RATING SYSTEM

ABSOLUTE MAXIMUM RATING SYSTEM

Absolute maximum ratings are limiting values of operating and environmental conditions applicable to any electronic device of a specified type as defined by its published data, which should not be exceeded under the worst probable conditions.

These values are chosen by the device manufacturer to provide acceptable service-ability of the device, taking no responsibility for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electronic devices in the equipment.

The equipment manufacturer should design so that, initially and throughout life, no absolute maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply voltage variation, equipment component variation, equipment control adjustment, load variations, signal variation, environmental conditions, and variations in characteristics of the device under consideration and of all other electronic devices in the equipment.

DATA HANDBOOK SYSTEM

Our Data Handbook System is a comprehensive source of information on electronic components, subassemblies and materials; it is made up of three series of handbooks each comprising several parts.

ELECTRON TUBES SEMICONDUCTORS AND INTEGRATED CIRCUITS RED COMPONENTS AND MATERIALS GREEN

The several parts contain all pertinent data available at the time of publication, and each is revised and reissued periodically.

Where ratings or specifications differ from those published in the preceding edition they are pointed out by arrows. Where application information is given it is advisory and does not form part of the product specification.

If you need confirmation that the published data about any of our products are the latest available, please contact our representative. He is at your service and will be glad to answer your inquiries.

This information is furnished for guidance, and with no guarantee as to its accuracy or completeness; its publication conveys no licence under any patent or other right, nor does the publisher assume liability for any consequence of its use; specifications and availability of goods mentioned in it are subject to change without notice; it is not to be reproduced in any way, in whole or in part without the written consent of the publisher.

ELECTRON TUBES (BLUE SERIES)

This series consists of the following parts, issued on the dates indicated.

Part 1a	Transmitting tubes for communication and Tubes for r.f. heating Types PE05/25 - TBW	December 1975
Part 1b	Transmitting tubes for communication Tubes for r.f. heating Amplifier circuit assemblies	January 1976
Part 2	Microwave products	May 1976
	Communication magnetrons Magnetrons for microwave heating Klystrons Travelling-wave tubes	Diodes Triodes T-R Switches Microwave semiconductor devices Isolators — circulators
Part 3	Special Quality tubes; Miscellaneous devices	January 1975
Part 4	Receiving tubes	March 1975
Part 5a	Cathode-ray tubes	August 1976
Part 5b	Camera tubes; Image intensifier tubes	May 1975
Part 6	Products for nuclear technology	January 1977
	Channel electron multipliers Geiger-Mueller tubes Neutron tubes	
Part 7	Gas-filled tubes	August 1975
	Voltage stabilizing and reference tubes Counter, selector, and indicator tubes Trigger tubes Switching diodes	Thyratrons Ignitrons Industrial rectifying tubes High-voltage rectifying tubes
Part 8	TV Picture tubes	October 1975
Part 9	Photomultiplier tubes Phototubes (diodes)	June 1976

SEMICONDUCTORS AND INTEGRATED CIRCUITS (RED SERIES)

This series consists of the following parts, issued on the dates indicated.

Part 1a Rectifier diodes, thyristors, triacs

March 1976

Rectifier diodes

Voltage regulator diodes (>1,5 W) Transient suppressor diodes Rectifier stacks Thyristors Triacs

Part 1b Diodes

October 1975

Small signal germanium diodes Small signal silicon diodes

Special diodes

Voltage regulator diodes (< 1,5 W) Voltage reference diodes

Tuner diodes

Part 2 Low-frequency transistors

December 1975

Part 3 High-frequency and switching transistors

April 1976
June 1976

Part 4a Special semiconductors

Transmitting transistors Microwave devices Field-effect transistors Dual transistors
Microminiature devices for
thick- and thin-film circuits

Part 4b Devices for optoelectronics

July 1976

Photosensitive diodes and transistors Light emitting diodes Displays

Photocouplers Infrared sensitive devices Photoconductive devices

Part 5a Professional analogue integrated circuits

November 1976

N.B. Consumer circuits will be issued in part 5b

Part 6 Digital integrated circuits

May 1976

LOCMOS HE family GZ family

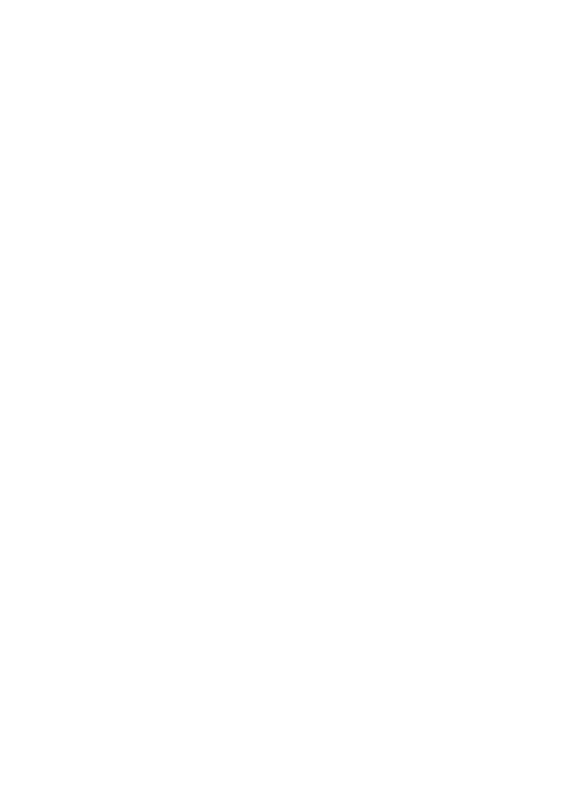

COMPONENTS AND MATERIALS (GREEN SERIES)

This series consists of the following parts, issued on the dates indicated.

		the state of the s
Part 1	Functional units, Input/output devices, Peripheral devices	November 1975
	High noise immunity logic FZ/30-Series Circuit blocks 40-Series and CSA70 Counter modules 50-Series NORbits 60-Series, 61-Series	Circuit blocks 90-Series Input/output devices Hybrid integrated circuits Peripheral devices
Part 2a	Resistors	February 1976
	Fixed resistors Variable resistors Voltage dependent resistors (VDR) Light dependent resistors (LDR)	Negative temperature coefficient thermistors (NTC) Positive temperature coefficient thermistors (PTC) Test switches
Part 2b	Capacitors	April 1976
	Electrolytic and solid capacitors Paper capacitors and film capacitors	Ceramic capacitors Variable capacitors
Part 3	Radio, Audio, Television	February 1975
	FM tuners Loudspeakers Television tuners and aerial input assemblies	Components for black and white television Components for colour television
Part 4a	Soft ferrites	October 1976
	Ferrites for radio, audio and television Beads and chokes	Ferroxcube potcores and square cores Ferroxcube transformer cores
Part 4b	Piezoelectric ceramics, Permanent magnet mate	rials December 1976
Part 5	Ferrite core memory products	July 1975
	Ferroxcube memory cores Matrix planes and stacks	Core memory systems
Part 6	Electric motors and accessories	September 1975
	Small synchronous motors Stepper motors	Miniature direct current motors
Part 7	Circuit blocks	September 1971
	Circuit blocks 100 kHz-Series Circuit blocks 1-Series Circuit blocks 10-Series	Circuit blocks for ferrite core memory drive

Part 9	Piezoelectric quartz devices	March 1976
Part 10	Connectors	November 1975

Channel electron multipliers

GENERAL EXPLANATORY NOTES CHANNEL ELECTRON MULTIPLIERS

DESCRIPTION

A channel electron multiplier is a small curved glass tube, the inside wall of which is coated with a resistive material. When a potential is applied between the ends of the tube the resistive surface forms a continuous dynode, analagous to the separate dynodes of a conventional photomultiplier together with its associated resistive chain.

An electron entering the negative potential end of the multiplier generates secondary electrons on collision with the wall of the tube. These are accelerated along the tube until they strike the wall again where they generate further secondary electrons. This avalanching process continues along the length of the tube producing a large pulse of electrons at the positive end of the tube.

The channel electron multiplier must operate in a vacuum. For space research, the environmental vacuum is sufficient but in the laboratory the multiplier must be used in a vacuum chamber.

DEFINITIONS

Gain

The output pulse corresponding to one input electron will show a statistical spread. Due to saturation effects in the multiplier this spread is approximately Gaussian and the gain is defined as its median value.

For a gain of 1,0 x 10^8 a single input electron will produce an output of 16 picocoulombs.

The gain is constant up to a count rate of 1000 pulses per second. Above this the gain falls by approximately 3 dB per octave. The count rate capability of the system may be increased by lowering the measuring threshold.

Background

The background pulse count rate is the number of pulses detected per second above the specified threshold and operating voltage when the input end of the multiplier is closed. There is no appreciable variation of background count rate when either the applied voltage or ambient temperature is changed.

Starting voltage

The starting voltage is the operating voltage at which 90% of the output pulses from single electron inputs exceed the specified threshold.

GENERAL CHANNEL ELECTRON MULTIPLIERS

Resolution

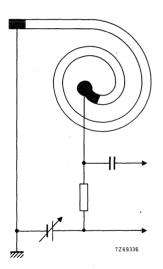

The resolution of the multiplier is calculated from the pulse height distribution by taking the full width half maximum (F.W.H.M.) spread divided by its median value. This is expressed as a percentage.

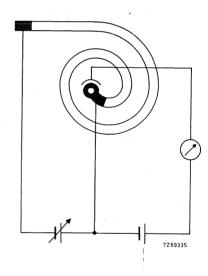

Effective input aperture

The effective input aperture is defined as the boundary within which the count above the equivalent threshold remains greater than 50% of its maximum value.

MODE OF OPERATION

The multiplier is most commonly used with pulse counting circuits to detected individual particles of quanta. For this application closed end multipliers are recommended. A typical circuit is shown in Figure 1. The output pulse is capacitively coupled into a suitable charge sensitive pulse amplifier and discrimator. Under certain circumstances the multiplier may be used as a current amplifier. In this case an openended multiplier is necessary, the output being collected at a separate electrode as shown in Figure 2.

The collector electrode is biased positively to ensure collection of all output electrons. For satisfactory linearity the multiplier should be operated with a gain of less than $1\,x\,10^5$ and the output current should not exceed 1% of the standing current.

OPERATIONAL NOTES

Mounting

It is recommended that, in general, the leads are not used for mounting the device as sustained vibration may result in fracture of the electrical connections.

Vacuum environment

Normal vacuum precautions should be observed. In particular gross contamination with hydrocarbon vapours will cause rapid loss of gain and should be avoided. If necessary the device may be cleaned in iso-propyl alcohol and air dried at a temperature not exceeding 70 $^{\rm oC}$.

The device is stable in air and may be vacuum cycled repeatedly without damage.

Baking conditions

The specified baking conditions apply when the device is under vacuum. The temperature must not exceed the specified maximum operating and storage temperature unless the pressure is less than 50 mN/m 2 (3,7 x 4 torr). No voltage should be applied to the device during bake-out.

Thermal stability

Due to negative temperature coefficient of resistance of the devices thermal runaway is possible. Operation below the maximum voltage and temperature limits specified will ensure that this does not occur.

Choice of operating voltage

Use of an operating voltage approximately 500 volts greater than the starting voltage will ensure that all output pulses exceed the threshold and are recorded. If, as a result of prolonged use the median gain of the multiplier falls, the operating voltage may be increased in order to restore the gain to its original value.

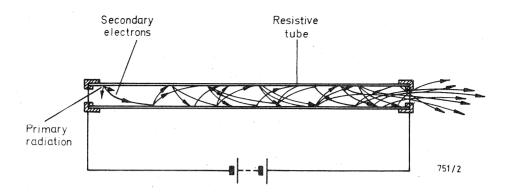

GENERAL EXPLANATORY NOTES CHANNEL PLATES

PRINCIPLES OF OPERATON

Multi-channel plates depend on the same physical phenomenon as single channel electron multipliers. They comprise a plate of special glass through which pass a large number of channels. The walls of the holes are specially processed to coat them with a high resistance material which also has a coefficient of secondary emission greater than 1. If a potential is applied between opposite faces of the plate each channel becomes a continuous dynode analogous to the separate dynodes of a photomultiplier together with its resistive chain.

As with single channel multipliers, the channel plate operates in a vacuum. It is important that the vacuum should be better than 13,3 mPa (1 X 10^{-4} torr). An electron entering the low voltage end of one of the channels will generate secondary electrons on striking the wall. These in turn will be accelerated by the axial field and will again strike the wall, producing a further increase in the number of secondaries and so on. The avalanching process produces a large burst of electrons at the output end of the channel, corresponding to each input electron. As illustrated in Fig. 1 there is a statistical variation in pulse size depending on several factors. The channels are set at an angle to the face of the plate to ensure that electrons approaching the plate normally will not fail to strike the wall. The output contains about 10^3 electrons for each input electron. The gain is a steep function of applied voltage and the supply should be well regulated for stability of operation.

The multiplier is usually used to amplify the electrons emitted from a photocathode placed close to the input face, and excites a phosphor screen placed close to the output, preserving the spatial resolution and making an amplified image of the information on the photocathode. The input of the channel is also sensitive to ions, beta particles, X-rays, or any radiation of a suitable energy and this extends its use to many other applications. Since the resistive path is continuous, many electron paths are possible and the number of stages of amplification is indeterminate. The electron trajectories are scaled in proportion to the dimensions of the channel for a given applied voltage. Thus if the length to diameter ratio is kept constant the gain per channel remains constant, irrespective of the absolute length of the channel. For most applications the spatial resolution is important and in order to achieve the highest resolutions the channel diameters and the walls between channels are kept as small as possible.

IONIC FEEDBACK

The electron cloud at the output of the plate is sufficiently intense to generate an appreciable number of ions and these drift towards the input of the channel and on striking the wall can produce a further burst of secondary electrons. This pulse, starting near the output, will be smaller than the first pulse, but may also generate ions which will drift backwards, so that a train of pulses is generated. This train of pulses alters the charge on the wall, which reduces the gain. This effect limits the voltage that can be applied to the plate and thus the gain that can be achieved. By placing two plates in cascade with the channels angled in opposite directions, ions fed back from the output plate cannot enter the input plate and high gain can be achieved without excessive ion feedback and consequent loss of linearity.

SATURATION DUE TO SPACE CHARGE

If the charge in the output pulse reaches about 10^8 electrons the gain cannot increase further. The space charge in the output end of the channel repels secondary electrons, causing them to return to the wall without generating further electrons. When this occurs with an imaging application it will cause poor highlights and loss of detail. Imaging plates usually operate at gains of around 10^3 .

SATURATION DUE TO FIELD DISTORTION

When the current in the output averages more than 10% of the total current, the voltage gradient in the wall is no longer linear and the gain falls so that there is a loss of linearity between input and output currents and a loss of highlights in the image.

SATURATION DUE TO FIELD EMISSION

It is important to keep channel plates scrupulously clean. Particles lodging in a channel can give rise to field emission which is multiplied in the channel and produces a permanently saturated condition. This is known as a switched on channel and is a condition extremely difficult to correct.

RESISTANCE

The resistance of a channel plate is the value measured in vacuum between electrodes applied to the input and output faces.

DARK CURRENT

Dark current is generally very low, much less than 1 count/s/cm² of plate area.

OPEN AREA

Open area is the total cross-section of all the channels in the plate expressed as a percentage of the total area of the plate.

GAIN

Gain in the linear region of operation is defined as the output current divided by the input current. This is always better than 1000 for 1000 volt applied to the plate and increases one order for each 200 V increase in applied voltage. The recommended operating voltage is 800 to 1200 V. Outside these limits spatial non-uniformity can become a problem.

MOUNTING

The opposite faces of channel plates are ground flat and parallel during manufacture. As the devices are fragile, care must be taken to ensure that they are not stressed unduly when mounting them in systems. It is recommended that they are placed between perfectly flat polished stainless steel rings spring loaded only sufficiently to ensure reliable connections to the metallized faces of the plate. A loading of 3 N per cm of periphery has been found adequate. Care must be taken to minimize the possibility of leakage or other currents between the contact rings when the working voltage is applied.

OPERATING TEMPERATURE AND OUTGASSING

The devices can be operated up to a maximum of 70 °C and degassed up to a maximum of 300 °C. Further evolution of gas may take place during operation. The pressure should never be allowed to rise above 13,3 mPa (1 X 10^{-4} torr) whilst the operating voltage is applied, but exposure to atmosphere for a few hours at a time does not cause any loss of performance. It is prudent to store devices in a well desiccated container if they have to be removed from the vacuum environment for longer periods. The devices may be damaged permanently if exposed to gross contamination by hydrocarbon vapours.

If the output is to be detected by means of a phosphor screen it is desirable to place it as close to the channel plate as can be arranged, commensurate with voltage and mechanical considerations. The electrons leave the outputs over a very wide angle, and detail can be lost if the spacing is excessive. For similar reasons a photocathode input source should be placed close to the input face.

A suitable distance for the channel plate/screen gap is 1 mm, with a potential between screen and channel plate output of about 5 kV. Either the screen distance or the screen potential may be adjusted in order to optimize the resolution of the system.

Operating voltage	max.	3.	5	kV
Temperature, operating and storage	max.	70		°C
Bake temperatures, see note 2)	max.	400		°C
Ambient pressure with high voltage applied	max.	50 3,	7 x 10 ⁻²	mN/m ² torr

MASS 4.0 g

MOUNTING POSITION

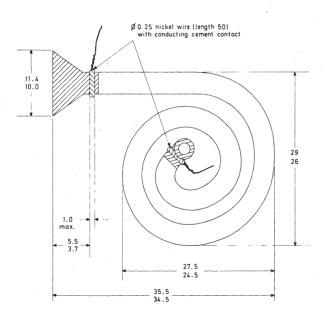

Any. In environments where vibration may be encountered the device should not be supported by the leads alone.

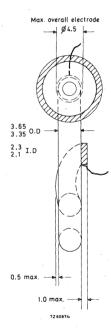

NOTES

- 1) The gain of a typical multiplier will increase by a factor of 2 for an increase of operating voltage of 500 V.
- 2) Baking will cause a permanent slight loss in gain and it is advisable to keep the baking time to a minimum, for example, baking for 16 hours at 400 °C will reduce gain by approximately a factor of 2.

DIMENSIONS AND CONNECTIONS

Dimensions in mm

CHANNEL ELECTRON MULTIPLIER PLATE

An array of channel electron multipliers fused into the shape of a disc. The multipliers are electrically connected in parallel by means of nickel-chromium electrodes evaporated on to the faces of the disc.

SPECIFICATION

Diameter of disc			$27, 1 \pm 0, 1$	l mm
Useful diameter		min.	26, 5	mm
Thickness of disc			$1,0 \pm 0,1$	mm
Channel diameter			25	μm
Channel pitch			31	μm
Open area		approx.	60	%
Electrode material			nickel-chr	omium
Electrical resistance between electrod	des	approx.	50	$M\Omega$
Current gain at 1 kV		min.	1000	

For linear relationship between input and output the output current must not exceed 0, 1 of the standing current.

The plates are cut such that the channel electron multipliers form an angle of $13^{\rm O}$ to the perpendicular axis of the plate.

APPLICATIONS

These devices must operate in a vacuum, and may be used to detect electrons, ions, soft X-rays and ultra-violet photons falling on the input face of the disc, by producing electron pulses from the output face of the corresponding channel.

For space experiments the environmental vacuum is adequate for their operation.

In laboratory use they must be incorporated in a vacuum chamber, where they will have important applications in field ion microscopy, electron microscopy and allied areas of work.

Data based on pre-production devices

Α

GENERAL OPERATIONAL RECOMMENDATIONS GEIGER-MUELLER TUBES

1. GENERAL

- 1.1 A Geiger-Mueller tube (GM tube) is a gas-filled device which reacts to individual ionizing events, thus enabling them to be counted.
- 1.2 A Geiger-Mueller tube basically consists of an electrode at a positive potential (anode) surrounded by a metal cylinder at a negative potential (cathode). The cathode forms part of the envelope or is enclosed in a glass envelope. Quanta or particles may enter the tube either through a foil (the window), or through the cylinder wall itself.
- 1.3 Typical radiations are:

alpha;

beta:

gamma or X-ray; thermal neutrons.

- 1.4 The gas filling normally consists of a mixture of rare gases and a quenching agent.
- 1.5 Quenching is the process of terminating a pulse of ionization current in a counter tube.

2 CAPACITANCE

The capacitance of a GM tube is the capacitance between anode and cathode, the connections being completely shielded.

3 OPERATING CHARACTERISTICS

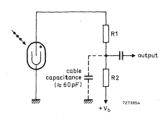

- 3.1 Starting voltage This is the minimum anode supply voltage applied to a GM tube at which pulses of 1 V amplitude appear across the tube.
- 3.2 Operating voltage This is the anode supply voltage at which the GM tube should be used. If this is not quoted, the middle of the minimum plateau (i.e. $\frac{V_{b_1} + V_{b_2}}{2}$) should be regarded as the recommended operating voltage.
- 3.3 Plateau The range of anode supply voltage values for which the count rate varies relatively little under constant conditions of irradiation. Unless otherwise stated, the plateau is measured at a count rate of approximately 100 c/s.
- 3.4 Plateau slope The percentage change in count rate for a given change (usually 1 V) in anode supply voltage.
- 3.5 Background The count rate of a GM tube in the absence of radiation which the tube is meant to measure.

- 3.6 Dead time This is the time interval after the initiation of a voltage pulse during which (assuming no interference by an external circuit) a subsequent ionizing event does not produce a discharge.
 - Unless otherwise stated the dead time is given at a count rate of 100 c/s.

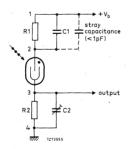

MEASURING CIRCUITS

4. 1 Measuring circuit A

Note: The value of R1 should not be lower than specified under "Limiting values". The resistor should be mounted as close as possible to the anode terminal.

4.2 Measuring circuit B

Notes

- 1. The input resistance and the input capacitance of the measuring equipment are incorporated in R_2 and C_2 , respectively.
- The value of R1 should be as specified by the manufacturer.The resistor should be mounted as chose as possible to the anode terminal.
- 3. When applying a rectangular pulse at 1, with the tube inserted but short-circuited, capacitor C_2 should be so adjusted that the pulse at 3 is undistorted. Under these conditions R_1 . $(C_1 + \text{stray capacitance}) = R_2 \cdot C_2$.
- 4. The measuring equipment consists of a cathode follower with a pulse shaper, a

limiting amplifier and a scaler.

Unless otherwise stated, the tubes are measured with the measuring circuit given in the data sheet and with a 60Co source at

$$V_b = \frac{V_{b_1} + V_{b_2}}{2}$$
 and at $t_{amb} = 25$ °C.

5. OPERATIONAL NOTES

- 5.1 Pulse amplitude The pulse amplitude of the GM tubes may be estimated generally at $P = b.(V_b V_{ign})$. In this formula V_b is the anode supply voltage and V_{ign} the starting voltage of the tube. The factor b originates from the tap on the anode resistor, as indicated in the recommended measuring circuit. The influence of the connected capacitive load is thus minimized.
- 5.2 Scaler The resolving time of the scaler should be shorter than the minimum dead time of the counter tube. For normal use and at moderate count rates an input sensitivity of approximately 0, 25V will be sufficient. At very high count rates the mean level of the anode voltage of the counter tube will drop appreciably below V_b , and the pulse amplitude will decrease accordingly so that the smallest pulses will be lost at the input of the scaler. In this case it is possible to increase the sensitivity of the measuring equipment by means of a pulse amplifier combined with a pulse shaper.
- 5.3 Pulse shaper and amplifier The circuit should have a resolving time shorter than the minimum deadtime of the counter tube. The pulse amplitude should not be influenced by the pulse shaper. Pulse amplification should be sufficiently high and the rise time of the amplifier should be considerably smaller than the rise time of the pulse from the counter tube.
- 5.4 Load Normally the tubes should be operated with an anode resistor having a value as indicated in the data sheets or higher. Decreasing the resistance of the anode resistor not only decreases the dead time, but also the plateau length. A decrease in resistance below the indicated minimum value may affect tube life and even lead to its early destruction. The anode resistor should be connected direct to the anode connector (terminal) of the tube to ensure that parasitic capacitances of leads will not considerably increase the capacitive load on the tube. An increase in capacitive load has the tendency of increasing the pulse amplitude, the pulse duration, the dead time, and the plateau slope, whereas the plateau length will be shortened appreciably. Shunt capacitances of 20 pF or more may destroy the tube.
- 5.5 Count rate After every pulse the tube is temporarily insensitive during a period called dead time. Consequently, the pulses that occur during this period are not counted. At a count rate of N c/s the tube will be insensitive during 100 N τ % of the time, so that approximately 100 N τ % of the counts will be lost. If the counting losses should not exceed 1%, N should be less than 0,01 τ c/s. The maximum count rate is approximately $1/\tau$. For continuous stable operation it is recommended that the count rate be adjusted to a value in the linear part of the count rate/dose rate curve.
- 5.6 Count rate/dose rate curves are measured with ⁶⁰Co perpendicular to the tube axis, at an operating voltage in the middle of the plateau, unless otherwise stated.

 The curves shown are typical curves. Deviations up to approximately ±10% may occur.

5.7 Current/dose rate curves are measured with 60 Co perpendicular to the tube axis, unless otherwise stated.

The curves shown are typical curves. Deviations up to approximately $\pm 10\%$ may occur.

6 LIMITING VALUES

6.1 The limiting values of radiation counter tubes are given in the absolute maximum rating system in accordance with IEC Publication 134.

Absolute maximum ratings are limiting values of operating and environmental conditions applicable to any electronic device of a specified type as defined by its published data, which should not be exceeded under the worst probable conditions.

These values are chosen by the device manufacturer to provide acceptable service-ability of the device, taking no responsibility for equipment variations, environment-al variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electronic devices in the equipment.

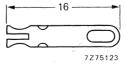

The equipment manufacturer should design so that, initially and throughout life, no absolute maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply voltage variation, equipment component variation, equipment control adjustment, load variations, signal variation, environmental conditions, and variations in characteristics of the device under consideration and of all other electronic devices in the equipment.

6.2 The ambient temperature is the temperature of the surroundings of the tube.

7 MOUNTING

- 7. 1 Unless otherwise stated, any mounting position is permissible.
- 7.2 Low capacitance mounting of the tube is required (shortest possible connection between anode terminal and load resistor; low capacitance between anode and cathode leads).
- 7.3 Soldering to the cathode can or the anode pin will destroy the tube.

Tubes with anode pin are supplied with an anode connector (see drawing). Only this connector should be used for connecting the anode.

8 STORAGE AND HANDLING

- 8.1 The tube should not be stored at ambient temperatures outside the limits given under the heading "Limiting values" on the data sheets. \cdot
- 8.2 To prevent leakage between anode and cathode the tube should be dry and clean.
- 8.3 Condensation of water vapour may cause a short circuit between anode and cathode.

8.4 Some types of tube have thin windows and/or cathode walls. To prevent damage, these tubes should be handled and mounted with utmost care. The mica-window types are provided with a cap to protect the window when not in operation.

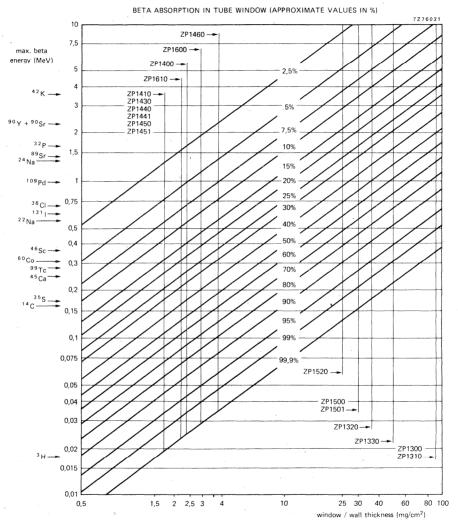

9. OUTSIDE PRESSURE

- 9.1 Tubes provided with a window should not be subjected to an outside pressure lower than 33,3 kPa (33,3 mbar, ~25 cm Hg) or higher than the normal atmospheric pressure (unless otherwise stated).
 Variations in pressure should be gradual.
- 9.2 Do not expose tubes with very thin envelopes to pressures substantially higher than normal atmospheric.

Never:

- 1. Exceed the "Limiting values".
- 2. Solder to the tube.
- 3. Bend the anode pin.
- 4. Touch the mica window.

Recommended supply voltage		1000	\mathcal{V}^{T}			
Plateau (at 50 c/s)	800 to	1200	V			
Plateau slope (at 50 c/s)	≤	0,03	%/V			
Background, shielded with 100 mm Fe and 30 mm Pb, Fe outside, at $V_h = 1000 \text{ V}$, , ≤ ,	70	count/min			
Dead time (at 50 c/s)	≤	1	ms			
LIMITING VALUES (Absolute max. rating system)	LIMITING VALUES (Absolute max. rating system)					
Anode resistor	min.	10	$M\Omega$			
Anode voltage	max.	1200	V .			
Ambient temperature for continuous operation	min. max. max.	-50 +75 +50	°C °C °C			

LIFE EXPECTANCY

Life expectancy at $t_{amb} = 25$ °C, count rate 1300 c/s 5×10^{10} count

MEASURING CIRCUIT

For use as guard counter tube in anticoincidence circuits in combination with ZP1440 or ZP1450: recommended circuit see Fig. 2.

$$R_1 = 10 \text{ M}\Omega$$

$$R_2 = 10 \text{ M}\Omega$$

$$R_2 = 10 \text{ M}\Omega$$

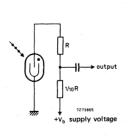

Fig. 1

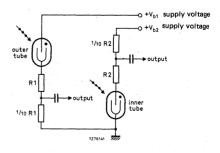

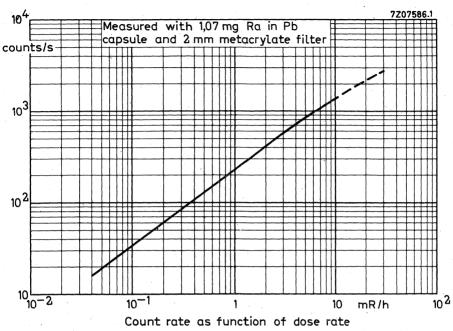

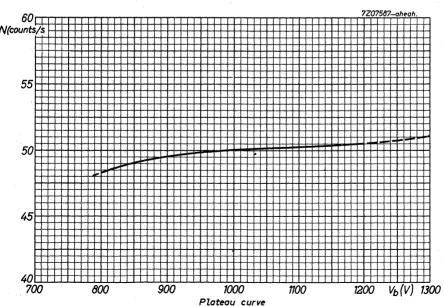

Fig. 2

(MX178)

GEIGER-MÜLLER TUBE

Halogen quenched beta (>0,3 MeV) and gamma radiation counter tube. Replacement type (ZP1330).

Neutron tubes

NEUTRON TUBES

Sealed-off accelerating tubes generating 14 MeV neutrons on the basis of the $^3\mathrm{H}$ (d,n) $^4\mathrm{He}$ reaction.

The gas filling (a mixture of deuterium and tritium) is controlled by a pressure regulator. Deuterium and tritium ions emitted from a Penning ion source are accelerated towards a titanium/tritium target bringing about the 3 H (d,n) 4 He reaction whilst replenishing the tritium in the target. This guarantees a lasting and even target performance throughout tube life.

Examples of application:

Activation analysis
Radio biology
Radio chemistry
Neutron radiography
Neutron dosimetry
Investigation of neutron collimation
Investigation of radiation damage
Isotope production
Fast reactor control
Nuclear physics research
Solid state physics
Education
Nuclear safeguards

NEUTRON TUBE TYPES	Minimum out	put (n/s)
	continuous	pulse
18600R	1 x 10 ⁸	-
18601C	1×10^{8}	5 x 10 ⁹
18603C	1×10^8	5 x 10 ⁹

Further particulars on request.

Semiconductor radiation detectors

SEMICONDUCTOR RADIATION DETECTORS

Energy range	Application	Technology		Basic types	
		Lithium drifted germanium			
10 keV to 10 MeV 7	High resolution gamma and X-ray spectrometry in nuclear science (e.g. decay schemes) and industrial research (e.g. activation analysis)		coaxial	double open-ended	APY21 to APY27
40 keV to 10 MeV γ	High resolution gamma and X-ray spectrometry in nuclear science (e.g. decay schemes) and industrial research (e.g. activation analysis)			single open-ended	APY41 to APY49
40 keV to 10 MeV γ	Virtually 4 m measurement of gamma radiation and X-rays in: absolute activity measurement source calibration sum peak coincidence experiments			well-type	APY56 to APY59
40 keV to 8 MeV γ	Gamma and high energy X-ray spectrometry		planar		APY16 to APY19
		Si	licon surface b	parrier	
< 80 MeV α < 1,5 MeV β	Spectrometry of alpha and low energy beta radiation, particles and fission products. Particle identification systems		partially depleted	circular	BPY51 to BPY57 BPW25
< 80 MeV α < 1,2 MeV β				annular	BPY58 to BPY59
< 75 MeV α < 1,2 MeV β	Spectrometry of alpha and low energy beta radiation, particles and fission products. Particle identification systems		totally depleted	circular	BPY81 to BPY87
< 75 MeV α < 1,2 MeV β				annular	BPY88, BPY89

For detailed information please ask for the "Product Survey Semiconductor Radiation Detectors".
