# Integrated circuits

Part 4

July 1983

Digital integrated circuits

CMOS HE4000B family

**Elcoma** – Philips Electronic Components and Materials Division – embraces a world-wide group of companies operating under the following names:

**IBRAPE**

**Miniwatt**

**signetics**

**Mullard**

**VALVO**

**PHILIPS**

Elcoma offers you a technological partnership in developing your systems to the full. A partnership to which we can bring

- world-wide production and marketing
- know-how
- systems approach
- continuity
- broad product line
- fundamental research
- leading technologies
- applications support
- quality

## DATA HANDBOOK SYSTEM

Our Data Handbook System is a comprehensive source of information on electronic components, sub-assemblies and materials; it is made up of four series of handbooks each comprising several parts.

ELECTRON TUBES	BLUE
SEMICONDUCTORS	RED
INTEGRATED CIRCUITS	PURPLE
COMPONENTS AND MATERIALS	GREEN

The several parts contain all pertinent data available at the time of publication, and each is revised and reissued periodically.

Where ratings or specifications differ from those published in the preceding edition they are pointed out by arrows. Where application information is given it is advisory and does not form part of the product specification.

If you need confirmation that the published data about any of our products are the latest available, please contact our representative. He is at your service and will be glad to answer your inquiries.

---

This information is furnished for guidance, and with no guarantee as to its accuracy or completeness; its publication conveys no licence under any patent or other right, nor does the publisher assume liability for any consequence of its use; specifications and availability of goods mentioned in it are subject to change without notice; it is not to be reproduced in any way, in whole or in part without the written consent of the publisher.

---

## ELECTRON TUBES (BLUE SERIES)

The blue series of data handbooks is comprised of the following parts:

- T1** Tubes for r.f. heating
- T2** Transmitting tubes for communications
- T3** Klystrons, travelling-wave tubes, microwave diodes
- ET3** Special Quality tubes, miscellaneous devices (will not be reprinted)
- T4** Magnetrons
- T5** Cathode-ray tubes  
Instrument tubes, monitor and display tubes, C.R. tubes for special applications
- T6** Geiger-Müller tubes
- T7** Gas-filled tubes  
Segment indicator tubes, indicator tubes, dry reed contact units, thyratrons, industrial rectifying tubes, ignitrons, high voltage rectifying tubes, associated accessories
- T8** Picture tubes and components  
Colour TV picture tubes, black and white TV picture tubes, colour monitor tubes for data graphic display, monochrome monitor tubes for data graphic display, components for colour television, components for black and white television and monochrome data graphic display
- T9** Photo and electron multipliers  
Photomultiplier tubes, phototubes, single channel electron multipliers, channel electron multiplier plates
- T10** Camera tubes and accessories, image intensifiers
- T11** Microwave components and assemblies

## SEMICONDUCTORS (RED SERIES)

The red series of data handbooks is comprised of the following parts:

- S1 Diodes**  
Small-signal germanium diodes, small-signal silicon diodes, voltage regulator diodes (< 1,5 W), voltage reference diodes, tuner diodes, rectifier diodes
- S2 Power diodes, thyristors, triacs**  
Rectifier diodes, voltage regulator diodes (> 1,5 W), rectifier stacks, thyristors, triacs
- S3 Small-signal transistors**
- S4 Low-frequency power transistors and hybrid IC modules**
- S5 Field-effect transistors**
- S6 R.F. power transistors and modules**
- S7 Microminiature semiconductors for hybrid circuits**
- S8 Devices for optoelectronics**  
Photosensitive diodes and transistors, light-emitting diodes, displays, photocouplers, infrared sensitive devices, photoconductive devices.
- S9** Taken into handbook T11 of the blue series
- S10 Wideband transistors and wideband hybrid IC modules**

## INTEGRATED CIRCUITS (PURPLE SERIES)

The purple series of data handbooks is comprised of the following parts:

- IC1** Bipolar ICs for radio and audio equipment
- IC2** Bipolar ICs for video equipment
- IC3** ICs for digital systems in radio, audio and video equipment
- IC4** Digital integrated circuits  
CMOS HE4000B family
- IC5** Digital integrated circuits – ECL  
ECL10 000 (GX family), ECL100 000 (HX family), dedicated designs
- IC6** Professional analogue integrated circuits
- IC7** Signetics bipolar memories
- IC8** Signetics analogue circuits
- IC9** Signetics TTL logic
- IC10** Signetics Integrated Fuse Logic (IFL)
- IC11** Microprocessors, microcomputers and peripheral circuitry

## COMPONENTS AND MATERIALS (GREEN SERIES)

The green series of data handbooks is comprised of the following parts:

- C1 Assemblies for industrial use**  
PLC modules, PC20 modules, HNIL FZ/30 series, NORbits 60-, 61-, 90-series, input devices, hybrid ICs
- C2 Television tuners, video modulators, surface acoustic wave filters**
- C3 Loudspeakers**
- C4 Ferroxcube potcores, square cores and cross cores**
- C5 Ferroxcube for power, audio/video and accelerators**
- C6 Electric motors and accessories**  
Permanent magnet synchronous motors, stepping motors, direct current motors
- C7 Variable capacitors**
- C8 Variable mains transformers**
- C9 Piezoelectric quartz devices**  
Quartz crystal units, temperature compensated crystal oscillators, compact integrated oscillators, quartz crystal cuts for temperature measurements
- C10 Connectors**
- C11 Non-linear resistors**  
Voltage dependent resistors (VDR), light dependent resistors (LDR), negative temperature coefficient thermistors (NTC), positive temperature coefficient thermistors (PTC)
- C12 Variable resistors and test switches**
- C13 Fixed resistors**
- C14 Electrolytic and solid capacitors**
- C15 Film capacitors, ceramic capacitors**
- C16 Piezoelectric ceramics, permanent magnet materials**

**Rating systems**

**Handling MOS devices**

**CECC qualified products**

**Burn-in options**

**Ordering information**

## RATING SYSTEMS

The rating systems described are those recommended by the International Electrotechnical Commission (IEC) in its Publication 134.

### DEFINITIONS OF TERMS USED

*Electronic device.* An electronic tube or valve, transistor or other semiconductor device.

#### Note

This definition excludes inductors, capacitors, resistors and similar components.

*Characteristic.* A characteristic is an inherent and measurable property of a device. Such a property may be electrical, mechanical, thermal, hydraulic, electro-magnetic, or nuclear, and can be expressed as a value for stated or recognized conditions. A characteristic may also be a set of related values, usually shown in graphical form.

*Bogey electronic device.* An electronic device whose characteristics have the published nominal values for the type. A bogey electronic device for any particular application can be obtained by considering only those characteristics which are directly related to the application.

*Rating.* A value which establishes either a limiting capability or a limiting condition for an electronic device. It is determined for specified values of environment and operation, and may be stated in any suitable terms.

#### Note

Limiting conditions may be either maxima or minima.

*Rating system.* The set of principles upon which ratings are established and which determine their interpretation.

#### Note

The rating system indicates the division of responsibility between the device manufacturer and the circuit designer, with the object of ensuring that the working conditions do not exceed the ratings.

### ABSOLUTE MAXIMUM RATING SYSTEM

Absolute maximum ratings are limiting values of operating and environmental conditions applicable to any electronic device of a specified type as defined by its published data, which should not be exceeded under the worst probable conditions.

These values are chosen by the device manufacturer to provide acceptable serviceability of the device, taking no responsibility for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electronic devices in the equipment.

The equipment manufacturer should design so that, initially and throughout life, no absolute maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply voltage variation, equipment component variation, equipment control adjustment, load variations, signal variation, environmental conditions, and variations in characteristics of the device under consideration and of all other electronic devices in the equipment.

## DESIGN MAXIMUM RATING SYSTEM

Design maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electronic device of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

These values are chosen by the device manufacturer to provide acceptable serviceability of the device, taking responsibility for the effects of changes in operating conditions due to variations in the characteristics of the electronic device under consideration.

The equipment manufacturer should design so that, initially and throughout life, no design maximum value for the intended service is exceeded with a bogey device under the worst probable operating conditions with respect to supply voltage variation, equipment component variation, variation in characteristics of all other devices in the equipment, equipment control adjustment, load variation, signal variation and environmental conditions.

## DESIGN CENTRE RATING SYSTEM

Design centre ratings are limiting values of operating and environmental conditions applicable to a bogey electronic device of a specified type as defined by its published data, and should not be exceeded under normal conditions.

These values are chosen by the device manufacturer to provide acceptable serviceability of the device in average applications, taking responsibility for normal changes in operating conditions due to rated supply voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all electronic devices.

The equipment manufacturer should design so that, initially, no design centre value for the intended service is exceeded with a bogey electronic device in equipment operating at the stated normal supply voltage.

## HANDLING MOS DEVICES

Though all our MOS integrated circuits incorporate protection against electrostatic discharges, they can nevertheless be damaged by accidental over-voltages. In storing and handling them, the following precautions are recommended.

### *Caution*

Testing or handling and mounting call for special attention to personal safety. Personnel handling MOS devices should normally be connected to ground via a resistor.

### Storage and transport

Store and transport the circuits in their original packing. Alternatively, use may be made of a conductive material or special IC carrier that either short-circuits all leads or insulates them from external contact.

### Testing or handling

Work on a conductive surface (e.g. metal table top) when testing the circuits or transferring them from one carrier to another. Electrically connect the person doing the testing or handling to the conductive surface, for example by a metal bracelet and a conductive cord or chain. Connect all testing and handling equipment to the same surface.

Signals should not be applied to the inputs while the device power supply is off. All unused input leads should be connected to either the supply voltage or ground.

### Mounting

Mount MOS integrated circuits on printed circuit boards *after* all other components have been mounted. Take care that the circuits themselves, metal parts of the board, mounting tools, and the person doing the mounting are kept at the same electric (ground) potential. If it is impossible to ground the printed-circuit board the person mounting the circuits should touch the board before bringing MOS circuits into contact with it.

### Soldering

Soldering iron tips, including those of low-voltage irons, or soldering baths should also be kept at the same potential as the MOS circuits and the board.

### Static charges

Dress personnel in clothing of non-electrostatic material (no wool, silk or synthetic fibres). After the MOS circuits have been mounted on the board proper handling precautions should still be observed. Until the sub-assemblies are inserted into a complete system in which the proper voltages are supplied, the board is no more than an extension of the leads of the devices mounted on the board. To prevent static charges from being transmitted through the board wiring to the device it is recommended that conductive clips or conductive tape be put on the circuit board terminals.

### Transient voltages

To prevent permanent damage due to transient voltages, do not insert or remove MOS devices, or printed-circuit boards with MOS devices, from test sockets or systems with power on.

### Voltage surges

Beware of voltage surges due to switching electrical equipment on or off, relays and d.c. lines.

## CECC QUALIFIED PRODUCTS

### INTRODUCTION

The basis of the quality assessment of the CMOS ICs described in this handbook is formed by the rules and procedures of the well known CECC system (European system of quality assessment for electronic components). As a consequence, all CMOS manufacturing activities are now fully qualified and supervised by independent, internationally recognized, National Inspectorates (e.g. KEMA for The Netherlands).

Our CMOS ICs are homologated according to the CECC 90 000 Specification.

### CECC - WHAT DO CUSTOMERS GET?

- Products, wholly manufactured in CECC approved premises.
- Products, released by an Inspection Organization which is approved by the National Supervising Inspectorate (NSI).
- Products, released in accordance with CECC adopted specifications.
- Mandatory sample life tests and environmental tests.
- Delivery in packages, which are sealed with the mark of conformity under supervision of the NSI.
- Certified test records compiled every six months and available on request.
- Audits of the production facilities by the NSI.

### THE CECC SCHEME

CECC is a scheme for providing electronic components of assessed quality controlled by the National Supervising Inspectorate (NSI, e.g. KEMA). It is set up by the CENELEC (European Committee for Electrotechnical Standardization) Electronic Components Committee (CECC) and the International Electrotechnical Commission (IEC).

The CECC scheme includes two essential features of any Quality Assurance Scheme:

- a specification system,
- a certification procedure supported by an independent inspectorate.

### CECC IN OPERATION

The CECC scheme operates essentially in three parts.

Part 1: the plant qualification

Part 2: the device qualification

Part 3: quality conformance inspection of deliveries

#### Part 1

Established to the satisfaction of the NSI that the organization has adequate quality systems, procedures and standards to control the manufacturing of electronic components to the minimum standard as defined in the CECC system.

#### Part 2

Established by demonstration to the NSI that the electronic components are capable of meeting the requirements of detail specifications which are prepared in accordance with the CECC system. This is accomplished by performing the qualification activity.

### Part 3

Established on a lot-by-lot and periodic sampling basis such, that the devices are in conformance with the specifications to which they were initially qualified. Data on the results of these tests are provided as Certified Test Records (CTRs), certified by a representative of the NSI and they are published at six-monthly intervals.

At this stage, if any lot should be classified as rejected, it will become disqualified from being released as a CECC device. Re-submission of rejected lots is not permitted.

## CECC - QUALIFICATION FEATURES

### Lot-by-lot tests

#### Group A inspection

Group A prescribes the visual examination and electrical measurements to be made on a lot-by-lot basis to assess the principal electrical properties of a circuit (see CECC 00 107).

Group A inspection is divided into appropriate Sub-Groups.

#### Group B inspection

Group B prescribes the procedures to be used on a lot-by-lot basis to assess certain additional properties of the circuit, including environmental and endurance tests which can be completed in less than one week (see CECC 00 107).

Group B inspection is divided into appropriate Sub-Groups.

### Periodic tests

#### Group C inspection

Group C prescribes the procedures to be used on a periodic basis to assess certain properties of the circuit including environmental and endurance tests which are appropriate for checking at intervals of 3 months.

Group C inspection is divided into appropriate Sub-Groups.

#### Group D inspection

Group D prescribes the procedures to be used on a periodic basis at intervals of 12 months.

## CECC - QUALIFICATION PROCEDURE

- Raise detail specification in accordance with appropriate rules.
- Detail specification approved by NSI and NAI (National Authorized Institution).
- Submit 3 separate lots for qualification.
- Pass all group A and B tests on each of the 3 lots.
- Pass all group C tests on a combined sample from the 3 lots.
- Pass all group C tests, except test C8 (endurance).
- Pass C8 endurance test at 1000 hours, submit test records countersigned by supervising inspector and apply for provisional approval.

## CECC - PRODUCTS

Our CMOS products are available up to the highest assessment level R. Products qualified by CECC are recognized by the symbol  on the individual data sheets in this handbook. The appropriate CECC detail specification number is also given.

## BURN-IN OPTIONS

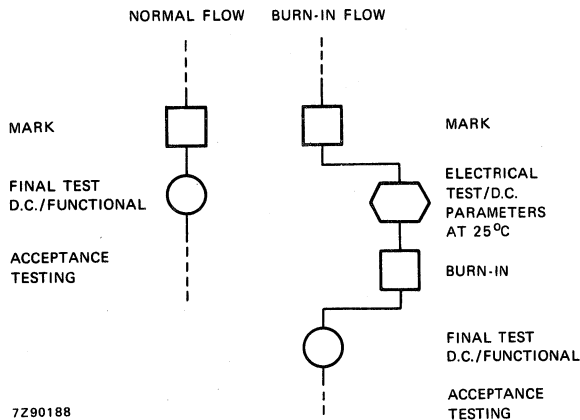

Production quality control ensures that the quality inherent in a design is realized during manufacture of our CMOS integrated circuits. This is achieved by monitoring the quality, both conformity and reliability, of finished ICs; by inspection of the materials and components to be used in the process; by calibration of the equipment; and by monitoring the temperature, humidity and dust content of the manufacturing area.

Careful integration of the production and quality-control functions is essential for good and improving quality.

The BURN-IN option is an additional feature and is available on all our plastic and ceramic (cerdip) DIL packaged CMOS ICs. The features are:

- reduced infant mortality
- reduced printed-circuit board and system re-design
- reduced equipment down-time
- reduced field failures

### Flow-charts

Burn-in is performed under the following conditions:

$V_{DD}$	15 V	} or equivalent
$T_{amb}$	125 °C	
time	168 hours	
bias	static	

## ORDERING INFORMATION

### TYPE DESIGNATION

HEX4512BXX

HE	family identification
X	operating temperature range (C = full, F = limited)
4512	device number
B	JEDEC "B" series CMOS specification
X	package code (P = plastic, D = ceramic (cerdip), T = plastic SO mini-pack)
X	screening class (B = burn-in; see also chapter BURN-IN OPTIONS)

Example: HEF4512BDB

### MARKING

### ORDERING

N (a) integrated circuit HEF (b) 4512B, R (c) level, B class (d), D (e) package, following NL-CECC 90 104-066, Issue 1.

Complete type number: HEF4512BDB

Note: Always use the complete type number when ordering (see above). Complete type number are given in the device data sheets.

- a: quantity
- b: operating temperature range (HEF or HEC)
- c: quality assessment level (R)
- d: screening class, burn-in (optional)
- e: package code D = ceramic (cerdip); P = plastic; T = plastic SO mini-pack

## **PACKAGE OUTLINES**

14-LEAD DUAL IN-LINE; PLASTIC (SOT-27K,M,T)

- ⊕ Positional accuracy.
- (M) Maximum Material Condition.
- (1) Centre-lines of all leads are within  $\pm 0,127$  mm of the nominal position shown; in the worst case, the spacing between any two leads may deviate from nominal by  $\pm 0,254$  mm.
- (2) Lead spacing tolerances apply from seating plane to the line indicated.

Dimensions in mm

SOLDERING

1. By hand

Apply the soldering iron below the seating plane (or not more than 2 mm above it). If its temperature is below 300 °C it must not be in contact for more than 10 seconds; if between 300 °C and 400 °C, for not more than 5 seconds.

2. By dip or wave

The maximum permissible temperature of the solder is 260 °C; this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

3. Repairing soldered joints

The same precautions and limits apply as in (1) above.

16-LEAD DUAL IN-LINE; PLASTIC (SOT-38Z)

- ⊕ Positional accuracy.
- Ⓜ Maximum Material Condition.
- (1) Centre-lines of all leads are within  $\pm 0,127$  mm of the nominal position shown; in the worst case, the spacing between any two leads may deviate from nominal by  $\pm 0,254$  mm.
- (2) Lead spacing tolerances apply from seating plane to the line indicated.

SOLDERING

The reflow solder technique

The preferred technique for mounting miniature components on hybrid thick or thin-film circuits is reflow soldering. Solder is applied to the required areas on the substrate by dipping in a solder bath or, more usually, by screen printing a solder paste. Components are put in place and the solder is reflowed by heating.

Solder pastes consist of very finely powdered solder and flux suspended in an organic liquid binder. They are available in various forms depending on the specification of the solder and the type of binder used. For hybrid circuit use, a tin-lead solder with 2 to 4% silver is recommended. The working temperature of this paste is about 220 to 230 °C when a mild flux is used.

For printing the paste onto the substrate a stainless steel screen with a mesh of 80 to 105 μm is used for which the emulsion thickness should be about 50 μm. To ensure that sufficient solder paste is applied to the substrate, the screen aperture should be slightly larger than the corresponding contact area.

The contact pins are positioned on the substrate, the slight adhesive force of the solder paste being sufficient to keep them in place. The substrate is heated to the solder working temperature preferably by means of a controlled hot plate. The soldering process should be kept as short as possible: 10 to 15 seconds is sufficient to ensure good solder joints and evaporation of the binder fluid. After soldering, the substrate must be cleaned of any remaining flux.

16-LEAD MINI-PACK; PLASTIC (SO-16; SOT-109A)

Dimensions in mm

**HE4000B FAMILY - INTRODUCTION**

## INTRODUCTION TO THE HE4000B FAMILY DATA SHEETS

The LOCMOS HE4000B range is a fully buffered digital integrated circuit family which meets the Jedec-B specification. The members of this family are pin-compatible with the well-known C-MOS 4000 and 14500 ranges. The HE family has the same advantages as conventional C-MOS circuits, plus the additional LOCMOS advantages.

LOCMOS means: Local Oxidation Complementary MOS.

The main effect of LOCMOS is a considerable reduction in the chip area required for a given function. Also important is the reduction in stray capacitance due to the smaller contact areas - hence the higher switching speed. Another benefit, brought about by the manufacturing process, is the self-alignment of the source and drain diffusions. This means that tolerance margins in the diffusions are unnecessary, thus further reducing the stray capacitances.

### Advantages of C-MOS:

- low power dissipation - typically 10 nW per gate (static);
- wide operating supply voltage range;
- wide operating temperature range -  $-40$  to  $+85$  °C;
- high d.c. fan-out;
- inputs and outputs are protected against electrostatic voltages.

In addition to these, the LOCMOS HE4000B range has:

- buffered outputs on all circuits;
- higher speed;
- higher packing density - essential for MSI/LSI;
- excellent noise immunity.

The HE family is designed with standardized output drive characteristics which, combined with relative insensitivity to output capacitance loading, simplify system design.

### Note

On page 1 of most of the device data sheets are shown a pinning diagram together with a functional diagram. In addition to this functional diagram, a more detailed logic diagram is given, which also shows the buffered outputs.

## BUFFERED OUTPUTS

To minimize any pattern sensitivity of propagation delay, and to standardize delay and output drive, all HE family devices have an output buffer stage (see Fig. 1). Buffering improves the static noise immunity because the increased voltage gain gives nearly ideal transfer characteristics and the low output impedance gives significant improvement of the dynamic noise immunity. Significant pulse shaping is obtained because output transitions are virtually independent of input rise and fall times.

Fig. 1 Two-input NOR gate with fully buffered output; a typical LOCMOS circuit. In an unbuffered device the output would be taken from the point marked\*.

Fig. 2 Typical transfer characteristic showing improvement in buffered LOCMOS device as compared with unbuffered C-MOS device.

(a)

(b)

Fig. 3 The two graphs show how the output transitions are independent of input rise time (a) and fall time (b).

## DESIGN CONSIDERATIONS

## General

Local Oxidation Complementary MOS digital integrated circuits of SSI and MSI complexity have been hailed as the ideal logic family. A few LOCMOS devices, such as bidirectional analogue switches, exploit the unique feature of C-MOS technology; some take advantage of the smaller device size and higher potential packing density to achieve true LSI complexity, and perform logic functions that have been available in TTL for many years. Therefore, it is both helpful and practical to compare the performance of LOCMOS with that of the more familiar TTL (see table below).

LOCMOS speed is about three to six times lower than TTL or low-power Schottky (LS-TTL). Static noise immunity and fan-out are almost ideal, supply voltage is non-critical, and the quiescent power consumption is close to zero — several orders of magnitude lower than for any competing technology.

For dynamic noise immunity, see NOISE IMMUNITY.

	standard TTL	low-power Schottky	4000 LOCMOS 5 V	4000 LOCMOS 10 V	4000 LOCMOS 15 V
propagation delay $C_L = 15 \text{ pF}$	10 ns	10 ns	40 ns	20 ns	15 ns
flip-flop clock frequency	35 MHz	45 MHz	8 MHz	16 MHz	20 MHz
quiescent power	10 mW	2 mW	10 nW	10 nW	10 nW
noise immunity	1 V	0,8 V	2,25 V	4,5 V	6,75 V
fan-out	10	10	50 *	50 *	50 *

\* Or as determined by permissible propagation delay.

## Supply voltage range

LOCMOS is guaranteed to function over the unprecedented range of 3 to 15 V supply voltage. Characteristics are guaranteed for 5, 10 and 15 V operation and can be extrapolated for any voltage in between. Operation below 4,5 V is not very meaningful because of the increase in delay (loss of speed), the increase in output impedance and the loss of noise immunity. Operation above 15 V is not recommended because of high dynamic power consumption and risk of noise spikes on the power supply exceeding the breakdown voltage (typ. > 20 V), causing SCR-latch-up and destroying the device unless the current is externally limited.

The lower limit of power supply voltage, including ripple, is determined by the required noise immunity, propagation delay or interface to TTL. The upper limit of supply voltage, including ripple and transients, is determined by power dissipation or direct interface to other logic. The HEF4049B, HEF4050B and HEF4104B provide level transition between TTL and LOCMOS when LOCMOS supply voltages over 5 V are used.

Low static power consumption combined with wide supply voltage range make LOCMOS the ideal logic family for battery-operated equipment.

## Power consumption

Under static conditions, the p-channel and the n-channel transistors are not conducting simultaneously thus only leakage current flows from the positive ( $V_{DD}$ ) to the negative ( $V_{SS}$ ) supply connection. This leakage current is typically 0,5 nA per gate, resulting in a very attractive low power consumption of 2,5 nW per gate (at 5 V).

Whenever a LOCMOS circuit is exercised, when data or clock inputs change, additional power is consumed to charge and discharge capacitances (on-chip parasitic capacitances as well as load capacitances). Moreover, there is a short time during the transition when both the p-channel and n-channel transistors are partially conducting. This dynamic power consumption is obviously proportional to the frequency at which the circuit is exercised, to the load capacitance and to the square of the supply voltage.

As shown in Fig. 4, the power consumption of a LOCMOS gate exceeds that of a low-power Schottky gate somewhere between 500 kHz and 2 MHz of actual output frequency. Comparing the power consumption of more complex devices (MSI) in various technologies may show a different result.

In any complex design, only a small fraction of the gates actually switch at the full clock frequency, most gates operate at a much lower average rate and therefore consume much less power. A realistic comparison of power consumption between different technologies involves a thorough analysis of the average switching speed of each gate in the circuit.

The maximum values of the quiescent device current ( $I_{DD}$ ) are given in the Family Specifications, the typical dynamic power dissipation is given in the individual data sheets. The total device power dissipation is the sum of the quiescent and dynamic power dissipation.

Fig. 4 Typical power dissipation per gate as a function of input frequency for several logic families.

- 1 Schottky TTL
- 2 Standard TTL
- 3 Low-power Schottky
- 4 LOCMOS ( $V_{DD} = 15 \text{ V}$ )
- 5 LOCMOS ( $V_{DD} = 10 \text{ V}$ )
- 6 LOCMOS ( $V_{DD} = 5 \text{ V}$ )

**Additional power consumption (due to slow input rise and fall times)**

As long as the input voltage of a LOCMOS circuit is below the N-transistor threshold voltage, or higher than the supply voltage minus the P-transistor threshold voltage, one of the input transistors is always in the OFF-state and no 'through' current flows in the input stage.

When the input voltage equals the N-transistor threshold voltage (typ. 1.5 V), the N-transistor starts conducting and a drain current starts to flow.

Figure 5 shows the drain current as a function of the input voltage for a typical LOCMOS input.

Fig. 5 Drain current as a function of input voltage.

This drain current reaches a maximum at  $\frac{1}{2} V_{DD}$  and the peak value depends on the geometrics of the transistors used. This current is proportional to  $V_{DD}^n$ , in which  $n > 2$ .

For Schmitt triggers, unbuffered types, and circuits comprising a single stage inverter, typical current transfer characteristics are given in the device data sheets.

When squaring up slow pulses by means of Schmitt triggers, the through current gives additional power consumption.

By applying RC-oscillators, or oscillators constructed with Schmitt triggers, the phenomenon described gives a frequency-independent power consumption.

## Propagation delay

Compared to TTL and LS-TTL, all C-MOS devices are slow and very sensitive to capacitance loading (see Fig. 6).

The HE family uses both advanced processing (LOCMOS) and improved circuit design (buffered gates) to achieve propagation delays and output transition times that are superior to any other junction-isolated C-MOS design.

LOCMOS processing achieves lower parasitic capacitances which reduce the on-chip delay and increase the maximum clock frequency of flip-flops, registers and counters. Buffering all outputs, even on gates, results in lower output impedance and thus reduces the effect of capacitive loading.

Propagation delay is affected by three parameters: capacitive loading, supply voltage, and temperature.

Fig. 6 Normalized propagation delay as a function of load capacitance for TTL, C-MOS and LOCMOS.

## Capacitive loading effect

Historically, semiconductor manufacturers have always specified the propagation delay at an output load of 15 pF, not because this was considered a representative systems environment, but rather because it was the lowest practical test-jig capacitance. It also generated the most impressive specifications. For example, TTL with an output impedance in the LOW state of typically  $25 \Omega$  is little affected by an increase in capacitive loading. LOCMOS, however, with an output impedance of typically  $250 \Omega$  (at 5 V) is 10 times more sensitive to capacitive loading. As an example Fig. 7 shows the positive and negative-going delays as functions of load capacitance for the HEF4011B and Fig. 8 shows the output transition times for standard output stages. For detailed information see Family Specifications and the individual data sheets. It should be noted that most unbuffered gates have an even higher output impedance, a larger dependence on output loading, and do not show the same symmetry.

Fig. 7 Positive and negative-going propagation delay as functions of load capacitance for the HEF4011B.

Fig. 8 Output transition times as functions of load capacitance.

### Supply voltage effect

1. Speed; Fig. 9 shows propagation delays as functions of supply voltage. The best choice for slow applications is 5 V. For reasonably fast systems, choose 10 or 12 V. Any application requiring 15 V to achieve short delays and fast operation should be investigated for excessive power dissipation and should be weighed against an LS-TTL approach.
2. Noise immunity; improves with higher supply voltage (see NOISE IMMUNITY).

Fig. 9 Propagation delays (symmetrical) as functions of power supply voltage for the HEF4011B.

## Temperature effect

The temperature dependence of LOCOS is much simpler than with TTL, where three factors contribute: increase of beta with temperature, increase of resistor value with temperature, and decrease of junction forward voltage drop with increasing temperature. In LOCOS, essentially only the carrier mobility changes, thus increasing the impedance, and hence the delay, with temperature. For more details see Family Specifications and the individual data sheets, for example see Fig. 10.

Fig. 10 Propagation delays as functions of ambient temperature, with  $V_{DD} = 10$  V for HEF4011B.

## Noise immunity

One of the most advertised and also misunderstood C-MOS features is noise immunity. The input threshold of a C-MOS gate is approximately 50% of the supply voltage and the voltage transfer curve is almost ideal. As a result, LOCOS can claim very good voltage noise immunity, typically 45% of the supply voltage, i.e., 2,25 V in a 5 V system, 4,5 V in a 10 V system and 6,75 V in a 15 V system. Compare this with the TTL transfer curve in Fig. 11 and its resultant 1 V noise immunity in a lightly loaded system and only 0,4 V worst case. Fig. 12 shows the transfer characteristic between  $-55$  and  $+125$  °C.

Since LOCOS output impedance, output voltage and input threshold are symmetrical with respect to the supply voltage, the LOW and HIGH level noise immunities are practically equal. Therefore, a LOCOS system can tolerate ground or  $V_{DD}$  drops and noise on these supply lines of more than 1 V, even in a 5 V system. Moreover, the inherent LOCOS delays act as a noise filter; 10 ns spikes tend to disappear in a chain of LOCOS gates, but are amplified in a chain of TTL gates. Because of these features, LOCOS is very popular with designers of industrial control equipment that must operate in an electrically and electromagnetically 'polluted' environment.

Unfortunately these impressive noise margin specifications disregard one important fact: the output impedance of LOCOS is 3 to 10 times higher than that of TTL. C-MOS interconnections are therefore less 'stiff' and more susceptible to capacitively coupled noise. In terms of such current-injected crosstalk from high noise voltages through small coupling capacitances, the tables on the next page give a comparison between LOCOS and TTL/LS-TTL.

Fig. 11 Typical transfer characteristic for TTL and LOCMOS.

LOCMOS/TTL (normalized to TTL)

$V_{DD}$	5 V	10 V	15 V
factor	0,5	1	2

From the tables can be seen that LOCMOS operating at  $V_{DD} = 10\text{ V}$  has a dynamic noise immunity which is comparable with TTL and 3 times as good as LS-TTL.

In terms of voltage injected noise the nearly ideal transfer characteristic and the relatively slow response of LOCMOS circuits make them at least 5 times less sensitive to magnetically coupled noise than TTL/LS-TTL.

Fig. 12 Voltage transfer characteristic over  $-55$  to  $+125\text{ }^\circ\text{C}$  range.

LOCMOS/LS-TTL (normalized to LS-TTL)

$V_{DD}$	5 V	10 V	15 V
factor	1	3	5

## Input protection

The gate input to any MOS transistor appears like a small value ( $< 1 \text{ pF}$ ), very low leakage ( $< 1 \text{ pA}$ ) capacitor. Without special precautions, such inputs could be electrostatically charged to a high voltage, causing a destructive breakdown of the dielectric and permanently damaging the device. Therefore, all LOCOS inputs are protected by a combination of series resistor and shunt diodes. Different manufacturers have different approaches; some use a single diode, others use two diodes, and some use a resistor with a parasitic substrate diode.

With the exception of a few devices, each member of the HE family utilizes a series resistor, nominally  $400 \Omega$ , and two diodes, one to  $V_{DD}$ , and the other to  $V_{SS}$  (see Fig. 13). The resistor is a polysilicon 'true resistor' without a parasitic substrate diode. This ensures that the input impedance is always at least  $400 \Omega$  under all biasing conditions, even when  $V_{DD}$  is short-circuited to  $V_{SS}$ . A parasitic substrate diode would represent a poorly defined shunt to  $V_{SS}$  in this particular case.

The diodes exhibit typical forward voltage drops of  $0.9 \text{ V}$  at  $1 \text{ mA}$  and reverse breakdown voltages of  $20 \text{ V}$ . For certain special applications such as oscillators, the diodes actually conduct during normal operation, in this case the current should be limited to  $1 \text{ mA}$ . Input currents averaging  $10 \text{ mA}$  or more may destroy the device.

Fig. 13 Standard HE family LOCOS input protection circuit.

Fig. 14 The input protection for the HEF4049B and HEF4050B.

Figure 14 shows the input protection for the types HEF4049B and HEF4050B. Diode D1 is the inherent drain to  $V_{SS}$  diode of the protection device. Under operational conditions, this input may exceed the supply voltage  $V_{DD}$ .

## Power supply regulation and decoupling

The LOCOS technology suggests that any supply voltage between  $3$  and  $15 \text{ V}$  will do, thus rendering supply voltage regulation unnecessary. However, it must be realized that the supply voltage has influence on the system speed (see Fig. 9), noise immunity (see Figs 11 and 12) and dissipation (see Fig. 4) and see text concerning all these Figures.

Any dynamic system generates voltage spikes on the supply line. These spikes influence the noise immunity, they may damage the circuit, or may have a negative influence on proper operation of the circuit. Therefore a matched decoupling of the supply line is necessary. Generally an electrolytic capacitor of  $3 \mu\text{F}$  per  $10$  devices is sufficient. However, some circuits require special attention:

1. HEF4511B: BCD to 7-segment latch/decoder/driver; an electrolytic capacitor of  $3 \mu\text{F}$  should be added to each device to avoid excessive voltage spikes due to high  $di/dt$ .
2. HEF4528B: dual retriggerable/resettable monostable multivibrator; for circuits of this nature it is recommended to use proper decoupling to avoid pulse length variations due to supply line ripple.
3. Circuits that operate in the linear mode, such as RC or crystal oscillators, a minimum supply voltage of at least  $4 \text{ V}$  is recommended.

## 3-state outputs

Fig. 15 Logic symbol of a 3-state output.

Function table

inputs		output O
I	EO	
X	L	Z
L	H	L
H	H	H

H = HIGH state (the more positive voltage)

L = LOW state (the less positive voltage)

X = state is immaterial

Z = high impedance OFF-state

Fig. 16 Circuit diagram of 3-state output.

When EO is HIGH, the output is enabled and the transistors P4 and N4 act as a transmission gate, and they connect the gates of the output transistors together. A LOW level at EO puts the output in the high impedance OFF-state; transistors P3 and N3 function as pull-up and pull-down transistors respectively.

**FAMILY SPECIFICATIONS**

These specifications cover the common electrical characteristics of the entire HE4000B family, unless otherwise specified in the individual device data sheet.

The LOC MOS HE4000B family devices will operate over a recommended  $V_{DD}$  power supply range of 3 to 15 V, as referenced to  $V_{SS}$  (usually ground). Parametric limits are guaranteed for  $V_{DD}$  of 5, 10 and 15 V. Because of the wide operating voltage range, power supply regulation is less critical than with other types of logic. The lower limit of the supply voltage is 3 V, or as determined by required system speed and/or noise immunity or interface to other logic. The recommended upper limit is 15 V or as determined by power dissipation constraints or interface to other logic. Unused inputs must be connected to  $V_{DD}$ ,  $V_{SS}$  or another input. Inputs and outputs are protected against electrostatic effects in a wide variety of device-handling situations. However, to be totally safe, it is desirable to take handling precautions into account.

## RATINGS

Limiting values in accordance with the Absolute Maximum System (IEC 134)

Supply voltage	$V_{DD}$	-0,5 to + 18 V
Voltage on any input	$V_I$	-0,5 to $V_{DD} + 0,5$ V
D.C. current into any input or output	$\pm I$	max. 10 mA
Power dissipation per package (for plastic and ceramic DIL)		
for $T_{amb} = -40$ to $+60$ °C	$P_{tot}$	max. 400 mW
for $T_{amb} = +60$ to $+85$ °C		derate linearly with 8 mW/°C to 200 mW
Power dissipation per package (for plastic SO mini-pack)		
for $T_{amb} = -40$ to $+70$ °C	$P_{tot}$	max. 200 mW
for $T_{amb} = +70$ to $+85$ °C		derate linearly with 5 mW/°C to 125 mW
Power dissipation per output	$P$	max. 100 mW
Storage temperature	$T_{stg}$	-65 to +150 °C
Operating ambient temperature	$T_{amb}$	-40 to +85 °C

D.C. CHARACTERISTICS  $V_{SS} = 0\text{ V}$ ; for all devices unless otherwise specified

parameter	$V_{DD}$ V	symbol	$T_{amb}$ (°C)			unit	conditions
			-40 min.	+25 min.	+85 max.		
Quiescent device current	5	$I_{DD}$	1,0	1,0	7,5	$\mu\text{A}$	all valid input combinations; $V_I = V_{SS}$ or $V_{DD}$
	10		2,0	2,0	15,0	$\mu\text{A}$

## A.C. CHARACTERISTICS

Clock input rise and fall times ( $t_r$ ,  $t_f$ )

The upper limits on  $t_r$  and  $t_f$  vary widely from device to device and with supply voltage. Unless otherwise specified in the individual data sheets it is recommended that input rise and fall times be less than 15  $\mu$ s for  $V_{DD} = 5$  V; 4  $\mu$ s for  $V_{DD} = 10$  V; 1  $\mu$ s for  $V_{DD} = 15$  V.

Output transition times ( $t_{TLH}$ ,  $t_{THL}$ )

$V_{SS} = 0$  V;  $T_{amb} = 25$  °C;  $C_L = 50$  pF; input transition times  $\leq 20$  ns

	$V_{DD}$ V	symbol	min.	typ.	max.	typical extrapolation formula	
Output transition times HIGH to LOW	5	$t_{THL}$		60	120	ns	$10 \text{ ns} + (1,0 \text{ ns/pF}) C_L$
	10		30	60	ns	$9 \text{ ns} + (0,42 \text{ ns/pF}) C_L$	
	15		20	40	ns	$6 \text{ ns} + (0,28 \text{ ns/pF}) C_L$	
LOW to HIGH	5	$t_{TLH}$		60	120	ns	$10 \text{ ns} + (1,0 \text{ ns/pF}) C_L$
	10		30	60	ns	$9 \text{ ns} + (0,42 \text{ ns/pF}) C_L$	
	15		20	40	ns	$6 \text{ ns} + (0,28 \text{ ns/pF}) C_L$	

Temperature coefficient (typical values)

Propagation delays +0,35%/°C

Output transition times +0,35%/°C

Input capacitance (digital inputs)

Maximum input capacitance  $C_I = 7,5$  pF.

Set-up times, hold times, recovery times and propagation delays for sequential logic circuits.

### Note

In the waveforms above the active transition of the clock input is going from LOW to HIGH and the active level of the forcing signals (SET, CLEAR and PRESET) is HIGH. The actual direction of the active transition of the clock input and the actual active levels of the forcing signals are specified in the individual device data sheet.

# FAMILY SPECIFICATIONS

Propagation delays of 3-state outputs.

Test circuit of 3-state output ICs.

**DEFINITION OF SYMBOLS AND TERMS USED IN DATA SHEETS**

**Currents**

Positive current is defined as conventional current flow into a device. Negative current is defined as conventional current flow out of a device.

$I_{IN}$	Input current; the current flowing into a device at specified input voltage and $V_{DD}$ .
$I_{OH}$	Output current HIGH; the drive current flowing out of the device at specified HIGH output voltage and $V_{DD}$ .
$I_{OL}$	Output current LOW; the drive current flowing into a device at specified LOW output voltage and $V_{DD}$ .
$I_{DD}$	Quiescent power supply current; the current flowing into the $V_{DD}$ lead at specified input and $V_{DD}$ conditions.
$I_{OZ}$	Output OFF current; the leakage current flowing into or out of the output of a 3-state device in the OFF state when the output is connected to $V_{DD}$ or $V_{SS}$ .
$I_{IL}$	Input current LOW; the current flowing into a device at a specified LOW level input voltage and a specified $V_{DD}$ .
$I_{IH}$	Input current HIGH; the current flowing into a device at a specified HIGH level input voltage and a specified $V_{DD}$ .
$I_{DDL}$	Quiescent power supply current LOW; the current flowing into the $V_{DD}$ lead with a specified LOW level input voltage on all inputs and specified $V_{DD}$ conditions.
$I_{DDH}$	Quiescent power supply current HIGH; the current flowing into the $V_{DD}$ lead with a specified HIGH level input voltage on all inputs and specified $V_{DD}$ conditions.
$I_Z$	OFF state leakage current; the leakage current flowing into the output of a 3-state device in the OFF state at a specified output voltage and $V_{DD}$ .

**Voltages**

All voltages are referenced to  $V_{SS}$ , which is the most negative potential applied to the device.

$V_{DD}$	Supply voltage; the most positive potential on the device.
$V_{SS}$	Supply voltage; for a device with a single negative power supply, the most negative power supply, used as the reference level for other voltages; typically ground.
$V_{EE}$	Supply voltage; one of two ( $V_{SS}$ and $V_{EE}$ ) negative power supplies. For a device with dual negative power supply, the most negative power supply as a reference level for other voltages.
$V_{IH}$	Input voltage HIGH; the range of input voltages that represents a logic HIGH level in the system.
$V_{IL}$	Input voltage LOW; the range of input voltages that represents a logic LOW level in the system.
$V_{OH}$	Output voltage HIGH; the range of voltages at an output terminal with specified output loading and supply voltage. Device inputs are conditioned to establish a HIGH level at the output.
$V_{OL}$	Output voltage LOW; the range of voltages at an output terminal with specified output loading and supply voltage. Device inputs are conditioned to establish a LOW level at the output.
$V_P$	Trigger threshold voltage; positive-going signal.
$V_N$	Trigger threshold voltage; negative-going signal.

**Analogue terms**

$R_{ON}$	ON resistance; the effective ON state resistance of an analogue transmission gate, at specified input voltage, output load and $V_{DD}$ .
$\Delta R_{ON}$	$\Delta$ ON resistance; the difference in effective ON resistance between any two transmission gates of an analogue device at specified input voltage, output load and $V_{DD}$ .

**A.C. switching parameters**

$f_i$	Input frequency; for combinatorial logic devices the maximum number of inputs and outputs switching in accordance with the device truth table. For sequential logic devices the clock frequency using alternate HIGH and LOW for data input or using the toggle mode, whichever is applicable.
$f_o$	Output frequency; each output.
$f_{max}$	Clock frequency; clock input waveform should have a 50% duty cycle and be such as to cause the outputs to be switching from 10% $V_{DD}$ to 90% $V_{DD}$ in accordance with the device truth table.
$t_r, t_f$	Clock input rise and fall times; 10% to 90% value.
$t_{PLH}$	Propagation delay time; the time between the specified reference points, normally 50% points on the input and output waveforms, with the output changing from the defined LOW level to the defined HIGH level.
$t_{PHL}$	Propagation delay time; the time between the specified reference points, normally 50% points on the input and output waveforms, with the output changing from the defined HIGH level to the defined LOW level.
$t_{TLH}$	Transition time, LOW-to-HIGH; the time between two specified reference points on a waveform, normally 10% and 90% points, that is changing from LOW to HIGH.
$t_{THL}$	Transition time, HIGH-to-LOW; the time between two specified reference points on a waveform, normally 90% and 10% points, that is changing from HIGH to LOW.
$t_w$	Pulse width; the time between 50% amplitude points on the leading and trailing edges of pulse.
$t_{hold}$	Hold time; the interval immediately following the active transition of the timing pulse (usually the clock pulse) or following the transition of the control input to its latching level, during which interval the data to be recognized must be maintained at the input to ensure their continued recognition. A negative hold time indicates that the correct logic level may be released prior to the timing pulse and still be recognized.
$t_{su}$	Set-up time; the interval immediately preceding the active transition of the timing pulse (usually the clock pulse) or preceding the transition of the control input to its latching level, during which interval the data to be recognized must be maintained at the input to ensure their recognition. A negative set-up time indicates that the correct logic level may be initiated sometime after the active transition of the timing pulse and still be recognized.
$t_{PHZ}$	3-state output disable time, HIGH to Z; the time between the specified reference points, normally the 50% point on the output enable input voltage waveform and a point representing a 0,1 $V_{OH}$ drop on the output voltage waveform of a 3-state device, with the output changing from the output HIGH level ( $V_{OH}$ ) to a high impedance OFF-state.
$t_{PLZ}$	3-state output disable time, LOW to Z; the time between the specified reference points, normally the 50% point on the output enable input voltage waveform and a point representing a 0,1 ( $V_{DD}-V_{OL}$ ) rise on the output voltage waveform of a 3-state device, with the output changing from the output LOW level ( $V_{OL}$ ) to a high impedance OFF-state.
$t_{PZH}$	3-state output enable time, Z to HIGH; the time between the specified reference points, normally 50% point on the output enable input voltage waveform and a point representing 0,1 $V_{OH}$ voltage rise on the output voltage waveform of a 3-state device, with the output changing from a high impedance OFF-state to the output HIGH level ( $V_{OH}$ ).
$t_{PZL}$	3-state output enable time, Z to LOW; the time between the specified reference points, normally the 50% point on the output enable input voltage waveform and a point representing 0,1 ( $V_{DD}-V_{OL}$ ) voltage drop on the output voltage waveform of a 3-state device, with the output changing from a high impedance OFF-state to the output LOW level ( $V_{OL}$ ).
$t_R$	Recovery time; the time between the end of an overriding asynchronous input, typically a clear or reset input, and the earliest permissible beginning of a synchronous control input, typically a clock input, normally measured at 50% points on both input voltage waveforms.

**DEVICE DATA**

## DUAL 3-INPUT NOR GATE AND INVERTER

The HEF4000B provides the positive dual 3-input NOR function. A single stage inverting function with standard output performance is also accomplished. The outputs are fully buffered for highest noise immunity and pattern insensitivity of output impedance.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4000BP : 14-lead DIL; plastic (SOT-27K, M, T).  
HEF4000BD : 14-lead DIL; ceramic (cerdip) (SOT-73).

**APPLICATION INFORMATION**

Some examples of applications for the HEF4001UB are shown below.

Because of the fact that this circuit is unbuffered, it is suitable for use in (partly) analogue circuits.

INH	O
H	L
L	OSC

(a)

(b)

Fig. 9(a) Astable relaxation oscillator using two HEF4001UB gates; the diodes may be BAW62; C2 is a parasitic capacitance. (b) Waveforms at the points marked A, B, C and D in the circuit diagram.

In Fig. 9 the oscillation frequency is mainly determined by  $R1C1$ , provided  $R1 \ll R2$  and  $R2C2 \ll R1C1$ .

The function of R2 is to minimize the influence of the forward voltage across the protection diodes on the frequency; C2 is a stray (parasitic) capacitance. The period  $T_p$  is given by  $T_p = T_1 + T_2$ , in which

$$T_1 = R1C1 \ln \frac{V_{DD} + V_{ST}}{V_{ST}} \text{ and } T_2 = R1C1 \ln \frac{2 V_{DD} - V_{ST}}{V_{DD} - V_{ST}} \text{ where}$$

$V_{ST}$  is the signal threshold level of the gate. The period is fairly independent of  $V_{DD}$ ,  $V_{ST}$  and temperature. The duty factor, however, is influenced by  $V_{ST}$ .

Fig. 10 Example of a crystal oscillator using one HEF4001UB gate.

Fig. 11 Output voltages as a function of supply voltage.

Fig. 12 Test set-up for measuring graph of Fig. 11. Condition: all other inputs connected to ground.

### NOTES

If a gate is just used as an amplifying inverter, there are two possibilities:

- Connecting the inputs together gives simpler wiring, but makes the device output not completely symmetrical.
- Connecting one input to  $V_{SS}$  will give the device a symmetrical output.

## 18-STAGE STATIC SHIFT REGISTER

The HEF4006B is an 18-stage shift register arranged as two 4-stage and two 5-stage shift registers with a common clock input ( $\overline{CP}$ ). The two 4-stage shift registers each have a data input ( $D_A$ ,  $D_B$ ) and a data output ( $O_{3A}$ ,  $O_{3B}$ ); the two 5-stage shift registers each have a data input ( $D_C$ ,  $D_D$ ) and data outputs from the fourth and fifth stages ( $O_{3C}$ ,  $O_{4C}$ ,  $O_{3D}$ ,  $O_{4D}$ ).

The registers can be operated in parallel or interconnected to form a single shift register of up to 18 bits. Data are shifted into the first register position of each register from the data inputs ( $D_A$  to  $D_D$ ) and all the data in each register are shifted one position to the right on the HIGH to LOW transition of  $\overline{CP}$ .

**APPLICATION INFORMATION**

Some examples of applications for the HEF4007UB are:

- High input impedance amplifiers
- Linear amplifiers
- (Crystal) oscillators
- High-current sink and source drivers
- High impedance buffers.

Fig. 6 Voltage gain ( $V_O/V_I$ ) as a function of supply voltage.

Fig. 13 High current source driver.

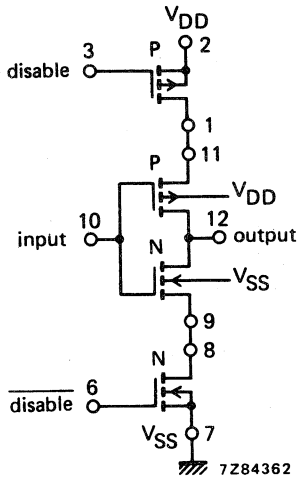

Fig. 14 High impedance buffer.

FUNCTION TABLE for Fig. 14.

input	disable	output
H	L	L
L	L	H
X	H	open

H = HIGH state (the more positive voltage)

L = LOW state (the less positive voltage)

X = state is immaterial

**NOTE**

Rules for maintaining electrical isolation between transistors and monolithic substrate:

Pin number 14 must be maintained at the most positive (or equally positive) potential with respect to any other pin of the HEF4007UB.

Pin number 7 must be maintained at the most negative (or equally negative) potential with respect to any other pin of the HEF4007UB.

Violation of these rules will result in improper transistor operation and/or possible permanent damage to the HEF4007UB.

## 4-BIT BINARY FULL ADDER

The HEF4008B is a 4-bit binary full adder with two 4-bit data inputs ( $A_0$  to  $A_3$ ,  $B_0$  to  $B_3$ ), a carry input ( $C_{IN}$ ), four sum outputs ( $S_0$  to  $S_3$ ), and a carry output ( $C_{OUT}$ ). The IC uses full look-ahead carry across 4-bits to generate  $C_{OUT}$ . This minimizes the necessity for extensive look-ahead and carry-cascading circuits.

Fig. 1 Functional diagram.

's' is the observed standard deviation.

**APPLICATION INFORMATION**

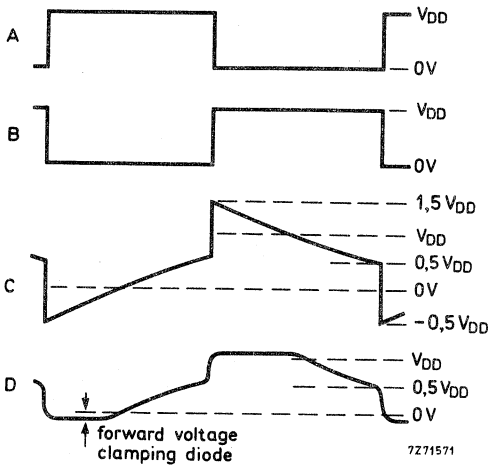

Some examples of applications for the HEF4011UB are shown below.

Because of the fact that this circuit is unbuffered, it is suitable for use in (partly) analogue circuits.

INH	O
L	H
H	OSC

(a)

(b)

Fig. 9 (a) Astable relaxation oscillator using two HEF4011UB gates; the diodes may be BAW62; C2 is a parasitic capacitance. (b) Waveforms at the points marked A, B, C and D in the circuit diagram.

In Fig. 9 the oscillation frequency is mainly determined by  $R1C1$ , provided  $R1 \ll R2$  and  $R2C2 \ll R1C1$ .

The function of R2 is to minimize the influence of the forward voltage across the protection diodes on the frequency; C2 is a stray (parasitic) capacitance. The period  $T_p$  is given by  $T_p = T_1 + T_2$ , in which

$$T_1 = R1C1 \ln \frac{V_{DD} + V_{ST}}{V_{ST}} \quad \text{and} \quad T_2 = R1C1 \ln \frac{2V_{DD} - V_{ST}}{V_{DD} - V_{ST}} \quad \text{where}$$

$V_{ST}$  is the signal threshold level of the gate. The period is fairly independent of  $V_{DD}$ ,  $V_{ST}$  and temperature. The duty factor, however, is influenced by  $V_{ST}$ .

## NOTES

If a gate is just used as an amplifying inverter, there are two possibilities:

- Connecting the inputs together gives simpler wiring, but makes the device output not completely symmetrical.
- Connecting one input to  $V_{DD}$  will give the device a symmetrical output.

## DUAL D-TYPE FLIP-FLOP

The HEF4013B is a dual D-type flip-flop which features independent set direct ( $S_D$ ), clear direct ( $C_D$ ), clock inputs (CP) and outputs (O,  $\bar{O}$ ). Data is accepted when CP is LOW and transferred to the output on the positive-going edge of the clock. The active HIGH asynchronous clear-direct ( $C_D$ ) and set-direct ( $S_D$ ) are independent and override the D or CP inputs. The outputs are buffered for best system performance. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

APPLICATION INFORMATION

Some examples of applications for the HEF4013B are:

- Counters/dividers
- Registers
- Toggle flip-flops

Fig. 6 Typical application of the HEF4013B in an n-stage shift register.

Fig. 7 Typical application of the HEF4013B in a binary ripple up-counter; divide-by- $2^n$ .

Fig. 8 Typical application of the HEF4013B in a modified ring counter; divide-by-(n + 1).

## 8-BIT STATIC SHIFT REGISTER

The HEF4014B is a fully synchronous edge-triggered 8-bit static shift register with eight synchronous parallel inputs ( $P_0$  to  $P_7$ ), a synchronous serial data input ( $D_S$ ), a synchronous parallel enable input (PE), a LOW to HIGH edge-triggered clock input (CP) and buffered parallel outputs from the last three stages ( $O_5$  to  $O_7$ ).

Operation is synchronous and the device is edge-triggered on the LOW to HIGH transition of CP. Each register stage is of a D-type master-slave flip-flop. When PE is HIGH, data is loaded into the register from  $P_0$  to  $P_7$  on the LOW to HIGH transition of CP. When PE is LOW, data is shifted to the first position from  $D_S$ , and all the data in the register is shifted one position to the right on the LOW to HIGH transition of CP. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times

**APPLICATION INFORMATION**

Some examples of applications for the HEF4014B are:

- Parallel-to-serial converter
- Serial data queueing
- General purpose register

## DUAL 4-BIT STATIC SHIFT REGISTER

The HEF4015B is a dual edge-triggered 4-bit static shift register (serial-to-parallel converter). Each shift register has a serial data input (D), a clock input (CP), four fully buffered parallel outputs ( $O_0$  to  $O_3$ ) and an overriding asynchronous master reset input (MR). Information present on D is shifted to the first register position, and all the data in the register is shifted one position to the right on the LOW-to-HIGH transition of CP. A HIGH on MR clears the register and forces  $O_0$  to  $O_3$  to LOW, independent of CP and D. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

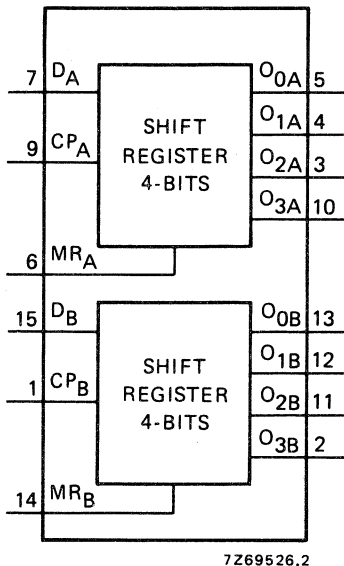

Fig. 2 Pinning diagram.

HEF4015BP: 16-lead DIL; plastic (SOT-38Z).

HEF4015BD: 16-lead DIL; ceramic (cerdip) (SOT-74).

HEF4015BT: 16-lead mini-pack; plastic (SO-16; SOT-109A).

## QUADRUPLE BILATERAL SWITCHES

The HEF4016B has four independent analogue switches (transmission gates). Each switch has two input/output terminals (Y/Z) and an active HIGH enable input (E). When E is connected to  $V_{DD}$  a low impedance bidirectional path between Y and Z is established (ON condition). When E is connected to  $V_{SS}$  the switch is disabled and a high impedance between Y and Z is established (OFF condition). Current through a switch will not cause additional  $V_{DD}$  current provided the voltage at the terminals of the switch is maintained within the supply voltage range;  $V_{DD} \geq (V_Y, V_Z) \geq V_{SS}$ . Inputs Y and Z are electrically equivalent terminals.

Fig. 1 Functional diagram.

## 5-STAGE JOHNSON COUNTER

The HEF4017B is a 5-stage Johnson decade counter with ten spike-free decoded active HIGH outputs ( $O_0$  to  $O_9$ ), an active LOW output from the most significant flip-flop ( $\bar{O}_{5-9}$ ), active HIGH and active LOW clock inputs ( $CP_0$ ,  $\bar{CP}_1$ ) and an overriding asynchronous master reset input (MR).

The counter is advanced by either a LOW to HIGH transition at  $CP_0$  while  $\bar{CP}_1$  is LOW or a HIGH to LOW transition at  $\bar{CP}_1$  while  $CP_0$  is HIGH (see also function table).

When cascading counters, the  $\bar{O}_{5-9}$  output, which is LOW while the counter is in states 5, 6, 7, 8 and 9, can be used to drive the  $CP_0$  input of the next counter.

A HIGH on MR resets the counter to zero ( $O_0 = \bar{O}_{5-9} = \text{HIGH}$ ;  $O_1$  to  $O_9 = \text{LOW}$ ) independent of the clock inputs ( $CP_0$ ,  $\bar{CP}_1$ ).

Automatic code correction of the counter is provided by an internal circuit: following any illegal code the counter returns to a proper counting mode within 11 clock pulses.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4017BP : 16-lead DIL; plastic (SOT-38Z).

HEF4017BD : 16-lead DIL; ceramic (cerdip) (SOT-74).

## APPLICATION INFORMATION

Some examples of applications for the HEF4017B are:

- Decade counter with decimal decoding
- 1 out of n decoding counter (when cascaded)
- Sequential controller
- Timer.

Figure 7 shows a technique for extending the number of decoded output states for the HEF4017B. Decoded outputs are sequential within each stage and from stage to stage, with no dead time (except propagation delay).

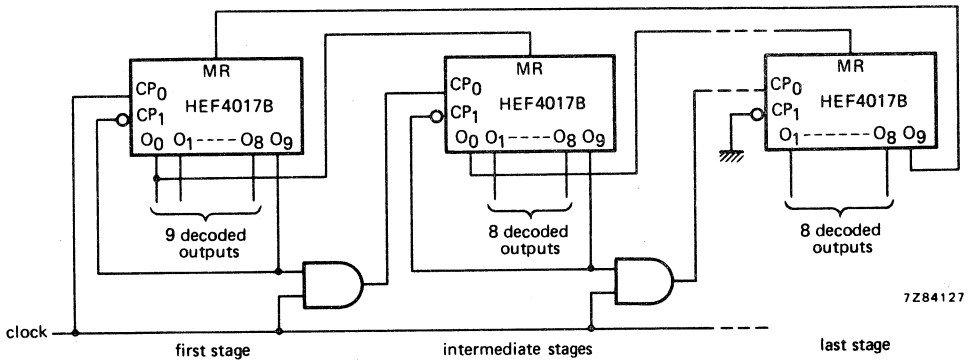

Fig. 7 Counter expansion.

## Note

It is essential not to enable the counter on  $\overline{CP}_1$  when  $CP_0$  is HIGH, or on  $CP_0$  when  $\overline{CP}_1$  is LOW, as this would cause an extra count.

## PRESETTABLE DIVIDE-BY-N COUNTER

The HEF4018B is a 5-stage Johnson counter with a clock input (CP), a data input (D), an asynchronous parallel load input (PL), five parallel inputs ( $P_0$  to  $P_4$ ), five active LOW buffered outputs ( $\bar{O}_0$  to  $\bar{O}_4$ ), and an overriding asynchronous master reset input (MR).

Information on  $P_0$  to  $P_4$  is asynchronously loaded into the counter while PL is HIGH, independent of CP and D inputs. When  $P_L$  is LOW, the counter advances on the LOW to HIGH transition of CP. By connecting  $\bar{O}_0$  to  $\bar{O}_4$  to D, the counter operates as a divide-by-n counter ( $n = 2$  to  $10$ ; see also function selection below). Each register stage is a D-type master-slave flip-flop with a set-direct/clear-direct input. An internal code correction circuit provides automatic code correction of the counter. From any illegal code the counter is in a proper counting mode within 11 clock pulses.

A HIGH on MR resets the counter ( $\bar{O}_0$  to  $\bar{O}_4 = \text{HIGH}$ ) independent of all other inputs.

Fig. 1 Functional diagram.

### FUNCTION SELECTION

counter mode; divide by	connect D input to	remarks
10	$\bar{O}_4$	no external components needed
8	$\bar{O}_3$	
6	$\bar{O}_2$	
4	$\bar{O}_1$	
2	$O_0$	
9	$\bar{O}_3 \cdot \bar{O}_4$	AND gate needed; counter skips all HIGH states
7	$\bar{O}_2 \cdot \bar{O}_3$	
5	$\bar{O}_1 \cdot \bar{O}_2$	
3	$\bar{O}_0 \cdot \bar{O}_1$	

Fig. 2 Pinning diagram.

HEF4018BP: 16-lead DIL; plastic (SOT-38Z).

HEF4018BD: 16-lead DIL; ceramic (cerdip) (SOT-74).

HEF4018BT: 16-lead mini-pack; plastic (SO-16; SOT-109A).

### PINNING

- PL parallel load input
- $P_0$  to  $P_4$  parallel inputs
- D data input
- CP clock input (LOW to HIGH edge triggered)
- MR master reset input
- $\bar{O}_0$  to  $\bar{O}_4$  buffered output (active LOW)

### APPLICATION INFORMATION

Some examples of applications for the HEF4018B are:

- Programmable divide-by-n counter
- Programmable frequency division
- Timers

## QUADRUPLE 2-INPUT MULTIPLEXER

The HEF4019B provides four multiplexing circuits with common select inputs ( $S_A$ ,  $S_B$ ); each circuit contains two inputs ( $A_n$ ,  $B_n$ ) and one output ( $O_n$ ). It may be used to select four bits of information from one of two sources.

The A inputs are selected when  $S_A$  is HIGH, the B inputs when  $S_B$  is HIGH. When  $S_A$  and  $S_B$  are HIGH, output ( $O_n$ ) is the logical OR of the  $A_n$  and  $B_n$  inputs ( $O_n = A_n + B_n$ ). When  $S_A$  and  $S_B$  are LOW, output ( $O_n$ ) is LOW independent of the multiplexer inputs.

- True/complement selection.

## 14-STAGE BINARY COUNTER

The HEF4020B is a 14-stage binary ripple counter with a clock input ( $\overline{CP}$ ), an overriding asynchronous master reset input (MR) and twelve fully buffered outputs ( $O_0, O_3$  to  $O_{13}$ ). The counter advances on the HIGH to LOW transition of  $\overline{CP}$ . A HIGH on MR clears all counter stages and forces all outputs LOW, independent of the state of  $\overline{CP}$ . Each counter stage is a static toggle flip-flop. A feature of the HEF4020B is: high speed (typ. 35 MHz at  $V_{DD} = 15$  V).

## 8-BIT STATIC SHIFT REGISTER

The HEF4021B is an 8-bit static shift register (parallel-to-serial converter) with a synchronous serial data input ( $D_S$ ), a clock input (CP), an asynchronous active HIGH parallel load input (PL), eight asynchronous parallel data inputs ( $P_0$  to  $P_7$ ) and buffered parallel outputs from the last three stages ( $O_5$  to  $O_7$ ).

Each register stage is a D-type master-slave flip-flop with a set direct/clear direct input. Information on  $P_0$  to  $P_7$  is asynchronously loaded into the register while PL is HIGH, independent of CP and  $D_S$ . When PL is LOW, data on  $D_S$  is shifted into the first register position and all the data in the register is shifted one position to the right on the LOW to HIGH transition of CP. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4021BP : 16-lead DIL; plastic (SOT-38Z).  
HEF4021BD : 16-lead DIL; ceramic (cerdip) (SOT-74).

## 4-STAGE DIVIDE-BY-8 JOHNSON COUNTER

The HEF4022B is a 4-stage divide-by-8 Johnson counter with eight spike-free decoded active HIGH outputs ( $O_0$  to  $O_7$ ), an active LOW output from the most significant flip-flop ( $\bar{O}_{4-7}$ ), active HIGH and active LOW clock inputs ( $CP_0$ ,  $\bar{CP}_1$ ) and an overriding asynchronous master reset input (MR).

The counter is advanced by either a LOW to HIGH transition at  $CP_0$  while  $\bar{CP}_1$  is LOW or a HIGH to LOW transition at  $\bar{CP}_1$  while  $CP_0$  is HIGH (see also function table). Either  $CP_0$  or  $\bar{CP}_1$  may be used as clock input to the counter and the other clock input may be used as a clock enable input. When cascading counters, the  $\bar{O}_{4-7}$  output, which is LOW while the counter is in states, 4, 5, 6 and 7, can be used to drive the  $CP_0$  input of the next counter.

A HIGH on MR resets the counter to zero ( $O_0 = \bar{O}_{4-7} = \text{HIGH}$ ;  $O_1$  to  $O_7 = \text{LOW}$ ) independent of the clock inputs ( $CP_0$ ,  $\bar{CP}_1$ ).

Automatic code correction of the counter is provided by an internal circuit, following any illegal code the counter returns to a proper counting mode within 11 clock pulses.

## APPLICATION INFORMATION

Some of the features of the HEF4022B are:

- High speed
- Spike-free decoded outputs
- Carry output for cascading

Figure 7 shows a technique for extending the number of decoded output states for the HEF4022B. Decoded outputs are sequential within each stage and from stage to stage, with no dead time (except propagation delay).

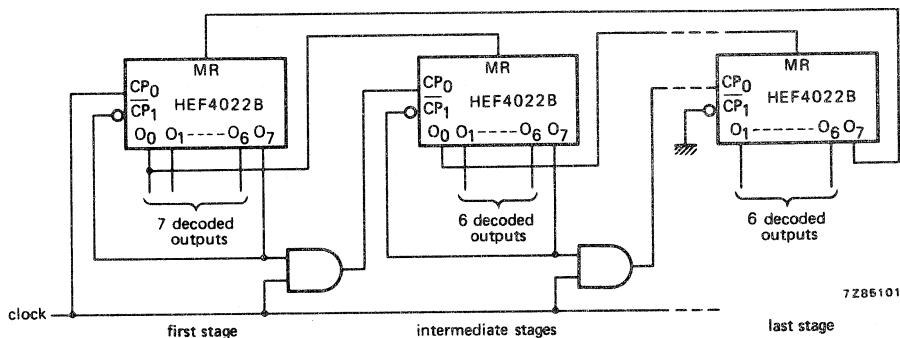

Fig. 7 Counter expansion.

## TRIPLE 3-INPUT NAND GATE

The HEF4023B provides the positive triple 3-input NAND function. The outputs are fully buffered for highest noise immunity and pattern insensitivity of output impedance.

## 7-STAGE BINARY COUNTER

The HEF4024B is a 7-stage binary ripple counter with a clock input ( $\overline{CP}$ ), and overriding asynchronous master reset input (MR) and seven fully buffered parallel outputs ( $O_0$  to  $O_6$ ). The counter advances on the HIGH to LOW transition of  $\overline{CP}$ . A HIGH on MR clears all counter stages and forces all outputs LOW, independent of  $\overline{CP}$ . Each counter stage is a static toggle flip-flop.

Fig. 1 Functional diagram.

## DUAL JK FLIP-FLOP

The HEF4027B is a dual JK flip-flop which is edge-triggered and features independent set direct ( $S_D$ ), clear direct ( $C_D$ ), clock (CP) inputs and outputs ( $O, \bar{O}$ ). Data is accepted when CP is LOW, and transferred to the output on the positive-going edge of the clock. The active HIGH asynchronous clear-direct ( $C_D$ ) and set-direct ( $S_D$ ) are independent and override the J, K, and CP inputs. The outputs are buffered for best system performance. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

#### APPLICATION INFORMATION

Some examples of applications for the HEF4027B are:

- Registers
- Counters
- Control circuits

1-OF-10 DECODER

The HEF4028B is a 4-bit BCD to 1-of-10 active HIGH decoder. A 1-2-4-8 BCD code applied to inputs  $A_0$  to  $A_3$  causes the selected output to be HIGH, the other nine will be LOW. If desired, the device may be used as a 1-of-8 decoder with enable; 3-bit octal inputs are applied to inputs  $A_0$ ,  $A_1$  and  $A_2$  selecting an output  $O_0$  to  $O_7$ . Input  $A_3$  then becomes an active LOW enable, forcing the selected output LOW when  $A_3$  is HIGH. The HEF4028B may also be used as an 8-output ( $O_0$  to  $O_7$ ) demultiplexer with  $A_0$  to  $A_2$  as address inputs and  $A_3$  as an active LOW data input. The outputs are fully buffered for best performance.

Fig.1 Functional diagram. 7273681.1

Fig.2 Pinning diagram

	15		$C_L$ = load capacitance (pF)
			$\Sigma(f_o C_L)$ = sum of outputs
			$V_{DD}$ = supply voltage (V)

## SYNCHRONOUS UP/DOWN COUNTER, BINARY/DECADE COUNTER

The HEF4029B is a synchronous edge-triggered up/down 4-bit binary/BCD decade counter with a clock input (CP), an active LOW count enable input ( $\overline{CE}$ ), an up/down control input (UP/ $\overline{DN}$ ), a binary/decade control input (BIN/ $\overline{DEC}$ ), an overriding asynchronous active HIGH parallel load input (PL), four parallel data inputs ( $P_0$  to  $P_3$ ), four parallel buffered outputs ( $O_0$  to  $O_3$ ) and an active LOW terminal count output ( $\overline{TC}$ ).

Information on  $P_0$  to  $P_3$  is asynchronously loaded into the counter while PL is HIGH, independent of CP.

The counter is advanced one count on the LOW to HIGH transition of CP when  $\overline{CE}$  and PL are LOW. The  $\overline{TC}$  signal is normally HIGH and goes LOW when the counter reaches its maximum count in the UP mode, or the minimum count in the DOWN mode provided  $\overline{CE}$  is LOW.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

### PINNING

- PL parallel load input
- $P_0$  to  $P_3$  parallel data inputs
- BIN/ $\overline{DEC}$  binary/decade control input
- UP/ $\overline{DN}$  up/down control input
- $\overline{CE}$  count enable input (active LOW)
- CP clock input (LOW to HIGH, edge triggered)
- $O_0$  to  $O_3$  buffered parallel outputs
- $\overline{TC}$  terminal count output (active LOW)

- HEF4029BP : 16-lead DIL; plastic (SOT-38Z).
- HEF4029BD : 16-lead DIL; ceramic (cerdip) (SOT-74).

### APPLICATION INFORMATION

Some examples of applications for the HEF4029B are:

- Programmable binary and decade counting/frequency synthesizers - BCD output.
- Analogue-to-digital and digital-to-analogue conversion.
- Up/down binary counting.
- Magnitude and sign generation.
- Up/down decade counting.
- Difference counting.

APPLICATION INFORMATION (continued)

Fig. 10 Example of parallel clocking when cascading HEF4029B ICs.

Fig. 11 Example of ripple clocking when cascading HEF4029B ICs. Ripple clocking mode: the up/down control can be changed at any count; the only restriction on changing the up/down control is that the clock input to the first counting stage must be HIGH.

**Note**  
TC lines at all stages after the first may have a negative-going glitch pulse resulting from differential delays of different HEF4029B ICs. These negative-going glitches do not affect proper HEF4029B operation; however if the TC signals are used to trigger other edge-sensitive logic devices, such as flip-flops or counters, the TC signals should be gated with the clock signal using a 2-input OR gate such as HEF4071B.

## QUADRUPLE EXCLUSIVE-OR GATE

The HEF4030B provides the positive quadruple exclusive-OR function. The outputs are fully buffered for highest noise immunity and pattern insensitivity of output impedance.

## 64-STAGE STATIC SHIFT REGISTER

The HEF4031B is an edge-triggered 64-stage static shift register with two serial data inputs ( $D_A$ ,  $D_B$ ), a data select input  $\bar{A}/B$ , a clock input (CP), a buffered clock output (CO), and buffered outputs from the 64th bit position ( $O_{63}$ ,  $\bar{O}_{63}$ ). The output  $O_{63}$  is capable of driving one TTL load.

Data from  $D_A$  or  $D_B$ , as determined by the state of  $\bar{A}/B$ , is shifted into the first shift register position and all the data in the register is shifted one position to the right on the LOW to HIGH transition of CP.  $D_A$  is selected by a LOW, and  $D_B$  by a HIGH on  $\bar{A}/B$ . Registers can be cascaded either by connecting all CP inputs together or by driving CP of the most right-hand register with the system clock and connecting CO to CP of the preceding register. When the second technique is used in the recirculating mode, a flip-flop must be used to store  $O_{63}$  of the most right-hand register until the most left-hand register is clocked.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

### PINNING

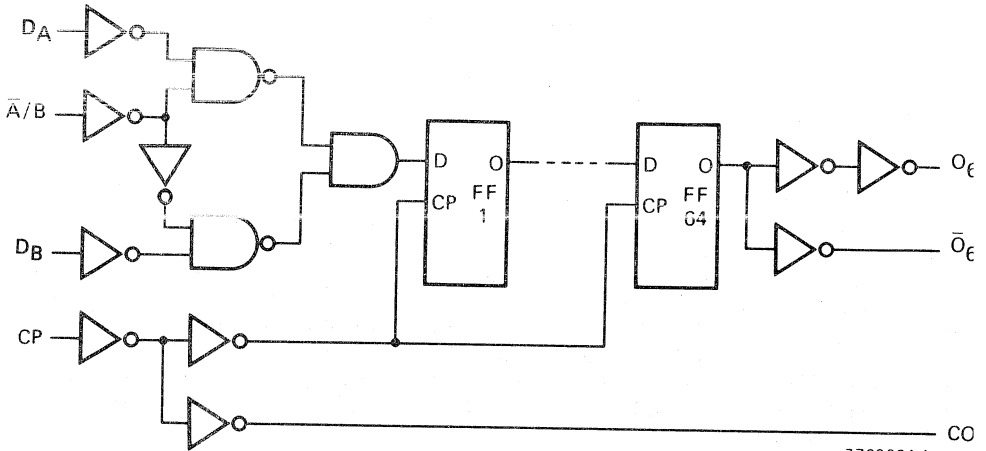

- $D_A$ ,  $D_B$  data inputs
- $\bar{A}/B$  data select input
- CP clock input (LOW to HIGH edge-triggered)
- CO buffered clock output
- $O_{63}$  buffered output from the 64th stage
- $\bar{O}_{63}$  complementary buffered output from the 64th stage

- HEF4031BP : 16-lead DIL; plastic (SOT-38Z).
- HEF4031BD: 16-lead DIL; ceramic (cerdip) (SOT-74).
- HEF4031BT : 16-lead mini-pack; plastic (SO-16; SOT-109A).

#### APPLICATION INFORMATION

An example of an application for the HEF4031B is:

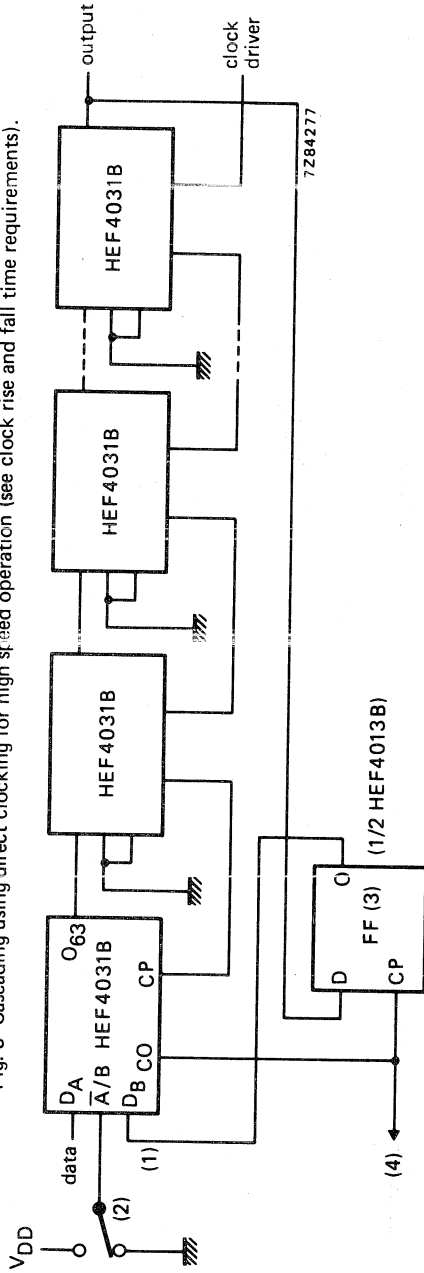

- Serial shift register.

APPLICATION INFORMATION

7284278

(1) Recirculating input.  
(2) Mode control: V<sub>DD</sub> = recirculation; ground (V<sub>SS</sub>) = new data.  
Fig. 5 Cascading using direct clocking for high speed operation (see clock rise and fall time requirements).

7284277

(1) Recirculating input.  
(2) Mode control: V<sub>DD</sub> = recirculation; ground (V<sub>SS</sub>) = new data.  
(3) For recirculation mode only, FF to delay data until first register delayed clocking has occurred.  
(4) Delayed clock-to-clock; new data into first register.  
Fig. 6 Cascading using delayed clocking for reduced clock driver requirements

## 4-BIT UNIVERSAL SHIFT REGISTER

The HEF4035B is a fully synchronous edge-triggered 4-bit shift register with a clock input (CP), four synchronous parallel data inputs ( $P_0$  to  $P_3$ ), two synchronous serial data inputs (J,  $\bar{K}$ ), a synchronous parallel enable input (PE), buffered parallel outputs from all 4-bit positions ( $O_0$  to  $O_3$ ), a true/complement input ( $T/\bar{C}$ ) and an overriding asynchronous master reset input (MR). Each register is of a D-type master-slave flip-flop.

Operation is synchronous (except for MR) and is edge-triggered on the LOW to HIGH transition of the CP input. When PE is HIGH, data is loaded into the register from  $P_0$  to  $P_3$  on the LOW to HIGH transition of CP.

When PE is LOW, data is shifted into the first register position from J and  $\bar{K}$  and all the data in the register is shifted one position to the right on the LOW to HIGH transition of CP. D-type entry is obtained by interconnecting J and  $\bar{K}$ . When J = HIGH and  $\bar{K}$  = LOW the first stage is in the toggle mode. When J = LOW and  $\bar{K}$  = HIGH the first stage is in the hold mode.

The outputs ( $O_0$  to  $O_3$ ) are either inverting or non-inverting, depending on  $T/\bar{C}$  state. With  $T/\bar{C}$  HIGH,  $O_0$  to  $O_3$  are non-inverting (active HIGH) and when  $T/\bar{C}$  is LOW,  $O_0$  to  $O_3$  are inverting (active LOW). A HIGH on MR resets all four bit positions ( $O_0$  to  $O_3$  = LOW if  $T/\bar{C}$  = HIGH,  $O_0$  to  $O_3$  = HIGH if  $T/\bar{C}$  = LOW) independent of all other input conditions.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4035B are:

- Counters, registers, arithmetic-unit registers, shift-left/shift-right registers.
- Serial-to-parallel/parallel-to-serial conversions.
- Sequence generation.
- Control circuits.
- Code conversion.

Fig. 6 Shift-left/shift-right register.

## 12-STAGE BINARY COUNTER

The HEF4040B is a 12-stage binary ripple counter with a clock input ( $\overline{CP}$ ), an overriding asynchronous master reset input (MR) and twelve fully buffered outputs ( $O_0$  to  $O_{11}$ ). The counter advances on the HIGH to LOW transition of  $\overline{CP}$ . A HIGH on MR clears all counter stages and forces all outputs LOW, independent of  $\overline{CP}$ . Each counter stage is a static toggle flip-flop. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4040BP : 16-lead DIL; plastic (SOT-38Z);  
HEF4040BD : 16-lead DIL; ceramic (cerdip) (SOT-74).  
HEF4040BT : 16-lead mini-pack; plastic  
(SO-16; SOT-109A).

### PINNING

$\overline{CP}$  clock input (HIGH to LOW edge-triggered)  
MR master reset input (active HIGH)  
 $O_0$  to  $O_{11}$  parallel outputs

### APPLICATION INFORMATION

Some examples of applications for the HEF4040B are:

- Frequency dividing circuits
- Time delay circuits
- Control counters

QUADRUPLE TRUE/COMPLEMENT BUFFER

The HEF4041B is a quadruple true/complement buffer which provides both an inverted active LOW output ( $\bar{O}$ ) and a non-inverted active HIGH output (O) for each input (I). The buffers exhibit high current output capability suitable for driving TTL or high capacitive loads.

## QUADRUPLE D-LATCH

The HEF4042B is a 4-bit latch with four data inputs ( $D_0$  to  $D_3$ ), four buffered latch outputs ( $O_0$  to  $O_3$ ), four buffered complementary latch outputs ( $\bar{O}_0$  to  $\bar{O}_3$ ) and two common enable inputs ( $E_0$  and  $E_1$ ). Information on  $D_0$  to  $D_3$  is transferred to  $O_0$  to  $O_3$  while both  $E_0$  and  $E_1$  are in the same state, either HIGH or LOW.  $O_0$  to  $O_3$  follow  $D_0$  to  $D_3$  as long as both  $E_0$  and  $E_1$  remain in the same state. When  $E_0$  and  $E_1$  are different,  $D_0$  to  $D_3$  do not affect  $O_0$  to  $O_3$  and the information in the latch is stored.

$\bar{O}_0$  to  $\bar{O}_3$  are always the complement of  $O_0$  to  $O_3$ . The exclusive-OR input structure allows the choice of either polarity for  $E_0$  and  $E_1$ . With one enable input HIGH, the other enable input is active HIGH; with one enable input LOW, the other enable input is active LOW.

QUADRUPLE R/S LATCH WITH 3-STATE OUTPUTS

The HEF4043B is a quadruple R/S latch with 3-state outputs with a common output enable input (EO). Each latch has an active HIGH set input ( $S_0$  to  $S_3$ ), an active HIGH reset input ( $R_0$  to  $R_3$ ) and an active HIGH 3-state output ( $O_0$  to  $O_3$ ).

When EO is HIGH, the state of the latch output ( $O_n$ ) can be determined from the function table below. When EO is LOW, the latch outputs are in the high impedance OFF-state. EO does not affect the state of the latch.

The high impedance off-state feature allows common bussing of the outputs.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4043BP : 16-lead DIL; plastic (SOT-38Z).  
HEF4043BD : 16-lead DIL; ceramic (cerdip) (SOT-74).

**APPLICATION INFORMATION**

An example of application for the HEF4044B is:

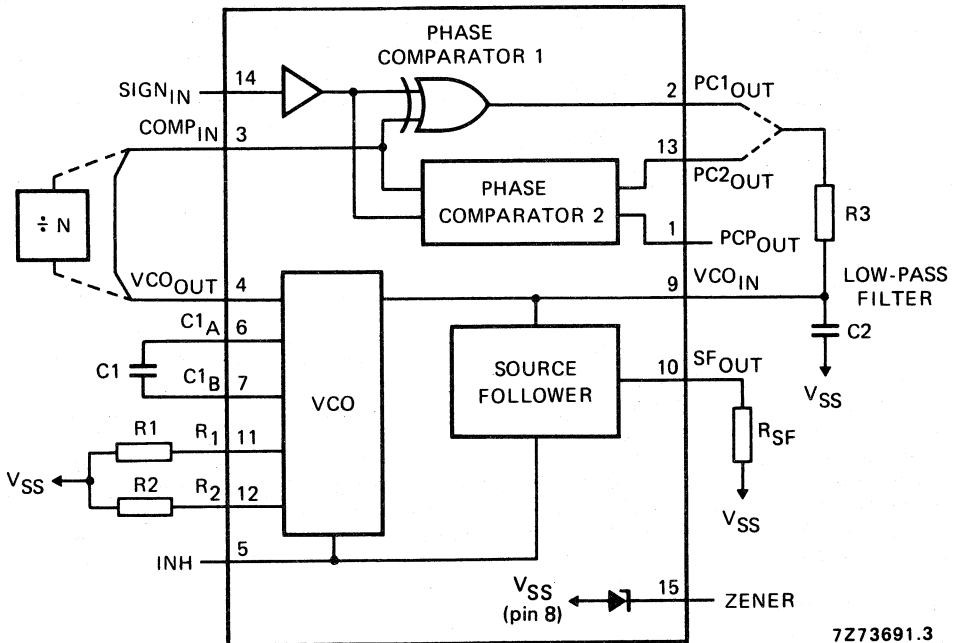

- Four-bit storage with output enable

## PHASE-LOCKED LOOP

The HEF4046B is a phase-locked loop circuit that consists of a linear voltage controlled oscillator (VCO) and two different phase comparators with a common signal input amplifier and a common comparator input. A 7 V regulator (zener) diode is provided for supply voltage regulation if necessary. For functional description see further on in this data.

## FUNCTIONAL DESCRIPTION

## VCO part

The VCO requires one external capacitor (C1) and one or two external resistors (R1 or R1 and R2). Resistor R1 and capacitor C1 determine the frequency range of the VCO. Resistor R2 enables the VCO to have a frequency off-set if required. The high input impedance of the VCO simplifies the design of low-pass filters; it permits the designer a wide choice of resistor/capacitor ranges. In order not to load the low-pass filter, a source-follower output of the VCO input voltage is provided at pin 10. If this pin (SF\_OUT) is used, a load resistor (R<sub>SF</sub>) should be connected from this pin to V<sub>SS</sub>; if unused, this pin should be left open. The VCO output (pin 4) can either be connected directly to the comparator input (pin 3) or via a frequency divider. A LOW level at the inhibit input (pin 5) enables the VCO and the source follower, while a HIGH level turns off both to minimize stand-by power consumption.

## Phase comparators

The phase-comparator signal input (pin 14) can be direct-coupled, provided the signal swing is between the standard HE4000B family input logic levels. The signal must be capacitively coupled to the self-biasing amplifier at the signal input in case of smaller swings. Phase comparator 1 is an EXCLUSIVE-OR network. The signal and comparator input frequencies must have a 50% duty factor to obtain the maximum lock range. The average output voltage of the phase comparator is equal to  $\frac{1}{2} V_{DD}$  when there is no signal or noise at the signal input. The average voltage to the VCO input is supplied by the low-pass filter connected to the output of phase comparator 1. This also causes the VCO to oscillate at the centre frequency ( $f_0$ ). The frequency capture range ( $2 f_c$ ) is defined as the frequency range of input signals on which the PLL will lock if it was initially out of lock. The frequency lock range ( $2 f_L$ ) is defined as the frequency range of input signals on which the loop will stay locked if it was initially in lock. The capture range is smaller or equal to the lock range.

With phase comparator 1, the range of frequencies over which the PLL can acquire lock (capture range) depends on the low-pass filter characteristics and this range can be made as large as the lock range. Phase comparator 1 enables the PLL system to remain in lock in spite of high amounts of noise in the input signal. A typical behaviour of this type of phase comparator is that it may lock onto input

frequencies that are close to harmonics of the VCO centre frequency. Another typical behaviour is, that the phase angle between the signal and comparator input varies between  $0^\circ$  and  $180^\circ$  and is  $90^\circ$  at the centre frequency. Figure 3 shows the typical phase-to-output response characteristic.

Figure 4 shows the typical waveforms for a PLL employing phase comparator 1 in locked condition of  $f_0$ .

Fig. 4 Typical waveforms for phase-locked loop employing phase comparator 1 in locked condition of  $f_0$ .

## FUNCTIONAL DESCRIPTION (continued)

Phase comparator 2 is an edge-controlled digital memory network. It consists of four flip-flops, control gating and a 3 state output circuit comprising p and n-type drivers having a common output node. When the p-type or n-type drivers are ON, they pull the output up to  $V_{DD}$  or down to  $V_{SS}$  respectively. This type of phase comparator only acts on the positive-going edges of the signals at  $SIGN_{IN}$  and  $COMP_{IN}$ . Therefore, the duty factors of these signals are not of importance.

If the signal input frequency is higher than the comparator input frequency, the p-type output driver is maintained ON most of the time, and both the n and p-type drivers are OFF (3-state) the remainder of the time. If the signal input frequency is lower than the comparator input frequency, the n-type output driver is maintained ON most of the time, and both the n and p-type drivers are OFF the remainder of the time. If the signal input and comparator input frequencies are equal, but the signal input lags the comparator input in phase, the n-type output driver is maintained ON for a time corresponding to the phase difference. If the comparator input lags the signal input in phase, the p-type output driver is maintained ON for a time corresponding to the phase difference. Subsequently, the voltage at the capacitor of the low-pass filter connected to this phase comparator is adjusted until the signal and comparator inputs are equal in both phase and frequency. At this stable point, both p and n-type drivers remain OFF and thus the phase comparator output becomes an open circuit and keeps the voltage at the capacitor of the low-pass filter constant.

Moreover, the signal at the phase comparator pulse output ( $PCP_{OUT}$ ) is a HIGH level which can be used for indicating a locked condition. Thus, for phase comparator 2 no phase difference exists between the signal and comparator inputs over the full VCO frequency range. Moreover, the power dissipation due to the low-pass filter is reduced when this type of phase comparator is used because both p and n-type output drivers are OFF for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range, independent of the low-pass filter. With no signal present at the signal input, the VCO is adjusted to its lowest frequency for phase comparator 2. Figure 5 shows typical waveforms for a PLL employing this type of phase comparator in locked condition.

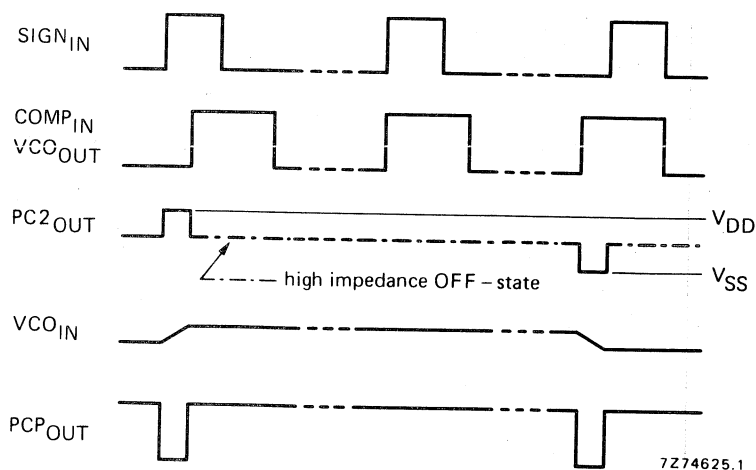

Fig. 5 Typical waveforms for phase-locked loop employing phase comparator 2 in locked condition.

Figure 6 shows the state diagram for phase comparator 2. Each circle represents a state of the comparator. The number at the top, inside each circle, represents the state of the comparator, while the logic state of the signal and comparator inputs are represented by a '0' for a logic LOW or a '1' for a logic HIGH, and they are shown in the left and right bottom of each circle.

The transitions from one to another result from either a logic change at the signal input (S) or the comparator input (C). A positive-going and a negative-going transition are shown by an arrow pointing up or down respectively.

The state diagram assumes, that only one transition on either the signal input or comparator input occurs at any instant. States 3, 5, 9 and 11 represent the condition at the output when the p-type driver is ON, while states 2, 4, 10 and 12 determine the condition when the n-type driver is ON. States 1, 6, 7 and 8 represent the condition when the output is in its high impedance OFF state; i.e. both p and n-type drivers are OFF, and the PCP<sub>OUT</sub> output is HIGH. The condition at output PCP<sub>OUT</sub> for all other states is LOW.

S ↑ : 0 to 1 transition at the signal input.  
 C ↓ : 1 to 0 transition at the comparator input.

Fig. 6 State diagram for comparator 2.

## MONOSTABLE/ASTABLE MULTIVIBRATOR

The HEF4047B consists of a gatable astable multivibrator with logic techniques incorporated to permit positive or negative edge-triggered monostable multivibrator action with retriggering and external counting options.

Inputs include + TRIGGER, - TRIGGER, ASTABLE, ASTABLE, RETRIGGER and MR (Master Reset). Buffered outputs are O,  $\bar{O}$  and OSCILLATOR OUTPUT. In all modes of operation an external capacitor ( $C_t$ ) must be connected between  $C_{TC}$  and  $RC_{TC}$ , and an external resistor ( $R_t$ ) must be connected between  $R_{TC}$  and  $RC_{TC}$  (continued on next page).

Fig. 1 Functional diagram.

FAMILY DATA

$I_{DD}$  LIMITS category MSI

see Family Specifications

# HEF4047B

MSI

Astable operation is enabled by a HIGH level on the ASTABLE input. The period of the square wave at O and  $\bar{O}$  outputs is a function of the external components employed. 'True' input pulses on the ASTABLE or 'complement' pulses on the ASTABLE input, allow the circuit to be used as a gated multivibrator. The OSCILLATOR OUTPUT period will be half of the O output in the astable mode. However, a 50% duty factor is not guaranteed at this output.

In the monostable mode, positive edge-triggering is accomplished by applying a leading-edge pulse to the + TRIGGER input and a LOW level to the - TRIGGER input. For negative edge-triggering, a trailing-edge pulse is applied to the - TRIGGER and a HIGH level to the + TRIGGER. Input pulses may be of any duration relative to the output pulse. The multivibrator can be retriggered (on the leading-edge only) by applying a common pulse to both the RETRIGGER and + TRIGGER inputs. In this mode the output pulse remains HIGH as long as the input pulse period is shorter than the period determined by the RC components.

An external count down option can be implemented by coupling O to an external 'N' counter and resetting the counter with the trigger pulse. The counter output pulse is fed back to the ASTABLE input and has a duration equal to N times the period of the multivibrator. A HIGH level on the MR input assures no output pulse during an ON-power condition. This input can also be activated to terminate the output pulse at any time. In the monostable mode, a HIGH level or power-ON reset pulse must be applied to MR, whenever  $V_{DD}$  is applied.

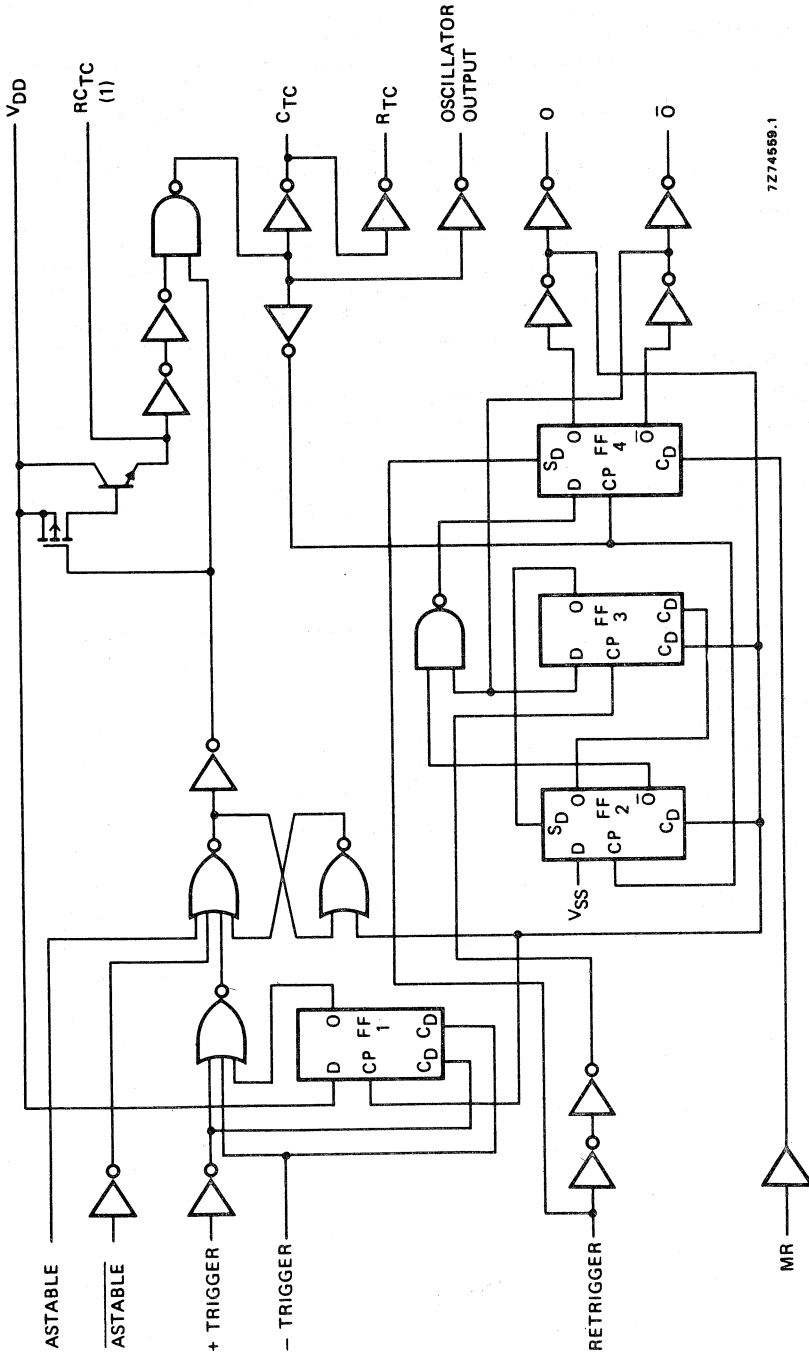

Fig. 2 Pinning diagram.

HEF4047BP : 14-lead DIL; plastic (SOT-27K, M, T).

HEF4047BD : 14-lead DIL; ceramic (cerdip) (SOT-73).

HEF4047BT : 14-lead mini-pack; plastic (SO-14; SOT-108A).

(1) Special input protection that allows operating input voltages outside the supply voltage lines. Compared to the standard input protection pin 3 is more sensitive to static discharge; extra handling precautions are recommended.

## APPLICATION INFORMATION

## General features:

- Monostable (one-shot) or astable (free-running) operation
- True and complemented buffered outputs
- Only one external R and C required

## Monostable multivibrator features:

- Positive- or negative-edge triggering
- Output pulse width independent of trigger pulse duration
- Retriggerable option for pulse-width expansion
- Long pulse width possible using small RC components by means of external counter provision
- Fast recovery time essentially independent of pulse width
- Pulse-width accuracy maintained at duty cycles approaching 100%

## Astable multivibrator features:

- Free-running or gatable operating modes
- 50% duty cycle
- Oscillator output available

1. Astable mode design information

a. Unit-to-unit transfer-voltage variations

The following analysis presents worst-case variations from unit-to-unit as a function of transfer-voltage ( $V_{TR}$ ) shift for free running (astable) operation.

Fig. 4 Astable mode waveforms.

$$t_1 = -R_t C_t \ln \frac{V_{TR}}{V_{DD} + V_{TR}}$$

$$t_2 = -R_t C_t \ln \frac{V_{DD} - V_{TR}}{2V_{DD} - V_{TR}}$$

$$t_A = 2(t_1 + t_2) = -2R_t C_t \ln \frac{(V_{TR})(V_{DD} - V_{TR})}{(V_{DD} + V_{TR})(2V_{DD} - V_{TR})}, \text{ where } t_A = \text{Astable mode pulse width.}$$

Values for  $t_A$  are:

	typ. : $V_{TR} = 0,5 V_{DD}$ ; $t_A = 4,40 R_t C_t$
$V_{DD} = 5 \text{ or } 10 \text{ V}$	{ min. : $V_{TR} = 0,3 V_{DD}$ ; $t_A = 4,71 R_t C_t$
	{ max. : $V_{TR} = 0,7 V_{DD}$ ; $t_A = 4,71 R_t C_t$
$V_{DD} = 15 \text{ V}$	{ min. : $V_{TR} = 4 \text{ V}$ ; $t_A = 4,84 R_t C_t$
	{ max. : $V_{TR} = 11 \text{ V}$ ; $t_A = 4,84 R_t C_t$

thus if  $t_A = 4,40 R_t C_t$  is used, the maximum variation will be (+7,0%; -0,0%) at 10 V.

## APPLICATION INFORMATION (continued)

*b. Variations due to changes in  $V_{DD}$* 

in addition to variations from unit-to-unit, the astable period may vary as a function of frequency with respect to  $V_{DD}$ .

Typical variations are presented graphically in Figs 5 and 6 with 10 V as a reference.

Fig. 5 Typical O and  $\bar{O}$  period accuracy as a function of supply voltage; astable mode;  $T_{amb} = 25\text{ }^{\circ}\text{C}$ .

curve	$f_o$ kHz	$C_t$ pF	$R_t$ k $\Omega$
A	10	100	220
B	5	100	470
C	1	1000	220

Fig. 6 Typical O and  $\bar{O}$  period accuracy as a function of supply voltage; astable mode;  $T_{amb} = 25\text{ }^{\circ}\text{C}$ .

curve	$f_o$ kHz	$C_t$ pF	$R_t$ k $\Omega$
A	500	10	47
B	225	100	10
C	100	100	22
D	50	100	47

## APPLICATION INFORMATION (continued)

## 2. Monostable mode design information

The following analysis presents worst case variations from unit-to-unit as a function of transfer-voltage ( $V_{TR}$ ) shift for one-shot (monostable) operation.

Fig. 7 Monostable waveforms.

$$t_1' = -R_t C_t \ln \frac{V_{TR}}{2V_{DD}}$$

$$t_M = (t_1' + t_2)$$

$$t_M = -R_t C_t \ln \frac{(V_{TR})(V_{DD} - V_{TR})}{(2V_{DD} - V_{TR})(2V_{DD})}, \text{ where } t_M = \text{Monostable mode pulse width.}$$

Values for  $t_M$  are:

	typ. : $V_{TR} = 0,5 V_{DD}$ ; $t_M = 2,48 R_t C_t$
$V_{DD} = 5 \text{ to } 10 \text{ V}$	min. : $V_{TR} = 0,3 V_{DD}$ ; $t_M = 2,78 R_t C_t$
	max. : $V_{TR} = 0,7 V_{DD}$ ; $t_M = 2,52 R_t C_t$
$V_{DD} = 15 \text{ V}$	min. : $V_{TR} = 4 \text{ V}$ ; $t_M = 2,88 R_t C_t$
	max. : $V_{TR} = 11 \text{ V}$ ; $t_M = 2,56 R_t C_t$

thus if  $t_M = 2,48 R_t C_t$  is used, the maximum variation will be (+ 12%; -0,0%) at 10 V.

## Note

In the astable mode, the first positive half cycle has a duration of  $t_M$ ; succeeding durations are  $\frac{1}{2} t_A$ .

3. Retrigger mode operation

The HEF4047B can be used in the retrigger mode to extend the output pulse duration, or to compare the frequency of an input signal with that of the internal oscillator. In the retrigger mode the input pulse is applied to pins 8 and 12, and the output is taken from pin 10 or 11. Normal monostable action is obtained when one retrigger pulse is applied (Fig. 8).

Extended pulse duration is obtained when more than one pulse is applied. For two input pulses,  $t_{RE} = t_1' + t_1 + 2t_2$ .

For more than two pulses,  $t_{RE}$  (output O), terminates at some variable time,  $t_D$ , after the termination of the last retrigger pulse;  $t_D$  is variable because  $t_{RE}$  (output O) terminates after the second positive edge of the oscillator output appears at flip-flop 4.

Fig. 8 Retrigger mode waveforms.

4. External counter option

Time  $t_M$  can be extended by any amount with the use of external counting circuitry. Advantages include digitally controlled pulse duration, small timing capacitors for long time periods, and extremely fast recovery time. A typical implementation is shown in Fig. 9.

The pulse duration at the output is:

$$t_{ext} = (N - 1)(t_A) + (t_M + \frac{1}{2} t_A)$$

Where  $t_{ext}$  = pulse duration of the circuitry, and N is the number of counts used.

Fig. 9 Implementation of external counter option.

**APPLICATION INFORMATION** (continued)**5. Timing component limitations**

The capacitor used in the circuit should be non-polarized and have low leakage (i.e. the parallel resistance of the capacitor should be an order of magnitude greater than the external resistor used). There is no upper or lower limit for either  $R_t$  or  $C_t$  value to maintain oscillation. However, in consideration of accuracy,  $C_t$  must be much larger than the inherent stray capacitance in the system (unless this capacitance can be measured and taken into account).  $R_t$  must be much larger than the LOC MOS 'ON' resistance in series with it, which typically is hundreds of ohms.

The recommended values for  $R_t$  and  $C_t$  to maintain agreement with previously calculated formulae without trimming should be:

$$C_t \geq 100 \text{ pF, up to any practical value,}$$

$$10 \text{ k}\Omega \leq R_t \leq 1 \text{ M}\Omega.$$

**6. Power consumption**

In the standby mode (monostable or astable), power dissipation will be a function of leakage current in the circuit.

For dynamic operation, the power needed to charge the external timing capacitor  $C_t$  is given by the following formulae:

Astable mode:  $P = 2 C_t V^2 f$  (f at output pin 13)

$$P = 4 C_t V^2 f \text{ (f at output pins 10 and 11)}$$

Monostable mode:  $P = \frac{(2,9 C_t V^2)(\text{duty cycle})}{T}$  (f at output pins 10 and 11)

Because the power dissipation does not depend on  $R_t$ , a design for minimum power dissipation would be a small value of  $C_t$ . The value of R would depend on the desired period (within the limitations discussed previously).

Typical power consumption in astable mode is shown in Figs 10, 11 and 12.

7284346

Fig. 10 Power consumption as a function of the output frequency at O or  $\bar{O}$ ;  $V_{DD} = 5V$ ; astable mode.

7284345

Fig. 11 Power consumption as a function of the output frequency at O or  $\bar{O}$ ;  $V_{DD} = 10V$ ; astable mode.

## APPLICATION INFORMATION (continued)

## HEX INVERTING BUFFERS

The HEF4049B provides six inverting buffers with high current output capability suitable for driving TTL or high capacitive loads. Since input voltages in excess of the buffers' supply voltage are permitted, the buffers may also be used to convert logic levels of up to 15 V to standard TTL levels. Their guaranteed fan-out into common bipolar logic elements is shown in the table on next page.

Fig. 1 Functional diagram.

Fig. 3 Logic diagram (one gate).

Fig. 2 Pinning diagram.

HEF4049BP : 16-lead DIL; plastic (SOT-38Z).  
HEF4049BD : 16-lead DIL; ceramic (cerdip) (SOT-74).  
HEF4049BT : 16-lead mini-pack; plastic (SO-16; SOT-109A).

### APPLICATION INFORMATION

Some examples of applications for the HEF4049B are:

- LOCMOS to DTL/TTL converter
- HIGH sink current for driving 2 TTL loads
- HIGH-to-LOW level logic conversion

# 8-CHANNEL ANALOGUE MULTIPLEXER/DEMULTIPLEXER

The HEF4051B is an 8-channel analogue multiplexer/demultiplexer with three address inputs ( $A_0$  to  $A_2$ ), an active LOW enable input ( $\bar{E}$ ), eight independent inputs/outputs ( $Y_0$  to  $Y_7$ ) and a common input/output ( $Z$ ).

The device contains eight bidirectional analogue switches, each with one side connected to an independent input/output ( $Y_0$  to  $Y_7$ ) and the other side connected to a common input/output ( $Z$ ).

With  $\bar{E}$  LOW, one of the eight switches is selected (low impedance ON-state) by  $A_0$  to  $A_2$ . With  $\bar{E}$  HIGH, all switches are in the high impedance OFF-state, independent of  $A_0$  to  $A_2$ .

$V_{DD}$  and  $V_{SS}$  are the supply voltage connections for the digital control inputs ( $A_0$  to  $A_2$ , and  $\bar{E}$ ). The  $V_{DD}$  to  $V_{SS}$  range is 3 to 15 V. The analogue inputs/outputs ( $Y_0$  to  $Y_7$ , and  $Z$ ) can swing between  $V_{DD}$  as a positive limit and  $V_{EE}$  as a negative limit.  $V_{DD}-V_{EE}$  may not exceed 15 V.

For operation as a digital multiplexer/demultiplexer,  $V_{EE}$  is connected to  $V_{SS}$  (typically ground).

Fig. 1 Functional diagram.

- L = LOW state (the less positive voltage)
- X = state is immaterial

## RATINGS

Limiting values in accordance with the Absolute Maximum System (IEC 134)

Supply voltage (with reference to V<sub>DD</sub>)

V<sub>EE</sub> -18 to +0,5 V

## NOTE

To avoid drawing V<sub>DD</sub> current out of terminal Z, when switch current flows into terminals Y, the voltage drop across the bidirectional switch must not exceed 0,4 V. If the switch current flows into terminal Z, no V<sub>DD</sub> current will flow out of terminals Y, in this case there is no limit for the voltage drop across the switch, but the voltages at Y and Z may not exceed V<sub>DD</sub> or V<sub>EE</sub>.

Fig. 4 Logic diagram.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4051B are:

- Analogue multiplexing and demultiplexing.
- Digital multiplexing and demultiplexing.
- Signal gating.

**NOTE**

If break before make is needed, then it is necessary to use the enable input.

# DUAL 4-CHANNEL ANALOGUE MULTIPLEXER/DEMULTIPLEXER

The HEF4052B is a dual 4-channel analogue multiplexer/demultiplexer with common channel select logic. Each multiplexer/demultiplexer has four independent inputs/outputs ( $Y_0$  to  $Y_3$ ) and a common input/output ( $Z$ ). The common channel select logic includes two address inputs ( $A_0$  and  $A_1$ ) and an active LOW enable input ( $\bar{E}$ ).

Both multiplexers/demultiplexers contain four bidirectional analogue switches, each with one side connected to an independent input/output ( $Y_0$  to  $Y_3$ ) and the other side connected to a common input/output ( $Z$ ).

With  $\bar{E}$  LOW, one of the four switches is selected (low impedance ON-state) by  $A_0$  and  $A_1$ . With  $\bar{E}$  HIGH, all switches are in the high impedance OFF-state, independent of  $A_0$  and  $A_1$ .

$V_{DD}$  and  $V_{SS}$  are the supply voltage connections for the digital control inputs ( $A_0$ ,  $A_1$  and  $\bar{E}$ ). The  $V_{DD}$  to  $V_{SS}$  range is 3 to 15 V. The analogue inputs/outputs ( $Y_0$  to  $Y_3$ , and  $Z$ ) can swing between  $V_{DD}$  as a positive limit and  $V_{EE}$  as a negative limit.  $V_{DD} - V_{EE}$  may not exceed 15 V.

For operation as a digital multiplexer/demultiplexer,  $V_{EE}$  is connected to  $V_{SS}$  (typically ground).

### APPLICATION INFORMATION

Some examples of applications for the HEF4052B are:

- Analogue multiplexing and demultiplexing.
- Digital multiplexing and demultiplexing.
- Signal gating.

### NOTE

If break before make is needed, then it is necessary to use the enable input.

## TRIPLE 2-CHANNEL ANALOGUE MULTIPLEXER/DEMULTIPLXER

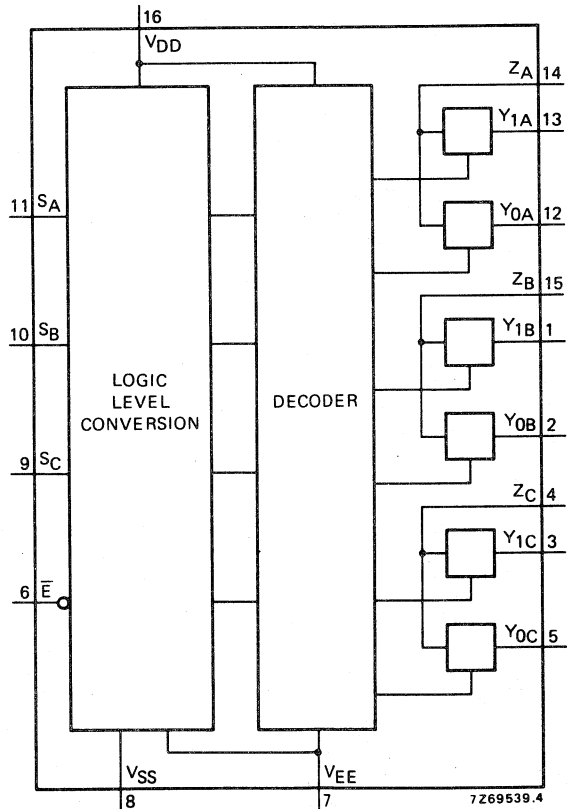

The HEF4053B is a triple 2-channel analogue multiplexer/demultiplexer with a common enable input ( $\bar{E}$ ). Each multiplexer/demultiplexer has two independent inputs/outputs ( $Y_0$  and  $Y_1$ ), a common input/output ( $Z$ ), and select inputs ( $S_n$ ). Each also contains two-bidirectional analogue switches, each with one side connected to an independent input/output ( $Y_0$  and  $Y_1$ ) and the other side connected to a common input/output ( $Z$ ).

With  $\bar{E}$  LOW, one of the two switches is selected (low impedance ON-state) by  $S_n$ . With  $\bar{E}$  HIGH, all switches are in the high impedance OFF-state, independent of  $S_A$  to  $S_C$ .

$V_{DD}$  and  $V_{SS}$  are the supply voltage connections for the digital control inputs ( $S_A$  to  $S_C$  and  $\bar{E}$ ). The  $V_{DD}$  to  $V_{SS}$  range is 3 to 15 V. The analogue inputs/outputs ( $Y_0$ ,  $Y_1$  and  $Z$ ) can swing between  $V_{DD}$  as a positive limit and  $V_{EE}$  as a negative limit.  $V_{DD}-V_{EE}$  may not exceed 15 V.

For operation as a digital multiplexer/demultiplexer,  $V_{EE}$  is connected to  $V_{SS}$  (typically ground).

## NOTES

 $V_{is}$  is the input voltage at a Y or Z terminal, whichever is assigned as input.

 $V_{os}$  is the output voltage at a Y or Z terminal, whichever is assigned as output.

 1.  $R_L = 10 \text{ k}\Omega$  to  $V_{EE}$ ;  $C_L = 50 \text{ pF}$  to  $V_{EE}$ ;  $\bar{E} = V_{SS}$ ;  $V_{is} = V_{DD}$  (square-wave); see Fig. 8.

 2.  $R_L = 10 \text{ k}\Omega$ ;  $C_L = 50 \text{ pF}$  to  $V_{EE}$ ;  $\bar{E} = V_{SS}$ ;  $S_n = V_{DD}$  (square-wave);  $V_{is} = V_{DD}$  and  $R_L$  to  $V_{EE}$  for  $t_{PLH}$ ;  $V_{is} = V_{EE}$  and  $R_L$  to  $V_{DD}$  for  $t_{PHL}$ ; see Fig. 8.

 3.  $R_L = 10 \text{ k}\Omega$ ;  $C_L = 50 \text{ pF}$  to  $V_{EE}$ ;  $\bar{E} = V_{DD}$  (square-wave);

 $V_{is} = V_{DD}$  and  $R_L$  to  $V_{EE}$  for  $t_{PHZ}$  and  $t_{PZH}$ ;

 $V_{is} = V_{EE}$  and  $R_L$  to  $V_{DD}$  for  $t_{PLZ}$  and  $t_{PZL}$ ; see Fig. 8.

 4.  $R_L = 10 \text{ k}\Omega$ ;  $C_L = 15 \text{ pF}$ ; channel ON;  $V_{is} = \frac{1}{2} V_{DD(p-p)}$  (sine-wave, symmetrical about  $\frac{1}{2} V_{DD}$ );  $f_{is} = 1 \text{ kHz}$ ; see Fig. 9.

 5.  $R_L = 1 \text{ k}\Omega$ ;  $V_{is} = \frac{1}{2} V_{DD(p-p)}$  (sine-wave, symmetrical about  $\frac{1}{2} V_{DD}$ );

 $20 \log \frac{V_{os}}{V_{is}} = -50 \text{ dB}$ ; see Fig. 10.

 6.  $R_L = 10 \text{ k}\Omega$  to  $V_{EE}$ ;  $C_L = 15 \text{ pF}$  to  $V_{EE}$ ;  $\bar{E}$  or  $S_n = V_{DD}$  (square-wave); crosstalk is  $|V_{os}|$  (peak value); see Fig. 8.

 7.  $R_L = 1 \text{ k}\Omega$ ;  $C_L = 5 \text{ pF}$ ; channel OFF;  $V_{is} = \frac{1}{2} V_{DD(p-p)}$  (sine-wave, symmetrical about  $\frac{1}{2} V_{DD}$ );

 $20 \log \frac{V_{os}}{V_{is}} = -50 \text{ dB}$ ; see Fig. 9.

 8.  $R_L = 1 \text{ k}\Omega$ ;  $C_L = 5 \text{ pF}$ ; channel ON;  $V_{is} = \frac{1}{2} V_{DD(p-p)}$  (sine-wave, symmetrical about  $\frac{1}{2} V_{DD}$ );

 $20 \log \frac{V_{os}}{V_{is}} = -3 \text{ dB}$ ; see Fig. 9.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4053B are:

- Analogue multiplexing and demultiplexing.
- Digital multiplexing and demultiplexing.
- Signal gating.

**NOTE**

If break before make is needed, then it is necessary to use the enable input.

PROGRAMMABLE DIVIDE-BY-N COUNTER

The HEF4059B is a divide-by-n counter which can be programmed to divide an input frequency by any number *n* from 3 to 15 999. The output signal is a one clock-cycle wide pulse and occurs at a rate equal to the input frequency divided by *n*. The single output (O) has TTL drive capability. The down counter is preset by means of 16 jam inputs (J1 to J16); continued on next page.

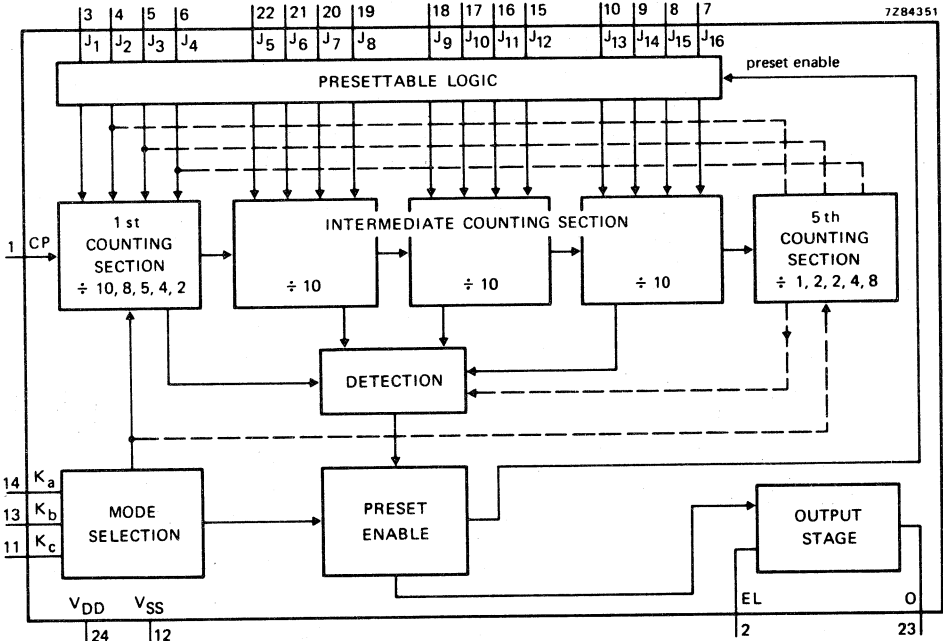

Fig. 1 Functional block diagram.

PINNING

- CP clock input
- K<sub>a</sub>, K<sub>b</sub>, K<sub>c</sub> mode select inputs
- J<sub>1</sub> to J<sub>16</sub> programmable jam inputs (BCD)
- EL latch enable input
- O divide-by-n output

Fig. 2 Pinning diagram.

- HEF4059BD: 24-lead DIL; ceramic (cerdip) (SOT-94).
- HEF4059BT: 24-lead mini-pack; plastic (SO-24; SOT-137A).

FAMILY DATA

see Family Specifications

I<sub>DD</sub> LIMITS category MSI

The three mode selection inputs  $K_A$ ,  $K_B$  and  $K_C$  determine the modulus ('divide-by' number) of the first and last counting sections in accordance with Table 1.

Every time the first (fastest) counting section goes through one cycle, it reduces, by 1, the number that has been preset (jammed) into the three decades of the intermediate counting section and into the last counting section (which consists of flip-flops that are not needed for operating the first counting section).

For example, in the  $\div 2$  mode, only one flip-flop is needed in the first counting section. Therefore the last (5th) counting section has three flip-flops that can be preset to a maximum count of seven with a place value of thousands.

This counting mode is selected when  $K_A$ ,  $K_B$  and  $K_C$  are set to HIGH. In this case input  $J_1$  is used to preset the first counting section and  $J_2$  to  $J_4$  are used to preset the last (5th) counting section.

If  $\div 10$  mode is desired for the first section,  $K_A$  is set HIGH,  $K_B$  to HIGH and  $K_C$  to LOW. The jam inputs  $J_1$  to  $J_4$  are used to preset the first counting section and there is no last counting section. The intermediate counting section consists of three cascaded BCD decade ( $\div 10$ ) counters, presettable by means of the jam inputs  $J_5$  to  $J_{16}$ .

When clock pulses are applied to the clock input after a number  $n$  has been preset into the counter, the counter counts down until the DETECTION circuit detects the zero state. At this time the PRESET ENABLE circuit is enabled to preset again the number  $n$  into the counter and to produce an output pulse.

The preset of the counter to a desired  $\div n$  is achieved as follows:

$$n = (\text{MODE}^*) (1000 \times \text{decade 5 preset} + 100 \times \text{decade 4 preset} + 10 \times \text{decade 3 preset} + 1 \times \text{decade 2 preset}) + \text{decade 1 preset.}$$

\* MODE = first counting section divider (10, 8, 5, 4 or 2).

To calculate preset values for any  $n$  count, divide the  $n$  count by the selected mode. The resultant is the corresponding preset values of the 5th to the 2nd decade with the remainder being equal to the 1st decade value.

$$\text{preset value} = \frac{n}{\text{mode}}$$

If  $n = 8479$ , and the selected mode = 5, the preset value =  $8479 \div 5 = 1695$  with a remainder of 4, thus the jam inputs must be set as follows:

4	1	5						9				6			
J <sub>1</sub>	J <sub>2</sub>	J <sub>3</sub>	J <sub>4</sub>	J <sub>5</sub>	J <sub>6</sub>	J <sub>7</sub>	J <sub>8</sub>	J <sub>9</sub>	J <sub>10</sub>	J <sub>11</sub>	J <sub>12</sub>	J <sub>13</sub>	J <sub>14</sub>	J <sub>15</sub>	J <sub>16</sub>
L	L	H	H	L	H	L	H	L	L	L	H	L	H	H	L

The mode select inputs permit frequency-synthesizer channel separations of 10, 12, 5, 20, 25 and 50 parts. These inputs set the maximum value of  $n$  at 9999 (when the first counting section divides by 5 or 10) or at 15 999 (when the first counting section divides by 8, 4 or 2).

The three decades of the intermediate counting section can be preset to a binary 15 instead of a binary 9. In this case the first cycle of a counter consists of 15 count pulses, the next cycles consisting of 10 count pulses. Thus the place value of the three decades are still 1, 10 and 100. For example, in the  $\div 8$  mode, the number from which the intermediate counting section begins to count-down can be preset to:

```

3rd decade: 1500
2nd decade:  150
1st decade:   15
-----
              1665

```

The last counting section can be preset to a maximum of 1, with a place value of 1000. The total of these numbers (2665) times 8 equals 21 320. The first counting section can be preset to a maximum of 7. Therefore, 21 327 is the maximum possible count in the  $\div 8$  mode. The highest count of the various modes is shown in Table 1, in the column entitled 'extended counter range'. Control inputs  $K_B$  and  $K_C$  can be used to initiate and lock the counter in the 'master preset' mode. In this condition the flip-flops in the counter are preset in accordance with the jam inputs and the counter remains in that mode as long as  $K_B$  and  $K_C$  both remain LOW. The counter begins to run down from the preset state when a counting mode other than the 'master preset' mode is selected. Whenever the 'master preset' mode is used, control signals  $K_B = L$  and  $K_C = L$  must be applied for at least 3 full clock pulses. After the master preset mode inputs have been changed to one of the counting modes, the next positive-going clock transition changes an internal flip-flop so that the count-down can begin at the second positive-going clock transition. Thus, after a 'master preset' mode, there is always one extra count before the output goes HIGH. Figure 3 illustrates the operation of the counter in mode  $\div 8$  starting from the preset state 3.

7284352

Fig. 3 Total count of 3.

If the 'master preset' mode is started two clock cycles or less before an output pulse, the output pulse will appear at the time due. If the 'master preset' mode is not used the counter is preset in accordance with the 'jam inputs when the output pulse appears. A HIGH level at the latch enable input (EL) will cause the counter output to remain in the HIGH state until EL input returns to LOW. If the EL input is LOW, the output pulse will remain HIGH for only one cycle of the clock input signal. When  $K_a = L$ ,  $K_b = H$ ,  $K_c = L$  and  $EL = L$ , the counter operates in the 'preset inhibit' mode, with which the dividend of the counter is fixed to 10 000, independent of the state of the jam inputs. When in the same state of mode select inputs  $EL = H$ , the counter operates in the normal  $\div 10$  mode, however, without the latch operation at the output. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## 14-STAGE RIPPLE-CARRY BINARY COUNTER/DIVIDER AND OSCILLATOR

The HEF4060B is a 14-stage ripple-carry binary counter/divider and oscillator with three oscillator terminals (RS,  $R_{TC}$  and  $C_{TC}$ ), ten buffered outputs ( $O_3$  to  $O_9$  and  $O_{11}$  to  $O_{13}$ ) and an overriding asynchronous master reset input (MR). The oscillator configuration allows design of either RC or crystal oscillator circuits. The oscillator may be replaced by an external clock signal at input RS. The counter advances on the negative-going transition of RS. A HIGH level on MR resets the counter ( $O_3$  to  $O_9$  and  $O_{11}$  to  $O_{13}$  = LOW), independent of other input conditions.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

Fig. 1 Functional diagram.

$V_{DD}$  = supply voltage (V)

$C_t$  = timing capacitance (pF)

$f_{osc}$  = oscillator frequency (MHz)

RC oscillator

Typical formula for oscillator frequency:

$$f_{osc} = \frac{1}{2,3 \times R_t \times C_t}$$

Fig. 4 External component connection for RC oscillator.

Timing component limitations

The oscillator frequency is mainly determined by  $R_t C_t$ , provided  $R_t \ll R_2$  and  $R_2 C_2 \ll R_t C_t$ . The function of  $R_2$  is to minimize the influence of the forward voltage across the input protection diodes on the frequency. The stray capacitance  $C_2$  should be kept as small as possible. In consideration of accuracy,  $C_t$  must be larger than the inherent stray capacitance.  $R_t$  must be larger than the LOCMOS 'ON' resistance in series with it, which typically is 500  $\Omega$  at  $V_{DD} = 5$  V, 300  $\Omega$  at  $V_{DD} = 10$  V and 200  $\Omega$  at  $V_{DD} = 15$  V.

The recommended values for these components to maintain agreement with the typical oscillation formula are:

- $C_t \geq 100$  pF, up to any practical value,
- $10$  k $\Omega \leq R_t \leq 1$  M $\Omega$ .

Typical crystal oscillator circuit

In Fig. 5,  $R_2$  is the power limiting resistor. For starting and maintaining oscillation a minimum transconductance is necessary.

## QUADRUPLE BILATERAL SWITCHES

The HEF4066B has four independent bilateral analogue switches (transmission gates). Each switch has two input/output terminals (Y/Z) and an active HIGH enable input (E). When E is connected to  $V_{DD}$  a low impedance bidirectional path between Y and Z is established (ON condition). When E is connected to  $V_{SS}$  the switch is disabled and a high impedance between Y and Z is established (OFF condition).

The HEF4066B is pin compatible with the HEF4016B but exhibits a much lower ON resistance. In addition the ON resistance is relatively constant over the full input signal range.

7269571.2

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

### PINNING

$E_0$  to  $E_3$  enable inputs

$Y_0$  to  $Y_3$  input/output terminals

$Z_0$  to  $Z_3$  input/output terminals

HEF4066BP : 14-lead DIL; plastic (SOT-27K, M, T).  
HEF4066BD : 14-lead DIL; ceramic (cerdip) (SOT-73).  
HEF4066BT : 14-lead mini-pack; plastic (SO-14; SOT-108A).

### APPLICATION INFORMATION

An example of application for the HEF4066B is:

- Analogue and digital switching

## 16-CHANNEL ANALOGUE MULTIPLEXER/DEMULTIPLEXER

The HEF4067B is a 16-channel analogue multiplexer/demultiplexer with four address inputs ( $A_0$  to  $A_3$ ), an active LOW enable input ( $\bar{E}$ ), sixteen independent inputs/outputs ( $Y_0$  to  $Y_{15}$ ) and a common input/output ( $Z$ ).

The device contains sixteen bidirectional analogue switches, each with one side connected to an independent input/output ( $Y_0$  to  $Y_{15}$ ) and the other side connected to the common input/output ( $Z$ ).

With  $\bar{E}$  LOW, one of the sixteen switches is selected (low impedance ON-state) by  $A_0$  to  $A_3$ . All unselected switches are in the high impedance OFF-state. With  $\bar{E}$  HIGH all switches are in the high impedance OFF-state, independent of  $A_0$  to  $A_3$ .

The analogue inputs/outputs ( $Y_0$  to  $Y_{15}$  and  $Z$ ) can swing between  $V_{DD}$  as a positive limit and  $V_{SS}$  as a negative limit.  $V_{DD}$  to  $V_{SS}$  may not exceed 15 V.

### APPLICATION INFORMATION

Some examples of applications for the HEF4067B are:

- Analogue multiplexing and demultiplexing.
- Digital multiplexing and demultiplexing.
- Signal gating.

### NOTE

If break before make is needed, then it is necessary to use the enable input.

# 8-INPUT NAND GATE

The HEF4068B provides the 8-input NAND function. The outputs are fully buffered for highest noise immunity and pattern insensitivity of output impedance.

## APPLICATION INFORMATION

Some examples of applications for the HEF4069UB are shown below.

In Fig. 7 an astable relaxation oscillator is given. The oscillation frequency is mainly determined by  $R1C1$ , provided  $R1 \ll R2$  and  $R2C2 \ll R1C1$ .

(a)

(b)

Fig. 7(a) Astable relaxation oscillator using two HEF4069UB inverters; the diodes may be BAW62;  $C2$  is a parasitic capacitance. (b) Waveforms at the points marked A, B, C and D in the circuit diagram.

The function of  $R2$  is to minimize the influence of the forward voltage across the protection diodes on the frequency;  $C2$  is a stray (parasitic) capacitance. The period  $T_p$  is given by  $T_p = T_1 + T_2$ , in which

$$T_1 = R1C1 \ln \frac{V_{DD} + V_{ST}}{V_{ST}} \quad \text{and} \quad T_2 = R1C1 \ln \frac{2V_{DD} - V_{ST}}{V_{DD} - V_{ST}} \quad \text{where}$$

$V_{ST}$  is the signal threshold level of the inverter. The period is fairly independent of  $V_{DD}$ ,  $V_{ST}$  and temperature. The duty factor, however, is influenced by  $V_{ST}$ .

7284369

(1) This inverter is added to amplify the oscillator output voltage to a level sufficient to drive other LOC MOS circuits.

## QUADRUPLE D-TYPE REGISTER WITH 3-STATE OUTPUTS

The HEF4076B is a quadruple edge-triggered D-type flip-flop with four data inputs ( $D_0$  to  $D_3$ ), two active LOW data enable inputs ( $\overline{ED}_0$  and  $\overline{ED}_1$ ), a common clock input (CP), four 3-state outputs ( $O_0$  to  $O_3$ ), two active LOW output enable inputs ( $\overline{EO}_0$  and  $\overline{EO}_1$ ), and an overriding asynchronous master reset input (MR).

Information on  $D_0$  to  $D_3$  is stored in the four flip-flops on the LOW to HIGH transition of CP if both  $\overline{ED}_0$  and  $\overline{ED}_1$  are LOW. A HIGH on either  $\overline{ED}_0$  or  $\overline{ED}_1$  prevents the flip-flops from changing on the LOW to HIGH transition of CP, independent of the information on  $D_0$  to  $D_3$ . When both  $\overline{EO}_0$  and  $\overline{EO}_1$  are LOW, the contents of the four flip-flops are available at  $O_0$  to  $O_3$ . A HIGH on either  $\overline{EO}_0$  or  $\overline{EO}_1$  forces  $O_0$  to  $O_3$  into the high impedance OFF-state. A HIGH on MR resets all four flip-flops, independent of all other input conditions.

$I_{DD}$  LIMITS category MSI

Fig. 3 Logic diagram.

FUNCTION TABLE

inputs					outputs
MR	CP	$\overline{E}D_0$	$\overline{E}D_1$	$D_n$	$O_n$
H	X	X	X	X	L
L	/	H	X	X	no change
L	/	X	H	X	no change
L	/	L	L	H	H
L	/	L	L	L	L
L	\	X	X	X	no change

$\overline{E}O_0 = \overline{E}O_1 = \text{LOW}$

When either  $\overline{E}O_0$  or  $\overline{E}O_1$  is HIGH, the outputs are disabled (high impedance OFF-state).

H = HIGH state (the more positive voltage)

L = LOW state (the less positive voltage)

X = state is immaterial

/ = positive-going transition

\ = negative-going transition

A.C. CHARACTERISTICS

## 4-WIDE 2-INPUT AND-OR-INVERT GATE

The HEF4086B is a 4-wide 2-input AND-OR-invert (AOI) gate with two additional inputs ( $I_8$  and  $\bar{I}_9$ ) which can be used as either expander or inhibit inputs by connecting them to any standard LOCMOS output. A HIGH on  $I_8$  or a LOW on  $\bar{I}_9$  forces the output (O) LOW independent of the other eight inputs ( $I_0$  to  $I_7$ ). The output (O) is fully buffered for highest noise immunity and pattern insensitivity of output impedance.

Fig. 1 Functional diagram.

**APPLICATION INFORMATION**

Figure 4 shows two HEF4086B ICs connected to obtain an 8-wide 2-input AOI function. The output ( $O_A$ ) of the first IC is fed directly into the  $\bar{I}_{9B}$  gate input of the second IC. Similarly, any NAND gate output can be fed directly into the  $\bar{I}_9$  gate input to obtain a 5-wide AOI function. In addition, any AND gate output can be fed directly into the  $I_9$  gate input with the same result.

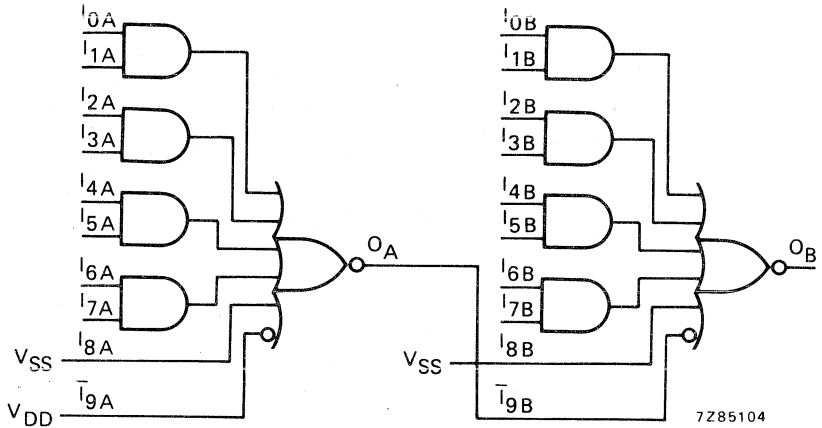

Fig. 4 Two HEF4086B ICs connected as an 8-wide 2-input AOI gate.

Logic equation for Fig. 4:

$$O_B = I_{0A} \cdot I_{1A} + I_{2A} \cdot I_{3A} + I_{4A} \cdot I_{5A} + I_{6A} \cdot I_{7A} + I_{0B} \cdot I_{1B} + I_{2B} \cdot I_{3B} + I_{4B} \cdot I_{5B} + I_{6B} \cdot I_{7B}$$

## QUADRUPLE 2-INPUT NAND SCHMITT TRIGGER

The HEF4093B consists of four Schmitt-trigger circuits. Each circuit functions as a two-input NAND gate with Schmitt-trigger action on both inputs. The gate switches at different points for positive and negative-going signals. The difference between the positive voltage ( $V_P$ ) and the negative voltage ( $V_N$ ) is defined as hysteresis voltage ( $V_H$ ).

APPLICATION INFORMATION

Some examples of applications for the HEF4093B are:

- Wave and pulse shapers
- Astable multivibrators
- Monostable multivibrators.

Fig. 10 The HEF4093B used as a astable multivibrator.

Fig. 11 Schmitt trigger driven via a high impedance ( $R > 1 \text{ k}\Omega$ ).

If a Schmitt trigger is driven via a high impedance ( $R > 1 \text{ k}\Omega$ ) then it is necessary to incorporate a capacitor C of such value that:  $\frac{C}{C_p} > \frac{V_{DD}-V_{SS}}{V_H}$ , otherwise oscillation can occur on the edges of a pulse.

$C_p$  is the external parasitic capacitance between inputs and output; the value depends on the circuit board layout.

Note

The two inputs may be connected together, but this will result in a larger through-current at the moment of switching.

## 8-STAGE SHIFT-AND-STORE BUS REGISTER

The HEF4094B is an 8-stage serial shift register having a storage latch associated with each stage for strobing data from the serial input to parallel buffered 3-state outputs  $O_0$  to  $O_7$ . The parallel outputs may be connected directly to common bus lines. Data is shifted on positive-going clock transitions. The data in each shift register stage is transferred to the storage register when the strobe (STR) input is HIGH. Data in the storage register appears at the outputs whenever the output enable (EO) signal is HIGH.

Two serial outputs ( $O_s$  and  $O_s'$ ) are available for cascading a number of HEF4094B devices. Data is available at  $O_s$  on positive-going clock edges to allow high-speed operation in cascaded systems in which the clock rise time is fast. The same serial information is available at  $O_s'$  on the next negative-going clock edge and provides cascading HEF4094B devices when the clock rise time is slow.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4094B are:

- Serial-to-parallel data conversion
- Remote control holding register

Fig. 5 Remote control holding register.

## QUADRUPLE LOW TO HIGH VOLTAGE TRANSLATOR WITH 3-STATE OUTPUTS

The HEF4104B quadruple low voltage to high voltage translator with 3-state outputs provides the capability of interfacing low voltage circuits to high voltage circuits, such as low voltage LOCMOS and TTL to high voltage LOCMOS. It has four data inputs ( $I_0$  to  $I_3$ ), an active HIGH output enable input (EO), four data outputs ( $O_0$  to  $O_3$ ) and their complements ( $\bar{O}_0$  to  $\bar{O}_3$ ).

With EO HIGH,  $O_0$  to  $O_3$  and  $\bar{O}_0$  to  $\bar{O}_3$  are in the low impedance ON-state, either HIGH or LOW as determined by  $I_0$  to  $I_3$ ; with EO LOW,  $O_0$  to  $O_3$  and  $\bar{O}_0$  to  $\bar{O}_3$  are in the high impedance OFF-state.

The device uses a common negative supply ( $V_{SS}$ ) and separate positive supplies for inputs ( $V_{DD1}$ ) and outputs ( $V_{DD0}$ ).  $V_{DD1}$  must always be less than or equal to  $V_{DD0}$ , even during power turn-on and turn-off. For the permissible operating range of  $V_{DD1}$  and  $V_{DD0}$  see graph Fig. 4.

Each input protection circuit is terminated between  $V_{DD0}$  and  $V_{SS}$ . This allows the input signals to be driven from any potential between  $V_{DD0}$  and  $V_{SS}$ , without regard to current limiting. When driving from potentials greater than  $V_{DD0}$  or less than  $V_{SS}$ , the current at each input must be limited to 10 mA.

## STROBED HEX INVERTER/BUFFER

The HEF4502B consists of six inverter/buffers with 3-state outputs. When the output enable input ( $\overline{EO}$ ) is HIGH all six outputs ( $O_1$  to  $O_6$ ) are in the high impedance OFF-state. When the enable input ( $\overline{E}$ ) is HIGH all six outputs are switched to LOW. The outputs have a 2-TTL load drive capability.

## 64-BIT, 1-BIT PER WORD RANDOM ACCESS READ/WRITE MEMORY

The HEF4505B is a 64-bit, 1-bit per word, fully decoded and completely static, random access memory. The memory is strobed for reading or writing only when the strobe input (ST), chip enable inputs (CE<sub>1</sub> and CE<sub>2</sub>) are HIGH simultaneously. The output data is available at the data output (D<sub>OUT</sub>) only when the memory is strobed, the read/write input (R/W) is HIGH and after the read access time has passed. Note that the three-state output is initially disabled and always goes to the LOW state before data is valid. The output is disabled in the high-impedance OFF-state, when the memory is not strobed or R/W is LOW. R/W may remain HIGH during a read cycle or LOW during a write cycle. The output data has the same polarity as the input data.

APPLICATION INFORMATION

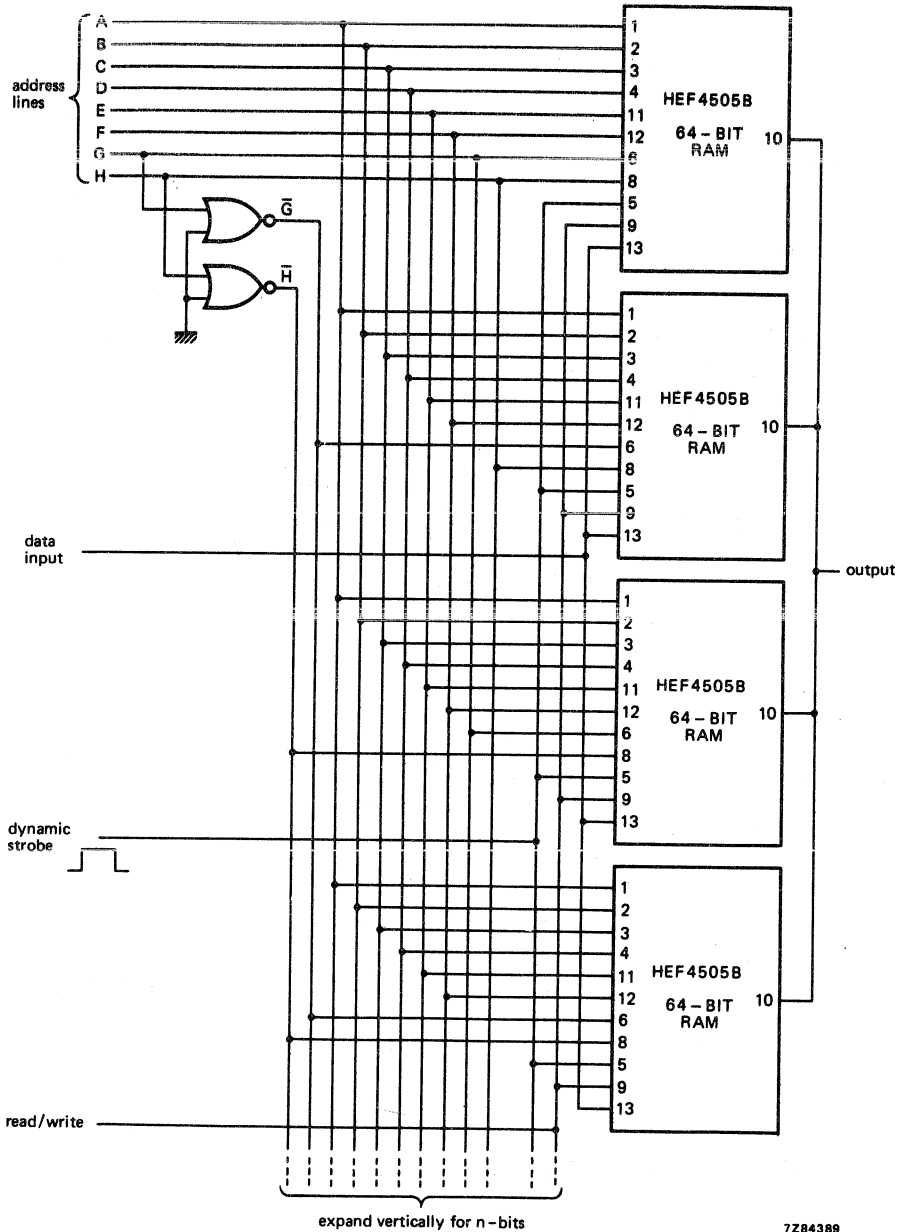

Fig. 5 256-word by n-bit static read/write memory using HEF4505B ICs.

Figure 5 shows a 256-word by n-bit static RAM system. The outputs of the four HEF4505B circuits are tied together to form 256 words by 1-bit. Additional bits are attained by paralleling the inputs in groups of four. Memories of larger words can be attained by decoding the most significant bits of the address and AND-ing them with the strobe input.

Fan-in and fan-out of the memory are limited only by speed requirements. The extremely low input and output leakage currents keep the output voltage levels from changing significantly as more outputs are tied together. With the output levels independent of fan-out, most of the power supply range is available as logic swing, regardless of the number of units wired together. As a result, high noise immunity is maintained under all conditions.

The memory system shown in Fig. 5 can be interfaced directly with other ICs of the LOCMOS HE family. No external components are required.

Non-volatile information storage is allowed due to very low power dissipation when the memory is powered by a small standby battery. Figure 6 shows an optional standby power supply circuit for making a LOCMOS memory 'non-volatile'. When the usual power fails, a battery is used to sustain operation or maintain stored information. While normal power supply voltage is present, the battery is trickle-charged through a resistor (R) which sets the charging rate. In Fig. 6 the sustaining voltage is  $V_B$ , and +V is the ordinary voltage from a power supply.  $V_{DD}$  is connected to the power supply pin of the memory. Low-leakage diodes are recommended to conserve battery power.

Fig. 5 Standby battery circuit.

## DUAL 4-BIT LATCH

The HEF4508B is a dual 4-bit latch, which consists of two identical independent 4-bit latches with separate strobe (ST), master reset (MR), output-enable input ( $\overline{EO}$ ) and 3-state outputs (O).

With the ST input in the HIGH state, the data on the D inputs appear at the corresponding outputs provided  $\overline{EO}$  is LOW. Changing the ST input to the LOW state locks the data into the latch. A HIGH on the reset line forces the outputs to a LOW level regardless of the state of the ST input. The 3-state outputs are controlled by the output-enable input. A HIGH on  $\overline{EO}$  causes the outputs to assume a high impedance OFF-state regardless of other input conditions. This allows the outputs to interface directly with bus orientated systems. When  $\overline{EO}$  is LOW the contents of the latches are available at the outputs.

## BCD UP/DOWN COUNTER

The HEF4510B is an edge-triggered synchronous up/down BCD counter with a clock input (CP), an up/down count control input (UP/DN), an active LOW count enable input ( $\overline{CE}$ ), an asynchronous active HIGH parallel load input (PL), four parallel inputs ( $P_0$  to  $P_3$ ), four parallel outputs ( $O_0$  to  $O_3$ ), an active LOW terminal count output ( $\overline{TC}$ ), and an overriding asynchronous master reset input (MR).

Information on  $P_0$  to  $P_3$  is loaded into the counter while PL is HIGH, independent of all other input conditions except the MR input, which must be LOW. With PL LOW, the counter changes on the LOW to HIGH transition of CP if  $\overline{CE}$  is LOW. UP/DN determines the direction of the count, HIGH for counting up, LOW for counting down. When counting up,  $\overline{TC}$  is LOW when  $O_0$  and  $O_3$  are HIGH and  $\overline{CE}$  is LOW. When counting down,  $\overline{TC}$  is LOW when  $O_0$  to  $O_3$  and  $\overline{CE}$  are LOW. A HIGH on MR resets the counter ( $O_0$  to  $O_3$  = LOW) independent of all other input conditions.

Fig. 1 Functional diagram.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4510B are:

- Up/down difference counting
- Synchronous frequency dividers

Fig. 8 Example of parallel clocking when cascading HEF4510B ICs.

Fig. 9 Example of ripple clocking when cascading HEF4510B ICs. Ripple clocking mode: the up/down control can be changed at any count; the only restriction on changing the up/down control is that the clock input to the first counting stage must be HIGH.

## BCD TO 7-SEGMENT LATCH/DECODER/DRIVER

The HEF4511B is a BCD to 7-segment latch/decoder/driver with four address inputs ( $D_A$  to  $D_D$ ), an active LOW latch enable input ( $\overline{EL}$ ), an active LOW ripple blanking input ( $\overline{BI}$ ), an active LOW lamp test input ( $\overline{LT}$ ), and seven active HIGH n-p-n bipolar transistor segment outputs ( $O_a$  to  $O_g$ ).

When  $\overline{EL}$  is LOW, the state of the segment outputs ( $O_a$  to  $O_g$ ) is determined by the data on  $D_A$  to  $D_D$ . When  $\overline{EL}$  goes HIGH, the last data present on  $D_A$  to  $D_D$  are stored in the latches and the segment outputs remain stable. When  $\overline{LT}$  is LOW, all the segment outputs are HIGH independent of all other input conditions. With  $\overline{LT}$  HIGH, a LOW on  $\overline{BI}$  forces all segment outputs LOW. The inputs  $\overline{LT}$  and  $\overline{BI}$  do not affect the latch circuit.

Fig. 1 Functional diagram.

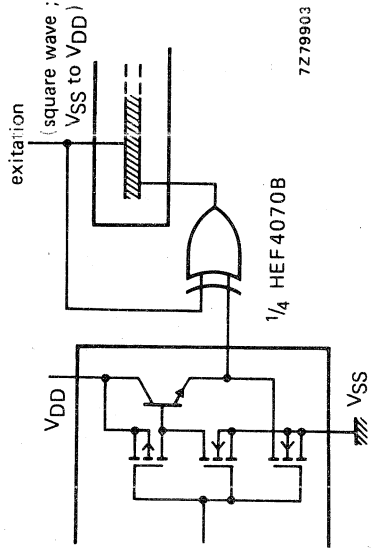

Fig. 14 Connection to liquid crystal (LCD) display readout. Direct d.c. drive of LCDs not recommended for life of LCD readouts.

## 8-INPUT MULTIPLEXER WITH 3-STATE OUTPUT

The HEF4512B is an 8-input multiplexer with 8 binary inputs ( $I_0$  to  $I_7$ ), an enable input ( $\bar{E}$ ) and an output enable input ( $\bar{EO}$ ). One of eight binary inputs is selected by select inputs  $S_0$ ,  $S_1$  and  $S_2$ , and is routed to the output  $O$ . A HIGH on  $\bar{EO}$  causes  $O$  to assume a high impedance OFF-state, regardless of other input conditions. This allows the output to interface directly with bus oriented systems (3-state). When the active LOW enable ( $\bar{E}$ ) is HIGH, it forces the output LOW provided  $\bar{EO}$  is LOW. By proper manipulation of the inputs, the device can provide any logic functions of four variables. It cannot be used to multiplex analogue signals.

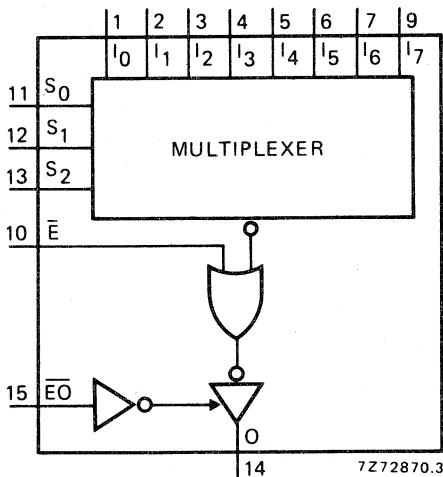

Fig. 1 Functional diagram.

### PINNING

- $S_0, S_1, S_2$  select inputs
- $\bar{EO}$  output enable (active LOW)
- $\bar{E}$  enable (active LOW)
- $I_0$  to  $I_7$  multiplexer inputs
- $O$  multiplexer output

## 1-OF-16 DECODER/DEMULTIPLEXER WITH INPUT LATCHES

The HEF4514B is a 1-of-16 decoder/demultiplexer, having four binary weighted address inputs ( $A_0$  to  $A_3$ ), a latch enable input (EL), and an active LOW enable input ( $\bar{E}$ ). The 16 outputs ( $O_0$  to  $O_{15}$ ) are mutually exclusive active HIGH. When EL is HIGH, the selected output is determined by the data on  $A_n$ . When EL goes LOW, the last data present at  $A_n$  are stored in the latches and the outputs remain stable. When  $\bar{E}$  is LOW, the selected output, determined by the contents of the latch, is HIGH. At  $\bar{E}$  HIGH, all outputs are LOW. The enable input ( $\bar{E}$ ) does not affect the state of the latch. When the HEF4514B is used as a demultiplexer,  $\bar{E}$  is the data input and  $A_0$  to  $A_3$  are the address inputs.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

## PINNING

$A_0$ to $A_3$	address inputs
$\bar{E}$	enable input (active LOW)
EL	latch enable input
$O_0$ to $O_{15}$	outputs (active HIGH)

HEF4514BP: 24-lead DIL; plastic (SOT-101A).

HEF4514BD: 24-lead DIL; ceramic (cerdip) (SOT-94).

HEF4514BT: 24-lead mini-pack; plastic (SO-24; SOT-137A).

## APPLICATION INFORMATION

Some examples of applications for the HEF4514B are:

- Digital multiplexing.
- Address decoding.
- Hexadecimal/BCD decoding.

## BINARY UP/DOWN COUNTER

The HEF4516B is an edge-triggered synchronous up/down 4-bit binary counter with a clock input (CP), an up/down count control input (UP/DN), an active LOW count enable input (CE), an asynchronous active HIGH parallel load input (PL), four parallel inputs (P<sub>0</sub> to P<sub>3</sub>), four parallel outputs (O<sub>0</sub> to O<sub>3</sub>), an active LOW terminal count output (TC), and an overriding asynchronous master reset input (MR).

Information on P<sub>0</sub> to P<sub>3</sub> is loaded into the counter while PL is HIGH, independent of all other input conditions except MR which must be LOW. When PL and CE are LOW, the counter changes on the LOW to HIGH transition of CP. Input UP/DN determines the direction of the count, HIGH for counting up, LOW for counting down. When counting up, TC is LOW when O<sub>0</sub> to O<sub>3</sub> are HIGH and CE is LOW. When counting down, TC is LOW when O<sub>0</sub> to O<sub>3</sub> and CE are LOW. A HIGH on MR resets the counter (O<sub>0</sub> to O<sub>3</sub> = LOW) independent of all other input conditions.

Fig. 1 Functional diagram.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4516B are:

- Up/down difference counting
- Synchronous frequency dividers

Fig. 8 Example of parallel clocking when cascading HEF4516B ICs.

Fig. 9 Example of ripple clocking when cascading HEF4516B ICs. Ripple clocking mode: the up/down control can be changed at any count; the only restriction on changing the up/down control is that the clock input to the first counting stage must be HIGH.

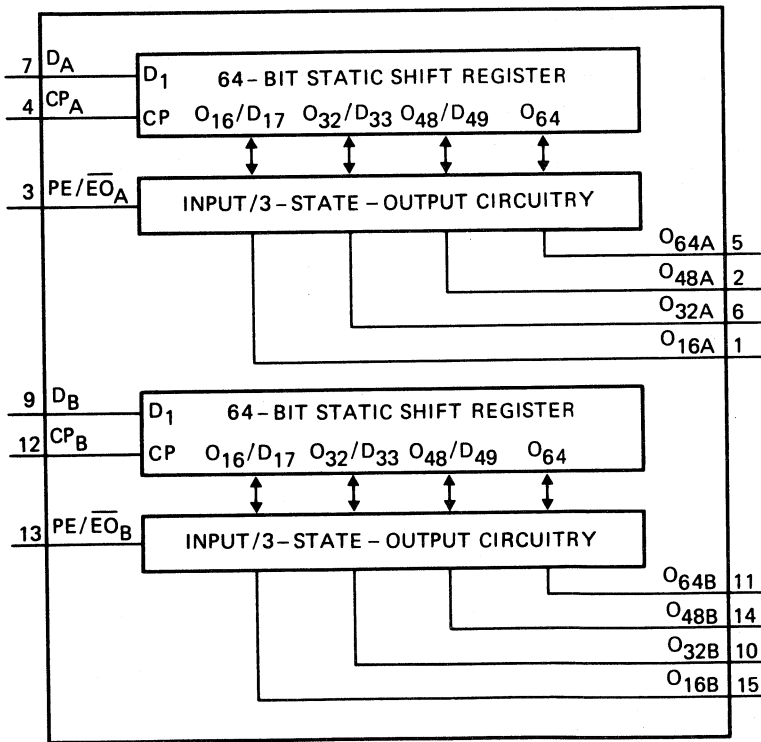

## DUAL 64-BIT STATIC SHIFT REGISTER

The HEF4517B consists of two identical, independent 64-bit static shift registers. Each register has separate clock (CP), data input (D), parallel input-enable/output-enable (PE/EO) and four 3-state outputs of the 16th, 32nd, 48th and 64th bit positions ( $O_{16}$  to  $O_{64}$ ). Data at the D input is entered into the first bit on the LOW to HIGH transition of the clock, regardless of the state of PE/EO.

When PE/ $\overline{EO}$  is LOW the outputs are enabled and the device is in the 64-bit serial mode.

When PE/ $\overline{EO}$  is HIGH the outputs are disabled (high impedance OFF-state), the 64-bit shift register is divided into four 16-bit shift registers with D,  $O_{16}$ ,  $O_{32}$  and  $O_{48}$  as data inputs of the 1st, 17th, 33rd, and 49th bit respectively. Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## DUAL BCD COUNTER

The HEF4518B is a dual 4-bit internally synchronous BCD counter. The counter has an active HIGH clock input ( $CP_0$ ) and an active LOW clock input ( $\overline{CP}_1$ ), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and an active HIGH overriding asynchronous master reset input (MR). The counter advances on either the LOW to HIGH transition of the  $CP_0$  input if  $\overline{CP}_1$  is HIGH or the HIGH to LOW transition of the  $\overline{CP}_1$  input if  $CP_0$  is LOW. Either  $CP_0$  or  $\overline{CP}_1$  may be used as the clock input to the counter and the other clock input may be used as a clock enable input. A HIGH on MR resets the counter ( $O_0$  to  $O_3 = \text{LOW}$ ) independent of  $CP_0$ ,  $\overline{CP}_1$ .

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

QUADRUPLE 2-INPUT MULTIPLEXER

The HEF4519B provides four multiplexing circuits with common select inputs ( $S_A$ ,  $S_B$ ); each circuit contains two inputs ( $A_n$ ,  $B_n$ ) and one output ( $O_n$ ). It may be used to select four bits of information from one of two sources.

The 'A' inputs are selected when  $S_A$  is HIGH, the 'B' inputs when  $S_B$  is HIGH. When  $S_A$  and  $S_B$  are HIGH, the output ( $O_n$ ) is the logical EXCLUSIVE-NOR of the  $A_n$  and  $B_n$  inputs ( $O_n = A_n \odot B_n$ ). When  $S_A$  and  $S_B$  are LOW, the output ( $O_n$ ) is LOW, independent of the multiplexer inputs ( $A_n$  and  $B_n$ ). The HEF4519B cannot be used to multiplex analogue signals. The outputs utilize standard buffers for best performance.

**APPLICATION INFORMATION**

Some examples of applications for the HEF4519B are:

- 2-input multiplexers.
- True/complement selectors.

## DUAL BINARY COUNTER

The HEF4520B is a dual 4-bit internally synchronous binary counter. The counter has an active HIGH clock input ( $CP_0$ ) and an active LOW clock input ( $\overline{CP}_1$ ), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and an active HIGH overriding asynchronous master reset input (MR). The counter advances on either the LOW to HIGH transition of the  $CP_0$  input if  $\overline{CP}_1$  is HIGH or the HIGH to LOW transition of the  $\overline{CP}_1$  input if  $CP_0$  is LOW. Either  $CP_0$  or  $\overline{CP}_1$  may be used as the clock input to the counter and the other clock input may be used as a clock enable input. A HIGH on MR resets the counter ( $O_0$  to  $O_3 = \text{LOW}$ ) independent of  $CP_0$ ,  $\overline{CP}_1$ .

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## 24-STAGE FREQUENCY DIVIDER

The HEF4521B consists of a chain of 24 toggle flip-flops with an overriding asynchronous master reset input (MR), and an input circuit that allows three modes of operation. The single inverting stage ( $I_2/O_2$ ) will function as a crystal oscillator, or in combination with  $I_1$  as an RC oscillator, or as an input buffer for an external oscillator. Low-power operation as a crystal oscillator is enabled by connecting external resistors to pins 3 ( $V_{SS}'$ ) and 5 ( $V_{DD}'$ ).

Each flip-flop divides the frequency of the previous flip-flop by two, consequently the HEF4521B will count up to  $2^{24} = 16\,777\,216$ . The counting advances on the HIGH to LOW transition of the clock ( $I_2$ ). The outputs of the last seven stages are available for additional flexibility.

## COUNT CAPACITY

output	count capacity
O18	$2^{18} = 262\,144$
O19	$2^{19} = 524\,288$
O20	$2^{20} = 1\,048\,576$
O21	$2^{21} = 2\,097\,152$
O22	$2^{22} = 4\,194\,304$
O23	$2^{23} = 8\,388\,608$
O24	$2^{24} = 16\,777\,216$

## FUNCTIONAL TEST SEQUENCE

inputs		control terminals			outputs	remarks
MR	I <sub>2</sub>	O <sub>2</sub>	VSS'	VDD'	O <sub>18</sub> to O <sub>24</sub>	
H	L	L	VDD	VSS	L	counter is in three 8-stage sections in parallel mode; I <sub>2</sub> and O <sub>2</sub> are interconnected (O <sub>2</sub> is now input); counter is reset by MR
L	⌋	⌋	VDD	VSS	H	255 pulses are clocked into I <sub>2</sub> . O <sub>2</sub> (the counter advances on the LOW to HIGH transition)
L	L	L	VSS	VSS	H	VSS' is connected to VSS
L	H	L	VSS	VSS	H	the input I <sub>2</sub> is made HIGH
L	H	L	VSS	VDD	H	VDD' is connected to VDD; O <sub>2</sub> is now made floating and becomes an output; the device is now in the 2 <sup>24</sup> mode
L	⌋		VSS	VDD	L	counter ripples from an all HIGH state to an all LOW state

A test function has been included for the reduction of the test time required to exercise all 24 counter stages. This test function divides the counter into three 8-stage sections by connecting VSS' to VDD and VDD' to VSS. Via I<sub>2</sub> (connected to O<sub>2</sub>) 255 counts are loaded into each of the 8-stage sections in parallel. All flip-flops are now at a HIGH state. The counter is now returned to the normal 24-stage in series configuration by connecting VSS' to VSS and VDD' to VDD. One more pulse is entered into input I<sub>2</sub>, which will cause the counter to ripple from an all HIGH state to an all LOW state.

## PROGRAMMABLE 4-BIT BCD DOWN COUNTER

The HEF4522B is a synchronous programmable 4-bit BCD down counter with an active HIGH and an active LOW clock input ( $CP_0$ ,  $\overline{CP}_1$ ), an asynchronous parallel load input (PL), four parallel inputs ( $P_0$  to  $P_3$ ), a cascade feedback input (CF), four buffered parallel outputs ( $O_0$  to  $O_3$ ), a terminal count output (TC) and an overriding asynchronous master reset input (MR).

This device is a programmable, cascadable down counter with a decoded TC output for divide-by-n applications. In single stage applications the TC output is connected to PL. CF allows cascade divide-by-n operation with no additional gates required.

Information on  $P_0$  to  $P_3$  is loaded into the counter while PL is HIGH, independent of all other input conditions except MR, which must be LOW. When PL and  $\overline{CP}_1$  are LOW, the counter advances on a LOW to HIGH transition of  $CP_0$ . When PL is LOW and  $CP_0$  is HIGH, the counter advances on a HIGH to LOW transition of  $\overline{CP}_1$ . TC is HIGH when the counter is in the zero state ( $O_0 = O_1 = O_2 = O_3 = \text{LOW}$ ) and CF is HIGH and PL is LOW. A HIGH on MR resets the counter ( $O_0$  to  $O_3 = \text{LOW}$ ) independent of other input conditions.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## PROGRAMMABLE 4-BIT BINARY DOWN COUNTER

The HEF4526B is a synchronous programmable 4-bit binary down counter with an active HIGH and an active LOW clock input ( $CP_0$ ,  $\overline{CP}_1$ ), an asynchronous parallel load input (PL), four parallel inputs ( $P_0$  to  $P_3$ ), a cascade feedback input (CF), four buffered parallel outputs ( $O_0$  to  $O_3$ ), a terminal count output (TC) and an overriding asynchronous master reset input (MR).

This device is a programmable, cascadable down counter with a decoded TC output for divide-by-n applications. In single stage applications the TC output is connected to PL. CF allows cascade divide-by-n operation with no additional gates required.

Information on  $P_0$  to  $P_3$  is loaded into the counter while PL is HIGH, independent of all other input conditions except MR, which must be LOW. When PL and  $\overline{CP}_1$  are LOW, the counter advances on a LOW to HIGH transition of  $CP_0$ . When PL is LOW and  $CP_0$  is HIGH, the counter advances on a HIGH to LOW transition of  $\overline{CP}_1$ . TC is HIGH when the counter is in the zero state ( $O_0 = O_1 = O_2 = O_3 = \text{LOW}$ ) and CF is HIGH and PL is LOW. A HIGH on MR resets the counter ( $O_0$  to  $O_3 = \text{LOW}$ ) independent of other input conditions.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## BCD RATE MULTIPLIER

The HEF4527B is a BCD rate multiplier with two buffered rate outputs ( $O_1$  and  $\bar{O}_1$ ), two buffered terminal count outputs (TC and  $\bar{TC}$ ), four BCD rate select inputs ( $S_A$ ,  $S_B$ ,  $S_C$ ,  $S_D$ ), a common clock input (CP), a preset input (PL), an overriding asynchronous clear input (CL), a strobe input (STR), a cascade input (CAS) and an active LOW count enable input ( $\bar{CE}$ ).

The BCD rate multiplier provides an output pulse rate based upon the BCD input number. For example, if 6 is the BCD number, there will be six output pulses for every ten clock input pulses. The output is clocked on the negative-going transition of the clock.

When  $\bar{CE}$ , STR, CAS, CL and PL are LOW, the rate pulses are available at the outputs  $O_1$  and  $\bar{O}_1$ , the terminal count pulses at TC and  $\bar{TC}$ .

A HIGH on CL resets the counter, independent of all other input conditions and a rate of 10 pulses is available at  $O_1$  and  $\bar{O}_1$  when  $S_D$  is HIGH. When  $\bar{CE}$  is HIGH, the counter is disabled, the state of the outputs ( $O_1$ ,  $\bar{O}_1$ ) depend on the content of the counter.

A HIGH on PL sets the counter in the '9' state and TC becomes HIGH.

A HIGH on STR inhibits the outputs  $O_1$  and  $\bar{O}_1$ . A HIGH on CAS forces the output  $O_1$  to HIGH, while the state of  $\bar{O}_1$  depends on the inputs  $S_A$  to  $S_D$  (see lines 1 to 16 of function table).

This device may be used to perform arithmetic operations. For the add mode and multiply mode see Figs 5 and 6.

Schmitt-trigger action in the clock input makes the circuit highly tolerant to slower clock rise and fall times.

## DUAL MONOSTABLE MULTIVIBRATOR

The HEF4528B is a dual retriggerable-resettable monostable multivibrator. Each multivibrator has an active LOW input ( $\bar{I}_0$ ), and active HIGH input ( $I_1$ ), an active LOW clear direct input ( $\bar{C}_D$ ), an output ( $O$ ) and its complement ( $\bar{O}$ ), and two pins for connecting the external timing components ( $C_{TC}$ ,  $R_{TC}$ ).

An external timing capacitor ( $C_t$ ) must be connected between  $C_{TC}$  and  $R_{TC}$  and an external resistor ( $R_t$ ) must be connected between  $R_{TC}$  and  $V_{DD}$ . The duration of the output pulse is determined by the external timing components  $C_t$  and  $R_t$ .

A HIGH to LOW transition on  $\bar{I}_0$  when  $I_1$  is LOW or a LOW to HIGH transition on  $I_1$  when  $\bar{I}_0$  is HIGH produces a positive pulse (LOW-HIGH-LOW) on  $O$  and a negative pulse (HIGH-LOW-HIGH) on  $\bar{O}$  if the  $\bar{C}_D$  is HIGH. A LOW on  $\bar{C}_D$  forces  $O$  LOW,  $\bar{O}$  HIGH and inhibits any further pulses until  $\bar{C}_D$  is HIGH.

## Notes

- $R_t = 5 \text{ k}\Omega$ ;  $C_t = 15 \text{ pF}$ ; for other  $R_t$ ,  $C_t$  combinations and  $C_t < 0,01 \mu\text{F}$  see graph Fig. 4.
- $R_t = 10 \text{ k}\Omega$ ;  $C_t = 1000 \text{ pF}$ ; for other  $R_t$ ,  $C_t$  combinations and  $C_t > 0,01 \mu\text{F}$  use formula  $t_{WO} = K \cdot R_t \cdot C_t$ .

where:  $t_{WO}$  = output pulse width (s)

$R_t$  = external timing resistor ( $\Omega$ )

$C_t$  = external timing capacitor (F)

- $T_{amb} = -40$  to  $+85 \text{ }^\circ\text{C}$ ;  $\Delta t_{WO}$  is referenced to  $t_{WO}$  at  $T_{amb} = 25 \text{ }^\circ\text{C}$ .

$K = 0,42$  for  $V_{DD} = 5 \text{ V}$

$K = 0,32$  for  $V_{DD} = 10 \text{ V}$

$K = 0,30$  for  $V_{DD} = 15 \text{ V}$

Fig. 4 Output pulse width ( $t_{WO}$ ) as a function of external timing capacitor ( $C_t$ ).

Fig. 5 Waveforms showing minimum  $\bar{I}_0$ ,  $I_1$  and O pulse widths, set-up and recovery times. Set-up and recovery times are shown as positive values but may be specified as negative values.

APPLICATION INFORMATION

An example of an application for the HEF4528B is:

- Non-retriggerable monostable multivibrator

7284350

Fig. 6 Two examples for a non-retriggerable monostable multivibrator using half of HEF4528B (LOW to HIGH and HIGH to LOW triggered).

## 13-INPUT PARITY CHECKER/GENERATOR

The HEF4531B is a parity checker/generator with 13 parity inputs ( $I_0$  to  $I_{12}$ ) and a parity output ( $O$ ). When the number of parity inputs that are HIGH is even, the output is LOW. When the number of parity inputs that are HIGH is odd, the output is HIGH. For words of 12 bits or less, the output can be used to generate either odd or even parity by appropriate termination of the unused parity input(s). For words of 14 or more bits, the devices can be cascaded by connecting the output of one device to any parity input of another device. When cascading devices, it is recommended that the output of one device be connected to the  $I_{12}$  input of the other device since there is less delay to the output from the  $I_{12}$  input than from any other input ( $I_0$  to  $I_{11}$ ).

## 8-INPUT PRIORITY ENCODER

The HEF4532B is an 8-input priority encoder with eight active HIGH priority inputs ( $I_0$  to  $I_7$ ), three active HIGH outputs ( $O_0$  to  $O_2$ ), an active HIGH enable input ( $E_{in}$ ), an active HIGH enable output ( $E_{out}$ ) and an active HIGH group select output (GS). Data is accepted on inputs  $I_0$  to  $I_7$ . The binary code corresponding to the highest priority input ( $I_0$  to  $I_7$ ) which is HIGH, is generated on  $O_0$  to  $O_2$  if  $E_{in}$  is HIGH. Input  $I_7$  is assigned the highest priority. GS is HIGH when one or more priority inputs and  $E_{in}$  are HIGH.  $E_{out}$  is HIGH when  $I_0$  to  $I_7$  are LOW and  $E_{in}$  is HIGH.  $E_{in}$ , when LOW, forces all outputs ( $O_0$  to  $O_2$ , GS,  $E_{out}$ ) LOW.

Fig. 3 Error detection timing diagram.

The skew time is the time difference between the LOW to HIGH transition of CPA and the HIGH to LOW transition of CPE or vice versa (see Fig. 4). The skew time is typically proportional to the external capacitor ( $C_{ext}$ ) connected from  $C_{ext1}$  and  $C_{ext2}$  (pins 1 and 22) to  $V_{SS}$ . The error detector will count an error when a positive edge on the counter clock CPA is not succeeded by a negative edge on the error detector clock  $\overline{CPE}$  within a skew time  $t_{SK1}$  (adjustable by  $C_{ext1}$  at pin 1). The same holds for a negative edge at  $\overline{CPE}$  succeeded by a positive on CPA within a skew time  $t_{SK2}$  (adjustable by  $C_{ext2}$  at pin 22). If error detection is not needed, CPE must be either HIGH or LOW and no  $C_{ext}$  is applied. For further information see Fig. 5.

Fig. 4 Skew times timing diagram;  $t_{WCPA} > t_{SK1}$ ;  $t_{WCPE} > t_{SK2}$ .

Fig. 5 Typical clock skew as a function of the supply voltage. This graph is accurate for  $C_{ext} \geq 100$  pF and  $T_{amb} = 25$  °C.

Notes to Fig. 5

1. Skew in this area results in counted error.
2. Skew in the area between max. and min. curves may or may not result in counted error.
3. Skew in this area results in no error counted.

Fig. 6 Carry timing diagram.

Fig. 7 Scanner timing diagram.

Note: If  $S_B = H$ , the 1st decade is inhibited and the cycle will be shortened to four stages (see dotted lines).

APPLICATION INFORMATION

Fig. 9 Two HEF4534B ICs connected for cascade operation. TC is HIGH for a single clock period when all five BCD decades go to zero. TC also goes HIGH when MR is applied.

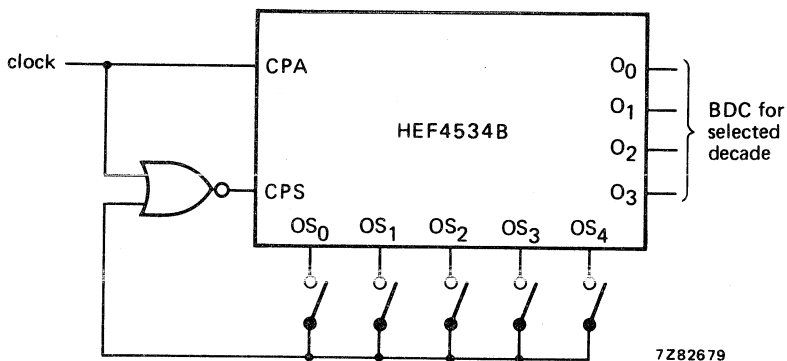

Fig. 10 Forcing a decade to the  $O_n$  outputs. When the  $O_n$  outputs of a given decade are required, this configuration will lock-up the selected decade within four clock cycles. The select line feed back may be hardwired or switched.

## DUAL PRECISION MONOSTABLE MULTIVIBRATOR

The HEF4538B is a dual retriggerable-resettable monostable multivibrator. Each multivibrator has an active LOW trigger/retrigger input ( $\bar{I}_0$ ), an active HIGH trigger/retrigger input ( $I_1$ ), an overriding active LOW direct reset input ( $\bar{C}_D$ ), an output (O) and its complement ( $\bar{O}$ ), and two pins ( $C_{TC}$ ,  $R_{TC}$ ) for connecting the external timing components  $C_T$  and  $R_T$ . Typical pulse width variation over temperature range is  $\pm 0,2\%$ .

The HEF4538B may be triggered by either the positive or the negative edges of the input pulse and will produce an accurate output pulse with a pulse width range of  $10 \mu\text{s}$  to infinity. The duration and accuracy of the output pulse are determined by the external timing components  $C_T$  and  $R_T$ . The output pulse width (T) is equal to  $R_T \times C_T$ . The linear design techniques in LOC MOS guarantee precise control of the output pulse width.

A LOW level at  $\bar{C}_D$  terminates the output pulse immediately. The minimum reset pulse width depends on the value of the external timing capacitor  $C_T$ .

Schmitt-trigger action in the trigger inputs makes the circuit highly tolerant to slower rise and fall times.

## DUAL 4-INPUT MULTIPLEXER

The HEF4539B is a dual 4-input multiplexer with common select logic. Each multiplexer has four multiplexer inputs ( $I_0$  to  $I_3$ ), an active LOW enable input ( $\bar{E}$ ) and a multiplexer output ( $O$ ). When HIGH,  $\bar{E}$  forces  $O$  of the respective multiplexer LOW, independent of the select inputs ( $S_0$  and  $S_1$ ) and  $I_0$  to  $I_3$ . When  $\bar{E}$  is LOW,  $S_0$  and  $S_1$  determine which multiplexer input ( $I_0$  to  $I_3$ ) on each of the multiplexers is routed to the respective multiplexer output ( $O$ ).

## APPLICATION INFORMATION

Some examples of applications for the HEF4539B are:

- Data selectors.
- Data multiplexers.

PROGRAMMABLE TIMER

The HEF4541B is a programmable timer which consists of a 16-stage binary counter, an integrated oscillator to be used with external timing components, an automatic power-on reset and output control logic. The frequency of the oscillator is determined by the external components  $R_T$  and  $C_T$  within the frequency range 1 Hz to 100 kHz. This oscillator may be replaced by an external clock signal at input RS, the timer advances on the positive-going transition of RS. A LOW on the auto reset input ( $\overline{AR}$ ) and a LOW on the master reset input (MR) enables the internal power-on reset. A HIGH level at input MR resets the counter independent on all other inputs. Resetting disables the oscillator to provide no active power dissipation.

A HIGH at input  $\overline{AR}$  turns off the power-on reset to provide a low quiescent power dissipation of the timer. The 16-stage counter divides the oscillator frequency by  $2^8$ ,  $2^{10}$ ,  $2^{13}$  or  $2^{16}$  depending on the state of the address inputs ( $A_0$ ,  $A_1$ ). The divided oscillator frequency is available at output O. The phase input (PH) features a complementary output signal. If the mode select input (MODE) is LOW or HIGH the timer can be used respectively as a single transition timer or  $2^n$  frequency divider.

**FREQUENCY SELECTION TABLE**

A <sub>0</sub>	A <sub>1</sub>	number of counter stages n	$\frac{f_{osc}}{f_{out}} = 2^n$
L	L	13	8 192
L	H	10	1 024
H	L	8	256
H	H	16	65 536

**FUNCTION TABLE**

inputs				mode
$\overline{AR}$	MR	PH	MODE	
H	L	X	X	auto reset disabled
L	L	X	X	auto reset enabled
X	H	X	X	master reset active
X	L	X	H	normal operation selected
X	L	X	L	division to output
X	L	L	X	single-cycle mode*
X	L	L	X	output initially LOW, after reset
X	L	H	X	output initially HIGH, after reset

H = HIGH state (the more positive voltage)  
 L = LOW state (the less positive voltage)  
 X = state is immaterial

\* The timer is initialized on a reset pulse and the output changes state after  $2^{n-1}$  counts and remains in that state (latched). Reset of this latch is obtained by master reset or by a LOW to HIGH transition on the MODE input.

## RC oscillator

Typical formula for oscillator frequency:

$$f_{osc} = \frac{1}{2,3 \times R_t \times C_t}$$

Fig. 4 External component connection for RC oscillator;  $R_s \approx 2R_t$ .

#### Timing component limitations

The oscillator frequency is mainly determined by  $R_t C_t$ , provided  $R_t \ll R_s$  and  $R_s C_2 \ll R_t C_t$ . The function of  $R_s$  is to minimize the influence of the forward voltage across the input protection diodes on the frequency. The stray capacitance  $C_2$  should be kept as small as possible. In consideration of accuracy,  $C_t$  must be larger than the inherent stray capacitance.  $R_t$  must be larger than the LOCOS 'ON' resistance in series with it, which typically is  $500 \Omega$  at  $V_{DD} = 5 \text{ V}$ ,  $300 \Omega$  at  $V_{DD} = 10 \text{ V}$  and  $200 \Omega$  at  $V_{DD} = 15 \text{ V}$ .

The recommended values for these components to maintain agreement with the typical oscillation formula are:

$$C_t \geq 100 \text{ pF, up to any typical value,}$$

$$10 \text{ k}\Omega \leq R_t \leq 1 \text{ M}\Omega.$$

Fig. 5 RC oscillator frequency as a function of  $R_t$  and  $C_t$  at  $V_{DD} = 5$  to  $15 \text{ V}$ ;  $T_{amb} = 25 \text{ }^\circ\text{C}$ .

## BCD TO 7-SEGMENT LATCH/DECODER/DRIVER

The HEF4543B is a BCD to 7-segment latch/decoder/driver for liquid crystal and LED displays. It has four address inputs ( $D_A$  to  $D_D$ ), an active HIGH latch disable input (LD), an active HIGH blanking input (BI), an active HIGH phase input (PH) and seven buffered segment outputs ( $O_a$  to  $O_g$ ).

The circuit provides the function of a 4-bit storage latch and an 8-4-2-1 BCD to 7-segment decoder/driver. It can invert the logic levels of the output combination. The phase (PH), blanking (BI) and latch disable (LD) inputs are used to reverse the function table phase, blank the display and store a BCD code, respectively.

For liquid crystal displays a square-wave is applied to PH and the electrical common back-plane of the display. The outputs of the device are directly connected to the segments of the liquid crystal.

## DUAL 1-OF-4 DECODER/DEMULTIPLEXER

The HEF4555B is a dual 1-of-4 decoder/demultiplexer. Each has two address inputs ( $A_0$  and  $A_1$ ), an active LOW enable input ( $\bar{E}$ ) and four mutually exclusive outputs which are active HIGH ( $O_0$  to  $O_3$ ). When used as a decoder,  $\bar{E}$  when HIGH, forces  $O_0$  to  $O_3$  LOW. When used as a demultiplexer, the appropriate output is selected by the information on  $A_0$  and  $A_1$  with  $\bar{E}$  as data input. All unselected outputs are LOW.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

HEF4555BP : 16-lead DIL; plastic (SOT-38Z).  
 HEF4555BD : 16-lead DIL; ceramic (cerdip) (SOT-74).

## APPLICATION INFORMATION

Some examples of applications for the HEF4556B are:

- Code conversion.
- Address decoding.
- Demultiplexing: when using the enable input as data input.

# 1-to-64 BIT VARIABLE LENGTH SHIFT REGISTER

The HEF4557B is a static clocked serial shift register whose length may be programmed to be any number of bits between 1 and 64. The number of bits selected is equal to the sum of the subscripts of the enabled length control inputs ( $L_1$ ,  $L_2$ ,  $L_4$ ,  $L_8$ ,  $L_{16}$  and  $L_{32}$ ) plus one. Serial data may be selected from the  $D_A$  or  $D_B$  data inputs with the  $A/\bar{B}$  select input. This feature is useful for recirculation purposes. Information on  $D_A$  or  $D_B$  is shifted into the first register position and all the data in the register is shifted one position to the right on the LOW to HIGH transition of  $CP_0$  while  $\bar{CP}_1$  is LOW or on the HIGH to LOW transition of  $\bar{CP}_1$  while  $CP_0$  is HIGH. A HIGH on master reset (MR) resets the register and forces  $O$  to LOW and  $\bar{O}$  to HIGH, independent of the other inputs.

Fig. 1 Functional diagram.

### PINNING

- $D_A$ ,  $D_B$  data inputs

## Note

The set-up, hold and recovery times vary with the minimum number of bits selected. For other values as specified one may interpolate as shown in the table (see previous page).

Fig. 4 Waveforms showing recovery time for MR and minimum CP<sub>0</sub>,  $\overline{CP}_1$  and MR pulse widths, set-up and hold times for D<sub>A</sub>, D<sub>B</sub> and A/ $\overline{B}$  to CP<sub>0</sub> and  $\overline{CP}_1$ . Set-up and hold times are shown as positive values but may be specified as negative values.

## 4-BIT MAGNITUDE COMPARATOR

The HEF4585B is a 4-bit magnitude comparator which compares two 4-bit words (A and B), whether they are 'less than', 'equal to', or 'greater than'. Each word has four parallel inputs ( $A_0$  to  $A_3$  and  $B_0$  to  $B_3$ );  $A_3$  and  $B_3$  being the most significant inputs. Three outputs are provided; A greater than B ( $O_A > B$ ), A less than B ( $O_A < B$ ) and A equal to B ( $O_A = B$ ). Three expander inputs ( $I_A > B$ ,  $I_A < B$  and  $I_A = B$ ) allow cascading of the devices without external gates.

For proper compare operation the expander inputs to the least significant position must be connected as follows:  $I_A = B = I_A > B = \text{HIGH}$ ,  $I_A < B = \text{LOW}$ . For words greater than 4-bits, units can be cascaded by connecting outputs  $O_A < B$  and  $O_A = B$  to the corresponding inputs of the next significant comparator (input  $I_A > B$  is connected to a HIGH).

Operation is not restricted to binary codes, the devices will work with any monotonic code. The function table describes the operation of the device under all possible logic conditions.

## APPLICATION INFORMATION

Some examples of applications for the HEF4585B are:

- Process controllers.
- Servo-motor control.

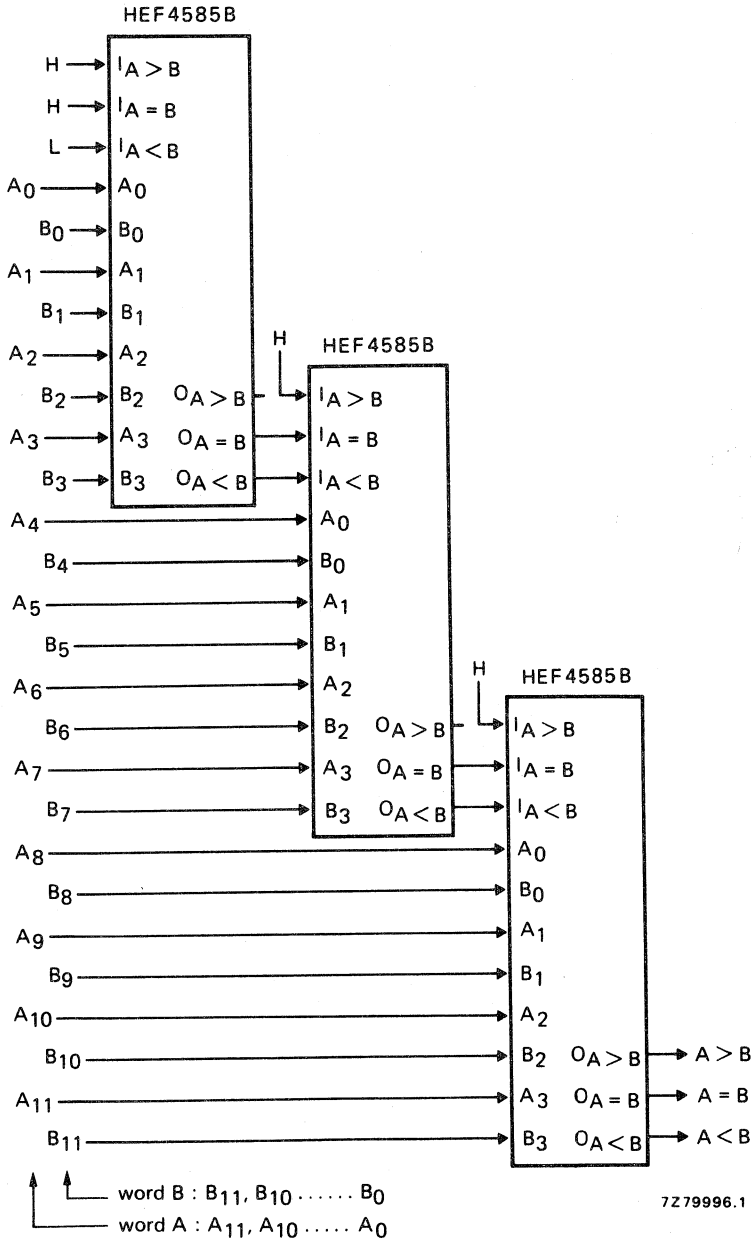

Fig. 4 Example of cascading comparators.

## 256-BIT, 1-BIT PER WORD RANDOM ACCESS MEMORIES

The HEF4720B and HEF4720V are 256-bit, 1-bit per word random access memories with 3-state outputs. The memories are fully decoded and completely static.

Recommended supply voltage range for HEF4720B is 3 to 15 V and for HEF4720V is 4,5 to 12,5 V; minimum stand-by voltage for both types is 3 V.

The use of LOC MOS gives the added advantage of very low stand-by power. The circuits can be directly interfaced with standard bipolar devices (TTL) without using special interface circuits. The memory operates from a single power supply. The separate chip select input ( $\overline{CS}$ ) allows simple memory expansion when the outputs are wire-ORed. If  $\overline{CS}$  is HIGH, the outputs are floating and no new information can be written into the memory. The signal at O has the same polarity as the data input D, while the signal at  $\overline{O}$  is the complement of the signal at O. The write control W must be HIGH for writing into the memory.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

## APPLICATION INFORMATION

### Extension of memory capacity

The memory capacity of the HEF4720B; V is 256 bits (or 256 words of 1 bit). The capacity of a system can be extended in various ways by the connection of further HEF4720B; V ICs.

#### *Extending the word length*

By connecting a number of HEF4720B; V ICs as shown in Fig. 6, the word length (i.e. bits per word) is multiplied by that number. That is, each device stores 1 bit per word but the total number of words remains 256. For example, if four devices are used in this way, 256 four-binary-bit words can be stored.

#### *Extending the number of words*

If a number of HEF4720B; V ICs are connected as shown in Fig. 7, the words available are multiplied by that number, but the word length remains 1 bit. Notice that in this case additional addresses are used in conjunction with the  $\overline{CS}$  input. In the case shown in Fig. 7 (4 x HEF4720B; V in parallel), the addresses and data inputs are loaded with four inputs (= 20 pF), the  $\overline{CS}$  inputs are loaded with one input each.

#### *Extending both the word length and number of words*

Figure 8 shows how a combination of the extensions described above can be used to obtain both greater word length and additional words. It is clear that the capacitive load of the driving circuits puts a limit to the free choice of the interface. In Fig. 8, each address is loaded with 16 inputs, i.e.  $16 \times 5 = 80$  pF: each CS inverter is loaded with 8 inputs, i.e.  $8 \times 5 = 40$  pF. The data inverters in this case are loaded with only two inputs each.

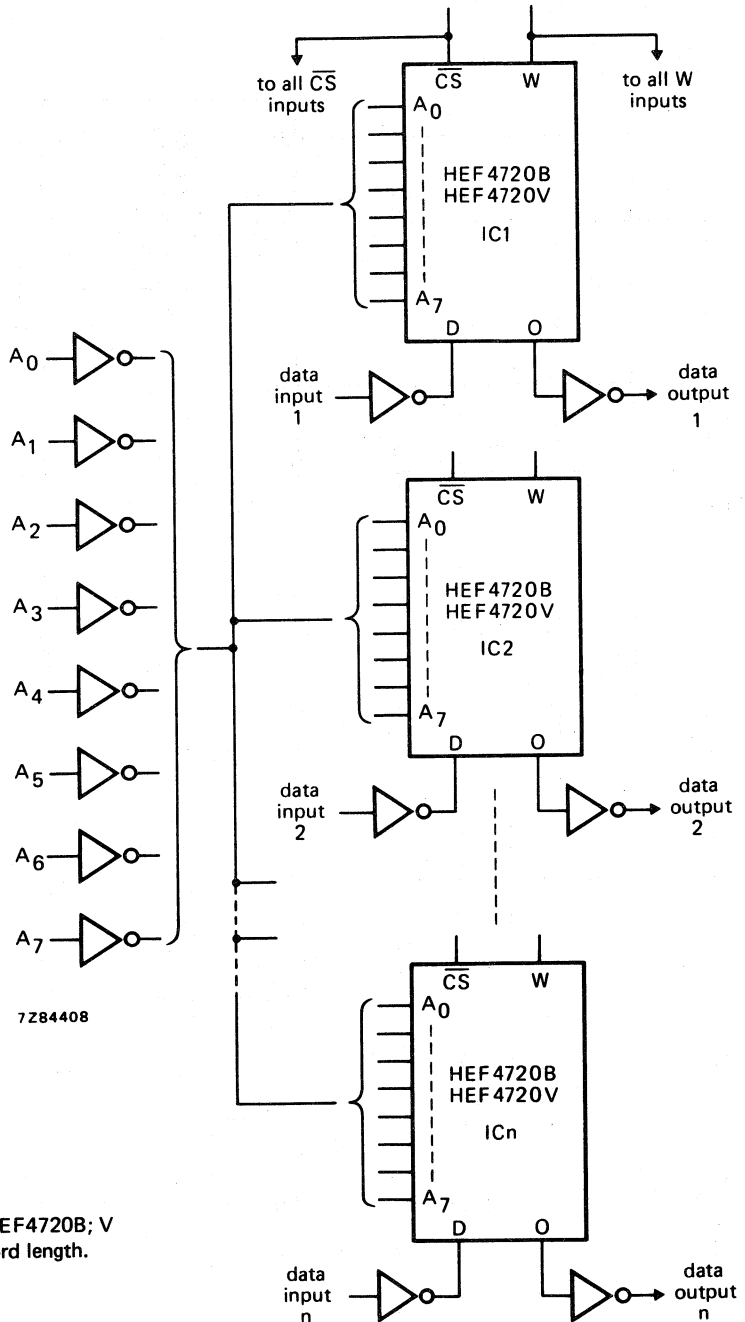

Fig. 6 Using extra HEF4720B; V ICs to extend the word length.

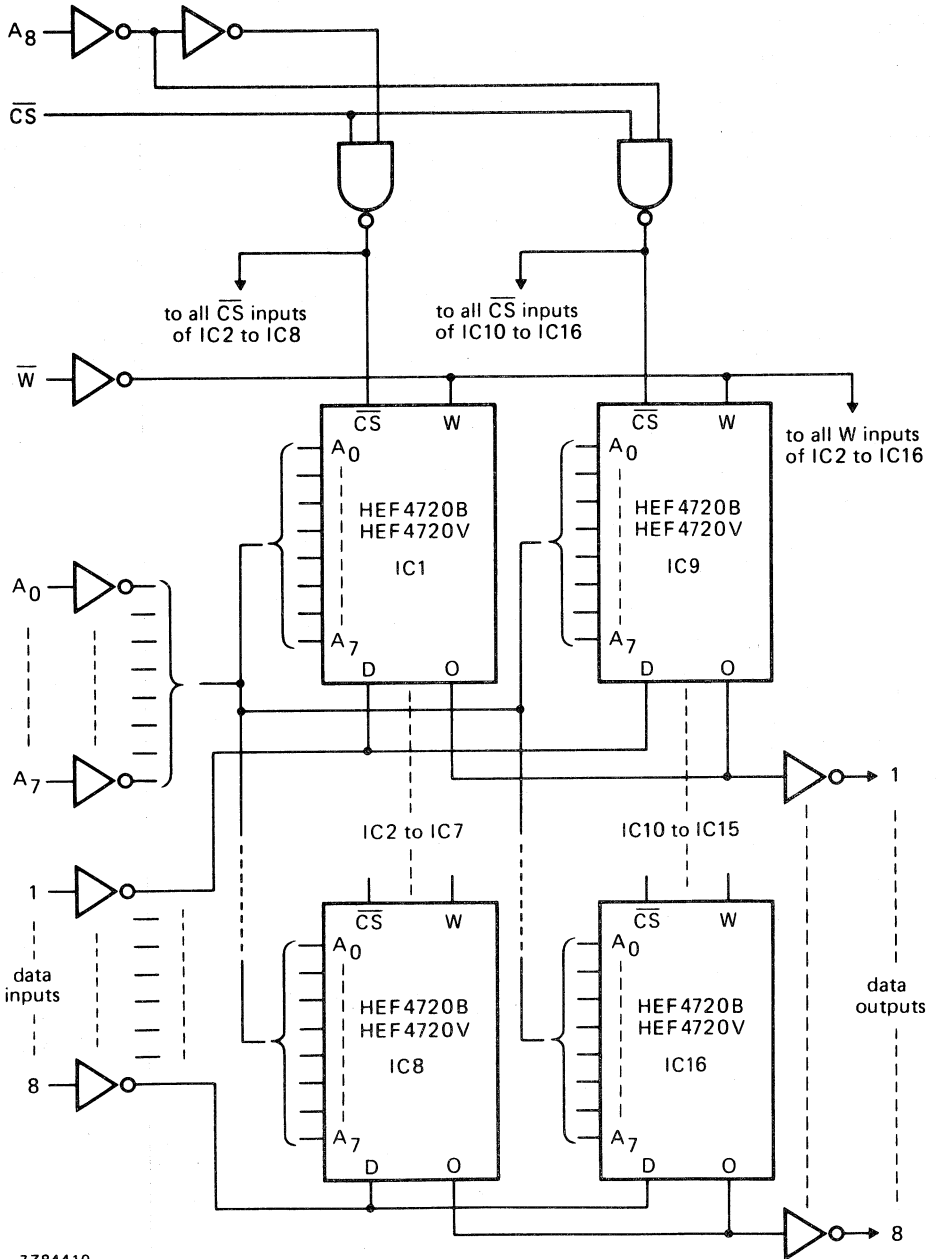

Fig. 8 Using extra HEF4720B; V ICs to obtain more words and greater word length.

**APPLICATION INFORMATION** (continued)**Memory retention**

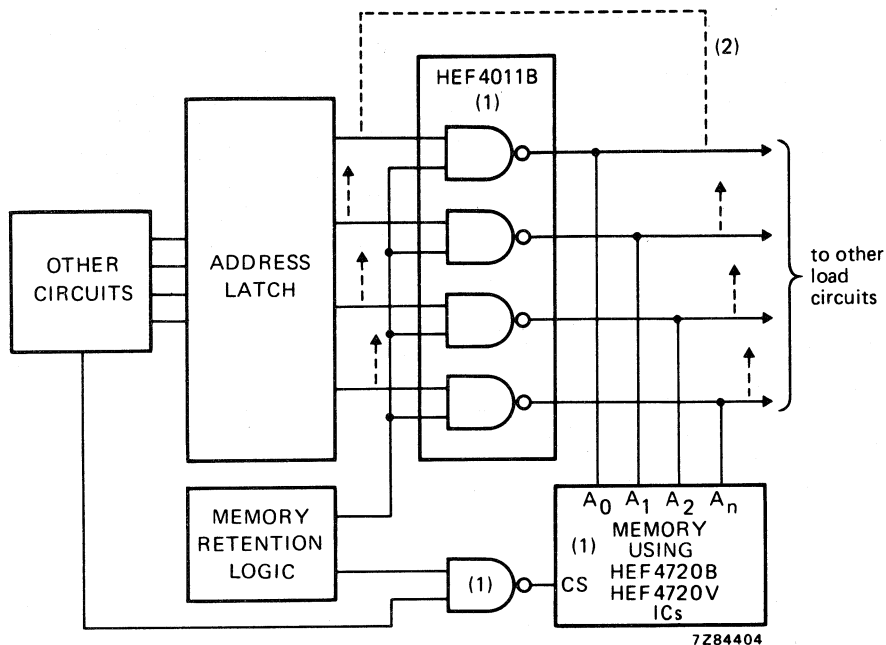

It is sometimes necessary to ensure that the information stored in the memory cannot be erased inadvertently. This can be arranged by adding detection circuits, by measures in the timing, and by the addition of a battery. With the HEF4720B; V, memory retention is very easily obtained because its current drain in the stand-by condition is almost zero. The wide supply voltage range makes it possible to keep the memory active by means of a simple battery, thereby preventing information loss.

In designing the memory retention circuits, two aspects should be kept in mind. The memory retention will not function in an optimum way if the battery voltage is low or if the voltage transitions at the address input are too slow. The first of these is usually the result of using too simple a battery back-up circuit, e.g. a battery charged via a diode from the TTL supply voltage. In this case, the LOCMOS supply voltage falls below the safe operating voltage. Special arrangements should be made to overcome this.

Slow address transitions (the second cause of memory loss) are due to a long RC-time in the power system. When the power is switched on or off, the 5 V line changes between 0 and 5 V in milliseconds to seconds so producing a correspondingly long transition time in the various logic outputs. This creates problems in the proper operation of the HEF4720B; V, with loss of memory as a possible result. This can be prevented by ensuring that input rise and fall times do not exceed 10  $\mu$ s.

Three possibilities for controlling the rise and fall times at the HEF4720B; V interface are given here:

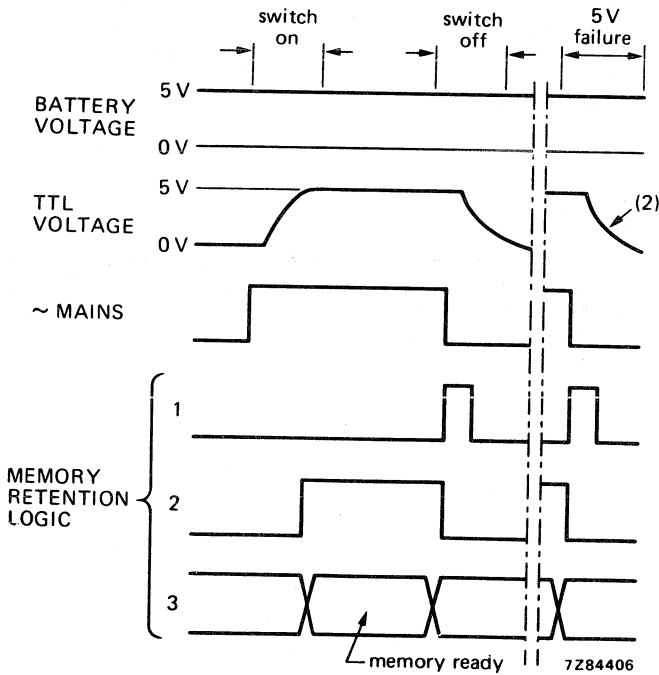

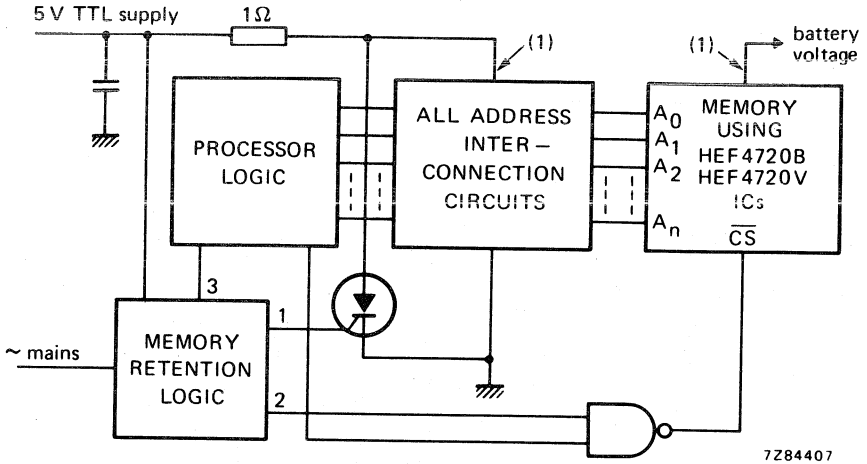

1. LOCMOS gates can be connected between the address latch and the HEF4720B; V (Fig. 9). In the event of a low voltage, or mains supply failure, the gates can be blocked by a signal from the memory retention logic thus isolating the HEF4720B; V from the address and  $\overline{CS}$  inputs.
2. The interface power supply can be separated from the TTL power supply by means of a low-value resistor (Fig. 10); a thyristor is connected from the interface power supply to earth. The system is arranged so that, upon switching off or failure of the interface supply, the thyristor turns on thus ensuring a rapid fall of the supply voltage.
3. The best solution is to select the interface circuits from the LOCMOS family and to feed all these circuits from the battery (Fig. 11). These stages then remain active when the TTL 5 V supply fails. The interface circuits are mostly only active on a clock pulse, have the possibility of being inactive on a gate level, or can be forced into one position.

7Z84404

- (1) These devices have a battery supply.
- (2) Alternative connection.

Fig. 9 Use of battery-operated LOCMOS gates to isolate the memory in case of power supply failure. Devices marked (1) are connected to the battery. The HEF4011B can sink about 0,7 mA: if the load is greater than this, only the memory should be connected, other loads being connected to the address latch as shown by the dashed-line connections.

(1) Leads should be so arranged to prevent cross-talk; thyristor connections must be short.  
(2) Slope  $> 500 \text{ mV}/\mu\text{s}$  in the vicinity of the threshold.

Fig. 10 Using a thyristor to ensure a rapid fall of interface supply at switch-off or supply failure.

## 8-BIT ADDRESSABLE LATCH

The HEF4724B is an 8-bit addressable latch with three address inputs ( $A_0$  to  $A_2$ ), a data input ( $D$ ), an active LOW enable input ( $\bar{E}$ ), an active HIGH clear input ( $CL$ ), and eight parallel latch outputs ( $O_0$  to  $O_7$ ).

When  $\bar{E}$  and  $CL$  are HIGH, all outputs ( $O_0$  to  $O_7$ ) are LOW. Eight-channel demultiplexing or active HIGH 1-of-8 decoding with output enable operation occurs when  $CL$  is HIGH and  $\bar{E}$  is LOW. When  $\bar{E}$  and  $CL$  are LOW, the selected output ( $O_0$  to  $O_7$ ; determined by  $A_0$  to  $A_2$ ) follows  $D$ . When  $\bar{E}$  goes HIGH, the contents of the latch are stored. When operating in the addressable latch mode ( $\bar{E} = CL = LOW$ ), changing more than one bit of  $A_0$  to  $A_2$  could impose a transient wrong address. Therefore, this should only be done while in the memory mode ( $\bar{E} = HIGH, CL = LOW$ ).

## QUADRUPLE 64-BIT STATIC SHIFT REGISTER

The HEF4731B and HEF4731V are quadruple 64-bit static shift registers each with separate serial data inputs ( $D_A$  to  $D_D$ ), clock inputs ( $\overline{CP}_A$  to  $\overline{CP}_D$ ) and data outputs ( $O_{63A}$  to  $O_{63D}$ ) from the 64th register position.

Recommended supply voltage range for HEF4731B is 3 to 15 V and for HEF4731V is 4,5 to 12,5 V.

Data are shifted to the next stage on the negative-going transitions of the clock. Low impedance outputs are provided for direct interface to TTL.

## QUADRUPLE STATIC DECADE COUNTERS

The HEF4737B and HEF4737V are static quadruple decade counters for frequencies from 0 to 10 MHz. The counters are supplied with an extra overload flip-flop giving a total count capability of 19 999. The counter has the following inputs and outputs: a count input (CP), an asynchronous reset input (MR), an asynchronous preset input (PL), a transfer input (T), an output enable input (EO) (which controls the BCD outputs), the digit select inputs ( $S_A$ ,  $S_B$ ,  $S_C$ ) (which perform selection of the contents of the latches to the 3-state BCD outputs ( $O_0$  to  $O_3$ )), and the carry outputs ( $CO_2$  to  $CO_5$ ) (which give the carry signals of the decades except from the first decade).

The complementary MOS structure gives the devices very low stand-by and operating dissipation. Operating from a single supply voltage all outputs can drive one standard TTL input without interface circuitry under all specified operating conditions.

The BCD digit outputs are LOC MOS 3-state outputs. The high impedance off-state feature allows common bussing of the outputs. The counters are supplied with asynchronous reset and preset to 19 999 facilities making them suitable for counter and time base applications. All carry signals are available except from the first decade.

Schmitt-trigger action in the inputs makes the circuit highly tolerant to slower input rise and fall times.

Recommended supply voltage range for HEF4737B is 3 to 15 V and for HEF4737V is 4,5 to 12,5 V.

Fig. 2 Block diagram.

## FUNCTIONAL DESCRIPTION

### Input signals

#### Count input (CP)

The signal to be counted is applied to this input. When PL and MR are LOW the contents of the counter increments by one at a LOW to HIGH transition of CP.

#### Reset input (MR)

This is an asynchronous reset. A HIGH level applied to this input will reset the counter to zero independent of the level at the count input and preset input.

#### Preset input (PL)

This is an asynchronous preset. When MR is LOW a HIGH at the PL input will preset the counter to 19999 independent of the level at the count input.

#### Transfer input (T)

A HIGH level applied to this input allows the information held by the counter to pass to the latches.

Quadruple static decade counters

*Output enable input (EO)*

A HIGH level at this input enables the BCD outputs and information can be read out of the latches using the multiplexer. A LOW level at this input disables the BCD outputs making them floating (high impedance off-state).

*Digit select inputs (SA, SB, SC)*

SA	SB	SC	
L	L	L	selects D1 (LSD)
H	L	L	selects D2
L	H	L	selects D3
H	H	L	selects D4
X	X	H	selects D5 (MSD)

When D5 is selected, the contents of D5 is available at O<sub>0</sub> and O<sub>1</sub>, O<sub>2</sub> and O<sub>3</sub> are LOW.

LSD = least significant divider  
MSD = most significant divider

H = HIGH state (the more positive voltage)

L = LOW state (the less positive voltage)

X = state is immaterial

**Output signals**

The carry outputs are active LOW outputs.

*Carry output CO<sub>2</sub>*

When the contents of the first two decades of the counter are both 9 then the CO<sub>2</sub> output becomes LOW. It remains LOW until the next LOW to HIGH transition of the count input, i.e. until the contents of the first two decades are zero. CO<sub>2</sub> is LOW when the contents of the counter are: 00 099, 00 199, 00 299 etc.

*Carry output CO<sub>3</sub>*

When the contents of the first three decades of the counter are all 9 then the CO<sub>3</sub> output becomes LOW. It remains LOW until the next LOW to HIGH transition of the count input, i.e. until the contents of the first three decades are zero. CO<sub>3</sub> is LOW when the contents of the counter are 00 999, 01 999, 02 999 etc.

*Carry output CO<sub>4</sub>*

When the contents of the first four decades of the counter are all 9 then the CO<sub>4</sub> output becomes LOW. It remains LOW until the next LOW to HIGH transition of the count input, i.e. until the contents of the first four decades are zero. CO<sub>4</sub> is LOW when the contents of the counter are 09 999 and 19 999.

The carry signals CO<sub>2</sub>, CO<sub>3</sub> and CO<sub>4</sub> are suppressed while the preset is active. A HIGH to the preset input sets the counter to 19 999 but the carry signals remain HIGH until preset input returns to LOW, then the carry outputs will also become LOW.

*Carry output CO<sub>5</sub>*

When the content of the counter is 10 000 the CO<sub>5</sub> output becomes LOW. It returns to HIGH when the content of the counter is zero.

*Digit outputs (O<sub>0</sub> to O<sub>3</sub>)*

The digit outputs give the contents of the selected latch. The output is in the form of BCD, positive logic.

7289301.2

The values given at  $V_{DD} = 15\text{ V}$  in the following d.c. and a.c. characteristics, are not applicable to the HEF4737V, because of its reduced supply voltage range.

D.C. CHARACTERISTICS  $V_{SS} = 0\text{ V}$

	$V_{DD}$ V	$V_{OH}$ V	$V_{OL}$ V	symbol	$T_{amb} (^\circ\text{C})$						
					-40		+25		+85		
					min.	max.	min.	max.	min.	max.

## IEC/IEEE BUS INTERFACE

The HEF4738V is an implementation of the IEC-bus as described in IEC report 66 CO 22 (interface system for programmable measuring apparatus) as well as in IEEE standard 488-1975 (standard digital interface for programmable instrumentation).

Together with bus-drivers, level converters and multiplexers it is suitable for connecting electronic programmable and non-programmable equipment to an IEC/IEEE interface bus.

All inputs have standard HE4000B family levels.

In the circuit the following standard interface functions are incorporated:

- Complete source handshake (subset SH1)
- Complete acceptor handshake (subset AH1)
- Basic talker with serial poll and talk-only mode (when  $I_t = \text{LOW}$ , subset T1;  $I_t = \text{HIGH}$ , subset T5)
- Basic listener with listen-only mode (when  $I_t = \text{LOW}$ , subset L1;  $I_t = \text{HIGH}$ , subset L3)
- Complete service request (subset SR1)
- Complete remote local (subset RL1)
- Remote parallel poll configuration (subset PP1)
- Complete device clear (subset DC1)
- Complete device trigger (subset DT1)
- Some controller facilities

## GENERAL DESCRIPTION

The inputs  $\overline{IRFD}$ ,  $\overline{IDAC}$ ,  $\overline{IDAV}$ ,  $\overline{IFC}$ ,  $\overline{IREN}$ ,  $\overline{IATN}$ ,  $\overline{IIDY}$  and  $\overline{IDIO1}$  to  $\overline{IDIO7}$  must be connected via an inverting TTL to LOC MOS level converter to the respective bus lines:  $\overline{NRFD}$ ,  $\overline{NDAC}$ ,  $\overline{DAV}$ ,  $\overline{IFC}$ ,  $\overline{REN}$ ,  $\overline{ATN}$ ,  $\overline{IDY}$  and  $\overline{DIO1}$  to  $\overline{DIO7}$ .

The outputs  $\overline{ORFD}$ ,  $\overline{ODAC}$ ,  $\overline{ODAV}$  and  $\overline{OSRQ}$  can drive one standard TTL load and are suitable for driving  $\overline{NRFD}$ ,  $\overline{NDAC}$ ,  $\overline{DAV}$  and  $\overline{SRQ}$  via an inverting bus-driver circuit.

The parallel poll outputs  $\overline{OP1}$ ,  $\overline{OP2}$ ,  $\overline{OP3}$  and  $\overline{OPP}$  can also drive one standard TTL load. Outputs  $\overline{OP1}$ ,  $\overline{OP2}$  and  $\overline{OP3}$  are connected to flip-flops, which store the attendant bits P1, P2 and P3 of the last PPE message.  $\overline{OP1}$ ,  $\overline{OP2}$  and  $\overline{OP3}$  have to be decoded externally and multiplexed to the DIO-lines when  $\overline{OPP}$  is LOW.

All other output stages are standard HE4000B family.

Most of the functions in the IEC/IEEE interface IC are realized with synchronous sequential logic, which is driven from the clock input CP. HIGH to LOW transitions are used to synchronize input signals and LOW to HIGH transitions trigger the internal flip-flops. In order to meet the IEC/IEEE timing specifications, the maximum clock frequency is 2 MHz. The maximum data transfer is then 200 kbytes/second.

Input  $\overline{Irdy}$  (not ready for next message) and output  $\overline{Odv}$  (data valid device) are intended for a two-wire handshake procedure between the acceptor function in the IC and the data input of the device (instrument to be connected to the interface system). The procedure is made so, that if the device reacts fast enough, the handshake procedure can be omitted by interconnecting  $\overline{Odv}$  and  $\overline{Irdy}$ . The conditions to be fulfilled by the device are:

- The device must be able to accept a data byte within one clock period after  $\overline{dvd}$  goes HIGH under all conditions.
- The device must be ready to process a data byte within two clock periods plus the minimum settling time of the talker devices under all conditions.

Input  $\overline{Inba}$  (not new byte available) and output  $\overline{Odc}$  (don't change data) are intended for a two-wire handshake procedure with the source function in the IC and the data output of the device (instrument). The procedure is so made that if the device reacts fast enough the handshake procedure can be omitted by interconnecting  $\overline{Odc}$  and  $\overline{Inba}$ . The conditions to be fulfilled by the device are:

- The device must be able to set a new data byte on the bus within one clock period after  $\overline{dcd}$  goes LOW under all conditions.
- The device must be able to have the next data byte available within seven clock periods under all conditions.

Input  $\overline{Isr}$  and output  $\overline{Ored}$  should be connected to an external parallel-in/serial-out (when  $\overline{Ored}$  is HIGH parallel-in, when LOW serial-out) shift register, which must be connected to the clock CP and must trigger on the LOW to HIGH transitions. The data on the parallel inputs of this external shift register are loaded in parallel and shifted-out via input  $\overline{Isr}$  into an internal shift register. The eleven serial input signals are in the order of shifting: A5, A4, A3, A2, A1, ton, lon, lt, rsv, rtl and ist. Signals A5, A4, A3, A2 and A1 represent the device talker and listener address. When signal lt (either listener or talker) is HIGH, a listener addressing sets the talker to the idle state and a talker addressing sets the listener to the idle state (subset T5 and L3). With lt LOW, the device can be addressed to be a listener and a talker. Because of the serial input procedure, all these input signals arrive in the interface functions of the IC between 16 and 32 clock cycles.

The signals ton, lon, rsv, rtl and ist are standard IEC/IEEE inputs. When using ton or lon no controller action is possible.

The output  $\overline{Oclr}$  or  $\overline{Otrg}$  is HIGH for one clock pulse if DCAS (device clear active state) or DTAS (device trigger active state) respectively is active.

The output  $Oloc$  is HIGH when  $LOCS$  (local state) or  $LWLS$  (local with lock-out state) is active. Output  $\overline{OSRQ}$  is HIGH when the  $rsv$  signal is read from the external shift register and the  $SRQS$  (request service state) is active. After this request has been answered by a serial poll,  $\overline{ORQS}$  is HIGH in the  $APRS$  (affirmative poll response state). The inverted signal on  $\overline{ORQS}$  must be multiplexed to bus-line  $DIO7$ , together with the status byte of the other  $DIO$  lines, when output  $Osp$  is HIGH in the  $SPAS$  (serial poll active state).

When the device is in the  $SPAS$  state the signal  $rsv$  may be removed (can be checked on  $\overline{ORQS}$ ).

N.B.: When the interface has asked for service via  $rsv$  and is addressed as talker in the serial poll mode, a handshake must be initialized by the device via  $\overline{Inba}$ .

Input  $Icats$  and output  $Otct$  are intended for use of this IC in a controller. When  $Icats$  is HIGH, the source handshake function will exit  $SIDS$  and  $SIWS$  and enter respectively  $SGNS$  and  $SWNS$ . When the controller function is not used, the input  $Icats$  must be connected to  $V_{SS}$ . Output  $Otct$  is HIGH if the  $tct$  message is sent over the interface and the  $ACDS$  state is active. A HIGH on input  $Ipon$  sets each function to its initial state. This level can be set to LOW after the IC has received 32 clock pulses at stabilized supply voltage.

 19 = OSRQ output SRQ not  
 21 = ORQS output RQS not  
 22 = Odcd output dcd  
 23 = ODAV output DAV not  
 29 = Osp output sp  
 30 = Ota output ta  
 32 = Oloc output loc  
 33 = Oclr output clr  
 34 = Otct output tct  
 35 = Otrg output trg

**Supply pins**

20 = VSS: more negative supply line  
 40 = VDD: more positive supply line

\* Isr is serial input for signals A5, A4, A3, A2, A1, ton, lon, lt, rsv, rtl and ist.

**Note**

Because the circuit uses positive logic and the bus uses negative logic, all inputs and outputs to the bus must be inverted. For that reason, all terminals that are working with the bus have mnemonics which are the inverted ones of those on the bus.

## LIST OF USED ABBREVIATIONS

A1 to A5	address	SGNS	source generate state
ACDS	acceptor data state	SIDS	source idle state
APRS	affirmative poll response state	SIWS	source idle wait state
ATN	attention	sp	serial poll
AVD	address valid	SPAS	serial poll active state
cats	controller active or transfer state	SPD	serial poll disable
clr	device clear	SPE	serial poll enable
CVD	command valid	sr	shift register
DAC	data accepted	SRQ	service request
DAV	data valid	SRQS	request service state
DCAS	device clear active state	SWNS	source wait for new cycle state
dcd	don't change data	ta	talker active
DCL	device clear	tct	talk control
DIO	data input output	ton	talk only
DTAS	device trigger active state	trg	trigger

## FREQUENCY SYNTHESIZER

The HEF4750V frequency synthesizer is one of a pair of LOC MOS devices, primarily intended for use in high-performance frequency synthesizers, e.g. in all communication, instrumentation, television and broadcast applications. A combination of analogue and digital techniques results in an integrated circuit that enables high performance. The complementary device is the universal divider type HEF4751V.

Together with a standard prescaler, the two LOC MOS integrated circuits offer low-cost single loop synthesizers with full professional performance. Salient features offered (in combination with HEF4751V) are:

- Wide choice of reference frequency using a single crystal.
- High-performance phase comparator — low phase noise — low spuri.
- System operation to  $> 1$  GHz.
- Typical 15 MHz input at 10 V.
- Flexible programming:
  - frequency offsets
  - ROM compatible
  - fractional channel capability.
- Programme range  $6\frac{1}{2}$  decades, including up to 3 decades of prescaler control.
- Division range extension by cascading.
- Built-in phase modulator.
- Fast lock feature.
- Out-of-lock indication.
- Low power dissipation and high noise immunity.

### APPLICATION INFORMATION

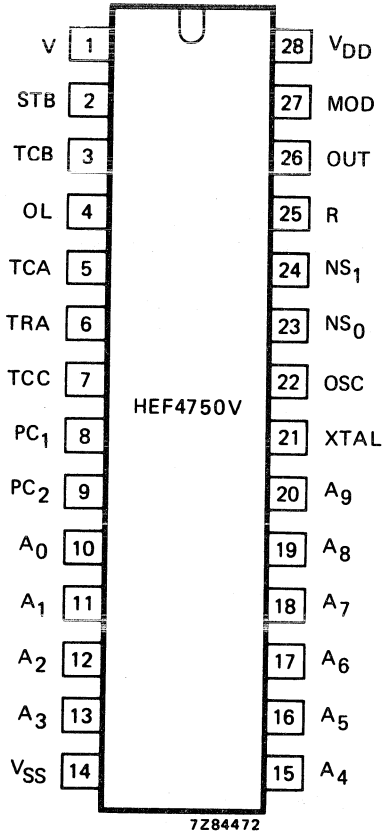

Some examples of applications for the HEF4750V in combination with the HEF4751V are:

- VHF/UHF mobile radios.
- HF s.s.b. transceivers.
- Airborne and marine communications and nav aids.
- Broadcast transmitters.
- High quality radio and television receivers.
- High performance citizens band equipment.

Fig. 2 Block diagram comprising five basic functions: phase comparator 1 (PC1), phase comparator 2 (PC2), phase modulator, reference oscillator and reference divider. These functions are described separately.

N.B. PC1 = analogue output; PC2 = 3-state output.

FUNCTIONAL DESCRIPTION

Phase comparator 1

Phase comparator 1 (PC1) is built around a SAMPLE and HOLD circuit. A negative-going transition at the V-input causes the hold capacitor ( $C_A$ ) to be discharged and after a specified delay, caused by the Phase Modulator by means of an internal  $V'$  pulse, it produces a positive-going ramp. A negative-going transition at the R-input terminates the ramp. Capacitor  $C_A$  holds the voltage that the ramp has attained. Via an internal sampling switch this voltage is transferred to  $C_C$  and in turn buffered and made available at output  $PC_1$ .

If the ramp terminates before an R-input is present, an internal end of ramp (EOR) signal is produced. These actions are illustrated in Fig. 3.

Fig. 3 Waveforms associated with PC1.

The resultant phase characteristic is shown in Fig. 4.

Fig. 4 Phase characteristic of PC1.

PC1 is designed to have a high gain, typically 3200 V/cycle (at 12,5 kHz). This enables a low noise performance.

**Phase comparator 2**

Phase comparator 2 (PC2) has a wide range, which enables faster lock times to be achieved than otherwise would be possible. It has a linear  $\pm 360^\circ$  phase range, which corresponds to a gain of typically 5 V/cycle. This digital phase comparator has three stable states:

- reset state,
- V' leads R state,
- R leads V' state.

Conversion from one state to another takes place according to the state diagram of Fig. 5.

Fig. 5 State diagram of PC2.

Output PC2 produces positive or negative-going pulses with variable width; they depend on the phase relationship of R and V'. The average output voltage is a linear function of the phase difference. Output PC2 remains in the high impedance OFF-state in the region in which PC1 operates. The resultant phase characteristic is shown in Fig. 6.

FUNCTIONAL DESCRIPTION (continued)

Fig. 6 Phase characteristic of PC<sub>2</sub>.

**Strobe function**

The strobe function is intended for applications requiring extremely fast lock times. In normal operation the additional strobe input (STB) can be connected to the V-input and the circuit will function as described in the previous sections.

In single, phase-locked-loop type frequency synthesizers, the comparison frequency generally used is either the nominal channel spacing or a sub-multiple. PC<sub>2</sub> runs at the higher frequency (a higher reference frequency must also be used), whilst strobing takes place on the lower frequency, thereby obtaining a decrease in lock time. In a system using the Universal Divider HEF4751V, the output OFS cycles on the lower frequency, the output OFF cycles on the higher frequency.

**Out-of-lock function**

There are a number of situations in which the system goes from the locked to the out-of-lock state (OL goes HIGH):

1. When V' leads R, however out of the range of PC<sub>1</sub>.
2. When R leads V'.
3. When an R-pulse is missing.
4. When a V-pulse is missing.
5. When two successive STB-commands occur, the first without corresponding V-signal.

**Phase modulator**

The phase modulator only uses one external capacitor, C<sub>B</sub> at pin TCB. A negative-going transition at the V-input causes C<sub>B</sub> to produce a positive-going linear ramp. When the ramp has reached a value almost equal to the modulation input voltage (at MOD), the ramp terminates, C<sub>B</sub> discharges and a start signal to the C<sub>A</sub>-ramp at TCA is produced. A linear phase modulation is reached in this way. If no modulation is required, the MOD-input must be connected to a fixed voltage of a certain positive value up to V<sub>DD</sub>. Care must be taken that the V' pulse is never smaller than the minimum value to ensure that the external capacitor of PC<sub>1</sub> (C<sub>A</sub>) can be discharged during that time. Since the V' pulse width is directly related to the TCB ramp duration, there is a requirement for the minimum value of this ramp duration.

**Reference oscillator**

The reference oscillator normally operates with an external crystal as shown in Fig. 2. The internal circuitry can be used as a buffer amplifier in case an external reference should be required.

**Reference divider**

The reference divider consists of a binary divider with a programmable division ratio of 1 to 1024 and a prescaler with selectable division ratios of 1, 2, 10 and 100, according to the following tables:

## ● Binary divider

N (A <sub>0</sub> to A <sub>9</sub> )	division ratio
0	1024
$0 \leq N \leq 1023$	N

## ● Prescaler

programming word (NS <sub>0</sub> , NS <sub>1</sub> )	division ratio
0	1
1	2
2	10
3	100

In this way suitable comparison frequencies can be obtained from a range of crystal frequencies. The divider can also be used as a 'stand alone' programmable divider by connecting input TRA to V<sub>DD</sub>, which causes all internal analogue currents to be switched off.

**Biasing circuitry**

The biasing circuitry uses an external current source or resistor, which has to be connected between the TRA and V<sub>SS</sub> pins. This circuitry supplies all analogue parts of the circuit. Consequently the analogue properties of the device, such as gain, charge currents, speed, power dissipation, impedance levels etc., are mainly determined by the value of the input current at TRA. The TRA input must be decoupled to V<sub>DD</sub>, as shown in Fig. 7. The value of C<sub>D</sub> has to be chosen such that the TRA input is 'clean', e.g. 10 nF at R<sub>A</sub> = 68 kΩ.

Fig. 7 Decoupling of input TRA.

## RATINGS

Limiting values in accordance with the Absolute Maximum System (IEC 134)

Supply voltage	$V_{DD}$	-0,5 to +15 V
Voltage on any input	$V_I$	-0,5 to $V_{DD} + 0,5$ V

## UNIVERSAL DIVIDER

The HEF4751V is a universal divider (U.D.) intended for use in high performance phase lock loop frequency synthesizer systems. It consists of a chain of counters operating in a programmable feedback mode. Programmable feedback signals are generated for up to three external (fast)  $\div 10/11$  prescaler.

The system comprising one HEF4751V U.D. together with prescalers is a fully programmable divider with a maximum configuration of: 5 decimal stages, a programmable mode M stage ( $1 \leq M \leq 16$ , non-decimal fraction channel selection), and a mode H stage ( $H = 1$  or  $2$ , stage for half channel offset). Programming is performed in BCD code in a bit-parallel, digit-serial format.

To accommodate fixed or variable frequency offset, two numbers are applied in parallel, one being subtracted from the other to produce the internal programme.

The decade selection address is generated by an internal programme counter which may run continuously or on demand. Two or more universal dividers can be cascaded, each extra U.D. (in slave mode) adds two decades to the system. The combination retains the full programmability and features of a single U.D. The U.D. provides a fast output signal FF at output OFF, which can have a phase jitter of  $\pm 1$  system input period, to allow fast frequency locking. The slow output signal FS at output OFS, which is jitter-free, is used for fine phase control at a lower speed.

X = state is immaterial

**PROGRAMME DATA INPUT** (see also Figs 3 and 4)

The programming process is timed and controlled by input PC and PE. When the programme enable (PE) input is HIGH, the positive edges of the programme clock (PC) signal step through the internal programme counter in a sequence of 8 states. Seven states define fetch periods, each indicated by a LOW signal at one of the corresponding data address outputs ( $\overline{OD}_0$  to  $\overline{OD}_6$ ). These data address signals may be used to address the external programme source. The data fetched from the programme source is applied to inputs  $\overline{A}_0$  to  $\overline{A}_3$  and  $\overline{B}_0$  to  $\overline{B}_3$ . When PC is LOW in a fetch period an internal load pulse is generated, the data is valid during this time and has to be stable. When PE is LOW, the programming cyclus is interrupted on the first positive edge of PC. On the next negative edge at input PC fetch period 6 is entered. Data may enter asynchronously in fetch period 6.

Ten blocks in the U.D. need programme input signals (see Fig. 2). Four of these ( $CO_b$ , C3, C4 and RSH) are concerned with the configuration of the U.D. and are programmed in fetch period 6. The remaining blocks (RS0 to RS4 and C1) are programmed with number P, consisting of six internal digits  $n_0$  to  $n_5$ .

$$P = (n_5 \cdot 10^4 + n_4 \cdot 10^3 + n_3 \cdot 10^2 + n_2 \cdot 10 + n_1) \cdot M + n_0$$

These digits are formed by a subtractor from two external numbers A and B and a borrow-in ( $b_{in}$ ).

$$P = A - B - b_{in} \text{ or if this result is negative; } P = A - B - b_{in} + M \cdot 10^5.$$

The numbers A and B, each consisting of six four bit digits  $n_{0A}$  to  $n_{5A}$  and  $n_{0B}$  to  $n_{5B}$ , are applied in fetch period 0 to 5 to the inputs  $\overline{A}_0$  to  $\overline{A}_3$  (data A) and  $\overline{B}_0$  to  $\overline{B}_3$  (data B) in binary coded negative logic.

$$A = (n_{5A} \cdot 10^4 + n_{4A} \cdot 10^3 + n_{3A} \cdot 10^2 + n_{2A} \cdot 10 + n_{1A}) \cdot M + n_{0A}.$$

$$B = (n_{5B} \cdot 10^4 + n_{4B} \cdot 10^3 + n_{3B} \cdot 10^2 + n_{2B} \cdot 10 + n_{1B}) \cdot M + n_{0B}.$$

Borrow-in ( $b_{in}$ ) is applied via input SI in fetch period 0 (SI = HIGH: borrow, SI = LOW: no borrow).

Counter C1 is automatically programmed with the most significant non-zero digit ( $n_{ms}$ ) from the internal digits  $n_5$  to  $n_2$  of number P. The counter chain C - 2 to C1 (see Fig. 3) is fully programmable by the use of pulse rate feedback.

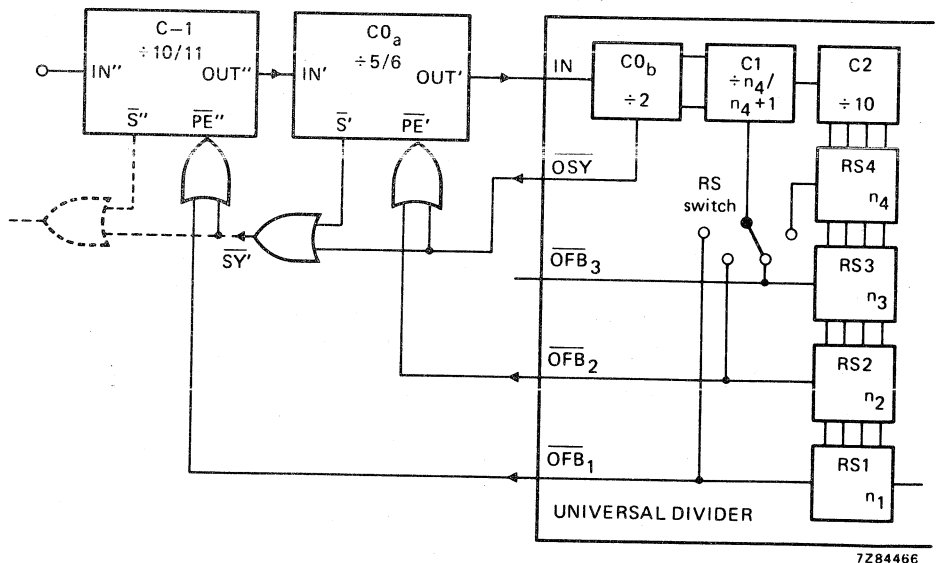

Rate feedback is generated by the rate selectors RS4 to RS0 and RSH, which are programmed with digits  $n_4$  to  $n_0$  and  $n_h$  respectively. In fetch period 6 the fractional counter C3, half channel counter C4 and  $CO_b$  are programmed and configured via data B inputs. Counter C3 is programmed in fetch period 6 via data A inputs in negative logic (except all HIGH is understood as:  $M = 16$ ). The counter C0 is a side steppable 10/11 counter composed of an internal part  $CO_b$  and an external part  $CO_a$ .  $CO_b$  is configured via  $\overline{B}_3$  and  $\overline{B}_2$  to a division ratio of 1 or 2 or 5 or 10/11;  $CO_a$  must have the complementary ratio 10/11 or 5/6 or 2/3 or 1 respectively. In the latter case  $CO_b$  comprises the whole C0 counter with internal feedback,  $CO_a$  is then not required.

The half channel counter C4 is enabled with  $\overline{B}_0 = \text{HIGH}$  and disabled with  $\overline{B}_0 = \text{LOW}$ . With C4 enabled, a half channel offset can be programmed with input  $\overline{B}_1 = \text{HIGH}$ , and no offset with  $\overline{B}_1 = \text{LOW}$ .

### FEEDBACK TO PRESCALERS (see also Figs 5 and 6)

The counters C1, C0, C-1 and C-2 are side-steppable counters, i.e. its division ratio may be increased by one, by applying a pulse to a control terminal for the duration of one division cycle. Counter C2 has 10 states, which are accessible as timing signals for the rate selectors RS1 to RS4. A rate selector, programmed with  $n$  ( $n_1$  to  $n_4$  in the U.D.) generates  $n$  of 10 basic timing periods an active signal. Since  $n \leq 9$ , 1 of 10 periods is always non-active. In this period RS1 transfers the output of rate selector RS0, which is timed by counter C3 and programmed with  $n_0$ . Similarly, RS0 transfers RSH output during one period of C3. Rate selector RSH is timed by C4 and programmed with  $n_1$ . In one of the two states of C4, if enabled, or always, if C4 is disabled, RSH transfers the LOW active signal at input  $\bar{R}1$  to RS0. If  $\bar{R}1$  is not used it must be connected to HIGH. The feedback output signals of RS1, RS2 and RS3 are externally available as active LOW signals at outputs  $\overline{OFB}_1$ ,  $\overline{OFB}_2$  and  $\overline{OFB}_3$ .

Output  $\overline{OFB}_1$  is intended for the prescaler at the highest frequency (if present),  $\overline{OFB}_2$  for the next (if present) and  $\overline{OFB}_3$  for the lowest frequency prescaler (if present). A prescaler needs a feedback signal, which is timed on one of its own division cycles in a basic timing period. The timing signal at  $\overline{OSY}$  is LOW during the last U.D. input period of a basic timing period and is suitable for timing of the feedback for the last external prescaler. The synchronization signal for a preceding prescaler is the OR-function of the sync. input and sync. output of the following prescaler (all sync. signals active LOW).

7284466

Fig. 5 Block diagram showing feedback to prescalers.

Fig. 6 Timing diagram showing signals occurring in Fig. 5.

**CASCADING OF U.D.s** (see also Fig. 8)

A U.D. is programmed into the 'slave' mode by the programme input data:  $n_{2A} = 11$ ,  $n_{2B} = 10$ ,  $n_{3A} = n_{4A} = n_{3B} = n_{4B} = n_{5B} = 0$ . A U.D. operating in the slave mode performs the function of two extra programmable stages C2' and C3' to a 'master' (not slave) mode operating U.D. More slave U.D.s may be used, every slave adding two lower significant digits to the system.

Output  $\overline{OFB}_3$  is converted to the borrow output of the programme data subtractor, which is valid after fetch period 5. Input SI is the borrow input (both in master and in slave mode), which has to be valid in fetch period 0. Input SI has to be connected to output  $\overline{OFB}_3$  of a following slave, if not present, to LOW. For proper transfer of the borrow from a lower to a higher significant U.D. subtractor, the U.D.s have to be programmed sequentially in order of significance or synchronously if the programme is repeated at least the number of U.D.s in the system.

Rate input  $\overline{RI}$  and output OFS must be connected to rate output  $\overline{OFB}_1$  and the input IN of the next slave U.D. The combination thus formed retains the full programmability and features of one U.D.

**OUTPUT** (see also Fig. 7)

The normal output of the U.D. is the slow output OFS, which consists of evenly spaced LOW pulses. This output is intended for accurate phase comparison. If a better frequency acquisition time is required, the fast output OFF can be used. The output frequency on OFF is a factor  $M \cdot H$  higher than the frequency on OFS. However, phase jitter of maximum  $\pm 1$  system input period occurs at OFF, since the division ratio of the counters preceding OFF are varied by slow feedback pulse trains from rate selectors following OFF.

## A.C. MOTOR CONTROL CIRCUIT

The HEF4752V is a circuit for a.c. motor speed control utilizing LOCMOS technology. The circuit synthesizes three 120° out of phase signals, of which the average voltage varies sinusoidally with time in the frequency range 0 to 200 Hz. The method employed is based upon the pulse width modulation principle, in order to achieve a sufficient accuracy of the output voltages over the whole frequency range. A pure digital waveform generation is used.

All outputs are of the push-pull type. Inputs and outputs are protected against electrostatic effects in a wide variety of device-handling situations. However, to be totally safe, it is desirable to take handling precautions into account.

**APPLICATION INFORMATION**

Figure 2 shows the functional block diagram of a 3-phase a.c. motor speed control system using a thyristorized inverter with variable frequency output. The inverter control signals are generated by the HEF4752V (PWM-IC). A special feature of the PWM (Pulse-Width Modulation) - IC is here, that the motor is supplied by sinoidally modulated pulses, hence the resulting motor current will approach a sine-wave with a minimum on higher harmonics. In this way, an optimum speed drive with high performance is obtained.

Furthermore, the HEF4752V contains all logic circuitry required for this special waveform generation, so that the amount of control circuit components is reduced considerable. The speed drive system in Fig. 2 is controlled by the analogue control section.

The FCT and VCT clock pulse oscillators are driven in such a way, that a fast response speed control of the a.c. motor is obtained, depending on: the reference values for speed; motor voltage; motor current (Limited by the measured motor current via DCCT - d.c. current transformer -); the increasing value of  $V_{Cb}$  during braking action.

## UNIVERSAL TIMER MODULE

The HEF4753B is a universal timer module for counting and dividing as well as for event-recognition and manipulation of input sequences.

The following functions are included: synchronization and edge-detection of the input signal, programmable counter, clock divider with different lengths, operating mode decoder, control logic and output multiplexer.

Depending on the operating mode and the application, the circuit works as a presettable 8-bit counter with transient-pulse suppression, pulse duration selector divider, counter, positive or negative edge delaying module or low-frequency control circuit.

All manipulation possibilities depend on a time scaling, which is adjustable by the 8-bit programmable counter and the system clock. The system clock can be divided internally by 1, 16, 256 or 4096 as input clock for the counter. In all cases the manipulated input sequence appears at the only output OUT.

## FUNCTIONAL DESCRIPTION

### Clock divider and decoder

The clock signal at input CP is, at its original frequency, the system clock, but it also drives the programmable counter. The counter input frequency can be predivided by the factors 1/16, 1/256 and 1/4096, depending on the logic state of inputs W and X (according to the function tables above).

### 8-bit programmable counter

The 8 inputs A to H are the set inputs of the 8 counter flip-flops. The setting is triggered by an edge of the input signal (at input IN) depending on of the chosen mode.

**Event flip-flops, synchronization and edge-detection**

The event flip-flops are used to recognize the positive and/or negative edge of the input signal at IN. Parts of the flip-flops are used together with the programmable 8-bit counter as a retriggerable mono-flop, which defines the time scaling for event recognition. The input IN is synchronized by the clock signal CP.

**Mode switch and output multiplexer**

This function switches the chosen output to the output (OUT) and gives the mode of which the edge at input IN has to be detected. The inputs Z, Y and LFC give 7 modes +1, that means in mode 'Digital Filter' the input LFC can be HIGH or LOW.

**OPERATING MODES**

The circuit has 6 operating modes which are activated by the logic state of inputs LFC, Y and Z. An extra mode is possible by using two circuits which are connected such so they function as a digital band-filter.

**1. Counter mode (LFC = LOW; Y = LOW; Z = HIGH)**

In this mode the output OUT should be connected to input IN. If not, only one counter cycle starts after a transition at input IN (see Fig. 3 and note 1).

Fig. 3 Timing diagram for counter mode;  $t_1$  = delay until set of 8-bit counter;  $t_2$  = delay to set 8-bit counter;  $t_3$  = predefined delay by programming.

OPERATING MODES (continued)

2. Divider mode (LFC = LOW; Y = HIGH; Z = LOW)

In this mode the output OUT should be connected to input IN. If not, only one counter cycle starts after a transition at input IN (see Fig. 4 and note 1).

Fig. 4 Timing diagram for divider mode;  $t_1$  = delay until set of 8-bit counter;  $t_2, t_3$  see Fig. 3.

3. Delayed LOW to HIGH edge mode; see note 2 (LFC = HIGH; Y = HIGH; Z = LOW)

Fig. 5 Timing diagram for delayed LOW to HIGH edge mode;  $t_1$  = delay until set of 8-bit counter;  $t_2$  = delay to set 8-bit counter;  $t_3$  = predefined delay by programming;  $t_4$  = delay until next negative clock edge;  $t_5$  = delay until next positive clock edge.

4. Delayed HIGH to LOW edge mode; see note 2 (LFC = HIGH; Y = LOW; Z = HIGH)

Fig. 6 Timing diagram for delayed HIGH to LOW edge mode; for  $t_1$  to  $t_5$  see Fig. 5.

5. Transient pulse suppression and pulse delaying mode; see note 2 (LFC = Y = Z = HIGH)

In this mode the circuit is working as a digital low-pass filter. An undisturbed pulse will only be delayed (see Fig. 7).

Fig. 7 Timing diagram for transient pulse suppression and pulse delaying mode; for  $t_1$ ,  $t_2$  and  $t_3$  see Fig. 5.

OPERATING MODES (continued)

6. Frequency recognition mode (LFC = LOW; Y = HIGH; Z = HIGH)

The incoming signal must be symmetrical within the limits as given by the specified delay time in note 2, to achieve lower or higher frequency detection (see Fig. 8).

Minimum dividing number is 3.

Fig. 8 Timing diagram for frequency recognition mode;  $t_x$  = time shorter than  $t_3$  (OUT = H);  $t_y$  = time greater than  $t_3$  (OUT = L); for  $t_1$ ,  $t_2$  and  $t_3$  see Fig. 5.

7. Digital pulse duration selector mode (Y = Z = LOW)

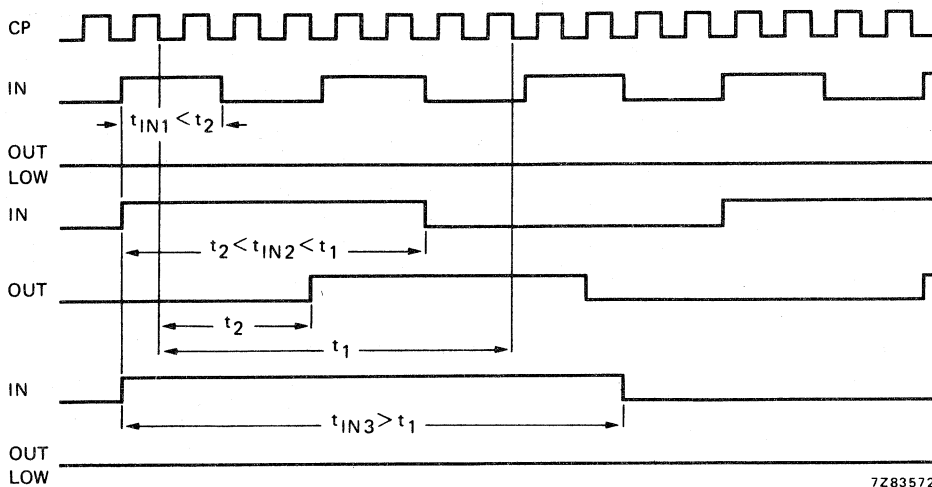

This mode is a combination of two circuits, both used for frequency recognition. Both circuits are driven by the same clock and same input signal, but programmed for different frequencies. The LFC input of the low-frequency circuit is set to logic LOW, the output is connected to the LFC input of the high-frequency circuit, whose output (OUT) is the 'filter' output. The delay time depends on the same facts as given in note 2. For timing diagram see Fig. 9.

A	B	C	D	E	F	G	H	W	X	LFC	Y	Z	
L	L	L	H	H	H	H	H	L	L	L	H	H	IC1
L	L	H	H	H	H	H	H	L	L	OUT (IC1)	L	L	IC2

Minimum dividing number is 3.

7283572

Fig. 9 Timing diagram for digital pulse duration selector mode;  $t_{IN1}$ ,  $t_{IN2}$  and  $t_{IN3}$  are the IN input pulse durations;  $t_1$  = predefined delay by programming IC1;  $t_2$  = predefined delay by programming IC2.

#### Notes to operating modes

1. The number of clocks for one cycle in the counter and divider mode is:
  - a. Contents of programmable counter plus one if  $X = W = \text{LOW}$ .
  - b. Contents of programmable counter multiplied by 16, 256 or 4096 if X and/or W = HIGH.
2. The delay in the modes 3, 4, 6 and 7, and the delay which is identical to the maximum duration of the transient pulse in mode 5 depend on the optional divided clock frequency, the input conditions of the 8-bit presetable counter and in addition, different times of propagation delays, jitter and maximum one half of a clock frequency period.

H	L	X	thermometer; no peak value
H	H	L	thermometer; peak value, repetitively reset
H	H	H	thermometer; peak value, manually reset

H = HIGH state (the more positive voltage)

L = LOW state (the less positive voltage)

X = state is immaterial

**GENERAL DESCRIPTION**

The HEF4754V drives an 18-element bar graph LCD in linear relation to the control voltage ( $V_C$ ) in a pointer or thermometer mode. The first bar lights up when  $V_C$  is smaller than  $V_{T(\text{bar})2}$  (see equation [3] below).

In the pointer mode, the circuit can drive 9 or 18 bars; in the thermometer mode, the circuit also drives the peak value indication. This can be reset or repetitively reset, after 1,5 to 2 seconds.

The circuit has analogue and digital parts. The analogue part consists of 17 comparators, with their non-inverting inputs connected together and coupled to the control input  $V_C$ . The inverting inputs of the comparators are connected in succession to the nodes of an 18-part resistor divider. The distance between the switching levels of the comparators is defined by the voltage difference across this divider. The extremities of the resistor divider are coupled via high-input amplifiers to the maximum reference voltage input and the minimum reference voltage input.

The digital part has one reference output ( $O_R$ ) to drive the back plate, and 18 outputs ( $O_1$  to  $O_{18}$ ) to drive each bar. Three latches and some gates are incorporated for each bar output. An on-chip oscillator (1024 Hz) with external R and C drives the circuit. The outputs are driven at 64 Hz. The select inputs  $I_1$  to  $I_3$  are provided with an on-chip pull-up element, and they may therefore be left floating (equals HIGH state).

**LINEARITY**

$V_{DD} = 10 \text{ V}$ ;  $V_{\text{ref max}} = 9,5 \text{ V}$ ;  $V_{\text{ref min}} = 0,5 \text{ V}$ ;  $T_{\text{amb}} = 25 \text{ }^\circ\text{C}$   
 $\Delta V_1 = 250 \text{ mV}$  (this is the tolerance of the step voltage).

$$V_{\text{step}} = V_{\text{step}'} + \Delta V_1 \quad [1]$$

$V_{\text{step}'}$  is the (internal) voltage drop across the resistor-ladder network.

$$V_{\text{step}'} = \frac{(V_{\text{ref max}} \pm \Delta V_2) - (V_{\text{ref min}} \pm \Delta V_2)}{18} \quad [2]$$

$\Delta V_2$  is the maximum offset voltage spread of the on-chip voltage follower.

$\Delta V_2 = 250 \text{ mV}$ .

The linearity is guaranteed for  $V_{DD} > 10 \text{ V}$ .

The monotony between  $V_{DD} = 5 \text{ V}$  and  $10 \text{ V}$  is guaranteed. During ramping-up of the input voltage a maximum of two bars might be activated simultaneously.

**ABSOLUTE VOLTAGE TRIGGER LEVEL**

The absolute voltage trigger level at the  $V_C$  pin is  $V_{T(\text{bar})n}$ :

$$V_{T(\text{bar})n} = (V_{\text{ref min}} \pm \Delta V_2^*) + \{ (n-1) V_{\text{step}'} \pm \Delta V_1 \}, \text{ in which} \quad [3]$$

$n$  = number of bars;  $2 \leq n \leq 18$ .

For  $n = 1$  (first bar) see text above.

\* For  $\Delta V_2$  the same sign (+ or -) should be used as in equation [2].

# DEVELOPMENT SAMPLE DATA

This information is derived from development samples made available for evaluation. It does not necessarily imply that the device will go into regular production.

HEF4755V  
LSI

## TRANSCEIVER FOR SERIAL DATA COMMUNICATION

The HEF4755V transceiver is a circuit for serial data communication. It provides maximum transmission security and effectiveness. Therefore, in addition to the normal precautions, it contains a programmable digital bit-check, a programmable CRC (Cyclic Redundancy Check; Hamming distance 4 or 6) and format protection.

The circuit has 8 possible operating modes:

- synchronous
  - error checking only
  - receiving
  - transmitting
  - receiving with data out and transmitting the same message
- asynchronous
  - error checking only
  - receiving
  - transmitting
  - receiving with data out and transmitting of a regenerated message.

### FEATURES

- Transmission rate: 

V <sub>DD</sub>	synchronous	asynchronous
5 V	0,8 Mbaud	31 kbaud
7 V	1,6 Mbaud	62 kbaud
10 V	3,2 Mbaud	125 kbaud
- Inputs: standard LOC MOS
- Outputs: TTL compatible (1 TTL load)
- Operating ambient temperature range: -40 to + 85 °C
- Transmit or receive a serial binary data stream
- Start bit generation and recognition
- Format protection and checking
- Redundancy byte generation and checking
- Digital bit check
- Error recognition and error distinguishing
- 8-bit parallel input/output transfer

### SUPPLY VOLTAGE/CURRENT

rating	recommended operating
V <sub>DD</sub> -0,5 to + 15	4,75 to 12,6 V
I <sub>SS</sub> 30	- mA

## PINNING

1	TST	Test pin; during normal use connected to $V_{SS}$ . When TST is HIGH ( $V_{DD}$ ), internal check points are connected to the data bus.
2	MLO	Input code for message length (see Table 1).
3	ML1	
4	DIO0	Bidirectional data bus.
5	DIO1	
6	DIO2	
7	DIO3	
8	DIO4	Mode input: receive Mode input: transmit Mode input: asynchronous } see Table 2
9	DIO5	
10	DIO6	
11	DIO7	Reset; a positive signal resets all internal registers.
12	RX	Input start in transmitting mode; synchronization input (from MOS) in synchronous receiving mode.
13	TX	Output busy; active during receiving or transmitting a message.
15	AS	Hamming distance; determines the length of the redundancy byte: LOW = 7 bit (HD = 4) HIGH = 15 bit (HD = 6)
16	R	Output message synchronization used in synchronous mode.
17	START	Message output.
18	BUSY	Message input.
19	HD	Output data pulse; take-over pulse for data on the data bus.
20	MOS	Output error; an active output means that at least 1 transmission error is recognized.
21	MO	Clock input; in synchronous mode equal to the transmission bit rate.
22	MI	Programming of the permissible time tolerance in bit distortion (see Table 3).
23	DP	
24	ERR	Positive supply voltage; 4,5 V to 12,5 V (is the logic HIGH level).
25	CP	Ground (is the logic LOW level).
26	TT1	
27	TT0	
28	$V_{DD}$	
14	$V_{SS}$	

**Table 1** Input code for message length

7284754

**FUNCTIONAL DESCRIPTION****General**

The HEF4755V is used for protected-bit serial data communication. This protection makes it necessary to subdivide the serial data stream into data blocks called messages.

**Messages**

In the synchronous mode the HEF4755V will transmit or receive a message as follows:

The first bit of a transmitted message is the start-bit which cannot be mis interpreted. It instructs the receiver, that information transfer has started and it defines the time-window for the following bits. The start-bit is only necessary in the asynchronous mode and it is omitted in the synchronous mode. The first byte contains the number of data bytes that will follow. This byte is checked by the receiver and if a discrepancy is found, the receiver reports a code-error. This first byte is called 'size'. The number of data bytes can also be fixed by wiring of the transmitter as well as the receiver. In this case the size byte is omitted.

There is no protocol on the information of the data bytes, so the maximum number of informations per message is  $2^{56} \approx 10^{17}$ .

The redundancy check byte secures the data bytes against transmission errors. This byte is calculated in parallel to the data stream and it is send as last byte by the transmitter. The receiver calculates its own redundancy byte and compares it with the received one. If there is a discrepancy, the receiver reports a code error.

**Code protection***Size*

The coding of the size byte is as follows:

$$\left. \begin{array}{l} \text{DIO0} = \text{C} \\ \text{DIO1} = \text{B} \\ \text{DIO2} = \text{A} \\ \text{DIO3} = \text{P} \end{array} \right\} n = \text{C} \cdot 2^2 + \text{B} \cdot 2^1 + \text{A} \cdot 2^0$$

$$= \overline{\text{C} \oplus \text{B} \oplus \text{A}}$$

The information is transmitted as follows:

With this, a hamming distance of 4 is obtained.

**FUNCTIONAL DESCRIPTION** (continued)*Redundancy byte*

The redundancy byte completes the data bytes with 15 (7) bits as a code word. If only one bit in the information has changed during the transmission, the two code words will differ by at least 6 (4) bit positions. So a change of up to 5 (3) bits will always be observed, even every odd number of false bits will be recognized. The HEF4755V has a programmable redundancy bit calculator which carries out this protection (the numbers given in parentheses are valid for the alternative possibility).

If the transmission line carries extreme noise, this kind of message protection is less effective. In this case, the message is protected by checking bit-per-bit in a smaller time scale (see 'bit protection' below).

**Bit protection**

The HEF4755V checks every received bit within the time window defined by the start-bit. The programmed time tolerance (19%, 25%, 31% and 37%) determines that the bit protection circuit decides after 32 samples which bit is a true logic HIGH or LOW level, or an error. In the latter case, there are too many samples HIGH to obtain a LOW and, too many samples LOW to obtain a HIGH.

**Transmitting**

In the transmitting mode the HEF4755V uses the data pulse signal (DP, pin 23) to take 8 bits from the data bus. These parallel bits are shifted serially to the message output (MO).

**Receiving**

In the receiving mode the HEF4755V receives serial bits at the message input (MI). The circuit checks the message for transmission errors and, with every data pulse, 8 bits are transferred in parallel to the data bus. Every recognized error is stored and the error output is activated. The kind of error can be recognized by reading the status register over the data bus.

**Asynchronous and synchronous mode**

If only one transmission line is available, then the receiver waits for the start-bit, synchronizes itself on the start bit and receives all the data bits of one message. This is called the *asynchronous mode*. By using 3 transmission lines, the circuit can go to the *synchronous mode*. In this case it is possible to transmit also the clock signal (CP) and message synchronization signal (MOS) in parallel with the data bits. The start bit and the bit check are omitted. In the synchronous mode the maximum transmission speed is 32 times the maximum speed in the asynchronous mode.

In asynchronous receive mode a reset pulse is necessary between two messages. It is possible to derive this reset pulse from the busy signal by using hardware. The duration of the START-pulse at the transmitter must always be shorter than the message to be transferred. A good procedure for achieving this is to use the BUSY-signal to end the START-pulse. The recovery time between two messages must be at least two bit periods. During this time, the line must remain stable to prevent generation of an error. This must be ensured with external hardware/software.

In the synchronous receive mode, the duration of the START-pulse at the transmitter must always be shorter than the message to be transferred. A good procedure for achieving this is to use the BUSY-signal to end the START-pulse. A continuous START-signal will cause malfunction. The recovery time between two messages must be at least one bit period. During this time, the message line must remain stable. A good way to achieve this is to use the trailing-edge of the BUSY-signal to generate a START-signal. In practice, if data is delivered to the transmitter fast enough, START can be  $\overline{\text{BUSY}}$ . If the lines have different delays, the message line should have the longest delay. If it is not certain which line has the longest delay it is possible to phase-shift the clock signal of the receiver by inverting it. This is only possible with point-to-point lines.

# HEX INVERTING SCHMITT TRIGGER

Each circuit of the HEF40106B functions as an inverter with Schmitt-trigger action. The Schmitt-trigger switches at different points for the positive and negative-going input signals. The difference between the positive-going voltage ( $V_p$ ) and the negative-going voltage ( $V_N$ ) is defined as hysteresis voltage ( $V_H$ ).

This device may be used for enhanced noise immunity or to "square up" slowly changing waveforms.

Fig. 1 Functional diagram.

Fig. 9 Typical switching levels as a function of supply voltage  $V_{DD}$ ;  $T_{amb} = 25\text{ }^{\circ}\text{C}$ .

Fig. 10 Schmitt trigger driven via a high impedance ( $R > 1\text{ k}\Omega$ ).

If a Schmitt trigger is driven via a high impedance ( $R > 1\text{ k}\Omega$ ) then it is necessary to incorporate a capacitor  $C$  of such value that:  $\frac{C}{C_p} > \frac{V_{DD}-V_{SS}}{V_H}$ , otherwise oscillation can occur on the edges of a pulse.

$C_p$  is the external parasitic capacitance between input and output; the value depends on the circuit board layout.

**APPLICATION INFORMATION**

Some examples of applications for the HEF40106B are:

- Wave and pulse shapers
- Astable multivibrators
- Monostable multivibrators.

Fig. 11 The HEF40106B used as an astable multivibrator.

## 4-BIT SYNCHRONOUS DECADE COUNTER WITH ASYNCHRONOUS RESET

The HEF40160B is a fully synchronous edge-triggered 4-bit decade counter with a clock input (CP), an overriding asynchronous master reset ( $\overline{MR}$ ), four parallel data inputs ( $P_0$  to  $P_3$ ), three synchronous mode control inputs (parallel enable ( $\overline{PE}$ ), count enable parallel (CEP) and count enable trickle (CET)), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and a terminal count output (TC).

Operation is fully synchronous (except for the  $\overline{MR}$  input) and occurs on the LOW to HIGH transition of CP. When  $\overline{PE}$  is LOW, the next LOW to HIGH transition of CP loads data into the counter from  $P_0$  to  $P_3$  regardless of the levels of CEP and CET inputs.

When  $\overline{PE}$  is HIGH, the next LOW to HIGH transition of CP advances the counter to its next state only if both CEP and CET are HIGH; otherwise, no change occurs in the state of the counter. TC is HIGH when the state of the counter is 9 ( $O_0 = O_3 = \text{HIGH}$ ,  $O_1 = O_2 = \text{LOW}$ ) and when CET is HIGH. A LOW on  $\overline{MR}$  sets all outputs ( $O_0$  to  $O_3$  and TC) LOW, independent of the state of all other inputs. Multistage synchronous counting is possible without additional components by using a carry look-ahead counting technique; in this case, TC is used to enable successive cascaded stages. CEP, CET and  $\overline{PE}$  must be stable only during the set-up time before the LOW to HIGH transition of CP.

**APPLICATION INFORMATION**

An example of an application for the HEF40160B is:

- Programmable decade counter.

clock

**NOTE**

On the TC outputs, glitches can occur during counting. In totally synchronous mode they will not have any adverse affect. However the TC output in asynchronous mode can cause problems.

Fig. 10 Synchronous multi-stage counting scheme.

## 4-BIT SYNCHRONOUS BINARY COUNTER WITH ASYNCHRONOUS RESET

The HEF40161B is a fully synchronous edge-triggered 4-bit binary counter with a clock input (CP), an overriding asynchronous master reset ( $\overline{MR}$ ), four parallel data inputs ( $P_0$  to  $P_3$ ), three synchronous mode control inputs (parallel enable (PE), count enable parallel (CEP) and count enable trickle (CET)), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and a terminal count output (TC).

Operation is fully synchronous (except for the  $\overline{MR}$  input) and occurs on the LOW to HIGH transition of CP. When  $\overline{PE}$  is LOW, the next LOW to HIGH transition of CP loads data into the counter from  $P_0$  to  $P_3$  regardless of the levels of CEP and CET inputs.

When  $\overline{PE}$  is HIGH, the next LOW to HIGH transition of CP advances the counter to its next state only if both CEP and CET are HIGH; otherwise, no change occurs in the state of the counter. TC is HIGH when the state of the counter is 15 ( $O_1$  to  $O_3 = \text{HIGH}$ ) and when CET is HIGH. A LOW on  $\overline{MR}$  sets all outputs ( $O_0$  to  $O_3$  and TC) LOW, independent of the state of all other inputs. Multistage synchronous counting is possible without additional components by using a carry look-ahead counting technique; in this case, TC is used to enable successive cascaded stages. CEP, CET and PE must be stable only during the set-up time before the LOW to HIGH transition of CP.

## 4-BIT SYNCHRONOUS DECADE COUNTER WITH SYNCHRONOUS RESET

The HEF40162B is a fully synchronous edge-triggered 4-bit decade counter with a clock input (CP), four synchronous parallel data inputs ( $P_0$  to  $P_3$ ), four synchronous mode control inputs (parallel enable ( $\overline{PE}$ ), count enable parallel (CEP), count enable trickle (CET) and synchronous reset ( $\overline{SR}$ )), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and a terminal count output (TC).

Operation is synchronous and occurs on the LOW to HIGH transition of CP. When  $\overline{PE}$  is LOW, the next LOW to HIGH transition of CP loads data into the counter from  $P_0$  to  $P_3$ . When  $\overline{PE}$  is HIGH, the next LOW to HIGH transition of CP advances the counter to its next state only if both CEP and CET are HIGH; otherwise no change occurs in the state of the counter. TC is HIGH when the state of the counter is 9 ( $O_0 = O_3 = \text{HIGH}$ ,  $O_1 = O_2 = \text{LOW}$ ) and when CET is HIGH. A LOW on  $\overline{SR}$  sets all outputs ( $O_0$  to  $O_3$  and TC) LOW on the next LOW to HIGH transition of CP, independent of the state of all other synchronous mode control inputs (CEP, CET and  $\overline{PE}$ ). Multistage synchronous counting is possible without additional components by using a carry look-ahead counting technique; in this case, TC is used to enable successive cascaded stages. CEP, CET,  $\overline{PE}$  and  $\overline{SR}$  must be stable only during the set-up time before the LOW to HIGH transition of CP.

**APPLICATION INFORMATION**

An example of an application for the HEF40162B is:

- Programmable decade counter.

clock

**NOTE**

On the TC outputs, glitches can occur during counting. In totally synchronous mode they will not have any adverse affect. However the TC output in asynchronous mode can cause problems.

Fig. 10 Synchronous multi-stage counting scheme.

## 4-BIT SYNCHRONOUS BINARY COUNTER WITH SYNCHRONOUS RESET

The HEF40163B is a fully synchronous edge-triggered 4-bit binary counter with a clock input (CP), four synchronous parallel data inputs ( $P_0$  to  $P_3$ ), four synchronous mode control inputs (parallel enable ( $\overline{PE}$ ), count enable parallel (CEP), count enable trickle (CET) and synchronous reset ( $\overline{SR}$ )), buffered outputs from all four bit positions ( $O_0$  to  $O_3$ ) and a terminal count output (TC).

Operation is fully synchronous and occurs on the LOW to HIGH transition of CP. When  $\overline{PE}$  is LOW, the next LOW to HIGH transition of CP loads data into the counter from  $P_0$  to  $P_3$ . When  $\overline{PE}$  is HIGH, the next LOW to HIGH transition of CP advances the counter to its next state only if both CEP and CET are HIGH; otherwise no change occurs in the state of the counter. TC is HIGH when the state of the counter is 15 ( $O_0$  to  $O_3$  = HIGH) and when CET is HIGH. A LOW on  $\overline{SR}$  sets all outputs ( $O_0$  to  $O_3$  and TC) LOW on the next LOW to HIGH transition of CP, independent of the state of all other synchronous mode control inputs (CEP, CET and  $\overline{PE}$ ). Multistage synchronous counting is possible without additional components by using a carry look-ahead counting technique; in this case, TC is used to enable successive cascaded stages. CEP, CET,  $\overline{PE}$  and  $\overline{SR}$  must be stable only during the set-up time before the LOW to HIGH transition of CP.

**APPLICATION INFORMATION**

An example of an application for the HEF40163B is:

- Programmable binary counter.

**NOTE**

On the TC outputs, glitches can occur during counting. In totally synchronous mode they will not have any adverse affect. However the TC output in asynchronous mode can cause problems.

Fig. 10 Synchronous multi-stage counting scheme.

## HEX D-TYPE FLIP-FLOP

The HEF40174B is a hex edge-triggered D-type flip-flop with six data inputs ( $D_0$  to  $D_5$ ), a clock input (CP), an overriding asynchronous master reset input ( $\overline{MR}$ ), and six buffered outputs ( $O_0$  to  $O_5$ ). Information on  $D_0$  to  $D_5$  is transferred to  $O_0$  to  $O_5$  on the LOW to HIGH transition of CP if  $\overline{MR}$  is HIGH. When LOW,  $\overline{MR}$  resets all flip-flops ( $O_0$  to  $O_5 = \text{LOW}$ ) independent of CP and  $D_0$  to  $D_5$ .

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

## APPLICATION INFORMATION

Some examples of applications for the HEF40175B are:

- Shift registers
- Buffer/storage register
- Pattern generator

## 4-BIT UP/DOWN DECADE COUNTER

The HEF40192B is a 4-bit synchronous up/down decade counter. The counter has a count-up clock input ( $CP_U$ ), a count-down clock input ( $CP_D$ ), an asynchronous parallel load input ( $\overline{PL}$ ), four parallel data inputs ( $P_0$  to  $P_3$ ), an asynchronous master reset input ( $MR$ ), four counter outputs ( $O_0$  to  $O_3$ ), an active LOW terminal count-up (carry) output ( $\overline{TC}_U$ ) and an active LOW terminal count-down (borrow) output ( $\overline{TC}_D$ ).

The counter outputs change state on the LOW to HIGH transition of either clock input. However, for correct counting, both clock inputs cannot be LOW simultaneously. The outputs  $\overline{TC}_U$  and  $\overline{TC}_D$  are normally HIGH. When the circuit has reached the maximum count state of '9', the next HIGH to LOW transition of  $CP_U$  will cause  $\overline{TC}_U$  to go LOW.  $\overline{TC}_U$  will stay LOW until  $CP_U$  goes HIGH again. Likewise, output  $\overline{TC}_D$  will go LOW when the circuit is in the zero state and  $CP_D$  goes LOW. When  $\overline{PL}$  is LOW, the information on  $P_0$  to  $P_3$  is asynchronously loaded into the counter. A HIGH on  $MR$  resets the counter independent of all other input conditions. The counter stages are of a static toggle type flip-flop.

## 4-BIT UP/DOWN BINARY COUNTER

The HEF40193B is a 4-bit synchronous up/down binary counter. The counter has a count-up clock input ( $CP_U$ ), a count-down clock input ( $CP_D$ ), an asynchronous parallel load input ( $\overline{PL}$ ), four parallel data inputs ( $P_0$  to  $P_3$ ), an asynchronous master reset input ( $MR$ ), four counter outputs ( $O_0$  to  $O_3$ ), an active LOW terminal count-up (carry) output ( $\overline{TC}_U$ ) and an active LOW terminal count-down (borrow) output ( $\overline{TC}_D$ ).

The counter outputs change state on the LOW to HIGH transition of either clock input. However, for correct counting, both clock inputs cannot be LOW simultaneously. The outputs  $\overline{TC}_U$  and  $\overline{TC}_D$  are normally HIGH. When the circuit has reached the maximum count state of '15', the next HIGH to LOW transition of  $CP_U$  will cause  $\overline{TC}_U$  to go LOW.  $\overline{TC}_U$  will stay LOW until  $CP_U$  goes HIGH again. Likewise, output  $\overline{TC}_D$  will go LOW when the circuit is in the zero state and  $CP_D$  goes LOW. When  $\overline{PL}$  is LOW, the information on  $P_0$  to  $P_3$  is asynchronously loaded into the counter. A HIGH on  $MR$  resets the counter independent of all other input conditions. The counter stages are of a static toggle type flip-flop.

## 4-BIT BIDIRECTIONAL UNIVERSAL SHIFT REGISTER

The HEF40194B is a 4-bit bidirectional shift register with two mode control inputs ( $S_0$  and  $S_1$ ), a clock input (CP), a serial data shift left input ( $D_{SL}$ ), a serial data shift right input ( $D_{SR}$ ), four parallel data inputs ( $P_0$  to  $P_3$ ), an overriding asynchronous master reset input ( $\overline{MR}$ ), and four buffered parallel outputs ( $O_0$  to  $O_3$ ). When LOW,  $\overline{MR}$  resets all stages and forces  $O_0$  to  $O_3$  LOW, overriding all other input conditions. When  $\overline{MR}$  is HIGH, the operation mode is controlled by  $S_0$  and  $S_1$  as shown in the function table.

Serial and parallel operation are edge-triggered on the LOW to HIGH transition of CP. The inputs at which the data are to be entered and  $S_0$ ,  $S_1$  must be stable for a set-up time before the LOW to HIGH transition of CP.

Fig. 1 Functional diagram.

#### APPLICATION INFORMATION

Some examples of applications for the HEF40194B are:

- Arithmetic unit register
- Serial/parallel converter.

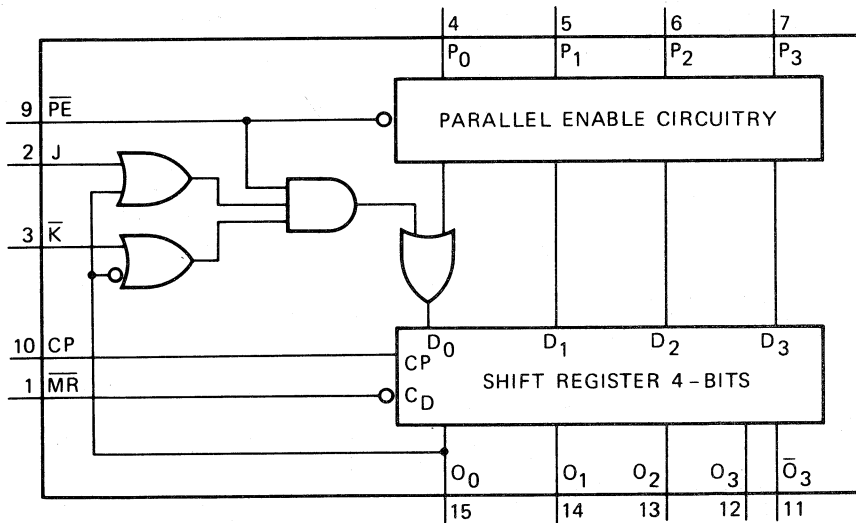

## 4-BIT UNIVERSAL SHIFT REGISTER

The HEF40195B is a fully synchronous edge-triggered 4-bit shift register with a clock input (CP), four synchronous parallel data inputs ( $P_0$  to  $P_3$ ), two synchronous serial data inputs (J,  $\bar{K}$ ), a synchronous parallel enable input ( $\overline{PE}$ ), buffered parallel outputs from all 4-bit positions ( $O_0$  to  $O_3$ ), a buffered inverted output from the last bit position ( $\bar{O}_3$ ) and an overriding asynchronous master reset input ( $\overline{MR}$ ). Each register stage is of a D-type master-slave flip-flop.

Operation is synchronous (except for  $\overline{MR}$ ) and is edge-triggered on the LOW to HIGH transition of the CP input. When  $\overline{PE}$  is LOW, data are loaded into the register from  $P_0$  to  $P_3$  on the LOW to HIGH transition of CP. When  $\overline{PE}$  is HIGH, data are shifted into the first register position from J and  $\bar{K}$  and all the data in the register are shifted one position to the right on the LOW to HIGH transition of CP. D-type entry is obtained by interconnecting J and  $\bar{K}$ .

When J is HIGH and  $\bar{K}$  is LOW, the first stage is in the toggle mode. When J is LOW and  $\bar{K}$  is HIGH, the first stage is in the hold mode.

A LOW on  $\overline{MR}$  resets all four bit positions ( $O_0$  to  $O_3 = \text{LOW}$ ,  $\bar{O}_3 = \text{HIGH}$ ) independent of all other input conditions.

#### APPLICATION INFORMATION

Some examples of applications for the HEF40195B are:

- Serial data transfer
- Parallel data transfer
- Serial to parallel data transfer
- Parallel to serial data transfer

## OCTAL BUFFERS WITH 3-STATE OUTPUTS

The HEF40240B is an octal inverting buffer with 3-state outputs. It features output stages with high current output capability suitable for driving highly capacitive loads.

The 3-state outputs are controlled by the output enable inputs  $\overline{EO}_A$  and  $\overline{EO}_B$ . A HIGH on  $\overline{EO}$  causes the outputs to assume a high impedance OFF-state. The device also features hysteresis on all inputs to improve noise immunity.

Schmitt-trigger action in the inputs makes the circuit highly tolerant to slower input rise and fall times.

The HEF40240B is pin and functionally compatible with the TTL '240' device.

## OCTAL BUS TRANSCEIVER WITH 3-STATE OUTPUTS

The HEF40245B is an octal bus transmitter/receiver designed for 8-line asynchronous, 2-way data communication between data buses. It features output stages with high current output capability suitable for driving highly capacitive loads.

The direction input (DR) controls transmission of data from bus A to bus B, or bus B to bus A, depending on its logic level. The 3-state outputs are controlled by the enable input  $\overline{E}O$ . A HIGH on  $\overline{E}O$  causes the outputs to assume a high impedance OFF-state. The device also features hysteresis on all inputs to improve noise immunity.

Schmitt-trigger action in the inputs makes the circuit highly tolerant to slower input rise and fall times.

The HEF40245B is pin and functionally compatible with the TTL '245' device.

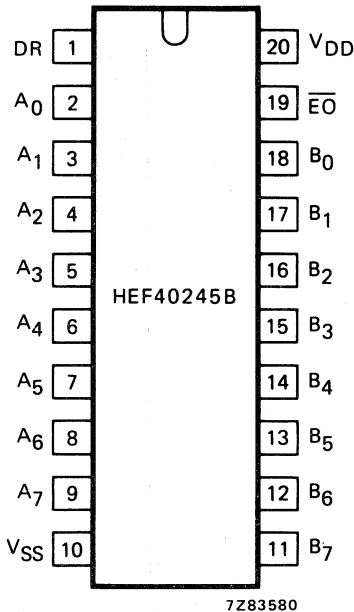

Fig. 1 Pinning diagram.

## OCTAL TRANSPARENT LATCH WITH 3-STATE OUTPUTS

The HEF40373B is an 8-bit transparent latch with 3-state buffered outputs. The output stages have high current output capability suitable for driving highly capacitive loads. The latch outputs follow the data inputs when the latch enable (E) is HIGH. When E is LOW, the data that meets the set-up times is latched. The 3-state outputs are controlled by the output enable input  $\overline{EO}$ . A HIGH on  $\overline{EO}$  causes the outputs to assume a high impedance OFF-state. The device features hysteresis on the E input to improve noise rejection.

Schmitt-trigger action in the E input makes the circuit highly tolerant to slower input rise and fall times.

The HEF40373B is pin and functionally compatible with the TTL '373' device.

Supply voltage range: 3 to 15 V.

Fig. 1 Functional diagram.

Fig. 2 Pinning diagram.

## OCTAL D-TYPE FLIP-FLOP WITH 3-STATE OUTPUTS

The HEF40374B is an octal D-type flip-flop with 3-state buffered outputs with a common clock input (CP). The device is used primarily as an 8-bit positive edge-triggered storage register for interfacing with a 3-state bus. Data on the D-inputs is transferred to storage during the LOW-to-HIGH transition of the clock (CP) input. The 3-state output buffers are controlled by an active LOW output enable input ( $\overline{EO}$ ). A HIGH on  $\overline{EO}$  forces the eight outputs to a high impedance OFF-state. When  $\overline{EO}$  is LOW, the data in the register appears at the outputs.

The output stages have high current output capability suitable for driving highly capacitive loads. The device features hysteresis on the CP input to improve noise rejection. Schmitt-trigger action in the E input makes the circuit highly tolerant to slower input rise and fall times.

The HEF40373B is pin and functionally compatible with the TTL '374' device.  
Supply voltage range: 3 to 15 V.

Fig. 1 Functional diagram.
