called again after transmission of each subsequent byte, until a negative acknowledge is received from the reading I²C master.

Constraints:

- Send_Slave must write to the S1DAT register.
- Send_Slave may not effect any other SIO1 hardware registers/bits.
- Send_Slave is only allowed to use the accumulator and register R0 in the current registerbank.

Example:

```
Send_Slave:  mov r0,Slave_Sub_Address      ; Pick up Sub Address
             mov S1DAT,@r0              ; Send Data
             inc Slave_Sub_Address      ; Postincrement Sub.
             ret
```

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

Author: J.C.P.M. Pijenburg, Eindhoven

1. INTRODUCTION

This report describes the I²C drivers which are written for the 8xC751/2. The report describes not only how to use the routines, but also the structure of the software. The software is written around a set of basic routines and a message handler. The message handler does not contain any specific 8xC751 code, so the software can be easily rewritten for any other bit level I²C interface by rewriting the set of basic routines. In the rest of this report, when 8xC751 is written, it means 8xC751/2.

The package supports also the multimaster features of the I²C bus.

The maximum bit rate possible when using those routines is approximately 70Kbit/sec.

References:

2. GENERAL

2.1 Memory Usage & File Structure

The driver software consists of 3 main parts:

- I²C message handler
- I²C basic routines
- I²C slave routines

During I²C usage it claims register bank 1, however, register bank 1 does not contain any static I²C data and can be used by the application program outside the I²C routines (this data will be destroyed by I²C routines). The accumulator is also modified during I²C transfer.

The message handler uses a Message Control Block which consists of 8 bytes RAM. In those bytes, the following parameters are stored:

For block 1: I2C_ADDR_1, BUF_LEN and BUF_PTR_1

For block 2: I2C_ADDR_2, BUF_LEN and BUF_PTR_2

2 bytes of bit addressable RAM for STATUS and CONTROL information

The STATUS byte is returned into the accumulator. If you do not need a detailed status, you can test the carry bit, this is a copy of the I2C_ERROR bit of the status register (returned in the acc.). The status register contains the following information:

BIT	NAME	FUNCTION
0	RETRY_0	
1	RETRY_1	– Retry counter (0..7), as given during I2C_INIT
2	RETRY_2	
3	I2C_ERR	I2C error if set (also available in carry)
4	TIME_ERR	Bus timeout occurred if set
5	RECOVER	– (no value for user) always 0
6	BUS_RECOVERED	If set, bus K recovered after timeout
7	NO_ACK	No acknowledge received

The slave function uses 2 bytes of RAM, those contain the own slave address (OWN_SLV_ADDR) and a pointer the slave transmit/receive buffer of the 8xC751. This is the buffer from/in which the 8xC751 gets/stores the data bytes in slave mode.

The I²C module is built around a message handler which calls basic functions such as I2C_TRX_BYTE and I2C_START. Each function calls the message handler after loading the correct mask into the I2C_CTRL byte.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

FILENAME	FUNCTION	INCLUDE/LINK	CODE SIZE (BYTE)
I2C_DATA.GLO	I ² C global data definitions	I, each I ² C function and assembler main	0
I2C_DATA.LOC	I ² C local data definitions	I, each I ² C function	0

I2C_INIT.ASM	Init_I2C (does not use message handler)	Link	22
I2C_DEF.ASM	Define MCB & _I2C_XXX_BYTEs	Link	0
I2C_HAND.ASM	I ² C Message handler	Link	144
I2C_BASI.ASM	I ² C basic functions, and T1 interrupt handling	Link	293
I2C_TDEV.ASM	I ² C Test_Device	Link, if used	5
I2C_WRIT.ASM	I ² C Write	Link, if used	5
I2C_WSUB.ASM	I ² C Write_Sub	Link, if used	5
I2C_WSWI.ASM	I ² C Write_Sub_SWinc & Write_Mem	Link, if used	36
I2C_WSUW.ASM	I ² C Write_Sub_Write	Link, if used	5
I2C_WSUR.ASM	I ² C Write_Sub_Read	Link, if used	5
I2C_WCOW.ASM	I ² C Write_Com_Write	Link, if used	11
I2C_WREW.ASM	I ² C Write_Rep_Write	Link, if used	5
I2C_WRER.ASM	I ² C Write_Rep_Read	Link, if used	5
I2C_READ.ASM	I ² C Read and Read_Status	Link, if used	11
I2C_RSUB.ASM	I ² C Read_Sub	Link, if used	5
I2C_RRER.ASM	I ² C Read_Rep_Read	Link, if used	5
I2C_RREW.ASM	I ² C Read_Rep_Write	Link, if used	5
I2C_SLAV.ASM	I ² C Slave Function	Link	56

The total memory usage for the full package is

ROM	:	520 (single function) to 623 (all functions) bytes
RAM	byte addressable	: 8 bytes
	bit addressable	: 2 bytes
	register bank 1	: 8 bytes

The message handler, causes the other functions to be very small, to further reduce the code, all functions are placed in separate modules, which are put into a library I2C_751.LIB. If this library is linked to an application program, only the object modules which are used by the application program are linked in the output file.

The I2C_CODE.H file contains the references to the separate functions (EXTRN CODE definitions). The use must not include this file into main, but only copy the definitions which he needs into the source file. If this file is included, all functions will be linked, the library approach is of no use in this case.

2.2 Retries

During initialization, the user defines whether he wants to use retries or not. If an I²C message fails, and retries >= 0, the program restarts the message. This is done for at most 7 times. If the message remains unsuccessful, the message handler returns to the main program, indicating that the message has failed (carry set).

2.3 Error Handling

In case of an error while operating as master, the program returns to the message handler. The message handler decides whether to invoke a retry or to return to the main program.

The I²C interface of the 8xC751 generates a timeout interrupt if the bus hangs for more than 1022 cycles, in this case, if the 8xC751 is master (RECOVER = 1), a bus recover routine is started, if the 8xC751 is not master, the I²C bus is released. Retries are only invoked in the master situation.

2.4 Development Tools

The following software tools from Tasking/BSO are used for program development:

- OM4142 Cross Assembler 8051 for DOS: V3.0b
- OM4144 PL/M 8051 Compiler for DOS: V3.0a
- OM4136 C8051 Compiler for DOS: V1.1a
- OM4129 XRAY51 debugger: V1.4c

EIE/AN91007

3. MASTER ROUTINES

3.1 Message Handler

To make the I²C protocols as described in paragraphs 3.2 to 3.15, and I²C message handler is written. The message control block (I2C_MCB) together with the I²C control byte (I2C_CTRL) form the input for the message handler. The I2C_MCB includes 6 bytes of data, containing:

- I2C_ADDR1, first address in the protocol
- BUF_LEN_1, length of the first data buffer
- BUF_PTR_1, pointer to the first data buffer
- I2C_ADDR2, second address in the protocol
- BUF_LEN_2, length of the second data buffer
- BUF_PTR_2, pointer to the second data buffer

The I2C_CTRL byte is bit addressable. It contains 8 bits that determine the flow through the message handler. This byte must be loaded with the corresponding mask before starting the message handler.

The I2C_CTRL byte contains the following bits:

- REP_STRT_BLK1 must we send a repeated start before the first data block? (0=NO, 1=YES)
- RWN_BLK1 read (1) or write (0) the first block of data
- ADDR2 is there a second address in the protocol? (0=NO, 1=YES)
- ADDR2_SUB is the 2nd address a sub address, only relevant if ADDR2=1.
- BLOCK2 is there a second block of data in the protocol? (0=NO, 1=YES)
- RWN_BLK1 read (1) or write (0) the first block of data
- REP_STRT_BLK1 must we send a repeated start before the second data block?
- TEST_DEVICE is it the test device protocol

When an I²C protocol is handled successfully by the message handler, it returns control to the main program; if not it can do a retry by resending the message (maximum 5 retries are possible).

The message handler return value is stored in the I2C_STAT byte. The I2C_ERROR bit indicates whether the transfer has succeeded.

NOTE: It is better to copy this byte into Acc before returning the control to the main program, this way a byte can be saved (I2C_STAT can be placed in register bank 1) and the main program can do a JZ/JNZ test (must be changed).

3.2 I2C_INIT

Description

Init_I2C must be called after RESET, before any procedure is called. The I²C interface and I²C interrupt will be enabled (STEB ETI, EI2 and EA). Own_Slave_Address is passed to Init_I2C for use as slave. Slave_Sub_Address is the pointer to a DATA buffer that is used for data transfer in slave mode. When used as master in a single master system, these parameters are not used. Retry is the number of retries on messages when an error occurs. 0 means no retry (just 1 attempt to send a message), while the maximum amount of retries is 7.

I²C Protocol

none (no action at I²C bus)

Calling Sequence

```
C          : I2C_INIT(Own_Slv_Addr,Slv_Buf_Addr,Retry);
PL/M51    : I2C_INIT(Own_Slv_Addr,Slv_Buf_Addr,Retry);
Assembler : %I2C_INIT(Own_Slv_Addr,Slv_Buf_Addr,Retry);
           (macro call)
```

Parameters

```
Own_Slave_Adr : 8xC751 own slave address
Slave_Buffer_Adr : Base address of buffer, to transmit data from, or receive data in, when 8xC751 is in slave mode.
Retry          : Number of times to do a retry in case of an error. 0 = No Retry, maximum retries is 7.
```

NOTE:

The Init_I2C function enables the I²C watchdog timer interrupt (TI). This watchdog generates an interrupt when during and I²C transfer, SCL is held longer than 1022 machine cycles (ca. 760µs @ 16MHz). If this time is too short for your application, you can disable the TI (CLR ETI). In this case, the main program must check if a bus hangup occurs, and take proper action when the bus is hangup.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.3 I2C_TEST_DEVICE

Description

I2C_Test_Device just sends the slave address to the I²C bus. It can be used to check the presence of a device on the I²C bus.

I²C Protocol

Slv_W : Slave_Adr + Write bit

Device is present

Device is not present

Calling Sequence

C : I2C_TEST_DEVICE(Slv_Adr);
 PL/M51 : I2C_TEST_DEVICE(Slv_Adr);
 Assembler : %I2C_TEST_DEVICE(Slv_Adr);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to be tested.

3.4 I2C_WRITE

Description

I2C_Write is the most basic procedure to write a message to a slave device.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 D0..Dn : Data bytes

Calling Sequence

C : I2C_WRITE(Slv_Adr,Count,Source_Ptr);
 PL/M51 : I2C_WRITE(Slv_Adr,Count,Source_Ptr);
 Assembler : %I2C_WRITE(Slv_Adr,Count,Source_Ptr);

Parameters

Slave_Adr : Slave address of the device to write to.
 Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
 Source_Ptr : Pointer to data buffer, to transmit bytes from.
 (macro call)

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.5 I2C_WRITE_SUB**Description**

I2C_Write_Sub writes a message preceded by a sub-address to a slave device.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 Sub : Sub_Adr
 D0..Dn : Data bytes

**Calling Sequence**

C : I2C_WRITE_SUB(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 PL/M51 : I2C_WRITE_SUB(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 Assembler : %I2C_WRITE_SUB(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to write to.
 Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
 Source_Ptr : Pointer to data buffer, to transmit bytes from.
 Sub_Adr : Sub address.

3.6 I2C_WRITE_SUB_SWINC**Description**

Some I²C devices addressed with a sub-address do not automatically increment the sub-address after reception of each byte.

I2C_Write_Sub_SWInc can be used for such devices the same way as I2C_Write_Sub is used. I2C_Write_Sub_SWInc splits up the message in smaller messages and increments the sub-address itself.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 Sub+x : Sub_Adr+x
 D0..Dn : Data bytes

. . . .

**Calling Sequence**

C : I2C_WRITE_SUB_SWINC(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 PL/M51 : I2C_WRITE_SUB_SWINC(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 Assembler : %I2C_WRITE_SUB_SWINC(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to write to.
 Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
 Source_Ptr : Pointer to data buffer, to transmit bytes from.
 Sub_Adr : Sub address.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.7 I2C_WRITE_MEMORY

Description

I²C Non-Volatile Memory devices (such as PCF8582) need an additional delay after writing a byte to it. I2C_Write_Memory can be used to write to such devices the same way I2C_Write_Sub is used. I2C_Write_Memory splits up the message in smaller messages and increments the sub-address itself. After transmission of each message, a delay of 40 milliseconds ($f_{XTAL} = 16\text{MHz}$) is inserted.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 Sub+x : Sub_Adr+x
 D0..Dn : Data bytes

40 mS

40 mS

. . . .

40 mS

40 mS

Calling Sequence

C : I2C_WRITE_MEMORY(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 PL/M51 : I2C_WRITE_MEMORY(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 Assembler : %I2C_WRITE_MEMORY(Slv_Adr,Count,Source_Ptr,Sub_Adr);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to write to.
 Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
 Source_Ptr : Pointer to data buffer, to transmit bytes from.
 Sub_Adr : Sub address.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.8 I2C_WRITE_SUB_WRITE**Description**

I2C_Write_Sub_Write writes 2 data blocks preceded by a sub-address in one message to a slave device. This procedure can be used for devices that need an extended addressing method, without the need to put all data into one large buffer. Such a device is the ECCT (I²C controlled teletext device; see example).

I²C Protocol

Slv_W : Slave_Adr + Write bit
 Sub : Sub_Adr
 D1.0..D1.n : Data bytes in first block
 D2.0..D2.p : Data bytes in second block

S	Slv_W	A	Sub	A	D1.0	A	D1.1	A	...	A	D1.n	A	D2.0	A	...	A	D2.p	A	P
---	-------	---	-----	---	------	---	------	---	-----	---	------	---	------	---	-----	---	------	---	---

Calling Sequence

C : I2C_WRITE_SUB_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 PL/M51 : I2C_WRITE_SUB_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 Assembler : %I2C_WRITE_SUB_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of the device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Source_Ptr_1 : Pointer to first block of data to transmit.
 Sub_Adr : Sub address.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Source_Ptr_2 : Pointer to second block of data to transmit.

3.9 I2C_WRITE_SUB_READ**Description**

I2C_Write_Sub_Read writes a data block preceded by a sub-address, generates an I²C restart condition, and reads a data block. This procedure can be used for devices that need an extended addressing method. Such a device is the ECCT.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 Slv_R : Slave_Adr + Read bit
 Sub : Sub_Adr
 D1.0..D1.n : Data bytes in first block (write)
 D2.0..D2.p : Data bytes in second block (read)

S	Slv_W	A	Sub	A	D1.0	A	D1.1	A	...	A	D1.n	A	S	Slv_R	A	D2.0	A	D2.1	A	...	A	D2.p	N	P
---	-------	---	-----	---	------	---	------	---	-----	---	------	---	---	-------	---	------	---	------	---	-----	---	------	---	---

Calling Sequence

C : I2C_WRITE_SUB_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count,Dest_Ptr);
 PL/M51 : I2C_WRITE_SUB_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count,Dest_Ptr);
 Assembler : %I2C_WRITE_SUB_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count,Dest_Ptr);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of the device to write and read to/from.
 Count_1 : Number of bytes to transmit (D1.0 .. D1.n, n = count - 1)
 Source_Ptr_1 : Pointer to first block of data to transmit.
 Sub_Adr : Sub address.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Dest_Ptr_2 : Pointer buffer to receive second block of data in.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.10 I2C_WRITE_COM_WRITE

Description

I2C_Write_Com_Write writes two data blocks from different data buffers in one message to a slave receiver. This procedure can be used for devices where the message consists of 2 different data blocks. Such devices are, for instance, LCD-drivers, where the first part of the message consists of addressing and control information, and the second part is the data string to be displayed.

I²C Protocol

Slv_W : Slave_Adr + Write bit
 D1.0..D1.n : Data bytes in first block (write)
 D2.0..D2.p : Data bytes in second block (write)

S	Slv_W	A	D1.0	A	D1.1	A	D1.2	A	...	A	D1.n	A	D2.0	A	...	A	D2.p	A	P
---	-------	---	------	---	------	---	------	---	-----	---	------	---	------	---	-----	---	------	---	---

Calling Sequence

C : I2C_WRITE_COM_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Count_2,Source_Ptr_2);
 PL/M51 : I2C_WRITE_COM_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Count_2,Source_Ptr_2);
 Assembler : %I2C_WRITE_COM_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Count_2,Source_Ptr_2);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Source_Ptr_1 : Pointer to first block of data to transmit.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Source_Ptr_2 : Pointer to second block of data to transmit.

3.11 I2C_WRITE_REP_WRITE

Description

Two data strings are sent to separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

Slv1W : Slave_Adr_1 + Write bit
 Slv2W : Slave_Adr_2 + Write bit
 D1.0..D1.n : Data bytes in first block (write to first slave)
 D2.0..D2.p : Data bytes in second block (write to second slave)

S	Slv1W	A	D1.0	A	D1.1	A	D1.2	A	...	A	D1.n	A	P
---	-------	---	------	---	------	---	------	---	-----	---	------	---	---

Calling Sequence

C : I2C_WRITE_REP_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 PL/M51 : I2C_WRITE_REP_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 Assembler : %I2C_WRITE_REP_WRITE(Slv_Adr,Count_1,Source_Ptr_1,Sub_Adr,Count_2,Source_Ptr_2);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of first device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Source_Ptr_1 : Pointer to first block of data to transmit.
 Slave_Adr_2 : Slave address of second device to write to.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Source_Ptr_2 : Pointer to second block of data to transmit.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.12 I2C_WRITE_REP_READ**Description**

A data string is sent and received to/from two separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

Slv1W : Slave_Adr_1 + Write bit
 Slv2R : Slave_Adr_2 + Read bit
 D1.0..D1.n : Data bytes in first block (write to first slave)
 D2.0..D2.p : Data bytes in second block (write to second slave)

S	Slv1W	A	D1.0	A	D1.1	A	D1.2	A	...	A	D1.n	A	S	Slv2R	A	D2.0	A	D2.1	A	...	A	D2.p	N	P
---	-------	---	------	---	------	---	------	---	-----	---	------	---	---	-------	---	------	---	------	---	-----	---	------	---	---

Calling Sequence

C : I2C_WRITE_REP_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count_2,Dest_Ptr);
 PL/M51 : I2C_WRITE_REP_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count_2,Dest_Ptr);
 Assembler : %I2C_WRITE_REP_READ(Slv_Adr,Count_1,Source_Ptr,Sub_Adr,Count_2,Dest_Ptr);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of first device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Source_Ptr_1 : Pointer to first block of data to transmit.
 Slave_Adr_2 : Slave address of second device to read from.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Dest_Ptr_2 : Pointer buffer to receive second block of data in.

3.13 I2C_READ**Description**

I2C_Read is the most basic procedure to read a message from a slave device.

I²C Protocol

Slv_R : Slave_Adr + Read bit
 D0 .. Dn : Data bytes

S	Slv_R	A	D0	A	D1	A	D2	A	...	A	Dn	A	P
---	-------	---	----	---	----	---	----	---	-----	---	----	---	---

Calling Sequence

C : I2C_READ(Slv_Adr,Count,Dest_Ptr);
 PL/M51 : I2C_READ(Slv_Adr,Count,Dest_Ptr);
 Assembler : %I2C_READ(Slv_Adr,Count,Dest_Ptr);
 (macro call)

Parameters

Slave_Adr : Slave address of the device to be tested.
 Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
 Dest_Ptr : Pointer to data buffer, to receive bytes in.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.14 I2C_READ_STATUS

Description

Several I²C devices can send a one byte status-word via the bus. I2C_Read_Status can be used for this purpose. I2C_Read_Status works the same way as I2C_Read, but the user does not have to pass a count parameter.

I²C Protocol

Slv_R : Slave_Adr + Read bit
Status : Status bytes

Calling Sequence

C : I2C_READ_STATUS(Slv_Adr, Dest_Ptr);
PL/M51 : I2C_READ_STATUS(Slv_Adr, Dest_Ptr);
Assembler : %I2C_READ_STATUS(Slv_Adr, Dest_Ptr);
(macro call)

Parameters

Slave_Adr : Slave address of the device to be tested.
Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
Dest_Ptr : Pointer to data buffer, to receive status byte in.

3.15 I2C_READ_SUB

Description

I2C_Read_Sub reads a message from a slave device, preceded by a write of the sub-address. Between writing the sub-address and reading the message, an I²C restart condition is generated without releasing the bus. This prevents other masters from accessing the slave device in between and overwriting the sub-address.

I²C Protocol

Slv_W : Slave_Adr + Write bit
Slv_R : Slave_Adr + Read bit
Sub : Sub_Adr

Calling Sequence

C : I2C_READ_SUB(Slv_Adr, Count, Dest_Ptr, Sub_Adr);
PL/M51 : I2C_READ_SUB(Slv_Adr, Count, Dest_Ptr, Sub_Adr);
Assembler : %I2C_READ_SUB(Slv_Adr, Count, Dest_Ptr, Sub_Adr);
(macro call)

Parameters

Slave_Adr : Slave address of the device to be tested.
Count : Number of bytes to transmit (D0 .. Dn, n = count - 1)
Dest_Ptr : Pointer to data buffer, to receive bytes in.
Sub_Adr : Sub address.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

3.16 I2C_READ_REP_READ**Description**

Two data strings are read from separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

Slv1R : Slave_Adr_1 + Read bit
 Slv2R : Slave_Adr_2 + Read bit
 D1.0 .. D1.n : Data bytes in first block (read from first slave)
 D2.0 .. D2.p : Data bytes in second block (read from second slave)

**Calling Sequence**

C : I2C_READ_REP_READ(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Dest_Ptr_2);
 PL/M51 : I2C_READ_REP_READ(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Dest_Ptr_2);
 Assembler : %I2C_READ_REP_READ(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Dest_Ptr_2);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of first device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Dest_Ptr_1 : Pointer buffer to receive first block of data in.
 Sub_Adr_2 : Slave address of second device to read from.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Dest_Ptr_2 : Pointer buffer to receive second block of data in.

3.17 I2C_READ_REP_WRITE**Description**

A data string is received and sent from/to two separate slave devices, separated with a repeat START condition. This has the advantage that the bus does not have to be released with a STOP condition before the transfer from the second slave.

I²C Protocol

Slv1R : Slave_Adr_1 + Read bit
 Slv2W : Slave_Adr_2 + Write bit
 D1.0 .. D1.n : Data bytes in first block (read from first slave)
 D2.0 .. D1.p : Data bytes in second block (read from second slave)

**Calling Sequence**

C : I2C_READ_REP_WRITE(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Source_Ptr);
 PL/M51 : I2C_READ_REP_WRITE(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Source_Ptr);
 Assembler : %I2C_READ_REP_WRITE(Slv_Addr,Count_1,Dest_Ptr_1,Sub_Addr,Count_2,Source_Ptr);
 (macro call)

Parameters

Slave_Adr_1 : Slave address of first device to write to.
 Count_1 : Number of bytes to transmit in first block (D1.0 .. D1.n, n = count_1 - 1)
 Dest_Ptr_1 : Pointer buffer to receive first block of data in.
 Sub_Adr_2 : Slave address of second device to read from.
 Count_2 : Number of bytes to transmit in second block (D2.0 .. D2.p, p = count_2 - 1)
 Dest_Ptr_2 : Pointer buffer to transmit second block of data from.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

4. SLAVE ROUTINES

The slave-mode protocol is very application dependent. In this note the basic slave-receive and slave-transmit routines are given and should be considered as examples. The user may, for instance, send NO_ACK after receiving a number of bytes to signal to the master-transmitter that a data buffer is full. A listing of the slave routines is given in Appendix III.

The I²C slave function has two entries:

1. The I²C interrupt.

This can only occur at an idle slave, because when a transmission is in progress, the I²C interrupt is disabled.

2. Through the master routines.

During transmission of a slave-address in master-mode, arbitration is lost to another master. The interface must then switch to slave-receiver mode to check if this other master wants to address the 8xC751 I²C interface. If the 8xC751 recognizes his own slave address, the slave mode routines are entered at labels I2C_SLV_TRX or I2C_SLV_RCV.

Interfacing the master routines, if the user wants to adapt the slave routines to his own needs, he has to keep in mind that the master routines use the I2C_SLV_TRX and I2C_SLV_RCV entries. The I²C slave routines are entered after the acknowledge has been sent, therefore the ATN flag will be set when entering the slave routines at I2C_SLV_TRX or I2C_SLV_RVC.

The slave routines, as given, make use of a single data buffer. When addressed as slave transmitter, data bytes from the data buffer are transmitted over the I²C bus until a not acknowledge or stop is received. When addressed as slave receiver, the data from the I²C bus is received into the data buffer until a not acknowledge or a stop is received.

The data buffer is initialized during the Init_I2C function, one of the parameters of this function is the pointer to the data buffer (SLV_BUF_PTR DS 1).

4.1 Slave Transmitter

The slave transmitter function transmits data bytes from the 8xC751 data buffer (ACALL I2C_TRX_BYTE) until a not acknowledge or a stop is received. The function is also exit on an I²C error. The function is exit with the ATN bit set.

4.2 Slave Receiver

The slave receiver function receives data bytes into the 8xC751 data buffer (ACALL I2C_RCV_BYTE) until a stop is received. The function is also exit on an I²C error. The function is exit with the ATN bit set. If a byte has been received, an acknowledge is sent.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

5. EXAMPLES

5.1 Introduction

Some examples are given on how to use the I²C routines in an application program. Examples are given for an assembly, PL/M and C programs. The program displays time from the PCF8583P clock/calendar/RAM on an LCD display driven by the PCF8577. The example can be executed on the OM4151 I²C evaluation board.

5.2 Using the Routines in Assembly Sources

Appendix VII shows the listing of the example program. The most important aspect when using the I²C routines is preparing the input parameters before the sub-routine call. The parameters must be transferred to the MCB (Message Control Block). Below are 2 examples of how to transfer the necessary parameters to MCB (_I2C_Read and _I2C_Write_Sub_Read).

```
MOV _I2C_MCB,#Slave_Adr
MOV _I2C_MCB+1,#Count_1
MOV _I2C_MCB+2,#Dest_Ptr_1
ACALL _I2C_READ

MOV _I2C_MCB,#S1_Adr
MOV _I2C_MCB+1,#Cnt_1
MOV _I2C_MCB+2,#S_Ptr_1
MOV _I2C_MCB+3,#Sub_Adr
MOV _I2C_MCB+4,#Cnt_2
MOV _I2C_MCB+5,#S_Ptr_2
ACALL _I2C_WRITE_SUB_READ
```

Note that the order of defining the parameters is the same as in PL/M- and C-calls (Calling sequences in paragraphs 3.2 to 3.17). An easier way to call the routines is to make a macro that includes the to transfer of the parameters.

The example program makes use of macros. I2C_Read is then called in the following way:

```
%I2C_READ(Slave_Adr,Count_1,Source_Ptr_1);
```

Note that in the listing the macro call is replaced by the contents of the macro.

The macro must be written as follows:

```
%* DEFINE (I2C_READ(Slave_Adr,Count_1,Dest_Ptr_1))
(
  MOV _I2C_MCB,%%Slave_Adr
  MOV _I2C_MCB+1,%%Count_1
  MOV _I2C_MCB+2,%%Dest_Ptr_1
  ACALL _I2C_READ
)
```

File I2C_MAC.DEF contains the macro calls for the routines as described in paragraphs 3.2 to 3.17. This file should be included in all assembler modules in which calls to the I²C routines are made.

The file I2C_CODE.GLO contains the global function definitions (EXTRN CODE) of the I²C functions, copy the ones you need into your application. The file I2C_DATA.GLO contains the global data definitions of the I²C functions. Therefore, this file must also be included in all assembler modules in which calls to the I²C routines are made.

All I²C routines return a status into the CY-bit. If the CY-bit is set, and error has occurred.

5.3 Using the Routines in PL/M-51 Sources

Appendix VIII shows the listing of the example program in PL/M-51. All procedures return a BIT value. The file I2C_PL/M.H contains the procedure declarations, this file can be included in the modules which call I²C routines. The routines are used the same way as in the examples of paragraph 5.2.

5.4 Using the Routines in C Sources

Appendix IX shows the listing of the example program in C. All functions are return a bit value. The file I2C_C.H contains the function prototypes, this file can be included in the modules which call I²C routines. The routines are used the same way as in the examples of paragraph 5.2.

I²C driver routines for 8XC751/2 microcontrollers

EIE/AN91007

Read.Me

```

*-----*
*
* PACKAGE: I2C drivers for 8xC751/2 microcontroller
*
* DESCRIPTION: To use the package just link the library: I2c_751.lib
*              to your application program
*
* NOTES: If you use the package with assembler sources, you must include
*        \USER\INCLUDE\I2C_DATA.GLO and \USER\INCLUDE\I2C_MAC.DEF into
*        your main application(s).
*        \USER\INCLUDE\I2C_CODE.GLO contains external code definitions,
*        select the ones you need and copy them into your main application*
*        If you include this file, the linker assumes that you use all I2C*
*        functions and therefore links the complete package to your
*        application (in this case the library approach is of no use!)
*
*        If you use the package with PLM sources, you must include
*        \USER\INCLUDE\I2C_PLM.H in each file which uses an I2C function
*
*        If you use the package with C sources, you must include
*        \USER\INCLUDE\I2C_PLM.C in each file which uses an I2C function
*
*-----*

```

CONTENTS OF DISK

The disk contains 3 directories:

1:\USER :This directory contains 2 directories:

```

\INCLUDE :

;MPF:::I2C::I2C_INIT.ASM:I2C_INIT=====
;*
;* FUNCTION NAME:      I2C_INIT
;* PACKAGE:           I2C
;* DESCRIPTION:
;* Initialize I2C interface: set SDA & SCL, enable time out
;* timer, allow 16 MHz (CT1,CT0 = 0). Set the number of
;* retries (max 7) into the I2C_STAT. Bit 7,6 and 5 of the
;* I2C_STAT contain the number of retries. Those bits may
;* not be changed during the I2C routines.
;*
;* INPUT:
;* Before calling I2C_INIT the main program must take care
;* that the correct parameters are available in
;* OWN_SLV_ADDR, SLV_BUF_PTR and _I2C_INIT_BYTE+2, this
;* is done automatically when using C, PL/M or the pre-
;* defined assembler macro (available in I2C_MAC.DEF)
;*
;* OUTPUT:
;* initialized I2C and retry number in I2C_STAT 7..5
;*

Exploring I²C

Authors: Steven Sarns and Jack Woehr

Serial data buses are a well-proven tool in embedded systems. When you are communicating with slow peripheral devices, serial buses are often more convenient and less expensive than parallel buses. Additionally, a serial interface featuring a UART or similar intermediary chip can also serve to isolate the CPU from noise and line glitches that might bring down the house if they were to occur on the processor bus. Peripherals can usually be controlled over a much greater distance by a serial bus. The serial approach offers greater resilience and noise immunity.

The price you pay for the convenience is a slower transmission rate and, possibly, the need for added interface circuitry at higher voltages. Many peripheral devices, however, are not in constant communications with the CPU and are not greatly affected by a slower bus. On the hardware side, any added interface circuitry required for serial bus support is frequently compensated for by the resulting simplicity and tighter pinout of the serial peripherals.

CHOOSING THE PROPER ROUTE

Having decided that a serial bus makes sense for your application, your next task is to select the most appropriate bus and protocol. Here, as with rapid transit, your choice should be determined by your destination. Contrary to what some people may tell you, the choice of bus and protocol depends at least as much on the nature of the system's software as it does on the manufacturer's data sheets.

Consider, for example, the serial-peripheral interface (SPI) and multidrop serial buses. Both buses are popular, but each exhibits severely constrained performance in large networks. SPI, as embodied in the Motorola 6800 family, was designed primarily for one-on-one exchanges between two devices. Similarly, the multidrop approach used in various 8051 family members as well as in the 68HC11 and various UART chips finds its broadest expression in RS485/422 half-duplex transmissions. Multidrop has no deterministic arbitration scheme between multiple masters, leaving it mainly suitable for single-master multiple-slave situations. (*For more on multidrop, see Jack Woehr's article "Multidrop Processing". Embedded Systems Programming, March 1990, pp 58-67.*) A different approach is to use a three-wire protocol called MicroWire, available from National Semiconductor in Santa Clara, California, which is fine

for use with addressable peripherals, but requires an individual chip select for each device addressed. The added wiring offers no advantage to developers, and the bus offers nothing towards achieving multiple-mastering capabilities.

One of the more versatile options available to developers is the I²C bus promulgated by Philips Semiconductors in Sunnyvale, California. I²C allows you to set up a multiple-master, multiple-slave communications bus with conflict arbitration, using only twisted-pair wiring to connect the processors and peripherals. Philips Semiconductors has moved to support this protocol (which is quite popular in Europe) with a large assortment of interesting doodads, and is actively encouraging other manufacturers to join in the fun. If your next design features a microprocessor that supports I²C or you are prepared to implement I²C in software using a PIA as this article illustrates, your reward could be a decreased chip count and lower power consumption—along with a comfortable distributed-programming model for peripheral devices.

I²C is more flexible than the protocols noted above, since only two wires are required to service a large network of addressable masters and addressable slaves. A third wire may be added if interrupt service is required, though Philips Semiconductors microprocessor featuring I²C support feature on-chip circuitry and are capable of interrupting the processor upon receipt of a valid address.

HOW I²C WORKS

The I²C bus consists of two lines: serial clock (SCL) and serial data (SDA). The beauty of the I²C bus is that each of these lines is bi-directional. Bi-directional means that everything on the bus is equal, unlike most other serial-peripheral buses such as SPI or MicroWire, which have dedicated inputs and outputs. Each I²C transaction line (SCL and SDA) is an open collector of output and input. The pullup resistor is external.

Open-collector (actually, they are CMOS, so "open-drain" is more appropriate) configuration means that the output stage can only pull the node to ground. A passive resistor pulls the node high, which means that any number of open collector outputs can be connected together with no deleterious results, because it is impossible to pull more current through

Exploring I²C

the resistor than any one output will produce. Tying outputs together will produce disastrous results if the same procedure is tied with standard TTL outputs. If some of the outputs go high and some are low, the current is unlimited and the logic level of the output will be in an indeterminate state. Tying open-collector outputs together is also known as "wire ORing" because if either A or B goes low, so does the single-output line.

The I²C bus speed is specified at a maximum SCL rate of 100kHz SCL, which, admittedly, is not blazingly fast. The speed limit stems from the meager ability of a pullup resistor to source current to a long distributed line of peripherals. The 10-microsecond period allows plenty of time to charge the parasitic capacitance of the wires. (The maximum specified wire capacitance is 400pF.)

PUTTING IT TOGETHER

Although I²C supports multiple-master operation, here we use single-master, single-slave transactions to keep the example code simple. The master, as you might imagine, is defined as the unit that initiates the data transfer and generates the SCL signal. (In a multimaster system, each master would be responsible for generating its own SCL signal.) In our example, based strongly on the design of one of our company's single-board computers, the processor doesn't directly support I²C. Instead, we've implemented the I²C bus using a couple of the pins on an 8255 peripheral I/O chip. Consequently, the bulk of the example application code is simple setup and housekeeping routines. (*Steven R. Wheeler's example application listing was a bit too long to run in this issue. Interested readers may download it from the library 12 of CLMFORUM on CompuServe or from the Embedded Systems Programming bulletin board service at (415)905-2689.*)

By definition, a slave can be any processor or peripheral that responds to the master. Slaves all have

unique, 7-bit addresses that are based on the device type and the wiring of address pins on the chip. All I²C peripherals have the top nibble of an address build in. For the PCF8574 I/O-port expanders, we're using as examples, the address is 0100xxx. The xxx indicates the address selected by the state of the three address pins on the peripheral.

I²C serial transactions are always eight bits of data from the transmitter followed by a ninth ACK bit from the receiver. The first step in any I²C data transfer is to send the address of the slave on the SDA line. This act might seem confusing, since we seem to be mixing 7-bit addresses with 8-bit data. In practice, it's quite easy to work with: addresses are always seven bits long, and the eighth bit is used to determine whether the operation is a read or a write. For example, upon transmitting 01000001 to the PCF8574, the slave, assuming it exists on the bus and is strapped to address 000, will respond with a low on the SDA line after the master has finished with its last (eighth) data bit. The master leaves the line high. If it doesn't find a slave with address 10000, the data line will remain high and a failed communication attempt can be detected.

If a slave is connected, it begins putting data on the SDA line as soon as it has detected that the eighth bit is set (which is a read request). The SDA line is driven to the data level when the SCL line is low. Data is read when SCL is high, so SDA must not change when SCL is high. This protocol leads to a simple definition of the start of an I²C transaction—SDA goes from high to low when the clock is high.

The end of a transaction is equally simple to detect: SDA goes from low to high when SCL is high. This cycle leaves SDA and SCL in the high state, which is necessary if any other open-collector I²C peripheral wants to access to the bus. Figure 2 illustrates the start and stop conditions of an I²C bus transaction.

Figure 1. Generation of Acknowledge

Figure 2. Start and Stop Conditions

ADDITIONAL DESIGN NOTES

As you've seen, the I²C protocol is easy to work with and relatively simple to implement, even if you're not using a processor that directly implements it. If you're not planning to use Philips Semiconductors microprocessor with onboard I²C support (such as the 68070) or various members of the 8051 family), you can still use the wide variety of available peripheral chips.

The number of integrated circuits using the I²C serial bus is increasing all the time. Application-oriented integrated circuits that support I²C include a voice synthesizer, a transcoder for IR remote control, several digital tuning circuits for computer-controlled television, several audio processors, PLL frequency synthesizers, tone generators, and frequency synthesizers. General-purpose integrated circuits using I²C include LCD drivers, digital-to-analog converters, SRAMs, EEPROMs, and a RAM clock/calendar.

I²C is very popular in Europe, where Philips has been aggressively marketing this flexible method of extending peripheral support to control projects, and it is currently catching fire on this side of the Atlantic. It

seems reasonable to expect that, given the burden of printed-wire requirements for embedded systems based on increasingly wider chip buses, more and more designers seeking economy of means will be attracted to the economy of I²C.

Programming the I²C interface

Author: Mitchell Kahn

Dr. Dobb's

JOURNAL

The Inter-Integrated Circuit Bus ("I²C Bus" for short) is a two-wire, synchronous, serial interface designed primarily for communication between intelligent IC devices. The I²C bus offers several advantages over "traditional" serial interfaces such as Microwire and RS-232. Among the advanced features of I²C are multimaster operation, automatic baud-rate adjustment, and "plug-and-play" network extensions.

Mention the I²C bus to a group of American engineers and you'll likely get hit with an abundance of blank stares. I say American engineers because until recently the I²C bus was primarily a European phenomenon. Within the last year, however, interest in I²C in the United States has risen dramatically. Embedded systems designers are realizing the cost, space, and power savings afforded by robust serial interchip protocols.

The idea of serial interconnect between integrated circuits is not new. Many semiconductor vendors offer devices designed to "talk" via serial links with other processors. Current examples include Microwire (National Semiconductor), SPI (Motorola), and most recently Echelon's Neuron chips. In all cases, the goal is the same: to reduce the wiring and pincount necessary for a parallel data bus. It simply does not make

Mitch is a senior strategic development engineer for Intel and can be contacted at 5000 W. Chandler Blvd., Chandler, AZ 85226 or at mkahn@sedona.intel.com.

economic sense to route a full-speed parallel bus to a slow peripheral.

Unfortunately for most serial-bus-capable devices, the choice of a bus protocol will dictate the CPU architecture. For example, only two CPU architectures implement an on-chip I²C port. If your choice of architecture precludes use of these architectures, then your only option is to implement the protocol in software.

The software implementation of the I²C protocol discussed in this article came about as a result of an implicit challenge during a staff meeting. One of our managers proposed that we hire a consultant to write a software I²C driver for the Intel 80C186EB embedded processor. Being somewhat new to the

group, I took exception (although not verbally!) to his suggestion. A weekend of intense hacking later, I presented the first prototype of the driver. My reward? I got to write a generic version of the driver for general distribution.

Design Trade-offs

Three distinct tasks are involved in implementing the I²C protocol: watching the bus, waiting for a specific amount of time, and driving the bus. This became apparent when I flowcharted 1 byte of a typical bus transaction; see Figure 1. The time delays associated with creating the bus waveforms would normally have been relegated to the 80C186EB's on-chip timers. I could not, however, assume that the end users of my code would be able to spare a timer for the software I²C port. I had to forego the elegance (and to some extent accuracy) of the on-chip timers for the sledgehammer approach of software timing loops. Luckily, the I²C protocol is extremely forgiving with regard to timing accuracy. The decision to use assembly instead of a high-level language stemmed directly from the need to control program-execution time. I had neither the time nor the inclination to hand-tune high-level code.

Having made the decision to use assembly language, I faced my next problem: Could I make the code portable? Intel offers a plethora of CPU and embedded-controller architectures. Would it be possible to make the code somewhat portable between disparate assembly languages? I found my answer in the use of macros.

Programming the I²C interface

All the basic building blocks of the I²C protocol (watching, waiting, and doing) can be compartmentalized into distinct macros. The algorithms that make up the I²C driver are written with these macros as the framework. You don't need to understand the intricacies of the I²C protocol to port these routines—you just need to know how to make your CPU watch, wait, and do.

For example, a 4.7_μs delay is a common event during a transfer. The macro %Wait_4_7_μs implements just such a delay by using the 8086 LOOP instruction with a couple of NOPs for tuning; see Example 1(a). Total execution time is readily calculated from instruction timing tables. The same macro is ported to the i960 architecture in Example 1(b). Although I am a neophyte when it

comes to i960 programming, I had no problems porting the core macros.

Hardware Dependencies

A few words about the target hardware are in order before I discuss the code. Any implementation of the I²C protocol requires two open-drain (or open-collector), bidirectional port pins for the Serial Clock (SCL) and Serial Data (SDA) lines. The code in this article was designed for the 80C186EB embedded processor, which has two open-drain ports on-chip. The two pins, P2.6 (SCL) and P2.7 (SDA), are part of a larger 8-bit port. Processors without open-drain I/O ports can easily implement I²C with the addition of an external open-collector latch.

Two special-function registers, P2PIN and P2LTCR, are used to read and write the state of the port pins. The 80C186EB allows the special-function registers to be located anywhere in either memory or I/O space. For this implementation, I chose to leave the registers in I/O space, even though this limited my choice of instructions. The 80186 architecture does not provide for read-modify-write instructions in I/O space (an AND to I/O, for example); it can only load and store (IN and OUT). So why did I limit myself? Again, I had to assume the lowest common denominator for our customers when designing my code.

Building the Framework

Early on in development, I decided to partition my code macros according to physical processes involved in the I²C

protocol. Code not directly involved in mimicking the actions of a hardware I²C port was not written as macros. For example, the code necessary to access the stack frame is not written as a macro, whereas the code needed to toggle the clock line is. This was done to isolate architecture-dependent code sequences from the more generic I²C functions. Macros were also not used for "gray areas" such as the shifting of serial data, which is both architecture dependent and physical in nature. The I²C functions that passed the litmus test fell into the three aforementioned categories of watching, waiting, and doing.

The "waiting" macros provide a fixed-minimum time delay. They are implemented using a simple LOOP \$ delay. The LOOP instruction decrements the CX register, then branches to the target (in this case itself) if the result is non-zero. The delay is (n-1)*15+5 clocks, where n is the starting value in the CX register. All the delays were calculated assuming a 16-MHz clock rate (62.5 nanoseconds per clock). The code still works at lower CPU speeds because the I²C protocol only specifies minimum timings. In fact, the delay macros are only "accurate enough," providing timings as close as I could get to the specified minimum without undue tuning.

The "watching" macros are "spin-on-bit" polling loops. These pieces of code wait for a transition on the appropriate I²C line to occur before allowing execution to continue. There are two polling macros for each of the two I²C signal lines; one for high-to-low transitions and one for low-to-high transitions. The

Programming the I²C interface

polling of the SCL line that gives rise to an important feature of I²C: automatic, bit-by-bit baud-rate adjustment. Any device on the I²C bus may hold the clock line low in order to stall the bus for more time (a serial wait state). The other devices on the bus are then forced to poll the SCL line until the slow device releases control of the clock.

The `%Get_SDA_Bit` macro also falls under the category of "watching." Its function is simply to return the state of the SDA line without waiting for a transition. `%Get_SDA_Bit` is used primarily to pull the serial data off the bus when the clock is valid.

The "doing" macros control the state of the clock and data lines. As with the polling macros, there are four types—one for each transition of the SCL or SDA lines. The "doing" macros are named to reflect the physical operations they perform. For example, `%Drive_SCL_Low` always drives the SCL line to a low state. `%Release_SCL_High`, on the other hand, relinquishes control of the SCL line, which may then be pulled high or driven low by another device on the bus. A read-modify-write operation is used for the bit manipulation so that the other 6 bits of Port 2 are not affected by the I²C operations.

Getting on the Bus

Three procedures were created using the macro framework. I'll describe only the master transmit (Listing One, page

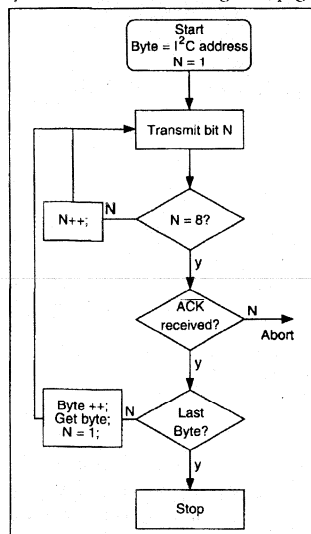

Figure 2: Flowchart for I²C transmit procedure.

106) and master receive functions (Listing Two, page 108), as they represent the needs of most I²C users. The slave procedure is long and intricate and will not be described here.

An I²C master transmission proceeds as follows:

1. The master polls the bus to see if it is in use.
2. The master generates a start condition on the bus.
3. The master broadcasts the slave address and expects an acknowledge (ACK) from the addressed slave.
4. The master transmits 0 or more bytes of data, expecting an ACK following each byte.
5. The master generates a stop condition and releases the bus.

The stack frame for the master transmit procedure, `I2CXA.A86`, includes a far pointer to the message for transmission, the byte count for the message, and the slave address. Far pointers and far procedure calls are used in all the procedures. No attempt was made to conform to a specific high-level language calling convention, although such a conversion would be trivial. The procedures save only the state of the modified segment registers.

The master transmit procedure performs error checking on the passed parameters before attempting to send the message. The maximum message length is set at 64 Kbytes by the segmentation of the 80186 memory space. This restriction could be removed by including code to handle segment boundaries. The transmit procedure also checks the direction bit in the slave address to ensure that a reception was not erroneously indicated. Errors are reported back to the calling procedure through the AX register. (The exact code is in Listing One.)

The first step in sending a message is getting on the I²C bus. The macro `%Check_For_Bus_Free` simply polls the bus to determine if any transactions are in progress. If so, the transmit procedure aborts with the appropriate error code. If the bus is free, a start condition is generated. The start condition is defined as a high-to-low transition of SDA with SCL high followed by a 4.7 μ S pause. These waveforms are easily generated with the `%Drive_SDA_Low` and `%Wait_4_7_uS` macros.

All communication on the I²C bus between the stop and start conditions, including addressing and data, takes place as an 8-bit data value followed by an acknowledge bit. This led to the natural nested loop structure for the body of the procedure; see Figure 2.

The inner loop is responsible for transmitting the 8 bits of each data byte. Each transmitted bit generates the appropriate data (SDA) and clock (SCL) waveforms while checking for both serial wait states and potential bus collisions. A bus collision occurs when two masters attempt to gain control of the

*Three distinct tasks
are involved in
implementing the
I²C protocol:
watching the bus,
waiting for a specific
amount of time, and
driving the bus*

bus simultaneously. The I²C protocol handles collisions with the simple rule: "He who transmits the first 0 on the SDA line wins the bus." To ensure that we (the master transmit procedure) own the bus, the SDA line is checked whenever transmitting a 1. If a 0 is present, then a collision has occurred (because another master is pulling the line low), and the transfer must be aborted.

Control is turned over to the outer loop after the 8 bits of data (or address) have been transmitted. The outer loop immediately checks for an acknowledge from the addressed slave. The transfer is aborted if an acknowledge is not received. At the end of the ACK bit the message length counter is decremented. Control is returned to the inner loop if more data remains, otherwise a stop condition is generated and the master transmit procedure terminates.

Registers are used for intermediate result storage throughout the body of the procedure. For example, the AH register is used to hold the current value (either address or data) being shifted onto the SDA line. This eliminates the need for local data storage within the procedure.

On the Receiving End

The steps involved in an I²C master receive transaction are almost identical to those in transmission:

1. The master polls the bus to see if it is in use.
2. The master generates a start condi-

Programming the I²C interface

- tion on the bus.
3. The master broadcasts the slave address and expects an ACK from the addressed slave.
 4. The master receives 0 or more bytes of data and sends an ACK to the slave after each byte. The master signals the last byte by not sending an ACK.
 5. The master generates a stop condition and releases the bus.

A far pointer to the receive buffer is passed on the stack to the master receive procedure. The remainder of the parameters—slave address and message count—are identical between the two procedures. The received message length is fixed at 64 Kbytes, again because of segmentation. The error-checking, bus-availability sensing, and start-condition generation sections of the receive procedure are lifted verbatim from the transmit code.

The structure of the receive procedure differs slightly once the start con-

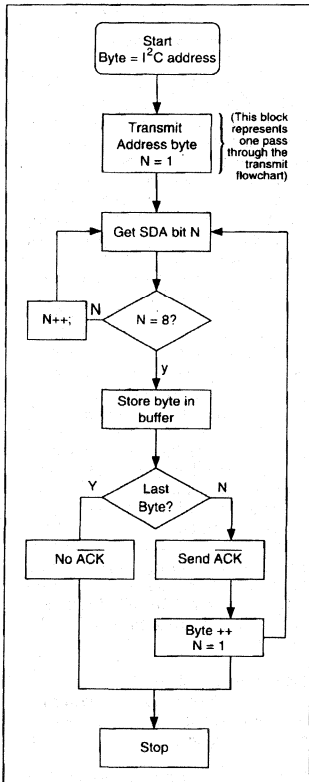

Figure 3: Flowchart for I²C receive procedure.

dition has been generated; see Figure 3. The slave address is transmitted using one iteration of the transmit procedure's outer loop. Control is passed to the receive loop once the slave acknowledges its address.

The receive loop structure is patterned after that of the transmit procedure. The inner loop controls the clocking of the SCL line and the shifting of the serial data off the SDA line into the CPU. Eight iterations of the inner loop are performed to receive each byte. The outer loop stores the received byte in the buffer, decrements the byte count, then sends an ACK to the slave. The last data byte is signalled by not sending an ACK.

Using the Procedures

Listing Three (page 110) shows a short program that uses both the master transmit and master receive procedures. The call to procedure I2C_XMIT displays the word "BUS-" on a four-character, seven-segment display controlled by the SAA1064 I²C compatible display driver. The time of day is read from the PCF8583 real-time clock by the call to procedure I2C_RECV.

Please note that interrupts must be disabled during the execution of both procedures. An interruption at an inopportune time (when the master is not in control of the clock) could cause the bus to hang. If you need to service interrupts periodically, then enable them only when the clock is driven low.

These procedures have been tested on a wide array of I²C devices ranging from serial EEPROMs to voice synthesizers. No compatibility problems have been seen to date.

Enhancing the Code

I've kicked around many ideas for enhancing the I²C procedures. You could,

for example, replace the timing loops with timed interrupts. That way, the CPU could perform useful work during the pauses. Along the same lines, the pauses could be scheduled using a real-time kernel, again improving CPU throughput. Finally, you could add a high-level language calling structure.

The use of timed interrupts adds an order of magnitude to the complexity of the code, but would be worth it for high-performance, real-time systems.

Conclusion

I²C is not the only game in town when it comes to serial protocols. Hopefully, some of the techniques presented here will carry over into the development of other "simulated" serial protocols, such as those targeted at the home-automation market. Who knows, maybe someday a snippet of my code may find its way into a truly intelligent dishwasher. I'll be waiting....

Software driven serial communication routines for the 83C751 and 83C752 microcontrollers

AN423

DESCRIPTION

The need often arises to make use of a serial port in connection with a microcontroller that does not have a hardware UART on-chip. Aside from the obvious cases where the microcontroller application intrinsically requires RS-232 communications to achieve its purpose, a serial output may often be a simple and convenient method of providing detailed diagnostic information to the outside world while using only a single I/O port pin. In many cases, the solution may be to implement the UART function in software. The routines included here demonstrate a method to add such a function to a microcontroller without the benefit of a hardware UART.

Examples of microcontrollers that do not have on-chip UARTs are the 83C751 and 83C752. While it is possible to connect an external UART chip to these microcontrollers, it tends to use up many I/O port pins and begins to become less economical than simply using a standard 80C51. There are several factors to be considered in deciding if the software UART method will be usable in a particular application. The first is whether the serial communication channel is to be simplex (transmit only or receive only), half-duplex (transmit and receive, but not simultaneously), or full-duplex (simultaneous transmit and receive). Both simplex and half-duplex operation are fairly easy to implement in software on an 80C51-type microcontroller, and will be covered by this application note. Full-duplex operation is more difficult to implement in software and can use up a large portion of the microcontroller's time and resources.

A second consideration to be taken into account is the amount of system resources that will be "used up" by the serial communication software. First of all, such software routines will almost always require the use of at least one counter/timer to generate the time slices for the serial bit cells. Next, the physical connection to the outside world will require one I/O port pin each for the serial input and the serial output. Moreover, the port pin used for serial input should be an external interrupt input pin. This allows the software to be interrupted automatically at the beginning of an incoming start bit and synchronize the timer accurately to the serial data stream. Additional port pins may be used to implement signals such as Request to Send (RTS), Clear to Send (CTS), etc.

Finally, serial communication software will take up a certain amount of CPU time, more than would be required to operate a hardware UART. The overhead of software implemented serial communication may or may not be an issue, depending on the application, the throughput of the serial channel(s), the baud rate, other tasks the CPU is handling and how time-critical they are, etc.

The program listing that is included here is a demonstration of half-duplex serial routines on the 83C751 or 83C752 microcontrollers. The operation of the software would be the same on other 80C51 derivatives, except that the counter/timer operation is slightly different. The program, as listed, will send a canned message to the serial output (port pin P1.0 in this case), then wait for data on the serial input (port pin P1.5/INT0). When a character has been received on the serial input, it will be echoed through the serial output. Since the software is inherently half-duplex, the rate at which characters are received must be less than half the rate that would be possible on a full-duplex channel. This example has been set up to receive and transmit at 9600 baud when run with a 16 MHz crystal.

The operation of the routines is fairly straightforward. Beginning with a start bit occurring on the serial input line, an interrupt (external interrupt 0) will occur. At the interrupt service routine into, the counter/timer is loaded with a value that will result in a time delay that is approximately equivalent to half a bit cell time for the baud

rate being used, less some constant to account for the elapsed time between a timer interrupt and the point where the serial input is actually sampled. The timer reload register is loaded with a value that will result in a time delay that is as close as can be calculated to one full bit cell time. The program then starts the timer and simply returns to the main program, waiting for the timer to time out, generating another interrupt.

At that point, the serial start bit should be about halfway through its nominal duration. When the first timer interrupt occurs, the timer interrupt routine Timr0 calls the receive bit routine RxBit which checks to make sure that the start bit is still valid and flags an error if it is not. The RxBit routine will then return control to the main program routine, waiting for the next timer interrupt.

On the second timer interrupt, the RxBit routine reads the serial input line and shifts the value into the serial holding register RxDat. This process is repeated until 8 bits have been read in on consecutive timer interrupts. Finally, on the tenth timer interrupt, the receive routine looks for a valid stop bit and flags an error if one is not detected. At this point, the RcvRdy flag is set to inform the main program that a character is waiting in the holding register.

The transmit routine works in a somewhat similar fashion, beginning with a call to the byte transmit routine XmtByte, which first checks to make sure that a byte receive operation is not already in progress. The RSXmt routine will then set up the timer and timer reload registers to correspond to one bit cell time, start the timer, and assert a start bit.

At each subsequent timer interrupt, the routine TxBit shifts out the next bit from the transmit holding register XmtDat, until all 8 bits have been transmitted. Once all of the data has been sent, the stop bit is asserted on the next timer interrupt. A final timer interrupt is required to insure that the stop bit lasts at least one full bit cell time. At this point, transmit flag TxFlag is cleared in order to inform the main program that the transmission is completed.

Different baud rates and different crystal frequencies can be handled easily by simply changing the values in the program for BaudVal and StrtVal. BaudVal is simply the number of 8x751 machine cycles that occur during one bit call time in the serial transmission. So, it may be calculated as the crystal frequency /12, divided by the baud rate. This number is rounded to the nearest integer and expressed as a negative number in the code. For example, the value shown in the listing is for 9600 baud with a 16MHz crystal. 16 million divided by 12, divided by 9600 = 138.8889. This is stated in the program as -139.

StrtVal is used to position the sampling of the serial input during a receive operation to the approximate middle of the bit cell. This is nominally half the value of BaudVal, minus some overhead to account for the interrupt latency, plus the time it takes to get to the instruction that actually reads the input. StrtVal may be calculated as $BaudVal / 2 + 30$. For example, using the BaudVal value from the listing:

$$-139 / 2 + 30 = -39.$$

A few other useful routines are embedded in the sample program: PrByte, which converts a byte of data to hexadecimal form and transmits it; HexAsc, which converts one nibble of raw data to hexadecimal form; and Mess, which transmits an absolute string of data (usually a text message) which is terminated by a 0 byte.

This demonstration of software driven serial port routines uses 5 bytes of microcontroller RAM, two port bits (including one external interrupt input), one counter/timer, and about 256 bytes of code space, excluding the message string at the end of the listing.

Software driven serial communication routines for the 83C751 and 83C752 microcontrollers

Controlling air core meters with the 87C751 and SA5775

AN426

INTRODUCTION

Often, certain classes of microcontroller applications surface where large amounts of on-chip resources such as a large program memory space and numerous I/O pins are not required. These applications are typically cost sensitive and desirable attributes of the MCU include low cost and modest on-chip resources such as program and data memory, I/O, and timer-counters. Substantial benefits of reduced design cycle time can be realized by using an industry-standard architecture having software compatibility with existing popular microcontrollers.

THE 87C751

The Philips 87C751 is one such microcontroller that easily meets these requirements. This device, shown in Figure 1, has a 2k x 8 program memory, 64 bytes of RAM, 19 parallel I/O lines, and a 16-bit autoreload timer-counter. It also includes an I²C serial interface and a fixed rate timer. The 87C751 is based on the 80C51 core and thus uses an industry-standard architecture and instruction set. The device is available in both ROM (83C751) and EPROM (87C751) versions. The EPROM version is available in both UV erasable and OTP packages. References to the 87C751 in this document also apply to the 83C751, unless explicitly stated.

TYPICAL APPLICATION

A typical example of such an application is the interface between the 87C751 and the Philips SA5775 Serial Gauge Driver, SGD, shown in Figure 2. This circuit includes the 87C751 microcontroller, the SA5775 Serial Gauge Driver, an NE555 timer, and discrete support components.

An air core meter differs from a conventional (d'Arsonval) meter movement in that it has no spring to return the needle to a predetermined position, no zeroing adjustment, and no permanent magnet in the classical sense. Instead, it consists of two coils of wire wound in quadrature with each other around a central core in which there is a disc magnetized along its diameter. A shaft is placed through the center of this disc so that the shaft rotates with the disc. An indicating needle attached to this shaft will rotate with it.

SA5775 Serial Gauge Driver

The SA5775 is a monolithic driver for controlling air core meters typically used in automotive instrument clusters and is shown in Figure 3. The SA5775 receives a 10-bit serial word and converts that word to four voltage outputs that appear at the SINE+, SINE-, COSINE+, and COSINE- outputs. The differential voltage at the SINE outputs are applied to one coil of the meter and the COSINE outputs are applied to the other coil of the meter.

The currents through these coils produce a resultant magnetic force which is the vector sum of the magnetic forces produced by each of the two coils. Since the currents through the coils are bidirectional this magnetic vector can rotate through a full 360 degrees. The magnetized disc within the air core meter will follow the rotating vector and the needle will indicate the vector's current position. Since 10 bits are used, there are 1024 discrete words available resulting in an angular displacement of 0.3516 degrees per bit. This is small enough to provide an apparently smooth movement of the needle. The smoothness of the motion will depend greatly on the damping factor of the meter movement.

A simplified block diagram of the SA5775 is shown in Figure 4. This device consists of a serial-in/parallel-out shift register, a data latch, a D/A converter, a multiplexer, and output buffers.

A logic high must be present on the chip select (CS) input to clock in the data. Data appearing on the data input (DI) pin is clocked into the shift register on the rising edge of the clock (CLK) input. The data output (DO) pin is the overflow from the shift register, allowing the user to daisy chain multiple SA5775 devices. Note that data is clocked out of this pin on the falling edge of the clock. The CS pin is also used to latch the parallel outputs of the shift register into the data latch. The outputs of the data latch feed the inputs to the D/A converter. The D/A converter outputs are buffered to form the drive signals for the meter coils.

The D/A converter circuits, multiplexer and associated output buffers are purposely designed such that the span of these circuits do not include the power supply rails. This is to avoid inaccuracies that would otherwise occur if the output were to become very close to either supply rail. With a supply voltage of 14 volts (VIGN), the outputs will span a range of approximately 1 to 11 volts. The SA5775 is designed to drive air core meters having a

minimum winding impedance of 180Ω at -40°C.

The clock high and low time requirements are 175ns minimum and the maximum data rate is 1.6 megabits per second. At this rate it would require approximately 6.4ms to ramp from zero to full scale if all binary codes were loaded into the SA5775. However, the air core meter cannot respond to such data rates. Both inertia of the movement and damping build into the design of typical air core meter movements limit their response speed.

A high on the output enable input pin (OE) is required to permit the SA5775 to drive the air core gauge. In Figure , OE is held low while the microcontroller is being reset to prevent the gauge from being driven.

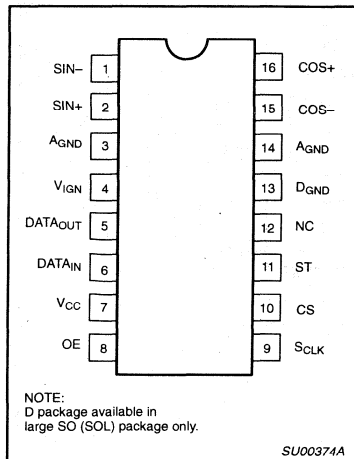

Figure 3. D and N Packages

87C751 Microcontroller

The 87C751 microcontroller provides all of the intelligence in this application. It samples various input ports to determine which demonstration programs to run, the incremental step sizes for angular displacement of the meter core, and the time delay between increments. In one of the demonstration modes, it also samples a variable frequency input and positions the meter core in response to the frequency of that input. The 87C751 also transmits the 10-bit serial data to the SA5775. Data input (DI), Clock (CLK), and Chip Select (CS) lines are driven from the 87C751.

Port 0 of the 87C751 is a 3-bit wide port and is used for communicating data to the SGD. Data is transmitted, MSB first, in a serial stream clocked into the DI of the SA5775 on the rising edge of the clock. In order to clock in data, the CS pin of the SA5775 must be high. The data in the input register is shifted into a latch that drives the DAC on the high to low transition of the CS line. As data is shifted into the SGD, it overflows through the Data Out (DO) pin on the falling edge of the clock. With this facility, multiple SGDs can be daisy-drained with DO of one SGD being connected to DI of the next one, and common clock and chip select lines may be used. This simplifies the interfacing to multiple meter drivers.

The 78L05 regulator (Q2) provides 5 Volt power for the board so that single supply of +14 volts can be applied to the board.

Three rotary switches are used on this board. The PROGRAM SELECT switch (S3) is used to select the program routine that is

executed, the INC SELECT (S2) switch selects the incremental step sizes of two of the routines, and the DELAY switch (S4) is used to set the delay between successive word transmissions in one of the routines.

The START/COUNT button (S5) is used to begin execution of a routine, and to cause the next incremental step in Routine #1.

The COUNT UP/DOWN switch (S6) is used in Routine #1 to determine whether the count is increased or decreased with transmission of successive words.

NE555 Timer

The NE555 timer shown in this application example is used as a free running squarewave generator used to simulate sensor inputs such as those which might be found in an automobile, etc. The NE555 timer (U4) operates in the astable mode to produce an output frequency that can be varied from about 1Hz to about 200 Hz. Three of the program routines measure the input period and produce an output code that is proportional to the frequency present at pin 20 (TO) of the microcontroller. A RATE switch (S7) is used to select between the on board oscillator or an external source.

The program listing is included at the end of this application note.

Program Entry

The program starts at address 030(hex) on line 21 of the program listing. The first task is to write 1's to all pins of each port.

Lines 25 and 26 clear registers 6 and 7. These registers are used in this program only to hold the data that is sent out to the SGD. The registers are cleared to be sure that the starting value is zero.

At line 27 the program waits until the START/COUNT button (S5) is depressed before continuing. Lines 28 and 29 set the timer to overflow after 10ms. This is done by setting the timer registers for a count of 10,000 microseconds less than full scale. When the timer counter overflows the timer flag is set, and the timer is reloaded with the value in the timer register. By examining the timer flag we know when 10ms has expired.

Line 30 calls subroutine RPS (Read Port Selected), which reads Port 3 to determine which routine has been selected. Since the PROGRAM SELECT switch (S3) is connected to port pins P3.2 through P3.4, subroutine RPS (lines 507 through 511 at the end of the program) first reads Port 3 into the accumulator, then complements it because the switches used are complementary binary. The reading is then rotated right once and the upper nibble and the LSB (least significant

bit) are masked off, leaving twice the value of the port selected in the accumulator. Twice the read value is needed for the next few main program lines that determine which routine to execute.

Line 31 moves the address of label JMPTBL (Jump Table) to the 16-bit Data Pointer (DPTR) register. Line 32 causes a program jump to the address that is the sum of the value in the accumulator (two times the routine number selected) plus the DPTR register. Since each of the commands on lines 33 through 40 are two byte commands, these addresses are all separated by two bytes; hence, the need for the accumulator to contain a number that is twice the number of the selected routine.

Routine 0

This routine begins on line 41 by incrementing the 10-bit word in registers 7 and 6 by the amount indicated by the setting of the INCREMENT SELECT switch, then sending that word to the SA5775. When a full scale overflow is detected, a full scale code (3FF hex) is sent out, followed by a delay of 500 ms, then successive output codes are sent out, decremented by an amount indicated by the INCREMENT SELECT switch. When an underflow is detected a code of zero scale is sent and the routine returns to the beginning of the program. This routine is implemented with a series of subroutine calls.

The SO subroutine begins on line 356 and starts by sending out whatever ten bits that in the two LSBs of register 7 (R7) plus the 8 bits of R6 by calling the SENDIT subroutine. Then it calls the UP subroutine, which increases the word value to be sent out. The program then jumps to the beginning of this subroutine, repeating the process of sending out a word and incrementing to the next word until an overflow from the tenth bit (bit 2 of R7) is detected at line 362.

The SENDIT subroutine (beginning on line 476) brings the CS line high, sets a bit counter (R1) to 2 (to send out two bits of R7), brings the value of R7 to the accumulator, rotates the accumulator to the right three times through the carry bit to bring the two LSBs to the position of the two MSBs, calls the SEND1 routine, which sends the number of bits in the accumulator, starting with the MSB, indicated by R1. Counter R1 is then set to 8 to send out all 8 bit of R6 and the accumulator is loaded with the contents of R6. The SEND1 routine is again called to send out the final 8 bits, and, on line 491, the CS line is brought low, loading the SA5775 internal parallel latch with the contents of the input shift register.

Controlling air core meters with the 87C751 and SA5775

AN426

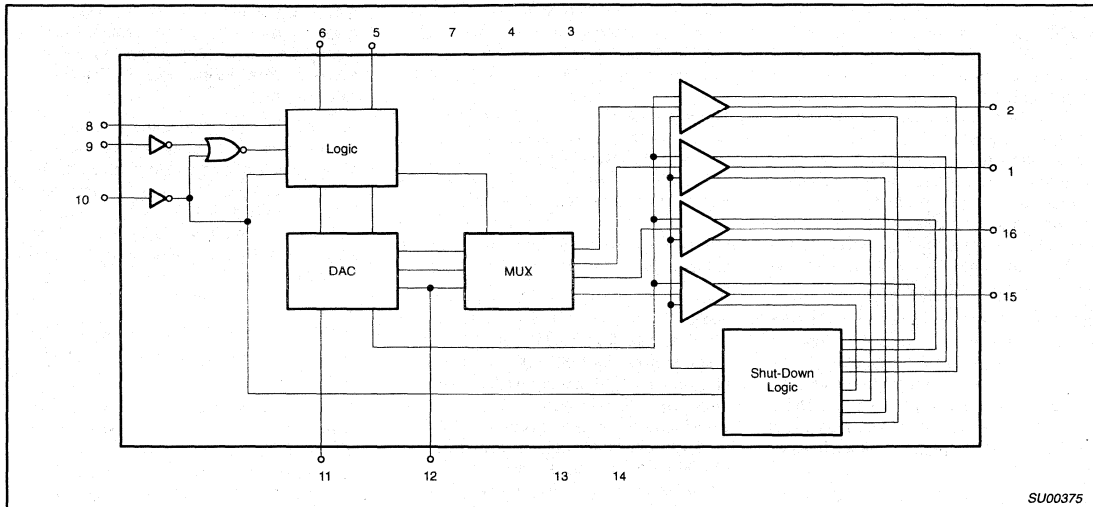

Figure 4. Block Diagram of the SA5775

The SEND1 routine rotates the accumulator left through the carry bit, moves the value of the carry bit to port pin PO.1 (SDA—Serial Data pin), waits to provide a setup time, brings the clock low, waits, brings the clock high, waits, then decrements bit counter sends the next bit if the counter is not zero. A return is executed when the counter becomes zero.

The UP subroutine, beginning at line 364, reads the delay selected by switch S4 at port pin P1, complements it (again, because the rotary switches are complementary binary), masks off the upper four bits (because the delay switch has just four positions and is connected to the lower four bits of the port), multiplies it by 4 (rotates left twice), then moves the result to R1. If R1 is not zero, the program jumps around line 376 and calls a 10ms delay (subroutine DLY10MS) the number of times entered into R1.

The 10ms delay subroutine (starting at line 436) sets the timer for 10ms, waits at line 446 for the timer flag to be set, clears the timer flag, stops the timer, and returns, in this case, to line 379, where the program decrements R1 and repeats the 10ms delay until R1 is zero.

If the selected delay was zero, the program jumps from line 376 to line 380 and reads port 3 to determine the amount the sent out word is to change from the value previously sent out. The accumulator is complemented and the upper 6 bits masked off to recover only the two bits of the selected increment amount. Since increments of 1, 2, 3, or

4 LSBs are hardly noticeable, the program then multiplies the result by 8 (rotate left three times). To insure a minimum change amount, the accumulator is incremented by one at line 386. This all means that the increment amounts that can be selected are 1, 9, 17, or 25 LSBs. This amount is added, in lines 387 through 391, to the word previously sent out and we return from this subroutine.

After calling the S0 subroutine, PR0GO call the FULLSC (full scale) subroutine, which sends out the full scale code of 3E8(hex). Although a 10-bit full scale code would be 3FF(hex), going only to 3E8 allows an easy distinction between zero scale and full scale when looking at the display. The FULLSC subroutine is found at line 352.

After advancing to full scale, there is a 500ms delay, found at line 464 and called from line 48, then 49 calls the S0D subroutine to send out decreasing word values.

The S0D subroutine begins at line 393 and begins by sending out the current word in R7 and R6 from line 398, then calling subroutine DOWN, which calculates the next (decreasing) word to send out. DOWN begins at line 402. It essentially does the same thing as the UP subroutine, but subtracts the INCREMENT SELECT value from the previously sent word rather than adding to it.

At line 50 subroutine ZEROSC is called to send a zero scale code to the SA5775, then the program branches back to the beginning.

Routine 1

This routine is selected with the PROGRAM SELECT switch is in position 1 or position 9. Routine 1 (PROG1) increments or decrements the word send out, depending upon the setting of the COUNT UP/COUNT DOWN switch, S6. The amount of change is determined by the setting of the INC SELECT switch, S2.

At line 63, the program examines S6 at port pin P3.6 and jumps to the decrement portion of the routine if the pin is low. If this pin is high, the UP subroutine is called from line 64 to increase the R7/R6 word value. The UP subroutine was previously described.

If pin P3.6 is low, the DOWN subroutine (line 402) decreases the previous word sent out by the amount determined from the INC SELECT switch setting.

To insure enough delay to allow the user time to release the START/COUNT button (S5), a delay of 200ms is included at line 66 before jumping to line 27, where another depression of the START/COUNT button is awaited. If S3 (PROGRAM SELECT) is still set to 1 or 9, depression of S5 will cause a jump back to line 52. If another program is selected, the program will jump to the selected routine.

Holding down S5 with PROGRAM SELECT set at position 1 or 9 will cause increasing or decreasing word values to be sent to the SA5775.

Controlling air core meters with the 87C751 and SA5775

AN426

Routine 2

PROG2 is the most complex of all these routines. The purpose of this routine is to cause the air core meter deflection to represent the frequency presented at the timer/counter input to the microcontroller. This is done by measuring the period of the input square wave and taking the inverse of the period. The input here must be a square wave because a slow rise and fall time at this input will cause fluctuating readings. To determine the frequency by counting pulses for a time would require a much longer time and, therefore, is impractical.

The MEAS (measure) subroutine is called at line 79 to measure the period of the input waveform and the CALC (calculate) subroutine is called at line 80 to calculate the code to send to the SA5775. The SENDIT subroutine is then called to send the word to the SA5775 and the program jumps back to line 28.

The MEAS subroutine begins at line 83 by being sure the timer is not running and clearing the timer (overflow) flag, then entering zero into both high and low bytes of the timer and the timer register. The carry bit is then cleared (line 90) and the timer started and the timer interrupt enabled.

Lines 93 and 94 form a short loop that waits until either the carry bit is set or until the TO input is low. The carry bit is set when the timer has gone beyond one second. This is done by the timer interrupt subroutine, found at lines 16 through 19. If the TO input never goes low, we know the frequency is at or near zero and the program jumps to GZS (line 108) where R3 is loaded with a 1F (hex) to cause the CALC subroutine to load zero scale into R7/R6.

When (and if) TO is found to be low, the program jumps to line 95 and waits for that input to go high. Time out process is the same as above.

Now that the TO input is found high (if it is before the one second time out), the timer and carry bit are cleared in lines 97 through 100 (R3 is an extension of the timer).

At lines 101 through 107 we wait for one complete cycle at the TO input, with the timer/counter measuring that period, then return to line 80, where the CALC subroutine is called.

The CALC subroutine, starting at line 113, begins by initializing the word to send out (R7/R6) to zero, clearing the carry bit, checking to see if R3 indicates a time above one second, returning to line 81 if it does. Otherwise the program continues at line 26, where the program checks to see if the input frequency is beyond full scale (timer reading above 00 12 88 hex). If it is, R7/R6 is loaded with 12 88 hex (full scale of decimal 1,000). This value was chosen because it is easily discerned from zero scale on the display.

If the result is not to be full scale or zero scale, the program continues at line 140 with a shift and subtract divide routine. The dividend would be 1,000,000 (decimal) to convert back to frequency in Hertz (period measurements is in microseconds), but that would provide a maximum count of 200 at 200Hz, only one fifth of the full scale desired of 1,000. So we made the dividend to be 5,000,000 decimal, or 4C 4B 40 hex.

This algorithm is found in lines 156 through 192 and works as follows:

1. Clear a counter.
2. Rotate dividend until the first one is in the second MSB position. Since a code of 4C has already provides that, no shifting is necessary.
3. Rotate the divisor (the period in microseconds in this case) left until the first one is in the second MSB position, but the first byte is LESS THAN the first byte of the dividend. Increment the counter each time the divisor is rotated.
4. Initialize a counter to zero.
5. Rotate the quotient (answer) and dividend one bit left.
6. If first byte of quotient is smaller than the first byte of the quotient, jump to step 8.
7. Add one to the quotient and subtract the divisor from the dividend.
8. Decrement the counter and go to step 5 if it is not zero.

Once the CALC subroutine is completed, the program calls SENDIT from line 81 and jumps, ultimately, to the selected routine.

Routine 3

PROG3, beginning at line 194, measures the input period four times, then calculates the code to display that is the average of these four readings.

It starts by setting a counter for three readings, taking those three readings and storing them in memory, beginning at RAM address 20 hex, using register RO as an index register.

At line 212 the program takes a fourth reading, then adds the three previous readings to it in lines 213 through 227; and divides the sum by four (rotates right twice) in lines 229 through 239. The word to send out is then calculated from line 240 and sent to the SGD, after which the program then looks for and jumps to the selected routine.

Routine 4

PROG4 begins at line 243 and displays the average of the current and last three words sent out.

RAM space used is first initialized to zero and a new reading is taken and a new word is calculated and saved. At lines 264 through 284, the new word is added to the last three readings and the average calculated and stored in RAM locations 28 and 29 (hex), and the average word is sent out.

At line 286, the program reads for the program selected and jumps to line 254 if this routine is selected, otherwise it goes to line 28.

Routine 5

PROG5 begins at line 293 and, very simply, send in sequence the codes for 1/8 through full scale in 1/8 scale steps, with 500ms between steps. It then steps down to zero scale in 1/8 scale steps, then returns to line 28.

Routine 6

PROG6 begins at line 314 and does the same as PROG5, but steps in 1/4 scale increments.

Routine 7

PROG7 loads the code for 3/8 scale into R7/R6, sends it, waits 500ms, changes r& for 5/8 scale, sends it, waits for 500ms, then repeats this sequence 9 more times (for a total of ten times), waits 500ms, then returns the output to zero scale and the program jumps to line 28.

Timer I for the 83/87C748/749 and the 83/87C751/752 (non-I²C applications) microcontrollers

AN427

The small package 83/87C748, 83/87C749, 83/87C751 and 83/87C752 microcontrollers include two hardware-implemented timers: a 16-bit programmable timer, and a 10-bit fixed-rate timer. The programmable timer is available for the application program, and its operation is similar to the timer/counter of the 80C51 timer in mode 2. The fixed-rate timer, Timer I, is typically employed as a watchdog timer for the I²C port communications and is not available for other uses.

In applications which do not take advantage of the I²C communications capability, the "silicon real estate" taken by Timer I is not necessarily lost—it can be used as a fixed-rate timer by the application. This timer can become useful in various cases, such as simple control applications that need a delay while doing some software activities in parallel, or generating a free-running repetitive waveform where the exact timing is not important. Another type of application is a watchdog timer prompting the user about unexpected operation of a system or its hardware, or resetting a program that "lost track."

TIMER I IMPLEMENTATION

Timer I is clocked once per machine cycle, which is the oscillator frequency divided by 12. The timer operation is enabled by setting the TIRUN bit (bit 4) in the I2CFG register. Writing a 0 into the TIRUN bit will stop and clear the timer. The timer is 10 bits wide, and when it reaches the terminal count of 1024 it carries out and sets the Timer I interrupt flag. An interrupt will occur if the Timer I interrupt is enabled by bit ETI (bit 4) of the Interrupt Enable (IE) register, and global interrupts are enabled by bit EA (bit 7) of the same IE register.

The vector address for the Timer I interrupt is 1B hex, and the interrupt service routine must start at this address. As with all 8051 family microcontrollers, only the Program Counter is pushed onto the stack upon interrupt (other registers that are used both by the interrupt service routine and elsewhere must be explicitly saved). The Timer I interrupt flag is cleared by setting the CLRTI bit (bit 5) of the I2CFG register.

Note that when the I²C interface is not operating—SLAVEN, MASTRQ, and MASTER bits are all 0—the I²C hardware does not affect Timer I. The SCL and SDA pins can be used as I/O pins, and the activity of these pins will not cause the timer to run, stop, or reset. Upon hardware reset of the microcontroller, the SLAVEN, MASTRQ, and MASTER bits are all reset, so the programmer does not have to worry about interaction between the SDA/SCL pins and the timer.

FIXED-RATE TIMER

The first programming example demonstrates simple fixed-rate operation. Upon reset, interrupts are enabled, and Timer I is started. A wait loop simulates the "application" program. The demonstration service routine simply sets a flag—in real life it could do something more useful, such as toggling an output pin. Note that the interrupt flag is cleared by setting CLRTI prior to returning from the service routine. Upon overflow, the timer will go on running, as the TIRUN bit is still set, so the interrupts will be spaced exactly 1024 clock cycles apart. If the service routine would toggle an output pin instead of setting a flag, its output would be a square wave with a period of 2048 cycles. For an application that demands a "one-shot" delay only, the service routine should clear the TIRUN bit in order to avoid subsequent interrupts.

WATCHDOG TIMER

A watchdog timer mechanism is typically applied in order to detect "abnormal" behavior of hardware. If the microcontroller operates in a very noisy environment, there might be a fear of the program "running wild" as a result of extremely violent EMI interference. In such a case, a watchdog may take care to reset the microcontroller when the Timer I interrupt occurs. This could be applied in application programs with a repetitive nature—the software needs to reset the timer within 1024 machine cycles of the last reset.

In a system where something is supposed to occur regularly—for example, an interrupt for an external event—the watchdog is designed to "bite" when the hardware "sleeps" and the expected "something" does not happen for too long a time. The timer is allowed to run continuously, but when the expected event occurs, it resets the timer back to 0. When the timer is reset within 1024 cycles of the last reset, the application runs normally. If the event does not occur, the Timer I interrupt service routine will be activated to take care of the exception.

The second programming example demonstrates the watchdog. Upon Reset, the TIRUN bit, ETI, and global interrupts are enabled. The watchdog timer is reset and restarted by the small subroutine WdRst. The application is simulated by a loop of delays. Delay 1 is less than 1024 cycles, and when WdRst is called within Delay 1 intervals, no Timer I interrupt occurs. This represents normal operation of a "real life" application. When the delay from last reset is greater than 1024 cycles—representing a hardware exception—the interrupt will occur. The service routine for the watchdog is somewhat unusual, as it does not return to the program location where the interrupt occurred. Instead, the operation of the microcontroller is restarted at Reset. Upon entering the service routine, the interrupt is cleared and the timer is reset. Because execution does not return to the interrupted program with a RETI instruction, the interrupt pending flag is cleared by a call to a dummy subroutine XRETI. The program is restarted at Reset with a regular AJMP instruction. The stack pointer is explicitly reinitialized for the warm reset, so there is no danger of stack overflow upon repeated watchdog invocations.

Timer I Watchdog

11-06-90 PAGE 1

```

1 ;*****
2
3 ;               Timer I Watchdog Timer Usage
4
5 ;This program demonstrates how to use Timer I on the 83C751 or 83C752
6 ;microcontrollers as a watchdog timer when the I2C port is not used.
7 ;Once started, Timer I must be cleared more often than once every 1024
8 ;machine cycles. If Timer I is allowed to overflow, a Timer I
9 ;interrupt will be generated. Thus, if global interrupts or the Timer
10 ;I interrupt are inhibited, the watchdog function will be disabled.
11 ;Also, if the watchdog interrupt occurs during another interrupt
12 ;service, it will be delayed until an RETI (return from interrupt)
13 ;instruction is executed. The I2C bus pins SCL and SDA may be used as
14 ;open drain outputs.

Using the ADC and PWM of the 83C752/87C752

AN428

The Philips 83C752/87C752 is a single-chip control-oriented microcontroller. It is an 80C51 derivative, having the same basic architecture and powerful instruction set in a small 28-pin package. As "add-on" functions to a standard microcontroller, it offers an I²C small area network port, a five-channel multiplexed 8-bit analog-to-digital converter (ADC), and a pulse width modulation (PWM) output. The part is essentially the popular 8XC751 with the addition of the ADC and the PWM output.

There are many control applications for which this microcontroller can provide an almost-complete, low-cost solution. The A/D converter can monitor analog voltages of up to five sources. The PWM output can be used to generate an analog control voltage with the addition of a simple integrator circuit. Another potential use for the PWM output is as a driver of power-switching circuits for DC motor speed control.

The analog-to-digital converter has 8-bit resolution, and the conversion takes 40 machine cycles. A multiplexer selects one out of five input pins. The operation of the A/D converter and the multiplexer is controlled by the ADCON register.

The repetition frequency of the PWM output pulses is determined by an 8-bit prescaler, programmed at register PWMP. The duty cycle of these pulses is determined by the contents of a compare register, PWM. In order to implement the pulse width modulator, the prescaler output drives an 8-bit counter. When the counter value matches the contents of the compare (PWM) register, the PWM output is set high, and when the counter reaches zero, the output is

set low. The counter is modulo 255, so the duty cycle generated will be the PWM contents multiplied by 1/255.

The enclosed listing demonstrates usage of the A/D converter and the PWM. In order to communicate with the outside world, the program sends messages on a software-driven RS-232 port. The routines for sending messages via a software-controlled serial port can be quite useful, and for further discussion on those, please refer to Application Note 423: "Software Driven Serial Communication Routines for the 83C751 and 83C752 Microcontrollers."

Bit 5 of port 1 is used for the RS-232 communications, and in order to hook the microcontroller to a terminal, a buffer (e.g., MC1488) is needed. Timer 0 is used as the baud rate generator, where the timer value is defined by the symbol BaudVal. The programmed value will generate a 9600 baud rate with a 16MHz crystal.

The program, after initialization and sending a message to the terminal, scans all five A/D channel inputs and outputs the voltage read on the serial port, as a hexadecimal value. Circuit operation can be verified by comparing channel voltages with the reading at the terminal. The program follows with an infinite loop in which channel 0 of the A/D converter is read, and its value is used to program the PWM. A simple verification of the duty cycle can be done with a voltmeter: since it acts as an integrator, its reading will be proportional to the duty cycle. Reading of a voltmeter on the PWM output should be proportional to the channel 0 input voltage. If the analog reference voltage AV_{CC} , which is full-scale of the A/D measurement, is set to be exactly as V_{CC} , the PWM output will track channel 0 within about 20mV.

Using the ADC and PWM of the 83C752/87C752

2
3 ;*****
4
5 ;           87C752 A/D and PWM Demonstration Program
6
7 ; This program first reads all five A/D channels and outputs the values in
8 ; hexadecimal as RS-232 data. Next, the PWM output is set to reflect the
9 ; value on A/D channel 0, and again outputs the A/D value to RS-232. Note
10 ; that the A/D value is inverted before being moved to the PWM compare
11 ; register in order to compensate for the inversion on the PWM output pin.
12 ; This process is repeated continuously.
13
14 ; Thus, a voltage may be applied to ADC0 (P1.0, pin 13) to vary the PWM pulse
15 ; width. A simple test of this function is to measure the voltage on ADC0
16 ; and PWM with a voltmeter. A typical voltmeter will integrate the waveform
17 ; on the PWM output and show a voltage within about 20mV of that on ADC0.
18
19 ; The RS-232 output appears on Port 1 pin 5, which must be buffered with an
20 ; MC1488 or perhaps a MAX232 chip prior to being connected to a terminal.
21 ; The transmission rate will be 9600 baud when the 87C752 is operated from
22 ; 16MHz crystal.

Airflow measurement using the 83/87C752 and "C"

AN429

INTRODUCTION

This application note describes a low-cost airflow measurement device based on the Philips 83/87C752 microcontroller. Airflow measurement—determining the volume of air transferred per unit time (cubic feet per minute, or cfm)—is intrinsic to a variety of industrial and scientific processes.

Airflow computation depends on three simultaneous physical air measurements—velocity, pressure, and temperature. This design includes circuits and sensors allowing the 8XC752 to measure all three parameters.

The design also includes seven-segment LED displays, discrete LEDs, and pushbutton switches to allow selective display of airflow, temperature, and pressure. Furthermore, airflow is continuously compared with a programmer-defined setpoint. Should the measured airflow exceed the setpoint, an output relay is energized. In actual application, this relay output could be used to signal the setpoint violation (via lamp or audio annunciator) or otherwise control the overall process (e.g., emergency process shutdown). Of course, the setpoint, comparison criteria (greater, less than, etc.) and violation response (relay on, relay off) are easily changed by program modification to meet actual application requirements.

Referring to Figure 1, the overall operation of the airflow device is as follows.

Normally the unit continuously displays the airflow (in cfm) on the seven-segment displays. The discrete CFM LED is also lit to confirm the parameter being displayed.

Pressing the TEMP pushbutton switches the display to temperature (in degrees C) and lights the TEMP LED. As long as the pushbutton remains pressed, the temperature is displayed. When the pushbutton is released, the display reverts to the default pressure display.

Similarly, pressing the PSI pushbutton displays the atmospheric pressure (in pounds per square inch) and lights the PSI LED. The pressure is displayed as long as the pushbutton is pressed, and the default airflow display resumes when the pushbutton is released.

Finally, pressing the SET-POINT pushbutton displays the programmed airflow setpoint (in cfm) and lights the SET-POINT LED. Again, releasing the pushbutton causes the display to revert to the default airflow measurement.

CONTROL PROGRAMMING IN "C"

While, thanks to advanced semiconductor processing, hardware price/performance continues to improve, software development technology has changed little over time. Thus, given ever-rising costs for qualified personnel, software "productivity" is arguably in decline. Indeed, for low-unit cost and/or low-volume applications, software development has emerged as the major portion of total design cost. Furthermore, beyond the initial programming cost, "hidden" costs also arise in the form of life-cycle code maintenance and revision and lost revenue/market share due to excessive time-to-market.

Traditionally, control applications have been programmed in assembly language to overcome microcontroller resource and performance constraints. Now, thanks to more powerful microcontrollers and advanced compiler technology, it is feasible to program control applications using a High-Level Language (HLL).

The primary benefit of using an HLL is obvious—one HLL program "statement" can perform the same function as many lines of assembly language. Furthermore, a well-written HLL program will typically be more "readable" than an assembly language equivalent, resulting in reduced maintenance and revision/upgrade costs.

Of the many popular HLLs, the "C" language has emerged as the major contender for control applications. More than other languages, C gives the programmer direct access to, and control of, low-level hardware resources—a requirement for deterministic, real-time I/O applications. Furthermore, C is based on a "minimalist" philosophy in which the language performs only those functions explicitly requested by the programmer. This approach is well-suited for control applications, which are often characterized by strict cost and performance requirements.

Airflow measurement using the 83/87C752 and “C”

AN429

8XC752 OVERVIEW

The 83C752/87C752 (ROM/EPROM-based) combine the performance advantages of the 8-bit 80C51 architecture with the low cost, power consumption, and size/pin count of a 4-bit microcontroller. Therefore, the 8XC752 is uniquely capable of bringing high processing speed and HLL programming to even the most cost-sensitive applications such as handheld (battery driven) instruments, automotive distributed processing, “smart” appliances, and sophisticated consumer electronics.

Obviously, the 8XC752 can be used for cost-reduced versions of existing 8-bit applications. The device can also replace similarly priced 4-bit devices to achieve benefits of higher performance and, most importantly, easier s/w development including the use of HLL. Indeed, the component and system design costs associated with the 8XC752 are so low that it is a viable candidate for first-time computerization of formerly non-microcontroller-based designs.

Figure 2 shows the block diagram of the 8XC752. Major features of the device include the following.

Full-Function, High-Speed (to 16MHz) 80C51 CPU Core

The popular 80C51 architecture features 8- and 16-bit processing and high-speed execution. Most instructions execute in a single machine cycle (the slowest instructions require only two cycles). Though a streamlined architecture, the CPU core, unlike 4-bit devices, includes all the basic capabilities (such as stack, multiply instruction, interrupts, etc.) required to support HLL compilation. The CPU core also includes a unique Boolean processor which is well-suited for the bit-level processing and I/O common to control applications.

Low-Power CMOS and Power-Saving Operation Modes

Thanks to the advanced CMOS process, the 8XC752 features extremely low power consumption, which helps to extend battery life in handheld applications and otherwise reduce power supply and thermal dissipation costs and reliability concerns. Low ACTIVE mode (full-speed operation) power consumption—only 11mA typical at 12MHz—is further complemented by two program-initiated power-saving operation modes—IDLE and POWER-DOWN.

In idle mode, CPU instruction processing stops while on-chip I/O and RAM remain powered. Power consumption drops to 1.5 μ A (typical, 12MHz) until processing is restarted by interrupt or reset. Power-down mode cuts power consumption further (to only 10 μ A typical at 12MHz) by stopping both instruction and I/O processing. Return to full-speed operation from power-down mode is via reset.

Note that power consumption can be further cut by reducing the clock frequency as much as application performance requirements allow, as shown in Figure 3.

Another virtue of the CMOS process is superior tolerance to variations in V_{CC} , a requirement inherent in the targeted applications. The EPROM-based device (87C752) operates over a V_{CC} range of 4.5V to 5.5V, while the ROM-based device (83C752) will operate from 4V to 6V.

On-Chip ROM (83C752), EPROM (87C752), and RAM

The 8XC752 integrates 2048 bytes of program ROM/EPROM and 64 bytes of data RAM. This relatively small amount of memory reflects the fact that the targeted applications, though they may require high-speed processing, are typically characterized by simple algorithms and data structures. High code efficiency of the architecture means even this small amount of memory can effectively support the use of C. If necessary, the judicious use of assembly language can help bypass code size (and performance) constraints.

Five-Channel 8-Bit A/D Converter

Most control applications are characterized by the need to monitor “real-world” (i.e., analog) parameters. To this end, the 8XC752 includes a medium-speed (40 clock cycle conversion) 8-bit analog-to-digital (A/D) converter. Five separate input lines are provided along with multiplexer logic to select an input for conversion. The A/D converters speed, resolution, and accuracy are more than adequate to measure temperature, pressure, and other common environmental parameters.

Timer/Counters

Control applications, due to their “real-time” nature, invariably call for a variety of timing and counting capabilities. The 8XC752 meets the need by integrating three separate functions—a 16-bit auto-reload counter/timer, an 8-bit pulse width modulator (PWM) output/timer, and a fixed-rate timer for timebase generation. Together, these timing/counting resources can serve a range of tasks, including waveform generation, external event counting, elapsed time calculation, periodic interrupt generation, and watchdog timer.

I²C Bus

The Inter-Integrated Circuit (I²C) bus is a patented serial peripheral interface. The virtue of I²C is the ability to expand system functionality with acceptable performance and minimum cost. Notably, the pin and interconnect count is radically reduced compared to expansion via a typical microprocessor bus—I²C requires only two lines, while a parallel bus often consumes 20-30 lines and may call for extra glue logic (decoder, address latch, etc.). The 8XC752 I²C port allows easy connection to a wide variety of compatible peripherals such as LCD drivers, A/D and D/A converters, consumer/telecom and special-purpose memory (e.g., EEPROM). I²C can also be used to build distributed processing systems connecting multiple I²C-compatible microcontrollers.

Figure 3. I_{CC} vs. FREQ**8XC752 PIN FUNCTIONS**

Since the 8XC752 is packaged in a cost/space-saving 28-pin package DIP or PLCC, a flexible mapping of I/O functions to pins is required to ensure the widest possible application coverage.

Of the 28 pins, seven pins are allocated to basic functions, including digital power (V_{CC}, V_{SS}), analog reference (AV_{CC}, AV_{SS}), clock

oscillator (X1, X2), and reset (RST). Thus, 21 pins, organized into three ports (5-bit port 0, 8-bit ports 1 and 3), are available for user I/O.

Figure 4 shows the alternative uses for these 21 lines. As shown, the mapping is quite versatile, which maximizes the access to on-chip I/O functions and helps ensure full pin utilization.

AN429

AIRFLOW METER CIRCUIT DESCRIPTION

Figure 5 is the schematic diagram of the airflow meter circuit. As shown, the 8XC752 is connected to the following function blocks.

Discrete and Seven-Segment LED Display

The seven-segment LEDs display the parameter of interest (airflow, temperature, pressure, or setpoint). A discrete LED associated with each parameter is lit when that parameter is being displayed.

The seven-segment LEDs are identified as X0.1, X1, and X10, reflecting their decimal position (tenths, ones, and tens, respectively). Each display has eight data inputs (the seven segments and a decimal point) and common terminals which allow the display to be enabled or blanked. The eight data inputs, and the four discrete LEDs, are driven from port 3 of the 8XC752 via high-current driver U2 and current limiting resistors RP1.

Since all the segmented and discrete LEDs share common data lines, data display must be time multiplexed. Transistors Q1-Q4 connect to separate output lines of port 0, allowing a particular seven-segment LED or the discrete LEDs (as a group) to be individually enabled for display. This type of LED multiplexing is quite common since, at a fast enough refresh rate, the switching between displays is not perceptible by the operator. The major benefit is the reduction of I/O lines required (without multiplexing, 28, rather than 8, data lines would be required).

Pushbutton Switch Inputs

Three pushbuttons select the parameter to be displayed—temperature, pressure, or setpoint (when no button is pressed, airflow is displayed). The four states (SW1, SW2, SW3, or no button pressed) are effectively encoded onto two port 1 input lines (taking advantage of the capability to use port 1 lines configured as A/D for TTL input) as follows:

	P1.3	P1.4
No button pressed	HIGH	HIGH
SW1 (TEMP) pressed	LOW	HIGH
SW2 (PSI) pressed	HIGH	LOW
SW3 (SETPOINT) pressed	LOW	LOW

The only impact of this encoding scheme is that SW3 has a higher priority than the other pushbuttons—a factor of no concern in this simple application. Similarly, latching, debouncing, rollover, or other conditioning of the pushbutton inputs is not required.

Setpoint Control

This is simply a variable resistor voltage divider which serves to establish an analog voltage corresponding to an airflow threshold at which action is taken. It connects to a port 1 A/D input.

Relay Output

When an airflow setpoint violation is detected, DPDT relay K1 is energized via P1.6, which is configured as a TTL output, buffered by transistor Q5.

Flowmeter Input

Measurement of the air velocity is via an air turbine tachometer connected, via optoisolator U7, to P1.5, which is configured as a TTL input. The tachometer input is assumed to be a negative-going pulse train with less than 10% duty cycle.

Air Pressure Sensor

To determine airflow, the air velocity must be factored by ambient pressure—for a given velocity (and temperature), lower/higher atmospheric pressure will correspond with lower/higher airflow. The pressure sensor, U3, outputs a voltage differential corresponding to the pressure. Amplifier U4 conditions the pressure sensor output to the range of AV_{SS} to AV_{CC} (the analog references for the 8XC752 A/D converter). The conditioned pressure sensor output is presented to A/D input P1.0.

To calibrate the pressure sensor, press the PSI pushbutton and adjust the gain pot (R1) until the display matches the local atmospheric pressure in pounds per square inch (14.7 at sea level).

Air Temperature Sensor

Similar to pressure, ambient temperature also affects the airflow calculation. For a given air velocity (and pressure), higher/lower temperature will correspond with lower/higher airflow. Temperature sensor U5 outputs an absolute voltage corresponding to temperature. Amplifier U6 conditions the temperature sensor output to the range AV_{SS} to AV_{CC} for connection to A/D input P1.1.

To calibrate the temperature sensor, adjust the gain pot (R5) so that the display (while pressing the TEMP pushbutton) matches the measured output of U5 (LM35).

Figure 6 summarizes the usage of the 8XC752 I/O lines in this application.

Figure 6. Airflow Meter I/O Port Usage

SOFTWARE DEVELOPMENT PROCEDURE

The airflow meter application software is almost entirely written in C using a development package from Franklin Software. The Franklin Software C compiler is a cross-compiler that runs on the IBM PC (and compatibles) while generating code suitable for execution by any 80C51-based product, including the 8XC752. For more information, contact:

Franklin Software
888 Saratoga Ave., #2
San Jose, CA 95129

The process of developing a C program using the Franklin package (the process is similar for other third-party cross-compilers) is as follows:

1. The program is entered/edited on the PC using the programmer's preferred text editor.
2. The program is compiled on the PC with the Franklin C compiler.
3. Should compile errors (also known as syntax errors) occur, they are corrected by returning to step 1 until an error-free compile is achieved.
4. Before testing the compiled program, it needs to be combined, using the Franklin-supplied linker, with any required assembly language routines. Besides routines explicitly written by the

programmer, every Franklin C program requires an assembly language startup routine (supplied by Franklin and, if necessary, edited by the programmer) which performs basic reset initialization and configuration operations before transferring control to the C program.

5. The compiled object code is tested for correct operation. This can either be accomplished by using an 80C51-family simulator running on the PC or by downloading the object code to an in-circuit emulator. The simulator approach has the virtues of low cost and consolidation of all work on the PC at the cost of non-real-time operation/debug constraints (the simulator may execute 100-1000 times slower than the microcontroller). The in-circuit emulator provides real-time operation and the additional benefit of assisting hardware design debug at somewhat higher cost.
6. Should program execution prove faulty (known as semantic errors), return to step 1 until error-free operation is achieved.
7. The error-free (syntax and semantic) and linked object code, in the form of a .HEX file, is transferred to an EPROM programmer. Fitted with a suitable adaptor, the EPROM programmer can "burn" the object file into the targeted EPROM-based 80C51-family device. For ROM-based devices, the object file is transferred to the factory for custom masking.

Airflow measurement using the 83/87C752 and “C”

AN429

PROGRAM DESCRIPTION

Figure 7 is a flowchart of the program; following the flowchart is the program listing. The flowchart shows the basic processing and flow, while the listing documents the details of the program's implementation.

The program consists of four interrupt-driven (i.e., foreground) routines and a main program (i.e., background). The background program is entered at reset and executes forever, interrupted periodically by the foreground interrupts. Communication between the background program and the foreground handlers is via shared variables.

The four interrupt routines are as follows.

- multiplex () (INT3)

Free-running Timer 1 generates an interrupt at approximately 1000Hz and is used to multiplex the seven-segment and discrete LED display data. In a round-robin manner, at each interrupt, the program turns off the previously enabled display and writes data to, and enables, the next display. Finally, the interrupt routine sets a pointer to the next display—at the next interrupt, that display will be refreshed. Thus, each display (tens, ones, tenths, discrete LEDs) will be refreshed every fourth interrupt, which is more than fast enough for a flicker-free display.

- read_switch () (INT6)

The PWM prescaler is configured to generate a periodic interrupt (INT6) at about 97Hz. The program counts these interrupts, and every 32nd interrupt sets an “update” variable. The main program will change the display data when it detects that “update” is set and clear “update” to prepare for the next display cycle. Thus, display change frequency is about 33Hz (i.e., 33ms), which eliminates display glitches associated with pushbutton switch bounce.

- calc_cfm () (INT0)

The air velocity turbine tachometer drives the 8XC752 INT0 interrupt pin. At each interrupt, the program reads Timer 0, which keeps track

of the elapsed time (the low 16 bits of a 24-bit count in microseconds) between INT0 interrupts. The high-order 8-bit elapsed time count is cleared for possible updating by the following routine.

- overflow () (INT1)

When Timer 0 overflows (generating an interrupt), the program increments the high-order 8 bits of a 24-bit variable, counting the microseconds between tachometer interrupts (handled by the previous routine). If this 8-bit value becomes too large (i.e., tachometer interrupts stop), a NOFLOW variable is set, which will cause the main program to display an EEE out-of-range indicator on the seven-segment LEDs.

With the interrupt handlers executing the low-level timing and I/O, the main program, which is entered on reset and executes forever, consists of only three major steps.

The temperature/pressure compensated airflow is calculated. First, the “base” cfm rate, as tracked by the calc_cfm () tachometer interrupt is adjusted by removing the execution time of the calc_cfm () handler itself. Next, the temperature is determined (A/D channel 1), and airflow is compensated. Similarly, the air pressure is determined (A/D channel 0) and airflow compensated again.

Now that the true airflow is calculated, it is compared with the setpoint (adjusted with the variable resistor), which is determined by reading A/D channel 2. If the airflow is greater than the setpoint, the relay is closed. Otherwise, the relay is opened.

Finally, the UPDATE flag (set by the 33Hz read_switch () interrupt) is checked. If it is time to update, the data to be displayed is determined based on the pushbutton status and the state of the NOFLOW flag. The updated display data is initialized for later display on the LEDs by the multiplex () display refresh interrupt handler.

“Opti-Mizer” power management for notebook computers using the 8XC752 microcontroller

AN436

INTRODUCTION

With conventional microprocessor based systems, the market was primarily concerned with performance, cost and features. With the advent of hand-held and portable computers, the prominent market requirements focus on size, weight and battery life.

Given a mature 386SX/AT architecture that provides more than adequate performance for average notebook application usage, the design challenges for these machines revolve around developing low power systems that maximize battery usage.

The features of a notebook PC are usually characterized as weight and battery life. The heaviest component of a PC is usually the battery and the choice of battery is dictated by the power required. Thus the performance of the power management scheme has a direct bearing on both these parameters.

The battery life targets for notebook machines is around 5 hours (the air commute time from coast to coast USA).

OVERVIEW

Most of the power consumed by a fully powered PC is wasted. The hard disk spins constantly even though data transfers from the disk are very sporadic. PCs may sit unattended for periods where the user is distracted by a telephone call, for instance.

There are two principle challenges in designing a power management system: the ability to power down various devices without affecting other devices on the same bus, and ensuring full compatibility with existing operating systems and applications.

The largest user of power in a PC is the display sub-system (3–5 Watts) followed by the peripherals such as the hard disk (2–4 Watts), the main system memory (0.5–1.5 Watts), and the core logic (1 Watt).

INTEGRATED POWER MANAGEMENT

The conventional PC architecture needs to be extended to support power management. Hardware needs to be added to provide power-down capabilities and software needs to be added to support the hardware and provide DOS compatibility. The software support is usually realized in the BIOS. The hardware support can be implemented with external circuitry. This external circuitry manages the power resources to individual sub-sections of the PC system as these

resources dictate. The external circuitry monitors battery power, system activities and timed events.

Conventionally, the external circuitry is comprised of a digital power management ASIC and associated components. The use of this part increases the chip count of the PC system.

The power management system has to determine how the system resources are being used. The resource usage of a PC can be determined by monitoring events or activities. User activity is usually determined by monitoring the keyboard controller for keystroke events. Keystroke events can be indicated by interrupts to the PC core logic or IO reads to the keyboard controller location.

The power management ASIC solutions on the market today, such as the VADEM/INTEL 82C347, VLSI VL82C312 and INTEL 80C386SL all require external analog support circuitry to completely implement the power management functions. For example, low battery detect is implemented by the use of external comparator chains and complex, close tolerance level detect circuitry. The cost of this external circuitry is usually a significant proportion of the overall cost of the power management solution. The 83/87C752 employs an internal analog-to-digital converter (ADC). The ADC can be used to implement the battery level detection function at no extra cost and with no extra support circuitry.

The 83/87C752 is a member of the Philips 8051 family of high performance 8-bit microcontrollers. These processors have been optimized for sequential real time control applications. The 83/87C752 contains most of the features of the 80C51 and has the following features:

- 2k bytes ROM
- 64 bytes RAM
- Single level interrupt structure
- 16 bit programmable counter/timer
- Two 8-bit and one 5-bit bi-directional IO ports
- I²C serial interface
- PWM with interrupt and overflow capability
- 5 channels of 8-bit A/D
- 28-pin DIP and PLCC.

FLEXIBILITY

ASIC solutions to power management offer rigid schemes which work adequately with a few notebook architectures, but rarely offer

exactly what the designer requires. With the current competitive arena for laptop development, time-to-market and value added features have a significant impact on the sales success of a particular product. The 83/87C752 offers flexibility at a low price. The power management design requirements can be coded and configured in the controller software and One Time Programmable (OTP) devices can offer a quick low-cost implementation of the coded scheme.

With these integrated functions that the 83/87C752 offers, and its ability to provide a complete solution to power resource control, this device is emerging to be the industry standard for power management.

TOPOLOGY

Figure 1 shows a block diagram of a typical system implementation. It employs the integrated power management scheme using the Philips microcontroller to handle the keyboard and power management functions. The CPU and coprocessor reside on the local bus with the system memory. A local bus controller monitors CPU bus cycles to see if they are memory or ISA cycles. It also integrates the interrupt and DMA functions. The ISA bus controller processes non-system memory bus cycles. A frequency generator is used to provide the system clocks and clock multiplexing. The peripheral controller integrates the communications and mass storage sub-system. The VGA sub-system shares the ISA bus with the peripheral controller. The VGA controller has associated VGA memory.

Figure 2 shows the microcontroller with the external support devices. The frequency generator provides the system clocks. It must have the ability to change the frequency of the clocks without violating the minimum high or low times for the core logic. The Philips microcontroller can control the speed of the system clocks via frequency select pins on the frequency generator. Frequency generators such as the Avasem AV9127 can change the processor clock speed gradually and continuously without violating the minimum high or low times.

The integrated controller monitors system activity via its digital input ports. It uses internal timers to time the intervals between activity. The power to the VGA and peripheral sub-systems is controlled by the digital output port pins via MOSFETs.

Battery level and V_{CC} is monitored by the onboard A/D converter.

OPERATION

The power management system operates like a state machine. Transitions from state to state are controlled by expiring timers which are retriggered by external events. On entering a state, external power is switched or clocks are modified. A typical power management system would employ six states: Full Power, Doze, Shutdown, Sleep, Suspend, and Off.

The state diagram of Figure 3 shows the power management states and their interrelationships.

Full Power

Entry to this state is controlled by a transition of the ON/OFF switch. In this state all the power control outputs are asserted, and the clock generator is selected for the highest speed. The system runs at full speed and power.

Doze

This state is entered from the FULL POWER state. Entry into this state is controlled by an expired timer (typically 30 secs). The timer expired as a result of not being reloaded by a transition on an activity monitor input pin. In this state the frequency generator is instructed to reduce the clock speed to about half that of the previous state.

Shutdown

This state is also entered from the FULL POWER state and operates in parallel with the DOZE state. Entry into this state is controlled by the DOZE state. Entry into this state is controlled by an expired timer (typically 30 secs). The timer expired as a result of not being reloaded by a transition on an activity monitor pin. In this state the power to a particular peripheral or group of peripherals is removed via an external FET.

Shutdown-Doze

This is an intermediate state which implements the features of both the SHUTDOWN and DOZE states. Entry into this state from the DOZE state is controlled by an expired timer (typically 30 secs). The timer expired as a result of not being reloaded by a transition on an activity monitor pin. Entry into this state from the SHUTDOWN state is controlled by an expired timer also. The timer expired as a result of not being reloaded by a transition on an activity monitor input pin. In this state the power to a particular peripheral or group of peripherals is removed via an external FET and the frequency generator is instructed to reduce the clock speed to about half that of the FULL POWER state.

Sleep

This state is entered from either the DOZE state or SHUTDOWN state. Entry into this state is controlled by an expired timer (typically 30 secs). The length of this timer is usually longer than that employed in the DOZE or SHUTDOWN states. The timer expired as a result of not being reloaded by a transition on an activity monitor pin. The activity monitor may look for keystrokes or video activity as described below. In this state power is removed from the backlight and LCD modulation voltage regulator via external FETs.

Suspend

This state is entered from any of the above states. Entry into this state is controlled by a transition on an external suspend switch or a command from the BIOS. During this state, the microcontroller takes over the task of refreshing the system memory and removes the power from the rest of the system via external FETs.

Off

This state is entered from any of the above states. Entry into this state is controlled by a transition on an external switch or a command from the BIOS.

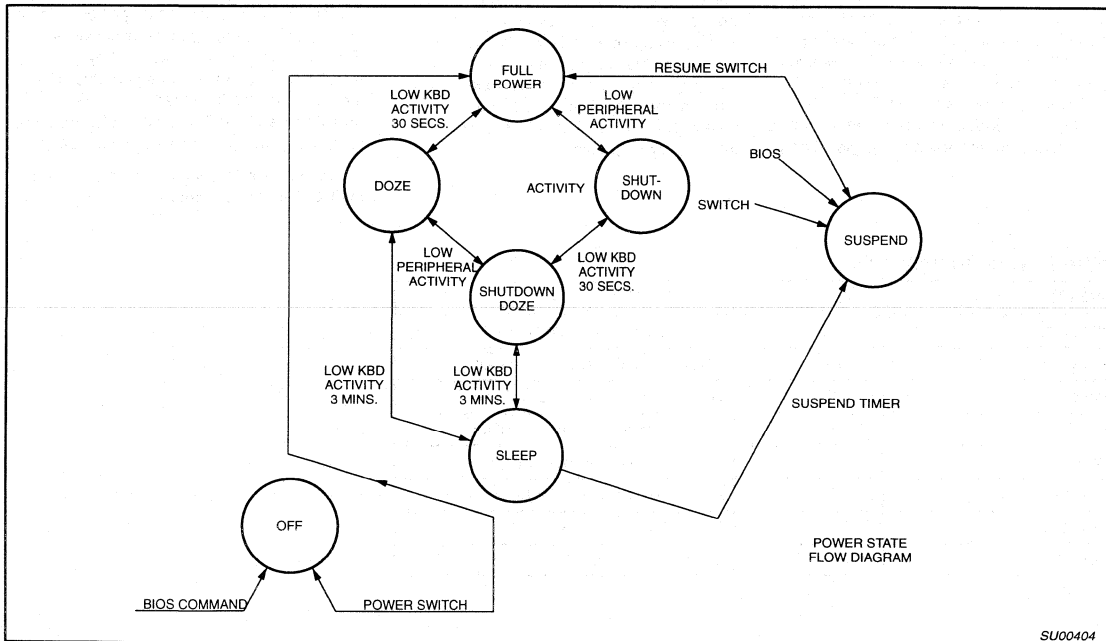

Figure 3. Multi-State Power Management Scheme

AN436

POWER MANAGEMENT ELEMENTS

Figure 4 shows the internal power management elements of the Philips controller. The Activity monitors contain combinatorial algorithms to monitor or poll an activity or combination of activities. The activity monitors reload programmable timers which toggle clock control and power control output pins.

Each functional block is discussed in more detail below.

Power Outputs

The power outputs are logic level signals that control MOSFETs via level shifting circuitry.

The MOSFETs switch power to the various blocks under power management control and are chosen to have a low R_{ds} on which reduces the voltage drop across the DRAIN-SOURCE channel.

The level shifting circuitry and MOSFET orientation is shown in Figure 5.

C1 and R1 control the switchon edge and should be chosen to make the edge sufficiently slow to minimize the inrush current. This is necessary where the notebook computer employs solid chip tantalum capacitors which fail short-circuit on switchon current transients.

R1 pulls the gate to the NiCAD supply rail. The NiCAD battery voltage is usually greater than +12 Volts. We can exploit this relatively high voltage to turn the MOSFETs hard on and further reduce the R_{ds} on. The NPN transistor is operated as a cascode and gives no net inversion between the logic level and

the state of the MOSFET. This is necessary to handle the default powerup mode of the port pins.

For a lower performance and cost reduced system, a logic level FET can be used such as a MTM25N06L and driven directly from the microcontroller port. These logic level FETs usually have R_{ds} on specifications in the region of 100 milliohms. The finite drain-source resistance implies that a small amount of power is wasted in this channel while power is applied to the switched group of devices.

Clock Control

The clock control module controls the speed of the system clocks. Where the notebook system has a synchronous ISA clock, it is derived directly from CLK2, the processor clock. The clock control outputs can be fed directly to a frequency generator such as an AVASEM AV9127 where pins are committed to encode a frequency select scheme. The scheme employs two programmable clock generators; one with eight preset frequencies used for the system clock; and the other with four preset frequencies used for the mass storage subsystem. Figure 6 shows the interconnection between the clock control port and frequency generator.

By changing the assignments of the encoded select lines, the system clock frequency can be reduced. Frequency generators employ analog voltage controlled oscillators which, when instructed to change frequency, will steadily and gradually change frequency in a smooth transition. This scheme does not violate the minimum high and low times for the core logic devices.

Timers

The timers should run independently of the keyboard scanning function. The timers are used as timeouts for a combination of external events or activities. The timers are constructed of reloadable timers and reloaded by transitions or conditions on external events. A typical timeout period is between 1 and 4 minutes, therefore the timeout must be constructed from both timer hardware and support software. Figure 7 shows the interrelationships between hardware and software. The software must record the instances of timeout cycles. If the number of cycles is allowed to reach a predetermined number, the timeout elapses and the assigned power control output is negated, or the clock control outputs proceed to the next state. The count of the number of cycles is reset by a command for the activity monitor.

The activity monitor asserts flags during the background and interrupt tasks. The timer software processes these flags to determine the state of the timeout. The software uses a count variable to measure the instances of the timer elapsing and a flag to determine whether activity has occurred.

Activity Monitor

The activity monitor sets the activity flags for the timers. The monitors contain combinatorial elements which poll an external activity or a number of external activities. External activity can be detected by transitions or levels on input port pins. The interrupt pins would be better suited for transition detect while the general input ports could be used to poll for external conditions.

There are several key activity indicators on the PC. See Table 1 below.

Table 1. Key Activity Indicators

SIGNAL	TYPE	DEVICE/PERIPHERAL

AN436

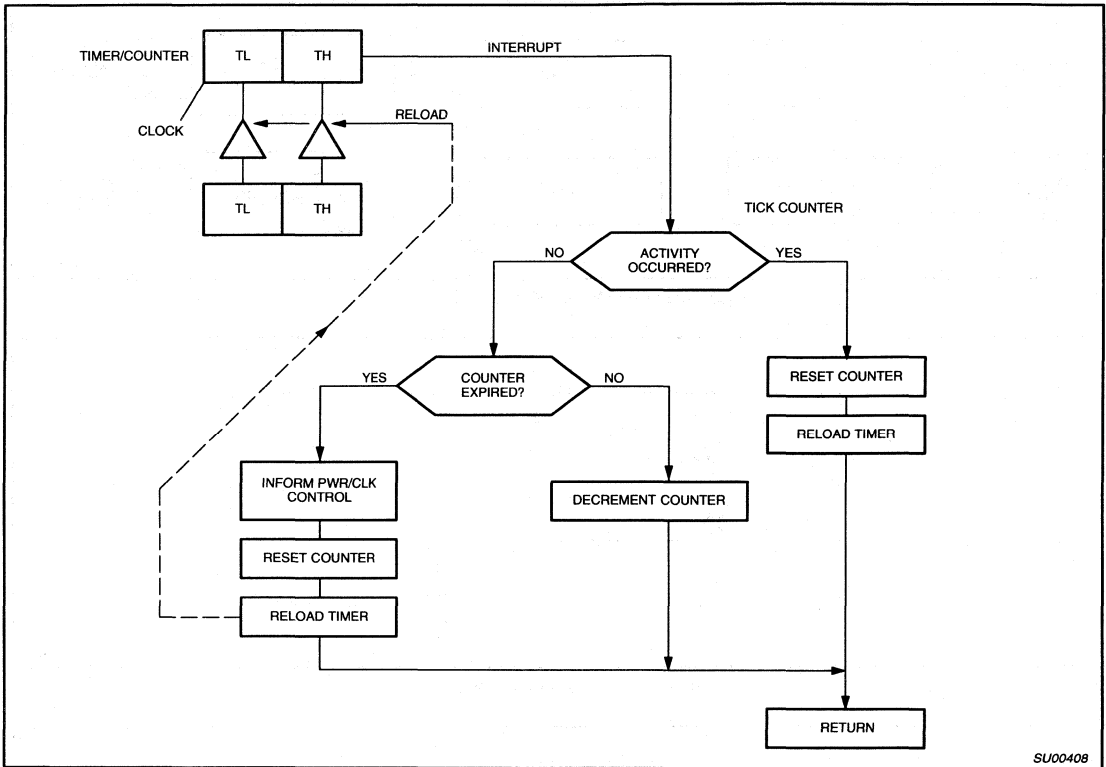

Figure 7. Hardware–Software Interrelationships

Suspend Control

During the suspend state, power is removed from all the system devices except the power management controller and system memory. Before the system is allowed to enter the suspend state, the BIOS empties all the DMA holding registers, makes a copy of the CPU registers and stack pointer into reserved main memory. The VGA memory is also copied into main memory. Once this transaction has been completed, the system BIOS instructs the power management controller to enter the suspend state.

At the start of the suspend state, the microcontroller takes over the memory refresh. This is achieved with the use of an external refresh mux. The mux is switched over to the microcontroller refresh lines when REFSEL is asserted. Switchover must only be executed after the system memory controller has performed a complete refresh cycle (512 / 1024 rows). The external multiplexer asserts all the individual *CAS lines while switched over to the controller.

The *RAS lines are all driven by a single *REFRESH command from the controller.

Battery Monitor

The ADC can be used to monitor the battery condition via an external resistor divider. This monitor can be used to assess the condition of the system batteries during system use and while being charged.

A simple “minus delta V” algorithm may be implemented to measure the slope of the battery voltage over time. The charging curve of Figure 8 shows the characteristic of the voltage across the NiCAD cells with a constant current applied. As the NiCADs become charged, the internal temperature of the cells rises and thus their internal resistance increases. This results in a droop of the voltage across the cells. The charging current must be terminated when a droop of greater than 50mV per cell over 1 second is detected.

This minus delta V algorithm can be implemented in the microcontroller software.

The analog to digital controller can be used to sample the NiCAD battery voltage level at regular intervals. The sample is compared against the last sample for a negative result. If the magnitude of the result is greater than 50mV per cell, then the charging circuit must be given a command to switch off.

A battery condition detector can also be implemented in the microcontroller. This detector can be used to give an early indication of an exhausted battery. When a NiCAD cell reaches its supply capacity, the voltage across the cell drops rapidly, thus the system supply can only sustain the core logic for a matter of seconds. The battery condition monitor should give the system and user an early indication of this condition. This can be implemented by monitoring the battery voltage. When a preset slope or level is reached or exceeded, the controller can issue an NMI to the core logic. The core logic can execute a shutdown routine which saves the state of the machine on the hard disk and preserves the integrity of the user’s data.

“Opti-Mizer” power management for notebook computers using the 8XC752 microcontroller

AN436

PERFORMANCE

Table 2 shows the power performance of the 83/87C752 in a typical notebook system. During each power management state, the core logic system and peripherals demand lower and lower power as the clock speeds are reduced, resets are asserted and power is removed from the device or peripheral.

During the suspend mode, power is completely removed from the core logic devices and peripherals, only the DRAMs remain energized so that the system state can be restored to the next post suspend cycle on the detection of an activity.

The FULL-ON figures are maximums, In reality, the processor executes sporadic scripts and then idles in tight loops awaiting IO. This means that the actual power required by the system under normal conditions will be lower than that estimated in that column of the table.

Table 2.

STATE	FULL-ON POWER (W)	SHUTDOWN-DOZE (W)	SLEEP POWER (W)	SUSPEND POWER (W)
DEVICE	(MAX)			
Am386SX	2.14	0.7	0.5	0
DRAM + Controller	1.7	0.6	0.4	0.025
Local bus controller	0.3	0.3	0.2	0
ISA bus controller	0.2	0.18	0.07	0
87C752	0.08	0.08	0.08	0.015
BIOS ROM	0.11	0.002	0.002	0
Floppy drive	3.1	0.035	0.035	0
IDE drive	3.3	0.68	0.68	0

AN436

OTHER INTEGRATION OPPORTUNITIES

The 83/87C752 offers a complete power management solution as described above. The functionality and IO capability of this device can be used as a common denominator for other, larger Philips microcontrollers. The 83/87C552 offers the same internal functionality while providing more integration capabilities with its increased IO, memory and timer functions.

An example of an integration opportunity would be to combine the keyboard scanner function with the power management

function. The Philips 83/87C552 microcontroller is ideal for this task. The microcontroller can implement the scanning and code generation schemes associated with the keyboard function, implement the activity monitors, timers and power control scheme required for power management as well as provide an integrated solution to battery condition detection by exploiting the onboard A/D converters.

The PC keyboard scanner is traditionally an 8051 microcontroller. The keyboard scanning and code generation can be performed by an 8051 running at 6MHz. A 12 or 16MHz

83/87C552 microcontroller would have the bandwidth to take on other tasks.

Figure 9 shows the 83/87C552 integrated as a power management unit and keyboard scanner.

Other members of the Philips family of 8051 derivative microcontrollers can also provide an integrated solution to power management (see Table 4).

As can be seen, the 83/87C550 provides an intermediate solution to the 83/87C552 and 83/87C752. It has more memory and IO than the 83/87C752 and has three more ADC channels.

Table 4. Microcontrollers with A/D

87C751 fast NiCad charger

AN439

DESCRIPTION

This application note describes a portable standalone, automatic constant current NiCad battery charger using the Philips Semiconductors 87C751 microcontroller. This unit will fast charge NiCad batteries from a 12V source such as an automobile battery or a DC power supply. The charge current is 2.5A which is suitable for charging NiCad cells of 1200mAh capacity in little over 1/2 hour.

Use of a microcontroller provides complete flexibility of design parameters such as the number of cells, their capacity and charge rate requirements. A number of key microcontroller techniques described in this application note are a state machine, a low-cost, high-resolution single slope analog-to-digital converter comprised of the microcontroller and a comparator as well as an analog control system.

As shown in the block diagram (Figure 1), the charger consists of the 87C751, a switching charge current regulator, an analog-to-digital converter and some LED indicators.

DESIGN OBJECTIVES

The goal of this design is to achieve a maximum charge rate without damage to the NiCad cells. To determine the requirements for such a charger, we need to examine the most important characteristics of NiCad cells.

As a NiCad cell charges, gas bubbles are released from the electrolyte and accumulate on the plates, reducing the effective plate area and increasing cell impedance. When the cell gets near full charge the rate of gas generation and temperature rise increase, since the charge current produces gas rather than stored charge. At that point the process goes into thermal runaway. The cell pressure rises sharply causing the case to vent. A large enough venting can destroy the cell immediately. If the venting is of a lesser magnitude, as would be the case with a relatively low charge current, the cell capacity is reduced.

The standard technique is to charge the cells at such low current that there is no risk of thermal runaway. The electrolyte then reabsorbs the gas bubble at the same rate as they are generated. Usually this implies a charge current of 0.1 times the cell capacity

and a charge time of 16 hours. We want to achieve full charge in about half an hour. Slow charging also increases the likelihood of dendrite formation. Dendrites are crystalline fingers that can propagate through the plate separators and short the cell internally. Fast charging tends to clear these shorts before they have a chance to become significant.

CHARGE TERMINATION

There are two methods commonly used for terminating NiCad fast charges: delta-peak voltage detection and delta-temperature detection. This charger uses the delta-peak voltage method. It is simpler to implement, especially if interchangeable battery packs are to be charged, because the temperature sensing method requires a temperature sensor to be attached to the battery pack. The temperature change in the battery pack depends on how well the pack is thermally coupled to its surroundings, which also makes temperature sensing somewhat tricky.

The voltage on a NiCad pack rises during charging, steeply at first, and then at a lower rate. When the pack is nearly full, the voltage rate of rise increases a little, then falls to zero as the voltage peaks. As the pack goes into over-charge the voltage starts to drop and the internal temperature and pressure rise. A typical voltage drop used for charge termination is 1% of the peak voltage as shown in the battery voltage waveform (Figure 2). This charger uses 1% of the measured peak voltage as the threshold, which means that it can charge any number of cells from 1 to 6 without any external input to select a number of cells.

THE 87C751 MICROCONTROLLER

The Philips Semiconductors 87C751 contains a 2k byte ROM, a 64 byte RAM, 19 I/O lines, a 16 bit auto-reload timer, a five-source fixed-priority interrupt structure, a bidirectional I²C serial bus interface and an on-chip oscillator.

In this application note, the timer is used as a 'tick-timer', scheduling events and measuring periods. The ports are used to control and monitor the external analog circuitry. The software is written in C using the Franklin C compiler.

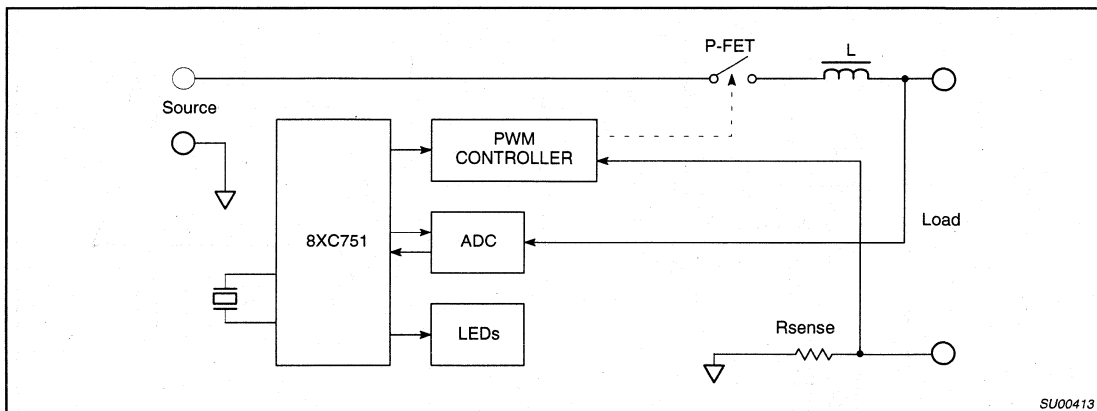

Figure 1. Block Diagram

SU00413

87C751 fast NiCad charger

AN439

Figure 2. Battery Voltage Waveform During Charging

SU00414

SOFTWARE

Scheduler

The timer generates events at a fixed interval by updating the variable **tick** in the timer interrupt service routine. The timer is initialized and reloaded with $ffff_{hex}$, which corresponds to a period of 71 milliseconds. The choice of this period is related to the analog-to-digital converter, which is described below.

The variable **tick** is incremented once every 71 ms so that 14 ticks make a second. The scheduler calls the **charger** procedure when **tick** equals zero, the **leds** procedure when **tick** equals 7 and it resets **tick** to zero as well as incrementing the **seconds** variable when **tick** reaches 14.

State Machine

The state machine in the **charger** procedure is the heart of the system. The state machine processes the current state and the filtered battery voltage. Figure 3 shows the topology of the state machine. There are four states: **FAULT**, **INITIALIZING**, **CHARGING** and **DONE**. The variable **state** keeps track of the current state. The operation of the states is as follows:

FAULT

This is the default state. When the system powers up and is reset, the state variable is initialized with this state. The filtered battery voltage is checked using the **check_limits** procedure (see Figure 3). If the measured voltage is within a predetermined range, it is

assumed that a battery has been connected and the state variable is set to the **INITIALIZING** state. A voltage out of range will always set the state variable to **FAULT** no matter what the current state is.

INITIALIZING

During this state the running average noise rejection filter and other variables used by the charging algorithm are initialized by sampling the battery voltage for a preset number of passes through the state machine without making any decisions about the charging process. The number of passes is defined in the constant **INITIALIZATION_TIME** which is an integer number of seconds.

When the initialization time is over, the state variable is updated to the **CHARGING** state.

CHARGING

During this state the battery voltage is processed in the **delta_peak** procedure. A watchdog timer is also used to ensure that the battery is not overcharged in the unlikely event that the **delta_peak** procedure misses the termination conditions. Until the battery peaks or the watchdog timer times out, the state machine remains in the **CHARGING** state. If a voltage peak is detected and the voltage drops below the peak by 1%, or the watchdog timer expires, the state variable is updated to the **DONE** state.

DONE

After **MAINTENANCE_PERIOD** seconds, charging current is applied to the battery for 1 second. If the battery voltage falls out of range (i.e., it has been disconnected), the state variable is updated to **FAULT**, the default state.

AN439

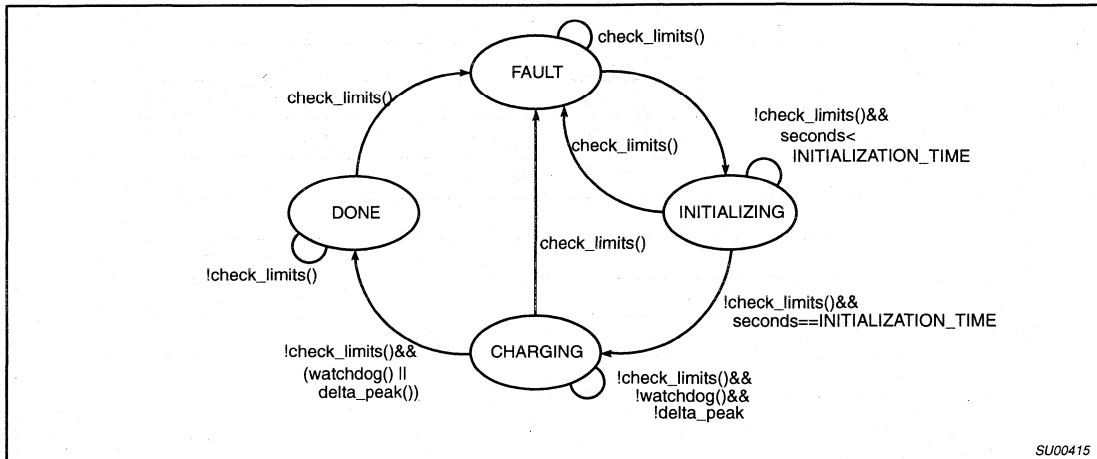

Figure 3. Charger State Machine

SU00415

HARDWARE

Buck Converter Current Source

There are two basic converter topologies from which the others are derived. They are the buck and boost converters. As the names imply, the buck converter produces an output lower than its input and the boost converter does the opposite. The transformer isolated versions of the buck and boost circuits are known as the forward and flyback converters. Since the input supply voltage is greater than the maximum expected output voltage and no isolation is required, the buck topology is a good choice for simplicity and high efficiency.

The required values of inductors and capacitors for a switching converter are inversely proportional to operating frequency, while switching losses are proportional to frequency, so that a compromise is made in the choice of operating frequency. To keep the converter compact and avoid excessive switching losses, the switching frequency was chosen at 100kHz.

The Unitrode UC3843D is a low-cost surface mount current-mode switching power supply controller. In this application, the voltage feedback loop is left open and the controller is driven from its compensation input (pin 1). The UC3843 data sheet shows that this node in the IC is driven by an active pulldown and a fixed 0.5 mA pullup current source. If the voltage feedback, pin 3, is grounded, the internal voltage error amplifier will turn off its output, allowing control of the node voltage by pulling current out of pin 1.

The ICL7667 is an inverting MOS gate driver. It provides the correct polarity for the mosfet gate signal and its 1.5A peak output improves efficiency by switching the fet quickly. The Amobead is an optional component which reduces EMI at the expense of increased drain voltage swing. The scope traces were taken without the Amobead in place.

Analog-to-Digital Converter

The analog-to-digital converter consists of Q104, C118, R114, U104 as well as R115, R116 and C119 operating in conjunction with the 87C751. In this application a simple, low-cost ADC with relatively high resolution is required, but it does not need linearity, absolute accuracy or long term stability because the detection method is relative to the peak voltage and happens over a period less than one hour. The circuit functions as a voltage-to-period converter. Although the capacitor voltage follows an exponential curve, it is nearly linear in the operating region from 0V to the comparison threshold of 454mV since the battery voltage which drives it is typically 5 to 6V for a four cell pack under charge. With a single cell the period can stretch to near the 71ms tick period. The capacitor voltage is described by the equation

$$V_C = V_{BATT}(1 - e^{-t/RC})$$

where C=0.1µF and R=1M in this circuit. The straight line approximation we are using is the tangent to the actual curve at t=0. This can be found by differentiating the above equation with respect to time

$$dV_C/dt = V_{BATT}/RC \cdot e^{-t/RC}$$

and setting t=0. Then the expression becomes

$$dV_C/dt = V_{BATT}/RC$$

Integrating the above expression yields a straight line

$$V_C = V_{BATT}/RC \cdot t$$

from the origin to the point (RC, V_{BATT}). If you solve for t using the straight line and V_C=454mV, V_{BATT}=5.50V, you get t=8.255ms. Substituting this back into the first equation and solving for V_{BATT} yields 5.73V, which is within 5% of the actual voltage. The absolute accuracy of the conversion is only important when using the battery voltage measurement to detect a battery connected to the output, versus a short circuit or an open circuit. All the critical sensing is done within 1% of the peak voltage and is relative to the peak.

To avoid contamination of the battery voltage reading by switching noise, the voltage sensing is done during a quiet period when the switching current source is turned off by the processor.

87C751 fast NiCad charger

AN439

Waveforms

The first trace (Figure 4) shows drain to ground voltage on the P-channel FET. Note that the peak negative voltage is -17.66V and there is minimal flyback ringing. The positive spike on turn-on may be due to sense resistor inductance.

The second trace (Figure 5) shows the voltage across the 0.1Ω sense resistor at a DC output current of 2.5A and an input voltage of 12.2V . Voltage spikes due to trace and sense resistor inductance are filtered out by R105, C112 to prevent false triggering of the UC3843 current comparator.

The third trace (Figure 6) shows the FET gate voltage. FET gates are usually rated at $\pm 20\text{V}$ maximum, but reliability is enhanced if they are kept within $\pm 15\text{V}$. In this case the gate voltage is well within range for reliable operation.

(BCM) 87C751 Specification for a bus-controlled monitor

AN442

SUMMARY

BCM87C751 is a powerful, flexible and low cost Digital Controlled Monitor System, based on the 87C751 microcontroller. It employs I²C bus control with various I²C bus controlled peripherals (PCF8582EP-EEPROM and TDA8444 D/A converter). The control function is implemented via 8 6-bit DC voltage output from TDA8444.

Some features of the system:

- Flexible approach, especially for multisync or auto sync operation
- Mode detection and frequency measurements by microprocessor
- Mode switching under software control
- Elimination of potentiometers
- Quick factory alignment (DACs can be preset)
- Automatic factory alignment possible

This document describes the operation and the use of the system. It provides necessary information concerning operation, required hardware, flow charts and their effect on the performance.

INTRODUCTION

Figure 1 shows the block diagram of a high-performance color monitor with microcontroller and several parts that communicate via the two-wire I²C-bus.

The system can perform the following:

- Determine the mode and standard of incoming signals with the stored values in memory (e.g., multisync modes).
- Enter parameters of user defined modes into memory via a keyboard.
- Control analog parameters such as contrast and brightness via the bus from keyboard inputs.
- Control mode and standard parameters (such as picture geometry parameters and the free-running oscillator frequency).

Features

- Multisync or Autosync operation
 - FH = 31kHz–95kHz
 - FV = 50Hz–114Hz
- Selectable four or five function control configurations
- Selectable one digit, or one and one-half digit, or null seven segment mode display.
- Selectable Horizontal direct ratio or indirect ratio F to V converter DAC output configurations
- Selectable ten user modes plus ten factory modes, or, one user mode plus 19 factory modes configurations
- Selectable multiple up/down keys or minimum keyboard configuration
- Change function without save key, all keys but the reload key have a repeat function
- Both Horizontal and Vertical outputs have F-to-V converter DAC outputs

- Four outputs of Horizontal PLL capacitor selection signal. This can be easily adapted for further extension.

IC DESCRIPTIONS

87C751

A derivative of the 8051 family of microcontrollers, the 87C751 has an 8-bit CPU, 2k bytes EPROM, 64 bytes RAM, 19 I/O lines, a bi-directional inter-integrated circuit (I²C) serial bus interface, and an on-chip oscillator.

PCF8581/2

A 1k- or 2k-bit, 5V electrically erasable programmable read only memory (EEPROM) organized as 128 or 256 × 8 bits. The stored information is electrically alterable on a word-by-word basis, I²C-bus controlled.

TDA8444

Comprises eight DACs, each controlled via the I²C-bus. The DACs are individually programmed using a 6-bit word to select an output from one of 64 voltage steps. The maximum output voltage of all DACs is set by the input VMAX and the resolution is approximately VMAX/64.

For detailed information on these devices, please refer to their respective data sheets.

AN442

OPERATION INSTRUCTION

Function Selection and Change

When the monitor is powered on it will automatically enter the corresponding mode depending on the input signal. Different configurations and functions can be defined by users with the use of different features. The following configuration's functions are examples for user's reference. See Figure 2 for Configurations 1 through 4.

To adjust functions such as V-size, V-shift, H-center, H-shift, and PCC (Pincushion Correction Circuitry):

1. The "Function" key should be pressed until the required function LED is lit.
2. If the V-shift LED is on, the user can then adjust V-shift by pressing Up or Down key. If the Up key is pressed, the V-shift DAC output will increase one step. While the Down key is pressed, the V-shift DAC output will decrease one step. The user can repeat the Up or Down key simply by pressing it longer than 0.5 second. It will then automatically repeat approximately 2 times per second until the key is released.

Mode Selection and Change

(See Figure 4)

In Figures 3 and 4, the mode number is displayed on the two seven-segment LEDs.

Each number denotes one mode. Modes 10 through 19 are user modes, which can be defined by the user. When there is a new mode entering the monitor that does not belong to any mode stored in the EEPROM, the mode display will show "19". If the user presses the Reload key while the mode display is "19", the display will flash. When the mode display is flashing, the user can select the destination mode by pressing the Up/Down keys. The destination mode is between 10 and 19.

Every press of the Up key causes the flashing display to add one, unless it already reached 19. Every press of the Down key causes the flashing display to subtract one, unless it has reached 10. When the user lets the destination mode flash on the display, the user can press the Reload key to store the new mode to destination mode. When the mode display stops flashing, the new mode is stored. The newly stored destination mode is permanent, unless the user repeats the entire procedure.

To change an old user mode, already stored in EEPROM, to a different user mode, press the Reload key for longer than 8 seconds while the monitor is working in the old mode. The mode display will flash the old mode, then the user can use the Up/Down key to select the new mode. Press the Reload key again to copy the old to new destination user

mode. If the user forgets to press the Reload key again, the flashing of the mode display will last for 2 minutes, then the program will cancel the copy old mode to new user mode command.

During the flash period, the program still monitors the Horizontal and Vertical sync signal to adapt the DAC to the proper mode. For example, while the user tries to copy new mode 13 to mode 15, and the mode display 13 (15) is flashing, if the PC sends out a signal for mode 3, the program will change the DAC output to adjust the monitor to work in mode 3, but the mode display is still flashing on user mode 13 (15) and the store procedure is still going on until the user presses the Reload key again, or terminates the copy procedure after the 2 minutes time out. The mode display then shows 3.

NOTE: Upon request, we can also program in advance those 10 user-defined modes that can still be changed by the user if necessary for further extension.

For Configuration 5 to Configuration 8, see Figure 3.

To adjust functions, the user can simply press the corresponding push button. The upper push button will increase the DAC output. The lower push button will decrease the DAC output. (A total of 64 steps can be programmed in advance.)

SOFTWARE FLOW CHART DESCRIPTION

(See Figures 5 through 7)

When power is on, software initializes the hardware first. The microcontroller waits 100µs for the settlement of the hardware, then initializes itself by specifying stack, setting timer, clearing RAM, arranging interrupt, . . . , etc.

SU00426

Table 1.

	ADD DIODE	REMOVE DIODE
D1	Indirect ratio of VCO output (JP4)—See Figure 8.	Direct ratio of VCO output (JP4)—See Figure 8.
D2	10 user modes 10 factory modes (JP5)	1 user mode 19 factory modes (JP5)
D3	4 adjustable functions (JP6)	5 adjustable functions (JP6)
D4	Multiple Up/Down keys (JP7)	Single Up/Down keys (JP7)

Referring to previous section, *Function Selection and Change*, software can detect the hardware configuration by pulling 87C751 microcontroller pin P0.2 LOW to read the diode arrangement. Each diode denotes one change in the hardware configuration. Table 1 explains the usage of each diode.

After the configuration detection, then it goes to check EEPROM status. If the EEPROM is blank, the program will start to move all factory set data from the microcontroller's PROM to EEPROM. The last byte datum in the microcontroller's PROM is 66 used for blank check. First it reads address DD in the EEPROM, then compares it with 66. If they are equal, the software will skip the EEPROM

program procedure. If they are not equal, the software will program the EEPROM. This means that monitor makers can define their own factory modes by programming the EEPROM in advance.

The following programs are endless loops. Please refer to the main flow chart (Figure 5). There are three tasks in the endless loop.

The first task is Function Selection, basically a keyboard process program.

The second task is Mode Detection, which includes search mode and change mode.

The third task is Mode and Function Display, which includes flash mode display.

(BCM) 87C751

Specification for a bus-controlled monitor

AN442

Mode Detection

Beginning with branch "B", Mode Detection Flow Chart (Figure 7), the block at the top of the flow chart is "Read Previous Mode" (the time before 0.5 second ago) and includes Horizontal Sync Frequency, Vertical Sync Frequency, Horizontal Sync Polarity, and Vertical Sync Polarity. The second block is a comparison test block. When current mode (from 0.5 second ago until now) parameters are the same as those in previous mode, the program will branch to the right test block. Since the mode is not changed, the second test block in the right part of the flow chart will branch to leave the Mode Detection section.

If the current mode (from 0.5 second ago until now) parameters are not the same as the previous mode (the time before 0.5 second ago), the first test block from the top of the flow chart will branch to search all mode parameters in the EEPROM to find out what the current mode should be. The left loop of the flow chart checks for the end of the search procedure, i.e., if all modes in the EEPROM are searched and checked, and

the outcome is the same, then this test block will branch to set up a new user mode (19), as per the 4 steps indicated in the central flow chart line.

The first step in setting up a new user mode is to "Put New Parameters" (such as Horizontal Sync Frequency, Vertical Sync Frequency, Horizontal Sync Polarity, and Vertical Sync Polarity) into the EEPROM. The new mode parameters are always saved in the last mode address. If the configuration allowing 10 user modes is selected, then diode 2 is added. If one was found to be the same, the program will branch to the right test block. If it then finds that there is a mode change, it will branch to Reload Mode Data to DAC to complete the mode change procedure.

When the mode change procedure is completed, the monitor will be working in a new mode. Since the program enters the Mode Detection task every 0.5 second, it takes from 0.5 to 1.0 second to finish the change of mode. To save the new user mode (mode 19) to other user mode (10-18), the

user can use the RELOAD key to save the new user mode to other user mode (modes 10 through 18).

If the configuration for 10 user modes is selected, it is highly recommended that you save new user mode to other user mode (10-18) because the last mode "mode 19", will be overwritten by any new user mode whenever a new user mode is detected, after new user mode parameters are detected.

The second step in setting up a new user mode is "Calculating VCO Output Value" (see Figure 8). There are two different curves for the designer to select. If diode 1 is removed, the VCO Output Voltage will be in direct ratio to the Horizontal Sync Frequency. If diode 1 is added, the VCO Output Voltage will have an indirect ratio.

The third step in setting up a new user mode is "Put VCO Value to EEPROM".

The last step is "Reload Mode Data to DAC". After reloading the DAC, the monitor is changed to the new user mode.

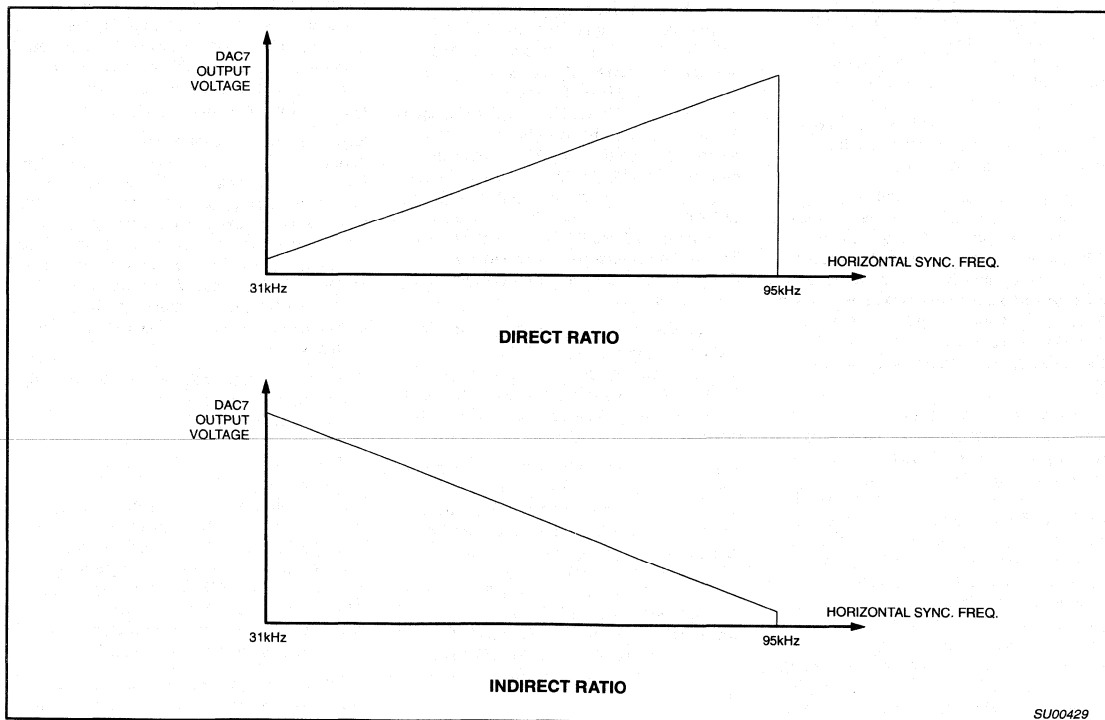

Figure 8. Horizontal VCO Output

(BCM) 87C751

Specification for a bus-controlled monitor

AN442

Key Function Selection

The first task is Function Selection (see Figure 6). When the program scans the keyboard, it first checks for the function key. If it is depressed, the program will branch right to change function VALUE(+1). the function LEDs are lit in sequence, i.e., when the second LED is lighting and the program detects a press in function key, the program will light the third LED and turn off the second LED. If the program detects that the last LED is lighting, it will turn on the first LED and turn off the last LED.

If the key pressed by the user is not a function key, the program will check if it is the reload key. If it is not, then the second test block will branch left to check Up/Down keys. both the Up and Down keys have two different definitions. When the user is updating function contents, Up and Down keys are used to change the function contents stored in the EEPROM. In that situation, the flash flag is not set; after the program branch left from the reload key test block, the program will test flash flag, then the program will change the output of DAC.

If a flash flag is set (see next paragraph, also), Up and Down keys will change the flashing mode displayed on two seven-segment LED displays. The flashing mode is valid between 10 and 19. The Up key will add one to the flashing mode unless the flashing mode is already 19, while the Down key will subtract one unless the flashing mode is already 10.

If the reload key is pressed while the program is in last mode (19), i.e., a new mode which is not the same as any mode entered in the EEPROM, the program will check to see if this is the first press. If this is the first press, the fourth test block in the middle will branch right to set the flash flag, after the flash flag is set, the mode displayed on the two seven-segment LED displays will start to flash.

Between the first press of the reload key and the second press of the reload key, the Up and Down keys can be used to change the flashing mode to a destination mode. When the program detects the second press of the reload key, the program will execute all the center blocks in the flow chart. First, starting to clear the flash flag; second, to get last mode data from EEPROM; and third, to put the mode data into a new address. The destination is decided by the user via Up and Down keys to select flashing mode, then pressing the reload key to make the flashing mode be a still mode. After mode display is still, the user finishes defining the destination user mode. This destination user mode will last forever unless the reload key is used to redefine it.

If the user presses the reload key, and the program is not in the last mode, it will branch right to reset mode data in EEPROM, starts to read original mode data in microcontroller's PROM, then puts these data to EEPROM, the outputs to DAC. This function is to help the user to restore the monitor when the monitor display is out of control. For example, if the user adjusts the Horizontal phase too broad, then monitor may become out of sync. As a consequence the screen will be a mess, and it is not easy for the user to re-adjust for correction. This feature will minimize possible complaints from customers.

CIRCUIT DESCRIPTION

U1-87C751 is an 8-bit microcontroller and the heart of the Bus-Controlled Monitor. The 87C751 receives Vertical Sync and Horizontal Sync signals from pins P1.5 and P1.6. The R3,C5 in pin P1.5 is a low pass protection circuit. It can prevent the Vertical Sync signals, including Horizontal Sync Pulse, from interfering with the counting of the Vertical Sync Frequency. The R2 in pin P1.6 is only used for protection of 87C751.

The 87C751 automatically checks the mode parameters from these two pins, then switches the DAC from the old mode to a new mode. When 87C751 is checking the mode, it reads different mode parameters from the EEPROM via I²C bus, then decides whether there has been a change in mode. If a change is needed, the 87C751 will first mute video by sending a LOW to pin P0.2, then reads the correct mode data from the EEPROM via the I²C bus. It then puts the data to the DAC via I²C bus. Because of the I²C bus, the connections between the EEPROM, DAC, and the microcontroller are very simple.

The system clock is provided by a 12MHz crystal connected to Pins 10, 11 of the 87C751. Basically, port1 is used for input, but P1.4 and P1.7 are used for output. P1.0 to P1.3 are used for keyboard and configuration input.

Port0 has only three pins; P0.0 and P0.1 are used for I²C control. P0.2 is an output pin used to test configurations. Port3 is basically used for output; P3.0 to P3.4 are used for mode seven-segment LED display output; P3.5 to P3.7 are used for function display. Both mode display and function display need extra decoders, an HEF4511B seven-segment display driver is used to display the mode, while an HEF4556B dual 2-to-4 decoder is used to display function LEDs.

PCF8582 is a 2k-bit EEPROM. R4,C1 constructs an external R-C time to program the EEPROM. In normal operation the

EEPROM needs 30ms to program one byte. C2 is a decoupling capacitor to stabilize the DC supply voltage for PCF8582.

TDA8444 is an octal 6-bit DAC. R7,VR5,C# constructs a reference voltage to define the DAC's maximum output voltage. In practice, the reference voltage must be below 10.5 volts, so R7 is added to prevent the reference voltage from exceeding that limit. C4 is also a decoupling capacitor to stabilize the DC supply voltage for TDA8444.

The upper half of the HEF4556 is used to provide a switch signal to select Horizontal OSC time constant capacitors. The four outputs are Active-LOW. When the Horizontal Sync Frequency (H.S.F.) falls in one of the four ranges, the corresponding output pin will go low. The four ranges are:
(H.S.F. < 35kHz),
(35kHz < H.S.F. < 40kHz),
(40kHz < H.S.F. < 50kHz),
(H.S.F. > 50kHz).

The enable input in the upper part of the HEF4556B can be used to extend the upper limit of the switch signal. The lower part of the HEF4556B is used to display function LEDs, the fifth LED is driven by an NPN transistor. When the transistor is turned on by the microcontroller, it also disables the lower part of the HEF4556B. If multiple Up/Down keys are configured, the function LEDs are replaced by five pairs of Up/Down keys.

Because the tenth digit of the mode display is either "1" or blank, the driver of the tenth digit uses only one transistor. The driver of the base digit employs an HEF4511B, it is a BCD seven-segment display driver with output Active-HIGH, so only common cathode types can be used. The factory can use one LED to replace a BCD display. When the LED is lit, the BCD display can display user mode, or factory mode. This is one way to reduce the system cost.

If multiple Up/Down keys are not configured, the keyboard has four keys:

- Function key,
- Up key
- Down key
- Reload key.

If multiple Up/Down keys are configured, there will be no function key, but five pairs of Up/Down keys and one Reload key. The multiple Up/Down keys are configured by adding a diode in JP7. If adding a diode in JP6, there will be only four functions available, i.e., there will be only four pairs of Up/Down keys or four function LEDs.

LM7805 is a power regulator IC, it changes 12V to 5V to supply the whole circuit except TDA8444, which uses a 12V power supply to provide a wider range of DAC output.

Specification for a bus-controlled monitor

AN442

There is a table to explain the usage of each pin in the JP1 socket. JP2 and JP8 are connected together, JP3 is only used for future automatic alignment (including production line) if necessary. JP4 to JP7 are used to select hardware configurations as previously mentioned.

SPECIFICATION OF THE SYSTEM

- The input signals to the system are Horizontal Sync and Vertical Sync. The system accepts standard TTL level signals, i.e., $V_{IH} > 2V$, and $V_{IL} < 0.4V$. Horizontal Sync tolerance is $\pm 0.5kHz$, and Vertical Sync tolerance is $\pm 2/-2 Hz$.
- There are eight DAC output signals. Their maximum output voltage can be preset by setting a voltage on the TDA8444's V_{MAX} pin. The voltage on the V_{MAX} pin must be below 10.5V and also below the voltage on the TDA8444's V_p pin. For other detailed output current characteristics, please refer to Philips data books IC02a, IC02b and 80C51 and Derivative Microcontrollers.
- The Horizontal switch outputs have four pins. they are standard CMOS B-type buffered outputs. They are Active-LOW, i.e., there will be only one output active at any time. If the designers wants to add ranges in higher Horizontal Sync Frequency, the designer can put extra circuits onto the demo board. For example, an OPA can be added as a comparator to detect the VCO output. If the VCO output is higher than a certain voltage (VCO's 60kHz output voltage), the OPA will be triggered and the upper half of the HEF 4556 can be disabled by the OPA via HEF4556's Pin 1, when HEF4556 is disabled, the four Horizontal switch outputs will remain HIGH, then the OPA's output can be used as another switch output.
- Total current consumption is around 25-90mA, depending on the number of LED and seven-segment displays being lit.

APPENDIX B

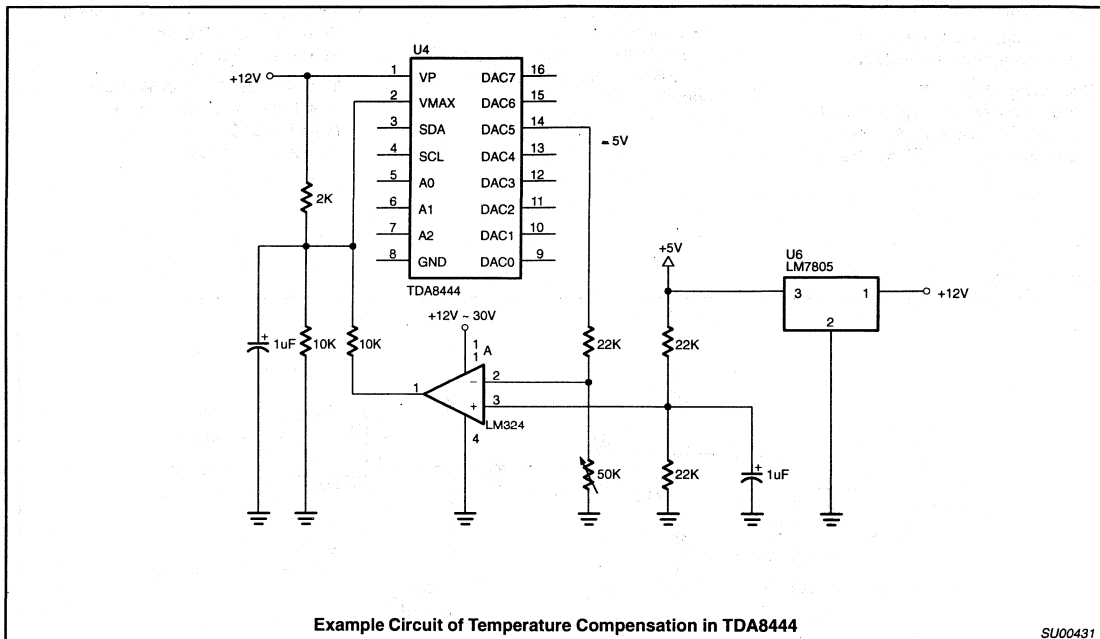

When you want to determine Vtrig signal, please disconnect Pulse Signal Generator (P.S.G.) Output to H. Sync demoboard from monitor and connect, and use input, set P.S.G. to 60kHz, TTL level output, then power on the demoboard, the mode display should display "19", the the voltage in DAC H-V output pin is the trigger level voltage of 60kHz.

You can set P.S.G to 70kHz to measure trigger level voltage of 70kHz.

APPENDIX C

All VRs in this application note can be charged to fix resistors, when proper dividing voltage is determined.

A software duplex UART for the 751/752

AN446

Author: Greg Goodhue

The following program contains routines that will allow an 8xC751 or 8xC752 to implement a software UART that can send and receive serial data simultaneously. Other published software UARTs only allow either transmit or receive to occur at any one time. The demo application shown in the code listing waits for data to be received, then echoes it and follows this with a hexadecimal interpretation of the data plus a space. For instance, if the program receives the character "\$", it echoes back the string "\$24". The reason for echoing these additional characters is to make it easy to force the receiver buffer to fill up in order to test the handshaking. If the program simply echoed what was received, it would likely never use more than the very first receiver buffer location since it can normally transmit just as fast as it can receive.

CHIP RESOURCES

The UART routines use about 400 bytes of code space and use the timer to provide a constant time interrupt to synchronize both transmit and receive operations. The hardware connections require four device pins to accomplish serial I/O with RTS/CTS handshaking. Only two pins would be needed if handshaking is not required. Three of the four pin functions may be assigned to any port pin. The serial input pin must be assigned as one of the external interrupt pins. Another two pins are used in the demo application to input a selection of one of four baud rates (1200, 2400, 4800, or 9600).

LIMITATIONS

To obtain duplex operation, a fairly large portion of the chip's time is used. The routines were tested up to 9600 baud running on a 16 MHz 87C751. When serial input and output were both occurring at the same time, the routines could not support continuous operation with no pauses between characters. At 4800 baud, full speed light reception and transmission worked flawlessly. In other words, 4800 baud should work with all applications, while 9600 baud may not work with all applications.

THEORY OF OPERATION

There are three possible sequences of events when serial transmit and receive may both be operating at once: transmit and receive begin simultaneously; transmit is requested while the receiver is busy; and receive starts while the transmitter is busy. The first 2 cases could be handled fairly simply with only one interrupt for each bit time. In the first case, everything is already in synch and only one timer and one interrupt per bit is needed to do both operations. In the second case (transmit is requested while the receiver is busy) the program could just wait for the next bit time to start transmitting. Unfortunately, the third case presents a problem. If the program is already transmitting, it cannot always wait for the next bit time to start sampling the serial data if the application is not to lose bits. Also, the timer cannot be adjusted to the incoming data since this would distort the duration of one of the transmitted bits.

The method used here to deal with this problem is to always divide all bit times into 4 sub-bit times. When transmission and/or reception is in progress, the timer runs at 4X the bit rate for the selected baud rate. The variables TxTime and RxTime are used to count sub-bit times for the transmitter and the receiver, respectively. Both are initialized to a negative value and count up to simplify testing for an active sub-bit time. The maximum baud rate that can be supported is essentially determined by the maximum amount of time that it might take the microcontroller to do all of the operations associated

with transmitting one bit and receiving one bit. This must be done within the time between timer interrupts.

When both transmit and receive operations are scheduled for the same timer interrupt, priority is given to the transmitter routine. The reason for this is that a great deal of jitter can be tolerated in the timing of the received bit sampling, but the transmitted data must "look" good to the outside world.

The actual bit times for transmit and receive are counted by the variables TxCnt and RxCnt, respectively. When an active sub-bit time slice occurs, these variables tell the transmit and receive routines what to do in the current time slice. The value 11 hex indicates a start bit, 10 hex indicates a stop bit, and the values 8 through F hex indicate a data bit. The values were chosen to allow quick determination of the appropriate action by the code.

The routines provide for a small amount of data buffering for both the transmitter and the receiver. As implemented here, the transmitter buffer is only one byte deep, allowing one data byte to be held while another is being transmitted. The receiver buffer is larger, allowing three bytes to be held while a fourth is being received. If the receiver buffer fills up (indicated by the flag RxFull), the application code must retrieve one byte before a fourth one finishes, or data will be lost. If this happens, a flag will be set (OverrunErr) to indicate that the receiver buffer has been overrun. There is no similar flag for the transmitter, since the transmit request routine waits for the transmitter buffer to be available (indicated by the TxFull flag) before taking action. It is up to the application code to check this flag in advance if it does not want to stall execution while waiting to transmit data.

As each routine finishes a whole data byte by completing the send or receive of a stop bit, it checks to see if there is something still happening to warrant having the time slice interrupt running. In the case of a received stop, the transmit activity flag (TxOn) is examined. If it is not set, the timer is turned off. The timer will be turned back on if an interrupt from a serial start bit is received or the main code requests data to be transmitted. In the case of a transmitted stop, both the receiver activity flag (RxOn) and the transmit buffer flag (TxFull) are examined. If the receiver is active or there is more data to transmit, the timer is left running.

All of the status flags are in the "Flags" register. Other status flags found there are: RxAvail, which indicates that the receiver buffer contains unprocessed data; and FramingErr which is set when the receiver routines find an improper start or stop bit, usually caused by mismatched baud rates.

Flow control handshaking is provided by the RTS/CTS scheme. The transmit routine looks at the incoming CTS line before beginning each start bit transmission, and simply exits, waiting for the next time slice, if CTS is not asserted. The receive routine checks the buffer status whenever a start bit interrupt occurs and de-asserts the outgoing RTS line if the buffer already contains two bytes (i.e., it will be full when the current byte finishes). If the device at the other end of the communication line follows the same rules (which may very well NOT be the case) the program should be able to communicate without buffer overflows in either direction.

Baud rates in both the send and receive routines are determined by two things: the timer interrupt rate; and the number of time slices per bit. The method of calculating the timer value for various baud rates is discussed in the code listing at the BaudRate routine. This discussion has centered on there being four time slices per bit, but if the user wants, either the transmitter or the receiver can be set to run at a baud rate that is a multiple of the other by adjusting the value of the constant TxBitLen or RxBitLen. The baud rate would be

A software duplex UART for the 751/752

AN446

calculated as indicated for the faster channel, and TxBitLen or RxBitLen would be changed for the slower channel. For example, the transmitter can be set to run at half of the receiver baud rate by setting TxBitLen to $-8 + 1$.

The routines shown also make provision for changing the baud rate "on the fly", although the application code given does not implement this feature. If the application code changes the baud rate for some reason, the change will be effected when the next data transmission or reception begins, if both the transmitter and receiver were already idle. This prevents the timer value from being changed in the middle of a data byte.

THE CODE

There are a number routines in the code of which the user should be aware:

- Intr0
Called (by interrupt) when a serial start bit is received.
- Timer0
Called (by interrupt) for every sub-bit time slice.
- RS232TX
Called by Timer0 when the transmitter has business to conduct in the current time slice.
- RS232RX
Called by Timer0 when the receiver has business to conduct in the current time slice.
- BaudRate
Sets the baud rate variables BaudHigh and BaudLow based on the accumulator value.
- TxSend
Called by the application code to request that a data byte be transmitted. The data to be transmitted is in the accumulator.
- GetRx
Called by the application code to request return of a received data byte from the buffer. Data is returned in the accumulator. This routine should not be called unless the receiver buffer has data available.
- Reset
Start of the initialization code to set up the UART.
- MainLoop
Start of the mainline code of the demo application.

Using the 87C751 microcontroller to gang program PCF8582/PCF8581 EEPROMs

AN453

Author: David Chen, Shanghai Philips Technology Applications Lab

SUMMARY

This Application Note describes how to use the 87C751 microcontroller to implement a gang programmer for the Philips PCF8582 and PCF8581 I²C EEPROMs. Included are software, schematic, and PCB layout to allow copying from one 16-pin source EEPROM into ten slave EEPROMs. When the process is completed, a green LED turns on and a small buzzer sounds. A red LED by each slave socket indicates a failed IC.

The PCF8582 is a 256x8 CMOS EEPROM with I²C interface. It comes in a variety of 8- and 16-pin plastic packages. This particular layout uses the 16-pin Dual In-Line package. The PCF8581 is a 128x8 CMOS EEPROM.

This Gang Programmer was designed to program default set-up parameters into Philips Television sets which use I²C EEPROMs. The design is being presented here, not just to show how to make an I²C interfaced programmer, but to also serve as an example of using the 87C751 I²C interface.

The programmer reads data from a source EEPROM and copies the data into ten slave EEPROMs. It can also compare the data between the master and the target. There are just two push buttons on the unit, Copy and Reset. Reset goes directly to the Reset pin on the '751, and shorts out the power-on reset capacitor. Copy is connected to INT0, and gets the micro's attention so that the copy process can start.

The programmer is powered from a wall mount, 9V @ 300mA supply. A 5V regulator is on the board. A yellow LED is used to indicate that power has been applied to the board. A green and a pink LED indicate the status of the programming operation, and there is a red LED at each socket to indicate a failure in the programming process to that IC. If everything goes well, the green LED will signal the successful completion of the programming process and a buzzer will also sound. The pink LED will come on if there are any errors in any EEPROM, and the appropriate red LED will indicate the faulty IC. If the pink LED is on and none of the red LEDs are on, there has been an error in the I²C communication link.

OPERATION

Since the PCF8582 only has three Chip Select lines, and there are eleven parts in the system, a different addressing scheme had to be devised. In this system, A0 and A1 have four possible combinations of addresses. A2 is then used as a bank select which is driven by P1.2, P1.3 and P1.4 on the '751. The 10 red LEDs and the pink and green LEDs are multiplexed, since there are not enough port pins left to directly drive them. Port 3 drives a 74LS244 which in turn drives the anodes of the LEDs through 100Ω resistors. The two banks for the multiplexing are driven to ground by discrete transistors which receive their base drive from P1.0 and P1.1.

Jumpers on P1.6 and P1.7 are used to select different options. Jumpering P1.6 to ground selects the PCF8581 and leaving that jumper off selects the PCF8582. If P1.7 is jumpered to ground, the programmer will only do a compare between the source and the slaves. This compare operation is done in 16-byte segments. If no jumper, then the normal programming sequence will be done.

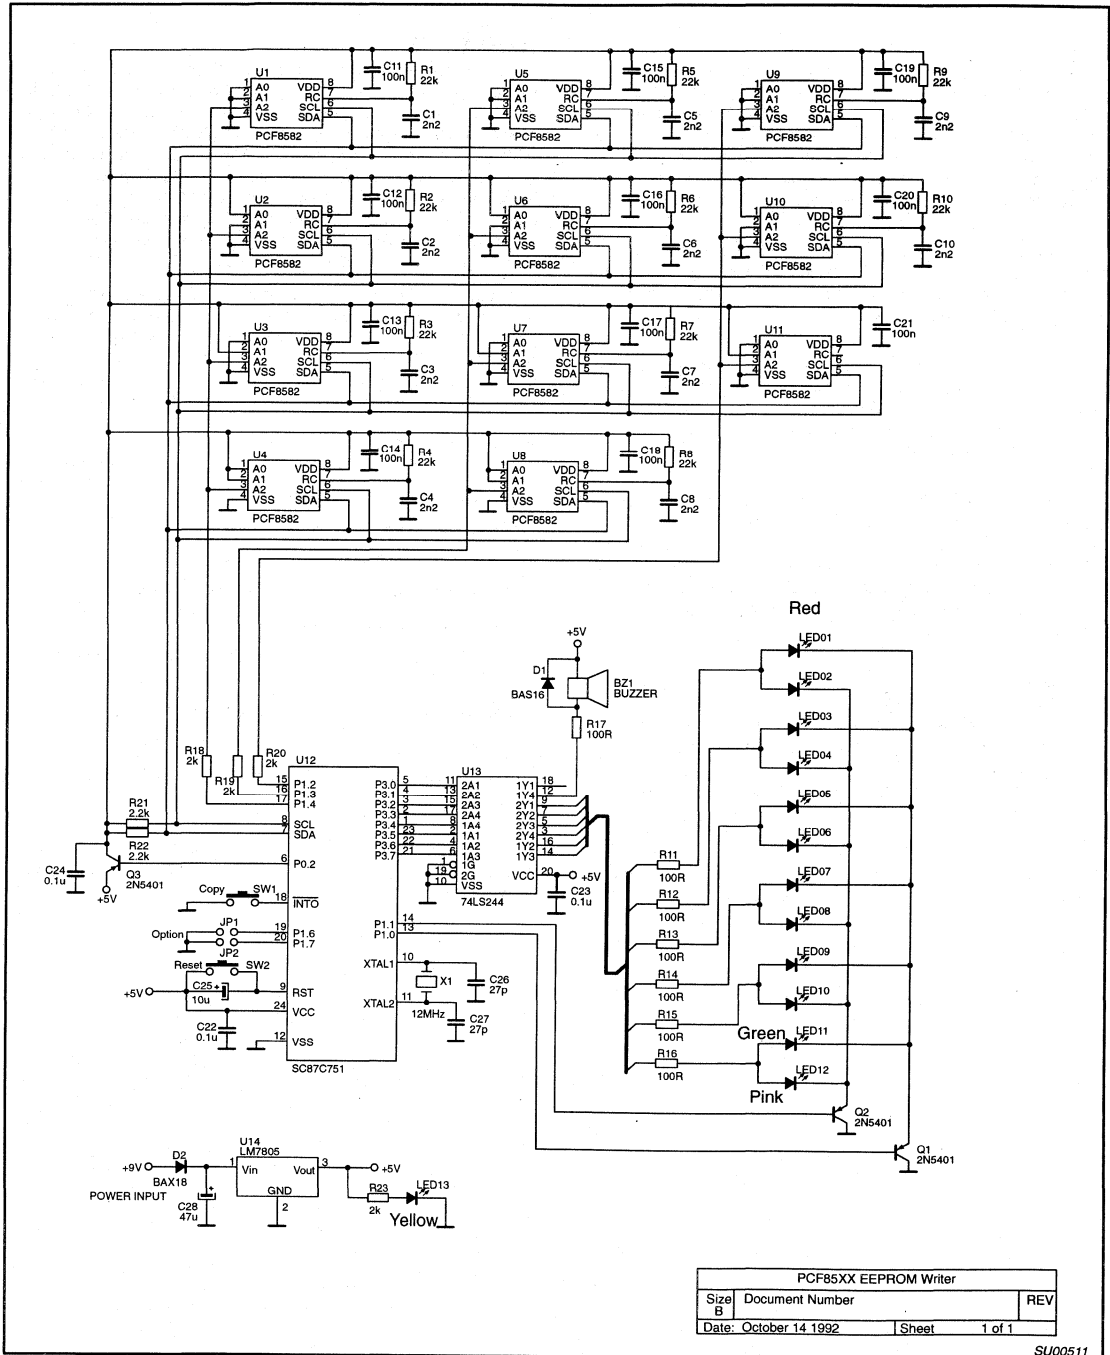

Program Flow

1. Turn on source EEPROM and initialize '751 pointers in RAM
2. Read two bytes of source data
3. Enable target EEPROM array
4. Write the 2-byte data to each of the ten targets
5. Increment subaddress and get next data from source
6. Repeat write to other targets
7. Wait 70ms to allow the information to be written internally to the EEPROM cells
8. Read each target to verify that correct write was done
9. Repeat the 2-byte write and read cycles until done
10. Disable EEPROM power and turn on the green LED and beep
11. Wait for next input

The '751 keeps track of any problems with the programming process, and it skips the verify and subsequent programming of bad or missing targets.

Interfacing the 83C576/87C576 to the ISA bus

AN454

INTRODUCTION

The most interesting feature of the Philips 83C576, and the principal subject of this application note is its Universal Peripheral Interface (UPI). The UPI is a microprocessor slave interface which allows the '576 to communicate with a microprocessor or microcontroller host with minimal support logic. The UPI acts as a "bus gasket" between the 8051 core inside the '576 and the host. Commands and Data can easily be exchanged over this interface. Along with the hardware interface, a simple, effective bidirectional software protocol can be implemented for reliable data transfer. Each device can pace the exchange of data using a double bi-directional data register implemented as part of the UPI inside the '576. As part of the UPI definition, hardware flow control is supported so that both the host and 8051 core can each establish whether the other has written or read any data to the UPI. This flow control scheme is the heart of a synchronous interface that is independent of the performance of the host or 8051 core.

The UPI is ideal for the PC environment and provides an almost seamless interface to the PC host via the ISA bus. This application note demonstrates in both hardware and software terms how to interface the '576 to a PC host. The UPI interface occupies two locations in the memory or IO space of each device. The first location is the Data register and the second is the Status register. The Data register is simply a pair of registers one directed to the host and the other directed to the 8051 core. This allows both the host and 8051 core to write to the data register simultaneously without effecting each-others data. The write cycle events are recorded as 'buffer flags' (IBF and OBE) in the Status register. One further unique feature of this interface is the concept of 'Commands and Data' in that any data written to the Status register address is directed to the Data register and a flag is set in the Status register recording this cycle as a Command. This flag is known as the 'AF' flag and indicates that a write cycle has been performed on the Status register.

From a software perspective the host device is the 'master' of the UPI. Even though from a hardware sense, each device can pace the cycles, the provision of a single AF flag precludes the implementation of a multi-master protocol. This limitation, however, is not severe, in that this provides a simple scheme for exchanging data between the devices. This interface provides the mechanisms

for many protocol schemes, the most effective one is used in PCs over the keyboard interface and operates as follows:

HOST (Master)	SLAVE ('576 core)
Write a command to the Status register.	AF flag set, the byte in the data register is a Command
Poll the IBF flag in the Status register; wait for it to be 0.	Read the command.
Write the Information byte to the Data register.	AF=0, read the information byte from the Data register; Execute the Command.
Poll OBE, wait for it to be cleared in the Status register; this means that a response is available in the data register.	Write a Response byte to the data register.
Read the Response byte.	

DESCRIPTION

The purpose of this Application Note is to demonstrate the use of the '576 in a PC environment. This example shows the use of a '576 as a peripheral to the PC/AT. The example shows the implementation of a data acquisition card with digital IO and analog IO. Some software is described to show how to exchange data and commands between the PC and the '576. In this example, the PC is the host of the transfers and the '576 is the slave. An example circuit is also described which details the electrical interface to the PC/AT ISA bus.

Figure 1 shows the basic configuration of the acquisition system.

SU00519

Interfacing the 83C576/87C576 to the ISA bus

AN454

UPI DEFINITION

The Universal Peripheral Interface (UPI) functions as a microprocessor slave interface. This allows the '576 to interface directly to a microprocessor bus as a slave or peripheral device.

The UPI is an 8-bit bidirectional data register, P0, with an associated status register, UCS. The data buffer is comprised of two registers; the input register and, the output register. The input register can be written by the host and read by the '576. The output register can be written by the '576 and read by the host. The status register may be read or written by the '576 core but may only be read by the host. The Status register bits can also be affected by hardware events, for example, a host write cycle to the data register will set the IBF flag.

The host control interface for these registers is comprised of four signals, -RD, -WR, an address line A0, and a chip select -CS. Data transfer is directed to the UPI as shown below:

-CS	A0	-RD	-WR	CONDITION
0	0	0	1	Read Output Data Register
0	1	0	1	Read Status Register
0	0	1	0	Write Input Data Register, AF=0
0	1	1	0	Write Input Data Register, AF=1
1	X	X	X	Disable IO

Write cycles to the data register with A0 = 1 cause the AF flag to be set in the status register. These cycles are generally interpreted as commands. Write cycles to the data register with A0 = 0 cause the AF flag to be cleared in the status register. These cycles are usually interpreted as data.

The status register has 4 control bits and 4 user defined status bits. They are defined as follows:

UCS

7	6	5	4	3	2	1	0
ST7	ST6	ST5	ST4	UE	AF	IBF	OBE

- UCS.7 ST7 User defined status bit
- UCS.6 ST6 User defined status bit
- UCS.5 ST5 User defined status bit
- UCS.4 ST4 User defined status bit
- UCS.3 UE UPI enable bit. 0 = Disabled, 1 = Enabled.
- UCS.2 AF Address Flag – contains the state of the A0 (Address) pin on the last write cycle.

- 0 = write cycle with A0 cleared
- 1 = write cycle with A0 set
- UCS.1 IBF Input Buffer Full Flag – set by hardware on the rising edge of a write command to the Input Data Register. Cleared by hardware on the completion of a read cycle of the Input Data Register by the '576.
- UCS.0 OBE* Output Buffer Empty Flag – Cleared by hardware on the completion of a write cycle to the Output Data Register by the '576. Set by hardware on the rising edge of the read command of the Output Data Register by the host.

* NOTE: This flag is OBE when read by the MCU, but is inverted or OBF (Output Buffer Full) when read by an external host.

General Handshaking Protocol

Host write cycles with A0 set are directed to the Input Data Register. The '576 can distinguish the cycles by monitoring the AF flag (Address Flag) in the status register.

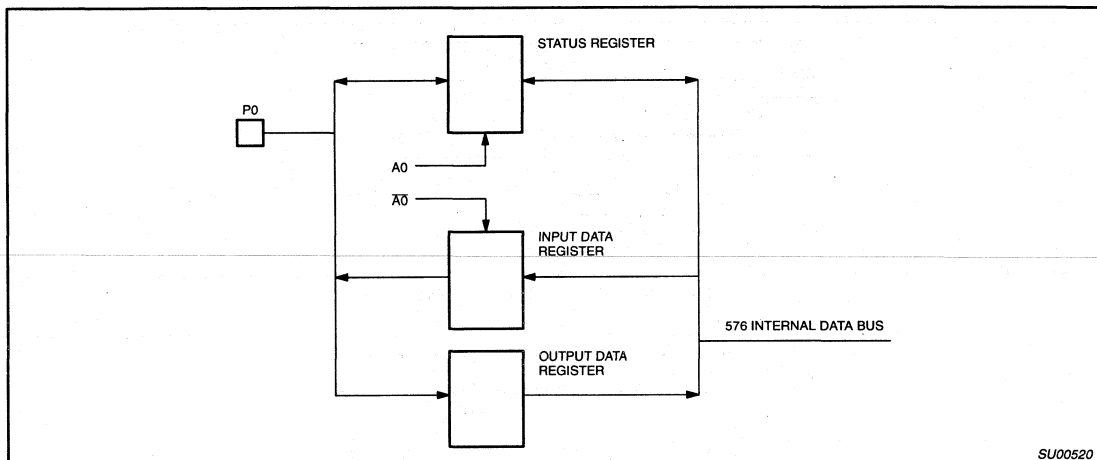

Figure 2. Internal Structure of the UPI Registers

Interfacing the 83C576/87C576 to the ISA bus

AN454

ISA BUS INTERFACE

The data acquisition system is comprised of the '576 microcontroller and an address decoder. The '576 provides an almost seamless interface to the PC/AT IO channel. The interface to the PC is known as the ISA (Industry Standard Architecture) bus. This bus is an asynchronous, command driven bus. Most notebook and PDA chipsets provide programmable or fixed address decoders assigned to an output pin. This pin is used to control the $\overline{\text{CS}}$ input of the '576 thus providing a completely seamless interface to the ISA bus.

Address Path

In this application the '576 is interfaced as an IO device. The IO space on a PC is 0 to 03FFH (1Kbytes), therefore SA0 to SA9 must be decoded to locate the '576 in a single region. SA0, however, is used to select between the Data and Status registers, thus the '576 occupies two locations in IO space. For the acquisition card we selected 0300H for the Data register and 0301H for the Status register. 300H and 301H have been chosen because they are assigned to a "prototyping area" in the PC ISA IO space map. The address decoder must reject the address during DMA cycles. For this purpose, AEN is used in the decoder and qualified for its low, inactive state (AEN, when active indicates that the current cycle is a DMA cycle). Output Y0 of U2 is asserted (low) when SA5 to SA7 are low, SA8 is high and AEN is low. U3 further decodes the address and output Y0 is asserted (low) when Y0 of U2 is low together with SA1 to SA4 low and SA9 high. Output Y0 of U3 is fed to the $\overline{\text{CS}}$ input of the '576, it is asserted (low) when the address is 300H with AEN low or 301H with AEN low.

Data Path

The '576 interfaces to the least significant 8 bits of the data bus, SD0 to SD7. When the '576 is configured in UPI mode, PORT0 is configured as push-pull outputs for host read cycles. ISA requires 24mA I_{OL} for this interface. The '576 can only handle 15mA. The 24mA requirement goes back to the XT-TTL days and with current CMOS motherboards 12mA is probably sufficient with a fully loaded system.

Interrupt

An interrupt is employed to completely demonstrate the integration of the '576 to the PC. The first free interrupt is IRQ10. For this reason alone, we need to connect to the extended AT ISA slot where this interrupt line is available. Interrupts on PCs are edge sensitive, sometimes shared and are usually pulled-up on the motherboard just to make life more complicated. If we want to generate an interrupt, port pin P2.3 must be driven low then high. The 8259 interrupt controller in the PC will see the interrupt on the rising edge. Once the host acknowledges the interrupt by say, reading the Data register (detected by the assertion of OBE) the '576 must drive P2.3 high, returning IRQ10 to a high impedance state.

Timing

Another aspect of the design is to consider the timing implications of the UPI. The diagrams below show the relationships of the control, address and data signals.

SYMBOL	PARAMETER	LIMITS
t_{AS}	Address Setup time	21ns MIN
t_{PW}	Command pulse width	600ns MIN (assumes 8.33MHz bus)
t_{DS}	Data setup time	15ns MIN
t_{DH}	Data hold time	15ns MIN
t_{CR}	Cycle recovery time	55ns MIN

The address setup time is lengthened by the two 3 to 8 line decoders, U2 and U3. The ISA worst case is 9ns, we are adding 2 further delays of 6ns giving 21ns of address setup. If the ISA bus is clocked at a higher rate as in some PDAs and some notebooks, the Command pulse width will be shortened. The ISA bus can be clocked as high as 11.1MHz, yielding a minimum command pulse width of 450ns.

Figure 3. ISA Cycle IO Read Timing

Figure 4. ISA Cycle IO Write Timing

Interfacing the 83C576/87C576 to the ISA bus

AN454

SOFTWARE

The example below shows a typical protocol employed here to exchange data between the PC and the '576.

The protocol that we are employing is only a subset of what can be achieved with this Command / Data, two byte protocol. To complete a transaction, the PC sends two bytes, a Command and Information byte, then the '576 returns two bytes; a response and information byte. Sometimes the information bytes will be meaningless; that's okay, as long as we stick to the protocol.

COMMANDS

	Command	Information	
01H	Get Analog Channel	Channel	[0, 1, 2, 3]
02H	Get Digital Byte	NULL	
03H	Put Digital Byte	Data Byte	
04H	Increase PWM	Channel	[0, 1]

RESPONSES

	Response	Information
01H	Get Analog Channel Complete	M.S. 8 bits of ADC conversion
02H	Get Digital Byte Complete	Data Byte
03H	Put Digital Byte Complete	NULL
04H	Increase PWM Complete	NULL

DRIVERS

PC Driver

The PC must write a command. This is done by making an IO cycle to port 0301H. This sets the AF flag in the status register and causes an IBF interrupt in the '576. The PC can poll the status register to see when the IBF flag has cleared, this means that the '576 has read the Command in the Input Data Register. The PC then sends the Information byte; this is done in the same way except that the cycle is made to 300H.

'576 Driver

Communication from the '576 to the PC is established by driving the interrupt request line, IRQ10, high. The PC first reads the status register to check if the interrupt was from the '576 instead of some other external device. If the OBF flag is set, the PC knows that the data in the Output Data Register is valid. The PC then reads to Output Data Register which causes the OBF flag to become cleared. Once the '576 detects this read cycle, the interrupt line, P2.3, can be returned to its low state. The AF bit in the Status register indicates whether the data is a Response byte to a previous command (AF set) or an associated Information byte (AF cleared).

Interfacing the 83C576/87C576 to the ISA bus

unsigned char interrupt_received = 0;

/* declare a variable to store the pointer of the current interrupt service routine */
void (_interrupt _far *old_int)();

/*Module put_byte().

put_byte() has two parameters; the address of the IO port (port) and the value to be written to the IO
port (data). A dummy variable is declared for lint purposes, since the C function outp() returns an
unsigned short. First put_byte() uses the C outp() function to write the byte to the IO port then,
put_byte() monitors the IBF flag in the status register to see if the '576 has read the byte. When the PC
writes the byte to the input register, the '576 automatically sets the IBF flag. When the '576 core reads
the input register, the IBF flag is automatically cleared. The while() loop breaks when the IBF is 0. The
C function inp() is used to read the status register, the returned value is logically ANDed with the
constant IBF (0x02) and the result is complemented and evaluated by the while() statement. */

void
put_byte (
    unsigned short port,
    unsigned char data) {

    unsigned short dummy;

    dummy = outp(port, UPI_DATA_REG);    // send the byte
    while (~((inp(UPI_STATUS_REG) && IBF))); // check to see if '576 has read it
}

```

Interfacing the 83C576/87C576 to the ISA bus

AN454

```
/*Module get_byte()
```

get_byte() has 1 parameter and 1 return value. The parameter is used to pass the address of the IO port to read. The return value is used to pass back the contents of the read port as a byte. get_byte first waits for the byte to be written to the UPI port by the '576. This is achieved by monitoring the OBE flag in the status register. The C function inp() is used to read the contents of the status register. The returned word is masked (ANDed) with the constant OBF (0x01) and the negated result is evaluated by the while() statement. If the IBF flag is 0, the while loop continues to read and evaluate the status register, if the IBF flag is set the while loop breaks. When the while loop breaks, there must be something to read in the output data register, the C function inp() is used to read the input data register whose address is past in the variable 'port'. The result is cast as a byte and returned to the calling routine. */

```
unsigned char
get_byte (
```

```
    unsigned short port) {
```

```
    while (!(inp(UPI_STATUS_REG) && OBF));           // wait for the byte
    return ((byte)inp(port));
```

```
/*Module send_command()
```

send_command assembles a two byte message comprising of a command byte followed by an information byte. If we direct the first byte to the address of the status register, it will appear in the output data register and the AF flag will automatically be set. The '576 will read the status register before the data register, the set AF flag will tag the data as a command. The information byte is directly written to the output data register, thus the AF flag will be cleared and the '576 will interpret the byte as information. */

```
void
```

```
send_command (
```

```
    unsigned char command,
    unsigned char information ) {
```

```
    put_byte(UPI_STATUS_REG,command);
    put_byte(UPI_DATA_REG,information);
```

```
/* Module get_response()
```

This module has no parameters and 1 return value. get_response strips out the information byte from a two-byte message from the '576. The first byte is always the echoed command and is discarded by assigning it to a dummy variable. The send byte is always the information and is read using the get_byte() function and returned to the calling function. */

```
unsigned char
```

```
get_response (
```

```
    void ) {
```

```
    unsigned char dummy;
```

```
    dummy = get_byte(UPI_DATA_REG);           // get the response
    return(get_byte(UPI_DATA_REG));          // return the info byte
```

Interfacing the 83C576/87C576 to the ISA bus

AN454

```
/* Module EnableIRQ10()
```

This module enables the hardware interrupt, IRQ10 via the 8259 programmable interrupt controller (PIC) inside the PC. IRQ 10 is a cascaded interrupt driven by a second PIC attached to IRQ2 of the first. Therefore both PICs need to be unmasked. The C function disable() issues a CLI instruction to the processor disabling interrupts. The current value of the interrupt mask for PICA is read and ANDed with the mask cleared for IRQ2. The current value of the interrupt mask for PICB is read and ANDed with the mask cleared for IRQ10. The new masks are written to the PICs consecutively. Interrupts are re-enabled using the C function enable() which issues an STI instruction to the processor. */

```
void
EnableIRQ10 (void) {

    unsigned short mask;

    _disable();
    mask = _inp(P8259A_IMR);
    mask &= ENABLE_IRQ2
    _outp (P8259A_IMR,mask);

80C451 operation of port 6

AN408

INTRODUCTION

The features of the 80C451 are shared with the 80C51 or are conventional except for the operation of port 6. The flexibility of this port facilitates high-speed parallel data communications. This application note discusses the use of port 6 and is divided into the following sections:

1. Port 6 as a processor bus interface.
2. Using port 6 as a standard pseudo bidirectional I/O port.
3. Implementation of parallel printer ports.

This information applies to all versions of the part: 80C451, 83C451, and the 87C451.

PORT 6 AS A PROCESSOR BUS INTERFACE

Port 6 allows use of the 80C451 as an element on a microprocessor type bus. The host processor could be a general purpose MPU or the data bus of a microcontroller like the 80C451 itself. This feature allows single or multiple 80C451 controllers to be used on a bus as flexible peripheral processing elements. Applications could include keyboard scanners, serial I/O controllers, servo controllers, etc.

OPERATION

On reset, port 6 is programmed correctly for use as a bus interface (see 2). This prevents the interface from disrupting data on the bus of the host processor during power-up. Software initialization of the CSR (Control Status Register) is not required. A dummy read of port 6 may be required to clear the IBF (Input Buffer Full) flag since it could be set by turn on transients on the bus of the host processor. On reset, the CSR of the 83C451 is programmed to allow the following:

1. AFLAG is an input controlling the port select function. If AFLAG is high, the contents of the CSR is output on port 6 when the port is read by the host. If AFLAG is low, then the contents of the output latch is output when port 6 is read by the host.
2. BFLAG is an input controlling the port enable function. In this mode when BFLAG is high, the input latch and the output drivers are disabled and the flags are not affected by the IDS (Input Data Strobe) or ODS (Output Data Strobe) signals. When BFLAG is low, the port is enabled for reading and writing under the control of IDS and ODS pins.

Figure 1 shows one possible example of an 80C451 on a memory bus. This arrangement allows the main processor to query port 6 for flag status without interrupting the 80C451. If the address decoder, shown in Figure 1, enables port 6 on the 80C451 when the address is 8000H or 8001H, and the address line A0 controls the port select feature, then the host processor can read and write to port 6 using address 8000H. Since the port select function is being controlled by the address line A0, the CSR contents can be read by the host processor at address 8001H.

By testing the CSR contents in this way, the host processor can tell if new data has been written to the port 6 output latch since it last read the port or if the 80C451 has read the last byte that the host wrote to the port. Conversely, the 80C451 can poll the flags in its CSR to see if the host processor has written to or read from port 6 since the last time it serviced the port.

If desired, an interrupt source for the 80C451 can be derived easily from the port enable source as shown by the dashed line in Figure 1.

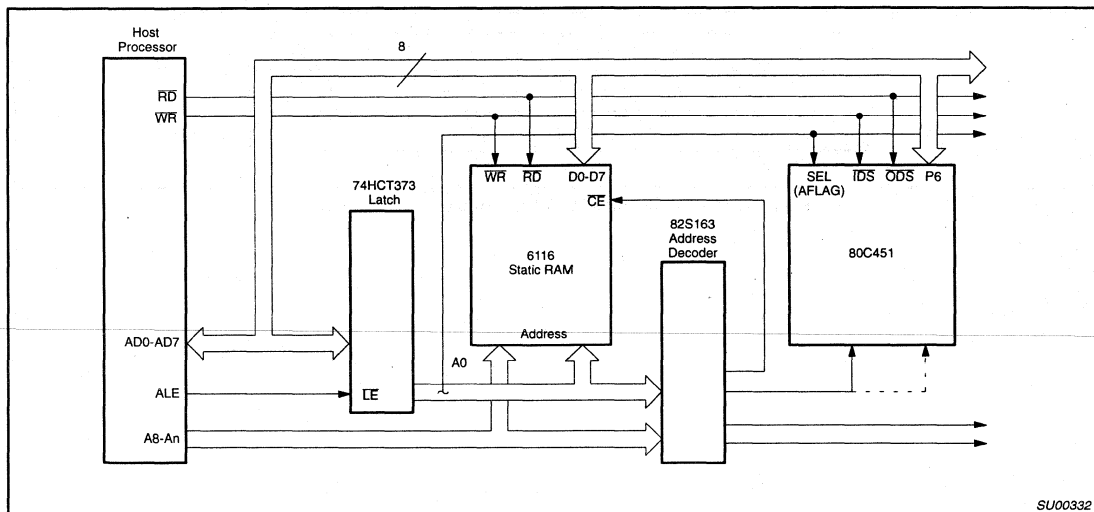

Figure 1. An 83C451 on a Microprocessor Memory Bus

80C451 operation of port 6

AN408

SOFTWARE EXAMPLES

To write to port 6 on the bus shown in Figure 1, the host processor first reads the CSR contents at address 8001H, and tests

the input buffer full flag (CSR bit 0). If the flag is clear, the host writes a byte to address 8000H. This loads the input buffer latch of port 6 and sets the input buffer full flag.

Conversely, the 80C451 polls the IBF flag and reads a byte from port 6 when it finds the flag set. The flag is automatically reset when this internal read occurs.

80C451 ROUTINE TO READ ONE BYTE FROM HOST VIA PORT 6

```

RCVR:    JNB CSR.0,RCVR    ;TEST IBF FLAG
         MOV A,P6         ;WHEN FLAG IS SET READ BYTE
         RET
    
```

80C451 ROUTINE TO WRITE ONE BYTE TO THE 83C451 PORT 6

If the host processor is an 80C51, the following routine will write a byte of data to the 80C451. The data involved is passed to the routine through register 1.

```

XMIT:    MOV DPTR,8001H
TEST:    MOVX A,@DPTR     ;READ THE CSR
         JB ACC.0,TEST    ;TEST IBF FLAG
         MOV DPTR,8000H
         MOV A,R1
         MOVX @DPTR,A     ;WRITE DATA TO THE 451
         RET
    
```

80C451 ROUTINE TO WRITE ONE BYTE TO HOST VIA PORT 6

Routines for data transfer in the opposite direction are similar to the above two. The 80C451 version is given below.

```

XMIT:    JB CSR.1,XMIT     ;TEST OBF FLAG
         MOV P6,A         ;WRITE DATA
         RET
    
```

AN408

USING PORT 6 AS A STANDARD QUASI-BIDIRECTIONAL I/O PORT

To use port 6 as a common I/O port, all of the control pins are tied to ground (see Figure 3). On hardware reset, bits 2 - 7 in the CSR are set to one. Port operation and electrical characteristics become identical to port 1 on the 80C51 and the 80C451 ports 1, 4, and 5. No software initialization is required.

If desired, AFLAG and BFLAG can be used as outputs while port 6 is operating as a standard quasi-bidirectional I/O port (see Figure 4). In this case, only IDS and ODS are tied to ground and the CSR is initialized to allow operation of AFLAG and BFLAG as simple outputs (see Figure 5).

AN408

IMPLEMENTATION OF PARALLEL PRINTER PORTS USING PORT 6

The 80C451 is an excellent choice for a printer controller. The 80C451 has the facilities to permit all of the intelligent features of a common printer to be handled by a single chip:

1. The features of port 6 allow a parallel printer port to be designed with only line driving and receiving chips required as additional hardware.
2. The onboard UART allows RS232 interfacing with only level shifting chips added.
3. The 8-bit parallel ports 0 to 6 are ample to drive onboard control functions, even when ports are used for external memory access, interrupts, and other functions.
4. The RAM addressing ability of ports 0 and 2 can be used to address up to 64k bytes of a hardware buffer/spooler. AFLAG and BFLAG as simple outputs (see Figure 5).
5. The 64k byte ROM addressing capability allows space for the most sophisticated software.

In addition, either end of a parallel interface can be implemented using port 6, and the interfaces can be interrupt driven or polled in either case.

THE INTERFACE

Data transfer on a parallel printer interface occurs across eleven signal lines. The other conductors on the standard plug are used as ground returns or for auxiliary functions (see Figure 6). Only the data transfer signals will be considered.

The Data Transfer Format

The parallel printer interfaces are far more standardized in features than their serial

counterpart. However, at least three significant variations exist in handshake style in printers using generic parallel interfaces. This fact influences the design of both port hardware and software. A good transmitter should be able to drive devices with all three styles of handshakes, and a good receiver should generate the handshake most likely compatible with any transmitter.

The Variations

Type 1—Figure 7 shows a common style of handshake and is the style that will be implemented in the receiver examples. A busy signal and an acknowledge strobe pulse are generated for every byte received.

Type 2—Another style of handshake generates a busy signal only when the printer will not be able to accept more data for a relatively long time. Acknowledge pulses are created after every byte received. When the busy signal is generated after a byte is received, the associated acknowledge pulse does not occur until *after* the busy signal returns to logic zero (see Figure 7).

Type 3—A third handshake style does not generate acknowledge pulses, but a busy signal is produced after every byte is received.

PARALLEL PRINTER INTERFACES USING POLLING

Transmitter Operation

This application illustrates the flexibility of the port 6 logic in solving an applications problem. We need to be able to handle all types of acknowledge signals that might be received by the transmitter. We will use the ODS pin and output buffer full flag logic to record the receipt of the acknowledge pulse (see Figure 8), but not all parallel receivers generate acknowledge pulses. We could poll

the busy signal line, but not all receivers generate busy signals for each byte received; so lack of a busy signal does not imply that we can send another byte. We can, however, expect an acknowledge pulse very shortly after the end of a busy signal if one is going to arrive at all. So we can send a new data byte after having received either a positive transition on the acknowledge line, or shortly after receiving a negative edge on the busy line.

The CSR is programmed to the output only mode. In this mode, the ODS pin does not control the output drivers but only the output buffer full flag. The flag serves to record the positive transition of the acknowledge signal. The input latch is not used, but the IDS pin is used to set the input buffer full flag. This is used to record the negative transition at the end of the busy signal. Dummy reads by the 80C451 of port 6 will be used to clear the flag. In this example, the AFLAG mode is set only to place the port in the output only mode. The AFLAG pin is not actually used (see Figure 10).

The transmitter's CSR (control status register) is programmed to the following mode (see Figure 9):

1. CSR bit 6 controls the BFLAG output and therefore the strobe line.
2. The OBF (output buffer full) flag controls the AFLAG output.
3. The OBF is cleared on the positive edge of the ODS input.
4. The IBF flag is cleared on the negative edge of the IDS strobe.

NOTE:

With this combination of modes set, port 6 is in the output only mode.

Receiver Operation

In receiver operation, the IDS input is used to latch in the data transmitted on receipt of the strobe pulse. The receiver's CSR is programmed to allow the following (see Figure 11):

1. The input buffer full flag is output through the BFLAG pin and is used as the busy signal to the transmitter.
2. The IBF flag is set and data is latched on the positive edge of IDS.
3. Writing to the CSR bit 4 controls the AFLAG output and therefore the acknowledge line.

SOFTWARE EXAMPLES

This polled parallel transmit routine outputs one byte passed to it in the accumulator.

```

P_INIT:    MOV CSR,#064H      ;INITIALIZE PORT 6 OPERATING MODE
P_OUT:    JB P5.0            ;WAIT IF BUSY SIGNAL IS HIGH
          MOV P6,ACC        ;OUTPUT DATA
          MOV R1,P6         ;DUMMY READ TO CLEAR IBF FLAG
          MOV R1,#02H       ;INITIALIZE DELAY COUNTER
          CLR CSR.6         ;START STROBE PULSE
          DJNZ R1,$         ;TIME 6 MICROSECOND STROBE PULSE
          SETB CSR.6        ;END STROBE PULSE
WAIT:     JNB CSR.1,OUT     ;EXIT IF ACKNOWLEDGE RCV'D
          JNB CSR.0,WAIT    ;EXIT IF NEGATIVE BUSY EDGE RCV'D
  
```

This polled parallel receive routine places one byte in the accumulator each time it is called.

```

P_INIT:    MOV CSR,#09CH      ;INITIALIZE PORT 6 OPERATING MODE
          MOV R7,P6         ;DUMMY READ TO CLEAR IBF FLAG
P_IN:     JNB CSR.0         ;INPUT BUFFER LATCH FULL?
          CLR CSR.4         ;BEGIN ACKNOWLEDGE PULSE
          MOV R7,#02H       ;INITIALIZE DELAY COUNTER
          DJNZ R7,$         ;TIME ACKNOWLEDGE PULSE
          MOV A,P6          ;READ BYTE - CLEAR BUSY SIGNAL
          MOV R7,#02H       ;INITIALIZE DELAY COUNTER
          DJNZ R7,$         ;TIME ACKNOWLEDGE PULSE
          SETB CSR.4        ;END ACKNOWLEDGE PULSE
          RET
  
```

80C451 operation of port 6

AN408

INTERRUPT DRIVEN PARALLEL PRINTER INTERFACE

(See Figure 13)

Transmitter Operation

The transmitter's CSR (control status register) is programmed to the following mode (see Figure 14):

1. CSR bit 6 controls the BFLAG output and therefore the strobe line.
2. The OBF (output buffer full) flag controls the AFLAG output.
3. The OBF is cleared on the positive edge of the IDS (output data strobe) input.
4. The IBF flag is set on the negative edge of the IDS (input data strobe) pin.

NOTE:

With this combination of AFLAG and BFLAG modes set, port 6 is in the output only mode. The output drivers are always enabled and the ODS input is only used to clear the OBF flag.

INTO is programmed to be negative edge sensitive and is connected to the OBF flag

through the AFLAG pin. The OBF is cleared on the positive edge of ODS . The net result is that INTO is triggered on the end of the ACK pulse (a positive edge). This signals the transmitter that another byte may be transmitted. The transmitting 83C451 is free to do other tasks prior to this interrupt.

In this routine, Figure 15, the main program establishes a buffer in data memory ended by an ASCII end of text character. To begin outputting the buffer, the routine PSEND is called. The rest of the buffer is emptied by the interrupt vectors to PSEND1.

For printers which generate acknowledge pulses, output rates of 25k transfers per second are achieved. Timer generated interrupts are used to periodically return program execution to the routine to service non-acknowledging printers and to provide a timeout feature. Non-acknowledging printers are serviced at a rate of about 2.5k transfers per second. This maximum rate may be varied by adjusting the timer reload value. As written, the time out procedure attempts to retransmit a byte when the printer has not acknowledged for an excessively long time.

Receiver Operation

In receiver operation, the IDS input is used to latch in the data transmitted on receipt of the strobe pulse. The receiver's CSR is programmed to allow the following (see Figure 16):

1. The input buffer full flag is output through the BFLAG pin and is used as the busy signal to the transmitter. The IBF flag is set and data is latched on the positive edge of IDS .
2. Writing to the CSR bit 4 controls the AFLAG output and therefore the acknowledge line.

The receiver is interrupted on the negative edge of the data strobe. Data is latched in on the positive edge of the strobe pulse (see Figure 17). Since the strobe pulse is normally very short, there is little time lost between receiving the interrupt and having valid data in the input latch. The receiver is free to do other tasks prior to receiving the INTO interrupt.

SOFTWARE EXAMPLES

The software for the interrupt driven parallel receiver is similar to the polled receiver example. However, after an interrupt is received, this routine checks to confirm that data has been latched by the positive edge of the strobe pulse before proceeding with the routine.

256k Centronics printer buffer using the 87C451 microcontroller

AN417

DESCRIPTION

This application note describes a stand alone Centronics type parallel printer buffer using the 87C451 expanded I/O microcontroller. This type of unit would typically be placed between a personal computer and its printer. It captures the data to be printed at high speed, freeing the personal computer to go to other tasks, and sends data to the printer as required. As described here, 256k dynamic RAMs are used, providing over one quarter million characters of storage. If desired the design is easily modified to work with 1 megabit DRAMs. Although written with the 87C451 in mind, this design is applicable to the 80C451 and 83C451.

Design Objectives

The objectives kept in mind during the design of this device were: provide a substantial size of buffer, keep the parts count and the power consumption to a minimum, and use readily available components.

A buffer size of 256k bytes was chosen because, although a 64k byte buffer is very easily implemented using the 8051 family's 64k external data storage capabilities, it is a little too small for today's printing applications that print a page of text in graphics mode, using up twenty times as many bytes as standard printing mode. Presenting a method for controlling 256k DRAMs shows off the I/O capabilities of the 87C451, and it is very easy to add the extra address line for one megabit devices if a larger buffer is needed.

The 8XC451 Microcontroller

The 8XC451 is an 8-bit microcontroller based on the familiar 8051 family of devices. In fact, it is an 80C51 with three added ports: P4, P5, and P6. Ports 4 and 5 give 12 (16 in PLCC) additional quasi-bidirectional I/O lines. Port 6 provides another 8 bits of I/O, plus 4 handshake lines that can be programmed to operate in several useful modes for interfacing. The 8XC451 comes in three versions: ROMless 80C451, 83C451 with 4k x 8 ROM, and 87C451 with 4k x 8 EPROM.

In this note, port 6 is used in the I/O mode as a Centronics compatible printer output port. Additionally, the /IDS and BFLAG pins normally associated with port 6 are used as part of the input port logic. For a complete discussion of port 6 operating modes and programming, see the application note AN408 titled "83C451 Microcontroller Operation of Port 6."

Circuit Description

Figure 1 is a schematic diagram of the printer buffer circuit. Other than the 87C451 (U1), and the eight 256k DRAMs (U5-U12), only two 74LS244 buffers (U2, U3) and a 76HCT374 (U4) octal flip-flop are needed. The U2 and U3 buffers are included to provide full drive capability for the output port and some of the handshake signals on the input port, as the output buffers on the 87C451 can only drive 3 LSTTL loads. U4 has 8-bit data strobed into it by the /STB pulse of the input port.

As the code size for this application is quite small (less than 1k bytes), the on-chip instruction memory is quite sufficient for program storage. For a production version, the 87C451 could be replaced with the 83C451 with a 4k x 8 masked ROM on chip. Note that port 0 and port 1 are not used in the present design; thus the 80C451 may be used in this application with the addition of an external address latch and EPROM.

The /RAS, /CAS, and /WR signals for the DRAM array are provided by port 3 bits /WR, /RD, and T1. Note that as in the 80C51, all port 3 signals are multifunctional. That is, each can be treated as a regular quasi-bidirectional port bit, or as having the special function

indicated by its name. This feature is an advantage when using /WR and /RD as /RAS and /CAS control signals for a DRAM array. Treated as a normal port bit, the /WR pin is cleared and set by individual CLR and SETB instructions for a normal length RAM read or write cycle. However, when performing a refresh cycle, /RAS (port 3/WR) can be pulsed low using a dummy MOVX @R0,A (move to external data memory) instruction. This allows DRAM refresh to be done much more quickly than would otherwise be possible.

Port 1 and one bit from port 4 form the 9-bit address required when addressing the DRAM array. The data inputs to the array come from the parallel input data lines which are latched by U4. The RAM data outputs are fed to port 5. By making the data outputs available to the processor, it is possible to add some additional features to the firmware, such as control codes for printing multiple copies of a document, data compression, data conversion, etc. which are not implemented in this design.

Port 6 Operation

The /IDS (input data strobe) and BFLAG pins are normally used in conjunction with the port 6 bidirectional mode. In this mode, the /IDS pin is used to strobe data into the port 6 input latches, and BFLAG is used as flag output. In this application, however, these two bits are used to good effect as part of the (separate) input port logic. When a byte of data is strobed into U4 by the printer port of the host computer, the /STB signal connected to /IDS sets the input buffer full flag (IBF). BFLAG is programmed to mirror the contents of IBF, and therefore becomes asserted. This makes it ideal to be used as the BUSY output for the input port. After the input port data has been read and stored in the RAM buffer, BFLAG is de-asserted by performing a dummy read of port 6, which clears IBF. To complete the input port logic, one of the port 3 pins, P3.4, is used as the acknowledge signal, and is asserted/de-asserted by software. The /ODS pin is tied to ground to permanently enable the port 6 output drivers. This does not cause difficulty as no data is being input into the port.

Note that programming port 6 to operate in the bidirectional mode as described above means the loss of /ODS as an acknowledge input. The acknowledge input is normally used to clear the OBF (output buffer full) flag, indicating that the printer is ready for another character. On the other hand, operating port 6 in the "output only" mode causes the loss of BFLAG as BUSY output. Because the input port requires an instant BUSY indication while the output port only needs to remember the occurrence of an acknowledge pulse, it makes sense to program port 6 to operate in the bidirectional mode, with /ODS grounded to enable the output drivers. The /INT1 pin can be used instead of /ODS to record the occurrence of an acknowledge pulse with the interrupt system.

Priority and Execution of Tasks

There are three tasks that must be performed in this system: Receive—servicing the input port and storing the input character; Transmit—sending stored characters to the output port as required; and Refresh—performing DRAM refresh. The timers and interrupt system are used to manage the execution and priority of these tasks. Figure 2 and Figure 3 illustrate the flow charts of these tasks. Firmware, broken into sections, performing these three functions as well as an initialization routine is provided.

The 51C256 DRAMs require a 256 row refresh every 4 milliseconds. Rather than do an entire refresh cycle every 4 milliseconds, it is done as 64 rows every millisecond. This leaves time for other tasks to get service "slices" more frequently. As DRAM refresh is obviously the highest priority, timer 0 is used as the refresh interval timer, and is programmed to the 16-bit mode, and set to the higher

256k Centronics printer buffer using the 87C451 microcontroller

AN417

priority level in the interrupt priority (IP) register. The refresh code is written in-line rather than in a loop to maximize speed.

An interesting point to note is that when there are no characters stored, the DRAM does not need to be refreshed. If power consumption is of concern, the 87C451 could be programmed to go into idle mode whenever the buffer were empty. A character strobed into the input port would cause an interrupt, restarting the 87C451; DRAM refresh would be maintained until the buffer was once again empty.

The next highest priority should be input port service, as the reason for having a printer buffer is to get the data out of the computer as quickly as possible. Therefore, the input port /STB signal is connected to the /INT0 pin (as well as U4's clock pin and /DS). Interrupt 0 is programmed in the interrupt priority register to be at the lower interrupt level so it cannot prevent refresh service. The interrupt 0 service routine stores the input character at the next location in the DRAM array, using the technique of a circular FIFO buffer. The routine also sends back an acknowledge pulse by clearing and setting the P3.4 pin, and then clears the BUSY (BFLAG) pin by performing a dummy read of port 6 (unless this character caused the buffer to be completely full).

During periods of access to the DRAM array by the input and output routines, the global interrupt enable bit (EA) is cleared so that the refresh interrupt does not disturb the contents of ports 1 and 4, or the /RAS, /CAS, and /WR signals.

The printer (output port) service routine runs all the time, except when the CPU is called to service the other conditions, therefore having the lowest priority. If there are characters in the buffer, polling is used to check for output port BUSY status. If the printer is not busy, then the character is sent, and the output port /STB pin (P4.3) is cleared and set. The output port /ACK line is connected to the /INT1 pin, so that the negative going edge of the /ACK signal is recorded as an interrupt pending. A very short INT1 service routine sets a software flag to indicate that the printer acknowledged the last character.

Possible Enhancements

There are a number of features that could be added to this design. As mentioned previously, the microcontroller could be put into the idle mode when the buffer is empty, conserving power.

The software could be enhanced to provide features such as multiple copies of a document, data compression, data conversion, automatic printer setup, etc. The PC operating system could be suitably modified to send a header for each file to be printed, containing these parameters. There is plenty of room for operating firmware expansion, and plenty of horsepower left in the 87C451 to handle these features.

The two serial port pins Rx/D and Tx/D were deliberately left unused so that input and/or output ports are easily implemented for serial interfaces or printers using the built-in UART. The pins used for parallel port handshaking could then be used as serial handshaking lines, providing the standard "modem" signals.

Combining the above two features, this circuit could act as a "splitter." By connecting a daisy-wheel printer to the serial port, a dot-matrix printer to the parallel port, and sending an "address" flag in the file header, simultaneous letter-quality and draft printing could be done.

The size of the DRAM array is easily expanded to one megabyte or large devices by connecting the additional address pins to port 4 bits 1 and 2. Only slight modifications to the operating firmware would be required.

Conclusion

The SC8XC451 microcontrollers provide plenty of I/O pins that previously had to be implemented by clumsy I/O expansion methods. The flexibility of port 6 means that this device can be used in a wide variety of applications requiring special port functions, while still using the industry standard 8051 instruction set.

The Application Note, describing a typical parallel printer buffer, makes full use of the 8XC451 features, yet allows room for enhancement and expansion.

PORT USAGE:

```
P0      Not used (reserved for data/address bus when external
        program memory is used).
P1      Lower 8 bits of DRAM address (A0 - A7).
P2      Not used (reserved for high-order address bus when external
        program memory is used).

P3.0    (Reserved for serial port.)
P3.1    (Reserved for serial port.)
P3.2 (/INT0) Input port strobe input (interrupt).
P3.3 (/INT1) Output port acknowledge input (interrupt).
P3.4    Input port acknowledge output.
P3.5    DRAM write enable output.
P3.6 (/WR) DRAM row address select output.
P3.7 (/RD) DRAM column address select output.

P4.0    Upper bit of DRAM address (A8).
P4.1    Reserved as an extra address line for 1 megabit DRAMS.
P4.2    Not used.
P4.3    Output port busy input (OBUSY).
P4.4-P4.7 Unused (not available on 64-pin DIP package).

P5      DRAM output data.

P6      Parallel output port.
/IDS    Input port strobe input (ISTB).
BFLAG   Input port busy output (IBUSY).

AFLAG   Output port strobe output (OSTB).
/ODS    Port 6 output enable, tied low.
```

Internal Register/RAM Usage:

```
REFCNT EQU 020h ; Low order refresh byte.;
```

```
The following refer to the circular FIFO buffer
implemented in the DRAM array.
```

```
INLOW EQU 22h ; Incoming address low byte.
INMID EQU 23h ; Incoming address mid byte.
INHI EQU 24h ; Incoming address high byte.
OUTLOW EQU 25h ; Outgoing address low byte.
OUTMID EQU 26h ; Outgoing address mid byte.
OUTHIGH EQU 27h ; Outgoing address high byte.

OACK EQU 28h ; Holds flag for output port acknowledge.
FOACK BIT OACK.0 ; Bit-address of output port acknowledge flag.
```

Counter/timer 2 of the 83C552 microcontroller

AN418

INTRODUCTION TO THE 83C552

The 83C552 is an 80C51 derivative with several extended features: 8k ROM, 256 bytes RAM, 10-bit A/D converter, two PWM channels, two serial I/O channels, six 8-bit I/O ports, and four counter/timers. The architecture of the 83C552 is identical to that of the 80C51, making the two devices fully code compatible. The additional peripheral functions are added to the 80C51 Special Function Register space, and the interrupt structure is modified accordingly. This information is detailed in other references on the 83C552. The focus of this application note is on one of the timers of the 83C552, Counter/Timer 2.

This counter/timer includes capture, compare, and high-speed output capabilities which facilitate many control oriented tasks. The objective of this note is to make users of the 83C552 aware of this counter/timer subsystem and assist the use of this subsystem by a detailed explanation of its operation supported by actual application examples.

TIMER 2 OF THE 83C552

Timer 2 of the 83C552 is in fact a timing controller and has an associated programmable array. The Timer 2 subsystem consists of three parts:

1. The time base consists of a 16-bit timer with a 3-bit prescaler. The master clock for the subsystem can be derived from the on-chip oscillator (fosc) or an external input, T2. It has an external reset, RT2, by which a signal applied to this input can reset the timer if the external reset is enabled.
2. A capture system consisting of four capture registers and four capture inputs which can be used for a wide variety of time measurements on external signals.
3. A compare system consisting of three compare registers and eight associated high-speed outputs which can be activated upon a match between the 16-bit timer and one of the compare registers.

For reference a complete block diagram of the 83C552 Counter/Timer 2 subsystem is shown in Figure 1.

16-BIT COUNTER/TIMER

The description of Counter/Timer 2 in the following paragraphs is intended to be a general overview. Details on architecture, address locations, interrupt structure, and timer operation are given in the 83C552 Users Manual. This users manual may be useful to complement the material presented in this application note. References to registers, bits, I/O ports, and on-chip hardware will relate directly to 83C552 Users Manual nomenclature. This application note will focus on the use of Counter/Timer 2 as a powerful input capture and high-speed output facilitator through some specific examples and not on the detailed coding.

The counter/timer consists of a 16-bit counter which is readable by software through special function registers TM2L and TM2H. The timer itself has two overflow flags, one after the entire 16-bit counter and one attached to the eighth stage. This latter flag reflects an overflow from the first byte of the counter. These two flags are present in register TM2IR and are labeled T2BO for the overflow from the first byte and T2OV for the overflow from the entire 16 bits. These flags may be used to generate an interrupt.

The counter timer is controlled directly through the special function register TM2CON, the timer 2 control register. This register also contains certain status flags.

The prescaler divides the input clock by a programmable ratio. The prescaler divide value is programmable to divide by 1, 2, 4, or 8 as controlled by T2PO and T2P1 in TM2CON.

The input clock to the prescaler is either fosc/12 or the external input, T2. The clock input to the prescaler may also be shut off. This clock input selection is controlled by bits T2MS0 and T2MS1 in TM2CON.

If T2 is used as the input clock to the timer 2 subsystem, the hardware logic samples this input and looks for a low-to-high transition. If the logic detects a logic 0 at the T2 input in state S2P1 of the microcontroller and a logic 1 in state S5P1, then this is recognized as a low-to-high transition, and the prescaler is incremented. The prescaler is incremented in the second cycle after the cycle in which the transition was detected. If the transition is detected before S2P1 is finished, the prescaler is incremented in the next cycle. This timing is shown in Figure 2. Note that this sampling rate is twice that of the normal 80C51 timers, T0 and T1; therefore T2 has twice the maximum external counting rate as compared to the standard timers.

Any programming of the clock source or the prescaler divide ratio results in a reset of the prescaler. This allows the state of the timer subsystem to be in a known state upon programming. The main 16-bit timer cannot be reset by software but it is reset by activating the reset pin or using the external reset, RT2. The external reset, RT2, can be enabled or disabled by bit T2ER in TM2CON. These resets reset the prescaler as well as the 16-bit counter.

Only one interrupt is available from the 16-bit counter timer. Two bits in TM2CON control whether TM2L, TM2H, or both flags will be used to generate the interrupt. A selection for no interrupt is also possible.

Capture System

The capture system is a powerful tool to measure the width of pulses or repetition rates. There are four independent inputs for the signals to be analyzed, CTI0 through CTI3. These inputs are alternate functions to port 1. Each input is connected to a dedicated capture register. A transition at any of these inputs will cause the content of the 16-bit counter/timer to be loaded into the respective capture register. The capture can occur upon various conditions of the input signal as specified by certain bits in the capture control register, CTCON. Each input can be set to cause a capture on a low-to-high transition, a high-to-low transition, or on both transitions. Upon a capture taking place, each input causes an interrupt flag to be set in the Timer 2 Interrupt Flag Register, TM2IR. If enabled, an interrupt will be generated.

One of the capture inputs is shown in more detail in Figure 3. All of the other capture inputs are similar to this one. The capture input is gated with the capture enable bits CTN0 and CTP0, which are located in CTCON. According to the status of these bits, the desired edges are selected to generate the capture enable pulse. The input pulse transient detection is at the input of the enable pulse generator. The input signal is sampled at S1P1 of the machine cycle. If a logic 1 is detected when a logic 0 was detected at the same time in the previous cycle, then the event is taken as a transition. An enable pulse is sent to the capture register, and the contents of timer 2 is copied into the capture register at the end of this machine cycle. The interrupt flag CTI0 is also set.

Compare System

The compare system of Timer 2 can be used to generate a set of outputs whose transitions are controlled directly by the time defined by the 16-bit counter/timer. There are eight of these high-speed outputs which are directly controlled from Counter/Timer 2. These outputs are alternate functions to port 4. Six of these outputs are set-reset controlled (CMSR0 through CMSR5), and two are toggle controlled (CMT0 and CMT1). To clarify the operation, these two types will be discussed separately. In the following discussions, refer to Figure 4, which shows the compare system for P4.5 (a set-reset high-speed output) and P4.6 (a toggle high-speed output).

There are two compare registers associated with the set-reset outputs. These registers are CM0 and CM1. In addition, there are two enable registers: one to enable setting of an output and the other to enable resetting of an output. These registers are STE and RTE, respectively. The contents of CM0 and CM1 are continuously compared to the contents of the 16-bit counter. Whenever there is a match between the 16-bit counter and the contents of CM0, a SET pulse is generated. Similarly, whenever there is a match between the timer and the contents of CM1, a RESET pulse is generated. The set pulse is applied to the set-reset outputs, CMSR0 through CMSR5, through gates controlled by bits in STE. Bits 0 through 5 in STE control the application of the SET pulse to one of the high-speed outputs. For example, STE.0 controls the gating of the SET pulse to CMSR0, STE.1 controls the gating of the SET pulse to CMSR1, and so forth. Thus, if the corresponding SET enable bit in

STE is a 1 and a compare occurs with CM0, then that high-speed output will become set. Similarly, the reset pulse from CM1 is applied to the high-speed outputs CMSR0 through CMSR5 through gates controlled by bits in RTE. As with STE, bits 0 through 5 in RTE control the application of the reset pulse to one of the high-speed outputs. If a compare occurs between the timer and CM1, a high-speed output will be reset if its corresponding enable bit in RTE is a 1. Compares with CM0 and CM1 set interrupt flags which, if enabled, can be used to generate an interrupt.

The two toggle-controlled outputs are CMT0 and CMT1, and these are associated with compare register CM2. These outputs are also alternate functions on port 4. Upon a compare between the counter and the contents of CM2, CM2 generates a toggle pulse which is applied to the high-speed outputs CMT0 and CMT1 through a set of gates. The gates control the application of the toggle pulse to the toggle outputs as specified by the high-order bits of register RTE. RET.6 controls CMT0, and RET.7 controls CMT1. Should the corresponding bit of RTE be set, then the toggle pulse is enabled to the associated high-speed output and that output will toggle upon generation of the toggle pulse from CM2. The structure of these toggled outputs is different from the other high-speed outputs in that the toggling is actually accomplished in a separate toggled flip-flop and not directly in the port latch. This toggle flip-flop cannot be controlled directly by software and powers up in an indeterminate state. The state of the toggle flip-flops is readable in STE bits 6 and 7.

AN418

**APPLICATION EXAMPLE—
TIMED FUEL INJECTION**

In modern automobiles, optimal combustion is necessary to meet emission standards and improve fuel consumption. Optimal combustion depends on several factors and is enhanced by proper fuel injection based upon these factors which vary according to engine speed and other factors. Thus the task is to control the opening and closing of the engine fuel injectors of each cylinder relative to the crankshaft reference point.

For the application example here, we will not consider the factors which determine the timing relationships. These are assumed to be given quantities. The example here will focus upon the implementation of the injector timing control signals and how they are generated using the Counter/Timer 2 system. The illustration considers a four cylinder engine. While this is an automotive application which serves to clearly illustrate Counter/Timer 2 Subsystem operation, it is clear that many systems share similar timing requirements, and the techniques employed here are applicable to a wide class of timing tasks. The 83C552 will also support six cylinder engine control.

Figure 5 shows the injection timing required for two consecutive revolutions of the engine crankshaft. Start and stop of the injection are given relative to a reference point on the crankshaft. The cylinders are numbered in the order of the injection sequence (not with reference to their physical location). Start of the injection is usually given in angular measure with respect to top dead center, and the injection duration is assumed to be a time value calculated from engine environmental factors and operating parameters. The angle for the start of the injection must be converted into time with respect to the reference point.

The injector drivers are assumed to be connected to the port 4 high-speed outputs CMSR0 through CMSR3. To obtain the top dead center reference point, the signal from the appropriate sensor is connected to the capture input CTOI. The interrupt for this capture input is enabled so that software can synchronize its operation to this time reference and make use of the top dead center time in the injector timing calculations. The software synchronization takes two

forms. First, the captured time is an absolute reference for all real-time output operations. This time is available in capture register CTO. Note that at 12 MHz operation, Timer 2 can have a resolution as fine as 1 microsecond with a total time before overflow of over 65 milliseconds, and these times are adjustable by increasing the prescaler divide ratio. A proper selection can make the timing calculations relatively simple. Second, at the time the input is captured, flags which keep track of the phases of the crankshaft cycle are reset when cylinder 1 is at top dead center. These flags are used in the interrupt service routines to tell which action is required for that phase of the crankshaft.

Consider now the sequence of events in one rotation of the engine crankshaft and refer to Figure 5 during the discussion. Assume that the engine is running, that all relevant parameters are available, and that it has been determined that the processor is responding to the interrupt associated with the top dead center capture, CTOI. Interrupts for CTOI, CM0 (compare register 0), and CM1 (compare register 1) are enabled. Upon entering the interrupt service routine for CTOI, the previous value of the captured top dead center time is subtracted from the present value, and the crankshaft rotation time is determined. This is used to compute the time to open the first injector from the required angle at which the injector is to open. This time is made available for the interrupt service routine which responds to a compare from CM0. The interrupt service routine is exited.

The next interrupt to occur per the figure for this example is a result of a compare with CM1 which will be a result of the injector stop time for cylinder 4 having been reached. The flags in an internal status register are employed to keep track of the cylinder number that is presently active for both injection stop and injection start times. After identifying this interrupt from the flags, the processor uses the injector start time for cylinder 1 (previously loaded into CM0) and the predetermined duration to calculate the injector stop time for cylinder 1. This value is loaded into compare register CM1 and the reset enable bit for high-speed output CMSR0 is programmed to a 1. This is bit RTE.0 The reset enable bit for the cylinder 4 injector is set to 0 (bit RET.3). The interrupt routine is now exited.

Figure 5. Four Cylinder Injection Timing

Counter/timer 2 of the 83C552 microcontroller

AN418

The next interrupt to occur will be for the start time for the injector for cylinder 2. This and all subsequent cases follow the same sequence of events as for the cylinder 1 CM0 interrupt described above. In this case, calculations are made for cylinder 2 and loaded into CM0. STE.1 is programmed to a 1, and STE.0 is programmed to a 0. Similarly, the next interrupt for CM1 is treated in the same way, and the sequence of events rotates around through all cylinders in turn. The flag bits associated with this operation keep track of the injector sequencing.

While this example shows the injection stop time of one cylinder overlapping into the injector on time of the subsequent cylinder, close examination of the operations described above reveal that the start and stop events are independent and can overlap or not as required. In this way all injectors may be driven independently and have overlapping on times.

Given that this is an example applicable to general usage, it is possible that interrupt service routine could be relatively long as it would be in an actual injector application. Since the service routine has other interrupts disabled, the length may cause real-time conflicts. To eliminate this potential problem, the interrupt service routines are divided into two parts. In the first part, all other interrupts are disabled, and the essential register loading is done to prepare for the next interrupt. After this is completed, all interrupts are enabled and the ancillary service routine functions are performed prior to a return to the main routine.

As an example, consider the interrupt service routine for CM0. Upon entering the routine, all interrupts are disabled. Then the following actions are performed:

- Set bit in STE to start next injector
- Clear bit in STE for injector just started
- Load CM0 with start time for next injector
- Clear CMIO interrupt flag in TM2IR

Now that the essential set-up is made for the next interrupt, all interrupts are now enabled. However, the return to the main program is not invoked until the following ancillary processing is completed:

- Calculate the next absolute start time for the next injector (the next load value for CM0)
- Increment the flag so that the next entry to this interrupt service routine will be able to identify the next injector to start.

The process performing these calculations can be interrupted to service real-time functions.

APPLICATION EXAMPLE—TIMED IGNITION

In electronic ignition systems, multiple ignition coils may be used and each coil is fired by electronic means rather than with the old style mechanical breakers. In a four cylinder engine, there may be two ignition coils, one coil providing spark for a pair of cylinders. Both plugs fire at the same time. For one cylinder, the spark occurs at the appropriate time while for the other cylinder, the spark occurs at the end of the exhaust stroke and has no effect. With timing references to crankshaft top dead center provided by an external sensor, the ignition timing for the engine may be generated in the 83C552 and applied to the electronic drivers for the ignition coils.

To illustrate the toggle high-speed outputs of the 83C552 Counter/Timer 2 subsystem, the following example will discuss the ignition timing in a four cylinder engine employing the two coil approach with one coil for a pair of cylinders. The coil timing is illustrated in Figure 6. A reference time is used which is a given interval prior to top dead center so that the times used in the illustration can be always after the reference. There are two times of interest for each coil: the load time and the ignition point.

Ignition advance is usually given in degrees crankshaft angle prior to top dead center. As with injection, this angle is assumed to be derived from other calculations and is a given value for this illustration. This angle must be converted in to a time with respect to the reference point. The load time (the time at which the coil has to be switched on to reach the current that will give sufficient energy for an adequate spark) must be subtracted from the desired ignition point. At the ignition time, the coil will be switched off and the spark will be generated.

The coil driver electronics are connected to port bits P4.6 and P4.7. Ignition coil 1 is connected to P4.6, and ignition coil 2 is connected to P4.7. These outputs are the toggle high-speed outputs controlled by the 16-bit compare register, CM2. The program simply needs to set up the compare and control registers to turn the coils on and off at the appropriate times. It is assumed in this example that the ignition and load times are given quantities and have been determined previously.

Figure 6. Four Cylinder, Two Coil Ignition Timing

SU00357

Counter/timer 2 of the 83C552 microcontroller

AN418

Consider now the sequence of events in two rotations of the engine crankshaft and refer to Figure 6. Assume that the engine is running, that all relevant parameters are available, and that it has been determined that the processor is responding to the interrupt associated with a compare to CM2. The top dead center time and crankshaft rotation speed have been already determined through the top dead center capture, CTOI. This is the same as in the injector example. The interrupt for CTOI is enabled. From the top dead center time, the times to turn on and turn off the coil drivers are computed and made available in data storage locations in the microcontroller. It is also convenient to have flags to identify the step in the complete ignition cycle. The flags are cleared in the interrupt service routine for top dead center of cylinder 1.

Upon entering the interrupt service routine, other interrupts are disabled. Examination of the flags reveals that the state of the ignition sequence is that coil 1 has been turned on to begin the current build up (load time). The next event will therefore be turning off coil 2 to cause ignition. The interrupt service routine then performs the following actions: The time to turn off coil 2 is moved into compare register 2, CM2. Bit 6 of RTE is cleared; this disconnects the output of CM2 from the toggle flip-flop of P4.6 (coil 1). Bit 7 of RTE is set; this connects the output of CM2 to the toggle flip-flop of P4.7 (coil 2). The flags are incremented to indicate that the next interrupt will be a result of coil 2 turning off and causing ignition. The other interrupts can be enabled and a return to the main program can be executed. After the other interrupts are enabled and before a return is made to the main program, it may be convenient to do any necessary calculations to determine the time value to be loaded into CM2 in the next CM2 interrupt.

Since the flip-flops are toggled, it is likely that upon power up of the microcontroller, the toggle flip-flops will not be in the desired state. To get the toggle flip-flops in the correct state in the ignition cycle, the flip-flops must be toggled if they are in the wrong state. To determine if this is necessary, the state of the toggle flip-flops can be read from the STE register. The state of the P4.6 flip-flop is present in STE bit 6 and the state of the P4.7 flip-flop is present in STE bit 7. Comparing the actual state to the required state determines which if any or both of the flip-flops must be toggled. If a toggle is necessary to put one or both of the flip-flops in the correct state, the corresponding bits in RTE would be set for those flip-flops requiring the toggle, and CM2 would be loaded with a value that is slightly larger than the present contents of timer 2. If desired for reliability purposes, the state of the flip-flops could be checked periodically against the ignition cycle flags to determine if a correction is necessary.

CONCLUSION

This application note has examined one aspect of the 83C552 CMOS 80C51 derivative microcontroller. The Counter/Timer 2 Subsystem has been applied to a complex timing task of gasoline engine injector valve and ignition coil timing control. While this is a specific application to the automotive interests, the results are applicable to a wide variety of time measurement and control applications. The 83C552 would be ideal for many electromechanical systems such as copy machines, fax machines, industrial process control equipment, automatic transmission control, and anti-skid and anti-lock braking control.

These application areas are those which can successfully employ the 83C552 Counter/Timer 2; however, the other features should not be overlooked. When combined with the 10-bit A to D Converter, the Pulse Width Modulator, the I²C serial bus, and peripheral device family, the 83C552 provides minimum component count solutions for cellular radio systems, professional audio systems, and medical instrumentation products such as bedside patient monitors and analyzers for home care and sports use.

Using up to 5 external interrupts on 80C51 family microcontrollers

AN420

80C51 family microcontrollers are equipped with up to two inputs which may be used as general-purpose interrupts. A typical device provides a total of 5 interrupt sources. Timer 0 and Timer 1 generate vectored interrupts, as does the Serial Port. Applications that require more than two externally signaled vectored interrupts, and do not use one or more of the counters or the serial port, can be configured to use these facilities for additional external interrupt inputs.

This note describes a method to configure the timer/counters and the serial port for use as interrupt inputs (see Figure 1). Minimum response time is a goal for this configuration.

Another popular method to implement extra interrupt inputs is to poll under software control a port pin configured as an input. This method is necessary when the on-chip peripherals are in use. Applications where this approach is recommended are ones in which the processor spends more than half of the time executing a "wait loop," or a short code sequence which jumps or branches back on itself without performing any functions. In this case, the instructions that will check the state of input used as an interrupt source are inserted into this sequence. Consequently, this input is ignored when other routines are being executed. This input may have to be latched externally, or the processor may miss the signal while executing other routines.

Dedicated interrupt inputs that vector the processor to individual service routines (as the two general-purpose interrupt inputs work) do not have the drawbacks of the method described above.

COUNTER/TIMER CONFIGURATION

Timers 0 and 1 are placed in mode 2, which configures the timer/register as an 8-bit counter with automatic reload. The counter and reload register are loaded with FF hexadecimal which is stored in TH1 and TL1 or TH0 and TL0.

To prepare one of the timers for this kind of operation, a number of control bits have to be set up. The following is a list of these bits and their values:

In TMOD:	In TCON:	In IE:
GATE = 0	TRI = 1	ETi = 1
C/T = 1		EA = 1
M1 = 1		
M0 = 0		

Where "i" is the timer number being used as the external interrupt. The TMOD value would be 66 hexadecimal if both timers are being used as external interrupt sources, x6 hex for timer 0, and 6x hex for timer 1. The interrupt priority may also be set in the IP register.

A falling edge on the corresponding Timer 0 or Timer 1 input (T0 or T1) will cause the

counter to overflow and generate a timer interrupt. The counter will be automatically loaded with another FF from the reload register, so the interrupt can occur again as soon as the interrupt service routine completes. Counter/Timer operation is described in detail elsewhere in this manual.

SERIAL PORT CONFIGURATION

The serial port can be placed in mode 2, which is a 9-bit UART with the baud rate derived from the oscillator. The external interrupt is signaled through this port on the RxD receive data pin. Reception is initiated by a detected 1-to-0 transition at RxD. The signal must stay at 0 for at least five-eighths of a bit period for this level to be recognized. Refer to the description of baud rates to determine the length of a bit period at the oscillator frequency selected for the application. The input signal should remain low for at least one bit period and for not more than 9 bit periods.

To prepare the serial port for use as an external interrupt, the following bits must be set up:

In SCON:
SM0 = 1
SM1 = 0
SM2 = 0
REN = 1

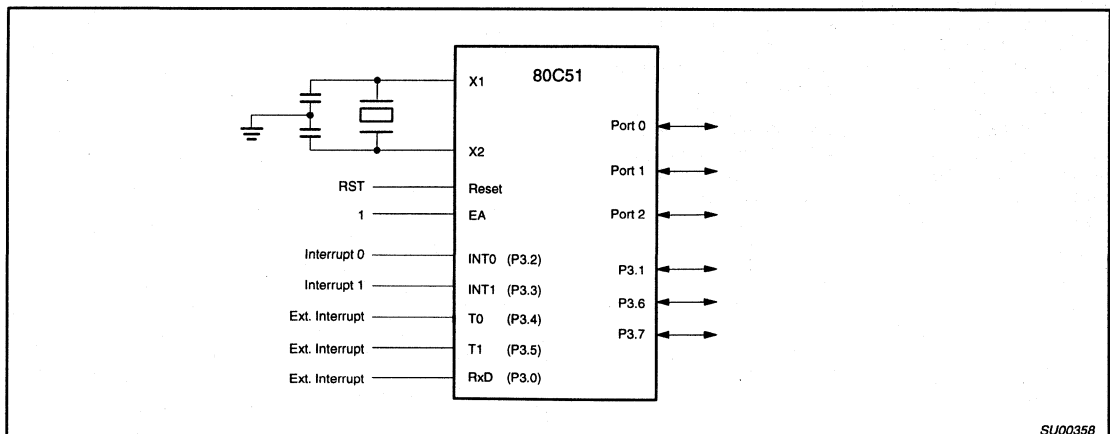

Figure 1. 80C51 Five Interrupt Configuration

SU00358

Using up to 5 external interrupts on 80C51 family microcontrollers

AN420

The Serial Port Interrupt is then used as a general-purpose interrupt. The contents of receive buffer should be ignored, and will subsequently be overwritten during the next interrupt.

Note that the response time for this input will be slower than for the Counter/Timer inputs. This is due to the fact that the RI is generated after the eighth serial data bit time after the falling edge on Rx D.

8051 family warm boot determinations

AN424

DESCRIPTION

For some classes of applications, it may be desirable to know if the application of the reset signal to a microcontroller is due to an initial power-on sequence, or is the result of an external signal such as an operator pressing a reset pushbutton, or the result of a watchdog timer or similar event.

While there are perhaps numerous hardware solutions that can be employed, a simple software solution can offer a high degree of confidence in making this determination. The task is to determine the differences in state of resources internal to the microcontroller that would occur as a result of these two types of reset conditions. With respect to the 80C51 family of microcontrollers, on-chip resources consist of the special function registers (SFRs) and the internal data memory (RAM). Most of the SFR locations are initialized as a result of a reset condition and thus cannot be used for this determination. The data memory contents are unaffected by reset. Thus, valid data loaded into the RAM of the 80C51 while executing a program would not be affected by the application of an external reset signal provided the power source for the microcontroller has not been removed (as is the case for a "warm boot").

The contents of data memory as a result of an initial application of power, however, is indeterminate. While this effect has not been extensively characterized, empirical observation suggests that it is highly random in nature. If it is assumed, for the moment, that the behavior of a given byte of data memory is such that it will power-up with a value that is totally random, then there is a one in eight chance that it will power-up with a predetermined value. If the assumption is extended to two bytes, a 16-bit number, then there is one in 2^{16} chance that both bytes will power-up with predetermined values. Extending this to four bytes results in a one in 2^{32} chance; a very small probability. This is the basis for the software determination of a warm or cold boot condition.

The technique consists of evaluating the contents of four consecutive bytes of data memory following a reset condition to determine whether these bytes had been previously loaded with known data values. If the contents of all four bytes match

predetermined values, this is interpreted to be a warm boot condition. If there is no match, it is then interpreted to be a cold boot condition. At this point, it is necessary to load these four bytes with predetermined data to prepare for the possibility of a subsequent warm boot condition.

The software example included in this application brief can be used to perform this warm or cold boot determination.

The symbols WARM1 through WARM4 represent the predetermined values. The symbol WARM is the address of the first of the four consecutive bytes in data memory. It is set to 30H to avoid conflict with the four register banks, the stack, and the bit-addressable locations in data memory. The symbol WARMBT is a bit-addressable location used as a status bit. It is set as the result of a warm boot and cleared as a result of a cold boot.

The label START is the location of the first instruction to be executed following a reset (address = 0000H). An instruction is located here to jump into the main body of the program to bypass the interrupt vector locations.

The main program body begins by loading register R0 with the address of the first byte in data memory to be evaluated. The contents of this first byte is compared with the first predetermined value. If there is no match, the conclusion is that it is a cold boot. However, if a match is found, this does not imply that it is a warm boot since all four bytes must match, and therefore the remaining three bytes must also be evaluated. Register R0 is incremented to point to the second byte and then compared to the second predetermined value. Comparison of the bytes proceeds until either a no match condition is found or until all four bytes have been evaluated successfully. If all four bytes compared favorable, then a status bit (WARMBT) is set to indicate a warm boot and the remainder of the application program is completed.

An unsuccessful comparison results in branching to the label COLD. This section of code clears the status bit (WARMBT) to indicate a cold boot, and loads the four bytes of data memory with the predetermined values preparing the system for a subsequent possible warm boot. Program flow then continues with the remainder of the application program.

RAM loader program for 80C51 family applications

AN440

Author: Greg Goodhue

The following program allows an 80C51 family microcontroller to load most of its code into a RAM over a serial link after power up and execute out of the RAM for normal operation. This can allow a final product to have firmware updates done by a simple diskette mailing. Such a program is often called a "bootstrap loader".

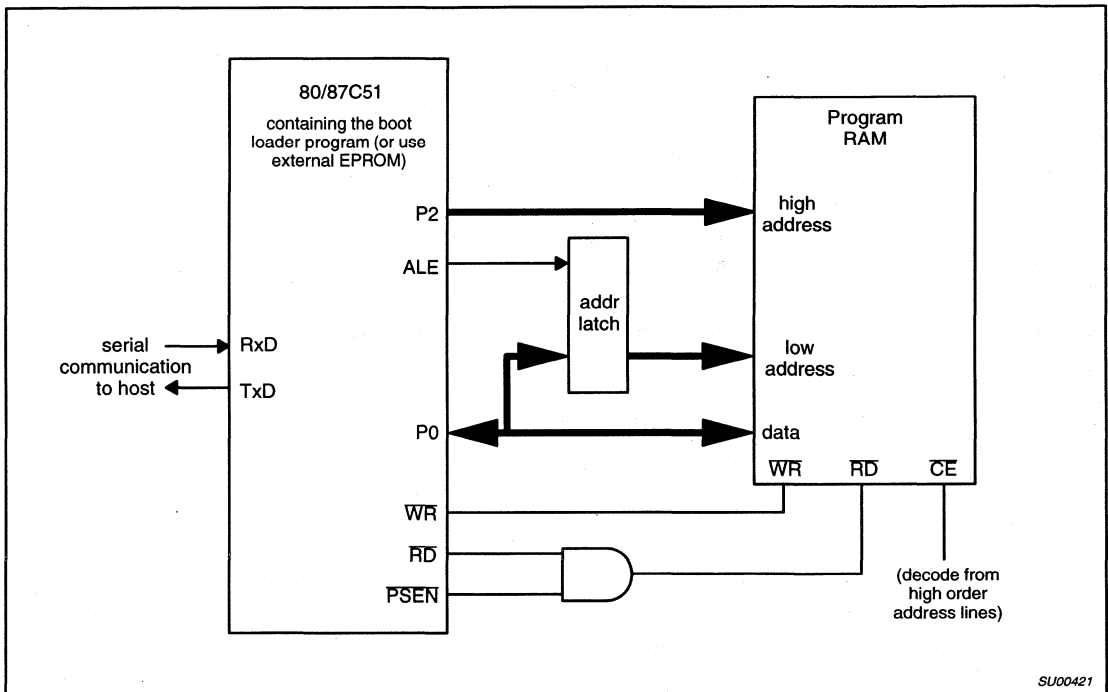

For this example, it is assumed that the code download is done via a serial communication link, although the program could be adapted to other forms of download. The comments at the beginning of the listing are intended to document the program and its use completely.

An additional comment would be that any static routines (low level

routines that are unlikely to change over time) can probably be put into the permanent program memory (on-chip or off-chip ROM or EPROM) along with the bootstrap loader to save program RAM space for other things.

The source code file for this program is available for downloading from the Philips computer bulletin board system. This system is open to all callers, operates 24 hours a day, and can be accessed with modems at 2400, 1200, and 300 baud. The telephone numbers for the BBS are: (800) 451-6644 (in the U.S. only) or (408) 991-2406.

BASIC DIAGRAM OF RAM CONNECTIONS FOR THE BOOT LOADER

SU00421

RAM loader program for 80C51 family applications

AN440

```

;=====
;
;           Bootstrap Loader for Hexadecimal Files
;           written by G. Goodhue, Philips Electronics
;
; This program allows downloading a hexadecimal program file over an
; asynchronous serial link to a code RAM in an 80C51 system. The downloaded
; code may then be executed as the main program for the system. This technique
; may be used in a system that normally connects to a host PC so that the code
; may come from a disk and thus be easily updated. The system RAM must be
; wired to the 80C51 system so that it appears as both data and program memory
; (wire the RAM normally, but use the logical AND of RD and PSEN for the
; output enable.)
;
; To use the bootstrap program, an Intel Hex file is sent through the serial
; port in 8-N-1 format at 9600 baud. The baud rate and format may be altered
; by making small changes in the serial port setup routine (SerStart).
;
; Note that there is no hardware handshaking (e.g. RTS/CTS or XON/XOFF)
; implemented between the host and the bootstrap system. This was done to keep
; the protocol between the two systems as simple as possible.
;
; Since the bootstrap program does not echo the data file, there is no chance
; of an overrun unless the 80C51 is running very slowly and/or the
; communication is very fast. An 80C51 running at 11.0592 MHz (the most
; commonly used frequency in systems with serial communication) will be able
; to easily keep up with 38.4K baud communication without handshaking.
;=====
; The download protocol for this program is as follows:
;
; - When the bootstrap program starts up, it sends a prompt character ("=")
;   up the serial link to the host.
;
; - The host may then send the hexadecimal program file down the serial link.
;   At any time, the host may send an escape character (1B hex) to abort and
;   restart the download process from scratch, beginning from the "=" prompt.
;   This procedure may be used to restart if a download error occurs.
;
; - At the end of a hex file download, a colon (":") prompt is returned. If
;   an error or other suspicious circumstance occurred, a flag value will
;   also be returned as shown below. The flag is a bit map of possible
;   conditions and so may represent more than one problem. If an error
;   occurs, the bootstrap program will refuse to execute the downloaded
;   program.
;
; Exception codes:
;   01 - non-hexadecimal characters found embedded in a data line.
;   02 - bad record type found.
;   04 - incorrect line checksum found.
;   08 - no data found.
;   10 - incremented address overflowed back to zero.
;   20 - RAM data write did not verify correctly.
;
; - If a download error occurs, the download may be retried by first sending
;   an escape character. Until the escape is received, the bootstrap program
;   will refuse to accept any data and will echo a question mark ("?" ) for
;   any character sent.
;
; - After a valid file download, the bootstrap program will send a message
;   containing the file checksum. This is the arithmetic sum of all of the
;   DATA bytes (not addresses, record types, etc.) in the file, truncated to
;   16 bits. This checksum appears in parentheses: "(abcd)". Program
;   execution may then be started by telling the bootstrap program the
;   correct starting address. The format for this is to send a slash ("/")
;   followed by the address in ASCII hexadecimal, followed by a carriage
;   return. Example: "/8A31<CR>"

```

RAM loader program for 80C51 family applications

AN440

```
; - If the address is accepted, an at sign ("@" ) is returned before executing
; the jump to the downloaded file.
```

```
; The bootstrap loader can be configured to re-map interrupt vectors to the
; downloaded program if jumps to the correct addresses are set up. For
; instance, if the program RAM in the system where this program is to be used
; starts at 8000 hexadecimal, the re-mapped interrupts may begin at 8003 for
; external interrupt 0, etc.
```

IEEE Micro Mouse using the 87C751 microcontroller

AN443

Author: Tracy Ching

DESCRIPTION

Micro Mouse is an IEEE contest first proposed by the author of IEEE Spectrum in 1977. It consists of an autonomous robot known as a "mouse" which navigates through a maze of 256 two-inch-high, seven-inch squares in a 16 x 16 arrangement. The robot is self powered and has no knowledge of the maze configuration prior to releasing it in the maze. The first time it is released into the maze, its prime objective is to find a path from the starting square which is located in a corner of the maze to the destination square which can be located in the center or a different corner depending on competition level. The destination square for the advanced level can be found only by using a smart algorithm which will make the mouse gravitate towards the center without becoming lost. The destination square for a novice contest can be found by using a wall hugging algorithm. The analogy for this algorithm is to imagine a blind person holding their right hand out against a wall and following the walls until they reach the destination. A maximum of ten runs or 15 minutes is given to each mouse. Leaving the starting square constitutes one run. The mouse with the fastest run time from the starting square to the destination square wins.

The contest is held with different competition levels for novices and advanced. The novice level is typically held for college students trying to exercise newly acquired hardware and software skills, whereas the advanced level encompasses international talent and may require the implementation of a proportional integral derivative (PID) controller in software to utilize commutated or brushless DC motors and complex navigation algorithms.

DESIGN OBJECTIVES

Several design objectives were as follows: minimize weight, minimize part size and count, minimize power consumption which allows the use of smaller and lighter batteries, minimize cost and maximize speed.

The main objective was to keep the total weight at a minimum to obtain the fastest acceleration from the stepper motors and to reduce wheel slippage during deceleration and turning. The objectives are inter-related such that changing one will affect the other. Hence, having a low part count means lighter weight, faster acceleration and lower cost.

A typical mouse may consist of a microcontroller with supporting memory and GLU logic to interface the motor controllers and sensors. The 87C751 is suitable for this application with its small size. The need for external RAM is eliminated by using the internal RAM to store minimum maze information suitable for the novice level. Nickel cadmium batteries are used because of the cost, size and power density obtainable versus other battery types. Nickel metal hydride was not available during development but would be a good choice over nickel cadmium batteries.

The 87C751 Microcontroller

The 87C751 is an 8-bit microcontroller based on the 8051 microcontroller family. It is code compatible with the exception of the MOVX, LJMP, and LCALL instructions. The MOVX instruction and external memory accesses are not supported. LJMP and LCALL instructions are not needed since AJMP and ACALL can reach the entire program memory range (2k bytes) of the 751. The 87C751 contains a 2k x 8 EPROM, a 64 x 8 RAM, 19 I/O lines, a 16 bit auto-reload counter/timer, a fixed rate timer, a five source fixed priority interrupt structure, a bidirectional Inter-Integrated circuit (I²C) bus interface, and an internal oscillator. The 87C751 comes in an erasable quartz package (87C751), one time programmable (87C751), and mask ROM (83C751).

HARDWARE DESCRIPTION

Figure 1 is a schematic diagram of the mouse. The stepper motors are 4 volts 0.95 amperes per coil giving about 14 oz-inches of torque. Each motor is driven by an Allegro UCN-5804B unipolar stepper motor translator/driver which contains the sequencing logic and high current darlington outputs. The sequencing logic only requires clock, direction of rotation, and output enable signals from the 87C751 which relieves the chore of having to cycle through a sequencing table for both motors therefore reducing code size. Fast recovery diodes are used to protect the darlington outputs from negative voltage due to motor winding flyback.

The infrared (IR) emitters are Optek OP-240A. The sensors are Optek OPL-560-OC which have a built-in light amplifier and TTL open collector output. Each sensor bank is enabled via a high side P-channel MOSFET. A 74LS04 (U4) is used to drive the P-channel MOSFET. Data from each bank of eight IR sensors is fed into port 3. By using open collector output sensors, the need for latching the data using a 3-State buffer is eliminated. Port pins P0.0 and P0.1 are used for enabling either the left or right sensor bank via the 74LS04 (U4) and the MOSFETs. Each sensor bank hangs over the two inch high walls whereby the light emitted from the OP-240 is reflected into the OPL-560-OC if a wall is present. Two sensor pairs in the middle of the array are typically sensing the presence of a wall and the remaining sensors are used for guidance to keep the mouse running parallel to the walls.

A 74LS573 connected to port 3 which latched data into eight LEDs was used in the debugging process. P1.7 was used on the latch signal for the 74LS573. Since the eight LEDs and latch were not needed for the final product, they were removed thus reducing weight and battery drain. LEDs D1 and D2 were also used in the debugging process and are currently used for visual feedback when selecting options during operation.

Power for the digital circuitry is fed by an 8.4 volt NiCAD battery pack, packaged in a 9 volt battery case, via a 7805 regulator. The circuit can run constantly with the sensors taking "snapshots" of the walls intermittently for at least 30 minutes satisfying the 15 minute maximum requirement. Power for the motors is fed by four "A" size NiCAD cells which have enough energy to run the motors for 15 minutes before becoming useless at about 1 volt per cell.

TASK PRIORITIES

Several tasks take place during program execution which are as follows in order of importance: pulsing the stepper motors according to a velocity profile table, gathering sensor data, deciding whether to accelerate, decelerate, turn left or right.

In-line coding is used to avoid calling subroutines that cause the program counter to be pushed onto the stack and use valuable RAM for the turn decisions. Interrupt subroutines are an exception.

Interrupt timer 0 (T0) vectors to the routine which supplies a pulse to the stepper motor drivers. This is the most important task because the stepper motors require a smooth train of pulses in order to prevent jerky or sporadic motions. Thus, T0 must have the highest priority and must not be interrupted. Although timer 0 is a 16 bit timer, only eight bits are used with the higher byte set to FFH. T0 takes care of pulsing the left and right motor drivers at different times by using two external registers which are used as prescalers. Each motor can be assigned a different prescale value via the assigned register in order to step each motor at a different step rate.

The velocity profile table for T0 was designed using a spreadsheet program with visual graphing. This aided the ability to derive an

IEEE Micro Mouse using the 87C751 microcontroller

AN443

exponential table for the fastest stepper motor acceleration using qualitative observations.

The first part of the in-line code contains the routine to accelerate the mouse from a stopped position. A pointer for each motor is incremented until the end of the velocity profile table is reached. During acceleration, the left and right sensors are strobed and stored after each step caused by T0.

The routine that strobes the sensors for wall data returns several results through the use of flags. The routine first stores the sensor data in registers. This information is used to determine if the sensor array or mouse is too far right, left, or aligned in a square and to set the corresponding flags. It also returns the presence of a front wall using the innermost sensor pairs. The deceleration routine is similar to the acceleration routine except the pointers decrement through the velocity profile table skipping a few values each time. Deceleration uses less steps than acceleration.

The routine which decides whether to continue acceleration, deceleration, or turn left or right keeps track of step count or position of the mouse within a square in order to store wall information at the proper time. After the previous routines have stored the data for the front, left, and right walls, a decision is obtained. If the mouse is not in a back-up mode, the wall information, status of the back-up flag and left/right algorithm flag forms an offset byte. If the mouse is in a back-up mode, the decision from above plus the previous decision on the stack is used to form the offset byte. This offset is stored in the accumulator. The decision which contains the direction to turn is obtained using the MOVC instruction which points to the table using the data pointer. The logic table is shown in Tables 1 and 2 below.

External interrupt 0 (INT0) vectors to the routine which brings the mouse to a halt. INT0 subroutine disables T0, sets output enable high on the stepper motor drivers, and sets the return address for the program counter to 0000H. This causes the mouse to restart program execution without losing the internal RAM.

Table 1. Logic Table: Non-Back-Up Mode

B-U = back-up flag

stack = RAM used for storing decisions (not for the program counter)

Non back-up mode:

(1) wall hugging algorithm (user selected)

(2) walls surrounding present square

(3) direction to turn

(4) operations to perform

IEEE Micro Mouse using the 87C751 microcontroller

AN443

Table 2. Logic Table: Back-Up Mode

(1)	(2)	(3)	(4)
R	R	R	push S onto stack, clear B-U
R	L	L	pop stack only
R	S	S	push L onto stack, clear B-U
L	R	R	pop stack only
L	L	L	push S onto stack, clear B-U
L	S	S	push R onto stack, clear B-U
S	R	R	push L onto stack, clear B-U
S	L	L	push R onto stack, clear B-U
S	S	S	pop stack only

NOTES:

Abbreviations used:

R = right

L = left

F = front

S = straight

B-U = back-up flag

stack = RAM used for storing decisions (not for the program counter)

Back-up mode:

- (1) previous decision from top of stack
- (2) decision from the above table for this current square
- (3) direction to turn (should be equal to (2))
- (4) operations to perform (all operations require lowering the stack by one before pushing data)

OPERATION**Reset**

True reset is accomplished only during power on. After completing the maze, the operator brings the mouse to a stop using the start/stop switch which effectively disables the motors and resets the program counter to 0000H, restarting the mouse's program with the exception that the RAM contains vital maze information.

Starting/Stopping

After power-up, the mouse remains idle with the motors and sensors disabled, awaiting an interrupt from switch SW1. The first time the switch is pressed, the mouse will start. The second time the switch is pressed, the mouse will stop and the cycle repeats.

Selecting right or left wall hugging

After power on reset, the program defaults to right wall hugging. Pressing switch SW2 will cause the mouse to follow the left walls. If it is pressed again, it will follow the right walls— toggling between the left and right wall hugging algorithm each time it is pressed.

Increasing motor speed

After completing the first run, pressing switch SW2 causes the timer value to increase by an index of one, increasing the speed of the

motors. This allows the mouse to be run at increasing speeds each run in order to attain the fastest possible time before crashing into a wall or incurring a condition in the stepper motors called "pull-out". Pull-out is a condition wherein the fields are changing in the coils faster than the rotor can maintain synchronism with the coils, causing the rotor to stall.

SOFTWARE LIMITATIONS

The 87C751 has 64 bytes of RAM. The program requires 31 bytes of RAM leaving 33 bytes for storing decisions. One hundred thirty two decisions can be stored in 33 bytes of RAM since four decisions are stored per byte. Although there are 16 times 16 squares with possibly 256 decisions to be made, this condition is not very probable since every square typically is not made into a turning point. Long straight ways are used as well as turning points. The probability that the RAM will fill to the maximum capacity is very slim in the novice level where there are typically 50 decisions to be made. Hence, RAM which can hold 132 decisions is adequate but not infallible.

FUTURE ENHANCEMENTS

Although the 87C751 has minimal RAM, I²C RAM could be easily added by switching the MOSFET drivers using the LED port pins and placing the I²C RAM on port pins P0.0 and P0.1. This would allow the implementation of a full mapping algorithm thus allowing entry to the advanced class. The code size for the I²C routines and recursive algorithm to find the center of the maze would add about 800 bytes more of code. Since some of the code for the novice class would be eliminated, it would bring the total code size to less than 2k bytes. A few maze solving algorithms have been implemented successfully on other mice. These are the flooding or Bellman's algorithm, backtracking algorithm and others. The first two algorithms are recursive, thus the code sizes are quite small.

Another added feature would be the ability to execute a rounded turn rather than pivot. This requires a more complex navigation scheme and velocity profiler to make the motors turn at differing speeds in order to make the rounded turn.

In addition to the enhancements aforementioned, methods to track a wall through the use of an A/D converter which measures the reflectivity strength from infrared sensors pointing at the sides of the walls can also be implemented on the I²C bus. This would eliminate the array of sensors hanging in front of the mouse on top of the walls thus decreasing the weight.

CONCLUSION

The 87C751 microcontroller provides the required computing resources and I/O ports necessary to control a robotics device known as a "Micro Mouse". The I²C interface allows for an abundance of variations on this robotics device.

Automatic baud rate detection for the 80C51

AN447

Author: Greg Goodhue

This note documents a method to automatically establish the correct baud rate for serial communications in many 80C51 family applications. The first character received after a program is started is used to measure the baud rate empirically.

This can eliminate the need to have setup switches whose settings are difficult to remember and all of the other headaches associated with applications that use multiple baud rates. One might assume that a reliable method of accomplishing this might be impossible without severely limiting the characters that could be recognized. The problem is in finding a timing interval that can be measured in a large number of possible characters under a wide variety of conditions.

Measuring a single bit time would be the obvious way to quickly determine what baud rate is being received. However, many ASCII characters don't have an example of a single bit time in the RS-232 pattern. For most characters, the length of the entire transmission from the start bit to the last "visible" transition will fall within certain ranges as long as some reasonable assumptions can be made about the possible baud rates (i.e. that they are standard baud rates). Moreover, many systems now use 8 data bits and no parity for ASCII transmissions. In this format, normal ASCII characters will never have the MSB set and since UARTs send data LSB first/MSB last, the program would always be able to "see" the beginning of the stop bit.

The following baud rate detection routine waits for a start bit (falling edge) on the serial input pin and then starts timer 0. At every subsequent rising edge of the serial data, the timer value is captured and saved. When the timer overflows, the last captured value will indicate the duration of the serial character from the start bit to the last 0 to 1 transition (hopefully the stop bit).

The table CmpTable contains the maximum timer measurement that is accepted for each baud rate. These values were picked such that a timed interval of only 4 data bit times (plus the start bit time) will still produce the correct baud rate.

There is an assumption in this method that anyone using it needs to be aware of. That is, that this technique depends on only one character being received during the sampling window, which has to be at least as long as a typical character at the slowest baud rate that can be accepted. Essentially this means that the data must normally come from someone typing at a keyboard.

On our PCs, we were not able to fool the program by typing two characters in quick succession. The PC function keys did present a problem because they send two characters in a tight sequence, and

fooled the program into detecting the wrong baud rate. In the example program, which is designed for a 12 MHz clock, the total sample interval is about 65 milliseconds, or about twice the duration of an RS-232 character sent at 300 baud.

If parity is used, a possibility of a baud rate determination error happens when the four MSBs and the parity bit of the character received are all ones. This can happen for the lower case letters "p" through "z", plus curly brackets, vertical bar (|), tilde (~), and "delete", depending on whether the system uses odd or even parity. Note that the usual prompt characters that a user would type to get a system's attention (e.g. space, carriage return, and escape) are NOT subject to this limitation.

Because of the way this program works, the first input character that is used to detect the baud rate is lost since the UART cannot be set to the correct baud rate until after the first character has been timed. Also, most "real" programs using this technique would want to repeat the baud rate detection process if framing errors are detected at the UART during normal operation.

To calculate CmpTable values for other oscillator frequencies and baud rates, use the following equation:

$$\text{Table entry} = \frac{\text{Osc(MHz)}}{\text{Baud Rate}} \times \frac{5}{12}$$

Remember that the table entry is a two byte value, so the result of the above must be split into upper and lower bytes (easy if you have a hexadecimal calculator). It may also be possible to get the assembler to do all of the calculations for you.

The above equation was derived as follows:

$$\frac{\text{maximum timer value}}{\text{(table entry)}} = \frac{\text{minimum recognition time}}{\text{machine cycle time}}$$

$$\text{Minimum recognition time} = \frac{\text{bits-to-recognize}}{\text{\#-of-bits}} \times \text{byte time}$$

Note: '#-of-bits' (the number of "visible" bits) is 9, and bits-to-recognize (the minimum # of bits to recognize) is 5 for 8-N-1 communication.

$$\text{byte time} = \frac{1}{\text{baud rate}} \times \text{\#-of-bits}$$

$$\text{machine cycle time} = \frac{\text{Osc frequency}}{12}$$

Determining baud rates for 8051 UARTs and other UART issues

AN448

Author: Greg Goodhue

The purpose of this note is to expand upon and clarify some aspects of determining baud rates and crystal frequencies for using a standard 8051 or 80C51 UART for ordinary RS-232 type serial communication. The standard baud rate equation is simplified here and is restated to allow solving for other variables such as the crystal frequency and timer reload values.

The following discussion assumes that the reader has some knowledge of the 8051/80C51 UART and timers. This should be considered a supplement to the information presented in the Philips 80C51 Family Microcontroller Data Book sections on Timer/Counters and the Standard Serial Interface.

Since this discussion assumes the use of a standard UART for RS-232 serial communications, the UART will be used in modes 1 or 3 (variable baud rates) and timer 1 will be used in mode 2 (8-bit auto-reload mode) as the baud rate generator. All of the equations shown here give an option for two clock divisors depending on whether the SMOD bit is used on a CMOS microcontroller. For an NMOS device, always use the default value (SMOD is not = 1).

The basic equation for a timer reload value can be stated as:

$$TH1 = 256 - \frac{\text{Crystal Frequency}/384 \text{ (or 192 if SMOD = 1)}}{\text{Baud Rate}}$$

Example:

To obtain a timer reload value for a 9600 baud serial data rate with an 11.0592 MHz crystal:

$$256 - \frac{11,059,200/384}{9600} = 256 - 3 = 253, \text{ or FD hexadecimal}$$

The equation can also be solved to derive the baud rate or the crystal frequency from the other information as follows:

$$\text{Baud Rate} = \frac{\text{Crystal Frequency}/384 \text{ (or 192 if SMOD = 1)}}{256 - TH1}$$

$$\text{Minimum crystal frequency for a given baud rate} = \text{Baud Rate} \times 384 \text{ (or 192 if SMOD = 1)}$$

Thus, the minimum crystal frequency that may be used for 19.2k baud communication on a CMOS part with SMOD = 1 would be 19200×192 , which gives 3.6864 MHz. When using this equation, the timer reload value TH1 for the maximum baud rate is always 255 (256 - 1) or FF hexadecimal.

Of course, any even multiple of the frequency obtained in this manner will also support the same baud rate with a different timer reload value. For instance, four times 3.6864 MHz is 14.7456 MHz. At that crystal frequency, 19.2k baud is attained with a timer reload value that gives one fourth of the timer overflow rate: 252 (256 - 4) or FC hexadecimal.

Determining baud rates for 8051 UARTs and other UART issues

AN448

CRYSTAL FREQUENCIES USED FOR STANDARD BAUD RATES

The following chart shows possible crystal frequencies for use with the 80C51 UART at standard baud rates. The chart assumes use of the UART in modes 1 or 3 (variable baud rates) and timer mode 2 (8-bit auto-reload mode). The chart also assumes a minimum requirement of at least 9600 baud (including the use of SMOD for baud rate doubling). More crystal frequencies are available if a lower maximum baud rate is required.

The minimum timer count column indicates how many timer counts are required at the stated crystal frequency in order to obtain the

maximum baud rate shown. The last column shows the timer reload value that is used to obtain the minimum timer count. This is simply 256 minus the minimum timer count.

Timer reload values for other baud rates at the same crystal frequency are determined by multiplying the minimum timer count by two successively and calculating a new reload value as previously mentioned. For instance, for 4800 baud at 1.8432 MHz, the timer count would be 2 (twice what it is for 9600 baud), giving a timer reload value of 254 (256 - 2) or FE hexadecimal.

Maximum Standard Crystal (MHz)	Maximum Baud Rate	Timer Count	Timer Reload Value (in hex)
1.8432	9600	1	FF
3.6864	19200	1	FF
5.5296	9600	3	FD
7.3728	38400	1	FF
9.2160	9600	5	FB
11.0592	19200	3	FD
12.9024	9600	7	F9
14.7456	76800 (2 × 38400)	1	FF
16.5888	9600	9	F7
18.4320	19200	5	FB
20.2752	9600	11	F5
22.1184	38400	3	FD
23.9616	9600	13	F3
25.8048	19200	7	F9
27.6840	9600	15	F1
29.4912	153600 (4 × 38400)	1	FF
31.3344	9600	17	EF
33.1776	19200	9	F7
35.0208	9600	19	ED
36.8640	38400	5	FB

Determining baud rates for 8051 UARTs and other UART issues

AN448

THE EFFECT OF USING OFF-FREQUENCY CRYSTALS

Occasionally, one may wish to use an off-frequency crystal in a design, but still want to make use of the UART for debug purposes.

Since most terminals (or other RS-232 devices) will communicate with another device that has a baud rate that is off by several percent, this can often be done successfully. WARNING: running the UART off-frequency is NOT recommended if part of the application's normal operation involves communication with other RS-232 devices.

There is no exact limit on how much frequency error is tolerable, since this depends on the devices communicating, the baud rates, precise frequencies used by both devices, etc. However, a rule of thumb may be used that the communication is likely to work if the frequency is off by less than 5%. This somewhat arbitrary number was arrived at as follows: for a ten-bit serial code (one start, 8 data bits, one stop), a 10% data rate error will put the receiver off by about plus or minus one bit time at the end of one data frame. A one bit-time error seems rather excessive if one wants fairly reliable communications. So, consider using half of that value (5%) as a rule of thumb.

The consequence of all this is that one may often find a more standard "off-the-shelf" crystal frequency to use in an application, if the UART is being used for debugging, factory testing, etc. As an example, consider the well-known "color burst" crystal. At 3.579545 MHz, this crystal is only about 3% slower than the 3.6864 MHz crystal that may be desired for baud rate generation. As such, this lower cost crystal could be used in place of the less standard one in some cases. Another obvious replacement is to use the standard 14.31818 MHz crystal in place of the not-so-standard 14.7456 MHz crystal that appears in the table. This replacement also yields a less than 3% error and may be handy because it gives a fast instruction execution rate for the 80C51, whereas 3.58 MHz may be too slow for many applications.

It should also be remembered that RS-232 communications are most robust if characters are not transmitted back-to-back. This can become more important when the UART is deliberately used out of spec as described here. When data is sent at full speed, there is no chance for the receiver to re-synchronize to the transmitted frames if it once gets out of synch. However, when there is a short pause between characters (about 2 to 3 bit times or longer), the receiver will generally be able to correctly locate start bits without framing errors. In the worst case, a pause of one byte-time or longer in a transmission should ALWAYS re-synchronize any receiver no matter how out of synch it has become.

A LITTLE KNOWN PHENOMENON

In the UART setup code for most applications, the actual timer count register (TL1) is not initialized. In many applications, this DOES have an effect on the way the UART behaves on the first character sent, although the chances of this being noticed are slight. This can be seen by trying to observe the first character sent from the UART on a logic analyzer that is being triggered by the end of microcontroller reset. The first character will begin so far down the time line that it will not be seen at any resolution on the logic analyzer that would show any of the individual bits.

This effect occurs because TL1 has to time-out once before the first character is transmitted. If TL1 is not initialized in the program, it will have a reset value of 0. This could give the first timeout a duration of up to 255 normal bit times, depending on the reload value for TH1 (which again depends on the baud rate and crystal frequency).

Again, in most applications, this would never be an issue. In fact, it may often be an advantage to have a delay before the first serial character is sent after power-up. But if the first serial character should start sooner, TL1 may be initialized to some value other than zero. For no delay, the same value used in TH1 should be used.

Measure resistance and capacitance without an A/D

AN449

Author: Don Sherman

This article describes how to measure values of a variable resistor or a variable capacitor using a microcontroller to measure the RC charge time to a constant threshold voltage. A variety of these "one-shot" circuits are described and the accuracy of the various methods is measured. Sample programs for the 87C51 family are presented at the end of the article.

The old "one-shot" monostable multivibrator circuit has been around since the discovery of the electron. Popular IC versions of this variable pulse width generator include the 74123 and the famous (Philips) Signetics NE555 timer. These circuits use the time to charge a capacitor to a predefined voltage as their time delay. If the threshold voltage is $1-1/e$ (e is the natural log base), then the time delay in seconds is exactly the product of the resistance in ohms and the capacitance in Farads ($t=RC$). This is a linear equation and it can be used to measure an unknown value of R if C and t are known. The purpose of this article is to describe ways to measure a RESISTANCE by using this technique with an 80C51 type of microcontroller.

Examining the voltage across the Capacitor versus time graph in Figure 2, it is obvious, I hope, that the time to reach any given voltage will be directly proportional to the value of R. In fact the equation for the delay time becomes:

$$V_C = V_{CC} (1 - e^{-t/RC})$$

From this equation, it follows that:

$$V_C/V_{CC} = 1 - e^{-t/RC}$$

and

$$1 - V_C/V_{CC} = e^{-t/RC}$$

Since we are solving for time, t:

$$\ln(1 - V_C/V_{CC}) = -t/RC$$

so that

$$t = RC(-\ln(1 - V_C/V_{CC}))$$

or

$$t = RC(K)$$

where

$$K = 1/(-\ln(1 - V_C/V_{CC}))$$

Note that K becomes a constant if V_C/V_{CC} is held constant. This ratio of voltages is determined by the threshold of the comparator which is connected to monitor the voltage, V_C , across the capacitor. Thus, for a constant threshold voltage for V_C and a constant value for the capacitance, C, the equation for TIME reduces to:

$$t = R \times \text{"a constant"}$$

which is a simple linear equation.

We can see from the above equations that any point is valid as the threshold voltage as long as it remains the same for each set of readings. The threshold for the LM324 comparator, shown in Figure 3, is $2/3 V_{CC}$. If 74HCTxx type of digital logic is used, the threshold will be approximately 1.2 volts. If 74HCxx logic is used the threshold will be approximately 2.5 volts. However, if the threshold is different than $1-1/e$, and/or, if the capacitance is not known exactly, it will be necessary to calibrate the system with a known resistance.

Figure 2.

SU00438

Measure resistance and capacitance without an A/D

AN449

In this article I have investigated different hardware techniques for generating a pulse with the microcontroller, and then the resultant characteristics are summarized. The matrix of variables consists of the following basic one-shot circuits shown in Figures 2 through 12 and various time measurement methods available in common microcontrollers. To be more specific, time was measured by dividing the microcontroller's oscillator frequency with an internal timer and gating a counter on and off by the one-shot. The other method of timing was to use the one-shot time to enable and then stop a software DJNZ counter loop.

In order to obtain some statistical comparison of the different circuits, I wrote an 80C51 assembly language program to generate data for a histogram so that standard deviation of the values could be calculated. The program first took 256 readings of the 16 bit counter/timer and added all of the results to obtain a 3 byte wide answer. The top two bytes were then used as the average of the 16 bit readings. This was the equivalent of dividing the answer by 256 (shifting the 3 byte sum right by 8 bits). In the next sequence a single reading was taken and the average was subtracted from it. The displacement of the answer, which is the deviation from the average, is used to increment a RAM location. RAM locations were allocated -16 and +15 locations around the "average" value's location. This process was repeated for 255 readings. Thus, if 241 readings are the same as the average and five readings are one less than the average and nine readings are one greater than the average, the result is shown in Table 1.

Values beyond the allocated deviation are summarized in the counters at the two ends of the allocated area. If a significant

number of readings appear in these overflow and underflow counters, I included a 16 bit shift routine to reduce the number of bits of the reading until a reasonable spread in values could be plotted. All of the assembly language programs which I used are available from the Philips BBS.

The first thing that I noticed when I started to evaluate the circuits was a strong shift in the center of the readings from the average. By using some freeze mist and an old hair drier, I found that the cheap old monolithic capacitor which I was using as my C, was quite temperature sensitive. So, RULE NUMBER 1 for successful and dependable R readings is to use a capacitor which does not vary with temperature. Polycarbonate, polypropylene, and mylar are good low temperature coefficient dielectrics. These usually come in some high voltage ratings and are also quite large in size compared to the monolithic capacitor. NPO versions of monolithics are available, but be sure to check the temp-co. Don't even think of using an electrolytic capacitor.

The first circuit which I evaluated is shown in Figure 3 and is an attempt to copy the NE555 interior. One half of a LM324 quad comparator was used to implement the circuitry which is external to the microcontroller. The statistical program and the A/D Assembly language program are at the end of this article.

RU and RL were chosen to be in the same ratio as the NE555 timer. This value gives a threshold voltage of $2/3 V_{CC}$, which is very close to the $(1 - 1/e)$ value for a one-shot delay time of $t = RC$. The actual NE555 equation is $t = 1.1 RC$.

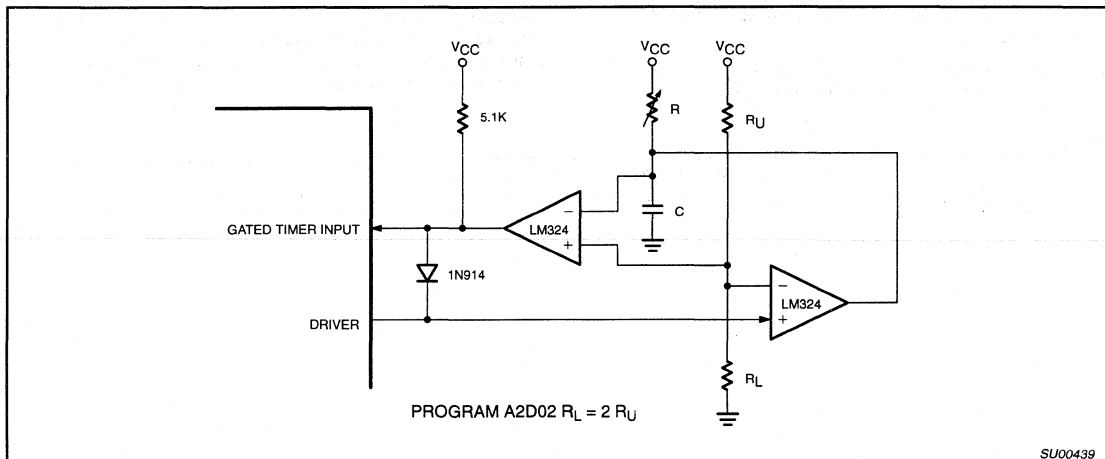

Figure 3.

Measure resistance and capacitance without an A/D

AN449

In this circuit the microcontroller "Driver" outputs a logic 0 to the non-inverting input of the comparator. The open collector output of the comparator follows the input and shorts the timing capacitor, C, to ground. It is important to allow enough time to discharge the capacitor to ground, since any residual charge on the capacitor will cause errors in the readings. The "Gated Timer Input" will allow an internal timer to count signals divided down from the microprocessor clock. The divided down oscillator signals are gated into a counter while the "Gated Timer Input" is held high. The measurement cycle starts when the "Driver" transitions to a logic 1 and simultaneously releases the short to ground on C and, through the diode, allows the Gated Timer Input to be driven high by the other comparator which is monitoring the voltage across the timing capacitor. When the capacitor voltage exceeds the $\frac{2}{3} V_{CC}$ reference voltage ($R_L/(R_L+R_U)$) on the comparator, the Gated Timer Input is driven low by the comparator and the 16 bit timer is halted.

If only one resistor is to be measured, it is possible to eliminate the diode by using one of the two left over comparators in the LM324. The inverting side should be connected to the junction of RU and RL. The non-inverting input is connected to the "Driver" output. The Open Collector output of the comparator is connected to the "Gated Timer Input". This will hold the Gated Timer Input low while the capacitor is being discharged and will release the Gated Timer Input line to go high at the same time that the Capacitor is released.

Eleven resistor values were used to obtain a spread of timer values which were then plotted to determine the linearity of readings and to also check out the theory that this entire process is really linear. Amazingly enough, the plot was really linear! The spread in the 255 samples per resistor value was greater for larger values of resistance. Using a 0.47 mfd polycarbonate timing capacitor with a 91KΩ R, the average value was 0BEC0H and the deviation table is shown in Table 2.

From these deviation readings we can see that 99% (3 sigma) of the readings are within 5 counts of the average. Shifting the answer right 2 places (dividing by 4) will result in a 14 bit accuracy answer ± 1 bit. This is not too bad a performance for the price of half of a 35 cent IC and a capacitor.

The rest of the circuits which I have shown use a digital input in place of the precision comparator of the first example. As a result,

the accuracy of the resistance reading dropped to the 8 bit range. Readings were taken with the Gated Timer Input method and with a 1 byte wide software DJNZ loop. The accuracy between the two techniques was virtually the same, but the speed of the conversion was four times faster with the timer. The timer counts at 1/12 of the microprocessor oscillator frequency. Thus, a full scale reading of 0FFH would take $255 \times (1/12\text{MHz}) \times 12 = 255$ microseconds. The software timer loop consists of a loop formed by JB (24 clock cycles) + DJNZ (24 clock cycles) for an oscillator frequency divided by 48 time for 1 count. The equation for the maximum integration time is then: $255 \times (1/12\text{MHz}) \times 48 = 1.02$ milli-seconds for the software timer.

The first of the digital gate instead of a comparator circuits is shown in Figure 4. Figure 4a shows the implementation of a single channel resistance measuring circuit and Figure 4b shows one possible way to implement a two resistor measuring circuit. The A/D conversion subroutine for Figure 4a is called A2D82.

The timing capacitor is shorted to ground by the open drain digital output of a 74HC05 Hex inverter by making the microcontroller Driver output go to logic 1. Upon the release of the capacitor hold down signal, the other digital gate acts as a high input impedance comparator with a threshold of approximately one half of V_{CC} if it is CMOS or about 1.4 volts if it is HCT. The two resistor version in Figure 4b is run by alternately shorting out the timing capacitor on one side while starting the timer to measure the opposite side. When the wire NORed circuit sees a logic 1 from Vcap exceeding the inverter threshold, the active inverter pulls the Gated Timer Input low to stop the timer. There will be a slight offset error caused by the nonsimultaneity of releasing the capacitor and the start of the gated timer. This offset will be a constant and can be dealt with in the calibration process by subtracting a constant from the answer. Note that the wired NOR circuit is depending on the quasi-bi-directional I/O port pull up resistor inside of the 80C51 type of microcontroller. If the input to the microcontroller is really open drain, it will be necessary to add a pull-up resistor.

This circuit idea can be extended to a 3 channel circuit using the last two inverters in the 74HC05 IC package. The three channel circuit uses four port pins. Likewise, if two ICs are used, 6 channels can be implemented using seven port pins.

AN449

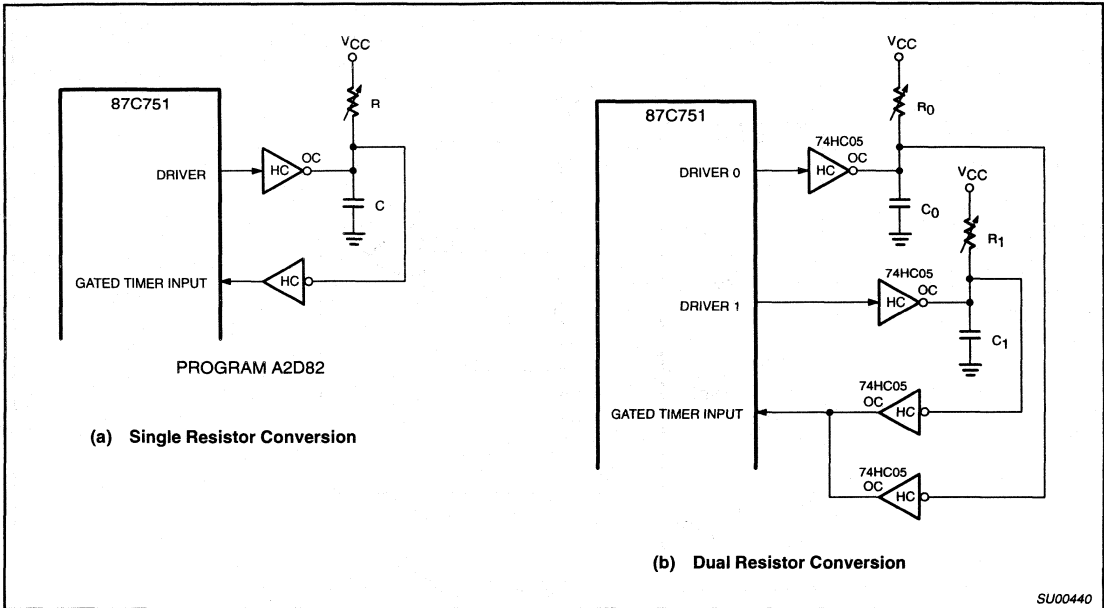

Figure 4.

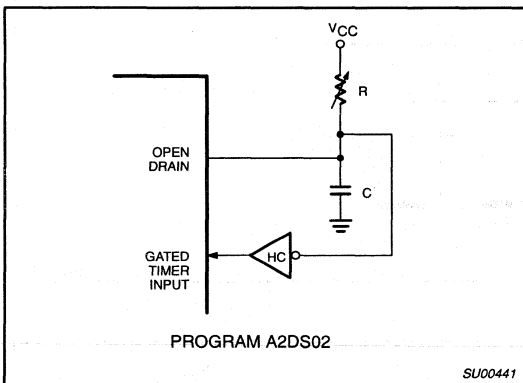

Figure 5.

The previous circuits will work with just about any type of microcontroller port I/O. Some microcontrollers can be programmed to have an open drain output configuration and some port outputs are only available as open drain. Examples of the latter type are port 0 of the 87C51 family and I2C and Vpp pins on some of the 87C51

family derivatives (i.e., SDA, SCL, Vpp on the 87C751). With these open drain outputs, the open drain buffer can be eliminated as shown in Figure 5.

Using this configuration, the open drain output is first set to 0 to discharge the capacitor to ground and then the gated timer is enabled and then the open drain output is programmed to 1 as shown in Program "A2DS02", which is on the Philips BBS. The slight offset error caused by the nonsimultaneity of releasing the capacitor and the start of the gated timer can be dealt with in the calibration process by subtracting a constant from the answer.

Figure 6 is an example of how multiple channels can also be created using the Figure 5 configuration. Since there are 8 open drain outputs on the 87C51 Port 0, it is possible to make an 8 channel resistance reader which uses all of port 0's 8 bits and an additional input for the timer for a total of 9 port pins.

In Figure 6, the timer runs from the release of the capacitor hold down to the detection of a low level on the Software Timer Input port pin. The heavy dark lines labeled "Time" indicate the timing periods for each of the four capacitor timing circuits. The detection of a logic high on the one capacitor which is integrating current causes the Nor gate to go low. The software timer halts when the logic low is detected and then the driver transistor is turned on to discharge the capacitor. As soon as the capacitor voltage goes below the threshold for logic one, the Nor gate returns to a high logic level as shown on the "Input" section of Figure 6.

Measure resistance and capacitance without an A/D

AN449

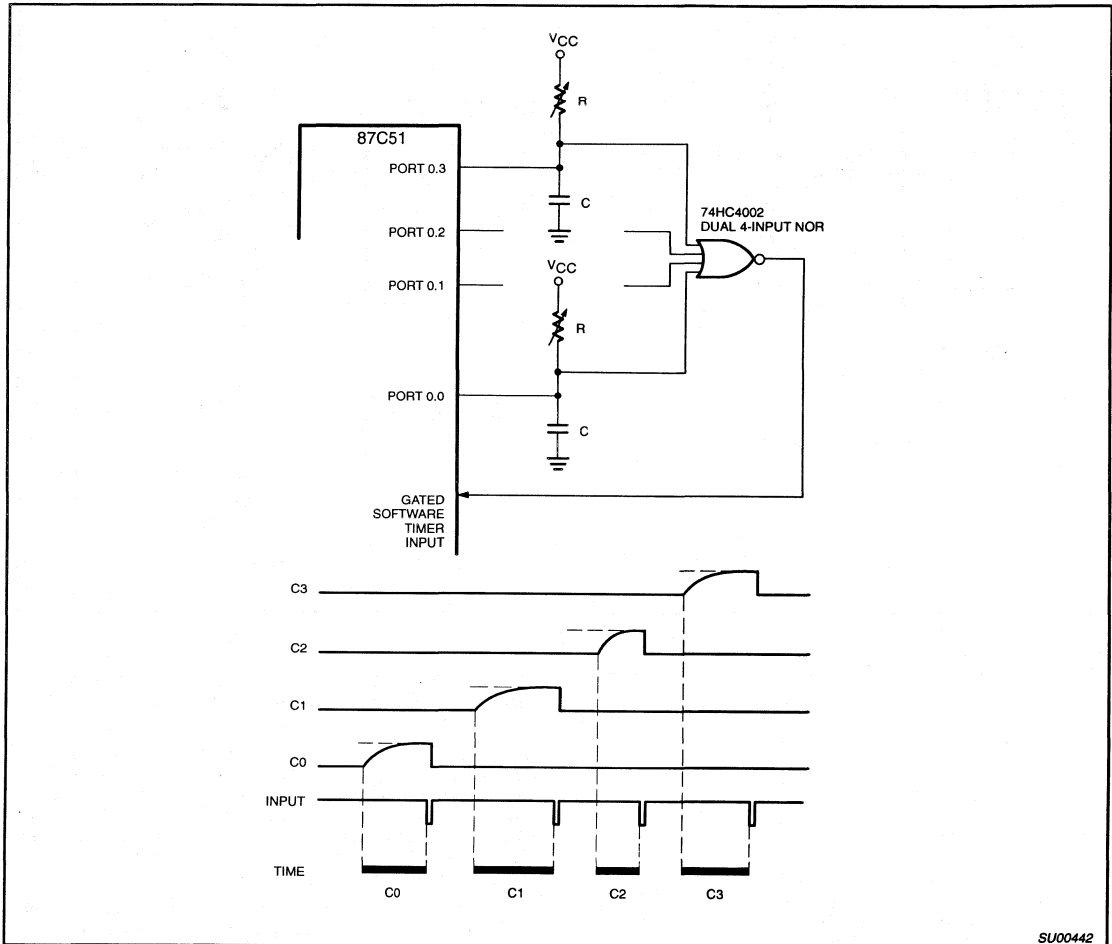

Figure 6.

In Figure 7 we have the simplest embodiment of the RC timer. This configuration will not allow the use of the Gated Timer, since the Gated Timer input pin is not open drain. The software counter technique is used, where a counter is decremented and the input is checked for a logic high (see Figure 8).

When the counter is stopped, the value is inverted to give a count-up appearing output. Ground bounce on the microcontroller caused by the clock distribution is probably the main source of the noise with this configuration. The result is an 8 bit answer, but it is only repeatable to within 5 bits of accuracy.

Figure 9.

Measure resistance and capacitance without an A/D

AN449

Figure 9 operates when a square wave is output by the Driver and then buffered by the 74HC00 to give the waveform shown as B. The falling edge of B will generate the waveform shown in C. The output of the 2 input NAND gate, F, will produce a logic 1 while the input is below the HC threshold voltage of approximately 2.5 volts.

The rising edge of B will be differentiated by the CR circuit and produce the waveform shown in D. The decay back to ground will have the same type of exponential curve as described in the original Figure 2. The decaying waveform, D, is turned into a digital pulse by the inverter's output as the signal, E. Again the two input NAND gate output, F, will go high while the input from E is low.

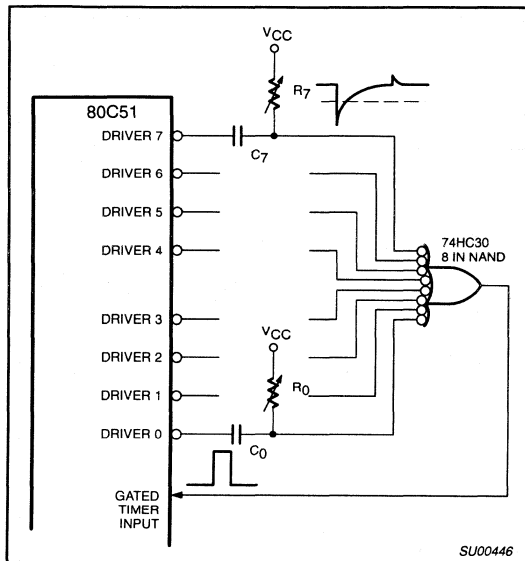

Figure 10.

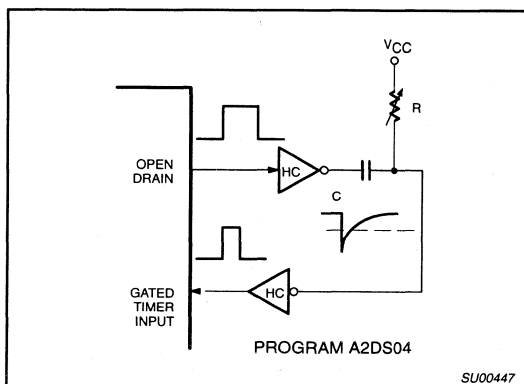

Figure 11.

The constant in the $t = R \times \text{a constant}$ equation will be different for the C waveform than for the D waveform. However, the readings from C and from D will be linearly correct, but the C and D readings can not be compared and must be separately calibrated. The good news is that the 74HC00 is the most common and probably one of the cheapest digital ICs available.

The circuit in Figure 10 uses the strong pull-down drivers of the 80C51 to produce the waveform shown next to R7. Each of the successive drivers is taken low and held there until the 74HC30's output returns to zero, indicating that the input threshold has been exceeded. At this point, the Gated Timer has stopped counting and the results are saved in RAM and the associated driver is returned to a logic one to allow the capacitor to recover. The test circuit for this type of configuration is shown in Figure 11.

In Figure 12, a 10 output Johnson counter is first reset to Q0 by a long pulse from the driver, and then a sequence of "short" pulses activates the successive RCs. The time that the output of the Johnson counter is high is used to precharge the capacitor, and the "short" pulse must be long enough to allow for the voltage to settle to less than 1 LSB below V_{CC} . When the counter increments, the previously high output falls to zero and produces the waveform shown on the "Cx" section. While the voltage on the capacitor is less than the threshold of the 74HC30, it will be perceived as a digital logic low. The NAND gate will produce a pulse as long as one of the inputs is "low". Again, the gated timer input will allow the counter to run as long as the 74HC30 output is high, and then save the 16 bit results in RAM and proceed to generating the next "short" pulse from the driver. Note that the $R_R C_R$ time constant should be at least three times as long as the longest $R_X C_X$ time to insure that the Reset threshold is not exceeded.

The circuit in Figure 13 uses a 74HC138 3 to 8 line decoder to produce the negative going edges to turn on the 74HC30 8 in NAND gate. This circuit will do conversions faster than the Figure 12 Johnson Counter, because the capacitor precharging occurs while the 7 other RCs are being read. The not selected outputs of the decoder are at logic one and will precharge the capacitors. When an output is selected by the three Address inputs, A0, A1, and A2, the selected output will go to a logic zero and start the timing sequence with the gated timer input. Note that a sufficient time must be allowed for the capacitor to precharge to less than 1 LSB, ($V_{CC} - V_{CC}/255$), before the output is selected again.

The circuit in Figure 14 is another way of producing a one-shot. The timer is run from the time that the Driver is set to a logic 0 and the time that the Gated Timer Input goes low.

TEST RESULTS

The accuracy of the readings seemed to depend on the accuracy of the detection of the threshold voltage. The circuit in Figure 3 which used a comparator allowed readings to 3 sigma of 14 ± 1 bit. The circuits which used digital logic gates to detect the threshold voltage, produced readings which were accurate to $8 \pm 1/4$ bit. For these circuits the results were of the same accuracy whether a software or the internal hardware timer was used. Finally, using the microcontroller's Port pin as the digital threshold detection device, shown in Figure 7, could only produce 8 ± 3 bit answers. As bad as this is, it can still provide useful inputs if truncated to 5 bits and used as a Joy Stick type input.

In-circuit programming of the Philips 87C576 microcontroller

AN455

Author: Bill Houghton

Introduction

The 87C576 includes *two* separate methods of programming the EPROM array, the traditional modified Quick-Pulse method, and a new On-Board Programming technique (OBP).

Quick Pulse programming is a method using a number of device pins in parallel (see Figure 1) and is the traditional way in which 87C51 family members have been programmed. The Quick-Pulse method supports the following programming functions:

- program USER EPROM
- verify USER EPROM
- program KEY EPROM
- program security bits
- verify security bits
- read signature bytes

The Quick-Pulse method is quite easily suited to standard programming equipment as evidenced by the numerous vendors of 87C51 compatible programmers on the market today. One disadvantage is that this method is not well suited to programming in the embedded application because of the large number of signal lines that must be isolated from the application. In addition, parallel signals from a programmer would need to be cabled to the application's circuit board, or the application circuit board would need to have logic built-in to perform the programming functions. These requirements have generally made in-circuit programming using the modified Quick Pulse method impractical in almost all 87C51 family applications.

On-Board Programming (OBP)

The Philips On-Board Programming (OBP) facility has made in-circuit programming in an embedded application possible with a minimum of additional expense in components and circuit board area. The OBP function uses three pins in addition to V_{CC} and V_{SS} (see Figure 2). The diode shown is added so that in the absence of the five pin connector the V_{PP} pin will be pulled up above the V_{IH} level in normal system operation allowing the 87C576 to execute from internal code memory.

The On-Board Programming facility consists of a series of internal hardware resources coupled with internal firmware to facilitate remote programming of the 87C576 through the serial port. This firmware is provided by Philips and embedded within each 87C576 device. The On-Board Programming facility supports the following programming functions:

- program USER EPROM
- display USER EPROM
- program security bits
- verify security bits
- specify timing parameters

The OBP function is invoked by having the EAV_{PP} pin at the V_{PP} voltage level at the time that the part exits reset. The OBP function uses five pins (TxD, RxD, V_{SS} , V_{CC} , and V_{PP}). Only a small connector needs to be available to interface your application to an external circuit in order to use this feature. The V_{PP} supply should be adequately decoupled and V_{PP} not allowed to exceed datasheet limits.

Using the On-Board Programming (OBP)

The OBP feature allows for a wide range of baud rates to be used in your application, independent of the oscillator frequency. It is also

adaptable to a wide range of oscillator frequencies. This is accomplished by measuring the bit-time of a single bit in a received character. This information is then used to program the baud rate in terms of timer counts based on the oscillator frequency. The OBP feature requires that an initial character (an uppercase U) be sent to the 87C576 to establish the baud rate. The OBP firmware provides auto-echo of received characters.

Once baud rate initialization has been performed, the OBP firmware will only accept Intel Hex-type records. Intel Hex records consist of ASCII characters used to represent hexadecimal values and are summarized below:

```
:NNAAARRDD.DDCC<crlf>
```

In the Intel Hex record, the "NN" represents the number of data bytes in the record. The "AAAA" string represents the address of the first byte in the record. If there are zero bytes in the record this field is often set to 0000. The "RR" string indicates the record type. A record type of "00" is a data record. A record type of "01" indicates the end-of-file mark (Intel Hex records were once used to load microprocessor programs from a paper tape, hence the need for an end-of-file marker). In this application additional record types will be added to indicate either commands or data for the OBP facility. The maximum number of data bytes in a record is limited to 16 (decimal). OBP commands are summarized in Table 1.

As a record is received by the 87C576 the information in the record is stored internally and a checksum calculation is performed. The operation indicated by the record type is not performed until the entire record has been received. Should an error occur in the checksum, the 87C576 will send an "X" out the serial port indicating a checksum error. If the checksum calculation is found to match the checksum in the record then the command will be executed. In most cases successful reception of the record will be indicated by transmitting a "." character out the serial port (displaying the contents of the internal program memory is an exception).

In the case of a Data Record (record type 00) an additional check is made. A "." character will NOT be sent unless the record checksum matched the calculated checksum and all of the bytes in the record were successfully programmed. For a data record an "X" indicates that the checksum failed to match and an "R" character indicates that one of the bytes did not properly program. It is necessary to send a type 02 record (specify timing parameters) to the 87C576 before programming data or security bits.

Programming requires two delay times for the 87C576. A 50 μ S programming pulse needs to be generated along with a 10 μ S minimum delay between pulses. The OBP facility was designed so that specific crystal frequencies were not required in order to generate baud rates or time the programming pulses. The user thus needs to provide the 87C576 with information required to generate the proper timing. Record type 02 is provided for this purpose. This function uses timer 0 of the 87C576. Thus the times are specified in terms of the timer 0 reload values necessary to produce the required time periods based on the oscillator frequency in the application.

$$50\mu\text{S timer value} = -\text{FOSC} * 50/12$$

$$10\mu\text{S timer value} = -\text{FOSC} * 10/12$$

The two security bits can be programmed using the 03 record type. The record length is one data byte. Bit 0 corresponds to security bit 0 and bit 1 corresponds to security bit 1. A logical one in either bit position indicates that the particular security bit is to be programmed. Either zero, one, or two bits may be specified.

In-circuit programming of the Philips 87C576 microcontroller

AN455

Table 1.

RECORD TYPE	COMMAND/DATA FUNCTION
00	Indicates a data record. Programs the part with data indicated in the record starting with load address in the record.
01	EOF record, no operation
02	Specify timing parameters. The record length is 3 bytes. load address = xxxx 1st byte = timer count for 50uS programming pulse 2nd byte = timer count for 10uS delay between pulses 3rd byte = 0AH
03	Program security bits The record length is 1 byte. load address = xxxx 1st byte = sec bit values (xxxx xxB2B1)
04	Display contents of USER EPROM array The record length is zero (no data bytes are in this record). load address =xxxx
05	Verify security bit status The record length is zero (no data bytes are in this record). load address =xxxx

Record type 04 causes the contents of the entire 8Kbyte EPROM array to be sent out the serial port in a formatted display. This display consists of an address and the contents of 16 bytes starting with that address. No display of the device contents will occur if security bit 2 has been programmed. Instead an "S" character will be sent to indicate a security violation. The dumping of the device data to the serial port is terminated by the reception of any character.

The status of security bits can be verified using a record type of 05. Two characters are sent out the serial port representing a byte quantity. Bits 1 and 2 of this byte represent security bits 1 & 2, respectively, where a logical one means the security bit has not been programmed.

Some examples of Intel-Hex records used with On-Board Programming are shown below:

```
:03000002CEF60A2D <set timing parameters for 12MHz osc>
:03000000010203F7 <program data = 01,02,03>
:0100000301FB <program security bits 1>
:00000004FC <display contents of EPROM>
```

Using Your PC as an OBP Programmer

While the process of using OBP is relatively simple, a PC can be used to simplify the procedure. The PC can calculate the timing parameters based on your oscillator frequency, perform the baud rate initialization, perform file downloading/programming, and translate the EPROM contents display into a blank-check feature. At the time of this writing, a DOS-based version of such a program is available from the Philips Microcontroller Bulletin Board (1-800-451-6644). An OBP demo board for the 87C576 is available for qualified customers through your local Philips sales office or representative.

SU00616

Using LC oscillator circuits with Philips microcontrollers

AN456

Author: William Houghton

There are two basic types of LC oscillators, Colpits and Hartley. The Colpits is the two capacitor type shown in Figure 1. It is generally favored over the Hartley (shown in Figure 2). This is because of the simplicity of requiring only one inductor, which are generally more expensive and difficult to obtain than capacitors C2 and C1. Feedback is determined by the ratio of C2 and C1 (for our application, this is approximately 2:1). The center frequency for Figure 1 is given by:

$$f = \frac{\sqrt{(1/L_1) (1/C1 + 1/C2)}}{2\pi}$$

Figure 1. Colpits Oscillator

Figure 2. Hartley Oscillator

Table 1 contains measured frequencies for various combinations of inductor and capacitor values. The test circuit (Figure 1) was a Philips P87C750PBPN, using the internal inverting amplifier. The results compare well with the frequency predicted by the above formula at low frequencies. At higher frequencies, however, the gain of the amplifier becomes a significant factor, as do the internal capacitances of the device. The inductor identified as 10T0.16 is an air core coil 10 turns on a 0.16 diameter form using 26 gauge magnet wire close wound.

The inductors used in this test were TOKO types 5K, 5PH, 5P 5mm coils (adjustable ±5%). If the frequency is not critical, then a fixed inductor would be suitable. TOKO produces a range of inductors from 1µH to 1mH in the 144LY series. These are available from Digi-Key.

Using LC oscillator circuits with Philips microcontrollers

AN456

TEMPERATURE COMPENSATION

Using a 6.8μH inductor, 47p and 100p capacitors gives a frequency of approximately 10MHz at room temperature. As the temperature changes, so do the values of both the capacitors and inductor. There is also an effect with the microcontrollers changing gain, however, this is small compared with the capacitors and inductor. This variation is shown in Figure 3. These results were obtained using NPO capacitors. NPO capacitors are zero temperature coefficient (nominally). Also available are other temperature coefficients (see Table 2). By trial and error we can pick one of these temperature coefficients which will compensate for the inductor. Just about all inductors have a positive temperature coefficient. Using an N750 for the capacitors C1 and C2, the following results were obtained (Figure 4). This a large improvement on the uncompensated design.

Figure 3. Frequency Variation Using NPO Capacitors

Figure 4. Frequency Variation Using N750 Capacitors

AIR WOUND INDUCTORS

The most expedient source of inductors are air wound (wind them yourself). Although probably not suitable for production, these offer the designer an infinite variation of inductance values. The table below gives a few useful values for use in microcontroller oscillators.

NUMBER OF TURNS (T)	INDUCTANCE (μH)	OSCILLATOR FREQUENCY (MHz) (with C1 = 47p; C2 = 100p)
10	0.3	47
15	0.68	32
20	1	27
25	1.5	23
30	1.8	21

All were close-wound with 26 gauge magnet wire on a 0.19" diameter form. Greater than 30 turns requires a permanent form.

START UP

Although an LC oscillator will start much quicker than a crystal oscillator after power is applied, this effect is not apparent in this application. Although the Q expressed as rate of change in impedance versus frequency of a crystal is very high, the losses can be quite large (resistive). This can lead to starting problems (given a low gain amplifier). With an LC oscillator the losses are much lower than with a crystal, thus the LC oscillator will start more reliably than a crystal oscillator.

SUPPLY VOLTAGE EFFECTS

Figure 5 depicts a Supply Voltage versus oscillator frequency graph for the test circuit shown in Figure 1, using C1 = 47p, C2 = 100p and L1 = 6.8μH.

Figure 5. Supply Voltage vs. Frequency

80C51 External Memory Interfacing

AN457

INTRODUCTION

The '51 family is arguably the most popular 8-bit embedded controller lineup thanks to efficient yet powerful architecture, multi-sourcing by the world's top semiconductor companies and unprecedented third-party tool support. A byproduct of the chip's popularity is a lot of technical know-how embodied in legions of experienced system designers and software programmers.

However, since the chips continue to attract new applications and customers, it shouldn't be taken for granted that 'everyone' already knows how to design it in. Evidence to the contrary is the fact that many of the FAQs (Frequently Asked Questions) continue to be frequently asked.

This application note is written to assist those designers new to the '51 family who typically fit into one or more of the following categories:

- Designers of extremely cost conscious systems that could previously only afford discrete logic or 4-bit solutions now upgrading their designs with superior price/performance and easier to program 8-bit microprocessors.
- Designers that previously used different micros and are now switching to the '51 family.
- New designers, most of whom were quite young at the time of the '51 introduction when design techniques were actively disseminated.

In addition, even experienced designers might find it useful to review this application note, since many of the traditional design techniques and 'conventional wisdom' have been superseded by faster CPUs and memories, changing timing specifications and more sophisticated application requirements. Indeed, those who have simply done it the way somebody else did it before are advised to confirm the validity of their design assumptions.

The application note starts with a basic description of the '51 family memory organization and expansion bus characteristics. Since all the technical details are completely documented in the data sheet and other application notes (see the references section at the end), this section simply highlights the basic operation and timing considerations.

Next, the operation and characteristics of the most often used memories – specifically JEDEC standard byte-wide EPROMs and SRAMs – are described. Specifications are presented for a variety of actual memories.

Having described the CPU and memories, timing analysis is performed for a typical system configuration. The goal of this section is to illustrate how to answer one of the most frequently asked FAQs – "What speed memory should I use with my xxMHz CPU?".

'51 FAMILY MEMORY ORGANIZATION

Though dozens of derivatives, are offered, all '51 family members share a common memory architecture and similar expansion bus. For this application note, the 80C31/8XC51 (Figure 1) will be used. The only difference between these two devices is that the 80C31 has no on-chip instruction memory while the 8XC51 has 4KB of ROM (80C51) or EPROM (87C51) instruction memory on-chip. The entire range of '51 family derivatives encompasses devices with 0KB (80C31) to 64KB (8XC560) of on-chip instruction memory of various types including ROM, EPROM (window package), OTP (One Time Programmable), and even EEPROM.

A primary characteristic is that the '51 is logically a 'Harvard' machine referring to an organization consisting of separate instruction and data buses. One key byproduct is that the '51 family offers twice the memory expandability (64KB each of code and data) compared to most other 8-bit micros (typically 64KB total).

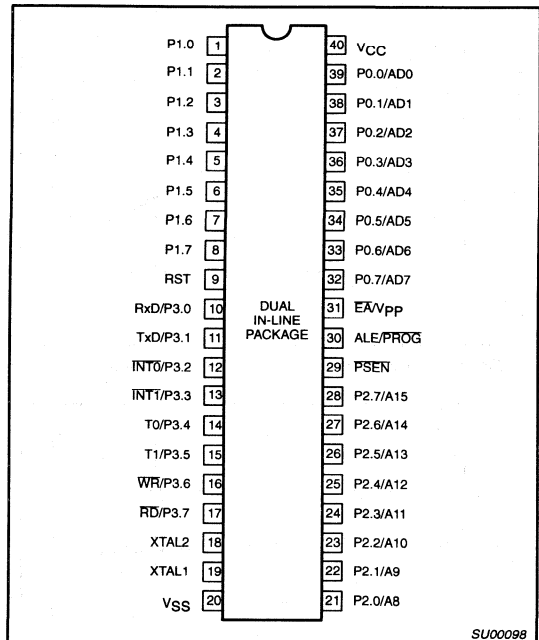

Figure 1. 80C31/8XC51 Pinout

SU00098

80C51 External Memory Interfacing

AN457

As shown in Figure 2, the CPU operates in one of two modes determined at reset (RST pin) by the state of the \overline{EA} (External Access) pin. If \overline{EA} is asserted, on-chip instruction (but not data) memory is disabled and the entire 64KB of instruction space is accessed externally (this is the only option for the 80C31). Otherwise (\overline{EA} deasserted), on-chip instruction memory is enabled and only addresses beyond the end of on-chip instruction memory (i.e., $\geq 1000H$ for the 8XC51) are accessible externally.

The situation for on-chip data memory (i.e., RAM) is somewhat different. First, all '51 family devices include a basic complement of on-chip RAM comprised of CPU register banks, SFRs (Special Function Registers, i.e., built-in I/O functions such as UART, timer, etc.) and general purpose RAM. The on-chip data memory for the 80C31/8XC51 is shown in Figures 3 and 4. By convention, which is

used in this application note, a CPU said to have 'xx' bytes of RAM (which varies from 64 bytes to 1.5 KB across the '51 family) actually contains 'xx' bytes of 'general purpose RAM' in addition to the space (128 bytes) allocated to SFRs.

Unlike instruction memory, the state of the \overline{EA} pin at reset doesn't affect on-chip data RAM which is always enabled and accessible. Another difference is related to the way the presence of on-chip RAM affects the external data memory space. For CPUs with up to 256 bytes of on-chip RAM, the full 64KB external data space is available. Devices with more than 256 bytes of RAM map the excess portion (i.e., 768 bytes for a CPU with 1K bytes of RAM) to the bottom of the external address space (Figure 5). In this case, an SFR bit (ARD – Auxillary RAM Disable) determines whether the accesses to the lower space are on- or off-chip.

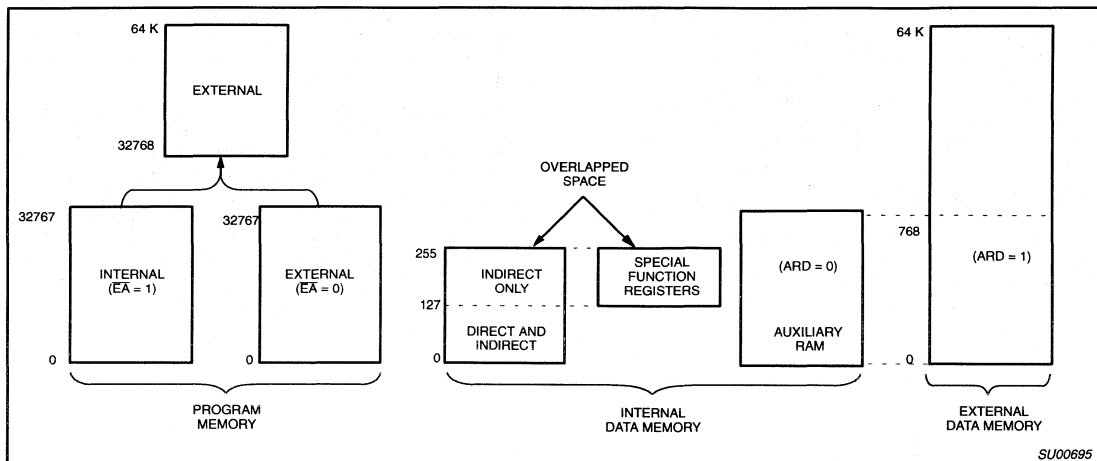

Figure 5. On-chip RAM Memory Map > 256 Bytes

80C31/8XC51 EXPANSION BUS INTERFACE

'51 family devices with 40 or more pins generally feature four I/O ports (P0–P3). P0, P2 and a portion of P3 (two pins, \overline{RD} and \overline{WR}), along with dedicated ALE (Address Latch Enable) and \overline{PSEN} (Program Store Enable) pins, comprise the expansion bus interface.

P0.0–P0.7

For both program and data access, P0 is used as a multiplexed address/data bus (AD0–7) that outputs the low order address bits (A0–A7) and inputs/outputs the 8-bit data (D0–D7). Note that P0 is open collector, so pull-up resistors are typically required when interfacing to external memory or I/O chips.

P2.0–P2.7

For all external program accesses, P2 outputs the high order address bits (A8–A15). The same is true for external data accesses with 16-bit addresses (MOVX A, @DPTR and MOVX @DPTR, A). However, external data accesses with 8-bit addresses (MOVX A, @Ri and MOVX @Ri, A) do not affect P2.

ALE (Address Latch Enable)

ALE is used to demultiplex the AD0–7 bus. At the beginning of the external cycle ALE is high and the CPU emits A0–A7 which should be externally latched when ALE goes low. Note that ALE is always active, even during internal program and data accesses.

 \overline{PSEN} (Program Store Enable)

\overline{PSEN} is the read strobe for external instruction access. Unlike ALE, \overline{PSEN} is not asserted during internal accesses.

 \overline{RD} (Data Read)

\overline{RD} is the read strobe for external data access and (like \overline{PSEN}) is not asserted during internal accesses.

 \overline{WR} (Data Write)

\overline{WR} is the write strobe for external data access and (like \overline{PSEN} and \overline{RD}) is not asserted during internal accesses.

Thus, there are three types of external access – instruction read (\overline{PSEN}), data read (\overline{RD}) and data write (\overline{WR}) as shown in Figures 6, 7, and 8.

From this brief description, a number of system design implications can be drawn.

ALE is essentially a continuous clock that runs at 1/6 the oscillator frequency regardless of the mix of internal and external accesses. However, note that one ALE cycle is skipped during external data access.

The skipping of the ALE cycle and assertion of \overline{RD} or \overline{WR} only occur during external data access. The MOVX instruction, and only the MOVX instruction, performs external data access. Thus, if the program contains no MOVX instructions, ALE can be used as a timebase (i.e., no skipping) and \overline{RD} and \overline{WR} as general purpose outputs.

External program reads (\overline{PSEN}), whatever the address or cause (i.e., fetch beyond the end of internal instruction memory or EA pin asserted at reset) always use 16-bit addresses and thus require all pins of P0 and P2. [P0 & P2 can be used for general purpose I/O during non- \overline{PSEN} times? P0 SFR is overwritten by \overline{PSEN} but what about P2?]

External data accesses affect on P0 and P2 is a little more complicated. 16-bit address accesses (MOVX using DPTR) always drive P0 and P2 with A0–A15. However, 8-bit address accesses (MOVX using Ri) instead drive P2 with the value programmed into the P2 SFR, i.e., P2 is essentially general purpose I/O during an 8-bit address external data access.

However, while the P0 SFR is overwritten by any external data access, the P2 SFR is only modified temporarily for the duration of a 16-bit address (DPTR) access. Subsequently, the P2 SFR is restored to whatever value it contained prior to the external data access.

80C51 External Memory Interfacing

AN457

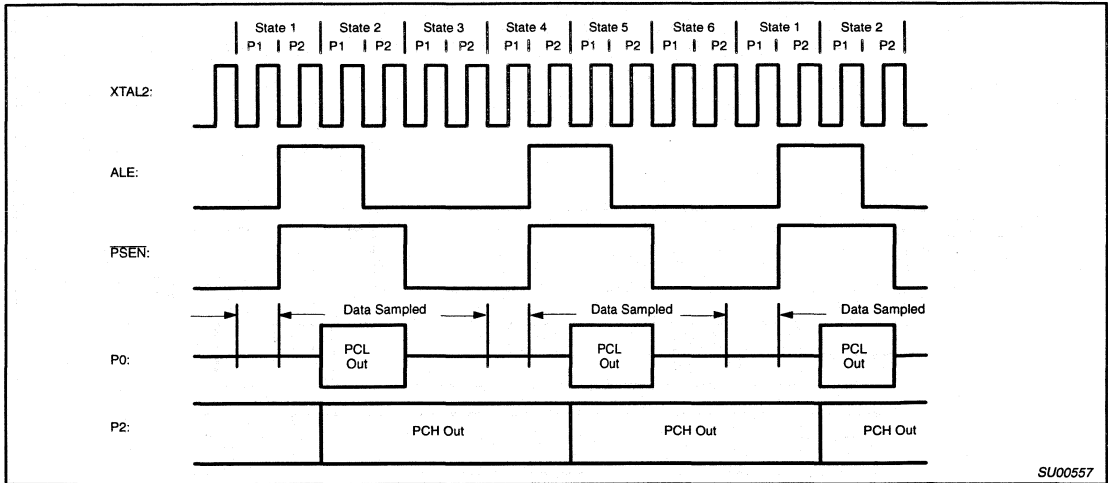

Figure 6. External Program Memory Fetches

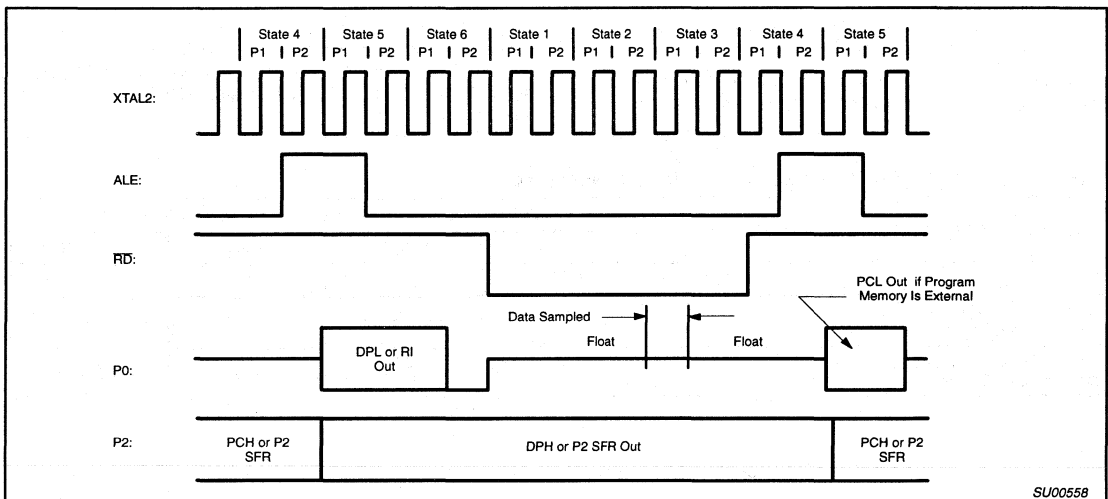

Figure 7. External Data Memory Read Cycle

80C51 External Memory Interfacing

AN457

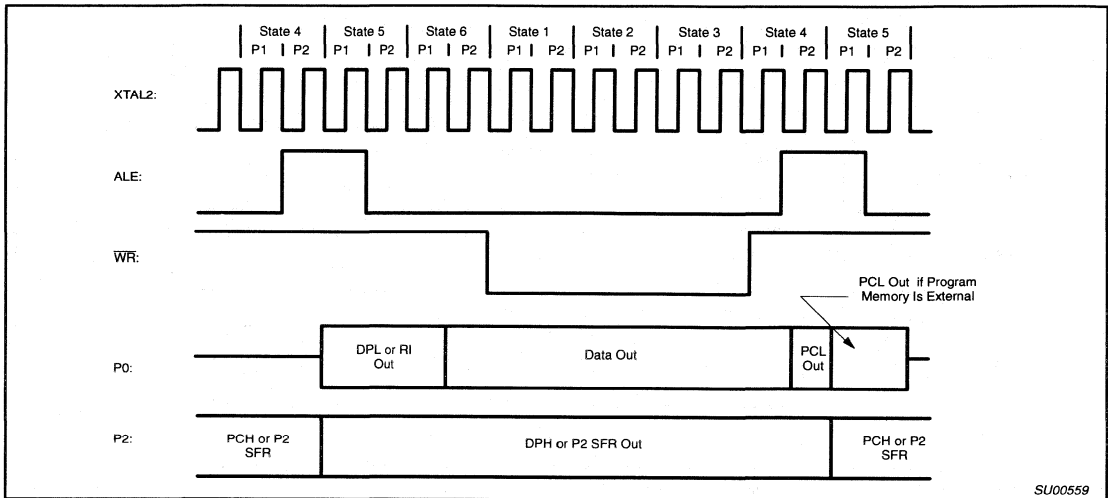

Figure 8. External Data Memory Write Cycle

Table 1 summarizes the usage and modification of the P0 and P2 SFRs depending on the cycle type.

Exploiting this information, system designers can make optimal use of all pins depending on the system configuration. For instance,

systems that make no external program accesses and only 8-bit address external data accesses are free to use P2 for general purpose I/O. Just remember that CPUs with more than 256 bytes of on-chip RAM must use 16-bit addresses (DPTR) to perform external data access.

Table 1. P0 and P2 SFR Usage During External Memory Access

EXTERNAL ACCESS TYPE	DURING ACCESS		AFTER ACCESS	
	P0 SFR	P2 SFR	P0 SFR	P2 SFR
Instruction Access	0FFH	0FFH	0FFH	0FFH
Data Access – 8-bit Address (MOVX using Ri)	0FFH	Prev. Value	0FFH	Prev. Value
Data Access – 16-bit Address (MOVX using DPTR)	0FFH	0FFH	0FFH	Prev. Value

80C51 External Memory Interfacing

AN457

EPROMs

Before continuing, it should be pointed out that the original reason the '51 supported external code – limited ROM-only on-chip space – is hardly applicable today. Windowed EPROM-based CPUs appeared long ago and recently low-cost no-window OTP EPROM devices have become quite popular. Now, even EEPROM-based devices are starting to appear. As for capacity, Philips currently offers derivatives with up to 64KB of on-chip memory including EPROM (windowed and OTP) and ROM.

That being said, there are still situations calling for external code memory. Systems requiring relatively high capacity, say 32KB–64KB and beyond, may still be best served by external EPROM, though the advantage will continue to wane. Conversely, due to the dynamics of the memory market in which 'old' devices quickly become non-price competitive, low-capacity applications (say 1KB–16KB) are, even without considering the intrinsic advantages of single-chip form factor, arguably best served with on-chip memory.

Using external EPROM can be appropriate when an existing design is simply being upgraded to higher speed without PCB change. Also, certain products such as 'general-purpose' single-board computers need external memory since different code will be programmed by each customer. Along the same lines, 'Rev.0' products may use external EPROM until the code stabilizes, after which the design can migrate to a single-chip. Finally, some applications, such as handheld translators or dictionaries, call for large capacity (EP)ROMs.

The JEDEC (Joint Electron Devices Engineering Council – an international standards body) standard defines the pinout applied to a number of memory technologies including ROM, EPROM, bulk- and byte-erasable EEPROM, etc. However, though the general function is well-defined, detailed timing specifications are left to each manufacturer and may differ slightly. Figure 9 shows the pinout, Figure 10 shows the block diagram, and Table 2 shows the truth table of a 512k bit (64KB) EPROM organized as 64Kx8.

The bulk of the functionality is defined by the sixteen address lines A0–A15 that select a byte for output on the eight data lines O0–O7. Only two control lines are necessary – Chip Enable (CE) and Output Enable (OE). Notice that deasserting CE places the EPROM in 'standby' mode, consuming typically 1/2 to 1/3 the active (CE asserted) power. Also, observe that both CE and OE must be asserted to enable the data output drivers.

Referring to the timing diagram (Figure 11) shows that operation of the EPROM is quite simple, typically characterized by only a few specifications.

The first, t_{AA} , defines the maximum time after the address stabilizes that the EPROM will return valid data. This parameter is commonly referred to as the 'access time' of the device.

Similarly, t_{CE} defines the maximum time after the CE input is asserted that the EPROM will return data. This spec is typically, though not always, the same as t_{AA} .

t_{OE} defines the maximum time from OE assertion to valid data output much like t_{CE} . However, because OE only enables the output drivers as opposed to powering up the device, t_{OE} is typically much less than t_{CE} .

Having delivered the data, the remaining two specs deal with what happens at the end of the cycle, i.e., following the deassertion of either CE or OE (remember, both are required to enable the output). t_{OH} indicates the minimum time the data is guaranteed to remain

valid after CE/OE deassertion. The other side of the coin, t_{DF} , defines the maximum time after which the output is guaranteed to completely float.

Table 3 shows the specifications for 70ns EPROMs from two different suppliers. Comparing the difference in specs highlights the point that not all 'xx' nanosecond EPROMs are created equal. Notice the significant difference in output enable (t_{OE}) and float (t_{DF}) times as well as t_{CE}/t_{OE} ratios.

Further, notable differences can be observed even within a single suppliers product line. Table 4 shows a spectrum of EPROMs comprised of high-speed selections from one supplier and low-speed selections from another.

For the high-speed supplier, notice how t_{AA} and t_{CE} are equal (as expected) down to 35ns but then start to diverge. This points out the need for careful spec review since many designers might presume a t_{CE} of 35ns implies a 35ns, not 30ns, 'access time'. Also, except for t_{AA} itself, none of the timings change in a 'linear' way across speed ranges. For instance t_{CE} gets 'stuck' at 35ns for both the –35 and –30 parts while both t_{OE} and t_{DF} plateau at 18ns for the –45, –35 and –30 selections. A byproduct is that key ratios (ex: t_{AA}/t_{OE} , t_{AA}/t_{CE} , t_{OE}/t_{CE} , etc.) vary for practically every part. For example, the t_{AA}/t_{OE} ratio for the –70 part is almost 3:1 (70ns/25ns) while it's less than 2:1 (30ns/18ns) for the –30.

On the other hand, the low-speed supplier specs extrapolate from speed-grade to speed-grade in a more consistent and intuitive way. For instance t_{AA} always equals t_{CE} and the variance of timing ratios between speed-grades is reduced.

AN457

SRAMs

Compared to EPROMs, SRAMs are less subject to competition from ever higher integrated CPUs. Across the entire Philips '51 family the largest on-chip RAM offered is 2KB, with the majority of CPUs featuring only 64–512 bytes. Thus an application that requires 2KB–64KB or more of data definitely calls for external SRAM. SRAM is also useful as instruction memory in those applications (such as a PC-plug in) that exploit 'downloadable' code to vary their functionality at runtime.

Figure 12 shows the pinout, Figure 13 shows the block diagram, and Table 5 shows the truth table for a 256k bit (32K bytes) SRAM organized as 32Kx8. Reflecting JEDEC standardization, the pinout and functionality is nearly the same as EPROMs, the major difference being addition of a WE (Write Enable) line. Once again, CE is responsible for controlling power consumption and OE simply enables the output reflected in the t_{CE}/t_{OE} differential. For all practical purposes, an SRAM is little distinguishable from an EPROM as far as reads are concerned.

AN457

Figure 14 shows the read cycle timing for an 85ns SRAM which is quite similar to that of an EPROM. Depending on the supplier, the naming of certain specs may be slightly different, but for ease of comparison this application note translates to a common nomenclature. This SRAM (as do some EPROMS), defines separate \overline{CE} and \overline{OE} data float specs (t_{CHZ} , t_{OHZ}) instead of a single t_{DF} . Since the SRAM (unlike the EPROM) can be written, it also specifies the other side of the data float coin (i.e., enable to output driven) with t_{CLZ} and t_{OLZ} .

Now let's examine how \overline{WE} factors into the SRAM operation. When \overline{WE} is asserted, the SRAMs output buffers are disabled while the input buffers are enabled to receive data.

Figure 15 shows the write cycle timing which is slightly more complicated than reads. Write time (t_{WP}) is defined as the time during which both \overline{CE} and \overline{WE} are asserted. Thus, various setup and hold timings that are specified relative to the 'end' of the write cycle (such as t_{DW} , t_{DH} , t_{WR} , etc.) should refer to whichever signal (\overline{CE} or \overline{WE}) terminates first.

t_{WC} simply defines the write cycle time which, along with t_{RC} , is the same as the 'access time', i.e., 85ns. This is in contrast to other types of memory (notably DRAMs) in which the cycle time may be longer than the access time due to 'precharge' delay.

t_{CW} and t_{AW} specify the minimum time from valid \overline{CE} and address inputs to the end of the write cycle (\overline{CE} or \overline{WE} high, whichever comes first). They are the write cycle corollary to the read cycles t_{CE} and t_{AA} specs and in this (the usual, but not always as we saw for EPROMs) case are the same. The SRAM also defines an address setup to the beginning of the write cycle (t_{AS}).

t_{WP} simply specifies the minimum write pulse (the overlap of \overline{CE} and \overline{WE}) width. t_{WR} specifies a minimum write 'recovery' time, essentially an address hold time after the end of write. This SRAM specs t_{WR} at 10ns minimum, but many SRAMs need no address hold (i.e., $t_{WR}=0$ ns minimum) should the spec prove troublesome. Remember, the 'end' of the write cycle is defined as the earlier of \overline{CE} or \overline{WE} deassertion.

t_{DW} and t_{DH} specify the input data setup and hold times relative to the end of write. Finally, t_{OHZ} reappears as a reminder that a write cycle shouldn't drive the bus until previous read data disappears to avoid bus contention.

There's no need to repeat the previous EPROM spec comparison exercise to emphasize that various suppliers of SRAMs may exhibit subtle, but possibly critical, timing differences.

Figure 15. 256KB SRAM Write Cycle Timing Diagram

80C31/8XC51 – 33MHz INTERFACE EXAMPLE

One major contributor to the longevity of the '51 family is that Philips has continued to upgrade the maximum clock rate. In the case of the 80C31/8XC51, speed selections up to 33MHz are available. Boosting performance to nearly 3 MIPS (≈ 360 ns instruction cycle) offers an easy upgrade path for existing designs as well as enabling new ones.

Of course, higher performance is only possible with faster memories. Fortunately, thanks largely to the 'need for speed' on desktop PCs, memory suppliers have responded to the call.

Let's perform a detailed analysis of an example 33MHz design, pointing out the useful tips, and possible traps, along the way. Note that, like memories, individual members of the '51 family may exhibit slightly different specs. However, the principles and techniques explained in this application note are generally applicable for any CPU at any clock rate.

Table 6, reproduced from the data sheet for convenience, details the timing specification for each of the three external bus cycle types – instruction read (PSEN), data read (RD) and data write (WR). Rather than explain every spec up front, let's simply propose and evaluate a design to focus on the relevant, and possibly critical, timing parameters.

First of all, since the CPU is available in many speed grades, notice that most specs are stated in terms of t_{CLCL} , i.e., the clock cycle. For a 33MHz part, t_{CLCL} is 30.3ns. To ease calculations, this can be rounded to 30ns with the caveat final timing should be confirmed, especially if a marginal situation arises. Observing that the maximum t_{CLCL} multiplication factor shown on the datasheet is 9 (t_{ADV}), watch out for margins of ≈ 3 ns (i.e., 9×0.3 ns = 2.7ns) or less when approximating.

t _{CLCX}	19	Low time	12		ns
t _{CLCH}	19	Rise time		20	ns
t _{CHCL}	19	Fall time		20	ns

NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- For all Philips North America speed versions only.
- Interfacing the 80C31/51 to devices with float times up to 50ns is permitted. This limited bus contention will not cause damage to port 0 drivers.

80C51 External Memory Interfacing

AN457

EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE

- P – PSEN
- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

Examples: t_{AVLL} = Time for address valid to ALE low.
 t_{LLPL} = Time for ALE low to PSEN low.

EPROM INTERFACE

Let's start with the 'classic' circuit shown in Figure 20 that uses a transparent latch to demultiplex the address/data bus AD0-7 (P0). The latch, (a '573 which combines the function of the well-known '373 with an easy to layout 'broadside' pinout) shown in Figure 21, is controlled with two pins – E (Enable) and OE (Output Enable). It's called transparent because as soon as E is asserted, the inputs will begin to flow to the outputs and are subsequently latched on the trailing edge of E. This is exactly the behavior called for to demultiplex the CPU AD0-7 bus (P0) with the ALE output from the CPU. Usually, OE is simply connected to ground enabling the output at all times.

Now is a good time to say a few words about 'glue' logic like the '573. Based on the previous memory spec comparison, it should be no surprise that all glue logic, including latches, buffers, decoders, etc. not to mention PLDs, is not created equal.

For instance, as shown in Table 7, there are a myriad of 'TTL' variants – HC, HCT, LS, ALS, AS, FAST, etc. – covering a rather broad (=5:1) range of speed and power. The important point to note is that these absolutely small differences and delays were easier to ignore in yesterdays slow speed designs, but can become critical as the CPU clock rate increases.

The first step is to confirm the CPU meets the setup and hold times for the chosen latch. Referring back to the CPU timing (Table 6, Figures 16, 17, 18, and 19)...

$$t_S < t_{AVLL} \text{ (address valid to ALE low)} = t_{CLCL} - 13 = 17\text{ns}$$

$$t_H < t_{LLAX} \text{ (address hold after ALE low)} = t_{CLCL} - 20 = 10\text{ns}$$

In this case, the choice of TTL technology proves non-critical. For reference, t_S & t_H cover a spectrum from 15 & 5ns for an HCT '574 to 3 & 0ns for a FAST '574.

The next decision is how to connect the EPROM CE and OE control lines. A simple 'no glue' solution is to simply ground CE. This has the benefit of eliminating the t_{CE}/t_{OE} differential as a component of access time, though at the expense of higher power consumption. With CE grounded, access time depends only on OE which is connected to the CPU PSEN line.

Note that this scheme (grounding CE) limits code expansion to a single EPROM, otherwise decoding is required. However, this is not an unreasonable restriction given the typical code size of '51 applications relative to the high density of modern EPROMs.

Finally, it is important to remember that applications exploiting the low power modes of the CPU (IDLE and POWERDOWN) must accommodate the behavior of ALE and PSEN. Specifically, during IDLE, ALE and PSEN = 0 and during POWERDOWN, ALE and PSEN = 1. In general, this requires externally gating CE, ALE, OE, etc. Since the optimal solution is very dependent on the particulars of the configuration and application, the issue is not addressed further in this application note.

AN457

EPROM TIMING ANALYSIS

With a design established, it is now possible to perform an initial timing evaluation. The procedure is simply to step through each EPROM spec one by one to identify a speed grade that meets all the relevant CPU timing requirements.

Starting with t_{AA} , it is apparent that address access time for the EPROM must be less than the CPU t_{AVIV} (address to valid instruction in). However, don't forget that the '573 propagation delay must also be factored in. The conclusion is expressed in the form of an equation as...

$$t_{AA} (\text{EPROM}) < t_{AVIV} (\text{CPU}) - t_{PROP} (\text{TTL})$$

t_{PROP} , depending on the choice of TTL technology, varies from approximately 10ns (FAST) to 40ns (HCT). Throughout this application note, t_{PROP} for the latch is assumed to be 10ns.

Substituting the CPU data sheet value for t_{AVIV} (5 t_{CLCL} -55) and solving yields a required t_{AA} of...

$$t_{AA} < ((5t_{CLCL})-55)-t_{PROP} = ((5 \times 30)-55)-10 = 85\text{ns}$$

According to the EPROM spec chart (refer back to Table 4), this calls for a '-70' (70ns) EPROM.

Since \overline{CE} is grounded, it meets the t_{CE} spec of any EPROM and need not be considered in this design.

The only 'access-time' related spec remaining to check is t_{OE} . Connected directly to the CPU \overline{PSEN} with no intervening TTL, the equation is simply...

$$t_{OE} < t_{PLIV} = 3t_{CLCL}-45 = (3 \times 30)-45 = 45\text{ns}$$

...a spec easily met by the -70 EPROM (t_{OE} max. = 25ns).

Able to access the EPROM successfully, all that's left is to verify the EPROM data hold (t_{OH}) and float (t_{DF}) specs.

The EPROM t_{OH} spec is 0ns (whatever the speed), i.e., the EPROM output is not held after deselection. On the CPU side, since \overline{PSEN} is controlling the EPROM selection (via \overline{OE}), the corresponding spec is t_{PXIZ} (input instruction hold after \overline{PSEN}) which is also 0ns. This may sound tight but actually isn't a problem. First, there's the simple fact that the CPU will 'see' \overline{PSEN} go high before the EPROM by virtue of the package and PCB wiring delays. Second, though it's convenient for the EPROM manufacturer to spec 0ns, it's clear that the outputs can't shut off in zero time.

Finally, t_{DF} can be checked against the CPU t_{PXIZ} (input instruction float after \overline{PSEN}) spec.

$$t_{DF} < t_{PXIZ} = t_{CLCL}-10 = (30-10) = 20\text{ns}$$

Oops, unfortunately a -70 EPROM, with t_{DF} max. 25ns, can't meet this spec. This is a bus contention situation in which the next cycle

address driven by the CPU will collide with the remnants of the previous cycle EPROM output. Though access time is certainly important, the lesson is that 'unaccess' (i.e., float) time can't be overlooked.

So, what are the options to resolve the problem?

The straightforward solution is to select an EPROM with better t_{DF} spec by moving to a faster speed grade (for instance, the -55 which cuts t_{DF} to an acceptable 20ns). Alternatively, another vendor may offer a -70 with better t_{DF} spec (note the difference between supplier A & B -90 t_{DF} spec as an example).

Another option is to insert a buffer or transceiver with a fast shutdown in the datapath as shown in Figure 22. Take care to choose a TTL technology is actually faster. For instance, the output disable time for a FAST '244 is a speedy 6ns, but that for an HCT '244 is a leisurely 31ns which doesn't help at all.

Also, make sure solving the problem at the 'back-end' of the cycle doesn't just push it to the 'front-end'. Remember that propagation delay through the buffer or transceiver must now be subtracted from available access time (t_{AA} , t_{OE}). Re-evaluating the access times shows that t_{PROP} must be less than 15ns, or a faster EPROM has to be selected anyway. For reference, t_{PROP} for a FAST '244 is only 7ns but an unhelpful 28ns for HCT.

A final, and rather widely used, option is to simply ignore the problem. Referring back to Table 6, note 4 at the bottom of the page points out that the Philips CPU P0 drivers are designed to tolerate contention (i.e., t_{DF} up to 50ns). Determining whether the memory is similarly robust requires confirmation by the particular EPROM supplier.

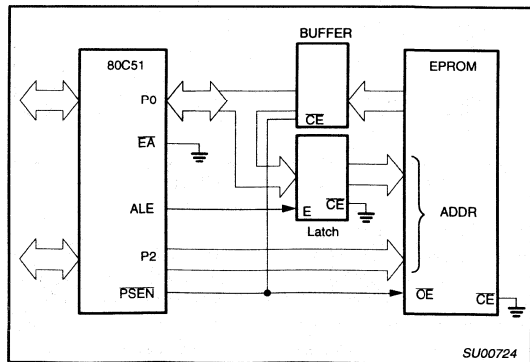

Figure 22. CPU + Latch + EPROM +Xcvr Diagram

80C51 External Memory Interfacing

AN457

SRAM INTERFACE

Though other configurations are possible, this example illustrates the most common one in which the SRAM is used for data-only (as opposed to instruction or instruction & data) storage. Should the SRAM be used for instruction storage, the previous CPU instruction access timings used in evaluating the EPROM interface apply.

Instead of grounding the SRAM \overline{CE} line, since it requires only 15 address lines (i.e., 32Kx8), it is connected to the CPU A15 (P2.7). Thus, the SRAM occupies the lower 32K bytes of the data space, leaving the upper 32KB for I/O expansion. The SRAM \overline{OE} and \overline{WE} lines are connected to the CPU \overline{RD} and \overline{WR} lines respectively as shown in Figure 23.

This configuration can take advantage of the previously mentioned operating characteristics of P2 (A8–A15), specifically the fact that P2 (and thus A15 which is connected to the SRAM \overline{CE} line) reverts to prior levels programmed into the SFR when not performing an external data access. By programming P2.7 (A15) to output a 1, the SRAM will be deselected when it is not being accessed, saving power. Further, unlike the EPROM case, no extra control line gating logic is required to accommodate the CPU low power (IDLE and POWERDOWN) modes.

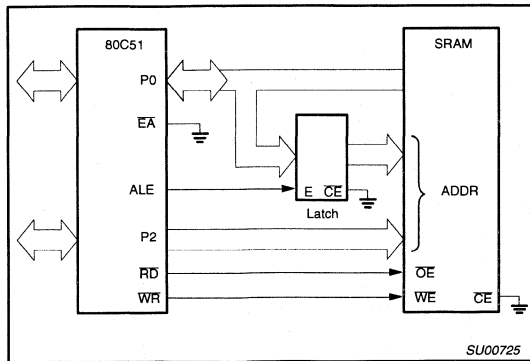

Figure 23. CPU + Latch + SRAM Diagram

SRAM Timing Analysis

The process of evaluating the 32Kx8 SRAM interface is similar to that for the EPROM, recognizing that the CPU external data access (\overline{RD} , \overline{WR}) timing is different than instruction access (\overline{PSEN}) and both read and write cycles must be checked.

Starting with the read cycle, t_{RC} is clearly not an issue since the CPU data access bus cycle of 360ns is well beyond the 85ns SRAM spec.

For a data read, the SRAM t_{AA} is compared with the CPU t_{AVDV} (address to valid data in). Once again, as for the EPROM, propagation delay through the address latch is considered (10ns assumed)...

$$t_{AA} < t_{AVDV} - t_{PROP} = ((9t_{CLCL}) - 165) - t_{PROP} = ((9 \times 30) - 165) - 10 = 95ns$$

...which meets the -85 SRAM t_{AA} spec of 85ns.

Since \overline{CE} is no longer grounded, it must be evaluated as well. Connected to A15 without intervening TTL, the equation is simply the same as that for t_{AA} without t_{PROP} derating...

$$t_{CE} < t_{AVDV} = (9t_{CLCL}) - 165 = (9 \times 30) - 165 = 105ns$$

...meeting the SRAM t_{CE} spec of 85ns with even more margin.

The SRAM \overline{OE} is connected to the CPU \overline{RD} line so t_{OE} is evaluated as...

$$t_{OE} < t_{RLDV} = (5t_{CLCL}) - 90 = (5 \times 30) - 90 = 60ns$$

...meeting the SRAM t_{OE} spec of 45ns.

Unlike the EPROM, the SRAM guarantees some output data hold time ($t_{OH} = 5ns$ min) while the CPU still only requires 0ns (t_{RHDX}).

Though the EPROM had a problem with float time (t_{DF}) note that for data cycles...

$$t_{DF} < t_{RHDX} = (2t_{CLCL}) - 28 = (2 \times 30) - 28 = 32ns$$

...showing that the SRAM t_{DF} spec (30ns), though worse than the EPROM spec (25ns for -70), is actually met. This highlights the more relaxed timing of CPU data access compared to instruction access.

On the other side of the data float equation, is it possible for the SRAM to start to return data before the address has been removed from the CPU AD0–7 bus thus causing bus contention? The SRAM will start to drive the bus within 5ns (t_{OLZ}) of \overline{OE} assertion. Fortunately, the CPU t_{RLAZ} spec of 0ns guarantees that the address is off the bus at the time \overline{RD} (connected to the SRAM \overline{OE}) is asserted.

This completes the SRAM read cycle evaluation and shows there is plenty of margin due to the relaxed nature of data access timing. Now, let's move on to the write cycle evaluation.

Once again, the SRAM t_{WC} (as was t_{RC}) spec of 85ns is easily met since the CPU data access bus cycle is 360ns ($12 \times 30ns$).

The SRAM t_{AW} (address valid to end of write) is compared against the sum of the CPU t_{AVWL} (address valid to write low) and t_{WLWH} (write low to write high) specs again considering the latch propagation delay...

$$t_{AW} < t_{AVWL} + t_{WLWH} - t_{PROP}$$

or...

$$t_{AW} < ((4t_{CLCL}) - 75) + ((6t_{CLCL}) - 100) - t_{PROP}$$

thus...

$$t_{AW} < ((4 \times 30) - 75) + ((6 \times 30) - 100) - 10 = 115ns$$

...which easily meets the SRAM t_{AW} spec of 75ns.

Meanwhile, the SRAM t_{AS} spec defines the time addresses must be setup prior to the assertion of \overline{WE} which is connected to the CPU \overline{WR} line so...

$$t_{AS} < t_{AVWL} - t_{PROP} = ((4t_{CLCL}) - 75) - t_{PROP} = ((4 \times 30) - 75) - 10 = 35ns$$

...again easily met by the t_{AS} spec of 0ns.

Since the SRAM \overline{CE} pin is simply connected to the CPU A15 without intervening TTL, calculation of t_{CW} (\overline{CE} to write end) is the same as for t_{AW} without derating for t_{PROP} ...

$$t_{CW} < t_{AVWL} + t_{WLWH} = 125ns$$

...meeting the t_{CW} spec (75ns, same as t_{AW}) with an additional t_{PROP} (10ns) margin.

Remembering that the SRAM write pulse is defined as the overlap of \overline{CE} and \overline{WE} , t_{WP} (write pulse width) is simply defined by t_{WLWH} ...

$$t_{WP} < t_{WLWH} = (6t_{CLCL}) - 100 = (6 \times 30) - 100 = 80ns$$

...which meets the SRAM t_{WP} spec of 60ns.

80C51 External Memory Interfacing

AN457

The SRAM t_{WR} (write recovery) spec defines how long the addresses must be held after the end of write, which is the end of CPU WR in this design. Since addresses are guaranteed to remain stable while ALE is low, this becomes t_{WHLH} (RD or WR high to ALE high)...

$$t_{WR} < t_{CLCL} - 20 = 30 - 20 = 10\text{ns}$$

...which just meets the SRAM spec of 10ns.

As for t_{DS} (data setup to end of write), the corresponding CPU timing is derived by summing t_{QVWX} (data valid to WR transition) and t_{WLWH} (WR pulse width) so...

$$t_{DS} < t_{QVWX} + t_{WLWH} = (t_{CLCL} - 20) + ((6 \times t_{CLCL}) - 100)$$

thus...

$$t_{DS} < (30 - 20) + ((6 \times 30) - 100) = 90\text{ns}$$

...easily meeting the SRAM spec of 45ns.

The SRAM hold spec t_{DH} is simply compared with t_{WHQX} (data hold after write)...

$$t_{DH} < t_{CLCL} - 20 = 30 - 20 = 10\text{ns}$$

...which meets the SRAM 0ns hold spec.

As for possible bus contention with previous SRAM read data, the SRAM spec indicates the data bus shouldn't be driven until t_{OHZ} after the end of a previous read cycle to the same SRAM. Whether this presents a problem depends on the system configuration.

In this example, the SRAM is being used for data access only (i.e., connected to RD and WR). Noting that external data cycles are always separated by an (internal or external) instruction fetch, it is impossible for back-to-back accesses to occur with a data-only memory.

Though not a factor in this example, meeting the t_{OHZ} spec could be of concern in a system that 1) overlaps code and data into a single 64K space (i.e., by ANDing $PSEN$ and RD) and 2) fetches a data write instruction (ex: $MOVX @DPTR, A$) from the same SRAM to which the write is targeted. In this case, the tail end of the opcode ($MOVX$) fetch may collide with the beginning of the subsequent address ($DPTR$) output if the t_{OHZ} spec isn't met.

In this (and only this) rather rare situation, the SRAM t_{OHZ} spec must meet the tighter CPU instruction float ($t_{PIXZ} = t_{CLCL} - 10$,

i.e., 20ns @ 33MHz) rather than the more relaxed data float ($t_{RHDZ} = 2t_{CLCL} - 28$, i.e., 32ns @ 33MHz) timing. As stated in the earlier EPROM analysis, this can be accomplished by selecting a faster SRAM chip, isolating the SRAM data bus with a fast shutoff transceiver or confirming the SRAM can operate reliably and correctly despite the bus contention.

SUMMARY AND CONCLUSIONS

This application note examined the detailed timing of a 33MHz 80C31/8XC51 system based on actual EPROM and SRAM specifications. Beyond the particulars of this example, the techniques shown are applicable to any design.

One important point illuminated was the degree to which CPU, memory and glue logic specs can vary and thus must be considered on a supplier-by-supplier, speed grade-by-speed grade basis.

For instance, ostensibly equivalent parts from different suppliers may vary in one or more parameters, an example being '-70' EPROMs from two different suppliers which differ in a number of important specs.

Furthermore, even parts from a single supplier may exhibit non-intuitive spec variations across derivatives, speed-grades or process technology. In particular, a part that is 'twice as fast' in terms of one spec does not imply that other specs are similarly improved.

These caveats apply to memories, TTL & glue logic and even CPUs themselves, whether from different suppliers or derivatives within a single suppliers catalog.

The development of very fast memories has largely removed 'access time' as a barrier for high-speed '51 family-based designs. However, despite the natural tendency to focus on 'access time', other specifications prove equally, if not more, critical.

Most notably 'float time', as it relates to bus contention, cannot be overlooked. Though in practice some degree of bus contention may be tolerable, no recommendation other than to meet the specs can be officially made. Philips explicitly guarantees acceptable behavior of their 80C31/8XC51 in this regard (i.e., note #4) but only the other chip suppliers can vouch for the integrity of their parts.

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

1. INTRODUCTION

The routing of the traces on a Printed Circuit Board (PCB) largely effect the ElectroMagnetic Compatibility (EMC) performance of the PCB with respect to both ElectroMagnetic (EM) radiation as susceptibility to EM-fields.

The PCB will connect electronic components such as passive components, transistors and ICs. Furthermore, cables to interconnect the PCB with other system parts, e.g., another PCB, signal generator, CATV wall-outlet, DC power source or an AC-mains connection, will largely influence the PCB with respect to EMC [7].

In order to get a PCB on which the circuits function properly, the trace routing, the placement of components/connectors and the decoupling used with certain ICs will have to be optimized according to the constraints given in this report.

To reach an economic and functional PCB design, the following items have to be kept in mind:

4. Correct choice of the PCB format (mono, bi- or multi-layer)
5. Take care that "every" signaltrace has its signalreturn nearby
6. Proper decoupling for each IC or group of ICs
7. Allowed tracelengths and allowed loopareas
8. Placément of the connectors
9. Right cable choice with a proper connector
10. Proper use and placement of filters and filterparts.

These items with the appropriate measures will be further explained.

The main target is to get control over your PCB currents.

2. GENERAL

2.1. Conductors

Single conductors have, as a rule of thumb, an inductance of 1µH/m. At low frequencies only, below 1kHz, R_{dc} applies. These impedances, together with the currents that will flow through these impedances, will be responsible for the voltage drop between points as Ohms law applies. The voltage drop can be diminished by either reducing the impedance or lowering the current through that impedance.

In typical digital designs the voltage drop will be frequency independent. A square wave current, resulting from a square wave output voltage to a resistive load, can be described as a series of sinewaves of which the amplitude of the harmonics decrease proportional with the frequency (Fourier expansions), see Figure 1b. The impedance of the inductor increases proportional with frequency (see Figure 1a), therefore the product; voltage drop (Figure 1c) remains constant.

When the current has a triangular waveshape, as function of time, due to capacitive loading, the amplitude of the harmonics decreases with the frequency square and the voltage drop across the inductor reduces proportional with frequency.

2.2. Transmissionlines

By using the inductance of a single wire, L_1 , the mutual coupling, M , and the capacitance between the traces, C_1 , a transmissionline, shown in Figure 2, can be defined of which the characteristic impedance, Z_0 , equals:

$$Z_0 = \sqrt{(L_{eff} / C)}$$

where:

$$L_{eff} = L_1 + L_2 - 2M, k = \sqrt{(L_1 + L_2) / M}$$

$$\text{and } C = C_1 + C_2.$$

When the coupling, k , between the traces of the transmissionline is high, the effective inductance will decrease rapidly. Some coupling factors are given in Table 1.

An indifferent signal path design (Figure 3a) can be changed into a transmissionline design (Figure 3b). This change will lower the effective inductance, L_{eff} , between the two circuit blocks and will therefore lower the voltage drop between the two references of those circuits.

Table 1. Coupling Factors between the Conductors of a Transmissionline

TRANSMISSIONLINE TYPE	COUPLING
Parallel wires	0.5 – 0.7
Bi-layer PCB	0.6 – 0.9
Multi-layer PCB	0.9 – 0.97
Coaxial cable	0.8 – 1.0
RG-58 coax	0.996

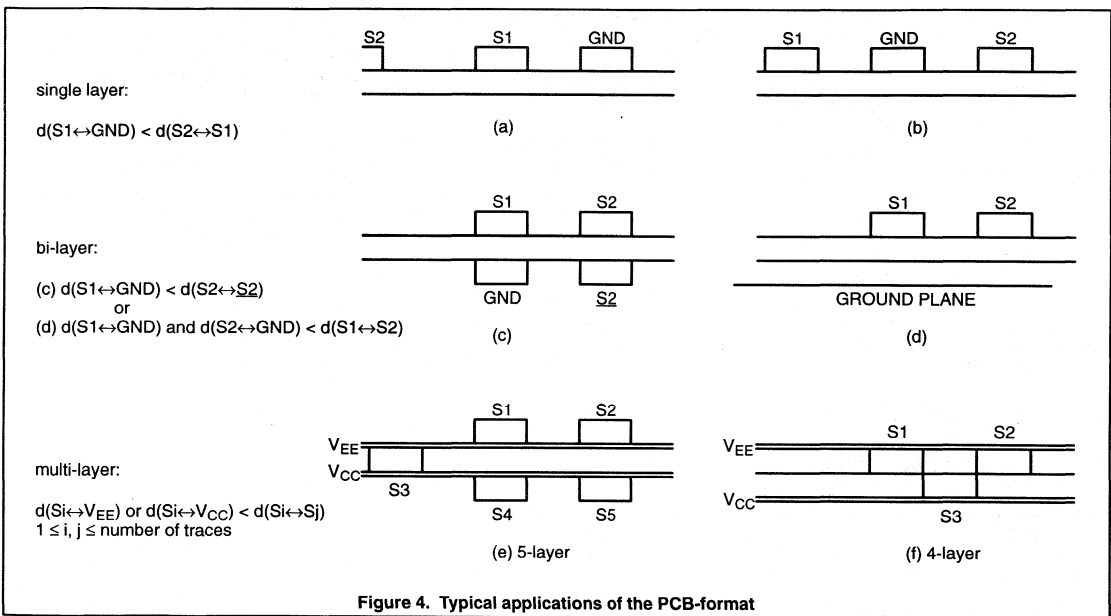

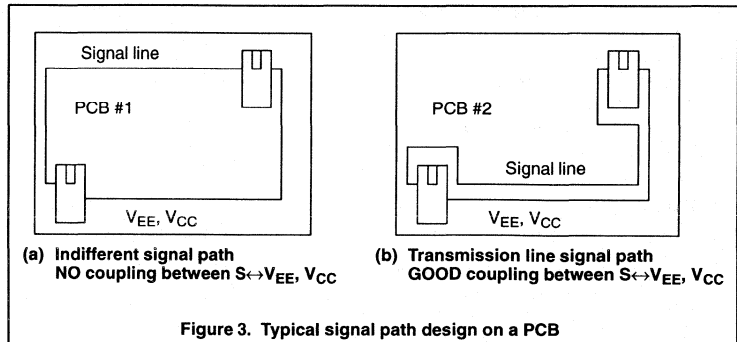

Figure 1. The relation between voltage drop as a result of current and impedance as function of frequency

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

2.3. Capacitive and Inductive Coupling

Separately, the capacitive and inductive values, derived from the definition of the transmissionline, can also be used to calculate the crosstalk between adjacent traces, not being a function signal path. The capacitive coupling, representing and induced current, is given by:

$$I_{CK} = 1/C_k \cdot dV/dt,$$

where:

C_k = coupling capacitance between adjacent traces; in practice: 100pF/m

(depends upon the vicinity of other traces, see Appendix A),

and the inductive coupling, representing an induced voltage, is given by:

$$V_{MK} = M_k \cdot di/dt,$$

where:

M_k = mutual coupling between two traces (For further detail see Chapter 4.)

In both coupling modes, the transfer function will typically show a high pass behavior.

3. CHOICE OF THE PCB-MATERIAL

By a proper choice of the PCB-material and the routing of the traces, a good transmissionline with low coupling to other traces can be created. Low coupling, or little crosstalk, can be obtained when the distance, d , between the transmissionline conductors is less than their distance to other adjacent conductors (see Figure 4).

By using these examples of geometry of traces the definition of the transmissionline between S_1 , S_2 , S_i , j and (S_2) GND, V_{EE} and/or V_{CC} are well defined and the coupling between the traces S_2 and S_1 is low.

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

The most economic PCB format has to be chosen based on:

- the legal and/or functional EMC requirements for the product,
- trace density,
- assembly and manufacturer capabilities,
- CAD-system capabilities,
- design-costs,
- PCB quantities, and
- the costs of EM-shielding.

Special attention must be given to the integral costs (components packaging/pinning + PCB-format + EM-shielding + construction + assembly) when a product definition is considered by using a NON-shielded cover. In many cases the choice of a proper PCB-format may expel the need for a metallized box within the plastic cover.

To improve immunity and to lower unwanted emission, both in fast analog and all digital applications, transmissionlines are needed. Dependent upon the transition of the output signal, a transmissionline needs to be present between $S \leftrightarrow V_{CC}$, $S \leftrightarrow V_{EE}$, and $V_{EE} \leftrightarrow V_{CC}$, as indicated in Figure 5.

The signal current will be determined by the output-stage symmetry of the circuit. For MOS: $I_{OL} = I_{OH}$, while for TTL: $I_{OL} > I_{OH}$.

The Logic Family and functional reasons determine the typical characteristic impedance, Z_0 , for that transmissionline which is given in Table 2.

Table 2. The Transmissionline Impedances, Z_0 , for Several Signal Paths

FUNCTION/LOGIC	Z_0 (Ω)
Supply (typ.)	$\ll 10$
Signal ECL	50
Signal TTL	100
Signal HC(T)	200

For two traces next to each other the following formula applies [10, 11].

$$Z_0 = \frac{120 \ln(\pi \cdot h / (b + c))}{\sqrt{\epsilon} \cdot r}$$

where:

- h = distance between traces
- b = width of the trace
- c = thickness of the trace; typical 17 μ m,

for two traces on top of each other:

$$Z_0 = \frac{120 \pi \cdot (h / (h + b))}{\sqrt{\epsilon} \cdot r}$$

where:

- h = 1.5mm (typical thickness of epoxy).

When the trace is above a groundplane the following formula applies:

$$Z_0 = \frac{87 \ln(6 \cdot h / (.8 \cdot b + c))}{\sqrt{(\epsilon \cdot r + \sqrt{2})}}$$

and in case of a trace between two (ground-) planes the formula yields:

$$Z_0 = \frac{60 \ln(4 \cdot K / (.67 \cdot \pi \cdot b \cdot (.8 + c/b)))}{\sqrt{\epsilon} \cdot r}$$

where:

- K = distance in-between the planes.

Typically the permittivity for epoxy material equals: $\epsilon_r = 4.7$.

4. THE SIGNALTRACE AND ITS SIGNALRETURN

Signaltraces need to have their signal-return-traces as close as possible in order to prevent emission from that looparea enclosed by these traces and to reduce susceptibility due to voltages which can be induced in this loop, e.g., by RF-transmitters and ESD.

Commonly, when the distance between two traces equals the width of the traces, the coupling factor is about 0.5 to 0.6. The effective inductance of the traces has gone down from 1 μ H/m to 0.4 - 0.5 μ H/m.

This means that 40 to 50% of the signal-return current may run freely through the other traces of the PCB.

For each signal path between two (sub-)blocks either analog or digital **three** properly defined transmissionlines need to be present with the impedances given in Table 2 and shown in Figure 5.

With TTL logic the sink-current; the high-to-low transition, is higher than the source-current. In this case the transmissionline should be defined between V_{CC} and S instead of V_{EE} and S, which is commonly considered.

Figure 5. Typical diagram of an interconnection between (digital) ICs which shows 3 specific transmissionlines

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

The mutual coupling between two parallel traces can be calculated from the double integral [9]:

$$M_k = \mu / (4 \cdot \pi) \cdot \int_{l_1} \int_{l_2} ds_1 \cdot ds_2 \cdot dr / |r|$$

where:

- l_1, l_2 = length of traces 1 and 2
- r = relative distance between line segments, ds_1, ds_2 , of each trace.

Substituting the geometry of two parallel lines results in:

$$M_k = 200 [1 \cdot \ln \{ (l + \sqrt{(l^2 + h^2)}) / h \} + \sqrt{(l^2 + h^2) + h}] [nH]$$

where:

- l = length of the two parallel traces and
- h = distance between the traces (trace thickness and width are neglected).

If the coupling between the two conductors of a transmissionline is too low, a ferrite toroid ($\mu_r > 200$ (-5000)), with some windings, will increase this coupling to ≈ 1 .

By using ferrite toroids one can get full control over the signal- and signal-return currents.

In case of parallel conductors, the characteristic impedance of this transmissionline may be influenced by the ferrite. In case of coaxial cable, the presence of the ferrite will only be noticeable on the outer parameters of the cable.

CONCLUSIONS:

- I. Use traces as thin as possible next to one another instead on top of each other (separation commonly less than 1.5mm + epoxy thickness of a bi-layer).
- II. Create a layout where every signalline has its signal-return at the closest possible interval (applies to both signal- and supply-traces).
- III. If the coupling between the conductors of the transmissionline is insufficient a ferrite toroid may be used.

5. PROPER DECOUPLING WITH EACH IC

ICs will be commonly decoupled by capacitors only. Because capacitors are not ideal, resonances will occur. Above the resonance frequency the capacitor behaves as an inductor, which means that the dl/dt is limited. The value of this capacitor is determined by the voltage-fluctuations which are allowed across the power supply pins of the IC. According to good designers practice, this voltage fluctuation should be less than 25% of the signal-line worst-case noise margin. From the following equation the optimal decoupling capacitor for each logic family output gate can be calculated:

$$l = c \cdot dV/dt$$

The worst-case signal-line noise margins for several logic families are given in Table 3, together with the recommended decoupling

capacitor value, C_{dec} , which need to be added with each output gate.

The values of the decoupling capacitors for fast logic families may no longer be useful if the capacitor incorporates a large series inductance, either caused by the construction of the capacitor, long connecting wires or PCB traces. Additional small ceramic capacitors (100–100pF) need then to be added, *as close as possible to the pins of the IC*, in parallel to these "LF-" decoupling capacitors. The resonance frequency of this ceramic capacitor (including the trace length towards the supply pins of the IC) should be above the bandwidth of the logic [$1 / (\pi \cdot \tau_r)$], where τ_r is the voltage risetime of the logic.

If the decoupling capacitor is placed with every IC the signalreturn current may choose which path is most convenient, V_{EE} or V_{CC} . This choice is determined by the mutual coupling present between the signaltrace and one of the supply traces.

Between two decoupling capacitors, one for each IC, and the inductance, L_{trace} , formed by the supply traces, a series resonant circuit will result. This resonance is only allowed when it occurs at low frequencies (<1MHz) or when the Q of this resonance circuit is low (<2).

This resonance can be kept below 1MHz by using a choke with high RF-losses in series with the V_{CC} network and the decoupled IC. Too less RF-losses can be compensated by either adding a resistor in parallel or in series (Figure 6).

Table 3. Recommended Decoupling Capacitor

FAMILY NOISE-MARGIN	dl / dt			C_{dec} nF

HCT	0.7	50	2–3	12.8
HC (5V)	1.2	50	2–3	7.5
ACT	1.7	175	1–2	35.0

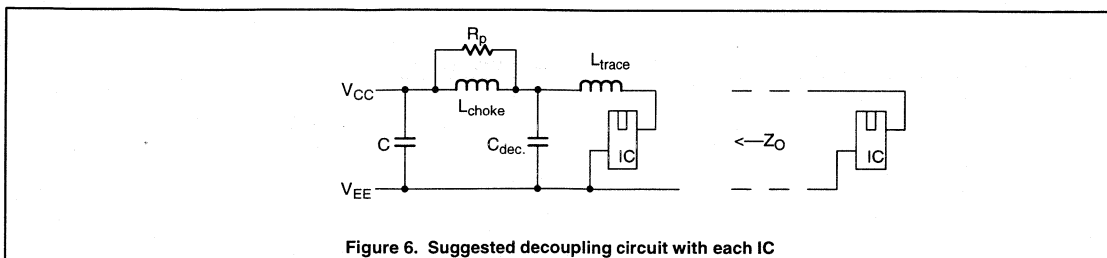

Figure 6. Suggested decoupling circuit with each IC

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

The choke may never have an open core, because then it will either act as a RF-transmitter or a ferroceptor for magnetic fields.

Example:

$$1\text{MHz} \times 1\mu\text{H} \rightarrow Z_1 = 6.28\Omega \rightarrow R_s = 3.14\Omega$$

$$Q \leq 2 \quad R_p = 12.56\Omega$$

Above the resonance frequency, the characteristic impedance, Z_0 , of the "transmissionline" (in this case the impedance of the IC sees at its supply terminals) will be equal to:

$$Z_0 = \sqrt{L_{\text{trace}} / C_{\text{decoupling}}}$$

The series inductance of the decoupling capacitor and the inductance of the interconnecting traces have a negligible effect on the RF supply-current distribution,

when a choke of $1\mu\text{H}$, for example, is used. Still it determines the voltage fluctuations between the supply pins of the IC. With a 25% signal-to-noise margin dissipation by the power supply, the recommended maximum inductances, L_{trace} , are given in Table 4.

With the decoupling as suggested in Figure 6, the number of transmissionlines between the two ICs has gone down from 3 to 1 (see Figure 7).

CONCLUSION:

IV. By using proper decoupling with each IC: $L_{\text{choke}} + C_{\text{dec}}$, *only one* transmissionline needs to be defined between the circuit blocks.

With high speed logic, $\tau_f < 3\text{ns}$, the total inductance in series with the decoupling capacitor needs to be low (see Table 4). A

trace, in series with the supply pins, of 50mm equals an inductance of 50nH. Together with the load conditions at an output, 50pF typical, this will give a minimum risetime of 3.2ns. If faster risetimes are required, shorter leads from the decoupling capacitor (preferred leadless) and shorter leads within the IC package are necessary. This can be obtained by using, for example, IC-decoupling capacitors, or better, using center (supply) pinned ICs in combination with small leadless ceramic capacitors with a 3E pitch (DIL). A multi-layer board with supply and ground planes can be another option. Further improvements can be reached by applying SO-packages with center pinned supply connections.

CONCLUSION:

V. When using fast logic: multi-layer panels should be used.

6. MINIMIZE TRACELLENGTH AND LIMITED LOOPAREAS

The maximum tracelength is determined by reflections which will occur at NON-terminated transmissionlines. The loopareas and tracelengths are limited by the EM-radiation which is allowed by mandatory requirements for the product. The latter requirements will directly apply to the PCB if it is used in an unshielded box/cover.

6.1. Allowed Tracelengths Due to Reflections

The first limitation of the tracelength is determined by functional requirements. A transmissionline can be made reflection free by either adding a load resistor at the end of the line, which without series capacitance will cause DC-dissipation, or by adding a resistor in series with the driver. In this case the output impedance of the circuit plus the series resistor must be equal to the characteristic impedance of the transmissionline.

When the transmissionline is NOT terminated the allowed trace length is determined by the noise-margin of the logic used, its bandwidth and the propagation delay of the line, which is assumed to be 5ns/m. The bandwidth

determines the dynamic noise margin which by approximation is inverse proportional to the disturbance pulse halfwidth time. Applying the requirement that the noise, in this case the reflected signal, has to be less than 25% of the (dynamic) noise margin the tracelengths in Table 5 result.

CONCLUSION:

VI. A transmissionline should, if necessary, be series-terminated at the drivers side. If the trace lengths are long compared to those given in the table, END-termination is inevitable.

6.2. Allowed Loopareas Due to Radiation

The emission from a PCB (or a complete product) is limited to 100µV/m at 10 meters distance from the object at frequencies above 30MHz [FCC, IEC CISPR publications, class B]. This emission is determined by the product of the looparea, A, the loopcurrent, I, and the permeability of the medium within that loop, µ_r (commonly equal to 1). This product is called the magnetic dipole-moment, M.

In case a number of loops are present, operating at the *same* frequency or

clock-rate, the limit of the dipole-moment strength should be divided by √(n), in which n = number of loops, hence the signals will add as random noise.

$$M(\text{freq}) = I(\text{freq}) \cdot A \cdot \mu_r$$

The limit value for the magnetic dipole-moment can be calculated from the radiated power [7, 8]:

$$E = (7/r) \cdot \sqrt{P_{\text{rad}}}$$

$$P_{\text{rad}} = 31200 \cdot I^2 \cdot A^2 / \lambda^4 = 31200 \cdot \underline{M}^2 / \lambda^4$$

where:

- I = loopcurrent as function of frequency
- A = looparea
- λ = wavelength belonging to the frequency component of the loopcurrent

By substitution the following results:

$$E = (7/r) \cdot 176 \cdot I \cdot A / \lambda^2$$

Filling in the requirement, given above, that E ≤ 100µV/m at 10 meters distance from the source the following equation results for the looparea and current as function of frequency:

$$I \cdot A / \lambda^2 \leq 8.1 \cdot 10^{-7} [A], \text{ or}$$

$$\underline{M} \leq 8.1 \cdot 10^{-7} \cdot \lambda^2 [A \cdot m^2]$$

Table 5. Allowed NON- or Series-Terminated Tracelength

FAMILY NOISE-MARGIN	volt	dt ns	MAXIMUM TRACELLENGTH (m)	
			NON-TERMINATED	SERIES TERMINATED
CMOS	1.75	100	14.3	— ¹
TTL-LS	0.4	10	0.4	0.5
TTL-F	0.4	2–3	0.08	0.15
HCT	0.7	2–3	0.14	∞
HC	1.2	2–3	0.24	— ¹
ACT	1.7	1–2	0.18	— ¹

NOTE:

1. If series termination is used in an asynchronous logic circuit design, attention must be given to the occurrence of metastability; especially symmetrical logic input-circuitry cannot decide whether the input signal is high or low and a non-defined output status may/will result.

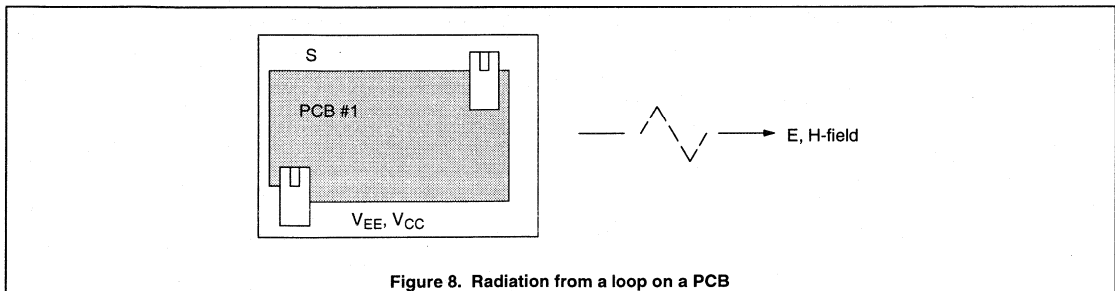

Figure 8. Radiation from a loop on a PCB

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

The spectral current amplitude, for logic signals in the frequency domain, decrease above the bandwidth of the logic ($= 1 / \pi \cdot \tau_r$) proportional with frequency square. At this corner frequency, the radiation resistance of the loop still increases proportional with frequency square. Therefore one can calculate the maximum looparea which is determined by the clockrate or repetition rate, the risetime or bandwidth of the logic and the current waveshape in the time-domain. The current waveshape is derived from the voltage waveshape and the current halfwidth time is by approximation equal to the voltage risetime (Figure 9).

The current amplitude at the corner frequency ($= 1 / \pi \cdot \tau_r$) becomes:

$$I(f) = 2 \cdot I \cdot \tau_r / T$$

where:

- I = current amplitude in the timedomain,
- $T = 1 / \text{clockrate} = \text{period time}$,
- $\tau_r = \text{voltage risetime} \cong \tau_H$ current halfwidth time.

From this equation the maximum looparea at a clockrate for a certain logic family can be calculated. These loopareas are given in Table 6.

CONCLUSION:

VII. The maximum looparea is determined by the clockrate, the logic family (= output current) and the number, n, of simultaneous switching loops on that PCB.

When a bi-layer is used with a thickness of 1.5mm, the maximum allowable tracelength, derived from the looparea, will be much less than the tracelength found from the reflection point of view. If clockrates are used above 30MHz, the use of a multi-layer will be inevitable. In this case the epoxy thickness depends upon the number of layers used and may vary between 60 – 300µm. When only a limited number of high clockrate signals are distributed on the PCB, careful routing, by using side-to-side traces, may lead to acceptable results on a bi-layer.

Table 6. The Allowed Single Looparea for Each Logic Family

FAMILY	dl mA	dt ns	MAXIMUM LOOPAREA IN mm ² AT CLOCKRATE OF:			
			f = 4MHz	f = 10MHz	f = 30MHz	f = 100MHz
CMOS	2	100	4.5 10 ⁶	1.8 10 ⁶	—	—
TTL-LS	50	10	1.8 10 ⁶	7200	2400	—
TTL-F	50	2 – 3	1.8 10 ⁶	1400	480	144
HCT	50	2 – 3	1.8 10 ⁶	1400	480	144
HC	50	2 – 3	1.8 10 ⁶	1400	480	144
ACT	175	1 – 2	515	206	69	21 (note 1)

NOTE:

1. In this case, when using common DIL packages, the looparea limit will be exceeded and additional shielding measures, together with proper filtering will be inevitable.

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

6.3. Allowed Tracelength Due to Radiation

The allowed tracelength are even less, when the transmissionline is directly coupled to the system reference and an unshielded outgoing cable leaving the product, then the values found up to now. A simple diagram is given in Figure 10. The voltage drop between the two references with each IC has become the driving source of the antenna formed by reference system and the outgoing cable. The worst case radiation resistance of the antenna is assumed to be 150Ω and frequency independent [7]. The amplitude of the driving source, U, is now limited to:

$$P_{rad} = U^2 / 150\Omega.$$

Applying the radiation requirements as given earlier the voltage drop has to be:

$$U \leq 1.75mV.$$

The voltage drop is determined by the current amplitude, at the logic bandwidth's frequency, and the effective inductance of the transmissionline between these points.

$$U(f) = I(f) \cdot Z(f) = I(f) \cdot j \cdot \omega \cdot (L-M) = I(f) \cdot j \cdot \omega \cdot L \cdot (1-k)$$

Taking Table 1 and the current amplitude in the frequency domain, the tracelengths in Table 7 can be found.

This table shows that many practical applications shall not fulfill the radiation requirements.

In most cases, filtering or shielding of the outgoing cable, which leaves the product will be sufficient. Shielding of the entire product, plus necessary filtering, becomes inevitable

when the magnetic loop constraints are exceeded.

CONCLUSION:

VIII. Circuit designs shall be made in such a way that the voltage drop between references shall not directly excite an antenna being any outgoing cable.

Simple approximations will give the number for the required filtering or shielding performance whenever necessary. These can be found by using the Tables 6 and 7 and counting the number of correlated sources in the product.

In the chapters 7, 8, and 9 some basic information is given about the cable shield performance and filtering techniques.

ESG89001

7. PLACEMENT OF THE CONNECTORS

All connectors, which provide the interconnections to other panels and/or units, must be placed as close as possible to one another. In this way common-mode currents, which are induced in those cables, will NOT flow through the traces of the circuit on the PCB. In addition, voltage drop between references on the PCB will not excite the (antenna)-cables.

To avoid such common-mode effects, it may be necessary to make a separation between the reference-strip near to the connectors and the groundplane, groundgrid or reference of the circuitry on the PCB. This groundstrip shall, if applicable, be connected to the metal cover of the product. From this separate groundstrip, only high impedances; inductors, resistors, reed relays and opto-couplers are allowed in between these two grounds. This will be explained when the filter networks are described, Chapter 9.

CONCLUSION:

IX. All connectors need to be placed as close as possible to one another in order to prevent external currents running through the traces or reference of the PCB.

8. RIGHT CABLE CHOICE WITH A PROPER CONNECTOR

Cables have, when they are shielded, a transferimpedance, see Appendix B.

Determined by the amplitude and the frequency content of the signals flowing through these cables a choice shall be made. In case cables, leaving the enclosure of the product, contain data above a 10kHz clockrate, shielding will be inevitable (product requirement). This shielding shall be connected to ground (metal cover product) on both ends of the cable, this to assure that the shield acts both as an electric and a magnetic shield.

If separate grounds are used, this shall be done to the "connector-ground" instead of the "circuit-ground".

In case the clockrate is above 10kHz and below 1MHz *and* the risetime of the logic is kept as slow as possible, an optical coverage of 80% or more or a transferimpedance which equals less than 10nH/m will do. Above 1MHz clockrates, better shielded cables are always necessary.

In general, coaxial cable excluded, the shield of the cable shall not be used as signalreturn.

By using passive filters in series with the signal input/outputs to the ground/reference, to reduce the RF-content, the necessity of a high quality shielding and the corresponding connector can be avoided.

A proper shielded cable will have a transferimpedance equal to or less than $l_j \cdot \omega \cdot 10 \text{ nH/m}$. Every wire has an inductance of 1 nH/mm (refer to chapter 2.1.). In case the shielding of such a cable is wrapped into a pigtail, the inductance of that pigtail will degrade the shielding performance, thus increase the transferimpedance, of the cable.

CONCLUSION:

X. A good shielded cable deserves a proper connector.

9. PROPER USE AND PLACEMENT OF FILTERS AND FILTER PARTS

Signal bandwidth reduction shall be achieved by using RC low-pass filters. In case the voltage drop across the series resistor is unacceptable an inductor with high RF-losses shall be used. The LC low-pass filter will always show resonances and therefore its Q must be kept low.

The filter can be used in two directions; namely, to prevent emission from the PCB *and* to improve the immunity of the board to external sources, e.g. RF-transmitters, ESD, etc.

The lay-out of the interconnection of the shield of the cable and a low-pass RCR-filter is given in Figure 12. The lay-out of the filter shall be such that the requirements for the maximum tracelength, Table 7, are not violated.

CONCLUSIONS:

XI. Currents, which do not belong to the circuit signals, should be by-passed using another path.

XII. The bandwidth of signals should be limited to the lease functional bandwidth. Use the slowest logic family suitable for the function.

10. PCB DEMO-BOARD, ROUTING AND DECOUPLING EFFECTS

An EURO-card PCB (100 × 160 mm²) has been chosen to demonstrate the effects of signal lines and their signal returns with respect to magnetic radiation.

The board contains a relaxation oscillator, created by 3 inverters (NANDs) and an RC-network (1kΩ, 560pF), which will produce a squarewave voltage signal. The frequency will be determined by the used logic and its threshold voltages. This oscillator is placed in one corner of the board together with some switches to change signal-return path and supply decoupling. In the opposite corner of the PCB another quad NAND has been placed as a capacitive load. These NANDs are all cascaded and will change status with some skew. The last NAND is terminated by a resistor. The supply decoupling of this IC can be altered as well. The diagram of the circuit with the switches is given in Figure 13 and the physical layout of the PCB and component placement are given in Figure 14.

The layout has been chosen such that the supply traces are as close as possible to one another, which is commonly arranged by a proper CAD-tool. In parallel to the signal trace a signal return trace has been placed, according to Chapter 4. At the supply pins of the ICs decoupling capacitors are added to each IC. By means of jumpers or switches a

series inductor may be short-circuited or added to the circuit.

In total 4 relevant situations can be evaluated which are given in Table 8.

Situation 1.

Supply decoupling only takes place by the capacitors and the signal return has been established through the supply trace V_{EE} (V_{DD}).

Situation 2.

Supply decoupling only takes place by the capacitors and the signal return has been established through the supply trace V_{EE} (V_{DD}) and a trace in parallel to the signal trace. The coupling between signal and signal return determines that only a small portion of the signal-return current will flow through the supply traces.

Situation 3.

The supply trace, V_{EE} (V_{DD}), has been taken out and the I_{CC} and signal-return current have to flow through the trace next to the signal line. The high frequency components of the signal-return current shall still flow through the V_{CC} (V_{SS}) trace due to the (de-)coupling capacitors at the supply pins of the ICs.

Situation 4.

By adding the inductors, with sufficient RF-loss, in series with the supply trace, V_{CC}, of both ICs ALL the signal-return

current will have to flow through the trace next to the signal line and radiation from the loop on the PCB has diminished.

The effects with respect to the radiation can be measured both in time as in frequency-domain. The latter has the advantage of showing the differences between situation 3 and 4 which are marginally discernable on an oscilloscope. These RF-effects are of extreme importance with respect to radiation as explained in Chapter 6.

To demonstrate the phenomena on an oscilloscope, a 50 (100) MHz bandwidth version shall be used. A small (electrically shielded) loop shall be used as measuring probe. If not available, a loop made by using a voltage probe of which the ground strap is short-circuited to the measuring tip can be used. This "loop" shall be placed on the PCB as some secondary loop near the supply traces. On the oscilloscope the effects of the positions of the switches can be observed. Measured results in the time domain are given in Appendix C.

In case a spectrum analyzer is used, an electrically shielded measuring loop shall be placed on the PCB as some secondary loop near the supply traces. On the screen the effects of the positions of the switches can be observed. Measured results in the frequency domain are given in Appendix D.

Table 8. A List of the Relevant Configurations of the Switches on the Demo-board with Respect to Emission Measures.

SITUATION	POSITION OF THE SWITCHES			
	SW 1	SW 2	SW 3	SW 5
1	ON	ON	ON	OFF
2	ON	ON	ON	ON
3	OFF	ON	ON	ON
4	OFF	OFF	OFF	ON

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

The behaviour of the PCB has been simulated with PHILPAC for a unity sinewave signal source and the sum of the currents through the V_{EE} and V_{DD} traces are given in Figure 15. In the simulated circuit the parasitic capacitance across the chokes has been taken into account, which leads to the

same result at higher frequencies with respect to situation 3 and 4. As long as the measuring loop is kept from the oscillator area, which itself (also due to the switches) radiates the effects can be shown unambiguously.

REMARK:

As radiation from a certain passive network is reciprocal, the same results could have been obtained in case of an immunity set-up.

APPENDIX A. CAPACITIVE COUPLING BETWEEN TRACES

In this appendix the graphical presentation is given of the capacitive coupling between two traces in free space and for two traces above a reference plane [12, form. 24.25].

It shows the necessity of a reference plane at a height, h , closer to the traces than the distance, D , to reduce the capacitive coupling between the traces.

Electro magnetic compatibility and printed circuit board (PCB) constraints

ESG89001

APPENDIX B. THE TRANSFER IMPEDANCE OF VARIOUS CABLE SCREENS

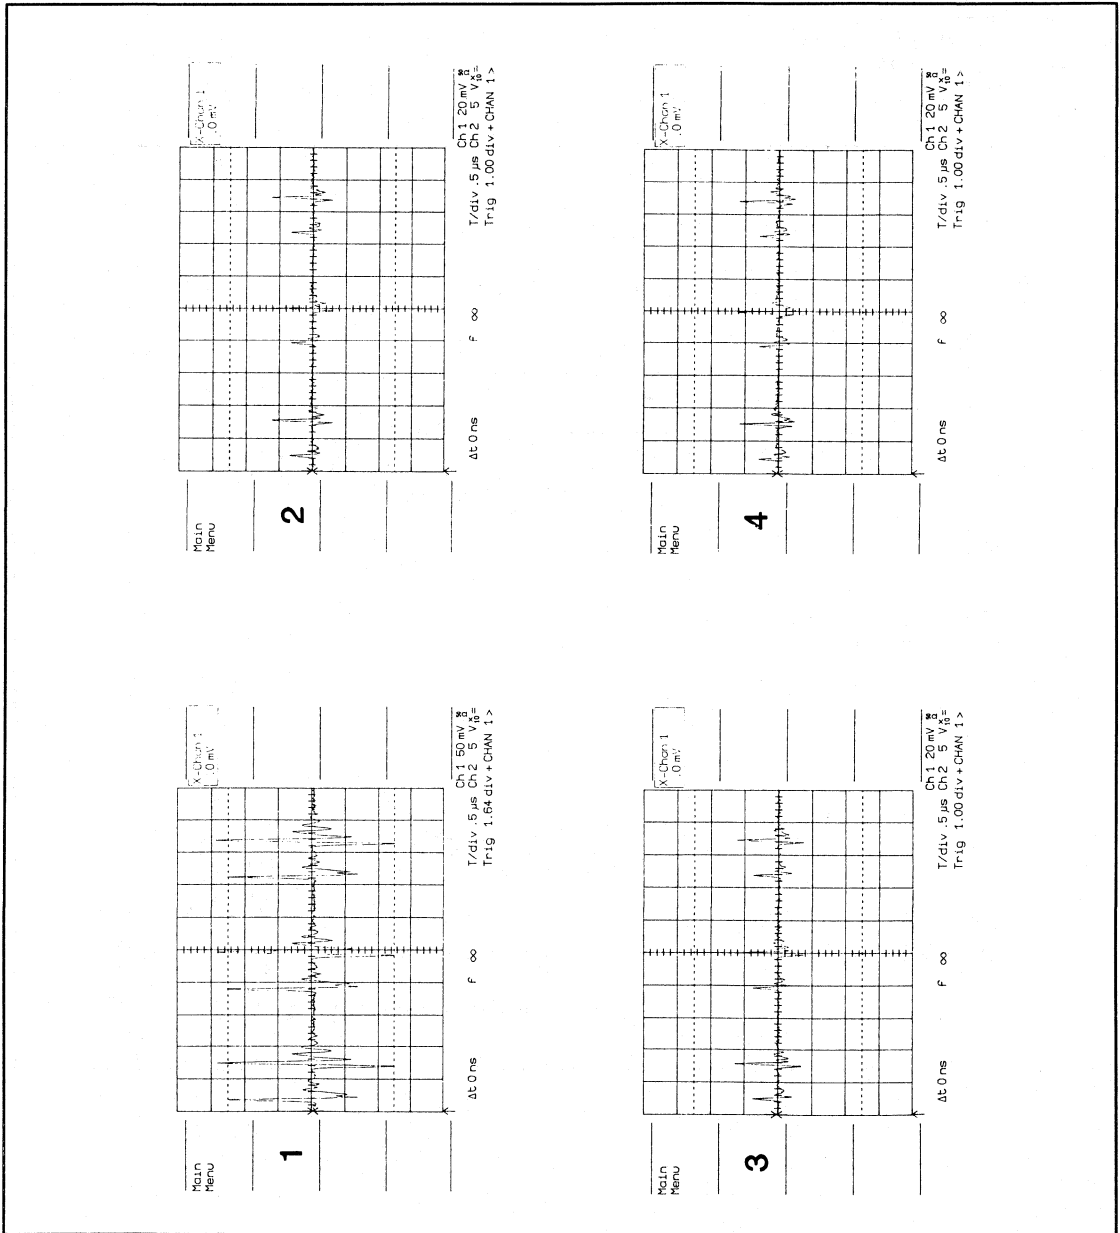

The transfer impedance, Z_T , is the relation between the current through the screen due to an external source and the induced voltage across the nominal load impedances of that cable. Further information about the measuring method to obtain information of the screening efficiency or the transfer impedance can be found in IEC publication 96.

Workbench EMC evaluation method

EIE/AN91001

1 INTRODUCTION

In many mass manufactured electrical and electronic products, printed wiring boards (PWBs) are used in a non-shielded application because it would be too expensive to do otherwise, e.g. hand-held cassette players, telephones, televisions, etc. As such, the product related EMC requirements directly apply to the (main) PWB containing semiconductors. To meet economic constraints, EMC solutions need to be taken, as far as possible, within the semiconductors, such that the needs for external measures diminish. In order to select between the various applications suggested by different vendors, an EMC qualification is required too.

Generally, the designer will face problems with CAD tools for PWB and semiconductor lay-out. The main problem is that all routers known are random routers which can do their functional job quite well on a bi- or multi-layer PWB, or with single or double metal processes. It will therefore be such that if the PWB or semiconductor is routed several times, using the same input, the results can be totally different. EMC results are commonly bad, mainly because the router is not told which lines need priority and which need to be close together.

An additional problem to face is that both product and semiconductor developments need to go faster, by using all available tools. By adding as few as possible external (passive) components and considering geometrical constraints given by the automatic assembly tools we hope that it complies with the often stringent mandatory EMC requirements.

The above given problems ask for an EMC evaluation method, by which the designer can, at any stage of the design, determine the degree of satisfying the EMC requirements. This EMC evaluation technique must be easy to use, easy to handle and not too expensive to assure usage of this method. The concept is based on the technical information now available in draft IEC 801-6. This concept will be explained in chapter 2.

Workbench EMC evaluation method

EIE/AN91001

2 TEST METHOD

2.1 EMC regulations and standards

With respect to EMC-standards we can concentrate ourselves best to the generic emission and immunity requirements given in European Standards EN 50081-1 and EN 50082-1 which become legally enforceable from 1992 onwards, especially to the European Market. In these standards reference is made to either IEC documents or CENELEC standards in which certain disturbance or emission phenomena are depicted. For most product groups, the IEC CISPR 11/22 documents or CENELEC European Norm 55011/22, class B apply for RF-emission, whereas for immunity phenomena IEC 801-2 through -6 or CENELEC 55024-x apply.

In our particular case, considering IC-development and IC-application, the most important document is draft IEC 801-6 as it can be applied both to immunity and emission. The validity is given by the fact that the EM-radiation properties of cables and wires connected to the Device or Equipment Under Test (DUT or EUT) are substituted by simple passive networks. As passive networks have reciprocity both emission and immunity can be evaluated in the same set-up.

2.2 Basic Concept

With the method, according to draft IEC 801-6, immunity to **conducted** RF-disturbances is tested. The set-up simulates the EM radiation effects by coupling the induced disturbing signals through Coupling/Decoupling Networks (CDNs) via the cables and wires to the PWB under test in a defined way, Fig.1. This method is applicable in the frequency range 150 kHz up to 230 (1000) MHz. The set-up with CDNs simulates "passive" cables which are, from the radiation point of view, at resonant length. The dimension of the PWB(s) between these cables and wires is assumed to be short compared to wavelengths involved.

According to the existing radiation measurement procedures, either the cable contributions are eliminated by adding ferrites on them to serve reproducibility (EN 55020) or the cables shall be adjusted in length and geometry with each frequency to obtain maximum radiation (EN 55011/22). With the conducted "interaction" method, which simulates radiated RF-field phenomena, both problems are solved.

Note 1: This method also reproduces the electric and magnetic near-fields to the PWB, associated with the source of disturbance (E and H in figure 2).

Note 2: The method of publication 801-6 does not provide the injection (or measurement) of the current from an ideal current or voltage source. It rather provides the coupling of the disturbance signal from a real source, having a "radiation" resistance of 150 Ω , i.e. short-circuit current as well as open voltage are limited.

CDNs are mainly defined by the common-mode impedance represented at the EUT-port side, which needs to be about 150 Ω to reference ($\pm 20 \Omega$, freq. ≤ 30 Mhz, $+60/-45 \Omega$, freq. > 30 Mhz). Every CDN fulfilling the impedance requirements given in draft IEC 801-6 can be used. Typical application examples are given in the figures 3a) for shielded and 3b) for unshielded cables. In figure 3c) a simplified drawing for mechanical construction is given. By using new NiZn ferrite ($\mu_r \geq 1000$), the entire frequency range can be covered by using one toroid on which we have 17 windings, $L_{(150 \text{ kHz})} \geq 280 \mu\text{H}$, and one bead-on-cable only.

Workbench EMC evaluation method

Fig.3c. Mechanical drawing for the Coupling/Decoupling Network (CDN).

2.3 Test set-up for individual PWB units

According to draft IEC 801-6, the PWB is placed on an insulating support, 0,1 metre above an earth reference plane. If the PWB will be used in a cabinet where a metal part is more near to the PWB than 0,1 metre, e.g. an adjacent PWB or a metal floor plate, then that shorter distance must be used. The earth reference plane shall exceed the projected geometry of the PWB and the used CDNs on all sides by at least 0,2 m.

On all cables measures to obtain high common-mode impedances at the frequencies of interest or CDNs must be inserted. The number of CDNs should be limited (between 3 and 5) by restricting oneself to the representative functions and main (disturbing) current distributions occurring to the application in practice. The CDNs need to be placed directly on the earth reference plane, making proper contact to it, at a maximum distance of 0,3 metre from the PWB. The cables between the CDNs and the PWB shall be as short as possible. Their height over the earth reference plane must be kept between 30 and 50 mm (as long as possible).

All auxiliary equipment, AE, required for the defined operation of the PWB, according to the specifications of the product, must be connected through high common-mode impedances or through CDNs to the PWB, e.g. communication, modem, printer, sensor, etc. This shall also be

Workbench EMC evaluation method

EIE/AN91001

done for all auxiliary equipment necessary for ensuring proper data transfer and assessment of the functions.

*Warning 1: As measures to obtain high common-mode impedances **and** CDNs are transparent for functional signals, part of the disturbance signal may enter the auxiliary equipment in this way. As such, filtering measures will be inevitable.*

2.4 Workbench Faraday cage

The present proposal, suitable for small application boards and semiconductor evaluation, is a table-top size Faraday cage where all the connections to DC-supply and other auxiliary equipment are made through filters mounted on the wall of the Faraday cage. The wires and cables from these filters to the PWB need to be wrapped on a ferrite toroid, Philips NiZn material 4A15, to create a high common-mode impedance towards the walls of the Faraday cage (= earth reference plane), similar to the construction given in Fig.3c. Then, by means of resistors defined impedances, 150 Ω (100 Ω in series with an external 50 Ω coaxial load), are applied to simulate the radiation or reception performance of the cables or wires which might be connected to this application board in practical (product) application.

Note 3: When a workbench Faraday cage is used, the earth reference plane is extended all around the PWB under test. As a result of the dimensions of the workbench Faraday cage, distance between PWB and CDN will remain $\leq 0,3$ metre.

To keep this method simple, the maximum number of common-mode measurement points is set to 3. All other wires and cables must be provided with a RF-blocking (high common-mode impedance) device towards the feed-through panel on the wall of the Faraday cage.

The common-mode measurement points on the PWB selected for evaluation are:

- at the DC-power supply connector,
- at the input port connector and
- at the output port connector.

Dependent on the implementation of the application board, containing one or several ICs, the emission or immunity performance can be measured, Fig.6 and 7. In those set-ups the coaxial 50 Ω loads outside the Faraday cage shall be exchanged in turn with either the selective voltmeter (spectrum analyzer) or the disturbance source.

For worst-case testing the three connector positions, which are selected as common-mode points, are distributed all alongside the PWB, Fig.4a. This arrangement is chosen because one can not predict the geometrical lay-out the customer is going to use in his product.

Note 4: Only if an application is required (to fulfil the requirements) such that all connectors are placed on one side only, Fig.4b. it must be tested as such. As a result, this condition then, shall be clearly stated in the application report.

The determination of the common-mode points of the selected ports is based on the cables or wire-geometries likely to occur in product application. Furthermore, dependent on the product application, the appropriate CDN shall be selected.

Workbench EMC evaluation method

EIE/AN91001

- When shielded cables are used, the shielding is referred to as common-mode point of that port (towards the wall of the Faraday cage), no matter how many wires are within that shielding.
- When unshielded cables are used, the common-mode impedance shall be established by placing a number of resistors to each individual wire such that the total common-mode resistance equals $100\ \Omega$ (+ $50\ \Omega$ external) towards the reference, being the wall of the Faraday cage. In series with those resistors capacitors ($C_{total} \geq 20\ \text{nF}$) must be applied such that the impedance requirements are still met.

In product applications where an IC is fed by a signal source properly defined, i.e. signal and ground return are adjacent tracks, separation $\ll 1\ \text{mm}$, **and** the tracks are short, length $\leq 0,1\ \text{metre}$, a coaxial CDN-type can be applied. The same applies for the output configuration. Commonly, supply traces are not kept adjacent properly from IC to supply and therefore an unbalanced two-wire CDN should be used. If an IC is properly decoupled, supply and ground will be RF-short-circuited and a coaxial CDN can be applied.

Warning 2: With analog circuits, outputs often cannot handle high capacitive loading which is represented by CDNs and its cables. As only the demodulated component at 1 kHz is of interest, an RC-filter need to be used in-between output and CDN, see Fig.5.

Fig.4. Typical arrangements of inputs, outputs and supply alongside the IC.

EIE/AN91001

2.5 Test equipment verification

The verification of the disturbance signal used with immunity testing shall be done as follows:

1. The RF generator is set at 10 MHz **un-modulated**. The output level shall be adjusted such that an rms voltage of e.g. 3 Volts appears at the port which will be connected to the coaxial feed-throughs (with the 100 Ω series resistor behind) of the Faraday cage. This voltage is measured across the output of the 50 Ω impedance matching network using a high input impedance RF-voltmeter.
2. Amplitude modulation must be turned on, using a 1 kHz sinewave (987.5 Hz / 1005 Hz, see chapter 3) and the modulation depth must be set to 80 %. By means of an oscilloscope this AM-signal shall be observed, Neither clipping nor modulation inversion may occur on the signal wave shape.

In this case the peak-to-peak level will be 15,3 Volt.

3 Volt rms = 4,24 Volt peak = 8,48 Volt peak-to-peak un-modulated.

3 Volt 80 % modulated then becomes 15,27 Volt_{p-p}.

3. When this verification is accomplished this signal is provided to the coaxial feed-through connected to the common-mode point under test.

With respect to emission measurements and the verification of the receiver used, further reference is made to IEC CISPR publication 16.

If the emission limit is given in Quasi-Peak or Average limits the emission performance shall be measured in Peak-mode first (because it is fastest to apply).

1. If the PWB satisfies the Average requirements, using the Peak-mode, no further measurements have to be carried out.
2. When the PWB **does not** satisfy the Average requirements but complies with the Quasi-Peak requirements, additional measurements in Average mode need to be carried out.
3. When the PWB **does not** fulfil either of the requirements, both measurements; Quasi-Peak and Average have to be carried out. Normally, there will be insufficient margin and PWB modifications will be necessary.

Note 5: If the RF-signal is a continuous sinusoidal wave, then the indications from either Peak, Quasi-Peak and Average-mode detectors will be equal.

2.6 Requirements

With conducted immunity measurements, the limit applicable to the product, e.g. draft IEC 801-6, can be used directly for verifying the IC application.

When radiated immunity requirements are given, a transformation from electric fieldstrength requirements to induced voltages and currents has to be considered. For indication the following relation can be considered:

Workbench EMC evaluation method

EIE/AN91001

- 1 Volt_{emf} (150 Ω in series) shall be taken for 1 Volt/metre (travelling wave, far field condition, generated by a tuned dipole antenna, distance ≥ 3 metre) in case the cables and EUT are exposed to the EM-field, i.e. transformation ratio = 0 dB.
- 0,3 Volt_{emf} (150 Ω in series) shall be taken for 1 Volt/metre (travelling wave, far field condition, generated by parallel plate or strip-line set-ups) in case only the EUT is exposed to the EM-field and cables are excluded, i.e. transformation ratio = -10 dB.

Note 6: The transformation ratio will depend on product size, the way cables are routed and frequency.

When carrying out conducted emission measurements in the frequency range, freq. ≥ 30 Mhz, where the radiation limits are given in μVolt/metre, measured at 10 metre distance, the following approximation can be applied:

$$E_{\text{limit}} = 30 \text{ dB}\mu\text{V/m} (= 30 \mu\text{V/m}) \text{ at 10 metre distance from the object.}$$

$$E = (7/d) \cdot \sqrt{P_t}, \quad P_t = U^2/150 \Omega,$$

$$E = (7/10) \cdot \sqrt{(U^2/150)} = U/17,5$$

$$E(\text{dB}\mu\text{V/m}) = U(\text{dB}\mu\text{V}) - 25 \text{ dB.}$$

In some emission standards, e.g. automotive and information technology equipment, conducted emission requirements are given over a large frequency range. Those requirements shall be adhered without any transformation.

In portable applications such as radio or television where an on-top antenna is used, functional requirements will be much more severe than the legal requirements. Those functional limits need to be measured on the product, without any annoying disturbances, and thereafter the relation given in chapter 2.6 can be applied to the found limit.

Workbench EMC evaluation method

EIE/AN91001

3 EXAMPLES.

All applications, e.g. a single op-amp, a transmission/speech circuit for telephone, μP or video processor are tested on immunity with impedances (symmetrical and a-symmetrical loading) at inputs and outputs applied according to the application instructions (which shall be stated in the application report !!).

When these (input, output) impedances are passive, they can be either outside or inside the workbench Faraday cage. When these are active, they should be outside. When coaxial feed-throughs are used, care must be taken by additional measures (low-pass-filters, see Fig.5) that the RF-energy which will be superimposed on either input or output lines does not adversely affect the performance of the auxiliary equipment **and** that by measures the source or load impedance remains properly defined (even at RF).

The signal wires going from the application board to the feed-through connectors or filters shall be provided with an RF-blocking impedance, represented by 14 - 17 turns on a 4C65 (freq ≥ 1 MHz) or better 4A15 ferrite toroid.

By means of three $100\ \Omega$ resistors (PR 37 or PR 52, or equivalent power metal film resistors), the common of the input, output and supply is then coupled to the three coaxial feed-through connectors as indicated in paragraph 2.3. Externally, these connections are either coupled to the RF-disturbance generator, the selective voltmeter or terminated by a $50\ \Omega$ coaxial resistor.

Note 7: The lay-out of the PWB shall be made such that either the typical performance of the circuit is tested (non-optimized mono- or bi-layer) or on e.g. multi-layer with every precaution taken to have optimal EMC performance of the IC in this application.

Note 8: If the latter application cannot satisfy the EMC requirements, then no designer/customer will be capable of making a proper product with it at reasonable costs.

3.1 Audio applications.

3.1.1 Immunity

The audio circuit shall be set at nominal (gain) conditions. When necessary or obtainable, a 1 kHz generator can be used to make the required setting. The baseband 1 kHz output signal across the normal load shall be measured. This level will be taken as a reference for the immunity performance testing.

The disturbance signal (RF, 80 % modulated by 1 kHz) shall be applied to one of the common-ports of the PWB under test in turn, while the other ports are terminated to reference by $50\ \Omega$. A demodulated signal level (1 kHz only) of 40 dB less than the nominal signal level across that load is acceptable for proper operation. This level can be measured either by a low frequency spectrum analyzer or a sensitive AC-Voltmeter with a 1 kHz band-pass in front (as described in EN 55020). A typical pass-band bandwidth of 500 Hz is sufficient for these kind of measurements.

Workbench EMC evaluation method

EIE/AN91001

Example: The nominal level on the a,b-lines of a telephone system is 100 mV (across 600 Ω). The signal level across the earpiece can be measured and may be 30 mV (example only !!, determined by dynamic sensitivity of the earpiece). The level of the demodulated signal across that same earpiece, with the disturbance signal applied to the PWB shall be less than 0.3 mV.

3.1.2 Emission

In most cases the emission from linear applications is nil unless it contains some oscillator. In the latter case, the disturbance generator shall be replaced by a spectrum analyzer covering the frequency range of interest, commonly 9 kHz to 1 GHz. As the emission will be continuous (at the fundamental and its harmonics), the detector chosen in the spectrum analyzer will not influence the readings. Where possible, the bandwidth requirements as stated in IEC CISPR publication 16 shall be adhered to.

3.2 Video applications

3.2.1 Immunity

With video applications it will be such that most applications are based on an interlaced video frame sequence of 25 or 30 Hz. In both situations the spectrum around 1 kHz is fully crowded by harmonics of the frame frequency. It is therefore, that the modulation frequency, nominal 1 kHz should be shifted a little up/down such that it becomes an inter-harmonic of the frame frequency.

Examples: 25 Hz \rightarrow 987,5 Hz
30 Hz \rightarrow 1005 Hz

To obtain nominal settings of the video application a colour bar signal is applied to the circuit to be fully operational.

The demodulated signal at the outputs, e.g. CVBS, RGB or sync. can be measured by using a spectrum analyzer with a resolution bandwidth of ≤ 6 Hz. This selectivity is required to obtain a signal-to-noise ratio sufficient to discriminate the demodulated signal from the wanted signal. Here the demodulated signal to nominal signal level, $\frac{\text{demodulated signal}}{\text{nominal signal level}}_{(\text{peak-to-peak})}$ ratio has to be about -55 to -60 dB to be just not perceptible on the screen. This limit level can be found by superimposing a 1 kHz signal to the normal signal while observing the picture. The 1 kHz generator level is increased up to a level where it becomes just perceptible on the screen. This level referred to the functional signal is then taken as limit for the signal-to-interference ratio (S/I).

Note 9: Special care shall be taken to assure that the demodulation of the spectrum analyzer is much less than the limit level to be measured. Additional low-pass filters, see Fig.5, may be required !! Furthermore, it may be necessary to use a comb-filter to lower the level of the frame harmonics.

Example: The video signal level of the G-signal from the processor board to the video output stage is 3600 mV_{p-p}. Then the demodulated signal shall be less than 3,6 mV_(peak).

Note 10: Disturbing signals may also effect synchronization and as such appear as vertical zig-zag lines on the screen. This effect can only be measured by using a jitter or phase modulation meter between sync-out of the pattern generator and the output signal coming from the PWB.

Workbench EMC evaluation method

EIE/AN91001

3.2.2 Emission

As indicated above emission from the PWB is measured by replacing the disturbance generator by a spectrum analyzer or selective voltmeter. In analog applications, emission will be caused by the video signal itself and some oscillator signals used for demodulation, mixing, etc. According to the emission standard EN 55013, the test page pattern of teletext shall be used as video information. Where possible, the bandwidth and detector requirements as stated in IEC CISPR publication 16 shall be adhered.

3.3 Digital applications

3.3.1 Immunity

With digital applications, the main problem will be the fact that it needs wide address and data buses for operation. As these wide buses are inconvenient for this method, these shall be limited by simplifying the circuit or by introducing parallel-to-series and series-to-parallel decoders. Preferable, these decoders must be used on the PWB under test such that only one serial line will be fed through the wall of the cage. To isolate the decoders from the IC under test, series resistors, e.g. 1 k Ω , shall be used in-between the decoders and the IC. The common-mode points on the PWB needs to be chosen close to the IC to be tested instead of the serial decoder input and output ports indicated in chapter 2.4.

By means of a tap, the signals at the output of the IC shall be monitored by means of an oscilloscope or a logic analyzer with an analog input and adjustable threshold levels. As criteria, the output signal of the IC may not exceed the specified high/low levels other than during functional transitions.

When testing the inputs, the worst case DC-levels shall be superimposed to the input signal (if it does not already contain a DC-component from a previous stage). When the disturbance signal is applied to the common-mode points chosen, the signal levels at the outputs shall be observed.

With more complex circuits it can be such that analog and digital inputs and outputs are available. By closing the loop; data \rightarrow dig.out \rightarrow dig.in \rightarrow analog out \rightarrow analog in \rightarrow compare with initial data and turn on/off a flag, which drives a LED, a powerful test program is carried out.

3.3.2 Emission

For proper operation, the normal program or coding shall be applied to the IC such that the emission measured is representative for a typical application. In case of a μ P, the outputs can be driven such that a digital ramp function (bit 0 = frequency F0, bit 1 = F0/2, etc) is generated over its 4, 8 or 16 bits wide data bus. All buses will have typical length e.g. 0,1 metre. The end of the bus shall be terminated as indicated in the application report e.g. by 50 pF//3.3 k Ω . The common-mode points for the IC under test shall be taken (similar as with immunity) to measure the emission performance of the IC in its application.

Workbench EMC evaluation method

EIE/AN91001

4 THE WORKBENCH CAGE PARAMETERS

The size of the workbench Faraday cage is chosen in such a way that it can contain most typical application and evaluation boards:

Length:	500 mm
Width :	350 mm
Height:	150 mm

The Workbench Faraday cage is made from carbon-free iron 1,5 mm thick. A conductive gasket is used between the box and the cover to make proper contact. The inside of the box is covered with an anti-static insulating material.

The connections through the wall can be made by:

Coax	:	5 x BNC,
Single line	:	4 x π -filter,(2 x 1,35 nF + 8 μ H, 2 Amp., 50 Volt max.),
	:	6 x Feed-through capacitors, (62 nF, 16 Amp., 500 Volt max.).

The shielding effectiveness in H_{xyz} directions is better than 60 dB in the frequency range 1 to 1000 MHz, measured with two 60 mm electrically shielded loops according to Mil.Std. 220. An example of the shielding effectiveness of the workbench Faraday cage is given in Fig.7.

The characteristics of the π -filters (Low-Pass-Filter at 1 MHz) and the feed-through capacitors are given in Fig.8. The choice for these filters is made such that by additional external measures the filtering performance can be enhanced at low frequencies. For most applications the given performance will be sufficient. These π -filters can also be used at the outputs of digital circuits when using a 100 Ω resistor in series. In this case, the pass-band is limited to about 500 kHz, which is still sufficient to allow e.g. I²C-communication.

A/D conversion with P83CL410 PCF1252-x

EIE/AN91006

Author: Th. v. Daele, Product Concept & Application Laboratory, Eindhoven, The Netherlands

1. INTRODUCTION

With an 83CL410 microcontroller and a PCF1252-x reset circuit, it is possible to make a software driven A-to-D converter. In this application note, an example is described where an 83CL410 measures its own supply voltage. The resolution of the measurement is 0.1V. The program example also refers to this application.

Chapter 2 describes the algorithm of the conversion. In chapter 3 the example with 83CL410/PCF1252 is described. Both hardware and software of this example are explained.

References:

- 80C51-based 8-bit microcontrollers; Data Handbook IC20
- PCF1252-x data sheet

2. A-TO-D CONVERSION PRINCIPLE

The basic principle of the conversion is to convert the voltage to a time measurement. A microcontroller without an on-chip A-to-D converter cannot measure voltages directly, but if converted to a time measurement, this can be done by software or with the help of an on-chip timer/count.

Figure 1 shows the basic circuit to do the conversion. The circuit consists of an integrator circuit, a voltage reference and an analog input switch S. The analog input switch is controlled by the microcontroller. The integrator is built around a comparator whose output is connected to a microcontroller input.

Before the measurement is started, the analog switch connects the integrator input to ground, so that the integration capacitor is fully discharged. The measurement is started by connecting the integrator input to the unknown voltage. The integration capacitor will charge up. When the non-inverting input exceeds the reference voltage, the comparator output will switch from LOW to HIGH.

A/D conversion with P83CL410 PCF1252-x

EIE/AN91006

The time between starting the measurement and the moment that the comparator output becomes HIGH, is measured by the microcontroller and is:

$$T_1 = -RC \cdot \ln \frac{V_x - V_{ref}}{V_x}$$

The charging continues until the capacitor is fully charged. Then the integrator input is grounded via the analog switch. The integration capacitor discharges while the comparator output is HIGH. When the input voltage becomes lower than the reference voltage, the comparator output becomes LOW again. The time between the start of the discharging and the moment that the comparator output becomes LOW, is measured by the microcontroller and is:

$$T_2 = -RC \cdot \ln \frac{V_{ref}}{V_x}$$

When the microcontroller uses the ratio between T_1 and T_2 , the result becomes independent of the values R and C. The resulting ratio can then be used as a pointer to a look-up table that may contain an indication for the measured parameter or display data.

3. EXAMPLE OF CONVERSION PRINCIPLE

3.1 Hardware

In the example, an application is used where a microcontroller measures its own supply voltage. The supply voltage is generated by solar cells, so power consumption should be minimized. The measured voltage is shown on an LCD display.

An 83CL410 is used as microcontroller. This controller is an 80C51 family member. Compared with a standard 80C51, it has the following extra features:

- Wide supply voltage range of 1.8V to 6V.
- Wide operating frequency range of 32kHz to 20MHz with internal oscillator. With external oscillator there are no limitations on the lower frequency limit.
- Byte I²C interface instead of UART.
- 8 extra external interrupt inputs on P1. The interrupt level is programmable. These interrupts can terminate the power-down mode.
- 3 mask programmable I/O port configurations.
These configurations are:
 - Standard quasi-bidirectional I/O
 - Open-drain output, standard input
 - Push-pull output, no input
- I/O port levels after RESET are mask programmable.

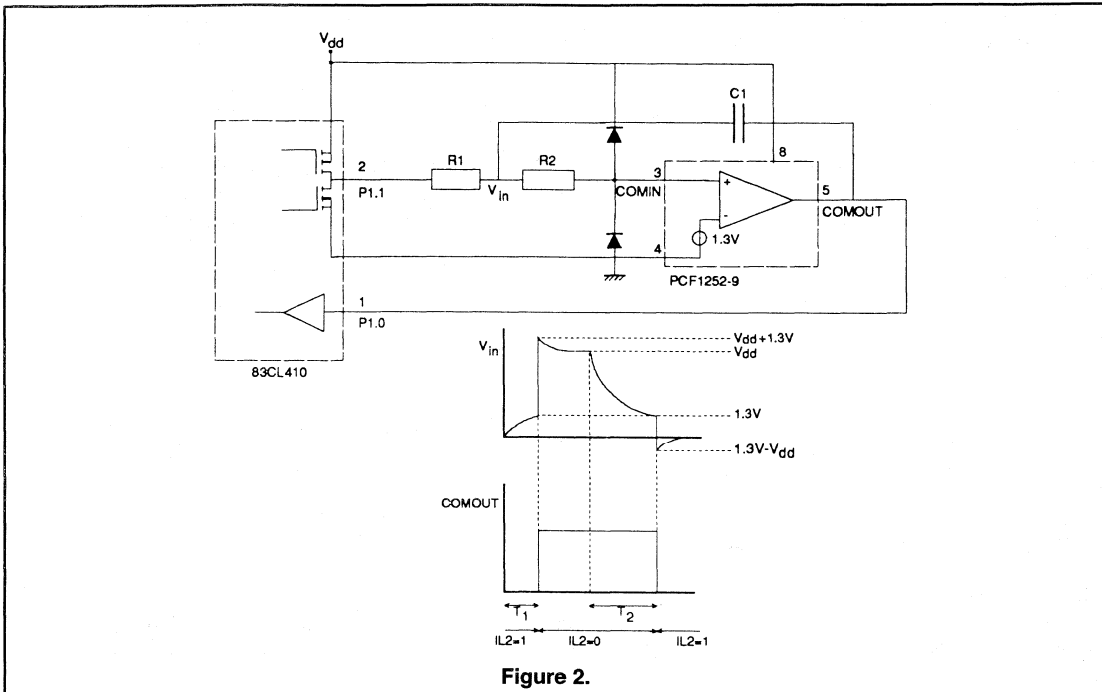

Of these features, only the byte I²C interface is not used.

The PCF1252 is used for monitoring the power supply voltage and generating a reset pulse when the supply drops too much. Several versions of PCF1252 are available, every one with its own trip voltage. The PCF1252 also has an unused comparator. This comparator is used for the integrator circuit. The inverting input is internally connected to a 1.3V reference.

Figure 2 shows the A-to-D conversion part of the circuit.

A/D conversion with P83CL410 PCF1252-x

EIE/AN91006

R1 and C1 determine the time-constant of the circuit. The input of the integrator is connected to P1.1 of the microcontroller. This port line has a push-pull configuration. It is used as the analog switch shown in Figure 1. When this output line is made HIGH, the integrator is connected to the supply voltage. This is the voltage to be measured. The voltages on the non-inverting input and the output are shown in Figure 2. The output of the comparator is LOW, and the capacitor will be charged. When the voltage at the non-inverting input becomes higher than 1.3V, the comparator output will become HIGH. This HIGH level will cause an interrupt on P1.0 (IL2=1). The voltage on the inverting input will want to rise to $V_{CC} + 1.3V$. This voltage is limited by 2 external diodes. R2 is a current limit resistor.

Next step is that P1.1 becomes LOW, so that the capacitor will be discharged. The P1.0 input is now programmed to generate an interrupt on a LOW level (IL2=0). This will happen when the voltage on the inverting input has dropped below 1.3V.

At this point, both charge and discharge times are known, and the supply voltage can be calculated. In this circuit, the PCF1252-9 is used, which will generate a reset pulse when the supply voltage is lower than 2.55V. This limits the lower end of the supply voltage range. However, the 83CL410 is able to go as low as 1.8V.

To minimize power consumption, the lowest frequency is used where the internal oscillator can still be sued. this is 32.768kHz. This parameter, together with the resolution that must be met, determine the minimum value of R1.C1. In this example, a resolution of 0.1V is achieved. The software is made to handle voltage measurements from 1.8V to 5V.

A/D conversion with P83CL410 PCF1252-x

EIE/AN91006

To determine the minimum value of R1C1, the measurement of 5.0V and 4.95V is important because here the distance between measurements of T₁ and T₂ is minimal.

$$\begin{aligned} V_x = 5.0V: \quad T_1 &= 0.301RC \\ T_2 &= 1.347RC \\ T_2/T_1 &= 4.437 \end{aligned}$$

$$\begin{aligned} V_x = 4.95V: \quad T_1 &= 0.304RC \\ T_2 &= 1.337RC \\ T_2/T_1 &= 4.398 \end{aligned}$$

$$\begin{aligned} V_x = 4.9V: \quad T_1 &= 0.308RC \\ T_2 &= 1.327RC \\ T_2/T_1 &= 4.308 \end{aligned}$$

Because of latency in the interrupt routine, a deviation Δt may occur in T₁ and T₂. The following conditions must be met:

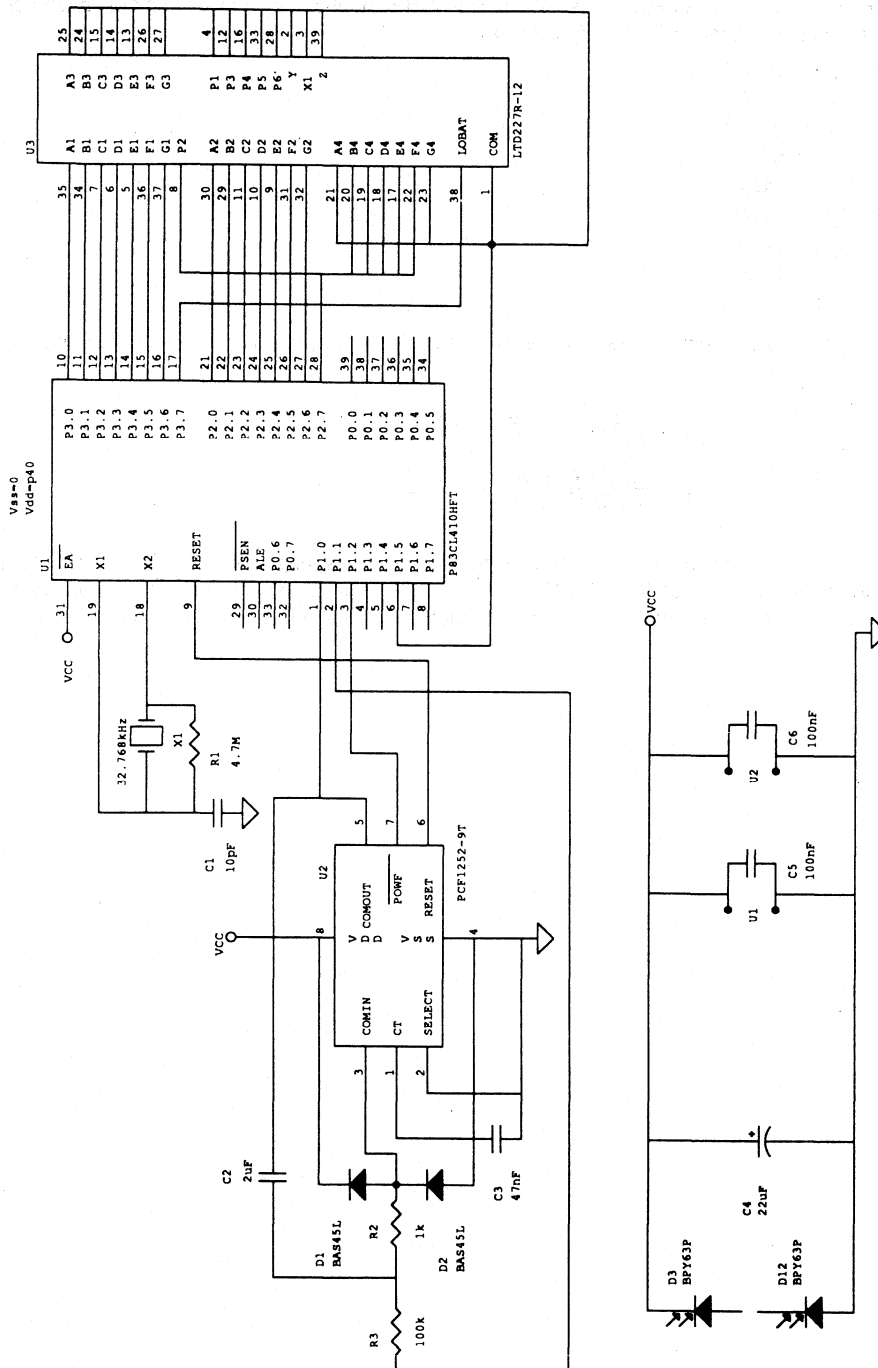

$$V_x = 5.0V: \quad \frac{T_2}{T_1} \frac{1.347RC \pm \Delta t}{0.301RC \pm \Delta t} \geq 4.398$$

$$V_x = 4.9V: \quad \frac{T_2}{T_1} \frac{1.327RC \pm \Delta t}{0.308RC \pm \Delta t} \geq 4.398$$

In this example, there is an uncertainty of 2 machine cycles when measuring T₁ and T₂. Given an XTAL frequency of 32.768kHz, the minimum value of RC is 0.172. The complete circuit diagram is shown of the example with the LCD connections. Since the LCD connections are only outputs, the push-pull configuration is used for this.

3.2 Software

In chapter 4 the listing of the program is shown.

After RESET the initialization takes place from L.45 to L.70.

The following timers 83CL410 are used:

- Timer_0: Used to measure the T1 and T2 (mode_1).
- Timer_1: Used to generate a timer interrupt for LCD polarity reverse (mode_2).
This is the auto-reload mode. Every 10ms an interrupt is generated.

3 interrupts are used:

- INT2: External interrupt for the A-to-D conversion. Priority level-1.
- INT4: Interrupt from PCD1252-9 when supply voltage is smaller than 2.55V. Priority level_1.
- Timer_1: Interrupt for LCD polarity reverse. Priority level_0.

The measurement is started at L74. The interrupt level of INT2 is set to '1' and time_0 is started to measure T1. P1.1 is set, so that the supply-voltage is connected to the integrator input. While the integration capacitor is charging, the 83CL410 is in IDLE-mode to reduce power consumption. This part of the measurement is identified by ADC_Status=1. When INT2 is generated, the interrupt routine is entered (from L.181). Timer_0 is read and its value is stored in R4 (MSB) and R5 (LSB). The interrupt level of INT2 is cleared to '0' for the second part of the measurement. After clearing the interrupt flag, the main program is entered again at L.85. a delay is entered at this point so that the integration capacitor can be discharged sufficiently from $V_x + 1.3V$ to V_x . The delay is 32 time-outs of timer_1. During this delay, the controller is in IDLE mode. After the delay, P1.0 is cleared to discharge the integration capacitor. Timer_0 is started to measure T2. Again the microcontroller enters the IDLE mode until INT2 is generated. In the interrupt routine, the interrupt level is now set to '1' again for the next A-to-D conversion. In the main program, T2 is copied to R6 (MSB) and R7 (LSB) (L.96 and L97).

Now that T1 and T2 are known, the measured voltage can be determined. This is done by calculating the ratio between T1 and T2, and converting this to a pointer which points to a table with the segment data of the LCD display. In the calculation, the ratio between T1 and T2 should be equal or greater than 1. If $T2 < T1$ (L.107) then the flag 'gr_2V6' will be cleared (L1.65) and [R4.R5] and [R6.R7] are exchanged. This point is met when the input voltage is 2.55V.

Normally, voltages < 2.55V will not be measured, because by then the PCF1252-9 has generated an interrupt on INT4. This means a power-failure and the only way to start the measurement again, is that the PCF1252-9 resets the microcontroller. The INT4 routine is from L.227 .. L.237). The program, however, contains the conversion table for input voltages as low as 1.8V.

The pointer to the table (stored in [R6.R7]) is calculated by: $[R6.R7] = 16 * [R6.R7] / [R4.R5]$. The division is done by the subroutine '_sdivi'. This is a library function contained in the C-library of the BSO/Tasking C-compiler package (type number OM41326). This library must be linked to this program.

Of the result, only R7 is relevant. The segment data contains 2 bytes, so pointer R7 is multiplied by 2 (L.134). There are 2 segment tables: one for voltages > 2.55V (L.247 .. L.274) and one for voltages < 2.55V (L.284 .. L.304). DPTR is used as pointer for this table and is calculated by adding the table base (L.129 .. L.132) and R7 (L.134 .. L.137). The following table shows the relation between the measured voltage, $16 * T1 / T2$ or $16 * T2 / T1$, the pointer and the segment data.

Now the data can be displayed on the LCD display. When writing data to the LCD, the timer_1 interrupt is disabled. The value of output LCD_COM (controlled by timer_1 interrupt routine) determines whether the data must be written inverted to the LCD or not. The data is written non-inverted from L.147 .. L.150, inverted from L.153 .. L.158. When the data is written, timer_1 interrupt is enabled again, and a new A-to-D conversion is started at label Start_ADC.

From L.210 .. L.219 the timer_1 interrupt routine is shown. In this routine the segment lines to the LCD display are inverted (on P2 and P3). Also LCD_COM is inverted, which is the COMMON pin of the display.

On L218 the value Dis_tim is incremented. This is for the delay between the measurement of T1 and T2 (see L.85).

Driver for 8xC851 E2PROM

EIE/AN91009

1. INTRODUCTION

A set of software functions is given to access the E²PROM on the 8xC851 microcontrollers. These functions can be called from application programs written in assembly, PL/M-51 or C. The functions are found in the E2PROM.OBJ file that can be linked to the application program.

The driver is written and tested with the following software tools from BSO-Tasking:

Assembler:	ASM51 V3.2	(OM4142)
PL/M51:	PL/M51 V3.0A	(OM4144)
C Comp.:	C51 V2.0	(OM4136)
Debugger:	XRAY51 V1.4c	(OM4129)

Resources used by driver:

- Exclusive use of 1 register bank (default RB1)
- Accumulator
- PSW
- 1 static bit addressable RAM byte

2. FUNCTION DESCRIPTIONS

The functions that use write and/or erase actions are interrupt driven except for E2PROM_wr_byte_pol. The application can check the status of these actions by testing the flag E2PROM_BUSY. This flag is available via the function E2PROM_status.

In the 8xC851, the E²PROM interrupt is combined with the UART interrupt. To enable the E²PROM interrupt, EA (in the IE-register) must be set (should be done in application program), the combined UART/E²PROM enable bit must be set (ES in the IE-register, done with function E2PROM_int_en) and the E²PROM interrupt enable bit (EEINT in ECNTRL register) must be set. The E²PROM interrupt flag is automatically set by functions that use erase/write actions. This means that the UART interrupt enable cannot be disabled while the E²PROM interrupt is completely enabled. The E²PROM can be disabled separately with the E2PROM_int_dis function.

The priority level for UART and E²PROM interrupt are the same and are defined with the E2PROM_int_en function.

The E²PROM driver has a link to a UART interrupt handler. When a UART interrupt occurs, the status of the controller is pushed on the stack and then interrupt flags are tested to determine the source of the interrupt. When the source of the interrupt is the UART, then subroutine _UART_HDL is called. the implementation of the UART interrupt handler is done by the user. On the disk a file UART.SRC is available that contains this subroutine. This routine will only clear the trx-interrupt flag (TI) and rcv-interrupt flag (RI).

Driver for 8xC851 E2PROM

EIE/AN91009

2.1 E2PROM_init

Function description:

This function must be called before any of the other functions is called. The timing register for writing/erasing the E²PROM is initialized and the register bank that the E²PROM functions can use is defined.

The default registerbank is RB1; the ETIM register which determines the write/erase timing is default initialized with 0x7B (XTAL = 12MHz). If other values are required, the parameters REGISTERBANK and XTAL must be changed in the equate list of the source file (E2PROM.ASM).

The E²PROM/UART interrupt is enabled and set to priority level '0'.

Calling Sequence:

```
E2PROM_init();
```

Function prototype:

```
void E2PROM_init (void)
```

Parameters:

None

2.2 E2PROM_int_en

Function description:

This function will enable the E²PROM/UART interrupt. The global enable bit EA is not effected and must be controlled by the application program.

The priority level of the E²PROM/UART is controlled by the parameter 'Pr_Level'.

Calling Sequence:

```
E2PROM_int_en (Pr_Level);
```

Function prototype:

```
void E2PROM_int_en (data char Pr_Level)
```

Parameters:

Pr_Level: This parameter determines the priority level on which the E²PROM/UART interrupts are handled. Values greater than 0x01 will be interpreted as 0x01.

2.3 E2PROM_int_dis

Function description:

This function will disable the E²PROM/UART interrupt.

Calling Sequence:

```
E2PROM_Int_Dis;
```

Function prototype:

```
void E2PROM_Int_Dis (void)
```

Parameters:

None

Driver for 8xC851 E2PROM

EIE/AN91009

2.4 E2PROM_status

Function description:

This function will return the E2PROM_BUSY bit, which indicates whether a read/write transfer from/to the E²PROM, or an erase action is finished.

'1' indicates that a read/write transfer is still in progress.

'0' indicates that no read/write transfer is in progress.

If the application program calls an E²PROM function while another E²PROM function is still in progress, parameters may be overwritten and an erroneous result will be obtained. There are 2 exceptions on this rule. When the functions "E2PROM_rd_byte_pol" or "E2PROM_wr_byte_pol" are called, parameters are passed to different registers in the registerbank, the E2PROM status is stored and the transfer is done by polling.

Note that the E2PROM_BUSY bit is not the same as EWP-flag in the ECNTRL register. For write operations the EWP-flag indicates when the writing/erasing of a byte to the E²PROM is finished. The E2PROM_BUSY flag indicates when a complete block of data (e.g., from the E2PROM_wr_block function) has been written to the E²PROM.

Calling Sequence:

```
bit Status;  
Status = E2PROM_Status;
```

Function prototype:

```
bit E2PROM_Status (void)
```

Parameters:

None

2.5 E2PROM_wr_byte

Function description:

This function will write a byte to E²PROM.

If the source byte has the same value as the byte in the E²PROM, no write action will take place.

Byte transfer is done on interrupt basis. The status of the transfer can be checked with the "E2PROM_Status" function.

This function will automatically enable the E²PROM interrupt. The application program should take care of the E²PROM/UART interrupt enable (with E2PROM_int_en) and the EA bit.

Calling Sequence:

```
E2PROM_wr_byte (Src_Byte, Dest_Ptr);
```

Function prototype:

```
void E2PROM_wr_byte (data char Src_Byte, data char Dest_Ptr)
```

Parameters:

```
Src_Byte:    Byte to be written to E2PROM  
Dest_Ptr:    Address of E2PROM
```

Driver for 8xC851 E2PROM

EIE/AN91009

2.6 E2PROM_rd_byte

Function description:

This function will read a byte from E²PROM. The status of the transfer can be checked with the "E2PROM_Status" function.

Calling Sequence:

```
data char Result;
Result = E2PROM_rd_byte (Src_Ptr);
```

Function prototype:

```
char E2PROM_rd_byte (data char Src_Ptr)
```

Parameters:

Src_Ptr: Address of E²PROM

2.7 E2PROM_wr_block

Function description:

This function will write a block of data from internal RAM to E²PROM.

Byte transfer is done on interrupt basis. The status of the transfer can be checked with the "E2PROM_Status" function.

This function will automatically enable the E²PROM interrupt. The application program should take care of the E²PROM/UART interrupt enable (with E2PROM_int_en) and the EA bit.

If the source bytes are the same as the bytes in the E²PROM, no write action will take place. This function will automatically generate ROW-erases, whenever this will reduce programming time. If during execution of this function, the destination address to the E²PROM is equal to the beginning of an E²PROM row (3 least significant address bits are '0') and at least 8 more bytes have to be programmed, a check will be done whether a ROW-erase will reduce programming time. If no RWO-erase is done, the time to program the ROW will be:

$$T_{\text{prog}} = A \cdot t_W + B \cdot (t_E + t_W)$$

A: Byte in E²PROM is 0x00; source byte in RAM is not 0x00
 B: Byte in E²PROM is not 0x00; source byte in RAM <> E²PROM byte

If a ROW-erase is done, programming the ROW will take:

$$T_{\text{prog}} = t_E + C \cdot t_W$$

C: Source byte in RAM <> '0'

Because the erase time (t_E) and the write time (t_W) are equal, the function will do a ROW-erase if $A + 2 \cdot B - C - 1 \geq 0$

Calling Sequence:

```
E2PROM_wr_block (Src_Ptr, Dest_Ptr, Nr_Bytes);
```

Function prototype:

```
void E2PROM_wr_block (data char *data Src_Ptr, data char Dest_Ptr, data char Nr_Bytes)
```

Parameters:

Src_Ptr: Address pointer to internal RAM
 Dest_Ptr: Address of first E²PROM byte
 Nr_Bytes: Number of bytes to write to E²PROM

Driver for 8xC851 E2PROM

EIE/AN91009

2.8 E2PROM_rd_block

Function description:

This function will read a block of data from E²PROM and store it in internal RAM. The status of the transfer can be checked with the "E2PROM_Status" function.

Calling Sequence:

```
E2PROM_rd_block (Src_Ptr, Dest_Ptr, Nr_Bytes);
```

Function prototype:

```
void E2PROM_rd_block (data char Src_Ptr, data char *data Dest_Ptr, data char Nr_Bytes)
```

Parameters:

Src_Ptr:	Address of first E ² PROM byte
Dest_Ptr:	Address pointer to internal RAM
Nr_Bytes:	Number of bytes to read from E ² PROM

2.9 E2PROM_wr_byte_pol

Function description:

This function will write a byte from internal RAM to E²PROM.

If the source byte has the same value as the byte in the E²PROM, no write action will take place.

If an E²PROM function is in progress (except E2PROM_rd_byte_pol), this function will be interrupted but its status will be saved so that the interrupted function will be resumed when the E2PROM_wr_byte_pol function is finished.

Byte transfer is done by polling.

This function may be used, e.g., in interrupt service routines, where the possibility exists that the interrupted main program has already started an E²PROM transfer.

Calling Sequence:

```
E2PROM_wr_byte_pol (Src_Byte, Dest_Ptr);
```

Function prototype:

```
void E2PROM_wr_byte_pol (data char Src_Byte, data char Dest_Ptr)
```

Parameters:

Src_Byte:	Byte to be written to E ² PROM
Dest_Ptr:	Address of E ² PROM

Driver for 8xC851 E2PROM

EIE/AN91009

2.10 E2PROM_rd_byte_pol

Function description:

This function will read a byte from E²PROM.

If an E²PROM function is in progress (except E2PROM_wr_byte_pol), this function will be interrupted but its status will be saved so that the interrupted function will be resumed when the E2PROM_rd_byte_pol function is finished.

This function may be used, e.g., in interrupt service routines, where the possibility exists that the interrupted main program has already started an E²PROM transfer.

Calling Sequence:

```
data char Result;  
Result = E2PROM_rd_byte_pol (Src_Ptr);
```

Function prototype:

```
char E2PROM_Rd_Byte_Pol (data char Src_Ptr)
```

Parameters:

Src_Ptr: Address of E²PROM

2.11 E2PROM_block_erase

Function description:

This function will erase all 256 E²PROM bytes.

The erase function is done on interrupt basis. The status of the transfer can be checked with the "E2PROM_Status" function.

This function will automatically enable the E²PROM interrupt. The application program should take care of the E²PROM/UART interrupt enable (with E2PROM_int_en) and the EA bit.

Calling Sequence:

```
E2PROM_block_erase();
```

Function prototype:

```
void E2PROM_block_erase (void)
```

Parameters:

None

Driver for 8xC851 E2PROM**EIE/AN91009**

2.12 E2PROM_security_on**Function description:**

This function inhibits access to E²PROM from external program memory.
The following scheme gives the access possibilities when this function is executed.

EA pin	Address of E2PROM access instruction	Access to E2PROM
1	< 4096	YES
1	>= 4096	NO
0	< 4096	NO
0	>= 4096	NO

The write function is done on interrupt basis. The status of the transfer can be checked with the "E2PROM Status" function.

This function will automatically enable the E²PROM interrupt. The application program should take care of the E²PROM/UART interrupt enable (with E2PROM_int_en) and the EA bit.

Calling Sequence:

```
E2PROM_security_on();
```

Function prototype:

```
void E2PROM_security_on (void)
```

Parameters:

None

Driver for 8xC851 E2PROM

EIE/AN91009

2.13 E2PROM_security_off**Function description:**

This function will remove E²PROM protection. Access to E²PROM from external program memory is now possible if this function is executed from the right program memory.

The following scheme gives the possibilities when 'E²PROM_security_off' is executed after completion of the 'E²PROM_security_on' function.

The following table assumes that the address at which 'E²PROM_security_off' resides is smaller than 4096.

EĀ pin	Address of E2PROM access instruction	Mode	Access to E2PROM	E2PROM erased
1	< 4096	0	YES	NO
1	>= 4096	0	YES	NO
1	< 4096	1	YES	YES
1	>= 4096	1	YES	YES
0	< 4096	0	NO	NO
0	>= 4096	0	NO	NO
0	< 4096	1	YES	YES
0	>= 4096	1	YES	YES

The following table assumes that the address at which 'E²PROM_security_off' resides is greater than 4096.

EĀ pin	Address of E2PROM access instruction	Mode	Access to E2PROM	E2PROM erased
1	< 4096	0	YES	NO
1	>= 4096	0	NO	NO
1	< 4096	1	YES	YES
1	>= 4096	1	NO	YES
0	< 4096	0	NO	NO
0	>= 4096	0	NO	NO
0	< 4096	1	YES	YES
0	>= 4096	1	YES	YES

Calling Sequence:

E2PROM_Security_Off;

Function prototype:

void E2PROM_Security_Off (data char Mode)

Parameters:

Mode: If '0', then the protection will only be removed when this function is executed from internal program memory. When executed from external memory, the protection remains.
If '1', then the protection can also be removed when this function is executed from external memory, however, all E²PROM bytes will be erased.

Driver for 8xC851 E2PROM

EIE/AN91009

3. PROGRAM EXAMPLES

Three examples are given that show how to use these functions with C, PL/M51 and assembly programs. In the examples, a string of characters is written to and read from E²PROM. When reading back the string, spaces are replaced by underscores.

3.1 C example

The disk contains the file E2PROM.H that should be included in the C application program. E2PROM.H contains the function prototypes of the E²PROM functions. The example program can be found on the disk in file TEST_C.C.

When the application module is compiled and assembled, it should be linked to the E²PROM function module E2PROM.OBJ and the UART interrupt handler UART.OBJ.

3.2 PL/M51 example

The disk contains the file E2PROM.DCL that should be included in the PL/M51 application program. E2PROM.DCL contains the external function declarations for the E²PROM functions. The example program can be found on the disk in file TEST_PLM.PLM.

When the application module is compiled and assembled, it should be linked to the E²PROM function module E2PROM.OBJ and the UART interrupt handler UART.OBJ. When linking, the linking control 'NOCASE' must be used!

3.3 Assembly example

The disk contains the file E2PROM.MAC which contains the macro definitions of the functions. Including these macro's in the source file eases programming. For instance, the sequence:

```
MOV _E2PROM_rd_block_BYTE ,Src_Ptr      ;Pointer to E2PROM
MOV _E2PROM_rd_block_BYTE+1, Dest_Ptr   ;Pointer to RAM
MOV _E2PROM_rd_block_BYTE+2, #Nr_Bytes  ;Number of bytes to transfer
LCALL _E2PROM_rd_block                  ;Call function
```

can be replaced by

```
%E2PROM_rd_block(Src_Ptr, Dest_Ptr, #Nr_Bytes)
```

The file E2PROM.GLO contains the EXTRN-definitions of the functions and constants that are used by the driver. Only the definitions used by the source program should be included.

When the application module is compiled and assembled, it should be linked to the E²PROM function module E2PROM.OBJ and the UART interrupt handler UART.OBJ.

3.4 Listing of examples

LISTING C EXAMPLE:

```

#include "E2PROM.h"
#include <string.h>
#define E2PROM_Base_Address 0x58

rom char txt_tab[] = "This is an E2PROM test for 8xC851"

void main(void)
{
    data char    Data_Buffer[35];
    data char    Count;

    E2PROM_init();          /* Initialize E2PROM */
    E2PROM_int_en(0x01);   /* E2PROM interrupt level 1 */
    EA=1;                  /* Global interrupt enable */

    romidmove(&Data_Buffer,&Txt_tab,sizeof(Txt_tab)-1); /* Copy string from ROM
                                                         to RAM */
    E2PROM_wr_block(&Data_Buffer,E2PROM_Base_Address,sizeof(Txt_tab)-1);
                                                         /* Copy setting to E2PROM */

    /* Time to do other useful things while data is being written to
       E2PROM on interrupt basis */

    while (E2PROM_status()); /* Wait till transfer to E2PROM is finished */

    /* Read string from E2PROM and replace spaces " " by underscores "_" */
    for (Count=0;Count != sizeof(Txt_tab)-1;Count++)
    {
        /* Read E2PROM byte */
        Data_Buffer[Count] = E2PROM_rd_byte(E2PROM_Base_Address+Count);
        if (Data_Buffer[Count] == ' ')
            Data_Buffer[Count] = '_';
    }

    E2PROM_block_erase(); /* Erase E2PROM */
    /* Time to do other things while erasing */

    while (E2PROM_status()); /* Wait till erasing is finished */
    EA=0;
}

4. DEBUG MACROS

The disk contains some debug macros that ease the debugging of programs that use the 8xC851 E²PROM. These macros can be executed by the XRAY51 High Level Language debugger. The user can read from and write to E²PROM bytes without programming the individual SFRs.

Before the macros can be executed, they must be loaded by XRAY51. This will be done automatically if the file 'E2PROM.INC' is included when invoking XRAY51 or during a debug session. E2PROM.INC will load the macros and define some symbols used by the macros. If not all macros are used, the file E2PROM.INC can be edited to prevent the loading of these macros. This may be necessary when there is insufficient memory to load the macros, because, for instance, other macros have been loaded. Another advantage of only loading the relevant macros is reduction of loading time.

When a macro is called from the debugger, the following SFRs will remain unchanged: ECNTRL, EADRH, EADRL and ETIM. During macro execution, all interrupts will be disabled. Access to the E²PROM with the macros is independent of the state of the security bit. The execution and results of the macro are visible on the I/O screen of XRAY51 (VSCREEN 3).

Read(Start address, Stop address):

The value of E²PROM bytes from 'START ADDRESS' to 'STOP ADDRESS' will be shown.
If 'START ADDRESS' <= 'STOP ADDRESS' only the value of 'START ADDRESS' will be shown.

Write(Start address, Stop address, Value):

The E²PROM bytes from 'START ADDRESS' to 'STOP ADDRESS' will be programmed with 'VALUE'.
If 'START ADDRESS' > 'STOP ADDRESS', no E²PROM bytes will be programmed.
If the ETIM register contains the value 0x08, it is considered that ETIM is not initialized. The macro will give a warning, and return to the debug screen.

Copyto(Ram address, E2PROM address, Count):

Macro will copy 'COUNT' bytes, starting from internal RAM address 'RAM ADDRESS' to the E²PROM, starting at address 'E2PROM ADDRESS'.
If during copying, the RAM address becomes > 0x7F or the E²PROM address becomes > 0xFF, copying will be stopped and a warning is given that an address limit is reached.
If the ETIM register contains the value 0x08, it is considered that ETIM is not initialized. The macro will give a warning, and return to the debug screen.

Copyfrom(E2PROM address, Ram address, Count):

Macro will copy 'COUNT' bytes from E²PROM address 'E2PROM ADDRESS' to the internal RAM, starting at address 'RAM ADDRESS'.
If during copying, the RAM address becomes > 0x7F or the E²PROM address becomes > 0xFF, copying will be stopped and a warning is given that an address limit is reached.

Erase():

All E²PROM bytes will be erased.
If the ETIM register contains the value 0x08, it is considered that ETIM is not initialized. The macro will give a warning, and return to the debug screen.

Driver for 8xC851 E2PROM**EIE/AN91009**

5. CONTENTS OF DISK

The disk contains the following 3 directories:

1. \USER

This directory contains the files that may be included or linked to the source program.

E2PROM.ASM	:Source file of E ² PROM driver
E2PROM.OBJ	:Object file of E ² PROM driver
E2PROM.H	:Header file for C applications
E2PROM.DCL	:Declaration file for PL/M51
E2PROM.MAC	:Macro definitions for assembly applications
E2PROM.GLO	:Global definitions for assembly applications
UART.SRC	:UART interrupt handler (will only clear flags; user should customize it)
UART.OBJ	:Object file of UART interrupt handler

2. \DEBUG

This directory contains the macros and include file used with XRAY51 debugger.

E2PROM.INC	:Include file that reads macro files in XRAY51
*.MAC	:XRAY51 macros

3. \EXAMPLE

This directory contains the source files of the example programs described in the note

TEST_C.C	:C example
TEST_PLM.PL	:PL/M51 example
TEST_ASM.ASM	:ASM51 example

Low RF-emission applications with a P83CE654 microcontroller

EIE/AN92001

1. Introduction

Quite recently customers asked for dedicated 8-bit microcontrollers at high clockrates which would not cause Radio Frequency (RF-) disturbances in consumer and communication applications, e.g. key-board control, tuning, etc...

Up to now either a slower 4-bit microcontroller was used or a more modern 8-bit microcontroller is in use with additional RF-shielding and filtering measures.

With a carradio manufacturer, a bargain was set for a new (EMC friendly) 8-bit microcontroller such that the product would maintain equal receiving performance with more control features. The new receiver would then only be modified for the microcontroller part.

To set the emission requirements, for a microcontroller in this application, the measurement technique described in the application note, EIE/AN91001 "Workbench EMC evaluation method", was used and applied to the existing receiver in which the new microcontroller has to fit in.

Later on, the same technique was used to verify the basic and modified samples which contained one or more measures to reduce RF-emission.

Each (mask) shrinking event will cause circuits to become faster and produce more RF-disturbances for these kind of appliances. As such, more EMC measures need to be taken after each shrinking event to maintain the above set emission requirements.

2. Measures to reduce RF-emission

Up to now, evident measures are known to reduce RF-emission. Within a few years time, new techniques will mature to keep pace with shrinking actions.

So far it is only interesting to take emission reducing measures on-chip for a microcontroller when there are no external ROM, RAM or (E)EPROM-busses. The externally required data- and address-busses will cause much more RF-radiation, when used in a non-shielded way.

We've restricted ourselves to stand-alone controllers, which can control most functions locally with, when required low speed serial busses e.g. I²C (100 kbit/s or 400 kbit/s with output-edge-control), or parallel communication to another controller.

To compare our results, reference is made to an existing standard microcontroller based on the INTEL 80C51-core mounted in a 40 pin DIL package.

Dedicated software has been used to allow true comparison between all microcontrollers in a defined application.

Low RF-emission applications with a P83CE654 microcontroller

EIE/AN92001

2.1 IC-package

Density problems demand smaller packages to allow further integration of functions within a certain product size. It was decided to take the Quad Flat Pack (QFP) 44, because it was the lowest pin number package available above the 40 pins required to apply the circuit as stated above.

The advantage of this package is the smaller loop area enclosed by the currents running through the circuit. As a result, direct radiation will be reduced. The worst-case area difference between the package sizes is:

DIL 40:	48,46 x 15,24 x 4,3 mm (l x w x h, h = PCB + die-path height)
	diagonal: 50,8 mm
	looparea: 218,5 mm ²
QFP 44:	11,4 x 8,8 x 1,2 mm (l x w x h, h = die-path height)
	diagonal: 14,4 mm
	looparea: 17,3 mm ²

When package radiation is considered only, the magnetic dipole moment produced by the package will be reduced by a factor of 12,6, which can give a decrease in electromagnetic emission of about 22 dB.

External supply decoupling capacitors can be placed more closely to the pins where needed. The latter will shorten the length of the current path between Vdd and Vss, thus resulting in a lower voltage drop appearing in-between reference point taken on the PCB. Considering this, the current path reduction will be a factor of 4,5 which would result in an RF-emission reduction of about 12 dB. One should consider that also I/O-pins will contribute to the RF-emission.

Practical radiation figures have shown a decrease of about 12 dB.

2.2 IC-pinning

As already given above, supply and I/O pinning will determine emission performance, due to the fact that radiation is determined by the way currents flow through a device. For some years it is known that each output pin should be embedded in-between a Vdd and a Vss pin. As such, the 3 one-byte wide busses would need $3 \times (2 \times 8 + 1)$ pins (O, Vdd, Vss), equals at least 51 pins. For such a device this seems unpractical.

The advantage of such a pinning will be that currents will always flow through adjacent leadframe fingers and as such, emission will be absolutely minimal. For this application, I/O will commonly occur at low frequencies, and as such, their contribution to RF-emission will be low. In CMOS applications these currents will mainly occur during transitions by charging and discharging the output load.

A more serious contribution will arise from the ground-bounce or supply-bounce which will occur between the PCB-reference and the IC's-substrate. This disturbance voltage will be superimposed to all I/O's which are either coupled to Vss or Vdd. When these lines are long, longer than the path involved for supply decoupling, their contribution to radiation

Low RF-emission applications with a P83CE654 microcontroller

EIE/AN92001

can be high. The disturbance source, being the supply- or ground-bounce voltage, has a negligible impedance (ωL , L = leadfinger + bondingwire inductance) and will be difficult to filter by using simple and cheap components such as capacitors. More often, radiation will increase by such measures due to the increased current through these I/O's.

The most effective action will be the use of several ground and supply pins. The ground pins must be spread around the circumference of the package while the supply pins need to be adjacent to these grounds to benefit the mutual coupling in-between. This mutual coupling reduces the 'effective' series inductance with the external decoupling capacitor.

With the DIL 40, pin 20 is de Vss-pin as pin 40 is the supply pin, Vdd. The I/O-pins are randomly located. With the QFP-44, for the Vss the following pins are selected: 6, 16, 28, 39 and the supply pins are: 17 (for I/O) and 38 (for the core).

Another cause for ground-bounce can be the X-tal oscillator's output with its external capacitance. Normally, this contribution can be reduced by adding some series impedance with the output and changing the capacitors values such that the X-tal circuit operation remains within its linear range with sufficient amplitude.

All together, the ground-bounce, which will be emitted by the I/O, can be reduced by a factor of 4 (4 gnd pins QFP versus 1 gnd pin DIL), assuming random I/O current distributions. Individual decoupling of the I/O and core supply will dampen the supply bounce even further.

As such these measures will reduce emissions further by some 12 dB. The expectation of even more drastic effects can be accounted for by the shorter leadframe finger lengths comparing DIL 40 to QFP 44.

2.3 On-chip decoupling measures

From the above, it will be clear that RF-emission will primarily come from the core and that the lower frequencies will be mainly caused by the I/O. For the latter output-edge-rate control can be considered, when the number of outputs are high compared to the number of Vss and Vdd pins.

When core decoupling is integrated, the high frequency low energy currents can close their loop on silicon. As a result these RF-currents will not flow through the leadframe any longer and will not add to any additional ground-bounce.

If the latter is implemented without further considerations, the effect can be quite negative. The original circuit design assumed that all charge (current) comes from the external decoupling capacitor. This charge (current) then, flows from the capacitor, through its leadwires, PCB traces, IC leadframe, interconnect to the circuit (that needed it) and then back. When on-chip decoupling is used, charge is there and switching will occur instantaneously.

In our case, most bus-driving circuits were re-designed such that waveforms maintain within their specifications under worst-case conditions (temperature, supply voltage, etc.).

The overall result is that on-chip decoupling will require little space due to the fact that all

Low RF-emission applications with a P83CE654 microcontroller

EIE/AN92001

empty areas can be used, even within the circuit-blocks, and that bus-driving circuits can be made much smaller with respect to the present dimensions.

2.4 PCB design measures

The QFP-package and the pinning of the controller will only reduce the RF-emission when the PCB is laid out following some constraints.

An example of a good supply and ground plane lay-out is given in Fig.1. The microcontroller is mounted on the component side of a double layer PCB. The supply pairs Vss1/Vdd1 for the I/O-supply and Vss3/Vdd2 for the core supply are connected directly to the ceramic chip capacitors C1 and C2, which are surface mounted on the solder side. A short connection of Vss3/Vdd2 to the capacitor C2 minimizes loop inductance. Thus, the external supply current drawn by the core will flow in this loop mainly. This current path can be ensured by the insertion of an inductor (L2) in series to the +5V general supply. An equal action is taken for the I/O-supply.

The implemented on-chip decoupling allows a separation between core and I/O-ports. The PCB lay-out shall use these Vdd/Vss connections to minimize the loop areas in-between signal lines from each port pin to any load via the ground plane back to these Vss/Vdd-pins.

By applying these hints, Vss2 may be used as the return pin for ALE, PSEN, port0 and port2 because Vss2 is connected very near to them. Vss3 shall be used for the core supply mainly. Vss1 is nearest to lower part of port2, upper part of port3 and the crystal oscillator. Even though Vss1 may be the best return for port2 and port3, this pin shall in any case be used as return for the external crystal oscillator capacitors (not shown here). Vss4 is located nearest to the lower part of port3 and the whole port1, being the best return for these ports.

3 Future developments

Existing products are shrunk, to cut costs and increase complexity. Recent developments (SAC3 → SAC2 → SAC1, C300 → C250 → C200 and others) have demonstrated an upwards tendency in the RF-emission following shrinking when EMC is not considered. This means that the end in taking measures to reduce RF-emission has not been reached. Further improvements are still possible and already considered for new products, such as:

- ☛ a PLL-circuit, to replace the high frequency X-tal oscillator,
- ☛ output-edge-control (application dependent),
- ☛ further circuit improvements on-chip e.g. coplanar supply, decoupling measures within cell-blocks, multi-phase clock systems to prevent simultaneous switching

4 Results

All measurements were carried out under the same conditions, using the same kind of PCB, with the same software and the same bus loadings, Fig.2.

Low RF-emission applications with a P83CE654 microcontroller

EIE/AN92001

Tested were the following applications:

- ☛ 1 87C51, DIL 40, 12 MHz X-tal → 0 dB(rel)
- ☛ 2 80C31, QFP 44, but with 2 V_{ss} and only one V_{dd} → 13 dB
connection, 12 MHz X-tal
- ☛ 3 83CE654, QFP 44, with Address Latch Enable → 32 dB
(ALE) active, 12 MHz X-tal
4 V_{ss} and 2 V_{dd} pins as given above.
- ☛ 4 83CE654, QFP 44, ALE off, 12 MHz X-tal → 50 dB
- ☛ 5 83CE654, QFP 44, ALE off, externally 12 MHz, → 54 dB
500 mV sinewave.

5 Conclusions

With the measures indicated in chapter 2, RF-emission can be reduced substantially, especially for stand-alone microcontroller applications. Up to now, a number of measures have been implemented which indicate an improvement of about 40 dB in the FM-region when changing from a DIL 40, annex 1 to a QFP 44 application, annex 4, taking into account minor additional supply measures. The inclusion of a PLL can make the improvement even further to about 50 dB, annex 5.

With these measures, some 12 to 22 dB can be accounted for by the choice of the package, same 12 dB due to the pinning and the rest due to the internal measures.

The advantage of these measures can be easily wasted by insufficient measures on the PCB. Constraints are given in chapter 2.4.

When considering the reducing effects PCB-layouts might have to RF-emission, the following relative information needs to be considered:

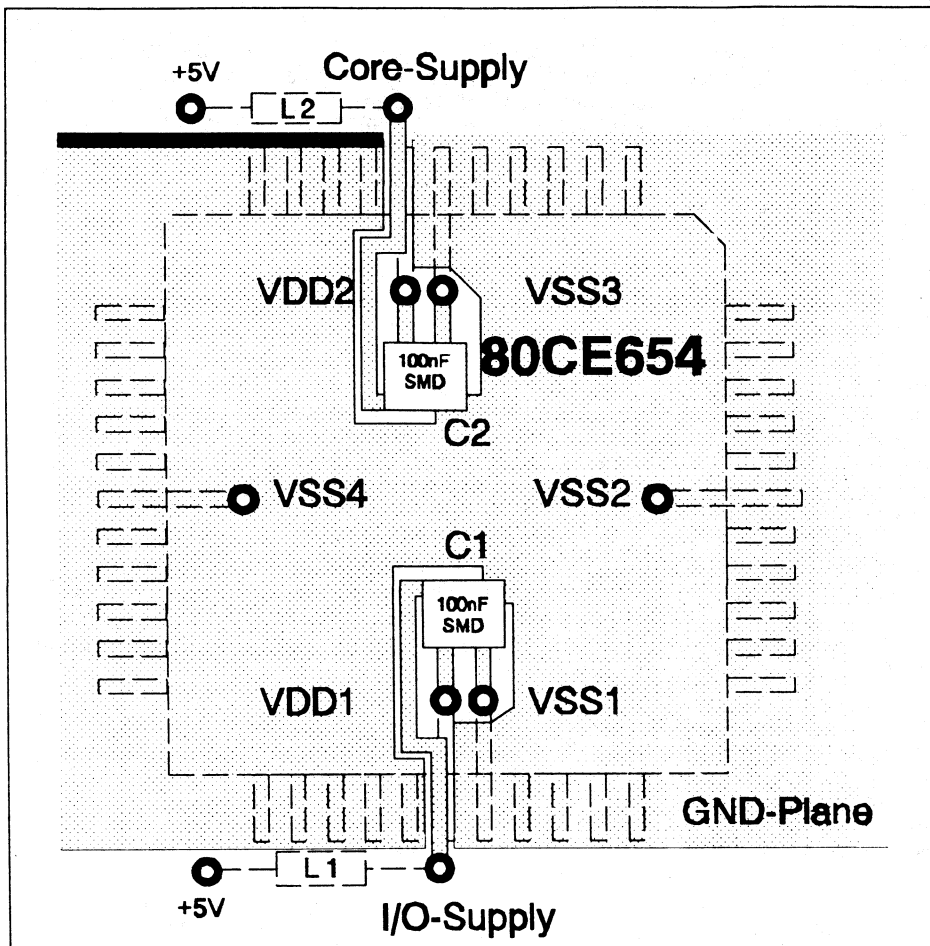

- ☛ single layer board → 0 dB (relative)
- ☛ double layer board → 26 dB (best case)
- ☛ multi layer board → 44 dB (4-layer, best case)

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

Author: Theo van Daele, Philips Semiconductors Product Concept & Application Laboratory Eindhoven, the Netherlands

SUMMARY

On the 80C552 microcontroller, an 8-input 10-bit ADC is available. To get correct results from the ADC, the slew-rate of the input signal during sampling must be limited. 10 Bit accuracy will be obtained if the layout of the 80C552 application is done correctly. EMC measures must be taken into account. Some software examples are given on how to use the ADC.

1.0 INTRODUCTION

The 80C552 microcontroller has an on-chip ADC. The converter consists of an 8 input analog multiplexer, and a 10-bit binary successive approximation ADC. A conversion takes 50 machine cycles (is 20µs at 30MHz oscillator frequency). The ADC has dedicated analog supply and reference voltages to minimize influence from digital circuitry. The DAC of the successive approximation ADC is a resistor ladder network. This ensures that there no missing codes.

To obtain the 10-bit accuracy, it is important to pay attention to the design of the application. First the operation of the ADC will be described. Then design and layout subjects are described that can influence the accuracy of the conversion result.

2.0 INTERNAL OPERATION OF THE ADC

2.1 General Description

Figure 1 shows a general block diagram of the ADC.

The inputs of P5 are connected to a multiplexer and an input buffer with Schmitt-trigger inputs.

When the digital value on P5 must be read (e.g., with a MOV A,P5 instruction), the output of the Schmitt-trigger is taken. This output can be used for further processing.

An analog input signal on P5 that must be converted is selected by the input multiplexer. The bits ADCON.0 . . . ADCON.2 of the ADCON special function register select the input signal. The output of the multiplexer is connected to the input of a comparator. The sampling capacitor is included in the comparator. The ADC control block of the ADC controls the timing of the sampling and conversion.

After the input signal is sampled, the actual analog-to-digital conversion starts. The comparator compares the input signal V_{IN} with the output of the 10-bit DAC V_{DAC} . The output voltage of the DAC is determined by the output of the successive approximation register (SAR). The range of the DAC signal varies between AV_{REF-} and AV_{REF+} . These two signal levels also define the voltage range of the input signal.

Figure 1.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

2.2 Conversion Process

Figure 2 shows an example of the conversion principle with 3 bit resolution.

The SAR will make its output bits SAR2 . . . SAR0 successively high from MSB to LSB. Every time a SAR-line is made HIGH, a DA-conversion will take place. If the output of the DAC (V_{DAC}) is higher than the input voltage (V_{IN}), the SAR output bit that was made HIGH the last time will be made LOW. If V_{DAC} is smaller than V_{IN} , the SAR output bit will remain HIGH. The process will proceed

for the subsequent SAR output bits. At the end of the conversion, V_{DAC} has converged to a value of $V_{IN} \pm 1/2 \text{LSB}$.

Example: V_{IN} is $11/16 * V_{REF}$. The conversion sequence is shown in Table 1.

After STEP 3 the conversion is finished. The SAR register contains the result of the AD-conversion.

The ADC in the 80C552 has 10 bits resolution. The conversion in this ADC will take 10 conversion steps.

Table 1.

	SAR Value (SAR2.SAR1.SAR0)	V_{DAC} ($*V_{REF}$)	Output Comparator	Action by SAR
START	000	0	0	SAR2=1
STEP 1	100	4/8	0	SAR1=1
STEP 2	110	6/8	1	SAR1=0, SAR0=1
STEP 3	101	5/8	0

EIE/AN93017

2.3 The ADC in the 80C552

Figure 3 shows a block diagram of the implementation of the ADC in an 80C552 microcontroller.

The analog input signal V_{IN} is connected to the non-inverting input of the comparator via switch S1 during the sampling interval. Internally the comparator consists of 3 serially connected sampled-data-comparator stages $A_1 \dots A_3$. The stages are capacitively coupled. The coupling capacitor of the first comparator that is connected to S1 will also act as sample capacitor for V_{IN} .

Sampled-data-comparators are used to minimize the effect of offsets and temperature drive. During the sampling interval, the value of the offset voltage of the comparator stages are stored on the coupling capacitors. This voltage will have the opposite sign of the comparators stages' offset, so it will cancel this offset voltage. This process is called auto-zeroing, and will be explained in 2.3.2.

The non-inverting input of the comparator is connected to $\frac{1}{2}V_{REF}$ via switch S2. S2 consists of 2 parallel switches. There is always 1 switch closed, so the voltage on this input is always $\frac{1}{2}V_{REF}$. Although S2 looks superfluous from a functional point of view, it assures that, for instance, switching glitches of S1 and S2 appear on both inputs of the comparator and will cancel each other.

When the sampling is finished, the actual conversion will start. S1 will connect the inverting input of the comparator with the output of the DAC. At this moment, the output of the DAC is connected to the center tap of the resistor network. The voltage on the inverting input of the comparator will be $\frac{1}{2}V_{REF}$ (V_{REF} is defined as $\frac{1}{2}(V_{REF+} - V_{REF-})$). During conversion, the output of the SAR will determine which tap of the ladder-network will be connected to the

inverting input. Using a ladder-network guarantees a monotonic characteristic of the DAC. This in turn will result in an ADC-characteristic without missing codes. The relative deviations of the resistor values result in a non-linear transfer characteristic.

The following three phases in the ADC conversion can be determined and will be described in more detail:

- Start phase
- Sampling phase
- Conversion phase.

Timing of these phases is shown in Figure 4.

2.3.1 Start Detection Phase

An ADC conversion can be started by software or by a hardware trigger on the STADC pin.

Software start

When an ADC start is initiated by software (set ADSC in ADCON register), the internal start signal will immediately be active at S6P2 (for state timing, see [Reference]). The value of ADSC can be read by software. However, there is a delay of 2 machine cycles between the internal start signal and the ability of reading a '1' from ADSC.

Hardware start

A hardware start of an ADC conversion is initiated by a rising edge on STADC. The 80C552 samples STADC every machine cycle during S6P2. When a valid edge is detected, the internal start signal will be active at S1P2 in the subsequent machine cycle. To ensure that the edge is detected, the high and low time should be at least 1 machine cycle each. When a valid edge is detected, 'ADSC' is set.

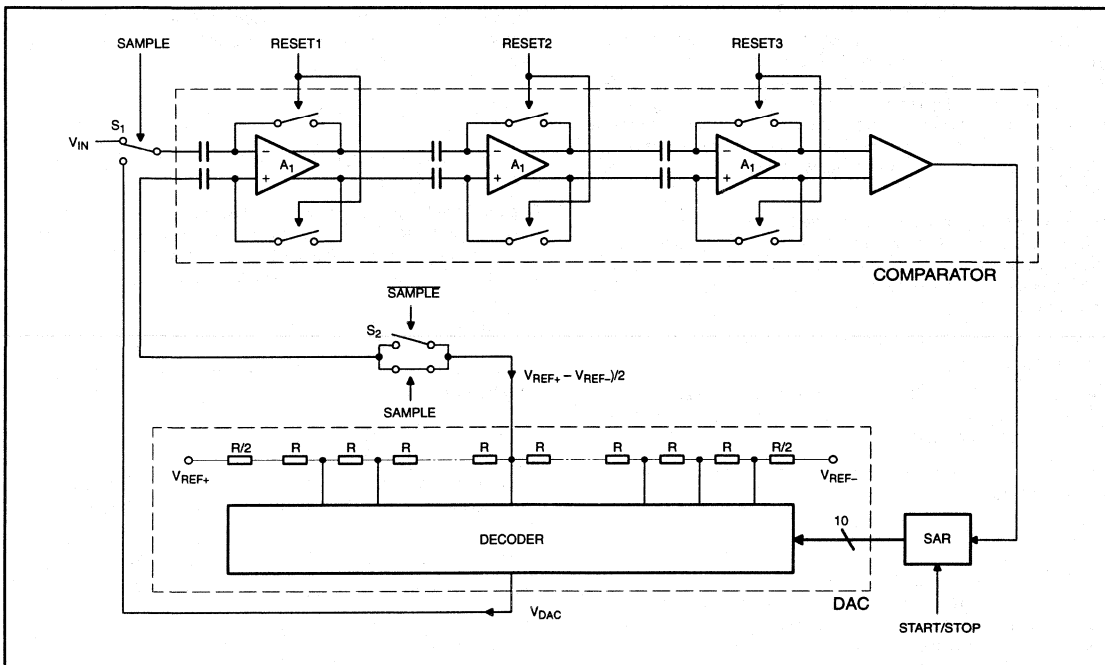

Figure 3.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

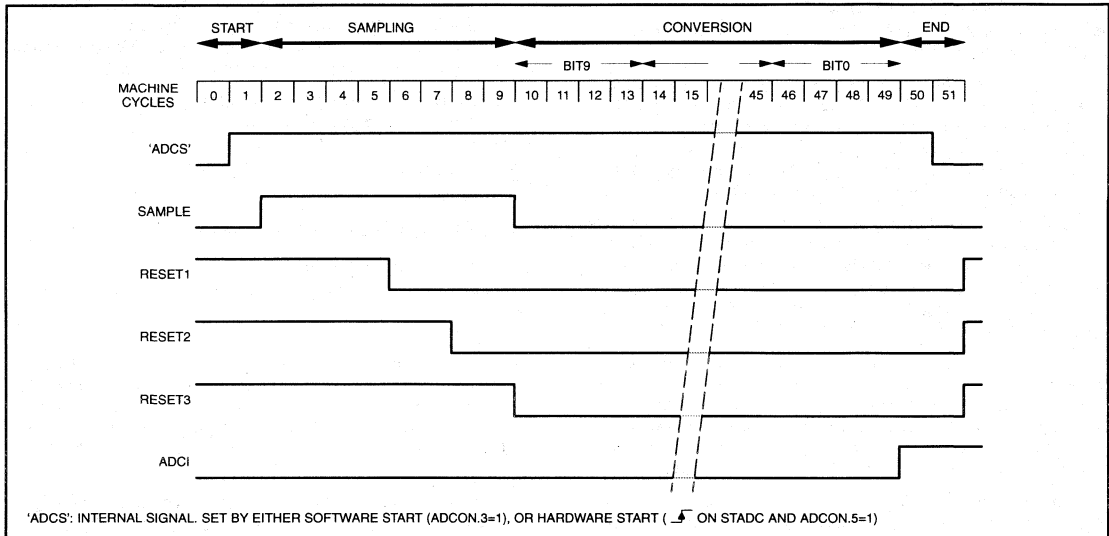

Figure 4.

2.3.2 Sample Phase

The 8 machine cycles following the start detection is the sample interval (Figure 4). In this time interval, the input signal is sampled and the 3 comparator stages are auto-zeroed.

The actual sampling of the analog input signal on the input capacitor starts at machine cycle '2' (Figure 4). The sample capacitor is connected between V_{IN} and the output of the first comparator stage (Figure 3). The sampling is finished at the end of machine cycle '5'. After this machine cycle, the sample capacitor is connected between V_{IN} and the input of the first comparator stage. Since this is a very high impedance input, no extra charge will be stored in the sampling capacitor.

At the start of the sample phase, the inverting input of the comparator is connected to V_{IN} via a coupling capacitor. This coupling capacitor also serves as sampling capacitor. The non-inverting input is connected to the DAC via a coupling capacitor to a voltage of $\frac{1}{2}V_{REF}$.

Figure 5 shows the sampling and auto-zeroing of the first comparator stage.

When the $RESET1=1$, switches will connect the outputs of the individual comparator stages to their inputs. The outputs will settle to the unity-gain output voltage V_{UG} .

The differential voltage (error voltage) on the inputs of the first comparator stage will be:

$$V_{IL} = V_{OL} = -V_{OS1} \times \frac{A_1}{A_1 + 1}$$

- V_{IN} = Input voltage of ADC
- V_{IL} = Differential input voltage of first comparator stage
- V_{OL} = Differential output voltage of first comparator stage
- V_{OS1} = Offset voltage of first comparator stage
- A_1 = Open loop gain of first comparator stage

The switches are opened when $RESET1=0$. The differential voltage on the comparator inputs is still V_{IL} because of the stored charge on the coupling capacitors.

The resulting offset voltage $V_{OS1,i}$ seen on the input of the comparator stage is obtained by adding this differential voltage V_{IL} to the input offset voltage V_{OS1} .

$$V_{OS1,i} = V_{OS1} + V_{IL} = V_{OS1} \times \left(\frac{A_1}{1 + A_1} \right)$$

The effective offset voltage at the input of the comparator stage is reduced with a factor $(1+A_1)$.

The auto-zeroing procedure described above will be repeated successively for the following 2 stages. After auto-zeroing the third comparator stage, the differential output voltage of the total comparator (all 3 comparators in series) will be:

$$V_{O,3} = A_3 \times \frac{V_{OS3}}{1 + A_3}$$

This voltage can be translated to an effective input offset voltage by dividing it by the total gain of the comparator:

$$V_{OS,i} = \frac{V_{OS3}}{A_1 \times A_2 \times (1 + A_3)}$$

If auto-zeroing was not used, and all comparator stages were DC-coupled, the differential output voltage of the comparator would be:

$$V_{O3} = A_1 \times A_2 \times A_3 \times V_{OS1} + A_2 \times A_3 \times V_{OS2} + A_3 \times V_{OS3}$$

The effective input offset voltage in this case is:

$$V_{OS,i} = V_{OS1} + \frac{V_{OS2}}{A_1} + \frac{V_{OS3}}{A_1 \times A_2}$$

As can be seen, the auto-zeroing reduces the effect of the individual comparator stages considerably.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

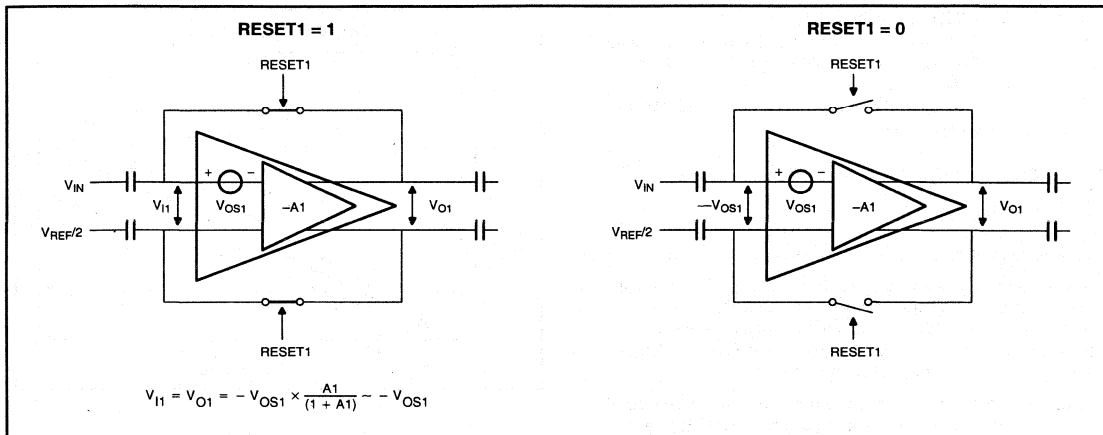

Figure 5.

Figure 6.

2.3.3 Conversion Phase

Just before the sampling phase is finished, the following voltages are present over the coupling capacitors of the first comparator stage:

- Capacitor on inverting input: $V_{IN} - V_{UG}$
- Capacitor on non-inverting input; $\frac{1}{2}V_{REF} - V_{UG}$

For clarity, the offset voltages are neglected.

When the conversion phase is started, S1 (Figure 6) will connect the coupling capacitor of the inverting input to the output of the DAC. The effective voltage on the comparator input is the voltage applied to the coupling capacitor minus the voltage that was stored on the capacitor during the sampling phase.

The following voltages are present on the input of the first comparator stage:

- Inverting input: $V_{DAC} - V_{IN} + V_{UG}$
- Non-inverting input: V_{UG}

The comparator stage amplifies the differential voltage between its inputs. The output voltage of the first comparator stage will be:

$$V_{OL} = A_1 \times (V_{UG} - (V_{DAC} - V_{IN} + V_{UG})) = A_1 \times (V_{IN} - V_{DAC})$$

After amplification by the 3 comparator stages the input signal for the SAR is $|A_1 \times A_2 \times A_3 \times (V_{IN} - V_{DAC})|$. Depending on the sign of this signal, the SAR will set or clear the MSB. In the following cycles of the conversion, the other bits of the SAR will be updated. At the end of the conversion V_{DAC} will have a value of $V_{IN} \pm 0.5LSB$. The contents of the SAR that generates this V_{DAC} is the result of the AD-conversion.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

3.0 APPLICATION INFORMATION

Although the ADC in the 80C552 has a resolution of 10 bits, the user must be careful in the design of the application to really get this resolution. The constraints can be divided in 2 categories:

- Constraints on the analog input signal and the input signal source
- Layout constraints of the design.

3.1 Analog Input Signal Constraints

3.1.1 Range of Analog Input Signal

The value of the analog input signal must be between V_{REF+} and V_{REF-} . The span of the analog input signal is $V_{REF} = (V_{REF+} - V_{REF-})$.

There is a minimum limit to the span. This limit depends on the gain of the comparators. A differential voltage of 1LSB (1LSB = $V_{REF}/1024$) on the inputs of the comparator should be able to generate a logic '1' or '0' level on the input of the SAR. If not, the resolution of 10 bits for the ADC will not be met.

the comparator in the 80C552 needs a minimum differential input voltage of 0.3mV to generate a valid logic output level. For the 10-bits ADC in the 80C552, this means that V_{REF} should be at least $1024 \cdot 0.3mV = 0.31V$ to get 10-bit resolution. The absolute values of V_{REF+} and V_{REF-} that determine this span may not exceed AV_{SS} and AV_{DD} .

3.1.2 Slew Rate of Analog Input Signal

A distinction must be made between 2 different slew-rate constraints. The first slew-rate constraint deals with the required accuracy during sampling. The second constraint to prevent wrong readings deals with a limitation on the slew rate that may otherwise lead to a conversion result that has no relation at all with the analog input signal.

1: To obtain a stable reading from the ADC, the analog input signal should be stable during the sampling time. The sampling may be triggered by an external event (via ADEX pin). From this trigger point until machine cycle '5' (see Figure), the input signal is sampled and should not change more than the desired accuracy.

Example: If a stability of 0.5LSB is required, then the analog input signal should not change more than 0.5LSB in 6 machine cycles. In that situation the maximum slew-rate of the analog input signal is:

$$\frac{dV}{dt} = \frac{0.5LSB}{6T}$$

where T is the machine cycle time.

The following graph gives the maximum slew-rate as function of the operating frequency for various values of V_{REF} and a required stability of $1/2LSB$ for a 10-bit conversion.

When the slew-rate of the input signal is more than the maximum slew-rate as determined above, the read-out stability will decrease. The conversion result will be the digital value of the input signal somewhere between machine cycle '0' and machine cycle '5'. Consecutive conversions of a signal that consists of a DC-value with an AC-component that has high slew-rates as mentioned above, and that has the same amplitude between machine cycle '0' and machine cycle '1', may give different read-outs. However, the accuracy of the sampled signal will not be affected.

2: If the slew-rate exceeds a certain value, the accuracy of the conversion will decrease rapidly. The result of the conversion will not have any result anymore with the analog input signal. Tests have shown that the most probable conversion result is 0x3ff (result bits ADS.0 . . . ADC.9 are '1').

This error situation will occur when the slew rate is too high in the time frame from machine cycle '2' to machine cycle '9' of the conversion. In this time frame, the comparators are auto-zeroing their offsets. For proper auto-zeroing, the comparator stages must work in their linear region.

If the input signal is changing rapidly, the voltage change may couple through the coupling capacitors to the input of the comparator stage. If this voltage change is sufficiently high, it may saturate the comparator stage. The comparator stage is not working in its linear region anymore, and the saturation voltage (equal to about the supply voltage) is stored on the coupling capacitors.

The ADC has the highest sensitivity to these high slew-rate signals in the time frame from machine cycle '8' to machine cycle '9'. In this time frame the RESET switches of comparator stage 1 and 2 are open; the RESET switch of comparator stage 3 is closed for auto-zeroing. An analog input signal with sufficient slew rate may couple through to comparator stage 3 via the coupling capacitors of stage 1 and 2. The high sensitivity comes from the fact that the signal is amplified by comparator stages 1 and 2 before it reaches the input of comparator stage 3.

When the saturation voltage is stored on the coupling capacitors, the following comparator stage is not useful anymore to determine the sign of $(V_{IN} - V_{DAC})$. Suppose the coupling capacitors on the input of the second comparator stage are charged to the saturation voltage V_{SAT} . The differential output voltage of the first comparator stage will be $A_1 \times (V_{IN} - V_{DAC})$. This signal is fed to the input of the second comparator stage whose output signal will be $A_2 \times [A_1 \times (V_{IN} - V_{DAC}) \pm V_{SAT}]$. Since the differential output voltage of the comparator stages can never be higher than $\pm V_{SAT}$, the output of this comparator stage will stay at its saturation level, independent of the value of $(V_{IN} - V_{DAC})$.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

The only way to avoid the error mentioned above is to limit the slew rate during the sampling interval (machine cycle 2 to 9). For the ADC in the 80C552 the slew rate of the analog input signal must be lower than 10V/ms.

From the discussion above, it becomes evident that it is essential that the slew-rate of the input signal is limited to 10V/ms. Although 'clean' DC signals may be applied to the ADC, noise spikes or crosstalk from neighboring signals may still result in signal components with a slew-rate >10V/ms on the DC signal during the sampling interval.

The following measures can be taken to reduce the slew rate on analog input signals:

- Supply the analog signal from a source with low output impedance. This will reduce the sensitivity to cross-talk.
- Keep the analog input signal lines away from digital signal lines. Analog signals may be screened from digital signal lines with a grounded guard ring on the PCB.
- Do not mix analog and digital signals on P5 pins.
- Connect an RC filter to the analog inputs. The time constant should be $\geq 500\mu\text{s}$.

For a 5V_{PP} input sine-signal, the slew rate constraint of 10V/ms results in a maximum input frequency of 637Hz. When we use the Nyquist criterion ($f_{\text{SAMPLE}} \geq 2 \cdot f_{\text{SIGNAL}}$), the maximum input signal frequency is 1kHz when the 80C552 runs on 1.2MHz (1 conversion every 500 μs).

This shows that the maximum input signal frequency for the ADC of the 80C552 is determined by the **slew-rate**. So, increasing the XTAL frequency on which the 80C552 is operating, does not automatically imply that the maximum input signal frequency also scales to a higher value. This scaling is only allowed for signals with a slew rate <10V/ms.

3.1.3 Analog Signal Drive

The output resistance of the analog signal source should be small enough not to add a significant error to the conversion result. The output impedance has two effects on the accuracy of the conversion, that is, the voltage drop over the source resistance and the time constant to charge the sampling capacitor.

1: The voltage drop over the output impedance due to the input current of the ADC. In the 80C552, the input current is a leakage current. this leakage current is specified as less than 1 μA . Practically, however, the leakage current will be less than 100nA.

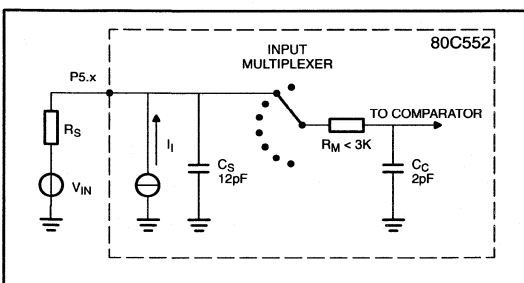

Figure 7.

Figure 7 shows the input circuit. The leakage current comes mainly from circuitry directly connected to the P5.x pin. Compared with this leakage current, the input current of the comparator can be neglected. C_S represents the contribution of the stray capacitances; C_C represents the sampling capacitor. Before the sampling capacitor, there is the series resistance R_M of the analog multiplexer.

The output resistance R_S of the input signal source will cause a voltage drop due to the input leakage current. The voltage that will be converted is the voltage on the sampling capacitor. This voltage is the input voltage V_{IN} minus the voltage drop over R_S . This voltage drop will give an error contribution in the conversion result of V_{IN} .

When an accuracy of $1/2\text{LSB}$ is required, the maximum source resistance R_S is:

$$R_S < \frac{0.5\text{LSB}}{I_I}$$

Example: If $V_{REF} = 5.12\text{V}$ and $I_I = 1\mu\text{A}$, the source resistor should be less than 2.5k Ω .

When this constraint on output resistance of the signal source cannot be met, the analog signal should be buffered with a buffer of sufficiently low output resistance. This buffer should be placed as close as possible to the analog source. The longer leads from buffer to the ADC input will be less sensitive to cross-talk (low impedance source resistance) than long leads from signal source to buffer (high impedance source resistance). Filtering may be included in the buffer stage to limit the slew-rate of the signal to <10V/ms.

2: The ability to charge the sampling capacitor within the sampling interval. Figure 7 also shows the dimensions of the capacitances as seen from the analog input. The capacitances consist of stray-capacitances and the actual sample capacitance. These capacitances must be charged within 4 machine cycles (machine cycle '2' until '5'), which will put a constraint on the maximum source resistance.

Example: An input signal with a slope of 10V/ms applied to the ADC input. For simplicity, assume that the capacitance that must be charged via R_S is 14pF and the 80C552 is running on 30MHz. At this frequency, the available charging time for the capacitor is 1.6 μs . With the given slew-rate and the charging time of the capacitor, the analog voltage V_{IN} has changed 16mV. The response of an RC-network on an input ramp signal is:

$$A \left[t - RC \left(1 - e^{-\frac{t}{RC}} \right) \right]$$

A is slew-rate of input signal; RC is time constant of input RC-network.

The term:

$$ARC \left(1 - e^{-\frac{t}{RC}} \right)$$

represents the deviation of the capacitor voltage from V_{IN} .

If this deviation must be less than $1/2\text{LSB}$ (is 2.5mV at $V_{REF} = 5.12\text{V}$) after 1.6 μs , then the RC-time must be less than 0.25 μs . Given that $R_S = 2.5\text{k}\Omega$ and $C = 124\text{pF}$, the RC time of the input circuit of the 8XC552 is 35ns. Hence, there will be no significant error contribution because of the charging time of the input capacitance.

The two constraints on R_S mentioned above show that the effect of the input leakage current determines the maximum value for R_S .

Conclusion: R_S should not exceed 2.5k Ω .

EIE/AN93017

3.2 Layout Considerations

Although this application note handles subjects related to the ADC, the following layout considerations are also valid for applications that do not use the ADC. For more general information on PCB layout design, see Reference 5.

3.2.1 Decoupling

The analog and digital circuit parts in the 80C552 have their own set of power supply pins. Mutual inductance between on-chip AV_{DD} and AV_{SS} signal lines will cause the analog AC current I_A to flow in the AV_{DD} and out of the AV_{SS} pin. The same is true for the digital AC current I_D in the V_{DD} and V_{SS} pins (Figure 8).

Because this mutual inductance is harder to realize off-chip, a low-impedance signal path must be created for both I_A and I_D . This

is realized with decoupling capacitors between AV_{DD} and AV_{SS} for the analog signal part; a decoupling capacitor between V_{DD} and V_{SS} will decouple the digital signal part.

To ensure a low impedance ground path, the use of a ground plane is recommended. The decoupling capacitors (for example, 100nF ceramic capacitors) must be placed as close as possible to the AV_{DD} and V_{DD} to minimize the loop area of the supply currents. Series inductors in the power supply lines may be used to improve decoupling (for example, 1..5 μ H). Using this decoupling scheme, both analog and digital supply connections can be connected together to a single (stable) +5V.

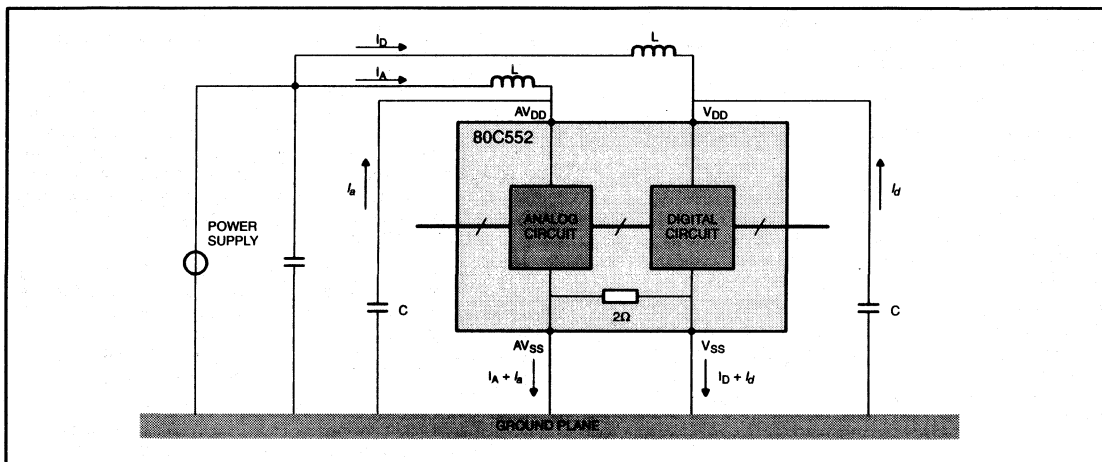

Figure 8.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

3.2.2 Grounding

When using both analog and digital circuits on the same PCB, it is common practice to isolate the analog power supply and ground as much as possible from the digital power supply and ground. This will reduce crosstalk via common ground impedances. Common impedances may result in noise in the (sensitive) analog circuitry caused by crosstalk of noise that originates from the digital circuitry.

At some point however, both analog and digital grounds must be tied together. When this takes place far from the microcontroller, it will increase impedance between the analog and digital ground connections. This can create a considerable differential voltage between the analog and digital ground lines. Analog and digital circuitry inside the microcontroller will operate at different ground levels and improper functioning may be the result. A second effect of large ground impedance is that the crosstalk between the analog and digital circuits does not take place via the common ground impedance anymore, but via internal parasitic capacitances and substrate contacts.

To prevent differences in ground levels, the analog and digital ground inside the 80C552 are connected together via an impedance of $\pm 2\Omega$ (Figure 8). This will keep both grounds at the same DC level. This impedance does not mean that now a common ground pin for analog and digital ground currents can be used. Impedance of the common bondwire will cause ground bounce, and thus crosstalk between digital and analog circuits.

When the supply lines are properly decoupled, mutual inductance between the on-chip supply traces will assure that the AC-part of the supply current that flows inside AV_{DD} and V_{DD} will leave via the AV_{SS} and V_{SS} pin even though AV_{SS} and V_{SS} are connected together via a 2Ω impedance. The best place on the PCB to connect AV_{SS} and V_{SS} to each other is directly outside the microcontroller. This is also the best place for the ground connection of the decoupling capacitors. If the ground connection is to a ground plane, a ground plane on the component side is preferred.

Two separate grounds are needed if the application has more analog ICs on the PCB, apart from the 80C552. In that case, the AV_{SS} and V_{SS} of the 80C552 should be connected to the analog ground. The digital ground may be the return path for, for instance, line drivers. This will result in a ground that is less 'clean' than the analog ground. For the digital circuits this less 'clean' ground is less of a problem because they always have a certain noise margin. An alternative is to create a 'star-point'. This is a connection between AV_{SS} and V_{SS} at the ADC area of the 80C552. Care should be taken to avoid ground loops in the other circuit parts up to the power supply.

If the 80C552 application also uses external digital circuits, noise margin may be lost due to possible different ground levels. This can be reduced by the connecting two anti-parallel diodes close to the ground pins of the 80C552 and the connected digital circuits (Figure 9).

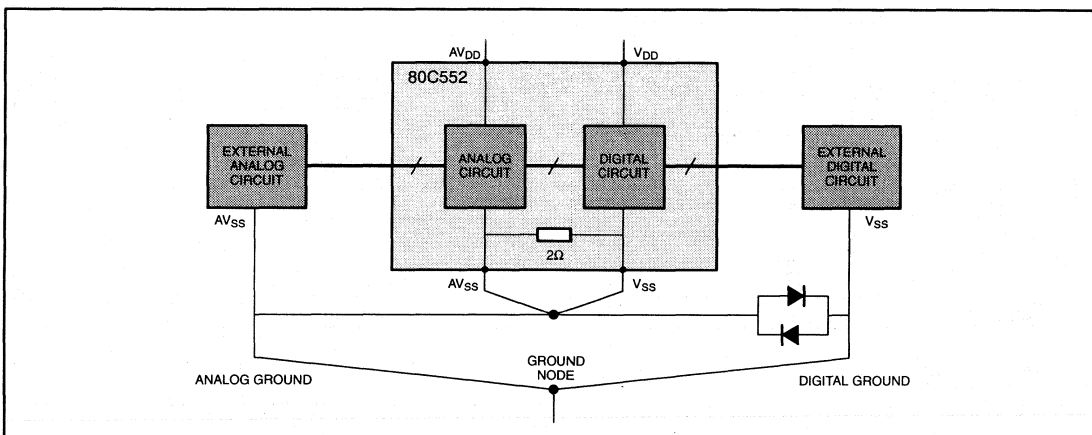

Figure 9.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

3.2.3 Placement of External Components

External circuits connected to the microcontroller should be placed as close as possible to the microcontroller. This will reduce signal loops and common impedances on which high frequent signals may occur. These signals may come from an external source or may be generated by the microcontroller itself. When the disturbing signals are coming from an external source, they may cause improper functioning of the microcontroller. If originating from the microcontroller, they will cause unwanted radiation.

When a common ground plane cannot be implemented, the microcontroller and circuits directly connected to the 80C552 must have a local groundplane (Figure 10). This local ground should have a connection to the main ground of the application at some point.

If, for layout reasons, it is not possible to place the external circuitry close to the microcontroller, an RC-filter may be placed between the microcontroller and the external circuit (Figure 10). When microcontroller lines are connected to Off-PCB circuits, it is also advised to connect an RC network to the I/O line. The reason is sensitivity of the microcontroller to short (4 . . 5ns) high-voltage (30 . . 40V) spikes. Although these pulses will not damage the

microcontroller, they may be responsible for incorrect functioning. With microcontrollers becoming faster, the on-chip I/O drivers will have increased bandwidths, hence become more sensitive for short spikes.

The resistor of the filter should be connected as close as possible to the output of the driving device. The capacitor of the filter should be connected as close as possible to the input of the receiving device. Also the ground connection of the capacitor must be connected as close as possible to the ground of the receiving device.

Values of the resistor of the filter depend on the drive capability of the outputs and the input impedances/levels of the inputs connected to the filter. The series resistor will reduce some noise margin. Typical capacitor values are 470pF. When connected to 80C552 inputs, the resistor value may be 1k; for 80C552 outputs 100Ω may be used.

NO (filter)-capacitors should be connected directly to outputs! This will cause (dis)charge currents to flow in the supply and ground lines. This can cause severe noise problems in the application.

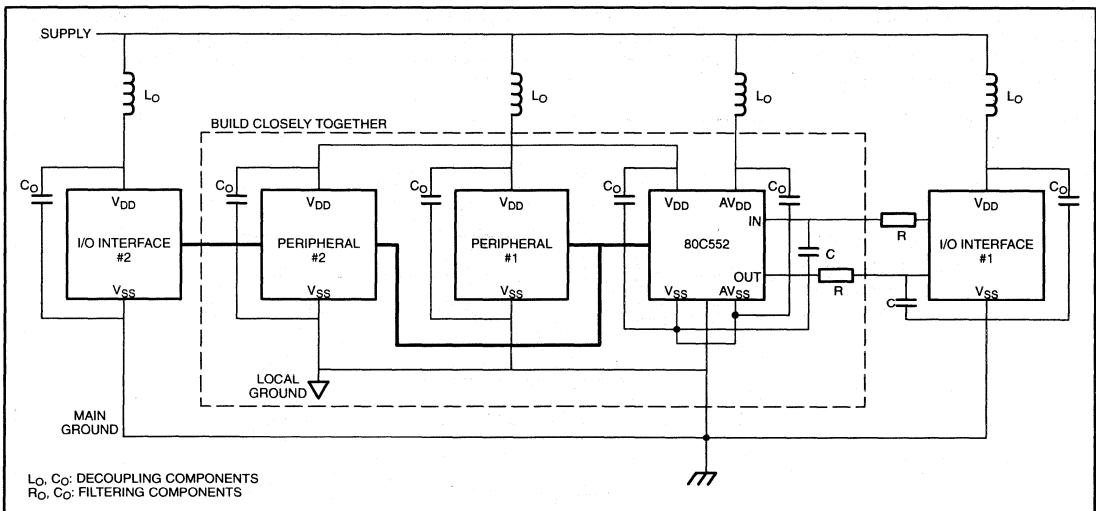

Figure 10.

Using the analog-to-digital converter of the 8XC552 microcontroller

EIE/AN93017

4.0 PROGRAM EXAMPLES

Two program examples are given that show how to operate the ADC with software. The sources are written in 'C'. The program 'ADC_pol.c' works on polling basis; the program 'ADC_int.c' works on interrupts.

The programs will start scanning all ADC inputs when a rising edge appears on the STADC pin. This can be realized with a resistor from ground to STADC and a switch from STADC to V_{DD}. If STADC is connected to P4.0, a conversion of all channels will start every 1.14ms. Timer T2 controls the timing of P4.0. When all analog input signals on P5 are converted, the results will be sent to the UART and be made visible on a terminal. The communication part of the program is given in the file 'output.c'. After compiling and assembling 'output.c', it should be linked to 'ADC_pol' or 'ADC_int'.

The required terminal settings are:

- 8 data bits
- no parity
- 1 STOP-bit
- 19200 baud.

The 80C552 must run on 11.0592MHz.

The following points are important when writing code for the ADC:

- ADCS and ADCI must be cleared, before programming AADC0..AADR2.

- Channel selection bits AADR0..AADR2 must be programmed before setting ADCS (software start) or ADEX (enabling hardware start)
- When working in polling mode, use ADCI to test if the conversion is finished.
 - Do not test 'ADCS=0' for this purpose.
 - When an ADC conversion is initiated by software, there is a delay of 2 machine cycles between the moment of writing a '1' to ADCS and reading a '1' from the ADCS-bit in ADCON.
 - When an ADC conversion must be initiated by a rising edge on ADEX, it is not known when ADCS becomes '1'. This depends on the external signal that starts the conversion.

The following development tools were used on a PC (DOS 5.0):

TOOL	TYPE	PHILIPS NUMBER

Chips push CAN bus into embedded world

This week:
Special Report
Surface-mount technology
gets bigger as packages
get smaller

Sunnyvale, Calif. — The Controller Area Network (CAN) serial bus is being thrust into a key role in embedded systems, boosted by a series of recent silicon announcements. Delta-t GmbH, Intel Corp., Motorola Semiconductor and Philips/Signetics Co. have all prepared new chips that should slash the cost of a CAN bus connection, increase bus functionality and accelerate the bus's migration from a little-known automotive standard to a widely used industrial interconnect scheme.

Developed by Intel with Robert Bosch GmbH in the mid-1980s to solve cabling and control problems in vehicles, the CAN bus combines an inexpensive, one-wire or two-wire medium with multimaster, error-correcting protocol and very high resistance to electromagnetic interference. Unlike most multi-master buses, however, CAN also guarantees a maximum latency, often in the neighborhood of 1 ms, for high-priority messages while making room for lower-priority traffic as well.

Thus, although the bus was originally conceived as a way to reduce the literally miles of wire in a modern automobile, it is in many ways ideally suited for a wide range of industrial control applications as well.

General-purpose bus

CAN has since emerged as a general-purpose sensor/actuator bus system for distributed real-time control applications that extend beyond the automotive realm. "CAN was spotted by the industry as a very promising field-bus technology in the area of industrial automation," said Tom Suters, systems architect at Philips Medical Systems, in Da Best, the Netherlands.

"We are beginning to see CAN as a widely used standard in trucks and farm equipment, industrial automation and even some medical equipment," agreed Signetics marketing manager Mike Thomson.

But CAN's opponents have often criticized its high implementation cost as well as the lack of controller chips and supporting tools. Proponents have argued that volume production for the automotive market would inevitably bring down the silicon prices, but that has yet to happen. Now vendors are pointing to a new generation of low-cost or highly integrated controllers as the solution.

Motorola is sampling a controller, dubbed the 68HC705X4, that will be supported by an evaluation board and an emulator. Other implementations based on the 68HC11 and the 68HC16/683XX are in the pipeline.

Intel Corp., working in conjunction with design partner Bosch, has sampled a next-generation CAN chip, the 82527, that offers support for two sizes of message identifiers—11 bit and 29 bit—as specified in CAN Spec. 2.0, released in September.

Craig Szydowski, product marketing engineer for CAN at Intel, said the original CAN 1.2 standard allowed for only 11-bit message identifiers. Supporters of J1850—the competing automotive bus favored by the Society of Automotive Engineers—fought for an optional larger message field so 1850-style 27-bit commands could be easily mapped into CAN protocols.

"This gives CAN the ability to broadcast commands using what had been essentially an address field," explained Signetics' Thomson. "For example, a CPU might send out a command telling all of the

lamps in a vehicle to test themselves for conductivity and report any burn-outs."

The new format does not imply that CAN and J1850 physical buses can be easily interfaced, Szydowski emphasized, only that the message structure would be similar.

Just the next step

The Intel chip "looks like a smart RAM," Szydowski said, with RAM space on-chip to store 14 8-byte receive/transmit message objects (with a fifteenth area for received message objects). The message objects are stored at fixed RAM locations. One on-chip filter is dedicated to the receive message object, with a global acceptance filter mask used for the other 14 message objects.

Intel's new chip is merely the next step in integration, to be followed by efforts to embed 527 functionality into a standard Intel 16-bit controller architecture.

Philips/Signetics has added to its product line as well but from a different direction. The company has integrated a CAN bus controller into a heavily configured 8051-type MCU to come out with the 8XC592. The chip combines large ROM and RAM space with five 8-bit I/O ports, a 10-bit A/D, two 8-bit-resolution PWM outputs, and the usual counter/timers and UART.

The announcement puts Philips and Intel in a confrontation over processing power. Intel will pursue a strategy of integrating CAN controllers into 16-bit MCUs and driving up node performance. The Dutch giant is going in the opposite direction, starting with a high-end commodity 8-bit part and heading downward in cost.

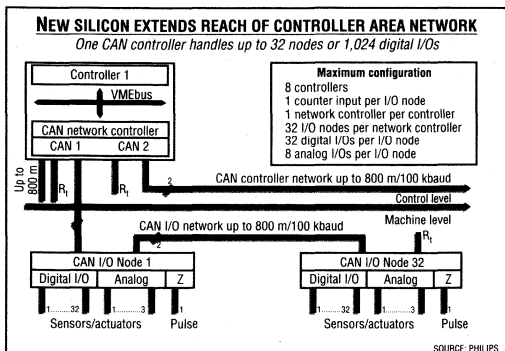

"Customers will want a part for a real simple node, without even a CPU on it," claimed Thomson. "You don't hang an 8051 on a light bulb. We are working on a controller solution for under \$1." Philips has also announced a high-speed CAN transceiver that can be hooked directly to its controllers.

The IX controller from Delta-t GmbH, meanwhile, should prove useful to manufacturers of sub-systems for multiprotocol environments when it debuts sometime next year. The protocol used for each application will be able to be programmed into a flash-memory section of the controller.

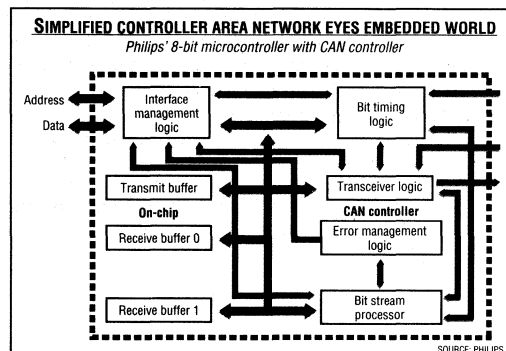

The design activity promises to both lower the cost of a simple CAN-bus node and increase the computing power that can be integrated into an expensive node. Both moves should expand the market deeper into industrial control and instrumentation applications, although CAN partisans see little hope of displacing J1850 from the big three domestic makers.

CAN is a multimaster bus topology network that connects several stations. An International Standards Organization draft from 1990 specifies the first two layers of the Open Systems Interconnect (OSI) model: the physical layer and the data link layer. Philips Medical Systems developed an application layer, using CAN to control X-ray diagnostic systems, control real-time image acquisition and connect user-interface devices. Today, the three layers together form the CAN Reference Model.

by Ron Wilson

Handling CAN-controller complexity has been a barrier to acceptance for this control-oriented bus.

Chips push CAN bus into embedded world

NEWS

Controller Area Network (CAN) Products From Philips Semiconductors

8XC592 CAN Microcontroller - The 8XC592 is a stand-alone high-performance microcontroller based on the 80C51 architecture. Its on-chip CAN interface makes it ideal for applications with a harsh, noisy environment.

The **8XC592 Features** include:

- 16K x 8 EPROM (87C592)
- 16K x 8 ROM (83C592)
- ROMless (80C592)
- 512 x 8 RAM, expandable externally to 64k bytes
- Three Standard 16-bit timer/counters
- A 10-bit ADC with 8 Multiplexed Analog Inputs
- Two 8-bit Resolution, Pulse Width Modulation Outputs
- Five 8-bit I/O Ports Plus One 8-bit Input Port Shared with Analog Inputs
- CAN Controller with DMA Transfer between Internal Data RAM and CAN Registers
- Standard 80C51 UART
- On-Chip Watchdog Timer

82C200 CAN Interface - The 82C200 is a highly integrated stand-alone controller for CAN. The 82C200 with a simple bus line connection performs all the functions of the physical and data-link layers. The application layer of an electronic control unit (ECU) is provided by a microcontroller, to which the 82C200 provides versatile interface.

The **82C200 Features** include:

- Multi-Master Architecture
- Interfaces with a Large Variety of Microcontrollers
- 2032 Message Identifiers
- Powerful Error Handling Capability
- Configurable Bus Interface

82C150 Serial Linked I/O CAN Interface - The 82C150 Serial Linked I/O CAN is a single-chip 16-bit I/O device with an on-chip CAN-controller. 82C150 is a very cost-effective way of increasing the I/O-capability of a microcontroller as well as reducing the amount and complexity of wiring. Advanced safety provided by the CAN protocol combined with low-cost makes the 82C150 a very attractive product for a wide variety of applications.

The **82C150 Features** include:

- Single-Chip I/O Device with CAN Protocol Controller
- 16 Configurable Digital or Analog I/O Ports
- Each Port Individually Configurable via the CAN bus
- 10-bit A/D converter with up to 6 Multiplexed Inputs
- Bit Rate 20 kbit/sec to 125 kbit/sec

All the latest VCRs have on-screen programming in an effort to simplify the notorious task. Now you can have your HCS II or any other computer send you messages while you're watching your favorite TV show.

SPECIAL SECTION

Bill Houghton

S

Suppose, for the moment, you've built and installed the HCS II home control system described primarily in issues 25 and 26 (February/March and April/May '92) of the *Computer Applications Journal*. In issue 27 (June/July '92), Ed Nisley described an add-on LCD output device as a way to obtain information about the status of the system and its various nodes. It's a nice addition to the network, but useful only when you're near to the display module. What do you do if you're across the room watching TV settled into your favorite armchair? You could get up and venture across the room. Or, if you build the interface described in this article, you could hit a button on your HCS II IR remote and

see network information displayed on your TV set overlaid onto the program you are watching.

This article describes an On-Screen Display (OSD) terminal for HCS II (we'll call it "TV-Link" to match the other HCS II modules) that allows color text characters to be displayed on top of a background color video signal. The terminal is built around the Philips/Signetics 87C054 OSD microcontroller.

FEATURES OF 87C054

The 87C054 is an 80C51-based microcontroller designed to provide an advanced OSD for TV and video applications. It can produce characters in eight foreground and eight background colors. In addition, the background color can be removed, showing through the original video. It also has nine pulse-width modulator outputs for controlling analog functions. Similar to a standard 80C51, it has 28 digital I/O pins, two external interrupts, and two timer/counters. RAM and ROM spaces on the 87C054 are larger than the 80C51: 192 bytes of RAM and 16K bytes of EPROM. (The OSD has *additional* RAM and EPROM areas that are not part of the normal 80C51 memory map.)

One unique feature of the 87C054 is what Signetics describes as a "soft-

Photo 1—The TV-Link can be used by your computer to overlay messages on any video signal.

Add Text Overlay to Any Video Display

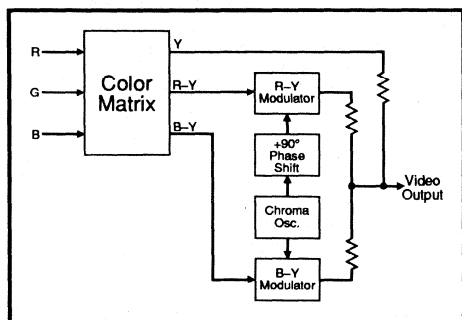

Figure 1—Converting from RGB to NTSC involves modulating and adding difference signals.

ware ADC." This ADC consists of an internal 4-bit DAC that feeds one input of a comparator. The other comparator input can be connected to one of four I/O pins. The output of the comparator is tied to a status bit in a register that is testable by software. A TV set often uses this logic for measuring the AGC voltage during tuning. A real-time clock and other low-precision analog measurements can also use it as a zero-crossing detector.

The OSD of the 87C054 consists of a 128-character RAM array (OSDRAM), a 64-character font EPROM, a video clock oscillator, and the OSD logic. The OSD logic accepts horizontal sync (*HSYNC*) and vertical sync (*VSYNC*) signals and provides three digital video outputs for character information. In the datasheet for this part, these outputs are called *VID0*, *VID1*, and *VID2*, but they can also (and perhaps better) be thought of as *RED*, *GREEN*, and *BLUE*. A multiplexer control output is also present to indicate when to display character data or original video information.

The video clock oscillator provides timing for the character dots. In most applications, this oscillator is simply an LC tank circuit connected to the *VCLK* pins. The frequency controls the character width. One nice feature is that the video clock is killed at the leading edge of *HSYNC* and restarted at the trailing edge of *HSYNC*, which causes the video clock to start in the same phase on every line, ensuring the dots align vertically from one scan line to the next.

The character font stores the binary pattern for the individual characters. Characters are 14 dots wide and 18 scan lines high.

The OSDRAM stores the characters to be displayed on the screen along with certain attribute data pertaining to those characters. Once a character has been written

to the OSD, no further CPU intervention is required to "refresh" the screen.

Many OSD architectures have been developed over the years for use in the consumer television market. Almost all of them have required fixed character row formats, limiting the designer's flexibility in designing video menus and screens.

The 87C054 was designed to avoid such constraints, and there are no architectural limits on the number of characters in a row of text or the number of rows of text to a screen. (There are physical limits imposed by the dot clock frequency and the scan rate, of course.)

The *HSTART* and *VSTART* parameters in the *OSORG* (on-screen origin) register define the initial position of the start of the OSD. Once the initial vertical and horizontal positions have been found, the 87C054 will "fetch" characters from the OSDRAM and place them sequentially on the screen. In order to have multiple rows of text, a special character has been

defined and is referred to as *NEWLINE*. The *NEWLINE* character is much like a carriage return/line feed sequence on a computer in that it terminates the current row of characters and starts a new row of text. One advantage of this architecture is that it eliminates the need to pad display memory with space characters. The fetching and painting of rows of text will continue until either a new vertical sync pulse is detected or until an *END* attribute is fetched along with a *NEWLINE* character.

NOW FOR THE DETAILS...

Now that you understand the concepts of an OSD operation and the capabilities of the 87C054, focus your attention on the details required to overlay characters onto live video.

The 87C054 OSD has a multiplexer output for switching video sources. Simply switching between the input video signal and the OSD character data would be nice. Unfortunately, you can't because the input video (from our home entertainment center) is in NTSC format and the character data is in RGB format. (Keep in mind that the goal is to input live video, add on-screen text, and present the result as a video signal at the output of our circuit.)

One solution is to decode the input video into separate red, green, blue, *HSYNC*, and *VSYNC* signals. Then you could perform the multiplexing between video information and character data in RGB format. The resultant signals could then be encoded back into baseband video. If there were other reasons for the conversion into RGB, such a conversion

Figure 2—A typical line of NTSC video consists of an initial horizontal sync pulse, followed by a short color burst signal, then the actual picture information.

Add Text Overlay to Any Video Display

Figure 3—At the core of the TV-Link is the Signetics 87C054 microcontroller. The unit supports both RS-232 and RS-485 communications with a host computer.

would be the way to go. However, the process of converting to RGB and then converting back to video introduces some distortion that could be visible on the screen.

Another solution is to find a way to encode the RGB data from the OSD microcontroller into video. Then you can simply switch between the two sources. Sound simple? The situation gets a little more complex when you consider the issues of making the characters appear with the proper color in NTSC. Reviewing how color is

encoded in NTSC is in order.

COLOR TELEVISION

When you first look at video, you often wonder why in the world it was done the way it was. A long time ago, before Americans had ever heard the names of Japanese TV makers, RCA research labs were developing color television. One of the requirements imposed on designers by the FCC was that the broadcast signal needed to be compatible with existing black-and-white TV sets and had to be contained

within the same bandwidth as a B/W signal. Such requirements meant that some component of the signal had to contain overall brightness information, which is the main reason why they could not simply transmit separate R, G, and B channels within the video bandwidth allowed. To make a very long story short, the engineers involved decided that the scene brightness (which they called "Y" or luminance) could be described by the relationship

$$Y = 0.59G + 0.3R + 0.11B$$

Someone observed that if they took two copies of the luminance signal and subtracted one copy from one of the colors (say, RED) and did the same with a different color (say, BLUE), the result would be two signals that contained all of the information needed to represent color. These resultant signals, R-Y and B-Y, are the color difference signals.

Now that you have two signals, how can they be transmitted on one RF carrier? The answer they came up with was to modulate one of the signals (B-Y) with an RF carrier. The

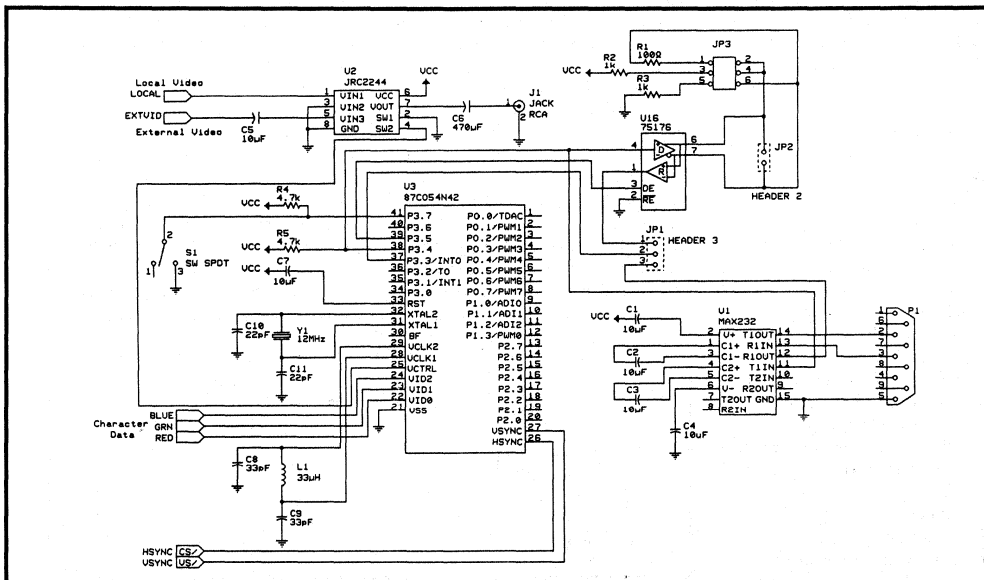

Figure 4a—The JRC2244 switches between the incoming video signal and the on-screen characters under control of the 87C054 MCU.

Add Text Overlay to Any Video Display

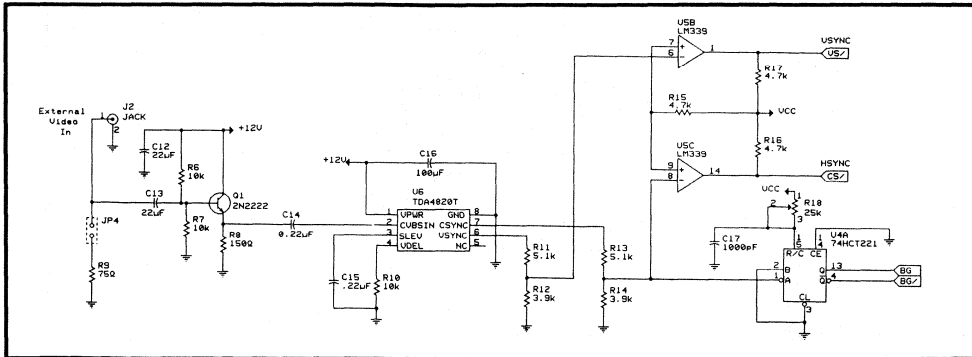

Figure 4b—The TDA4820T sync separator provides the processor with horizontal and vertical sync signals.

other signal (R-Y) was to be modulated with the same RF carrier, but the carrier would be shifted by 90°. When the outputs of the two modulators are added together, the result is the *vector sum* of the two signals, containing both an amplitude and a direction (phase angle). See Figure 1.

We now have a single signal that contains all of the color information. The TV receiver needs just one more piece of information to demodulate this signal. It needs a reference for the carrier used for the modulation, that is, the receiver needs to know where 0° of the color carrier is (in video, this color carrier is referred to as the *chroma subcarrier*). In order to give this reference to the receiver, a small number, or "burst," of cycles of the color subcarrier (hence, the term color burst) are transmitted on the back porch of the horizontal sync pulse. In most NTSC systems, this chroma subcarrier has a frequency of approximately 3.58 MHz. A typical line of color NTSC video is shown in Figure 2.

In order to convert the character data from the OSD into NTSC, you will need to sum the data into R-Y and B-Y components. Then you will need to modulate these components with a chroma subcarrier at 0° for B-Y and +90° for R-Y.

One more item to consider. If you have an output video signal composed of a video source with characters overlaid onto it, the chroma subcarrier reference (i.e., color burst) present on

the output video signal is the color burst provided in the original input video. In order for the receiver/monitor to interpret the color of the OSD characters correctly, the chroma subcarrier used to modulated the OSD's R-Y and B-Y components must have exactly the same frequency and phase as the color burst on the original video input signal.

Once you get the OSD information in the form just described, you can switch between this "OSD video" and the original input video to produce the final output.

THE TV-LINK HARDWARE SOLUTION

Figure 3 shows a block diagram of the TV-Link, while Figure 4 shows the schematic.

Referring to the schematic, the original input video connects to J2 and is AC coupled into buffer amplifier, Q1. This amplifier provides load isolation between the video signal source and the circuits on the TV-Link board. JP4 is a jumper allowing for a 75-ohm termination resistor to be connected to J2. The output of the Q1 buffer amplifier feeds the sync separator, the video switch, and the chroma subcarrier regenerator circuits.

SYNC SEPARATION

The sync separator consists of U6, a TDA4820T Philips sync separator. The video signal is coupled into the TDA4820T through capacitor C14, where it is amplified with a gain of 15.

The black level clamping voltage is stored in capacitor C14. From the stored black level voltage and the peak sync voltage, the 50% value of the peak sync voltage is generated and stored in capacitor C15. A slicing level control circuit ensures a constant 50% peak sync voltage regardless of the picture content amplitude provided the sync pulse amplitude is between 50 mV and 500 mV. A comparator in the composite sync slicing stage compares the amplified video signal with the DC voltage derived from the 50% peak sync voltage, producing the composite sync output. Vertical slicing circuits compare the composite sync signal with a DC level equal to 40% of the peak sync signal, producing the vertical sync output. The reduced vertical slicing level ensures more energy for the vertical pulse integration. The slope is double integrated to eliminate the effects of interference caused by noise or line reflections. The value of resistor R10 sets the vertical integration delay time.

The outputs of the sync separator are positive-going signals with peak amplitudes exceeding 10 V. Resistor pairs R11/R12 and R13/R14 serve as voltage dividers for the VSYNC and CSYNC outputs, respectively. An LM339 comparator, U5, serves as an inverter for the sync signals because the modulator circuits require active low sync signals.

There is a great tendency with video circuits to make the coupling capacitors very large to pass the low-

Add Text Overlay to Any Video Display

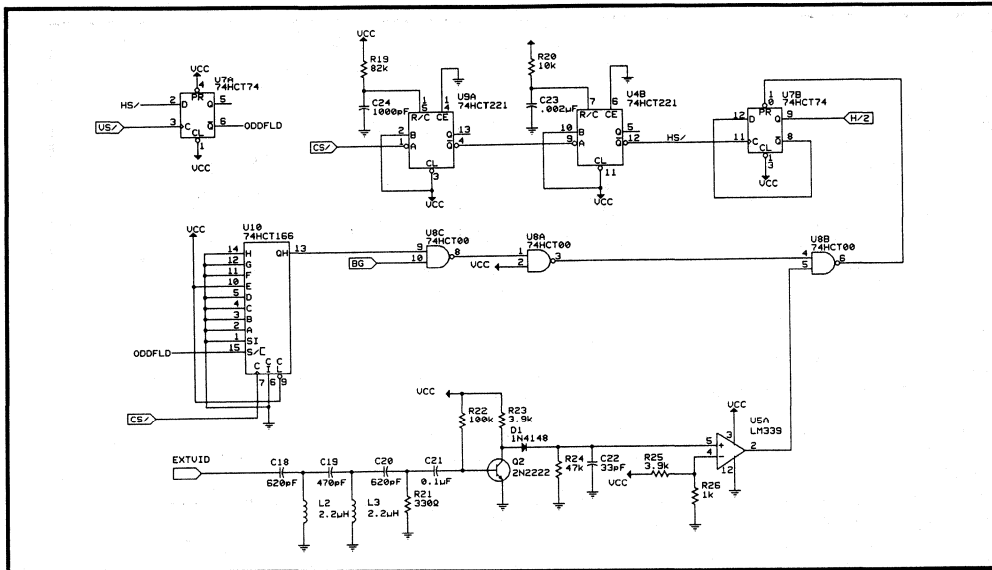

Figure 4c—In order to properly overlay colors onto a PAL signal, you must know whether you're on an odd or an even field, so extra circuitry must be included on the board to support PAL.

frequency sync components (60/50 Hz, typically) into low-impedance nodes. The TDA4820T has a moderately high input impedance on pin 2. Because the black level is stored in C14, the value of C14 should be kept close to 0.22 μ F.

THE 87C054 MCU WITH OSD

The 87C054 microcontroller, U3, accepts composite sync and vertical sync signals from the sync separator and provides RGB digital outputs for character data. The multiplexer control output, *VCTRL*, connects to the video switch, U2, a JRC2244.

Inductor L1 and capacitors C8 and C9 form a video clock oscillator that determines the width of a character font dot. The values of these components are not critical but are typically chosen such that a video dot width is equal to the spacing between scan lines. This oscillator is killed at the leading edge of the *HSYNC* signal and allowed to startup at the trailing edge. Such synchronization causes the oscillator to start at exactly the same point from one scan line to the next, causing character dots to appear in exactly the same spot on each line.

In addition to the OSD functions, the 87C054 also performs network interfacing and protocol tasks. This microcontroller has plenty of performance bandwidth because the OSD logic is self-refreshing and independent of the MCU core.

VIDEO SIGNAL SWITCHING

The JRC2244 video switch, U2, contains three video inputs, two of which are used in this application. One of these inputs, *VIN1*, is capacitively coupled to the OSD video signal. This signal is the 87C054's RGB data after encoding into baseband video. The other input, *VIN3*, is capacitively coupled to the original video input signal. The JRC2244 provides internal bias sources to provide DC restoration to its video inputs. The JRC2244 accepts a switching control signal from the 87C054 and switches its output between the original video input and the OSD video signal. The video switch also has an internal 75-ohm line driver in its output stage.

The JRC2244 has a moderate input impedance of about 15k ohms, allowing 10- μ F coupling capacitors to

be used. The output coupling capacitor is large because this signal can be used to drive 75-ohm loads.

RGB ENCODING

The LM1886, U13, and the LM1889, U14, encode the RGB data from the 87C054 into baseband video. The LM1886 has three DACs, one for each color. Each of these DACs has 3-bit inputs, but because the 87C054 data is digital, the inputs to the LM1886 DACs are tied together yielding an output for each DAC that is either full-scale or zero. The outputs of the three DACs are internally summed to produce the luminance, R-Y, and B-Y amplitudes. The LM1889 accepts the regenerated chroma subcarrier, modulates the R-Y and B-Y signals, and produces baseband video on pin 13. Transistor Q5 is used as a buffer amplifier with voltage dividers R49 and R50 producing proper levels for the video switch. Note that the LM1889 accepts an external subcarrier signal at the junction of R46 and C52, but this subcarrier undergoes a phase shift caused by the resistor and capacitor networks associated with pins 1

Add Text Overlay to Any Video Display

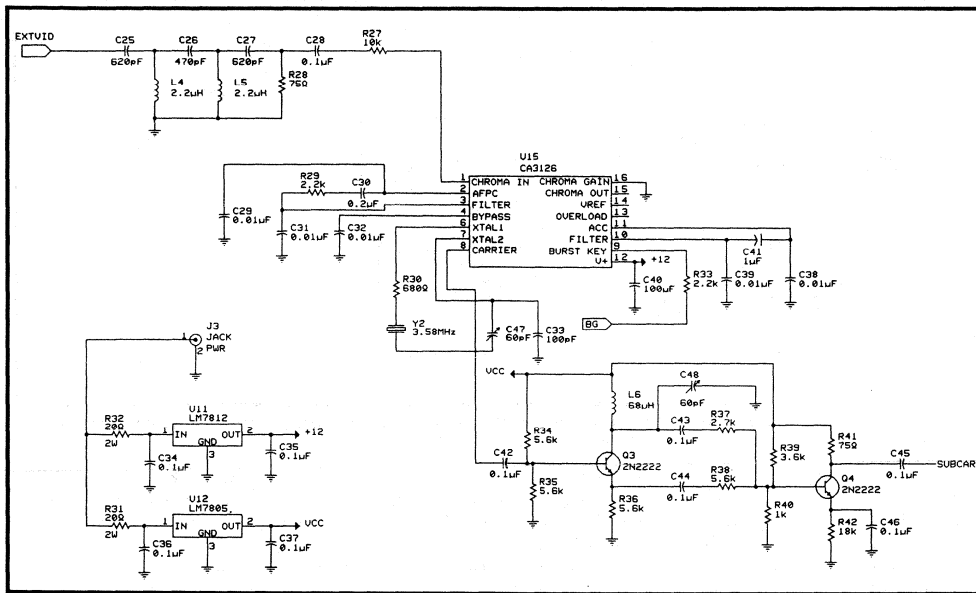

Figure 4d—The CA3126 TV chroma processor is designed specifically for regenerating chroma subcarriers.

and 18 of the LM1889. This phase shift will need to be considered when the subcarrier is regenerated.

CHROMA SUBCARRIER REGENERATION

The circuits that reproduce a chroma subcarrier in the same frequency and phase as the color burst consist of a high-pass filter, a sample-and-hold phase-locked loop (PLL), and a phase shift network and amplifier.

The passive high-pass filter consists of inductors L4 and L5, resistor R28, and capacitors C25, C26, and C27. The filter starts passing signals at about 3.2 MHz, allowing the chroma subcarrier to pass through to the CA3126, U15.

The CA3126 is a TV Chroma Processor IC designed specifically for regenerating chroma subcarriers. This IC contains a VCO and a PLL with sample-and-hold circuits in the error correction loop. As a result, the VCO-generated carrier is compared with the chroma signal from the high-pass filter during the time that color burst is present, indicated by the burst gate pulse (which I will describe later).

The regenerated carrier output is present on pin 8 of the CA3126. Even though this carrier is phase locked to the color burst, it is not at exactly the same phase as the color burst. The nature of a PLL is such that the output will be locked but will always have some constant fixed phase delay relative to the input. Also, recall that the input circuits of the LM1889 added an additional constant phase shift to the injected carrier.

The phase shift network and amplifier consisting of the Q3 and Q4 stages compensate for these fixed phase delays. This circuit provides an output whose phase is adjustable by means of variable capacitor C48, and has a tuning range of approximately 0° to 160° of phase shift. For a given input signal amplitude, the output signal amplitude is constant, regardless of the phase shift introduced. The output of this circuit is the signal injected into the LM1889 circuits.

CONNECTING TO THE HCS II

Now that you have a working terminal circuit for overlaying text onto live video, you still need to

connect it to the HCS II network. In order to do this, you will need a serial interface compatible with the network, some software that handles network message formats, and software that interprets network messages and creates responses or actions (or both) to those HCS II network messages.

This particular design includes both an RS-232 and an RS-485 interface. U1, a MAX232, provides the RS-232-to-TTL conversion for both the transmitter and receiver. U16, a 75176, provides the RS-485-to-TTL conversion. JP1 connects the receiver pin of the 87C054 to either the RS-232 or RS-485 interfaces. The transmitter pin of the 87C054 connects to both the RS-232 and RS-485 interfaces. One pin of the 87C054, P3.5, controls the driver enable of the 75176, allowing for selective talking on the HCS II network. JP3 provides for termination of the network.

"But, wait a minute! The 87C054 doesn't have a UART," you say. True. There is no built-in UART on the 87C054 and the part does not have a transmitter pin or receiver pin.

Add Text Overlay to Any Video Display

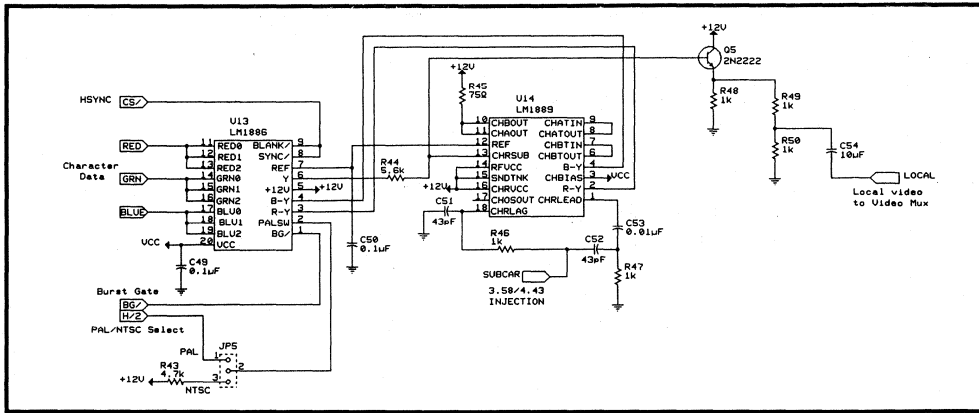

Figure 4e—Encoding the RGB data into baseband video is accomplished with an LM1886, which contains three DACs, and an LM1889, which accepts the regenerated chroma subcarrier, modulates the R-Y and B-Y signals, and produces baseband video.

In this application, the serial data transmission and reception has been performed in software. The routine that handles serial transmission and reception was taken from the Signetics BBS ([800] 451-6644). It was originally designed for the 87C751 and had to be slightly modified to operate with one of the 87C054's timer/counters. The technique is often called "bit banging" and has the advantage of saving some hardware if you can afford the necessary time required of the software.

NETWORK PROTOCOL PROCESSING

As I indicated earlier, in addition to the serial interface software, you need code that handles network message formats. The code starts by waiting until either a "#" or an "!" is received, either of which indicates the start of a network message, then the entire message is stored in a buffer.

Once the carriage return has been stored, the beginning character of the message is checked to see whether the message includes a checksum. If the message does not contain a checksum, the packet is assumed to be valid and the contents of the packet are processed. If a checksum is included, then the VERIFY routine is called to perform a checksum calculation on the packet. If the checksum matches, the packet is processed; otherwise, it is ignored and I return to waiting for the

next network message.

My original plans for handling network checksums included a checksum generator for sending network responses and a checksum checker for received messages. However, when I flowcharted the needs of both routines, I found that an awful lot of the logic was common to both. I went back and looked at the suggestions that Ed Nisley had provided for handling the checksums and understand now why he made those suggestions. My VERIFY routine's logic is based on Ed's previous work.

The VERIFY routine performs two functions. First, it takes the checksum digits in the packet, converts them to binary numbers, and stores them in temporary variables. Next, the checksum digits are replaced with ASCII zeros and the checksum of the string is calculated. If the checksum matches, the error flag, CHKERR, is cleared; otherwise, it is set. The checksum that was calculated is converted to ASCII and stuffed into the checksum digits position, replacing the ASCII zeros.

To prepare a string for transmission, all that is necessary is to stuff the message in the buffer with the checksum digits set to ASCII zeros and call the VERIFY routine. To check a message for correct checksum, simply call the VERIFY routine and check the CHKERR flag on return.

Once the checksum verification (if required) has been performed, you still need to process the packet to see if it belongs to this terminal, and if it does, then you need to determine what action the network controller is asking you to take.

The PROCESS routine first scans the packet, converting characters into upper case until the end of the packet has been reached. Next, the first character is examined to determine if the packet has checksums or not and a pointer is set to the NODEID position of the packet. The NODEID in the packet is compared with the NODEID variable. If there is no match, the packet is ignored and you wait for the next network message. If it does belong to this terminal, you can process the body of the network message.

NETWORK COMMANDS AND SYNTAX

The real essence of a network message is to carry a command from the network controller to the terminal or carry a response from the terminal back to the network controller. Table 1 shows the syntax of the commands available for operating the TV-Link terminal. These commands allow the HCS II Supervisory Controller to manipulate ports on the 87C054, format text for display, implement special built-in display functions such as color bars, and to read and write

Add Text Overlay to Any Video Display

A = string	Set HCS II network address to string
Fx	Execute special function <ul style="list-style-type: none"> 0 Initialize screen 1 Display on 2 Display off 3 Display color bars 4 Wipe on 5 Wipe off
Hxy	Set Px.y high
Lxy	Clear Px.y low
Nn	Network response mode <ul style="list-style-type: none"> N0 = normal network interface, no auto error or acknowledge responses N1 = auto error and acknowledge response
Px	Query port x <ul style="list-style-type: none"> 0 = Port 0 1 = Port 1 2 = Port 2 3 = Port 3
Px= nn	Write to port x where nn= two-digit hex value <ul style="list-style-type: none"> 0 = Port 0 1 = Port 1 2 = Port 2 3 = Port 3
Rx	Query register x; returns two-digit hex number <ul style="list-style-type: none"> 0 = OSDT (contents undefined) 1 = OSAT 2 = OSCON 3 = OSORG 4 = OSMOD 5 = Default char. attribute 6 = Default background space attr 7 = Default NEWLINE attribute
Rx = nn	Write to register x; for use from outside of a string of text; writes to these registers from within a string; should use the \Wxnn command <ul style="list-style-type: none"> 0 = OSDT 1 = OSAT 2 = OSCON 3 = OSORG 4 = OSMOD 5 = Default char. attribute 6 = Default background space attr 7 = Default NEWLINE attribute
S= string	String for OSD display; can include escape sequences for text formatting, color, selection, etc.
\Wxnn	Write to register x; for use within a string; functionally equiv. to the Rx = nn command
Special characters for use within a string of text	
\E	End of Display at current position
\B	Background Space
\S	Split Background Space
\N	NEWLINE

Table 1—The set of supported commands resembles that of most of the other HCS II network modules.

OSD registers directly, giving full control of the OSD to the HCS II.

CONCLUSIONS

Developing this application was interesting and enjoyable. It also

presented some challenges.

The 87C054 proved well suited to this application in large part because of the 80C51 core and that the OSD is independent of the CPU. Once characters have been written to the OSD, you

can forget the OSD until you want to change the display, and the CPU is free to pursue other tasks.

The on-screen display and the microcontroller operations are primarily digital functions. The question of how to combine this technology with an analog video signal can be perplexing to most system designers whose professional experiences have been mostly digital circuits. One of the most perplexing issues during this project was how to re-create the chroma subcarrier. I knew that every color TV set had to perform this function, but finding out solutions took some searching before I discovered the CA3126. I'm hopeful you can profit from my experiences on this project. ☐

My thanks to Herb Kniess and George Ellis of Signetics for their help. Thanks also to Greg Goodhue from Signetics, who wrote the software-based UART code for the 87C751 that I modified for this project.

Control Area Network (CAN) overview

CAN OVERVIEW

The Control Area Network (CAN) is a multiplexed wiring protocol developed by Bosch for use in automotive applications. As products supporting CAN have been made available by Philips Semiconductors and other semiconductor manufacturers, the protocol has become used in other industries including: industrial automation, machine tools, medical equipment, and building environmental control, to name a few. The CAN protocol is attractive for use in a wide range of applications because it has powerful error detection capabilities and features differential drive, and can be used comfortably in critical high noise environments. CAN is also very flexible in terms

of the transmission media and the connection scheme, and is generally easy to adapt to most applications.

Philips offers a wide range of parts that support the CAN protocol, including stand-alone parts as well as microcontrollers with integrated CAN interfaces. Datasheets for the 82C200 (Stand-alone CAN controller), 82C150 (CAN serial Linked I/O device), and 82C250 (CAN transceiver) are included in this section of this databook. Datasheets for the microcontrollers that have an integrated CAN interface (8XC592 and 8XC598) are included with Philips' 80C51 family products in Section 3 of the IC20 databook.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

1 FEATURES

- Single-chip I/O device with CAN protocol controller
- Meets CAN protocol specification version 2.0 A and B (passive) with restricted bit timing
- Fully integrated clock oscillator (no crystal required)
- 16 configurable digital or analog I/O port pins
- Each of the port pins individually configurable via CAN-bus: port direction, port mode and event capture facilities for inputs (event driven or polling)
- Up to sixteen digital inputs; automatic transmission of a CAN message on a change on inputs individually selectable
- Up to sixteen 3-state outputs
- Up to two quasi-analog outputs with 10-bit accuracy
- 10-bit analog-to-digital converter with up to six multiplexed analog input channels (for accuracy see Section 11.6)
- Two general purpose comparators
- Bit rate from 20 kbit/s up to 125 kbit/s using internal oscillator
- Automatic bit rate detection and calibration
- Up to sixteen P82C150 nodes for one CAN-bus system
- Four identifier bits programmable
- SLIO functions controlled by a single intelligent node ('host')
- Sleep-mode with wake-up via CAN-bus
- Differential CAN-bus input comparator and CAN-bus output driver
- Supply voltage: 5 V \pm 4%
- Operating temperature: two ranges -40 to +85 °C and -40 to +125 °C.

3 ORDERING INFORMATION

TYPE NUMBER	PACKAGE			TEMPERATURE RANGE (°C)
	NAME	DESCRIPTION	VERSION	
P82C150 AFT	SO28	plastic small outline package; 28 leads; body width 7.5 mm	SOT136-1	-40 to +85
P82C150 AHT				-40 to +125

2 GENERAL DESCRIPTION

The P82C150 is a single-chip 16-bit I/O device including a Controller Area Network (CAN) protocol controller with automatic bit rate detection and calibration. It features 16 configurable I/O port pins with programmable direction, digital and analog modes.

The P82C150 provides a configurable event capture facility supporting automatic transmission caused by a change on the port input pins.

The clock oscillator requires no external components, thus, the cost of the CAN link is reduced significantly.

The P82C150 is a very cost-effective way to increase the I/O capability of a microcontroller based CAN node as well as to reduce the amount and complexity of wiring. Advanced safety is provided by the CAN protocol.

Applications:

- Body electronics and instrumentation in automotive applications
- Sensor/actuator interface in automotive and general industrial applications
- Extension of I/O capabilities of microcontroller based CAN nodes.

6.2 Pin description

Table 1 Pin description for P82C150; SO28; see note 1

SYMBOL	PIN	DESCRIPTION
P2	1	I/O Ports P2 to P3; Identifier programming input.
P3	2	
P4	3	I/O Port 4; DPM2 output.
V _{SS}	4	Ground, digital part (0 V; logic circuits and CAN-bus driver).
P5	5	I/O Ports P5 to P6; analog input.
P6	6	
P7	7	I/O Port 7; analog input or analog-to-digital comparator 1 output.
V _{DD}	8	Power supply, digital part (+5 V; logic circuits and CAN-bus driver).
P8	9	I/O Port 8; analog input or comparator 3 output.
P9	10	I/O Port 9; analog input or comparator 2 output.
P10	11	I/O Port 10; comparator 3 inverting input or DPM1 output.
P11	12	I/O Port 11; comparator 3 non-inverting input.
P12	13	I/O Port 12; comparator 2 inverting input.
P13	14	I/O Port 13; comparator 2 non-inverting input.
P14	15	I/O Port 14; multiplexed analog signal.
P15	16	I/O Port 15; analog-to-digital comparator input.
P16	17	Feedback output of analog-to-digital converter.
AV _{DD}	18	Power supply, analog part (+5 V; CAN input, oscillator and reference).
REF	19	Reference voltage output ($\frac{1}{2} \times AV_{DD}$).
AV _{SS}	20	Ground, analog part (0 V; CAN input, oscillator, reference).
RX0	21	CAN-bus input.
RX1	22	
RST	23	External reset input (active-HIGH) for internal oscillator mode; pulled to +5 V for external oscillator mode (see Section 11.3).
XMOD	24	Connected to GND for internal oscillator mode; external reset input (active-LOW) for external oscillator mode (see Section 11.3).
TX0	25	Open-drain CAN-bus output: dominant = LOW; recessive = floating.
TX1	26	Open-drain CAN-bus output: dominant = HIGH; recessive or at bus mode 2 floating.
P0/CLK	27	I/O Port P0, Identifier programming input in internal oscillator mode; clock input in external oscillator mode (see Section 11.3).
P1	28	I/O Port P1; identifier programming input.

Note

1. In this documentation the port pins are referred to by their symbols, not by their pin number. For example P15 means I/O Port 15 at pin 16.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7 FUNCTIONAL DESCRIPTION

7.1 I/O functions

The P82C150 provides 16 port pins (P15 to P0) which are individually configurable via CAN-bus. Besides the digital I/O functions some of these port pins provide analog I/O functions.

7.1.1 DIGITAL INPUT FUNCTIONS

Input levels HIGH and LOW on the port pins (P15 to P0) can be read in two ways by the host node:

- **Polling:** a Remote Frame is sent to the P82C150 to be answered by a Data Frame containing the Data Input Register contents.
- **Event capture:** in case of edge-triggered mode, the P82C150 sends the same Data Frame caused by the event of a rising and/or falling edge on the corresponding port pins (see Table 3).

7.1.2 DIGITAL OUTPUT FUNCTIONS

The Data Output Register is set via a CAN message. Its content is only output when the corresponding bits of the Output Enable Register are set to logic 1s.

7.1.3 ANALOG INPUT/OUTPUT FUNCTIONS

- Up to six multiplexed analog input signals for analog-to-digital conversion or general purpose
- Up to two quasi-analog output channels (DPM; Distributed Pulse Modulation)
- Two input comparators, for example for window comparator applications
- A separate analog-to-digital input comparator with feedback output.

Analog-to-digital converted digital results are obtained by reading the Analog-to-Digital Conversion (ADC) Register. Analog functions of each port pin are individually controlled by the Analog Configuration Register.

Writing the I/O registers is done serially via CAN-bus by Data Frames. The first data byte contains the register address, and the second and third data bytes represent the register contents. If a read only register is addressed, the contents of the second and third data bytes are ignored.

It is recommended to set unused port pins to HIGH (100 k Ω resistor to V_{DD}).

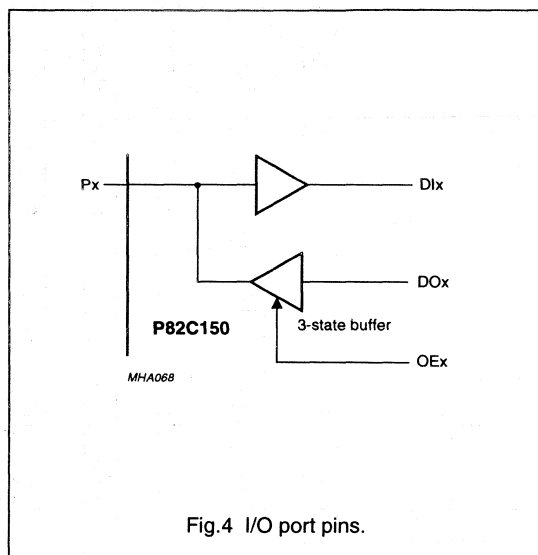

Fig.4 I/O port pins.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.2.1 DATA INPUT REGISTER (ADDRESS 0)

This read only register contains the states of port pins P15 to P0 which are transmitted on request, or automatically by change of one of the input levels, provided that the respective input is configured to event capture mode (see Table 3). When an edge is detected the port state is loaded into the transmit buffer after the Control Field of the triggered message is sent. Therefore a delay for input settling is provided. If between edge detection and transmission of the data input register another input signal change at the input port occurs, the corresponding data input register bit is overwritten by the current input port value. Additionally the register content is sent automatically after wake-up or bus mode change, once the bit time has been calibrated (part of the 'sign-on' message).

7.2.2 POSITIVE EDGE REGISTER (ADDRESS 1)

This write only register contains configuration information per port pin for the event capture facility. The corresponding PE-bit (see Table 3) has to be set to logic 1 to enable capturing of the rising edge.

7.2.3 NEGATIVE EDGE REGISTER (ADDRESS 2)

This write only register contains configuration information per port pin for the event capture facility. The corresponding NE-bit (see Table 3) has to be set to logic 1 to enable capturing of the falling edge.

The combination of PE and NE functions is possible.

7.2.4 DATA OUTPUT REGISTER (ADDRESS 3)

This write only register contains the output data for the port pins. The output drivers are bitwise enabled by OE (see Section 7.2.5). New data for the output port register are processed and written to the output ports directly after the corresponding CAN message to the P82C150 is successfully checked and becomes valid.

7.2.5 OUTPUT ENABLE REGISTER (ADDRESS 4)

This write only register controls the output drivers of the port pins. The corresponding Output Enable Register bit has to be set to logic 1 to enable an output driver. If set to logic 0, the corresponding output driver is disabled (floating; see Fig.7).

Table 3 Programming of the I/O registers to event capture on edge or to digital output

Falling	0	1	X
Rising and Falling	1	1	X

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.2.6 ANALOG CONFIGURATION REGISTER (ADDRESS 5)

This read/write register contains the bits ADC, OC3 to OC1, M3 to M1 and SW3 to SW1 (see Fig.7).

- ADC bit (analog-to-digital conversion start bit; write only bit). The P82C150 starts an analog-to-digital conversion cycle at ADC = 1 ended with the transmission of a message containing the result. After that, the ADC bit is reset automatically.
- OC3 to OC1 bits (comparator output data; read only bits). The bits OC3 to OC1 represent the logical output level of the analog comparators at input port pins P10, P11, P12, P13 and P15. The P82C150 sends back the logical output value of these comparators after having received a Data Frame (see Section 7.3.3) addressing the Analog Configuration Register. The comparator outputs can be monitored at the output port pins P8, P9 and P7.
- M3 to M1 bits (multiplexer control bits; write only bits). The logical value of the comparators is monitored on port pins P8, P9 and P7 (see Fig.7) by setting M3 to M1 to logic 1, provided that these pins are configured as outputs (OE = 1). Additionally the register content is sent automatically when the corresponding port bits in the Positive Edge Register and/or Negative Edge Register and the corresponding bits in the Output Enable Register are set.
- SW3 to SW1 (analog switch control bits; write only bits). One of the analog switches S1 to S6 can be closed by setting the switch bits to the corresponding value (see Fig.7 and Table 4).

Table 4 Analog switch selection by SW3, SW2, SW1.

SW3	SW2	SW1	SWITCH STATE
0	0	0	no switch closed (S0); note 1
0	0	1	S1 closed
0	1	0	S2 closed
0	1	1	S3 closed
1	0	0	S4 closed
1	0	1	S5 closed
1	1	0	S6 closed
1	1	1	reserved

Note

1. Evidently if P14 is driven, it may not be connected to any other driven pin via the internal analog switches (avoid short-circuit!).

7.2.7 DPM1 REGISTER (ADDRESS 6)

This write only register contains data for a quasi-analog output signal on port pin P10, which is generated by Distributed Pulse Modulation (DPM; see Fig.9). The Output Enable bit must be set for this functions (OE10 = 1). The DPM1 output signal is inverted by setting DO10 = 1. The number of output pulses during a DPM period is given by the DPM1 Register value. These pulses have $4 \times t_{CLK}$ length and are distributed over the DPM period. An analog voltage is provided after smoothing the output signal by an external RC combination.

7.2.8 DPM2 REGISTER (ADDRESS 7)

This write only register contains data for a quasi-analog output signal on port pin P4. The function of the DPM2 corresponds to the definition of DPM1.

7.2.9 ANALOG-TO-DIGITAL CONVERSION (ADC) REGISTER (ADDRESS 8)

This read only register contains the result of the analog-to-digital converted level of that I/O pin which was selected by the SW bits. The conversion is started by ADC-bit set to logic 1 (see Section 7.2.6), or by transmitting a Data Frame addressing the ADC Register.

P82C150

7.3 CAN functions

The P82C150 meets the CAN protocol specification version 2.0 A and B (passive) with restricted bit timing because of the on-chip RC-oscillator and the automatic bit rate detection.

In a system with P82C150 nodes there must be at least one conventional crystal-driven CAN controller (host node) which is compatible to the CAN specification V1.2 or later to control P82C150 nodes. Host nodes compatible to CAN specification V1.1 can also be used provided that the P82C150 nodes are powered by a high-accuracy power supply or they are in external oscillator mode (refer to Section 11.3).

Each time a P82C150 node receives a Data Frame, it initiates the transmission of a Data Frame containing four bits status information, the register address (previously received) and the current contents of the addressed register (exception: see Section 7.3.3.1). This enables the

host node to verify that the addressed register has correctly been written in case of writeable registers, and to read the contents in case of readable registers.

7.3.1 CAN IDENTIFIER

Data and Remote Frames to be processed by the P82C150 are of Standard Format with 11 Identifier bits ID.10 to ID.0. Frames with extended Identifier (CAN specification version 2.0 B) are ignored.

The way of identifier programming is based on two facts:

- Each P82C150 operates with only two Identifiers distinguished by the LSB (see Tables 5, 6 and 7). The identifier with the higher priority is used for Data Frame reception. An extra Identifier is used for calibration purposes.
- There can be maximum sixteen P82C150 circuits in one network.

Table 5 Message types and format

FRAME	TRANSMISSION BY 82C150	RECEPTION AT 82C150
Data Frame	yes (DLC = 3; DIR = 1)	yes (DLC = 3; DIR = 0; calibration message with DLC = 2 to 8 allowed, see Section 7.3.10)
Remote Frame	no	yes (DLC = 3; DIR = 1)
Error Frame	yes	yes
Overload Frame	yes (only as a response)	yes

Note

1. DLC = Data Length Code; DIR = LSB of Identifier (see Section 7.3.1).

Table 6 Standard Format Identifier bits ID.10 to ID.0

1 = recessive; 0 = dominant

IDENTIFIER											
ID.10	ID.9	ID.8	ID.7	ID.6	ID.5	ID.4	ID.3	ID.2	ID.1	ID.0	
0	1	P3	1	0	P2	P1	P0	1	0	DIR	RTR

Table 7 Description of the Standard Format Identifier bits

BIT	SYMBOL	DESCRIPTION
ID.8	P3	Programmable identifier bits read from Port pins P3 to P0 during reset. The input levels on P3 to P0, for example set by resistors to V _{SS} or to V _{DD} , are latched in the Identifier latch with the falling edge of the RST input signal. They represent the variable part of the Identifier, while the remaining bits are fixed (mask-programmed), P3 to P0 can be used as I/O ports after reset.
ID.5 to ID.3	P2 to P0	
ID.0	DIR	DIR = 1 for transmission of Data Frames to the host. It must be set to a logic 1 in Remote Frames and to a logic 0 in Data Frames received from the host.
	RTR	Remote Transmission Request bit.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.3.2 TRANSMISSION OF DATA FRAMES

Data Frames transmitted by the P82C150 contain three data bytes (see Fig.7). The first data byte contains the status information and the register address A3 to A0 (see Tables 8 and 9), the other two data bytes contain the content of the addressed I/O Register.

After each successful message transmission, the P82C150 delays the transmission of a possibly further pending message for three bit times. The reason is to give other CAN controllers - with a lower identifier priority - the possibility to transmit a message in case of faulty contact at one of the edge-triggered port pins.

7.3.3 RECEPTION OF DATA FRAMES AND REMOTE FRAMES

Received Data Frames have the same format as transmitted ones, only the DIR-bit (ID.0) in the Arbitration Field is different. The status bits RSTD, EW, BM1 and BM0 are ignored during reception.

The P82C150 confirms each reception of a Data Frame by transmitting a Data Frame containing the (new) contents of the addressed I/O Register.

7.3.3.1 Exceptions to the rule

1. Analog Configuration Register: If a P82C150 receives a Data Frame addressing the Analog Configuration Register and the ADC bit is set to logic 1, it will respond with two messages. The first message returns the contents of the Analog Configuration Register. The control instructions are executed (e.g. next analog input channel selected), and an analog-to-digital conversion cycle is started after a set-up time. After finishing the analog-to-digital conversion cycle, the second message is transmitted containing the result (ADC Register).

2. ADC Register: On receiving a Data Frame addressing the ADC Register, the P82C150 starts an analog-to-digital conversion cycle. It automatically returns the result of the conversion (ADC Register) by transmitting a respective Data Frame after finishing the analog-to-digital conversion cycle.
3. At normal operation, the calibration messages are confirmed by returning a dominant bit in the acknowledge slot. There is no particular confirmation message returned by the P82C150. Only after entering the calibrated state (start-up), a Data Frame ('sign-on' message) containing the Data Input Register contents is transmitted indicating to the host node, that the P82C150 is now ready for transmission.

7.3.3.2 Remote Frame

Received Remote Frames must have the Data Length Code DLC = 3 (Remote Frames with DLC ≠ 3 are ignored). It is answered by a Data Frame containing the contents of the Data Input Register.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

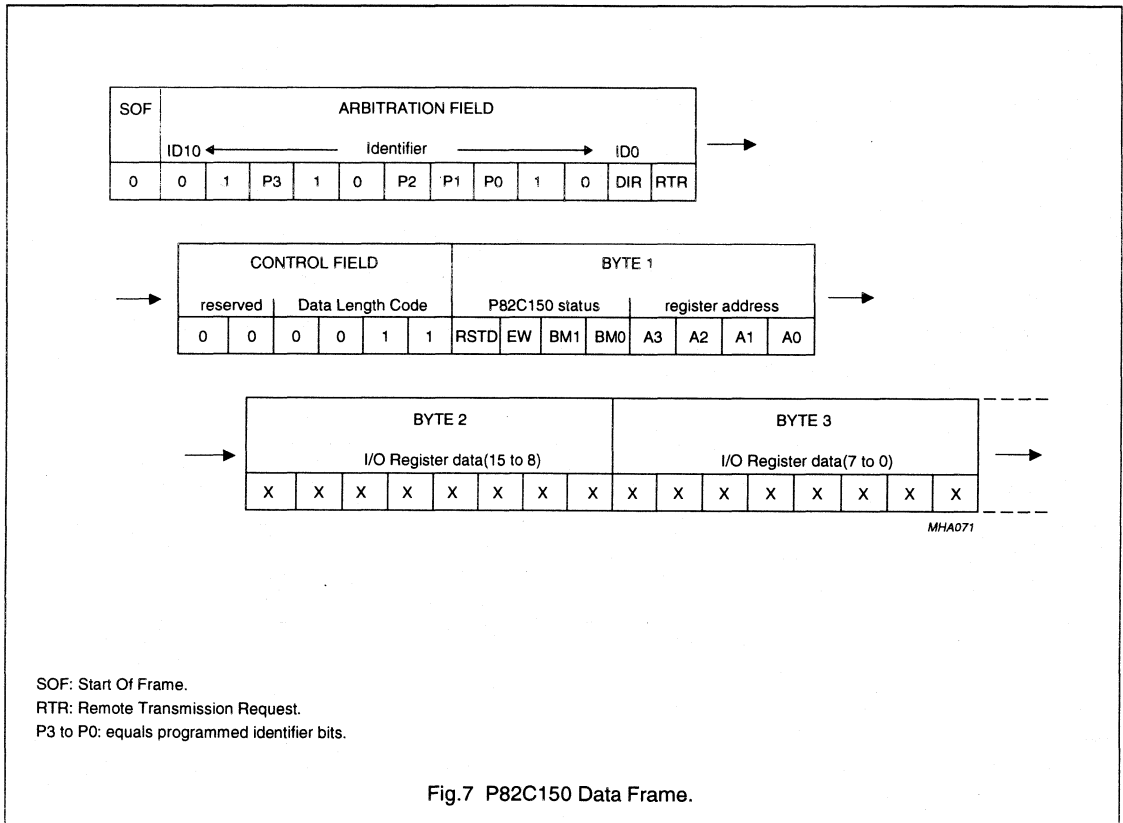

P82C150

Table 8 Data Frame Byte 1

STATUS				REGISTER ADDRESS			
RSTD	EW	BM1	BM0	A3	A2	A1	A0

Table 9 Description of Data Frame Byte 1 bits

SYMBOL	DESCRIPTION
Status	
RSTD	It is logic 1 in the first message ('sign-on' message) after the successful detection of the bit rate (bit time calibrated).
EW	Logic 1, if the error warning limit (32) is reached. In the "sign-on" message EW is always logic 1. The EW status bit is set when the Receive Error Counter or the Transmit Error Counter have exceeded the Error Warning Limit of 32, also temporarily, since the last successful transmission of a message.
BM1	Bus mode status bits.
BM0	
Register address	
A3 to A0	Register address bits.

SOF: Start Of Frame.
 RTR: Remote Transmission Request.
 P3 to P0: equals programmed identifier bits.

Fig.7 P82C150 Data Frame.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.3.4 CAN-BUS MODES

The P82C150 can pass through four CAN-bus modes under certain conditions (see Fig.8). In the bus modes 0 to 2 (see Table 10) the P82C150 is operating with different input comparator configurations. Bus mode 3 is the power reduced Sleep Mode.

The bus modes support:

- Communication on two balanced wires (differential system)
- Communication on one wire in a two-wire differential system
- Sleep Mode with wake-up via either a dominant signal on RX0 or RX1 input
- Connection of a second transmission medium (redundancy)

There are two possibilities for condition 1 to switch to the next mode (see Fig.8):

- Overflow of the bit counter when 8192 is reached since the last calibration message
- Overflow of the Transmit Error Counter (>255; bus-off limit reached).

When the bus mode changes, all I/O Registers are cleared and outputs become floating (OE bits cleared). That means the I/O ports return to a fail-safe state whenever the P82C150 loses connection to its host controller. This is a kind of network watchdog function. The status bits are set to the following values after a bus mode change:

- RSTD = 1
- EW = 0
- $BM_{new} = BM_{old} + 1$.

The programmed Identifier bits remain unchanged.

After reset the P82C150 changes directly into bus mode 3 (Sleep Mode). During Sleep Mode, the internal RC oscillator is stopped, and all the output drivers are disabled (I/O Register contents cleared). A P82C150 in Sleep Mode can be woken up via CAN-bus lines (dominant level on RX0 or RX1) or by a reset condition.

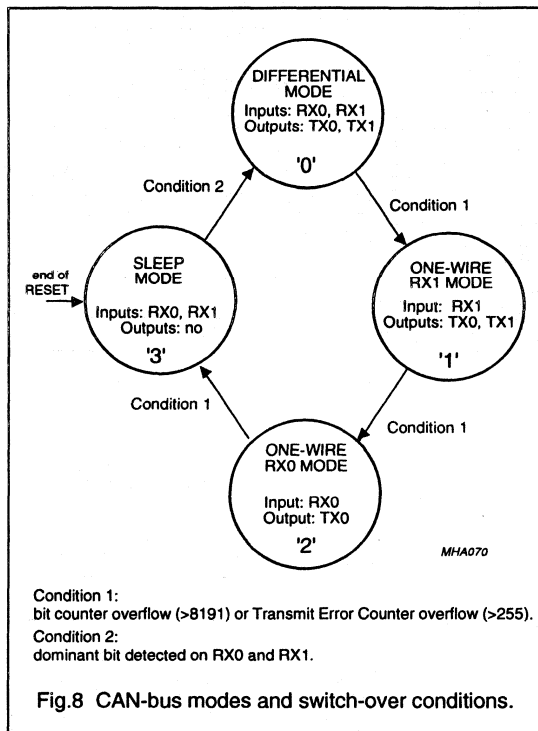

Table 10 Can-bus modes

BUS MODE	BITS		RECEPTION LEVEL		TRANSMISSION	
	BM1	BM0	RECESSIVE	DOMINANT	TX1	TX0
0 = Differential	0	0	RX0 > RX1	RX0 < RX1	enabled	enabled
1 = One-wire RX1	0	1	RX1 < REF	RX1 > REF	enabled	enabled
2 = One-wire RX0	1	0	RX0 > REF	RX0 < REF	disabled	enabled
3 = Sleep	1	1	RX0 > REF and RX1 < REF	RX0 < REF or RX1 > REF	disabled	disabled

Note

1. Output TX1 is disabled in bus mode 2 to tolerate short-circuit between the CAN-bus wires CAN_H and CAN_L.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.3.5 BIT TIMING

The Nominal Bit Time of the P82C150 is subdivided into 10 Time Quanta. The Synchronization Time Segment (SYNC_SEG) and the Propagation Time Segment (PROP_SEG) are each one Time Quantum long. The Phase Buffer Segment 1 (PHASE_SEG1) and the Phase Buffer Segment 2 (PHASE_SEG2) are each four Time Quanta long. The Resynchronization Jump Width (SJW) is four Time Quanta long.

The sample point is located at the end of the Phase Buffer Segment 1. The Nominal Bit Time is internally adjusted to

that bit timing which is provided by the crystal driven host (calibration message).

The usable bus length at a given bit rate is reduced in comparison to other CAN controllers with programmable bit timing because the Propagation Time Segment is fixed to $\frac{1}{10}$ length of the Nominal Bit Time. The bit segmentation of the crystal driven host should be programmed like the fixed bit segmentation of the P82C150, e.g. one bit time segment is $\frac{1}{10}$ length of the Nominal Bit Time (refer also to Table 15 for bit time programming).

Table 11 Bit time subdivision

1 BIT TIME									
BT1	BT2	BT3	BT4	BT5	BT6	BT7	BT8	BT9	BT10
SYNC_SEG	PROP_SEG	PHASE_SEG1				PHASE_SEG2			

7.3.6 CAN-BUS TRANSCEIVER

The transceiver of the P82C150 consists of the configurable input comparator and of complementary open-drain driver outputs. The reference voltage REF is an additional output.

7.3.6.1 CAN-bus input comparator (RX0, RX1)

The input comparator monitors the transient voltage on RX1 and RX0.

The result of the input comparator is logic 1 if the voltage levels of the CAN-bus lines are regarded as recessive, and logic 0 if they are regarded as dominant.

The recessive state and the dominant state are not equivalent and may not be mixed-up.

The input comparator is configurable depending on the four CAN-bus modes (see Table 10), supporting battery-powered applications (Sleep Mode) and tolerance against bus wiring failures.

7.3.6.2 CAN-bus output drivers (TX0, TX1)

The output driver function is shown in Table 12. The output driver TX1 is disabled in bus mode 2 to tolerate a short-circuit between the CAN-bus lines in a two-wire differential CAN physical layer.

Table 12 CAN-bus driver output function

CAN OUTPUT	RECESSIVE	DOMINANT		RESET STATE, BUS-OFF AND SLEEP MODE (MODE 3)
		MODES 0 AND 1	MODE 2	
TX0	floating	LOW	LOW	floating
TX1	floating	HIGH	floating	floating

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.3.7 TRANSMIT AND RECEIVE LOGIC

The transmit and receive logic stores the destuffed bit stream which was received or is about to be transmitted. The incoming Identifier is compared with that of the P82C150. The content of the message is transferred to the port logic in case of matching.

At transmission, the message about to be sent is put together: the Identifier, the status information, the register address and the content of the addressed register from the port logic.

7.3.8 BIT STREAM PROCESSOR AND ERROR MANAGEMENT LOGIC

The Bit Stream Processor (BSP) is a sequencer to control the data stream between the transmit/receive logic (parallel data) and the on-chip CAN transceiver (serial data). Reception/transmission, bit stuffing/destuffing, arbitration and error detection, according to CAN protocol specification version 2.0 A and B (passive), are performed. Further, automatic re-transmission of corrupted messages is handled by means of continuously comparing the output bit stream with the input bit stream. Moreover, the Bit Stream Processor provides control information to calibrate the internal bit time.

The Error Management Logic is responsible for the complete CAN-inherent error management.

7.3.9 OSCILLATOR AND CALIBRATION

The P82C150 contains an on-chip RC-oscillator. The bit time is automatically calibrated by messages being received via CAN-bus. During start-up (after wake-up or reset) any message is used to calibrate the bit time until the calibration is sufficient to receive messages correctly.

From this time on, the bit time is calibrated and fine-tuned by calibration messages with a special Identifier transmitted by the crystal-controlled host.

Only P82C150 nodes being calibrated by calibration messages can transmit messages. The first message is transmitted directly after entering the calibrated state ('sign-on' message). Since the P82C150 is not able to transmit as long as the bit time is not calibrated, it cannot wake-up other CAN nodes via the bus line. Hence to keep the network alive, the calibration message must be transmitted regularly by a crystal-controlled (host) node with a maximum repetition period of 8192 bit (bit length measured by the 82C150). It is recommended to select a repetition period between 3800 and maximum 8000 bit times.

7.3.10 CALIBRATION MESSAGE

The calibration message has to meet the following requirements

- Transmitted by a crystal-controlled node (host node)
- Identifier: 000 1010 1010 (1 = recessive; 0 = dominant)
- RTR bit: 0
- Allowed control field: DLC = 2 to 8
- The first recessive to dominant transition after the control field must be followed by another recessive to dominant transition in a distance of exactly 32 bit (stuff bits included).

Example of a suitable calibration message (there are others using different data bytes; see Table 13):

- Data length code: 0010
- 1st data byte: 1010 1010 (AAH)
- 2nd data byte: 0000 0100 (04H).

Table 13 Example of a suitable calibration message

The two important I/O transitions are marked by underlines; see note 1.

SOF	ARBITRATION FIELD	CONTROL FIELD	DATA BYTE 1	DATA BYTE 2	CRC FIELD
0	000 1010 1010 0	000 <u>l</u> 010	<u>l</u> 010 1010	0000 <u>l</u> 0100	000 <u>l</u> 0 1011 1000 00 <u>l</u> 0

Note

1. **l** = stuff bit (recessive); the total length is 67 bit from start-of-frame to end-of-intermission.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

7.4 Initialization

7.4.1 IDENTIFIER PROGRAMMING

Most of the P82C150 identifier bits are fixed. Four bits are programmable via port pins P3 to P0. All output drivers are disabled at reset, also P3 to P0. Thus the outputs are floating unless the input level is defined by external components to define identifier bits. They are latched at the end of reset, and P3 to P0 can be used as port pins. It is not allowed, according to the CAN protocol specification, that multiple bus nodes transmit the same identifier bit combination. Therefore a P82C150 must have one of the 16 possible identifier bit combinations, one that is not yet occupied.

7.4.2 RESET FUNCTION

RST = HIGH disables all output drivers P16 to P0, TX0 and TX1. All I/O Registers are automatically cleared and set to logic 0. The bit time is set greater than 50 μ s.

If a particular clock period is necessary, e.g. for a dedicated DPM output frequency, this can be achieved by feeding an external clock signal into P0. RST and TEST must be permanently HIGH for this special mode. A reset is then performed as usual (RST = HIGH; TEST = LOW).

Table 14 Situation after RESET

STATUS BITS	IDENTIFIER BITS
RSTD = 1	ID.8 equals P3
EW = 1	ID.5 equals P2
BM1 = 0	ID.4 equals P1
BM0 = 0	ID.3 equals P0

7.4.3 BIT TIME CALIBRATION

The P82C150 must receive at least three messages to calibrate its bit time after reset or change of bus mode. The first message is used to detect the bit time length (rough calibration) between two consecutive falling edges at the output of the CAN input comparator. Therefore the bit stream should contain a sequence of '1010'.

After rough calibration the P82C150 can receive any valid CAN message correctly and executes respective commands without giving an acknowledge. With another valid CAN message and additionally with one valid calibration message the P82C150 is fully calibrated and sends its 'sign-on' message. As long as the P82C150 is fully calibrated the P82C150 acts as an active CAN node.

The P82C150 treats any CAN message (including the calibration message) as a valid message, when these messages are terminated by an error passive frame because of a missing acknowledge. This situation may occur whenever a host node works together with P82C150's and the host node doesn't receive an acknowledge as long as the P82C150's are not fully calibrated.

7.4.3.1 Sign-on message

This special Data Frame is transmitted once by the P82C150 after entering the calibrated state. It indicates to the host node that the P82C150 is ready for transmission.

The sign-on message returns the contents of the Data Input Register, and can be recognized by the host mode by checking the RSTD status bit:

- Sign-on message RSTD = 1
- Other Data Frames RSTD = 0

Note that in the sign-on message the EW bit is logic 1. Nevertheless the P82C150 status with the error counters are set to logic 0.

Notes

1. Other bit time values are possible with the external oscillator mode (refer to Chapter 11.3).
2. These values are characterized but not 100% production tested.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

11 APPLICATION INFORMATION

11.1 Maximum bus length

The bit timing parameters refer to using a P8xCE598 or P8xC592 microcontroller with on-chip CAN interface as a host node (see Fig.20).

11.1.1 ASSUMPTIONS

- The total in/out delay of external transceiver circuit is less than 180 ns (e.g. PCA82C250 CAN transceiver; see Fig.20).
- The propagation delay on the transmission medium is 5.0 ns/m.

Table 15 Maximum bus length for CAN-bus systems with P82C150 nodes.

BIT RATE (kbit/s)	$t_{prop}^{(1)}$ (μ s)	INDICATION FOR MAXIMUM BUS LENGTH (m)	BIT TIMING (P8xCE598/P8xC592)		
			f_{CLK} (MHz)	BTR0 ⁽²⁾	BTR1 ⁽²⁾
125	0.8	25	15	C5H	34H
100	1	45	16	C7H	34H
50	2	145	16	CFH	34H
20	5	445	16	E7H	34H

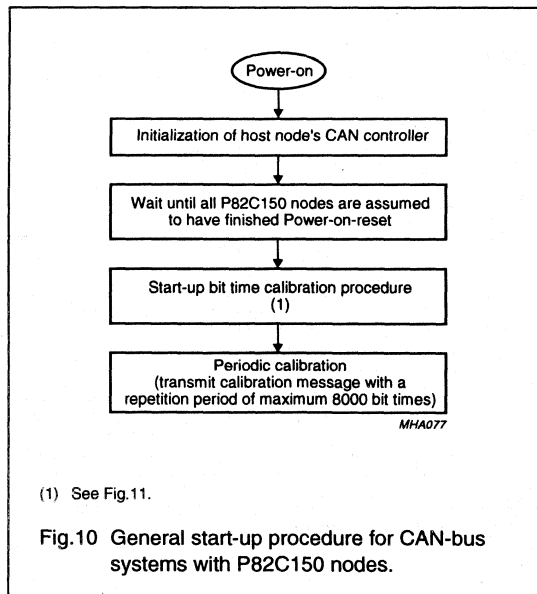

Notes

1. t_{prop} is the maximum propagation delay between two CAN-bus nodes (delays of on- and off-chip transceiver circuits included).
2. BTR0 and BTR1 (hex values) are particular configuration registers referring to bit timing.

11.2 Start up sequence

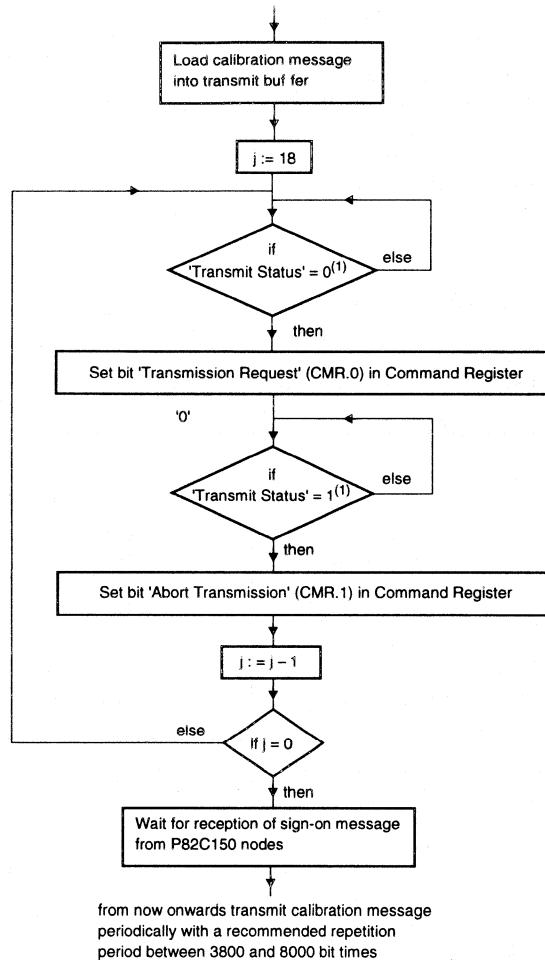

The following start-up sequence, illustrated by Figures 10 and 11, shows a simple example how P82C150 nodes can be controlled from a host node. This application example works with different system configurations:

- One conventional crystal-controlled CAN node and one or more P82C150 nodes.
- More than one conventional crystal-controlled CAN node and one or more P82C150 nodes.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

P82C150

11.3 External oscillator mode

In this mode the P82C150 operates with an external clock instead with the on-chip RC-oscillator. Figure 14 shows the application with an external clock.

In this mode the P82C150 can achieve bit rates below 20 kbit/s and above 125 kbit/s. The DPM pulse width is $4 \times t_{CLK}$ of the external clock. The corresponding CAN identifier bit at Port P0 is set to a logic 0. Therefore only eight P82C150 based CAN nodes operate within the same network in external oscillator mode.

11.3.1 NOTE

The external oscillator mode is not the normal operation mode.

11.4 Using digital I/O port functions

Figures 12 and 13, show the principle application for digital input and output.

11.5 Using DPM

The simplest way to generate an analog voltage using the P82C150 is to apply an external low pass filter at one of the DPM (Distributed Pulse Modulation) outputs. The simplest implementation concept is a RC-filter of the first order (refer to Fig.15). Regarding the selection of the time constant (edge frequency) of this filter, a trade-off between minimizing of the ripple voltage for maximum accuracy and minimum of the settling time has to be considered.

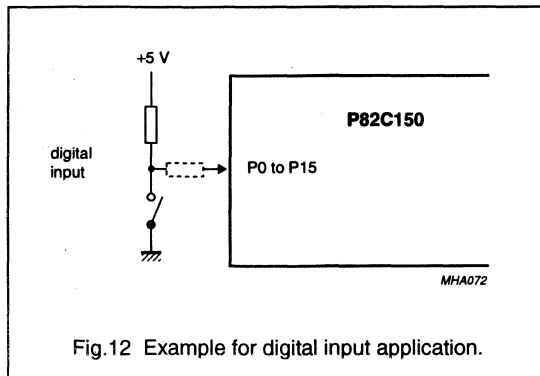

Fig.12 Example for digital input application.

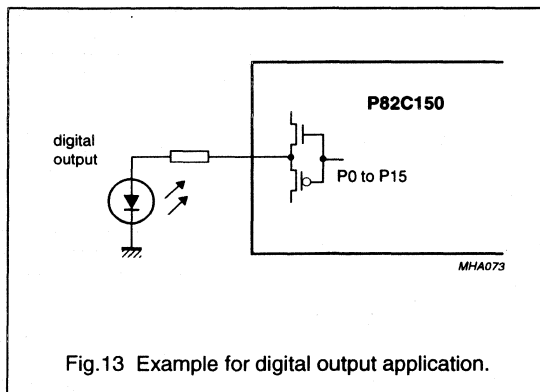

Fig.13 Example for digital output application.

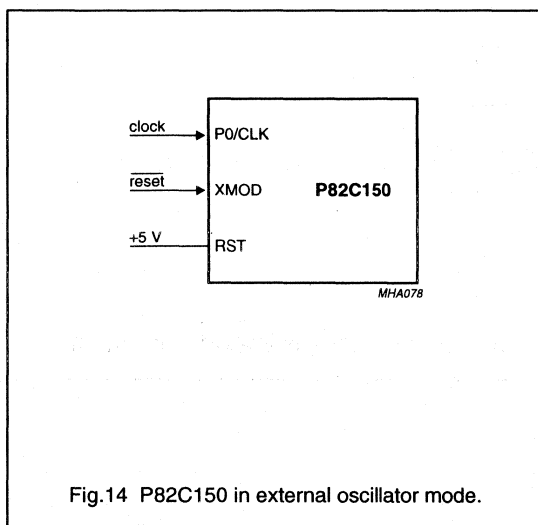

Fig.14 P82C150 in external oscillator mode.

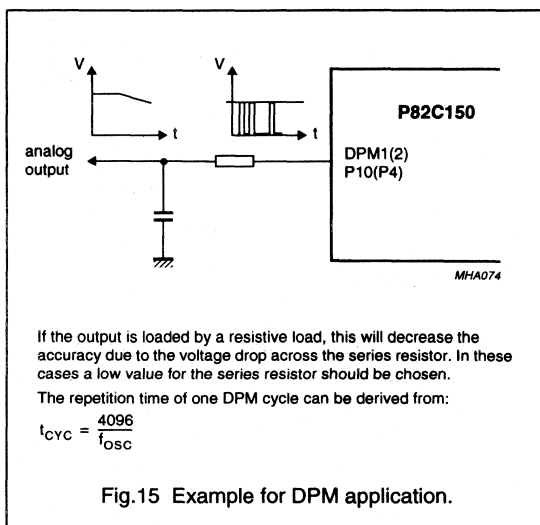

Fig.15 Example for DPM application.

CAN Serial Linked I/O device (SLIO) with digital and analog port functions

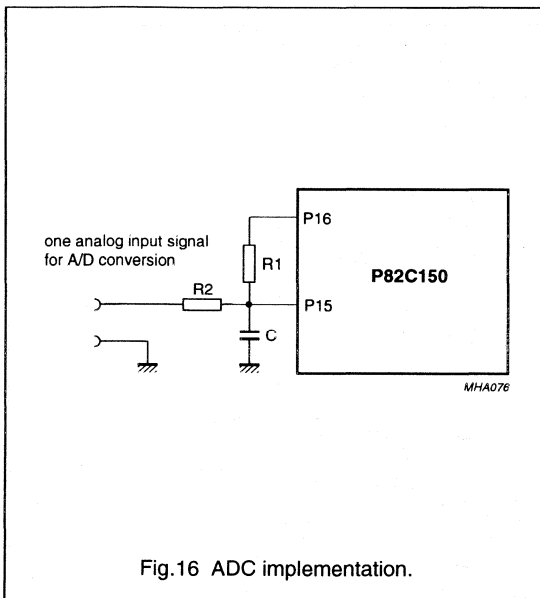

P82C150

11.6 Using ADC

The application in Fig. 16 can be used for analog-to-digital conversion for only one analog input signal. The evaluation of ADC were done with the values $R1 = R2 = 100\text{ k}\Omega$ and $C = 3.3\text{ nF}$; under these conditions the ADC may reach an accuracy of 7 to 8 bit (depends on application). The external components should be connected close to the port pins P15 and P16 with short wiring to avoid disturbances at the analog input port pin P15.

Using the on-chip multiplex function the P82C150 provides up to six input port pins to convert analog input signals to digital values (see Fig. 17).

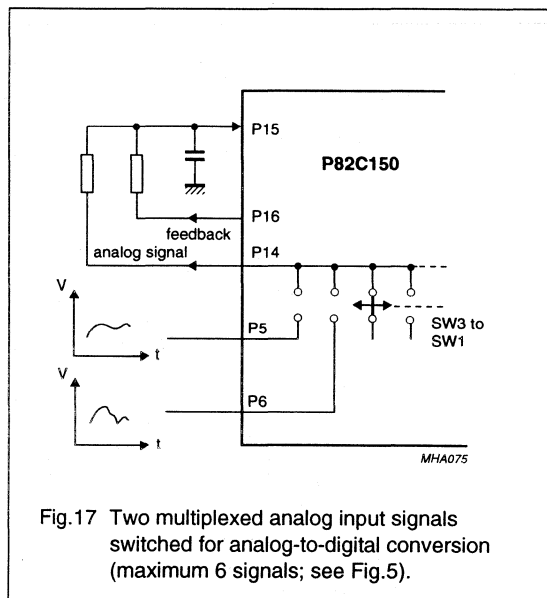

The period for one ADC cycle is identical to the length of one DPM cycle.

11.7 Using analog input port functions

Figure 18 shows the wide range of analog input applications:

- Comparison of two analog input signals.
- Comparison of one analog input signal against a fixed threshold.
- Window comparator including monitoring the comparator outputs at the port pins P8 and P9; additional automatically generated messages, when the corresponding port bits in the Negative Edge and/or Positive Edge register are set.
- Local control two-step system.

Stand-alone CAN-controller

82C200

1 FEATURES

- Multi-master architecture
- Interfaces with a large variety of microcontrollers
- Bus access priority (determined by the message identifier)
- 2032 message identifiers
- Guaranteed latency time for high priority messages
- Powerful error handling capability
- Data length from 0 to 8 bytes
- Configurable bus interface
- Programmable clock output
- Multicast and Broadcast message facility
- Non destructive bit-wise arbitration
- Non-return-to-zero (NRZ) coding/decoding with bit-stuffing
- Programmable transfer rate (up to 1 Mbit/s)
- Programmable output driver configuration
- Suitable for use in a wide range of networks including the SAE networks Class A, B and C
- 16 MHz clock frequency
- -40 to +85/125 °C operating temperature.

2 GENERAL DESCRIPTION

The PCA82C200; PCF82C200 (hereafter generically referred to as PCX82C200) is a highly integrated stand-alone controller for the controller area network (CAN) used within automotive and general industrial environments. The temperature range includes an automotive temperature range version (PCA82C200) of -40 to +125 °C and a -40 to +85 °C version (PCF82C200) for general applications.

The PCX82C200 contains all necessary features required to implement a high performance communication protocol. The PCX82C200 with a simple bus line connection performs all the functions of the physical and data-link layers. The application layer of an Electronic Control Unit (ECU) is provided by a microcontroller, to which the PCX82C200 provides a versatile interface. The use of the PCX82C200 in an automotive or general industrial environment, results in a reduced wiring harness and an enhanced diagnostic and supervisory capability.

4 PINNING

Stand-alone CAN-controller

82C200

Pinning description

SYMBOL	PIN	DESCRIPTION
AD7-AD0	2, 1, 28-23	Multiplexed address/data bus.
ALE	3	ALE signal (Intel mode) or AS input signal (Motorola mode).
CS	4	Chip select input, LOW level allows access to the PCX82C200.
\overline{RD}	5	\overline{RD} signal (Intel mode) or E enable signal (Motorola mode) from the microcontroller.
WR	6	WR signal (Intel mode) or RD/WR signal (Motorola mode) from the microcontroller.
CLK OUT	7	Clock output signal produced by the PCX82C200 for the microcontroller. The clock signal is derived from the built-in oscillator, via the programmable divider (see section 6.5). This output is capable of driving one CMOS or NMOS load.
V_{SS1}	8	Ground potential for the logic circuits.
XTAL1 (note 1)	9	Input to the oscillator's amplifier. External oscillator signal is input via this pin.
XTAL2 (note 1)	10	Output from the oscillator's amplifier. Output must be left open when an external oscillator signal is used.
MODE	11	Mode select input: connected to V_{DD} selects Intel mode; connected to V_{SS} selects Motorola mode.
V_{DD3}	12	5 V power supply for the output driver.
TX0	13	Output from the output-driver 0 to the physical bus-line.
TX1	14	Output from the output-driver 1 to the physical bus-line.
V_{SS3}	15	Ground potential for the output driver.
INT	16	Interrupt output, used to interrupt the microcontroller (see section 6.2.4). \overline{INT} is active if the Interrupt Register contains a logic HIGH bit (present). \overline{INT} is an open drain output and is designed to be a wired-OR with other \overline{INT} outputs within the system. A LOW level on this pin will reactivate the IC from the sleep mode (see section 6.2.2).
RST	17	Reset input, used to reset the CAN interface (LOW level). Automatic power-ON reset can be obtained by connecting RST via a capacitor to V_{SS} and via a resistor to V_{DD} (e.g. C = 1 μ F; R = 50 k Ω).
V_{DD2}	18	5 V power supply for the input comparator.
RX0-RX1	19, 20	Input from the physical bus-line to the input comparator of the PCX82C200. A dominant level will wake-up the PCX82C200. A recessive level is read if RX0 is higher than RX1 and vice versa for the dominant level.
V_{SS2}	21	Ground potential for the input comparator.
V_{DD1}	22	5 V power supply for the logic circuits.

Note

1. XTAL1 and XTAL2 pins should be connected to V_{SS} via 15 pF capacitors.

Stand-alone CAN-controller

82C200

5 FUNCTIONAL DESCRIPTION

The PCX82C200 contains all necessary hardware for a high performance serial network communication (see Fig.1). The PCX82C200 controls the communication flow through the area network using the CAN-protocol. The PCX82C200 meets the following automotive requirements:

- short message length
- guaranteed latency time for urgent messages
- bus access priority, determined by the message identifier
- powerful error handling capability
- configuration flexibility to allow area network expansion.

The latency time defines the period between the initiation (Transmission Request) and the start of the transmission on the bus. Latency time is dependent on a variety of bus related conditions. In the case of a message being transmitted on the bus and one distortion the latency time can be up to 149 bit times (worst case). For more information see section 7.

5.1 Interface Management Logic (IML)

The IML interprets commands from the microcontroller, allocates the message buffers (TBF, RBF0 and RBF1) and provides interrupts and status information to the microcontroller.

5.2 Transmit Buffer (TBF)

The TBF is a 10 byte memory into which the microcontroller writes messages which are to be transmitted over the CAN network.

5.3 Receive Buffers (RBF0 AND RBF1)

The RBF0 and RBF1 are each 10 byte memories which are alternatively used to store messages received from the CAN network. The CPU can process one message while another is being received.

5.4 Bit Stream Processor (BSP)

The BSP is a sequencer, controlling the data stream between the Transmit Buffer, the Receive Buffer (parallel data) and the CAN-bus (serial data).

5.5 Bit Timing Logic (BTL)

The BTL synchronizes the PCX82C200 to the bitstream on the CAN-bus.

5.6 Transceiver Control Logic (TCL)

The TCL controls the output driver.

5.7 Error Management Logic (EML)

The EML performs the error confinement according to the CAN-protocol.

5.8 Controller Interface Logic (CIL)

The CIL is the interface to the external microcontroller. The PCX82C200 can directly interface with a variety of microcontrollers.

6 CONTROL SEGMENT AND MESSAGE BUFFER DESCRIPTION

The PCX82C200 appears to a microcontroller as a memory-mapped I/O device due to the on-chip RAM, guaranteeing the independent operation of both devices.

6.1 Address allocation

The address area of the PCX82C200 consists of the Control Segment and the message buffers. The Control Segment is programmed during an initialization download in order to configure communication parameters (e.g. bit timing). Communication over the CAN-bus is also controlled via this segment by the CPU. During initialization the CLOCK OUT signal may be programmed to a value determined by the microcontroller (see Fig.1). A message which is to be transmitted, must be written to the Transmit Buffer. After a successful reception the microcontroller may read the message from the Receive Buffer and then release it for further use.

6.2 Control Segment layout

The exchange of status, control and command signals between the microcontroller and the PCX82C200 is performed in the control segment. The layout of this segment is shown in Fig.3. After an initial down-load, the contents of the registers Acceptance Code, Acceptance Mask, Bus Timing Registers 0 and 1, and Output Control should not be changed. These registers may only be accessed when the Reset Request bit in the Control Register, is set HIGH (see section 6.2.1).

Notes

1. The Test Register is used for production testing only.
2. Register 30 is not implemented.

Stand-alone CAN-controller

82C200

6.2.1 CONTROL REGISTER (CR)

The contents of the Control Register are used to change the behaviour of the PCX82C200. Control bits may be set or reset by the attached microcontroller which uses the Control Register as a read/write memory.

Table 2 Description of the Control Register bits

CR	ADDRESS 0			
BIT	SYMBOL	NAME	VALUE	FUNCTION
CR.7	TM	Test Mode (note 1)	HIGH (enabled) LOW (disabled)	PCX82C200 enters Test Mode (normal operation impossible). Normal operating mode.
CR.6	S	Sync (note 2)	HIGH (2 edges) LOW (1 edge)	Bus-line transitions from recessive-to-dominant and vice versa are used for resynchronization (see sections 7.2 and 8). Only transitions from recessive-to-dominant are used for resynchronization.
CR.5	–	–	–	Reserved.
CR.4	OIE	Overrun Interrupt Enable	HIGH (enabled) LOW (disabled)	If the Data Overrun bit is set (see section 6.2.3), the microcontroller receives an Overrun Interrupt signal. Microcontroller receives no Overrun Interrupt signal from the PCX82C200.
CR.3	EIE	Error Interrupt Enable	HIGH (enabled) LOW (disabled)	If the Error or Bus Status change (see section 6.2.3), the microcontroller receives an Error Interrupt signal. Microcontroller receives no Error Interrupt signal.
CR.2	TIE	Transmit Interrupt Enable	HIGH (enabled) LOW (disabled)	When a message has been successfully transmitted or the transmit buffer is accessible again, (e.g. after an Abort Transmission command) the PCX82C200 transmits a Transmit Interrupt signal to the microcontroller. No transmission of the Transmit Interrupt signal by the PCX82C200 to the microcontroller.
CR.1	RIE	Receive Interrupt Enable	HIGH (enabled) LOW (disabled)	When a message has been received without errors, the PCX82C200 transmits a Receive Interrupt signal to the microcontroller. No transmission of the Receive Interrupt signal by the PCX82C200 to the microcontroller.
CR.0	RR	Reset Request (note 3)	HIGH (present) LOW (absent)	Detection of a Reset Request results in the PCX82C200 aborting the current transmission or reception of a message and entering the reset state. On the HIGH-to-LOW transition of the Reset Request bit, the PCX82C200 returns to its normal operating state.

Notes

- The Test Mode is intended for factory testing and not for customer use.
- The Sync bit should only be modified if the Reset Request bit is set HIGH (present), otherwise it is ignored. It is possible to set the Sync bit while the Reset Request bit is changed from HIGH to LOW.
- During an external reset ($\overline{RST} = \text{LOW}$) or when the Bus Status bit is set HIGH (Bus-Off), the IML forces the Reset Request HIGH (present). During an external reset the microcontroller cannot set the Reset Request bit LOW (absent). Therefore, after having set the Reset Request bit LOW (absent), the microcontroller must check this bit to ensure that the external reset pin is not being held HIGH (present). After the Reset Request bit is set LOW (absent) the PCX82C200 will wait for:
 - one occurrence of the Bus-Free signal (11 recessive bits, see section 8.9.6), if the preceding reset (Reset Request = HIGH) was due to an external reset or a microcontroller initiated reset
 - 128 occurrences of Bus-Free, if the preceding reset (Reset Request = HIGH) was due to a PCX82C200 initiated Bus-Off, before re-entering the Bus-On mode (see section 8.9).
 When Reset Request is set HIGH (present), for whatever reason, the control, command, status and interrupt bits are affected, see Table 3. When Reset Request is set HIGH (present) the registers at addresses 4 to 8 are accessible but the TBF is not.

Stand-alone CAN-controller

82C200

Table 3 Effects of setting the Reset Request bit HIGH (present)

TYPE	BIT	FUNCTION	EFFECT
Control	CR.7	Test Mode	LOW (disabled)
Command	CMR.4	Goto Sleep	LOW (wake-up)
	CMR.3	Clear Overrun Status	HIGH (clear)
	CMR.2	Release Receive Buffer	HIGH (released)
	CMR.1	Abort Transmission	LOW (absent)
	CMR.0	Transmission Request	LOW (absent)
Status	SR.7	Bus Status	LOW (Bus-On) (note 1)
	SR.6	Error Status	LOW (no error) (note 1)
	SR.5	Transmit Status	LOW (idle)
	SR.4	Receive Status	LOW (idle)
	SR.3	Transmission Complete Status	HIGH (complete)
	SR.2	Transmit Buffer Access	HIGH (released)
	SR.1	Data Overrun	LOW (absent)
	SR.0	Receive Buffer Status	LOW (empty)
Interrupt	IR.3	Overrun Interrupt	LOW (reset)
	IR.1	Transmit Interrupt	LOW (reset)
	IR.0	Receive Interrupt	LOW (reset)

Note

1. Only after an external reset; see note 1 to Table 5 "Description of the Status Register bits".

Stand-alone CAN-controller

82C200

6.2.2 COMMAND REGISTER (CMR)

A command bit initiates an action within the transfer layer of the PCX82C200. The Command Register appears to the microcontroller as a write only memory. If a read access is performed to this address the byte 11111111 (binary) is returned.

Table 4 Description of the Command Register bits

CMR	ADDRESS 1			
BIT	SYMBOL	NAME	VALUE	FUNCTION
CMR.7	–	–	–	Reserved.
CMR.6	–	–	–	Reserved.
CMR.5	–	–	–	Reserved.
CMR.4	GTS	GoTo Sleep (note 1)	HIGH (sleep) LOW (wake up)	The PCX82C200 enters sleep mode, if the $\overline{\text{INT}} = \text{HIGH}$ (no interrupt signal from the PCX82C200 to the microcontroller pending or external source pending) and there is no bus activity. The PCX82C200 functions normally.
CMR.3	COS	Clear Overrun Status (note 2)	HIGH (clear) LOW (no action)	The Data Overrun status bit is set to LOW (see section 6.2.3). No action.
CMR.2	RRB	Release Receive Buffer (note 3)	HIGH (released) LOW (no action)	The receive buffer attached to the microcontroller is released. No action.
CMR.1	AT	Abort Transmission (note 4)	HIGH (present) LOW (absent)	If not already in progress, a pending Transmission Request is cancelled. No action.
CMR.0	TR	transmission Request (note 5)	HIGH (present) LOW (absent)	A message shall be transmitted. No action.

Notes

1. The PCX82C200 will enter sleep mode, if Goto Sleep is set HIGH (sleep), there is no bus activity and $\overline{\text{INT}} = \text{HIGH}$ (inactive). After sleep mode is set, the CLK OUT signal continues until at least 15 bit times have passed. The PCX82C200 will wake up when one of the three previously mentioned conditions is negated: after Goto Sleep is set LOW (wake up), there is bus activity or $\overline{\text{INT}}$ is driven LOW (active). On wake up, the oscillator is started and a Wake-Up Interrupt (see section 6.2.4) is generated. A PCX82C200 which is sleeping and then awakened by bus activity will not be able to receive this message until it detects a Bus-Free signal (see section 8.9.6).
2. This command bit is used to acknowledge the Data Overrun condition signalled by the Data Overrun status bit. It may be given or set at the same time as a Release Receive Buffer command bit.
3. After reading the contents of the Receive Buffer (RBF0 or RBF1) the microcontroller must release this buffer by setting the Release Receive Buffer bit HIGH (released). This may result in another message becoming immediately available.
4. The Abort Transmission bit is used when the microcontroller requires the suspension of the previously requested transmission, for example to transmit an urgent message. A transmission already in progress is not stopped. In order to determine if the original message had been transmitted successfully, or aborted, the Transmission Complete status bit should be checked after the Transmit Buffer Access bit has been set HIGH (released) or a Transmit Interrupt has been generated (see section 6.2.4).
5. If the Transmission Request bit was set HIGH in a previous command, it cannot be cancelled by setting the Transmission Request bit LOW (absent). Cancellation of the requested transmission may be performed by setting the Abort Transmission bit HIGH (present).

Stand-alone CAN-controller

82C200

6.2.3 STATUS REGISTER (SR)

The contents of the Status Register reflect the status of the PCX82C200 bus controller. The Status Register appears to the microcontroller as a read only memory.

Table 5 Description of the Status Register bits

SR	ADDRESS 2			
BIT	SYMBOL	NAME	VALUE	FUNCTION
SR.7	BS	Bus Status (note 1)	HIGH (Bus-Off) LOW (Bus-On)	The PCX82C200 is not involved in bus activities. The PCX82C200 is involved in bus activities.
SR.6	ES	Error Status	HIGH (error) LOW (ok)	At least one of the Error Counters (see section 8.10.3) has reached the microcontroller Warning Limit. Both Error Counters have not reached the Warning Limit.
SR.5	TS	Transmit Status (note 2)	HIGH (transmit) LOW (idle)	The PCX82C200 is transmitting a message. No message is transmitted.
SR.4	RS	Receive Status (note 2)	HIGH (receive) LOW (idle)	The PCX82C200 is receiving a message. No message is received.
SR.3	TCS	Transmission Complete Status (note 3)	HIGH (complete) LOW (incomplete)	Last requested transmission has been successfully completed. Previously requested transmission is not yet completed.
SR.2	TBS	Transmit Buffer Access (note 3)	HIGH (released) LOW (locked)	The microcontroller may write a message into the TBF. The microcontroller cannot access the Transmit Buffer. A message is either waiting for transmission or is in the process of being transmitted.
SR.1	DO	Data Overrun (note 4)	HIGH (overrun) LOW (absent)	This bit is set HIGH (Overrun), when both Receive Buffers are full and the first byte of another message should be stored. No data overrun has occurred since the Clear Overrun command was given.
SR.0	RBS	Receive Buffer Status (note 5)	HIGH (full) LOW (empty)	This bit is set when a new message is available. No message has become available since the last Release Receive Buffer command bit was set.

Notes

- When the Bus Status bit is set HIGH (Bus-Off), the PCX82C200 will set the Reset Request bit HIGH (present). It will stay in this state until the microcontroller sets the Reset Request bit LOW (absent). Once this is completed the PCX82C200 will wait the minimum protocol-defined time (128 occurrences of the Bus-Free signal) before setting the Bus Status bit LOW (Bus-On), the Error Status bit LOW (ok) and resetting the Error Counters.
- If both the Receive Status and Transmit Status bits are LOW (idle) the CAN-bus is idle.
- If the microcontroller tries to write to the Transmit Buffer when the Transmit Buffer Access bit is LOW (locked), the written bytes will not be accepted and will be lost without this being signalled. The Transmission Complete Status bit is set LOW (incomplete) whenever the Transmission Request bit is set HIGH (present). If an Abort Transmission command is issued, the Transmit Buffer will be released. If the message, which was requested and then aborted, was not transmitted, the Transmission Complete Status bit will remain LOW.
- If Data Overrun = HIGH (Overrun) is detected, the currently received message is dropped. A transmitted message, granted acceptance, is also stored in a Receive Buffer. This occurs because it is not known if the PCX82C200 will lose arbitration and so become a receiver of the message. If no Receive Buffer is available, Data Overrun is signalled.
- If the command bit Release Receive Buffer is set HIGH (released) by the microcontroller, the Receive Buffer Status bit is set LOW (empty) by IML. When a new message is stored in any of the receive buffers, the Receive Buffer Status bit is set HIGH (full) again.

Stand-alone CAN-controller

82C200

6.2.4 INTERRUPT REGISTER (IR)

The Interrupt Register allows the identification of an interrupt source. When one or more bits of this register are set, the $\overline{\text{INT}}$ pin is activated. All bits are reset by the PCX82C200 after this register is read by the microcontroller. This register appears to the microcontroller as a read only memory.

Table 6 Description of the Interrupt Register bits

IR	ADDRESS 3			
BIT	SYMBOL	NAME	VALUE	FUNCTION
IR.7	–	–	–	Reserved.
IR.6	–	–	–	Reserved.
IR.5	–	–	–	Reserved.
IR.4	WUI	Wake-Up Interrupt	HIGH (set) LOW (reset)	The Wake-Up Interrupt bit is set HIGH, when the sleep mode is left (see section 6.2.2). Wake-Up Interrupt bit is reset by a read access of Interrupt Register by the microcontroller.
IR.3	OI	Overrun Interrupt (note 1)	HIGH (set) LOW (reset)	This bit is set HIGH, if both Receive Buffers contain a message and the first byte of another message should be stored (passed acceptance), and the Overrun Interrupt Enable is HIGH (enabled). Overrun Interrupt bit is reset by a read access of Interrupt Register by the microcontroller.
IR.2	EI	Error Interrupt	HIGH (set) LOW (reset)	This bit is set on a change of either the Error Status or Bus Status bits (see section 6.2.3) if the Error Interrupt Enable is HIGH (enabled). The Error Interrupt bit is reset by a read access of the Interrupt Register by the microcontroller.
IR.1	TI	Transmit Interrupt	HIGH (set) LOW (reset)	This bit is set on a change of the Transmit Buffer Access bit from LOW to HIGH (released) and Transmit Interrupt Enable is HIGH (enabled). Transmit Interrupt bit will be reset after a read access of the Interrupt Register by the microcontroller.
IR.0	RI	Receive Interrupt (note 2)	HIGH (set) LOW (reset)	This bit is set when a new message is available in the Receive Buffer and the Receive Interrupt Enable bit is HIGH (enabled). Receive Interrupt bit is automatically reset by a read access of Interrupt Register by the microcontroller.

Notes

1. Overrun Interrupt bit (if enabled) and Data Overrun bit (see section 6.2.3) are set at the same time.
2. Receive Interrupt bit (if enabled) and Receive Buffer Status bit (see section 6.2.3) are set at the same time.

Stand-alone CAN-controller

82C200

6.2.5 ACCEPTANCE CODE REGISTER (ACR)

The Acceptance Code Register is part of the acceptance filter of the PCX82C200. This register can be accessed (read/write), if the Reset Request bit is set HIGH (present). When a message is received which passes the acceptance test and if there is an empty Receive Buffer, then the respective Descriptor and Data Field (see Fig.4) are sequentially stored in this empty buffer. In the case that there is no empty Receive Buffer, the Data Overrun bit is set HIGH (overrun), see sections 6.2.3 and 6.2.4. When the complete message has been correctly received the following occurs:

- the Receive Buffer Status bit is set HIGH (full)
- if the Receive Interrupt Enable bit is set HIGH (enabled), the Receive Interrupt is set HIGH (set).

The Acceptance Code bits (AC.7-AC.0) and the eight most significant bits of the message's Identifier (ID.10-ID.3) must be equal to those bit positions which are marked relevant by the Acceptance Mask bits (AM.7-AM.0). If the following equation is satisfied, acceptance is given:

$$[(ID.10 \dots ID.3) = (AC.7 \dots AC.0)] \text{ or } (AM.7 \dots AM.0) = 1111 \ 1111 \text{ binary}$$

During transmission of a message which passes the acceptance test, the message is also written to its own Receive Buffer. If no Receiver Buffer is available, Data Overrun is signalled because it is not known at the start of a message whether the PCX82C200 will lose arbitration and so become a receiver of the message.

Table 7 Acceptance Code Register bits

ACR	ADDRESS 4

6.2.6 ACCEPTANCE MASK REGISTER (AMR)

The Acceptance Mask Register is part of the acceptance filter of the PCX82C200. This register can be accessed (read/write) if the Reset Request bit is set HIGH (present). The Acceptance Mask Register qualifies which of the corresponding bits of the acceptance code are "relevant" or "don't care" for acceptance filtering.

Table 8 Acceptance Mask Register bits

AMR	ADDRESS 5						
7	6	5	4	3	2	1	0
AM.7	AM.6	AM.5	AM.4	AM.3	AM.2	AM.1	AM.0

Table 9 Description of the Acceptance Mask Register bits

ACCEPTANCE MASK BIT	VALUE	COMMENTS
AM.7 to AM.0	HIGH (don't care)	This bit position is "don't care" for the acceptance of a message.
	LOW (relevant)	This bit position is "relevant" for acceptance filtering.

Stand-alone CAN-controller

82C200

6.2.7 BUS TIMING REGISTER 0 (BTR0)

The contents of Bus Timing Register 0 defines the values of Baud Rate Prescaler (BRP) and the Synchronization Jump Width (SJW). This register can be accessed (read/write) if the Reset Request bit is set HIGH (present).

Table 10 Bus Timing Register 0 bits

BTR0		ADDRESS 6					
7	6	5	4	3	2	1	0
SJW.1	SJW.0	BRP.5	BRP.4	BRP.3	BRP.2	BRP.1	BRP.0

Baud Rate Prescaler (BRP)

The period of the system clock t_{SCL} is programmable and determines the individual bit timing. The system clock is calculated using the following equation:

$$t_{SCL} = 2t_{CLK} (32BRP.5 + 16BRP.4 + 8BRP.3 + 4BRP.2 + 2BRP.1 + BRP.0 + 1)$$

t_{CLK} = time period of the PCX82C200 oscillator.

Synchronization Jump Width (SJW)

To compensate for phase shifts between clock oscillators of different bus controllers, any bus controller must resynchronize on any relevant signal edge of the current transmission. The synchronization jump width defines the maximum number of clock cycles a bit period may be shortened or lengthened by one resynchronization:

$$t_{SJW} = t_{SCL} (2SJW.1 + SJW.0 + 1)$$

For further information on bus timing see sections 6.2.8 and 7.

6.2.8 BUS TIMING REGISTER 1 (BTR1)

The contents of Bus Timing Register 1 defines the length of the bit period, the location of the sample point and the number of samples to be taken at each sample point. This register may be accessed (read/write) if the Reset Request bit is set HIGH (present).

Table 11 Bus Timing Register 1 bits

BTR1		ADDRESS 7					
7	6	5	4	3	2	1	0
SAM	TSEG2.2	TSEG2.1	TSEG2.0	TSEG1.3	TSEG1.2	TSEG1.1	TSEG1.0

Sampling (SAM)

Table 12 Selection of sampling

BIT	VALUE	COMMENTS
SAM	HIGH (3 samples)	Three samples are taken.
	LOW (1 sample)	The bus is sampled once.

SAM = LOW (logic 0) is recommended for high speed buses (SAE class C), while SAM = HIGH (logic 1) is recommended for slow/medium speed buses (class A and B) where filtering of spikes on the bus-line is beneficial (see section 7.1.6).

Stand-alone CAN-controller

82C200

Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2)

TSEG1 and TSEG2 determine the number of clock cycles per bit period and the location of the sample point:

$$t_{TSEG1} = t_{SCL} (8TSEG1.3 + 4TSEG1.2 + 2TSEG1.1 + TSEG1.0 + 1)$$

$$t_{TSEG2} = t_{SCL} (4TSEG2.2 + 2TSEG2.1 + TSEG2.0 + 1)$$

For further information on bus timing see sections 6.2.7 and 7.

6.2.9 OUTPUT CONTROL REGISTER (OCR)

The Output Control Register allows, under software control, the set-up of different output driver configurations. This register may be accessed (read/write) if the Reset Request bit is set HIGH (present).

Table 13 Output Control Register bits

OCR		ADDRESS 8					
7	6	5	4	3	2	1	0
OCTP1	OCTN1	OCPOL1	OCTP0	OCTN0	OCPOL0	OCMODE1	OCMODE0

If the PCX82C200 is in the sleep mode (Goto Sleep = HIGH) a recessive level is output on the TX0 and TX1 pins. If the PCX82C200 is in the reset state (Reset Request = HIGH) the output drivers are floating.

Normal Output Mode

In Normal Output Mode the bit sequence (TXD) is sent via TX0 and TX1. The voltage levels on the output driver pins TX1 and TX0 depend on both the driver characteristic programmed by OCTPx, OCTNx (float, pull-up, pull-down, push-pull) and the output polarity programmed by OCPOLx (see Fig.4).

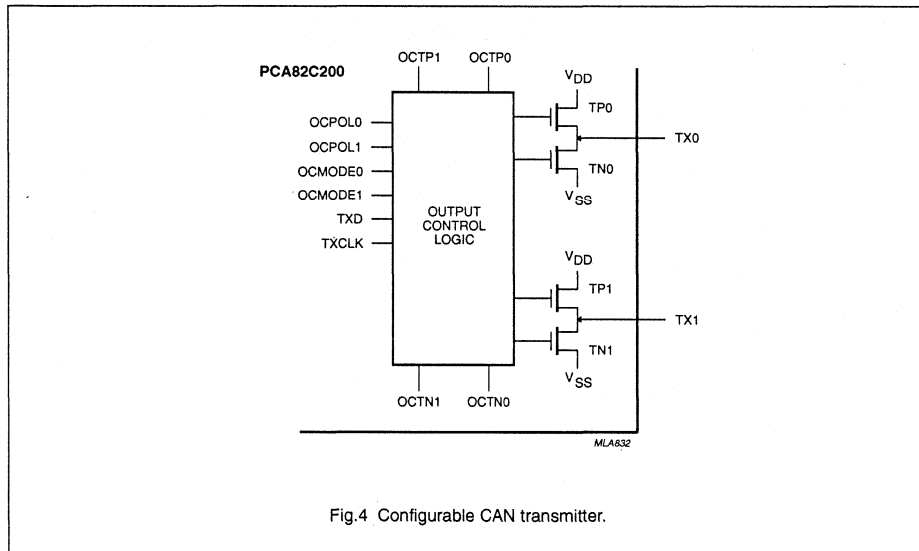

Fig.4 Configurable CAN transmitter.

Stand-alone CAN-controller

82C200

Clock Output Mode

For the TX0 pin this is the same as in Normal Output Mode. However, the data stream to TX1 is replaced by the transmit clock (TXCLK). The rising edge of the transmit clock (non inverted) marks the beginning of a bit period. The clock pulse width is t_{SCL} .

Bi-phase Output Mode

In contrast to Normal Output Mode the bit representation is time variant and toggled. If the bus controllers are galvanically decoupled from the bus-line by a transformer, the bit stream is not allowed to contain a DC component. This is achieved by the following scheme. During recessive bits all outputs are deactivated (3-state). Dominant bits are sent alternately on TX0 and TX1, i.e. the first dominant bit is sent on TX0, the second is sent on TX1, and the third one is sent on TX0 again, etc.

Test Output Mode

For the TX0 pin this is the same as in Normal Output Mode. To measure the delay time of the transmitter and receiver this mode connects the output of the input comparator (COMP OUT) with the input of the output driver TX1. This mode is used for production testing only.

The following two tables, Table 14 and Table 15, show the relationship between the bits of the Output Control Register and the two serial output pins TX0 and TX1 of the PCX82C200, connected to the serial bus (see Fig.1).

Table 14 Description of the Output Mode bits

OCMODE1	OCMODE0	DESCRIPTION
1	0	Normal Output Mode; TX0, TX1: bit sequence (TXD; note 1).
1	1	Clock Output Mode; TX0: bit sequence, TX1: bus clock (TXCLK).
0	0	Bi-phase Output Mode.
0	1	Test Output Mode; TX0: bit sequence, TX1: COMP OUT.

Note

1. TXD is the data bit to be transmitted.

Stand-alone CAN-controller

	1	1	1	0	ON	OFF	HIGH
	1	1	1	1	OFF	ON	LOW

Notes

1. TPx is the on-chip output transistor x, connected to V_{DD} ; x = 0 or 1.
2. TNx is the on-chip output transistor x, connected to V_{SS} ; x = 0 or 1.
3. TXx is the serial output level on pin TX0 or TX1. It is required that the output level on the CAN-bus is dominant with TXD = 0 and recessive with TXD = 1 (see section 8.1.1).

6.2.10 TEST REGISTER (TR)

The Test Register is used for production testing only.

Stand-alone CAN-controller

82C200

6.3 Transmit Buffer layout

The global layout of the Transmit Buffer is shown in Fig.3. This buffer serves to store a message from the microcontroller to be transmitted by the PCX82C200. It is subdivided into Descriptor and Data Field. The Transmit Buffer can be written to and read from by the microcontroller (see note 3 to Table 2).

6.3.1 DESCRIPTOR

Table 16 Descriptor Byte 1 (DSCR1)

DSCR1	ADDRESS 10						
7	6	5	4	3	2	1	0
ID.10	ID.9	ID.8	ID.7	ID.6	ID.5	ID.4	ID.3

DSCR2	ADDRESS 11						
7	6	5	4	3	2	1	0
ID.2	ID.1	ID.0	RTR	DLC.3	DLC.2	DLC.1	DLC.0

Identifier (ID)

The Identifier consists of 11 bits (ID.10 to ID.0). ID.10 is the most significant bit, which is transmitted first on the bus during the arbitration process. The Identifier acts as the message's name, used in a receiver for acceptance filtering and also determines the bus access priority during the arbitration process. The lower the binary value of the Identifier the higher the priority. This is due to the larger number of leading dominant bits during arbitration (see section 8.7 "Bus organization").

*Remote Transmission Request bit (RTR)***Table 18** Description of the RTR bit

BIT	VALUE	COMMENTS
RTR	HIGH (remote)	Remote Frame will be transmitted by the PCX82C200.
	LOW (data)	Data Frame will be transmitted by the PCX82C200.

Data Length Code (DLC)

The number of bytes (Data Byte Count) in the Data Field of a message is coded by the Data Length Code. At the start of a Remote Frame transmission the Data Length Code is not considered due to the RTR bit being HIGH (remote). This forces the number of transmitted/received data bytes to be 0. Nevertheless, the Data Length Code must be specified correctly to avoid bus errors, if two CAN-controllers start a Remote Frame transmission simultaneously.

The range of the Data Byte Count is 0 to 8 bytes and coded as follows:

$$\text{Data Byte Count} = 8\text{DLC.3} + 4\text{DLC.2} + 2\text{DLC.1} + \text{DLC.0}$$

For reasons of compatibility no Data Byte Counts other than 0 to 8 should be used.

6.3.2 DATA FIELD

The number of transferred data bytes is determined by the Data Length Code. The first bit transmitted is the most significant bit of data byte 1 at address 12.

Stand-alone CAN-controller

82C200

6.4 Receive Buffer layout

The layout of the Receive Buffer and the individual bytes correspond to the definitions given for the Transmit Buffer layout, except that the addresses start at 20 instead of 10 (see Fig.3).

6.5 Clock Divider Register (CDR)

The Clock Divider Register controls the CLK OUT frequency for the microcontroller (see Fig.1). It can be written to or read by the microcontroller. The default state of the register is divide by 12 for Motorola mode and divide by 2 for Intel mode. Values from 0 to 7 may be written into this register and will result in the CLK OUT frequencies shown in Table 20.

Table 19 Clock Divider Register bits

CDR	ADDRESS 31						
7	6	5	4	3	2	1	0
-	-	-	-	-	CD.2	CD.1	CD.0

Note

Bits CDR.7 to CDR.3 are reserved.

Table 20 CLK OUT frequency selection

CD.2	CD.1	CD.0	CLK OUT FREQUENCY
0	0	0	$f_{CLK}/2$
0	0	1	$f_{CLK}/4$
1	1	0	$f_{CLK}/6$
0	1	1	$f_{CLK}/8$
1	0	0	$f_{CLK}/10$
1	0	1	$f_{CLK}/12$
1	1	0	$f_{CLK}/14$
1	1	1	f_{CLK}

Note

- f_{CLK} is the frequency of the oscillator.

Stand-alone CAN-controller

82C200

7 BUS TIMING/SYNCHRONIZATION

The Bus Timing Logic (BTL) monitors the serial bus-line via the on-chip input comparator and performs the following functions (see section 5):

- monitors the serial bus-line level
- adjusts the sample point, within a bit period (programmable)
- samples the bus-line level using majority logic (programmable, 1 or 3 samples)
- synchronization to the bit stream:
 - hard synchronization at the start of a message
 - resynchronization during transfer of a message.

The configuration of the BTL is performed during the initialization of the PCX82C200. The BTL uses the following three registers:

- Control register (Sync)
- Bus Timing Register 0
- Bus Timing Register 1.

7.1 Bit timing

A bit period is built up from a number of system clock cycles (t_{scl}), see section 6.2.7. One bit period is the result of the addition of the programmable segments TSEG1 and TSEG2 and the general segment SYNCSEG (see sections 6.2.7 to 6.2.8).

7.1.1 SYNCHRONIZATION SEGMENT (SYNCSEG)

The incoming edge of a bit is expected during this state; this state corresponds to one system clock cycle ($1 \times t_{scl}$).

7.1.2 TIME SEGMENT 1 (TSEG1)

This segment determines the location of the sampling point within a bit period, which is at the end of TSEG1. TSEG1 is programmable from 1 to 16 system clock cycles (see section 6.2.8).

The correct location of the sample point is essential for the correct functioning of a transmission. The following points must be taken into consideration:

- a Start-Of-Frame (see section 8.2.1) causes all PCX82C200's to perform a 'hard synchronization' (see section 7.2.1) on the first recessive-to-dominant edge. During arbitration, however, several PCX82C200's may simultaneously transmit. Therefore it may require twice the sum of bus-line, input comparator and the output driver delay times until the bus is stable. This is the propagation delay time.
- to avoid sampling at an incorrect position, it is necessary to include an additional synchronization buffer on both sides of the sample point. The main reasons for incorrect sampling are:
 - incorrect synchronization due to spikes on the bus-line
 - slight variations in the oscillator frequency of each PCX82C200 in the network, which results in a phase error.

Time Segment 1 consists of the segment for compensation of propagation delays and the synchronization buffer directly before the sample point (see Fig.5).

7.1.3 TIME SEGMENT 2 (TSEG2)

This time segment provides:

- additional time at the sample point for calculation of the subsequent bit levels (e.g. arbitration)
- synchronization buffer segment directly after the sample point (see section 7.1.2).

TSEG2 is programmable from 1 to 8 system clock cycles (see section 6.2.8).

Stand-alone CAN-controller

82C200

Stand-alone CAN-controller

82C200

7.1.4 SYNCHRONIZATION JUMP WIDTH (SJW)

SJW defines the maximum number of clock cycles (t_{SCL}) a bit period may be reduced or increased by one resynchronization. SJW is programmable from 1 to 4 system clock cycles (see section 6.2.7).

7.1.5 PROPAGATION DELAY TIME

The propagation delay time (t_{prop}) is calculated by summing the maximum propagation delay times of the physical bus, the input comparator and the output driver. The resulting sum is multiplied by 2 and then rounded up to the nearest multiple of t_{SCL} .

$$t_{prop} = 2 \times (\text{physical bus delay} + \text{input comparator delay} + \text{output driver delay})$$

7.1.6 BIT TIMING RESTRICTIONS

Restrictions on the configuration of the bit timing are based on internal processing. The restrictions are:

- $t_{TSEG2} \geq 2t_{SCL}$
- $t_{TSEG2} \geq t_{SJW}$
- $t_{TSEG1} \geq t_{TSEG2}$
- $t_{TSEG1} \geq t_{SJW} + t_{prop}$

The three sample mode (SAM = 1) has the effect of introducing a delay of one system clock cycle on the bus-line. This must be taken into account for the correct calculation of TSEG1 and TSEG2:

- $t_{TSEG1} \geq t_{SJW} + t_{prop} + 2t_{SCL}$
- $t_{TSEG2} \geq 3t_{SCL}$

7.2 Synchronization

Synchronization is performed by a state machine which compares the incoming edge with its actual bit timing and adapts the bit timing by hard synchronization or resynchronization.

7.2.1 HARD SYNCHRONIZATION

This type of synchronization occurs only at the beginning of a message. The PCX82C200 synchronizes on the first incoming recessive-to-dominant edge of a message (being the leading edge of a message's Start-Of-Frame bit; see section 7.1).

7.2.2 RESYNCHRONIZATION

Resynchronization occurs during the transmission of a message's bit stream to compensate for:

- variations in individual PCX82C200 oscillator frequencies
- changes introduced by switching from one transmitter to another (e.g. during arbitration).

As a result of resynchronization either t_{TSEG1} may be increased by up to a maximum of t_{SJW} or t_{TSEG2} may be decreased by up to a maximum of t_{SJW} :

- $t_{TSEG1} \leq t_{SCL} ((TSEG1 + 1) + (SJW + 1))$
- $t_{TSEG2} \geq t_{SCL} ((TSEG2 + 1) - (SJW + 1))$

Note: TSEG1, TSEG2 and SJW are the programmed numerical values.

The phase error (e) of an edge is given by the position of the edge relative to SYNCSEG, measured in system clock cycles (t_{SCL}). The value of the phase error is defined as:

- $e = 0$, if the edge occurs within SYNCSEG
- $e > 0$, if the edge occurs within TSEG1
- $e < 0$, if the edge occurs within TSEG2.

The effect of resynchronization is:

- the same as that of a hard synchronization, if the magnitude of the phase error (e) is less or equal to the programmed value of t_{SJW} (see section 6.2.7)
- to increase a bit period by the amount of t_{SJW} , if the phase error is positive and the magnitude of the phase error is larger than t_{SJW}
- to decrease a bit period by the amount of t_{SJW} , if the phase error is negative and the magnitude of the phase error is larger than t_{SJW} .

7.2.3 SYNCHRONIZATION RULES

The synchronization rules are as follows:

- only one synchronization within one bit time is used
- an edge is used for synchronization only if the value detected at the previous sample point differs from the bus value immediately after the edge
- hard synchronization is performed whenever there is a recessive-to-dominant edge during Bus-Idle (see section 7)

Stand-alone CAN-controller

82C200

- all other edges (recessive-to-dominant and optionally dominant-to-recessive edges if the Sync bit is set HIGH; see section 6.2.1) which are candidates for resynchronization will be used with the following exception:
 - a transmitting PCX82C200 will not perform a resynchronization as a result of a recessive-to-dominant edge with positive phase error, if only these edges are used for resynchronization. This ensures that the delay times of the output driver and input comparator do not cause a permanent increase in the bit time.

8 COMMUNICATION PROTOCOL

8.1 Frame types

The PCX82C200 bus controller supports the four different CAN-protocol frame types for communication:

- Data Frame, to transfer data
- Remote Frame, request for data
- Error Frame, globally signal a (locally) detected error condition
- Overload Frame, to extend delay time of subsequent frames (an Overload Frame is not initiated by the PCX82C200).

8.1.1 BIT REPRESENTATION

There are two logical bit representations used in the CAN-protocol:

- a recessive bit on the bus-line appears only if all connected PCX82C200's send a recessive bit at that moment
- dominant bits always overwrite recessive bits i.e. the resulting bit level on the bus-line is dominant.

8.2 Data Frame

A Data Frame carries data from a transmitting PCX82C200 to one or more receiving PCX82C200's. A Data Frame is composed of seven different bit-fields:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field (may have a length of zero)
- CRC Field
- Acknowledge Field
- End-Of-Frame.

Fig.6 Data Frame.

Stand-alone CAN-controller

82C200

8.2.1 START-OF-FRAME BIT

Signals the start of a Data Frame or Remote Frame. It consists of a single dominant bit used for hard synchronization of a PCX82C200 in receive mode.

8.2.2 ARBITRATION FIELD

Consists of the message Identifier and the RTR bit (see section 6.3.1). In the event of simultaneous message transmissions by two or more PCX82C200's the bus access conflict is solved by bit-wise arbitration, which is active during the transmission of the Arbitration Field.

Identifier

This 11-bit field is used to provide information about the message, as well as the bus access priority. It is transmitted in the order ID.10 to ID.0 (LSB). The situation that the seven most significant bits (ID.10 to ID.4) are all recessive must not occur.

An Identifier does not define which particular PCX82C200 will receive the frame, because a CAN based communication network does not discriminate between a point-to-point, multicast or broadcast communication.

Remote Transmission Request bit (RTR)

A PCX82C200, acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). If the data source simultaneously transmits a Data Frame containing the requested data, it uses the same Identifier. No bus access conflict occurs due to the RTR bit being set LOW (data; dominant bus level) in the Data Frame.

8.2.3 CONTROL FIELD

This field consists of six bits. It includes two reserved bits (for future expansions of the CAN-protocol), transmitted with a dominant bus level, and is followed by the Data Length Code (4 bits). The number of bytes in the (destuffed; number of data bytes to be transmitted/received) Data Field is indicated by the Data Length Code. Admissible values of the Data Length Code and hence the number of bytes in the (destuffed) Data Field, are 0 to 8. A logic 0 (logic 1) in the Data Length Code is transmitted as a dominant (recessive) bus level, respectively.

8.2.4 DATA FIELD

The data, stored within the Data Field of the Transmit Buffer, are transmitted according to the Data Length Code. Conversely, data of a received Data Frame will be stored in the Data Field of a Receive Buffer. Data is stored byte-wise both for transmission by the microcontroller and on reception by the PCX82C200. The most significant bit of the first data byte (lowest address) is transmitted/received first.

8.2.5 CYCLIC REDUNDANCY CODE FIELD (CRC)

The CRC Field consists of the CRC Sequence (15 bits) and the CRC Delimiter (1 recessive bit). The Cyclic Redundancy Code (CRC) encloses the destuffed bit stream of the Start-Of-Frame, Arbitration Field, Control Field, Data Field and CRC Sequence. The most significant bit of the CRC Sequence is transmitted/received first. This frame check sequence, implemented in the PCX82C200, is derived from a cyclic redundancy code best suited for frames with a total bit count of less than 127 bits, see section 8.8.3 With Start-Of-Frame (dominant bit) included in the code word, any rotation of the code word can be detected by the absence of the CRC Delimiter (recessive bit).

8.2.6 ACKNOWLEDGE FIELD (ACK)

The Acknowledge Field consists of two bits, the Acknowledge Slot and the Acknowledge Delimiter, which are transmitted with a recessive level by the transmitter of the Data Frame. All PCX82C200's having received the matching CRC Sequence, report this by overwriting the transmitter's recessive bit in the Acknowledge Slot with a dominant bit (see section 8.9.2). Thereby a transmitter, still monitoring the bus level recognizes that at least one receiver within the network has received a complete and correct message (i.e. no error was found). The Acknowledge Delimiter (recessive bit) is the second bit of the Acknowledge Field. As a result, the Acknowledge Slot is surrounded by two recessive bits: the CRC Delimiter and the Acknowledge Delimiter.

All nodes within a CAN network may use all the information coming to the network by the PCX82C200's (shared memory concept). Therefore, acknowledgement and error handling are defined to provide all information in a consistent way throughout this shared memory. Hence, there is no reason to discriminate different receivers of a message in the acknowledge field. If a

Stand-alone CAN-controller

82C200

node is disconnected from the network due to bus failure, this particular node is no longer part of the shared memory. To identify a 'lost node' additional and application specific precautions are required.

8.2.7 END-OF-FRAME

Each Data Frame or Remote Frame is delimited by the End-Of-Frame bit sequence which consists of seven recessive bits (exceeds the bit stuff width by two bits). Using this method a receiver detects the end of a frame independent of a previous transmission error because the receiver expects all bits up to the end of the CRC sequence to be coded by the method of bit-stuffing (see section 8.7.3). The bit-stuffing logic is deactivated during the End-Of-Frame sequence.

8.3 Remote Frame

A PCX82C200, acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). The Remote Frame is similar to the Data Frame with the following exceptions:

- RTR bit is set HIGH
- Data Length Code is ignored
- no Data Field contained.

Note that the Data Length Code value should be the same as for the corresponding Data Frame (although this is ignored for a Remote Frame).

A Remote Frame is composed of six different bit fields:

- Start-Of-Frame
- Arbitration Field
- Control Field
- CRC-Field
- Acknowledge Field
- End-Of-Frame.

See section 8.2 for a more detailed explanation of the Remote Frame bit fields.

8.4 Error Frame

The Error Frame consists of two different fields. The first field is accomplished by the superimposing of Error Flags contributed from different PCX82C200s. The second field is the Error Delimiter (see Fig.7).

8.4.1 ERROR FLAG

There are two forms of an Error Flag:

- Active Error Flag, consists of six consecutive dominant bits
- Passive Error Flag, consists of six consecutive recessive bits unless it is overwritten by dominant bits from other PCX82C200's.

An error-active PCX82C200 (see section 8.9) detecting an error condition signals this by transmission of an Active Error Flag. This Error Flag's form violates the bit-stuffing law (see section 8.7.3) applied to all fields, from Start-Of-Frame to CRC Delimiter, or destroys the fixed form of the fields Acknowledge Field or End-Of-Frame (see Fig.6). Consequently, all other PCX82C200's detect an error condition and start transmission of an Error Flag. Therefore the sequence of dominant bits, which can be monitored on the bus, results from a superposition of different Error Flags transmitted by individual PCX82C200's. The total length of this sequence varies between six (minimum) and twelve (maximum) bits.

An error-passive PCX82C200 (see section 8.9) detecting an error condition tries to signal this by transmission of a Passive Error Flag. The error-passive PCX82C200 waits for six consecutive bits with identical polarity, beginning at the start of the Passive Error Flag. The Passive Error Flag is complete when these six identical bits have been detected.

8.4.2 ERROR DELIMITER

The Error Delimiter consists of eight recessive bits and has the same format as the Overload Delimiter. After transmission of an Error Flag, each PCX82C200 monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished sending its Error Flag and all PCX82C200's start transmission of seven recessive bits (plus the recessive bit at dominant-to-recessive transition, results in a total of eight recessive bits). After this event and an Intermission Field all error-active PCX82C200's within the network can start a transmission simultaneously.

If a detected error is signalled during transmission of a Data Frame or Remote Frame, the current message is spoiled and a retransmission of the message is initiated.

Stand-alone CAN-controller

82C200

Fig.7 Error Frame.

If a PCX82C200 monitors any deviation of the Error Frame, a new Error Frame will be transmitted. Several consecutive Error Frame's may result in the PCX82C200 becoming error-passive and leaving the network unblocked.

In order to terminate an Error Flag correctly, an error-passive CAN-bus controller requires the bus to be Bus-Idle (see section 8.6.2) for at least three bit periods (if there is a local error at an error-passive receiver). Therefore a CAN-bus should not be 100% permanently loaded.

8.5 Overload Frame

The Overload Frame consists of two fields, the Overload Flag and the Overload Delimiter. There are two conditions in the CAN-protocol which lead to the transmission of an Overload Flag:

- condition 1; receiver circuitry requires more time to process the current data before receiving the next frame (receiver not ready)
- condition 2; detection of a dominant bit during Intermission Field (see section 8.6.1).

The transmission of an Overload Frame may only start:

- condition 1; during the first bit period of an expected Intermission Field

- condition 2; one bit period after detecting the dominant bit during Intermission Field.

The PCX82C200 will never initiate transmission of a condition 1 Overload Frame and will only react on a transmitted condition 2 Overload Frame, according to the CAN-protocol. No more than two Overload Frames are generated to delay a Data Frame or a Remote Frame. Although the overall form of the Overload Frame corresponds to that of the Error Frame, an Overload Frame does not initiate or require the retransmission of the preceding frame.

8.5.1 OVERLOAD FLAG

The Overload Flag consists of six dominant bits and has a similar format to the Error Flag.

The Overload Flag's form corrupts the fixed form of the Intermission Field. All other PCX82C200's detecting the overload condition also transmit an Overload Flag (condition 2).

8.5.2 OVERLOAD DELIMITER

The Overload Delimiter consists of eight recessive bits and takes the same form as the Error Delimiter. After transmission of an Overload Flag, each PCX82C200 monitors the bus-line until it detects a transition from a

Stand-alone CAN-controller

82C200

dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished sending its Overload Flag and all PCX82C200's start simultaneously transmitting seven more recessive bits.

8.6 Inter-Frame Space

Data Frames and Remote Frames are separated from preceding frames (all types) by an Inter-Frame Space, consisting of an Intermission Field and a Bus-Idle. Error-passive PCX82C200's also send a Suspend Transmission (see section 8.9.5) after transmission of a message. Overload Frames and Error Frames are not preceded by an Inter-Frame Space.

8.6.1 INTERMISSION FIELD

The Intermission Field consists of three recessive bits. During an Intermission period, no frame transmissions will be started by any PCX82C200. An Intermission is required to have a fixed time period to allow a CAN-controller to execute internal processes prior to the next receive or transmit task.

8.6.2 BUS-IDLE

The Bus-Idle time may be of arbitrary length (minimum 0 bit). The bus is recognized to be free and a CAN-controller having information to transmit may access the bus. The detection of a dominant bit level during Bus-Idle on the bus is interpreted as the Start-Of-Frame.

8.7 Bus organization

Bus organization is based on five basic rules described in the following paragraphs.

8.7.1 BUS ACCESS

PCX82C200's only start transmission during the Bus-Idle state. All PCX82C200's synchronize on the leading edge of the Start-Of-Frame (hard synchronization).

8.7.2 ARBITRATION

If two or more PCX82C200's simultaneously start transmitting, the bus access conflict is solved by a bit-wise arbitration process during transmission of the Arbitration Field.

During arbitration every transmitting PCX82C200 compares its transmitted bit level with the monitored bus level. Any PCX82C200 which transmits a recessive bit and monitors a dominant bus level immediately becomes

the receiver of the higher priority message on the bus without corrupting any information on the bus. Each message contains a unique Identifier and a RTR bit describing the type of data within the message.

The Identifier together with the RTR bit implicitly define the message's bus access priority. During arbitration the most significant bit of the Identifier is transmitted first and the RTR bit last. The message with the lowest binary value of the Identifier and RTR bit has the highest priority. A Data Frame has higher priority than a Remote Frame due to its RTR bit having a dominant level.

For every Data Frame there is an unique transmitter. For reasons of compatibility with other CAN-bus controllers, use of the Identifier binary bit pattern ID = 111111XXXX (X being bits of arbitrary level) is forbidden. The number of available different Identifiers is 2032 ($2^{11} - 2^4$).

8.7.3 CODING/DECODING

The following bit fields are coded using the bit-stuffing technique:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence.

When a transmitting PCX82C200 detects five consecutive bits of identical polarity to be transmitted, a complementary (stuff) bit is inserted into the transmitted bit-stream.

When a receiving PCX82C200 has monitored five consecutive bits with identical polarity in the received bit streams of the above described bit fields, it automatically deletes the next received (stuff) bit. The level of the deleted stuff bit has to be the complement of the previous bits; otherwise a Stuff Error will be detected and signalled (see section 8.8.2).

The remaining bit fields or frames are of fixed form and are not coded or decoded by the method of bit-stuffing.

The bit-stream in a message is coded according to the Non-Return-to-Zero (NRZ) method, i.e. during a bit period, the bit level is held constant, either recessive or dominant.

Stand-alone CAN-controller

82C200

8.7.4 ERROR SIGNALLING

A PCX82C200 which detects an error condition, transmits an Error Flag. Whenever a Bit Error, Stuff Error, Form Error or an Acknowledgement Error is detected, transmission of an Error Flag is started at the next bit. Whenever a CRC Error is detected, transmission of an Error Flag starts at the bit following the Acknowledge Delimiter, unless an Error Flag for another error condition has already started. An Error Flag violates the bit-stuffing law or corrupts the fixed form bit fields. A violation of the bit-stuffing law affects any PCX82C200 which detects the error condition. These devices will also transmit an Error Flag.

An error-passive PCX82C200 (see section 8.9) which detects an error condition, transmits a Passive Error Flag. A Passive Error Flag is not able to interrupt a current message at different PCX82C200's, but this type of Error Flag may be cancelled by other PCX82C200's. After having detected an error condition, an error-passive PCX82C200 will wait for six consecutive bits with identical polarity and when monitoring them, interpret them as an Error Flag.

After transmission of an Error Flag, each PCX82C200 monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every PCX82C200 has finished transmitting its Error Flag and all PCX82C200's start transmitting seven additional recessive bits (Error Delimiter, see section 8.4.2).

The message format of a Data Frame or Remote Frame is defined in such a way, that all detectable errors can be signalled within the message transmission time and therefore, it is very simple for a PCX82C200 to associate an Error Frame to the corresponding message and to initiate retransmission of the corrupted message.

If a PCX82C200 monitors any deviation of the fixed form of an Error Frame, it transmits a new Error Frame.

8.7.5 OVERLOAD SIGNALLING

Some CAN-controllers (but not the PCX82C200) require to delay the transmission of the next Data Frame or Remote Frame by transmitting one or more Overload Frames. The transmission of an Overload Frame must start during the first bit of an expected Intermission. Transmission of Overload Frames which are reactions on a dominant bit during an expected Intermission Field, start one bit after this event.

Though the format of Overload Frame and Error Frame are identical, they are treated differently. Transmission of an Overload Frame during Intermission Field does not initiate the retransmission of any previous Data Frame or Remote Frame.

If a CAN-controller which transmitted an Overload Frame monitors any deviation of its fixed form, it transmits an Error Frame.

8.8 Error detection

The processes described in the following paragraphs are implemented in the PCX82C200 for error detection.

8.8.1 BIT ERROR

A transmitting PCX82C200 monitors the bus on a bit-by-bit basis. If the bit level monitored is different from the transmitted one, a Bit Error is signalled. The exceptions being:

- during the Arbitration Field, a recessive bit can be overwritten by a dominant bit. In this case, the PCX82C200 interprets this as a loss of arbitration
- during the Acknowledge Slot, only the receiving PCX82C200's are able to recognize a Bit Error.

8.8.2 STUFF ERROR

The following bit fields are coded using the bit-stuffing technique:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence.

There are two possible ways of generating a Stuff Error:

- the disturbance generates more than the allowed five consecutive bits with identical polarity. These errors are detected by all PCX82C200's
- a disturbance falsifies one or more of the five bits preceding the stuff bit. This error situation is not recognized as a Stuff Error by the receivers. Therefore, other error detection processes may detect this error condition such as: CRC check, format violation at the receiving PCX82C200's or Bit Error detection by the transmitting PCX82C200.

Stand-alone CAN-controller

82C200

8.8.3 CRC ERROR

To ensure the validity of a transmitted message all receivers perform a CRC check. Therefore, in addition to the (destuffed) information digits (Start-Of-Frame up to Data Field), every message includes some control digits (CRC Sequence; generated by the transmitting PCX82C200 of the respective message) used for error detection.

The code used for the PCX82C200 bus controller is a (shortened) BCH code, extended by a parity check and has the following attributes:

- 127 bits as maximum length of the code
- 112 bits as maximum number of information digits (maximum 83 bits are used by PCX82C200)
- length of the CRC Sequence amounts to 15 bits
- Hamming distance $d = 6$.

As a result, (d-1) random errors are detectable (some exceptions exist).

The CRC Sequence is calculated by the following procedure:

1. the destuffed bit stream consisting of Start-Of-Frame up to the Data Field (if present) is interpreted as a polynomial with coefficients of 0 or 1
2. this polynomial is divided (modulo-2) by the following generator polynomial:

$$f(X) = (X^{14} + X^9 + X^8 + X^6 + X^5 + X^4 + X^2 + X + 1) (X + 1) = 1100010110011001 \text{ binary.}$$

The remainder of this polynomial division is the CRC Sequence which includes a parity check. Burst errors are detected up to a length of 15 [degree of $f(X)$]. Multiple errors (number of disturbed bits at least $d = 6$) are not detected with a residual error probability of 2^{-15} ($\approx 3 \times 10^{-5}$) by CRC check only.

8.8.4 FORM ERROR

Form Errors result from violation of the fixed form of the following bit fields:

- End-Of-Frame
- Intermission
- Acknowledge Delimiter
- CRC Delimiter.

During the transmission of these bit fields an error condition is recognized if a dominant bit level instead of a recessive one is detected.

8.8.5 ACKNOWLEDGEMENT ERROR

This is detected by a transmitter whenever it does not monitor a dominant bit during the Acknowledge Slot.

8.8.6 ERROR DETECTION BY AN ERROR FLAG OF ANOTHER PCX82C200

The detection of an error is signalled by transmitting an Error Flag. An Active Error Flag causes a Stuff Error, a Bit Error or a Form Error at all other PCX82C200's.

8.8.7 ERROR DETECTION CAPABILITIES

Errors which occur at all PCX82C200's (global errors) are 100% detected. For local errors, i.e. for errors occurring at some PCX82C200's only, the shortened BCH code, extended by a parity check, has the following error detection capabilities:

- up to five single bit errors are 100% detected, even if they are distributed randomly within the code
- all single bit errors are detected if their total number (within the code) is odd
- the residual error probability of the CRC check amounts to 3×10^{-5} . As an error may be detected not only by CRC check but also by other detection processes described in sections 8.8.1 to 8.8.5, the residual error probability is several magnitudes less than 3×10^{-5} for undetected errors.

8.9 Error confinement (definitions)

8.9.1 BUS-OFF

A PCX82C200 which has too many unsuccessful transmissions, relative to the number of successful transmissions, will enter the Bus-Off state. It remains in this state, neither receiving nor transmitting messages until the Reset Request bit is set LOW (absent) and both Error Counters are set to '0' (see note 1 to Table 5 and section 8.10.3).

8.9.2 ACKNOWLEDGE (ACK)

A PCX82C200 which has received a valid message correctly, indicates this to the transmitter by transmitting a dominant bit level on the bus during the Acknowledge Slot, independent of accepting or rejecting the message.

Stand-alone CAN-controller

82C200

8.9.3 ERROR-ACTIVE

An error-active PCX82C200 is in its normal operating state able to receive and to transmit normally and also to transmit an active Error Flag (see section 8.10.3).

8.9.4 ERROR-PASSIVE

An error-passive PCX82C200 may transmit or receive messages normally. In the case of a detected error condition it transmits a Passive Error Flag, instead of an Active Error Flag. Hence the influence on bus activities by an error-passive PCX82C200 (e.g. due to a malfunction) is reduced.

8.9.5 SUSPEND TRANSMISSION

After an error-passive PCX82C200 has transmitted a message, it sends eight recessive bits after the Intermission Field and then checks for Bus-Idle. If during Suspend Transmission another PCX82C200 starts transmitting a message the suspended PCX82C200 will become the receiver of this message; otherwise being in Bus-Idle it may start to transmit a further message.

8.9.6 START-UP

A PCX82C200 which was either switched off or is in the Bus-Off state, must run a start-up routine in order to:

- synchronize with other available PCX82C200's, before starting to transmit. Synchronizing is achieved, when 11 recessive bits, equivalent to Acknowledge Delimiter, End-Of-Frame and Intermission Field, have been detected (Bus-Free)
- wait for other PCX82C200s without passing into the Bus-Off state (due to a missing acknowledge), if there is no other PCX82C200 currently available.

8.10 Aims of error confinement

8.10.1 DISTINCTION OF SHORT AND LONG-LASTING DISTURBANCES

The microcontroller must be informed when there are long-lasting disturbances and when bus activities have returned to normal operation. During long-lasting disturbances, a PCX82C200 enters the Bus-Off state and the microcontroller may use default values.

Minor disturbances of bus activities will not affect a PCX82C200. In particular, a PCX82C200 does not enter the Bus-Off state or inform the microcontroller of a short-lasting bus disturbance.

8.10.2 DETECTION AND LOCALIZATION OF HARDWARE DISTURBANCES AND DEFECTS

The rules for error confinement are defined by the CAN-protocol specification (and implemented in the PCX82C200), in that the PCX82C200, being nearest to the error-locus, reacts with a high probability, the quickest (i.e. becomes error-passive or Bus-Off), hence errors can be localized and their influence on normal bus activities is minimized.

8.10.3 ERROR CONFINEMENT

All PCX82C200's contain a Transmit Error Counter and a Receive Error Counter, which registers errors during the transmission and the reception of messages, respectively.

If a message is transmitted or received correctly, the count is decreased. In the event of an error, the count is increased. The Error Counters have a non-proportional method of counting: an error causes a larger counter increase than a correctly transmitted/received message causes the count to decrease. Over a period of time this may result in an increase in error counts, even if there are fewer corrupted messages than uncorrupted ones. The level of the Error Counters reflect the relative frequency of disturbances. The ratio of increase/decrease depends on the acceptable ratio of invalid/valid messages on the bus and is hardware implemented to eight.

If one of the Error Counters exceeds the Warning Limit of 96 error points, indicating a significant accumulation of error conditions, this is signalled by the PCX82C200 (Error Status, Error Interrupt).

A PCX82C200 operates in the error-active mode until it exceeds 127 error points on one of its Error Counters. At this point it will enter the error-passive state.

A transmit error which exceeds 255 error points results in the PCX82C200 entering the Bus-Off state.

Stand-alone CAN-controller

82C200

9 LIMITING VALUES

Limiting values in accordance with the Absolute Maximum Rating System (IEC134)

SYMBOL	PARAMETER	MIN.	MAX.	UNIT
V_{DD}	supply voltage range	4.5	5.5	V
I_I	input/output current on any pin except from TX0 and TX1	–	±10	mA
I_{OT}	sink current of TX0 and TX1 together (note 1)	–	28	mA
I_{OT}	source current of TX0 and TX1 together (note 1)	–	–20	mA
T_{amb}	operating ambient temperature range:			
	PCA82C200	–40	+125	°C
	PCF82C200	–40	+85	°C
T_{stg}	storage temperature range	–65	+150	°C
P_{tot}	total power dissipation (note 2)	–	1	W

Notes

- I_{OT} is allowed in case of a bus failure condition because then the TX-outputs are switched off automatically after a short time (Bus-Off state). During normal operation I_{OT} is a peak current, permitted for $t < 100$ ms. The average output current must not exceed 10 mA for each TX-output.
- The value is based on the maximum allowable die temperature and the thermal resistance of the package, not on device power consumption.

10 DC CHARACTERISTICS

$V_{DD} \leq 5$ V ±10%; $V_{SS} = 0$ V; $T_{amb} = -40$ to $+125$ °C for the PCA82C200 and $T_{amb} = -40$ to $+85$ °C for the PCF82C200. All voltages measured with respect to V_{SS} unless otherwise specified

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT
Supply					
V_{DD}	supply voltage range		4.5	5.5	V
I_{DD}	supply current: operating	$\overline{RST} = V_{SS};$ $f_{CLK} = 16$ MHz (note 1)	–	15	mA
I_{sm}	sleep mode	oscillator inactive (note 2)	–	40	µA
Inputs					
V_{IL1}	LOW level input voltage (except XTAL1, RX0 and RX1)		–0.5	0.8	V
V_{IL2}	XTAL1 LOW level input voltage		–	$0.2V_{DD}$	V
V_{IH1}	HIGH level input voltage (except XTAL1, \overline{RST} , RX0 and RX1)		3.2	$V_{DD} + 0.5$	V
V_{IH2}	XTAL1 HIGH level input voltage		$0.7V_{DD}$	–	V
V_{IH3}	\overline{RST} HIGH level input voltage		3.3	$V_{DD} + 0.5$	V
I_L	input leakage current (except XTAL1, RX0 and RX1)	0.45 V $< V_I < V_{DD}$	–	±10	µA

Stand-alone CAN-controller

12 DEVELOPMENT SUPPORT AND TOOLS

12.1 The PCX82C200 Evaluation Board

Philips offers powerful support during the design and test stages of CAN networks, working closely with customers to develop their systems. The 'Philips Stand-alone CAN-Controller (PSCC) Evaluation Board' is a versatile tool being a ready-to-use hardware and software module, very similar to a real CAN module. Since a 5 V power supply is provided, the board can be used in any vehicle without modification. An RS232 interface allows a terminal or a PC with terminal-emulation software to be connected to the board. The board comprises:

- a PCX82C200 CAN-bus controller
- a PCA80C552 microcontroller with up to 32K x 8 bits external RAM and EPROM

- a 5 V power supply with protection against car battery disturbances
- two different physical CAN-bus interfaces (selectable)
- an RS232 interface
- demonstration hardware
- a wrap field for customer-specific circuitry.

The software provided with the board supports "learning about CAN" and assists in prototype (e.g. in-vehicle) networks. It provides:

- demonstration software (automatically-initiated)
- the menu-driven software comprises:
 - a facility to alter the contents of the PCX82C200 registers
 - a bus monitor to receive messages from the CAN-bus and to display them on a terminal
 - a download facility for the user's application software.

With these facilities the board is a basis for prototype modules; when using entirely your own software, the board can be used as a custom, debugged and proven hardware module.

12.2 Advanced support

For further development support, Philips subcontractor I+ME offers a complete set of development tools including:

- a CAN simulator; CAN/Net Sim
- an emulator; CAN/Net Emu
- a network analyzer; CAN/Net Anal.

I+ME can be contacted through the following address:

I+ME GmbH
Ferdinandstrasse 15 A
D-3340 Wolfenbuettel
West Germany.

Phone: ++49-5331-72066
Fax: ++49-5331-32455

CAN controller interface**PCA82C250****FEATURES**

- Fully compatible with the "ISO/DIS 11898" standard
- High speed (up to 1 Mbaud)
- Bus lines protected against transients in an automotive environment
- Slope control to reduce radio frequency interference (RFI)
- Differential receiver with wide common-mode range for high immunity against electromagnetic interference (EMI)
- Thermally protected
- Short-circuit proof to battery and ground
- Low current standby mode
- An unpowered node does not disturb the bus lines
- At least 110 nodes can be connected.

APPLICATIONS

- High-speed applications (up to 1 Mbaud) in cars.

GENERAL DESCRIPTION

The PCA82C250 is the interface between the CAN protocol controller and the physical bus. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller.

QUICK REFERENCE DATA

CAN controller interface

PCA82C250

FUNCTIONAL DESCRIPTION

The PCA82C250 is the interface between the CAN protocol controller and the physical bus. It is primarily intended for high-speed applications (up to 1 Mbaud) in cars. The device provides differential transmit capability to the bus and differential receive capability to the CAN controller. It is fully compatible with the "ISO/DIS 11898" standard.

A current limiting circuit protects the transmitter output stage against short-circuit to positive and negative battery voltage. Although the power dissipation is increased during this fault condition, this feature will prevent destruction of the transmitter output stage.

If the junction temperature exceeds a value of approximately 160 °C, the limiting current of both transmitter outputs is decreased. Because the transmitter is responsible for the major part of the power dissipation, this will result in a reduced power dissipation and hence a lower chip temperature. All other parts of the IC will remain in operation. The thermal protection is particularly needed when a bus line is short-circuited.

The CANH and CANL lines are also protected against electrical transients which may occur in an automotive environment. Pin 8 (Rs) allows three different modes of operation to be selected: high-speed, slope control or standby.

For high-speed operation, the transmitter output transistors are simply switched on and off as fast as possible. In this mode, no measures are taken to limit the rise and fall slope. Use of a shielded cable is recommended to avoid RFI problems. The high-speed mode is selected by connecting pin 8 to ground.

For lower speeds or shorter bus length, an unshielded twisted pair or a parallel pair of wires can be used for the bus. To reduce RFI, the rise and fall slope should be limited. The rise and fall slope can be programmed with a resistor connected from pin 8 to ground. The slope is proportional to the current output at pin 8.

If a HIGH level is applied to pin 8, the circuit enters a low current standby mode. In this mode, the transmitter is switched off and the receiver is switched to a low current. If dominant bits are detected (differential bus voltage >0.9 V), RxD will be switched to a LOW level. The microcontroller should react to this condition by switching the transceiver back to normal operation (via pin 8). Because the receiver is slow in standby mode, the first message will be lost.

Table 1 Truth table of CAN transceiver.

SUPPLY	TxD	CANH	CANL	BUS STATE	RxD
4.5 to 5.5 V	0	HIGH	LOW	dominant	0
4.5 to 5.5 V	1 (or floating)	floating	floating	recessive	1
<2 V (not powered)	X	floating	floating	recessive	X
$2\text{ V} < V_{CC} < 4.5\text{ V}$	$>0.75V_{CC}$	floating	floating	recessive	X
$2\text{ V} < V_{CC} < 4.5\text{ V}$	X	floating if $V_{Rs} > 0.75V_{CC}$	floating if $V_{Rs} > 0.75V_{CC}$	recessive	X

Table 2 Rs (pin 8) summary.

CONDITION FORCED AT Rs	MODE	RESULTING VOLTAGE OR CURRENT AT Rs
$V_{Rs} > 0.75V_{CC}$	standby	$I_{Rs} < 110\text{ }\mu\text{A}$
$-10\text{ }\mu\text{A} < I_{Rs} < -200\text{ }\mu\text{A}$	slope control	$0.4V_{CC} < V_{Rs} < 0.6V_{CC}$
$V_{Rs} < 0.3V_{CC}$	high-speed	$I_{Rs} < -500\text{ }\mu\text{A}$

CAN controller interface

PCA82C250

LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134). All voltages are referenced to pin 2; positive input current.

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT
V_{CC}	supply voltage		-0.3	+9.0	V
V_n	DC voltage at pins 1, 4, 5 and 8		-0.3	$V_{CC} + 0.3$	V
$V_{6,7}$	DC voltage at pins 6 and 7	$0\text{ V} < V_{CC} < 5.5\text{ V}$; no time limit	-8.0	+18.0	V
V_{trt}	transient voltage at pins 6 and 7	see Fig.8	-150	+100	V
T_{stg}	storage temperature		-55	+150	°C
T_{amb}	operating ambient temperature		-40	+125	°C
T_{vj}	virtual junction temperature	note 1	-40	+150	°C

Note

1. In accordance with "IEC 747-1".

An alternative definition of virtual junction temperature T_{vj} is: $T_{vj} = T_{amb} + P_d \times R_{th\ vj-amb}$, where $R_{th\ vj-amb}$ is a fixed value to be used for the calculation of T_{vj} .

The rating for T_{vj} limits the allowable combinations of power dissipation (P_d) and ambient temperature (T_{amb}).

HANDLING

Classification A: human body model; C = 100 pF; R = 1500 Ω ; V = ± 2000 V.

Classification B: machine model; C = 200 pF; R = 0 Ω ; V = ± 200 V.

QUALITY SPECIFICATION

Quality specification "SNW-FQ-611 part E" is applicable and can be found in the "Quality reference pocket-book" (ordering number 9398 510 34011).

THERMAL CHARACTERISTICS

SYMBOL	PARAMETER	VALUE	UNIT
$R_{th\ j-a}$	thermal resistance from junction to ambient in free air		
	PCA82C250	100	K/W
	PCA82C250T	160	K/W

CAN controller interface

CHARACTERISTICS

$V_{CC} = 4.5$ to 5.5 V; $T_{amb} = -40$ to $+125$ °C; $R_L = 60$ Ω; $I_B > -10$ μA; unless otherwise specified.

All voltages referenced to ground (pin 2); positive input current; all parameters are guaranteed over the ambient temperature range by design, but only 100% tested at $+25$ °C.

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
Supply						
I_3	supply current	dominant; $V_1 = 1$ V	–	–	70	mA
		recessive; $V_1 = 4$ V; $R_8 = 47$ kΩ	–	–	14	mA
		recessive; $V_1 = 4$ V; $V_8 = 1$ V	–	–	18	mA
		standby; $T_{amb} < 90$ °C; note 1	–	100	170	μA
DC bus transmitter						
V_{IH}	HIGH level input voltage	output recessive	$0.7V_{CC}$	–	$V_{CC} + 0.3$	V
V_{IL}	LOW level input voltage	output dominant	–0.3	–	$0.3V_{CC}$	V
I_{IH}	HIGH level input current	$V_1 = 4$ V	–200	–	+30	μA
I_{IL}	LOW level input voltage	$V_1 = 1$ V	100	–	600	μA
$V_{6,7}$	recessive bus voltage	$V_1 = 4$ V; no load	2.0	–	3.0	V
I_{LO}	off-state output leakage current	-2 V < (V_6, V_7) < 7 V	–2	–	+1	mA
		-5 V < (V_6, V_7) < 18 V	–5	–	+12	mA
V_7	CANH output voltage	$V_1 = 1$ V	2.75	–	4.5	V
V_6	CANL output voltage	$V_1 = 1$ V	0.5	–	2.25	V
$\Delta V_{6,7}$	difference between output voltage at pins 6 and 7	$V_1 = 1$ V	1.5	–	3.0	V
		$V_1 = 1$ V; $R_L = 45$ Ω; $V_{CC} \geq 4.9$ V	1.5	–	–	V
		$V_1 = 4$ V; no load	–500	–	+50	mV
I_{sc7}	short-circuit CANH current	$V_7 = -5$ V; $V_{CC} \leq 5$ V	–	–	105	mA
		$V_7 = -5$ V; $V_{CC} = 5.5$ V	–	–	120	mA
I_{sc6}	short-circuit CANL current	$V_6 = 18$ V	–	–	160	mA
DC bus receiver: $V_1 = 4$ V; pins 6 and 7 externally driven; -2 V < (V_6, V_7) < 7 V; unless otherwise specified						
$V_{diff(r)}$	differential input voltage (recessive)		–1.0	–	0.5	V
		-7 V < (V_6, V_7) < 12 V; not standby mode	–1.0	–	0.4	V
$V_{diff(d)}$	differential input voltage (dominant)		0.9	–	5.0	V
		-7 V < (V_6, V_7) < 12 V; not standby mode	1.0	–	5.0	V
$V_{diff(hys)}$	differential input hysteresis	see Fig.5	–	150	–	mV
V_{OH}	HIGH level output voltage (pin 4)	$I_4 = -100$ μA	$0.8V_{CC}$	–	V_{CC}	V
V_{OL}	LOW level output voltage (pin 4)	$I_4 = 1$ mA	0	–	$0.2V_{CC}$	V
		$I_4 = 10$ mA	0	–	1.5	V
R_i	CANH, CANL input resistance		5	–	25	kΩ

CAN controller interface

PCA82C250

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
R_{diff}	differential input resistance		20	–	100	k Ω
C_i	CANH, CANL input capacitance		–	–	20	pF
C_{diff}	differential input capacitance		–	–	10	pF
Reference output						
V_{ref}	reference output voltage	$V_B = 1\text{ V};$ $-50\ \mu\text{A} < I_5 < 50\ \mu\text{A}$	$0.45V_{CC}$	–	$0.55V_{CC}$	V
		$V_B = 4\text{ V};$ $-5\ \mu\text{A} < I_5 < 5\ \mu\text{A}$	$0.4V_{CC}$	–	$0.6V_{CC}$	V
Timing (see Figs 4, 6 and 7)						
t_{bit}	minimum bit time	$V_B = 1\text{ V}$	–	–	1	μs
t_{onTxD}	delay TxD to bus active	$V_B = 1\text{ V}$	–	–	50	ns
t_{offTxD}	delay TxD to bus inactive	$V_B = 1\text{ V}$	–	40	80	ns
t_{onRxD}	delay TxD to receiver active	$V_B = 1\text{ V}$	–	55	120	ns
t_{offRxD}	delay TxD to receiver inactive	$V_B = 1\text{ V}; V_{CC} < 5.1\text{ V};$ $T_{amb} < +85\text{ }^\circ\text{C}$	–	82	150	ns
		$V_B = 1\text{ V}; V_{CC} < 5.1\text{ V};$ $T_{amb} < +125\text{ }^\circ\text{C}$	–	82	170	ns
		$V_B = 1\text{ V}; V_{CC} < 5.5\text{ V};$ $T_{amb} < +85\text{ }^\circ\text{C}$	–	90	170	ns
		$V_B = 1\text{ V}; V_{CC} < 5.5\text{ V};$ $T_{amb} < +125\text{ }^\circ\text{C}$	–	90	190	ns
t_{onRxD}	delay TxD to receiver active	$R_B = 47\text{ k}\Omega$	–	390	520	ns
		$R_B = 24\text{ k}\Omega$	–	260	320	ns
t_{offRxD}	delay TxD to receiver inactive	$R_B = 47\text{ k}\Omega$	–	260	450	ns
		$R_B = 24\text{ k}\Omega$	–	210	320	ns
ISRI	differential output voltage slew rate	$R_B = 47\text{ k}\Omega$	–	14	–	V/ μs
t_{WAKE}	wake-up time from standby (via pin 8)		–	–	20	μs
t_{dRxDL}	bus dominant to RxD LOW	$V_B = 4\text{ V};$ standby mode	–	–	3	μs
Standby/slope control (pin 8)						
V_B	input voltage for high-speed		–	–	$0.3V_{CC}$	V
I_B	input current for high-speed	$V_B = 0\text{ V}$	–	–	–500	μA
V_{stb}	input voltage for standby mode		$0.75V_{CC}$	–	–	V
I_{slope}	slope control mode current		–10	–	–200	μA
V_{slope}	slope control mode voltage		$0.4V_{CC}$	–	$0.6V_{CC}$	V

Note

1. $I_1 = I_4 = I_5 = 0\text{ mA}; 0\text{ V} < V_6 < V_{CC}; 0\text{ V} < V_7 < V_{CC}; V_8 = V_{CC}.$

Development support tools

DEVELOPMENT SUPPORT TOOLS

Philips Semiconductors manufactures support tools and also works closely with many "third-party" vendors who provide support tools for our wide variety of 80C51-based microcontroller derivatives.

Development Systems

In most cases, development systems are available in two versions for ROM and ROMless applications. The ROM emulation products are capable of supporting all versions of a given device type, including EPROM, ROM, and ROMless devices. In contrast, a ROMless emulator can only support applications designed for a ROMless microcontroller. Most development systems are designed to connect to an IBM-PC or compatible personal computer.

EPROM Programming Support

Philips Semiconductors works closely with major suppliers of EPROM programming equipment to support our family of EPROM microcontrollers. As a result, EPROM programming support is available within the programming facilities of many major distributors.

The following is a list of vendors that offer support for Philips Semiconductors 80C51 microcontroller family.

PRODUCT	DESCRIPTION & DEVICES SUPPORTED
PCx509x Emulator Bases:	iceMASTER Pcx509x Emulator Base, 128K emulation memory (40 MHz) 16K trace buffer
PCx509x Probe Cards: PC-5097-5V-RB-28 PC-5097-3V-RB-14	28 MHz (PCA5090 and PCA5097 (5V system)) 14 MHz (PCA5090 and PCA5097 (3V system))

Microtek International Inc.	
PRODUCT	DESCRIPTION & DEVICES SUPPORTED
EasyPack 8031/32	Real time emulation to 40MHz, 128KB overlay memory, 32K trace buffer (40 bits wide). Includes EasyView HLLD, Macro Assembler, ICE probe diagnostic test board.
EasyPack 80C51/52	Real time emulation to 20MHz, 128KB overlay memory, 32K trace buffer (40 bits wide). Includes EasyView HLLD, Macro Assembler, ICE probe diagnostic test board.
EasyPack 80652/654	Real time emulation to 20MHz, 128KB overlay memory, 32K trace buffer (40 bits wide). Includes EasyView HLLD, Macro Assembler, ICE probe diagnostic test board. Supports 8xC652, 83C654, 87C654.
EasyPack 80C51FA	Real time emulation to 16MHz, 128KB overlay memory, 32K trace buffer (40 bits wide). Includes EasyView HLLD, Macro Assembler, ICE probe diagnostic test board. Supports 80C51FA.
EasyPack 8XC552	Real time emulation to 16MHz, 128KB overlay memory, 32K trace buffer (40 bits wide). Includes EasyView HLLD, Macro Assembler, ICE probe diagnostic test board. Supports 8xC552.

NOHAU Corporation	
PRODUCT	DESCRIPTION & DEVICES SUPPORTED
EMUL51-PC/E32	12MHz Emulator, 32k emulation memory
EMUL51-PC/E128	12MHz Emulator, 128k emulation memory
EMUL51-PC/E32-16	16MHz Emulator, 32k emulation memory
EMUL51-PC/E128-16	16MHz Emulator, 128k emulation memory
EMUL51-PC/E128-20	20MHz Emulator, 128k emulation memory
EMUL51-PC/E128-24	24MHz Emulator, 128k emulation memory
EMUL51-PC/E128-30	30MHz Emulator, 128k emulation memory
EMUL51-PC/E128-BSW	12MHz Emulator, 128k bankswitched CODE memory
EMUL51-PC/E128-33	33MHz Emulator, 128k emulation memory
POD-C054	12MHz 83C053, 83C054, 87C054, 87C055 pod
POD-31	12MHz 8031 pod
POD-C31	12MHz 80C31 pod
POD-C31-1	16MHz 80C31 pod
POD-C31-20	20MHz 80C31 pod
POD-C31-24	24MHz 80C31 pod
POD-C31-30	30MHz 80C31 pod
POD-C31-33	33MHz 80C31 pod
POD-32	12MHz 8032 pod
POD-C32	12MHz 80C32 pod
POD-C32-16	16MHz 80C32 pod
POD-C652	12MHz 80C652 pod
POD-C652-16	16MHz 80C652 pod

Development support tools

MICROCONTROLLER DEVELOPMENT SYSTEMS (Continued)

NOHAU Corporation (Continued)	
PRODUCT	DESCRIPTION & DEVICES SUPPORTED
POD-C51B	12MHz bondout pod for 8051, 80C51, 83C652, 83C654, 83C851, and EPROM or ROMless versions of these parts
POD-C51B-16	16MHz version of the above
POD-C51B-24	24MHz version of the above
POD-L51P-16	16MHz 8xL51FA/FB pod
POD-C52	12MHz 80C32, 80C52, 87C52 pod
POD-C52-16	16MHz 80C32, 80C52, 87C52 pod
POD-CL410	12MHz 8xCL410, 8xCL610, 80CL51 pod
POD-C451-DIP	12MHz 80C451 DIP pod
POD-C451-DIP-16	16MHz 80C451 DIP pod
POD-C451-PGA	12MHz 80C451 PLCC pod (PGA from pod)
POD-C451-PGA-16	16MHz 80C451 PLCC pod (PGA from pod)
POD-C451B-PGA	12MHz bondout pod for 83C451, 87C451, 80C451PLCC (PGA from pod)
POD-C451B-PGA-16	16MHz bondout pod for 8x451 (PGA from pod)
POD-C528	12MHz 83C524, 87C524, 83C528, 87C528 pod
POD-C528-16	16MHz 83C524, 87C524, 83C528, 87C528 pod
POD-C552-PGA	12MHz 80C552 PLCC (PGA from pod)
POD-C552-PGA-16	16MHz 80C552 PLCC (PGA from pod)
POD-C552-PGA-24	24MHz 80C552 PLCC (PGA from pod)
POD-C552-PGA-30	30MHz 80C552 PLCC (PGA from pod)
POD-C552B-PGA	12MHz bondout pod for 83C552, 87C552, 80C552, 80C562, 83C562 PLCC (PGA from pod)
POD-C552B-PGA-16	16MHz bondout pod for 83C552, 87C552, 80C552, 80C562, 83C562 PLCC (PGA from pod)
POD-C552B-PGA-24	24MHz bondout pod for 8XC552/562 (PGA from pod)
POD-C558-16	16MHz 80CE558, 83CE558, 89CE558 pod
POD-C562-PGA-16	16MHz 80C562 PLCC (PGA from pod)
POD-C575	12MHz 83C575, 87C575, 80C575 pod
POD-CL580	12MHz 83CL580, 87CL580 pod
POD-C592-PGA	12MHz 80C592, 83C592, 87C592 pod
POD-C598	Order as POD-C592-PGA plus adapters (contact Nohau)
POD-C652B	Order as POD-C51B
POD-C851B	Order as POD-C51B
POD-C751	12MHz 8xC748, 8xC750, 8xC751 pod
POD-C751-16	16MHz 8xC748, 8xC750, 8xC751 pod
POD-C752	12MHz 8xC749, 8xC752 pod
POD-C752-16	16MHz 8xC749, 8xC752 pod
POD-CL782	12MHz 83CL781, 83CL782, 83CL52 pod
EMUL51-PC/TR4	12MHz 4k trace buffer option
EMUL51-PC/TR16	12MHz 16k trace buffer option
EMUL51-PC/TR4-16	16MHz 4k trace buffer option
EMUL51-PC/TR16-16	16MHz 16k trace buffer option
EMUL51-PC/TR16-20	20MHz 16k trace buffer option
EMUL51-PC/TR16-24	24MHz 16k trace buffer option
EMUL51-PC/TR16-30	30MHz 16k trace buffer option
EMUL51-PC/TR16-33	33MHz 16k trace buffer option
EMUL51-PC/ATR64-16	16MHz 64k advanced trace buffer option
EMUL51-PC/ATR64-24	24MHz 64k advanced trace buffer option
EMUL51-PC/ATR64-33	33MHz 64k advanced trace buffer option
EMUL51-PC/ATR256-16	16MHz 256k advanced trace buffer option
EMUL51-PC/ATR256-20	20MHz 256k advanced trace buffer option
EMUL51-PC/ATR256-30	30MHz 256k advanced trace buffer option

PRODUCT	DESCRIPTION & DEVICES SUPPORTED
EMUL51-PC/BOX-S	Box with serial port and cable. Box allows operation of emulator external to PC.
EMUL51-PC/BOX-M	Box with serial port and modem
EMUL51-PC/BOX-CS	Serial box with emulator (E128-16) and trace (TR16-16)
EMUL51-PC/BOX-CS-20	Serial box with emulator (E128-20) and trace (TR16-20)
EMUL51-PC/BOX-CS-24	Serial box with emulator (E128-24) and trace (TR16-24)
EMUL51-PC/BOX-CS-30	Serial box with emulator (E128-30) and trace (TR16-30)

Philips Semiconductors (from New Zealand group)		
PRODUCT	12NC	DESCRIPTION & DEVICES SUPPORTED
PDS51 SD	9351 719 40112	Emulator motherboard with 64K code memory. Requires daughter board for operation.
PDB055 SD	9352 097 80112	Daughter board for 8xC055/054/053. 42-pin SDIL footprint.
PDB51FB SD	9351 719 50112	Daughter board for 8xC51FB/FA, 52/51. 40-pin DIL footprint.
PDB51FC SD	9352 097 90112	Daughter board for 8xC51FC/FB/FA, 51/52/54/58. 40-pin DIL footprint.
PDB52 SD	9351 719 60112	Daughter board for 8xC52/51. 40-pin DIL footprint.
PDB453 SD	9352 099 10112	Daughter board for 8xC453/451. 68-PLCC footprint.
PDB528 SD	9352 098 00112	Daughter board for 8xC528/524 40-pin DIL footprint.
PDB550 SD	9351 949 50112	Daughter board for 8xC550. 40-pin DIL footprint.
PDB552 SD	9351 719 70112	Daughter board for 8xC552/562/654/652/51. 68-pin PLCC and 40-pin DIL footprints.
PDB592 SD	9352 098 10112	Daughter board for 8xC592. 68-pin PLCC footprint.
PDB654 SD	9351 719 80112	Daughter board for 8xC654/652/51. 40-pin DIL footprint.
PDB752 SD	9351 720 00112	Daughter board for 8xC752/751/750/749/748. 28-pin and 24-pin DIL footprints.
PDA28-750 SD	-	PLCC adapter for 8xC751, 750, 748.
PDA28-752 SD	9351 954 80112	PLCC adapter for 8xC752, 749.
PDA44 SD	9351 708 20112	40-pin DIL to 44-pin PLCC adapter.

PROGRAMMING ADAPTERS

DEVICE	MANUFACTURER	PART NUMBER	COMMENTS
87C51/52/652/654/528 PLCC	Logical Systems	PA51-44	Use with any 40-pin microcontroller programming site that supports the appropriate EPROM size.
87C51FA/FB/FC PLCC	Logical Systems	PA51-44	Use with any 40-pin microcontroller programming site that supports the appropriate EPROM size.
87C51/52/652/654/528 QFP	Logical Systems (also Philips)	PA52-QFP (PA52-QFP SD)	Use with any 40-pin microcontroller programming site that supports the appropriate EPROM size.
87C51FA/FB/FC QFP	Logical Systems (also Philips)	PA52-QFP (PA52-QFP SD)	Use with any 40-pin microcontroller programming site that supports the appropriate EPROM size.
87C451 DIP	Logical Systems	PA451-64	Use with any 87C51 40-pin programming site.
87C451 PLCC	Logical Systems	PA451-68	Use with any 87C51 40-pin programming site.
87C550 DIP	Logical Systems	550BASE	Use with any 87C51 40-pin programming site.
87C550 PLCC	Logical Systems	PA550-44	Use with any 87C51 40-pin programming site.
87C552 PLCC	Logical Systems	PA552-68	Use with any 8752/87C52/87C552/ 87C51FA (8K microcontroller) 40-pin programming site.
87C575 DIP	North Valley Products	GPA575	Use with any 8K 8xC51 family programming site. Also allows operation of the '575 in a standard '51 family socket (by inverting Reset).
87C592 PLCC	Logical Systems	PA592-68	Use with any 87C654/87C51FB (16K microcontroller) 40-pin programming site.
87C748 PLCC	Philips	Call MCO	Use with any programmer that programs the 87C748 in the DIP package.
87C750 PLCC	Philips	Call MCO	Use with any programmer that programs the 87C750 in the DIP package.
87C751 PLCC	Philips	Call MCO	Use with any programmer that programs the 87C751 in the DIP package.
87C748 SSOP	Logical Systems	PA24SO.601	Use with any programmer that programs the 87C748 in the DIP package.
87C750 SSOP	Logical Systems	PA24SO.601	Use with any programmer that programs the 87C750 in the DIP package.
87C751 SSOP	Logical Systems	PA24SO.601	Use with any programmer that programs the 87C751 in the DIP package.
87C749 PLCC	Logical Systems	PA28-28	Use with any programmer that programs the 87C749 in the DIP package.
87C752 PLCC	Logical Systems	PA28-28	Use with any programmer that programs the 87C752 in the DIP package.
87C749 SSOP	Logical Systems	PA28SO.601	Use with any programmer that programs the 87C749 in the DIP package.
87C752 SSOP	Logical Systems	PA28SO.601	Use with any programmer that programs the 87C752 in the DIP package.
P51XAG37 PLCC	Logical Systems	PA-XAG3FC-44	Use with any programmer that supports the 87C51FC in the DIP package.

NOTE:

Other various programming, emulation, and general purpose socket adaptors are available from EDI and Emulation Technology, see Programming Support Contact List.

Development support tools

8051 SUPPORT SOFTWARE SOURCES

MANUFACTURER	DESCRIPTION
2500AD Software, Inc.	C Compiler, assembler, and simulator for 80C51 family.
Archimedes Software	C Compiler, assembler, and simulator for 80C51 family.
Avocet Systems, Inc.	C Compiler, Pascal compiler, assembler, and simulator for 80C51 family.
BSO/Tasking	C Compiler, PLM compiler, assembler, and simulator for 80C51 family.
Dunfield Development Systems	C Compiler, assembler, and simulator for 80C51 family.
Micro Computer Control (MCC)	C Compiler, assembler, and simulator for 80C51 family.
Franklin Software	C Compiler, assembler, and simulator for 80C51 family.
Production Languages Corp.	C Compiler, BASIC compiler, assembler, and simulator for 80C51 family.

PILOT-MVP Universal Programmer

- ▲ All members of the 87C51 family are supported
- ▲ All packages: DIP, PLCC, QFP, SOIC and PGA are supported
- ▲ Controlled by IBM PCs/notebooks or compatibles
- ▲ Standard parallel printer port interface, no PC slot required
- ▲ Powerful, flexible and friendly software
- ▲ Four (4) years of free software updates via high speed BBS
- ▲ Industrial quality
- ▲ Approved by major semiconductor manufacturers
- ▲ Made in USA

Contact Information

Advin Systems, Inc.
1050-L East Duane Ave
Sunnyvale, CA USA
Tel: (800) 627-2456
Tel: (408) 243-7000
Fax: (408) 736-2503

Product Information

PILOT-MVP is a very cost-effective and reliable solution for programming microcontrollers. It is a universal programmer capable of programming a wide range of micros plus EPROMs, EEPROMs, Flash memories, PALs, GALs, FPGAs and many others.

It is controlled by Advin's easy-to-use and fast software, operating on IBM PCs and compatibles. Since the PC-interface is through a standard parallel printer port, no PC slot is required. Therefore you get the benefit of easy portability from one PC to another. You can also operate them from a notebook computer via its standard printer port.

Its macro/batch facility allows you to collect often used commands in a macro file which can be submitted later for fully automated operations. This and other popular features make the programmer a time-saving instrument for you. They also shorten the training process for your production people.

Advin Systems Inc. has been a dependable and responsive supplier of reliable programming instruments for over eight years. It is recognized and recommended by major IC manufacturers such as Altera, AMD, Intel, Microchip, Motorola, Philips, WSI and Xilinx.

For quality-conscious engineers who need almost instant support when new devices come to market, Advin's small-company high-quality mentality will fit very well.

Ordering Information

USA prices:

PILOT-MVP:	40-pin Universal Programmer (\$1295)
PILOT-145:	40-pin E/EPROM, Micros Programmer (\$795)
PILOT-U84:	84-pin Universal Programmer (\$2995)

All capable of programming microcontrollers, E/EPROMs and Flash memories.
(Universal Programmers also support PALs, EPLDs, GALs, FPGAs, etc).

Please contact Advin for product details, pricing and delivery.

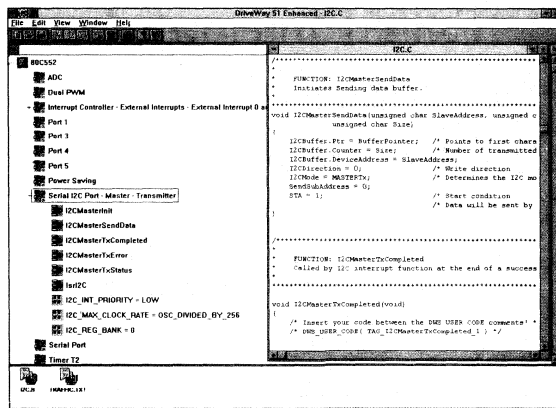

DriveWay™51 Device Drivers Code Generation Tool

- ▲ Generates complete device drivers in 'C' source code
- ▲ Generates initialization routines
- ▲ Generates your 'main' template
- ▲ Generates complete test functions
- ▲ Includes Interactive Data Sheet (IDS)
- ▲ Runs under MS-Windows
- ▲ Shortens time to market
- ▲ Reduces product development costs
- ▲ Improves code quality
- ▲ Eliminates the need to learn chip internals

E-mail: dw_51@aisys.co.il

Product Information

DriveWay-51 is an automatic application code generator that supports 8051 family microcontrollers. It is an easy-to-use Windows-based software tool that produces tested and documented 'C' source code to control 8051 on-chip peripherals.

Aisys provides a series of DriveWay products which support a variety of popular microcontrollers. These DriveWay products address the need of embedded system designers for full hardware and software integration of on-chip peripherals. DriveWay is a revolutionary class of tools for developing device drivers which produces tested and documented 'C' code to control on-chip peripherals.

DriveWay eliminates the tedious coding of peripheral functions and the need to learn the internals of each supported chip. This results in a shorter time to market, reduced product development costs, and higher-quality code.

Most of the development cycle can benefit dramatically by using DriveWay, from the 'S/W and H/W Design' stage to the 'System Test & Integration' stage, via the 'Device Driver S/W Implementation' and the 'H/W and S/W Test Integration' stages.

DriveWay also provides on-line Interactive Data Sheet (IDS) which provides hypertext data describing the chip, peripherals, modes, registers and pins that you need to program and can be used as a simpler kind of chip data handbook.

Archimedes IDE-8051

IDE-8051 Integrated Development Environment

- ▲ Optimizing ANSI C Compiler—
Compiler supports in-line assembly
- ▲ Macro-Assembler
- ▲ Optimizing Linker
- ▲ Object Decoder
- ▲ Librarian
- ▲ ANSI Libraries
- ▲ SimCASE-Simulator/Debugger
- ▲ Real-Time C/ASM Debuggers
- ▲ Windows Editor, Make, EPROM Utility
- ▲ Emulator Support

Contact Information

Archimedes Software, Inc.
303 Parkplace Center
Suite 125
Kirkland, WA 98033
Tel: (206) 822-6300
Fax: (206) 822-8632
WWW: <http://www.archimedesinc.com/devtools>

Product Information

Archimedes IDE for Windows is the first embedded development tool product line to integrate a powerful, Windows-based development and debugging environment with an optimizing C Cross-Compiler and Assembler. The Windows based Archimedes IDE development and debugging environment allows "point and click" access and control of all aspects of the software development cycle.

The ANSI standard C Cross-Compiler is based on a modern architecture and features state-of-the-art code optimization technology. With the High-Level In-Line Assembler, single or multiple assembly instructions can be inserted directly in-line within the C source. The Object Decoder disassembles object files created by the compiler and generates a list file with C source declarations, headers, and in-line assembly. The list file can then be manually optimized and recompiled.

Archimedes IDE for Windows consists of all the necessary development tools to produce high performance ROMable code.

Archimedes IDE for Windows represents the next generation of embedded development tools from Archimedes Software, Inc. You will be enjoying award winning technical and customers support from the recognized leader in embedded software development.

Host Systems Supported

PC (Windows 3.x), Sun Sparc (OpenLook or Motif), and VAX/VMS (Motif).

Processors Supported

8051, 68HC05/08, 68HC11, 68HC16, 683xx, 68K, CPU32/CPU32+, and others.

Ordering Information

Call 1-800-338-1453 or visit our home page at <http://www.archimedesinc.com/devtools>. Visa and MasterCard are accepted.

CTS51 Microprocessor Development Systems for Philips Microcontrollers

Ashling's CTS51 Universal Microprocessor Development System for Philips Microcontrollers

Features of Ashling's Microprocessor Development systems:

- ◆ Integrated Development Environment for Philips 8051 under Windows
- ◆ Real-time in-circuit emulator for all Philips 8051 derivatives; full-speed, non-intrusive emulation
- ◆ Real-time, DSP-based performance Analysis and Code Coverage systems for Software Quality Assurance
- ◆ Source-Level Debugging for 8051 programs, under Windows and DOS hosts
- ◆ Emulation and probe support for Philips low-voltage microcontrollers and Smart-Card microcontrollers
- ◆ Hardware break-before-execute breakpoints at every code and data address
- ◆ Stand-alone system, with built-in power supply; interchangeable probe cards for all derivatives and packages
- ◆ Programmer for all Philips 8051-family EPROM and EEPROM microcontrollers
- ◆ ISO9001-Certified Supplier; Ashling Microsystems Ltd. is certified to EN ISO9001/ASQC Q91

The Development Systems Company

Ashling

Product Information

Ashling's CTS51 Universal Microprocessor Development System provides a complete hardware and software development environment for the Philips 8051 microcontroller family and all of its derivatives.

In-Circuit Emulator

The CTS51 In-Circuit Emulator provides real-time emulation in both Single-Chip and Expanded modes. Target voltages in the range 2.7 – 5 Volts are supported; the emulation voltage can be set at 3.0, 3.3V or 5.0V, or can track the target system voltage throughout the range.

ICE Probes

In-Circuit emulation probes are available for all device-packages, including DIP-24, DIP-28, DIP-40, PLCC-44, QFP-44, SDIP-42, SDIP-52, PLCC68, QFP-80, QFP-100, and Philips Smart-Card Microcontrollers in ISO7816 or SIM (GSM) card-format.

Devices Supported

Using field-upgradeable personality probes, the CTS51 Universal Development System supports all Philips 8051 derivatives, including:

80C51B/80C31B	80C31/80C52 80CL51	83C550/80C550	80C51FA/FB/FC
83C552/80C552	83C562/80C562	83C053/54 83C654	PCD509x
83C750 83C751 83C752	83C851	83CE598/80CE598	SAA5290
83C592/80C592	83C528/80C528 83C575	83CE558/80CE558	83CL434
83CL410 83CL580	83CL782	83C852/855	83CL168

Support for new Philips microcontrollers

Ashling's close technical collaboration with Philips Semiconductors ensures that new Philips microcontroller devices and device-architectures are supported at, or soon after, their introduction by Philips. New Ashling personality probes are regularly introduced for new standard microcontrollers and microcontroller-based ASICs from Philips.

Philips Smart Card development support

Developed in co-operation with Philips, Ashling's CTS51 Microprocessor Development System provides a complete development-environment for Philips' 80C852/83C852 family of Smart Card Microcontrollers. Probes are available for ISO7816 and GSM (SIM) card formats. Ashling also supplies the SCPC4281 Smart Card Verification kit for stand-alone smart-card program emulation.

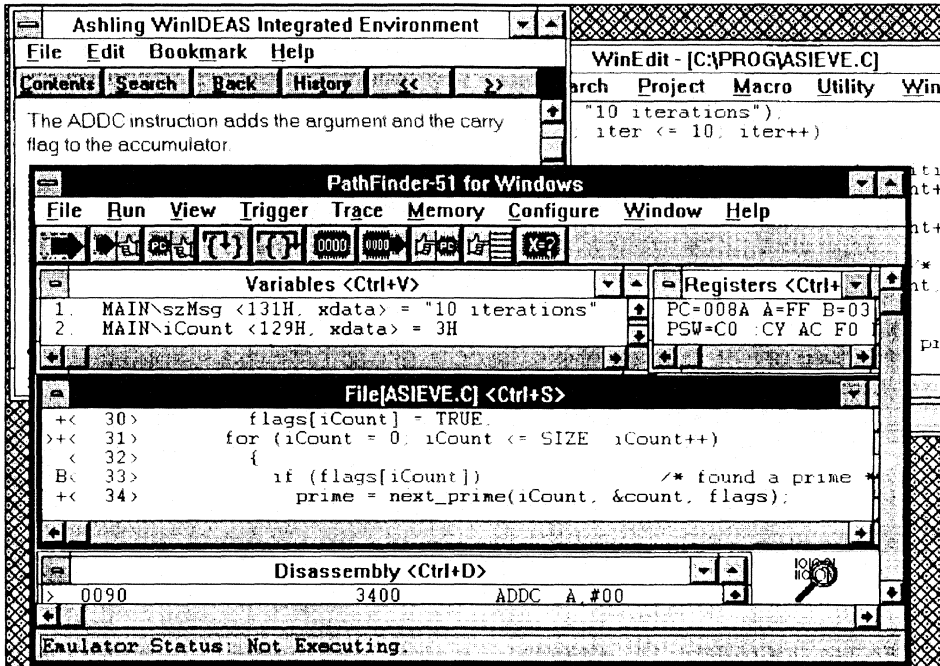

ISO9001 Certification; Quality Management System

Ashling Microsystems Ltd. operates a company-wide Quality Management System, formally certified to the ISO9001 international standard (NSAI Registration No. M619). This certification applies to all of Ashling's product development, manufacturing and customer-support activities.

The Development Systems Company

Ashling

Ashling WinIDEAS: With the Windows Integrated Development Environment for Ashling Systems supports the full Philips Microcontroller family. A single keystroke moves you between the edit, help-lookup, compile, debug and emulate stages.

Integrated Development Environment

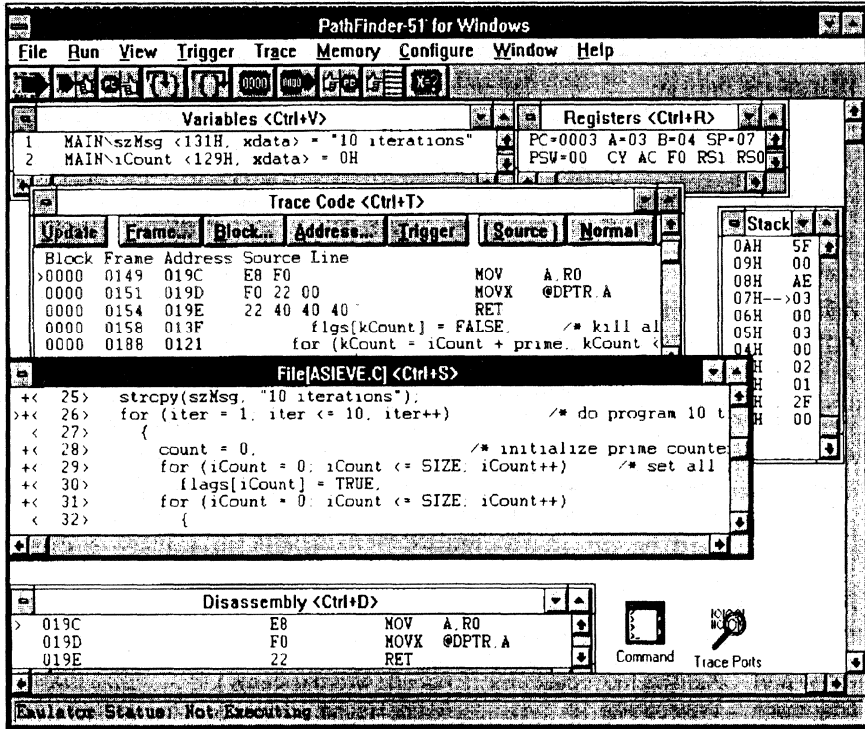

WinIDEAS, the Windows Integrated Development Environment allows you to edit, compile, assemble, simulate, debug, download and execute code on your Philips microcontroller target system in the Windows™ environment throughout. WinIDEAS provides a uniform, flexible and extensible windows interface for Editing, C Compiling, Assembling, Fuzzy-logic design and compilation, Linking, In-circuit emulation, Performance Analysis, Code Coverage Measurement, Software Validation reporting, and EPROM/EEPROM programming on Philips Microcontroller projects.

System Execution Analyser

The System Execution Analyser (SEA) is a built-in, DSP-based option for Ashling's Universal Microprocessor Development System. It provides real-time, non-intrusive, non-statistical Performance Analysis, Code Coverage and Report Generation. The SEA also provides symbolic function-trace, time-stamping, timing analysis and software verification. You can measure maximum, minimum and average execution times, execution counts and percentage code execution at Source or Assembly level.

Code Coverage System

The Code Test Management System (CTMS) option for the Ashling's Universal Microcontroller Development Systems measures 8051 code execution in real-time throughout a test session. It maps tested and untested code; identifies all tested, partially-tested or untested C source statements and assembler instructions; generates formal, annotated test reports; identifies redundant code; and provides a formal measurement of test completeness.

This Pathfinder for Windows screen shows the Source program, Disassembly, Real-Time Trace (source-level, disassembly and opcodes), Variables-watch, On-chip Registers and Stack contents for an 8051 program.

Windows Source-Level Debugger

Ashling's Pathfinder for Windows Source-Level debugger supports all popular microcontroller C and PL/M Compilers and Assemblers for the Philips microcontroller device family. Pathfinder provides up to 20 display-windows, controlled by mouse, menu-bar, command-line, accelerator keys or button-bar. Assembly-language source level debugging is a unique feature of Pathfinder for Windows.

Microcontroller EPROM/EEPROM Programming

Ashling's CTP51 PROM Programming System is used with the Universal Microprocessor Development System, to program the entire Philips 8751 EPROM/EEPROM microcontroller family. Features include:

- ◆ Programming support for all Philips 8751-family EPROM microcontrollers, including 87C51, 87C51FC, 87C52, 87C528, 87C550, 87C552, 87C592, 87C751 and 87C752; plus all Philips 89C51-family EEPROM microcontrollers, including 89CE528, 89CE558, 89CE598 and SAA5290NV.
- ◆ Software-driven programming data files allow easy upgrade for new Philips devices.
- ◆ Programming Adapters are available for all Philips EPROM/EEPROM microcontroller packages.

The Development Systems Company

AvCase51 Complete Embedded Software Development

- ▲ ANSI standard optimizing C compiler
- ▲ Compiled-stack optimization
- ▲ IEEE695 compatibility w/leading ICE vendors
- ▲ Bank switching
- ▲ Macro assembler/linker
- ▲ C-source level simulator debugger
- ▲ ROM monitor debugger
- ▲ Project-build utility
- ▲ GUI-based integrated development environment
- ▲ On-line help

AVOCET
 SYSTEMS, INC.

Product Information

AvCase is a set of integrated tools designed to turn your PC into an efficient working environment for embedded-system software development. Using the AvCase Integrated Development Environment (IDE), everything is only a mouse click away—editor, C compiler, assembler, linker, utilities, source-level simulator debugger, source level monitor debugger, on-line reference manual and project builder. Package discounts are available on the popular Cactus and Metalink ICEs, which can be operated from the IDE. The heart of the package though, is Avocet's mature full featured C Compiler and Assembler. When debugging is necessary, our revolutionary new Source-Level Simulator Debugger has power to spare. User-Defined Menus and port assignments along with the fully-configurable front-end make this package a must for any serious developer.

Processors Supported

All 8051 8 bit Derivatives.

Host Systems Supported

PC Compatibles.

Ordering Information

The Full AvCase Package (C Compiler, Assembler, Simulator & ROM Monitor Debugger) may be purchased for \$1595.00.

Component prices are as follows:

C Compiler/Assembler	\$ 895.00
Assembler	\$ 495.00
Source-Level Simulator	\$ 795.00
AVSIM Symbolic Simulator	\$ 495.00
Remote Monitor Debugger	\$ 95.00

Orders may be placed by telephone, mail-order or FAX. We accept VISA, Mastercard, Checks, Money Orders and Wire Transfers. Purchase Orders require prior credit approval. Please call for more details.

The Total Development Solution for the 8051 Family

The BSO/TASKING C-51 cross-compiler offers a new approach to high-level language programming for the 8051 family. It combines our 15+ years of experience in producing software tools for the embedded marketplace and our considerable expertise with the 8051 microcontroller.

Although intended as a general purpose programming language, C is perhaps most powerful in the area of real-time programming for embedded microcontrollers. Since the operators and type definitions match so well with the instruction sets and word lengths of microcontrollers, C is very efficient in terms of code size and execution speed for these devices.

C Compiler

Efficient ANSI C compiler with powerful 8051 extensions for all derivatives

Assembler

Intel compatible macro assembler and linker/locator with libraries supplied in source

CrossView Debugger

C and assembly level debugging with a full Windows interface

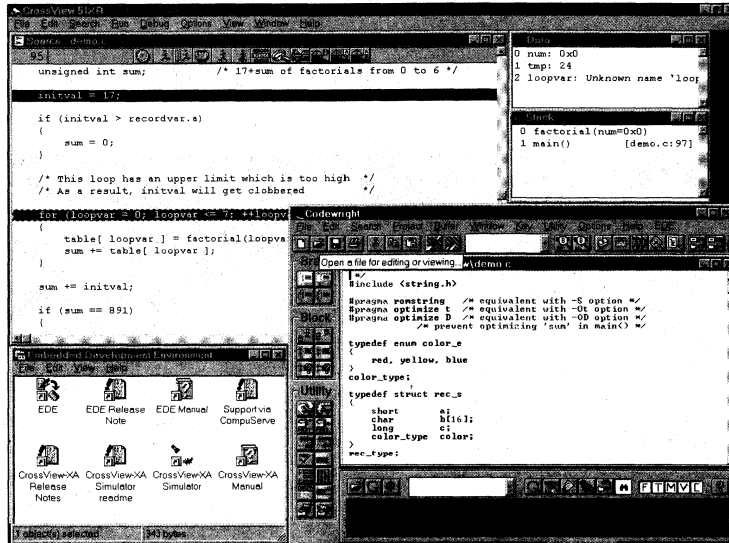

Embedded Development Environment

CODEWRIGHT WINDOW

Executive view where child windows for tools and manuals are launched and menu items are accessed.

OUTPUT WINDOW

Shows the results of compiling a source file. If errors are found they are reported together with the line number in the source where they occurred.

SOURCE WINDOW
The choice is available to create and/or edit text or binary files and check differences or merge files.

BSO/TASKING's EDE is a total programming environment that integrates all the tools a developer needs to create, edit, build, and debug an embedded application and provides:

- ▲ Accessible push-button control over a variety of development tasks spread over many tools
- ▲ Tight integration of tools enabling a rapid edit compile-debug process that leads to higher productivity by automating repetitive tasks
- ▲ Push button access to third party tools such as PVCS® from INTERSOLV or ApBUILDER from Intel

Contact Information

Product Information

To achieve all this we have integrated Codewright™ from Premia® in EDE. Codewright is more than a language sensitive editor, it is a complete environment which gives you direct access to the tools and features you need to be your most productive.

Codewright lets you define project environments with a set of commands (compile, assemble, make, debug etc.) for each type of file or project; so the files associated with an 8051, MCS 251 or XA project will automatically use the correct BSO/TASKING tools (compiler, assembler, make, debugger etc.). Codewright understands the error messages generated by the compiler and assembler, and shows you where the errors are, so you can fix them quickly. Interfacing to Version Control is easy. You can use the default commands, specify your own, or use the interface to PVCS we provide.

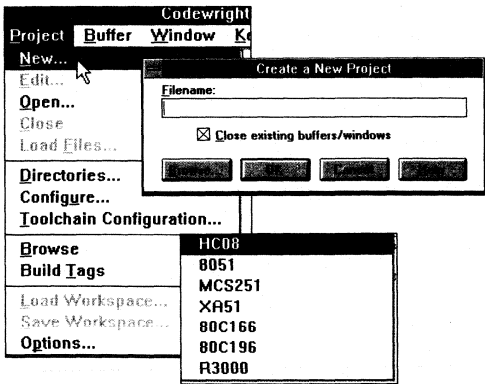

Call us today for a free demonstration kit.

BSO/TASKING UK	Tel: +44 1252 510014

Working with EDE

You start by setting up your project via the project menu; give the project a name, specify which files belong to the project and which microcontroller you are going to use.

Once you have done this, Codewright knows which toolset to use when you use the ribbon menu to access the compiler, or Make, or the CrossView debugger.

It also loads the correct user manuals for the microcontroller you have chosen.

The next step is to start coding using Codewright's language templates to help you. Once you have written some code you need to compile it to make sure there are no errors.

If errors occur then the error parsing mechanism recognizes the errors and displays the relevant source code with the cursor at the first error for you to correct it.

You then go to the next error by clicking a button in the ribbon menu until all errors have been corrected.

Then you recompile the code. Having got an error free file your next step is to run the code in the debugger. First you need to produce an executable by using *Make*. The 'makefile' specifies what actions need to be carried out to produce a complete and up-to-date executable.

The GCB11 Package provides a complete low-cost solution for

prototyping or small-scale production of networked or standalone control and data acquisition applications. High-

When you invoke the 'makefile' that you have tailored for your project (we provide examples) you compile, assemble, link, locate and format all the necessary files to produce your complete software product including any necessary C and runtime libraries.

The file produced is then ready to be loaded into CrossView for debugging.

level C libraries are provided for a variety of functions resulting in rapid prototyping and shorter time to market.

Click on the CrossView debugger icon on the ribbon menu and CrossView is launched without having to leave the embedded environment. Using CrossView's advanced features you verify that your program is correct.

Call us today for a free demonstration kit.

the C Compiler

The BSO/TASKING 8051 C compiler is built using the latest compiler technology, including optimization and multi-layering. It is essentially a one pass compiler, translating on a function by function basis, achieving very fast compilation and a large span for the optimization process. Significant effort was made to obtain a well-defined, layered product.

The top layer basically consists of a lexical and grammar analyzer with co-routine structures to serve both the preprocessing and compilation needs. The grammar analyzer is produced by an LALR(1) parser generator, eliminating a potential source of error. A second layer separates the actual code-generation layer from the top layer and simplifies retargeting of the compiler to other target processors. This is where most of the optimizations are done and it is designed to represent the translated program independent of the language and the target. The code-generation layer is driven both by the second layer and by a set of tables and rules reflecting the target assembly language and the behavior of individual instructions.

The 8051 family ANSI C compiler uses a number of sophisticated techniques to produce highly efficient code. The features that ANSI has brought to C compilers, together with the BSO/TASKING 8051 specific features and extensions brings a new dimension to programming the 8051 microcontroller family:

- Full ANSI C to ensure early error detection
- Complete 8051 family support
- In-line assembly
- Single precision floating point
- Memory keywords; data, idat, pdat, xdat and rom
- C level access to special function registers
- C level bit, interrupt and bit addressable 'chars' & 'ints'
- Automatic register bank switching
- Data overlay mechanism
- Powerful extensions including:
 - bit-type to use the on-chip bit addressable area
 - interrupt <number> and using <registerbank> for interrupt servicing at C-level
- Generates Intel compatible assembly source
- Outputs symbol information for source level debugging
- 4 memory models to best meet application requirements
- Complete C and run-time library support,
- Generates reentrant and relocatable code and data
- Full Intel OMF51 and IEEE695 v4.1 object formats
- Full calling interface with parameter passing to our PL/M51 compiler
- Intelligent configuration of startup code
- Keyword *_at* to connect a global or static variable to a logical address

▲ Efficiency

The C compiler has a number of features which make code production very efficient. The compiler also makes use of 8051 memory very efficiently.

- Function prototyping gives the user control over the size of parameters
- Parameter passing between functions is done using static 'fast internal RAM'
- Pointer sizes are automatically determined
- The compiler recognizes automatic variables and register variables that are used repeatedly and stores them in internal RAM
- In-line expansion of predefined functions such as 'rol', 'ror', 'da', 'testclear', 'setbit', 'putbit'
- Character 'switch' statement produces fast inline code
- Very efficient pointer arithmetic
- Fast 8 bit char arithmetic
- Fast parameter passing by avoiding the stack.

▲ The Target Environment

There are specific features in the 8051 C compiler that let the user tailor the output to the specific target environment

- 4 Different memory models - see next page
- Interrupt service routines can be written in C or assembly language
- ROMable code
- 8051 derivative is switch selectable
- User controlled mapping of code and data

▲ Memory Models

The compiler supports 4 different memory models: small, auxpage, large and reentrant. This enables the compiler to generate the best possible code for the particular hardware implementation. See the Memory Model table.

▲ Data Types

All ANSI types are supported. In addition to these types, bit, sfrbyte, sfrbit and bitbyte are added. The keywords sfrbyte and sfrbit are available to access special function registers which deal with I/O. Sfr's are treated like variables declared with the volatile type qualifier.

▲ Data Sizes

<u>type</u>	<u>size (in bytes)</u>
bit	1 bit
char	1
short int	2
int	2
long int	4
float, (long) double	4 (IEEE single precision)
pointer type	1 or 2

Pointers to data, idata and pdat have a size of 1 byte, but pointers to rom, xdat and functions have a size of 2 bytes.

▲ Code Optimizations

The compiler intermediate layer performs general code optimizations and the code generator does some final 8051 specific optimizations.

General optimizations include:

- Register allocation
- Branch optimization
- Dead code elimination
- Constant folding
- Arithmetic simplification
- Strength reduction
- Jump chaining
- Common subexpression elimination
- Loop rotation
- Induction variable elimination
- Sharing of string literals

Code generator optimizations:

- Store-copy optimization
- Peephole optimization

▲ Pragmas

The #pragma directive supplies target dependent data to the compiler without violating the ANSI C language, making the resultant program portable. In the BSO/TASKING C 8051 compiler pragmas are used to merge C lines with generated assembly, to control code generation for interrupt service routines and to support inline assembly programming.

▲ Libraries

The compiler is delivered with libraries for all combinations of the 8051 family. The libraries include ANSI C libraries, run time libraries including I/O calls (+ printf), memory management, arithmetic functions and floating point. Special libraries are included for floating point using internal RAM only. There is also a separate library to support the 80C751 derivative.

Source code is provided for most of the library routines allowing the user to tailor the libraries to their specific application.

▲ Compiler Switches

- ? Display invocation syntax
- Ccpu Use special function register definitions for cpu
- Dmc[=df] Define preprocessor macro

- E[m] Preprocess only or emit dependencies
- Hfile Include file before starting compilation
- Idirectory Look in directory for include files
- Ms Compile using small memory model
- Ma Compile using auxpage memory model
- Ml Compile using large memory model
- Mr Compile using reentrant memory model
- N Check for use of new style prototyping
- Oa Relax alias checking
- OA Strict alias checking
- Oc Enable common subexpression elimination (CSE)
- OC Disable CSE
- Od Enable constant and copy propagation
- OD Disable constant and copy propagation
- Of Produce fast code
- OF Produce small code
- Og Enable global CSE
- OG Disable global CSE
- Oo Overlay data
- OO Do not overlay data
- Ov Enable loop variable detection
- OV Disable variable detection
- Rm[=nm] Change segment name
- S Put strings in ROM only
- _Umac Remove preprocessor macro
- asize Change allocated space for variable argument list
- bnumber Specify default register bank number
- e Remove output file if compilation errors occur
- err Send diagnostics to error list file
- f file Read options from file
- g Enable symbolic debug information
- gt Enable symbolic debug information with function prototypes
- go Enable symbolic debug information for older debugger versions
- l Generate listfile
- li Generate listfile with expanded include files
- mm=size Specify memory size
- n Send output to standard output
- o file Specify output file name
- rs Select small ROM model
- rm Select medium ROM model
- rl Select large ROM model
- s Merge C source code with assembly output
- t Display module summary
- u Treat 'char' variables as unsigned
- v Don't generate interrupt vectors
- w[num] Suppress warning messages, or just one indicated by its number
- xsize Extend amount of internal RAM for automatics

▲ Memory Models

<u>model</u>	<u>data allocation</u>
small	static, in on-chip direct addressable RAM (data)
auxpage	static, in first page of external RAM (pdat)
large	static, in external RAM (xdat)
reentrant	dynamic + static, in external RAM (xdat)

<u>application</u>
fast programs in small environments
derivatives with 256 bytes on-chip "external" RAM
fast, non reentrant with large external RAM
large, reentrant programs in large environments

the Assembler

The BSO/TASKING assembler is an integral part of the toolset and delivers features that enable it to be used on its own. It is supplied complete with linker/locator, librarian and object format utilities.

The 8051 assembler translates 8051 assembly language into relocatable object code. The assembler accepts Intel compatible assembler source programs and produces relocatable (.obj) object files. An absolute or executable load image is then obtained by using the linker/locator. Features of the assembler include:

- Produces relocatable object code and listing files
- Accepts Intel compatible source programs
- Supports all members of the 8051 family
- Compatible with BSO/TASKING C and PL/M 8051 compilers
- Compatible with high level and assembly level debuggers
- Optimizes jmp/call instructions from the compiler
- Supports segment overlay at the assembly level
- Intel compatible macro preprocessor
- Number of symbols only limited by available host memory
- Extensive section directives
- Error file with textual error reporting

the Linker/Locator

The linker and locator is an essential part of the software building process that enables you to configure the code to match your target environment. The linker/locator brings together all the necessary relocatable objects, including library modules, resolves external references and then locates the modules in memory according to your specification. Features include:

- Intel compatible linker controls
- Accepts object files and object libraries in the Intel OMF-51 file format
- Supports absolute Intel OMF-51 and IEEE695 object formats
- Automatic segment overlaying using information from the compiler and assembler
- Absolute map files and diagnostic messages
- Incremental linking
- Automatic inclusion of library modules
- Map listing to help with debugging

Utilities

▲ Librarian

Listing utility with numerous options for showing:

- section records
- symbol table
- code bytes and much more

Format conversion utilities

▲ EDE

BSO/TASKING's new embedded development environment for the PC which includes:

- make utility
- C interface generator
- line searcher and sorter
- interface to INTERSOLV PVCS

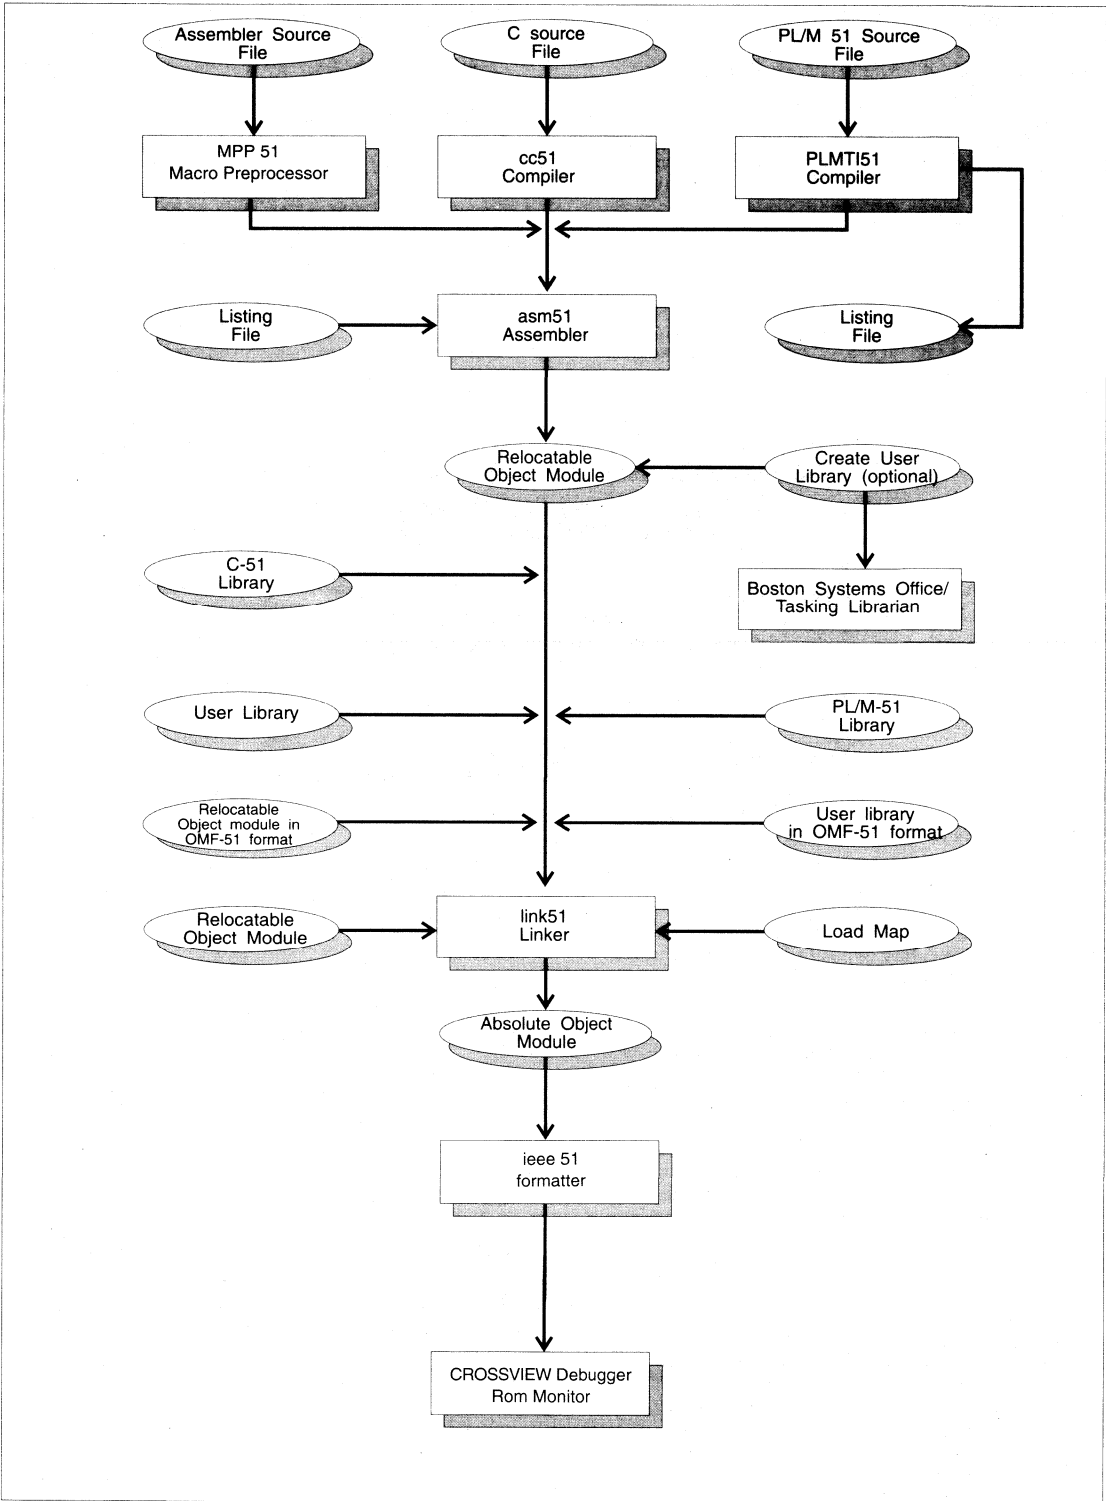

Availability

C compiler and Assembler are available now to run on:

PC DOS	SUN SPARC SUNOS
HP9000 HPUX	SUN SPARC Solaris
VAX VMS	IBM RS6000 AIX

Available from Philips as:

OM4144	80C51 Cross-Assembler / PL/M-Compiler package for PC/DOS
OM4285	80C51 Cross-Assembler / C-Compiler package for PC/DOS
OM4286	Cross View PC/DOS – MS/Windows Debugger for SDS80C51 (OM4120S)

8051 Tool-chain overview

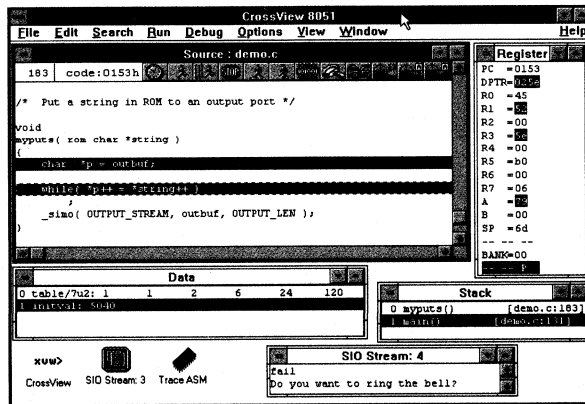

the Debugger CrossView Windows

CrossView is our high level language debugger designed to deliver functionality that will reduce the time spent testing and debugging. It combines the flexibility of the C language with the control of code execution found in assembly language debugging. CrossView brings the full power of Microsoft and X Windows to the debugging environment by displaying and updating the most critical execution data in an organized way.

Productive Debugging

CrossView has a number of productive debugging features designed specially for the embedded systems programmer:

- ▲ Single Stepping allows you to watch a program execute line by line. You can step single lines of source or, step in or over procedure calls.
- ▲ Code in C Debug in C. Automatic correlation of variables and line numbers
- ▲ Stack Trace shows the program's function calling path. Function calling sequence and parameter values passed are displayed at each level.
- ▲ Code breakpoints let you halt the program in critical places and observe values. Code breakpoints can be permanent, temporary or conditional by specifying standard C conditions
- ▲ Assertions let you execute user specified command lists after running every line of source code. This is the software equivalent of data breakpoints, they can be used to set up sophisticated error checking mechanisms that uncover the most elusive bug.
- ▲ Simulated I/O enables you to debug without input/output devices being available. Screen, keyboard or files can be used as I/O devices and eight streams can be active at a time.
- ▲ Data Monitoring is used to monitor any expression or variable continually.
- ▲ C Expression Evaluation lets you enter C expressions or CrossView commands in any combination and have them evaluated. You can even evaluate expressions which call functions defined in the source code.

- ▲ Command Line Function Calls used to pass sample parameter values and then checking the result is an ideal way to test subroutines.
- ▲ Macros let you store and recall complex commands and expressions via buttons.
- ▲ Context Sensitive Help provides complete command syntax and detailed description with hypertext links to the user manual.
- ▲ On-Line Tutorial is included and demonstrates the use of common CrossView command and debugging techniques in a real on-line debugging session.

Multi-window Interface

CrossView brings the full power of Microsoft and X Windows to organize and display every facet of the application as it is running in the target system. CrossView features multiple child windows, extensive menus and dialog boxes and user programmable buttons for macros. CrossView also has an accelerator bar which provides quick access to

frequently used debugging commands. Windows available include:

- Command Window
- Stack Window
- Source Window
- Simulated I/O Window
- Data Window
- Breakpoint Window
- Register Window
- Help Window
- Macro Window
- Trace window

ROM Monitor Environment

CrossView is supplied with a monitor for loading into RAM or ROM and can be configured for any 8051 family target board. All files required to build the monitor are shipped as source with CrossView, including a make file and documentation for retargeting the monitor.

The monitor program is approximately 3Kb. The internal data requirements are kept to a minimum: it only uses register bank 3, 20 bytes of stack space and 12 bits in bit addressable memory. All other monitor data (74 bytes) is stored in external memory

CrossView communicates with the monitor on the target board via an RS232 interface. It is possible to communicate directly with the ROM monitor with a terminal only, or from within CrossView via transparency mode.

Transparency Mode

CrossView enables direct communication with the target to give you access to the low level hardware features of the target system. There are 35 monitor commands which manipulate the registers, memory control execution.

Availability

CrossView Windows for 8051 will be available to run on:

PC DOS	SUN SPARC SUNOS
HP9000 HPUX	SUN SPARC Solaris
VAX VMS	IBM RS6000 AIX

Customer Support

Purchasing BSO/TASKING products marks the beginning of a long term relationship . BSO/TASKING is dedicated to providing quality products and support worldwide. This support includes program quality control, product update service and support personnel to answer questions by telephone or fax.

BSO/TASKING product support begins before the purchase of any of our products with extensive testing in order to ensure our high standard of quality assurance.

A 90 day maintenance plan is included with the purchase of BSO/TASKING products and entitles the customer to enhancements and improvements as well as individual response to problems. Annual maintenance contracts are available at the end of the 90 day maintenance plan. This extremely valuable service, in return for a small annual fee, provides the user with all program enhancements released during the period of the program maintenance agreement, and assures response to all problem reports submitted by the user.

BSO/TASKING

BSO/TASKING is an international software manufacturing company with headquarters in Massachusetts. Founded in 1974, BSO/TASKING is privately held with 100+ employees and revenues of \$19M. BSO/TASKING has offices in the United States, the Netherlands, Italy, Japan, Germany and the United Kingdom.

BSO/TASKING develops, manufactures, and supports software development tools for DOS, Unix and VMS programming environments. In 1974, the company pioneered the concept of 'cross development' on DEC platforms.

Today, BSO/TASKING is the leading supplier of software development tools for embedded and system applications across industry standard computing platforms. Software Products from BSO/TASKING are developed with great care at our innovative "Software Factory". A fully integrated environment for software development, modeled after and compatible with the standards defined in the ESPRIT project PCTE (Portable Common Tool Environment). This paradigm facilitates the creation of tools that execute in multiple environments (DOS, Unix, VMS) from a single master source file that is then verified with the Plum Hall Test Suite.

To complement the software development tools BSO/TASKING delivers cost effective hardware systems - in-circuit emulators and evaluation boards - integrated with our software to provide you with a Total Solution for all your embedded development needs. BSO/TASKING also provides consulting and training services to complement each product area.

BSO/TASKING supports products on PC/DOS, Sun SPARC, DEC VMS, DECStation/Ultrix, IBM RS6000, HP9000/300,400,700.

The company mission is to provide customers with highly integrated, leading-edge cross software development tools across industry standard computing platforms, coupled with the most comprehensive support and training services available.

Boston Systems Office, BSO, Boston Systems Office/TASKING, BSO/TASKING and CrossView are registered trademarks of Boston Systems Office Inc and TASKING B.V.

BSO/Tasking assumes no responsibility for any errors which may appear in this document.

BSO/TASKING retains the right to make changes to the specification at any time, without notice. Contact your local sales office to obtain the latest information.

Integrated Debugging System/LC (IDS/LC™)

- ▲ Combines the functions of an In-Circuit Emulator, 128K PROM emulator, editor and C source level symbolic and object code debugger in a Borland™ Turbo C like environment
- ▲ Works with 8051 C-compilers from Franklin, Keil, Archimedes/IAR, Avocet, Intermetrics/Whitesmith/Cosmic and 2500AD
- ▲ Provides real-time operation with no additional wait states
- ▲ Single Target Interface Unit™ supports 8051 family variants up to 20 MHz without costly adapters or pods. Our high speed option provides support of 33 MHz processors
- ▲ Offers 1,000 source or assembly level breakpoints
- ▲ Provides complete control of program execution with Run, Reset, Run to Cursor, Step and Stop commands
- ▲ Has 30-day money back guarantee and one year warranty

Product Information

Cactus Logic's low cost, real-time emulator, the Integrated Debugging System/LC (IDS/LC) provides a PC-based environment for 8051 firmware debugging and testing through your target system's PROM socket.

You control the debugging, editing, compiling and object code downloading functions using simple keystrokes or mouse clicks along with pull-down command menus and dialog boxes.

The command menu control the operation of the IDS and they can be activated with either the keyboard or the mouse. Hot-keys are provided for most commands.

Up to 1,000 powerful source and assembly level breakpoints are simple to set. They can be assigned to groups which can be enabled or disabled by other breakpoints to provide complex triggering. Breakpoints can also provide simulated input or output and logging of registers and variables.

CEIBO DS-51 Microprocessor Development System

In-Circuit Emulator for 8051 Family of Microcontrollers

FEATURES

- Real-Time and Transparent In-Circuit Emulator
- Supports Most of the 8051 Derivatives
- Emulates 1.5V to 6V Microcontrollers
- Maximum Frequency of 42MHz
- 128K of Internal Memory
- Banking Support
- 32K Trace Memory "on the Fly"
- 64K Hardware and Conditional Breakpoints
- DOS and MS-Windows Debuggers
- Source Level Debugger for Assembler, PLM and C
- On-line Assembler and Disassembler
- Performance Analyzer
- Serially linked to IBM PC at 115 Kbaud

CEIBO

TEL: 314-830-4084

FAX: 314-8304083

CEIBO DS-51 In-Circuit Emulator

DESCRIPTION

DS-51 is a real-time in-circuit emulator dedicated to the 8051 family of microcontrollers. It is serially linked to PC or compatible systems and carries out a transparent emulation on the target microcontroller.

The system emulates almost every 8051 derivative in the complete voltage and frequency range specified by the microcontroller manufacturer.

DS-51 also supports the new low-power and low-voltage 8051 microcontrollers and derivatives and can emulate the microcontrollers using either the built-in 5V power supply or any voltage applied to the target circuitry. The permitted voltage range is from 1.5V to 6V or higher.

The DOS and MS-Windows software includes Source Level Debugger for PLM and C, a unique Assembler Debugger, Performance Analyzer, On-line Assembler and Disassembler, Conditional Breakpoints and many other features.

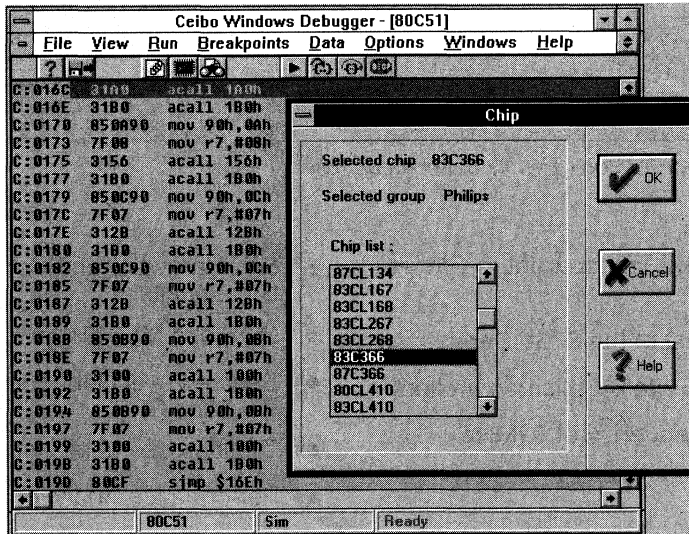

Files generated by the most common 8051 Assemblers and High-Level Language Compilers are accepted by DS-51.

Standard systems are supplied with 128 KBytes of internal memory with mapping capabilities, 64K hardware breakpoints, 32K real-time trace memory and logic analyzer with triggers and external test points, and personality probe C51 supporting most of the 40-pin DIP or 44-pin PLCC/QFP microcontrollers.

CEIBO DS-51 In-Circuit Emulator

SPECIFICATIONS

EMULATOR MEMORY

DS-51 provides 128 KBytes of code memory with software mapping and banking capabilities. This memory may be extended to 512 KBytes for additional banking support.

HARDWARE BREAKPOINTS

Breakpoints allow real-time program execution until an opcode is executed at a specified address. Breakpoints on data read or write and an AND/OR combination of two external signals are also implemented.

CONDITIONAL BREAKPOINTS

A complete set of conditional breakpoints permit halting program emulation on code addresses, source code lines, access to external and on-chip memory, port and register contents.

SOFTWARE ANALYZER

A 64 KByte buffer is used to record any software and hardware events of your program, such as executed code, memory accesses, port and internal register states, external or on-chip data memory contents and more.

LANGUAGES AND FILE FORMATS

DS-51 accepts files with many different formats. Assemblers and high-level languages such as C and PLM may be used with DS-51. Supported vendors are Intel, IAR, BSO/Tasking, Keil, Archimedes, 2500AD, MCC, etc.

SOURCE LEVEL DEBUGGER

The DS-51 Software includes a Source Level Debugger. This function may be used to debug code written in Assembler, PLM and C. The Source Level Debugger includes commands which allow the user to get all the information necessary for testing the programs and hardware in real-time. The commands permit setting breakpoints on high-level language lines, adding a watch window with the symbols and variables of interest, modifying variables, displaying floating point values, showing the trace buffer, executing assembly steps and many more useful functions.

PERSONALITY PROBES

DS-51 uses standard and bond-out microcontrollers for hardware and software emulation. The selection of a different microcontroller is made by replacing the microcontroller on the probe or changing the probe. The Personality Probes run at the frequency of the crystal on them or from the clock source supplied by the user hardware. Therefore, the same probe may be adapted to your frequency requirements. The minimum and maximum frequencies are determined by the emulated chip characteristics, while the emulator maximum frequency is 42MHz.

Most of the Philips devices are emulated by using standard devices operating in a special emulation mode. Therefore you may use the same personality probe for many derivatives, just by replacing the microcontroller. An example of the capabilities of a personality probe is given in the following table:

Microcontroller on the Probe Supported Microcontrollers

Philips 80C32 or 87C52	80C31/2, 8xC51/2/4/8
Philips 87C524 or 87C528	8xC524, 8xC528
Philips 87C51FB	8xC51FA/FB/FC
Philips 87C504	8xC504/8
Philips 87C550	8xC550
Philips 87C654	8xC652 8xC654

Probe C51 and Supported Microcontrollers

TRACE AND LOGIC ANALYZER

The 32 KByte trace memory is used to record the microprocessor activities. Eight lines are user selectable test points. Trigger inputs and conditions are available for starting and stopping the trace recording. The trace buffer can be viewed in disassembled instructions or high level language lines embedded with the related instructions. The trace window may be displayed on the fly, thus without stopping the emulation.

ITEMS SUPPLIED AS STANDARD

In-circuit emulator with 64 KByte breakpoints, 128 KByte internal code memory. Personality probe C51 for 8051 microcontrollers. User software including Source Level Debugger, On-line Assembler and Disassembler. User's Manual and Operating Instructions. RS-232 cable. Power supply.

OPTIONS

Personality probes for the different microcontrollers. Memory bank setup. Adapter for 44-pin PLCC devices.

PERFORMANCE ANALYZER

This useful function checks the software trace buffer and provides time statistics on modules and procedures as a percentage of the total execution time.

COMMAND SET

The available functions include: FILE (load, save), VIEW (watches, variables, module, CPU, dump, registers, trace, file), RUN (run, go, trace into, step over, execute, animate, halt, reset), BREAKPOINTS (toggle, expression true global, hardware breakpoint, delete all), DATA (inspect, evaluate, add watch), OPTIONS (environment, path, communications, architecture, mode, save, load), WINDOW (zoom, next, size, move, close), HELP (index, previous topic).

INPUT POWER

5VDC/1.5A.

MECHANICAL DIMENSIONS

26mm x 151mm x 195mm (1" x 6" x 7").

WARRANTY

Two years limited warranty, parts and labor.

CEIBO DS-51 In-Circuit Emulator

DS-51 WINDOWS DEBUGGER

DS-51 is supplied with a Source Level Debugger and Simulator for the 8051 architecture. The program allows fast and reliable debugging at source-level for PLM, C and Assembler of most of the available vendors. The Debugger operated with or without the DS-51 Emulator. Together with DS-51, the software executes all functions in real-time. You may also use the debugger as a stand-alone simulator to test your software even without any hardware, although not in real-time and at a speed depending on your PC.

The Debugger includes an On-line Assembler which you can invoke to change the executable code during the debugging session. As the Debugger is fully MS-Windows oriented, multiple windows and multi-tasking are permitted.

Global and Local Menus

A Global Menu lists the commands and is accessible through a menu bar that runs along the top of the window. From there, pull-down menus are available for every item on the menu bar.

The Debugger is context-sensitive and uses Local Menus tailored to the particular window you are in.

Input Boxes

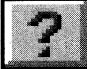

Many of the Windows Debugger Command Options are available in Input Boxes. An Input Box prompts you to type in a string. All your entries are recorded in a History Buffer, so you can pick up any entry just by selecting it with the arrow keys.

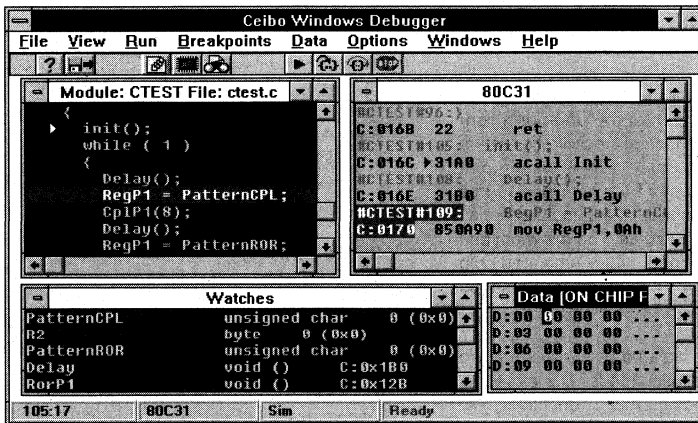

Status Line

The Status Line on the bottom of the main application window displays messages related to the cursor position in the Module window, chip type, operating mode (simulation, emulation or in-circuit simulation) and current status (program running, ready, error). It also provides on-line help information on selected menus.

Toolbar

The buttons on the Toolbar are the commands you need to operate the most useful functions:

-  get help information
-  open a File Dialog Box
-  open the list of Modules Dialog Box
-  select the CPU window
-  select the Watches window
-  run a program
-  instruction step
-  step with skip calls
-  halt a program

Windows Debugger

CEIBO DS-51 In-Circuit Emulator

TRACE OPTIONS

A selection of source code, disassembled instruction or mixed source and disassembled code is available to display the Trace Memory without stopping the emulation. Time Stamps can be used to display absolute or relative cycles or time. Filters may be defined to specify which instructions or sequences are of your interest. The software also has the capability to save the trace buffer in a disk file.

External Trace Start/Stop Triggers

DS-51 has two External Trigger signals that allow starting and stopping of the trace recording upon external events.

Stop Trace when Full or Continuous Recording Mode

There are two trace recording modes: Cyclic and Trace Full. In the Cyclic Mode the trace is continuously filled with recorded data. In the Full Mode recording stops when trace is full.

Selectable Trace Trigger Levels

The trigger state permits selecting the way trigger signals behave. The active mode may be either level or edge for the external start and stop trigger signals.

Trace Status on the Fly

Trace Status allows viewing information without stopping emulation. The Trace Status includes buffer full, buffer empty, length, etc.

Trace Filtering on Address Ranges

Up to 10 different ranges are allowed to filter the recorded data into the trace memory. The start and stop addresses of modules and procedures can be entered using special prefixes.

Trace Trigger Conditions

The bus cycle type, address and data bus contents are used to trigger the trace collection. Trace triggers recognize user-defined events, such as cycles, address matches and passcounts. A cycle specifies the execution state. The address match selects the address value or range. Addresses can be entered as symbols, modules and line numbers or as physical addresses. Passcount selects the number of times the event will be recognized before the trace trigger occurs.

The screenshot shows a window titled "Trace Dump (from -4610 to -1)". The window contains a table with the following columns: Frame #, Cycle, Adrs, and Instruction. The table lists various instructions and their addresses. A context menu is open over the table, listing options such as Goto..., Origin, Inspect, Display mode, Time stamps, Trace filters..., TP recording, Trace triggers..., Clear trace, Trace status..., Read all trace, and Print to file...

Frame #	Cycle	Adrs	Instruction
(-00166)	1	C:01BB E508	mov a,DelayCnt
(-00165)	1	C:01BD 950D	subb a,DelayValue
(-00164)	2	C:01BF 5000	inc CDELAY#29
(-00163)	2	C:01C0 22	ret
(-00162)	1	C:010E E590	mov a,RegP1
(-00160)	1	C:0112 FF	
(-00159)	2	C:0113 DF800	
(-00158)	1	C:0120 F590	
(-00157)	1	C:0122 25E0	
(-00156)	1	C:0124 F590	
(-00155)	1	C:0126 0510	
(-00154)	2	C:0128 8000	

Trace Window

CEIBO DS-51 In-Circuit Emulator

BREAKPOINT OPTIONS

DS-51 commands let Breakpoints be displayed, set and cleared. The different options are used to stop the emulation upon execution of simple events as well as combinations of complex hardware and software conditions. You may halt your program according to a selection of cycle type, address match condition, address range and passcount.

Breakpoint on Data Read/Write and Address
Real-time Hardware Breakpoints can be set on Data Read, Data Write, Data Read or Write and Opcode Fetch in any address range.

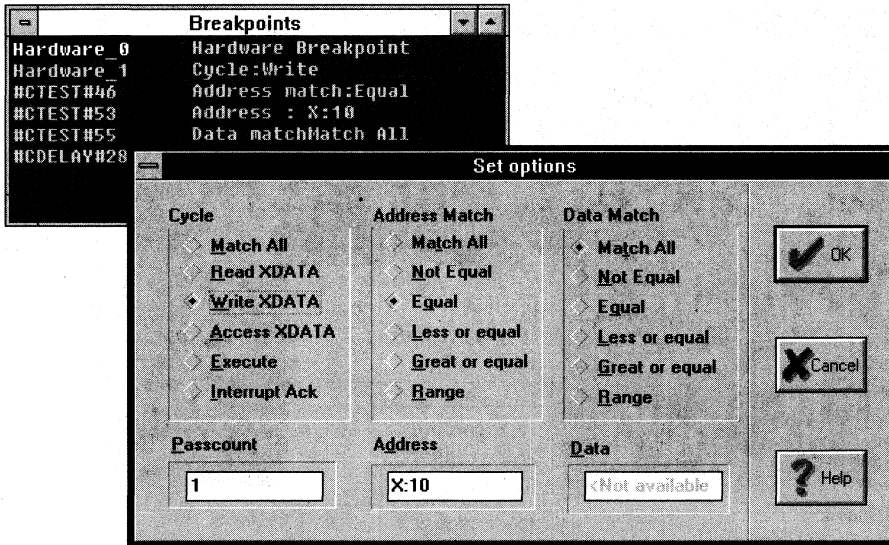

Stop Emulation on Passcount
Passcount on any event including opcode may be specified by the number of occurrences.

Breakpoint on External Events
Trace Testpoints may be used as External Breakpoints on hardware events if enabled. The External Breakpoint Triggers

may also be used as a Trace Full Condition; in this case, program execution will stop once it is full. The Logic Operator Commands allow selection of AND/OR combinations of the two External Breakpoints. The options are both low, any one is low, both are high, only one is high, both are leading edge, etc.

Expression True Global
The Expression True Global Command allows setting a breakpoint that will occur when the value of the specified memory space location matches the specified data value.

Change Memory Global
This command may be used to set a breakpoint on access to any specified memory space, regardless of the data contents.

Breakpoint Window

CEIBO DS-51 In-Circuit Emulator

Performance Analyzer

This function processes the information recorded in the trace buffer and provides a graphics representation of the executed modules and the percentage of time spent in each of them. The local menu of this window may be used to get more useful information about your software performance.

Configuration

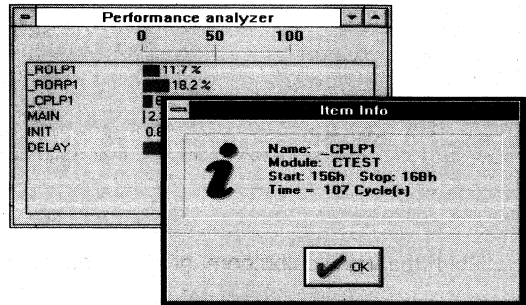

A dialog box allows the selection of the functions belonging to the module that you may want to include in the performance analysis; thus, you may configure the performance analyzer according to the relevant parameters.

Real-time Analysis

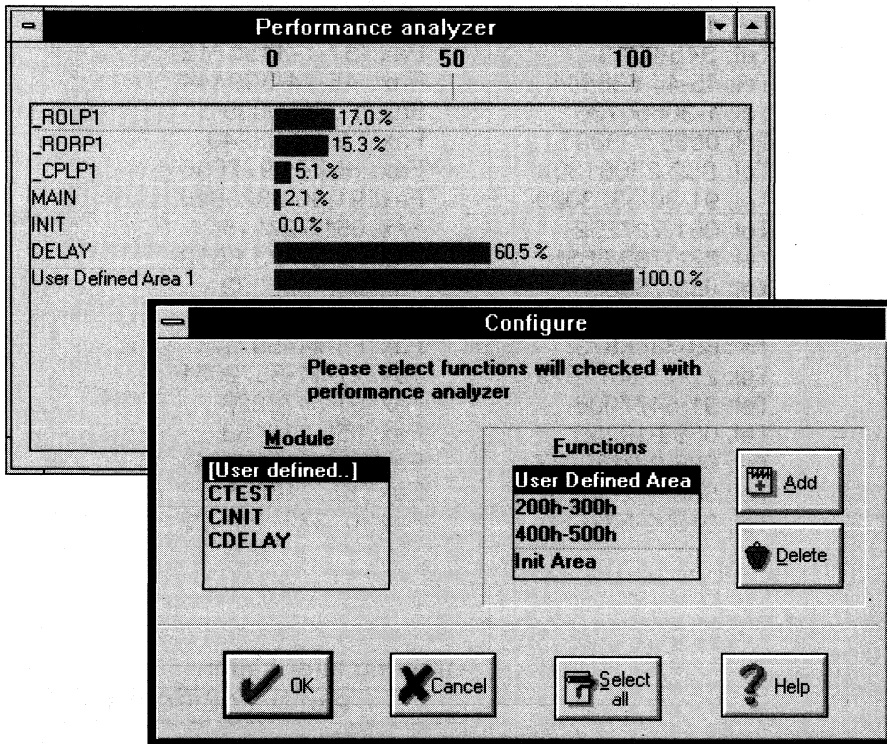

The window may be refreshed with the new data accumulated in the trace buffer without stopping the emulation.

Software Information

The Performance Analyzer provides all the relevant information related to a selected software module in the window.

CEIBO EB-51 Emulation Board

Development Tool for 80C51 Microcontrollers

FEATURES

- Emulates 80C51 Microcontrollers and Derivatives
- Real-Time Operation up to 40 MHz
- 3.3V or 5V Voltage Operation
- Simulation Debug Mode
- Source-Level Debugger for C, PLM and Assembler
- Runs under DOS and Windows Software
- Support for ROMless and ROMed Microcontrollers
- 64K of Code and 64K of Data Memory
- Data Memory with Mapping Capabilities
- Performance Analyzer
- Real-Time and Conditional Breakpoints
- Emulation Header and Signal Testpoints
- Serially Linked to IBM PC at 115K Baud

CEIBO

TEL: 314-830-4084

FAX: 314-8304083

CEIBO EB-51 Emulation Board

EB-51 is an Emulation Board dedicated to all Philips 80C51 microcontroller derivatives with a 40 or higher pin count. It is serially linked to PC or compatible systems and can emulate the microcontroller using either the built-in Clock Oscillator or any other clock source connected to the microcontroller. The Clock Oscillator generates 24MHz, 16MHz, 12MHz and 6MHz. The system emulates the microcontroller in both ROMless and ROMed mode. A special emulation technology is used to recreate Port 0 and 2 with standard devices, releasing most of the microcontroller resources to the user. A two microcontroller architecture leaves the serial port for user applications. The software includes a Source Level Debugger for C, PLM and Assembler, On-line Assembler and Disassembler, Software Trace, Conditional Breakpoints and many other features. The Debuggers run under DOS and MS-Windows operating systems. The Code Memory permits downloading and modifying of user's programs. Mapping the 64 KByte Data Memory to a target circuit or to the system is possible. Breakpoints allow real-time execution until an opcode is executed at a specified address or line of the Source Code. All I/O lines are easily accessed and may be connected to the on-board switches and LEDs when trying out a specific idea. The system is supplied with a User's Manual, Software, Emulation Cable and a Power Supply.

SPECIFICATIONS

SYSTEM MEMORY

EB-51 provides 64K of User Code Memory and 64K of User Data Memory. This RAM Memory permits downloading and modifying of user's programs and variables.

CODE MEMORY

The system includes 64 KBytes of RAM to be used as Code Memory. The upper 1 KByte of this memory are not available for programs and they are automatically loaded with a monitor program which links the microcontroller to the host computer and controls the emulation of the application software in real-time.

DATA MEMORY

Data Memory is accessed by MOVX instructions and can be mapped as belonging to the system or to the target circuitry.

BREAKPOINTS

Breakpoints allow real-time program execution until an opcode is executed at a specified address.

SOFTWARE TRACE

Program execution can be recorded in a 64K buffer. Conditional Breakpoints may be defined to stop program execution. The user can define events and variables to be added to the Software Trace. The Software Trace is not a real-time function and is performed by slowing down the emulation speed.

USER SOFTWARE

EB-51 is supplied with two software packages, one running under DOS and the other under MS-Windows exclusively. The DOS software is based on pull-down menus. The Windows program carries out similar functions as the DOS program with all the features and benefits of this operating system.

SOURCE LEVEL DEBUGGER

The EB-51 software includes a source level debugger for assembler and high level languages (PLM, C and others) with the capability of executing lines of the program while displaying the state of any variable.

FREQUENCY

The system includes a Crystal Oscillator able to support clock frequencies of 24MHz, 16MHz, 12MHz and 6MHz. The operating frequency range is from the microcontroller fmin to fmax in ROMless mode. The fmax in ROMed mode is 20MHz.

SIMULATION DEBUG MODE

The Simulation Debug Mode allows the software to be tested without any hardware. All the emulation functions are supported by this powerful Simulation Debugger.

VOLTAGE

The system has a built-in voltage regulator that permits selection of either a 5V or a 3.3V voltage supply. Selection is done by setting the position of the power switch to the desired voltage.

PERSONALITY ADAPTERS

EB-51 uses standard microcontrollers for hardware and software emulation. The selection of a different microcontroller is made by replacing the microcontroller on the board with the appropriate microcontroller or a daughter board.

SUPPORTED MICROCONTROLLERS

The supported microcontrollers are most of the Philips 80C51 derivatives in both ROMless and ROMed versions:

8031/2, 80C51/2/4/8, 87C51/2/4/8, 8xC51FA/FB/FC, 8xL51FA/FB/FC, 8xC504/8, 8xC524, 8xC528, 8xC550, 8xC552, 8xC562, 8xC652, 8xC654.

Consult Ceibo for other supported microcontrollers.

EMULATION RESTRICTIONS

The following emulation restrictions are valid for EB-51:

- RD and WR lines may not be used as I/O ports. There are no restrictions while RD and WR are activated by MOVX instructions.
- The system uses some of the microcontroller resources to emulate it: one interrupt (either INTO or INT1 according to software selection) and 3 Bytes of the internal stack.

MECHANICAL DIMENSIONS

10cm x 10cm.

ITEMS SUPPLIED AS STANDARD

Emulation board, 40-pin Emulation Header, User Software including Source Level Debugger, Simulator, Assembler, User's Manual, RS-232 Interface Cable and Power Supply.

WARRANTY

Two years limited warranty, parts and labor..

CEIBO EB-51 Emulation Board

EMULATION MODES

Three working modes are available: Real-time, Simulator and In-Circuit Simulator. In the Real-time Mode the user software is executed transparently and without interfering with the microcontroller speed. Breakpoints can be added to stop program execution at a specific address. The Simulation Mode is used to debug the software without any hardware. Therefore, EB-51 may be disconnected from your PC while using the simulation mode. In the In-Circuit Simulation Mode an additional microprocessor is used to take control of the microcontroller lines and to simulate its operation but not in real-time. This operating mode allows access to all the microcontroller functions (I/O, timers, etc.) and interacts with the hardware according to the user software execution or directly by means of emulator commands sent from the host computer. The Trace, Complex Breakpoints, Performance Analyzer and many other useful functions are enabled in the In-Circuit Simulation Mode. The combination of all the available working modes allows an easy way to debug hardware and software functions.

CIRCUIT DESCRIPTION

Circuit Layout

On the top of the board you will find six 8-pin connectors. They may be used to easily interface EB-51 to an application board or to carry out test programs using the on-board resources. The Switches connector provides logic states to input ports. The LEDs connector permits to connect any logic signal and to observe its logic state. Port 0 to 3 are accessed through the 8-pin connectors, additionally to the Emulation Header. Port 0 and 2 are taken from the reconstructed signals. That means, these ports are being recreated and are not the direct bus signals from the microcontroller. You may also connect the supplied flat cable with the 40-pin socket attached to Emulation Header to a target circuit. EB-51 is supplied with an 8-wire ribbon cable to connect the ports to LEDs and Switches, thus allowing to easily test your program.

EB-51 emulation frequency is defined by the 24MHz crystal oscillator installed on a socket. The 24MHz is the maximum frequency you can apply to the microcontroller while emulating the on-chip ROM. In ROMless mode the maximum frequency may be up to 40MHz, depending on the microcontroller installed in the board. A lower frequency is achieved by dividing the 24MHz according to a jumper selection. You can connect any frequency you desire to the microcontroller from an external clock source. Different frequency options may be achieved by replacing the 24MHz crystal oscillator by another oscillator.

EMULATION SUPPORT

The list of emulation support for standard EB-51 systems is as follows:

Microcontroller on EB-51	Supported Microcontrollers
Philips 80C32 or 87C52	80C31/2, 80C51/2, 87C51/2
Philips 87C524 or 87C528	8xC524, 8xC528
Philips 87C51FB	8xC51FA/FB/FC
Philips 87C550	8xC550
Philips 87C504	8xC504/8
Philips 87C654	8xC652, 8xC654

Supported Microcontrollers

Using Philips microcontrollers activate the "ROM Emulation Mode". Using different microcontrollers not listed above may cause the system to operate only in ROMless mode. 3.3V and 5V operation may be achieved by using a 3.3V set of chips that are able to operate at both voltages.

The following table gives the 3.3V and 5V supported devices:

Microcontroller on EB-51	Supported Microcontrollers
Philips 87L51FB	8xL51FA/FB/FC

3.3V and 5V Supported Microcontrollers

By using different Daughter Boards, you can emulate additional 80C51 derivatives. The addition of the 80C552 Daughter Board allows emulation of the microcontrollers listed in the following table:

Microcontroller on EB-51	Supported Microcontrollers
Philips 87C552	80C552, 83C552, 87C552, 80C562, 83C562 80C552

Supported Microcontrollers

As the list of supported devices and available Daughter Boards is continuously evolving, call Ceibo to receive the latest update.

CEIBO EB-51 Emulation Board

DEBUG CAPABILITIES

The Windows Debugger is used to load a program, execute it in real-time, simulate the software environment as well as many other functions. Following are the capabilities of the debugger.

TRACING

Your program may be executed one line at a time. You can trace a program using high-level language lines or assembly instructions.

STEPPING

This is like tracing but program execution steps over CALL instructions without leaving the current procedure.

VIEWING

Ceibo Windows Debugger opens special windows showing your program state from various perspectives: variables and their values, breakpoints, a source file, CPU registers, memory, peripheral registers, etc.

INSPECTING

The debugger can delve deeper into your program and show you the variable contents.

CHANGING

The current value of a variable can be replaced with your specified value.

WATCHING

Program variables can be isolated and their values kept track of while the program runs.

The screenshot displays the Ceibo Windows Debugger interface for a 80C51 microcontroller. The main window shows the source code for 'Module: SERIAL File: serial.c' with the following code:

```

SystemInit();          /* 8051-board init
while (1)              /* Endless loop
{
    SendTestMessage();
    if ( CommError != NoError )
}
    
```

Below the source code is a 'Trace Dump (from -282 to -1)' window showing the following data:

Frame #	Cycle	Adrs	Instruction
(-00009)			TMOD = (TMOD)
(-00009)	1	C:0113	E589 mov
(-00008)	1	C:0115	540E and
(-00007)	1	C:0117	4428 orl
(-00006)	1	C:0119	F589 mov
(-00005)			TMODSave = T
(-00005)	2	C:011B	858925 mov
(-00004)			#UART#68: }
(-00004)	2	C:011E	22 ret
(-00003)			#SERIAL#46: }

On the right side, there are two windows showing peripheral registers:

- Serial**: SCON = 0x50, SBUF = 0x0
- Interrupt**: IE = 0x90, IP = 0x0

At the bottom, there is a '80C51' window showing assembly code for the 'SendTestMessage' function:

```

#SERIAL#105: SendTestMessag
C:0262 1201E1 lcall SendTestMe
#SERIAL#106: if ( CommError
C:0265 E511 mov a,CommError
C:0267 4518 orl a,CommError
C:0269 680A jz SERIAL#111
#SERIAL#108: P1 = ~P1;
C:026B 6390FF xrl P1,0FFh
#SERIAL#109: PrintError(C
C:026E AF11 mov r7,CommError
    
```

The status bar at the bottom shows '105:27', '80C51', 'Sim', and 'Ready'.

CEIBO DB-51 Development Board

Development Board for Philips 80C51 Microcontrollers

FEATURES

- Supports Most of the Philips 80C51 Microcontrollers
- Serially linked to IBM PC or Compatible Hosts
- 32K of User Code Memory
- Software Breakpoints
- Examine and Alter Chip Registers, RAM and Ports
- Source Level Debugger FOR C, PLM and Assembler
- Upload and Download of Object and Hex Files
- Special Wire-Wrap Area for Prototyping
- User's Manual with Examples and Applications
- Adaptable to 80C51XA Microcontrollers

CEIBO DB-51 Development Board

DB-51 is a high-performance system design board dedicated to the Philips 80C51 family of microcontrollers. It provides an easy-to-use flexible instrument which enables the user to build a primary prototype, analyze and debug it, make changes and continue debugging. You can improve your design decisions by using the DB-51 to check and test the advantages of several different microcontrollers. The DB-51 is also a great training and tutorial aid for becoming familiar with designs using the 80C51 architecture. Note that the DB-51 is not intended to replace a full emulator system in complex microcontroller designs.

SPECIFICATIONS

SYSTEM MEMORY

DB-51 provides 32K of User Code Memory. This RAM memory permits downloading and modifying of user's programs.

BREAKPOINTS

Breakpoints allow real-time program execution until an opcode is executed at a specified address.

CONDITIONAL BREAKPOINTS

A complete set of Conditional Breakpoints permits halting program emulation on code addresses, source code lines, access to on-chip memory, ports and register contents.

USER SOFTWARE

Three software packages are included: C51DB, DW51 and DB51. C51DB is the most advanced debugger and is the recommended software package for working with DB-51. DW51 program is based on pull down menus while DB51 software is based on line-commands. On-line Assembler and Disassembler are provided together with upload and download capabilities of hexadecimal and object files. Also, DB-51 includes the following functions: Source Level Debugger for PLM and C, Software Trace, Conditional Breakpoints, Performance Analyzer and a unique Assembler Debugger.

SOURCE LEVEL DEBUGGER

DB-51 gives full support for debugging directly in PLM and C source code. From your code source you can specify a breakpoint, execute a line step or an assembly instruction, open a flexible-in-size watch window to display any variable, use the function keys to display the trace memory, registers and data, redefine the Program Counter and reset the microcontroller.

SOFTWARE ANALYZER

A 64 KByte buffer is used to record any software and hardware events of your program, such as executed code, memory accesses, port and internal register states, on-chip data memory and others. The Trace Buffer can be viewed in disassembled symbolics or high-level language source code.

LANGUAGES AND FILE FORMATS

DB-51 accepts files generated by Intel software (Assembler, PLM) or compatibles in hex or object formats. Other assemblers and high-level languages such as C with Intel OMF51 compatible format (BSO/Tasking, Keil, IAR, etc.) are also supported.

SUPPORTED MICROCONTROLLERS

8x31/51, 8x32/52, 8xC31/51, 8xC51FA/FB/FC, 8xC32/52/54/58, 8xC652, 8xC654, 8xC851, 8xC550, 8xC552, 8xC562, 8xC451, 8xC528 and others with external memory addressing and a UART are fully supported. 8xCL410, 8xC751 and 8xC752 have very limited support.

80C51XA SUPPORT

A complete kit including a Windows Debugger, firmware and hardware adapters are available to upgrade DB-51 for supporting 80C51XA microcontrollers. Call Ceibo for more information.

LIMITATIONS

"Fully supported" microcontrollers are self-debugging on the DB-51. Thus, some of the chip resources are used by the board: the monitor program uses the bottom 32K of program memory; chips are always operated in the external memory mode; the UART is used to communicate with the PC and is not normally available to the user program; interrupt response is slowed slightly by re-vectoring from the monitor program to the user program; use of watchdog timers and power-down and idle modes of operation are limited due to interaction with the monitor program. "Limited supported" microcontrollers do not have on-chip UARTs and most do not support external program memory. Thus, download of programs to these parts is not supported on the DB-51. The 87C751 or 87C752 provided with the board is pre-programmed with a "micro" monitor program and some predefined experiments described in the user manual. Also, these parts use the I²C bus to communicate with the PC, limiting the use of I²C for other purposes.

INPUT POWER

7.5 VDC to 12.0 VDC (9 VDC wall transformer supplied).

MECHANICAL DIMENSIONS

20cm x 25cm.

ITEMS SUPPLIED AS STANDARD

DB-51 board, 80C552 and 87C751 or 87C752 microcontrollers, Monitor EPROM, Power Supply, RS-232 Cable. User Software including Symbolic Debugger, On-line Assembler and Disassembler. User's Manual and Operating Instructions.

WARRANTY

Two years limited warranty, parts and labor.

CEIBO DS-750 Microcontroller Development Tool

Development Tool for 87C750 Microcontrollers

FEATURES

- Emulates 87C750 Microcontrollers in Real-Time
- Programmable Clock up to 40MHz
- Built-in Programmer for 87C750/1/2 and 87C748/9
- Simulator Debug Mode
- Source-Level Debugger for C, PLM and Assembler
- Runs under DOS and Windows
- 24-pin DIP Emulation Header
- Serially Linked to IBM PC at 115 Kbaud

CEIBO

TEL: 314-830-4084

FAX: 314-8304083

CEIBO DS-750 Microcontroller Development Tool

DS-750 is a development tool that supports Philips 87C750 microcontrollers at any frequency allowed by the devices. It is serially linked to a PC or compatible system and can emulate the microcontroller using either the built-in Clock Oscillator or any other clock source connected to the microcontroller. The Clock Oscillator generates 40MHz, 20MHz, 16MHz, 10MHz and 5MHz. Emulation is carried out by programming an 87C752 microcontroller with the user software and an embedded monitor program. DS-750 provides the on-board programming capabilities and locates the monitor in the upper 1K that is not available for the 87C750. Two working modes are available: Real-time and Simulator Debug Mode. In the Real-time Mode the user software is executed transparently and without interfering with the microcontroller speed. Breakpoints can be added to stop program execution at a specific address. In the Simulator Debug Mode, an additional microcontroller is used to take control of the 87C750 lines and to simulate its operation but not in real-time. This operating mode allows access to all the microcontroller functions (I/O, timers, interrupts, etc.) and interacts with the hardware according to the user software execution or directly by means of emulator commands sent from the host computer. The combination of the two available working modes allows an easy way to debug hardware and software functions. The software includes C and PLM and Assembler Source Level Debugger, On-line Assembler and Disassembler, Software Trace, Conditional Breakpoints and many other features. The software is based on DOS pull-down menus and runs also under MS-Windows. The system is supplied with a User's Manual, microcontroller documentation, two samples of the 87C752 and one of the 87C750 (all windowed EPROM microcontrollers) and a power supply.

SPECIFICATIONS

MONITOR PROGRAM

The Monitor Program links the microcontroller to the host computer and is used to control the emulation of the application software in real-time. The monitor code is transparent for the 87C750 and does not reduce the 1KByte of available code for the application.

BREAKPOINTS

Breakpoints allow real-time program execution until an opcode is executed at a specified address. Breakpoints are set when an EPROM device is programmed with a user's code, but can be disabled although disabling a breakpoint implies adding a few cycles to the program execution.

USER SOFTWARE

DS-750 program runs under DOS and MS-Windows. The program is based on pull-down menus with many useful debugging functions.

SYMBOLIC DEBUGGER

DS-750 allows symbolic debugging of assembler or high-level languages. The Symbolic Debugger uses symbols contained in the absolute file generated by the most commonly used Assemblers and high-level language Compilers.

SOURCE LEVEL DEBUGGER

The DS-750 software includes a Source Level Debugger for Assembler and high-level languages (PLM, C and others) with the capability of executing lines of the program while displaying the state of any variable.

SOFTWARE TRACE

Program execution can be recorded in a 64K buffer. Conditional Breakpoints may be defined to stop program execution. The Software Trace is not a real-time function and is performed by slowing down the emulation speed.

FREQUENCY

The system includes a Crystal Oscillator able to supply clock frequencies of 5MHz, 10MHz, 16MHz, 20MHz and 40 MHz. Additionally, the user may select any other frequency by connecting an external clock source through the application hardware. Frequency selection is done by means of jumpers.

SIMULATOR DEBUG MODE

The Simulator allows breakpoints to be set at any address and condition even though the user software is actually programmed in the 87C752 EPROM. The Simulator Debug Mode will be automatically activated in case a breakpoint is enabled and not programmed in the device.

BUILT-IN PROGRAMMER

The Built-in Programmer may be used to program the following devices: 87C748, 87C749, 87C750, 87C751 and 87C752. All the programming features like security and encryption are fully supported.

EMULATION RESTRICTIONS

The following restrictions are valid for DS-750:

1. The system uses some of the microcontroller resources to emulate it: one Interrupt (either INT0 or INT1 according to software selection) and 5 bytes of the Internal Stack.
2. If you specify a breakpoint not programmed in the device, program execution will be slowed down by the Simulator.
3. Disabling a programmed breakpoint will add a few cycles to the program execution. This only happens while reaching the specified condition, otherwise the real time is not affected.

HOST CHARACTERISTICS

IBM PC or compatible systems with 640 KBytes of RAM, one floppy disk drive, one RS-232C Interface card for the PC, PC-DOS 5.0 or later.

INPUT POWER

15V to 30VDC (15 VDC/120 VAC wall transformer supplied).

MECHANICAL DIMENSIONS

10cm x 10cm.

ITEMS SUPPLIED AS STANDARD

Development System with Built-in Programmer. 24-pin Emulation Header. User Software including Source Level Debugger, On-line Assembler and Disassembler. User's Manual and Operating Instructions. RS-232 Interface Cable. Power supply.

WARRANTY

Two years limited warranty, parts and labor.

CEIBO DS-752

In Circuit Emulator

In-Circuit Emulator for 8xC7548/9 and 8xC750/1/2 Microcontrollers

FEATURES

- Real-time and Transparent In-Circuit Emulator
- Supports Philips 8xC748/9 and 8xC750/1/2 Microcontrollers
- Adaptable to other 80C51 Derivatives
- 2K of Internal Memory
- 2K Hardware Breakpoints and Conditional Breakpoints
- 32K Real-Time Trace "On the fly"
- DOS and MS-Windows Software
- Performance Analyzer
- Source-Level Debug for C and PLM
- On-line Assembler and Disassembler
- Serially Linked to PC or Compatible

CEIBO

TEL: 314-830-4084

FAX: 314-8304083

CEIBO DS-752 In Circuit Emulator

DS-752 is a real-time, high performance microcontroller development system dedicated to 8x748/9 and 8x750/1/2 single-chip microcontrollers. DS-752 provides both a low-cost solution for developing embedded applications with the Philips small microcontrollers and the possibility to upgrade the system for any other 80C51 derivative you may need. This adaptability consists of a kit including a personality probe for other desired microcontrollers, software and hardware replacements. The system features real-time trace and breakpoints and comes with DOS and MS-Windows Debuggers. The software includes Source Level Debugger for C and PLM, Performance Analyzer, On-line Assembler and Disassembler, Conditional Breakpoints and many other useful functions. Files generated by the most common 8051 Assemblers and high-level language Compilers are accepted by DS-752. Standard systems are supplied with 2 KBytes of Internal Memory, 2K Hardware Breakpoints, 32K Real-Time Trace Memory and Logic Analyzer with external test points, and adapters for 24-pin and 28-pin DIP devices.

SPECIFICATIONS

EMULATOR MEMORY

DS-752 provides 2 KBytes of Code Memory expandable for other 80C51 derivative support.

HARDWARE BREAKPOINTS

Breakpoints allow real-time program execution until an opcode is executed at a specified address. Breakpoints on an AND/OR combination of two external signals are also implemented.

CONDITIONAL BREAKPOINTS

A complete set of Conditional Breakpoints permit halting program emulation on code addresses, source code lines, access to on-chip memory, port and register contents.

LANGUAGES AND FILE FORMATS

DS-752 accepts files with Intel OMF51 object or hex format. Assemblers and high-level languages such as C with OMF51 format (Intel, Keil, Archimedes, IAR, MCC, BSO/Tasking, AD2500, etc.) are also supported.

SOURCE LEVEL DEBUGGER

The DS-752 software includes a Source Level Debugger for Assembler and high-level languages (PLM, C and others) with the capability of executing lines of the program while displaying the state of any variable.

TRACE AND LOGIC ANALYZER

The 32 KByte real-time Trace Memory is used to record the microprocessor activities. Eight lines are user selectable test points. Trigger inputs and conditions are available for starting and stopping the trace recording. The trace buffer can be viewed "on the fly" in disassembled instructions or high level language lines embedded with the related instructions.

FREQUENCY CHARACTERISTICS

The emulator runs at the frequency of the crystal included in the system or from the clock source supplied by the target hardware. Therefore the emulator may be adapted to your frequency requirements. The minimum and maximum frequencies are determined by the Philips emulation chip characteristics, while the emulator maximum frequency is 42MHz.

PERFORMANCE ANALYZER

This useful function checks the software trace buffer and provides time statistics on modules and procedures as a percentage of the total execution time.

SUPPORTED DEVICES

83C748, 87C748, 83C749, 87C749, 83C750, 87C750, 83C751, 87C751, 83C752, 87C752.

HOST CHARACTERISTICS

IBM PC or compatible system with 1 MBytes of RAM and one RS-232C port.

INPUT POWER

5VDC/1.5A.

MECHANICAL DIMENSIONS

26mm x 151mm x 195mm (1" x 6" x 7").

ITEMS SUPPLIED AS STANDARD

In-Circuit Emulator with 2 KByte Breakpoints, 2 KByte Internal Code Memory. 24- and 28-pin DIP Emulation Header. User Software including Source Level Debugger, On-line Assembler and Disassembler. User's Manual and Operating Instructions. RS-232 Cable. Power Supply.

OPTIONS

Upgrade kit to other 80C51 microcontrollers. Call Ceibo for more information.

WARRANTY

Two years limited warranty, parts and labor.

CEIBO MP-51 Programmer

EPROM, Flash, PLD and Microcontroller Programmer

FEATURES

- Programs all the Philips 80C51 and 80C51XA Microcontrollers
- EPROM, Flash, PLD and Microcontroller Programmer
- Programs 16-bit Microcontrollers
- Supports 24 to 32-pin EPROMs
- Programs 32-pin Flash Memories
- Programs PLD and PSD Devices
- Serially Linked to PC
- Macros and Easy to Follow Menus
- Handles Hex, Binary, Object and JEDEC Files
- Programs DIP, QFP, LCC and PLCC Devices
- Supports Lock Bits, Encryption Table and Security Bits

CEIBO

TEL: 314-830-4084

FAX: 314-8304083

CEIBO MP-51 Programmer

Ceibo MP-51 is an EPROM, Flash Memory, PLD and Microcontroller Programmer dedicated to standard 24 to 32-pin EPROMs, all of the microcontrollers belonging to the 8051 family, 16-bit microcontrollers, high-density PLDs, PSD devices and Flash Memories. Its modern design provides a high performance instrument, which is easy to use and conveniently sized. MP-51 operates with an IBM PC or compatible personal computer and carries out a set of powerful functions on the selected device. An RS-232 Interface is used to link MP-51 to a PC. The unit consists of the instrument and adapters. The adapters may be replaced to suit the user's requirements. Adapters are available for all the possible packages such as DIP, LCC, PLCC and QFP. MP-51 software handles a PC Memory Buffer where code is loaded from a disk or filled with the contents of a device. Furthermore, this buffer may be saved on a disk file, parts of the buffer can be moved from one location to another, filled with a constant, or modified by the user. The Memory Buffer can be displayed, and finding values or strings in it is possible. Before programming, MP-51 checks if the installed adapter is compatible with the device type selected by the user. This test is done before programming any device. MP-51 has the capability to check if the device is totally erased, and can also compare if the contents of the plugged device are equal to the contents of the Memory Buffer. Address range can be specified for both operations. MP-51 allows the PLD or microcontroller security capabilities to be enabled or disabled and handles the Lock Bit 1, Lock Bit 2, Lock Bit 3 and the Encryption Table available in several microcontrollers.

SPECIFICATIONS

SUPPORTED DEVICES

Following is a list of supported devices:

EPROMs: 2716, 2732, 2764, 27128, 27256, 27512, 27010, 27020, 27040, both NMOS and CMOS versions for all the available programming voltages.

FLASH MEMORIES: 28F256, 28F512, 28F010, 28F020.

8/16 BIT MICROCONTROLLERS: PCD3745A, PCD3755A, PCD3756A, 8751H, 8751BH, 87C51, 87C51FA, 87C51FB, 87C51FC, 87L51FA, 87L51FB, 87L51FC, P51XAG17, P51XAG27, P51XAG37, 8752BH, 87C52, 87C54, 87C58, 87CL134, 87C451, 87C453, 87C504, 87C508, 87C520, 87C524, 87C528, 87C530, 87C550, 87C552, 87C560, 87C575, 87C576, 87C592, 87C598, 87C652, 87C654, 87C748, 87C749, 87C750, 87C751, 87C752, 87C754, 87C766, 87C769, 87CL880, 87C054, 87C055, 89CE558, PCA5097 and many others.

PLDs: AT22V10, ATV750, ATV2500, ATV5000, ATV5100. PSDs: PSD301, PSD301L, PSD302, PSD302L, PSD303, PSD303L, PSD311, PSD311L, PSD312, PSD312L, PSD313, PSD313L.

FILE FORMATS

MP-51 loads different file formats: Intel Hex and Motorola S-records, Binary files, Object files and JEDEC files. It saves portions of memory in Intel, Motorola, Binary and JEDEC formats.

USER SOFTWARE

The MP-51 commands are organized in pull-down menus and windows. This software is powerful yet extremely user friendly.

INPUT POWER

85VAC to 265VAC, 50Hz to 60Hz. That makes this unit suitable for any country outlet.

MECHANICAL DIMENSIONS

MP-51 is 155mm long, 60mm high and 250mm wide.

ITEMS SUPPLIED AS STANDARD

MP-51 Programmer, User Software, User's Manual, RS-232 Cable. PMP-51 includes PPA-51X (87C51D-40 pin DIP adapter). Power cord not included.

ADAPTERS AND SUPPORTED DEVICES

The following list shows which adapter should be used for the different supported microcontrollers.

WARRANTY

Two years limited warranty, parts and labor.

ADAPTER	SUPPORTED PHILIPS DEVICES

ChipView®-51

ChipView®-51 High-Level/Low-level Debugger

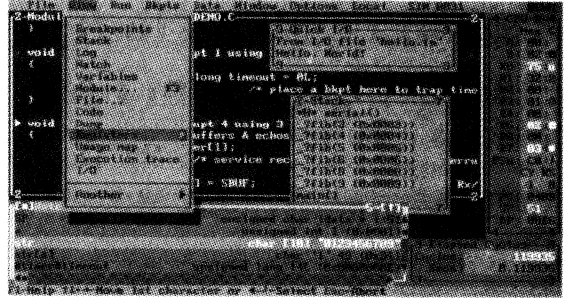

- ▲ No learning curve— ChipView-51 is key-compatible with Borlands's popular turbo debugger
- ▲ High-level support for C compilers, PL/M and assemblers from Archimedes, Franklin, IAR, Intel, Keil and BSO/Tasking
- ▲ Point & click to toggle bkpts, or to watch or inspect C expressions with a mouse, menus or hot-keys
- ▲ C-level debug displays C call stack and C data browsers with full variable data type & scope information
- ▲ Fully interactive VGA+ Windows— over 14 different views can be overlapped, moved, and resized
- ▲ One-key 'Build' launches the 'Edit-Recompile-Reload' loop and on return totally restores user's debug context
- ▲ 3 engines behind a common user interface support all phases of design & testing: high-speed simulator, emulator, and ROM monitor

CHIPTOOLS®

Product Information

Turbo C programmers can move to debugging 8051 embedded C instantly, as ChipView-51 is key-compatible with Borland's popular Turbo Debugger. It is available with a High-Performance Simulation engine, a ROM monitor engine, or interfaced for popular 8051 emulators.

ChipView-51 is the only 8051 debugger to support all popular 8051 C compilers at high-level. Unlike debuggers that support only simple data types, ChipView-51 lets you browse through C structures, unions, enumerations, bit-fields, pointers and arrays. With ChipView-51 you can simply point & click your way along a linked list!

ChipView-51's High-Performance Simulator Engine achieves the real-time speed of a 12 MHz 8051 when run on a 33 MHz 486 PC. It is ideal for testing entire programs before the target hardware is ready, with up to 32 banks! Off-chip I/O can be simulated by files or keypresses. And you can attach to real-world I/O for in-circuit simulation or serial I/O via COM ports.

The ROM monitor includes full source code of the 700 byte 8051 kernel, so that you can embed debug support into every product you ship – royalty free! The Emulator version is tailored to fully support Nohau's trace, emulator and bank-switch boards, and provides the extra power to trace 256K of source lines, mixed with a full trace of selected functions, all chosen by point & click!

Support

- MS-DOS, OS/2, Windows 3.x, Desqview, Windows 95
- IBM AT or compatible with 3MB RAM
- Derivatives such as 8xC51Fx, 80C517, 8xC552, DS80C320
- Custom version for Nohau's EMUL51-PC emulator
- High-level support for C compilers from Archimedes, BSO/Tasking, Franklin, IAR and Keil
- Source-level support for Assemblers and PL/M-51 compilers from Intel. Others supported at OMF51

Warranty

All ChipTools products have a 30-day money-back guarantee, and one year of free updates and technical support to registered users.

Real-Time Multi-Tasking Operating System For Microprocessors and Microcomputers

- ▲ No royalties on embedded code
- ▲ All source code supplied
- ▲ Extremely fast context switch times
- ▲ Very low interrupt latency times
- ▲ Several "C" vendors supported
- ▲ Scheduler and interrupt handler written in assembly for speed and optimization
- ▲ All CMX functions contained in library
- ▲ User configurable
- ▲ Task management
- ▲ Event management
- ▲ Timer management
- ▲ Message management
- ▲ Circular queue management
- ▲ Resource management
- ▲ Fixed block memory management
- ▲ Specialized UART management
- ▲ Automatic power down management
- ▲ Full pre-emption and ability to also have cooperative and time slice scheduling

CMX is also a distributor of C compilers for 8051 & all derivatives, 80251 & XA families.

CMX
COMPANY

TASK MANAGEMENT

- Create a task.
- Remove a task.
- Start a task.
- Suspend a task, with time-out provision.
- Wake a suspended task.
- Forcefully wake a task.
- Change a task's priority.
- Terminate a task early.
- Do a cooperative rescheduling.
- Disable task scheduling.
- Enable task scheduling.

EVENT MANAGEMENT

- Wait on event(s), with time-out provision.
- Set an event.
- Clear an event.

QUEUE MANAGEMENT

- Create a circular queue.
- Reset queue to empty.
- Add to top of queue.
- Add to bottom of queue.
- Remove from top of queue.
- Remove from bottom of queue.

UART MANAGEMENT

- Initialize UART.
- Put UART char, with time-out provision.
- Put UART string, with time-out provision.
- Get UART char, with time-out provision.
- Get UART string, with time-out provision.
- Update UART buffer(s).
- Initialize UART buffer(s).

TIMER MANAGEMENT

- Create a cyclic timer.
- Change a cyclic timer event parameters.
- Start a cyclic timer.
- Restart a cyclic timer.
- Restart a cyclic timer, with new initial time period and/or new cyclic time period.
- Stop a cyclic timer.

MEMORY MANAGEMENT

- Create a fixed block pool.
- Request free block from pool.
- Release block back to pool.

RESOURCE MANAGEMENT

- Get a resource.
- Reserve a resource, with time-out provision.
- Release a resource.

MESSAGE MANAGEMENT

- Get a message.
- Wait for a message, with time-out provision.
- Send a message.
- Send a message, wait for reply.
- Wake task that sent message, if waiting on reply.
- Wait on mailbox(s), with time-out provision.

SYSTEM MANAGEMENT

- Initialize CMX.
- Enter CMX.
- Enter interrupt.
- Exit interrupt.
- Enter power down mode.

CMX also supports other microcomputers and microprocessors.

8051 Real-Time In-Circuit OpenEmulator™

- ▲ Supports 8051 family and derivatives (including over 160 popular MCUs)
- ▲ Supports multiple 8-, 16-, and 32-bit architectures
- ▲ Latest FPGA technology
- ▲ Full speed emulation to 42 MHz
- ▲ Integrated Development Environment (IDE), project manager, and multi-file editor
- ▲ 32K x 96-bit trace buffer option
- ▲ 256KB/16MB overlay RAM
- ▲ 256K/16M breakpoints
- ▲ Background Debug Mode support (BDM)
- ▲ Easy-to-use, powerful interface
- ▲ High-level debugging
- ▲ 24-hour, 7-day a week, post-sale support
- ▲ 14-day evaluation period

EMULATION TECHNOLOGY, INC.

Product Information

The ET-iC2000 is a high performance real-time in-circuit emulator for over 160 MCUs including the 8051 family and derivatives. Its optimized, integrated environment provides for more efficient development of embedded systems. The OpenEmulator™ design supports multiple 8-, 16- and 32-bit architectures. The emulator can be configured with up to 16MB of overlay RAM and 16M breakpoints, a trace option, and a high-speed PC link.

Breakpoint Flexibility

The intelligent, real-time breakpoints can be set to stop the real-time execution of the program on fetch, read or write, at a single address or within a large range.

Trace Module

The powerful trace module feature includes high-level support, real-time code coverage, complex triggering, performance analyzer and logic analyzer function. The trace buffer is 96-bit x 32K frames.

Development Environment

The development environment includes a SAA standard user interface, a debugger, a multi-file editor, and a powerful, integrated project management tool. A flexible interface complements third-party C compilers, assemblers, and linkers.

Processors Supported

8051 family and derivatives.

Host Systems Supported

386/486/Pentium® class PCs.

Languages and File Formats

Third party assemblers and C compilers from Archimedes, IAR, Cosmic, Intermetrics and others. File formats include Archimedes, IAR (UBROF), OMF51, Tektronix, Motorola S, Motorola Hex, IEEE-695, 2500AD, ICOFF, PLM51, OMF86, Borland and others.

Ordering Information

The ET-iC2000 OpenEmulator™ includes the base unit, emulator module, trace module, external power supply, PC interface cable, software with source level debugger, and user manual. Adapters are available for all pod to target interconnections.

8051 Adapters

8051 Emulator Adapters, Test Clips and Accessories

- ▲ Support for 8051 family and derivatives
- ▲ Over 100 different adapters available
- ▲ All versions of PQFP packages supported
- ▲ Unlimited applications consulting
- ▲ Custom adapters available
- ▲ Fully tested and guaranteed for 180 days, parts and labor
- ▲ Free 1996 VLSI and SMT Interconnect Solutions Catalog

EMULATION TECHNOLOGY, INC.

Product Information

Emulation Technology offers a full line of development adapters and accessories for the 8051 family. These development tools provide you with an interface between your device and your logic analyzer, oscilloscope, or emulator, supporting you at every stage of the design process.

Emulator Tools

Adapt-A-Pod® and Adapt-A-Clip® emulator adapters attach to the socketed or soldered-on MPU and provides your emulator or other test equipment with alternate female footprints.

Logic Analyzer/Scope Adapters

Bug Catchers extend the leads and label the signals of your IC so it's easy to attach test leads to it. These adapters fit between your MPU and its socket or surface-mount pads, and accept test leads from logic analyzers and oscilloscopes.

Logic Analyzer Preprocessors

Our passive preprocessors provide a complete interface between the MPU in your target system and your HP logic analyzer, eliminating the time-consuming task of individually connecting each logic analyzer channel to your IC under test.

PQFP Test Clips

The ET PQFP Clip® allows for hands-free testing of surface-mounted PQFP devices. It provides hardware connection for testing, logic analysis, and emulation.

Debugging Accessories

We offer a large line of grabbers, handling tools, test probes, insertion/extraction tools, emulator probe rotators, and cost reduction adapters.

Processors Supported

8051 family and derivatives.

Ordering Information

Call ET Headquarters for International Sales offices. Ask about our PC-based 8- and 16-bit OpenEmulator™ products, logic analyzers, A/D waveform generators, digital storage oscilloscopes, universal programmers, simulators, and software.

8051, MCS® 51/251, Software Development Tool Suites

- ▲ Modern modular “Building Blocks” approach lets you choose just those tools you need to do your job
- ▲ Common, consistent, familiar, performance oriented interface
- ▲ Easily upgrade or increment your tools as your needs or the demands of your project increase
- ▲ Enables the professional embedded systems developer to easily switch microcontrollers to accommodate the most demanding projects
- ▲ Each kit or suite of tools is a complete product, ready for immediate use, backed by a full year of our top-notch product support
- ▲ Completely supported by all major emulator vendors
- ▲ This is the software recommended by all 8051 chip vendors and tool suppliers

Contact Information

Franklin Software, Inc.

CompuServe: 75442, 1423

Franklin Software, Inc. was formed in the late 1980's to provide the first truly useful cross development tools for the 8051 embedded systems market. Our premise was simple, and apparently in this industry, unique: Provide powerful, high quality, high-performance, effective, easy-to-use development tools to the embedded controller marketplace.

Microcontroller Development Tools: Franklin supports application development for the 8051, MCS® 51 and MCS® 251, family of microcontrollers with a powerful set of development languages, debugging tools, multitasking Real-Time Operating Systems and utilities. All tools run on any standard PC system and guarantee an easy, efficient and reliable way to create programs for each of these microcontrollers and all of their derivatives.

The 8051 and MCS® 51 Architecture: The Intel 8051 has been in widespread service since the early 1980's. Complete with a wide variety of outstanding features and peripherals, the 8051 CPU core is destined to see service well into the 21st century. More than 200 different 8051 derivatives and variations are available today from a variety of chip vendors.

More than half of all embedded microcontroller projects use members of the 8051 microcontroller family. As an embedded processor, it has no equal, especially given its wide acceptance and remarkable ability to adapt to new and ever changing peripheral needs.

A typical 8051 family member contains the 8051 CPU core, data memory, code memory and some versatile peripheral functions—all on a single chip. A flexible memory interface allows expansion of the capabilities of these devices with standard microprocessor peripherals and memory devices.

The MCS® 251 Architecture: In response to demands for more power and capability, Intel has developed a powerful new 8/16-bit microcontroller; the MCS® 251.

Highlights of the 251 CPU core

- powerful 8, 16, and 32-bit instructions
- flexible 8, 16, and 32-bit registers
- fully linear 16MB address space
- direct support for 16 & 32-bit pointers
- 16-bit stack and stack addressing capability
- very fast 64KB direct addressing mode
- completely 8051 code compatible
- compact, RISC like, instruction set

A pin-for-pin replacement for the 80C51FX, the 251 is completely 8051 execution and object code compatible, and will execute all of your existing 8051 code up to **5 times faster**. Existing 8051 applications recompiled with the new Franklin C251 C compiler are up to **15 times faster**.

(Continued)

Why Use Franklin Development Tools? Franklin has become synonymous with quality embedded development tools, outstanding support, and continuous update and refinement of existing tools. We're constantly striving to improve every aspect of our tools performance. From superior code generation, integrated development environments, newer and vastly improved manuals, the addition of PC-lint, to the endless task of adding new capabilities to meet the express demands of newer and faster chips. This benefits you directly! Franklin tools will always be on the cutting edge of code generation technology, and overall product quality. We've made our name with this, and we don't intend to change our ways!

A look through any of the relevant trade publications will quickly reveal that there is no shortage of vendors willing to sell you a plethora of software "odds-and-ends" portrayed as 8051 software development tools. Only Franklin Software is committed to bringing you the best development tools your money can buy. Often users cite price as the main reason affecting their selection. In all cases, you will always get what you pay for.

Only Franklin Software has the experience and development expertise to bring you complete ready-to-go development software for your 8051, or MCS[®] 251, projects. While most of our tools are available separately, we've taken the extra step of bundling them into four carefully selected "suites". Each suite is complete and able to generate high quality software with a minimum of delay.

There may be up to several hundred files in each delivery. By grouping individual products into functional groups for you, we provide the professional user with an arsenal of development tool capability and prices. To meet the overall needs of the professional embedded software developer, we carry four primary development suites:

A51: Our fully Intel ASM-51 source compatible macro assembler kit. A51 includes our powerful PV51 integrated developers environment.

C51: Our ANSI compliant C51 compiler kit. With full math, string, and transcendental libraries complete with sources to all I/O and start-up functions. This kit includes the A51 assembler kit described previously, and adds PC-lint, a powerful C language syntax and semantic checker to the basic C51 compiler product.

DK51: Our best value. This complete developers package adds our high-performance dScope-51 (DS51) debugger/simulator, the powerful new tScope-51 (TS51) target debugger, and our reconfigurable MONITOR-51 with startup and I/O sources; to the C51 kit described above. New in mid-1994; for students, experimenters, hobbyists,

and novice users; we're offering two DK51 Lite versions with some size and capability restrictions. DK51 Lite will execute up to 8Kbytes of 8052 code in the SMALL memory model.

PK51: The true professionals choice. This complete package adds our 2 megabyte CODE banking linker, and our powerful RTX51 Tiny Real-Time executive kernel to the DK51 kit described above. With PK51, no project is too large, or too complex.

We've designed each kit to completely subsume the previous kit. This permits the frugal embedded systems developer to purchase a kit expressly tailored to his or her specific needs. If and when it becomes necessary to upgrade for more capability, the only charge is the difference in cost.

In addition to the complete kits described above, we also carry: **RTX51 Professional**, a sophisticated full featured Real Time Operating System (a completely compatible super-set of RTX51 Tiny) for the 8051. RTX51 Professional comes complete with both BITBUS and CAN controller interfaces.

And finally, our newest addition: **DriveWay - 8051**; a powerful new Windows(based source CODE generation tool designed to speed and ease your introduction into the 8051 working environment by eliminating the tedium of having to learn and implement the "fine print" in each of the various chip vendors manuals.

Using just your mouse, DriveWay will select and generate; all of your driver code, interrupts, and main() routine complete with diagnostics, test code, and documentation for a wide variety of chips!

ProView—Turbo Tools

ProView—8051 Turbo Tools

- ▲ Complete turbo development capabilities designed expressly for the best 8051 development tools (our very own, of course) available today to speed your products to market
- ▲ A modern robust windowing system, for DOS, ProView smoothly and completely integrates all existing Franklin tools
- ▲ ProView features a configurable full function editor, program and object file management, pull down menus, dialog boxes, and comprehensive tools menu
- ▲ Full screen, multiple file, interactive turbo edit capability for both source and object files
- ▲ Easy access to the Editor, Tools, Projects, and Targets via fast efficient pull-down menus
- ▲ As with all Franklin tools, ProView is simple and easy to install and use

Contact Information

 WWW: fsinfo@fsinc.com
 CompuServe: 75442, 1423

- ▲ Instant “Hot Key” switching between ASCII text or hex object code, manage and scan an *error list* keyed directly to the source line in question
- ▲ Complete *project management* automates the compilation and production of your code modules and minimizes version control housekeeping
- ▲ Fully supports all Franklin Software tools, and our ProROM 64 ROM socket emulator
- ▲ Efficient symbolic user interface does not require MS Windows to operate
- ▲ Easily navigate through multiple display windows, with full user control of colors, sizing, and complete access to all files and tools

Product Information

Our all new ProView provides a powerful “turbo C” like environment for the industries most powerful 8051 development tools. ProView enhances your Franklin 8051 development software with a familiar turbo C like user interface and mouse controls.

Use your mouse to access pull-down menus and pop-up dialog boxes. These provide a simple direct means to control both the development process and view the results. At the heart of ProView is a powerful configurable new editor. This editor is intimately coupled to Franklin’s 8051 development tools to manage all aspects of error free target code production.

ProView’s configurable windowed environment is instantly familiar to C programmers familiar with “Turbo C”. The “Brief” like editor uses smoothly integrated windows and pull-down menus to link our 8051 C compiler and libraries, A51 macro assembler, DS51 high level language debugger/simulator, L51 and BL51 linkers, and TS51 target monitor in a fast, sophisticated, configurable, yet easy-to-use mouse oriented graphical environment.

Do You Need More Information?

If you have a touch-tone phone and a fax machine, you can call Franklin’s 24 hour information HOTLINE at:
 (408) 296-8056. Select documents #1001 and #1020.

ProView—Turbo Tools

(Continued)

The Project Concept

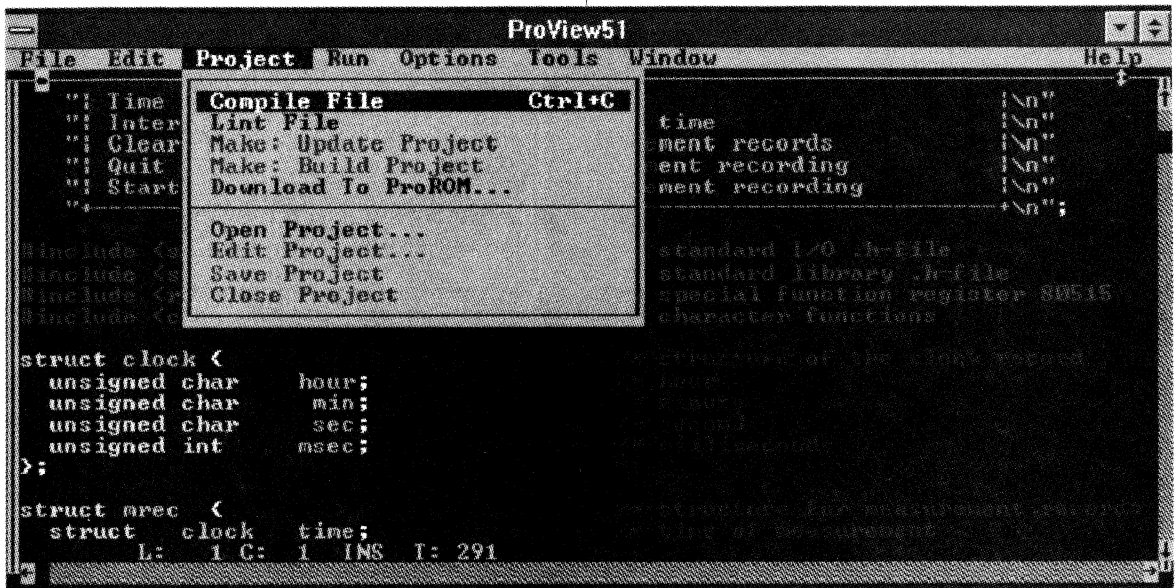

ProView organizes 8051 development activities and resources around the concept of a "Project". A project lists each source file (C, PL/M, or assembler), associated objects, and loadable target files in a Project file. ProView tracks include files, and manages and automates the entire software production process. Each modified file is a verified and either compiled or assembled as required, and re-linked into a new load module.

ProView also directly supports and interfaces with our high-speed 64K ROM emulator (available separately). This permits direct modification, translation, linking, and down-loading with optional execution of your code.

Usage Information

ProView requires Franklin C51 compiler V3.20, and DS51 debugger/simulator V5.01, or higher. ProView completely integrates all Franklin 8051 tools, including: The C51 compiler, DS51 debugger/simulator, A51 macro assembler, L51 and BL51 linker/locators, Lib51 library manager, and other utilities.

Special *Pop-Up* dialog boxes enable the user to configure and define a wide variety of operational parameters. ProView is completely transparent to all supported hardware and software tools. Contact us to inquire about availability of support for additional vendors 8051 hardware and software tools.

ProView provides a familiar pull-down menu bar. Users of "Turbo C" and Microsoft's "PWB" will feel right at home.

Platform and Host

ProView runs on all IBM compatible PC/AT's running MS or PC-DOS 3.0 and up, with a '286/386/486 or higher processor and at least 512K bytes of RAM. An EGA or VGA graphics controller and display are also required. ProView is completely compatible, and will work well with all software tools from Keil Elektronik GmbH.

ProView (PV51), with complete documentation, is available for immediate delivery. Request Franklin part number 3070. Delivery consists of a manual, and a 1.44MB DOS diskette.

Professional products, providing professional solutions, for the professional user!

Specifications and Requirements

Hardware:

IBM PC-AT or compatible
 DOS 3.0 or higher
 512K Bytes of RAM
 EGA or VGA graphics adapter
 Hard disk drive with at least 2 megabytes available

Software:

C51 V3.20 (Release V) and up is required
 DS51 V5.01 (Release V) and up is recommended

- ▲ Window oriented user interface displays:
 - Command input & output
 - High level language display, or mixed with comments, assembler mnemonics, and trace buffer
 - View/Modify all CPU registers and memory areas
 - Watch variables
 - Serial Communications
- ▲ Full debug information with object types
- ▲ High-speed simulation engine
- ▲ A reconfigurable target monitor suitable for all versions and derivatives of the 8051 is included
- ▲ Simple command entry with:
 - Mouse
 - Command Line
 - Pull-down menus
 - Function & cursor keys
- ▲ Extensive break capabilities
- ▲ Includes an interface to Hitex, Intel, and Nohau in-circuit emulators

Product Information

dScope-51 is a source level debugger for Franklin's C51 and A51, and Intel's PL/M-51. dScope-51 is both a powerful simulator and target debugger. The complete package includes the DS51 debugger/simulator, a reconfigurable target monitor, and TS51 — our powerful DS51 like interface to the monitor, and Hitex, Intel, and Nohau in-circuit emulators.

DS51 can simulate the whole 8051 CPU including the peripherals of most 8051 derivatives available today. A 'C' like macro language add the capability to simulate a wide variety of complex input signals or external I/O functions.

The MON51 target monitor considerably expands the capability of dScope-51 with its direct interface to your target hardware.

Our TS51 (Target Scope) interface presents the same screen, and most of the same capabilities of DS51 to the user. But instead of running the simulation engine, TS51 can interface via the serial port to your target monitor, or to your Hitex, Intel, or Nohau in-circuit emulators, eliminating the need to learn yet another new software program.

A51 Macro Assembler Kit

- ▲ As with all Franklin 8051 tools, the assembler output is Intel OMF-51 object module compatible
- ▲ Fully Intel ASM-51 code and macro language compatible
- ▲ Delivered with ProView-51 Integrated Developers Environment
- ▲ Accommodates the Motorola macro language too, making ports from other less capable microcontrollers quick, simple, and easy
- ▲ Includes L51 linker/locator
- ▲ Includes Lib51 library manager to allow building and maintenance of fast efficient libraries
- ▲ Includes OH51 to permit quick and easy absolute file to Intel HEX conversion for loading into in-circuit emulators and PROM burners
- ▲ Delivered complete with include (*.INC) files for most popular microcontrollers available today

 WWW: fsinfo@fsinc.com
 Compuserve: 75442, 1423

Product Information

Franklin's **A51** macro assembler is the latest version in our solid line of basic 8051 and MCS 251 programming tools. **A51** even translates your Intel ASM-51 source files. As with all Franklin 8051 and MCS* 51tools, **A51** emits an Intel OMF-51 object module.

A51 is delivered with ProView-51, our Integrated Development Environment. **PV51** features a reconfigurable "Brief" like editor and project wide build or make facility.

The **L51** linker/locator links or binds **A51**, **ASM-51**, **C51**, and **PL/M-51** modules into a single executable module. Detailed program flow analysis, the ability to expressly locate elements of all kinds at any location, and advanced listing and reporting features are an intrinsic part of this important and necessary tool.

The **Lib51** library manager is provided to generate specifically formatted - easily accessed, cataloged, indexed, and ordered libraries of code modules.

Finally, the **OH51**, Object module to Intel HEX file converter, is provided to complete the code generation process by generating files suitable to loading into most emulators and PROM burners.

Scope of Delivery

As with all Franklin products, this product delivery is complete and ready to use. The following individual products comprise the **A51** delivery:

- **A51**: High performance macro assembler.
- **L51**: High performance overlaying linker/locator.
- **Lib51**: Library manager.
- **OH51**: Object to Intel HEX file converter.
- **PV51**: Integrated Development Environment.

C51 C Language Compiler Kit for the Professional User

- ▲ As with all Franklin 8051 tools, the compiler output is Intel OMF-51 object module compatible
- ▲ Fully ANSI compliant for fast easy code portability. Complete library support for full math, floating-point, string, and I/O routines with sources
- ▲ Fully supports all the multiple data pointers available on many of today's high performance chips
- ▲ Fully supports all 200+ known derivatives of the 8051 family
- ▲ Fully supports the new high speed Dallas Semiconductors '320 family
- ▲ Fully supports the ALU in the Siemens '517 family
- ▲ Individually definable REENTRANT and INTERRUPT functions
- ▲ The basic "must have" product for today's complex and time critical designs. Recommended by all major 8051 chip vendors

Product Information

C is a high level programming language which combines structured programming, versatile data structures, code efficiency, and a wide variety of mathematical, logical and string operations. As a language, C is not dedicated to specific applications. However, many applications can be dealt with more easily and much more efficiently than with other more specialized languages.

The availability of C for many common microcontrollers, allows the use of generic C code in many different applications with little or no modification.

C51 features

C51 is ANSI compliant complete with all standard, string, math, and transcendental library functions. C51 includes sources for all library input, output, and startup routines. C51 fully supports all members of the MCS-51 family and all derivatives without regard to vendor.

C51 supports chips with multiple data pointers, multiple serial ports, arithmetic co-processors, A to D converters and other "special" peripherals. C51 easily and completely accommodates the restricted/enhanced/alterd capabilities of the Signetics '750, '751 and '752's, the Siemens '517 series, and the Dallas DS2500, DS5000, and '320 series of controllers among others.

C51 also includes a Franklin configured version of Gimpel Software's PC-lint. The compiler kit is complete in every way as delivered and is ready to make executable code.

The C51 package contains: The C compiler, and all libraries and includes as described above. In addition, it also includes the entire A51 Macro assembler package itemized previously, and examples and other illustrative code.

If you have to write code; make it fast, make it tight, make it right. Make it with C51!

Scope of Delivery

- C51: Compiler & all libraries and includes.
- ProView51: Integrated Development Environment with high performance multiple file editor.
- PC-Lint: C language semantic analyzer.
- A51: The complete Intel ASM-51 compliant high performance macro assembler kit described previously.
- L51: High performance overlay Linker/Locator.
- Lib51: Library Manager for the creation and maintenance of code libraries.
- OH51: An 8051 executable object module to Intel Hex file converter.

DK51—Complete 8051 Developers Kit

- ▲ The most cost effective 8051 product development kit available today
- ▲ With our powerful DK51 kit you can assemble, compile, debug, simulate, build a monitor, and even interface to your in-circuit emulator
- ▲ DK51 contains all of the following:
 - PV51 Integrated Production Environment as described on page 4
 - A51 Macro Assembler suite as described on page 11
 - C51 Compiler suite (with PC-lint) as described on page 12
 - DS51 Debugger/Simulator suite as described on page 10
- ▲ DK51 is also available in two “Lite” versions for students and hobbyists
 - CASPER has an 8K maximum code size limit (inclusive of library code)
 - EINSTEIN has a 1K maximum code size limit (exclusive of library code)

To meet the overall needs of the professional embedded software developer, we carry 4 primary development suites: The A51 Macro assembler suite, the C51 'C' language compiler suite, the DK51 developers suite, and the PK51 Professional developers suite.

By grouping individual products into functional groups for you, we provide the conscientious user with a range of development tool capability and prices.

Product Information

DK51 represents our best value for the cost conscious 8051 product developer. The DK51 package adds our powerful DS51 debugger/simulator to the C51 compiler suite. By adding this powerful tool set, the developer is able to assemble, compile, debug, and simulate his or her project. All aspects of complete project development are bundled into these cost effective kits.

We've developed two new *Lite* versions to enable students, hobbyists, and those with projects that don't require the full power of our tools to still use the best tools available today for the 8051 microcontroller.

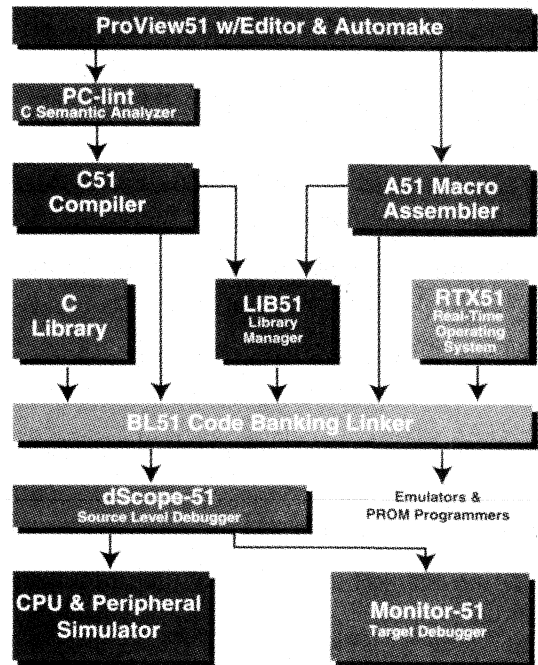

The *Lite* kits are explicitly designed to generate small memory model code for the 8052 microcontroller. Both kits contain full math libraries with floating point. We've limited the final code size a bit, and taken out the A51 macro assembler, the Lib51 librarian, the compact and large memory models, and support for controllers other than the 8052. The **CASPER** version, designed for the hobbyist, has an overall 8K Byte code size limit — including library code. The **EINSTEIN** version, designed for the student or novice, has a 1K Byte code size limit exclusive of library code.

PK51—The Professional 8051 Developers Kit

- ▲ Designed expressly for the professional user who demands, and can afford, the best tools available
- ▲ When quality matters, and when the tools you use are the foundation for your business or its survival, then only the best will do
- ▲ PK51 contains all of the following:
 - PV51; Integrated Developers Environment as described on page 4
 - A51; Macro Assembler suite as described on page 11
 - C51; Compiler suite (with PC-lint) as described on page 12
 - DS51; Debugger/Simulator suite as described on page 10
 - BL51; 2 megabyte code banking linker as described on page 8
 - RTX51 Tiny; complete with sources as described on page 9
- ▲ 1 Full year of technical support

To meet the overall needs of the professional embedded software developer, we carry 4 primary development suites: The A51 Macro assembler suite, the C51 'C' language compiler suite, the DK51 developers suite, and the PK51 Professional developers suite.

By grouping individual products into functional groups for you, we provide the conscientious user with a range of development tool capability and prices.

Product Information

For 1995 the PK51 developers kit has been refined to meet the exacting needs of the professional embedded systems development engineer. It is a complete software development package and contains all the tools necessary to effect efficient and reliable software design: C Compiler, Macro Assembler, Linker & utilities for code banking, multi-tasking Real Time Operating System, and a powerful source level debugger complete with simulator, Monitor, and Emulator interfaces.

PK51 represents our best product package. PK51 was expressly designed to meet the needs of the professional embedded systems developer. The PK51 package adds both BL51 and our fast RTX51 Tiny Real Time Executive to the basic DK51 developers kit described previously.

With BL51 and RTX51 Tiny the professional user can address all aspects of 8051 product development.

DryICE/DryICE Plus

DryICE 8051 Family In-Circuit Emulators

- ▲ Real-time in-circuit debugger/emulator for the expanded memory mode
- ▲ No host slots required - connects to the COM port of any PC or Mac
- ▲ UART for emulation frees processor's UART
- ▲ Help feature displays available commands
- ▲ 48K emulation RAM
- ▲ Line-by-line assembler and complete disassembler
- ▲ Prices start at \$149

 WWW: <http://www.hte.com>

Product Information

The DryICE provides most of the features of an In-Circuit Emulator (ICE) at a significantly lower price. The 8051 Family In-Circuit Emulator has powerful functions to assist the designer in software and hardware development. The system integration, debug and test phases are performed faster with the DryICE. Also, there are built-in utility commands such as: load code RAM, single step, real-time execute to a breakpoint, view and modify bit/registers/ memory, fill memory, load code, line-by-line assembly, disassembly, and even a hex calculator function.

The user can easily:

- Load and execute code
- Interpret the results of emulation activity
- Enter and line-by-line assemble mnemonics
- Disassemble program memory
- Examine and modify the CPU's internal registers/RAM, external memory, or ports

teletest 51

In-Circuit Emulators

- ▲ Professional development system for the 8051 family
- ▲ Support of more than 70 derivatives of the 8051 microcontrollers from Intel/Philips, Philips, Siemens, AMD, Dallas, MHS, Oki, Valvo
- ▲ Modular design and excellent functionality
- ▲ Fully windowed operating environment with *HiTOP*
- ▲ Runs on every PC under DOS or Windows
- ▲ Real-time emulation up to 40 MHz
- ▲ 256K bytes of emulation memory
- ▲ 64K hardware breakpoints
- ▲ Sophisticated performance analysis
- ▲ Non-intrusive access to internal RAM in real-time via triggers

Product Information

The **teletest 51** emulation system offers a highly modular design for powerful emulation of the 8051 family. More than 70 variants of the 8051 microcontroller family can be supported by simply exchanging the appropriate adaptation cable. The **teletest 51** emulation system can be obtained by three different emulator models - **TX51**, **MX51**, **AX51**!

TX51

TX51 is an In-Circuit Emulator at a very attractive price. It can be used for ROMless variants of the 8051 family, simply by exchanging the appropriate adaptation cable. All emulation adapters for the **TX51** are reusable with the **MX51** and **AX51** emulator. 8051 derivatives with a maximum operating frequency of 24 MHz are supported. The **TX51** offers 63.75K Byte emulation memory code and 32K Byte for Xdata. Hardware breakpoints make the debugging easy.

MX51

The **MX51** can be used for ROM and ROMless variants of the 8051 family, simply by exchanging the appropriate adapter cable. The maximum operating frequency is 42 MHz. **MX51** offers hardware breakpoints and complex trigger conditions. You can use them to control trace recording and the real-time counter. In addition, **MX51** offers logical combination of triggers in sequences and non-intrusive on-the-fly functions. The emulation memory (128K Byte) covers the complete code and xdata segment of 64K Bytes each.

AX51

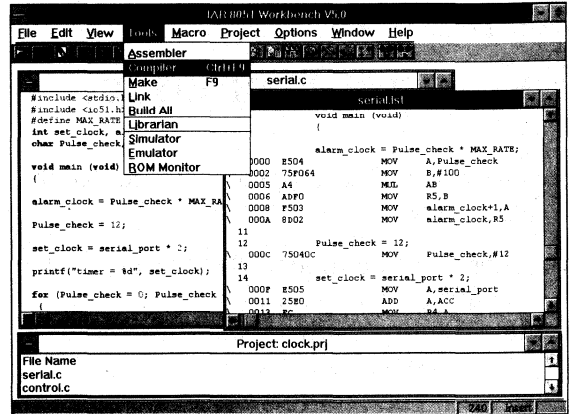

This emulator is the most powerful of the **teletest 51** system. It is the professional development system for the 8051 family. In addition to the **MX51**s features, this system offers high-end banking support and performance analysis. The **AX51** has a parallel and serial interface to the host computer. The built-in power supply works from 110 to 240 Volts with 50 or 60 MHz.

hitex

8051 Compiler

8051 Embedded Workbench for Windows™

- ▲ Fully integrated development environment under Windows (DOS version still supported)
- ▲ ANSI standard C Compiler
- ▲ Extended Keywords specific for 8051
- ▲ Built-in advanced chip-specific optimizer generating highly compact code
- ▲ Multiple memory models supporting single-chip to banked designs with up to 8MB of code
- ▲ Individually definable REENTRANT or STATIC functions
- ▲ Memory specific pointers
- ▲ Dynamic register variables and efficient use of parameter passing via registers
- ▲ Nine levels of each Code or speed optimizations
- ▲ Support for 10 data types and up to 32768 external references
- ▲ Extended C library (100+ functions) with optimized floating point
- ▲ Easy & fast interrupt handling directly in C
- ▲ Generates mixed C & assembly listings from the compiler & fully comprehensive cross reference map file after linkage
- ▲ Supports all 8051 derivatives

IAR 8051 Embedded Workbench

IAR's 8051 kit comes with IAR's optimized C compiler V5.0, C-SPY Windows debugger, relocatable macro-assembler, universal linker XLINK, librarian XLIB, Tiny Kernel, and a Windows editor & user interface.

IAR optimized C Compiler

The IAR 8051 compiler contains an advanced chip-specific optimizer with extensions adapted both to the 8051 architecture and to embedded C programming.

Macro-Assembler

The IAR 8051 package comes with a relocatable macro-assembler for time-critical routines. Interfacing between C and assembly is straight forward. It allows you to use relocatable as well as absolute code segments.

Linker and Librarian

The linker XLINK supports complete linking, relocation and format generation to produce PROMable code. XLINK generates over 32 different formats and is compatible with most popular emulators. The librarian XLIB allows you to create and maintain relocatable libraries that get loaded only if they're called.

Windows Editor and User Interface

A full featured Windows editor and a very friendly point and click Windows user interface are at the heart of the IAR 8051 Workbench. You will be able to go through all of your development cycle without leaving the Workbench and Windows. (DOS version still supported).

Hosts Systems Supported

IBM PC & compatible (386 or above); SUN 4 (SPARC); HP 9000 series 700.

C-SPY 8051 for Windows™

- ▲ Point & Click debugging environment under Windows™
- ▲ Watchpoints on variables (Globals & Autos) as well as expressions
- ▲ Unlimited number of breakpoints
- ▲ Point & modify content of registers, memory locations, and variables
- ▲ Debugging on C and assembler levels
- ▲ Function call list (with parameter) and function trace
- ▲ Command and log file control
- ▲ C-like macro language to simulate I/O's and interrupts
- ▲ Powerful yet easy-to-use command set
- ▲ Supports debugging of banked code

Product Information

C-SPY 8051 is a very powerful debugger available as part of the IAR Embedded Workbench for the Intel MCS® 51 microcontroller, or as a separate product. It has a true Windows™ interface, with windows for the source code, registers, watchpoints, memory space, terminal I/O emulation and command input. With a point and click interface, C-SPY provides you a 'Plug & Play' environment while executing powerful debugging commands.

C-SPY is designed to help you speed up your troubleshooting time and quickly zoom in on the problem areas in your code.

Registers & Memory

A register window allows you to monitor or point & modify the content of the 8051 registers during code execution. And a memory window allows you to display or change the content of your RAM space. Also used to display ROM space and monitor Stack manipulations.

Watchpoint & Terminal I/O

You can put watchpoints on any global or auto variable. You can also display content of arrays, structures, and pointers. A terminal I/O window displays your outputs on screen and accepts inputs from the keyboard.

Commands

A powerful yet easy-to-use command set; includes all what you need in a debugging environment. Frequently used commands are invoked through PF keys.

C-SPY/Monitor

C-SPY is also available as a ROM-Monitor version. The monitor is user configurable and could be used with any board fulfilling the basic requirements of the ROM-Monitor.

C-SPY Emulator version

C-SPY could also be connected to an emulator. This way you get all the C-SPY features and ease-of-use while running in real-time emulation mode. (Please call and ask for the latest list of supported emulators).

Hosts Systems Supported

IBM PC & compatible (386 or above), SUN 4 (SPARC); HP 9000 series 700.

TRACE32 ICE-51

TRACE32

- ▲ Universal in-circuit emulator for 8- to 32-bit microprocessors
- ▲ Unlimited hardware breakpoints
- ▲ Up to 16M byte dual-ported emulation memory
- ▲ Speed more than 30 MHz
- ▲ Support for external bank switching
- ▲ High-speed link via Ethernet LAN or fiber optic
- ▲ Up to 4M Frame trace buffer
- ▲ Real-time trace and trigger
- ▲ Integrated high-level language debugger
- ▲ Multi-task debugger
- ▲ Performance analysis and statistic functions
- ▲ Timing-analyzer with pattern generator and line tester

Contact Information

Lauterbach Datentechnik GmbH
 Fichtenstr. 27
 D-85649 Hofolding GERMANY
 Tel: (08104) 8943-0
 Fax: (08104) 8943-49

**Product Information**

TRACE32 provides a complete set of development and testing tools. The advanced modularity of TRACE32 makes it very easy to upgrade the system to future needs. By adding or changing personality modules another microprocessor or a new feature can be supported.

TRACE32 has more inter-faces to PCs and workstations than any other system. The communication link to the host is done by the fiber optic interface or Ethernet allowing a high-speed transfer. Other standard interfaces such as SCSI, RS-232, RS-422 and a low-cost parallel connection are also supported. As software drivers are available for most systems, it is possible to share a TRACE32 in a LAN of PCs and workstations.

The integrated HLL-Debugger with its powerful trigger and trace capabilities supports multi-task kernels as well as real-time systems, interrupts can be served at any time during single-step emulation (Ada, C, C++, Modula 2, Pascal, PL/M and assembly languages supported).

The analyzer offers selective state trace as well as software performance analysis and statistic functions. The comfortable windowed user interface is completely configurable by the user, no system offers more flexibility. With its powerful printer interface hardcopies of windows or screens can be made in text or graphic form which are best suited for technical documentation.

The testing language PRACTICE-II with its macro concept can be used for automatic hardware and software test routines.

8051 Adapters

8051 Family Programming Adapters and Socket Adapters

- ▲ Use new devices on your current programmer
- ▲ Program 87C51s, '552s and others in common footprints
- ▲ Eliminate expensive new equipment purchases
- ▲ Easy to use; no software
- ▲ Friendly technical support
- ▲ High quality Textool, Yamaichi, and Enplas sockets
- ▲ Priced from \$70 to \$249
- ▲ 30-day satisfaction guaranteed
- ▲ New designs being released all the time, call and tell us what you need

Ordering Information

- Visa, Mastercard, Discover, Amex, COD or Pre-payment by check. Purchase orders accepted from approved companies
- UPS ground delivery included
- For custom work contact Mitchell Burko

iceMASTER-PE™ 8051 Family In-Circuit Emulator

NOW
8051, 8052,
8xC51FX
SUPPORT

PRODUCT DESCRIPTION

The unique **iceMASTER-PE** packs an advanced feature set into a tiny, palm-sized package that any engineer can afford. Designed for demanding projects, **iceMASTER-PE** supports frequencies up to 42 MHz with a full complement of emulation memory, external data memory, and a transparent trace buffer 16K frames deep with advanced searching capabilities. The entire emulator plugs directly into the target application or operates in a stand-alone mode.

The **iceMASTER-PE** is the world's most portable emulator because the emulator and probe electronics are both integrated into a pocket-able package about the size of a PC mouse. To achieve this dramatic breakthrough in the size and cost of high-performance emulation, MetaLink invented a new emulation system architecture, Advanced Emulator Technology (AET, patent pending).

The **iceMASTER-PE's** windowed user interface delivers the highest development productivity and is easy to learn and easy to use, including a context-sensitive hypertext and hyperlinked help system. This powerful, productive interface gives the user total control and flexibility in the configuration of the size, position, content, and color of each window.

The **iceMASTER-PE** includes a full symbolic and source-level debugger for Assemblers and Compilers. The emulator supports all 9 of the most popular 8051 Assemblers and Compilers.

The **iceMASTER-PE** sets the new standard for excellence, portability and value in 8051 family emulation.

KEY CHARACTERISTICS

- Supports 8051 family devices up to 42MHz
- Support for 8031, 8051, 8x32, 8x52, 8xC54, 8xC58, 8xC51FA, 8xC51FB, 8xC51FC, 8xC751, 8xC752, 8xC750, NMOS, CMOS, ROM, EPROM/OTP Devices.
- Full-Featured, Real-time & Transparent Emulator
- Emulator and Probe electronics integrated into a single package only 3" x 4" x 1"
- Plugs directly into target applications or operates in a stand-alone mode
- Patent-pending AET system architecture

HARDWARE CAPABILITIES

- Up to 64K Program & 64K External Data Memory
- 16K frame trace buffer
- View trace while executing
- Up to 128K hardware breakpoints
- Up to 64K Trace ON & 64K Trace OFF triggers
- Integrated diagnostic self-test capability

SYSTEM FEATURES

- PC-hosted via RS-232 serial link
- Efficient, powerful, easy to learn
- User control of window size, content & color
- Supports third party Assemblers & Compilers
- Full Symbolic & Source-Level debug
- Complete system includes Emulator, 8051 Macro Cross Assembler, RS-232 cable & power supply

FLEXIBLE, EASY-TO-USE INTERFACE

iceMASTER has an advanced, windowed user interface that emphasizes ease of use. Each window can be sized, moved, highlighted, scrolled, color-controlled, added, or removed completely. iceMASTER provides pull-down and pop-up menus, function keys, and context-sensitive help. The contents of any memory space may be perused and altered directly from the appropriate window using the keyboard or a mouse.

You have immediate access to the hypertext/hyperlinked, context-sensitive, on-line help system which clearly explains what your options are (at any detail level you choose), keeping you productive. There is even a HELP-FOR-HELP feature. Whether you are beginning your first design project, or are a veteran designer searching for the fastest possible debugging method, you will appreciate the EASE-OF-USE features designed into iceMASTER.

Novices can navigate smoothly through a debugging session by accessing the commands and menus as standard pull-downs. Experienced designers can instantaneously pop-up their menu of choice by using redefinable hot keys.

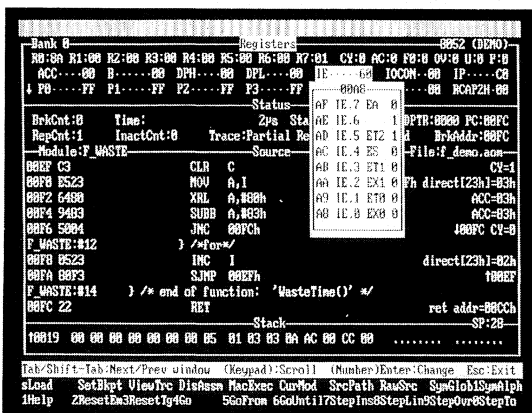

DECREASED DEVELOPMENT TIME

Your iceMASTER source window accelerates the debugging process with Dynamically Annotated Code. When single-stepping, instruction execution information is displayed and retained next to each instruction. You can clearly see the data behind your program's flow, including contents of all accessed (read or write) memory locations and registers, as well as flow-of-control direction change markers. A moving color bar indicates the current position in the program as it executes.

At your option, the iceMASTER source window allows operations on three different views of code memory: disassembled instructions, instructions mixed with High Level Language (HLL) source statements, or HLL source only.

HLL source statements and symbolic disassembly information are also displayed when you disassemble the program or view the trace buffer.

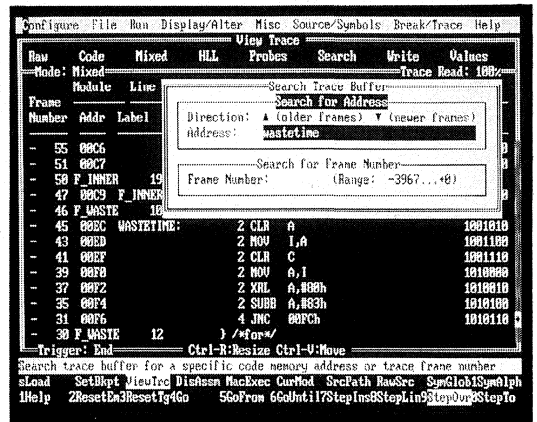

THE COMPLETE DEBUGGER

The trace buffer captures data in real-time. Trace information consists of address and data bus values and user-selectable probe clips. You can view the trace buffer data through several display filters: raw hex, disassembled instructions, instructions mixed with HLL source statements, or HLL source only. You can display the probe clip bit values in binary, hex, or digital waveform formats.

You can trigger the trace to begin capturing data on all instructions leading up to a breakpoint, around (before and after) a breakpoint, or following a breakpoint. Capture filtering allows you to focus attention only on areas of interest, eliminating clutter.

To further speed your design process, an integrated search mechanism allows you to locate any label, HLL source line number, or address in the trace buffer in either the backward or forward direction. The days of manually scanning or post-processing a large buffer of trace data are gone!

If you WRITE your program in a HLL, you should be able to DEBUG it that way – iceMASTER lets you do just that!

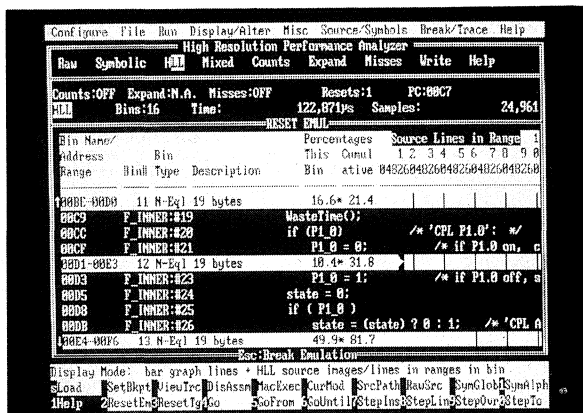

IMPROVING THE QUALITY OF YOUR PRODUCT: FINDING THE HOT (OR NOT SO HOT) SPOTS

iceMASTER emulators (Model 400 & PE) provide a PERFORMANCE ANALYZER that allows you to monitor the time spent executing specific portions of your program to find "hot spots" or "dead code." You can define and analyze memory areas based on code address, module, line number or label ranges.

You can view results dynamically during emulation or later for a more detailed analysis. You can toggle the display from bar graph format to actual frequency counts, and you can filter the level of detail in the displayed results to include raw data, code labels, and/or HLL source statements.

iceMASTER Model 400 provides an additional Performance Analyzer that is the absolute best in the industry for tuning and testing your code. It is very flexible and far more accurate than most other emulators, with a resolution of less than six microseconds. You can define and analyze up to 15 memory areas and each of these 15 memory areas can consist of non-contiguous, logically related subranges, (e.g. groupings of related functions which are not necessarily contiguous in memory).

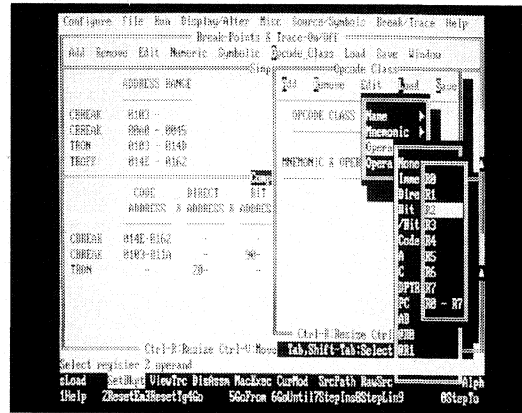

FINDING THAT BUG

You have access to as many as 128K breakpoints and 64K tracetriggers. These triggers can be enabled, disabled, set or cleared. Simple triggers are based on code or external data addresses or address ranges. Simple breakpoints can be set or cleared directly in the source window at disassembled instructions or HLL source statements.

Breakpoints can also be complex triggers, based on code address, direct address, bit address, opcode value, opcode class or immediate operand. Complex triggers can be ANDed and ORed together.

Finding that elusive bug is now much easier!

SMALL AND POWERFUL

Some companies design emulators that use one or two full size PC expansion board slots. These companies take it for granted that you have the "right" kind of PC, that you don't need the expansion slots for something else, and that you don't mind taking apart your computer to install their emulator!

At MetaLink, we don't take our customers for granted.

The iceMASTER family is the culmination of over 7 years of focused engineering by MetaLink to bring advanced semiconductor technologies to emulator design. Using state-of-the-art PALs (PEELs), LCAs, VLSI memories and microprocessors, MetaLink designed world-class emulation capability into the smallest emulator footprints in the industry, combining powerful and complex emulation features with all-around ease-of-use.

The high speed serial link connects easily to the back of your computer with a standard RS-232 cable. The emulators are smaller than the size of a VCR tape, fit neatly in crowded work spaces and are easy to move around on the bench or to other computers. **PORTABLE PRODUCTIVITY!**

iceMASTER-PE Development System

MetaLink specializes in enhancing the emulation technology required by EMBEDDED SYSTEMS DESIGNERS. MetaLink has consistently led the industry in emulation technology: The first PC-based 8051 emulator; the first 8052 emulator; the first to offer support for all the unique features of the 8051 family components, such as watchdog-timer, idle modes, power down mode, DMA and A/D.

MetaLink is a full-service emulation company. We support our customers over the long term with services such as repair, discounted upgrades, rental units, 10-day trial purchase periods and free technical support for applications problems. A network of world-wide sales and service representatives is augmented by a well-trained telemarketing staff at headquarters.

❑ HOST SPECIFICATIONS

Host IBM PC, XT, AT, 386, 486, PS/2, Laptop, Notebook or compatible system, 640K bytes of RAM, Hard Disk Drive, Monochrome or Color Display, with a Standard RS-232 Serial Port. Operating System DOS 2.0 or greater.

❑ EMULATOR SOFTWARE SPECIFICATIONS

File Formats Supported with Symbolic or Source-Level Debugging:
2500AD, Archimedes, Avocet, BSO/Tasking, Franklin, IAR Systems, Intel OMF, Keil, MCC, Microtec Research, Motorola 'S' Record, Systronix and Intel HEX.

Source/Symbol Support:
Assembler, BASIC, C and PL/M Languages
Symbolic or Source-Level Debug:

Setting of Breakpoints
Setting of Trace ON/OFF
Viewing of Trace Buffer
Viewing of Source Window Display
Viewing of Performance Analyzer
Assembly/Disassembly of Code

HLL Structure/Content Display of:
Modules Line Numbers
Scopes Program Variables

❑ EMULATOR HARDWARE SPECIFICATIONS

iceMASTER-PE MODELS:

8031: Supports 8031 and 80C31
Operates up to 33MHz
40-Lead DIP or optional 44-Lead PLCC

8032: Supports 8031, 80C31, 8032, 80C32 and C501
Operates up to 42MHz
40-Lead DIP or optional 44-Lead PLCC

83752: Supports 83C751, 87C751, 83C752, 87C752 and 87C750
Operates up to 16MHz
24- & 28-Lead DIP or optional 28-Lead PLCC

8351FX: Supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752, 87C52, 80C51FA, 83C51FA, 87C51FA, 83C51FB, 87C51FB, 83C51FC, 87C51FC, 80C54, 87C54, 80C58 and 87C58
Operates up to 16MHz
40-Lead DIP or optional 44-PLCC

❑ OPERATING CHARACTERISTICS

Clock frequency user-selectable between external target crystal/clock or internal clock source
Real-time, Electrically and Operationally Transparent

❑ USER INTERFACE

Keyboard or Mouse Control
Pull-down & Pop-up menus with fill-in boxes
Available Main Screen Windows:
Registers and PSW bits
Bit Memory
Stack data displayed in HEX &/or ASCII
Up to 5 Internal Data Memory displayed in HEX &/or ASCII
Up to 5 External Data Memory displayed in HEX &/or ASCII
Up to 5 Code Memory displayed in HEX &/or ASCII
Source Program displayed in Code, HLL Source or Mixed
Watch window for variable data
System Status data

Main Screen Window Display Controls:
Movable Selectable (On/Off)
Sizable Color selection
Scrollable Highlighting of key data

Function/Hot Key Access:

User-assignable for commands
User-displayable for quick reference

❑ MEMORY OPERATIONS

Emulation Memory:
iceMaster-PE Models: 8031 8032 8351FX 83752
Program Memory: 64K 64K 64K 2K
External Data Memory: 64K 64K 64K N/A
Mapping Resolution:
Program: Down to 1-byte
External Data: Down to 1-byte

Program Memory:
Single Line Assembler (full instruction set support)
Disassemble in Code or Source/Code mode
Disassembly may be written to a disk file

Data Memory:
Internal or External Memory
Fill a block of memory with data
Copy a block of data to another area
Change a single address data content
Compare any two blocks of addressed data
Displayed data may be written to a file

Registers/SFRs/Bit Memory:
Examine or Modify

Program Variables:
Examine or Modify

❑ EMULATION CONTROLS

Reset from Emulator and Go
Reset from Target and Go
Reset Processor
Go from current Program Counter
Go From a new Program Counter
Go Until a Program Counter/Label
Slow Motion (Repetitive Step commands)
Step by machine instruction
Step by Line Number
Step Over calls
Step To next function or procedure

❑ HARDWARE BREAKPOINTS

Up to 64K real-time Program Addresses
Up to 64K real-time External Data Addresses

❑ TRIGGER CONDITIONS

Set directly in Source window or Pull-down menu
PC address & range of addresses
Opcode Value
Opcode Class
SFRs/Registers
Direct byte address & range of addresses
Direct bit address & range of addresses
Immediate operand value
Read/Write to bit address
Register address modes
Read/Write to Register address
Logical AND/OR of any of the above
External Data address & range of addresses
Break Count Overflow
External (CLIP) Break Input
External (CLIP) Trigger Output

❑ TRACE

Real-time trace with view while executing code
16K-Frame Trace Buffer
Start, Center, End and Variable Trace Trigger settings
Up to 64K Trace ON/OFF triggers for trace filtering

Trace Contents consist of:
16-bits Address Bus
8-bits Data Bus
7-bits External Clips

Trace Display Modes:
Raw Hex
Symbolic
HLL Source
Mixed

External Clips display format:
Binary data
HEX data
Digital waveform

Trace Buffer Operations:
Write trace buffer to a disk file
Search trace buffer for labels & addresses

❑ PERFORMANCE ANALYZER

Program profiling capability

iceMASTER™ 8051 In-Circuit Emulators

PRODUCT DESCRIPTION

The **iceMASTER-8051** Model 200/400 emulator represents a culmination of 7 years of focused engineering to create the world's most affordable and portable full-featured emulators.

The **iceMASTER-8051** emulators offer real-time and transparent emulation at up to 24MHz for a broad number of derivative devices through the use of interchangeable probe cards. Powerful breakpoint systems allow an engineer to stop a program at any time and examine all states and conditions. Trace memory provides a complete history of each event that has occurred, including source-level information, address, data, status, searching and external logic events. The best performance analyzer capability in the industry allows a thorough evaluation of the program to decide what areas are taking the most time and simplify those areas requiring improved performance.

The **iceMASTER-8051** emulators support symbolic and source-level debugging for the most popular 8051 Cross Assemblers, 'C' Compilers, and PL/M Compilers. These capabilities allow the designer to debug their system the way it was designed, at the symbolic or source-level. This methodology increases productivity while decreasing cost and time-to-market.

The **iceMASTER-8051** emulators provide pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyperlinked help. The advanced windowed user interface emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, color-controlled, added or removed completely. The contents of any memory space may be perused and altered directly from the appropriate window, with multiple memory spaces displayable simultaneously.

KEY CHARACTERISTICS

- Full-Featured, Real-time & Transparent Emulator
- Supports 8051 family devices up to 24MHz
- Interchangeable Probe Cards
- Hosted on any PC or compatible, including Laptops, Notebooks, or Micro Channel
- 115K baud serial link using a standard comm port
- Unlimited user support

HARDWARE CAPABILITIES

- 64K Program & 64K External Data Memory
- 4K frame trace buffer
- Advanced trace search ability
- 128K hardware breakpoints
- 64K Trace ON/OFF triggers
- Broad 8051 derivative device support (more than 65 devices)
- Dual Performance Analyzers

SYSTEM FEATURES

- Efficient, powerful, easy to learn
- User control of window size, content & color
- Supports third party Assemblers & Compilers
- Full Symbolic & Source-Level debug
- Complete system - includes Emulator, 8051 Macro Cross Assembler, RS-232 cable & power supply

FLEXIBLE, EASY-TO-USE INTERFACE

iceMASTER has an advanced, windowed user interface that emphasizes ease of use. Each window can be sized, moved, highlighted, scrolled, color-controlled, added, or removed completely. iceMASTER provides pull-down and pop-up menus, function keys, and context-sensitive help. The contents of any memory space may be perused and altered directly from the appropriate window using the keyboard or a mouse.

You have immediate access to the hypertext/hyperlinked, context-sensitive, on-line help system which clearly explains what your options are (at any detail level you choose), keeping you productive. There is even a HELP-FOR-HELP feature. Whether you are beginning your first design project, or are a veteran designer searching for the fastest possible debugging method, you will appreciate the EASE-OF-USE features designed into iceMASTER.

Novices can navigate smoothly through a debugging session by accessing the commands and menus as standard pull-downs. Experienced designers can instantaneously pop-up their menu of choice by using redefinable hot keys.

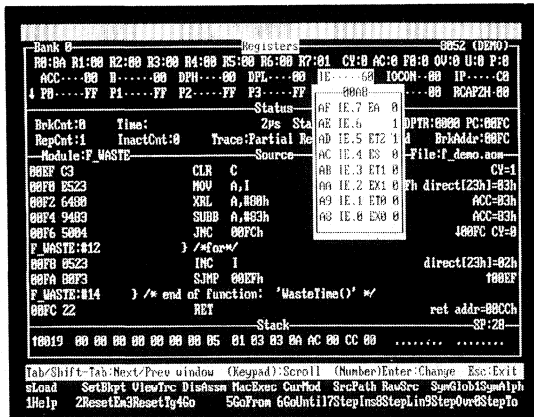

DECREASED DEVELOPMENT TIME

Your iceMASTER source window accelerates the debugging process with Dynamically Annotated Code. When single-stepping, instruction execution information is displayed and retained next to each instruction. You can clearly see the data behind your program's flow, including contents of all accessed (read or write) memory locations and registers, as well as flow-of-control direction change markers. A moving color bar indicates the current position in the program as it executes.

At your option, the iceMASTER source window allows operations on three different views of code memory: disassembled instructions, instructions mixed with High Level Language (HLL) source statements, or HLL source only.

HLL source statements and symbolic disassembly information are also displayed when you disassemble the program or view the trace buffer.

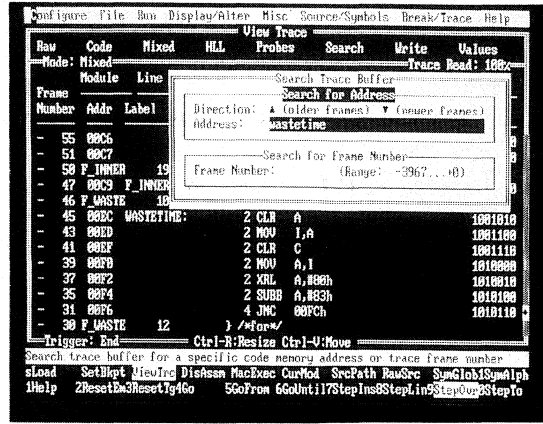

THE COMPLETE DEBUGGER

The trace buffer captures data in real-time. Trace information consists of address and data bus values and user-selectable probe clips. You can view the trace buffer data through several display filters: raw hex, disassembled instructions, instructions mixed with HLL source statements, or HLL source only. You can display the probe clip bit values in binary, hex, or digital waveform formats.

You can trigger the trace to begin capturing data on all instructions leading up to a breakpoint, around (before and after) a breakpoint, or following a breakpoint. Capture filtering allows you to focus attention only on areas of interest, eliminating clutter.

To further speed your design process, an integrated search mechanism allows you to locate any label, HLL source line number, or address in the trace buffer in either the backward or forward direction. The days of manually scanning or post-processing a large buffer of trace data are gone!

If you WRITE your program in a HLL, you should be able to DEBUG it that way - icEMASTER lets you do just that!

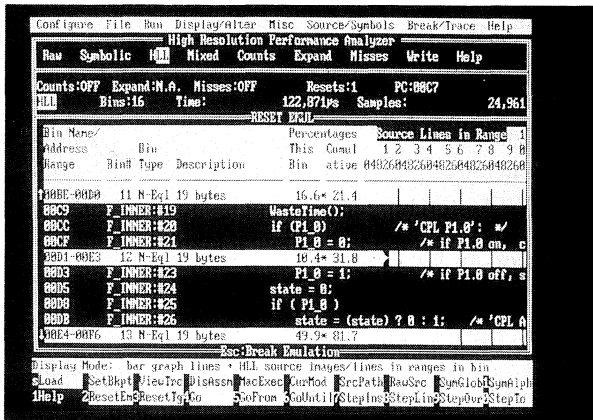

IMPROVING THE QUALITY OF YOUR PRODUCT: FINDING THE HOT (OR NOT SO HOT) SPOTS

icEMASTER emulators (Model 400 & PE) provide a PERFORMANCE ANALYZER that allows you to monitor the time spent executing specific portions of your program to find "hot spots" or "dead code." You can define and analyze memory areas based on code address, module, line number or label ranges.

You can view results dynamically during emulation or later for a more detailed analysis. You can toggle the display from bar graph format to actual frequency counts, and you can filter the level of detail in the displayed results to include raw data, code labels, and/or HLL source statements.

icEMASTER Model 400 provides an additional Performance Analyzer that is the absolute best in the industry for tuning and testing your code. It is very flexible and far more accurate than most other emulators, with a resolution of less than six microseconds. You can define and analyze up to 15 memory areas and each of these 15 memory areas can consist of non-contiguous, logically related subranges, (e.g. groupings of related functions which are not necessarily contiguous in memory).

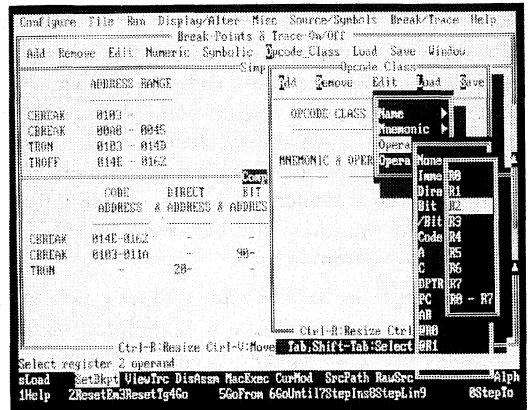

FINDING THAT BUG

You have access to as many as 128K breakpoints and 64K tracetriggers. These triggers can be enabled, disabled, set or cleared. Simple triggers are based on code or external data addresses or address ranges. Simple breakpoints can be set or cleared directly in the source window at disassembled instructions or HLL source statements.

Breakpoints can also be complex triggers, based on code address, direct address, bit address, opcode value, opcode class or immediate operand. Complex triggers can be ANDed and ORed together.

Finding that elusive bug is now much easier!

SMALL AND POWERFUL

Some companies design emulators that use one or two full size PC expansion board slots. These companies take it for granted that you have the "right" kind of PC, that you don't need the expansion slots for something else, and that you don't mind taking apart your computer to install their emulator!

At MetaLink, we don't take our customers for granted.

The iceMASTER family is the culmination of over 7 years of focused engineering by MetaLink to bring advanced semiconductor technologies to emulator design. Using state-of-the-art PALs (PEELs), LCAs, VLSI memories and microprocessors, MetaLink designed world-class emulation capability into the smallest emulator footprints in the industry, combining powerful and complex emulation features with all-around ease-of-use.

The high speed serial link connects easily to the back of your computer with a standard RS-232 cable. The emulators are smaller than the size of a VCR tape, fit neatly in crowded work spaces and are easy to move around on the bench or to other computers. **PORTABLE PRODUCTIVITY!**

iceMASTER-8051 Model 200/400 Development Systems

Metalink specializes in enhancing the emulation technology required by EMBEDDED SYSTEMS DESIGNERS. Metalink has consistently led the industry in emulation technology: The first PC-based 8051 emulator; the first 8052 emulator; the first to offer support for all the unique features of the 8051 family components, such as watchdog-timer, idle modes, power down mode, DMA and A/D.

Metalink is a full-service emulation company. We support our customers over the long term with services such as repair, discounted upgrades, rental units, 10-day trial purchase periods, and free technical support for applications problems. A network of world-wide sales and service representatives is augmented by a well-trained telemarketing staff at headquarters.

❑ HOST SPECIFICATIONS

Host IBM PC, XT, AT, 386, 486, PS/2, Laptop, Notebook or compatible system, 640K bytes of RAM, Hard Disk Drive, Monochrome or Color/Graphic Display, with a Standard RS-232 Serial Port. Operating System DOS 2.0 or greater.

❑ EMULATOR SOFTWARE SPECIFICATIONS

File Formats Supported with Symbolic or Source-Level Debugging:

Archimedes, Avocet, BSO/Tasking, Franklin, IAR Systems, Intel OMF, Keil, MCC, Microtec Research, Motorola 'S' records and Intel HEX.

Source/Symbol Support:

Assembler, C and PL/M Languages

Symbolic or Source-Level Debug:

Setting of Breakpoints
Setting of Trace ON/OFF
Viewing the Trace Buffer
Viewing of Source Window Display
Viewing of Performance Analyzer
Assembly/Disassembly of Code

HLL Structure/Content Display of:

Modules Line Numbers
Scopes Program Variables

❑ EMULATOR HARDWARE SPECIFICATIONS

iceMASTER-8051 Models:

200 Basic Emulator
400 Enhanced Emulator with:

4K Trace Buffer
2 Performance Analyzers
Full Watchdog Timer Support

Operating Modes:

Single-Chip ROM
Romless

Interchangeable Probe Card

Used to support the functional derivatives of each micro controller family as well as the full range of NMOS, CMOS, EPROM, and OTP technology variations. Contact Metalink for the latest information on any device supported.

Device Unique Support

A-to-D Converter
FIFO
Multiple-Divide Unit
Multiple DPTRs

❑ OPERATING CHARACTERISTICS

Clock frequency user-selectable between external target crystal/clock or internal crystal source
Electrically and Operationally Transparent
Real-time: 0.5-24MHz

❑ USER INTERFACE

Keyboard or Mouse Control
Pull-down & Pop-up menus with fill-in boxes

Available Main Screen Windows:

Registers and PSW bits
Bit Memory
Stack data displayed in HEX &/or ASCII
Up to 5 Internal Data Memory displayed in HEX &/or ASCII
Up to 5 External Data Memory displayed in HEX &/or ASCII
Up to 5 Code Memory displayed in HEX &/or ASCII
Source Program displayed in Code, HLL Source or Mixed

Watch window for variable data
System Status data displayed in HEX

Main Screen Window Display Controls:

Movable Selectable (On/Off)
Sizable Color selection
Scrollable Highlighting of key data

Function/Hot Key Access:

User-assignable for commands
User-displayable for quick reference

❑ MEMORY OPERATIONS

Emulation Memory:

64K Program Memory
64K External Data Memory

Mapping Resolution:

Program: 16-bytes/block
External Data: 16-bytes/block

Program Memory:

Single Line Assembler (full instruction set support)
Disassemble in Code or Source/Code mode
Disassembly may be written to a disk file

Data Memory:

Internal or External Memory
Fill of a block of memory with data
Copy a block of data to another area
Change a single address data content
Compare any two blocks of addressed data
Displayed data may be written to a file

Registers/SFRs/Bit Memory:

Examine or Modify

Program Variables:

Examine or Modify

❑ EMULATION CONTROLS

Reset from Emulator and Go

Reset from Target and Go

Reset Processor

Go from current Program Counter

Go From a new Program Counter

Go Until a Program Counter/Label

Slow Motion (Repetitive Step commands)

Step by machine instruction

Step by Line Number

Step Over calls

Step To next function or procedure

❑ HARDWARE BREAKPOINTS

64K real-time Program Addresses

64K real-time External Data Addresses

❑ TRIGGER CONDITIONS

Set directly in Source window or Pull-down menu
PC address & range of addresses

Opcode Value

Opcode Class

SFRs/Registers

Direct byte address & range of addresses

Direct bit address & range of addresses

Immediate operand value

Read/Write to bit address

Register address modes

Read/Write to Register address

Logical AND/OR of any of the above

External Data address & range of addresses

Break Count Overflow

External (CLIP) Break Input

External (CLIP) Trigger Output

❑ TRACE (Model 400)

4K-Frame Trace Buffer

Start, Center, End & Variable Trace Trigger settings

64K Trace ON/OFF triggers for trace filtering

Trace Contents consist of:

16-bits Address Bus
8-bits Data Bus
7-bits External Clips
DMA Activity

Trace Display Modes:

Raw Hex
Symbolic
HLL Source
Mixed

External Clips display format:

Binary data
HEX data
Digital waveform

Trace Buffer Operations:

Write trace buffer to a disk file
Search trace buffer for labels & addresses

❑ PERFORMANCE

ANALYZERS (Model 400)

Real-time Program profiling capability

5.4µ-sec sampling period

7 year duration

Display options:

Bar Graph
Frequency Count

Display Modes:

Raw Symbolic
Mixed HLL Source Lines

Up to 999 Bin capacity

User-controlled Bin set-up:

By Address By Symbol
By Module By Line Number
Automatic

❑ HELP

On-Line

Context sensitive

Hypertext/Hyperlinked

❑ MACRO

Repetitive routines

User-created and callable

❑ ELECTRICAL SPECIFICATIONS

Input Power (maximum):

1.5 A @ +5 VDC +/-5%

❑ MECHANICAL SPECIFICATIONS

Emulator Dimensions:

7.0" x 5.5" x 1.0"

17.8cm x 14cm x 2.54cm

Emulator weight:

2.0lbs 0.9kg

❑ ANNUNCIATORS

Power, Reset, Break, and Active LEDs

Power ON/OFF, Reset, Break switches

❑ WARRANTY

One (1) year limited warranty, parts and labor

Ordering Information**Philips Semiconductors 8051 Family Microcontroller Support****iceMASTER-PE Emulators**

The iceMASTER-PE emulators for the 8051 family are self-contained units, each dedicated to a particular member of the 8051 family. The emulator and probe card electronics are combined into a single, small package. Every iceMASTER-PE emulator comes with 64K of Code memory, 64K of External Data memory, a 16K frame Trace Buffer (which can be viewed without breaking emulation), power supply, RS-232 cable and an 8051 Macro Cross Assembler. All iceMASTER-PE emulators support an optional Break-Input signal clip, a Trigger-Output signal clip and seven user-placeable Trace-Capture-Input signal clips.

The following iceMASTER-PE emulators are currently available:

PE-8031-33

This emulator supports device operation from DC to 33MHz and has a 40-lead DIP footprint. This emulator supports the 8031 and 80C31 devices, regardless of process variation.

PW-8032-30

This emulator supports device operation from DC to 30MHz and has a 40-lead DIP footprint. This emulator supports the 8031, 80C31, 8032 and 80C32 devices, regardless of process variation.

PE-83752-16

This emulator supports device operation from DC to 16MHz and has a 28-lead DIP footprint. This emulator supports the 83C750, 87C750, 83C751, 87C751, 83C752 and 87C752 devices, regardless of process variation. This emulator is supplied with a 28-lead DIP to 24-lead DIP converter (CONV11) for 8xC751 support.

PE-8351FX

This emulator supports device operation from DC to 16MHz and has a 40-lead DIP footprint. This emulator supports the 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 8052, 80C52, 8752, 87C52, 8xC51FX, 80C54, 87C54, 80C58 and 87C58, regardless of process variation.

The following iceMASTER-PE emulators will be available in Q2'94.

PE-87L51FB

This emulator supports device operation from 3.5 to 16MHz and has a 40-lead DIP footprint. This emulator supports the 87L51FB device from 3.0 to 5.5 volts.

PE-8XCL410

This emulator supports device operation from 0.5 to 16MHz and has a 40-lead DIP footprint. This emulator supports the 83CL410 and 80CL410 devices from 1.8 to 6 volts.

PE-80CL51

This emulator supports device operation from 32kHz to 16MHz and has a 40-lead DIP footprint. This emulator supports the 80CL51 and 80CL31 devices from 1.8 to 6 volts.

iceMASTER Model 200 & Model 400 Emulators

All iceMASTER Model 200 & Model 400 emulators support full probe card interchangeability. To emulate several different devices, you need purchase only a single emulator base unit, the iceMASTER-8051, and then one probe card for each unique device to be emulated.

Both the iceMASTER-8051 Model 200 and the iceMASTER-8051 Model 400 emulators come with 64K of Code memory and 64K of External Data memory, power supply, RS-232 cable and an 8051 Macro Cross Assembler.

The IceMASTER Model 400 emulator has the following additional features/capabilities:

1. 4K-Frame Trace Buffer
2. Performance Analyzers
 - a. High Resolution
 - b. High Bin Count
3. Full Watchdog Timer (WDT) Support in all emulation modes

Philips Semiconductors 8051 Family Probe Cards

All MetaLink probe cards include a Break-Input signal clip, a Trigger-Output signal clip and seven user-placeable Trace-Capture-Input signal clips. In addition, there is a user-selectable jumper for XTAL source. Most probe cards have other user-selectable jumpers to control/configure the unique capabilities of each particular device. Some probe cards also contain a user-selectable jumper for V_{CC} source. iceMASTER-8051 emulators fully supports:

All I/O ports, with no restrictions.

The CMOS Idle and Power Down modes of operation, in those devices having such capabilities.

The Watchdog Timer (WDT), in those devices having such a capability. (iceMASTER-8051 Model 400 only)

Correct device interconnection footprints.

Following is a list of all Philips Semiconductors 8051 Family Probe Cards which MetaLink currently offers. Since MetaLink is constantly adding to its list of supported devices, please contact MetaLink for information on any device not listed below.

If support for a particular device is available at different maximum frequencies (MHz), the description of the Probe Card appears only once, with the speed variations noted in the Probe Card names above the description. Example: 8031-24 for a 24MHz 8031 Probe Card and 8031-20 for a 20MHz 8031 Probe Card.

MHW-8031-20**MHW-8031-24**

The 8031 Probe Card supports device operation from 0.5 to 24MHz and has a 40-lead DIP package interface. This probe card supports 8031 and 80C31 devices, regardless of process variation.

MHW-8032-20

The 8032 Probe Card supports device operation from 0.5 to 20MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C32 and 80C32 devices, regardless of process variation.

MHW-80C51FA-16

The 80C51FA Probe Card supports device operation from 0.5 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C51FA and 80C32 devices, regardless of process variation.

MHW-83C51FX-16

The 83C51FC Probe Card supports device operation from 0.5 to 16MHz and has either a 40-lead DIP or a 44-lead PLCC package interface. This probe card supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8x51FA, 8x51FB, 8052, 80C52, 8752 and 87C52 devices, regardless of process variation.

MHW-8052-16

The 8052 Probe Card supports device operation from 0.5 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, 8032, 80C32, 8051, 80C51, 8052, 80C52, 8751, 87C51, 8752, and 87C52 devices, regardless of process variation.

MHW-83C053-12

The 83C053 Probe Card supports device operation from 6 to 12MHz and has a 42-lead Shrink DIP package interface. This probe card supports 83C053, 83C054, 87C054, 83C055 and 87C055 devices, regardless of process variation.

MHW-80CL410-12

The 80CL410 Probe Card supports device operation from 0.5 to 12MHz and has a 40-lead DIP package interface. This probe card supports the 80CL410 device (4.5V-5.5V only).

MHW-80C451-16

The 80C451 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C451 device, regardless of process variation. Converter #5 is available to convert the probe card to a 64-lead DIP footprint.

MHW-83C451-12

The 83C451 Probe Card supports device operation from 1.2 to 12MHz and has a 68-lead PLCC package interface. This probe card supports the 80C451, 83C451 and 87C451 devices, regardless of process variation. Converter #5 is available to convert the probe card to a 64-lead DIP footprint.

MHW-80C528-16

The 80C528 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports the 80C528 device.

MHW-83C528-12**MHW-83C528-16**

The 83C528 Probe Card supports device operation from 1.2 to 16MHz and has either a 40-lead DIP or 44-lead PLCC package interface. This probe card supports 80C528, 83C528, 87C528, 83C524 and 87C524 devices, regardless of process variation.

MHW-83C550-12

The 83C550 Probe Card supports device operation from 1.2 to 12MHz and has a 44-lead PLCC package interface. This probe card supports the 83C550, 80C550 and 87C550 devices, regardless of process variation.

MHW-80C552-16

The 80C552 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C552 and 80C562 devices, regardless of process variation. Converter #7 is available to convert the probe card interface to a 40-lead DIP footprint for operation as an 8031, 8032, 80C31, 80C32 or 80C652.

MHW-83C552-16

The 83C552 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C552, 83C552, 87C552, 80C562, 83C562 and 87C562 devices, regardless of process variation. Converter #7 is available to convert the probe card interface to a 40-lead DIP footprint for operation as an 8031, 8032, 80C31, 80C32, 8x51, 8xC51, 8x52, 8xC52, 8xC652 or 8xC654.

MHW-83C575-16

The 83C575 Probe Card supports device operation from 0.5 to 16MHz and has either a 40-lead DIP or a 44-lead PLCC package interface. This Probe Card supports 80C575, 83C575 and 87C575 devices, regardless of process variation.

MHW-83C592-16

The 83C592 Probe Card supports device operation from 1.2 to 16MHz and has a 68-lead PLCC package interface. This probe card supports the 80C592, 83C592 and 87C592 devices, regardless of process variation.

MHW-80C652-16

The 80C652 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31 and 80C652 devices from any IC manufacturer, regardless of process variation.

MHW-83C652-16

The 83C652 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 80C652, 83C652 and 87C652 devices from any IC manufacturer, regardless of process variation.

MHW-83C654-16

The 83C654 Probe Card supports device operation from 1.2 to 16MHz and has a 40-lead DIP package interface. This probe card supports 80C652, 83C654 and 87C654 devices from any IC manufacturer, regardless of process variation.

MHW-83C751-16

The 83C751 Probe Card supports device operation from 0.5 to 16MHz and has a 24-lead Skinny DIP package interface. This probe card supports 83C751 and 87C751 devices, regardless of process variation.

MHW-83C752-12

The 83C752 Probe Card supports device operation from 0.5 to 12MHz and has a 28-lead DIP package interface. This probe card supports 83C752 and 87C752 devices, regardless of process variation.

MHW-80C851-12

The 80C851 Probe Card supports device operation from 1.2 to 12MHz and has a 40-lead DIP package interface. This probe card supports 8031, 80C31, and 80C851 devices, regardless of process variation.

MHW-83C851-12

The 83C851 Probe Card supports device operation from 1.2 to 12MHz and has a 40-lead DIP package interface. This probe card supports 80C851, and 83C851 devices, regardless of process variation.

iceMASTER Converters

iceMASTER converters are used with the iceMASTER-8051 Probe Card to allow the user to change the device footprint supported by the Probe Card to new device footprint or to allow the iceMASTER-8051 Probe Card to support a new device with the existing Probe Card.

MHW-CONV5

A 68-lead PLCC to 64-lead DIP converter for 83C451 or 80C451 Probe Cards to 80C451, 83C451 and 87C451 devices.

MHW-CONV7

A 68-lead PLCC to 40-lead DIP converter for 83C552 or 80C552 Probe Cards to 8031, 8032*, 80C31, 80C32*, 8051, 8751, 80C51, 87C51, 8052*, 8752*, 80C52*, 80C652, 83C652, 87C652, 87C654, 83C654 and 87C52* devices.

*Not all modes of Timer 2 supported.

MHW-CONV11

A 28-lead DIP to 24-lead DIP converter for the PE-83752 or 83C752 Probe Card to 83C751 and 87C751 devices.

MHW-CONV12

A 24-lead Skinny DIP to 28-lead PLCC converter for 83C751 Probe Card to 83C751 and 87C751 devices.

MHW-CONV13

A 28-lead DIP to 28-lead PLCC converter for PE-83752 and 83C752 Probe Card to 83C752 and 87C752 devices.

MHW-CONV14

A 40-lead DIP to 44-lead PLCC converter for PE-8031, 8031 Probe Card to 8031, 80C31, 8031 and 80C31 devices.

A 40-lead DIP to 44-lead PLCC converter for PE-8032, 8032 Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032 and 80C32 devices.

A 40-lead DIP to 44-lead PLCC converter for 8052 Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752 and 87C52 devices.

A 40-lead DIP to 44-lead PLCC converter for 8351FB Probe Card to 8031, 80C31, 8031, 80C31, 80C32, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8052, 80C52, 8752, 87C52, 8XC51FA and 8XC51FB devices.

A 40-lead DIP to 44-lead PLCC converter for 80410 Probe Card to 80CL410 devices.

A 40-lead DIP to 44-lead PLCC converter for 80652 and 83652 Probe Cards to 80C652, 87C652, 83C652, 87C654 and 83C654 devices.

A 40-lead DIP to 44-lead PLCC converter for 80528 and 83528 Probe Cards to 80C528, 87C528, 83C528, 87C524 and 83C524 devices.

A 40-lead DIP to 44-lead PLCC converter for 80851 and 83851 Probe Cards to 80C851 and 83C851 devices.

MHW-CONV19

A 68-lead PLCC to 44-lead PLCC converter for 83552 and 80552 Probe Cards to 8031, 8032*, 80C31, 80C32*, 8051, 8751, 80C51, 87C51, 8052*, 8752*, 80C52*, 80C652, 83C652, 87C652, 87C654, 83C654 and 87C52* devices.

MHW-CONV23

A 44-lead PLCC to 40-lead DIP converter for 80550 Probe Card to 80C550, 87C550 and 83C550 devices.

iceMASTER-8051 and PE Hardware Miscellaneous Products**MHW-EXT24DIP**

A 24-lead Skinny DIP, 6 inch target interface extension cable for 83C751 and 87C751 devices.

MHW-EXT28DIP

A 28-lead DIP, 6 inch target interface extension cable for 83C752 and 87C752 devices.

MHW-EXT40DIP

A 40-lead DIP, 6 inch target interface extension cable for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

MHW-EXT28PLCC

A 28-lead PLCC, 6 inch target interface extension cable for 83C751, 87C751, 83C752 and 87C752 devices.

MHW-EXT44PLCC

A 44-lead PLCC, 6 inch target interface extension cable for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 80C550, 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

MHW-EXT68PLCC

A 68-lead PLCC 6 inch target interface extension cable for 83C552, 87C552, 83C562, 87C562, 80C552, 83C451, 87C451, 80C451, 87C592, 80C592 and 83C592 devices.

MHW-DIPSE24/3

A 24-lead Skinny DIP pin isolator for 83C751 and 87C751 devices.

MHW-DIPSE28/6

A 28-lead DIP pin isolator for 83C752 and 87C752 devices.

MHW-DIPSE40/6

A 40-lead DIP pin isolator for 8031, 80C31, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C550, 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

MHW-DIPSE42S/6

A 42-lead Shrink DIP pin isolator for 87C054, 83C054 and 83C053 devices.

MHW-PLCSE28

A 28-lead PLCC pin isolator for 83C751, 87C751, 83C752 and 87C752 devices.

MHW-PLCSE44

A 44-lead PLCC pin isolator for 8031, 8032, 80C32, 8051, 80C51, 8751, 87C51, 8051FA, 83C51FA, 87C51FA, 8051FB, 83C51FB, 87C51FB, 8052, 80C52, 8752, 87C52, 80C528, 83C528, 87C528, 83C524, 87C524, 80C550, 83C550, 87C550, 80C652, 83C652, 87C652, 83C654, 87C654, 80CL410, 80C851 and 83C851 devices.

MHW-PLCSE68

A 68-lead PLCC pin isolator for 83C552, 87C552, 83C562, 87C562, 80C552, 83C451, 87C451, 80C451, 87C592, 80C592 and 83C592 devices.

With Windows[®]-based Source Level Debugger support for

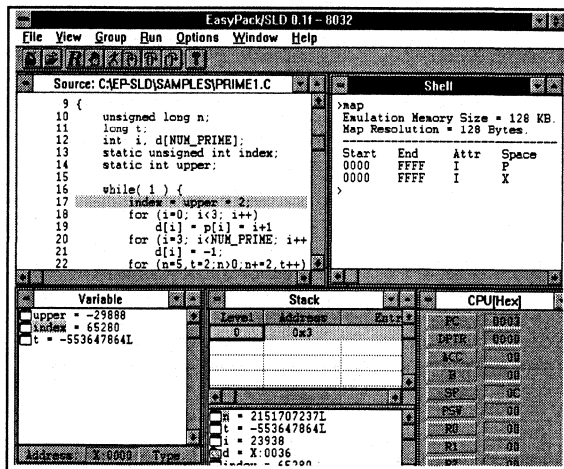

- ❖ 8031/32, 8052, 80C31, 8xC51
- ❖ 8xC550
- ❖ 8xC552, 80C562
- ❖ 8xC652, 83C654
- ❖ 8xC752, 83C750/751
- ❖ 85CL000
- ❖ 85CL580
- ❖ 85CL781/782
- ❖ *and other derivatives*

MICROTEK

The Leader in Development Systems Technology

Features

- ◆ Realtime Emulation up to 40MHz for 80C31 & 20MHz for 80C51
- ◆ 128KB overlay memory with 128 bytes mapping resolution
- ◆ Trace buffer supports 32K frame deep and 40 bits wide
- ◆ 64K hardware execution breakpoints
- ◆ Windows[®]-based source level debugger supported
- ◆ On-the fly feature supported
- ◆ Idle and Powerdown mode supported
- ◆ Hardware trace qualifier supported
- ◆ Two multiple setting bus breakpoints
- ◆ One external trigger input breakpoint
- ◆ BSO/Tasking, IAR/Archimedes, Keil/Franklin and 2500AD tool chains supported
- ◆ Two levels of event trigger; can be any logical constructions of OR & AND
- ◆ Support trace collection with flexible trigger (Pre, Post and Center trigger)
- ◆ One External Trigger Input and One External Trigger Output supported
- ◆ Execution time can be measured by self-contained timer up to 36.4 hours with 1 msec timebase
- ◆ On-line help, softkeys and user's defined symbol (up to 40 characters) supported
- ◆ Download data format supported: INTEL Hex & OMF 51, IEEE-695 and UBROF
- ◆ Optional EPROM writer
- ◆ One year Warranty

MICROTEK

MICROTEK INTERNATIONAL INC.

In-Circuit Emulation and source code debugging support the following microcontrollers families: 8031/32, 8X51/52, 8XC652/654, 80C154, 8344, 80C51FA, 8XC552, 83C752/751/750, 8XC152 and more variants.

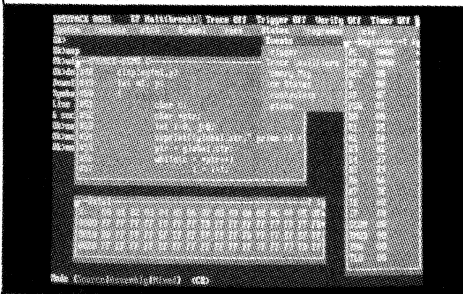

The EasyPack 8052F is a new generation of advance development tool supporting design, development and debugging of 8051 based family of embedded systems. A text windowed source level debugger, EasyView, developed for EasyPack series of emulators provides full control of the emulator.

An optional EasyPack EPROM Writer modules is also available to facilitate users to write program directly to EPROM right after it has been debugged with the EasyPack emulator.

System Feature:

Real-time Emulation

- Real-time emulation
 - * 40MHz for 8031/32
 - * 20MHz for 8051/52
- Idle and Powerdown mode supported
- Mini target test board provides:
 - * standalone clock source
 - * a diagnostic test for probe
- "On-the-fly" feature supported

EasyView is a text windowed source level debugger for EasyPack series of in-circuit emulator. It communicates with users through MS-DOS environment. With EasyView it gives you full control of your EasyPack emulator.

EasyPack 8052F

A member of Microtek's MICE product line for embedded systems development

High-Performance Overlay Memory

- 128K overlay memory with 128 bytes mapping resolution
- Mapping attributes: I (Internal), E (External), IR (Internal Read only), ER (External Read only), G (non-Existence), C (Combination) and CR (Combination Read only)
- Target processor can retain its entire Memory and I/O space

Real-time Trace Buffer

- Trace buffer is 32K frames deep and 40 bits wide, including 16 bits address, 8 bits data, 3 bits status, 5 bits external trace points and 8 bits port status (port selectable)
- Support trace On/Off function
- Trace buffer is accessible even the emulation processor is running
- Hardware trace qualifiers supported

Real-time Hardware Breakpoints

- 64K hardware execution breakpoints
- 2 multiple setting bus breakpoints
- 1 external trigger input breakpoint

EasyPack 8052F Models Summary

Model	Type	Support CPU
8051/52	ROM	8051/52, 80C51/52
8031/32	ROMless	8031/32, 80C31/32
83C652	ROM	83/80C652, 83C654
80C652	ROMless	80C652
8344	ROMless	8344
80C51FA	ROMless	Intel 80C51FA
80C154	ROMless	80C154
83C552	ROM	83/80C552, 80C562
83C752*	ROM	83/80C752, 83C751/750
83C152*	ROM	83/80C152JA, 83C152JB

* These models and 3V versions will be available soon.

* Generally EPROM devices, e.g. 87xx, can be supported by ROM types above via changing emulation processor.

Complex Event/Trigger

- Up to 2 levels of event triggering; each level may be a single event or any logical constructions of OR and AND triggering conditions
- Event counter provides a matched count triggering
- Trace collection with flexible trigger (PRE, POST and CENTER trigger trace) supported
- Provides one External Trigger Input (ETI) and one External Trigger Output (ETO) for device synchronization

Non-intrusive Program Execution Control

- Single step and step over in source or assembly levels
- Cycle step displays the status of executed bus cycle, address, data, port status and external trace bit status

Execution Time Measurement

- Execution time can be measured by self-contained timer (The maximum length is 36.4 hours with 1 μ sec timebase)

EasyView Source-Level Language Debugger

- A text windowed source level debugger
- Support Zoom up or down of viewpoints, pull-down menu and dialog box with mouse or keyboard
- Support on-line help, softkeys, user defined symbols (up to 40 characters)
- Download data format supported:
 - Intel hex-format & OMF-51 format
- Toolchains supported:
 - IAR, Franklin & 2500AD toolchain

Host PC requirement

- 286 based PC or above with MS-DOS 3.0 or later, 640KB of RAM, 1MB disk space for EasyView and a mouse is preferable

Physical Characteristics

Physical

Length	27cm (10.6 in.)
Width	23cm (9.0 in.)
Height	6cm (2.4 in.)
Weight	1.5kg (3.3 lbs.)

Electrical

Input	90-240VAC
	50 ~ 60 Hz
Consumption	35W (Maximum)

Environmental

Operating temp.	0 to 50 degrees C
Storage temp.	-10 to 65 degrees C
Humidity	20 to 80%

Service Warranty

Microtek International, Inc. products are warranted against defects in materials or workmanship for a period of one year. Contact your sales representative for extended warranty service.

EMUL51-PC

EMUL51-PC

- ▲ Support for all 8051 derivatives
- ▲ Real-time emulation at maximum chip speed
- ▲ Use of bond-out, hooks or regular chips for accurate emulation
- ▲ Choice of host hardware interfaces: PC plug-in, RS-232 port or workstations via LanICE
- ▲ Choice of user interface:
 - a) Microsoft Windows or OS/2
 - b) DOS based Borland keypress compatible (ChipView)
 - c) DOS based command line/pull-down windows
 - d) Several third party interfaces
- ▲ High level support for popular C-compilers
- ▲ Real-time trace boards, up to 256K deep, 64 bits wide, with eight trigger levels, timestamp and filtering
- ▲ Unlimited breakpoints, bankswitching, program performance analysis

To learn more, please call (408) 866-1820 for a FREE Demo Disk. For more information via your Fax, call our 24-hour Information Center at (408) 378-2912.

 WWW: <http://www.nohau.com/nohau>

NOHAU
 CORPORATION

Hosted on PCs and workstations.

The emulator was designed to be plugged into a full size PC AT style slot. The optional trace needs a second slot.

These same boards can also be supplied in an "RS-232 box" which communicates with the PC over a standard COM port.

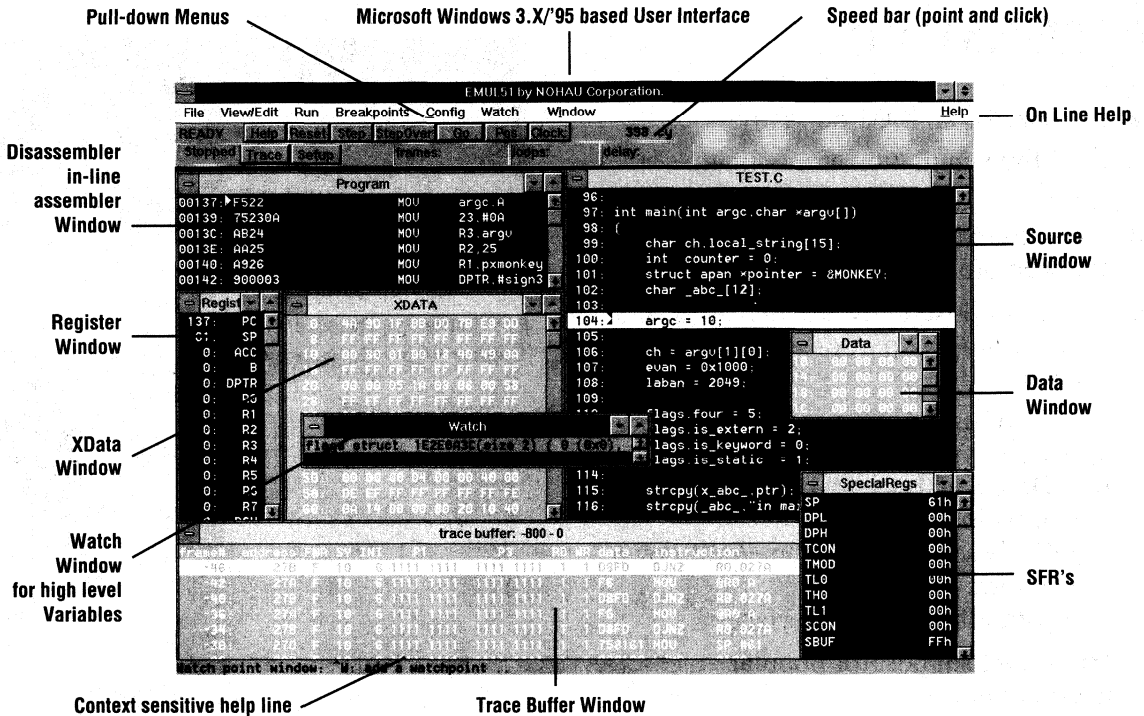

To use the EMUL51-PC on X Windows workstations such as SUN or HP, the Nohau LanICE is available. Because LanICE uses a high-speed (10 Mbit/second) local area network, not only can it be placed far away from the workstation, but it maintains the high code loading speed of the Nohau emulator plugged into your PC on your desktop.

(Continued)

EMUL51-PC

(Continued)

8051

The world's most popular 8051 emulator.

Since its introduction in 1986, Nohau has delivered over 10,000 EMUL51-PC emulators. Each emulator is often utilized on several projects where different 8051 derivatives are used. Since the emulator supports virtually all 8051 derivatives, only a change of the probe is required when a new derivative needs emulation support.

The EMUL51-PC's popularity is built on a solid word-of-mouth reputation for being a feature-rich product with excellent customer support. When we advertise the EMUL51-PC we boast about all the features like high-level debugging, bond-out support, multi-level triggering etc., but when we ask our customers about what they like best about EMUL51-PC the answer often is "it works".

Contact Information

Nohau Corporation

 Fax: (408) 378-7869
 WWW: <http://www.nohau.com/nohau>

NOHAU
 CORPORATION

Choice of different user interfaces.

Early in the evolution of the EMUL51-PC's user interface it became clear that customers had different opinions of how they would like the interface to work and what features were important to them. On these pages we show two of the three main user interface choices for the EMUL51-PC: Microsoft Windows 3.x/95, and ChipView's Borland keypress compatible. (Nohau's original pull-down / command line is not shown.) For an even better look at the Microsoft Windows interface, please see our ad on inside front cover. Recognizing EMUL51-PC's enormous popularity, several third party compiler vendors have ported their user software to the EMUL51-PC to provide emulator interfaces similar to their simulator interfaces. Among these vendors are: IAR, Intermetrics / Whitesmiths, Keil / Franklin and Production Languages Corporation.

In-depth support for all 8051 derivatives.

Nohau works closely with major 8051 chip vendors like Intel, Philips and Siemens. They give us access to special emulation chips called "bond-out chips" which makes it possible for us to emulate the 8051 in both Single Chip mode (all pins used for I/O), and External mode (P0 and P2 used for address/data).

NOHAU EMUL51-PC – PC-based in-circuit emulator

1.0 System Architecture

Features of the Nohau EMUL51-PC in-circuit emulator include:

- Low-cost full real-time emulation
- IBM PC-bus plug-in boards, or stand alone Box version with 115K baud RS232-C connection to IBM PC
- Easy-to-learn user interfaces with windows and pull-down menus
- Choice of interfaces: Windows, DOS, ChipView (Borland keypress compatible), other third-party interfaces
- Source-level debugging in C, PL/M or Pascal with full support for typed symbols
- 256k frames by 64 bit real-time trace option with time stamp
- Program Performance Analyzer

The Nohau EMUL51-PC consists of a board which plugs directly into the IBM PC/XT/AT bus for fast file transfer. An optional external box with a serial link is also available. The LanICE option supports network workstations. The optional Trace board features an advanced trace function with many trigger capabilities.

The POD, which plugs into the target system, is connected with a 5 ft (1.5 m) ribbon cable to the Emulator board to provide a useful operating range.

The EMUL51-PC uses no wait states and does not intrude on memory, stack, I/O or interrupt pins.

fig 1 EMUL51-PC plug-in board version

fig 2 External Box version

2.0 User Interfaces

2.1 DOS Interface

The user interface is based on MS-DOS software. It incorporates a variety of techniques. The user can select to operate either with short typed commands or using pull-down menus. On-screen features include windows to monitor or alter:

- Assembly or high level language source code
- CPU registers
- Internal data and Special Function Registers
- External data
- Watch variables in C, PL/M or assembly
- Trace setup and display

All commands are supported with context-sensitive help and full on-line manual.

2.2 Windows Interface

- Pull-down menus
- Speed bar (point and click)
- Source Window
- Watch Window for high-level variables

All the ease and flexibility of Microsoft Windows.

2.3 ChipView-51 Interface

- High Level / Low Level Debugger
- Keypress-compatible with Borland's Turbo Debugger
- Resizable moveable windows
- C call stack
- Support all emulator variations

3.0 Specific Features

3.1 Source Level Debugging

Using high level language for code generation is a way to cut development time. Therefore the EMUL51-PC gives full support for debugging directly in C or PL/M source code. This eliminates the need for paper listings. Breakpoints can be marked directly in the source code window. The user can single step through the program line by line and follow the program execution on the screen listing.

The trace permits the user to trace his source code in real-time.

All variables can be displayed and altered. This includes full support for typed symbols which permits the user to address such variables as floating-point, arrays and structures — both global and local.

3.2 Emulation Memory

The EMUL51-PC features 64 K of code memory and 64 K of external data memory. The addressable memory can be mapped either to target or to the emulator in 4K pages.

The emulator can load all common file formats and the user can view and alter all registers and memory areas of the microcontroller.

3.3 Breakpoints

The EMUL51-PC permits the user to generate program breakpoints in a number of ways:

- 64K program breakpoints
- 64K data read and 64K data write breakpoints
- Break on external signal
- Break on direct access to internal bit or byte memory
- Break on contents of internal register or memory
- Break on program access out-of-boundary

Using the Trace board it is possible to break on combinations of address, data, control signals, port signals and external signals.

3.4 Macros and debug session logging

Test session automation is made possible using the Macro commands. This permits the user to define his own command sequences using structures like IF/ELSE and REPEAT/WHILE. Such command sequences can be stored to a file which can be loaded automatically when the emulator is invoked.

A complete debug session and all setups can also be recorded to a file.

3.5 Trace Memory

The optional trace board features a trace buffer capable of storing up to 256k frames of 64 bit data each. The 64 bits consist of address, data, control signals, port signals, external signals and a time stamp.

The trace memory can be displayed, reprogrammed and restarted during emulation.

3.5.1 Trace Filter

The trace filter makes it possible to select what events are stored in the trace buffer. The qualifiers permit the user to define the criteria for which bus cycles are stored. The qualifiers can specify address, data, control signals, port signals and external signals.

3.5.2 Trace Trigger

The trace works much like a logic analyzer. It is therefore possible to trigger the trace on an event and display what happened before or after that event.

The trigger event can be defined using any of the qualifiers in up to eight levels. It is possible to trigger on boolean combinations of the qualifiers, or sequential combinations including a loop counter.

The trigger point can be selected anywhere within the 256k trace buffer to give full choice of pre/post trigger alignment.

3.5.3 Trace Display

The trace information can be displayed in high-level language statements, in disassembled form or in binary/hex form. It can also be stored to a file.

3.5.4 Program Performance Analyzer

With the PPA, information can be generated showing which addresses the user program spends its time on. The information can be displayed as statistics or in histogram form.

4.0 General Specifications

- Host:** IBM PC/XT/AT/386/486, PS/2 or compatible with 640K of RAM. Monochrome, color or enhanced graphics display.
- External Box:** The emulator boards can be installed in an external box with serial communication to the PC.
- Processors supported:** 8051, 8052, 8031, 8032, 80C51, 80CL51, 80C52, 80CL52, 80C31, 80CL31, 80C32, 8XC053/054/055, 83/80CL410/610, 83/80C451, 8XC524, 8XC528, 8XC550, 83/80C552, 8XCE558, 80C562, 8XC575, 80CL580, 8XC592, 8XC598, 83/80C652, 8XC748, 8XC749, 83/87C750, 83/87C751, 83/87C752, 8XCL781, 8XCL782, 83/80C851, 8XC51FA/FB (For more details, please refer to the following pages.)
A switch from one microcontroller to another is made by changing the low cost POD.
- File formats supported:** Intel HEX/OBJ/SYM/OMF, Avocet, Archimedes/IAR, BSO/Tasking, Franklin/Keil, Intermetrics/Whitesmiths/Comic, and many more.
- Clock speed:** Allows operation up to 33 MHz in real-time.
- Power supply:** The boards are powered from the PC-bus. The Emulator board requires 1.7A/5V and the Trace board 1.3A/5V.

5.0 Ordering information

PHILIPS SEMICONDUCTORS Microcontroller Support

EMULATOR UNITS

Includes software and ribbon cable. Must be connected to a POD to operate. Each step up in frequency rating covers all lower frequency steps. Includes DIP isolator if ordered with 40-pin POD. Emulator software has high-level debug and all options.

Order Number	Description
EMUL51-PC/E32	12 MHz Emulator, 32 kB (kiloByte) Emulation Memory.
EMUL51-PC/E32-16	16 MHz Emulator, 32 kB Emulation Memory.
EMUL51-PC/E128	12 MHz Emulator, 128 kB Emulation Memory.
EMUL51-PC/E128-16	16 MHz Emulator, 128 kB Emulation Memory.
EMUL51-PC/E128-20	20 MHz Emulator, 128 kB Emulation Memory.
EMUL51-PC/E128-24	24 MHz Emulator, 128 kB Emulation Memory.
EMUL51-PC/E128-30	30 MHz Emulator, 128 kB Emulation Memory.
EMUL51-PG/E128-33	33 MHz Emulator, 128 kB Emulation Memory.

TRACE BOARD OPTIONS

Optional second PC plug-in board. Emulator board contains no trace capability. Each frequency step covers all lower steps.

Order Number	Description
EMUL51-PC/TR4	12 MHz 4 kiloframe (4096 frames) Trace Buffer.
EMUL51-PC/TR4-16	16 MHz 4 k Trace Buffer.
EMUL51-PC/TR16	12 MHz 16 k Trace Buffer.
EMUL51-PC/TR16-16	16 MHz 16 k Trace Buffer.
EMUL51-PC/TR16-20	20 MHz 16 k Trace Buffer.
EMUL51-PC/TR16-24	24 MHz 16 k Trace Buffer.
EMUL51-PC/TR16-30	30 MHz 16 k Trace Buffer.
EMUL51-PC/TR16-33	33 MHz 16 k Trace Buffer.

Advanced Trace Boards feature 32-bit timestamping with 16-bit prescaler, eight-level triggers, state and counter functions, search.

Order Number	Description
EMUL51-PC/ATR64-16	16 MHz 64 k Advanced Trace Buffer.
EMUL51-PC/ATR256-16	16 MHz 256 k Advanced Trace Buffer.
EMUL51-PC/ATR64-24	24 MHz 64 k Advanced Trace Buffer.
EMUL51-PC/ATR256-24	24 MHz 256 k Advanced Trace Buffer.
EMUL51-PC/ATR64-33	33 MHz 64 k Advanced Trace Buffer.
EMUL51-PC/ATR256-30	30 MHz 256 k Advanced Trace Buffer.

BONDOUT PODS, 24-PIN, 40-PIN, 68-PIN, 84-PIN

Allow full emulation of internal, external and mixed modes of bus or port input/output. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

Order Number	Description
POD-C51B	12 MHz Bondout POD for 80C51, 8051, 87C51, 8751, 80C31, 8031, 80C/83C652, 83C654, 80C/83C662, 80C/83C851 single-chip or external mode.
POD-C51B-16	16 MHz Bondout POD for 80C/87C51-1, 80C/87C51, 80/8751, 80C31-1, 80C31, 8031, 80C/83C652, 83C654, 80C/83C662, 80C/83C851 single-chip or external mode.
POD-C51B-24	24 MHz POD for 80C/87C51-24, 80/8751, 80C31-24, 80C/83C652/654, 80C/83C662, 80C/83C851 single-chip or external mode. Special Requirement: Due to bondout chip timing, this POD requires a 30 MHz emulator board and trace board must be 30 MHz if used.
POD-CL410	POD for 83CL410, 83CL610, 80CL31, 80CL51. Target voltage range: 1.5–5.0V. Maximum frequency: 12 MHz at 5.0V. This POD is intended for emulating internal code. External bus operation is limited.
POD-C451B-PGA	12 MHz Bondout POD for 83C451, 87C451, 80C451 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.
POD-C451B-PGA-16	16 MHz Bondout POD for 83C451, 87C451, 80C451 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.
POD-C552B-PGA	12 MHz Bondout POD for 83C552, 87C552, 80C552 PLCC, single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.
POD-C552B-PGA-16	16 MHz Bondout POD for 83C552, 87C552, 80C552 16 MHz, 12 MHz single-chip or external mode. PGA from POD. Use optional adapter for PLCC target.
POD-C552B-PGA-24	24 MHz Bondout POD for 8XC552 or 8XC562 PLCC single-chip or external mode. PGA from POD. Use optional adapter (etc). Special Requirement: Due to bondout chip timing, this POD requires a 30MHz emulator board and trace board must be 30 MHz if used.
POD-CL580	12MHz Bondout POD for 83CL580.
POD-C652B	Order as POD-C51B.
POD-C751	12 MHz 83C750, 87C750, 83C751, 87C751, DIP POD. Includes EXT-DIP24.
POD-C751-16	16 MHz 83C750, 87C750, 83C751, 87C751, DIP POD. Includes EXT-DIP24.
POD-CL782	12 MHz POD for 83CL781, 83CL782, 83CL52

“HOOKS” MODE PODS, 28-PIN, 40-PIN, 42-PIN, 44-PIN, 68-PIN

Standard chip operated in special “hooks” emulation mode for single-chip or external modes. Some electrical characteristics are different from microcontroller’s. On-board POD crystal is 12 MHz on all PODs of any frequency specification.

Order Number	Description
POD-C52	12 MHz POD for 80C31, 80C32, 80C51, 80C52, 87C51, 87C52.
POD-C52-16	16 MHz POD for 80C31, 80C32, 80C51, 80C52, 87C51, 87C52.
POD-L51P-16	16 MHz POD for 8XC51FA/FB.
POD-C528	12 MHz POD for 80C528, 83C528, 87C528, 83C524, 83C528.
POD-C528-16	16 MHz POD for 80C528, 83C528, 87C528, 83C524, 83C528.
POD-C550-PGA	12 MHz POD for 80C550, 83C550, 87C550. PGA from POD. Use optional adapter for PLCC target.
POD-C550-PGA-16	16 MHz POD for 80C550, 83C550, 87C550. PGA from POD. Use optional adapter for PLCC target.
POD-C558-16	16 MHz POD for 83CE558/89CE558. Use optional adapter.
POD-C575	12 MHz 87C575, 87C575 chip may have to be supplied by user.
POD-C592-PGA	12 MHz POD for 8XC592. 8XC592 chip may have to be supplied by user. PGA from POD. Use optional adapter for PLCC target.
POD-C592-PGA-16	16 MHz POD for 8XC592. 8XC592 chip may have to be supplied by user. PGA from POD. Use optional adapter for PLCC target.
POD-C752	12 MHz 83C752, 87C752 DIP POD. Includes EXT-DIP28.
POD-C752-16	16 MHz 83C752, 87C752 DIP POD. Includes EXT-DIP28.
POD-C054	12 MHz POD for 8XC053, 8XC054, 8XC055 (Micocontroller-for-Television-Video).
POD-C575	16 MHz POD for 8XC575.

POD BOARDS, 40 PIN EXTERNAL MODE

Port 2 is upper address bus only. Port 0 is address/data bus. P3.6 is WRITE, P3.7 is READ. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

Order Number	Description
POD-31	12 MHz 8031 POD.
POD-C31	12 MHz 80C31 POD.
POD-32	12 MHz 8032 POD.
POD-C32	12 MHz 80C32 POD.
POD-C652	12 MHz 80C652 POD.
POD-C31-1	16 MHz 80C31-1 POD.
POD-C32-16	16 MHz 80C32 POD.
POD-C31-20	20 MHz 80C31 POD.
POD-C31-24	24 MHz 80C31 POD.
POD-C31-30	30 MHz 80C31 POD.
POD-C31-33	33 MHz 80C31 POD.

-S version of the above boards allows P3.6, P3.7 to be used either as unidirectional I/O or write and read. (Example: POD-31-S; POD-C31-S-1; POD-C32-S-16.)

EXTERNAL MODE PODS, 64-PIN, 68-PIN

Port 2 is upper address bus only. Port 0 is address/data bus. P3.6 is WRITE, P3.7 is READ. On-board POD crystal is 12 MHz on all PODs of any frequency specification. Each step up in frequency rating covers all lower frequency steps.

Order Number	Description
POD-C451-DIP	12 MHz 80C451 DIP POD.
POD-C451-DIP-16	16 MHz 80C451 DIP POD.
POD-C451-PGA	12 MHz 80C451 PLCC POD. PGA from POD.
POD-C451-PGA-16	16 MHz 80C451 PLCC POD. PGA from POD.
POD-C552-PGA	12 MHz 80C552 POD. PGA from POD. Use optional adapter for PLCC target.
POD-C552-PGA-16	16 MHz 80C552 POD. PGA from POD.
POD-C552-PGA-24	24 MHz 80C552 POD. PGA from POD.
POD-C552-PGA-30	30 MHz 80C552 POD. PGA from POD.
POD-C562-PGA-16	16 MHz 80C562 POD. PGA from POD.

LanICE LOCAL AREA NETWORK OPTION FOR XWindows (Sun, HP, and other workstations)

Order Number	Description
LanICE	XWindows Sun or HP workstation option for TCP/IP networks. Order this LanICE plus any emulator and POD unit. Trace buffer units are optional. The LanICE can accommodate multiple emulators.

BOX OPTIONS

Box units are AC line-powered. Emulator software runs under DOS on PC and uses a COM port at 110 baud to 115 kilobaud. Serial cable included.

Order Number	Description
EMUL51-PC/BOX-S	Serial Box. Select emulator separately; trace optional. POD not included.
EMUL51-PC/BOX-CS	Serial Box with E128-16 Emulator and TR16-16 Trace. POD not included.
EMUL51-PC/BOX-CS-20	Serial Box with E128-20 Emulator and TR16-20 Trace. POD not included.
EMUL51-PC/BOX-CS-24	Serial Box with E128-24 Emulator and TR16-24 Trace. POD not included.
EMUL51-PC/BOX-CS-30	Serial Box with E128-30 Emulator and TR16-30 Trace. POD not included.

MISCELLANEOUS OPTIONS

Order Number	Description
EMUL51-PC/PRG	Universal Programmer (EPROM, 8751, 87C51, PAL).
EMUL51-PC/PRG751	Programmer for 87C751, 87C752.
PHILIPS/LCPX5X	Single board programmer for DIP parts: 87C750, 'C751 and 'C752; PLCC parts: 87C451 and 'C552.
PHILIPS/LCPX5X40	Single board programmer for Philips 87C51, 'C51FA, 'C51FB, 'L51FB, 'C52, 'C524, 'C528, 'C550, 'C575, 'C652 and 'C654 DIP or PLCC.
EMUL51-PC/EXT-DIP24	Additional extender cable for 24 pin DIP.
EMUL51-PC/DIP24-ISO	24 pin DIP Isolator.
EMUL51-PC/DIP24-PLCC28	24 pin DIP to 28 pin PLCC.
EMUL51-PC/EXT-DIP24-PLCC28	Extender cable, 24 pin DIP to 28 pin PLCC.
EMUL51-PC/EXT-DIP28	Extender cable, 28 pin DIP.
EMUL51-PC/DIP28-PLCC28	28 pin DIP to 28 pin PLCC.
EMUL51-PC/DIP28-ISO	Additional 28 pin DIP Isolator.
EMUL51-PC/DIP28-DIP24-ADAP	28-pin (0.600-In) to 24-pin (0.300-In) adapter to plug POD-C752 into 8XC751 target. The user is responsible for port and register compatibility.
EMUL51-PC/EXT-DIP40	Extender cable for 40 pin DIP.
EMUL51-PC/DIP40-ISO	Additional 40 pin DIP Isolator.
EMUL51-PC/DIP40-PLCC44	40 pin DIP to 44 pin PLCC.
EMUL51-PC/DIP40-ONCE-DIP40	Clips over target microcontroller. Disables target micro to allow emulation without removing target chip. Works only on chips with on-chip emulation (ONCE) disable feature.
EMUL51-PC/DIP40-ONCE-PLCC44	Clips over target microcontroller. Disables target micro to allow emulation without removing target chip. Works only on chips with on-chip emulation (ONCE) disable feature.
EMUL51-PC/PGA44-PLCC44	PGA to PLCC adapter, 44 pin.
EMUL51-PC/PGA44-PLCC44-EL2	PGA to PLCC "elevator" or "tower" rigid 2-inch extender-adapter.
EMUL51-PC/PGA44-DIP40-C550	Adapter to use POD-C550-PGA in DIP target.
EMUL51-PC/EXT-DIP48	Extender cable for 48 pin DIP.
EMUL51-PC/DIP48-ISO	48 pin DIP Isolator.
EMUL51-PC/PGA68-PLCC68	PGA to PLCC adapter unit, 68 pin.
EMUL51-PC/PGA68-DIP84	PGA to DIP adapter unit for 451 PGA PODs to plug into DIP target.
EMUL51-PC/PGA68-ISO	68 pin PGA Isolator.
QIEXT-1	Extractor tool for PLCC parts.
EMUL51-PC/EZ	E-Z-Hook® wires for trace.
EMUL51-PC/CBL10-S	10 foot substitute for 5 foot POD cable (not for bondout PODs).
EMUL51-PC/CBL10-A	Additional 10 foot POD cable (not for bondout PODs)
EMUL51-PC/CBL5-A	Replacement 5 foot POD cable

E-Z-Hook is a registered trademark of Tektest, Inc.

BANKSWITCH EMULATOR BOARDS

User selectable as two banks of 64 kBytes, or as three switchable banks in upper half (8000 – FFFF) with lower half (0000 – 7FFF) not switchable. MOVX read-write data memory is only separate from code if data is mapped to target.

Order Number	Description
EMUL51-PC/E128-BSW	12 MHz Bankswitch Emulator, 128 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E128-BSW-16	16 MHz Bankswitch Emulator, 128 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E128-BSW-24	24 MHz Bankswitch Emulator, 128 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E128-BSW-33	33 MHz Bankswitch Emulator, 128 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E256-BSW	12 MHz Bankswitch Emulator, 256 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E256-BSW-16	16 MHz Bankswitch Emulator, 256 kB Emulation Memory. Requires Bankswitch POD.
EMUL51-PC/E256-BSW-24	24 MHz Bankswitch Emulator, 256 kB Emulation Memory. Requires Bankswitch POD.

Examples:

POD-31-BSW	12 MHz 8031 Bankswitch POD.
POD-C31-BSW-1	16 MHz 80C31-1 Bankswitch POD.
POD-31-S-BSW	12 MHz 8031 -S option Bankswitch POD.

The EMUL51-PC Emulator, Trace, POD, and Box hardware is sold with a one-year warranty. The EMUL51-PC Emulation software is sold with no warranty, but upgrades will be distributed to all customers up to one year from the date of purchase. Nohau Corporation makes no warranties, express or implied, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. In no event will Nohau Corporation be liable for consequential damages. The SIMUL51-PC Simulator software includes updates for a period of one year. Third-party software and programmers sold by Nohau carry manufacturers' warranties.

CHOOSING PODS for the EMUL51-PC

People sometimes ask: "How do I choose which POD to use for the 8051-family chip I want to emulate?"

Which POD you pick for your application depends on several things. What micro you are using, the frequency, the mode you are using it in, your target configuration, and price all play a part. The **EMUL51-PC ORDER INFORMATION** can help you choose among the POD types available from Nohau.

Nohau has several categories of PODs: (1) External-mode PODs; (2) Bondout PODs; and (3) "Hooks"-mode PODs.

1. External-Mode PODs

External or microprocessor-mode PODs have several clear advantages. They are the cheapest type of POD. They have easily-replaceable standard microcontrollers. Your program runs on the real production part, with most of the lines directly connected to your target. You can use them where your microcontroller has external program or external read-write memory. With this type of POD, Port 2 is used only for the upper address bus and not as port input-output (I/O). Port 0 is used as a multiplexed address and data bus. In most of these PODs, P3.6 can only be used as the write line and P3.7 as only the read line. The **POD-31** is a typical external POD.

Your target system shares Port 0 and Port 2 with the emulator. The emulator uses Port 0 to run its monitor code when it is not executing your code in real-time. When you are not running real-time emulation, the POD holds the Program Store ENable line (PSEN/) high so that your external read-only memory (ROM) is not enabled. It also holds the ReaD/ line and WRite/ lines high so that none of your external read-write random access memory (RAM) or I/O is enabled.

But in the monitor (not emulating) mode, the address lines of both Port 2 and Port 0 are active and can output any address in the 64 kByte address range. It is up to your target system to prevent enabling any device unless the PSEN/ or the RD/ or the WR/ line goes low.

If you are emulating a ROM-less part, like the 8031, you can use the **POD-31** type of POD. You also might use this POD for some internal ROM applications. You could use it for designs that have all of Port 2 and Port 0 used as external buses. This is true even though the program can be executed from on-chip 8051 program memory in your final product. This is a case where your target schematic, rather than the device you are using lets you use this type of POD. So though the part may ultimately be an 8051 or 8751, you can use a **POD-31** because you are using the ports as buses.

If you are emulating the 80C31, 8032, 80C32 or 80C652, you can get external-mode PODs for these microcontrollers. With the **POD-31**, you can emulate all those parts in external mode at up to 12 MHz. You can get the POD with the correct micro installed, such as a **POD-32**. Or you can change among the types by changing the microcontroller component in the POD yourself.

16 MHz, 20 MHz, 24 MHz, 30 MHz and 33 MHz PODs are available for 40-pin parts. If you use a **POD-C31-1** with a 16 MHz rated emulator, you can support such parts as the 80C31-1, 80C32-1 and 80C652-1. Any higher-frequency POD and emulator set can support all the lower frequencies.

For emulating the 80C451, 80C552, or 80C562 other external mode PODs are available. PODs for dual inline package (DIP) parts have a DIP plug coming out of the bottom of the POD. PODs for plastic leaded chip carrier (PLCC) parts have a pin-grid array (PGA) plug coming out from the bottom of the POD. To plug a PGA POD into a PLCC socket, you can get an optional adapter. The PGA68-PLCC68 is a typical adapter. If your target board has feed-through holes and you solder a PGA socket into it, you don't need an adapter. If your target board already has a PGA socket, you don't need an adapter.

POD-31-S: All the above external PODs use P3.6 as WR/ and P3.7 as RD/. But there is a 40-pin external mode POD version that lets you use these two lines as I/O. The basic board is the **POD-31-S**. This special -S option lets you select whether the two lines are to be WR/ and RD/ or else I/O. They can be unidirectional port lines (input-input, input-output, output-input, or output-output). You also can get this POD in the variations of 16 MHz and 20 MHz and any of the 40-pin part variations listed above.

2. Bondout PODs

Bondout PODs use special microcontrollers that the semiconductor manufacturers designed to perform all the functions of the part. They also have additional lines "bonded out" from the chip that allow control for emulation. PODs with these special chips cost more than PODs with widely available commercial chips, but give you a greater flexibility in how you use the ports. These PODs allow you to use any combination of internal or external mode of the chip, and respond to the state of the External Access (EA/) pin.

Nohau has bondout PODs for many different microcontrollers.

You can emulate the 80/80C51, 87/87C51, 80/80C31, 80C/83C/87C652, 83C/87C654, 80C/83C662 and 80C/83C851 with the **POD-C51B**. 16 MHz and 24 MHz versions are available.

To emulate the 83C451, 87C451 and 80C451 in the PLCC package, you can use the **POD-C451B-PGA**. See the previous discussion about PGAs.

For emulating the 80C/83C/87C552 and 80C/83C/87C562 you can use the **POD-C552B-PGA**. It also is available in a 16 MHz and 24MHz versions.

For emulating the 83C750, 87C750, 83C751 and 87C751, use the **POD-C751**. It has a 24 pin DIP plug on the bottom of the POD. You also can get an adapter to plug into 28 pin PLCC sockets. A 16 MHz version is available.

For emulating the 8XCL410, 8XCL31, and 8XCL51, use the **POD-CL410**.

For emulating the 83CL580, use the **POD-CL580** and a special adapter.

For emulating the 83CL781, 87CL781, 83CL782, 87CL782 and 80CL52, use the **POD-CL782**.

You should be aware of one small problem that most 8051 bondout parts have with serial communication. Specifically, if your program has written to SBUF, but the TI flag has not been set, and you then break emulation, the TI flag will never be set after you resume emulation.

Bondout PODs give you the best of both worlds. They let you mix how you use the ports. So you can emulate the single-chip mode using the ports as I/O. Or you can emulate external bus mode. Or you can emulate a mix of both modes.

3. "Hooks"-Mode PODs

The "hooks" type of POD Nohau offers uses a different technique for emulating. Certain chips can be put into a proprietary "hooks" mode that multiplexes the port information in and out of the part. The chip can still put out address and data. Most have 16 MHz versions available. This group includes these PODs:

The **POD-C752** is for emulating the 83C752 and 87C752. It has a 28 pin DIP plug on the bottom of the POD. You also can get an adapter to plug into 28 pin PLCC sockets.

The **POD-C52** can emulate the 80/80C/87/87C51, 80/80C/87/87C52, 80/80C31 and 80/80C32. You can use this POD when you need to emulate the 8052-type parts in single-chip mode when you are using Timer 2.

The **POD-L51P-16** can emulate the 8XL51FA/FB and can operate down to 3.0 volts.

The **POD-C528** can emulate the 80/80C/87/87C528 and 83/87C524.

The **POD-C592-PGA** can emulate the 8XC592. See the previous discussion about PGAs.

The **POD-C550-PGA** can emulate the 80/80C/87/87C550. It has a 44-pin PGA plug. You also can get an adapter to plug into 44-pin PLCC sockets.

The **POD-C558-16** can emulate the 83CE558 and 89CE558.

The **POD-C575** can emulate the 8X575.

The **POD-C054** can emulate the 8XC053/054/055 "MTV" chip.

With the "Hooks"-Mode PODs, you use jumpers to select whether the code is to be fetched from the emulator RAM or from external ROM. You also select whether the read-write memory is in the emulator or on your target board. The ports on these PODs may have slightly different electrical characteristics than the microcontroller. Specifically, some output signals can appear up to three clock cycles later than on the actual part. Also, some ports have greater current sink or sink and source capacity or slightly higher impedance than the actual part. For almost all applications, these differences will have no detrimental effects.

You can use any size **EMUL51-PC** emulator and optional trace board with any POD you choose in Nohau's **EMUL51-PC** family. Choose an emulator and trace board with frequencies as fast or faster than the frequency of your fastest POD. If you need more information about which POD would best fit your application, please contact Nohau.

PCE-51 Real-Time In-Circuit Emulator

- ▲ Supports virtually all 8051 derivatives in both internal and external ROM versions
- ▲ Supports Dallas DS320 core
- ▲ Fully transparent emulation up to 42 MHz
- ▲ Code banking for applications up to 512KB, with 512K breakpoints
- ▲ Full source level debugging and C variable support
- ▲ Complex break and trigger conditions
- ▲ Unlimited number of hardware breakpoints on all addressable spaces
- ▲ Multi mode real time trace, with program performance analyzer
- ▲ Highly advanced design using multiple FPGAs and SMD technology
- ▲ High speed (115K Baud) serial link with opto-isolation
- ▲ Powerful Windows or DOS based interface

Product Information

The RAISONANCE PCE-5130C is a full featured real-time in-circuit emulator specifically dedicated to the 8051 family of microcontrollers.

The system operates at crystal frequencies up to 42 MHz. The 128KB Code emulation memory allows code banking and is expandable to 512KB by the user, with 512K of hardware breakpoints. The memory mapping is one byte resolution for both Code and XData. The 64KB XData emulation memory is dual-ported and allows read/modify during execution.

The trace board offers a wide range of modes designed to make optimum use of all trigger conditions up to the capacity of the trace buffer. The trace frame includes the contents of the 32-bit timer, 32 external signals, and the program counter.

The software includes a source-level debugger for PL/M and C, a performance analyzer, an in-line assembler and intelligent disassembler, conditional breakpoints, loop counters, and many other features.

PCE-51 emulates virtually every 8051 derivative across the complete voltage and frequency range specified by each microcontroller manufacturer.

Microcontrollers Supported

DALLAS: DS80C320
INTEL: 80(C)31/32, 8X(C)51/52, 8XC51FA/FB/FC, 8XL51FA/FB/FC, 80C152
MATRA MHS: 8XC154
PHILIPS: 80CL31, 80CL51, 8XCL410, 8XC528, 80C451, 8XC550, 8XC552, 8XC562, 8XCL580, 8XC592, 8XC652, 8XC654, 8XC748/49/50/51/52, 8XC781/782, 8XC851
SIEMENS: SAB-C501, SAB-C502, 80C515/535, 80C517/537, 8XC515A, 8XC517A

RAISONANCE

STIMGATE®

Target Controller for ANSI-C

- ▲ Universal C development platform for embedded processors
- ▲ Uses Borland-C or Microsoft-C as debugger frontend
- ▲ Debug your target application in real-time on the PC. I/O and interrupt operations use the real target processor hardware
- ▲ Stimuli-Gateway I/O functions make your code portable and C compiler independent
- ▲ Uniform target interface via memory sockets
- ▲ Supports all present and future processor derivatives at no extra cost
- ▲ Test messages on the PC screen with portable stream functions
- ▲ Software configuration for the processor families, 8051, 8086, 68K, 68HC11, 68HC16, and several others

RAMTEX®
 A/S

Product Information

The STIMGATE system is a high performance development tool for embedded processors. It is specifically designed to give an optimized environment to develop your C program.

STIMGATE uses the well-known Borland-C or Microsoft-C tools as frontend and creates a universal and processor independent development platform. The highly productive integrated environment in these tools can be used directly, without limits, to execute, debug and test C programs for different embedded processor families.

The STIMGATE Target Controller connects your target processor system to the PC hardware in such a way that both on-chip I/O, external I/O and interrupt hardware in your target become a virtual part of the PC. All I/O and interrupt operations operate transparently on the real target hardware. STIMGATE is extremely fast, so most target applications can be executed in real-time from the PC. The probe interfaces via EPROM or RAM sockets in target. STIMGATE controls the real target processor with software instructions and lets it handle all I/O and interrupt operations. The target interface itself is therefore totally independent of processor derivatives and processor package types.

I/O and interrupt operations are "standardized" in ANSI-C with Stimuli-Gateway functions. These functions make your C program platform and C-compiler independent. They generate no code overhead when your program is finally compiled with a C compiler for the target processor. The resulting target hexfile can be downloaded in the memory emulator in the Target Controller, for final execution and test in target.

A comprehensive C source library with more than 70 I/O driver functions for timers, serial communication etc. is included with the STIMGATE CPU family software package.

SG Stream Windows contains more than 40 portable stream functions for handling of runtime test messages from embedded software. They have an ANSI-C like syntax and use post-formatting which gives minimum overhead in the target code and maximum writing speed. Writing from target to the PC screen takes place through the STIMGATE tool.

USP-51 In-Circuit Emulator

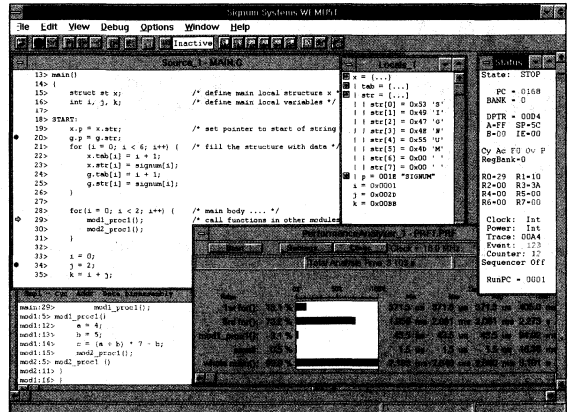

- ▲ Up to 256 KB of dual-ported zero-wait-state emulation memory allows read & write access during execution
- ▲ Non-intrusive emulation up to 42 MHz
- ▲ Supports nearly all 8051 derivatives
- ▲ Breakpoints on register values and Internal Data
- ▲ Source level debugging for C, & PL/M
- ▲ 32K by 80-bit selective trace buffer
- ▲ 32-bit synchronized time stamp
- ▲ Complex hardware breakpoints and passpoints
- ▲ Unlimited address and data match breakpoints
- ▲ Software performance analysis
- ▲ Execution coverage monitor
- ▲ High speed serial interface to a PC host
- ▲ Windows and MS-DOS user interface

SIGNUM

SYSTEMS

Product Information

USP-51 offers true real time in-circuit development and debugging in machine code, assembler source, and High Level Language (HLL) modes.

USP-51 comes with 64 KB of code memory (256KB banking model is optional), 64KB of xdata memory, source debugger for C, PL/M and ASM, 80 bit wide by 32K deep trace, and a sophisticated Graphical Event Triggering System (GETS). GETS uses a combination of address and data comparators, sequencer, external probes, and pass counters to create almost any complex trigger condition by selecting objects with a mouse on the graphical screen.

The zero-wait-state, dual-ported emulation memory allows the user full read/write access to program and xdata memory without slowing down the running processor. Watching and modifying the variables and parameters may be done without stopping the processor and causing your motor to run off, or the system to lose synchronization.

Selective tracing of only the meaningful data is easily achieved with the aid of our Graphical Event Triggering System. A 32-bit time stamp displays exact time relationships between instructions and routines in absolute, relative, and delta modes.

The HLL debugger provides support for all of the popular C and PL/M compilers. Unlimited number of breakpoints and passpoints may be set or cleared with a mouse, by simply clicking on the desired instruction in the Source window. You can watch variables change on-the-fly, and zoom in on any member of a complex structure with a click of a mouse.

Emulation CPU (either bondout or standard) is mounted on a probe assembly, as close as possible to target system for the best possible emulation

Other products

Signum carries a full line of emulators for 80C51, 196, 186, 386, 486, 320C1X/2X DSP, HPC, 68K, HC11, H8, Z8, Z80, Z180, Z380, 7700, 80C166, and others.

BCI51 Pro/Dallas Development Board

BCI51 Pro BASIC Cross-Compiler

- ▲ Develop professional quality 8051 code with easy-to-use BASIC—a true compiled, real-time, BASIC

Product Information

BCI51 Pro combines the ease of use of BASIC with the power of a true compiler. BCI51's runtime libraries and AI engine automatically take care of microcontroller reset, initialization, serial I/O, interrupt handling, startup code, and all interrupt vectors, letting you concentrate on your application. With BCI51 you can easily create your own custom input and output drivers such as input from a keypad and output to a liquid crystal display.

BCI51 supports interrupt-driven, ring buffered, full duplex serial I/O, an additional serial output, and a Pulse Width Modulation output. BCI51 supports four integer data types (8 and 16 bit).

BCI51 has the power and flexibility to grow with your requirements. A variety of configuration options, sophisticated error handling, and In-line assembly code provide you with a tool that is simple to use yet sophisticated enough for industrial-strength projects.

System Requirements

PC-compatible with 512K RAM and hard disk, MS-DOS 3.0 or later. Compatible with Microsoft Windows.

Controllers Supported

All 8031/32, 80C31/32, 8051/52, 80C51/52, 8751/52, and 87C51/52 with external data RAM. Dallas and 524/528 with on-board and/or external memory.

- Extensive documentation, phone hotline, 24-hour FAX, and a 24-hour BBS provide you with outstanding support
- All Systronix products have a 30-day money-back guarantee

Systronix®

Dallas Soft 8051 Development Board

- ▲ Supports all Dallas DIP and SIPstick 8051 soft microcontrollers
- ▲ Easy program loading from your PC serial port—no EPROMs
- ▲ Enclosures, keypads, LCDs also available

Product Information

Experiment with the entire Dallas 8051-compatible soft microcontroller family on one convenient board which accepts any Dallas DIP or SIPstick processor. Change to a different processor in seconds.

DPB2 is a versatile single board computer with LCD and keypad interfaces, serial I/O, rugged digital inputs and outputs, analog to digital conversion, voltage regulator, and a generous prototyping area.

Add our easy-to-use BCI51PRO BASIC compiler and you'll have your system completed in a flash!

- All processor ports brought out to labeled headers
- 8x2 header easily connects I/O and power to external equipment
- 19.2K baud RS-232 I/O port and 19.2K baud RS-232 serial printer port
- 4 by 4 keypad encoder/debouncer
- Parallel 4- or 8- bit LCD interface
- Four 350 mA 35V open collector digital outputs
- Four rugged digital inputs
- 8-bit ADC, adjustable input range
- Generous prototyping area for DIP, PGA, ZIP and SIMM packages
- Standard 100mm by 160mm size

Description

The PDS51 is a board-level, full featured, 12 MHz In-Circuit Emulator for the Philips 8XC51 family of Microcontrollers. It allows the user complete access to the internal registers and full execution control with no chip resources being consumed. This means that the microcontroller in the target system can be replaced with the PDS51 enabling the target system to be easily run, monitored and debugged without any changes to code or hardware. The PDS51 is supplied with sufficient memory to enable emulation of the complete 64K of directly addressable code memory and a 28K line by 32 bit wide, real-time trace buffer.

The PDS51 system consists of two interconnected modules. One board (the motherboard), contains the systems that are common to any derivative emulation such as the control microcontroller, logic, communication interface and power supply. The second board (the daughterboard), contains the bondout microcontroller which determines the target devices able to be emulated. Most daughterboards are able to emulate more than one derivative, thereby enhancing system flexibility with minimal expense.

External breakpoint and trace control inputs, along with emulation running and fetch address controlled output trigger signals, are provided for interfacing and synchronising to external equipment.

The PDS51 is controlled via an RS232 serial interface by a PC running terminal emulation or the PDS51-IDE debugger supplied. The Integrated Development Environment is a windowed command and display environment which runs on PC XT, AT, 386, 486 or compatibles. The PDS51 requires an external 6.5-9.5V 750mA DC power source.

PDS51 pictured with PDB552

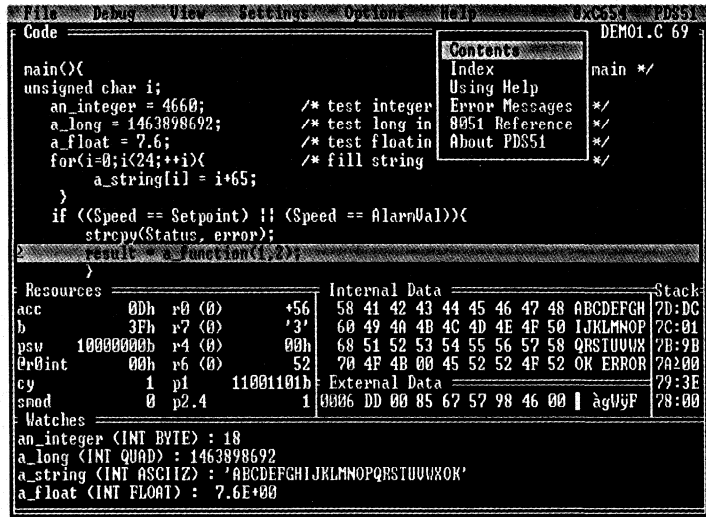

FEATURES

- Supports Philips 80C51 family
- Universal motherboard
- Bondout dependent daughterboard
- In-Circuit emulation
- No stolen resources
- 64K emulation code space
- Hardware breakpoints (64K) on:
 - Fetch address
 - Fetch address and external signal
- Real-time trace (28K frames)
- Traced information:
 - Fetch Address
 - 12 External trace probes
 - Control info (inta, c1)
- Conditional trace on:
 - Fetch address
 - External signal
- RS232 interface to PC
- Controlled via the Integrated Debugger or Terminal Emulation using the SDS command set
- Integrated Development Environment:
 - Windowed interface
 - Pull down menus
 - Borland style keystrokes
 - Symbolic or Source level debugging
- File formats supported:
 - BSO/Tasking
 - Kiel
 - Franklin
 - IAR
 - Archemedies
 - Metalink
 - Intel Hex
 - OMF51
- On-line help:
 - context sensitive
 - hypertext style

The PDS51 IDE (Integrated Development Environment) is a full screen, full featured debug and analysis interface to the PDS51 Development System.

It provides an easy to use windowed environment that consists of 6 non-overlapping resizable panes that display Code, SFR Resources, Watch Variables, Internal Data RAM, External Data RAM (if enabled) and the Stack area.

The IDE integrates the user's text Editor and Compiler/Assembler programs into the debug environment by providing fast and easy hot-key access.

The enhanced PDS51 IDE now facilitates source-level debugging for a variety of high level language compilers for the 80C51 including BSO/Tasking, Franklin/Keil and IAR/Archemedes 'C' compilers, as well as assemblers like Metalink.

Borland compatible hot-keys provide fast and familiar access to frequently used functions, while pull down menus lead the new user to the desired operation. A comprehensive on-line help facility provides indexed, context sensitive, and hypertext style help on PDS51 IDE operation, as well as 80C51 architecture and instruction set.

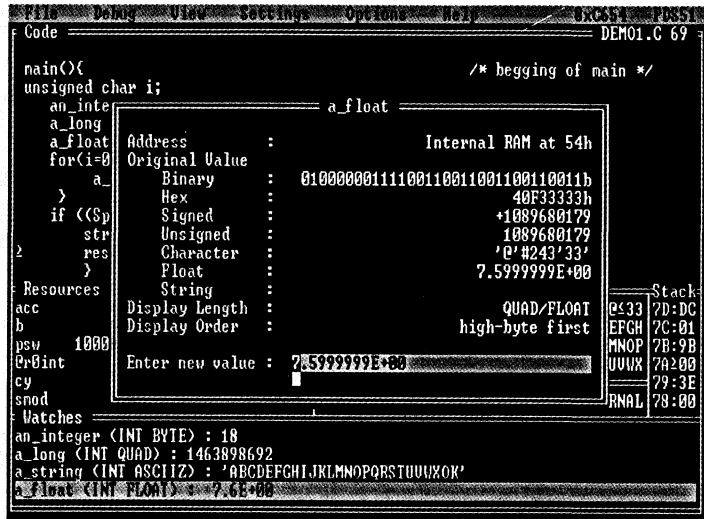

The code pane can be selected to display either a disassembly of the currently loaded program, or the source code itself. These modes are termed assembly-level and source-level respectively, and are readily switched between. A cursor is used to direct the debug operations with execution proceeding either at full speed or single stepped. Displayed variables are updated to accurately reflect the status of the emulator.

When programming using a compiler, your source code (C, Pascal etc.) will appear in the code pane in source-level mode, and debugging can be done

directly in terms of the high-level language statements. By switching to assembly-level mode, you will see the assembly-language code which the compiler has generated. When programming using an assembler, your source code (including all comments etc.) will appear in the code pane in source-level mode and by switching to assembly-level mode, you will see only the assembly-language code.

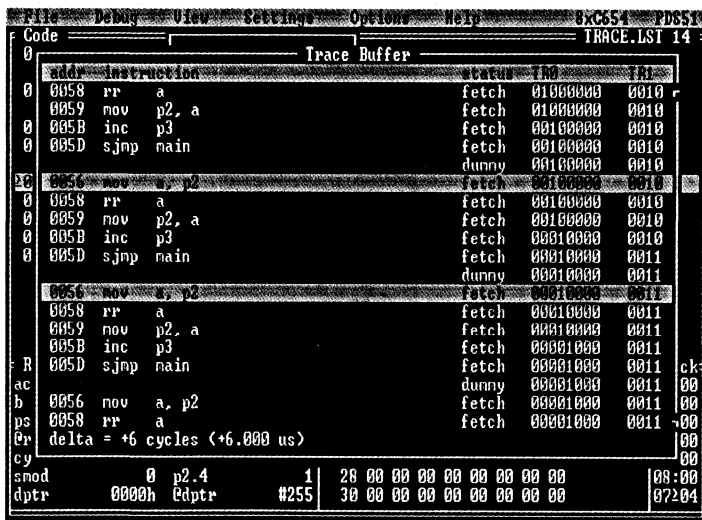

Breakpoints, triggers, trace inhibits and external breakpoints may be hot-key set and cleared at the cursor and are visible to the user as background shading of the corresponding lines of code. These settings may be specified in partitions and / or selected from a symbolic picklist.

The resource pane provides access to the special function register resources of the emulated derivative, while the watch pane provides access to user defined variables contained in the internal/external RAM. The layout, content and display format of these panes are user definable and may be edited at any time. Valid entry and display formats are hexadecimal, ascii, binary, signed and unsigned decimal, as well as IEEE floating point, Pascal string and 'C' string. Data may also be entered directly into internal and external memory and stack areas.

The huge 28K x 32 bit trace buffer is loaded in real time to provide subsequent viewing of past events. Executed code is presented in symbolic

format on a cycle by cycle basis along with 12 user configurable sampled inputs. Trace buffer viewing is aided by a cursor and a moveable reference bar between which code execution times are calculated.

An Execution Profiler is provided for identifying hot-spots or dead code for subsequent code optimization. This is in the form of a histogram of program fetches vs address bins. The address bin size and scale are adjustable.

Support for enhanced video display modes is provided for VGA and EGA displays to allow for more information on screen.

SPECIFICATIONS

- **Emulation:**
64K bytes of code space
In-circuit emulation via bondout
No stolen resources
Real time
Universal motherboard
Bondout dependant daughterboard
(each emulating several derivatives)
- **Trace Memory:**
28K bytes deep, 32 bits wide
16 bit program address
12 bits of port lines or user signals
External probes sampled S5P1
Control info (C1, INTA)
Trace input filtering on the fetch address
- **Breakpoints:**
Hardware implemented
Up to 64K on program fetch addresses
Up to 64K on external signal input AND
specified program fetch address
- **User Interfaces:**
1) Windowed full screen debug environment
Requires:
PC/XT/AT/386/486 or compatible
MSDOS ver 3.10 or later
512K bytes of available RAM
Monochrome/EGA/VGA

2) Dumb Terminal Emulation
using SDS command line instructions
- **Integrated Development Environment:**
File Formats Supported with Symbolic or Source-Level Debugging:
BSO/Tasking, Franklin/Keil, IAR/Archemedes, Metalink,
Intel Hex, OMF51, and more.
Windowed environment with 6 non-overlapping resizable panes:
HLL source or symbolic disassembly code
SFR resources
Internal/external RAM
Stack area
User watch variables
Pull-down menus
Enhanced video display modes available (28/50 line VGA, 43 line EGA)
Keyboard control, intuitive keystrokes and Borland compatible hotkeys
Fast hotkey access to user Editor/Assembler/Compiler applications
Data entry and display formats (examine/modify):
Hexadecimal, Ascii, Binary, Signed and unsigned decimal
IEEE floating point, Pascal string or 'C' string
Emulation Controls:
Reset bondout
Run from current program counter
Run from current program counter to cursor
Modify program counter
Single step (source-level line or assembly instruction)
Step over calls
Step into next call or procedure
Reposition cursor at address (or label selected from picklist)
Follow program without executing
Trace Display:
Window into 28K lines of trace buffer
Fetch addresses
Symbolic code format
Status (fetch, dummy, inta etc.)
12 external probes (boolean format)
Adjustable references for execution time calculation
64K of trace ON/OFF settings (trace filter)
- **Execution Profiler:**
Bar graph: No. of Fetches vs Address bins
Adjustable bin sizes and scaling
- **Settings:**
Breakpoints, external breakpoints, triggers, trace filters
all setable via specified address range, symbol picklist, or
keybinding over 64K code space.
- **On-line Help:**
Context sensitive
Indexed, Hypertext style
8051 architecture/Instruction set
- **Interface Signals:**
Force Trace I/P pin
Overrides trace input filter
External Breakpoint I/P pin
Breaks on an external event.
Fetch address sensitive over
64K range (sampled S2P1)
Emulation Active O/P pin
Signals when program running
External Trigger O/P pin
Trigger O/P for synchronising
external test equipment.
Fetch address controlled
over 64K range
(updated S2P1)
- **Speed:**
3.5 to 12 MHz
no wait states
no stolen cycles
- **Serial Interface:**
RS232C
Asynchronous, 8 data, no parity,
1 stop bit
9 Pin 'D' connector
Rxd/Txd jumper swappable
9.6K/19.2K/38.4K/115.2K Baud
(jumper selectable)
Xon/Xoff handshaking
- **Size:**
Motherboard with daughterboard
130mm x 110mm x 42mm (L.W.H)
- **Power Supply:**
9V nominal (6.5-9.5V)
800mA max, 500mA typical
3.5mm Phono plug centre +ve

Description

The P8051LCP40 SD and P8051LCPX SD are low cost, board level products which together program most of Philips 87C51 microcontroller derivatives.

The programmers connect to the serial port of a PC or compatible and are controlled by the interface software supplied.

The programmers will read, blank check, program and verify code bytes, security bits and the encryption array. Both EPROM and EEPROM programming algorithms are supported.

The P8051LCP40 SD has ZIF sockets which accommodate 40-Pin DIP and 44-Pin PLCC 87C51 derivatives while the P8051LCPX SD has ZIF sockets which accommodate 24- and 28-Pin DIP, and 68-Pin PLCC 87C51 derivatives. Adapters are available which extend the range of devices and package types able to be programmed by each programmer.

Up to 8 programmers may be serially connected together ("ganged") for the simultaneous programming of multiple devices.

An external 9V DC power source is required (200mA per board).

Features

- Program code space
- Read code space
- Verify
- Blank Check
- Program security fuses
- Program encryption array
- PC software user interface
- Diskfile I/O (Intel Hex)
- Cascadable for "gang" programming
- Zero insertion force sockets
- Adapters extend the range of programmable devices
- Upgradable

The P8051LCPX and P8051LCP40 programmers are supplied with a full screen PC interface.

The intuitive display shows an outline of the programmer hardware indicating what sockets and devices to use and accurately reflecting the programmers current status.

The function keys allow fast and easy control of the basic operations:

- Blank Check Check ROM locations are all FFh
- Program Writes code from buffer into device
- Verify Ensures a match between buffer code and micro controller code
- Security Program and verify security bits

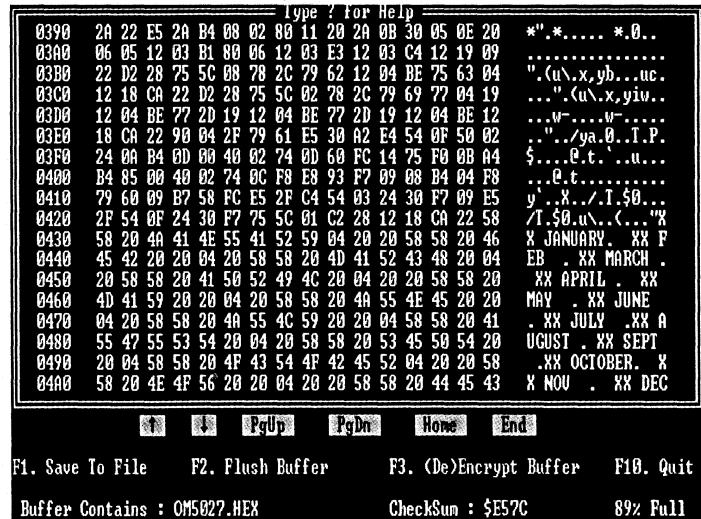

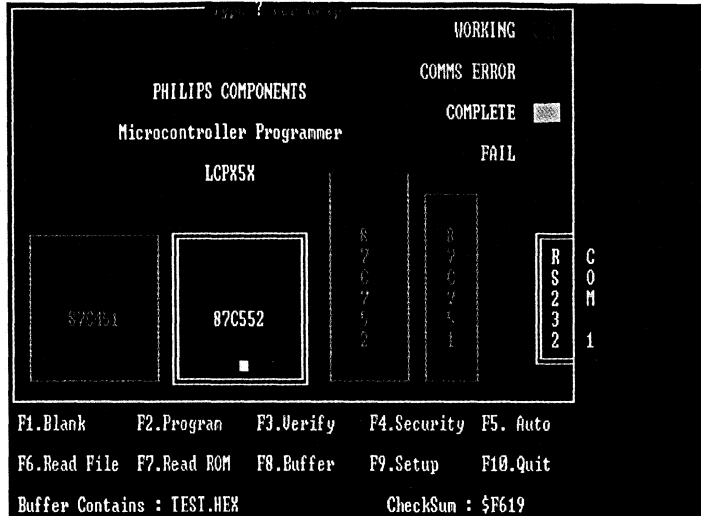

The Auto function performs all of the above operations sequentially to minimise operator intervention.

Only a single PC interface is required to coordinate the operations of up to 8 'gang-connected' programmers for programming multiple devices simultaneously.

The Read ROM function allows the master ROM contents to be read from the target microcontroller into the PC code buffer which may then be inspected (hex format), saved to disk (Intel hex file), or reprogrammed into other devices.

Hex files may also be read from disk to the buffer for subsequent programming, viewing or encryption.

The programmer interface is fully equipped for programming and

verifying encryption arrays and encrypted code. Data read or verified is automatically de-encrypted.

The new operator is assisted by the on-line context-sensitive help facility.

The interface is continuously upgraded in support of new devices as they become available. Upgrade kits are available from your nearest Philips dealer.

The software requires a host IBM PC/XT/AT/386/486 personal computer with an RS-232 serial port.

Each Programmer Kit Includes:

(both kits include the necessary hardware and software to program Philips microcontrollers using an IBM compatible PC/XT/AT/386/486)

- Programmer board with zero insertion force I.C sockets, 9 pin serial D connector (RS232), 9V power connector
- Control software on 3½" floppy disk
- User manual
- Phono power plug and cable for connection to external power supply

(plus in U.S.A only: RS-232 cable, 9-25 pin D connector adaptor, 110V AC to 9V DC adaptor)

Adaptors:

A range of adaptors is available which extends the list of devices and package types able to be programmed. Most adaptors are two-piece adaptors which consist of a Package Adaptor fitted to a specific Device Adaptor, which in turn is inserted into the 40 pin DIL ZIF socket on the P8051LCP40 SD. They are designed so one package adaptor may be shared between several device adaptors, thus minimising costs. See the selection table opposite.

*Support for the 87C504, 87C51FC, 87C54, 87C58, 87C576, 87C134 and 24/28 pin SSOP devices is intended but not available at the time of printing.

Description

The S87C00KSD Evaluation Board is a low cost, board-level product designed for evaluation of the I²C bus and Philips 80C51 microcontrollers. Its modular board layout and modular software make it useful for fast prototyping and as an educational tool.

This board is supplied with an 87C751 microcontroller pre-programmed with software which demonstrates I²C implementation, and application of a number of I²C peripherals.

Sockets for the 87C752, 87C654/528, and the 87C552 are included on the board to facilitate customer development of these microcontrollers.

A comprehensive user manual is supplied which includes circuit diagrams and demonstration source code listing. The board requires an external 9V 200mA DC power supply.

Board Modules:

- Microcontroller (87C751)
- LCD Display (PCF8577 / LTD226F-12)
- LED Display (SAA1064)
- 8-bit Parallel I/O (8574A)
- 8-bit Parallel I/O (8574)
- RAM (PCF8570)
- EEPROM (PCF8582)
- Clock/Calendar (PCF8583)
- DTMF Dialer (PCF3312 / TDA7050T)
- A/D and D/A (PCF8591)
- Socket for 87C752
- Socket for 87C654/528
- Socket for 87C552 with external RAM and Latch
- RS232 Interface
- Prototyping Area

CAN evaluation board with the 8XC552 and 82C200 CAN controller

OM4130

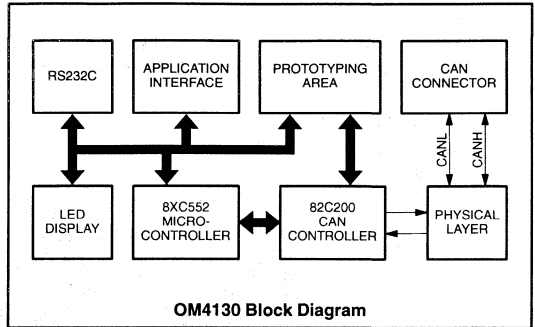

For evaluation of the 82C200 CAN-bus controller hooked to a 8XC552 microcontroller, Philips Semiconductors offers the OM4130 board. It is a low-cost prototyping board for interactive development of programs for full access to the CAN bus.

Major features of the OM4130 include:

- Evaluation of the 82C200 CAN controller
- Full support of the CAN communication utilities:
 - demonstration and monitor software for the CAN-bus system supports CAN communication of up to 1 Mbits/sec
 - interactive configuration of the CAN controller
 - CAN physical layer circuitry for balanced bus wires
 - LED display
- Interactive software development with up/down-loading of user-specific hex files
- On-board monitor software (EPROM)
- RS232C interface for connection to a PC, a terminal such as a VT100 or a workstation with terminal emulation
- Wire-wrap area for prototyping, an application interface and a two-wire CAN-bus connector

- Supply voltage: 7.5 to 18 V
- Dimensions: 100 × 200 mm.

The OM4130 comes with serial interface and supply voltage connectors.

OM4130 — CAN Evaluation Board with 8XC552 Microcontroller and 82C200 CAN Controller

Ordering Code: OM4130

CAN evaluation board with the 8XC592 microcontroller

OM4239

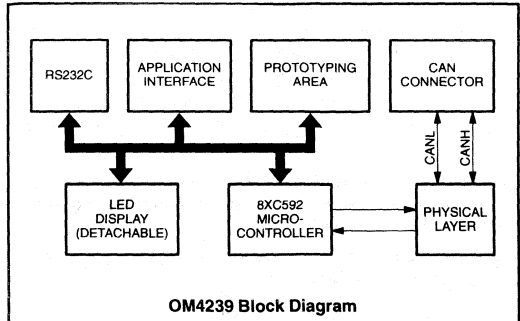

For evaluation of the 8XC592 microcontroller's CAN-bus interface, Philips Semiconductors offers the OM4239 board. It is a low-cost prototyping board providing powerful monitor functions for interactive development of programs for full access to the CAN bus.

Major features of the OM4239 include:

- Evaluation of the 8XC592 microcontroller's CAN interface
- Full support of the CAN communication utilities:
 - demonstration and monitor software for the CAN-bus system supports CAN communication of up to 1 Mbits/sec
 - interactive configuration of the CAN controller
 - CAN physical layer circuitry for balanced bus wires
 - detachable LED display
- Interactive software development with up/down-loading of user-specific hex files
- On-board monitor software (EPROM)
- RS232C interface for connection to a PC, a terminal such as a VT100 or a workstation with terminal emulation
- Wire-wrap area for prototyping, an application interface and a two-wire CAN-bus connector

- Supply voltage: 7.5 to 18 V
- Dimensions: 100 × 160 mm.

The OM4239 comes with serial interface and supply voltage connectors.

OM4239 — CAN Evaluation Board with the 8XC592 Microcontroller

Ordering Code: OM4239

Evaluation board for the 8XCE598 microcontroller

OM4240

For evaluation of the 8XCE598 microcontroller and its CAN-bus interface, Philips Semiconductors offers the OM4240 board. It is a low-cost prototyping board providing powerful monitor functions for interactive development of programs for full access to the CAN bus.

Major features of the OM4240 include:

- Evaluation of the 8XCE598 microcontroller and its CAN interface
- Full support of the CAN communication utilities:
 - demonstration and monitor software for the CAN-bus system supports CAN communication of up to 1 Mbits/sec
 - interactive configuration of the CAN controller
 - a plug-in CAN physical layer baby board with the 82C250 CAN transceiver IC for balanced bus wires
 - LED display
- Interactive software development with up/down-loading of user-specific hex files, single/multi-step breakpoint setting and software trace functions
- On-board monitor software (EPROM) and a PC-DOS compatible cross-assembler on a diskette
- On-board programming of a 87CE598
- RS232C interface for connection to a PC

- Wire-wrap area for prototyping, an application interface and a two-wire CAN-bus connector
- Supply voltage: 7.5 to 18 V
- Dimensions: 200 × 160 mm.

The OM4240 comes with serial interface cable and a supply voltage connector.

OM4240 — Evaluation Board for the 8XCE598 Microcontroller

Ordering Code: OM4240

SLIO evaluation board with the 82C150 and 82C250 CAN ICs

OM4272

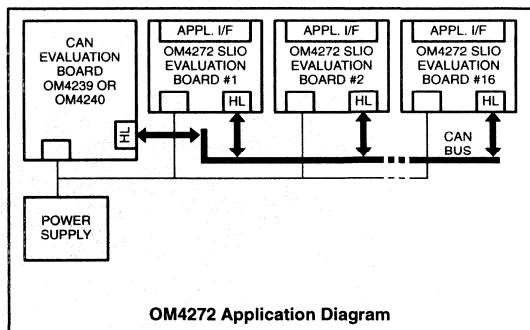

For a cost-effective implementation of CAN nodes, Philips Semiconductors offers the OM4272 SLIO (Serial Linked I/O) board. The board includes a P82C150 single-chip I/O device with a CAN protocol controller and a PCA82C250 CAN transceiver which interfaces to a physical bus complying with the ISO/DIS 11898 standard.

Major features of the OM4272 include:

- Low-cost interface between I/O and CAN bus
- Meets CAN protocol specification version 2.0A and B (passive) with restricted bit timing
- Sample software is provided for control/configuration of up to 16 OM4272 nodes via the CAN bus:
 - ready to use for exercising the P82C150
 - runs on an OM4239 or OM4240 board
 - uses all types of SLIO messages
 - sends calibration messages, checks presence of SLIO devices and switches the on-board LED connected to a port pin of the P82C150
 - source code written in C and down-loadable hex files are provided on a 3.5" diskette
- Full automatic bit rate detection and calibration
- 10-bit analog-to-digital conversion with up to six multiplexed analog input channels
- Up to 2 quasi-analog outputs with 10-bit accuracy

- On-board facilities for low-pass RC filters for analog-to-digital converter and quasi-analog outputs
- The application interface connector is hooked to all I/O ports, reset, test, and power pins
- Optional external clock mode via the application connector
- Supply voltage: 7.5 to 18 V
- Dimensions: 50 × 52 mm.

The OM4240 comes with serial interface cable and a supply voltage connector.

P83C852 Smart Card crypto-controller demonstration kit

OM4280

For the fast growing market of smart cards, Philips Semiconductors offers the OM4280 demonstration kit for evaluating its P83C852 Crypto Controller. This demo kit enables the user to evaluate the smart card operating system implemented on the P83C852. The operating system provides several functions including PIN verification, various memory functions and debiting. It also supports more complex functions required for, e.g., point-of-sale applications and encryption/decryption functions for confidential data transfer including a personal signature in, e.g., open FAX systems.

The wide spread use of smart cards requires thorough information security. The OM4280 demo kit particularly addresses this issue. The P83C852 Crypto Controller has an on-chip accelerator for fast asymmetric enciphering using the RSA algorithm.

A sample program on the OM4280 supports secret and public keys

for two persons named Alice and Bob. The user can assign, however, any other pair of secret/private keys on the card.

The demonstration kit is supplied with:

- An operating manual
- A full description of the card operating system
- Two Smart Cards each with a P83C852 CMOS crypto controller
- A card reader
- A PC interface cable
- A mains adaptor
- Diskettes with the Smart Card demo software and source code for an RS-232 interface to a PC's serial port

OM4280, P83C852 Smart Card Crypto Controller Demonstration Kit

Ordering Code: OM4280

Evaluation board

PEB552

The PEB552 is a low-cost, easily customized single extended euro-card for the Philips high performance PCB80C552 microcontroller. The PEB552 can be programmed in high-level PLM51, Forth, Basic, C languages or conventional assemblers.

A major design feature of the PEB552 is its large, 11 × 38, wire-wrap prototyping area in a 0.1-inch grid. All the microprocessor signals, I/O decoding and an uncommitted 96-pin connector are conveniently routed to the edge of the prototyping area. The fully expanded memory offers 124 kbytes of RAM and EPROM and 4 kbytes of reconfigurable decoded I/O space.

The PEB552 has been designed for on-board EPROM programming. These programs can be executed at power-up or reset. The high programming voltages required for the EPROMs are provided by a piggy-back module which readily plugs into the PEB552.

To operate the PEB552, simply connect it to your PC and run a suitable terminal emulator program. The turn on the board's 5 V power supply and the PEB552 will respond with a message indicating that it is ready to use.

PEB552 FEATURES

- CMOS PCB80C552 processor based on the industry standard 80C51
- Wire-wrap prototyping area with uncommitted 96-pin DIN41612 connector
- All processor pins available on pin-headers near the prototyping area
- Full duplex RS232 interface to 25-pin or 9-pin D-shell connectors
- Two-wire I²C serial communication bus
- 32 kbytes of RAM expandable to 64 kbytes
- Optional battery back-up
- 256 bytes of RAM on the PCB80C552
- 32 kbytes of EPROM including a powerful monitor program. Expandable to 64 kbytes.
- Optional on-board EPROM programming capability for up to 32 kbytes of EPROM
- Optional on-board 87C552 microcontroller programming
- Reconfigurable memory-mapped I/O decoding
- Eight analog inputs multiplexed to a 10-bit ADC
- Two PWM outputs can be used as 8-bit DACs
- Five 8-bit I/O ports
- One 8-bit input port shared with the analog inputs
- Two 16-bit timer/counters
- One 16-bit timer counter coupled to four capture registers and three compare registers
- Two watchdog timers
- Fifteen interrupt vectors
- Single 5 V supply
- Power-on reset
- Power-fail detect and automatic battery back-up switch over.

PEB552 Evaluation Board

Evaluation board

PEB552

HARDWARE SPECIFICATIONS

Processor and Memory

The heart of the PEB552 is the Philips PCB80C552 microcontroller operating at 11.059 MHz. The board is supplied with 32 kbytes of static RAM and 32 kbytes of EPROM. The memory can be further expanded to 64 kbytes of RAM and 64 kbytes of EPROM. Two RAM sockets enable the use of either 8 or 32 kbyte devices and two EPROM sockets enable the use of 8, 16 or 32 kbyte devices. The second of the two EPROM sockets is available for EPROM programming. The memory and I/O maps are completely configurable by either jumper selections or, for customized requirements, via an industry standard programmable logic device.

Serial I/O

A full-duplex RS232 interface is implemented on the PEB552. The RS232 connector on the board enables a flat cable to be made up for the 25-pin or 9-pin D-shell connector conventions required by the IBM PC/XT and /AT computers and compatibles. Jumpers are provided to select the conventions for the transmit, receive and ground signals. The 11.059 MHz crystal frequency on the PEB552 can be used in conjunction with an on-chip timer to generate baud rates up to 19200 baud.

An I²C-bus controller for two-wire serial communication with I²C-bus compatible ICs is also provided. The I²C serial I/O has complete autonomy in byte handling and operates in 4 modes:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

Parallel I/O

All of the processor signals are routed to pin headers at the edge of the prototyping area. The PCB80C552 processor offers five 8-bit I/O ports and one 8-bit input port. When using the processor in expanded mode, a dedicated 4 kbyte memory-mapped I/O space is enabled. The memory-mapped I/O is further decoded to produce 8 I/O select signals available on a pin header close to the prototyping area.

Watchdog Timers

Watchdog timers are an important feature of embedded microcontroller applications. The purpose of a watchdog timer is to reset the microcontroller if it enters an erroneous state within a reasonable period of time. The PEB552 has two watchdog timers: one is external to the PCB80C552 and has a time-out period of 1.4 s, and the other is part of the processor and has a programmable time-out period between 2 ms and 500 ms. Both watchdog timers are enabled with jumpers on the PEB552. If either watchdog times out, a reset pulse is generated.

External Connections

An uncommitted DIN41612 connector is available at the edge of the card and positioned in front of the prototyping area. Its 96 connections are routed to holes on the prototyping matrix.

All of the PCB80C552 processor pins with the exception of the crystal pins are available on the pin headers.

EPROM and 87C662 Processor Programming

For easy on-board EPROM programming, sufficient board area is available on the PEB552 for a 28-pin ZIF socket to hold an 8, 16, or 32 kbyte EPROM. Source code developed using high-level languages or assemblers can be burnt into the EPROM by using the optional PEB552VA voltage converter adapter and a pre-programmed 87C552 microcontroller. The PEB552VA plugs into a connector on the PEB552 and converts the 5 V supply voltage to 5, 6, and 12.5 V required for EPROM programming. The adapter is

controlled by a signal from the controller. A 87C552 can be programmed using an optional 87C552 programming adapter.

Battery Back-up

An external 2 to 4 V battery can be used to retain data in RAM. A precision voltage level detector automatically switches the 5 V supply over to the battery supply when the 5 V supply drops 50 mV below the battery level. Battery supply is switched to the main supply when the main voltage rises 50 mV above the battery level.

The precision voltage level detector also provides a power-fail signal that is available as an interrupt signal to the processor.

SOFTWARE SUPPORT

The PEB552 is supplied with a monitor program — MON552 — consisting of a diskette and a 27C256 EPROM. The diskette is IBM PC-compatible and contains the host module for the monitor program. The EPROM code executes on the PEB552 and uses approximately 2 kbytes of the supplied 32 kbytes EPROM. Existing systems can be upgraded with a pre-programmed 87C552 to replace the EPROM monitor and to provide both EPROM and 87C552 programming capability with the aid of the appropriate adapters.

The monitor module provides the minimum functionality required to:

- Read and write to internal and external RAM
- Read from program memory
- Read and write to the special function registers
- Load and save Intel hex files
- Program execution control such as jump to a start address
- Disassemble program memory
- Single step through a program in RAM or EPROM
- Set multiple break points

The purpose of the host module is to provide a user interface for the monitor module. The host module communicates with the PEB552 via the serial RS232 interface. Commands and parameters are transmitted to the PEB552. The monitor module then interprets these commands and transmits the required data back to the host. The host software provides a window environment, a lexical analyzer and command interpreter. Higher level languages including PLM51, Forth, Basic, C and assemblers are readily available from various sources to develop executable code for the PEB552.

USER SUPPORT

Users must register the serial number of their PEB552 with Micro Amps Ltd., the designer and manufacturer of the board, to receive support. This registration entitles the user to receive telephone support, information regarding new software releases, details regarding associated software tools, operating systems and customization facilities.

ORDERING INFORMATION

The ordering code for the complete PEB552 package: 9339 953 0112

This package includes:

- PEB552 evaluation board
- PEB552 hardware manual
- MON552 monitor manual
- PCB80C552 user manual
- REG552 registration form.

Optionally available:

- PEB552VA voltage adapter and 87C552 microcontroller for on-board EPROM programming
- Adapter for on-board 87C552 microcontroller programming

DATA HANDBOOK SYSTEM

Philips Semiconductors data handbooks contain all pertinent data available at the time of publication and each is revised and reissued regularly.

Loose data sheets are sent to subscribers to keep them up-to-date on additions or alterations made during the lifetime of a data handbook.

Catalogs are available for selected product ranges (some catalogs are also on floppy discs).

Our data handbook titles are listed here.

Integrated Circuits

<i>Book</i>	<i>Title</i>
IC01	Semiconductors for Radio and Audio Systems
IC02	Semiconductors for Television and Video Systems
