FAST TTL LOGIC SERIES

SUPPLEMENT

Signetics reserves the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Signetics assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified. Applications that are described herein for any of these products are for illustrative purposes only. Signetics makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

LIFE SUPPORT APPLICATIONS

Signetics Products are not designed for use in life support appliances, devices, or systems where malfunction of a Signetics Product can reasonably be expected to result in a personal injury. Signetics customers using or selling Signetics' Products for use in such applications do so at their own risk and agree to fully indemnify Signetics for any damages resulting from such improper use or sale.

Signetics registers eligible circuits under
the Semiconductor Chip Protection Act.

PREFACE

Since the publication in 1988 of the Integrated Circuits Data Handbook IC15 'FAST TTL Logic series', a number of new FAST products have been released to production and other new products are in development. This supplement to IC15 includes final specifications for the recently released products, preliminary specifications that were not previously published and additional application notes supporting the FAST family. An updated functional index is also included.

This supplement should be read in conjuction with Handbook IC15. Supplement data that supersedes Handbook IC15 data is indicated in the index and, for ease of reference, a data sheet status and location list is provided.

Numerical index (supplement data sheets)

Numerical index (supplement data sheets)

* Supplement data supersedes Handbook IC15 data.

Numerical index (supplement data sheets)

* Supplement data supersedes Handbook IC15 data.

Numerical index (supplement data sheets)

* Supplement data supersedes Handbook IC15 data.

Function selection guide (all FAST products)

GATES

FUNCTION	DEVICE NUMBER
INVERTERS	
Hex Inverter	74F04
Hex Inverter, Schmitt Trigger	74F14
NAND	
Quad 2-Input	74F00
Triple 3-Input	74F10
Dual 4-Input, Schmitt Trigger	74F13
Dual 4-Input	74F20
8-Input	74F30
Quad 2-Input, Schmitt Trigger	74F132
13-Input	74F133
NOR	
Quad 2-Input	74F02
Triple 3-Input	74F27
Dual 5-Input	74F260
AND	
Quad 2-Input	74F08
Triple 3-Input	74F11
OR	
Quad 2-Input	74F32
EXCLUSIVE OR	
Quad 2-Input	74F86
COMBINATION	
Dual 2-Wide, 2-Input AND-OR-Invert	74F51
4-2-3-2 Input AND-OR-Invert	74F64
HIGH CURRENT DRIVERS	
Hex Inverter Buffer/Driver OC	74F06
Hex Buffer/Driver OC	74F07
Dual 4-Input NAND	74F40
Dual 4-Input NAND 30Ω Transmission Line Driver	74F3040
Quad 2-Input NAND	74F37
Quad 2-Input NAND, OC	74F38
Quad 2-Input NAND 30Ω Transmission Line Driver	74F3037
Quad 2-Input NAND 30Ω Transmission Line Driver, OC	74F3038
Hex 2-Input NAND	74F804
Hex 2-Input NAND Center Power Pin	74F1804
Hex 2-Input NOR	74F805
Hex 2-Input NOR Center Power Pin	74F1805
Hex 2-Input AND	74F808
Hex 2-Input AND Center Power Pin	74F1808
Hex 2-Input OR	74F832
Hex 2-Input OR Center Power Pin	74F1832

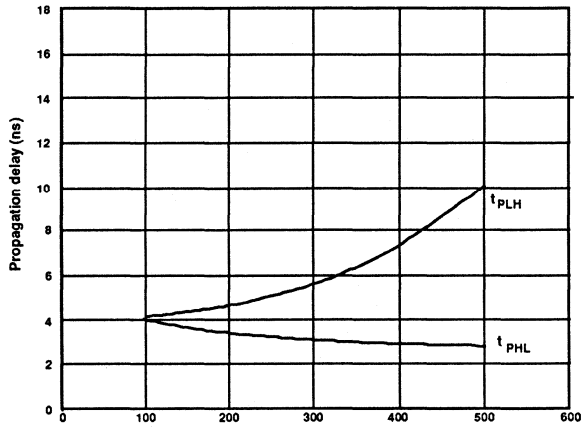
NOTE: For all waveforms, V_M = 1.5V.

TYPICAL PROPAGATION DELAYS VERSUS LOAD FOR OPEN COLLECTOR OUTPUTS



NOTE:
When using Open-Collector parts, the value of the pull-up resistor greatly affects the value of the t_{PLH}. For example, changing the specified pull-up resistor value from 500Ω to 100Ω will improve the t_{PLH} up to 50% with only a slight increase in the t_{PHL}. However, if the value of the pull-up resistor is changed, the user must make certain that the total I_{OL} current through the resistor and the total I_{IL}'s of the receivers does not exceed the I_{OL} maximum specification.

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F74A is a dual positive edge-triggered D-type flip-flop featuring individual Data, Clock, Set and Reset inputs; also true and complementary outputs.

Set ($\overline{S}_0$) and Reset ($\overline{R}_0$) are asynchronous active-Low inputs and operate independently of the Clock (CP) input. Data must be stable just one setup time prior to the Low-to-High transition of the clock for guaranteed propagation delays.

Clock triggering occurs at a voltage level and is not directly related to the transition time of the positive-going pulse. Following the hold time interval, data at the D input may be changed without affecting the levels of the output.

The 74F74A is designed so that the outputs can never display a metastable state due to setup and hold times violations. If setup and hold times are violated the propagation delays may be extended beyond the specifications but the outputs will not glitch or display a metastable state. Typical metastability parameters for the 74F74A are: $\tau < .100$ns, $T_o = 1\mu$s, and h=3.3ns.

		CP_n, $\overline{S}_{Dn}$, $\overline{R}_{Dn}$					-50	µA
I_{OS}	Short-circuit output current[3]		V_{CC} = MAX		-60		-150	mA
I_{CC}	Supply current[4] (total)		V_{CC} = MAX			10	16	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.
4. Measure I_{CC} with the clock input grounded and all outputs open, then with Q and $\overline{Q}$ outputs High in turn.

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F109A is a dual positive edge-triggered JK-type flip-flop featuring individual J, $\overline{K}$, Clock, Set and Reset inputs; also true and complementary outputs.

Set ($\overline{S}_D$) and Reset ($\overline{R}_D$) are asynchronous active-Low inputs and operate independently of the Clock (CP) inputs.

The J and $\overline{K}$ are edge-triggered inputs which control the state changes of the flip-flops as described in the Function Table. The J and $\overline{K}$ inputs must be stable just one setup time prior to the Low-to-High transition of the clock for guaranteed propagation delays. The J$\overline{K}$ design allows operation as a D flip-flop by tying J and $\overline{K}$ inputs together.

The 74F109A is designed so that the outputs can never display a metastable state due to setup and hold time violations. If setup and hold times are violated the propagation delays may be extended beyond the specifications but the outputs will not glitch or display a metastable state. Typical metastability parameters for the 74F109A are: $\tau < .100$ns, T_o=1µs, and h=3.3ns.

				±5%V_{CC}	2.7	3.4		V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX, V_{IH} = MIN, I_{OL} =MAX	±10%V_{CC}		0.30	0.50	V
				±5%V_{CC}		0.30	0.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input current at maximum input voltage	J, $\overline{K}$, CP_n	V_{CC} = MAX, V_I = 7.0V				0.1	mA
		$\overline{S}_{Dn}$, $\overline{R}_{Dn}$					0.2	mA
I_{IH}	High-level input current	J, $\overline{K}$, CP_n	V_{CC} = MAX, V_I = 2.7V				20	µA
		$\overline{S}_{Dn}$, $\overline{R}_{Dn}$					20	µA
I_{IL}	Low-level input current	J, $\overline{K}$	V_{CC} = MAX, V_I = 0.5V				-100	µA
		CP_n, $\overline{S}_{Dn}$, $\overline{R}_{Dn}$					-50	µA
I_{OS}	Short-circuit output current[3]		V_{CC} = MAX		-60		-150	mA
I_{CC}	Supply current (total)		V_{CC} = MAX			10	16	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.
4. Measure I_{CC} with the clock input grounded and all outputs open, then with Q and $\overline{Q}$ outputs High in turn.

Product Specification

FEATURES

- **16-line demultiplexing capability**
- **Mutually exclusive outputs**
- **2-input enable gate for strobing or expansion**

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
N74F154	5.5 ns	26mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F154N
24-Pin Plastic SOL	N74F154D

DESCRIPTION

The 74F154 decoder accepts four active High binary address inputs and provides 16 mutually exclusive active Low outputs. The 2-input Enable ($\overline{E}_0$, $\overline{E}_1$) gate can be used to strobe the decoder to eliminate the normal decoding "glitches" on the outputs, or it can be used for expansion othe decoder. The Enable gate has two AND'ed inputs which must be Low to enable the outputs.

The 74F154 can be used as a 1-of-16 demultiplexer by using one of the Enable inputs as the multiplexed data input. When the other Enable is Low, the addressed output will follow the state of the applied data.

FAST 74F164
Shift Register

8-Bit Serial-In Parallel-Out Shift Register
Product Specification

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F164	100MHz	33mA

FEATURES
- **Gated serial data inputs**
- **Typical shift frequency of 100MHz**
- **Asynchronous Master Reset**
- **Fully buffered clock and data inputs**
- **Fully synchronous data transfers**

DESCRIPTION

The 74F164 is an 8-bit edge-triggered shift register with serial data entry and an output from each of the eight stages. Data is entered through one of two inputs (D_{sa}, D_{sb}); either input can be used as an active High enable for data entry through the other input. Both inputs must be connected together or an unused input must be tied High.

Data shifts one place to the right on each Low-to-High transition of the Clock (CP) input, and enters into Q_0 the logical AND of the the two data inputs (D_{sa}, D_{sb}) that existed one setup time before the rising clock edge. A Low level on the Master Reset ($\overline{MR}$) input overrides all other inputs and clears the register asynchronously, forcing all outputs Low.

ORDERING INFORMATION

FAST 74F189A
64-Bit TTL Bipolar RAM

Product Specification

DESCRIPTION

The 74F189A is a high-speed, 64-bit RAM organized as a 16-word by 4-bit array. Address inputs are buffered to minimize loading and are fully decoded on-chip. The outputs are 3-State and are in the High-impedance state whenever the Chip Select ($\overline{CE}$) input is High. The outputs are active only in the Read mode and the output data is the complement of the stored data.

Ordering information can be found on the following page.

FEATURES

- **Address access time: 10ns max**
- **Power dissipation: 4.3mW/bit typ**
- **Schottky clamped TTL**
- **One chip enable input**
- **I/O**
  - **Inputs: PNP Buffered**
  - **Outputs: 3-State**

APPLICATIONS

- **Scratch pad memory**
- **Buffer memory**
- **Push down stacks**
- **Control store**

NOTES:
1. All voltage measurements are referenced to the ground terminal. Terminals not specifically referenced are left electrically open.
2. Output sink current is supplied through a resistor to V_{CC}.
3. All sense outputs in Low state.
4. To guarantee a Write into the slowest bit.
5. Positive current is defined as into the terminal referenced.
6. I_{CC} is measured with the Write enable and memory enable inputs grounded, all other inputs at 0.45V, and the output open.
7. Test each input one at a time.
8. Measured at a delta of 0.3V from the logic level with $R_1 = 500\Omega$, $R_2 = 500\Omega$ and $C_L = 50pF$.
9. Measured with minimum t_{WP}.
10. Measured with minimum t_{WSA}.
11. For I_{OS} test: V_{CC} = 5.75 V V_{OUT} = 0.5 V

FAST 74F198
Shift Register

8-Bit Bidirectional Universal Shift Register
Product Specification

FEATURES
- **Buffered clock and control inputs**
- **Shift right, shift left, and parallel load capability**
- **Asynchronous Master Reset**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
N74F198	95MHz	73mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F198N
24-Pin Plastic SOL	N74F198D

DESCRIPTION

The 74F198, Bidirectional Universal Shift Register is designed to incorporate virtually all of the features a system designer may want in a shift register. This circuit features parallel inputs and outputs, shift right and shift left serial inputs, operating mode select inputs, and a direct overriding master reset input. The register has four distinct modes of operation:

Parallel (broadside) load
Shift right (in the direction Q_0 toward Q_7)
Shift left (in the direction Q_7 toward Q_0)
Inhibit clock (do nothing)

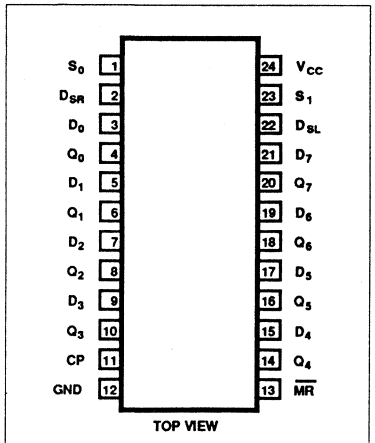
Synchronous parallel loading is accomplished by applying the 8 bits of data and taking both mode control inputs, S_0 and S_1, High. The data is loaded into the associated flip-flop and appears at the outputs after the positive transition of the clock input. During loading, serial data flow is inhibited.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

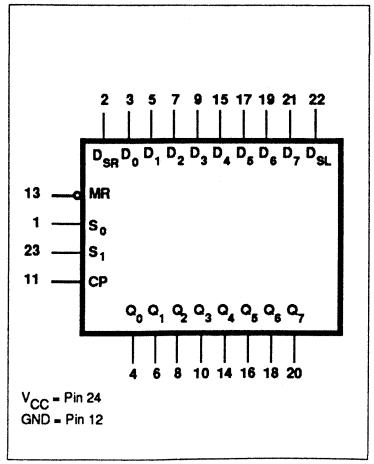
PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_0 - D_7	Parallel data inputs	1.0/1.0	20µA/0.6mA
D_{SR}	Serial data input (Shift Right)	1.0/1.0	20µA/0.6mA
D_{SL}	Serial data input (Shift Left)	1.0/1.0	20µA/0.6mA
S_0 - S_1	Mode Select inputs	1.0/1.0	20µA/0.6mA
CP	Clock Pulse input (Active rising edge)	1.0/1.0	20 A/0.6mA
$\overline{MR}$	Master Reset input (Active Low)	1.0/1.0	20µA/0.6mA
Q_0 - Q_7	Data outputs	50/33	1.0mA/20mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

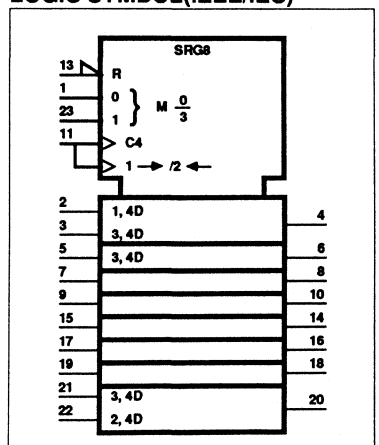
PIN CONFIGURATION



LOGIC SYMBOL



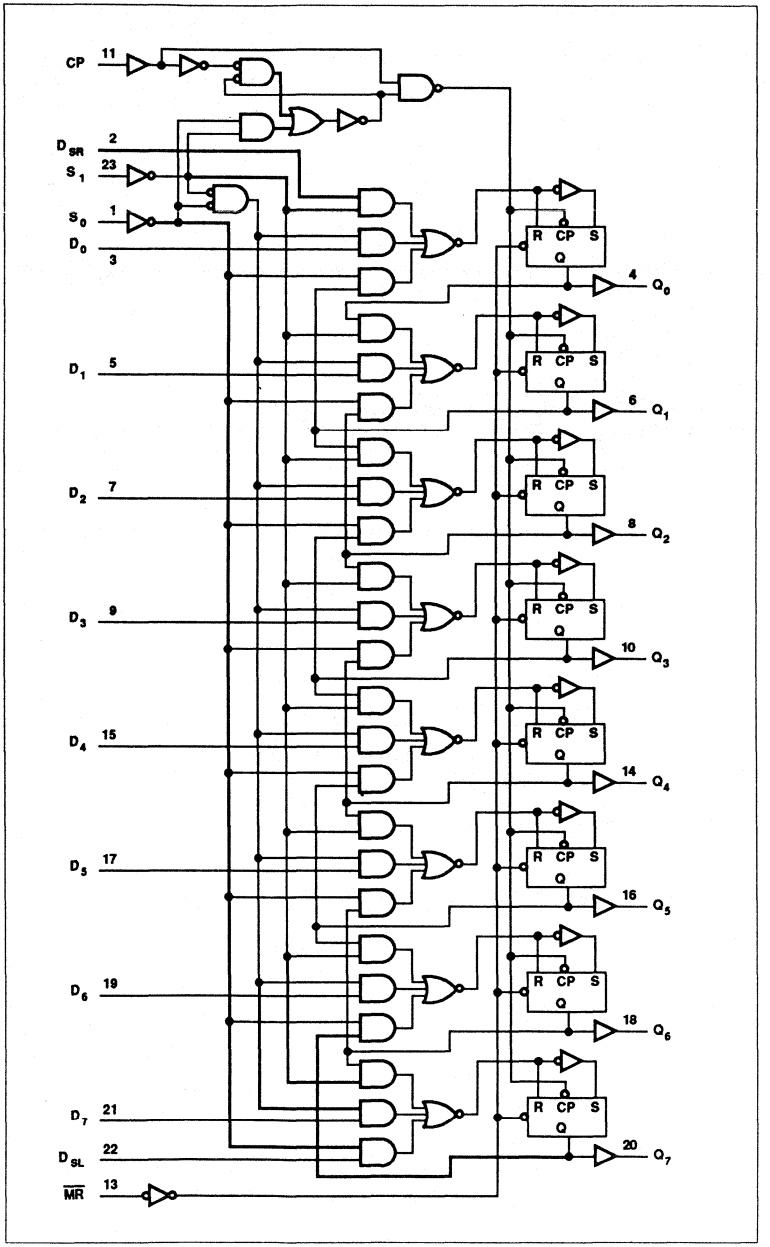
LOGIC SYMBOL(IEEE/IEC)



Shift right is accomplished synchronously, with the rising edge of the clock pulse when S_0 is High and S_1 is Low. Serial data for this mode is entered at the right data input (D_{SR}). When S_0 is Low and S_1 is High, data shifts left synchronously and new data is entered at the shift-left serial input (D_{SL}).

Clocking of the flip-flops is inhibited when both mode control inputs are Low.

LOGIC DIAGRAM



FUNCTION TABLE

INPUTS							OUTPUTS				
$\overline{MR}$	Mode		CP	Serial		Parallel	Q_0	Q_1	...	Q_6	Q_7
	S_0	S_1		Left	Right	0...7					
L	X	X	X	X	X	X	L	L		L	L

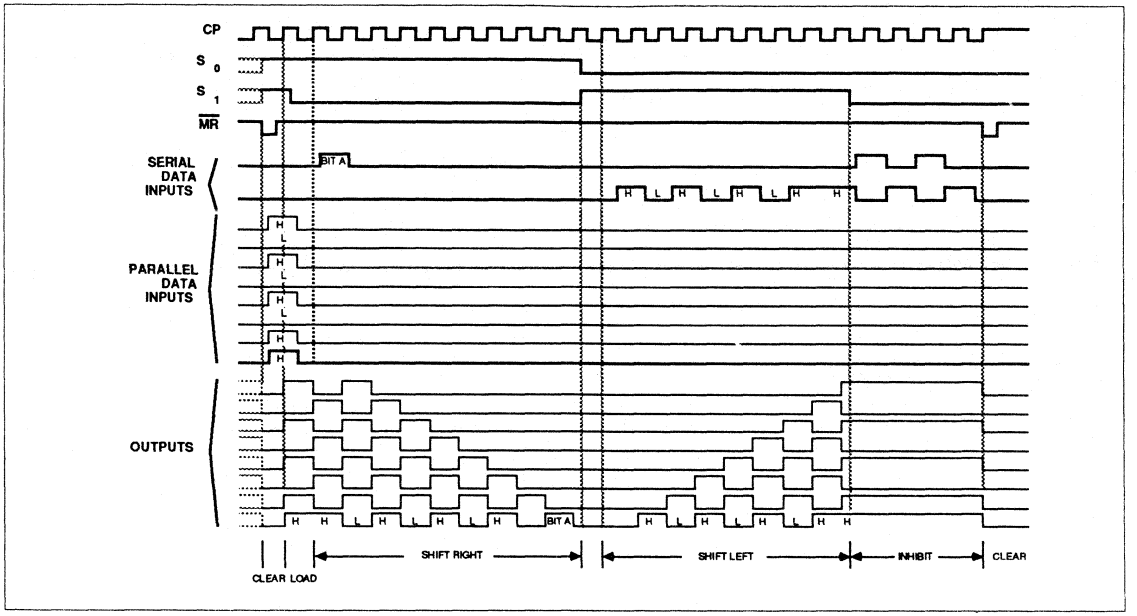
I_{OH}	High-level output current			-1	mA
I_{OL}	Low-level output current			20	mA
T_A	Operating free-air temperature range	0		70	°C

TYPICAL TIMING DIAGRAM



DC ELECTRICAL CHARACTERISTICS (Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER		TEST CONDITIONS[1]		LIMITS Min	LIMITS Typ[2]	LIMITS Max	UNIT
V_{OH}	High-level output voltage		V_{CC} = MIN, V_{IL} = MAX, V_{IH} = MIN, I_{OH} = MAX	±10%V_{CC}	2.5			V
				±5%V_{CC}	2.7	3.4		V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX, V_{IH} = MIN, I_{OL} = MAX	±10%V_{CC}		0.35	0.50	V
				±5%V_{CC}		0.35	0.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input clamp current at maximum input voltage		V_{CC} = MAX, V_I = 7.0V				100	µA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V				20	µA
I_{IL}	Low-level input current		V_{CC} = MAX, V_I = 0.5V				-0.6	mA
I_{OS}	Short circuit output current[3]		V_{CC} = MAX		-60		-150	mA
I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX			70	100	mA
		I_{CCL}				75	110	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F199
Shift Register

8-Bit Parallel-Access Shift Register
Product Specification

FEATURES

- **Buffered clock and control inputs**
- **Shift right and parallel load capability**
- **Fully synchronous data transfers**
- **J - $\overline{K}$(D) inputs to first stage**
- **Clock enable for hold (do nothing) mode**
- **Asynchronous Master Reset**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
N74F199	95MHz	70mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F199N
24-Pin Plastic SOL	N74F199D

DESCRIPTION

The 74F199 is an 8-bit Parallel Access Shift Register and its functional characteristics are indicated in the Logic diagram and Function Table. The device is useful in a variety of shifting, counting and storage applications. It performs serial, parallel, serial to parallel, or parallel to serial data transfers at very high speeds.

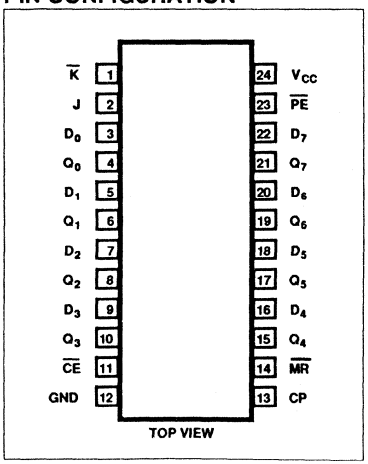
The 74F199 operates in two primary modes: shift right ($Q_0 \rightarrow Q_1$) and parallel load, which are controlled by the state of the Parallel Enable ($\overline{PE}$) input. Serial data enters the first flip-flop (Q_0) via the J and $\overline{K}$ inputs when the $\overline{PE}$ input is High, and is shifted one bit in the direction $Q_0 \rightarrow Q_1 \rightarrow Q_2$ following each Low-to-High clock transition.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

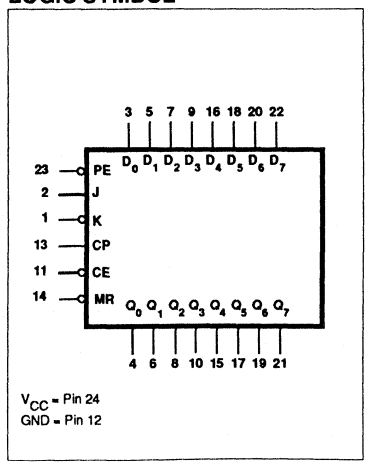
PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_0 - D_7	Parallel data inputs	1.0/1.0	20µA/0.6mA
J, $\overline{K}$	J and K inputs	1.0/1.0	20µA/0.6mA
$\overline{PE}$	Parallel Enable input	1.0/1.0	20µA/0.6mA
$\overline{CE}$	Mode Select inputs	1.0/1.0	20µA/0.6mA
CP	Clock Pulse input (Active rising edge)	1.0/1.0	20 A/0.6mA
$\overline{MR}$	Master Reset input (Active Low)	1.0/1.0	20µA/0.6mA
Q_0 - Q_7	Data outputs	50/33	1.0mA/20mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

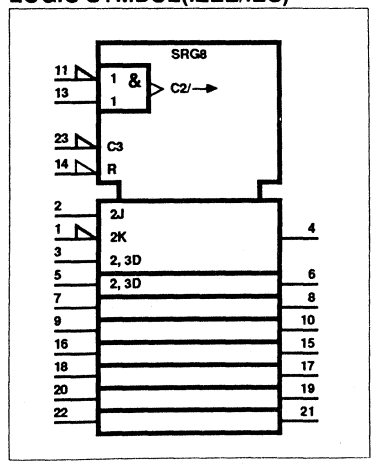
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



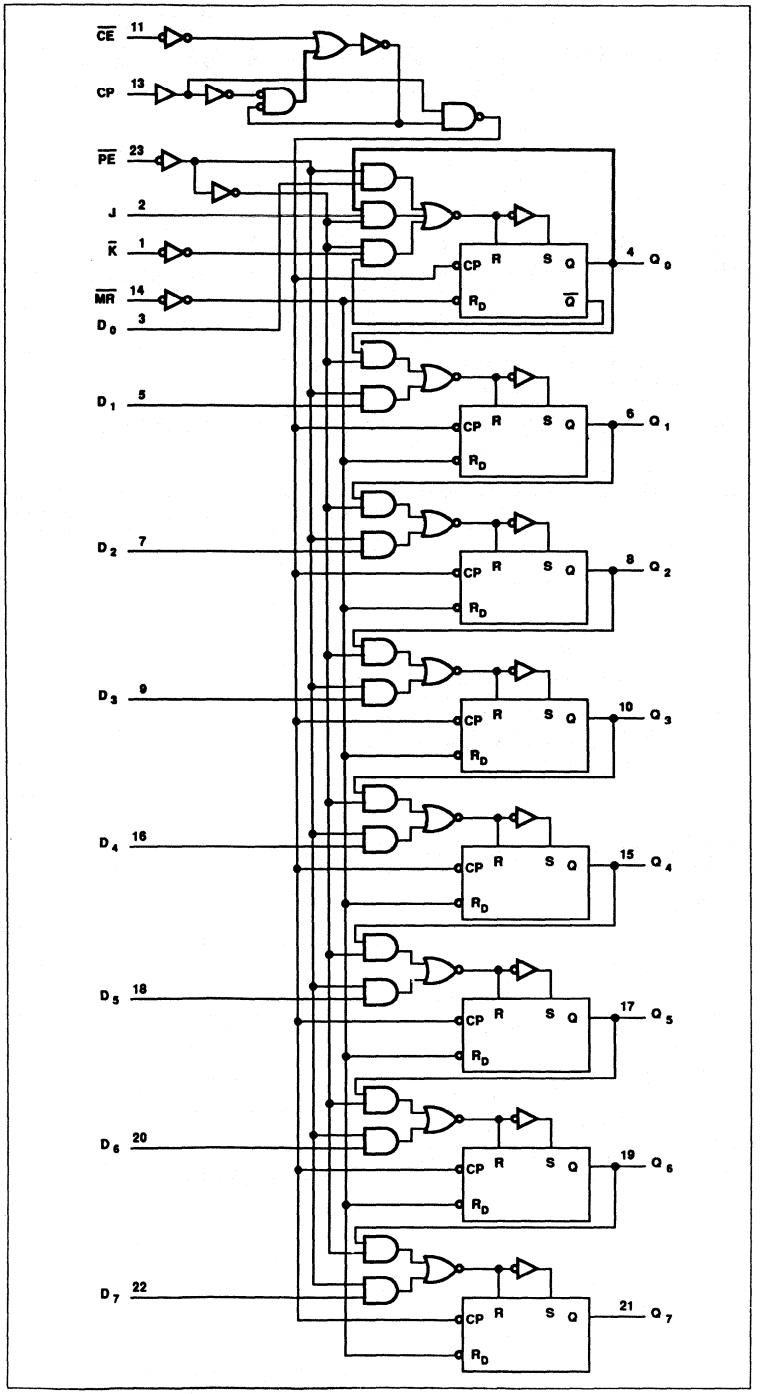
The J and $\overline{K}$ inputs provide the flexibility of the J-$\overline{K}$ type input for special applications, and by tying the two together the simple D-type input is made for general applications.

The device appears as eight common clocked D flip-flops when the $\overline{PE}$ input is Low. After the Low-to-High clock transition, data on the parallel inputs (D_0 - D_7) is transferred to the respective Q_0 - Q_7 outputs.

All parallel and serial data transfers are synchronous, occurring after each Low-to-High clock transition. The 74F199 utilizes edge-triggered, therefore there is no restriction on the activity of the J, $\overline{K}$, Dn, and $\overline{PE}$ inputs for logic operation, other than the set-up and hold time requirements.

A Low on the Master Reset ($\overline{MR}$) input overrides all other inputs and clears the register asynchronously forcing all bit positions to a Low state.

LOGIC DIAGRAM



FUNCTION TABLE

INPUTS							OUTPUTS					OPERATING MODES
$\overline{MR}$	CP	$\overline{CE}$	$\overline{PE}$	J	$\overline{K}$	D_n	Q_0	Q_1	...	Q_6	Q_7

FAST 74F219A
64-Bit TTL Bipolar RAM

Product Specification

FAST Products

DESCRIPTION

The 74F219A is a high-speed, 64-bit RAM organized as a 16-word by 4-bit array. Address inputs are buffered to minimize loading and are fully decoded on-chip. The outputs are 3-State and are in the High-impedance state whenever the Chip Select ($\overline{CE}$) input is High. The outputs are active only in the Read mode and are of the same polarity as of the stored data.

Ordering information can be found on the following page.

FEATURES

- **Address access time: 10ns max**
- **Power dissipation: 4.3mW/bit typ**
- **Schottky clamped TTL**
- **One chip enable input**
- **Non-inverting data outputs. (For inverting see 74F189A)**
- **I/O**
  - **Inputs: PNP Buffered**
  - **Outputs: 3-State**

APPLICATIONS

- **Scratch pad memory**
- **Buffer memory**
- **Push down stacks**
- **Control store**

NOTES:
1. All voltage measurements are referenced to the ground terminal. Terminals not specifically referenced are left electrically open.
2. Output sink current is supplied through a resistor to V_{CC}.
3. All sense outputs in Low state.
4. To guarantee a Write into the slowest bit.
5. Positive current is defined as into the terminal referenced.
6. I_{CC} is measured with the Write enable and memory enable inputs grounded, all other inputs at 0.45V, and the output open.
7. Test each input one at a time.
8. Measured at a delta of 0.3V from the logic level with $R_1 = 500\Omega$, $R_2 = 500\Omega$ and $C_L = 50pF$.
9. Measured with minimum t_{WP}.
10. Measured with minimum t_{WSA}.
11. For I_{OS} test: V_{CC} = 5.75 V V_{OUT} = 0.5 V

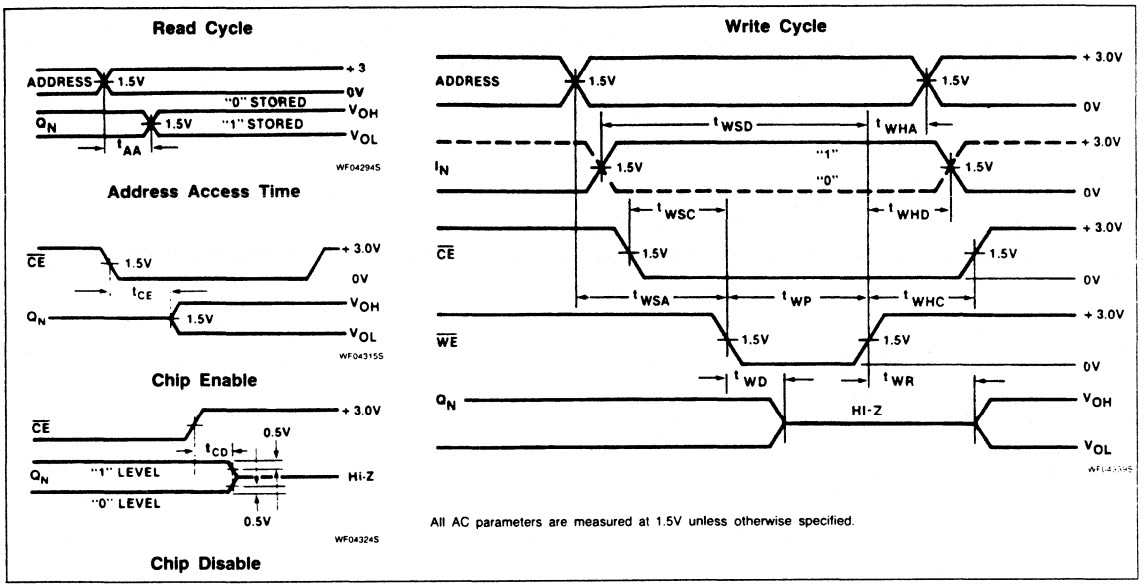
TIMING DIAGRAMS



All AC parameters are measured at 1.5V unless otherwise specified.

FAST 74F222

16X4 Synchronous FIFO (3-State)

Preliminary Specification

FEATURES

- **Independent synchronous inputs and outputs**
- **Organized as 16-words of 4 bits**
- **DC to 50Mhz data rate**
- **3-state outputs**
- **Cascadable in word-width and depth direction**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F222	50MHz	90mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
20-Pin Plastic DIP	74F222N
20-Pin Plastic SOL	74F222D

DESCRIPTION

This 64-bit active element First-In-First-Out (FIFO) is a monolithic Schottky-clamped transistor-transistor logic (STTL) array organized as 16-words of 4-bits each. A memory system using the 'F222 can be easily expanded in multiples of 15m+1 words or of 4n bits, or both, (where n is the number of packages in the vertical array and m is the number of packages in the horizontal array) and no external gating is required (see in Figure 2). The 3-state outputs controlled by a single enable input (OE) make bus connection and multiplexing easy. The 'F222 processes data in a parallel format at any desired clock rate from DC to 50Mhz.

Reading or writing is done independently utilizing separate synchronous data clocks. Data may be written into the array on the high-to-low transition of the load clock (LDCK) input. Data may be read out of the array on the low-to-high transition of the unload clock (UNCK). The FIFO is full when the number of words clocked in exceeds the number of words clocked out by 16. When the FIFO is full, LDCK signals have no effect. When the FIFO is empty, UNCK signals have no effect.

Status of the 'F222 is provided by two outputs. Input Ready (IR) monitors the status of the last word location and signifies when the FIFO is full. This output is high whenever the FIFO is available to accept new data and LDCK input is low. Output Ready (OR), is high when the first word location contains valid data and UNCK is high. Both IR and OR outputs are enabled by Input Ready Enable (IRE) and Output Ready Enable (ORE) inputs respectively. The first word location is defined as the location from which data is provided to the outputs.

DESCRIPTION

This 64-bit active element First-In-First-Out (FIFO) is a monolithic Schottky-clamped transistor-transistor logic (STTL) array organized as 16-words of 4-bits each. A memory system using the 'F224 can be easily expanded in multiples of 15m+1 words or of 4n bits, or both, (where n is the number of packages in the vertical array and m is the number of packages in the horizontal array) however some external gating is required (see in Figure 2). For longer words using the 'F224, the IR signals of the first-rank packages and OR signals of the last-rank packages must be ANDed for proper synchronization. The 3-state outputs controlled by a single enable input (OE) make bus connection and multiplexing easy. The 'F224 processes data in a parallel format at any desired clock rate from DC to 50Mhz.

Reading or writing is done independently utilizing separate synchronous data clocks. Data may be written into the array on the high-to-low transition of the load clock (LDCK) input. Data may be read out of the array on the low-to-high transition of the unload clock (UNCK). The FIFO is full when the number of words clocked in exceeds the number of words clocked out by 16. When the FIFO is full, LDCK signals have no effect. When the FIFO is empty, UNCK signals have no effect.

Status of the 'F224 is provided by two outputs. Input Ready (IR) monitors the status of the last word location and signifies when the FIFO is full. This output is high whenever the FIFO is available to accept new data and LDCK input is low. Output Ready (OR), is high when the first word location contains valid data and UNCK is high. The first word location is defined as the location from which data is provided to the outputs.

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
20-Pin Plastic DIP	74F225N
20-Pin Plastic SOL	74F225D

DESCRIPTION

This 80-bit active element First-In-First-Out (FIFO) is a monolithic Schottky-clamped transistor-transistor logic (STTL) array organized as 16-words of 5-bits each. A memory system using the 'F225 can be easily expanded in multiples of 16-words or of 5-bits as shown in Figure 2. The 3-state outputs controlled by a single enable input ($\overline{OE}$) make bus connection and multiplexing easy. The 'F225 processes data in a parallel format at any desired clock rate from DC to 50Mhz.

Reading or writing is done independently utilizing separate synchronous data clocks. Data may be written into the array on the low-to-high transition of either load clock (CP_A or CP_B) input. Data may be read out of the array on the low-to- high transition of the unload clock (CP_{IN}).When writing data into the FIFO, one of the load clock inputs must be held high while the other strobes data into the FIFO. This arrangement allows either load clock to function as an inhibit for the other. Status of the 'F225 is provided by three outputs. Input Ready (IR) monitors the status of the last word location and signifies when the FIFO is full. This output is high whenever the FIFO is available to accept new data. The unload clock output (CP_{OUT}) also monitors the last word location. This output generates a low-logic-level pulse (synchronized to the internal clock pulse) when the location is vacant. The third status output, Output Ready (OR), is high when the first word location contains valid data and unload clock input is high. When unload clock input goes low, OR will go low and remain low until new valid data is in the first word location. The first word location is defined as the location from which data is provided to the outputs.

The data outputs are noninverting with

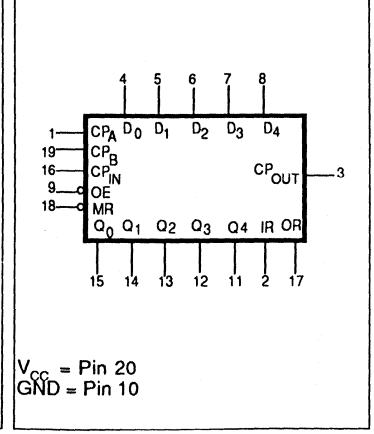
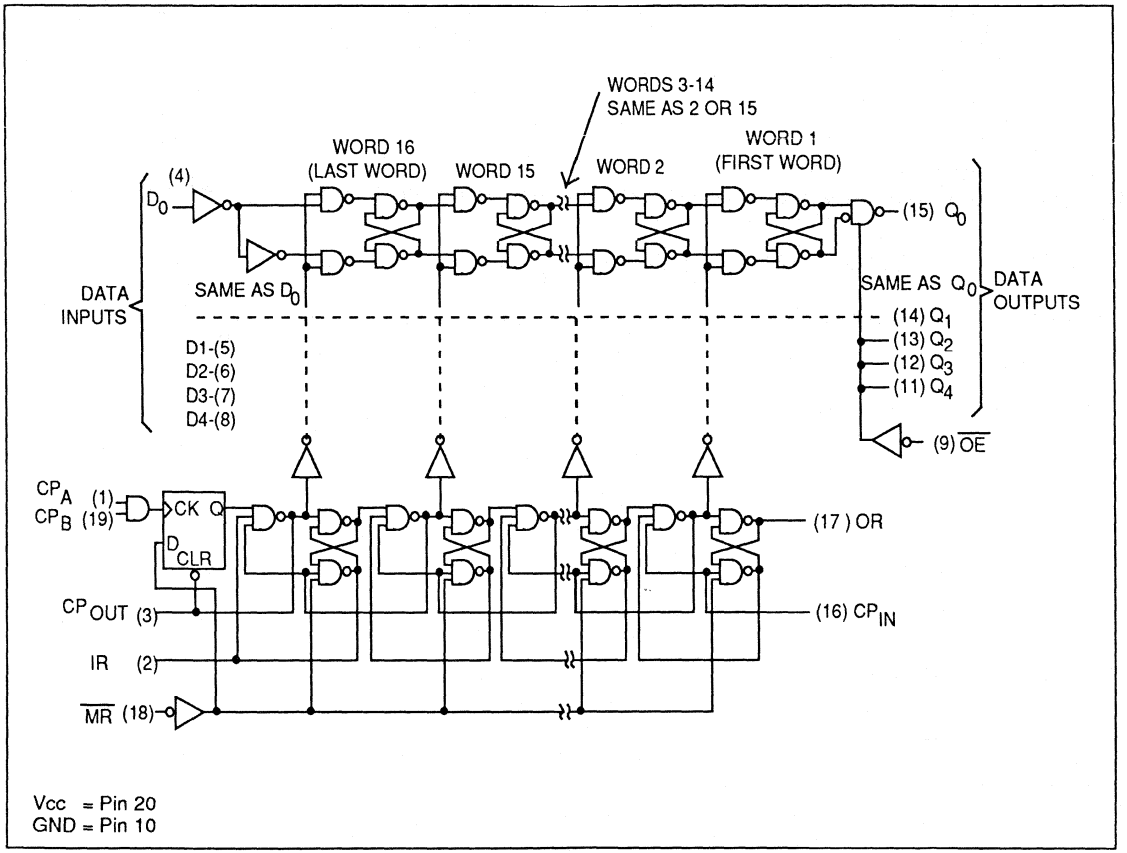
LOGIC SYMBOL



respect to the data inputs and are 3-stated when $\overline{OE}$ input is high. When $\overline{OE}$ is low, the data outputs are enabled to function as totem-pole outputs.

A high-to-low transition on the Master Reset ($\overline{MR}$) input invalidates all data stored in the FIFO by clearing the control logic and setting OR low. This high-to-low transition on the $\overline{MR}$ input does not effect the data outputs but since OR is driven low, it signifies invalid data on the outputs.

LOGIC DIAGRAM



ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V
I_{IN}	Input current	-30 to +5	mA
V_{OUT}	Voltage applied to output in High output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in Low output state	48	mA
T_A	Operating free-air temperature range	0 to +70	°C
T_{STG}	Storage temperature	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

SYMBOL	PARAMETER	LIMITS			UNIT
		Min	Nom	Max	
V_{CC}	Supply voltage	4.5	5.0	5.5	V
V_{IH}	High-level input voltage	2.0			V
V_{IL}	Low-level input voltage			0.8	V

I_{OH}	High-level output current			-3	mA
I_{OL}	Low-level output current			24	mA
T_A	Operating free-air temperature range	0		70	°C

DC ELECTRICAL CHARACTERISTICS (Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER		TEST CONDITIONS[1]		LIMITS			UNIT
					Min	Typ[2]	Max	
V_{OH}	High-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}	2.4			V
			V_{IH} = MIN, I_{OH} = MAX	±5%V_{CC}	2.7	3.3		V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}		0.35	0.50	V
			V_{IH} = MIN, I_{OL} = MAX	±5%V_{CC}		0.35	0.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input current at maximum input voltage		V_{CC} = MAX, V_I = 7.0V				100	µA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V				20	µA
I_{IL}	Low-level input current	All inputs	V_{CC} = MAX, V_I = 0.5V				-0.6	mA
I_{OS}	Short circuit output current[3]		V_{CC} = MAX		-60		150	mA
I_{CC}	Supply current (total)		V_{CC} = MAX			55	80	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F322
Register

8-Bit Serial/Parallel Register With Sign Extend (3-State)

Product Specification

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F322	125 MHz	60mA

FEATURES

- Multiplexed parallel I/O ports
- Separate serial input and output
- Sign extend function
- 3-state outputs for bus applications
- Direct Overriding Clear

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
20-Pin Plastic DIP	N74F322N
20-Pin Plastic SOL	N74F322D

DESCRIPTION

The 74F322 is an 8-bit shift register with provision for either serial or parallel loading and with 3-state parallel outputs plus a bi-state serial output. Parallel data inputs and outputs are multiplexed to minimize pin count. State changes are initiated by the rising edge of the clock. Four synchronous modes of operation are possible: hold (store), shift right with serial entry, shift right with sign extend, and parallel load. An asynchronous Master Reset ($\overline{MR}$) input overrides clocked operation and clears the register.

The 'F322 contains eight D-type edge triggered flip-flops and the interstage gating required to perform right shift and the intrastage gating necessary for hold and synchronous parallel load operations. A Low signal on $\overline{RE}$ enables the shift right mode a High signal on $\overline{SE}$ function. A High signal on $\overline{OE}$ disables the shifting or parallel loading, while a High signal enables the hold mode. A High signal on S/$\overline{P}$ enables shift right, while a Low signal disables the 3-state output buffers and enables parallel loading. In enables serial entry from either D_0 or D_1, as determined by the S input. A Low signal on $\overline{SE}$ enables shift right but Q_7 reloads its contents thus performing the sign extend 3-state output buffers, regardless of the other control inputs. In this condition the shifting and loading operations can still be performed.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_0, D_1	Serial data inputs	1.0/1.0	20µA/0.6mA

					±5%V_{CC}		0.35	0.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}				-0.73	-1.2	V
I_I	Input current at maximum input voltage	others	V_{CC} = MAX, V_I = 7.0V					100	µA
		I/O_n	V_{CC} = MAX, V_I = 5.5V					1	mA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V					20	µA
I_{IL}	Low-level input current	$\overline{SE}$	V_{CC} = MAX, V_I = 0.5V					-1.8	mA
		S						-1.2	mA
		others						-0.6	mA
$I_{IH}+I_{OZH}$	Off-state output current High-level voltage applied		V_{CC} = MAX, V_I = 2.7V					70	µA
$I_{IL}+I_{OZL}$	Off-state output current Low-level voltage applied		V_{CC} = MAX, V_I = 0.5V					-0.6	mA
I_{OS}	Short-circuit output current[3]		V_{CC} = MAX			-60		-150	mA
I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				50	75	mA
		I_{CCL}					60	90	mA
		I_{CCZ}					65	95	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

Register Stack — 16 X 4 RAM 3-State Output Register

Product Specification

FEATURES
- **Edge-triggered output register**
- **Typical access time of 24ns**
- **3-State outputs**
- **Optimized for register stack operation**
- **18-pin package**

DESCRIPTION
The 'F410 is a register-oriented high-speed 64-bit Read/Write Memory organized as 16-words by 4-bits. An edge-triggered 4-bit output register allows new input data to be written while previous data is held. 3-State outputs are provided for maximum versatility. The 'F410 is fully compatible with all TTL families.

Register Stack — 16 X 4 RAM 3-State Output Register

FAST 74F410

FUNCTIONAL DESCRIPTION

Write Operation — When the three control inputs, Write Enable ($\overline{WE}$), Chip Select ($\overline{CS}$), and Clock (CP), are Low the information on the data inputs ($D_0 - D_3$) is written into the memory location selected by the address inputs ($A_0 - A_3$). If the input data changes while $\overline{WE}$, $\overline{CS}$, and CP are Low, the contents of the selected memory location follow these changes, provided setup and hold time criteria are met.

Read Operation — Whenever $\overline{CS}$ is Low, $\overline{WE}$ is High, and CP goes from Low-to-High, the contents of the memory location selected by the address inputs ($A_0 - A_3$) are edge-triggered into the Output Register.

The ($\overline{OE}$) input controls the output buffers. When $\overline{OE}$ is High the four outputs ($Q_0 - Q_3$) are in a high impedance or OFF state; when $\overline{OE}$ is Low, the outputs are determined by the state of the Output Register.

20-Pin Plastic DIP	N74F547N
20-Pin Plastic SOL	N74F547D

DESCRIPTION

The 74F547 is a 3-to-8 line address decoder withn latches for address storage. Designed primarily to simplify multiple-chip selection in a microprocessor system, it contains one active Low and two active High Enables to conserve address space. Also included is an active Low Acknowledge output that responds to either a Read or Write input signal when the Enables are active.

For applications in which the separation of latch enable and chip enable functions is not required, LE and $\overline{E}_0$ can be tied together such that when High the outputs are OFF and the latches are transparent, and when Low the latches are storing and the selected output is enabled. The open-collector Acknowledge ($\overline{ACK}$) output is normally High (i.e.OFF) and goes Low when $\overline{E}_0$, E_1 and E_2 are all active and either the Read ($\overline{RD}$) or Write ($\overline{WR}$) input is Low, as indicated in the Acknowlege Function Table.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
A_0 - A_3	Output select address input	1.0/1.0	20µA/0.6mA
$\overline{E}_0$	Chip enable input (active Low)	1.0/1.0	20µA/0.6mA
E_1, E_2	Chip enable inputs	1.0/1.0	20µA/0.6mA
LE	Latch enable input	1.0/1.0	20µA/0.6mA
$\overline{RD}$	Read ackowledge input (active Low)	1.0/1.0	20µA/0.6mA
$\overline{WR}$	Write ackowledge input (active Low)	1.0/1.0	20µA/0.6mA
Q_0 -Q_7	Decoder outputs (active Low)	50/33	1.0mA/20mA
$\overline{ACK}$	Open collector Acknowledge output (active Low)	OC/33	OC/20mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.
OC=Open collector

I_{IL}	Low-level input current		V_{CC} = MAX, V_I = 0.5V					-0.6	mA
I_{OS}	Short-circuit output current[3]	Except $\overline{ACK}$	V_{CC} = MAX			-60		-150	mA
I_{CC}	Supply current (total)		V_{CC} = MAX				17	25	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

NOTE:
1. Thermal mounting technique are recommended. See AN SMD-100 Process Applications (page 17) for a discussion of thermal consideration for surface mounted devices.

DESCRIPTION

The 74F552 Octal Registered Transceiver contains two 8-bit registers for temporary storage of data flowing in either direction. Each register has its own clock (CPR, CPS) and Clock Enable ($\overline{CER}$, $\overline{CES}$) inputs, as well as a flag flip-flop that is set automatically as the register is loaded. The flag output will be reset when the Output Enable returns to High after reading the output port. Each register has a separate Output Enable ($\overline{OEAS}$, $\overline{OEBR}$) for its 3-state buffer. The separate Clocks, Flags and Enables provide considerable flexibility as I/O ports for demand-response data transfer. When data is transferred from the A port to the B port, a parity bit is generated. On the other hand, when data is transferred from the B port to the A port, the parity of input data on B_0-B_7 is checked.

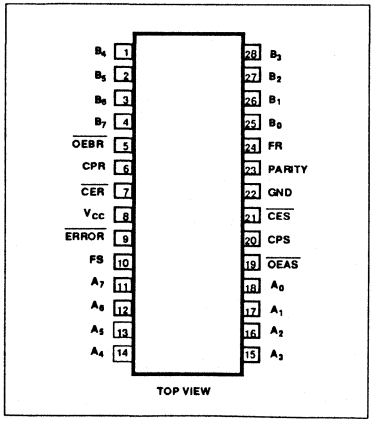
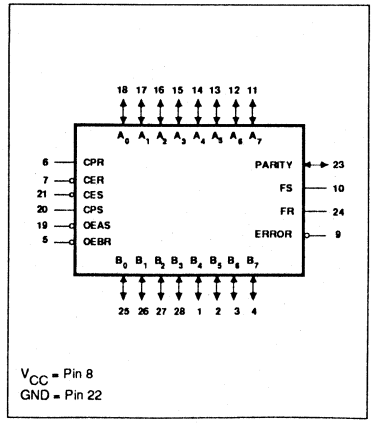
FS	B-to-A Status Flag output (active High)	50/33.3	1.0mA/20mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

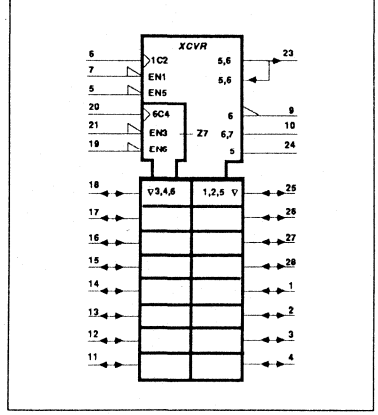
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



FUNCTIONAL DESCRIPTION

Data applied to the A inputs are entered and stored on the rising edge of the CPR clock pulse, provided that the $\overline{CER}$ is Low; simultaneously, the status flip-flop is set and the A-to-B flag (FR) output goes High. As the $\overline{CER}$ returns to High, the data will be held in R register. This data entered from the A inputs will appear at the B port I/O pins after the $\overline{OEBR}$ has gone Low. When $\overline{OEBR}$ is Low, a parity bit appears at the PARITY pin, which will be set High when there is an even number of 1s or all 0s at the Q outputs of the R register. After the data is assimilated, the receiving system clears the flag FR, by changing the signal at the $\overline{OEBR}$ pin from Low to High. Data flow from B-to-A proceeds in the same manner described for A-to-B flow. A Low at the $\overline{CES}$ pin and a Low-to-High transition at the CPS pin enters the B input data and the parity input data into the S register and the parity register respectively and set the flag output FS.to HIgh. A Low signal at the $\overline{OEAS}$ pin enables the A port I/O pins and a Low-to-High transition of the $\overline{OEAS}$ signal clears the FS flag. When $\overline{OEAS}$ is Low, the parity check output $\overline{ERROR}$ will be High if there is an odd number of 1s at the Q outputs of the S registers and the parity register.

Latch/Flip-Flop

74F563 Octal Transparent Latch (3-State)
74F564 Octal D Flip-Flop (3-State)
Product Specification

FEATURES

- **74F563 is broadside pinout version of 74F533**
- **74F564 is broadside pinout version of 74F534**
- **Inputs and Outputs on opposite side of package allow easy interface to Microprocessors**
- **Useful as an Input or Output port for Microprocessors**
- **3-State Outputs for Bus Interfacing**
- **Common Output Enable**
- **74F573 and 74F574 are non-inverting versions of 74F563 and 74F564 respectively**
- **These are High-Speed replacements for N8TS807 and N8TS808**

DESCRIPTION

The 74F563 is an octal transparent latch coupled to eight 3-State output buffers. The two sections of the device are controlled independently by Enable (E) and Output Enable ($\overline{OE}$) control gates.

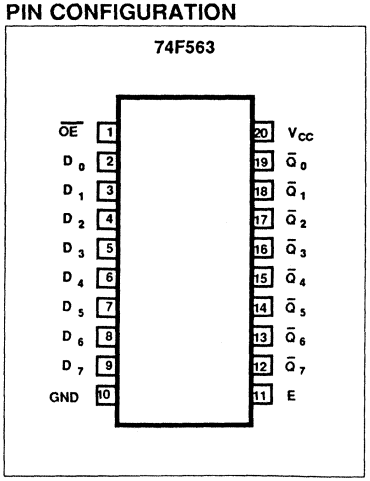
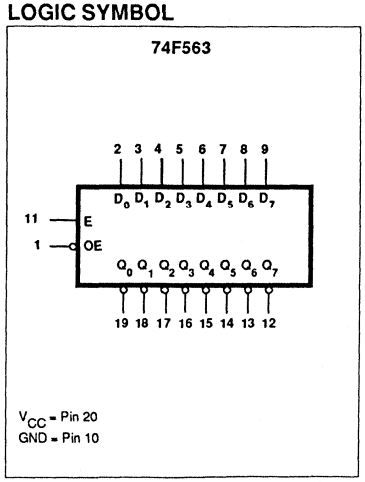
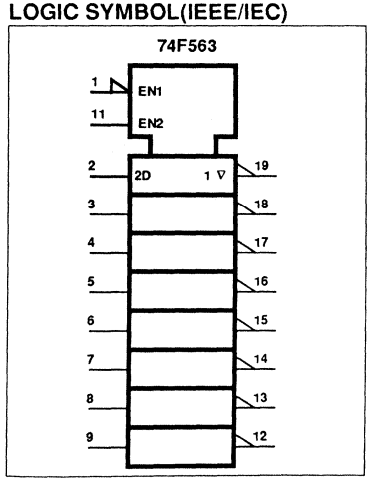
PIN CONFIGURATION



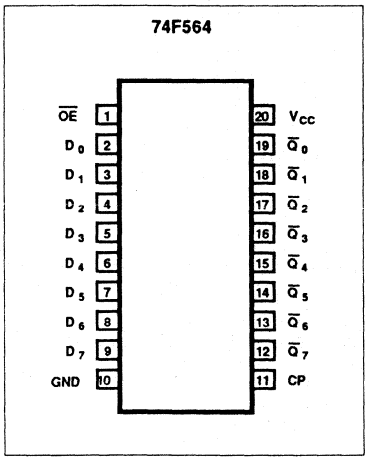
LOGIC SYMBOL



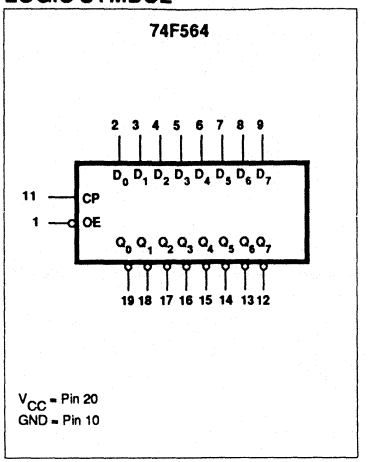
LOGIC SYMBOL(IEEE/IEC)



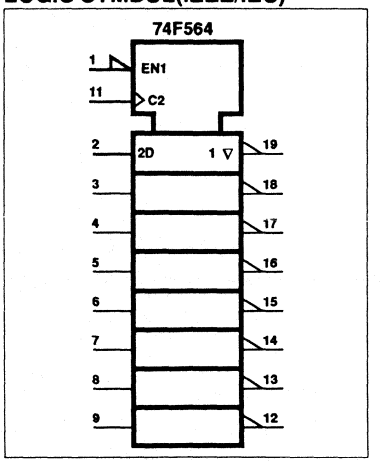
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



The 74F563 is functionally identical to the 74F533 but has a broadside pinout configuration to facilitate PC board layout and allow easy interface with microprocessors.

The data on the D inputs is transferred to the latch outputs when the Enable (E) input is High. The latch remains transparent to the data input while E is High and stores the data that is present one set-up time before the High-to-Low enable transition.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independently of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

The 74F564 is functionally identical to the 74F534 but has a broadside pinout configuration to facilitate PC board layout and allow easy interface with microprocessors.

It is an 8-bit, edge triggered register coupled to eight 3-State output buffers. The two sections of the device are controlled independently by the clock (CP) and Output Enable ($\overline{OE}$) control gates. The register is fully edge triggered. The state of each D input, one set-up time before the Low-to-High clock transition is transferred to the corresponding flip-flop's $\overline{Q}$ output.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independent of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

		I_{CCH}	74F564	V_{CC} = MAX			45	65	mA
		I_{CCL}					50	75	mA
		I_{CCZ}					55	80	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

Latch/Flip-Flops

74F573 Octal Transparent Latch (3-State)
74F574 Octal D Flip-Flop (3-State)
Product Specification

FEATURES

- **74F573 is broadside pinout version of 74F373**
- **74F574 is broadside pinout version of 74F374**
- **Inputs and Outputs on opposite side of package allow easy interface to Microprocessors**
- **Useful as an Input or Output port for Microprocessors**
- **3-State Outputs for Bus interfacing**
- **Common Output Enable**
- **74F563 and 74F564 are inverting version of 74F573 and 74F574 respectively**
- **These are High-Speed replacements for N8TS805 and N8TS806**

DESCRIPTION

The 74F573 is an octal transparent latch coupled to eight 3-State output buffers. The two sections of the device are controlled independently by Enable (E) and Output Enable ($\overline{OE}$) control gates.

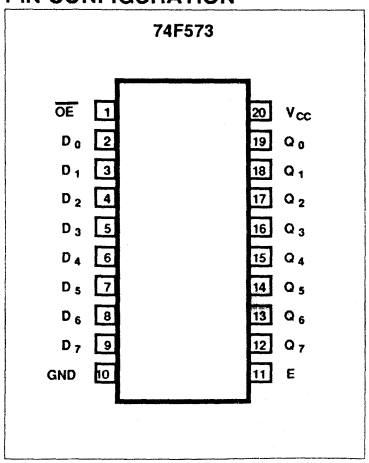
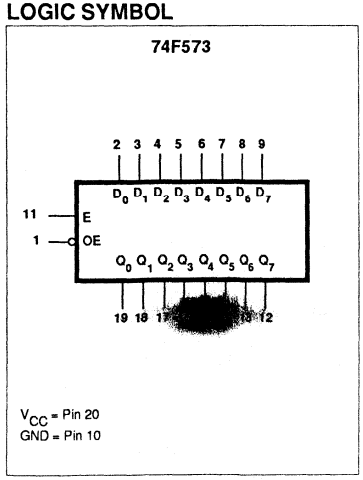
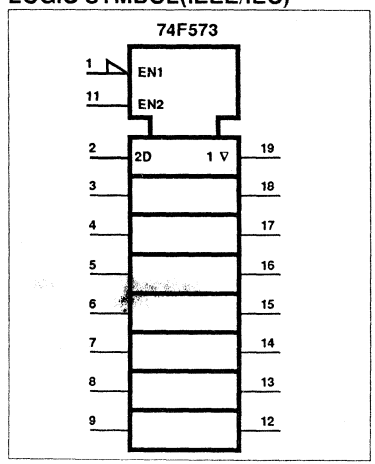
PIN CONFIGURATION



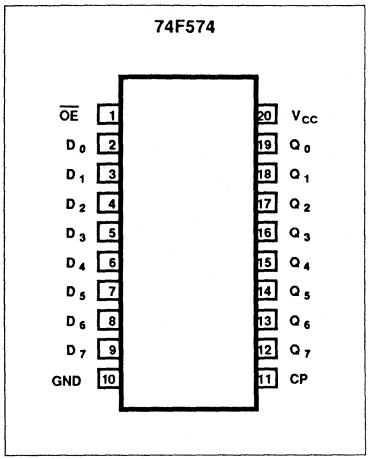
LOGIC SYMBOL



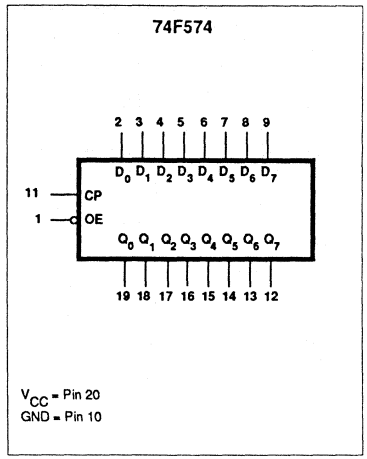
LOGIC SYMBOL(IEEE/IEC)



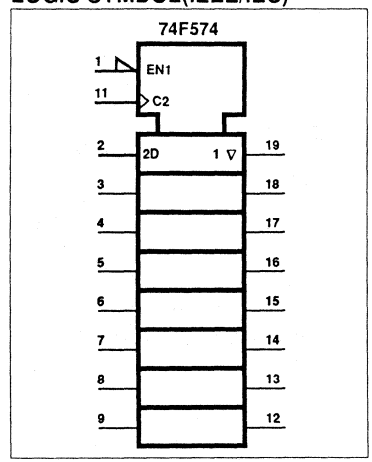
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



The 74F573 is functionally identical to the 74F373 but has a broadside pinout configuration to facilitate PC board layout and allow easy interface with microprocessors.

The data on the D inputs is transferred to the latch outputs when the Enable (E) input is High. The latch remains transparent to the data input while E is High and stores the data that is present one set-up time before the High-to-Low enable transition.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independent of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

The 74F574 is functionally identical to the 74F374 but has a broadside pinout configuration to facilitate PC board layout and allow easy interface with microprocessors.

It is an 8-bit, edge triggered register coupled to eight 3-State output buffers. The two sections of the device are controlled independently by the clock (CP) and Output Enable ($\overline{OE}$) control gates. The register is fully edge triggered. The state of each D input, one set-up time before the Low-to-High clock transition is transferred to the corresponding flip-flop's Q output.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independent of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

FAST 74F595
Shift Register

8-Bit Shift Register with Output Latches (3-state)
Product Specification

FEATURES

- **High impedance NPN base input for reduced loading (20μA in High and Low states)**
- **8-bit serial-in, serial-out shift register with storage**
- **3-state outputs**
- **Shift register has direct clear**
- **Guaranteed shift frequency-DC to 120MHz**

DESCRIPTION

The 74F595 contains an 8-bit serial-in, parallel-out shift register that feeds an 8-bit D-type storage register. The storage register has parallel 3-state outputs. Separate clocks are provided for both the shift register and the storage register. The shift register and storage register clocks are positive edge-triggered. If the user wishes to connect both clocks together, the shift register state will always be one clock pulse ahead of the storage register.

		I_{CCL}					70	85	mA
		I_{CCZ}					80	95	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

74F646/646A Octal Transceiver/Register, Non-Inverting (3-State)
74F648/648A Octal Transceivers/Register, Inverting (3-State)
Preliminary Specification for 74F646A and 74F648A
Product Specification for 74F646 and 74F648

FEATURES

- **Combines 'F245 and 'F374 type functions in one chip**
- **High impedance base inputs for reduced loading (70µA in High and Low states)**
- **Independent registers for A and B buses**
- **Multiplexed real-time and stored data**
- **Choice of non-inverting and inverting data paths**
- **Controlled ramp outputs for 'F646A/'F648A**
- **3-state outputs**
- **300 mil wide 24-pin Slim Dip package**

DESCRIPTION

The 74F646/646A and 74F648/648A Transceivers/Registers consist of bus transceiver circuits with 3-state outputs, D-type flip-flops, and control circuitry arranged for multiplexed transmission of data directly from the input bus or from the internal registers. Data on the A or B bus will clocked into the registers as the appropriate clock pin goes High. Output Enable ($\overline{OE}$) and DIR pins are provided to control the transceiver function. In the transceiver mode, data present at the high impedance port may be stored in either the A or B register or both.

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F646/648	115MHz	140mA
74F646A/648A	115MHz	120mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F646N, N74F646AN, N74F648N, N74F648AN
24-Pin Plastic SOL[1]	N74F646D, N74F646AD, N74F648D, N74F648AD

NOTE 1: Thermal mounting techniques are recommended. See SMD Process Applications (page 17) for a discussion of thermal consideration for surface mounted devices.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
A_0 - A_7, B_0 - B_7	A and B inputs for 'F646/'F648	3.5/0.166	70µA/70µA
A_0 - A_7, B_0 - B_7	A and B inputs for 'F646A/'F648A	1.0/0.033	20µA/20µA
CPAB	A-to-B clock input	1.0/0.033	20µA/20µA
CPBA	B-to-A clock input	1.0/0.033	20µA/20µA
SAB	A-to-B select input	1.0/0.033	20µA/20µA
SBA	B-to-A select input	1.0/0.033	20µA/20µA
DIR	Data flow Directional control Enable input	1.0/0.033	20µA/20µA
$\overline{OE}$	Output enable input	1.0/0.033	20µA/20µA
A_0 - A_7	A outputs	750/106.7	15mA/64mA
B_0 - B_7	B outputs	750/106.7	15mA/64mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

PIN CONFIGURATION

LOGIC SYMBOL

LOGIC SYMBOL(IEEE/IEC)

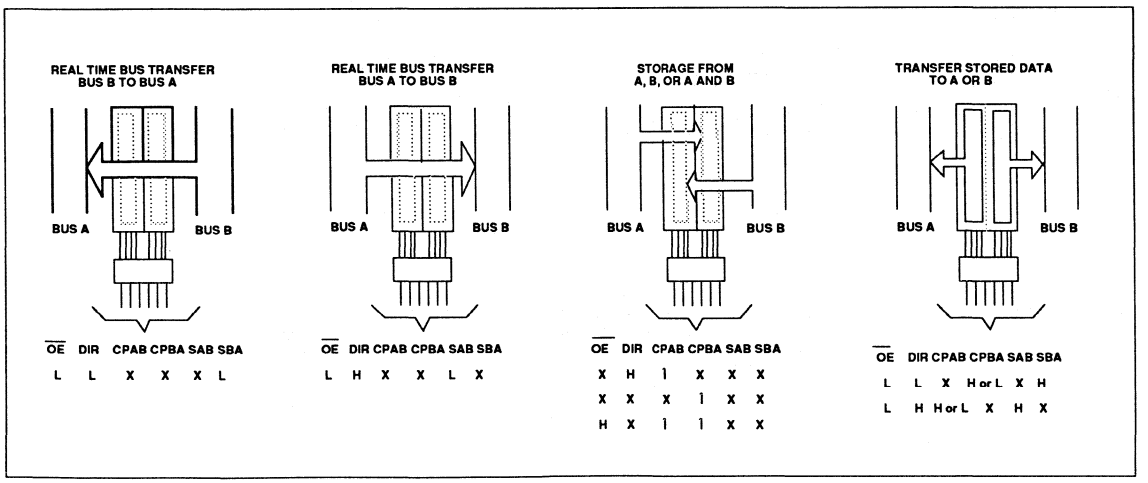
The select (SAB, SBA) pins determine whether data is stored or transfered through the device in real-time.The DIR determines which bus will receive data when the $\overline{OE}$ is active Low. In the isolation mode ($\overline{OE}$ = High), data from Bus A may be stored in the B register and/or data from Bus B may be stored in the A register. When an output function is disabled, the input function is still enabled and may be used to store and transmit data. Only one of the two busses , A or B may be driven at a time. The following examples demonstrates the four fundamental bus-management functions that can be performed with the 'F646/646A and 'F648/648A.



FUNCTION TABLE

INPUTS						DATA I/O		OPERATING MODE	
$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA	A_0-A_7	B_0-B_7	'F646/646A	'F648/648A
X	X	↑	X	X	X	input*	Unspecified	Store A, B unspecified*	Store A, B unspecified*
X	X	X	↑	X	X	Unspecified	Input*	Store B, A unspecified*	Store B, A unspecified*
H H	X X	↑ H or L	↑ H or L	X X	X X	Input	Input	Store A and B data Isolation, hold storage	Store A and B data Isolation, hold storage
L L	L L	X X	X H or L	X X	L H	Output	Input	Real time B data to A bus Store B data to A bus	Real time $\overline{B}$ data to A bus Store $\overline{B}$ data to A bus
L L	H H	X H or L	X X	L H	X X	Input	Output	Real time A data to B bus Store A data to B bus	Real time $\overline{A}$ data to B bus Store $\overline{A}$ data to B bus

H= High voltage level
L= Low voltage level
X=Don't care
↑ =Low-to-High clock transition
*= The data output function may be enabled or disabled by various signals at the $\overline{OE}$ and DIR inputs. Data input functions are always enable, i.e., data at the bus pins will be stored on every Low-to-High transition of the clock.

Thermal mounting techniques are recommended. See SMD Process Applications (page 17) for a discussion of thermal consideration for surface mounted devices.

DESCRIPTION

The 74F651/74F651A and 74F652/74F652A Transceivers/ Registers consist of bus transceiver circuits with 3-state outputs, D-type flip-flops, and control circuitry arranged for multiplexed transmission of data directly from the input bus or the internal registers. Data on the A or B bus will clocked into the registers as the appropriate clock pin goes High. Output Enable (OEAB, $\overline{OEBA}$) and Select (SAB, SBA) pins are provided for bus management.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
A_0 - A_7	A inputs	3.5/0.116	70μA/70μA
B_0 - B_7	B inputs	3.5/0.116	70μA/70μA
CPAB	A-to-B clock input	1.0/0.033	20μA/20μA

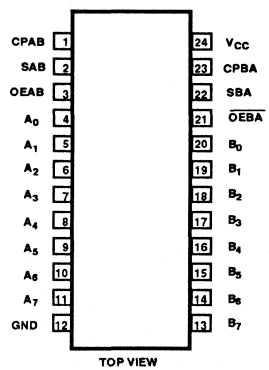
B_0 - B_7	B outputs	750/106.7	15mA/64mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6mA in the Low state.

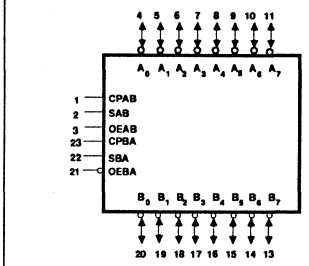
PIN CONFIGURATION

'F651/651A



LOGIC SYMBOL

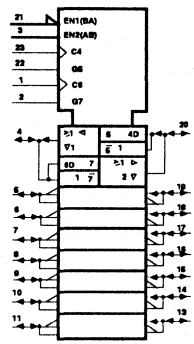
'F651/651A



V_{CC} = Pin 24
GND = Pin 12

LOGIC SYMBOL(IEEE/IEC)

'F651/651A



The following examples demonstrate the four fundamental bus-management functions that can be performed with the '74F651/651A and '74F652/652A.
The select pins determine whether data is stored or transferred through the device in real time.
The Output Enable pins determine the direction of the data flow.

			I_{CCL}				120	155	mA
			I_{CCZ}				130	170	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.
4. These values are for worst case only. Worst case is defined as all (16) I/O pins selected as outputs. When using worst case conditions thermal mounting is required.

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
74F657	8.0ns	100mA
74F657A	7.0ns	100mA

FEATURES

- **Combines 74F245 and 74F280A functions in one package**
- **High impedance base input for reduced loading (70μA in High and Low states)**
- **Ideal in applications where High output drive and light bus loading are required (I_{IL} is 70μA vs FAST std of 600μA)**
- **3-state buffer outputs sink 64mA and source 15 mA**
- **Input diodes for termination effects**
- **24-pin plastic Slim Dip (300mil) package**

DESCRIPTION

The 74F657 is an octal transceiver featuring non-inverting buffers with 3-state outputs and an 8-bit parity generator/checker, and is intended for bus-oriented applications. The buffers have a guaranteed current sinking capability of 24mA at the A ports and 64mA at the B ports. The Transmit/Receive (T/$\overline{R}$) input determines the direction of the data flow through the bidirectional transceivers. Transmit (active-High) enables data from A ports to B ports; Receive (active-Low) enables data from B ports to A ports.

The 74F657A is the faster version of 74F657.

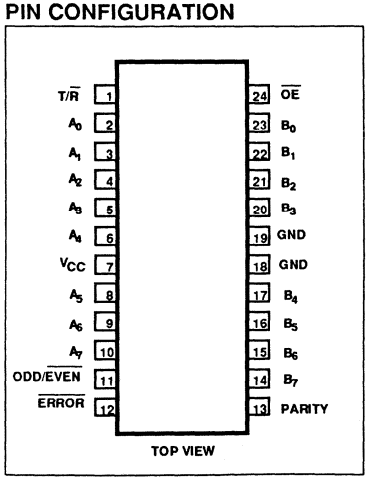
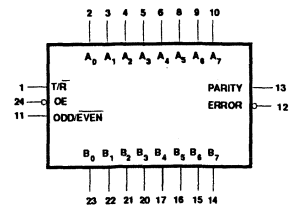
PIN CONFIGURATION

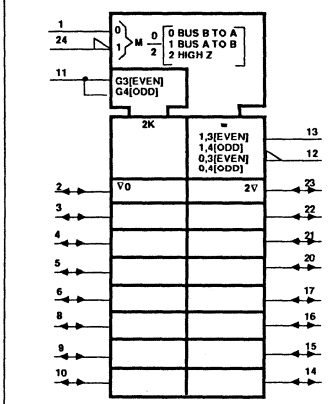


LOGIC SYMBOL



V_{CC} = Pin 7
GND = Pin 18, 19

LOGIC SYMBOL(IEEE/IEC)



The Output Enable ($\overline{OE}$)input disables both the A and B ports by placing them in a high impedance condition when the $\overline{OE}$ input is High. The parity select (ODD/$\overline{EVEN}$) input gives the user the option of odd or even parity systems. The parity (PARITY) pin is an output from the generator/checker when transmitting from the port A to B (T/$\overline{R}$=High) and an input when receiving from port B to A port (T/$\overline{R}$=Low). When transmitting (T/$\overline{R}$=High) the parity select (ODD/$\overline{EVEN}$) input is set, then the A port data is polled to determine the number of High bits. The parity (PARITY) output then goes to the logic state determined by the parity select (ODD/$\overline{EVEN}$) setting and by the number of High bits on port A. For example, if the parity select (ODD/$\overline{EVEN}$) is set Low (even parity), and the number of High bits on port A is odd, then the parity (PARITY) output will be High, transmitting even parity. If the number of High bits on port A is even, then the parity (PARITY) output will be Low, keeping even parity. When in receive mode (T/$\overline{R}$=Low) the B port is polled to determine the number of High bits. If parity select (ODD/$\overline{EVEN}$) is Low (even parity) and the number of Highs on port B is:

(1) odd and the parity (PARITY) input is High, then $\overline{ERROR}$ will be High, signifying no error.

(2) even and the parity (PARITY) input is Low, then $\overline{ERROR}$ will be asserted Low, indicating an error.

FUNCTION TABLE

NUMBER OF INPUTS THAT ARE HIGH	INPUTS			INPUT/ OUPUT	OUTPUTS	
	$\overline{OE}$	T/$\overline{R}$	ODD/$\overline{EVEN}$	PARITY	$\overline{ERROR}$	OUTPUTS MODE

		I_{CCL}					106	150	mA
		I_{CCZ}					98	145	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F670
Register File

4X4 Register File (3-State)
Product Specification

FEATURES

- **Simultaneous and Independent Read and Write operations**
- **Expandable to almost any word size and bit length**
- **3-state outputs**

DESCRIPTION

The 74F670 is a 16 bit 3-state Register File organized as 4 words of 4 bits each. Separate Read and Write Address and Enable inputs are available, permitting simultaneous writing into one word location and reading from another location. The 4-bit word to be stored is presented to four data inputs. The Write Address inputs (W_A and W_B) determine the location of the stored word. The Write Address inputs should only be changed when the $\overline{WE}$ input is High for conventional operation. When the Write Enable ($\overline{WE}$) input is Low, the data is entered into the addressed location. The addressed location remains transparent to the data while the $\overline{WE}$ is Low. Data supplied at the inputs will be read out in true (non-inverting) form from the 3-state outputs. Data and address inputs are inhibited when $\overline{WE}$ is High. Direct acquisition of data stored in any of the four registers is made possible by individual Read Address inputs (R_A, R_B). The addressed word appears at the four outputs when the Read Enable ($\overline{RE}$) is Low. Data outputs are in the High impedance "off" state when the $\overline{RE}$ is High. This permits outputs to be tied together to increase the word capacity to very large numbers.

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)

16-Pin Plastic SOL	N74F670D

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_0 - D_3	Data inputs	1.0/1.0	20µA/0.6mA
W_A, W_B	Write address inputs	1.0/1.0	20µA/0.6mA
R_A, R_B	Read address inputs	1.0/1.0	20µA/0.6mA
$\overline{WE}$	Write Enable input	1.0/1.0	20µA/0.6mA
$\overline{RE}$	Read Enable input	1.0/1.0	20µA/0.6mA
Q_0 - Q_3	Data outputs	150/40	3.0mA/24mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

Up to 128 devices can be stacked to increase the word size to 512 locations by tying the 3-state outputs together. Since the limiting factor for expansion is the output High current, further stacking is possible by tying pullup resistors to the outputs to increase the I_{OH} current available. Design of the Read Enable signals for the stacked devices must ensure that there is no overlap in the Low levels which cause more than one output tobe active at the same time. Parallel expansion to generate n-bit words is accomplished by driving the Enable and address inputs of each device in parallel.

Shift Register

16-Bit Shift Register, Parallel-In/Serial-Out (3-State)
Product Specification

FEATURES

- **16-bit serial I/O shift register**
- **16-bit parallel-in/serial-out converter**
- **Recirculating serial shifting**
- **Common serial data I/O pins (3-state)**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
N74F674	95MHz	55mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F674N
24-Pin Plastic SOL	N74F674D

DESCRIPTION

The 74F674 is a 16 bit shift register with serial and parallel load capability and serial output. A single pin serves alternately as an input for serial entry or as 3-state serial output. In the serial out mode the data recirculates in the register. Chip select, Read/Write and Mode inputs provide control flexibility. The 'F674 operates in one of four modes, as indicated in the Function Table.

Hold : a High signal on the Chip Select ($\overline{CS}$) input prevents clocking and forces the Serial Input/Output (SI/O) 3-state buffer into the high impedance state.

Serial load : data present on the SI/O pin shifts into the register on the falling edge of $\overline{CP}$. Data enters the D_0 position and shifts toward Q_{15} on successive clocks.

Serial output : the SI/O 3-state buffer is active and the register contents are shifted out from Q_{15} and simultaneously shifted back into Q_0.

Parallel load : data present on D_0-D_{15} IS entered into the register on the falling edge of $\overline{CP}$. The SI/O 3-state buffer is active and represents the Q_{15} output.

To prevent false clocking, $\overline{CP}$ must be Low during a Low-to-High transition of $\overline{CS}$.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

Preliminary Specification

FEATURES for 74F711/711-1

- Consists of five 2-to-1 Multiplexers
- Equivalent to two 'F257As or 'F258As
- High impedance NPN base inputs for reduced loading (20μA in High and Low states)
- Designed for address multiplexing of dynamic RAM and other applications
- Output inverting/non-inverting option
- A 30 ohm series termination resistor on each output-'F711-1
- Outputs sink 64mA

FEATURES for 74F712/712-1

- Consists of five 3-to-1 Multiplexers
- Equivalent to four 'F157As or 'F158As
- High impedance NPN base inputs for reduced loading (20μA in High and Low states)
- Designed for address multiplexing of dynamic RAM and other applications
- A 30 ohm series termination resistor on each output-'F712-1

DESCRIPTION

The 74F711/711-1 consists of five 2-to-1 multiplexers designed for address multiplexing for dynamic RAMs and other multiplexing applications. The 'F711 has a common select (S) input, an Output Enable ($\overline{OE}$) input and an Output Inverting ($\overline{INV}$) input to control the 3-state outputs.

PIN CONFIGURATION

LOGIC SYMBOL

LOGIC SYMBOL(IEEE/IEC)

The 'F711-1 is as same as 'F711 except that it has a 30 ohm series termination resistor on each output to reduce line noise. The inverting ($\overline{INV}$) input, when Low, changes data path to inverting in To improve speed and noise immunity, multiple side pins are used by V_{CC} and GND pins. The 3-state outputs source 15mA and sink 64mA.

The 74F712/712-1 consists of four 3-to-1 multiplexers designed for address multiplexing for dynamic RAMs and other multiplexing applications. The 'F712 has two select (S_0,S_1) inputs to determine which set of five inputs will be propagated to the five outputs. The 'F712-1 is as same as 'F712 except that it has a 30 ohm series termination resistor on each output to reduce line noise. The outputs source 15mA and sink 64mA.

I_{CC}	Supply current (total)	'F723/723-1	I_{CCH}	V_{CC} = MAX		28		mA
			I_{CCL}			26		mA
			I_{CCZ}			30		mA
		'F725/725-1	I_{CCH}			29		mA
			I_{CCL}			28		mA
			I_{CCZ}			30		mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
14-Pin Plastic DIP	N74F728N
14-Pin Plastic SO	N74F728D

DESCRIPTION

The 74F728 is a dual positive edge-triggered D-type flip-flop featuring individual Data, Clock, Set and Reset inputs; also true and complementary outputs.

Set ($\overline{S}_n$) and Reset ($\overline{R}_n$) are asynchronous active-Low inputs and operate independently of the Clock (CP) input. They set and reset both flip-flops of a cascaded pair simultaneously. Data must be stable just one setup time prior to the Low-to-High transition of the clock for guaranteed propagation delays.

Clock triggering occurs at a voltage level and is not directly related to the transition time of the positive-going pulse. Following the hold time interval, data at the D input may be changed without affecting the levels of the output. Data entering the 'F728 requires two clock cycles to arrive at the outputs. The 'F728 is designed so that the outputs can never display a metastable state due to setup and hold times violations. If setup and hold times are violated the propagation delays may be extended beyond the specifications but the outputs will not glitch or display a metastable state. Typical metastability parameters for the 74F728 are: $\tau < .100$ns, $T_o = 1\mu$s, and h=3.3ns.

Estimated Mean TIme Between Failures on the output flops with data and clock at 100 MHz (failures being any extension of the propagation delays is ~1.55X 10^{26} seconds or ~5X10^{18} years).

Multiplexers

74F732 Quad Data Multiplexer, Inverting (3-State)
74F733 Quad Data Multiplexer, Non-Inverting (3-State)
Product Specification

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
74F732	6.0ns	65mA
74F733	6.0ns	75mA

FEATURES

- **Quad 2-to-1 Multiplexer (two busses to one bus)**
- **Data can flow in either direction between busses (A → B, A → C, B → C, B → A, C → A, C → B)**
- **A built-in "break-before-make" feature eliminates current glitches and simplifies PC board design**
- **Output Enable for each bus to allow flexible contention control**
- **3-State outputs sink 64mA**

DESCRIPTION

The 74F732/74F733 are Quad Data Multiplexers designed to provide a simple means to control the flow of bidirectional data between three data busses.

The 74F732/74F733 consist of four multiplexers. Each multiplexer has three I/O (A_n, B_n, C_n) pins and uses one Output Enable pin ($\overline{OEA}$, $\overline{OEB}$, $\overline{OEC}$). There are two Select (S_0, S_1) pins and a Direction (DIR) pin to control data flow paths for all four multiplexers.

With the Select control, data can flow in the following directions between busses: A to B, A to C, B to A, B to C, C to B, A to B and C. A built-in "break-before-make" feature eliminates current glitches common to systems using 3-State transceivers to accomplish the same function.

		74F733	I_{CCH}	V_{CC} = MAX			70	100	mA
			I_{CCL}				80	115	mA
			I_{CCZ}				80	110	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F739
Shift Register

8-Bit Shift Register With Multiplexed Inputs
Preliminary Specification

FEATURES

- **8-bit shift register with multiplexed inputs**
- **Facilitates parallel to serial conversion from two sources**
- **Slim DIP 300 MIL package**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
N74F739	130 MHz	45mA

DESCRIPTION

The 74F739 is an 8-bit Shift Register With Multiplexed Inputs. The shift register is an 8-bit parallel/serial in /serial out shift register. The multiplexed inputs consist of eight 2-input multiplexers with outputs internally connected to the 8-bit shift regsiter. The shift register will shift right on each Low-to-High transition of the CLock (CP) input when Clock Enable ($\overline{CE}$) input is Low and Parallel Enable ($\overline{PE}$) input is High. When $\overline{PE}$ input is Low, then the shift is inhibited and a byte on one of the two sets of inputs can be loaded into the shift register on each Low-to-High transition of the CP input regardless of the state of the $\overline{CE}$. If the Select (S) input is Low, then the D_{0a}-D_{7a} set of input will be selected for loading, and if the S input is High, the D_{0b}-D_{7b} set will be selected. When the $\overline{PE}$ input and $\overline{CE}$ input are both are High, the shift register will hold the data.

OC=Open Collector

DESCRIPTION

The 74F755 is an octal three state register with simple handshaking logic. Data is latched into and read from the part in the same manner as the 'F374 or other octal registers with the exception that the 'F755 has a Clock Enable pin. Handshaking can be performed in either a polled or interrupt environment by using the D_8 input and the Q_7 or Q_8 output. D_8 is latched along with the other data bits on the rising edge of the clock, but is handled differently on the output. The status of this bit can be sampled on the Q_8 open collector output and used as an interrupt or other control function. The status of D_8 can also be sampled on the Q_7 output with the appropriate combination of $\overline{OE}_0$ and $\overline{OE}_1$ for polled operation. The D_8 register is automatically reset when Q_0-Q_7 are sampled, resetting the handshaking for the next cycle. The 'F755 is equipped with a true Clock Enable ($\overline{CE}$) pin. There are no functional restrictions on the use of the $\overline{CE}$ pin. $\overline{CE}$ may be cycled with the clock input either Low or High with no false clocks generated. The 'F755 can serve as a single chip communications channel with simple handshaking, or two can be used for a bidirectional channel.

I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				50	70	mA
		I_{CCL}					65	90	mA
		I_{CCZ}					60	90	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

74F756 Octal Inverter Buffer (Open Collector)
74F757 Octal Buffer (Open Collector)
74F760 Octal Buffer (Open Collector)

Product Specification

FEATURES

- **Octal bus interface**
- **Open collector versions of 74F240, 74F241 and 74F244**

DESCRIPTION

The 74F756, 74F757 and 74F760 are octal buffers that are ideal for driving bus lines of buffer memory address registers. The 74F756 is the open collector version of 74F240, 74F757 is the open collector version of 74F241 and 74F760 is the open collector version of 74F244. These devices feature two Output Enables, $\overline{OE}_a$ and $\overline{OE}_b$ (or OE_b for the 'F757), each controlling four of the outputs.

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
74F756	9.0ns	40mA
74F757	9.0ns	45mA

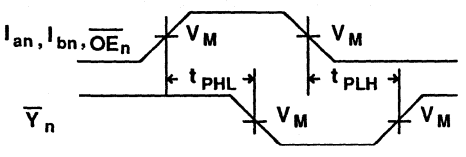
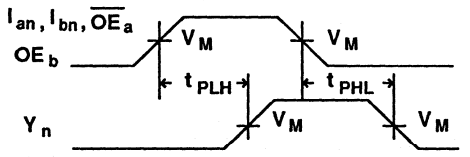
AC WAVEFORMS



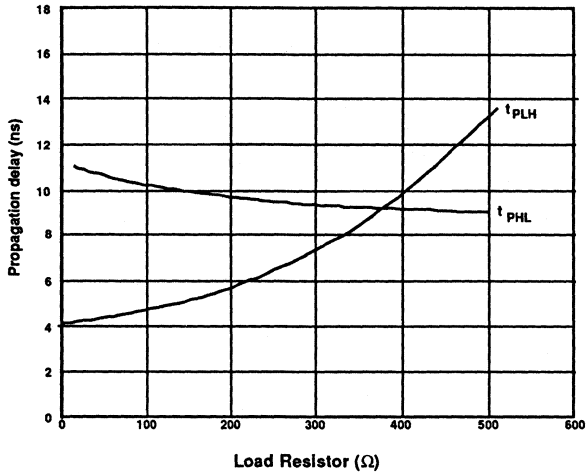
Waveform 1. For Inverting Outputs



Waveform 2. For Non-Inverting Outputs

NOTE: For all waveforms, V_M = 1.5V.

TYPICAL PROPAGATION DELAYS VERSUS LOAD FOR OPEN COLLECTOR OUTPUTS



NOTE:
When using open-collector parts, the value of the pull-up resistor greatly affects the value of the t_{PLH}. For example, changing the pull-up resistor value from 500 Ω to 100Ω will improve the t_{PLH} up to 50% with only slight increase in the t_{PHL}. However, if the pull-up resistor is changed, the user must make certain that the total I_{OL} current through the resistor and the total I_{IL}'s of the receivers do not exceed the I_{OL} maximum specification.

FAST 74F776

Pi-Bus Transceiver

Octal Bidirectional Latched Transceiver (Open Collector)
Product Specification

FEATURES

- **Octal Latched Transceiver**
- **Drives heavily loaded backplanes with equivalent load impedances down to 10 ohms**
- **High drive (100mA) open collector drivers on B-port**
- **Reduced voltage swing (1 volt) produces less noise and reduces power consumption**
- **High speed operation enhances performance of backplane buses and facilitates incident wave switching**
- **Compatible with Pi-bus and IEEE 896 Futurebus Standards**
- **Built-in precision band-gap reference provides accurate receiver thresholds and improved noise immunity**
- **Controlled output ramp and multiple GND pins minimize ground bounce**
- **Glitch-free power up / power down operation**
- **Multiple package options**

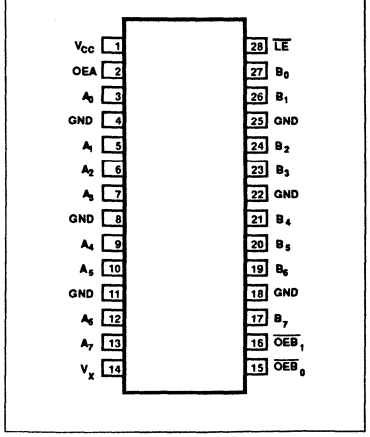
* OC = Open Collector

DESCRIPTION

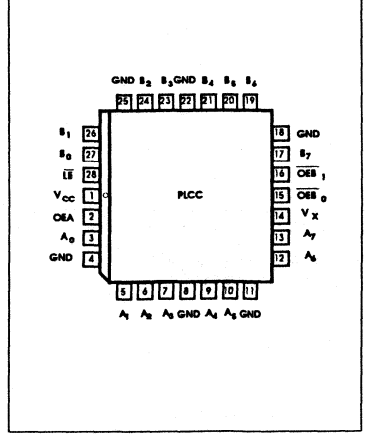
The 74F776 is an octal bidirectional latched transceiver and is intended to provide the electrical interface to a high performance wired-or bus. The B port inverting drivers are low-capacitance open collector with controlled ramp and are designed to sink 100 mA from 2 volts. The B port inverting receivers have a 100 mV threshold region and a 4ns glitch filter.

The 74F776 B port interfaces to 'Backplane Transceiver Logic' (BTL). BTL features a reduced (1V) voltage swing for lower power consumption and a series diode on the drivers to reduce capacitive

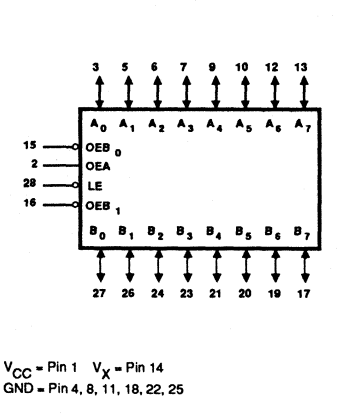
PIN CONFIGURATION



PIN CONFIGURATION PLCC



LOGIC SYMBOL



VCC = Pin 1 VX = Pin 14
GND = Pin 4, 8, 11, 18, 22, 25

DESCRIPTION (Continued)

loading (<5 pF). Incident wave switching is employed, therefore BTL propagation delays are short. Although the voltage swing is much less for BTL, so is its receiver threshold region, therefore noise margins are excellent.

BTL offers low power consumption, low ground bounce, EMI and crosstalk, low capacitive loading, superior noise margin and low propagation delays. This results in a high bandwidth, reliable backplane.

The 74F776 A port has TTL 3-State drivers and TTL receivers with a latch function. A separate High-level control voltage input (V_x) is provided to limit the A side output level to a given voltage level (such as 3.3V). For 5.0V systems, V_x is simply tied to V_{CC}.

The 'F776 has a designed feature to control the B output transitions during power sequencing. There are two possible sequences, They are as follows:

1. When $\overline{LE}$=Low and $\overline{OEB}_n$= Low then the B outputs are disabled until the $\overline{LE}$ circuitry takes control. Then the B outputs will follow the A inputs, making a maximum of one transition during power-up (or down).
2. If $\overline{LE}$=High or $\overline{OEB}_n$= High then the B outputs will be disabled durng power-up (or down).

PIN DESCRIPTION

FUNCTION TABLE

INPUTS						LATCH	OUTPUTS		MODE
A_n	B_n*	$\overline{LE}$	OEA	$\overline{OEB_0}$	$\overline{OEB_1}$	STATE	A_n	B_n	
H	X	L	L	L	L	H	Z	Z	A 3-state, Data from A to B
L	X	L	L	L	L	L	Z	L	
X	X	H	L	L	L	Q_n	Z	Q_n	A 3-state, Latched data to B
–	–	L	H	L	L	(1)	(1)	(1)	Feedback: A to B, B to A
–	H	H	H	L	L	H(2)	H	Z(2)	Preconditioned Latch enabling data transfer from B to A
–	L	H	H	L	L	H(2)	L	Z(2)	
–	–	H	H	L	L	Q_n	Q_n	Q_n	Latch state to A and B
H	X	L	L	H	X	H	Z	Z	B and A 3-state
L	X	L	L	H	X	L	Z	Z	
X	X	H	L	H	X	Q_n	Z	Z	
–	H	L	H	H	X	H	H	Z	B 3-state, Data from B to A
–	L	L	H	H	X	L	L	Z	
–	H	H	H	H	X	Q_n	H	Z	
–	L	H	H	H	X	Q_n	L	Z	
H	X	L	L	X	H	H	Z	Z	B and A 3-state
L	X	L	L	X	H	L	Z	Z	
X	X	H	L	X	H	Q_n	Z	Z	
–	H	L	H	X	H	H	H	Z	B 3-state, Data from B to A
–	L	L	H	X	H	L	L	Z	
–	H	H	H	X	H	Q_n	H	Z	
–	L	H	H	X	H	Q_n	L	Z	

H = High voltage level
L = Low voltage level
X = Don't care
– = Input not externally driven
Z = High Impedance (off) state
Q_n = High or Low voltage level one setup time prior to the Low-to-High $\overline{LE}$ transition
(1) = Condition will cause a feedback loop path; A to B and B to A
(2) = The latch must be preconditioned such that B inputs may assume a High or Low level while $\overline{OEB_0}$ and $\overline{OEB_1}$ are Low and $\overline{LE}$ is High.
B* = Precaution should be taken to insure the B inputs do not float. If they do they are equal to Low state.

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

		I_{CCZ}	V_{CC} = MAX, V_{IL} = 0.5V			80	100	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type. Unless otherwise specified, V_X = V_{CC} for all test conditions.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.
4. Due to test equipment limitations, actual test conditions are for V_{IH}=1.6V and V_{IL}=1.3V.

R_T = Termination resistance should be equal to Z_{OUT} of pulse generators.

C_D = Load capacitance includes jig and probe capacitance; see AC CHARACTERISTICS for value.

R_U = Pull up resistor; see AC CHARACTERISTICS for value.

FAST 74F779, 74F779A Counters

8-Bit Bidirectional Binary Counter (3-state)

Preliminary Specification for 74F779A
Product Specification for 74F779

FEATURES

- **Multiplexed 3-state I/O ports for bus oriented applications**
- **Built-in look-ahead carry capability**
- **Center power pins to reduce effects of package inductance**
- **Count frequency 145MHz typical**
- **Supply current 90mA typical**
- **See 'F269 for 24 pin separate I/O port version**
- **See 'F579 for 20 pin version**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F779/779A	145MHz	90mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
16-Pin Plastic DIP	N74F779N, N74F779AN
16-Pin Plastic SOL	N74F779D, N74F779AD

DESCRIPTION

The 74F779/74F779A are fully synchronous 8-stage Up/Down Counter with multiplexed 3-state I/O ports for bus-oriented applications. All control functions (hold, count up, count down, synchronous load) are controlled by two mode pins (S_0,S_1). The device also features carry look-ahead for easy cascading. All state changes are initiated by the rising edge of the clock. When $\overline{CET}$ is HIgh the data outputs are held in their current state and $\overline{TC}$ is held High. The $\overline{TC}$ output is not recommended for use as a clock or asynchronous reset due to the possibility of decoding spikes.

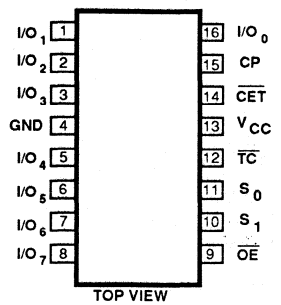
The 74F779A differs from 74F779 in that it has an additional hold mode as described in the Function Table.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

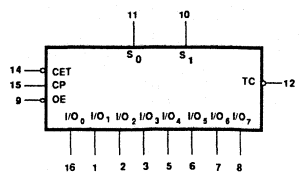
PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
I/O_n	Data inputs	3.5/1.0	70µA/0.6mA
	Data outputs	150/40	3.0mA/24mA
S_0,S_1	Select inputs	1.0/1.0	20µA/0.6mA
$\overline{OE}$	Output enable input (active Low)	1.0/1.0	20µA/0.6mA
$\overline{CET}$	Count Enable Trickle input (active Low)	1.0/1.0	20µA/0.6mA
CP	Clock input	1.0/1.0	20µA/0.6mA
$\overline{TC}$	Terminal count output (active Low)	50/33	1.0mA/20mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

PIN CONFIGURATION

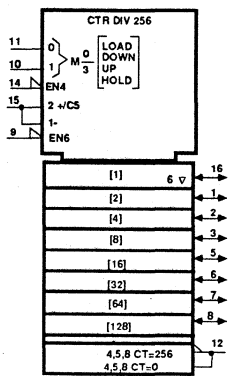


LOGIC SYMBOL

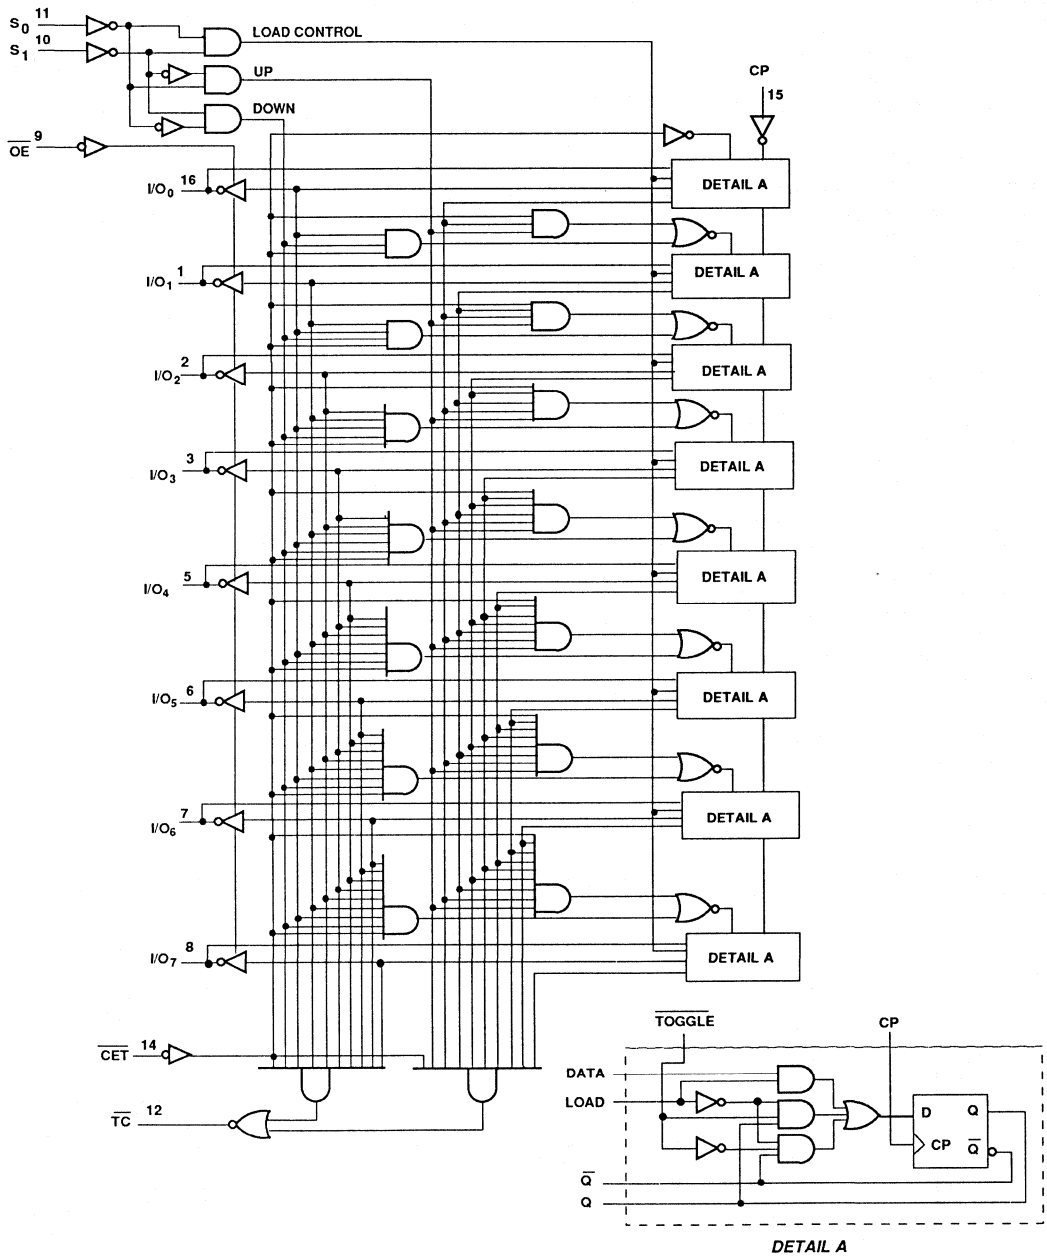


V_{CC} = Pin 13
GND = Pin 4

LOGIC SYMBOL(IEEE/IEC)



LOGIC DIAGRAM



V_{CC} = pin 13

16-Pin Plastic DIP	74F786N
16-Pin Plastic SO	74F786D

FEATURES

- **Arbitrates between 4 asynchronous inputs**
- **Separate grant output for each input**
- **Common output enable**
- **On-board 4 input AND gate**
- **Metastable-free outputs**

DESCRIPTION

The 74F786 is an asynchronous 4-bit arbiter designed for high speed real-time applications. The priority of arbitration is determined on a first-come first-served basis. Separate Bus Grant ($\overline{BG}_n$) outputs are available to indicate which one of the request inputs is served by the arbitration logic. All $\overline{BG}_n$ outputs are enabled by a common enable ($\overline{EN}$) pin. In order to generate a bus request signal, a separate 4-input AND gate is provided which may also be used as an independent AND gate. Unused Bus Request ($\overline{BR}_n$) inputs may be disabled by tying them High.

The 'F786 is designed so that contention between two or more $\overline{BR}_n$ inputs will not cause the $\overline{BG}_n$ outputs to glitch or display a metastable condition. In this situation however, an increase in the $\overline{BR}_n$ to $\overline{BG}_n$ propagation delay (t_{PHL}) may be observed. A typical 'F786 has an h = 6.6ns, τ = .41ns and T_0 = 5µsec. Where:

h= Typical propagation delay through the device.

τ= Rate at which a latch in a metastable state resolves that condition.

& T_0= The measurement of the propensity of a latch to enter a metastable state.

For further information, please refer to the 'F786 application note.

The $\overline{BR}_n$ inputs have no inherent priority. The arbiter assigns priority to the incoming requests as they are received, therefore, the first $\overline{BR}_n$ asserted will have the highest priority. When a bus request is received its corresponding bus grant becomes active, provided that $\overline{EN}$ is Low. If additional bus requests are made during this time they are queued. When the first request is removed, the arbiter services the bus request with the next highest priority. If a request is removed while a previous request is being serviced, it loses its priority.

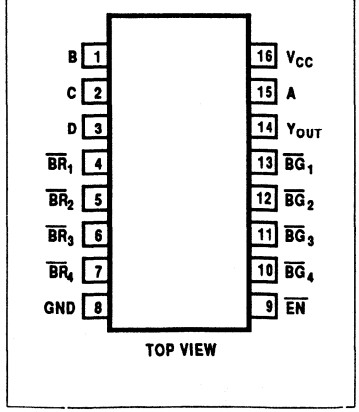
For example, if $\overline{BR}_1$ is the first request received, followed by $\overline{BR}_2$ and finally by $\overline{BR}_3$, $\overline{BR}_2$ will have priority over $\overline{BR}_3$. However, if $\overline{BR}_2$ is removed before $\overline{BR}_1$ is negated, it will lose its place and $\overline{BR}_3$ will become next in priority. If three or more requests are asserted precisely at the same time, and one of them is re-

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

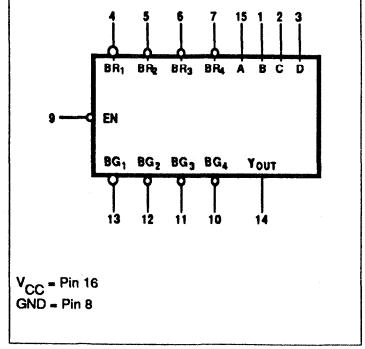
PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
$\overline{BR}_1$ - $\overline{BR}_4$	Bus Request inputs (active Low)	1.0/3.0	20µA/1.8mA
A, B, C, D	AND gate inputs	1.0/1.0	20µA/0.6mA
$\overline{EN}$	Common Bus Grant output enable input (active Low)	1.0/1.0	20µA/0.6mA
Y_{OUT}	AND gate output	150/40	3.0mA/24mA
$\overline{BG}_1$ - $\overline{BG}_4$	Bus Grant outputs (active Low)	150/40	3.0mA/24mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

PIN CONFIGURATION



LOGIC SYMBOL



moved prior to being serviced, it may cause premature termination of the present grant and assertion of another grant. Therefore, the user should not remove ungranted requests when arbitrating between three or four requests. This does not apply to arbitration between two requests.

If two or more $\overline{BR}_n$ inputs are asserted at precisely the same time, one of them will be selected at random, and all $\overline{BG}_n$ outputs will be held in the High state until the selection is made. This guarantees that an erroneous $\overline{BG}_n$ will not be generated even though a metastable condition may occur internal to the device.

When the $\overline{EN}$ input is High, all $\overline{BG}_n$ outputs are forced High.

PIN DESCRIPTION

SYMBOL	PINS	TYPE	NAME AND FUNCTION
$\overline{BR}_1$ - $\overline{BR}_4$	4 - 7	I	Bus Request inputs (Active Low) - The logic of this device arbitrates between these four inputs. Unused inputs should be tied high.
$\overline{BG}_1$ - $\overline{BG}_4$	13 - 10	O	Bus Grant outputs (Active Low) - These outputs indicate the selected bus request. $\overline{BG}_1$ corresponds to $\overline{BR}_1$, $\overline{BG}_2$ to $\overline{BR}_2$, etc1
A, B, C, D	15, 1 - 3	I	Inputs of the 4-input AND gate.
Y_{OUT}	14	O	Output of the 4-input AND gate.
$\overline{EN}$	9	I	Enable input - When Low it enables the $\overline{BR}_1$ - $\overline{BR}_4$ outputs.

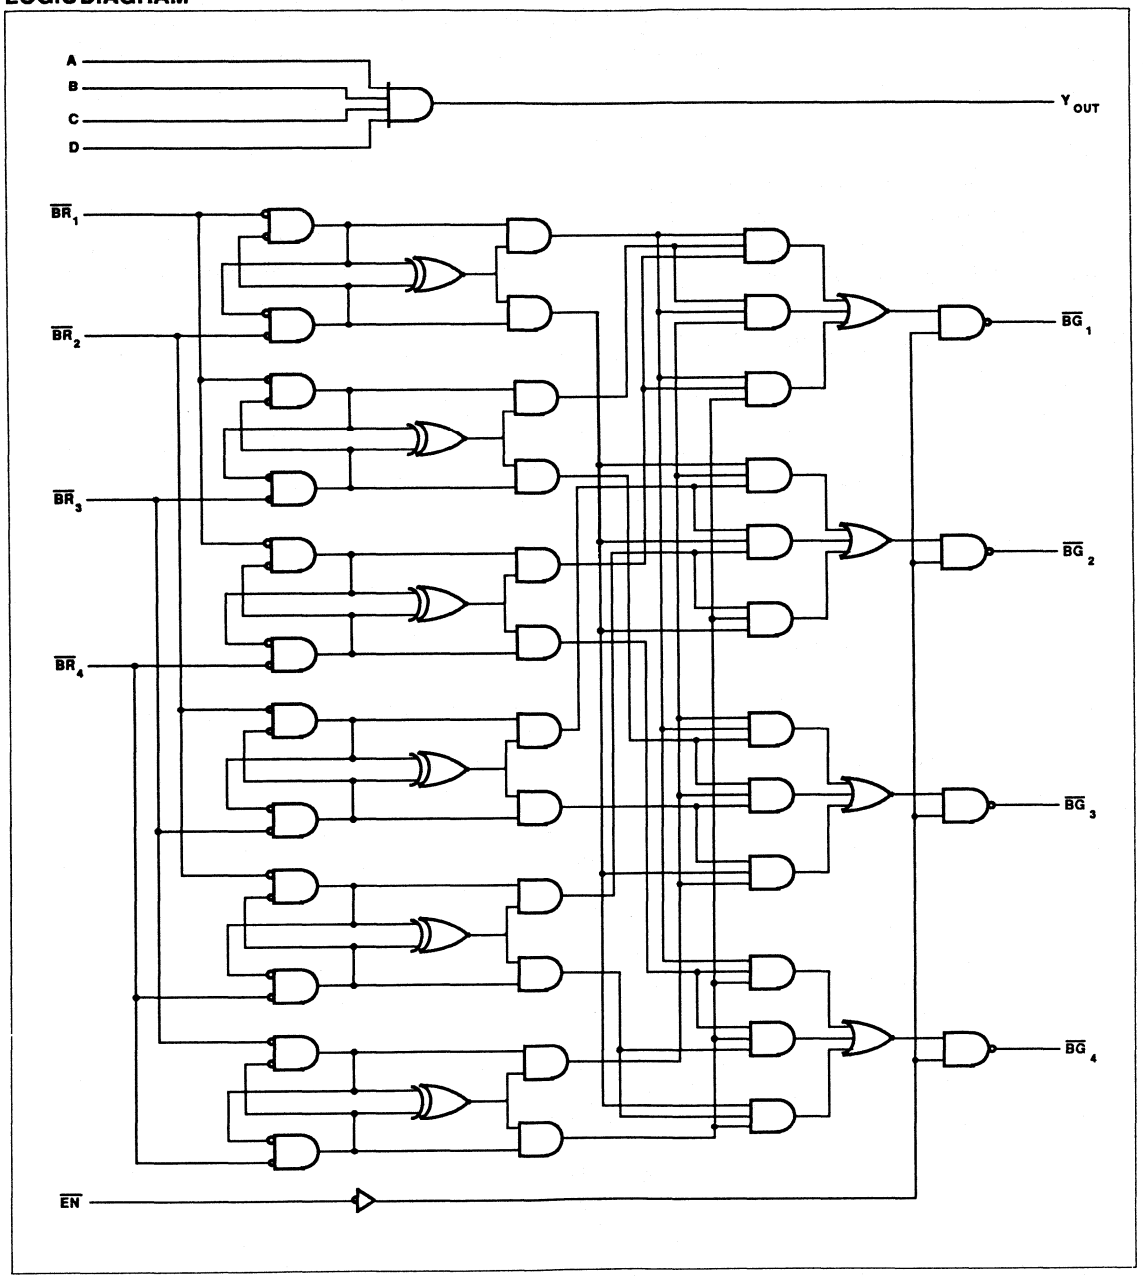
LOGIC DIAGRAM



ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V
I_{IN}	Input current	-30 to +5	mA
V_{OUT}	Voltage applied to output in High output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in Low output state	48	mA
T_A	Operating free-air temperature range	0 to +70	°C
T_{STG}	Storage temperature	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

SYMBOL	PARAMETER	LIMITS			UNIT
		Min	Nom	Max	
V_{CC}	Supply voltage	4.5	5.0	5.5	V
V_{IH}	High-level input voltage	2.0			V
V_{IL}	Low-level input voltage			0.8	V
I_{IK}	Input clamp current			-18	mA
I_{OH}	High-level output current			-3	mA
I_{OL}	Low-level output current			24	mA
T_A	Operating free-air temperature range	0		70	°C

DC ELECTRICAL CHARACTERISTICS

(Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER		TEST CONDITIONS[1]		LIMITS			UNIT
					Min	Typ[2]	Max	
V_{OH}	High-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}	2.4			V
			V_{IH} = MIN, I_{OH} = MAX	±5%V_{CC}	2.7	3.3		V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}		0.35	0.50	V
			V_{IH} = MIN, I_{OL} = MAX	±5%V_{CC}		0.35	0.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input current at maximum input voltage		V_{CC} = MAX, V_I = 7.0V				100	µA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V				20	µA
I_{IL}	Low-level input current	A-D, $\overline{EN}$	V_{CC} = MAX, V_I = 0.5V				-0.6	mA
		$\overline{BR_n}$					-1.8	mA
I_{OS}	Short circuit output current[3]		V_{CC} = MAX		-60		150	mA
I_{CC}	Supply current (total)		V_{CC} = MAX			55	80	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

Bus Interface Registers

'F821/'F822 10-Bit Bus Interface Registers, NINV/INV (3-State)
'F823/'F824 9-Bit Bus Interface Registers, NINV/INV (3-State)
'F825/'F826 8-Bit Bus Interface Registers, NINV/INV (3-State)
Product Specification

FEATURES

- **High speed parallel registers with positive edge-triggered D-type flip-flops**
- **High performance bus interface buffering for wide data/address paths or busses carrying parity**
- **High impedance PNP base inputs for reduced loading (20μA in High and Low states)**
- **I_{IL} is 20μA vs 1000μA for AM29821 series**
- **Buffered control inputs to reduce AC effects**
- **Ideal where high speed, light loading, or increased fan-in as required with MOS microprocessors**
- **Positive and negative over-shoots are clamped to ground**
- **3-state outputs glitch free during power-up and power-down**
- **Slim Dip 300 mil package**
- **Broadside pinout compatible with AMD AM 29821-29826 series**
- **Outputs sink 64mA and source 24mA**

NOTE:
One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F821 series Bus Interface Registers are designed to eliminate the extra packages required to buffer existing registers and provide extra data width for wider data/address paths of busses carrying parity.

The 'F821/'F822 are buffered 10-bit wide versions of the popular 'F374/'F534 functions.
The 'F822 is the inverted output version of 'F821.

The74F823 and 74F824 are 9-bit wide buffered registers with Clock Enable($\overline{CE}$) and Master Reset ($\overline{MR}$) which are ideal for parity bus interfacing in high microprogrammed systems.
The 'F 824 is the inverted output version of 'F823.

The74F825 and 74F826 are 8-bit buffered registers with all the 'F823/'F824 controls plus Output Enable ($\overline{OE}_0$, $\overline{OE}_1$, $\overline{OE}_2$) to allow multiuser control of the interface, e.g., $\overline{CS}$, DMA, and RD/$\overline{WR}$. They are ideal for use as an output port requiring High I_{OL}/I_{OH}.
The 'F826 is the inverted output version of 'F825.

			I_{CCL}					75	105	mA
			I_{CCZ}					75	115	mA
		'F823 'F824	I_{CCH}	V_{CC} = MAX				65	100	mA
			I_{CCL}					70	105	mA
			I_{CCZ}					75	110	mA
		'F825 'F826	I_{CCH}	V_{CC} = MAX				60	85	mA
			I_{CCL}					60	90	mA
			I_{CCZ}					65	95	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

Product Specification

FEATURES
- **Combines the 'F373, two 'F157s, and the 'F166 functions in one package**
- **Interleaved loading with 2:1 mux**
- **Dual 8-bit Parallel inputs**
- **Transparent Latch on all "B" inputs**
- **Guaranteed Serial Shift Frequency to 60MHz**
- **Expandable to 16-bits or more with serial input**

DESCRIPTION

The 74F835 is a high speed 8-bit parallel/serial-in, serial-out shift register whose parallel inputs have been connected to an internal octal two-to-one multiplexer with all the 'B' inputs connected to an octal latch.

It is useful in any design where a 2:1 mux input with a transparent latch is needed.

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
74F835	85MHz	45mA

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V
I_{IN}	Input current	-30 to +5	mA
V_{OUT}	Voltage applied to output in High output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in Low output state	40	mA
T_A	Operating free-air temperature range	0 to +70	°C
T_{STG}	Storage temperature	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

SYMBOL	PARAMETER	LIMITS			UNIT
		Min	Nom	Max	
V_{CC}	Supply voltage	4.5	5.0	5.5	V
V_{IH}	High-level input voltage	2.0			V
V_{IL}	Low-level input voltage			0.8	V
I_{IK}	Input clamp current			-18	mA
I_{OH}	High-level output current			-1	mA
I_{OL}	Low-level output current			20	mA
T_A	Operating free-air temperature range	0		70	°C

DC ELECTRICAL CHARACTERISTICS (Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER		TEST CONDITIONS[1]		LIMITS Min	LIMITS Typ[2]	LIMITS Max	UNIT
V_{OH}	High-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}	2.5			V
			V_{IH} = MIN, I_{OH} = MAX	±5%V_{CC}	2.7	3.4		V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}		.30	.50	V
			V_{IH} = MIN, I_{OL} = MAX	±5%V_{CC}		.30	.50	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input current at maximum input voltage		V_{CC} = MAX, V_I = 7.0V				100	µA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V				20	µA
I_{IL}	Low-level input current		V_{CC} = MAX, V_I = 0.5V				-0.6	mA
I_{OS}	Short circuit output current[3]		V_{CC} = MAX		-60		-150	mA
I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX			45	65	mA
		I_{CCL}				45	65	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F838
Microprogram Sequence Controller

Preliminary Specification

FEATURES

- **5-bit address generator (32 micro-instruction addressability)**
- **Two subroutine branching capability**
- **Interrupt branching**
- **Cascadable for increased addressing**
- **Direct branching over full address range**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F838	90MHz	65mA

ORDERING INFORMATION

DESCRIPTION	COMMERCIAL RANGE V_{CC} = 5V ± 10%; T_A = 0°C to +70°C
20-Pin Plastic DIP	N74F838N
20-Pin Plastic SOL	N74F838D

DESCRIPTION

The Signetics 74F838 Microprogram Sequence Controller generates addresses to access instructions from a microprogram memory.

This high-speed device provides an efficient means of controlling the flow through a microprogram by providing a powerful set of sequencing functions.

In addition to providing branching facility over the entire address range, the device also supports two subroutines and an interrupt level.

The 74F838 can directly address up to 32 micro-instructions. However, two or more devices may be cascaded for increased addressing. For example, two devices can address 1K and three can address up to 32K of program storage.

Combined with memory, the 74F838 forms a powerful control section for CPUs and I/O controllers.

The device is available in a 20-pin DIP and SOL Packages.

INPUT AND OUTPUT LOADING AND FANOUT TABLE

PINS	DESCRIPTION	74F (U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
$JS_0 - JS_4$	Jump State input	1.0/1.0	20μA/0.6mA

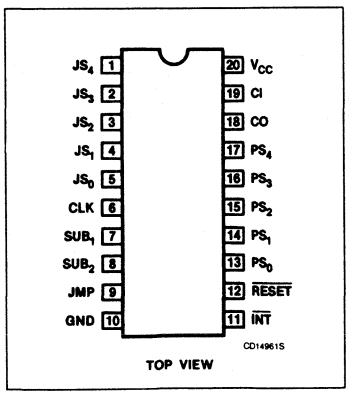
$PS_0 - PS_4$	Present State output	150/40	3mA/24mA

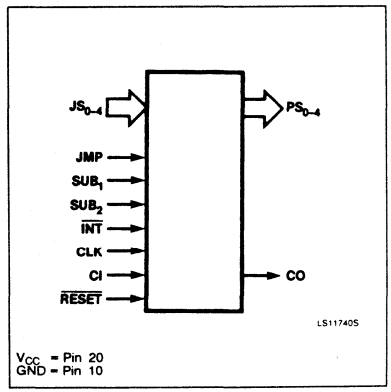
NOTE:
1. One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6 mA in the Low state.

PIN CONFIGURATION



TOP VIEW

LOGIC SYMBOL



VCC = Pin 20
GND = Pin 10

PIN DESCRIPTION

SYMBOL	PIN	TYPE	NAME	FUNCTION
JS_0 JS_1 JS_2 JS_3 JS_4	5 4 3 2 1	Input Input Input Input Input	Jump State	Address on these inputs is transferred to the $PS_0 - PS_4$ outputs if the JMP input is High or the SUB_1 or SUB_2 inputs change from Low-to-High. These inputs are ignored if neither of the above conditions is true.
SUB_1 SUB_2	7 8	Input Input	Subroutine	On a Low-to-High transition, the Present State address ($PS_0 - PS_4$) plus one is saved internally as a return address, and the address on pins $JS_0 - JS_4$ will be transferred to the $PS_0 - PS_4$ outputs. On a High-to-Low transition, the saved return address will be enabled onto the $PS_0 - PS_4$ outputs.
JMP	9	Input	Jump	When JMP is High, the next state address will be $JS_0 - JS_4$.
$\overline{INT}$	11	Input	Interrupt	On a High-to-Low transition, the next address to appear on the $PS_0 - PS_4$ output is saved internally as a return address and $PS_0 - PS_4$ are forced to all ones. If this feature is used, a microcode jump would normally be stored at state address 11111. SUB_1 and SUB_2 inputs are ignored when $\overline{INT}$ is Low. On a Low-to-High transition, the saved return address is enabled onto the $PS_0 - PS_4$ outputs.
CLK	6	Input	Clock	This clock determines the sequence rate of the controller.
$\overline{RESET}$	12	Input	Reset	When Low, all internal registers and $PS_0 - PS_4$ outputs are set to zeros.
CI	19	Input	Cascade In	This input should be tied to V_{CC} for the least significant device. For all other devices, CI is connected to CO of the previous device.
CO	18	Output	Cascade Out	This signal is connected to CI of the next device. One device permits 32 states, two devices allow 1024 states, three devices allow 32,768 states, and so forth.
PS_0 PS_1 PS_2 PS_3 PS_4	13 14 15 16 17	Output	Present State	Present State address outputs.

FUNCTIONAL OPERATION

As shown in the block diagram, the address appearing on the $PS_0 - PS_4$ outputs is selected from five different sources:

- Incremented address
- SUB_1 return address
- SUB_2 return address
- Interrupt return address
- $JS_0 - JS_4$ inputs

The selection of a specific source of address (as explained in the Function Table) is determined by the state of SUB_1, SUB_2, JMP and $\overline{INT}$ inputs. When Low, the $\overline{RESET}$ input unconditionally forces all registers and the $PS_0 - PS_4$ outputs to all zeros. The "increment" function increments the Present State ($PS_0 - PS_4$) by one on the rising edge of the CLK input and automatically wraps around from the highest address (all 1's) to the lowest address (all 0's).

Subroutine Calls

Two subroutine calls, SUB_1 and SUB_2, are supported by the F838. On a Low-to-High transition of SUB_1, $PS_0 - PS_4$ address plus one is stored in the SRA_1 register as a return address and $JS_0 - JS_4$ inputs are transferred to the $PS_0 - PS_4$ outputs on the rising edge of CLK. Similarly, $PS_0 - PS_4$ plus one is stored in the SRA_2 register when SUB_2 makes a Low-to-High transition and $JS_0 - JS_4$ inputs are enabled onto the $PS_0 - PS_4$ outputs on the rising edge of CLK. The rising CLK edge, after the High-to-Low transition on the SUB_1 or SUB_2 inputs, enables the stored return address onto the $PS_0 - PS_4$ outputs. (Please refer to the Function Table for illegal conditions.)

Jump

When this input is High, $PS_0 - PS_4$ outputs are forced to the address indicated by the $JS_0 - JS_4$ inputs. This occurs on the first rising CLK edge after the JMP input has gone High.

Interrupt

The rising CLK edge following a High-to-Low transition on this input will store the next address to appear on the $PS_0 - PS_4$ outputs in the IRA register and force $PS_0 - PS_4$ outputs to all ones (1's). The saved return address is output on the $PS_0 - PS_4$ outputs on the rising CLK edge following a Low-to-High transition on the $\overline{INT}$ input.

↑ = Low-to-High transition
H or L = Either High or Low
⊥ = Anything except a High-to-Low transition
0 = Low Output
1 = High Output

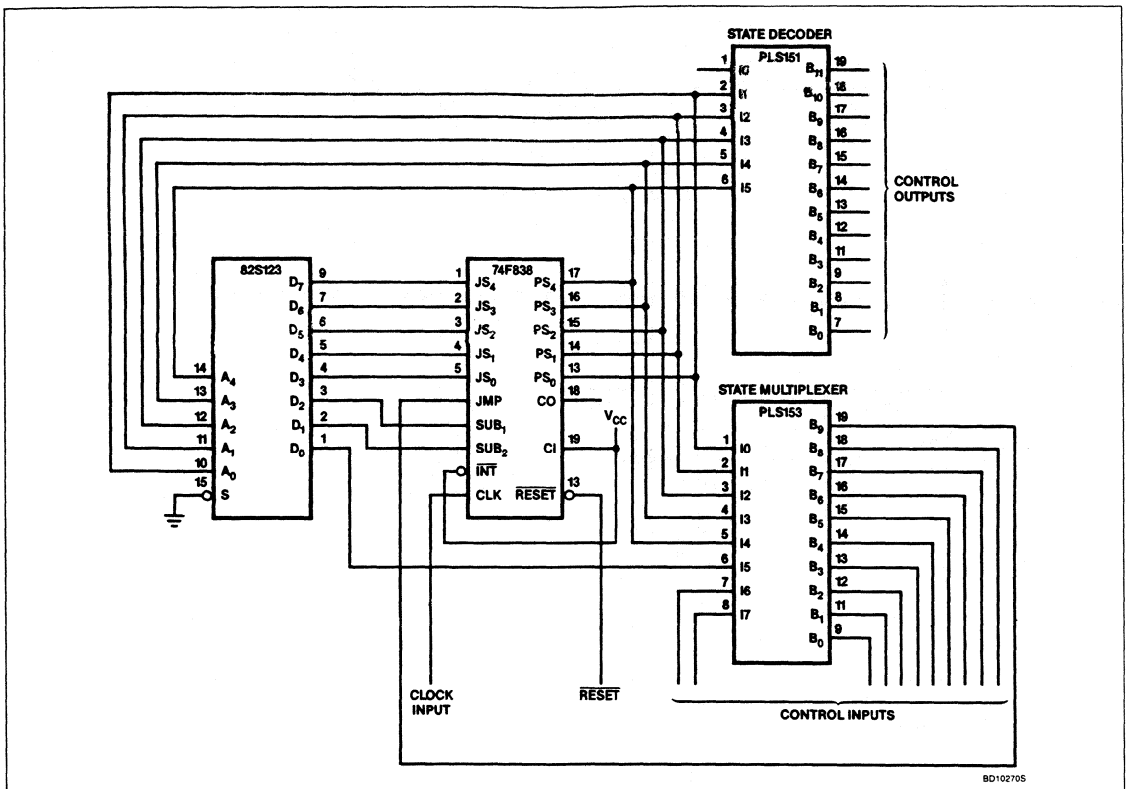

Figure 1

As shown in Figure 1, a PROM (82S123) paired with the 74F838 creates a state machine. When reset, the $PS_0 - PS_4$ outputs are zero. These outputs are decoded by the PLS151 to generate control outputs. When a state has a branch option based on the state of a control signal, the $PS_0 - PS_4$ outputs are used as address inputs to a multiplexer. This application uses a PLS153 as a state multiplexer. One output of the multiplexer connects to the JMP input of the 74F838. When the proper state is decoded, the associated control input is passed on to the JMP input. In addition, the D_0 output of the PROM is connected to one of the control inputs of the multiplexer to implement an unconditional jump. All input signals to the 74F838 are sampled on the rising edge of the input clock, except the interrupt input ($\overline{INT}$) which is sampled on the falling edge of the Clock.

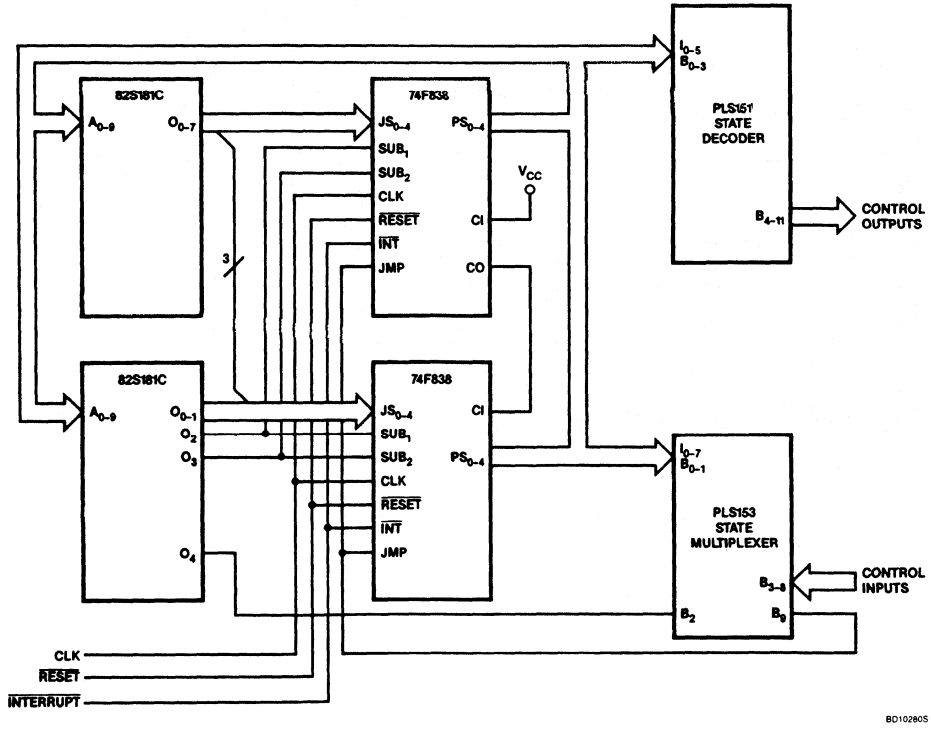

Figure 2. Cascade Mode Interface

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted, these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	LIMITS	UNIT

Product Specification

FEATURES

- **High speed parallel latches with**
- **Extra data width for wide address/ data paths or busses carrying parity**
- *** High impedance NPN base input structure minimizes bus loading**
- *** I_{IL} is 20μA vs 1000μA for AM29841 series**
- **Buffered control inputs to reduce AC effects**
- **Ideal where high speed, light loading, or increased fan-in is required as with MOS microprocessors**
- **Positive and negative over-shoots are clamped to ground**
- **3-state outputs glitch free during power-up and power-down**
- **48mA sink current**
- **Slim Dip 300 mil package**
- **Broadside pinout**
- **Pin-for-pin and function compatible with AMD AM29841-846 series**

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_n	Data inputs	1.0/0.033	20μA/20μA
LE	Latch Enable input	1.0/0.033	20 A/20 A
$\overline{OE}$, $\overline{OE}_n$	Output Enable input (active-Low)	1.0/0.033	20μA/20μA
$\overline{MR}$	Master Reset input (active-Low)	1.0/0.033	20μA/20μA
$\overline{PRE}$	Preset input (active-Low)	1.0/0.033	20μA/20μA
Q_n	Data outputs	750/80	15mA/48mA
$\overline{Q}_n$	Data outputs	750/80	15mA/48mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 'F841-'846 bus interface latch series are designed to provide extra data width for wider address/data paths of busses carrying parity.

The 'F841-'F842 series are functionally and pin compatible to the AMD AM29841-AM29846 series.

The 'F841 consists of ten D-type latches with 3-state outputs. The flip-flops appear transparent to the data when Latch Enable (LE) is High. This allows asynchronous operation, as the output transition follows the data in transition.On the LE High-to-Low transition, the data that meets the setup and hold time is latched.

Data appears on the bus when the Output Enable ($\overline{OE}$) is Low. When $\overline{OE}$ is High the output is in the High-impedance state. The 'F842 is the inverted output version of 'F841.

The 'F843 consists of nine D-type latches with 3-state outputs.

In addition to the LE and $\overline{OE}$ pins, the 'F843 has a Master Reset ($\overline{MR}$) pin and Preset ($\overline{PRE}$) pin. These pins are ideal for parity bus interfacing in high performance systems. When $\overline{MR}$ is Low, the outputs are Low if $\overline{OE}$ is Low. When $\overline{MR}$ is High, data can be entered into the latch. When $\overline{PRE}$ is Low, the outputs are High, if $\overline{OE}$ is Low. $\overline{PRE}$ overrides $\overline{MR}$. The 'F844 is the inverted output version of 'F843.

The 'F845 consists of eight D-type latches with 3-state outputs.

In addition to the LE, $\overline{OE}$, $\overline{MR}$ and $\overline{PRE}$ pins, the 'F845 has two additional $\overline{OE}$ pins making a total of three Output Enables ($\overline{OE}_0$, $\overline{OE}_1$, $\overline{OE}_2$) pins.

The multiple Output Enables ($\overline{OE}_0$, $\overline{OE}_1$, $\overline{OE}_2$) allow multiuser control of the interface, e.g., $\overline{CS}$, DMA, and RD/$\overline{WR}$. The'F846 is the inverted output version of 'F845.

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
20-Pin Plastic DIP	N74F847N
20-Pin Plastic SOL	N74F847D

DESCRIPTION

The 74F847 is a high speed 10/9-bit Serial/Parallel-In Serial Out Shift Register. Data is shifted right on every Low to High transition of the CP input when the $\overline{CE}$ input is Low and the $\overline{PE}$ input is High. While the $\overline{PE}$ input is High, the shift is inhibited, and a word present on the inputs (D_0-D_7) will be loaded into the shift register on every Low to High transition of the CP input with no regard to the state of of the $\overline{CE}$ input. Three outputs are provided: Q_8 for 9 bit applications and Q_9 and $\overline{Q}_9$ for 10 bit applications. Q_9 and $\overline{Q}_9$ can be used independently or together to drive a twisted pair.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
D_0-D_9	Parallel data inputs	1.0/1.0	20µA/0.6mA
D_S	Serial data input (Shift right)	1.0/1.0	20µA/0.6mA
CP	Clock input (Active rising edge)	1.0/1.0	20µA/0.6mA
$\overline{CE}$	Clock Enable input (Active Low)	1.0/1.0	20µA/0.6mA
$\overline{PE}$	Parallel Enable input (Active Low)	1.0/1.0	20µA/0.6mA
$\overline{MR}$	Master Reset input (Active Low)	1.0/1.0	20µA/0.6mA
Q_8,Q_9	True data outputs	50/33	1.0mA/20mA
$\overline{Q}_9$	Complementary data output	50/33	1.0mA/20mA

NOTE:

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V
I_{IN}	Input current	-30 to +5	mA
V_{OUT}	Voltage applied to output in High output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in Low output state	40	mA
T_A	Operating free-air temperature range	0 to +70	°C
T_{STG}	Storage temperature	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

SYMBOL	PARAMETER	LIMITS			UNIT
		Min	Nom	Max	
V_{CC}	Supply voltage	4.5	5.0	5.5	V
V_{IH}	High-level input voltage	2.0			V
V_{IL}	Low-level input voltage			0.8	V
I_{IK}	Input clamp current			-18	mA
I_{OH}	High-level output current			-1	mA
I_{OL}	Low-level output current			20	mA
T_A	Operating free-air temperature range	0		70	°C

DC ELECTRICAL CHARACTERISTICS

(Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER	TEST CONDITIONS[1]		LIMITS			UNIT
				Min	Typ[2]	Max	
V_{OH}	High-level output voltage	V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}	2.5			V
		V_{IH} = MIN, I_{OH} = MAX	±5%V_{CC}	2.7	3.4		V
V_{OL}	Low-level output voltage	V_{CC} = MIN, V_{IL} = MAX	±10%V_{CC}		0.35	0.50	V
		V_{IH} = MIN, I_{OL} = MAX	±5%V_{CC}		0.35	0.50	V
V_{IK}	Input clamp voltage	V_{CC} = MIN, I_I = I_{IK}			-0.73	-1.2	V
I_I	Input current at maximum input voltage	V_{CC} = MAX, V_I = 7.0V				100	µA
I_{IH}	High-level input current	V_{CC} = MAX, V_I = 2.7V				20	µA
I_{IL}	Low-level input current	V_{CC} = MAX, V_I = 0.5V				-0.6	mA
I_{OS}	Short circuit output current[3]	V_{CC} = MAX		-60		-150	mA
I_{CC}	Supply current (total)	V_{CC} = MAX			55		mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F899

Dual Latch Transceiver with Parity

9-Bit Dual Latch Transceiver With 8-bit Parity Generator/Checker (3-State Outputs)
Preliminary Specification

FEATURES

- **Combines 'F543 and 'F280 functions into one package**
- **Combines 'F657 and 'F373 functions into one package (No need to change T/$\overline{R}$ to check parity)**
- **Output sink of 24 mA for the A-Bus and 64 mA for the B-bus**
- **Symmetrical (A and B bus functions are identical)**
- **Selectable generate parity or "feed-through" parity for A-to-B and B-to-A directions**
- **Independant transparent latches for A-to-B and B-to-A directions**
- **Selectable ODD/$\overline{EVEN}$ parity**
- **Continously checks parity of both A bus and B bus latches as $\overline{ERRA}$ and $\overline{ERRB}$**
- **Ability to simultaneously generate and check parity**
- **Can simultaneously read/latch A and B bus data**

DESCRIPTION

The 'F899 is a 9-bit to 9-bit parity transceiver with separate transparent latches for the A bus and B bus. Either bus can generate or check parity. The parity bit can be fed-through with no change or the generated parity can be substituted with in 3-State.

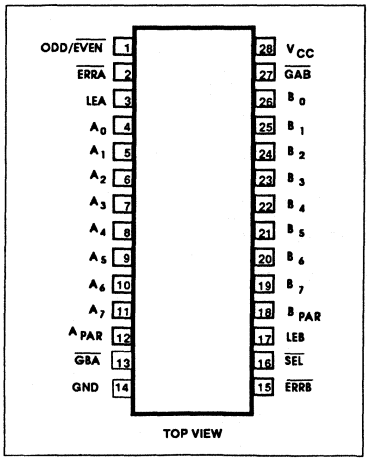
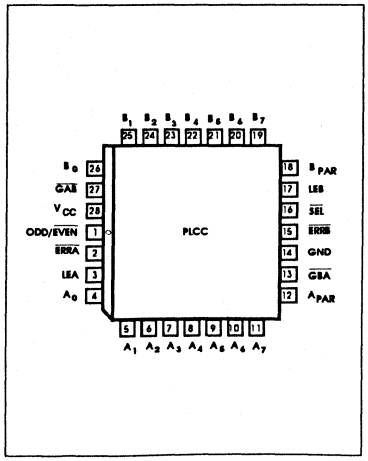
NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

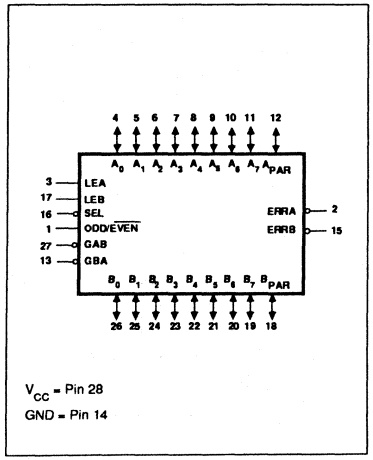
DIP PIN CONFIGURATION



PLCC PIN CONFIGURATION



LOGIC SYMBOL



The device has a guaranteed current sinking capability of 24 mA for the A-bus and 64 mA for the B-bus. Otherwise, the part is symmetrical (A and B bus functions are identical).

The 'F899 features independent latch enables for the A and B bus latches, a select pin for ODD/$\overline{\text{EVEN}}$ parity, and separate error signal output pins for checking parity.

FUNCTIONAL DESCRIPTION:

The 'F899 has three principal modes of operation which are outlined below. All modes apply to both the A-to-B and B-to-A directions.

Transparent latch, Generate parity, Check A and B bus parity:
Bus A (B) communicates to Bus B (A), parity is generated and passed on to the B (A) Bus as B_{PAR} (A_{PAR}). If LEA and LEB are High and the Mode Select ($\overline{\text{SEL}}$) is Low, the parity generated from A_0-A_7 and B_0-B_7 can be checked and monitored by $\overline{\text{ERRA}}$ and $\overline{\text{ERRB}}$. (Fault detection on both input and output buses.)

Transparent latch, Feed-through parity, Check A and B bus parity:
Bus A (B) communicates to Bus B (A) in a feed-through mode if $\overline{\text{SEL}}$ is High. Parity is still generated and checked as $\overline{\text{ERRA}}$ and $\overline{\text{ERRB}}$ and can be used as an interrupt to signal a data/parity bit error to the CPU.

Latched input, Generate/Feed-through parity, Check A (and B) bus parity:
Independent latch enables (LEA and LEB) allow other permutations of:
Transparent latch / 1bus latched / both busses latched
Feed-through parity / generate parity
Check in bus parity / check out bus parity / check in and out bus parity
See function table below.

FUNCTION TABLE

INPUTS					OPERATING MODE
$\overline{\text{GAB}}$	$\overline{\text{GBA}}$	$\overline{\text{SEL}}$	LEA	LEB	
H	H	X	X	X	3-state A bus and B bus (Input A & B simultaneously)

28-Pin Plastic DIP	N74F1604N
28-Pin Plastic SOL	N74F1604D

DESCRIPTION

The 74F1604 is a Dual Octal Transparent Latch. Organized as 8-bit A and B latches, the latch outputs are connected by pairs to eight 2-input multiplexers. A Select (SELECT A/$\overline{B}$) input determines whether the A or B latch contents are multiplexed to the eight outputs. Data entered from the B inputs are selected when SELECT A/$\overline{B}$ is Low: data from the A inputs are selected when SELECT A/$\overline{B}$ is High. Data enters the latch on the falling edge of the Latch Enable ($\overline{LE}$) input. The Latch remains transparent to the data inputs while $\overline{LE}$ is Low, and stores the data that is present one setup time before the Low-to-High Latch Enable transition.

I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				60	82	mA
		I_{CCL}					75	100	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F1761
DRAM and Interrupt Vector Controller

Preliminary Specification

November 1986

FEATURES

- **Programmable DRAM signal timing generator**
- **Automatic refresh circuitry**
- **Provides byte selection for 16 and 32 bit buses**
- **Interrupt Priority Encoder included**
- **Interrupt Acknowledge vector generator on-chip**

DESCRIPTION

The Signetics DRAM and Interrupt Vector Controller (DIVC) is a high performance bipolar device designed to reduce board space and improve performance in micro-processor-based systems. The DIVC's functions include a DRAM signal interface with user programmable timing to match the performance of specific DRAMs used in a system. With a maximum clock frequency of 100 Mhz., this means a timing resolution of 10 nsec. The DRAM Controller section also includes automatic refresh arbitration, with the duration and frequency of refresh totally programmable by the user. When used with the 74F1762 Memory Address Controller, the DIVC provides a complete system solution for DRAM and Interrupt Control. For Interrupt Control, the DIVC contains an Interrupt Priority Decoder with latched inputs controlled by the Interrupt Latch Enable (ILE) input. In addition, the DIVC contains an Interrupt Acknowledge Controller which passes a program-mable 8-bit vector on the system data bus upon receipt of an interrupt acknowledge. There are 7 interrupt acknowledge vectors, each accessable by placing the priority number of the interrupt acknowledge on the A1-A3 signal inputs while acknowledging an interrupt.

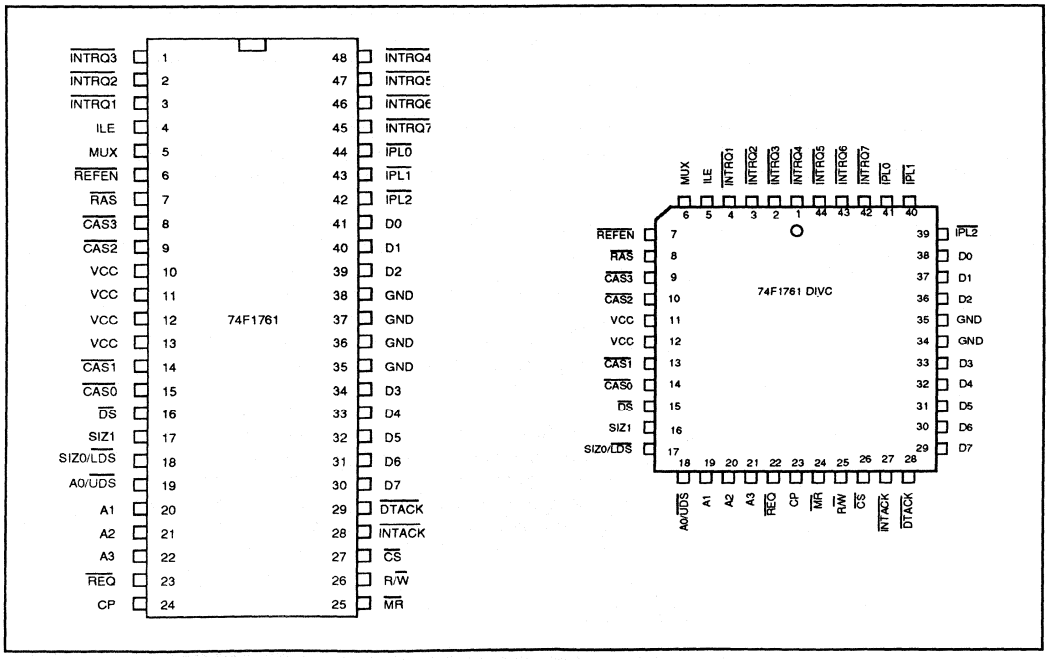
PIN CONFIGURATION



NOTE: Pinout assignments are strictly preliminary and are subject to change.

PIN DESCRIPTION

SYMBOL	PINS		TYPE	NAME AND FUNCTION
	DIP	PLCC		
$\overline{DS}$	2	2	I	Active LOW Data Strobe used to enable the Data Bus during register access cycles and the CAS outputs during DRAM access cycles.
SIZ0/$\overline{LDS}$	3	3	I	In 16-bit Mode, an active LOW Lower Data Strobe signal used to enable the $\overline{CAS1}$ output during a DRAM access cycle. In 32-bit Mode, an active HIGH SIZE 0 signal used with SIZ1 to indicate to the DIVC the size of the DRAM access transaction.
SIZ1	4	4	I	In 32-bit Mode, an active HIGH SIZE 1 signal used with SIZ0 to indicate to the DIVC the size of the DRAM access transaction.
A0/$\overline{UDS}$	5	5	I	In 16-bit Mode, an active LOW Upper Data Strobe used to enable the $\overline{CAS0}$ output during a DRAM access cycle. In 32-bit Mode, used with A1 to indicate to the DIVC the byte boundary of the DRAM access transaction.
A1	6	6	I	During DIVC register access, forms the least significant address bit of the register address. During DRAM access and in 32-bit Mode, used with A0 to indicate to the DIVC the byte boundary of the DRAM access transaction.
A2,A3	7,8	7,8	I	During DIVC register access, forms the most significant two address bits of the register address.
$\overline{REQ}$	1	1	I	Active LOW DRAM Access Request indicating to the DIVC that the processor wishes to access the DRAM controlled by the DIVC.
$\overline{CS}$	9	9	I	Active LOW Chip Select used for Register Access with the DIVC.
R/$\overline{W}$	10	10	I	Read/Write signal used to indicate the direction of register access with the DIVC.
V_{CC}	11,12 13,14	11,12		Power Supply +5V ± 10%
$\overline{INTACK}$	15	13	I	Active LOW Interrupt Acknowledge signal used with the A1,A2, and A3 inputs to assert the contents of one of seven internal Interrupt Vector Registers on the data bus (D0-D7).
$\overline{DTACK}$	16	14	O	Active LOW Data Transfer Acknowledge. Indicates to the processor the completion of a DIVC register or DRAM access cycle. For DRAM access, this signal's timing is programmable internally. Open Collector Output.
D0-D7	17-24	15-22	I/O	Active HIGH Tri-StateData Bus over which data is transferred between the processor and internal registers of the DIVC.
$\overline{IPL0}$ $\overline{IPL1}$ $\overline{IPL2}$	34 33 32	32 31 30	O O O	Active LOW Interrupt Priority Level signals indicating to the processor the priority level of the highest latched interrupt request on the INTRQ1-7 inputs. A level of all ONES indicates no interrupt rrequest pending.
ILE	39	35	I	Active HIGH Interrupt Latch Enable which causes the internal latches connected to the INTRQ1-7 inputs to become transparent. A HIGH-to-LOW transition causes the INTRQ1-7 signals to be internally latched.

PIN DESCRIPTION

SYMBOL	PINS		TYPE	NAME AND FUNCTION
	DIP	PLCC		
$\overline{\text{INTRQ1-7}}$	31-25	29-23	I	Active LOW Interrupt Request inputs.
CP	40	36	I	DIVC Clock Input
$\overline{\text{MR}}$	41	37	I	Active LOW Master Reset input.
$\overline{\text{CAS0-3}}$	45-42	41-38	O	Active LOW Column Address Strobe outputs.
$\overline{\text{REFEN}}$	46	42	O	Active LOW Refresh Enable Output. Indicates that the refresh address should be asserted.
MUX	47	43	O	Active HIGH Multiplexer output. Indicates that the Column address should be asserted to the DRAMs.
$\overline{\text{RAS}}$	48	44	O	Active LOW Row Address Strobe output.
GND	35-38	33-34		Ground Reference.

FUNCTIONAL DESCRIPTION

Figure 1 shows the overall architecture of the 74F1761. The DRAM Interface Timing section produces the RAS, MUX, CAS, DTACK and Refresh Enable (REFEN) signals in response to the Request (REQ) input. The timing of these signals is configurable by programming a register set within the F1761 (see **REGISTER DESCRIPTION**). The timing section also includes a refresh arbiter that allows for refreshing the DRAM at a frequency programmable by the user. While a refresh cycle is being executed, the REFEN output is asserted, allowing a companion memory address generator (such as the 74F1762 Memory Address Controller) to assert a refresh row address on the DRAM address inputs.

The Bus Sizing Logic section is a configurable decoder that allows for multiple CAS outputs depending on the state of the DS, SIZ0/LDS, SIZ1, A0/UDS, and A1 signal inputs, and the selected bus size scheme (See **Table 4. CAS DECODING SUMMARY**). By programming the Configuration Register, the F1761 can respond to a variety of 8, 16, and 32 Bit Processor signal outputs. In the 8-bit mode, the F1761 will assert one of four CAS outputs depending on the state of the A0 and A1 inputs during the CAS signal assertio time determined by the timing logic. In the 16-bit mode, the F1761 will assert CAS0 and/or CAS1 depending on the state of the UDS and LDS inputs, respectively. In the 32 Bit mode, the A1, A0, SIZ1 and SIZ0 determine the CAS outputs to be asserted according to the 68020 byte-selection scheme.

The Control and Interrupt Logic section determines the response of the F1761 in one of two modes. The internal registers of the device can be accessed by asserting the CS and DS inputs while placing the address of the register to be accessed on the A1,A2, and A3 inputs. The R/W input indicates to the F1761 the direction of data transfer when accessing a particular register. In addition, the configuration register contains one bit of register addressing that is initialized to 0. The lower order registers contain the timing information for the DRAM interface, while the upper order registers contain the Interrupt Vectors to be passed during an interrupt acknowledge. All internal registers are read/write, with unused bits being read as zeros and ignored during write cycles. In the Interrupt Acknowledge mode, the INTACK input signals the F1761 that an interrupt acknowledge is occuring. The F1761 responds by placing the contents of one of seven vector registers on the data outputs, according to the value of the A1,A2, and A3 signal inputs. For both Register Access and Interrupt Acknowledge modes, the device will assert DTACK to indicate the completion of the cycle. This DTACK signal is also asserted by the DRAM timing logic in response to a Request from the processor, with its timing programmed by the user.

The F1761 also includes an 8 to 3 bit Interrupt Priority Encoder which can be used to interface with the 68000 family of processors, with the Interrupt inputs (INTRQ1 - INTRQ7) latched on the falling edge of the Interrupt Latch Enable (ILE) input. The ILE input can be connected to the processor clock for glitch-free interrupting.

All of the DRAM interface timing is based upon the Master Clock (CP) input. Numerical values programmed into the Timing Registers indicate the number of clock cycles between events. When a 0 value is programmed into a timing skew, the two events indicated will happen simultaneously. The AC specifications indicate the amount of timing variation due to propogation delays within the device. The Master Reset input (MR) initializes all timing registers to their maximum delay (All ones) and clears the Configuration Register.

Note 1: RSS = Register Set Select Bit in the Configuration Register

REGISTER DESCRIPTION

Register Map

The DIVC contains a set of registers which can be programmed by a controlling processor to configure the DIVC for different bus sizes, DRAM timing, and Interrupt Vectors. Table 2 shows the Register Map of the DIVC. Note that the higher-order bit of the register address (RSS) is contained in the Configuration Register. Access to the Configuration Register is independent of the value of the RSS bit. By toggling the RSS bit, two sets of registers can be accessed. Those registers accessed with RSS = 0 are the DRAM timing registers for programming events during DRAM access. With RSS = 1, the seven Interrupt Vector registers can be accessed.

Configuration Register (CR)

This register configures the mode of access and register set select for the DIVC. **Bits 7 and 6** are used to specify the size of the bus to be used with the DRAM controlled by the DIVC. In the 8-bit mode, the Column Address Strobe outputs will respond to CAS signal assertion from the Timing Block by asserting one of the CAS outputs depending on the state of the A0 and A1 inputs, in binary fashion (i.e. If A0=A1=0 then CAS0=0; if A0=0 and A1=1 then CAS2=0). In 16-bit mode, the DIVC responds to a CAS assertion from the Timing Block by asserting CAS0 and CAS1 depending on the state of the UDS and LDS inputs, respectively. In 32-bit mode, the SIZ0, SIZ1, A0, and A1 inputs determine the state of the CAS outputs according to the decoding used with the 68020 Microprocessor, with CAS0 corresponding to the most significant byte and CAS3 corresponding to the least significant byte of the 32-bit bus. **Bit 5** is used as a register set select (RSS) for accessing the other registers in the DIVC. When RSS is low, registers 1 through 5 correspond to the Refresh Timing Register and Timing Registers 2 through 5. With RSS high, registers 1 through 7 correspond to Vector Registers 1 through 7. **Bit 4** is used to disable the refreshing operation of the DRAM Controller section of the DIVC. When set, no refreshes will be performed and internally generated Refresh Requests will be ignored, regardless of the state of the refresh timing parameters. Other bits in the Configuration Register are ignored on write cycles and are read as zeros on read cycles. All implemented bits of this register are reset to zeros when the DIVC is reset.

Refresh Timing Register (RTR)

The value in this register is used with a reloadable counter within the DIVC to generate refresh requests. Each time the counter counts down (using the CP clock divided by sixteen), a refresh request will be generated inside the DIVC. If no DRAM access is taking place, the DIVC immediately performs a refresh cycle, using the REFRESH RASON to RASOFF delay programmed into Timing Register 2, and the RASOFF to REFRESHOFF delay programmed into Timing Register 3. If a DRAM access cycle has already begun, the DIVC will wait until the completion of the DRAM access cycle, after which it will perform the refresh cycle as explained. A value of all zeros will program the DIVC with the shortest possible delay between refresh requests: 16 CP clock cycles. At 100 Mhz., this register gives a refresh period resolution of 160 nsec. Resetting the DIVC changes all bits to ones.

Timing Register 2 (TR2)

Bits 0 to 4 of this register program the RAS pulse width of a refresh cycle in CP clock cycles. Although a value of zero would normally result in no RAS pulse during a refresh cycle, internal propagation delays cause a small RAS pulse to be output. Resetting the DIVC will result in all these bits being set to ones. **Bits 5 to 7** are ignored during write cycles and read as zeros during read cycles.

Timing Register 3 (TR3)

Bits 0 to 3 of this register program the delay between RAS negated and the end of a refresh cycle. Because an access cycle could begin immediately after the

refresh, some delay may be desired between RASOFF and the end of the refresh cycle to accomodate RAS precharge requirements of the DRAMs. The value programmed into these bits should be one less than the number of clock cycle delays desired. Resetting the DIVC will result in these bits being set to ones. **Bits 4 to 7** are ignored during write cycles and read as zeros during read cycles.

Timing Register 4 (TR4)

Bits 5-7 of this register program the DIVC with the ACCESS GRANT TO RAS delay of a DRAM access cycle in CP clock cycles. Since the REFEN output is asserted during a refresh cycle, it is commonly used as a select signal for address multiplexers that select between a processor address and the refresh row address. If, on the completion of a refresh cycle, the DIVC immediately performs an access cycle, there may be a need to wait until the processor's row address has become stable at the DRAMs, before asserting RAS. (Since the REFEN output is negated at the same time as the refresh RAS output, and there is a programmable delay between RASOFF and REFRESHOFF, the problem is associated with the application. See explanation of bits 3-7 in Timing Register 3) These bits can be programmed with the number of clock cycles to wait from the time that an access is granted until RAS is asserted. A value of zero will result in no delay between events. **Bits 3 and 4** configure the timing between RAS and the MUX output asserted in CP clock cycles. A value of zero in these bits will cause no delay between RAS and MUX. **Bits 0 to 2** configure the timing between MUX asserted and CAS asserted in CP clock cycles. A value of zero in these bits will cause no delay between MUX and CAS. Resetting the DIVC sets all bits of this register to ones.

Timing Register 5 (TR5)

Bits 5 to 7 of this register program the delay between the assertion of CAS and the negation of RAS, in CP clock cycles. A value of zero in these bits results in no delay between these events. **Bits 0 to 4** program the delay beween the assertion of RAS and the assertion of DTACK back to the processor over the chip's DTACK signal pin. A value of zero in these bits results in no delay between these events. Resetting the DIVC will result in all bits of this register being set to ones.

Interrupt Vector Registers 1 to 7 (VR1-7)

Each of these registers can be programmed to contain the 8-bit vector to be placed on the DIVC's data bus during an Interrupt Acknowledge cycle. When the processor asserts the INTACK and DS inputs and places the Interrupt Priority on the A1, A2, and A3 inputs, the DIVC will respond by placing the contents of the Interrupt Vector Register addressed by these address inputs on the data bus and asserting DTACK. In this way, peripheral devices which do not contain the interrupt acknowledging circuitry can be used with a processor which expects these kinds of acknowledge cycles to occur. Resetting the DIVC does not affect the contents of these registers.

I_I	Input current at maximum input voltage	V_{CC} = 0.0V, V_I = 7.0V					100	µA
I_{IH}	HIGH-level input current	V_{CC} = MAX, V_I = 2.7V					20	µA
I_{IL}	LOW-level input current	V_{CC} = MAX, V_I = 0.5V					-0.6	mA
I_{OS}	Short circuit output current	V_{CC} = MAX			-100		-225	mA
I_{CC}	Supply current (total)	V_{CC} = MAX				200	220	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at Vcc = 5V, T_A = 25°C.
3. I_{OH2} is the current necessary to guarantee a LOW to HIGH transition in a 70Ω transmission line and is specified for the RAS, CAS0-3, MUX, and REFEN signals.
4. I_{OL2} is the current necessary to guarantee a HIGH to LOW transition in a 70Ω transmission line and is specified for the RAS, CAS0-3, MUX, and REFEN signals.

NOTES

1: For these signals, refer to Test Circuit #2

2: Worst case REQ to RAS assumes that REQ did not meet setup time requirements on the last rising edge of CP, that 000 was programmed into the GRANT to RAS delay in TR4, and that no refresh request is pending or being executed. T_{cp} is AC parameter number 1.

3: Numbers in parentheses indicate propogation delay with 0 programmed into the appropriate delay field.

4: For DTACK test load, refer to Test Circuit #3.

FAST 74F1762

Memory Address Multiplexer

Product Specification

FEATURES

- **Provides refresh and multiplexed row and column addresses for DRAMs**
- **Addressing up to 4MBit DRAMs**
- **Compatible with 74F1761 DIVC and other DRAM controllers**
- **High-performance outputs**
- **High-speed address multiplexing**
- **On-chip 11-bit refresh counter**

PRODUCT DESCRIPTION:

The Signetics Memory Address Multiplexer is designed for use in very high performance dynamic RAM applications. In addition to multiplexing row and column addresses, the device also generates and multiplexes refresh addresses. Though specifically designed to be used with the 74F1761, DRAM and Interrupt Vector Controller, it may be used with any other custom or standard DRAM timing controller chip.

The 'F1762 contains 22 address inputs (RA_0 - RA_{10}) and (CA_0 - CA_{10}), an 11-bit refresh counter, and eleven 3-to-1 multiplexers. The multiplexed row, column or refresh address is output on the eleven high-performance outputs ($\overline{MA}_0$ - $\overline{MA}_{10}$). This enables direct addressing of up to 4MBit dynamic RAMs. Combined with the 'F1761, the 'F1762 provides a complete 4MBit DRAM and interrupt control solution. This solution can control dynamic RAMs with access times down to 40ns.

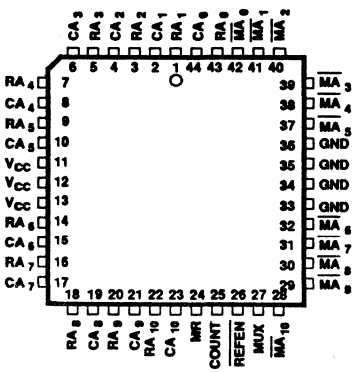
A Package



PIN DESCRIPTION

SYMBOL	PINS		TYPE	NAME AND FUNCTION
	DIP	PLCC		
RA_0 - RA_{10}	39, 1, 3, 5, 7, 9, 12, 14, 16, 18, 20	43, 1, 3, 5, 7, 9, 14, 16, 18, 20, 22	I	Row Address Inputs. When $\overline{REFEN}$ is negated and MUX is Low, these inputs are inverted and propogated to the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs.
CA_0 - CA_{10}	40, 2, 4, 6, 8, 10, 13, 15, 17, 19, 21	44, 2, 4, 6, 8, 10, 15, 17, 19, 21, 23	I	Column Address Inputs. When $\overline{REFEN}$ is negated and MUX is High, these inputs are inverted and propogated to the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs.
$\overline{MA_0}$ - $\overline{MA_{10}}$	38, 37, 36, 35, 34, 33, 30, 29, 28, 27, 26	42, 41, 40, 39, 38, 37, 32, 31, 30, 29, 28	O	Active Low Memory Address Outputs. These outputs contain the address from either the internal refresh counter, the Row Address inputs, or the Column Address inputs depending on the state of the $\overline{REFEN}$ and MUX signal inputs.
$\overline{REFEN}$	24	26	I	Active Low Refresh Enable Input. When asserted, the address contained in the internal refresh counter is asserted on the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs.
MUX	25	27	I	Row / Column Address Multiplex Input. If $\overline{REFEN}$ is High, this signal will multiplex the inverted Row or Column address inputs on the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs when it is asserted Low or High respectively.
COUNT	23	25	I	Refresh Counter Count Clock Input. A Low to High transition on this input will increment the internal refresh counter by one, regardless of the state of REFEN.
MR	22	24	I	Active High Refresh Counter Master Reset Input. A High level on this input will reset the internal refresh counter to all zeros.
V_{CC}	11	11, 12, 13		+5V ± 10% Supply input.
GND	31, 32	33, 34, 35, 36		Ground.

FUNCTIONAL DESCRIPTION:

Functionally, the 'F1762 Memory Address Multiplexer is quite simple. Referring to the logic diagram, the 11-bit Refresh Counter is controlled by the COUNT input, which increments the value stored in the refresh counter on every Low to High transition. When the 'F1762 is used with the 'F1761, this pin is usually connected to the $\overline{REFEN}$ input, so that at the end of every refresh cycle, the refresh counter will be incremented. The Master Reset (MR) input clears the contents of the refresh counter, and may be used for diagnostic testing or initializing after power-up. The eleven 3-to-1 multiplexers are controlled by the MUX and $\overline{REFEN}$ inputs. When $\overline{REFEN}$ is asserted, regardless of the state of the MUX signal, the contents of the internal refresh counter are inverted and asserted at the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs. When $\overline{REFEN}$ is negated, the MUX signal controls which set of address inputs will be propagated to the outputs. With MUX Low, the Row Address inputs (RA_0 - RA_{10}) will be inverted and asserted at the $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs. When MUX is High, the Column Addresses (CA_0 - CA_{10}) will be correspondingly asserted.

The $\overline{MA_0}$ - $\overline{MA_{10}}$ outputs have specialized drivers to switch 70 ohm transmission lines (typical of DRAM arrays) on the incident edge, thus improving overal system performance. For more information on the driving characteristics, please refer to the DC electrical characteristics and also Signetics application note number AN218.

FUNCTION TABLE

INPUTS						OUTPUTS	COUNTER
MR	COUNT	MUX	$\overline{REFEN}$	RA_n	CA_n	$\overline{MA}_n$	COUNTER CONTENTS
H	X	X	X	X	X	UN*	Reset to 0
L	↑	X	X	X	X	UN*	Increment by 1
H	X	X	L	X	X	L	Reset to 0
L	X	X	L	X	X	COUNTER CONTENTS	Unchanged
L	X	L	H	L	X	H	Unchanged
L	X	L	H	H	X	L	Unchanged
L	X	H	H	X	L	H	Unchanged
L	X	H	H	X	H	L	Unchanged

* The state of the outputs is dependant on the state of the MUX and $\overline{REFEN}$ inputs. The Counter is reset any time MR is High, and if MR is Low, it is incremented on every low to high transistion of COUNT.

UN = Unspecified

H = High level voltage

L = Low level voltage

X = Don't care

↑ = Low-to-High transition

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V

					±5%V_{CC}		0.35	0.5	V
				I_{OL2} = 60mA	±5%V_{CC}		0.45	0.8	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}				-0.73	-1.2	V
I_I	Low-level output voltage		V_{CC} = 0.0V, V_I = 7.0V					100	µA
I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V					20	µA
I_{IL}	Low-level input current		V_{CC} = MAX, V_I = 0.5V					-0.6	mA
I_{IO}[5]	Output current		V_{CC} = MAX, V_{OUT} = 2.25V			-30		-120	mA
I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				55	80	mA
		I_{CCL}					90	120	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. I_{OH2} is the current necessary to guarantee a Low-to-High transition in a 70Ω transmission line.
4. I_{OL2} is the current necessary to guarntee a High-to-Low transition in a 70Ω transmission line.
5. The output conditions have been chosen to produce a current that closely approximates one-half of the short circuit current, I_{OS}.

FAST 74F1763
Intelligent DRAM Controller (IDC)

Preliminary Specification

September 1988

FEATURES

- **DRAM signal timing generator**
- **Automatic refresh circuitry**
- **Selectable row address hold and $\overline{RAS}$ precharge times**
- **Supports page mode accesses**
- **Controls 1 MBit DRAMs**
- **Intelligent burst-mode refresh after page-mode access cycles**

PRODUCT DESCRIPTION:

The Signetics Intelligent Dynamic RAM Controller is a 1 MBit, single-port version of the popular 74F764 Dual Port Dynamic RAM Controller . It contains automatic signal timing, address multiplexing and refresh control required for interfacing with dynamic RAMs. Additional features have been added to this device to take advantage of technological advances in Dynamic RAMs. A Page-Mode access pin allows the user to assert $\overline{RAS}$ for the entire access cycle rather than the predefined four-clock-cycle pulse width used for normal random access cycles. In addition, the user has the ability to select the $\overline{RAS}$ precharge time and Row-Address Hold time to fit the particular DRAMs being used. $\overline{DTACK}$ has been modified from previous family parts to become a negative true, tri-stated output. The options for latched or unlatched address are contained on a single device by the addition of an Address Latch Enable ($\overline{ALE}$) input. Finally, a burst refresh monitor has been added to ensure complete refreshing after lengthy page-mode access cycles. With a maximum clock frequency of 100 Mhz, the F1763 is capable of driving DRAM arrays with access times down to 40 nsec.

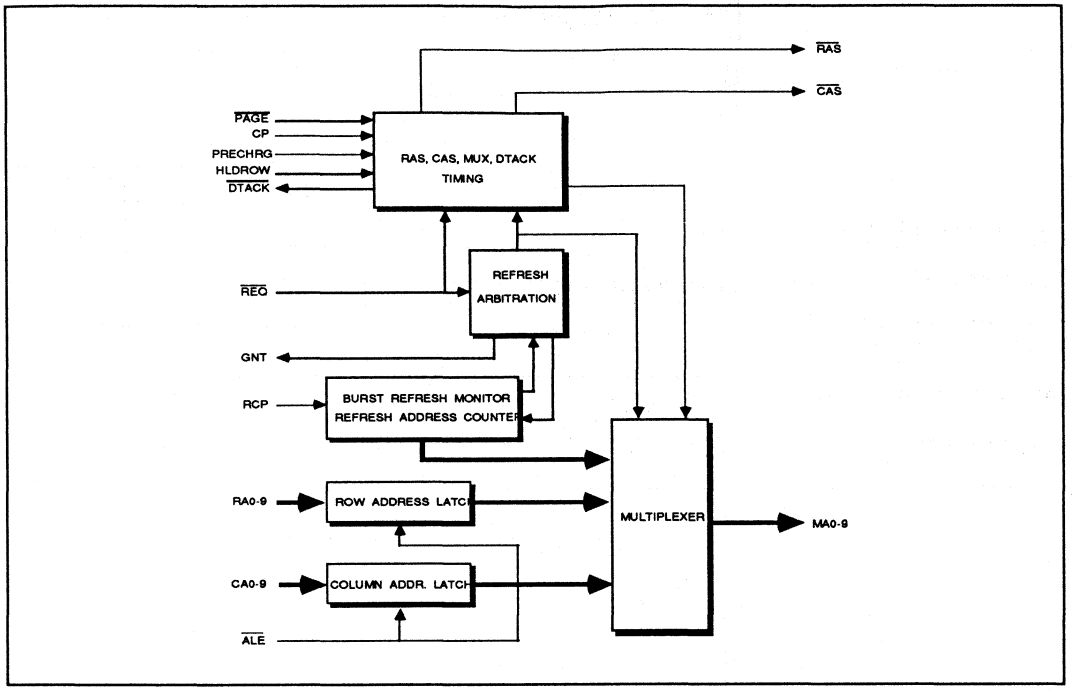
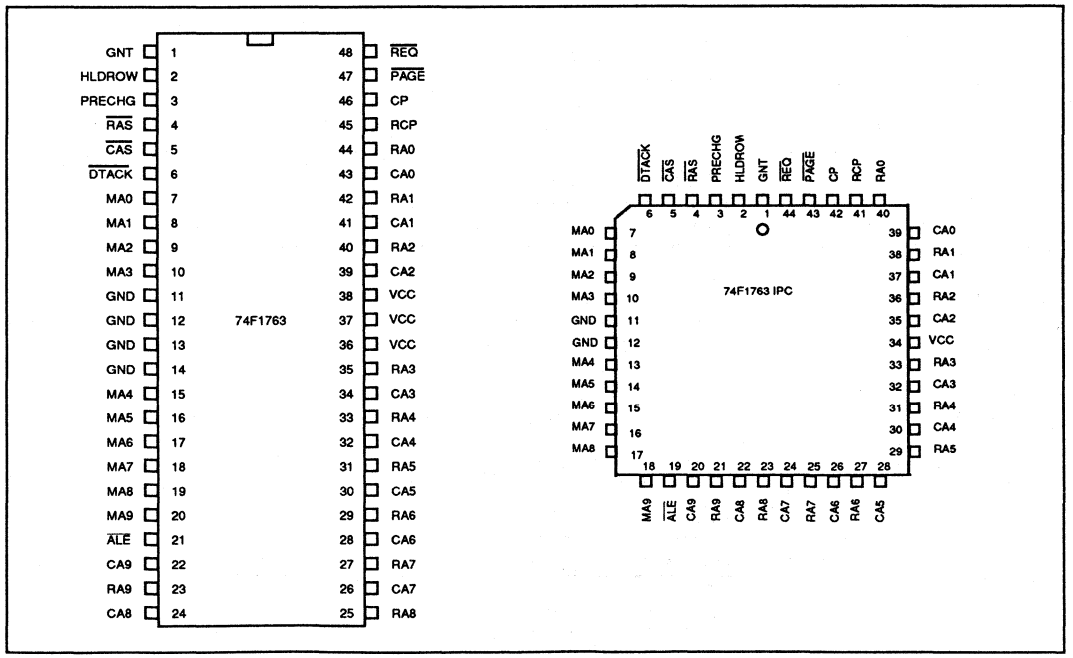
$\overline{ALE}$	Address Latch Enable Input	1.0/1.0	20 A/0.6 mA
$\overline{RAS}$	Row Address Strobe Output	N/A	35 mA/60 mA
$\overline{CAS}$	Column Address Strobe Output	N/A	35 mA/60 mA
MA0-MA9	DRAM Address Outputs	N/A	35 mA/60 mA

NOTE:
One (1.0) FAST Unit Load is defined as 20 uA in the HIGH state and 0.6 mA in the LOW state. FAST Unit Loads do not correspond to DRAM Input Loads. See Functional Description for details.

BLOCK DIAGRAM



PIN CONFIGURATION



PIN DESCRIPTION

SYMBOL	PINS		TYPE	NAME AND FUNCTION
	DIP	PLCC		
$\overline{REQ}$	48	44	I	Active Low Memory Access Request input, ust be asserted for the entire DRAM access cycle. REQ is sampled on the rising edge of the CP clock.
GNT	1	1	I	Active High Grant output. When High ndicates that a DRAM access cycle has begun. Asserted from the rising edge of the CP clock.
$\overline{PAGE}$	47	43	I	Active Low Page-Mode Access input. Forces the IDC to keep $\overline{RAS}$ asserted for as long as the $\overline{PAGE}$ input is Low.
HLDROW	2	2	I	Row Address Hold input. If Low will configure the IDC to maintain the row addresses for a full CP clock cycle after $\overline{RAS}$ is asserted. If High will program the IDC to maintain row addresses for a 1/2 CP clock cycle.
PRECHRG	3	3	I	$\overline{RAS}$ Precharge input. A Low will program the IDC to guarantee a minimum of 4 CP clock cycles of precharge. A High will guarantee 3 clock cycles of precharge.
CP	46	42	I	Clock input. Used by the Controller for all timing and arbitration functions.
RCP	45	41	I	Refresh Clock input. Divided internally by 64 to produce an internal Refresh Request.
$\overline{DTACK}$	6	6	O	Active Low, 3-state Data Transfer Acknowledge output. Enabled by the $\overline{REQ}$ input and asserted four clock cycles after the assertion of $\overline{RAS}$.
RA0-RA9			I	Row Address inputs. Propogated to the MA0-9 outputs when GNT is asserted.
CA0-CA9			I	Column Address inputs. Propogated to the MA0-9 outputs 1 CP clock cycle after $\overline{RAS}$ is asserted, if HLDROW=0 or 1/2 clock cycle later if HLDROW is 1.
$\overline{RAS}$	4	4	O	Active Low Row Address Strobe. Asserted for four clock cycles during each refresh cycle. Also asserted for four clock cycles during processor access if the $\overline{PAGE}$ input is false. If PAGE is true, $\overline{RAS}$ is negated upon negation of $\overline{PAGE}$ or $\overline{REQ}$, whichever occurs first.
$\overline{CAS}$	5	5	O	Active Low Column Address Strobe. Asserted 1 CP clock cycle after $\overline{RAS}$ if HLDROW=1, or 11/2 clock cycle later if HLDROW=0. Negated upon negation of $\overline{REQ}$.
MA0-MA9			O	DRAM multiplexed address outputs. Row and column addresses asserted on these pins during an access cycle. Refresh counter addresses presented on these outputs during refresh cycles.
$\overline{ALE}$	21	19	I	Active Low Address Latch Enable input. A Low on this pin will cause the address latches to be transparent. A Low to High transition will latch the RA0-9 & CA0-9 inputs.
V_{cc}	36-38	34		+5 V ± 10% Supply Input.
GND	11-14	11,12		Ground

FUNCTIONAL DESCRIPTION

The 74F1763 1 Megabit Intelligent DRAM Controller (IDC) is a synchronous device with all signal timing being a function of the CP input clock.

Arbitration:

When a memory access request ($\overline{REQ}$) is asserted and sampled by the IDC, internal arbitration takes place between this request and any pending refresh requests. Refresh always has priority over a memory access cycle and is serviced either immediately or following the current memory access cycle (if any). The IDC will perform a refresh cycle immediately when it becomes due if it is not performing a memory access cycle. If a memory refresh becomes due during a memory access cycle the controller will wait until after its completion before starting a refresh cycle. Similarly, if a memory access request is made when a refresh cycle is in process, the DRAM controller will wait until the cycle is completed before granting access to the requesting processor. If no refresh cycle is in process, and the $\overline{RAS}$ precharge requirement of the DRAM has been satisfied, the access will be granted within one clock cycle of the CP clock . The Grant (GNT) output goes high at this time to indicate the start of a memory access cycle.

Address multiplexing:

The row (RA0-9) and column (CA0-9) address inputs may be latched at any time using the $\overline{ALE}$ input pin. Otherwise the $\overline{ALE}$ input should remain Low to allow the addresses to propagate to the MA0-9 address outputs. When GNT becomes valid, the RA0-9 address inputs will have already propagated to the MA0-9 outputs for the row address. At this time, the $\overline{RAS}$ output becomes valid. One or one-half CP clock cycles later (depending on the state of the HLDROW input) the CA0-9 address inputs are propagated to the MA0-9 outputs for a column address. $\overline{CAS}$ is always asserted one and one-half CP clock cycles after $\overline{RAS}$ is asserted. If the $\overline{PAGE}$ input is High, $\overline{RAS}$ will be negated approximately four CP clock cycles after its initial assertion. At this time the $\overline{DTACK}$ output becomes valid indicating the completion of a memory access cycle. The IDC will maintain the state of all its outputs untill the $\overline{REQ}$ input is negated (see AC electrical characteristics).

Row address hold times:

If the HLDROW input of the IDC is High the row address outputs will remain valid 1/2 CP clock cycle after $\overline{RAS}$ is asserted. If the HLDROW input is Low the row address outputs will remain valid one CP clock cycle after $\overline{RAS}$ is asserted.

$\overline{RAS}$ precharge timing:

In order to meet the $\overline{RAS}$ precharge requirement of dynamic RAMs, the controller will hold-off a subsequent $\overline{RAS}$ signal assertion due to a processor access request or a refresh cycle for four or three full CP clock cycles from the previous negation of $\overline{RAS}$, depending on the state of the PRECHG input. If the PRECHG input is Low, $\overline{RAS}$ remains High for at least 4 CP clock cycles. If the PRECHG input is High $\overline{RAS}$ remains High for at least 3 CP clock cycles.

Refresh timing:

The refreshing block of the controller functions by accepting a refresh clock (RCP) and dividing it down internally by 64 to produce an internal refresh request. This refresh request is recognized either immediately or at the end of a running memory access cycle. Due to the possibility that page mode access cycles may be lengthy, the controller keeps track of how many refresh requests have been missed by logging them internally (up to 128) and services any pending refresh requests at the end of the memory access cycle. The controller performs $\overline{RAS}$-only refresh cycles until all pending refresh requests are depleted.

Page-mode access:

Fast accesses to consecutive locations of DRAM can be realized by asserting the $\overline{PAGE}$ input while requesting access to the memory. In this mode, the controller does not automatically negate $\overline{RAS}$ after four CP clock cycles, but keeps it asserted throughout the access cycle. By using external gates, the $\overline{CAS}$ output can be gated on and off while changing the column address inputs to the controller, which will propogate to the MA0-9 address outputs and provide a new column address. This is only useful if the $\overline{ALE}$ input is Low, enabling the user to change addresses. This mode can be used with DRAMs that support page or nibble mode addressing.

Output driving characteristics:

Considering the transmission line characteristic of the DRAM arrays, the outputs of the IDC have been designed to provide incident-edge switching, needed in high performance systems. For more information on the driving characteristics, please refer to Signetics application note number AN218.

ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

PARAMETER		LIMITS	UNIT
VCC	Supply Voltage	-0.5 to +7.0	V
V_{IN}	Input Voltage	-0.5 to +7.0	V
I_{IN}	Input Current	-30 to +5	mA
V_{OUT}	Voltage applied to output in HIGH output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in LOW output state	120	mA
T_{STG}	Storage temperature range	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

PARAMETER			LIMITS			UNIT
			Min	Nom	Max	
V_{CC}	Supply Voltage		4.5	5.0	5.5	V
V_{IH}	HIGH-level input voltage		2.0			V
V_{IL}	LOW-level input voltage				+0.8	V
I_{IK}	Input clamp current				-18	mA
I_{OH}	HIGH-level output current				-35	mA
I_{OL}	LOW-level output current	Buffer			60	mA
T_A	Operating free-air temperature		0		70	°C

DC ELECTRICAL CHARACTERISTICS (Over recommended free-air temperature range unless otherwise noted.)

PARAMETER		TEST CONDITIONS[1]			LIMITS			UNIT
					Min	Typ[2]	Max	
V_{OH}	HIGH-level output current	V_{CC} = MIN, V_{IL} = MAX, V_{IH} = MIN	I_{OH} = -15mA	±10% V_{CC}	2.5	3.2		V
				±5% V_{CC}	2.7	3.4		V
			I_{OH2}[3] = -35 mA	±10% V_{CC}	2.4			V
V_{OL}	LOW-level output voltage	V_{CC} = MIN, V_{IL} = MAX, V_{IH} = MIN	I_{OL} = 24mA	±10% V_{CC}		0.35	0.50	V
				±5% V_{CC}		0.35	0.50	V

V_{IK}	Input clamp voltage	V_{CC} = MIN, I_I = I_{IK}				-0.73	-1.2	V
I_I	Input current at maximum input voltage	V_{CC} = 0.0V, V_I = 7.0V					100	µA
I_{IH}	HIGH-level input current	V_{CC} = MAX, V_I = 2.7V					20	µA
I_{IL}	LOW-level input current	V_{CC} = MAX, V_I = 0.5V					-0.6	mA
I_{OS}	Short circuit output current	V_{CC} = MAX			-100		-225	mA
I_{CC}	Supply current (total)	V_{CC} = MAX					200	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at Vcc = 5V, T_A = 25°C.
3. I_{OH2} is the current necessary to guarantee a LOW to HIGH transition in a 70Ω transmission line.
4. I_{OL2} is the current necessary to guarantee a HIGH to LOW transition in a 70Ω transmission line.

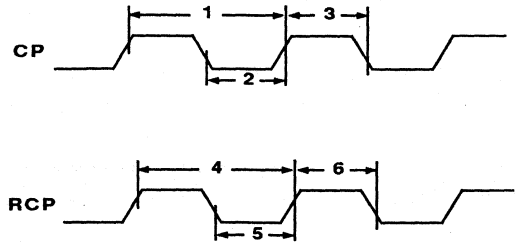

Figure 1: Clock cycle Timing

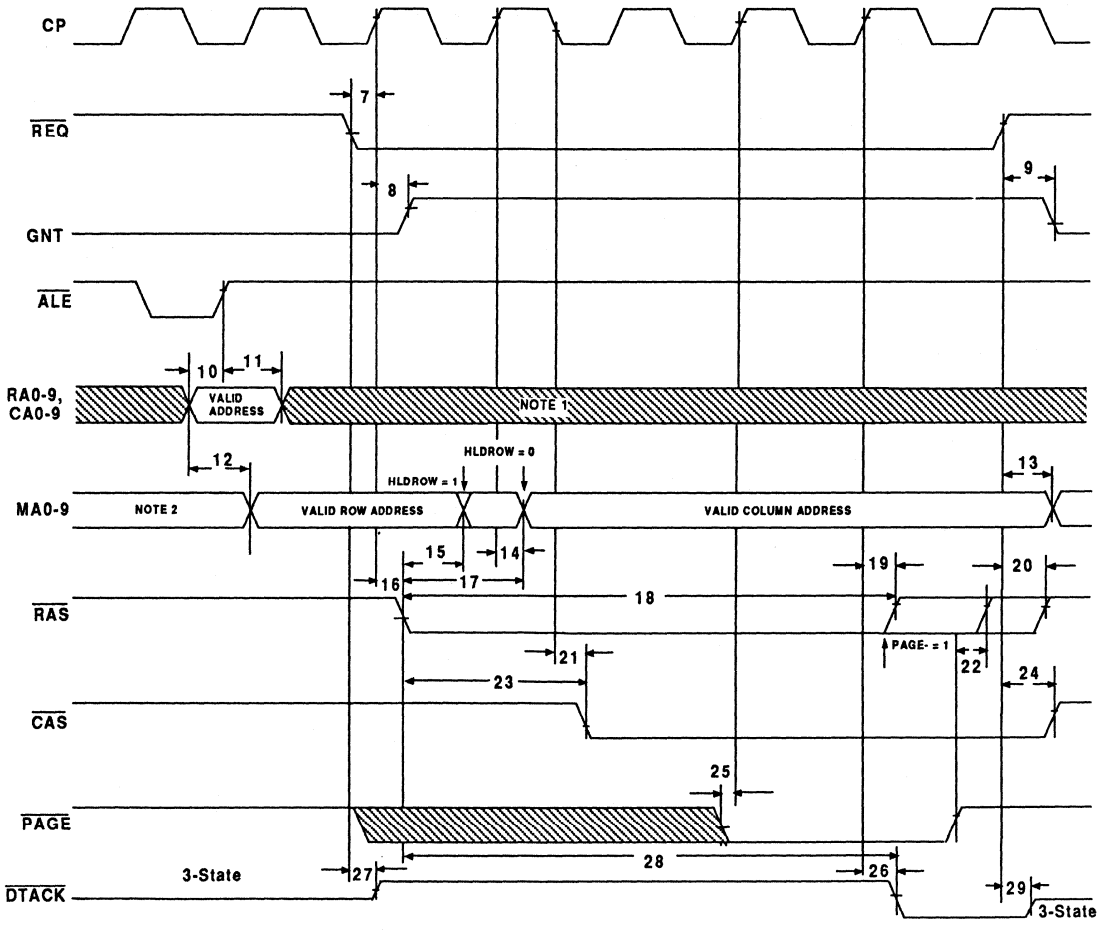

Figure 2: Memory access cycle timing

Note 1: If the RA0-9 & CA0-9 address inputs are not latched, they should remain valid until the corresponding $\overline{REQ}$ is negated.
Note 2: MA0-9 outputs will contain the present row address on the RA0-9 inputs or the last row address latched into the device.

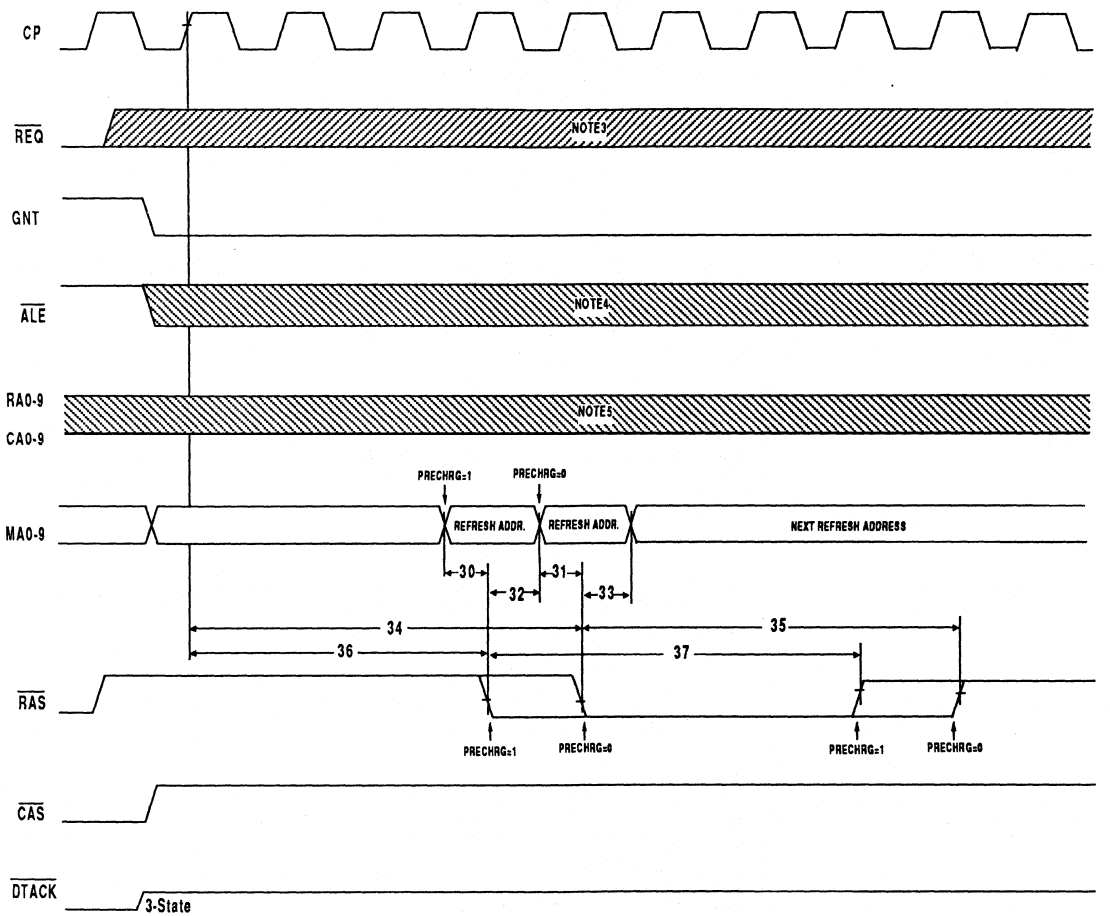

Figure 3: Refresh cycle timing following a memory access cycle

Note 3: $\overline{REQ}$ input is a don't care during a memory refresh cycle. If $\overline{REQ}$ is asserted during a refresh cycle, it will be recognized at the first rising CP clock edge, but GNT will not be asserted until after the completion of the refresh cycle (see Figure 4).

Note 4: RA0-9 & CA0-9 address inputs may be latched at anytime during a memory refresh cycle. However, a memory access cycle will not begin until after the completion of the refresh cycle.

Note 5: RA0-9 & CA0-9 are don't care during a memory refresh cycle.

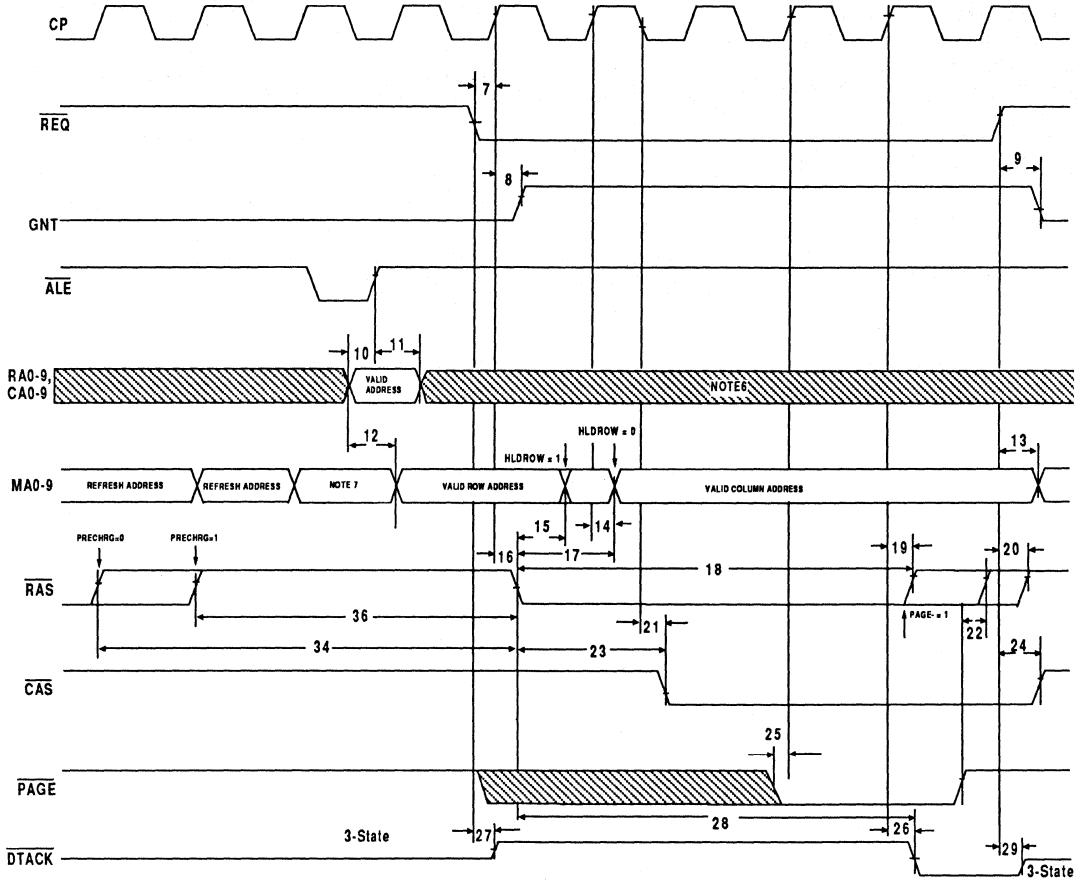

Figure 4: Memory access cycle timing following a refresh cycle

Note 6: If RA0-9 & CA0-9 address inputs are not latched, they should remain valid until the corresponding $\overline{REQ}$ is negated.
Note 7: MA0-9 outputs will contain the present row address on the RA0-9 inputs or the last row address latched into the device.

FAST 74F2952, 74F2953 Transceivers

'F2952 Registered Transceiver, Non-Inverting (3-State)
'F2953 Registered Transceiver, Inverting (3-State)
Product Specification

FEATURES

- **8-bit Registered Transceivers**
- **Two 8-bit , back-to-back registers store data moving in both directions between two bidirectional busses**
- **Separate Clock, Clock Enable and 3-state Enable provided for each register**
- **'F2952 Non-inverting 'F2953 Inverting**
- **AM2952/2953 functional equivalent**
- **A outputs sink 24mA and source 3mA**
- **B outputs sink 64mA and source 15mA**
- **300 mil wide 24-pin Slim DIP package**

TYPE	TYPICAL f_{MAX}	TYPICAL SUPPLY CURRENT (TOTAL)
74F2952	160MHz	105mA
74F2953	160MHz	105mA

ORDERING INFORMATION

PACKAGES	COMMERCIAL RANGE V_{CC} = 5V±10%; T_A = 0°C to +70°C
24-Pin Plastic Slim DIP (300mil)	N74F2952N, N74F2953N
24-Pin Plastic SOL[1]	N74F2952D, N74F2953D

NOTE:
1.Thermal mounting techniques are recommended. See SMD Process Applications (page 17) for a discussion of thermal consideration for surface mounted devices.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
A_0 - A_7	Port A, 3-state inputs	3.5/1.0	70µA/0.6mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F2952 and 74F2953 are 8-bit Registered Transceivers. Two 8-bit back to back registers store data flowing in both directions between two bi-directional busses. Data applied to the inputs is entered and stored on the rising edge of the Clock ($\overline{CPXX}$) provided that the Clock Enable ($\overline{CEXX}$) is Low. The data is then present at the 3-state output buffers, but is only accessible when the Output Enable ($\overline{OEXX}$) is Low. Data flow from A inputs to B outputs is the same as for B inputs to A outputs.

Quad FutureBus Backplane Transceiver

(3 State +Open Collector)

FEATURES

- **Ouad Backplane Transceiver**
- **Drives heavily loaded backplanes with equivalent load impedances down to 10 ohms**
- **Reduced voltage swing (1 volt) produces less noise and reduces power consumption**
- **High speed operation enhances performance of backplane buses and facilities incident wave switching**
- **Compatible with IEEE 896 Futurebus Standards**
- **Built-in precision band-gap (BG) reference provides accurate receiver threshold and improved noise immunity**
- **Controlled output ramp and multiple GND pins minimize ground bounce**
- **Glitch-free power up / power down operation**
- **Pin and function compatible with NSC DS3893**

OC = Open Collector

DESCRIPTION

The 74F3893 is a quad backplane transceiver and is intended to be used in very high speed bus systems.

The 74F3893 interfaces to 'Backplane Transceiver Logic' (BTL) . BTL features a reduced (1V) voltage swing for lower power consumption and a series diode on the drivers to reduce capacitive loading (< 7 pF). Incident wave switching is employed, therefore BTL propagation delays are short. Although the voltage swing is much less for BTL, so is its receiver threshold region, therefore noise margins are excellent.

BTL offers low power consumption, low ground bounce, EMI and crosstalk, low capacitive loading, superior noise margin and low propagation delays. This results in a high bandwidth, reliable backplane.

I_{IH}	High-level input current		V_{CC} = MAX, V_I = 2.7V				40	µA
I_{IL}	Low-level input current	D_n, $\overline{RE}$	V_{CC} = MAX, V_I = 0.0V				-100	µA
		DE	V_{CC} = MAX, V_I = 0.0V				-400	µA
I_{OZH} + I_{IH}	Off-state output current, High-level voltage applied		V_{CC} = MAX, V_O =2.7V				50	µA
I_{OZL} + I_{IL}	Off-state output current, Low-level voltage applied		V_{CC} = MAX, V_O =0.5V				-50	µA
I_{OS}	Short-circuit output current[3]		V_{CC} = MAX				-200	mA
I_{CC}	Supply current (total)		V_{CC} = MAX			70		mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

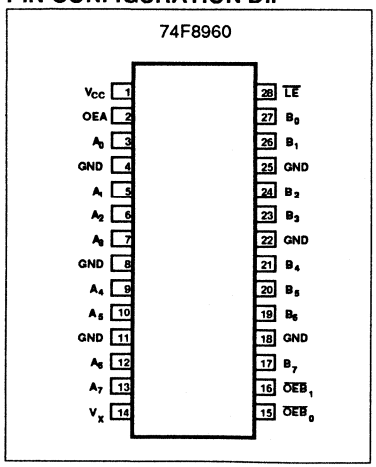
* OC = Open Collector

DESCRIPTION

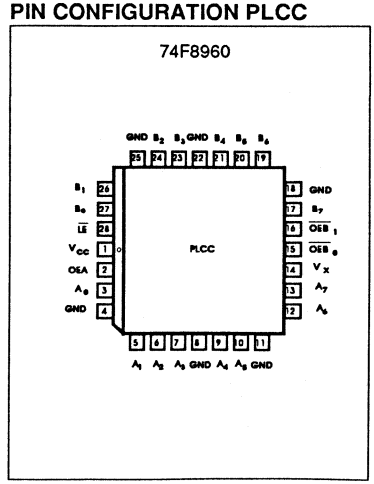
The 74F8960 and 74F8961 are octal bidirectional latched transceivers and are intended to provide the electrical interface to a high performance wired-OR bus. The B port inverting drivers are low-capacitance open collector with controlled ramp and are designed to sink 100 mA from 2 volts. The B port receivers have a 100 mV threshold region and a 4 ns glitch filter.

The B port interfaces to 'Backplane Transceiver Logic' (BTL). BTL features a reduced (1V) voltage swing for lower power consumption and a series diode on the drivers to reduce capacitive loading (<5 pF).

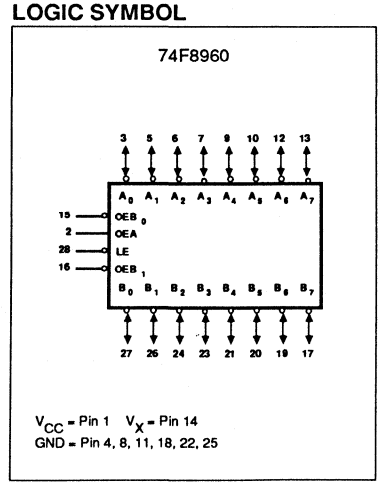
PIN CONFIGURATION DIP



PIN CONFIGURATION PLCC



LOGIC SYMBOL



V_{CC} = Pin 1 V_X = Pin 14
GND = Pin 4, 8, 11, 18, 22, 25

DESCRIPTION (Continued)

Incident wave switching is employed, therefore BTL propagation delays are short. Although the voltage swing is much less for BTL, so is its receiver threshold region, therefore noise margins are excellent.

BTL offers low power consumption, low ground bounce, EMI and crosstalk, low capacitive loading, superior noise margin and low propagation delays. This results in a high bandwidth, reliable backplane. The 74F8960A and 74F8961A ports have TTL 3-State drivers and TTL receivers with a latch function. A separate High level control input (V_X) is provided to limit the A port output level to a given voltage level (such as 3.3V). For 5.0V systems, V_x is simply tied to V_{CC}.

74F8961 is the non-inverting version of 74F8960.

		I_{CCZ}	V_{CC} = MAX, V_{IL} = 0.5V			80	100	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type. Unless otherwise specified, V_X = V_{CC} for all test conditions.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.
4. Due to test equipment limitations, actual test conditions are for V_{IH}=1.6V and V_{IL}=1.3V.

FAST 74F11240, 74F11244 Buffers

74F11240 Octal Inverter Buffer (3-State)
74F11244 Octal Buffer (3-State)
Preliminary Specification

FEATURES

- **Same function as 'F240 and 'F244but with ACL compatible pinout**
- **Light loading input structure reduces bus loading (20μA in High and Low states)**
- **Multiple, centered V_{CC} and GND pins minimize package inductance and reduced ground bounce**
- **Controlled output ramp minimizes ground bounce**
- **High internal speed provides performance upgrade over 'F240 and 'F244 while consuming less power**
- **Flow through pinout structure simplifies PC board design-Octal bus interface**
- **3-State buffer outputs sink 64mA and source 15mA**

NOTE:
One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F11240 and 74F11244 are functionally equivalent to the 74F240 and 74F244. However, the pinout of the 74F11240 and 74F11244 differs from the 74F240 and 74F244 in that additional centered V_{CC} and GND pins have been added to minimize the effects of package inductance. These pinouts are compatible with the ACL standard pinouts.The 74F11240 and 74F11244 also feature a light loading input structure, a controlled output ramp to minimize ground bounce and high performance A/C characteristics which provide an upgrade to existing 74F240 and 74F244.

The 74F11240 and 74F11244 are octal buffers that are ideal for driving bus lines of buffer memory address registers. The outputs are all capable of sinking 64mA and sourcing up to 15mA, producing very good capacitive drive characteristics. The device features two Output Enables, $\overline{OE}$, each controlling four of the 3-state outputs.

added to minimize the effects of package inductance. These pinouts are compatible with the ACL standard pinouts.The 74F11373 and 74F11374 also feature a light loading input structure, a controlled output ramp to minimize bounce and high performance A/C characteristics which provide an upgrade to existing74F373 and 74F374.

The 74F11373 is an octal transparent latch coupled to eight 3-State output buffers. The two sections of the device are controlled independently by Enable (E) and Output Enable ($\overline{OE}$) control gates.

The data on the D inputs is transferred to the latch outputs when the Enable (E) input is High. The latch remains transparent to the data input while E is High and stores the data that is present one set-up time before the High-to-Low enable transition.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independent of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

The 74F11374 is an 8-bit, edge triggered register coupled to eight 3-State output buffers. The two sections of the device are controlled independently by the clock (CP) and Output Enable ($\overline{OE}$) control gates.

The register is fully edge triggered. The state of each D input, one set-up time before the Low-to-High clock transition is transferred to the corresponding flip-flop's Q output.

The 3-State output buffers are designed to drive heavily loaded 3-State buses, MOS memories, or MOS microprocessors. The active Low Output Enable ($\overline{OE}$) controls all eight 3-State buffers independent of the latch operation. When $\overline{OE}$ is Low, the latched or transparent data appears at the outputs. When $\overline{OE}$ is High, the outputs are in high impedance "off" state, which means they will neither drive nor load the bus.

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

FAST 74F11543, 74F11544, Transceivers

74F11543 Octal Latched Transceiver, Non-Inverting (3-State)
74F11544 Octal Latched Transceiver, Inverting (3-State)
Preliminary Specification

FEATURES

- Same function as 'F543 and 'F544 but with ACL compatible pinout
- Combines 'F245 and 'F373 type functions in one chip
- 8-bit octal transceiver with D-type latch
- 'F11543 Non-inverting
  'F11544 Inverting
- 64mA current sinking capability (B port)
- Back-to-back latches for storage
- Separate controls for data flow in each direction
- Light loading input structure reduces bus loading (20μA in High and Low states)
- Multiple, centered V_{CC} and GND pins minimize package inductance and reduced ground bounce
- Controlled output ramp minimizes ground bounce
- High internal speed provides performance upgrade over 'F543 and 'F544 while consuming less power
- Flow through pinout structure simplifies PC board design
- 3-State Output buffers
- Common 3-state Output Enable
- Independent latch and 3-state buffer operation

TYPE	TYPICAL PROPAGATION DELAY	TYPICAL SUPPLY CURRENT (TOTAL)
74F11543	6.0ns	80mA
74F11544	6.0ns	80mA

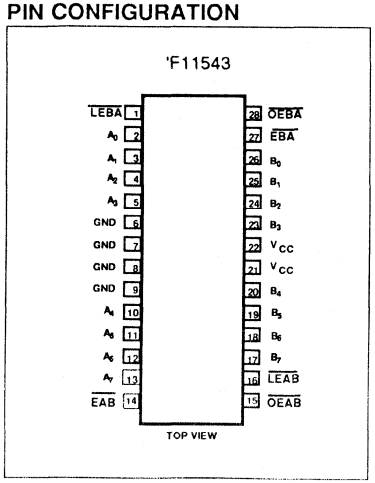
NOTE:
One (1.0) FAST Unit Load is defined as: 20μA in the High state and 0.6mA in the Low state.

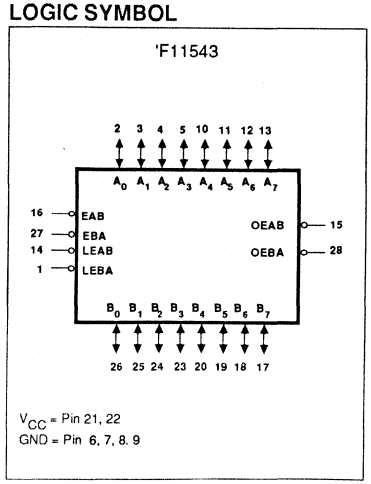
DESCRIPTION

The 74F11543 and 74F11544 are func-

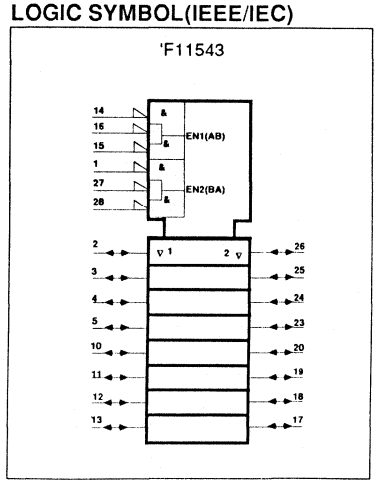
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



tionally equivalent to the 74F543 and 74F544. However, the pinout of the 'F11543 and 'F11544 differs from the 'F543 and 'F544 in that additional centered V_{CC} and GND pins have been added to minimize the effects of package inductance. These pinouts are compatible with the ACL standard pinouts.The 'F11543 and 'F11544 also feature a light loading input structure, a controlled output ramp to minimize ground bounce and high performance A/C characteristics which provide an upgrade to existing 'F543 and 'F544. The 'F11543 and 'F11544 Octal Latched Transceivers contain two sets of D-type latches for temporary storage of data flowing in either direction. Separate Latch Enable ($\overline{LEAB}$, $\overline{LEBA}$) and Output Enable ($\overline{OEAB}$, $\overline{OEBA}$) inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow.While the 'F11543 has non-inverting data path, the 'F11544 inverts data in both directions. The A outputs are guaranteed to sink 24mA while the B outputs are rated for 64mA.

FUNCTIONAL DESCRIPTION

The 'F11543 and 'F11544 contain two sets of eight D-type latches, with separate input and controls for each set. For data flow from A to B, for example, the A-to-B Enable ($\overline{EAB}$) input must be Low in order to enter data from A_0-A_7 or take data from B_0-B_7, as indicated in the Function Table. With $\overline{EAB}$ Low, a Low signal on the A-to-B Latch Enable ($\overline{LEAB}$) input makes the A-to-B latches transparent; a subsequent Low-to High transition of the $\overline{LEAB}$ signal puts the A latches in the storage mode and their outputs no longer change with the A inputs. With $\overline{EAB}$ and $\overline{OEAB}$ both Low, the 3-state B output buffers are active and display the data present at the outputs of the A latches.

Control of data flow from B to A is similar, but using the $\overline{EBA}$, $\overline{LEBA}$, and $\overline{OEBA}$ inputs.

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

DESCRIPTION

The 74F11646 and 74F11648 are functionally equivalent to the 74F646 and 74F648. However, the pinout of the 74F11646 and 74F11648 differs from the 74F646 and 74F648 in that additional-centered V_{CC} and GND pins have been added to minimize the effects of package inductance. These pinouts are compatible with the ACL standard pinouts.The 74F11646 and 74F11648 also feature a light loading input structure, a controlled output ramp to minimize ground bounce and high performance AC characteristics which provide an upgrade to the existing 74F646 and 74F648.

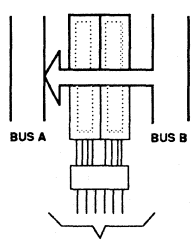
The 74F11646 and 74F11648 Transceivers/ Registers consist of bus transceiver circuits with 3-state outputs, D-type flip-flops, and control circuitry arranged for multiplexed transmission of data directly from the input bus or the from internal registers. Data on the A or B bus will clocked into the registers as the appropriate clock pin goes High. Output Enable ($\overline{OE}$) and DIR pins are provided to control the transceiver function. In the transceiver mode, data present at the high impedance port may be stored in either the A or B register or both. The select(SAB, SBA) pins determine whether data is stored or transfered through the device in real-time.The DIR determines which bus will receive data when the $\overline{OE}$ is active Low. In the isolation mode($\overline{OE}$ = High), data from Bus A may be stored in the B register and/or data from Bus B may be stored in the A register.

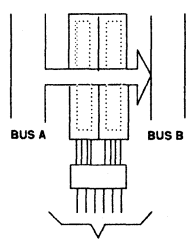
When an output function is disabled,the input function is still enabled and may be used to store and transmit data. Only one of the two busses , A or B may be driven at a time. The following examples demonstrates the four fundamental bus-management functions that can be performed with the 74F11646 and 74F11648.

REAL TIME BUS TRANSFER
BUS B TO BUS A



$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA
L	L	X	X	X	L

REAL TIME BUS TRANSFER
BUS A TO BUS B



$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA

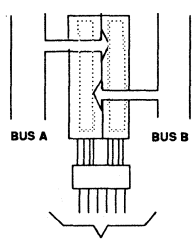
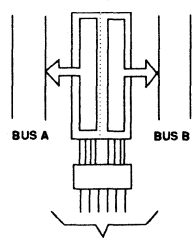
STORAGE FROM
A, B, OR A AND B



$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA
X	H	↑	X	X	X
X	X	X	↑	X	X
H	X	↑	↑	X	X

TRANSFER STORED DATA
TO A OR B



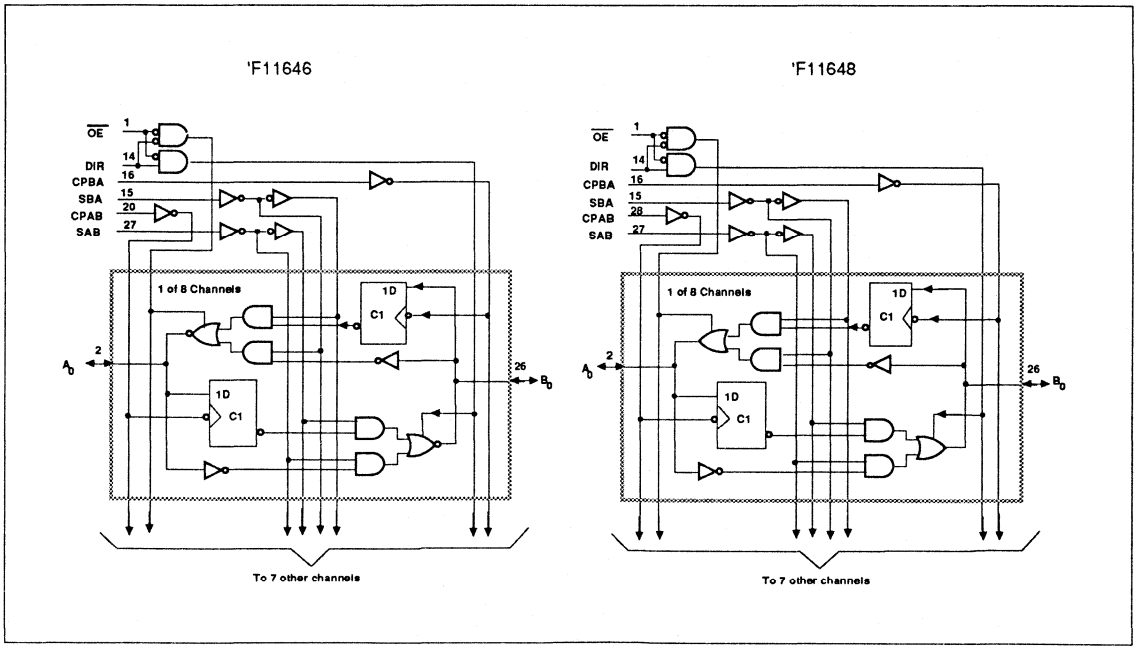
$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA
L	L	X	H or L	X	H
L	H	H or L	X	H	X

FUNCTION TABLE

INPUTS						DATA I/O		OPERATING MODE	
$\overline{OE}$	DIR	CPAB	CPBA	SAB	SBA	A_0-A_7	B_0-B_7	'F11646	'F11648
X X	X X	↑ X	X ↑	X X	X X	input *Un-specified	Unspecified input *	Store A, B unspecified* Store B, A unspecified*	Store A, B unspecified* Store B, A unspecified*
H H	X X	↑ H or L	↑ H or L	X X	X X	Input	Input	Store A and B data Isolation, hold storage	Store A and B data Isolation, hold storage
L L	L L	X X	X H or L	X X	L H	Output	Input	Real time B data to A bus Stored B data to A bus	Real time $\overline{B}$ data to A bus Stored $\overline{B}$ data to A bus
L L	H H	X H or L	X X	L H	X X	Input	Output	Real time A data to B bus Stored A data to B bus	Real time $\overline{A}$ data to B bus Stored $\overline{A}$ data to B bus

H= High voltage level
L= Low voltage level
X=Don't care
↑ =Low-to-High clock transition
*= The data output function may be enabled or disabled by various signals at the $\overline{OE}$ and DIR inputs. Data input functions are always enable, i.e., data at the bus pins will be stored on every Low-to-High transition of the clock.

LOGIC DIAGRAM



ABSOLUTE MAXIMUM RATINGS

(Operation beyond the limits set forth in this table may impair the useful life of the device. Unless otherwise noted these limits are over the operating free-air temperature range.)

SYMBOL	PARAMETER	RATING	UNIT
V_{CC}	Supply voltage	-0.5 to +7.0	V
V_{IN}	Input voltage	-0.5 to +7.0	V
I_{IN}	Input current	-30 to +5	mA
V_{OUT}	Voltage applied to output in High output state	-0.5 to +V_{CC}	V
I_{OUT}	Current applied to output in Low output state	128	mA
T_A	Operating free-air temperature range	0 to +70	°C
T_{STG}	Storage temperature	-65 to +150	°C

RECOMMENDED OPERATING CONDITIONS

SYMBOL	PARAMETER	LIMITS			UNIT
		Min	Nom	Max	
V_{CC}	Supply voltage	4.5	5.0	5.5	V
V_{IH}	High-level input voltage	2.0			V
V_{IL}	Low-level input voltage			0.8	V
I_{IK}	Input clamp current			-18	mA
I_{OH}	High-level output current			-15	mA
I_{OL}	Low-level output current			64	mA
T_A	Operating free-air temperature range	0		70	°C

DC ELECTRICAL CHARACTERISTICS (Over recommended operating free-air temperature range unless otherwise noted.)

SYMBOL	PARAMETER		TEST CONDITIONS[1]			LIMITS			UNIT
						Min	Typ[2]	Max	
V_{OH}	High-level output voltage		V_{CC} = MIN, V_{IL} = MAX V_{IH} = MIN,	I_{OH}=-3mA	±10%V_{CC}	2.4			V
					±5%V_{CC}	2.7	3.4		V
				I_{OH}=-15mA	±10%V_{CC}	2.0			V
V_{OL}	Low-level output voltage		V_{CC} = MIN, V_{IL} = MAX V_{IH} = MIN,	I_{OL}=48mA	±10%V_{CC}		0.38	0.55	V
				I_{OL}=64mA	±5%V_{CC}		0.42	0.55	V
V_{IK}	Input clamp voltage		V_{CC} = MIN, I_I = I_{IK}				-0.73	-1.2	V
I_I	Input current at maximum input voltage	others	V_{CC} = 0.0V, V_I = 7.0V					100	µA
		A_0-A_7, B_0-B_7	V_{CC} = 5.5V, V_I = 5.5V					1	mA
I_{IH}	High-level input current	$\overline{OE}$,DIR, CPAB, CPBA SAB, SBA	V_{CC} = MAX, V_I = 2.7V					20	µA
I_{IL}	Low-level input current		V_{CC} = MAX, V_I = 0.5V					-20	µA
$I_{IH}+I_{OZH}$	Off-state output current High level voltage applied	A_0-A_7, B_0-B_7	V_{CC} = MAX, V_O= 2.7V					70	µA
$I_{IL}+I_{OZL}$	Off-state output current Low level voltage applied		V_{CC} = MAX, V_O = 0.5V					-70	µA
I_{OS}	Short-circuit output current[3]		V_{CC} = MAX			-100		-225	mA
I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				110	145	mA
		I_{CCL}					120	155	mA
		I_{CCZ}					130	170	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

INPUT AND OUTPUT LOADING AND FAN-OUT TABLE

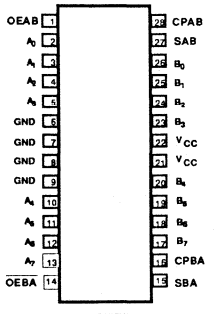
PINS	DESCRIPTION	74F(U.L.) HIGH/LOW	LOAD VALUE HIGH/LOW
A_0 - A_7	A inputs	3.5/0.116	70µA/70µA
B_0 - B_7	B inputs	3.5/0.116	70µA/70 A
CPAB	A-to-B clock inputs	1.0/0.033	20µA/20µA
CPBA	B-to-A clock inputs	1.0/0.033	20µA/20µA
SAB	A-to-B select input	1.0/0.033	20µA/20µA
SBA	B-to-A select input	1.0/0.033	20µA/20µA
OEAB	A-to-B output enable input	1.0/0.033	20µA/20µA
$\overline{OEBA}$	B-to-A output enable input	1.0/0.033	20µA/20µA
A_0 - A_7	A outputs	750/106.7	15mA/64mA
B_0 - B_7	B outputs	750/106.7	15mA/64mA

NOTE:
One (1.0) FAST Unit Load is defined as: 20µA in the High state and 0.6mA in the Low state.

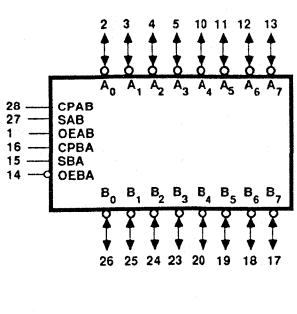
DESCRIPTION

The 74F11651 and 74F11652 are functionally equivalent to the 74F651 and 74F652. However, the pinout of the 74F11651 and 74F11652 differs from the 74F651 and 74F652 in that additional centered V_{CC} and GND pins have been added to minimize the effects of package inductance. These pinouts are compatible with the ACL standard pinouts.The 74F11651 and 74F11652 also feature a light loading input structure, a controlled output ramp to minimize ground bounce, and high performance AC characteristics which provide an upgrade to the existing 74F651 and 74F652.

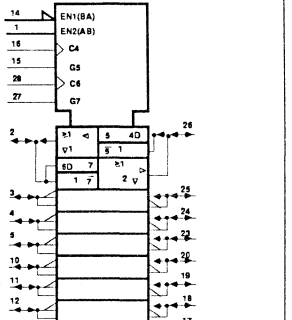
PIN CONFIGURATION



LOGIC SYMBOL



LOGIC SYMBOL(IEEE/IEC)



The 74F11651 and 74F11652 Transceivers/ Registers consist of bus transceiver circuits with 3-state outputs, D-type flip-flops, and control circuitry arranged for multiplexed transmission of data directly from the input bus or the internal registers. Data on the A or B bus will be clocked into the registers as the appropriate clock pin goes High. Output Enable (OEAB, $\overline{OEBA}$) and Select (SAB, SBA) pins are provided for bus management. The following examples demonstrate the four fundamental bus-management functions that can be performed with the 'F11651 and 'F11652. The select pins determine whether data is stored or transferred through the device in real time. The output enable pins determine the direction of the data flow.

LOGIC SYMBOL

'F11652

I_{CC}	Supply current (total)	I_{CCH}	V_{CC} = MAX				110	145	mA
		I_{CCL}					120	155	mA
		I_{CCZ}					130	170	mA

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_A = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter test, I_{OS} tests should be performed last.

74F30XXX FAMILY APPLICATIONS

High Current Buffers/Transceivers

Application Note

The 74F30XXX Family

- 74F3037 Quad 2-Input NAND, Totem-Pole Buffer
- 74F3038 Quad 2-Input NAND, Open Collector Buffer
- 74F3040 Dual 4-Input NAND Totem-Pole Buffer
- 74F30240 Octal, Inverting, Open Collector Buffer
- 74F30244 Octal, Non-Inverting Open Collector Buffer
- 74F30245 Octal, Non-Inverting, Transceiver
- 74F30640 Octal, Inverting, Transceiver

Major Family Features

- Incident-Wave, 30Ω Transmission Line Drivers
- High Output Currents - I_{OL}/I_{OH} = +160mA/−67mA
- 74FXXX Speeds - Gate Speeds <6.5 ns
- "Flow-Through" Signal Design
- Multiple, Center-Package Supply Pins
- Low V_{CC} Shut-Off Circuit
- Low Impedance Voltage Reference
- Active (Dynamic) Pull-Off Circuit
- "Light-Load" ±20μA NPN Inputs
- Applications Described on Page 6

Introduction

The Signetics 74F30XXX Family is a new series of very high output current, high performance drivers designed to handle low impedance environments of printed circuit board transmission lines and signal busses. This Family can drive lines with characteristic impedances as low as 30Ω at standard 74F speed.

This Application Note explains how the 74F30XXX's design innovations (2 patents) will give you several major advantages over other high current TTL gate, buffer and transceiver designs. It also illustrates how to use the 74F30XXX's superior characteristics in many applications that currently cannot be handled by standard TTL buffer products.

The totem-pole structure of the 74F3037/40 can easily sink 100mA @ 0.55V (160mA @ 0.8V) and source −45 mA @ 2.5V (−67mA @ 2.0V). The open collector (OC) 74F3038 Quad and 74F30240/244 Octal Buffers use only the 74F3037/40's high current pull-down output structure. The 74F30245/640 Octal Transceivers use high current OC outputs for the B_N port with the A_N port's 3-State outputs able to handle +24/−3mA at TTL (0.5V/2.4V) logic output voltage levels.

Speed is not sacrificed for high output current drive. The 74F30XXX's propagation delays are similar to standard 74F

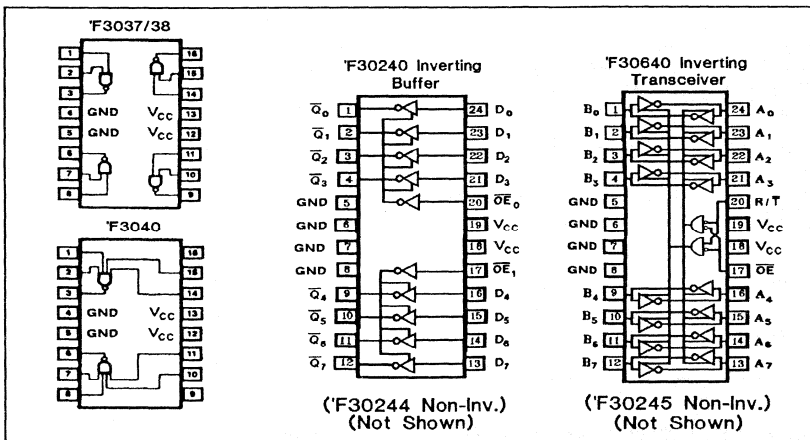

Figure 1a. 74F30XXX Block Diagram & Pin Configuration

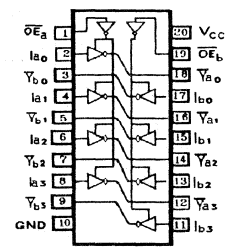

Figure 1b. 74F240

devices. As an example, the 74F3037 and the 74F37 both have guaranteed propagation delays between 1.5 and 6.5ns (min/max).

Flow-Through Design

Figure 1a shows the Block Diagrams and Pin Configuration of 5 of the 7 parts of the 74F30XXX Family (74F30244/245 not shown). Notice that each device has at least one ground pin for every two outputs and one V_{CC} pin for every four outputs. Also, the 74F30XXX Octals use a "broadside" design to allow signals to "flow-through" the package. I/O control pins are placed on both sides of the V_{CC} pins.

Comparing the standard 74F240 Pin-Configuration (Figure 1b) with that of the 74F30240, you can see that the 74F30XXX's Flow-through design simplifies the design and layout of large, bus-oriented PC boards.

Input Structures

As shown in Figure 2a (74F3037/40 Circuit Diagram), the input structure is a simple diode AND gate driving the base of Q1. D1 is the input Schottky clamp diode. D2 is the AND input terminal with an input threshold of 2 V_{BE} voltage drops and an I_{IL} (V_I = 0.5V) of 600μA. When all of the inputs are HIGH and one input goes LOW, the input speed-up Schottky diode, D3, discharges the base stored-charge of Q3A & Q3B to ground allowing them to be quickly turned OFF.

A patented "Light-Load" NPN input is used on the inputs of the 74F30240/244 Octal Buffers and the A_N port inputs of the 74F30245/640 Octal Transceivers (Figure 4a). Its input bias current is less than ±20μA for V_I between 0.0V and 5.5V. This NPN input also has a patented NPN transistor turn OFF speed-up circuit (D2/Q2/D4). These patents are discussed in the "Light-Load Input Drivers and Transceivers" Applications Note AN215.

74F3037/40 Output Drive

Figure 3 shows a simplified version of the 74F3037/40's typical output LOW (I_{OL}) and HIGH (I_{OH}) currents versus the output voltage. Note the symmetry of the HIGH and LOW output resistance. As V_{OL} is swept from 0.16V to 5V, R_{OL} (output LOW resistance) changes from ~2.4Ω to ~23Ω. For the same output voltage sweep, R_{OH} (output HIGH resistance) goes from ~23Ω to ~3.6Ω to Hi-Z.

At V_O = 1.5V, the 74F3037's HI and LOW output resistances are approximately 23Ω. If the slope of these sourcing and sinking 23Ω resistances are extended to zero output current, they appear to be switched between equivalent supply busses of +4.75V and -7.75V. This symmetrical output resistance characteristics and the 12.5V apparent output swing are the major reasons that the 74F3037/40 show such excellent 30Ω unterminated transmission line, incident wave switching performance.

Referring to Figure 2a, both Q6 and R8 of the 74F3037/40 are very large area devices producing a relatively large, parasitic capacitance to ground at the collector of Q6. During LOW-to-HIGH output transitions. This 7-10pF capacitance produces a small amount of additional transient I_{OH} drive which helps produce a smooth output transition.

74F3037/40 Output Feed-Through Current

The 74F3037/40's totem-pole output has been designed with virtually no output current spiking or feed-through current. Feed-through current can occur during any output transition when both the pull-up and pull-down output transistors are ON simultaneously. In standard TTL circuits, feed-through current is one of the prime contributors to power supply noise and increased power dissipation with increasing frequency of operation.

To minimize feed-through current, internal circuit delays are used to prevent the upper and lower structures of the 74F3037/40's totem pole output from being ON at the same time. Without this feed-through current, supply plane noise is significantly reduced.

Many standard TTL gate output structures have feed-through currents which are limited only by their pull-up I_{OS} resistors. This condition significantly reduces the amount of output current available during switching transitions. Under heavy load conditions, feed-through can cause non-linearities or flattening in the output switching waveforms. The innovative 74F3037/40 design virtually eliminates feed-through current, allowing the outputs to have significantly more available output transition current and producing very linear output switching transitions.

Figure 2a. 74F3037/40 Circuit Diagram

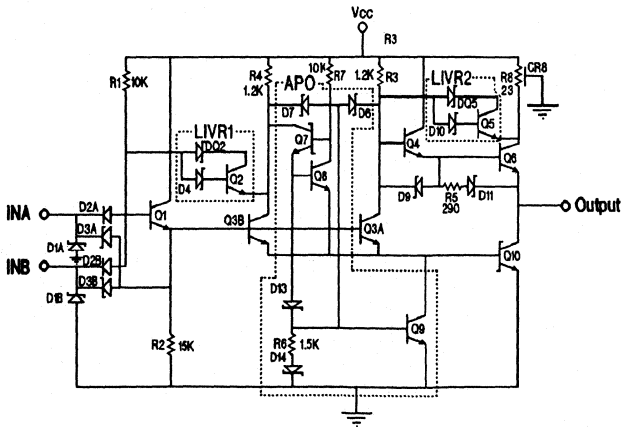

Figure 2b. Non-LIVR Buffer Output

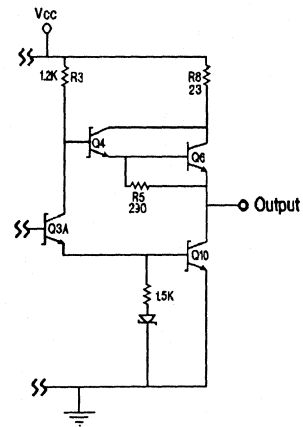

Figure 2. 74F3037/40 Circuit Diagram & Non-LIVR Buffer

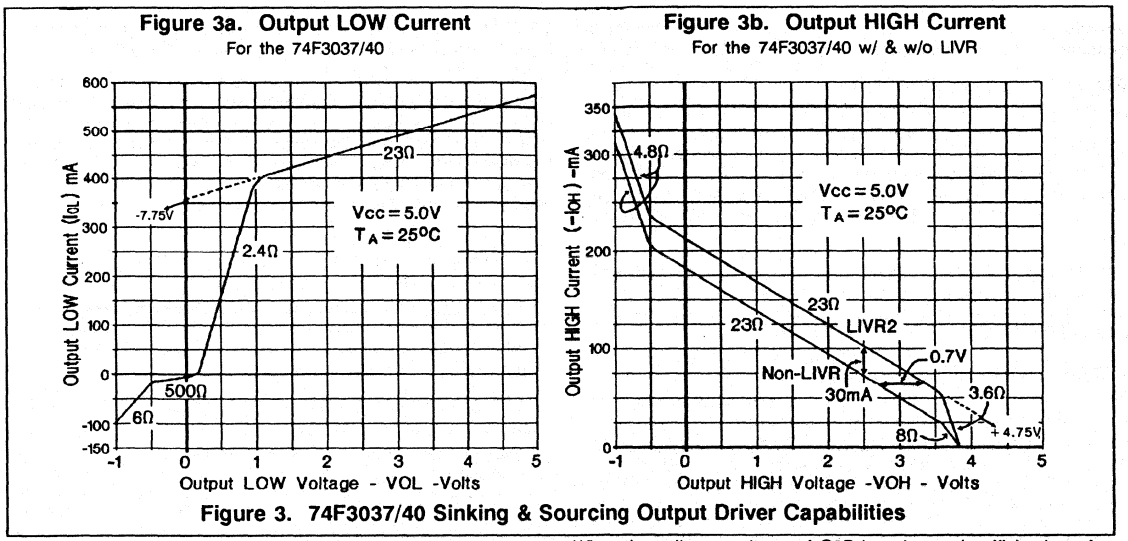

Figure 3. 74F3037/40 Sinking & Sourcing Output Driver Capabilities

Low Impedance Voltage Reference

The patented Low Impedance Voltage Reference is a temperature compensating voltage reference used throughtout the 74F30XXX Family for input speed up (LIVR1) and output noise immunity improvement (LIVR2). The 74F3037 (Figure 2a) is used in the following analyses of the LIVR1 and LIVR2 circuits.

LIVR1 Operation

Refering to Figure 2a, the combination Q1, Q3B and LIVR1 (D4, DQ2 and Q2) is a "kicker circuit" which reduces input propagation delay. LIVR1 is connected between the base of the input transistor, Q1, and the collector of Q3B. When all inputs switch HIGH, current from R1 flows into the base of Q1. Q1's collector-emitter current rapidly turns ON the phase-splitter transistor, Q3A, which turns OFF the output pull-up structure.

When the collector voltage of Q3B has dropped sufficiently to forward bias LIVR1, it begins to regulate Q1's base drive, and a low quiescent Q3A/B base drive current is established. With Q1's collector tied directly to Vcc, it cannot saturate and, therefore, can be turned OFF quickly.

LIVR2 Operation

This section compares a standard Schottky Darlington pull-up (non-LIVR Figure 2b) with that of the 74F3037/40's LIVR2 pull-up (Figure 2b). For simplicity, the same circuit resistor values will be used.

Assumptions:

- The Q6 $V_{CE(SAT)}$ of the Darlington output pull-up structure will be aproximatley 0.9V.
- The LIVR2 allows the Q6 $V_{CE(SAT)}$ to drop to 0.2V
- R8, the Ios resistor, for both output HIGH driver circuits is 23Ω.

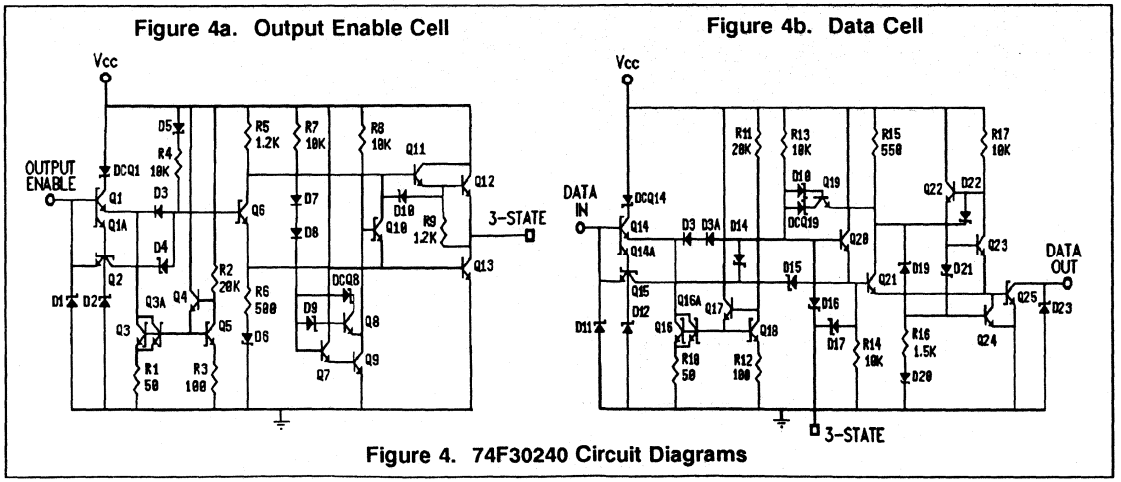

Figure 4. 74F30240 Circuit Diagrams

Under these conditions, the LIVR2 output can supply an additional 30mA (23Ω x 0.7V) output HIGH current (I_{OH}) at any specified output HIGH voltage. Also, at the same I_{OH}, the LIVR2 increases V_{OH} by ~0.7V over that of the standard non-LIVR, Darlington pull-up. Refer to Figure 3b.

Active Pull-Off Circuitry

The patented Active Pull-Off (APO) circuit (Figure 2a) consists of a dynamic base discharge and a quiescent pull-off network for the output pull-down transistor (Q10). The APO reduces I_{CCL} (I_{CC} with outputs LOW) requirements by about 30% in comparison to passive pull-off circuits by eliminating the standby pull-off current. This circuit is also part of the timing network for eliminating any totem pole feed-through current.

Low VCC Shut-Down Circuit

In a multi-card bus system where power to one card could be disrupted for any reason, the powerless card must not effect access to the system by the other cards. Systems with common signal busses and power supply planes must continue to operate regardless of any subsystem failure. Many bus driver products in common use today do not provide an output disable circuitry that disables or Hi-Zs all shared system interconnections when V_{CC} drops below its nominal operating range.

The Signetics 74F30XXX octals have solved this problem with a very effective Low V_{CC} Shut-Down circuit. This circuit is shown in the 74F30240's Output Enable Cell (Figure 4a). It detects when V_{CC} falls below 4 V_{BE} voltage drops (R7 biasing D7, D8, Q7 & Q9) then turns Q9 OFF and Q10/Q13 ON by allowing the current through R8 to drive Q10's base instead of being shunted to ground by Q9. This V_{CCZ} value will be >2.0V for T_A = 0° to 70°C.

When Q13 is ON, D16 and D17 (in the 74F30240's Data Cell Figure 4b) shunt the base drive of both Q20 and Q21 to ground. With these transistors OFF, the Data Cell's open collector output (Q25) cannot be turned ON.

The 74F30245/640 Octal Transceivers also have blocking-diodes in the output pull-ups of the A_N port which effectively block any output leakage current through the pull-up path when power is off.

Power Dissipation

The Active Pull-Off and the Low Impedance Voltage Reference circuits used throughout the 74F30XXX Family significantly reduce the I_{CC} over standard advanced Schottky design techniques. In fact, without these innovations, the 74F30XXX Family would not be practical due to lower performance and excessive transient and quiescent power dissipation.

Because the 74F3037/40's totem-pole output has virtually no output feed-through current, I_{CC} does not increase significantly due to increasing frequency. This is not true for most other TTL logic families.

For the 74F30240, the I_{CCH} is about 1/3 of the I_{CCL}. The guaranteed values of I_{CCH} and I_{CCL} are <23mA and <95mA. For reference, the standard 74F240's I_{CCH}/I_{CCL} guarantees are 18/70mA, which is 75% of the 74F30240 version.

The 74F30240 in a 24-pin, 0.3 inch lead centers, plastic dual in-line package is an example of the chip/package power dissipation handling capabilities of the Family:

- With I_{CCL} = 95mA @ V_{CC} = 5.5V, 8 fully loaded outputs @ I_{OL} = 160mA and V_{OL} = 0.5V @ 70°C, the total package power dissipation will be equal to 1.16W.
- Using T_A = 70°C, T_J = 130°C and θJA = 50°C/W (with an air flow of 200 LFPM) yields a package power dissipation capability of 1.2W.

However, assuming that not all conditions will be worst case simultaneously, the total chip power dissipation should never exceed 1.0W. In designs utilizing 74F30XXX parts near their maximum specified drive capabilities, conservative design precautions dictate that the thermal resistance of the packages be reduced by increasing the air-flow across and/or heat sinking the packages.

Ground & VCC Bounce

A major problem with sourcing and sinking large amounts of current at a dV/dt of >1V/ns is inductance in the ground leads of a package (Figure 5a) which causes "ground bounce" during output transitions due to the load currents being switched ON and OFF. Another component of "ground bounce" in standard TTL circuits is feed-through current which has been eliminated in the 74F3037/40 totem-pole output devices. Changes in output current must overcome the inductances of the package power supply and output leads before being able to drive any load. In doing so, voltages are developed across these inductances which can effect the internal logic thresholds of high-speed logic devices.

V_{CC} bounce is not nearly as critical as ground bounce since a TTL gate's input threshold is referenced only to package ground lead. Also, the V_{CC}-to-output current (I_{OH}) (zero for open collector devices) is usually much smaller than output-to-ground current (I_{OL}).

Figure 5b illustrates the measured lead inductance for both 16- and 24-pin plastic DIPs. Note that the center pins of any PDIP package, being the closest to the chip, have the lowest inductance. Lead length and cross-sectional area equate to inductance. The longer the ground lead, the greater the lead inductance and the larger the ground bounce.

$$dV_{GND} = L(dI/dt)$$

A comparison of the actual measured lead inductance for 16- and 24-pin plastic DIPs with both corner and center (with and without multiple) supply pins devices is shown below:

#/PINS	PWR PINS	# V_{CC}/GND PINS	EQUIV. IND.
16-Pins	Corner	16/8	10.5nH
16-Pins	Center	12/4	3.3nH
16-Pins	Center	12,13/4,5	1.7nH
24-Pins	Corner	24/12	18.1nH
24-Pins	Center	18/6	3.7nH
24-Pins	Center	18,19/5,6,7,8	1.9/1.2nH

On the 24-pin PDIP the ratio between the lead inductance of a single, corner ground lead (18.1nH) and 4 center grounds (1.2nH) is 15:1.

Using the example of a 74F30240 with all eight outputs switching simultaneously from a HIGH-to-LOW state into 30Ω loads, I_{CC} changes plus the total output current into the ground lead will be:

$$dI_{CC} = 95mA(LOW) - 23mA(HIGH) = 72mA$$
$$dI_{OUT} = 8 \times (5.0V-0.5V)/30\Omega = 8 \times (0.15A) = 1.2A$$
$$dI_{GND} = dI_{CC} + dI_{OUT} = 72mA + 1.2A = 1.27A$$

For 1 Corner Ground Pin - L_{GND} = 18.1nH

$$dV_{GND} = L(dI/dt) = 18.1nH \times (1.27A/2ns) = 11.5V$$

For 4 Center Ground Pins L_{GND} = 1.2nH

$$dV_{GND} = L(dI/dt) = 1.2nH \times (1.27A/2ns) = 763mV$$

In use, the internal ground bounce will not actually reach these calculated voltage levels. The ground bounce is divided between the equivalent inductance in series with the 8 outputs (paralleled 1.6nH) and the 4 ground supply pins' equivalent inductance (1.2nH).

Also, because the length of the PC board trace to any load increases the effective output lead inductance and, because the supply pins are tied to large, low inductance supply planes, the ground bounce voltage is significantly reduced by dividing the potential ground voltage rise between the output and supply inductances.

Minimizing the effects of supply bounce on the internal logic threshold levels of TTL logic chips allows faster systems to be built. If corner supply pins parts are used, the logic LOW level threshold can be jeopardized by ground bounce, whereas, the ground bounce on the 74F30240/244/245/640 chips, with their multiple, center supply pin design, only effects the chip's thresholds by $<0.7V$ during HIGH-to-LOW transitions.

Living with Ground Bounce

If non-inverting buffers and transceivers (74F30244/ 245) are used, the ground bounce actually enhances the noise immunity of the chip. Changes in the current through the ground lead inductance reinforce the input thresholds by creating a very effective dynamic input hysteresis.

Care should be taken to minimize supply bounce during output switching transitions. These include minimizing supply lead inductance by keeping their PC board traces as short and as wide as possible. Inductance in the output lead actually reduces supply bounce as mentioned earlier.

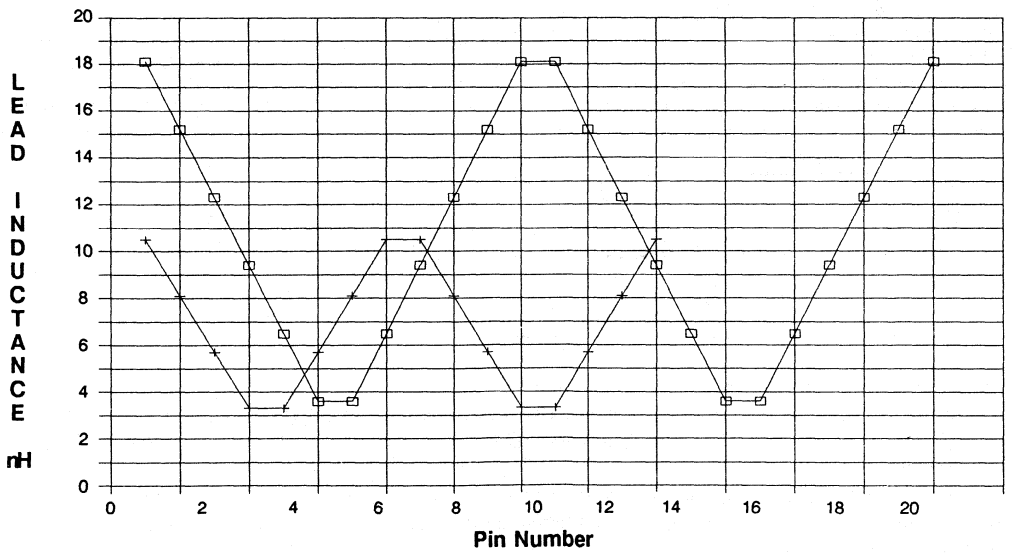

Figure 5b. Lead Inductance Per Lead for 16- & 24-Pin Plastic DIPs

High Performance Transmission Line Drivers

Introduction

The use of the 74F30XXX Family devices in high performance printed circuit board applications requires an understanding of some fundamental transmission line principles. It is assumed that you have some background in transmission line theory. Because of the unique requirements of every system, specific PC board design techniques will not be covered. The Signetics ECL Manual has some good background information on high performance PC board design.

This Application Note is intended to provide enough practical information to utilize the significant high performance advantages of the 74F30XXX Family in driving low impedance, high performance PC board transmission lines.

Incident wave signal switching of a transmission line requires the driver be able to achieve and maintain initial TTL input logic levels without having to wait for a signal reflection. The driver must also be able to continue to supply enough sinking and sourcing current to guarantee good noise margin during line reflections or crosstalk.

With standard TTL buffers unable to support incident wave switching, waiting for a reflection before a driver can achieve solid TTL input logic levels would be a major source of system timing error and noise. The reflected signal will take several nanoseconds to return to the driver source. During this time, the incident signal level could be in the input threshold region of a receiving gate creating the potential for that gate to oscillate or detect incorrect logic states.

PC board busses and backplanes usually have low, irregular characteristic impedances, Z_0, and are difficult to terminate properly (See Figure 6). To obtain incident wave switching of TTL voltage levels in this environment requires very high current drivers. Where proper termination is impractical, the 74F3037/40 Totem-Pole Output Gates could be the only solution. They can drive unterminated transmission lines of $Z_0 \geq 30\Omega$.

All 74F30XXX devices can drive properly terminated, low impedance transmission lines. When the line is correctly terminated, during the LOW-to-HIGH output transition, the driver output (whether open collector or totem-pole) will switch to V_{EQ} (the equivalent termination voltage) in <2ns, as if it were driving a resistor network tied directly to the output. If the V_{EQ} is less than 5V, the Family can also drive line impedances lower than 30Ω (See Figure 6b):

$$Z_0 = dV/I_{OL} = [V_{EQ} - V_{OL}]/I_{OL}$$

where:

V_{OL} = 0.5V @ I_{OL} = 160mA

Z_0 (V_{EQ} = 5.0V) = [5.0V - 0.5V]/160mA ≅ 30Ω

Z_0 (V_{EQ} = 3.0V) = [3.0V - 0.5V]/160mA ≅ 16Ω

When a buffer or transceiver is placed in the middle of a 70Ω PC board (typical) bus transmission line, its output sees two paralleled 70Ω impedances or 35Ω. With this heavy loading, standard TTL buffer outputs cannot generate TTL input logic level. However, the 74F30XXX Family was developed specifically for these types of difficult bus driver applications.

Characteristic Impedance

A driver switching the voltage onto a transmission line will see neither capacitance nor inductance but primarily resistance. This resistance, Z_0, is the characteristic impedance of the transmission line. The characteristic line impedance is calculted by:

$$Z_0 = \sqrt{[L_D/(C_D + C_i)]}$$

where: (See Figure 6)

C_D = Distributed Capacitance Per Unit Length

C_i = Total Input Capacitance Per Unit Length

L_D = Distributed Inductance Per Unit Length

In large device arrays such as memory PC boards, C_D, C_i and L_D (and therefore Z_0) are determined primarily by both the pitch of the package pins and the pitch the package placement rather than the number of devices attached to a bus. Example, SIP (single in-line packages) memory chips can be placed much closer together than

Figure 6a

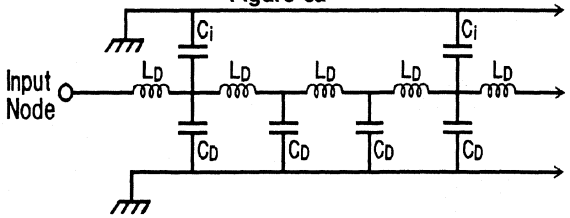

Figure 6b

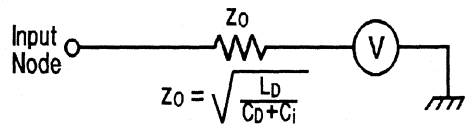

a.... A simplified signal bus or transmission line model showing the first 2 DRAM inputs on the line. C_i is a DRAM's input capacitance. C_D is the distributed PC trace capacitance. L_D is the distributed PC trace inductance.

b.... Equivalent circuit for the Input Node. If Z_0 is given by the equation shown. The current to drive the Input Node is: $I_{OL} = V_{EQ}/Z_0$, where V is the difference between the Input Node voltage and the quiescent voltage on the line.

Figure 6. Transmission Line Model

can DIPs. Therefore, the input capacitance per unit length of the PC trace, C_i, can be much larger for SIPs than for DIPs, which reduces Z_o. Also, the newer surface mount packaging technologies tend to produce transmission lines with lower characteristic impedance than through-hole (DIP/SIP) technologies.

Line Propagation Delays & Reflections

The basic resistive characteristic of Z_o and the signal propagation speed of transmission lines, regardless of their termination, is a function of its cross section area and distributed/mutual L & C. The line termination determines only the magnitude and polarity of the reflected signal, not the initial impedance seen by a bus driver.

Three rules of thumb:

- Modern PC board designs can easily produce transmission lines with Z_o of 70Ω or lower.
- Signal propagation speeds will be in the 1.5ns per foot range. Although, with very large distributed input capacitance per unit length (C_i), 4.5-5.0ns/ft is possible.
- An abrupt change in Z_o causes a signal to be partially reflected. $V_{(reflected)}/V_{(incident)}$ is determined by the impedance immediately before and after the change. The magnitude of the propagated and reflected signal voltages will be::

$$V_{(ref)} = V_{(inc)}[(Z_1 - Z_o)/(Z_1 + Z_o)]$$
$$V_{OUT} = V_{(inc)} + V_{(ref)}$$
$$= 2V_{(inc)}[(Z_1)/(Z_1 + Z_o)]$$

where:

$V_{(ref)}$ = Reflected Signal Voltage
$V_{(inc)}$ = Incident Signal Voltage
V_{OUT} = Total Propagated & Reflected Signal
Z_o = Incident Line Z_o
Z_1 = Next Section Line Z_o

Also, because of the real-world limitation of PC board design, the characteristic impedance of a line will change at different points along the line. These impedance variations will cause reflections. However, since the driver only has one shot at incident wave switching of a line (at the driving point), the signal wave traveling away from the source should initially encounter the lowest line impedance followed by incrementally increasing or the same characteristic impedances, if possible.

When the transmission line's Z_o decreases, the propagating signal voltage will be reduced and a negative reflection generated. Also, if the propagating signal sees an increase in Z_o, the signal voltage will be increased and a positive reflection voltage will be generated.

Incident Wave Switching Line Drivers

When comparing logic families, you will find that the 74F30XXX drivers are the only products available which are able to handle incident wave switching into a 30Ω transmission line. Under very heavy loading, the 74F3037/40 outputs produce significantly greater HIGH logic level noise margin than any competing standard device.

The 74F3037/40 has been designed specifically for the higher current and speed requirements of high performance PC board busses and transmission lines where the Z_o may have significant variations. Their totem-pole output structure provides enough current drive capability to force TTL input logic levels into a 30Ω load tied to either V_{CC} or GND.

Figure 7 illustrates the excellent noise immunity provided by the totem pole output structure of a 74F3037 output (P_0) driving a 40", 30Ω transmission line terminated with only the input of another 74F3037 (P_1). The 40" line's propagation delay is about 5ns or t_{TPD} = 1.5ns/ft. The waveforms are simplified to illustrate the concept. In an actual system, you could expect to see many small reflections traveling along the transmission line.

Since the line is nearly an open circuit at P_1, the 4.0V HIGH-to-LOW output transition tries to double when it arrives at P_1 (+5ns), driving P_1 negative until the input clamp is forward biased. This signal is reflected back to the P_0 source (+10ns), pulling it below ground momentarily.

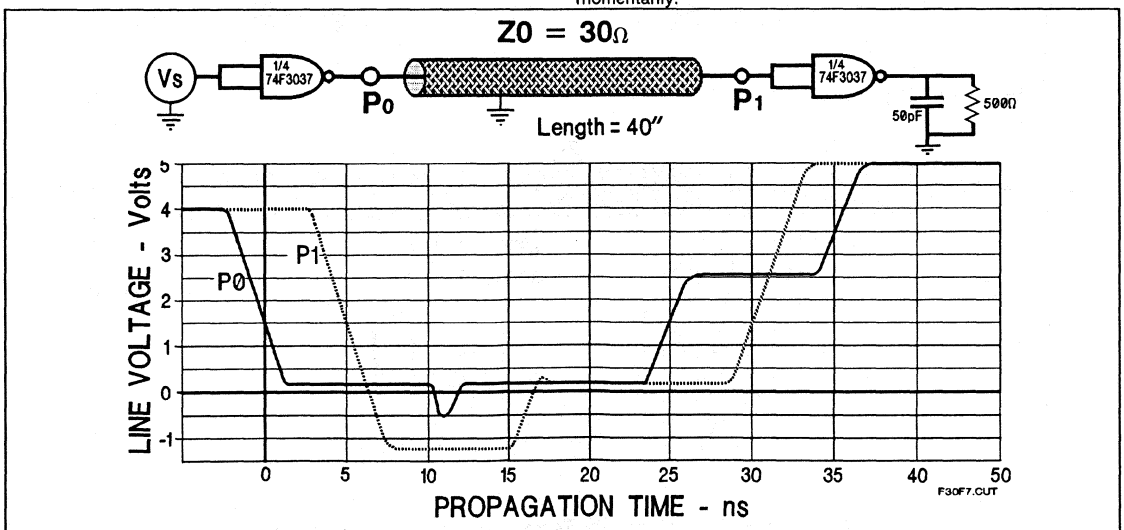

Figure 7. 74F3037/40 Driving Unterminated 30Ω Transmission Line (Simplifed

At the LOW-to-HIGH output transition, the 74F3037 initially achieves a full 2.5V level before running out of steam. The 2.5V signal travels down the line to P_1 (+5ns) where it is doubled and reflected. The reflected signal arrives back at P0 (+10ns), reenforcing the HIGH level to nearly 5.0V and completely turning off the 74F3037 pull-up structure. With the pull-up structure OFF, no additional charge can be pumped into the line, and the line voltage stops rising.

Open Collector Buffers & Transceivers

Figure 8 is an illustration of a typical multi-tap 70Ω transmission line with each end terminated by a resistive voltage divider producing a V_{EQ} = 3.0V and R_{EQ} = Z_0 = 70Ω. As shown, one of the B_N port outputs of a 74F30245 Open Collector Octal Transceiver (with no output pull-up resistor) can be placed anywhere along the middle of a transmission line (PC board trace). This output has to drive the equivalent of two paralleled 70Ω ($Z_0/2$ = 35Ω) transmission lines tied to 3.0V.

During the LOW-to-HIGH driver output transition, the OC driver output turns OFF, and the signal snaps up to 3.0V in less than 2ns. The output reacts as if it were tied to a 3.0V, 35Ω resistive termination. No reflections of the incident signal voltage occur from either end of the transmission line because both are terminated with Z_0. These terminations also absorb the HIGH-to-LOW output transition signal voltage without reflection.

Crosstalk

Crosstalk signals or injected noise can be inductively and/or capacitively coupled between two parallel signal lines. Crosstalk between adjacent transmission lines can be significant with large mutual inductance and capacitance even when the ends of the transmission lines are correctly terminated or tied to a line driver. Crosstalk noise travels down a transmission line (similar to actual data) and is absorbed or reflected at the terminations at each end of the line.

Crosstalk noise is a basic characteristic of the physical layout of adjacent transmission lines, not a failure of the driver. Long parallel signal lines can have a fairly high mutual inductance and capacitance if care is not taken in their design. The increased crosstalk due to narrower spacing between lines could pose system problems as denser memory and surface mount technology (SMT) packaging become more popular.

Shielding should be used to reduce the electromagnetic and electrostatic field strengths between adjacent lines. Multilayer PC boards significantly reduce mutual inductance and capacitance by isolating signal planes from each other through the use of alternating signal and ground planes. Further isolation can be achieved by inserting narrow, grounded filaments between each signal line on the same wiring plane.

Concerns that the 74F30XXX Family can produce more crosstalk is valid. However, the Family was specifically designed to drive large amounts of output current at very high speeds. Therefore, PC board design must take into consideration the high output current and fast edge rates generated by 74F30XXX devices.

Negative Reflections Cause MOS Failures

If the minimum input voltage specification of -1.0V is exceeded, the reliability of MOS devices can be seriously degraded. Transmission lines using end termination techniques should be incorporated into high performance PC board designs to minimize the negative excursion of reflected signals. Correct line termination is essential to prevent blowing up MOS device I/O ports connected to PC board bus lines!

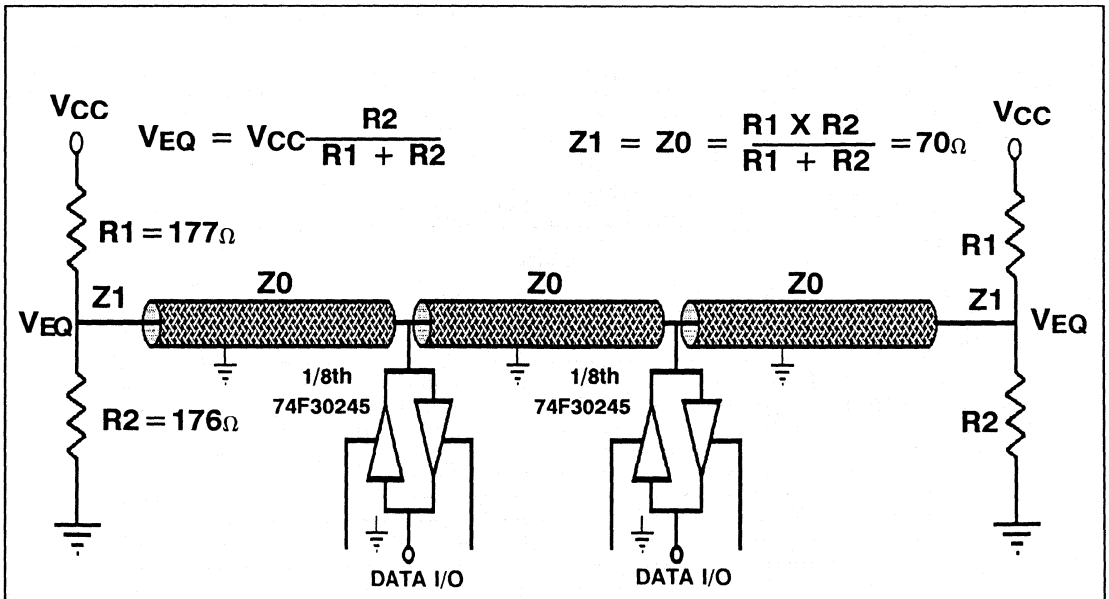

Figure 8. 74F30245 Multiple-Tap, Correctly Terminated 70Ω Transmission Line Transceiver

Summary of Recommendations

Significant factors influencing PC board designs are easily overlooked. Here are a few recommendations that must be taken into consideration:

- Keep signal line lengths as short as possible to reduce crosstalk, reflections and signal timing skews. Break long lines into shorter parallel lengths.
- In applications where there can be significant variations in Z_O, use 74F3037/40 Totem-Pole output drivers. If possible, terminate a transmission line with an impedance that is equal to or slightly higher than the Z_O at the terminal end of the line. If variations in Z_O must occur, Z_O should increase as the distance from the driver increases. Try to keep the incremental Z_O changes per unit length of transmission line to a minimum.
- To keep the negative reflected voltage at the I/Os of MOS devices less than 1.0V, correctly terminate the end(s) of the signal transmission line. For additional protection, you can also use the Schottky clamp diodes available across all I/O pins of Signetics' 74FXXX and 74F30XXX devices.
- The most elegant solution to driving low Z_O transmission lines is to use the Signetics 74F30XXX Octal Open Collector Output Buffers and Transceivers. If both ends of the line are terminated with its characteristic impedance (Z_O), these drivers can be tapped into any point along the line. Direct and injected crosstalk signals are absorbed at the end terminations minimizing system noise. The line driver will see heavy, predominantly resistive loads.
- Since you now need the speed and drive capabilities of the 74F30XXX Family, you are automatically in the high performance end of the speed spectrum. In these high-speed applications, multi-layer PC boards are virtually mandatory. Keep the ground paths as wide and as short as possible to minimize induced ground noise.
- Capacitively bypass the supply pins of all devices with a 0.1 - 0.33μF ceramic and/or tantalum capacitor as close to the supply pins as possible.

High Current Driver Applications

Figure 9 illustrates that under controlled conditions, the open collector 74F30240 and 74F30244 Octal Buffers can be used to drive eight power MOSFETs, lamps (incandescent and LED), solenoids and relays.

Octal Power MOSFET Driver

Power MOSFETs are well known for their extraordinary switching speeds -- much faster than the best power bipolar transistors of equivalent current/voltage handling capabilities. When comparing MOSFETs to equivalent power bipolar transistors, MOSFETs exhibit many advantages:

- Turn ON & OFF in 2ns vs. Bipolar's 200ns
- Negative vs. Positive Gain Tempco --- No Thermal Run-Away Characteristic
- Gate Turn-ON Thresholds Between 2V and 6V
- Low R_{ON} with 0V V_{DS} offset vs. $V_{CE(OFFSET)}$ > 0.15V
- R_{ON} < 0.15 Ohm @ I_{DS} > 10A
- Voltage-to-R_{ON} vs. Current-to-Current Amplification
- Capacitive AC Input vs. Current Base Drive Equivalent Gate Capacitance < 2000pF
- Low Cost 50V to 250V Power Transistors @ > 12A

The rise/fall switching speeds of MOSFETs are of primary consideration in high efficiency switching applications such as switched mode power supplies. The 74F30244 Buffer can easily switch an equivalent power MOSFET gate capacitance of 1000pF in <50ns.

An excellent example of today's leading edge power MOSFETs is the Siliconix BUZ71. At 25°C, the BUZ71's specifications are:

- V_{GSON} = ON Gate-Source Threshold < 5.0V
- I_{DSON} = Drain-Source ON Current > 12A
- V_{DSO} = Drain-Source Breakdown Voltage > 50V
- R_{DSON} = Drain-Source ON Resistance < 0.150Ω
- C_{GS} = Gate-Source Capacitance < 650pF
- C_{DG} = Drain-Gate Capacitance < 160pF
- P_{DSON} = Chip ON Power Dissipation < 22W
- P_L = Power to Load = 500W

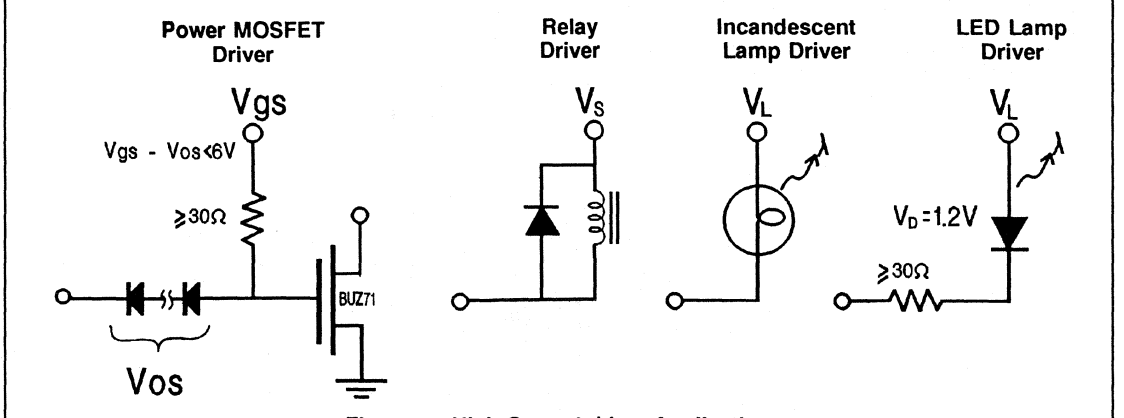

Figure 9. High Current driver Applications

The high current capabilities of the 74F30244 can easily drive the AC loading of the 650pF gate-source capacitance and 160pF drain-gate Miller capacitance. However, an offset voltage (Vos = 3 Schottky diodes or more) should be provided to speed the LOW-to-High transition and increase the gate supply voltage. Since power MOSFETs are very fast and an oscillating driver could cause load switching problems, a non-inverting driver (such as the 74F30244) should be used to take advantage of the dynamic input threshold hysteresis generated by ground bounce.

Octal Solenoid or Relay Drivers

Since solenoids and relays are inductive circuit elements, the ON load current exponentially increases from zero to quiescent value of current. When the driver tries to turn OFF the load current, a quenching diode, placed across the coil, prevents the output of the driver from being damaged by the coil's back-EMF inductive kick.

A 74F30240 can easily handle eight 160mA, 5V solenoid or relays with the back-EMF diodes in place.

Octal Incandescent Lamp Drivers

All incandescent lamps have positive filament resistance temperature coefficients. At room temperature, a lamp's filament resistance can easily be less than 10% of its ON resistance. Therefore, a 100mW (5V at 20mA) lamp could have a cold or inrush current of 200mA. The absolute maximum output LOW current specified for the 74F30XXX Family is 320mA. For this reason, we suggest that the inrush not exceed 320mA in incandescent lamp applications. Therefore, assuming a 10:1 ON:OFF resistance ratio, the ON current should be in the 32mA range. Outputs may be paralleled for additional output drive current.

When the lamp is turned ON, the initial filament current exponentially decays to the quiescent ON current within 10 to 100ms depending upon its size. When the lamp is turned OFF, the thermal decay time constant is very long compared to the turn-ON time constant, greater than 100 times, since the filament, being in a vacuum, has a very high thermal resistance. Therefore, the only time the inrush or cold filament current must be taken into consideration is in applications in which the lamp is OFF for seconds.

Octal LED Lamp Drivers

LEDs (Light Emitting Diodes) have none of the inrush current problems of incandescent lamps. Low cost LEDs are available with spectral emissions from infrared (IR) to green. The intrinsic forward-biased diode voltage drop ranges from 1.2V to 1.6V, depending on the technology -- GaAs, GaAsP, as well as other mixtures. Visible LEDs, red-yellow-green, are used as indicators and don't require fast switching times. If the design requires low cost, high current octal LED drivers, the 74F30240/244 Buffers are excellent solutions.

IR LEDs are used in communications applications where the receiver is a photo-sensitive semiconductor material. Silicon PIN diodes make excellent, very high- speed receivers for emmissions of IR LEDs. Both the emitter's spectral energy output and the receiver's maximum spectral sensitivity are in the 900Å range. The 74F3037 is an ideal Fiber Optic Communications (FOC) IR LED transmitter driver.

Fiber Optic Communications (FOC)

74F3037 FOC LED Driver

High performance, low cost FOC LED transmitter drivers using the 74F3037 can achieve data rates greater than 170MBaud depending upon the length of the fiber optic cable. Using 5% tolerance components, 1/2 of a 74F3037 and a Hewlett-Packard HFBR-1402.4 FOC LED, a one kilometer, 170MBaud FOC link can be produced with an optical output pulse width distortion of less than 15% (See Figure 10). Since the FOC LED is much harder to turn ON than OFF, the 74F3037's fast, HIGH level turn ON and large pull-up output current is nearly an ideal combination for high-speed fiber optic communication. The peaking capacitor, C, compensates for the LED's slow turn-ON time and peaks the LED's light output during both the ON and OFF transitions. Contact Hewlett-Packard's Optical Communication Div., San Jose, CA, for more information on FOC LED transmitters, PIN photo diode receivers and fiber optic cable.

FOC Photo PIN Diode Receiver

The receiver consists of an HP HFBR-2208 Photo Pin Diode driving a Signetics NE5212 Transimpedance Current, Differential Amplifier followed by a Signetics 10116 Triple ECL Line Receiver. The Trans-Z Amp's ~7KΩ (single-ended) internal feedback resistance converts the PIN diode's photon generated currents into 100mV differential output swings. The NE5212's outputs are capacitively-coupled into the input of the 3-stage ECL amplifier where it is quantized into solid ECL logic levels in the last stage.

The NE5212 Trans-Z Amp has a nearly flat DC-to-120MHz bandwidth. Contact Signetics Linear Division for more information on this and many other FOC products.

One more important point ---- the cost of this FOC transmitter/receiver pair is less than $50 using off-the-shelf standard parts.

74F Extended Octal–Plus Family Applications

Application Note

74F Extended Octal-Plus Family Features

- 8-, 9- & 10-Bit "Light–Load" Bus Products
  - Buffers/Drivers
    - With & Without Latches or Registers
    - With & Without 8–Bit Parity Checker/Generator
  - Tranceivers
    - With & Without Dual Registers
    - With & Without 8–Bit Parity Checker/Generator
- Patented "Light–Load" Inputs:
  - Input Current = ±20μA per Input
  - Transceiver I/O Pins = ±70μA
- High Performance Output Drive Currents:
  - I_{OL} = 64mA/48mA @ ±5%/10% V_{CC}
  - I_{OH} = –15mA/–3mA @ ±5%/10% V_{CC}
- "Flow–Through" or "Broadside" I/O Pin-Configuration
- Ideal for MOS CPU, Peripherals and Semi-custom Bus Interface
- 24-Pin, 300mil, Plastic Slim-DIPs
- High Performance Buffers – – – – – $t_{P(max)}$ = 7.5ns
- High Performance Latches/Registers – f_T = 100MHz

Introduction

The 74F Extended Octal–Plus© Family incorporates all of the latest Signetics' octal, 9–bit and 10–bit buffer, transceiver, latch and register functions. All devices in this Family utilize the Signetics patented "Light–Load" NPN, ±20μA input current structure and have "Flow–Through" or "Broadside" input/output pin configurations where the inputs and outputs are lined–up on opposite sides of a standard 24–pin Slim–DIP package. The "Light–Load" inputs, "Broadside" design and high functional density/performance of the Family make this product line ideal for buffering the limited drive capabilities of standard, custom and semicustom MOS VLSI devices to the rigorous environments of today's leading edge high performance logic designs. The Family also is an excellent choice for all general interface applications.

"Flow–Through" Design

The "Flow–Through" or "Broadside" chip layout/package design is illustrated in Figure 214–1 showing the Block Diagrams and Pin Configurations of the 74F828 10–Bit Inverting Buffer. Note that all of these "Broadside" designs allow logic signals to flow into one side and out of the other without crossing or folding back on signal paths such as the 74F240 Octal Buffers (Figure 214–2). If you compare the physical layout requirements of the path of PC board bus lines for the 74F828 to that of the 74F240's "Zig-Zag" path, you will see the significant advantages of the 74F Extended Octal–Plus© Family's "Flow–Through" design in simplifying the design and layout of large, high density, bus–oriented PC boards.

The 24–Pin, 300mil Slim–DIP Solution

With the advent of advanced Schottky TTL technology came the ability to significantly increase the functional density of standard logic building blocks. However, not until the development of the 24–pin, 300mil Slim–DIP package was it possible to take full advantage of these new chip densities. The entire Family provides significant advantages in package count, pin count and packing density when compared to older technologies. Further density enhancements can be achieved by using Signetics' surface mounted packages.

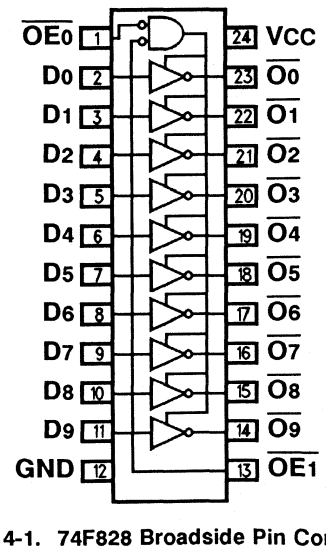

Figure 214-1. 74F828 Broadside Pin Configuration

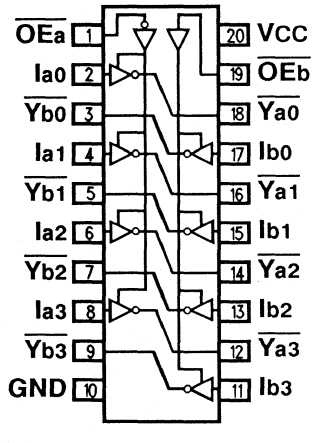

Figure 214-2. 74F240 "Zig-Zag" Pin Configuration

74F Extended Octal-Plus Family Applications AN214

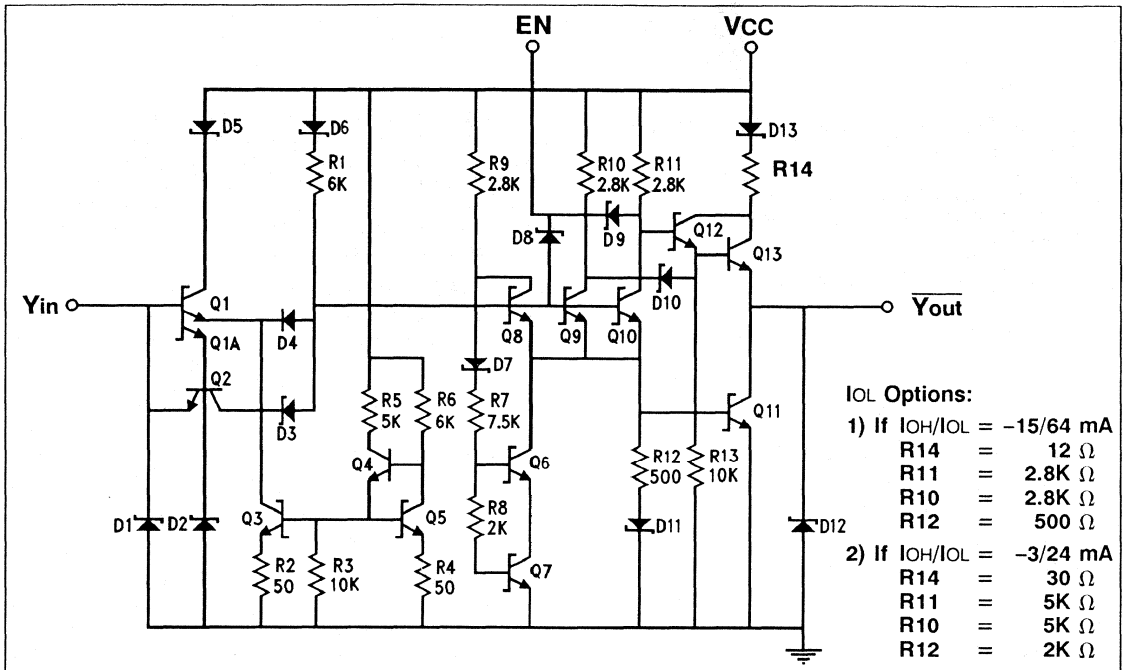

Figure 214–3. 74F455 Buffer/Drive Cell Circuit Diagram

By combining high functional density into a 24-pin, 300mil Slim-DIP package, the Signetics 74F Extended Octal-Plus© Family allows the reduction of PC board parts count and cost while optimizing layout with "Broadside" chip designs, reducing total system power dissipation and increasing system reliability.

The 8-, 9- & 10-Bit Series 24-Pin Solution

Whether your system requires an 8-, 9- or 10-bit bus interface, the Extended Octal-Plus© Family has standardized solutions in 24-pin/Slim-DIP/Broadside input/output packages with corner power supply pins (12 & 24) and standard designations for common control functions located at or near the package corners. Octals offer more mode control inputs than do the 9- or 10-bit products. Virtually all Family devices with 3-State outputs are guaranteed to source/sink -15/64mA @ V_{OH}/V_{OL} = 2.0/0.55V (Except for the 74F841-846 Latched Drivers which are spec'ed at -15mA/48mA). The A_N port outputs of several of the Family's transceivers are guaranteed to supply -3mA/48mA).

The Octal Parity Bus Series offers several notable exceptions to the above standard pinouts. This Series has three parts with two center-package ground pins to minimize ground-bounce noise. All outputs (except the A_N port of the 74F657 Parity Bus Transceiver spec'ed at -3mA/24mA) are guaranteed to source/sink more than -15mA/64mA.

Table 214–1. Family Output Drive Capabilities using the 74F657 Parity Bus Transceiver

DC ELECTRICAL CHARACTERISTICS (Over recommended operating conditions, V_{IL} = MAX and V_{IH} = MIN)

PARAMETER			TEST CONDITIONS		Min	Typ	Max	UNITS
V_{OH}	HIGH-level Output Voltage	All Outputs	I_{OH} = -3mA	±10%V_{CC}	2.4			V
V_{OH}	HIGH-level Output Voltage	All Outputs	I_{OH} = -3mA	±5%V_{CC}	2.7	3.4		V
V_{OH}	HIGH-level Output Voltage	B_N Port, PARITY $\overline{ERROR}$	I_{OH} = -15mA	±10%V_{CC}	2.0			V
V_{OH}	HIGH-level Output Voltage	B_N, PARITY $\overline{ERROR}$	I_{OH} = -15mA	±5%V_{CC}	2.0			V
V_{OL}	LOW-Level Output Voltage	A_N Port	I_{OL} = 24mA	±10%V_{CC}		0.35	0.50	V
V_{OL}	LOW-Level Output Voltage	A_N Port	I_{OL} = 24mA	±5%V_{CC}		0.35	0.50	V
V_{OL}	LOW-Level Output Voltage	B_N Port, PARITY, $\overline{ERROR}$	I_{OL} = 48mA	±10%V_{CC}		0.40	0.55	V
V_{OL}	LOW-Level Output Voltage	B_N Port, PARITY, $\overline{ERROR}$	I_{OL} = 64mA	±5%V_{CC}		0.40	0.55	V
I_{OS}	A_N Output HIGH Level Short Circuit Current (R14 = 30Ω)			VCC = MAX.			-150	mA
I_{OS}	B_N Output HIGH Level Short Circuit Current (R14 = 12Ω)			VCC = MAX.			-225	mA

74F Extended Octal-Plus Family Applications AN214

Current PC board, multi-layer technology make it possible to take into consideration the physical location of input/output pins, transmission line characteristics and supply power distribution. Lining up all inputs and output on opposite sides of the package allows the address, data and control bus signal to flow in a direct physical path from the μP CPU through the bus interface chips and onto the appropriate bus. This "Broadside" bus design approach produces very clean PC board layouts and may, in fact eliminate an entire PC board interconnection layer. Standardization of power supply, mode control and input/output pins whether 8-, 9- or 10-bit bus functions permits simplified, structured PC board layout.

Input Structures

Referring to Figure 214-3, the 74F455 Inverting Buffer/Driver Cell Circuit Diagram is an example of the Family's input and output circuitry. The patented Signetics "Light-Load" NPN input structure (Q1/3/4/5, R1/2/3/4/5/6 & D4) and turn-OFF speed-up circuit (Q2 & D2/3) are used throughout the 74F Extended Octal-Plus© Family. The "Light-Load" NPN input is actually a high speed, differential amplifier with the reference side, the anode of D4, clamped at two diode voltage drops above ground (BE junctions of Q8/9/10 and Q11 of ~1.4V at 25°C). When the V_{IH} rises above this clamp voltage, the BE junction of Q1 is forward based allowing beta amplified, CE current to flow into the <1.0mA constant current source, Q3 (driven by Q4/5 & R2/3/4/5/6) . The beta of Q1 is guaranteed, by design, to be >50, thereby, guaranteeing that the input base bias current will be <20μA. The emitter of Q1 rises to $1V_{BE}$ (~300mV) below the V_{IH}, reverse biasing D4 and permitting Q8/9/10 base bias current to flow through R1.

The patented turn-OFF circuit consisting of Q2 and D2/3 produces a dynamic speed to help turn Q8/9/10 OFF quickly. During the time that the Q1 is turned-ON (input = V_{IH} >2.0V), the reverse-biased Schottky diode, D2, acting as a capacitor, will be charged to the voltage at the emitter of Q1A or $1V_{BE}$ voltage drop below the input (>2.0 – $1V_{BE}$). When the input in switched to <V_{IL} (or <0.8V), the D2 stored charge discharges through the BE of Q2. Q2 CE current through D3 rapidly turns Q8/9/10 OFF.

These circuit innovations produce high performance, very low input bias current (±20μA) gate inputs. This input leakage represents a 30X reduction over the standard 74F Family's 600uA input current with virtually no loss in speed. The 74F Extended Octal-Plus© Transceivers have an input loading current of ±70μA which is the combination of the "Light-Load" NPN input structure's ±20μA and the 3-State Hi-Z output's ±50μA leakage current.

The low "Light-Load" input current and high speed performance make this Family ideal for interfacing to low drive capability, slower MOS CPU, peripherals and semi-custom chips used in most of today's state-of-the-art logic designs. Besides very low input current requirements, this "Light-Load" input has another significant advantage over "traditional" input structures: Very lower input capacitance (smaller stored charge) due to very small devices geometries. Therefore, when Extended Octal-Plus devices are connected to a bus, they present less AC bus loading and do not significantly lower the characteristic impedance of the bus to the extend "traditional" input structures do. Thus, the amount of the AC current a bus driver has to produce to change the state of the bus is lowered and in many cases can make a difference between incident wave switching of the bus vs. losing time waiting for a reflected wave.

The Signetics 74F "Light-Load" Input Structure is discussed in more detail in Application Note AN215.

Output Drive Capabilities

Virtually all devices in the Extended Octal-Plus© Family are guaranteed to source/sink more than –15mA/64mA @ V_{OH}/V_{OL} = 2.0/0.55V. One exception is the 74F841-thru-846 Series of Bus Interface Latches which are specified at –15/48mA. Several of the Family's transceiver products have lower A_N output drive

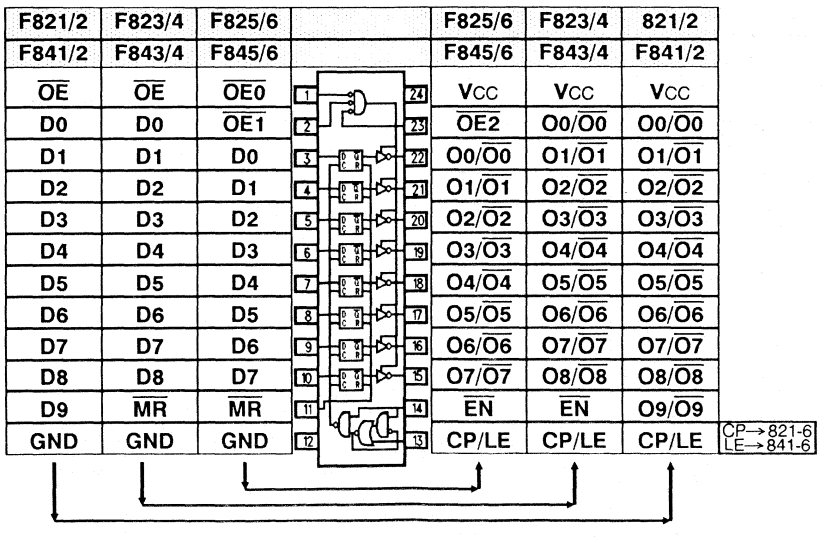

Figure 215-4a. 74F82X & 74F8X Registered/Latched Buffer Pin Configurations

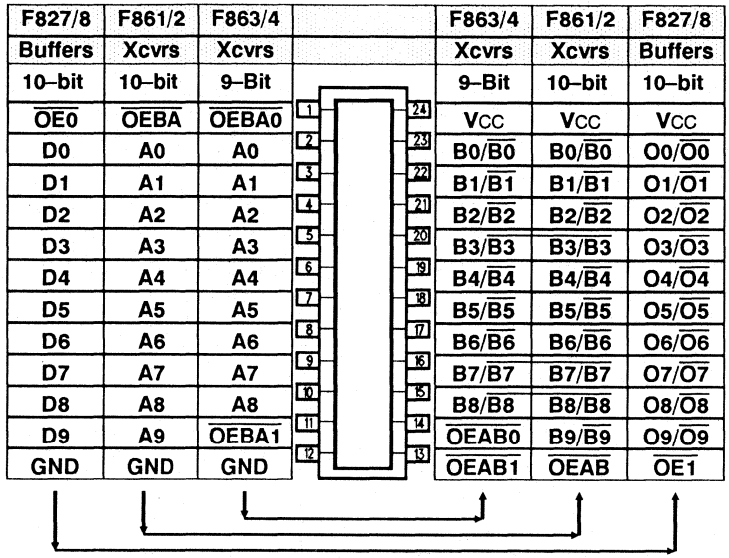

Figure 214-4b. 74F827/8 & 74F861–4 Buffers & Transceivers Pin Configurations

capabilities to reduce package power dissipation. Refer to Tables 214–1 and 3.

For example, the 74F657 Parity Bus Transceiver has two output ports with different capacities: The A_N port is guaranteed to source/sink –3mA/24mA (I_{OH}/I_{OL} = 2.4/0.50V), and the B_N port has an output drive capability of –15mA/64mA at 2.0V/0.55V. The 74F657's A_N port is designed to interface the chip side of the PC board to the backplane bus, while the B_N Port is capable of driving a transmission line or bus backplane line.

Referring to Figure 214–3, all of the Family's 3-State, totem–pole output structures have a Schottky blocking diode, D13, in their pull–up output structures. These diodes block leakage current from flowing into the outputs when V_{CC} is either open or shorted to ground.

This gives a very important advantage of being able to power down a PCB (or several PCBs) without disabling the bus and even without producing any glitching on the bus due to an undesired

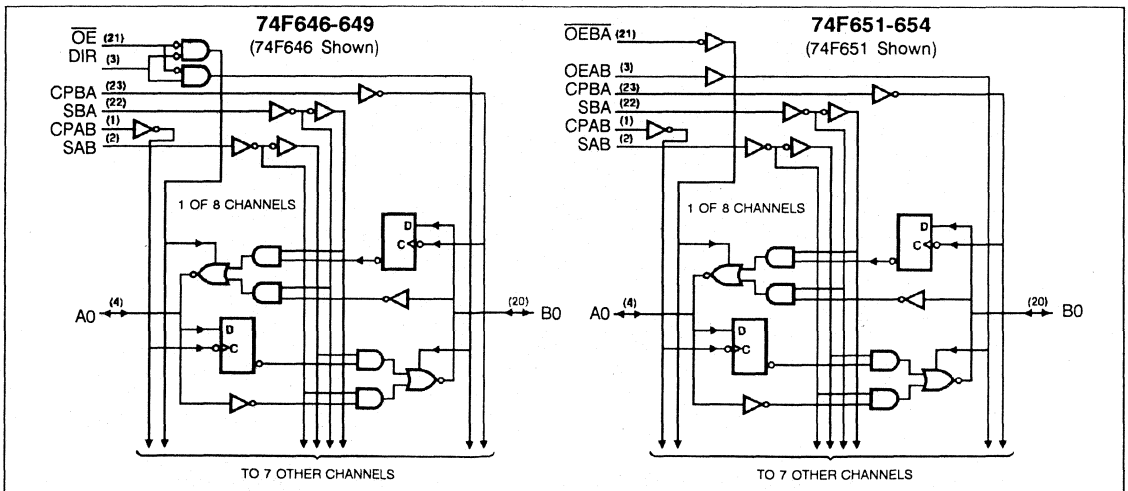

Figure 214-5a. 74F646–649 & 74F651–654 Registered Transceivers Simplified Logic Block Diagram

74F Extended Octal-Plus Family Applications AN214

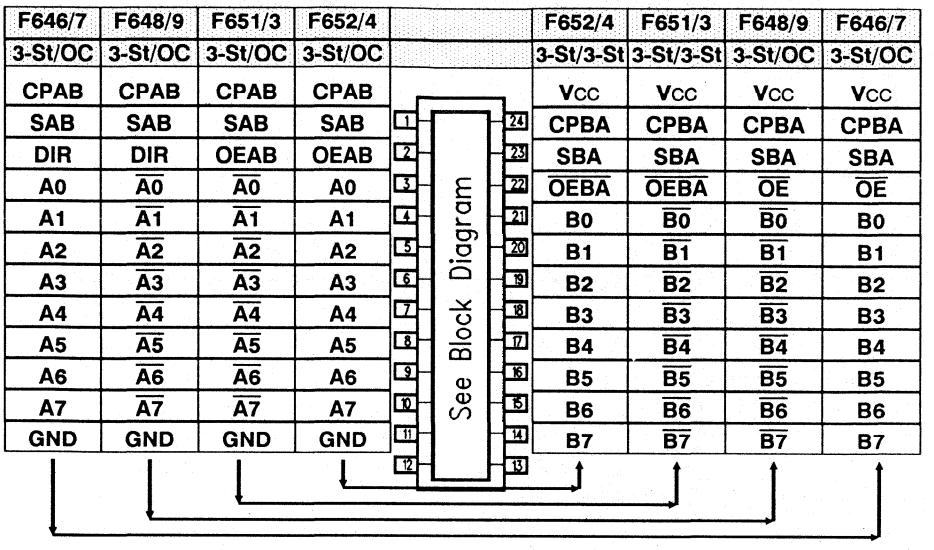

Figure 214-5b. 74F646–649 & 74F651–653 Dual Registered Transceivers Pin Configurations

change in the output state of the device being powered down.

The output short-circuit (I_{OS}) limiting resistor (R14), the anode-to-cathode resistance/voltage drop of D13 and the collector-to-emitter/base-to-emitter resistance/voltage drop of Q13 limit the amount of current that can be sourced from a HIGH level output at a specified V_{OH}. For most of the parts in the Family, R14 is equal to 12Ω. The A_N port of several of the transceivers utilize an R14 of 30Ω producing I_{OH} (@ V_{OH} = 2.0V) of –6mA versus –15mA from the BN ports 12Ω R14.

The output HIGH level sourcing current, I_{OH}, at a specified output voltage, V_{OH}, can be calculated by subtracting the voltage drops of D13, the pull-up darlington transistor, Q12/13, and the desired V_{OH} level from V_{CC} and dividing by the value of R14 plus the anode-to-cathode resistance of D13 and the collector-to-emitter/base-to-emitter resistance.

Assumptions:
$V_{D13} \cong 0.5V$ @ $R_{ON} = 3\Omega$ @ 25°C),
$V_{Q12/13} \cong 1.2V$ @ $R_{ON} = 8\Omega$ @ 25°C)
$I_{OH} = -[V_{CC}-(V_{D13}+V_{Q12/Q13}+V_{OH})]/(R14+R_{D13}+R_{Q13})$.
$I_{OH}(R14 = 12\Omega) = -[4.5V-(0.5V+1.2V+2.0V)]/23\Omega = -35mA$
$I_{OH}(R14 = 30\Omega) = -[4.5V-(0.5V+1.2V+2.0V)]/41\Omega = -20mA$
$I_{OS} = I_{OH}$ @ $V_{OH} = 0.0V$ and $V_{CC} = 5.5V$
$I_{OS}(R14 = 12\Omega) = -[5.5V-(0.5V+1.2V)]/23\Omega = -165mA$
$I_{OS}(R14 = 30\Omega) = -[5.5V-(0.5V+1.2V)]/41\Omega = -93mA$

Obviously, we have been very conservative in the I_{OH} specification to guardband against all conditions of temperature and input/output/supply voltage levels. The R_{ON} resistances of the output pullup transistors and blocking diode are large enough to prevent I_{OS} from exceeding –225mA for R14 = 12Ω and –150mA for R14 = 30Ω. (Refer to Table 214-1)

74F821 – 74F863 Series

The 74F821 through 74F863 Series of Octal, 9-bit and 10-bit Buffers, Latch Buffers, Register Buffers and Transceivers are standardized around the AMD 298XX series with one significant difference – the Signetics' "Light-Load" NPN input offers a 50:1 reduction in input loading (1000uA vs. 20μA). This Series illustrates the standardized on 24-pin/300mil Slim-DIP packages, "Broadside" input/output pinouts and control function pins. All 74F8XX 3-state outputs are guaranteed to source/sink –15mA/64mA, except for the 74F84X Latched Buffers which are specified at –15/48mA.

The logic diagram and pin configurations of the 74F828 Non-Inverting 10-Bit Buffer (Figure 214–1) and the 74F821–826 and 74F841–6 Registered/Latched Buffers (Figure 214–4a) are excellent illustrations of the standardized pin configuration illustrating "Broadside" chip design.

Figure 214–4b shows the pin-outs of the 74F827/8 Buffers and 74F861–4 Transceivers. There currently are no 9-bit buffer offerings in this Series.

Registered Transceivers Series

The 74F646–9 and 74F651–4 Octal Dual-Registered Transceivers offer a "Light-Load" combination of a 74F245 type transceiver with two 74F373/374 type octal registers within a 24-pin, Slim-DIP, Broadside input/output package. This Series offers a significant 6:1 package count reduction advantage over older technologies.

Figure 214–5a shows the 74F646 and 74F651 Transceivers Simplified Block Diagrams, and this Series' Pin Configurations are depicted in Figure 214–5b. Figure 214–6 graphically illustrates four optional storage and transfer modes of the 74F651 Octal, Non-Inverting, 3-State, Dual-Registered Transceiver. The 74F651 will be used to explain the operation of the entire Series. The 74F646/8 (3-State, INV/NINV) and the 74F647/9 (O.C., INV/NINV) Octal Dual-Registered Transceivers offer optional signal direction control logic and output enable to the 74F651–4 series.

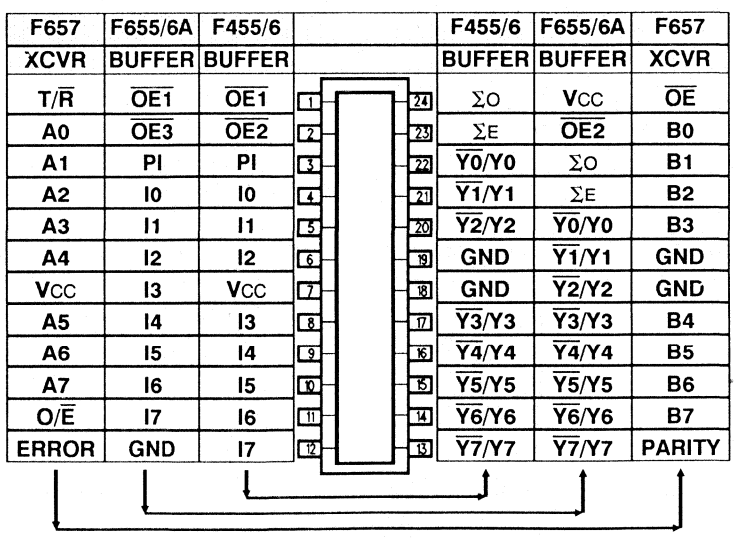

Figure 214–7. 74F Octal Parity Drivers/Transceiver Pin Configurations

74F Extended Octal-Plus Family Applications AN214

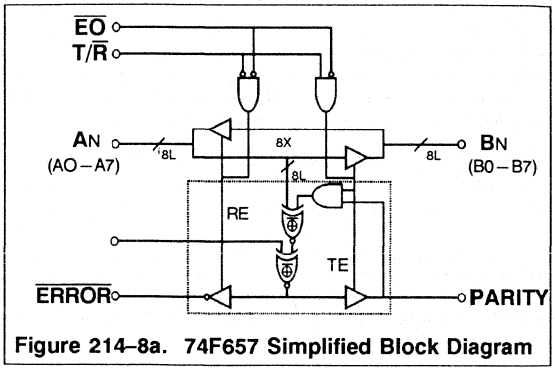

Figure 214–8a. 74F657 Simplified Block Diagram

This Series allows you to store or real-time transfer data in either direction through the transceiver function. Data at the A_N port can be stored in either the A_N port register or the B_N port register and, then, can be transferred either from the A_N port register to the B_N port outputs or from the B_N port register to the A_N port outputs.

The same capabilities are available to data presented to the B-port. When a port's output buffers are enabled ($\overline{OE}$ = LOW and DIR = LOW for A_N outputs enabled or HIGH for B_N outputs enabled), the SXX select inputs (SAB and SBA) control the two EX-OR gates allowing the output port data to come either directly from the other port (real-time transfer) or from the other port's input storage register.

The CPAB and CPBA inputs are the LOW-to-HIGH edge-triggered clock inputs for the A_N port register and B_N port register. Data presented to either port's inputs can be clocked into its input register on a LOW-to-HIGH CPXX input regardless of the logic levels on any of the other mode control inputs.

The 74F651-4's OEAB and $\overline{OEBA}$ output enable inputs may be tied together to enable the B_N outputs when HIGH or A_N outputs when held LOW or can be used separately to independently control the two output ports. Tying the 74F651-4's OEAB and $\overline{OEBA}$ together is logically equivalent to the DIR input of the 74F646-9.

Parity Bus Series Advantages

The increased functional density of the Parity Bus Series produces a 2:1 package reduction (plus 1 AND gate) and, therefore, 38:24 pin reduction. Power dissipation savings of 82.5mW for the 74F455/456/655A/656A Drivers and 137.5mW for the 74F657 are also achieved through shared internal logic. Table 214-2 shows the package/pin advantage as well as the worst case propagation delays and I_{CC} of the Family versus their competition.

Figure 214-7 is a summary of the pin configurations of entire Parity Bus Drivers and Transceiver Series.

The 74F455/456/655A/655A Octal Parity Bus Drivers and the 74F657 Octal Parity Bus Transceiver Series combines the popular Signetics 75F24X buffer/transceiver functions with the 74F280 9-bit Parity Generator/Checker, "Broadside" input/output pin configurations, "Light-Load" inputs and an increased guaranteed sink/source capabilities of −15mA/64mA for low impedance bus environments. The 74F445/446 Drivers with their multiple center-package ground supply pins are logically identical to the 74F655A/656A Drivers except for the latters' single corner-package supply pins and an additional $\overline{Output\ Enable}$ input. The 74F657 Parity Bus Transceiver allows the parity to be generated and checked in both directions in a single package replacing one 74F245 Transceiver, 20-pin DIP and two 74F280, 16-pin DIPs plus a couple of gates.

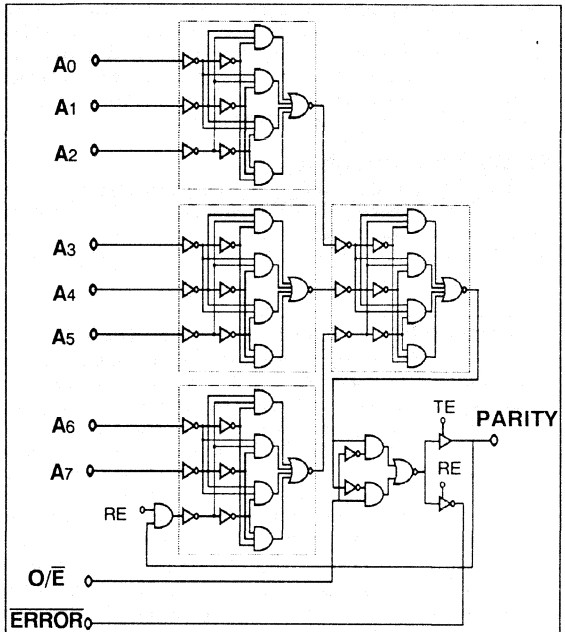

Figure 214–8b. 74F657 Parity Tree Logic Diagram

74F657 Operation

The 74F657 Parity Bus Transceiver, as shown in its simplified logic diagram Figure 214–8a, is a combination of a 74F245 Octal Transceiver and a 74F280A 9-Bit Parity Generator/Checker plus one AND gate. Figures 214–8b expands the logic block diagram of the Family's Parity Tree Logic (inside the dashed line of Figure 214-8a).

During TRANSMIT mode (A_N = Hi-Z), the PARITY and $\overline{ERROR}$ outputs are generated from the A_N input/output port. In the RECEIVE mode, the B_N port is the input from the system or mother board bus (B-port outputs = Hi-Z).

For best speed performance, PARITY should always be generated from the A_N port for the B_N port (TRANSMIT mode), and parity $\overline{ERROR}$ should always be checked for data coming in on the B-port (RECEIVE mode). EVEN or ODD parity generation and checking is determined by the EVEN/$\overline{ODD}$ input (EVEN = HIGH & ODD = LOW).

In the TRANSMIT mode (T/$\overline{R}$ = HIGH), transmitted data travels from the A-port to the B-port in less than 8.0ns generating a PARITY bit output in less than 16.0ns. Whereas, in the RECEIVE mode (T/$\overline{R}$ = LOW), received data traverses from the B-port to the A-port path in, again, less than 8.0ns, but then, the $\overline{ERROR}$ checking output, being generated from the output data presented to the A-port and the PARITY input, takes an additional 16.5ns or less to

stabilize. Therefore, the total RECEIVEd-data-to-$\overline{\text{ERROR}}$ checking output propagation time is the sum of the B_N-to-A_N delay (8ns) and the A_N/PARITY-to-$\overline{\text{ERROR}}$ output delay (16.5ns) or 22.5ns.

However, in many cases, the propagation delay that has to be taken into consideration does not have to include parity calculation time and could be equal to that of just the transceiver part (8ns). This is due to the fact that it may not be too late to interrupt whatever needs to be interrupted in case of a parity error after the data has already gone by (i.e. via late bus error).

Parity Tree Analysis

The basic 3-Input Comparator Cell, inside the dashed line in Figure 214-8b, is used throughout the Parity Bus Series. If there are an even number of HIGH inputs (0 or 2) the output of the 3-input Comparitor Cell will be HIGH, while an odd number (1 or 3) will produce an output LOW. The 74F657's Parity Tree Logic, combines four of the 3-Input Comparators with a 2-input comparator, a 2-input AND gate and output buffers for PARITY and $\overline{\text{ERROR}}$ to produce the complete parity generator/checker logic.

The 74F588 IEEE-488 Octal Transceiver

The 74F588 is a non-inverting IEEE-488 standard transceiver contains eight bidirectional 3-state buffers. The B_N port outputs can source/sink -15mA/64mA (guaranteed) and have series termination resistors as specified in the IEEE-488 specification. The A_N port, which interfaces to the PC board or system logic bus, is guaranteed to source/sink -3mA/24mA. The 74F588 pinout in identical to that of the 74F545 Octal Transceiver with the IEEE-488 termination resistors in series with the B_N port.

Metastability in Latches and Registers

Interfacing a basically asynchronous real-world with synchronous logic systems can and does cause many circuit designer headaches. The problem: latches and registers which are normally considered to have only two stable states (High and Low) actually have a third – The METASTABLE State. This third operating point occurs when the cross-coupled latch is exactly balanced. This state is only stable when there is no noise on the chip which would tend to destablize the perfect energy balance between the bistable states of the latch. Refer to Figure 214-9.

Metastability can occur when input data violate the setup time or hold time specifications at the clocking or strobing edge of the synchronizing clock input. With no system noise the latch can't decide "yes or no" so it is possible for the latch to "go metastable" or "maybe." With noise on the chip, random energy will "nudge" the latch toward one of its "bistable" states – HIGH or LOW. This metastable state time can range from nanoseconds to milliseconds. With today's very high performance logic families, the metastable condition can last for perhaps 1000 times the latch's normal propagation delay time. A metastable latch has an unpredictable delay time during which the output is between logic levels. This metastable state can easily last more than 50ns with today's high performance logic families and WILL cause systems to "crash" if great care isn't taken with asynchronous, real-world interfacing.

The D-type latch shown in Figure 214-9 has DATA applied to NAND gate 1 and $\overline{\text{DATA}}$ applied to NAND gate 2. When the LE (Latch Enable) input is LOW, gates 1 & 2 outputs are HIGH and the G3/4 R-S latch is latched and stable. When LE is HIGH, the latch appears to be transparent to the DATA input – Q equals DATA. On the HIGH-to-LOW transition of LE, the DATA logic level that meets the latch's setup and hold time is stored in the latch.

If DATA changes during the setup time to hold time period, it is possible for both outputs of gates 1 & 2 to be in the input tresholds region of gates 3 & 4, respectively. Under these conditions, the latch (gates 3 & 4) could be perfectly balanced in the METASTABLE state. Eventually, chip and system noise will cause the latch to be force into a HIGH/LOW stable state.

The Extended Octal-Plus© Family, while not entirely immune, has been made metastable resistant by using design techniques which force the latch toward a stable state much more quickly than older bus interface families.

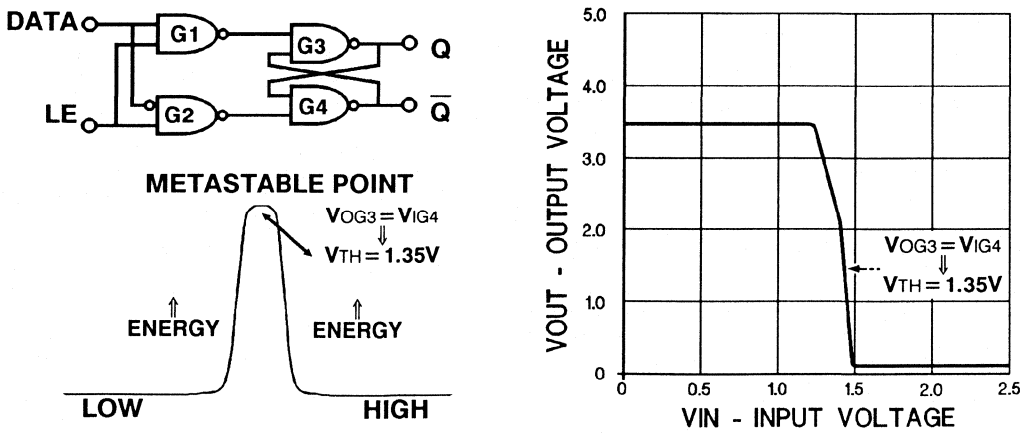

Figure 214-9. Metastability in Latches and Registers

74F Extended Octal-Plus Family Applications AN214

Dual–Registered Transceiver Applications

Figure 214–10 illustrates how the 74F646–9 and 74F651–4 can be used to either synchronize data transfer between two systems or pipeline data. Data is stored in a register, then, while retreiving more data, the first data is read. When the second is available it can either be stored or read directly. Two slower systems can be multiplexed into a high speed system in the same way.

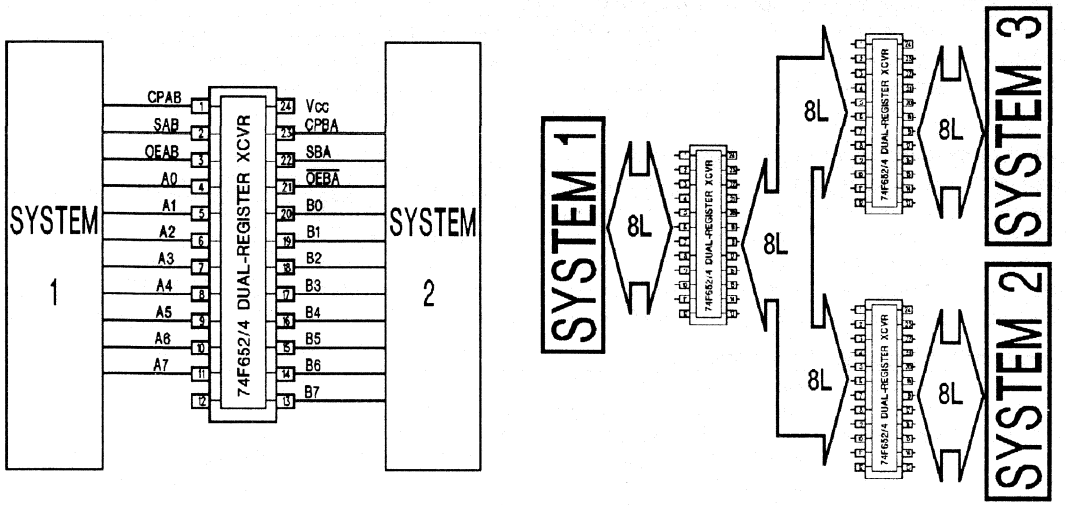

Figure 214-10. 74F Extended Octal–Plus© Dual–Registered Transceiver Applications

Parity Bus Transceiver Applications

Figure 214–11 illustrates the functional density advantages of the Parity Bus Series using the 74F657 in a typical microprocessor/data bus transceiver application. Note the 74F245 + 74F280A version would still require a 2–input AND gate and 3–state buffers for the PARITY and $\overline{\text{ERROR}}$ outputs. And, of course, it would require an order of magnitude higher input current than a single 74F657 would and would also introduce much higher capacitive loading (for both the bus and the microcontroller).

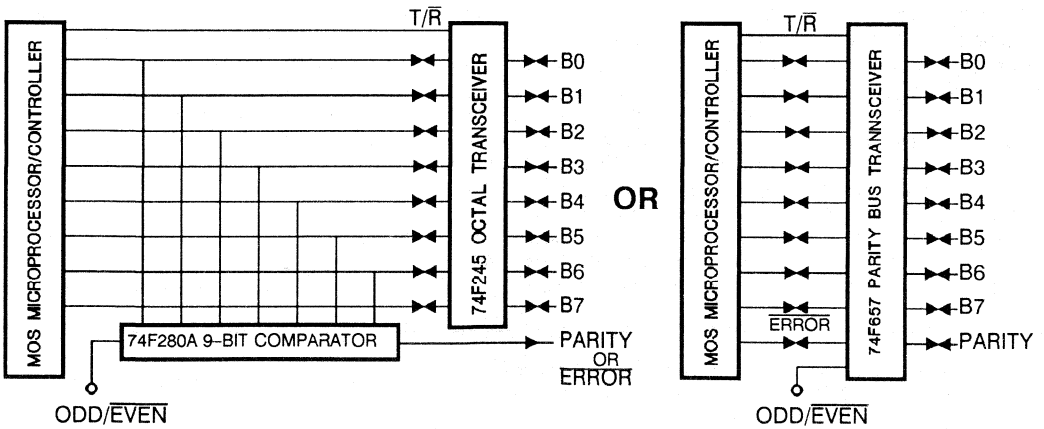

Figure 214-11 74F657 Parity Bus Transceiver Applications

AN215

74FXXXX "Light Load" Input Products

Application Note

Major "Light-Load" Input Features

- Patented "Light-Load" NPN Input Structure
  - Normal Input Pins = ±20μA per input
  - Transceiver I/O Pins = ±70μA per I/O pin
  - Primarily Capacitive Loading = <10pF
- Ideal for MOS CPU, Peripherals & Semi-custom Bus Interfaces
- Patented Turn-OFF Speed-up Circuit
- No Significant Speed Disadvantage -- Standard 74F Speeds
- PC Board Transmission Line Drive Capability: -15/64mA I_{OH}/I_{OL}
- "Broadside" Design in 20-, 24- and 28-Pin Slim-DIP Packages
- "Light-Load" Family Includes:
  - 19 Buffers and Line Driver Parts
  - 19 Shift Register, Register & Latch Parts
  - 19 Transceivers (No Storage)
  - 8 Dual Registered Transceivers
  - 7 Arithmetic Functions

Introduction

The Signetics 74F "Light Load" product line is a high performance, TTL bus compatible series of very low input bias current (±20μA), buffer/driver, transceiver, register, multiplexer and arithmetic MSI functions. The patented "Light Load", ±20μA NPN input structure, shown in Figure 215-1, combined with a unique input speed-up circuit (also patented) makes this product line ideal for interfacing with all MOS devices, without any speed degradation. When compared to the I_{IL} of standard FAST inputs of 600μA (larger for some other logic families) this "Light Load" input shows a 30:1 reduction in I_{IL} loading (600μA/20μA).

These devices were specifically designed to meet the requirements of buffering low output drive MOS VLSI/LSI devices from the rigorous loading environment PC board/mother-board busses and system back planes. The "Light Load" Inputs and improved speed performance make this product line ideal for interfacing to low output drive capability, slower MOS CPU, peripherals and semi-custom chips used in most state-of-the-art logic designs today's. Using these "Light Load" Input bus products, MOS chip outputs will only have to drive the small amount of distributed PC trace capacitance and inductance loading. The MOS device output drive capability isn't wasted on drivers/transceivers with large DC input current drive requirements.

See Table 215-1 for a complete listing of the part numbers and functions of the "Light Load" product line.

"Flow-Through" Design

Figure 215-2 illustrates the pin configurations of the 74F84X Latched Buffer Series. Notice that all of the "Light Load" Input data bus products use a "Flow-Through" design which allows logic signals to flow into one side and out of the other without crossing or folding back on signal paths such as the 74F24X octal series. Comparing the physical PC board signal bus path layout required for the 74F845 Octal Registered Buffer to that of the zig-zag signal

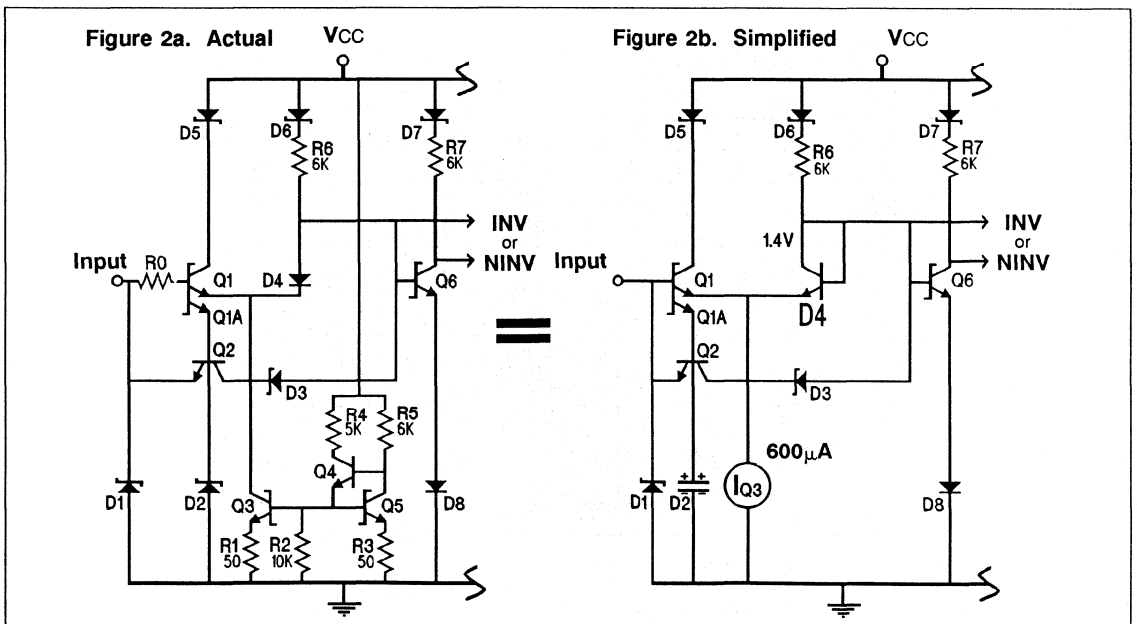

Figure 215-1. The "Light-Load" and Speed-Up Circuit Input Structure (Actual & Simplified)

The 74F "Light Load" Input Products

AN215

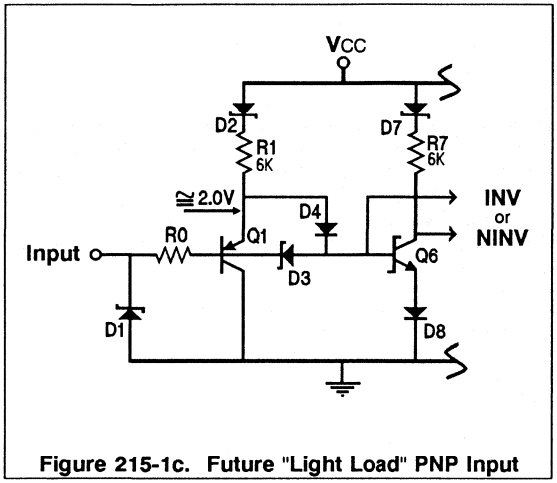

Figure 215-1c. Future "Light Load" PNP Input

path of the 74F240 Octal Inverting Buffer, you will see the significant advantages of the this product line's "Flow-Through" design in simplifying the design and layout of large, bus-oriented PC boards.

The "Light Load" Input product line combines "Flow-Through" design, high speed performance and high functional density into 20-, 24-and 28-pin, 300-mil Slim-DIP packages significantly reducing system propagation delays, parts count, power dissipation, PC board area/complexity and, therefore, total cost while enhancing total system reliability.

Input Structure - Differential Amplifier

Figure 215–1 shows the circuit diagram of the patented "Light Load" NPN Input (Q1/3, R6 & D4) and the Turn-OFF Speed-Up Circuit (Q2, D2 & D3). This input structure is actually a linear differential amplifier consisting of Q1, D4 and a constant current sink made up of Q3/4/5 and R1/2/3. The input bias current of this amplifier is less than $\pm 20\mu A$ for V_I between 0.0V and 5.5V. The Turn-OFF Speed-Up circuit (D2/Q2/D3) quickly discharges Q6's base-collector stored-charge to ground. The following analysis assumes room temperature and 5.0V_{CC} operation.

The Q1's base is the input side of the differential amplifier and D4's anode is the reference side. When the input is HIGH (2.0V), Q1 is turned-ON and I_{CE} plus I_{BE} current flows into Q3's constant current sink network of ~600μA. Since D4's anode is clamped at 1.3V to 1.4V by the V_{BE} of Q6 plus D8's voltage drop, and since Q1's emitter voltage is pulling the cathode of D4 up to greater than ~1.4V (the 2.0V_{IH} minus Q1's 0.6V_{BE}), R6's (6K) current can not flow through D4 and forward biases Q6's base-emitter.

Since Q6 is a Schottky clamped transistor, it has a V_{CEsat} ~0.5V. When Q6 is turned-ON by R6, the voltage at its collector drops to ~0.9V from ground (adding in D8 voltage drop) which turns-OFF the output totem-poll pull-down driver transistors and turns-ON the pull-up. This topic will be discussed in more detail in the next section (Refer to Figure 215-3).

Input Structure - Constant Current Sink

The constant current sink produced by Q3/4/5 and R1/2/3/4/5 sinks a relatively constant 600μA to ground. This "current mirror" circuit drives the base-to-ground voltage of Q3 and Q5 to Q5 V_{BE} plus the voltage drop across R3. Since Q3 and Q5 are identical, the voltage drops across R1 will equal that of R3. Therefore, the current

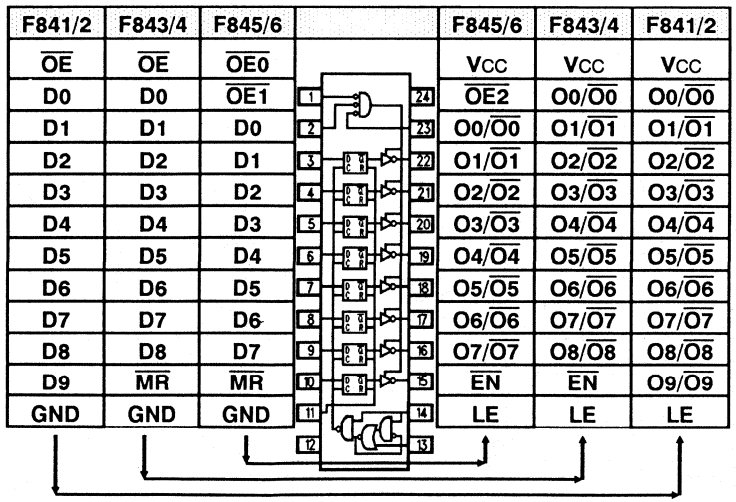

Figure 215-2. 74F84X Latched Buffer Pin Configurations

through R1 equal the current through R3 times the ratio of R3:R1.

The base bias currents for Q3 and Q5 is supplied by Q4. Because of the relatively high βs of Q3 and Q5 (>50), their base currents of ~10μA do not significantly effect the currents through R3 and R1 (β or BETA = transistor current gain). At 25°C and V_{CC} = 5.0V, R3's current is approximately equal to:

$I_{R3} = [V_{CC} - (V_{BE\text{-}Q4} + V_{BE\text{-}Q5})]/(R3 + R5)$

$I_{R3} = (5.0V - 1.2V)/(50\Omega + 6000\Omega) \cong 600\mu A$

Therefore:

$I_{CE\text{-}Q3} \cong I_{R1} = I_{R5} * (R3/R1) \cong 600\mu A$

With Q1's β also greater than 50, the HIGH logic level input bias current is less than 20μA:

$I_{OH} = I_{CE\text{-}Q3}/BETA_{Q1} \cong 600\mu A/>50) < 12\mu A$

The "Light Load" PNP Input

We will soon be introducing a new product line of "Light Load" PNP devices. One of the first products will be the 74F821 through 74F826 Registered Buffers which will have the same pin configurations and options as the 74F841 through 74F846 Latched Buffers (See Figure 215–2). The 74F82X series will provide a positive–going edge triggered clock input to its 8-, 9- and 10-bit register storage parts versus the 74F84X series' HIGH level Latch Enabled latches.

With Signetics' latest oxide–isolated process, a new, high performance "Light Load" PNP input structure will soon be available. This new PNP input, shown in Figure 215–1c, provides a high impedance AND input structure versus the NPN input OR input and reduces the chip power dissipation by eliminating the requirement for a constant current source for each input.

The PNP input is still a differential amplifier with the cathode of D3 referenced to 2 V_{BE} voltage drops from ground. When the input is HIGH ($V_{IH} \geq 2V$), no Q1 emitter–base current can flow because the anode of D3 is clamped to the 2 V_{BE}. As D4 forward biased with the current from R1, the output driver transistor (Q6) turns ON. When the input is LOW ($V_{IL} \leq 0.8V$), Q1's emitter–base junction is forward biased which turns ON the β amplified emitter–collector current of Q1. When Q1 is ON, the anode of D4 is clamped OFF by the input V_{IL} voltage plus Q1's emitter–base drop ($V_{IL} + Q1V_{BE} \leq 0.8V + 0.6V = 1.4V$). Therefore, the input threshold at the base of Q1 is ≅ 1.4V (2 V_{BE}) at 25°C.

With the β of Q1 typically greater than 100, the V_{IL} input bias current is guaranteed to be less than 20μA. With the input HIGH, the input leakage is also guaranteed to be less than 20μA. The β amplification of Q1 is basically the only difference between this PNP input's 20μA I_{IL} and the standard diode input's I_{IL} of 600μA.

When the base of Q1 is switched LOW, the Schottky diode D3 provides a turn–OFF speed–up path to ground which quickly discharges the base of the driver transistor (Q6).

Output Structures

A characteristic example of the output structures found throughout the 74FXXXX Light Load Product Line is the 74F657 Parity Bus Transceiver which has two basic output designs. Figure 215-3 illustrates the 74F657's output structure designs of these output structures: A_N Port's output (Figure 3b) is guaranteed to handle –3/+24mA (2.4/0.5V V_{OH}/V_{OL}), and the B_N Port (Figure 3a) can drive greater than –15/+64mA (2.0/0.55V V_{OH}/V_{OL}). The A_N port is

designed to drive the chip side of the PC board to backplane interface, while the B_N Port is capable of driving PC board data transmission lines and back plane signal line with a characteristic impedance as low as 70Ω.

Referring back to Figure 215–1a, the base drive current for Q9/10/11 comes from either R6 for an inverting output or R7, if the output is non-inverting. For the inverting case, D4 is back-biased when the base voltage applied to Q1 ($\geq 2.0V_{OH}$) and Q9 base drive is supplied from R6. Q9's base is clamped at the sum of base-emitter forward biased voltage drops of Q9/10/11 and Q12. Q12's base drive primarily comes from R10/11/12 when Q9/10/11 are ON.

When Q9/10/11 begin to turn–ON, the base drive for Q12 must first overcome the R13/D13 base clamp before current can flow into Q12's base. During the output voltage HIGH to LOW transition, this delay minimizes totem–pole feed–through current into the ground lead by allowing the collector of Q11 (Phase Splitter Transistor – Q_{PS}) to pull down toward 1 V_{BE} + 1 V_{CEsat} and, thereby, turning–OFF the Q13/14 darlington totem–pole output pull–up driver before Q12 completely turns–ON.

When the gate input switches from V_{IH} to V_{IL} ($\leq 0.8V$), the charge stored in D2 discharges through the base–emitter of Q2. Q2 (through D3) quickly pulls the bases of Q9/10/11 toward ground. When the collector of Q9 rises high enough (~1.3V) to forward bias the Q12 base clamping network of D9/R8/R9/Q7/Q8, Q12 is quickly turned–OFF before the Q13/14 totem pole pull–up can turn–ON. This design minimizes feed–through ground during the output voltage LOW to HIGH transition.

The 3-state, totem-pole output structures of both the A_N and B_N ports have Schottky blocking diodes, D15, in their pull-ups. Their purpose is to block leakage current from flowing into the outputs when V_{CC} is either open or shorted to ground. These diodes will not let current flow until the output voltage reaches 5.5V.

The I_{OS} limiting resistors, R15, limit the amount of current that can be sourced from the HIGH to ground. Note that R15 is 12Ω for the B_N outputs and 30Ω for the A_N outputs. Therefore, under the same conditions, the B_N output pull-up structure will be able to source 2.5 time more current than the A_N outputs.

Minimizing Ground Bounce

Refer to Application Note AN213 – 74F30XXX Family Applications for a detailed discussion of "ground-bounce" and internal noise generation due to reduced ground lead inductance. When a TTL output switches from LOW to HIGH or HIGH to LOW some feed-through or crossover current will be injected into the ground lead of the IC while both the pull-up and pull-down output drive structures are ON simultaneously. The larger the number of switched outputs the larger the feed-through current and "ground bounce."

"Ground bounce" directly effects the input threshold of a gate and, therefore, its noise sensitivity. The newer output structure design used in the "Light Load" NPN Input Product Line allow all outputs to switch simultaneously with minimal "ground bounce."

Arbitration In Shared Resource Systems

Application Note

INTRODUCTION

The need for more powerful and faster systems gave birth to multiprocessing and multitasking systems. But to achieve this, cost and reliability were not to be sacrificed. To reduce cost it is vital to share resources, but to do so requires reliable means of arbitration. In a multiprocessing system, a single bus may be shared between various processors or intelligent peripherals. The resources shared by processors (Figure 1) are generally termed as global resources and those shared between the local processor and the peripherals (Figure 2) are typically known as local resources. Whether local or global, there always exists a protocol that will connect and disconnect various devices to and from the shared resources. Various bus architectures in existence today have different ways of doing this.

No matter what the protocol of a specific bus, there is always a method which dictates how arbitration shall be performed between two or more devices. Some systems employ synchronous arbitration and some use an asynchronous approach. The third option is not to use arbitration at all, but instead to employ time-multiplexing. This is used mainly in data communications by dividing the common media into various time slots. Each processor (station) is assigned a predetermined time for using the media. If the station does not need to use the media during its assigned time-slot, it may pass control to the next station. This obviously results in an inefficient use of the bus bandwidth.

Synchronous and asynchronous arbitration have their advantages and disadvantages, and are both used in system designs. Some applications may even use a combination of the two. Generally, synchronous arbitration is used in systems where the designer can take the time to synchronize signals with the master clock. In synchronous arbitration the request is sampled on a clock edge, and therefore if it is asserted close to, but after the sampling clock edge, it will not be recognized

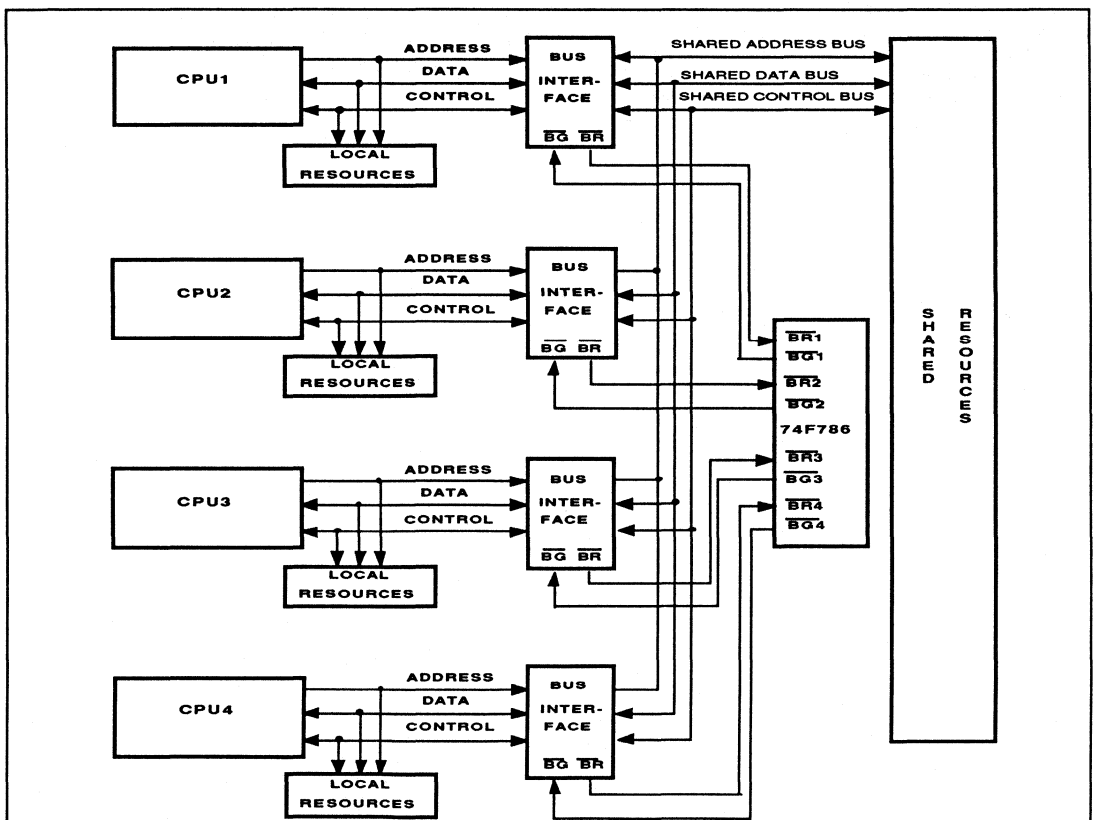

Figure 1: Sharing global resources

July 18, 1988

until after a whole clock cycle. Todays applications, where speeds are being pushed to their limits may not find that an optimal solution. Therefore more and more designers tend towards asynchronous arbitration because it is much faster on the average. Since applications vary drastically from one to another, some may be better served by first-come-first-serve arbitration, some with fixed priority and some with dynamic priority.

In a first-come-first-served scheme as the name implies, the request to be asserted first is selected first. All other requests made after the first are queued in their respective order of assertion. After the current request is serviced, the request asserted second will be selected and so on. If the request just serviced is asserted again, before all other active requests are serviced, it will be placed at the end of the queue. In a fixed priority method all inputs have a hard-wired priority and cannot be changed. In a dynamic priority assignment the user can change the priority depending upon the system needs. For example, processors performing vital tasks may be placed at a higher priority as compared to processors doing background tasks.

Arbitration, whether synchronous or asynchronous, always brings up the question of "metastability". A hard fact that relates itself all the way back to the beginning of the history of electronics. In its simplest definition it is the state of a flip- flop that is neither a logic"1" or a logic"0", and is a result of violations of its set-up and hold times. This condition must be allowed and dealt with in arbitration and synchronization designs.

Metastability

Various publications have talked about this subject and given recommendations for reducing but not completely eliminating this potential problem. Briefly the suggestions consist of using very fast flip-flops (with very small set-up and hold times), using multiple flip-flops and delay lines and designing of metastable-hardened flip-flops. Please note that a metastable-hardened flip-flop does not necessarily mean that it will never enter a metastable state, but rather it is a flip-flop that is highly optimized to be used in applications where the system designer can not guarantee the minimum set-up and hold times specified by the manufacturer. Since, as of today, the design of a metastable free flip-flop is not practically possible, the next best thing that could be done is design of a flip-flop with significantly reduced set-up and hold times and reduced propagation delays. This will ensure reduced probability of being in a metastable state. Since we still will have some probability of not meeting the minimum set-up and hold times and potentially being in a metastable state, another requirement to be im-

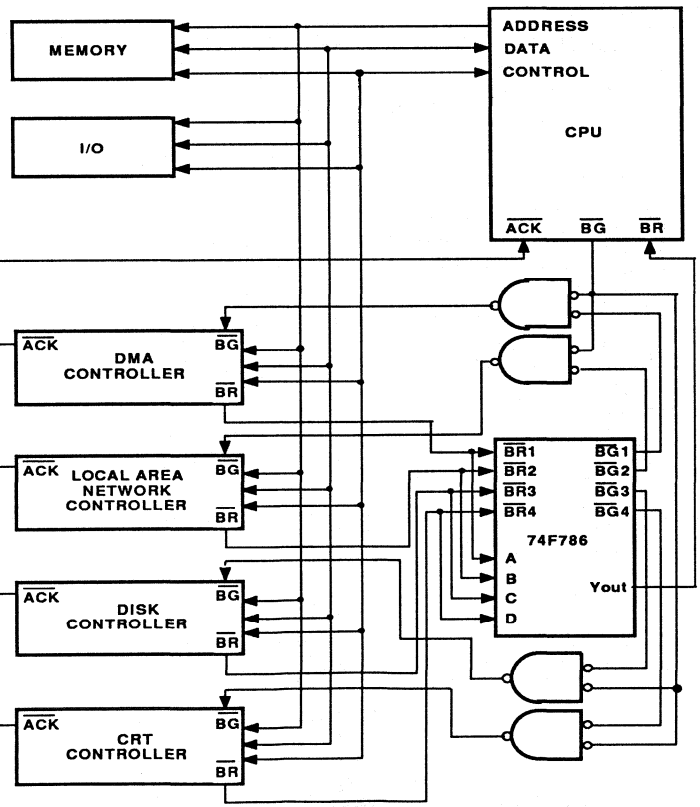

Figure 2: Sharing local resources

posed on this flip-flop would be to hold its previous state and not to propagate this invalid state to its outputs until it has decided to settle in a "0" or a "1" state. By doing so it could be guaranteed that the outputs of a flip-flop will never be in an undetermined state even though the flip-flop may internally be in a metastable state. The penalty that the user would expect to pay in such a design will be a propagation delay that can extend beyond the maximum specified in the data sheet.

74F786- 4-Input Asynchronous Arbiter

The key consideration when arbitrating for shared resources is that access may not be granted to more than one device at a given time. If this could be guaranteed, it would improve reliability. This application note describes a product from Signetics, which guarantees against simultaneous grants and does so at very high speeds. The Signetics 74F786 (Figure 3) is a general purpose asynchronous bus arbiter designed to address the needs for real-time applications, where arbitration is desired between multiple devices sharing common resources. The design goal was to provide for a device, the outputs of which could be guaranteed against logic hazards (glitches), metastability and that no more than one output could be active at a given time. The arbiter has four Bus Request ($\overline{BR}_n$) inputs which allow arbitration between two to four asynchronous inputs. The priority

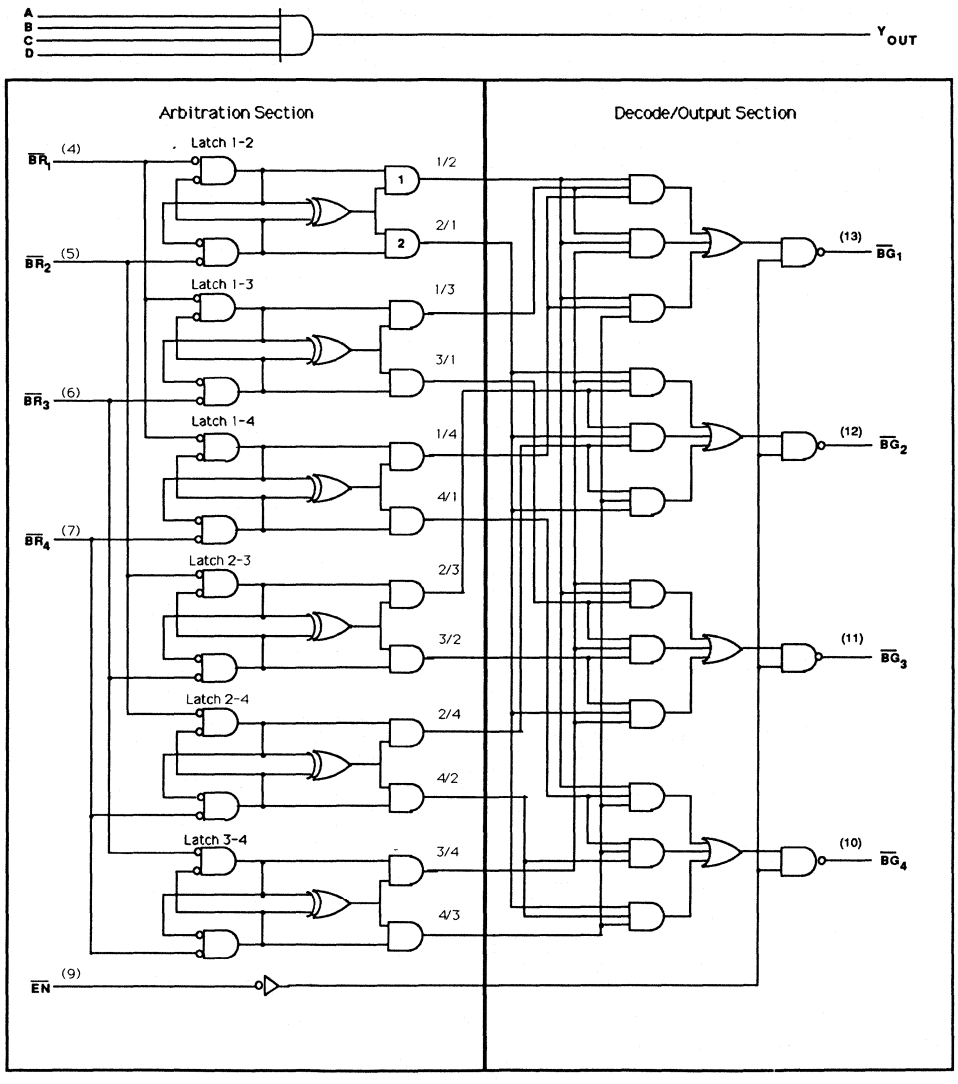

Figure 3: 74F786 logic diagram

is determined on a first-come-first-served basis. Corresponding to each input is a separate Bus Grant ($\overline{BG_n}$) output which indicates which one of the request inputs is served by the arbiter at a given time. All these outputs are enabled by a common enable ($\overline{EN}$) input. Also included on-chip, is a general purpose four-input AND gate which may be used to generate a bus request signal (Figures 2) or as an independent AND gate.

Since the Bus Request inputs have no inherent priority, the arbiter assigns priority to the incoming requests as they are received. Therefore, the first request asserted will have the highest priority. When a Bus Request is received, its corresponding Bus Grant becomes active, provided $\overline{EN}$ is LOW, and no other Bus Grant is active. Typically, a Bus Grant is selected in 6.6 nsec from the time of assertion of a request input. If additional Bus Requests are made after the first request goes LOW, they are queued in their respective order. When the first request is removed, the arbiter services the request with the next highest priority, based upon a first-come-first-served algorithm.

Metastable-Free Outputs

The 74F786 logic diagram (Figure 3) consists of two sections: the arbitration section and the decoding/output section. Within the arbitration section lie six independent 2-input arbiters each of which arbitrates between the two Bus Request ($\overline{BR_n}$) inputs connected to that specific arbiter. Each 2-input arbiter is comprised of two cross-coupled NOR gates, an EX-OR gate and two AND gates. The cross-coupled NOR gates are designed so that they are securely latched when a schottky diode voltage difference appears between the outputs of these NOR gates. The EX-OR gate is designed so that its output will remain LOW until there is at least 1Vbe difference between its inputs. This creates a noise-margin of 1Vbe (base to emitter voltage)-1Vsky (schottky voltage) ≈ 0.3 Volts and assures that the output of the EX-OR will not go HIGH until after the two NOR gates have resolved any contention problems. This guarantees that neither of the outputs of a 2-input arbiter can be in a metastable state, and also that both outputs cannot be high simultaneously. As is clear from Figure 3, the first 2-input arbiter is responsible for deciding between the $\overline{BR_1}$ and $\overline{BR_2}$ inputs. Since both AND gate outputs cannot be high at the same time, the other three possible configurations are; First, AND gate1 is HIGH indicating that $\overline{BR_1}$ arrived at the latch before $\overline{BR_2}$ (designated 1/2); second, AND gate2 is HIGH indicating $\overline{BR_2}$ arrived before $\overline{BR_1}$ (designated 2/1) and third both AND gates are LOW indicating that neither $\overline{BR_1}$ nor $\overline{BR_2}$ has been latched.

Glitch-Free Outputs

The decode section of the 'F786 is responsible for insuring that the outputs do not glitch or produce a logic hazard. While there are three possible Karnaugh mappings, to produce an optimum decode section with a minimum number of transistors and balanced propagation times, the mapping in Table 1 was chosen. Solving Table 1 for $\overline{BG_1}$-$\overline{BG_4}$ yields the following equations:

$\overline{BG_1}$=1/2.1/3.1/4+1/2.1/3.3/4+1/2.1/4.4/3
$\overline{BG_2}$=2/1.2/3.2/4+2/1.2/3.3/4+2/1.2/4.4/3
$\overline{BG_3}$=3/1.3/2.3/4+1/2.3/1.3/4+2/1.3/2.3/4
$\overline{BG_4}$=4/1.4/2.4/3+1/2.4/1.4/3+2/1.4/2.4/3

To see if a glitch can occur let's take the worst possible case, that is, let $\overline{BR_1}$ beat $\overline{BR_2}$, 2 beat 3, 3 beat 4 and 4 beat 1 (a possible situation when all inputs are asserted simultaneously). Also, let's have the outputs of the arbitration section switch sequentially. Initially, all the variables in the equations are false (remember, the outputs of the arbitration section have three possible states). First, when 1/2 goes true 2/1 must remain false. This eliminates several terms from playing a role in deciding which output becomes active. In fact, $\overline{BG_2}$ has been removed from the list and is no longer a contender. At this point, while all the outputs are high (inactive) we have decided that $\overline{BG_2}$ will remain inactive. This leaves us with the following equations.

$\overline{BG_1}$=1/2.1/3.1/4+1/2.1/3.3/4+1/2.1/4.4/3
$\overline{BG_3}$=3/1.3/2.3/4+1/2.3/1.3/4+~~2/1.3/2.3/4~~
$\overline{BG_4}$=4/1.4/2.4/3+1/2.4/1.4/3+~~2/1.4/2.4/3~~

Similarly when 2/3 goes true 3/2 must remain false, which further eliminates a term from thus set of 3 equations.

$\overline{BG_1}$=1/2.1/3.1/4+1/2.1/3.3/4+1/2.1/4.4/3
$\overline{BG_3}$=~~3/1.3/2.3/4~~+1/2.3/1.3/4+~~2/1.3/2.3/4~~
$\overline{BG_4}$=4/1.4/2.4/3+1/2.4/1.4/3+~~2/1.4/2.4/3~~

Now when 3/4 goes true 4/3 must remain false. This eliminates $\overline{BG_4}$ from the contending list and the contest now is between $\overline{BG_1}$ and $\overline{BG_3}$ as indicated from the following equations.

$\overline{BG_1}$=1/2.1/3.1/4+1/2.1/3.3/4+~~1/2.1/4.4/3~~
$\overline{BG_3}$=~~3/1.3/2.3/4~~+1/2.3/1.3/4+~~2/1.3/2.3/4~~

When 4/1 goes true 1/4 must remain false.

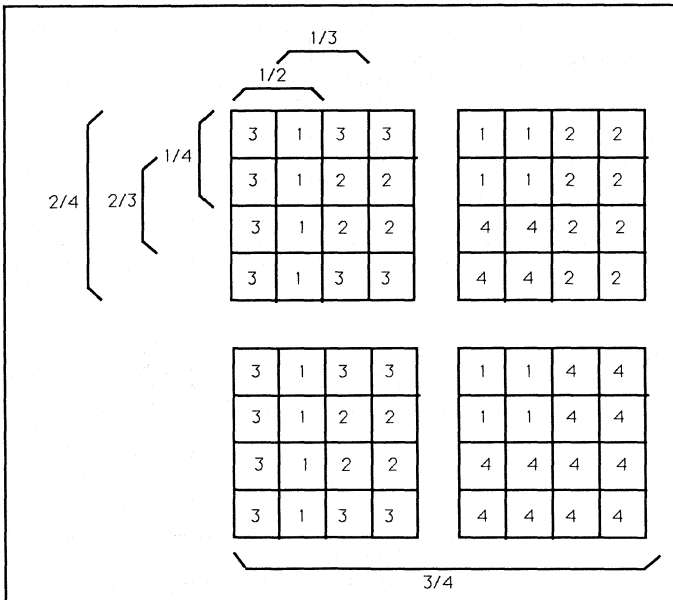

Table 1: 74F786 Karnaugh mappings

Still no decision has been made and is dependent on the two 2-4 and 1-3 latches not taken into account yet. In this case the 2-4 latch status is a don't care, so the outcome of the 1-3 latch dictates the Bus Request granted.

$\overline{BG}_1$=1/2.1/3.3/4
$\overline{BG}_3$=1/2.3/1.3/4
If the 1-3 latch settles in the 1/3 state $\overline{BR}_1$ gets the grant, and with 3/1 remaining false, $\overline{BG}_3$ will remain inactive. Similarly if the 1-3 latch goes to the 3/1 state $\overline{BR}_3$ gets the grant, and with 1/3 remaining false $\overline{BG}_1$ will remain inactive.

Notice that the Bus Grant was given in this case without regard to the 2-4 latch. In fact, a quick review shows that neither the 2-3 latch nor the 1-4 latch played a role in making the decision. Each grant is dependent on the state of three latches. By the nature of the encoding logic, as the three activating latches are switched, three outputs are forced to remain in an inactive state. This insures a glitch-free output.

Let's assume that in the example above, the 1-3 latch goes to the 1/3 state and hence $\overline{BG}_1$ is asserted. At this time the other five latches in the circuit will be in 1/2, 4/1, 2/3, 2/4 and 3/4 states. If at this point $\overline{BR}_3$ is removed, then latch 3-4 changes from 3/4 to 4/3 and hence $\overline{BR}_4$ steals the grant (with 1/2.4/1.4/3). This concludes that if three or more requests are asserted precisely at the same time, and one of them is removed prior to being serviced, it may cause premature termination of the present grant and assertion of another grant. Therefore, when using three or more Bus Requests it is not advised to remove a request before being serviced. On the other hand, arbitration between two requests does not have this restriction. The user if necessary, may decide to remove an ungranted request at his discretion.

Extended Propagation Delays

Since the outputs of the six 2-input arbiters can not display a metastable condition, the Bus Grant outputs can not display a metastable condition because the decoding/output section does not have any storage element to go metastable. Even though the Bus Grant outputs can't go metastable, the cross-coupled NOR gates can. To determine the metastability characteristics of these NOR gates, the 'F786 was evaluated by Mr. Thomas J. Chaney of Washington University in St. Louis, Missouri, who is considered to be a leading expert in this field. Table 2 gives of the 19 devices supplied to him, the test results from the fastest, the slowest and a typical package. In order to determine the Mean Time Between Package Unresolved (MTBPU) with the relative arrival times of the two input signal transitions uniformly distributed, the following formula is used:

MTBPU= $[\exp(t'/\tau)]/[T_0(\text{Input 1 rate})(\text{Input 2 rate})]$.
Where:
t'= Time given to resolve contention between inputs after they are asserted and τ and T_0 are device parameters derived from tests and can most nearly be defined as:

τ= A function of the rate at which a latch in a metastable state resolves that condition.
& T_0= A function of the measurement of the propensity of a latch to enter a metastable state. T_0 is also a very strong function of the normal propagation delay of the device.

Solving for t', the resolving time measured from the arrival of the first input, and setting up the equation so the value of T_0 in Table 2 (given in nsec.) can be substituted directly is:

$t'=(\tau)\ln[(T_0)(3E14)]$.
The implication of the above equation is that, even though typical propagation delay through the arbiter is about 6.6nsec, contention between inputs may extend this time significantly and can be calculated from Table 2.

Package	Latch	Output Measured	τ (nsec)	T_0 (nsec)	h (nsec)	t' for 1 failure/century (Inputs at 10E6hz)
FASTEST	1-2	13	.38	175E2	6.6	16.6
	1-3	13	.39	79E2	6.6	16.4

Metastability Tests For The 74F786- A 4-Input Asynchronous Bus Arbiter

Application Note

INTRODUCTION

Under contract with Signetics, Mr. Thomas J. Chaney of Washington University, St. Louis tested a set of nineteen 74F786 samples (packages) to determine the metastable state recovery statistics for the circuits. The tests were conducted using a procedure described in a paper entitled "Characterization and Scaling of MOS Flip-Flop Performance", (section IV), by T. Chaney and F. Rosenberger, presented at the CalTech Conference on VLSI, Jan. 1979. The general test procedure was to test all 19 packages under one condition, then test the best, worst, and an average package in more detail. According to Mr. Chaney, the test results from the 19 packages formed one of the tightest groupings that he had ever seen. As the parts were numbered, package No. 7 had the fastest resolving times, No.11 produced some of the slowest resolving times, and No.1 had resolving times near the middle of the test results. This ranking of the test results from 3 packages remained the same through out the balance of the test program, which supports the complete testing of only 3 packages. In general, the poorest performance resulted when the packages were heated to near 75 °C with Vcc = 4.5vdc and the best performance resulted when the packages were cooled to near 0 °C with Vcc = 5.5vdc.

The variation within one package caused by the temperature and Vcc changes was greater than the variation from package to package. It must be noted that none of the packages tested even approached the data sheet input to output worst case propagation delay of 10.5ns. All the packages tested for a single active output, had propagation delays of about 6ns. Typically, the parts with longer propagation delays also have slower resolving times. Thus one would expect that the delay time needed to have only one failure in 32 years using a 10nsec. propagation delay part would be much longer than a value derived from just adding 10-6=4 ns to the above calculations. Thus it appears that the poorest performance measured in this study should be considered a measurement at the edge of the typical range for 74F786 parts.

It must also be noted that the tight grouping of this set of packages means that, when comparing differences between these test results, the measured error, as outlined in "Measured Flip-Flop Responses to Marginal Triggering", IEEETC, Dec. 1983, is significant. This is illustrated in association with Table 5.

Test Program And Data

Through out the test period, the connections to some of the package pins was as shown in Figure 1. The 4 input pins (1, 2, 3 and 15) to the AND gate were all grounded. The output of the AND, pin 14, was left open. The output enable $\overline{EN}$ pin (9) was grounded. The power ground pin (8) was grounded and the Vcc power pin (16) was connected to Vcc. The 4 input pins to the arbiter (4, 5, 6 and 7) were treated as a group with two of the pins always receiving an input from the tester and the other two inputs always connected to Vcc through 1KΩ resistors. For any arbiter input pair configuration, there are two outputs (of the set: Pins 10, 11,12 and 13) active. These two active output pins are each connected to a grounded 510Ω resistor, a grounded 30pF silvered mica capacitor, and a grounded scope probe (13pF). Thus each active output pin has a load of approximately 500Ωs to ground and 50pF to ground (43pF plus 5 to 10pF wiring capacitor). In addition, the active output pin being tested was connected to the input of a comparator (3pF max.). The other input to this comparator was referenced to 1.5vdc. The 1.5vdc reference voltage was not varied with Vcc. The two arbiter input signals generated by the tester were negative going pulses, each of the same width (approximately 100ns), which were time shifted relative to each other to produce metastable behavior in the arbiter circuit. This form of input causes only one of the two possibly active outputs to switch low.

First Pass Through Packages

The test conditions used for the selection process from the 19 packages is shown in Figure 1 with the results shown in Table 1. The values reported in Table 1 were calculated with t' (defined later) at 7.60 and 9.93ns. Note that the active inputs are pins 6 and 7 and the output tested is pin 11. The last column of this table is the period, after two requests, required to assure that the pack-

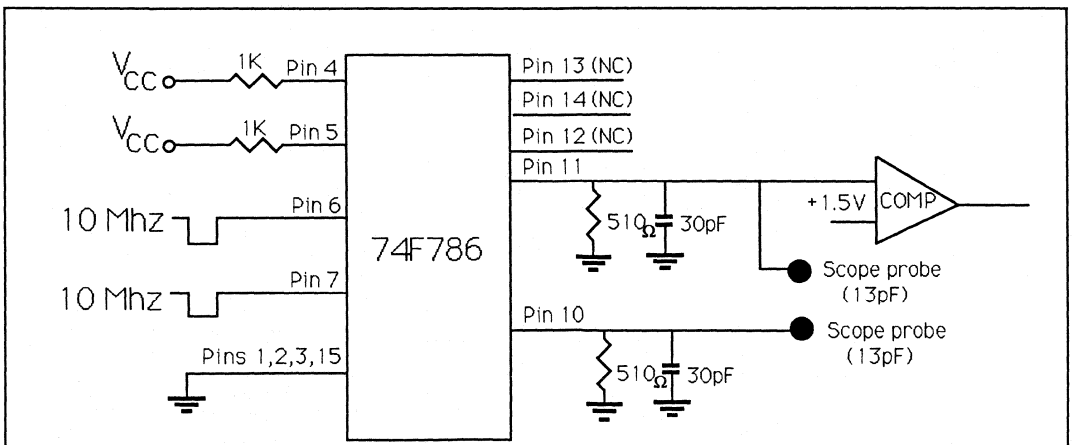

Figure 1: Test set-up for the 74F786

July 18, 1988

Metastability Tests For The 74F786- A 4-Input Asynchronous Bus Arbiter

AN217

age would fail to resolve less than once per century. These numbers are based on the assumption that the 2 inputs are not synchronized and both are running at 10mhz (a 100ns clock period). It is assumed that the relative arrival times of the two input signal transitions are uniformly distributed over the clock period. The Mean Time Between Package Unresolved (MTBPU) is then:

MTBPU = [exp(t'/τ]/[(T_0)(Input1 rate)(Input2 rate)]

Where:

t'= Time given to resolve contention between inputs after they are asserted and τ and T_0 are device parameters derived from tests and can most nearly be defined as:

τ = A function of the rate at which a latch in a metastable state resolves that condition and

T_0= A function of the measurement of the propensity of a latch to enter a metastable state. T_0 is also a very strong function of the normal propagation delay of the device. Also one century = 3E9 seconds.

Solving for t', the resolving time measured from the arrival of the first request, and setting up the equation so the value of T_0 in Table 1 (given in ns) can be substituted directly gives:

$$t' = (\tau)1n[(T0)(3E14)]$$

As a result of the first round of tests, three packages were selected for further testing. Package 7 was selected as the fastest, package 11 as the slowest, and package 1 as a typical package.

Package Number	τ (ns)	T_0(ns)	h (ns)	t' for 1 failure/century (inputs at 10E6hz)

Second Set Of Tests

Using the logic diagram of the 74F786 (Figure 2), it is possible to construct Table 2. Note from Table 2 that thus far, all testing has been conducted on latch 3-4 (pins 6 &7). The second set of tests, conducted only on the 3 packages selected from the first set of tests, involved testing each of the 6 latches in the package to select the poorest performing latch in each package. This step also included testing each of the two active output pins for each input condition to select the path with the longest propogation delay.

Package Number	Latch	Output Measured	τ (ns)	T_0(ns)	h (ns)	t' for 1 failure/century (inputs at 10E6hz)
7	1-2	13	.38	175E2	6.6	16.6
7	1-3	13	.39	79E2	6.6	16.4
7	1-4	13	.39	69E2	6.6	16.4
7	2-3	12	.38	109E2	6.6	16.1
7	2-4	12	.39	68E2	6.6	16.5
7	3-4	11	.38	181E2	6.6	16.3
11	1-2	13	.44	34E2	6.6	18.1
11	1-3	13	.44	17E2	6.6	18.0
11	1-4	13	.43	26E2	6.6	17.8
11	2-3	12	.44	16E2	6.6	17.9
11	2-4	12	.46	8E2	6.6	18.5
11	3-4	11	.44	29E2	6.6	18.2
1	1-2	13	.41	56E2	6.6	17.3
1	1-3	13	.42	24E2	6.6	17.2
1	1-4	13	.43	17E2	6.6	17.5
1	2-3	12	.43	18E2	6.6	17.4
1	2-4	12	.39	72E2	6.6	16.6
1	3-4	11	.41	49E2	6.6	17.2

Table 3: Test results for all 6 latches from packages 7, 11 and 1. All tests with V_{cc} = 5.0vdc and at room temperature

The results of this comparison testing is shown in Table 3. The results from this Table indicate that latches1-2 and 3-4 have longer propogation delays than the middle four latches. This propagation delay difference is less than 0.4ns. For each of the conditions tested and reported in Table 3, there is a second active pin that could have been used to measure the performance of the latch under test. For package 1 only, the other active pin was tested for each of the latchs. The results of this test are shown in Table 4. In theory, the results should be the same except for possible differences in propogation delay. The value of τ should be the same, but the value of T_0 could be different. In all 6 cases, the active pin previously not tested had a shorter propagation delay (function of T_0) than the active pin that was tested.

Table 4 also indicates something else. That

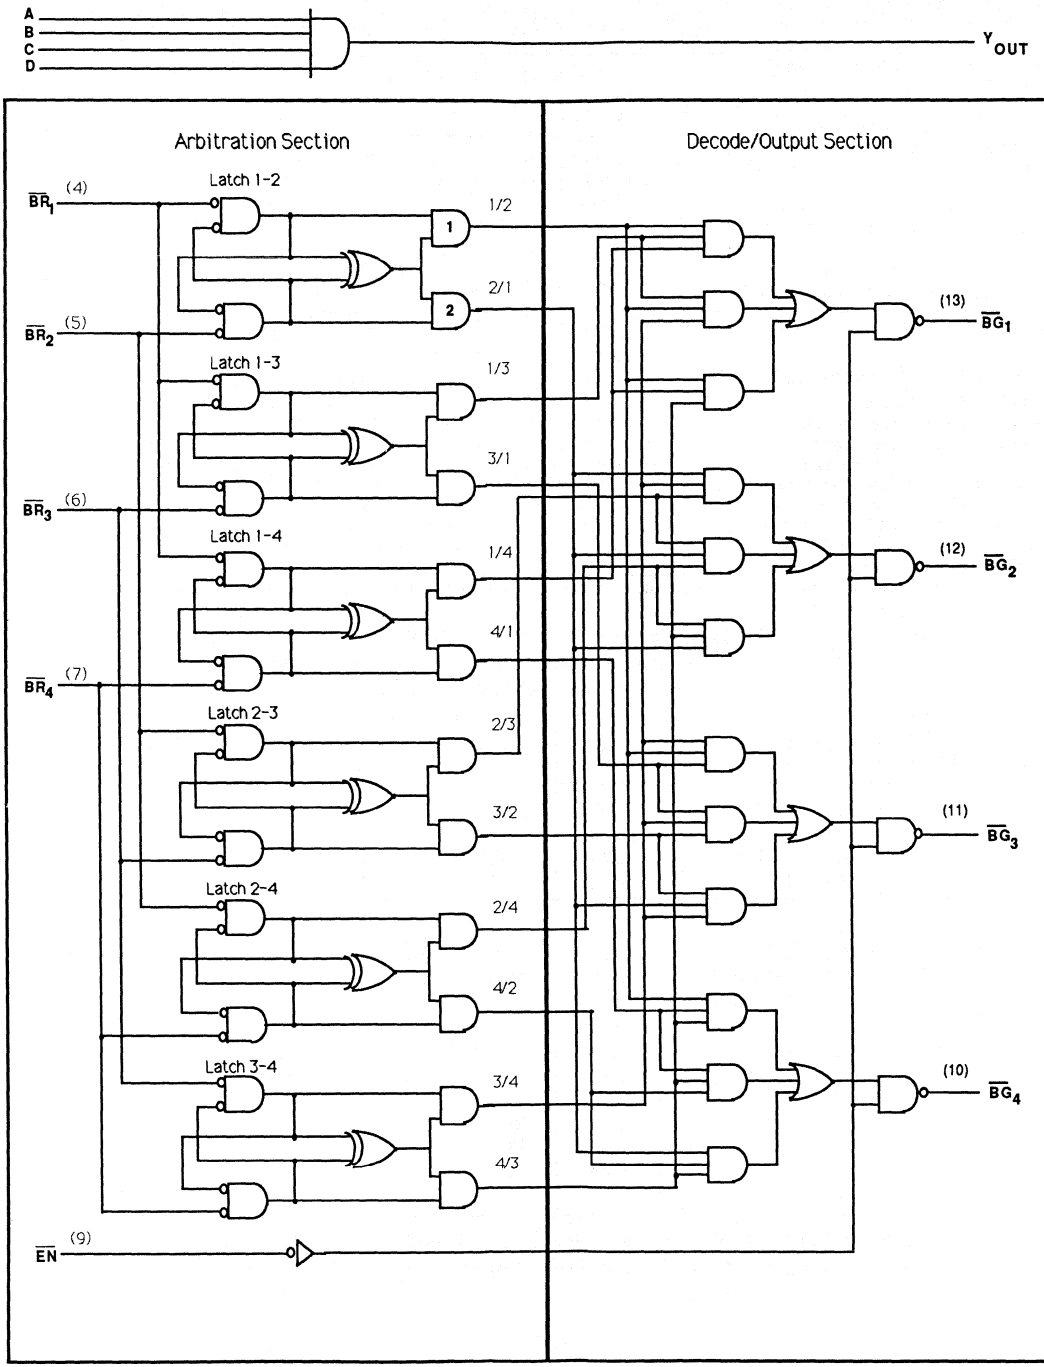

Figure 2: 74F786 logic diagram

is the accuracy with which the data in this report can be interpreted. Note that τ varies as much as 0.05ns, which is within the 0.06ns measurement error range of the test equipment used.

The results of the second set of tests are:
(1) The 6 latches in each of the 3 selected packages behaved the same, relative to each other.
(2) In all 3 packages, the latch selected is of little importance, therefore, Latch1-2 was selected at random for further testing.
(3) It was reasonable to continue with the 3 selected packages and to restrict further testing to latch1-2 and to only record data from pin 13.

Temperature And Power Supply Variation Testing

The temperature and power supply variation testing was conducted on packages 1, 7 and 11. These tests were conducted on latch1-2 only of each package (inputs 4 and 5, results measured at pin 13). The results are shown in Table 5. The poorest performance was measured again from package 11. The worst case condition was measured at Vcc = 4.5vdc and the case temperature at 75°C and is shown in Table 5 as a bold entry. This line gives what could be considered the worst case measured performance from the 19 packages tested.

Package Number	Latch	Output Measured	τ (ns)	T_0(ns)	h (ns)	t' for 1 failure/century (inputs at 10E6hz)

AN218
DESIGN HIGH PERFORMANCE MEMORY BOARDS USING FAST LOGIC AND SIMPLE TRANSMISSION LINE TECHNIQUES

Application Note

INTRODUCTION AND OVERVIEW

With ever increasing memory speeds and correspondingly higher speed drivers, transmission line effects in memory boards are becoming more and more of a problem. An engineer can easily control, manipulate or work around the transmission line effects if he has all the information he needs and he understands how to use it. This article will supply that information and understanding as well as a fairly detailed look at some of the most common problems encountered in memory board design.

The article has three main parts. The first part lists and briefly explains the transmission line equations which will be used in the rest of the paper. The second part provides capacitance, inductance, and driver current/voltage information which is useful when applying the transmission line equations to memory boards. The third part is a detailed look at problems which often arise in memory board design and an evaluation of the solutions in common use.

PART 1: TRANSMISSION LINE EQUATIONS

A signal line in the memory array of a bare printed circuit board has both capacitance and inductance (L) distributed along its length. When the memory chips are inserted, the input capacitance of each input the signal line must drive is added to the line's distributed capacitance to give the total capacitance (C). The characteristic impedance (Z_0) of the signal line is given by Equation 1. Note that since (L) and (C) are both directly proportional to the length of the line, characteristic impedance is not a function of line length.

Eq. 1 $Z_0=(L/C)^{1/2}$

Equation 2 gives the current (I) a driver needs to source in order to change the voltage on a signal line by an amount (V). Notice that I-V relationship of the line at its input is that of a resistance (Z_0) to the voltage existing on the line before the driver tried to change it.

Eq. 2 $I=V/Z_0$

When the voltage is changed at the driven end of a signal line, the voltage wave travels down the line at a finite speed. Equation 3 gives the time (T) it takes for a transition to propagate from one end of the signal line to the other.

Eq. 3 $T=(LC)^{1/2}$

When a voltage wave ($V_{incident}$)travels down a signal line and encounters an impedance change from Z_0 to some new impedance (Z_1), $V_{incident}$ will split into a reflected part ($V_{reflected}$) and transmitted part ($V_{transmitted}$). $V_{reflected}$ will (as the name implies) travel back up the line toward the driver, and $V_{transmitted}$ will travel on down the line in the original direction of propagation. $V_{reflected}$ and $V_{transmitted}$ are given by Equations 4 and 5.

Eq. 4 $V_{reflected}=V_{incident}(Z_1-Z_0)/(Z_1+Z_0)$

Eq. 5 $V_{transmitted}=V_{incident}+V_{reflected}$

PART 2: TRANSMISSION LINE PARAMETERS IN MEMORY BOARDS

In order to use the preceding equations, an engineer will need to know the inductance and the capacitance of the signal lines in his memory board, and the output I-V relationship of the drivers on that board. This section provides the information needed for a quantitative understanding of all the examples which will be shown later. However, there are simply too many memory drivers and memory parts to fully document here. The information will still provide a very broad qualitative understanding of transmission line behavior in memory boards, and this qualitative understanding is a very powerful design and debug tool.

INDUCTANCE AND CAPACITANCE

Figures 1 and 2 show how the distributed inductance and capacitance of a signal line vary with width and dielectric thickness on a fiberglass memory board with a ground plane. These figures are not exact, but they don't have to be exact. A 15 percent error in the calculated characteristic impedance or propagation delay of a memory board signal line is unlikely to cause any problems, and this means that a 30 to 35 percent error in the inductance or the capacitance of a signal line will likely be allowable (because of the square root relationship between L and C and Z_0). By the same reasoning, a typical input capacitance of 3pF is suggested for calculations, although from some memory suppliers it will be closer to 2pF, while from others it will be closer to 4pF.

Note that on a two layer memory board there is no ground plane, so Figures 1 and 2 can't be applied. The distributed capacitance for 15 mil line on a typical 60 mil thick two layer memory board is about 1pF/inch, and the distributed inductance is around 20nH/inch.

BALLPARK CALCULATIONS

Ballpark estimates for the characteristic impedance and propagation speed can be calculated using the preceding information and typical packing densities for various memory packaging modes. The dual-in-line package (DIP), for instance, is typically packed on a board at around a 0.5 inch pitch so that there are two inputs for a one inch length of line. This means that the input capacitance on a one inch length of line will be 6pF. Figures 1 and 2 show that for a typical four layer memory board, with a line width of 10 mils and a dielectric thickness of 15 mils, the distributed capacitance for a one inch length of line will be about 3pF, and the distributed inductance for the line will be about 12nH. The values for L and C (required for use in Equations 1 and 3) for this one inch DIP

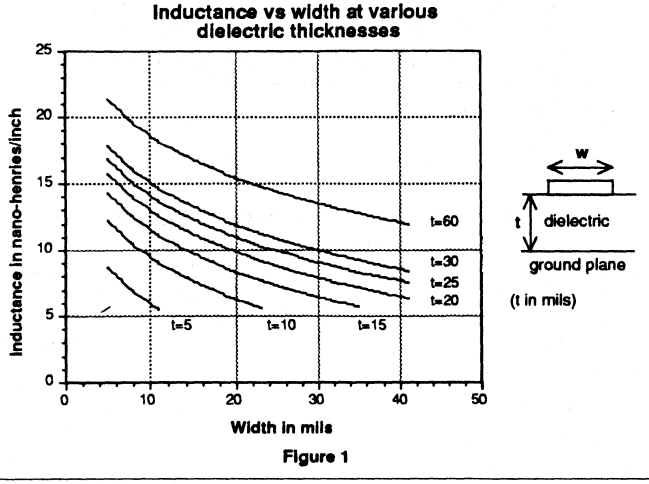

Figure 1

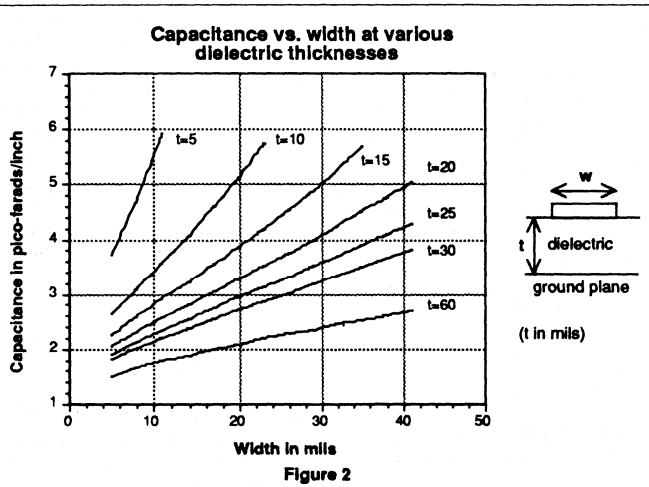

Figure 2

Package	Pitch	L	C	Z0	T
DIP	0.5 inch	12 nH	9 pF	37 ohms	0.3ns
ZIP	0.2 inch	12 nH	18 pF	26 ohms	0.5ns
SIP	0.3 inch	12 nH	103 pF*	11 ohms	1.1ns

* SIP capacitance includes on-module wiring capacitance of 6 pF per module.

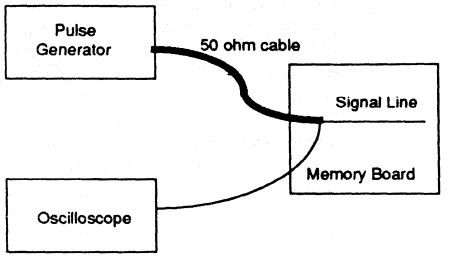
Table 1

memory line will be 12nH and 9pF. The ballpark characteristic impedance and propagation delay for one inch lengths of DIP, ZIP, and SIP memory lines are shown in Table 1.

MEASURING IMPEDANCE AND PROPAGATION DELAY

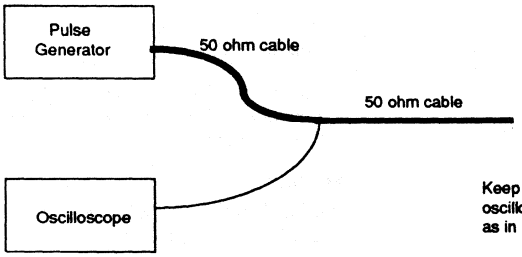
Often an engineer will want to analyze a board which has already been built. In this case, it is easy to directly measure the characteristic impedance and the propagation delay of the signal lines using an oscilloscope and a pulse generator rather than calculating it from its inductance and capacitance. To do this, connect the pulse generator, unterminated signal line, and oscilloscope as shown in Figure 3a. The oscilloscope waveform will have the same basic shape as the one in Figure 3c. The initial voltage drop (V1) is the transmitted signal from the 50 ohm cable to the signal line, and the second voltage drop (V2) is its reflection from the unterminated (infinite impedance terminated) end of the signal line. Notice that for a change in impedance from some finite impedance (Z_0) to an infinite impedance, Equation 4 predicts that the reflected signal will be of the same magnitude and sign as the incident signal, i.e., the initial voltage drop will travel to the end of the line and then reflect as a voltage drop of the same magnitude as the first, and then it will propagate back up the signal line to the oscilloscope input. The time difference (2T) between the midpoints of these two voltage drops is twice the propagation delay of the signal line. Measure V1 and record it as $V_{transmitted}$. Then replace the signal line with a length of 50 ohm cable about a meter long as shown in Figure 3b. The oscilloscope waveform will still have the same basic shape, but the initial voltage drop will probably be different. Since this time the initial voltage drop (V1) is the transmitted signal from 50 ohms to 50 ohms, it will be equal to the incident signal. Measure V1 and this time record it as $V_{incident}$. Application of Equations 4 and 5 followed by a little algebraic manipulation yields the characteristic impedance of the signal line:

$$Z_0 = (V_{transmitted}/(2V_{incident}-V_{transmitted})) 50\Omega$$



Notes: The pulse generator must be set with a low enough amplitude and a high enough DC offset that reflections don't go below ground or above Vcc. The signal's edge rate must be less than twice the line delay. The oscilloscope probe must have a high impedance. The memory board should have power applied and the memory chips installed.

Figure 3a



Keep the pulse generator and oscilloscope settings the same as in Figure 3a.

Figure 3b

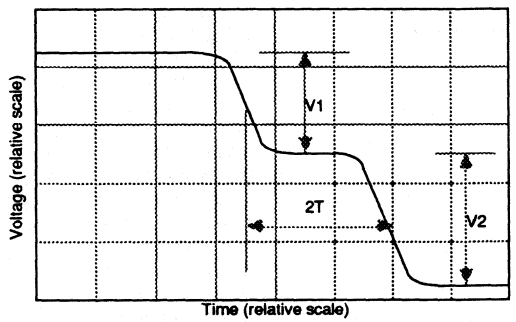


Figure 3c

DRIVER I-V CHARACTERISTICS

In order to anticipate the behavior of a particular driver in a memory board, an engineer will need to know the driver's I-V output characteristics. This information is given in Figures 4 and 5 for the parts which are used later as examples. Figure 4 shows the current each part will sink as a function of output voltage when it is in the low state, and Figure 5 shows the current each part will source as a function of output voltage when it is in the high state.

It should be noted that the curves for the 74F765 are representative of the standard 24ma FAST™ output, the curves for the 74F3037 are representative of the standard FAST™ 30 ohm line driver output, and the curves for the 74F765-1 are representative of all Signetics DRAM controllers which have a "dash one" designation.

PART 3: COMMON PROBLEMS AND THEIR SOLUTIONS

Transmission line problems in memory boards generally become significant when signal line propagation delays approach or exceed 1ns. The reasons for this will become apparent in the analysis of the following problems. A look at the "ballpark" estimates made earlier shows that a 1ns long transmission line translates to about 3 inches of DIP, 2 inches of ZIP, or 1 inch of SIP based memory line. Since these lengths are exceeded in most memory boards, transmission line problems are very common.

UNDERSHOOT

One of the most common problems noticed in memory design is a violation of the specified minimum input voltage of the memory chips (-1v). An example of this is shown in Figure 6 where a 24ma FAST™ part drives a 60 ohm line hard enough that the reflection at the opposite end of the line goes 3.5 volts below ground. This violation (usually referred to as "undershoot") would almost certainly cause the memory chips to malfunction.

The analysis of Figure 6 starts with a load-line method which proves to be very important for determining the incident wave. The 60 ohm transmission line of Figure 6 is initially settled to a high voltage of about 5 volts. When the line's driver then goes into the low state, its output voltage and current is given by the intersection of the driver's output I-V curve (Figure 4) with the input I-V curve of the transmission line. This input I-V curve is a line through the points (5v,0ma) and (0v,83ma) (from Equation 2), and the point of intersection of the two curves is about (.75v, 75ma). The incident voltage wave ($V_{incident}$) is a -4.25 volt change from 5 volts to .75 volts. This voltage wave propagates to the end of the line opposite the driver where it encounters an impedance change from 60 ohms to an infinite impedance. The reflected wave (from Equation 4) at this impedance change will be $V_{reflected} = V_{incident} = -4.25$ volts, i.e., a change from .75 volts to -3.5 volts, and subsequent reflections of this wave account for the continued peaks and valleys.

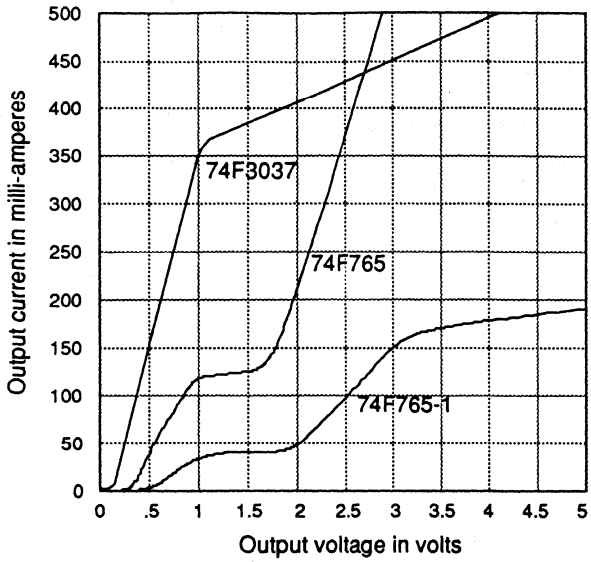

Figure 4 Voltage vs Current of Low State Outputs

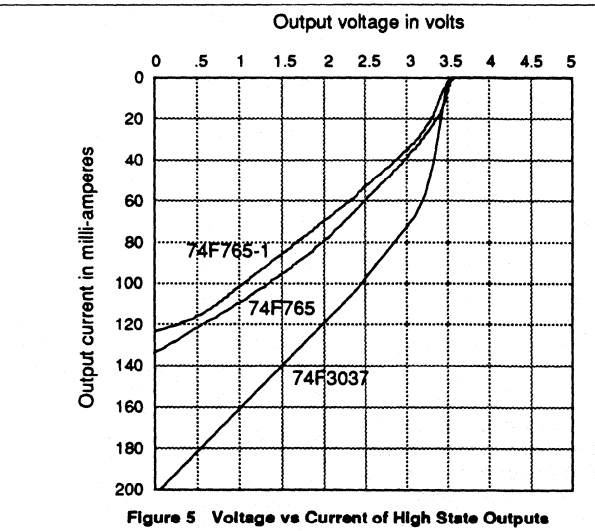

Figure 5 Voltage vs Current of High State Outputs

There are three basic methods an engineer can use to work around this problem.

Method 1. Use a slower driver and/or drive pieces of the line in parallel to effectively speed up the line.

Method 2. Increase the impedance of the driver or decrease that of the line.

Method 3. Put some finite impedance on the end of the line opposite the driver.

Method 1 (Slow Driver, Fast Line)

The idea behind the first method is to allow only one volt of the transition to fit onto the line at a time. By limiting the slew rate of the driver to less than 1 volt in twice the propagation delay of the line, one can guarantee that the undershoot will also be less than a volt. To apply this method to the example in Figure 6, we would break the 5ns long transmission line into four 1.25ns long sections and use a driver which made the 5 volt transition in a minimum of eight nanoseconds. The drawbacks of this method make it impractical for most designs. These drawbacks include:

- the requirement for a controlled slew rate driver with a very specific slew rate;
- the impact on timing due to the required slow transition time;
- the layout inconvenience of short memory lines in systems having more than an eight bit word.

Method 2 (Reflected Wave Switching, or "series termination")

The idea behind the second method is to reduce $V_{incident}$ to 50% of the total desired transition and then rely on the reflection from the unterminated end of the line to complete the transition. The usual way of doing this is by putting a resistor in series with the output of the driver (see Figure 7a) so that the impedance of the driver is roughly matched to that of the line. It is easy to show (from Equation 2) that this will result in an incident wave equal to half the desired transition and (from Equation 4) that the reflection from the unterminated end of the line will complete the transition. Since the driver's impedance is equal to that of the line, the reflected wave will not produce a second reflection when it returns to the driver (see Equation 4).

The two ends of a line driven with the series termination method are monitored by an oscilloscope in Figure 7b. Notice that the voltage at the driven end of the line is in the input threshold region for a time equal to twice the propagation delay of the line. This time spent in the threshold region often skews the address lines enough with respect to the row and column address strobes in dynamic memory boards that the row and column address setup times fail or become marginal. This problem can be avoided by allowing for an extra 2T worth of setup time in the design, but the increased delay quickly becomes

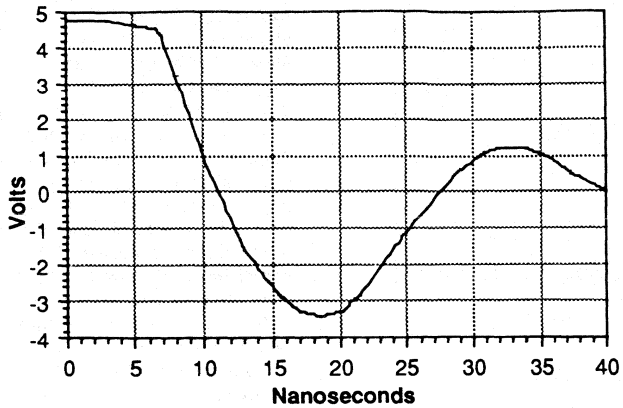

Figure 6 Oscilloscope view of the un-terminated end of an address line. The line has 32 DIPs, a line delay of 5ns, and it is driven by a 74F153.

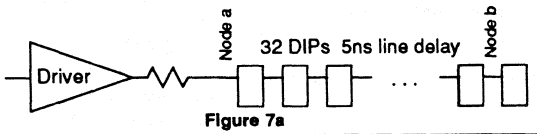

Figure 7a

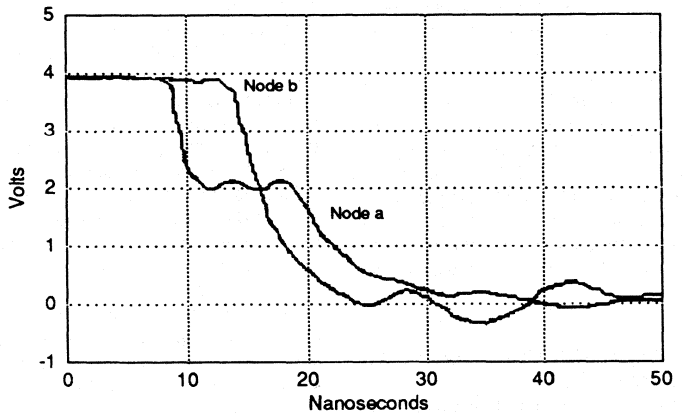

Figure 7b

a problem in large memory boards. Since any ground noise can easily cause multiple transitions to be made on signals which are left in the threshold region, this method should be used with caution on the strobe lines.

Series termination is probably the most widely used method for driving signal lines on memory boards. One reason for its popularity is that a very rough match between the driver's impedance and the impedance of the line will still make a memory line behave properly. It can be shown from Equations 2 and 4 that if the driver's impedance is within +50% and –40% of the line's characteristic impedance, the reflected wave will not violate the –1 volt minimum input voltage specification or the .8 volt maximum low input voltage specification. Thus a 30 ohm output impedance will work reasonably well with the ballpark estimates made previously for DIP and ZIP packages even if a large variation in input capacitance occurs from one memory chip vendor to the next.

The series termination method is offered by Signetics and several other companies in integrated circuits (the 74F721 and 74F723 for example). Signetics also offers an extension of this idea in some of its dynamic RAM controllers (see Figure 8). The output stage for these controllers will reflected wave switch lines in the 17 to 67 ohm range rather than the 18 to 45 ohm range one gets with the more conventional 30 ohm output impedance.

Method 3 (Terminations)

The basic idea behind this method is to place some terminating impedance at the end of the line opposite the driver. The simplest form of this would be a resistor ($R=Z_0$) to a constant voltage. In this case the reflection (undershoot) would be eliminated (see Equation 4). This termination can be generalized to the two resistor network in Figure 9c in which two resistors in parallel equal Z_0 and the terminating voltage is usually set to around three volts by a 2 to 3 ratio in the resistors. This termination offers very high performance, and it is particularly suited to high speed, high drive, open collector drivers like the 74F3038.

The high D.C. power dissipation of termination 9c can be avoided by using a capacitor to provide the constant voltage (see Figure 9e). This termination offers adequate undershoot suppression, and at the same time the lack of D.C. current flow often provides higher noise margins. This termination and the previous one should only be used in cases where the driver has adequate drive to fully switch the line with the incident wave, because there will be no reflection to make up for partial transitions.

Finally, Figure 9d shows a diode termination which can be used with any driver whether it is switching lines on the incident wave or not, and this termination has a lower power dissipation than either of the previous two terminations. This termination will also tend to speed up the transition time at the terminated end of the transmission line (notice that this transition time is always slow due to losses in

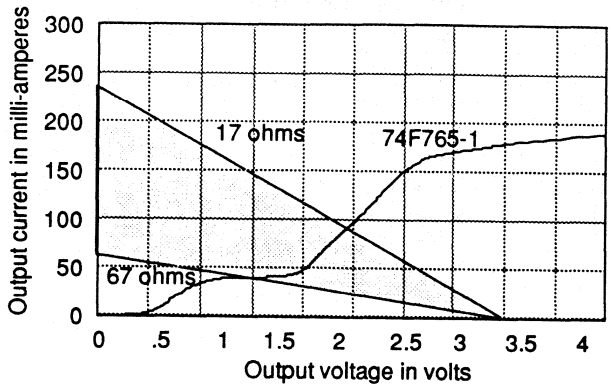

Figure 8 Current vs voltage for 74F765-1 output and 17 to 67 ohm transmission lines settled to 4 volts. Since the intersection of the output curve with each of the transmission line curves is between 1.5 and 2.4 volts, these impedances are all suited to first reflected wave switching by the 74F765-1 (the incident wave to 2.4 v will reflect to .8 v and the incident wave to 1.5 v will reflect to -1 v).

the line). The 74F133 has a high speed Schottky diode from ground to each of its 13 inputs, so it can be used as a low cost termination pack for this method. The method typically limits undershoot to just short of a volt which is not as good as can be achieved with the previous terminations, and the method is somewhat worse in relation to noise, but it can be used very effectively.

NOISE

Often, when one signal line is switched, voltage spikes (noise) will appear on adjacent lines. These voltage spikes can generally be traced to the lead frame inductance of the driver, the inductance of the ground plane, or the mutual inductance between adjacent signal lines. This noise is generally increased as transition times and line spacings are decreased and as line lengths are increased. Lines with terminations 9a, 9b and 9d will typically exhibit more noise than those terminated with 9c and 9e.

Noise can easily become a very serious problem in memory design, but Figure 10 shows that adherence to a few simple guidelines will keep noise down to an acceptable level even under the most adverse conditions. First, use a ground plane or minimize the length of the ground trace from the driver to the memory chips. Second, use lots of decoupling capacitors (especially on two layer boards). Finally, if noise does become a problem, change to a different termination and/or driver.

BRANCH INDUCED WAVEFORM DISTORTION

Infrequently, memory lines travel a considerable distance as a single line (several nanoseconds) and then branch into two or more directions. This can result in severe waveform distortion like that shown in Figure 11. In this example, a series terminated line travels 3ns as a single line and then splits into two parallel branches which are each 3ns long. The 2 volt incident wave travels down the line to the branch where the impedance of the line is effectively halved. At this point a reflection of $2\,V \times (.5\,Z_0 - Z_0)/(.5\,Z_0 + Z_0) = -.67$ volts travels back towards the driver, which drops the voltage of this first section of line back down from 2 volts to 1.3 volts. This section of the line stays at 1.3 volts for 6ns, at which point the reflections return from the unterminated ends of the two branches and bring the voltage back up above the input threshold again. The glitch seen at the driven end of this line would clearly be undesirable on any memory signal line.

Avoid long branches.

SUMMARY

The steadily increasing speed of memories, memory drivers and the systems these devices are being used in has created a need for engineers to understand, manipulate, subdue, or work around transmission line effects. This paper has presented the basic tools needed to accomplish this task, and it has given insight into where they are useful. Although several line driving and terminating techniques have been discussed, their individual advantages and disadvantages make it difficult to make general recommendations which are not tied to specific applications. The basic equations which govern transmission line behavior should augment the discussions on line driving and terminating techniques and their impact on undershoot and crosstalk, allowing the reader to adapt the ideas to his specific application.

 Figure 9a	Reflections	- Large, edge rate dependent
	Noise	- Poor
	Power	+ Low power
	Noise Margins	+ Large noise margins
	Hints	Often equivalent to 9b when driving SIPs or parallel banks of DIPs or Zips
 Figure 9b	Reflections	+ Limits or eliminates undershoot
	Noise	Poor on very low impedances, but good on higher impedances.
	Power	+ Low power
	Noise Margins	+ Good DC noise margins
		- Leaves signals in the threshold for 2T during transitions
	Hints	Increases setup times by 2T
 Figure 9c	Reflections	+ Limits or eliminates undershoot
	Noise	+ Low noise
	Power	- High power
	Noise Margins	- Usually has poor noise margins unless high current drivers are used
	Hints	Works well with high speed, high drive, open collector parts like the 74F3038 Only good for incident wave switched lines $Z_0 = R1R2/(R1+R2)$
 Figure 9d	Reflections	+ Typically limits undershoot to just less than a volt
	Noise	- Poor
	Power	+ Low power
	Noise Margins	+ Large noise margins once reflections have settled out -1 volt undershoot tends to reflect for several times the line delay which leaves the line somewhat susceptable to noise
	Hints	74F133 can be used as a diode pack. Avoid extremely fast edge rates.
 Figure 9e	Reflections	+ Limits or eliminates undershoot
	Noise	+ Good
	Power	+ Low DC power dissipation
	Noise Margins	+ Large noise margins
	Hints	Primarily for incident wave switched lines

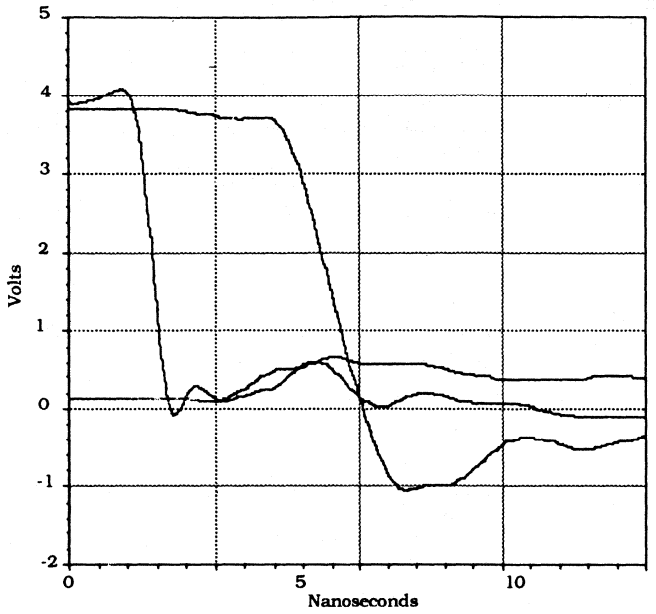

Figure 10 Two adjacent diode terminated lines driven by a 74F3037 on a dual layer Board. The sub-nanosecond edge rate of the driver does not induce excessive noise on the adjacent line even in this poor environment.

DATA HANDBOOK SYSTEM

DATA HANDBOOK SYSTEM

Our Data Handbook System comprises more than 60 books with specifications on electronic components, subassemblies and materials. It is made up of six series of handbooks:

INTEGRATED CIRCUITS

DISCRETE SEMICONDUCTORS

DISPLAY COMPONENTS

PASSIVE COMPONENTS*

PROFESSIONAL COMPONENTS**

MATERIALS*

The contents of each series are listed on pages iii to viii.

The data handbooks contain all pertinent data available at the time of publication, and each is revised and reissued periodically.

When ratings or specifications differ from those published in the preceding edition they are indicated with arrows in the page margin. Where application is given it is advisory and does not form part of the product specification.

Condensed data on the preferred products of Philips Components is given in our Preferred Type Range catalogue (issued annually).

Information on current Data Handbooks and how to obtain a subscription for future issues is available from any of the Organizations listed on the back cover.
Product specialists are at your service and enquiries will be answered promptly.

* Will replace the Components and materials (green) series of handbooks.
** Will replace the Electron tubes (blue) series of handbooks.

INTEGRATED CIRCUITS

This series of handbooks comprises:

code	handbook title
IC01	**Radio, audio and associated systems** Bipolar, MOS
IC02a/b	**Video and associated systems** Bipolar, MOS
IC03	**ICs for Telecom** Bipolar, MOS Subscriber sets, Cordless Telephones
IC04	**HE4000B logic family** CMOS
IC05	**Advanced Low-power Schottky (ALS) Logic Series**
IC06	**High-speed CMOS; PC74HC/HCT/HCU** Logic family
IC07	**Advanced CMOS logic (ACL)**
IC08	**ECL 10K and 100K logic families**
IC09N	**TTL logic series**
IC10	**Memories** MOS, TTL, ECL
IC11	**Linear Products**
Supplement to IC11	**Linear Products**
IC12	**I^2C-bus compatible ICs**
IC13	**Semi-custom** Programmable Logic Devices (PLD)
IC14	**Microcontrollers** NMOS, CMOS
IC15	**FAST TTL logic series**
Supplement to IC15	**FAST TTL logic series**
IC16	**CMOS integrated circuits for clocks and watches**
IC17	**ICs for Telecom** Bipolar, MOS Radio pagers Mobile telephones ISDN
IC18	**Microprocessors and peripherals**
IC19	**Data communication products**

DISCRETE SEMICONDUCTORS

This series of data handbooks comprises:

current code	new code	handbook title
S1	**SC01**	**Diodes** High-voltage tripler units
S2a	**SC02***	**Power diodes**
S2b	**SC03***	**Thyristors and triacs**
S3	**SC04***	**Small-signal transistors**
S4a	**SC05**	**Low-frequency power transistors and hybrid IC power modules**
S4b	**SC06**	**High-voltage and switching power transistors**
S5	**SC07***	**Small-signal field-effect transistors**
S6	**SC08***	**RF power transistors**
	SC09	**RF power modules**
S7	**SC10**	**Surface mounted semiconductors**
S8a	**SC11***	**Light emitting diodes**
S8b	**SC12**	**Optocouplers**
S9	**SC13***	**PowerMOS transistors**
S10	**SC14***	**Wideband transistors and wideband hybrid IC modules**
S11	**SC15**	**Microwave transistors**
S15**	**SC16**	**Laser diodes**
S13	**SC17**	**Semiconductor sensors**
S14	**SC18***	**Liquid crystal displays and driver ICs for LCDs**

* Not yet issued with the new code in this series of handbooks.
** New handbook in this series; will be issued shortly.

DISPLAY COMPONENTS

This series of data handbooks comprises:

current code	new code	handbook title
T8	**DC01**	**Colour display systems**
T16	**DC02**	**Monochrome monitor tubes and deflection units**
C2	**DC03***	**Television tuners, coaxial aerial input assemblies**
C3	**DC04***	**Loudspeakers**
C20	**DC05***	**Wire-wound components for TVs and monitors**

* These handbooks are currently issued in another series; they are not yet issued in the Display Components series of handbooks.

PASSIVE COMPONENTS

This series of data handbooks comprises:

current code	new code	handbook title
C14	**PA01**	**Electrolytic capacitors; solid and non-solid**
C11	**PA02***	**Varistors, thermistors and sensors**
C12	**PA03***	**Potentiometers, encoders and switches**
C7	**PA04***	**Variable capacitors**
C22	**PA05***	**Film capacitors**
C15	**PA06***	**Ceramic capacitors**
C9	**PA07***	**Piezoelectric quartz devices**
C13	**PA08***	**Fixed resistors**

* Not yet issued with the new code in this series of handbooks.

PROFESSIONAL COMPONENTS

This series of data handbooks comprises:

current code	new code	handbook title
T1	*	**Power tubes for RF heating and communications**
T2a	*	**Transmitting tubes for communications, glass types**
T2b	*	**Transmitting tubes for communications, ceramic types**
T3	**PC01**	**High-power klystrons**
T4	*	**Magnetrons for microwave heating**
T5	**PC02**	**Cathode-ray tubes**
T6	**PC03**	**Geiger-Müller tubes**
T9	**PC04**	**Photo and electron multipliers**
T10	**PC05**	**Plumbicon camera tubes and accessories**
T11	**PC06**	**Microwave diodes and sub-assemblies**
T12	**PC07**	**Vidicon and Newvicon camera tubes and deflection units**
T13	**PC08**	**Image intensifiers**
T15	**PC09**	**Dry reed switches**
C8	**PC10**	**Variable mains transformers; annular fixed transformers**
	PC11	**Solid state image sensors and peripheral integrated circuits**

* These handbooks will not be reissued.

** Not yet issued with the new code in this series of handbooks.

MATERIALS

This series of data handbooks comprises:

current code	new code	handbook title
C4 } **C5** }	**MA01***	**Soft Ferrites**
C16	**MA02****	**Permanent magnet materials**
C19	**MA03****	**Piezoelectric ceramics**

* Handbooks C4 and C5 will be reissued as one handbook having the new code MA01.

** Not yet issued with the new code in this series of handbooks.

Philips Components – a worldwide Group of Companies

Argentina: PHILIPS ARGENTINA S.A., Div. Philips Components, Vedia 3892, 1430 BUENOS AIRES, Tel. (01) 541-4261.
