DATA HANDBOOK SYSTEM

Our Data Handbook System comprises more than 60 books with specifications on electronic components, subassemblies and materials. It is made up of four series of handbooks:

| | |
|--------------------------|--------|
| ELECTRON TUBES | BLUE |
| SEMICONDUCTORS | RED |
| INTEGRATED CIRCUITS | PURPLE |
| COMPONENTS AND MATERIALS | GREEN |

The contents of each series are listed on pages iv to viii.

The data handbooks contain all pertinent data available at the time of publication, and each is revised and reissued periodically.

When ratings or specifications differ from those published in the preceding edition they are indicated with arrows in the page margin. Where application information is given it is advisory and does not form part of the product specification.

Condensed data on the preferred products of Philips Electronic Components and Materials Division is given in our Preferred Type Range catalogue (issued annually).

Information on current Data Handbooks and on how to obtain a subscription for future issues is available from any of the Organizations listed on the back cover.

Product specialists are at your service and enquiries will be answered promptly.

ELECTRON TUBES (BLUE SERIES)

The blue series of data handbooks comprises:

- T1 Tubes for r.f. heating**
- T2a Transmitting tubes for communications, glass types**
- T2b Transmitting tubes for communications, ceramic types**
- T3 Klystrons, travelling-wave tubes, microwave diodes**
- ET3 Special Quality tubes, miscellaneous devices (will not be reprinted)**
- T4 Magnetrons for microwave heating**
- T5 Cathode-ray tubes**
Instrument tubes, monitor and display tubes, C.R. tubes for special applications
- T6 Geiger-Müller tubes**
- T7 Gas-filled tubes**
Segment indicator tubes, indicator tubes, dry reed contact units, thyratrons, industrial rectifying tubes, ignitrons, high-voltage rectifying tubes, associated accessories
- T8 Picture tubes and components**
Colour TV picture tubes, black and white TV picture tubes, colour monitor tubes for data graphic display, monochrome monitor tubes for data graphic display, components for colour television, components for black and white television and monochrome data graphic display
- T9 Photo and electron multipliers**
Photomultiplier tubes, phototubes, single channel electron multipliers, channel electron multiplier plates
- T10 Camera tubes and accessories**
- T11 Microwave semiconductors and components**
- T12 Vidicons and Newvicons**
- T13 Image intensifiers**
- T14 Infrared detectors**
- T15 Dry reed switches**
- T16 Monochrome tubes and deflection units**
Black and white TV picture tubes, monochrome data graphic display tubes, deflection units

Data collations on these subjects are available now.
Data Handbooks will be published in 1985.

SEMICONDUCTORS (RED SERIES)

The red series of data handbooks comprises:

- S1 Diodes**
Small-signal germanium diodes, small-signal silicon diodes, voltage regulator diodes (< 1,5 W), voltage reference diodes, tuner diodes, rectifier diodes
- S2a Power diodes**
- S2b Thyristors and triacs**
- S3 Small-signal transistors**
- S4a Low-frequency power transistors and hybrid modules**
- S4b High-voltage and switching power transistors**
- S5 Field-effect transistors**
- S6 R.F. power transistors and modules**
- S7 Surface mounted semiconductors**
- S8 Devices for optoelectronics**
Photosensitive diodes and transistors, light-emitting diodes, displays, photocouplers, infrared sensitive devices, photoconductive devices.
- S9 Power MOS transistors**
- S10 Wideband transistors and wideband hybrid IC modules**
- S11 Microwave semiconductors (to be published in this series in 1985)**
At present available in Handbook T11
- S12 Surface acoustic wave devices**

INTEGRATED CIRCUITS (PURPLE SERIES)

The purple series of data handbooks comprises:

EXISTING SERIES

Superseded by:

| | | |
|------|---|-----------------|
| IC1 | Bipolar ICs for radio and audio equipment | |
| IC2 | Bipolar ICs for video equipment | IC02N |
| IC3 | ICs for digital systems in radio, audio and video equipment | |
| IC4 | Digital integrated circuits CMOS HE4000B family | |
| IC5 | Digital integrated circuits – ECL ECL10 000 (GX family), ECL100 000 (HX family), dedicated designs | IC08N |
| IC6 | Professional analogue integrated circuits | |
| IC7 | Signetics bipolar memories | |
| IC8 | Signetics analogue circuits | |
| IC9 | Signetics TTL logic | IC09N and IC15N |
| IC10 | Signetics Integrated Fuse Logic (IFL) | IC13N |
| IC11 | Microprocessors, microcomputers and peripheral circuitry | |

NEW SERIES

| | | |
|--------------|--|------------------|
| IC01N | Radio, audio and associated systems Bipolar, MOS | |
| IC02N | Video and associated systems Bipolar, MOS | (published 1985) |
| IC03N | Integrated circuits for telephony Bipolar, MOS | (published 1985) |
| IC04N | HE4000B logic family CMOS | |
| IC05N | HE4000B logic family uncased integrated circuits CMOS | (published 1984) |
| IC06N | PC54/74HC/HCU/HCT logic families HCMOS | |
| IC07N | PC54/74HC/HCU/HCT uncased integrated circuits HCMOS | |
| IC08N | 10K and 100K logic family ECL | (published 1984) |
| IC09N | Logic series TTL | (published 1984) |
| IC10N | Memories MOS, TTL, ECL | |
| IC11N | Linear LSI | (published 1985) |
| IC12N | Semi-custom gate arrays & cell libraries ISL, ECL, CMOS | |
| IC13N | Semi-custom Integrated Fuse Logic | (published 1985) |
| IC14N | Microprocessors, microcontrollers & peripherals Bipolar, MOS | |
| IC15N | Logic series FAST TTL | (published 1984) |

Note

Books available in the new series are shown with their date of publication.

COMPONENTS AND MATERIALS (GREEN SERIES)

The green series of data handbooks comprises:

- C1 Programmable controller modules**
PLC modules, PC20 modules
- C2 Television tuners, video modulators, surface acoustic wave filters**
- C3 Loudspeakers**
- C4 Ferroxcube potcores, square cores and cross cores**
- C5 Ferroxcube for power, audio/video and accelerators**
- C6 Synchronous motors and gearboxes**
- C7 Variable capacitors**
- C8 Variable mains transformers**
- C9 Piezoelectric quartz devices**
Quartz crystal units, temperature compensated crystal oscillators, compact integrated oscillators, quartz crystal cuts for temperature measurements
- C10 Connectors**
- C11 Non-linear resistors**
Voltage dependent resistors (VDR), light dependent resistors (LDR), negative temperature coefficient thermistors (NTC), positive temperature coefficient thermistors (PTC)
- C12 Variable resistors and test switches**
- C13 Fixed resistors**
- C14 Electrolytic and solid capacitors**
- C15 Ceramic capacitors***
- C16 Permanent magnet materials**
- C17 Stepping motors and associated electronics**
- C18 D.C. motors**
- C19 Piezoelectric ceramics**
- C20 Wire-wound components for TVs and monitors**
- C21 Assemblies for industrial use**
HNIL FZ/30 series, NORbits 60-, 61-, 90-series, input devices

* Film capacitors are included in Data Handbook C22 which will be published in 1985. The September 1982 edition of C15 should be retained until C22 is issued.

PREFACE

The continuing trend of system integration has created new challenges for the design engineer. He must strive to consolidate higher complexity, more feature-laden circuits into his designs without sacrificing flexibility. Today's competitive electronic marketplace has created the need for logic devices which can provide cost-effective methods of reducing random logic requirements and interface with fixed LSI custom logic, yet retain the flexible features required to modify the system prior to production. Signetics has developed IFL (Integrated Fuse Logic) as a programmable logic family to address that need.

The IFL family consists of a relatively few devices which are designed to address logic needs from random gates in the case of the Field Programmable Gate Arrays to highly sophisticated state machines in the case of the Field Programmable Logic Sequencers. Signetics has pioneered since 1975 the concept of total AND/OR/INVERT programmability. IFL can encompass these wide-ranging levels of integration without the necessity of providing a multitude of devices; each dedicated to a specific application or I/O structure. The flexible programming structure allows the designer to "mold" the individual device's architecture to the complete range of requirements typically found in system design.

Since the production process utilized to manufacture IFL is identical to the process used on the Signetics Bipolar PROM Family, it is possible to provide a highly manufacturable, high-performance, cost-effective product family. The 1984 IFL Data Manual contains information the designer will require in order to effectively utilize IFL. For information on the Signetics PROM Family, refer to the Signetics 1984 Bipolar Memory Data Manual. For the convenience of the designer, a Product Selection Guide has been included in this publication.

ORDERING INFORMATION

ORDERING INFORMATION

Signetics Bipolar Memory integrated circuit products may be ordered by contacting either the local Signetics sales office, Signetics representatives and/or Signetics authorized distributors. A complete listing is located in the back of this manual.

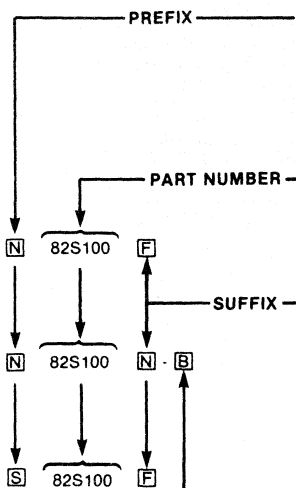

The table shown provides part number

definition for Signetics memory products. The Signetics part number system allows complete definition for ordering a device. The part number itself and the product description is defined on each data sheet. The suffix is a single letter defining a package type (as shown in the table on this page). Additional or special process-

ing is defined by adding the processing indicator when required.

The military qualification, Full MIL Signetics or Full JAN slash sheet status, can be determined by referring to the military section of this manual. Verification of the military status can be made by contacting your local Signetics sales office.

Table 1 PART NUMBER DESCRIPTION

| USED TO DEFINE OPERATING TEMPERATURE RANGE | |
|--|--------------------------|
| PREFIX | DEVICE TEMPERATURE RANGE |
| N | 0°C to + 75°C |
| S | - 55°C to + 125°C |

NOTES:

- Output circuit
 OE = Open Emitter
 OC = Open Collector
 TS = 3 State
- Output logic
 T = Transparent—input data appears on output during Write
 B = Blanked—output is blanked during Write
 R = Registers
 I/O = Programmable input/output option
- Commercial (0°C to +75°C)
- Temperature range
 C = Commercial (0°C to +75°C)
 M = Military (-55°C to +125°C)
- Packages:
 N = Plastic Dual In Line (N3 = 300 mil wide, N6 = 600 mil wide) *
 R = Ceramic Flat Pack
 G = Ceramic Square Leadless Chip Carrier
 A = Plastic Square Leaded Chip Carrier
 F = Hermetic Cerdip Dual In Line (Military only) (F3 = 300 mil wide, F6 = 600 mil wide) *
 D = Small Outline Large (SO-L)
 * Whenever a single device is offered in both 300 mil wide and 600 mil wide packages, designate either N3 (300 mil) or N6 (600 mil) to assure proper order entry and shipment.
- Part numbers:
 82Sxxx Junction Isolated
 82HSxxx Oxide Isolated
- Objective spec (under product development)

Section 2
What is IFL?
An Introduction

WHAT IS INTEGRATED FUSE LOGIC?

In 1975, Signetics Corporation developed a new product family by combining its expertise in semi-custom gate array products and fuse-link Programmable Read Only Memories (PROMs). Out of this marriage came Integrated Fuse Logic (IFL). The 82S100 Field Programmable Logic Array (FPLA) was the first member of this family. The FPLA was an important industry first in two ways. First, the AND/OR/INVERT architecture allowed the custom implementations of Sum of Product logic equations. Second, the three-level fusing allows complete flexibility in the use of this device family. All logic interconnections from input to output are programmable.

Development of this family did not stop with the 82S100. In 1977, the 82S103 Field Programmable Gate Array (FPGA) and the 82S107 Field Programmable ROM Patch (FPRP) were introduced.

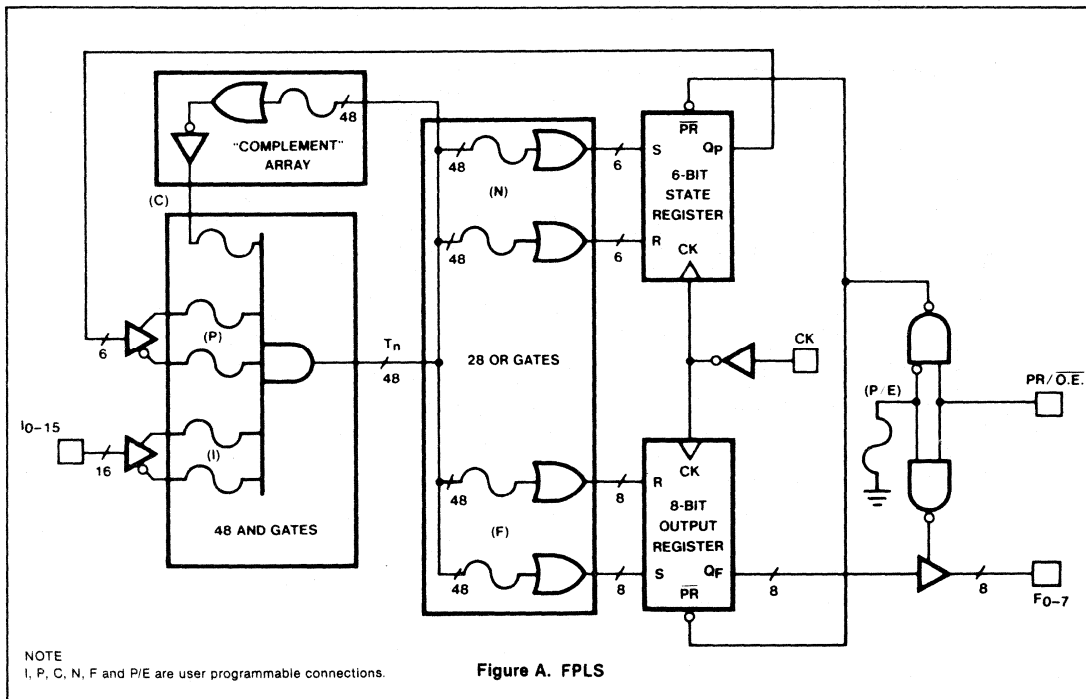

The 82S105 Field Programmable Logic Sequencer (FPLS) was announced in 1979. This device represents a significant step forward for IFL. The FPLS is a fully implemented Mealy State

Machine on a chip. Incorporated into its architecture are 48 P-Terms, an 8-bit output register, and a 6-bit internal state register. Reference Figure A.

The FPLS can synchronously perform sequential routines at 20MHz. All of these products are now known as the IFL Series 28 Programmable Logic Family.

Signetics' next innovation in this area was the Series 20 Programmable Logic Family. All members of this family are assembled in 20-pin packages. While reducing the number of pins in this family, Signetics has utilized controlled I/O in order to maintain the utility of the Series 20. Appropriate control terms have been included to allow active control of pin direction. Reference Figure C.

The latest addition to the IFL Programmable Logic families is the Series 24 devices. The 82S161 FPLA and the 82S167 FPLS are 24-pin devices comparable to the 28-pin 82S100 and 82S105 respectively. These devices will be followed by the 82S162/82S163 FPGA and the 82S165/82S169 FPLS later this year.

Figure B. IFL Product Family

PRODUCT DESCRIPTION

While all IFL devices are architecturally similar, the Field Programmable Logic Array is most representative of the concepts involved. The FPLA is an AND/ORINVERT device, with all internal interconnections programmable via fuse links. If we compare the 82S100 FPLS to the familiar 7450 AOI gate, the similarity of function becomes apparent.

INTEGRATED FUSE LOGIC

INTRODUCTION

Package-Gate Replacement Potential

All Signetics IFL devices are capable of replacing multiple discrete logic devices. The number of packages is dependent on the application and the device used.

If all product terms and inputs on the 82S100 are utilized a total of 272 gates and 140 I.C.s can theoretically be replaced. Since the 82S100 is made up of logic structures which are not available as commercial logic devices; such as 32 input AND gates and 48 input OR gates, these numbers are based on breakdowns of these high complexity logic structures into structures which are available as discrete logic.

Table 1 GATE REPLACEMENT (All Terms Used)

| | Gates | I.C.s |
|---|-------|-------|
| Each P-Term = 2 8-Input AND Gates & 1 2-Input AND Gate = | 144 | 108 |
| OR Matrix = 16 4-Input OR Gates = | 128 | 32 |
| | 272 | 140 |

The typical application does not fully utilize the FPLA however. We can assume that the typical application is as defined in Table 2.

Table 2 TYPICAL APPLICATION

| | |
|--------------------|-------------|
| 4 Variables/P-Term | 40 Gates |
| 4 P-Terms/Output | 15-20 I.C.s |

The replacement of 15-20 I.C.s with one 82S100 is not unusual.

IFL ECONOMICS

The reason any product line exists is because it solves a problem in a cost effective manner.

IFL is no different in this respect. Let's assume that one 82S100 is replacing 15 TTL logic packages.

If we assume that the average selling price of an SSI level device is \$0.25, then we have a basis for comparison.

$$15 \text{ I.C.s @ } \$0.25 = \underline{\$3.75} \quad 1 \text{ 82S100 FPLA} = \underline{\$7.00}$$

Considering piece part cost alone does not fare well for the 82S100 FPLA. But, part cost is one of the smaller costs in systems manufacturing. Let's next consider PC board costs.

PC BOARD

The purchase price of a PCB is calculated on a per square inch basis. Typical costs at the 5K level are \$0.23/in², the cost for LS' is 1.2 in² = \$0.23/in² = \$0.28. For a 28-pin FPLA device, the packing density is 1-82S100 per 2.5 in², giving a cost of 2.5 in² x \$0.23/in² = \$0.58.

PCB FABRICATION:

Now let's consider the cost of building the board. The primary cost for PCB fabrication is parts preparation and stuffing.

Estimates by PCB manufacturers indicate a nominal cost of \$0.14 per device for LS TTL and \$0.16 for 28-pin FPLA. There is also a basic cost of \$0.02 per in² for handling, soldering, and inspecting.

The cost of incoming inspection and inventory/usage must also be considered in any fair comparison.

INCOMING INSPECTION

The cost of incoming inspection can be calculated on a per-pin basis. Assuming an equal mix of 14 and 16-pin SSI parts and a testing cost of \$0.01 per pin, the LS TTL cost is \$0.15 per IC. The corresponding cost for the 82S100 would be \$0.01 x 28 or \$0.28 total.

COMPONENT INVENTORY/USAGE:

The inventory cost for LS TTL parts is dominated by inventory maintenance, while the LSI type parts, the piece price dominates. Assuming a 2% usage rate due to parts breakage, burn-out, etc., in the manufacturing process, the parts cost for LS TTL is 2% x \$0.25 = \$0.005. Adding \$0.02 per device for inventory maintenance, the total LS cost \$0.03. For FPLA, 2% = \$7.00 + \$0.02 = \$0.16.

Consideration must also be given to testing the completed PCB and Rework costs.

PCB TESTING

Testing costs are generally figured on a PCB basis and are usually go-no-go tests using a "bed of nails". For this comparison, assume a PCB of 5" x 7". The cost for testing the completed PCB is estimated to be \$3.60 for 20 I.C.s. This breaks down as \$0.18 per LS TTL device or about \$0.45 per FPLA device.

PCB REWORK

The main causes of rework are poorly plated holes, solder bridges, and parts inserted incorrectly. The "bed of nails" test can usually detect all of the faults. Rework costs about 50% of test costs. The result is \$1.80 per PCB or \$0.09 per device for LS TTL and \$0.18 for the 28-pin FPLA.

System manufacturing costs are harder to define. For this comparison we estimated \$0.28 for each LS device and about \$0.65 for the FPLA. These costs include backplane wiring, final system assembly and test costs.

Now using these figures, the following comparison can be made:

COST ANALYSIS

| | LS TTL | FPLA |
|-----------------------------|---|------|
| IC COMPONENTS | .25 | 7.00 |
| PCB MANUFACTURING | | |
| Incoming Inspection | .15 | .28 |
| Component Inventory/Usage | .03 | .16 |
| PC Board | .28 | .58 |
| Fabrication | .14 | .16 |
| Test | .18 | .45 |
| Rework | .09 | .18 |
| ASSEMBLY LABOR | .28 | .65 |
| COST PER COMPONENT | 1.40 | 9.46 |
| NUMBER OF COMPONENTS | x 15 | x 1 |
| TOTAL | 21.00 | 9.46 |
| CONCLUSION: | | |
| | THE FPLA is a 55% savings over the LS TTL DESIGN. | |

2

IFL-LOGIC SYNTHESIS

28-PIN

IFL is capable of logic Synthesis. No intermediate step is required to implement Boolean Logic Equations with IFL. Each

term in each equation simply becomes a direct entry into the Logic Program Table. The following example illustrates this straightforward concept.

$$X_0 = AB + \bar{C}D + B\bar{D}$$

$$\bar{X}_1 = \bar{A}B + \bar{C}D + EFG$$

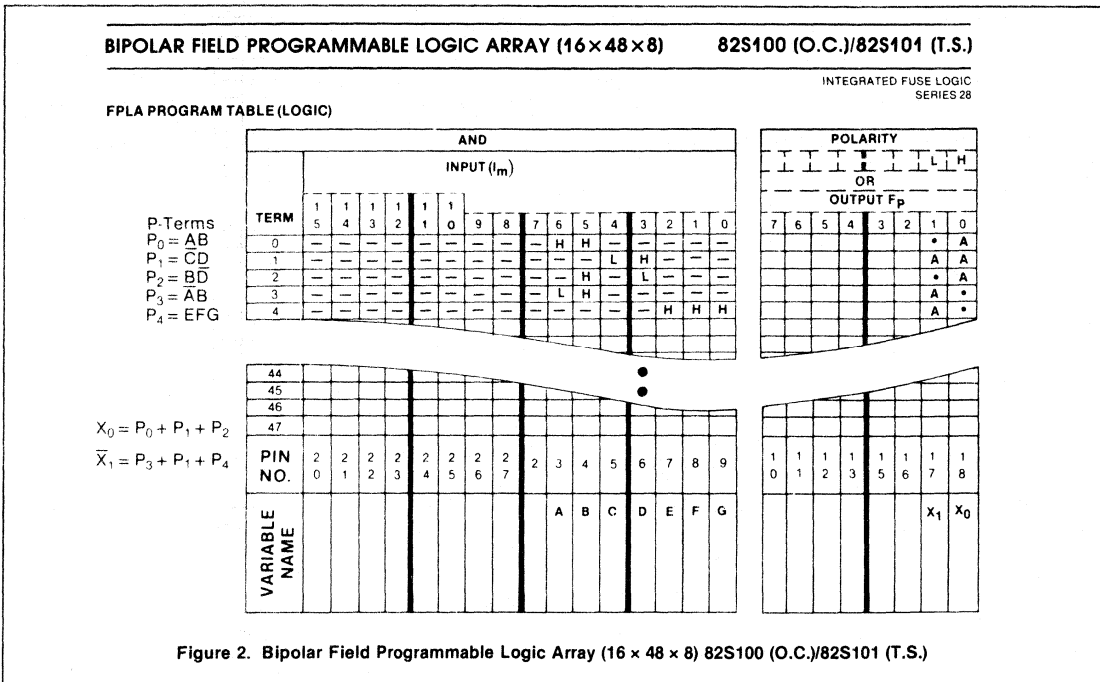

Figure 2. Bipolar Field Programmable Logic Array (16 x 48 x 8) 82S100 (O.C.)/82S101 (T.S.)

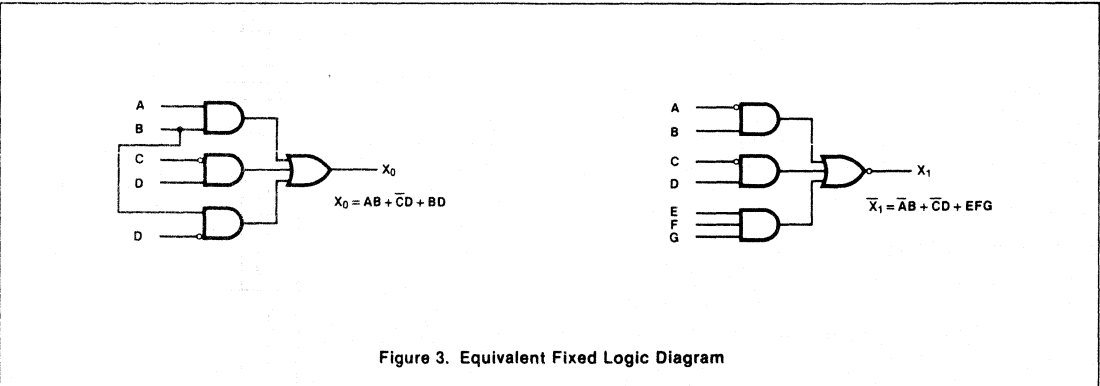

Figure 3. Equivalent Fixed Logic Diagram

INTEGRATED FUSE LOGIC

INTRODUCTION

In the previous example the two Boolean Logic equations were broken into Product Terms. Each P-Term was then programmed into the P-term section of the FPLA Program Table. This was accomplished in the following manner:

Step 1

Select which input pins I_0-I_{15} will correspond to the input variables. In this case A-G are the input variable names. I_6 through I_0 were selected to accept inputs A-G respectively.

Figure 4

Step 2

Transfer the Boolean Terms to the FPLA Program Table. This is done simply by defining each term and entering it on the Program Table.

e.g., $P_0 = AB$

This P-term translates to the Program Table by selecting

$A = I_6 = H$ and $B = I_5 = H$ and entering the information in the appropriate column.

$$P_1 = \bar{C}D$$

This term is defined by selecting $C = I_4 = L$ and $D = I_3 = H$, and entering the data into the Program Table. Continue this operation until all P-terms are entered into the Program Table.

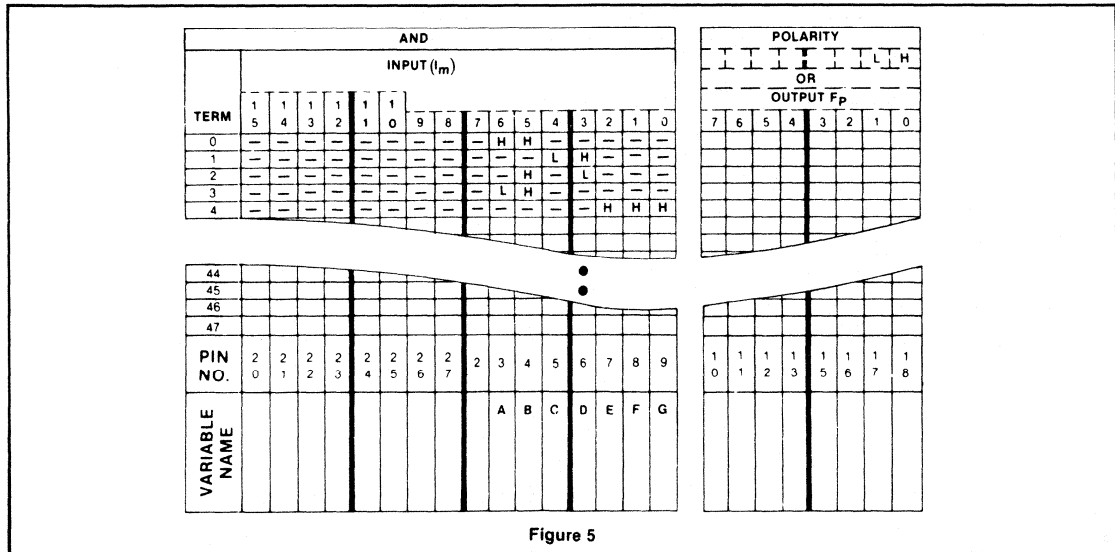

Figure 5

INTEGRATED FUSE LOGIC

INTRODUCTION

Step 3

Select which output pins correspond to each output function. In this case $F_0 = \text{Pin } 18 = X_0$, and $F_1 = \text{Pin } 17 = X_1$.

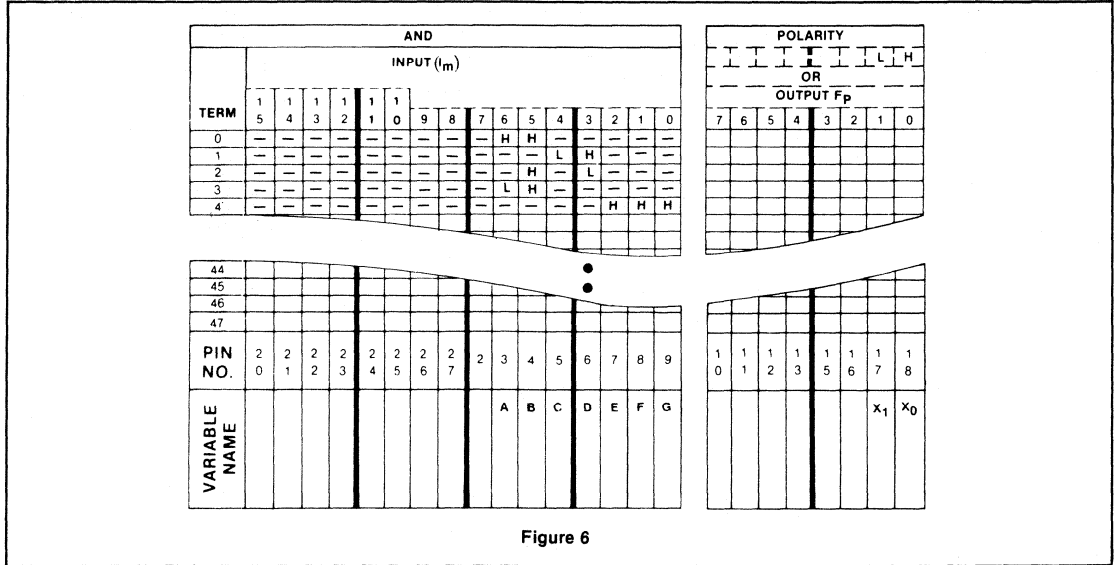

Figure 6

Step 4

Select the Output Active Level desired for each Output Function. For X_0 the active level is high for a positive logic expression of this equation. Therefore it is only necessary to place an (H) in

the Active Level box above Output Function 0, (F_0). Conversely, X_1 can be expressed as X_1 by placing an (L) in the Active Level box above Output Function 1, (F_1).

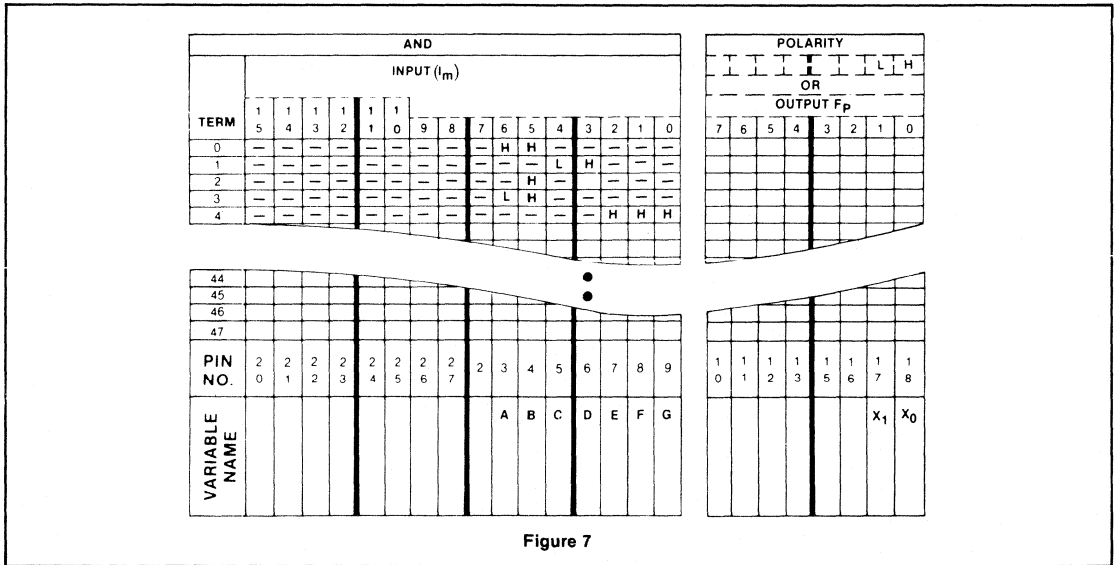

Figure 7

Step 5

Select the P-Terms you wish to make active for each Output Function. In this case $X_0 = P_0 + P_1 + P_2$, so an A has been placed in the intersection box for P_0 and X_0 , P_1 and X_0 and P_2 and X_0 .

Terms which are not active for a given output are made inactive by placing a (•) in the box under that P-term. Leave all unused P-terms unprogrammed.

Continue this operation until all outputs have been defined in the Program Table.

Step 6

Enter the data into a Signetics approved programmer. The input format is identical to the Signetics Program Table. You specify the P-Terms, Output Active Level, and which P Terms are active for each output exactly the way it appears on the Program Table.

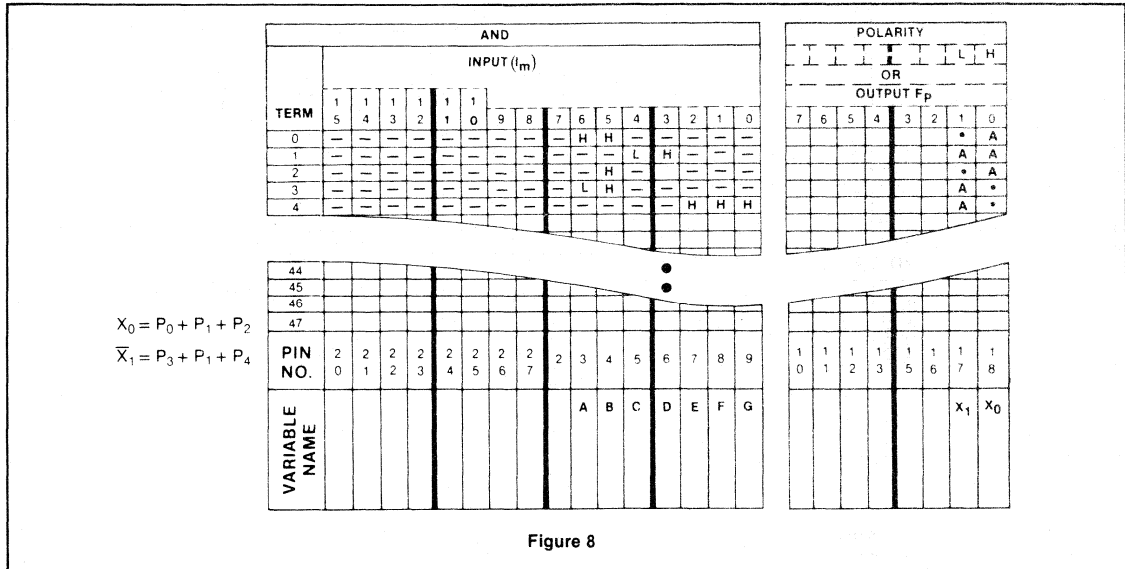

Figure 8

IFL LOGIC SYNTHESIS

20-PIN

When fewer inputs and outputs are required in a logic design and low cost is most important, the Signetics 20-pin IFL should be considered first choice. The 82S153 is an FPLA with 8 inputs,

10 I/O pins, and 42 product terms. The user can configure the device by defining the direction of the I/O pins. This is easily accomplished by using the direction control terms D_0 - D_9 to establish the direction of pins B_0 - B_9 . The D-terms control the tri-state buffers found on the outputs of the EX-OR gates. Figures 10 and 11 show how the D-term configures each B_x pin.

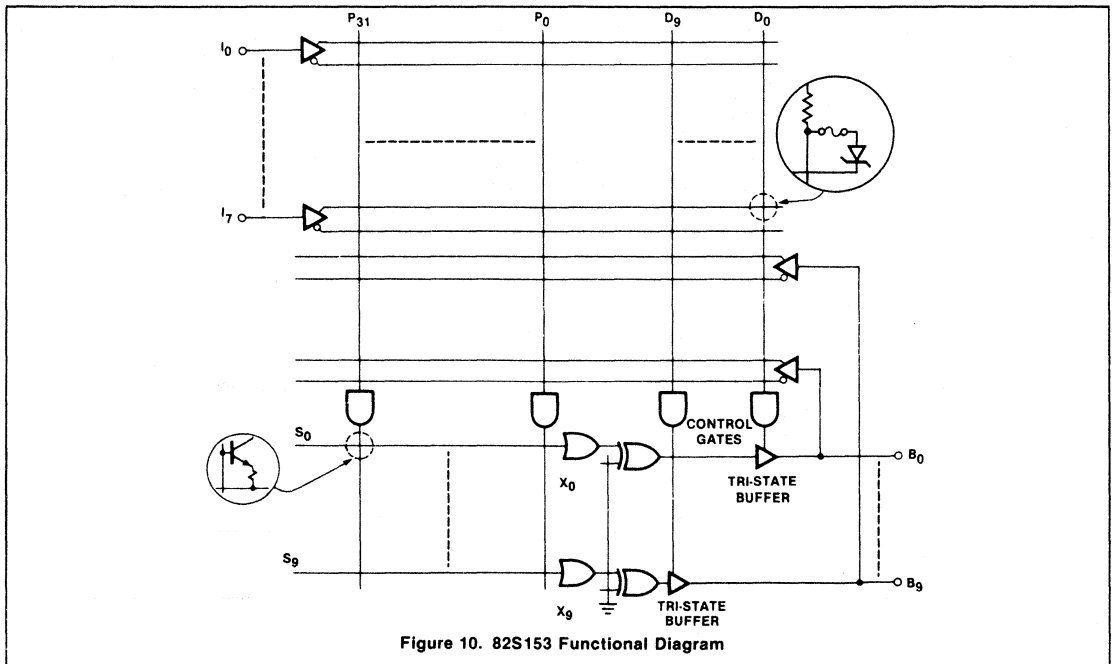

Figure 10. 82S153 Functional Diagram

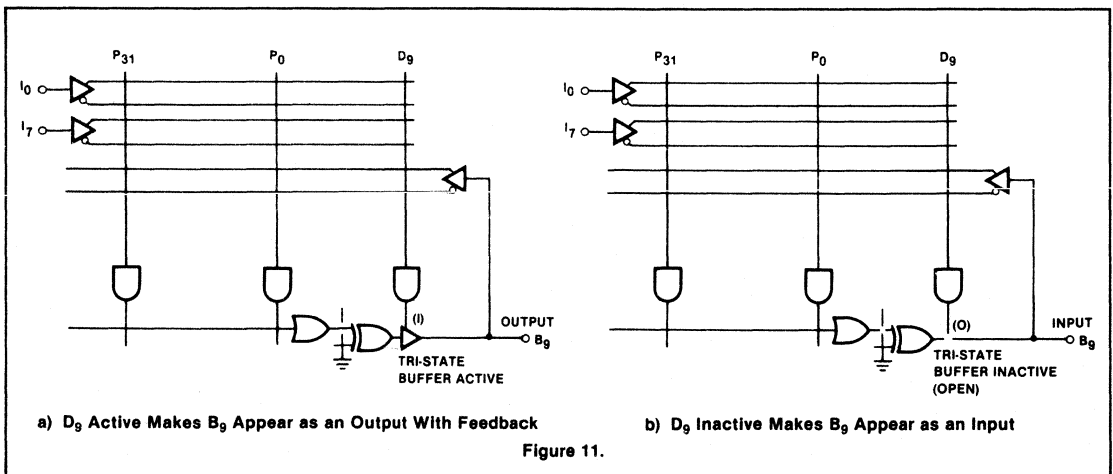

Figure 11.

To control each D-term, it is necessary to understand that each control gate is a 36-input AND gate. To make the Tri-State buffer active (B_x pin an output), the output of the control gate must be at logic HIGH (1). This can be accomplished in one of two ways. A HIGH can be forced on all control gate input nodes or fuses can be programmed. When a fuse is programmed that control

gate input node is internally pulled up to HIGH (1). See Figure 12 and Figure 13.

Programming the fuse permanently places a HIGH (1) on the input to the control gate. The input pin no longer has any effect on that state.

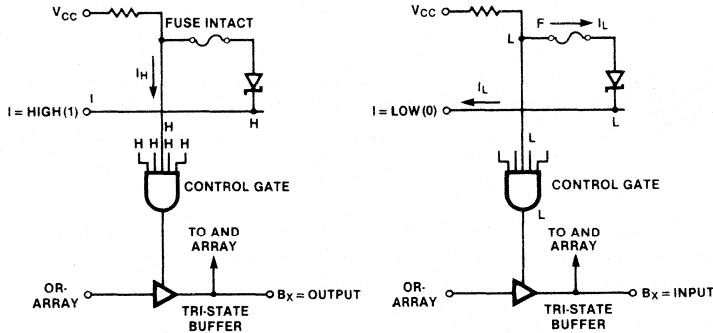

Figure 12. Input Effect on Control Gates (Fuse Intact)

Figure 13. Effect on Control Gate if Fuse is Programmed

INTEGRATED FUSE LOGIC

INTRODUCTION

By placing a (—) don't care in each input box you are specifying that the true and complement fuses are programmed on each Control Gate thus permanently dedicating the B₀ and B₁ pins as outputs. By placing a (0) in all input boxes for B₂-B₉, you are specifying that both true and complement fuses are intact. This causes a low (0) to be forced on half of the Control Gate inputs, guaranteeing the output of the Control Gate will be low (0). When the Control Gate outputs are low (0), the tri-state buffer is inactive and the B₂-B₉ pins are enabled as inputs. All B_x pin directions can be controlled in this manner.

direction of the B_x pins without permanently dedicating them. Some applications which require this include tri-state bus enable, multi-function decoding, etc. This can easily be done by programming the control gate to respond to one or more input pins. It is only necessary to select which I_x and B_x pins will control the pin directions and the active level HIGH (H) or LOW (L) that will be used. The 82S153 Program Table in Figure 15 shows the method of controlling B₀-B₉ with I₇. When I₇ is LOW (L), pins B₀-B₉ are outputs when I₇ is HIGH (H), pins B₀-B₉ are inputs. Note that by programming all other I_x and B_x pins as DON'T CARE (—) they are permanently disconnected from control of B_x pin direction.

ACTIVE DIRECTION CONTROL

Sometimes it is necessary to be able to actively change the

NOTES

- The FPLA is shipped with all links intact. Thus a background of entries corresponding to states of virgin links exists in the table, shown BLANK for clarity.
- Unused I and B bits in the AND array are normally programmed Don't Care (—).
- Unused product terms can be left blank.

Figure 15. Active Control of B₀-B₉ Using I₇ Active Low (L)

SEQUENTIAL LOGIC CONSIDERATIONS

The 82S105 and 82S155/82S159 represent significant increases in complexity when compared to the combinational logic devices previously discussed. By combining the AND-OR combinational logic with clocked output flip-flops and appropriate feedback, Signetics has created the first family of totally flexible sequential logic machines.

The 82S105 FPLS (Field Programmable Logic Sequencer) is an example of a high-order machine whose applications are manifold. Application areas for this device include high-speed data control-

lers, microprocessor and minicomputer bus arbitration, industrial controls, timing generation, multi-function counters and shift registers, and microprocessor-driven microcontrollers. The 82S105 is fully capable of performing fast sequential operations in relatively low-speed microprocessor systems. By placing repetitive sequential operations on the 82S105, microprocessor overhead is reduced. Each 82S105 can be viewed as a high-speed, 48-state subroutine.

The following pages summarize the 82S105 architecture and features.

FPLS ARCHITECTURE

The 83S105 Logic Sequencer is a programmable state machine of the Mealy type, in which the output is a function of the present state and the present input.

With the FPLS a user can program any logic sequence expressed as a series of jumps between stable states, triggered by a valid input condition (I) at clock time (t). All stable states are arbitrarily assigned and stored in the State Register. The logic output of the machine is also programmable, and is stored in the Output Register.

CLOCKED SEQUENCE

A synchronous logic sequence can be represented as a group of circles interconnected with arrows. The circles represent stable states, labeled with an arbitrary numerical code (binary, hex, etc.) corresponding to discrete states of a suitable register. The arrows represent state transitions, labeled with symbols denoting the jump condition and the required change in output. The number of states in the sequence depends on the length and complexity of the desired algorithm.

STATE JUMPS

The state from which a jump originates is referred as the present state (P), and the state to which a jump terminates is defined as the next state (N). A state jump always causes a change in state, but may or may not cause a change in machine output (F).

State jumps can occur only via "transition terms" T_n . These are logical AND functions of the clock (t), the present state (P), and a valid input (I). Since the clock is actually applied to the State Register, $T_n = I \cdot P$. When T_n is "true", a control signal is generated and used at clock time (t) to force the contents of the State Register from (P) to (N), and to change the contents of the Output Register (if necessary). The simple state jump below, involving 2 inputs, 1 state bit, and 1 output bit, illustrates the equivalence of discrete and programmable logic implementations.

FPLS LOGIC STRUCTURE

The FPLS consists of programmable AND and OR gate arrays which control the Set and Reset inputs of a State Register, as well as monitor its output via an internal feedback path. The arrays also control an independent Output Register, added to store output commands generated during state transitions, and to hold the output constant during state sequences involving no output changes. If desired, any number of bits of the Output Register can be used to extend the width of the State Register, via external feedback.

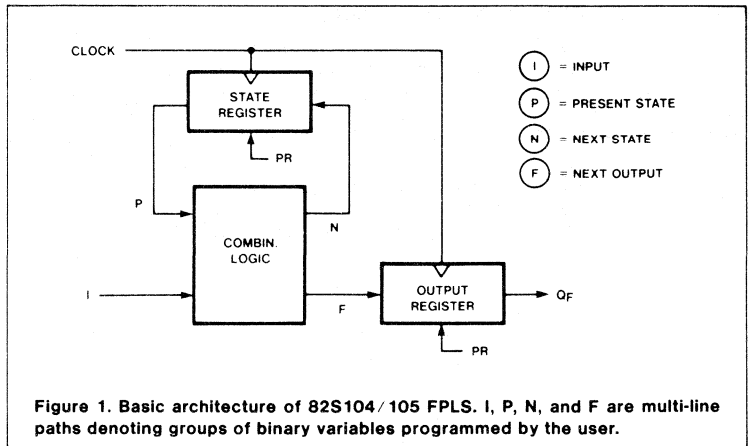

Figure 1. Basic architecture of 82S104/105 FPLS. I, P, N, and F are multi-line paths denoting groups of binary variables programmed by the user.

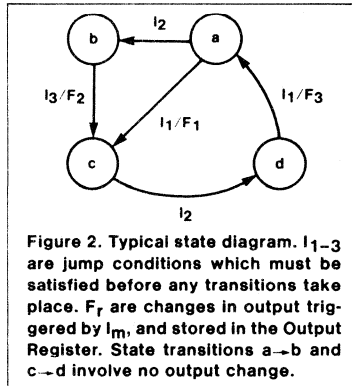

Figure 2. Typical state diagram. I_{1-3} are jump conditions which must be satisfied before any transitions take place. F_1 are changes in output triggered by I_m , and stored in the Output Register. State transitions a→b and c→d involve no output change.

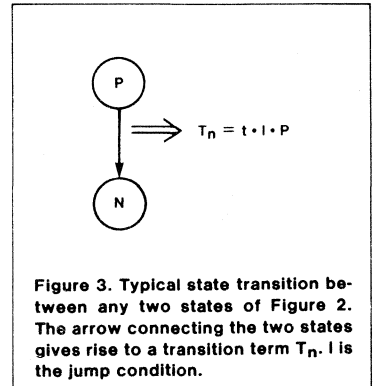

Figure 3. Typical state transition between any two states of Figure 2. The arrow connecting the two states gives rise to a transition term T_n . I is the jump condition.

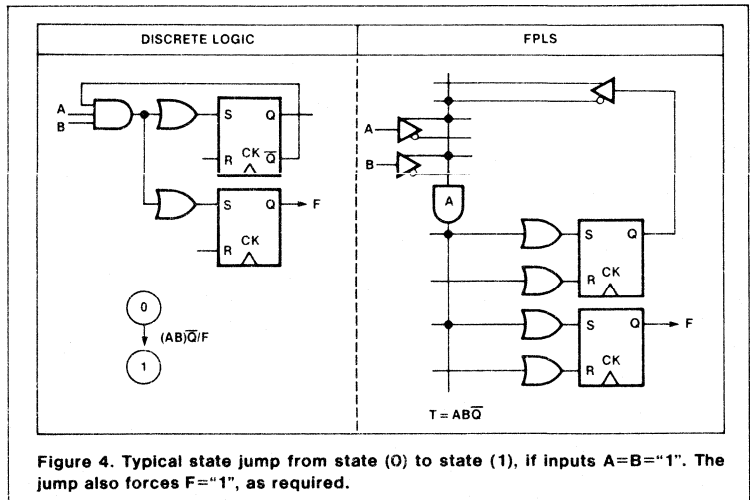

Figure 4. Typical state jump from state (0) to state (1), if inputs A=B="1". The jump also forces F="1", as required.

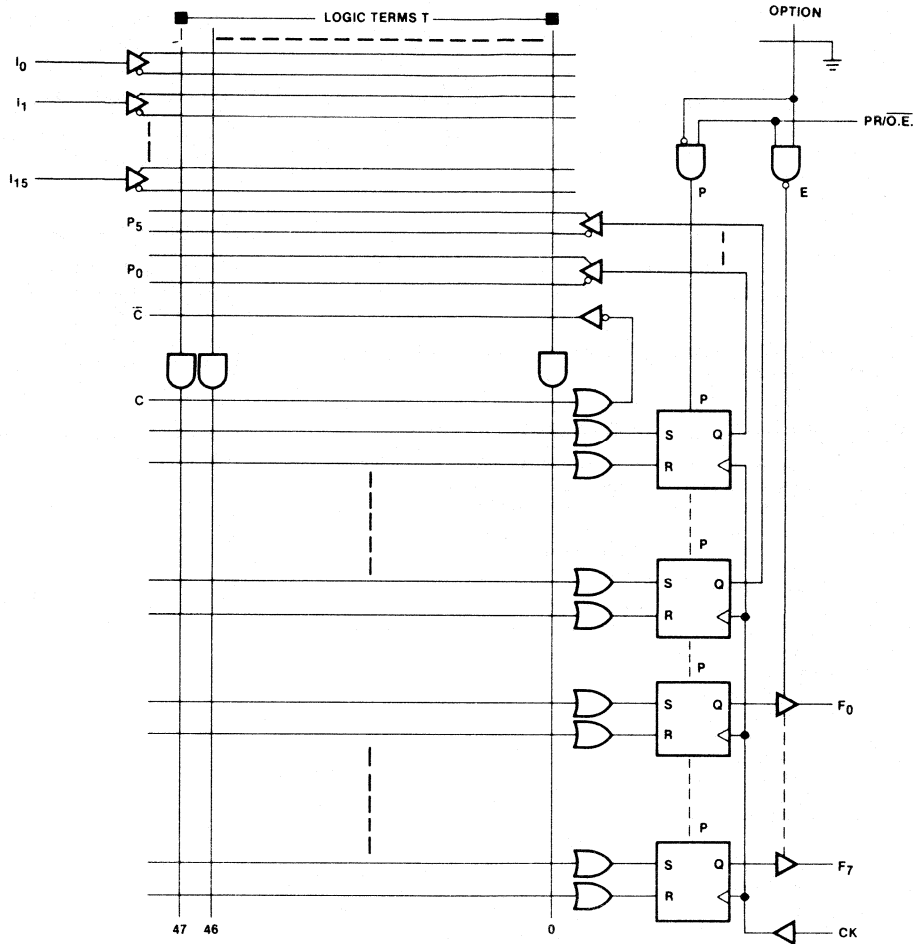

Figure 5. Simplified Logic Diagram of 82S104/105 FPLS

INPUT BUFFERS

16 external inputs (I_m) and 6 internal inputs (P_s), fed back from the state register, are combined in the AND array through two sets of True/Complement (T/C) buffers. There are a total of 22 T/C buffers, all connected to multi-input AND gates via fusible links which are initially intact.

Selective fusing of these links allows coupling either True, Complement, or Don't Care values of (I_m) and (P_s).

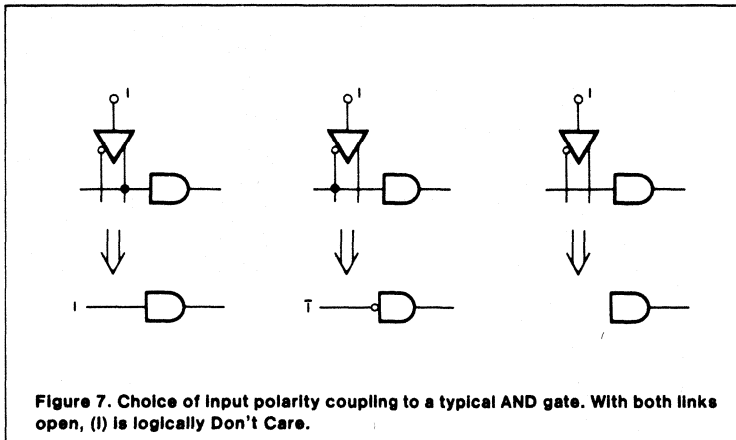

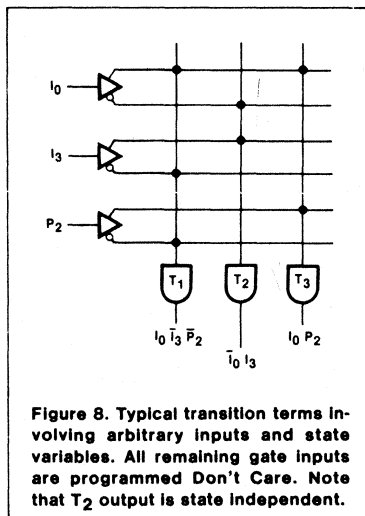

Figure 6. Typical AND gate coupled to (I) and (P) inputs. If at least one link pair remains intact, T_n is unconditionally forced Low.

“AND” ARRAY

State jumps and output changes are triggered at clock time by valid transition terms T_n . These are logical AND functions of the present state (P) and the present input (I).

The FPLS AND array contains a total of 48 AND gates. Each gate has 45 inputs—44 connected to 22 T/C input buffers, and 1 dedicated to the Complement Array. The outputs of all AND gates are propagated through the OR array, and used at clock time (t) to force the contents of the State Register from (P) to (N). They are also used to control the Output Register, so that the FPLS 8-bit output F_r is a function of the inputs and present state.

“OR” ARRAY

In general, a clocked sequence will consist of several stable states and transitions, as determined by the complexity of the desired algorithm. All state and output changes in the state diagram imply changes in the contents of state and output registers.

Thus, each flip-flop in both registers may need to be conditionally set or reset several

times with T_n commands. This is accomplished by selectively ORing through a programmable OR array all AND gate outputs T_n necessary to activate the proper flip-flop control inputs.

The FPLS OR array consists of 14 pairs of OR gates, controlling the S/R inputs of 14 state and output register stages, and a single OR gate for the Complement Array. All gates have 48 inputs for connecting to all 48 AND gates.

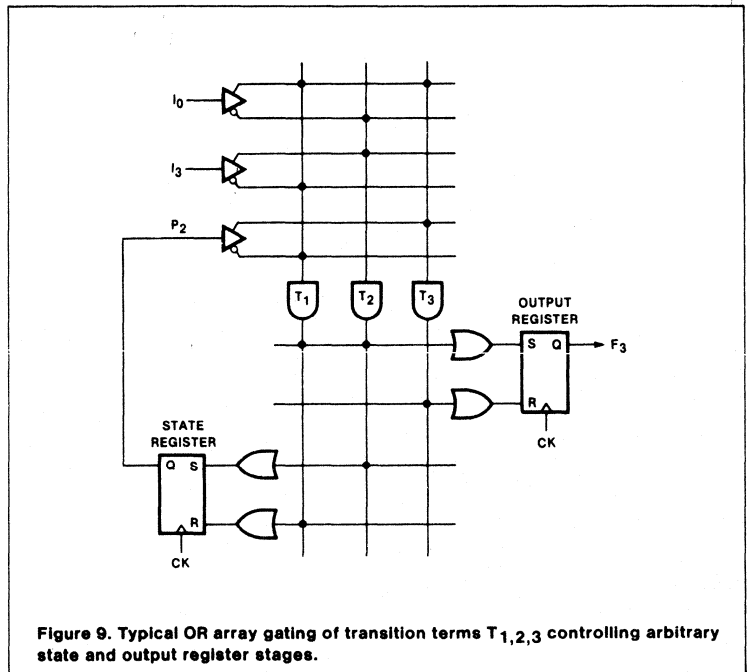

COMPLEMENT ARRAY

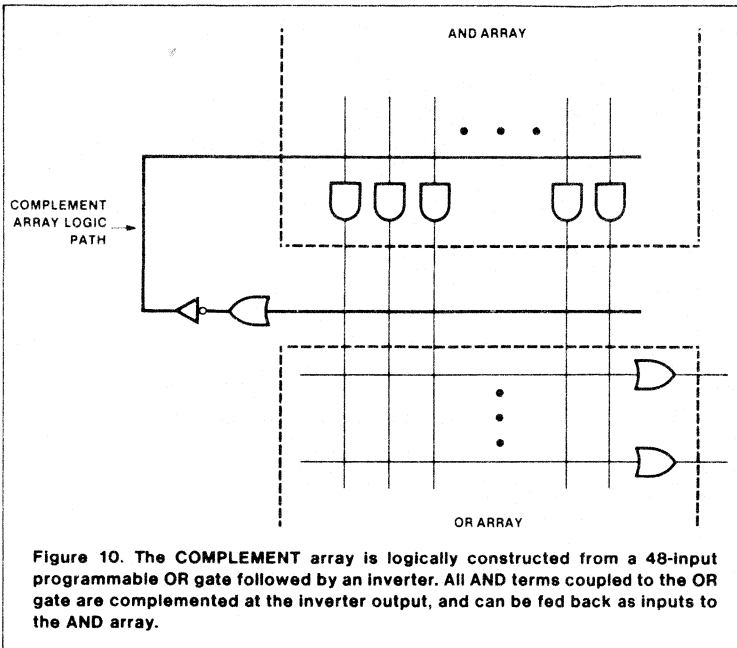

The COMPLEMENT array provides an asynchronous feed back path from the OR array back to the AND array.

This structure enables the FPLS to perform both direct and complement sequential state jumps with a minimum of transition (AND) terms.

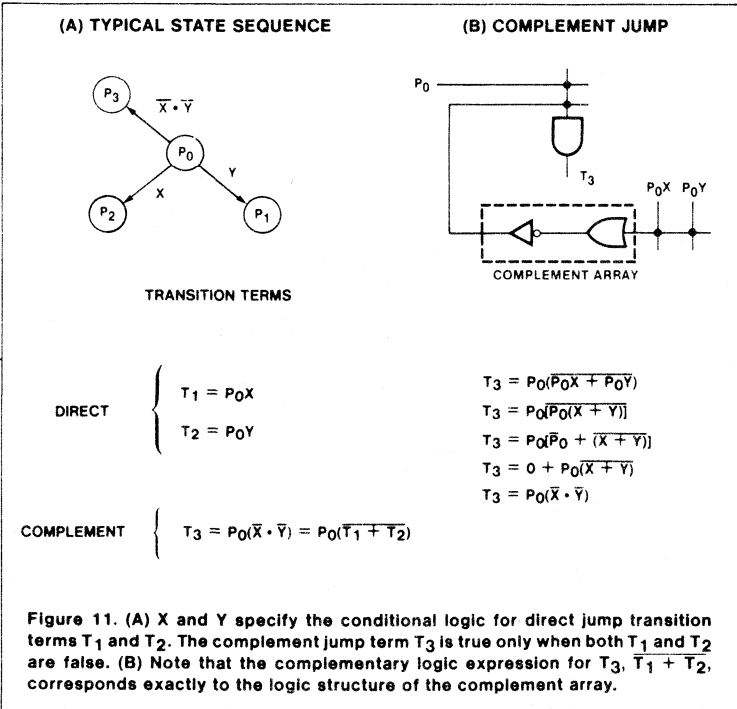

Typically direct jumps, such as T_1 and T_2 in Figure 11 require only a single AND gate each.

But a complement jump such as T_3 generally requires many AND gates if implemented as a direct jump. However, by using the complement array, the logic requirements for this type of jump can be handled with just one more gate from the AND array.

As indicated in Figure 12, the single complement array gate may be used for many states of the state diagram. This happens because all transition terms linked to the OR gate include the present state as a part of their conditional logic. In any particular state only those transition terms which are a function of that state are enabled; all other terms coupled to different states are disabled and do not influence the output of the complement array. As a general rule of thumb, the complement array can be used as many times as there are states.

(A) STATE DIAGRAM

(B) LOGIC DEFINITION

$$T_{d1} = I_0 \bar{I}_1 P_0$$

$$T_{d2} = I_2 P_0$$

$$T_{c3} = (T_{d1} + T_{d2}) P_0 = (I_0 \bar{I}_1 + I_2) P_0$$

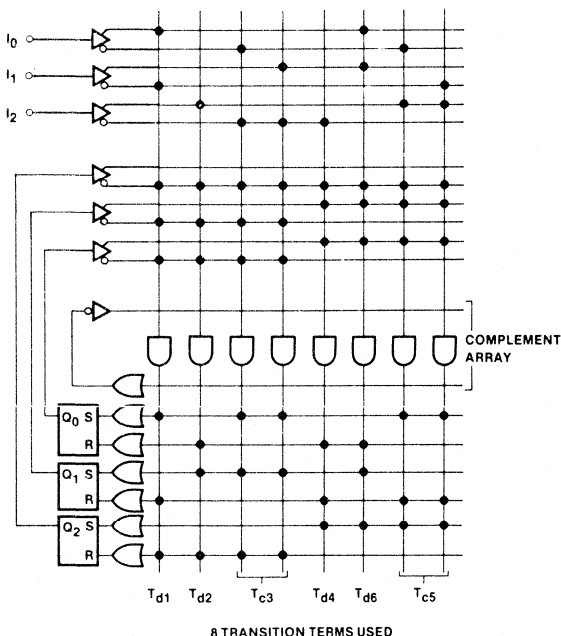

$$T_{d4} = \bar{I}_2 P_3$$

$$T_{d6} = I_0 I_1 P_3$$

$$T_{c5} = (T_{d4} + T_{d6}) P_3 = (I_0 I_1 + \bar{I}_2) P_3$$

 T_{dn} = DIRECT STATE TRANSITION TERM
 P_n = PRESENT STATE

(C) STATE LOGIC WITHOUT USING THE COMPLEMENT ARRAY

(D) STATE LOGIC USING THE COMPLEMENT ARRAY

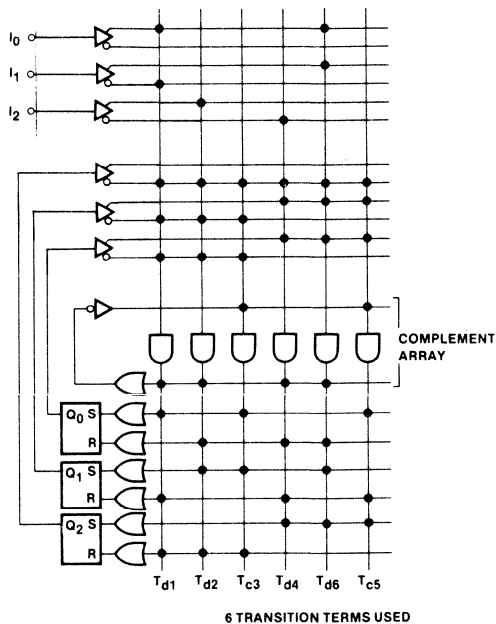

Figure 12. Logic reduction with the complement array. The logic state diagram in (a) includes complement jumps T_{c3} and T_{c5} defined in (b). When using the complement array a savings of 2 transition terms results, as shown in (c) and (d).

IFL-20 SEQUENTIAL DEVICES

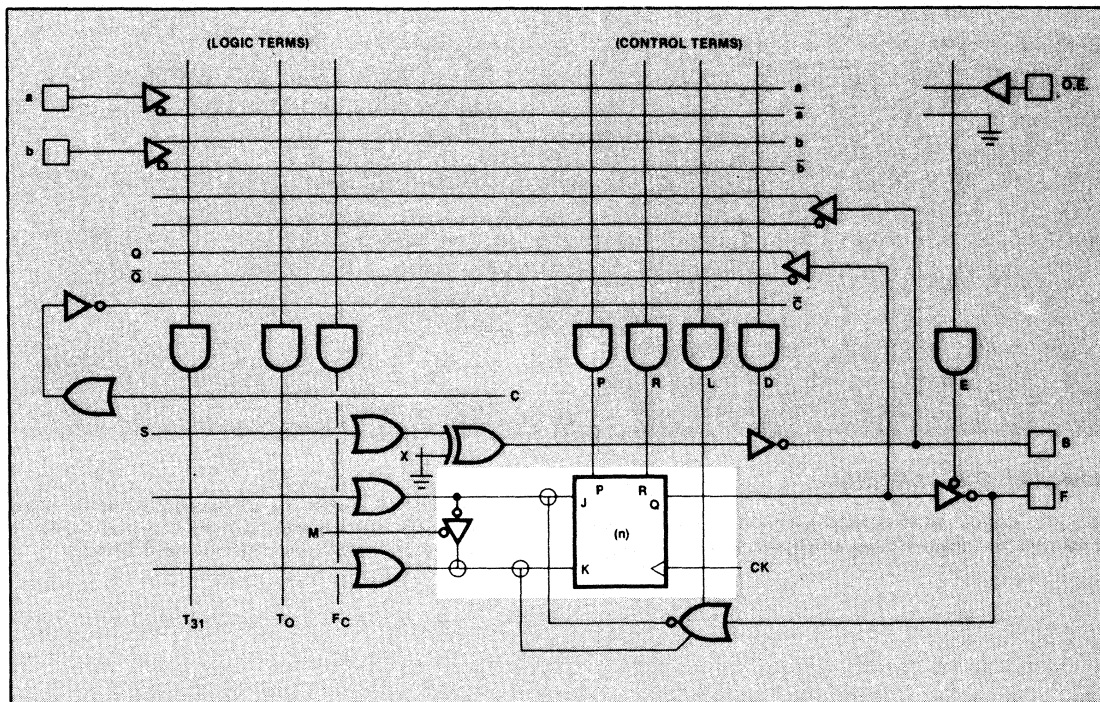

The 20-pin IFL family also includes sequential devices. These devices are all similar in architecture. The major difference consists of the number of outputs which are registered. The following table summarizes the IFL-20 sequential family.

| DEVICE | REGISTERED OUTPUTS | OUTPUT TYPE |
|--------|--------------------|-------------|
| 82S155 | 4-Bit Register | T.S. |
| 82S157 | 6-Bit Register | T.S. |
| 82S159 | 8-Bit Register | T.S. |

FEATURES

The IFL-20 sequencers have been designed with a maximum of flexibility in mind. Each element of the architecture contributes to the ease of use the IFL-20 family provides. Each part has the features listed:

- J/K flip-flop Output Register
- Dynamic control of flip-flop type (J/K or D)
- Parallel bus load
- Asynchronous preset and reset capability
- Combinational I/O pins
- Programmable enable pins
- Output feedback to AND array available

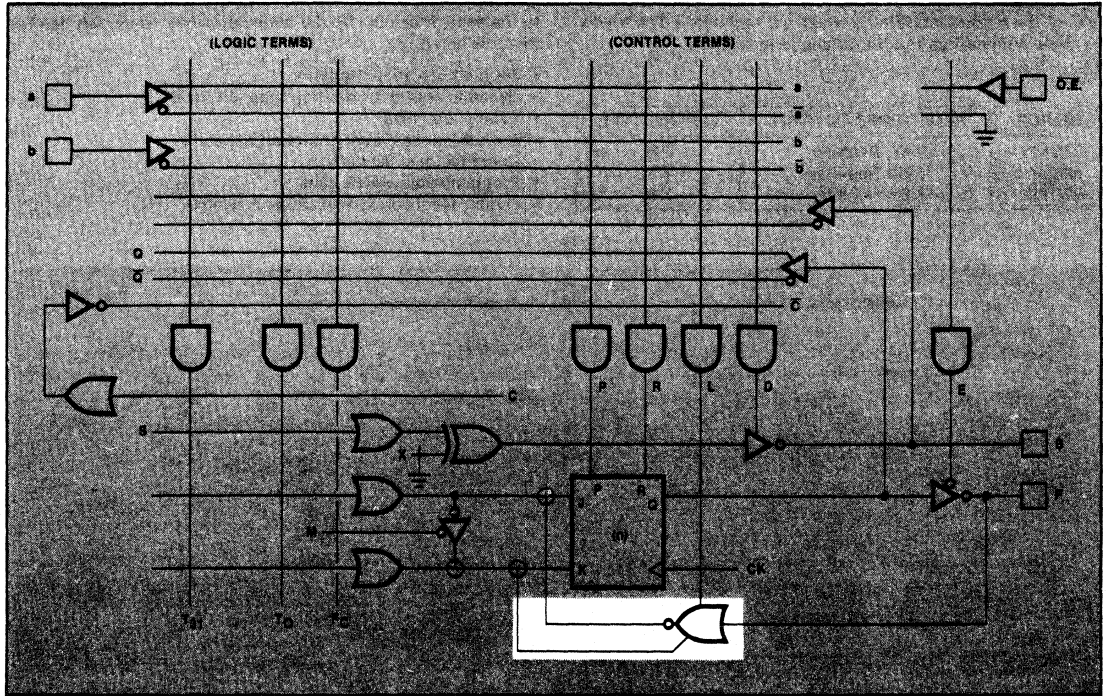

OUTPUT REGISTER

The output register of the IFL-20 sequential devices are comprised of fully implemented J/K flip-flops. Each flip-flop is positive edge-triggered from a common clock.

In addition, a dynamically controllable "foldback" buffer between the J and K inputs to the flip-flop allows the designer to change the function of the flip-flop from J/K to D type under the control of the flip-flop control term (F). A fuse allows the designer to dedicate the flip-flop as a permanent D-type by programming the fuse.

By leaving the fuse intact, the flip-flop control line (F) is maintained as the active mode control. If the output of F is logic Low (0), then the flip-flop is configured as a D-type. If the output of F is a logic High (1), then the flip-flop is configured as a J/K type. Term F is programmed in the same manner as the 32 logic transition terms (T). It is well to note at this time that when the flip-flop is configured as a D-type, the OR-term driving the K input must not be active.

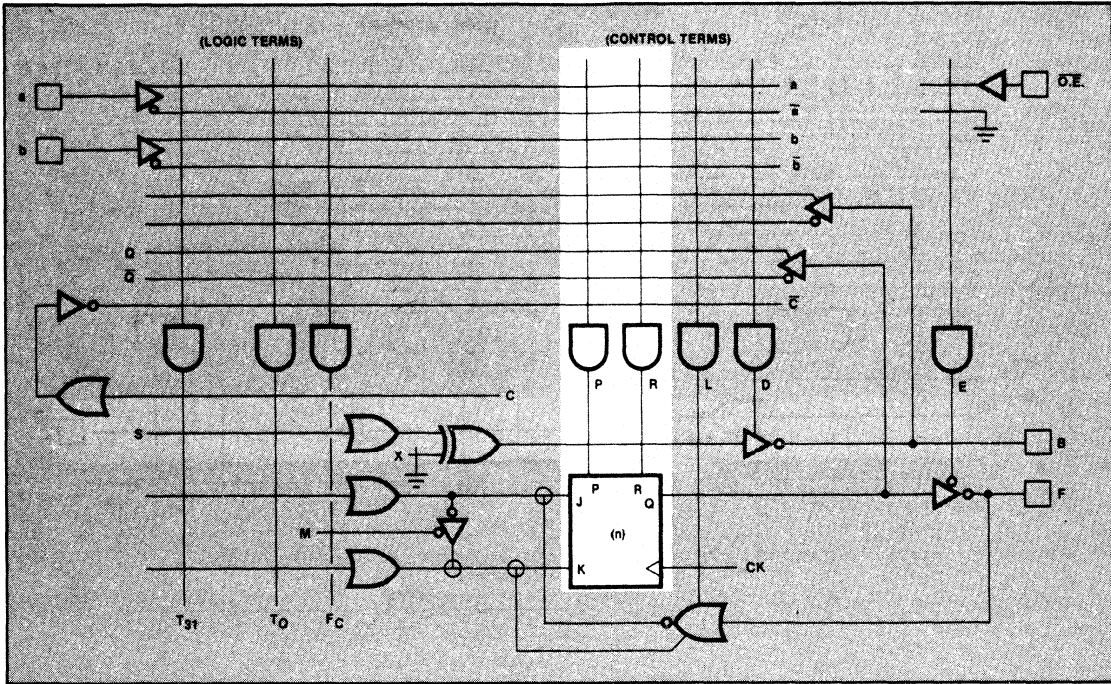

During all modes of operation, the output register data is fed back to the AND array. This feedback is used to establish present-state to next-state jumps.

PARALLEL BUS LOADING

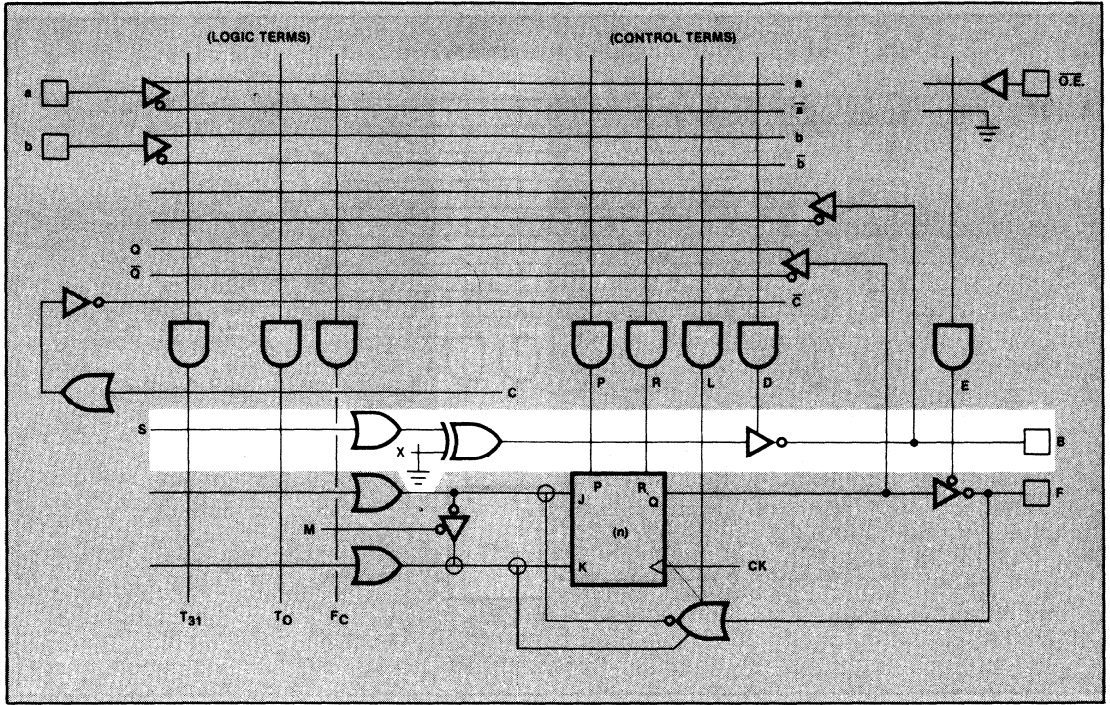

The output register may be loaded from the bus via the load control term (L). This feature forces the data contained on the F_0 pin

into the J/K flip-flop. It operates synchronously with the rising edge of the clock. This feature can be used to preload a state into the machine, or to latch input data into the AND array.

PRESET AND RESET

Asynchronous preset and reset capability has been provided on the IFL-20 sequential devices. This feature is controlled in the AND-array on the 82S159. The remainder of the IFL-20 devices are controlled via the OR-array. See the individual data sheet for details.

COMBINATIONAL I/O PINS

Each IFL-20 sequential device has a number of combinational pins (B₀) which can be programmed and used exactly as the B

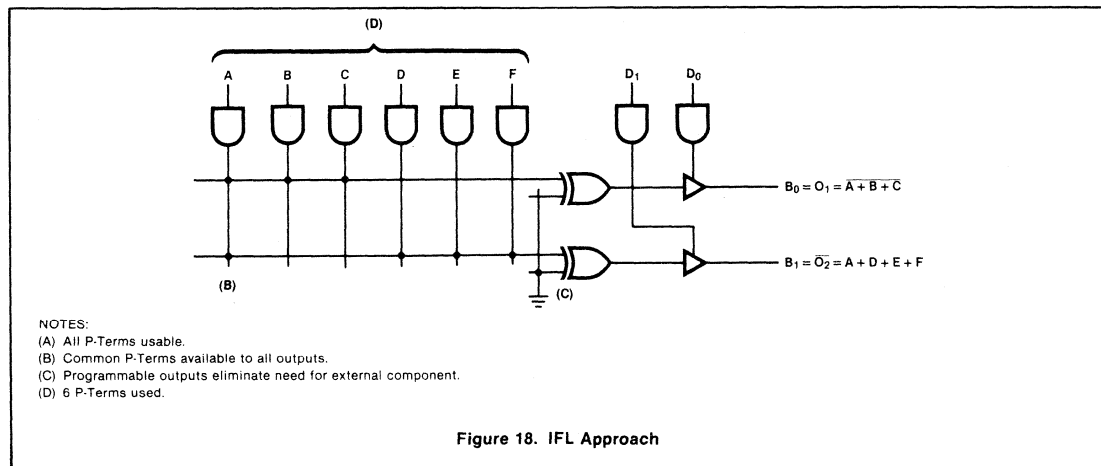

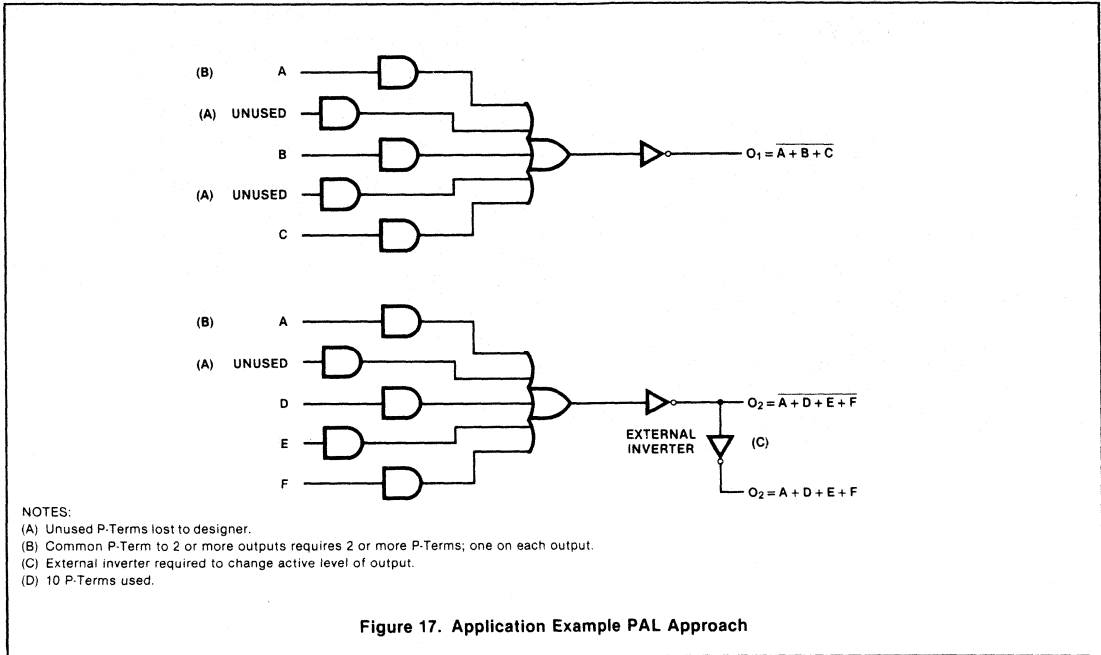

pins on the 82S153 FPLA. The direction control term (D) establishes the data flow on these pins. The individual data sheet should be consulted for the quantity and pin number assignment for each device.

PLA vs. PAL® arrays

The PLA architecture provides the most efficient means of implementing logic. The 28-pin devices, 82S100/101 and 82S102/103 are unique in their ability to directly implement logic.

They offer the most useable P-terms, the highest number of inputs and outputs, and the most straightforward programming of any logic device in the industry. The following diagrams illustrate the relative ease of programming the flexible PLA structure against the fixed OR array of the PAL.

IFL FAMILY SUMMARY

FIELD PROGRAMMABLE GATE ARRAYS

| | | | |
|--------|---------|--------|-------------|
| 82S103 | 16 × 9 | 28-pin | Three-State |
| 82S151 | 18 × 12 | 20-pin | Three-State |
| 82S162 | 12 × 9 | 24-pin | Three-State |
| 82S163 | 16 × 5 | 24-pin | Three-State |

FIELD PROGRAMMABLE LOGIC ARRAYS

| | | | |
|--------|--------------|--------|----------------|
| 82S100 | 16 × 48 × 8 | 28-pin | Three-State |
| 82S101 | 16 × 48 × 8 | 28-pin | Open Collector |
| 82S153 | 18 × 32 × 10 | 20-pin | Three-State |
| 82S161 | 12 × 48 × 8 | 24-pin | Three-State |

FIELD PROGRAMMABLE LOGIC SEQUENCERS

| | | | |
|--------|--------------|--------|--------------------------|
| 82S105 | 16 × 48 × 8 | 28-pin | T.S. Mealy State Machine |
| 82S155 | 16 × 32 × 12 | 20-pin | T.S. 4-bit Sequencer |
| 82S157 | 16 × 32 × 12 | 20-pin | T.S. 6-bit Sequencer |
| 82S159 | 16 × 32 × 12 | 20-pin | T.S. 8-bit Sequencer |
| 82S167 | 14 × 48 × 6 | 24-pin | T.S. 6-bit Sequencer |

The Signetics approach to programmable logic gives the designer the flexibility he needs where he needs it — in the device itself. The combination of totally flexible architecture, more useable product terms, and ease of logic implementation make Signetics Integrated Fuse Logic the obvious choice.

PROGRAMMING INFORMATION

IFL PROGRAMMING

The Signetics family of Integrated Fuse Logic (IFL) products are high-performance bipolar devices which use a nickel-chromium (Ni-Cr) alloy fuse to provide the many benefits of field programming. Programming is accomplished by application of voltages above those used for normal operation; therefore, no special pins are required for programming. The programming voltages and timing requirements make unintentional programming virtually impossible.

PROGRAMMING INFORMATION

Complete programming system specifications for IFL 20-, 24-, and 28-pin products are available upon request from Bipolar Memory Marketing.

Signetics encourages the purchase of programming equipment from a manufacturer who has a full line of programming products to offer. Signetics also encourages the manufacturers of IFL programming equipment to submit their equipment for verification of electrical parameters and programming procedures. Information on manufacturers offering equipment certified by Signetics is available on request from Bipolar Memory Marketing.

SIGNETICS DISCOURAGES THE CONSTRUCTION AND USE OF "HOMEMADE" PROGRAMMING EQUIPMENT

In order to consistently achieve excellent programming yields, periodic calibration of the programming equipment is required. Consult the equipment manufacturer for the recommended calibration interval. Records of programming yield, by device type, should be kept and any downward trend or sudden change should be considered as an indication of a need to recalibrate the programming equipment.

FIELD PROGRAMMABLE GATE ARRAY (18x15x12)

82S151 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

DESCRIPTION

The 82S151 is a single level logic element, consisting of 12 AND gates with fusible link connections for programming I/O polarity, I/O direction and output enable control.

All gates are linked to 6 inputs (I) and 12 bidirectional I/O lines (B). These yield variable I/O gate configurations via 3 direction control gates (D), ranging from 18 inputs to 12 outputs.

On chip T/C buffers couple either True (I, B) or Complement (\bar{I} , \bar{B}) input polarities to each AND gate. The polarity of all gate outputs is individually programmable through a set of EX-OR gates for implementing AND/NAND logic functions. Alternately, if desired, OR/NOR logic functions can also be realized by programming for each gate the complement of its inputs and output (DeMorgan's Theorem).

The 82S151 is field programmable, enabling the user to quickly generate custom patterns using standard programming equipment.

This device is available in a 20-pin slim-line package. For the commercial temperature range (0°C to +75°C), specify N82S151N. For the military temperature range (-55°C to +125°C), specify S82S151F.

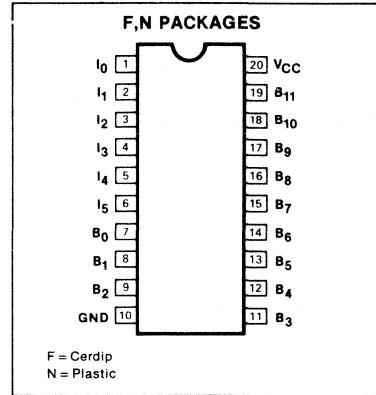

FEATURES

- Field Programmable (Ni-Cr link)
- 6 inputs
- 15 Product Terms:
12 Logic Terms
3 Control Terms
- 12 bidirectional I/O lines
- Active high or low outputs
- Programmable output enable
- Power dissipation: 650mW (typ)
- I/O propagation delay: 25ns (max)
- Input loading
N82S151: -100µA (max)
S82S151: -150µA (max)
- Output: three-state
- TTL compatible

APPLICATIONS

- Random gating functions
- Address decoding
- Code detectors
- Memory mapped I/O
- Fault monitors
- I/O port decoders

PIN CONFIGURATION

3

LOGIC FUNCTIONS

Typical Output Functions:

Active-High

$$X = A \cdot \bar{B} \cdot C \cdot \dots$$

Active-Low

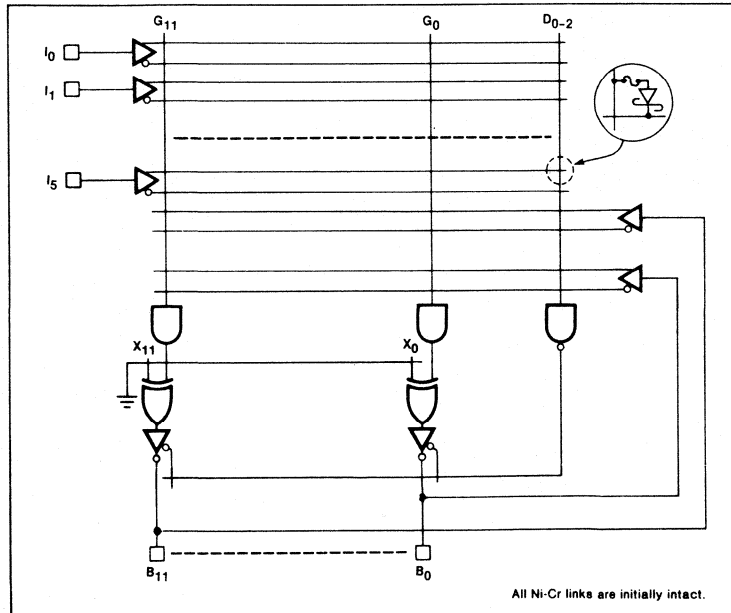

$$X = A \cdot \bar{B} \cdot C \cdot \dots$$

$$X = \bar{A} + B + \bar{C} + \dots$$

NOTES:

1. For each of the 12 outputs, either function X (active-high) or \bar{X} (active-low) is available, but not both. The desired output polarity is programmed via the EX-OR gates.
2. X, A, B, C, etc. are user defined connections to fixed inputs (I) and bidirectional pins (B).

LOGIC PROGRAMMING

In a virgin device all Ni-Cr links are intact.

The FPGA can be programmed by means of Logic programming equipment.

With Logic programming, the AND/EX-OR gate input connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table on the following page.

In this Table the logic state of variables I and B associated with each gate Gn, Dn is assigned a symbol which results in the proper fusing pattern of corresponding links defined as follows:

I/O DIRECTION — (B)

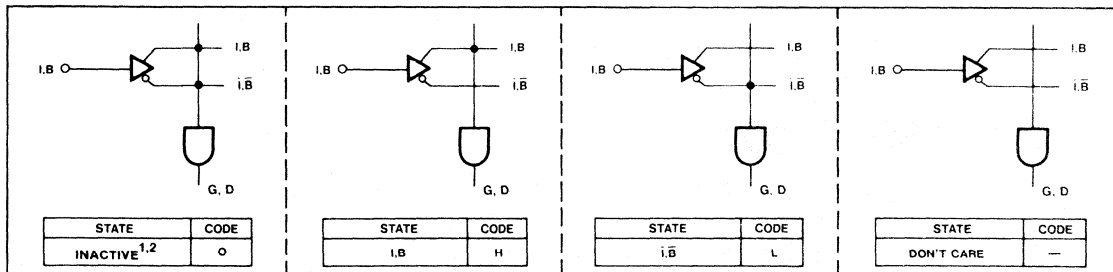

OUTPUT POLARITY — (B)

3

"AND" ARRAY — (I,B)

NOTES:

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates Gn, Dn.
2. Any gate Gn, Dn will be unconditionally inhibited if any one of the (I, B) link pairs is left intact.

FIELD PROGRAMMABLE LOGIC ARRAY (18 × 42 × 10) 82S153/82S153A (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

DESCRIPTION

The 82S153 and 82S153A are two-level logic elements, consisting of 32 AND gates and 10 OR gates with fusible link connections for programming I/O polarity and direction.

All AND gates are linked to 8 inputs (I) and 10 bidirectional I/O lines (B). These yield variable I/O gate configurations via 10 direction control gates (D), ranging from 18 inputs to 10 outputs.

On chip T/C buffers couple either True (I, B) or Complement (I, B) input polarities to all AND gates, whose outputs can be optionally linked to all OR gates. Their output polarity, in turn, is individually programmable through a set of EX-OR gates for implementing AND/OR or AND/NOR logic functions.

The 82S153 and the 82S153A are field programmable, enabling the user to quickly generate custom patterns using standard programming equipment.

Both devices are available in a 20-pin slim line package. For the commercial temperature range (0°C to +75°C) specify N82S153 N or F and N82S153A N or F. For the military temperature range (-55°C to +125°C) specify S82S153 F only and S82S153A F only.

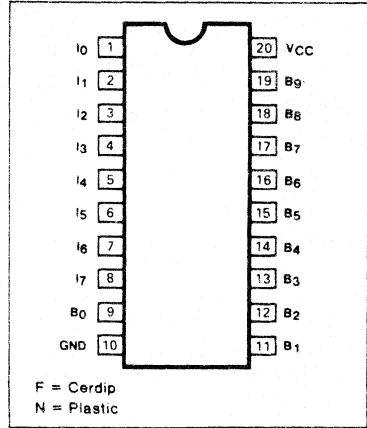

FEATURES

- Field Programmable (Ni-Cr links)
- 8 inputs
- 32 AND gates
- 10 OR gates
- 10 bidirectional I/O lines
- Active high or low outputs
- 42 Product Terms:
 - 32 Logic Terms
 - 10 Control Terms
- I/O propagation delay:
 - N82S153: 40ns (max)
 - N82S153A: 30ns (max)
 - S82S153: 60ns (max)
 - S82S153A: 45ns (max)
- Input loading
 - N82S153: -100µA (max)
 - S82S153: -150µA (max)
- Power dissipation: 650mW (typ)
- Output: three-state
- TTL compatible

APPLICATIONS

- Random logic
- Code converters
- Fault detectors
- Function generators
- Address mapping
- Multiplexing

PIN CONFIGURATION

3

LOGIC FUNCTION

Typical product term:
 $P_n = A \cdot \bar{B} \cdot C \cdot D \cdot \dots$

Typical logic function:
 At Output Polarity = H
 $Z = P_0 + P_1 + P_2 \dots$

At Output Polarity = \bar{L}
 $Z = P_0 + P_1 + P_2 + \dots$
 $Z = P_0 \cdot P_1 \cdot P_2 \dots$

NOTES:
 1. For each of the 10 outputs, either function Z (active-high) or Z (active-low) is available, but not both. The desired output polarity is programmed via the EX-OR gates.
 2. Z, A, B, C, etc. are user defined connections to fixed inputs (I) and bidirectional pins (B).

LOGIC PROGRAMMING

The FPLA can be programmed by means of Logic programming equipment.

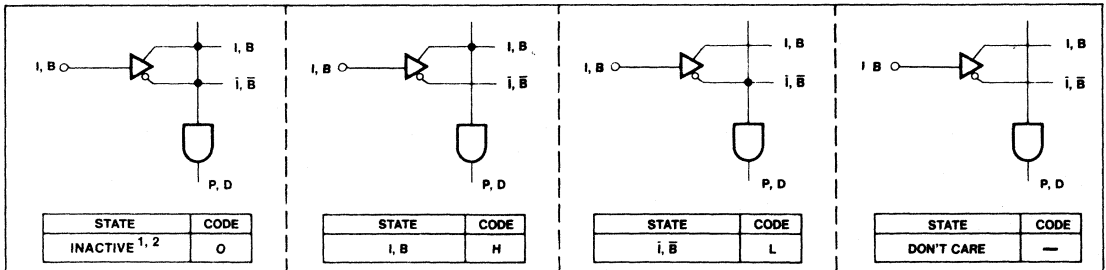

With Logic programming, the AND/OR/EX-OR gate input connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table on the following page.

In this Table the logic state of variables I, P, and B associated with each Sum Term S is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

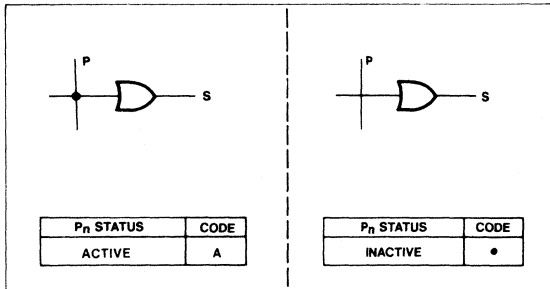

OUTPUT POLARITY — (B)

“AND” ARRAY — (I, B)

“OR” ARRAY — (B)

VIRGIN STATE

A factory shipped virgin device contains all fusible links intact, such that:

1. All outputs at “H” polarity.
2. All P_n terms are disabled.
3. All P_n terms are active on all outputs.

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates P_n, D_n.
2. Any gate P_n, D_n will be unconditionally inhibited if any one of its (I, B) link pairs is left intact.

FIELD PROGRAMMABLE LOGIC ARRAY (18x42x10) 82S153/82S153A (T.S.)

SERIES 20

TWX TAPE CODING (LOGIC FORMAT)

The FPLA Program Table can be sent to Signetics in ASCII code format via airmail using any type of 8-level tape (paper, mylar,

fanfold, etc.), or via TWX: just dial (910) 339-9283, tell the operator to turn the paper puncher on, and acknowledge. At the end of transmission instruct the operator to send tape to Signetics Order Entry.

A number of Program Tables can be sequentially assembled on a continuous tape as follows, however, limit tape length to a roll of 1.75 inch inside diameter and 4.25 inch outside diameter.

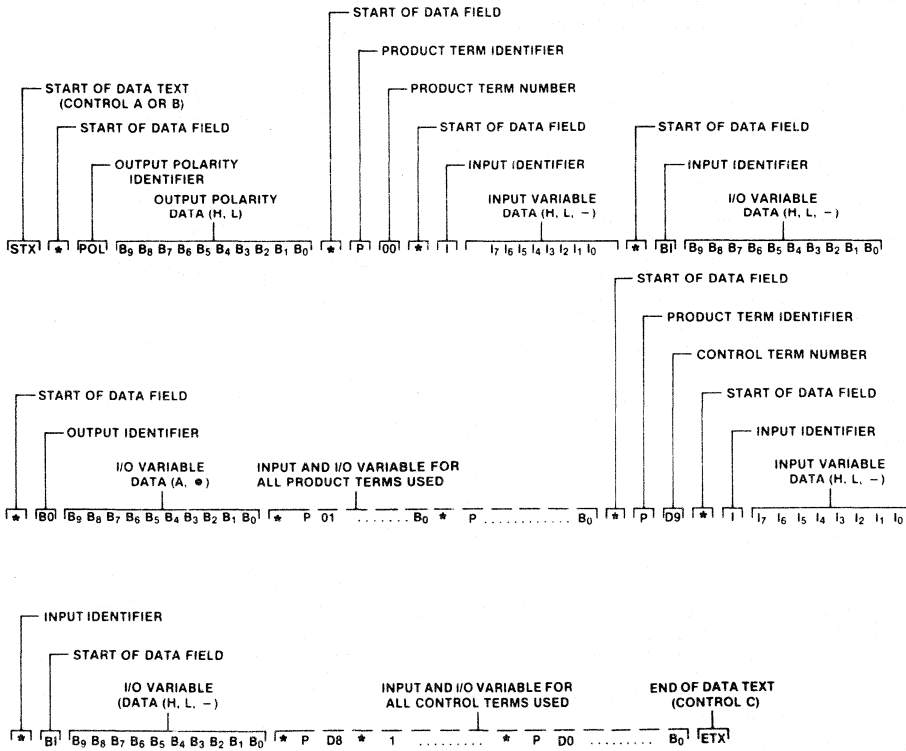

A. The MAIN HEADING at the beginning of tape includes the following information, with each entry preceded by a (\$) character, whether used or not:

1. Customer Name _____
2. Customer TWX No. _____
3. Date _____
4. Purchase Order No. _____
5. Number of Program Tables _____
6. Total Number of Parts _____

B. Each SUB HEADING should contain specific information pertinent to each Program Table as follows, with each entry preceded by a (\$) character, whether used or not:

1. Signetics Device No. _____
2. Program Table No. _____
3. Revision _____
4. Date _____
5. Customer Symbolized Part No. _____
6. Number of Parts _____

C. Program Table data blocks are initiated with an STX character, and terminated with an ETX character. The body of the data consists of output polarity, product term, and output information separated by appropriate identifiers in accordance with the following format. Entries for the data fields correspond to those defined in the Logic PROGRAM TABLE:

3

FIELD PROGRAMMABLE LOGIC SEQUENCER
(16x45x12)

82S155 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

DESCRIPTION

The 82S155 is a Three-State output, registered logic element combining AND/OR gate arrays with clocked J-K flip-flops, dynamically convertible to D-type via a "fold-back" inverting buffer and control gate F_C. It features 4 registered I/O outputs (F) in conjunction with bidirectional I/O lines (B). These yield variable I/O gate and register configurations via control gates (D, L) ranging from 16 inputs to 12 outputs.

The AND/OR arrays consist of 32 logic AND gates, 10 control AND gates, and 21 OR gates with fusible link connections for programming I/O polarity and direction. All AND gates are linked to 4 inputs (I), bidirectional I/O lines (B), internal flip-flop outputs (Q), and Complement Array output (C̄). The Complement Array consists of a NOR gate optionally linked to all AND gates for generating and propagating complementary AND terms.

On-chip I/C buffers couple either True (I, B, Q) or Complement (Ī, B̄, Q̄, C̄) input polarities to all AND gates, whose outputs can be optionally linked to all OR gates. One group of AND gates drives bidirectional I/O lines (B), whose output polarity is individually programmable through a set of EX-OR gates for implementing AND-OR or AND-NOR logic functions. Another group drives

the J-K inputs of all flip-flops. The Asynchronous Preset and Reset lines (P, R), are driven from the OR matrix.

All flip-flops are positive edge-triggered and can be used as input, output or I/O (for interfacing with a bidirectional data bus) in conjunction with load control gates (L), steering inputs (I), (B), (Q) and programmable output select lines (E).

The 82S155 is field programmable, enabling the user to quickly generate custom patterns using standard programming equipment.

The 82S155 is available in a 20-pin, slim line package. For the commercial temperature range (0°C to +75°C), specify N82S155N. For the military range (-55°C to +125°C), specify S82S155F only.

FEATURES

- Field programmable (Ni-Cr link)
- 4 dedicated inputs
- 13 control gates
- 32 AND gates
- 21 OR gates
- 45 product terms:
 32 logic terms
 13 control terms
- 8 bidirectional I/O lines
- 4 bidirectional registers

PIN CONFIGURATION

- J-K, T, or D-type flip-flops
- Asynchronous Preset/Reset
- Complement Array
- Active HIGH or LOW outputs
- Programmable OE control
- Positive edge-triggered clock
- Clock frequency: N82S155: 15MHz (max)
- Inut loading: N82S155: -100µA (max)
 S82S155: -150µA (max)
- Power dissipation: 650mW (typ)
- TTL compatible

APPLICATIONS

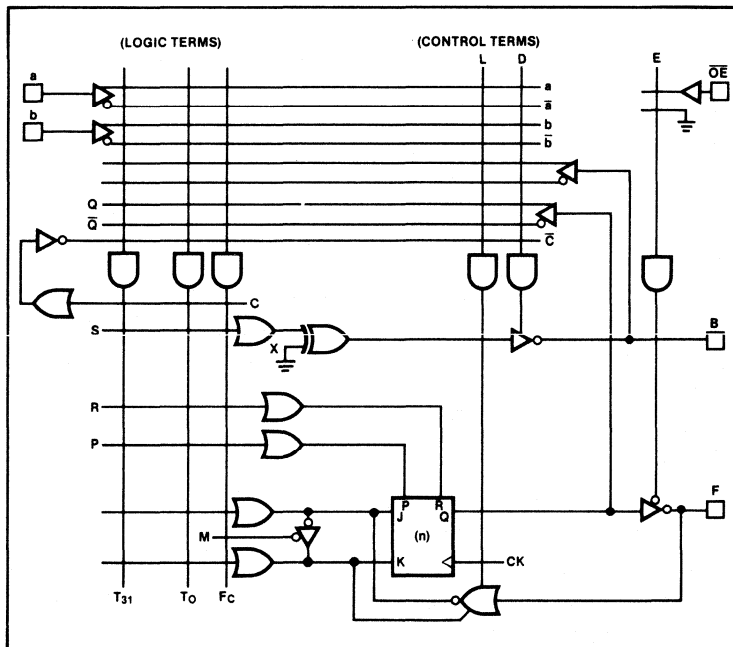

- Random sequential logic
- Synchronous up/down counters
- Shift registers
- Bidirectional data buffers
- Timing function generators
- System controllers/synchronizers
- Priority encoder/registers

FLIP-FLOP TRUTH TABLE

| VCC | OE | L | CK | P | R | J | K | Q | F |
|------|----|---|----|---|---|---|---|---|--------|

- NOTES
1. Positive Logic:
J/K = T₀ + T₁ + T₂ + ... + T₄₇
T_n = C̄ • (I₀ • I₁ • I₂ • ...) • (Q₀ • Q₁ • ...) • (B₀ • B₁ • ...)
 2. ↑ denotes transition from Low to High level.
 3. X = Don't Care
 4. * = Forced at F_n pin for loading J/K flip-flop in I/O mode. L must be enabled, and other active T_n disabled via steering input(s) I, B, or Q.
 5. At P = R = H, Q = H. The final state of Q depends on which is released first.
 6. ** = Forced at F_n pin to load J/K flip-flop independent of program code (Diagnostic mode).

- NOTES
- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device of these of any other condition above those indicated in the operation of the device specifications is not implied.
 - All typical values are at V_{CC} = 5V, T_A = 25°C.
 - All voltage values are with respect to network ground terminal.
 - Test one at a time.
 - Measured with V_{IH} applied to \overline{OE} .
 - Duration of short circuit should not exceed 1 second.
 - I_{CC} is measured with the \overline{OE} input grounded, all other inputs at 4.5V, and the outputs open.
 - Leakage values are a combination of input and output leakage.

The FPLS can be programmed by means of Logic Programming equipment.

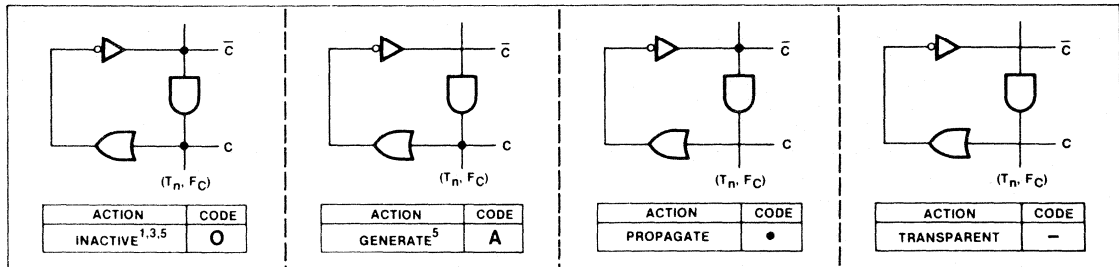

OR input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Tables on the following pages.

In these Tables, the logic state or action of all I/O, control, and state variables is assigned a symbol which results in the proper fusing pattern of corresponding links defined as follows:

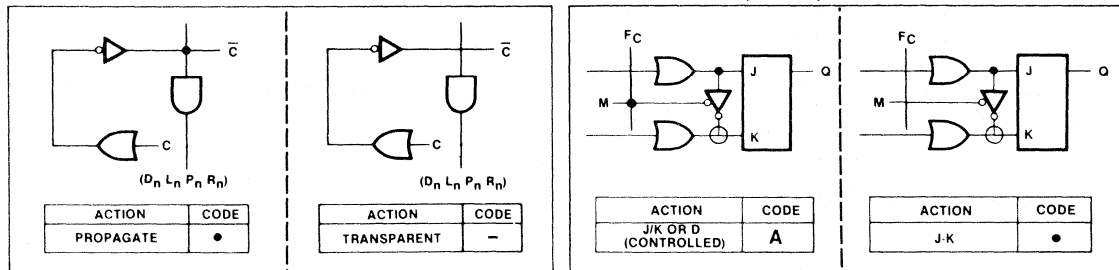

“AND” ARRAY – (I), (B), (Qp)

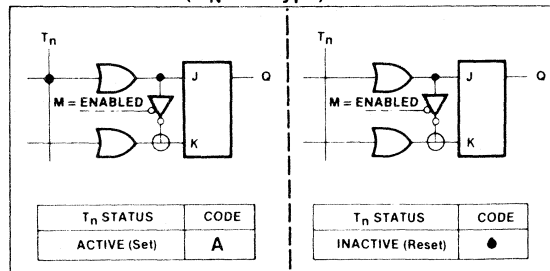

“COMPLEMENT” ARRAY – (C)

“OR” ARRAY – (MODE)

“OR” ARRAY – (Q_N = D-Type)

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates.
2. Any gate (T, F_C, L, P, R, D)_n will be unconditionally inhibited if any one of the I, B, or Q link pairs is left intact.
3. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n, F_C .
4. $E_n = O$ and $E_n = *$ are logically equivalent states, since both cause F_n outputs to be unconditionally enabled.
5. These states are not allowed for control gates (L, P, R, D)_n due to their lack of "OR" array links.

TEST ARRAY (82S155)

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on chip test array.

The array consists of test transition terms 32 and 50, factory programmed as shown below for the 82S155.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I₀₋₃ and B₀₋₃ as shown in the test circuit timing diagram.

TWX TAPE CODING (LOGIC FORMAT)

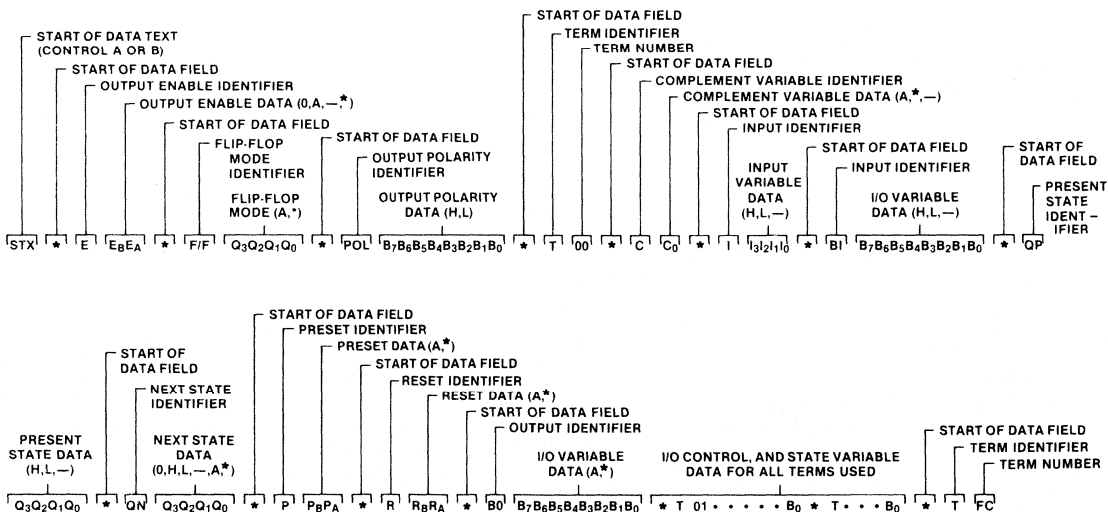

The FPLA Program Table can be sent to Signetics in ASCII code format via airmail using any type of 8-level tape (paper, mylar,

fanfold, etc.), or via TWX: just dial (910) 339-9283, tell the operator to turn the paper puncher on, and acknowledge. At the end of transmission instruct the operator to send tape to Signetics Order Entry.

A number of Program Tables can be sequentially assembled on a continuous tape as follows, however, limit tape length to a roll of 1.75 inch inside diameter and 4.25 inch outside diameter.

- A. The MAIN HEADING at the beginning of tape includes the following information, with each entry preceded by a (\$) character, whether used or not:
 1. Customer Name _____
 2. Customer TWX No. _____
 3. Date _____
 4. Purchase Order No. _____
 5. Number of Program Tables _____
 6. Total Number of Parts _____
- B. Each SUB HEADING should contain specific information pertinent to each Program Table as follows, with each entry preceded by a (\$) character, whether used or not:
 1. Signetics Device No. _____
 2. Program Table No. _____
 3. Revision _____
 4. Date _____
 5. Customer Symbolized Part No. _____
 6. Number of Parts _____
- C. Program Table data blocks are initiated with an STX character, and terminated with an ETX character. The body of the data consists of output polarity, product term, and output information separated by appropriate identifiers in accordance with the following format. Entries for the data fields correspond to those defined in the Logic PROGRAM TABLE:

82S157 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

DESCRIPTION

The 82S157 is a Three-State output, registered logic element combining AND/OR gate arrays with clocked J-K flip-flops, dynamically convertible to D-type via a "fold-back" inverting buffer and control gate F_c . It features 8 registered I/O outputs (F) in conjunction with bidirectional I/O lines (B). These yield variable I/O gate and register configurations via control gates (D, L) ranging from 16 inputs to 12 outputs.

The AND/OR arrays consist of 32 logic AND gates, 13 control AND gates, and 21 OR gates with fusible link connections for programming I/O polarity and direction. All AND gates are linked to 4 inputs (I), bidirectional I/O lines (B), internal flip-flop outputs (Q), and Complement Array output (\bar{C}). The Complement Array consists of a NOR gate optionally linked to all AND gates for generating and propagating complementary AND terms.

On-chip I/C buffers couple either True (I, B, Q) or Complement (\bar{I} , \bar{B} , \bar{Q} , \bar{C}) input polarities to all AND gates, whose outputs can be optionally linked to all OR gates. One group of AND gates drives bidirectional I/O lines (B), whose output polarity is individually programmable through a set of EX-OR gates for implementing AND-OR or AND-NOR logic functions. Another group drives the J-K inputs of all flip-flops. The Asynchronous Preset and Reset lines (P, R) for

two of the registers are driven from the AND matrix. The Preset and Reset lines (P, R) controlling the lower four registers are driven from the OR matrix.

All flip-flops are positive edge-triggered and can be used as input, output or I/O (for interfacing with a bidirectional data bus) in conjunction with load control gates (L), steering inputs (I), (B), (Q) and programmable output select lines (E).

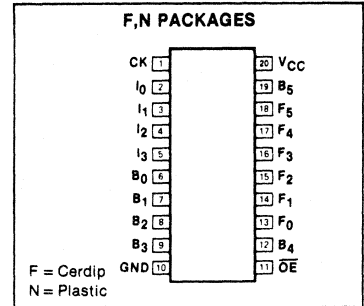

The 82S157 is field programmable, enabling the user to quickly generate custom patterns using standard programming equipment.

The 82S157 is available in a 20-pin, slim line package. For the commercial temperature range (0°C to +75°C), specify N82S157N. For the military range (-55°C to +125°C), specify S82S157F only.

FEATURES

- Field programmable (Ni-Cr link)
- 4 dedicated inputs
- 13 control gates
- 32 AND gates
- 21 OR gates
- 45 product terms:
32 logic terms
13 control terms
- 6 bidirectional I/O lines
- 6 bidirectional registers
- J-K, T, or D-type flip-flops

PIN CONFIGURATION

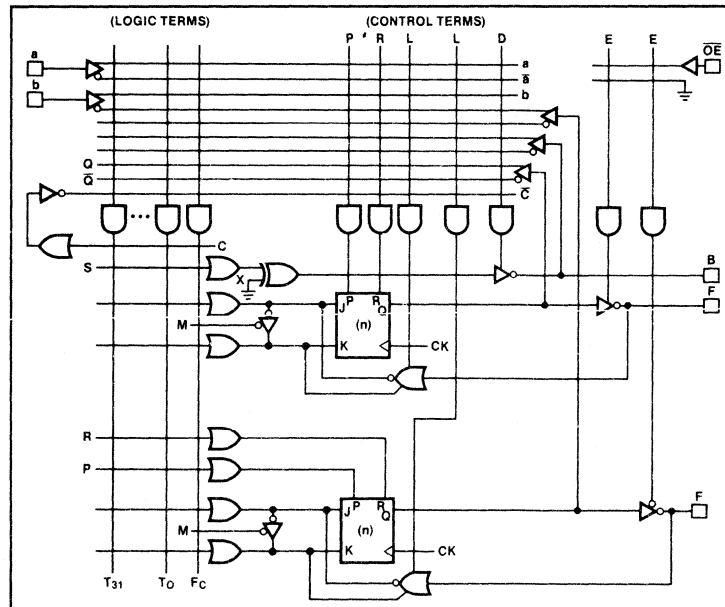

- Asynchronous Preset/Reset
- Complement Array
- Active HIGH or LOW outputs
- Programmable $\bar{O}\bar{E}$ control
- Positive edge-triggered clock
- Clock frequency: N82S157: 15MHz (max)
- Inut loading: N82S157: -100µA (max)
S82S157: -150µA (max)
- Power dissipation: 650mW (typ)
- TTL compatible

APPLICATIONS

- Random sequential logic
- Synchronous up/down counters
- Shift registers
- Bidirectional data buffers

| | X | ↑ | X | X | H | L | H | L** | |

- NOTES
1. Positive Logic:
 $J/K = T_0 + T_1 + T_2 + T_4 + T_7$
 $T_n = \bar{C} \cdot (I_0 + I_1 + I_2 + \dots) \cdot (Q_0 + Q_1 + \dots) \cdot (B_0 + B_1 + \dots)$
 2. ↑ denotes transition from Low to High level.
 3. X = Don't Care
 4. * = Forced at F_n pin for loading J/K flip-flop in I/O mode. L must be enabled, and other active T_n disabled via steering input(s) I, B, or Q.
 5. At $P = R = H$, $Q = H$. The final state of Q depends on which is released first.
 6. ** = Forced at F_n pin to load J/K flip-flop independent of program code (Diagnostic mode).

NOTES

- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device of these of any other condition above those indicated in the operation of the device specifications is not implied.
- All typical values are at V_{CC} = 5V, T_A = 25°C.
- All voltage values are with respect to network ground terminal.
- Test one at a time.
- Measured with V_{IH} applied to \overline{OE} .
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the \overline{OE} input grounded, all other inputs at 4.5V, and the outputs open.
- Leakage values are a combination of input and output leakage.

- NOTE
1. All typical values are at $V_{CC} = 5\text{V}$, $T_A = 25^\circ\text{C}$
 2. To prevent spurious clocking, clock rise time (10%:90%) $\leq 10\text{ns}$
 3. Measured at $V_T = V_{OL} + 0.5\text{V}$
 4. When using the Complement Array $T_{CKP} = 75\text{ns}$ (min)
 5. Limits are guaranteed with 12 product terms maximum connected to each sum term line.

TIMING DIAGRAMS

MEMORY TIMING DEFINITIONS

- TCKH Width of input clock pulse.
- TCKL Interval between clock pulses.
- TCKP Clock period.
- TPRH Width of preset input pulse.
- TIS1 Required delay between beginning of valid input and positive transition of clock.
- TIS2 Required delay between beginning of valid input forced at flip-flop output pins, and positive transition of clock.
- TIH1 Required delay between positive transition of clock and end of valid input data.
- TIH2 Required delay between positive transition of clock and end of valid input data forced at flip-flop output pins.
- TCKO Delay between positive transition of clock and when Outputs become valid (with \overline{OE} low).
- TOE1 Delay between beginning of Output Enable Low and when Outputs become valid.
- TOD1 Delay between beginning of Output Enable High and when Outputs are in the off state.
- TPD Propagation delay between combinational inputs and outputs.
- TOE2 Delay between predefined Output Enable High, and when combinational Outputs become valid.
- TOD2 Delay between predefined Output Enable Low and when combinational Outputs are in the off state.
- TPRO Delay between positive transition of predefined Preset/Reset input, and when flip-flop outputs become valid.

FIELD PROGRAMMABLE LOGIC SEQUENCER
(16x45x12)

82S157 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

The FPLS can be programmed by means of Logic Programming equipment.

OR input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Tables on the following pages.

In these Tables, the logic state or action of all I/O, control, and state variables is assigned a symbol which results in the proper fusing pattern of corresponding links defined as follows:

“AND” ARRAY – (I), (B), (Qp)

| <p>(T, F_C, L, P, R, D)_n</p> <table border="1" style="width:100%; border-collapse: collapse;"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>INACTIVE^{1,2}</td><td>O</td></tr> </table> | STATE | CODE | INACTIVE ^{1,2} | O | <p>(T, F_C, L, P, R, D)_n</p> <table border="1" style="width:100%; border-collapse: collapse;"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>I, B, Q</td><td>H</td></tr> </table> | STATE | CODE | I, B, Q | H | <p>(T, F_C, L, P, R, D)_n</p> <table border="1" style="width:100%; border-collapse: collapse;"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>I, B, Q</td><td>L</td></tr> </table> | STATE | CODE | I, B, Q | L | <p>(T, F_C, L, P, R, D)_n</p> <table border="1" style="width:100%; border-collapse: collapse;"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>DON'T CARE</td><td>—</td></tr> </table> | STATE | CODE | DON'T CARE | — |

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates.
2. Any gate (T_n, F_C, L, P, R, D_n) will be unconditionally inhibited if any one of the I, B, or Q link pairs is left intact.
3. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n, F_C .
4. $E_n = 0$ and $E_n = \bullet$ are logically equivalent states, since both cause F_n outputs to be unconditionally enabled.
5. These states are not allowed for control gates (L, P, R, D_n) due to their lack of "OR" array links.

TEST ARRAY (82S157)

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on chip test array.

The array consists of test transition terms 32 and 50, factory programmed as shown below for the 82S157.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I₀₋₃ and B₀₋₃ as shown in the test circuit timing diagram.

TWX TAPE CODING (LOGIC FORMAT)

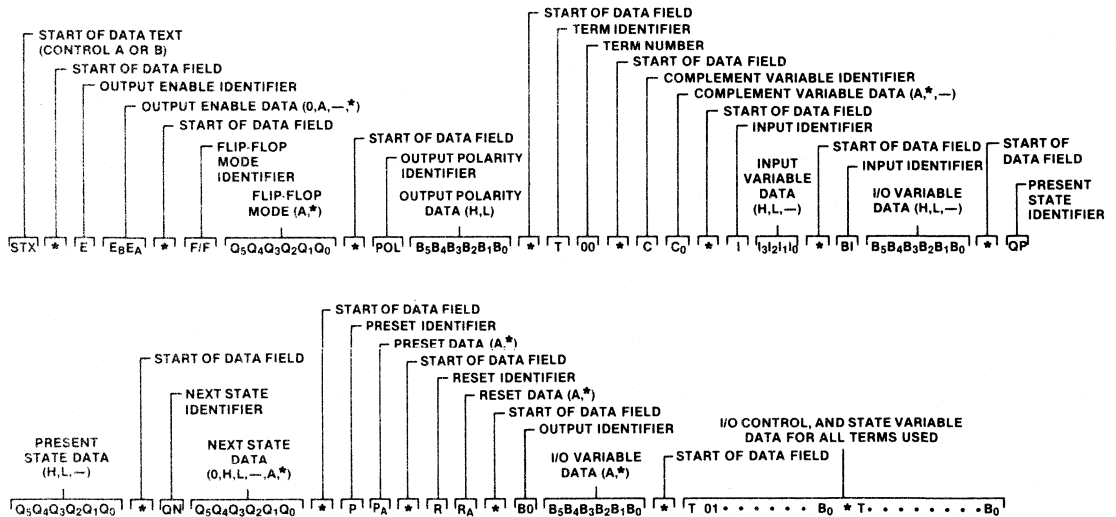

The FPLA Program Table can be sent to Signetics in ASCII code format via airmail using any type of 8-level tape (paper, mylar,

fanfold, etc.), or via TWX: just dial (910) 339-9283, tell the operator to turn the paper puncher on, and acknowledge. At the end of transmission instruct the operator to send tape to Signetics Order Entry.

A number of Program Tables can be sequentially assembled on a continuous tape as follows, however, limit tape length to a roll of 1.75 inch inside diameter and 4.25 inch outside diameter.

- A. The MAIN HEADING at the beginning of tape includes the following information, with each entry preceded by a (\$) character, whether used or not:
- Customer Name _____
 - Customer TWX No. _____
 - Date _____
 - Purchase Order No. _____
 - Number of Program Tables _____
 - Total Number of Parts _____
- B. Each SUB HEADING should contain specific information pertinent to each Program Table as follows, with each entry preceded by a (\$) character, whether used or not:
- Signetics Device No. _____
 - Program Table No. _____
 - Revision _____
 - Date _____
 - Customer Symbolized Part No. _____
 - Number of Parts _____
- C. Program Table data blocks are initiated with an STX character, and terminated with an ETX character. The body of the data consists of output polarity, product term, and output information separated by appropriate identifiers in accordance with the following format. Entries for the data fields correspond to those defined in the Logic PROGRAM TABLE:

82S159 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 20

DESCRIPTION

The 82S159 is a Three-State output, registered logic element combining AND/OR gate arrays with clocked J-K flip-flops, dynamically convertible to D-type via a "fold-back" inverting buffer and control gate F_C . It features 8 registered I/O outputs (F) in conjunction with bidirectional I/O lines (B). These yield variable I/O gate and register configurations via control gates (D, L) ranging from 16 inputs to 12 outputs.

The AND/OR arrays consist of 32 logic AND gates, 13 control AND gates, and 21 OR gates with fusible link connections for programming I/O polarity and direction. All AND gates are linked to 4 inputs (I), bidirectional I/O lines (B), internal flip-flop outputs (Q), and Complement Array output (\bar{C}). The Complement Array consists of a NOR gate optionally linked to all AND gates for generating and propagating complementary AND terms.

On-chip I/C buffers couple either True (I, B, Q) or Complement (\bar{I} , \bar{B} , \bar{Q} , \bar{C}) input polarities to all AND gates, whose outputs can be optionally linked to all OR gates. One group of AND gates drives bidirectional I/O lines (B), whose output polarity is individually programmable through a set of EX-OR gates for implementing AND-OR or AND-NOR logic functions. Another group drives the J-K inputs of all flip-flops, as well as asynchronous Preset and Reset lines (P, R).

All flip-flops are positive edge-triggered and can be used as input, output or I/O (for interfacing with a bidirectional data bus) in conjunction with load control gates (L), steering inputs (I), (B), (Q) and programmable output select lines (E).

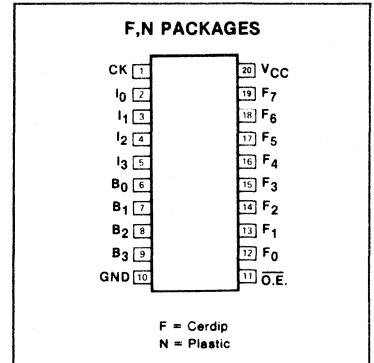

The 82S159 is field programmable, enabling the user to quickly generate custom patterns using standard programming equipment.

The 82S159 is available in a 20-pin, slim line package. For the commercial temperature range (0°C to +75°C), specify N82S159N. For the military range (-55°C to +125°C), specify S82S159F only.

FEATURES

- Field programmable (Ni-Cr link)
- 4 dedicated inputs
- 13 control gates
- 32 AND gates
- 21 OR gates
- 45 product terms:
- 32 logic terms
- 13 control terms
- 4 bidirectional I/O lines
- 8 bidirectional registers
- J/K, T, or D-type flip-flops
- Asynchronous Preset/Reset
- Complement Array
- Active high or low outputs
- Programmable $\bar{O.E.}$ control
- Positive edge trigger clock
- Power-on reset on all flip-flops ($F_N = "1"$)
- Clock frequency: N82S159: 15 MHz (max)
S82S159: MHz
- Input loading: N82S159: -100 μ A (max)
S82S159: -150 μ A (max)
- Power dissipation: 650mW (typ)
- TTL Compatible

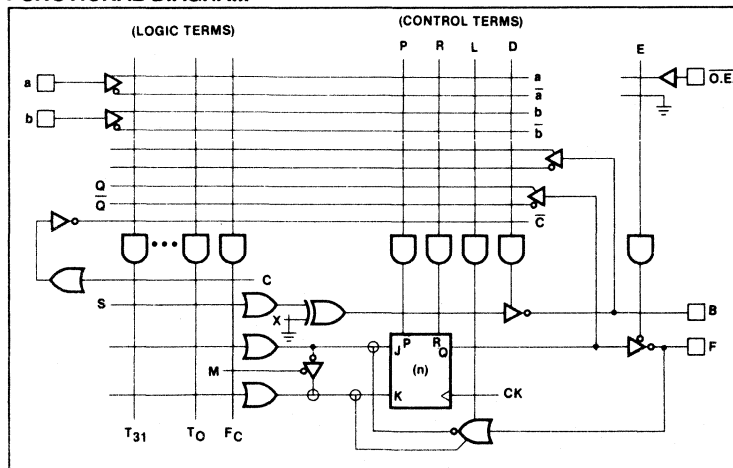

PIN CONFIGURATION

APPLICATIONS

- Random sequential logic
- Synchronous up/down counters
- Shift registers
- Bidirectional data buffers
- Timing function generators
- System controllers/synchronizers
- Priority encoder/registers

- NOTES
1. Positive Logic:
 $J/K = T_0 + T_1 + T_2 + \dots + T_{47}$
 $T_n = \bar{C} \cdot (i_0 \cdot i_1 \cdot i_2 \dots) \cdot (Q_0 \cdot Q_1 \dots) \cdot (B_0 \cdot B_1 \dots)$
 2. † denotes transition from Low to High level.
 3. X = Don't Care
 4. * = Forced at F_N pin for loading J/K flip-flop in I/O mode. L must be enabled, and other active T_n disabled via steering input(s) I, B, or Q.
 5. At $P = R = H$, $Q = H$. The final state of Q depends on which is released first.
 6. ** = Forced at F_N pin to load J/K flip-flop independent of program code (Diagnostic mode).

- NOTES
- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device of these of any other condition above those indicated in the operation of the device specifications is not implied.
 - All typical values are at V_{CC} = 5V, T_A = 25°C.
 - All voltage values are with respect to network ground terminal.
 - Test one at a time.
 - Measured with V_{IH} applied to \overline{OE} .
 - Duration of short circuit should not exceed 1 second.
 - I_{CC} is measured with the \overline{OE} input grounded, all other inputs at 4.5V, and the outputs open.
 - Leakage values are a combination of input and output leakage.

- NOTE
1. All typical values are at V_{CC} = 5V, T_A = 25°C.
 2. To prevent spurious clocking, clock rise time (10%-90%) ≤ 10ns.
 3. Measured at V_T = V_{OL} + 0.5 V.
 4. When using the Complement Array T_{CKP} = 75ns (min).
 5. Limits are guaranteed with 12 product terms maximum connected to each sum term line.

TIMING DIAGRAMS

MEMORY TIMING DEFINITIONS

- T_{CKH} Width of input clock pulse.
- T_{CKL} Interval between clock pulses.
- T_{CKP} Clock period.
- T_{PRH} Width of preset input pulse.
- T_{IS1} Required delay between beginning of valid input and positive transition of clock.
- T_{IS2} Required delay between beginning of valid input forced at flip-flop output pins, and positive transition of clock.
- T_{IH1} Required delay between positive transition of clock and end of valid input data.
- T_{IH2} Required delay between positive transition of clock and end of valid input data forced at flip-flop output pins.
- T_{CKO} Delay between positive transition of clock and when Outputs become valid (with \overline{OE} low).
- T_{OE1} Delay between beginning of Output Enable Low and when Outputs become valid.
- T_{OD1} Delay between beginning of Output Enable High and when Outputs are in the off state.
- T_{PD} Propagation delay between combinational inputs and outputs.
- T_{OE2} Delay between predefined Output Enable High, and when combinational Outputs become valid.
- T_{OD2} Delay between predefined Output Enable Low and when combinational Outputs are in the off state.
- T_{PRO} Delay between positive transition of predefined Preset / Reset input, and when flip-flop outputs become valid.

INTEGRATED FUSE LOGIC
SERIES 20

The FPLS can be programmed by means of Logic Programming equipment.

OR input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Tables on the following pages.

In these Tables, the logic state or action of all I/O, control, and state variables is assigned a symbol which results in the proper fusing pattern of corresponding links defined as follows:

“EX-OR” ARRAY — (B)

“O.E.” ARRAY — (E)

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates.
2. Any gate (T, F, L, P, R, D)_n will be unconditionally inhibited if any one of the I, B, or Q link pairs is left intact.
3. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T, F, C .
4. $E_n = 0$ and $E_n = \bullet$ are logically equivalent states, since both cause F_n outputs to be unconditionally enabled.
5. These states are not allowed for control gates (L, P, R, D)_n due to their lack of “OR” array links.

TEST ARRAY (82S159)

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on chip test array.

The array consists of test transition terms 32 and 50, factory programmed as shown below for the 82S159.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I₀₋₃ and B₀₋₃ as shown in the test circuit timing diagram.

TWX TAPE CODING (LOGIC FORMAT)

The FPLA Program Table can be sent to Signetics in ASCII code format via airmail using any type of 8-level tape (paper, mylar,

fanfold, etc.), or via TWX: just dial (910) 339-9283, tell the operator to turn the paper puncher on, and acknowledge. At the end of transmission instruct the operator to send tape to Signetics Order Entry

A number of Program Tables can be sequentially assembled on a continuous tape as follows, however, limit tape length to a roll of 1.75 inch inside diameter and 4.25 inch outside diameter.

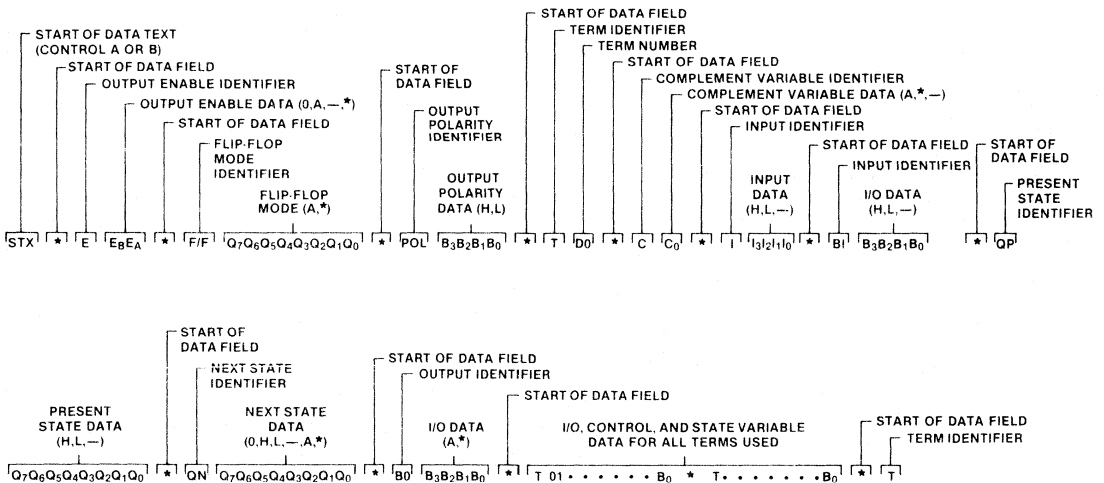

A. The MAIN HEADING at the beginning of tape includes the following information, with each entry preceded by a (\$) character, whether used or not:

- 1. Customer Name _____
- 2. Customer TWX No. _____
- 3. Date _____
- 4. Purchase Order No. _____
- 5. Number of Program Tables _____
- 6. Total Number of Parts _____

B. Each SUB HEADING should contain specific information pertinent to each Program Table as follows, with each entry preceded by a (\$) character, whether used or not:

- 1. Signetics Device No. _____
- 2. Program Table No. _____
- 3. Revision _____
- 4. Date _____
- 5. Customer Symbolized Part No. _____
- 6. Number of Parts _____

C. Program Table data blocks are initiated with an STX character, and terminated with an ETX character. The body of the data consists of output polarity, product term, and output information separated by appropriate identifiers in accordance with the following format. Entries for the data fields correspond to those defined in the Logic PROGRAM TABLE:

FIELD PROGRAMMABLE LOGIC ARRAY (12 × 48 × 8)

82S161 (T.S.)

INTEGRATED FUSE LOGIC

DESCRIPTION

The 82S161 is a Bipolar, Fuse Link Programmable Logic Array (FPLA). The device utilizes the standard AND/OR/Invert architecture to directly implement custom sum of product logic equations.

This device consists of 12 dedicated inputs and 8 dedicated outputs. Each output is capable of being actively controlled by any or all of the 48 product terms. The true, complement, or don't care condition of each of the 12 inputs ANDed together comprise one P-term. All 48 P-terms are then ORed to each output. The user must then only select which P-terms will activate an output by disconnecting terms which do not affect the output. In addition each output can be fused as active-high (H) or active-low (L).

The 82S161 is fully TTL compatible, and includes a chip enable input for output inhibit control and expansion of input variables.

This FPLA is available in commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C) specify N82S161 F or N, and for the military temperature range (-55°C to +125°C) specify S82S161 F.

LOGIC FUNCTION

Typical Product Term
 $P_0 = I_0 \cdot I_1 \cdot \overline{I_2} \cdot I_5 \cdot \overline{I_{11}}$

Typical Output Functions: @ $\overline{CE} = 0$:

$F_0 = (P_0 + P_1 + P_2)$ @ L = Closed

$F_0 = (\overline{P_0} \cdot \overline{P_1} \cdot \overline{P_2})$ @ L = Open

NOTE

For each of the 8 outputs either the function F_p (active-high) or $\overline{F_p}$ (active-low) is available, but not both. The required function polarity is programmed via link (L).

FEATURES

- Input variables: 12
- Field programmable (NiCr link)
- Output functions: 8
- Product terms: 48
- Address access time:
 S82S161 80ns Max
 N82S161 50ns Max
- Power dissipation: 600mW typ.
- Input loading:
 S82S161 150 μ A Max
 N82S161 100 μ A Max
- Chip enable input
- Output disable function
- Separate I/O architecture

APPLICATIONS

- CRT display systems
- Random logic
- Code conversion
- Peripheral controllers
- Function generators
- Look-up and decision tables
- Microprogramming
- Address mapping
- Character generators
- Sequential controllers
- Data security encoders
- Fault detectors
- Frequency synthesizers

NOTES

- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operation of the device specifications is not implied.
- All values are at V_{CC} = 5V, T_A = 25°C.
- All voltage values are with respect to network ground terminal.
- Test one at a time.
- Measured with V_{IL} applied to CE and a logic high stored.
- Measured with a programmed logic condition for which the output test is at a low logic level. Output sink current is applied thru a resistor to V_{CC}.
- Measured with V_{IH} applied to CE.
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V and the outputs open.

LOGIC PROGRAMMING

The FPLA can be programmed by means of Logic programming equipment.

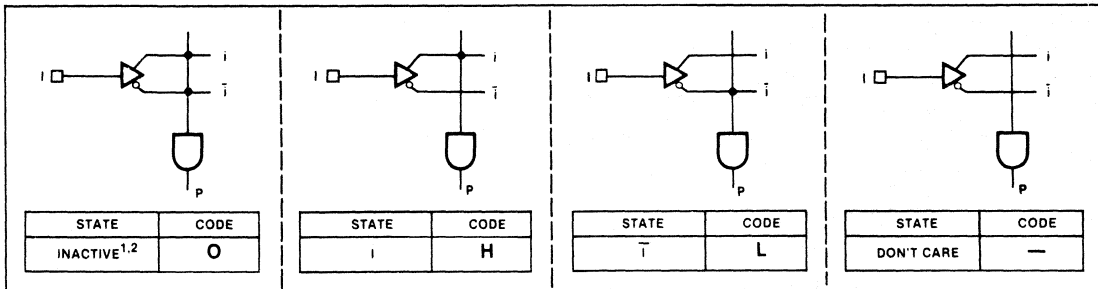

With Logic programming, the AND/OR/EX-OR gate input connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table on the following page.

In this Table the logic state or action of variables I, P, and F, associated with each Sum Term S_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

EX-OR ARRAY-(F)

“AND” ARRAY-(I)

4

“OR” ARRAY-(F)

NOTES

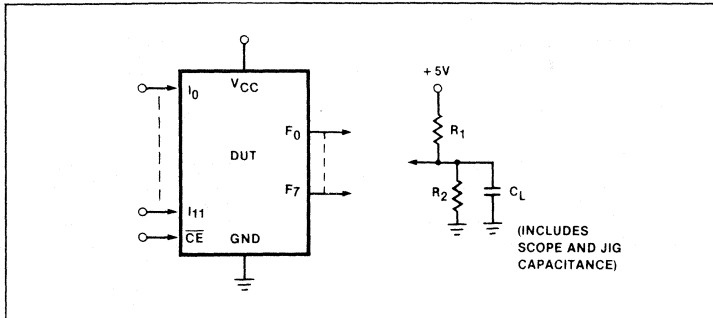

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates P_n .
2. Any gate P_n will be unconditionally inhibited if any one of its (I) link pairs is left intact.

FIELD PROGRAMMABLE LOGIC ARRAY (12 × 48 × 8)

INTEGRATED FUSE LOGIC

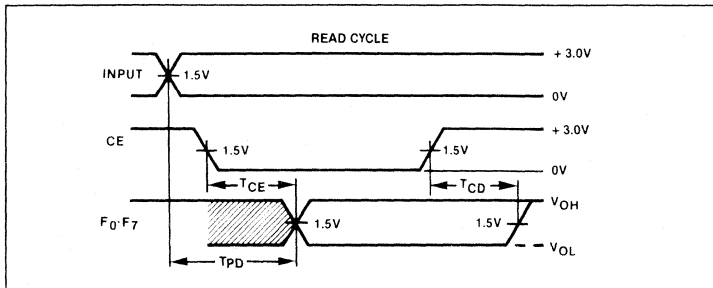

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

TIMING DIAGRAM

TIMING DEFINITIONS

- T_{CE} Delay between beginning of Chip Enable low (with Input valid) and when Data Output becomes valid.
- T_{CD} Delay between when Chip Enable becomes high and Data Output is in off state (Hi-Z or high).
- T_{PD} Delay between beginning of valid Input (with Chip Enable low) and when Data Output becomes valid.

VIRGIN DEVICE

The 82S161 are shipped in an unprogrammed state, characterized by:

1. All internal Ni-Cr links are intact.
2. Each product term (P-term) contains both true and complement values of every input variable I_m (P-terms always logically "false").
3. The "OR" Matrix contains all 48 P-terms.
4. The polarity of each output is set to active high (Fp function).
5. All outputs are at a low logic level.

82S161 (T.S.)

INTEGRATED FUSE LOGIC

FPLA LOGIC DIAGRAM

FIELD PROGRAMMABLE GATE ARRAY (16x5)

82S162 (T.S.)

Preliminary

DESCRIPTION

The 82S162 is a bipolar, fuse-programmable gate array. The device consists of five AND/NAND gates which share 16 common inputs. The type of gate is selected by programming the output as active-HIGH (H) or active-LOW (L). Each of the 16 inputs I_0 - I_{15} can be programmed to provide the True (H), Complement (L), or Don't Care (-) state to each of the five AND/NAND gates. OR/NOR logic functions can also be implemented by complementing the inputs and outputs via on-chip inverting buffers.

The device is field programmable, which means that custom patterns are immediately available.

The 82S162 includes chip-enable control for output strobing and inhibit. It features 3-State outputs for ease of expansion of input variables and application in bus-organized systems.

The 82S162 is available in the commercial temperature range. For the range (0°C to +75°C), specify N82S162N. This is the 24-pin, 300-mil-wide plastic package.

FEATURES

- Field programmable (Ni-Cr link)
- 16 input variables
- 5 output functions
- Chip enable input
- I/O propagation delay:
N82S162: 30 ns max
- Power dissipation: 600mW typ
- Input loading:
N82S162: -100µA max
- Output: 3-State
- Output disable function: HI-Z
- Fully TTL compatible

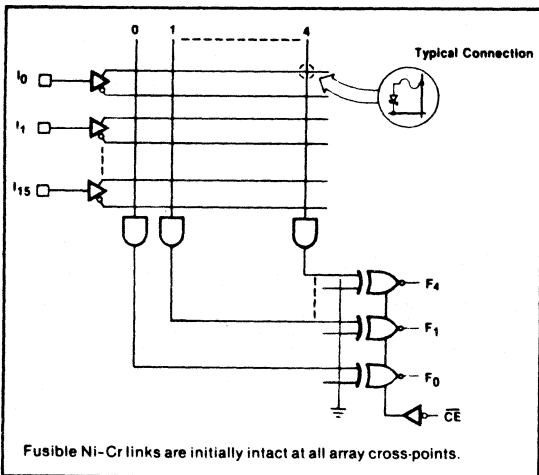

APPLICATIONS

- Random logic
- Address decoders
- Code detectors
- Peripheral selectors
- Fault monitors
- Machine state decoders

NOTES

- All voltage values are with respect to network ground terminal.
- All typical values are at V_{CC} = 5V, T_A = 25°C.
- Test each output one at a time.
- Measure with a programmed logic condition for which the output under test is at a low logic level. Output sink current is supplied through a resistor to V_{CC}.
- Measured with V_{IL} applied to \overline{CE} and a logic high at the output.
- Measured with V_{IH} applied to \overline{CE} .
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V, and the outputs open.

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

LOGIC PROGRAMMING

In a virgin device all Ni-Cr links are intact.

The FPGA can be programmed by means of Logic programming equipment.

With Logic programming, the AND/EX-OR gate connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table.

In this table, the logic state of variables I and F associated with each gate G_n is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

OUTPUT POLARITY—(F)

“AND” ARRAY—(I)

NOTES

- This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates G_n .
- Any gate G_n will be unconditionally inhibited if any one of its (I) link pairs is left intact.

VIRGIN DEVICE

The 82S162 is shipped in an unprogrammed state, characterized by:

- All internal Ni-Cr links are intact.
- Each gate contains both true and complement values of every input variable I_m (logic Null state).
- The polarity of each output is set to active low (F_p function).
- All outputs are at a high logic level.

FIELD PROGRAMMABLE GATE ARRAY (12x9)

82S163 (T.S.)

Preliminary

INTEGRATED FUSE LOGIC
SERIES 24

DESCRIPTION

The 82S163 is a bipolar, fuse-programmable gate array. The device consists of nine AND/NAND gates which share 12 common inputs. The type of gate is selected by programming the output as active-HIGH (H) or active-LOW (L). Each of the 12 inputs I_0-I_{11} can be programmed to provide the True (H), Complement (L), or Don't Care (—) state to each of the nine AND/NAND gates. OR/NOR logic functions can also be implemented by complementing the inputs and outputs via on-chip inverting buffers.

The device is field programmable, which means that custom patterns are immediately available.

The 82S163 includes chip-enable control for output strobing and inhibit. It features 3-State outputs for ease of expansion of input variables and application in bus-organized systems.

The 82S163 is available in the commercial and military temperature range. For the range (0°C to +75°C), specify N82S163N. This is the 24-pin, 300-mil-wide plastic package.

FEATURES

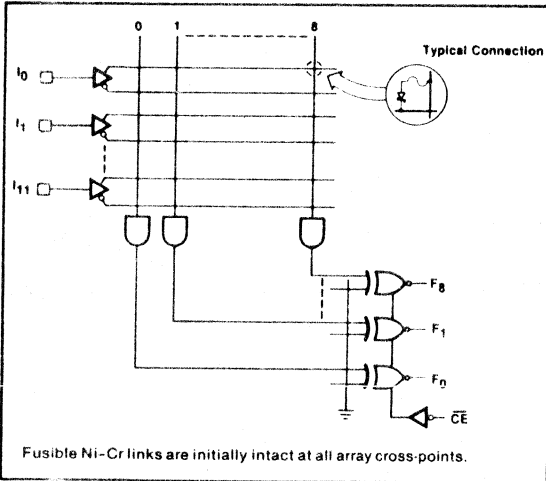

- Field programmable (Ni-Cr link)
- 12 input variables
- 9 output functions
- Chip enable input
- I/O propagation delay:
N82S163: 30 ns max
- Power dissipation: 600mW typ
- Input loading:
N82S163: -100µA max
- Output: 3-State
- Output disable function: HI-Z
- Fully TTL compatible

APPLICATIONS

- Random logic
- Address decoders
- Code detectors
- Peripheral selectors
- Fault monitors
- Machine state decoders

NOTES

- All voltage values are with respect to network ground terminal.
- All typical values are at V_{CC} = 5V, T_A = 25°C.
- Test each output one at a time.
- Measure with a programmed logic condition for which the output under test is at a low logic level. Output sink current is supplied through a resistor to V_{CC}.
- Measured with V_{IL} applied to CE and a logic high at the output.
- Measured with V_{IH} applied to CE.
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V, and the outputs open.

LOGIC PROGRAMMING

In a virgin device all Ni-Cr links are intact.

The FPGA can be programmed by means of Logic programming equipment.

With Logic programming, the AND/EX-OR gate input connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table.

In this table, the logic state of variables I and F associated with each gate G_n is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

OUTPUT POLARITY—(F)

“AND” ARRAY—(I)

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates G_n .
2. Any gate G_n will be unconditionally inhibited if any one of its (I) link pairs is left intact.

VIRGIN DEVICE

The 82S163 is shipped in an unprogrammed state, characterized by:

1. All internal Ni-Cr links are intact.
2. Each gate contains both true and complement values of every input variable I_m (logic Null state).
3. The polarity of each output is set to active low (\bar{F}_p function).
4. All outputs are at a high logic level.

FIELD PROGRAMMABLE LOGIC SEQUENCER (14 × 48 × 6)

82S167 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 24

DESCRIPTION

The 82S167 is a bipolar, programmable state machine of the Mealy type. It contains logic AND-OR gate arrays with user programmable connections which control the inputs of on-chip state and output registers. These consist respectively of 8 Q_p , and 4 Q_i edge-triggered, clocked S/R flip-flops, with an asynchronous preset option.

All flip-flops are unconditionally preset to "1" during power turn-on.

The AND array combines 14 external inputs, I_{0-13} , with 8 internal inputs, P_{0-7} , fed back from the State register to form up to 48 transition terms (AND terms). In addition, bit-0 and bit-1 of the internal state register are brought off-chip to allow extending the output register to 6 bits, if so desired.

All transition terms can include True, False, or Don't Care states of the controlling variables, and are merged in the OR array to issue next-state and next-output commands to their respective registers on the low to high transition of the Clock pulse.

Both True and Complement transition terms can be generated by optional use of the internal variable (C) from the complement array. Also, if desired, the Preset in-

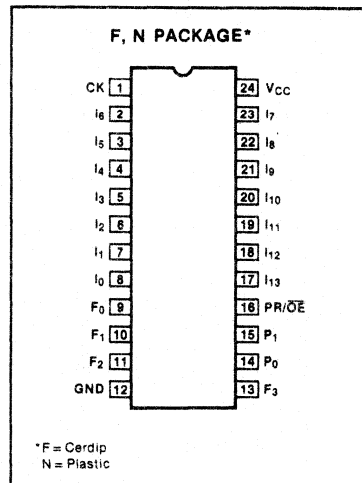

put can be converted to output-enable function, as an additional user programmable option.

The device is available in the commercial temperature range. For the commercial temperature range (0°C to +75°C) specify N82S167F or N.

FEATURES

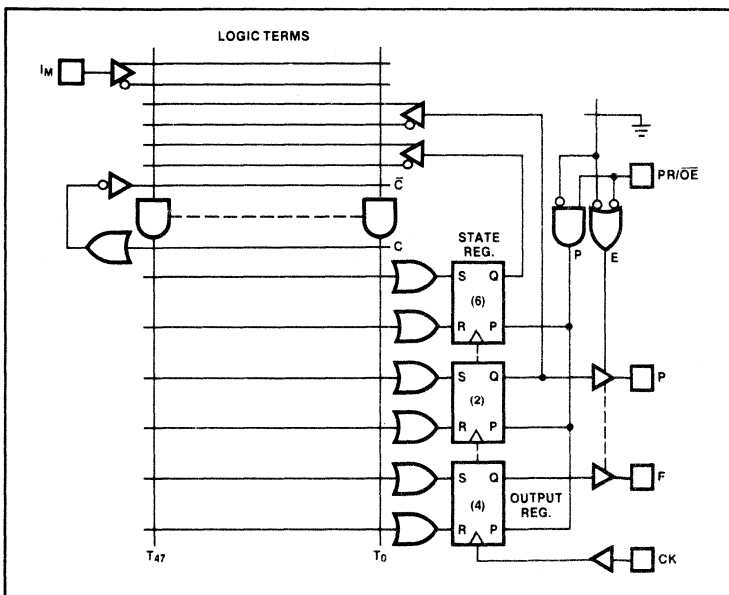

- Field programmable (Ni-Cr link)
- 14 True/Complement buffered inputs
- 48 programmable AND gates
- 25 programmable OR gates
- 8-bit state register
- 2-bit shared state/output register
- 4-bit output register
- Transition complement array
- Programmable asynchronous preset/output enable
- Positive edge-trigger clock
- Power-on preset to logic "1" of all registers
- Automatic logic "HOLD" state via S/R flip-flops
- On-chip test array
- $f_{(max)}$: 13.9MHz (82S167)
- Power: 650mW (typ)
- TTL compatible
- Tri-state outputs
- Single +5V supply
- 300 mil wide 24-pin DIP

NOTES

- Stresses above those listed under "Absolute Maximum Ratings" may cause malfunction or permanent damage to the device. This is a stress rating only. Functional operation at these or any other condition above those indicated in the operational and programming specification of the device is not implied.
- All typical values are at V_{CC} = 5V, T_A = 25 °C.
- All voltage values are with respect to network ground terminal.
- Test one at a time.
- Measured with V_{IL} applied to \overline{OE} and a logic high stored, or with V_{IH} applied to PR.
- Measured with a programmed logic condition for which the output is at a low logic level, and V_{IL} applied to PR/ \overline{OE} . Output sink current is supplied through a resistor to V_{CC}.
- Measured with V_{IH} applied to PR/ \overline{OE} .
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the PR/ \overline{OE} . Input grounded, all other inputs at 4.5V and the outputs open.
- See OR DRIVE limitations on page 4-14.

TIMING DIAGRAMS

TIMING DEFINITIONS

- T_{CKH} Width of input clock pulse.
- T_{CKL} Interval between clock pulses.
- T_{CKP} Clock period—when not using Complement array.
- T_{IS1} Required delay between beginning of valid input and positive transition of clock.
- T_{CKP2} Clock period—when using Complement array.
- T_{IS2} Required delay between beginning of valid Input and positive transition of clock, when using optional Complement Array (two passes necessary through the AND array).
- T_{VS} Required delay between V_{CC} (after power-on) and negative transition of clock preceding first reliable clock pulse.
- T_{PRS} Required delay between negative transition of asynchronous Preset and negative transition of clock preceding first reliable clock pulse.
- T_{IH} Required delay between positive transition of clock and end of valid input data.
- T_{CKO} Delay between positive transition of clock and when Outputs become valid (with $\overline{PR}/\overline{O.E.}$ low).
- T_{OE} Delay between beginning of Output Enable Low and when Outputs become valid.
- T_{OD} Delay between beginning of Output Enable High and when Outputs are in the off state.
- T_{SRE} Delay between input I_0 transition to Diagnostic mode and when the Outputs reflect the contents of the State Register.
- T_{SRD} Delay between input I_0 transition to Logic mode and when the Outputs reflect the contents of the Output Register.
- T_{PR} Delay between positive transition of Preset and when Outputs become valid at "1".
- T_{PPR} Delay between V_{CC} (after power-on) and when Outputs become preset at "1".
- T_{PRH} Width of preset input pulse.
- f_{MAX} Maximum clock frequency.

OR DRIVE LIMITS

Because of internal overdrive limitations, the following guideline must be observed during normal operation:

"The number of AND gates T_{SDO} simultaneously driving to logic '1' the same OR gate (Set/Reset line) at T_{CKH} time must be no greater than 4."

This is illustrated in Figure 1. Note that the rule does not limit the total number of AND gates which can be connected to an OR line. It only limits the number of any of those which can be simultaneously active.

Figure 1. Although the OR Line Above is Connected to 7 Terms, Only 4 of Them Are Allowed To Be Logically Active (1) at Any One Time.

OR overdrive can lead to logic malfunction, and is generally caused by *logic overlap* due to "—" present in the Program Table for I_m and P_s variables (except unused variables).

Limiting T_{SDO} imposes some programming restrictions in anticipation of certain input conditions. As an example, Figure 2 shows the application of this rule in a typical case where, to prevent OR overdrive, one of the variables must be eliminated from the state-jump definition.

Figure 2. Unless I_0 through I_4 Are Mutually Exclusive, When in State "000" Input Code (11001) Will Activate Terms T_1 through T_5 . To Prevent Overdriving the Set/Reset Lines of Flip-Flops P_{0-2} , One of the Inputs and Associated Term (I_4 , T_5) Must Be Eliminated.

SPEED VS. "OR" LOADING

The maximum frequency at which the FPLS can be clocked while operating in sequential mode is given by:

$$(1/f_{MAX}) = T_{CY} = T_{IS} + T_{CKO}$$

This frequency depends on the number of transition terms T_n used. Having all 48 terms connected in the AND array does not appreciably impact performance; but the number of terms connected to each OR line affects T_{IS} , due to capacitive loading. The effect of this loading can be seen in Figure 1, showing the variation of T_{IS1} with the number of terms connected per OR.

The AC electrical characteristics contain three limits for the parameters T_{IS1} and T_{IS2} . The first, T_{IS1A} is guaranteed for a device with 48 terms connected to any OR line. T_{IS1B} is guaranteed for a device with 32 terms connected to any OR line. And T_{IS1C} is guaranteed for a device with 24 terms connected to any OR line.

Figure 1. T_{IS1} vs. Terms/OR Connected.

The three other entries in the AC table, T_{IS2} A, B, and C are corresponding 48, 32, and 24 term limits when using the on-chip Complement Array.

The worst case T_{IS} for a given application can be determined by identifying the OR line with the maximum number of T_n con-

nections. This can be done by referring to the interconnect pattern in the FPLS logic diagram, typically illustrated in Figure 2, or by counting the maximum number of "H" or "L" entries in one of the columns of the device Program Table.

This number plotted on the curve in Figure 1 will yield the worst case T_{IS} and, by implication, the maximum clocking frequency for reliable operation.

Note that for maximum speed all UNUSED transition terms should be disconnected from the OR array.

Figure 2. Typical OR Array Interconnect Pattern.

FIELD PROGRAMMABLE LOGIC SEQUENCER (14x48x6)

82S167 (T.S.)

LOGIC PROGRAMMING

The FPLS can be programmed by means of Logic programming equipment.

With Logic programming, the AND/OR gate input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Table on the following page.

In this table, the logic state or action of control variables C, I, P, N, and F, associated with each Transition Term T_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

PRESET/ $\overline{O.E.}$ OPTION - (P/E)

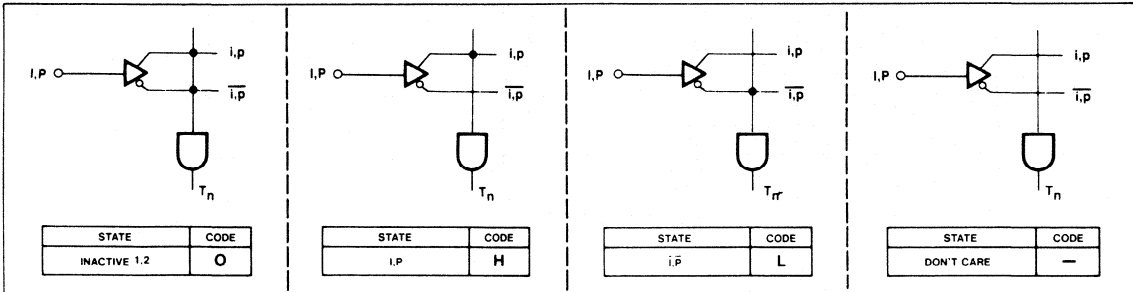

| OPTION | CODE |
|--------|------|
| PRESET | H |

| OPTION | CODE |
|-------------------|------|
| $\overline{O.E.}$ | L |

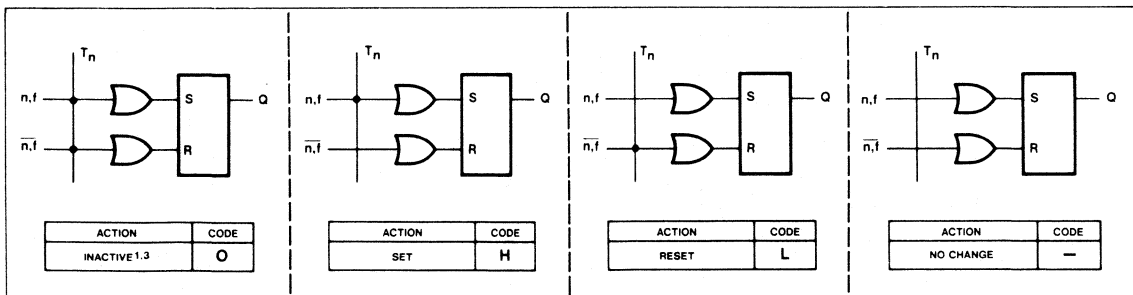

PROGRAMMING

The 82S167 has a power-up preset feature. This feature insures that the device will power-up in a known state with all register elements (state and output register) at a logic high (H). When programming the device it is important to realize this is the initial state of the device. You *must* provide a next state jump if you do not wish to use all highs (H) as the present state.

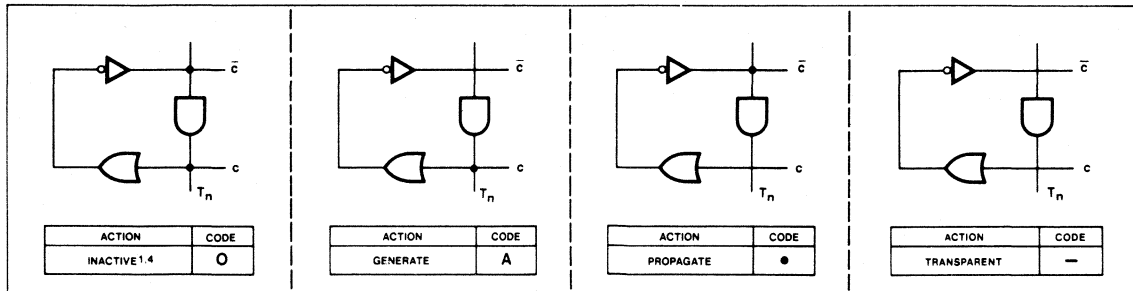

"AND" ARRAY - (I), (P)

"OR" ARRAY - (N), (F)

"COMPLEMENT" ARRAY - (C)

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates T_n .
2. Any gate T_n will be unconditionally inhibited if any one of its I or P link pairs is left intact.
3. To prevent simultaneous Set and Reset flip-flop commands, this state is not allowed for N and F link pairs coupled to active gates T_n (see flip-flop truth tables).
4. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n .

TEST ARRAY

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on-chip test array.

The array consists of test transition terms 48 and 49, factory programmed as shown below.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I_{0-9} as shown in the test circuit timing diagram.

FIELD PROGRAMMABLE LOGIC SEQUENCER (14 × 48 × 6)

82S167A (T.S.)

INTEGRATED FUSE LOGIC
SERIES 24

DESCRIPTION

The 82S167A is a bipolar, programmable state machine of the Mealy type. It contains logic AND-OR gate arrays with user programmable connections which control the inputs of on-chip state and output registers. These consist respectively of 8 Q_p , and 4 Q_f edge-triggered, clocked S/R flip-flops, with an asynchronous preset option.

All flip-flops are unconditionally preset to "1" during power turn-on.

The AND array combines 14 external inputs, I_{0-13} , with 8 internal inputs, P_{0-7} , fed back from the State register to form up to 48 transition terms (AND terms). In addition, bit-0 and bit-1 of the internal state register are brought off-chip to allow extending the output register to 6 bits, if so desired.

All transition terms can include True, False, or Don't Care states of the controlling variables, and are merged in the OR array to issue next-state and next-output commands to their respective registers on the low to high transition of the Clock pulse.

Both True and Complement transition terms can be generated by optional use of the internal variable (C) from the complement array. Also, if desired, the Preset in-

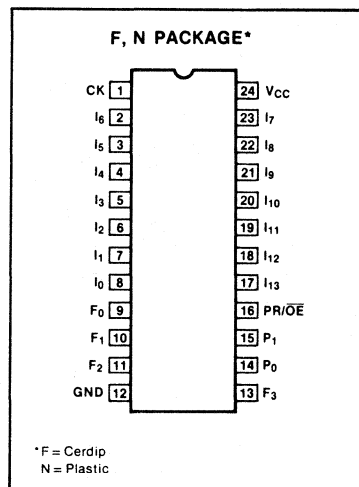

put can be converted to output-enable function, as an additional user programmable option.

The device is available in the commercial temperature range. For the commercial temperature range (0°C to + 75°C) specify N82S167AN.

FEATURES

- Field programmable (Ni-Cr link)
- 14 True/Complement buffered inputs
- 48 programmable AND gates
- 25 programmable OR gates
- 8-bit state register
- 2-bit shared state/output register
- 4-bit output register
- Transition complement array
- Programmable asynchronous preset/output enable
- Positive edge-trigger clock
- Power-on preset to logic "1" of all registers
- Automatic logic "HOLD" state via S/R flip-flops
- On-chip test array
- $f_{(max)}$: 20MHz
- Power: 650mW (typ)
- TTL compatible
- Tri-state outputs
- Single + 5V supply
- 300 mil wide 24-pin DIP

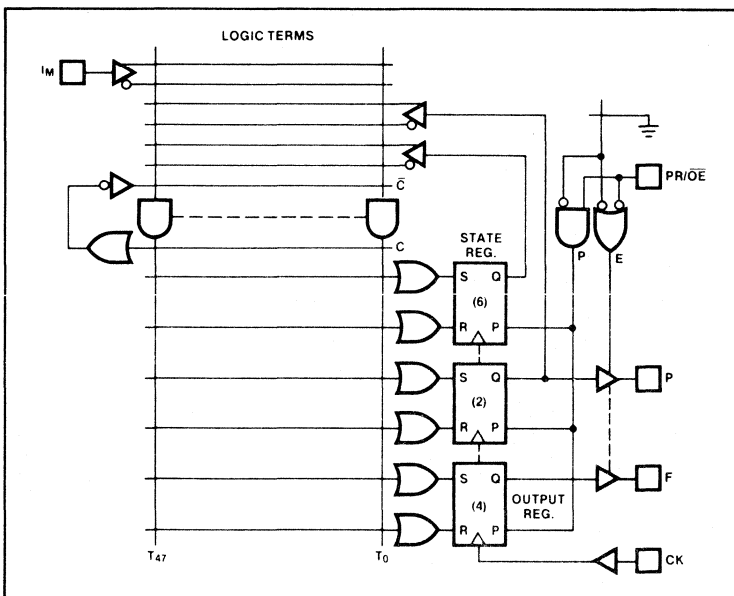

PIN CONFIGURATION

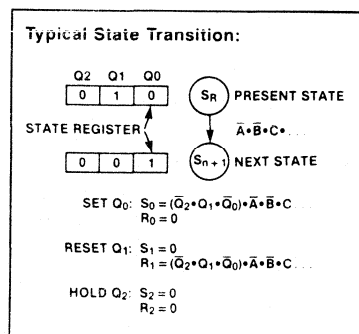

APPLICATIONS

- Interface protocols
- Sequence detectors
- Peripheral controllers
- Timing generators
- Sequential circuits
- Elevator controllers
- Security locking systems
- Counters
- Shift registers

FIELD PROGRAMMABLE LOGIC SEQUENCER (14 × 48 × 6)

82S167A (T.S.)

**INTEGRATED FUSE LOGIC
SERIES 24**

PIN DESIGNATION

| PIN NO. | SYMBOL | NAME AND FUNCTION | POLARITY |
|------------------|-------------------|---|---|
| 1 | CK | CLOCK The Clock input to the state and output registers. A low-to-high transition on this line is necessary to update the contents of both registers. | Active-high |
| [2-7] [17-23] | I ₁₋₁₃ | LOGIC INPUTS The 13 external inputs to the AND array used to program jump conditions between machine states, as determined by a given logic sequence. | Active-high/low |
| 8 | I ₀ | LOGIC/DIAGNOSTIC INPUT A 14th external logic input to the AND array, as above, when exercised with standard TTL levels. When I ₀ is held at +10V, device outputs F _{0,3} and P _{0,1} reflect the contents of state register bits P _{2,7} (see Diagnostic Output Mode diagram on page 8). The contents of flip-flops P _{0,1} and F _{0,3} remain unaltered. | Active-high/low |
| [9-11] [13] | F _{0,3} | LOGIC/DIAGNOSTIC OUTPUTS Four device outputs which normally reflect the contents of output register bits Q _{0,3} , when enabled. When I ₀ is held at +10V, F _{0,3} = (P _{2,5}). | Active-high |
| [14-15] | P _{0,1} | LOGIC/DIAGNOSTIC OUTPUTS Two register bits with shared function as least significant state register bits, or most significant output register bits. When I ₀ is held at +10V, P _{0,1} = (P _{6,7}). | Active-high |
| 16 | PR/ <u>O.E.</u> | PRESET OR OUTPUT ENABLE INPUT A user programmable function: <ul style="list-style-type: none"> PRESET Provides an asynchronous preset to logic "1" of all state and output register bits. Preset overrides Clock, and when held high, clocking is inhibited and P_{0,1} and P_{0,3} are high. Normal clocking resumes with the first full clock pulse following a high-to-low clock transition, after Preset goes low. OUTPUT ENABLE Provides an Output Enable function to all output buffers. | Active-high (H) Active-low (L) |

- NOTES**
- Positive Logic
S/R = T₀ + T₁ + T₂ + . . . + T₄₇
T_n = C (I₀ I₁ I₂ . . .) (P₀ P₁ . . . P₅)
 - Either Preset (active-HIGH) or Output Enable (active-LOW) are available, but not both. The desired function is a user-programmable option.
 - ↑ denotes transition from LOW-to-HIGH level.
 - R = S = HIGH is an illegal input condition
 - * = H/L/ +10V
 - X = Don't Care (≤ 5.5V)

VIRGIN STATE

A factory shipped virgin device contains all fusible links intact, such that:

- PR/O.E. option is set to PR. Thus, all outputs will be at "1", as preset by initial power-up procedure.
- All transition terms are disabled (0).
- All S/R flip-flop inputs are disabled (0).
- The device can be clocked via a Test Array pre-programmed with a standard test pattern.
NOTE: The Test Array pattern MUST be deleted before incorporating a user program.

- NOTES
- Stresses above those listed under "Absolute Maximum Ratings" may cause malfunction or permanent damage to the device. This is a stress rating only. Functional operation at these or any other condition above those indicated in the operational and programming specification of the device is not implied.
 - All typical values are at V_{CC} = 5V, T_A = 25 °C.
 - All voltage values are with respect to network ground terminal.
 - Test one at a time.
 - Measured with V_{IL} applied to \overline{OE} and a logic high stored, or with V_{IH} applied to PR.
 - Measured with a programmed logic condition for which the output is at a low logic level, and V_{IL} applied to PR/ \overline{OE} . Output sink current is supplied through a resistor to V_{CC}.
 - Measured with V_{IH} applied to PR/ \overline{OE} .
 - Duration of short circuit should not exceed 1 second.
 - I_{CC} is measured with the PR/ \overline{OE} , input grounded, all other inputs at 4.5V and the outputs open.
 - See OR DRIVE limitations on page 4-25.

NOTES

- All typical values are at $V_{CC} = 5V$, $T_A = 25^\circ C$.
- To prevent spurious clocking, clock rise time (10%-90%) $\leq 30ns$.
- See "Speed vs. OR Loading" on page 4-25.

TIMING DIAGRAMS

TIMING DEFINITIONS

- TCKH Width of input clock pulse.
- TCKL Interval between clock pulses.
- TCKP Clock period—when not using Complement array.
- TIS1 Required delay between beginning of valid input and positive transition of clock.
- TCKP2 Clock period—when using Complement array.
- TIS2 Required delay between beginning of valid Input and positive transition of clock, when using optional Complement Array (two passes necessary through the AND array).
- TVS Required delay between VCC (after power-on) and negative transition of clock preceding first reliable clock pulse.
- TPRS Required delay between negative transition of asynchronous Preset and negative transition of clock preceding first reliable clock pulse.
- TIH Required delay between positive transition of clock and end of valid Input data.
- TCKO Delay between positive transition of clock and when Outputs become valid (with PR/ $\overline{O.E.}$ low).
- TOE Delay between beginning of Output Enable Low and when Outputs become valid.
- TOD Delay between beginning of Output Enable High and when Outputs are in the off state.
- TSRE Delay between input I_Q transition to Diagnostic mode and when the Outputs reflect the contents of the State Register.
- TSRD Delay between input I_Q transition to Logic mode and when the Outputs reflect the contents of the Output Register.
- TPR Delay between positive transition of Preset and when Outputs become valid at "1".
- TPPR Delay between VCC (after power-on) and when Outputs become preset at "1".
- TPRH Width of preset input pulse.
- fMAX Maximum clock frequency.

**INTEGRATED FUSE LOGIC
SERIES 24**

TIMING DIAGRAMS (Cont'd)

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

OR DRIVE LIMITS

Because of internal overdrive limitations, the following guideline must be observed during normal operation:

"The number of AND gates T_{SDO} simultaneously driving to logic '1' the same OR gate (Set/Reset line) at T_{CKH} time must be no greater than 4."

This is illustrated in Figure 1. Note that the rule does not limit the total number of AND gates which can be connected to an OR line. It only limits the number of any of those which can be simultaneously active.

Figure 1. Although the OR Line Above is Connected to 7 Terms, Only 4 of Them Are Allowed To Be Logically Active (1) at Any One Time.

OR overdrive can lead to logic malfunction, and is generally caused by logic overlap due to "-" present in the Program Table for I_m and P_S variables (except unused variables).

Limiting T_{SDO} imposes some programming restrictions in anticipation of certain input conditions. As an example, Figure 2 shows the application of this rule in a typical case where, to prevent OR overdrive, one of the variables must be eliminated from the state-jump definition.

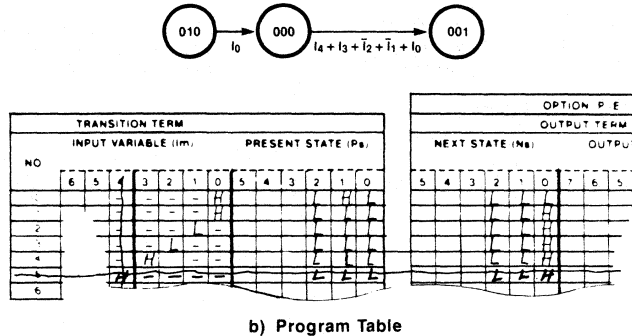

Figure 2. Unless I_0 through I_4 Are Mutually Exclusive, When in State "000" Input Code (11001) Will Activate Terms T_1 through T_5 . To Prevent Overdriving the Set/Reset Lines of Flip-Flops P_{0-2} , One of the Inputs and Associated Term (I_4, T_5) Must Be Eliminated.

SPEED VS. "OR" LOADING

The maximum frequency at which the FPLS can be clocked while operating in sequential mode is given by:

$$(1/f_{MAX}) = T_{CY} = T_{IS} + T_{CKO}$$

This frequency depends on the number of transition terms T_n used. Having all 48 terms connected in the AND array does not appreciably impact performance; but the number of terms connected to each OR line affects T_{IS} , due to capacitive loading. The effect of this loading can be seen in Figure 1, showing the variation of T_{IS1} with the number of terms connected per OR.

The AC electrical characteristics contain two limits for the parameters T_{IS1} and T_{IS2} . The first, T_{IS1A} is guaranteed for a device with 24 terms connected to any OR line. T_{IS1B} is guaranteed for a device with 16 terms connected to any OR line.

Figure 1. T_{IS1} vs. Terms/OR Connected.

The two other entries in the AC table, T_{IS2} A and B are corresponding 24 and 16 term limits when using the on-chip Complement Array.

The worst case of T_{IS} for a given application can be determined by identifying the OR line with the maximum number of T_n

connections. This can be done by referring to the interconnect pattern in the FPLS logic diagram, typically illustrated in Figure 2, or by counting the maximum number of "H" or "L" entries in one of the columns of the device Program Table.

This number plotted on the curve in Figure 1 will yield the worst case T_{IS} and, by implication, the maximum clocking frequency for reliable operation.

Note that for maximum speed all UNUSED transition terms should be disconnected from the OR array.

Figure 2. Typical OR Array Interconnect Pattern.

FIELD PROGRAMMABLE LOGIC SEQUENCER (14x48x6)

82S167A (T.S.)

LOGIC PROGRAMMING

The FPLS can be programmed by means of Logic programming equipment.

With Logic programming, the AND/OR gate input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Table on the following page.

In this table, the logic state or action of control variables C, I, P, N, and F, associated with each Transition Term T_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

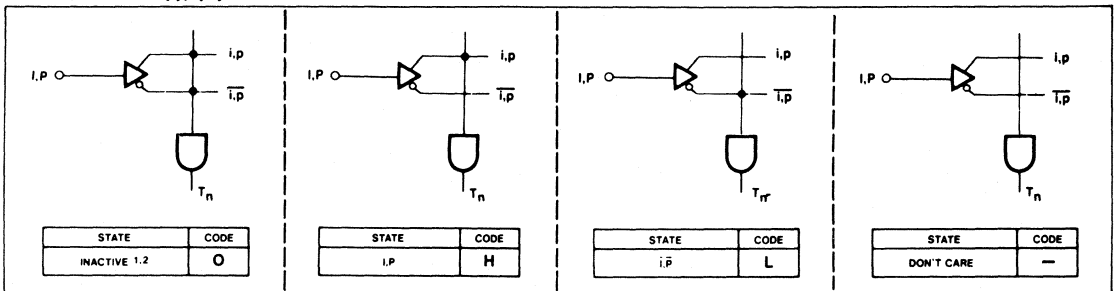

PRESET/ $\overline{O.E.}$ OPTION - (P/E)

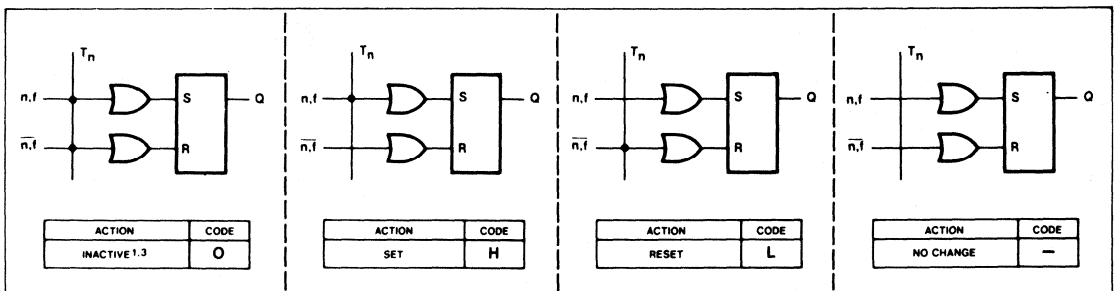

PROGRAMMING

The 82S167A has a power-up reset feature. This feature insures that the device will power-up in a known state with all register elements (state and output register) at a logic High (H). When programming the device it is important to realize this is the initial state of the device. You must provide a next state jump if you do not wish to use all Highs (H) as the present state.

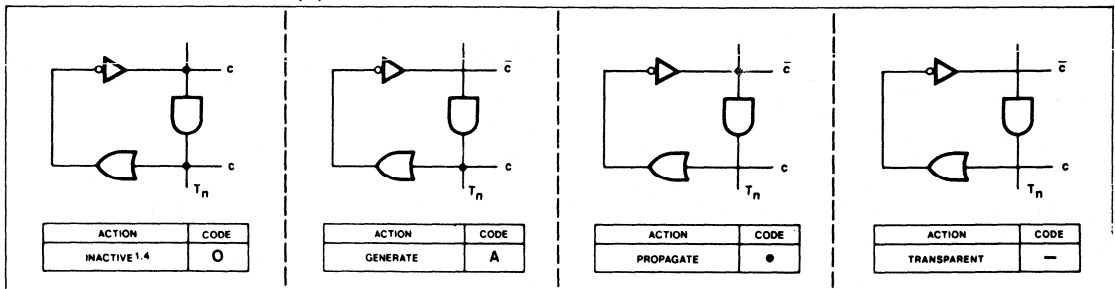

"AND" ARRAY - (I), (P)

"OR" ARRAY - (N), (F)

"COMPLEMENT" ARRAY - (C)

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates T_n .
2. Any gate T_n will be unconditionally inhibited if any one of its I or P link pairs is left intact.
3. To prevent simultaneous Set and Reset flip-flop commands, this state is not allowed for N and F link pairs coupled to active gates T_n (see flip-flop truth tables).
4. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n .

INTEGRATED FUSE LOGIC
SERIES 24

TEST ARRAY

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on-chip test array.

The array consists of test transition terms 48 and 49, factory programmed as shown below.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I_{0-9} as shown in the test circuit timing diagram.

FIELD PROGRAMMABLE LOGIC ARRAY (16x48x8) 82S100 (T.S.)/82S101 (O.C.)

INTEGRATED FUSE LOGIC
SERIES 28

DESCRIPTION

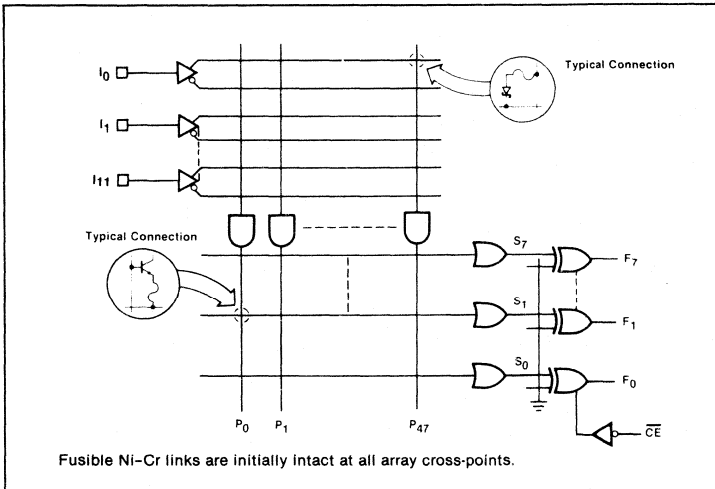

The 82S100 (Three-State) and 82S101 (Open Collector) are Bipolar, Fuse-Link Programmable Logic Arrays (FPLAs). Each device utilizes the standard AND/OR/Invert architecture to directly implement custom sum of product logic equations.

Each device consists of 16 dedicated inputs and 8 dedicated outputs. Each output is capable of being actively controlled by any or all of the 48 product terms. The true, complement, or don't care condition of each of the 16 inputs ANDed together comprise one P-term. All 48 P-terms are then ORed to each output. The user must then only select which P-terms will activate an output by disconnecting terms which do not affect the output. In addition, each output can be fused as active HIGH (H) or active-LOW (L).

The 82S100 and 82S101 are fully TTL compatible, and include chip-enable control for expansion of input variables and output inhibit. They feature either Open Collector or Three-State outputs for ease of expansion of product terms and application in bus-organized systems.

Both devices are available in commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C), specify N82S100/101, F or N and for the military temperature range (-55°C to +125°C), specify S82S100/101, F, G or R.

LOGIC DIAGRAM

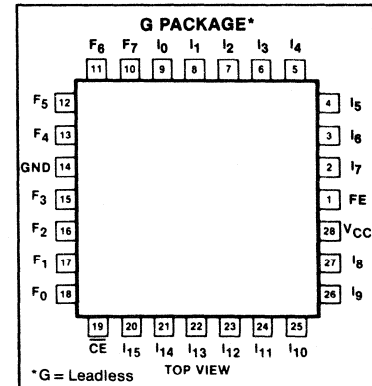

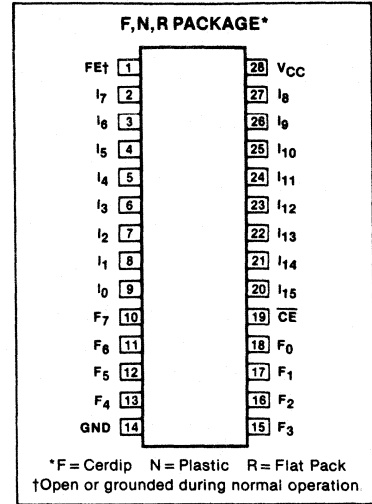

FEATURES

- Field programmable (Ni-Cr link)
- Input variables: 16
- Output functions: 8
- Product terms: 48
- Address access time:
S82S100/101: 80ns max
N82S100/101: 50ns max
- Power dissipation: 600mW typ
- Input loading:
S82S100/101: -150μA max
N82S100/101: -100μA max
- Chip enable input
- Output option:
82S100: Three-State
82S101: Open Collector
- Output disable function:
Three-State: Hi-Z
Open Collector: Hi
- Separate I/O architecture

APPLICATIONS

- CRT display systems
- Random logic
- Code conversion
- Peripheral controllers
- Function generators
- Look-up and decision tables
- Microprogramming
- Address mapping
- Character generators
- Data security encoders
- Fault detectors
- Frequency synthesizers
- 16-bit to 8-bit bus interface
- Random logic replacement

NOTES

- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operation of the device specifications is not implied.
- All values are at V_{CC} = 5V, T_A = 25°C.
- All voltage values are with respect to network ground terminal.
- Test one at a time.
- Measured with V_{IL} applied to CE and a logic high stored.
- Measured with a programmed logic condition for which the output test is at a low logic level. Output sink current is applied thru a resistor to V_{CC}.
- Measured with V_{IH} applied to CE.
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V and the outputs open.

FIELD PROGRAMMABLE LOGIC ARRAY (16x48x8) 82S100 (T.S.)/82S101 (O.C.)

INTEGRATED FUSE LOGIC
SERIES 28

LOGIC PROGRAMMING

The FPLA can be programmed by means of Logic programming equipment.

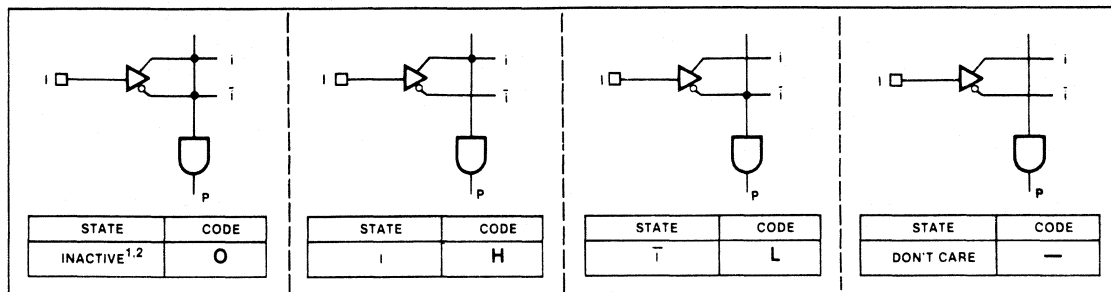

With Logic programming, the AND/OR/EX-OR gate input connections necessary to implement the desired logic function are coded directly from logic equations using the Program Table.

In this Table the logic state or action of variables I , P , and F , associated with each Sum Term S_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

OUTPUT POLARITY-(F)

"AND" ARRAY-(I)

"OR" ARRAY-(F)

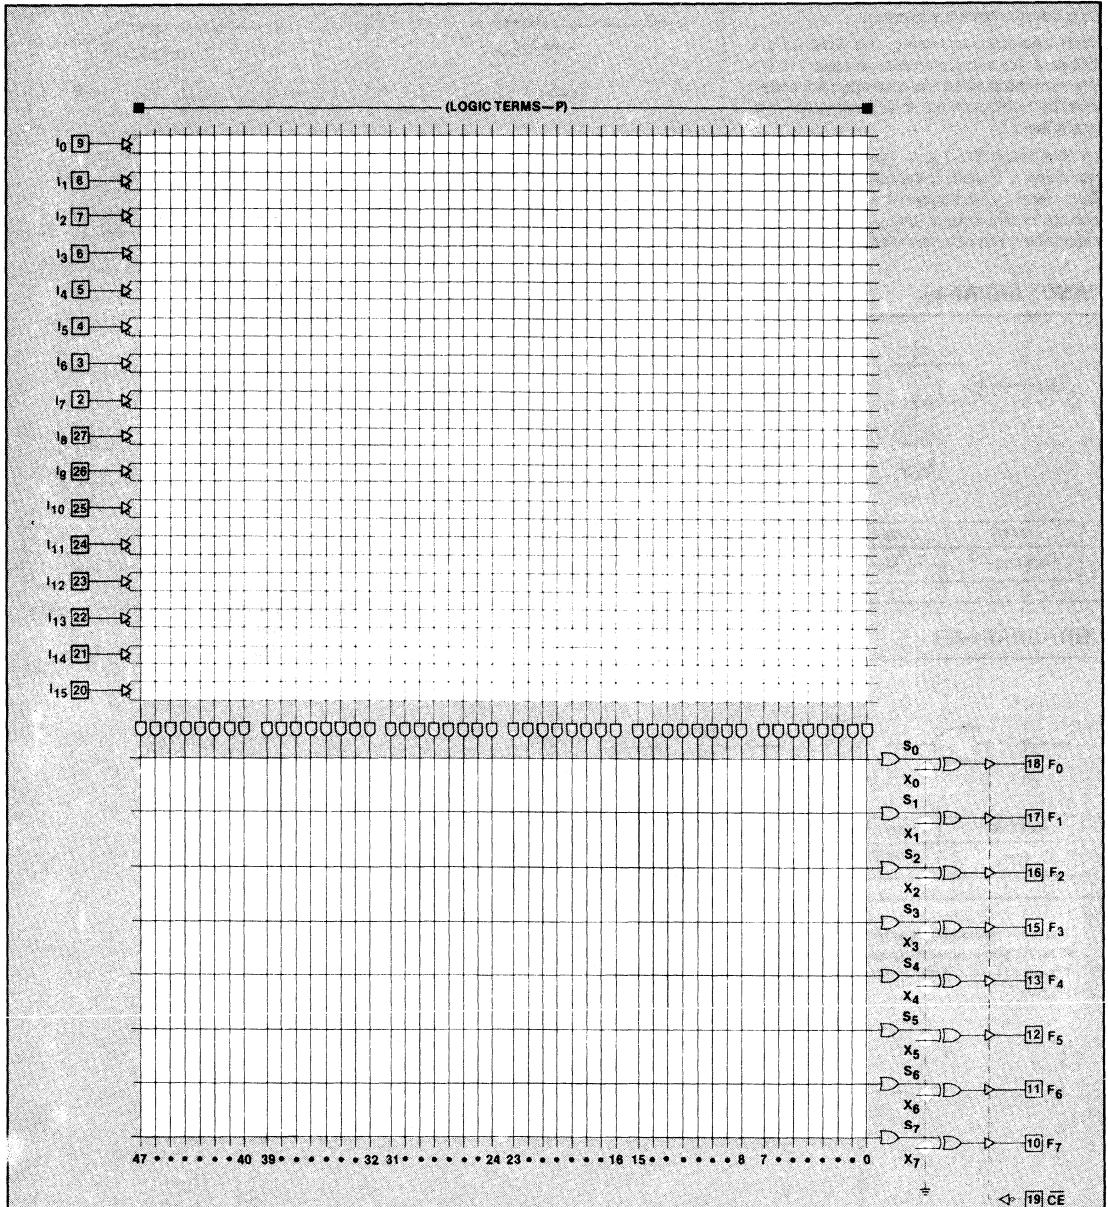

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates P_n .
2. Any gate P_n will be unconditionally inhibited if any one of its (I) link pairs is left intact.

TIMING DIAGRAM

TIMING DEFINITIONS

- T_{CE} Delay between beginning of Chip Enable low (with Input valid) and when Data Output becomes valid.
- T_{CD} Delay between when Chip Enable becomes high and Data Output is in off state (Hi-Z or high).
- T_{IA} Delay between beginning of valid Input (with Chip Enable low) and when Data Output becomes valid.

VIRGIN DEVICE

The 82S100/101 are shipped in an unprogrammed state, characterized by:

1. All internal Ni-Cr links are intact.
2. Each product term (P-term) contains both true and complement values of every input variable I_m (P-terms always logically "false").
3. The "OR" Matrix contains all 48 P-terms.
4. The polarity of each output is set to active high (Fp function).
5. All outputs are at a low logic level.

FIELD PROGRAMMABLE GATE ARRAY (16x9x9)

82S103 (T.S.)

INTEGRATED FUSE LOGIC
SERIES 28

DESCRIPTION

The 82S103 is a bipolar, fuse-programmable gate array. The device consists of nine AND/NAND gates which share 16 common inputs. The type of gate is selected by programming the output as active-HIGH (H) or active-LOW (L). Each of the 16 inputs I_0 - I_{15} can be programmed to provide the True (H), Complement (L), or Don't Care (—) state to each of the nine AND/NAND gates. OR/NOR logic functions can also be implemented by complementing the inputs and outputs via on-chip inverting buffers.

The device is field programmable, which means that custom patterns are immediately available.

The 82S103 includes chip-enable control for output strobing and inhibit. It features either Open Collector or Three-State outputs for ease of expansion of input variables and application in bus-organized systems.

The 82S103 is available in commercial and military temperature ranges. For the commercial range (0°C to +75°C), specify N82S103N and for the military range (-55°C to +125°C), specify S82S103F, G, or R.

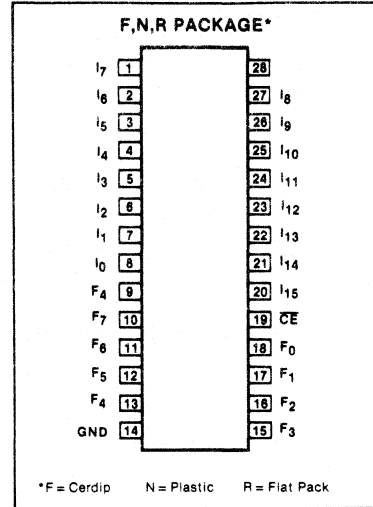

FEATURES

- Field programmable (Ni-Cr link)
- 16 input variables
- 9 output functions
- Chip enable input
- I/O propagation delay:
N82S103: 35ns max
S82S103: 50ns max
- Power dissipation: 600mW typ
- Input loading:
N82S103: -100 μ A max
S82S103: -150 μ A max
- Output: Three-state
- Output disable function: HI-Z
- Fully TTL compatible

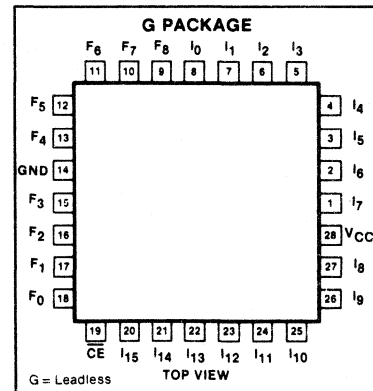

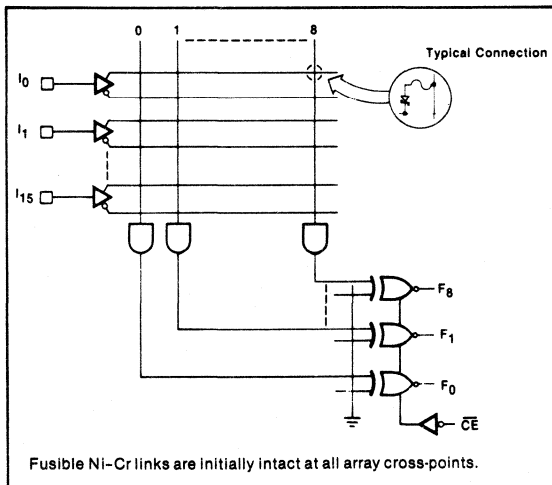

APPLICATIONS

- Random logic
- Address decoders
- Code detectors
- Peripheral selectors
- Fault monitors
- Machine state decoders

NOTES

- All voltage values are with respect to network ground terminal.
- All typical values are at V_{CC} = 5V, T_A = 25°C.
- Test each output one at a time.
- Measure with a programmed logic condition for which the output under test is at a low logic level. Output sink current is supplied through a resistor to V_{CC}.
- Measured with V_{IL} applied to \overline{CE} and a logic high at the output.
- Measured with V_{IH} applied to \overline{CE} .
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the chip enable input grounded, all other inputs at 4.5V, and the outputs open.

FIELD PROGRAMMABLE LOGIC SEQUENCER (16x48x8)

82S105 (T.S.)

INTEGRATED FUSE LOGIC SERIES 28

DESCRIPTION

The 82S105 is a bipolar programmable state machine of the Mealy type. It contains logic AND-OR gate arrays with user programmable connections which control the inputs of on-chip State and Output registers. These consist respectively of 6 Q_P, and 8 Q_F edge triggered, clocked S/R flip-flops, with an asynchronous Preset option. All flip-flops are unconditionally preset to "1" during power turn on.

The AND array combines 16 external inputs I₀₋₁₅ with six internal inputs P₀₋₅ fed back from the State register to form up to 48 transition terms (AND terms). All transition terms can include True, False, or Don't Care states of the controlling variables, and are merged in the OR array to issue next-state and next-output commands to their respective registers on the LOW-to-HIGH transition of the Clock pulse. Both True and Complement transition terms can be generated by optional use of the internal input variable (C) from the Complement array. Also, if desired, the Preset input can be converted to Output Enable function, as an additional user-programmable option.

The device is available in commercial and military temperature ranges. For the commercial temperature range (0°C to +75°C) specify N82S105, F or N, and for the military temperature range (-55°C to +125°C) specify S82S105 F, G or R.

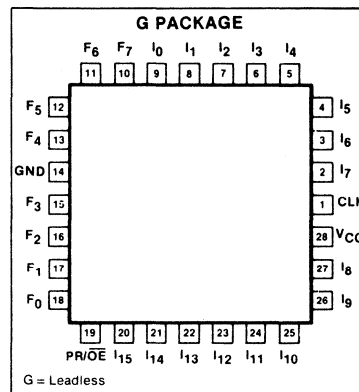

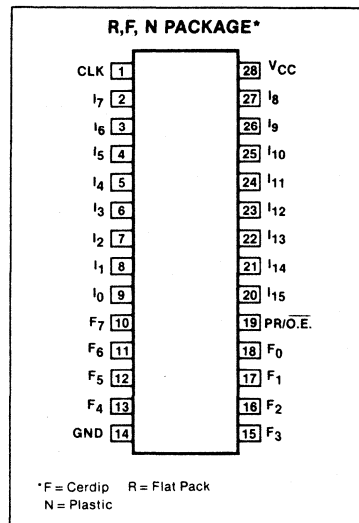

FEATURES

- Field programmable (Ni-Cr link)
- 16 input variables
- 8 output functions
- 48 transition terms
- 6-bit state register
- 8-bit output register
- Transition complement array
- Positive edge trigger clock
- Programmable asynchronous preset or output enable
- Power-on preset to all "1" of internal registers
- f(max) = 13.9MHz
- 650mW power dissipation (typical)
- TTL compatible
- Single +5V supply
- Open collector and tri-state versions
- TRI-STATE outputs

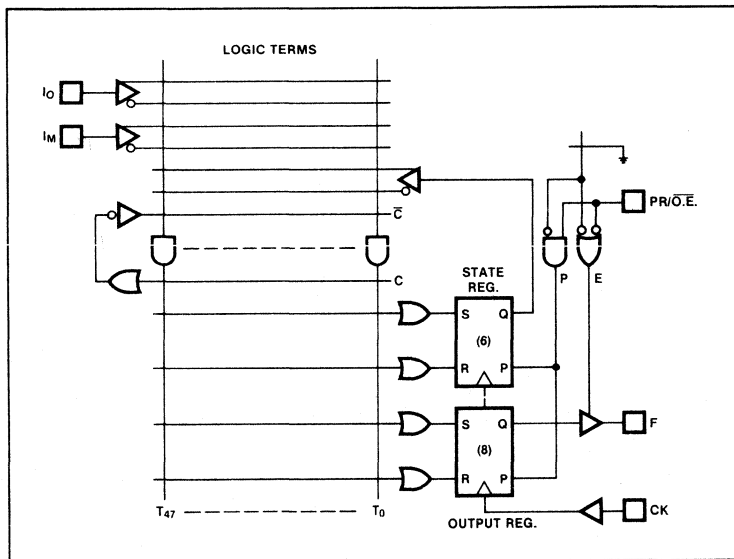

APPLICATIONS

- Interface protocols
- Sequence detectors
- Peripheral controllers
- Timing generators
- Sequential circuits
- Elevator controllers
- Security locking systems
- Counters
- Shift registers

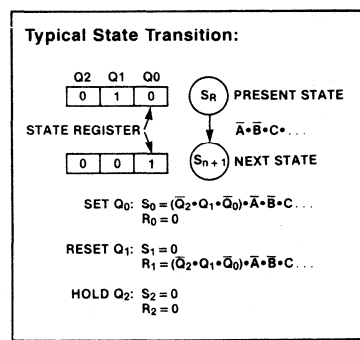

PIN CONFIGURATION

LOGIC DIAGRAM

LOGIC FUNCTION

PIN DESIGNATION

| PIN NO. | SYMBOL | NAME AND FUNCTION | POLARITY |
|--------------------|-------------------|---|---------------------------------------|
| 1 | CK | CLOCK The clock input to the State and Output Registers. A Low-to-High transition on this line is necessary to update the contents of both registers. | Active-High |
| [2-8 20-27] | I ₁₋₁₅ | LOGIC INPUTS The 15 external inputs to the AND array used to program jump conditions between machine states, as determined by a given logic sequence. | Active-High/Low |
| 9 | I ₀ | LOGIC/DIAGNOSTIC INPUT A 16th external logic input to the AND array, as above, when exercised with standard TTL levels. When I ₀ is held at +10V, device outputs F ₀₋₅ reflect the contents of State Register bits P ₀₋₅ . The contents of the Output Register remain unaltered. | Active-High/Low |
| [10-13 15-18] | F ₀₋₇ | LOGIC/DIAGNOSTIC OUTPUTS Eight device outputs which normally reflect the contents of Output Register bits Q ₀₋₇ , when enabled. When I ₀ is held at +10V, F ₀₋₅ = (P ₀₋₅), and F _{6, 7} = Logic "1". | Active-High |
| 19 | PR/ <u>OE</u> | PRESET OR OUTPUT ENABLE INPUT A user programmable function: <ul style="list-style-type: none"> • PRESET Provides an asynchronous preset to logic "1" of all State and Output Register bits. Preset overrides Clock, and when held High, clocking is inhibited and F₀₋₇ are High. Normal clocking resumes with the first full clock pulse following a High-to-Low clock transition, after Preset goes Low. • OUTPUT ENABLE Provides an output enable function to buffers F₀₋₇ from the Output Register. | Active-High (H) Active-Low (L) |

| | ■ | ■ | X | ! | H | H | IND. | IND. |
| | ■ | ■ | X | X | X | X | H | ■ |
| | ■ | ■ | X | X | X | X | H | ■ |

- NOTES:
- Positive Logic:
 $S/R = T_0 + T_1 + T_2 + \dots + T_{47}$
 $T_n = C (I_0 I_1 I_2 \dots) (P_0 P_1 \dots P_5)$
 - Either Preset (active-High) or Output Enable (active-LOW) are available, but not both. The desired function is a user programmable option.
 - ! denotes transition from Low to High level.
 - R = S = High is an illegal input condition.
 - * = H/L + 10V
 - X = Don't Care ($\leq 5.5V$)

VIRGIN STATE

A factory shipped virgin device contains all fusible links intact, such that:

- PR/OE option is set to PR. Thus, all outputs will be at "1", as preset by initial power-up procedure.
- All transition terms are disabled (0).
- All S/R flip-flop inputs are disabled (0).
- The device can be clocked via a Test Array pre-programmed with a standard test pattern.
NOTE: The Test Array pattern MUST be deleted before incorporating a user program.

- NOTES
- Stresses above those listed under "Absolute Maximum Ratings" may cause malfunction or permanent damage to the device. This is a stress rating only. Functional operation at these or any other condition above those indicated in the operational and programming specification of the device is not implied.
 - All typical values are at V_{CC} = 5V, T_A = 25 °C.
 - All voltage values are with respect to network ground terminal.
 - Test one at a time.
 - Measured with V_{IL} applied to \overline{OE} and a logic high stored, or with V_{IH} applied to PR.
 - Measured with a programmed logic condition for which the output is at a low logic level, and V_{IL} applied to $\overline{PR/OE}$. Output sink current is supplied through a resistor to V_{CC}.
 - Measured with V_{IH} applied to $\overline{PR/OE}$.
 - Duration of short circuit should not exceed 1 second.
 - I_{CC} is measured with the $\overline{PR/OE}$ input grounded, all other inputs at 4.5V and the outputs open.

NOTES

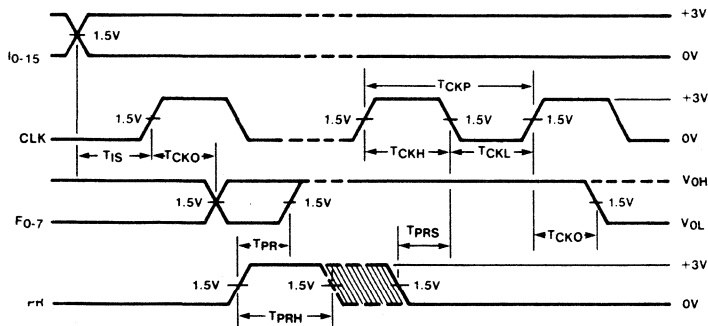

1. All typical values are at $V_{CC} = 5V$, $T_A = 25^\circ C$.
2. To prevent spurious clocking, clock rise time (10% - 90%) $\leq 30ns$.
3. See "Speed vs. OR Loading" on page 5-19.

TIMING DIAGRAMS

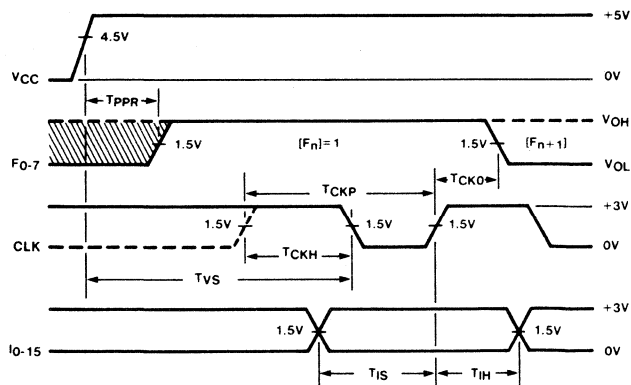

SEQUENTIAL MODE

ASYNCHRONOUS PRESET

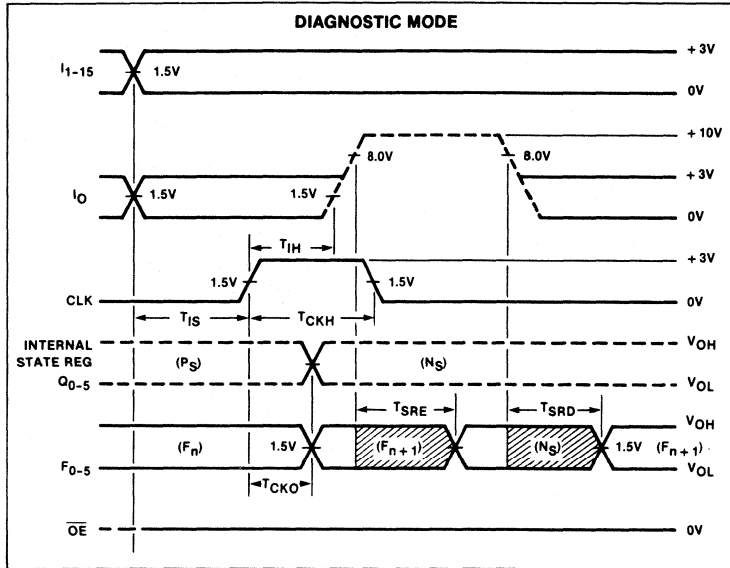

POWER-ON PRESET

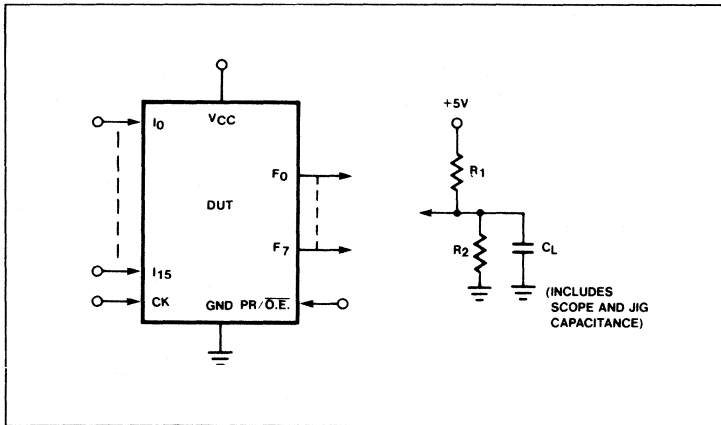

TIMING DEFINITIONS

- T_{CKH} Width of input clock pulse.
- T_{CKL} Interval between clock pulses.
- T_{CKP} Clock period—when not using Complement array.
- T_{IS1} Required delay between beginning of valid input and positive transition of clock.
- T_{CKP2} Clock period—when using Complement array.
- T_{IS2} Required delay between beginning of valid input and positive transition of clock, when using optional Complement Array (two passes necessary through the AND array).
- T_{VS} Required delay between V_{CC} (after power-on) and negative transition of clock preceding first reliable clock pulse.
- T_{PRS} Required delay between negative transition of asynchronous Preset and negative transition of clock preceding first reliable clock pulse.
- T_{IH} Required delay between positive transition of clock and end of valid input data.
- T_{CKO} Delay between positive transition of clock and when Outputs become valid (with PR/O.E. low).
- T_{OE} Delay between beginning of Output Enable Low and when Outputs become valid.
- T_{OD} Delay between beginning of Output Enable High and when Outputs are in the off state.
- T_{SRE} Delay between input I₀ transition to Diagnostic mode and when the Outputs reflect the contents of the State Register.
- T_{SRD} Delay between input I₀ transition to Logic mode and when the Outputs reflect the contents of the Output Register.
- T_{PR} Delay between positive transition of Preset and when Outputs become valid at "1".
- T_{PPR} Delay between V_{CC} (after power-on) and when Outputs become preset at "1".
- T_{PRH} Width of preset input pulse.
- f_{MAX} Maximum clock frequency.

TIMING DIAGRAMS (Cont'd)

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

SPEED VS. "OR" LOADING

The maximum frequency at which the FPLS can be clocked while operating in *sequential mode* is given by:

$$(1/f_{MAX}) = T_{CY} = T_{IS} + T_{CKO}$$

This frequency depends on the number of transition terms T_n used. Having all 48 terms connected in the AND array does not appreciably impact performance; but the number of terms connected to each OR line affects T_{IS} , due to capacitive loading. The effect of this loading can be seen in Figure 1, showing the variation of T_{IS1} with the number of terms connected per OR.

The AC electrical characteristics contain three limits for the parameters T_{IS1} and T_{IS2} . The first, T_{IS1A} is guaranteed for a device with 48 terms connected to any OR line. T_{IS1B} is guaranteed for a device with 32 terms connected to any OR line. And T_{IS1C} is guaranteed for a device with 24 terms connected to any OR line.

Figure 1. T_{IS1} vs. Terms/OR Connected.

The three other entries in the AC table, T_{IS2} A, B, and C are corresponding 48, 32, and 24 term limits when using the on-chip Complement Array.

The worst case T_{IS} for a given application can be determined by identifying the OR line with the maximum number of T_n con-

nections. This can be done by referring to the interconnect pattern in the FPLS logic diagram, typically illustrated in Figure 2, or by counting the maximum number of "H" or "L" entries in one of the columns of the device Program Table.

This number plotted on the curve in Figure 1 will yield the worst case T_{IS} and, by implication, the maximum clocking frequency for reliable operation.

Note that for maximum speed all UNUSED transition terms should be disconnected from the OR array.

Figure 2. Typical OR Array Interconnect Pattern.

FIELD PROGRAMMABLE LOGIC SEQUENCER (16x48x8)

82S105 (T.S.)

INTEGRATED FUSE LOGIC SERIES 28

LOGIC PROGRAMMING

The FPLS can be programmed by means of Logic programming equipment.

With Logic programming, the AND/OR gate input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Table on the following page.

In this Table, the logic state or action of control variables C, I, P, N, and F, associated with each Transition Term T_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

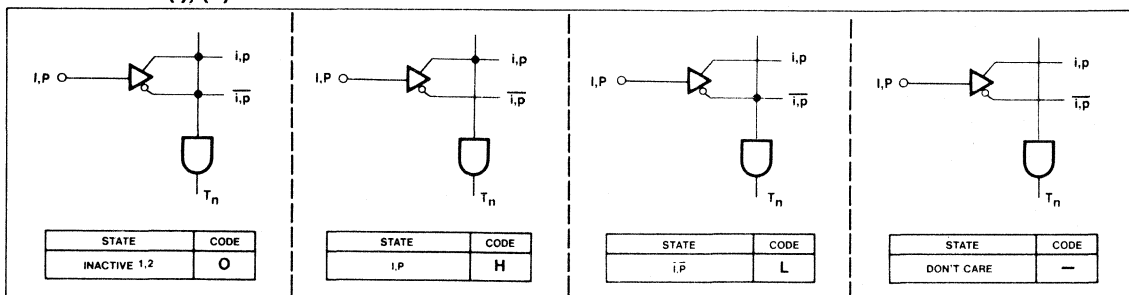

PRESET/O.E. OPTION - (P/E)

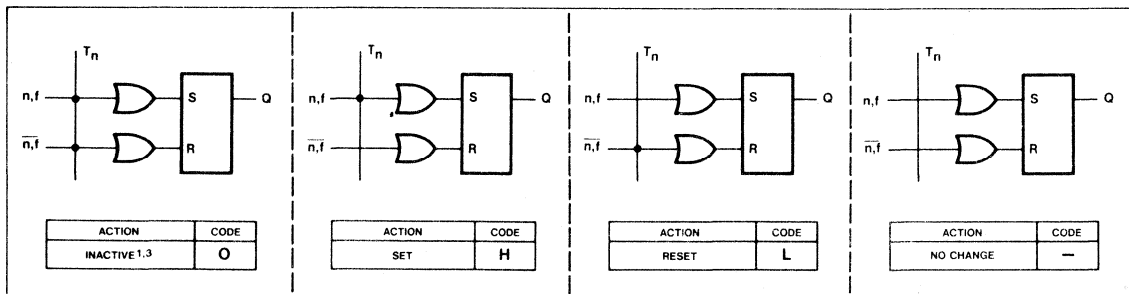

PROGRAMMING THE 82S104/105

The 82S104/105 has a power-up preset feature. This feature insures that the device will power-up in a known state with all register elements (state and output register) at a logic high (H). When programming the device it is important to realize this is the initial state of the device. You *must* provide a next state jump if you do not wish to use all highs (H) as the present state.

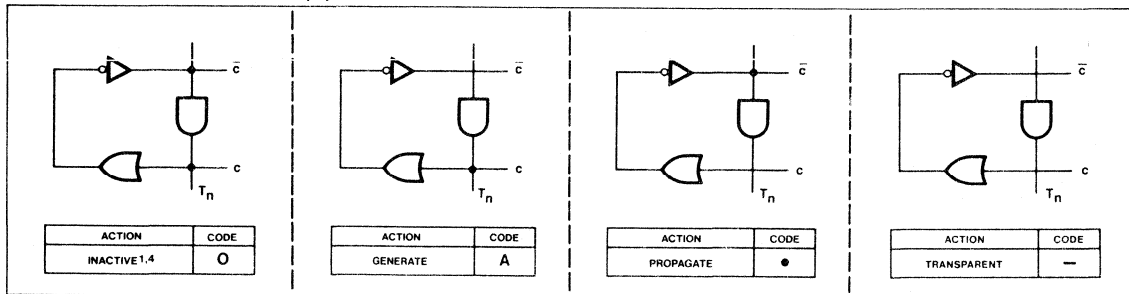

"AND" ARRAY - (I), (P)

"OR" ARRAY - (N), (F)

"COMPLEMENT" ARRAY - (C)

NOTES

- This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates T_n .
- Any gate T_n will be unconditionally inhibited if any one of its I or P link pairs is left intact.
- To prevent simultaneous Set and Reset flip-flop commands, this state is not allowed for N and F link pairs coupled to active gates T_n (see flip-flop truth tables).
- To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n .

FIELD PROGRAMMABLE LOGIC SEQUENCER (16x48x8)

82S105 (T.S.)

INTEGRATED FUSE LOGIC SERIES 28

TEST ARRAY

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on chip test array.

The array consists of test transition terms 48 and 49, factory programmed as shown below.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I_{0,7} as shown in the test circuit timing diagram.

STATE DIAGRAM

FIELD PROGRAMMABLE LOGIC SEQUENCER (16x48x8)

82S105A (T.S.)

INTEGRATED FUSE LOGIC SERIES 28

DESCRIPTION

The 82S105A is a bipolar programmable state machine of the Mealy type. It contains logic AND-OR gate arrays with user programmable connections which control the inputs of on-chip State and Output registers. These consist respectively of 6 Q_P , and 8 Q_F edge triggered, clocked S/R flip-flops, with an asynchronous Preset option. All flip-flops are unconditionally preset to "1" during power turn on.

The AND array combines 16 external inputs I_{0-15} with 6 internal inputs P_{0-5} fed back from the State register to form up to 48 Transition terms (AND terms). All Transition terms can include True, False, or Don't Care states of the controlling variables, and are merged in the OR array to issue next-state and next-output commands to their respective registers on the Low to High transition of the Clock pulse. Both True and Complement Transition terms can be generated by optional use of the internal input variable (C) from the Complement array. Also, if desired, the Preset input can be converted to Output-Enable function, as an additional user programmable option.

The device is available in commercial temperature range. For the commercial temperature range (0°C to +75°) specify N82S105A, F or N.

FEATURES

- Field programmable (Ni-Cr link)
- 16 input variables
- 8 output functions
- 48 transition terms
- 6-bit state register
- 8-bit output register
- Transition complement array
- Positive edge trigger clock
- Programmable asynchronous preset or output enable
- Power-on preset to all "1" of internal registers
- $f(\text{max}) = 20\text{MHz}$
- 650mW power dissipation (typical)
- TTL compatible
- Single +5V supply
- Open collector and tri-state versions
- TRI-STATE outputs

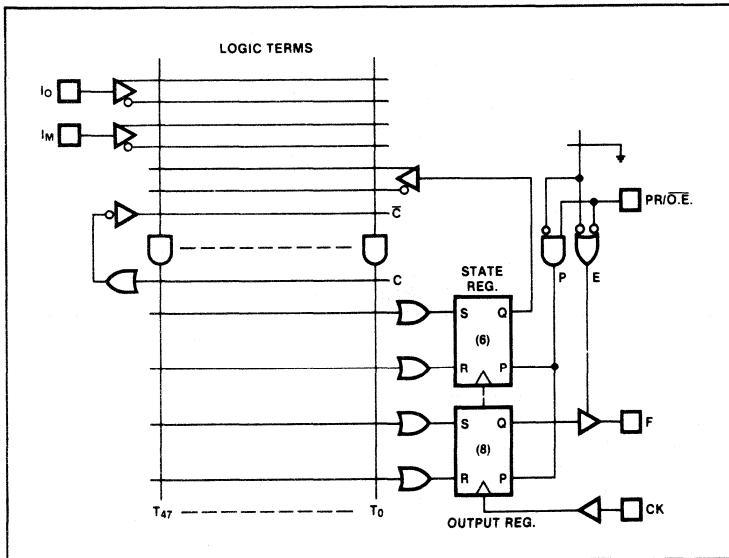

APPLICATIONS

- Interface protocols
- Sequence detectors
- Peripheral controllers
- Timing generators
- Sequential circuits
- Elevator controllers
- Security locking systems
- Counters
- Shift registers

LOGIC SEQUENCER (16x48x8)**

82S105A (T.S.)

INTEGRATED FUSE LOGIC
SERIES 28

PIN DESIGNATION

| PIN NO. | SYMBOL | NAME AND FUNCTION | POLARITY |
|--------------------|-----------------------|---|---------------------------------------|
| 1 | CK | CLOCK The clock input to the State and Output Registers. A Low-to-High transition on this line is necessary to update the contents of both registers. | Active-High |
| [2-8 20-27] | I ₁₋₁₅ | LOGIC INPUTS The 15 external inputs to the AND array used to program jump conditions between machine states, as determined by a given logic sequence. | Active-High/Low |
| 9 | I ₀ | LOGIC/DIAGNOSTIC INPUT A 16th external logic input to the AND array, as above, when exercised with standard TTL levels. When I ₀ is held at +10V, device outputs F ₀₋₅ reflect the contents of State Register bits P ₀₋₅ . The contents of the Output Register remain unaltered. | Active-High/Low |
| [10-13 15-18] | F ₀₋₇ | LOGIC/DIAGNOSTIC OUTPUTS Eight device outputs which normally reflect the contents of Output Register bits Q ₀₋₇ , when enabled. When I ₀ is held at +10V, F ₀₋₅ = (P ₀₋₅), and F _{6, 7} = Logic "1". | Active-High |
| 19 | PR/ $\overline{O.E.}$ | PRESET OR OUTPUT ENABLE INPUT A user programmable function: <ul style="list-style-type: none"> PRESET Provides an asynchronous preset to logic "1" of all State and Output Register bits. Preset overrides Clock, and when held High, clocking is inhibited and F₀₋₇ are High. Normal clocking resumes with the first full clock pulse following a High-to-Low clock transition, after Preset goes Low. OUTPUT ENABLE Provides an output enable function to buffers F₀₋₇ from the Output Register. | Active-High (H) Active-Low (L) |

TRUTH TABLE^{1,2,3,4,5,6}

| | 1 | X | X | X | X | X | H | |
| | | X | X | X | X | X | H | |

NOTES:

- Positive Logic:
 $S/R = T_0 + T_1 + T_2 + \dots + T_{27}$
 $T_n = C(I_0 I_1 I_2 \dots) (P_0 P_1 \dots P_4)$
- Either Preset (active-High) or Output Enable (active-LOW) are available, but not both. The desired function is a user programmable option.
- ↑ denotes transition from Low to High level.
- R = S = High is an illegal input condition.
- * = H/L/+10V
- X = Don't Care (\leq 5.5V)

VIRGIN STATE

A factory shipped virgin device contains all fusible links intact, such that:

- PR/ $\overline{O.E.}$ option is set to PR. Thus, all outputs will be at "1", as preset by initial power-up procedure.
- All transition terms are disabled (0).
- All S/R flip-flop inputs are disabled (0).
- The device can be clocked via a Test Array pre-programmed with a standard test pattern.
 NOTE: The Test Array pattern MUST be deleted before incorporating a user program.

NOTES

- Stresses above those listed under "Absolute Maximum Ratings" may cause malfunction or permanent damage to the device. This is a stress rating only. Functional operation at these or any other condition above those indicated in the operational and programming specification of the device is not implied.
- All typical values are at V_{CC} = 5V, T_A = 25°C.
- All voltage values are with respect to network ground terminal.
- Test one at a time.
- Measured with V_{IL} applied to $\overline{O.E.}$ and a logic high stored, or with V_{IH} applied to PR.
- Measured with a programmed logic condition for which the output is at a low logic level, and V_{IL} applied to PR/ $\overline{O.E.}$. Output sink current is supplied through a resistor to V_{CC}.
- Measured with V_{IH} applied to PR/ $\overline{O.E.}$.
- Duration of short circuit should not exceed 1 second.
- I_{CC} is measured with the PR/ $\overline{O.E.}$ input grounded, all other inputs at 4.5V and the outputs open.

NOTES

- All typical values are at $V_{CC} = 5V$, $T_A = 25^\circ C$.
- To prevent spurious clocking, clock rise time (10%-90%) $\leq 30ns$.
- See "Speed vs. OR Loading" on page 5-30.

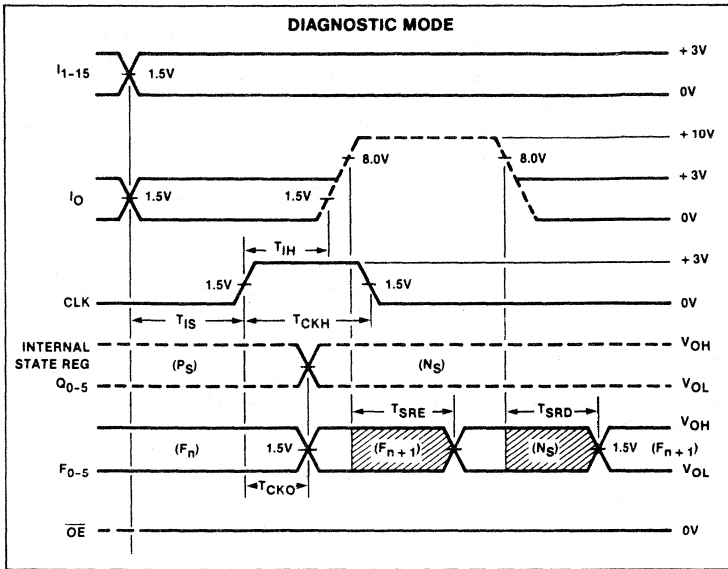

TIMING DIAGRAMS

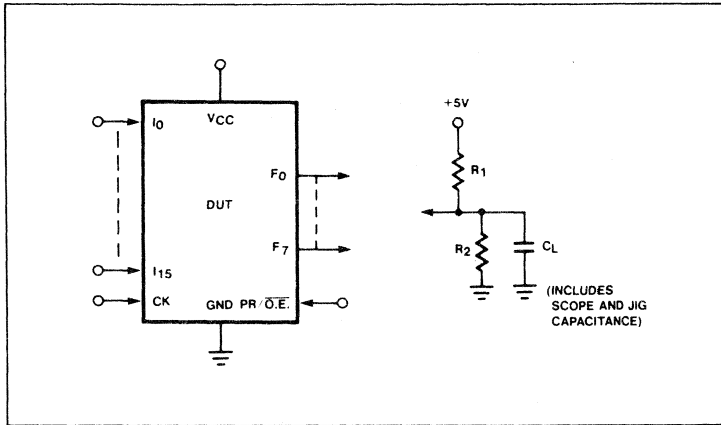

TIMING DEFINITIONS

- TCKH** Width of input clock pulse.
- TCKL** Interval between clock pulses.
- TCKP** Clock period—when not using Complement array.
- TCKP₂** Clock period—when using Complement array.
- TIS1** Required delay between beginning of valid input and positive transition of clock.
- TIS2** Required delay between beginning of valid Input and positive transition of clock, when using optional Complement Array (two passes necessary through the AND array).
- Tvs** Required delay between V_{CC} (after power-on) and negative transition of clock preceding first reliable clock pulse.
- TPRS** Required delay between negative transition of asynchronous Preset and negative transition of clock preceding first reliable clock pulse.
- TIH** Required delay between positive transition of clock and end of valid Input data.
- TCKO** Delay between positive transition of clock and when Outputs become valid (with PR/ $\overline{O.E.}$ low).
- TOE** Delay between beginning of Output Enable Low and when Outputs become valid.
- TOD** Delay between beginning of Output Enable High and when Outputs are in the off state.
- TSRE** Delay between input I_0 transition to Diagnostic mode and when the Outputs reflect the contents of the State Register.
- TSRD** Delay between input I_0 transition to Logic mode and when the Outputs reflect the contents of the Output Register.
- TPR** Delay between positive transition of Preset and when Outputs become valid at "1".
- TPPR** Delay between V_{CC} (after power-on) and when Outputs become preset at "1".
- TPRH** Width of preset input pulse.
- f_{MAX}** Maximum clock frequency.

TIMING DIAGRAMS (Cont'd)

TEST LOAD CIRCUIT

VOLTAGE WAVEFORM

SPEED VS. "OR" LOADING

The maximum frequency at which the FPLS can be clocked while operating in *sequential mode* is given by:

$$(1/f_{MAX}) = T_{CY} = T_{IS} + T_{CKO}$$

This frequency depends on the number of transition terms T_n used. Having all 48 terms connected in the AND array does not appreciably impact performance; but the number of terms connected to each OR line affects T_{IS} , due to capacitive loading. The effect of this loading can be seen in Figure 1, showing the variation of T_{IS1} with the number of terms connected per OR.

The AC electrical characteristics contain two limits for the parameters T_{IS1} and T_{IS2} . The first, T_{IS1A} is guaranteed for a device with 24 terms connected to any OR line. T_{IS1B} is guaranteed for a device with 16 terms connected to any OR line.

Figure 1. T_{IS1} vs. Terms/OR Connected.

The two other entries in the AC table, T_{IS2} A and B are corresponding 24 and 16 term limits when using the on-chip Complement Array.

The worst case of T_{IS} for a given application can be determined by identifying the OR line with the maximum number of T_n

connections. This can be done by referring to the interconnect pattern in the FPLS logic diagram, typically illustrated in Figure 2, or by counting the maximum number of "H" or "L" entries in one of the columns of the device Program Table.

This number plotted on the curve in Figure 1 will yield the worst case T_{IS} and, by implication, the maximum clocking frequency for reliable operation.

Note that for maximum speed all UNUSED transition terms should be disconnected from the OR array.

Figure 2. Typical OR Array Interconnect Pattern.

FIELD PROGRAMMABLE LOGIC SEQUENCER (16x48x8)

82S105A (T.S.)

LOGIC PROGRAMMING

The FPLS can be programmed by means of Logic programming equipment.

With Logic programming, the AND/OR gate input connections necessary to implement the desired logic function are coded directly from the State Diagram using the Program Table on the following page.

In this Table, the logic state or action of control variables C, I, P, N, and F, associated with each Transition Term T_n , is assigned a symbol which results in the proper fusing pattern of corresponding link pairs, defined as follows:

"AND" ARRAY - (I), (P)

| <table border="1"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>INACTIVE 1,2</td><td>O</td></tr> </table> | STATE | CODE | INACTIVE 1,2 | O | <table border="1"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>I, P</td><td>H</td></tr> </table> | STATE | CODE | I, P | H | <table border="1"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>i, P-bar</td><td>L</td></tr> </table> | STATE | CODE | i, P-bar | L | <table border="1"> <tr><th>STATE</th><th>CODE</th></tr> <tr><td>DON'T CARE</td><td>-</td></tr> </table> | STATE | CODE | DON'T CARE | - |

| DON'T CARE | - | | | | | | | | | | | | | | | | | | |

PROGRAMMING THE 82S104/105

The 82S104/105 has a power-up preset feature. This feature insures that the device will power-up in a known state with all register elements (state and output register) at a logic high (H). When programming the device it is important to realize this is the initial state of the device. You *must* provide a next state jump if you do not wish to use all highs (H) as the present state.

"OR" ARRAY - (N), (F)

| <table border="1"> <tr><th>ACTION</th><th>CODE</th></tr> <tr><td>INACTIVE 1,3</td><td>O</td></tr> </table> | ACTION | CODE | INACTIVE 1,3 | O | <table border="1"> <tr><th>ACTION</th><th>CODE</th></tr> <tr><td>SET</td><td>H</td></tr> </table> | ACTION | CODE | SET | H | <table border="1"> <tr><th>ACTION</th><th>CODE</th></tr> <tr><td>RESET</td><td>L</td></tr> </table> | ACTION | CODE | RESET | L | <table border="1"> <tr><th>ACTION</th><th>CODE</th></tr> <tr><td>NO CHANGE</td><td>-</td></tr> </table> | ACTION | CODE | NO CHANGE | - |

| ACTION | CODE | | | | | | | | | | | | | | | | | | |
| TRANSPARENT | - | | | | | | | | | | | | | | | | | | |

NOTES

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates T_n .
2. Any gate T_n will be unconditionally inhibited if any one of its I or P link pairs is left intact.
3. To prevent simultaneous Set and Reset flip-flop commands, this state is not allowed for N and F link pairs coupled to active gates T_n (see flip-flop truth tables).
4. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n .

TEST ARRAY

The FPLS may be subjected to AC and DC parametric tests prior to programming via an on chip test array.

The array consists of test transition terms 48 and 49, factory programmed as shown below.

Testing is accomplished by clocking the FPLS and applying the proper input sequence to I₀₋₇ as shown in the test circuit timing diagram.

STATE DIAGRAM

Military
Products**

MILITARY PRODUCT GUIDE

MILITARY PRODUCTS/ PROCESS LEVELS

The Signetics MIL-M-38510 and MIL-STD-883 Programs are organized to provide a broad selection of processing options, structured around the most commonly requested customer flows. These programs are designed to provide our customers:

- Fully compliant 883/M5004 flows on all products.
- Standard processing flows to help minimize the need for custom specifications.
- Cost savings realized by using standard processing flows in lieu of custom flows.
- Better delivery lead times by minimizing spec negotiation time, plus allow customers to buy products off-the-shelf or in various stages of production rather than waiting for devices started specifically to custom specifications.

The following explains the different processing options available. Special device marking clearly distinguishes the type of screening performed. Refer to Tables 2 and 3.

JAN QUALIFIED (JS and JB)

JAN Qualified product is designed to give you the optimum in quality and reliability. The JAN processing level is offered as the result of the government's product standardization programs, and is monitored by the Defense Electronic Supply Center (DESC), through the use of industry-wide procedures and specifications.

JAN Qualified products are manufactured, processed and tested in a government certified facility to Mil-M-38510, and appropriate device slash sheet specifications. Design documentation, lot sampling plans, electrical test data and qualification data for each specific part type has been approved by the Defense Electronic Supply Center (DESC) and products appear on the DESC Qualified Products List (QPL 38510).

Quality conformance inspection testing, per MIL-STD-883, Method 5005, is performed according to Mil-M-38510 as follows:

- Group A; each subplot. (Alternate Group A)
- Group B; one subplot for each package type every week. (Alternate Group B)
- Group C; one subplot for each microcircuit group every 13 weeks.

| JAN CASE OUTLINE AND LEAD FINISH | SIGNETICS MILITARY PACKAGE TYPES | | | | | |
|----------------------------------|----------------------------------|--------|--------|--------|--------|--------|
| | CERAMIC | | | | | |
| | 8-PIN | 14-PIN | 16-PIN | 18-PIN | 20-PIN | 24-PIN |
| PB | FE | — | — | — | — | — |
| CB | — | F | — | — | — | — |
| EB | — | — | F | — | — | — |
| JB | — | — | — | — | — | F |
| DB | — | W | — | — | — | — |
| FB | — | — | W | — | — | — |
| RB | — | — | — | — | F | — |
| VB | — | — | — | F | — | — |

All products listed are also available in Die form.

Table 2 MILITARY SUMMARY

- Group D; one subplot for each package type every 26 weeks.

NOTE: This category of part conforms to Quality Level B ($\pi_Q=1.0$) of MIL-HDBK-217D.

In addition to the common specs used throughout the industry for processing and testing, JAN Qualified products also possess a requirement for a standard marking used throughout the IC industry.

By implementing this government standardization program, Signetics complies with the trend of reducing the numerous similar Source Control Drawings (SCD's). This standardized trend results in a *single* complete and comprehensive specification, a *single* product flow, and a *single* administrative effort—for both the aerospace community and for Signetics. Because the list of Signetics' qualified products will change periodically, you may wish to contact your nearest Signetics' Sales Office or refer to the *Products Qualified* under Military Specification from DESC for our current update.

JAN Class S products are quoted on a unit price basis only (similar to present Class B programs). There will be no lot charges for SEM inspection, electrical testing, or Group B or D quality conformance inspection. All additional charges are amortized in the unit price.

Package types currently qualified are:

- 1) Cerdip—ceramic dual-in-line
- 2) Cerpac—ceramic flat pack

Government Source Inspection (GSI) is a requirement of the JAN 38510 Class S specification. No alterations to this specification may be instituted. Therefore, the only allowed customer source inspection option is at pre-ship (verification only).

Additional program data options (such as wafer lot acceptance, attributes, Group B, D, and others) are available upon request for a nominal fee.

MIL-STD-883, LEVEL B

Processing to this option is ideal when no JAN slash sheets are released on devices required. Product is processed to MIL-STD-883 Method 5004, and is 100% electrically tested to Signetics data sheets.

Quality conformance inspection per MIL-STD-883, Method 5005, Group A, is performed on each subplot. Group A subgroup electrical parameters are those included in the detailed Signetics data book. Contact the factory for parametric subgroup assignments.

Generic quality conformance data per Method 5005, Groups B, C, and D, is generally available on popular device types and packages, but availability is not guaranteed. The factory must be consulted

MILITARY PRODUCT GUIDE

prior to ordering generic data. When available, generic data is defined as follows:

- Group B: Performed once per package type every six weeks of seal.
- Group C: Performed once per microcir-

cuit group every 52 weeks of seal.

- Group D: Performed once per package type every 52 weeks of seal.
- Quality conformance endpoint electrical parameters for Groups C and D are the

Group A subgroups 1, 2, and 3.

Copies of generic data, Groups A, B, C, and D, may be ordered by customers at a nominal charge.

NOTE: This category of part conforms of Quality Level B-2 ($\pi_Q = 6.5$) of MIL-HDBK-217D.

Table 3. REQUIREMENTS AND SCREENING FLOWS FOR STANDARD PRODUCTS (Continued)

MILITARY PRODUCTS GUIDE

ORDERING INFORMATION

The Signetics Military Products are available in a variety of different process levels and several different packages. The correct ordering code or part number for the devices is an alphanumeric sequence as explained below. Not all devices are available in all

the packages. The ordering codes on the individual data sheets indicate the present or planned availability of the products. However, availability of specific part numbers can be obtained from your local sales office or franchised distributor.

Ordering Code

NOTE:

- 1) and 2) JAN qualified products.
- 3) and 4) Non-JAN MIL-STD-883 products.

For minimum quantity orders, contact your local Signetics sales representative.

PACKAGES AVAILABLE*

- F = Ceramic DIP
- I = Ceramic DIP
- G = Ceramic Leadless Chip Carrier
- W = Ceramic Flatpack

* See Package Outlines section for more information

For the latest military product information, please request a Military Products Guide from Publications Services, 408/746-2111.

Section 7 Packages

PACKAGES—GENERAL INFORMATION

INTRODUCTION

The following information applies to all packages unless otherwise specified on individual package outline drawings.

General

1. Dimensions shown are metric units (millimeters), except those in parentheses which are English units (inches).
2. Lead spacing shall be measured within this zone.
 - a. Shoulder and lead tip dimensions are to centerline of leads.
3. Tolerances non-cumulative
4. Thermal resistance values are determined by utilizing the linear temperature dependence of the forward voltage drop across the substrate diode in a digital device to monitor the junction temperature rise during known power application across V_{CC} and ground. The values are based upon 120 mils square die for plastic packages and a 90 mils square die in the smallest available cavity for hermetic packages. All units were solder mounted to P.C. boards, with standard stand-off, for measurement.

Plastic Only

5. Lead material: Olin 194 (copper alloy) or equivalent, solder dipped.
6. Body material: Plastic (epoxy)
7. Round hole in top corner denotes lead No. 1.
8. Body dimensions do not include molding flash.
9. SO packages—microminiature packages:
 - a. Lead material: Olin 194 (copper alloy) or equivalent, solder dipped.
 - b. Body material: Plastic (epoxy).

Hermetic Only

10. Lead material
 - a. ASTM alloy F-15 (KOVAR) or equivalent—gold plated, tin plated, or solder dipped.
 - b. ASTM alloy F-30 (Alloy 42) or equivalent—tin plated, gold plated or solder dipped.
 - c. ASTM alloy F-15 (KOVAR) or equivalent—gold plated.
11. Body Material
 - a. Eyelet, ASTM alloy F-15 or equivalent—gold or tin plated, glass body.
 - b. Ceramic with glass seal at leads.
 - c. BeO ceramic with glass seal at leads.
 - d. Ceramic with ASTM alloy F-30 or equivalent.

12. Lid Material

- a. Nickel or tin plated nickel, weld seal.
 - b. Ceramic, glass seal.
 - c. ASTM alloy F-15 or equivalent, gold plated, alloy seal.
 - d. BeO Ceramic with glass seal.
13. Signetics symbol, angle cut, or lead tab denotes Lead No. 1.
 14. Recommended minimum offset before lead bend.
 15. Maximum glass climb .010 inches.
 16. Maximum glass climb or lid skew is .010 inches.
 17. Typical four places.
 18. Dimension also applies to seating plane.

NOTES

Section 8 Applications

Applications section IFL handbook

Note: This section contains most of the IFL applications data and technical articles which have been published in the past. The sole purpose of this applications section is to *guide* the engineer as to how problems could be solved using Integrated Fuse Logic. The reader should realize that some data is not correct anymore in the sense that formats have been changed and new IFL types have been developed, making more cost effective solutions possible.

FEATURES

- Programmable pulse-width/delay
- Maximum 256 clock cycles
- Asynchronous TRIGGER input
- Active HIGH and active LOW outputs
- Asynchronous RESET
- 20-pin package

THEORY OF OPERATION

The one-shot consists of an FPLS 82S159 and an external clock which may be part of the system in which this one-shot is to work. As shown in Figure 1 and Table 1 the FPLS is configured to have a latch and an eight-bit binary up counter which is presettable by input data to any number less than 256. Since the input data is inverted before it is loaded into the registers, counting from the input down to 00 will give the correct number of counts as counting from the input down to 00.

Pulse-width/delay inputs may be the outputs of another device or switches. When /RESET goes LOW, flip flops are set to all 1s (terms # PB and PA). At the rising edge of the next clock, data is latched into the registers (terms # LB and LA). When /TRIG goes LOW, it is latched into the input latch formed by term # 0, 1, 2 and 13. The output O_1 of the latch goes HIGH and O_2 goes LOW which enables the 8-bit counting cycle. The O_1 and \bar{O}_1 will remain their output level until the end of the counting cycle at which time the counter reaches the count FF, resets the latch by term # 13, and sets O_2 HIGH. At the rising edge of the next clock, terms # LA and LB cause data to be loaded again into the registers, and the device is ready for another /TRIG input. The output wave-forms are illustrated in Figure 2.

If the /TRIG pulse-width is longer than the desired pulse-width of the one-shot, the device will react as mentioned above, and at

the end of the count cycle new data will be loaded, another count cycle begins while the outputs remain set by the /TRIG input without changing throughout the change-over of one count cycle to another. O_{1a} , on the other hand, will go LOW for one clock period at the change-over. As long as the /TRIG is LOW, O_{1a} will continue to pulse LOW for one clock period at the change-over of one count cycle to another. The output O_2 will pulse HIGH for one clock cycle at the change-over. Figure 2 illustrates output wave-forms for both cases. The output wave-forms are as illustrated in Figure 2.

The one-shot is implemented by programming the 82S159 as shown in Table 1. The logic representation of the program is shown in Figure 3.

COMMENTS: This one-shot will load data at the end of the count cycle. If TRIG pulse-width is longer than the count cycle, output B3 will go LOW for one clock period and go HIGH again for another count cycle. Outputs B2 and B0 stay LOW and HIGH respectively until TRIG goes HIGH and count cycle is completed without interruption.

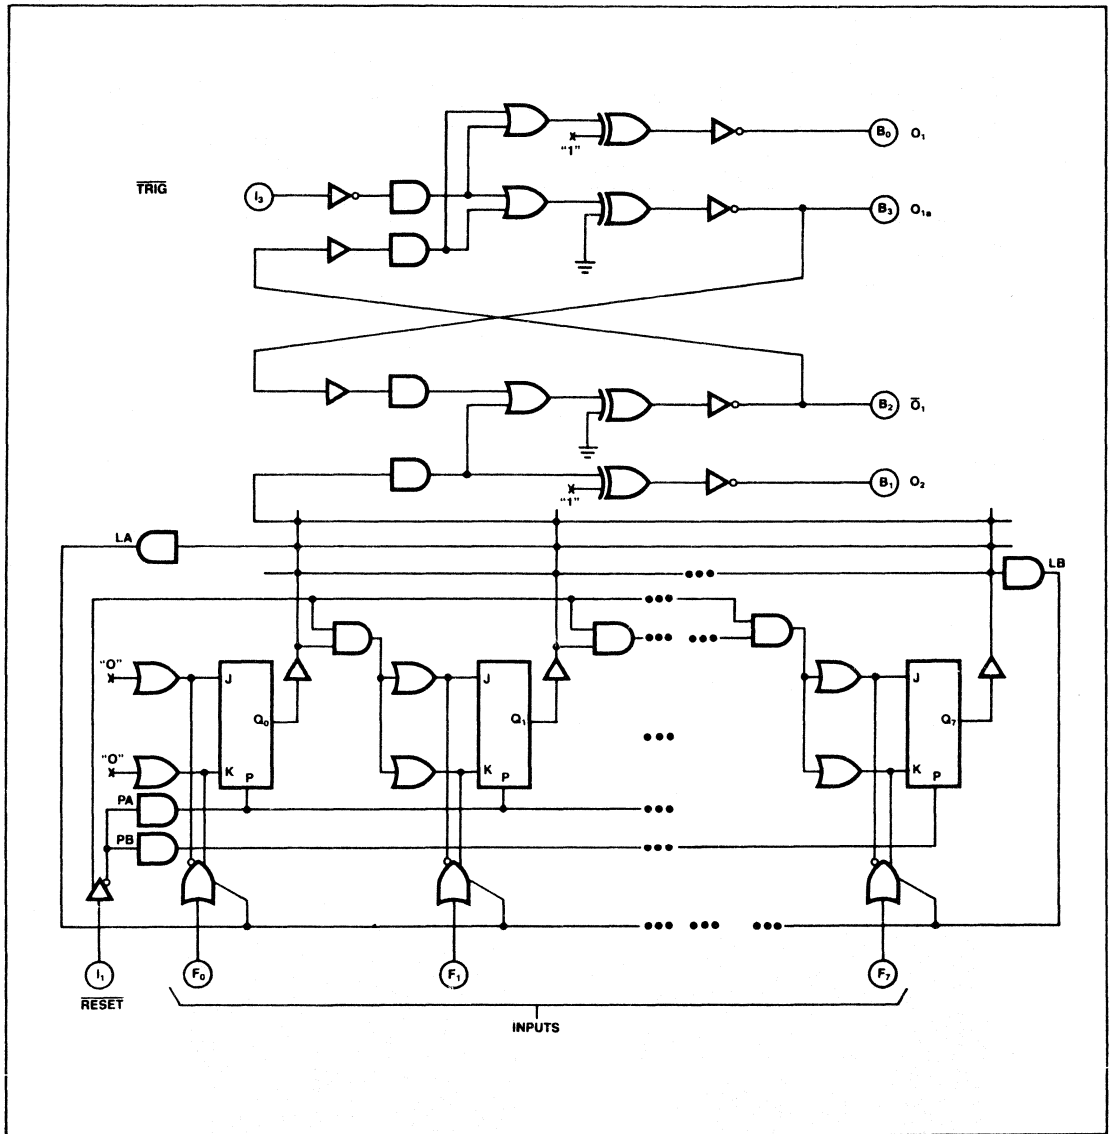

Figure 3. Logic Representation of Table 1

INTRODUCTION

The Field Programmable Logic Sequencer 82S159 may be a self-contained system except that it requires a system clock which is generally provided by an external source. Using a simple R-C network, two bi-directional I/O pins, one can make a simple oscillator which can provide a clock frequency up to 7MHz (typical) with a pulse width of about 75ns. The frequency of oscillation is set by adjusting the RC network, or by adjusting a reference voltage, V. The circuit is shown in Figure 1. This circuit may be used to clock the flip flops on the same chip, or provide a clock for a bigger system. While this circuit uses only two AND-terms and one control term, the rest of the chip may be used for other circuits.

Initially, the capacitor has zero charge and thus is at zero volt. Output is also at a LOW which disables the tri-state buffer. As the capacitor is being charged up, its voltage increases. At about 1.6 volts, the non-inverting input buffer begins to turn on. One propagation delay later, the output goes HIGH which enables the tri-state buffer after another propagation delay. Since the tri-state buffer is unconditionally programmed to a LOW, it begins to discharge the capacitor at a fast rate. As the input voltage to the non-inverting buffer drops below 1.6 volts, the buffer begins to change state. One propagation delay later, output goes LOW which disables the tri-state buffer after another propagation delay. The R-C network is ready to start all over again.

To implement this circuit, we first choose B_1 to input voltage from the RC network and B_0 to be the output pin. As shown in Figure 2, we enable the output $B(O)_0$ by "dashing out" the AND-term D_0 , make the output non-inverting by programming POLARITY "H" and connect it to term-0 by entering an A in column $B(O)_0$ term 0. We then program an H in $B(I)_1$, term-0 to connect the non-inverting input of B_1 to term-0. Since we don't need the rest of the inputs and outputs, we "dash out" all other input entries and "dot out" all unused outputs in term-0. To create a LOW output on $B(O)_1$, we may either have a LOW input on the OR and have the output non-inverted, or have a HIGH on the input of OR and have the output inverted to produce a LOW. We will arbitrarily use the second method. Here we dash out all inputs and outputs in term-1 except $B(O)_1$ which is programmed an A. We then program the POLARITY of $B(O)_1$, "L" to be inverting. Finally we program an H in $B(I)_0$ and term- D_1 and dash out all unused inputs so that when $B(O)_0$ becomes HIGH, D_1 will enable the output buffer $B(O)_1$. The program is further illustrated by Figure 3.

Since the HIGH output pulsewidth is about two propagation delays of B_1 to B_0 , it is wide enough to drive the clock input of the 82S159. If a square wave is desired, one of the flip flops may be programmed to toggle, as shown in Figure 2, term-4, in which case the output frequency of the square wave is half that of $B(O)_0$.

The stability of the output frequency can be controlled by

1. making V a stable voltage source,
2. making the charging current of the RC network much greater than the input current of $B(I)_1$ (see Figure 5 for input current characteristics),
3. making the period of oscillation much greater than four times the internal propagation delay (typical $t_{PD} = 35$ nS).

Recommendations:

- a) use capacitance less than 500pf,
- b) choose R such that $V/R \gg I_{IL}$ (since $I_{IL} = -100\mu A$, worst case, over temperature range, V/R may be 1mA, for example).

The recommendations above put a limit to the range of frequency which the 82S159 may operate in exchange for stable operating frequency. One may extend its range by reducing C to zero (remove the capacitor) and thus operate the circuit at its maximum frequency, or increase the resistance to infinite (remove the resistor), and let the external capacitor be charged by the input current I_{IL} , which gives a much lower frequency.

COMMENTS:

- D₁ is controlled by B(1)₀, which enables B(O)₁ when B(O)₀ outputs a HIGH.
- Q(N)₀ is programmed as J-K flip flop, and will toggle automatically at each rising-edge of the clock.

NOTE:

- In order for the flip flop to work the clock output (B₀) must be externally connected to pin 1.

DESCRIPTION

Using the simple AND, OR, and INVERT logic functions of the 82S153, memory functions such as latches and edge-triggered flip-flops may be implemented with a relatively small part of the chip and without external wiring. In this application note, we will discuss the implementation of two R-S latches, a D-latch, an edge-triggered R-S flip-flop, and an edge-triggered D flip-flop.

INTRODUCTION TO 82S153

To implement this function, let's first take a look at the 82S153 logic diagram and its programming table as shown in Appendices A and B. On the left-hand side of the logic diagram are eight dedicated inputs, I_0 to I_7 , each of which has a true and a complement output. Each output is connected to the inputs of thirty-two AND functions (we will call them AND-terms from now on), the outputs of which are, in turn, connected to the inputs of ten OR functions. The output of each OR function is connected to one input of an Exclusive-OR function which is in turn connected to a non-inverting output buffer. The function of the XOR is to control the output polarity. The output, in its virgin state, is non-inverting since one side of the XOR is connected to ground by the fuse X_n , where $n = 0, 1, 3...9$. To have the output inverted, one needs only to blow fuse X_n open so that the X_n input is unconditionally HIGH. The output buffers are all three-state buffers which may be enabled or disabled by their corresponding AND gates. The output buffers are disabled in their virgin state. All pins labelled "B" are bidirectional. Input buffers of the "B" pins are identical to those of the "I" pins.

The programming table shown in Appendix B emulates a truth table. All the inputs to the device are positioned on the left-hand side, and all the outputs are on the right-hand side. Each row in the table corresponds to an 18-input AND-term with up to ten outputs. On the left-hand side, or the input side of the table, each column represents an input. There is a total of 18 columns representing input buffers I_0 to I_7 , B_0 to B_9 . To distinguish between inputs and outputs of the bidirectional pin, $B(I)$ is used for input and $B(O)$ is used for outputs as shown in the programming table. On the right-hand side of the table, each column represents an output circuit ($B(O)_{0-9}$) which consists of an OR gate, an XOR, and a non-inverting three-state buffer. The output buffers are controlled by AND-terms D_0 to D_9 , the inputs of which may be connected to any number of the eighteen inputs. The polarity of the outputs are defined by the POLARITY entries which are on the upper right-hand corner of the programming table.

To program the inputs to the AND-terms, an "H" will cause the fuse of the inverting input buffer to be blown, leaving the non-inverting buffer connected to the AND-term, whereas an "L" will do the opposite. A "-" will cause both fuses to be blown and therefore the programmed input is a "don't care". A "0", the virgin state of the device, has both fuses intact, which causes the output of the AND-term to be unconditionally LOW.

To program the outputs, a "-" causes the fuse which connects the output of an AND-term to the input of an OR to be blown and thus renders the output inactive. An "A" causes the fuse to remain intact and thus the output is active.

The output polarity of each output buffer may be programmed by entering an "H" or an "L" in the POLARITY section. An "L" causes the XOR to blow its grounding fuse and become inverted, whereas an "H" leaves the fuse intact and the output is non-inverted.

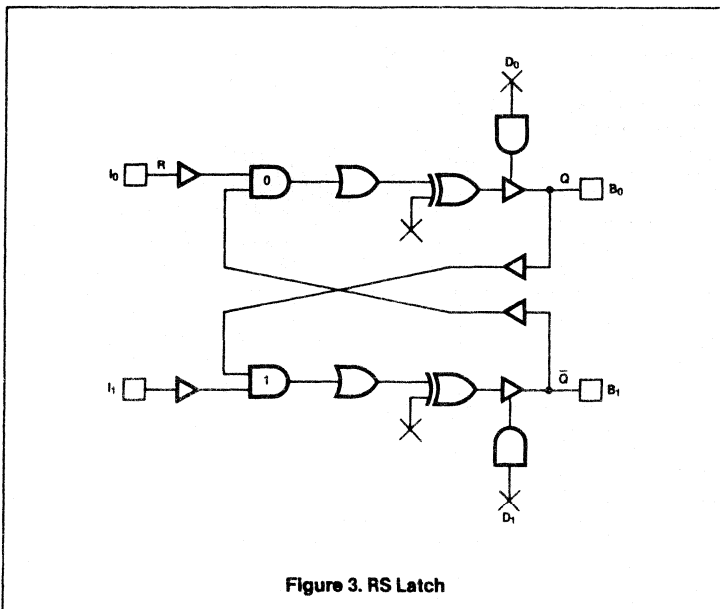

To AND several inputs, we put them in a row, to OR several inputs, we put them in different rows as shown in illustrations in Appendix B.

SIMPLE R-S LATCH

A simple R-S latch may be formed by cross-coupling two NAND functions together as shown in Figure 1.

As an illustration, let's assign the input R to I_0 of the 82S153, input S to I_1 , output Q to B_0 , and output \bar{Q} to B_1 . As shown in Figure 2, to form the NAND gates we need to program the POLARITY LOW on $B(O)_0$ and $B(O)_1$. To unconditionally enable the output buffers, we "dash" out all inputs to D_0 and D_1 . As for the inputs, we put an "H" on I_0 , term-0 for the input R, non-inverted; another "H" on $B(I)_1$, term-0 for the feedback from Q. In the same manner, we program I_1 , term-1 and $B(O)_0$ "H". The POLARITY, rows 0, 1, D_0 and D_1 forms a "truth table" with which one can analyze his own or someone else's design. The program in Figure 2 may be illustrated as shown in Figure 3.

ANOTHER SIMPLE R-S LATCH

Another way to implement a simple latch is shown in Figure 4 in which two NOR functions are cross-coupled to form a latch.

As with the previous example, we first define the input and output pins. For this example, we use I_2 for the R input, I_3 for the S input, B_2 for the Q output, and B_3 for the \bar{Q} output. We program B_2 and B_3 to have inverted outputs by programming POLARITY of B_2 and B_3 LOW as shown in Figure 5. Terms 6 and 7 are ORed together by $B(O)_2$, rows 6 and 7. In the same manner $B(O)_3$ ORs Terms 8 and 9. The programmed table of this design may be represented as shown in Figure 6.

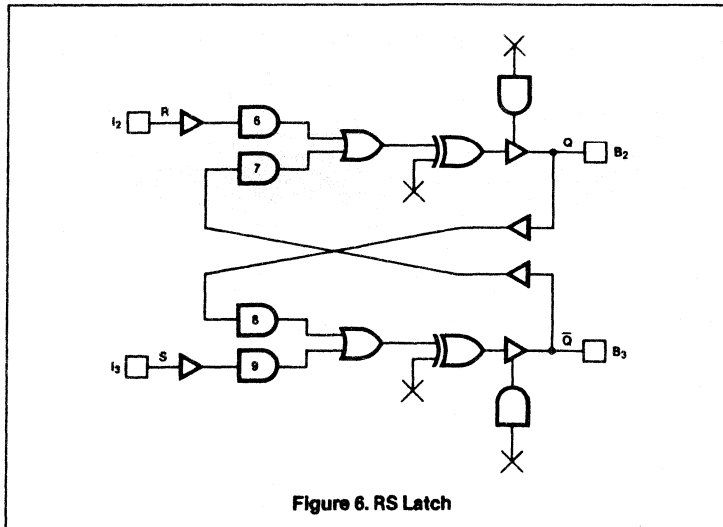

Figure 6. RS Latch

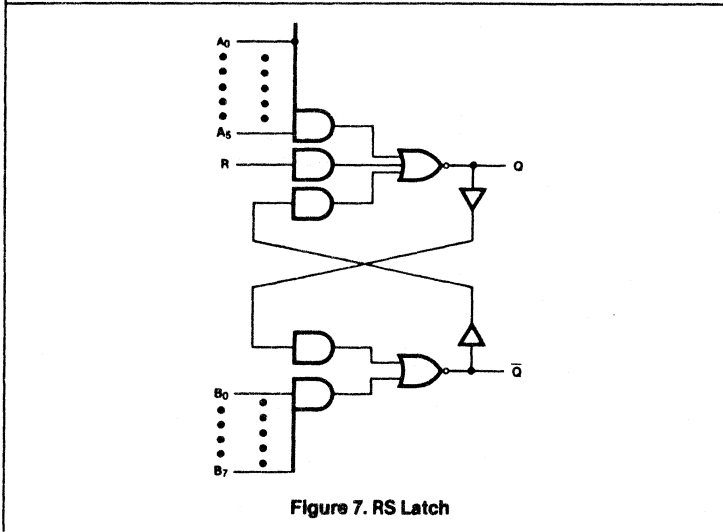

Figure 7. RS Latch

Since each AND-term of the 82S153 can accommodate up to eighteen inputs (true or inverting inputs of eight from I_0 to I_7 , and ten from B_0 to B_9), and each OR circuit can be connected to up to thirty-two AND-terms, we can add additional features such as shown in Figure 7.

The programming of this design is left to the reader as an exercise.

D-LATCH

A simple D-latch can be constructed with an 82S153 as shown in Figure 8.

This circuit may be easily programmed into the 82S153 as shown in Figure 9. The program may, in turn, be represented as shown in Figure 10.

This circuit may be expanded to have multiple D-latches using the same latch enable (LE).

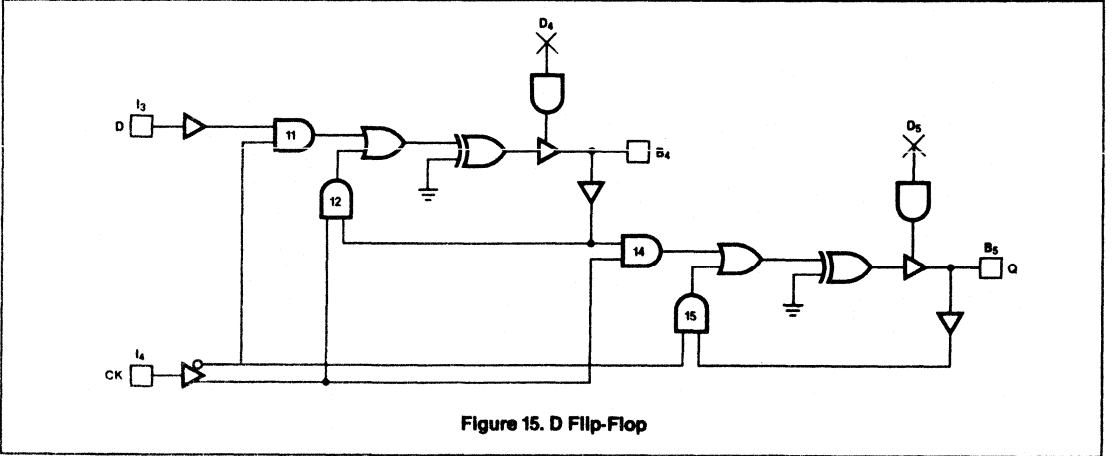

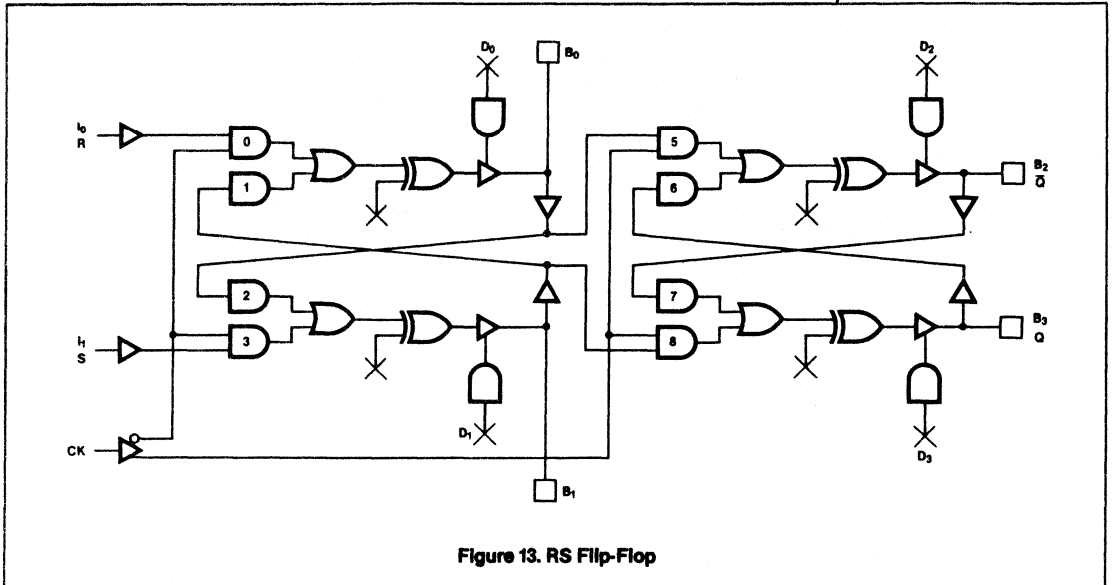

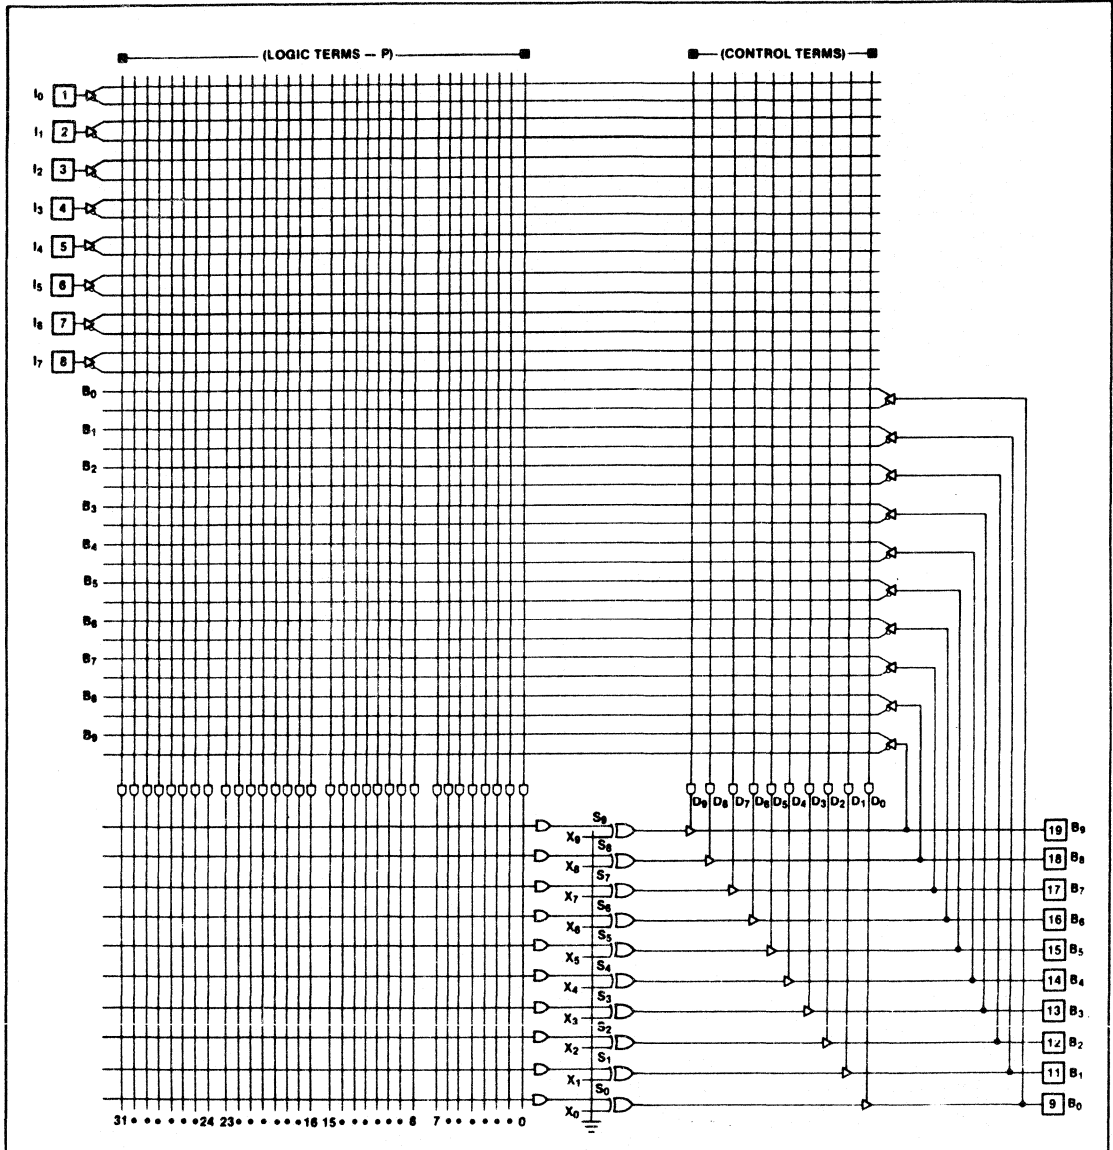

Figure 8. D Latch

Product Specification

Bipolar Memory Products

INTRODUCTION

The 82S159 is a field programmable logic sequencer which consists of four dedicated inputs, four bidirectional I/O's, eight flip flops, thirty two 16-input AND gates, twenty 32-input OR gates, and a complement array. Each flip flop has a bidirectional I/O and may be individually programmed as J-K or D flip flop, or switch between the two types dynamically. The flip flops will accept data from the internal logic array or from the bidirectional I/O, or they may be set or reset asynchronously from the AND array. The output polarity of the four bidirectional I/O's are programmable and the direction is controlled by the AND array. Figure 1 is the logic diagram of 82S159.

PROGRAMMING THE 82S159

The programming table is shown in Table 1 where there is a place for every-

thing that is shown in Figure 1. The program table is basically divided into two main sections. The left hand side of the table, section A, represents the input side of the AND gates, while the right hand side, section B, represents the OR gates sections which includes the flip flops and the combinatorial outputs B(0) to B(3). The flip flops modes are defined in section C and the output polarities of the combinatorial outputs are defined in section E. The programming symbols are detailed in Figure 2.

As shown in Table 1, the programming table is very similar to a truth table. Each column in section A represents an input to the 32 AND gates, and each row represents an AND gate connecting to 17 inputs. Columns I_0 to I_3 represent the 4 dedicated inputs, I_0 to I_3 . Columns B(1)₀ to B(1)₃ represent the inputs of the 4 bidirectional I/O, B₀ to B₃. Columns

Q(P)₀ to Q(P)₇ represent the feedback, F₀ to F₇, from the flip flops (the present state).

As shown in Figure 1, the outputs of the AND gates are connected to an array of OR gates which, in turn, are connected to either flip flops or output circuits. Columns Q(N)₀ to Q(N)₇ represent the next state which the flip flops will be in. Columns B(O)₀ to B(O)₃ represent the combinatorial outputs B₀ to B₃.

Each row represents an AND gate with 17 inputs each of which may be true and/or complement and is, therefore, a perfect decoder. Referring to the programming symbols in Figure 2, to implement the equation

$$Z = A * B * C * D,$$

all one has to do is to enter one line as shown in Table 2, term -0.

Product Specification

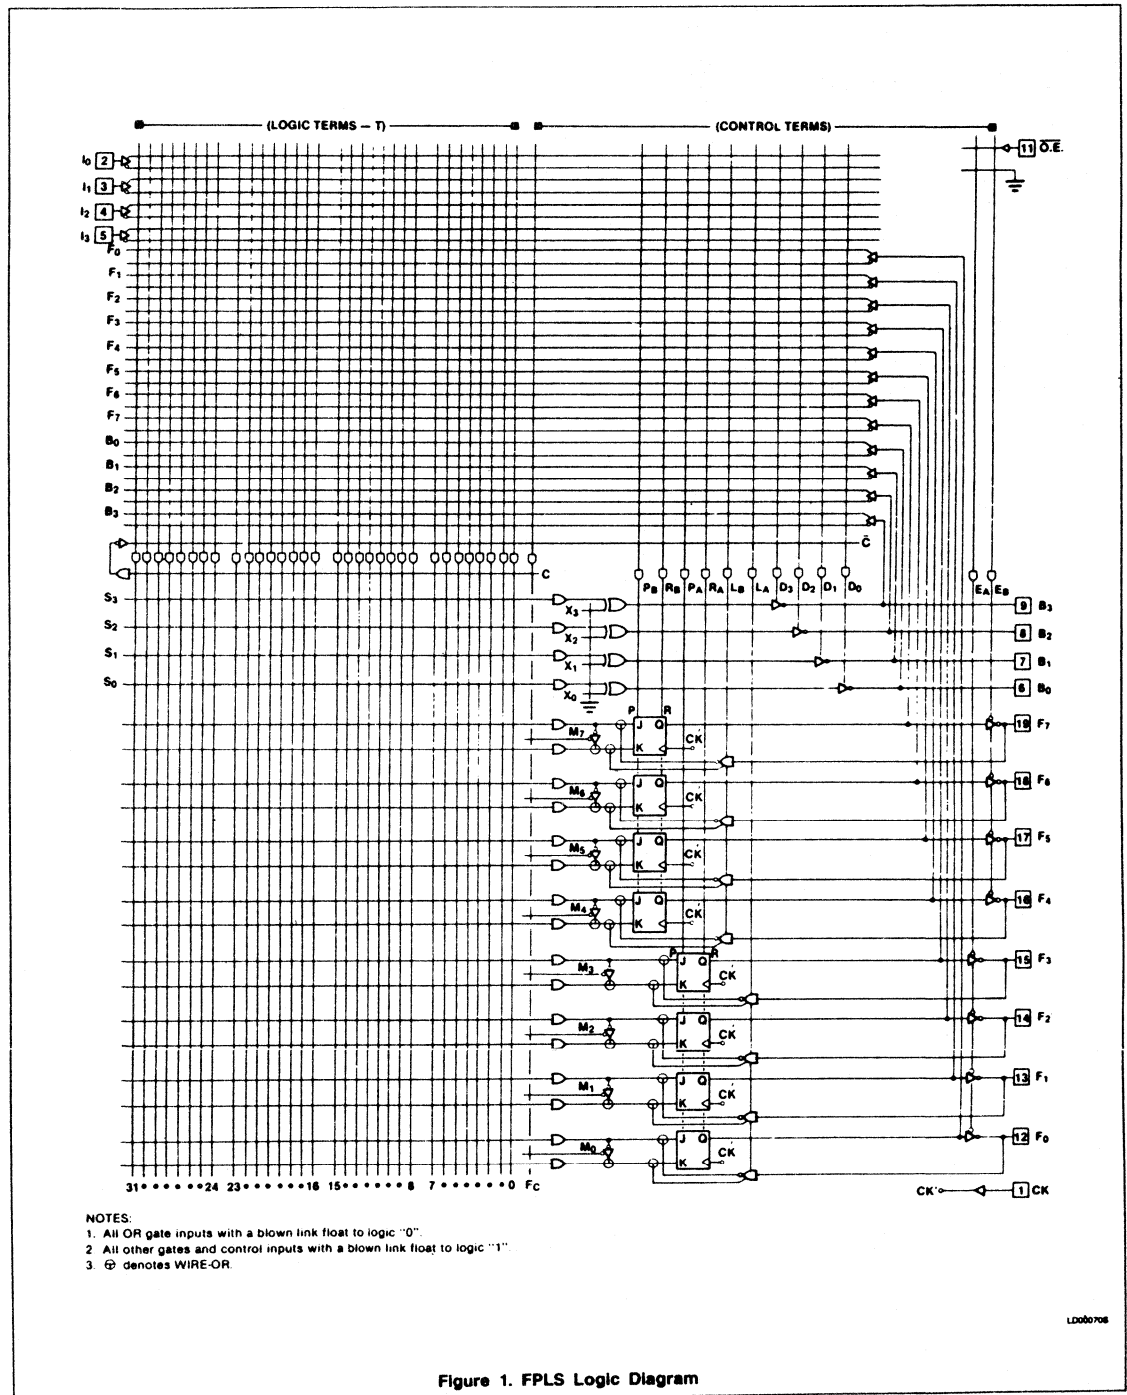

Figure 1. FPLS Logic Diagram

Product Specification

The FPLS can be programmed by means of Logic Programming equipment.

The desired logic function are coded directly from the State Diagram using the Program Tables on the following pages.

In these Tables, the logic state or action of all I/O, control, and state variables is assigned a symbol which results in the proper fusing pattern of corresponding links defined as follows:

With Logic programming, the AND/OR-EX-OR input connections necessary to imple-

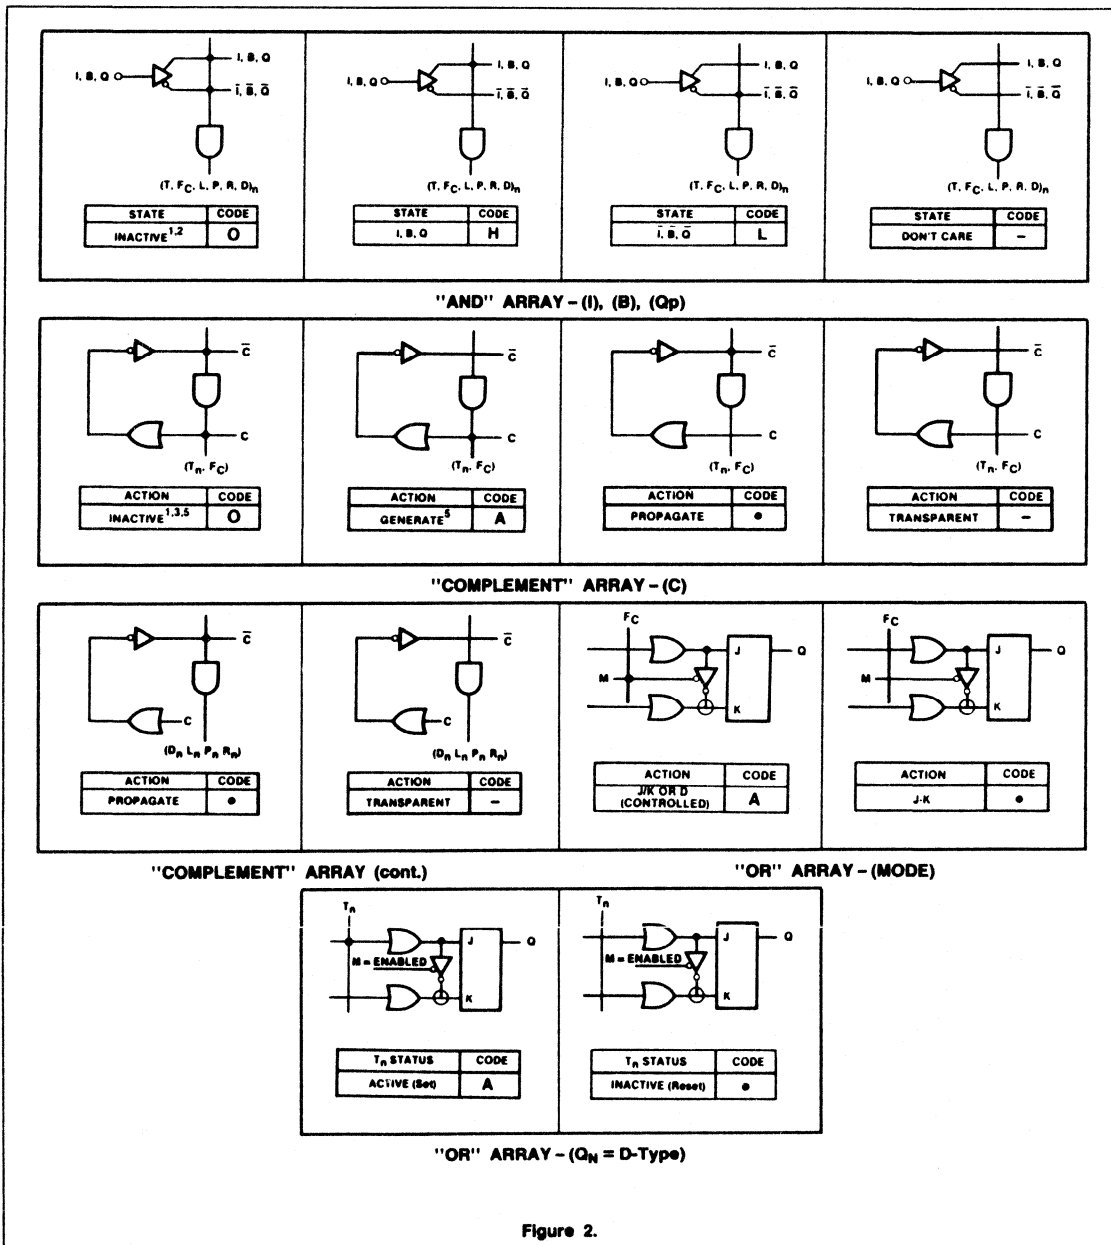

Figure 2.

Product Specification

"OR" ARRAY - (Q_n = J-K Type)

"OR" ARRAY - (S or B), (P), (R)

"EX-OR" ARRAY - (B)

"O.E." ARRAY - (E)

Notes:

1. This is the initial unprogrammed state of all link pairs. It is normally associated with all unused (inactive) AND gates.
2. Any gate (T, F_C, L, P, R, D)_n will be unconditionally inhibited if any one of the I, B, or Q link pairs is left intact.
3. To prevent oscillations, this state is not allowed for C link pairs coupled to active gates T_n, F_C.
4. E_n = 0 and E_n = • are logically equivalent states, since both cause F_n outputs to be unconditionally enabled.
5. These states are not allowed for control gates (L, P, R, D)_n due to their lack of "OR" array links.

Figure 2 (cont).

Product Specification

Notice that only I_0 to I_3 on the left hand side and $B(O)_4$ on the right hand side have entries to implement the equation all unused columns are dashed out or dotted out.

To implement the equation

$$Y = /A * B * /C,$$

enter one line as shown in Table 2, term-2 where the entry "H" represents the non-inverting input buffer while the entry "L" represents the inverting buffer. To have the AND gate to be unconditionally "HIGH", dash out all the inputs of that particular AND gate as shown in Table 2, term-4. The virgin condition of the device, as shipped from the factory, has all connections intact, which means that the inverting and the non-inverting buffers of the same inputs are connected together. Such connection will cause the AND gate to be unconditionally "LOW" as shown in Table 2, terms 6 and 7. The unconditional HIGH and LOW states are normally useful only internally and seldom brought out to the output pins.

To implement the equation

$$W = A * /B + C * /D,$$

enter one line for $A * /B$ and another line for $C * /D$ as shown in Table 2, terms 9 and 10. Use one line to AND something together; use different lines to OR something together — one line per item to be OR'ed.

All the pins which are labelled B's are bidirectional I/O pins. Their input buffers are represented by the B(I) columns on the left hand side of the programming table. An "H" entry represents the non-inverting buffer and an "L" entry represents the inverting buffer. Their output buffers are represented by the B(O) columns on the right hand side of the table. An "A" entry means that the output is

active (connected to the AND gates); a "." entry means that the output is inactive (not connected). The outputs may be programmed to be inverting or noninverting. The polarity of each output is determined by its exclusive OR gate (Figure 1 and Figure 2). To have a non-inverting output, enter an "H" in the section labelled "POLARITY" (Table 1, Section E). To have an inverting output, enter an "L". For example, Table 3, terms -0 and -2 implement the equation

$$Z = /(A * B) \\ \text{and } Y = A * B$$

respectively. The above two equations may also be implemented by term-4 which uses the same AND gate to drive two OR gates.

Besides being able to have programmable active high or active low output, the programmable output polarity feature also allows the user to minimize his AND term utilization by converting his logic equation into other forms such as conversion by De Morgan Theorem.

Example:

The equation

$$W = A + B + C + D$$

takes four AND terms to implement as shown in Table 3, terms 6 to 9. By using De Morgan Theorem, the same equation is changed to

$$/W = /A * /B * /C * /D$$

The result is as shown in term 11 — a saving of three AND terms. The output buffers are disabled in their virgin states so that they all behave as inputs. The buffers are enabled or disabled by their corresponding Control AND terms D_0 to D_3 (see Figure 1). The Control AND terms are represented in the programming table on the last four rows on the left hand side. Dashing out all the inputs will cause the output buffer to be unconditionally

enabled, whereas a "0" (zero) will cause the buffer to be unconditionally disabled. The buffers may also be controlled by a logical condition, e.g. $A * /B * /C$, etc.

There are eight flip flops on the chip each of which may be programmed as a J/K or a D flip flop, or they may be programmed to switch dynamically. As shown in Figure 1, each flip flop is a J/K to begin with. A tri-state inverter is connected in between the J and K inputs of each flip flop, which when enabled by the AND gate F_C , will cause the flip flop to function as a D flip flop. The inverters are enabled by F_C through fuses M_0 to M_7 . A "." in the F/F Mode entry of the programming table means that particular fuse is to be disconnected and that particular flip flop is to be J/K. An "A" entry will leave the M fuses intact, which allow the flip flop to be D or J/K as controlled by the output of F_C (see Figure 2, "OR" ARRAY — (MODE)). The inputs to the flip flops is represented by the programming table as the next state, $Q(N)_0$ to 7 since their inputs are from the OR array. The outputs of these registers are connected to their respective tri-state inverting output buffers, four of which are controlled by EA and the other four by EB. A "." in EA will enable outputs F_0 to F_3 , whereas a "." will disable them. An "A" will allow the output buffers to be controlled by /OE, pin 11. Table 4, terms 0, 1 and 3 represent the following equations

$$Q_0: J = A * C + /B * /E \quad \text{eq. 1}$$

$$Q_0: K = A * /C \quad \text{eq. 2}$$

Notice that the J input in equation 1 is represented by the "H" entry in terms-0 and 1, column $Q(N)_0$ while the K input in equation 2 is represented by the "L" entry in term-3, column $Q(N)_0$. An undefined input, J or K, is considered "LOW".

Product Specification

A D flip flop may be implemented by first entering an "A" in F/F MODE. Then enter "-" in the row F_C , which will unconditionally enable the tri-state inverter between the J and K inputs. The following logic equation may be implemented as shown in Table 4, term 5

$$Q_1: D = /A * /B * /C + E.$$

Notice that the entries in term 5, columns $Q(N)_0$ to 7 are "A" and "-" instead of "H" and "L" as in the case of J/K flip flops. The entry "A" will cause the fuse connecting to the "K" input to be disconnected and the "J" fuse to be intact. Whereas the entry "-" will cause both fuses to be disconnected. This feature enables the user to quickly recognize the mode in which the flip flops are operating without having to go through the control terms. Some commercially available device programmers in the market may not have the software capability to implement this feature, in which case an "H" and a "-" may be used in place of "A" and "-" respectively as shown in Table 4, terms 8 and 9.

Of course, the term F_C may have inputs instead of dashes, in which case the flip flop modes are controlled dynamically.

When both the J and K inputs are "1's", the flip flop will toggle. A simple 3-bit counter may be implemented using only AND terms as shown in terms 11, 12 and 13. The logic equations for the three flip flops are as the following:

$$\begin{aligned} Q_5: T &= 1; & (Q_5 \text{ toggles unconditionally}) \\ Q_6: T &= Q_5; & (Q_6 \text{ toggles when } Q_5 = 1) \\ Q_7: T &= Q_5 Q_6; & (Q_7 \text{ toggles when } Q_5 = \\ & & Q_6 = 1) \end{aligned}$$

The above equations represent an octal up-counter. However, since the outputs of the flip flops are inverted, the counting sequence of the outputs is that of a down-counter.

The flip flops may be asynchronously set and reset by the Control AND terms PA/PB and RA/RB respectively. As shown in Figure 1,

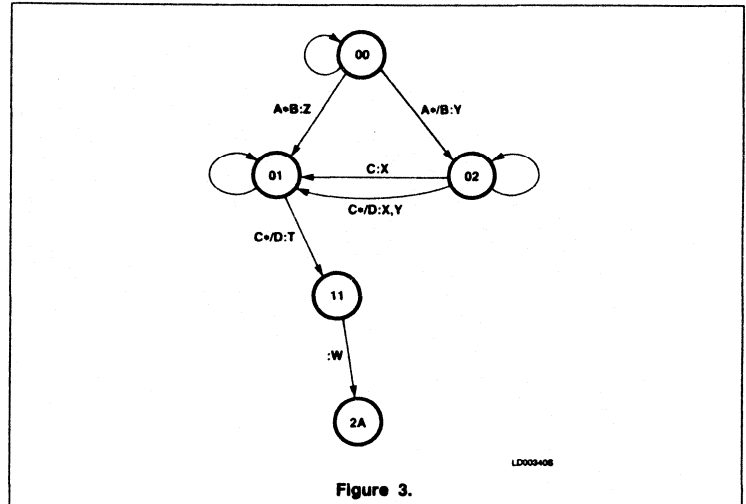

Figure 3.

PA and RA controls flip flops F_0 to F_3 , while PB and RB control F_4 to F_7 .

In order to save the number of input pins, the eight flip flops may be synchronously loaded directly from their own output pins. To use this feature, EA and/or EB must be programmed "A" so that the output buffers may be disabled before loading. As shown in Figure 1, every flip flop has an OR/NOR gate the input of which is directly connected to the output pin and the outputs of the OR/NOR are connected to the K and J inputs respectively. This OR/NOR gate inverts the input and feeds it to the flip flop in a "wire-OR" fashion. Therefore, when loading data directly into the flip flops from the output pins, caution must be exercised to insure that the inputs from the OR array does not interfere with the data being loaded. For example, if the data being loaded is a "1" on the output pin, the J

input will be a "0" and the K input will be a "1". If, at the same time, a "1" is present at the J-input from the OR array, the flip flop will see "1's" in both J and K inputs. It will toggle as a result. The OR/NOR gates are enabled by the Control AND terms LA and LB. LA controls flip flops F_0 to F_3 and LB controls F_4 to F_7 .

All Control AND terms function and are programmed in the same manner as the other AND terms. The only difference is that the Control AND terms are not connected to the OR array.

The outputs of the flip flops may be fed back into the AND array as the present state, $Q(P)$. The output of the AND array into the OR array and the inputs to the flip flops is the next state, $Q(N)$. As an example, Figure 3 is a state machine implemented in an 82S159 as shown in Table 5, terms 0 to 6.

82S159

82S159 As Modulo Counters

AN16 Product Specification

Bipolar Memory Products

DESCRIPTION

The field programmable logic sequencer (FPLS) 82S159 has eight edge-triggered flip flops which may be individually programmed to be J/K, D, or toggle flip flops. The detail logic diagram of the device is shown in Figure 2.

A counter may be constructed by having individual flip flops toggle when they are at certain states. Implementing such counters requires one toggle flip flop per bit and an associating AND gate as a decoder for each flip flop. Such a method allows the 82S159 to be a counter from modulo 2 to 256 or from one bit to 8 bits.

MODULO-8 UP/DOWN COUNTER

The Up-Counter

The 82S159 has an inverting output buffer for each flip flop. Therefore the counting sequence of the flip flops is from 7 to 0 so that the outputs will count

from 0 to 7. Table 1 is the truth table of the internal counting sequence.

Table 1.

| count | Q ₂ | Q ₁ | Q ₀ |
|-------|----------------|----------------|----------------|
| 0 | 1 | 1 | 1 |
| 1 | 1 | 1 | 0 |
| 2 | 1 | 0 | 1 |
| 3 | 1 | 0 | 0 |
| 4 | 0 | 1 | 1 |
| 5 | 0 | 1 | 0 |
| 6 | 0 | 0 | 1 |
| 7 | 0 | 0 | 0 |

From Table 1, logic equations for the flip flops may be generated as the following:

$$\begin{aligned} Q_0: T &= 1; && (Q_0 \text{ unconditionally toggles}) \\ Q_1: T &= \overline{Q_0}; && (Q_1 \text{ toggles if } Q_0 = 0) \\ Q_2: T &= \overline{Q_0} \cdot Q_1; && (Q_2 \text{ toggles if both } Q_0 \\ &&& \overline{Q_0} \cdot Q_1; \text{ and } Q_1 = 0) \end{aligned}$$

The equations are implemented as shown in Table 2, terms 0, 1, and 2. E_A is enabled, and the mode for the three flip flops is set to J/K. All unused flip flops and outputs (the B(0)'s) associating to AND-terms are "dashed" or "dotted" out. The event to be counted is connected to the clock input, pin 1 of the device.

The Down-Counter

The down-counter is constructed in the same manner as the up-counter except that the counting sequence is reversed. The down-counter is implemented in Table 2, terms 6 to 7 with the corresponding flip flop mode set to J/K and E_B enabled.

Modulo-16 Counter

Expanding the modulo-8 counter to 4-bit, the counter becomes modulo-16, Table 3, terms 0 to 3 and the associating F/F MODE and E_B implement a modulo-16 up-counter, while terms 5 to 8 and the associating F/F MODE and E_A implement the modulo-16 down-counter.

DECADE COUNTER

The Decade Up-Counter

The truth table of a decade counter is as shown in Table 4.

Table 4.

| count | Q ₃ | Q ₂ | Q ₁ | Q ₀ |
|-------|----------------|----------------|----------------|----------------|
| 0 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 0 |
| 2 | 1 | 1 | 0 | 1 |
| 3 | 1 | 1 | 0 | 0 |
| 4 | 1 | 0 | 1 | 1 |
| 5 | 1 | 0 | 1 | 0 |
| 6 | 1 | 0 | 0 | 1 |
| 7 | 1 | 0 | 0 | 0 |
| 8 | 0 | 1 | 1 | 1 |
| 9 | 0 | 1 | 1 | 0 |
| 0 | 1 | 1 | 1 | 1 |

Logic equations may be generated from Table 4 as the following:

$$\begin{aligned}
 Q_0:T &= 1; \\
 Q_1:T &= /Q_0 * Q_3; \\
 Q_2:T &= /Q_0 * /Q_1 * Q_3; \\
 Q_3:T &= /Q_0 * /Q_1 * /Q_2 * Q_3 + /Q_0 * Q_1 * Q_2 * /Q_3;
 \end{aligned}$$

Figure 1.

The equations are implemented as shown in Table 5, terms 0 to 3 and the associating flip flop mode and ER settings.

Decade Down-Counter

The decade down-counter is identical to the decade up-counter except that the counting sequence is reversed from 0 to 9 as shown in Table 5, terms 5 to 10 with the associating F/F MODE set to J/K and E_B to ENABLE.

DIVIDE-BY-N COUNTER

This counter, shown in Figure 1, takes an input (maximum = 8 bits for each device) and counts down from there until all flip flops become 0000, then a terminal count is sent out (divide-by-N). Since there are 8 flip flops, the maximum count is 256. Table 6 shows an implementation of the divide-by-n counter.

New developments in integrated fuse logic

Custom logic is expensive – too expensive if your production run is short. ‘Random logic’ is cheaper but occupies more sockets and board space. Integrated Fuse Logic bridges the gap. Using IFL, you can configure an off-the-shelf chip to perform just the logic functions you need. Design and development times are much shorter, and risk much lower, than for custom logic. Connections are fewer than for random logic and, for all but the simplest functions, propagation delay is usually shorter. Yet another advantage that IFL has over custom logic is that it allows you to redesign the functions without redesigning the chip – giving you an invaluable margin not only for cut-and-try during system development but also for later revision of system design. You’re not tied down by the need to recover capital invested in a custom chip.

An IFL chip is an array of logic elements – gates, inverters, and flip-flops, for instance. In the virgin state everything is connected to everything else by nichrome fuses and, although the chip has the capacity to perform an extensive variety of logic functions, it doesn’t have the ability to. What gives it that is programming: selectively blowing undesired fuses so that those that remain provide the interconnections necessary for the required functions.

Signetics Series 20 IFL, named for the number of pins, supplements the well-known Series 28. The package is smaller – little more than a third the size, in fact – but the improved architecture, with user-programmable shared I/O, compensates for the fewer pins. The series comprises the following members, in order of increasing complexity:

- 82S150/82S151 – field-programmable gate array
- 82S152/82S153 – field-programmable logic array
- 82S154/82S159 – field-programmable logic sequencer

The even-numbered types have open-collector, and the odd-numbered types three-state outputs.

Entry to all the devices is via a product matrix, an array of input and shared I/O lines fuse-connected to the multiple inputs of an array of AND gates (see Fig. 1, 2 and 6). To exploit the capacity of any device it is important to make the most economical use of the AND gates it has available. Application of the Morgan’s theorem can help in this. For example, inputs for the function

$$F = A + B + C + D$$

would occupy four of the AND gates of the product matrix. However, the same function rewritten as

$$\bar{F} = \bar{A} \bar{B} \bar{C} \bar{D}$$

would occupy only one. Moreover, the second function could be done on the simplest of the Series 20 devices (and leave eleven gates over for other functions), whereas the first could not. The fact that all inputs of the Series 20 devices, including the shared ones, incorporate double buffers that make the true and complement forms of all input variables equally accessible, greatly facilitates the use of de Morgan’s theorem for logic minimisation.

To convert the minimised logic equations to the pattern of fuses to be blown you can use either a programming sheet (see e.g. Fig.5) or boolean equation program-entry software that lets you enter the equations via the keyboard of a terminal. The direct programmability of logic equations makes system design with IFL simple and sure. Functional changes can be made by replacing one IFL chip by another, differently programmed. In many cases you can even remove the original one, reprogram it on the spot, and re-insert it. Programming machines qualified for the Series 20 are at present available from DATA I/O, KONTRON, and STAG.

Fig. 1 Field-programmable gate array 82S151. A, dedicated inputs; A', programmable I/O. B, product (NAND) matrix with fused connections C; each of the vertical lines in the matrix represents 36 inputs to the terminating NAND gate. D, exclusive-OR array with inputs grounded via fuses for polarity control. E, programmable three-state output buffers. F, fuse-programmable control matrix. Square dots (■) represent permanent connections, round dots (●) intact fuse connections. Connected as shown, the array is programmed for the functions

$$\bar{B}_{11} = I_0 I_1 \bar{I}_5 \quad \text{and} \quad B_{10} = \bar{I}_0 \bar{I}_1 \bar{I}_5$$

FPGA 82S150/82S151

The field-programmable gate array is the simplest of the Series 20 IFL devices; Fig.1 shows the functional diagram. The array can accept up to 18 inputs. There are six dedicated input pins (A) and twelve (A') that can be programmed as inputs, outputs, or bidirectional I/O. All input variables, whether on dedicated or programmed input pins, are available in both true and complement form in the product matrix (B), and both forms are buffered: either form can drive all twelve product lines if required. In the virgin state, all the input variables and their complements are connected to all the product lines via a diode and a fuse (C), and the product matrix is effectively inoperative. To enable it to generate the required functions, unrequired connections between individual input lines and product lines are severed by blowing the connecting fuses.

At the output of the product matrix are twelve NAND gates, each with 36 inputs to accommodate the 18 possible input variables and their complements. Each of the product terms is normally active-Low, but a unique feature of Signetics IFL is that any or all of them can be independently programmed active-High. This is done by means of an array of exclusive-OR gates (D) at the NAND-gate outputs; when the fuse that grounds the second input of each OR gate is blown, the output of that gate is inverted.

The product matrix and exclusive OR-gate connections shown in Fig.1 illustrate the flexibility conferred by having buffered complements of all input variables internally available, together with independently programmable output polarities. Output B₁₁, shown with its exclusive OR-gate fuse intact, is programmed

$$\overline{B}_{11} = I_0 I_1 \overline{I_5}$$

At the same time, and without using any additional inputs, output B₁₀ (fuse blown) is programmed

$$B_{10} = \overline{I_0} \overline{I_1} \overline{I_5}$$

Each of the exclusive-OR gates drives a three-state output buffer. In the virgin state all the buffers (E) are disabled and therefore in the high-impedance state. The function of the programmable I/O pins (A') is then determined by the I/O control matrix (F). The three AND gates at the control-matrix output are active-High, and when one of them is in the High state the four output buffers it controls are enabled; the corresponding I/O pins then act as outputs. Conversely, when a control-matrix AND-gate output is Low and the control fuse for the corresponding three-state buffer is intact, the pins controlled by that gate act as inputs. Thus, these pins can be programmed in groups of up to four to act as inputs or outputs according to the state of selected input variables. If required, any of the programmable I/O pins can be made a dedicated output by blowing the control fuse of the output buffer associated with it.

The speed of the FPGA compares favourably with TTL, although its propagation delay (currently specified as 30 ns)

is longer than the individual gate delay of TTL. When the number of inputs required is large, however, the FPGA more than makes up for this. When more than eight inputs are required, for example, the FPGA has a distinct advantage. Then, the overall propagation delay of TTL often amounts to two or three gate delays, but that of the FPGA to only one (see Table 1).

TABLE 1
Comparison of propagation delays for FPGA and TTL

| number of inputs | TTL gates in series | t _{pd} (ns) | | | |
|------------------|---------------------|----------------------|-----|------|-----|
| | | FPGA | TTL | | |
| | | | 74 | 74LS | 74S |
| ≤8 | 1 | 30 | 20 | 17 | 7 |
| >8 | 2 | 30 | 40 | 35 | 16 |

FPLA 82S152/82S153

Architecture

With two levels of logic, embodied in a product matrix terminating in 32 AND gates coupled to a ten-output OR matrix (Fig.2), the FPLA is a step up in complexity from the FPGA. Again, there is provision for 18 input variables, internally complemented and buffered, but here divided between eight dedicated input pins and ten individually programmable I/O pins. As before, exclusive-OR gates grounded by fuses provide output polarity control, and any of the programmable I/O pins can be made a dedicated output by blowing the control fuse of the output buffer associated with it.

Programming

The first step in programming the FPLA is to define the required functions in boolean equations. These do not necessarily have to be minimised, but a good principle is: the fewer terms you use, the more capacity you will have left for implementing other function on the same FPLA or for altering the program during prototype development. Karnaugh maps will yield sums of products suitable for the FPLA. Logic minimisation methods (Quine-McCluskey, for instance, Ref.1,2) are particularly useful for complicated functions and are often necessary for reducing them to minimum-sums-of-products (MSP). A program called LOG-MIN, accessible via data link to Signetics' computer, derives MSPs for an array of up to 16 inputs and 8 outputs.

When the required functions have been defined, corresponding programming instructions are entered in a programming table the layout of which reflects the FPLA

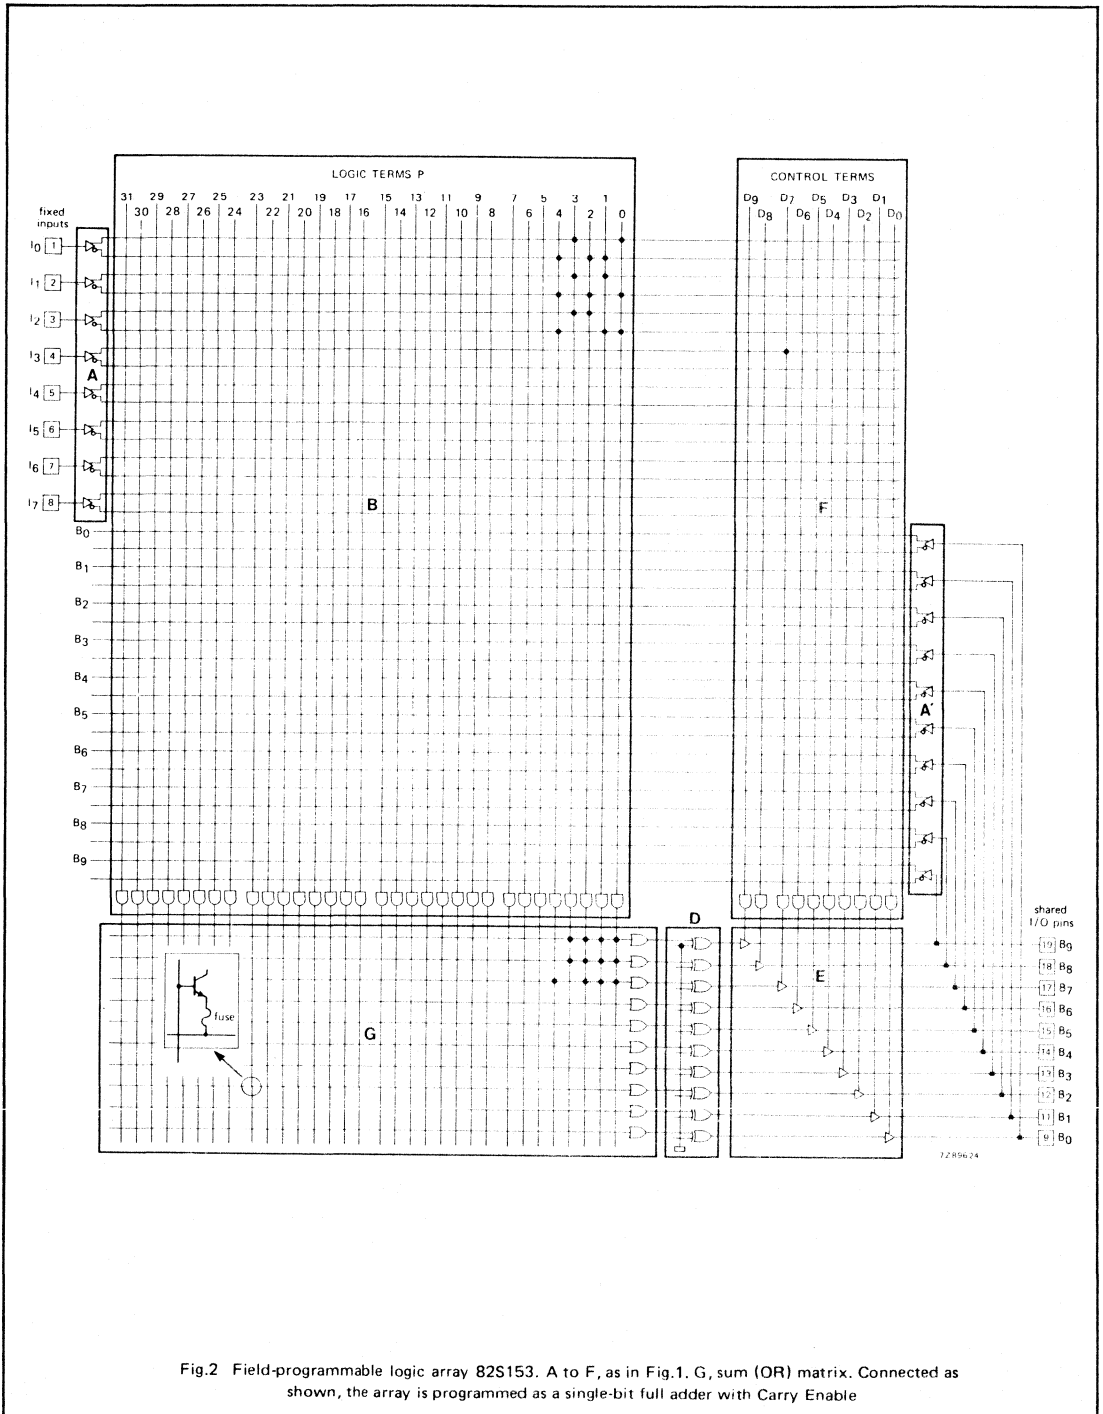

Fig.2 Field-programmable logic array 82S153. A to F, as in Fig.1. G, sum (OR) matrix. Connected as shown, the array is programmed as a single-bit full adder with Carry Enable

architecture. (A computer program that accepts boolean equations as input and generates an FPLA programming table as output is also available.) The programming machine blows the FPLA fuses in the pattern prescribed by the table.

As an illustration of FPLA programming, consider a full adder. Figure 3 shows a TTL version (74LS80) and the corresponding logic equations. Note that the feedback of \bar{C}_{n+1} introduces a second propagation delay. In the FPLA this is eliminated by redefining Σ in terms of A, B and C_n , as shown in Fig.4, and using the right-hand side of the equation for \bar{C}_{n+1} instead of the term itself. At first glance this would appear to require a minimum of three product terms for \bar{C}_{n+1} plus four for Σ , or a total of seven. The Karnaugh maps, however, show considerable overlap between the two functions: the map for \bar{C}_{n+1} differs from that for Σ only by having $A B C_n$ instead of $\bar{A} \bar{B} \bar{C}_n$. Rewriting the equation for \bar{C}_{n+1} to introduce $\bar{A} \bar{B} \bar{C}_n$ and eliminate $A B C_n$,

$$\bar{C}_{n+1} = A \bar{B} \bar{C}_n + \bar{A} B \bar{C}_n + \bar{A} \bar{B} C_n + \bar{A} \bar{B} \bar{C}_n$$

increases the number of product terms by one, but now \bar{C}_{n+1} and Σ have three terms in common. Therefore, since the FPLA allows multiple use of product terms, it is sufficient to program each of the common terms only once; thus, the original seven product terms are effectively reduced to five.

To fill in the programming table (Fig.5), first allocate inputs and outputs.

| | | | |
|--------|---------------------------------|----------|-----------------------|
| Inputs | A = I ₀ | Outputs: | $\bar{C}_{n+1} = B_7$ |
| | B = I ₁ | | $\Sigma = B_8$ |
| | C _n = I ₂ | | $\Sigma = B_9$ |

Next, enter the product terms of Σ in the product-matrix (AND) part of the table, using H to indicate a true input and L a false one.

- Term 0 is $A \bar{B} \bar{C}_n$: mark H, L, L in columns I₀, I₁, I₂ of row 0
- Term 1 is $\bar{A} B \bar{C}_n$: mark L, H, L in columns I₀, I₁, I₂ of row 1
- Term 2 is $\bar{A} \bar{B} C_n$: mark L, L, H in columns I₀, I₁, I₂ of row 2
- Term 3 is $A B C_n$: mark H, H, H in columns I₀, I₁, I₂ of row 3.

Fill the rest of rows 0, 1, 2, and 3 with dashes to indicate that all other inputs are to be disconnected from Terms 0, 1, 2, and 3 (fuses blown).

The product terms of Σ must be added to form the sum-of-products required at output B₉. Indicate the required addition by putting an A (for Attached, i.e. fuse unblown) in the Term 0, 1, 2 and 3 spaces of column B(O)₉; Term 4 is not required for Σ , so put a dot in the Term 4 space to indicate that it is to be disconnected (fuse blown). To indicate that the output is to be active-High, put an H in the polarity square above the B(O)₉ column. Finally, fill row D₉ with

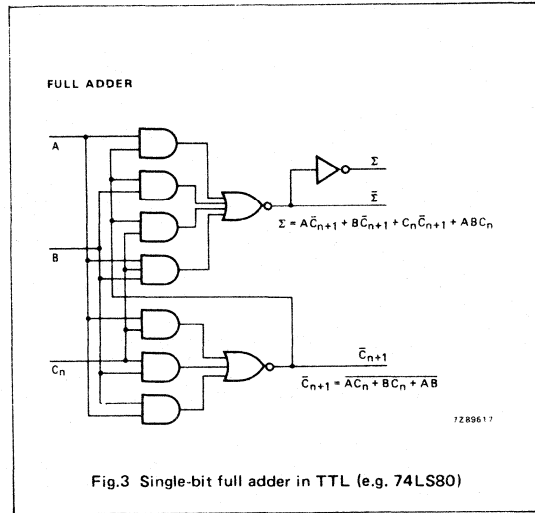

Fig.3 Single-bit full adder in TTL (e.g. 74LS80)

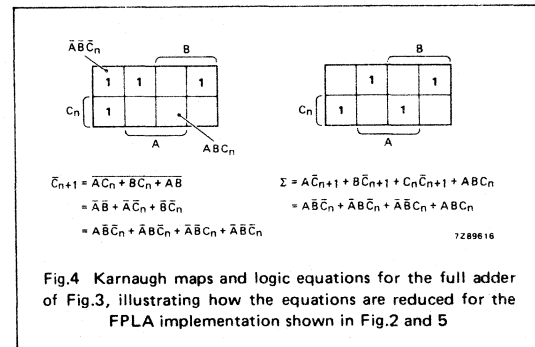

Fig.4 Karnaugh maps and logic equations for the full adder of Fig.3, illustrating how the equations are reduced for the FPLA implementation shown in Fig.2 and 5

dashes to indicate that all fuses on line D₉ of the control matrix are to be blown and B₉ is to be a dedicated output. This completes the programming of Σ .

The $\bar{\Sigma}$ output on B₈ is programmed in just the same way, except that the polarity square above the B(O)₈ column is marked L to indicate active-Low. (Note that in the FPLA the Σ and $\bar{\Sigma}$ outputs change simultaneously, because all output signals traverse the exclusive-OR array (D), whether they are active-High or active-Low. In the TTL full adder shown in Fig.3 the output inverter delays the change of Σ with respect to $\bar{\Sigma}$.)

The output C_{n+1} on B₇ contains three of the same terms as Σ , plus the term $\bar{A} \bar{B} C_n$. Only this last term needs to be additionally programmed in the product matrix: mark L, L, L in columns I₀, I₁, I₂ of the Term 4 row. Indicate the addition

$$A \bar{B} \bar{C}_n + \bar{A} B \bar{C}_n + \bar{A} \bar{B} C_n + \bar{A} \bar{B} \bar{C}_n$$

by putting an A in rows 0, 1, 2 and 4 of column B(O)₇, and show that Term 3 ($A B C_n$) is not required by putting a dot

output buffer is true. Thus, a Carry Enable can be provided via the I_3 input by leaving the fuse for active-High operation of the enable signal to control term D_7 intact. To indicate this, put an H in the I_3 column of row D_7 and fill the rest of the row with dashes.

The full adder with output Carry Enable uses only four of the eight dedicated inputs, three of the ten programmable I/O pins, and five of the 32 AND gates. The remaining capacity can be used for programming other functions which may, if required, also make use of AND-gate outputs already programmed for the full adder.

All fuses not indicated as blown in the programming table are normally left intact to preserve capacity for later program revisions or the addition of supplementary functions. If it is essential to minimise propagation delay, however, the finalised program should include instructions for blowing all unused fuses to minimise load capacitance.

Table 2 compares the propagation delay of the FPLA and TTL; the value given for the FPLA is a worst-case value with all fuses intact.

TABLE 2
Comparison of two-level logic propagation delays for FPLA and TTL

| number of of inputs | TTL gates in series | FPLA | t_{pd} (ns) | | |
|------------------------|------------------------|------|---------------|------|-----|
| | | | 74 | 74LS | 74S |
| <4 | 1 | 40 | 40 | 33 | 14 |
| 5-8 | 2 | 40 | 43 | 35 | 16 |
| >8 | 3 | 40 | 63 | 53 | 25 |

FPLS 82S154 – 82S159

Architecture

The FPLS (Fig.6, page 170) is the most complex of the Series 20 IFL devices. Like the FPLA, it has a 32-term product matrix followed by an OR matrix. In the FPLS, however, the OR matrix is larger and comprises three distinct parts, with architecture differing in detail from type to type. In the 82S154 and 82S155, for instance, the first part consists of eight 32-input gates coupled, like those of the FPLA, to an output-polarity-controlling exclusive-OR array. The second consists of twelve additional gates which control four flip-flops. These are what give the FPLS its sequential character, enabling it to dictate its next state as a function of its present state. The third part is the deceptively simple complement array (I in Fig.6): a single OR gate with its output inverted and fed back into the product matrix. This enables a chosen sum-of-products to become a common factor of

any or all the product terms and makes it possible to work factored sum-of-products equations. It is also useful for handshaking control when interfacing with a processor and for altering the sequence of a state machine without resorting to a large number of product terms.

The 82S154 and 82S155 have four dedicated inputs and eight programmable I/O pins that can be allocated in the same way as in the FPLA. It also has four shared I/O pins (L) whereby the flip-flops can be interfaced with a bi-directional data bus. Two product terms, L_A and L_B in the control matrix F, control the loading of the flip-flops, in pairs, synchronised with the clock.

Figure 7 shows the architecture of the flip-flop circuitry in the 82S154 and 82S155. The flip-flops are positive-edge triggered and can be dynamically changed to J-K, T, or D-types according to the requirements of the function being performed; this considerably lessens the demands on the logic. The three-state inverter between the J and K inputs governs the mode of operation, under the control of the product term F:

- When the inverter is in the high-impedance state the flip-flop is a J-K type, or a T type when $J = K$.
- When the inverter is active, $K = \bar{J}$ and the flip-flop is a D type; the K input must then be disconnected from the OR matrix.

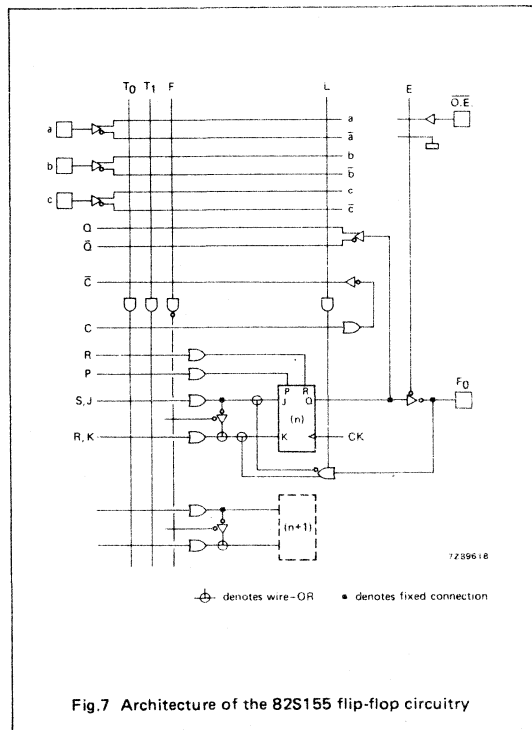

Fig.7 Architecture of the 82S155 flip-flop circuitry

Fig.6 Field-programmable logic sequencer 82S155. A to G, as in Fig.3. H, flip-flops and bus-load buffer. J, clock input. K, output-buffer enable. L, three-state flip-flop output buffers

All the product terms from the product matrix (T_0 to T_{31} in Fig.6) are fuse-connected to the J and K input OR gates. If both fuses of any one product term are left intact, $J = K$ and the flip-flop is a T type.

The flip-flops of the 82S154 and 82S155 have asynchronous Preset and Reset controlled by terms in the OR matrix that take priority over the clock. When power is applied all flip-flops are set to a defined state. Their three-state output buffers can be controlled from the enable pin OE or permanently enabled or disabled by blowing fuses or leaving them intact in the enable array (K in Fig.6).

The 82S156/7 and 82S158/9 sequencers have, respectively, six and eight flip-flops. The architecture differs in detail but is similar in principle to that of 82S154 and 82S155.

Programming

The FPLS is programmed in much the same way as the FPLA, using a table to instruct the machine that blows the undesired fuses. It is not necessary to work with a circuit diagram; in fact, it is even undesirable to do so, since applying the necessary logic reduction techniques would in most cases make the diagram difficult to read and more a hindrance than a help. An example of how to program the FPLS as a universal counter/shift-register is given in the Appendix.

DEVELOPMENT AND PRODUCTION ECONOMY WITH IFL

Underlying the design philosophy of the Signetics Series 20 IFL is the concept of programmable arrays whose architecture emulates logic equation formats rather than mere aggregations of gates. The unique combination of features which support this philosophy includes:

- double-buffered true and complement inputs
- programmable-polarity outputs
- programmable I/O for internal feedback and maximum freedom in allocating inputs and outputs
- truth-table programming format.

These features are common to all the IFL devices. In the field-programmable logic sequencers they are further supported by:

- flip-flops with dynamically alterable operating modes
- a complement array for simplified handshaking control.

From the development engineer's point of view an important advantage of IFL is that it eliminates breadboarding. Once he has worked out the functions required in terms of minimised logic equations, he can program an IFL device accordingly. Once programmed, it will perform those functions.

Loading the instructions into the programming machine usually takes no more than a couple of hours; after that, the machine can program the devices at a rate of 100 an hour. Moreover, since any IFL device can be programmed in many different ways, IFL has considerable potential for simplifying purchasing and stock control. One type of device can be programmed to perform a diversity of tasks for which it would otherwise be necessary to purchase and stock many different devices.

Series 20 IFL is second-sourced by Harris Semiconductor.

APPENDIX

Programming an FPLS as a counter/shift-register

Objective: to program an 82S155 FPLS as a count-up, count-down, shift-right, shift-left machine governed by three control terms — COUNT/SHIFT, RIGHT/UP, LEFT/DOWN. Direct implementation would result in a machine with 64 state transitions (see Table A1), which is beyond the scope of the 82S155 or even the 28-pin 82S105. Logic reduction is therefore necessary.

As there are only four feedback variables (D, C, B, A), you can do the reduction by hand, one mode at a time; the control terms need not be included till the summary equations are written. Using the transition mapping method suggested here, you can examine the excitation equations for all types of flip-flops (R-S, J-K, D, T) and choose those types that will perform the required functions using the fewest product terms. Table A2 summarises the rules for flip-flop implementation using transition maps; the transition symbols used in the table mean:

| present state | next state | transition symbol |
|---------------|------------|-------------------|
| 0 | 0 | 0 |
| 0 | 1 | α |
| 1 | 0 | β |
| 1 | 1 | 1 |

Using these symbols, construct Table A3 from Table A1 to enable you to examine the excitation equations for all types of flip-flops. Proceeding one mode at a time, transfer the state conditions from Table A3 to Karnaugh maps, as in Fig.A1. Following the rules in Table A2, derive the excitation equations for the different types of flip-flops (the examples shown in Fig.A1 omit the T type because it is the same as the J-K type when $J = K$). In deciding which types of flip-flop to use, remember that logic minimisation with IFL is different from logic minimisation with 'random logic':

TABLE A1
Present-state/next-state table for counter/shift-register

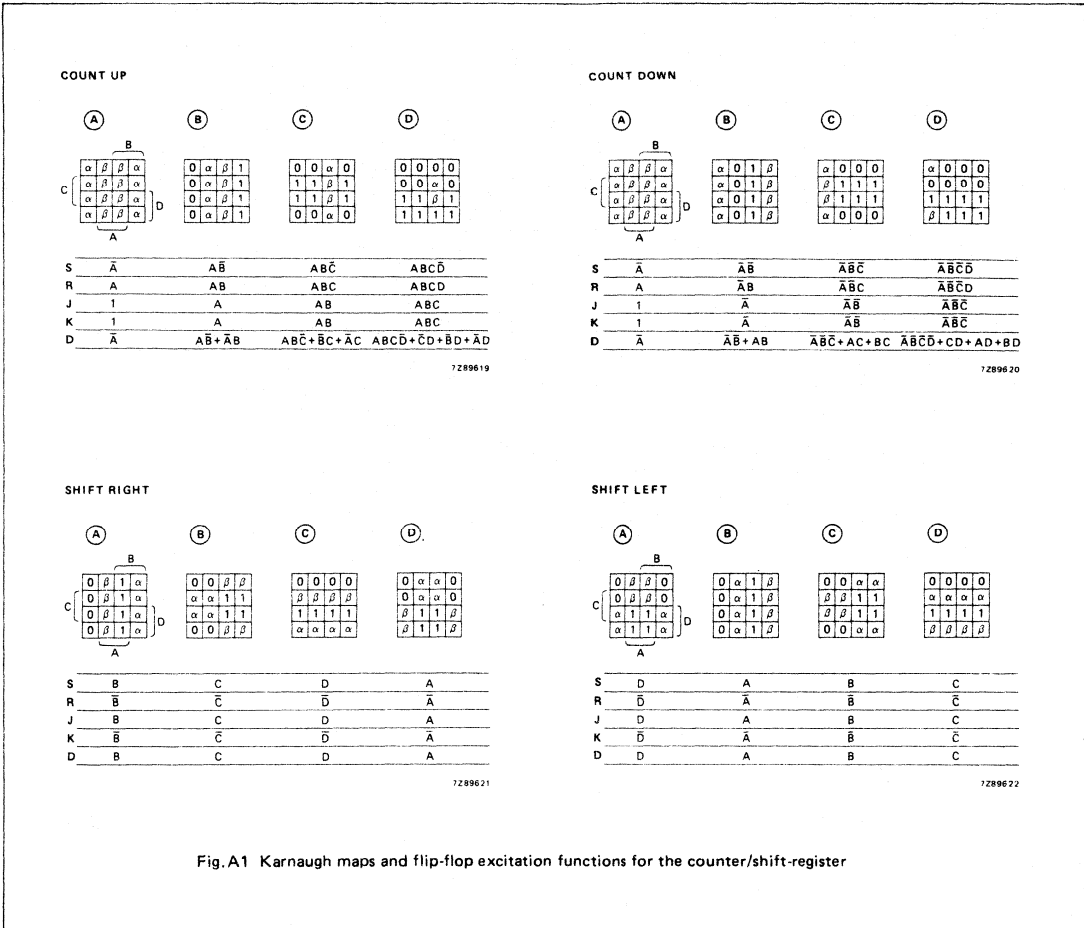

Fig. A1 Karnaugh maps and flip-flop excitation functions for the counter/shift-register

TABLE A2

Rules for flip-flop implementation using transition maps

| flip-flop type | input | must include | must exclude | redundant |
|----------------|-------|-----------------|--------------|----------------|
| R-S | S | α | $\beta, 0$ | 1, x |
| | R | β | $\alpha, 1$ | 0, x |
| D | D | $\alpha, 1$ | $\beta, 0$ | x |
| T | T | α, β | 0, 1 | x |
| J-K | J | α | 0 | 1, β, x |
| | K | β | 1 | 0, α, x |

TABLE A4

Number of product terms required for counter/shift-register flip-flop excitation

| flip-flop type | count up | count down | shift right | shift left | total |
|----------------|----------|------------|-------------|------------|-------|
| S R only | 8 | 8 | 8 | 8 | 32 |
| J K only | 4 | 4 | 8 | 8 | 24 |
| D only | 10 | 10 | 4 | 4 | 28 |
| FPLS | 4(J-K) | 4(J-K) | 4(D) | 4(D) | 16 |

with random logic you seek to reduce the number of standard packages required; with IFL you seek to reduce the number of product terms.

From Fig. A1 it is evident that you should choose J-K or T flip-flops for the counter mode and D flip-flops for the

shift mode, for you then require only one product term per flip-flop per mode. Table A4 summarises the number of product terms per mode the various types of flip-flops would require.

Figure A2 shows the completed programming table for

the counter/shift-register. The programming of Terms 0 to 15 reflects the flip-flop excitation equations and illustrates the value of being able to switch the flip-flops dynamically from one type of operation to another. Terms 16, 17 and 18, respectively, provide for INITIALIZE, asynchronous RESET, and STOP functions.

The programming of the two additional inputs $\overline{\text{HALT}}$ and $\overline{\text{BUSY}}$ illustrates the value of the complement array, which is made active when $\overline{\text{HALT}}$ and $\overline{\text{BUSY}}$ are Low (A in the Complement square of Term 18) and propagated into all the other terms (dot in the Complement squares of Terms 0 to 17). This means that unless the $\overline{\text{HALT}}$ and $\overline{\text{BUSY}}$ inputs are High none of the product terms will be true and the state of the machine will not change. If the complement array were not used, twice the number of product terms would be required, even if one of the additional inputs were omitted.

As it is, the design uses only 19 of the 32 product terms available, so there is ample capacity for extending its capabilities. For example, the shift-left function can be augmented by a binary multiplication capability, using a D type flip-flop to make it shift one, two, or three places according to the state of two extra inputs, X and Y. Figure A3 shows the revised programming table. The binary multiplication function occupies nine additional product terms and is an

example of why initial product-term minimisation is always worthwhile: it affords design flexibility and frees capacity for additional features or refinements that might not otherwise be feasible.

The IFL counter/shift-register has a set-up time of 50 ns – just half what it would be if LS TTL were used.

LOGMIN USERS MANUAL

1.0 LOGMIN INTRODUCTION

LOGMIN is a computer program which performs multiple output AND-OR logic minimization. It can find a nearly minimal AND-OR network for any problem with 16 or fewer inputs and eight or fewer outputs.

Its main purpose is to minimize program tables for the Signetics' 82S100/101 Field Programmable Logic Array. Minimization can be a key concern to the array designer, since it allows him to compress more logic functions in each FPLA, thereby reducing the number of logic elements, power, and cost required to implement any given function.

2.0 WHAT IS AN FPLA?

Signetics' FPLAs are fast, user programmable, TTL logic elements with memory, which can streamline logic system design by integrating the equivalent of 528 TTL gates in 196 packages into a single IC package.

In terms of logic, the FPLA is a two level AND-OR, AND-NOR combinational logic element, consisting of a system of logic gates with programmable inputs and outputs as shown in Figure 1. These, by means of on-chip programmable connectors, enable the user to quickly implement eight logic functions with a maximum of 48 product (AND) terms, involving up to 16 input variables.

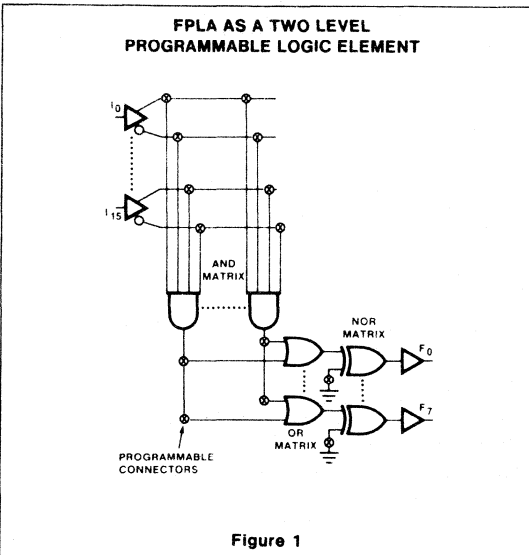

Figure 1

A more detailed organization of the FPLA is shown in Figure 2. The device consists of an upper resistor-diode AND matrix containing 48 product term columns (P-terms), and a lower emitter-follower OR matrix containing eight sum term rows (S-terms), one for each output function. Each P-term in the AND matrix is initially coupled to 16 true and complement input variables via 32 fusible Ni-Cr links for programming any desired input combination.

Each P-term is also coupled to each S-term in the OR matrix through an emitter fuse, for pulling the summing node to a high level when the P-term is activated. Each S-term in turn is coupled to its respective output via an Ex-OR gate, which has programmable transmission polarity by means of an input to ground fusible link.

Selective programmability of the internal links allows the user to create specific logic paths for producing any logic functions as a sum of products, defined in the typical Karnaugh Map of Figure 3.

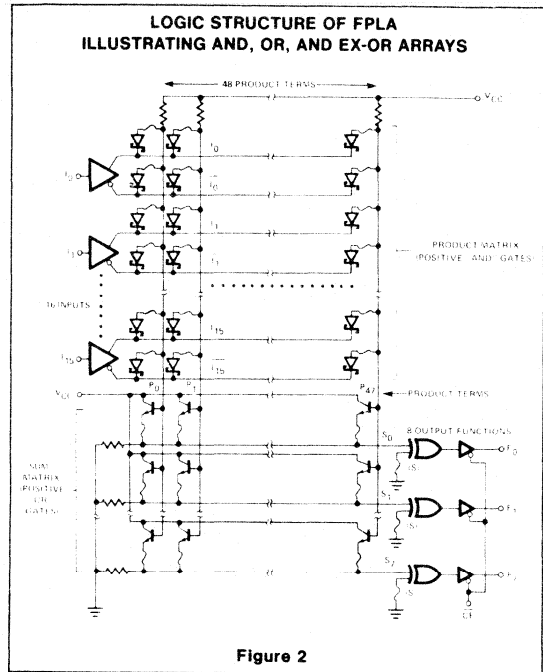

Figure 2

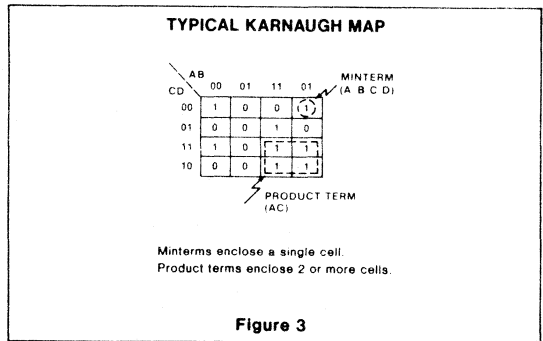

Figure 3

The transmission through the FPLA can be traced along the equivalent logic path shown in Figure 4. From this figure, it is apparent that Signetics' FPLA is basically a two level logic element. The first level produces 48 internal AND functions, P₀ through P₄₇, of up to 16 logic input variables, or their complement. The second level produces eight OR output functions, F₀ through F₇, each involving up to 48 of the internally generated AND terms. Alternately, if desired, this second logic level can be programmed to provide 8 NOR output functions F₀^{*} through F₇^{*}. However, for each of the 8 outputs, either the function F_p (active-high), or F_p^{*} (active-low) is available, but not both. The required output polarity is programmed by the user via link (S). The overall logic function provided by each FPLA output is summarized in Figure 5.

When viewed strictly as a logic element, the FPLA can be used to implement sets of logic equations of the type:

$$\begin{aligned}
 F_0 &= I_0 + I_1 \bar{I}_5 + I_2 \bar{I}_3 I_7 \dots \\
 F_1 &= \bar{I}_0 + I_1 \bar{I}_5 + I_6 I_7 I_8 \dots \\
 \bar{F}_2 &= \bar{I}_2 + I_7 I_5 + \dots \text{etc.}
 \end{aligned}$$

INTEGRATING LOGIC WITH FPLAs

F₁ modified by deleting term X₁ in the OR matrix and adding new term \bar{X}_1 .

Figure 9

These features and organization combine into an easy to use, high performance device, affording distinct user benefits:

A. 16-input variables

The 16X8 I/O configuration permits direct byte manipulations required by intelligent terminals, peripherals, microprocessor based emulators, minicomputers, and all the way up to the larger mainframes. Also, in address mapping applications, it provides the capability to scan an address field 65,536 words deep.

B. Chip Enable input

The Chip Enable input is a major improvement over alternate devices:

- Eases expansion of input variables and/or product terms.
- Permits application of tri-state device in bus organized systems.
- Provides logic inhibit or preconditional decoding functions.
- Provides a unique "default" logic state for all outputs, regardless of programmed output polarity.

C. Fastest access time

50ns maximum over the commercial temperature range renders the replacement of random logic feasible.

D. Fully buffered devices

All product terms can be utilized as many times as required, without affecting device speed and power dissipation.

E. 48 product terms (P-terms)

Allow the user to store in the FPLA 48 distinct words of eight bits each. These 48 words can be addressed by a minimum of 48 input address combinations, chosen by the user among a total available pool of 2^{16} (65,536).

F. Polarity of all outputs individually programmable active-high or active-low

This feature is particularly useful in achieving further product term minimization in cases where the complement of an output function can be implemented with fewer product terms.

Example:

As shown in Figure 10, a 50% reduction in P-terms is obtained when the output of the logical structure of F₁ is inverted by means of a gate external to the elementary FPLA. The desired function F₁ is then realized with penalties in hardware, and circuit delays (however small). These are eliminated when using an FPLA with output polarity programmed active-low to realize the function zero's, rather than one's.

3.0 LOGIC MINIMIZATION TECHNIQUES

Three Logic minimization approaches are useful with the FPLA.

As shown in Figure 10, the use of the output polarity exclusive-or gate can reduce required FPLA resources. It will be shown in FPLA EXPANSION how this gate can also be used to directly parallel "N" FPLA's such that they perform as a single FPLA but with "N" times the product term resources.

The bit slice technique of minimization involves solving each output function separately in terms of its input variables. A popular method of accomplishing this is through the use of Karnaugh Maps. Although bit slice minimization provides a minimal solution for each output function, the overall system realization with all outputs viewed together may not be minimum.

The third minimization approach is Simultaneous Minimization. Whereas bit slice minimization provides a minimum single output solution but not necessarily a minimum system solution, simultaneous minimization provides a minimum system realization but not necessarily a minimum solution for each output. Systematic methods such as the Quine-McClusky method yield good results for problems smaller than eight or nine inputs with five or six outputs, but extension to larger problems requires laborious hand manipulations which inevitably are prone to error.

Figure 10

To illustrate bit slice and simultaneous minimization methods, the results of an FPLA code conversion problem will be examined in Figure 11. The unminimized code conversion table shown in 11a shows that 83 product terms are required to map the 16-bit input code into a six bit output code. Through multiple use of Karnaugh Maps and traditional Boolean Algebra, the bit slice method is able to implement the same code conversion in 52 P-terms. This particular minimization will require two FPLA's to implement just like the unminimized table. The only benefit that one has gained from this effort is perhaps program space to perform future code additions or modifications. The simultaneous minimization in 11c provides a conversion in just 44 product terms; eight less than the bit slice method, but more important in this application, it has enabled the designer to implement the entire code conversion in one FPLA instead of two!

4.0 GENERAL DESCRIPTION OF SIGNETICS' SIMULTANEOUS MINIMIZATION PROGRAM

Most all existing AND-OR minimization algorithms fall into two basic categories. The first category is successive approximation. It includes algorithms which start with a realization and improve it

iteratively through random permutations of the realization and localized application of classical ideas from switching theory. IBM's "MINI" algorithm is an example in this category. Algorithms of this type have not been very effective on problems which have a significant proportion of ones in their truth tables.

The other category includes various implementations of the Quine-McClusky method. Algorithms in this class fail on large problems because of the size of the multiple output prime implicant covering table. An upper bound on the table size is $3^N \times 2^N \times (2^M - 1)$ bits, where N and M are the number of inputs and outputs, respectively. For 16 inputs and eight outputs, that number is over 10^{14} bits!

Signetics' program fits into neither category. It is based on two new and proprietary logic synthesis algorithms. It is much faster than the current state-of-the-art because it does not use the enormous prime implicant covering table of the Quine-McClusky method. The AND-OR realizations produced are not absolutely minimal solutions, but usually are very good.

The algorithm quickly discovers all essential multiple output prime implicants in the truth table. Since most truth tables are not completely covered by essential prime implicants, the second algorithm completes the realization by calling a subroutine called CLEANUP. CLEANUP takes most of the time consumed by the minimization algorithm.

5.0 USE OF LOGMIN

LOGMIN (Logic Minimization) is a preprocessing program that assembles AND-OR input data into a file suitable for use as a minimization source file. There are two data entry modes presently available, keyboard and paper tape.

Keyboard AND-OR data entry is done from the user's terminal in a conversational manner. LOGMIN will direct the user to key in the necessary AND-OR data in the correct format and will also provide error diagnostics for the case of incorrect data entry.

Paper tape entry is done via a teletype tape reader. LOGMIN will ask a few preliminary questions and then request that the user's paper tape be sent. The paper tape format is that of a standard FPLA programming tape. As before, LOGMIN assembles the tape entry into a minimization source file. The minimized output file generated may be listed on the user's terminal and/or a paper tape can be punched on the user's teletype. The output paper tape is of suitable format to program an FPLA.

Field-programmable arrays: powerful alternatives to random logic

Bridging design gap, TTL-compatible logic family
is described in Part 1 of a two-part article

by Napoleone Cavlan and Stephen J. Durham, *Signetics Corp., Sunnyvale, Calif.*

□ With the steady growth of integrated circuit technologies, hardly a day goes by without the news that yet another chip has made scores of discrete TTL packages obsolete. Yet, though large-scale integration is packing entire system architectures onto a few chips, it is still impossible to complete a design without some discrete logic to hold the framework together.

The increase of LSI has thus created the need for efficient ways to bridge the gaps between large functional islands. Because of complexity, performance, or uniqueness, these bridges have evolved into nontrivial random-logic configurations that still rely on clusters of small- and medium-scale integrated circuits, whose fixed functions never quite fit the problem. Now Signetics

Corp. has attempted to meet the need with a field-programmable logic family.

The family spans three ranges of complexity: at the low end are the field-programmable gate arrays (FPGAs); covering the middle range are the more complex logic arrays (FPLAs); and finally there are the logic sequencers (FPLSS). These last, most complex elements have built-in registers and enable the designer to proceed from state diagram directly to hardware. The family, summed up in the table on p.182, is compatible with TTL and operates from a +5-volt supply.

The devices provide a powerful and compact alternative to random logic, replacing discrete gates, wires, and connectors, with significant savings in board space,

| FIELD-PROGRAMMABLE LOGIC FAMILY | | | | | | | | | | |
|---------------------------------|--|--------|--------|-----------------------|---------------------------------|----------------|-------------|--------------|-----------------------|---|

power, and cost. Moreover, since all devices can be programmed and modified in the field (as programmable read-only memories can) using readily available programming equipment, the logic can be changed to meet new customer requirements or specifications, or to recover quickly from design errors—after delivery to the field—without expensive printed-circuit-board retooling.

Programming options

Depending on their complexity, members of the programmable logic family have internal AND gates, OR gates, S-R flip-flops, true or complement buffers, and exclusive-OR (EXOR) gates. Those elements can be combined to perform single-level, double-level, and sequential logic functions—all by blowing fuse links.

There are other fuse options in output structures for the entire logic family, too, since either active-high or active-low functions can be generated without additional hardware or signal delay. Finally, the family is well suited to bus-organized environments such as microprocessor systems, since all its members offer, in addition to open-collector outputs, three-state outputs whose signals are in the high-impedance state until activated by a chip-enable input.

All the logic elements perform standard logic functions that can be represented by augmenting conventional logic symbols with a few new definitions so that they can represent multiple-input gates (see "How the FPLA defines logic," p.183).

The gate arrays

The simplest member in the family is the field-programmable gate array, which performs single-level logic functions. The equivalent logic diagram for the FPGA is shown in Fig. 1. The two gate arrays currently available are open-collector (82S102) and three-state output (82S103) versions of the same array, which comprise nine NAND gates fuse-selectively connected to 16 common inputs by true/complement buffers.

Fuses in the FPGAs allow individual outputs to be complemented to AND, so that by proper manipulation of the input polarities, and by using De Morgan's theorem, AND, OR, NAND, and NOR logic functions can be easily implemented. The parts thus serve as universal logic elements that can be tailored to applications requiring random logic, as in fault monitors, code detectors, and address decoders for microcomputer systems with memory-mapped I/O.

The logic arrays

Devices performing two-level combinational logic functions are grouped into the field-programmable logic array (FPLA) category. These elements are a step up in complexity from gate arrays, capable of generating AND-OR, AND-NOR, and their De Morgan equivalents. There are at present two array types in the FPLA family, each with either open-collector or three-state outputs.

The equivalent logic diagram of the first array type, the open-collector output 82S101 (or three-state output 82S100), is shown in Fig. 2. The first level of logic in the device is made up of 48 AND gates fuse-connectable to any of 16 common inputs by true/complement buffers. The second logic level consists of eight OR gates—one per device output—each capable of being selectively coupled to any of the 48 gates. Finally, fusing options are included for generating true or complementary outputs.

The second logic array type, the 82S106/107, has nearly the same organization as the first. The exception is that an additional OR gate with fixed inputs has been added to generate an internal enable command for the output structure. That self-enable is generated whenever any of the AND gates become logically true, which occurs when the external input code matches the internal AND-gate program. In the absence of such a match, all device outputs are unconditionally disabled. The self-enable signal is available externally—the chip-enable input (\overline{CE}) pin on the 82S100/101 becomes an open-collector output called FLAG. Because of this feature, the 82S106/107 can be viewed as a content-addressable programmable read-only memory, ideally suited to modifying data in large ROMs, as will be shown in the second part of this article.

Shared gates

Both array types benefit from the second level of logic. The advantage here is that the AND gates can be shared—OR gates can couple with up to 48 AND gates. Also, a key advantage of this arrangement over single-level logic is that it allows editing—disconnecting invalid AND terms from the OR array and replacing them with spare AND gates (Fig. 3).

Open-collector versions of both gate-array and logic-array devices can form wired-AND outputs in order to expand the number of AND gates available on a single chip. This solves the problem that is posed by applications exceeding the resources of a single device. The only restriction is that the expanded outputs have to be programmed to be active-low.

By far the most powerful members of the family are the field-programmable logic sequencers (FPLS), which add on-chip registers to arrays of AND and OR gates. The

How the FPLF defines logic

For the most part, schematic representation of logic in the field-programmable logic family follows conventional notation—the devices include AND, OR, and exclusive-OR (EXOR) gates, as well as set-reset (S-R) flip-flops and true or complement buffers. To simplify the representation of fuse-link programmability, however, the FPLF schematics use a matrix arrangement with cross-point coupling to represent intact fuse links.

For example, (a) in the figure shows a typical input and AND gate of a gate array. The square "solder dot" represents a fixed internal connection. Both the line from input A and the line from the output of the inverter intersect the vertical input line of the AND gate; in actuality, fuse links make both connections. An intact fuse link is represented by a round solder dot. Blowing either of the fuse links will determine whether the input to the AND gate is A, or its complement, \bar{A} . (Leaving both fuses intact holds the output of the AND low, whereas blowing both fuses results in a "don't care" situation, an output that is independent of either input.)

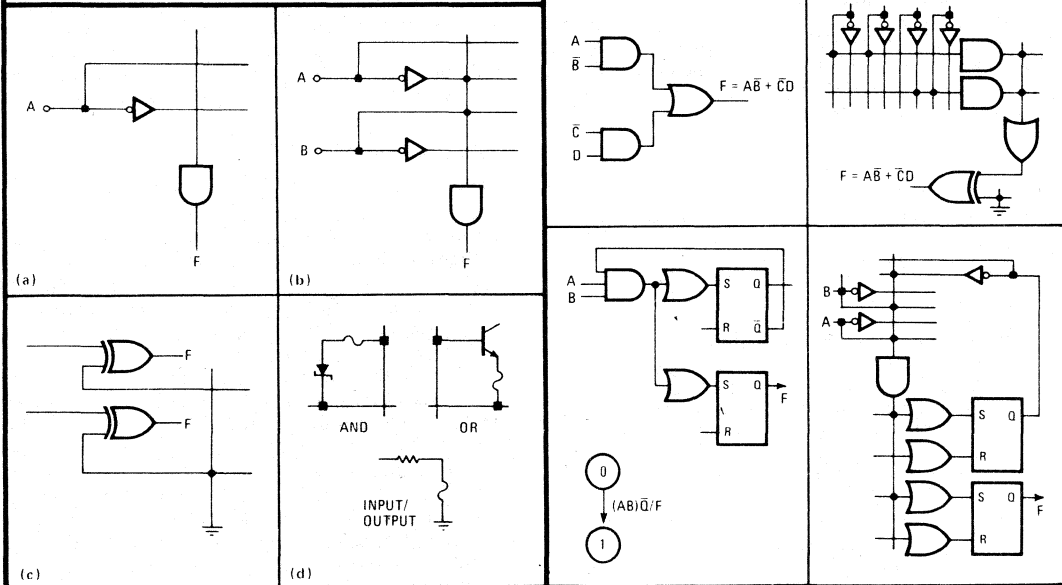

Extending the matrix and cross-point coupling approach a step further, (b) shows the configuration of a two-input AND gate. Since the input to the AND gate crosses the four lines of inputs A and B as well as their complements, the gate serves as a four-input AND while appearing to be a single-input gate. Since the members of the field-programmable logic family have 16 inputs intersecting each AND gate, the gates are actually 32-input devices; the number of inputs used is determined finally by the number of fuses left intact. Thus, in (b), solder dots (or

intact fuse links) create the logical equation $F = \bar{A}\bar{B}$.

The exclusive-OR gates on all outputs of the logic-family devices allow programming for either active-high or active-low output signals. As shown in (c), a fuse link grounding one of the two inputs of an EXOR gate results in an active-high output; blowing the fuse results in an output that is active-low.

The details of the fusing mechanisms are shown in (d). AND gates have a fuse in series with a Schottky diode, while OR gate fusing uses an npn transistor. The fuses for the true/complement input buffers and active-high/active-low outputs are in series with resistors.

The analogy between fixed and programmed logic is best shown by the examples in the table. The first example is typical of the single-level logic to which the gate array is applicable. The two-level logic of the second example is satisfied by the logic arrays. Finally, the registered state machine that executes the state transition of the third example is a candidate for the field-programmable logic sequencers.

sequencers are actually self-contained state machines, since they can be programmed to perform any synchronously clocked logic sequence.

State machines, whose general structure is shown in Fig. 4a, usually take two forms: Moore machines, in

which the output is a function of the present state only; and Mealy machines, whose output is a function of both the present state and the present input.

Figure 4b shows the basic architecture of the open-collector output 82S104 (or three-state output 82S105),

1. Gate array. The simplest device in Signetics' field-programmable logic is the gate array, capable of single-level logic. Any of 16 inputs can connect to nine NAND gates by true/complement buffers. Since outputs can be complemented to AND, manipulating De Morgan's theorem makes the device a universal logic element.

the first members of the FPLS family. With the FPLS, a user may program any logic sequence that can be expressed as a series of jumps between stable states which can be expressed as a series of jumps between stable states triggered by a valid input condition I at clock time t . The number of states in the sequence depends on the length and complexity of the desired algorithm.

A typical state diagram is shown in Fig. 5. The state from which a jump originates is called the present state P , and that at which it terminates is the next state N . A jump always causes a change in state, but may or may not cause a change in the machine's output F .

2. Double deep. The field-programmable logic array carries out two-level combinational logic. The 16 inputs couple to 48 AND gates, which in turn connect to any of nine OR gates. Either true or complement outputs are provided.

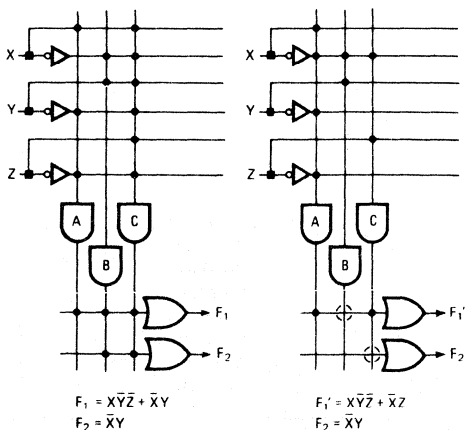

All states are arbitrarily assigned and stored in the state register, where the clock and next-state information from the combinational logic are the inputs. State jumps can occur only when transition terms are true. A transition term is, by definition, the logical AND function of the clock, present state, and valid inputs; hence, $T_n = t \cdot I \cdot P$. However, since the clock is actually applied to the state register, it may be removed from the equation. When T_n is true, a control signal is generated that, at clock time t , forces the contents of the state register from P to N and, if necessary, changes the contents of the output register.

FPLS organization

The architecture of the 82S104/105 is a natural extension of the static logic structure of the FPLA. It accepts 16 input variables and provides eight output functions. It has a 6-bit state register and an 8-bit output register; all the internal registers are automatically preset to logic 1 when power is applied. The FPLS provides for 48 transition terms, which can be selected to be either true or complementary.

A look at the equivalent logic diagram of the FPLS (Fig. 6) shows its extension of the static FPLA. The AND and OR gate arrays of the latter have been expanded to control the set and reset (S and R) inputs of six flip-flops (the state register) and to monitor the register's contents over an internal feedback path. Also, an independent 8-bit output register has been added to store output commands generated during state transitions and to hold the output constant during state sequences involving no output changes.

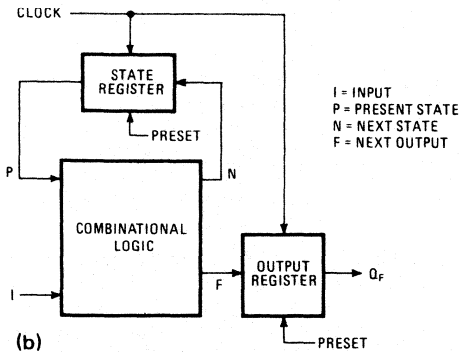

The AND array comprises 48 positive AND gates, each with 44 input connections from a set of true/complement buffers. The AND gates are used to form logic products of 16 external inputs (I_0 to I_{15}) with six present-state (P) inputs fed back from the state register. The gates are

3. Editing. The logic array's programmable OR gates allow sharing of AND gates, as with gate B at left. The OR array also allows easy editing of logic statements when design changes are made; note how spare gate C at right was used to modify output F_1 to F_1' .

(a)

(b)

I = INPUT
P = PRESENT STATE
N = NEXT STATE
F = NEXT OUTPUT

4. State machine. A state machine (a) takes either a Mealy or Moore form. The architecture of the field-programmable logic sequencer (b) is that of a self-contained Mealy machine, where the output is a function of both the present state and the present input.

therefore called transition terms because, like the transition terms in state diagrams, they issue next-state commands.

The OR array contains 28 positive OR gates, each with 48 input connections to all 48 AND gates. The outputs of the ORs drive the set and reset inputs of the 14 S-R flip-flops that are state and output registers.

The FPLS is made still more flexible by a complement array comprising a single 48-input OR gate that drives an inverter, which then feeds back into the AND array. The complement array forms a bridge between the AND and OR arrays for generating NAND functions of input-jump conditions; the user programs it in such a way as to suit each transition term.

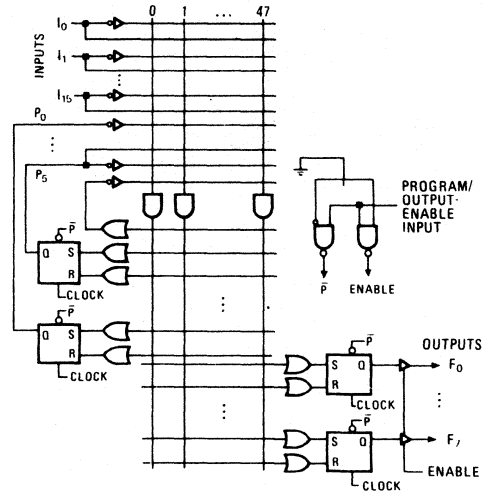

De Morgan's theorem

De Morgan's theorem to reduce logic terms can be easily implemented with the complementary array so that the most use is made of the AND gates. For example, if the transition term is $T = (Q)(\bar{X} + \bar{Y} + \bar{Z})$, where Q is the output of the state register and \bar{X} , \bar{Y} , and \bar{Z} are inputs, three AND gates in the FPLS are required. However, De Morgan's theorem changes the transition term to $T = (Q)\bar{X}\bar{Y}\bar{Z}$, which requires only two AND gates.

The complementary array is also an efficient means of aborting a clocked sequence in the absence of valid jump conditions. As Fig. 7 shows, considerable minimization

5. State diagram. Example of a state diagram (a) with four states—A, B, C, and D. I_1 – I_3 are jump conditions, which trigger output changes F_1 – F_3 . A state change (b) gives rise to transition term T_n , which is logical AND of clock t , input I , and present state P .

6. Sequencer. The field-programmable logic sequencer has 16 outputs, 48 AND gates, and 28 OR gates, plus 14 flip-flops that serve as state and output registers. Either an asynchronous preset input or an output-enable input is available as a programming option.

of AND gates is possible when the detection of valid jumps involves many complements of jump functions, especially as the number of variables increases.

All clocked S-R flip-flops that make up the state and output registers offer the option of asynchronous pre-setting to all 1s. The 64-state total that can be represented by the state register is adequate in most cases to chart algorithms involving fewer than 48 nonredundant transitions. The register accepts next-state commands (N) from the OR array and supplies present-state information (P) to the AND array.

The output register is similar to the state register, except it has eight states for servicing eight output functions. It accepts the next-output commands F_0 – F_7 .

$$T_1 = (Q_1 \bar{Q}_0)(\bar{Z}YX)$$

$$T_2 = (Q_1 \bar{Q}_0)(ZYX)$$

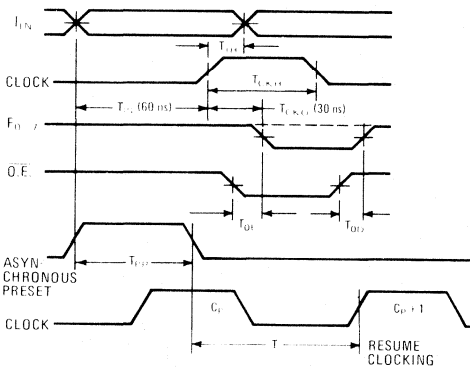

$$T_3 = \bar{T}_1 \cdot \bar{T}_2 = \bar{T}_1 + \bar{T}_2$$

| | | YX | | | |
|---|---|----------------|----|----|----------------|

| Z | 0 | - | - | - | T ₁ |
| | 1 | T ₂ | - | - | - |

Q₁ Q₀
T₁ · T₂

7. Complementary. Use of AND gates in the FPLS is greatly reduced by the complement array, a single 48-input OR gate driving an inverter that feeds back into the AND array. In this example, the default jump from state S₀ to S₃ is reduced from three AND gates to a single gate T₃.

8. Timing. Minimum clock duration for the FPLS is 20 nanoseconds. Minimum width of preset input, which overrides clock, is 40 ns. Normal clocking resumes with the first full clock pulse following a negative clock transition after the trailing edge of the preset signal.

from the OR array and then reflects its contents to the device outputs through the buffered Q outputs of each of the flip-flops. Also, as an added feature to enhance fault isolation, driving input I₀ to +10 volts will route the contents of the state register (P₀-P₃) directly to outputs F₀-F₃ without any alteration of the contents of the output register. However, the feature is not recommended for use in a normal mode of operation (as in a Moore machine). This is because it increases the device's maximum current by 5 to 10 milliamperes and thereby lowers the maximum ambient temperature rating of the package by approximately 5°C.

As a final programming option in the 82S104/105, a pin can function as either an active-high asynchronous preset (pr) or an active-low output enable (\overline{OE}). The output-enable function forces all outputs to logic 1 (or to

high impedance in the 82S105) and is normally used when the device is sharing a bus. It does not inhibit clocking of the internal registers. The asynchronous preset option, on the other hand, is useful when the logic sequence requires an immediate state-independent return to initial conditions. The state register and output register can also be synchronously preset independently of one another by dedicating that function to one of the input variables in conjunction with a single transition term and a clock pulse.

Timing constraints

The maximum clock rate of the 82S104/105 can be inferred from its timing diagram (Fig. 8), which shows worst-case delays and setup requirements during a typical I/O cycle. Using stable external inputs as a reference, the device can be clocked after a minimum setup time of 60 nanoseconds. The next output (as well as the next internal state) will be valid 30 ns after the positive edge of the clock, giving a total I/O delay of 90 ns. Since both output enable and disable delays are also 30 ns, when the \overline{OE} pin is used its signal's edge should occur prior to or coincidentally with the clock in order to avoid increasing I/O delays.

The asynchronous preset option includes a clock lockout feature that eliminates the potential hazard of spurious clocking. But, as the timing diagram shows, when using the lockout feature it is possible to miss one clock pulse, which may be prohibitive in some applications.

Applications

The second part of this article, to appear in the next issue of *Electronics*, will provide examples of applications for the gate- and logic-array devices. It will also describe in detail the development of a full-blown cartridge-tape drive controller built with a single logic-sequencer chip. The design example proceeds from flow chart to state-sequence diagram to hardware. □

Sequencers and arrays transform truth tables into working systems

by Napoleone Cavlan and Stephen J. Durham
Signetics Corp., Sunnyvale, Calif.

□ Because of its power and flexibility, the Signetics field-programmable logic family is ideal for replacing the discrete logic normally used to interface large-scale integrated devices, as shown in Part 1 [July 5, 1979, p.181]. The examples of applications that follow show how to exploit its special features.

In designing with these gate and logic arrays and logic sequencers, the user need concern himself only with generating truth tables associated with the state diagrams or sets of Boolean logic equations that define his function. The one restriction is that he must use logic symbols corresponding to the status of fuse links.

As indicated in Fig. 1, an extra set of symbols is needed to describe all the states of FPLF gates corresponding to all combinations of blown and unblown fuse links. Once ordered into truth tables, the user-defined functions are then directly mapped onto standard program tables furnished with FPLF elements, whose fuses are then blown by a logic-type programmer. As the user gains experience, he can manipulate logic variables intuitively and can eventually implement algorithms directly on the program tables with only the device schematics for reference. (The formal step of deriving state diagrams and logic equations will not be considered here.)

Because of their simple and uncommitted structure, FPLF elements are suited to a wide variety of applications, several of them already well documented. The following examples illustrate the typical use of each logic element and match devices with applications.

Bus translator

Signetics' Instructor 50 microcomputer system is built around the 2650 microprocessor; but for compatibility with other systems and peripheral devices in the hobbyist market, it interfaces to the S100 bus, which is based mainly on 8080 microprocessor signals. Yet to carry out the seemingly unwieldy task of bus translation, only a single FPGA is needed. The gate array translates the logical combinations of timing, enable, and control signals supplied by the 2650 and its I/O hardware into control signals entirely compatible with the S100 bus definitions, as shown in Fig. 2.

The programmable feature of the FPGA is strategically

invaluable in this case since the S100 bus is not yet totally standardized. The FPGA permits easy adaptation of the interface to changes in specifications, which are subject to arbitrary manipulation by manufacturers in the hobby arena.

Two-level logic

The logic arrays add a second level of combinational logic to the gate arrays, and thus another level of versatility. AND/OR combinations of the FPLAs are well suited to carrying out polynomial equations and the like, as shown in the next example.

In systems that transfer large blocks of data, a cyclic redundancy check (CRC) scheme can significantly improve data integrity. The technique appends a check word to a transmitted sequence of data, and the receiving end uses that word to check for errors. A cyclical division of the transmitted data by an industry-standard polynomial generates the CRC word; the remainder from the division forms the check word.

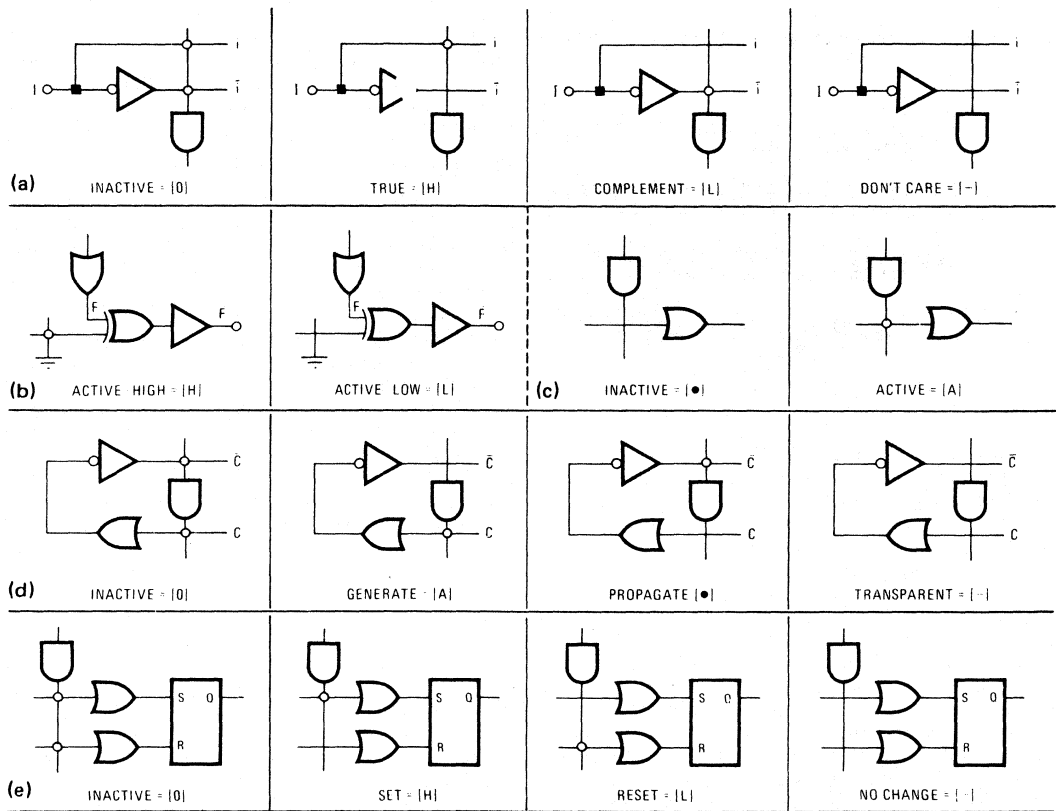

Polynomials lend themselves to serial manipulation, and serial CRC generation and checking are easy to implement. But in a multiple-line data system with parallel organization, a considerable amount of hardware may be needed for parallel-to-serial conversion. Moreover, the multiple-bit clocking for each word carries an inherent speed loss—a factor of 8 for a byte-oriented system. A parallel CRC generator-checker circuit is the answer, developed from the set of logic equations describing the function of the circuit in the form of a state machine.

The general design of the CRC circuit is shown in Fig. 3a, along with the logic equation set for the popular CRC polynomial $P(x) = x^{16} + x^{15} + x + 1$. Figure 3b shows that the entire byte-wide parallel CRC generator-checker circuit can be implemented with only five chips: two 8-bit latches, two FPLAs, and an FPGA. The FPLAs contain the set of logic equations controlling the flip-flop inputs, which are expanded from EXOR form to sum-of-products form. In Fig. 3a, variables N_0-N_{15} represent the next CRC word after clocking, based on the current word B_0-B_{15} and the present input byte D_0-D_7 .

CRC generation begins by driving the RESET line low to initialize the latches to zero. Pulsing the clock line then transfers the first byte of the data block in at D_0-D_7 . Subsequent bytes are clocked in the same way. The cyclic nature of this design places no limit on the size of the data block that can be processed. During data transmission, the 16-bit CRC word is available at outputs B_0-B_{15} after the last data byte has been clocked in; it is appended as two check bytes to the data in the block.

Checking

The circuit is used in the check mode when receiving data containing CRC characters. The last 2 bytes in the data block received are CRC send characters. They too are clocked in and contribute to form a final receive pair of CRC characters, which, for error-free transmission, must both be zero. If an error has occurred, B_0-B_{15} will be nonzero. The FPGA will detect the nonzero condition and generate an error signal. This parallel CRC format can operate on data blocks at speeds in excess of 5.7

NOTE: SQUARE SOLDER DOT (■) INDICATES FIXED CONNECTION; ROUND DOT (●) INDICATES INTACT FUSE LINK

1. New notation. The many combinations of blown and unblown fuse links in the field-programmable logic family require new notation. The four possibilities for AND gates are shown in (a), while those for exclusive-OR outputs are in (b). The combinations for OR gates are in (c). The complement array in the logic sequencers is detailed in (d). Finally, OR gates controlling the flip-flops in sequencers are in (e).

megabytes per second.

An interesting use for the FPLA is in changing data at a few locations of a read-only memory (see "How to patch a read-only memory," p. 192).

The abilities of the field-programmable logic sequencer are well demonstrated by its use as a controller for a cartridge-tape transport. In this example, one chip replaces many—a distinct advantage if the controller is to be packed on a single-board microcomputer. Although the chip's function is complex, it can be programmed methodically and worked directly from a flow chart.

Controller routines

The controller executes fixed routines in response to status and input commands that may originate from an input/output bus or a monitoring station. Its outputs operate the velocity servo that drives the cartridge, form I/O status signals, and enable writing of data. The input and output signals of the one-chip controller are shown in detail in Fig. 4.

The controller carries out these eight routines:

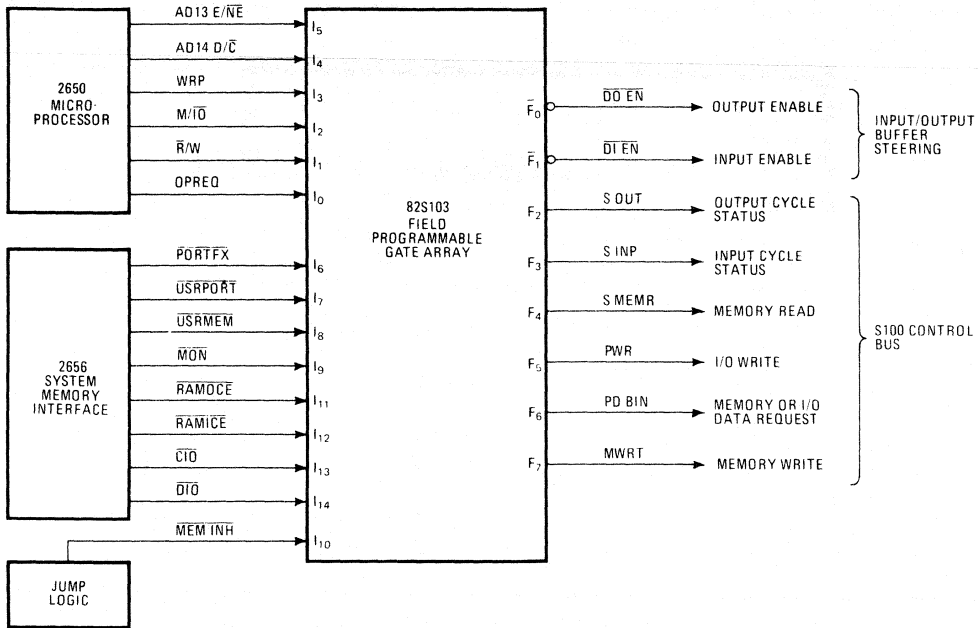

- Move tape fast-forward.

- Move tape slow-forward.
- Move tape fast-reverse.
- Move tape slow-reverse.
- Bring tape to load point when cartridge is inserted.
- Rewind tape to load point.
- Rewind tape to beginning and eject cartridge in response to unload command.
- Rewind tape to beginning and eject cartridge in response to auto-unload true condition.

The routines could be represented concisely in a conventional Mealy state diagram, but that often obscures the actual machine function. Flow charts are more easily understood, where input variables, machine states, and output functions are given variable names. Such a chart is shown in Fig. 5.

Diagramming the flow

What would be transition terms in a Mealy state machine become true/false statements regarding the system inputs (taken one at a time) in the chart. The correlation is most obvious in the simple example in Fig. 6. The flow chart in (a) shows a conditional change from

2. Translator. Getting S100 bus signals, which are mostly 8080 microprocessor signals, out of a 2650 microprocessor calls for a field-programmable gate array. One 82S103 translates signals from the 2650 and its companion 2656 interfacing chip to the hobby bus.

state A to state B. The conditions in the flow chart's diamonds must be simultaneously satisfied for the state change to occur. The conditions take on variable names, and for this example, which arbitrarily assumes a 4-bit state register, three inputs, and two outputs, the corresponding state diagram is shown in Fig. 6b.

The transition from A to B denotes a jump from 10 (1010₂) to 13 (1101₂) and an output transition to 2 (10₂) at the next clock pulse if the combination $X_n = 4$ (100₂) is true. The transition is synthesized by forming a transition term $T = P_3\bar{P}_2P_1\bar{P}_0I_2\bar{I}_1\bar{I}_0$ and using term T at the next clock pulse to generate next-state and next-output commands for the state and output registers, respectively. For the state register, flip-flops N_0 and N_2 are set by connecting T to set lines S_0 and S_2 , and flip-flop N_1 is reset by coupling T to the R_1 reset line. Similarly, for the output register bit F_0 is reset and bit F_1 is set by connecting T to corresponding flip-flop reset (R_0) and set (S_1) lines.

Controller conditions

Referring again to the controller flow chart, it can be seen that whenever the tape-drive power is turned on, or when an interlock is opened, the transport must be stopped. That is achieved by an input signal to the controller called $\overline{\text{INTRDY}}$ that resets the state register with an unconditional jump to state 1 or STOP. When that occurs, all outputs on the FPLS chip become inactive, WRITE is inhibited, and speed and direction are

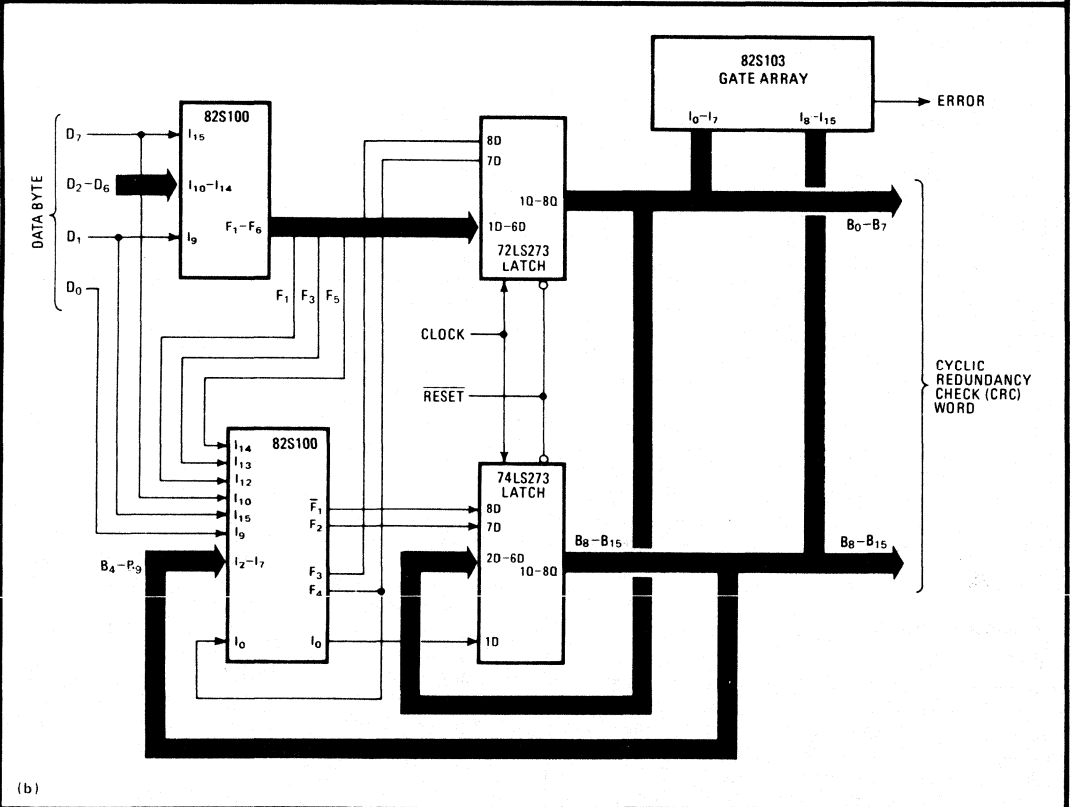

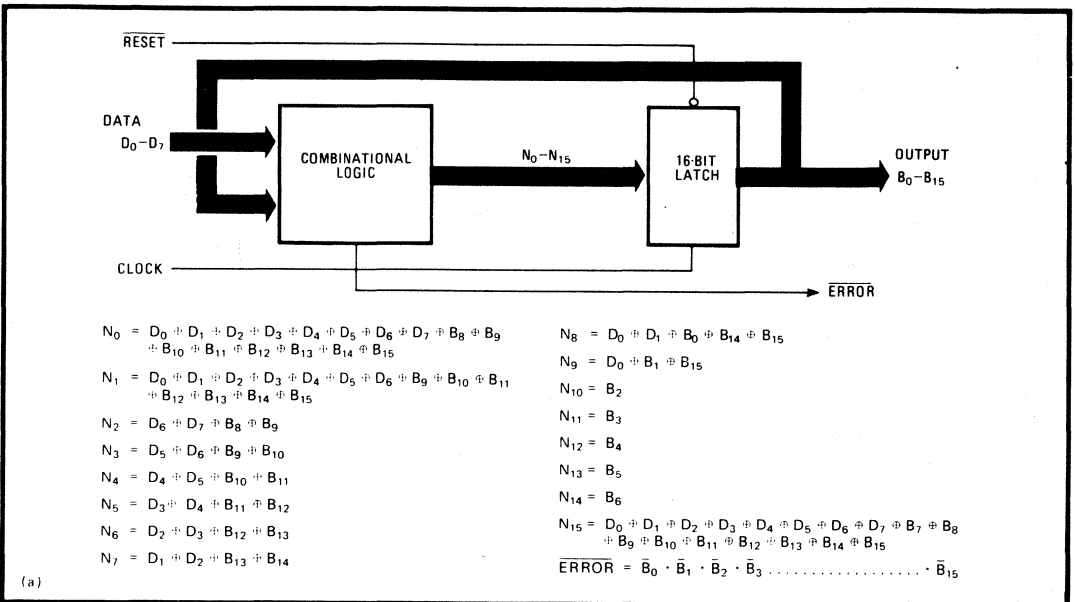

arbitrarily set to SLOW and REVERSE. From the STOP state, operation into any mode occurs by state and output jumps when all of the intervening conditions are simultaneously satisfied.

As an example, writing at normal speed will occur with a jump from state 1 to state 3, which requires that the following criteria be satisfied:

- The data cartridge is in place; therefore CIP is true.
- The drive has been addressed; SEL is true.
- The tape has been commanded to run; TR is true.
- The controller is not in state 6; state 6 is false.
- The tape should move slowly; therefore FAST is true (an active-low signal).
- The tape should move forward; $\overline{\text{FWD}}$ is true.

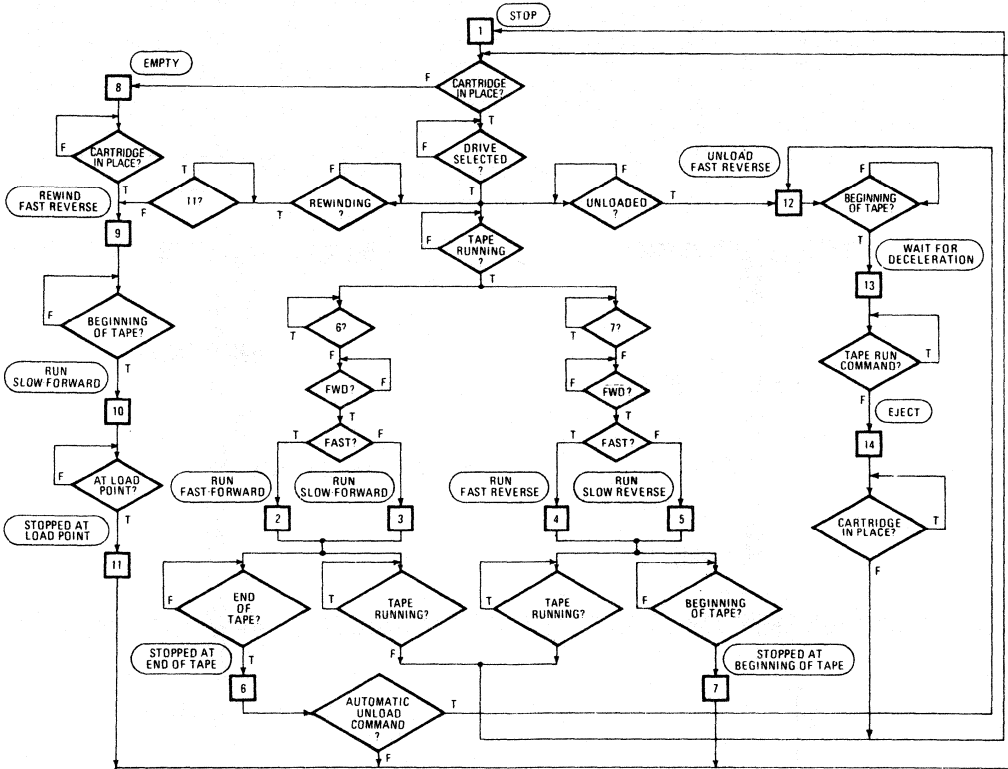

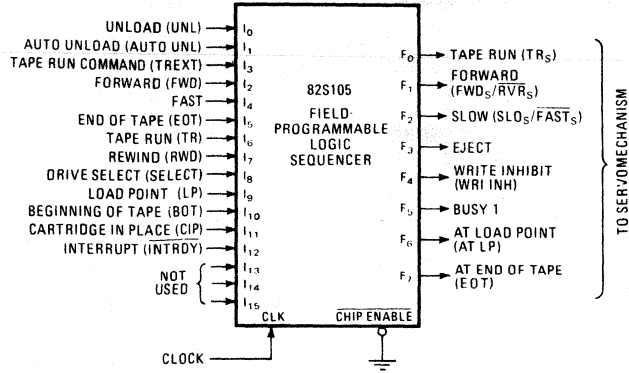

In tracing the jump between these states two things must be noted. First, the commands RWD, UNL, and TR are mutually exclusive, so that when either is true the others can be considered false or "don't care." Second, after $\text{TR} = \text{true}$, the condition (State = 6?) is inserted to indicate invalid jumps to states 2 and 3, which could originate from state 6 with an AUTO UNL false. Clearly, these should be avoided to inhibit honoring requests for read slow (or fast) forward while stopped at the end of the tape. So, the (State = 6?) condition is a reminder to avoid programming $6 \rightarrow 2$ and $6 \rightarrow 3$ state jumps in the FPLS. A similar argument holds for (State = 7?) and (State = 11?) conditions.

After data has been either written or read, the tape drive is commanded to stop by TR false, which causes a

3. Error-free. The technique of using a cyclic redundancy check (CRC) word for error-free data transmission requires complex logic to generate the word (a). A pair of logic arrays, two latches, and a gate array (b) do the job, which usually requires a boardful of chips.

4. Tape controller. A field-programmable logic sequencer like this tape controller can perform extremely complex tasks. The 82S105 receives commands from an input/output bus or monitor, and provides all the necessary signals for driving the tape-transport servo-motor mechanism.

5. Goes with the flow. The first step in designing the controller is preparing a flow chart of the operation. The chart is much easier to understand than a state diagram or Mealy machine, yet provides all the information needed for programming the logic-sequencer chip.

jump from state 3 (RUN SLOW FORWARD) to state 1. By similar arguments, the tape drive can be run either fast or slow in either forward or reverse directions by jumping to states 2, 4, and 5.

When the end of tape is reached (EOT true), the tape drive is stopped. That is implemented by jumps 2 → 6 or

3 → 6. Once in state 6, the tape drive can no longer move in the forward direction because of the State 6 false condition preceding states 2 and 3. If AUTO UNL is true, the drive will automatically rewind (state 12), wait for tape to decelerate (state 13), eject the tape cartridge (state 14) and stop. If AUTO UNL is false, the drive must

How to patch a read-only memory

It is a shame to throw away read-only memories. But often firmware-based systems must control programs to large mask-programmed ROMs, only to have a design revision requiring a new program—and a new ROM. If no pin-compatible, user-programmable ROM is available, the customer could end up waiting out the 5-to-10-week turnaround time for the new mask parts—and throwing away his inventory of old ROMs.

One way to save an obsolete ROM (or even PROMs—it hurts to throw them away, too) is by patching, which redirects certain addresses to an adjunct smaller memory. This can be done most efficiently with an 82S107 field-programmable logic array.

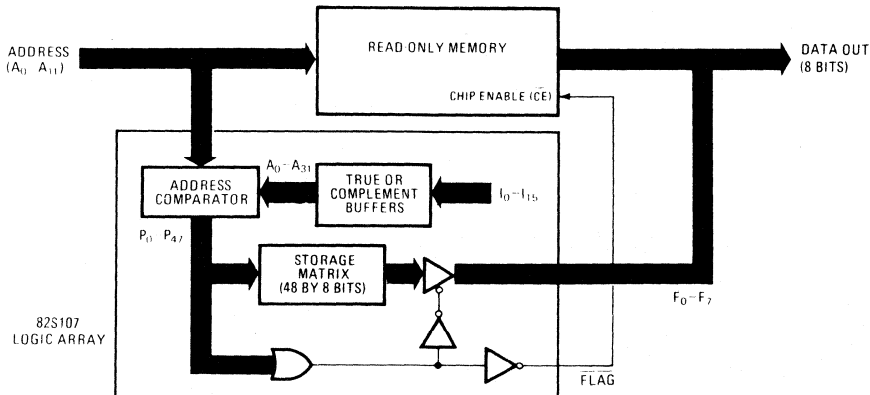

As a ROM patch (FPRP), the FPLA becomes a programmable, content-addressable PROM that continually monitors the address bus. As shown in the figure, when the FPRP encounters a match that signals a correction of data, its flag output (FL) disables the ROM, and new data from the FPRP is put on the output bus. If, for example, address 750 were to be given new data A9, address 5FE were to be given 7F, and addresses 0A4-0A7 were all to be reassigned B4, the FPRP would be programmed as in the table. For a 12-bit address, only inputs I_0 - I_{11} are used, and the remaining four, I_{12} - I_{15} then become "don't care." (Incidentally, inputs I_0 and I_1 in the

second product term are also "don't care" because they define an address block of four locations.)

The address comparator can patch up to 48 non-overlapping addresses anywhere within a memory field of 64 kilobytes. Block addressing is possible, too, using the FPRP's true or complement input buffers. Moreover, the number of addresses can be expanded by hooking several devices in parallel and wire-ANDing their flag outputs.

Since the outputs of the ROM patch primarily define a byte of memory data rather than a set of logic functions, output polarity is not controlled. Also, to maintain compatibility with the gate array, the FPRP generates its self-enable signal with a fixed multiple-input OR gate; the only disadvantage of that method is addresses (AND terms), once programmed, may no longer be deleted.

The ROM patch affords a recovery strategy effective in several design situations, including modifications of dedicated application programs, operating systems, assemblers, and monitor routines. It also permits on-site optimization of system parameters, in accordance with, say, environmental variables, and allows custom function options and product-line diversification. The customer need only allot board space next to the mask ROM for an FPRP; no parts are actually used until program changes are required after the product is in the field.

PROGRAM TABLE FOR ROM PATCH

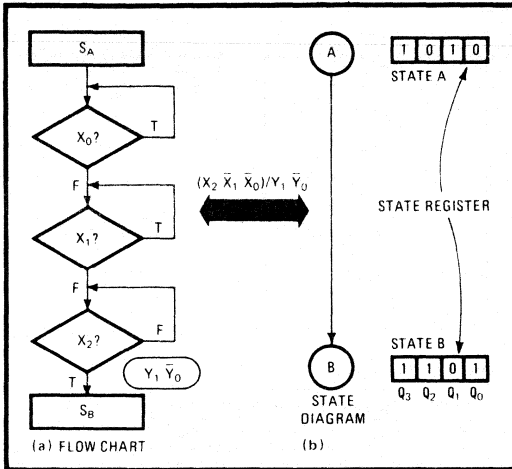

| Input address | No. | Product term | | | | | | | | | | | | | | | | Active level | | | | | | | | Output data |
|---------------|-----|------------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|-----------------|---|---|---|---|---|---|----|-------------|
| | | Comparator input | | | | | | | | | | | | | | | | Output function | | | | | | | | |
| | | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | H | H | H | H | H | H | H | H | |
| 750 | 0 | | | | | L | H | H | H | L | H | L | H | L | L | L | L | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | A9 |
| 5FE | 1 | | | | | L | H | L | H | H | H | H | H | H | H | H | L | • | A | A | A | A | A | A | A | 7F |

wait for either a rewind command (RWD), an unload command (UNL), or reverse command (FWD).

If the tape is moved in the reverse direction until the beginning (BOT), the drive is stopped. This is implemented by a jump from states 4 or 5 to state 7. Once in state 7, the tape drive can no longer move in the reverse

direction because of the state 7 false condition preceding states 4 and 5. The tape will remain stopped at the beginning until TWD, UNL, or FWD commands are given.

If no cartridge is in place (CIP false) when the tape drive is turned on, the controller will jump from state 1 to 8, and signal EMPTY. When a cartridge is installed,

6. Flow chart to state diagram. Simple transition from state A to state B is shown in flow chart (a). Three inputs (X_0, X_1, X_2) and two outputs (Y_0, Y_1) are assumed. The contents of a four-bit state register show the transition from state A (1010_2) to state B (1101_2).

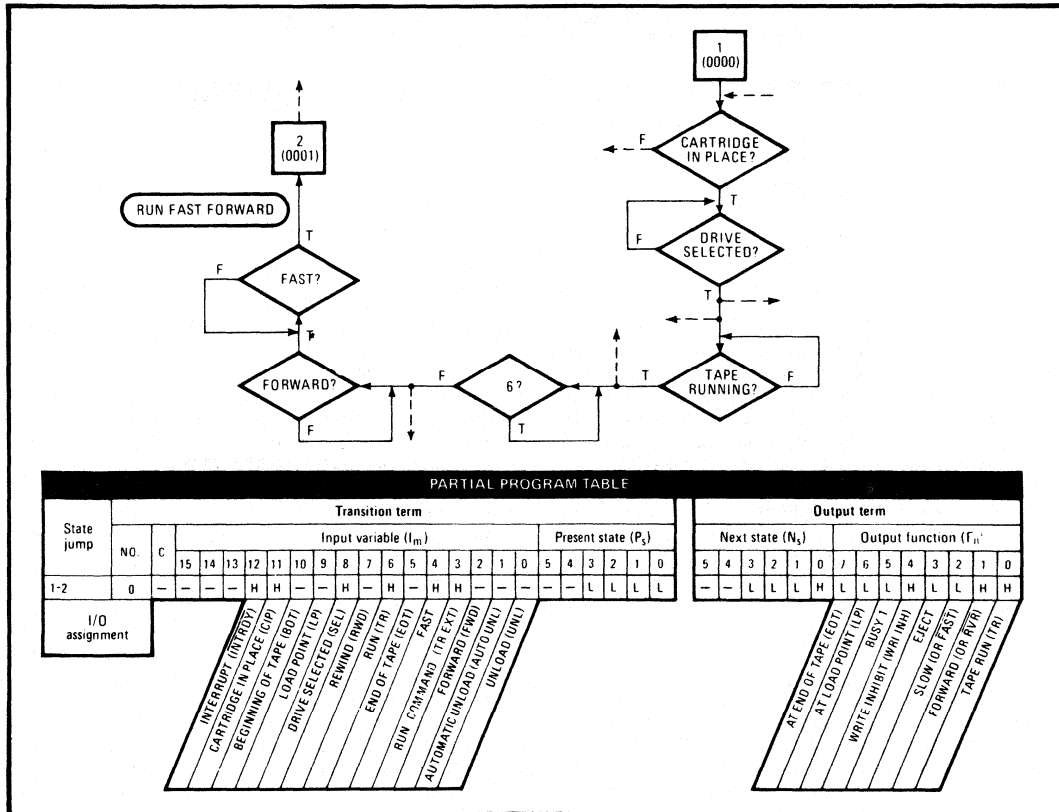

CIP = true implements a jump from state 8 to 9. In state 9 the tape will rewind in fast reverse until a BOT mark is reached. BOT true implements a jump from state 9 to 10. The tape now runs at slow speed in the forward direction until the load point (LP) is reached. LP true implements a jump from state 10 to 11 indicating STOPPED AT LP. From state 11, forward, reverse, or unload commands can be executed, but not rewind, because of the state 11 condition preceding state 9. That keeps RWD from being needlessly repeated.

State jump

A single state jump is shown in detail in Fig. 7. The transition is from state 1 to 2. In the latter, the controller is required to enter the READ FAST FORWARD routine from STOP when:

- CIP is true.
- SEL is true.
- TR is true.
- State 6 is false.
- FWD is true.
- FAST is true.

In response to this jump, the controller outputs that must change to issue the appropriate commands are run (TR),

7. Detailed state jump. The transition from state 1 (STOP) in the tape cartridge controller to state 2 (READ FAST FORWARD) is shown in flow-chart form. That part of the logic sequencer coding of the state jump is shown below, including transition and output terms.

TABLE 1. Comparison of design alternatives for tape controller.

| Parameter | Field-programmable logic sequencer | Discrete logic | Monolithic Memories Inc.'s Programmable Array Logic |

forward (FWD), and fast (FAST).

The flow chart of the controller routines is complete with 14 states and 36 state jumps (including synchronous reset). As such, four state-register flip-flops sufficiently represent all states. All state jumps can be directly programmed into the chip from the flow chart. All state jumps occur on the leading edge of the clock.

The advantage of a controller built with the FPLS is best shown by a comparison to discrete logic, which would comprise PROMs, latches, and gates, using the same state diagram as for the FPLS. Table 1 compares the FPLS controller with a discrete implementation as well as with Monolithic Memories Inc.'s Programmable Array Logic chips, in several aspects.

Programming

The key to design flexibility with programmable logic is the availability of programming equipment. The need for PROMs in this equipment has led to a large number of memory programmers being offered by several manufacturers. Generally, they operate with personality card sets that meet the requirements of various PROM technologies. Suppliers have already begun developing sets compatible with memory programmers for logic devices.

Hardware is expected to be available by the end of the third quarter of this year.

For the concept to work, the logic devices must be manipulated as memory chips are—by defining the desired fusing pattern in terms of an address-data relationship. Although this tends to obscure the logic function of the device, which is not visible on the program table, it is sure to provide low-cost programming equipment that can be manned by low-skilled labor.

Logic programming is another possibility, and low-cost equipment is already available from Signetics. Logic programmers allow direct entry of the logic function from the program table; no reference to the device logic diagram is necessary, and the user need not specify the status of each individual link in a device. Such programmers are more convenient for engineering use during the initial design phase, but with their high programming speed—about 10 seconds per device—can also be effective in production. Their only drawback is that they are dedicated machines and cannot program PROMs.

Some manufacturers offer a hybrid type of PROM programmer that can also be configured to do logic programming. Table 2 shows the various options available to prospective users now, or in the near future. □

Controllers using FPLAs

CONTENTS

| | |
|-------------------------------|------|

| 2 Signetics FPLAs | 8-81 |
| 3 Control systems using FPLAs | 8-87 |

1 STRUCTURE

An FPLA can be regarded as a set of buffers, inverters, an AND matrix and an OR matrix with many programmable nodes, see Fig. 1. Each AND gate (with buffers and inverters) generates a product term which is a logic product of a fixed number of inputs. The latter may be true, false or don't care. For example, $ABCD$ and $\bar{A}BCX$ are product terms in a 4-input device, ($X = \text{don't care}$).

The active logic levels of inputs to the AND gates are specified by the connections on the AND matrix. The output of an AND gate is activated when the logic input combination is identical to that programmed in the product term. Outputs of the AND gates are connected to the OR gates as specified in the OR matrix. The output of an OR gate is only activated when the output of an activated AND gate is connected to an input of that OR gate.

Fig. 1 Structure of an FPLA.

To increase the flexibility of the FPLA, the active output level can be programmed either HIGH or LOW. To achieve this, the outputs of the OR gates are connected to the output buffers via EX-OR gates (see Fig. 2). If a logic HIGH level is offered to the other input of this gate, the EX-OR has an inverting function and the output is active LOW. Alternatively, if a LOW level is applied to that input, the EX-OR is non-inverting and the output is active HIGH. The output buffers are activated by the chip enable input \bar{CE} .

Fig. 2 Exclusive OR gates and output buffers.

Figure 3 shows a simple example of translating a logic expression into FPLA hardware. In the program table, each horizontal line represents one of the available product terms. These terms describe which input connections will activate the AND gates. In product term 0 of the example in Fig. 3, inputs 4 and 2 are connected to the AND gate via inverters (L); inputs 3 and 0 are connected via buffers (H). None of the other inputs is connected to the AND gate (-). The output of AND gate 0 is connected to OR gates 7 and 5 (A). When the input combination is identical to the programmed logic combination of product term 0, outputs 7 and 5 are activated. The active level of output 6 is programmed LOW, so output 6 is LOW if the input combination of the FPLA corresponds to one of the product terms which activates the output. The Boolean expressions for the programmed functions are

$$F_7 = I_0 \bar{I}_2 I_3 \bar{I}_4 + I_1 I_3$$

$$\bar{F}_6 = I_1 I_3 + \bar{I}_0 I_3$$

$$F_5 = I_0 \bar{I}_2 I_3 \bar{I}_4$$

Fig. 3 Example of an FPLA program table.

2 SIGNETICS FPLAs

The 82S100 (three-state outputs) and 82S101 (open collector outputs) are bipolar FPLAs which contain 48 programmable product terms (AND gates) and 8 programmable sum terms (OR gates). For each product term a logic combination of 16 input variables (HIGH, LOW or don't care) can be programmed. Each OR gate supplies an output function which can be programmed either active HIGH or active LOW.

Figure 4 shows the block diagram of a Signetics FPLA, illustrating the basic structure of buffers/inverters, AND and OR matrices, EX-OR gates and output buffers. Each of the 16 input lines of the FPLA is connected via an inverter and a buffer to the 48 AND gates. These connections are made via fusible links which form the AND matrix. An input level can be programmed by fusing the appropriate link of the AND gate. Each product term can be programmed within a field of 32 fuses: see Fig. 4, Product Terms.

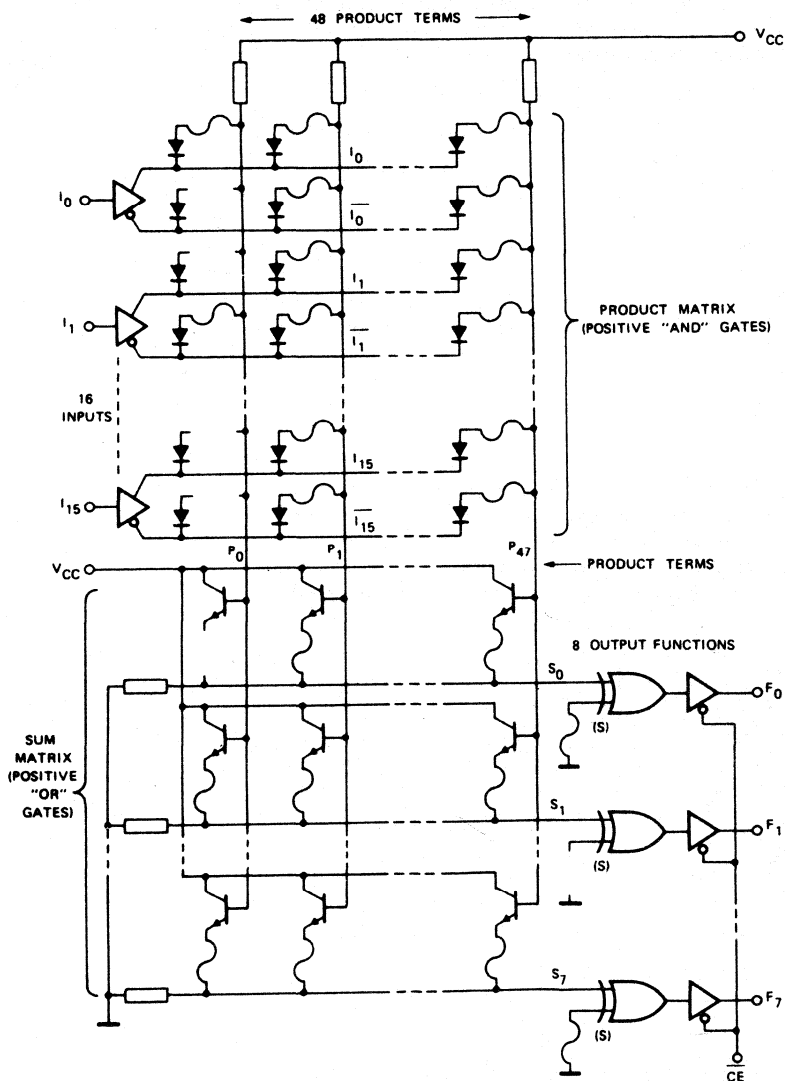

Fig. 4 Block diagram - note where links have been fused.

In product term 0, input I_0 has been programmed as true (HIGH), I_1 as false (LOW) and I_{15} as don't care. To program an input as true, the link of the inverted input must be fused. To program an input as false, the other input's link must be fused. For a don't care input, both links must be fused.

All outputs of the AND gates are connected to each of the 8 OR gates via emitter followers with fusible links. This field of fusible links is called the OR matrix. Each sum term can be programmed from a row of 48 fuses. A product term (AND gate) is disconnected from the OR gate by fusing the appropriate link. In Fig. 4, the product term P_0 has been disconnected from the OR gate of the output Function F_0 .

In virgin devices all output functions have an active HIGH output level. To program an output to active LOW, the earth link of the EX-OR gate must be fused. In Fig. 4 output function F_1 has been programmed as active LOW. Unused product terms need not be programmed.

Two versions of FPLA are available. The 82S100 has three-state outputs. When enabled (\overline{CE} LOW), the outputs are HIGH or LOW depending on the state of the function. In the inhibit condition (\overline{CE} HIGH), all outputs have high impedance (floating). The 82S101 has open collector outputs. When enabled (\overline{CE} LOW), the outputs are either LOW or floating, depending on the state of the function. When inhibited, all outputs are floating. With the open collector output there is no difference between the active HIGH and inhibit states.

2.1 EXPANSION OF VARIABLES

The FPLA has 16 inputs, 8 outputs and 48 product terms. In some applications, however, these may not be sufficient, in which case they can be expanded, generally by dividing the original program table into smaller ones.

2.1.1 Product term expansion

If the 48 product terms of a single FPLA are insufficient, more devices can be used.

When open collector FPLAs 82S101 are used, all inputs and all outputs of the required number of FPLAs should be connected in parallel. All \overline{CE} inputs should be connected to ground; see Fig. 5. The outputs must be programmed active LOW to realize the wired OR function. The total number of product terms available is $48n$, where n is the number of devices in parallel.

Fig. 5 Product term expansion with open collector output FPLAs.

When three-state devices are used, product term expansion cannot be achieved in the same way. As the three-state devices have an active pull-up, the outputs may be paralleled provided that only one FPLA is enabled at a time. An alternative is to divide the program table into two parts, each containing less than 48 product terms. This can be accomplished by examining one input variable and separating the product terms by placing those with HIGH levels of that variable into one table (A) and LOW levels into a second table (B). All product terms containing a don't care level for this variable must be programmed in both tables; see Fig. 6. The \overline{CE} inputs of the FPLAs are controlled by the input which has been chosen to divide the program table. Figure 7 shown an example where input I_2 controls the \overline{CE} line. When I_2 is HIGH the FPLA containing table A is enabled; when I_2 is LOW table B's FPLA is enabled. It should be noted that I_2 should not be programmed in any of the FPLA product terms. Product terms with up to 17 inputs can be programmed. In this way up to 96 product terms can be programmed.

Fig. 6 Dividing a 13 product term program table into two smaller tables.

Fig. 7 Product term expansion with three-state output FPLAs.

2.1.2 Input expansion

Within one FPLA it is difficult to expand the input variables. In principle, it is possible to multiplex the input variables in order to reduce the field of input variables to 16. In most applications it is more practical to expand the input variables by using more FPLA devices as shown in Figs. 8 and 9.

In the configuration in Fig. 8, the number of input variables can be expanded to 24. FPLA C reduces the 16 inputs $I_0 - I_{15}$ to the 8 input lines $I_0 - I_7$ of FPLA E. Inputs $I_{16} - I_{23}$ are connected directly to input lines $I_8 - I_{15}$ of FPLA E. Note that there is a difference in delay time for inputs $I_0 - I_{15}$ and $I_{16} - I_{23}$.

In the configuration of Fig. 9, the number of input variables can be expanded to 32. Here the delay times of all inputs are the same but twice that of a single FPLA. For these configurations, both the three-state and open collector devices can be used.

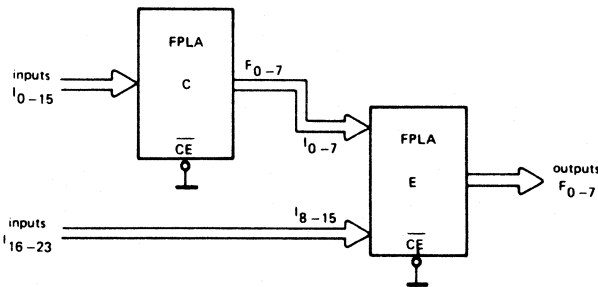

Fig. 8 Input expansion - 24 inputs.

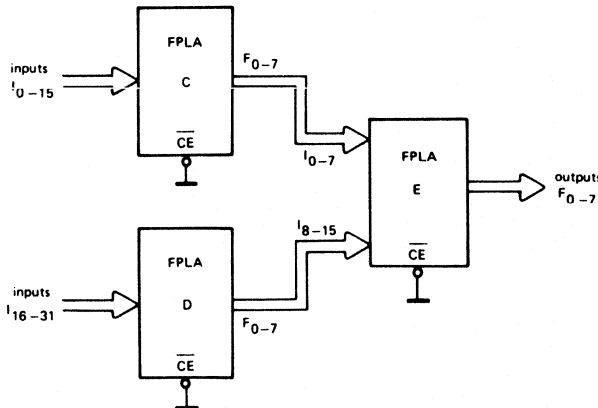

Fig. 9 Input expansion - 32 inputs.

2.1.3 Output expansion

The simplest way to expand the number of outputs is to use more FPLAs as shown in Fig. 10. The inputs of these FPLAs are connected in parallel and each FPLA controls 8 outputs. The product terms of outputs $F_0 - F_7$ are programmed in FPLA A and those of outputs $F_8 - F_{15}$ are programmed in FPLA B.

In appropriate applications, a more economical method for increasing the number of outputs is to use a 1 out of 16 decoder; see Fig. 11. The FPLA output lines $F_4 - F_7$ are decoded into the output lines $F_4 - F_{19}$. Note that only one of these outputs can be activated at a time and that their activated levels are LOW. In the inhibit state of the decoder N74154 all outputs are HIGH. When more than one of the expanded outputs must be activated simultaneously, normal decoders cannot be used. However, a PROM could be used as shown in Fig. 12. Here the number of outputs can be increased to 11. The inexpensive 32×8 PROM 82S123 decodes the outputs $F_3 - F_7$ from the FPLA and generates the outputs $F_3 - F_{10}$. Note that when using PROMs and decoders there is some difference in delay time between the direct outputs and the decoded ones.

Fig. 10 Output expansion using an extra FPLA.

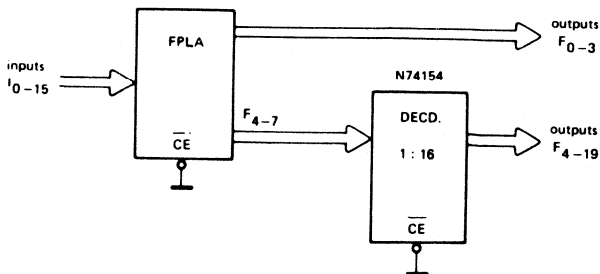

Fig. 11 Output expansion with a 1 : 16 decoder.

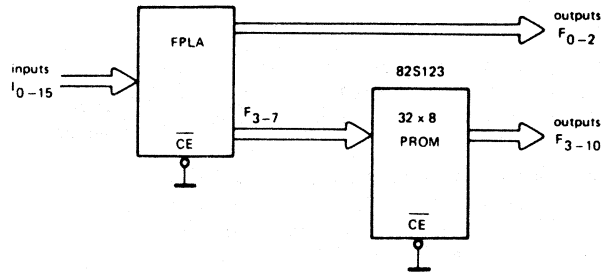

Fig. 12 Output expansion with a PROM.

2.2 EDITING FPLAs

FPLAs have inherent program editing capabilities. After programming, a number of program modifications can be incorporated as indicated in Fig. 13.

| | | | |
|--------|------------------------------------|-----|---|
| ADD | P-Term To F_p/F_p^+ | YES | Program desired logic function into any unused P-Term. Blow S-Term link(s) coupling P-Term to undesired output functions. |
| | $I_m/\overline{I_m}$ To P-Term | NO | Delete erroneous P-Term. Add new, corrected P-Term. |
| DELETE | P-Term From F_p/F_p^+ | YES | Blow S-Term link coupling P-Term to F_p/F_p^+ . |
| | $I_m/\overline{I_m}$ From P-Term | YES | Blow both links coupling the input variable to the P-Term. |
| CHANGE | $F_p \rightarrow F_p^+$ | YES | Blow EX-OR link of output to be inverted. |
| | $I_m/\overline{I_m} \rightarrow X$ | YES | Delete $\overline{I_m}/I_m$ from P-Term. |
| | $I_m \rightarrow \overline{I_m}$ | NO | Delete erroneous P-Term, and add a new P-Term. |
| | $F_p^+ \rightarrow F_p^-$ | NO | Use spare active-HIGH output. |

Fig. 13 Editing possibilities of an I-PLA.

3 CONTROL SYSTEMS USING FPLAs

In small machine control systems, an FPLA is a very powerful device by virtue of its programmability and flexibility. The FPLA can be used separately or in a structure of high level logic functions. To give some indication of the possibilities of FPLAs in control systems, a number of controllers increasing in complexity and flexibility are described in this section.

3.1 COMBINATIONAL CONTROLLERS

The basic structure of a combinational controller is a set of AND, OR and NOT functions. The outputs of such a controller are only determined by its input variables as with an FPLA. Because the FPLA has to be programmed as a sum of product terms, the logic expressions to be realized must also be written in this way. This is demonstrated with the aid of some examples.

A simple AND-OR logic function is shown in Fig. 14. The Boolean expression for this function is

$$F_7 = \bar{I}_0 \bar{I}_1 \bar{I}_2 + \bar{I}_0 \bar{I}_1 \bar{I}_{15} + I_0 I_1$$

This is programmed in the FPLA program table in Fig. 15; note that the unused inputs are programmed as don't care.

Fig. 14 Logic diagram of $F_7 = \bar{I}_0 \bar{I}_1 \bar{I}_2 + \bar{I}_0 \bar{I}_1 \bar{I}_{15} + I_0 I_1$.

| NO | PRODUCT TERM* | | | | | | | | | | ACTIVE LEVEL | | | | | | | | | | | | |

Fig. 15 Program table for the logic diagram of Fig. 14.

A second example is the *n*-bit exclusive OR function. The output of an EX-OR is activated when only one input condition is true. EX-OR functions with up to 16 bits can be programmed in a single FPLA. The equation for a three-bit exclusive OR function is

$$F_7 = I_0 \bar{I}_1 \bar{I}_2 + \bar{I}_0 I_1 \bar{I}_2 + \bar{I}_0 \bar{I}_1 I_2$$

The logic diagram for this function is shown in Fig. 16. This is represented in the FPLA program table, Fig. 17. A 16-bit EX-OR function is realized by using 16 product terms and one output.

Fig. 16 Three-bit exclusive-OR function.

Fig. 17 Program table for 3-bit EX-OR function.

Besides simple AND-OR functions, more complex functions such as the example shown in Fig. 18 can also be programmed in an FPLA. The logic equation of this function is

$$F_7 = I_7(I_{15} + I_{10} + I_1 I_2 \bar{I}_3)$$

In order to program this function into an FPLA, it must be rewritten as a sum of products

$$F_7 = I_7 I_{15} + I_7 I_{10} + I_1 I_2 \bar{I}_3 I_7$$

Figure 19 shows the corresponding FPLA program table.

Fig. 18 Logic diagram of $F_7 = I_7(I_{15} + I_{10} + I_1 I_2 \bar{I}_3)$.

3.2 SEQUENTIAL CONTROLLERS

In a sequential controller, the outputs are not only a function of the input variables at a given time, they are also dependent on previous input levels. Besides the AND, OR and NOT functions, the time element is introduced into sequential control systems. This time element is represented by the memory function. There are two types of sequential controller: the synchronous controller which uses clock pulses to synchronize the time when the outputs may be changed; and the asynchronous controller, the outputs of which can change independent of a clock pulse.

3.2.1 Asynchronous controllers

In simple asynchronous systems, the memory function can be obtained by a direct feedback of the output lines to the inputs. When using this configuration, it is important to avoid states in which the controller can start to oscillate, if several memory functions are used and a combination of outputs has to be changed into another combination, it is possible that one output can be faster than others. The intermediate state which appears can then influence the next state of the control system. Whenever there is a possibility of oscillations occurring, a synchronous system should be chosen. However, if there is no chance of oscillation an asynchronous system can be used successfully.

Figure 23 shows a simple memory configuration which can be expressed as

$$F_7 = I_1 I_2 \bar{I}_3 + F_7 I_4$$

To program this function into an FPLA, there must be feedback from the output F_7 to one of the inputs, for example I_0 ; see Fig. 24.

Fig. 23 A simple memory configuration.

| NO | PRODUCT TERM | | | | | | | | | | F7 | ACTIVE LEVEL | | | | | | | | | | | | |
|----|--------------|---|---|---|---|---|---|---|---|---|----|--------------|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | | |

Fig. 24 Program table for the logic diagram of Fig. 23.

Fig. 25 $F_7 = I_2 I_3 I_4 + F_7 (I_5 I_6 I_7 I_8)$.

A more complex memory function is shown in Fig. 25. This is represented by

$$F_7 = I_2 I_3 I_4 + F_7 (I_5 I_6 I_7 I_8)$$

There are two ways in which this can be programmed:

- (a) as a sum of products with one output activated;
- (b) as a sum of products using an extra output.

In (a) the function can be rewritten as

$$F_7 = I_2 I_3 I_4 + F_7 \bar{I}_5 + F_7 \bar{I}_6 + F_7 \bar{I}_7 + F_7 \bar{I}_8 .$$

The program of this function is given in Fig. 26. This method requires many product terms, especially when function F_6 (Fig. 25) has more inputs.

In (b), by using an extra input, function F_6 can be programmed in one product term and the whole function can be programmed in three terms. The expressions are

$$F_6 = \bar{I}_5 \bar{I}_6 \bar{I}_7 \bar{I}_8 \quad \text{and} \quad F_7 = I_2 I_3 I_4 + F_7 F_6 .$$

In the program table of Fig. 27, F_7 is connected to I_0 and F_6 to I_1 . Note that the active level of F_6 is programmed as LOW.

Fig. 27 Saving product terms by rewriting the function of Fig. 25 as $F_7 = I_2 I_3 I_4 + F_7 F_6$ and $F_6 = \bar{I}_5 \bar{I}_6 \bar{I}_7 \bar{I}_8$.

In an asynchronous control system in which several memory functions are required, the number of inputs and/or outputs may be insufficient. This problem is solved by using more FPLAs in a configuration such as Fig. 28, for example. In order to make memory functions, four outputs of both FPLAs A and B are fed back to the inputs. A total of 8 memory functions can be obtained in this way. All outputs of FPLAs A and B are connected to the inputs of FPLA C. The eight outputs of FPLA C are the outputs of the control system. The remaining 12 inputs of both FPLAs A and B are the 24 inputs of the system.

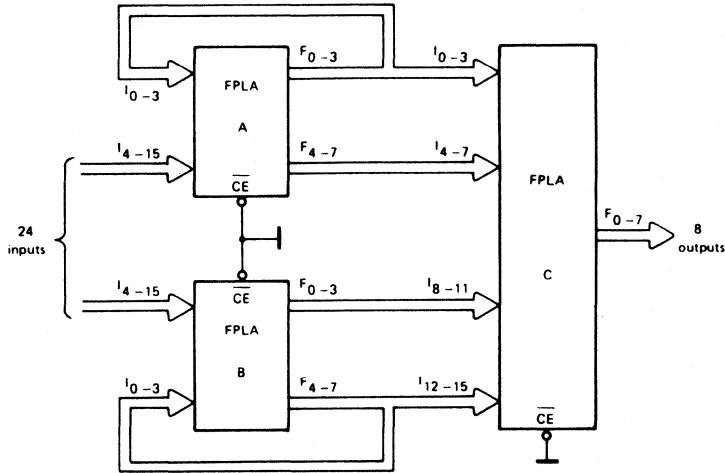

Fig. 28 Input expansion for an asynchronous control system with several memory functions.

3.2.2 Synchronous controllers

More complicated systems must be synchronized by clock pulses. Figure 29 shows a simple synchronous system. The outputs of the FPLA are clocked into the latches by the system clock. another approach to making a sequential controller is to feed back a number of FPLA outputs to the inputs via triggered flip-flops; see Fig. 30. This is the basic principle for all the synchronous sequential control systems described in this publication.

Fig. 29 A simple synchronous system.

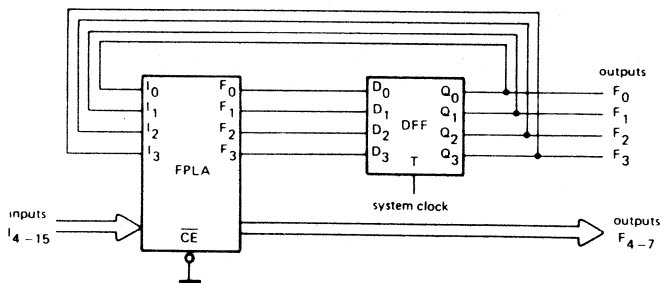

Fig. 30 Synchronous system with triggered flip-flops in the feedback paths.

The first step in designing a synchronous sequential control system is to make a state diagram or a flow chart. The whole controller function is divided into separate states, each represented by a defined combination of the levels of the feedback outputs. The state of the controller at a given time is determined by the previous state and the new input conditions. A simple example is a synchronous four-counter. The state diagram is given in Fig. 31 and program table in Fig. 32.

Each state of the control function is programmed into the product terms. When the controller is in a defined state, the next state is determined by the levels of outputs F_0 , F_1 , F_2 and F_3 . These are connected to the inputs via clocked D flip-flops; see Fig. 30. If the controller is in an undefined state: — i.e. the levels of the inputs do not correspond to a combination programmed in a product term — after one clock pulse, it is reset to the first state. Hence product term 3 need not be programmed.

Fig. 32 Program table for synchronous four-counter.

A more complex example is the same counter with decoding of the fourth state and synchronous reset to the first state. A state diagram of this function is given in Fig. 33. This function is represented in the program table Fig. 34. The conditions for $R = L$ do not have to be programmed because if the input combination does not correspond to a product term, the controller always returns to the first state (LLLL) at the next clock pulse. In this example, the output functions only depend on the state of the controller. This is the principle of the Moore model which is a sequential synchronous circuit where the output functions are only a function of the state of that circuit.

Fig. 33 Synchronous counter with reset to the first state.

| NO. | PRODUCT TERM* | | | | | | | | | | | ACTIVE LEVEL | | | | | | | | | | | | | | |

Fig. 34 Program table for Fig. 33.

In the last example, the output F_7 is activated when the controller is in state D (LLHH) irrespective of the level of the reset input R . If output F_7 is also a function of R , which is activated when HIGH, the state diagram should be changed. The level of F_7 must be defined for each level of R ; see Fig. 35.

This function is represented in program table Fig. 36. Note in particular that in state D, the level of output F_7 depends on R – in all other states, the level of F_7 is LOW. In this example, the outputs are functions of the state of the controller and of the levels of the inputs. This is the principle of the Mealy model.

3.2.3 Practical circuits

The diagram of a basic practical synchronous sequential control system is shown in Fig. 49. Hex edge-triggered D-type flip-flops N74174 are used in all the input lines to the FPLA including the feedback lines representing the state of the controller. Using this configuration, all output lines are only changed at the positive edge of the system clock. After this edge, all input and output lines of the FPLA are stable and so spurious pulses cannot effect the system when the clock signal is at either the HIGH or LOW level. Hence the system is fully synchronous and easy to test. In this case, four of the eight output lines are used in the feedback circuit. In general, five lines are used for this purpose and so in most applications output expansion is necessary.

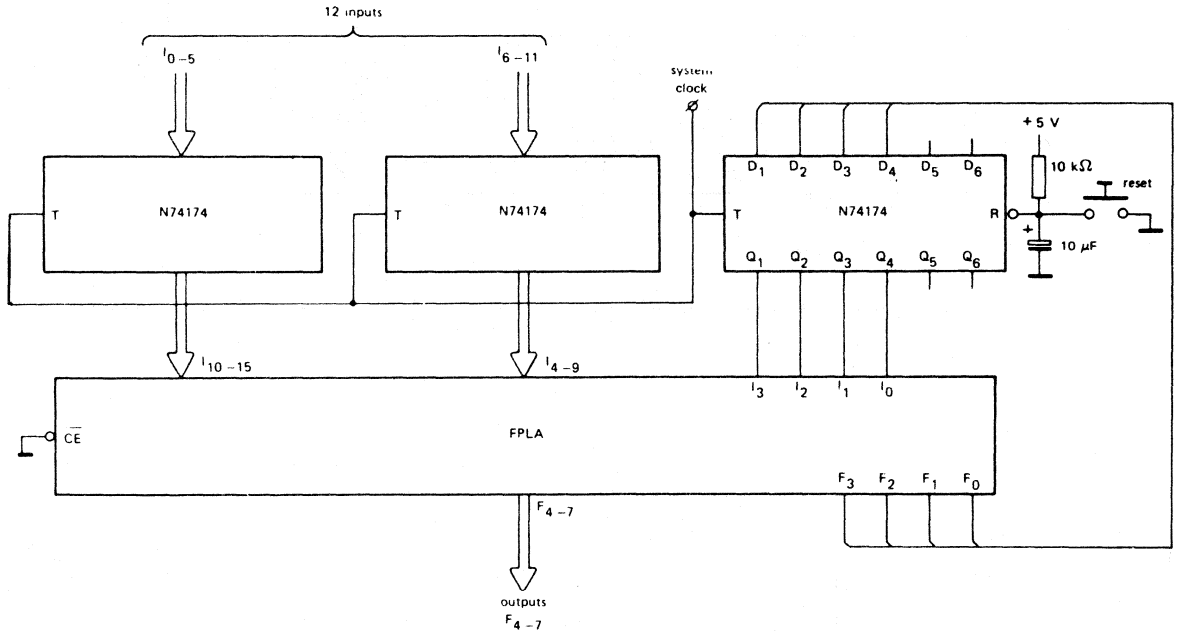

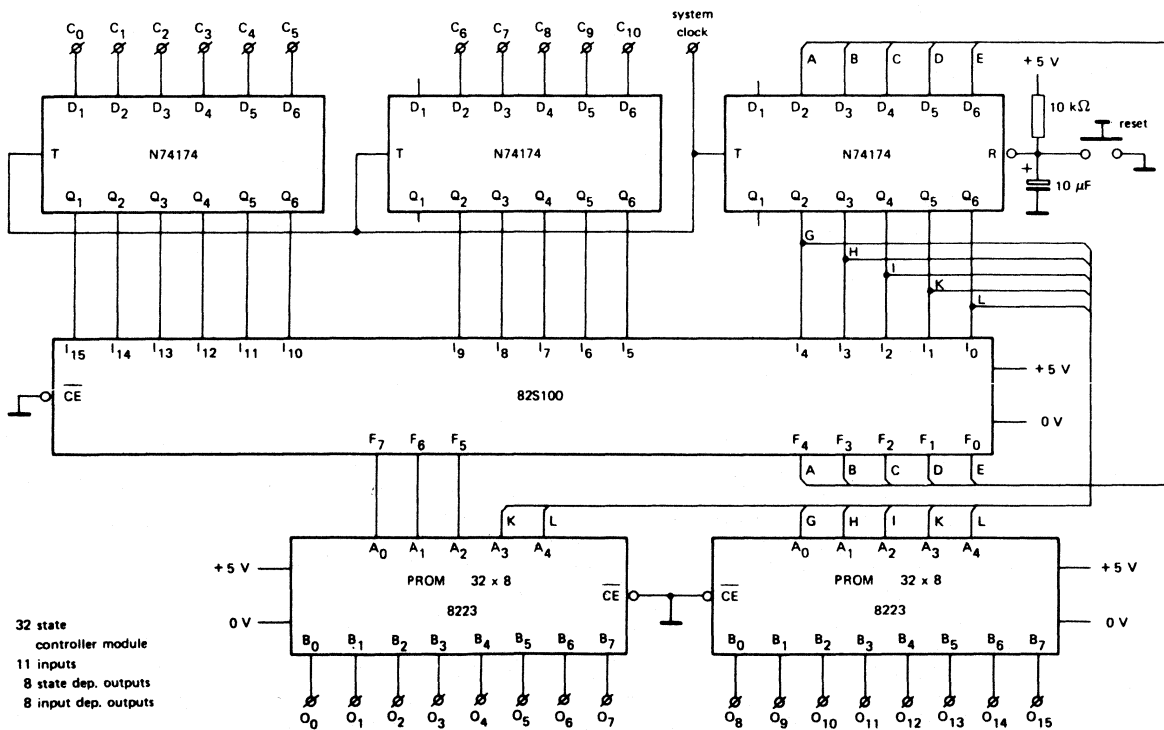

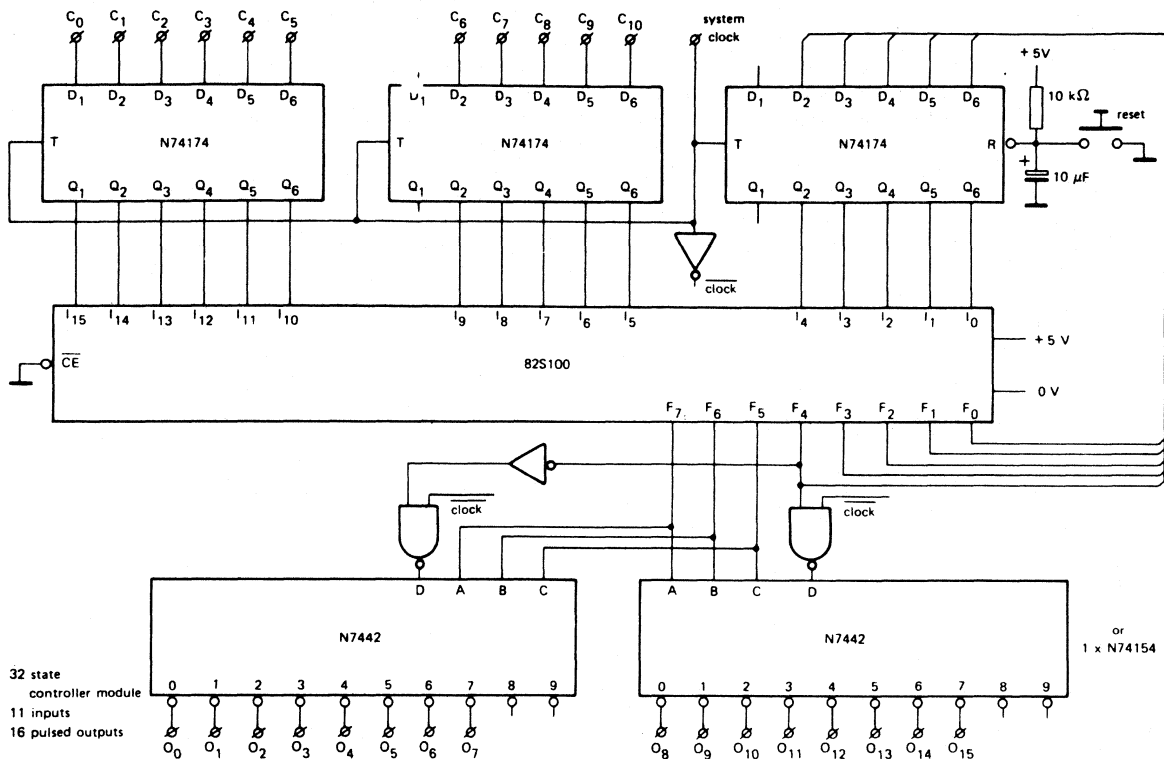

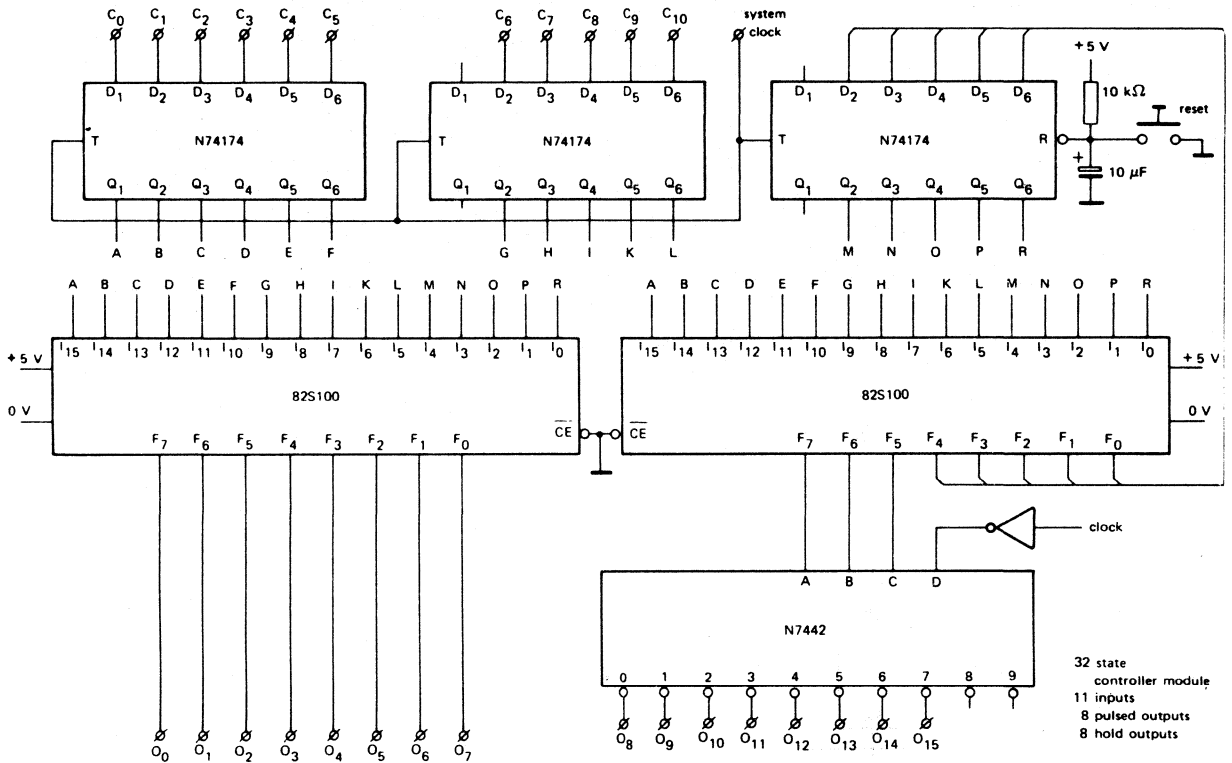

Fig. 49 Basic practical synchronous sequential controller.

Figure 50 shows an example of a controller in which 32 states can be programmed. There are 11 control inputs C_0 to C_{10} and 16 outputs, only one of which is activated at a time. In the states 0 to 15 one of the outputs O_0 to O_7 is activated and in the states 16 to 32 one of the outputs O_8 to O_{15} is activated. To avoid spurious pulses, the outputs are only activated when the clock input is LOW.

The example shown in Fig. 51 also has 32 programmable states and 11 control inputs. The output circuit comprises two inexpensive PROMs type 82S123, one for generating outputs O_0 to O_7 , the other for O_8 to O_{15} . Outputs O_8 to O_{15} are only functions of the state of the controller, whereas outputs O_0 to O_7 are functions of the controller and the input conditions of the FPLA. So in any state of the controller, depending on the PROMs' programs, up to 16 outputs can be activated simultaneously.

In the example shown in Fig. 52, which has the same input circuit as Figs. 50 and 51, two FPLAs are used. In one FPLA the states of the controller are programmed. The outputs of this FPLA are decoded and generate the outputs O_8 to O_{15} , only one of which can be activated at a time. All outputs of the other FPLA are a function of the state of the controller and the input conditions of the FPLA. These outputs can all be activated simultaneously.

52.

Single chip multiprocessor arbiter using the Signetics 82S105 FPLS

In multiprocessor environments there are considerable savings to be made through sharing system resources. If each processor must support its own bus structure, I/O devices and bulk storage medium, system cost can be very high. In the configuration shown in Fig. 1, all processors share a common communication bus plus a number of system resources.

Since every processor must use the common system bus to communicate with its peripherals, a priority structure that

resolves simultaneous processor bus requests into a single bus grant is required. In addition to making request-grant transactions, transient bus contention due to grant switching must be removed by inserting precise guard times between bus grants.

Signetics' Field Programmable Logic Sequencer provides a convenient and cost effective means of implementing a synchronous arbiter to perform these tasks, within a single chip.

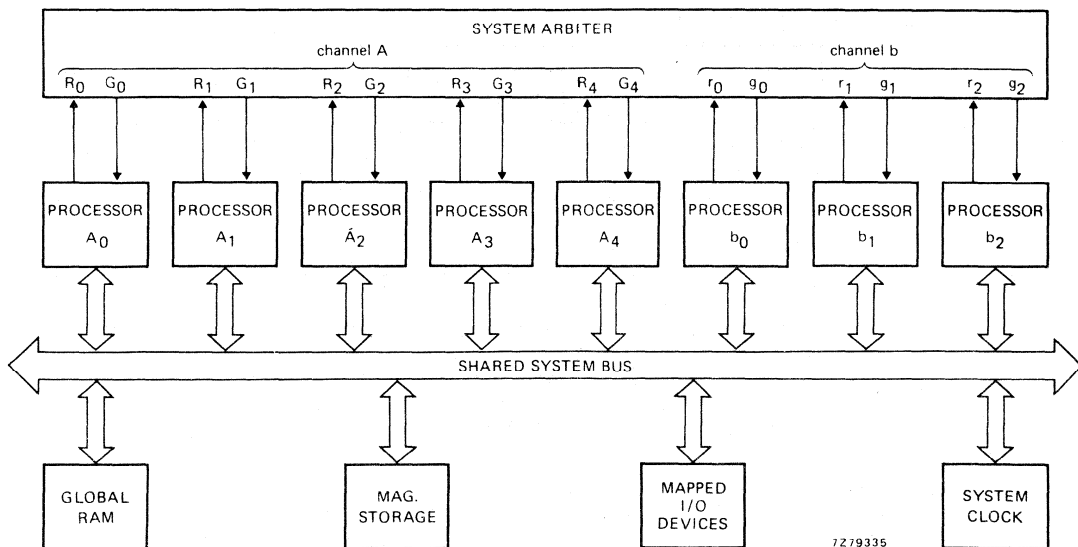

Fig. 1. Typical multiprocessor system structure.

Arbiter structure

Within a multiprocessor system, two general classes of processors may be recognized: priority A and priority b. Priority A processors have the highest request priority and must only compete with other priority A processors for bus control. The arbiter must issue A grants in a manner that prevents any priority A processor from locking out another priority A processor. To enable this, the priority A rules implemented here use a Last Granted Lowest Priority (LGLP) ring structure. After an A processor has completed a bus related task, his next arbitrated request priority will be lowest in the A request group. The previously second highest priority A processor will then have the highest priority. The net effect is that every priority A processor will take a turn at having highest priority. Priority A processors are typically ones that perform real time operations or vital system tasks. Priority b processors are

lower in priority than the As and may only be granted system control when no A requests are pending; b processors usually perform background tasks. Within the b group, further ordering exists such that each b processor has a fixed priority position.

Plumber (Ref. 1), Pearce (Ref. 2), Hojberg (Ref. 3) present asynchronous techniques of arbiter implementation. These methods all have hard-wired priority rules and imprecise guard times during grant switching. As pointed out in Hojberg (Ref. 4), a synchronous state machine can be configured as a Mealy type controller to provide not only precise guard times and programmable priority rules, but also programmable input/output polarity. The state machine in Fig. 2 is made from a control PROM array and an edge triggered latch. The A and b requests and the machine's present state are used by the control PROM to determine the next A and b grants and the next state.

7279336

Fig. 2. Arbiter constructed from a Mealy-type state machine.

(a) A and b service requests (R_N , r_N) plus the present state determine, through the control PROM, the next grant outputs (G_N , g_N).

(b) Requests R_0 , R_1 , r_0 , and r_1 are asserted low in the same clock sample period. The priority rules that determine the order in which the grants are issued, and the shaded guard areas are programmed into the control PROM. Note that the A and b request lines and the present state input to the PROM must have a set-up time equal to or greater than the latch set-up time plus the PROM access time.

System operation

Two machine states can be identified by inspection: a wait state and a grant state. The state machine enters a grant state as a response to a system request on either R_N or r_N . The machine will remain in this state with a single grant line asserted as long as the request remains asserted. Upon releasing the request line, the machine will pass through a single wait state before considering other pending requests. This provides a single state guard time. The requests received must meet the set-up requirement of the edge triggered latch after propagating through the control PROM. If these time considerations do not fit within a given multiprocessor structure, an input latch may be added such that the R_N and r_N lines are clocked through the latch by the system clock, thereby removing asynchronous set-up time considerations. On the basis of a state machine approach, two techniques of implementation are feasible:

1. using an architecturally advanced single IC controller, the FPLS;
2. a traditional PROM/latch configuration.

FPLS arbiter implementation

A five priority A and three priority b arbiter will be constructed such that all grant outputs will be asserted low for grants and all request inputs will be asserted low for system requests.

Brief FPLS description

The FPLS block diagram shown in Fig. 3(a) consists of a control PROM and 14 clocked S/R flip-flops. The control

PROM is actually an AND-OR logic array that functions as a Content Addressable PROM: CAPROM. The CAPROM is organized as 48 words of 28 bits with 16 external input lines, and 6 internal inputs fed back from the State Register. The 28 CAPROM outputs drive the S/R inputs of the 6 bit State Register and 8 bit Output Register. Note that the state feedback path is made inside the FPLS.

The I_N and present state inputs P_S represent 2^{22} possible CAPROM input codes; 48 of these codes may be mapped in the CAPROM to provide a 28 bit register control word. As shown in Fig. 4, each input code may be specified by assigning to the variables either, Low "L", High "H", or Don't Care "-" logic states. If any input code falls logically outside the programmed codes, the CAPROM asserts a Low on all its 28 internal outputs, thereby issuing a "no change" command to the R/S flip-flops.

This is an important architectural feature because it requires that only state or output transition terms be programmed. Looping terms that neither change state nor output need not be programmed in the FPLS owing to the "no-change" characteristic of S/R flip-flops when $S = R = 0$. An example of this is shown in Fig. 5.

The S/R inputs of both state and output registers are specified by CAPROM outputs ("AND" functions of request inputs and present state) in the program table of Fig. 4. The corresponding next state of each bit will be set to 0 for L, 1 for H, and No Change for "-". The FPLS PR/\overline{OE} line may be assigned either Asynchronous Preset or Output Enable functions, via a user programmable option.

The entire function is integrated into a single 28 pin package designated as 82S104 (open collector outputs) or 82S105 (three-state outputs).

7279333

Fig. 5 FPLS state and output transitions.

State algorithm

Figure 6 displays the circular state form and all possible state transitions of the LGLP priority structure. Hex states 3B, 3C, 3D, 3E, and 3F are arbiter wait states W_{0-4} . In these states, processor A and b requests are monitored. Figure 6 illustrates a typical grant to processor A1 in state 07_{16} . As long as A1 asserts its request line low, the next state will be 07_{16} and the next output will remain with G_1 asserted low and all the other grant outputs asserted high. Since no change in state or grant output results from this transition, no CAPROM resources are required.

As soon as processor A1 returns his request line, R_1 , to 1, a state transition is made to 3D and an output transition is made to set all outputs to 1. Since processor A1 was the last to be granted system resources, it will now have the lowest A level request priority (LGLP). In wait state W_2 , the highest priority processor will be A2, second A3, third A4, and fourth A0. To maintain the LGLP rule, grant transitions must follow the state rule $G_N \rightarrow W_{(N+1)}$ and wait states, W_M , must set their A priorities so that processor A_M is highest priority. Priority decreases as one proceeds clockwise around the state ring to the lowest priority processor, $A(m - 1)$.

When no A requests are pending, b requests may be granted. To avoid upsetting the LGLP priority rule, b grants must leave and return to the same wait state. Since the b priority structure is the same regardless of the wait state, only a single set of b transition terms are required.

For example, a grant transition to g_2 (Hex 20 - 25) can be issued only if there are no A, b0, or b1 requests pending. Given the binary wait state code 111XXX, where X represents Don't Care, a request code of 01111111 will transfer the arbiter to the grant state g_2 from any of the wait states W_{0-4} .

It is important to realize that in making this transition, the lower 3 state bits will not be changed — they provide the wait state return address. When r_2 returns high, 1XXXXXXX, a transition back to the previously exited wait state is made by forcing ones in the 3 most significant state bits and leaving the lower 3 state bits unchanged.

All output and state bits are initially preset to 1 through the use of the optional preset function. Grant output lines are only forced low when transitions are made to grant states, and returned to 1 when jumping back to a wait state.

The complete arbiter circuit is shown in Fig. 7(a).

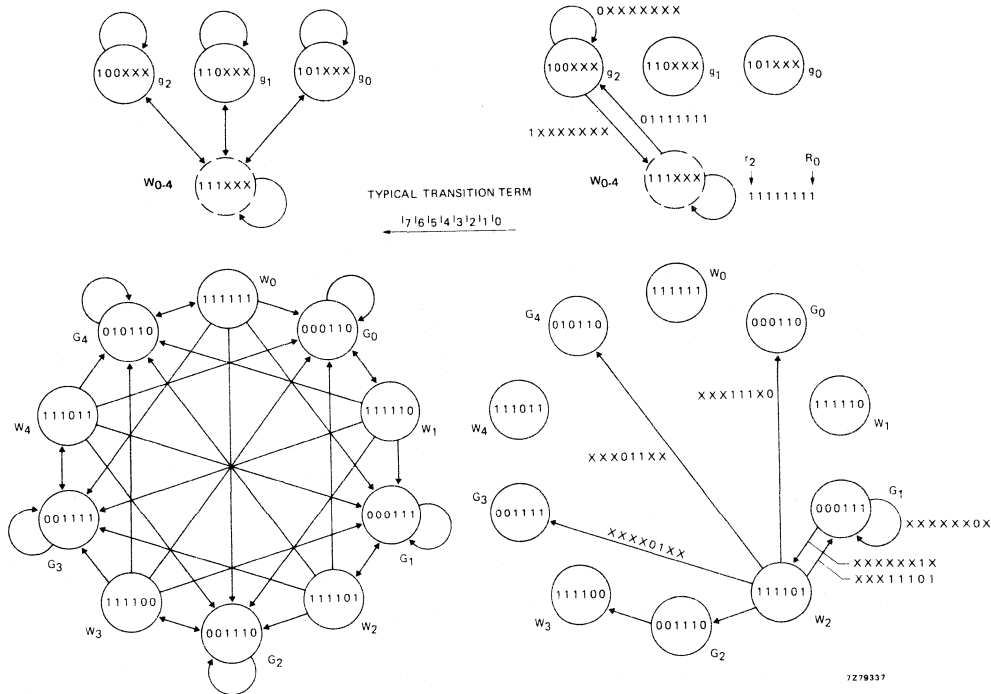

Fig. 6 State transition diagram for the priority arbiter.

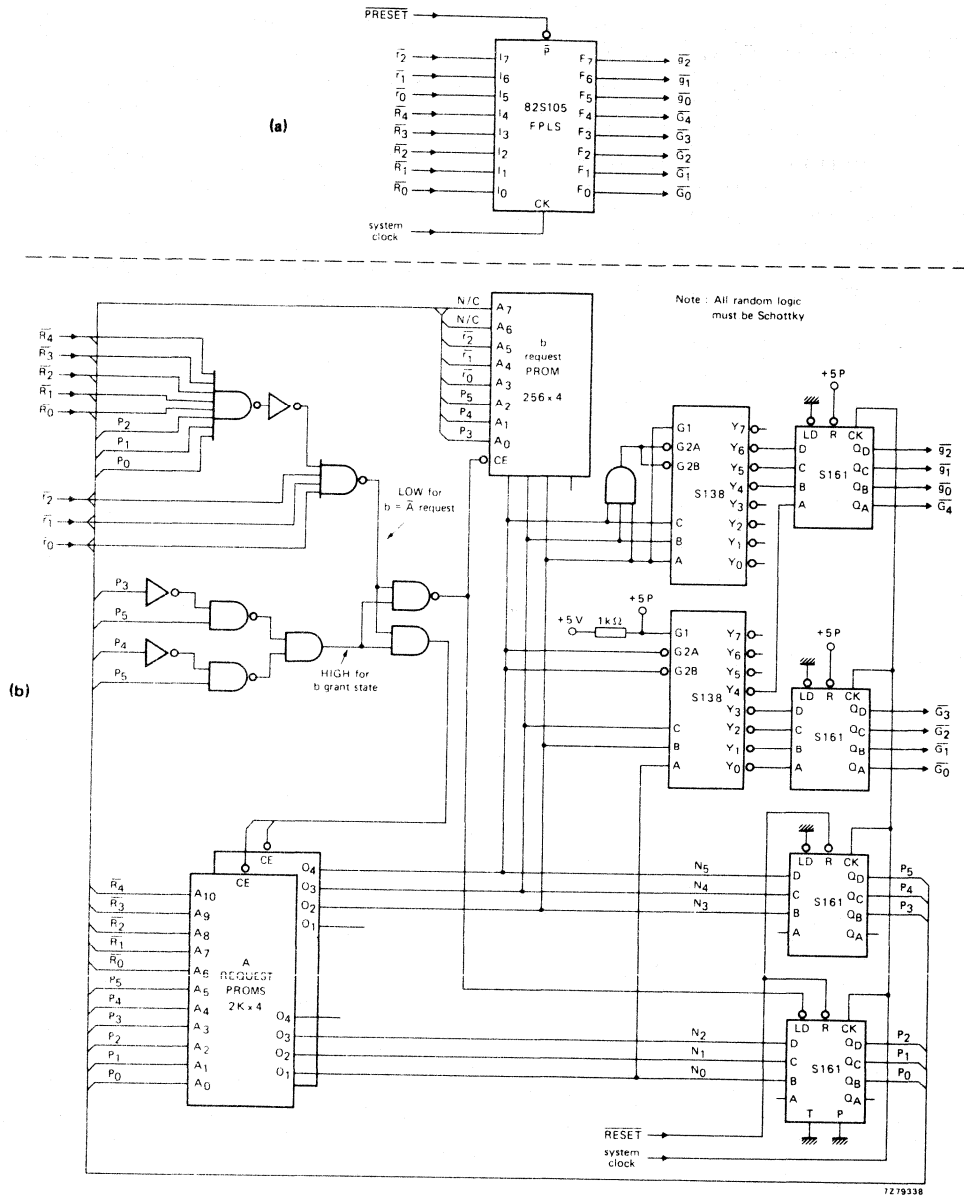

Fig. 7 Arbiter logic diagram (a) using FPLS (b) using PROMs and latches.

PROM/latch implementation

The same arbiter can be implemented with discrete PROMs and latches using the same state diagrams as for the FPLS, except that looping transition terms must now be programmed. Coding of all state and output transitions requires programming of 2 memory fields: the A request PROMs (2K x 6) and the b request PROM (64 x 3). The complete circuit diagram is shown in Fig. 7(b).

The A request PROMs determine the next machine state (N₀₋₅) at all times, except when there are no A requests pending and there is a b request, or if the machine is presently in a b grant state. In these cases, the b request PROM controls the machine's next state.

The grant control lines are decoded from the next state lines and latched in 2 quadruple output latches. This PROM/LATCH organization is conceptually the same as that shown in Fig. 2.

Evaluation of the two designs

As can be seen from the logic diagrams, the FPLS can offer significant advantages over discrete MSI arrays in the design of state machines. The comparison of both design alternatives for the priority arbiter is shown in Table 2. Clearly, the FPLS approach uses fewer parts, with savings in PC board space and power requirements. Furthermore, as many logic elements must be placed in the input-to-latch propagation path, the speed of the PROM/LATCH version is about 50% slower than that of the FPLS.

Table 2 Comparison of the two designs of arbiter.

| parameter | FPLS | PROM/LATCH |
|-------------|--------------------|---------------------|
| parts count | 1 IC | ≈ 19 ICs |
| PCB space | 51 mm ² | 542 mm ² |
| power | 0,65 W | 2,85 W |
| speed | 90 ns state | 159 ns state |
| voltage | +5 V | +5 V |

Expandable memory system using the Signetics Field Programmable Gate Array

The Signetics FPGA is a programmable array of nine bipolar AND/NAND gates, having sixteen common inputs. Input buffers generate both the true and complement forms of the input signals, avoiding the need for inversion of signals outside the chip. The true/complement forms of each of the 16 inputs are connected by two nichrome fuses to each of the AND gates; blowing one or both fuses

allows the user to program an input as true, false or don't care. The output of each AND gate is programmable, through a fuse and an exclusive-OR gate, to provide either an AND or NAND function. Both open-collector output (82S102) and three-state output (82S103) versions are available. The block diagram of the FPGA is shown in Fig. 1.

Fig. 1 Logic diagram of FPGA. Each NAND gate is initially connected to true and complement forms of the 16 input signals. The exclusive-OR gates allow programming of active-high or active-low outputs.

Expansion of a memory system at some time during its life is a common requirement. Unfortunately, replacing existing memory chips with larger capacity ones will not work; the chip-enable and address signals must be changed. Normally this will require changes to the printed wiring, resulting in a complete new print board. However, use of an FPGA to generate the chip-enable and some address signals, combined with a generic series of memory chips, greatly simplifies the problem. Figure 2 shows the pin allocation for the Signetics 4K PROM (82S141) and the 16K PROM (82S191). These devices are pin-compatible except for the substitution of pins \overline{CE}_1 and NC (not connected) by the pins A₉ and A₁₀ in the 16K device. In a similar manner, the Signetics 8K PROM (82S181) uses A₉ in place of NC. Future additions to the range, with larger capacities are expected to use remaining chip-enable inputs as higher-order address lines. This method allows PROMs from 512 x 8 to 8K x 8 to be made pin compatible.

The FPGA is used as a programmable address and chip-enable decoder as shown in Fig. 3. By changing the FPGA program, the system can accept PROMs in the range 4K, 8K, 16K, 32K or 64K, resulting in a memory of 2½ Kbytes to 40 Kbytes. All that need be changed is the FPGA and the PROMs. FPGA outputs F₀ to F₃ provide the appropriate chip-enable or address line according to the PROM in use. Table 1 shows the different signal requirements of the PROM range. Outputs F₄ to F₇ provide the chip-select signals for the individual PROMs. Note that the start address of the memory system can be programmed anywhere in the 64K address field of the 16 inputs. Another feature of the FPGA decoder is its simple compatibility with the system bus control mechanism: the control signal \overline{RD} can be connected to the FPGA

chip-enable input so that when \overline{RD} is low the memory system is enabled, when \overline{RD} is high the PROM outputs are held disabled.

8-bit parallel CRC generator/checker using Field Programmable Logic

The cyclic redundancy check (CRC) is a method of error detection that is widely used in data transmission and recording systems. The CRC method produces a unique check word that is appended to the end of the data sequence. Should any bit in the data or check word become corrupted, subsequent decoding will indicate an error. The check word is generated by the division of the data, in a serial stream, by a selected polynomial expression. The remainder generated by this division forms the unique check word. The CRC16 Reverse polynomial $[P(X) = X^{16} + X^{15} + X + 1]$ is one of the more common expressions to be used, and is the one considered in this Technical Note.

Conventional generator/checker

The conventional CRC circuit uses a serial data input and a shift register with feedback loops to simulate the code

polynomial. A typical circuit is shown in Fig. 1. The sequence starts with all the flip-flops being reset via the MR line. Each bit of the data is then sequentially clocked into the shift register via the D line. When the last bit of data has been clocked in, The CRC check word is available on the Q outputs of the flip-flops.

When the data is checked, it is entered into the the shift register, in the same way as for check-word generation, followed by the check word. If any bit of the data has been corrupted, the shift register contents are non-zero.

This serial method of CRC generation/checking is simple to implement providing that the data is already in a serial bit stream. However, when the data is in a parallel format, not only are parallel-to-serial and serial-to-parallel conversion circuits required, but the serial part of the system must work at several times the speed of the parallel data system. In the case of 8-bit bytes, the serial logic must be clocked 8 times faster than the parallel logic.

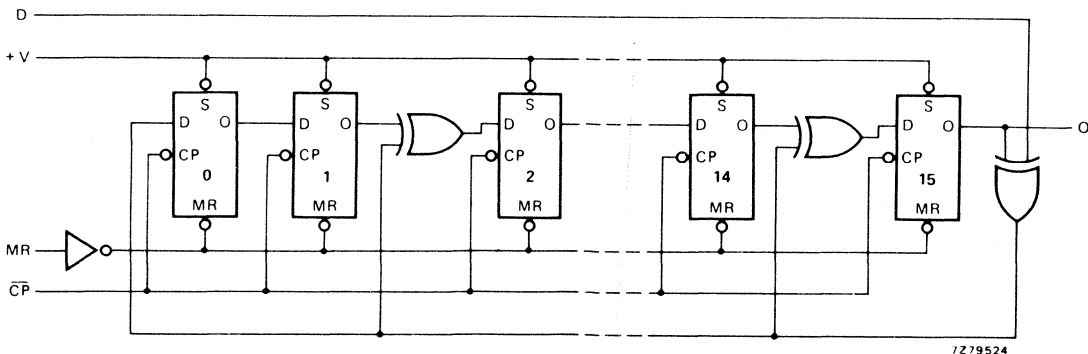

Fig. 1 Conventional serial CRC generator/checker circuit.

Parallel CRC generator/checker

A parallel CRC circuit can be constructed from clocked combinational logic to perform the same functions as the circuit of Fig. 1, and thus avoid the problem of format conversion and high speeds. However, the resulting logic circuit is complex and only becomes a practical proposition when it can be implemented in an IC such as the FPLA. Figure 2 shows the schematic diagram, while Table 1 gives the logic equations defining the next state of each output. A practical circuit is shown in Fig. 3: it uses only five ICs, one of which can be omitted if the checking function is not required. It has a data throughput rate of over 5.7 Mbytes/s.

Circuit operation begins with resetting the latches and then entering the first data byte at inputs D_0 to D_7 . The output of the FPLAs is then clocked into the latches before the next data byte is presented at D_0 to D_7 . In the generation mode, the check words are available on outputs B_0 to B_{15} after clocking the last data byte. In the check mode, the two check words must be entered after the data block. If an error has occurred, the $\overline{\text{ERROR}}$ line is set low. Tables 2, 3 and 4 show the programs for the two FPLAs and the FPGA.

A simple keyboard encoder using the FPLS

A keyboard encoding device must be able to perform four basic functions:

- keyboard scanning;
- contact bounce suppression;
- key encoding;
- signalling availability of valid output data.

The maximum size of keyboard that can be used with a given encoder depends largely on the time taken to scan the keyboard and the time taken to suppress the effects of key contact bounce. The longer that these times are, the slower the maximum data input rate becomes.

Contact bounce suppression can be performed by a low-pass filter consisting of an RC combination. A filter with a cut-off around 100 Hz is usually sufficient to remove the high-frequency bounce signals. However, the design of some encoders makes it more attractive to suppress the bounce signals in a digital manner. This can be done by regularly sampling the contact signal to ascertain its stability over a defined period. Figure 1 shows the flow chart of a simple bounce suppression system. Once a depressed key has been detected, there must be n consecutive 'no key pressed' samples before the scanning routine can be re-started. The number of samples required to suppress contact bounce depend on the sampling frequency, f_s , and low-pass cut-off frequency, f_c :

$$n = f_s / f_c.$$

For a 1 kHz sampling rate and a 100 Hz cut-off, there must be 10 samples with the key released before the system can continue scanning.

The key encoding mechanism may be fixed in the hardware, or may be programmable, allowing the user to select the code for each key. Fixed encoders normally conform to national or international standards for keyboards.

Once a depressed key is detected and encoded, the code must be presented at the output, accompanied by a signal to indicate the presence of a valid code. The form of this signal will depend upon the requirements of the application.

Obviously, the ideal keyboard encoder will be a single chip, providing the user with the facility to program all the operational parameters just mentioned. The simplest approach to this problem is to use the Signetics Field Programmable Logic Sequencer (FPLS). The FPLS is simple and quick to program and does not need the tedious assembly processes of a microprocessor. It is available in both open collector (N82S104) and three-state (N82S105) versions.

Fig. 1 State diagram of a digital filter to eliminate the effects of key bounce.

Key scanning

The keys are scanned in four columns of 15 keys each. The six present state bits are used to represent a four-bit row counter, counting from 1 to 15, and a two-bit column counter, counting 0 to 3. The row counter is automatically incremented by lines 0 to 3 as long as no key is pressed. When the count reaches 15, lines 4 to 6 ensure that the column counter is incremented and the row counter reset to 1. At the same time as the state counter is being incremented, the output register is incremented to hold the 3 most significant bits of the row counter. The least significant bit of the row counter cannot be held in the output register because output functions 0 to 3 are used to select the columns of keys. Figure 6 shows the state diagram of the scanning logic.

When a key is pressed, the row and column counters are incremented as described above until the correct column is selected and the row counter reaches the value corresponding to the pressed key. At this point, one of lines 9 to 23 is active, causing the $\overline{\text{Strobe}}$ output to go low. The state and output registers remain unchanged. The $\overline{\text{Strobe}}$ output, connected to input I_0 causes the system to enter the output mode on the next clock pulse. Figure 7 shows the interruption of the scanning sequence when a pressed key is detected.

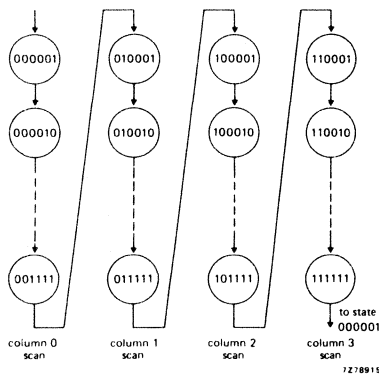

Fig. 6 State diagram for key scanning operation, no key pressed.

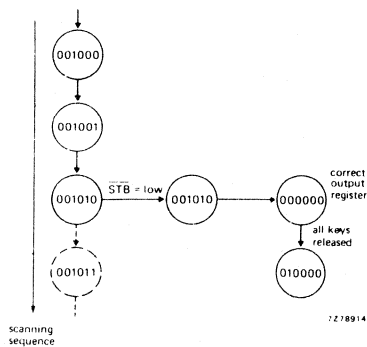

Fig. 7 Detection of pressed key (001010) during scanning mode.

Output strobing

With input I_0 ($\overline{\text{Strobe}}$) low, a transition occurs from the last counter state to state zero. In this state, output F_3 is set high or low, corresponding to the least significant bit of the row counter.

On the next cycle, output F_7 goes high to complete the output cycle. With F_7 high in state zero, the system enters the bounce suppression mode.

The code generated for each key is determined by the counting action. However, these codes are programmable because any key can be allocated to any state of the counter. The program linking the keys to the counter states can be found in lines 9 to 23 of the FPLS program.

Bounce suppression

While the key is still pressed, the system remains in state zero with bits F_0 to F_3 being set low. When the key is lifted, the system enters the bounce suppression sequence, lines 27 to 47. Detection of any key pressed during the bounce suppression sequence results in the sequence being started anew. By ensuring that no other keys are pressed, instead of simply the key just detected, the system overcomes the problems of two or more keys being detected at the same time: the first key to be scanned, when two or more are pressed, is the one detected.

Interface to a microprocessor

A keyboard encoder can be connected to a microprocessor in either a scanned or interrupt mode. In the scanned mode, the microprocessor regularly interrogates the encoder to see if a key has been pressed, and if so, reads the key code. In the interrupt mode, the encoder generates an interrupt signal to the microprocessor when a pressed key is detected. The interrupt signal causes the microprocessor to execute an interrupt service routine which reads and processes the key code.

Addition of an 8-bit register, shown in broken lines in Fig. 4, allows the FPLS encoder to be used in either mode with a microprocessor. The 8212 is a special interface register incorporating a service request latch, which is set by the $\overline{\text{STB}}$ input. The output $\overline{\text{INT}}$ is then set low until the data latches are read by the microprocessor.

Specifications of the encoder

| | |
|----------------------------|----------------------------------|
| Maximum number of keys | 60 |
| Key codes | programmable |
| Maximum keyboard scan time | 86 ms |
| Bounce suppression time | 8,6 ms |
| Power supply | 5,0 ± 0,25 V, 650 mW typical. |

Larger capacity keyboard

The circuit shown in Fig. 8 can be used to expand the encoder's capability up to 120 keys. Two open-collector FPLSs (82S104) with the same program as for the 60-key encoder are used. A Signetics Field Programmable Gate Array (82S103) provides the gated interconnections.

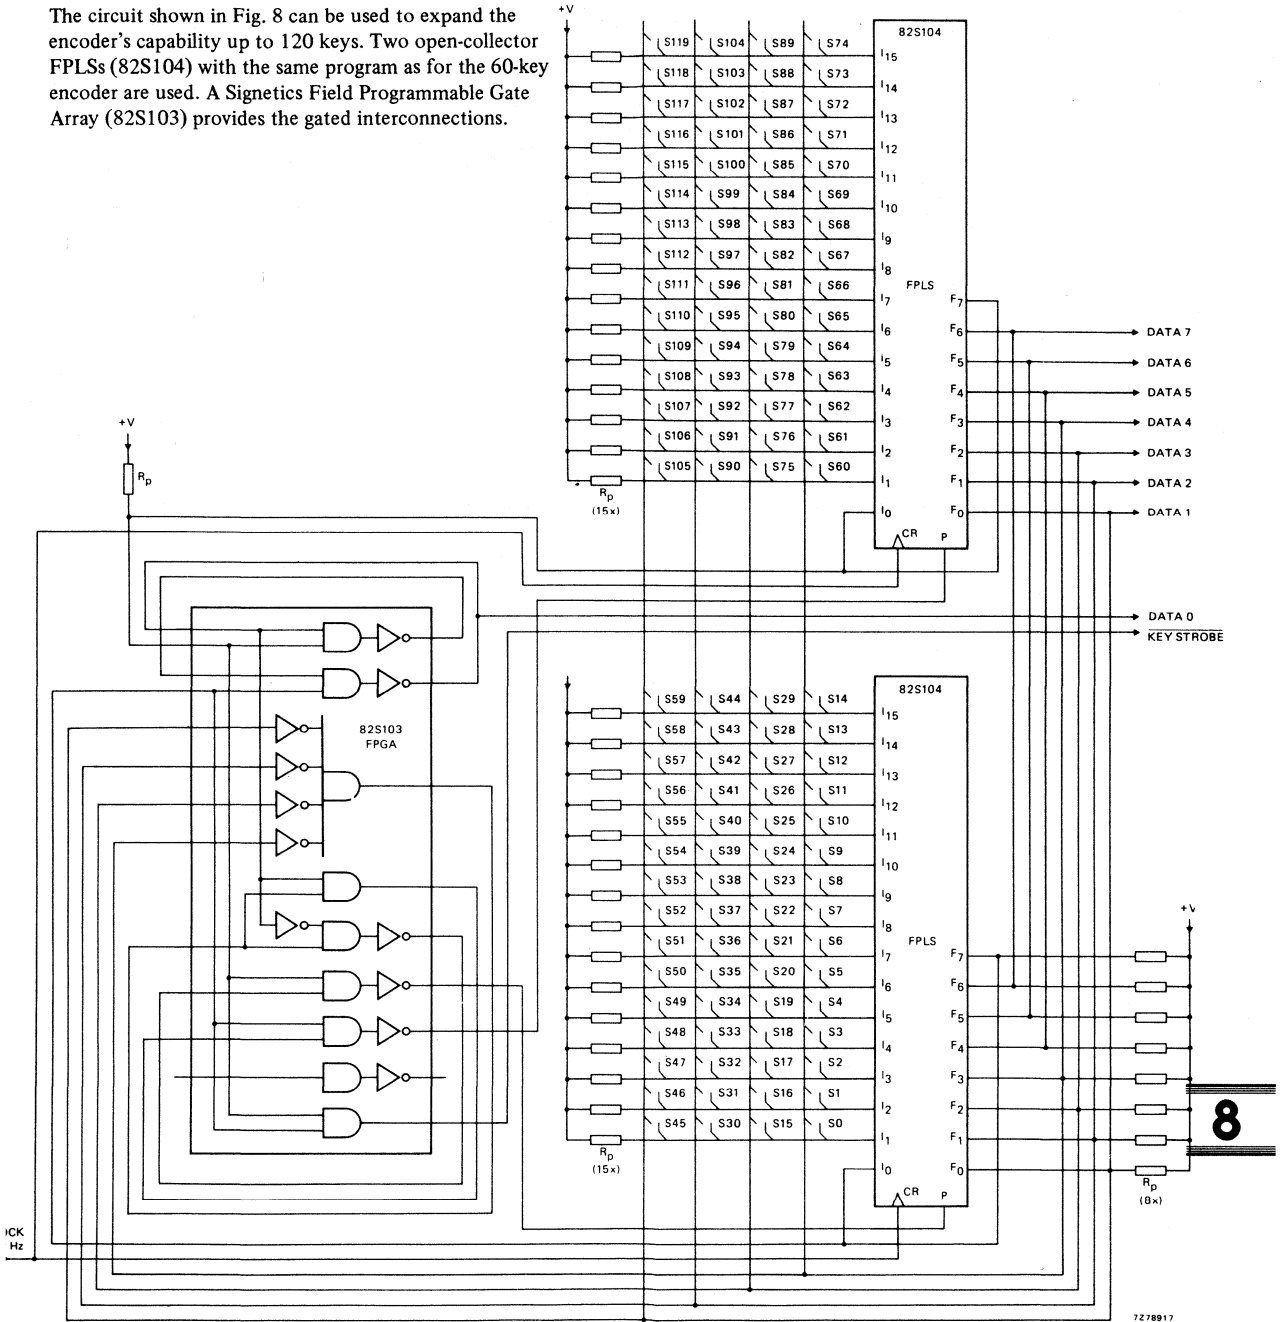

Fig. 8 120 key keyboard encoder.

THE FPLA ADDS DISPLAY FLEXIBILITY TO CRT CONTROLLERS

INTRODUCTION

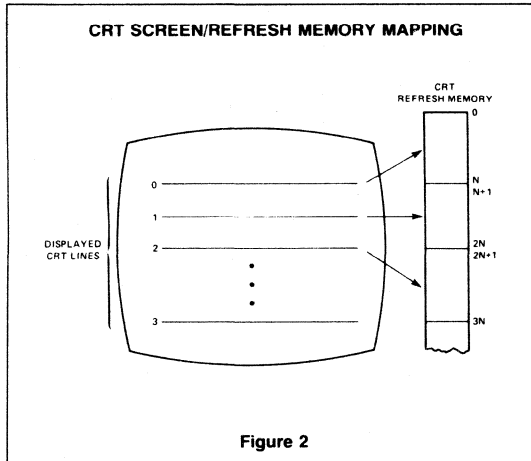

The FPLA may be used to add display flexibility in many raster scan CRT applications.

Most CRT controllers are designed to scan a screen a line at a time from the lefthand screen side to the right, and proceed line by line from the top of the screen to the last displayed line at the bottom of the screen.

This scan pattern is ideally suited for displaying text that is written in the same scan pattern, such as English. This allows a CRT refresh memory to store lines of text in a linear, contiguous manner. For instance, a typical 72 character wide by 64 line (72X64) CRT monitor could arrange its refresh memory such that it maps directly to the CRT scan pattern.

This allows the CRT scan address to be used as the refresh memory address.

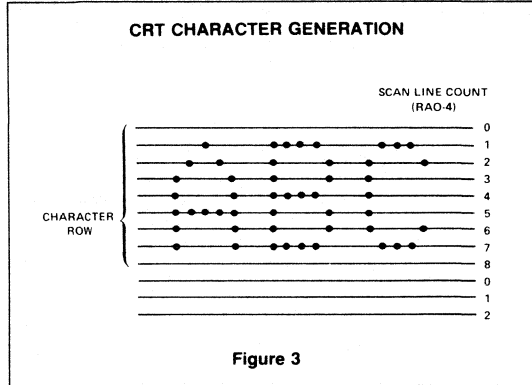

Although this works well for English text, the same CRT controller would have a difficult time displaying foreign text, such as Japanese which is written in lines from top to bottom and proceeds from right to left, or Arabic which is written in lines from right to left and proceeds from top to bottom. This discussion will show how the FPLA can add text display flexibility to a typical CRT controller; the 6845.

CRT CONTROLLER FUNCTIONS

It is the task of the CRT controller to configure and control the raster scan of the CRT in a manner that allows text to be easily displayed.

Towards this end, the 6845 uses the same line scan pattern shown in Figure 1. It combines many scan lines together to form a single character row. Figure 3 illustrates this technique. Also under its control is the number of characters displayed per character row and thus the horizontal dot pattern spacing.

As can be seen in Figure 4, lines RAO-4 address the scan lines within a character row. They sequence from a count of 0 to last character row scan line as shown in Figure 3.

Refresh memory address lines, MA0-13 sequence from a programmed start address on a character by character basis to the end of the last character displayed in the last character row. Figure 5 illustrates this sequential count for a 72 by 64 CRT display with a start address of 0.

The CRT controller has two primary operational modes: refresh memory update, and CRT refresh.

During the refresh memory update cycle, the refresh memory address multiplexer is switched towards the processor address bus. At this time the processor can insert new or updated data to be displayed on the CRT screen. Since this cycle requires refresh RAM address control, CRT refresh must be interlaced around the processor to RAM updates. A good time to update the RAM is during scan line retrace time (see Figure 1). At this time no CRT refresh operations are taking place and is, therefore, a perfect time window. The 6845 indicates this window via its DISPLAY ENABLE line.

During the CRT refresh cycle the refresh memory address multiplexer is switched towards the 6845, where lines MA0-13 provide addressing. Addressed refresh data is then latched and translated by the Character Generator ROM into a corresponding row dot pattern. This word is then shifted serially to the video buffer which provides the CRT display interface.

For a complete description of the operation of the 6845, refer to the 6845 data sheet. At this point the discussion shall focus on the way this typical CRT controller application may be adapted with an FPLA to provide foreign text display.

CRT REFRESH MEMORY MAPPING

As discussed earlier, English text is conveniently stored in refresh memory, since its written pattern directly corresponds to the CRT scan pattern.

For the same controller to display foreign text with a different written pattern than the given scan pattern an alteration is required in either; 1.) the way the data is stored in the refresh RAM, or 2.) the way the refresh data is accessed. For instance, Japanese text displayed on a 72X64 line CRT requires that the first character in the first text line be

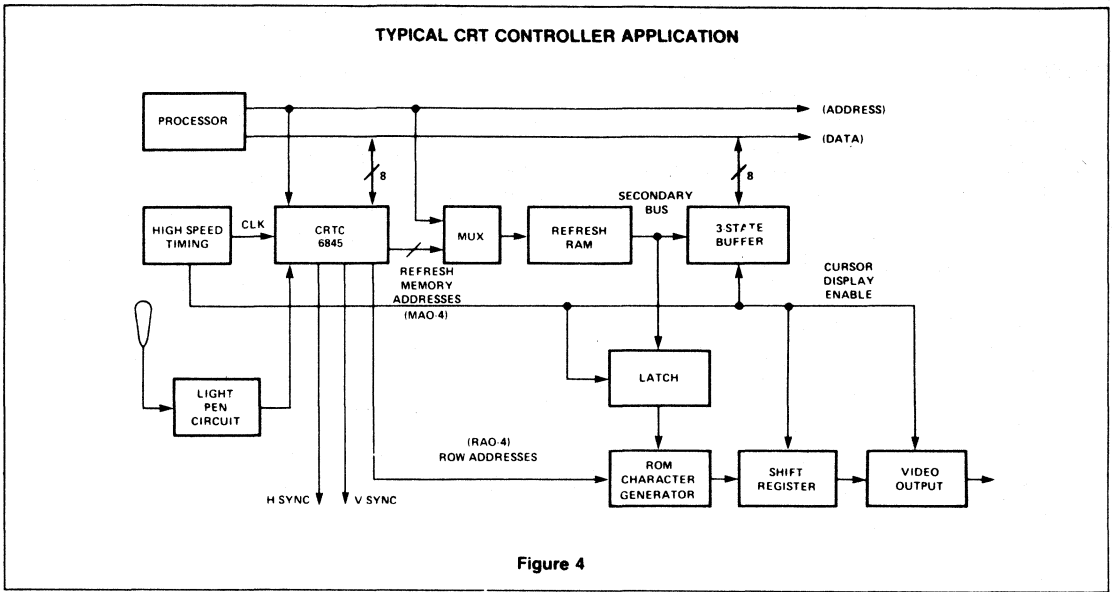

Figure 4

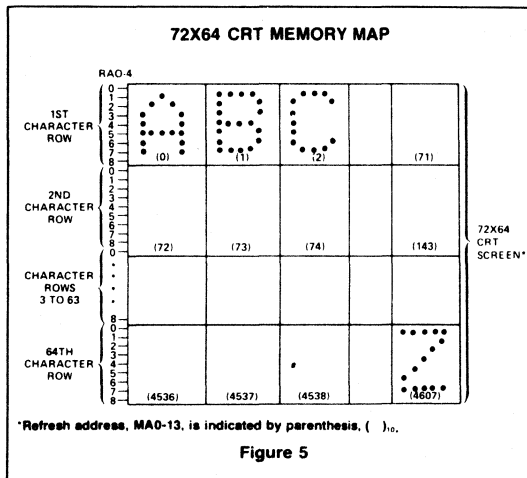

Figure 5

displayed in CRT character position 71 (MA0-13 = 71₁₀); the second in 143; and so on, to the last character in the last displayed vertical text line, where MA0-13 = 4536.

If the processor assumed this scrambling operation in a software map a great deal of overhead program memory and processor time would be consumed. This fact is extenuated when it is necessary to display multiple text patterns on the same monitor screen such as English, Japanese, and Arabic format.

The alternate method of altering the access sequence allows the processor to stack text in the refresh memory in the same way regardless of text. The first text character of the first text line will be placed in refresh memory address 0, the second in address 1, and so on until the end of the text line. The next text line will be stored in a contiguous manner directly after the first line and so on. Figure 6 shows the processor stored refresh text memory for English, Japanese, and Arabic formats.

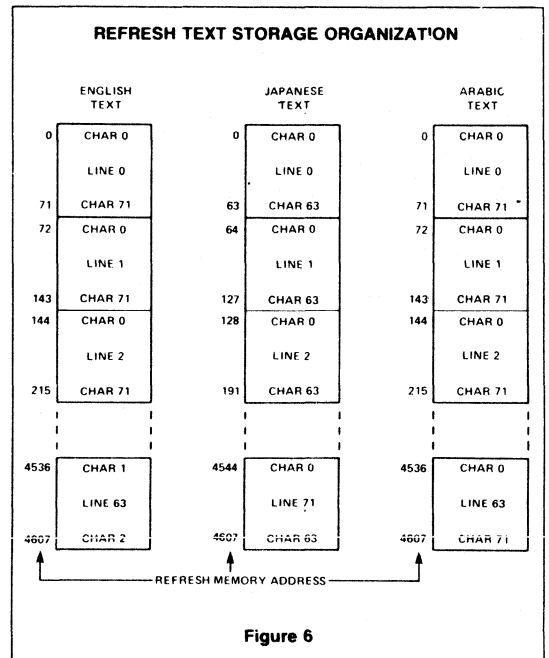

Figure 6

Given this storage organization, a modified refresh memory address, M0-13, must be supplied to the refresh address multiplexer that follows the sequence shown in Figure 7. This modified address sequence, if synchronized with the correspondingly shown MA0-13 count, arranges the stored text on the CRT monitor in a manner correct for each language format. Japanese or Chinese text will be displayed from top to bottom and right to left; Arabic will be right to left, top to bottom; and English will be from left to right, top to bottom.

MULTI-LANGUAGE REFRESH SEQUENCES

| TEXT CHARACTER POSITION (MA0-13)* | ENGLISH TEXT ADDRESS SEQUENCE* | JAPANESE TEXT ADDRESS SEQUENCE* | ARABIC TEXT ADDRESS SEQUENCE* | COUNT SEQUENCE CONDITIONS |

Figure 7

FPLA PRIMER

The FPLA is a programmable logic array that consists of 48 16-input AND gates, and eight 48-input OR gates with user programmable inputs and output polarity. It is functionally equivalent to 528 TTL gates in 196 I.C. packages. The AND and OR gate architecture is shown in Figure 8; a more detailed FPLA description maybe found in the FPLA, 82S100-101 data sheet.

FPLA ADDRESS SEQUENCER IMPLEMENTATION

An FPLA based sequencer is used to perform the three address sequences indicated in Figure 7. As can be seen in Figure 9, the Refresh Memory Sequencer circuit diagram, two FPLAs are used. Three sources of data are required to provide the address sequence: 1.) scan position at the end of a character row (MA0-13 N(72)-1), 2.) last scan line in a character row (RA0-4 max. 8), 3.) text address sequence (Text 1, Text 0).

The Address Map Monitor monitors the refresh address bus, MA0-13, and provides an active low output each time Equation 1 is satisfied.

$$\text{MA0-13 } N(72)-1 \quad \text{Equation: 1}$$

where: N 1,2,3, 64

Careful examination of Equation 1 reveals that the active low output corresponds to the last displayed character position in each character row; MA0-13 71, 143, 4607. A straight forward FPLA program requires 64 product terms to implement Equation 1, but with the aid of Signetics' Simultaneous Logic Minimization Program, the required number of product terms is reduced to just 48, the size of a single FPLA!

It can be seen from Figure 7 that this information plus the row address, RA0-4, is enough information to define a single text address sequence. For this particular application the maximum number of scan lines per character row is 9, therefore, the single row address line RA₄ provides the "RA0-4 max (imum count)" logic.

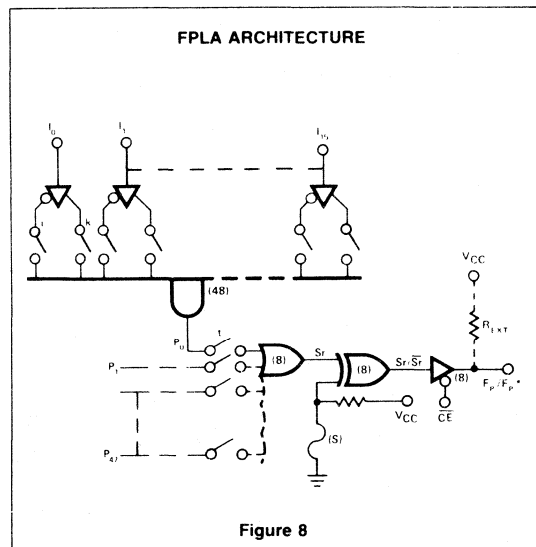

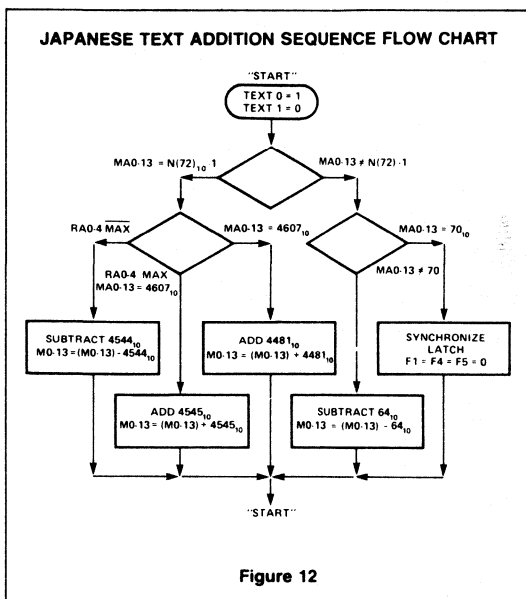

Figure 8

Figure 12 illustrates in flow chart form the conditional logic process the Add Controller follows in a Japanese address sequence. All subtract operations are implemented through two's complement addition. A similar flow chart maybe constructed for English and Arabic texts.

Add Controller output, F_0 , provides synchronization logic by monitoring MA0-13, such that M0-13 and MA0-13 track each other as shown in Figure 7. To force synchronization, Add Controller outputs F1, F4, and F5 are set to 0, thereby resetting the 14-bit register to, M0-13=0, when the following refresh memory states are detected.

SYNCHRONIZATION CODES

| DISPLAY FORMAT | MA0-13* |
|-----------------|--------------------------|
| Japanese | 70₁₀ |
| Arabic | 70₁₀ |
| English | 4607₁₀ |

*Synchronization takes place only when RA0-4 is maximum.

Table 2

SUMMARY

Where CRT display flexibility is indicated, either as a present design requirement or as a future possibility, the FPLA can provide an economic solution. Alternative comparable solutions require many more parts, power, and P.C. board real estate. For example, a PROM address sequencer implementation would require 64 8K PROMs, 26 Watts, and 17.6 square inches of P.C. board space; whereas the FPLA solution yields 2 FPLAs, 1.2 Watts, and 1.92 square inches of P.C. board space.

Signetics' FPLAs are logic elements with memory, and can be viewed in two basic ways.

In terms of logic, the FPLA is a two level AND-OR, AND-NOR *combinatorial* logic element, consisting of a system of logic gates with programmable inputs and outputs as shown in Figure 1. These, by means of on-chip programmable connectors, enable the user to quickly implement 8 logic functions with a maximum of 48 product (AND) terms, involving up to 16 input variables.

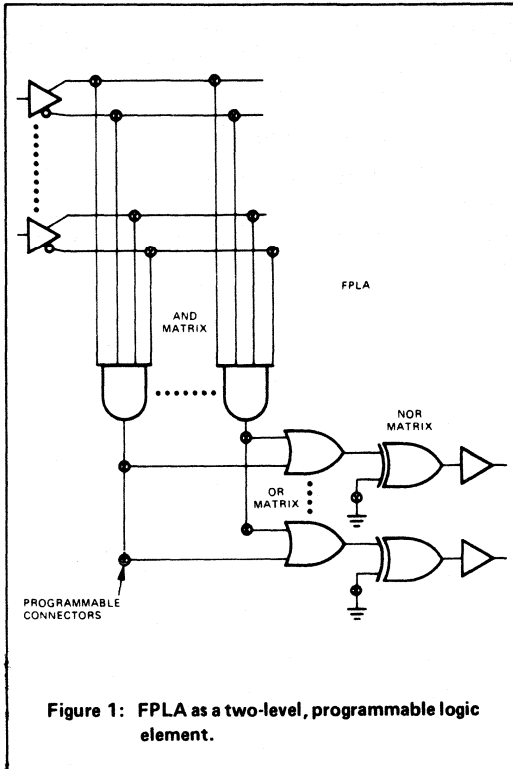

Figure 1: FPLA as a two-level, programmable logic element.

A more detailed organization of the FPLA is shown in Figure 2. The first logic level, the AND matrix, consists of 48 resistor-diode AND gates each connected to 16 True and Complement inputs via 32 fusible nichrome links. The second logic level, the OR matrix, consists of 8 emitter follower OR gates each connected by fusible links to all 48 outputs from the AND matrix. The output of each of these 8 OR gates is in turn buffered through an EX-OR gate which allows changing the logic to NOR via a fusible link to ground.

If your design involves a random logic structure, the FPLA can be used in place of discrete gates and wires. You gain

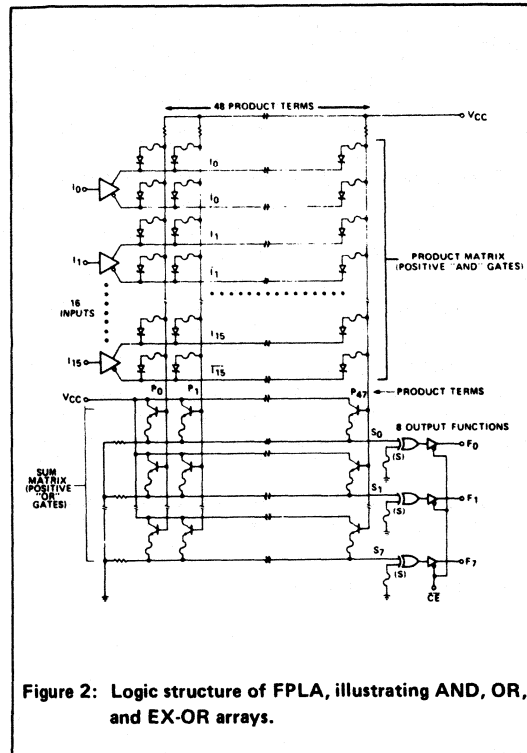

Figure 2: Logic structure of FPLA, illustrating AND, OR, and EX-OR arrays.

total flexibility from the immediate availability of your logic function for which you need only use as much of the FPLA as necessary for your particular application, with the rest available for later expansion or modification. But, if your design needs to be structured more like a memory, then the FPLA can be used in another, perhaps more effective way.

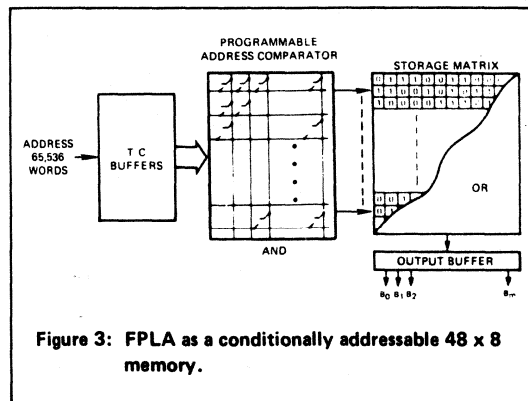

Figure 3: FPLA as a conditionally addressable 48 x 8 memory.

From the partitioning shown in Figure 3, the FPLA can also be viewed as a conditionally addressable memory; one in which the AND matrix functions as a programmable address comparator, recognizing only the preprogrammed address combinations used to activate the system, and ignoring all others. Plus, an OR matrix which then functions as a storage array for 48 output words, each containing 8 bits representing active or idle system commands. Or, to put it another way, you have a memory system that can logically scan a total address field up to 65,536 words deep, to linearly select down to 48 replies randomly scattered within that address space.

No matter how you look at it, generally FPLAs are effectively used in design situations where you have many input variables and few active logic states; and, with a maximum access time of 50ns, the FPLA is a practical alternative to the long logic chains necessary when dealing with several input variables.

The following example is a brief, but concise illustration of how to integrate random logic with discrete gates into a Signetics' FPLA.

Given the set of logic equations F_{1-4} below:

$$F_1 = X_1 + \bar{X}_2 \bar{X}_3$$

$$F_3 = X_3 + \bar{X}_1 \bar{X}_2$$

$$F_2 = X_2 + \bar{X}_1 \bar{X}_3$$

$$F_4 = \bar{X}_1 X_3 + \bar{X}_1 \bar{X}_2$$

These can be implemented with discrete gates as in the AND-OR-NOT logic network of Figure 4.

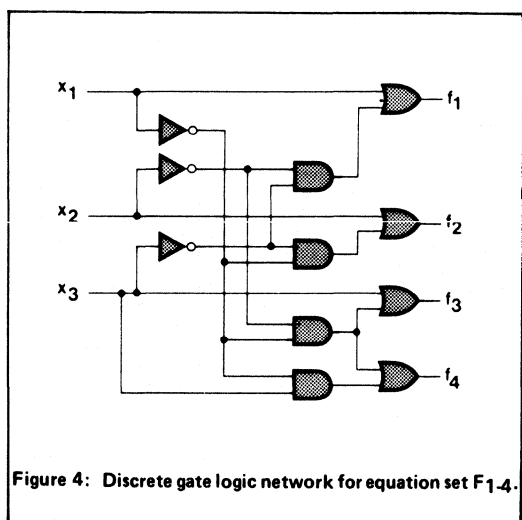

Figure 4: Discrete gate logic network for equation set F_{1-4} .

This method is practical for simple systems; but in more complex applications, it soon produces a distributed logic network with many I.C. packages and types, difficult to design, troubleshoot and modify.

On the other hand, the same set of equations can be easily coded in an FPLA Program Table and programmed in a device using inexpensive field equipment. Typically, F_1 would require the FPLA to contain the fused link pattern shown in Figure 5, as specified in the accompanying Program Table slice. Overall, all four logic functions would use 3 inputs, 4 outputs, and 7 product terms of the FPLA, leaving remaining resources spare for later modifications.

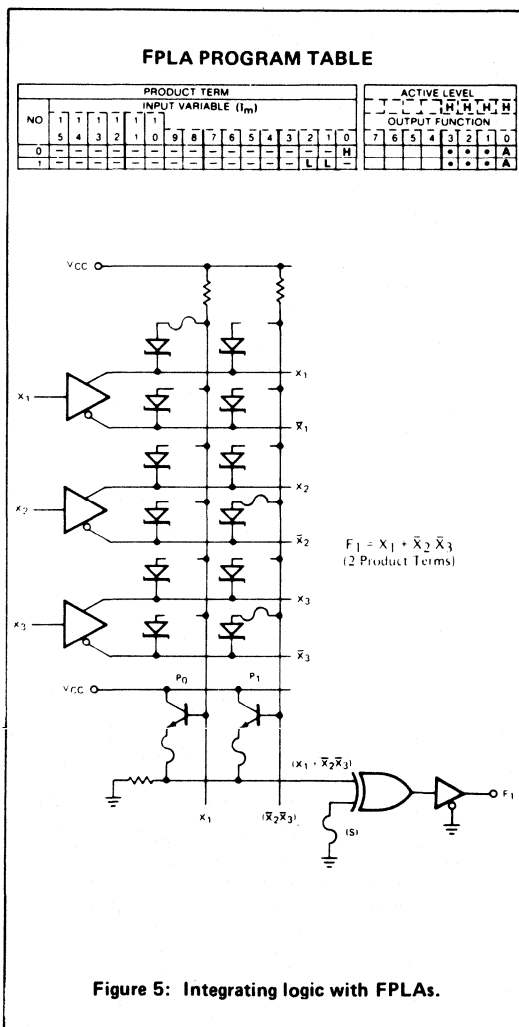

Figure 5: Integrating logic with FPLAs.

For example, if it becomes necessary to change the X_1 product term in F_1 to \bar{X}_1 , deleting the wrong product term and adding the new one becomes a trivial task, as indicated

in the modified pattern and revised Program Table of Figure 6.

FPLA PROGRAM TABLE

Figure 6: Modifying random logic with FPLAs. F_1 modified by deleting term X_1 in the OR matrix and adding new term \bar{X}_1 .

The circuit and associated state diagram in Figures 1 and 2 illustrate a 14-state logic machine which controls the tape motion of a Data Cartridge Tape Drive (Qantex Model 600). It allows the tape drive to be operated externally by a computer and internally according to the routines programmed into the FPLA. The FPLA contains all of the combinational logic required to implement the external commands and internal routines. And, by reducing total IC count, it contributed to reduce from 2 to 1 the number of circuit boards used in the tape drive.

In the circuit of Figure 1, all inputs are derived from I/O commands, the status of the tape drive, and the output of the four J-K flip-flops. The states of the flip-flops determine

which state the logic machine is in as defined in Figure 3. The outputs are used to operate the velocity servo which drives the Data Cartridge to form I/O status signals, and to enable the writing of data.

The current state of the logic machine (Q1, Q2, Q3, Q4) is decoded by the FPLA and combined with the other input signals to determine which state the machine will be switched to next. The possible sequences are described by the Flow Diagram of Figure 2. A jump to a following state can occur when the intervening conditions are true. All desired jumps are programmed in the FPLA Program Table of Figure 4. Jumps occur on the trailing edge of the clock pulse. The state codes (Figure 3) are decoded by the PROM

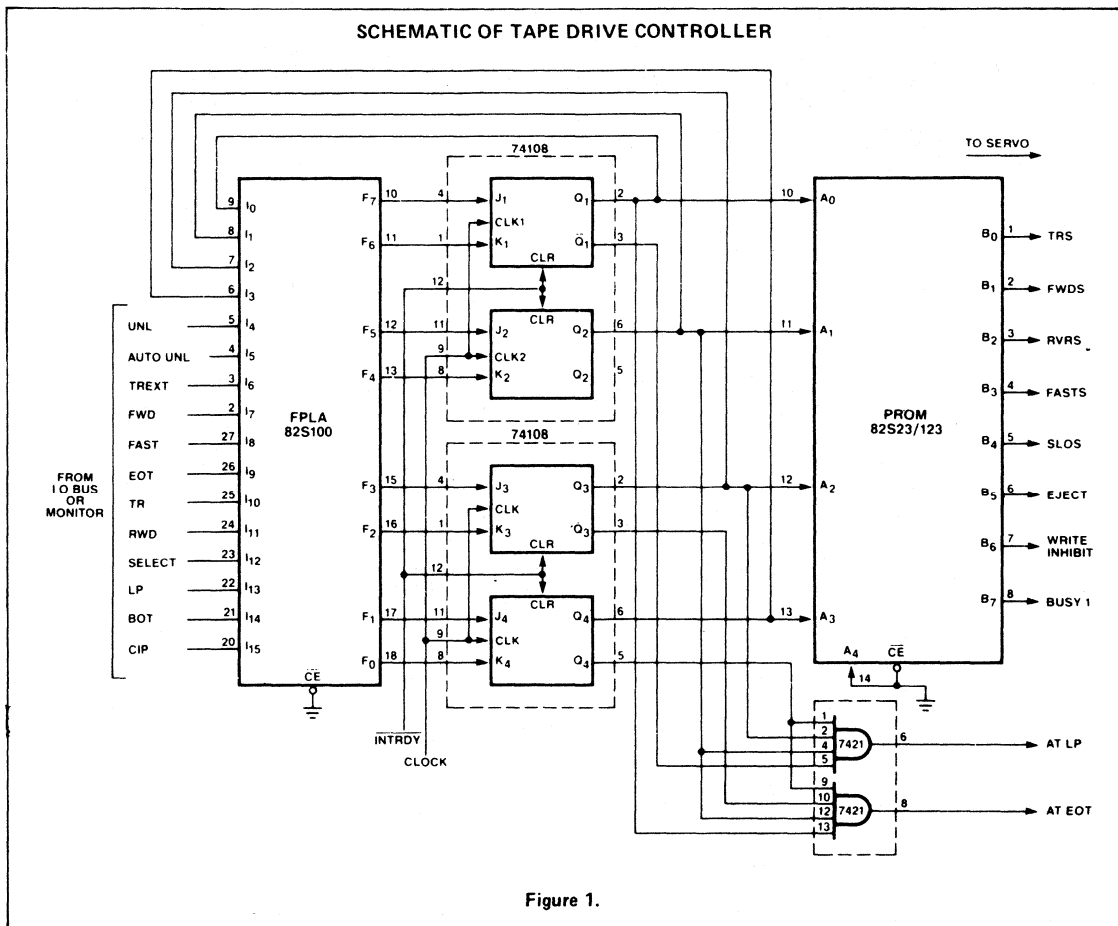

Figure 1.

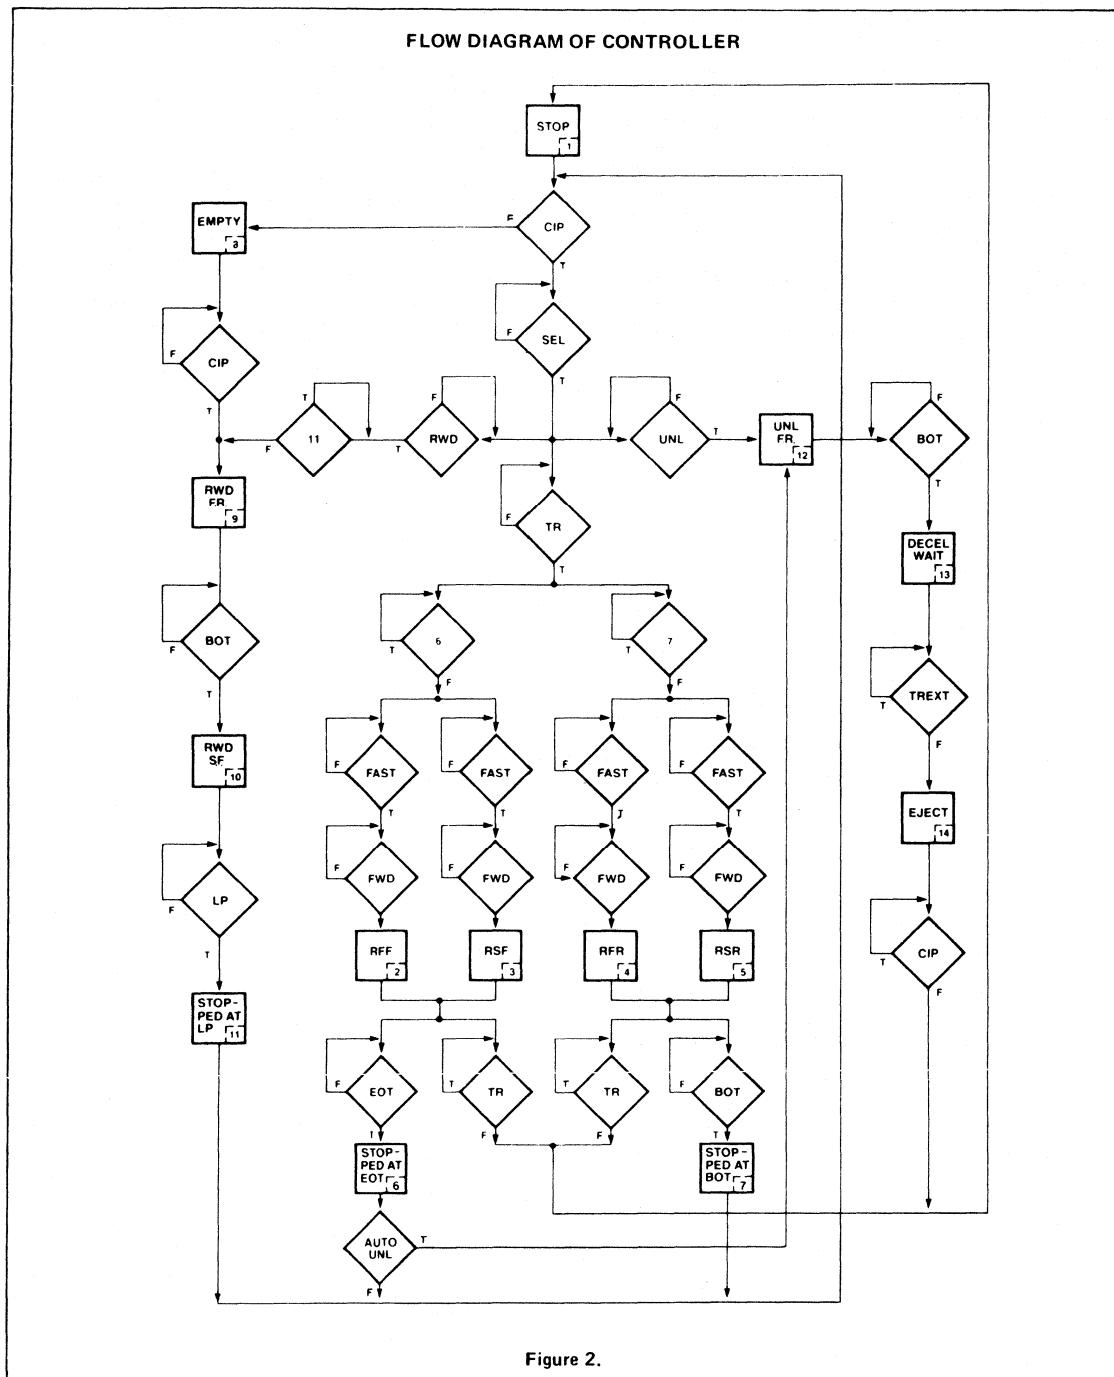

Figure 2.

STATE CODE ASSIGNMENTS

| STATE | | CODE | | | |
|-------|----------------|------|----|----|----|
| NO. | NAME | Q1 | Q2 | Q3 | Q4 |
| 1 | STOP | 0 | 0 | 0 | 0 |
| 2 | RFF | 1 | 0 | 0 | 0 |
| 3 | RSF | 0 | 1 | 0 | 0 |
| 4 | RFR | 0 | 0 | 1 | 0 |
| 5 | RSR | 0 | 0 | 0 | 1 |
| 6 | STOPPED AT EOT | 1 | 1 | 0 | 0 |

| 13 | DECEL WAIT | 1 | 0 | 1 | 1 |
| 14 | EJECT | 1 | 0 | 0 | 1 |

Figure 3.

and the two AND gates with the assignment tabulated in Figure 5. The decoded outputs provide the various signals needed to operate the tape drive.

Whenever the tape drive power is turned on, or an interlock opened, the tape drive is required to be stopped. This defines state 1, STOP, which has been assigned the code 0000. The state is achieved by using $\overline{\text{INTRDY}}$ to clear the four J-K flip-flops. Once set to STOP, operation at normal write speeds can occur when the following set of conditions are simultaneously satisfied, as diagrammed in Figure 2:

- a. Data cartridge is in place: CIP true
- b. Tape Drive has been addressed: SEL true
- c. Tape has been commanded to run: TR true
- d. The logic machine is *not* in state 6: 6 false
- e. Tape should move at slow speed: $\overline{\text{FAST}}$ true (=slow)
- f. Tape should move forward: FWD true

Then the logic machine will jump from state 1 to 3 (RSF). The preceding conditions are programmed in jump 1-3 of Figure 4. the outputs implemented by the new state are described in Figure 5 under state 3. Reading across the line for state 3 of Figure 5, notice that the servo will be driven (TRS true) in the forward direction (FWDS true) at the slow speed (SLOS true).

After data has been either written or read, the tape drive is commanded to stop (TR false). This allows a jump from state 3 (run-slow-forward) to state 1 (STOP). The jump

from state 3 to 1 is charted in Figure 2 and programmed in Figure 4. Figure 5 shows that the only output active in state 1 is Write Inhibit.

By similar arguments, the tape drive can be run either fast or slow in either forward or reverse direction (states 2, 4 and 5).

When the end of tape is reached (EOT true), the tape drive is stopped. This is implemented by a jump from 2-6 or 3-6. Once in state 6, the tape drive can no longer move in the forward direction because of the state 6 false condition preceding states 2 and 3. If auto-unload is true, the drive will automatically rewind (state 12), wait for tape to decelerate (state 13), eject the tape cartridge (state 14) and stop (state 1). If auto-unload is false, the tape drive must wait for either a rewind command (RWD), an unload command (UNL), or a reverse command.

If the tape should be moved in the reverse direction until the beginning of tape is reached, the tape drive is stopped. This is implemented by a jump from 4 to 6 to 7. Once in state 7, the tape drive can no longer move in the reverse direction because of the state 7 false condition preceding states 4 and 5. The tape drive will remain at state 7 (STOPPED AT BOT) until RWD, UNL, or FWD command is given.

If no Data Cartridge is in place (CIP false) when the tape drive is turned on, the logic machine will jump from 1 to 8 (EMPTY). When a cartridge is installed, CIP goes true implementing a jump to 8 to 9 (RWD FR). In state 9, the tape will be rewound in fast reverse until a BOT mark is reached. BOT true implements a jump from 9 to 10 (LDSF). Tape now runs at slow speed in the forward direction until load point (LP) is reached. LP true implements a jump from 10 to 11 (STOPPED AT LP). From state 11, a forward, reverse, or UNL command can be implemented. RWD cannot be implemented from state 11 because of the state 11 condition preceding state 9. This keeps RWD from being needlessly repeated.

The logic machine implements and controls the following tape drive operations and routines:

- a. move tape fast forward
- b. move tape slow forward
- c. move tape fast reverse
- d. move tape slow forward
- e. bring tape to load point when Data Cartridge installed
- f. rewind tape to load point
- g. rewind tape to BOT and eject cartridge in response to UNL command
- h. rewind tape to BOT and eject cartridge in response to an AUTO UNL true condition.

NOTES:

- 1) The rewind and unload routines are self-completing and need no further implementation once started.
- 2) BOT, EOT, LP, are pulses.

- 3) The ROM output line pairs of FWRS and RVRS, and FASTS and SLOS are required to operate latches which remember tape speed and direction during deceleration.
- 4) Whenever a Data Cartridge is removed, a CIP false pulse is generated which temporarily resets the logic machine to STOP.

FPLA PROGRAM TABLE FOR IMPLEMENTING ALL STATE JUMPS IN THE FLOW-CHART

Figure 5.

The circuit shown in Figure 1 is a sequential controller which implements all functions needed to control a dot matrix serial printer, and provides a simple, inexpensive, and reliable control circuit useful in many design environments.

The controller consists of an 82S100 FPLA as a program decoder, and two 74175 quad D-type flip-flops as feedback elements.

Parallel ASCII data is presented to the inputs of the FPLA along with an associated Data Strobe. If data detected by the FPLA is a printable character (as opposed to a control function) it will be entered into the buffer memory.

The buffer memory consists of two 3351's configured as an 80 x 9 F1F0, and will hold one full line of 80 characters.

When the memory is full, or if the FPLA detects an ASCII "carriage return," the controller will begin a print cycle, and print out the data stored in memory. The first character in memory will be presented to the inputs of the MK2302P Character Generator. The controller will strobe the Output Enable of the character generator, increment the column counter clock, step the print head, test the Counter Output of the character generator, and shift the next piece of data from the memory if the Counter Output is true. This sequence will continue until the memory is empty, as signaled by the Output Ready line of the second 3351.

The controller will then generate Carriage Return, Line Feed, and Ribbon Advance signals via the 7442 decoder. The print cycle is then complete and the controller awaits new data.

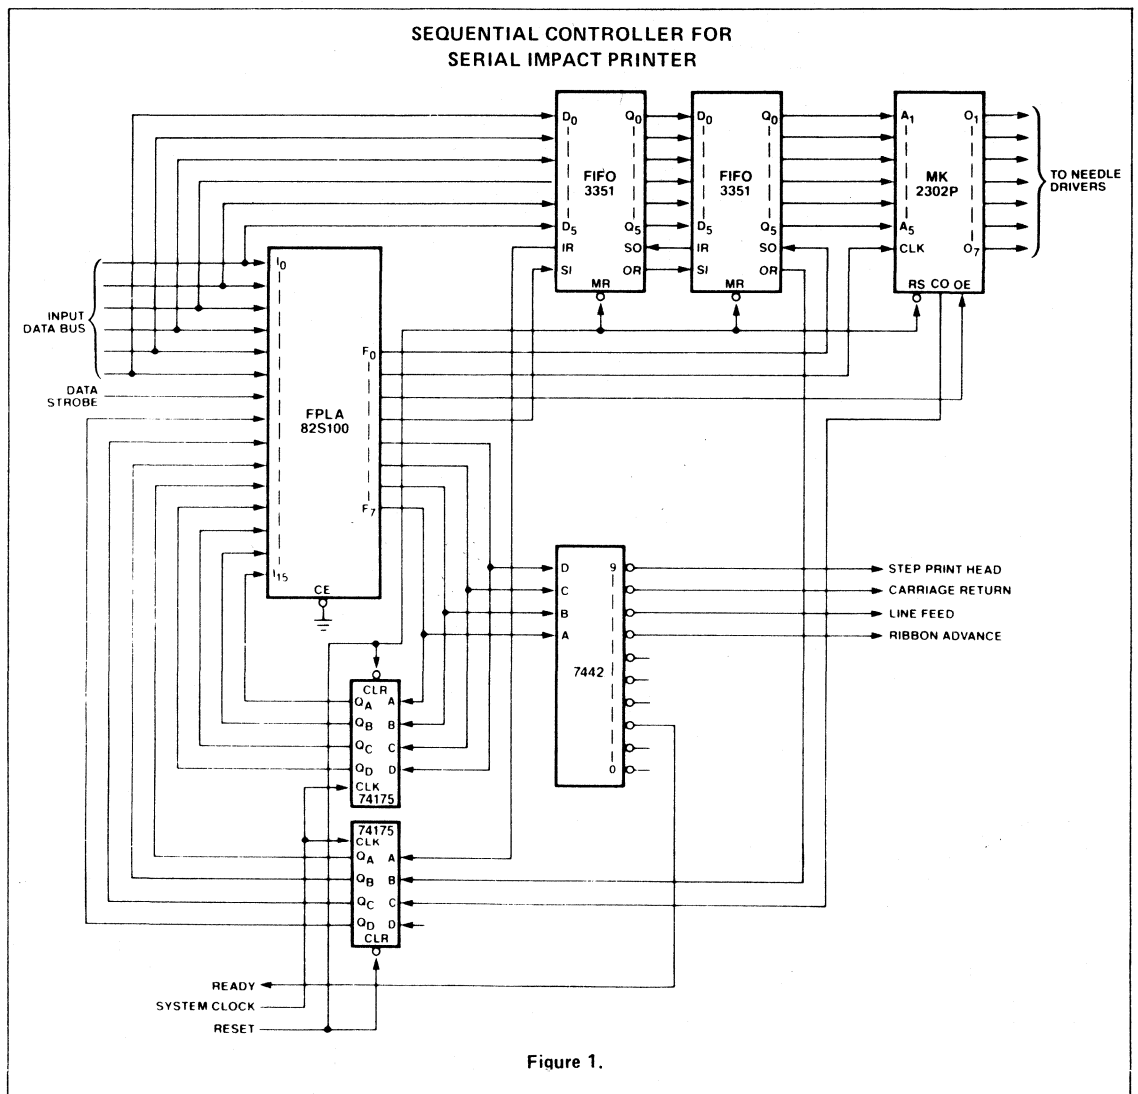

Figure 1.

In industrial or commercial processes it is often necessary to provide many contact closure type control points and/or contact sense points. A simple control system of this type can be implemented using the circuit of Figure 1, and any serial compatible send/receive terminal such as a Teletype or CRT controller.

The circuit has the following features:

- A. Up to 56 jumper selectable addressed units may be connected in series to a single control circuit. Address are in octal, excluding 00,11,22,33,44,55,66,77.
- B. Up to 16 contact closure output points (TTL level) for each unit. Points A thru P functions ("S"et and "R"eset).
- C. Up to 16 contact closure input points (TTL level) for each unit. Points A thru P function ("?" Read).

The serial IN(SI) and serial OUT(SO) drivers are not defined

in this circuit. A typical output communications sequence is (#34A^), where:

- "#" = Attention character that resets the address function in all units on the serial communications circuit.
- "3" = The 1st address character
- "4" = The 2nd address character
- "A" = The control point
- "S" = The control function

When sensing a contact point, replace the "R" or "S" function with a "?" function to read the sense point. The unit responds (in ASCII) with a "1" for a closed contact and a "0" for an open contact point.

Several different modifications of this basic circuit are possible to send BCD or ASCII data using the same or a modified decoding scheme. The decoding function for this circuit is shown in the FPLA program table of Figure 2.

Figure 2.

The output states of solenoid-controlled, air-operated process valves, are a function of logical combinations of input variables, which are gated by contacts to signify various process modes, sequence steps, other valve positions, flow, temperature, pressure, level, etc.

Occasionally it is desirable to change the function or equation of process valves. The FPLA provides an elegant

yet cost effective solution for reprogramming these valves and/or other process devices. In the circuit of Figure 1, the set of 4N2B couplers senses the status of input contacts and will command the 82S101 to operate the valve when the proper logical combination of inputs occurs. The PS101 will energize the solenoid valve when the output of the FPLA goes LOW.

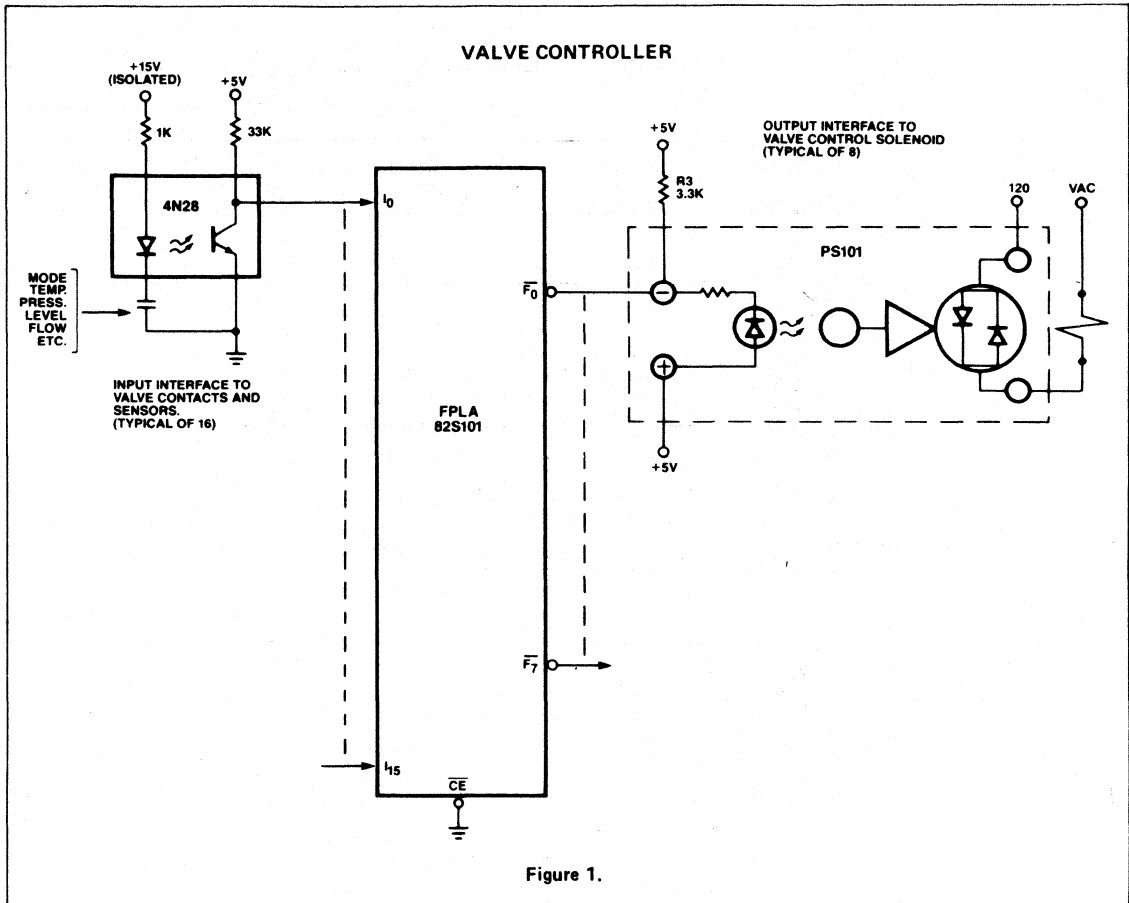

Figure 1.

This controller breaks the time of traffic flow into the four basic parts as shown in Figure 1. Notice that each crossroad is assigned a traffic light during each time frame, and that each time frame has a certain length in seconds. As shown

TIMING OF TRAFFIC LIGHTS

| | | | | |
|------------|--------|--------|--------|--------|
| TRAFFIC #1 | GREEN | YELLOW | RED | RED |
| TRAFFIC #2 | RED | RED | GREEN | YELLOW |
| TIME | 45 SEC | 15 SEC | 45 SEC | 15 SEC |
| STATE | 00 | 01 | 10 | 11 |

Figure 1.

in Figure 2, in order for the circuit to recognize the separate states, each state is assigned a state variable to be stored by FFI. The other flip-flops (#2 thru #4) will store the output information for the traffic lights.

Because of the limited number of outputs, the information is time multiplexed out of the FPLA over a 2 bit bus.

The two 7493's, and the 555 timer form a binary counter for counting up to 64 second in 0.5 second intervals.

The FPLA determines the state of the machine by I16 and I15 and the time elapsed by I7 thru I0. When the proper input conditions are met, the 7493 counter is reset, the state in FFI is updated, and the rest of the flip-flops are updated as needed. The time counter continues until a new change in state is indicated by the state of the inputs. At this time the process is repeated.

By programming the FPLA the designer can determine the length of the time segments, and the lights to be activated. Since several inputs are still available there is room to add vehicles and/or people sensors which would instruct the FPLA to change state and continue from there.

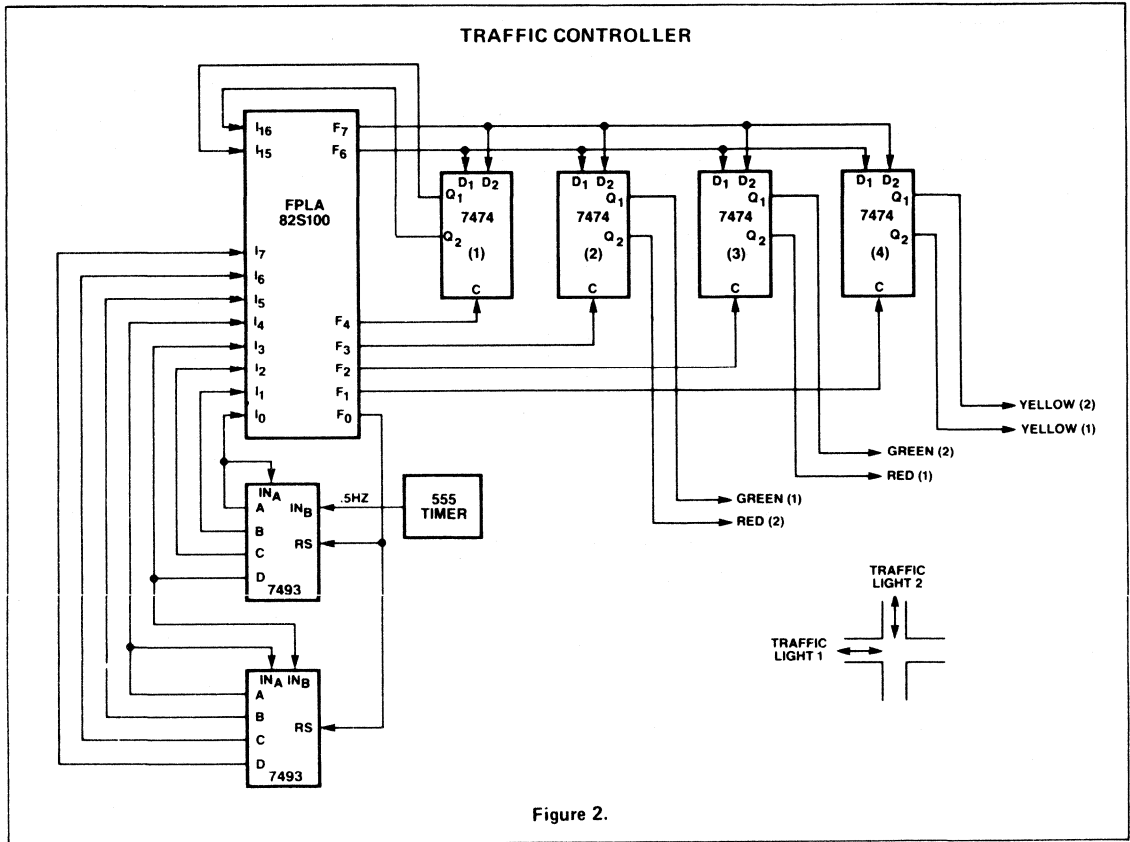

Figure 2.

In the circuit of Figure 1 an 82S101 FPLA is used together with a few other components to build a complete sequential control system on a single 5" x 7" PC card. In this example the circuit is used as a machine controller which recognizes specific starting conditions on its TTL and 120 VAC inputs, and drives the 120 VAC air solenoids in a predetermined sequence, interrupted by time delays as needed. Position feedback from limit switches is used to ensure that each step in the sequence is properly completed, and that the FPLA can detect jams and abort the sequence if any step requires too much time for completion. Logic level outputs are available for such functions as resetting external counters or starting A/D converters.

The system has six inputs and five outputs for interfacing with the machine. In this case, three inputs and two outputs are TTL-compatible, while the remainder are used with 120 VAC. The FPLA analyzes the inputs and internal states of the system, and uses this information to control the desired status of each output, the operation of the time delay circuit, and the advancement of the step counter. Resistor LED indicators can be used for troubleshooting or status checking, with some being driven directly by the FPLA. All 120 VAC interfaces are optically isolated. The 120 VAC

inputs come into the system through AC input modules, which provide TTL compatible signals and also drive LED status indicators. These inputs are coupled through debouncing gates before being taken to the FPLA. One of the debouncer sections, with a capacitor tied to its input, provides a startup delay signal, and the debouncer clock is used as the system clock.

An integrated counter/decoder/latch/display provides the sequential step number. The FPLA can either increment or reset the count, and the step number is made available both as a 7 segment display and as BCD data fed back to the FPLA. Time delays are generated by combining a programmable timer/counter with the FPLA. Some of the timer outputs are taken to the FPLA which combines them as required to build time delays of different lengths (50 ms to 12 sec, in this case).

The logic level outputs of the system are taken directly from the FPLA. Outputs to 120 VAC devices are provided by DIP solid state relays driven by the FPLA. LED indicators may be driven by the same FPLA outputs, to show which AC outputs are on. Fuses and varistors for protecting the AC outputs are also mounted on the card.

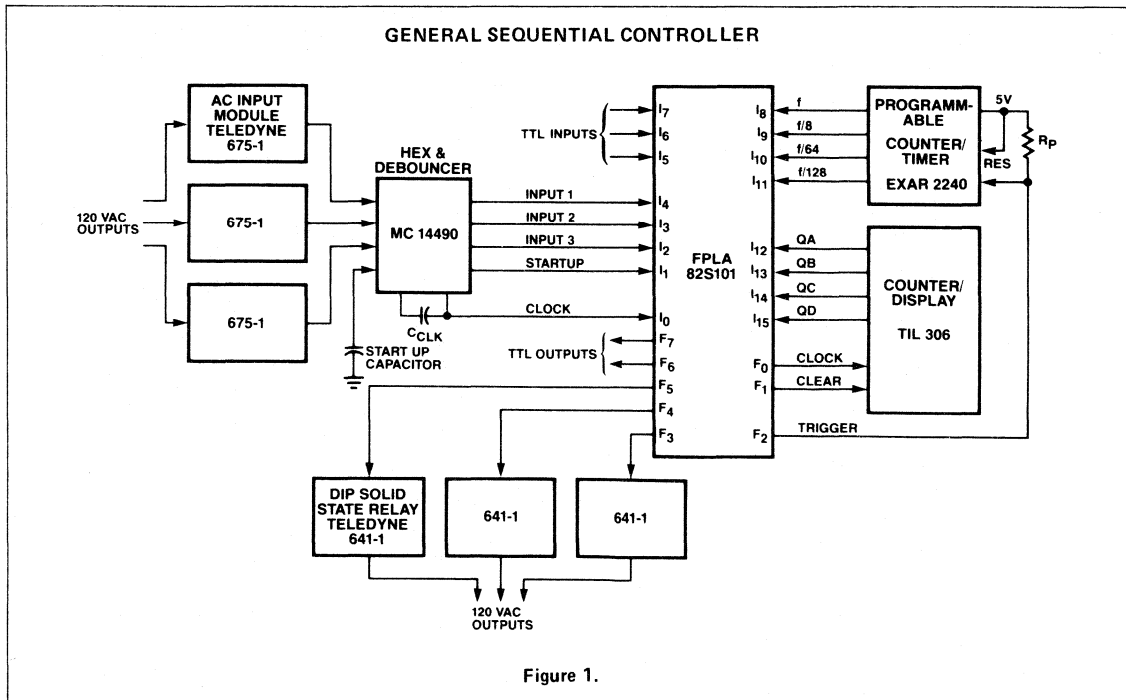

Figure 1.

It is common practice to provide redundant signal paths in today's high reliability military communication systems in order to ensure adequate mission availability. In these systems, it is necessary to monitor the performance of the various subsystems' display status in a concise manner, and provide controls for switching over to standby equipment in either manual or automatic modes. Customarily, a unique System Status and Control Logic Unit (SSCLU) is designed for a system which integrates these control and status functions at a central console. Random T²L Logic, mounted on a rack full of wire wrap boards, is typically used to implement the SSCLU functions. This approach is inherently costly, inflexible, and unreliable.

The introduction of the Field Programmable Logic Array (FPLA) provides a powerful tool which makes possible the general purpose "n" Expandable SSCLU circuit card set. These two unique circuit card types are all that is normally required to realize an SSCLU. The first circuit card type, shown in Figure 1, is referred to as Subsystem Circuit Card. The second, shown in Figure 2, is designated the Summary Circuit Card. One Subsystem Circuit Card is normally required to monitor and configure each of the subsystems making up a total communication system. Thus, a Satellite Communication Terminal can be divided into the

is straightforward. As shown in Figure 1, digital status, configuration and control data, which is normally in the form of contact closures from various subsystem fault sensors, enters the circuit card where it is latched with the exception of the configuration switch feedback signals. The switch feedback is routed directly to the FPLA inputs. The latches are all cleared simultaneously through the reset bus. All inputs to the FPLA have LED state indicators which constantly display the data being fed into it. This feature allows immediate verification of status and facilitates rapid fault isolation. The FPLA scans its input data and generates 3 output data groups based on its micro-program. Its first four outputs activate solid state relays which in turn result in configuration switching of the subsystems equipment. The next two FPLA outputs contain a 2-bit binary code which indicates the subsystem status summary as tabulated in Figure 3. The final two outputs carry a second 2-bit binary code representing the configuration of the subsystem also tabulated in Figure 3.

The SSCLU Summary Circuit Card is illustrated in Figure 2. Its primary purpose is to consolidate and interpret the 2-bit binary status and configuration data from up to 4 Subsystem Circuit Cards. It then generates the outputs based on its micro-program to drive visual and aural system level status and configuration indicators. The inputs to both of its FPLAs are paralleled, and all 16 of them have LED input state indicators. Each FPLA output feeds an open collector lamp driver. Based on the monitoring requirements of the particular system, the outputs of both FPLAs could also be paralleled, resulting in only eight status outputs, but allowing up to 96 product terms to be micro-programmed per Summary Circuit Card.

Figure 1.

following dual redundant subsystems: X-Band Downlink, X-Band Uplink, Tracking, and Up/Down Conversion. Each of these subsystems can normally be monitored and controlled by one Subsystem Circuit Card. Two or more simple subsystems could be accommodated by a single Subsystem Circuit Card, or conversely, two cards could possibly be required to service one complex subsystem. The function of the Subsystem Circuit Card is three-fold. It displays the incoming subsystem status and configuration data, reduces the data to develop configuration and status summary messages, and generates control signals to configure the subsystems. The operation of the Subsystem Circuit Card

Figure 3.

IGNITION TIMING FOR I/C ENGINE USING MULTI-DIMENSIONAL CURVE FIT

The diagram of Figure 1 shows a system for optimizing ignition timing of an internal combustion engine in terms of engine speed, temperature, and manifold vacuum. The greatest contribution to the correct spark advance comes from the speed of the engine. For this measurement two clocks are needed: a constant time base from a crystal oscillator and a full cycle from the output of a finely slotted disc in the distributor.

Next is the vacuum at the intake manifold. This is derived from a pressure transducer and an analog to digital converter.

Only six bits of resolution should be necessary. It would help keep the cost down and the conversion time below the 20 microsecond limit that would be encountered at high engine speeds and with a 360° slotted angular clock source.

A third transducer measuring coolant temperature uses comparators to look at only one warm-up setting and one threshold at which the engine has overheated to the extent it should be shut down.

Finally a strobe, PISTON CLK, is provided for system syn-

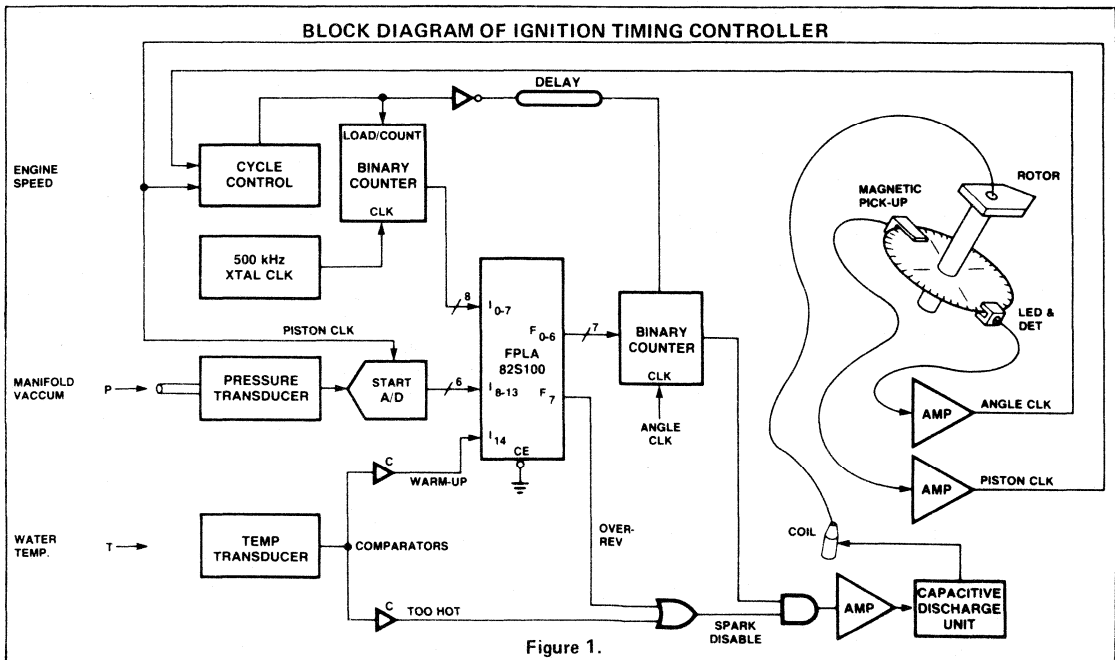

Figure 1.

chronization by adding a magnetic pick-up to the angular clock disc at a point just ahead of the maximum advance angle. This type of sensor would allow us to program for contingency operation in the event dirt fouled the LED source or detector.

FPLA computed spark advance values are loaded into the output counter via a short delay element as soon as the engine speed has been determined. At the same time, the angular clock input is enabled and the counter is incremented to its maximum value. This will trigger a capacitive discharge unit which in turn ignites the mixture in the combustion chamber. A gate has been added to disable the spark under FPLA determined stress conditions such as excessive engine speed.

Although there are only 48 terms available in the 82S100, this should be more than adequate resolution for an automotive ignition. Effective resolution of input and output

values, however, are not limited to one part in 48. Because of functional non-linearities and the involvement of more than one variable input dimension, there may be numerous paths to any of the 48 solutions. An increasing input slope will have a decreasing effect on an output and lower order bits can be programmed to a "Don't Care" state. Furthermore, as one input parameter becomes more dominant in determining output, the significance of the other may be diminished with the same technique.

While working out hypothetical solutions, it became apparent that it is preferable to keep input values in direct proportion to output. This way fewer bits are needed to define a new range where a new set of "Don't Care" positions can be programmed. This rule was violated only in the tachometer circuit in favor of response time. Here, several bit positions were necessary to determine the small time interval that represents an over-revved engine.

USING FPLAs AND SRGs TO STORE HUFFMAN CODES

In modern serial data transmission systems, the thrupt of a communications channel can be improved by using data compression techniques to reduce data redundancies. One method, developed by Huffman, encodes the set of symbols required to convey various messages into a variable length code set. The frequency of use of each symbol dictates the length of the code that is to be associated with that symbol.

Typically, variable length codes are stored in fixed length read only memory look-up tables with a delimiter bit to allow stripping away the extraneous bits stored with the codes. The original uncompressed symbols are then used to address the look-up table as each symbol occurs in the message. As each code is retrieved from the table, some special equipment must remove extraneous bits and compact the codes into byte size chunks for processing by a device such as a USART.

The circuit described here shows an alternative method of storing, retrieving and compacting variable length Huffman codes. This method uses some of the properties of Huffman codes and the properties of maximal length shift register generators (SRGs) to implement an addressable, variable length, storage device.

A typical but fictitious Huffman code set of 34 codes used to demonstrate the circuit implementation is shown in Figure 1. The codes, as shown, must be transmitted left-most bit first. The reason for this leads to a very important property of Huffman codes: no code may be coded in such a way to appear, digit for digit, as the first part of any other code of greater length. This characteristic allows a receiver

TYPICAL HUFFMAN CODE SET

| SYMBOL # | LENGTH | CODE | SYMBOL # | LENGTH | CODE |
|----------|--------|---------|----------|--------|----------|
| 0 | 2 | 00 | 17 | 7 | 0100111 |

Figure 1.

to uniquely decode an incoming message made up of a continuous stream of serial data by knowing only the code set and the starting point of the message. Two other properties of Huffman codes concern each possible sequence of digits of length one less than the longest code in the set, so that they must 1) be used either as a code, or must have one of its prefixes used as a code and that 2) every binary Huffman code set must have exactly two codes of length L, where L is the length of the longest code in the set.

Linear sequential shift register generators (SRGs) are a special class of non-binary counters whose operation can be described and analyzed by application of linear algebra techniques. These counters are made up of a number of delay stages which, except for the first stage, each receive as their input the output from the previous stage (just as

ordinary shift registers). The input to the first stage is derived from a Modulo-2 addition (EX-or function) of selected outputs of the delay stages. These counters repeatedly cycle through a defined sequence of states that are a function of the feedback used. The SRGs used here have a maximal length sequence of states, and thus generate all 2^k-1 states required for Huffman code sets, where k is the number of delay stages. The "all-zero" state is always missing in these counters since the exclusive-or feedback would cause the counter to remain in this state forever.

Since the longest code in Figure 1 is 8 bits long, an 8 stage maximal length SRG will be used in the generation of the code set, since only the last two codes are this long. The other codes in the set will be made up from combinations of less than 8 digits. Every combination of less than 8 digits (2^n , where $n = 1, 2, 3, 4, 5, 6, 7$) is available from an 8 stage maximal length SRG.

The maximal length SRG used here is defined by $1(X) =$

$X^8 + X^6 + X^5 + X^4 + 1$, which is the characteristic polynomial of an SRG with the outputs of the 8th, 4th, 3rd, and 2nd stages summed Modulo-2 and fed back to the 0th stage, the input. The connections for any SRG can be found directly from the characteristic polynomial associated with that SRG by subtracting from the order k of the polynomial each power of X present in the polynomial.

The selected SRG will produce all the sequences necessary to make up the code set; so all that is needed is circuitry to allow addressing the SRG to access the codes. FPLAs are ideally suited for this application since they can be used as programmable address decoders. This can be accomplished by using code addresses in combination with the outputs of each delay stage of the SRG as inputs to the FPLA.

In the circuit diagram of Figure 2, the SRG (8,4,3,2,0) is made up of U3, U4, U8-A, U8-B, and U8-C and is normally sequencing through its 255 states. An input code address latch is provided by U1, which could be an output port of a

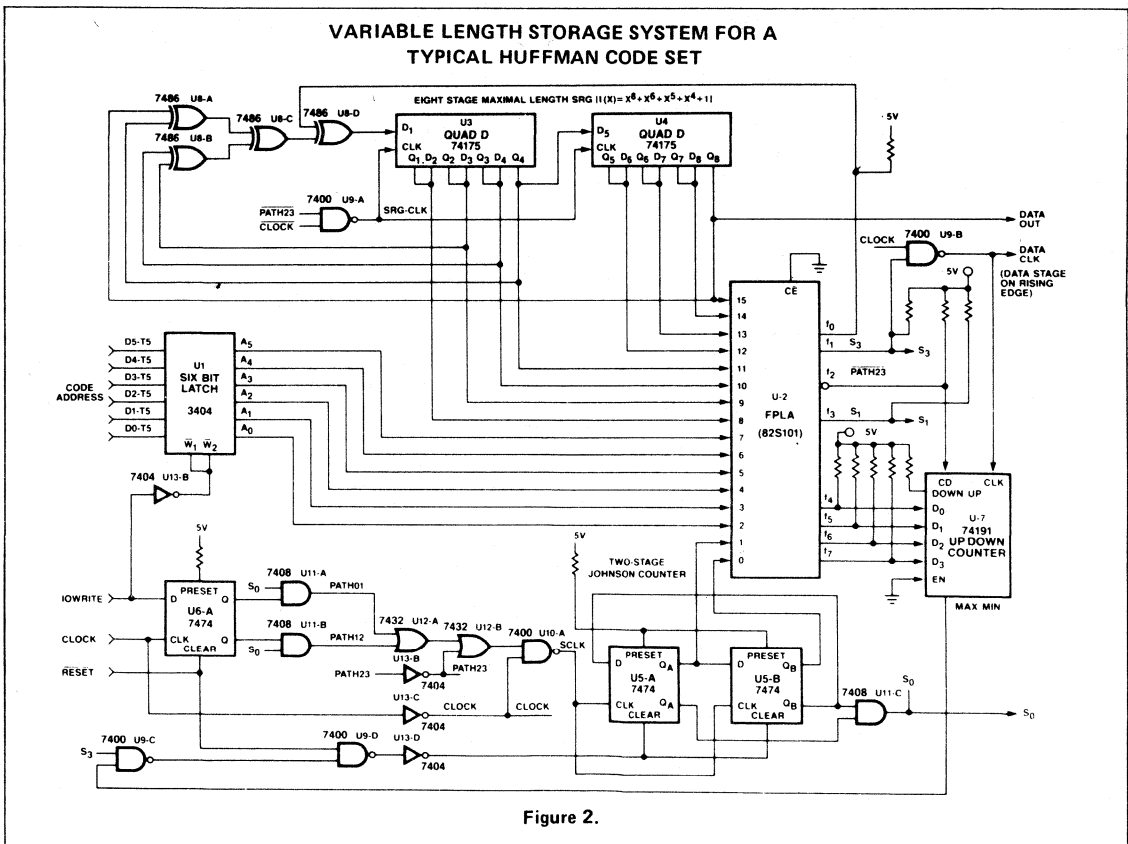

Figure 2.

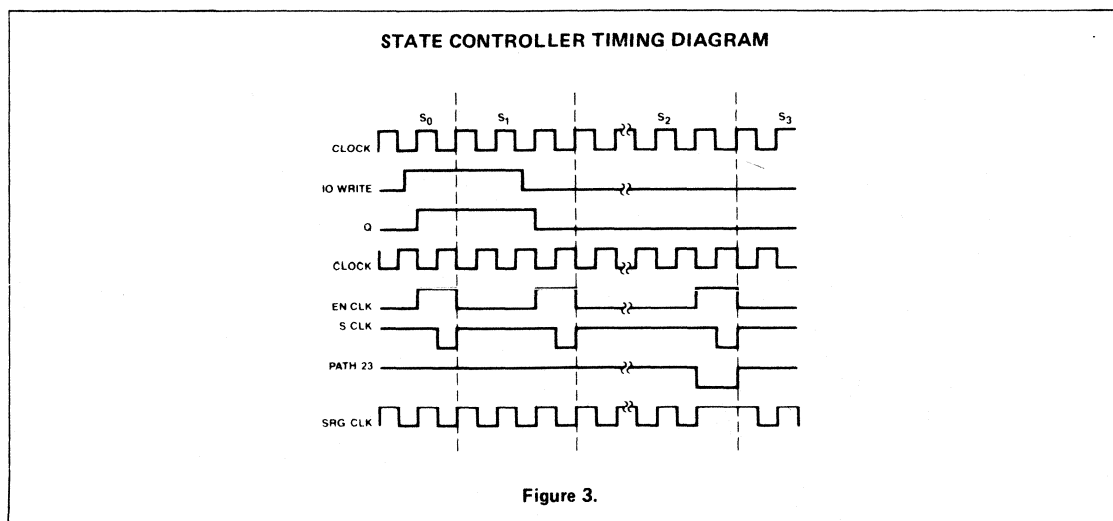

processor controlled system where the circuitry described here serves as a peripheral. An indication of the latch availability is provided with the output S_0 . The FPLA is used for address decoding and some state control functions. The D flip-flop, U6-A, serves to re-clock the "IOWRITE" signal for use by the state controller, which is implemented with a 2-stage Johnson counter by U-5. The up/down counter U-7 is used in conjunction with the FPLA to provide the proper number of data out clocks for each code addressed. With reference to Figure 3, initially the system is in state S_0 , and is waiting to be addressed. The S_0 output could be used in either an interrupt driven or a polled system to determine when the circuit is ready for the next code address. When the 6 bit input address latch is serviced the "IOWRITE" signal goes HIGH and is latched by U6-A. This causes the state controller to advance to S_1 on the next system clock. State S_1 is a do nothing state that is just waiting for "IOWRITE" to return back to a logic "0" condition, indicating that the address in the input latch is not stable. When "IOWRITE" goes to logic "0", \bar{Q} of U6-A will go HIGH on the next system clock, enabling the state counter to advance to S_2 on the next clock to find the code that has been addressed.

Since the SRG is free running through its 255 states, the Q_8 through Q_1 inputs to the FPLA are continuously changing. The FPLA is programmed in such a way that it looks for a match between the desired code (the input latch address) and the condition of the last L bits of the SRG, where L is

the length of the desired code. For example, as tabulated in Figure 4, the address of code #0 is $\bar{A}_0\bar{A}_1\bar{A}_2\bar{A}_3\bar{A}_4\bar{A}_5$ and code #0 is 00, so the FPLA contains the Product Term ($\bar{A}_0\bar{A}_1\bar{A}_2\bar{A}_3\bar{A}_4\bar{A}_5\bar{O}_8\bar{O}_7\bar{O}_A\bar{O}_B$). The Q_A and Q_B factors serve to ensure that this condition is met only in S_2 . When a match is found, the FPLA outputs $\bar{Path}23$ and a code length word of $f_4, f_5, f_6,$ and f_7 . The signal $\bar{Path}23$ does three things: 1) loads the code length word into the up/down counter, 2) disables the clock to the SRG so the desired code is held in the SRG, 3) enables the state counter to advance to S_3 . With the system in S_3 , the data clock is enabled and the SRG clock is re-enabled. The addressed code can now be collected by a device such as a high speed synchronous receiver tied to the data and data clock lines as the data is shifted out of the SRG in S_3 . Notice that the data clock is also connected to the clock input of the up/down counter. This will allow shifting out the L bits corresponding to the length of the code addressed. When all bits of the code have been shifted out the max/min signal from the up/down counter will go HIGH and reset the state counter back to S_0 to wait for the next code address.

The access time for the codes is directly proportional to the code length since the combination of bits to make the shorter codes occur more often in the 255 bit long SRG sequence.

Longer codes could be accommodated with the use of longer SRGs. Longer code sets could also be implemented using this method by using more FPLAs.

FPLA PROGRAM TABLE FOR HUFFMAN CODE SET AND STATE CONTROL FUNCTIONS

Figure 4.

Judicious partitioning of a set of input variables allows an FPLA to easily generate a 4-bit output N, where N equals the number of one's in the 8-bit input I_N . The FPLA Program Table implementing this function is shown in Figure 1, in which positive logic is assumed. The correct output appears after two passes have occurred in the array. A first

pass is used to calculate two interim values R_L and R_H . They are partial expressions of the number of one's over two 4-bit sections of input I_N called I_L and I_H respectively. R_L and R_H are fed back to inputs 12 through 15 in the input section, and together with I_N generate the final result N in a second array pass through product terms 20-33.

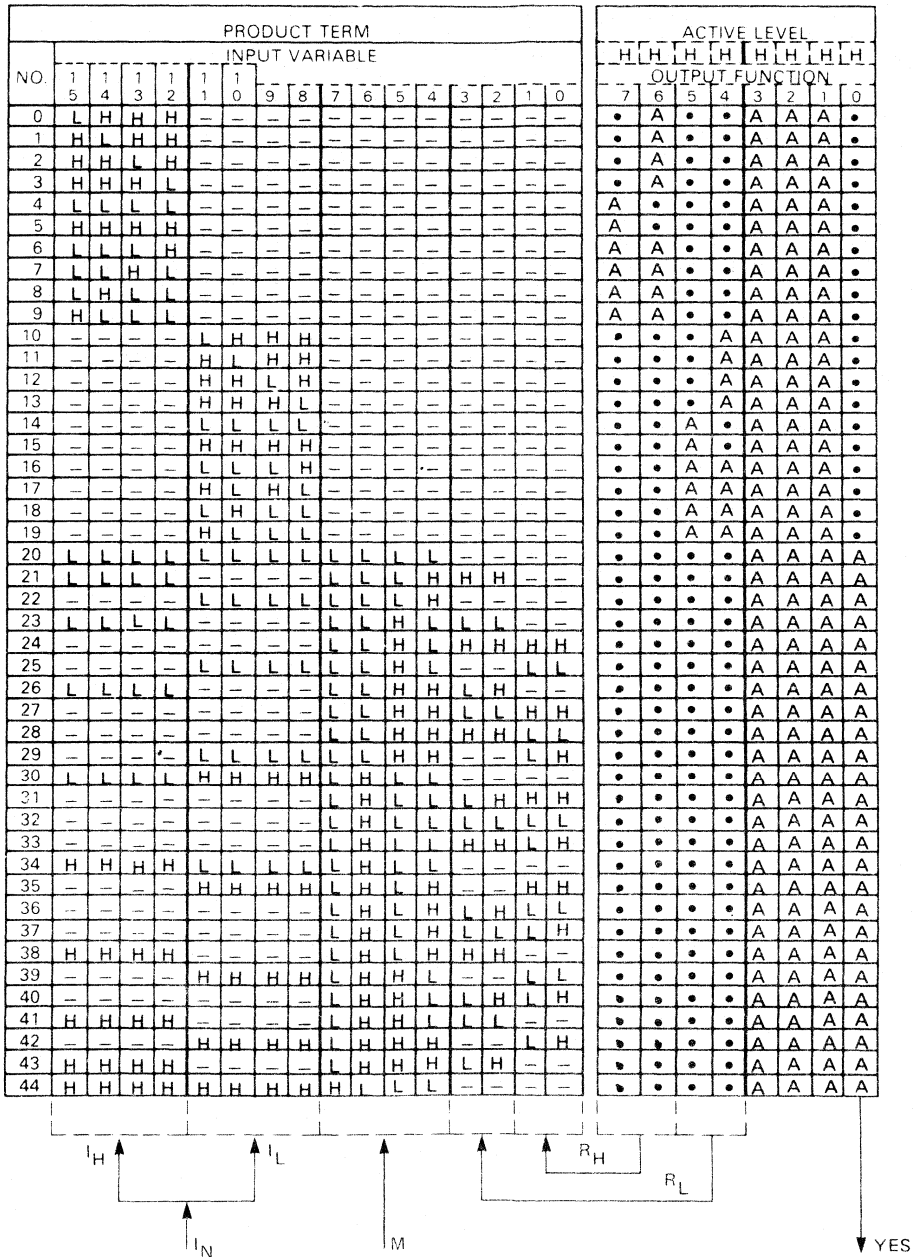

Figure 4.

A shift/logic unit (SLU) with FPLA's can provide high-speed field and bit manipulations for data packing in fast I/O controllers, and minicomputers used in number crunching applications. The block diagram of Figure 1 illustrates the SLU environment, consisting of a multi-port register file, such as Signetics' 82S112, and a control sequencer which could also be designed with additional FPLA's.

Any two registers, not necessarily different, can be read on the A and B ports and supplied as left and right operands to the SLU. The result, Z, can be returned to any register in the register file.

The SLU is composed of 4 FPLA pairs programmed as SLU1 and SLU2, for a total of 8 FPLA's. These are connected as shown in Figure 2 to implement the overall SLU instruction set tabulated in Figure 3.

The SLU and register file are 16 bits wide, and are both controlled by an 8-bit word from the control sequencer. The control word, mapped in Figure 4, commands the SLU to perform three basic operations which are selected by mode bits M0 and M1. These are:

Shift-type bits, S_R and S_L, control execution of circular or end-off shift. These bits are ignored in other than shift operation. Select bits S₀~3 supply the shift amount (0 thru 15) in shift modes, or determine one of 16 boolean functions in logic mode. The SLU instruction set has been partitioned in two distinct logic equation sets incorporated in two FPLA types designated respectively SLU1 and SLU2. The

I/O assignment for each FPLA type is defined in Figure 5. The program table for each FPLA can be derived by implementing the logic equation sets tabulated Figures 6 and 7 respectively. Both figures express in a short-hand notation (similar to a multiplication table) the logic equations for SLU1 and SLU2, involving their inputs, outputs, and number of Product Terms necessary to implement each function group. Unlisted input combinations are not allowed, and can be treated as Don't Care during minimization. For example, the logic equation for SLU1 output X₀ is obtained by minimizing with a Karnaugh map all logic products tabulated in Figure 6. These are formed by plotting all entries in column X₀ of the FPLA outputs in appropriate squares corresponding to the logic value of the FPLA inputs. This procedure is illustrated in the map of Figure 8,

in which all unlisted input combinations have been assigned a Don't Care because of input constraints.

After minimizing all adjacent squares, output X₀ is given by the sum of 12 product terms as follows:

$$X_0 = B_0(\bar{M}_1 M_0) + B_0(M_1 \bar{S}_1 \bar{S}_0) + B_{-1}(M_1 \bar{M}_0 \bar{S} \bar{S}_1 S_0) + B_{-2}(M_1 \bar{M}_0 S R S_1 \bar{S}_0) + B_{-3}(M_1 \bar{M}_0 S R S_1 S_0) + B_1(M_1 M_0 \bar{S}_1 S_0) + B_2(M_1 M_0 S_1 \bar{S}_0) + B_3(M_1 M_0 S_1 S_0) + (B_0 + B_1 + B_2 + B_3) \bar{M}_1 \bar{M}_0$$

Outputs X_{1,3} are treated the same way, and we obtain a total of 36 product terms which are tabulated in the FPLA Program Table for SLU1 in Figure 9. The Program Table for SLU2 is derived by following a similar procedure.

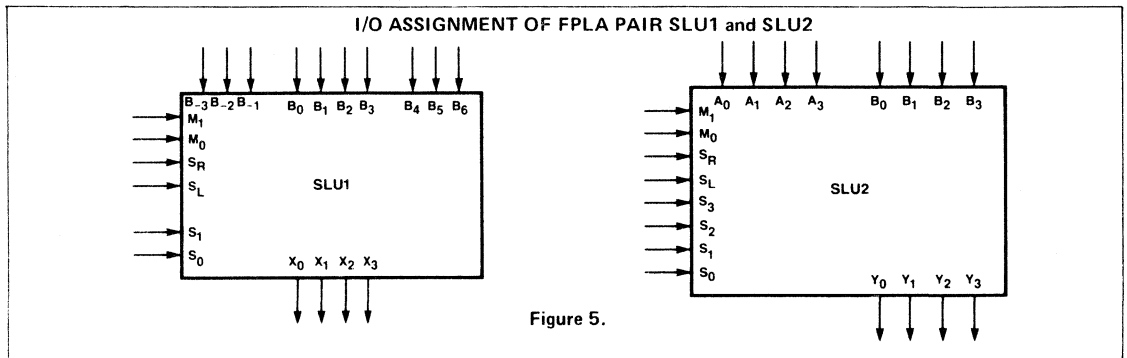

Figure 5.

Figure 9.

Two or more dissimilar pieces of digitally tuned communications equipment can be operated with a single bandswitch using an FPLA code converter. For example, two transceivers may be simultaneously bandswitched using the code from one transceiver. In another case, a power amplifier requiring a cyclic bandswitching code may be operated from a transceiver supplying a BCD code.

In an actual case a single FPLA is capable of replacing 10 IC's and 36 pull-up resistors.

The circuit in Figure 1 illustrates how to obtain a 5-wire code, such as used for positioning a power amplifier tuning turret, from a transceiver.

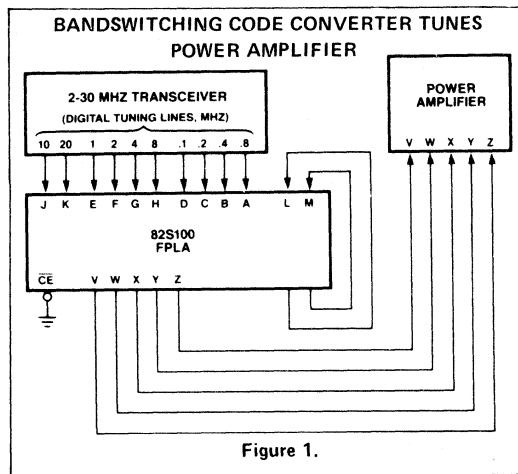

Figure 1.

The power amplifier's bandswitching code is tabulated in Figure 2. The 100KHz BCD tuning lines can be encoded in the FPLA for the X.0 to X.4 MHz and X.5 to X.9 MHz ranges according to the table in Figure 3. Two additional functions, L and M, are fed back into the FPLA to be encoded with the other BCD lines, and are defined as follows:

$$X.0 \text{ to } X.4 \text{ MHz} : L = \overline{AB} + \overline{BCD}$$

$$X.5 \text{ to } X.9 \text{ MHz} : M = A + BC + BD$$

If the other relevant BCD tuning lines are labelled E, F, G, H, J, K, for 1, 2, 3, 4, 8, 10, and 20 MHz lines respectively, a Boolean expression including the two 100KHz functions L and M can be written and encoded into the FPLA for each of the 5 desired output functions. For example, line Y of the 5-wire code is represented:

$$Y = \overline{EFGHJKM} + EFGHJKL + EFGHJKM + \overline{EFGHJK} + \overline{EFGHJK} + EFGHJK + \overline{EFGHJK} + EFGHJK + \overline{EFGHJK} + \overline{EFGHJK} + EFGHJK + \overline{EFGHJK} + \overline{EFGHJK} + \overline{EFGHJK}$$

The entire equation set can be programmed in a single FPLA using 12 inputs, 7 outputs, and 35 Product Terms.

Figure 3.

RF-CHANNEL CONTROL SELECTOR

14

The circuit shown in Figure 1 is used in the output scheduling portion of a digital controller subsystem that generates RF signals for testing receiver antennas in a multipurpose electromagnetic environment simulator.

In this system a channel match signal is used to determine available channels that can produce a signal. One channel match, or all eight channel matches can occur simultaneously. Therefore, the channel match signals and a 5-bit assignment code are used to address an FPLA programmed to resolve a preassigned priority.

The assignment code is used to control the selection of an RF channel in which a signal can be generated. The assignment parameter or code is intended to ensure that a particular signal will always appear on a specific channel when desired. Three levels of assignment priorities are used.

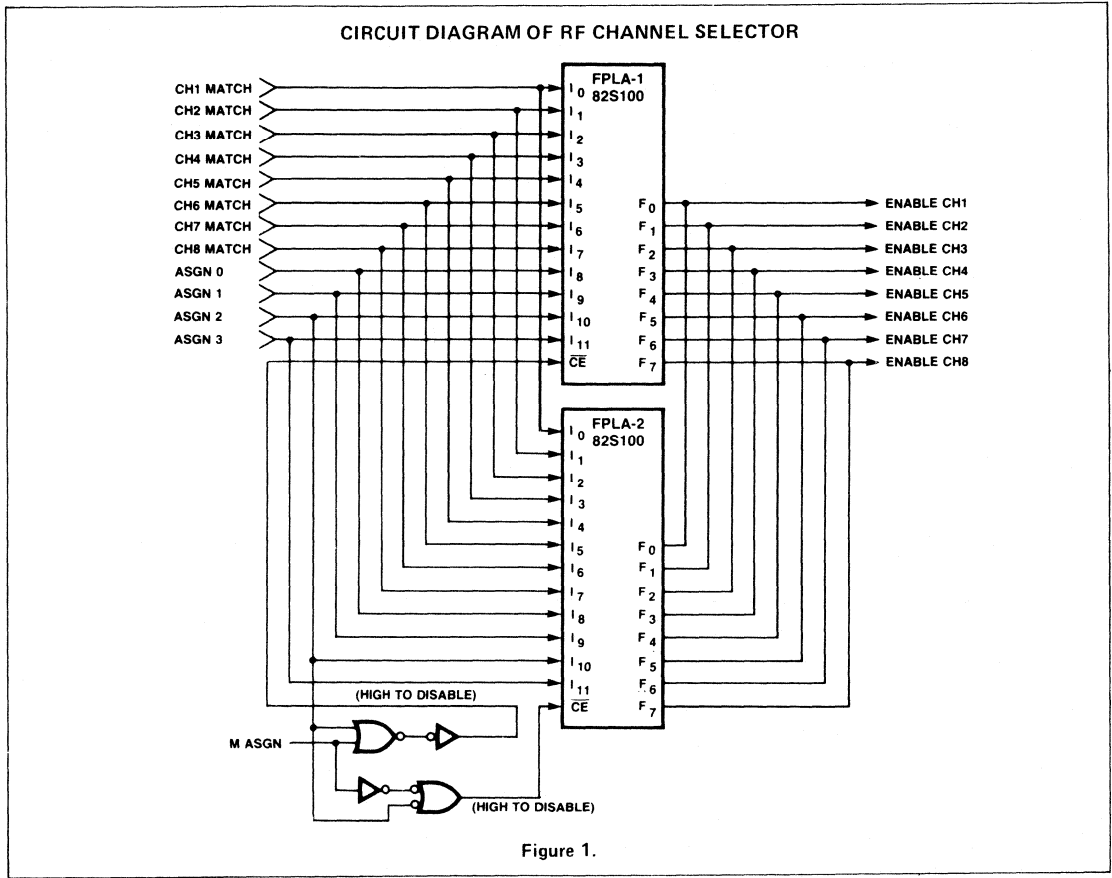

LEVEL 1 – No assignment; selects first available channel, beginning with lowest number channels.

LEVEL 2 – Preferential assignment; selects first available channel starting with the channel given in assignment code.

LEVEL 3 – Mandatory assignment – Selects only the channel given in assignment parameter.

The assignment parameter is a 5-bit code which is used as tabulated in Figure 2. The circuit in Figure 1 implements a matrix function for priority Levels 1 and 2. These are resident in 2 Tri-state FPLA's programmed respectively with sub-tables A and B, shown respectively in Figures 3 and 4. Both FPLAs are operated in parallel and controlled by ! Q_0 , the ASGN 2 signal, or by the M ASGN bit via their \overline{CE} input.

Priority Level 3 is a mandatory assignment and the FPLA's are disabled. The assignment code (AS0-AS3) is decoded and, provided the channel match for the decoded channel is present, the EN CH signal is then generated.

CHANNEL CODE ASSIGNMENT

| CASE | (msb) | | | (lsb) | | | CHANNEL |
|------|---------|-----|-----|-------|-----|-----|---------|
| | M ASGN* | AS3 | AS2 | AS1 | AS0 | | |
| 1 | 0 | 0 | 0 | 0 | 0 | Any | |
| 2 | M | 0 | 0 | 0 | 1 | 1 | |
| 3 | M | 0 | 0 | 1 | 0 | 2 | |
| 4 | M | 0 | 0 | 1 | 1 | 3 | |

Figure 4.

The circuit shown in Figure 1 filters asynchronous serial data as it enter an asynchronous receiver. These devices, often used to deserialize Teletype signals, typically sample each bit of a character only once, in the middle of the bit time.

If a noise pulse, perhaps caused by dirty Teletype distributor, occurs at a sample time, an error results. Low-pass filtering may remove the noise, but may also cause the receiver to start late and erratically since the leading edge of the start bit, used for a time reference is blurred.

A better solution to this problem can be obtained by using an FPLA to implement a 5-out-of-9 majority function from 9 samples of each bit stored in a 16-bit shift register. Since asynchronous receivers typically require a clock at 16 times the bit rate, this is used for the shift register also. For a clean start, an additional input is used to select between a single sample and the majority function. It is controlled by a one-shot which, when fired by the start bit, substitutes the majority function for the middle sample during the rest of the character.

Since a straightforward implementation of the majority function would require 6435 product terms, a 2 level approach is used. The inputs are grouped into triplets (I₇₋₉, I₁₀₋₁₂, and I₁₃₋₁₅). The 1-out-of-3 functions (F₀, F₁, and F₂, respectively) and 2-out-of-3 functions (F₃, F₄, and F₅, respectively) are generated for each triplet. These are fed back to unused inputs and the complete function obtained from output F₆. The complete equation set is tabulated in Fig. 2, which indicates that there are 16 inputs, 29 product terms, and 7 outputs. These are programmed in the FPLA Program Table of Fig. 3.

Other shift registers and receivers will work just as well as those shown. And, if a smaller number of samples is used, say for 4-out-of-8, set I₂ = I₁₅ = "1" in the FPLA equations.

The samples should be distributed nearly evenly across the shift register, but may be adjusted to accommodate known signal characteristics such as uncertain bit-boundary locations. The concept can be extended to other systems, such as communication equipment for telephone links etc., even to include nonuniform input weighting to solve a particular noise problem by modifying the FPLA program.

LOGIC EQUATION SET RESIDENT IN THE FPLA

$$\begin{aligned}
 I_0 = F_0 &= \overline{I_7} \overline{I_8} \overline{I_9} = I_7 + I_8 + I_9 \\
 I_1 = F_1 &= \overline{I_{10}} \overline{I_{11}} \overline{I_{12}} = I_{10} + I_{11} + I_{12} \\
 I_2 = F_2 &= \overline{I_{13}} \overline{I_{14}} \overline{I_{15}} = I_{13} + I_{14} + I_{15} \\
 I_3 = F_3 &= I_7 I_8 + I_7 I_9 + I_8 I_9 \\
 I_4 = F_4 &= I_{10} I_{11} + I_{10} I_{12} + I_{11} I_{12} \\
 I_5 = F_5 &= I_{13} I_{14} + I_{13} I_{15} + I_{14} I_{15} \\
 F_6 &= I_6 I_0 I_1 I_3 I_4 I_5 + I_6 I_0 I_4 I_5 + I_6 I_0 I_{10} I_{11} I_{12} I_2 + I_6 I_3 I_{13} I_{14} I_{15} + I_6 I_3 I_1 I_5 \\
 &\quad + I_6 I_3 I_4 I_2 + I_6 I_3 I_{10} I_{11} I_{12} + I_6 I_7 I_8 I_9 I_5 + I_6 I_7 I_8 I_9 I_1 I_2 + I_6 I_7 I_8 I_9 I_4 + \overline{I_6} I_7
 \end{aligned}$$

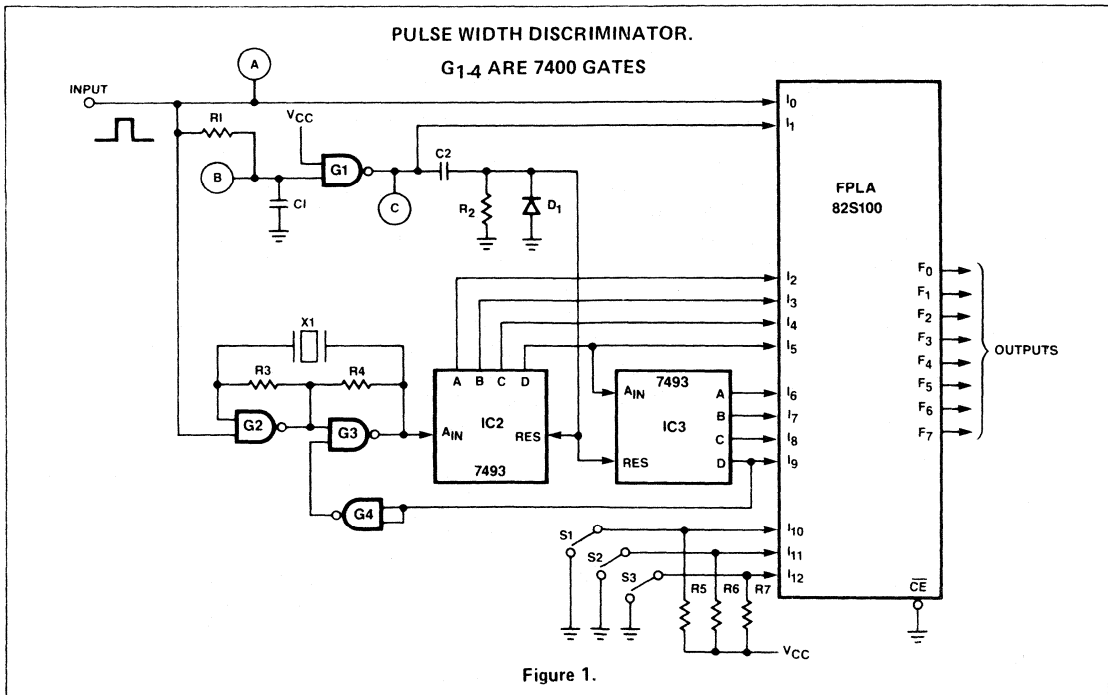

Figure 3.

The circuit shown in Figure 1 generates an output pulse on one of eight channels whenever the duration of an input pulse falls within the preselected window corresponding to that channel.

The input pulse is applied to input I_0 of the 82S100. It also drives network $R_1 C_1$, whose exponentially rising and falling output voltage is squared up by G_1 to look like a $1/4 \mu\text{s}$ delayed, inverted version of the input pulse, and is applied to input I_1 of the FPLA. The FPLA forms the logical product $I_0 \cdot I_1$ (see timing diagram, Figure 2) as part of each of its 48 product terms, to mark the trailing edge of the input pulse. Simultaneously, the input pulse turns on crystal controlled multivibrator G_2 - G_3 , whose pulse output is accumulated by counters IC_2 and IC_3 . Thus as long as the input pulse is high, FPLA inputs I_2 through I_9 will indicate elapsed microseconds. The FPLA is programmed with successive counts and selector switch settings as shown in the Program Table of Figure 3, so that when the trailing edge signal $\overline{I_0} \cdot \overline{I_1}$ is coincident with a specific count and switch setting, the coincidence pulse will appear on the appropriate output line. Network $R_2 C_2$ differentiates the trailing edge of the delayed input pulse to provide a reset pulse for the counter. The MSB on counter IC_3 is inverted by G_4 to cage multivibrator G_2 - G_3 whenever the counter overranges (i.e., goes to its upper half-range). This avoids

the ambiguity created when long extraneous noise pulses drive the multivibrator for several full counting cycles (256n counts) past any specific desired count. If the pulse transmission line is known to be free of noise pulses, this circuit can be deleted, doubling the count capacity of the counter. With the given program, the FPLA will detect input pulses in the pulse width windows 1 to $2\mu\text{s}$, 2 to $3\mu\text{s}$, 3 to $4\mu\text{s}$,, 48 to $49\mu\text{s}$. By programming the FPLA so that count bits I_2 through I_9 range from 49 (LLHLLLLH) through 96 (LHHLLLLL) the windows 49 to $50\mu\text{s}$,, 96 to $97\mu\text{s}$ can be detected instead. Thus with the overrange lock-out by G_4 , up to 127 separate pulse widths can be detected by some change in the programming; without the overrange lock-out implemented this number increases to 255.

This circuit can be used to control multi-function machines in several locations throughout a small plant by using the power mains as a pulse transmission line. The system is relatively noise-immune because of the narrow tolerances on the control pulse-widths. The output pulses F_0 through F_7 can be used to control latching solid state A.C. relays, SCRs for motor phase-control, stepper motors, and can even relay audio information by toggling a flip-flop whose filtered, buffered output is applied to a speaker.

of the control sequence is shown in Figure 3. The system interface is through the following signals:

Clock: 2 MHz TTL square wave.

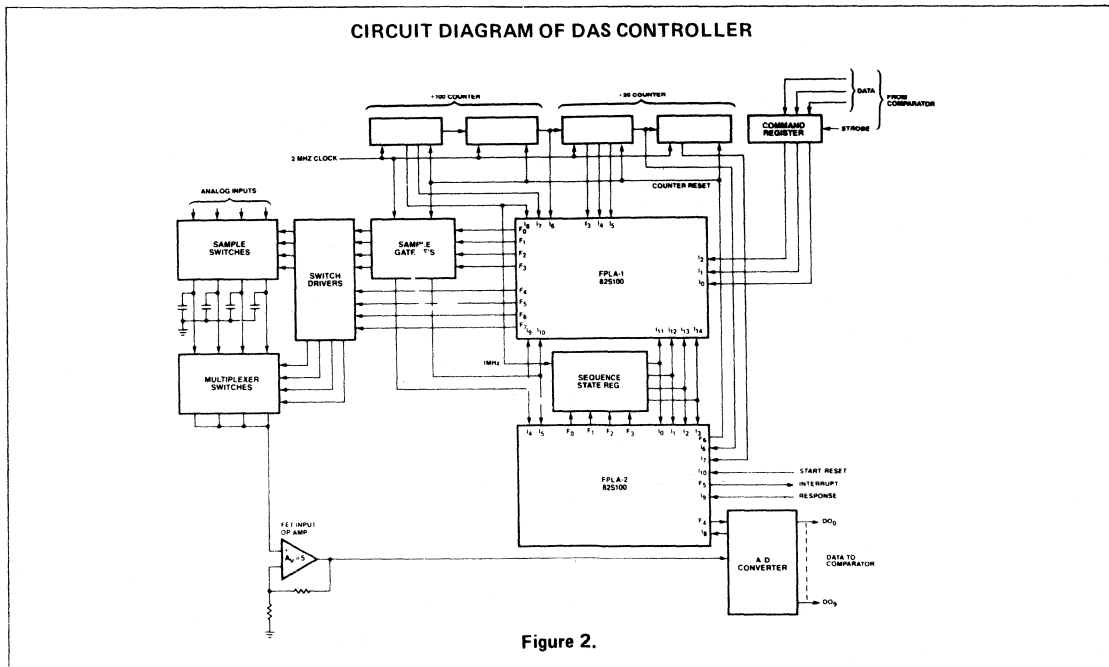

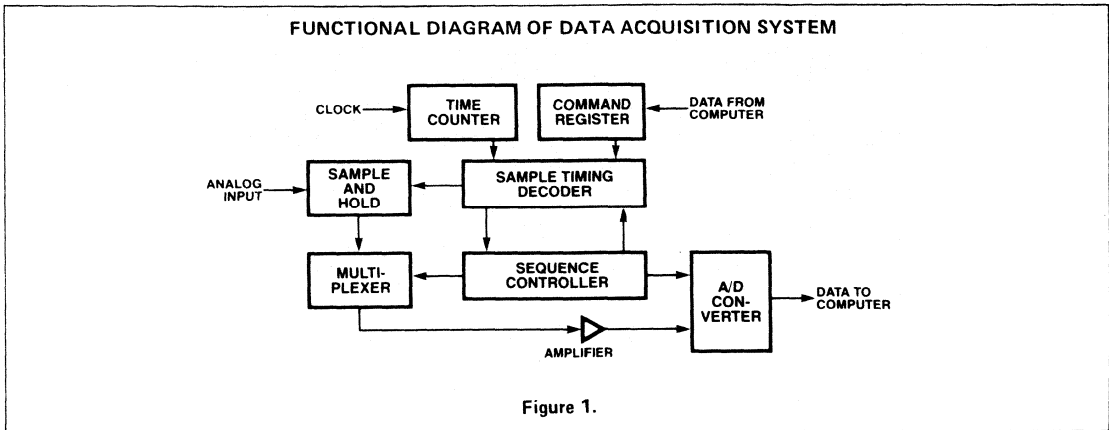

Analog Inputs: $F_C = 100$ KHz, 30 KHz Bandwidth Amplitude: ± 1 volt.

Data from Computer: 3 bits of command data and a strobe. The strobe is pulsed to load the command register after the computer has responded to all four interrupts in an interval.

Data to Computer: The A/D Converter provides 10 bits of parallel data in TTL compatible levels.

Interrupt: Low TTL level active while the controller has valid data for the computer to read.

Response to Interrupt: A 2 μ sec active-low pulse after the computer has read the A/D data.

FLOWCHART OF A/D CONVERSION AND DATA INTERFACE SEQUENCE

| 0-3: Four sequence state bits for next step. |
| 4: A/D Converter start pulse-high logic level for 1 µsec. |
| 5: Interrupt to computer. |
| 6: Reset signal to counter and Sample Gates |

Figure 5.

One application where the FPLA proves ideal is in the control for time-division multiplexing a data channel among a number of data sources according to a fixed schedule, or a small number of selectable fixed schedules.

In the system shown in Figure 1 there are two identical instruments providing data words upon demand. The proportion of the channel capacity allocated to each data source depends on the frequency with which that information is needed for the eventual data evaluation process. In this case there are three different formats which may be selected, depending on the currently available channel capacity, which requires skewing the ideal data word mix to neatly fit the aggregate bit rate. A further variation allows the choice of ignoring one of the two instruments, and devote the entire data output to the other instrument to allow higher resolution measurements to be performed. These functions are summarized in the Major Frame logic truth-

table of Figure 2, and incorporated in two FPLAs programmed as in Figures 3 and 4.

Each half-second increment in the format represents one complete measurement cycle for the instrument. Additional FPLAs can be used to implement a Minor Frame logic function for decoding time increments within that half-second interval to flag the start of new operating modes (zero-check, calibrate, gain-range, sweep, etc.), initiate old converter sequences, etc.

The outputs of the FPLAs for both Major and Minor logic decoding functions are logically ANDed together to produce the actual enable signals which connect a given data source to the output bus. This output bus then feeds the input of a first-in/first-out memory to smooth the data flow for application to the uniform-rate synchronous data channel. Applied to an actual working design, the two FPLAs for the Major Frame logic replaced 11 MSI and SSI logic packages.

Figure 4.

Until now designers of ATC (Air Traffic Control) transponder encoders have had little choice other than stacking up numerous stages of shift registers and banks of gates, or go the route of custom LSI. The former choice involves close to two dozen chips, while the second entails a large initial expense for masks. The design of Figure 1 uses an FPLA to solve the problem of converting large amounts (25 lines total) of parallel data into unique combinations of serial bit streams using only six commercially available chips. While the full capability of the FPLA's is not utilized, the design represents considerable savings over previous options, and with only slight modifications can be used in other parallel to serial data conversion applications.

With reference to Figure 1, the start command resets A4. The outputs of A4 start the external clock and allow counters A2 and A5 to toggle. A2 and A5 count until maximum count (19) is decoded by A1, which in turn sets A4, thereby stopping the cycle and resetting the counters. During the first 16 clock pulses, either the Mode-A or Mode-C programming is outputted from A3 or A6 respectively, depending on the state of the MODE CONTROL as gated through A7, A8 and A9. The special Mode-A IDENT pulse is decoded on the eighteenth (18th) clock pulse and enabled all through gates A10 and A11. A12 gates the output with the clock to eliminate ripple-through spikes and race problems.

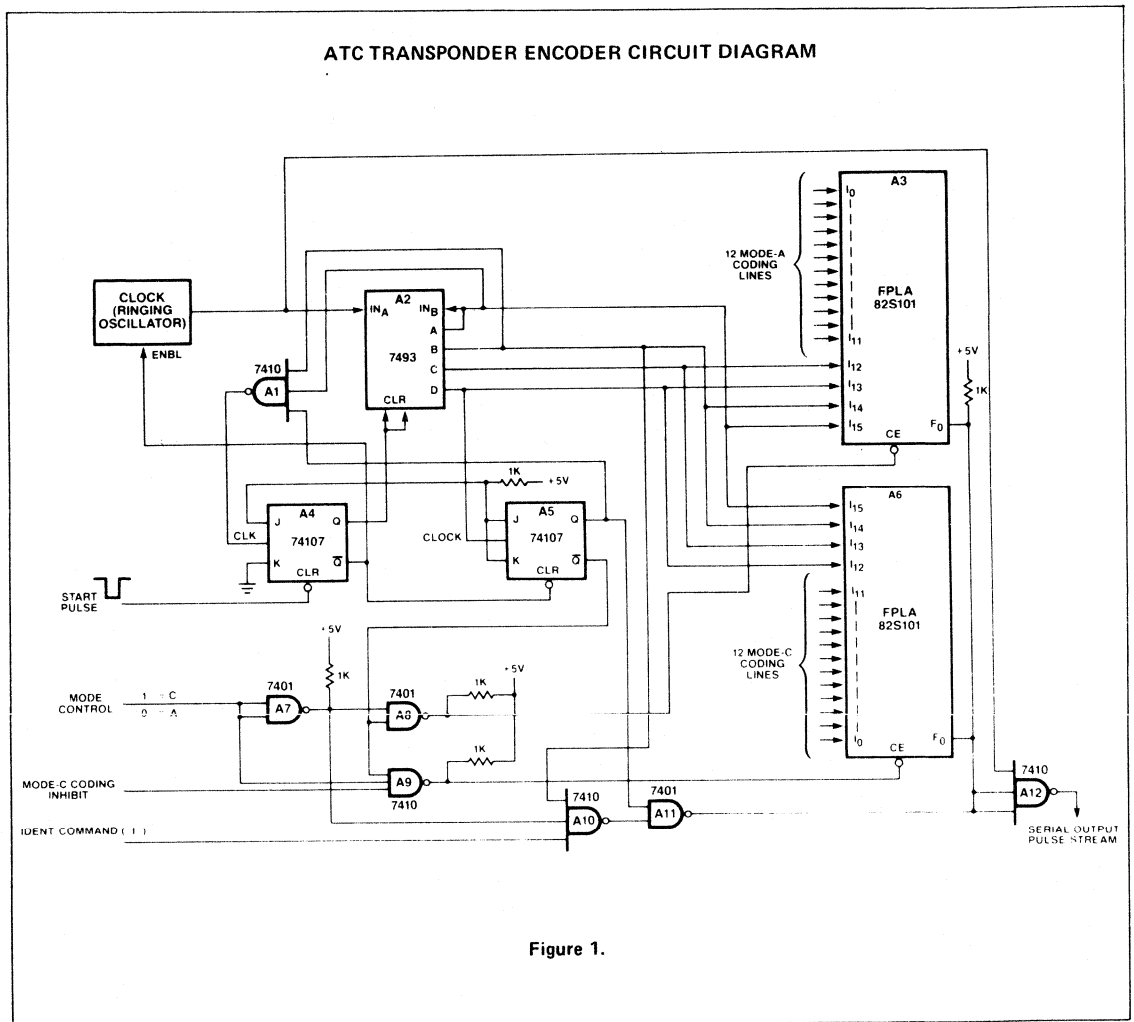

Figure 1.

In many applications it is necessary to have multi channel two way radiotelephone for mobile communications. However, in emergency situations it is important to be able to change channels rather quickly, especially when the transceiver is mounted in a vehicle where the driver cannot look at the radio channel selector switch and the driveway at the same time. This situation is analogous to the car radio stations. Channel selection can be made easier by incorporating in the transceiver a Frequency Synthesizer with a Field Programmable Logic Array as a Channel Memory, in which the channels are programmed digitally and are selected by a keyboard that has the channels designations JJ, JL, YL, . . . etc.

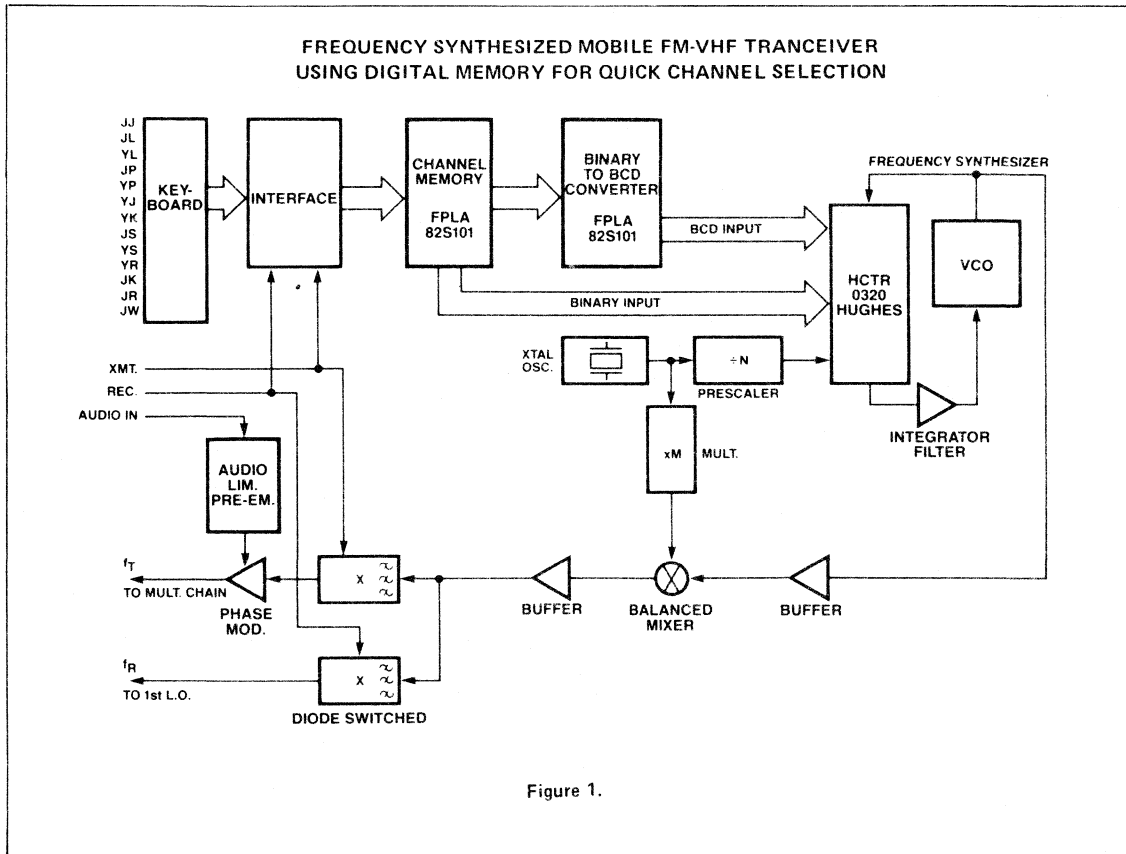

The block diagram of Figure 1 shows a Phase-Locked Channel Selector Synthesizer using a Hughes HCTRO320 Frequency Synthesizer integrated circuit operating at low frequencies (1-3 MHz), together with a Voltage Controlled Oscillator (VCO) and a low pass filter for closing the loop.

The HCTRO320 chip has a programmable counter/divider,

with BCD and binary inputs, which sets the output frequency to an exact multiple of the reference frequency. The reference frequency is generated by a stable crystal controlled oscillator and divided down by a prescaler (counter/divider) for supplying the 30 KHz channel spacing necessary for the VHF band.

An 82S101 FPLA programmed with different settings of the programmable counter fixes the channel frequencies, and is addressed by a keyboard that selects a channel by pressing one of its keys. Part of the binary output of this FPLA is used to set the programmable counter in the HCTRO320 chip. A second 82S101 FPLA is used as an optional binary to BCD converter for addressing the BCD inputs of the programmable counter in the Frequency Synthesizer chip.

An interface is placed between the keyboard and the FPLA Channel Memory, to provide contact debounce and for changing transmit and receive mode. This permits the use of one crystal for generating both transmitting frequencies and

the local oscillator frequencies for the receiver mixer. This can be done by mixing the signal from the crystal oscillator reference, previously multiplied, with the selected channel frequency from the synthesizer. A balanced mixer with diode switched bandpass filters, one for transmit and the other for receive is used. These are selected by a PTT switch or other suitable means.

In the transmit mode, the synthesized channel frequency goes thru a phase modulator that receives the audio signal from a limiter/pre-emphasis network. The output of the phase modulator is fed to a standard multiplier chain.

In the receive mode, the frequency generated f_R is used as a local oscillator for the receiver mixer ($f_R = F_T + f_{IF}$).

As the HCTRO320 can generate 1021 different frequencies/channels (in the programmable counter $3 \leq N \leq 1023$), it is possible to choose the Frequency Synthesizer output with its 13 channels centered in a convenient range as:

$$\begin{aligned} (3) \times 30 \text{ KHz} &\leq f_{VCO} \leq 30 \text{ KHz} \times (1023) \\ 90 \text{ KHz} &\leq f_{VCO} \leq 30,690 \text{ KHz} \end{aligned}$$

The choice of this center frequency is determined by the VCO available, quality of the mixer and the crystal frequency.

As noted, the second FPLA is optional, depending if the BCD inputs to the programmable counter are used or not, as this determines the high frequency operation of the Frequency Synthesizer. Alternately, these BCD inputs could be strapped such that the operating frequency of the VCO is around some desirable value.

The proposed Frequency Synthesizer with Channel Memory could form the basic building block for any two way radio telephone, as it has the definitive advantages of single crystal operation, and quick selection of the desired communication channel. The number of channels can be extended up to the limit set by the frequency synthesizer and the FPLA capacity.

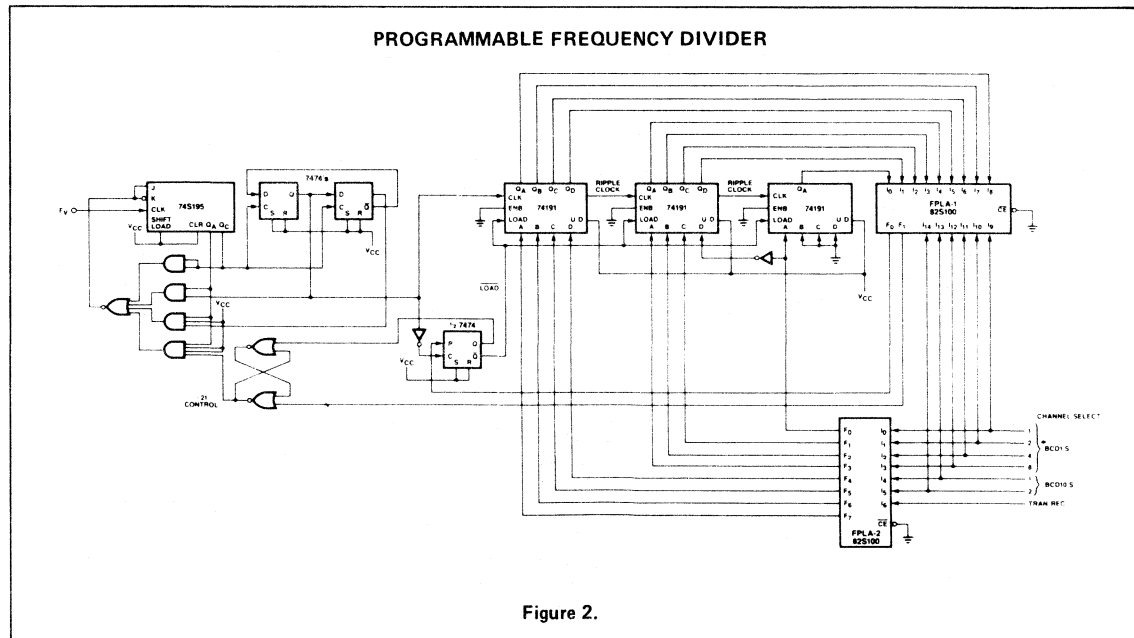

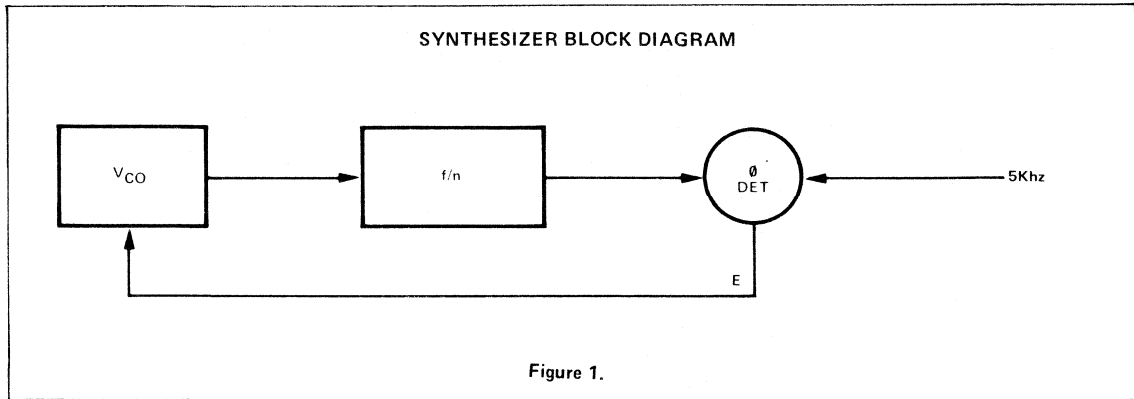

The circuit of Figure 2 uses FPLA's in a programmable divider for a frequency synthesizer, as part of a 23 channel CB transceiver using a 10.7 MHz IF frequency. There are spare resources in the two FPLA's to go to the new 40 channels, once the frequencies of the additional channels are established by the FCC.

The block diagram of the frequency synthesizer is shown in Figure 1.

The scheme utilizes a divide by 20/21 prescaler such that the total divide ratio is $N = (Px20) + Q$. Table 1 gives the values of P and Q for both transmit and receive. FPLA #1

decodes when the counters count down to Q+1, and F1 gives a HIGH output which resets the R-S NOR flip-flop causing the prescaler to divide by 21. When the counter reaches State 1, The F0 output goes HIGH, providing a HIGH input for the D shift register which drives LOAD. On the next rising edge of the clock, LOAD goes LOW and presets the counter to P1. Also at this time the ÷21 control is switched back to a divide by 20 mode.

Both Channel Select and Divide Control functions are programmed in the FPLA's as shown in the Program Tables of Figure 3 and 4.

P AND Q VALUES FOR TRANSMIT AND RECEIVE

| Channel # | Frequency | Divide Ratio | P ÷ 20 | Q ÷ 21 | Frequency | Divide Ratio | P ÷ 20 | Q ÷ 21 |

UNUSED

Figure 4.

The circuit shown in Figure 1 is a keyer and/or V.C.A., as part of a synthesizer. The FPLA is used as a memory to store the shape and amplitude of the envelope for a given selection of the switches. The programmable timer operates in the astable mode with "C_x" and "R_x" determining the frequency of the multivibrator. The FPLA compares the state of the timer/counter with the selection of the switches. Its output goes to the appropriate transmission gate(s) which, in conjunction with the precision resistors, determine the gain of the Op-Amp and the final output frequency envelope. It should be noted that the resistors used must be *precision* or the envelope will lack uniformity. This circuit is very practical in forming waveforms that would be virtually impossible by analog means.

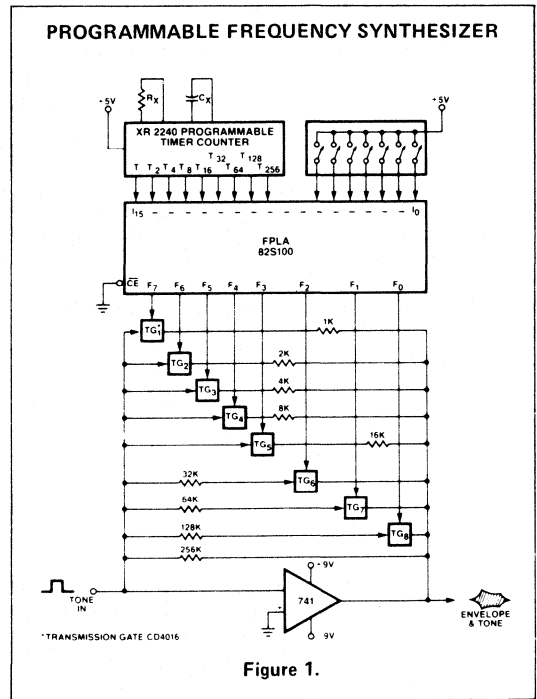

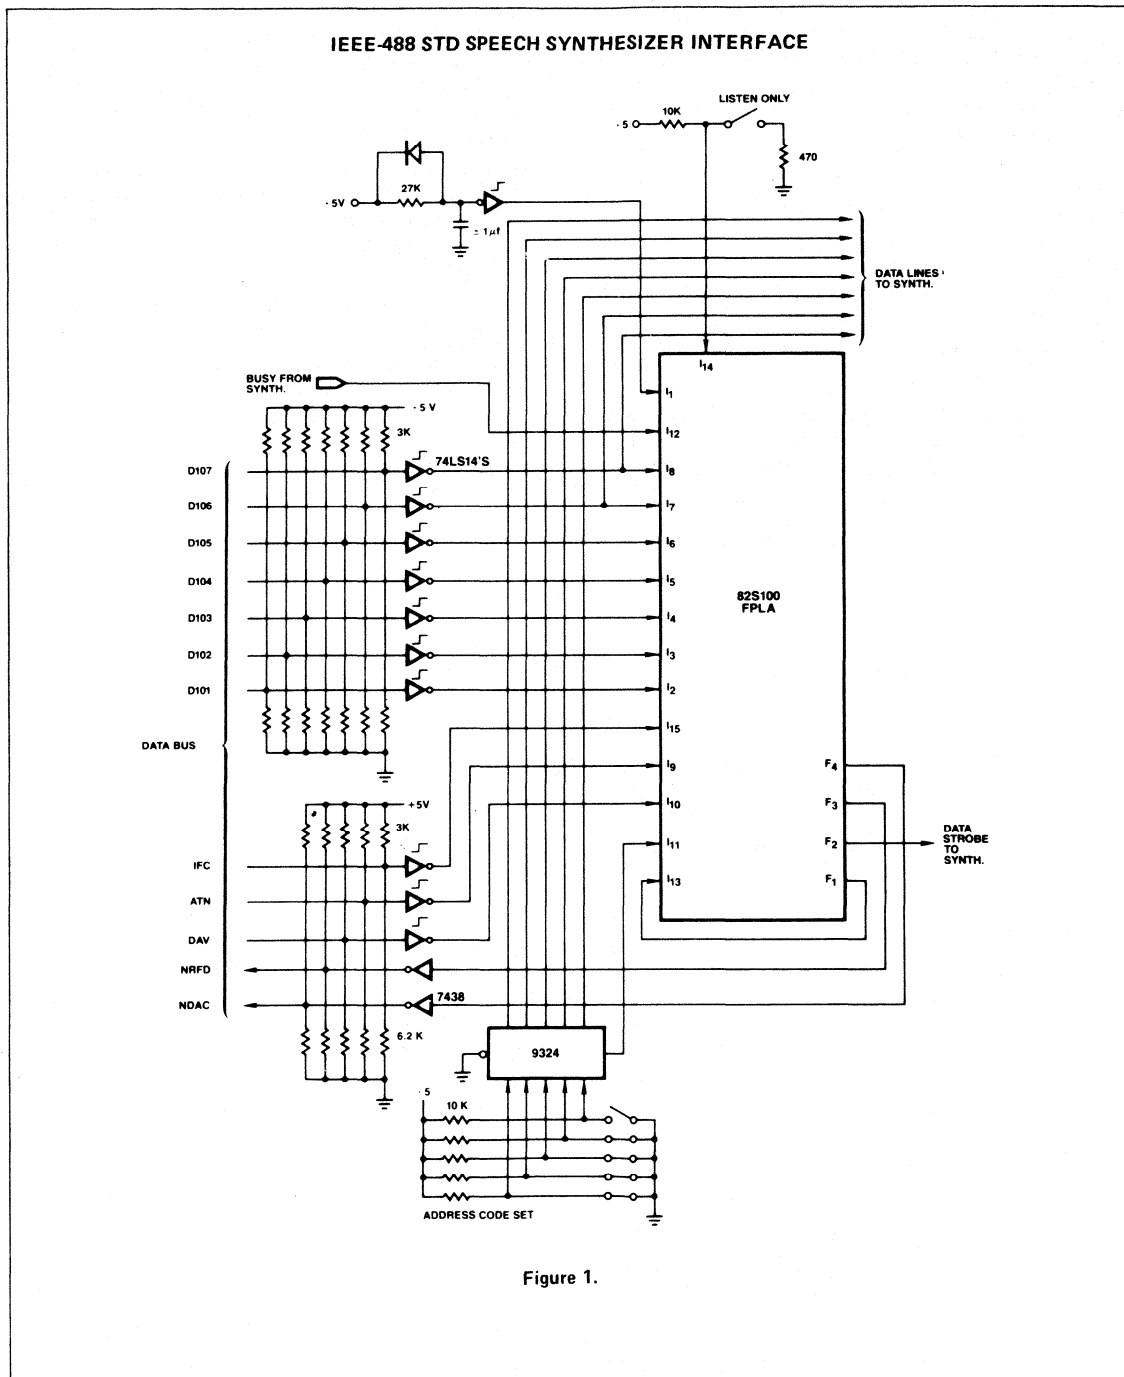

Figure 1.

The circuit shown in Figure 1 uses an FPLA for interfacing a Telesensory Systems Speech Synthesizer to an IEEE-488 standard instrument bus. This interface will allow blind electronic technicians to "hear" the digital output from digital test equipment equipped with an IEEE-488 interface. The S15001-A Speech Synthesizer, described in Telesensory Systems Inc., Application Note 003, requires a Data Strobe to clock data on the bus, and it provides a Busy signal to complete the handshake. The inputs to the FPLA are the bus data lines D101 through D107, ATN, DAV and IFC. A power-on Reset input is provided for circuit initialization. Other inputs are the address comparator output, the Busy line from the speech board, the Listen feedback output of the FPLA and the Listen Only switch. The outputs of the

FPLA are the bus handshake lines RFD and DAC, Listen, and Data Strobe. Circuit operation is as follows. The power on circuitry initializes the FPLA to a known state, unlisten or listen, depending on the Listen Always switch. Based on the interface bus signals, if the proper listen address is given and ATN is true, the handshake is completed and the Listen line goes true. When ATN is false and Listen is true, the interface accepts each successive byte of data with a Data Strobe signal to the speech board and then waits for the Busy signal from the speech board to go false to complete the bus handshake. The Unlisten command is implemented in FPLA programming; if the character "?" is sent on the data bus with ATN true, the feedback signal Listen goes false.

The circuit shown in Figure 1 is a CAMAC Module for a dual channel, 12-bit A/D converter. CAMAC is an international standard for interfacing modular instrumentation to computers through a bused backplane called the Dataway. Within the context of this application, the Dataway contains the following signals:

| SIGNAL | LINES | SIGNAL | LINES |
|--------------------------------|-------|---|-----------|
| Read Data | 24 | Station Number | 24 |
| Write Data | 24 | (control station address to each station) | |
| Function | 5 | Look-At-Me (LAM) | 24 |
| Sub Address | 4 | (control station interrupt) | |
| Status - Q, X | 2 | to each station) | |
| Control and Timing (Z, S1, S2) | 3 | Power | ±6V, ±24V |

There are 32 possible functions and 15 sub addresses in each module. The CAMAC rules state that modules must completely decode all Function and Sub Address lines, and

that the X status line must be asserted for every combination of Function and Sub Address implemented by the module. Q is a general purpose status line used primarily for testing conditions in modules. S1 and S2 are 200ns strobe signals which occur in sequence during a Dataway cycle. Z is a general reset function.

Decoding F and A, and generating Q, X, and LAM generally requires from 10 to 20 SSI and MSI packages. An FPLA can replace about 90% of this decoding logic, saving considerable design time and leaving more space for "functional" logic on the fixed size CAMAC printed circuit board.

The module in Figure 1 implements the functions tabulated in Figure 2.

Differing interpretations of the standards have resulted in some CAMAC users preferring A(15) for LAM functions while others prefer A(0). This example illustrates the power of the FPLA in that both options can be provided with no additional hardware.

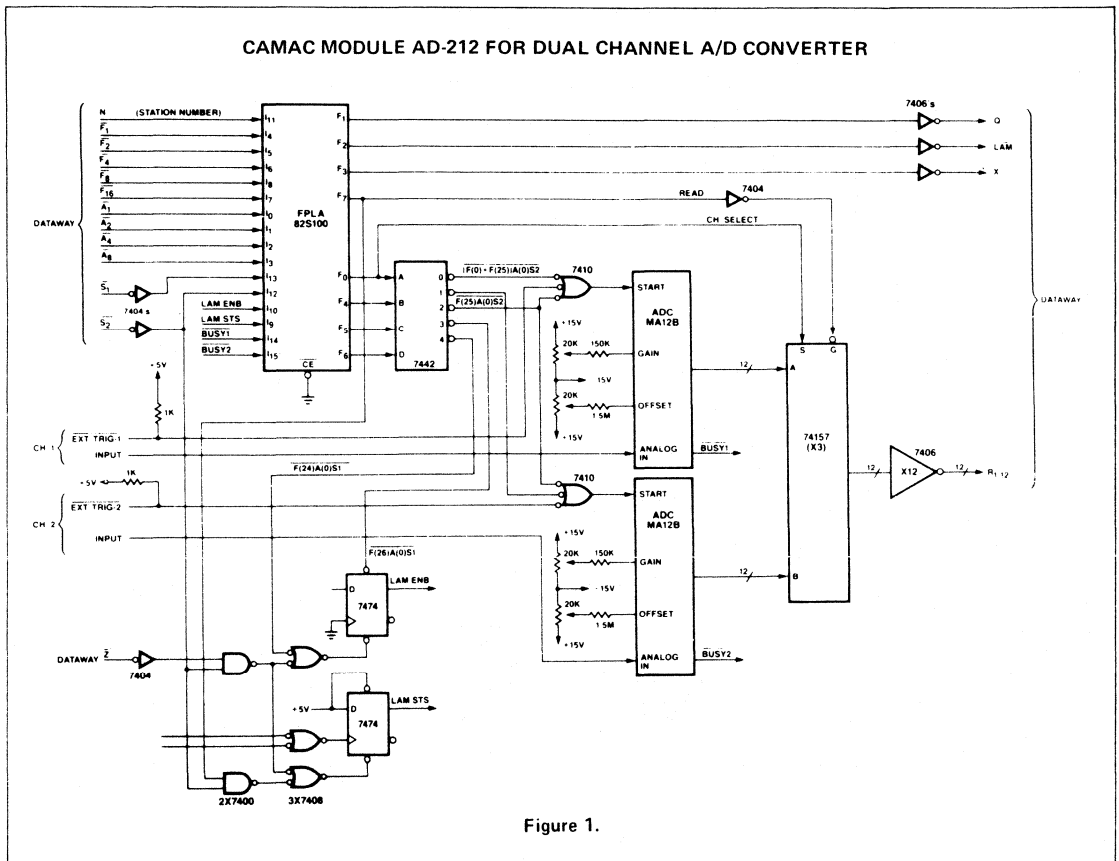

Figure 1.

FUNCTIONS EXECUTED BY CAMAC MODULE

| CONDITION | FUNCTION | STATUS |
|-------------|--------------------------------------|---|
| F(0) A(0) | Read Channel 1 | $Q = \overline{\text{BUSY}} 1$ |
| F(0) A(1) | Read Channel 2 | $Q = \overline{\text{BUSY}} 2$ |
| *F(2) A(0) | Read Channel 1, start new conversion | $Q = \overline{\text{BUSY}} 1$ |
| *F(2) A(1) | Read Channel 2, start new conversion | $Q = \overline{\text{BUSY}} 2$ |
| F(8) A(0) | Test LAM | $Q = \text{LAM}$ |
| F(8) A(15) | Test LAM | $Q = \text{LAM}$ |
| F(24) A(0) | Rest LAM Enable | $Q = 1$ |
| F(24) A(15) | Reset LAM Enable | $Q = 1$ |
| *F(25) A(0) | Start Conversion in Channel 1 | $Q = \overline{\text{BUSY}} 1$ |
| *F(25) A(1) | Start Conversion in Channel 2 | $Q = \overline{\text{BUSY}} 2$ |
| *F(25) A(2) | Start Conversion in both channels | $Q = \overline{\text{BUSY}} 1 + \overline{\text{BUSY}} 2$ |
| F(26) A(0) | Set LAM Enable | $Q = 1$ |
| F(26) A(15) | Set LAM Enable | $Q = 1$ |
| F(27) A(0) | Test Channel 1 BUSY | $Q = \text{BUSY} 1$ |
| F(27) A(1) | Test Channel 2 BUSY | $Q = \text{BUSY} 2$ |

* For F(2) and F(25) functions, conversion is not started if $Q=0$.

Figure 2.

An FPLA can provide an easy way of generating complex waveforms, whose shape can be quickly tailored to fit each application. In the circuit of Figure 1, a 16-stage binary counter drives the FPLA inputs which are programmed to detect specific counts. At each programmed count the FPLA supplies a corresponding binary weighted output which is summed thru the ladder network to set the desired amplifier gain.

The FPLA program table is derived from a staircase approximation of the desired output waveform, and duty cycle. The frequency is set by the clock. Each cycle is repeated by programming F7 to produce a "1" output at end of cycle count. At the next positive transition of the clock all counter stages are reset, and the cycle repeats until stopped by the start switch.

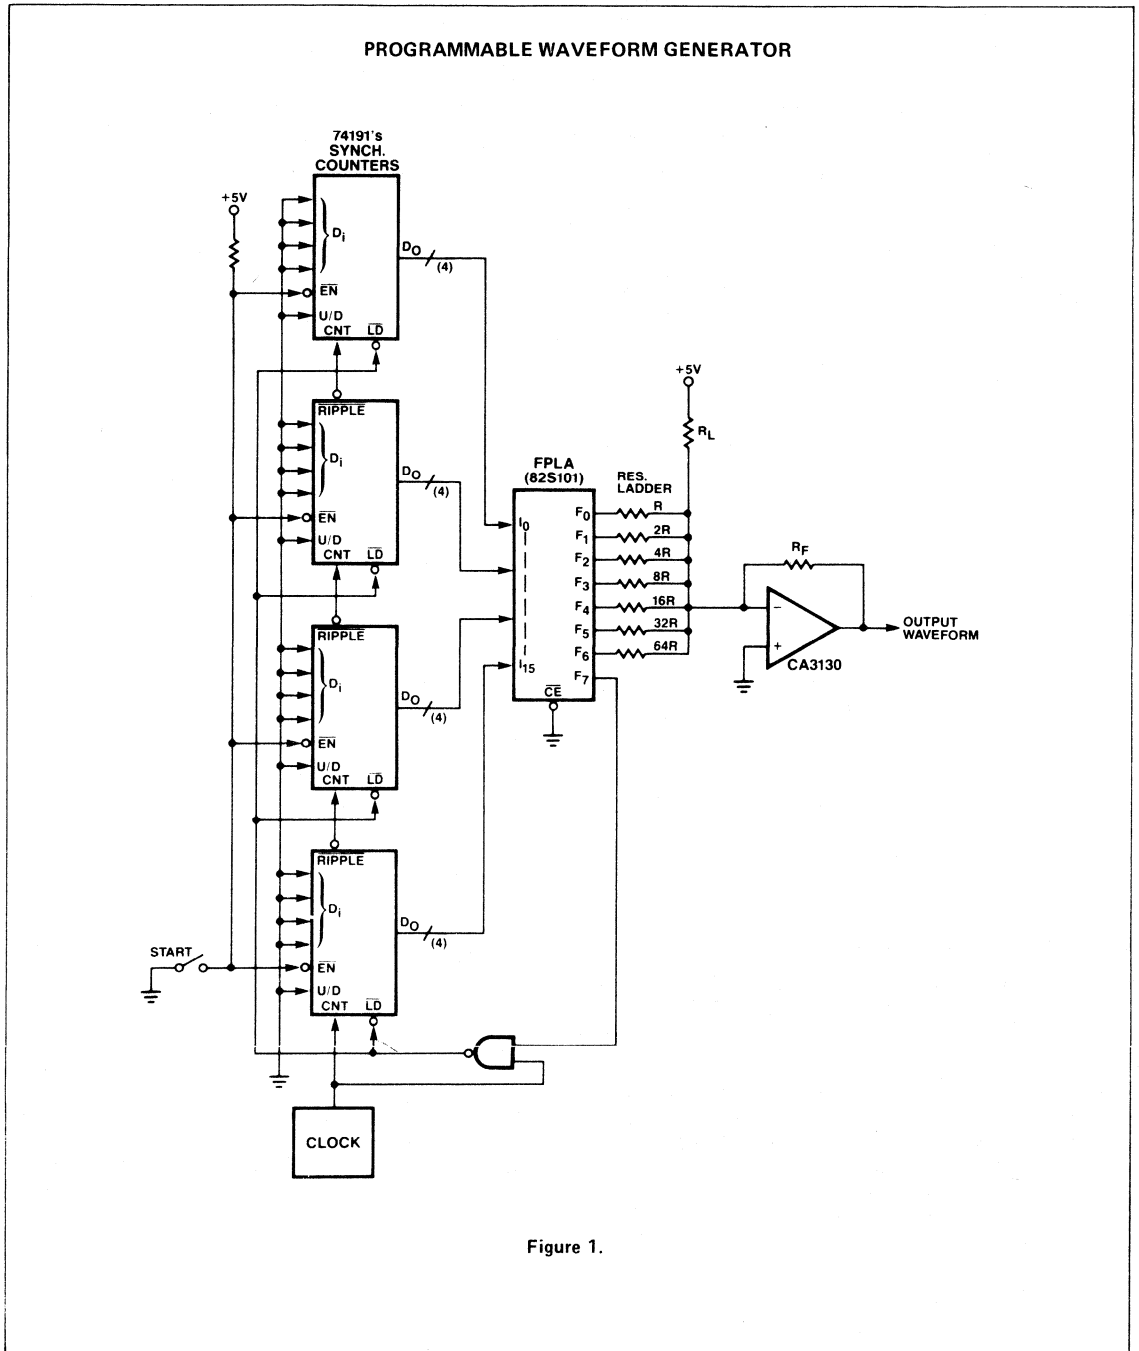

Figure 1.

The circuit shown in Figure 1 uses two FPLA's as the heart of a programmable function generator which can simulate any analog waveform by means of a piecewise linear approximation technique. A 555 timer serves as the clock generator for a 12-bit binary counter consisting of three 74LS163's, which establishes the time base of the generator. The FPLA's continually monitor the state of this counter to determine when the slope of the waveform should be changed and what its new value should be, as well as when to stop the clock, set the counter to zero, and discharge the output integrator. The value of the slope is retained in a pair of 74LS374 octal latches and fed into a 12-bit digital-to-analog converter (DA1201C), whose output is then inte-

grated by an LF356 op-amp to yield the analog output waveform as a continuous series of linear slope segments. Other support circuitry includes a means to encode up to 4 patterns in the same pair of FPLA's, and a provision to generate either one output cycle and stop, or to repeat continuously. It is interesting to note that the same features which make the FPLA's ideally suited for use in generating highly irregular analog waveforms also make them useful for generating some highly-repetitive waveforms, such as high-precision sine waves. Therefore, this circuit can also be very useful in applications requiring either a test generator or a waveform synthesizer.

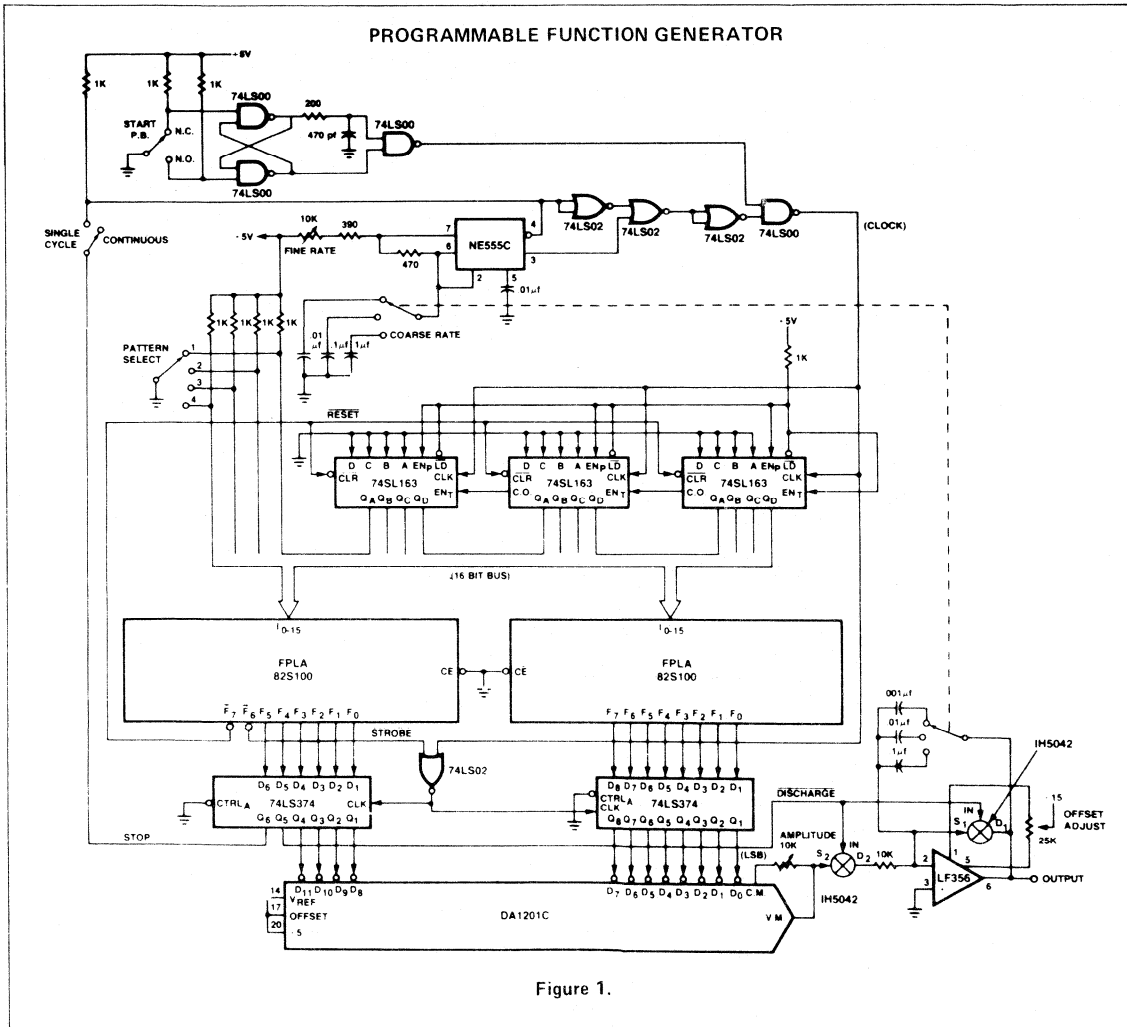

Figure 1.

The block diagram of Figure 1 shows an FPLA used to control the register select ports of 4-bit slice microprocessors in a microprogrammed processor. Four bits for each port come from the microcode when a fifth bit is 0, or from various bits of the machine language instruction when the fifth bit is 1. Independent control of the A and B ports for 4 instruction formats is obtained with the following assignments.

FPLA INPUTS

I₀→I₉ = Pipeline Register (Control ROM) bits

Where:

- I₀→I₃ = A Port select bits 0 thru 3
- I₄ = A Port key bit
- I₅→I₈ = B Port select bits 0 thru 3
- I₉ = B Port Key bit

I₁₀→I₁₅ = Instruction Register bits

Where:

- I₁₀ = IR Bit 3 I₁₃ = IR Bit 6
- I₁₁ = IR Bit 4 I₁₄ = IR Bit 13
- I₁₂ = IR Bit 5 I₁₅ = IR Bit 14

FPLA OUTPUTS

- I₀→I₃ = Drive A Port Bits 0 thru 3
- I₄→I₇ = Drive B Port Bits 0 thru 3

Registers in the microprocessor slice register files are assigned to programmable functions in the machine language being implemented by microprogramming as follows:

MACHINE REGISTER

SLICE REGISTER

| | |
|-----------------|---|
| A Accumulator | 0 |
| B Accumulator | 4 |
| Index Reg. 1 | 1 |
| Index Reg. 2 | 2 |
| Index Reg. 3 | 3 |
| Stack Pointer | 5 |
| Program Counter | 6 |

Registers are selected by the FPLA when executing machine language instructions in the following formats:

1. Single Word Memory Reference

- Bits 13 and 14 call for indexed addresses as:
- 00 = No Indexing 10 = Index Reg. 2
- 01 = Index Reg. 1 11 = Index Reg. 3

2. Double Word Memory Reference

Bits 4 and 5 call for indexed addressing, and are coded as above.

3. General Register Operations

- Bits 4, 5 and 6 indicate the register to be operated upon as:
- 000 = Illegal 100 = A Accumulator
- 001 = Index Reg. 1 101 = B Accumulator
- 010 = Index Reg. 2 110 = Stack Pointer
- 011 = Index Reg. 3 111 = Program Counter

4. Double Register Operations

Bits 3 and 4 indicate one operand as:

- 00 = A Accumulator 10 = Index Reg. 2
- 10 = Index Reg. 1 11 = Index Reg. 3

Bits 5 and 6 indicate the operand coded as above except: 00 = B Accumulator.

The FPLA is used to decode and multiplex bits for each register port according to Table 1. This gives rise to the final Program Table for the FPLA shown in Figure 2.

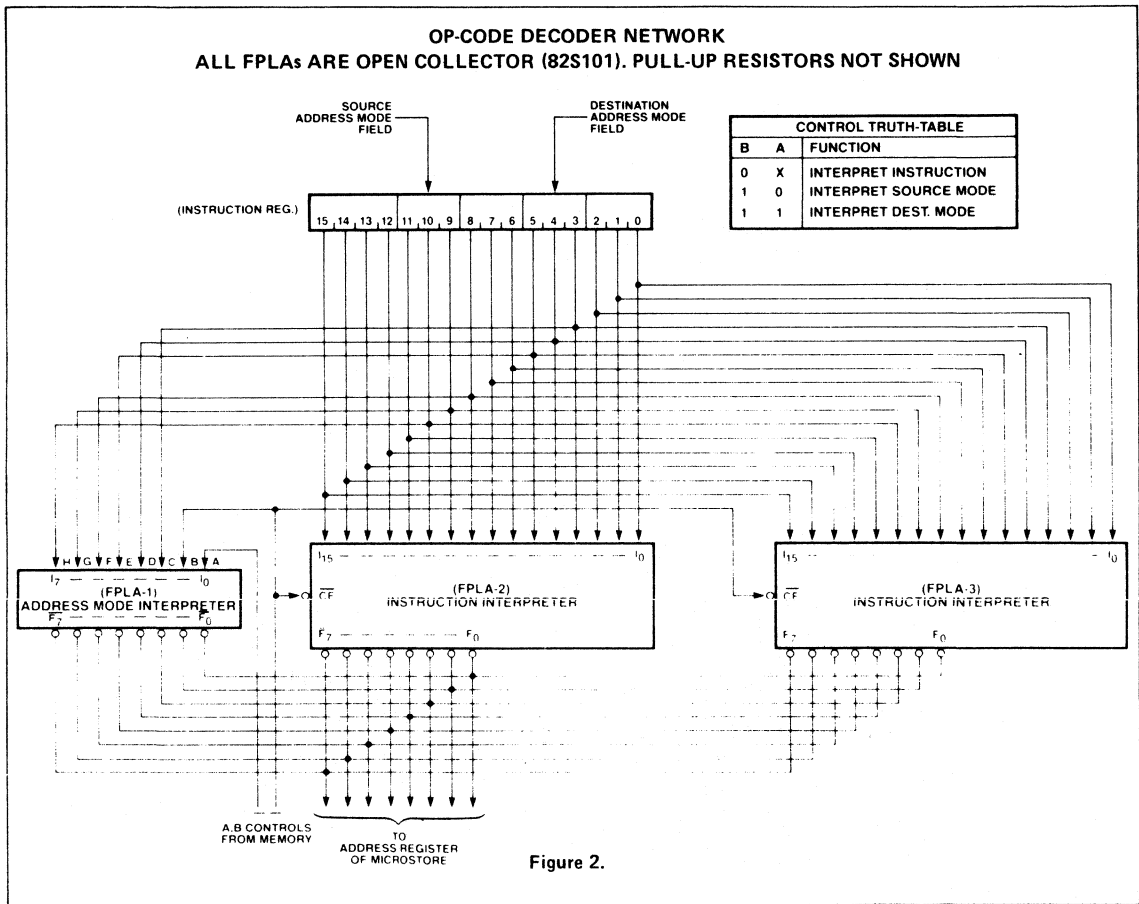

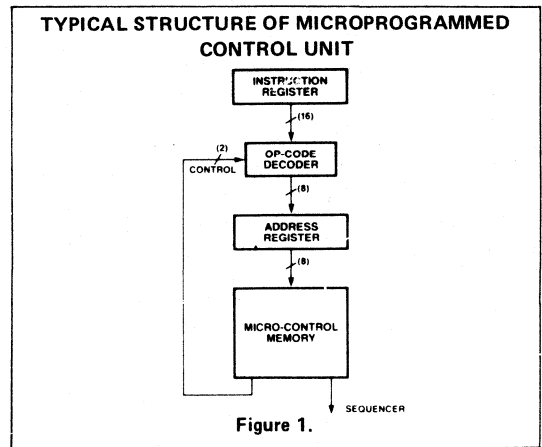

Figure 1.

FPLAs bring economy and flexibility to the design of the control unit in microprogrammed computers, by allowing complete freedom in allocating subroutines in microstore, and enhancing the use of variable formats in the op-code field from the Instruction Register.

The block diagram in Figure 1 shows a general MPCU organization. A key element in this structure is the op-code decoder for cracking each op-code from the IR into subroutine-start addresses in control memory, and address mode definition.

To implement these functions for the MPCU in the PDP-11 minicomputer, three FPLAs are all that is required, as shown in the circuit in Figure 2. The first FPLA is used as Address Mode Interpreter, while FPLA-2 and FPLA-3 function as Instruction Interpreter. Translator function (op-code, source address mode, or destination address mode) is selected by control inputs A and B from memory, also defined in Figure

2. PDP-11 instructions have variable formats, from 4 to 16 bits. Their binary codes are tabulated in the input field of the Program Tables in Figures 3 and 4 for the Instruction Interpreter FPLAs. The output field of both FPLAs is programmed with a binary number corresponding to an arbitrary starting address in control memory. Bits 3 to 5 and 9 to 11 of the IR contain address mode information which is decoded by FPLA-1 as shown in the input field of the Program Table in Figure 5. The outputs of this FPLA are also assigned an arbitrary code pointing to a starting

address in control memory. Note that all undefined instruction codes are not programmed, and will appear as an all 1's address from the interpreter. This leaves 13 spare product terms in the Instruction Interpreter FPLAs to be used for editing, or future expansion.

A ROM version of this circuit would require 65K x 8 for the Instruction Interpreter and 128 x 8 for the Addressing Mode Interpreter. With 4K x 8 ROMs, this would require a total of 17 packages.

Figure 5.

One of the most difficult tasks of a general purpose micro-programmed emulator shown in Figure 1 is the decoding of the target instruction. The circuit shown in Figure 2

provides a fairly general instruction decoder whose decoding can be changed to decode a variety of instruction sets by programming an FPLA. The equivalent circuit using

PROMs would take over one hundred IC's.

The circuit has as input a sixteen bit instruction and two bits that tell whether address calculation has taken place. This is so that when the instruction is decoded and no memory reference is required, the decoder will generate the microinstruction address of the appropriate macroinstruction routine. If the instruction requires a memory reference, the address of the address calculation routine is generated, in which the address calculation bit is set. The microinstruction causes the decoder to be used again, but the second time through, the presence of the address calculation bit causes the decoder to generate the address of the

appropriate microroutine, instead of the address calculation routine.

The FPLA in the circuit has been programmed to decode the DEC PDP-11 series of instructions. These are tabulated in the FPLA Program Table of Figure 3. Given a 16 bit opcode from a PDP-11, the circuit will return a microcode starting address. In addition, if a memory reference is required, the circuit will generate the address of the memory reference routine. The microcode can then set a status bit, so that during the second pass thru the network the memory reference routine is bypassed.

FPLA PROGRAM TABLE FOR PDP-11 DECODE

| PRODUCT TERM | | | | | | | | | | | | | | | | ACTIVE LEVEL | | | | | | | | COMMENTS | | | | |

Figure 3.

The 82S100 is ideally suited for decoding a 16 bit Address Bus into as many as 48 locations or blocks of locations. As shown in Figure 1, only 4 $\frac{1}{4}$ packages are required to generate 48 active-LOW chip enable or device select outputs.

FPLA outputs F4, F5, and F6 are programmed active-LOW. When an assigned address is on the bus, these outputs select one of the three 74154 Decoders, while outputs F0 through F3 functions as a 0-to-15 binary counter to index the decoder according to the programmed address.

assignments. The "don't care" input programming feature allows block sizes of integral powers of 2 (as in memory chips) to be as easily assigned as singly decoded addresses.

The proper memory clock timing for an M6800 system is provided to the 74154 decoders by the $\phi_2 \cdot VMA$ output of the 7400 NAND Gate.

This circuit would be most useful in a small microprocessor system having a lot of miscellaneous devices to be addressed.

INTERRUPT PRIORITY CONTROL FOR M6800 μ P

The circuit in Figure 1 provides interrupt prioritization for a maximum of eleven devices, thereby eliminating the need for software polling techniques. The FPLA combines the functions of an eleven input "OR" gate, a quad Multiplexer, an eleven input Priority Encoder, and a 13x4 ROM. The circuitry adds a maximum of 125 ns to the settling time of the address bus.

Without prioritizing, all interrupt request inputs would be OR'ed together and applied to the \overline{IRQ} input (pin 4) of the MPU. Upon receiving an interrupt request the microprocessor successively addresses FFF8 and FFF9. The 16 bits of data at these two addresses comprise the starting address for the interrupt routine. The MPU must then poll each device to determine who initiated the request and, in the case of multiple requests, must further determine which device will be serviced first. With the priority circuitry shown, all of the inputs are brought to the FPLA. Here they are OR'ed together at F4 to produce the \overline{IRQ} signal and where they are available for controlling F0 through F3 during the interrupt sequence. The other inputs are A1 through A4 from the MPU, and the output of the interrupt vector decode logic, for recognizing when the micropro-

cessor outputs addresses FFF8 and FFF9. The function of the circuit is summarized in the truth-table of Figure 2. When there is no interrupt request the address bus is the same as the address outputted by the MPU. When any of the inputs goes LOW, F4 goes LOW and the FPLA is ready to modify bits A1 thru A4 of the address bus with a specific starting address. These have been assigned to the device which initiated the interrupt in accordance with the vector table of Figure 3. This substitution occurs when I4 goes HIGH. With proper programming the FPLA will automatically indicate the correct starting address when multiple requests are present. For example, if I5 is to have the highest priority, the product matrix of I6 through I15 contain I5 as inhibit function. If I6 is the next highest priority, all the product matrices of I7 through I15 would also contain I6 as an inhibit function. The sum matrix is programmed according to the starting address assigned to the interrupt to be serviced. For example, if the device connected to I7 is to have a starting address at FFE4 and FFE5, the product term for I7 would be connected in the sum matrix to produce a (0010) at F0, F1, F2, and F3 respectively. The logic equation set to be programmed in the FPLA is tabulated in

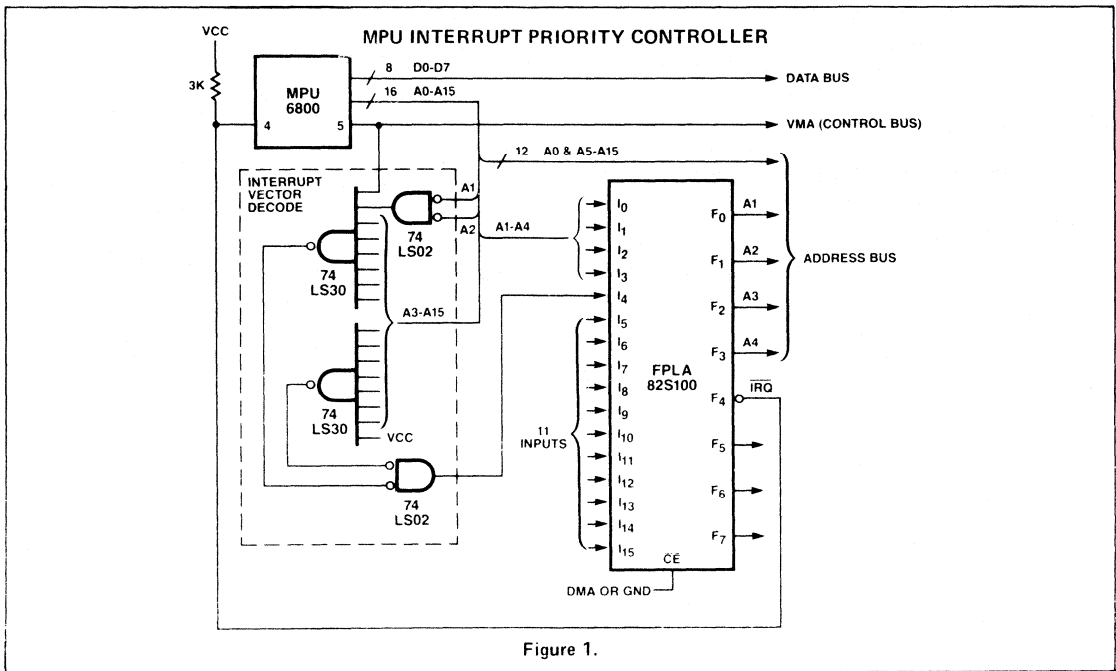

Figure 1.

Figure 4. The range of interrupt addresses is FFE0 through FFF9. The data at these locations can be either hardwired in, bootstrapped in during initialization, or firmware resident.

There are two extra address pairs and three spare outputs. These give the circuit a few additional capabilities not normally found with conventional priority circuits. The extra addresses can be used to designate special routines for certain combinations of multiple inputs. The extra outputs can be programmed to provide supplementary information. These can signal the operator, or MPU, of input combinations that are illegal or require immediate servicing. Outputs

F5, F6, and F7 could be used to illuminate LEDs and/or be applied to microprocessor inputs such as $\overline{\text{NMI}}$, $\overline{\text{HALT}}$, or $\overline{\text{RESET}}$. If there is a need to place the address bus in the Hi-Z state, $\overline{\text{CE}}$ of the FPLA would be a function of, for example, a DMA controller.

The circuit is designed for use with the M6800 MPU family of components, but can be easily applied to other microprocessors.

CIRCUIT TRUTH-TABLE

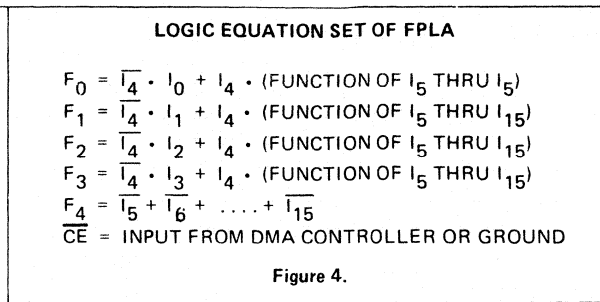

| I_{5-15} | I_4 | $\overline{\text{CE}}$ | $\overline{\text{F4}}$ | ADD. BUS |

Figure 3.

The circuit in Figure 1 monitors how often a specific address or a specific group of addresses is referenced on the PDP-11 unibus. Up to eight groups can be monitored at the same time. The FPLA outputs are programmed to recognize a specific input address or group of addresses. When a parti-

cular address is referenced, the corresponding output fires a pulse to the corresponding counter and increments it. A switch selectable LED display and a frequency counter measurement test point is also provided. The circuit is very useful in measuring the effective data rate of peripherals.

The circuit shown in Figure 1 can be used for implementing hardware MACROS, or for calling conditional Diagnostics in a general processing system.

If \overline{CE} , EN1 and EN2 are set, and a 'keyword' instruction is fetched from memory, the FPLA is actuated to sequentially place new instructions in the input instruction stream. If

possible the program counter is inhibited for subsequent instruction fetches, otherwise the last MACRO code resets the program counter. The next FPLA instruction is determined by decoding the last FPLA code (via 74174) until a 1's condition is set, which returns control to the memory bus. EN1 and EN2 allow conditional selection of different 'keyword' sets.

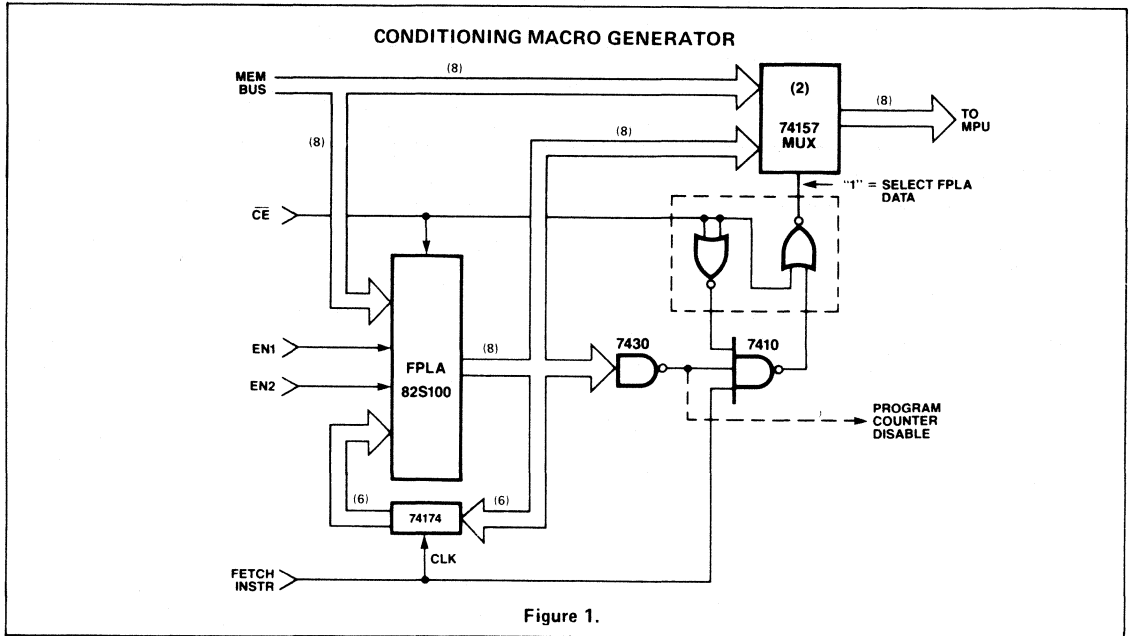

Figure 1.

In a microcoded 16 bit processor the instruction fetch/decode/execute cycles can be overlapped in a pipelined fashion to increase execution speed. As shown in the block diagram of Figure 1, while instruction A is executing in firmware, instruction B is decoded by the decode FPLA to generate the next starting firmware address, and instruction C is fetched from memory into the pipeline register.

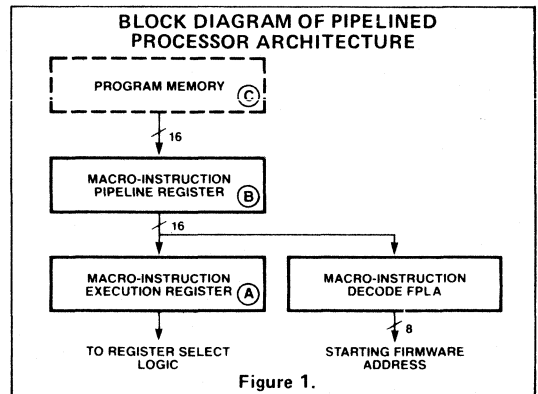

Figure 1.

The circuit in Figure 1 shows an FPLA as an 8-bit I/O port decoder for generating chip select signals to 32 PIA modules, type 6820, used in microprocessor designs. These could also be ACIA 6850, or other similar interface adapters.

Since the I/O address for 2 ports is fully decoded by one FPLA product term, the circuit can select 64 ports and a maximum of 96 when using all 48 product terms in one FPLA. For 16 or less ports, a single 1 of 16 decoder is sufficient.

Besides vastly reducing the number of decoding circuits, the FPLA avoids hardware limitations of software I/O addresses because it permits selection of more than one I/O port at a time, or one I/O port at more than one software address, or both. Also, since it allows to program some inputs as true "Don't Cares", a port can be assigned to be at an entire page or more of addresses.

Note that there remain two spare inputs to the FPLA. These can be used for hardware I/O control, such as automatic control for out of paper condition on printer.

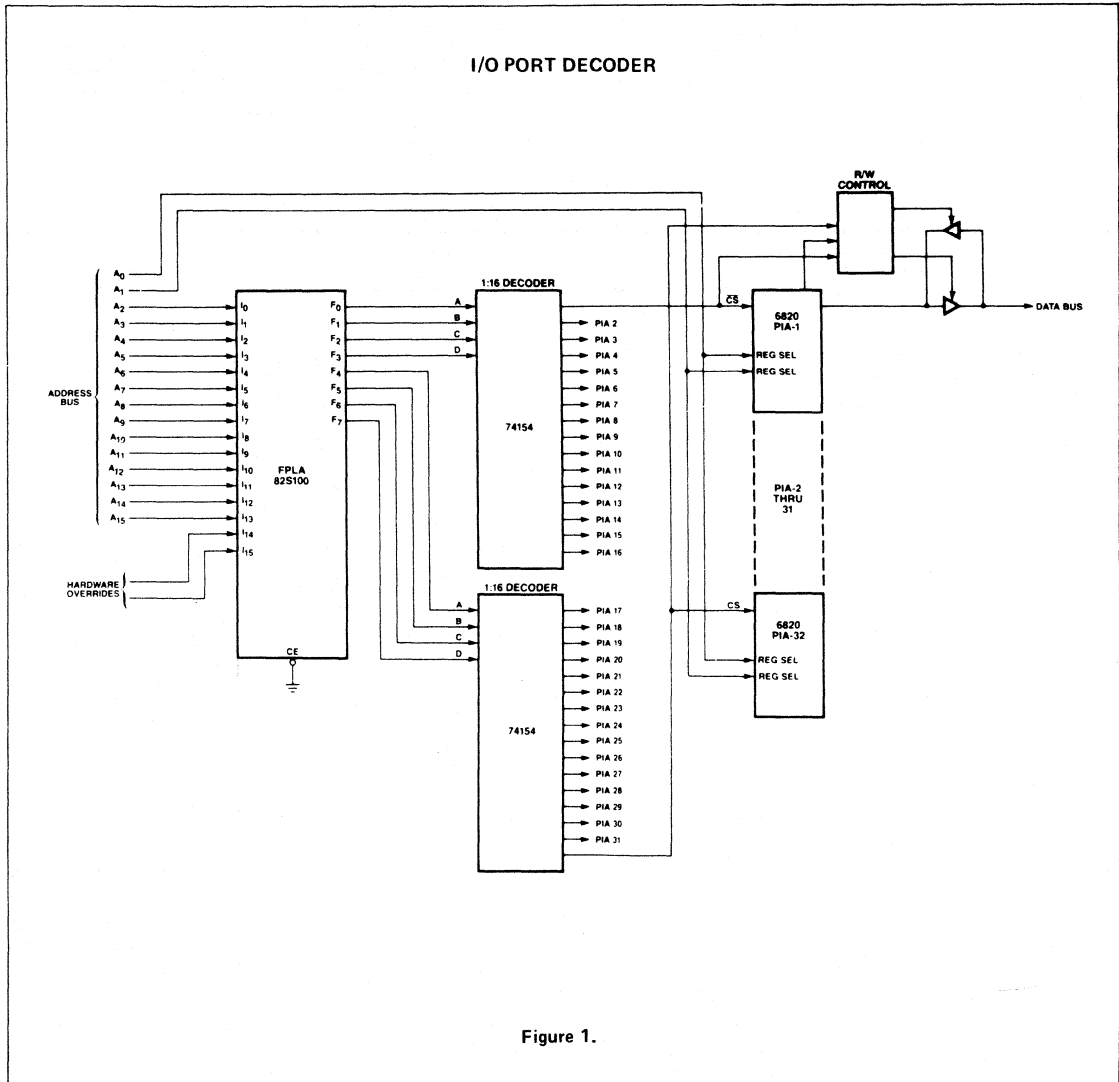

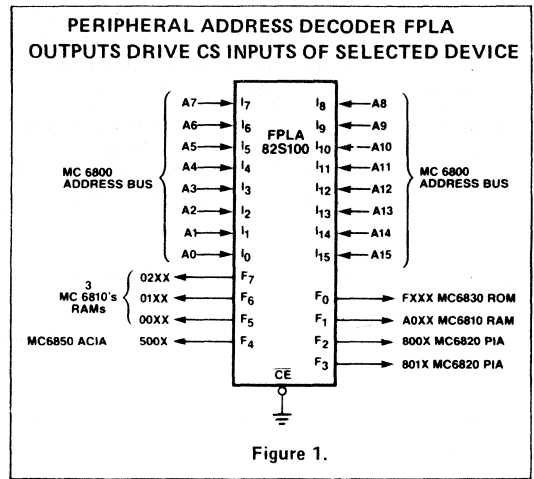

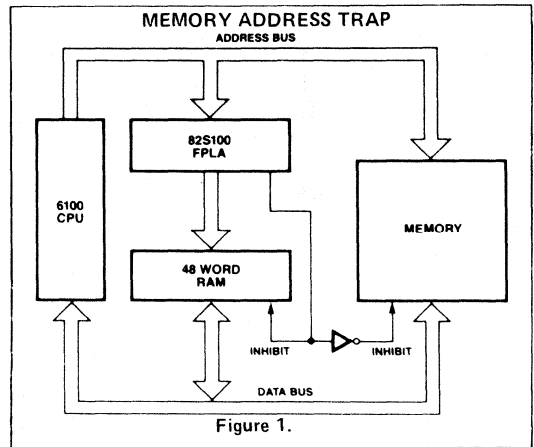

Figure 1.

The circuit shown in Figure 1 is a simple but effective network in designs using microprocessors. The FPLA is used to fully decode the addresses of all peripheral circuits supporting the microprocessor system. If there are more than 8 peripherals, they can be easily accommodated by another FPLA. The outputs of the FPLA are connected directly to the chip select input of each device.

MEMORY ADDRESS TRAP

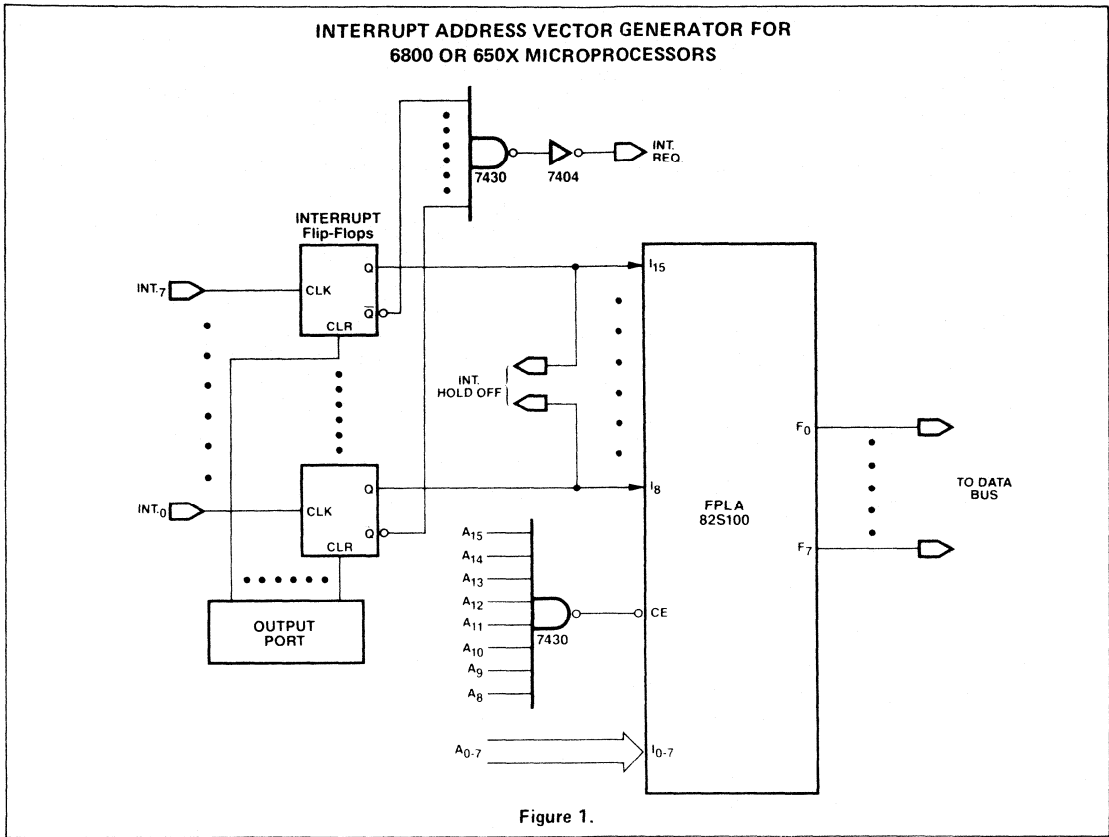

The block diagram of Figure 1 shows an FPLA in conjunction with a small RAM for implementing a logically compact address trap, which can be readily modified. The FPLA will trap up to 48 locations in ROM and substitute a RAM location so that software subroutines may be easily called.

MASKABLE INTERRUPT VECTOR GENERATOR

The circuit shown in Figure 1 generates maskable interrupt vectors for up to 8 interrupt sources. It also generates restart addresses and non-maskable interrupt addresses. Any of 8 possible interrupts sets the standard interrupt to the CPU by setting one of the interrupt flip-flops. When the CPU sends out the addresses which normally contains the vector address, the FPLA prioritizes the flip-flops so as to

return the proper address. Each interrupt handler should clear its associated flip-flop via the shown output port. The device hold-off signal can be used to hold off the source of interrupts until each is serviced. The output addresses shown in the FPLA Program Table of Figure 2 represent a typical assignment.

TYPICAL FPLA PROGRAM TABLE

Figure 2.

In interfacing multiple devices to a mini or micro-computer bus, some sort of interrupt priority structure is generally needed. A conventional scheme uses a daisy chain circuit which allows a priority signal to pass if the device is not requesting an interrupt, and blocks it otherwise. In most computers the interrupting device is allowed to place its identifying code on the bus. If several devices share one

P.C. board or chassis, one F.P.L.A. can be used to adjudicate priorities between the devices and generate the identifying codes, and thus save a large array of gates for each device serviced. The I/O assignment for the FPLA is shown in Figure 1. The FPLA program table is easily derived from the typical logic path in Figure 2, in which any arbitrary priority and device identification codes can be assigned.

FPLA SIMPLIFIES ALPHA-NUMERIC DISPLAY OPERATION

40

Controlling a cluster of 5 x 7 dot-matrix alpha-numeric displays is much more involved than numeric only, and generally requires a lot of circuitry which can be greatly reduced with FPLAs. The difficulty is that instead of displaying a whole character at once, as with 7-segment displays, multiplexing must occur on a column by column basis. Therefore the display must be fed information for part of each character, then illuminated, then the next part of each character and illuminated, etc.

The circuit shown in Figure 1 uses an FPLA to implement the necessary display control for any desired character-cluster lengths, obtained by simply reprogramming the FPLA. The circuit uses an H-P 5082-7150 display which requires all bits for column 1 of all characters to be serially clocked in. The display has a holding register, in this case 140 bits long (7 bits/column x 20 characters). When all 140 bits are clocked in, the serial clocking must stop and the column driver is turned on for the duration desired (1.5 ms). Then the column driver is turned off and the clocking begins for the next 140 bits. (all of the column 2 bits) and column 2 is turned on.

Obviously all of the data for each column for all 20 characters must be readily available to this circuit, so a RAM was

selected allowing external circuitry to load column data into the RAM. The circuit then takes this data and forms the 20 characters from it. In this case the RAM is loaded off of a transmission-line bus driven by a microprocessor. Placement of the data into the RAM is shown in Figure 2, and the microprocessor sends dot data to the RAM, not an ASCII character.

Close inspection of Figure 1 shows pin numbers and output bits mixed, but only to simplify PC layout. For instance, the RAM outputs feeding the 92L12 are mixed but not an error, so long as the RAM is being loaded with data in such a way as to form the character desired.

Since central control is afforded by the FPLA, the programming of the FPLA must be understood in order to know how the circuit works. With reference to Figure 3, note that all addresses are in octal. It takes 100 decimal memory locations to hold all of the data (5 cols/char x 20 chars). Assuming the RAM is loaded with the data in Figure 2, let's begin at address 0 set by the 93L66 counter, whose outputs also drive inputs to the 82S100 FPLA.

When the address is 0, column 5 is turned on by output F7, but nothing will be displayed yet. After the 96L02 expires,

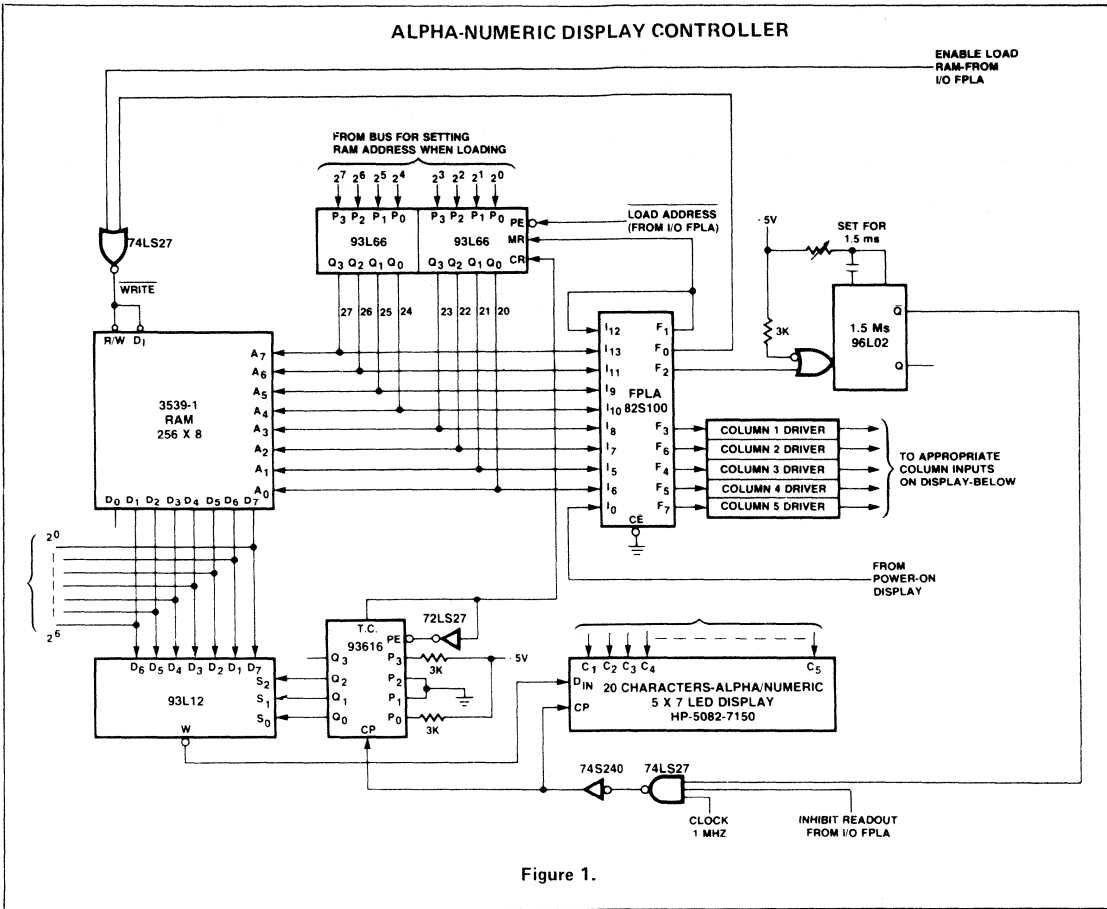

Figure 1.

data will begin to load into the display. Here's how it happens.

Since the address is 0, the RAM places the 7 column-1 bits for the character in address 0 on its output. The 93L16 is sitting at 001₂, thus the 93L12 is selecting a bit which appears at its W output, and is clocked into the display. At the next clock pulse, the 93L16 increments and the 93L12 selects the 2nd bit, which is subsequently clocked into the display. After 7 cycles the 93L16 hits top count, and the 93L66's are incremented causing address 1 to be referenced, which makes new data available to the 93L12. Top count also resets the 93L16 to octal 11, which is effectively 001₂. Note that the display and 93L16 use opposite trigger edges, so no race results. As the counter is incrementing nothing is happening at the 82S100, but as soon as address 24 is referenced the FPLA is activated. F₂ is enabled, which

blocks the clock from further shifting-counting-selecting for the duration of 96L02 delay.

Simultaneously, F₃ enables the column-1 driver which enables all column-1 bits of each character. (Remember that the display has a holding register).

When the delay expires the clock is allowed to continue, data is shifted-counted-selected as before until the 93L66 reaches address 50, at which point the clock is again stopped and column 2 is enabled. This cycle is repeated until finally address 144 is reached, and the FPLA is again activated. F₁ is now enabled, resetting the address counter to zero so that the circuit recycles back to do all columns over again.

To avoid meaningless data from being displayed upon power-up, the FPLA can save additional circuitry by

supplying a CLR RAM signal. When power-on occurs, a timer enables FPLA input I₀ which is programmed to unconditionally reset the 93L66 counters to address zero, and enable the RAM to write. Now the clock is not inhibited so the counter begins counting (after the power-on I₀ goes away). But since F₁ is tied to I₁₂ the counter addresses do not enable column drivers. Also, while counting, the RAM is writing zeros into itself, thus the RAM is being cleared at every address. Nothing else happens until the counter reaches 200, where the 82S100 is programmed to drop the F₀ output, and activate F₁. These will respective-

ly disable RAM write and reset the 93L66 counter. This time at address 0, normal operation resumes because I₀ and I₁₂ are not present.

The FPLA can also supply the additional function of clearing the RAM intentionally of its data. All that is required is to cause the 93L66 to be loaded with address 177, which the FPLA uses to force the circuit into the same clear-memory loop as the power-on did by enabling F₀ and F₁. This saves the trouble of loading each RAM address individually with zeros just to clear the display.

Figure 3.

AN ECONOMICAL DIGITAL DISPLAY CONDITIONER

Any digital instrument can be difficult to read when its measurements are displayed rapidly to high arithmetic precision, and are moderately noisy to begin with. The programmable discrete filter provides an inexpensive solution to this problem by performing a numerical smoothing operation on the data, as it arrives from the measurement device in BCD form. It is especially well suited in design situations where the raw signal being measured is inherently digital, and cannot be conditioned using analog techniques, such as a digital phase meter for navigational applications.

The design uses a single FPLA as a bus controller, data decoder, and fixed program sequencer to control an inexpensive 4-function calculator with display. This approach was selected primarily for its simplicity and low cost. But the "post-production" editing capability of the FPLA provides another important advantage: three program constants K, K-1, and B defined below are to be determined and updated periodically during instrument calibration in the field. Since efficient microcoding of the fixed program has left over fifty percent of the FPLA memory available for these variable parameters, each unit can be recalibrated several times before replacing the FPLA. In addition,

storing the instrument adjustments digitally within the FPLA should tend to discourage unauthorized modification.

The circuit mechanizes the following filter algorithm:

$$F_n = \frac{(K-1)F_{n-1} + (X_n - B)}{K}$$

where, in the present application,

F_n = the next filtered value to be displayed after processing the current measurement.

F_{n-1} = the last filtered value computed and displayed.

X_n = a five-digit BCD measurement.

B = a constant offset correction determined during instrument calibration (up to five digits in length).

K = a single-digit filter weight, which can be custom programmed to match the filter to its operation environment.

To avoid unnecessary transients at startup, the first filtered value (F₁) is initialized to the first available corrected data value (X₁-B) before beginning the smoothing process.

The following table demonstrates the dramatic improvement in display readability that is possible with the discrete filter operating on a noisy data stream in real time:

| Sample Number (n) | Raw Data (X_n) | Unfiltered Data ($X_n - B$) | Filtered Data (F_n) |
|-------------------|--------------------|-------------------------------|-------------------------|
| 1 | 124.87 | 123.45 | 123.45 |
| 2 | 126.67 | 125.25 | 123.65 |
| 3 | 126.87 | 125.45 | 123.85 |
| 4 | 120.77 | 119.35 | 123.35 |
| 5 | 126.57 | 125.15 | 123.55 |
| 6 | 126.77 | 125.35 | 123.75 |
| 7 | 121.57 | 120.15 | 123.35 |
| 8 | 127.47 | 126.05 | 123.65 |
| 9 | 122.37 | 120.95 | 123.35 |
| 10 | 125.67 | 124.25 | 123.45 |

The filter weight K and offset constant B used in this example are 9 and 1.42, respectively. Larger values of K produce heavier filtering (and greater noise rejection), but as K increases, the filter responds less rapidly to legitimate changes in the signal being measured. In fact, the discrete filter behavior is analogous to that of an RC low-pass filter whose time constant is

$$T = \ln \left[\frac{\Delta t}{K-1} \right]$$

where Δt is the time between measurement samples.

A flowchart of the 16-step algorithm, block diagram of the filter/display, FPLA program table, and detailed circuit diagram appear in Figures 1 thru 5.

In the block diagram of Figure 2, when the measurement cycle is complete and a valid five-digit BCD word is present on DIGIT 1 – DIGIT 5, the measurement device (not shown) pulls \overline{START} momentarily LOW. This begins the computation cycle by clearing the Program Counter.

\overline{DONE} is a handshake return from the filter to the measurement device which remains HIGH until the computation is complete. DIGIT 1 – DIGIT 5 should not be permitted to

change until \overline{DONE} goes LOW.

As shown in Figure 4 the first cycle in each program step is subdivided into 2 half-cycles: a 'Fixed Program' half-cycle and a 'Decode' half-cycle. During the first half-cycle, a digit address is always set up and latched for the Digit Selector Network. If the current program step calls for a fixed operation, key closures are also simulated continuously during this half-cycle. (The on-chip key debounce feature of the calculator dictates that each key closure be simulated without interruption for at least 11.4 msec, followed by a pause of the same duration).

During the second half-cycle, the selected data is decoded, and key closures are simulated for the appropriate digit key.

If the current program step does not call for a BCD digit to be decoded, the FPLA addresses a unique sixth digit during the 'Fixed Program' half-cycle. This sixth digit is hardwired to a binary 15, which is ignored during the 'Decode' half-cycle since it is not a valid BCD code.

FILTER IN/OUT must be LOW for at least one computation cycle after the unit is turned on, in order to 'unlock' the calculator chip and initialize the filter. A panel switch can be used to control this signal; this would permit the operator to select either filtered or unfiltered data for display. (Note that the bias offset correction is applied in either mode).

An external system clock controls the program sequence. CLOCK should be approximately 40 Hz, 50% duty cycle, and can be free-running.

The FPLA steps the calculator through the program, by simulating multiplexed key closures in the sequence dictated by the Program Counter.

When the last operation is completed, the FPLA is disabled, \overline{DONE} goes LOW, and the Program Counter remains locked in its final state. The calculator displays the results of the computation until the next \overline{START} pulse arrives from the external measurement device. FILTER IN/OUT may be permitted to change state at any time during this pause for display.

Each program step, corresponding to a single state of the Program Counter, consists of two separate cycles of equal time duration. The FPLA is always enabled for the first cycle and disabled for the second.

Figure 3.

There are numerous applications where a quick and accurate measurement of rate is desired. But in many of these cases, the events do not occur very often, and so they require a long time before a reading is obtained. Usually an analog low-pass filter is used to filter and derive the DC component of a monostable, triggered by the event. The voltage level is then directly proportional to the rate. However, in order to minimize errors due to the charging and discharging of the filter, long time constants are used, which adversely affect settling times. As illustrates in Figure 1, an accurate reading can only be made if the filter output is sampled when $V(\text{avg})$ equals $V(\text{charge})$ or $V(\text{discharge})$, as opposed to sampling at constant time intervals. Furthermore, if the proper sampling

time as a function of input rate were known, one could compensate for filters with a faster rise-time, and thus obtain readings much sooner. This technique can be incorporated in a rate monitor system as shown in the circuit of Figure 2. The FPLA is used as a look-up table addressed by the counters after the monostable (MONO) goes LOW. The output counters are loaded every time a product term is activated, causing output F7 to go HIGH. When an event occurs, the output counter has stored in it the proper sampling time (T_s), and will count down to zero during the monostable time. When it reaches zero, the A/D will be triggered.

Figure 1.

The value of T_s varies with $V(\text{max})$, T_m and the RC time constant of the averager. It can be computed for various values of \bar{T}_m as follows:

$$V_1 = V_2 \exp(-\bar{T}_m/RC) \quad (1)$$

$$V_2 = V_{\text{max}} + (V_1 - V_{\text{max}}) \exp(-T_m/RC) \quad (2)$$

V_2 can be found by substituting (2) into (1). Each corresponding value of T_s to be digitized in the FPLA is then obtained by solving:

$$V_{\text{avg}} = V_{\text{max}} \frac{T_m}{T_m + \bar{T}_m} = V_2 \exp(-T_s/RC)$$

This circuit can be used in many industrial, medical and control applications. Using Heart Rate as a example, $T_m = 150$ msec, implying a maximum rate of 400BPM. Minimum heart rate is a function of the number of inputs to the FPLA, and the counter clock rate. Using the Signetics 82S100, and 1 kHz, the minimum H.R. = 1 BPM. Since one FPLA output must be used as clock enable only 7 outputs remain. These should be sufficient, for in this case $T_s(\text{max}) = T_m/2 = 75$. As a result the 48 product terms have to be used sparingly, but in most cases this provides more than adequate precision. We can see how the FPLA lends itself to this kind of application for, if we were to use a PROM, it would require a 16K x 8 configuration.

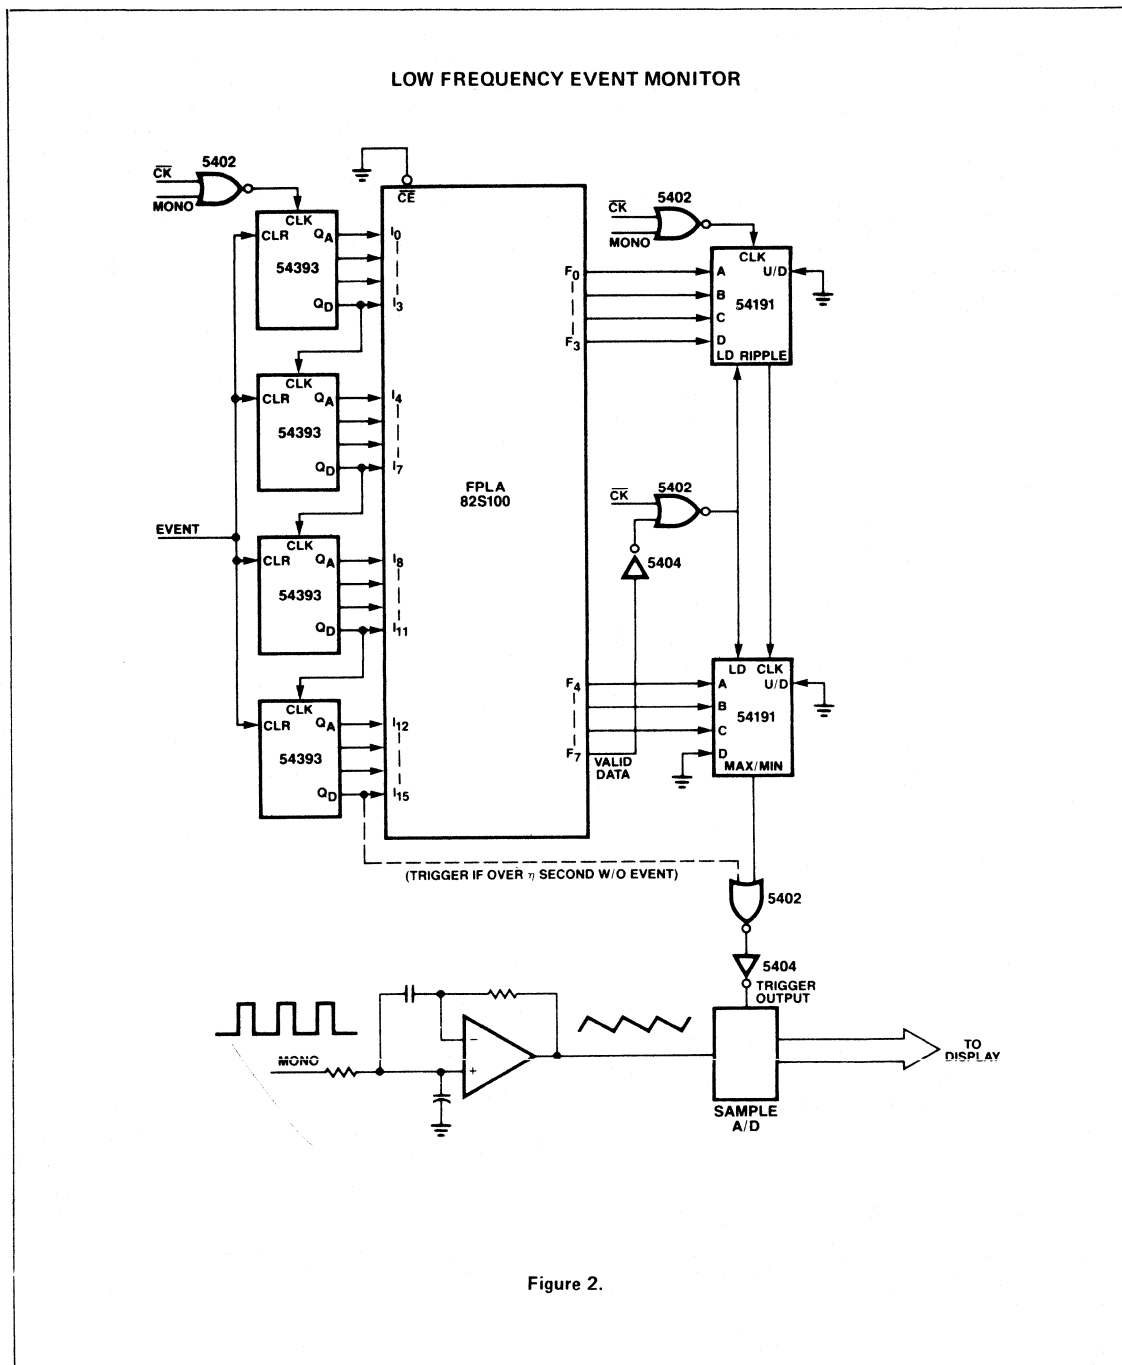

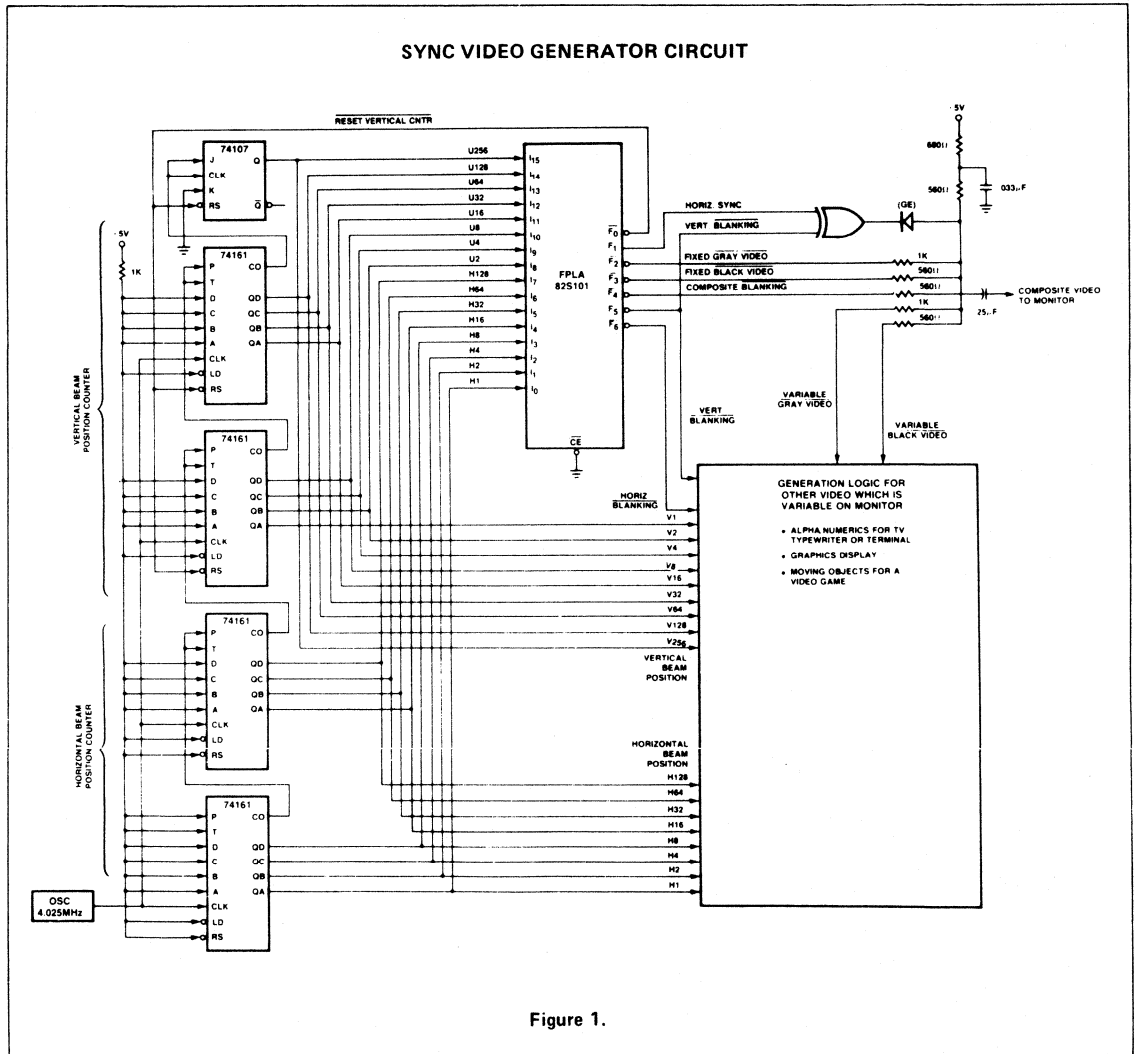

Figure 2.

In the design of any TV display it is necessary to develop the standard SYNC and BLANKING signals to drive the monitor. Although there are ICs which develop these signals, their beam position counter signals are not brought out to external pins. Therefore, to develop video one must duplicate the counter, and nothing will be saved. The circuit shown in Figure 1 uses an FPLA to develop SYNC and BLANKING, plus any video that remains fixed on the TV. Since the outputs of the vertical and horizontal beam position counter are available at the input to the FPLA, any combination of these signals can be used to develop fixed video on the monitor. This fixed video can be anything,

such as ruling lines for a TV typewriter, or the background for a video game. For example, in designing a Pong-like video game the FPLA could be used to make the border, the net across the center of the screen, a foul line around the periphery of the court, plus all the necessary SYNC and BLANKING. The remaining circuit would generate the two movable paddles and the ball.

The circuit in Figure 1 generates all necessary signals to operate a standard T.V. monitor in non-interlaced mode with 262 lines per frame, and 60 frames per second. It follows that $262 \text{ lines/frame} \times 60 \text{ frames/sec} = 15,720 \text{ lines/sec} \rightarrow 63.6 \mu\text{sec/line}$.

Assuming each horizontal time of $63.6 \mu\text{sec}$ to be divided into 256 time units called picture elements (pels), we obtain $63.6 \mu\text{sec}/256 = 248.44 \text{ ns}/(\text{time unit}) \rightarrow 4.025 \text{ MHz}$. The TV monitor visible area is partitioned timewise as shown in Figure 2. The total horizontal time (H_T) is composed of two parts:

- 1) The forward visible time (H_F)
- 2) The retrace time (H_R)

From the Radio Engineers Handbook we get the following information:

$$H_R = .155 H_T = 9.9 \mu\text{sec} = 40 \text{ pels}$$

$$H_{FP} = .02 H_T = 1.3 \mu\text{sec} = 5 \text{ pels}$$

$$H_{SP} = .08 H_T = 5.1 \mu\text{sec} = 19 \text{ pels}$$

$$H_{BP} = .06 H_T = 3.816 \mu\text{sec} = 16 \text{ pels}$$

$$V_R = 0.75 V_T = 20 \text{ lines}$$

The horizontal sync signals can be developed by using an eight bit counter, operating modulo 256 at the picture element rate of 4.025 MHz, with its outputs connected to an FPLA. There the appropriate counts will be decoded to generate the sync signals as follows:

| Count | Signal | Count | Signal |
|--------|----------|----------|----------|
| 0 → 39 | H_R | 25 → 39 | H_{BP} |
| 0 → 4 | H_{FP} | 40 → 255 | H_F |
| 5 → 23 | H_{SP} | | |

Every time the horizontal counter wraps back to all zeros, the vertical counter will be incremented by one. There will be 20 lines of vertical retrace (V_R), and 242 lines of vertical visible time (V_F) for a total vertical time (V_T) of 262 lines. Starting at the top of the screen the 9 bit vertical counter is all zeros, and is incremented by one at the end of each horizontal forward time (right hand edge of screen). When the counter reaches 241, the vertical blanking signal will be enabled and the polarity of horizontal sync reversed. The counting of horizontal lines continues until count 262 is reached, at which time the vertical counter is asynchronously reset to zero and the vertical blanking signal turned off, giving:

| Count | Signal |
|---------|---|
| 0-241 | V_F |
| 242-263 | V_R (reverse polarity of horizontal sync) |

The logic equation set for decoding the appropriate counts with the FPLA is tabulated in Figure 3, while the corresponding FPLA Program Table is shown in Figure 4.

Figure 2.

Where $H_T = H_F + H_R = 63.6 \mu\text{sec}$

The horizontal retrace time (H_R) is composed of three parts:

- 1) Front Porch (H_{FP})
- 2) Horizontal Sync Pulse (H_{SP})
- 3) Back Porch (H_{BP})

FPLA LOGIC EQUATION SET IN TERMS OF WEIGHTED BINARY INPUTS FROM THE COUNTER

| LOGIC EQUATION | ADDRESS SEQUENCE |

| <p>Reset Vertical CNTR = $256V \cdot 4V \cdot 2V$ (262V)</p> <p>Vertical Blanking = $(\overline{256V} \cdot \overline{128V} \cdot \overline{64V} \cdot \overline{32V} \cdot \overline{16V} \cdot \overline{8V} \cdot \overline{4V} \cdot 2V) +$ (242V - 262V) $+ (\overline{256V} \cdot \overline{128V} \cdot \overline{64V} \cdot \overline{32V} \cdot \overline{16V} \cdot \overline{8V} \cdot 4V) +$ $+ (\overline{256V} \cdot \overline{128V} \cdot \overline{64V} \cdot \overline{32V} \cdot \overline{16V} \cdot 8V) +$ $+ (256V)$</p> | |
| <p>Horizontal Blanking = $(\overline{128H} \cdot \overline{64H} \cdot \overline{32H}) +$ (0H-39H) $+ (\overline{128H} \cdot \overline{64H} \cdot \overline{32H} \cdot \overline{16H} \cdot \overline{8H})$</p> <p>Horizontal SYNC = $(\overline{128H} \cdot \overline{64H} \cdot \overline{32H} \cdot \overline{16H} \cdot \overline{8H} \cdot \overline{4H} \cdot \overline{2H} \cdot 1H) +$ (5H-23H) $+ (\overline{128H} \cdot \overline{64H} \cdot \overline{32H} \cdot \overline{16H} \cdot \overline{8H} \cdot 4H \cdot 2H) +$ $+ (\overline{128H} \cdot \overline{64H} \cdot \overline{32H} \cdot \overline{16H} \cdot 8H) +$ $+ (\overline{128H} \cdot \overline{64H} \cdot \overline{32H} \cdot 16H \cdot 8H)$</p> | |

Figure 3.

The circuit shown in Figure 1 provides tennis court boundaries and scorekeeping capabilities for electronic games, such as the one introduced in EDN August 5, 1976. The TV screen is divided into a matrix of 256 by 256 squares. The FPLA serves to connect the squares so that they take on the shape of a tennis court. Sync signals are generated

along with other signals that are necessary for determining which boundary the ball has hit. The score is displayed 0 to 15 using an 8 segment format. The score is disabled while the ball is rallied. The FPLA is particularly suited to this application since the scoreboard requires 16-input AND gates.

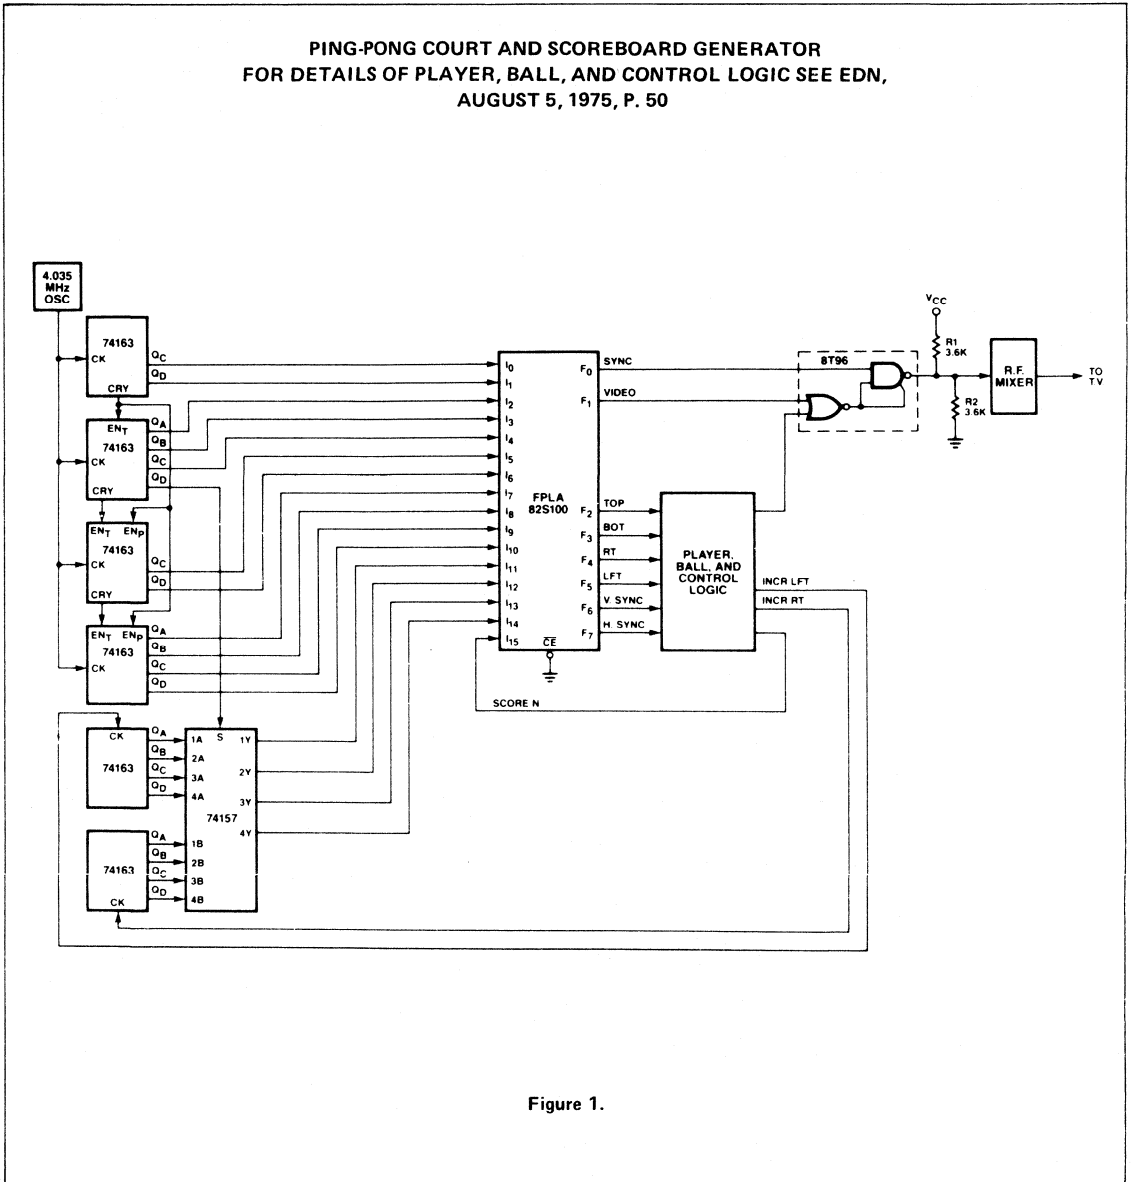

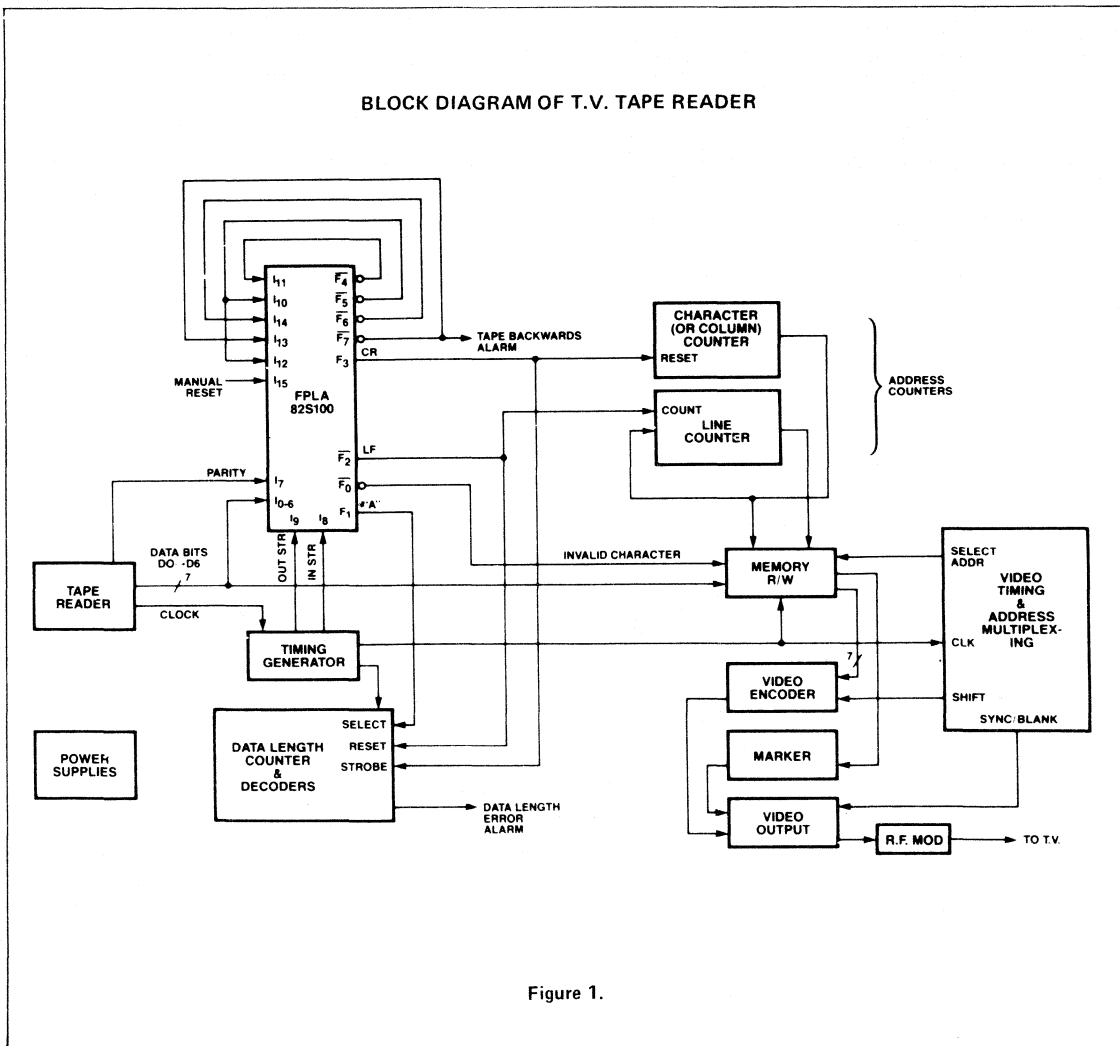

Figure 1.

A TV video display can be controlled via incoming data by using an FPLA to detect machine commands as data from a tape reader. Although a ROM could supply the necessary functions, it cannot use its extra inputs and outputs to form flip-flops that can be set internally by selected character or groups of characters. This technique is used in the proposed design to detect the order of characters passing through the tape reader for creating a "tape backward" alarm, used when reading tape by hand. The block diagram of Figure 1 shows an FPLA used to control the interface between a TV and a tape reader.

The system most critical control function is that of detecting invalid characters, including parity errors, which can be avoided by strobing the outputs, giving them time to settle. Carriage return (CR) is used to reset the character counter in the TV display, while line feed (LF) is used to advance the line counter by one. The "A" character designates a "time" message and is used to select one of two message lengths to detect dropouts or run-ons.

These functions are implemented in the FPLA connected as shown in Figure 2, and suitably programmed. Nothing that CR is always followed by LF, if the first F/F is set by CR

and reset by LF, its output state is determined by the last of the two characters read. The output that is HIGH after CR is received is "AND" gated with a character that is always present in a message, and then used to set a second F/F. If the tape is being read in the right direction, the 1st F/F is reset before its output can be used to set the 2nd F/F (which goes to the alarm). This approach permits any series of data to be checked for a certain order of characters to flag special conditions, where data can be a set of sensors outputs, as well as digital words.

The proposed TV tape reader processes incoming data, checking for invalid characters (including parity errors), length of messages (number of characters), which length out of two instructions for positioning characters on the TV screen, and which direction the data is moving through the reader. The same circuit using TTL gates would require over 25 chips. An FPLA instead allows up to 42 characters to be detected for validation and controls, with only six product terms dedicated to implement the fold-back flip-flops.

Figure 2.

DIGITAL MESSAGE DECODER

The input selection property of FPLAs can be combined with simple Set/Reset flip-flops to implement basic logic modules which can be cascaded as shown in Figure 1 to

detect group of words in a string of data, such as used by data terminals and other computer controlled devices.

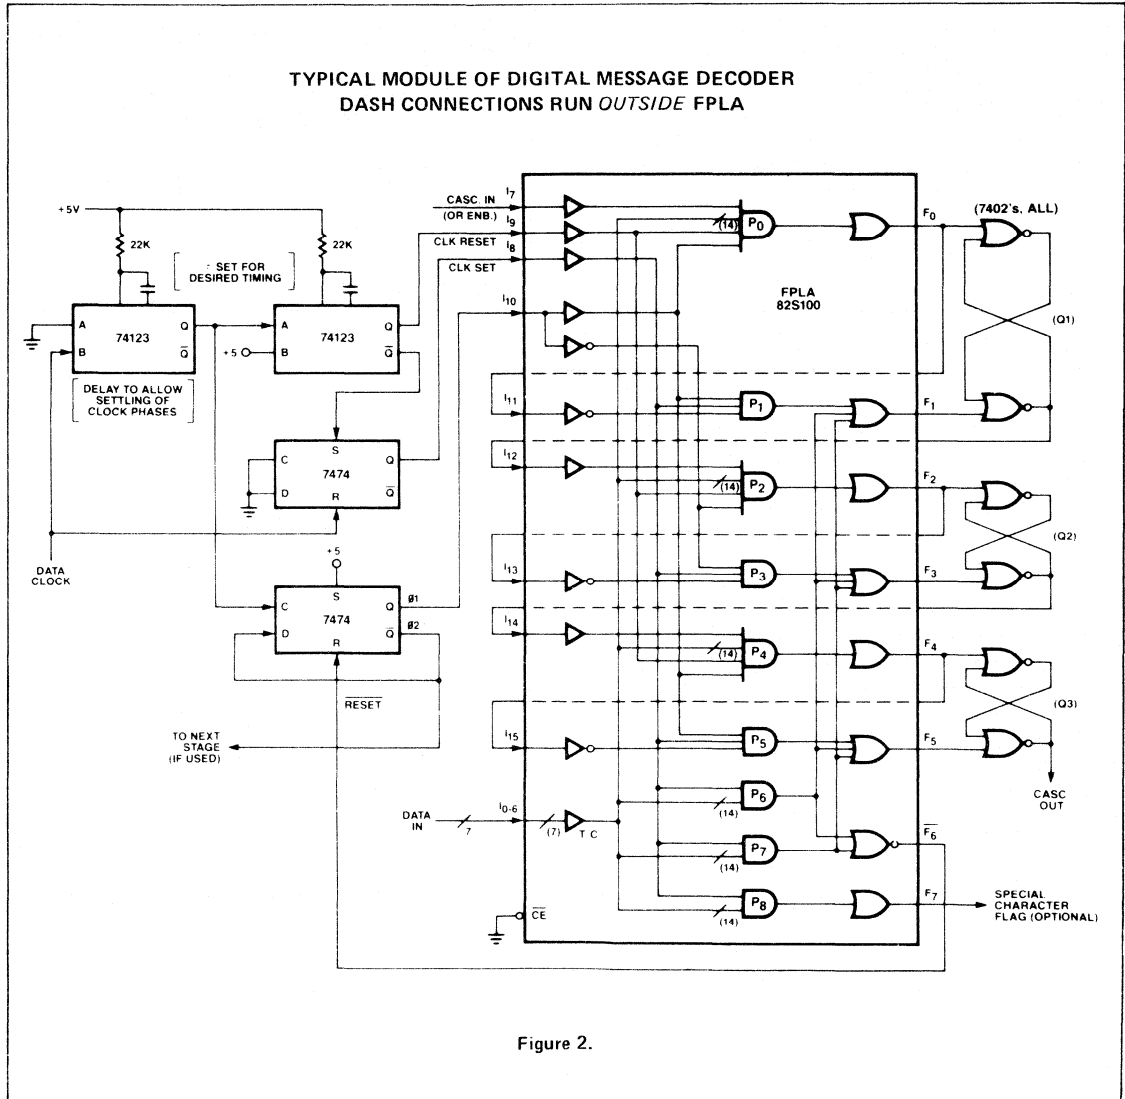

Figure 1.

A typical module, shown in Figure 2, contains 3 stages comprised of an FPLA controlling the setting and resetting of inputs of 3 flip-flops, after proper decoding of the incoming data. Additional circuitry common to all stages/modules generates all necessary clocking signals.

The FPLA is programmed such that product term P₀ contains inputs $\emptyset 1$, CLK SET, ENABLE (or CASC OUT) from the previous stage, and the True or Complement inputs of the data bus corresponding to the word being decoded.

When all these conditions are met, Q1 is set. But if the received word is incorrect, P₁ instead receives as inputs P₀, CLK RESET, and $\emptyset 1$. This will cause Q1 to be reset any time an incorrect word is clocked into the module.

To keep the data True signal from the previous stage from being lost while reading the current word, two clock phases are used. While the current state is in use, the previous one is disabled. And since clock $\emptyset 2$ is a simple inversion of $\emptyset 1$, only one FPLA input is needed for both.

Note that both phases are generated because if an additional module is used, its first clock phase will be number 2. This way if the circuit is used as an electronic combination lock, it can be changed partly by interchanging FPLAs. That is, each FPLA contains a three word code that can be moved to a different location. As additional security precaution, one person could hold the key, while only another is entrusted with the code. There could even be two keys, both simultaneously needed.

To appreciate the difficulty of breaking such a code to gain access of a system so equipped, note that with two PLA chips it would take over a century to check all the combinations, a rate of one thousand times a second. With four, the time is about 5×10^{11} years.

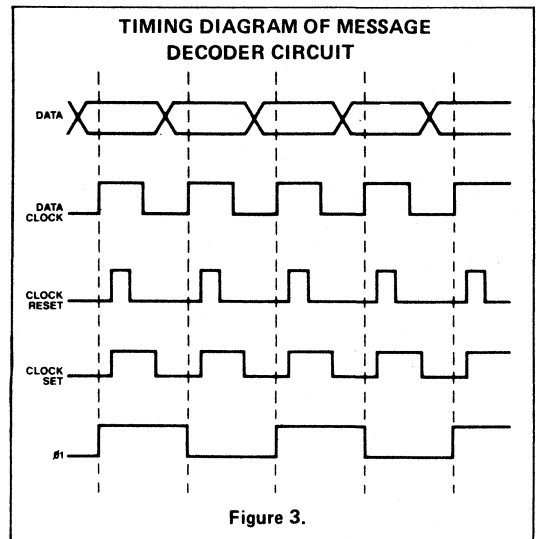

Figure 3.

An FPLA can provide an efficient means to interface a calculator chip to other circuits. The calculator can then be used as a terminal, a part of an instrument, or to drive a printer or CRT. The circuit also allows the calculator to be remotely operated. The interface is complete as shown in Figure 1. Timing is derived from the BCD Digit Output. The control and flow of data in and out is described below and by the calculator specification (National MM3738). The actual implementations of the equipment connected to the interface will depend on the desired application. The timing is derived from the Digit select outputs. The first 10 terms in the FPLA may be used alone as a 7 segment to BCD decoder.

The interface contains signals allocated to the FPLA inputs and outputs as follows:

A) Control – I₁₅-I₁₆, where:

| I ₁₅ | I ₁₆ | Function |
|-----------------|-----------------|-------------------------------|
| 0 | 0 | Read data from the calculator |
| 0 | 1 | Input numbers 0 - 9, ., % |
| 1 | 0 | Input functions +, -, etc. |
| 1 | 1 | Request D.P. location |

B) Data out – F₀-F₇, where:

- With interface control at "00", read multiplexed data in BCD form F₀ (A) to F₃ (D). Digit location corresponds to the BCD digit output. Also, F₇ is a "0" for output 1-9, and becomes a "1" when output 0 is displayed. Two other codes exist when F₇ is a "1":

| DCB A | Code |
|-------|-----------------|
| 111 0 | Negative Sign |
| 111 1 | Error Condition |

- With interface control at "11", and the D.P. line gated to I_g (Data input D), the DCP location will be output in BCD corresponding to the digit location of the decimal point. Two word cycles of the calculator output are required to get both data and decimal point location into a buffer or memory.

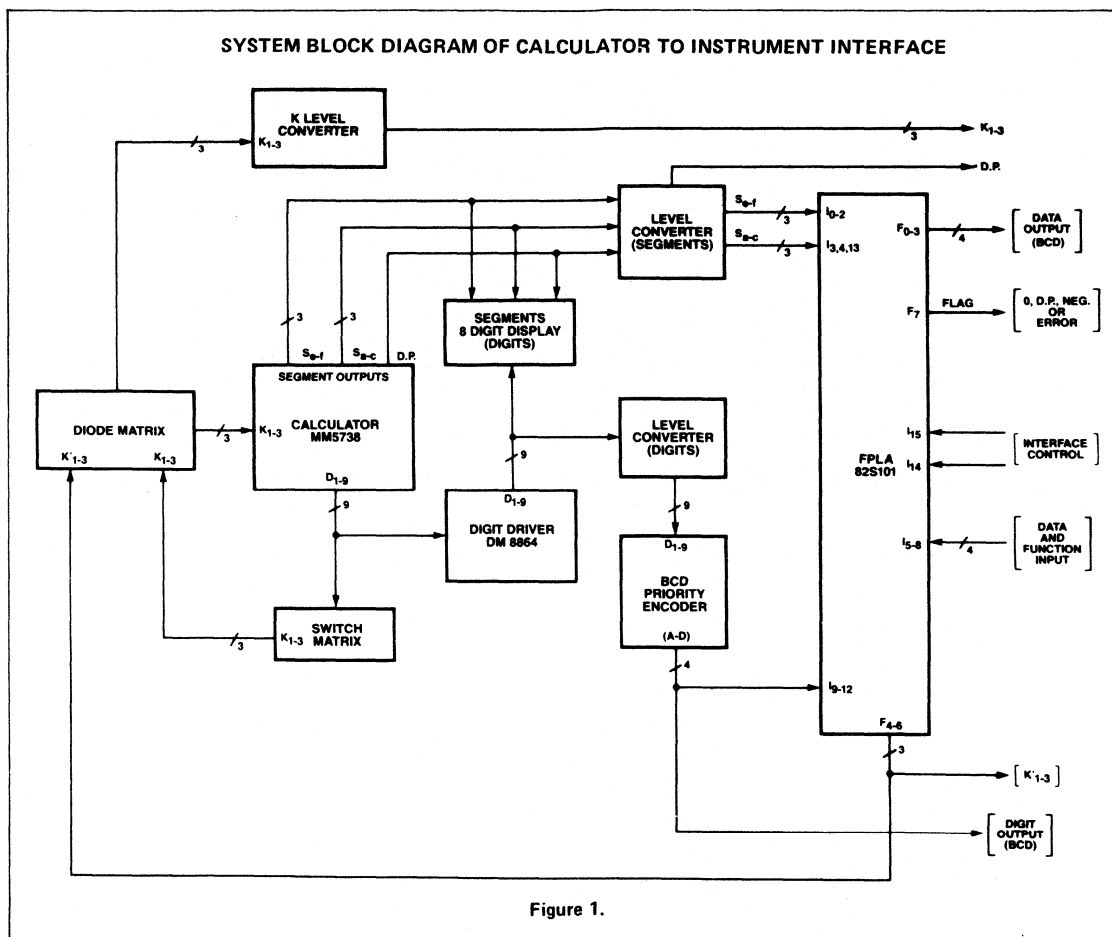

Figure 1.

C) Data Input – With the interface control at “01”, data is clocked in at I5, I6, I7, and I8 as follows:

| I8 | I7 | I6 | I5 | Data |
|----|----|----|----|------------|
| 0 | 0 | 0 | 0 | “0” |
| 0 | 0 | 0 | 1 | “1” |
| 0 | 0 | 1 | 0 | “2” |
| 0 | 0 | 1 | 1 | “3” |
| 0 | 1 | 0 | 0 | “4” |
| 0 | 1 | 0 | 1 | “5” |
| 0 | 1 | 1 | 0 | “6” |
| 0 | 1 | 1 | 1 | “7” |
| 1 | 0 | 0 | 0 | “8” |
| 1 | 0 | 0 | 1 | “9” |
| 1 | 0 | 1 | 0 | “.” |
| 1 | 0 | 1 | 1 | % function |

D) Function Input – With the interface control at “10”, functions are input as follows:

| I8 | I7 | I6 | I5 | Function |
|----|----|----|----|----------|
| 0 | 0 | 0 | 1 | C |
| 0 | 0 | 1 | 0 | K |
| 0 | 0 | 1 | 1 | - |
| 0 | 1 | 0 | 0 | + |
| 0 | 1 | 0 | 1 | MR |
| 0 | 1 | 1 | 0 | MS |
| 0 | 1 | 1 | 1 | X |
| 1 | 0 | 0 | 0 | ÷ |
| 1 | 0 | 0 | 1 | □ |

Note that when the Functions or Data are input to the calculator, they are read out on the data lines for comparison (if desired). This feature is different from the Data Output by the presence of a "1" in either K₁, K₂, or K₃.

- E) Digit Outputs (not an output of the FPLA) – These lines are the digit select outputs of the calculator encoded in BCD. They are used primarily when storing Output Data and Decimal Point location in memory.
- F) K₁, K₂, K₃ – These outputs at F₄, F₅ and F₆ are used to input data to the calculator. The calculator recognizes data on the basis of a K input and the Digit Select cycle. The FPLA will activate the proper K line in synchronism with the digit select lines. The K₁, K₂, and K₃ lines as shown on the

diagram will indicate switch (keyboard) operation as well as remote data input. The K lines may be used to discriminate between data input and data output functions at the interface.

- G) Digit Select inputs to FPLA, I₉, I₁₀, I₁₁, and I₁₂ (A' to D' respectively) – These lines are used to select the proper K output when inputting data or functions.
- H) Segment inputs to FPLA (I₀ to I₄) These are S_a, S_b, S_e, S_f, S_g respectively, and uniquely identify the BCD outputs of 0 to 9 and the (-) sign. The error condition requires segment S_c input to I₁₄ for a unique identification.

The FPLA Program Table containing all codes necessary to service the above interface lines is shown in Figure 2.

MICROPROCESSOR TO CALCULATOR-CHIP INTERFACE

The circuit shown in Figure 1 will interface directly between a microprocessor and a calculator chip in systems where low cost, high computational power, but no need for a high speed computation ability (i.e., FFTs and R.T. systems) exist. It could be used in low cost, low speed navigational systems and business applications. FPLA U1 acts as a keyboard simulator receiving output port information from the microprocessor via the data bus, and converting a binary code into the correct keyboard entry to the calculator. The MP will know when to output by interrogating Input Port 1 through FPLA U2 to ascertain if the matrix it wishes to talk to is available at that time. Since the calculator will run in the kHz range and the MP in the MHz range, no problem should be encountered in interfacing.

The U1, U2 combination provide the calculator with the serial inputs normally provided by push buttons. U3 and U4 provide the microprocessor with the answer when the computation is completed.

FPLA-U3 would decode from 8 strobe lines and 7 segment signals an appropriate binary code on to the data bus, thereby providing the microprocessor with answers and evidence of completion of a specific task. It also could provide a method of acknowledgement of receipt of numbers or tasks. FPLA-U4 decodes the upper eight bits of numbers. Since FPLAs are field programmable the system can be adapted to different calculator configurations and efficient software configurations for the microprocessor chosen.

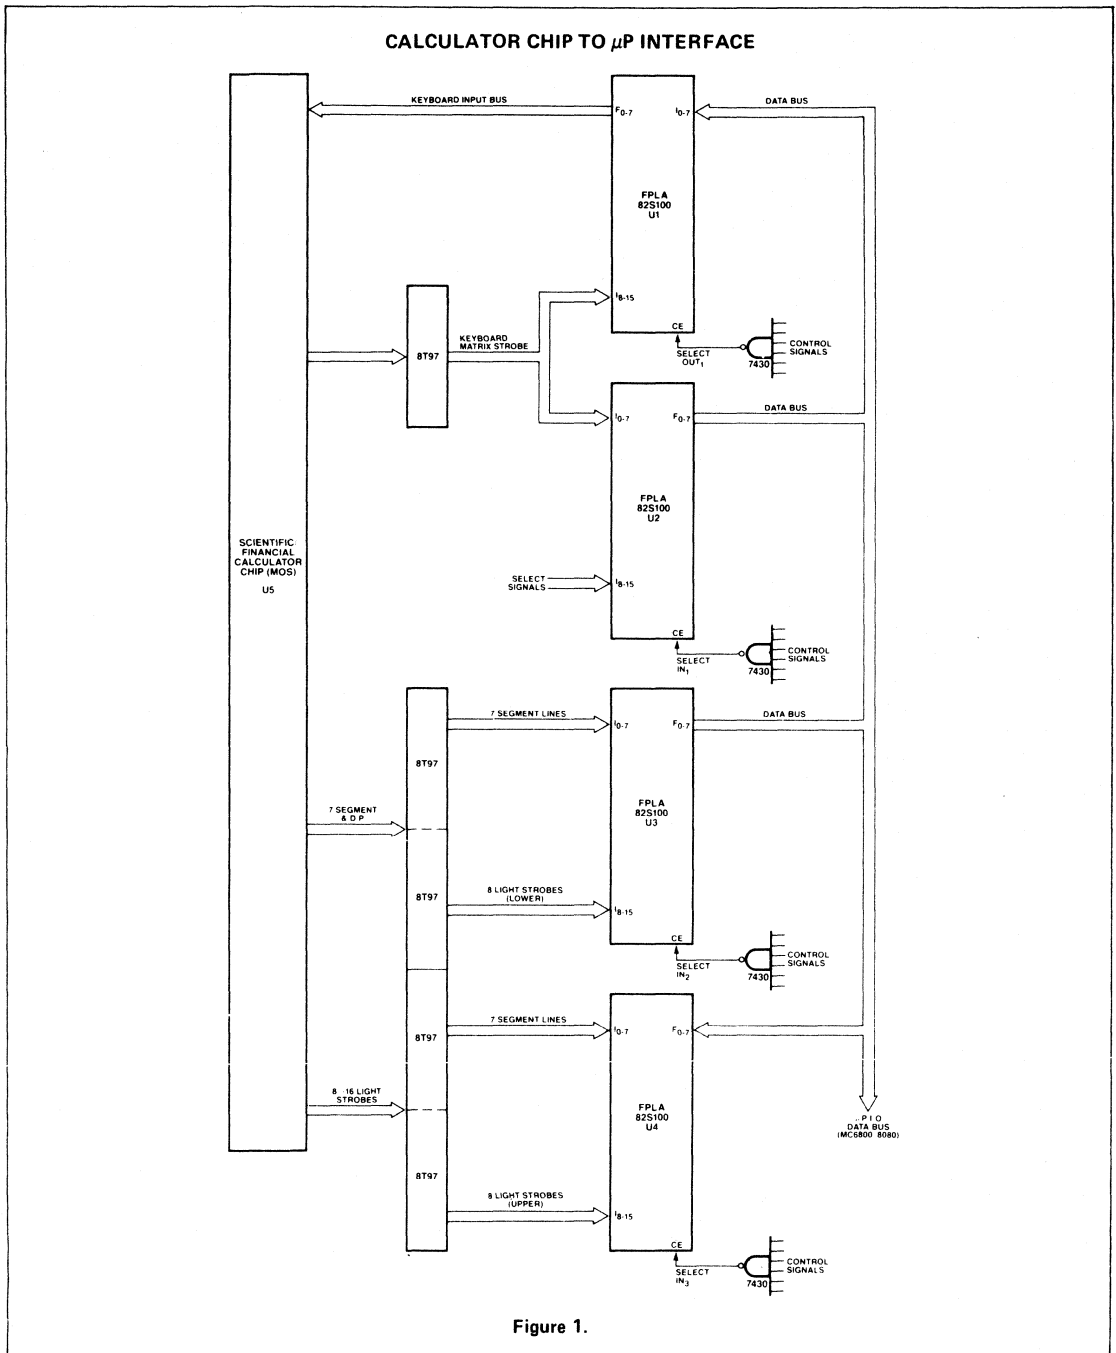

Figure 1.

The circuit shown in Figure 1 uses two Signetics' 82S100 FPLAs, and a few discrete components, to implement a full 64 character ASCII keyboard compact enough to be hand-held or built into the front panel of a computer. Its compactness is due to the use of only 23 keys: 16 character keys, 4 mode keys, and 3 special purpose keys. The keyboard switches need only be SPST-NO; the transistor is not critical, and the LEDs should be efficient enough to be visible with 6 mA current.

The circuit output is a positive logic 7-bit ASCII code, with data valid on the rising edge of the positive-going strobe pulse. Approximately 2 ms of strobe delay is provided for key contact debouncing.

Each of the 16 character keys generates 1 of 4 different characters, depending upon which of four modes the keyboard is in, as selected by the mode keys. When a mode is selected, the keyboard stays in that mode for as many characters as needed until another mode is selected. Included is protection against false character codes due to two keys

being depressed at once, key contact debouncing, and 2-key rollover to speed data entry. Also provided are three single purpose keys for carriage return, line feed, and rubout. All characters and functions are supplied by the two FPLAs, programmed as shown in the program tables in Figures 2 and 3, with just 17 Product Terms used in each FPLA. Partially used or partially functional FPLAs may also be used, as long as there are 17 useable Product Terms, and all the 8 outputs operate. The decoding scheme is straightforward. The 16 character keys are divided up into two 8-member groups, and within each group the individual keys are encoded down to the least significant 3 bits of the output. Bit 3 (the fourth bit) is "0" for the group (1) keys and "1" for the group (2) keys. Bits 4 and 5 are set by which of the four modes the keyboard is in. Bit 6 is simply the inverse of bit 5 except when one of the special keys (CR, LF, or RO) is depressed. The remaining of the 17 Product Terms are used to generate the strobe pulse and implement the 2-key rollover feature with the false code protection.

Figure 3.

In many applications it is desirable to expand the capabilities of inexpensive calculators so that they may be easily interfaced to printers, BCD displays, or computer data input. The output of most calculator chips is automatically multi-

plexed and presented in standard 7-segment form. For each digit there is a digit select output signal which appears sequentially while segment outputs provide the decoded figure.

CONVERSION TRUTH-TABLE TO BE PROGRAMMED IN THE FPLA

| NUMBER | INPUTS | | | | | | | | OUTPUTS | | | | | | | | | | | | | | |
|--------|-------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|--------------|---|---|---|---|---|---|----------------|----------------|----------------|----------------|----------------|----------------|--------|----------------|

* or (0000)

Figure 1.

The circuit in Figure 1 shows how an FPLA can provide a simple means for converting the 7-segment calculator output to Binary Coded Decimal. Further decoding of up to eight calculator digit select lines provides a binary number

indicating which digit is being displayed, along with a strobe pulse to indicate when a valid digit occurs. The full conversion truth-table to be programmed in the FPLA is tabulated in Figure 2.

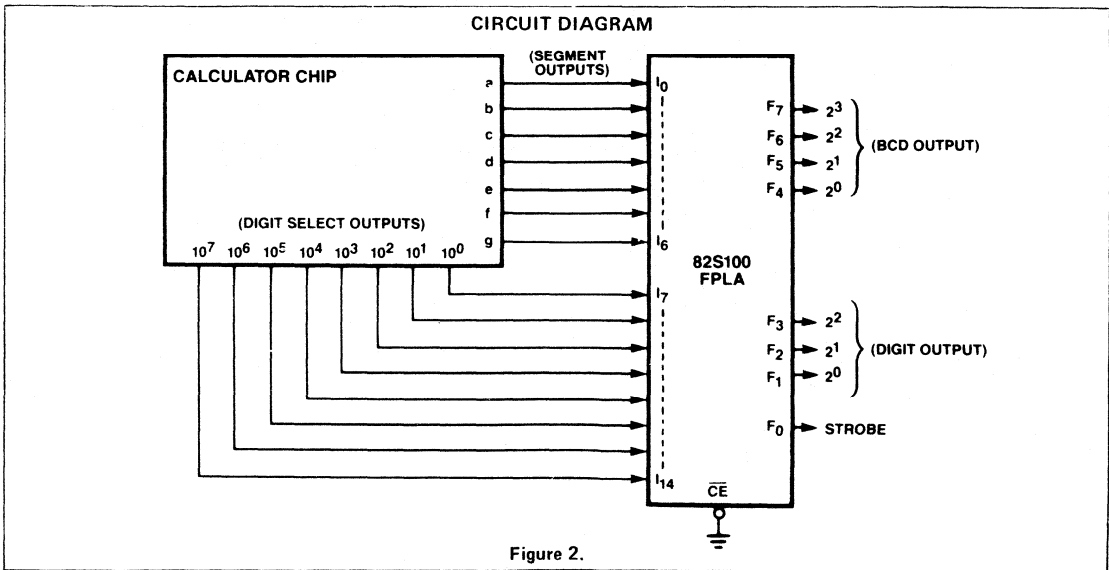

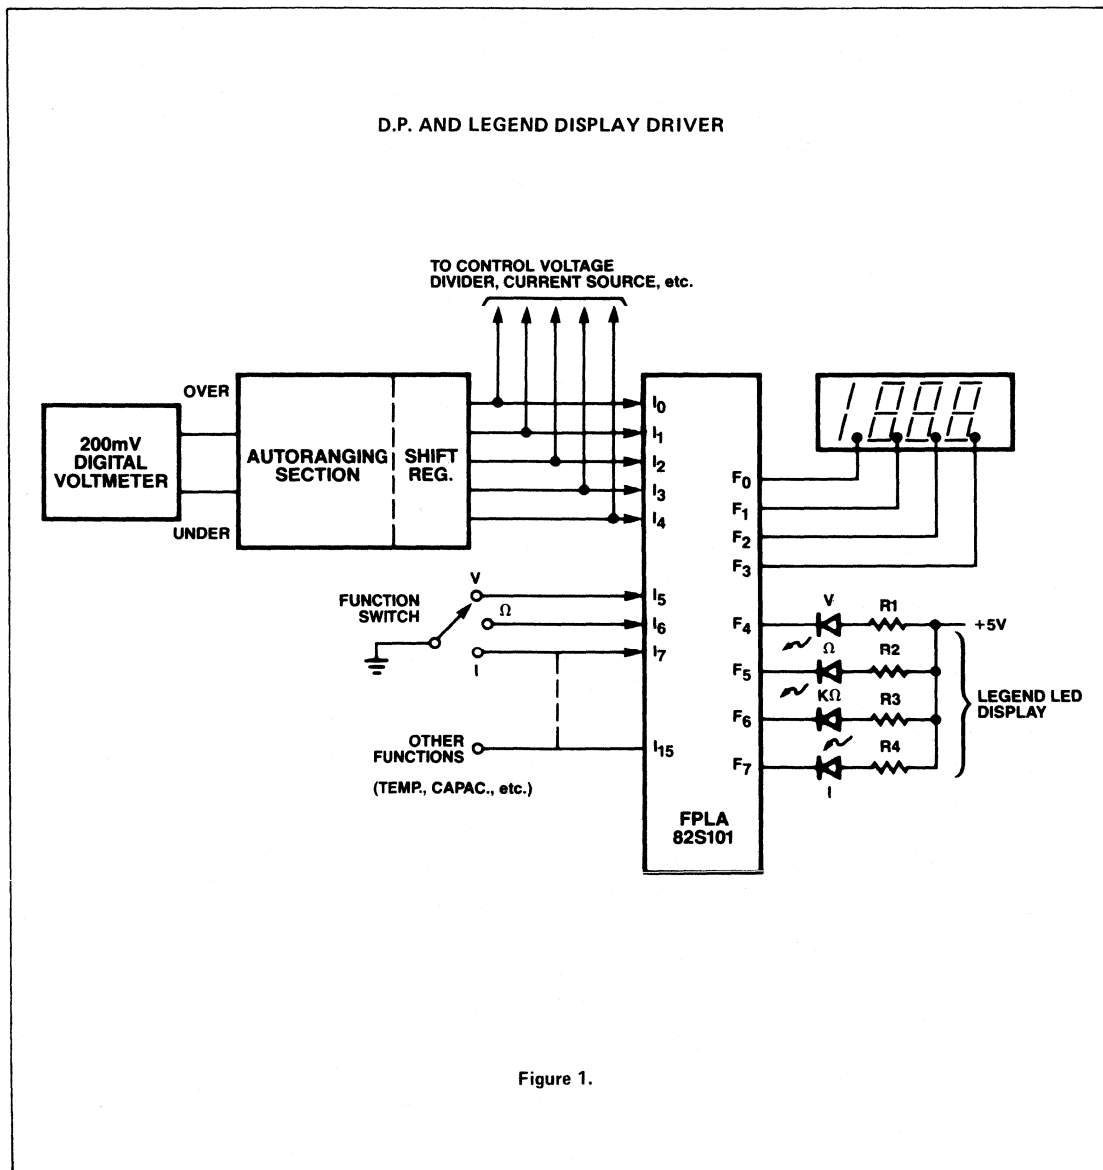

Figure 2.

In wide range and multifunction instruments, the FPLA can be effectively used to provide proper decimal point display and to illuminate function legends. The circuit in Figure 1 shows the application of an FPLA in an autoranging digital multimeter. The FPLA receives inputs from a shift register in the autoranging section. It also accepts inputs from the function select switch. The open collector outputs of the

FPLA could directly drive the decimal point within its limit. Other outputs are used to turn on appropriate LEDs displaying legends such as V, MV, R, $K\Omega$, A, MA etc. Buffering may be necessary. The FPLA can accommodate large flexible ranges as well as many functions, thus reducing design time and IC gate packages in a family of instruments.

The circuit diagrammed in Figure 1 is designed to accept a string of hexadecimal characters from a calculator type keyboard and provide a 10 second signal to a user defined actuator such as a solenoid driven door latch, when the character string matches the programmed combination.

Four 16-character combinations may be programmed in the FPLA. The combination to be used is specified by the position of the two combination select switches S1 and S2. Combinations of shorter length may be programmed to allow easier entry to the device being locked, but maximum security will be realized using a 16-character combination. Before using, the lock must first be reset in a known state. Depressing the RESET button on the keyboard forces the reset line LOW. The RESET signal is buffered by the FPLA

and appears as an active-LOW signal called BRESET, which causes the TRUE flip-flop to be forced true, the OPEN timer to be forced off, and the character counter to be loaded with zero. The trial combination is then entered by depressing the numerical keys in sequence. Upon depressing the last key in a correct sequence a 10 second actuation will occur.

Depressing a numerical key causes a hexadecimal data pattern to appear on the four data lines D0-D3. An active-LOW strobe from the keyboard informs the FPLA that a valid data pattern is being presented. The STROBE signal is buffered by the FPLA to become the active-LOW signal BSTROBE. While STROBE is LOW, the data field to the FPLA is compared to the programmed data character asso-

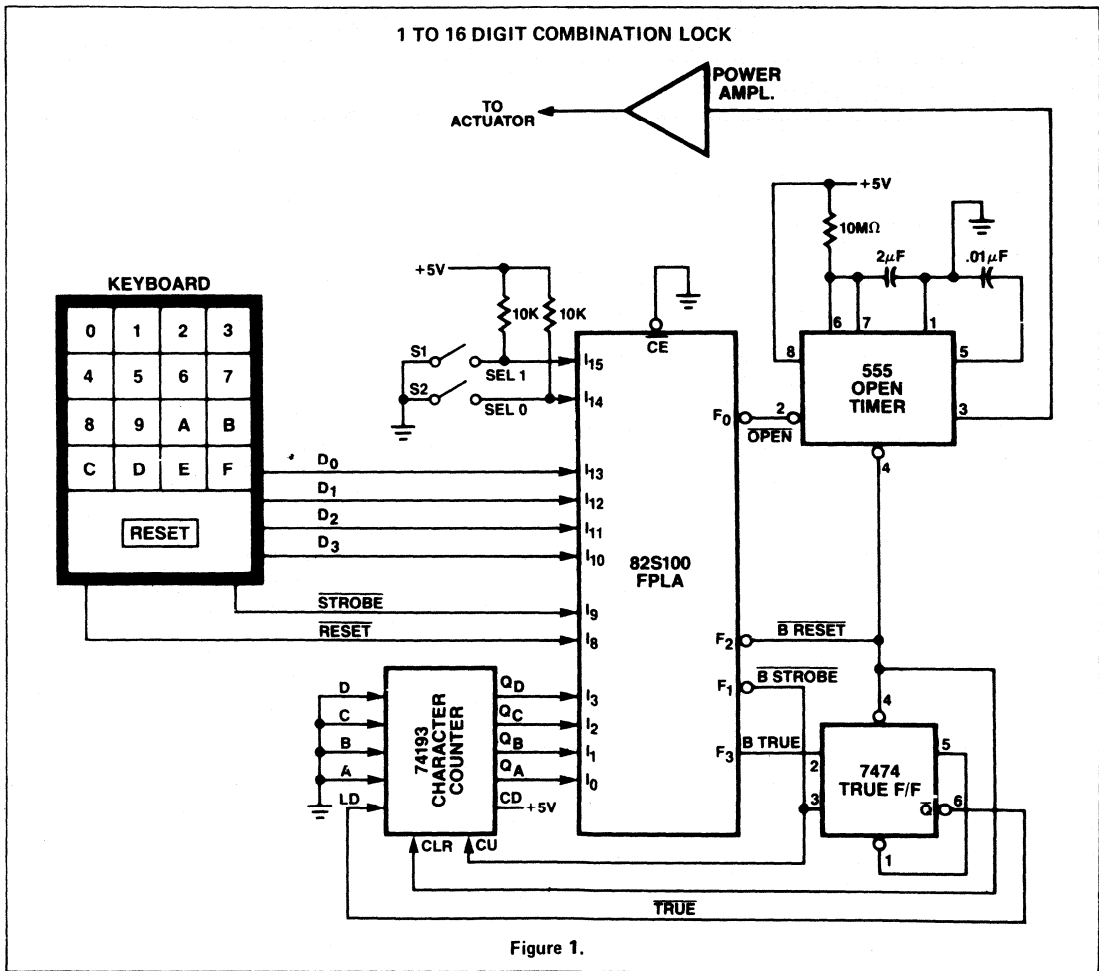

Figure 1.

ciated with the current character count (C_0-C_3), and combination select (SEL_0-SEL_1). If the data matches the programmed character, signal BTRUE will be forced HIGH; if not, it will appear as a LOW. At the rising edge of BSTROBE, the state of BTRUE is latched into the TRUE flip-flop, and the character counter is incremented. If a mismatch had existed between the data and the programmed character, a LOW would be clocked into the TRUE flip-flop, causing it to latch itself in the false state, resetting the character counter and ignoring all future data comparisons until the RESET key is depressed.

The character counter increments for each sequential successful match until a preprogrammed terminal count is reached. The OPEN signal is activated when the terminal count has been reached, STROBE is LOW, and the data field matches the programmed character associated with

terminal count and the selected combination. When the OPEN signal goes LOW, it fires a 10 second interval timer. The HIGH output from the running timer is applied to a power amplifier to drive the user defined actuator. For a safe, or door lock application, the actuator could be a solenoid driven latch pin. For automotive applications, the actuator could be an ignition enable relay. For computer applications, this device could provide restricted use of certain peripherals or of the entire computing mechanism.

Additional outputs are available in the FPLA to provide an alarm function. For example, an alarm bit could be programmed to be activated when an excessive number of characters were detected in a string. In safe door lock applications, a battery back up to the normal supply is recommended to prevent permanently sealing the safe upon loss of power to the unit.

DATA SECURITY ENCODER

The security of a data train on a common carrier is enhanced when data is encoded to a particular hard-wired encoded version. This results in the correct detection only in a similarly programmed receiving terminal.

The system shown in Figure 1 seems to have well over $8! = (403020)$ different combinations without resorting to anything but pulse permutations. In applications for computer systems, the computer could use a random sequence to program devices, as only devices which communicate need to know how they are programmed. Data security is assured, since only the programmer knows the permutation in use.

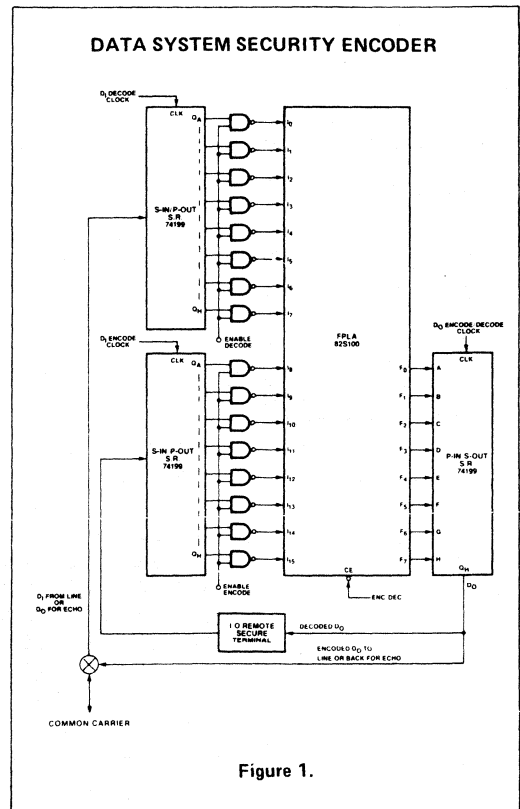

Figure 1.

The calendar clock date reminder decodes 48 unique dates in a calendar year. This would be used to give the owner a reminder of birthdays, anniversaries or any other special day he feels he should remember.

The FPLA is programmed to recognize the dates selected by the owner. Practically, it would be programmed to activate a monitor several days before the actual event, to give the owner time to respond to the reminder.

The circuit in Figure 1 gates the normally multiplexed output of a calendar clock circuit into 11 input lines to the

FPLA. To do this, it must demultiplex the BCD output and latch it into registers for a stable input to the FPLA. This is accomplished by the calendar clock's internal digit driver used to gate the appropriate 74175 register. For example, the clock digit driver that is used to display the least significant days digit, D₀, is used to latch this data into IC₄ for input into the FPLA as I₀ thru I₃.

When the month and day BCD input match the programmed date, the FPLA outputs F₀ - F₇ are used to visually indicate the reminder. This can be implemented simply with LEDs driven by the FPLA outputs to indicate various events.

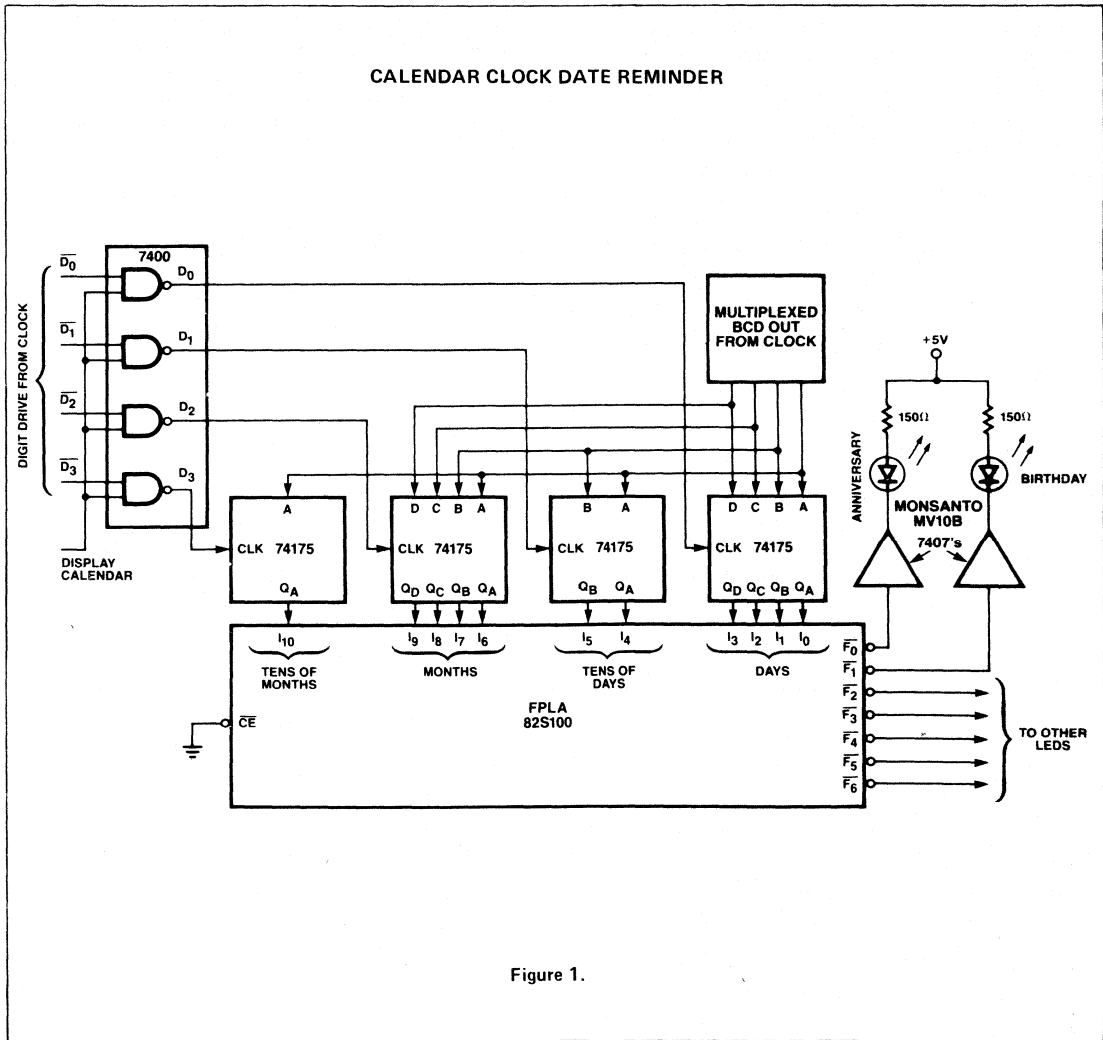

Figure 1.

A preventive Maintenance Monitor can be used to give an accurate visual or audio indication of maintenance required for any type of hardware or equipment at specified time intervals. It could be used with costly machinery that required various maintenance actions at diverse times, without which degradation of equipment would result.

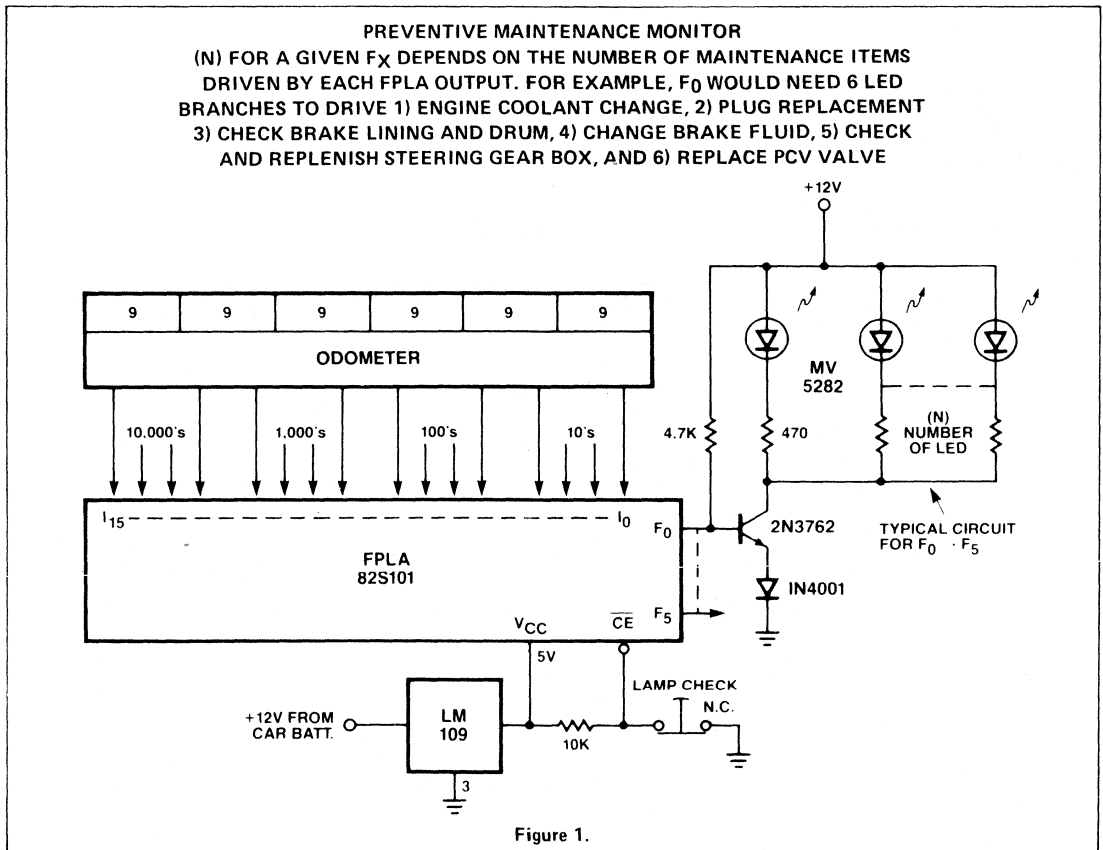

Equipment where such a positive maintenance indication can be utilized range from simple computer hardware such as mag-tape transports and disks, to more complex electro-mechanical machinery and systems such as airplanes, etc.

The circuit shown in Figure 1 utilizes the elapsed time meter usually present on any critical piece of hardware/system. The ETM can be modified, like a thumbwheel switch, to provide BCD outputs to the Preventive Maintenance Monitor.

Although general in principle, the circuit gives an example of a PMM utilized to implement a typical maintenance schedule for an automobile, as recommended by the manufacturer's specifications. The input to the system in this

case is the odometer reading. (The odometer has been modified to provide BCD outputs). The outputs of the system are real time indications of which items need maintenance, and when. There are two types of LED indicators: one indicates that some function should be checked, while the other indicates something needs to be replaced or changed.

The inputs to the FPLA are four BCD digits, representing miles in tens, hundreds, thousands, and tens of thousands. Using this scheme, when the odometer value is decoded by the FPLA to indicate a maintenance action, the LED indicators for that action will remain lit for ten miles until the tens BCD changes. By using less inputs the indicators would stay lit longer. For example, 12 inputs, (eliminating tens), would cause the indicators to stay on for a hundred miles, which may be more desirable. Any thing less than 12 inputs (3 BCD's) would make the degree of resolution time when action is required too low.

Just one FPLA easily implements the manufacturer's maintenance schedule outlined in Figure 2. As shown in the Program Table in Figure 3, only 34 product terms are necessary to carry maintenance out to 99,000 miles. After 100,000 miles the PMM system would wraparound and be functional for however long the car lasted. Five outputs (0-4) are used for the four frequency classes of maintenance as shown on the left column of the maintenance schedule.

In addition, F5 is used for indicating replacements or changes needed. F6 and F7 are not used but could be used, along with some of the unused product terms, for some other indication such as a reminder as to when the car should be brought in for its warranty check-ups. The momentary push button switch is used as a lamp-check by forcing all outputs to the default HIGH state via the CE input.

Software Support for IFL

SOFTWARE SUPPORT

AMAZE

Description

Automatic Map And Zap Equation Entry software program. The AMAZE software program consists of the following four modules:

- BLAST ('Boolean Logic And State Transfer entry program)
- PTI ('PAL To IFL' conversion program)
- DPI ('Device Programmer Interface program)
- IFL SIM ('IFL Simulator' program)

Each module performs specific tasks as outlined in the sections to the right. Each AMAZE software package will be made available in various combinations of the above modules.

Features

- Multiple modules allowing expansion for future requirements
- Each module designed to be user friendly
- Both HELP and ERROR messages displayed
- Document print out: Header, Boolean Equation & Fuse Map etc.
- Interfaces with most commercial programmers
- SIMULATOR programs provide both test and applications assistance.

Equipment

- AMAZE is capable of operating on a VAX computer with a VMS operating system and on an IBM PC computer with MS/DOS operating system.

BLAST

Description

Boolean Logic And State Transfer program is an interactive software package that supports the engineer in implementing logic design into Integrated Fuse Logic. It checks design data and automatically compiles a program table from Boolean equations. Data from the program table is then used to produce a Standard File which contains the fusing codes in a form acceptable to both the Device Programmer Interface program and the IFL Simulator program.

BLAST consists of a series of screens or menus that lead the operator, step-by-step, through the design input process. During this process, most of the screen displays present menus that assist in selecting specific areas (such as Control Array) to work on. Generally, a check for consistency and legality is performed upon the screen exit to verify that the design was carried out in accordance with the set rules. BLAST will alert the operator with an audible alarm and a display of an error code when an error is detected. An error code table can be invoked to explain the type of error that caused the alarm. HELP messages are available to provide descriptions of the use and operation of each screen in the BLAST software package.

Features

- Screen Menus for inputs
- HELP Call up from any screen
- Error messages available
- Full Compiler to perform Product Term manipulation
- Document print out: Header, Boolean Equation & Fuse Map etc.

PTI

Description

PAL⁴ To IFL is a conversion program to allow easy transfer of the MMI PAL 20 circuits to the IFL 20 pin series circuits.

PTI is operated by inputting the PALASMTM Boolean equations through files generated by the PALASM program (developed and supplied by MMI). The output of the system is a file that can be used to program the corresponding IFL circuits. The output file contains fusing codes in a form that is acceptable to commercial programmers.

Features

- Automatic Assembler
- Reduces duplicated P-terms
- Document print out: Header, Boolean Equation & Fuse Map

PAL⁴ is a registered trademark of Monolithic Memories, Inc.
PALASM is a trademark of Monolithic Memories, Inc.

DPI

Description

Device Programmer Interface is the software module that provides the interface between the Standard File created by the BLAST program and a commercial programmer. This module allows both down-load and up-load operations. The down-load function is performed in either the JEDEC or the Signetics H & L format to convey fusing information to the highest number of commercial programmers. The up-load function

allows reading of devices for editing and/or simulation of existing programmable logic devices.

Features

- Screen Menus for inputs
- JEDEC or Signetics H & L formats
- Down-load to commercial programmers
- Up-load for editing and simulation operations.

SIMULATOR

Description

The IFL SIMULATOR program is a software package that simulates the operation of the logic that can be configured with IFL products. The input to the software can be either a Truth Table input or a fuse table output of the AMAZE program. The simulator has the capability of running manually or automatically. In the automatic mode the simulator creates a file of test vectors that can be used to test the programmed devices. In the manual mode the program will allow the operator to assign an input vector and observe the resultant output.

Patterns generated by the IFL simulator will create a file which contains setup and parametric information that can be used to condition the device for production testing.

Features

- Simple Input Form
- Test Vector Generation
- Output can be used as input to IFL fault grader
- Applications support through software only

Programmer support

There is a choice of two programming formats: Logic or Memory. Logic programmers are convenient to use, particularly in the design phase. The Memory format, while requiring inputs from assembled logic statements or a 'master' device,

has the advantage of allowing conventional PROM programmers to be used by low-skilled labour in a production environment. Suppliers of such programmers include Digelec, Kontron, Data I/O and Stag.
