TABLE OF CONTENTS

* This data sheet may be obtained by writing to the appropriate Marketing Organization in your country.

INTRODUCTION

As one of the world's largest manufacturers of integrated circuits, Signetics designs, develops, manufactures, and sells over 1600 different types of integrated circuits. Signetics produces integrated circuits utilizing both bipolar and metal-oxide semiconductor (MOS) manufacturing processes for Memory, Microprocessor, Digital, and Analog applications.

The Analog division, one of eight divisions, is a major broad line supplier of Analog circuits consisting of Signetics' original designs, industry standard devices, and custom circuits for EDP, Automotive, Military, Communications, Industrial, and Consumer markets. The family of 555 Timers, the NE5534 High Performance Operational Amplifier, the NE5018 and NE5020 microprocessor compatible DAC's and the NE5560 Switched Mode Power Supply Regulator are a few examples of Signetics' original products. The breadth of the Analog product line offers the designer, the component engineer, and the purchasing agent a broad Analog circuit product line backed by Signetics' industry image as a quality manufacturer to whom the servicing of the customers' needs is paramount.

The 1981 Analog Data Manual is intended to serve as a single reference for Analog circuits by presenting information necessary to select Signetics' Analog products properly. The data manual is updated and rewritten to reflect data on new products issued in the past 2 years, as well as new package configurations such as the new microminiature packages which have recently been released for volume production. Designated the SO package (SO = Small Outline), this new package offers advantages to the hybrid as well as the P.C. board assembler in the purchasing of fully DC- and AC-tested circuits for substrate assembly. Complete details on this new package are available in the Packaging section at the end of this manual.

Additions and errata will be generated at periodic intervals as appropriate.

Your inputs to improve this or any of our publications would be greatly appreciated.

Lou Johnson
Marketing Manager, Analog Division

Table 1 provides part number information concerning for both Signetics originated products and industry standard products.

Table 2 is a cross reference of both the old and new package suffixes for all presently existing types, while Table 3 and 4 provide appropriate explanations on the various prefixes employed in the part number descriptions.

As noted in Table 3, Signetics defines device operating temperature range by the appropriate prefix. It should be noted however, that devices with a SE prefix (-55°C to +125°C) indicates only its operating temperature range and *not* its military qualification status. The military qualification status of any analog product can be determined by either looking in the Military Section in this manual and/or contacting your local sales office.

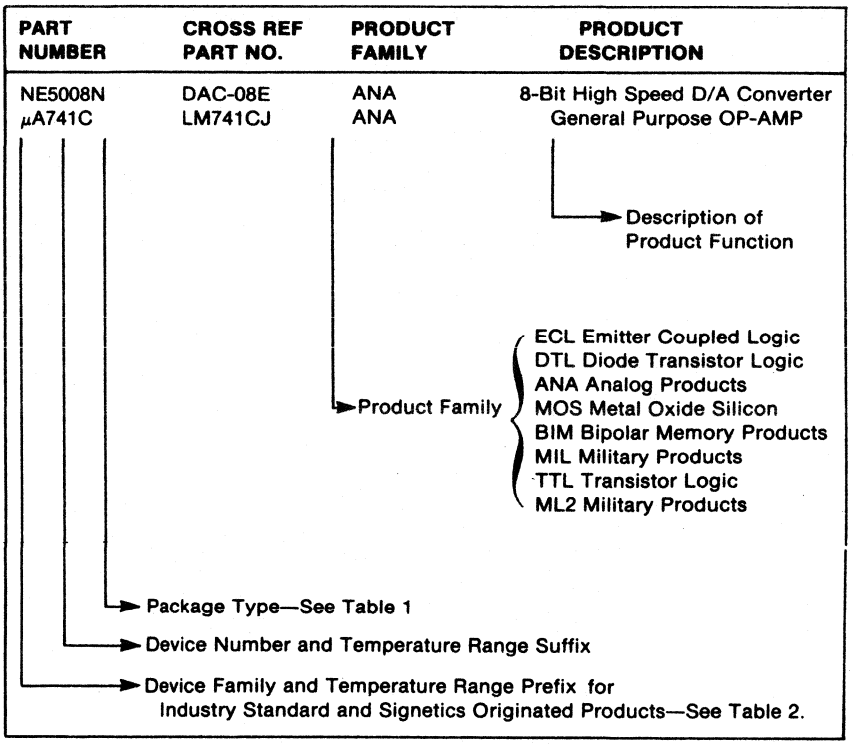

Table 1 PART NUMBER DESCRIPTION

SUFFIX		PACKAGE DESCRIPTION[2]
Old	New	
A,AA	N	14-lead plastic DIL
A	N-14	14-lead plastic DIL (Selected Analog products only)

QUALITY AND RELIABILITY

Quality and reliability are two important measures of a product's merit. Quality is a measure of an integrated circuit's conformance to agreed-upon criteria at a given time, while Reliability is a measure of the circuit's ability to continue to conform over a period of time. The Signetics SUPR II Program has been designed to upgrade the basic product quality through the use of more rigorous screening criteria at the critical process steps. These additional screens constitute the Level A portion of the Program. A burn-in option is available for those users requiring enhanced reliability performance, and this option is designated as Level B.

Quality

The quality of an integrated circuit is appraised by the user based on the ability of the circuit to meet the specified electrical criteria and external visual appearance. The SUPR II Program focuses on supplying to the user a product that has a high probability of meeting the user's needs through the sampling plans defined in MIL-STD-105D and the quality levels (AQL's) stated in Table II. Many of the inspection methods at critical process steps are now based on MIL-STD-883 criteria in order to build, rather than test, quality into the product.

Reliability

System performance over a period of time is the user's measure of an integrated circuit's reliability. The SUPR II Program improves system reliability by building quality into the product via additional manufacturing inspections and the offering of a burn-in screen. In addition to the SUPR II Program, Signetics performs periodic reliability testing via the SURE II/883A Program to assure continuing uniformity and long-term reliability of all product lines. This data base is available upon request as is the ten-year reliability summary, Signetics Product Reliability Report, R-363.

How Do Integrated Circuit Failures Occur?

Results from the Signetics Failure Analysis Lab over a three-year period on product returned from board checkout, system checkout, field usage and accelerated life testing are graphically presented in Figure 1. Under typical system operating conditions, random manufacturing defects, as outlined in Table 1, are the primary cause of true device failure. Also shown in Table 1 are the process controls that have been added via the SUPR II Program to minimize these defects prior to shipment to the customer. The device failure models are categorized as:

Half of the devices analyzed were found to be electrically good. They are attributed to being "false pulls" that occur during normal troubleshooting at the board and system levels.

Devices damaged by electrical over-stress account for 25% of the failures. Typical causes for electrical over-stress are incorrect board insertion, board shorts between device pins, power supply transients, and poor handling techniques.

The remaining 25% were verified to be true failures which occurred as a result of an in-process manufacturing defect or test escape.

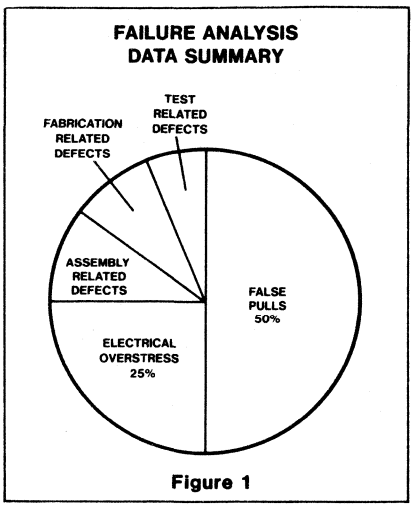

Figure 1

SIGNETICS SUPR II LEVEL A

Improved Quality Benefits

From the user's point of view, improved integrated circuit quality from the supplier means a lower cost of ownership. This cost saving can be effected through the reduction or elimination of involved incoming inspection testing, reduced PC board rework, simplified system checkout, reduced in-line inventories, and less complicated part tracking by Purchasing Management.

The SUPR II Program is Corporate in scope and covers Logic (Standard TTL, Schottky TTL, Low Power Schottky TTL, ECL, 8T Interface), Analog (Industrial, Consumer, Interface), Bipolar Memories (RAM's, ROM's, PROM's), and MOS Memories (RAM's, ROM's, Shift Registers), All package options are also available.

The SUPR II flow is detailed in Figure 5, including the test methods and Quality acceptance levels (Table 2 provides the electrical/mechanical finished product AQL's). Highlights of the flow are visual inspections, thermal shock preconditioning, hermeticity, and burn-in, all based on MIL-STD-883 criteria.

A good example of the savings which can be achieved by purchasing tighter inspection levels is given in Figure 2. Here we are comparing the various levels of inspection (AQL's) available for device functionality and its impact on the number of PC boards which must be reworked during system manufacturing. Using the standard commercial AQL in functionality of 1.0%, at 120 integrated circuit packages per board, typically more than 90% of boards will require rework. At 0.15% AQL, rework is reduced to 25%, and at 0.1%, typically only 12% rework is required.

SIGNETICS SUPR II LEVEL B

Infant Mortality Failures

Failure rates are most severe during the first few months of operating life. This is known as the "infant mortality" phase. A system

FAILURE MECHANISMS	CAUSES	SUPR II CONTROL
Die Fabrication Related	Metalization Oxide Defects Mechanical Scratches Contamination	SEM Monitor Visual Stabilization Bake Burn-In
Assembly Related	Bonding, Wire, Package and Seal Defects	Preseal Visual Thermal Shock Stabilization Bake Hermeticity Hot-Rail Testing
Test Related	Test Escapes	Tightened AQL Guarantees High Temperature Testing

Table 1

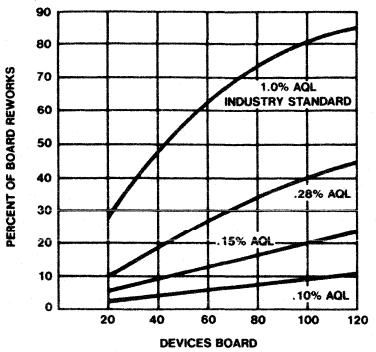

Figure 2

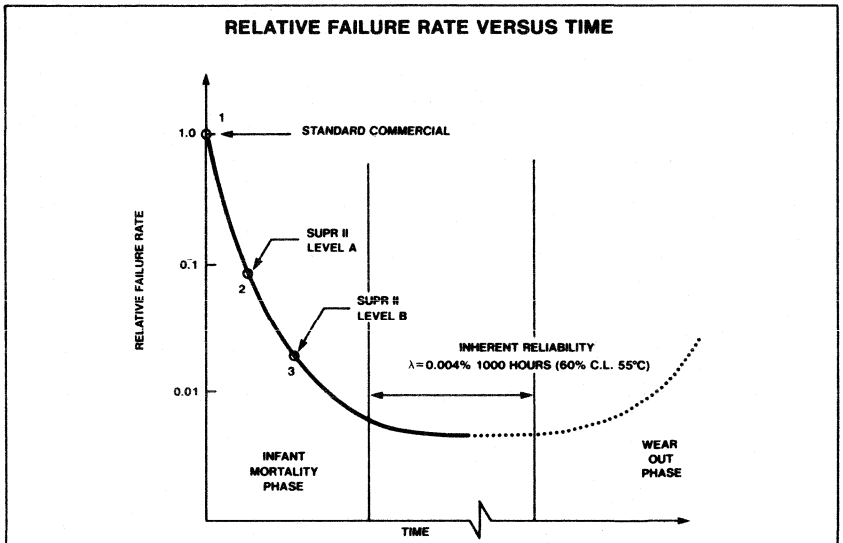

Figure 3

manufacturer has various options to solve problems arising from infant failures. He can ship his system to the end customer and repair field failures as they occur. He can operate the system in-house for this period and repair failures. Or he can purchase devices which have already been preconditioned to eliminate the early failures. Each customer must choose the most cost-effective method for his particular business. A considerable number of the reliabilty defects which cause early failures are eliminated by the manufacturing control and preconditioning steps of SUPR II Level A processing. More persistent defects can be removed by the use of "burn-in" techniques. The "burn-in" processing of SUPR II Level B effectively allows the system manufacturer to ship his equipment at Point 3 on the failure rate curve in Figure 3.

		ANALOG	
		Plastic	Ceramic Metal Can
HOT OPENS	100°C	.015%	-
FUNCTIONALITY (NOTE 1)	25°C	0.10	0.10
	HIGH	0.15	0.15
D.C. PARAMETRIC	25°C	0.15	0.15
TEMPERATURE	OVER	0.40	0.40
A.C. PARAMETRIC	25°C	0.65	0.65
MECHANICAL	MAJOR	0.25	0.25
	MINOR	1.0	1.0
SEAL TEST (CERAMIC METAL CAN ONLY)	FINE LEAK 1×10^{-7} cc/s	N/A	1.0
	GROSS LEAK 1×10^{-5} cc/s	N/A	0.65

NOTE

1. To insure AQL levels tighter than 0.65% on D.C. parameters usually requires continual correlation of test equipment between customer and vendor to avoid test interpretation problems. If the objective is to reduce system rework costs, functional operation of a device (does it switch or toggle in the system) is often more critical than the absolute value of a parameter. For this reason SUPR II focuses attention on tightened AQL's on functionality.
   For analog devices, D.C. parameters, such as input current and offset voltages, tend to be more critical to system operation than for logic devices. A 0.25% AQL is therefore offered on analog D.C. parameters, with the realization that careful attention must be paid to establishing correlation at the customer's incoming inspection.

Table 2 SUPRA II AQL GUARANTEE

Burn-In Conditions

MIL-STD-883A, Method 1015 describes a number of different conditions for integrated circuit burn-in. For SUPR II Level B, Signetics has selected Condition F. This is the accelerated burn-in method derived from MIL-STD-883A, utilizing a high temperature reversed bias condition. This bias scheme is preferred for infant mortality screening, while operating conditions are generally utilized for internal reliability programs oriented toward generating MTBF data for the system designer.

Integrated Burn-In Flow

Signetics SUPR II Level B burn-in is performed to provide reliability assurance equivalent to a 168-hour/125°C screen. This process has been integrated into the standard manufacturing flow to provide the customer with the most cost effective screen and significantly reduced delivery times.

BURN-IN FLOW

ASSEMBLY

The flow from SEM control through package seal is common to Levels A and B.

⇩

TEST

The pre-burn-in electrical screen is designed to remove assembly rejects and increase equipment efficiency.

⇩

BURN-IN

The 24-hour/155°C accelerated burn-in is well controlled to provide maximum screening effectiveness without damaging good devices.

⇩

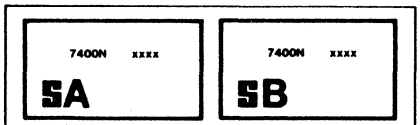
TEST

The post-burn-in electrical is a 100% production DC/function electrical test.

Figure 4

Marking Format

Product processed to the SUPR II manufacturing flow can be identified by an SA for Level A, and an SB for the Level B burn-in option.



NOTE
Marking for Level A in process of being implemented.

Figure 5 shows the generalized process flow for all Signetics integrated circuits purchased to the SUPR II program. Each product group (Analog, Bipolar Memory, Logic, and MOS) may follow slightly different procedures dictated by the specific device characteristics.

SUPR II PROCESS FLOW

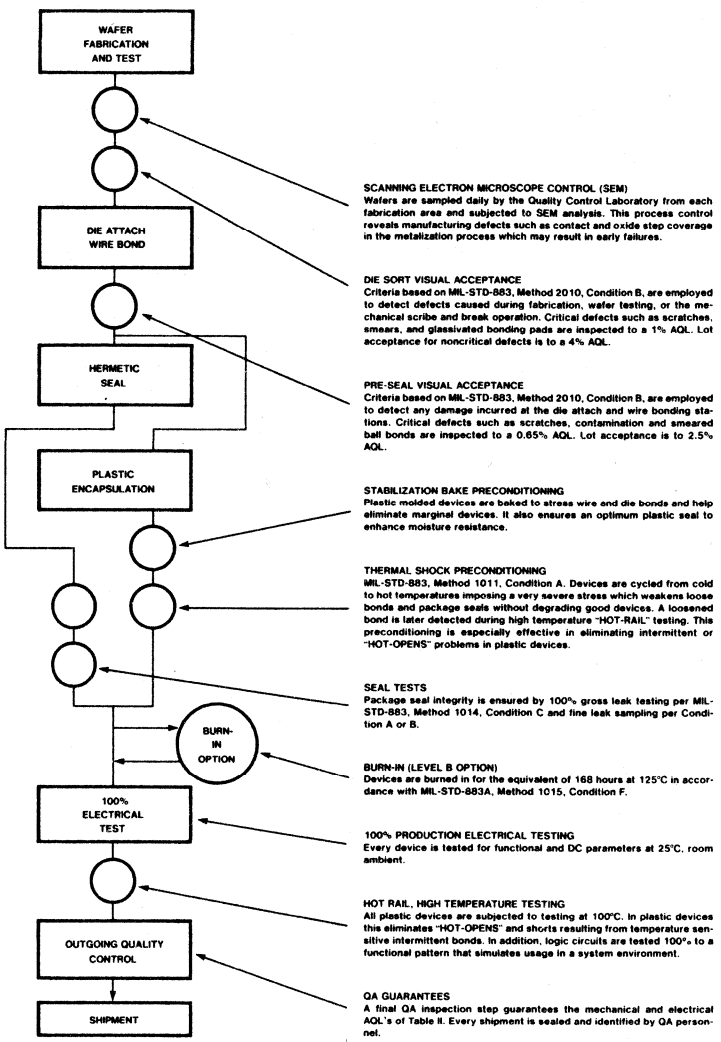


Figure 5

SURE II/883B RELIABILITY PROGRAM

Definition

Signetics is recognized as a manufacturer of reliable integrated circuts. Signetics realized long ago the need for a comprehensive reliability program to provide timely data representative of the entire Signetics product line. Thus the establishment of a Systematic and Uniform Reliability Evaluation program, known as SURE, which provides this data in a manner unique to the industry. Furthermore, this program is provided at no cost to customers.

The SURE Program is a Signetics in-house Qualification Test Program which has been in existence since 1963. The SURE Program is designed to monitor the continuing uniformity of all Signetics products and to demonstrate via periodic qualifications that Signetics products meet or exceed the stringent long-term reliability requirements of their intended applications.

The SURE Program is reviewed and modified annually to incorporate appropriate changes in military microelectronic test programs, products and demonstrated product capabilities, and market requirements. The 1978 SURE II/883B Reliability Program contains minor changes to the 1975 SURE II/883A Program, most significant of which is the inclusion of recent changes in military microelectronic test programs (i.e., inclusion of MIL-SD-883B, Method 5005.4 and MIL-M-38510D). The SURE II/883B Program continues to incorporate additional environmental tests to fulfill the need for special reliability assurance of plastic products.

For more detailed information regarding the SURE II program, refer to Section 11 of the 1979 Signetics Analog Applications Manual.

SECTION I
OPERATIONAL AMPLIFIERS

Section 1—OPERATIONAL AMPLIFIERS

OPERATIONAL AMPLIFIERS DEFINITIONS

T_A

Ambient temperature range. Range of the surrounding environment of the operating device.

T_J

Junction Temperature. The maximum temperature of the device. 150°C is standard for silicon devices.

T_{STG}

Storage temperature range. Temperature range that the device can be stored in a non-operating condition.

T_{SOLD}

Soldering Temperature. The temperature which can be applied to the lead frame of the device for short periods of time (normally specified for a duration of 10 sec).

Absolute Maximum Rating

Operating safe zones exceeding these limits could cause permanent damage to the device and are not meant to imply that devices can operate at these limits.

Power Dissipation

The power that the device can safely handle at 25°C. The dissipation must be derated as indicated for the individual package type.

Package Type Designation

See full package designations in Appendix.

V_{CC} ($-V_{CC}$)

Supply Voltage. The range of power supply voltage over which the device will operate safely.

Acquisition Time

The time required to acquire a new analog input voltage with an output step of 10V. Note that acquisition time is not just the time required for the output to settle, but also includes the time required for all internal nodes to settle so that the output assumes the proper value when switched to the hold mode.

Aperture Delay Time

The time elapsed from the hold command to the opening of the switch.

Aperture Jitter

Also called "aperture uncertainty time", it's the time variation or uncertainty with which the switch opens, or the time variation in aperature delay.

Aperture Time

The delay required between "hold" command and an input analog transition, so that the transition does not affect the hold output.

Bandwidth

The frequency at which the gain is down 3dB from its dc value. It's measured in sample (track) mode with a small-signal sine wave that doesn't exceed the slew rate limit.

Effective Aperture Delay

The time difference between the hold command and the time at which the input signal is at the held voltage.

Figure Of Merit

The ratio of the available charging current during sample mode to the leakage current during hold mode.

Hold-Mode Droop

The output voltage change per unit of time while in hold. Commonly specified in V/s, μV/μs or other convenient units.

Hold-Mode Feed Through

The percentage of an input sinusoidal signal that is measured at the output of a sample-hold when it's in hold mode.

Hold Settling Time

The time required for the output to settle within 1mV of final value after the "hold" logic command.

Sample-To-Hold Offset Error

The difference in output voltage between the time the switch starts to open, and the time when the output has settled completely. It is caused by charge being transferred to the hold capacitor switch as it opens.

Slew Rate

The fastest rate at which the sample & hold output can change (specified in V/μs).

Hold Step

The voltage step at the output of the sample and hold when switching from sample mode to hold mode with a steady (dc) analog input voltage. Logic swing is 5V.

Dynamic Sampling Error

The error introduced into the held output due to a changing analog input at the time the hold command is given. Error is expressed in mV with a given hold capacitor value and input slew rate. Note that this error term occurs even for long sample times.

Gain Error

The ratio of output voltage swing to input voltage swing in the sample mode expressed as a percent difference.

Threshold

Level shall be defined as that level which causes the switch control to change state.

Average Input Offset Current T^O coeff.

The change in input offset current divided by the change to ambient temperature producing it.

Average Input Offset Voltage T^O coeff.

The change in input offset voltage divided by the change in ambient temperature producing it.

Common Mode Input Resistance

The resistance looking into both inputs, with inputs tied together.

Common Mode Rejection Ratio (CMRR)

The ratio of the change of input offset voltage to the input common mode voltage change producing it.

Full Power Bandwidth

The maximum frequency at which the full sinewave output might be obtained.

Input Bias Current

The average of the two input currents at zero output voltage. In some cases, the input current is measured for either input independently.

OPERATIONAL AMPLIFIERS DEFINITIONS (Cont'd)

Input Capacitance

The capacitance looking into either input terminal with the other grounded.

Input Current

The current into an input terminal.

Input Noise Voltage

The square root of the mean square narrow-band noise voltage referred to the input.

Input Offset Current

The difference in the currents into the two input terminals with the output at zero volts.

Input Offset Voltage

That voltage which must be applied between the input terminals to obtain zero output voltage. The input offset voltage may also be defined for the case where two equal resistances are inserted in series with the input leads.

Input Resistance

The resistance looking into either input terminal with the other grounded.

Input Voltage Range

The range of voltages on the input terminals for which the amplifier operates within specifications. In some cases, the input offset specifications apply over the input voltage range.

Large-Signal Voltage Gain

The ratio of the maximum output voltage swing to the change in input voltage required to drive the output to this voltage.

Output Resistance

The resistance seen looking into the output terminal with the output at null. This parameter is defined only under small signal conditions at frequencies above a few hundred cycles to eliminate the influence of drift and thermal feedback.

Output Short-Circuit Current

The maximum output current available from the amplifier with the output shorted to ground or to either supply.

Output Voltage Swing

The peak output swing, referred to zero, that can be obtained.

Power Consumption

The dc power required to operate the amplifier with the output at zero and with the output at zero and with no load current.

Power Supply Rejection Ratio

The ratio of the change in input offset voltage to the change in supply voltages producing it.

Rise Time

The time required for an output voltage step to change from 10% to 90% of its final value.

Slew Rate

The maximum rate of change of output voltage under large signal condition.

Supply Current

The current required from the power supply to operate the amplifier with no load and the output at zero.

Temperature Stability of Voltage Gain

The maximum variation of the voltage gain over the specified temperature range.

NOTE

Refer to Section 3 of the 1979 Analog Applications Manual for an in depth explanation of Operational Amplifiers and their applications

DESCRIPTION

The LF355 and LF356 operational amplifiers employ well matched, high voltage JFET input structures on the same monolithic chip as bipolar devices. These amplifiers feature low input bias and offset currents, low offset voltage and offset voltage drift, coupled with offset adjust which does not degrade drift or common mode rejection. The devices are also designed for high slew rate, wide bandwidth, extremely fast settling time and low noise.

COMMON FEATURES

(TYPICAL)

- **Low input bias current 50pA**
- **Low input offset current 10pA**
- **High input impedance $10^{12}\Omega$**
- **Low input offset voltage 3mV**
- **Low V_{OS} temperature drift $5\mu V/°C$**
- **Low input noise current $0.01pA/\sqrt{Hz}$**

APPLICATIONS

- **Precision high speed integrators**
- **Fast A/D, D/A converters**
- **High impedance buffers**
- **Wideband, low noise, low drift amplifier**

NOTE

1. Settling time is defined here, for a unity gain inverter connection using 2kΩ resistors for the LF355/6. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter.

PARAMETER	LF355			LF356			UNIT
	Min	Typ	Max	Min	Typ	Max	
Supply current		2	4		5	10	mA

NOTES

1. These specifications apply for $V_S = \pm 15V$ and $0° C \leq T_A \leq +70°C$. V_{OS}, I_B and I_{OS} are measured at $V_{CM} = 0$.
2. The Temperature Coefficient of the adjusted input offset voltage changes only a small amount ($0.5\mu V/°C$ typically) for each mV of adjustment from its original unadjusted value. Common mode rejection and open loop voltage gain are also unaffected by offset adjustment.
3. The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J. Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, Pd. $T_j = T_A + \theta_{jA}$ Pd where θ_{jA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.
4. Supply Voltage Rejection is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.

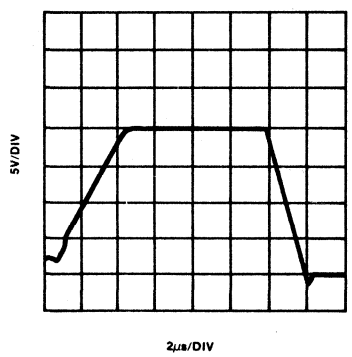
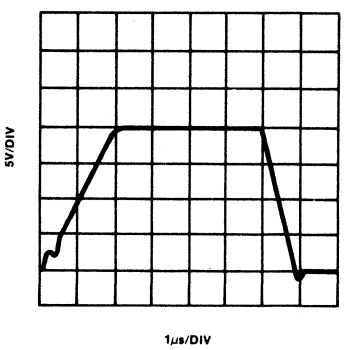
LF355



LF356



APPLICATIONS

The LF355 and LF356 are op amps with JFET input devices. These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will cause a reversal of the phase to the output and force the amplifier output to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

These amplifiers will operate with the common-mode input voltage equal to the positive supply. In fact, the common-mode voltage can exceed the positive supply by approximately 100mV independent of supply voltage and over the full operating temperature range. The positive supply can therefore be used as a reference on an input as, for example, in a supply current monitor and/or limiter.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

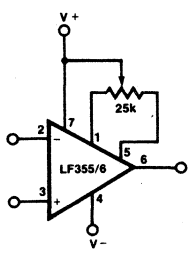
All of the bias currents in these amplifiers are set by FET current sources. The drain currents for the amplifiers are therefore essentially independent of supply voltage.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pickup" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

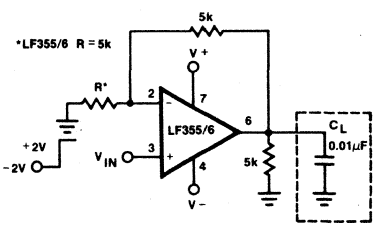
TYPICAL CIRCUIT CONNECTIONS

V_{OS} ADJUSTMENT



- V_{OS} is adjusted with a 25k potentiometer
- The potentiometer wiper is connected to V+
- For potentiometers with temperature coefficient of 100ppm/°C or less the additional drift with adjust is ≃ 0.5μV/°C/mV of adjustment
- Typical overall drift: 5μV/°C ± (0.5μV/°C/mV of adj.)

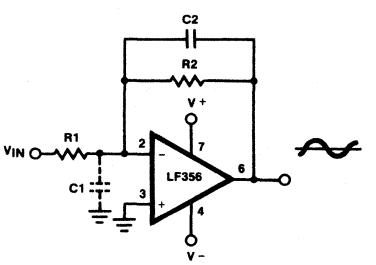
DRIVING CAPACITIVE LOADS



Due to a unique output stage design these amplifiers have the ability to drive large capacitive loads and still maintain stability. C_L max ≤ 0.01μF.
Overshoot ≤ 20%
Setting time (t_s) ≥ 5μs

TYPICAL APPLICATIONS

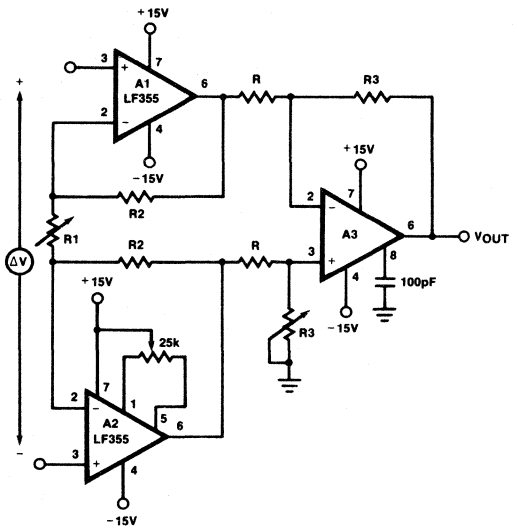
WIDE BW LOW NOISE, LOW DRIFT AMPLIFIER



- Power BW: $f_{MAX} = \frac{S_r}{2\pi p} \simeq 240kHz$
- Parasitic input capacitance C1 ≃ (3pF for LF355 and LF356, plus any additional layout capacitance) interacts with feedback elements and creates undesirable high frequency pole. To compensate add C2 such that: R2C2 ≃ R1C1.

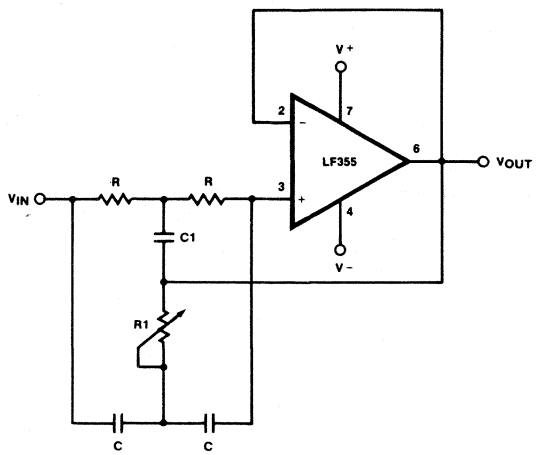
TYPICAL APPLICATIONS (Cont'd)

HIGH IMPEDANCE, LOW DRIFT INSTRUMENTATION AMPLIFIER



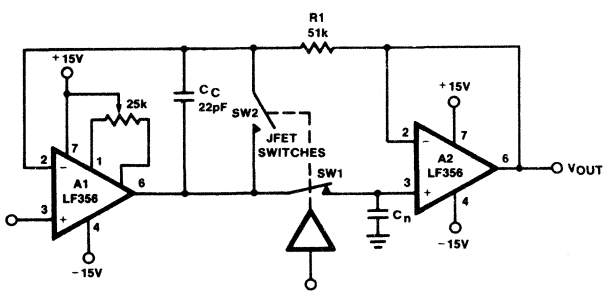
- $V_{OUT} = \frac{R3}{R}\left[\frac{2R2}{R1} + 1\right]\Delta V$, V- +2V ≤ V_{IN} Common-Mode ≤ V+
- System V_{OS} adjusted via A2 V_{OS} adjust
- Trim R3 to boost up CMRR to 120dB.

HIGH Q NOTCH FILTER



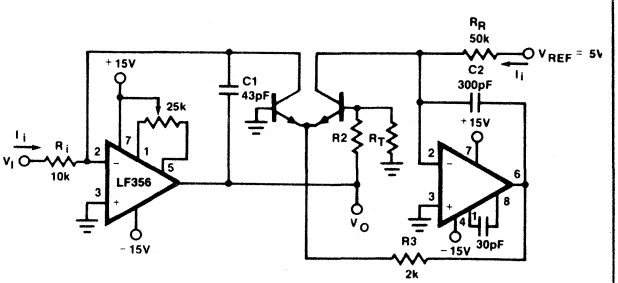
- 2R1 = R = 10MΩ
  2C = C1 = 300pF
- Capacitors should be matched to obtain high Q
- f_{NOTCH} = 120Hz, notch = 55dB, Q > 180
- Use LF355 for
  Δ Low I_B
  Δ Low supply current

HIGH ACCURACY SAMPLE AND HOLD



- By closing the loop through A2 the V_{OUT} accuracy will be determined uniquely by A1. No V_{OS} adjust required for A2.
- T_A can be estimated by same considerations as previously but, because of the added on propagation delay in the feedback loop (A2) the overshoot is not negligible.
- Overall system slower than fast sample and hold.
- R1, C_C: additional compensation
- Use LF356 for
  Δ Fast settling time
  Δ Low V_{OS}

FAST LOGARITHMIC CONVERTER



$$|V_{OUT}| = \left[1 + \frac{R2}{R}\right]\frac{kT}{q} \ln V_I \left[\frac{R_r}{V_{REF}\, R_i}\right] = \log V_I \frac{1}{R_i\, I_R}$$

R2 = 15.71, R_1 = 1k, 0.3%°C (for temperature compensation)

- Dynamic range: 100μA ≤ I_i ≤ 1mA (5 decades, $|V_O|$ = 1V/decades)
- Transient response: 3μs for Δ, = decades
- C1, C2, R2, R3: added dynamic compensation
- V_{OS} adjust the LF356 to minimize quiescent error
- R_T: Tel Labs type Q81 + 0.3%/°C.

GENERAL PURPOSE SINGLE SUPPLY OPERATIONAL AMPLIFIER

LM124/224/324/SA534-F,N
LM324-D

DESCRIPTION

The LM124/SA534 series consists of four independent, high gain, internally frequency compensated operational amplifiers designed specifically to operate from a single power supply over a wide range of voltages.

UNIQUE FEATURES

In the linear mode the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from only a single power supply voltage.

The unity gain cross frequency is temperature compensated.

The input bias current is also temperature compensated.

FEATURES

- **Internally frequency compensated for unity gain**
- **Large dc voltage gain—(100dB)**
- **Wide bandwidth (unity gain)—1MHz (temperature compensated)**
- **Wide power supply range**
  Single supply—(3Vdc to 30Vdc) or dual supplies—(±1.5Vdc to ±15Vdc)
- **Very low supply current drain—essentially independent of supply voltage (1mW/op amp at +5Vdc)**
- **Low input biasing current—(45nAdc temperature compensated)**
- **Low input offset voltage—(2mVdc) and offset current—(5nAdc)**
- **Differential input voltage range equal to the power supply voltage**
- **Large output voltage—(0Vdc to V+—1.5Vdc swing)**
- **LM124 Mil std 883A,B,C available**

	SA534	-40 to +85	°C
	LM124	-55 to +125	°C
	Storage temperature range	-65 to +150	°C
	Lead temperature (soldering, 10sec)	300	°C

NOTES

1. For operating at high temperatures, all devices must be derated based on a +125°C maximum junction temperature and a thermal resistance of 175°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient. LM 124/224 can be derated based on a +150°C maximum junction temperature.
2. Short circuits from the output to V+ can cause excessive heating and eventual destruction. The maximum output current is approximately 40mA independent of the magnitude of V+. At values of supply voltage in excess of +15Vdc continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction.
3. The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output, so no loading change exists on the input lines.

I_{SC}	Short circuit current[4]			40	60		40	60	mA
	Differential input voltage[6]				V+			V+	V

NOTES

1. $V_O \cong 1.4Vdc$, $R_S = 0\Omega$ with V+ from 5V to 30V and over full input common mode range (0Vdc+ to V+ −1.5V).
2. The direction of the input current is out of the IC due to the pnp input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.
3. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ −1.5, but either or both inputs can go to +32V without damage.
4. Short circuits from the output to V+ can cause excessive heating and eventual destruction. The maximum output current is approximately 40mA independent of the magnitude of V+. At values of supply voltage in excess of +15Vdc continous short-circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.
5. Due to proximity of external components, insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitive increases at higher frequencies.
6. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ −1.5V, but either or both inputs can go to +32Vdc without damage.

LM13600/13600A-D,N

DESCRIPTION

The LM13600 series consists of two current controlled transconductance amplifiers each with differential inputs and a push pull output. The two amplifiers share common supplies but otherwise operate independently. Linearizing diodes are provided at the inputs to reduce distortion and allow higher input levels. The result is a 10 dB signal-to-noise improvement referenced to 0.5 percent THD. Controlled impedance buffers are provided which are specifically designed to complement the dynamic range of the amplifiers.

FEATURES

- **gm adjustable over 6 decades**
- **Excellent gm linearity**
- **Excellent matching between amplifiers**
- **Linearizing diodes**
- **Controlled impedance buffers**
- **High output signal to noise ratio**
- **Wide supply range ±2V to ±22V.**
- **See Signetics NE5517 for typical circuit applications information**

APPLICATIONS

- **Current controlled amplifiers**
- **Current controlled impedances**
- **Current controlled filters**
- **Current controlled oscillators**
- **Multiplexers**
- **Timers**
- **Sample and hold circuits**

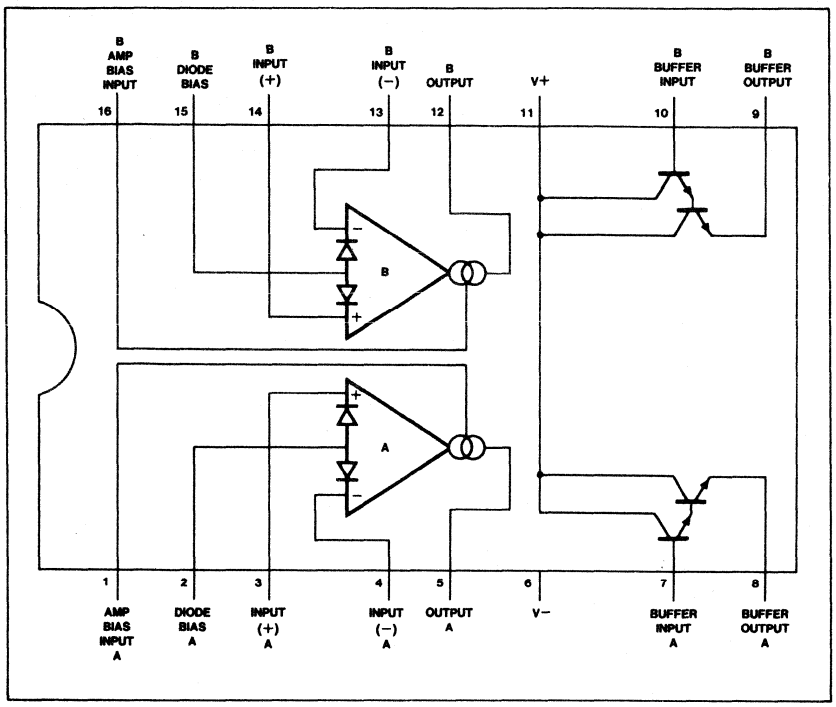
NOTES

1. For selections to a supply voltage above ±22V, contact factory.
2. For operating at high temperatures, the device must be derated based on a 150°C maximum junction temperature and a thermal resistance of 175° C/W which applies for the device soldered in a printed circuit board, operating in still air.
3. Buffer output current should be limited so as to not exceed package dissipation.
4. These specifications apply for V_S = ±15V, T_A = 25°C, amplifier bias current (I_{ABC}) = 500μA, pins 2 and 15 open unless otherwise specified. The inputs to the buffers are grounded and outputs are open.
5. These specifications apply for V_S = ±15V, I_{ABC} = 500 μA, R_{OUT} = 5Ω connected from the buffer output to $-V_S$ and the input of the buffer is connected to the transconductance amplifier output.

CONNECTION DIAGRAM



MC1456/1556-N

DESCRIPTION

The MC1456/1556 is an internally compensated precision monolithic operational amplifier featuring extremely low offset and bias currents and offset null capability. The MC1456/1556 is short circuit protected and its high common mode and differential input voltage range provides exceptional performance when used as an integrator, summing amplifier, and voltage follower.

FEATURES

- **Low input bias current—15nA maximum**
- **Low input offset current—2.0nA maximum**
- **Low input offset voltage—4.0mV maximum**
- **High slew rate—2.5V/μs typical**
- **Large power bandwidth—40kHz typical**
- **Low power consumption—45mW maximum**
- **Offset voltage null capability**
- **Output short circuit protection**
- **Input over-voltage protection**
- **Mil std 883A,B,C, available**

DESCRIPTION

The MC1458 is a high performance operational amplifier with high open loop gain, internal compensation, high common mode range and exceptional temperature stability. The MC1458 is short-circuit protected and allows for nulling of offset voltage.

The MC1458/SA1458/MC1558 consists of a pair of 741 operational amplifiers on a single chip.

FEATURES

- **Internal frequency compensation**
- **Short circuit protection**
- **Excellent temperature stability**
- **High input voltage range**
- **No latch-up**
- **1558/1458 are 2 "op amps" in space of one 741 package**
- **MC1558 Mil std 883A,B,C available**

NE/SE530-FE,N,H • NE/SE5530-H,N

DESCRIPTION

The 530/5530 are new generation operational amplifiers featuring high slew rates combined with improved input characteristics. Internally compensated, the SE530/5530 guarantee slew rates of 25V/μs with 2mV maximum offset voltage. Industry standard pinout and internal compensation allow the user to upgrade system performance by directly replacing general purpose amplifiers such as the 741, 747, 1458, 4558 and LF356 types.

FEATURES

- **Gain bandwidth product—3MHz**
- **35V/μs slew rate (Gain = -1)**
- **Internal frequency compensation**
- **Low input offset voltage 2mV max**
- **Low input bias current-60nA max**
- **Short circuit protection**
- **Offset null capability**
- **Large common mode and differential voltage ranges**

NE/SE531-N,H,FE

DESCRIPTION

The 531 is a fast slewing high performance operational amplifier which retains dc performance equal to the best general purpose types while providing far superior large signal ac performance. A unique input stage design allows the amplifier to have a large signal response nearly identical to its small signal response. The amplifier is compensated for truly negligible overshoot with a single capacitor. In applications where fast settling and superior large signal bandwidths are required, the amplifier out performs conventional designs which have much better small signal response. Also, because the small signal response is not extended, no special precautions need be taken with circuit board layout to achieve stability. The high gain, simple compensation and excellent stability of this amplifier allow its use in a wide variety of instrumentation applications.

FEATURES

- **35V/μsec slew rate at unity gain**
- **Pin for pin replacement for μA709, μA748 or LM101**
- **Compensated with a single capacitor**
- **Same low drift offset null circuitry as μA741**
- **Small signal bandwidth 1MHz**
- **Large signal bandwidth 500KHz**
- **True op amp dc characteristics make the 531 the ideal answer to all slew rate limited operational amplifier applications.**

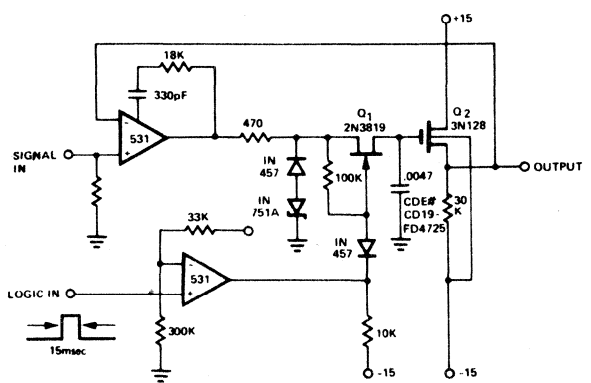
SAMPLE AND HOLD



NE/SE532-N,H,FE/SA532-N
LM158/258/358-N,H,FE

DESCRIPTION

The 532/358 consists of two independent, high gain, internally frequency compensated operational amplifiers designed specifically to operate from a single power supply over a wide range of voltages. Operation from dual power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

FEATURES

- **Internally frequency compensated for unity gain**
- **Large dc voltage gain—(100dB)**
- **Wide bandwidth (unity gain)—1MHz (temperature compensated)**
- **Wide power supply range**
  single supply—(3Vdc to 30Vdc)
  or dual supplies—(±1.5Vdc to ±15Vdc)
- **Very low supply current drain (400μA)—essentially independent of supply voltage (1mW/op amp at +5Vdc)**
- **Low input biasing current—(45nA dc temperature compensated)**
- **Low input offset voltage—(2mVdc) and offset current—(5nA dc)**
- **Differential input voltage range equal to the power supply voltage**
- **Large output voltage—(0Vdc to V+—-1.5Vdc swing)**
- **SE532 Mil std 883A,B,C available**

UNIQUE FEATURES

In the linear mode the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from only a single power supply voltage. The unity gain cross frequency is temperature compensated. The input bias current is also temperature compensated.

I_{SC} Short circuit current[5]			40	60		40	60	mA
Differential input voltage[6]				V+			V+	V

NOTES

1. $V_O \cong 1.4V$, $R_S = 0\Omega$ with V+ from 5V to 30V; and over the full input common-mode range (0V to V+ –1.5V).
2. The direction of the input current is out of the IC due to the pnp input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.
3. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ –1.5V, but either or both inputs can go to +32V without damage.
4. Due to proximity of external components, insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance coupling increases at higher frequencies.
5. Short circuits from the output to V+ can cause excessive heating and eventual destruction. The maximum output current is approximately 40mA independent of the magnitude of V+. At values of supply voltage in excess of +15Vdc, continuous short-circuits can exceed the power dissipation ratings and case eventual destruction.
6. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ –1.5V, but either or both inputs can go to +32Vdc without damage.
7. For operating at high temperatures, all devices must be derated based on a +125°C maximum junction temperature and a thermal resistance of 175°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient.

DESCRIPTION

The 535 and 5535 are new generation operational amplifiers featuring high slew rates combined with improved input characteristics. The 535 is a single device while the 5535 is a dual configuration. Internally compensated for unity gain, the SE535 and SE5535 feature a guaranteed unity gain slew rate of 10V/μs with 2mV maximum offset voltage. Industry standard pin out and internal compensation allow the user to upgrade system performance by directly replacing general purpose amplifiers, such as 741, 747 and 1558.

FEATURES

- **15V/μs unity gain slew rate**
- **Internal frequency compensation**
- **Low input offset voltage—2mV**
- **Low input bias current 80nA max**
- **Short circuit protected**
- **Offset null capability**
- **Large common mode and differential voltage ranges**

DESCRIPTION

The NE/SE538/5538 are new generation operational amplifiers featuring high slew rates combined with improved input characteristics. Internally compensated for gains of 5 or larger, the SE538/5538 offers guaranteed minimum slew rates of 40V/μs or larger. Featuring 2mV max input offset voltage, the 538 is a single amplifier while the 5538 is a dual amplifier. Industry standard pin out and internal compensation allow the user to upgrade system performance by directly replacing general purpose amplifiers, such as 748, 101A, 741, 747 and 1458.

FEATURES

- **2mV input offset voltage**
- **80nA max input offset current**
- **Short circuit protected**
- **Offset null capability**
- **Large common mode and differential voltage ranges**
- **60V/μs slew rate (gain of +5, −4 min)**
- **6MHz gain bandwidth product (gain +5, −4 minimum)**
- **Internal frequency compensation (gain of +5, −4 minimum)**
- **Pin out: 538 same as 741 (single)**
  5538 same as 747, 1458 (dual)

NE/SE5512-D,N,FE

DESCRIPTION

The 5512 series of high performance operational amplifier provides very good input characteristics. These amplifiers feature low input bias and voltage characteristics such as a 108 op amp with improved CMRR and a high differential input voltage limit achieved through the use of a bias cancellation and PNP input circuits with collector to emitter clamping. The output characteristics are like those of a 741 op amp with improved slew rate and drive capability yet have low supply quiescent current.

APPLICATIONS

- **AC amplifiers**
- **RC active filters**
- **Transducer amplifiers**
- **DC gain block**
- **Battery operation**
- **Instrumentation applications**

FEATURES

- **Low input bias $< \pm 3$nA**
- **Low input offset current $< \pm 3$nA**
- **Low input offset voltage < 1mV**
- **Low V_{OS} temperature drift 4μV/°C**
- **Low input bias temperature drift 30pA/°C**
- **Low input voltage noise 25nV/$\sqrt{Hz}$**
- **Low supply current 1.5mA/amp**
- **High slew rate 1.0V/μs**
- **High CMRR 100dB**
- **High input impedance 100MΩ**
- **High PSRR 110dB**
- **High differential input voltage limit**
- **No cross-over distortion**
- **Indefinite output short circuit protection**
- **Internally compensated for unity gain**

NOTE

* For operation at elevated temperature, N package must be derated based on a thermal resistance of 120°/W junction to ambient. Thermal resistance of the FE package is 125°/W.

BRIDGE TRANSDUCER AMPLIFIER

In applications involving strain gauges, accelerometers and thermal sensors a bridge transducer is often used. Frequently the sensor elements are high resistance units requiring equally high bridge resistance for good sensitivity. This type of circuit then demands an amplifier with high input impedance, low bias current and low drift. The circuit shown represents a possible solution to these general requirements (Figure 1).

For V_S = 10 volts, the common mode voltage is approximately +5 volts, well within the common mode limits of the NE5512.

The sensitivity of the input stage is approximately

$$\frac{RF \cdot Vs}{2R}$$

to a change in transducer resistance ΔR. This gives a gain factor of ≃50 for V_S = 10V and R = 25kΩ. The second stage gain is ×100 giving a total gain of ≃5000.

Noise is minimized by shielding the transducer leads and taking special care to determine a good signal ground. Common mode noise rejection is particularly important making matched differential impedance critical. The NE5512 typically provides 100dB of common mode rejection and will considerably reduce this undesirable effect.

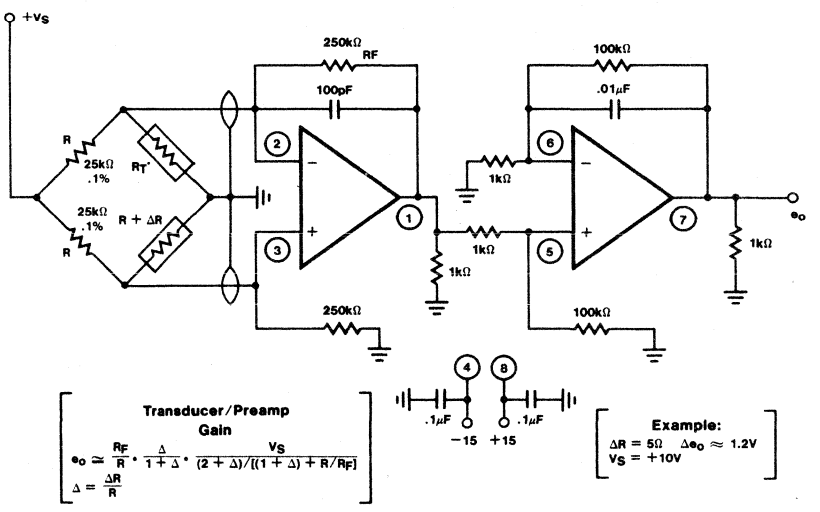
The following are sensitivity figures for the transducer circuits.

	ΔR	ΔE_{out}
leg 1	10Ω	−2.6V
	5Ω	−1.3V
leg 2	10Ω	+2.4
	5Ω	+1.2

Temperature compensation of the bridge element is accomplished by using low drift metal film resistors and also by providing a complimentary non-active sensor element to thermally track the offset in the active element.

High frequency roll-off provides attenuation of unwanted noise above the pass band of the transducer. The shunt capacitors across both stage feedback resistors are for this purpose.

NE/SE5512 BRIDGE TRANSDUCER AMPLIFIER



*NOTE
Thermal compensation transducer (non-active)

Figure 1

NE/SE5512 CURRENT TO VOLTAGE CONVERTER WITH 1% ACCURACY [SENSITIVITY: 1 VOLT PER MICROAMP]

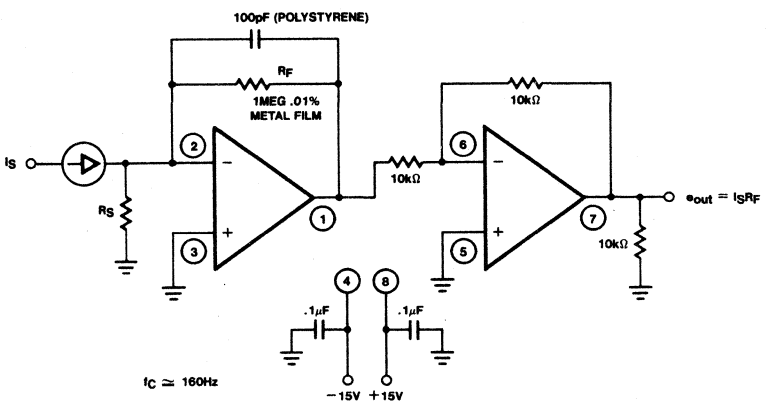


Figure 2

CURRENT TO VOLTAGE CONVERTER

Taking advantage of the very low bias current and offset of the NE5512 is demonstrated in its adaptation to a current to voltage converter as shown below (Figure 2).

The lower limit of measuring accuracy is determined by I_B (inverting) which is typically 6nA. In order to attain a measurement accuracy of 1% the following inequality must hold,

$$I_B \lesssim (.01)\, I_{Smin}$$

Where I_B = input bias current, I_{Smin} = minimum measured current. For I_B = 6nA and I_{Smin} = 1μA,

$$6nA \lesssim (.01)\, 1\mu A = 10nA$$

and the inequality hold.

DC offset and current noise gain is determined by

$$\frac{R_F + R_S}{R_S}$$

which ≃ 1 for $R_S \gg R_F$.

The measured results for this circuit appear below (V_{CC} = ± 15 volts).

INPUT CURRENT	OUTPUT VOLTAGE
1μA	1.008 Volts
5μA	5.00 Volts
10.00μA	10.00 Volts

NE5512 OPERATIONAL DIFFERENTIATOR

By utilizing the very high input impedance characteristic of the NE5512, an excellent active differentiator can be realized. Using the circuit shown (Figure 3), good results were obtained as shown by the wave forms in figures 4, 5 and 6. One of the primary problems with such circuits is the tendency toward instability and distortion either due to loading caused by input bias currents or amplifier non-linearity. In addition, gain increases with frequency requiring low input noise in the amplifier.

The relative stability is shown by the output signal wave forms mentioned above. Adding R_1 provides added compensation in the form of a zero near the amplifier unity gain frequency. Frequency range is 100Hz to 10kHz.

In order to obtain good differentiation, the network time constant, RC, must be small relative to the period of the highest frequency present at the input. Since the differentiator will attenuate the signal by a factor of ωRC which may be 100:1 in the operating region, the second amplifier stage is used to compensate for this loss. Various circuits are easily interfaced with the differentiator block due to the inherently low output impedance of the NE5512.

NE/SE5512 ACTIVE DIFFERENTIATOR WITH INVERTING ×10 BUFFER

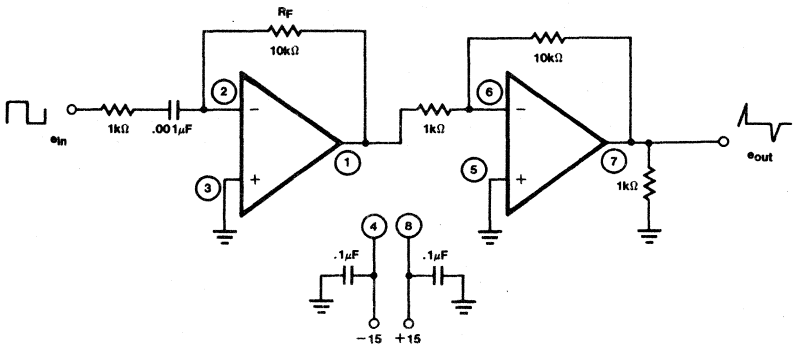

Figure 3

DIFFERENTIATOR WAVEFORMS

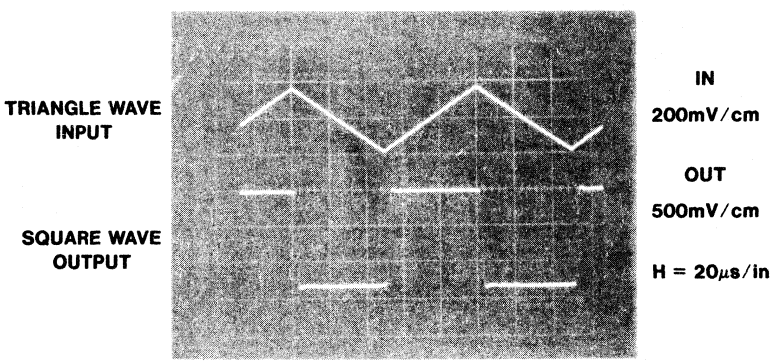

Figure 4

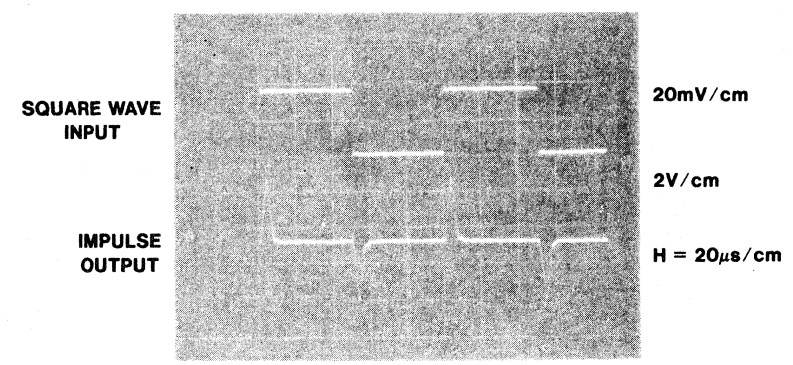

Figure 5

THE OPERATIONAL INTEGRATOR

The operational compliment of the active differentiator is the active integrator. The NE5512 is easily adapted to this function as shown in the circuit below (Figure 7). To obtain satisfactory integration the time constant must fulfill the following requirement:

$RC \geq 15T$

Where T is the period of the input wave form. For the ideal integrator

$$e_{out} = \frac{1}{RC} \int e_{in}\, dt$$

The factor 1/RC represents an attenuation of the input signal. The low signal level is increased by using the second half of the NE5512 as a gain stage following the operational integration. The wave forms in Figures 8 and 9 show the input-output relationship for both a sine wave and a square wave function. A good integrator must exhibit a phase shift of $\geq 89°$ for sine wave input over the active frequency range. For a square wave the resultant output must be a linear ramp. The circuit shown fulfills this requirement (see Figure 7). No external compensation is required since the amplifier is unity gain stable.

NE/SE5514-F,N

DESCRIPTION

The NE/SE5514 family of Quad Operational Amplifiers sets new standards in Bipolar Quad Amplifier Performance. The amplifiers feature low input bias current and low offset voltages. Pin-out is identical to LM324/LM348 which facilitates direct product substitution for improved system performance. Output characteristics are similar to a μA741 with improved slew and drive capability.

FEATURES

- Low input bias current: $<\pm 3$nA
- Low input offset current: $<\pm 3$nA
- Low input offset voltage: <1mV
- Low supply current: 1.5mA/Amp
- 1 V/μsec slew rate
- High input impedance: 100MΩ
- High common mode impedance: 10GΩ
- Internal compensation for unity gain

APPLICATIONS

- AC amplifiers
- RC active filters
- Transducer amplifiers
- DC gain block
- Instrumentation amplifier

FOUR QUADRANT PHOTO-CONDUCTIVE DETECTOR AMPLIFIER

When operating a photo diode in the photo-conductive mode (reverse biased) very small currents in the micro ampere range must be sensed in the photo active operating region. Dark currents in the nano amperes are common. Generally, for this reason, J-FET input preamps are used to prevent interaction and accuracy degradation due to input bias currents.

The 5514 has sufficiently low input bias current (6na) to allow its use under these circuit constraints as shown in a possible design used to sense four quadrant motion of a light source. By proper summing of the signals from the X and Y axes, four quadrant output may be fed to an X-Y plotter, oscilloscope or computer for simulation. (See figure 1).

The wide input common mode voltage range of the device allows a +10 volt supply to be used to drive the signal bridge giving high sensitivity and improved signal to noise. Obviously, input balancing is critical to achieving common mode signal rejection in addition to adequate shielding of the sensor leads. The sensor head itself must be shielded and the shield grounded to signal common to avoid unwanted noise pick up from power line and other local noise sources. Amplifier response may be shaped to aid in noise reduction by more complex filter configurations. If possible the 5514 should be located in close proximity to the sensor head.

System balance may be done under dark field conditions if adequate photo detector tracking results. However, for high accuracy systems a bipolar balance adjust added to the non-inverting output stage is more desirable. With this latter method the signal bridge is balanced for a null output under uniform light field conditions using the bridge balance pot as shown. D.C. offset is then adjusted using the balance pot on the output amplifier under dark field conditions.

FOUR QUADRANT PHOTO DETECTOR

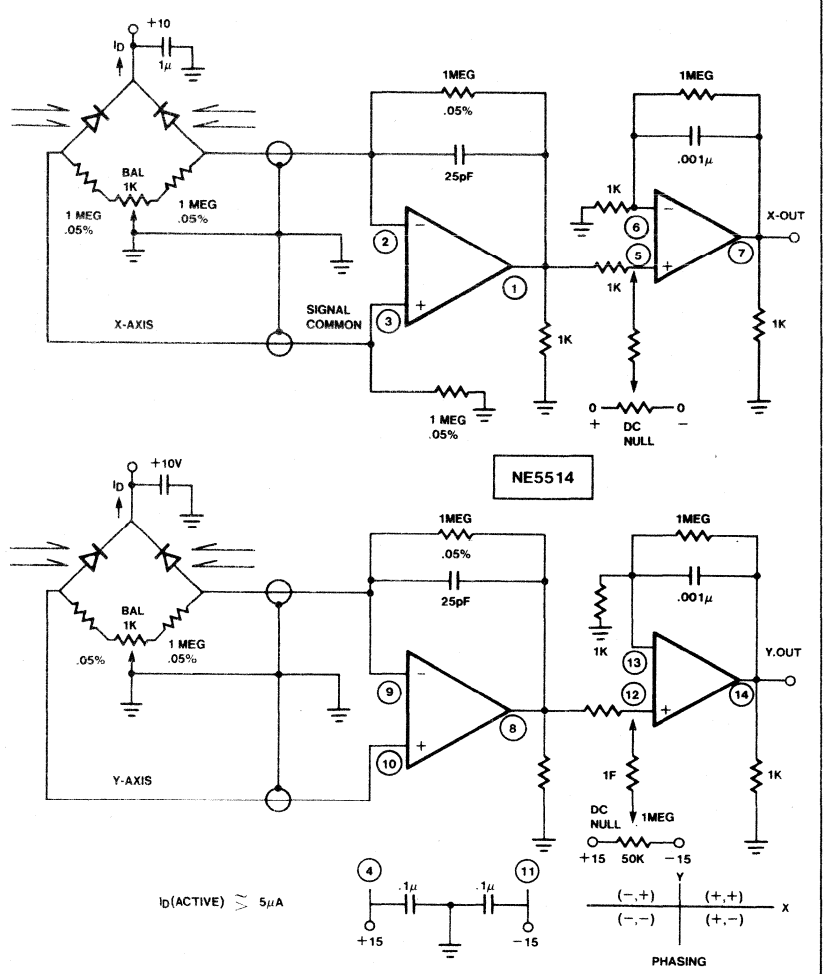

Figure 1

MULTI-TONE BANDPASS FILTER FOR PLL TONE DECODER

In the design of a multiple tone signaling system, particularly where signals are transmitted over long lines, noise and adjacent channel interference may be a significant barrier to reliable communications.

By the use of narrow band active pre-filters to attain selectivity and gain, the effective signal to noise ratio is greatly improved. The NE/SE5514 is easily adapted to such filter configurations due to its inherent stability. In addition its very high input impedance drastically reduces loading on the passive networks and allows for increased "Q" and large value resistors.

The circuit in Figure 2 demonstrates multiple feedback filters operating at four of the standard signaling frequencies. More channels may be added to increase the capacity of the system.

Test results obtained from this filter configuration were as follows:

Wide band signal to noise	63dB
Gain (Mid band)	30dB
Q (effective)	≈ 30
Output	OdBM ($.775v_{rms}$)

Note that the amplifiers are operated from a single +12 volt supply and are biased to half V_{CC} by a simple resistive divider at point B which connects to all non-inverting inputs.

4-STATION 0–50° TEMPERATURE SENSOR

By using an NPN transistor as a temperature sensing element, the NE5514 forms the basis for a multi-station temperature sensor as shown in Figure 3. The principle used is fundamental to the current-voltage relationship of a forward biased junction. The current flow across the base-emitter junction is determined by absolute temperature in the following way:

$$I_E = -(I_C + I_B)$$

and $$I_E \infty I_S \exp(V_{BE}/V_T);\ V_T = \frac{kt}{q}$$

therefore, $$V_{BE} \infty V_T \ln I_E/I_S$$

Where I_E is the forward current and I_S is the saturation current inherent in the junction, I_E must be high enough such that the I_S variation with temperature is small relative to I_E ($I_E >> I_S$). I_S is typically .05 pA, therefore, setting I_E to 1 or 2 μA gives the desired condition.

Diode D_1 serves to substantially reduce error due to power supply variation by giving a fixed voltage reference. To calibrate the sensor adjust R_4 for "O" volts output from the NE5514 at 0°C. Adjust R_6 tracking resistor for a scale factor of 100 millivolts per °C output.

Only the transistor need be placed in the temperature controlled environment. Figure 4 shows the addition of an A/D converter and display to give a digital thermometer.

NE5517/5517A-D,N

DESCRIPTION

The NE5517 contains two current controlled transconductance amplifiers, each with a differential input and push-pull output. The NE5517 offers significant design and performance advantages over similar devices for all types of programmable gain applications. Constant impedance buffers are provided which effectively eliminate changes in output offset voltage as the amplifier bias current is varied. Circuit performance is enhanced through the use of linearizing diodes at the inputs which enable a 10 dB signal to noise improvement referenced to .5 percent THD. The NE5517 is suited for a wide variety of industrial and consumer applications and is recommended as the preferred circuit in the Dolby* HX (Headroom Extension) system.

FEATURES

- **Constant impedance buffers**
- **ΔV_{BE} of buffer is constant with amplifier I_{BIAS} change**
- **Pin compatible with LM13600**
- **Excellent matching between amplifiers**
- **Linearizing diodes**
- **High output signal-to-noise ratio**

APPLICATIONS

- **Multiplexers**
- **Timers**
- **Electronic music synthesizers**
- **Dolby* HX Systems**
- **Current-controlled amplifiers, filters**
- **Current-controlled oscillators, impedances**

NOTE
*Dolby is a registered trademark of Dolby Laboratories Inc., San Francisco, Calif.

NOTES

1. For selections to a supply voltage above ±22V, contact factory.
2. For operating at high temperatures, the device must be derated based on a 150°C maximum junction temperature and a thermal resistance of 175° C/W which applies for the device soldered in a printed circuit board, operating in still air.
3. Buffer output current should be limited so as to not exceed package dissipation.
4. These specifications apply for V_S = ± 15V, T_A = 25°C, amplifier bias current (I_{ABC}) = 500μA, pins 2 and 15 open unless otherwise specified. The inputs to the buffers are grounded and outputs are open.
5. These specifications apply for V_S = ± 15V, I_{ABC} = 500μA, R_{OUT} = 5kΩ connected from the buffer output to $-V_S$ and the input of the buffer is connected to the transconductance amplifier output.
6. V_S = ± 15, R_{OUT} = 5Ω connected from Buffer output to $-V_S$ and 5μA ≤ I_{ABC} ≤ 500μA.

DESCRIPTION

The 5532 is a dual high-performance low noise operational amplifier. Compared to most of the standard operational amplifiers, such as the 1458, it shows better noise performance, improved output drive capability and considerably higher small-signal and power bandwidths.

This makes the device especially suitable for application in high quality and professional audio equipment, instrumentation and control circuits, and telephone channel amplifiers. The op amp is internally compensated for gains equal to one. If very low noise is of prime importance, it is recommended that the 5532A version be used which has guaranteed noise specifications.

FEATURES

- Small-signal bandwidth: 10MHz
- Output drive capability: 600Ω, 10V (rms)
- Input noise voltage: $5nV/\sqrt{Hz}$
- DC voltage gain: 50000
- AC voltage gain: 2200 at 10kHz
- Power bandwidth: 140kHz
- Slew-rate: $9V/\mu s$
- Large supply voltage range: ±3 to ±20V

APPLICATIONS

The Signetics 5532 High Performance Op Amp is an ideal amplifier for use in high quality and professional audio equipment which requires low noise and low distortion.

The circuit included in this application note has been assembled on a P.C. board, and tested with actual audio input devices (Tuner and Turntable). It consists of an RIAA pre-amp, input buffer, 5-band equalizer, and mixer. Although the circuit design is not new, its performance using the 5532 has been improved.

The RIAA pre-amp section is a standard compensation configuration with low frequency boost provided by the Magnetic cartridge and the RC network in the op amp feedback loop. Cartridge loading is accomplished via R1. 47k was chosen as a typical value, and may differ from cartridge to cartridge.

The Equalizer section consists of an input buffer, 5 active variable band pass/notch (depending on R9's setting) filters, and an

Figure 1

output summing amplifier. The input buffer is a standard unity gain design providing impedance matching between the pre amplifiers and the equalizer section. Because the 5532 is internally compensated, no external compensation is required. The 5-band active filter section is actually 5 individual active filters with the same feedback design for all 5. The main differance in all five stages is the values of C5 and C6 which are responsible for setting the center frequency of each stage. Linear pots are recommended for R9. To simplify use of this circuit, a component value table is provided, which lists center frequencies and their associated capacitor values. Notice that C5 equals (10) C6, and that the Value of R8 and R10 are related to R9 by a factor of 10 as well. The values listed in the table are common and easily found standard values.

The final stage is the summing amplifier/buffer stage, to sum the individual filters (Figure 2). Note the original signal is subtracted from the sum by a factor dependant on the number of filter stages. This subtraction is necessary to maintain a unity gain configuration at the output with all pots set to the flat position. If R13 were omitted the output with 1 volt at each stage would equal 5 volts (in this case) instead of the desired 1 volt. Full boost and cut using the table values is about ± 15dB. Although 5 bands were chosen for this application, the user may have as many bands as are required. Please note that the subtracting resistor R13, must be adjusted to meet the unity requirement using $R13 = \frac{100K}{\#\ of\ stages}$ i.e. 5 stages = 20k.

The remainder of the circuit employs the Philips TCA 730H volume, balance, and loudness-control circuit and the Signetics NE540 power driver circuit, which as shown will net about 35 watts per channel RMS. The NE540 can be found in the Signetics Analog Data Manual, and Applications Manual. Information on the TCA730A may be obtained from Signetics Analog Division.

NE5534-D

DESCRIPTION

The 5533/5534 are dual and single high-performance low noise operational amplifiers. Compared to other operational amplifiers, such as TL083, they show better noise performance, improved output drive capability and considerably higher small-signal and power bandwidths.

This makes the devices especially suitable for application in high quality and professional audio equipment, in instrumentation and control circuits and telephone channel amplifiers. The op amps are internally compensated for gain equal to, or higher than, three. The frequency response can be optimized with an external compensation capacitor for various applications (unity gain amplifier, capacitive load, slew-rate, low overshoot, etc.) If very low noise is of prime importance, it is recommended that the 5533A/5534A version be used which has guaranteed noise specifications.

FEATURES

- **Small-signal bandwidth: 10MHz**
- **Output drive capability: 600Ω, 10V (rms) at $V_S = \pm 18V$**
- **Input noise voltage: 4nV/$\sqrt{Hz}$**
- **DC voltage gain: 100000**
- **AC voltage gain: 6000 at 10kHz**
- **Power bandwidth: 200kHz**
- **Slew-rate: 13V/μs**
- **Large supply voltage range: ±3 to ±20V**

PIN CONFIGURATIONS

	Output short circuit duration[3]	indefinite	
	Lead temperature (soldering 10 sec)	300	°C

NOTES

1. Diodes protect the inputs against over-voltage. Therefore, unless current-limiting resistors are used, large currents will flow if the differential input voltage exceeds 0.6V. Maximum current should be limited to ±10mA.
2. For operation at elevated temperature, derate packages based on the following junction-to-ambient thermal resistances:
   8-pin ceramic (FE) 140°C/W
   14-pin ceramic (F) 110°C/W
   8-pin plastic (N) 162°C/W
   14-pin plastic (N) 150°C/W
3. Output may be shorted to ground at V_S = ±15V, T_A = 25°C. Temperature and/or supply voltages must be limited to ensure dissipation rating is not exceeded.

DC ELECTRICAL CHARACTERISTICS T_A = 25°C, V_S = ±15V unless otherwise specified.[1,2]

ULTRA HIGH FREQUENCY OPERATIONAL AMPLIFIER — NE/SE5539

NE/SE5539-F,N

DESCRIPTION

The Signetics NE5539 is a very wide bandwidth, high slew rate, monolithic operational amplifier for use in video amplifiers, RF amplifiers, and extremely high slew rate amplifiers.

Emitter follower inputs provide a true differential high input impedance device. Proper external compensation will allow design operation over a wide range of closed loop gains, both inverting and non-inverting, to meet specific design requirements.

FEATURES

- **Gain bandwidth product: 1.2GHz**
- **Slew rate: 600V/μsec**
- **Full power response: 48MHz**
- **A_{VOL}: 50dB**

APPLICATIONS

- **Fast pulse amplifiers**
- **RF oscillators**
- **Fast sample and hold**
- **High gain video amplifiers (BW > 20MHz)**

NE5539 COLOR VIDEO AMPLIFIER

The NE5539 wide band operational amplifier is easily adapted for use as a color video amplifier. A typical circuit is shown (figure 1) along with the Vectorscope photograph showing the amplifier response to a standard NTSC color signal. (Note that the input reference vectors are displayed simultaneously with the output.) The polar representation indicates amplifier differential phase error overall to be less than 2°. Gain also remains linear or constant with the varying input amplitudes.

The amplifier circuit was optimized for a 75Ω input and output termination impedance with a gain of 10 (20dB).

A second series of test waveforms show the amplifier's response to a 3.58MHz burst signal (figures 2 and 3).

Finally, the amplifier response is shown as a function of time for the NTSC signal with no perceptible droop or overshoot in response to step functions (see figure 4). Note that no external compensation was required since the gain was greater than 7 (17dB).

V_{CC} is ±8 volts for all cases shown.

Figure 10

SMALL SIGNAL RESPONSE

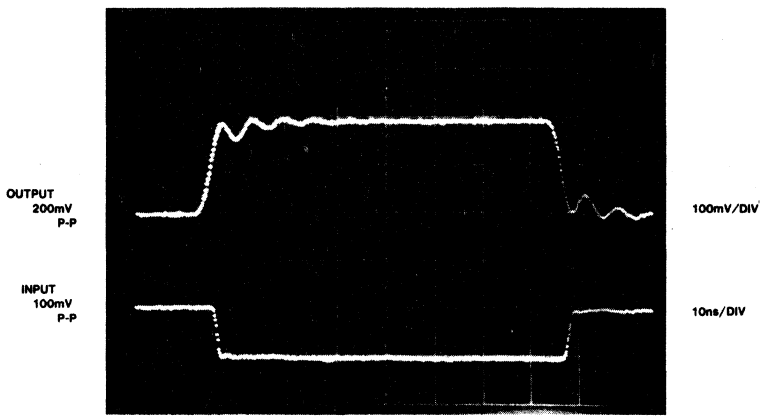

Figure 8

LARGE SIGNAL RESPONSE

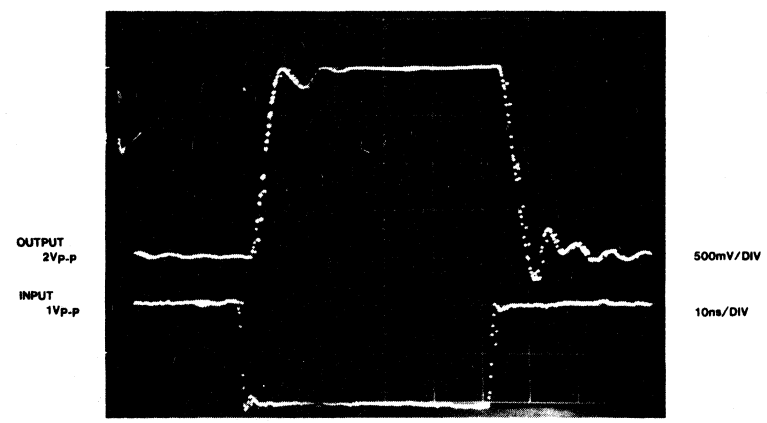

Figure 9

The primary reasoning behind this procedure is to force the closed loop circuit to appear as a gain of X7 above the critical frequency where phase changes rapidly (approx. 70MHz; refer to figure 7a). The lag network raises the phase at the upper operating frequencies, greatly improving the phase margin.

The calculations below show the application of these principles to the circuit in figure 7b.

The circuit shown has an inverting gain of 2, therefore solving for R_2:

$$R_2 \leqq \frac{R_f}{7 - |A_{CL}|} \leqq \frac{2K}{7 - 2} = 400$$

Let $R_2 = 330\Omega$

Assuming a gain band width product of 350 MHz, C_G may now be calculated as follows:

$$\therefore C_G \simeq \frac{5}{\pi \cdot 330 \cdot 350 \cdot 10^6} \simeq \boxed{14pF}$$

In the circuit shown, a lead compensation capacitor of $\simeq$ 1.6pF was used with a value of R_2 of 330Ω and C_G was a 2 – 20pF trimmer cap (JFD piston-type). Rise and fall times of 2.8 to 3ns were measured in the small signal mode with quite adequate range in the lag compensation trimmer to optimize overshoot and reduce ringing (see pulse response—figures 9 and 10).

Figure 7b

CIRCUIT LAYOUT CONSIDERATIONS

As may be expected for an ultra-high frequency, wide gain bandwidth amplifier, the physical circuit layout is extremely critical. A double-sided printed circuit board will result in more favorable system operation (see figure 10).

The effect of the distributed and input capacitance added by the inverting node of the amplifier must be considered when calculating actual system closed loop performance. The RC product of the input resistor (R_{IN}) in parallel with C_{dist}. and feedback resistor (R_F) create a pole at pin 14 (figure 5). This frequency must fall beyond the unity gain frequency of the system in order to maintain stability and system performance.

CLOSED LOOP GAIN LESS THAN 7

The NE5539 is stable for all closed loop gains greater than seven (7). When operating at gains less than seven (7), the device can become unstable. The circuit in figure 7 is an example of a unity gain inverting amplifier. The compensation components are added to obtain stable operation.

Capacitor C_L improves the phase margin (of the operational amplifier) by compensating for the lag introduced by the distributed capacitor (C_D).

It can be shown that the optimal conditions for amplifier stability occur when $R_1C_D = R_FC_L$; however, when the stability criteria is obtained, it should be noted that the actual bandwidth of the closed loop amplifier will be reduced.

The actual value for C_L, based on a distributed capacitance of 3.5pFd, would be $\simeq$ 2pF.

NON-INVERTING BLOCK DIAGRAM

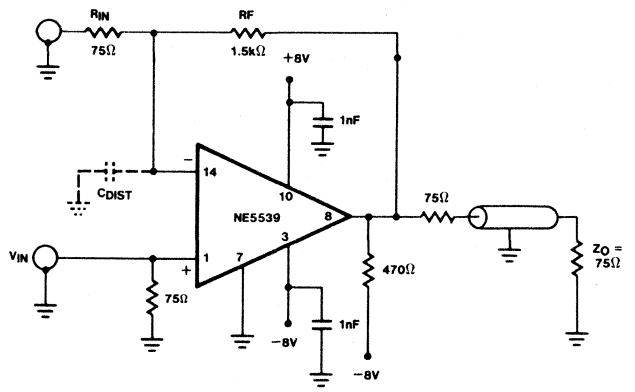

Figure 5

WIDE BAND UNITY GAIN INVERTING AMPLIFIER CIRCUIT IN A 75Ω SYSTEM

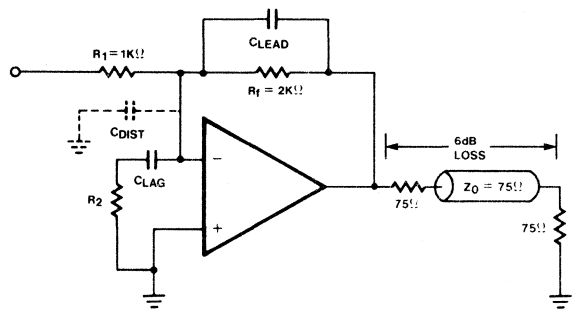

Figure 6

Determination of Compensation Capacitance:

$$C_{lead} = \frac{C_{dist}}{A_{CL}}$$

The above equation defines the relationship between the distributed capacitance, closed loop gain (A_{CL}), and the compensation capacitor (C_L). For closed loop stability and gains less than 5, C_{lead} becomes a practical consideration. When bandwidth is of primary concern, the simple lead compensation will usually be adequate. However, if transient response is also a factor in the design, then a lag compensation network (C_G, R_2) may be necessary.

For practical applications, the following equations can be used to determine the proper lag compensation components:

$$\frac{R_f}{R_1 \,||\, R_2} \geq 7 \qquad \text{(Equation 1)}$$

$$\therefore R_2 \leq \frac{R_f}{7 - A_{CL}} \qquad \text{(Equation 2)}$$

(Using Equation 1 to insure a closed loop gain of X7 above the network break frequency allows you to solve for R_2, the lag network resistor.)

C_{lag} may be approximated by the following equations. First set the lag network break frequency in relation to the amplifier total gain product (open loop).

$$\text{Set } \omega_{lag} \simeq \frac{2\pi \cdot GBW}{10} \text{ rad/sec}$$

$$\simeq \frac{\pi \cdot GBW}{5} \text{ rad/sec,}$$

$$\text{then } \omega_{lag} = \frac{1}{R_2 C_{lag}}$$

and C_{lag} may now be determined.

$$\therefore C_{lag} \simeq \frac{5}{\pi \cdot R_2 \cdot GBW}$$

< Assume GBW = 350MHz > (Equation 3)

DESCRIPTION

The μA741 is a high performance operational amplifier with high open loop gain, internal compensation, high common mode range and exceptional temperature stability. The μA741 is short-circuit protected and allows for nulling of offset voltage.

FEATURES

- **Internal frequency compensation**
- **Short circuit protection**
- **Excellent temperature stability**
- **High input voltage range**

μA747C-D

DESCRIPTION

The 747 is a pair of high performance monolithic operational amplifiers constructed on a single silicon chip. High common mode voltage range and absence of "latch-up" make the 747 ideal for use as a voltage follower. The high gain and wide range of operating voltage provides superior performance in integrator, summing amplifier, and general feedback applications. The 747 is short-circuit protected and requires no external components for frequency compensation. The internal 6dB/octave roll-off insures stability in closed loop applications. For single amplifier performance, see μA741 data sheet.

FEATURES

- **No frequency compensation required**
- **Short-circuit protection**
- **Offset voltage null capability**
- **Large common-mode and differential voltage ranges**
- **Low power consumption**
- **No latch-up**

DESCRIPTION

The 748 is a High Performance Operational Amplifier featuring high gain, short circuit immunity, offset voltage null capability, simplified compensation and excellent temperature stability.

FEATURES

- **Short circuit protection**
- **Offset voltage null capability**
- **Large common-mode and differential voltage ranges**
- **Low power consumption**
- **No latch-up**

ABSOLUTE MAXIMUM RATINGS

PARAMETER	RATING	UNIT
Supply voltage		
μA748	±22	V
μA748C	±18	V
Internal power dissipation[1]	500	mW
Differential output voltage	±30	V
Input voltage[2]	±15	V
Storage temperature range	-65 to +150	°C
Operating temperature range		
μA748	-55 to +125	°C
μA748C	0 to +70	°C
Lead temperature	300	°C
Output short circuit duration[3]	indefinite	

NOTES

1. Rating applies for case temperatures to +70°C.
2. For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.
3. Short circuit may be to ground or either supply. Rating applies to +70°C ambient temperature.

SECTION 2
VIDEO AMPLIFIERS

Section 2—VIDEO AMPLIFIERS

NE592-D,F,H,N
SE592-F,H

DESCRIPTION

The SE/NE592 is a monolithic, two stage, differential output, wideband video amplifier. It offers fixed gains of 100 and 400 without external components and adjustable gains from 400 to 0 with one external resistor. The input stage has been designed so that with the addition of a few external reactive elements between the gain select terminals, the circuit can function as a high pass, low pass, or band pass filter. This feature makes the circuit ideal for use as a video or pulse amplifier in communications, magnetic memories, display, video recorder systems, and floppy disc head amplifiers. The 592 is a pin-for-pin replacement for the μA733.

FEATURES

- **120MHz bandwidth**
- **Adjustable gains from 0 to 400**
- **Adjustable pass band**
- **No frequency compensation required**
- **Wave shaping with minimal external components**

FOR FREQUENCY $F_1 << 1/2\ \pi\ (32)\ C$

$V_0 \cong 1.4 \times 10^4 C \frac{dV_i}{dT}$

DESCRIPTION

The 733 is a monolithic differential input, differential output, wideband video amplifier. It offers fixed gains of 10,100 or 400 without external components, and adjustable gains from 10 to 400 by the use of an external resistor. No external frequency compensation components are required for any gain option. Gain stability, wide bandwidth and low phase distortion are obtained through use of the classic series-shunt feedback from the emitter follower outputs to the inputs of the second stage. The emitter follower outputs provide low output impedance, and enable the device to drive capacitive loads. The 733 is intended for use as a high performance video and pulse amplifier in communications, magnetic memories, display and video recorder systems.

FEATURES

- **120MHz bandwidth**
- **250kΩ input resistance**
- **Selectable gains of 10,100 and 400**
- **No frequency compensation required**
- **Mil std 883A,B,C available**

SECTION 3
POWER CONTROLLERS

Section 3—POWER CONTROLLERS

VOLTAGE REGULATOR DEFINITIONS

T_A
Ambient temperature range. Range of the surrounding environment of the operating device.

T_J
Junction Temperature. The maximum temperature of the device. 150°C is standard for silicon devices.

T_{STG}
Storage temperature range. Temperature range that the device can be stored in a non-operating condition.

T_{SOLD}
Soldering Temperature. The temperature which can be applied to the lead frame of the device for short periods of time (normally specified for a duration of 10 sec).

Truth Tables
0 is logic level low
1 is logic level high
X - don't care condition - has no effect under circuit conditions listed.

Absolute Maximum Rating
Operating safe zones exceeding these limits could cause permanent damage to the device and are not meant to imply that devices can operate at these limits.

Power Dissipation
The power that the device can safely handle at 25°C. The dissipation must be derated as indicated for the individual package type.

Package Type Designation
See full package designations in Appendix.

V_{CC} ($-V_{CC}$)
Supply Voltage. The range of power supply voltage over which the device will operate safely.

Line Regulation
Sometimes referred to as "static regulation". This term refers to the changes in the output as the input is varied slowly from its rated minimum value to its rated maximum value (from 105 VAC_{RMS} to 125 VAC_{RMS}). Measured in mv/V.

Load Regulation
Sometimes referred to as "dynamic regulation". This term refers to the changes in the output when load conditions are suddenly changed (from no load to full load). Measured in mv/V.

Thermal Regulation
Referred to as changes due to ambient variations or thermal drift. Also referred to as temperature coefficient, measured in ppm/°C or mv/°C.

Transient Response
The ability of a regulator to respond to rapid changes in line variations, load variations, or intermittent transient input conditions. (Transient Response is often referred to as "recovery time"). Measured in milliseconds (ms).

Voltage Limiting
The ability of the regulator to "shut down" in the event that the internal reference sources fail to function properly. Measured in Volts.

Current Limiting
The ability of the amplified segment to limit the output current of the device when safe operating limits are exceeded. Measured in amperes (pre-determined).

Thermal Shutdown
The ability of the regulator to shut itself down when the maximum die temperature is exceeded. Measured in degrees Celsius (C).

Power Dissipation
The ability of the regulator to tolerate excessively high levels of input power while maintaining its operation within the safe operating area of its active devices. Measured in watts.

Efficiency
Regarding a regulator, the ratio of the total power input to the usable power output. Expressed as a percentage. (For example, if a regulator has a 50 watt input and a 40 watt output, its efficiency is 80 percent).

EMI/RFI
("Electromagnetic Interference/Radio Frequency Interference") regarding regulators, magnetic field disturbance and radio frequency interference signals generated especially by SMPS devices. Measurement is generally unspecified.

Safe Operating Area Restriction (SOAR)
Limits the output current of the amplifier to maintain safe (no thermal runaway) operating conditions. (Accomplished through internal sensor amplifiers).

NOTE
Refer to Section 4 of Analog Applications Manual for an in-depth explanation of Voltage Regulators

DESCRIPTION

The NE/SE5553,4 are dual polarity tracking regulators designed to produce balanced or unbalanced output voltages from 5 to 20 volts with up to 300 mA output current. Similar in specifications to the 78MXX and 79MXX fixed regulators, the 5553/4 series can be continuously adjusted, balanced or unbalanced. The fixed voltage on the 5553 is ±12V, and on the 5554 is ±15V. Employing current limiting and thermal shutdown protection, these dual polarity regulators are ideal for local on-card regulation.

FEATURES

- **Output current to 300mA**
- **Internally current limited**
- **Thermal overload protected**
- **Input voltage to ±32V**
- **Output balance 1% typ.**
- **External balance control**
- **Continuously adjustable from 5 to 20 volts, balanced or unbalanced**
- **No external components required**
- **Short circuit current 400mA**
- **Maximum power capability can be achieved with proper heat sinking**

DESCRIPTION

The NE/SE5560 is a control circuit for use in switched mode power supplies. This single monolithic chip incorporates all the control and housekeeping (protection) functions required in switched mode power supplies, including an internal temperature compensated reference source, internal Zener reference, sawtooth generator, pulse width modulator, output stage and various protection circuits.

FEATURES

- **Stabilized power supply**
- **Temperature compensated reference source**
- **Sawtooth generator**
- **Pulse width modulator**
- **Remote on/off switching**
- **Current limiting**
- **Low supply voltage protection**
- **Loop fault protection**
- **Demagnetization/overvoltage protection**
- **Maximum duty cycle adjustment**
- **Feed forward control**
- **External synchronization**

DESCRIPTION

This monolithic integrated circuit contains all the control circuitry for a regulating power supply inverter or switching regulator. Included in a 16-pin dual-in-line package is the voltage reference, error-amplifier, oscillator, pulse width modulator, pulse steering flip-flop, dual alternating output switches and current limiting and shut-down circuitry. This device can be used for switching regulators of either polarity, transformer coupled DC to DC converters, transformerless voltage doublers and polarity converters, as well as other power control applications. The SG1524 is specified for operation over the full military temperature range of −55°C to +125°C, while the SG2524 and SG3524 are designed for commercial applications of 0°C to +70°C.

FEATURES

- **Complete PWM power control circuitry**
- **Single ended or push-pull outputs**
- **Line and load regulation of 0.2%**
- **1% maximum temperature variation**
- **Total supply current is less than 10mA**
- **Operation beyond 100kHz**

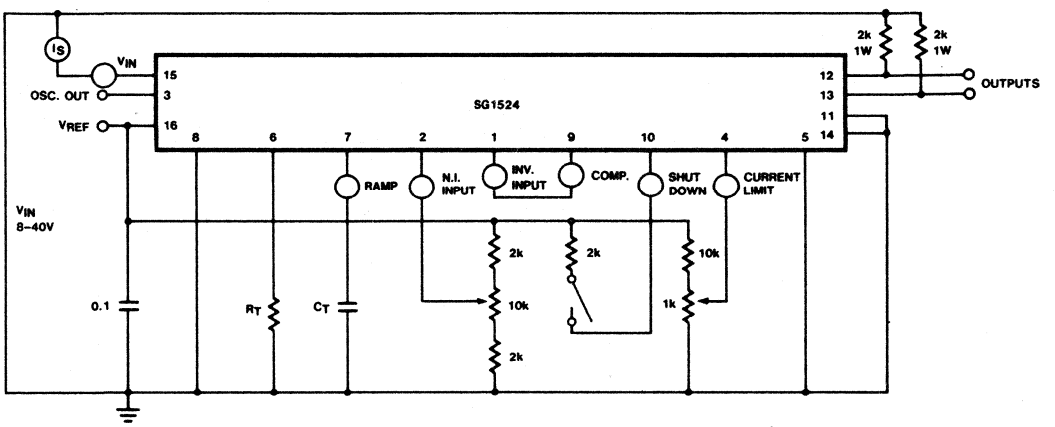
OPEN LOOP TEST CIRCUIT



APPLICATIONS

Voltage Reference

An internal series regulator provides a nominal 5 volt output which is used both to generate a reference voltage and is the regulated source for all the internal timing and controlling circuitry. This regulator may be bypassed for operation from a fixed 5 volt supply by connecting pins 15 and 16 together to the input voltage. In this configuration, the maximum input voltage is 6.0 volts.

This reference regulator may be used as a 5 volt source for other circuitry. It will provide up to 50mA of current itself and can easily be expanded to higher currents with an external PNP as shown in Figure 1.

Oscillator

The oscillator in the SG1524 uses an external resistor (R_T) to establish a constant charging current into an external capacitor (C_T). While this uses more current than a series connected RC, it provides a linear ramp voltage on the capacitor which is also used as a reference for the comparator. The charging current is equal to 3.6V ÷ R_T and should be kept within the range of approximately 30μA to 2mA, i.e., 1.8K<R_T<100K.

The range of values for C_T also has limits as the discharge time of C_T determines the pulse width of the oscillator output pulse. This pulse is used (among other things) as a blanking pulse to both outputs to insure that there is no possibility of having both outputs on simultaneously during transitions. This output dead time relationship is shown in Figure 2. A pulse width below approximately 0.5 microseconds may allow false triggering of one output by removing the blanking pulse prior to the flip-flops reaching a stable state. If small values of C_T must be used, the pulse width may still be expanded by adding a shunt capacitance (≈100pF) to ground at the oscillator output. (Note: Although the oscillator output is a convenient oscilloscope sync input, the cable and input capacitance may increase the blanking pulse width slightly.) Obviously, the upper limit to the pulse width is determined by the maximum duty cycle acceptable. Practical values of C_T fall between .001 and 0.1 microfarad.

The oscillator period is approximately t = R_TC_T where t is in microseconds when R_T = ohms and C_T = microfarads. The use of Figure 3 will allow selection of R_T and C_T for a wide range of operating frequencies. Note that for series regulator applications, the two outputs can be connected in parallel for an effective 0-90% duty cycle and the frequency of the oscillator is the frequency of the output. For push-pull applications, the outputs are separated and the flip-flop divides the frequency such that each outputs duty cycle is 0-45% and the overall frequency is one-half that of the oscillator.

External Synchronization

If it is desired to synchronize the SG1524 to an external clock, a pulse of ≈+3 volts may be applied to the oscillator output terminal with R_TC_T set slightly greater than the clock period. The same considerations of pulse width apply. The impedance to ground at this point is approximately 2K ohms.

If two or more SG1524's must be synchronized together, one must be designated as master with its R_TC_T set for the correct peri-

TYPICAL APPLICATION

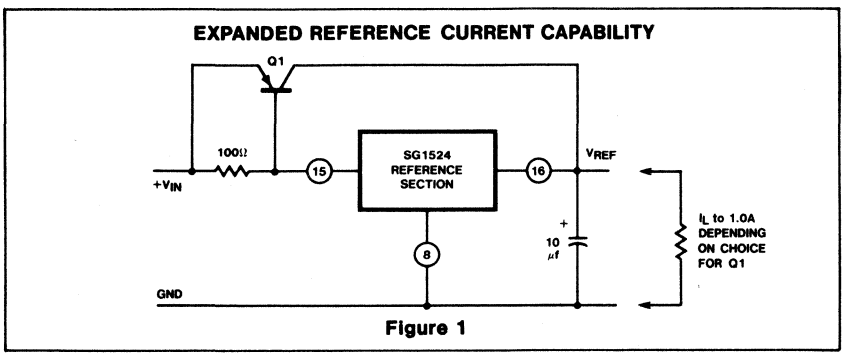


Figure 1

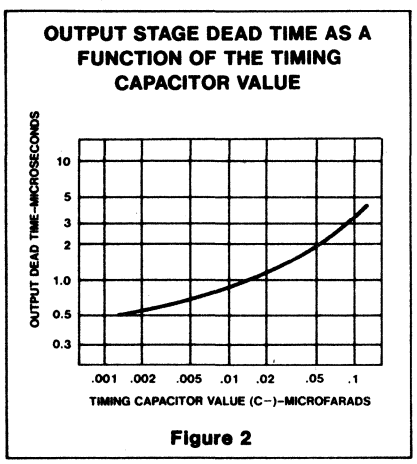

Figure 2

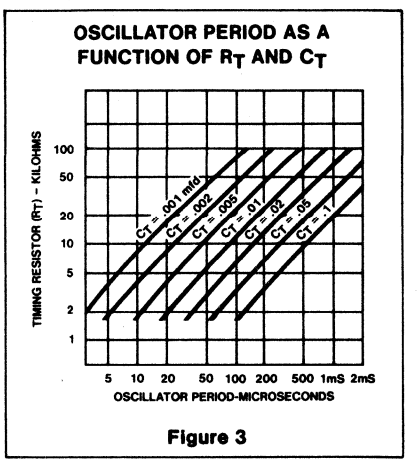

Figure 3

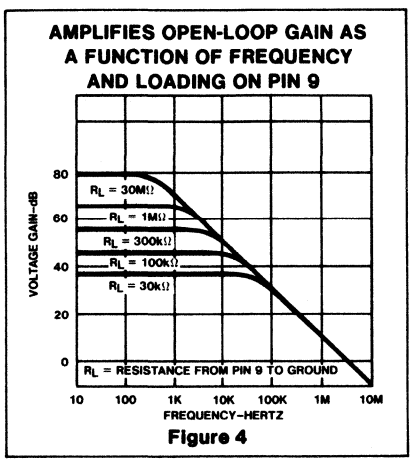

Figure 4

od. The slaves should each have an R_TC_T set for approximately 10% longer period than the master with the added requirement that C_T (slave) = one-half C_T (master). Then connecting Pin 3 on all units together will insure that the master output pulse—which occurs first and has a wider pulse width—will reset the slave units.

Error Amplifier

This circuit is a simple differential-input, transconductance amplifier. The output is the compensation terminal, pin 9, which is a high impedance node ($R_L \approx 5M\Omega$). The gain is

$$A_V = gmR_L = \frac{8\, I_C\, R_L}{2kT} \approx .002\, R_L$$

and can easily be reduced from a nominal of 10,000 by an external shunt resistance from pin 9 to ground, as shown in Figure 4.

In addition to DC gain control, the compensation terminal is also the place for AC phase compensation. The frequency response curves of Figure 4 show the uncompensated amplifier with a single pole at approximately 200Hz and a unity gain cross-over at 5MHz.

Typically, most output filter designs will introduce one or more additional poles at a significantly lower frequency. Therefore, the best stabilizing network is a series R-C combination between pin 9 and ground which introduces a zero to cancel one of the output filter poles. A good starting point is 50kΩ plus .001 microfarad.

One final point on the compensation terminal is that this is also a convenient place to insert any programming signal which is to override the error amplifier. Internal shutdown and current limit circuits are connected here, but any other circuit which can sink 200μA can pull this point to ground thus shutting off both outputs.

While feedback is normally applied around the entire regulator, the error amplifier can be used with conventional operational amplifier feedback and is stable in either the inverting or non-inverting mode. Regardless of the connections, however, input common-mode limits must be observed or output signal inversions may result. For conventional regulator applications, the 5 volt reference voltage must be divided down as shown in Figure 5. The error amplifier may also be used in fixed duty cycle applications by using the unity gain configuration shown in the open loop test circuit.

Current Limiting

The current limiting circuitry of the SG1524 is shown in Figure 6.

By matching the base-emitter voltages of Q1 and Q2, and assuming negligible voltage drop across R_1,

$$\text{Threshold} = V_{BE}(Q1) + I_1R_2 - V_{BE}(Q2)$$
$$= I_1R_2 \approx 200mV$$

Although this circuit provides a relatively small threshold with a negligible temperature coefficient, there are some limitations to its use, the most important of which is the ± 1 volt common mode range which requires sensing in the ground line. Another factor to consider is that the frequency compensation provided by R_1C_1 and Q1 provides a roll-off pole at approximately 300Hz.

Since the gain of this circuit is relatively low, there is a transition region as the current limit amplifier takes over pulse width control from the error amplifier. For testing purposes, threshold is defined as the input voltage to get 25% duty cycle with the error amplifier signaling maximum duty cycle.

In addition to constant current limiting, pins 4 and 5 may also be used in transformer-coupled circuits to sense primary current and shorten an output pulse, should transformer

saturation occur. (Refer to Figure 14). Another application is to ground pin 5 and use pin 4 as an additional shutdown terminal: i.e., the output will be off with pin 4 open and on when it is grounded. Finally, foldback current limiting can be provided with the network of Figure 7. This circuit can reduce the short-circuit current (I_{SC}) to approximately one-third the maximum available output current (I_{MAX}).

Output Circuits

The outputs of the SG1524 are two identical NPN transistors with both collectors and emitters uncommitted. This circuitry is very similar to that used in the SG111 comparator in that each output transistor has antisaturation circuitry for fast response, and current limiting set for a maximum output current of approximately 100mA. The availability of both collectors and emitters allows maximum versatility to enable driving either NPN or PNP external transistors.

In considering the application of the SG1524 to voltage regulator circuitry, there are a multitude of output configurations possible. In general, however, they fall into three basic classifications:

1. Capacitor-diode coupled voltage multipliers
2. Inductor-capacitor single-ended circuits
3. Transformer-coupled circuits

Examples of each category are shown in Figures 8, 9 and 10. In each case, the switches indicated can be either the output transistors in the SG1524 or added external transistors according to the load current requirements.

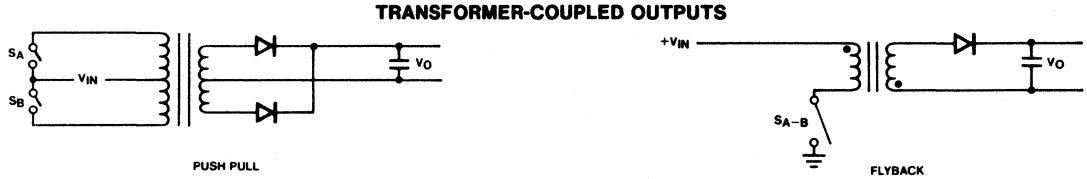
Figure 9

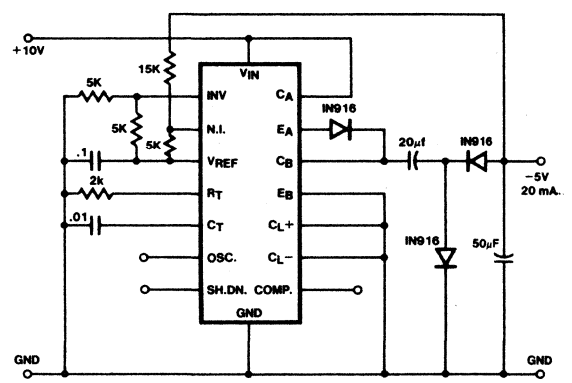
TRANSFORMER-COUPLED OUTPUTS



Transformer-coupled outputs need not relate to the input in either amplitude or polarity.

Figure 10

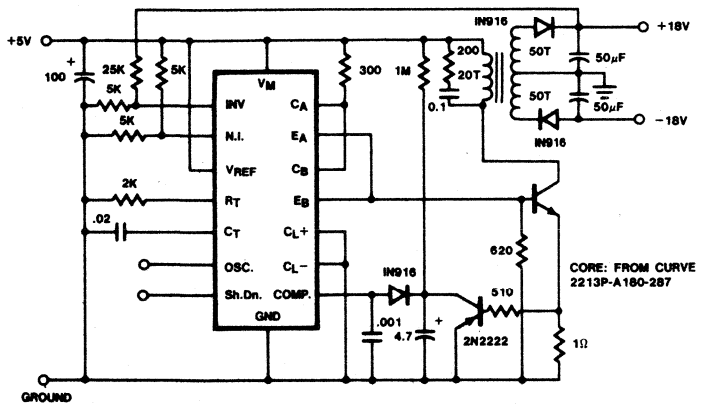
TYPICAL APPLICATION



The capacitor-diode output circuit is used here as a polarity converter to generate a −5 volt supply from +15 volts. This circuit is useful for an output current of up to 20mA with no additional boost transistors required. Since the output transistors are current limited, no additional protection is necessary. Also, the lack of an inductor allows the circuit to be stabilized with only the output capacitor.

Figure 11

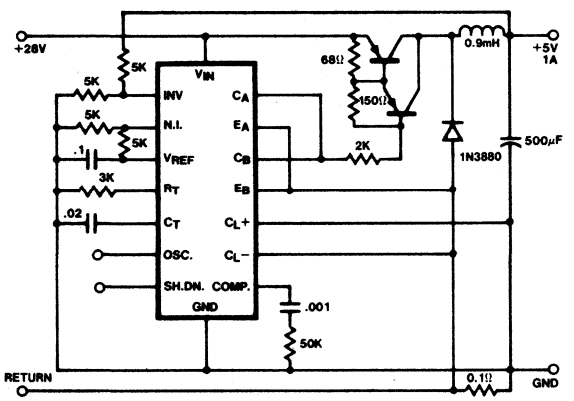
TYPICAL APPLICATION



Another low-current supply is the flyback converter used here to generate ±15 volts at 20mA from a +5 volt regulated line. The reference generator in the SG1524 is unused with the input voltage providing the reference. Current limiting in a flyback converter is difficult and is accomplished here by sensing current in the primary line and resetting a soft-start circuit.

Figure 12

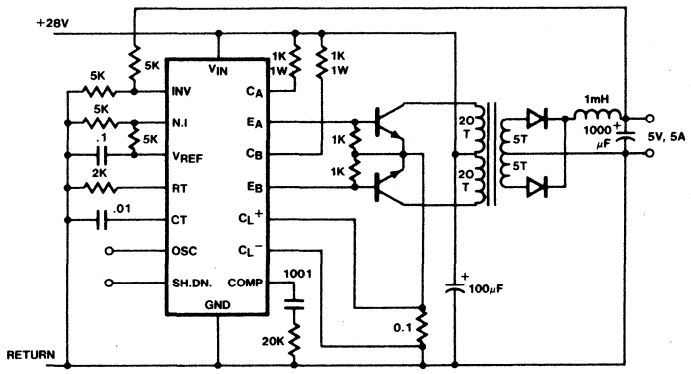
TYPICAL APPLICATION



In this conventional single-ended regulator circuit, the two outputs of the SG1524 are connected in parallel for effective .0-90% duty-cycle modulation. The use of an output inductor requires an R-C phase compensation network for loop stability.

Figure 13

TYPICAL APPLICATION



Push-pull outputs are used in this transformer-coupled DC-DC regulating converter. Note that the oscillator must be set at twice the desired output frequency as the SG1524's internal flip-flop divides the frequency by 2 as it switches the P.W.M. signal from one output to the other. Current limiting is done here in the primary so that the pulse width will be reduced should transformer saturation occur.

3

DESCRIPTION

The μA723/SA723C is a Monolithic Precision Voltage Regulator capable of operation in positive or negative supplies as a series, shunt, switching or floating regulator. The 723 contains a temperature compensated reference amplifier, error amplifier, series pass transistor, and current limiter, with access to remote shutdown.

FEATURES

- **Positive or negative supply operation**
- **Series, shunt, switching or floating operation**
- **.01% line and load regulation**
- **Output voltage adjustable from 2 to 37 volts**
- **Output current to 150mA without external pass transistor**
- **μA723 MIL STD 88 3A, B, C available**

$$I_{SHORT\ CKT} = \left[\frac{V_{SENSE}}{R_{SC}} \times \frac{R_3 + R_4}{R_4}\right]$$

$$\frac{R_4}{R_3} = \frac{V_{OUT}\,I_{SC}}{V_{SENSE}\,(I_{KNEE} - I_{SHORTCKT})} - 1$$

$$R_{SC} = \frac{V_{SENSE}}{I_{SC}}\left[1 + \frac{R_3}{R_4}\right]$$

SECTION 4
TIMERS

Section 4—TIMERS

NE/SE555/SE555C-F,H,N,FE

DESCRIPTION

The 555 monolithic timing circuit is a highly stable controller capable of producing accurate time delays, or oscillation. In the time delay mode of operation, the time is precisely controlled by one external resistor and capacitor. For a stable operation as an oscillator, the free running frequency and the duty cycle are both accurately controlled with two external resistors and one capacitor. The circuit may be triggered and reset on falling waveforms, and the output structure can source or sink up to 200mA.

FEATURES

- **Turn off time less than 2μs**
- **Maximum operating frequency greater than 500kHz**
- **Timing from microseconds to hours**
- **Operates in both astable and monostable modes**
- **High output current**
- **Adjustable duty cycle**

NOTES

1. Supply current when output high typically 1mA less.
2. Tested at $V_{CC} = 5V$ and $V_{CC} = 15V$.
3. This will determine the maximum value of $R_A + R_B$, for 15V operation, the max total R = 10 megohm, and for 5V operation, the max total R = 3.4 megohm.
4. Specified with trigger input high.
5. Time measured from a positive going input pulse from 0 to 0.8 x V_{CC} into the threshold to the drop from high to low of the output. Trigger is tied to threshold.

NOTES

See following page

NOTES

1. Supply current when output is high is typically 1.0mA less.
2. Tested at V_{CC} = 5V and V_{CC} = 15V.
3. This will determine the maximum value of $R_A + R_B$. For 15V operation, the maximum total R = 10 megohms, and for 5V operation, the max. total R = 3.4 megohms.
4. Matching characteristics refer to the difference between performance characteristics for each timer section in the monostable mode.
5. Specified with trigger input high.
6. Time measured from a positive going input pulse from 0 to 0.8 V_{CC} into the threshold to the drop from high to low of the output. Trigger is tied to threshold.

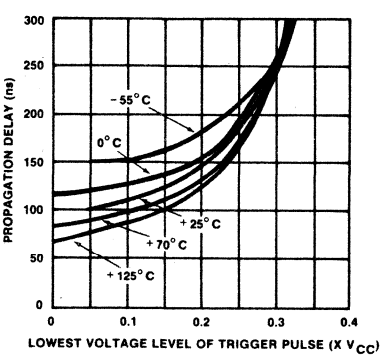
PROPAGATION DELAY vs VOLTAGE LEVEL OF TRIGGER PULSE



DESCRIPTION

The 558 Quad Timers are monolithic timing devices which can be used to produce four entirely independent timing functions. The 558 output sinks current. These highly stable, general purpose controllers can be used in a monostable mode to produce accurate time delays, from microseconds to hours. In the time delay mode of operation, the time is precisely controlled by one external resistor and one capacitor. A stable operation can be achieved by using two of the four timer sections.

The four timing sections in the 558 are edge triggered; therefore, when connected in tandem for sequential timing applications, no coupling capacitors are required. Output current capability of 100mA is provided in both devices.

FEATURES

- **100mA output current per section**
- **Edge triggered (no coupling capacitor)**
- **Output independent of trigger conditions**
- **Wide supply voltage range 4.5V to 18V**
- **Timer intervals from microseconds to hours**
- **Time period equals RC**
- **Military qualifications pending**

APPLICATIONS

- **Sequential timing**
- **Time delay generation**
- **Precision timing**
- **Industrial controls**
- **Quad one-shot**

Risetime of output	I_L = 100mA		100			100		ns
Falltime of output	I_L = 100mA		100			100		ns

NOTES

1. The trigger functions only on the falling edge of the trigger pulse only after previously being high. After reset the trigger must be brought high and then low to implement triggering.
2. For reset below 0.8 volts, outputs set low and trigger inhibited. For reset above 2.4 volts, trigger enabled.
3. The 558 output structure is open collector which requires a pull up resistor to V_{CC} to sink current. The output is normally low sinking current.

LM111/211/311/-F,N,N-14,H
LM311-D

DESCRIPTION

The LM111 series are voltage comparators that have input currents approximately a hundred times lower than devices like the μA710. They are designed to operate over a wider range of supply voltages; from standard ±15V op amp supplies down to the single 5V supply used for IC logic. Their output is compatible with RTL, DTL, and TTL as well as MOS circuits. Further, they can drive lamps or relays, switching voltages up to 50V at currents as high as 50mA.

Both the inputs and the outputs of the LM111 series can be isolated from system ground, and the output can drive loads referred to ground, the positive supply or the negative supply. Offset balancing and strobe capability are provided and outputs can be wire OR'ed. Although slower than the μA710 (200ns response time vs 40ns) the devices are also much less prone to spurious oscillations. The LM111 series has the same pin configuration as the μA710 series.

FEATURES

- **Operates from single 5V supply**
- **Maximum input bias current: 150nA (LM311 - 250nA)**
- **Maximum offset current: 20nA (LM311 - 50nA)**
- **Differential input voltage range: ±30V**
- **Power consumption: 135mW at ±15V**
- **High sensitivity—200V/mV**
- **Military qualification pending**

	$V_{IN} \leq -6mV$, $I_{SINK} \leq 8mA$		0.23	0.4		0.23	0.4	V
Output leakage current	$V_{IN} \geq 5mV$, $V_{OUT} = 35V$		0.1	0.5				μA
Positive supply current	$T_A = 25°C$		5.1	6.0		5.1	7.5	mA
Negative supply current	$T_A = 25°C$		4.1	5.0		4.1	5.0	mA

NOTES

1. This rating applies for ±15V supplies. The positive input voltage limit is 30V above the negative supply. The negative input voltage limit is equal to the negative supply voltage or 30V below the positive supply, whichever is less.
2. The maximum junction temperature of the LM311 is 110°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150° C/W, junction to ambient, in the N package, a thermal resistance of 162° C/W, and ° C/W for the Ceramic package. The maximum junction temperature of the LM111 is 150°C, while that of the LM211 is 110°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150° C/W, junction to ambient. The thermal resistance of the Cerdip package is 110° C/W, junction to ambient.
3. These specifications apply for $V_S = \pm 15V$ and $0°C < T_A < 70°C$ unless otherwise specified. With the LM211, however, all temperature specifications are limited to $-25°C \leq T_A \leq 85°C$ and for the LM111 is limited to $-55°C < T_A < 125°C$. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 5V supply up to ±15V supplies.
4. The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with 1mA load. Thus, these parameters define an error band and take into account the worst case effects of voltage gain and input impedance.
5. The response time specified (see definitions) is for a 100mV input step with 5mV overdrive.

LM119/219/319-F,H,N
LM319-D

DESCRIPTION

The LM119 series are precision high speed dual comparators fabricated on a single monolithic chip. They are designed to operate over a wide range of supply voltages down to a single 5V logic supply and ground. Further, they have higher gain and lower input currents than devices like the μA710. The uncommitted collector of the output stage makes the LM119 compatible with RTL, DTL and TTL as well as capable of driving lamps and relays at currents up to 25mA.

Although designed primarily for applications requiring operation from digital logic supplies, the LM119 series are fully specified for power supplies up to ±15V. It features faster response than the LM111 at the expense of higher power dissipation. However, the high speed, wide operating voltage range and low package count make the LM119 much more versatile than older devices like the μA711.

The LM119 is specified from -55°C to +125°C, the LM219 is specified from -25°C to +85°C, and the LM319 is specified from 0°C to +70°C.

FEATURES

- **Two independent comparators**
- **Operates from a single 5V supply**
- **Typically 80ns response time at ±15V**
- **Minimum fan-out of 3 (each side)**
- **Maximum input current of 1μA over temperature**
- **Inputs and outputs can be isolated from system ground**
- **High common mode slew rate**
- **Mil std 883 A, B, C available**

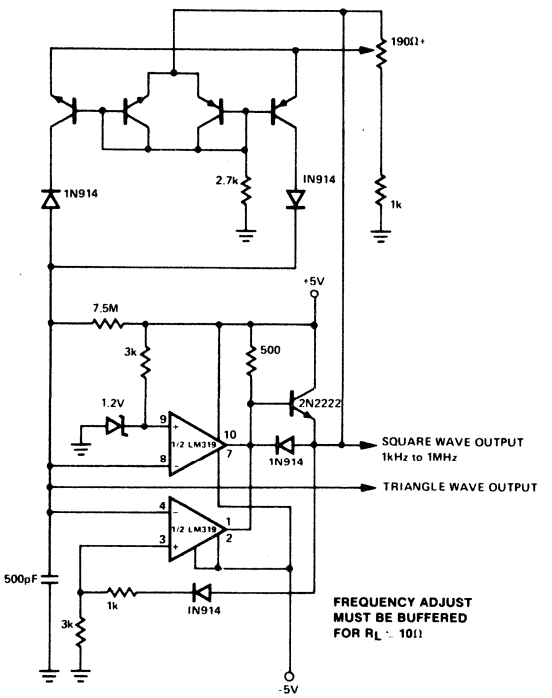
WIDE RANGE VARIABLE OSCILLATOR



LM139/239/339/2901/MC3302-F,N
LM339-D

DESCRIPTION

The LM139 series consists of four independent precision voltage comparators with an offset voltage specification as low as 2.0mV max for each comparator which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common mode voltage range includes ground, even though operated from a single power supply voltage.

The LM139 series was designed to directly interface with TTL and CMOS. When operated from both plus and minus power supplies, the LM139 series will directly interface with MOS logic where their low power drain is a distinct advantage over standard comparators.

FEATURES

- **Wide single supply voltage range 2.0Vdc to 36Vdc or dual supplies ±1.0Vdc to ±18Vdc**
- **Very low supply current drain (0.8mA) independent of supply voltage (1.0mW/-comparator at 5.0Vdc)**
- **Low input biasing current 25nA**
- **Low input offset currrent ±5nA and offset voltage ±2mV**
- **Input common-mode voltage range includes ground**
- **Differential input voltage range equal to the power supply voltage.**
- **Low output 250mV at 4mA saturation voltage**
- **Output voltage compatible with TTL, DTL, ECL, MOS and CMOS logic systems.**

APPLICATIONS

- **A/D converters**
- **Wide range VCO**
- **MOS clock generator**
- **High voltage logic gate**
- **Multivibrators**

NOTES

1. For operating at high temperatures, the LM339/339A, LM2901 and MC3302 must be derated based on a 125°C maximum junction temperature and a thermal resistance of 175°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM139/139A/239/239A must be derated on a 150°C maximum junction temperature. The low power dissipation and the "On-Off" characteristics of the outputs keep the chip dissipation very small ($P_D \leq 100mW$), provided the output transistors are allowed to saturate.
2. Short circuits from the output to V+ can cause excessive heating and eventual destruction. The maximum output current is approximately 20mA independent of the magnitude of V+.
3. This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the comparators to go to the V+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than -0.3Vdc.
4. Positive excursions of input voltage may exceed the power supply level. As long as the other voltage remains within the common-mode range, the comparator will provide a proper output state. The low input voltage state must not be less than -0.3Vdc (or 0.3Vdc below the magnitude of the negative power supply, if used).
5. At output switch point, $V_O \cong 1.4Vdc$, $R_S = 0\Omega$ with V+ from 5Vdc to 30Vdc; and over the full input common-mode range (0Vdc to V+ -1.5Vdc).
6. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ -1.5V, but either or both inputs can go to 30Vdc without damage.
7. The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the reference or input lines.
8. The response time specified is for a 100mV input step with a 5mV overdrive. For larger overdrive signals, 300ns can be obtained, see typical performance characteristics section.

LM193/293/393/193A/293A/393A/2903-N,FE,H

DESCRIPTION

The LM193 series consists of two independent precision voltage comparators with an offset voltage specification as low as 2.0mV max for two comparators which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common mode voltage range includes ground, even though operated from a single power supply voltage.

The LM193 series was designed to directly interface with TTL and CMOS. When operated from both plus and minus power supplies, the LM193 series will directly interface with MOS logic where their low power drain is a distinct advantage over standard comparators.

FEATURES

- **Wide single supply voltage range 2.0Vdc to 36Vdc or dual supplies ±1.0Vdc to ±18Vdc**
- **Very low supply current drain (0.8mA) independent of supply voltage (2.0mW/-comparator at 5.0Vdc)**
- **Low input biasing current 25nA**
- **Low input offset current ±5nA and offset voltage ±2mV**
- **Input common-mode voltage range includes ground**
- **Differential input voltage range equal to the power supply voltage.**
- **Low output 250mV at 4mA saturation voltage**
- **Output voltage compatible with TTL, DTL, ECL, MOS and CMOS logic systems.**

APPLICATIONS

- **A/D converters**
- **Wide range VCO**
- **MOS clock generator**
- **High voltage logic gate**
- **Multivibrators**

NOTES

1. For operating at high temperatures, the LM393/393A and LM2903 must be derated based on a 125°C maximum junction temperature and a thermal resistance of 175°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM193/193A/293/293A must be derated based on a 150°C maximum junction temperature. The low bias dissipation and the "On-Off" characteristics of the outputs keeps the chip dissipation very small ($P_D \leq 100mW$), provided the output transistors are allowed to saturate.
2. Short circuits from the output to V+ can cause excessive heating and eventual destruction. The maximum output current is approximately 20mA independent of the magnitude of V+.
3. This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the comparators to go to the V+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than -0.3Vdc.
4. Positive excursions of input voltage may exceed the power supply level. As long as the other voltage remains within the common-mode range, the comparator will provide a proper output state. The low input voltage state must not be less than -0.3Vdc (Vdc below the magnitude of the negative power supply, if used).
5. At output switch point, $V_O \cong 1.4Vdc$, $R_S = 0\Omega$ with V+ from 5Vdc to 30Vdc; and over the full input common-mode range (0Vdc to V+ -1.5Vdc).
6. The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V+ -1.5V, but either or both inputs can go to 30Vdc without damage.
7. With the LM293/293A, all temperature specifications are limited to $-25°C \leq T_A \leq +85°C$ and the LM393/393A, all temperature specifications are limited to $0°C \leq T_A \leq +70°C$. The LM2903 is limited to $-40°C \leq T_A \leq 85°C$.
8. The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the reference or input lines.
9. The response time specified is for a 100mV input step with a 5mV overdrive.
10. For input signals that exceed V_{CC}, only the overdriven comparator is affected. With a 5V supply, V_{IN} should be limited to 25V max., and a limiting resistor should be used on all inputs that might exceed the positive supply.

NE521-F,N
SE521-F

FEATURES

- 12ns maximum guaranteed propagation delay
- 20μA maximum input bias current
- TTL compatible strobes and outputs
- Large common mode input voltage range
- Operates from standard supply voltages
- Military qualifications pending

APPLICATIONS

- MOS memory sense amp
- A-to-D conversion
- High speed line receiver

FEATURES

- 15ns maximum guaranteed propagation delay
- 20μA maximum input bias current
- TTL compatible strobes and outputs
- Open collector output for wire-OR'd applications
- Large common mode input voltage range
- Operates from standard supply voltages

APPLICATIONS

- MOS memory sense amp
- A-to-D conversion
- High speed line receiver

NE527-F,H,N/SE527-F,H

DESCRIPTION

The SE/NE527 is a high speed analog voltage comparator which, in the first time mates state-of-the-art Schottky diode technology with the conventional linear process. This allows simultaneous fabrication of high speed T²L gates with a precision linear amplifier on a single monolithic chip. The SE/NE527 is similar in design to the Signetics SE/NE529 voltage comparator except that it incorporates a "Emitter Follower" input stage for extremely low input currents. This opens the door to a whole new range of applications for analog voltage comparators.

FEATURES

- **15ns propagation delay**
- **Complementary output gates**
- **TTL or ECL compatible outputs**
- **Wide common mode and differential voltage range**
- **Mil std 883A,B,C available**

APPLICATIONS

- **A/D conversion**
- **ECL to TTL interface**
- **TTL to ECL interface**
- **Memory sensing**
- **Optical data coupling**

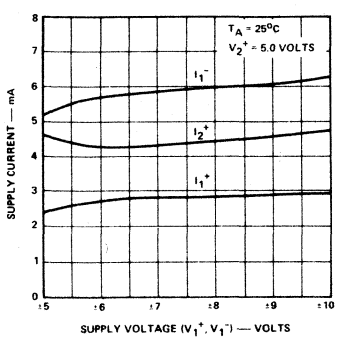
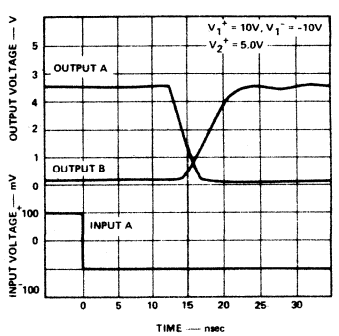
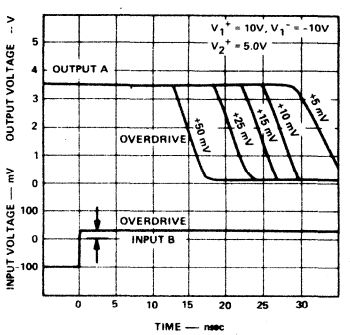
SUPPLY CURRENT vs SUPPLY VOLTAGE



OUTPUT PROPAGATION DELAYS



RESPONSE TIME FOR VARIOUS INPUT OVERDRIVES



APPLICATIONS

One of the main features of the device is that supply voltages (V1+, V1−) need not be balanced, as indicated in the following diagrams. For proper operation, however, negative supply (V1−) should always be at least six volts more negative than the ground terminal (pin 6). Input Common Mode range should be limited to values of two volts less than the supply voltages (V1+ and V1−) up to a maximum of ±6 volts as supply voltages are increased.

It is also important to note that Output A is in phase with Input A and Output B is in phase with Input B.

SECTION 6
MICROPROCESSOR INTERFACE

Section 6—MICROPROCESSOR INTERFACE

DESCRIPTION

The NE590/591 addressable peripheral drivers are high current latched drivers, similar in function to the 9334 address decoder. The device has 8 Darlington power outputs, each capable of 250mA load current. The outputs are turned on or off by respectively loading a logic high or logic low into the device data input. The required output is defined by a 3-bit address. The device must be enabled by a $\overline{CE}$ input line which also serves the function of further address decoding. A common clear input, $\overline{CLR}$, turns all outputs off when a logic low is applied.

The NE590 has 8 open collector Darlington outputs which sink current to ground. The device is packaged in a 16-pin molded or cerdip package.

The NE591 has 8 open emitter Darlington outputs which source current to an external load from a common collector line, V_S. This V_S line need not necessarily be the same as the 5 volt V_{CC} supply. The device is packaged in an 18-pin molded or cerdip package.

FEATURES

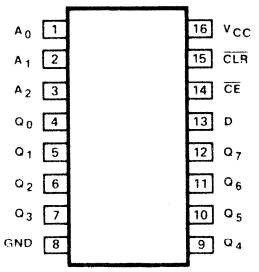
- **8 high current outputs**
- **Low-loading bus compatible inputs**
- **Power-on clear ensures safe operation**
- **NE590 will operate in addressable or demultiplex mode**
- **Allows random (addressed) data entry**
- **Easily expandable**
- **NE590 is pin compatible with 9334**

APPLICATIONS

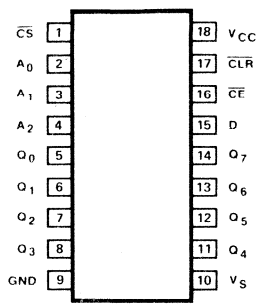
- **Relay driver**
- **Indicator lamp driver**
- **Triac trigger**
- **LED display digit driver**
- **Stepper motor driver**

PIN CONFIGURATIONS

NE590
F,N PACKAGE



NE591
F,N PACKAGE



PIN DESIGNATION

590 PIN NO.	591 PIN NO.	SYMBOL	NAME & FUNCTION
1-3	2-4	A_0-A_2	A 3-bit binary address on these pins defines which of the 8 output latches is to receive the data.
4-7, 9-12	5-8, 11-14	Q_0-Q_7	The 8 device outputs. The NE590 has open collector Darlington outputs. The NE591 has open emitter follower outputs.
13	15	D	The data input. When the chip is enabled, this data bit is transferred to the defined output such that: "1" turns output switch "ON" "0" turns output switch "OFF" Thus in logic terms, the NE590 inverts data to the relevant output. The NE591 retains true data at the output.
14	16	$\overline{CE}$	The chip enable. When this input is low, the output latches will accept data. When $\overline{CE}$ goes high, all outputs will retain their existing state, regardless of address or data input conditions.
15	17	$\overline{CLR}$	The clear input. When $\overline{CLR}$ goes low all output switches are turned "OFF". On the NE590, a high data input will override the clear function on the addressed latch. On the NE591, $\overline{CLR}$ low will override any other condition.
—	1	$\overline{CS}$	The chip select input provides for an additional level of address decoding.
—	10	V_S	The V_S line provides the power to all 8 output devices. It is connected to the collectors of all 8 output transistors. This pin may be connected to the V_{CC} or another supply.

SECTION 7
TRANSISTOR ARRAYS

Section 7—TRANSISTOR ARRAYS

DESCRIPTION

The CA3081 and CA3082 are monolithic integrated circuits, each consisting of seven separate npn transistors on a common substrate. The transistors are capable of driving loads of up to 100mA. At the same time, the transistor geometry used gives maximum current gain at quite low currents, making the devices also suitable for small-signal applications. In the CA3081, the transistors are connected in a common emitter configuration, while in the CA3082, the collectors are common. The transistor arrays are particularly suitable for driving light-emitting diodes and seven-segment displays, as well as for general purpose applications. The CA3081 and CA3082 are available in both 16-lead dual-in-line plastic and cerdip packages.

FEATURES

- **Seven transistors permit a wide range of applications in either a common emitter (CA3081) or common-collector (CA3082) configuration.**
- **High I_C: 100mA maximum**
- **Low $V_{CE\ sat}$ (at 50mA): 0.4V typical**

APPLICATIONS

- **Drivers for:**
  Incandescent display devices
  LED
  Relay control
  Thyristor firing

V_{CBO}	Collector to base voltage[1]	20	V
V_{CIO}	Collector to substrate voltage[1,2]	20	V
V_{EBO}	Emitter to base voltage[1]	5	V
I_C	Collector current[1]	100	mA
I_B	Base current[1]	20	mA

NOTES
1. Ratings apply for each transistor in the device.
2. The collector of each transistor of the CA3081 and CA3082 is isolated from the substrate by an integral diode. The substrate must be connected to a voltage which is more negative than any collector voltage in order to maintain isolation between transistors and provide normal transistor action. To avoid undesired coupling between transistors, the substrate terminal (5) should be maintained at either DC or signal (AC) ground. A suitable bypass capacitor can be used to establish a signal ground.

7

DESCRIPTION

These high-voltage, high-current Darlington transistor arrays are comprised of seven silicon NPN Darlington pairs on a common monolithic substrate. All units feature open collector outputs and integral suppression diodes for inductive loads. Peak inrush currents to 600mA are allowable, making them ideal for driving tungsten filament lamps also.

The Type ULN-2001 is a general-purpose array which may be used with DTL, TTL, PMOS, CMOS, etc. It is pinned with inputs opposite outputs to facilitate ease of circuit board layout and is priced to compete directly with discrete transistor alternatives.

The Type ULN-2003 has a series base resistor to each Darlington pair, and thus allows operation directly with TTL or CMOS operating at a supply voltage of 5V.

The Type ULN-2004 has an appropriate series input resistor to allow its operation directly from CMOS or PMOS outputs utilizing supply voltages of 6 to 15V. The required input current is below that of the Type ULN-2003.

In all cases, the individual Darlington pair collector current rating is 500mA. However, outputs may be paralleled for higher load current capability. All devices are supplied in a 16-pin dual in-line plastic package.

FEATURES

- **Peak inrush current 600mA**
- **Protected internally against inductive loads**
- **Open collector topology**
- **Compatible with most logic technologies**

INTERFACE

Section 8—INTERFACE

DS7820/8820-F,N

DESCRIPTION

The DS7820, specified from -55°C to 125°C, and the DS8820, specified from 0°C to 70°C, are digital line receivers with two completely independent units fabricated on a single silicon chip. Intended for use with digital systems connected by twisted pair lines, they have a differential input designed to reject large common mode signals while responding to small differential signals. The output is directly compatible with RTL, DTL or TTL integrated circuits.

The response time can be controlled with an external capacitor to eliminate noise spikes, and the output state is determined for open inputs. Termination resistors for the twisted pair line are also included in the circuit. Both the DS7820 and the DS8820 are specified, worst case, over their full operating temperature range, for ±10-percent supply voltage variations and over the entire input voltage range.

FEATURES

- **Operation from a single +5V logic supply**
- **Input voltage range of ±15V**
- **Independent channel strobing**
- **High input resistance**
- **Fanout of two with DTL or TTL**
- **Output can be wire OR'ed**
- **DS7820 Mil std 883A,B,C available**

PIN CONFIGURATION

DESCRIPTION

The DS7820A and the DS8820A are improved performance digital line receivers with two completely independent units fabricated on a single silicon chip. Intended for use with digital systems connected by twisted pair lines, they have a differential input designed to reject large common mode signals while responding to small differential signals. The output is directly compatible with RTL, DTL or TTL integrated circuits.

The response time can be controlled with an external capacitor to reject input noise spikes. The output state is a logic "1" for both inputs open. Termination resistors for the twisted pair line are also included in the circuit. Both the DS7820A and the DS8820A are specified, worst case, over their full operating temperature range (-55°C to 125°C and 0°C to 70°C respectively), over the entire input voltage range, for ±10% supply voltage variations.

FEATURES

- **Operation from a single +5V logic supply**
- **Input voltage range of ±15V**
- **Strobe low forces output to "1" state**
- **High input resistance**
- **Fanout of ten with either DTL or TTL integrated circuits**
- **Outputs can be wire OR'ed**
- **Series 54/74 compatible**

NOTES

1. These specifications apply for $4.5V \leq V_{CC} \leq 5.5V$, $-15V \leq V_{CM} \leq 15V$ and $-55°C \leq T_A \leq +125°C$ for the DS7820A or $0°C \leq T_A \leq +70°C$ for the DS8820A unless otherwise specified. Typical values given are for $V_{CC} = 5.0V$, $T_A = 25°C$ and $V_{CM} = 0V$ unless stated differently.
2. All currents into device pins shown as positive, out of device pins as negative, all voltages referenced to ground unless otherwise noted. All values shown as max or min on absolute value basis.
3. Only one output at a time should be shorted.
4. The specifications and curves given are for one side only. Therefore, the total package dissipation and supply currents will be double the values given when both receivers are operated under identical conditions.

AC ELECTRICAL CHARACTERISTICS $T_A = 25°C$, $V_{CC} = 5V$ unless otherwise specified.

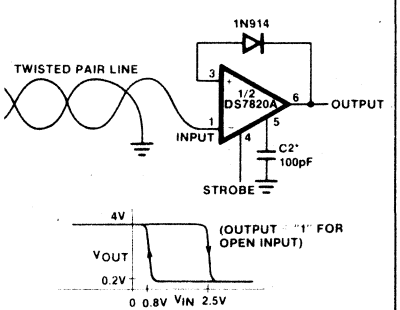
SINGLE ENDED (EIA-RS232C) RECEIVER WITH HYSTERESIS



DS7830/8830-F,N

DESCRIPTION

The DS7830/DS8830 is a dual differential line driver that also performs the dual four-input NAND or dual four-input AND function.

TTL (Transistor-Transistor-Logic) multiple emitter inputs allow this line driver to interface with standard TTL or DTL systems. The differential outputs are balanced and are designed to drive long lengths of coaxial cable, strip line, or twisted pair transmission lines with characteristic impedances of 50Ω to 500Ω. The differential feature of the output eliminates troublesome ground-loop errors normally associated with single-wire transmissions.

FEATURES

- **Single 5 volt power supply**
- **High speed**
- **Diode protected outputs for termination of positive and negative voltage transients**
- **Diode protected inputs to prevent line ringing**
- **Short circuit protection**
- **DS7830 Mil std 883A,B,C available**

MC1488-F,N

DESCRIPTION

The MC1488 is a quad line driver which converts standard DTL/TTL input logic levels through one stage of inversion to output levels which meet EIA Standard No. RS-232C and CCITT Recommendation V.24.

FEATURES

- **Current limited output: ±10mA Typ**
- **Power-off source impedance: 300Ω Min**
- **Simple slew rate control with external capacitor**
- **Flexible operating supply range**
- **Inputs are DTL/TTL compatible**

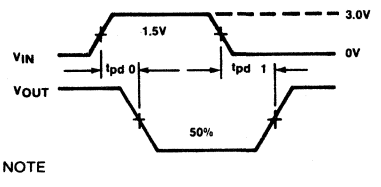
SWITCHING WAVEFORMS



NOTE

t_r and t_f are measured between 10% and 90% of the output waveform

APPLICATIONS

By connecting a capacitor to each driver output the slew rate can be controlled utilizing the output current limiting characteristics of the MC1488. For a set slew rate the appropriate capacitor value may be calculated using the following relationship

$$C = I_{SC}\,(\Delta T/\Delta V)$$

where C is the required capacitor, I_{SC} is the short circuit current value, and $\Delta V/\Delta T$ is the slew rate.

RS232C specifies that the output slew rate must not exceed 30V per microsecond. Using the worst case output short circuit current of 12mA in the above equation, calculations result in a required capacitor of 400pF connected to each output.

DESCRIPTION

The MC1489/MC1489A are quad line receivers designed to interface data terminal equipment with data communications equipment. They are constructed on a single monolithic silicon chip. These devices satisfy the specifications of EIA standard No. RS232C.

FEATURES

- **Four totally separate receivers per package**
- **Programmable threshold**
- **Built-in input threshold hysteresis**
- **"Fail safe" operating mode**
- **Inputs withstand ±30V**

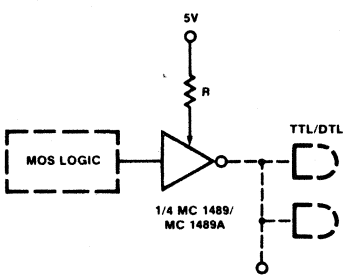
MOS TO TTL/DTL TRANSLATOR



75S107-F,N

DESCRIPTION

The 75S107 is a high speed dual line receiver that is functionally equivalent and pin compatible to the SN75107A. If features less than 17ns propagation delay without sacrificing input performance characteristics. This is accomplished through the utilization of Schottky technology.

The 75S107 maintains ±3V common mode voltage range, 7.5mV input offset voltage and 5μA offset current. It also features STTL compatible output levels with a minimum sink/source capability of 10 Schottky gate loads.

FEATURES

- **Functionally equivalent and pin compatible to SN75107A**
- **17ns maximum guaranteed propagation delay**
- **20μA maximum input bias current**
- **STTL compatible strobes and outputs**
- **Large common mode input voltage range**
- **Operates from standard supply voltages**

APPLICATIONS

- **MOS memory sense amp**
- **A/D conversion**
- **High speed line receiver**

75S207-F,N

DESCRIPTION

The 75S207 is a high speed dual sense amplifier that is functionally equivalent and pin compatible to the SN75207. The improved input sensitivity of ±10mV makes it suitable as a MOS memory sense amplifier which can result in faster memory cycles. The 75S207 features less than 17ns propagation delay without sacrificing input performance characteristics. This is accomplished through the utilization of Schottky technology.

The 75S207 also features STTL compatible output levels with a minimum sink/source capability of 10 Schottky gate loads.

FEATURES

- **Functionally equivalent and pin compatible to SN75207**
- **17ns maximum guaranteed propagation delay**
- **20μA maximum input bias current**
- **STTL compatible strobes and outputs**
- **Large common mode input voltage range**
- **Operates from standard supply voltages**

APPLICATIONS

- **MOS memories sense amp**
- **A/D conversion**
- **High speed line receiver**

75S208-F,N

DESCRIPTION

The 75S208 is a high speed dual sense amplifier that is functionally equivalent and pin compatible to the SN75208. The improved input sensitivity of ±10mV makes it suitable as a MOS memory sense amplifier which can result in faster memory cycles.

The 75S208 features less than 17ns propagation delay without sacrificing input performance characteristics. This is accomplished through the utilization of Schottky technology. It also features STTL compatible output levels with an open collector configuration for wired-AND logic applications.

FEATURES

- **Functionally equivalent and pin compatible to 75208**
- **17ns maximum guaranteed propagation delay**
- **20μA maximum input bias current**
- **STTL compatible strobes and outputs**
- **Open collector outputs**
- **Large common mode input voltage range**
- **Operates from standard supply voltages**

APPLICATIONS

- **MOS memories sense amp**
- **A/D conversion**
- **High speed line receiver**

SECTION 9
DISPLAY DRIVERS

Section 9—DISPLAY DRIVERS

DISPLAY DRIVER DEFINITIONS

T_A

Ambient temperature range. Range of the surrounding environment of the operating device.

T_J

Junction Temperature. The maximum temperature of the device. 150°C is standard for silicon devices.

T_{STG}

Storage temperature range. Temperature range that the device can be stored in a non-operating condition.

T_{SOLD}

Soldering Temperature. The temperature which can be applied to the lead frame of the device for short periods of time (normally specified for a duration of 10 sec).

Truth Tables

0 is logic level low
1 is logic level high
X - don't care condition - has no effect under circuit conditions listed.

Absolute Maximum Rating

Operating safe zones exceeding these limits could cause permanent damage to the device and are not meant to imply that devices can operate at these limits.

Power Dissipation

The power that the device can safely handle at 25°C. The dissipation must be derated as indicated for the individual package type.

Package Type Designation

See full package designations in Appendix.

V_{CC} ($-V_{CC}$)

Supply Voltage. The range of power supply voltage over which the device will operate safely.

LED

Light Emitting Diode

$\overline{XX}$

Negate Bar-when it appears over a function indicates that the "true" or valid condition of that function is a logic low level.

i.e. LE - would require a logic high level to cause a latch enable.
$\overline{LE}$ - would require a logic low level to cause a latch enable.

I_{SEG}

Segment Current. The amount of current supplied to each segment in a display. Current ratios are generally compared to segment 'b'.

BCD

Binary Coded Decimal

$\overline{BI}$/RBO

Blanking Input or Ripple Blanking Output.

$\overline{RBI}$

Ripple Blanking Input. The maximum clock frequency: the maximum input frequency at a clock input for the predictable performance. Above this frequency the device may cease to function.

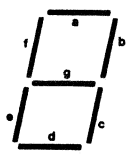
t_{PLH}

Propagation Delay Time. The time between the specified reference points on the input and output waveforms with the output changing from the defined LOW level to the defined HIGH level.

t_{PHL}

Propagation Delay Times. The time between the specified reference points on the input and output waveforms with the output changing from the defined HIGH level to the defined LOW level.

Segment Identification



t_h

Hold Time. The interval immediately following the active transition of the timing pulse (usually the clock pulse) or following the transition of the control input to its latching level, during which interval the data to be recognized must be maintained at the input to ensure its continued recognition. A negative hold time indicates that the current logic level may be released prior to the active transition of the timing pulse and still be recognized.

t_s

Setup Time. The interval immediately preceeding the active transition of the timing pulse (usually the clock pulse) or preceeding the transition of the control input to its latching level, during which interval the data to be recognized must be maintained at the input to ensure its recognition. A negative setup time indicates that the correct logic level may be initiated sometime after the active transition of the timing pulse and still be recognized.

t_W

Pulse Width. The time between the specified reference points on the leading and trailing edges of a pulse.

t_{rec}

Recovery Time. The time between the reference point on the trailing edge of an asynchronous input control pulse and the reference point on the activating edge of a synchronous (clock) pulse input such that the device will respond to the synchronous input.

V_S

Source Voltage. A separate V_{CC} line depending on part type.

I_{OH}

Output Current Source the device can supply while maintaining a specified voltage output level.

Typical Value

The typical value of a particular parameter determined by characterization of the device or sampling. Usually indicates that the particular device is not 100% tested for the parameter because it does not vary or can be determined by design and other tested variables. Occasionally typical values are given rather than min-

DISPLAY DRIVER DEFINITIONS (Cont'd)

max values because 100% testing would raise the cost of the product to a prohibitive level. If a typical value must be guaranteed to ensure specific operation, custom testing can often be provided at an additional cost to the user.

I_S

Source Current. Current flowing into the V_S supply terminal of the device with specified operating conditions.

Duty Cycle

Ratio of time on to time off. Generally expressed in percentage.

V_F

Forward voltage drop of a device at a specified current level.

I_B

Input Bias Current Current into an analog circuit input, specified at a particular voltage level.

CLR

Clear. Clear command will preset all internal circuits to a predetermined state.

CE

Chip Enable.

V_{IH}

Input High Voltage. The range of input voltages recognized by the device as a logic high.

V_{IL}

Input Low Voltage. The range of input voltages recognized by the device as a logic low.

V_{OH}

Output High Voltage. The minimum guaranteed High voltage at an output terminal for the specified output current I_{OH} and at the minimum V_{CC} value.

V_{OL}

Output Low Voltage. The maximum guranteed low voltage at an output terminal sinking the specified load current I_{OL}.

V_{BR}

Output Breakdown Voltage. Maximum voltage applied to a disabled (off) output to ensure a leakage current less than the specified value.

V_{IN}

The range of voltage on any input which the device can safely handle or a specified input voltage to the device.

V_{OUT}

The range of voltage on any output which the device can safely handle or a specified output voltage to the device.

$I_{CC}(-I_{CC})$

Supply Current. The current flowing into the $+V_{CC}$ $(-V_{CC})$ supply terminal of the circuit with specified input conditions and open outputs. Input conditions are chosen to guarantee worst case operation unless specified.

I_{IH}

Input High Current. The Current flowing into or out of an input when a specified High level voltage is applied to that input.

I_{IL}

Input Low Current. The current flowing out of an input when a specified Low level voltage is applied to that input.

I_{OL}

Output Low Current. The current flowing into an output when a which is in the Low State.

I_{OS}

Output Short-Circuit Current. The current flowing out of an output which is in the High state when that output is short circuit to the ground.

I_{CEX}

Output Leakage Current. The current flowing out of or into a disabled (off) output with a specified High output voltage applied.

NE582-N

DESCRIPTION

The NE582 is a general interface device comprising a high current output transistor and drive circuitry in each of 6 elements. Each output transistor is individually capable of sinking 400mA with a typical saturation voltage of 0.5V. Input loading is such that direct interfacing with P-MOS, N-MOS, C-MOS or TTL is possible.

The NE582 has applications as a LED display driver, low voltage relay/lamp drivers and many others where high current capability without speed constraints is required.

The NE582 is supplied in a 16-pin high dissipation dual-in-line plastic package.

FEATURES

- **Low saturation voltage (typically 0.5V) for minimum power dissipation**
- **High output sink current capability—400mA**
- **Low input current loading for MOS compatibility**
- **Low standby power consumption**
- **Suitable for 3 volt battery operation**
- **Inputs/outputs are compatible with 75494**

NE587-F,N

DESCRIPTION

The NE587 is a latch/decoder/driver for 7-segment common anode LED displays. The NE587 has a programmable current output up to 50mA which is essentially independent of output voltage, power supply voltage, and temperature. The data (BCD) inputs and $\overline{LE}$ (latch enable) input are low-loading so that they are compatible with any data bus system. The 7-segment decoding is implemented with a ROM so that alternative fonts can be made available.

FEATURES

- Latched BCD inputs
- Low loading bus-compatible inputs
- Ripple-blanking on leading and/or trailing edge zeros

APPLICATIONS

- Digital panel meters
- Measuring instruments
- Test equipment
- Digital clocks
- Digital bus monitoring

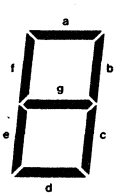
SEGMENT IDENTIFICATION



NE587 PROGRAMMING

NE587 output current can be programmed by using a programming resistor, R_P, connected between r_P (pin 8) and Gnd (pin 9). The voltage at r_P (pin 8) is constant ($\approx$1.40V). A partial schematic of the voltage reference used in the NE587 is shown in figure 1.

Output current to program current ratio, I_O/I_P, is 20 in the 15mA to 50mA range. Note that I_P must be derived from a resistor (R_P), and not from a high impedance source such as an I_{OUT} DAC used to control display brightness.

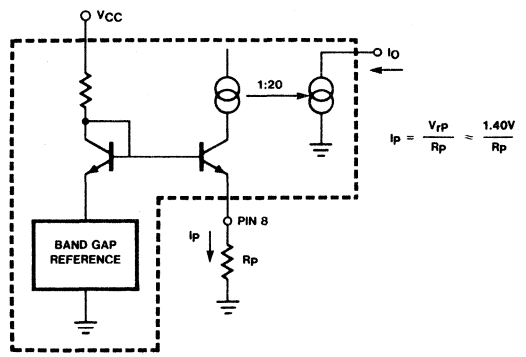


Figure 1

TIMING DIAGRAMS

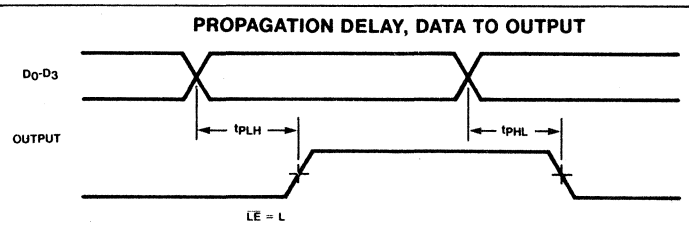

Figure 2

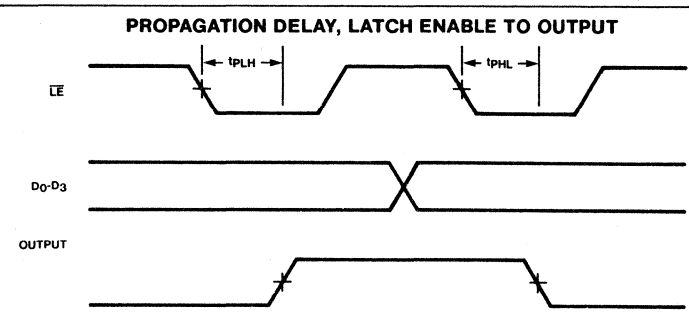

Figure 3

POWER DISSIPATION CONSIDERATIONS

LED displays are power-hungry devices, and inevitably somewhat inefficient in their use of the power supply necessary to drive them. Duty cycle control does afford one way of improving display efficiency, provided that the LEDS are not driven too far into saturation, but the improvement is marginal. Operation at higher peak currents has the added advantage of giving much better matching of light output, both from segment-to-segment and digit-to-digit.

An output current of 10 to 50mA was chosen so that it would be suitable for multiplexed operation of large size LED digits. When designing a display system, particular care must be taken to minimize power dissipation within the IC display driver. Since the output is a constant current source, all the remaining supply voltage, which is not dropped across the LED (and the digit driver, if used), will appear across the output. Thus, the power dissipation will go up sharply if the display power supply voltage rises. Clearly, then, it is good design practice to keep the display supply voltage as low as possible consistent with proper operation of the supply output current sources. Inserting a resistor or diode in series with the display supply is a good way of reducing the power dissipation within the integrated circuit segment driver, although, of course, total system power remains the same.

Power dissipation may be calculated as follows. Referring to figure 6, the two system power supplies are V_{CC} and V_S. In many cases, these will be the same voltage. Necessary parameters are:

V_{CC},	Supply voltage to driver
V_S,	Supply voltage to display
I_{CC},	Quiescent supply current of driver
I_{SEG},	LED segment current
V_F,	LED segment forward voltage at I_{seg}
K_{DC},	% Duty cycle

V_F, the forward LED drop, depends upon the type of LED material (hence the color) and the forward current. The actual forward voltage drops should be obtained from the LED display manufacturer's literature for the peak segment current selected; however, approximate voltages at nominal rated currents are:

Red	1.6 to 2.0V
Orange	2.0 to 2.5V
Yellow	2.2 to 3.5V
Green	2.5 to 3.5V

TIMING DIAGRAMS (Cont'd)

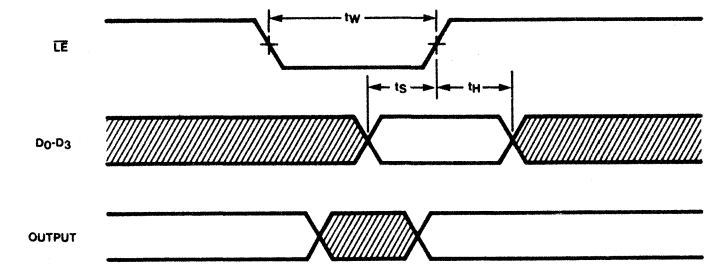

Figure 4

These voltages are all for single diode displays. Some early red displays had 2 series LEDS per segment; hence the forward voltage drop was around 3.5V.

Thus a maximum power dissipation calculation when all segments are on, is:

$P_d = V_{CC} \times I_{CC} + (V_S - V_F) \times 7 \times I_{seg} \times K_{DC}$ mW

Assuming $V_S = V_{CC} = 5.25V$
$V_F = 2.0V$
$K_{DC} = 100\%$
$P_{d\ max} = 5.25 \times 50 + 3.25 \times 7 \times 30$ mW
$= 945$ mW

TYPICAL PERFORMANCE CURVES (Cont'd)

OUTPUT CURRENT VS PROGRAM RESISTOR

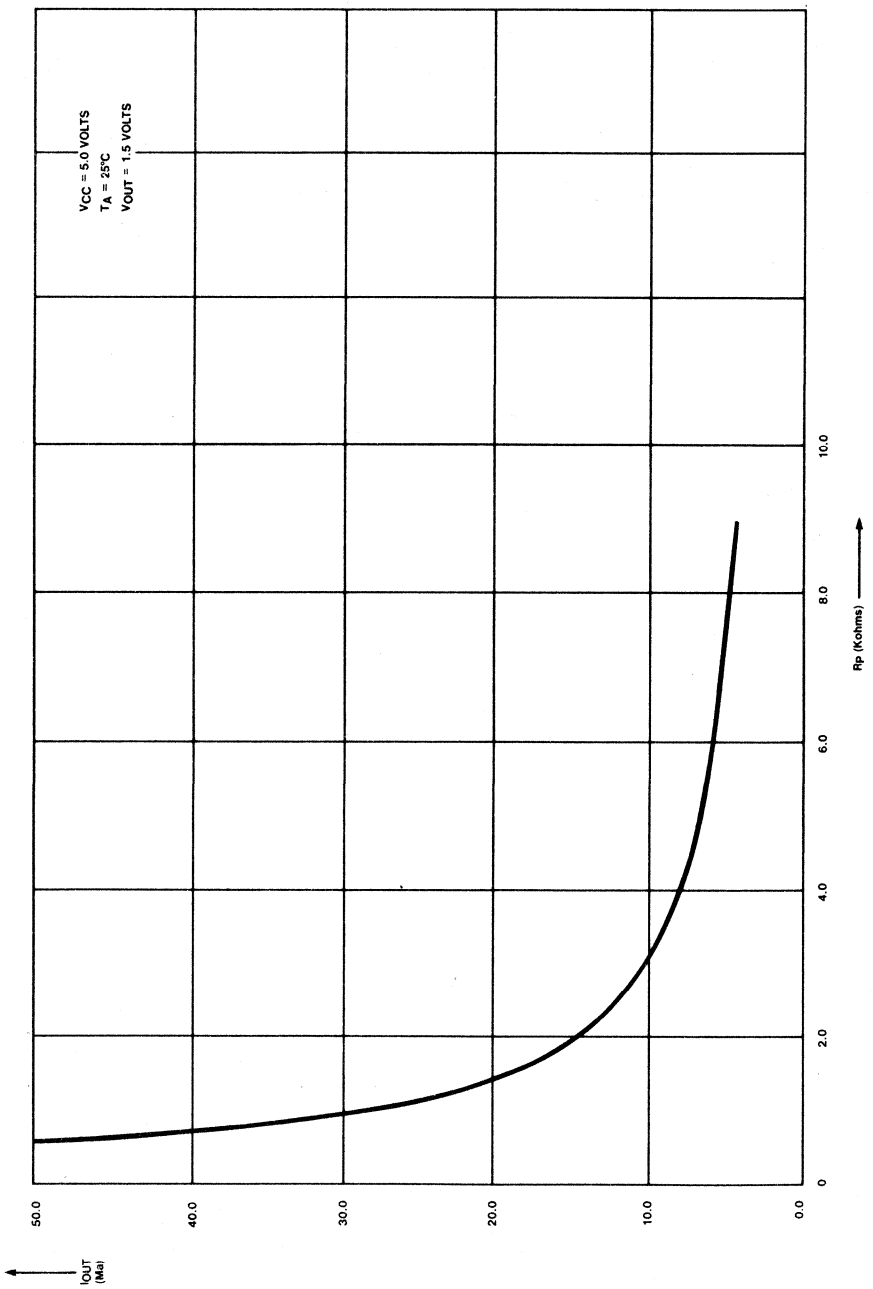

Figure 5

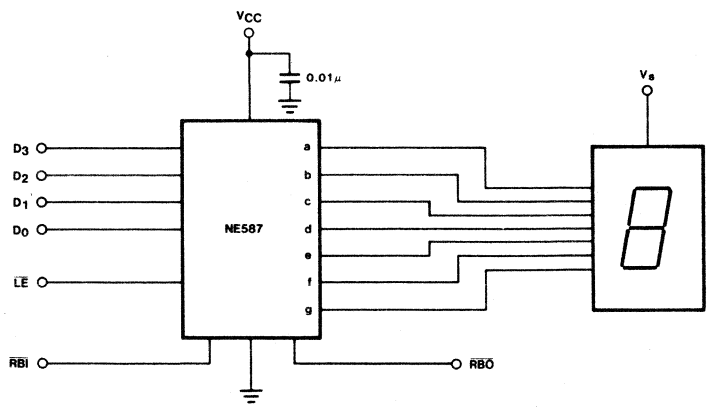
TYPICAL APPLICATIONS

DRIVING A SINGLE DIGIT



NOTE
Decoupling capacitor on V_{CC} should be 0.01 μF ceramic

Figure 6

However, the average power dissipation will be considerably less than this. Assuming 5 segments are on (the average for all output code combinations), then

$P_{d\,av} = 5.0 \times 30 + 3.00 \times 5 \times 25$ mW
$= 525$ mW

Operating temperature range limitations can be deduced from the power dissipation graph. (See Typical Performance Characteristics).

However, a major portion of this power dissipation ($P_{d\,max}$) is because the current source output is operating with 3.25 V across it. In practice, the outputs operate satisfactorily down to 0.5V, and so the extra voltage may be dropped external to the integrated circuit.

Suppose the worst case V_{CC}/V_S supply is 4.75 to 5.25V, and that the maximum V_E for the LED display is 2.25V. Only 2.75V is required to keep the display active, and hence 2.0V may be dropped externally with a resistor from V_{CC} to V_S. The value of this resistor is calculated by:

$$R_S = \frac{2.0}{7 \times I_{seg}} \simeq 10\Omega \text{ (½ W rating)}$$

assuming worst case I_{seg} of 30 mA

Hence now $P_{d\,max} = V_{CC} \times I_{CC} + (V_S - V_V - R_X \times 7 \times I_{seg}) \times 7 \times X\, I_{seg} \times K_{DC}$
$= 5.25 \times 50 + 1.25 \times 7 \times 30$ mW
$= 525$ mW

and $P_{d\,av} = 5.0 \times 30 + 1.25 \times 5 \times 25$
$= 306$ mW

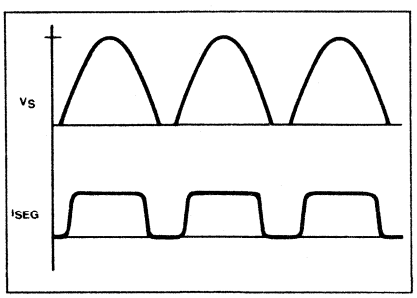
If a diode (or 2) is used to reduce voltage to the display, then the voltage appearing across the display driver will be independent of the number of "ON" segments and will be equal to

$V_S - V_F - nV_d$, $V_D \simeq 0.8V$

Where n is the number of diodes used, power dissipation can be calculated in a similiar manner.

In a multiplexed display system, the voltage drop across the digit driver must also be considered in computing device power dissipation. It may even be an advantage to use a digit driver which drops an appreciable voltage, rather than the saturating PNP transistors shown in figure 9. For example a darlington PNP or NPN emitter follower may be preferable. Figure 8 shows the NE591 as the digit driver in a multiplexed display system. The NE591 output drops about 1.8V which means that the power dissipation is evenly distributed between the two integrated circuits.

Where V_S and V_{CC} are two different supplies, the V_S supply may be optimized for minimum system power dissipation and/or cost. Clearly, good regulation in the V_S supply is totally unnecessary, and so this supply can be made much cheaper than the regulated 5V supply used in the rest of the system. In fact a simple unsmoothed full-wave rectified sine wave works extremely well if a slight loss in brightness can be tolerated. A transformer voltage of about 3-4.5V rms works well in most LED display systems. Waveforms are shown below:



The duty cycle for this system depends upon V_S, V_F and the output characteristics of the display driver.

With
$V_S = 4.9V$ pk.
$V_F = 2.0V$

The duty cycle is approximately 60%.

DESCRIPTION

The NE589 is a latch/decoder/driver for 7-segment common cathode LED displays. The NE589 has a programmable current output up to 50mA which is essentially independent of output voltage, power supply voltage, and temperature. The data (BCD) inputs and $\overline{LE}$ (latch enable) input are low-loading so that they are compatible with any data bus system. The 7-segment decoding is implemented with a ROM so that alternative fonts can be made available.

FEATURES

- Latched BCD inputs
- Low loading bus-compatible inputs
- Ripple-blanking on leading and/or trailing edge zeros

APPLICATIONS

- Digital panel meters
- Measuring instruments
- Test equipment
- Digital clocks
- Digital bus monitoring

Figure 12

However, the average power dissipation will be considerably less than this. Assuming 5 segments are on (the average for all output code combinations), then

$P_{d\,av} = 5.0 \times 30 + 3.00 \times 5 \times 25$ mW
$= 525$ mW

Operating temperature range limitations can be deduced from the power dissipation graph in figure 9.

However, a major portion of this power dissipation ($P_{d\,max}$) is because the current source output is operating with 3.25 V across it. In practice, the outputs operate satisfactorily down to 0.5V, and so the extra voltage may be dropped external to the integrated circuit.

Suppose the worst case V_{CC}/V_S supply is 4.75 to 5.25V, and that the maximum V_E for the LED display is 2.25V. Only 2.75V is required to keep the display active, and hence 2.0V may be dropped externally with a resistor from V_{CC} to V_S. The value of this resistor is calculated by:

$$R_S = \frac{2.0}{7 \times I_{seg}} \simeq 10\Omega \text{ (½ W rating)}$$

assuming worst case I_{seg} of 30 mA

Hence now $P_{d\,max} = V_{CC} \times I_{CC} + (V_S - V_V - R_X \times 7 \times I_{seg}) \times 7 \times X\, I_{seg} \times K_{DC}$
$= 5.25 \times 50 + 1.25 \times 7 \times 30$ mW
$= 525$ mW

and $P_{d\,av} = 5.0 \times 30 + 1.25 \times 5 \times 25$
$= 306$ mW

If a diode (or 2) is used to reduce voltage to the display, then the voltage appearing across the display driver will be independent of the number of "ON" segments and will be equal to

$V_S - V_F - nV_d$, $V_D \simeq 0.8V$

Where n is the number of diodes used, power dissipation can be calculated in a similiar manner.

In a multiplexed display system, the voltage drop across the digit driver must also be considered in computing device power dissipation. It may even be an advantage to use a digit driver which drops an appreciable voltage, rather than the saturating PNP transistors shown in figure 15. For example a darlington PNP or NPN emitter follower may be preferable. Figure 14 shows the NE591 as the digit driver in a multiplexed display system. The NE591 output drops about 1.8V which means that the power dissipation is evenly distributed between the two integrated circuits.

Where V_S and V_{CC} are two different supplies, the V_S supply may be optimized for minimum system power dissipation and/or cost. Clearly, good regulation in the V_S supply is totally unnecessary, and so this supply can be made much cheaper than the regulated 5V supply used in the rest of the system. In fact a simple unsmoothed full-wave rectified sine wave works extremely well if a slight loss in brightness can be tolerated. A transformer voltage of about 3-4.5V rms works well in most LED display systems. Waveforms are shown below:

NE/SA594-N,F

DESCRIPTION

The NE/SA594 is a display driver interface for vacuum fluorescent displays. The device is comprised of 8 drivers and a bias network and is capable of driving the digits and/or segments of most vacuum fluorescent displays.

The inputs are designed to be compatible with TTL, DTL, NMOS, PMOS or CMOS output circuitry.

There is an active pull-down circuit on each output so that display ghosting is minimized and no external components are required for most fluorescent display applications.

FEATURES

- **Digit and/or segment drivers**
- **Active output pull-down circuitry**
- **High output breakdown voltage**
- **Low supply voltage**
- **Input compatible with all logic outputs**

SECTION 10
DATA ACQUISITION

Section 10—DATA ACQUISTION

T_A
Ambient temperature range. Range of the surrounding environment of the operating device.

T_J
Junction Temperature. The maximum temperature of the device. 150°C is standard for silicon devices.

T_{STG}
Storage temperature range. Temperature range that the device can be stored in a non-operating condition.

T_{SOLD}
Soldering Temperature. The temperature which can be applied to the lead frame of the device for short periods of time (normally specified for a duration of 10 sec).

Truth Tables
0 is logic level low
1 is logic level high
X - don't care condition - has no effect under circuit conditions listed.

Absolute Maximum Rating
Operating safe zones exceeding these limits could cause permanent damage to the device and are not meant to imply that devices can operate at these limits.

Power Dissipation
The power that the device can safely handle at 25°C. The dissipation must be derated as indicated for the individual package type.

Package Type Designation
See full package designations in Appendix.

V_{CC} ($-V_{CC}$)
Supply Voltage. The range of power supply voltage over which the device will operate safely.

Accuracy
The maximum deviation of the DAC output relative to an ideal straight line drawn from zero to full scale; 1 LSB for any bit combination.

Monotonicity
For a 1 LSB increase of input code, the output either increases or remains the same.

Differential Linearity
The incremental error from an ideal 1 LSB analog output change when the digital input is changed 1 LSB; guaranteed monotonicity requires the differential linearity error be less than 1 LSB and with a tempco of essentially zero.

Absolute Accuracy
Error of a D/A converter output is the difference between the analog output expected and the actual output with a given code applied. Error of an A/D converter is the difference between the theoretical analog output required to produce a given output code and the actual input required to produce a given output code and the actual input required to produce that same code. The actual input is a range and the measured value is the midpoint of the measured band and the theoretical midpoint.

Resolution
The number of bits on the input or output of an A/D or D/A converter. The number of discrete steps or states is equal to 2^n when n is the resolution of the converter. However, n bits of resolution does not guarantee n bits of accuracy.

Quantizing Error
In an A/D converter, there is an infinite number of possible input voltages, but only 2^n output codes (n = number of bits). Therefore, there will be an error as great as 1/2LSB because of this quantizing effect and the greatest error will occur at the transition voltage where the output changes state.

No Missing Codes
This is a property of an A/D converter that is related to, but is more stringent than monotonicity. If a converter is guaranteed to have no missing codes, there will be no output digital state that will be skipped when the input voltage is varied over the entire range.

Most Significant Bit (MSB)
The highest-order bit or the bit with the greatest weight.

Least Significant Bit (LSB)
The lowest-order bit or the bit with the least weight.

Gain Error
The error in the input-to-output ratio, usually expressed in percent.

Offset Error
This is an error in the reference point of the transfer function. It appears as a constant amplitude error signal at a D/A output or an A/D input. It also appears as a constant frequency shift in the output of a V/F converter. It is nulled prior to adjusting gain error by setting the input to the most-negative input and adjusting the output to the proper value.

Settling Time
The time delay between a change of input signal value and the effected change in the output signal. It is usually expressed in terms of how long it takes the output to arrive at, and remain within, a certain error band around the final value and is often given for several different magnitudes of input step change.

Conversation Time
Time required for a complete measurement by an A/D converter. Conversion times are a function of the number of bits (resolution) and the clock frequency.

Switching Time
The time it takes for a multiplexer to change from one channel to the next with the new output signal being within a certain percentage of its final value. It is expressed for a maximum voltage transition.

Throughput Rate
An A/D converter or a data acquisition system has a finite number of points that it can convert in any given time. Throughput rate is an expression of that quantity. It is dependent on the time it takes to make a conversion and the time required to set up to make the next conversion. In a data acquisition system this time includes the composite delay due to switching and settling times of the mux, settling time of the amplifier and acquisition time of the sample-and-hold.

Full Scale Tempco
The change in DAC full scale current with change in temperature expressed in ppm/°C.

Differential Non-Linearity Tempco
The non-linearity specification over a specified range of temperatures. This specification generally appears as the range of tem-

A/D–D/A CONVERTERS DEFINITIONS (Cont'd)

peratures that the device is monotonic (DAC) or has no missing codes (ADC).

Leakage Current

Multiplexer input current that does not flow through to the output but is shunted internally. It is also current that flows from OFF channels into the ON channel. In a current output D/A converter, there is a digital input code that ideally yields zero output current. If current flows with that input code, it is called leakage current. It is analogous to output voltage offset in a voltage-output D/A converter.

Power Supply Sensitivity

The change in DAC output current with changes in power supply voltage.

Output Voltage Compliance

The range of allowable voltage levels the output pins can assume without a major effect on circuit performance.

Compliance Voltage Range

For a current source the maximum range of terminal voltage for which the current source will maintain its specified values.

NOTE
Refer to Section 5 (Interface Circuits) of the 1979 Analog Applications Manual for an in-depth explanation of Converters and their applications

LF398-H,N

DESCRIPTION

The Signetics LF398 is a monolithic sample and hold circuit which utilizes high-voltage Ion-Inplant JFET technology to obtain ultra-high dc accuracy with fast acquisition of signal and low droop rate. Operating as a unity gain follower, dc gain accuracy is 0.004% typical and acquisition time is as low as 6μs to 0.01%. A bipolar input stage is used to achieve low offset voltage and wide bandwidth. Input offset adjust is accomplished with a single pin and does not degrade input offset drift. The wide bandwidth allows the LF398 to be included inside the feedback loop of 1MHz op amps without having stability problems. Input impedance of $10^{10}\Omega$ allows high source impedances to be used without degrading accuracy.

P-channel junction FET's are combined with bipolar devices in the output amplifier to give droop rates as low as 5mV/min with a 1μF hold capacitor. The JFET's have much lower noise than MOS devices used in previous designs and do not exhibit high temperature instabilities. The overall design guarantees no feed-through from input to output in the hold mode even for input signals equal to the supply voltages.

Logic inputs on the LF398 are fully differential with low input current, allowing direct connection to TTL, PMOS, and CMOS. Differential threshold is 1.4V. The LF398 will operate from ±5V to ±18V supplies. It is available in an 8-lead TO-5 package or an 8-pin plastic DIP.

FEATURES

- **Operates from ±5V to ±18V supplies**
- **Less than 10μs acquisition time**
- **TTL, PMOS, CMOS compatible logic input**
- **0.5mV typical hold step at C_h = 0.01μF**
- **Low input offset**
- **0.002% gain accuracy**
- **Low output noise in hold mode**
- **Input characteristics do not change during hold mode**
- **High supply rejection ratio in sample or hold**
- **Wide bandwidth**
- **The LF398 is ideally suited for a wide variety of sample and hold applications including data acquisition, analog to digital conversion, synchronous demodulation, and automatic test setup.**

Differential logic threshold	$T_j = 25°C$	0.8	1.4	2.4	V

NOTES

1. The maximum junction temperature of the LF398 is 150°C. When operating at elevated ambient temperature, the TO-5 and plastic DIP packages must be derated based on a thermal resistance (θjA) of 150°C/W.
2. Although the differential voltage may not exceed the limits given, the common-mode voltage on the logic pins may be equal to the supply voltages without causing damage to the circuit. For proper logic operation, however, one of the logic pins must always be at least 2V below the positive supply and 3V above the negative supply.
3. Unless otherwise specified, the following conditions apply. Unit is in "sample" mode, $V_S = \pm 15V$, $T_j = 25°C$, $-11.5V \leq V_{IN} \leq +11.5V$, $C_h = 0.01\mu F$, and $R_L = 10k$. Logic reference voltage = OV and logic voltage = 2.5V.
4. Hold step is sensitive to stray capacitive coupling between input logic signals and the hold capacitor. 1pF, for instance, will create an additional 0.5mV step with a 5V logic swing and a $0.01\mu F$ hold capacitor. Magnitude of the hold step is inversely proportional to hold capacitor value.
5. Leakage current is measured at a junction temperature of 25°C. The effects of junction temperature rise due to power dissipation or elevated ambient can be calculated by doubling the 25°C value for each 11°C increase in chip temperature. Leakage is guaranteed over full input signal range.
6. The parameters guaranteed over a supply voltage of ±5 to ±18V.

DESCRIPTION

The MC1508/MC1408 series of 8-bit monolithic digital-to-analog converters provide high speed performance with low cost. They are designed for use where the output current is a linear product of an 8-bit digital word and an analog reference voltage.

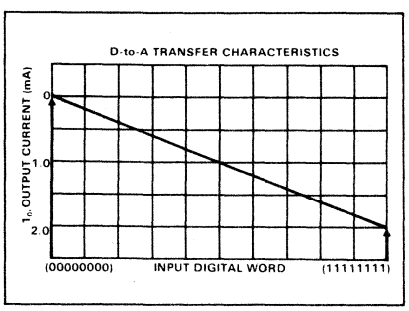
FEATURES

- **Fast settling time—300ns (typ)**
- **Relative accuracy ±0.19% (max error)**
- **Non-inverting digital inputs are TTL and CMOS compatible**
- **High speed multiplying rate 4.0mA/μs (input slew)**
- **Output voltage swing +.5V to -5.0V**
- **Standard supply voltages + 5.0V and -5.0V to -15V**
- **Military qualifications pending**

APPLICATIONS

- **Tracking A-to-D converters**
- **2½-digit panel meters and DVM's**
- **Waveform synthesis**
- **Sample and hold**
- **Peak detector**
- **Programmable gain and attenuation**
- **CRT character generation**
- **Audio digitizing and decoding**
- **Programmable power supplies**
- **Analog-digital multiplication**
- **Digital-digital multiplication**
- **Analog-digital division**
- **Digital addition and subtraction**
- **Speech compression and expansion**
- **Stepping motor drive**

TYPICAL PERFORMANCE CHARACTERISTICS



CIRCUIT DESCRIPTION

The MC1508/MC1408 consists of a reference current amplifier, and R-2R ladder, and 8 high speed current switches. For many applications, only a reference resistor and reference voltage need be added.

The switches are non-inverting in operation; therefore, a high state on the input turns on the specified output current component.

The switch uses current steering for high speed, and a termination amplifier consisting of an active load gain stage with unity gain feedback. The termination amplifier holds the parasitic capacitance of the ladder at a constant voltage during switching, and provides a low impedance termination of equal voltage for all legs of the ladder.

The R-2R ladder divides the reference amplifier current into binarily-related components, which are fed to the switches. Note that there is always a remainder current which is equal to the least significant bit. This current is shunted to ground, and the maximum output current is 255/256 of the reference amplifier current, or 1.992mA for a 2.0mA reference amplifier current if the NPN current source pair is perfectly matched.

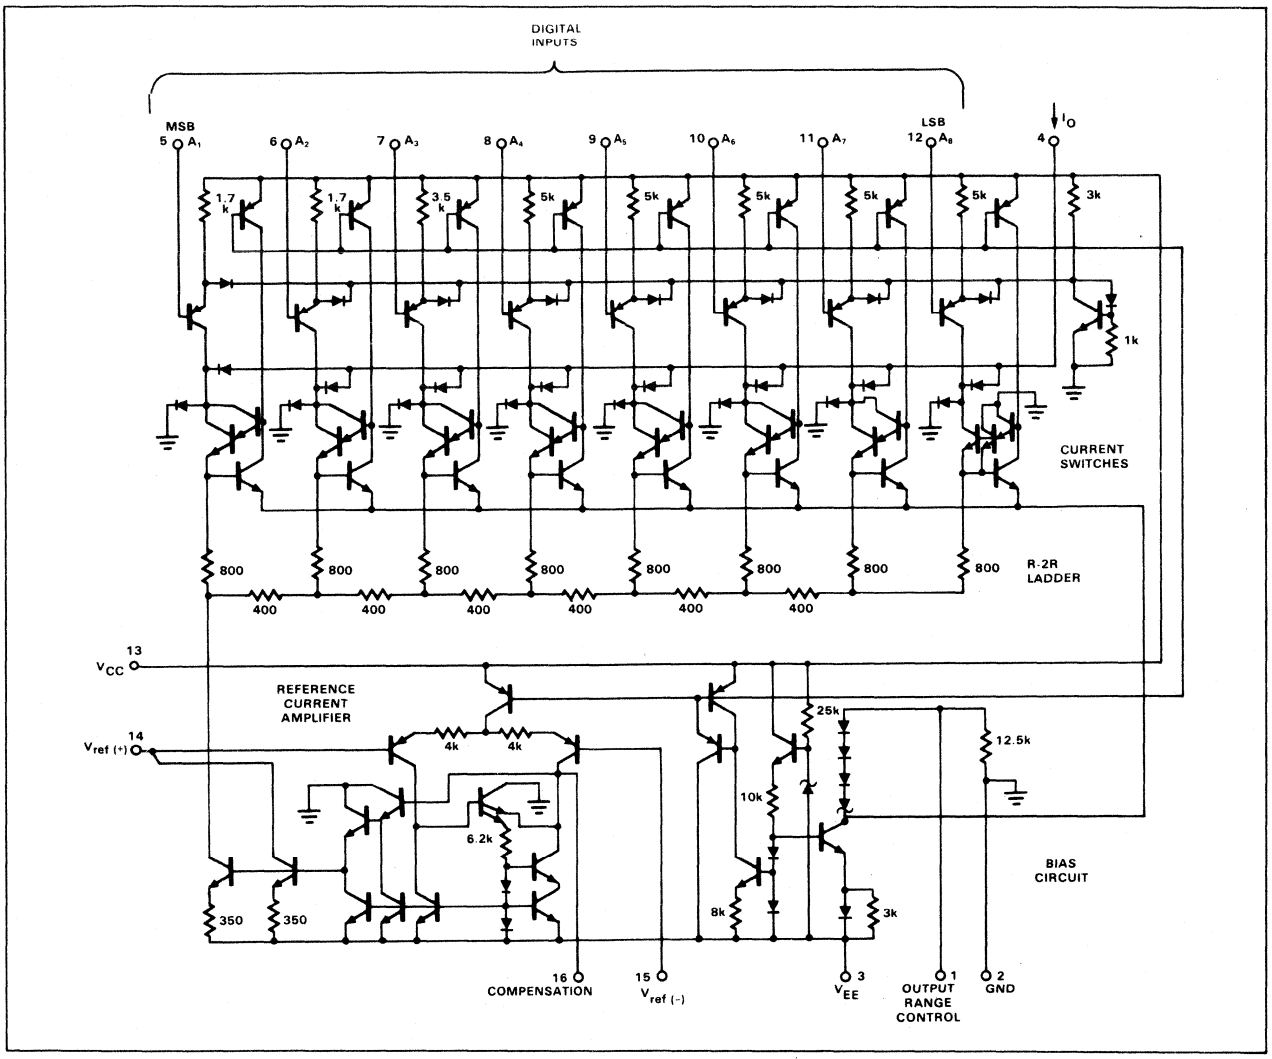
EQUIVALENT CIRCUIT SCHEMATIC



FUNCTIONAL DESCRIPTION

Reference Amplifier Drive and Compensation

The reference amplifier provides a voltage at pin 14 for converting the reference voltage to a current, and a turn-around circuit or current mirror for feeding the ladder. The reference amplifier input current (I_{14}) must always flow into pin 14 regardless of the setup method or reference voltage polarity.

Connections for a positive reference voltage are shown in Figure 1. The reference voltage source supplies the full current I_{14}. For bipolar reference signals, as in the multiplying mode, R_{15} can be tied to a negative voltage corresponding to the minimum input level. It is possible to eliminate R_{15} with only a small sacrifice in accuracy and temperature drift.

The compensation capacitor value must be increased with increases in R_{14} to maintain proper phase margin; for R_{14} values of 1.0, 2.5 and 5.0kΩ, minimum capacitor values are 15, 37, and 75pF. The capacitor may be tied to either V_{EE} or ground, but using V_{EE} increases negative supply rejection.

A negative reference voltage may be used if R_{14} is grounded and the reference voltage is applied to R_{15} as shown in Figure 2. A high input impedance is the main advantage of this method. Compensation involves a capacitor to V_{EE} on pin 16, using the values of the previous paragraph. The negative reference voltage must be at least 3.0V above the V_{EE} supply. Bipolar input signals may be handled by connecting R_{14} to a positive reference voltage equal to the peak positive input level at pin 15.

When a dc reference voltage is used, capacitive bypass to ground is recommended. The 5.0V logic supply is not recommended as a reference voltage. If a well regulated 5.0V supply which drives logic is to be used as the reference, R_{14} should be decoupled by connecting it to +5.0V through another resistor and bypassing the junction of the 2 resistors with 0.1μF to ground. For reference voltages greater than 5.0V, a clamp diode is recommended between pin 14 and ground.

If pin 14 is driven by a high inpedance such as a transistor current source, none of the above compensation methods apply and

the amplifier must be heavily compensated, decreasing the overall bandwidth.

Output Voltage Range

The voltage on pin 4 is restricted to a range of -0.6 to +0.5V at -24°C, due to the current switching methods employed in the MC1508/MC1408. When a current switch is turned off, the positive voltage on the output terminal can turn on the output diode and increase the output current level. When a current switch is turned on, the negative output voltage range is restricted. The base of the termination circuit Darlington transistor is 1 diode voltage below ground when pin 1 is grounded, so a negative voltage below ground when pin 1 is grounded, so a negative voltage below the specified safe level will drive the low current device of the Darlington into saturation, decreasing the output current level.

The negative output voltage compliance of the MC1508/MC1408 may be extended to -5.0V by opening the circuit at pin 1. The negative supply voltage must be more negative than -10V. Using a full scale current of 1.992mA and load resistor of 2.5kΩ between pin 4 and ground will yield a voltage output of 256 levels between 0 and -4.980V. Floating pin 1 does not affect the converter speed or power dissipation. However, the value of the load resistor determines the switching time due to increased voltage swing. Values of R_L up to 500Ω do not significantly affect performance, but 2.5kΩ load increases worst case settling time to 1.2μs (when all bits are switched on). Refer to the subsequent text section on settling time for more details on output loading.

If a power supply value between -5.0V and -10V is desired, a voltage of between 0 and -5.0V may be applied to pin 1. The value of this voltage will be the maximum allowable negative output swing.

Output Current Range

The output current maximum rating of 4.2mA may be used only for negative supply voltages more negative than -7.0V, due to the increased voltage drop across the 350Ω resistors in the reference current amplifier.

Accuracy

Absolute accuracy is the measure of each output current level with respect to its intended value, and is dependent upon relative accuracy and full scale current drift. Relative accuracy is the measure of each output current level as a fraction of the full scale current. The relative accuracy of the MC1508/MC1408 is essentially constant with temperature due to the excellent temperature tracking of the monolithic resistor ladder. The reference current may drift with temperature, causing a change in the absolute accuracy of output current. However, the MC1508/MC1408 has a very low full scale current drift with temperature.

The MC1508/±MC1408 series is guaranteed accurate to within ±1/2 LSB at +25°C at a full scale output current of 1.992mA. This corresponds to a reference amplifier output current drive to the ladder network of 2.0mA, with the loss of 1 LSB = 8.0μA which is the ladder remainder shunted to ground. The input current to pin 14 has a guaranteed value of between 1.9 and 2.1mA, allowing some mismatch in the NPN current source pair. The accuracy test circuit is shown in Figure 3. The 12-bit converter is calibrated for a full scale output current of 1.992mA. This is an optional step since the MC1508/MC1408 accuracy is essentially the same between 1.5 and 2.5mA. Then the MC1508/MC1408 circuits' full scale current is trimmed to the same value with R14 so that a zero value appears at the error amplifier output. The counter is activated and the error band may be displayed on an oscilloscope, detected by comparators, or stored in a peak detector.

Two 8-bit D-to-A converters may not be used to construct a 16-bit accurate D-to-A converter. Sixteen-bit accuracy implies a total error ±1/2 of 1 part in 65,536, or ±0.00076%, which is much more accurate than the ±0.19% specification provided by the MC1508/MC1408.

Multiplying Accuracy

The MC1508/MC1408 may be used in the multiplying mode with 8-bit accuracy when the reference current is varied over a range of 256:1. The major source of error is the bias current of the termination amplifier. Under worst case conditions, these 8 amplifiers can contribute a total of 1.6μA extra current at the output terminal. If the reference current in the multiplying mode ranges from 16μA to 4.0mA, the 1.6μA contributes an error of 0.1 LSB. This is well within 8-bit accuracy.

A monotonic converter is one which supplies an increase in current for each increment in the binary word. Typically, the MC1508/MC1408 in monotonic for all values of reference current above 0.5mA. The recommended range for operation with a dc reference current is 0.5 to 4.0mA.

Settling Time

The worst case switching condition occurs when all bits are switched on, which corresponds to a low-to-high transition for all bits. This time is typically 300ns for settling to within ±1/2 LSB for 8-bit accuracy and 200ns to 1/2 LSB for 7-bit accuracy. The turnoff is typically under 100ns. These times apply when $R_L \leq 500\Omega$ and C_O 25pF.

The slowest single switch is the least significant bit, which turns on and settles in 250ns and truns off in 80ns. In applications where the D-to-A converter functions in a positive going ramp mode, the worst case switching condition does not occur, and a settling time of less than 300ns may be realized. Bit A7 turns on in 200ns and off in 80ns, while bit A6 turns on in 150ns and off in 80ns.

The test circuit of Figure 4 requires a smaller voltage swing for the current switches due to internal voltage clamping in MC1508/MC1408. A 1.0kΩ load resistor from pin 4 to ground gives a typical settling time of 400ns. Thus, it is voltage swing and not the output R_C time constant that determines settling time for most applications.

Extra care must be taken in board layout since this is usually the dominant factor in satisfactory test results when measuring settling time. Short leads, 100μF supply bypassing for low frequencies, and minimum scope lead length are all mandatory.

DESCRIPTION

The 5007/5008 series of 8-bit monolithic multiplying Digital-to-Analog Converters provide very high speed performance coupled with low cost and outstanding applications flexibility.

Advanced circuit design achieves 85ns settling times with very low glitch and at low power consumption. Monotonic multiplying performance is attained over a wide 20 to 1 reference current range. Matching to within 1 LSB between reference and full scale currents eliminates the need for full scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

Dual complementary outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. True high voltage compliance outputs allow direct output voltage conversion and eliminate output op amps in many applications.

All 5007/5008 series models guarantee full 8-bit monotonicity and linearities as tight as 0.1% over the entire operating temperature range are available. Device performance is essentially unchanged over the ±4.5V to ±18V power supply range, with 33mW power consumption attainable at ±5V supplies.

The compact size and low power consumption make the 5007/5008 attractive for portable and military/aerospace applications.

FEATURES

- **Fast settling output current—85ns**
- **Full scale current prematched to ±1 LSB**
- **Direct interface to TTL, CMOS, ECL, HTL, PMOS**
- **Relative accuracy to 0.1% maximum over temperature range**
- **High output compliance—-10V to +18V**
- **True and complemented outputs**
- **Wide range multiplying capability**
- **Low FS current drift—±10ppm/°C**
- **Wide power supply range—±4.5V to ±18V**
- **Low power consumption—33mW at ±5V**
- **SE5008 military qualifications pending**

APPLICATIONS

- **8-bit, 1μs A-to-D converters**
- **Servo-motor and pen drivers**
- **Waveform generators**
- **Audio encoders and attenuators**
- **Analog meter drivers**
- **Programmable power supplies**
- **CRT display drivers**
- **High speed modems**
- **Other applications where low cost, high speed and complete input/output versatility are required**

NE5009-F,N • SE5009-F

DESCRIPTION

The 5009 monolithic 8-bit digital-to-analog converter is an electrical selection of the 5007/8 series of 8-bit D/A converters. Relative accuracy is specified to ±1/4 LSB maximum over the operating temperature range. Differential nonlinearity and settling times are also specified to maximum limits.

The device is specifically designed for precision applications in process control and military systems. The SE5009 is specified as equal or superior to the PMI DAC-08A in all respects. Additional relevant testing and application material is shown in the data sheet and application notes for the NE5007/8.

CROSS REFERENCE

The 5009 series are pin and functionally compatible with the DAC-08 series of devices.

±V *Range:
±5V for $R_1 = R_2 = 2.5K$
±10V for $R_1 = R_2 = 5.0K$

3 DIGIT BCD CONVERTER

A 3 digit BCD converter, using inexpensive 8-bit binary DACs, can achieve ±0.1% accuracy. The circuit shown in Figure 20 utilizes three DACs, one for each decade, to provide 0 to 999 output steps. DAC 1 contains the first four significant digits controlling the hundreds digit; DAC 2 controls the tens digit and DAC 3 steps 0 to 9. The feedback resistor (R_7) sets the zero scale at 0.00V.

The input coding is the popular 8-4-2-1 coding; i.e. the weighting ratios are 8, 4, 2 and 1. The full scale (999) BCD code is input code 100110011001.

Full scale adjustment procedure.

In the sequence below, switch on the following code combinations and adjust the indicated potentiometer for the proper output.

3 DIGIT BCD CONVERTER WITH ±0.1% ACCURACY

	INPUT CODE MSD	INPUT CODE LSD	ADJUST POT	DESIRED OUTPUT

4.	100110011001		R_1	9.99V

DESCRIPTION

The NE5018 is a complete 8-bit digital to analog converter subsystem on one monolithic chip. The data inputs have input latches, controlled by a latch enable pin. The data and latch enable inputs are ultra-low loading for easy interfacing with all logic systems. The latches appear transparent when the $\overline{LE}$ input is in the low state. When $\overline{LE}$ goes high, the input data present at the moment of transition is latched and retained until $\overline{LE}$ again goes low. This feature allows easy compatibility with most micro-processors.

The chip also comprises a stable voltage reference (5V nominal) and a high slew rate buffer amplifier. The voltage reference may be externally trimmed with a potentiometer for easy adjustment of full scale, while maintaining a low temperature co-efficient.

The output of the buffer amplifier may be offset so as to provide bipolar as well as unipolar operation.

FEATURES

- **8-bit resolution**
- **Input latches**
- **Low-loading data inputs**
- **On-chip voltage reference**
- **Output buffer amplifier**
- **Accurate to ± 1/2 LSB (.19%)**
- **Monotonic to 8 bits**
- **Amplifier and reference both short-circuit protected**
- **Compatible with 2650,8080 and many other μP's**

APPLICATIONS

- **Precision 8-bit D/A converters**
- **A/D converters**
- **Programmable power supplies**
- **Test equipment**
- **Measuring instruments**
- **Analog-digital multiplication**

DESCRIPTION

The NE5019 is a complete 8-bit digital to analog converter subsystem on one monolithic chip. The data inputs have input latches, controlled by a latch enable pin. The data and latch enable inputs are ultra-low loading for easy interfacing with all logic systems. The latches appear transparent when the $\overline{LE}$ input is in the low state. When $\overline{LE}$ goes high, the input data present at the moment of transition is latched and retained until $\overline{LE}$ again goes low. This feature allows easy compatibility with most micro-processors.

The chip also comprises a stable voltage reference (5V nominal) and a high slew rate buffer amplifier. The voltage reference may be externally trimmed with a potentiometer for easy adjustment of full scale, while maintaining a low temperature co-efficient.

The output of the buffer amplifier may be offset so as to provide bipolar as well as unipolar operation.

FEATURES

- 8-bit resolution
- Input latches
- Low-loading data inputs
- On-chip voltage reference
- Output buffer amplifier
- Accurate to ± 1/4 LSB (.1%)
- Monotonic to 8 bits
- Amplifier and reference both short-circuit protected
- Compatible with 2650,8080 and many other μP's

APPLICATIONS

- Precision 8-bit D/A converters
- A/D converters
- Programmable power supplies
- Test equipment
- Measuring instruments
- Analog-digital multiplication

DESCRIPTION

The NE5118 is a high-speed 8-bit digital to analog converter subsystem on one monolithic chip. The data inputs have input latches, controlled by a latch enable pin. The data and latch enable inputs are ultra-low loading for easy interfacing with all logic systems. The latches appear transparent when the $\overline{LE}$ input is in the low state. When $\overline{LE}$ goes high, the input data present at the moment of transition is latched and retained until $\overline{LE}$ again goes low. This feature allows easy compatibility with most microprocessors.

The chip also comprises a stable voltage reference (5V nominal). The voltage reference may be externally trimmed with a potentiometer for easy adjustment of full scale, while maintaining a low temperature co-efficient.

The output has high voltage compliance increasing versatility.

FEATURES

- 8-bit resolution
- Input latches
- Low-loading data inputs
- On-chip voltage reference
- Fast settling output current—200ns
- Accurate to ± 1/2 LSB (.19%)
- Monotonic to 8 bits
- Reference short-circuit protected
- Compatible with 2650, 8080 and many other μP's

APPLICATIONS

- Precision 8-bit D/A converters
- A/D converters
- Programmable power supplies
- Test equipment
- Measuring instruments
- Analog-digital multiplication
- CRT display drivers
- High-speed modems

SE5119-F • NE5119-N

DESCRIPTION

The NE5119 is a high-speed 8-bit digital to analog converter subsystem on one monolithic chip. The data inputs have input latches, controlled by a latch enable pin. The data and latch enable inputs are ultra-low loading for easy interfacing with all logic systems. The latches appear transparent when the $\overline{LE}$ input is in the low state. When $\overline{LE}$ goes high, the input data present at the moment of transition is latched and retained until $\overline{LE}$ again goes low. This feature allows easy compatibility with most microprocessors.

The chip also comprises a stable voltage reference (5V nominal). The voltage reference may be externally trimmed with a potentiometer for easy adjustment of full scale, while maintaining a low temperature co-efficient.

The output has high voltage compliance increasing versatility.

FEATURES

- 8-bit resolution
- Input latches
- Low-loading data inputs
- On-chip voltage reference
- Fast settling output current—200ns
- Accurate to ± 1/4 LSB (.1%)
- Monotonic to 8 bits
- Reference short-circuit protected
- Compatible with 2650, 8080 and many other μP's

APPLICATIONS

- Precision 8-bit D/A converters
- A/D converters
- Programmable power supplies
- Test equipment
- Measuring instruments
- Analog-digital multiplication
- CRT display drivers
- High-speed modems

PIN CONFIGURATION

F,N PACKAGE

NE5020-F,N

DESCRIPTION

The NE5020 is a microprocessor-compatible monolithic 10-bit digital to analog converter subsystem. This device offers 10-bit resolution and ±0.1% accuracy and monotonicity guaranteed over full operating temperature range.

Low loading latches, adjustable logic thresholds and addressing capability allow the NE5020 to directly interface with most microprocessor and logic controlled systems.

The NE5020 contains internal voltage reference, DAC switches and resistor ladder. Also, the input buffer and output summing amplifier are included. In addition, the matched application resistors for scaling either unipolar or bipolar output values are included on a single monolithic chip.

The result is a near minimum component count 10-bit resolution DAC system.

FEATURES

- **10-bit resolution**
- **Guaranteed monotonicity over operating range**
- **±0.1% relative accuracy**
- **Unipolar (0V to +10V) and Bipolar (±5V) output range**
- **Logic bus compatible**
- **5μsec settling time**

APPLICATIONS

- **Precision 10-bit D/A converters**
- **10-bit Analog to Digital converters**
- **Programmable power supplies**
- **Test equipment**
- **Measurement instruments**

CIRCUIT DESCRIPTION

The NE5020 provides ten data latches, an internal voltage reference, application resistors, and a scaled output voltage, in addition to the basic DAC components (see block diagram, figure 1).

Latch Circuit

Digital interface with the NE5020 is readily accomplished through the use of two latch enable ports ($\overline{LE}_1$ and $\overline{LE}_2$) and ten data input latches. $\overline{LE}_2$ controls the two most significant bits of data (DB_9 and DB_8) while $\overline{LE}_1$ controls the eight lesser significant bits (DB_7 through DB_ϕ). Both the latch enable ports ($\overline{LE}$) and the data inputs are static and threshold sensitive. When the latch enable ports ($\overline{LE}$) are high (Logic '1') the data inputs become very high impedances and essentially disappear from the data bus. Addressing the $\overline{LE}$ with a low (Logic '0') the latches become active and adapt the logic states present on the data bus. During this state, the output of the DAC will change to the value proportional to the data bus value. When the latch enable returns to a high state, the selected set of data inputs (i.e., depending on which $\overline{LE}$ goes high) 'memorize' the data bus logic states and the output changes to the unique output value corresponding to the binary word in the latch.

The data inputs are inactive and high impedance (typically requiring $-2\mu A$ for low (.8V max) or $0.1\mu A$ for high (2.0V min)) when the $\overline{LE}$ is high. Any changes on the data bus with $\overline{LE}$ high will have no effect on the DAC output.

The digital logic inputs ($\overline{LE}$ and DB) for the NE5020 utilize a differential input logic system with a threshold level of +1.4 volts with respect to the voltage level on the digital ground pin (Pin 1). Figure 11 details several bias schemes used to provide the proper threshold voltage levels for various logic families.

To be compatible with a bus orientated system the DAC should respond in as short a period as possible to insure full utilization of the microprocessor, controller and I/O control lines. Figure 10 shows the typical timing requirements of the latch and data lines. This figure indicates that data on the data bus should be stable for at least 50nsec after $\overline{LE}$ is changed to a high state.

The independent $\overline{LE}$ ($\overline{LE}_1$ and $\overline{LE}_2$) lines allow for direct interface from an 8 bit data bus (see figure 12). Data for the two MSB's is supplied and stored when $\overline{LE}_2$ is activated low and returned high according to the NE5020 timing requirements. Then $\overline{LE}_1$ is activated low and the remaining eight LSB's of data are transferred into the DAC. With $\overline{LE}_1$ returning high the loading of ten bit data word from an eight bit data bus is complete.

Occasionally the analog output must change to its data value within one data address operation. This is no problem using the NE5020 on a 16 bit bus or any other data bus with 10 or greater data bits. This can be accomplished from an 8 bit data bus by utilizing an external latch circuit to preload the two MSB data values. Figure 13 shows the circuit configuration.

After preloading (via $\overline{LE}$ pre-load) the external latch with the two MSB values, $\overline{LE}_2$ is activated low and the eight LSB's and the

NE5020 μP INTERFACE 8-BIT DATA BUS EXAMPLE

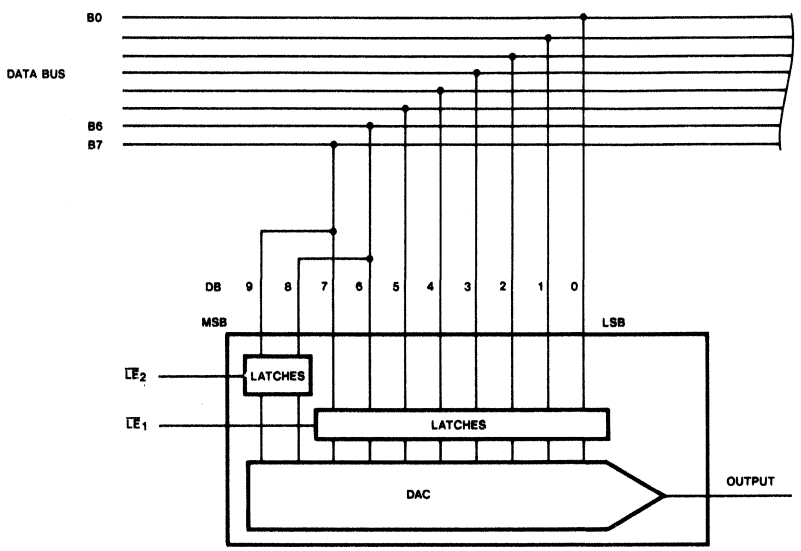

Figure 12

PRELOADING THE 2 MSB'S TO PROVIDE A SINGLE STEP OUTPUT

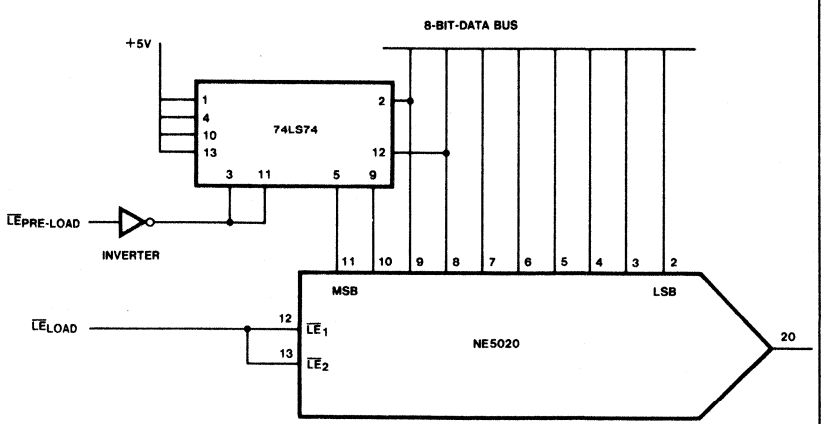

Figure 13

two MSB's are concurrently loaded into the DAC in one address operation. This permits the DAC output to make its appropriate change at one time.

Reference Interface

The NE5020 contains an internal bandgap voltage reference which is designed to have a very low temperature coefficient and excellent long term stability characteristics.

The internal bandgap reference (1.23V) is buffered and amplified to provide the 5 volt reference output. Providing a V_{REF}ADJ (pin 14) allows trimming of the reference output. Utilization of the adjust circuit shown in figure 16 performs not only V_{REF} adjustment but also full scale output adjust. Notice that the V_{REF}ADJ pin is essentially the sum node of an op amp and is sensitive to excessive node capacitance. Any capacitance on the node can be minimized by placing the external resistors as close as possible to the V_{REF}ADJ pin and observing good layout practices.

The V_{REF} out node can drive loads greater than the DAC V_{REF} input requirements and can be used as an excellent system voltage reference. However, to minimize load effects on the DAC system accuracy, it is recommended that a buffer amplifier is used.

Input Amplifier

The DAC reference amplifier is a high gain internally compensated op amp used to convert the input reference voltage to a precision bias current for the DAC ladder network.

Figure 1 details the input reference amplifier and current ladder. The voltage to current converter of the DAC amp will generate a 1mA reference current through Q_R with a 5 volt V_{REF}. This current sets the input bias to the ladder network. Data bit 9 (DB_9)(Q_9), when turned on, will mirror this current and will contribute 1mA to the output. DB_8 (Q_8) will contribute ½ of that value or 0.5mA and so on. These current values act as current sinks and will add at the sum node to produce a DAC ladder to sum node function of:

$$I_{OUT} = \frac{2V_{REF}}{R_{REF}} \left(\frac{DB9}{2} + \frac{DB8}{4} + \frac{DB7}{8} + \frac{DB6}{16} + \frac{DB5}{32} + \frac{DB4}{64} + \frac{DB3}{128} + \frac{DB2}{256} + \frac{DB1}{512} + \frac{DB0}{1024} \right)$$

Because of the fixed internal compensation of the reference amp, the slew rate is limited to typically 0.7V/μsec and source impedances at the V_{REF} INPUT greater than 5kΩ should be avoided to maintain stability.

The $-V_{REF}$ INPUT pin is uncommitted to allow utilization of negative polarity reference voltages. In this mode $+V_{REF}$ INPUT is grounded and the negative reference is tied directly to the $-V_{REF}$ INPUT. The $-V_{REF}$ INPUT contains a 5kΩ resistor that matches a like resistor in the $+V_{REF}$ INPUT to reduce voltage offset caused by op amp input bias currents.

Output Amplifier and Interface

The NE5020 provides an on chip output op amp to eliminate the need for additional external active circuits. Its two stage design with feed forward compensation allows it to slew at 15V/μsec and settle to within ± ½LSB in 5μsec. These times are typical when driving the rated loads of $R_L \geq 5k$ and $C_L \leq 50pF$ with recommended values of C_{FF} = 1nF and C_{FB} = 30pF. Typical input offset voltages of 5mV and 50k open loop gain insure an accurate current to voltage conversion is performed when using the on chip R_{FB} resistor. R_{FB} is matched to R_{REF} and R_{BIP} to maintain accurate voltage gain over operating conditions. The diode shown from ground to sum node prevents the DAC current switches from saturating the op amp during large signal transitions which would otherwise increase the settling time.

The output op amp also incorporates output short circuit protection for both positive and negative excursions. During this fault condition I_{OUT} will limit at ± 15mA typical. Recovery from this condition to rated accuracy will be determined by duration of short circuit and die temperature stabilization.

Bipolar Output Voltage

The NE5020 includes a thermally matched resistor, R_{BIP}, to offset the output voltage by 5 volts to obtain −5V to +5V output voltage range operation. This is accomplished by shorting pins 18 and 22 (see figure 14). This connection produces a current equal to ($V_{REF\ IN} - V_{sum\ node}$) ÷ R_{BIP}, (1mA nominal), which is injected into the sum node. Since full scale current out is approximately 2mA (1.9980mA), (2mA − 1mA)5k = 5V will appear at the output. For zero DAC output currents, 1mA is still injected into sum mode and V_{OUT} = −(5k)(1mA) = −5V. Zero scale adjust and full scale adjust are performed as described below, noting that full scale voltage is now approximately +5 volts, zero scale adjust may be used to trim V_{OUT} = 0.00 with the MSB high or V_{OUT} = −5.0V with all bits off.

Zero Scale Adjustment

The method of trimming the small offset error that may exist when all data bits are low is shown in figure 15. The trim is the result of injecting a current from resistor R_2 that counteracts the error current. Adjusting potentiometer R_1 until V_{OUT} equals 0.000 volts in the unipolar mode or −5.000 volts in the bipolar mode (see bipolar section) accomplishes this trim.

Full Scale Adjustment

A recommended full scale adjustment circuit when using the internal voltage reference is shown in figure 16. Potentiometer R_3 is adjusted until V_{OUT} equals 9.99023V. In many applications where the absolute accu-

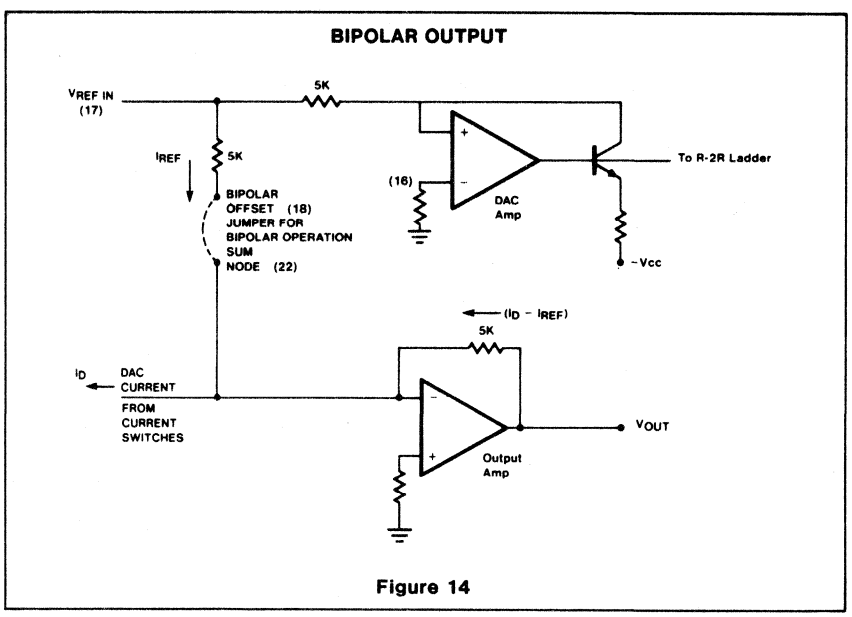

Figure 14

racy of full scale is of low importance when compared to the other system accuracy factors, then this adjustment circuit is optional.

As resistors R_{REF}, R_{fb} and R_{BIP} shown in figure 1 are integrated in close proximity, they match and track in value closely over wide ambient temperature variations. Typical matching is less than ±0.3% which implies that typical full scale (or gain) error is less than ±0.3% of ideal full scale value.

ZERO SCALE ADJUSTMENT

REFERENCE ADJUST CIRCUIT

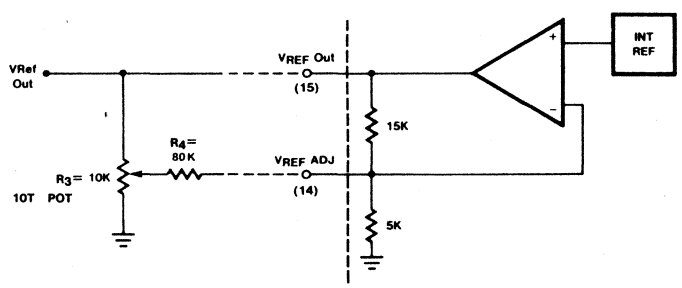

Figure 16

DESCRIPTION

The NE5537 monolithic Sample and Hold amplifier combines the best features of ion implanted JFET's with bipolar devices to obtain high accuracy, fast acquisition time, and low droop rate. This device is pin compatible with the LF198, and features superior performance in droop rate and output drive capability. The circuit shown in Figure 1 contains two operational amplifiers which function as a unity gain amplifier in the Sample mode. The first amplifier has bipolar input transistors which gives the system a low offset voltage. The second amplifier has JFET input transistors to achieve low leakage current from the hold capacitor. A unique circuit design for leakage current cancellation using current mirrors gives the NE5537 a low droop rate at higher temperature. The output stage has the capability to drive a 2KΩ load. The logic input is compatible with TTL, PMOS or CMOS logic. The differential logic threshold is 1.4V with the Sample mode occurring when the logic input is high. It is available in 8-lead TO-5 and 8-pin plastic DIP packages.

FEATURES

- Operates from ±5V to ±18V supplies
- Hold leakage current 6pA @ T_j25°C
- Less than 10μs acquisition time
- TTL, PMOS, CMOS compatible logic input
- 0.5mV typical hold step at C_h = 0.01μF
- Low input offset: 1MV (typical)
- 0.002% gain accuracy with R_L = 2kΩ
- Low output noise in hold mode
- Input characteristics do not change during hold mode
- High supply rejection ratio in sample or hold
- Wide bandwidth

ABSOLUTE MAXIMUM RATINGS

PARAMETER	RATING	UNIT
Supply voltage	± 18	V
Power dissipation (package limitation)[1]	500	mW
Operating ambient temperature range		
SE5537	−55 to +125	°C
NE5537	0 to +70	°C
Storage temperature range	−65 to +150	°C
Input voltage	Equal to supply voltage	
Logic to logic reference differential voltage[2]	+7, −30	V
Output short circuit duration	Indefinite	
Hold capacitor short circuit duration	10	sec
Lead temperature (soldering, 10sec)	300	°C

NOTES

1. The maximum junction temperature of the SE5537 is 150°C and for the NE5537 is100°C. When operating at elevated ambient temperature, the TO-5 and plastic DIP packages must be derated based on a thermal resistance (θja) of 150°C/W.
2. Although the differential voltage may not exceed the limits given, the common mode voltage on the logic pins may be equal to the supply voltages without causing damage to the circuit. For proper logic operation, however, one of the logic pins must always be at least 2V below the positive supply and 3V above the negative supply.

Supply voltage rejection ratio	V_{OUT} = 0	80	110		80	110		dB
Differential logic threshold	T_j = 25°C	0.8	1.4	2.4	0.8	1.4	2.4	V

NOTES

3. Unless otherwise specified, the following conditions apply. Unit is in "sample" mode, $V_S = \pm 15V$, T_j = 25°C, $-11.5V \leq V_{IN} \leq 11.5V$, C_h = 0.01μF, and R_L = 2kΩ. Logic reference voltage = 0V and logic voltage = 2.5V.
4. Hold step is sensitive to stray capacitive coupling between input logic signals and the hold capacitor. 1pF, for instance, will create an additional 0.5mV step with a 5V logic swing and a 0.01F hold capacitor. Magnitude of the hold step is inversely proportional to hold capacitor value.
5. Leakage current is measured at a junction temperature of 25°C. The effects of junction temperature rise due to power dissipation or elevated ambient can be calculated by doubling the 25°C value for each 11°C increase in chip temperature. Leakage is guaranteed over full input signal range.
6. These parameters guaranteed over a supply voltage range of ±5 to ±18V.

SAMPLE AND HOLD

INTRODUCTION

For many years designers have used the sample and hold (or track and hold) to operate on analog information in a time frame which is expedient.

By sampling a segment of the information and holding it until the proper timing for converting to some form of control signal or readout allows the designer certain freedom in performing predetermined manipulative functions. Therefore, the sample and hold can be defined as a "selective analog memory cell".

The memory is volatile and will also decay with time.

When using the sample and hold method for evaluating signal information, the designer is given the added feature of eliminating outside noise elements. With the analog to digital converter products available today the "dc memory" of the sample and hold can be easily converted to digital format and further incorporated into microprocessor based systems.

Parametric evaluation of the sample and hold will be discussed in the following paragraphs.

DEFINITION OF TERMS

ACQUISITION TIME: The time required to acquire a new analog input voltage with an output step of 10V. Note that acquisition time is not just the time required for the output to settle, but also includes the time required for all internal nodes to settle so that the output assumes the proper value when switched to the hold mode.

APERTURE DELAY TIME: The time elapsed from the hold command to the opening of the switch.

APERTURE JITTER: Also called "aperture uncertainty time", it's the time variation or uncertainty with which the switch opens, or the time variation in aperture delay.

APERTURE TIME: The delay required between "hold" command and an input analog transition, so that the transition does not affect the held output.

BANDWIDTH: The frequency at which the gain is down 3dB from its dc value. It's measured in sample (track) mode with a small-signal sine wave that doesn't exceed the slew rate limit.

EFFECTIVE APERTURE DELAY: The time difference between the hold command and the time at which the input signal is at the held voltage.

FIGURE OF MERIT: The ratio of the available charging current during sample mode to the leakage current during hold mode.

HOLD-MODE DROOP: The output voltage change per unit of time while in hold. Commonly specified in V/s, μV/μs or other convenient units.

HOLD-MODE FEEDTHROUGH: The percentage of an input sinusoidal signal that is measured at the output of a sample-hold when it's in hold mode.

HOLD SETTLING TIME: The time required for the output to settle within 1mV of final value after the "hold" logic command.

SAMPLE-TO-HOLD OFFSET ERROR: The difference in output voltage between the time the switch starts to open, and the time when the output has settled completely. It is caused by charge being transferred to the hold capacitor switch as it opens.

SLEW RATE: The fastest rate at which the sample & hold output can change (specified in V/μs).

HOLD STEP: The voltage step at the output of the sample and hold when switching from sample mode to hold mode with a steady (dc) analog input voltage. Logic swing is 5V.

DYNAMIC SAMPLING ERROR: The error introduced into the held output due to a changing analog input at the time the hold command is given. Error is expressed in mV with a given hold capacitor value and input slew rate. Note that this error term occurs even for long sample times.

GAIN ERROR: The ratio of output voltage swing to input voltage swing in the sample mode expressed as a percent difference.

THRESHOLD: Level shall be defined as that level which causes the switch control to change state.

BASIC BLOCK DIAGRAM

The basic circuit concept of the sample and hold circuit incorporates the use of two (2) operational amplifiers and a switch control mechanism (which determines sample, hold or track conditions). Reference figure 1.

The block diagram of the NE5537 is a closed loop non-inverting unity gain sample and hold system. The input buffer amplifier supplies the current necessary to charge the hold capacitor, while the output buffer amplifier closes the loop such that the output voltage is identical to the input voltage (with consideration for input offset voltage, offset current, and temperature variations which are common to *all* sample and hold circuits, be they monolithic, hybrid or modular).

When the sampling switch is open (in the hold mode) the clamping diodes close the loop around the input amplifier to keep it from being overdriven into saturation.

The switch control is driven by external logic levels via a timing sequence remote from the sample and hold device. Reference figure 2. The switch control has a floating reference (pin 7), referred to as the logic reference which makes the sample and hold device compatible to several types of external logic signals (TTL, PMOS, & CMOS). The switching device operates at a threshold level of 1.4V.

The switch mechanism is on (sampling an information stream) when the logic level is high (pin 8 is 1.4 volts higher than pin 7) and presents a load of 5 microamperes to the input logic signal. The analog sampled signal is amplified, stored (in the external holding capacitor), and buffered. At the end of the sampling period the internal switch mechanism turns off (switch opens) and the "stored analog memory" information on the external capacitor (pin 6) is loaded down by an operational amplifier connected in the unity gain non-inverting configuration. This amplifier, whose input impedance is effectively:

$$R = R_{IN}(A_{OL})/(1 + 1/A)$$

where
- R = Effective input impedance
- R_{IN} = Open loop input impedance
- A_{OL} = Open loop gain
- A = AC loop gain

Therefore, the higher the open loop gain of the second operational amplifier, the larger the effective loading on the capacitor. The larger the load, the lower the "leakage" current and the better the droop characteristics.

In actuality the amplifiers are designed with special leakage current cancellation circuits along with FET input devices. The leakage current cancellation circuits give better high temperature operation (remember that the FET amplifiers double in required bias current for every 10 degree increase in junction temperature).

Sampling time for the NE5537 is less than 10μsec, (measured to 0.1% of input signal). Leakage current is 6pA at a rate output load of 2kΩ.

BASIC APPLICATIONS

Multiplying DAC

As depicted in the block diagram of figure 3, the sample and hold circuit is used to supply a "variable" reference to the digital to analog converter. As the input reference varies, the output will change in accordance with equation 1, shown in figure 3.

Varying the input signal reference level can aid the system in performing both compression and expansion operations. The multiplying DAC's used are the Signetics SE/NE 5008; however, if the rate of change of the reference variation is kept slow enough a microprocessor compatible DAC can be incorporated, such as the NE5018 or the NE5020.

DATA ACQUISITION SYSTEMS

As mentioned earlier, the designer may wish to operate on several different segments of an "analog" signal; however he is limited by the fact that only one analog to digital converter channel is available to him. Figure 4 shows the means by which a multiplexing system may be accomplished.

APPLICATION HINTS

Hold Capacitor

A significant source of error in an accurate sample and hold circuit is dielectric absorption in the hold capacitor. A mylar cap, for instance, may "sag back" up to 0.2% after a quick change in voltage. A long "soak" time is required before the circuit can be put back into the hold mode with this type of capacitor. Dielectrics with very low hysteresis are polystyrene, polypropylene, and Teflon. Other types such as mica and polycarbonate are not nearly as good. Ceramic is unusable with >1% hysteresis. The advantage of polypropylene over polystyrene is that it extends the maximum ambient temperature from 85°C to 100°C. The hysteresis relaxation time constant in polystyrene, for instance, is 10-50ms. If A-to-D conversion can be made within 1ms, hysteresis error will be reduced by a factor of ten.

DC Zeroing

DC Zeroing is accomplished by connecting the offset adjust pin to the wiper of a 1kΩ potentiometer which has one end tied to V^+ and the other end tied through a resistor to ground. The resistor should be selected to give $\simeq$0.6mA through the 1KΩ potentiometer.

Sampling Dynamic Signals

Sampling errors due to moving (changing) input signals are of significant concern to designers employing sample and hold circuits. There exist finite phase delays through the sample and hold circuit causing an input-output phase differential for moving signals. In addition, the series protection resistor (300Ω to pin 6 of the NE5537) will add an RC time constant, over and above the slew rate limitation of the input buffer/current drive amplifier. This means that at the moment the "hold" command arrives, the hold capacitor voltage may be somewhat different than the actual analog input. The effect of these delays is opposite to the effect created by delays in the logic which switches the circuit from sample to hold. For example, consider an analog input of 20 Vp-p at 10kHz. Maximum dV/dt is 0.6V/μs. With no analog phase delay and 100ns logic delay, one could expect up to (0.1μs) (0.6V/μs) = 60mV error if the "hold" signal arrived near maximum dV/dt of the input. A positive going input would give a $\pm$60mV error. Now assume a 1MHz (3dB) bandwidth for the overall analog loop. This generates a phase delay of 160ns. If the hold capacitor sees this exact delay, then error due to analog delay will be (0.16μs) (0.6V/μs) = −96mV (analog) for a total of −36mV. To add to the confusion, analog delay is proportional to hold capacitor value while digital delay remains constant. A family of curves (dynamic sampling error) is included to help estimate errors.

A curve labeled *Aperture Time* has been included for sampling conditions where the input is steady during the sampling period, but may experience a sudden change nearly coincident with the "hold" command. This curve is based on a 1mV error fed into the output.

A second curve, *Hold Settling Time* indicates the time required for the output to settle to 1mV after the "hold" command.

Digital Feedthrough

Fast rise time logic signals can cause hold errors by feeding externally into the analog input at the same time the amplifier is put into the hold mode. To minimize this problem, board layout should keep logic lines as far as possible from the analog input. Grounded guarding traces may also be used around the input line, especially if it is driven from a high impedance source. Reducing high amplitude logic signals to 2.5V will also help.

Logic signals also couple to the hold capacitor. This hold capacitor should be guarded by a P.C. card trace connected to the sample-and-hold output. This will also minimize board leakage.

SPECIAL NOTES

1. Not all definitions herein defined are measured parametrically for the NE5537, but are legitimate terms used in sample and hold systems.
2. Reference should be made to Design Engineering, volumes 23 (Nov. 8, 1978), 25 (Dec. 6, 1978) and 26 (Dec. 20, 1978) for articles written by Eugene Zuch of Datel Systems, Inc. for a further discussion of sample and hold circuits.
3. Reference also made to National Semiconductor Corporation's Special Functions Data Book (1976).

CA3089-N

DESCRIPTION

CA3089 is a monolithic integrated circuit that provides all the functions of a comprehensive FM-IF system. Figure 6 is a block diagram showing the CA3089 features, which include a three-stage FM-IF amplifier/limiter configuration with level detectors for each stage, a doubly-balanced quadrature FM detector and an audio amplifier that features the optional use of a muting (squelch) circuit.

The advanced circuit design of the IF system includes desirable features such as delayed AGC for the RF tuner, an AFC drive circuit, and an output signal to drive a tuning meter and/or provide stereo switching logic. In addition, internal power supply regulators maintain a nearly constant current drain over the voltage supply range of +8 to +18 volts.

The CA3089 is ideal for high-fidelity operation. Distortion in a CA3089 FM-IF system is primarily a function of the phase linearity characteristic of the outboard detector coil.

The CA3089 utilizes a 16-lead dual-in-line plastic package and can operate over the ambient temperature range of -40°C to +85°C.

FEATURES

- **Exceptional limiting sensitivity: 10μV typ. at -3dB point**
- **Low distortion: 0.1% typ. (with double-tuned coil)**
- **Single-coil tuning capability**
- **High recovered audio: 400mV typ.**
- **Provides specific signal for control of interchannel muting (squelch)**
- **Provides specific signal for direct drive of a tuning meter**
- **Provides delayed AGC voltage for RF amplifier**
- **Provides a specific circuit for flexible AFC**
- **Internal supply/voltage regulators**

APPLICATIONS

- **High-fidelity FM receivers**
- **Automotive FM receivers**
- **Communications FM receivers**

SYSTEM DESIGN CONSIDERATIONS

The CA3089 is a very high gain device and therefore careful consideration must be given to the layout of external components to minimize feedback. The input by-pass capacitors should be located close to the input terminals and the values should not be large nor should the capacitors be of the type which might introduce inductive reactance to the circuit. An example of good by-pass capacitors would be ceramic disc with values in the range of .01 to .05 microfarad.

The input impedance of the CA3089 is approximately 10,000 ohms. It is *not* recommended to match this impedance. The value of the input termination resistor should be as low as possible without degrading system operation. The lower the value of this resistor the greater the system stability. An input terminating resistor between 50 and 100 ohms is recommended.

MC1496-F,N,H
MC1596-F,H

DESCRIPTION

The MC1496 is a monolithic Double-Balanced Modulator/Demodulator designed for use where the output voltage is a product of an input voltage (signal) and a switched function (carrier). The MC1596 will operate over the full military temperature range of −55°C to +125°C. The MC 1496 is intended for applications within the range of 0°C to +70°C.

APPLICATIONS

- **Suppressed carrier and amplitude modulation**
- **Synchronous detection**
- **FM detection**
- **Phase detection**
- **Sampling**
- **Single sideband**
- **Frequency doubling**

FEATURES

- **Excellent carrier suppression**
  65dB typ @ 0.5MHz
  50dB typ @ 10MHz
- **Adjustable gain and signal handling**
- **Balanced inputs and outputs**
- **High common-mode rejection—85dB typ**

CARRIER REJECTION AND SUPPRESSION

NE544/644-N,W
NE544-D

DESCRIPTION

The NE544 is a servo amplifier and pulse-width demodulator with internal motor drive transistors. It is designed for remote control applications in digital proportional systems but can be used in many other closed loop position control applications. It incorporates a linear one shot for improved positional accuracy and outputs for external pnp motor drive transistors.

FEATURES

- **500mA load current capability**
- **Bidirectional bridge output with single power supply**
- **Low standby power drain**
- **Adjustable deadband and trigger thresholds**
- **High linearity, 0.5% maximum error**
- **Output drive for external PNP transistors (optional)**
- **Wide supply voltage range**

NE5044-D,N

DESCRIPTION

The NE5044 is a programmable parallel input, serial output pulsewidth encoder. A multiplexed dual linear ramp technique is used to allow up to 7 inputs to be converted to a serial pulsewidth modulated signal with excellent linearity and minimal crosstalk. Fixed or variable frame rates can be used, externally controlled, for ease of demodulation. An onboard 5V regulator eliminates power supply sensitivities and provides up to 20mA current capability for driving external loads.

APPLICATIONS

- **Radio controlled aircraft, cars, boats, trains**
- **Industrial controllers**
- **Remote controlled entertainment systems**
- **Security systems**
- **Instrumentation recorders/controls**
- **Remote Analog/digital data transmission**
- **Automotive sensor systems**

PIN CONFIGURATION

D,N PACKAGE

FEATURES

- **3 to 7 channels, externally selectable**
- **Constant current dual linear ramp for linearity better than .3%**
- **Internal voltage regulator for low drift**
- **Wide supply range 4.5 – 16V**
- **Fixed or variable frame rate set by external R-C**
- **External control for channel gain or range**
- **Versatile applications; exponential rates, mixing, dual rate, reversing etc.**
- **Compatible with all transmission mediums**

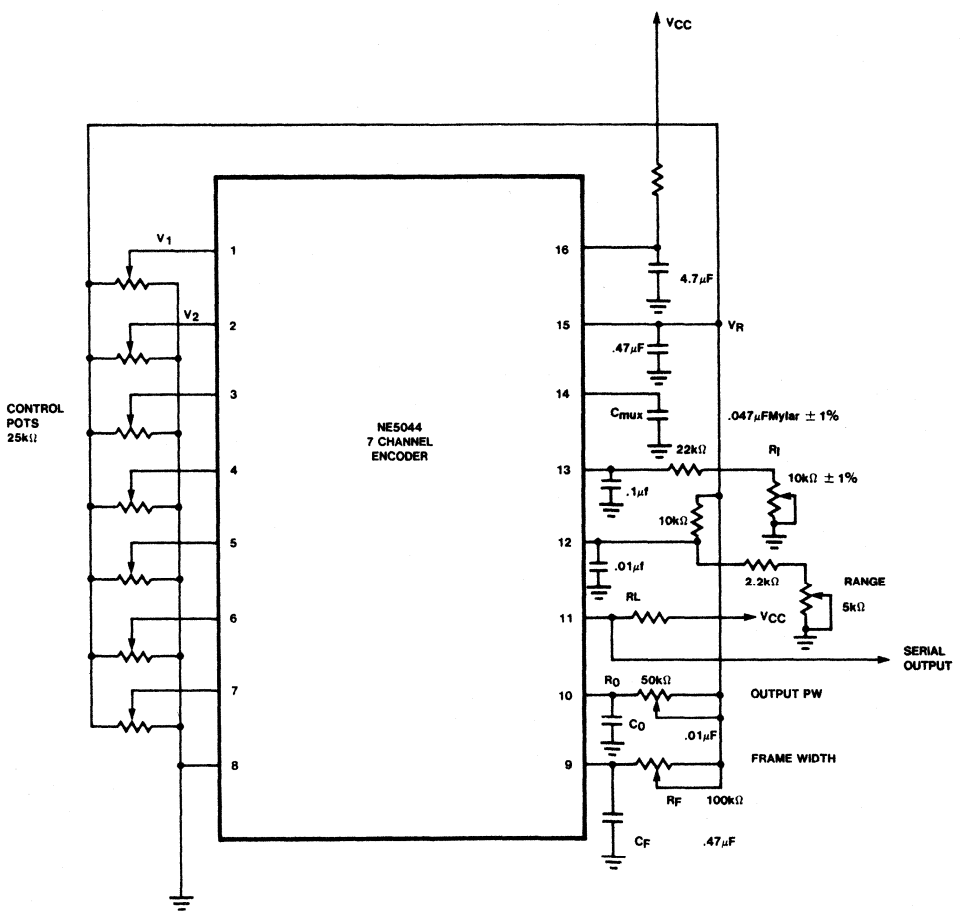
TEST CIRCUIT A



NE5045-D,N

DESCRIPTION

The NE5045 is a serial input, parallel output, decoder intended for applications in pulse width or pulse position modulation systems. The serial input pulse, either positive or negative, is shaped and amplified before being fed to the counter/decoder. An integrating type sync. separator detects pulses greater than $T_W = R_S C_S$. The amplified input pulse triggers an internal one-shot (minimum pulse) which in turn clocks the counter-decoder, thereby enhancing system noise rejection. A missing pulse detector resets the decoder during the sync. pause. An internal voltage regulator supplies power for the radio receiver providing excellent isolation from the power supply as well as the decoder logic.

APPLICATIONS

- **Radio controlled aircraft, cars, boats, trains**
- **Industrial controllers**
- **Remote controlled entertainment systems**
- **Security systems**
- **Instrumentation recorders/controls**
- **Remote Analog/digital data transmission**
- **Automotive sensor systems**

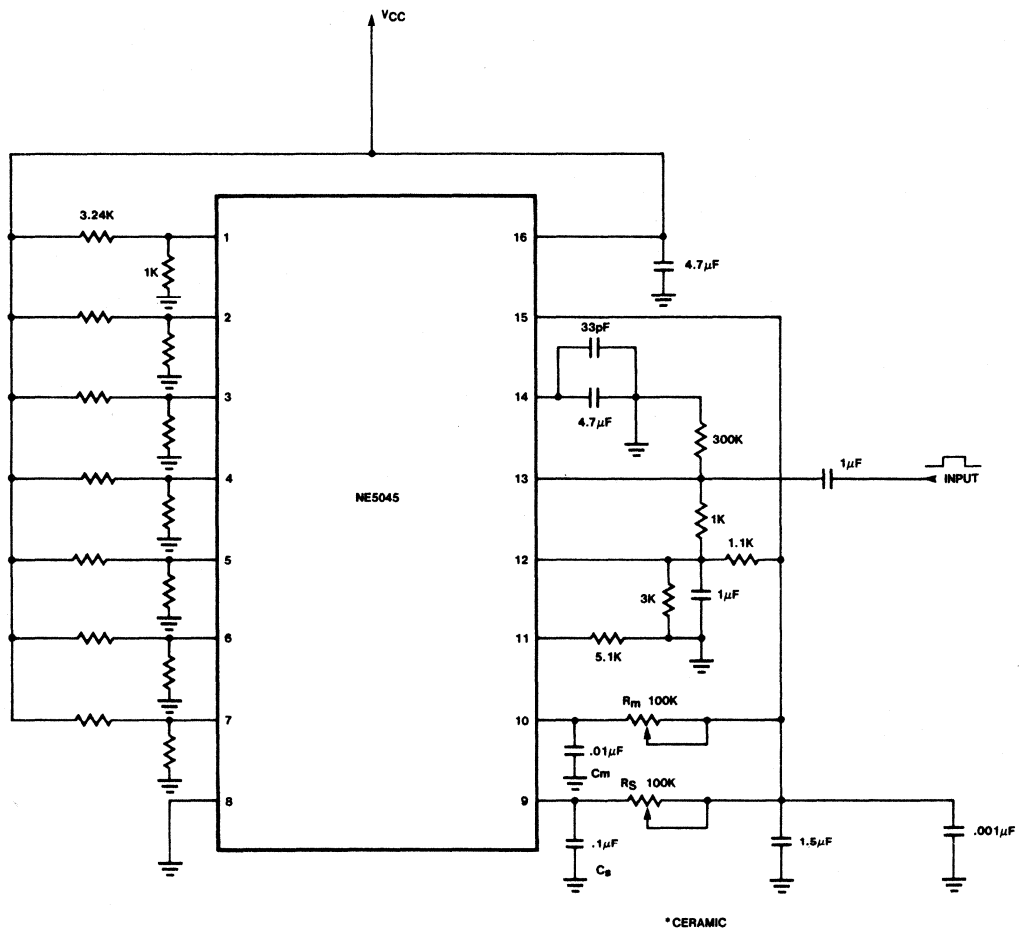
TEST CIRCUIT #1



NE5046-N

DESCRIPTION

The NE5046 is a serial input parallel output decoder designed for 2 channel digital proportional pulse width or pulse position modulation systems. The detection threshold is internally set and has hysteresis to prevent false triggering on noise. In a typical application, the serial input from the receiver is processed through an amplifier and pulse shaper, then converted to parallel output with a shift register. An internal sync separator detects the sync pause and clears the shift register. An internal voltage regulator provides power for the decoder and can be used to supply power for a radio receiver.

FEATURES

- **High gain input amplifier with hysteresis**
- **Externally adjustable sync separator**
- **Wide supply voltage range 3.6V–8V**
- **Noise and flutter rejection**
- **Outputs reset to zero without input**
- **Compatible with all transmission mediums**

APPLICATIONS

- **Radio-controlled aircraft, cars, boats, trains**
- **Industrial controllers**
- **Remote-controlled entertainment systems**
- **Security systems**
- **Instrumentation recorders/controls**
- **Remote Analog/digital data transmission**
- **Automotive sensor systems**

*A 2kΩ to 10kΩ resistor may be required to insure start-up under extreme load current and supply voltage conditions at low temperatures.

TCA440-N

DESCRIPTION

TCA440 is a monolithic IC, especially developed for AM receivers up to 30MHz. It includes a RF stage with AGC, a balanced mixer, separate oscillator and an IF amplifier with AGC. Because of its low current consumption and of its internal stabilization the TCA440 is perfectly suited for battery operated portables, car and home radios.

FEATURES

- **Balanced circuit**
- **Separately controllable prestage**
- **Multiplicative push-pull mixer with separate oscillator**
- **High signal handling capability even with 4.5V supply voltage**
- **100dB feedback control range in 5 stages**
- **Direct connection for tuning meter**
- **Minimum external components**

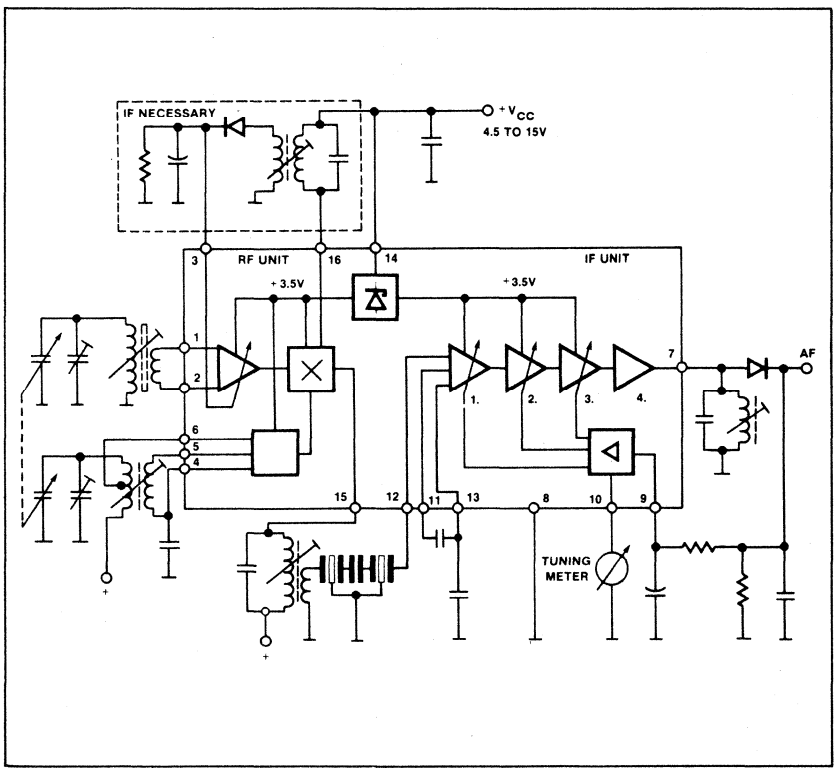
BLOCK DIAGRAM



TUNING METER

Recommended instruments:

or $500\mu A$ ($R_I = 800\Omega$)
$300\mu A$ ($R_I = 1.5k\Omega$)

The IC offers at pin 10 a tuning meter voltage of 600 mV_{EMP} max. with a source impedance of approx. 400Ω.

FUNCTION

As pictured in the circuit diagram the TCA440 comprises two control loops independent of each other which control the RF stage and the IF stages. By AGCing the RF stage, excellent signal handling is obtained. A voltage of $2.6V_{pp}$ on the IC input can be handled with very low distortion. The push-pull mixer operates multiplicatively, thereby resulting in few harmonic mixing products and whistling points. The oscillator which is separated from the mixer is also apted excellently for short waves. From the AGC of the RF amplifier a voltage is derived for a tuning meter which can be connected directly to the meter. The symmetric composition of the circuit provides high stability against oscillation and, at the same time, an AGC range of more than 100dB. The bridge circuit of the mixer provides good isolation of the oscillator.

TYPICAL APPLICATIONS (Cont'd)

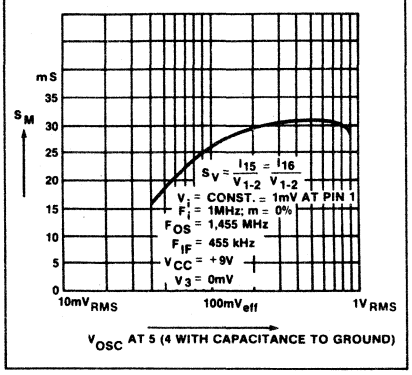
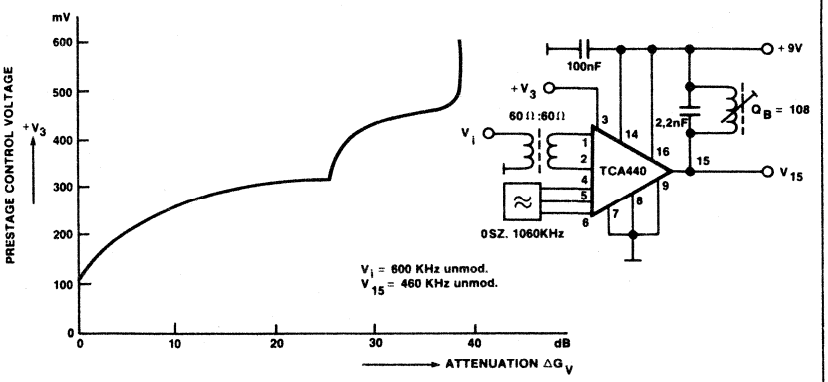
CONVERSION CONDUCTANCE vs OSCILLATOR VOLTAGE

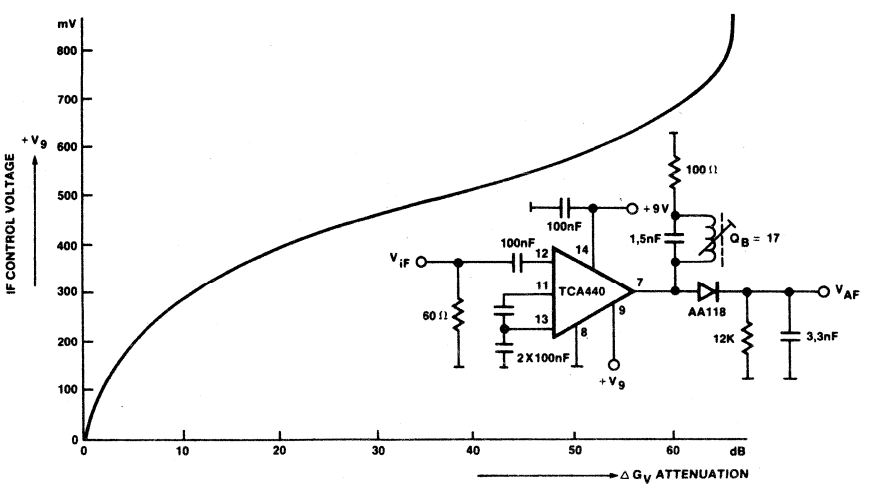


RF STAGE CONTROL



The input is not power matched and can be driven with a higher resistance, V_i is chosen so that a constant V_{15} is obtained (50mV$_{PP}$).

IF CONTROL



V_{IF} (469kHz; m = 80%; f_{mod} = 1kHz) is chosen so that always a constant V_{AF} is obtained (200mV$_{RMS}$)

μA758-N

DESCRIPTION

The μA758 is a monolithic phase-locked loop FM stereo multiplex decoder. The device decodes an FM stereo multiplex signal into right and left audio channels while inherently suppressing SCA information when it is contained in the composite input signal. The device includes automatic mono-stereo mode switching and drive for an external lamp to indicate stereo mode operation.

The μA758 operates over a large voltage range and requires a minimum number of external components. A simple setting of an external potentiometer adjusts the oscillator frequency. No coils are required.

FEATURES

- **45dB channel separation**
- **Automatic stereo/mono switching**
- **70dB SCA rejection**
- **10V to 16V supply range**
- **High impedance input—low impedance output**

PIN CONFIGURATION

TV CIRCUITS

Section 12—TV CIRCUITS

LM1880-F

DESCRIPTION

The LM1880 uses compatible Linear/I^2L technology to produce the first T.V. horizontal and vertical processing system which completely eliminates the hold controls. The heart of the system is a precision 32 times horizontal frequency VCO which is designed to use a low-cost ceramic resonator as a tuning element.

The VCO signal is divided down in the horizontal section to produce a pre-driver output which is locked to negative sync by means of an on-chip phases detector. The vertical output ramp is injection-locked by vertical sync subject to a sync window derived from the vertical countdown section. A gate pulse centered on the chroma burst is also provided.

FEATURES

- **No frequency set-up required for horizontal or vertical**
- **Ceramic resonator frequency reference**
- **Accurate horizontal pre-driver duty cycle**
- **Vertical sync window referenced to horizontal**
- **Precise interlaced vertical output**
- **APC loop parameters completely adjustable**
- **Vertical retrace time adjustable**
- **Chroma burst gate output**
- **Internal voltage regulator**

TBA120S-N

DESCRIPTION

An eight stage amplifier with balanced demodulator for amplifying, limiting and the demodulation of FM signals, specially designed for the sound-IF in TV and RF-IF amplifier in radios. An electronic Volume Control for the audio outputsignal is also provided.

Groups:

TBA120 S is delivered in groups:
An attenuation of –30dB of the audio output signal requires a resistor from pin 5 to ground typ. value 1.8K to 3.4K.

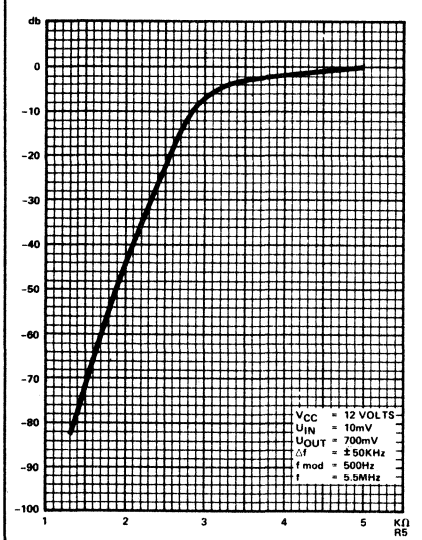
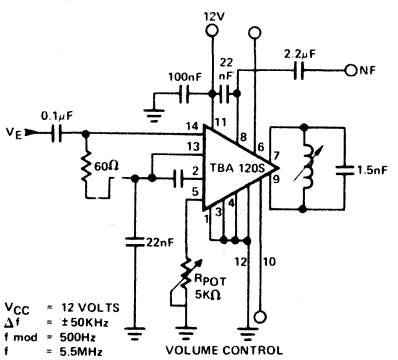
VOLUME CONTROL SIGNETICS TBA120S



TEST CIRCUIT



DESCRIPTION

The TBA1440G (for pnp tuner pre-stages) and TBA 1441G (for npn tuner pre-stages) have been developed from the TBA440P/N. Their improvements are as follows:

- Reduced residual IF at outputs 11 and 12
- Reduced residual IF at pin 13
- Considerably improved intermodulation distance
- Excellent tuning attitude even with low-ohmic tank circuit at demodulator

The IC's contain a high-amplifying controllable video IF amplifier, a controlled demodulator and two low-resistance video outputs with positive- and negative-going signals as well as the complete keyed control and delayed tuner control.

- Large control range with low noise and wide dynamic range
- High sensitivity
- Controlled demodulator, so minimum 1.07MHz disturbances
- Internal temperature stabilization
- The white levels of the video signals at the positive and negative video output are independent of the operating voltage
- The white and black levels can be adjusted separately

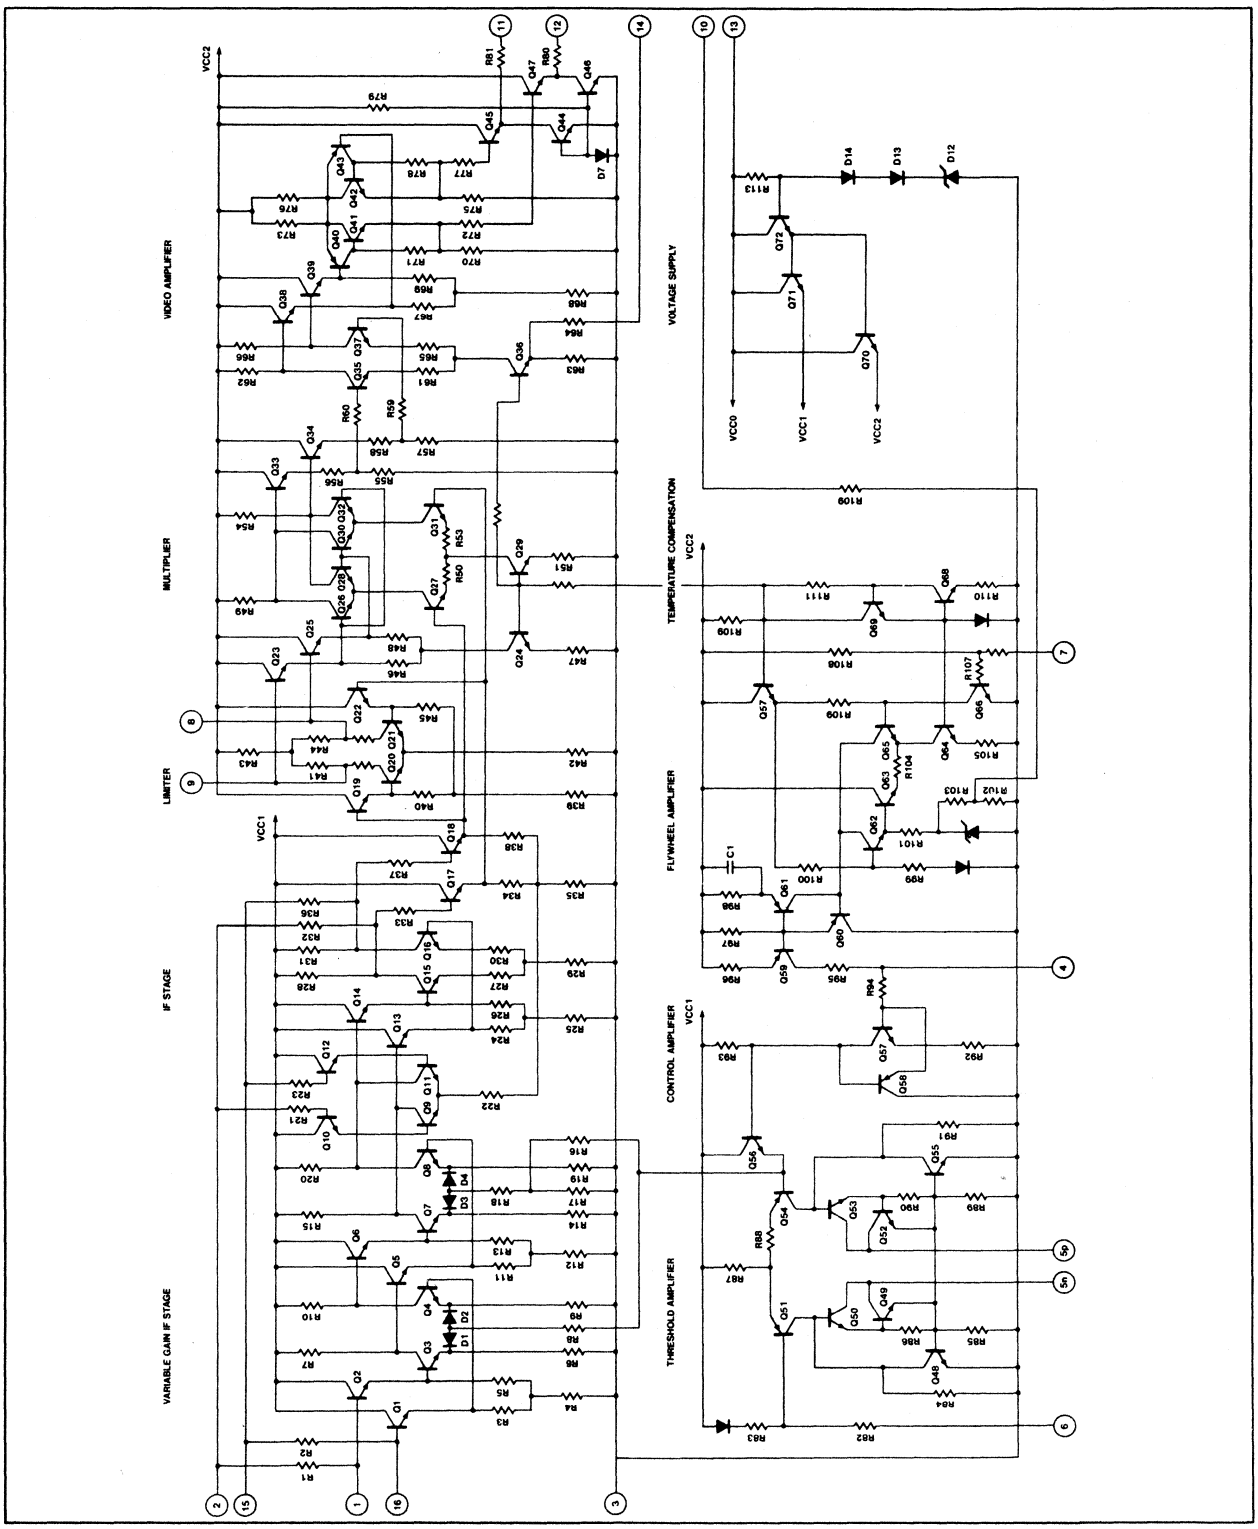
EQUIVALENT SCHEMATIC



ULN2211-N

DESCRIPTION

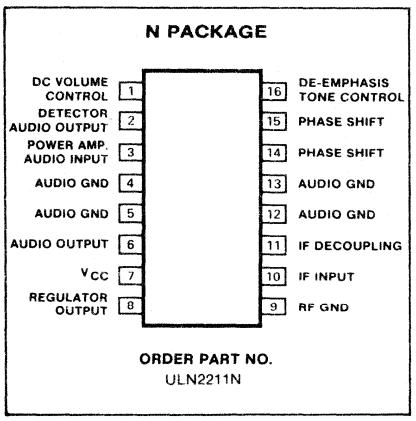
The ULN2211 contains a limiting amplifier, an FM quadrature detector, an electronic gain control stage and a 2-watt audio output stage. It can be used to detect and amplify any FM modulated signal having a 0.1-20MHz carrier frequency.

It is especially recommended as a complete TV sound channel requiring few external components and only one tuning adjustment for the 4.5MHz tank circuit. Provision is made for 6dB/octave de-emphasis and tone control.

FEATURES

- **2-watt output**
- **DC volume control attenuation, 70dB typ**
- **Limiter gain of 70dB**
- **Limiting threshold typically less than 200μV**
- **Automatic thermal shutdown**
- **Over-current limiting**
- **20dB ripple rejection**
- **Single supply operation (18-30V)**
- **No crossover distortion**

PIN CONFIGURATION



NOTE: Internal power dissipation in watts.

LM387-N

DESCRIPTION

The LM387 is a dual preamplifier for the amplification of low level signals in applications requiring optimum noise performance. Each of the two amplifiers is completely independent, with an internal power supply decoupler-regulator, providing 110dB supply rejection and 60dB channel separation. Other outstanding features include high gain (104dB), large output voltage swing (V_{CC} - 2V p-p), and wide power bandwidth (75kHz, 20V p-p). The LM387 operates from a single supply across the wide range of 9 to 40V.

The amplifiers are internally compensated for all gains greater than 10. The LM387 is available in an 8 lead dual-in-line package.

FEATURES

- **Low noise—0.8μV total input noise**
- **High gain—104dB open loop**
- **Single supply operation**
- **Wide supply range 9 to 40V**
- **Power supply rejection—110dB**
- **Large output voltage swing (VCC - 2V p-p)**
- **Wide bandwidth 15MHz unity gain**
- **Power bandwidth 75kHz, 20V p-p**
- **Internally compensated**
- **Short circuit protected**

NE/SE540-H

DESCRIPTION

The NE/SE540 is a monolithic, class AB power amplifier designed specifically to drive a pair of complementary output transistors. The device features low standby current yet retains a high output current drive capability with internal current limiting. A wide power bandwidth and excellent linearity make this device ideal for use an audio power amplifier.

FEATURES

- **Internal current limiting**
- **Low standby current**
- **High output current capability**
- **Wide power bandwidth**
- **Low distortion**

DESCRIPTION

The NE542 is a dual preamplifier for the amplification of low level signals in applications requiring optimum noise performance. Each of the two amplifiers is completely independent, with individual internal power supply decoupler-regulator, providing 110dB supply rejection and 70dB channel separation. Other outstanding features include high gain (104dB), large output voltage swing (V_{CC} -2Vp-p), and internal compensation to 10dB. The NE542 operates from a single supply across the wide range of 9 to 24V.

The NE542 is ideal for use in stereo phono, tape, or microphone preamps and other applications requiring low noise amplication of small signals.

FEATURES

- **Low noise—.7μV total input noise**
- **High gain—104dB open loop**
- **Single supply operation**
- **Wide supply range 9 to 24V**
- **Power supply rejection 110dB**
- **Large output voltage swing (V_{CC} -2V p-p)**
- **Wide bandwidth 15MHz unity gain**
- **Power bandwidth 100kHz (15V p-p)**
- **Internally compensated (stable at 10dB)**
- **Short circuit protected**
- **High slew rate 5V/μs**

CRIPTION

E570/571 is a versatile low cost dual ontrol circuit in which either channel e used as a dynamic range compres- expandor. Each channel has a full rectifier to detect the average value of signal; a linerarized, temperature ensated variable gain cell; and an tional amplifier.

E570/571 is well suited for use in tele- subscriber and trunk carrier systems, unications systems and hi-fi audio ns.

TURES

mperature compensated
ater than 110dB dynamic range
erates down to 6Vdc
tem levels adjustable with external mponents
tortion may be trimmed out

CUIT DESCRIPTION

NE570/571 compandor building s, as shown in the block diagram, are a ave rectifier, a variable gain cell, an tional amplifier and a bias system. The gement of these blocks in the IC result ircuit which can perform well with few nal components, yet can be adapted to diverse applications.

ull wave rectifier rectifies the input nt which flows from the rectifier input, internal summing node which is bi- at V_{REF}. The rectified current is aver- on an external filter capacitor tied to RECT terminal, and the average value input current controls the gain of the ble gain cell. The gain will thus be ortional to the average value of the signal for capacitively coupled voltage s as shown in the following equation. that for capacitively coupled inputs is no offset voltage capable of pro- g a gain error. The only error will come the bias current of the rectifier (sup- internally) which is less than .1μA.

$$\propto \frac{|V_{IN} - V_{REF}|_{ave}}{R_1}$$

or

$$\propto \frac{|V_{IN}|_{ave}}{R_1}$$

speed with which gain changes to fol- hanges in input signal levels is deter- d by the rectifier filter capacitor. A capacitor will yield rapid response but not fully filter low frequency signals. ripple on the gain control signal will ulate the signal passing through the ble gain cell. In an expandor or compressor application, this would lead to third harmonic distortion, so there is a tradeoff to be made between fast attack and decay times, and distortion. For step changes in amplitude, the change in gain with time is shown by this equation.

$$G(t) = (G_{initial} - G_{final})\ e^{-t/\tau} + G_{final};\ \tau = 10K \times C_{RECT}$$

The variable gain cell is a current in, current out device with the ratio I_{OUT}/I_{IN} controlled by the rectifier. I_{IN} is the current which flows from the ΔG input to an internal summing node biased at V_{REF}. The following equation applies for capacitively coupled inputs. The output current, I_{OUT}, is fed to the summing node of the op amp.

$$I_{IN} = \frac{V_{IN} - V_{REF}}{R_2} = \frac{V_{IN}}{R_2}$$

A compensation scheme built into the ΔG cell compensates for temperature, and cancels out odd harmonic distortion. The only distortion which remains is even harmonics, and they exist only because of internal offset voltages. The THD trim terminal provides a means for nulling the internal offsets for low distortion operation.

The operational amplifier (which is internally compensated) has the non-inverting input tied to V_{REF}, and the inverting input connected to the ΔG cell output as well as brought out externally. A resistor, R_3, is brought out from the summing node and allows compressor or expandor gain to be determined only by internal components.

APPLICATIONS

- **Telephone trunk compandor—570**
- **Telephone subscriber compandor—571**
- **High level limiter**
- **Low level expandor—noise gate**
- **Dynamic noise reduction systems**
- **Voltage controlled amplifier**
- **Dynamic filters**

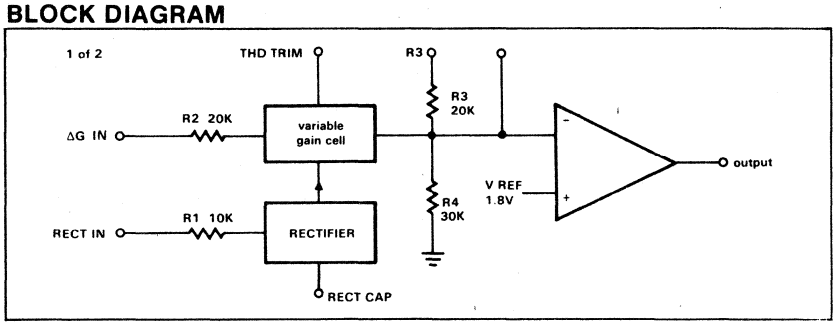
BLOCK DIAGRAM



13

The output stage is capable of ±20mA output current. This allows a +13dBm (3.5V rms) output into a 300Ω load which, with a series resistor and proper transformer, can result in +13dBm with a 600Ω output impedance.

A band gap reference provides the reference voltage for all summing nodes, a regulated supply voltage for the rectifier and ΔG cell, and a bias current for the ΔG cell. The low tempco of this type of reference provides very stable biasing over a wide temperature range.

The typical performance characteristics illustration shows the basic input-output transfer curve for basic compressor or expandor circuits.

MINARY SPECIFICATION NE572-N

CRIPTION

E572 is a dual channel, high perfor- gain control circuit in which either el may be used for dynamic gain com- on or expansion. Each channel has a ive rectifier to detect the average of input signal; a linearized, tempera- ompensated variable gain cell and a nic time constant buffer. The buffer s independent control of dynamic at- nd recovery time with minimum exter- mponents and improved low frequency ontrol ripple distortion over previous andors.

E572 is intended for noise reduction in erformance audio systems. It can also ed in a wide range of communication ns and video recording applications.

FEATURES

- **Independent control of attack and recovery time.**
- **Improved low frequency gain control ripple**
- **Complementary gain compression and expansion with external Op Amp**
- **Wide dynamic range—greater than 110dB**
- **Temperature compensated gain control**
- **Low distortion gain cell**
- **Low noise**
- **Wide supply voltage range—down to 6V.**
- **System level adjustable with external components.**

APPLICATIONS

- **Dynamic noise reduction system**
- **Voltage control amplifier**
- **Stereo expandor**
- **Automatic level control**
- **High level limiter**
- **Low level noise gate**
- **State variable filter**

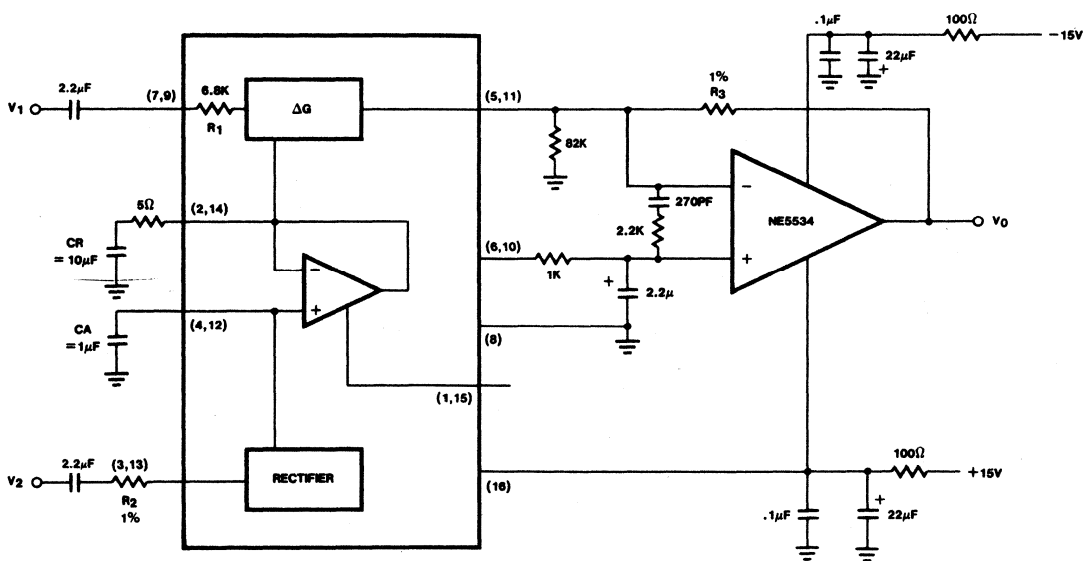
TEST CIRCUIT



DESCRIPTION

The NE645B/646B is a monolithic audio noise reduction system circuit. This circuit is used to reduce the level of background noise introduced during recording and playback of audio signals on magnetic tape, and to improve the noise level in FM broadcast reception. This circuit is intended for use in a Dolby* B-type noise reduction system and is available only to licensees of Dolby Laboratories Licensing Corporation, San Francisco.

NOTE

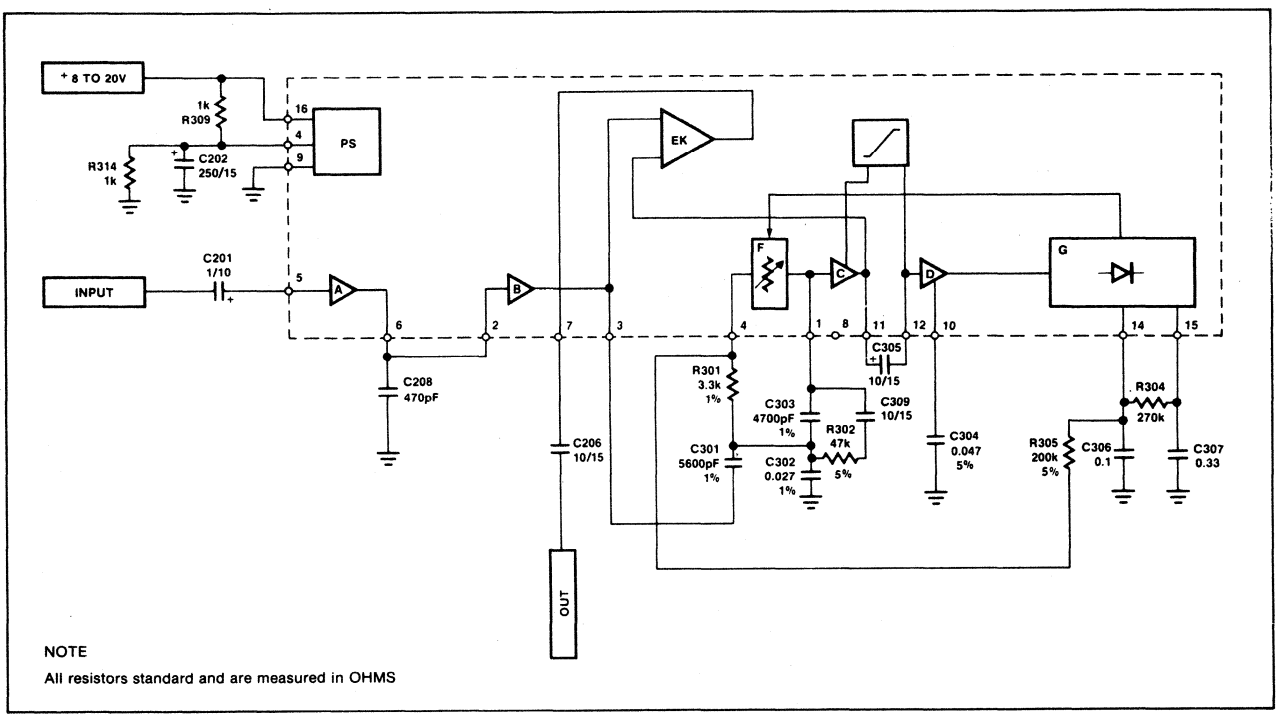
The figures given in this table are the average response of many of Dolby Laboratories' professional encoders, and are not intended to be taken as required consumer equipment performance characteristics. Thus, no inference should be drawn on the tolerances which licensees must maintain in consumer B-Type circuitry. The figures can however be used to plot typical characteristics.

APPLICATION INFORMATION

The NE645B/646B is a direct replacement for the NE545B. For a ±1dB back-to-back frequency response, the external compononts should be changed as shown in the test circuit. The critical component is R307 which should be shorted out. All other components, R303, R308, and C308 are now connected to empty pins. D301 will only effect the burst performance. C208 is only necessary in the test circuit in order to eliminate high frequency oscillation. In the actual application the 19kHz filter between pin 6 and 2 will perform the same high frequency roll off. All curcuit parameters are guaranteed at 12V V_{CC}.

TEST CIRCUIT NE645B/646B



NOTE

All resistors standard and are measured in OHMS

The following components have been eliminated from the NE545B test circuit: (over)

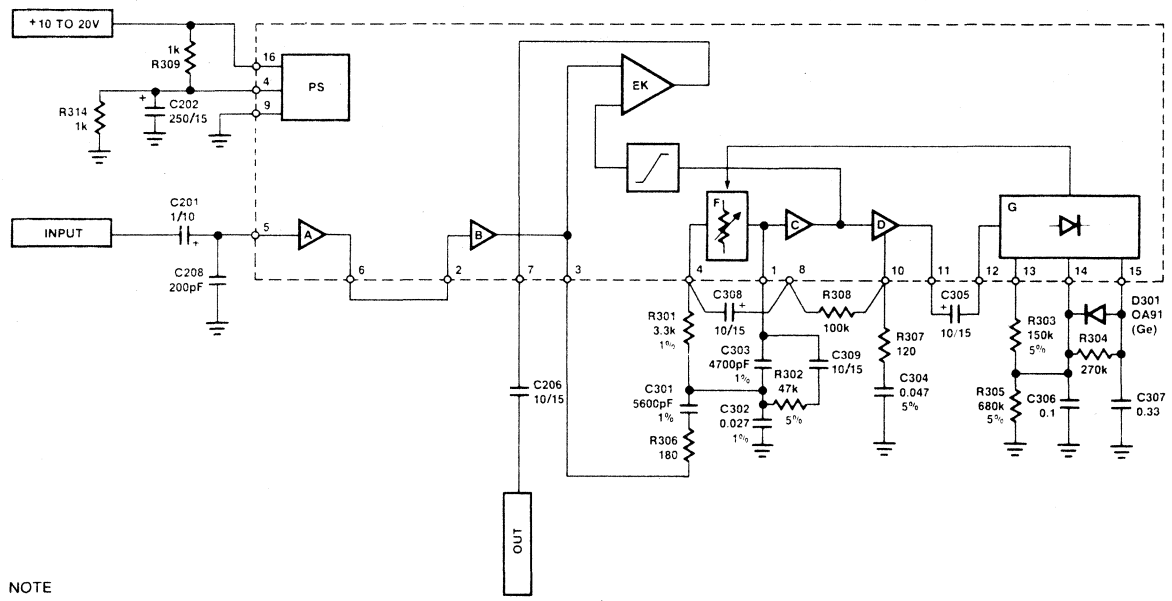
R303, R306, R307, R308, C308, D301

Component changes:

C208 is changed from 200pF to 470pF and is moved from pin 5 to pin 6/2

R305 is changed from 680K to 200K and terminated at pin 4

TEST CIRCUIT NE545B



NOTE

All resistors standard and are measured in OHMS.

SECTION 14
PHASE LOCKED LOOPS

Section 14—PHASE LOCKED LOOPS

PHASE LOCKED LOOPS DEFINITIONS

T_A

Ambient temperature range. Range of the surrounding environment of the operating device.

T_J

Junction Temperature. The maximum temperature of the device. 150°C is standard for silicon devices.

T_{STG}

Storage temperature range. Temperature range that the device can be stored in a non-operating condition.

T_{SOLD}

Soldering Temperature. The temperature which can be applied to the lead frame of the device for short periods of time (normally specified for a duration of 10 sec).

Truth Tables

0 is logic level low
1 is logic level high
X - don't care condition - has no effect under circuit conditions listed.

Absolute Maximum Rating

Operating safe zones exceeding these limits could cause permanent damage to the device and are not meant to imply that devices can operate at these limits.

Power Dissipation

The power that the device can safely handle at 25°C. The dissipation must be derated as indicated for the individual package type.

Package Type Designation

See full package designations in Appendix.

V_{CC} ($-V_{CC}$)

Supply Voltage. The range of power supply voltage over which the device will operate safely.

FREE-RUNNING FREQUENCY (f_o', ω_o').

Also called the *center frequency*, this is the frequency at which the loop VCO operates when not locked to an input signal. The "prime" superscripts are used to distinguish the free-running frequency from f_o' and ω_o' which are used for the general oscillator frequency. (Many references use f_o' and ω_o' for both the free-running and general oscillator frequency and leave the proper choice for the reader to infer from the context). The appropriate units for f_o' and ω_o' are Hz and radians per second respectively.

LOCK RANGE ($2f_L$, $2\omega_L$).*

The range of frequencies over which the loop will remain in lock. Normally the lock range is centered at the free-running frequency unless there is some nonlinearity in the system which limits the frequency deviation on one side of f_o'. The deviations from f_o' are referred to as the *Tracking Range* or *Hold-in Range*. (See figure 1.6). The tracking range is therefore one-half of the lock range.

CAPTURE RANGE ($2f_C$, $2\omega_C$).**

Although the loop will remain in lock throughout its lock range, it may not be able to acquire lock at the tracking range extremes because of the selectivity afforded by the low-pass filter. The capture range also is centered at f_o' with the equal deviations called the *Lock-in* or *Pull-in Ranges*. The capture range can never exceed the lock range.

LOCK-UP TIME (t_L).***

The transient time required for a free-running loop to lock. This time depends principally upon the bandwidth selectivity designed into the loop with the low-pass filter. The lock-up time is inversely proportional to the selectivity bandwidth. Also, lock-up time exhibits a statistical spreading due to random initial phase relationships between the input and oscillator phases.

PHASE COMPARATOR CONVERSION GAIN (K_d).

The conversion constant relating the phase comparators output voltage to the phase difference between input and VCO signals when the loop is locked. At low input signal levels, K_d is also a function of signal amplitude. K_d has units of volts per radian (V/rad).

VCO CONVERSION GAIN (K_o).

The conversion constant relating the oscillators frequency shift from f_o' to the applied input voltage. K_o has units of radians per second per volt (rad/sec/volt). K_o is a linear function of ω_o' and must be obtained using a formula or graph provided or experimentally measured at the desired ω_o'.

LOOP GAIN (K_v).

The product of K_d, K_o, and the low-pass filters gain at dc. K_d is evaluated at the appropriate input signal level and K_o at the appropriate ω_o'. K_v has units of $(sec)^{-1}$.

CLOSED LOOP GAIN (CLG).

The output signal frequency and phase can be determined from a product of the CLG and the input signal where the CLG is given by

$$CLG = \frac{K_v}{1 + K_v} \qquad \text{(Equation 1.4)}$$

NATURAL FREQUENCY (ω_n).

The characteristic frequency of the loop, determined mathematically by the final pole positions in the complex plane or determined experimentally as the modulation frequency for which an underdamped loop gives the maximum frequency deviation from f_o' and at which the phase error swing is the greatest.

DAMPING FACTOR (ζ).

The standard damping constant of a second order feedback system. For the PLL, ζ refers to the ability of the loop to respond quickly to an input frequency step without excessive overshoot.

LOOP NOISE BANDWIDTH (B_L).

A loop property relating ω_n and τ which describes the effective bandwidth of the received signal. Noise and signal components outside this bandwidth are greatly attenuated.

* Also called Synchronization Range.
** Also called Acquisition Range.
*** Also called Acquisition Time.

NOTE
Refer to Section 10 of the 1979 Analog Applications Manual for an in-depth explanation of Phase Locked Loops and their applications.

NE/SE564-D,F,N

DESCRIPTION

The NE564 is a versatile, high frequency Phase Locked Loop designed for operation up to 50MHz. As shown in the block diagram, the NE564 consists of a VCO, limiter, phase comparator, and post detection processor.

APPLICATIONS

- **High speed modems**
- **FSK receivers and transmitters**
- **Frequency synthesizers**
- **Signal generators**

FEATURES

- **Operation with single 5V supply**
- **TTL compatible inputs and outputs**
- **Operation to 50MHz**
- **External loop gain control**
- **Reduced carrier feedthrough**
- **No elaborate filtering needed in FSK applications**
- **Can be used as a modulator**
- **Variable loop gain (Externally Controlled)**

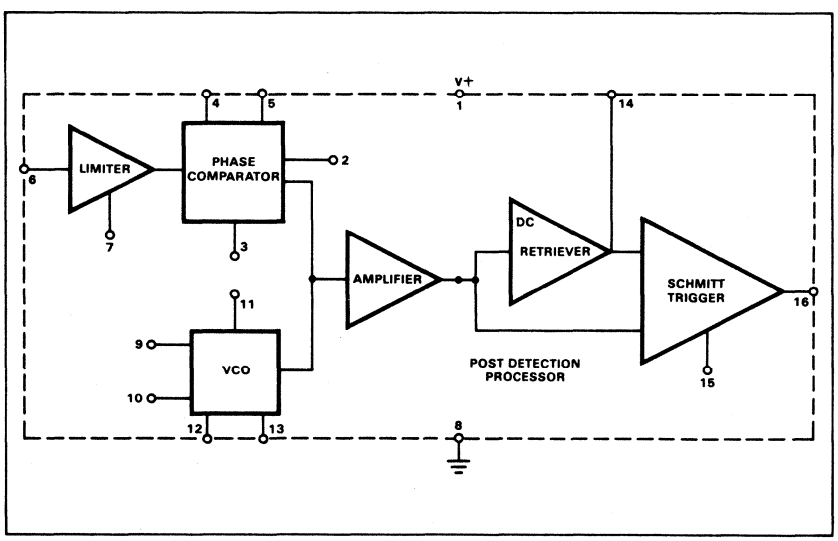
BLOCK DIAGRAM



FUNCTIONAL DESCRIPTION

The NE564 is a monolithic phase locked loop with a post detection processor. The use of Schottky clamped transistors and optimized device geometries extends the frequency of operation to greater than 50MHz. In addition to the classical PLL applications, the NE564 can be used as a modulator with a controllable frequency deviation.

The output voltage of the PLL can be written as shown in the following equation:

$$V_O = \frac{(f_{in} - f_o)}{K_{VCO}} \qquad \text{Equation 1}$$

K_{VCO} = conversion gain of the VCO (see figure 7)
f_{in} = frequency of the input signal
f_o = free running frequency of the VCO

The process of recovering FSK signals involves the conversion of the PLL output into logic compatible signals. For high data rates, a considerable amount of carrier will be present at the output of the PLL due to the wideband nature of the loop filter. To avoid the use of complicated filters, a comparator with hysterisis or Schmitt trigger is required. With the conversion gain of the VCO fixed, the output voltage as given by Equation 1 varies according to the frequency deviation of f_{in} from f_o. Since this differs from system to system, it is necessary that the hysterisis of the Schmitt trigger be capable of being changed, so that it can be optimized for a particular system. This is

accomplished in the 564 by varying the voltage at pin 15 which results in a change of the hysterisis of the Schmitt trigger.

For FSK signals, an important factor to be considered is the drift in the free running frequency of the VCO itself. If this changes due to temperature, according to Equation 1 it will lead to a change in the dc levels of the PLL output, and consequently to errors in the digital output signal. This is especially true for narrow band signals where the deviation in f_{in} itself may be less than the change in f_o due to temperature. This effect can be eliminated if the dc or average value of the signal is retrieved and used as the reference to the comparator. In this manner, variations in the dc levels of the PLL output do not affect the FSK output.

VCO Section

Due to its inherent high frequency performance, an emitter coupled oscillator is used in the VCO. In the circuit, shown in the equivalent schematic, transistors Q_{21} and Q_{23} with current sources Q_{25}–Q_{26} form the basic oscillator. The free running frequency of the oscillator is shown in the following equation:

$$f_o = \frac{1}{16R_cC_1} \qquad \text{Equation 2}$$

$R_c = R_{19} = R_{20} = 100\Omega$ (INTERNAL)
C_1 = external frequency setting capacitor

Variation of V_d (phase detector output voltage) changes the frequency of the oscillator. As indicated by Equation 2, the frequency of the oscillator has a negative temperature coefficient due to the positive temperature coefficient of the monolithic resistor. To compensate for this, a current I_R with negative temperature coefficient is introduced to achieve a low frequency drift with temperature.

Phase Comparator Section

The phase comparator consists of a double balanced modulator with a limiter amplifier to improve AM rejection. Schottky clamped vertical PNPs are used to obtain TTL level inputs. The loop gain can be varied by changing the current in Q_4 and Q_{15} which effectively changes the gain of the differential amplifiers. This can be accomplished by introducing a current at pin 2.

Post Detection Processor Section

The post detection processor consists of a unity gain transconductance amplifier and comparator. The amplifier can be used as a dc retriever for demodulation of FSK signals, and as a post detection filter for linear FM demodulation. The comparator has adjustable hysterisis so that phase jitter in the output signal can be eliminated.

As shown in the equivalent schematic, the dc retriever is formed by the transductance amplifier Q_{42}–Q_{43} together with an external capacitor which is connected at the am-

14

plifier output (pin 14). This forms an integrator whose output voltage is shown in the following equation:

$$V_O = \frac{g_m}{C_2} \int V_{in} dt \qquad \text{Equation 3}$$

g_m = transconductance of the amplifier
C_2 = capacitor at the output (pin 14)
V_{in} = signal voltage at amplifier input

With proper selection of C_2, the integrator time constant can be varied so that the output voltage is the dc or average value of the input signal for use in FSK, or as a post detection filter in linear demodulation.

The comparator with hysterisis is made up of Q_{49}–Q_{50} with positive feedback being provided by Q_{47}–Q_{48}. The hysterisis is varied by changing the current in Q_{52} with a resulting variation in the loop gain of the comparator. This method of hysterisis control, which is a dc control, provides symmetric variation around the nominal value.

Design Formula

The free running frequency of the VCO is shown by the following equation:

$$f_o = \frac{1}{16 R_C C_1} \text{ in Hz} \qquad \text{Equation 4}$$

R_C = 100Ω
C_1 = external cap in farads

The loop filter diagram shown is explained by the following equation:

$$F(s) = \frac{1}{1 + sRC_3} \qquad \text{Equation 5}$$

$R = R_{12} = R_{13} = 1.3k\Omega$ (INTERNAL)

By adding capacitors to pins 4 and 5, two poles are added to the loop transfer function at $\omega = \frac{1}{RC_3}$.

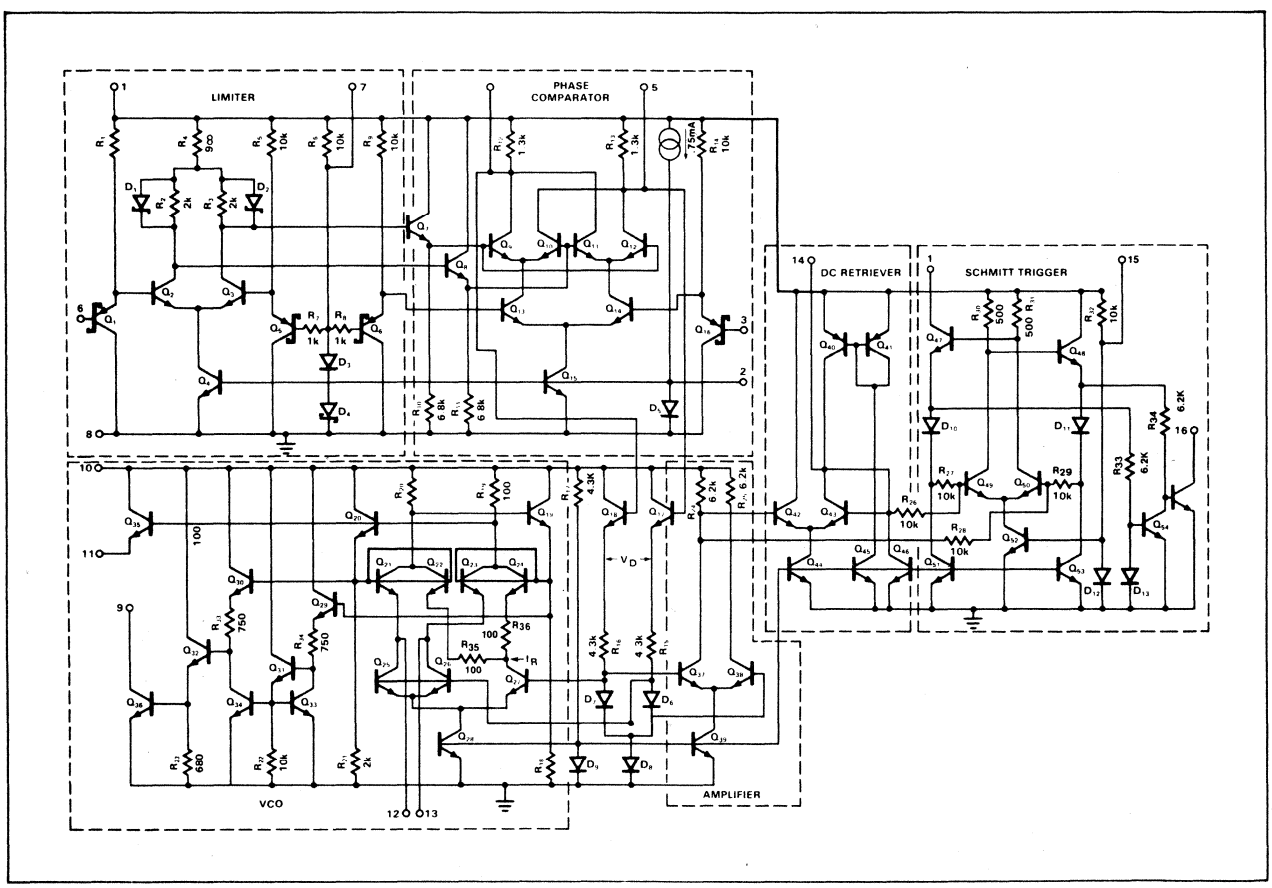
FM DEMODULATOR

The NE564 can be used as an FM demodulator. The connections for operation at 5V and 12V are shown in figures 2 and 3 respectively. The input signal is ac coupled with the output signal being extracted at pin 14. Loop filtering is provided by the capacitors at pins 4 and 5 with additional filtering being provided by the capacitor at pin 14. Since the conversion gain of the VCO is not very high, to obtain sufficient demodulated output signal the frequency deviation in the input signal should be fairly high (1% or higher).

MODULATION TECHNIQUES

The NE564 phase locked loop can be modulated at either the loop filter ports (pins 4 and 5) or the input port (pin 6) as shown in figure 4. The approximate modulation frequency can be determined from the frequency conversion gain curve shown in figure 5. This curve will be appropriate for signals injected into pins 4 and 5 as shown in figure 4.

EQUIVALENT SCHEMATIC



FSK Demodulation

The 564 PLL is particularly attractive for FSK demodulation since it contains an internal voltage comparator and VCO which have TTL compatible inputs and outputs, and it can operate from a single 5 volt power supply. Demodulated dc voltages associated with the mark and space frequencies are recovered with a single external capacitor in a dc retriever without utilizing extensive filtering networks. An internal comparator, acting as a Schmitt trigger with an adjustable hysteresis, shapes the demodulated voltages into compatible TTL output levels. The high frequency design of the 564 enables it to demodulate FSK at high data rates in excess of 1.0M baud.

Figure 6 shows a high-frequency FSK decoder designed for input frequency deviations of ± 1.0MHz centered around a free-running frequency of 10.8MHz. The value of the timing capacitance required was estimated from figure 8 to be approximately 40pF. A trimmer capacitor was added to fine tune f_o' to 10.8MHz.

Figure 9 indicates that the ± 1.0MHz frequency deviations will be within the lock range for input signal levels greater than approximately 50mV with zero pin 2 bias current. While strictly this figure is appropriate only for 5MHz, it can be used as a guide for lock range estimates at other f_o' frequencies.

The hysteresis was adjusted experimentally via the 10kΩ potentiometer and 2kΩ bias arrangement to give the waveshape shown in figure 7 for 20K, 500K, 2M baud rates with square wave FSK modulation. Note the magnitude and phase relationships of the phase comparators output voltages with respect to each other and to the FSK output. The high frequency sum components of the input and VCO frequency also are visible as noise on the phase comparators outputs.

DESCRIPTION

The SE/NE565 Phase-Locked Loop (PLL) is a self-contained, adaptable filter and demodulator for the frequency range from 0.001Hz to 500kHz. The circuit comprises a voltage-controlled oscillator of exceptional stability and linearity, a phase comparator, an amplifier and a low-pass filter as shown in the block diagram. The center frequency of the PLL is determined by the free-running frequency of the VCO; this frequency can be adjusted externally with a resistor or a capacitor. The low-pass filter, which determines the capture characteristics of the loop, is formed by an internal resistor and an external capacitor.

FEATURES

- **Highly stable center frequency (200ppm/°C typ.)**
- **Wide operating voltage range (±6 to ±12 volts)**
- **Highly linear demodulated output (0.2% typ.)**
- **Center frequency programming by means of a resistor or capacitor, voltage or current**
- **TTL and DTL compatible square-wave output; loop can be opened to insert digital frequency divider**
- **Highly linear triangle wave output**
- **Reference output for connection of comparator in frequency discriminator**
- **Bandwidth adjustable from < ±1% to > ±60%**
- **Frequency adjustable over 10 to 1 range with same capacitor**

APPLICATIONS

- **Frequency shift keying**
- **Modems**
- **Telemetry receivers**
- **Tone decoders**
- **SCA receivers**
- **Wideband FM discriminators**
- **Data synchronizers**
- **Tracking filters**
- **Signal restoration**
- **Frequency multiplication & division**

TYPICAL APPLICATIONS

FM Demodulation

The 565 Phase Locked Loop is a general purpose circuit designed for highly linear FM demodulation. During lock, the average dc level of the phase comparator output signal is directly proportional to the frequency of the input signal. As the input frequency shifts, it is this output signal which causes the VCO to shift its frequency to match that of the input. Consequently, the linearity of the phase comparator output with frequency is determined by the voltage-to-frequency transfer function of the VCO.

Because of its unique and highly linear VCO, the 565 PLL can lock to and track an input signal over a very wide bandwidth (typically ±60%) with very high linearity (typically, within 0.5%).

A typical connection diagram is shown in Figure 1. The VCO free-running frequency is given approximately by

$f_o = \frac{1.2}{4R_1C_1}$ and should be adjusted to be at the center of the input signal frequency range. C1 can be any value, but R1 should be within the range of 2000 to 20,000 ohms with an optimum value on the order of 4000 ohms. The source can be direct coupled if the dc resistances seen from pins 2 and 3 are equal and there is no dc voltage difference between the pins. A short between pins 4 and 5 connects the VCO to the phase comparator. Pin 6 provides a dc reference voltage that is close to the dc potential of the demodulated output (pin 7). Thus, if a resistance is connected between pins 6 and 7, the gain of the output stage can be reduced with little change in the dc voltage level at the output. This allows the lock range to be decreased with little change in the free-running frequency. In this manner the lock range can be decreased from ±60% of f_o to approximately ±20% of f_o (at ±6V).

A small capacitor (typically 0.001μF) should be connected between pins 7 and 8 to eliminate possible oscillation in the control current source.

A single-pole loop filter is formed by the capacitor C2, connected between pin 7 and the positive supply, and an internal resistance of approximately 3600 ohms.

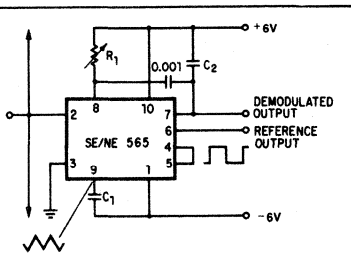

Figure 1

Frequency Shift Keying (FSK)

FSK refers to data transmission by means of a carrier which is shifted between two preset frequencies. This frequency shift is usually accomplished by driving a VCO with the binary data signal so that the two resulting frequencies correspond to the "0" and "1" states (commonly called space and mark) of the binary data signal.

A simple scheme using the 565 to receive FSK signals of 1070Hz and 1270Hz is shown in Figure 2. As the signal appears at the input, the loop locks to the input frequency and tracks it between the two frequencies with a corresponding dc shift at the output.

The loop filter capacitor C2 is chosen smaller than usual to eliminate overshoot on the output pulse, and a three-stage RC ladder filter is used to remove the carrier component from the output. The band edge of the ladder filter is chosen to be approximately half way between the maximum keying rate (in this case 300 baud or 150Hz) and twice the input frequency (approximately 2200Hz). The output signal can now be made logic compatible by connecting a voltage comparator between the output and pin 6 of the loop. The free-running frequency is adjusted with R1 so as to result in a slightly-positive voltage at the output with f_{IN} = 1070Hz.

The input connection is typical for cases where a dc voltage is present at the source and therefore a direct connection is not desirable. Both input terminals are returned to ground with identical resistors (in this case, the values are chosen to effect a 600-ohm input impedance).

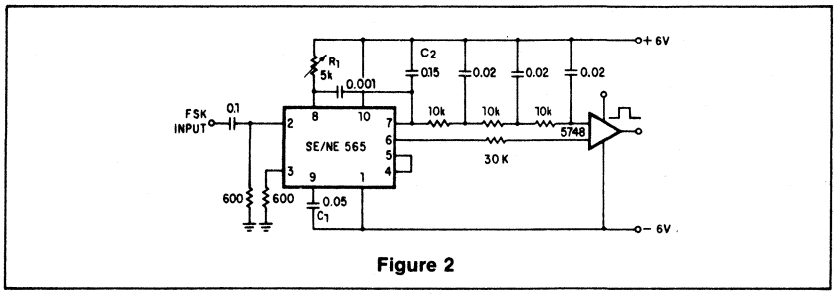

Figure 2

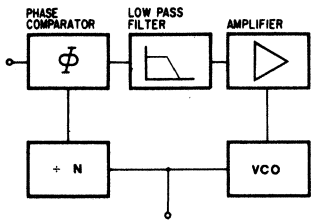

Figure 3

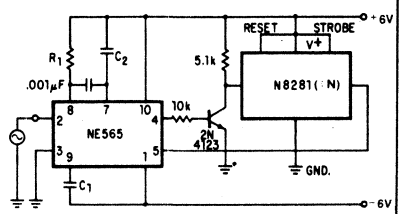

Figure 4

Frequency Multiplication

There are two methods by which frequency multiplication can be achieved using the 565:

1. Locking to a harmonic of the input signal.
2. Inclusion of a digital frequency divider or counter in the loop between the VCO and phase comparator.

The first method is the simplest, and can be achieved by setting the free-running frequency of the VCO to a multiple of the input frequency. A limitation of this scheme is that the lock range decreases as successively higher and weaker harmonics are used for locking. If the input frequency is to be constant with little tracking required, the loop can generally be locked to any one of the first 5 harmonics. For higher orders of multiplication, or for cases where a large lock range is desired, the second scheme is more desirable. An example of this might be a case where the input signal varies over a wide frequency range and a large multiple of the input frequency is required.

A block diagram of the second scheme is shown in Figure 3. Here the loop is broken between the VCO and the phase comparator, and a frequency divider is inserted. The fundamental of the divided VCO frequency is locked to the input frequency in this case, so that the VCO is actually running at a multiple of the input frequency. The amount of multiplication is determined by the frequency divider. A typical connection scheme is shown in Figure 4. To set up the circuit, the frequency limits of the input signal must be determined. The free-running frequency of the VCO is then adjusted by means of R1 and C1 (as discussed under FM demodulation) so that the output frequency of the divider is midway between the input frequency limits. The filter capacitor, C2, should be large enough to eliminate variations in the demodulated output voltage (at pin 7), in order to stabilize the VCO frequency. The output can now be taken as the VCO squarewave output, and its fundamental will be the desired multiple of the input frequency (f_{IN}) as long as the loop is in lock.

SCA (Background Music) Decoder

Some FM stations are authorized by the FCC to broadcast uninterrupted background music for commerical use. To do this a frequency modulated subcarrier of 67kHz is used. The frequency is chosen so as not to interfere with the normal stereo or monaural program; in addition, the level of the subcarrier is only 10% of the amplitude of the combined signal.

The SCA signal can be filtered out and demodulated with the NE565 Phase Locked Loop without the use of any resonant circuits. A connection diagram is shown in Figure 5. This circuit also serves as an example of operation from a single power supply.

A resistive voltage divider is used to establish a bias voltage for the input (pins 2 and 3). The demodulated (multiplex) FM signal is fed to the input through a two-stage high-pass filter, both to effect capacitive coupling and to attenuate the strong signal of the regular channel. A total signal amplitude, between 80mV and 300mV, is required at the input. Its source should have an impedance of less than 10,000 ohms.

The Phase Locked Loop is tuned to 67kHz with a 5000 ohm potentiometer; only approximate tuning is required, since the loop will seek the signal.

The demodulated output (pin 7) passes through a three-stage low-pass filter to provide de-emphasis and attenuate the high-frequency noise which often accompanies SCA transmission. Note that no capacitor is provided directly at pin 7; thus, the circuit is operating as a first-order loop. The demodulated output signal is in the order of 50mV and the frequency response extends to 7kHz.

NE/SE566-F,N,H

DESCRIPTION

The NE/SE 566 Function Generator is a voltage controlled oscillator of exceptional linearity with buffered square wave and triangle wave outputs.The frequency of oscillation is determined by an external resistor and capacitor and the voltage applied to the control terminal. The oscillator can be programmed over a ten to one frequency range by proper selection of an external resistance and modulated over a ten to one range by the control voltage, with exceptional linearity.

FEATURES

- **Wide range of operating voltage (up to 24 volts)**
- **High linearity of modulation**
- **Highly stable center frequency (200 ppm/°C typical)**
- **Highly linear triangle wave output**
- **Frequency programming by means of a resistor or capacitor, voltage or current**
- **Frequency adjustable over 10 to 1 range with same capacitor**

APPLICATIONS

- **Tone generators**
- **Frequency shift keying**
- **FM modulators**
- **Clock generators**
- **Signal generators**
- **Function generators**

OPERATING INSTRUCTIONS

The SE/NE 566 Function Generator is a general purpose voltage controlled oscillator designed for highly linear frequency modulation. The circuit provides simultaneous square wave and triangle wave outputs at frequencies up to 1MHz. A typical connection diagram is shown in Figure 1. The control terminal (pin 5) must be biased externally with a voltage (V_C) in the range

$$3/4\ V^+ \leq V_C \leq V^+$$

where V_{CC} is the total supply voltage. In Figure 1, the control voltage is set by the voltage divider formed with R_2 and R_3. The modulating signal is then ac coupled with the capacitor C_2. The modulating signal can be direct coupled as well, if the appropriate dc bias voltage is applied to the control terminal. The frequency is given approximately by

$$f_o \simeq \frac{2[(V^+) - (V_C)]}{R_1 C_1 V^+}$$

and R_1 should be in the range $2k\Omega < R_1 < 20k\Omega$.

A small capacitor (typically $0.001\mu f$) should be connected between pins 5 and 6 to eliminate possible oscillation in the control current source.

If the VCO is to be used to drive standard logic circuitry, it may be desirable to use a dual supply of ±5 volts as shown in Figure 2. In this case the square wave output has the proper dc levels for logic circuitry. RTL can be driven directly from pin 3. For DTL or T²L gates, which require a current sink of more than 1mA, it is usually necessary to connect a 5kΩ resistor between pin 3 and negative supply. This increases the current sinking capability to 2mA. The third type of interface shown uses a saturated transistor between the 566 and the logic circuitry. This scheme is used primarily for T²L circuitry which requires a fast fall time (<50ns) and a large current sinking capability.

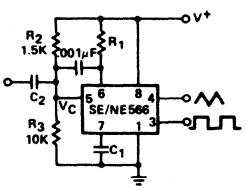

FIGURE 1

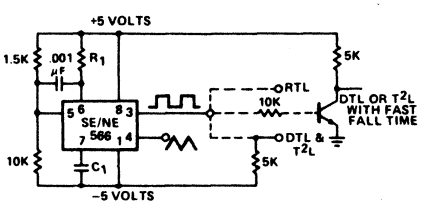

FIGURE 2

NE/SE567-F,N,H

DESCRIPTION

The SE/NE567 tone and frequency decoder is a highly stable phase-locked loop with synchronous AM lock detection and power output circuitry. Its primary function is to drive a load whenever a sustained frequency within its detection band is present at the self-biased input. The bandwidth center frequency, and output delay are independently determined by means of four external components.

FEATURES

- **Wide frequency range (.01Hz to 500kHz)**
- **High stability of center frequency**
- **Independently controllable bandwidth (up to 14 percent)**
- **High out-band signal and noise rejection**
- **Logic-compatible output with 100mA current sinking capability**
- **Inherent immunity to false signals**
- **Frequency adjustment over a 20 to 1 range with an external resistor**
- **Military processing available**

APPLICATIONS

- **Touch Tone® decoding**
- **Carrier current remote controls**
- **Ultrasonic controls (remote TV, etc.)**
- **Communications paging**
- **Frequency monitoring and control**
- **Wireless intercom**
- **Precision oscillator**

DESIGN FORMULAS

$$f_0 \simeq \frac{1.1}{R_1 C_1}$$

$$BW \simeq 1070\sqrt{\frac{V_i}{f_0 C_2}} \text{ in \% of } f_0,\ V_i \leq 200\text{mVrms}$$

Where

V_i = Input Voltage (Vrms)
C_2 = Low-Pass Filter Capacitor (μF)

PHASE LOCKED LOOP TERMINOLOGY CENTER FREQUENCY (fo)

The free-running frequency of the current controlled oscillator (CCO) in the absence of an input signal.

Detection Bandwidth (BW)

The frequency range, centered about f_o, within which an input signal above the threshold voltage (typically 20mVrms) will cause a logical zero state on the output. The detection bandwidth corresponds to the loop capture range.

Lock Range

The largest frequency range within which an input signal above the threshold voltage will hold a logical zero state on the output.

Detection Band Skew

A measure of how well the detection band is centered about the center frequency, f_0. The skew is defined as $(f_{max} + f_{min} - 2f_o)/2f_o$ where fmax and fmin are the frequencies corresponding to the edges of the detection band. The skew can be reduced to zero if necessary by means of an optional centering adjustment.

OPERATING INSTRUCTIONS

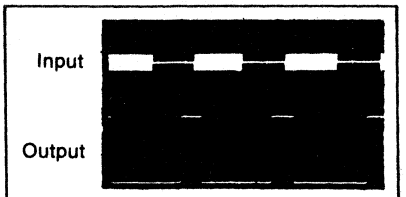
Figure 1 shows a typical connection diagram for the 567. For most applications, the following three-step procedure will be sufficient for choosing the external components R_1, C_1, C_2 and C_3.

1. Select R_1 and C_1 for the desired center frequency. For best temperature stability, R_1 should be between 2K and 20K ohm, and the combined temperature coefficient of the R_1C_1 product should have sufficient stability over the projected temperature range to meet the necessary requirements.

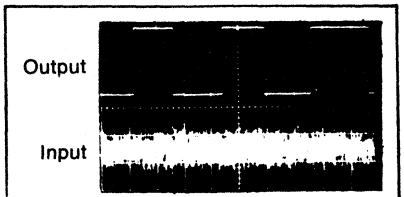
2. Select the low pass capacitor, C_2, by referring to the Bandwidth versus Input Signal Amplitude graph. If the input amplitude variation is known, the appropriate value of f_oC_2 necessary to give the desired bandwidth may be found. Conversely, an area of operation may be selected on this graph and the input level and C_2 may be adjusted accordingly. For example, constant bandwidth operation requires that input amplitude be above 200mVrms. The bandwidth, as noted on the graph, is then controlled solely by the f_oC_2 product (f_o (Hz), C_2 (μfd)).

3. The value of C_3 is generally non-critical. C_3 sets the band edge of a low pass filter which attenuates frequencies outside the detection band to elminate spurious outputs. If C_3 is too small, frequencies just outside the detection band will switch the output stage on and off at the beat frequency, or the output may pulse on and off during the turn-on transient. If C_3 is too large, turn-on and turn-off of the output stage will be delayed until the voltage on C_3 passes the threshold voltage. (Such delay may be desirable to avoid spurious outputs due to translent frequencies.) A typical minimum value for C_3 is $2C_2$.

TYPICAL RESPONSE



Response to 100mVrms tone burst.
R_L = 100 ohms.



Response to same input tone burst with wideband noise.
$\frac{S}{N}$ = -6db R_L = 100 ohms
Noise Bandwidth = 140Hz

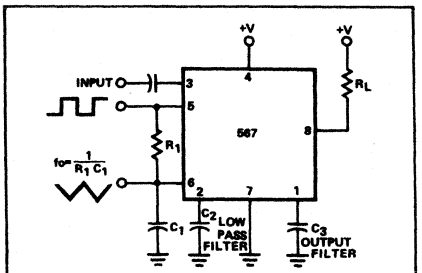


Figure 1

AVAILABLE OUTPUTS (Figure 2)

The primary output is the uncommitted output transistor collector, pin 8. When an in-band input signal is present, this transistor saturates; its collector voltage being less than 1.0 volt (typically 0.6V) at full output current (100mA). The voltage at pin 2 is the phase detector output which is a linear function of frequency over the range of 0.95 to 1.05 f_o with a slope of about 20mV per percent of frequency deviation. The average voltage at pin 1 is, during lock, a function of the inband input amplitude in accordance with the transfer characteristic given. Pin 5 is the controlled oscillator square wave output of magnitude $(+V - 2V_{be}) \approx (+V - 1.4V)$ having a dc average of +V/2. A 1kΩ load may be driven from pin 5. Pin 6 is an exponential triangle of 1 volt peak-to-peak with an average dc level of +V/2. Only high impedance loads may be connected to pin 6 without affecting the CCO duty cycle or temperature stability.

OPERATING PRECAUTIONS

A brief review of the following precautions will help the user achieve the high level of performance of which the 567 is capable.

1. Operation in the high input level mode (above 200mV) will free the user from bandwidth variations due to changes in the in-band signal amplitude. The input stage is now limiting, however, so that out-band signals or high noise levels can cause an apparent bandwidth reduction as the in-band signal is suppressed. Also, the limiting action will create in-band components from sub-harmonic signals, so the 567 becomes sensitive to signals at $f_o/3$, $f_o/5$, etc.

2. The 567 will lock onto signals near $(2n + 1)\ f_o$, and will give an output for signals near $(4n + 1)\ f_o$ where $n = 0, 1, 2$, etc. Thus, signals at $5f_o$ and $9f_o$ can cause an unwanted output. If such signals are anticipated, they should be attenuated before reaching the 567 input.

3. Maximum immunity from noise and out-band signals is afforded in the low input level (below 200mVrms) and reduced bandwidth operating mode. However, decreased loop damping causes the worse-case lock-up time to increase, as shown by the Greatest Number of Cycles Before Output vs Bandwidth graph.

4. Due to the high switching speeds (20ns) associated with 567 operation, care should be taken in lead routing. Lead lengths should be kept to a minimum. The power supply should be adequately bypassed close to the 567 with a 0.01μF or greater capacitor; grounding paths should be carefully chosen to avoid ground loops and

14

unwanted voltage variations. Another factor which must be considered is the effect of load energization on the power supply. For example, an incandescent lamp typically draws 10 times rated current at turn-on. This can cause supply voltage fluctuations which could, for example, shift the detection band of narrow-band systems sufficiently to cause momentary loss of lock. The result is a low-frequency oscillation into and out of lock. Such effects can be prevented by supplying heavy load currents from a separate supply or increasing the supply filter capacitor.

SPEED OF OPERATION

Minimum lock-up time is related to the natural frequency of the loop. The lower it is, the longer becomes the turn-on transient. Thus, maximum operating speed is obtained when C_2 is at a minimum. When the signal is first applied, the phase may be such as to initially drive the controlled oscillator away form the incoming frequency rather than toward it. Under this condition, which is of course unpredictable, the lock-up transient is at its worst and the theoretical minimum lock-up time is not achievable. We must simply wait for the transient to die out.

The following expressions give the values of C_2 and C_3 which allow highest operating speeds for various band center frequencies. The minimum rate at which digital information may be detected without information loss due to the turn-on transient or output chatter is about 10 cycles per bit, corresponding to an information transfer rate of $f_o/10$ baud.

$$C_2 = \frac{130}{f_o}\ \mu F$$

$$C_3 = \frac{260}{f_o}\ \mu F$$

In cases where turn-off time can be sacrificed to achieve fast turn-on, the optional sensitivity adjustment circuit can be used to move the quiescent C_3 voltage lower (closer to the threshold voltage). However, sensitivity to beat frequencies, noise and extraneous signals will be increased.

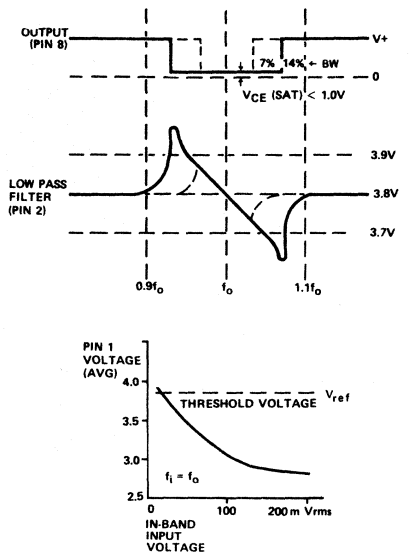

Figure 2

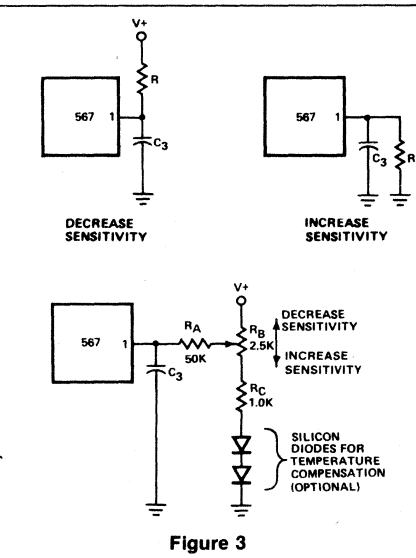

Figure 3

OPTIONAL CONTROLS (Figure 3)

The 567 has been designed so that, for most applications, no external adjustments are required. Certain applications, however, will be greatly facilitated if full advantage is taken of the added control possibilities available through the use of additional external components. In the diagrams given, typical values are suggested where applicable. For best results the resistors used, except where noted, should have the same temperature coefficient. Ideally, silicon diodes would be low-resistivity types, such as forward-biased transistor base-emmiter junctions. However, ordinary low-voltage diodes should be adequate for most applications.

SENSITIVITY ADJUSTMENT

(Figure 3)

When operated as a very narrow band detector (less than 8 percent), both C_2 and C_3 are made quite large in order to improve noise and outband signal rejection. This will inevitably slow the response time. If, however, the output stage is biased closer to the threshold level, the turn-on time can be improved. This is accomplished by drawing additional current to terminal 1. Under this condition, the 567 will also give an output for lower-level signals (10mV or lower).

By adding current to terminal 1, the output stage is biased further away from the threshold voltage. This is most useful when, to obtain maximum operating speed, C_2 and C_3 are made very small. Normally, frequencies just outside the detection band could cause false outputs under this condition. By desensitizing the output stage, the outband beat notes do not feed through to the output stage. Since the input level must be somewhat greater when the output stage is made less sensitive, rejection of third harmonics or in-band harmonics (of lower frequency signals) is also improved.

CHATTER PREVENTION (Figure 4)

Chatter occurs in the output stage when C_3 is relatively small, so that the lock transient and the AC components at the quadrature phase detector (lock detector) output cause the output stage to move through its threshold more than once. Many loads, for example lamps and relays, will not respond to the chatter. However, logic may recognize the chatter as a series of outputs. By feeding the output stage output back to its input (pin 1) the chatter can be eliminated. Three schemes for doing this are given in Figure 4. All operate by feeding the first output step (either on or off) back to the input, pushing the input past the threshold until the transient conditions are over. It is only necessary to assure that the feedback time constant is not so large as to prevent operation at the highest anticipated speed. Although chatter can always be eliminated by making C_3 large, the feedback circuit will enable faster operation of the 567 by allowing C_3 to be kept small. Note that if the feedback time constant is made quite large, a short burst at the input frequency can be stretched into a long output pulse. This may be useful to drive, for example, stepping relays.

DETECTION BAND CENTERING (OR SKEW) ADJUSTMENT

(Figure 5)

When it is desired to alter the location of the detection band (corresponding to the loop capture range) within the lock range, the

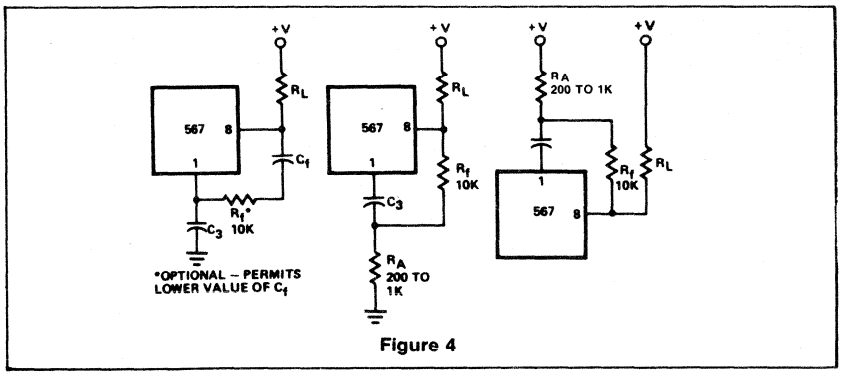

Figure 4

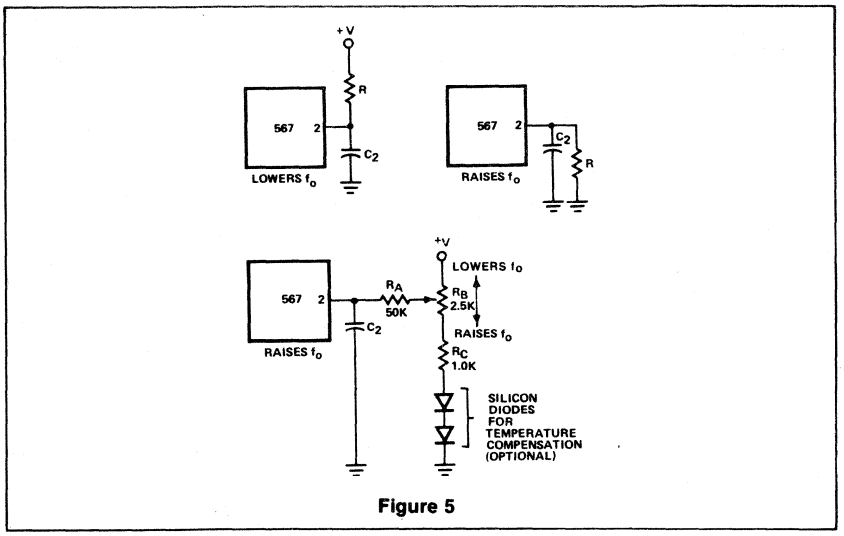

Figure 5

circuits shown above can be used. By moving the detection band to one edge of the range, for example, input signal variations will expand the detection band in only one direction. This may prove useful when a strong but undesirable signal is expected on one side or the other of the center frequency. Since R_B also alters the duty cycle slightly, this method may be used to obtain a precise duty cycle when the 567 is used as an oscillator.

ALTERNATE METHOD OF BANDWIDTH REDUCTION

(Figure 6)

Although a large value of C_2 will reduce the bandwidth, it also reduces the loop damping so as to slow the circuit response time. This may be undesirable. Bandwidth can be reduced by reducing the loop gain. This scheme will improve damping and permit faster operation under narrow-band conditions. Note that the reduced impedance level at terminal 2 will require that a larger value of C_2 be used for a given filter cutoff frequency. If more than three 567s are to be used, the network of R_B and R_C can be eliminated and the R_A resistors connected together. A capacitor between this junction and ground may be required to shunt high frequency components.

OUTPUT LATCHING (Figure 7)

To latch the output on after a signal is received, it is necessary to provide a feedback resistor around the output stage (between pins 8 and 1). Pin 1 is pulled up to unlatch the output stage.

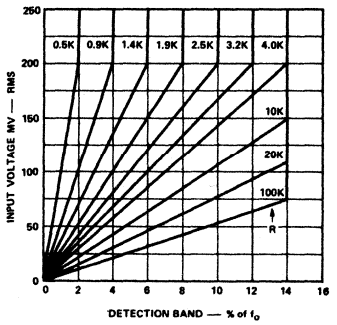
REDUCTION OF C1 VALUE

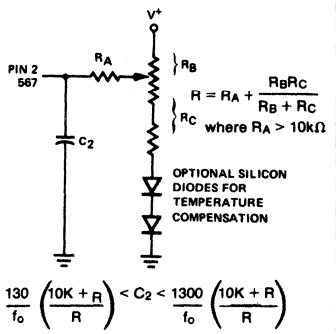
(Figure 8)

For precision very low-frequency applications, where the value of C_1 becomes large, an overall cost savings may be achieved by inserting a voltage follower between the R_1 C_1 junction and pin 6, so as to allow a higher value of R_1 and a lower value of C_1 for a given frequency.

PROGRAMMING

To change the center frequency, the value of R_1 can be changed with a mechanical or solid state switch, or additional C_1 capacitors may be added by grounding them through saturating npn transistors.





$$\frac{130}{f_o}\left(\frac{10K + R}{R}\right) < C_2 < \frac{1300}{f_o}\left(\frac{10K + R}{R}\right)$$

NOTE

SECTION 15
D-MOS FETS

Section 15—D-MOS

DESCRIPTION

The Signetics D-MOS SD210, 211, 212, 213, 214 and 215 are silicon, insulated gate, field effect transistors of the N-channel enhancement mode type. They are fabricated by the Signetics double-diffused process which gives high switching speed and low capacitance. A zener diode is connected between the gate and substrate of the SD211, 213 and 215. The diode bypasses any voltage transients which lie outside the range of -0.3V to +30V. Thus, the gate is protected against damage in all normal handling and operating situations. A drain-to-source breakdown of typically 35V makes the SD210 and 211 ideally suited for ±10V switch driver applications. Other characteristics allow them to be used as ±5V switches. The SD214 and 215 are designed to switch signals up to ±10V and the SD212 and 213 are designed to switch signals up to ±5V.

All the devices feature low gate node capacitance, extremely low drain node capacitance and very low feedback capacitance. Low "ON" resistance and hermetically sealed 4-lead TO-72 packages are also featured.

FEATURES

- **Low feedback capacitance: 0.30pF**
- **Low drain node capacitance: 1.3pF**
- **Low gate node capacitance: 2.4pF**
- **Low feedthrough and feedback transients**
- **Ion-implanted for greater reliability**
- **Excellent isolation from input to output: -120dB**
- **35V drain-to-source voltage for SD210/211**
- **Military qualifications pending**

APPLICATIONS

- **Switch driver**
- **Analog switch**
- **Multiplexers**
- **Digital switch**
- **Sample and hold**
- **Choppers**
- **A-TO-D converters**
- **D-TO-A converters**

SD300/303-EC
SD304-EE

DESCRIPTION

The Signetics D-MOS SD300/303/304 are silicon, dual-insulated-gate, field effect transistor of the N-channel enhancement mode type. It is fabricated by the Signetics double-diffused process which gives superior high frequency performance. Zener diodes are connected between the two gates and the substrate. These diodes bypass any voltage transients which lie outside the range of −0.3V to +25.0V. Thus, the gates are protected against damage in all normal handling and operating situations.

The device characteristics make it ideally suited for a variety of high frequency amplifier and mixer applications. The presence of two gates plus the incorporation of the drift region in the structure has made the feedback capacity (Crss) low. A wide AGC capability plus a significant reduction in cross-modulation distortion is now available because of the inherent linearity of these devices. The SD300/303/304 are hermetically sealed in a modified 4-lead TO-72 package.

GENERAL FEATURES

- **Lower cross-modulation and wider dynamic range than bipolar or single gate FETs**
- **Reverse AGC capability**
- **Linear mixing capability**
- **Diode protected gates**
- **High forward transconductance: 10mmhos**
- **ION-implanted**
- **Positive bias only**

SD305/306-EE

DESCRIPTION

The Signetics D-MOS SD305 and 306 are silicon, dual-insulated gate, field-effect transistors of the N-channel enhancement mode type. Zener diodes are connected between the two gates and the substrate. These diodes bypass any voltage transients which lie outside the range of -0.3V to +20.0V. Thus, the gates are protected against damage in all normal handling and operating situations. The characteristics of the devices make them ideally suited for a variety of VHF amplifier and mixer applications. The presence of two gates plus the incorporation of the drift region in the structure has made the feedback capacity (C_{G1D}) typically less than 0.03pF. A wide AGC capability plus significant reduction in cross modulation distortion is now available because of the inherent linearity of the devices. The SD305 and SD306 are hermetically sealed in a 4-lead TO-72 package.

GENERAL FEATURES

- **Positive bias only**
- **Low gate voltages**
- **Enhancement mode operation**
- **Wide AGC range: -50dB at 200MHz**
- **Zener diode gate protection**
- **ION implanted for greater reliability**

FEATURES—SD305 (VHF TV and FM Mixer)

- **High conversion gain: 17dB at 200MHz with $V_{G1S} = V_{G2S}$ for biasing simplicity**
- **Excellent isolation from Gate No. 1 (RF) to Gate No. 2 (LO): -20dB at 200MHz**
- **Low input capacitance: 4.0pF**
- **Low feedback capacitance: 0.03pF**
- **Excellent cross modulation performance and low noise operation**
- **High transconductance: 27mmhos**

FEATURES—SD306 (VHF TV and FM RF Amplifier)

- **High power gain without neutralization: 20dB at 200MHz**
- **Low noise figure: 1.5dB at 200MHz**
- **Low input and output capacitance: 3.3pF and 1.0pF constant with AGC**
- **Low feedback capacitance: 0.03pF**
- **Superior cross modulation performance**
- **High transconductance: 15mmhos**

TEST PROCEDURE FOR CROSS MODULATION DISTORTION MEASUREMENTS

1. Modulation on Generator #2 is set at 100kHz, 30% AM modulation (sidebands down 15.6dB) with an output signal frequency equal to 196MHz.
2. Generator #2 is set at approximately -15dbm, 200MHz.
3. While observing the test circuit output spectrum, adjust the signal level of the interfering frequency so that the sidebands on the desired frequency are 46dB down from the carrier. This corresponds to 1% cross modulation.
4. Turn off Generator #1 and turn off the modulation on Generator #2.
5. Using the RF voltmeter, measure the amplitude of the interfering signal at the test point.

DESCRIPTION

The Signetics D-MOS SD5000 series are monolithic arrays of silicon, insulated-gate, field-effect transistors using the N-channel enhancement mode technology.

This family of devices is designed to handle a wide variety of analog switching and driver applications. They are capable of high speed operation where excellent transient response, and wide voltage range are required. The SD5000 quad switch array quad multiplexer can handle high voltage analog signals (±10V). The SD5002 is designed for ±7.5V analog signals using ±15V power supplies. The SD5001 is designed for lower voltage applications.

FEATURES

- **Low input capacitance: 2.4pF**
- **Low feedback capacitance: 0.3pF**
- **Low output capacitance: 1.3pF**
- **±10V analog signal range**
- **Low propagation delay time: 600ps**
- **Low on resistance: 30Ω**
- **Low feedthrough and feedback transients**
- **Ion implanted for greater reliability**
- **High channel-to-channel isolation: 107dB**
- **Transient protection for gates**
- **Military qualifications pending**

APPLICATIONS

- **SD5000 applications**
  - **Analog switching (up to very high frequencies)**
  - **Audio routing**
  - **Choppers**
  - **Crosspoint switches**
  - **Sample and hold**

THEORY OF OPERATION

The SD5000 series consists of four SPST switches with analog signal capability of up to ±10 volts for the SD5000 and ±7.5 volts for the SD5002. Each switch of the array is a D-MOS N-channel field-effect transistor of the enhancement-mode type; that is, the device is normally off when gate-to-source voltage (V_{GS}) is zero volts. When V_{GS} exceeds the threshold voltage, V_T, the FET switch starts to turn ON with V_{GS} in excess of +10 volts, a low resistance path (typically 30Ω) exists between input and output of the switch. Figure 1 shows the normal mode of operation of a single switch of the array for ±5 volt analog signal processing. Note that the source is recommended for the input since feedback or reverse transfer capacitance is lower when drain is used as the output. When analog signals are routed from one point to another the important factors are **isolation, crosstalk between switches, feedthrough and feedback transients, insertion loss and speed of operation.** The SD5000 series offers superior performance in all these areas (Figure 1).

Isolation. ON resistance is typically 30Ω and OFF resistance is typically 10^{10}Ω, which results in an OFF to ON resistance ratio in excess of 10^9. Isolation from output to input from 3kHz analog signals is typically -107dB.

Feedback and feedthrough transients. These are kept to a minimum because of the very low feedback and feedthrough capacitances. This means that "glitchless" or "clean" signals appear at the output.

Insertion loss. This depends upon the source and load impedances involved. As an example, for 600Ω source impedance the insertion loss for voice signals (1V RMS at 3kHz) is less than 0.3dB. This indicates that the SD5000 series would make good telephone cross-point switches.

Speed. Because of the low ON resistance and low input capacitance, the SD5000 switches turn ON at sub-nanosecond speeds. They are also capable of handling very high frequency analog signals and still maintain excellent isolation (20-30dB at 1GHz).

SECTION 16
INDUSTRIAL CONTROLLERS

Section 16—INDUSTRIAL CONTROLLERS

NE5522-N

DESCRIPTION

The Signetics NE5522 may be used in a wide range of industrial applications where closed loop control of machine speed and acceleration is required. Uses such as conveyer systems, web infeed for plastic film or paper sheet, wire reel take-up and many other process motion control areas, which involve the predetermined ramp up and final speed setting under closed-loop control, can be handled by the Universal Controller.

Inputs to the device are descrete voltage level commands which tell the controller what function is desired such as "Set Memory", 'Memory Erase', 'Positive Ramp', 'Compare to Memory', etc. The closed loop control function is accomplished by an A-C tachometer frequency representative of the speed of the system being fed into the NE5522 where it is compared with an internal reference voltage after being processed by the F/V converter. An error signal is then generated which governs the corrective response of the output. The output function consists of three buffered open collector transistor ports which provide gating and on-off commands to peripheral circuitry. An analog error output is also available for interface with linear control systems.

Basically the NE5522 consists of a frequency to voltage converter, an internal reference oscillator, D to A converter, an I^2L logic encoder-decoder and 256 bit F/V D.C. level data storage.

The nominal supply voltage is +8.2V with a range of 7.4 to 9 volts allowed. Current drain is nominally 20mA for an 8.2V supply.

A typical operation sequence might be to bring a motor up to speed using the program accel mode. This would be accomplished by setting pin 3 (Command Input) to $\simeq .55V_{CC}$. A ramp function determined by R20-C11 (pins 14, 15) then automatically programs the error system to drive up at a fixed rate. Once the desired speed is reached a voltage of $.75V_{CC}$ is momentarily impressed on the command input and the motor speed will then be controlled to stay at that level previously programmed in memory. Note that a voltage level of $1.1V_{CC}$ must be applied momentarily to the command input (pin 3) upon initial turn-on in order to enable the device.

FEATURES

- Adjustable system gain
- Adjustable frequency sensitivity
- Adjustable ramp rate
- Voltage programmable command modes
  1. On
  2. Positive ramp and hold
  3. Compare to set memory
  4. Memory erase
  5. Set memory
  6. Off

APPLICATIONS

- Conveyer Controller
- Web infeed controller
- AC or dc motor speed control
- Actuator control loop
- Engine speed control
- Process control
- Magnetics tape transport control
- Mag/floppy disc controller

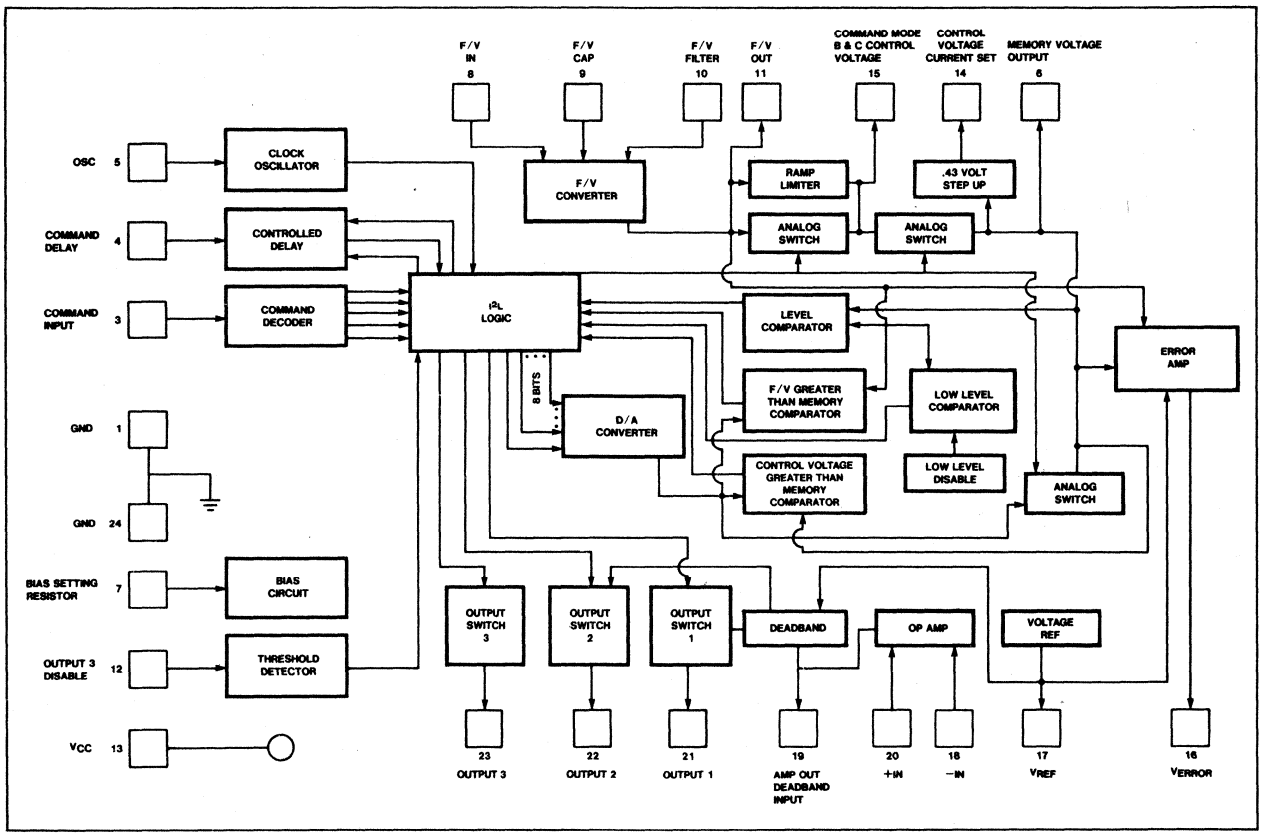
BLOCK DIAGRAM



FUNCTIONAL DESCRIPTION

(1) Input Power (V_{CC})—A regulated power source of 8.2 volts ± 10% must be applied between pin 13 and ground. Pins 1 and 24 are the IC ground pins. Pin 2 should be connected to ground also. Standby current drain is typically 20mA. A resistor of 43kΩ ± 5% must be connected between pin 7 and ground to establish the internal current sources.

(2) Frequency-to-Voltage Converter—The F/V input signal for this device is applied to pin 8. It may be in the form of any periodic wave with approximately 50% duty cycle at the zero crossings. Peak amplitudes greater than ±2 volts should be current limited by a resistor in series with pin 8. Maximum currents should not exceed 1mA. This input is internally amplified and limited at the zero crossings (refer to typical test circuit).

A capacitor, C_6, must be applied from pin 9 to ground. A capacitor, C_7, and resistor, R_{18}, must be applied in parallel between pin 10 and ground. A voltage will then appear on pin 11 with a d-c level, V_s, proportional to the input frequency, and a sawtooth ripple frequency equal to twice the input frequency, f_s. V_s and the peak-to-peak ripple amplitude, V_r, are given approximately by the following equations:

$$V_s = (4 \text{ volts})\,(R_{18})\,(C_6)\,(f_s)$$

$$V_r = (2 \text{ volts})\left(\frac{C_6}{C_7}\right)1 - \left[(80k\Omega)\,C_6\,f_s\right]$$

The maximum linear value of V_s is typically (V_{CC} − 1.0 volt). The maximum input frequency for linear output is given by:

$$f_{s\,max} = \frac{1}{(80k\Omega)C_6},$$

assuming symmetrical zero crossings in the input wave. A resistor of no less than 10kΩ from pin 11 to ground is allowable to maintain bias on the NPN emitter follower output stage.

The pin 11 voltage is applied internally to the positive input of the servo error amp.

(3) Input Command Signal (V_C)—The analog voltage applied to pin 3, V_C, determines the operating mode. This input signal should be current limited and well filtered to avoid noise pulses triggering spurious operating conditions.

a) Turn-on:—When power is first applied the part normally comes up in the Off state. If V_C is raised above V_{CC} so that the input current exceeds 100μa (in the current limited mode), the internal logic circuitry will go into the standby mode and be ready to receive other input commands.

b) Standby—To maintain the part in the standby or control mode, V_C should be maintained in the voltage range for mode A as indicated in the table.

c) Positive Ramp, Set—The voltage that appears on pin 6, V_m, is the internally generated servo drive voltage. This voltage is internally connected to the negative input of the servo error amp.

When V_C is in mode C as indicated in the table, the voltage V_m will increase at a rate given by (0.43 volts)/R_8C_1, where R_8 is the resistor between pins 14 and 15, and C_1 is the capacitor between pin 15 and ground. The capacitor must have a leakage at 8 volts of much less than 0.43v/R_8 under all

conditions to minimize the variability of this rate. Rates as low as 50mv/sec are practical.

When V_C is restored from mode C to mode A, the value of the pin 11 voltage, V_s, is stored in the internal memory, and this voltage then appears on pin 6 as the servo drive voltage, V_m.

The mechanism by which the value of V_s is stored is as follows. A digital counter whose output is applied to a DAC is turned on. When the DAC output reaches the level of V_s, the counter is stopped, and the DAC output appears on pin 6. The frequency that the counter counts is generated by an internal oscillator connected to a capacitor on pin 5. The oscillator frequency is inversely proportional to capacitor size, and .001μf produces about 75 kHz. This frequency determines the time that it takes for the DAC output to reach the V_s level and set. Since the maximum count is 256, a frequency of 75kHz (period = 13.3μs) provides a maximum set time of 3.4ms. Frequencies higher than 100kHz are not recommended.

d) Disable, Return to Memory—For normal servo and logic operation the voltage on the Disable input, pin 12, must be less than $V_{CC}/2$. If this voltage is raised above $V_{CC}/2$, the device reverts to the standby mode, except that the internal memory voltage, V_m, remains set at its current level. If the input command voltage, V_C, is then reduced momentarily to mode B, as given in the table, the servo drive voltage, V_m, on pin 6 will start at the current value of V_s and increase at the positive ramp rate described earlier until it reaches the level stored in memory. It will then remain at this value. A Disable-Return sequence when V_s is greater than the memory level will restore V_m to the memory level.

e) Memory Erase, Set—If the value of V_C is reduced to mode D given in the table, the part will revert to the standby mode and memory is erased. If V_C then returns to mode A, the memory and the servo drive voltage, V_m, will be set at the current value of V_s in the same manner as described earlier for the Positive Ramp, Set function.

f) Off—If the value of V_C is reduced to the Off level as given in the table, the device reverts to the inactive state until turned on again as described earlier.

g) Low Level Lockout—The device will revert to the standby condition whenever the value of the F/V output voltage, V_s, drops below the LLLO voltage, which is approximately 1.5 volts. However, the internal memory voltage is maintained. A Disable-Return sequence after V_s again rises above the LLLO voltage, will return the voltage V_m to the memory level in the manner described earlier.

h) Command-Delay—When the command voltage, V_C, changes from the standby level as described above, the logic will not see the change for a period of time given in all but one case by the following equation:

$$t_d = \frac{V_{CC}\, C_3}{(182\mu a)},$$

where C_3 is a capacitor that must be inserted between pin 4 and ground. C_3 = .68μf produces a delay of t_d = 30ms with nominal V_{CC}. The exception to this formula is the delay for the Return to Memory function. This delay is given by:

$$t_{dr} = \frac{V_{CC}\, C_3}{27\ \mu a},$$

so that a typical delay with C_3 = .68μf is 200ms. These delays are designed to eliminate switch bounce problems, as well as other noise that might appear on the input command signal. In a relatively noise free environment, C_3 may be small, reducing the delay times.

(4) Error Amplifier—This amplifier has a gain of aproximately unity. The differential inputs are connected as described above, so that the output, which appears on pin 16, is approximately $V_s - V_m$. The current drawn from pin 16 should be less than ±50μa. The maximum linear voltage swing is about ±0.5 volts. The output is referenced to a level roughly equal $V_{CC}/2$, which is typically equal to the reference level on pin 17. Output currents from pin 17 should also be limited to ±50μa maximum.

(5) Operational Amplifier—The non-inverting input of this amplifier is pin 20, the inverting input is pin 18, and the output is pin 19. The output is internally connected to the input of the deadband circuit. The output impedance at pin 19 is high, typically 600K, so that for loads on pin 19 of 100K or less, this becomes a transconductance amplifier. The amplifier input impedance is greater than one megohm, and the input bias current is typically less than 1μa. Low frequency open circuit output gain is typically 150, with a bandwidth of about 10kHz.

(6) Deadband Circuit—The input of this circuit comes from the Op Amp output, as described above. It is a differential amplifier with the second input internally connected to a voltage approximately equal to $V_{CC}/2$. The input on pin 19 can be forced to any desired level between zero and V_{CC} by external circuitry, if desired, without damaging the part. The maximum drive current required to do this is typcially ±100μa.

The circuit deadband is typically ±0.6 volts relative to $V_{CC}/2$. The circuit outputs appear on pins 21 and 22. These outputs are activated by the logic circuitry when it is in one of the control modes. If the pin 19 voltage is above the upper deadband level in the active mode, both outputs will be high. If the pin 19 voltage is between the two deadband levels, pin 21 will be high, and pin 22 low. If the pin 19 voltage is below the lower deadband voltage, both outputs will be low.

When deactivated by the logic, both outputs are low. The signal output on pin 23 indicates the logic state and is low when the pin 21 and 22 outputs are active. The pin 21, 22, and 23 outputs are essentially open collector outputs for voltages below 5 volts, with a current sinking capability typically better than 20ma.

(7) Motor Speed Control—In a typical speed control application an a-c tach signal is fed to the F/V input, pin 8, producing a d-c tach signal on pin 11 (V_s). This is compared to the servo drive voltage, V_m, on pin 6 in the error amplifier. The servo loop gain is established using the op amp with the negative input, pin 18, connected thru a suitable resistor (typically greater than 10kΩ) to the error amp output, pin 16. A feedback resistor between pins 19 and 18 sets the op amp gain. An acceleration feedback signal from the servo is also applied thru a suitable impedance to the negative input, pin 18. The sawtooth ripple from the F/V is amplified by the op amp sufficiently so that it sweeps thru one or both of the deadband circuit thresholds, producing pulse width modulated outputs on pin 21 and 22, the pulse widths increasing as the d-c level at pin 19 increases. The frequency of the pulse width modulation is, of course, the frequency of the ripple, which is twice the input tach frequency.

The pin 21 and 22 outputs are typically applied to some type of "bang-bang" type servo control in such a way that acceleration occurs when both outputs are high and deceleration occurs when both outputs are low.

DC MOTOR SPEED CONTROL APPLICATION

This circuit was developed to independently control the speed of two or more model trains running on the same pair of tracks. Each train is equipped with a receiver tuned to a different carrier frequency. The carrier frequency is modulated at the transmitter by a variable audio frequency which carries the speed and direction information. The train which is tuned to the carrier frequency being

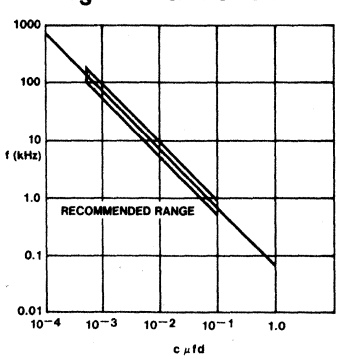
NOTE
Observe max. dissipation

CLOCK OSCILLATOR FREQUENCY VS PIN 5 CAPACITOR



transmitted will receive this signal and provide an enable command to the receiver circuit. The modulating audio frequency signal is demodulated and decoded. Train speed (motor voltage) adjusts to the decoded information. When the carrier frequency is removed the receiver stores the last decoded signal and the train (motor) maintains the set speed until it is again addressed using its carrier frequency and the speed can be adjusted.

THEORY OF OPERATION

(A) Transmitter—The transmitter's carrier frequency was selected to be in the 100 to 500kHz range and the modulating frequency in the 1 to 4kHz range. A simple oscillator/modulator was built using an NE556N dual timer.

The two required frequencies are generated by connecting each timer in the astable

mode. These circuits generated square waves whose frequency is adjusted by changing the variable resistors (figure 2) R_A and R_B respectively. The oscillation frequency is approximately equal to 0.72 divided by the RC product of the charging and discharging path. For the low frequency oscillator: fm = .72/(5K + R_A)(.02μ) and for the high frequency oscillator: fc = .72/(3K + R_B)(500p). This gives a carrier frequency which can be adjusted between 110 and 480kHz. Each carrier frequency is adjusted to its receiver frequency which is set by a fixed resistor. This was done to eliminate any adjustments at the receiver. The low frequency is variable between 1 and 3kHz. Modulation of the high frequency by the low is accomplished by connecting the low frequency output to the control voltage input of the high frequency oscillator thru a resistor whose value sets the amount of modulation.

The modulated signal is connected to the train track thru an isolation transformer. A variable resistor Rc is connected in series with the output to adjust the output signal.

(B) Receiver—The receiver is broken down into 5 sections for easier analysis (see figure 1);
(1) Receiver/Demodulator
(2) Frequency Converter/Memory
(3) Decoder
(4) Motor Driver
(5) Power Circuits

(1) Receiver/Demodulator (R/D)—An NE567N Phase Locked Loop is used to perform this function. The lock frequency is set by the resistor R whose value is 1.1 X 10^9 divided by the desired carrier frequency. Two signals from the R/D circuit are used to drive the next circuit block; a logic low level on pin 8 when the tuned carrier frequency is detected and the demodulated low frequency appearing on pin 1.

(2) Frequency Converter/Memory—An NE5522N Universal Analog Controller (UAC) is used for this function. The low frequency signal from the R/D circuit is amplified and applied to the f to V converter of the UAC. A d.c. voltage proportional to the input frequency is generated. The conversion factor is set by the capacitor on pin 9 and the resistor on pin 10; its value is: $V_{dc}/f = 4 R_{10}C_9$. Thus for the circuit values shown, V_{dc}/f = 1.72mV/Hz; at 1kHz, 1.72V, at 2kHz 3.44V and 3kHz 5.16V.

When the enable signal is removed (carrier frequency turned off) the converted D.C. voltage is stored and is continuously available on pin 6 of the UAC.

(3) Decoder—An NE324N quad op amp is used to decode the d.c. level from the UAC. One amplifier is connected to give an output which is proportional to the d.c. level. Its output goes to zero at about 3.65V. Another amplifier is connected so that its output is inversely proportional to the d.c. level below 3.25 volts. A deadband is set so that both amplifier outputs are at zero between 3.25 and 3.65V. A transfer characteristic of these two amplifiers is shown in figure 3.

The remaining two amplifiers are used as comparators, each going high when the amplifier driving it goes positive. Thus when the UAC pin 6 voltage is greater than 3.65V, amplifier (4) and comparator (2) have positive output voltages and when this voltage is less than 3.25V amplifier (3) and comparator (1) have positive output voltages.

(4) Motor Driver—The motor driver consists of four NPN transistors connected in an H bridge configuration. The bases of the upper transistors are driven by the decoder amplifier output voltages which are proportional to the UAC voltage as previously described. The bases of the lower transistors are driven by the decoder comparators and are either on or off depending on the UAC voltage above the deadband, inversely proportional to the UAC voltage below the deadband, and zero in the deadband. A system transfer function is shown in figure 4.

(5) Power Circuits—The power supply for the IC's and the transistor drivers is supplied from a bridge rectifier. The transistor bridge and motor are supplied with rectified unfiltered 60Hz. A filtered, regulated 8 volt d.c. supply is used for the IC's.

MILITARY PRODUCTS/ PROCESS LEVELS

The Signetics MIL 38510/883 Program is organized to provide a broad selection of processing options, structured around the most commonly requested customer flows. The program is designed to provide our customers:

- Fully compliant 883 flows on all products.
- Standard processing flows to help minimize the need for custom specs.
- Cost savings realized by using standard processing flows in lieu of custom flows.
- Better delivery lead times by minimizing spec negotiation time, plus allows customer to buy product off-the-shelf or in various stages of production rather than waiting for devices started specifically to custom specs

The following explains the different processing options available to you. Special device marking clearly distinguishes the type of screening performed. Refer to Tables 2, 3, 4 and 5

Table 2 MILITARY SUMMARY

JAN QUALIFIED (JB)

JAN Qualified product is designed to give you the optimum in quality and reliability. The JAN processing level is offered as the result of the government's product standardization programs, and is monitored by the Defense Electronic Supply Center (DESC) through the use of industry-wide procedures and specifications.

JAN Qualified products are manufactured, processed and tested in a government certified facility to Mil-M 38510, and appropriate device slash sheet specifications. Design documentation, lot sampling plans, electrical test data and qualification data for each specific part type has been approved by the Defense Electronic Supply Center (DESC) and products appear on the DESC Qualified Products List (QPL-38510).

Group B testing, per Mil-Std-883 Method 5005, is performed on each six weeks of production on each slash sheet for each package type. Group C, per Mil-Std-883 Method 5005 is performed every ninety days for each microcircuit group. Group D testing, per Mil-Std-883 Method 5005, is performed every six months for each package type.

In addition to the common specs used throughout the industry for processing and testing, JAN Qualified products also possess a requirement for a standard marking used throughout the IC industry.

MIL-STD-883, LEVEL B

Processing to this option is ideal when no JAN slash sheets are released on devices required. Product is processed to Mil-Std-883 Method 5004, and is 100% electrically tested to industry data sheets. Devices are selectively available as custom processed parts with electricals screened to the JAN Slash Sheets.

MIL-STD-883, LEVEL C

If you need a Military temp, range device, but do not require burn in screening performed, our 883C product is ideal. 883C parts are the standard full Mil-Temperature range product to the Signetics data sheet parameters and screened to MIL-STD-883, Class C.

MILITARY GENERIC DATA

Signetics has a new program for those customers who require quality conformance data on their products. This program allows our customers to obtain reliability information without the necessity or running Groups B, C and D inspections for their particular purchase order. It provides for the customer something that has not been readily available before in the semiconductor industry in that all Military Generic Data is controlled and audited by both Government Inspection in the case of JAN data and Signetics Quality Assurance.

Signetics Military Generic Data is compiled by the Military Products Division based on data from 1) JAN quality conformance lots, and 2) Data generated by quality conformance lots run for other reliability programs. Refer to Table 4.

A Military Generic family is defined as consisting of die function and package type families.

Military Generic Data

- Allows our customers to qualify Signetics products based on existing quality conformance data performed at Signetics.
- Allows our customers to reduce costs and improve deliveries.
- Provides assurance that all Signetics die function families and packages meet Mil-M-38510 and customer reliability requirements.
- Provides an attributes summary to the customer backed by lot identity and traceability.

PACKAGES

INTRODUCTION

The following information applies to all packages unless otherwise specified on individual package outline drawings.

General

1. Dimensions shown are metric units (millimeters), except those in parentheses which are English units (inches).
2. Lead spacing shall be measured within this zone.
   a. Shoulder and lead tip dimensions are to centerline of leads.
3. Tolerances non-cumulative
4. Thermal resistance values are determined by utilizing the linear temperature dependence of the forward voltage drop across the substrate diode in a digital device to monitor the junction temperature rise during known power application across V_{CC} and ground. The values are based upon 120 mils square die for plastic packages and a 90 mils square die in the smallest available cavity for hermetic packages. All units were solder mounted to P.C. boards, with standard stand-off, for measurement.

Plastic Only

5. Lead material: Alloy 42 (Nickel/Iron Alloy) Olin 194 (Copper Alloy) or equivalents, solder dipped.
6. Body material: Plastic (Epoxy)
7. Round hole in top corner denotes lead No. 1.
8. Body dimensions do not include molding flash.
9. SO Packages-microminature packages.
   a. Lead material: Alloy-42.
   b. Body material: Plastic (Epoxy).

Hermetic Only

10. Lead material
    a. ASTM alloy F-15 (KOVAR) or equivalent—gold plated, tin plated, or solder dipped.
    b. ASTM alloy F-30 (Alloy 42) or equivalent—tin plated, gold plated or solder dipped.
    c. ASTM alloy F-15 (KOVAR) or equivalent—gold plated.
11. Body Material
    a. Eyelet, ASTM alloy F-15 or equivalent—gold or tin plated, glass body.
    b. Ceramic with glass seal at leads.
    c. BeO ceramic with glass seal at leads.
    d. Ceramic with ASTM alloy F-30 or equivalent.
12. Lid Material
    a. Nickel or tin plated nickel, weld seal.
    b. Ceramic, glass seal.
    c. ASTM alloy F-15 or equivalent, gold plated, alloy seal.
    d. BeO Ceramic with glass seal.
13. Signetics symbol, angle cut, or lead tab denotes Lead No. 1.
14. Recommended minimum offset before lead bend.
15. Maximum glass climb .010 inches.
16. Maximum glass climb or lid skew is .010 inches.
17. Typical four places.
18. Dimension also applies to seating plane.

WHAT IS A MINIATURE IC PACKAGE?

In order to overcome the physical size constraint sometimes encountered with standard plastic dual-in-line packages, N.V. Philips of Eindhoven, the Netherlands, with which Signetics is affiliated, developed the SO package (SO = small outline). The true advantage of this miniature package is that it is possible to seal standard integrated circuit die inside of a dual-in-line package with significantly reduced outside dimensions.

This has advantages not only in the assembly of PC boards, but it also allows hybrid manufacturers to purchase fully DC- and AC-tested circuits for assembly onto substrates. Presently, with chip and wire assembly techniques, it is only possible to purchase DC-tested, unpackaged integrated circuits.

A BRIEF HISTORY

Early in the 1960's, hybrid circuit manufacturers began using unpackaged chips. Problems swiftly arose. Handling was difficult, mounting was messy, bonding was a hand operation, and AC- and DC-testing was almost impossible until the circuit was completed.

In 1967, Philips introduced the first miniature packages for discrete components in the form of SOT-23 devices. These brought outstanding improvements in manufacturing yields with significant cost reductions to hybrid circuits.

In 1971, Philips commenced a similar development of a miniature package for integrated circuits for use in the Swiss watch industry.

PRINCIPAL APPLICATIONS

The SO package is not only of interest for the hybrid manufacturer, but also for any equipment manufacturer when size, volume, and weight are critical. Miniaturization on a new scale now becomes possible. In many applications, the small size of the new SO packages opens up new possibilities for equipment manufacturers.

CURRENT USES OF THE NEW SO PACKAGES

- **Portable communications equipment (e.g. paging equipment)**
- **Automobile instrumentation**
- **Portable instruments**
- **Television cameras**
- **Photographic cameras**
- **Telephone transmission equipment**
- **Model control**

TYPES OF CIRCUITS CURRENTLY AVAILABLE

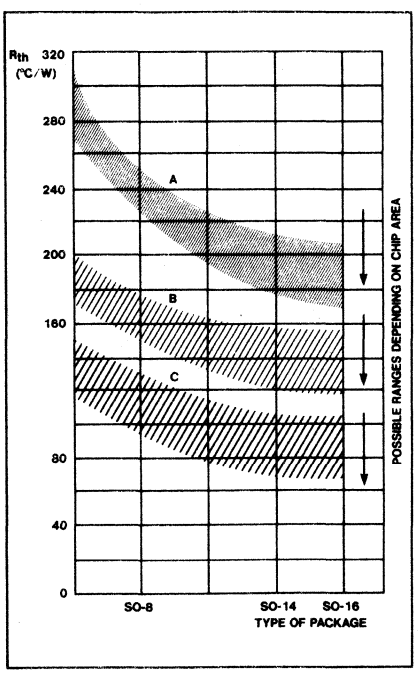
TYPE	PACKAGE	FUNCTION
LM301AD	SO-8	High performance op amp
LM311D	SO-8	Single general purpose comparator
LM319D	S0-14	Dual voltage comparator
LM324D	SO-14	Quad op amp
LM339D	SO-14	Quad voltage comparator
LM358D	SO-8	Dual op amp
LM13600D/AD	SO-8	Dual operational transconductance amplifier
MC1458D	SO-8	Dual op amp
NE532D	SO-8	Dual op amp
NE544D	SO-14	Servo amplifier
NE555D	SO-8	Timer
NE556D	SO-14	Dual timer
NE564D	SO-16	Phase locked loop
NE592D	SO-14	Video amplifier
NE5512	SO-8	Dual high performance op amp
NE5517D/AD	SO-16	Dual operational transconductance amplifier
NE5534D	SO-8	Low noise op amp
NE5539D	SO-14	Ultra high frequency op amp
NE5044D	SO-16	Seven channel R.C. encoder
NE5045D	SO-16	Seven channel R.C. decoder
μA723CD	SO-14	Precision voltage regulator
μA741CD	SO-8	General purpose op amp
μA747CD	SO-14	Dual general purpose op amp
μA748CD	SO-8	General purpose op amp

PLANS FOR NEW TYPES

Our analog product range will be extended to include devices in the new SO packaging. We are considering the full line of analog products.

POWER DISSIPATION

Considering their size, the SO packages exhibit excellent properties of power dissipation. When mounted on a ceramic substrate, the heat dissipated can be readily conducted away from the source. The thin size and short connections give a thermal resistance between junction and solder pads or heatsink about the same as for a normal DIP package mounted on a printed circuit board. The thermal resistance of the SO-8 package is about 110°C/W, while that of the SO-14 and SO-16 is about 100°C/W, or lower. Thermal resistance does, however, depend on chip size. The graph shows typical values of thermal resistance between the junction and heatsink or ambient for SO packages.



Curve A represents the thermal resistance when mounted on ceramic against a heatsink (.984 x .511 x .023 inches); curve B is when mounted on ceramic in free air; curve C is when mounted on a printed circuit board in free air.

RELIABILITY ENGINEERING QUALIFICATION REPORT ON THE "SO" PACKAGE

A Miniature Molded Epoxy Package

K. M. Self & P. J. Naumchik
Signetics Reliability Engineering

ABSTRACT

This report summarizes the Reliability Engineering activities undertaken to evaluate and qualify a miniature molded epoxy package configuration identified as the "SO." The evaluation demonstrated that the stress performance of the "SO" Package is equivalent to the larger standard molded epoxy dual-in-line package in all aspects, and mounted, the package thermal resistance characteristics are exceptional considering the reduced size and mass of the package.

BACKGROUND/ADVANTAGES

The "SO" Package was developed by N.V. Philips in 1967 for applications in hybrid structures and later for watch modules.

The reduced size of this package (refer to Figure 1) offers significant packing density improvements which up to now have been restricted to users of higher cost hermetic flat packages. For hybrid systems with limited size constraints, the "SO" offers an ease-of-use and testability advantage over conventional chip and wire hybrid approaches.

EVALUATION PROGRAM

Our evaluation/qualification program included three Analog products; LM311 voltage comparator, μA747 dual op amp, and NE532 dual op amp.

These devices encompass three wafer fabrication processes and both 8-Pin and 14-Pin package configurations.

All products were assembled on Alloy 42 lead frames, die attached utilizing conventional gold-silicon eutectic and molded in our standard Morton 410B epoxy Novalac compound. The devices were subjected to a series of accelerated stresses and tested to conventional data sheet parameters. Variables data was taken and drift analysis was performed.

The stress conditions employed were as follows:

- High Temperature Bias Life
  T_A = 125°C V_{CC} = ±15V
- High Temperature Storage Life
  T_A = 150°C
- Temperature/Humidity Bias Life
  T_A = 85°C RH = 85% V_{CC} = ±15V
- Temperature/Humidity/Pressure
  (Pressure Cooker) T_A = 121°C
  15 PSIG 100% Sat. Steam
- Thermal Shock (Liquid to Liquid)
  −65°C to 150°C

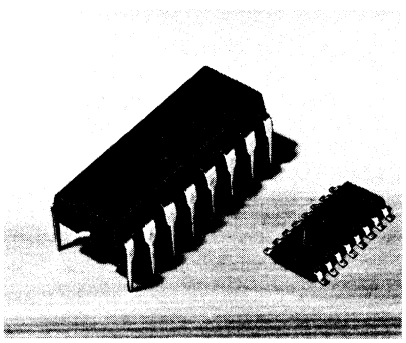


Figure 1

PROGRAM RESULTS

The details of all the stress results are included in Table I. The size of the "SO" Package tends to suggest that the structure may be less rugged than its molded dual-in-line counter part. The test results demonstrate how misleading a factor size can be. In all stresses the "SO" devices performed as well as standard dual-in-line product. Requirements for qualification were met or exceeded on all three products evaluated.

THERMAL RESISTANCE

Thermal resistance measurements were made with devices mounted on a 2CM x 1CM (13/16" x 3/8") ceramic substrate. The results were as follows:
8-Pin "SO" θ_{JA} = 110°C/W
14-Pin "SO" θ_{JA} = 100°C/W
16-Pin "SO" θ_{JA} = 100°C/W

CONCLUSIONS

The "SO" Package constructed with Alloy-42 lead frame, Au-Si eutectic die attach, and molded in 410B epoxy Novalac provides an integrated circuit with a reliable barrier to hostile external environmental conditions and stresses. It is qualified for use with any Signetics Bipolar Analog or Bipolar Logic device which can tolerate the physical limitations of die attach pad size and can operate reliably within the thermal resistance limitations of the package.

RELIABILITY EVALUATION RESULTS

RELIABILITY ENGINEERING PROJECT ID	SIGNETICS PRODUCT TYPE	STRESS	STRESS CONDITIONS	STRESS DURATION	CUMULATIVE RESULT	ANALYSIS
