|--------|----------|-----------------------------------------------------------------------------------------------------------------------------------|
| SMOD   | PCON.7   | Double baud rate bit. When set to a 1 and Timer 1 is used to generate baud rate, and the serial port is used in modes 1, 2, or 3. |

| Symbol | Position | Function                                                          |
|--------|----------|-------------------------------------------------------------------|
| SIDL   | PCON.6   | Separately idles the serial port for additional power savings.    |
| -      | PCON.5   | Reserved                                                          |
| -      | PCON.4   | Reserved                                                          |
| GF1    | PCON.3   | General-purpose flag bit.                                         |
| GF0    | PCON.2   | General-purpose flag bit.                                         |
| PD     | PCON.1   | Power-down bit. Starting this bit activates power-down operation. |
| IDL    | PCON.0   | Idle mode bit. Setting this bit activates idle mode operation.    |

If 1s are written to PD and IDL at the same time, PD takes precedence.

# CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

80C550/83C550/87C550

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Block Diagram, page 555).

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## IDLE MODE

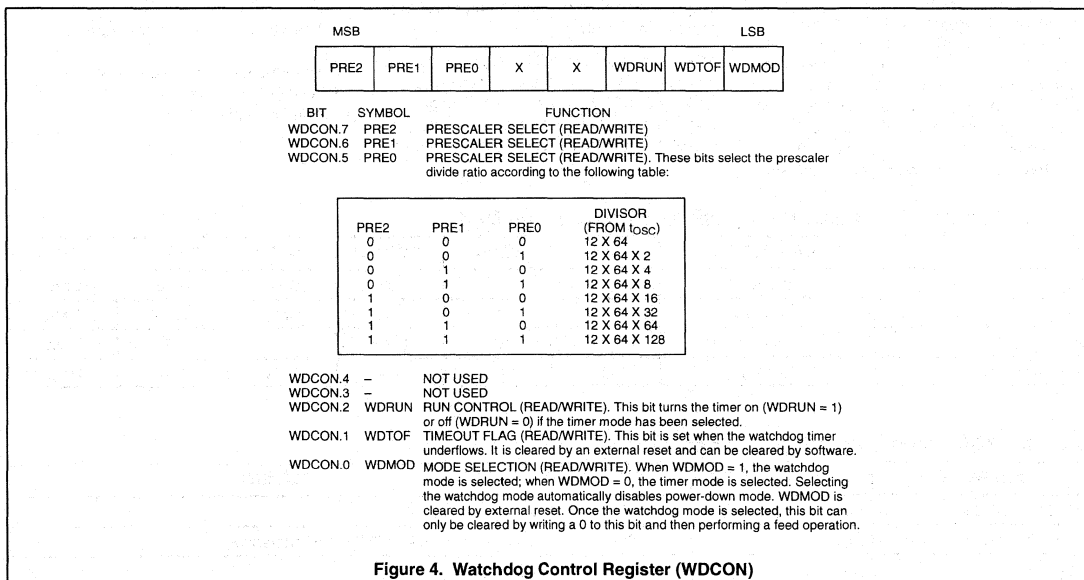

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals except the A/D stay active. the instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. An A/D conversion in progress will be aborted when idle mode is entered. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## Programmable Idle Modes

The programmable idle modes have been dispersed throughout the functional blocks. Each block has its own ability to be disabled. For example, if timer 0 is not commanded to be running (TR = 0), then the clock to the timer is disabled resulting in an idle mode power saving. An additional idle control bit has been added to the serial communications port.

## A/D Operation in Idle Mode

When in the idle mode, the A/D converter will be disabled. However, the current through the VREF pins will be present and will not be reduced internally in either the idle or the power-down modes. It is the responsibility of the user to disconnect VREF to reduce power supply current.

## CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

## 80C550/83C550/87C550

### DESIGN CONSIDERATIONS

At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when idle is terminated by reset, the instruction following the one that invokes idle should not be one that writes to a port pin or to external memory. Table 2 shows the state of I/O ports during low current operating modes.

### Encryption Table

The encryption table is a feature of the 83C550 and 87C550 that protects the code from being easily read by anyone other than the programmer. The encryption table is 32 bytes of code that are exclusive NORed with the program code data as it is read out. The first byte is XNORed with the first location read, the second with the second read, etc.

After the encryption table has been programmed, the user has to know its contents in order to correctly decode the program code data. The encryption table itself cannot be read out.

For the EPROM (87C550) part, the encryption table is programmed in the same manner as the program memory, but using the "Pgm Encryption Table" levels specified in Table 4. After the encryption table is programmed, verification cycles will produce only encrypted information.

For the ROM part (83C550) the encryption table information is submitted with the ROM code as shown in Table 3.

### Security Bits

There are two security bits on the 83C550 and 87C550 that, when set, prevent the program data memory from being read out or programmed further.

After the first security bit is programmed, the external MOV<sub>C</sub> instruction is disabled, and for the 87C550, further programming of the code memory or the encryption table is disabled. The other security bit can of course

still be programmed. With only security bit one programmed, the memory can still be read out for program verification. After the second security bit is programmed, it is no longer possible to read out (verify) the program memory.

To program the security bits for the 87C550, repeat the programming sequence using the "Pgm Security Bit" levels specified in Table 4. For the masked ROM 83C550 the security bit information is submitted with the ROM code as shown in Table 3.

### ROM Code Submission

When submitting a ROM code for the 83C550, the following must be specified:

1. The 4k byte user ROM program.
2. The 32 byte ROM encryption key.
3. The ROM security bits.
4. The watchdog timer parameters.

This information can be submitted in an EPROM (2764) or hex file with the format specified in Table 3.

**Table 2. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

#### NOTES:

- Conditions: V<sub>REF+</sub> = 4.99712V, V<sub>REF-</sub> = 0V. AI<sub>CC</sub> value does not include the resistor ladder current. For the 40-pin package, where the V<sub>REF-</sub> inputs are connected to AV<sub>CC</sub> and AV<sub>SS</sub>, the current AI<sub>CC</sub> will be increased by the register ladder current and may exceed the maximum shown here.
- The resistor ladder network is not disconnected in the power-down or idle modes. Thus to conserve power, the user must remove AV<sub>CC</sub> and V<sub>REF+</sub>.
- If the A/D function is not required, or if the A/D function is only needed periodically, AV<sub>CC</sub> can be removed without affecting the operation of the digital circuitry. Contents of ADCON and ADAT are not guaranteed to be valid. Digital inputs P1.0 to P1.7 will not function normally. No digital outputs are present on these pins.
- For this test, the Analog inputs must be at the supplies (either V<sub>DD</sub> or V<sub>SS</sub>).

| Operating temperature under bias                                                             | -40 to +85   | °C   |
| Storage temperature range                                                                    | -65 to +150  | °C   |
| Voltage on EA/V <sub>PP</sub> pin to V <sub>SS</sub> (87C550 only)                           | 0 to +13.0   | V    |
| Voltage on any other pin to V <sub>SS</sub>                                                  | -0.5 to +6.5 | V    |
| Input, output current on any two I/O pins                                                    | ±10          | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5          | W    |

#### NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

### DC ELECTRICAL CHARACTERISTICS

T<sub>amb</sub> = 0°C to +70°C or -40°C to +85°C, V<sub>CC</sub> = 5V ±10% (87C550), V<sub>CC</sub> = 5V ±20% (80/83C550), V<sub>SS</sub> = 0V

#### NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the V<sub>OL</sub>s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on ports 0 and 2 may cause the V<sub>OH</sub> on ALE and PSEN to momentarily fall below the 0.9V<sub>CC</sub> specification when the address bits are stabilizing.
- Pins of ports 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when V<sub>IN</sub> is approximately 2V.
- I<sub>CC</sub>MAX at other frequencies is given by: Active mode; I<sub>CC</sub>MAX = 1.43 × FREQ + 1.90; Idle mode; I<sub>CC</sub>MAX = 0.14 × FREQ + 2.31, where FREQ is the external oscillator frequency in MHz. I<sub>CC</sub>MAX is given in mA. See Figure 12.
- See Figures 13 through 16 for I<sub>CC</sub> test conditions.
- These values apply only to T<sub>amb</sub> = 0°C to +70°C. For T<sub>amb</sub> = -40°C to +85°C. See table on previous page.

| $t_{XHDV}$            | 8      | Clock rising edge to input data valid                      |             | 492 |                  | $10t_{CLCL}-133$ | ns   |

### NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.

# CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

80C550/83C550/87C550

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
  - R - RD signal
  - t - Time
  - V - Valid
  - W - WR signal
  - X - No longer a valid logic level
  - Z - Float
- Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

## 80C550/83C550/87C550

### EPROM CHARACTERISTICS

The 87C550 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C550 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an S87C550 manufactured by Philips.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 17 and 18. Figure 19 shows the circuit configuration for normal program memory verification.

### Quick-Pulse Programming

The setup for microcontroller quick-pulse programming is shown in Figure 17. Note that the 87C550 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 2 and 3, as shown in Figure 17. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 1 and 2 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The ALE/PROG is pulsed low 25 times as shown in Figure 18.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the  $EA/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

### Program Verification

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 2 and 3 as shown in Figure 19. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

### Reading the Signature Bytes

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P1.0 and P1.1 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 96H indicates S87C550

### Program/Verify Algorithms

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

### Erasure Characteristics

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000uW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/V <sub>PP</sub> | P2.7 | P2.6 | P1.1 | P1.0 |
|----------------------|-----|------|----------|--------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                  | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                  | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 0    | 0    |

#### NOTES:

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2.  $V_{PP} = 12.75V \pm 0.25V$ .

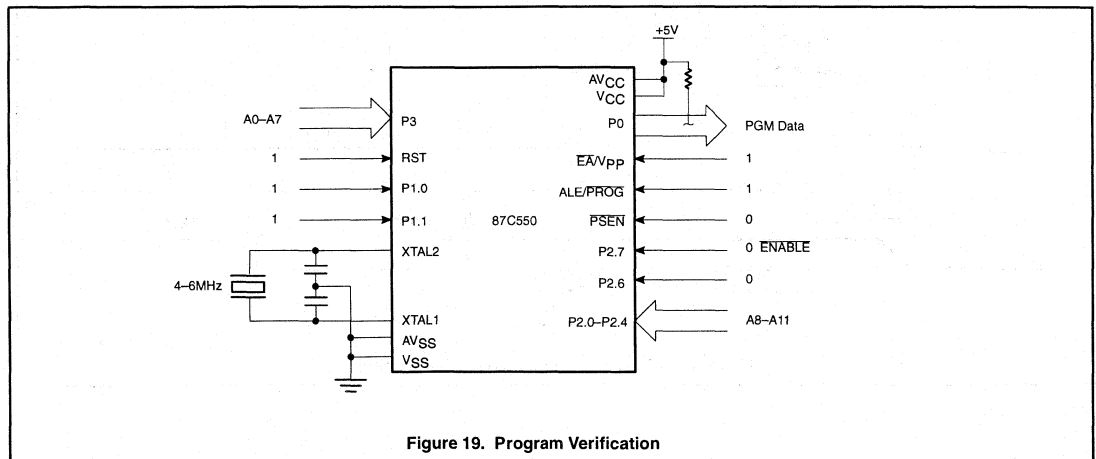

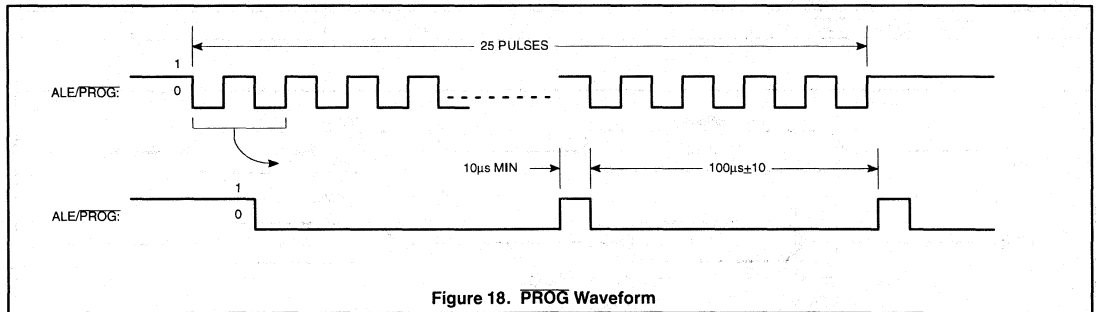

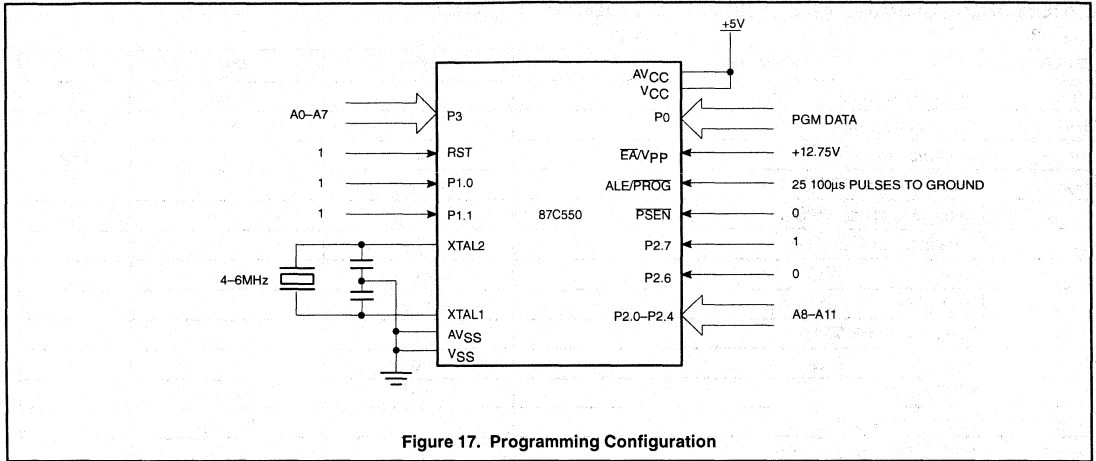

3.  $V_{CC} = 5V \pm 10\%$  during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100µs ( $\pm 10\mu s$ ) and high for a minimum of 10µs.

## 80C51 Family Derivatives

## 8XC552/562 overview

### 8XC552 OVERVIEW

The 8XC552 is a stand-alone high-performance microcontroller designed for use in real-time applications such as instrumentation, industrial control, and automotive control applications such as engine management and transmission control. The device provides, in addition to the 80C51 standard functions, a number of dedicated hardware functions for these applications.

The 8XC552 single-chip 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC552 uses the powerful instruction set of the 80C51. Additional special function registers are incorporated to control the on-chip peripherals. Three versions of the derivative exist although the generic term "8XC552" is used to refer to family members:

83C552: 8k bytes mask-programmable ROM, 256 bytes RAM

87C552: 8k bytes EPROM, 256 bytes RAM

80C552: ROMless version of the 83C552

The 8XC552 contains a nonvolatile 8k × 8 read-only program memory, a volatile 256 × 8 read/write data memory, five 8-bit I/O ports and one 8-bit input port, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a fifteen-source, two-priority-level, nested interrupt structure, an 8-input ADC, a dual DAC pulse width modulated interface, two serial interfaces (UART and I<sup>2</sup>C bus), a "watchdog" timer, and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC552 can be expanded using standard TTL compatible memories and logic

The 8XC552 has two software selectable modes of reduced activity for further power reduction—Idle and Power-down. The idle mode freezes the CPU and resets Timer T2 and the ADC and PWM circuitry but allows the other timers, RAM, serial ports, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to become inoperative.

### 83C562 OVERVIEW

The 83C562 has been derived from the 8XC552 with the following changes:

- The SIO1 (I<sup>2</sup>C) interface has been omitted.
- The output of port lines P1.6 and P1.7 have a standard configuration instead of open drain.
- The resolution of the A/D converter is decreased from 10 bits to 8 bits.
- The time of an A/D conversion has decreased from 50 machine cycles to 24 machine cycles.

All other functions, pinning and packaging are unchanged.

This chapter of the users' guide can be used for the 83C562 by omitting or changing the following:

- Disregard the description of SIO1 (I<sup>2</sup>C).
- The SFRs for the interface: S1ADR, S1DAT, S1STA, and S1CON are not implemented. The two SIO1 related flags ES1 in SFR IEN0 and PS1 in SFR IPO are also not implemented. These two flag locations are undefined after RESET. The interrupt vector for SIO1 is not used.
- Port lines P1.6 and P1.7 are not open drain but have the same standard configuration and electrical characteristics as P1.0-P1.5. Port lines P1.6 and P1.7 have alternative functions.
- The A/D converter has a resolution of 8 bits instead of 10 bits and consequently the two high-order bits 6 and 7 of SFR ADCON are not implemented. These two locations are undefined after RESET. The 8-bit result of an A/D conversion is present in SFR ADCH. The result can always be calculated from the formula:
 
$$256 \times \frac{V_{IN} - AV_{ref-}}{AV_{ref+} - AV_{ref-}}$$
 The A/D conversion time is 24 machine cycles instead of 50 machine cycles, and the sampling time is 6 machine cycles instead of 8 machine cycles. The conversion time takes 3 machine cycles per bit.
- The serial I/O function SIO0 and its SFRs S0BUF and S0CON are renamed to SIO,

SBUF, and SCON. The interrupt related flags ES0 and PS0 are renamed ES and PS. Interrupt source S0 is renamed S. The serial I/O function remains the same.

### Differences From the 80C51

#### Program Memory

The 8XC552 contains 8k bytes of on-chip program memory which can be extended to 64k bytes with external memories (see Figure 1). When the EA pin is held high, the 8XC552 fetches instructions from internal ROM unless the address exceeds 1FFFFH. Locations 2000H to FFFFH are fetched from external program memory. When the EA pin is held low, all instruction fetches are from external memory. ROM locations 0003H to 0073H are used by interrupt service routines.

#### Data Memory

The internal data memory is divided into 3 sections: the lower 128 bytes of RAM, the upper 128 bytes of RAM, and the 128-byte special function register areas. The lower 128 bytes of RAM are directly and indirectly addressable. While RAM locations 128 to 255 and the special function register area share the same address space, they are accessed through different addressing modes. RAM locations 128 to 255 are only indirectly addressable, and the special function registers are only directly addressable. All other aspects of the internal RAM are identical to the 8051.

The stack may be located anywhere in the internal RAM by loading the 8-bit stack pointer. Stack depth is 256 bytes maximum.

#### Special Function Registers

The special function registers (directly addressable only) contain all of the 8XC552 registers except the program counter and the four register banks. Most of the 56 special function registers are used to control the on-chip peripheral hardware. Other registers include arithmetic registers (ACC, B, PSW), stack pointer (SP), and data pointer registers (DHP, DPL). Sixteen of the SFRs contain 128 directly addressable bit locations. Table 1 lists the 8XC552's special function registers.

The standard 80C51 SFRs are present and function identically in the 8XC552 except where noted in the following sections.

## 8XC552/562 overview

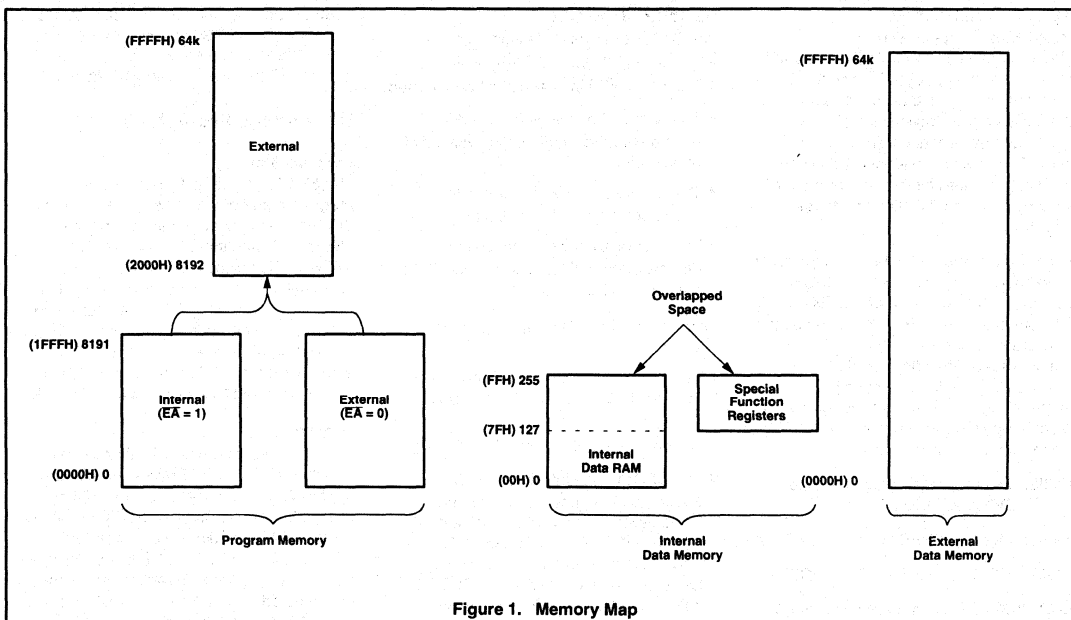

Figure 1. Memory Map

**Timer T2**

Timer T2 is a 16-bit timer consisting of two registers TMH2 (HIGH byte) and TML2 (LOW byte). The 16-bit timer/counter can be switched off or clocked via a prescaler from one of two sources:  $f_{osc}/12$  or an external signal. When Timer T2 is configured as a counter, the prescaler is clocked by an external signal on T2 (P1.4). A rising edge on T2 increments the prescaler, and the maximum repetition rate is one count per machine cycle (1MHz with a 12MHz oscillator).

The maximum repetition rate for Timer T2 is twice the maximum repetition rate for Timer 0 and Timer 1. T2 (P1.4) is sampled at S2P1 and again at SSP1 (i.e., twice per machine cycle). A rising edge is detected when T2 is LOW during one sample and HIGH during the next sample. To ensure that a rising edge is detected, the input signal must be LOW for at least 1/2 cycle and then HIGH for at least 1/2 cycle. If a rising edge is detected before the end of S2P1, the timer will be incremented during the following cycle; otherwise it will be incremented one cycle later. The prescaler

has a programmable division factor of 1, 2, 4, or 8 and is cleared if its division factor or input source is changed, or if the timer/counter is reset.

Timer T2 may be read "on the fly" but possesses no extra read latches, and software precautions may have to be taken to avoid misinterpretation in the event of an overflow from least to most significant byte while Timer T2 is being read. Timer T2 is not loadable and is reset by the RST signal or by a rising edge on the input signal RT2, if enabled. RT2 is enabled by setting bit T2ER (TM2CON.5).

When the least significant byte of the timer overflows or when a 16-bit overflow occurs, an interrupt request may be generated. Either or both of these overflows can be programmed to request an interrupt. In both cases, the interrupt vector will be the same. When the lower byte (TML2) overflows, flag T2B0 (TM2CON) is set and flag T2OV (TM2IR) is set when TMH2 overflows. These flags are set one cycle after an overflow occurs. Note that when T2OV is set, T2B0 will also be set. To enable the byte overflow

interrupt, bits ET2 (IEN1.7, enable overflow interrupt, see Figure 2) and T2IS0 (TM2CON.6, byte overflow interrupt select) must be set. Bit TWB0 (TM2CON.4) is the Timer T2 byte overflow flag.

To enable the 16-bit overflow interrupt, bits ET2 (IE1.7, enable overflow interrupt) and T2IS1 (TM2CON.7, 16-bit overflow interrupt select) must be set. Bit T2OV (TM2IR.7) is the Timer T2 16-bit overflow flag. All interrupt flags must be reset by software. To enable both byte and 16-bit overflow, T2IS0 and T2IS1 must be set and two interrupt service routines are required. A test on the overflow flags indicates which routine must be executed. For each routine, only the corresponding overflow flag must be cleared.

Timer T2 may be reset by a rising edge on RT2 (P1.5) if the Timer T2 external reset enable bit (T2ER) in T2CON is set. This reset also clears the prescaler. In the idle mode, the timer/counter and prescaler are reset and halted. Timer T2 is controlled by the TM2CON special function register (see Figure 3).

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

**Timer T2 Extension:** When a 12MHz oscillator is used, a 16-bit overflow on Timer T2 occurs every 65.5, 131, 262, or 524 ms, depending on the prescaler division ratio; i.e., the maximum cycle time is approximately 0.5 seconds. In applications where cycle times are greater than 0.5 seconds, it is necessary to extend Timer T2. This is achieved by selecting  $f_{osc}/12$  as the clock source (set T2MS0, reset T2MS1), setting the prescaler division ratio to 1/8 (set T2P0, set T2P1), disabling the byte overflow interrupt (reset T2IS0) and enabling the 16-bit overflow interrupt (set T2IS1). The following software routine is written for a three-byte extension which gives a maximum cycle time of approximately 2400 hours.

```

OVINT: PUSH ACC ;save accumulator
 PUSH PSW ;save status
 INC TIMEX1 ;increment first
 ;byte (low order)
 ;of extended timer

 MOV A,TIMEX1
 JNZ INTEX ;jump to INTEX if
 ;there is no
 ;overflow

```

```

 INC TIMEX2 ;increment second
 ;byte
 MOV A,TIMEX2
 JNZ INTEX ;jump to INTEX if
 ;there is no
 ;overflow

 INC TIMEX3 ;increment third
 ;byte (high order)

INTEX: CLR T2OV ;reset interrupt
 ;flag
 POP PSW ;restore status
 POP ACC ;restore
 ;accumulator
 RETI ;return from
 ;interrupt

```

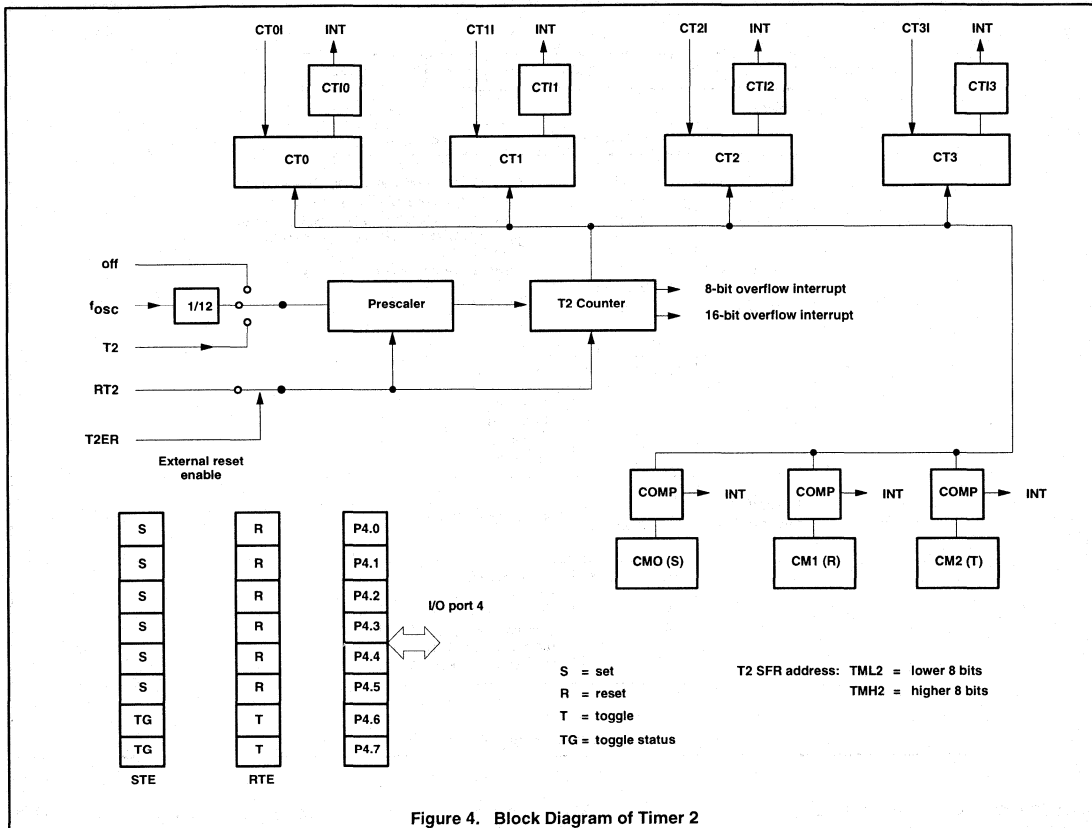

**Timer T2, Capture and Compare Logic:** Timer T2 is connected to four 16-bit capture registers and three 16-bit compare registers. A capture register may be used to capture the contents of Timer T2 when a transition occurs on its corresponding input pin. A compare register may be used to set, reset, or toggle port 4 output pins at certain pre-programmable time intervals.

The combination of Timer T2 and the capture and compare logic is very powerful in applications involving rotating machinery, automotive injection systems, etc. Timer T2 and the capture and compare logic are shown in Figure 4.

**Capture Logic:** The four 16-bit capture registers that Timer T2 is connected to are: CT0, CT1, CT2, and CT3. These registers are loaded with the contents of Timer T2, and an interrupt is requested upon receipt of the input signals CT0I, CT1I, CT2I, or CT3I. These input signals are shared with port 1. The four interrupt flags are in the Timer T2 interrupt register (TM2IR special function register). If the capture facility is not required, these inputs can be regarded as additional external interrupt inputs.

Using the capture control register CTCON (see Figure 5), these inputs may capture on a rising edge, a falling edge, or on either a rising or falling edge. The inputs are sampled during S1P1 of each cycle. When a selected edge is detected, the contents of Timer T2 are captured at the end of the cycle.

**Measuring Time Intervals Using Capture Registers:** When a recurring external event is represented in the form of rising or falling edges on one of the four capture pins, the time between two events can be measured using Timer T2 and a capture register. When an event occurs, the contents of Timer T2 are copied into the relevant capture register and an interrupt request is generated. The interrupt service routine may then compute the interval time if it knows the previous contents of Timer T2 when the last event occurred. With a 12MHz oscillator, Timer T2 can be programmed to overflow every 524ms. When event interval times are shorter than this, computing the interval time is simple, and the interrupt service routine is short. For longer interval times, the Timer T2 extension routine may be used.

**Compare Logic:** Each time Timer T2 is incremented, the contents of the three 16-bit compare registers CM0, CM1, and CM2 are compared with the new counter value of

Timer T2. When a match is found, the corresponding interrupt flag in TM2IR is set at the end of the following cycle. When a match with CM0 occurs, the controller sets bits 0-5 of port 4 if the corresponding bits of the set enable register STE are at logic 1.

When a match with CM1 occurs, the controller resets bits 0-5 of port 4 if the corresponding bits of the reset/toggle enable register RTE are at logic 1 (see Figure 6 for RTE register function). If RTE is "0", then P4.n is not affected by a match between CM1 or CM2 and Timer 2. When a match with CM2 occurs, the controller "toggles" bits 6 and 7 of port 4 if the corresponding bits of the RTE are at logic 1. The port latches of bits 6 and 7 are not toggled. Two additional flip-flops store the last operation, and it is these flip-flops that are toggled.

Thus, if the current operation is "set," the next operation will be "reset" even if the port latch is reset by software before the "reset" operation occurs. The first "toggle" after a

chip RESET will set the port latch. The contents of these two flip-flops can be read at STE.6 and STE.7 (corresponding to P4.6 and P4.7, respectively). Bits STE.6 and STE.7 are read only (see Figure 7 for STE register function). A logic 1 indicates that the next toggle will set the port latch; a logic 0 indicates that the next toggle will reset the port latch. CM0, CM1, and CM2 are reset by the RST signal.

The modified port latch information appears at the port pin during S5P1 of the cycle following the cycle in which a match occurred. If the port is modified by software, the outputs change during S1P1 of the following cycle. Each port 4 bit can be set or reset by software at any time. A hardware modification resulting from a comparator match takes precedence over a software modification in the same cycle. When the comparator results require a "set" and a "reset" at the same time, the port latch will be reset.

## 80C51 Family Derivatives

## 7XC552/562 overview

### Timer T2 Interrupt Flag Register TM2IR:

Eight of the nine Timer T2 interrupt flags are located in special function register TM2IR (see Figure 8). The ninth flag is TM2CON.4.

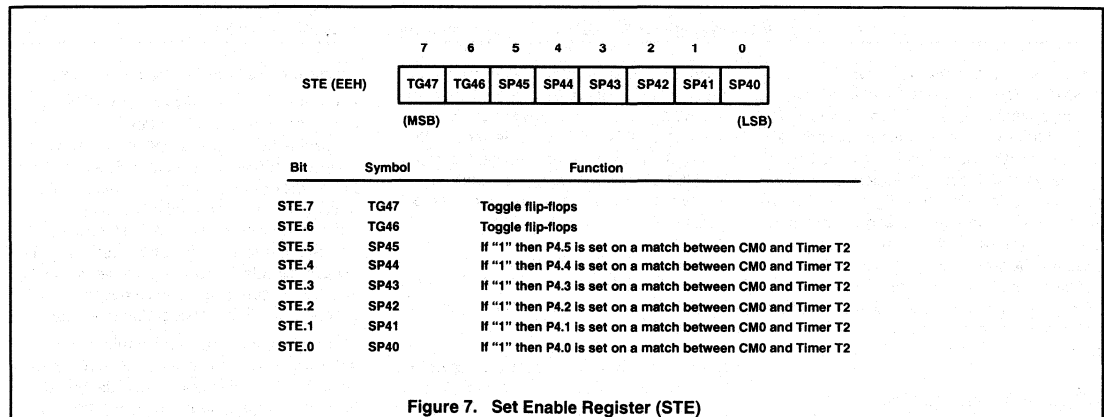

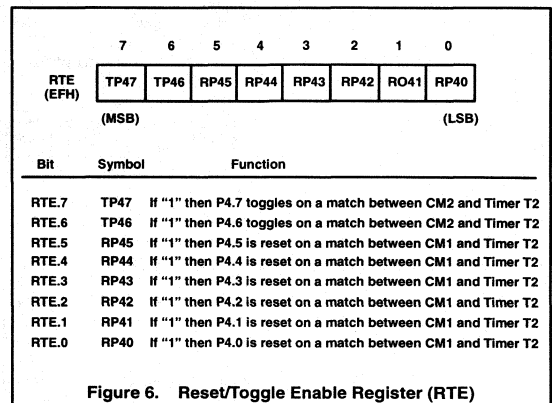

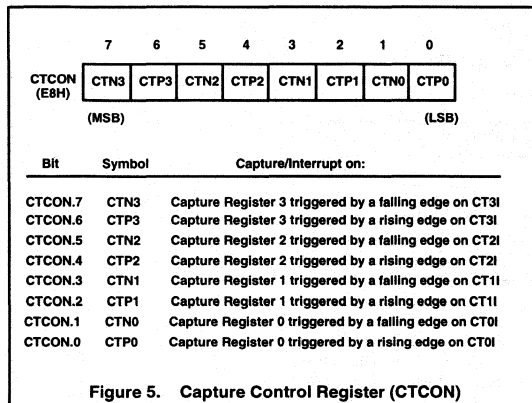

The CT0I and CT1I flags are set during S4 of the cycle in which the contents of Timer T2 are captured. CT0I is scanned by the interrupt logic during S2, and CT1I is scanned during S3. CT2I and CT3I are set during S6 and are scanned during S4 and S5. The associated interrupt requests are recognized during the following cycle. If these

flags are polled, a transition at CT0I or CT1I will be recognized one cycle before a transition on CT2I or CT3I since registers are read during S5. The CMI0, CMI1, and CMI2 flags are set during S6 of the cycle following a match. CMI0 is scanned by the interrupt logic during S2; CMI1 and CMI2 are scanned during S3 and S4. A match will be recognized by the interrupt logic (or by polling the flags) two cycles after the match takes place.

The 16-bit overflow flag (T2OV) and the byte

overflow flag (T2BO) are set during S6 of the cycle in which the overflow occurs. These flags are recognized by the interrupt logic during the next cycle.

Special function register IP1 (Figure 8) is used to determine the Timer T2 interrupt priority. Setting a bit high gives that function a high priority, and setting a bit low gives the function a low priority. The functions controlled by the various bits of the IP1 register are shown in Figure 8.

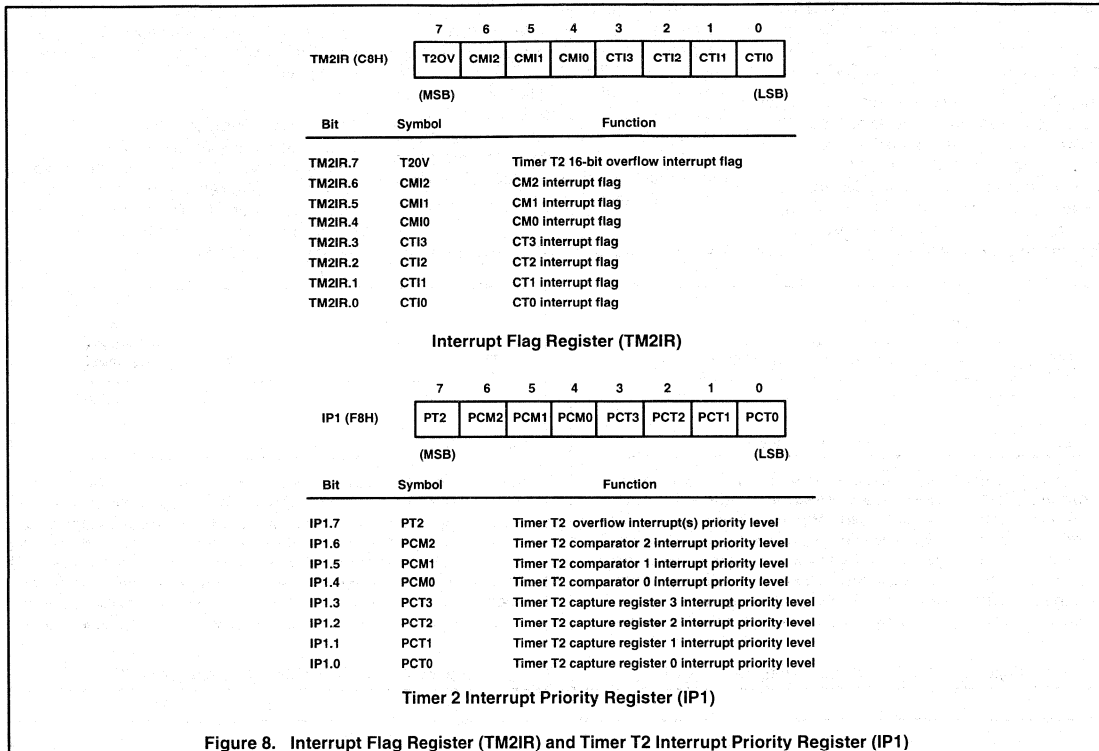

Figure 8. Interrupt Flag Register (TM2IR) and Timer T2 Interrupt Priority Register (IP1)

**Timer T3, The Watchdog Timer**

In addition to Timer T2 and the standard timers, a watchdog timer is also incorporated on the 8XC552. The purpose of a watchdog timer is to reset the microcontroller if it enters erroneous processor states (possibly caused by electrical noise or RFI) within a reasonable period of time. An analogy is the "dead man's handle" in railway locomotives. When enabled, the watchdog circuitry will generate a system reset if the user program fails to reload the watchdog timer within a specified length of time known as the "watchdog interval."

**Watchdog Circuit Description:** The watchdog timer (Timer T3) consists of an 8-bit timer with an 11-bit prescaler as shown in Figure 9. The prescaler is fed with a signal whose frequency is 1/12 the oscillator frequency (1MHz with a 12MHz oscillator). The 8-bit timer is incremented every "t" seconds, where:

$$t = 12 \times 2048 \times 1/f_{OSC}$$

$$(\text{=} 1.5\text{ms at } f_{OSC} = 16\text{MHz};$$

$$\text{=} 1\text{ms at } f_{OSC} = 24\text{MHz})$$

If the 8-bit timer overflows, a short internal reset pulse is generated which will reset the 8XC552. A short output reset pulse is also generated at the RST pin. This short output pulse (3 machine cycles) may be destroyed if the RST pin is connected to a capacitor. This would not, however, affect the internal reset operation.

Watchdog operation is activated when external pin EW is tied low. When EW is tied low, it is impossible to disable the watchdog operation by software.

**How to Operate the Watchdog Timer:** The watchdog timer has to be reloaded within periods that are shorter than the programmed watchdog interval; otherwise the watchdog timer will overflow and a system reset will be generated. The user program must therefore continually execute sections of code which reload the watchdog timer. The period of time elapsed between execution of these sections of code must never exceed the watchdog interval. When using a 16MHz oscillator, the watchdog interval is programmable between 1.5ms and 392ms. When using a 24MHz oscillator, the watchdog interval is

programmable between 1ms and 255ms.

In order to prepare software for watchdog operation, a programmer should first determine how long his system can sustain an erroneous processor state. The result will be the maximum watchdog interval. As the maximum watchdog interval becomes shorter, it becomes more difficult for the programmer to ensure that the user program always reloads the watchdog timer within the watchdog interval, and thus it becomes more difficult to implement watchdog operation.

The programmer must now partition the software in such a way that reloading of the watchdog is carried out in accordance with the above requirements. The programmer must determine the execution times of all software modules. The effect of possible conditional branches, subroutines, external and internal interrupts must all be taken into account. Since it may be very difficult to evaluate the execution times of some sections of code, the programmer should use worst case estimations. In any event, the programmer must make sure that the watchdog is not activated during normal operation.

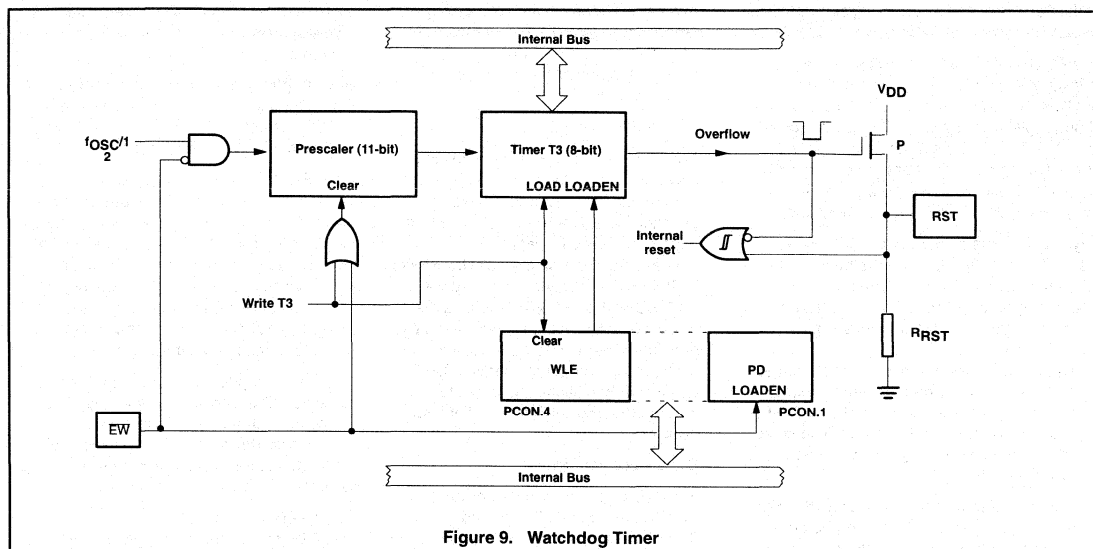

Figure 9. Watchdog Timer

The watchdog timer is reloaded in two stages in order to prevent erroneous software from reloading the watchdog. First PCON.4 (WLE) must be set. The T3 may be loaded. When T3 is loaded, PCON.4 (WLE) is automatically reset. T3 cannot be loaded if PCON.4 (WLE) is reset. Reload code may be put in a subroutine as it is called frequently. Since Timer T3 is an up-counter, a reload value of 00H gives the maximum watchdog interval (510ms with a 12MHz oscillator), and a reload value of 0FFH gives the minimum watchdog interval (2ms with a 12MHz oscillator).

In the idle mode, the watchdog circuitry remains active. When watchdog operation is implemented, the power-down mode cannot be used since both states are contradictory. Thus, when watchdog operation is enabled by tying external pin  $\overline{EW}$  low, it is impossible to enter the power-down mode, and an attempt to set the power-down bit (PCON.1) will have no effect. PCON.1 will remain at logic 0.

During the early stages of software development/debugging, the watchdog may be disabled by tying the  $\overline{EW}$  pin high. At a later stage,  $\overline{EW}$  may be tied low to complete the debugging process.

**Watchdog Software Example:** The following example shows how watchdog operation might be handled in a user program.

;at the program start:

```
T3 EQU 0FFH ;address of
 ;watchdog
 ;timer T3
PCON EQU 087H ;address of
 ;PCON SFR
WATCH-INTV EQU 156 ;watchdog
 ;interval
 ;(e.g., 2x100ms)
```

;to be inserted at each watchdog reload  
;location within the user program:

```
LCALL WATCHDOG
```

;watchdog service routine:

```
WATCHDOG: ORL PCON,#10H ;set
 ;condition
 ;flag
 ;(PCON.4)
 MOV T3,WATCH-INTV ;load T3
 ;with
 ;watchdog
 ;interval
 RET
```

If it is possible for this subroutine to be called in an erroneous state, then the condition flag WLE should be set at different parts of the main program.

#### Serial I/O

The 8XC552 is equipped with two independent serial ports: SIO0 and SIO1. SIO0 is a full duplex UART port and is

identical to the 80C51 serial port. SIO1 accommodates the I<sup>2</sup>C bus.

**SIO0:** SIO0 is a full duplex serial I/O port identical to that on the 80C51. Its operation is the same, including the use of timer 1 as a baud rate generator.

**SIO1, I<sup>2</sup>C Serial I/O:** The I<sup>2</sup>C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main features of the bus are:

- Bidirectional data transfer between masters and slaves
- Multimaster bus (no central master)
- Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
- Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
- Serial clock synchronization can be used as a handshake mechanism to suspend and resume serial transfer
- The I<sup>2</sup>C bus may be used for test and diagnostic purposes

The output latches of P1.6 and P1.7 must be set to logic 1 in order to enable SIO1.

The 8XC552 on-chip I<sup>2</sup>C logic provides a serial interface that meets the I<sup>2</sup>C bus specification and supports all transfer modes (other than the low-speed mode) from and to the I<sup>2</sup>C bus. The SIO1 logic handles bytes transfer autonomously. It also keeps track of

## 80C51 Family Derivatives

## 8XC552/562 overview

serial transfers, and a status register (S1STA) reflects the status of SIO1 and the I<sup>2</sup>C bus.

The CPU interfaces to the I<sup>2</sup>C logic via the following four special function registers: S1CON (SIO1 control register), S1STA (SIO1 status register), S1DAT (SIO1 data register), and S1ADR (SIO1 slave address register). The SIO1 logic interfaces to the external I<sup>2</sup>C bus via two port 1 pins: P1.6/SCL (serial clock line) and P1.7/SDA (serial data line).

A typical I<sup>2</sup>C bus configuration is shown in Figure 10, and Figure 11 shows how a data transfer is accomplished on the bus. Depending on the state of the direction bit (R/W), two types of data transfers are possible on the I<sup>2</sup>C bus:

1. Data transfer from a master transmitter to a slave receiver. The first byte transmitted by the master is the slave address. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte.
2. Data transfer from a slave transmitter to a master receiver. The first byte (the slave address) is transmitted by the master. The slave then returns an acknowledge bit. Next follows the data bytes transmitted by the slave to the master. The master returns an acknowledge bit after all received bytes other than the last byte. At the end of the last received byte, a "not acknowledge" is returned.

The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a repeated START condition. Since a repeated START condition is also the beginning of the next serial transfer, the I<sup>2</sup>C bus will not be released.

**Modes of Operation:** The on-chip SIO1 logic may operate in the following four modes:

### 1. Master Transmitter Mode:

Serial data output through P1.7/SDA while P1.6/SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the data direction bit. In this case the data direction bit (R/W) will be logic 0, and we say that a "W" is transmitted. Thus the first byte transmitted is SLA+W. Serial data is transmitted 8 bits

at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

### 2. Master Receiver Mode:

The first byte transmitted contains the slave address of the transmitting device (7 bits) and the data direction bit. In this case the data direction bit (R/W) will be logic 1, and we say that an "R" is transmitted. Thus the first byte transmitted is SLA+R. Serial data is received via P1.7/SDA while P1.6/SCL outputs the serial clock. Serial data is received 8 bits at a time. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are output to indicate the beginning and end of a serial transfer.

### 3. Slave Receiver Mode:

Serial data and the serial clock are received through P1.7/SDA and P1.6/SCL. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit.

### 4. Slave Transmitter Mode:

The first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit will indicate that the transfer direction is reversed. Serial data is transmitted via P1.7/SDA while the serial clock is input through P1.6/SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer.

In a given application, SIO1 may operate as a master and as a slave. In the slave mode, the SIO1 hardware looks for its own slave address and the general call address. If one of these addresses is detected, an interrupt is requested. When the microcontroller wishes to become the bus master, the hardware waits until the bus is free before the master mode is entered so that a possible slave action is not interrupted. If bus arbitration is lost in the master mode, SIO1 switches to the

slave mode immediately and can detect its own slave address in the same serial transfer.

### SIO1 Implementation and Operation:

Figure 12 shows how the on-chip I<sup>2</sup>C bus interface is implemented, and the following text describes the individual blocks.

#### INPUT FILTERS AND OUTPUT STAGES

The input filters have I<sup>2</sup>C compatible input levels. If the input voltage is less than 1.5V, the input logic level is interpreted as 0; if the input voltage is greater than 3.0V, the input logic level is interpreted as 1. Input signals are synchronized with the internal clock ( $f_{OSC}/4$ ), and spikes shorter than three oscillator periods are filtered out.

The output stages consist of open drain transistors that can sink 3mA at  $V_{OUT} < 0.4V$ . These open drain outputs do not have clamping diodes to  $V_{DD}$ . Thus, if the device is connected to the I<sup>2</sup>C bus and  $V_{DD}$  is switched off, the I<sup>2</sup>C bus is not affected.

#### ADDRESS REGISTER, S1ADR

This 8-bit special function register may be loaded with the 7-bit slave address (7 most significant bits) to which SIO1 will respond when programmed as a slave transmitter or receiver. The LSB (GC) is used to enable general call address (00H) recognition.

#### COMPARATOR

The comparator compares the received 7-bit slave address with its own slave address (7 most significant bits in S1ADR). It also compares the first received 8-bit byte with the general call address (00H). If an equality is found, the appropriate status bits are set and an interrupt is requested.

#### SHIFT REGISTER, S1DAT

This 8-bit special function register contains a byte of serial data to be transmitted or a byte which has just been received. Data in S1DAT is always shifted from right to left; the first bit to be transmitted is the MSB (bit 7) and, after a byte has been received, the first bit of received data is located at the MSB of S1DAT. While data is being shifted out, data on the bus is simultaneously being shifted in; S1DAT always contains the last byte present on the bus. Thus, in the event of lost arbitration, the transition from master transmitter to slave receiver is made with the correct data in S1DAT.

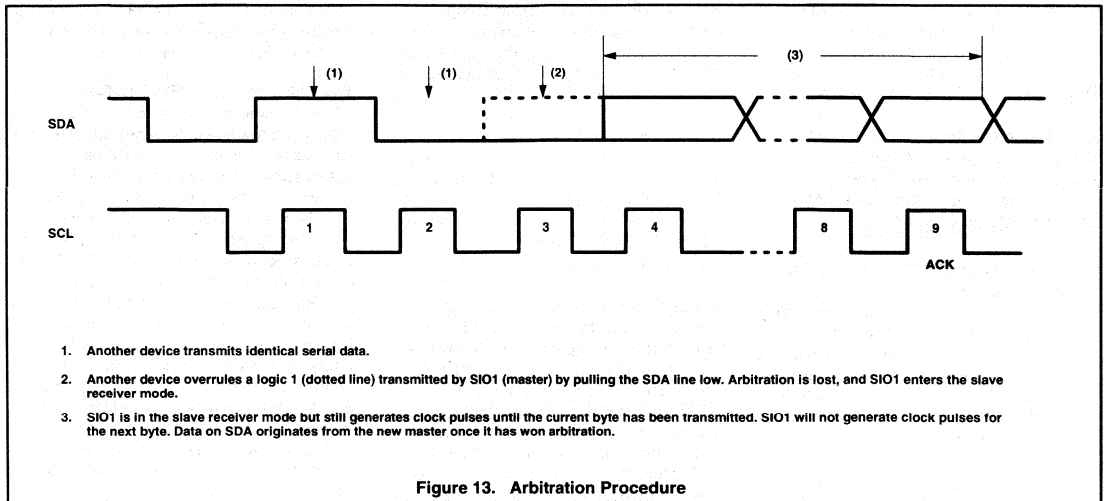

Figure 13. Arbitration Procedure

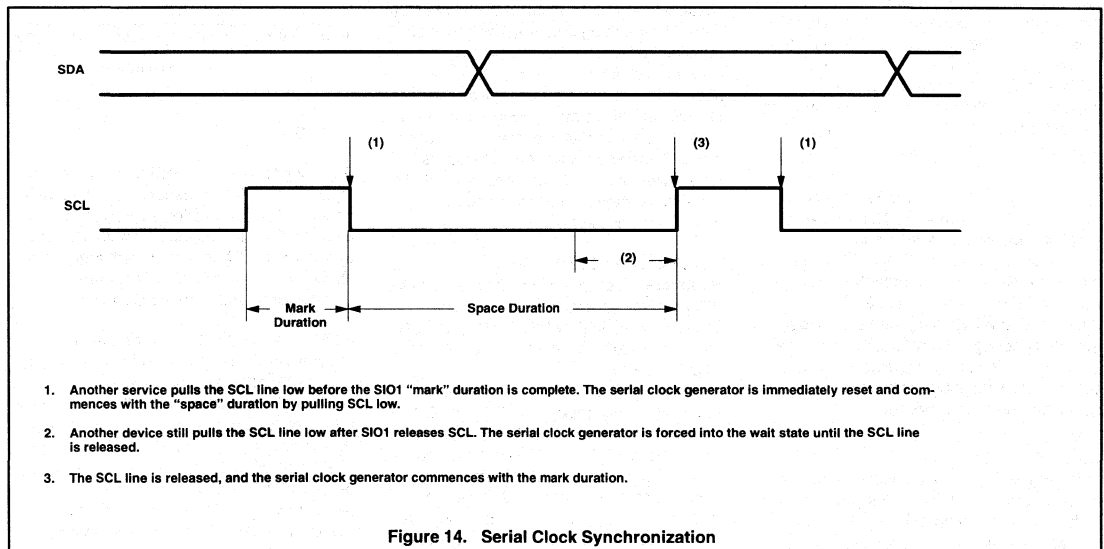

Figure 14. Serial Clock Synchronization

## 80C51 Family Derivatives

## 8XC552/562 overview

## ARBITRATION AND SYNCHRONIZATION LOGIC

In the master transmitter mode, the arbitration logic checks that every transmitted logic 1 actually appears as a logic 1 on the I<sup>2</sup>C bus. If another device on the bus overrides a logic 1 and pulls the SDA line low, arbitration is lost, and SIO1 immediately changes from master transmitter to slave receiver. SIO1 will continue to output clock pulses (on SCL) until transmission of the current serial byte is complete.

Arbitration may also be lost in the master receiver mode. Loss of arbitration in this mode can only occur while SIO1 is returning a "not acknowledge" (logic 1) to the bus. Arbitration is lost when another device on the bus pulls this signal LOW. Since this can occur only at the end of a serial byte, SIO1 generates no further clock pulses. Figure 13 shows the arbitration procedure.

The synchronization logic will synchronize the serial clock generator with the clock pulses on the SCL line from another device. If two or more master devices generate clock pulses, the "mark" duration is determined by the device that generates the shortest "marks," and the "space" duration is determined by the device that generates the longest "spaces." Figure 14 shows the synchronization procedure.

A slave may stretch the space duration to slow down the bus master. The space duration may also be stretched for handshaking purposes. This can be done after each bit or after a complete byte transfer. SIO1 will stretch the SCL space duration after a byte has been transmitted or received and the acknowledge bit has been transferred. The serial interrupt flag (SI) is set, and the stretching continues until the serial interrupt flag is cleared.

## SERIAL CLOCK GENERATOR

This programmable clock pulse generator provides the SCL clock pulses when SIO1 is in the master transmitter or master receiver mode. It is switched off when SIO1 is in a slave mode. The programmable output clock frequencies are:  $f_{OSC}/120$ ,  $f_{OSC}/9600$ , and the Timer 1 overflow rate divided by eight. The output clock pulses have a 50% duty cycle unless the clock generator is synchronized with other SCL clock sources as described above.

## TIMING AND CONTROL

The timing and control logic generates the timing and control signals for serial byte handling. This logic block provides the shift pulses for S1DAT, enables the comparator,

generates and detects start and stop conditions, receives and transmits acknowledge bits, controls the master and slave modes, contains interrupt request logic, and monitors the I<sup>2</sup>C bus status.

## CONTROL REGISTER, S1CON

This 7-bit special function register is used by the microcontroller to control the following SIO1 functions: start and restart of a serial transfer, termination of a serial transfer, bit rate, address recognition, and acknowledgment.

## STATUS DECODER AND STATUS REGISTER

The status decoder takes all of the internal status bits and compresses them into a 5-bit code. This code is unique for each I<sup>2</sup>C bus status. The 5-bit code may be used to generate vector addresses for fast processing of the various service routines. Each service routine processes a particular bus status. There are 26 possible bus states if all four modes of SIO1 are used. The 5-bit status code is latched into the five most significant bits of the status register when the serial interrupt flag is set (by hardware) and remains stable until the interrupt flag is cleared by software. The three least significant bits of the status register are always zero. If the status code is used as a vector to service routines, then the routines are displaced by eight address locations. Eight bytes of code is sufficient for most of the service routines (see the software example in this section).

## The Four SIO1 Special Function

**Registers:** The microcontroller interfaces to SIO1 via four special function registers. These four SFRs (S1ADR, S1DAT, S1CON, and S1STA) are described individually in the following sections.

**The Address Register, S1ADR:** The CPU can read from and write to this 8-bit, directly addressable SFR. S1ADR is not affected by the SIO1 hardware. The contents of this register are irrelevant when SIO1 is in a master mode. In the slave modes, the seven most significant bits must be loaded with the microcontroller's own slave address, and, if the least significant bit is set, the general call address (00H) is recognized; otherwise it is ignored.

The most significant bit corresponds to the first bit received from the I<sup>2</sup>C bus after a start

condition. A logic 1 in S1ADR corresponds to a high level on the I<sup>2</sup>C bus, and a logic 0 corresponds to a low level on the bus.

**The Data Register, S1DAT:** S1DAT contains a byte of serial data to be transmitted or a byte which has just been received. The CPU can read from and write to this 8-bit, directly addressable SFR while it is not in the process of shifting a byte. This occurs when SIO1 is in a defined state and the serial interrupt flag is set. Data in S1DAT remains stable as long as SI is set. Data in S1DAT is always shifted from right to left: the first bit to be transmitted is the MSB (bit 7), and, after a byte has been received, the first bit of received data is located at the MSB of S1DAT. While data is being shifted out, data on the bus is simultaneously being shifted in; S1DAT always contains the last data byte present on the bus. Thus, in the event of lost arbitration, the transition from master transmitter to slave receiver is made with the correct data in S1DAT.

## SD7 - SD0:

Eight bits to be transmitted or just received. A logic 1 in S1DAT corresponds to a high level on the I<sup>2</sup>C bus, and a logic 0 corresponds to a low level on the bus. Serial data shifts through S1DAT from right to left. Figure 15 shows how data in S1DAT is serially transferred to and from the SDA line.

S1DAT and the ACK flag form a 9-bit shift register which shifts in or shifts out an 8-bit byte, followed by an acknowledge bit. The ACK flag is controlled by the SIO1 hardware and cannot be accessed by the CPU. Serial data is shifted through the ACK flag into S1DAT on the rising edges of serial clock pulses on the SCL line. When a byte has been shifted into S1DAT, the serial data is available in S1DAT, and the acknowledge bit is returned by the control logic during the ninth clock pulse. Serial data is shifted out from S1DAT via a buffer (BSD7) on the falling edges of clock pulses on the SCL line.

When the CPU writes to S1DAT, BSD7 is loaded with the content of S1DAT.7, which is the first bit to be transmitted to the SDA line (see Figure 16). After nine serial clock pulses, the eight bits in S1DAT will have been transmitted to the SDA line, and the acknowledge bit will be present in ACK. Note that the eight transmitted bits are shifted back into S1DAT.

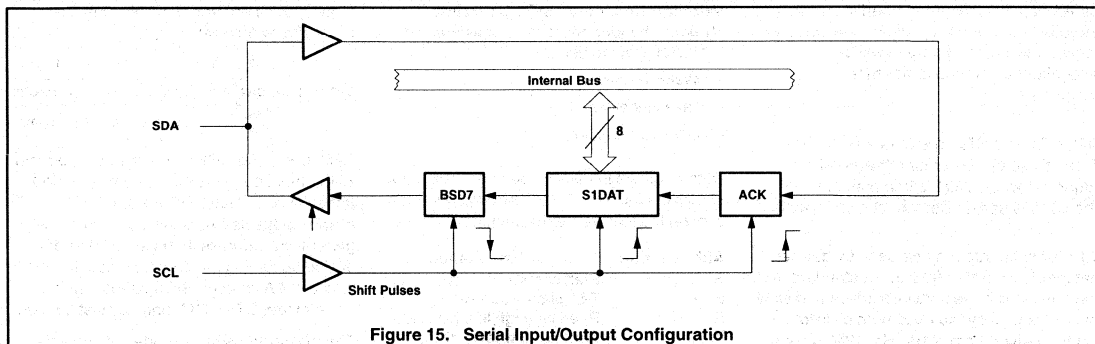

Figure 15. Serial Input/Output Configuration

**The Control Register, S1CON:** The CPU can read from and write to this 8-bit, directly addressable SFR. Two bits are affected by the SIO1 hardware: the SI bit is set when a serial interrupt is requested, and the STO bit is cleared when a STOP condition is present on the I<sup>2</sup>C bus. The STO bit is also cleared when ENS1 = "0".

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
|             | 7   | 6    | 5   | 4   | 3  | 2  | 1   | 0   |
| S1CON (D8H) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |

**ENS1, THE SIO1 ENABLE BIT**

ENS1 = "0": When ENS1 is "0", the SDA and SCL outputs are in a high impedance state. SDA and SCL input signals are ignored, SIO1 is in the "not addressed" slave state, and the STO bit in S1CON is forced to "0". No other bits are affected. P1.6 and P1.7 may be used as open drain I/O ports.

ENS1 = "1": When ENS1 is "1", SIO1 is enabled. The P1.6 and P1.7 port latches must be set to logic 1.

ENS1 should not be used to temporarily release SIO1 from the I<sup>2</sup>C bus since, when ENS1 is reset, the I<sup>2</sup>C bus status is lost. The AA flag should be used instead (see description of the AA flag in the following text).

In the following text, it is assumed that ENS1 = "1".

**STA, THE START FLAG**

STA = "1": When the STA bit is set to enter a master mode, the SIO1 hardware checks the status of the I<sup>2</sup>C bus and generates a START condition if the bus is free. If the bus is not free, then SIO1 waits for a STOP condition (which will free the bus) and generates a START condition after a delay of a half clock period of the internal serial clock generator.

If STA is set while SIO1 is already in a master mode and one or more bytes are transmitted or received, SIO1 transmits a repeated START condition. STA may be set at any

time. STA may also be set when SIO1 is an addressed slave.

STA = "0": When the STA bit is reset, no START condition or repeated START condition will be generated.

**STO, THE STOP FLAG**

STO = "1": When the STO bit is set while SIO1 is in a master mode, a STOP condition is transmitted to the I<sup>2</sup>C bus. When the STOP condition is detected on the bus, the SIO1 hardware clears the STO flag. In a slave mode, the STO flag may be set to recover from an error condition. In this case, no STOP condition is transmitted to the I<sup>2</sup>C bus. However, the SIO1 hardware behaves as if a STOP condition has been received and switches to the defined "not addressed" slave receiver mode. The STO flag is automatically cleared by hardware.

If the STA and STO bits are both set, the a STOP condition is transmitted to the I<sup>2</sup>C bus if SIO1 is in a master mode (in a slave mode, SIO1 generates an internal STOP condition which is not transmitted). SIO1 then transmits a START condition.

STO = "0": When the STO bit is reset, no STOP condition will be generated.

**SI, THE SERIAL INTERRUPT FLAG**

SI = "1": When the SI flag is set, then, if the EA and ES1 (interrupt enable register) bits are also set, a serial interrupt is requested. SI is set by hardware when one of 25 of the 26 possible SIO1 states is entered. The only state that does not cause SI to be set is state F8H, which indicates that no relevant state information is available.

While SI is set, the low period of the serial clock on the SCL line is stretched, and the serial transfer is suspended. A high level on the SCL line is unaffected by the serial interrupt flag. SI must be reset by software.

SI = "0": When the SI flag is reset, no serial interrupt is requested, and there is no stretching of the serial clock on the SCL line.

**AA, THE ASSERT ACKNOWLEDGE FLAG**

AA = "1": If the AA flag is set, an acknowledge (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when:

- The "own slave address" has been received
- The general call address has been received while the general call bit (GC) in S1ADR is set
- A data byte has been received while SIO1 is in the master receiver mode
- A data byte has been received while SIO1 is in the addressed slave receiver mode

AA = "0": if the AA flag is reset, a not acknowledge (high level to SDA) will be returned during the acknowledge clock pulse on SCL when:

- A data has been received while SIO1 is in the master receiver mode
- A data byte has been received while SIO1 is in the addressed slave receiver mode

When WIO1 is in the addressed slave transmitter mode, state C8H will be entered after the last serial is transmitted (see Figure 20). When SI is cleared, SIO1 leaves state C8H, enters the not addressed slave receiver mode, and the SDA line remains at a high level. In state C8H, the AA flag can be set again for future address recognition.

When SIO1 is in the not addressed slave mode, its own slave address and the general call address are ignored. Consequently, no acknowledge is returned, and a serial interrupt is not requested. Thus, SIO1 can be temporarily released from the I<sup>2</sup>C bus while the bus status is monitored. While SIO1 is released from the bus, START and STOP conditions are detected, and serial data is shifted in. Address recognition can be resumed at any time by setting the AA flag. If

## 80C51 Family Derivatives

## 8XC552/562 overview

the AA flag is set when the part's own slave address or the general call address has been partly received, the address will be recognized at the end of the byte transmission.

**CR0, CR1, AND CR2, THE CLOCK RATE BITS**

These three bits determine the serial clock frequency when SIO1 is in a master mode. The various serial rates are shown in Table 2.

A 12.5kHz bit rate may be used by devices that interface to the I<sup>2</sup>C bus via standard I/O port lines which are software driven and slow. 100kHz is usually the maximum bit rate and can be derived from a 16MHz, 12MHz, or a 6MHz oscillator. A variable bit rate (0.5kHz to 62.5kHz) may also be used if Timer 1 is not required for any other purpose while SIO1 is in a master mode.

The frequencies shown in Table 2 are unimportant when SIO1 is in a slave mode. In the slave modes, SIO1 will automatically synchronize with any clock frequency up to 100kHz.

**The Status Register, S1STA:** S1STA is an 8-bit read-only special function register. The three least significant bits are always zero. The five most significant bits contain the status code. There are 26 possible status codes. When S1STA contains F8H, no relevant state information is available and no serial interrupt is requested. All other S1STA values correspond to defined SIO1 states. When each of these states is entered, a serial interrupt is requested (SI = "1"). A valid status code is present in S1STA one machine cycle after SI is set by hardware and is still present one machine cycle after SI has been reset by software.

**More Information on SIO1 Operating**

**Modes:** The four operating modes are:

- Master Transmitter
- Master Receiver
- Slave Receiver
- Slave Transmitter

Data transfers in each mode of operation are shown in Figures 17–37. These figures contain the following abbreviations:

| Abbreviation | Explanation                             |
|--------------|-----------------------------------------|
| S            | Start condition                         |
| SLA          | 7-bit slave address                     |
| R            | Read bit (high level at SDA)            |
| W            | Write bit (low level at SDA)            |
| A            | Acknowledge bit (low level at SDA)      |
| Ā            | Not acknowledge bit (high level at SDA) |
| Data         | 8-bit data byte                         |
| P            | Stop condition                          |

In Figures 17-37, circles are used to indicate when the serial interrupt flag is set. The numbers in the circles show the status code held in the S1STA register. At these points, a service routine must be executed to continue or complete the serial transfer. These service routines are not critical since the serial transfer is suspended until the serial interrupt flag is cleared by software.

When a serial interrupt routine is entered, the status code in S1STA is used to branch to the appropriate service routine. For each status code, the required software action and details of the following serial transfer are given in Tables 3-7.

**Master Transmitter Mode:** In the master transmitter mode, a number of data bytes are transmitted to a slave receiver (see Figure 17). Before the master transmitter

mode can be entered, S1CON must be initialized as follows:

|             |          | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0        |
|-------------|----------|---|---|---|---|---|---|---|----------|
| S1CON (D8H) | CR2      |   |   |   |   |   |   |   |          |
|             | ENS1     |   |   |   |   |   |   |   |          |
|             | STA      |   |   |   |   |   |   |   |          |
|             | STO      |   |   |   |   |   |   |   |          |
|             | SI       |   |   |   |   |   |   |   |          |
|             | AA       |   |   |   |   |   |   |   |          |
|             | CR1      |   |   |   |   |   |   |   |          |
|             | CR0      |   |   |   |   |   |   |   |          |
|             | bit rate | 1 | 0 | 0 | 0 | 0 | X |   | bit rate |

CR0, CR1, and CR2 define the serial bit rate. ENS1 must be set to logic 1 to enable SIO1. If the AA bit is reset, SIO1 will not acknowledge its own slave address or the general call address in the event of another device becoming master of the bus. In other words, if AA is reset, SIO0 cannot enter a slave mode. STA, STO, and SI must be reset.

The master transmitter mode may now be entered by setting the STA bit using the SETB instruction. The SIO1 logic will now test the I<sup>2</sup>C bus and generate a start condition as soon as the bus becomes free. When a START condition is transmitted, the serial interrupt flag (SI) is set, and the status code in the status register (S1STA) will be 08H. This status code must be used to vector to an interrupt service routine that loads S1DAT with the slave address and the data direction bit (SLA+W). The SI bit in S1CON must then be reset before the serial transfer can continue.

When the slave address and the direction bit have been transmitted and an acknowledgment bit has been received, the serial interrupt flag (SI) is set again, and a number of status codes in S1STA are possible. There are 18H, 20H, or 38H for the master mode and also 68H, 78H, or B0H if the slave mode was enabled (AA = logic 1). The appropriate action to be taken for each of these status codes is detailed in Table 3. After a repeated start condition (state 10H), SIO1 may switch to the master receiver mode by loading S1DAT with SLA+R).

8XC552/562 overview

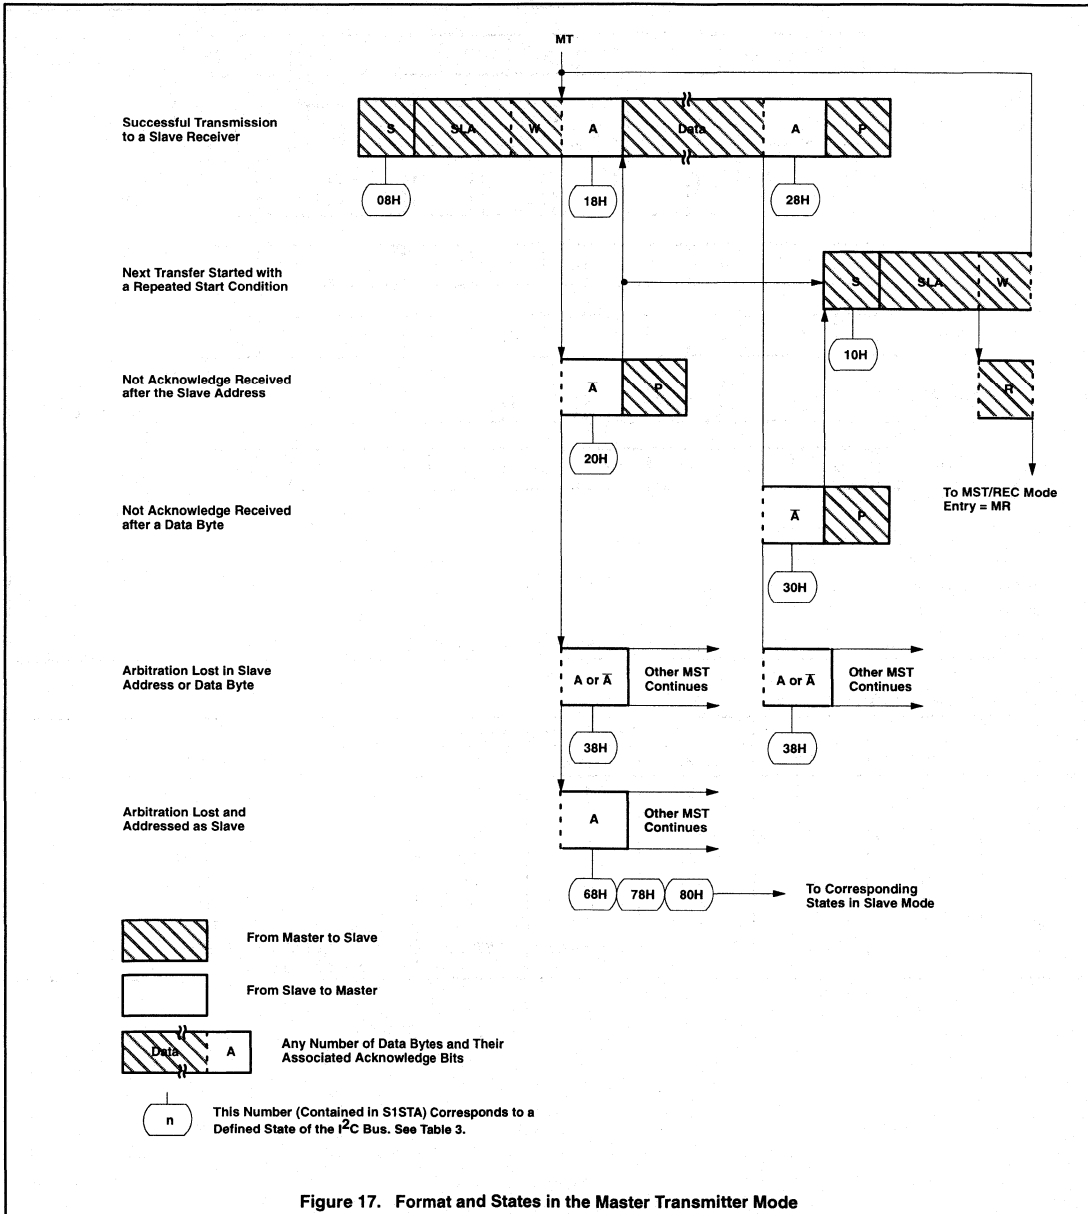

Figure 17. Format and States in the Master Transmitter Mode

80C51 Family Derivatives

8XC552/562 overview

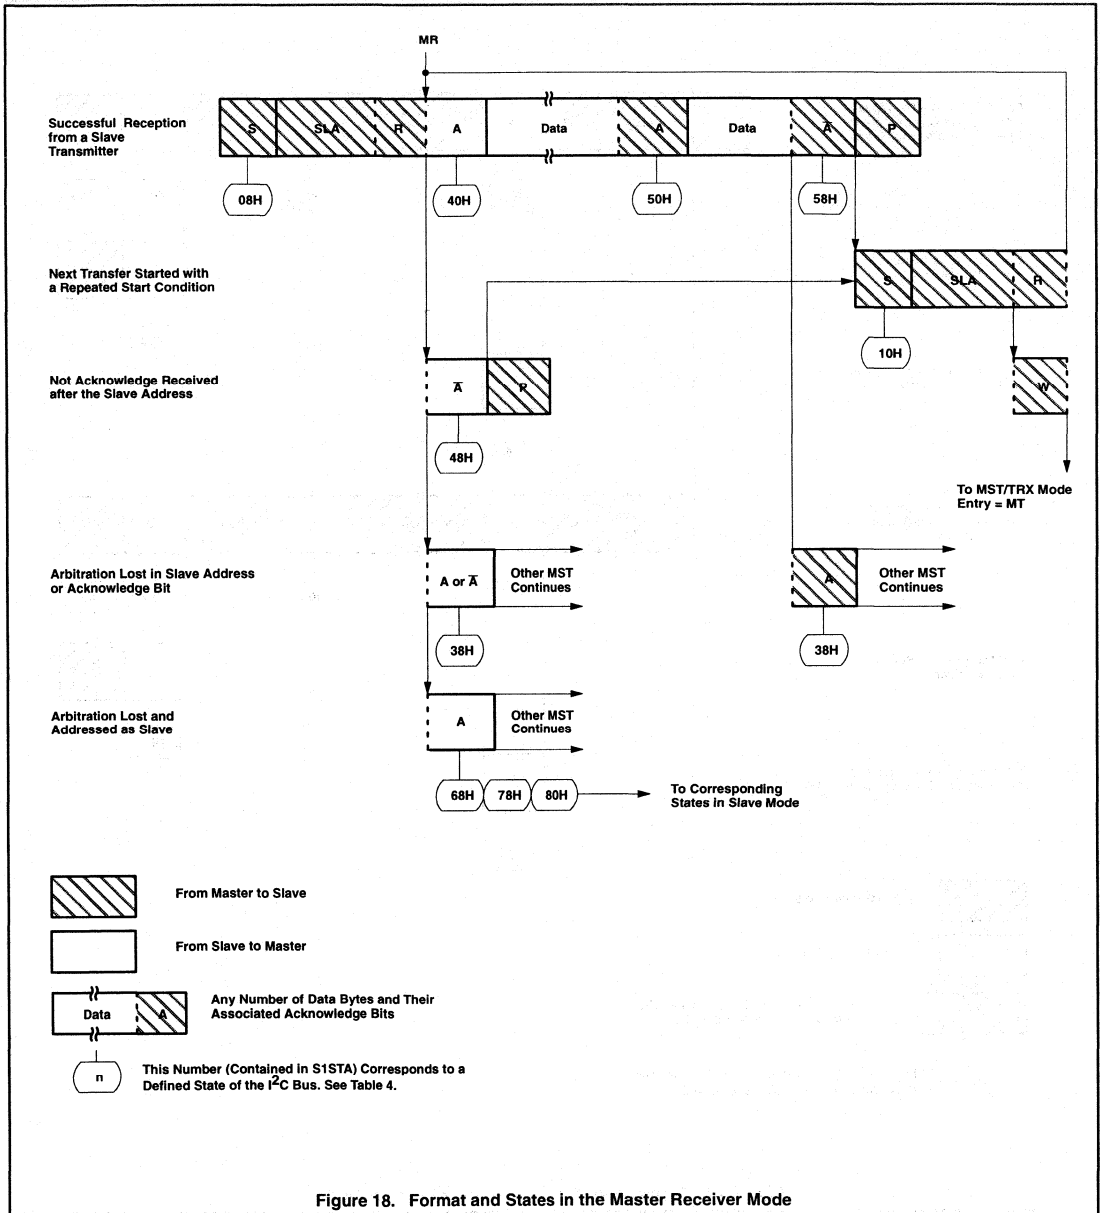

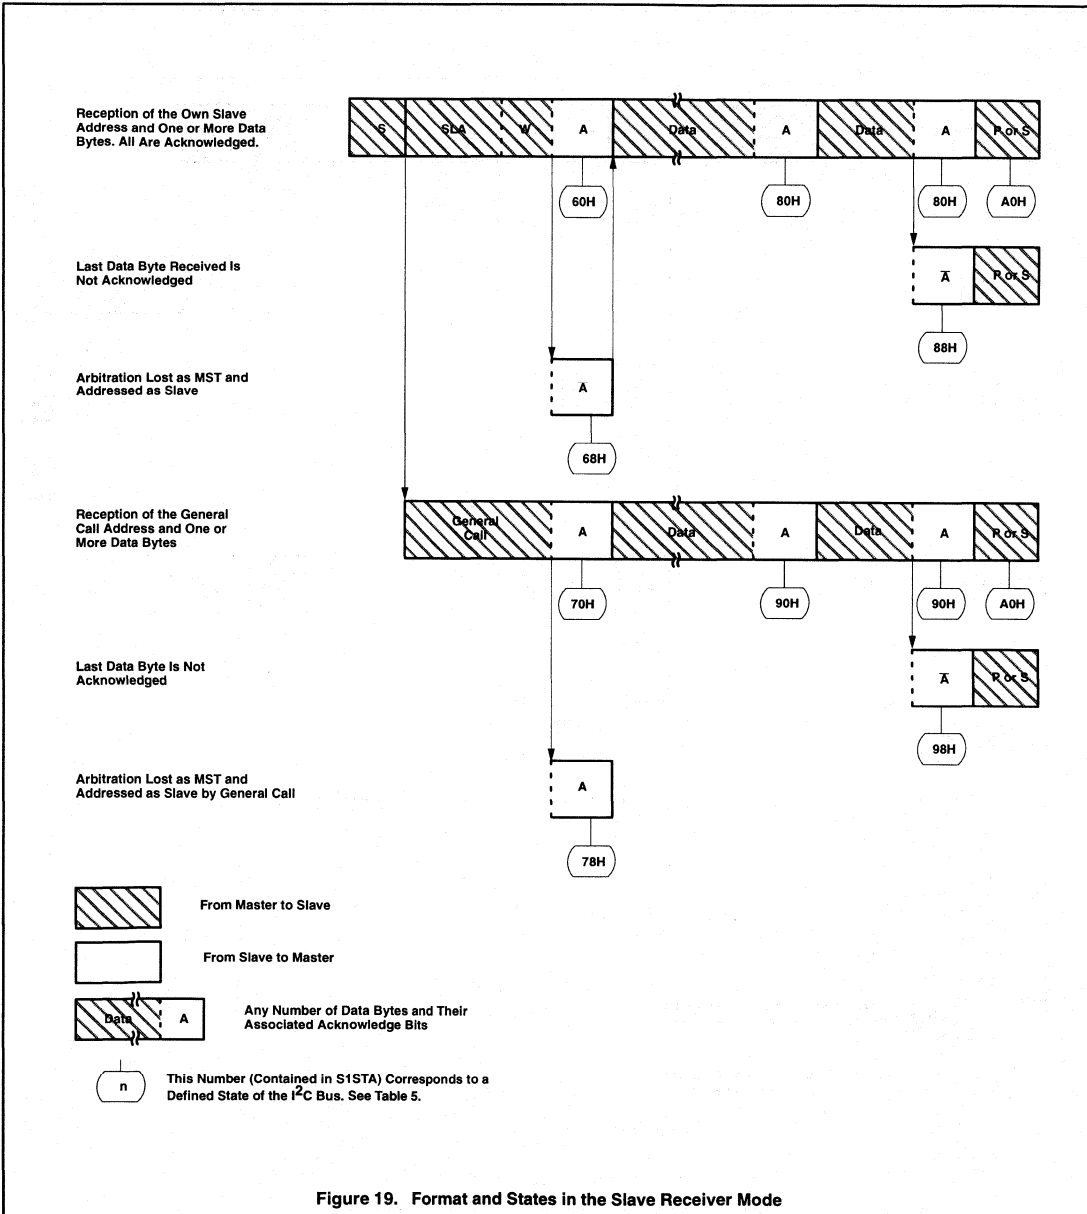

Figure 18. Format and States in the Master Receiver Mode

**Master Receiver Mode:** In the master receiver mode, a number of data bytes are received from a slave transmitter (see Figure 18). The transfer is initialized as in the master transmitter mode. When the start condition has been transmitted, the interrupt service routine must load S1DAT with the 7-bit slave address and the data direction bit (SLA+R). The SI bit in S1CON must then be cleared before the serial transfer can continue.

When the slave address and the data direction bit have been transmitted and an acknowledgment bit has been received, the serial interrupt flag (SI) is set again, and a number of status codes in S1STA are possible. These are 40H, 48H, or 38H for the master mode and also 68H, 78H, or B0H if the slave mode was enabled (AA = logic 1). The appropriate action to be taken for each of these status codes is detailed in Table 4. ENS1, CR1, and CR0 are not affected by the serial transfer and are not referred to in Table 4. After a repeated start condition (state 10H), SIO1 may switch to the master transmitter mode by loading S1DAT with SLA+W.

**Slave Receiver Mode:** In the slave receiver mode, a number of data bytes are received from a master transmitter (see Figure 19). To initiate the slave receiver mode, S1ADR and S1CON must be loaded as follows:

|             |                   |   |   |   |   |   |   |    |
|-------------|-------------------|---|---|---|---|---|---|----|
|             | 7                 | 6 | 5 | 4 | 3 | 2 | 1 | 0  |
| S1ADR (DBH) | X                 | X | X | X | X | X | X | GC |
|             | own slave address |   |   |   |   |   |   |    |

The upper 7 bits are the address to which SIO1 will respond when addressed by a master. If the LSB (GC) is set, SIO1 will respond to the general call address (00H); otherwise it ignores the general call address.

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
|             | 7   | 6    | 5   | 4   | 3  | 2  | 1   | 0   |
| S1CON (DBH) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|             | X   | 1    | 0   | 0   | 0  | 1  | X   | X   |

CR0, CR1, and CR12 do not affect SIO1 in the slave mode. ENS1 must be set to logic 1 to enable SIO1. The AA bit must be set to enable SIO1 to acknowledge its own slave address or the general call address. STA, STO, and SI must be reset.

When S1ADR and S1CON have been initialized, SIO1 waits until it is addressed by its own slave address followed by the data direction bit which must be "0" (W) for SIO1 to operate in the slave receiver mode. After its own slave address and the W bit have been received, the serial interrupt flag (I) is set and a valid status code can be read from S1STA. This status code is used to vector to an interrupt service routine, and the appropriate action to be taken for each of these status codes is detailed in Table 5. The slave receiver mode may also be entered if arbitration is lost while SIO1 is in the master mode (see status 68H and 78H).

If the AA bit is reset during a transfer, SIO1 will return a not acknowledge (logic 1) to SDA after the next received data byte. While AA is reset, SIO1 does not respond to its own slave address or a general call address. However, the I<sup>2</sup>C bus is still monitored and address recognition may be resumed at any time by setting AA. This means that the AA bit may be used to temporarily isolate SIO1 from the I<sup>2</sup>C bus.

## 80C51 Family Derivatives

## 8XC552/562 overview

**Slave Transmitter Mode:** In the slave transmitter mode, a number of data bytes are transmitted to a master receiver (see Figure 20). Data transfer is initialized as in the slave receiver mode. When S1ADR and S1CON have been initialized, SIO1 waits until it is addressed by its own slave address followed by the data direction bit which must be "1" (R) for SIO1 to operate in the slave transmitter mode. After its own slave address and the R bit have been received, the serial interrupt flag (SI) is set and a valid status code can be read from S1STA. This status code is used to vector to an interrupt service routine, and the appropriate action to be taken for each of these status codes is detailed in Table 6. The slave transmitter mode may also be entered if arbitration is lost while SIO1 is in the master mode (see state B0H).

If the AA bit is reset during a transfer, SIO1 will transmit the last byte of the transfer and enter state C0H or C8H. SIO1 is switched to the not addressed slave mode and will ignore the master receiver if it continues the transfer. Thus the master receiver receives all 1s as serial data. While AA is reset, SIO1 does not respond to its own slave address or a general call address. However, the I<sup>2</sup>C bus is still monitored, and address recognition may be resumed at any time by setting AA. This means that the AA bit may be used to temporarily isolate SIO1 from the I<sup>2</sup>C bus.

**Miscellaneous States:** There are two S1STA codes that do not correspond to a defined SIO1 hardware state (see Table 7). These are discussed below.

**S1STA = F8H:**

This status code indicates that no relevant information is available because the serial interrupt flag, SI, is not yet set. This occurs between other states and when SIO1 is not involved in a serial transfer.

**S1STA = 00H:**

This status code indicates that a bus error has occurred during an SIO1 serial transfer. A bus error is caused when a START or STOP condition occurs at an illegal position in the format frame. Examples of such illegal positions are during the serial transfer of an address byte, a data byte, or an acknowledge bit. A bus error may also be caused when external interference disturbs the internal SIO1 signals. When a bus error occurs, SI is set. To recover from a bus error, the STO flag must be set and SI must be cleared. This causes SIO1 to enter the "not addressed" slave mode (a defined state) and to clear the

STO flag (no other bits in S1CON are affected). The SDA and SCL lines are released (a STOP condition is not transmitted).

**Some Special Cases:** The SIO1 hardware has facilities to handle the following special cases that may occur during a serial transfer:

**Simultaneous Repeated START Conditions from Two Masters**

A repeated START condition may be generated in the master transmitter or master receiver modes. A special case occurs if another master simultaneously generates a repeated START condition (see Figure 21). Until this occurs, arbitration is not lost by either master since they were both transmitting the same data.

If the SIO1 hardware detects a repeated START condition on the I<sup>2</sup>C bus before generating a repeated START condition itself, it will release the bus, and no interrupt request is generated. If another master frees the bus by generating a STOP condition, SIO1 will transmit a normal START condition (state 08H), and a retry of the total serial data transfer can commence.

**DATA TRANSFER AFTER LOSS OF ARBITRATION**

Arbitration may be lost in the master transmitter and master receiver modes (see Figure 13). Loss of arbitration is indicated by the following states in S1STA; 38H, 68H, 78H, and B0H (see Figures 17 and 18).

If the STA flag in S1CON is set by the routines which service these states, then, if the bus is free again, a START condition (state 08H) is transmitted without intervention by the CPU, and a retry of the total serial transfer can commence.

**FORCED ACCESS TO THE I<sup>2</sup>C BUS**

In some applications, it may be possible for an uncontrolled source to cause a bus hang-up. In such situations, the problem may be caused by interference, temporary interruption of the bus or a temporary short-circuit between SDA and SCL.

If an uncontrolled source generates a superfluous START or masks a STOP condition, then the I<sup>2</sup>C bus stays busy indefinitely. If the STA flag is set and bus access is not obtained within a reasonable amount of time, then a forced access to the I<sup>2</sup>C bus is possible. This is achieved by setting the STO flag while the STA flag is still set. No STOP condition is transmitted. The SIO1 hardware behaves as if a STOP

condition was received and is able to transmit a START condition. The STO flag is cleared by hardware (see Figure 22).

**I<sup>2</sup>C BUS OBSTRUCTED BY A LOW LEVEL ON SCL OR SDA**

An I<sup>2</sup>C bus hang-up occurs if SDA or SCL is pulled LOW by an uncontrolled source. If the SCL line is obstructed (pulled LOW) by a device on the bus, no further serial transfer is possible, and the SIO1 hardware cannot resolve this type of problem. When this occurs, the problem must be resolved by the device that is pulling the SCL bus line LOW.

If the SDA line is obstructed by another device on the bus (e.g., a slave device out of bit synchronization), the problem can be solved by transmitting additional clock pulses on the SCL line (see Figure 23). The SIO1 hardware transmits additional clock pulses when the STA flag is set, but no START condition can be generated because the SDA line is pulled LOW while the I<sup>2</sup>C bus is considered free. The SIO1 hardware attempts to generate a START condition after every two additional clock pulses on the SCL line. When the SDA line is eventually released, a normal START condition is transmitted, state 08H is entered, and the serial transfer continues.

If a forced bus access occurs or a repeated START condition is transmitted while SDA is obstructed (pulled LOW), the SIO1 hardware performs the same action as described above. In each case, state 08H is entered after a successful START condition is transmitted and normal serial transfer continues. Note that the CPU is not involved in solving these bus hang-up problems.

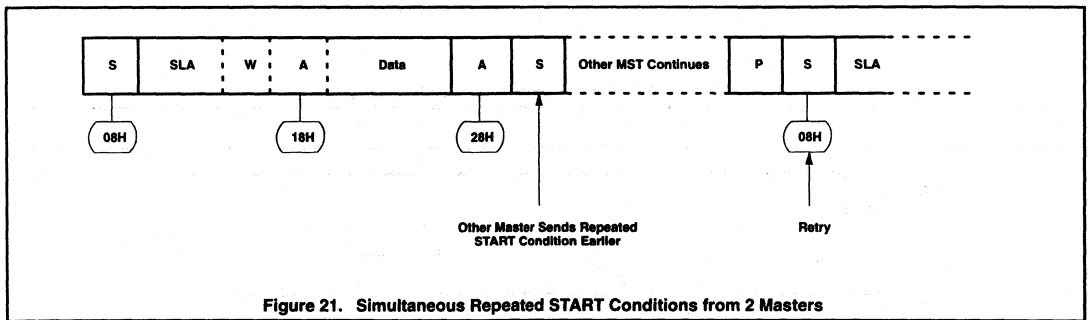

**BUS ERROR**

A bus error occurs when a START or STOP condition is present at an illegal position in the format frame. Examples of illegal positions are during the serial transfer of an address byte, a data or an acknowledge bit.

The SIO1 hardware only reacts to a bus error when it is involved in a serial transfer either as a master or an addressed slave. When a bus error is detected, SIO1 immediately switches to the not addressed slave mode, releases the SDA and SCL lines, sets the interrupt flag, and loads the status register with 00H. This status code may be used to vector to a service routine which either attempts the aborted serial transfer again or simply recovers from the error condition as shown in Table 7.

**Table 7. Miscellaneous States**

| STATUS CODE (S1STA) | STATUS OF THE I <sup>2</sup> C BUS AND SIO1 HARDWARE                                                                                                                         | APPLICATION SOFTWARE RESPONSE |                 |     |    |    | NEXT ACTION TAKEN BY SIO1 HARDWARE                                                                                                                                            |

Software Examples of SIO1 Service

**Routines:** This section consists of a software example for:

- Initialization of SIO1 after a RESET
- Entering the SIO1 interrupt routine
- The 26 state service routines for the
  - Master transmitter mode
  - Master receiver mode
  - Slave receiver mode
  - Slave transmitter mode

INITIALIZATION

In the initialization routine, SIO1 is enabled for both master and slave modes. For each mode, a number of bytes of internal data

RAM are allocated to the SIO to act as either a transmission or reception buffer. In this example, 8 bytes of internal data RAM are reserved for different purposes. The data memory map is shown in Figure 24. The initialization routine performs the following functions:

- S1ADR is loaded with the part's own slave address and the general call bit (GC)
- P1.6 and P1.7 bit latches are loaded with logic 1s
- RAM location HADD is loaded with the high-order address byte of the service routines
- The SIO1 interrupt enable and interrupt priority bits are set

- The slave mode is enabled by simultaneously setting the ENS1 and AA bits in S1CON and the serial clock frequency (for master modes) is defined by loading CR0 and CR1 in S1CON. The master routines must be started in the main program.

The SIO1 hardware now begins checking the I<sup>2</sup>C bus for its own slave address and general call. If the general call or the own slave address is detected, an interrupt is requested and S1STA is loaded with the appropriate state information. The following text describes a fast method of branching to the appropriate service routine.

## 80C51 Family Derivatives

## 8XC552/562 overview

## SIO1 INTERRUPT ROUTINE

When the SIO1 interrupt is entered, the PSW is first pushed on the stack. Then S1STA and HADD (loaded with the high-order address byte of the 26 service routines by the initialization routine) are pushed on to the stack. S1STA contains a status code which is the lower byte of one of the 26 service routines. The next instruction is RET, which is the return from subroutine instruction. When this instruction is executed, the high and low order address bytes are popped from stack and loaded into the program counter.

The next instruction to be executed is the first instruction of the state service routine. Seven bytes of program code (which execute in eight machine cycles) are required to branch to one of the 26 state service routines.

|    |      |       |                                           |
|----|------|-------|-------------------------------------------|
| SI | PUSH | PSW   | Save PSW                                  |
|    | PUSH | S1STA | Push status code (low order address byte) |
|    | PUSH | HADD  | Push high order address byte              |
|    | RET  |       | Jump to state service routine             |

The state service routines are located in a 256-byte page of program memory. The location of this page is defined in the initialization routine. The page can be located anywhere in program memory by loading data RAM register HADD with the page number. Page 01 is chosen in this example, and the service routines are located between addresses 0100H and 01FFH.

## THE STATE SERVICE ROUTINES

The state service routines are located 8 bytes from each other. Eight bytes of code are sufficient for most of the service routines. A few of the routines require more than 8 bytes and have to jump to other locations to obtain more bytes of code. Each state routine is part of the SIO1 interrupt routine and handles one of the 26 states. It ends with a RETI instruction which causes a return to the main

program.

## MASTER TRANSMITTER AND MASTER RECEIVER MODES

The master mode is entered in the main program. To enter the master transmitter mode, the main program must first load the internal data RAM with the slave address, data bytes, and the number of data bytes to be transmitted. To enter the master receiver mode, the main program must first load the internal data RAM with the slave address and the number of data bytes to be received. The R/W bit determines whether SIO1 operates in the master transmitter or master receiver mode.

Master mode operation commences when the STA bit in S1CION is set by the SETB instruction and data transfer is controlled by the master state service routines in accordance with Table 3, Table 4, Figure 17, and Figure 18. In the example below, 4 bytes are transferred. There is no repeated START condition. In the event of lost arbitration, the transfer is restarted when the bus becomes free. If a bus error occurs, the I<sup>2</sup>C bus is released and SIO1 enters the not selected slave receiver mode. If a slave device returns a not acknowledge, a STOP condition is generated.

A repeated START condition can be included in the serial transfer if the STA flag is set instead of the STO flag in the state service routines vectored to by status codes 28H and 58H. Additional software must be written to determine which data is transferred after a repeated START condition.

## SLAVE TRANSMITTER AND SLAVE RECEIVER MODES

After initialization, SIO1 continually tests the I<sup>2</sup>C bus and branches to one of the slave state service routines if it detects its own slave address or the general call address (see Table 5, Table 6, Figure 19, and Figure 20). If arbitration was lost while in the master mode, the master mode is restarted after the

current transfer. If a bus error occurs, the I<sup>2</sup>C bus is released and SIO1 enters the not selected slave receiver mode.

In the slave receiver mode, a maximum of 8 received data bytes can be stored in the internal data RAM. A maximum of 8 bytes ensures that other RAM locations are not overwritten if a master sends more bytes. If more than 8 bytes are transmitted, a not acknowledge is returned, and SIO1 enters the not addressed slave receiver mode. A maximum of one received data byte can be stored in the internal data RAM after a general call address is detected. If more than one byte is transmitted, a not acknowledge is returned and SIO1 enters the not addressed slave receiver mode.

In the slave transmitter mode, data to be transmitted is obtained from the same locations in the internal data RAM that were previously loaded by the main program. After a not acknowledge has been returned by a master receiver device, SIO1 enters the not addressed slave mode.

## ADAPTING THE SOFTWARE FOR DIFFERENT APPLICATIONS

The following software example shows the typical structure of the interrupt routine including the 26 state service routines and may be used as a base for user applications. If one or more of the four modes are not used, the associated state service routines may be removed but, care should be taken that a deleted routine can never be invoked.

This example does not include any time-out routines. In the slave modes, time-out routines are not very useful since, in these modes, SIO1 behaves essentially as a passive device. In the master modes, an internal timer may be used to cause a time-out if a serial transfer is not complete after a defined period of time. This time period is defined by the system connected to the I<sup>2</sup>C bus.

**Reset Circuitry**

The reset circuitry for the 8XC552 is connected to the reset pin RST. A Schmitt trigger is used at the input for noise rejection (see Figure 25). The output of the Schmitt trigger is sampled by the reset circuitry every machine cycle.

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods) while the oscillator is running. The CPU responds by executing an internal reset. During reset, ALE and PSEN output a HIGH level. In order to perform a correct reset, this level must not be affected by external elements. The RST line can also be pulled HIGH internally by a pull-up transistor activated by the watchdog timer T3. The length of the output pulse from T3 is 3 machine cycles. A pulse of such short duration is necessary in order to recover from a processor or system fault as fast as possible.

Note that the short reset pulse from Timer T3 cannot discharge the power-on reset capacitor (see Figure 26). Consequently, when the watchdog timer is also used to set external devices, this capacitor arrangement should not be connected to the RST pin, and a different circuit should be used to perform the power-on reset operation. A timer T3

overflow, if enabled, will force a reset condition to the 8XC552 by an internal connection, whether the output RST is tied LOW or not.

The internal reset is executed during the second cycle in which RST is HIGH and is repeated every cycle until RST goes low. It leaves the internal registers as follows:

The internal RAM is not affected by reset. At power-on, the RAM content is indeterminate.

### Interrupts

The 8XC552 has fifteen interrupt sources, each of which can be assigned one of two priority levels, as shown in Figure 27. The five interrupt sources common to the 80C51 are the external interrupts (INT0 and INT1), the timer 0 and timer 1 interrupts (IT0 and IT1), and the serial I/O interrupt (RI or TI). In the 8XC552, the standard serial interrupt is called SIO0. Since the subsystems which create these interrupts are identical on both parts, their functionality is likewise identical. The only differences are the locations of the enable and priority register configurations and the priority structure. This is detailed below along with the specifics of the interrupts unique to the 8XC552.

The eight Timer T2 interrupts are generated by flags CT10-CT13, CM10-CM12, and by the logical OR of flags T2OV and T2BO. Flags CT10 to CT13 are set by input signals CT01 to CT3i. Flags CM10 to CM12 are set when a match occurs between Timer T2 and the

compare registers CM0, CM1, and CM2.

When an 8-bit or 16-bit overflow occurs, flags T2BO and T2OV are set, respectively. These nine flags are not cleared by hardware and must be reset by software to avoid recurring interrupts.

The ADC interrupt is generated by the ADCl flag in the ADC control register (ADCON). This flag is set when an ADC conversion result is ready to be read. ADCl is not cleared by hardware and must be reset by software to avoid recurring interrupts.

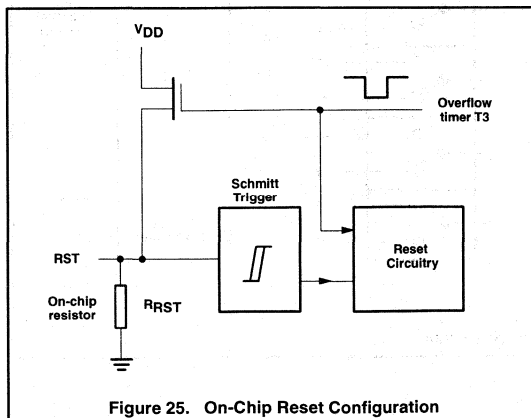

Figure 25. On-Chip Reset Configuration

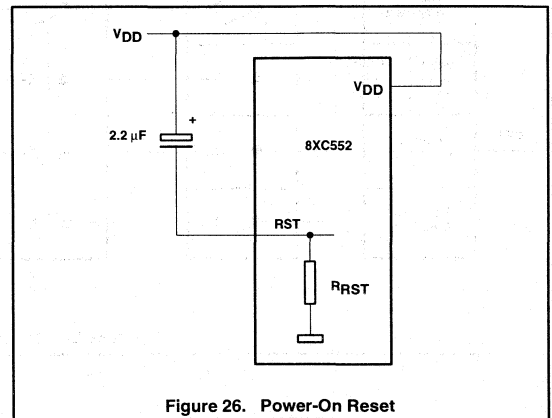

Figure 26. Power-On Reset

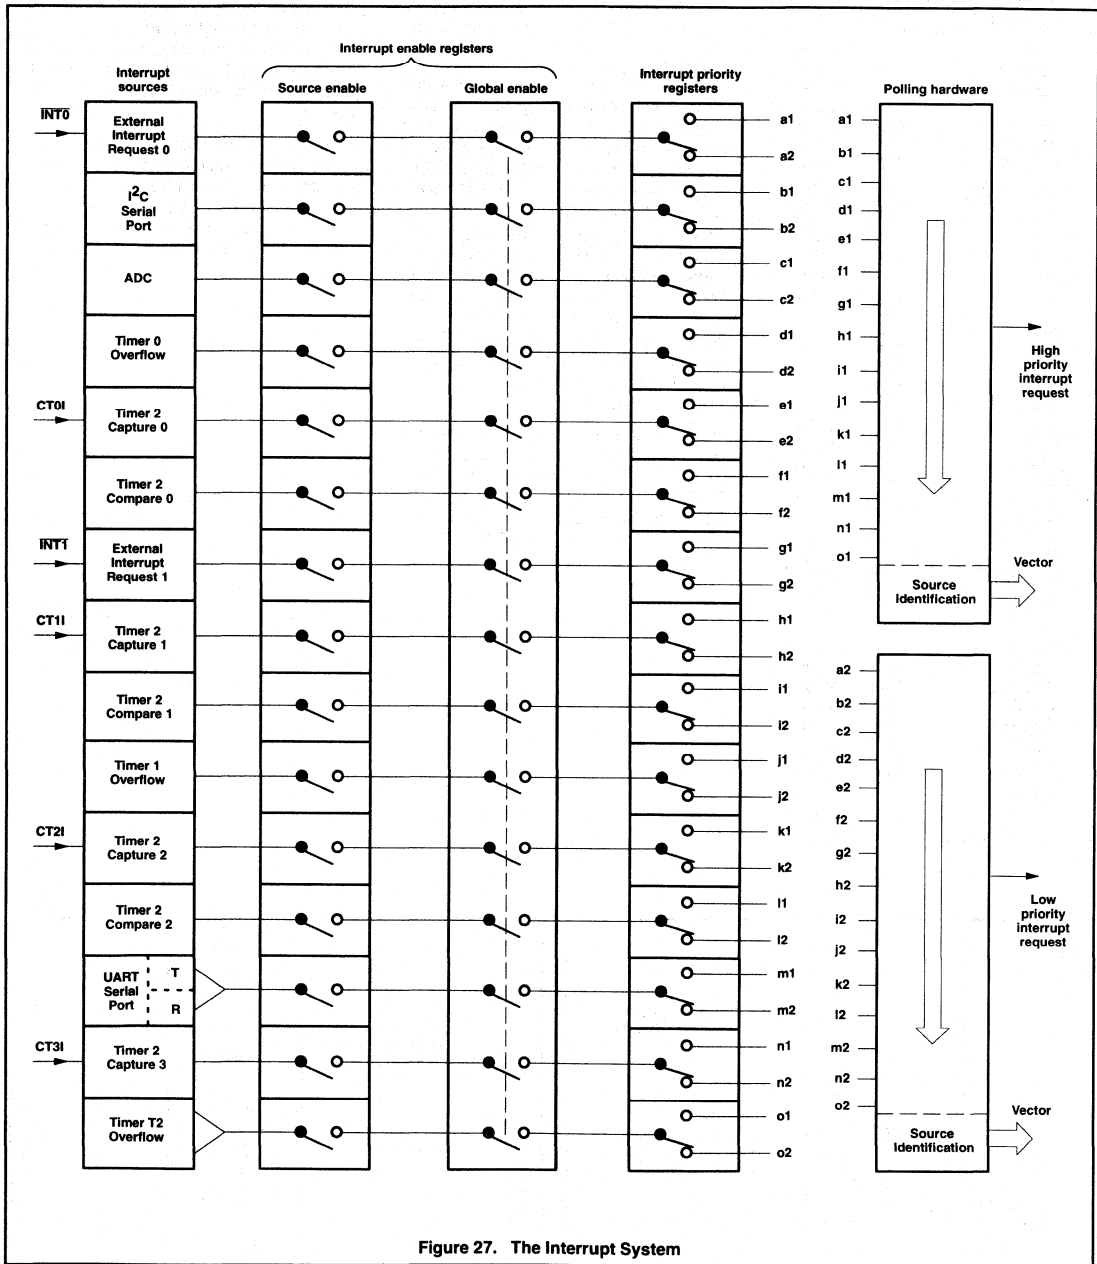

Figure 27. The Interrupt System

## 80C51 Family Derivatives

## 8XC552/562 overview

The SIO1 (I<sup>2</sup>C) interrupt is generated by the SI flag in the SIO1 control register (S1CON). This flag is set when S1STA is loaded with a valid status code.

The ADCL flag may be reset by software. It cannot be set by software. All other flags that generate interrupts may be set or cleared by software, and the effect is the same as setting or resetting the flags by hardware. Thus, interrupts may be generated by software and pending interrupts can be canceled by software.

**Interrupt Enable Registers:** Each interrupt source can be individually enabled or disabled by setting or clearing a bit in the interrupt enable special function registers IEN0 and IEN1. All interrupt sources can also be globally enabled or disabled by setting or clearing bit EA in IEN0. The interrupt enable registers are described in Figures 28 and 29.

**Interrupt Priority Structure:** Each interrupt source can be assigned one of two priority levels. Interrupt priority levels are defined by the interrupt priority special function registers IP0 and IP1. IP0 and IP1 are described in Figures 30 and 31.

Interrupt priority levels are as follows:  
 "0"—low priority  
 "1"—high priority

A low priority interrupt may be interrupted by a high priority interrupt. A high priority interrupt cannot be interrupted by any other interrupt source. If two requests of different priority occur simultaneously, the high priority

level request is serviced. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced. Thus, within each priority level, there is a second priority structure determined by the polling sequence. This second priority structure is shown in Table 8.

The above Priority Within Level structure is only used when there are simultaneous requests of the same priority level.

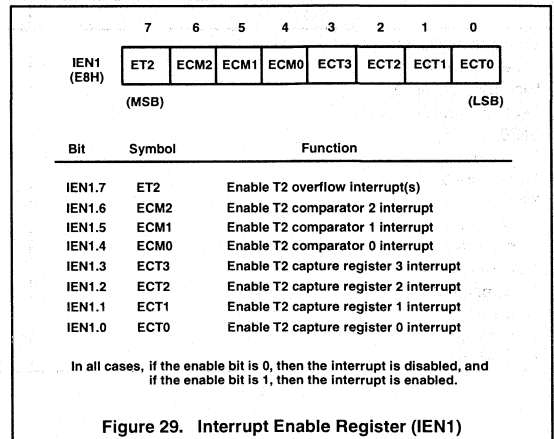

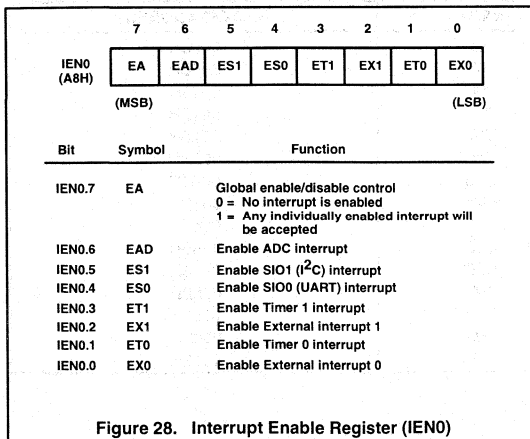

**Interrupt Handling:** The interrupt sources are sampled at S5P2 of every machine cycle. The samples are polled during the following machine cycle. If one of the flags was in a set condition at S5P2 of the previous machine cycle, the polling cycle will find it and the interrupt system will generate an LCALL to the appropriate service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of higher or equal priority level is already in progress.
2. The current machine cycle is not the final cycle in the execution of the instruction in progress. (No interrupt request will be serviced until the instruction in progress is completed.)
3. The instruction in progress is RETI or any access to the interrupt priority or interrupt enable registers. (No interrupt will be serviced after RETI or after a read or write to IP0, IP1, IE0, or IE1 until at least one other instruction has been subsequently executed.)

The polling cycle is repeated with every machine cycle, and the values polled are the values present at S5P2 of the previous machine cycle. Note that if an interrupt flag is active but is not being responded to because of one of the above conditions, and if the flag is inactive when the blocking condition is removed, then the blocked interrupt will not be serviced. Thus, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle is new.

The processor acknowledges an interrupt request by executing a hardware-generated LCALL to the appropriate service routine. In some cases it also clears the flag which generated the interrupt, and in others it does not. It clears the Timer 0, Timer 1, and external interrupt flags. An external interrupt flag (IE0 or IE1) is cleared only if it was transition-activated. All other interrupt flags are not cleared by hardware and must be cleared by the software. The LCALL pushes the contents of the program counter on to the stack (but it does not save the PSW) and reloads the PC with an address that depends on the source of the interrupt being vectored to as shown in Table 9.

Execution proceeds from the vector address until the RETI instruction is encountered. The RETI instruction clears the "priority level active" flip-flop that was set when this interrupt was acknowledged. It then pops the top two bytes from the stack and reloads the program counter. Execution of the interrupted program continues from where it was interrupted.

## 80C51 Family Derivatives

## 8XC552/562 overview

**I/O Port Structure**

The 8XC552 has six 8-bit ports. Each port consists of a latch (special function registers P0 to P5), an input buffer, and an output driver (port 0 to 4 only). Ports 0-3 are the same as in the 80C51, with the exception of the additional functions of port 1. The parallel I/O function of port 4 is equal to that of ports 1, 2, and 3. Port 5 may be used as an input port only.

Figure 32 shows the bit latch and I/O buffer functional diagrams of the unique 8XC552 ports. A bit latch corresponds to one bit in a port's SFR and is represented as a D type flip-flop. A "write to latch" signal from the CPU latches a bit from the internal bus and a "read latch" signal from the CPU places the Q output of the flip-flop on the internal bus. A "read pin" signal from the CPU places the actual port pin level on the internal bus. Some instructions that read a port read the actual port pin levels, and other instructions read the latch (SFR) contents.

**Port 1 Operation**

Port 1 operates the same as it does in the 8051 with the exception of port lines P1.6 and P1.7, which may be selected as the SCL and SDA lines of serial port SIO1 (I<sup>2</sup>C). Because the I<sup>2</sup>C bus may be active while the device is disconnected from V<sub>DD</sub>, these pins are provided with open drain drivers. Therefore pins P1.6 and P1.7 do not have internal pull-ups.

**Port 5 Operation**

Port 5 may be used to input up to 8 analog signals to the ADC. Unused ADC inputs may be used to input digital inputs. These inputs have an inherent hysteresis to prevent the input logic from drawing excessive current from the power lines when driven by analog signals. Channel to channel crosstalk (Ct) should be taken into consideration when both analog and digital signals are simultaneously input to Port 5 (see, D.C. characteristics in data sheet).

Port 5 is not bidirectional and may not be configured as an output port. All six ports are multifunctional, and their alternate functions are listed in Table 10. A more detailed description of these features can be found in the relevant parts of this section.

**Pulse Width Modulated Outputs**

The 8XC552 contains two pulse width modulated output channels (see Figure 33). These channels generate pulses of programmable length and interval. The repetition frequency is defined by an 8-bit prescaler PWMP, which supplies the clock for the counter. The prescaler and counter are common to both PWM channels. The 8-bit counter counts modulo 255, i.e., from 0 to 254 inclusive. The value of the 8-bit counter is compared to the contents of two registers: PWM0 and PWM1. Provided the contents of either of these registers is greater than the counter value, the corresponding PWM0 or PWM1 output is set LOW. If the contents of these registers are equal to, or less than the counter value, the output will be HIGH. The pulse-width-ratio is therefore defined by the contents of the registers PWM0 and PWM1. The pulse-width-ratio is in the range of 0 to 1 and may be programmed in increments of 1/255.

Buffered PWM outputs may be used to drive DC motors. The rotation speed of the motor would be proportional to the contents of PWMn. The PWM outputs may also be configured as a dual DAC. In this application, the PWM outputs must be integrated using conventional operational amplifier circuitry. If the resulting output voltages have to be accurate, external buffers with their own analog supply should be used to buffer the PWM outputs before they are integrated. The repetition frequency  $f_{PWM}$ , at the PWMn outputs is give by:

$$f_{PWM} = \frac{f_{osc}}{2 \times (1 + PWMP) \times 255}$$

This gives a repetition frequency range of 123Hz to 31.4kHz ( $f_{osc} = 16\text{MHz}$ ). At

$f_{osc} = 24\text{MHz}$ , the frequency range is 184Hz to 47.1Hz. By loading the PWM registers with either 00H or FFH, the PWM channels will output a constant HIGH or LOW level, respectively. Since the 8-bit counter counts modulo 255, it can never actually reach the value of the PWM registers when they are loaded with FFH.

When a compare register (PWM0 or PWM1) is loaded with a new value, the associated output is updated immediately. It does not have to wait until the end of the current counter period. Both PWMn output pins are driven by push-pull drivers. These pins are not used for any other purpose.

Prescaler frequency control register PWMP

|            |     |   |   |   |     |   |   |   |
|------------|-----|---|---|---|-----|---|---|---|
| PWMP (FEH) | 7   | 6 | 5 | 4 | 3   | 2 | 1 | 0 |
|            | MSB |   |   |   | LSB |   |   |   |

PWMP.0-7 Prescaler division factor = PWMP + 1.

Reading PWMP gives the current reload value. The actual count of the prescaler cannot be read.

|            |     |   |   |   |     |   |   |   |
|------------|-----|---|---|---|-----|---|---|---|
| PWM0 (FCH) | 7   | 6 | 5 | 4 | 3   | 2 | 1 | 0 |
| PWM1 (FDH) |     |   |   |   |     |   |   |   |
|            | MSB |   |   |   | LSB |   |   |   |

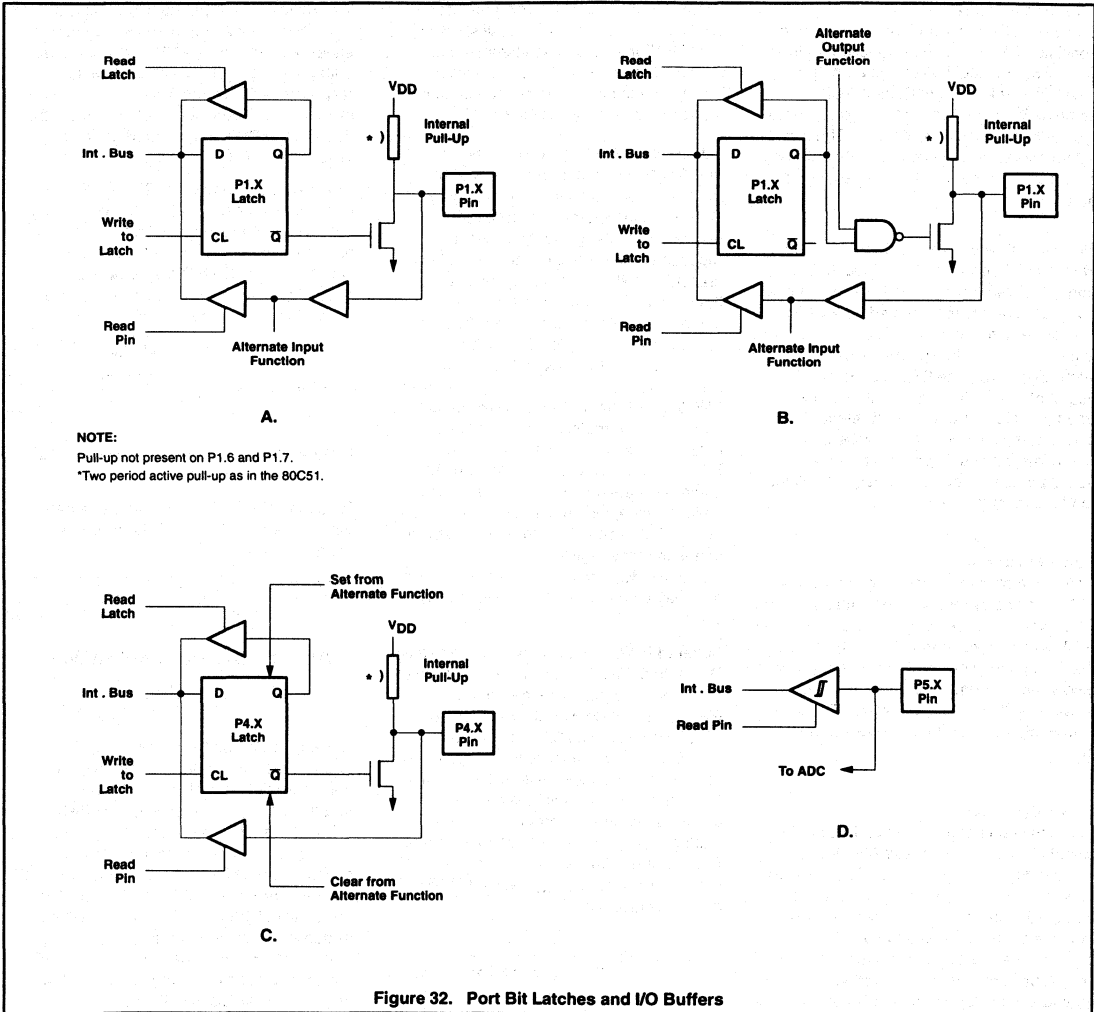

PWM0/1.0-7} Low/high ratio of PWMn =  $\frac{(PWMn)}{255 - (PWMn)}$

**Analog-to-Digital Converter**

The analog input circuitry consists of an 8-input analog multiplexer and a 10-bit, straight binary, successive approximation ADC. The analog reference voltage and analog power supplies are connected via separate input pins. The conversion takes 50 machine cycles, i.e., 37.5μs at an oscillator frequency of 16MHz, 25μs at an oscillator frequency of 24MHz. Input voltage swing is from 0V to +5V. Because the internal DAC employs a ratiometric potentiometer, there are no discontinuities in the converter characteristic. Figure 34 shows a functional diagram of the analog input circuitry.

## 80C51 Family Derivatives

## 8XC552/562 overview

**Analog-to-Digital Conversion:** Figure 35 shows the elements of a successive approximation (SA) ADC. The ADC contains a DAC which converts the contents of a successive approximation register to a voltage (VDAC) which is compared to the analog input voltage ( $V_{in}$ ). The output of the comparator is fed to the successive approximation control logic which controls the successive approximation register. A conversion is initiated by setting ADCS in the ADCON register. ADCS can be set by software only or by either hardware or software.

The software only start mode is selected when control bit ADCON.5 (ADEX) = 0. A conversion is then started by setting control bit ADCON.3 (ADCS). The hardware or software start mode is selected when ADCON.5 = 1, and a conversion may be started by setting ADCON.3 as above or by applying a rising edge to external pin STADC. When a conversion is started by applying a rising edge, a low level must be applied to STADC for at least one machine cycle followed by a high level for at least one machine cycle.

The low-to-high transition of STADC is recognized at the end of a machine cycle, and the conversion commences at the beginning of the next cycle. When a conversion is initiated by software, the conversion starts at the beginning of the machine cycle which follows the instruction that sets ADCS. ADCS is actually

implemented with two flip-flops: a command flip-flop which is affected by set operations, and a status flag which is accessed during read operations.

The next two machine cycles are used to initiate the converter. At the end of the first cycle, the ADCS status flag is set and a value of "1" will be returned if the ADCS flag is read while the conversion is in progress. Sampling of the analog input commences at the end of the second cycle.

During the next eight machine cycles, the voltage at the previously selected pin of port 5 is sampled, and this input voltage should be stable in order to obtain a useful sample. In any event, the input voltage slew rate must be less than 10V/ms in order to prevent an undefined result.

The successive approximation control logic first sets the most significant bit and clears all other bits in the successive approximation register (10 0000 0000B). The output of the DAC (50% full scale) is compared to the input voltage  $V_{in}$ . If the input voltage is greater than VDAC, then the bit remains set; otherwise it is cleared.

The successive approximation control logic now sets the next most significant bit (11 0000 0000B or 01 0000 0000B, depending on the previous result), and VDAC is compared to  $V_{in}$  again. If the input voltage is greater than VDAC, then the bit being tested remains set; otherwise the bit being

tested is cleared. This process is repeated until all ten bits have been tested, at which stage the result of the conversion is held in the successive approximation register. Figure 36 shows a conversion flow chart. The bit pointer identifies the bit under test. The conversion takes four machine cycles per bit.

The end of the 10-bit conversion is flagged by control bit ADCON.4 (ADCI). The upper 8 bits of the result are held in special function register ADCH, and the two remaining bits are held in ADCON.7 (ADC.1) and ADCON.6 (ADC.0). The user may ignore the two least significant bits in ADCON and use the ADC as an 8-bit converter (8 upper bits in ADCH). In any event, the total actual conversion time is 50 machine cycles for the 8XC552 or 24 machine cycles for the 8XC562. ADCI will be set and the ADCS status flag will be reset 50 (or 24) cycles after the command flip-flop (ADCS) is set.

Control bits ADCON.0, ADCON.1, and ADCON.2 are used to control an analog multiplexer which selects one of eight analog channels (see Figure 37). An ADCajmp RETmr conversion in progress is unaffected by an external or software ADC start. The result of a completed conversion remains unaffected provided ADCI = logic 1; a new ADC conversion already in progress is aborted when the idle or power-down mode is entered. The result of a completed conversion (ADCI = logic 1) remains unaffected when entering the idle mode.

| ADCON.6 | ADC.0  | Bit 0 of ADC result                                                                                                                                                                                                                                                                                                                                                                                   |   |                                                            |             |            |  |  |  |
| ADCON.5 | ADEX   | Enable external start of conversion by STADC<br>0 = Conversion can be started by software only (by setting ADCS)<br>1 = Conversion can be started by software or externally (by a rising edge on STADC)                                                                                                                                                                                               |   |                                                            |             |            |  |  |  |
| ADCON.4 | ADCI   | ADC interrupt flag: this flag is set when an A/D conversion result is ready to be read. An interrupt is invoked if it is enabled. The flag may be cleared by the interrupt service routine. While this flag is set, the ADC cannot start a new conversion. ADCI cannot be set by software.                                                                                                            |   |                                                            |             |            |  |  |  |
| ADCON.3 | ADCS   | ADC start and status: setting this bit starts an A/D conversion. It may be set by software or by the external signal STADC. The ADC logic ensures that this signal is HIGH while the ADC is busy. On completion of the conversion, ADCS is reset at the same time the interrupt flag is set. ADCS cannot be reset by software. A new conversion may not be started while either ADCS or ADCI is high. |   |                                                            |             |            |  |  |  |
|         |        | ADCI                                                                                                                                                                                                                                                                                                                                                                                                  |   | ADCS                                                       |             | ADC Status |  |  |  |

Figure 37. ADC Control Register (ADCON)

## 80C51 Family Derivatives

## 8XC552/562 overview

### ADC Resolution and Analog Supply:

Figure 38 shows how the ADC is realized. The ADC has its own supply pins ( $AV_{DD}$  and  $AV_{SS}$ ) and two pins ( $V_{ref+}$  and  $V_{ref-}$ ) connected to each end of the DAC's resistance-ladder. The ladder has 1023 equally spaced taps, separated by a resistance of "R". The first tap is located  $0.5 \times R$  above  $V_{ref-}$ , and the last tap is located  $1.5 \times R$  below  $V_{ref+}$ . This gives a total ladder resistance of  $1024 \times R$ . This structure ensures that the DAC is monotonic and results in a symmetrical quantization error as shown in Figure 40.

For input voltages between  $V_{ref-}$  and ( $V_{ref-} + 1/2$  LSB), the 10-bit result of an A/D conversion will be 00 0000 0000B = 000H. For input voltages between ( $V_{ref+} - 3/2$  LSB) and  $V_{ref+}$ , the result of a conversion will be 11 1111 1111B = 3FFH.  $AV_{ref+}$  and  $AV_{ref-}$

may be between  $AV_{DD} + 0.2V$  and  $AV_{SS} - 0.2V$ .  $AV_{ref+}$  should be positive with respect to  $AV_{ref-}$ , and the input voltage ( $V_{in}$ ) should be between  $AV_{ref+}$  and  $AV_{ref-}$ . If the analog input voltage range is from 2V to 4V, then 10-bit resolution can be obtained over this range if  $AV_{ref+} = 4V$  and  $AV_{ref-} = 2V$ .

The result can always be calculated from the following formula:

$$\text{Result} = 1024 \times \frac{V_{IN} - AV_{ref-}}{AV_{ref+} - AV_{ref-}}$$

### Power Reduction Modes

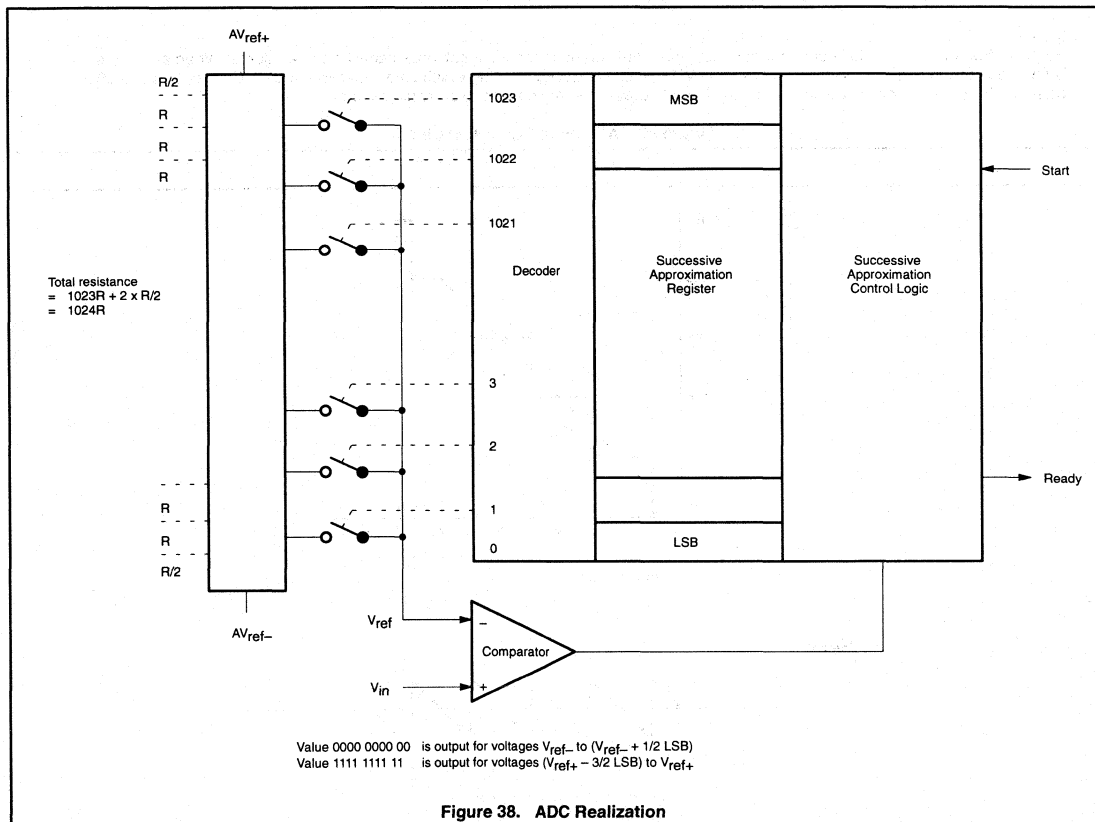

The 8XC552 has two reduced power modes of operation: the idle mode and the power-down mode. These modes are entered by setting bits in the PCON special function register. When the 8XC552 enters the idle mode, the following functions are disabled:

CPU (halted)  
 Timer T2 (halted and reset)  
 PWM0, PWM1 (reset; outputs are high)  
 ADC (conversion aborted if in progress).

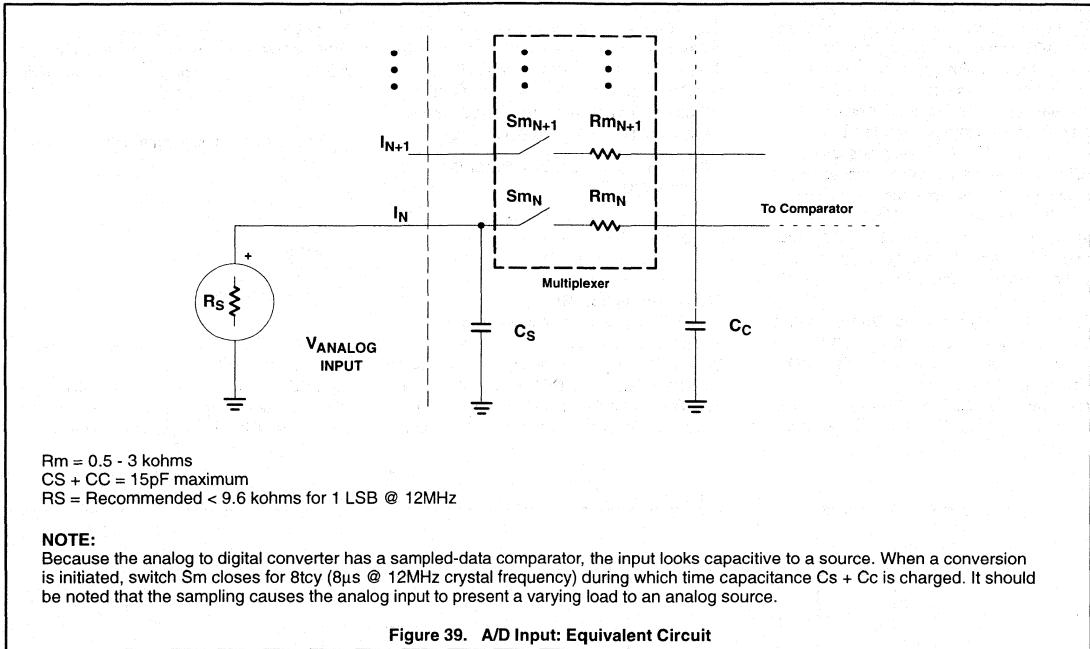

In idle mode, the following functions remain active:

Timer 0  
 Timer 1  
 Timer T3  
 SIO0 SIO1  
 External interrupts

When the 8XC552 enters the power-down mode, the oscillator is stopped. The power-down mode is entered by setting the PD bit in the PCON register. The PD bit can only be set if the EW input is tied HIGH.

## 80C51 Family Derivatives

## 8XC552/562 overview

**Power-Down Mode:** The instruction that sets PCON.1 will be the last instruction executed in the normal operating mode before the power-down mode is entered. In the power-down mode, the on-chip oscillator is stopped. This freezes all functions; only the on-chip RAM and special function registers are held. The port pins output the contents of their respective special function registers. A hardware reset is the only way to terminate the power-down mode. Reset re-defines all the special function registers, but does not change the on-chip RAM.

In the power-down mode,  $V_{DD}$  and  $AV_{DD}$  can be reduced to minimize power consumption.  $V_{DD}$  and  $AV_{DD}$  must not be reduced before the power-down mode is entered and must be restored to the normal operating voltage before the power-down mode is terminated. The reset that terminates the power-down mode also freezes the oscillator. The reset should not be activated before  $V_{DD}$  and  $AV_{DD}$  are restored to their normal operating level, and must be held active long enough to allow the oscillator to restart and stabilize (normally less than 10ms).

The status of the external pins during power-down is shown in Table 11. If the power-down mode is entered while the 8XC552 is executing out of external program memory, the port data that is held in the P2 special function register is restored to port 2. If a port latch contains a "1", the port pin is held HIGH during the power-down mode by the strong pull-up transistor.

**Power Control Register PCON:** The idle and power-down modes are entered by writing to bits in PCON. PCON is not bit addressable. See Figure 41.

#### Memory Organization

The memory organization of the 8XC552 is the same as in the 80C51, with the exception that the 8XC552 has 8k ROM, 256 bytes RAM, and additional SFRs. Addressing modes are the same in the 8XC552 and the 80C51. Details of the differences are given in the following paragraphs.

In the 8XC552, the lower 8k of the 64k program memory address space is filled by internal ROM. By tying the  $\overline{EA}$  pin high, the processor fetches instructions from internal program ROM. Bus expansion for accessing program memory from 8k upwards is automatic since external instruction fetches occur automatically when the program counter exceeds 8191. If the  $\overline{EA}$  pin is tied low, all program memory fetches are from external memory. The execution speed of the 8XC552 is the same regardless of whether fetches are from external or internal program memory. If all storage is on-chip, then byte location 8191 should be left vacant to prevent an undesired pre-fetch from external program memory address 8192.

Certain locations in program memory are reserved for specific programs. Locations 0000H to 0002H are reserved for the initialization program. Following reset, the CPU always begins execution at locations

0000H. Locations 0003H to 0075H are reserved for the fifteen interrupt request service routines.

Functionally, the internal data memory is the most flexible of the address spaces. The internal data memory space is subdivided into a 256-byte internal data RAM address space and a 128-byte special function register (SFR) address space, as shown in Figure 42.

The internal data RAM address space is 0 to 255. Four 8-bit register banks occupy locations 0 to 31. 128 bit locations of the internal data RAM are accessible through direct addressing. These bits reside in 16 bytes of internal data RAM at locations 20H to 2FH. The stack can be located anywhere in the internal data RAM address space by loading the 8-bit stack pointer. The stack depth may be 256 bytes maximum.

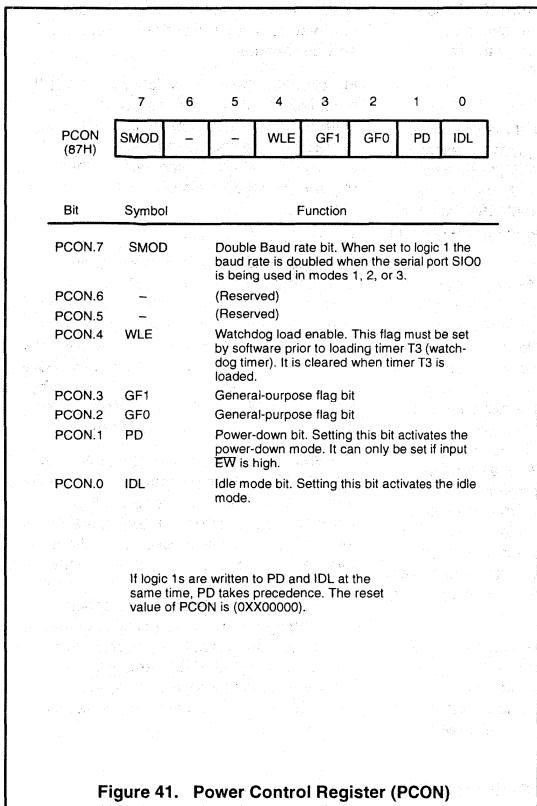

The SFR address space is 128 to 255. All registers except the program counter and the four 8-bit register banks reside in this address space. Memory mapping the SFRs allows them to be accessed as easily as internal RAM, and as such, they can be operated on by most instructions. The 56 SFRs are listed in Figure 43, and their mapping in the SFR address space is shown in Figures 44 and 45. RAM bit addresses are the same as in the 80C51 and are summarized in Figure 46. The special function bit addresses are summarized in Figure 47.

**Table 11. External Pin Status During Idle and Power-Down Modes**

| MODE       | MEMORY   | ALE | $\overline{PSEN}$ | PORT 0    | PORT 1    | PORT 2    | PORT 3    | PORT 4    | PWM0/PWM1 |
|------------|----------|-----|-------------------|-----------|-----------|-----------|-----------|-----------|-----------|
| Idle (1)   | Internal | 1   | 1                 | Port data | Port data | Port data | Port data | Port data | HIGH      |
| Idle (1)   | External | 1   | 1                 | Floating  | Port data | Address   | Port data | Port data | HIGH      |
| Power-down | Internal | 0   | 0                 | Port data | Port data | Port data | Port data | Port data | HIGH      |
| Power-down | External | 0   | 0                 | Floating  | Port data | Port data | Port data | Port data | HIGH      |

## Single-chip 8-bit microcontroller

## 80C552/83C552

Single-chip 8-bit microcontroller with 10-bit A/D, capture/compare timer, high-speed outputs, PWM

## DESCRIPTION

The 80C552/83C552 (hereafter generically referred to as 8XC552) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC552 has the same instruction set as the 80C51. Three versions of the derivative exist:

- 83C552—8k bytes mask programmable ROM
- 80C552—ROMless version of the 83C552
- 87C552—8k bytes EPROM (described in a separate chapter)

The 8XC552 contains a non-volatile 8k × 8 read-only program memory (83C552), a volatile 256 × 8 read/write data memory, five 8-bit I/O ports, one 8-bit input port, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a 15-source, two-priority-level, nested interrupt structure, an 8-input ADC, a dual DAC pulse width modulated interface, two serial interfaces (UART and I<sup>2</sup>C-bus), a "watchdog" timer and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC552 can be expanded using standard TTL compatible memories and logic.

In addition, the 8XC552 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial ports, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte, and 17 three-byte. With a 16MHz (24MHz) crystal, 58% of the instructions are executed in 0.75µs (0.5µs) and 40% in 1.5µs (1µs). Multiply and divide instructions require 3µs (2µs).

## FEATURES

- 80C51 central processing unit
- 8k × 8 ROM expandable externally to 64k bytes
- An additional 16-bit timer/counter coupled to four capture registers and three compare registers
- Two standard 16-bit timer/counters
- 256 × 8 RAM, expandable externally to 64k bytes
- Capable of producing eight synchronized, timed outputs
- A 10-bit ADC with eight multiplexed analog inputs
- Two 8-bit resolution, pulse width modulation outputs
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- Three speed ranges:
  - 1.2 to 16MHz
  - 1.2 to 24MHz (ROM, ROMless only)
  - 1.2 to 30MHz (ROM, ROMless only)
- Three operating ambient temperature ranges:
  - PCB83C552-5: 0°C to +70°C
  - PCF83C552-5: -40°C to +85°C (XTAL frequency max. 24 MHz)
  - PCA83C552-5: -40°C to +125°C (XTAL frequency max. 16 MHz)

## PIN CONFIGURATIONS

| Pin | Function         | Pin | Function    |
|-----|------------------|-----|-------------|
| 1   | P5.0/ADC0        | 35  | XTAL1       |

This pin must not float.                                                                                                                                                                                                       |
| PWM <sub>0</sub> | 4           | 75              | O    | <b>Pulse Width Modulation:</b> Output 0.                                                                                                                                                                                                                                                                                                                |
| PWM <sub>1</sub> | 5           | 76              | O    | <b>Pulse Width Modulation:</b> Output 1.                                                                                                                                                                                                                                                                                                                |
| EW               | 6           | 77              | I    | <b>Enable Watchdog Timer:</b> Enable for T3 watchdog timer and disable power-down mode. This pin must not float.                                                                                                                                                                                                                                        |
| P0.0-P0.7        | 57-50       | 58-51           | I/O  | <b>Port 0:</b> Port 0 is an 8-bit open-drain bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application it uses strong internal pull-ups when emitting 1s. |
| P1.0-P1.7        | 16-23       | 10-17           | I/O  | <b>Port 1:</b> 8-bit I/O port. Alternate functions include:                                                                                                                                                                                                                                                                                             |
|                  | 16-21       | 10-15           | I/O  | <b>(P1.0-P1.5):</b> Quasi-bidirectional port pins.                                                                                                                                                                                                                                                                                                      |

## NOTE:

- To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub> + 0.5V or V<sub>SS</sub> - 0.5V, respectively.

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol, page 635.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

### IDLE MODE

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers

remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 1 shows the state of the I/O ports during low current operating modes.

Table 1. External Pin Status During Idle and Power-Down Modes

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 | PORT 4 | PWM0/<br>PWM1 |
|------------|----------------|-----|------|--------|--------|---------|--------|--------|---------------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   | Data   | 1             |

## NOTES:

- These frequencies exceed the upper limit of 100kHz of the I<sup>2</sup>C-bus specification and cannot be used in an I<sup>2</sup>C-bus application.
- At  $f_{osc} = 24\text{MHz}/30\text{MHz}$  the maximum I<sup>2</sup>C bus rate of 100kHz cannot be realized due to the fixed divider rates.

ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>

| PARAMETER                                                                                    | RATING       | UNIT |
|----------------------------------------------------------------------------------------------|--------------|------|
| Storage temperature range                                                                    | -65 to +150  | °C   |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5 | V    |
| Input, output DC current on any single I/O pin                                               | 5.0          | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.0          | W    |

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## NOTES FOR DC ELECTRICAL CHARACTERISTICS:

- See Figures 10 through 15 for  $I_{DD}$  test conditions.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{EA} = \overline{RST} = \text{Port } 0 = \overline{EW} = V_{DD}$ ;  $\overline{STADC} = V_{SS}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\text{Port } 0 = \overline{EW} = V_{DD}$ ;  $\overline{EA} = \overline{RST} = \overline{STADC} = V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL2 not connected;  $\text{Port } 0 = \overline{EW} = V_{DD}$ ;  $\overline{EA} = \overline{RST} = \overline{STADC} = \text{XTAL1} = V_{SS}$ .
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below 1.5V will be recognized as a logic 0 while an input voltage above 3.0V will be recognized as a logic 1.
- Pins of ports 1 (except P1.6, P1.7), 2, 3, and 4 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $\overline{PSEN}$  to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- The following condition must not be exceeded:  $V_{DD} - 0.2\text{V} < AV_{DD} < V_{DD} + 0.2\text{V}$ .
- Conditions:  $AV_{REF-} = 0\text{V}$ ;  $AV_{DD} = 5.0\text{V}$ ;  $AV_{REF+}$  (80C552, 83C552) = 5.12V. ADC is monotonic with no missing codes. Measurement by continuous conversion of  $AV_{IN} = -20\text{mV}$  to 5.12V in steps of 0.5mV.
- The differential non-linearity ( $DL_e$ ) is the difference between the actual step width and the ideal step width. (See Figure 1.)
- The ADC is monotonic; there are no missing codes.
- The integral non-linearity ( $IL_e$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error. (See Figure 1.)
- The offset error ( $OS_e$ ) is the absolute difference between the straight line which fits the actual transfer curve (after removing gain error), and a straight line which fits the ideal transfer curve. (See Figure 1.)
- The gain error ( $G_e$ ) is the relative difference in percent between the straight line fitting the actual transfer curve (after removing offset error), and the straight line which fits the ideal transfer curve. Gain error is constant at every point on the transfer curve. (See Figure 1.)
- The absolute voltage error ( $A_e$ ) is the maximum difference between the center of the steps of the actual transfer curve of the non-calibrated ADC and the ideal transfer curve.
- This should be considered when both analog and digital signals are simultaneously input to port 5.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- $t_{CLCL} = 1/f_{OSC}$  = one oscillator clock period.  
 $t_{CLCL} = 83.3\text{ns}$  at  $f_{OSC} = 12\text{MHz}$ .  
 $t_{CLCL} = 62.5\text{ns}$  at  $f_{OSC} = 16\text{MHz}$ .
- These values are characterized but not 100% production tested.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.
- $t_{CLCL} = 1/f_{OSC}$  = one oscillator clock period.  
 $t_{CLCL} = 41.7ns$  at  $f_{OSC} = 24MHz$ .

| t <sub>RD</sub>                                     | SDA rise time                             | ≤ 1μs                  | - <sup>2</sup>                           |
| t <sub>FD</sub>                                     | SDA fall time                             | ≤ 0.3μs                | < 0.3μs <sup>3</sup>                     |

## NOTES:

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be < 1μs.
- Spikes on the SDA and SCL lines with a duration of less than 3 t<sub>CLCL</sub> will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- t<sub>CLCL</sub> = 1/f<sub>OSC</sub> = one oscillator clock period at pin XTAL1. For 62ns, 42ns, 33.3ns < t<sub>CLCL</sub> < 285ns (16MHz, 24MHz, 30MHz > f<sub>OSC</sub> > 1.2MHz) the SI01 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

### EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE
- P – PSEN

- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

Examples:  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## Single-chip 8-bit microcontroller

80C552/83C552

## NOTES:

## 1. Active Mode:

- The following pins must be forced to  $V_{DD}$ :  $\overline{EA}$ , RST, Port 0, and  $\overline{EW}$ .
- The following pins must be forced to  $V_{SS}$ : STADC,  $AV_{SS}$ , and  $AV_{ref-}$ .
- Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins.
- The following pins must be disconnected: XTAL2 and all pins not specified above.

## 2. Idle Mode:

- The following pins must be forced to  $V_{DD}$ : Port 0 and  $\overline{EW}$ .
- The following pins must be forced to  $V_{SS}$ : RST, STADC,  $AV_{SS}$ ,  $AV_{ref-}$ , and  $\overline{EA}$ .
- Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins. These pins must not have logic 0 written to them prior to this measurement.
- The following pins must be disconnected: XTAL2 and all pins not specified above.

## 3. Power Down Mode:

- The following pins must be forced to  $V_{DD}$ : Port 0 and  $\overline{EW}$ .
- The following pins must be forced to  $V_{SS}$ : RST, STADC, XTAL1,  $AV_{SS}$ ,  $AV_{ref-}$ , and  $\overline{EA}$ .
- Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins. These pins must not have logic 0 written to them prior to this measurement.
- The following pins must be disconnected: XTAL2 and all pins not specified above.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

## Single-chip 8-bit microcontroller

87C552

Single-chip 8-bit microcontroller with 10-bit A/D, capture/compare timer, high-speed outputs, PWM

## DESCRIPTION

The 87C552 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 87C552 has the same instruction set as the 80C51. Three versions of the derivative exist:

- 83C552—8k bytes mask programmable ROM
- 80C552—ROMless version of the 83C552
- 87C552—8k bytes EPROM

The 87C552 contains a  $8k \times 8$  volatile  $256 \times 8$  read/write data memory, five 8-bit I/O ports, one 8-bit input port, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a 15-source, two-priority-level, nested interrupt structure, an 8-input ADC, a dual DAC pulse width modulated interface, two serial interfaces (UART and I<sup>2</sup>C-bus), a "watchdog" timer and on-chip oscillator and timing circuits. For systems that require extra capability, the 87C552 can be expanded using standard TTL compatible memories and logic.

In addition, the 87C552 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial ports, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte, and 17 three-byte. With a 16MHz (24MHz) crystal, 58% of the instructions are executed in  $0.75\mu\text{s}$  ( $0.5\mu\text{s}$ ) and 40% in  $1.5\mu\text{s}$  ( $1\mu\text{s}$ ). Multiply and divide instructions require  $3\mu\text{s}$  ( $2\mu\text{s}$ ).

## FEATURES

- 80C51 central processing unit
- $8k \times 8$  EPROM expandable externally to 64k bytes
- An additional 16-bit timer/counter coupled to four capture registers and three compare registers
- Two standard 16-bit timer/counters
- $256 \times 8$  RAM, expandable externally to 64k bytes
- Capable of producing eight synchronized, timed outputs
- A 10-bit ADC with eight multiplexed analog inputs
- Two 8-bit resolution, pulse width modulation outputs
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- Three speed ranges:
  - 16MHz
- Extended temperature ranges
- OTP package available

## PIN CONFIGURATIONS

| EW              | 6           | 77              | I    | <b>Enable Watchdog Timer:</b> Enable for T3 watchdog timer and disable power-down mode.                                                                                                                                                                                                                                                                                                                                                                                |
| P0.0-P0.7       | 57-50       | 58-51           | I/O  | <b>Port 0:</b> Port 0 is an 8-bit open-drain bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application it uses strong internal pull-ups when emitting 1s. Port 0 is also used to input the code byte during programming and to output the code byte during verification. |
| P1.0-P1.7       | 16-23       | 10-17           | I/O  | <b>Port 1:</b> 8-bit I/O port. Alternate functions include:                                                                                                                                                                                                                                                                                                                                                                                                            |

## NOTE:

- To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub> + 0.5V or V<sub>SS</sub> - 0.5V, respectively.

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

### IDLE MODE

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers

remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 1 shows the state of the I/O ports during low current operating modes.

Table 1. External Pin Status During Idle and Power-Down Modes

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 | PORT 4 | PWM0/PWM1 |
|------------|----------------|-----|------|--------|--------|---------|--------|--------|-----------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   | Data   | High      |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   | Data   | High      |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   | Data   | High      |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   | Data   | High      |

| Storage temperature range                                                                    | –65 to +150  | °C   |
| Voltage on $\overline{EA}/V_{PP}$ to $V_{SS}$                                                | –0.5 to +13  | V    |
| Voltage on any other pin to $V_{SS}$                                                         | –0.5 to +6.5 | V    |
| Input, output DC current on any single I/O pin                                               | 5.0          | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.0          | W    |

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## DEVICE SPECIFICATIONS

| TYPE      | SUPPLY VOLTAGE (V) |     | FREQUENCY (MHz) |     | TEMPERATURE RANGE (°C) |

## NOTES FOR DC ELECTRICAL CHARACTERISTICS:

- See Figures 10 through 15 for  $I_{DD}$  test conditions.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS} + 0.5$ V;  $V_{IH} = V_{DD} - 0.5$ V; XTAL2 not connected;  $EA = RST = Port\ 0 = EW = V_{DD}$ ;  $STADC = V_{SS}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS} + 0.5$ V;  $V_{IH} = V_{DD} - 0.5$ V; XTAL2 not connected;  $Port\ 0 = EW = V_{DD}$ ;  $EA = RST = STADC = V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL2 not connected;  $Port\ 0 = EW = V_{DD}$ ;  $EA = RST = STADC = XTAL1 = V_{SS}$ .
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below 1.5V will be recognized as a logic 0 while an input voltage above 3.0V will be recognized as a logic 1.
- Pins of ports 1 (except P1.6, P1.7), 2, 3, and 4 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OLS}$  of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- The following condition must not be exceeded:  $V_{DD} - 0.2V < AV_{DD} < V_{DD} + 0.2V$ .
- Conditions:  $AV_{REF-} = 0$ V;  $AV_{DD} = 5.0$ V. Measurement by continuous conversion of  $AV_{IN} = -20$ mV to 5.12V in steps of 0.5mV, deriving parameters from collected conversion results of ADC.  $AV_{REF+}$  (87C552) = 4.977V. ADC is monotonic with no missing codes.
- The differential non-linearity ( $DL_e$ ) is the difference between the actual step width and the ideal step width. (See Figure 1.)
- The ADC is monotonic; there are no missing codes.
- The integral non-linearity ( $IL_e$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error. (See Figure 1.)
- The offset error ( $OS_e$ ) is the absolute difference between the straight line which fits the actual transfer curve (after removing gain error), and a straight line which fits the ideal transfer curve. (See Figure 1.)
- The gain error ( $G_e$ ) is the relative difference in percent between the straight line fitting the actual transfer curve (after removing offset error), and the straight line which fits the ideal transfer curve. Gain error is constant at every point on the transfer curve. (See Figure 1.)
- The absolute voltage error ( $A_e$ ) is the maximum difference between the center of the steps of the actual transfer curve of the non-calibrated ADC and the ideal transfer curve.
- This should be considered when both analog and digital signals are simultaneously input to port 5.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- $t_{\text{CLCL}} = 1/f_{\text{OSC}} = \text{one oscillator clock period.}$   
 $t_{\text{CLCL}} = 83.3\text{ns}$  at  $f_{\text{OSC}} = 12\text{MHz}$ .  
 $t_{\text{CLCL}} = 62.5\text{ns}$  at  $f_{\text{OSC}} = 16\text{MHz}$ .
- These values are characterized but not 100% production tested.

## NOTES:

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be < 1μs.
- Spikes on the SDA and SCL lines with a duration of less than 3 t<sub>CLCL</sub> will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- t<sub>CLCL</sub> = 1/f<sub>OSC</sub> = one oscillator clock period at pin XTAL1. For 62ns (42s) < t<sub>CLCL</sub> < 285ns (16MHz (24Hz) > f<sub>OSC</sub> > 3.5MHz) the SI01 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.
- These values are guaranteed but not 100% production tested.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

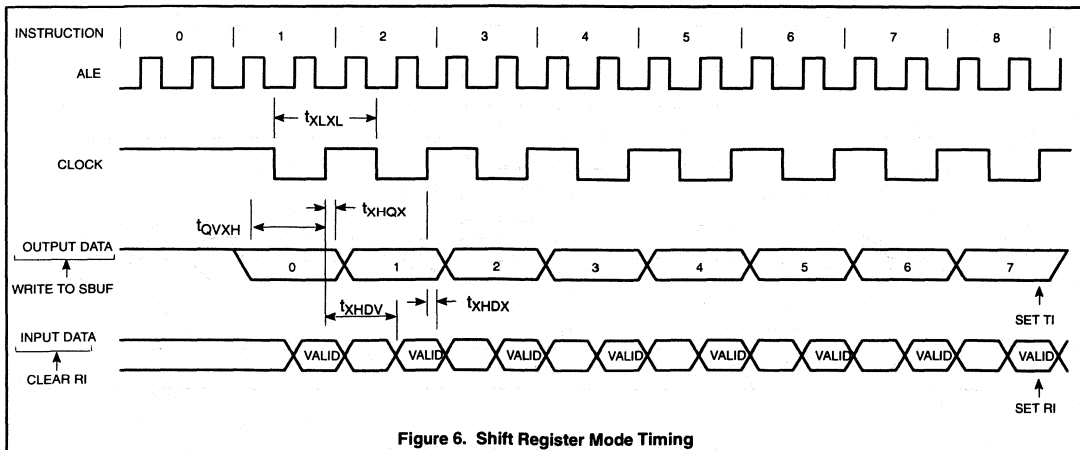

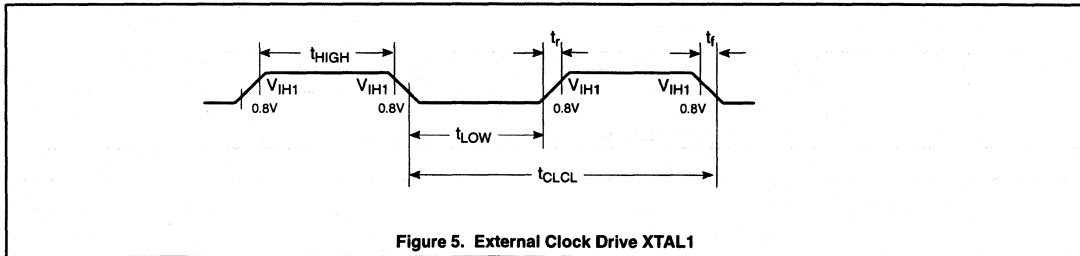

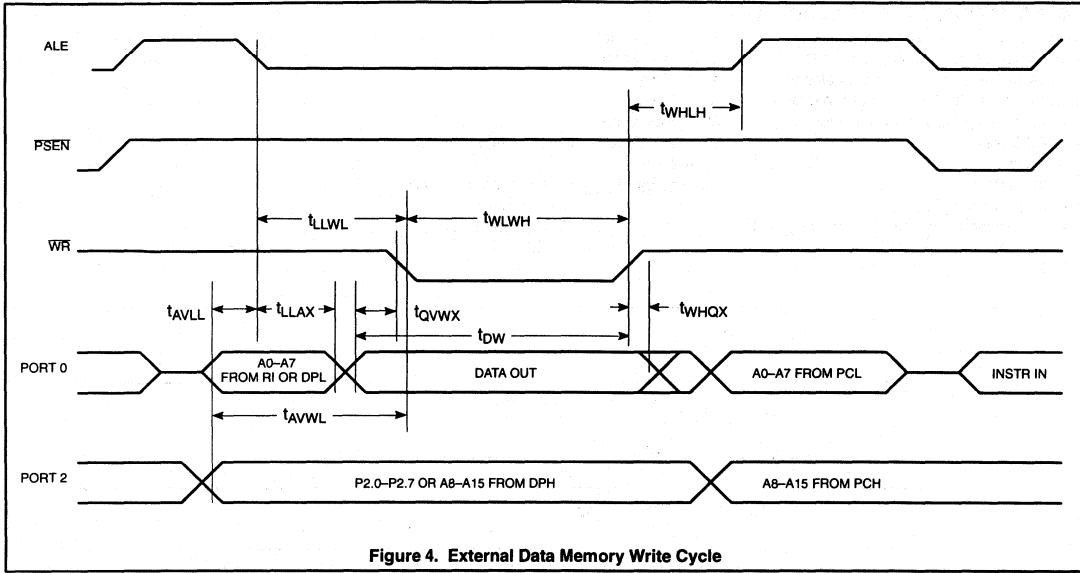

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

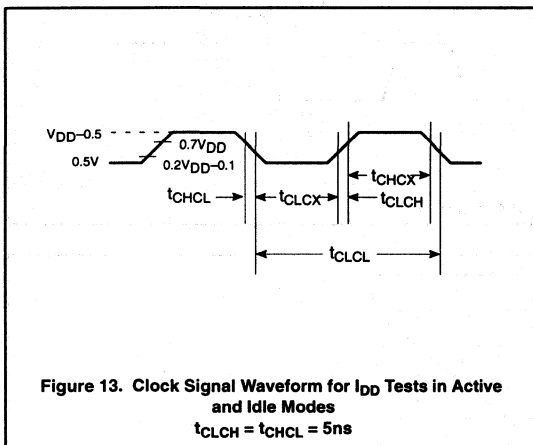

Figure 13. Clock Signal Waveform for  $I_{DD}$  Tests in Active and Idle Modes  
 $t_{CLCH} = t_{CHCL} = 5\text{ns}$

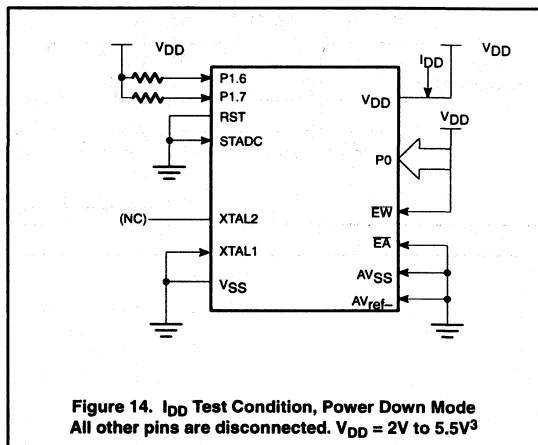

Figure 14.  $I_{DD}$  Test Condition, Power Down Mode  
All other pins are disconnected.  $V_{DD} = 2\text{V to } 5.5\text{V}^3$

## NOTES:

1. Active Mode:
  - a. The following pins must be forced to  $V_{DD}$ : EA, RST, Port 0, and EW.
  - b. The following pins must be forced to  $V_{SS}$ : STADC,  $AV_{SS}$ , and  $AV_{ref-}$ .
  - c. Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins.
  - d. The following pins must be disconnected: XTAL2 and all pins not specified above.
2. Idle Mode:
  - a. The following pins must be forced to  $V_{DD}$ : Port 0 and EW.
  - b. The following pins must be forced to  $V_{SS}$ : RST, STADC,  $AV_{SS}$ ,  $AV_{ref-}$ , and EA.
  - c. Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins. These pins must not have logic 0 written to them prior to this measurement.
  - d. The following pins must be disconnected: XTAL2 and all pins not specified above.
3. Power Down Mode:
  - a. The following pins must be forced to  $V_{DD}$ : Port 0 and EW.
  - b. The following pins must be forced to  $V_{SS}$ : RST, STADC, XTAL1,  $AV_{SS}$ ,  $AV_{ref-}$ , and EA.
  - c. Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins cannot exceed the  $I_{OL1}$  spec of these pins. These pins must not have logic 0 written to them prior to this measurement.
  - d. The following pins must be disconnected: XTAL2 and all pins not specified above.

## Single-chip 8-bit microcontroller

87C552

**EPROM CHARACTERISTICS**

The 87C552 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C552 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C552 manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 15 and 16. Figure 17 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 15. Note that the 87C552 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 15. The code byte to be programmed into that location is applied to port 0. RST, PSEN, and pins of ports 2 and 3 specified in Table 3 are held at the "Program Code Data" levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 16.

To program the encryption table, repeat the 25-pulse programming sequence for

addresses 0 through 1FH, using the "Pgm Encryption Table" levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25-pulse programming sequence using the "Pgm Lock Bit" levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the  $EA/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 17. The other pins are held at the "Verify Code Data" levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips Components  
(031H) = 94H indicates 87C552

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to the light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient. Erasure leaves the array in an all 1s state.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $EA/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|-------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1           | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1           | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$    | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$    | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$    | 1    | 1    | 0    | 0    |

**NOTES:**

- 0 = Valid low for that pin; 1 = valid high for that pin.
  - $V_{PP} = 12.75V \pm 0.25V$ .
  - $V_{DD} = 5V \pm 10\%$  during programming and verification.
- \* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

## GENERAL DESCRIPTION

The 80CE558/83CE558/89CE558 (hereafter generally referred to as 8XCE558) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XCE558 has the same instruction set as the 80C51. Three versions of the derivative exist:

- 83CE558 — 32k bytes mask programmable ROM
- 80CE558 — ROMless version of the 83CE558
- 89CE558 — 32k bytes FEEPROM

The 8XCE558 contains a non-volatile  $32k \times 8$  read-only program memory (83CE558) or FEEPROM (89CE558), a volatile  $1024 \times 8$  read/write data memory, five 8-bit I/O ports, one 8-bit input port, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a 15-source, two-priority-level, nested interrupt structure, an 8-input ADC, a dual DAC pulse width modulated interface, two serial interfaces

(UART and I<sup>2</sup>C-bus), a "watchdog" timer and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XCE558 can be expanded using standard TTL compatible memories and logic.

In addition, the 8XCE558 has two software selectable modes of power reduction — idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial ports, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte, and 17 three-byte. With a 16 MHz system clock, 58% of the instructions are executed in 0.75 $\mu$ s and 40% in 1.5 $\mu$ s. Multiply and divide instructions require 3 $\mu$ s.

## FEATURES

- 80C51 central processing unit
- $32k \times 8$  ROM resp. FEEPROM expandable externally to 64k bytes
- ROM/FEEPROM Code protection
- $1024 \times 8$  RAM, expandable externally to 64k bytes
- Seconds Timer
- Two standard 16-bit timer/counters

- An additional 16-bit timer/counter coupled to four capture registers and three compare registers
- A 10-bit ADC with eight multiplexed analog inputs and programmable autoscan
- Two 8-bit resolution, pulse width modulation outputs
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- 15 interrupt sources with 2 priority levels (2 to 6 external sources possible)
- Extended temperature range (–40 to +85°C)
- 4.5 to 5.5V supply voltage range
- Frequency range for 80C51 standard oscillator: 3.5 MHz to 16 MHz
- PLL oscillator with 32 kHz reference and software-selectable system clock frequency<sup>1</sup>
- Software enable/disable of ALE output pulse
- Electromagnetic compatibility improvements
- Wake-up from Power-down by external or seconds interrupt

**Note** <sup>1</sup> Not available yet in the 89CE558

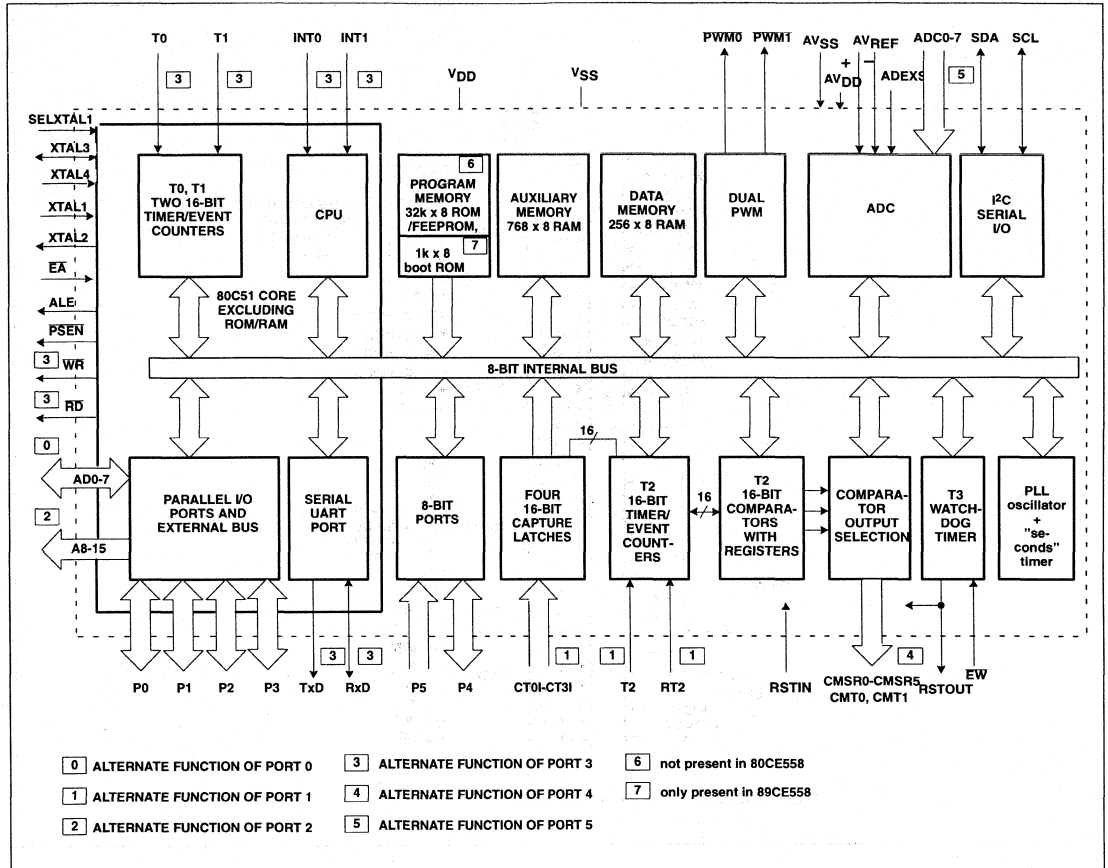

## ORDERING INFORMATION

| SDA         | 40      | <b>I<sup>2</sup>C-bus serial data I/O port</b><br>If SCL and SDA are not connected to I <sup>2</sup> C-buslines, their input levels should be defined otherwise (e.g. by a pull-up resistor to V <sub>DD</sub> ) in order to prevent these port input stages from floating, which could affect the total power consumption. Especially during Power-down Mode extra power consumption by floating inputs is an adverse effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Left open-circuit when an external oscillator clock is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| XTAL1       | 52      | <b>Crystal pin 1:</b> input to the inverting amplifier that forms the oscillator, and input to the internal clock generator. Receives the external oscillator clock signal when an external oscillator is used. Must be connected to logic HIGH if the PLL oscillator is selected (SELXTAL1 = LOW)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| P2.0 – P2.7 | 55 – 62 | <b>Port2:</b> 8-bit quasi-bidirectional I/O port with internal pull-ups. During access to external memories (RAM/ROM) that use 16-bit addresses (MOVX@DPTR) Port 2 emits the high order address byte. The alternative function of P2.7 for the 89CE558 is the output enable signal for verify/read modes (active low).<br>Port 2 can sink/source one TTL (=4 LSTTL) input. It can drive CMOS inputs without external pull-ups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PSEN        | 63      | <b>Program Store Enable output:</b> read strobe to the external program memory via Port 0 and 2. Is activated twice each machine cycle during fetches from external program memory. When executing out of external program memory two activations of PSEN are skipped during each access to external data memory. PSEN is not activated (remains HIGH) during no fetches from external program memory. PSEN can sink/source 8 LSTTL inputs. It can drive CMOS inputs without external pull-ups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ALE/WE      | 64      | <b>Address Latch Enable output:</b> latches the low byte of the address during access of external memory in normal operation. It is activated every six oscillator periods except during an external data memory access. ALE/WE can sink/-source 8 LSTTL inputs. It can drive CMOS inputs without an external pull-up.<br>The alternative function for the 89CE558 is the programming pulse input WE.<br><br>To prohibit the toggling of ALE pin (RFI noise reduction) the bit RFI in the PCON Register (PCON.5) must be set by software. This bit is cleared on RESET and can be set and cleared by software. When set, ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE as a normal MOVX.<br>ALE will retain its normal high value during Idle mode and a low value during Power-down mode while in the "RFI" mode. Additionally during internal access (EA = 1) ALE will toggle normally when the address exceeds the internal program memory size. During external access (EA = 0) ALE will always toggle normally, whether the flag "RFI" is set or not. |
| EA          | 65      | <b>External Access Input:</b> When, during RESET, EA is held at a TTL HIGH level the CPU executes out of the internal program memory, provided the program counter is less than 32768. When EA is held at a TTL low level during RESET, the CPU executes out of external program memory via Port 0 and Port 2. EA is not allowed to float. EA is latched during RESET and don't care after RESET.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| P0.7–P0.0   | 68 –75  | <b>Port 0:</b> 8-bit open drain bidirectional I/O port. It is also the multiplexed low-order address and data bus during accesses to external memory (during these accesses internal pull-ups are activated). Port 0 can sink/source 8 LSTTL inputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| XTAL3       | 78      | <b>Crystal pin,</b> output of the inverting amplifier that forms the 32 KHz oscillator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| XTAL4       | 79      | <b>Crystal pin,</b> input to the inverting amplifier that forms the 32 KHz oscillator, must be connected to logic LOW if the PLL oscillator is not selected (SELXTAL1 = HIGH).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SELXTAL1    | 80      | <b>Must be connected to logic HIGH level to select the HF oscillator, using the XTAL1/XTAL2 crystal. To avoid a 'latch-up' effect at Power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub>+ 0.5V or V<sub>SS</sub>- 0.5V respectively.

## ELECTROMAGNETIC COMPATIBILITY (EMC) IMPROVEMENTS

Primary attention was paid on the reduction of electromagnetic emission of the microcontroller 8xCE558.

The following features effect in reducing the electromagnetic emission and additionally improve the electromagnetic susceptibility:

- Four supply voltage pins ( $V_{DD}$ ) and four ground pins ( $V_{SS}$ ) with a pair of  $V_{DD}$  and  $V_{SS}$  at two adjacent pins in the center at one side of the package and at two adjacent pins at the opposite side of the package and one more  $V_{SS}$  pin at each of the other two sides of the package
- Separated  $V_{DD}$  pins for the internal logic and the port buffers
- Internal decoupling capacitance improves the EMC radiation behavior and the EMC immunity
- External capacitors are to be located as close as possible between pins  $V_{DD1}$  and  $V_{SS1}$ ,  $V_{DD2}$  and  $V_{SS2}$ ,  $V_{DD3}$  and  $V_{SS3}$  as well as  $V_{DD4}$  and  $V_{SS4}$ ; ceramic chip capacitors are recommended (100nF).

Useful in applications that require no external memory or temporarily no external memory:

- The ALE output signal (pulses at a frequency of  $f_{CLK}/6$ ) can be disabled under software control (bit 5 in the SFR PCON: "RFI"); if disabled, no ALE pulse will occur. ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE (external data memory is accessed). ALE will retain its normal HIGH value during Idle mode and a LOW value during Power-down mode while in the "RFI" reduction mode. Additionally during internal access (EA = 1) ALE will toggle normally when the address exceeds the internal program memory size. During external access (EA = 0) ALE will always toggle normally, whether the flag "RFI" is set or not.

The 8xCE558 is a control-oriented CPU with on-chip program and data memory. It can be extended with external program memory up to 64 K bytes. It can also access up to 64 K bytes of external data memory. For systems requiring extra capability, the 8xCE558 can be expanded using standard memories and peripherals.

The 8xCE558 has two software selectable modes of reduced activity for further power reduction - Idle and Power-down. The Idle mode freezes the CPU while allowing the RAM, timers, serial ports and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes the oscillator causing all other chip functions to be inoperative. The Power-down mode can be terminated by an external Reset and by any one of the two external interrupts. (see description Wake-up from Power-down mode).

## 18.0 FUNCTIONAL DESCRIPTION

### General

The 8xCE558 is a stand-alone high-performance microcontroller designed for use in real time applications such as instrumentation, industrial control, medium to high-end consumer applications and specific automotive control applications.

In addition to the 80C51 standard functions, the device provides a number of dedicated hardware functions for these applications.

### 1.1 Memory organization

The central processing unit (CPU) manipulates operands in three memory spaces; these are the 64 K-byte external data memory, 1024 byte internal data memory (consisting of 256 bytes standard RAM and 768 bytes AUX-RAM) and the 64 K-byte internal and external program memory (see Figure 1).

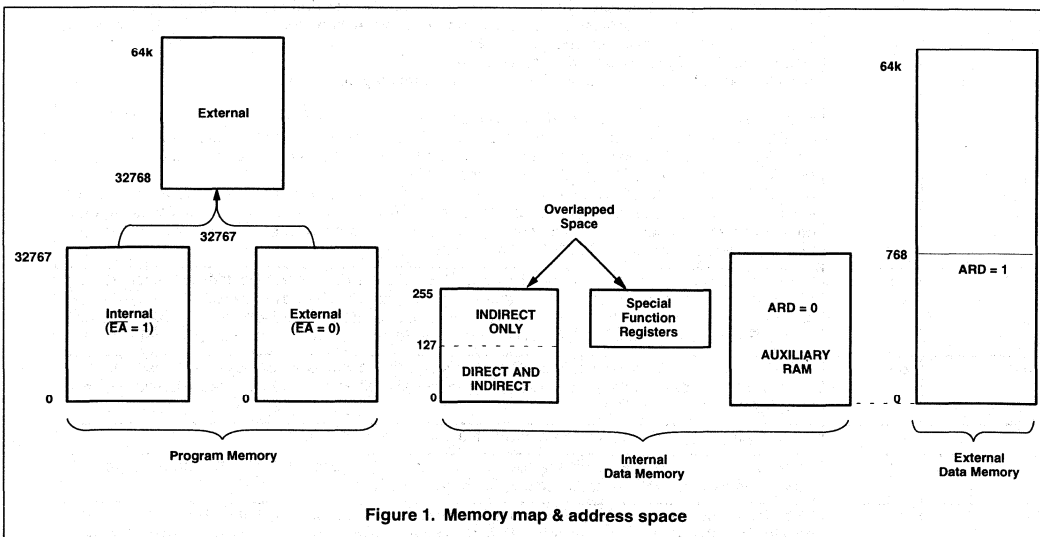

Figure 1. Memory map & address space

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

### 1.1.1 Program Memory

The program memory of the 8xCE558 consists of 32 Kbyte ROM resp. FEEPROM ("Flash Memory") on-chip, externally expandable up to 64 Kbyte. If the EA pin is held HIGH, the 8xCE558 executes out of the internal program memory unless the address exceeds 7FFFH. Locations 8000H through 0FFFFH are then fetched from the external program memory. If the EA pin was set LOW during RESET the 8xCE558 fetches all instructions from the external program memory. The EA input is latched during RESET and is don't care after RESET.

By setting a mask programmable security bit (ROM) resp. by software programmable security byte (FEEPROM) the internal program memory content is protected i.e. it cannot be read out at any time by any test mode or by any instruction in the external program memory space. The MOVC instructions are the only which have access to program code in the internal or external program memory. The EA input is latched during RESET and is 'don't care' after RESET. This implementation prevents from reading internal program code by switching from external program memory to internal program memory during MOVC instruction or an instruction that handles immediate data.

Table 1 lists the access to the internal and external program memory with MOVC instructions when the security feature has been activated.

### 1.1.2 Internal Data Memory

The internal data memory is divided into three physically separated parts:

256 byte of RAM, 768 byte of AUX-RAM, and a 128-byte special function area. These can be addressed each in a different way (see also Table 2).

- RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected registerbank.
- RAM 128 to 255 can only be addressed indirectly. Address pointers are R0 and R1 of the selected registerbank.
- AUX-RAM 0 to 767 is indirectly addressable as external DATA MEMORY locations 0 to 767 via MOVX-Datapointer instruction, unless it is disabled by setting ARD = 1.
- AUX-RAM 0 to 767 is indirectly addressable via pageregister (XRAMP) and MOVX-Ri instructions, unless it is disabled by setting ARD = 1 (see Figure 2). When executing from internal program memory, an access to

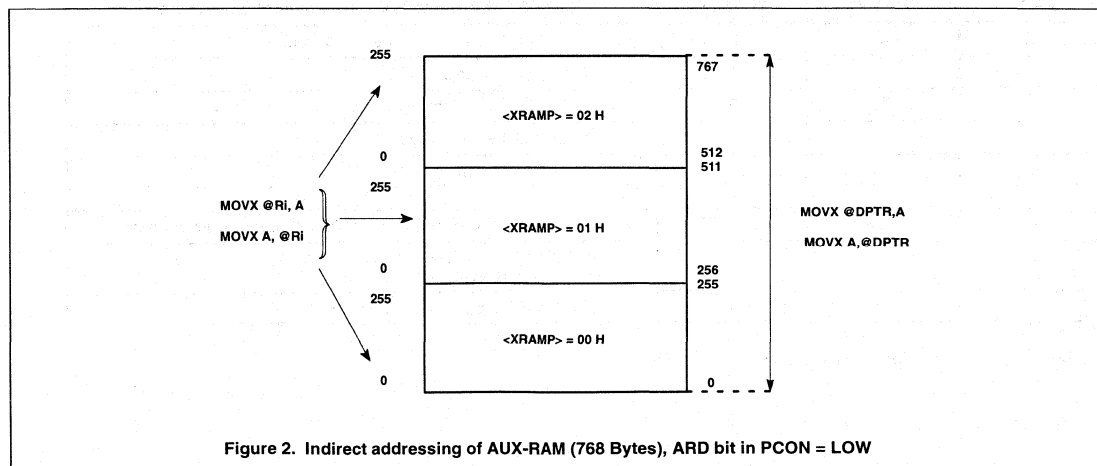

AUX-RAM 0 to 767 will not affect the ports P0, P2, P3.6 and P3.7. An access to external DATA MEMORY locations higher than 767 will be performed with the MOVX @ DPTR instructions in the same way as in the 80C51 structure, so with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read timing signals. Note that the external DATA MEMORY cannot be accessed with R0 and R1 as address pointer if the AUX-RAM is enabled (ARD = 0, default).

- The Special Function Registers (SFR) can only be addressed directly in the address range from 128 to 255 (see table 4).
- Four 8-register banks occupy locations 0 through 31 in the lower RAM area. Only one of these banks may be enabled at a time. The next 16 bytes, locations 32 through 47, contain 128 directly addressable bit locations. The stack can be located anywhere in the internal 256 byte RAM. The stack depth is only limited by the available internal RAM space of 256 bytes (see Figure 3). All registers except the program counter and the four 8-register banks reside in the Special Function Register address space.

**Table 1.**

|                                 | Access to Internal Program Memory | Access to External Program Memory |
|---------------------------------|-----------------------------------|-----------------------------------|
| MOVC in internal program memory | YES                               | YES                               |
| MOVC in external program memory | NO                                | YES                               |

If the security feature has not been activated, there are no restrictions for MOVC instructions.

**Figure 2. Indirect addressing of AUX-RAM (768 Bytes), ARD bit in PCON = LOW**

## Single-chip 8-bit microcontroller

Table 2.

| LOCATION |            | ADDRESSED               |
|----------|------------|-------------------------|
| RAM      | 0 to127    | Direct and Indirect     |
| AUX-RAM  | 0 to767    | Indirect Only with MOVX |
| RAM      | 128 to255  | Indirect Only           |
| SFR      | 128 to 255 | Direct Only             |

**AUX-RAM Page Register XRAMP**

The AUX-RAM Page Register is used to select one of three 256-byte pages of the internal 768-byte AUX-RAM for MOVX-accesses via R0 or R1. Its reset value is (XXXXXX00).

|              | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0      |
|--------------|---|---|---|---|---|---|--------|--------|
| XRAMP (0FAH) | x | x | x | x | x | x | XRAMP1 | XRAMP0 |

x: undefined during read, a write operation must write "0" to these location

| BIT     | SYMBOL | FUNCTION                                 |
|---------|--------|------------------------------------------|
| XRAMP.7 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.6 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.5 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.4 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.3 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.2 | -      | ( reserved for future use <sup>1</sup> ) |
| XRAMP.1 | XRAMP1 | AUX-RAM page select bit 1                |
| XRAMP.0 | XRAMP0 | AUX-RAM page select bit 0                |

**NOTES:**

- User software should not write 1s to reserved bits. These bits may be used in future 80C51 family products to invoke new features. In that case, the reset or inactive value of the new bit will be LOW, and its active value will be HIGH. The value read from a reserved bit is indeterminate.

Table 3 shows the memory locations for all possible MOVX-accesses:

Table 3.

## 1.2 Addressing

The 8xCE558 has five modes for addressing:

- Register
- Direct
- Register-Indirect
- Immediate
- Base-Register plus Index-Register-Indirect

The first three methods can be used for addressing destination operands. Most

instructions have a "destination/source" field that specifies the data type, addressing methods and operands involved. For operations other than MOVs, the destination operand is also a source operand.

Access to memory addresses is as follows:

- Register in one of the four 8-register banks through Register, Direct or Register-Indirect addressing
- 1024 bytes of internal RAM through Direct or Register-Indirect addressing. Bytes 0-127 of internal RAM may be addressed directly/indirectly. Bytes

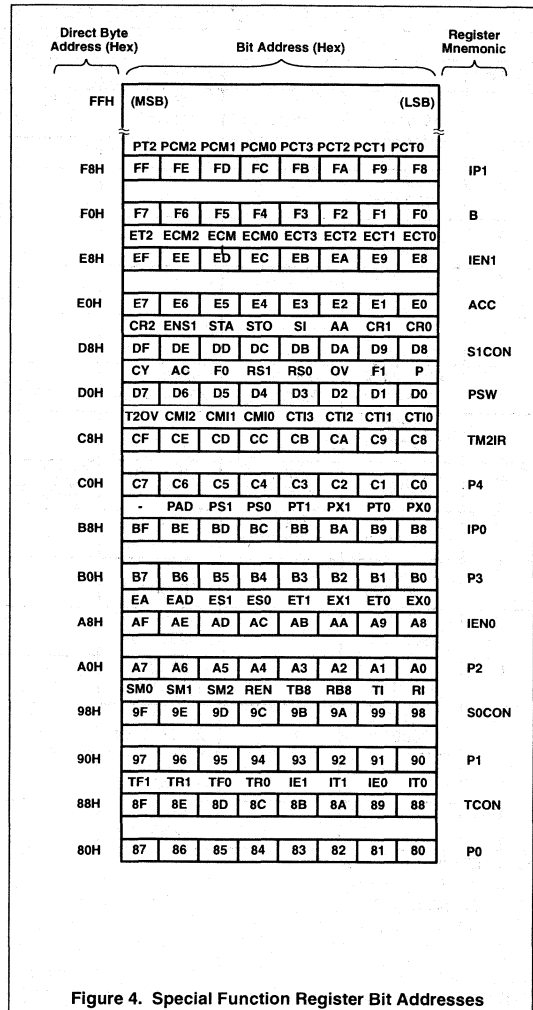

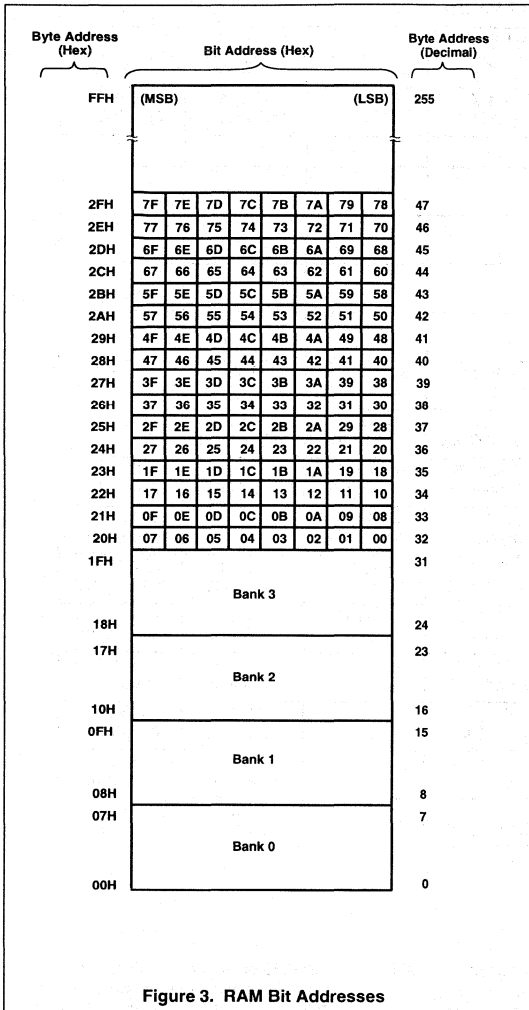

128-255 of internal RAM share their address location with the SFRs and so may only be addressed indirectly as data RAM. Bytes 0-767 of AUX-RAM can only be addressed indirectly via MOVX.

- Special Function Register through direct addressing at address locations 128-255 (see Figure 4).
- External data memory through Register-Indirect addressing
- Program memory look-up tables through Base- Register plus Index-Register-Indirect addressing

### 1.3 I/O facilities

The 8xCE558 has six 8-bit ports. Ports 0 to 3 are the same as in the 80C51, with the exception of the additional functions of Port 1. The parallel I/O function of Port 4 is equal to that of Ports 1, 2 and 3. Port 5 has a parallel input port function, but has no function as an output port.

The SDA and SCL lines serve the serial port SIO1 (I<sup>2</sup>C). Because the I<sup>2</sup>C-bus may be active while the device is disconnected from V<sub>DD</sub>, these pins, are provided with open drain drivers.

Ports 0, 1, 2, 3, 4 and 5 perform the following alternative functions:

- Port 0: provides the multiplexed low-order address and data bus used for expanding the 8xCE558 with standard memories and peripherals.
- Port 1: Port 1 is used for a number of special functions:
  - 4 capture inputs (or external interrupt request inputs if capture information is not utilized)
  - external counter input
  - external counter reset input

- Port 2: provides the high-order address bus when the 8xCE558 is expanded with external Program Memory and/or external Data Memory.
- Port 3: pins can be configured individually to provide:
  - external interrupt request inputs
  - counter inputs
  - receiver input and transmitter output of serial port SIO 0 (UART)
  - control signals to read and write external Data Memory

Single-chip 8-bit microcontroller

80CE558/83CE558/89CE558

- Port 4: can be configured to provide signals indicating a match between timer counter T2 and its compare registers.
- Port 5: may be used in conjunction with the ADC interface. Unused analog inputs can be used as digital inputs. As Port 5 lines may be used as inputs to the ADC, these digital inputs have an inherent hysteresis to prevent the input logic from drawing too much current from the power lines when driven by analog signals. Channel to channel crosstalk should be taken into consideration when both digital and analog signals are simultaneously input to Port 5 (see DC characteristics).

All ports are bidirectional with the exception of Port 5 which is an input port.

Pins of which the alternative function is not used may be used as normal bidirectional I/Os.

The generation or use of a Port 1, Port 3 or Port 4 pin as an alternative function is carried out automatically by the 8xCE558 provided the associated Special Function Register bit is set HIGH.

The pull-up arrangements of Ports 1 - 5 are shown in Figure 5.

1.4 Pulse Width Modulated Outputs

The 8XCE558 contains two pulse width modulated output channels (see Figure 6). These channels generate pulses of programmable length and interval. The

repetition frequency is defined by an 8-bit prescaler PWMP, which supplies the clock for the counter. The prescaler and counter are common to both PWM channels. The 8-bit counter counts modulo 255, i.e., from 0 to 254 inclusive. The value of the 8-bit counter is compared to the contents of two registers: PWM0 and PWM1. Provided the contents of either of these registers is greater than the counter value, the output will be HIGH. If the contents of these registers are equal to, or less than the counter value, the output will be LOW. The pulse-width-ratio is therefore defined by the contents of the registers PWM0 and PWM1. The pulse-width-ratio is in the range of 0/255 to 255/255 and may be programmed in increments of 1/255.

Buffered PWM outputs may be used to drive DC motors. The rotation speed of the motor would be proportional to the contents of PWMn. The PWM outputs may also be configured as a dual DAC. In this application, the PWM outputs must be integrated using conventional operational amplifier circuitry. If the resulting output voltages have to be accurate, external buffers with their own analog supply should be used to buffer the PWM outputs before they are integrated. The repetition frequency fpwm, at the PWMn outputs is give by:

$$f_{pwm} = \frac{f_{CLK}}{2 \times (1 + PWMP) \times 255}$$

This gives a repetition frequency range of 123Hz to 31.4kHz (fCLK = 16MHz). By

loading the PWM registers with either 00H or FFH, the PWM channels will output a constant HIGH or LOW level, respectively. Since the 8-bit counter counts modulo 255, it can never actually reach the value of the PWM registers when they are loaded with FFH.

When a compare register (PWM0 or PWM1) is loaded with a new value, the associated output is updated immediately. It does not have to wait until the end of the current counter period. Both PWMn output pins are driven by push-pull drivers. These pins are not used for any other purpose.

Prescaler frequency control register PWMP

PWMP (FEH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

MSB LSB

**Bit Function**  
 PWMP.0-7 Prescaler division factor = (PWMP) + 1.

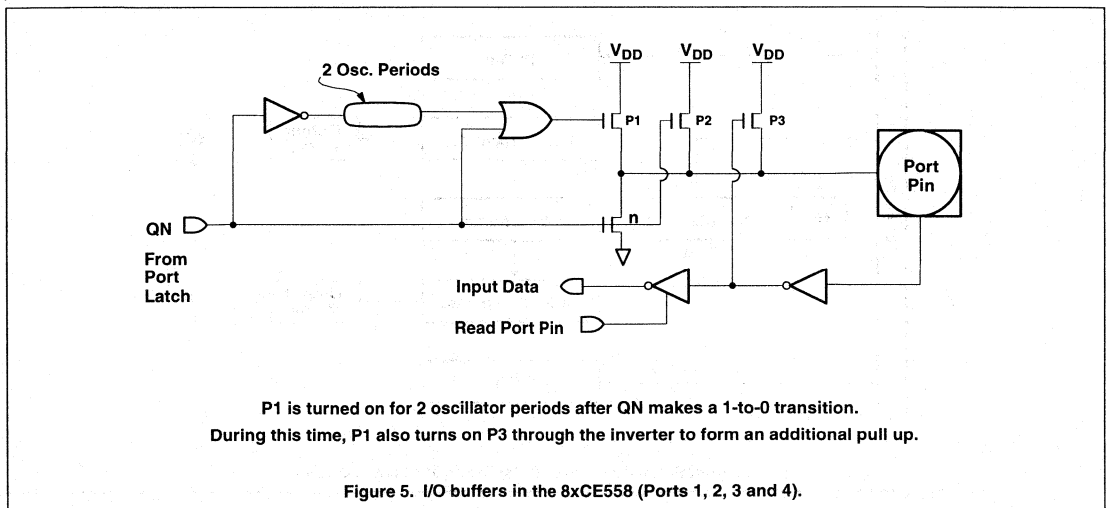

PWM0 (FCH)  
 PWM1 (FDH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

MSB LSB

Reading PWMP gives the current reload value. The actual count of the prescaler cannot be read.

## 1.5 Analog / Digital Converter

In order to have a minimum of ADC service overhead in the microcontroller program, the ADC is able to operate autonomously by its configurable autoscan feature and a set of 8 buffer registers (10 bit), which store the result of the conversion of each analog input channel. The functional diagram of the ADC is shown in Figure 7.

### Feature Overview:

- 10-bit resolution.
- 8 multiplexed analog inputs.
- Programmable autoscan of the analog inputs.
- Bit oriented 8-bit scan-select register to select analog inputs.
- Continuous scan or one time scan configurable from 1 to 8 analog inputs.
- Start of a conversion by software or with an external signal.
- Programmable prescaler (div by 2, 4, 6, 8) to adapt to different oscillator frequencies.
- Eight 10-bit buffer registers, one register for each analog input channel.
- Conversion time for one A/D conversion: 15µs ... 50µs
- Differential non-linearity : DLe 1 LSB.
- Integral non-linearity : ILe 2 LSB.
- Offset error : OSe 2 LSB.
- Gain error : Ge 0.4 %.

- Absolute voltage error : Ae 3 LSB.
- Channel to channel matching : Mctc 1 LSB.
- Crosstalk between analog inputs : Ct < -60dB. @ 10 0 kHz.
- Monotonic and no missing codes.
- Separated analog (AVDD, AVSS) and digital (VDD, VSS) supply voltages.
- Reference voltage at two special pins : AVREF- and AVREF+.

### 1.5.1 Functional description:

**Table 5.**

|        |                                                  |            |
|--------|--------------------------------------------------|------------|
| ADCON  | A/D control register                             | read/write |
| ADPSS  | Analog port scan-select register                 | read/write |
| ADRSLn | 8 A/D result registers, contain the 8 lower bits | read only  |
| ADRSnH | A/D result register, contains the 2 higher bits  | read only  |
| P5     | Digital input port (shared with analog inputs)   | read only  |

After a RESET of the microcontroller the ADCON and ADPSS register bits are initialized to zero, registers ADRSLn and ADRSH are undefined.

ADRSLn and ADRSH are specified as read only registers to prevent conflict situations between software write operation and writing the A/D conversion result in ADRSn by the hardware.

### 1.5.2 Idle and Power-down Mode for the A/D converter

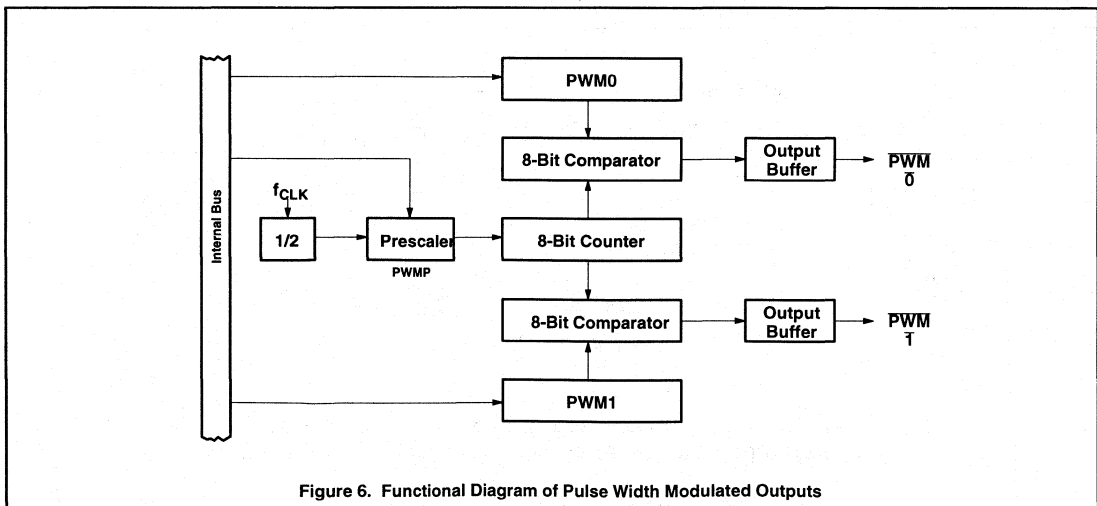

If the Idle or Power-down Mode is activated, then an A/D conversion in progress is aborted, the ADSST flag is cleared and the internal clock is halted. The interrupt flag ADINT will not be set. The ADRSn registers 10 bit buffer are not affected.

Table 6 shows resultant conversion times (tconv) at external clock frequencies (fCLK) and ADC prescaler divisors (m), which are programmable by the bits ADCON.7 and ADCON.6. For conversion times outside the specified range the specified characteristics are not guaranteed; those conversion times are put in brackets.

**Table 6. Configuration time configurable examples (tconv/ms)**

| fCLK<br>m | 6MHz | 8MHz   | 12MHz | 16MHz  |
|-----------|------|--------|-------|--------|
| 2         | 26   | 19.5   | [13]  | [9.75] |
| 4         | 50   | 37.5   | 25    | 18.75  |
| 6         | [74] | [55.5] | 37    | 27.75  |
| 8         | [98] | [73.5] | 49    | 36.75  |

conversion time = 6 x m + 1 machine cycles

| ADCON.5 | ADPOS  | ADPOS is reserved for future use. Must be "0" if ADCON is written.                                                                                                                                                                                                                                                                                                                                                                                       |
| ADCON.4 | ADINT  | ADC interrupt flag. This flag is set when all selected analog inputs are converted, as well in continuous scan as in one time scan mode. An interrupt is invoked if this interrupt is enabled. ADINT must be cleared by software. It cannot be set by software.                                                                                                                                                                                          |
| ADCON.3 | ADSST  | ADC start and status. Setting this bit by software or by hardware (via ADEXS input) starts the A/D conversion of the selected analog inputs. ADSST stays a 'one' in continuous scan mode. In one time scan mode, ADSST is cleared when the last selected analog input channel has been converted. As long as ADSST is a one, new start commands to the ADC- block are ignored. An A/D conversion in progress is aborted if ADSST is cleared by software. |
| ADCON.2 | ADCSA  | 1 = Continuous scan of the selected analog input after a start of A/D conversion.<br>0 = One time scan of the selected analog inputs after a start of A/D conversion.                                                                                                                                                                                                                                                                                    |
| ADCON.1 | ADSRE  | 1 = A rising edge at inputs ADEXS will start the A/D conversion and generate a capture signal.<br>0 = A rising edge at input ADEXS has no effect.                                                                                                                                                                                                                                                                                                        |
| ADCON.0 | ADSF E | 1 = A falling edge at input ADEXS will start the A/D conversion and generate a capture signal.<br>0 = A falling edge at input ADEXS has no effect.                                                                                                                                                                                                                                                                                                       |

## 1.5.4 A/D Input Port Scan-Select Register ADPSS

|             |        |        |        |        |       |        |        |        |
|-------------|--------|--------|--------|--------|-------|--------|--------|--------|
|             | 7      | 6      | 5      | 4      | 3     | 2      | 1      | 0      |
| ADPSS (E7H) | ADPSS7 | ADPSS6 | ADPSS5 | ADPSS4 | ADSS3 | ADPSS2 | ADPSS1 | ADPSS0 |

ADPSS7-0 For each individual bit position:  
0 = The corresponding analog input is skipped in the auto-scan loop.  
1 = The corresponding analog input is included in the auto-scan loop.

If all bits are 'zero' then no A/D conversion can be started. If ADPSS is written while an A/D conversion is in progress (ADSST in the ADCON register is 'one') then the auto-scan loop with the previous selected analog inputs is completed first. The next auto-scan loop is performed with the new selected analog inputs.

## 1.5.5 A/D Result Registers ADRLn and ADRESH:

There are 8 ADRLn registers and one ADRESH register. Reading an ADRLn register by software copies at the same time the two highest bits of the corresponding

10-bit conversion value in two latches. These two latches form bit position 0 and bit position 1 of register ADRESH. The upper 6 bits of ADRESH are all 0's if read. ADRLn and ADRESH are read only registers.

## 1.6 Timer / Counters

The 8xCE558 contains three 16-bit timer/event counters: Timer 0, Timer 1 and Timer T2 and one 8-bit timer, T3. Timer 0 and Timer 1 may be programmed to carry out the following functions:

- Measure time intervals and pulse durations
- Count events
- Generate interrupt requests

## 1.6.1 Timer 0 and Timer 1

Timers 0 and 1 each have a control bit in SFR TMOD that selects the timer or counter function of the corresponding timer.

In the timer function, the register is incremented every machine cycle. Thus, one can think of it as counting machine cycles. Since a machine cycle consists of 12 oscillator periods, the count rate is 1/12 of the oscillator frequency.

In the counter function, the register is incremented in response to a 1-to-0 transition at the corresponding external input pin, T0 or T1. In this function, the external input is sampled during S5P2 of every machine cycle. When the samples show a HIGH in one cycle and a LOW in the next cycle, the counter is incremented. Thus, it takes two machine cycles (24 oscillator periods) to recognize a 1- to-0 transition. There are no restrictions on the duty cycle of the external input signal, but to insure that a given level is sampled at least once before it changes, it should be held for at least one full machine cycle.

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

Timer 0 and Timer 1 can be programmed independently to operate in one of four modes:

- Mode 0: 8-bit timer or 8-bit counter each with divide-by-32 prescaler
- Mode 1: 16-bit time-interval or event counter
- Mode 2: 8-bit time-interval or event counter with automatic reload upon overflow
- Mode 3: -Timer 0: one 8-bit time-Interval or event counter and one 8-bit time-Interval counter  
-Timer 1: stopped

When Timer 0 is in Mode 3, Timer 1 can be

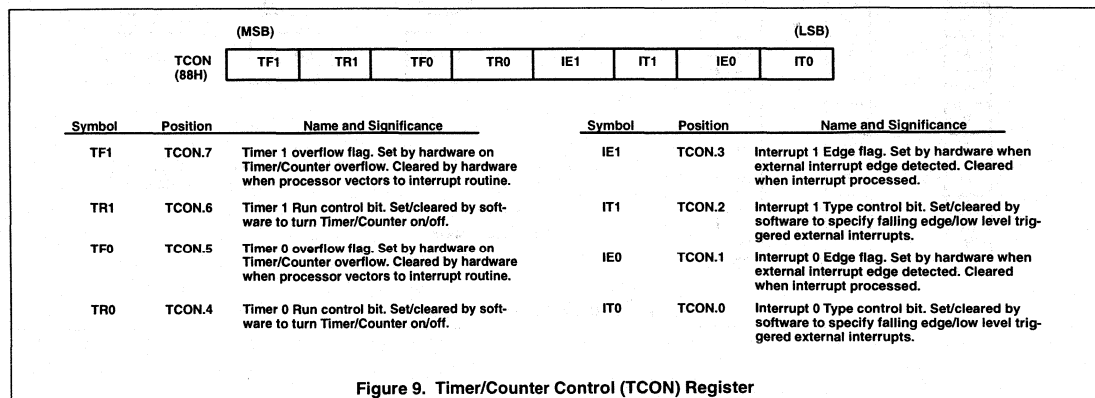

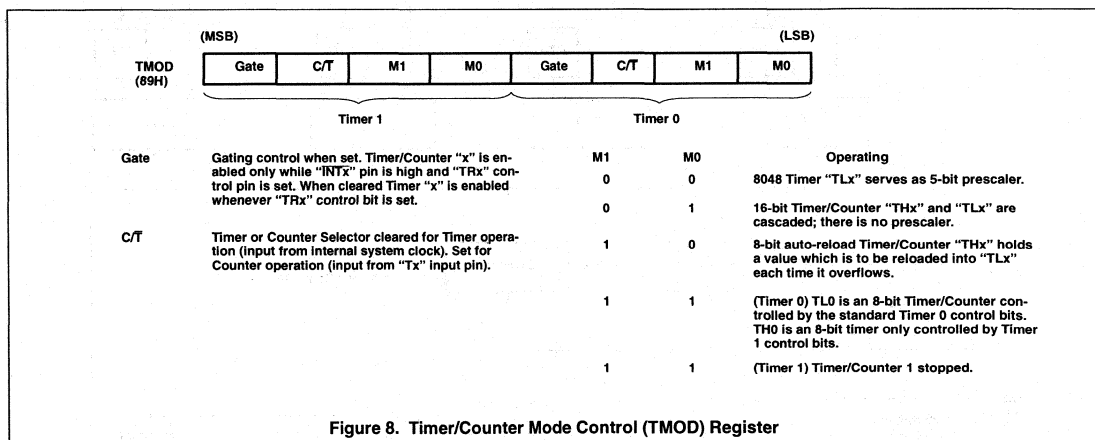

programmed to operate in Modes 0, 1 or 2 but cannot set an interrupt request flag or generate an interrupt. However the overflow from Timer 1 can be used to pulse the serial port baud-rate generator.

With a 16 MHz crystal, the counting frequency of these timer/counters is as follows:

- In the timer function, the timer is incremented at a frequency of 1,33 MHz - a division by 12 of the oscillator frequency
- 0 Hz to an upper limit of 0.66 MHz (1/24 of the oscillator frequency) when programmed for external inputs

Both internal and external inputs can be gated to the counter by a second external source for directly measuring pulse durations. When configured as a counter, the register is incremented on every falling edge on the corresponding input pin, T0 or T1. The incremented register value can be read earliest during the second machine cycle after that one, during which the incrementing pulse occurred.

The counters are started and stopped under software control. Each one sets its interrupt request flag when it overflows from all HIGHS to all LOWs (or automatic reload value), with the exception of mode 3 as previously described.

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

## 1.6.2 Timer T2

Timer T2 is a 16 bit timer/counter which has capture and compare facilities.

The operational diagram is shown in Figure 8.

The 16 bit timer/counter is clocked via a prescaler with a programmable division factor of 1, 2, 4 or 8. The input of the prescaler is clocked with 1/12 of the clock frequency, or by an external source connected to the T2 input, or it is switched off. The maximum repetition rate of the external clock source is  $f_{CLK}/12$ , twice that of Timer 0 and Timer 1. The prescaler is incremented on a rising

edge. It is cleared if its division factor or its input source is changed, or if the timer/counter is reset (see also Figure 11: TM2CON). T2 is readable 'on the fly', without any extra read latches; this means that software precautions have to be taken against misinterpretation at overflow from least to most significant byte while T2 is being read. T2 is not loadable and is reset by the RST signal or at the positive edge of the input signal RT2, if enabled. In the Idle mode the timer/counter and prescaler are reset and halted.

T2 is connected to four 16-bit Capture

Registers: CT0, CT1, CT2 and CT3. A rising or falling edge on the inputs CT0I, CT1I, CT2I or CT3I (alternative function of Port 1) results in loading the contents of T2 into the respective Capture Registers and an interrupt request.

Using the Capture Register CTCON (see Figure 12), these inputs may invoke capture and interrupt request on a positive, a negative edge or on both edges. If neither a positive nor a negative edge is selected for capture input, no capture or interrupt request can be generated by this input.

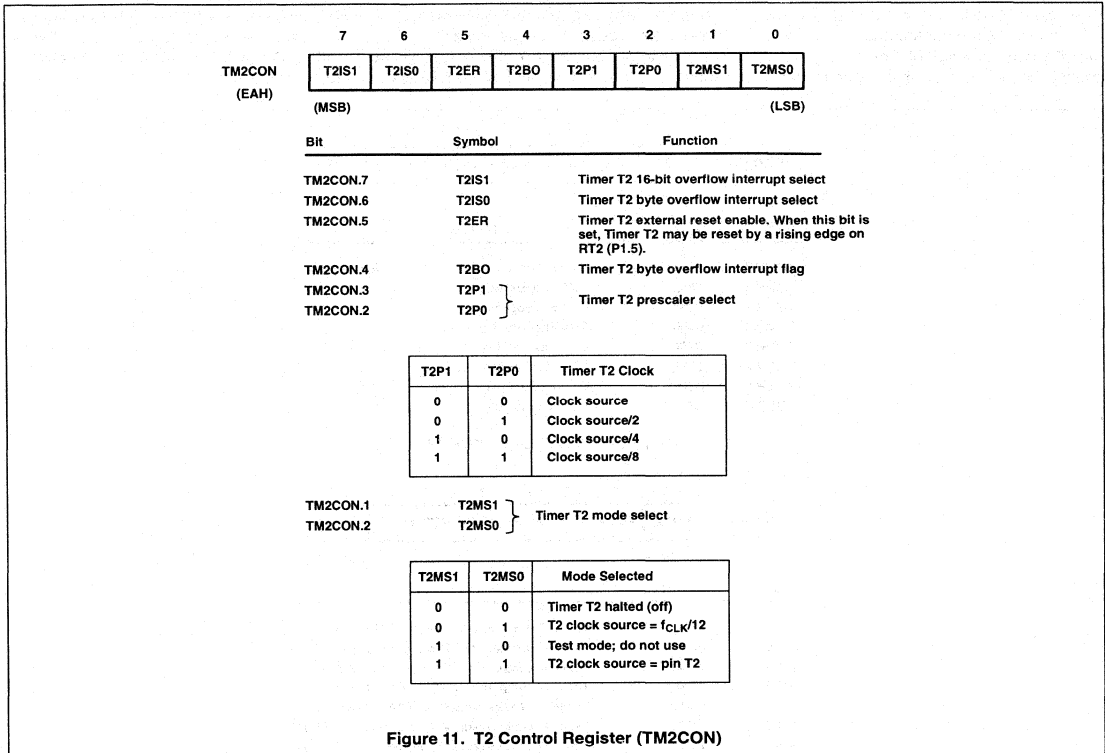

Figure 11. T2 Control Register (TM2CON)

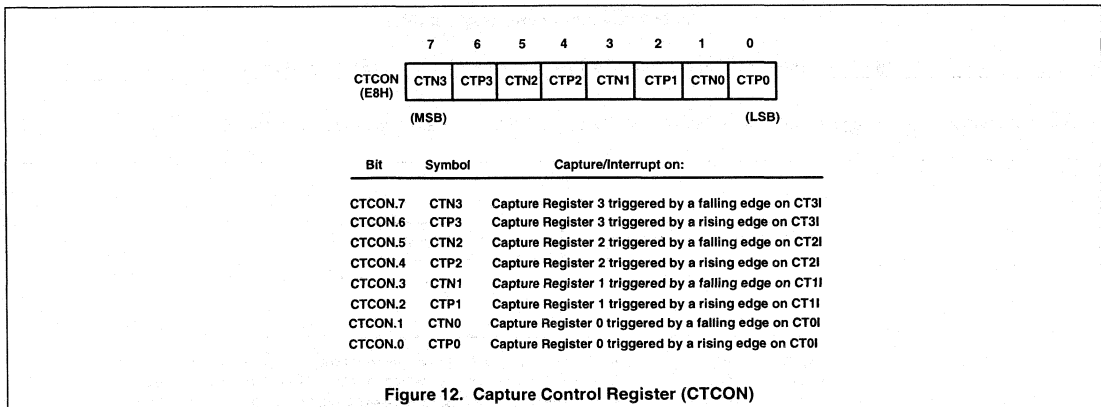

Figure 12. Capture Control Register (CTCON)

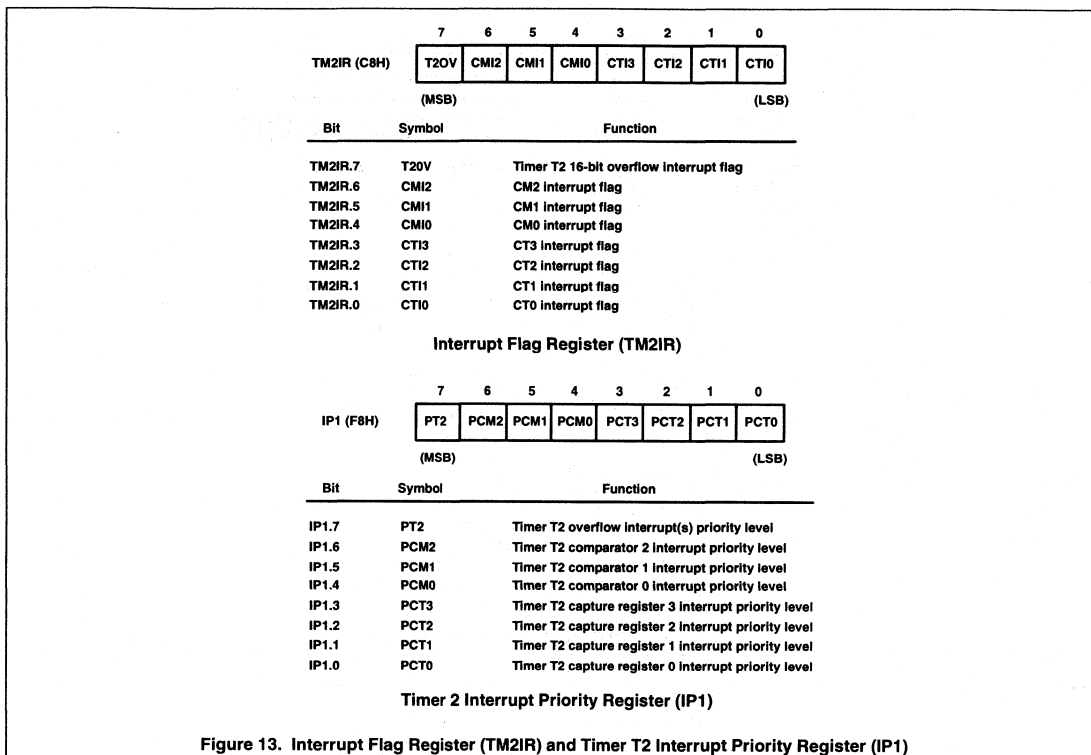

Single-chip 8-bit microcontroller

80CE558/83CE558/89CE558

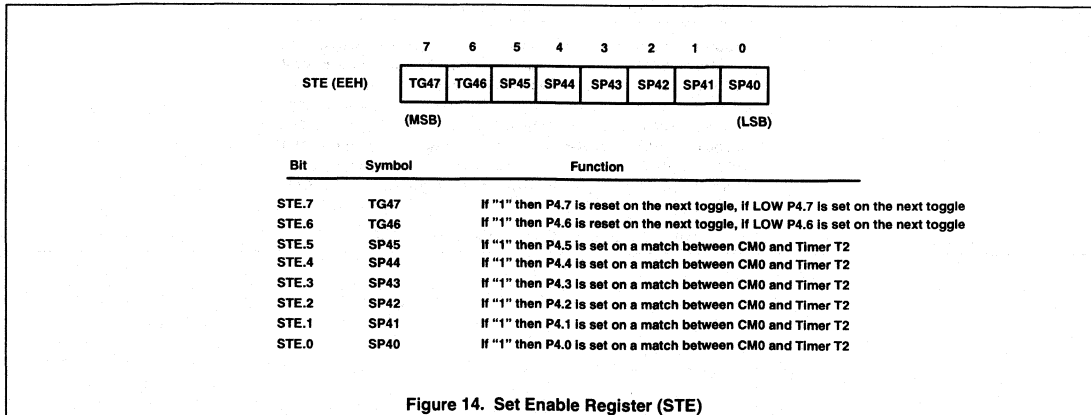

The contents of the Compare Registers CM0, CM1 and CM2 are continuously compared with the counter value of Timer T2. When a match occurs, an interrupt may be invoked. A

match of CM0 sets the bits 0-5 of Port 4, a CM1 match resets these bits and a CM2 match toggles bits 6 and 7 of Port 4, provided these functions are enabled by the STE resp.

RTE registers. A match of CM0 and CM1 at the same time results in resetting bits 0-5 of Port 4. CM0, CM1 and CM2 are reset by the RSTIN signal.

For more information concerning the TM2CON, CTCON, TM2IR and the STE/RTE registers see IC20 handbook 1994.

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

Port 4 can be read and written by software without affecting the toggle, set and reset signals. At a byte overflow of the least significant byte, or at a 16-bit overflow of the timer/counter, an interrupt sharing the same interrupt vector is requested. Either one or both of these overflows can be programmed to request an interrupt.

All interrupt flags must be reset by software.

## 1.7 Watchdog Timer (T3) (see Figure 16)

In addition to Timer T2 and the standard timers, a watchdog timer consisting of an 11-bit prescaler and an 8-bit timer is also incorporated.

The timer is incremented every 1,5 ms,

derived from the oscillator frequency of 16 MHz by the following:

$$t_{\text{timer}} = \frac{f_{\text{CLK}}}{12 \times 2048}$$

When a timer overflow occurs, the microcontroller - but not the PLL - is reset and a reset output pulse is generated at pin RSTOUT.

To prevent a system reset the timer must be reloaded in time by the application software. If the processor suffers a hardware/software malfunction, the software will fail to reload the timer. This failure will produce a reset upon overflow thus preventing the processor running out of control. The watchdog timer can only be reloaded if the condition flag

WLE = PCON.4 has been previously set by software.

At the moment the counter is loaded the condition flag is automatically cleared.

The time interval between the timer's reloading and the occurrence of a reset depends on the reloaded value. For example, this may range from 1,5 ms to 0,375 s when using an oscillator frequency of 16 MHz.

In the Idle state the watchdog timer and reset circuitry remain active.

The watchdog timer is controlled by the watchdog enable pin (EW). A LOW level enables the watchdog timer and disables the Power-down mode. A HIGH level disables the watchdog timer and enables the Power-down mode.

1.8 Serial I/O

The 8xCE558 is equipped with two independent serial ports: SIO0 and SIO1. SIO0 is the full duplex UART port, identical to the PCB80C51 serial port. SIO1 is an I<sup>2</sup>C-bus serial I/O interface with byte oriented master and slave functions.

1.8.1 SIO0 (UART)

SIO 0 is a full duplex serial I/O port - it can transmit and receive simultaneously. This serial port is also receive-buffered. It can commence reception of a second byte before the previously received byte has been read from the receive register. If, however, the first byte has still not been read by the time reception of the second byte is complete, one of the bytes will be lost. The SIO0 receive and transmit registers are both accessed via the S0BUF special function register. Writing to S0BUF loads the transmit register, and reading S0BUF accesses to a physically separate receive register. SIO0 can operate in 4 modes:

**Mode 0:** Serial data is transmitted and received through RXD. TXD outputs the shift clock. 8 data bits

are transmitted/received (LSB first). The baud rate is fixed at 1/12 of the oscillator frequency.

**Mode 0:** 10 bits are transmitted via TXD or received through RXD: a start bit (0), 8 data bits (LSB first), and a stop bit(1). On receive, the stop bit is put into RB8 (S0CON special function register). The baud rate is variable.

**Mode 0:** 11 bits are transmitted through TXD or received through RXD: a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmit, the 9th data bit (TB8 in S0CON) can be assigned the value of 0 or 1. With nominal software, TB8 can be the parity bit (P in PSW). During a receive, the 9th data bit is stored in RB8 (S0CON), and the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 of the oscillator frequency.

**Mode 0:** 11 bits are transmitted through TXD or received through RXD: a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and

a stop bit (1). Mode 3 is the same as Mode 2 except the baud rate which is variable in Mode 3.

In all four modes, transmission is initiated by any instruction that writes to the S0BUF function register. Reception is initiated in Mode 0 when RI = 0 and REN = 1. In the other three modes, reception is initiated by the incoming start bit provided that REN = 1.

Modes 2 and 3 are provided for multiprocessor communications. In these modes, 9 data bits are received with the 9th bit written to RB8. The 9th bit is followed by the stop bit. The port can be programmed so that with receiving the stop bit, the serial port interrupt will be activated if, and only if RB8 = 1.

This feature is enabled by setting bit SM2 in S0CON. This feature may be used in multiprocessor systems.

For more information about how to use the UART in combination with the registers S0CON, PCON, IEN0, S0BUF and Timer register refer to the 80C51 Data Handbook IC20 1992.

Where SM0, SM1 specify the serial port mode, as follows:

| SM0 | SM1 | Mode Rate | Description    | Baud                         |
|-----|-----|-----------|----------------|------------------------------|
| 0   | 0   | 0         | shift register | $f_{CLK}/12$                 |
| 0   | 1   | 1         | 8-bit UART     | variable                     |
| 1   | 0   | 2         | 9-bit UART     | $f_{CLK}/64$ or $f_{CLK}/32$ |
| 1   | 1   | 3         | 9-bit UART     | variable                     |

- SM2 enables the multiprocessor communication feature in modes 2 and 3. In mode 2 or 3, if SM2 is set to 1,, then RI will not be activated if the received 9th data bit (RB8) is 0. In mode 1, if SM2 = 1, then RI will not be activated if a valid stop bit was not received. In mode 0, SM2 should be 0.
- REN enables serial reception. Set by software to enable reception. Clear by software to disable reception.

- TB8 is the 9th data bit that will be transmitted in modes 2 and 3. Set or clear by software as desired.
- RB8 in modes 2 and 3, is the 9th data bit that was received. In mode 1, if SM2 = 0, RB8 is the stopbit that was received in mode 0, RB8 is not used.
- TI is the transmit interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or at the beginning of the stop bit in the other modes, in any serial transmission. Must be cleared by software.
- RI is the receive interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or halfway through the stop bit time in the other modes, in any serial reception (except see SM2). Must be cleared by software.

### 1.8.2 SIO1 (I<sup>2</sup>C-bus Interface)

The I<sup>2</sup>C-bus is a simple bidirectional 2-wire bus for efficient inter-IC data exchange. Out-standing features of the I<sup>2</sup>C-bus are:

- Only two bus lines are required: a serial clock line (SCL) and a serial data line (SDA)
- Each device connected to the bus is software addressable by a unique address
- Masters can operate as Master-transmitter or as Master-receiver
- It's a true multi-master bus including collision detection and arbitration to prevent data corruption if two or more masters simultaneously initiate data transfer
- Serial clock synchronization allows devices with different bit rates to communicate via the same serial bus
- ICs can be added to or removed from an I<sup>2</sup>C-bus system without affecting any other circuit on the bus
- Fault diagnostics and debugging are simple; malfunctions can be immediately traced

The on-chip I<sup>2</sup>C logic provides a serial interface that meets the I<sup>2</sup>C-bus specification, supporting all I<sup>2</sup>C-bus modes of operation, they are:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

The SIO1 logic performs a byte oriented data transport, clock generation, address recognition and bus control arbitration are all controlled by hardware. Via two pins the external I<sup>2</sup>C-bus is interfaced to the SIO1 logic:

SCL serial clock I/O and SDA (serial data I/O), (see Special Function Register bit S1CON.6/ENS1 for enabling the SIO1 logic).

The SIO1 logic handles byte transfer autonomously. It keeps track of the serial transfers, and a status register (S1STA) reflects the status of SIO1 and the I<sup>2</sup>C-bus.

Via the following four Special Function Registers the CPU interfaces to the I<sup>2</sup>C logic.

|       |                                                                                      |
|-------|--------------------------------------------------------------------------------------|
| S1CON | control register. Bit addressable by the CPU                                         |
| S1STA | status register whose contents may be used as a vector to service routines.          |
| S1DAT | data shift register. The data byte is stable as long as S1CON.3/SI=1.                |
| S1ADR | slave address register. It's LSB enables/ disables general call address recognition. |

The Control Register, S1CON:  
The CPU can read from and write to this 8-bit, directly addressable SFR. Two bits are affected by the SIO1 hardware: the SI bit is set when a serial interrupt is requested, and the STO bit is cleared when a STOP

condition is present on the I<sup>2</sup>C bus. The STO bit is also cleared when ENS1 = "0".

#### S1CON (D8H)

|     |      |     |     |    |    |     |     |
|-----|------|-----|-----|----|----|-----|-----|
| 7   | 6    | 5   | 4   | 3  | 2  | 1   | 0   |
| CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |

#### ENS1, the SIO1 Enable Bit

ENS1 = "0": When ENS1 is "0", the SDA and SCL outputs are in a high impedance state. SDA and SCL input signals are ignored, SIO1 is in the "not addressed" slave state, and the STO bit in S1CON is forced to "0". No other bits are affected.

ENS1 = "1": When ENS1 is "1", SIO1 is enabled.

In the following text, it is assumed that ENS1 = "1".

ENS1 should not be used to temporarily release SIO1 from the I<sup>2</sup>C-bus since, when ENS1 is reset, the I<sup>2</sup>C bus status is lost. The AA flag should be used instead (see description of the AA flag in the following text).

#### STA, the START Flag

STA = "1": When the STA bit is set to enter a master mode, the SIO1 hardware checks the status of the I<sup>2</sup>C bus and generates a START condition if the bus is free. If the bus is not free, then SIO1 waits for a STOP condition (which will free the bus) and generates a START condition after a delay of a half clock period of the internal serial clock generator.

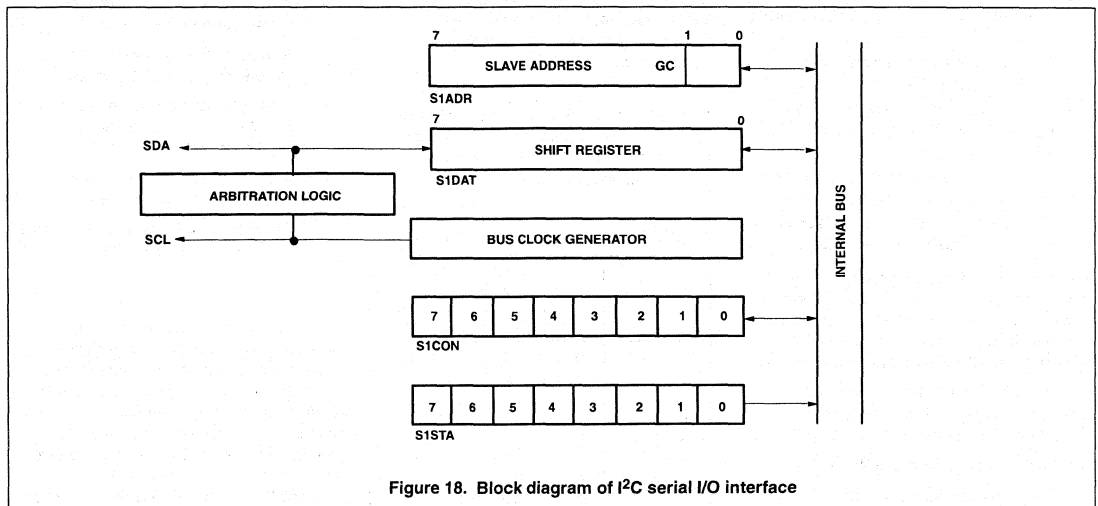

Figure 18. Block diagram of I<sup>2</sup>C serial I/O interface

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

If STA is set while SIO1 is already in a master mode and one or more bytes are transmitted or received, SIO1 transmits a repeated START condition. STA may be set at any time. STA may also be set when SIO1 is an addressed slave.

STA = "0": When the STA bit is reset, no START condition or repeated START condition will be generated.

**STO, the STOP Flag**

STO = "1": When the STO bit is set while SIO1 is in a master mode, a STOP condition is transmitted to the I<sup>2</sup>C bus. When the STOP condition is detected on the bus, the SIO1 hardware clears the STO flag. In a slave mode, the STO flag may be set to recover from an error condition. In this case, no STOP condition is transmitted to the I<sup>2</sup>C bus. However, the SIO1 hardware behaves as if a STOP condition has been received and switches to the defined "not addressed" slave receiver mode. The STO flag is automatically cleared by hardware.

If the STA and STO bits are both set, the a STOP condition is transmitted to the I<sup>2</sup>C bus if SIO1 is in a master mode (in a slave mode, SIO1 generates an internal STOP condition which is not transmitted). SIO1 then transmits a START condition.

STO = "0": When the STO bit is reset, no STOP condition will be generated.

**SI, the Serial Interrupt Flag**

SI = "1": When the SI flag is set, then, if the EA and ES1 (interrupt enable register) bits are also set, a serial interrupt is requested. SI is set by hardware when one of the following events occur:

- A START condition is generated in MST mode.
- The own slave address has been received during AA = logic 1.
- The general call address has been received while S1ADR.0 and AA = logic 1
- A data byte has been received or transmitted as selected slave.
- A STOP or START condition is received as selected slave receiver or transmitter.

While SI is set, the low period of the serial clock on the SCL line is stretched, and the serial transfer is suspended. A high level on the SCL line is unaffected by the serial interrupt flag. SI must be reset by software.

SI = "0": When the SI flag is reset, no serial interrupt is requested, and there is no stretching of the serial clock on the SCL line.

**AA, the Assert Acknowledge Flag**

AA = "1": If the AA flag is set, an acknowledge (low level to SDA) will be

returned during the acknowledge clock pulse on the SCL line when:

- The "own slave address" has been received
- The general call address has been received while the general call bit (GC) in S1ADR is set
- A data byte has been received while SIO1 is in the master receiver mode
- A data byte has been received while SIO1 is in the addressed slave receiver mode

AA = "0": if the AA flag is reset, a not acknowledge (high level to SDA) will be returned during the acknowledge clock pulse on SCL when:

- A data has been received while SIO1 is in the master receiver mode
- A data byte has been received while SIO1 is in the addressed slave receiver mode

When SIO1 is in the not addressed slave mode, its own slave address and the general call address are ignored. Consequently, no acknowledge is returned, and a serial interrupt is not requested. Thus, SIO1 can be temporarily released from the I<sup>2</sup>C bus while the bus status is monitored. While SIO1 is released from the bus, START and STOP conditions are detected, and serial data is shifted in. Address recognition can be resumed at any time by setting the AA flag. If the AA flag is set when the part's own slave address or the general call address has been partly received, the address will be recognized at the end of the byte transmission.

**CR0, CR1, and CR2, the Clock Rate Bits**

These three bits determine the serial clock frequency when SIO1 is in a master mode. The various serial rates are shown in Table 7.

**Table 7. Serial Clock Rates**

| CR2 | CR1 | CR0 | BIT FREQUENCY (kHz) AT f <sub>CLK</sub> |       |
|-----|-----|-----|-----------------------------------------|-------|
|     |     |     | 12MHz                                   | 16MHz |
| 1   | 0   | 0   | 50                                      | 66.7  |
| 1   | 0   | 1   | 3.75                                    | 5     |
| 1   | 1   | 0   | 75                                      | 100   |
| 1   | 1   | 1   | 100                                     | -     |
| 0   | 0   | 0   | 200                                     | 266.7 |
| 0   | 0   | 1   | 7.5                                     | 10    |
| 0   | 1   | 0   | 300                                     | 400   |
| 0   | 1   | 1   | 400                                     | -     |

The frequencies shown in Table 7 are unimportant when SIO1 is in a slave mode. In the slave modes, SIO1 will automatically synchronize with any clock frequency up to 100kHz.

Except from the bit rate selection (see Table 7) and the timing of the SCL and SDA signals (see AC electrical characteristics in section 10 of this data sheet) the SIO circuit is the same as described in detail in the 8xC552 section of this handbook.

**AA**

Assert acknowledge bit, When this bit is set, an acknowledge is returned after any one of the following conditions:

- Own slave address is received
- General call address is received (S1ADR.0 = logic 1)
- A data byte is received, while the device is programmed to be a master receiver
- A data byte is received, while the device is a selected slave receiver

When the bit is reset, no acknowledge is returned. Consequently, no interrupt is requested when the own address or general is received.

**SI**

SIO1 interrupt flag. This is set, and an interrupt request is generated, after any of the following events occur:

- A START condition is generated in MST mode
- The own slave address has been received during AA = logic 1
- The general call address has been received while S1ADR.0 and AA = logic 1
- A data byte has been received or transmitted in MST mode (even if arbitration is lost)
- A data byte has been received or transmitted as selected slave
- A STOP or START condition is received as selected slave receiver or transmitter

**STOP**

STOP flag. When in master mode, and this bit is set a STOP condition is generated. A STOP condition detected on the I<sup>2</sup>C-bus clears this bit. This bit may also be set in slave mode in order to recover from an error condition. Then no STOP condition is generated to the I<sup>2</sup>C-bus, but the hardware releases the SDA and SCL lines and switches to the not selected receiver mode. The STOP flag is cleared by the hardware.

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

**STA**

START flag. When this bit is set in slave mode, the hardware checks the I<sup>2</sup>C-bus and generates a START condition if the bus is free or after the bus becomes free. If the device operates in master mode it will generate a repeated START condition.

**ENS1**

0 = Serial I/O Disabled and reset. SDA and SCL outputs are open drain.

1 = Serial I/O Enabled.

**Serial status register S1STA** (S1STA is a read only register)

**S1STA (D9H)**

|     |     |     |     |     |   |   |   |
|-----|-----|-----|-----|-----|---|---|---|
| 7   | 6   | 5   | 4   | 3   | 2 | 1 | 0 |
| SC4 | SC3 | SC2 | SC1 | SC0 | 0 | 0 | 0 |

S1STA.3 - S1STA.7 hold a status code. S1STA.0 - S1STA.2 are held LOW. The contents of the status register may be used as a vector to a service routine. This optimizes the response time of the software and consequently that of the I<sup>2</sup>C-bus.

**Abbreviations used:**

|      |                                                   |
|------|---------------------------------------------------|
| SLA  | : 7-bit slave address                             |
| R    | : Read bit                                        |
| W    | : Write bit                                       |
| ACK  | : Acknowledgement (acknowledge bit = logic 0)     |
| ACK  | : Not acknowledgement (acknowledge bit = logic 1) |
| DATA | : 8-bit data byte to or from I <sup>2</sup> C-bus |
| MST  | : Master                                          |
| SLV  | : Slave                                           |
| TRX  | : Transmitter                                     |
| REC  | : Receiver                                        |

The following is a list of the status codes:

**MST/TRX mode****S1STA value**

|     |                                                          |
|-----|----------------------------------------------------------|
| 08H | - A START condition has been transmitted                 |
| 10H | - A repeated START condition has been transmitted        |
| 18H | - SLA and W have been transmitted, ACK has been received |
| 20H | - SLA and W have been transmitted, ACK received          |
| 28H | - DATA and S1DAT has been transmitted, ACK received      |
| 30H | - DATA and S1DAT has been transmitted, ACK received      |
| 38H | - Arbitration lost in SLA, R/W or DATA                   |

**MST/REC mode****S1STA value**

|     |                                                 |
|-----|-------------------------------------------------|
| 38H | - Arbitration lost while returning ACK          |
| 40H | - SLA and R have been transmitted, ACK received |
| 48H | - SLA and R have been transmitted, ACK received |
| 50H | - DATA has been received, ACK returned          |
| 58H | - DATA has been received, ACK returned          |

**SLV/REC mode****S1STA value**

|     |                                                                                                               |
|-----|---------------------------------------------------------------------------------------------------------------|
| 60H | - Own SLA and W have been received, ACK returned                                                              |
| 68H | - Arbitration lost in SLA, R/W as MST. Own SLA and W have been received, ACK returned                         |
| 70H | - General CALL has been received, ACK returned                                                                |
| 78H | - Arbitration lost in SLA, R/W as MST. General call has been received                                         |
| 80H | - Previously addressed with own SLA. DATA byte received, ACK returned                                         |
| 88H | - Previously addressed with own SLA. DATA byte received, ACK returned                                         |
| 90H | - Previously addressed with general call. DATA byte has been received, ACK has been returned                  |
| 98H | - Previously addressed with general call. DATA byte has been received, ACK has been returned                  |
| A0H | - A STOP condition or repeated START condition has been received while still addressed as SLV/REC or SLV/TRX. |

**SLV/TRX mode****S1STA value**

|     |                                                                                       |
|-----|---------------------------------------------------------------------------------------|
| A8H | - Own SLA and R have been received, ACK returned                                      |
| B0H | - Arbitration lost in SLA, R/W as MST. Own SLA and R have been received, ACK returned |
| B8H | - DATA byte has been transmitted, ACK returned                                        |
| C0H | - DATA byte has been transmitted, ACK returned                                        |
| C8H | - Last DATA byte has been transmitted (AA = logic 0), ACK received                    |

**Miscellaneous****S1STA value**

|     |                                                                      |
|-----|----------------------------------------------------------------------|
| 00H | - Bus error during MST mode or selected (AA = logic 0), ACK received |
|-----|----------------------------------------------------------------------|

**The data shift register S1DAT****S1DAT (DAH)**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

This register contains the serial data to be transmitted or data which has been received. Bit 7 is transmitted or received first; i.e. data is shifted from right to left.

**The address register S1ADR****S1ADR (DBH)**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

S1ADR.0, GC : 0 = general call address is not recognized  
1 = general call address recognized

S1ADR.7 - 1 : own slave address

This 8-bit register may be loaded with the 7-bit slave address to which the controller will respond when programmed as a slave receiver/transmitter. The LSB (GC) is used to determine whether the general call address is recognized.

**1.9 Interrupt System**

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronously to the execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution a multiple-source, two-priority-level, nested interrupt system is provided. Interrupt response time in a single-interrupt system is in the range from 2.25us to 6.75 us when using a 16 MHz crystal. The latency time depends on the sequence of instructions executed directly after an interrupt request.

The 8xCE558 acknowledges interrupt requests from 15 sources as follows (see Figure 19):

- UART serial I/O port receive/transmit interrupt
- I<sup>2</sup>C-bus interface serial I/O interrupt
- ADC autoscan completion interrupt
- 'Seconds' timer interrupt SEC (ORed with INT1)
- INT0 and INT1 external interrupts
- Timer 0 and Timer 1 internal timer/counter interrupts
- Timer 2 internal timer/counter byte and/or 16-bit overflow, 3 compare and 4 capture interrupts (or 4 additional external interrupts). (!)

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

The External Interrupts  $INT0$  and  $INT1$  can each be either level-activated or transition-activated, depending on bits  $IT0$  and  $IT1$  in register  $TCON$ . The flags that actually generate these interrupts are bits  $IE0$  and  $IE1$  in  $TCON$ . When an external interrupt is generated, the corresponding request flag is cleared by the hardware when the service routine is vectored to only if the interrupt was transition-activated. If the interrupt was level-activated then the interrupt request flag remains set until the external interrupt pin  $INTx$  goes high. Consequently the external source has to hold the request active until the requested interrupt is actually generated. Then it has to deactivate the request before the interrupt service routine is completed, or else another interrupt will be generated. As these external interrupts are active LOW a "wire-ORing" of several interrupt sources to one input pin allows expansion.

The Timer 0 and Timer 1 Interrupts are generated by  $TF0$  and  $TF1$ , which are set by a rollover in their respective timer/counter register (except for Timer 0 in Mode 3 of the serial interface). When a Timer interrupt is generated, the flag that generated it is cleared by the on-chip hardware when the service routine is vectored to.

The eight Timer/Counter T2 Interrupt sources are: 4 capture interrupts (1), 3 compare interrupts and an overflow interrupt. The appropriate interrupt request flags must be cleared by software.

The UART Serial Port Interrupt is generated by the logical OR of  $RI$  and  $TI$ . Neither of these flags is cleared by hardware. The service routine will normally have to determine whether it was  $RI$  or  $TI$  that generated the interrupt, and the bit will have to be cleared by software.

The  $I^2C$  Interrupt is generated by bit  $SI$  in register  $S1CON$ . This flag has to be cleared by software.

The ADC Interrupt is generated by bit  $ADINT$ , which is set when of all selected analog inputs to be scanned, the conversion is finished.  $ADINT$  must be cleared by software. It cannot be set by software.

All of the bits that generate interrupts can be

set or cleared by software, with the same result as though it had been set or cleared by hardware (except the ADC interrupt request flag  $ADINT$ , which cannot be set by software). That is, interrupts can be generated or pending interrupts can be cancelled in software.

The Interrupts  $X0$ ,  $T0$ ,  $X1$ ,  $T1$ ,  $SEC$ ,  $S0$  and  $S1$  are capable to terminate the Idle Mode.

#### Interrupt Enable Registers

Each interrupt source can be individually enabled or disabled by setting or clearing a bit in the interrupt enable special function registers  $IEN0$  and  $IEN1$ . All interrupt sources can also be globally enabled or disabled by setting or clearing bit  $EA$  in  $IEN0$ . The interrupt enable registers are described in Figures 20 and 21.

#### Interrupt Priority Structure

Each interrupt source can be assigned one of two priority levels. Interrupt priority levels are defined by the interrupt priority special function registers  $IP0$  and  $IP1$ .  $IP0$  and  $IP1$  are described in Figures 22 and 23.

Interrupt priority levels are as follows:

"0"—low priority  
"1"—high priority

A low priority interrupt may be interrupted by a high priority interrupt. A high priority interrupt cannot be interrupted by any other interrupt source. If two requests of different priority occur simultaneously, the high priority level request is serviced. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced. Thus, within each priority level, there is a second priority structure determined by the polling sequence. This second priority structure is shown in Table 8.

#### Interrupt Handling

The interrupt sources are sampled at  $S5P2$  of every machine cycle. The samples are polled during the following machine cycle. If one of the flags was in a set condition at  $S5P2$  of the previous machine cycle, the polling cycle will find it and the interrupt system will generate an  $LCALL$  to the appropriate service routine, provided this hardware-generated  $LCALL$  is not blocked by any of the following conditions:

1. An interrupt of higher or equal priority level is already in progress.
2. The current machine cycle is not the final cycle in the execution of the instruction in progress. (No interrupt request will be serviced until the instruction in progress is completed.)
3. The instruction in progress is  $RETI$  or any access to the interrupt priority or interrupt enable registers. (No interrupt will be serviced after  $RETI$  or after a read or write to  $IP0$ ,  $IP1$ ,  $IE0$ , or  $IE1$  until at least one other instruction has been subsequently executed.)

The polling cycle is repeated with every machine cycle, and the values polled are the values present at  $S5P2$  of the previous machine cycle. Note that if an interrupt flag is active but is not being responded to because of one of the above conditions, and if the flag is inactive when the blocking condition is removed, then the blocked interrupt will not be serviced. Thus, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle is new.

The processor acknowledges an interrupt request by executing a hardware-generated  $LCALL$  to the appropriate service routine. In some cases it also clears the flag which generated the interrupt, and in others it does not. It clears the Timer 0, Timer 1, and external interrupt flags. An external interrupt flag ( $IE0$  or  $IE1$ ) is cleared only if it was transition-activated. All other interrupt flags

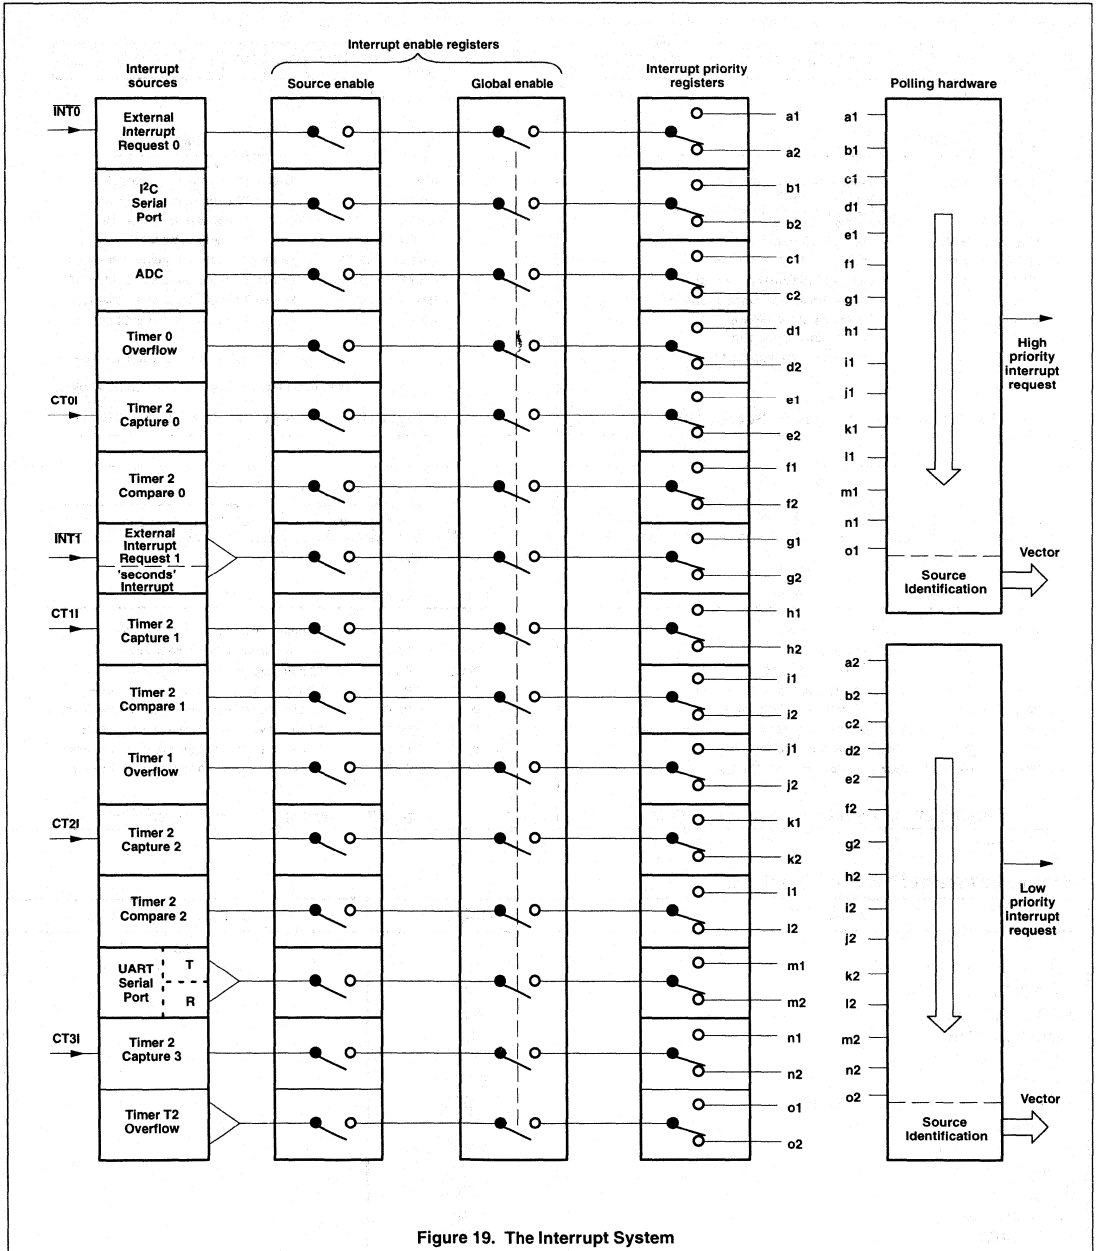

are not cleared by hardware and must be cleared by the software. The  $LCALL$  pushes the contents of the program counter on to the stack (but it does not save the  $PSW$ ) and reloads the PC with an address that depends on the source of the interrupt being vectored to as shown in Table 9.

Execution proceeds from the vector address until the  $RETI$  instruction is encountered. The  $RETI$  instruction clears the "priority level active" flip-flop that was set when this interrupt was acknowledged. It then pops the top two bytes from the stack and reloads the program counter. Execution of the interrupted program continues from where it was interrupted.

**Note 1):** If a capture register is unused and its contents is of no interest, then the corresponding input pin  $CTnI/P1.n$  ( $n: 0...3$ ) may be used as a (configurable) positive and/or negative edge triggered additional external interrupt input ( $INT2$ ,  $INT3$ ,  $INT4$ ,  $INT5$ ).

# Single-chip 8-bit microcontroller

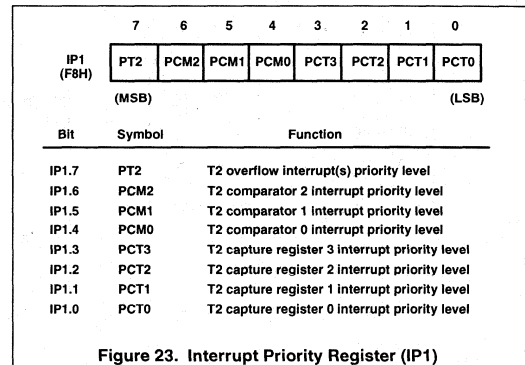

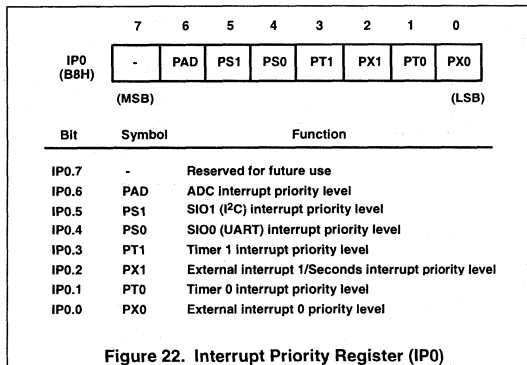

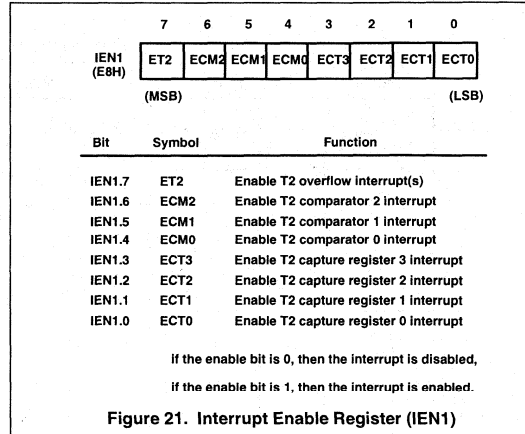

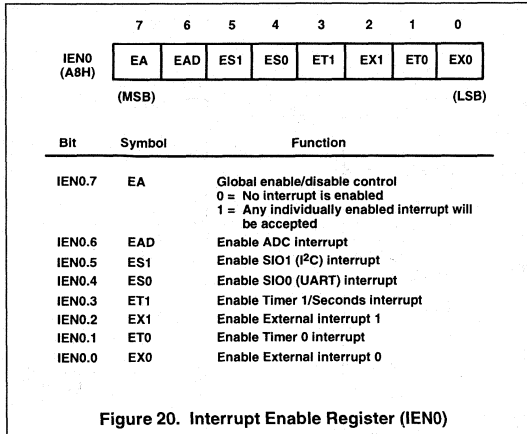

# 80CE558/83CE558/89CE558

## 1.10 Power reduction modes

Two software-selectable modes of reduced power consumption are implemented. These are the Idle Mode and the Power-down Mode.

Idle Mode operation permits the interrupt, serial ports and timer blocks T0, T1 and T3 to function while the CPU is halted. The following functions are switched off when the microcontroller enters the Idle Mode:

- CPU (halted)
- Timer 2 (stopped and reset)
- PWM0, PWM1 (reset, output = HIGH)
- ADC (aborted if conversion in progress)

The following functions remain active during Idle Mode. These functions may generate an interrupt or reset and thus terminate the Idle Mode:

- Timer 0, Timer 1, Timer 3 (Watchdog timer)
- UART
- I<sup>2</sup>C
- External interrupt
- Second Timer

In Power-down Mode the system clock is halted. If the PLL oscillator is selected (SELXTAL1 = 0) and the RUN32 bit is set, the 32 kHz oscillator keeps running, otherwise its stopped. If the HF-oscillator (SELXTAL1 = 1) is selected, it is freedzed after setting the bit PD in the PCON register.

### 1.10.1 Power Control Register

The modes Idle and Power-down are activated by software via the Special Function Register PCON. Its hardware address is 87h. PCON is not bit addressable. The reset value of PCON is (00000000).

### 1.10.2 Idle Mode

The instruction that sets PCON.0 is the last instruction executed in the normal operating mode before Idle mode is activated. Once in the Idle mode, the CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, RAM and all other registers maintain their data during Idle mode.

The status of external pins during Idle mode is shown in Table 10.

There are three ways to terminate the Idle mode:

Activation of any enabled interrupt X0, T0, X1, SEC, T1, S0 or S1 will cause PCON.0 to be cleared by hardware terminating Idle mode. The interrupt is serviced, and following return from interrupt instruction RETI, the next instruction to be executed will be the one which follows the instruction that wrote a logic 1 to PCON.0.

The flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or during Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When Idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.

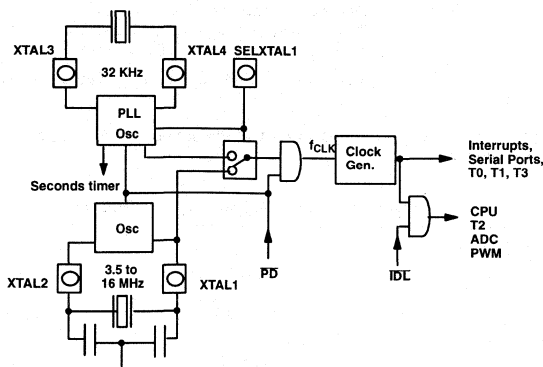

The second way of terminating the Idle mode is with an external hardware reset. Since the oscillator is still running, the hardware reset is required to be active for two machine cycles (24 HF oscillator periods) to complete the reset operation if the HF oscillator is selected.

**Table 10. External Pin Status During Idle and Power-Down Modes**

| MODE       | MEMORY   | ALE | PSEN | PORT 0   | PORT 1 | PORT 2  | PORT 3 | PORT 4 | SCL/SDA       | PWM0/PWM1 |
|------------|----------|-----|------|----------|--------|---------|--------|--------|---------------|-----------|
| Idle       | Internal | 1   | 1    | data     | data   | data    | data   | data   | operative (1) | HIGH      |
| Idle       | External | 1   | 1    | high - Z | data   | Address | data   | data   | operative (1) | HIGH      |
| Power-down | Internal | 0   | 0    | data     | data   | data    | data   | data   | high-Z        | HIGH      |
| Power-down | External | 0   | 0    | high - Z | data   | data    | data   | data   | high-Z        | HIGH      |

**NOTE:**

1. In Idle Mode SCL and SDA can be active as outputs only if SIO1 is enabled; if SIO1 is disabled (S1CON.6/ENS1 = 0) these pins are in a high-impedance state.

**Figure 25. Idle and Power Down Hardware**

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

When the PLL oscillator is selected a hardware reset of  $\geq 1 \mu\text{s}$  is required and the microcontroller restarts within 63 msec after the reset has finished.

The third way of terminating the Idle mode is by internal watchdog reset. The microcontroller restarts after 3 machine cycles in all cases.

### 1.10.3 Power-down mode

The instruction that sets PCON.1 is the last executed prior to going into the Power-down mode. Once in Power-down mode, the HF oscillator is stopped. The 32 KHz oscillator may stay running. The content of the on-chip RAM and the Special Function Registers are not saved. Note that the Power-down mode can not be entered when the watchdog has been enabled.

The Power-down mode can be terminated by an external RESET in the same way as in the 80C51 (RAM is saved, SFRs are cleared due to RESET) or in addition by any one of the external interrupts, INT0, INT1 or Seconds interrupt. (see description Wake-up from Power-down mode)

The status of the external pins during Power-down mode is shown in Table 10. If the Power-down mode is activated while in external program memory, the port data that is held in the Special Function Register P2 is restored to Port 2. If the data is a logic1, the port pin is held HIGH during the Power-down mode by the strong pull-up transistor P1 (see Figure 5)

**1.10.4 Wake-up from Power-down Mode**  
The Power-down mode of the 8xCE558 can also be terminated by any one of the three

enabled interrupts, INT0, INT1 or Seconds interrupt.

A termination with these interrupts do not affect the internal data memory and does not affect the Special Function Registers. This gives the possibility to exit Power-down without changing the port output levels. To terminate the Power-down mode with an external interrupt, INT0 or INT1 must be switched to be level-sensitive and must be enabled. The external interrupt input signal INT0 or INT1 must be kept LOW till the oscillator has restarted and stabilized (see Figure 26) in order to prevent any interrupt priority problems during wake-up. A Seconds interrupt will terminate the Power-down mode if enabled and INT1 is level sensitive. Wake-up time is 60 ms in this case. The priority of the desired wake-up interrupt should be higher than the priorities of all other enabled interrupt sources. The instruction following the one that put the device into the Power-down mode will be the first one which will be executed after the wake-up.

### 1.11 Oscillator circuits

The input signal SELXTAL1 selects for XTAL1, 2 oscillator (standard 80C51) or the PLL oscillator. The not selected oscillator is halted and its XTAL pin must be not connected.

#### 1.11.1 XTAL1, 2 Oscillator circuit (standard 80C51)

The oscillator circuit of the 8xCE558 is a single-stage inverting amplifier in a Pierce oscillator configuration. The circuitry between the XTAL1 and XTAL2 is basically an inverter biased to the transfer point. Either a crystal or

ceramic resonator can be used as the feedback element to complete the oscillator circuitry. Both are operated in parallel resonance. XTAL1 is the high gain amplifier input, and XTAL2 is the output (see Figure 27). To drive the 8xCE558 externally, XTAL1 is driven from an external source and XTAL2 left open-circuit (see Figure 28).

**1.11.2 XTAL3, 4 circuitry, PLL oscillator**  
See appendix 1, "Specification PLL oscillator for 80C51 derivatives."

### 1.12 Reset Circuitry

The reset input pin RSTIN is connected to a Schmitt trigger for noise reduction (see Figure 29). Is the HF-oscillator selected a reset is accomplished by holding the RSTIN pin HIGH for at least 2 machine cycles (24 system clock periods). Is the PLL-oscillator selected the RSTIN-pulse must have a width of  $1 \mu\text{s}$  at least, independent of the 32 kHz-oscillator is running or not (see PLL description). The CPU responds by executing an internal reset. The RSTOUT pin represents the signal resetting the CPU and can be used to reset peripheral devices.

The RSTOUT level also could be high due to a Watchdog timer overflow.

The length of the output pulse from T3 is 3 machine cycles. A pulse of such short duration is necessary in order to recover from a processor or system fault as fast as possible.

During reset, ALE and PSEN output a HIGH level. In order to perform a correct reset, this level must not be affected by external elements.

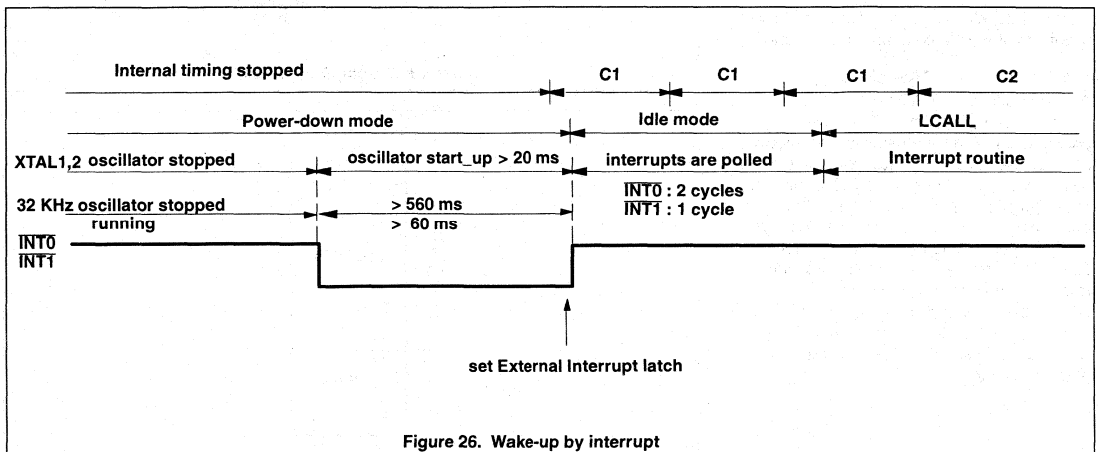

Figure 26. Wake-up by interrupt

| XRAMP     | xxxx    | xx00 |

The internal RAM is not affected by reset. At power-on, the RAM content is indeterminate.

### 1.13 Power-on Reset

An automatic reset can be obtained by switching on  $V_{DD}$ , if the RSTIN pin is connected to  $V_{DD}$  via a capacitor, as shown in Figure 30. Is the HF oscillator selected the  $V_{DD}$  rise time must not exceed 10 ms and the capacitor should be at least 2.2  $\mu\text{F}$ . The decrease of the RSTIN pin voltage depends on the capacitor and the internal resistor  $R_{RST}$ . That voltage must remain above the lower threshold for at minimum the HF-oscillator start-up time plus 2 machine cycles. Is the PLLC-oscillator selected a 0.1 nF capacitor is sufficient to obtain an automatic reset.

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

**2.0 INSTRUCTION SET**

The 8xCE558 uses the powerful instruction set of the PCB80C51. It consists of 49 single-byte, 45 two-byte and 17 three-byte instructions. Using a 16 MHz quartz, 64 of the instructions are executed in 0.75  $\mu$ s, 45 in 1.5  $\mu$ s and the multiply, divide instructions in 3  $\mu$ s.

A summary of the instruction set is given in Table 11.

The 8xCE558 has additional Special Function Registers to control the on-chip peripherals.

**2.1 Addressing Modes**

Most instructions have a "destination, source" field that specifies the data type, addressing modes and operands involved. For all these instructions, except for MOVs, the

destination operand is also the source operand (e.g. ADD A,R7).

There are five kinds of addressing modes:

- Register Addressing
  - R0 - R7 (4 banks)
  - A,B,C (bit), AB (2 bytes), DPTR (double byte)
- Direct Addressing
  - lower 128 bytes of internal Main RAM (including the 4 R0-R7 register banks)
  - Special Function Registers 1
  - 28 bits in a subset of the internal Main RAM
  - 128 bits in a subset of the Special Function Registers

- Register-Indirect Addressing
  - internal Main RAM (@R0, @R1, @SP [PUSH/POP])
  - internal Auxiliary RAM (@R0, @R1, @DPTR)
  - external Data Memory (@R0, @R1, @DPTR)
- Immediate Addressing
  - Program Memory (in-code 8 bit or 16 bit constant)
- Base-Register-plus Index-Register-Indirect Addressing
  - Program Memory look-up table (@DPTR+A, @PC+A)

The first three addressing modes are usable for destination operands.

| RLC                                                             | X    |    |    | CJNE        |      | X  |    |
| SETB C                                                          |      | 1  |    |             |      |    |    |

<sup>(1)</sup>Note that operations on SFR byte address 208 or bit addresses 209-215 (i.e., the PSW or bits in the PSW) will also affect flag settings.

**Notes on instruction set and addressing modes:**

Rn      Register R7-R0 of the currently selected Register Bank.

direct    8-bit internal data location's address. This could be an Internal Data RAM location (0-127) or a SFR [i.e., I/O port, control register, status register, etc. (128-255)].

@Ri      8-bit internal data RAM location addressed indirectly through register R1 or R0 of the actual register bank..

#data     8-bit constant included in the instruction.

#data 16   16-bit constant included in the instruction

addr 16   16-bit destination address. Used by LCALL and LJMP. A branch can be anywhere within the 64k-byte Program Memory address space.

addr 11   11-bit destination address. Used by ACALL and AJMP. The branch will be within the same 2k-byte page of program memory as the first byte of the following instruction.

rel       Signed (two's complement) 8-bit offset byte. Used by SJMP and all conditional jumps. Range is -128 to +127 bytes relative to first byte of the following instruction.

bit       Direct Addressed bit in Internal Data RAM or Special Function Register.

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

### 3.0 FLASH EEPROM

#### 3.1 General

- 32 kbyte electrically erasable internal program memory with Block-and-Page-Erase option ("Flash Memory").
- Internal fixed boot ROM.
- Up to 32 kbyte external program memory in combination with the internal FEEPROM ( $\overline{EA}=1$ ).
- Up to 64 kbyte external program memory if the internal program memory is switched off ( $\overline{EA}=0$ ).

The FEEPROM can be read and written byte-wise. Full Erase, Block Erase, and Page erase will erase 32 kbyte, 256 bytes and 32 bytes respectively. In-circuit programming and out-of-circuit programming is possible. On-chip erase and write timing generation and on chip high voltage generation contribute to a user friendly interface.

#### 3.2 Features

- Read: byte-wise
- Write: byte-wise within 2.5 ms. (previously erased by a page, block or full erase).
- Erase: Page Erase (32 bytes) within 5 ms. Block Erase (256 bytes) within 5 ms. Full Erase (32 kbyte) within 5 ms. Erased bytes contain FFH.
- Endurance: 100 erase and write cycles each byte at  $T_{amb} = 22^{\circ}\text{C}$
- Retention: 10 years
- Out-of-circuit programming: Parallel programming with 87C51 compatible hardware Interface to programmer.
- In-circuit programming: Serial programming via RS232 interface under boot ROM program control. Auto baud rate selection. Intel Hex Object file Format.
- The user program can call routines in the boot ROM for erase, write and verify of the FEEPROM.
- High programming voltage generation: on chip
- Zero point on-chip oscillator and timer to generate the write and erase time durations.
- Programmable security for the code in the FEEPROM to prevent software piracy. The Security Byte is located in the highest address (7FFFH) of the FEEPROM.

- Supply voltage monitoring circuit on-chip to prevent loss of information in the FEEPROM during power-on and power-off.

#### 3.3 Memory map

Figure 31 shows the memory map of the user program memory and the boot ROM. They are located in the same program address space. Two bits UBS1 and UBS0 of the FEEPROM control special function register FMCON select between the two memory blocks.

##### User program memory selection

If UBS1 and UBS0 are both 0, then the user program memory is mapped into the 64k program memory space and the boot ROM cannot be selected. This is the situation after a reset when  $\overline{PSEN}$  and ALE have not been pulled down during reset. Program execution starts at 0000H in the internal FEEPROM or in the external program memory dependent on the level of  $\overline{EA}$  during reset.

##### Boot ROM selection

If UBS1 and UBS0 are both '1' then the boot ROM is mapped into the 64k program memory space and the user program memory cannot be selected. This is the situation after a reset when during reset  $\overline{PSEN}$  and  $\overline{EA}$  are pulled down while ALE stay high. Program execution starts at 0000H of the boot ROM. The boot ROM size is 1 kbyte and its address map is repeated after each 1k addresses. Besides serial the in-circuit programming routines the Boot ROM contains the routines for erase write and verify of the FEEPROM which can be called by the user program (LJMP/LCALL to the address space between 63k and 64k).

##### Switching between user program memory and boot ROM

Switching between user program memory (internal or external) and boot ROM is possible if UBS1 and UBS0 are 0, 1 or 1, 0. Then in the program memory address space between 0 and 63k the user program memory is selected and in the memory space between 63k and 64k the boot ROM is selected.

To switch from user program memory to boot ROM first UBS0 must be set (UBS1 stay 0) and a jump or call instruction to a location >63k must be executed. At the moment of crossing the 63k address border by a call or jump instruction the switching between user and boot memory is performed without timing problems.

To switch from boot ROM to user program memory the boot program will be running between 63k and 64k. UBS1 is set and UBS0 is cleared and a jump or return instruction to

a location <63k must be executed. At the moment of crossing the 63k address border by a jump or return instruction the switching from boot ROM to user memory (internal or external) is performed. After crossing the 63k address border UBS1 is immediately cleared by hardware and the total 64k memory space is mapped as user program memory. By clearing UBS1 by hardware, no special requirements to the user program are necessary to do that after a boot routine or erase or write routine.

A small restriction for memory switching is that no memory switching is allowed from or to the address space between 63k and 64k of the user program memory because the UBS bits must stay 0 in this range and no 63k address crossing would take place. This restriction can be avoided if the memory switching is always done by a subroutine in the address range between 0 and 63k.

##### Description

The user program code in the FEEPROM is executed as in the standard 80C51 microcontroller. Erase and write cycles in the FEEPROM are always performed under control of the boot program in the boot ROM in the address space between 63k and 64k. Address and data parameters are passed via DPTR and accumulator A respectively. During an erase or write cycle in the FEEPROM no other access or program execution in the FEEPROM is possible. All interrupts must be disabled when the user program calls a user routine in the boot ROM.

The boot routine for serial programming takes care of addressing, data transfer, blank-check, verify, high voltage control, error message, interrupt disabling/enabling and return to the user program memory. It also contains the serial communication routine.

The FEEPROM control register FMCON is a special function register. It contains the control bits for verify, write, erase and boot ROM switching.

##### FMCON (FBH)

|      |      |    |    |      |      |      |      |
|------|------|----|----|------|------|------|------|
| 7    | 6    | 5  | 4  | 3    | 2    | 1    | 0    |
| UBS1 | UBS0 | HV | _1 | FCB3 | FCB2 | FCB1 | FCB0 |

Note 1): Reserved for future use; a write operation must write "0" to the location

|           |                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>HV</b> | <b>High voltage indication bit.</b> Read only. Is 1 as long as the high voltage for an erase or write operation is present. |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|

| FCB3 | FCB2 | FCB1 | FCB0 | Function Code Bits                 |
|------|------|------|------|------------------------------------|
| 0    | 0    | 0    | 0    | Value after reset.                 |
| 0    | 1    | 0    | 1    | Byte Write or byte read (verify)   |
| 1    | 1    | 0    | 0    | Page Erase (32 byte boundaries).   |
| 0    | 0    | 1    | 1    | Block Erase (256 byte boundaries). |
| 1    | 0    | 1    | 0    | Full Erase (32k byte).             |

The four FCB bits are by write protected if the security feature is activated. Then only instructions in the internal program memory (FEEPROM) are able to write FCB3-0, boot ROM and external program memory instructions cannot change FCB3-0 except the full erase code can be loaded.

The duration of a write or erase operation is determined by the FEEPROM timer. This timer includes a zero point RC oscillator and cannot be controlled by software.

For calling a user routine in the Boot ROM first all interrupts must be disabled and the DPTR and A have to be loaded with the desired values. After setting UBS0 = 1 and UBS1 = 0 and selecting the function via FCB-bits the respective user routine will be called.

The table below lists the boot ROM user routines, which can be called by the user program. The content of FMCON, A and DPTR before calling is by (IN) and by (OUT)

after described return. The boot ROM user routines do not change other registers or Data memory.

- X = don't care or not defined  
V = verified byte (read back)
- 1) = 5 LSB's of DPTR are don't care
  - 2) = 5 LSB's of DPTR are "0"
  - 3) = 8 LSB's of DPTR are don't care
  - 4) = 8 LSB's of DPTR contain 08H.

Example of user software (internal or external) that calls the Page Erase routine in the boot-ROM to erase a page in the FEEPROM (32 bytes) starting at address location 1260H.

```
CLR EA ; Disable all interrupts
MOV DPTR, # 1260H ; Load page-address
MOV FMCON, # 4CH ; Load Page-Erase code
LCALL 0FFAAH ; Call Page-Erase routine
 ; in boot-ROM (5 ms)
SETB EA ; Enable interrupts again
```

Example of user software (internal or external) that calls the Byte-Write routine in the boot-ROM to write the content of R5 into the FEEPROM address location 1263H.

```
CLK EA ; Disable all interrupts
MOV DPTR, # 1263H ; Load byte address
MOV A, R5 ; Load byte to be written
MOV FMCON, # 45H ; Load byte-write code
LCALL 0FFADH ; Call byte-write routine
 ; in boot-ROM (2.5 ms)
SETB EA ; Enable interrupts again
XRL A, R5 ; Compare the "read-back" byte
JNZ ; Jump if verify error
```

| BOOT-ROM ROUTINE | CALL ADDRESS | FMCON (IN) | FMCON (OUT) | A (IN) | A (OUT)  | DPTR (IN)                   | DPTR (OUT)                  |

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

### 3.4 Security

The security feature protects against software piracy and prevents that the content of the FEEPROM can be read undesirable. The Security Byte is located in the highest address location 7FFFH of the FEEPROM and is the same as all other bytes of the FEEPROM.

The Security Byte should be 01010000B to activate and 00H or FFH to activate the security feature. This security code is chosen in such a way that single bit failures will not change the security mode.

If the security feature is deactivated, then there are no access restrictions to the FEEPROM.

If the security feature is activated, then the external program memory has no access to the FEEPROM with the MOV<sub>C</sub> instructions. Also bits FCB3-0 of FMCON cannot be written by external program code or boot ROM code. This prevents in-circuit programming and verification. Only the Full Erase code can be written to FCB0-3 of FMCON. At the end of a full erase operation the security feature is deactivated. Also parallel programming and verify is inhibited if the security feature is activated, only a full

erase is possible. Note that the security mode does not change immediately when the security code is written into the security byte 7FFFH, but after a reset or power-on. This allows the verification of the loaded code in the FEEPROM, including the Security Byte.

### 3.5 Parallel programming

Unlike standard EPROM programming, no high programming supply voltage must be applied to the EA pin and only one programming pulse must be applied to the ALE/WE pin. The parallel programming mode is entered with the steady signals RST=1, PSEN=0, EA=1 and SELTAL1 = 1. The XTAL1, 2 clock must have a frequency between 4 and 6MHz. The following table shows the logic levels for programming, erasing, verifying and read signature.

| MODE            | ALE/WE | P2.7 | P2.6 | P3.7 | P3.6 |
|-----------------|--------|------|------|------|------|
| Full erase      |        | 1    | 1    | 0    | 1    |
| Program FEEPROM |        | 1    | 0    | 1    | 1    |
| Verify FEEPROM  | 1      | 0    | 0    | 1    | 1    |
| Read signature  | 1      | 0    | 0    | 0    | 0    |

ALE/WE Write Enable signal (program/erase), active low  
 P2.6, P2.7, P3.6, P3.7 output enable signal for verify/read modes, active low

#### Data and address bits:

P0.0-P0.7: D0 - D7 Program data input / verify or read data output  
 P1.0-P1.7 : A0 - A7 Input low order address bits.  
 P2.0-P2.5, P3.4 : A8 - A14 Input high order address bits.

The 89CE558 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. These bytes are read by the same procedure as for a normal verification of locations 30H and 31H, except that P3.6 and P3.7 need to be pulled to LOW.

| ADDRESS | CONTENT | MEANING |
|---------|---------|---------|
| 30H     | 15H     | Philips |
| 31H     | B5H     | 89CE558 |

The 89CE558 has a Security Byte in location 7FFFH (the highest address) of the FEEPROM, which should be programmed to 01010000B to activate the security feature.

Single-chip 8-bit microcontroller

80CE558/83CE558/89CE558

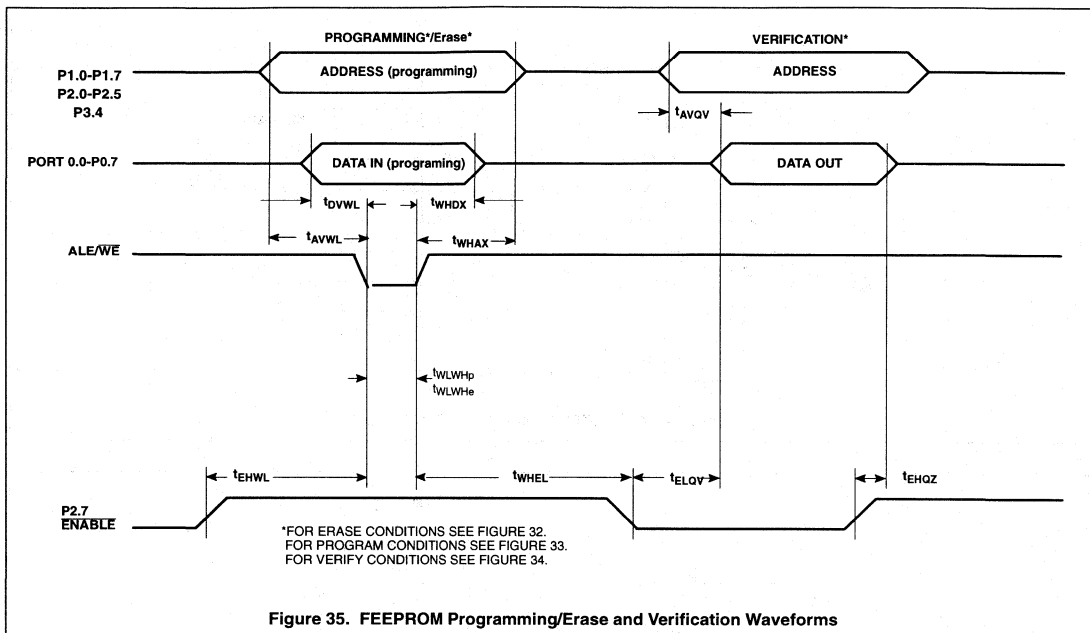

Figure 35. FEEPROM Programming/Erase and Verification Waveforms

3.6 Serial programming of FEEPROM

Serial in-circuit programming (boot-mode) is entered if during and after RESET PSEN and EA are pulled down, PSEN via a resistor of 2 kOhm to VSS. The two UBS bits are set to 1 by hardware and program execution starts at 0000H of the boot ROM. P3.0 (RXD) and P3.1 (TXD) form the serial RS232 interface. A baud rate of 4800 or 9600 Baud is possible after reset (μC clock is 11.01 MHz) if the PLL oscillator is selected. The receive and transmit channel have the same baud rate. The boot routine inputs the Intel Hex Object Format. The baud rate will be selected automatically after reception of the first character (:) of the object file. No other characters are allowed to precede the first (:) character. Programming is only started if the first received record has the right type indication (TT). If the security feature is activated then the programming starts with a Full Erase, otherwise only the addressed page(s) will be erased and the not altered bytes are rewritten. During the erase or write operation the next string of bytes can be received. Xon and Xoff handshake codes are used to control the serial transfer. At the end of the programming a message that indicates

a successful or not successful programming, will be returned over the RS232 interface channel. If the programming was successful then the user program can be started up at 0000H in FEEPROM by a reset for user mode (EA = high, PSEN not affected). If the programming was not successful the boot program halts and a retry can be started by a reset for the boot mode.

3.6 Boot Routine

The boot routine transmits the next "one ASCII character" messages via the RS232 interface:

- " . " After each record type TT = 00H indication in the HEX file.
- " X " Checksum error of a record in the HEX file detected.
- " Y " Wrong record type received
- " Z " Buffer overflow error (Check Xon/Xoff of terminal)
- " R " Verification error (of last written byte)
- " V " End record received and programming of FEEPROM was successful

No messages are transmitted if the baud rate of the first character (:) can not be detected.

The boot routine can also be started by the internal or external user program (LJMP FC07H). FMCON must be loaded previously with 40H. Interrupt registers, stack pointer, Timer 0, UART, P3.0 and P3.1 must be in the reset state. EA and PSEN must not be affected. A reset is needed to restart the user program after programming.

The next baudrates will be detected automatically within the specified μC clock range in MHz.

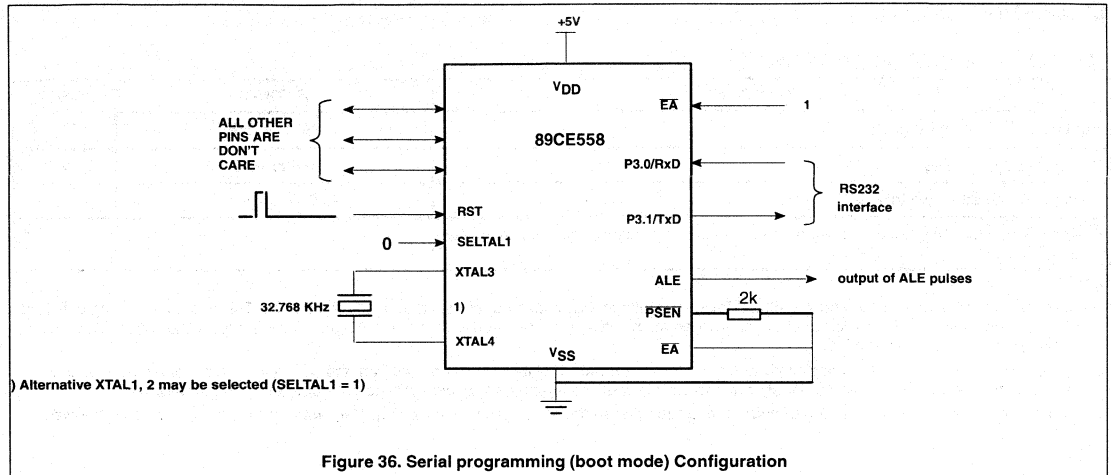

| Baudrate | f <sub>CLK</sub> (min) | f <sub>CLK</sub> (max) |
|----------|------------------------|------------------------|
| 1200     | 1 1)                   | 3.6                    |
| 2400     | 2 1)                   | 7.3                    |
| 4800     | 4                      | 19.7 1)                |
| 9600     | 7.9                    | 29.5 1)                |
| 19200    | 15.7                   | 59 1)                  |

Note 1): value outside the specified clock range

Note that the boot routines can (re) program any number of bytes from 1 byte to 32k bytes, independent in which order or at which location.

# Single-chip 8-bit microcontroller

# 80CE558/83CE558/89CE558

**NOTE:** In the following, each letter corresponds to one hexadecimal digit in ASCII representation (the digits 0 through 9, and the letters A through F).

Definitions:

- :** - Record start character
- BC** - Byte Count. The hexadecimal number of data bytes in the record. This may theoretically be any number from 0 to 255 prefer to deal with 16 data bytes per record (as shown in the example below).
- AAAA** - Load address in hexadecimal of first data byte in this record.
- TT** - Record type. The record type is 00 for data records and 01 for the end record.
- HH** - One hexadecimal data byte.
- CC** - Record checksum. This is the 2's complement of the summation of all of the bytes in the record from the byte count through the last data byte. While the summation is calculated, it is always truncated to a one byte result. Thus, if all of the bytes in the record are summed, including the checksum itself, the result will always be 00 if the record is valid.

Construction of data records (using the notation defined above) is as follows:

```
:: BCAAATTHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHCC
```

```
:: BCAAATTHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHCC
```

The last record in a file is the end record and contains no data. Usually the end record will appear as shown in the first example below. However, in some cases a 16 bit checksum of all of the data bytes in the entire file may be inserted in the address field of the end record. This checksum would correspond to one generated by an EPROM programmer during file load, and its inclusion does not violate the rules for this format. This is shown in the second example.

```
:00000001FF
```

```
:00B12C0122
```

Successive hex records need not appear in sequential address order. For instance, a record for address 0000 might appear after a record for address 7FE0. All of the bytes in a single record, however, must be in sequence. Any characters that appear outside of a record (i.e. after a checksum, but before the next ":") should be ignored, if present.

An example of a valid hex file follows:

```
:10010000C2F0E53030E704F4042DF08531F030F786
```

```
:100110000763F0FF05F0B2F0A430F00A63F0FFF4DB
```

```
:0C0120002401500205F085F032F5332276
```

```
:00000001FF
```

| Voltage on $V_{DD}$ to $V_{SS}$                                                              | -0.5 to +6.5           | V    |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to $V_{dd} + 0.5$ | V    |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.0                    | W    |

**NOTES:**

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions are taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## Single-chip 8-bit microcontroller

## 80CE558/83CE558/89CE558

**NOTES FOR DC ELECTRICAL CHARACTERISTICS:**

1. See Figures 37 and 39 through 41 for  $I_{DD}$  test conditions.
2. The operating supply current is measured with all output pins disconnected;  
XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  
 $\overline{EA} = \overline{RST} = \text{Port 0} = \overline{EW} = \text{SCL} = \text{SDA} = V_{DD}$ ;  $\text{ADEXS} = V_{SS}$ .
3. The idle mode supply current is measured with all output pins disconnected;  
XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  
 $\text{Port 0} = \overline{EW} = \text{SCL} = \text{SDA} = \text{SELXTAL 1} = V_{DD}$ ;  $\overline{EA} = \overline{RST} = \text{ADEXS} = V_{SS}$ .
4. The power-down current is measured with all output pins disconnected;  
XTAL2 not connected;  $\text{Port 0} = \overline{EW} = \text{SCL} = \text{SDA} = \text{SELXTAL 1} = V_{DD}$ ;  $\overline{EA} = \overline{RST} = \text{ADEXS} = \text{XTAL1} = V_{SS}$ .
5. The input threshold voltage of SCL and SDA (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below  $0.3 V_{DD}$  will be recognized as a logic 0 while an input voltage above  $0.7 V_{DD}$  will be recognized as a logic 1.
6. Pins of ports 1, 2, 3, and 4 source a transition current when they are being externally driven from HIGH to LOW. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
7. Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$  of ALE and ports 1, 3 and 4. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
8. Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $\overline{PSEN}$  to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
9. Conditions:  $\text{AV}_{REF-} = 0\text{V}$ ;  $\text{AV}_{DD} = 5.0\text{V}$ ,  $\text{AV}_{REF+} = 5.12\text{V}$ ,  $V_{DD} = 5.0\text{V}$ ,  $V_{SS} = 0\text{V}$ , ADC is monotonic with no missing codes. Measurement by continuous conversion of  $\text{AV}_{IN} = -20\text{mV}$  to  $5.12\text{V}$  in steps of  $0.5\text{mV}$ , deriving parameters from collected conversion results of ADC. ADC prescaler programmed according to the actual oscillator frequency, resulting in a conversion time within the specified range for  $t_{conv}$  ( $15\mu\text{s}$  ...  $50\mu\text{s}$ ).
10. The differential non-linearity ( $DL_e$ ) is the difference between the actual step width and the ideal step width.
11. The ADC is monotonic; there are no missing codes.
12. The integral non-linearity ( $IL_e$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error.
13. The offset error ( $OS_e$ ) is the absolute difference between the straight line which fits the actual transfer curve (after removing gain error), and a straight line which fits the ideal transfer curve. The offset error is constant at every point of the actual transfer curve.
14. The gain error ( $G_e$ ) is the relative difference in percent between the straight line fitting the actual transfer curve (after removing offset error), and the straight line which fits the ideal transfer curve. Gain error is constant at every point on the transfer curve.
15. The absolute voltage error ( $A_e$ ) is the maximum difference between the center of the steps of the actual transfer curve of the non-calibrated ADC and the ideal transfer curve.
16. This should be considered when both analog and digital signals are simultaneously input to port 5.
17. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 10 mA  
Maximum  $I_{OL}$  8-bit port -  
    Port 0 : 26 mA  
    Ports 1, 2, 3 and 4 : 15 mA  
Maximum total  $I_{OL}$  for all output pins : 86 mA  
  
If  $I_{OL}$  exceeds the test conditions,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
18.  $\text{Al}_D$  is measured with  $\text{SELXTAL1} = V_{DD}$ .
19.  $\text{Al}_D$  and  $\text{Al}_P$  are measured with the 32 kHz oscillator being halted, XTAL3 not connected and  $\text{XTAL4} = V_{SS}$ .

All values referred to V<sub>IH</sub> and V<sub>IL max</sub> levels.

NOTES:

1. A device must internally provide a hold time of at least 300 ns from the SDA signal (referred to the V<sub>IH min</sub> of the SCL signal) in order to bridge the undefined region of the falling edge of SCL.

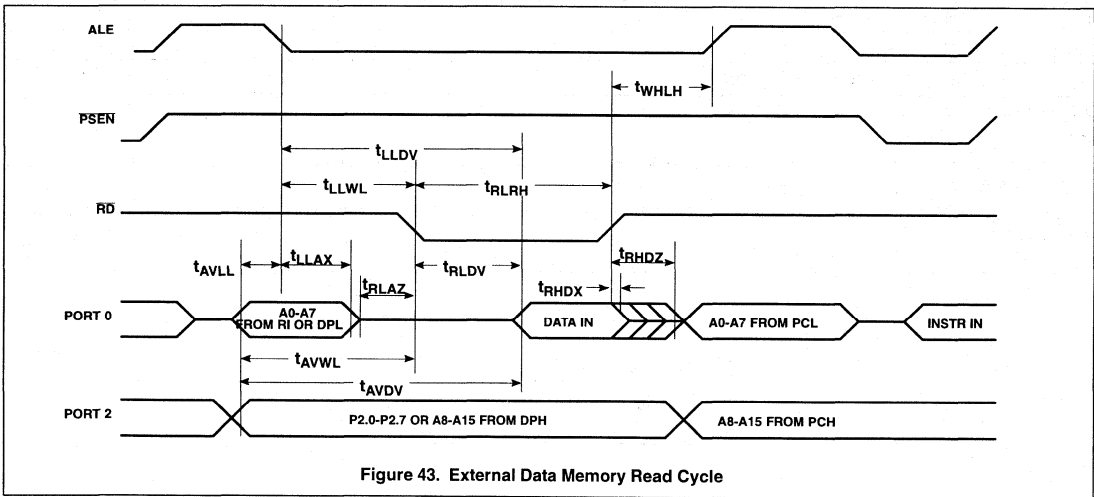

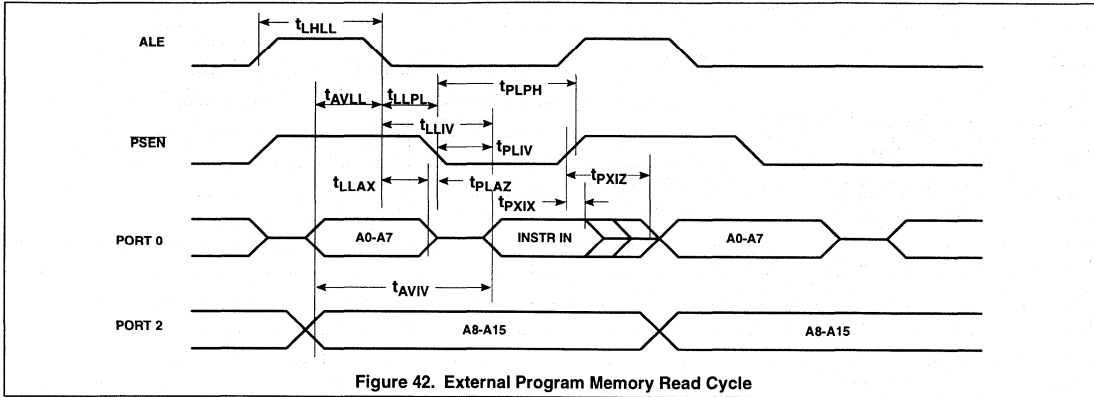

For 62ns < t<sub>CLCL</sub> < 570ns, 16MHz > f<sub>CLK</sub> > 3.5MHz) the SI01 interface meets concerning AC parameters the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# Single-chip 8-bit microcontroller

# 80C562/83C562

*Single-chip 8-bit microcontroller with 8-bit A/D, capture/compare timer, high-speed outputs, PWM*

## DESCRIPTION

The 80C562/83C562 (hereafter generically referred to as 8XC562) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 83C562/83C562 has the same instruction set as the 80C51.

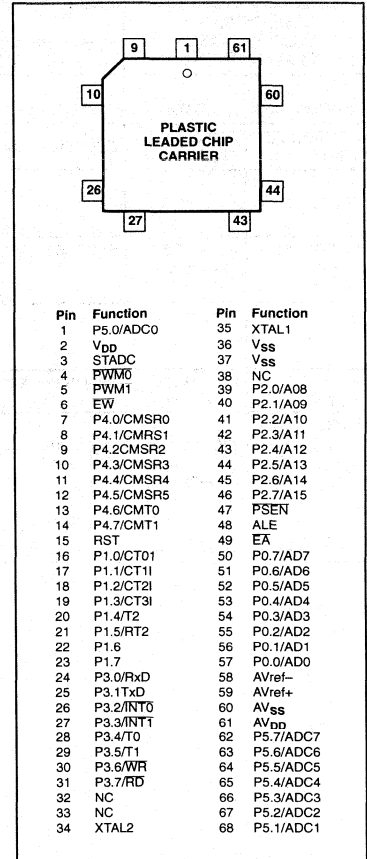

The 8XC562 contains a non-volatile 256 × 8 read-only program memory, a volatile 256 × 8 read/write data memory (83C562) (the 80C562 is ROMless), a volatile 256 × 8 read/write data memory, six 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a 15-source, two-priority-level, nested interrupt structure, an 8-input ADC, two pulse width modulated outputs, standard 80C51 UART, a "watchdog" timer and on-chip oscillator and timing circuits. For systems that require extra capability, the 83C562 can be expanded using standard TTL compatible memories and logic.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 12MHz crystal, 58% of the instructions are executed in 1µs and 40% in 2µs. Multiply and divide instructions require 4µs.

## FEATURES

- 80C51 instruction set
- 8k × 8 ROM expandable externally to 64k bytes
- 256 × 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- An additional 16-bit timer/counter coupled to four capture registers and three compare registers
- Capable of producing eight synchronized, timed outputs
- An 8-bit ADC with eight multiplexed analog inputs
- Two 8-bit resolution, pulse width modulated outputs
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- Three temperature ranges
  - 0 to +70°C
  - -40 to +85°C
  - -40 to +125°C

### NOTES:

- 80C562 and 83C562 frequency range is 1.2MHz–12MHz or 1.2MHz–16MHz.
- 87C552 frequency range is 3.5MHz–16MHz. For full specification, see the 87C552 data sheets.
- xxx denotes the ROM code number.

## NOTE:

- To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub> +0.5V or V<sub>SS</sub> – 0.5V, respectively.

# Single-chip 8-bit microcontroller

# 80C562/83C562

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To ensure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{DD}$  and RST must come up at the same time for a proper start-up.

## IDLE MODE

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers

remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 1 shows the state of the I/O ports during low current operating modes.

**Table 1. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 | PORT 4 | PWM0/PWM1 |
|------------|----------------|-----|------|--------|--------|---------|--------|--------|-----------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   | Data   | High      |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   | Data   | High      |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   | Data   | High      |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   | Data   | High      |

| PARAMETER                                                                                    | RATING       | UNIT |
|----------------------------------------------------------------------------------------------|--------------|------|
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5 | V    |
| Input, output DC current on any single I/O pin                                               | 5.0          | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.0          | W    |
| Storage temperature range                                                                    | -65 to +150  | °C   |

### NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## NOTES:

- See Figures 8 through 12 for  $I_{DD}$  test conditions.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ; XTAL2 not connected;  $\overline{EA} = RST = Port 0 = \overline{EW} = V_{DD}$ ;  $STADC = V_{SS}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ; XTAL2 not connected; Port 0 =  $\overline{EW} = V_{DD}$ ;  $\overline{EA} = RST = STADC = V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL2 not connected; Port 0 =  $\overline{EW} = V_{DD}$ ;  $\overline{EA} = RST = STADC = XTAL1 = V_{SS}$ .
- Pins of ports 1, 2, 3, and 4 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OLs}$  of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $PSEN$  to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- Conditions:  $AV_{REF-} = 0V$ ;  $AV_{DD} = 5.0V$ ;  $AV_{REF+} = 5.12V$ . ADC is monotonic with no missing codes.
- The differential non-linearity ( $DL_e$ ) is the difference between the actual step width and the ideal step width. (See Figure 1.)
- The ADC is monotonic; there are no missing codes.
- The integral non-linearity ( $IL_e$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error. (See Figure 1.)
- The offset error ( $OS_e$ ) is the absolute difference between the straight line which fits the actual transfer curve (after removing gain error), and a straight line which fits the ideal transfer curve. (See Figure 1.)
- The gain error ( $G_e$ ) is the relative difference in percent between the straight line fitting the actual transfer curve (after removing offset error), and the straight line which fits the ideal transfer curve. Gain error is constant at every point on the transfer curve. (See Figure 1.)
- This should be considered when both analog and digital signals are simultaneously input to port 5.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

# 80C562/83C562

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

## 80C575/83C575/87C575

## DESCRIPTION

The Philips 80C575/83C575/87C575 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. The Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. Philips epitaxial substrate minimizes latch-up sensitivity.

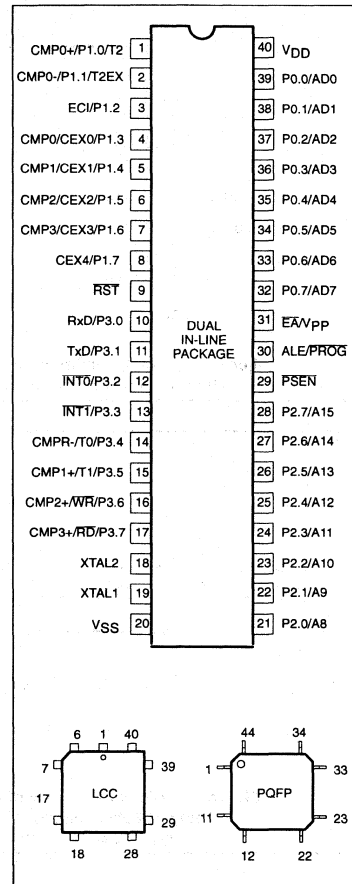

The 8XC575 contains an 8k × 8 ROM (83C575) EPROM (87C575), a 256 × 8 RAM, 32 I/O lines, three 16-bit counter/timers, a Programmable Counter Array (PCA), a seven-source, two-priority level nested interrupt structure, an enhanced UART, four analog comparators, power-fail detect and oscillator fail detect circuits, and on-chip oscillator and clock circuits.

In addition, the 8XC575 has a low active reset, and the port pins are reset to a low level. There is also a fully configurable watchdog timer, and internal power on clear circuit. The part includes idle mode and power-down mode states for reduced power consumption.

## FEATURES

- 80C51 based architecture
  - 8k × 8 ROM (83C575)
  - 8k × 8 EPROM (87C575)
  - ROMless (80C575)
  - 256 × 8 RAM
  - Three 16-bit counter/timers
  - Programmable Counter Array
  - Enhanced UART
  - Boolean processor
  - Oscillator fail detect
  - Low active reset
  - Asynchronous low port reset
  - Schmitt trigger inputs
  - 4 analog comparators
  - Watchdog timer
  - Low V<sub>CC</sub> detect
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- 4.0 to 16MHz
- Extended temperature ranges
- OTP package available

## PIN CONFIGURATIONS

## ORDERING INFORMATION

| P0.0-0.7        | 39-32      | 43-36        | 37-30        | I/O  | <b>Port 0:</b> Port 0 is an open-drain bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also receives code bytes during EPROM programming and outputs code bytes during program verification. External pull-ups are required during program verification. During reset, port 0 will be asynchronously driven low and will remain low until written to by software. All port 0 pins have Schmitt trigger inputs with 200mV hysteresis. A weak pulldown on port 0 guarantees positive leakage current (see DC Electrical Characteristics: I <sub>L1</sub> ).                                                               |
| P1.0-P1.7       | 1-8        | 2-9          | 40-44<br>1-3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port. Port 1 pins have internal pull-ups such that pins that have 1s written to them can be used as inputs but will source current when externally pulled low (see DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 receives the low-order address byte during program memory verification and EPROM programming. During reset, port 1 will be asynchronously driven low and will remain low until written to by software. All port 1 pins have Schmitt trigger inputs with 50mV hysteresis. Port 1 pins also serve alternate functions as follows:                                                                                                                                                                                                                                                                            |

| P2.0-P2.7       | 21-28      | 24-31        | 18-25        | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them can be used as inputs, but will source current when externally pulled low (see DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during accesses to external program and data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. Port 2 receives the high-order address byte during program verification and EPROM programming. During reset, port 2 will be asynchronously driven low and will remain low until written to by software. Port 2 can be made open drain by writing to the P2OD register (AIH). In open drain mode, weak pulldowns on port 2 guarantee positive leakage current (see DC Electrical Characteristics I <sub>L1</sub> ). |

| P3.0-P3.7       | 10-17      | 11,<br>13-19 | 5,<br>7-13   | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins except P3.1 that have 1s written to them can be used as inputs but will source current when externally pulled low (see DC Electrical Characteristics: I <sub>IL</sub> ). P3.1 will be a high impedance pin except while transmitting serial data, in which case the strong pull-up will remain on continuously when outputting a 1 level. The P3.1 output drive level when transmitting can be set to one of two levels by the writing to the P3.1 register bit. During reset all pins (except P3.1) will be asynchronously driven low and will remain low until written to by software. All port 3 pins have Schmitt trigger inputs with 200mV hysteresis, except P3.2 and P3.3, which have 50mV hysteresis. Port 3 pins serve alternate functions as follows:                               |

|                   | 17         | 19  | 13  | O    | <b>P3.7 RD</b> External data memory read strobe<br><b>CMP3+</b> Comparator 3 positive input                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RST               | 9          | 10  | 4   | I    | <b>Reset:</b> A low on this pin asynchronously resets all port pins to a low state except P3.1. The pin must be held low with the oscillator running for 24 oscillator cycles to initialize the internal registers. An internal diffused resistor to $V_{CC}$ permits a power on reset using only an external capacitor to $V_{SS}$ . RST has a Schmitt trigger input stage to provide additional noise immunity with a slow rising input voltage.                                                          |
| ALE/PROG          | 30         | 33  | 27  | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. ALE is switched off if the bit 0 in the AUXR register (8EH) is set. This pin is also the program pulse input (PROG) during EPROM programming. |
| PSEN              | 29         | 32  | 26  | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the device is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                        |
| EAV <sub>PP</sub> | 31         | 35  | 29  | I    | <b>External Access Enable/Programming Supply Voltage:</b> EAV must be externally held low to enable the device to fetch code from external program memory locations 0000H to 1FFFH. If EAV is held high, the device executes from internal program memory unless the program counter contains an address greater than 1FFFH. This pin also receives the 12.75V programming supply voltage ( $V_{PP}$ ) during EPROM programming.                                                                            |

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

1. Reset value depends on reset source.

# CMOS single-chip 8-bit microcontroller

# 80C575/83C575/87C575

## POWER ON CLEAR/ POWER ON FLAG

An on-chip Power On Detect Circuit resets the 8XC575 and sets the Power Off Flag (PCON.4) on power up or if  $V_{CC}$  drops to zero momentarily. The POF can only be cleared by software. The RST pin is not driven by the power on detect circuit. The POF can be read by software to determine that a power failure has occurred and can also be set by software.

## LOW VOLTAGE DETECT

An on-chip Low Voltage Detect circuit sets the Low Voltage Flag (PCON.3) if  $V_{CC}$  drops below  $V_{Low}$  (see DC Electrical Characteristics) and resets the 8XC575 if the Low Voltage Reset Enable bit (WDCON.4) is set. If the LVRE is cleared, the reset is disabled but LVF will still be set if  $V_{CC}$  is low. The RST pin is not driven by the low voltage detect circuit. The LVF can be read by software to determine that  $V_{CC}$  was low. The LVF can be set or cleared by software.

## OSCILLATOR FAIL DETECT

An on-chip Oscillator Fail Detect circuit sets the Oscillator Fail Flag (PCON.5) if the oscillator frequency drops below OSCF for one or more cycles (see AC Electrical Characteristics: OSCF) and resets the 8XC575 if the Oscillator Fail Reset Enable bit (WDCON.3) is set. If OFRE is cleared, the reset is disabled but OSF will still be set if the oscillator fails. The RST pin is not driven by the oscillator fail detect circuit. The OSF can be read by software to determine that an oscillator failure has occurred. The OSF can be set or cleared by software.

## LOW ACTIVE RESET

One of the most notable features on this part is the low active reset. At this time this is the only 80C51 derivative available that has low active reset. This feature makes it easier to interface the 8XC575 into an application to accommodate the power-on and low voltage conditions that can occur. The low active reset operates exactly the same as high active reset with the exception that the part is put into the reset mode by applying a low level to the reset pin. For power-on reset it is also necessary to invert the power-on reset circuit; connecting the 8.2K resistor from the reset pin to  $V_{CC}$  and the  $10\mu\text{f}$  capacitor from the reset pin to ground. Figure 1 shows all of the reset related circuitry.

When reset the port pins on the 87C575 are driven low asynchronously. This is different from all other 80C51 derivatives.

The 8XC575 also has Low voltage detection circuitry that will, if enabled, force the part to reset when  $V_{CC}$  (on the part) fails below a set level. Low Voltage Reset is enabled by a normal reset. Low Voltage Reset can be disabled by clearing LVRE (bit 4 in the WDCON SFR) then executing a watchdog feed sequence (A5H to WFEED1 followed immediately by 5A to WFEED2). In addition there is a flag (LVF) that is set if a low voltage condition is detected. The LVF flag is set even if the Low Voltage detection circuitry is disabled. Notice that the Low voltage detection circuitry does not drive the RST# pin so the LVF flag is the only way that the microcontroller can determine if it has been reset due to a low voltage condition.

The 8XC575 has an on-chip power-on detection circuit that sets the POF (PCON.4) flag on power up or if the  $V_{CC}$  level momentarily drops to 0V. This flag can be used to determine if the part is being started from a power-on (cold start) or if a reset has occurred due to another condition (warm start).

## TIMERS

The 87C575 has four on-chip timers.

Timers 0 and 1 are identical in every way to Timers 0 and 1 on the 80C51.

Timer 2 on the 8XC575 is identical to the 80C52 Timer 2 (described in detail in the 80C52 overview) with the exception that it is an up or down counter. To configure the Timer to count down the DCEN bit in the T2MOD special function register must be set and a low level must be present on the T2EX pin (P1.1).

The Watchdog timer operation and implementation is the same as that for the 8XC550 (described in the 8XC550 overview) with the exception that the reset values of the WDCON and WDL special function registers have been changed. The changes in these registers cause the watchdog timer to be enabled with a timeout of  $98304 \times T_{OSC}$  when the part is reset. The watchdog can be disabled by executing a valid feed sequence and then clearing WDRUN (bit 2 in the WDCON SFR).

## 80C575/83C575/87C575

**PROGRAMMABLE COUNTER ARRAY (PCA)**

The Programmable Counter Array is a special Timer that has five 16-bit capture/compare modules associated with it. Each of the modules can be programmed to operate in one of four modes: rising and/or falling edge capture, software timer, high-speed output, or pulse width modulator. Each module has a pin associated with it in port 1. Module 0 is connected to P1.3(CEX0), module 1 to P1.4(CEX1), etc.. The basic PCA configuration is shown in Figure 2.

The PCA timer is a common time base for all five modules and can be programmed to run at: 1/12 the oscillator frequency, 1/4 the oscillator frequency, the Timer 0 overflow, or the input on the ECI pin (P1.2). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD SFR as follows (see Figure 3):

| CPS1 | CPS0 | PCA Timer Count Source    |
|------|------|---------------------------|
| 0    | 0    | 1/12 oscillator frequency |
| 0    | 1    | 1/4 oscillator frequency  |
| 1    | 0    | Timer 0 overflow          |
| 1    | 1    | External Input at ECI pin |

In the CMOD SFR are three additional bits associated with the PCA. They are CIDL which allows the PCA to stop during idle mode, WDTE which enables or disables the watchdog function on module 4, and ECF which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows. These functions are shown in Figure 3.

The watchdog timer function is implemented in module 4 as implemented in other parts that have a PCA that are available on the market. However, if a watchdog timer is required in the target application, it is recommended to use the hardware watchdog timer that is implemented on the 87C575 separately from the PCA (see Figure 14).

The CCON SFR contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (refer to Figure 6). To run the PCA the CR bit (CCON.6) must be set by software. The PCA is shut off by clearing this bit. The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software. Bits 0 through 4 of the CCON register are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software. The PCA interrupt system shown in Figure 4.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (see Figure 7). The registers contain the bits that control the mode that each module will operate in. The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or 4 depending on the module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated module. PWM (CCAPMn.1) enables the pulse width modulation mode. The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register. The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.

The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition. The last bit in the register ECOM (CCAPMn.6) when set

enables the comparator function. Figure 8 shows the CCAPMn settings for the various PCA functions.

There are two additional registers associated with each of the PCA modules. They are CCAPnH and CCAPnL and these are the registers that store the 16-bit count when a capture occurs or a compare should occur. When a module is used in the PWM mode these registers are used to control the duty cycle of the output.

**PCA Capture Mode**

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated. Refer to Figure 9.

**16-bit Software Timer Mode**

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (see Figure 10).

**High Speed Output Mode**

In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (see Figure 11).

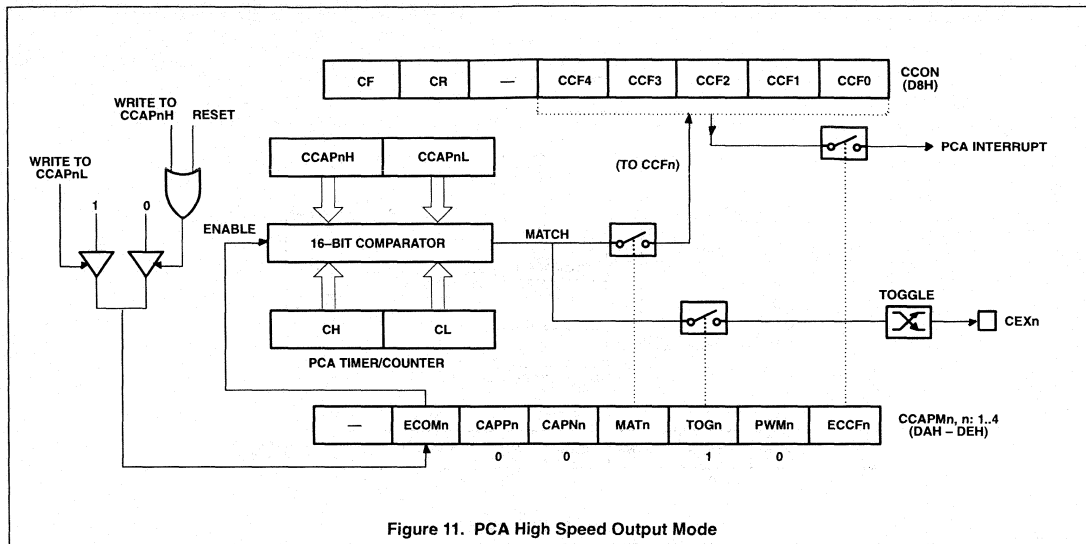

Figure 11. PCA High Speed Output Mode

**Pulse Width Modulator Mode**

All of the PCA modules can be used as PWM outputs. Figure 12 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. This allows updating the PWM without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

**WATCHDOG TIMER**

The watchdog timer is not directly loadable by the user. Instead, the value to be loaded into the main timer is held in an autoload register or is part of the mask ROM programming. In order to cause the main timer to be loaded with the appropriate value, a special sequence of software action must take place. This operation is referred to as feeding the watchdog timer.

To feed the watchdog, two instructions must be sequentially executed successfully. No

intervening instruction fetches are allowed, so interrupts should be disabled before feeding the watchdog. The instructions should move A5H to the WFEED1 register and then 5AH to the WFEED2 register. If WFEED1 is correctly loaded and WFEED2 is not correctly loaded, then an immediate underflow will occur.

The watchdog timer subsystem has two modes of operation. Its principal function is a watchdog timer. In this mode it protects the system from incorrect code execution by causing a system reset when the watchdog timer underflows as a result of a failure of software to feed the timer prior to the timer reaching its terminal count. If the user does not employ the watchdog function, the watchdog subsystem can be used as a timer. In this mode, reaching the terminal count sets a flag. In most other respects, the timer mode possesses the characteristics of the watchdog mode. This is done to protect the integrity of the watchdog function.

The watchdog timer subsystem consists of a prescaler and a main counter. The prescaler has 8 selectable taps off the final stages and the output of a selected tap provides the clock to the main counter. The main counter is the section that is loaded as a result of the software feeding the watchdog and it is the section that causes the system reset

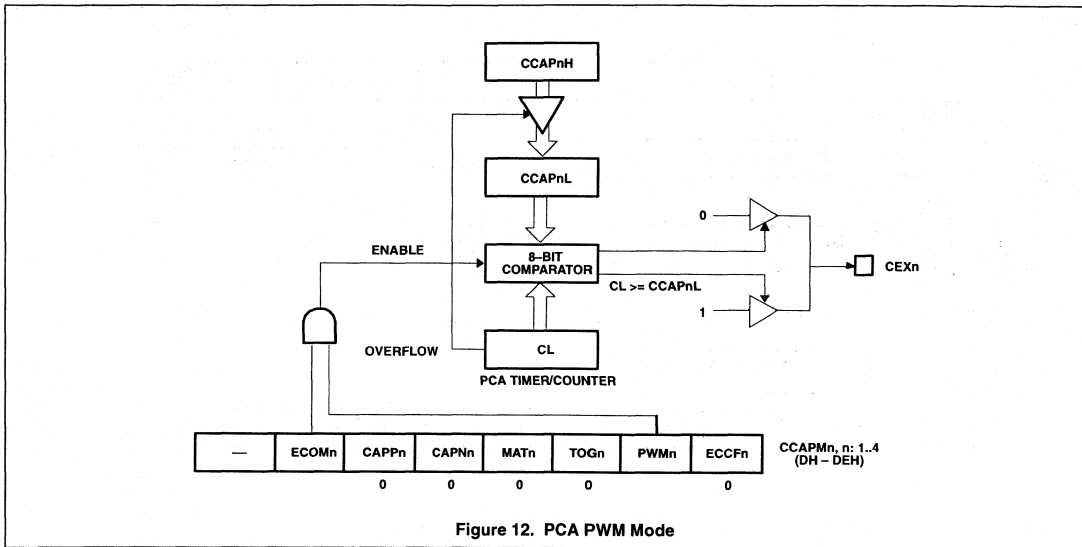

(watchdog mode) or time-out flag to be set (timer mode) if allowed to reach its terminal count.

**Programming the Watchdog Timer**

Both the EPROM and ROM devices have a set of SFRs for holding the watchdog autoload values and the control bits. The watchdog time-out flag is present in the watchdog control register and operates the same in all versions. In the EPROM device, the watchdog parameters (autoload value and control) are always taken from the SFRs. In the ROM device, the watchdog parameters can be mask programmed or taken from the SFRs. The selection to take the watchdog parameters from the SFRs or from the mask programmed values is controlled by EA (external access). When EA is high (internal ROM access), the watchdog parameters are taken from the mask programmed values. If the watchdog is mask programmed to the timer mode, then the autoload values and the pre-scaler taps are taken from the SFRs. When EA is low (external access), the watchdog parameters are taken from the SFRs. The user should be able to leave code in his program which initializes the watchdog SFRs even though he has migrated to the mask ROM part. This allows no code changes from EPROM prototyping to ROM coded production parts.

**Watchdog Detailed Operation**

**EPROM Device (and ROMless Operation: EA = 0)**

In the ROMless operation (ROM part, EA = 0) and in the EPROM device, the watchdog operates in the following manner (see Figure 14).

Whether the watchdog is in the watchdog or timer mode, when external RESET is applied, the following takes place:

- Watchdog mode bit set to watchdog mode.
- Watchdog run control bit set to ON.
- Autoload register set to 00 (min. count).
- Watchdog time-out flag cleared.
- Prescaler is cleared.
- Prescaler tap set to the highest divide.
- Autoload takes place.

The watchdog can be fed even though it is in the timer mode.

Note that the operational concept is for the watchdog mode of operation, when coming out of a hardware reset, the software should load the autoload registers, set the mode to watchdog, and then feed the watchdog (cause an autoload). The watchdog will now be starting at a known point.

If the watchdog is in the watchdog mode and running and happens to underflow at the time

the external RESET is applied, the watchdog time-out flag will be cleared.

When the watchdog is in the watchdog mode and the watchdog underflows, the following action takes place (see Figure 16):

- Autoload takes place.
- Watchdog time-out flag is set
- Mode bit unchanged.
- Watchdog run bit unchanged.
- Autoload register unchanged.
- Prescaler tap unchanged.
- All other device action same as external reset.

Note that if the watchdog underflows, the program counter will start from 00H as in the case of an external reset. The watchdog time-out flag can be examined to determine if the watchdog has caused the reset condition. The watchdog time-out flag bit can be cleared by software.

When the watchdog is in the timer mode and the timer software underflows, the following action takes place:

- Autoload takes place.
- Watchdog time-out flag is set
- Mode bit unchanged.
- Watchdog run bit unchanged.

- Autoload register unchanged.
- Prescaler tap unchanged.

**Mask ROM Device (EA = 1)**

In the mask ROM device, the watchdog mode bit (WDMOD) is mask programmed and the bit in the watchdog command register is read only and reflects the mask programmed selection. If the mask programmed mode bit selects the timer mode, then the watchdog run bit (WDRUN) operates as described under EPROM Device. If the mask programmed bit selects the watchdog mode, then the watchdog run bit has no effect on the timer operation (see Figure 15).

**Watchdog Function**

The watchdog consists of a programmable prescaler and the main timer. The prescaler derives its clock from the on-chip oscillator. The prescaler consists of a divide by 12 followed by a 13 stage counter with taps from stage 6 through stage 13. This is shown in Figure 17. The tap selection is programmable. The watchdog main counter is a down counter clocked (decremented) each time the programmable prescaler underflows. The watchdog generates an underflow signal (and is autoloaded) when the watchdog is at count 0 and the clock to decrement the watchdog occurs. The watchdog is 8 bits long and the autoload value can range from 0 to FFH. (The

## CMOS single-chip 8-bit microcontroller

## 80C575/83C575/87C575

autoload value of 0 is permissible since the prescaler is cleared upon autoload).

This leads to the following user design equations. Definitions:  $t_{OSC}$  is the oscillator period,  $N$  is the selected prescaler tap value,  $W$  is the main counter autoload value,  $t_{MIN}$  is the minimum watchdog time-out value (when the autoload value is 0),  $t_{MAX}$  is the maximum time-out value (when the autoload value is FFH),  $t_D$  is the design time-out value.

$$t_{MIN} = t_{OSC} \times 12 \times 64$$

$$t_{MAX} = t_{MIN} \times 128 \times 256$$

$$t_D = t_{MIN} \times 2^{PRESCALER} \times W + 1$$

(where prescaler = 0, 1, 2, 3, 4, 5, 6, or 7)

Note that the design procedure is anticipated to be as follows. A  $t_{MAX}$  will be chosen either from equipment or operation considerations and will most likely be the next convenient value higher than  $t_D$ . (If the watchdog were inadvertently to start from FFH, an overflow would be guaranteed, barring other anomalies, to occur within  $t_{MAX}$ ). Then the value for the prescaler would be chosen from:

$$\text{prescaler} = \log_2 (t_{MAX} / (t_{OSC} \times 12 \times 256)) - 6$$

This then also fixes  $t_{MIN}$ . An autoload value would then be chosen from:

$$W = t_D / t_{MIN} - 1$$

The software must be written so that a feed operation takes place every  $t_D$  seconds from the last feed operation. Some tradeoffs may need to be made. It is not advisable to include feed operations in minor loops or in subroutines unless the feed operation is a specific subroutine.

#### Watchdog Control Register (WDCON) (Bit Addressable) Address C0

The following bits of this register are read only in the ROM part when EA is high: WDMOD, PRE0, PRE1, and PRE2. That is, the register will reflect the mask programmed values. In the ROM part with EA high, these bits are taken from mask coded bits and are not readable by the program. WDRUN is read only in the ROM part when EA is high and

WDMOD is in the watchdog mode. When WDMOD is in the timer mode, WDRUN functions normally.

The parameters written into WDMOD, PRE0, PRE1, and PRE2 by the program are not applied directly to the watchdog timer subsystem. The watchdog timer subsystem is directly controlled by a second register which stores these bits. The transfer of these bits from the user register (WDMOD) to the second control register takes place when the watchdog is fed. This prevents random code execution from directly foiling the watchdog function. This does not affect the operation where these bits are taken from mask coded values.

The reset values of the WDCON and WDL registers will be such that the timer resets to the watchdog mode with a timeout period of  $12 \times 64 \times 128 \times t_{OSC}$ . The watchdog timer will not generate an interrupt. Additional bits in WDCON are used to disable reset generation by the oscillator fail and low voltage detect circuits. WDCON can be written by software only by executing a valid watchdog feed sequence.

#### WDCON Register Bit Definitions

|         |       |                                                    |
|---------|-------|----------------------------------------------------|
| WDCON.7 | PRE2  | Prescaler Select 2, reset to 1                     |
| WDCON.6 | PRE1  | Prescaler Select 1, reset to 1                     |
| WDCON.5 | PRE0  | Prescaler Select 0, reset to 1                     |
| WDCON.4 | LVRE  | Low Voltage Reset Enable, reset to 1 (enabled)     |
| WDCON.3 | OFRE  | Oscillator Fail Reset Enable, reset to 1 (enabled) |
| WDCON.2 | WDRUN | Watchdog Run, reset to 1 (enabled)                 |
| WDCON.1 | WDTOF | Watchdog Timeout Flag, reset to 0                  |
| WDCON.0 | WDMOD | Watchdog Mode, reset to 1 (watchdog mode)          |

#### Enhanced UART

The UART operates in all of the usual modes that are described in the first section of this book for the 80C51. In addition the UART can perform framing error detect by looking for missing stop bits, and automatic address recognition. The 87C575 UART also fully supports multiprocessor communication as does the standard 80C51 UART.

When used for framing error detect the UART looks for missing stop bits in the communication. A missing bit will set the FE bit in the SCON register. The FE bit shares the SCON.7 bit with SM0 and the function of SCON.7 is determined by PCON.6 (SMOD0) (see Figure 19). If SMOD0 is set then SCON.7 functions as FE. SCON.7 functions as SM0 when SMOD0 is cleared. When used as FE SCON.7 can only be cleared by software. Refer to Figure 18.

#### Automatic Address Recognition

Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes, mode 2 and mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the "Given" address or the "Broadcast" address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data. Automatic address recognition is shown in Figure 20.

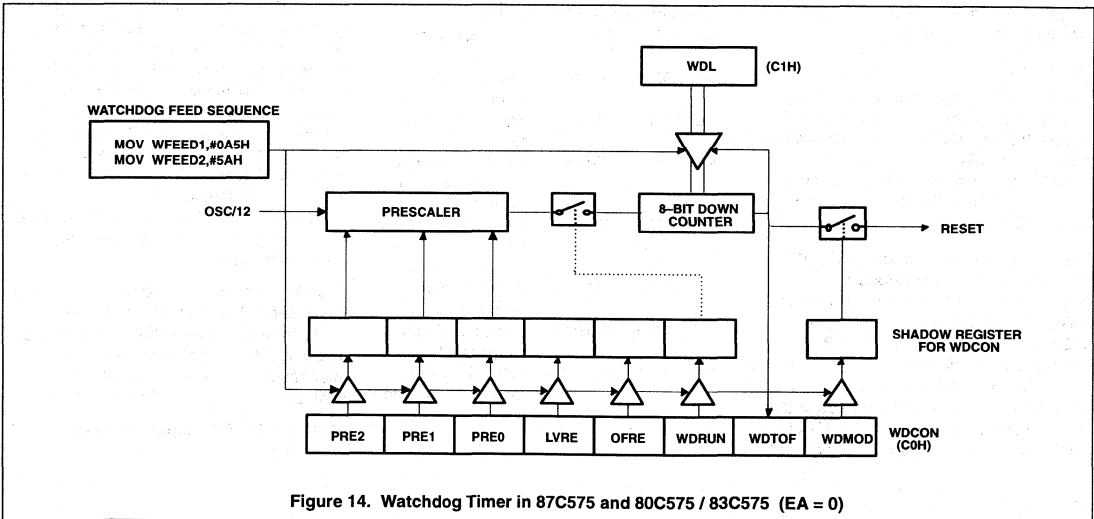

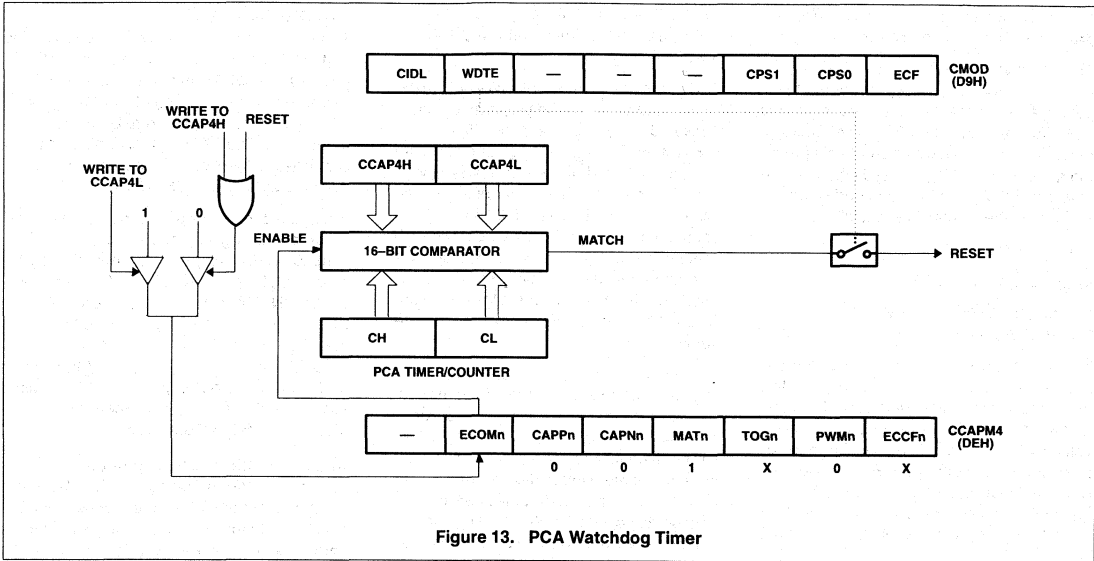

The 8 bit mode is called Mode 1. In this mode the RI flag will be set if SM2 is enabled and the information received has a valid stop bit following the 8 address bits and the information is either a Given or Broadcast address.

Mode 0 is the Shift Register mode and SM2 is ignored.

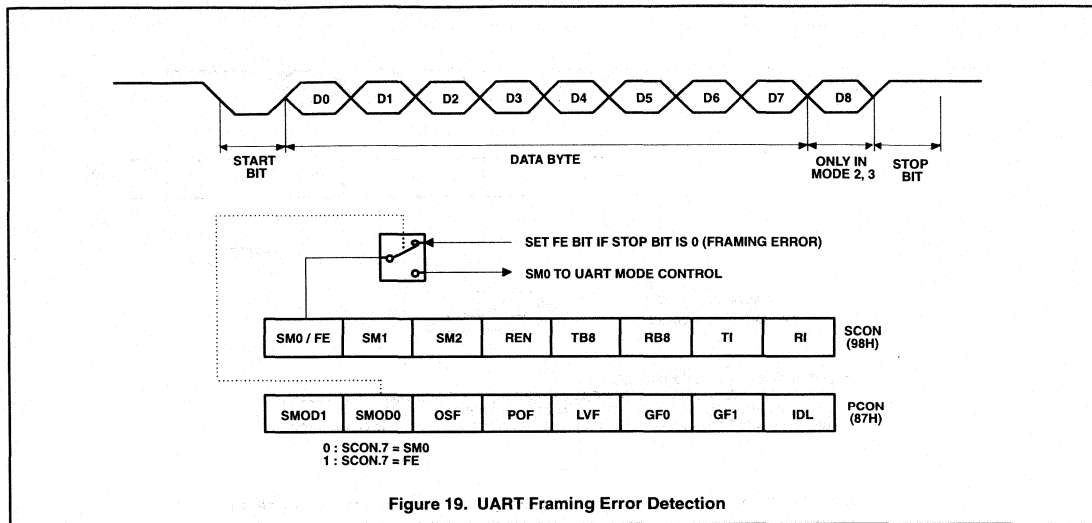

Figure 19. UART Framing Error Detection

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the SADDR to create the "Given" address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

|         |         |                  |
|---------|---------|------------------|
| Slave 0 | SADDR = | 1100 0000        |
|         | SADEN = | <u>1111 1101</u> |
|         | Given = | 1100 00X0        |
| Slave 1 | SADDR = | 1100 0000        |
|         | SADEN = | <u>1111 1110</u> |
|         | Given = | 1100 000X        |

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both

slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

|         |         |                  |
|---------|---------|------------------|
| Slave 0 | SADDR = | 1100 0000        |
|         | SADEN = | <u>1111 1001</u> |
|         | Given = | 1100 0XX0        |
| Slave 1 | SADDR = | 1110 0000        |
|         | SADEN = | <u>1111 1010</u> |
|         | Given = | 1110 0X0X        |
| Slave 2 | SADDR = | 1110 0000        |
|         | SADEN = | <u>1111 1100</u> |
|         | Given = | 1110 00XX        |

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated

as don't-cares. In most cases, interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR (SFR address 0A9H) and SADEN (SFR address 0B9H) are loaded with 0s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares". This effectively disables the Automatic Addressing mode and allows the microcontroller to use standard 80C51 type UART drivers which do not make use of this feature.

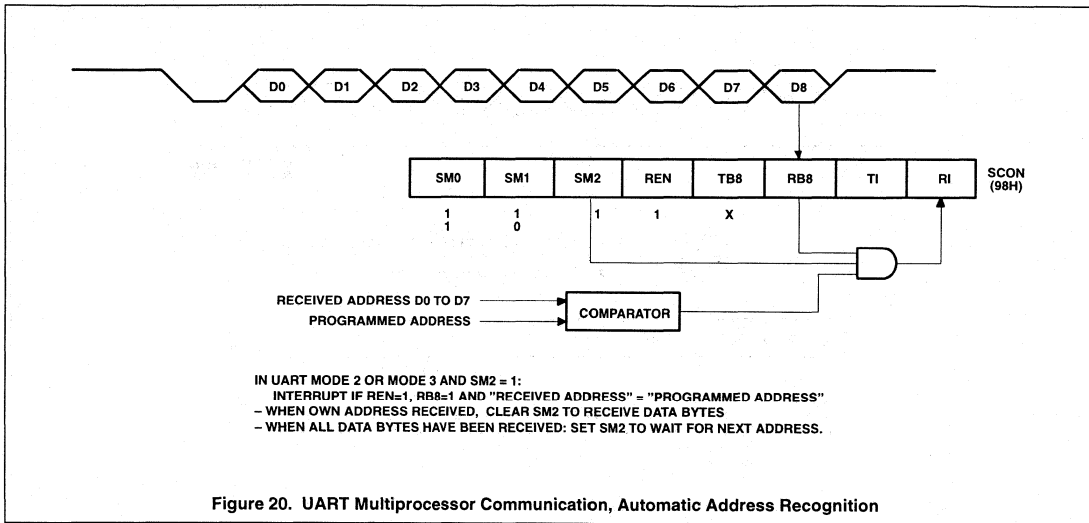

**Analog Comparators**

Four analog comparators are provided on chip. Three comparators have a common negative reference CMPR- and independent positive inputs CMP1+, CMP2+, CMP3+ on port 3. The fourth comparator has independent positive and negative inputs CMP0+ and CMP0- on port 1. The CMP register contains an output and enable bit for each comparator. The CMP register is bit addressable and is located at SFR address E8H. Figure 21 shows the connection of the comparators.

Pullups at the comparator input pins will be disabled by hardware when the comparator is enabled. In addition, to make inputs high impedance, the corresponding port SFR bits must be set by software to disable the pulldowns.

CMOS single-chip 8-bit microcontroller

80C575/83C575/87C575

**CMP Register Bit Definitions**

- CMP.7 enable comparator 3, disable pullups at P3.4, P3.7
- CMP.6 enable comparator 2, disable pullups at P3.4, P3.6
- CMP.5 enable comparator 1, disable pullups at P3.4, P3.5
- CMP.4 enable comparator 0, disable pullups at P1.0, P1.1
- CMP.3 comparator 3 output (read only)
- CMP.2 comparator 2 output (read only)
- CMP.1 comparator 1 output (read only)
- CMP.0 comparator 0 output (read only)

All comparators are disabled automatically in power down mode, in idle mode unused comparators should be disabled by software to save power. A comparator can generate an interrupt that will terminate idle mode when used to drive a PCA capture input.

The CMPE register contains bits to enable each comparator to drive external output pins or internal PCA capture inputs. Pullups at the output pins are disabled by hardware when the external comparator output is enabled. The comparator output is wire-ORed with the corresponding port SFR bit, so the SFR bit must also be set by software to enable the output.

**CMPE Register Bit Definitions**

- CMPE.7 enables comparator 3 to drive CEX3
- CMPE.6 enables comparator 2 to drive CEX2
- CMPE.5 enables comparator 1 to drive CEX1
- CMPE.4 enables comparator 0 to drive CEX0
- CMPE.3 enables comparator 3 output on P1.6 (open drain)
- CMPE.2 enables comparator 2 output on P1.5 (open drain)
- CMPE.1 enables comparator 1 output on P1.4 (open drain)
- CMPE.0 enables comparator 0 output on P1.3 (open drain)

When 1s are written to CMPE bits 7-4, the comparator outputs will drive the corresponding capture input. When 1s are written to CMPE bits 3-0 the comparator output will also drive the corresponding port 1 pin. If the comparator's enabled to drive the capture input but not the port pin, then the port pin can be used for general purpose I/O. When a comparator output is enabled, pullups at the output pin are disabled and the output becomes open drain.

There are two special function registers associated with the comparators. They are CMP which contains the comparator enables and a bit that can be read by software to determine the state of each comparator's output, and CMPE which controls whether the output from each comparator drives the

associated output pin or a capture input associated with one of the PCA modules.

The CMP registers bits 0-3 can be read by software to determine the state of the output of each comparator. To do this the associated comparator must be enabled but the output in port 1 can be disabled. This allows easy polling of the comparator output value without the need to use up a port pin.

The CMPE register allows the comparator to drive the associated PCA module capture input, so that on compare a capture can be generated in the PCA. Bits 0-3 of this register enable the comparator output to drive the associated port 1 output circuitry. Used as a comparator output this circuitry is open drain. To enable the comparator output to drive to port 1, the corresponding port bit must also be set to disable the pulldown. If the comparator is not enabled to drive the port 1 circuitry, the associated port 1 pin can be used for other I/O. This includes when a comparator is enabled to drive the capture input to a PCA module.

**Reduced EMI Mode**

There are two bits in the AUXR register that can be set to reduce the internal clock drive and disable the ALE output. AO (AUXR.0) when set turns off the ALE output. LO (AUXR.1) when set reduces the drive of the internal clock circuitry. Both bits are cleared on Reset. With LO set the 87C575 will still operate at 12MHz, but will have reduced EMI in the range above 100MHz.

# CMOS single-chip 8-bit microcontroller

80C575/83C575/87C575

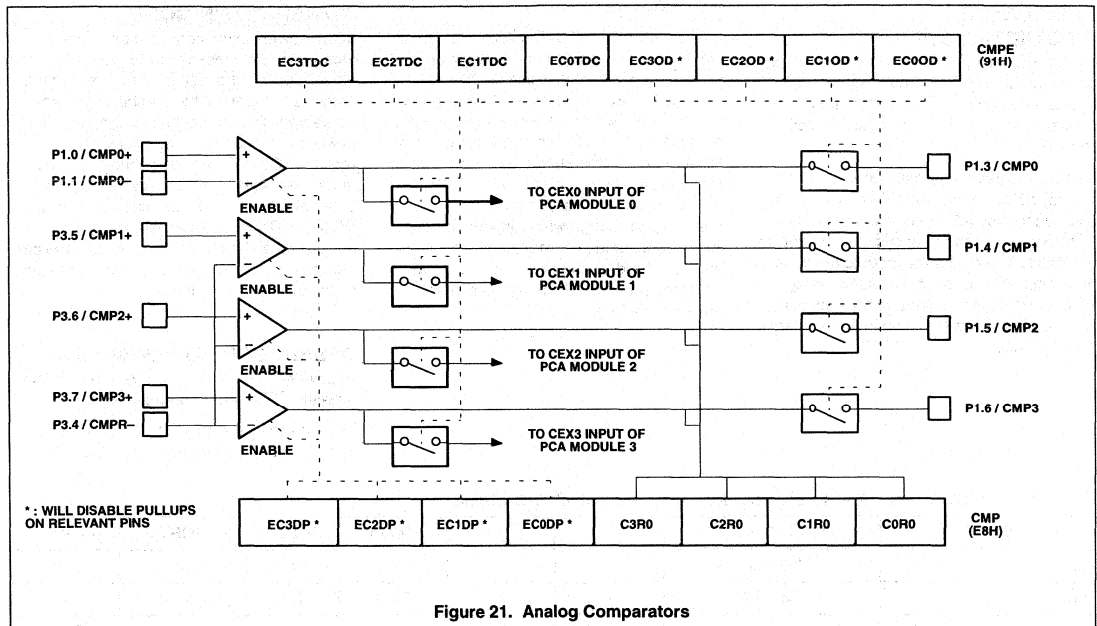

Figure 21. Analog Comparators

### 8XC575 Reduced EMI Mode

#### AUXR (0X8E)

AO: Turns off ALE output.

LO: Reduces drive of internal clock circuitry. 8XC575 spec'd to 12MHz when LO set.

### INTERNAL RESET

Internal resets generated by the power on, low voltage, and oscillator fail detect circuits are self timed to guarantee proper initialization of the 8XC575. Reset will be held approximately 24 oscillator periods after normal conditions are detected by all enabled detect circuits. Internal resets do not drive RST but will cause missing pulses on ALE.

#### Interrupt Enable (IE) Register

- EA IE.7 enable all interrupts
- EC IE.6 enable PCA interrupt
- ET2 IE.5 enable Timer 2 interrupt
- ES IE.4 enable Serial I/O interrupt
- ET1 IE.3 enable Timer 1 interrupt
- EX1 IE.2 enable External interrupt 1
- ET0 IE.1 enable Timer 0 interrupt
- EX0 IE.0 enable External interrupt 0

#### Interrupt Priority (IP) Register

- IP.7 reserved
- PPC IP.6 PCA interrupt priority
- PT2 IP.5 Timer 2 interrupt priority
- PS IP.4 Serial I/O interrupt priority
- PT1 IP.3 Timer 1 interrupt priority
- PX1 IP.2 External interrupt 1 priority
- PT0 IP.1 Timer 0 interrupt priority
- PX0 IP.0 External interrupt 0 priority

| Priority | Source     | Flag     | Vector               |
|----------|------------|----------|----------------------|
| 1        | INT0       | IE0      | 03H highest priority |
| 2        | Timer 0    | TF0      | 0BH                  |
| 3        | INT1       | IE1      | 13H                  |
| 4        | Timer 1    | TF1      | 1BH                  |
| 5        | PCA        | CF,CCFn  | 33H                  |
| 6        | Serial I/O | RI, TI   | 23H                  |
| 7        | Timer 2    | TF2/EXF2 | 2BH lowest priority  |

#### Power Control (PCON) Register

- SMOD1 PCON.7 double baud rate bit
- SMOD0 PCON.6 SCON.7 access control
- OSF PCON.5 oscillator fail flag
- POF PCON.4 power off flag
- LVF PCON.3 low voltage flag
- GF0 PCON.2 general purpose flag
- PD PCON.1 power down mode bit
- IDL PCON.0 idle mode bit

#### Auxiliary Register Bit Definitions (AUXR = 8EH)

- AO AUXR.0 ALE Off, when set turns off ALE
- LO AUXR.1 Low Speed, reduces internal clock drive

#### Port 2 Pullup Disable Register (P2OD = 0A1H)

Port 2 pullups can be disabled by writing ones to P2OD. Each bit in P2OD controls the corresponding bit in P2. P2OD resets to all zeros enabling Port 2 pullups. Writing one to a P2OD bit disables pullups at the corresponding port 2 bit making the output open drain.

## 80C575/83C575/87C575

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 741.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. The control bits for the reduced power modes are in the special function register PCON. Power-down mode can be terminated with either a hardware reset or external interrupt. With an external interrupt INT0 or INT1 must be enabled and configured as level sensitive. Holding the pin low restarts the oscillator and bringing the pin back high completes the exit.

**DESIGN CONSIDERATIONS**

At power-on, the voltage on  $V_{CC}$  must come up with  $RST$  low for a proper start-up.

Table 2 shows the state of I/O ports during low current operating modes.

**Table 2. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

## CMOS single-chip 8-bit microcontroller

80C575/83C575/87C575

**ROM CODE SUBMISSION**

When submitting ROM code for the 83C575, the following must be specified:

1. 8k byte user ROM data
2. 32 byte ROM encryption key
3. ROM security bits
4. The watchdog timer parameters.

| 2033H          | WDCON <sup>1</sup>                           | 0           | WDMOD                                                          |

**NOTES:**

1. See Watchdog Timer Specification for definition of WDL and WDCON bits.

**Security Bit 1:** When programmed, this bit has two effects on masked ROM parts:

1. External MOVX is disabled, and
2. EA# is latched on Reset.

**Security Bit 2:** When programmed, this bit inhibits Verify User ROM.

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING       | UNIT |
|----------------------------------------------------------------------------------------------|--------------|------|
| Operating temperature under bias                                                             | -55 to +125  | °C   |
| Storage temperature range                                                                    | -65 to +150  | °C   |
| Voltage on $\bar{E}A/V_{PP}$ pin to $V_{SS}$                                                 | 0 to +13.0   | V    |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5 | V    |
| Maximum $I_{OL}$ per I/O pin                                                                 | 15           | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5          | W    |

**NOTES:**

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

NOTES: (SEE NEXT PAGE)

## CMOS single-chip 8-bit microcontroller

80C575/83C575/87C575

**NOTES TO THE DC ELECTRICAL CHARACTERISTICS TABLE:**

1. Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
2. Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
3. Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
4. Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is between  $V_{IH}$  and  $V_{IL}$ .
5.  $I_{CCMAX}$  at other frequencies can be determined from Figure 29.
6. See Figures 30 through 33 for  $I_{CC}$  test conditions.
7. Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
8. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:

|                                         |      |
|-----------------------------------------|------|
| Maximum $I_{OL}$ per port pin:          | 10mA |
| Maximum $I_{OL}$ per 8-bit port:        | 26mA |
| Maximum total $I_{OL}$ for all outputs: | 71mA |

If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
9. Specification applies to Port 2 when P2OD bit is set.
10. 15pF MAX for the EA/ $V_{PP}$  and P0.0 pins.

| $t_{XHDX}$            | 25     | Clock rising edge to input data valid                      |                  | $10t_{CLCL}-133$ | ns            |

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 80C32/52 to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

CMOS single-chip 8-bit microcontroller

80C575/83C575/87C575

**EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE

- P – PSEN
- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

## 80C575/83C575/87C575

**EPROM CHARACTERISTICS**

To put the 87C575 in the EPROM programming mode, PSEN must be held high during power up, then driven low with reset active. The 87C575 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C575 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C575 manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 34 and 35. Figure 36 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 34. Note that the 87C575 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 34. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 35.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/ $V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 36. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips  
(B0H) = 97H indicates 87C575

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/ $V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|--------------|------|------|------|------|
| Read signature       | 0   | 0    | 1        | 1            | 0    | 0    | 0    | 0    |
| Program code data    | 0   | 0    | 0*       | $V_{PP}$     | 1    | 0    | 1    | 1    |
| Verify code data     | 0   | 0    | 1        | 1            | 0    | 0    | 1    | 1    |
| Pgm encryption table | 0   | 0    | 0*       | $V_{PP}$     | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 0   | 0    | 0*       | $V_{PP}$     | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 0   | 0    | 0*       | $V_{PP}$     | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2.  $V_{PP}$  = 12.75V ±0.25V.

3.  $V_{CC}$  = 5V ±10% during programming and verification.

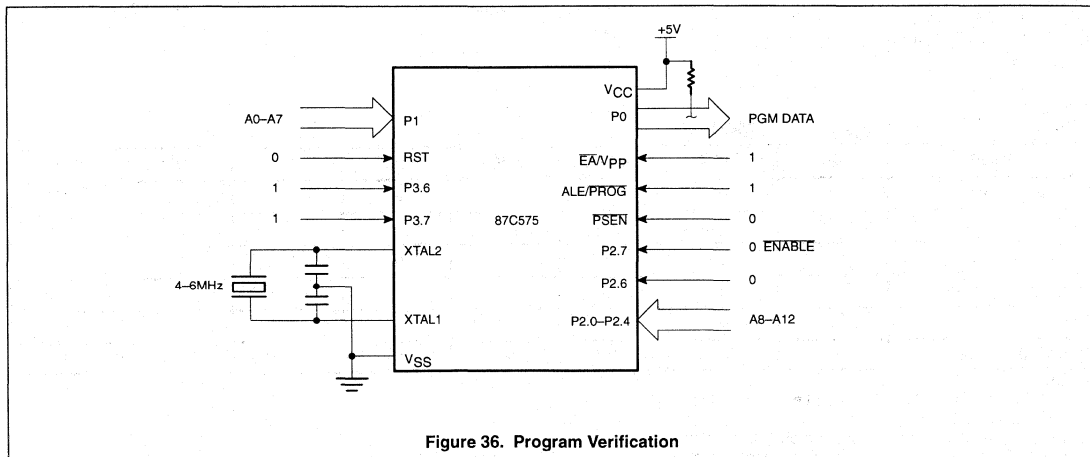

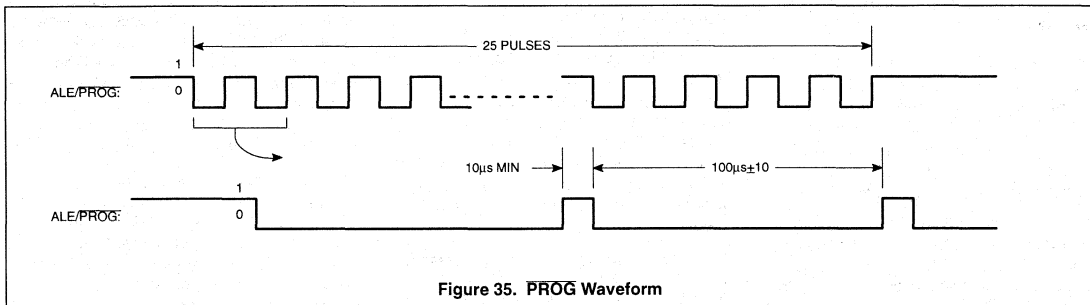

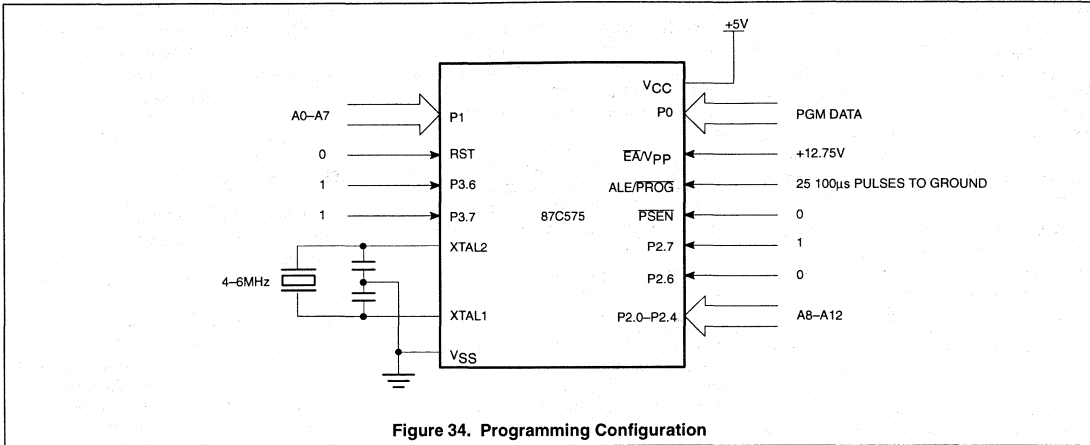

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

# CMOS single-chip 8-bit microcontroller

# 83C576/87C576

## DESCRIPTION

The Philips 83C576/87C576 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. The Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. Philips epitaxial substrate minimizes latch-up sensitivity.

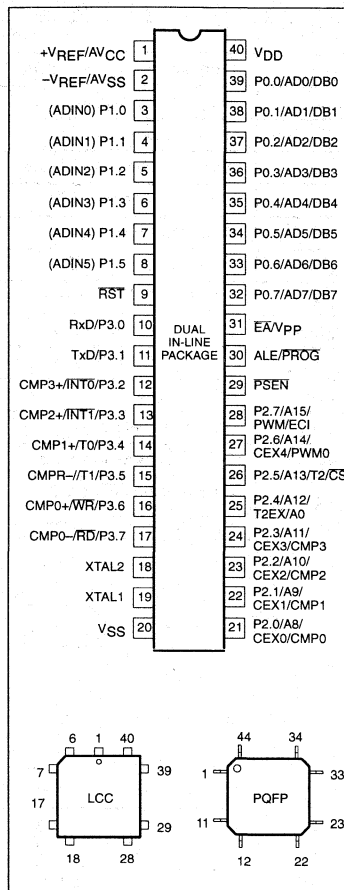

The 8XC576 contains an 8k × 8 ROM (83C576) EPROM (87C576), a 256 × 8 RAM, 32 I/O lines, three 16-bit counter/timers, a Programmable Counter Array (PCA), a 10-bit, 6 channel A/D, 2 PWM outputs, an 8-bit UPI interface, a fifteen-source, two-priority level nested interrupt structure, an enhanced UART, four analog comparators, power-fail detect and oscillator fail detect circuits, and on-chip oscillator and clock circuits.

In addition, the 8XC576 has a low active reset, and the port pins are reset to a low level. There is also a fully configurable watchdog timer, and internal power on clear circuit. The part includes idle mode and power-down mode states for reduced power consumption.

## FEATURES

- 80C51 based architecture
  - 8k × 8 ROM (83C576)
  - 8k × 8 EPROM (87C576)
  - 256 × 8 RAM
  - 10-bit, 6 channel A/D
  - Three 16-bit counter/timers
  - 2 PWM outputs
  - Programmable Counter Array
  - Universal Peripheral Interface
  - Enhanced UART
  - Oscillator fail detect
  - Low active reset
  - Asynchronous low port reset
  - Schmitt trigger inputs
  - 4 analog comparators
  - Watchdog timer
  - Low V<sub>CC</sub> detect
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- 4.0 to 16MHz
- Extended temperature ranges
- OTP package available
- EPROM/OTP versions can be programmed in circuit
- Software Reset
- 15 source, 2 level interrupt structure

## PIN CONFIGURATIONS

| P0.0-0.7        | 39-32      | 43-36                             | 37-30        | I/O                                 | <p><b>Port 0:</b> Port 0 is an open-drain bidirectional I/O port. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also receives code bytes during EPROM programming and outputs code bytes during program verification. External pull-ups are required during program verification. During reset, the port 0 pulldowns are turned on asynchronously, and the port register is loaded with 0's. Port 0 has 4 output modes selected on a per bit basis by writing to the P0MOD and POOE Special Function Registers as follows:</p> <table border="1"> <thead> <tr> <th>P0MOD.x</th> <th>POOE.x</th> <th>Mode Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Open drain (default). See Note 1.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Weak pullup. See Note 2.</td> </tr> <tr> <td>1</td> <td>0</td> <td>High impedance. See Note 3.</td> </tr> <tr> <td>1</td> <td>1</td> <td>Push-pull. See Note 4.</td> </tr> </tbody> </table> <p>Port 0 is also the data I/O port for the Universal Peripheral Interface (UPI). When the UPI is enabled, the port 0 drivers are normally disabled. Input/Output through P0 is controlled by pin CS, WR, RD, and A. Output is push-pull when enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | P0MOD.x | POOE.x | Mode Description | 0 | 0                                   | Open drain (default). | P1.0-P1.5       | 3-8        | 5-9                               | 42-44<br>1-3 | I/O                                 | <p><b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port. Port 1 receives the low-order address byte during program memory verification and EPROM programming. During reset, port 1 is configured as a high impedance analog input port. Digital push-pull outputs are enabled by writing 1's to the P1OE (port 1 output enable) register. The programmer must take care to prevent digital outputs from switching while an A/D conversion is in progress. Port 1 pins also serve alternate functions as follows:</p> <table border="1"> <tbody> <tr> <td>1</td> <td>2</td> <td>40</td> <td>I</td> <td>+V<sub>REF</sub>/AV<sub>CC</sub></td> </tr> <tr> <td>2</td> <td>3</td> <td>41</td> <td>I</td> <td>-V<sub>REF</sub>/AV<sub>SS</sub></td> </tr> <tr> <td>3</td> <td>4</td> <td>42</td> <td>I/O</td> <td>P1.0/ADIN0</td> </tr> <tr> <td>4</td> <td>5</td> <td>43</td> <td>I/O</td> <td>P1.1/ADIN1</td> </tr> <tr> <td>5</td> <td>6</td> <td>44</td> <td>I/O</td> <td>P1.2/ADIN2</td> </tr> <tr> <td>6</td> <td>7</td> <td>1</td> <td>I/O</td> <td>P1.3/ADIN3</td> </tr> <tr> <td>7</td> <td>8</td> <td>2</td> <td>I/O</td> <td>P1.4/ADIN4</td> </tr> <tr> <td>8</td> <td>9</td> <td>3</td> <td>I/O</td> <td>P1.5/ADIN5</td> </tr> </tbody> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 1       | 2      | 40               | I | +V <sub>REF</sub> /AV <sub>CC</sub> | 2                                 | 3 | 41 | I                        | -V <sub>REF</sub> /AV <sub>SS</sub> | 3 | 4                           | 42 | I/O | P1.0/ADIN0             | 4  | 5  | 43 | I/O         | P1.1/ADIN1  | 5                                             | 6  | 44 | I/O | P1.2/ADIN2  | 6           | 7                                             | 1  | I/O | P1.3/ADIN3 | 7           | 8           | 2                                             | I/O | P1.4/ADIN4 | 8  | 9           | 3           | I/O                                           | P1.5/ADIN5 |    |    |             |             |                       |    |    |    |             |           |                      |    |    |    |             |             |                           |    |    |    |             |            |                 |  |  |  |  |             |                                |

| P2.0-P2.7       | 21-28      | 24-31                             | 18-25        | I/O                                 | <p><b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 emits the high-order address byte during accesses to external program and data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. Port 2 receives the high-order address byte during program verification and EPROM programming. During reset, the port 2 pulldowns are turned on synchronously, and the port register is loaded with 0's. Port 2 has the following output modes which can be selected on a per bit basis by writing to P2MA and P2MB:</p> <table border="1"> <thead> <tr> <th>P2M1</th> <th>P2M2</th> <th>Mode Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Open drain (default). | P3.0-P3.7          | 10-17      | 11,<br>13-19                                                      | 5,<br>7-13 | I/O  | <p><b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins except P3.1 that have 1s written to them can be used as inputs but will source current when externally pulled low (see DC Electrical Characteristics: <math>I_{IL}</math>). P3.1 will be a high impedance pin except while transmitting serial data, in which case the strong pull-up will remain on continuously when outputting a 1 level. The P3.1 output drive level when transmitting can be set to one of two levels by the writing to the P3.1 register bit. During reset all pins (except P3.1) will be asynchronously driven low and will remain low until written to by software. All port 3 pins have Schmitt trigger inputs with 200mV hysteresis, except P3.2 and P3.3, which have 50mV hysteresis. Port 3 has the following output modes which can be selected on a per bit basis by writing to P3M1 and P3M2:</p> <table border="1"> <thead> <tr> <th>P3M1</th> <th>P3M2</th> <th>Mode Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Open drain. See Note 1.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Weak pullup (default). See Note 2.</td> </tr> <tr> <td>1</td> <td>0</td> <td>High impedance. See Note 3.</td> </tr> <tr> <td>1</td> <td>1</td> <td>Push-pull. See Note 4.</td> </tr> </tbody> </table> <p>Port 3 pins serve alternate functions as follows:</p> <table border="1"> <thead> <tr> <th>Pin</th> <th>Function</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>P3.0</td> <td>RxD</td> <td>Serial receive port</td> </tr> <tr> <td>P3.1</td> <td>TxD</td> <td>Serial transmit port (enabled only when transmitting serial data)</td> </tr> <tr> <td>P3.2</td> <td>INT0</td> <td>External interrupt 0</td> </tr> <tr> <td>P3.3</td> <td>INT1</td> <td>External interrupt 1</td> </tr> <tr> <td></td> <td>CMP3+</td> <td>Comparator 3 positive input</td> </tr> <tr> <td>P3.4</td> <td>T0</td> <td>Timer/counter 0 input</td> </tr> <tr> <td></td> <td>CMP1+</td> <td>Comparator 1 positive input</td> </tr> <tr> <td>P3.5</td> <td>T1</td> <td>Timer/counter 1 input</td> </tr> <tr> <td></td> <td>CMPR</td> <td>Common reference to comparators 1, 2, 3</td> </tr> <tr> <td>P3.6</td> <td>WR</td> <td>External data memory write strobe</td> </tr> <tr> <td></td> <td>CMP0+</td> <td>Comparator 0 positive input</td> </tr> <tr> <td>P3.7</td> <td>RD</td> <td>External data memory read strobe</td> </tr> <tr> <td></td> <td>CMP0-</td> <td>Comparator 0 negative input</td> </tr> </tbody> </table> | P3M1 | P3M2 | Mode Description | 0 | 0 | Open drain. See Note 1. | 0 | 1 | Weak pullup (default). See Note 2. | 1 | 0 | High impedance. See Note 3. | 1 | 1 | Push-pull. See Note 4. | Pin | Function | Description | P3.0 | RxD | Serial receive port | P3.1 | TxD | Serial transmit port (enabled only when transmitting serial data) | P3.2 | INT0 | External interrupt 0 | P3.3 | INT1 | External interrupt 1 |  | CMP3+ | Comparator 3 positive input | P3.4 | T0 | Timer/counter 0 input |  | CMP1+ | Comparator 1 positive input | P3.5 | T1 | Timer/counter 1 input |  | CMPR | Common reference to comparators 1, 2, 3 | P3.6 | WR | External data memory write strobe |  | CMP0+ | Comparator 0 positive input | P3.7 | RD | External data memory read strobe |  | CMP0- | Comparator 0 negative input |

| RST                | 9          | 10                                                                | 4          | I    | <b>Reset:</b> A low on this pin asynchronously resets all port pins to a low state except P3.1. The pin must be held low with the oscillator running for 24 oscillator cycles to initialize the internal registers. An internal diffused resistor to $V_{CC}$ permits a power on reset using only an external capacitor to $V_{SS}$ . RST has a Schmitt trigger input stage to provide additional noise immunity with a slow rising input voltage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |      |      |                  |   |   |                         |   |   |                                    |   |   |                             |   |   |                        |     |          |             |      |     |                     |      |     |                                                                   |      |      |                      |      |      |                      |  |       |                             |      |    |                       |  |       |                             |      |    |                       |  |      |                                         |      |    |                                   |  |       |                             |      |    |                                  |  |       |                             |
| ALE/PROG           | 30         | 33                                                                | 27         | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. ALE is switched off if the bit 0 in the AUXR register (8EH) is set. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |      |      |                  |   |   |                         |   |   |                                    |   |   |                             |   |   |                        |     |          |             |      |     |                     |      |     |                                                                   |      |      |                      |      |      |                      |  |       |                             |      |    |                       |  |       |                             |      |    |                       |  |      |                                         |      |    |                                   |  |       |                             |      |    |                                  |  |       |                             |
| PSEN               | 29         | 32                                                                | 26         | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the device is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |      |                  |   |   |                         |   |   |                                    |   |   |                             |   |   |                        |     |          |             |      |     |                     |      |     |                                                                   |      |      |                      |      |      |                      |  |       |                             |      |    |                       |  |       |                             |      |    |                       |  |      |                                         |      |    |                                   |  |       |                             |      |    |                                  |  |       |                             |

If EA is held high, the device executes from internal program memory unless the program counter contains an address greater than 1FFFH. This pin also receives the 12.75V programming supply voltage ( $V_{PP}$ ) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |      |                  |   |   |                         |   |   |                                    |   |   |                             |   |   |                        |     |          |             |      |     |                     |      |     |                                                                   |      |      |                      |      |      |                      |  |       |                             |      |    |                       |  |       |                             |      |    |                       |  |      |                                         |      |    |                                   |  |       |                             |      |    |                                  |  |       |                             |

## NOTES:

- When Open Drain mode is selected, ports 0 and 2 have weak pulldowns to guarantee positive leakage current (see DC electrical characteristic  $I_{IH}$ ).
- When Weak Pullup mode is selected, ports bits that have 1's written to them can be used as inputs but will source current when externally pulled low (see DC electrical characteristic  $I_{IL}$ ).
- When High Impedance mode is selected, all pullups and pulldowns are turned off. The only current sourced or sunk by the pin is the parasitic leakage current (see DC electrical characteristic  $I_{L2}$  or  $I_{LC}$ , as applicable).
- When Push-Pull mode is selected, strong pullups are on continuously when emitting 1's (see DC electrical characteristic  $V_{OH}$ ).

1. Reset value depends on reset source.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**POWER ON CLEAR/  
POWER ON FLAG**

An on-chip Power On Detect Circuit resets the 8XC576 and sets the Power Off Flag (PCON.4) on power up or if  $V_{CC}$  drops to zero momentarily. The POF can only be cleared by software. The RST pin is not driven by the power on detect circuit. The POF can be read by software to determine that a power failure has occurred and can also be set by software.

**LOW VOLTAGE DETECT**

An on-chip Low Voltage Detect circuit sets the Low Voltage Flag (PCON.3) if  $V_{CC}$  drops below  $V_{LOW}$  (see DC Electrical Characteristics) and resets the 8XC576 if the Low Voltage Reset Enable bit (WDCON.4) is set. If the LVRE is cleared, the reset is disabled but LVF will still be set if  $V_{CC}$  is low. The RST pin is not driven by the low voltage detect circuit. The LVF can be read by software to determine that  $V_{CC}$  was low. The LVF can be set or cleared by software.

**OSCILLATOR FAIL DETECT**

An on-chip Oscillator Fail Detect circuit sets the Oscillator Fail Flag (PCON.5) if the oscillator frequency drops below OSCF for one or more cycles (see AC Electrical Characteristics: OSCF) and resets the 8XC576 if the Oscillator Fail Reset Enable bit (WDCON.3) is set. If OFRE is cleared, the reset is disabled but OSF will still be set if the oscillator fails. The RST pin is not driven by the oscillator fail detect circuit. The OSF can be read by software to determine that an oscillator failure has occurred. The OSF can be set or cleared by software.

**LOW ACTIVE RESET**

One of the most notable features on this part is the low active reset. At this time this is the only 80C51 derivative available that has low active reset. This feature makes it easier to interface the 8XC576 into an application to accommodate the power-on and low voltage conditions that can occur. The low active reset operates exactly the same as high active reset with the exception that the part is put into the reset mode by applying a low level to the reset pin. For power-on reset it is also necessary to invert the power-on reset circuit; connecting the 8.2K resistor from the reset pin to  $V_{CC}$  and the  $10\mu\text{f}$  capacitor from the reset pin to ground. Figure 1 shows all of the reset related circuitry.

When reset the port pins on the 87C576 are driven low asynchronously. This is different from all other 80C51 derivatives.

The 8XC576 also has Low voltage detection circuitry that will, if enabled, force the part to reset when  $V_{CC}$  (on the part) fails below a set level. Low Voltage Reset is enabled by a normal reset. Low Voltage Reset can be disabled by clearing LVRE (bit 4 in the WDCON SFR) then executing a watchdog feed sequence (ASH to WFEED2). In addition there is a flag (LVF) that is set if a low voltage condition is detected. The LVF flag is set even if the Low Voltage detection circuitry is disabled. Notice that the Low voltage detection circuitry does not drive the RST# pin so the LVF flag is the only way that the microcontroller can determine if it has been reset due to a low voltage condition.

The 8XC576 has an on-chip power-on detection circuit that sets the POF (PCON.4) flag on power up or if the  $V_{CC}$  level momentarily drops to 0V. This flag can be used to determine if the part is being started from a power-on (cold start) or if a reset has occurred due to another condition (warm start).

**TIMERS**

The 87C576 has four on-chip timers.

Timers 0 and 1 are identical in every way to Timers 0 and 1 on the 80C51.

Timer 2 on the 8XC576 is identical to the 80C52 Timer 2 (described in detail in the 80C52 overview) with the exception that it is an up or down counter. To configure the Timer to count down the DCEN bit in the T2MOD special function register must be set and a low level must be present on the T2EX pin (P1.1).

The Watchdog timer operation and implementation is the same as that for the 8XC550 (described in the 8XC550 overview) with the exception that the reset values of the WDCON and WDL special function registers have been changed. The changes in these registers cause the watchdog timer to be enabled with a timeout of  $98304 \times T_{OSC}$  when the part is reset. The watchdog can be disabled by executing a valid feed sequence and then clearing WDRUN (bit 2 in the WDCON SFR).

**PROGRAMMABLE COUNTER ARRAY (PCA)**

The Programmable Counter Array is a special Timer that has five 16-bit capture/compare modules associated with it. Each of the modules can be programmed to operate in one of four modes: rising and/or falling edge capture, software timer, high-speed output, or pulse width modulator. Each module has a pin associated with it in port 1. Module 0 is connected to P1.3(CEX0), module 1 to P1.4(CEX1), etc. The basic PCA configuration is shown in Figure 2.

The PCA timer is a common time base for all five modules and can be programmed to run at: 1/12 the oscillator frequency, 1/4 the oscillator frequency, the Timer 0 overflow, or the input on the ECI pin (P1.2). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD SFR as follows (see Figure 3):

| CPS1 | CPS0 | PCA Timer Count Source    |
|------|------|---------------------------|
| 0    | 0    | 1/12 oscillator frequency |
| 0    | 1    | 1/4 oscillator frequency  |
| 1    | 0    | Timer 0 overflow          |
| 1    | 1    | External Input at ECI pin |

In the CMOD SFR are three additional bits associated with the PCA. They are CIDL which allows the PCA to stop during idle mode, WDTE which enables or disables the watchdog function on module 4, and ECF which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows. These functions are shown in Figure 3.

The watchdog timer function is implemented in module 4 as implemented in other parts that have a PCA that are available on the market. However, if a watchdog timer is required in the target application, it is recommended to use the hardware watchdog timer that is implemented on the 87C576 separately from the PCA (see Figure 14).

The CCON SFR contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (refer to Figure 6). To run the PCA the CR bit (CCON.6) must be set by software. The PCA is shut off by clearing this bit. The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software. Bits 0 through 4 of the CCON register are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software. The PCA interrupt system shown in Figure 4.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (see Figure 7). The registers contain the bits that control the mode that each module will operate in. The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or 4 depending on the module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated module. PWM (CCAPMn.1) enables the pulse width modulation mode. The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register. The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.

The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition. The last bit in the register ECOM (CCAPMn.6) when set

enables the comparator function. Figure 8 shows the CCAPMn settings for the various PCA functions.

There are two additional registers associated with each of the PCA modules. They are CCAPnH and CCAPnL and these are the registers that store the 16-bit count when a capture occurs or a compare should occur. When a module is used in the PWM mode these registers are used to control the duty cycle of the output.

**PCA Capture Mode**

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated. Refer to Figure 9.

**16-bit Software Timer Mode**

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (see Figure 10).

**High Speed Output Mode**

In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (see Figure 11).

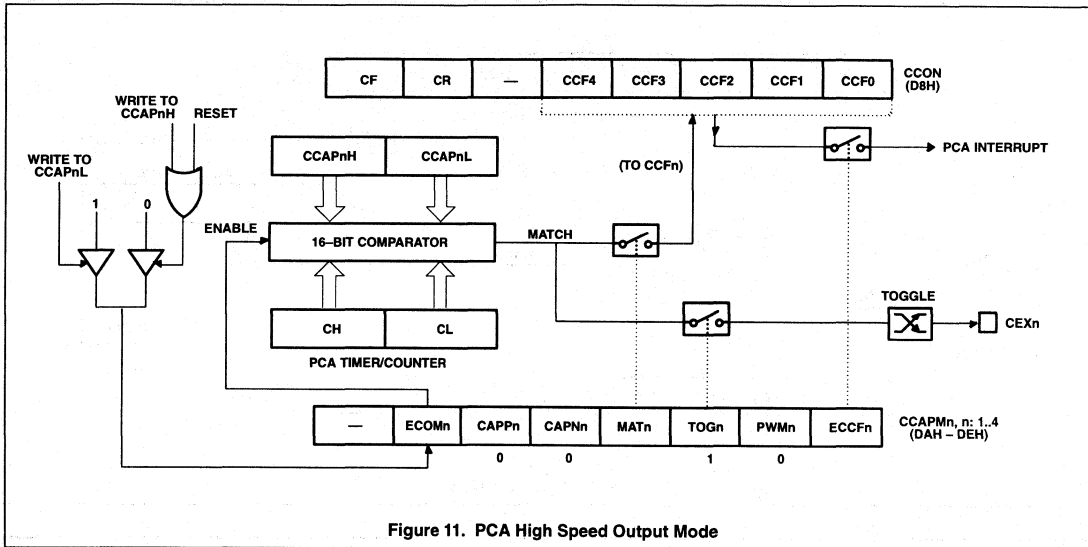

Figure 11. PCA High Speed Output Mode

**Pulse Width Modulator Mode**

All of the PCA modules can be used as PWM outputs. Figure 12 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPL<sub>n</sub>. When the value of the PCA CL SFR is less than the value in the module's CCAPL<sub>n</sub> SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPL<sub>n</sub> is reloaded with the value in CCAPH<sub>n</sub>. This allows updating the PWM without glitches. The PWM and ECOM bits in the module's CCAPM<sub>n</sub> register must be set to enable the PWM mode.

**WATCHDOG TIMER**

The watchdog timer is not directly loadable by the user. Instead, the value to be loaded into the main timer is held in an autoloader register or is part of the mask ROM programming. In order to cause the main timer to be loaded with the appropriate value, a special sequence of software action must take place. This operation is referred to as feeding the watchdog timer.

To feed the watchdog, two instructions must be sequentially executed successfully. No

intervening instruction fetches are allowed, so interrupts should be disabled before feeding the watchdog. The instructions should move A5H to the WFEED1 register and then 5AH to the WFEED2 register. If WFEED1 is correctly loaded and WFEED2 is not correctly loaded, then an immediate underflow will occur.

The watchdog timer subsystem has two modes of operation. Its principal function is a watchdog timer. In this mode it protects the system from incorrect code execution by causing a system reset when the watchdog timer underflows as a result of a failure of software to feed the timer prior to the timer reaching its terminal count. If the user does not employ the watchdog function, the watchdog subsystem can be used as a timer. In this mode, reaching the terminal count sets a flag. In most other respects, the timer mode possesses the characteristics of the watchdog mode. This is done to protect the integrity of the watchdog function.

The watchdog timer subsystem consists of a prescaler and a main counter. The prescaler has 8 selectable taps off the final stages and the output of a selected tap provides the clock to the main counter. The main counter is the section that is loaded as a result of the software feeding the watchdog and it is the section that causes the system reset

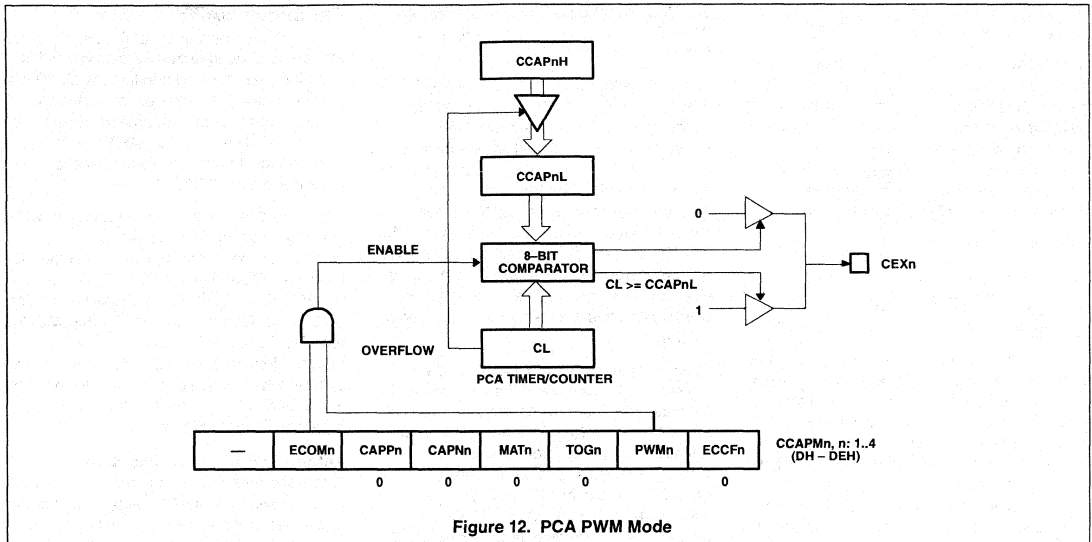

(watchdog mode) or time-out flag to be set (timer mode) if allowed to reach its terminal count.

**Programming the Watchdog Timer**

Both the EPROM and ROM devices have a set of SFRs for holding the watchdog autoloader values and the control bits. The watchdog time-out flag is present in the watchdog control register and operates the same in all versions. In the EPROM device, the watchdog parameters (autoloader value and control) are always taken from the SFRs. In the ROM device, the watchdog parameters can be mask programmed or taken from the SFRs. The selection to take the watchdog parameters from the SFRs or from the mask programmed values is controlled by EA (external access). When EA is high (internal ROM access), the watchdog parameters are taken from the mask programmed values. If the watchdog is mask programmed to the timer mode, then the autoloader values and the pre-scaler taps are taken from the SFRs. When EA is low (external access), the watchdog parameters are taken from the SFRs. The user should be able to leave code in his program which initializes the watchdog SFRs even though he has migrated to the mask ROM part. This allows no code changes from EPROM prototyping to ROM coded production parts.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**Watchdog Detailed Operation****EPROM Device (and ROMless Operation: EA = 0)**

In the ROMless operation (ROM part, EA = 0) and in the EPROM device, the watchdog operates in the following manner (see Figure 14).

Whether the watchdog is in the watchdog or timer mode, when external RESET is applied, the following takes place:

- Watchdog mode bit set to watchdog mode.
- Watchdog run control bit set to ON.
- Autoload register set to 00 (min. count).
- Watchdog time-out flag cleared.
- Prescaler is cleared.
- Prescaler tap set to the highest divide.
- Autoload takes place.

The watchdog can be fed even though it is in the timer mode.

Note that the operational concept is for the watchdog mode of operation, when coming out of a hardware reset, the software should load the autoload registers, set the mode to watchdog, and then feed the watchdog (cause an autoload). The watchdog will now be starting at a known point.

If the watchdog is in the watchdog mode and running and happens to underflow at the time

the external RESET is applied, the watchdog time-out flag will be cleared.

When the watchdog is in the watchdog mode and the watchdog underflows, the following action takes place (see Figure 16):

- Autoload takes place.
- Watchdog time-out flag is set
- Mode bit unchanged.
- Watchdog run bit unchanged.
- Autoload register unchanged.
- Prescaler tap unchanged.
- All other device action same as external reset.

Note that if the watchdog underflows, the program counter will start from 00H as in the case of an external reset. The watchdog time-out flag can be examined to determine if the watchdog has caused the reset condition. The watchdog time-out flag bit can be cleared by software.

When the watchdog is in the timer mode and the timer software underflows, the following action takes place:

- Autoload takes place.
- Watchdog time-out flag is set
- Mode bit unchanged.
- Watchdog run bit unchanged.

- Autoload register unchanged.
- Prescaler tap unchanged.

**Mask ROM Device (EA = 1)**

In the mask ROM device, the watchdog mode bit (WDMOD) is mask programmed and the bit in the watchdog command register is read only and reflects the mask programmed selection. If the mask programmed mode bit selects the timer mode, then the watchdog run bit (WDRUN) operates as described under EPROM Device. If the mask programmed bit selects the watchdog mode, then the watchdog run bit has no effect on the timer operation (see Figure 15).

**Watchdog Function**

The watchdog consists of a programmable prescaler and the main timer. The prescaler derives its clock from the on-chip oscillator. The prescaler consists of a divide by 12 followed by a 13 stage counter with taps from stage 6 through stage 13. This is shown in Figure 17. The tap selection is programmable. The watchdog main counter is a down counter clocked (decremented) each time the programmable prescaler underflows. The watchdog generates an underflow signal (and is auto-loaded) when the watchdog is at count 0 and the clock to decrement the watchdog occurs. The watchdog is 8 bits long and the autoload value can range from 0 to FFH. (The

## CMOS single-chip 8-bit microcontroller

83C576/87C576

autoload value of 0 is permissible since the prescaler is cleared upon autoload).

This leads to the following user design equations. Definitions:  $t_{OSC}$  is the oscillator period,  $N$  is the selected prescaler tap value,  $W$  is the main counter autoload value,  $t_{MIN}$  is the minimum watchdog time-out value (when the autoload value is 0),  $t_{MAX}$  is the maximum time-out value (when the autoload value is FFH),  $t_D$  is the design time-out value.

$$t_{MIN} = t_{OSC} \times 12 \times 64$$

$$t_{MAX} = t_{MIN} \times 128 \times 256$$

$$t_D = t_{MIN} \times 2^{PRESCALER} \times W + 1$$

(where prescaler = 0, 1, 2, 3, 4, 5, 6, or 7)

Note that the design procedure is anticipated to be as follows. A  $t_{MAX}$  will be chosen either from equipment or operation considerations and will most likely be the next convenient value higher than  $t_D$ . (If the watchdog were inadvertently to start from FFH, an overflow would be guaranteed, barring other anomalies, to occur within  $t_{MAX}$ ). Then the value for the prescaler would be chosen from:

$$\text{prescaler} = \log_2(t_{MAX} / (t_{OSC} \times 12 \times 256)) - 6$$

This then also fixes  $t_{MIN}$ . An autoload value would then be chosen from:

$$W = t_D / t_{MIN} - 1$$

The software must be written so that a feed operation takes place every  $t_D$  seconds from the last feed operation. Some tradeoffs may need to be made. It is not advisable to include feed operations in minor loops or in subroutines unless the feed operation is a specific subroutine.

#### Watchdog Control Register (WDCON) (Bit Addressable) Address C0

The following bits of this register are read only in the ROM part when EA is high: WDMOD, PRE0, PRE1, and PRE2. That is, the register will reflect the mask programmed values. In the ROM part with EA high, these bits are taken from mask coded bits and are not readable by the program. WDRUN is read only in the ROM part when EA is high and

WDMOD is in the watchdog mode. When WDMOD is in the timer mode, WDRUN functions normally.

The parameters written into WDMOD, PRE0, PRE1, and PRE2 by the program are not applied directly to the watchdog timer subsystem. The watchdog timer subsystem is directly controlled by a second register which stores these bits. The transfer of these bits from the user register (WDMOD) to the second control register takes place when the watchdog is fed. This prevents random code execution from directly foiling the watchdog function. This does not affect the operation where these bits are taken from mask coded values.

The reset values of the WDCON and WDL registers will be such that the timer resets to the watchdog mode with a timeout period of  $12 \times 64 \times 128 \times t_{OSC}$ . The watchdog timer will not generate an interrupt. Additional bits in WDCON are used to disable reset generation by the oscillator fail and low voltage detect circuits. WDCON can be written by software only by executing a valid watchdog feed sequence.

#### WDCON Register Bit Definitions

|         |       |                                                    |

| WDCON.0 | WDMOD | Watchdog Mode, reset to 1 (watchdog mode)          |

#### Enhanced UART

The UART operates in all of the usual modes that are described in the first section of this book for the 80C51. In addition the UART can perform framing error detect by looking for missing stop bits, and automatic address recognition. The 87C576 UART also fully supports multiprocessor communication as does the standard 80C51 UART.

When used for framing error detect the UART looks for missing stop bits in the communication. A missing bit will set the FE bit in the SCON register. The FE bit shares the SCON.7 bit with SM0 and the function of SCON.7 is determined by PCON.6 (SMOD0) (see Figure 19). If SMOD0 is set then SCON.7 functions as FE. SCON.7 functions as SM0 when SMOD0 is cleared. When used as FE SCON.7 can only be cleared by software. Refer to Figure 18.

#### Automatic Address Recognition

Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes, mode 2 and mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the "Given" address or the "Broadcast" address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data. Automatic address recognition is shown in Figure 20.

The 8 bit mode is called Mode 1. In this mode the RI flag will be set if SM2 is enabled and the information received has a valid stop bit following the 8 address bits and the information is either a Given or Broadcast address.

Mode 0 is the Shift Register mode and SM2 is ignored.

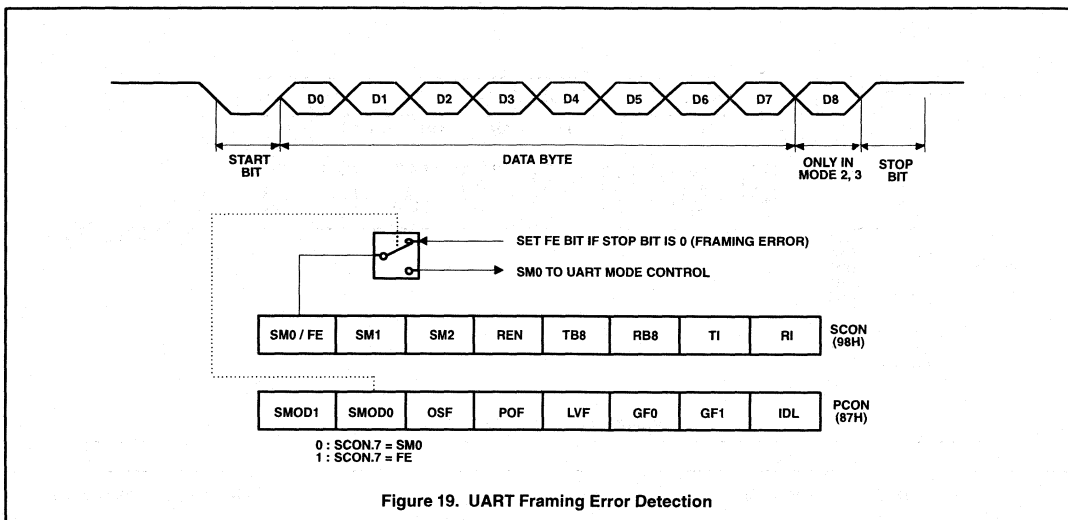

Figure 19. UART Framing Error Detection

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the SADDR to create the "Given" address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

|         |         |           |
|---------|---------|-----------|
| Slave 0 | SADDR = | 1100 0000 |
|         | SADEN = | 1111 1101 |
|         | Given = | 1100 00X0 |
| Slave 1 | SADDR = | 1100 0000 |
|         | SADEN = | 1111 1110 |
|         | Given = | 1100 000X |

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both

slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

|         |         |           |
|---------|---------|-----------|
| Slave 0 | SADDR = | 1100 0000 |
|         | SADEN = | 1111 1001 |
|         | Given = | 1100 0XX0 |
| Slave 1 | SADDR = | 1110 0000 |
|         | SADEN = | 1111 1010 |
|         | Given = | 1110 0X0X |
| Slave 2 | SADDR = | 1110 0000 |
|         | SADEN = | 1111 1100 |
|         | Given = | 1110 00XX |

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated

as don't-cares. In most cases, interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR (SFR address 0A9H) and SADEN (SFR address 0B9H) are loaded with 0s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares"; this effectively disables the Automatic Addressing mode and allows the microcontroller to use standard 80C51 type UART drivers which do not make use of this feature.

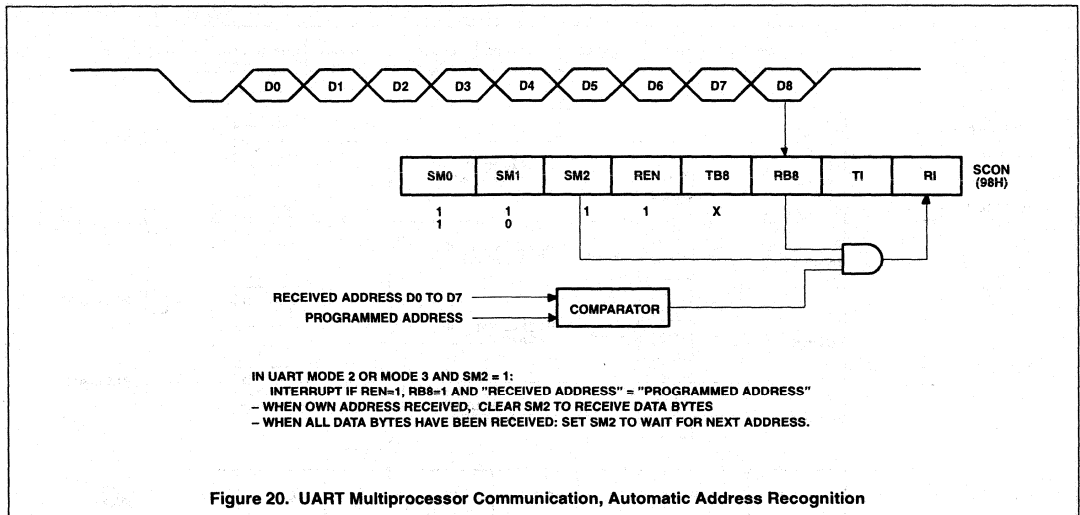

### Analog Comparators

Four analog comparators are provided on chip. Three comparators have a common negative reference CMPR- and independent positive inputs CMP1+, CMP2+, CMP3+ on port 3. The fourth comparator has independent positive and negative inputs CMP0+ and CMP0- on port 1. The CMP register contains an output and enable bit for each comparator. The CMP register is bit addressable and is located at SFR address E8H. Figure 21 shows the connection of the comparators.

Pullups at the comparator input pins will be disabled by hardware when the comparator is enabled. In addition, to make inputs high impedance, the corresponding port SFR bits must be set by software to disable the pulldowns.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**CMP Register Bit Definitions**

|       |                                                    |
|-------|----------------------------------------------------|
| CMP.7 | enable comparator 3, disable pullups at P3.4, P3.7 |
| CMP.6 | enable comparator 2, disable pullups at P3.4, P3.6 |
| CMP.5 | enable comparator 1, disable pullups at P3.4, P3.5 |
| CMP.4 | enable comparator 0, disable pullups at P1.0, P1.1 |
| CMP.3 | comparator 3 output (read only)                    |
| CMP.2 | comparator 2 output (read only)                    |
| CMP.1 | comparator 1 output (read only)                    |
| CMP.0 | comparator 0 output (read only)                    |

All comparators are disabled automatically in power down mode, in idle mode unused comparators should be disabled by software to save power. A comparator can generate an interrupt that will terminate idle mode when used to drive a PCA capture input.

The CMPE register contains bits to enable each comparator to drive external output pins or internal PCA capture inputs. Pullups at the output pins are disabled by hardware when the external comparator output is enabled. The comparator output is wire-ORed with the corresponding port SFR bit, so the SFR bit must also be set by software to enable the output.

**CMPE Register Bit Definitions**

|        |                                                  |
|--------|--------------------------------------------------|
| CMPE.7 | enables comparator 3 to drive CEX3               |
| CMPE.6 | enables comparator 2 to drive CEX2               |
| CMPE.5 | enables comparator 1 to drive CEX1               |
| CMPE.4 | enables comparator 0 to drive CEX0               |
| CMPE.3 | enables comparator 3 output on P1.6 (open drain) |
| CMPE.2 | enables comparator 2 output on P1.5 (open drain) |
| CMPE.1 | enables comparator 1 output on P1.4 (open drain) |
| CMPE.0 | enables comparator 0 output on P1.3 (open drain) |

When 1s are written to CMPE bits 7-4, the comparator outputs will drive the corresponding capture input. When 1s are written to CMPE bits 3-0 the comparator output will also drive the corresponding port 1 pin. If the comparator's enabled to drive the capture input but not the port pin, then the port pin can be used for general purpose I/O. When a comparator output is enabled, pullups at the output pin are disabled and the output becomes open drain.

There are two special function registers associated with the comparators. They are CMP which contains the comparator enables and a bit that can be read by software to determine the state of each comparator's output, and CMPE which controls whether the output from each comparator drives the

associated output pin or a capture input associated with one of the PCA modules.

The CMP registers bits 0-3 can be read by software to determine the state of the output of each comparator. To do this the associated comparator must be enabled but the output in port 1 can be disabled. This allows easy polling of the comparator output value without the need to use up a port pin.

The CMPE register allows the comparator to drive the associated PCA module capture input, so that on compare a capture can be generated in the PCA. Bits 0-3 of this register enable the comparator output to drive the associated port 1 output circuitry. Used as a comparator output this circuitry is open drain. To enable the comparator output to drive to port 1, the corresponding port bit must also be set to disable the pulldown. If the comparator is not enabled to drive the port 1 circuitry, the associated port 1 pin can be used for other I/O. This includes when a comparator is enabled to drive the capture input to a PCA module.

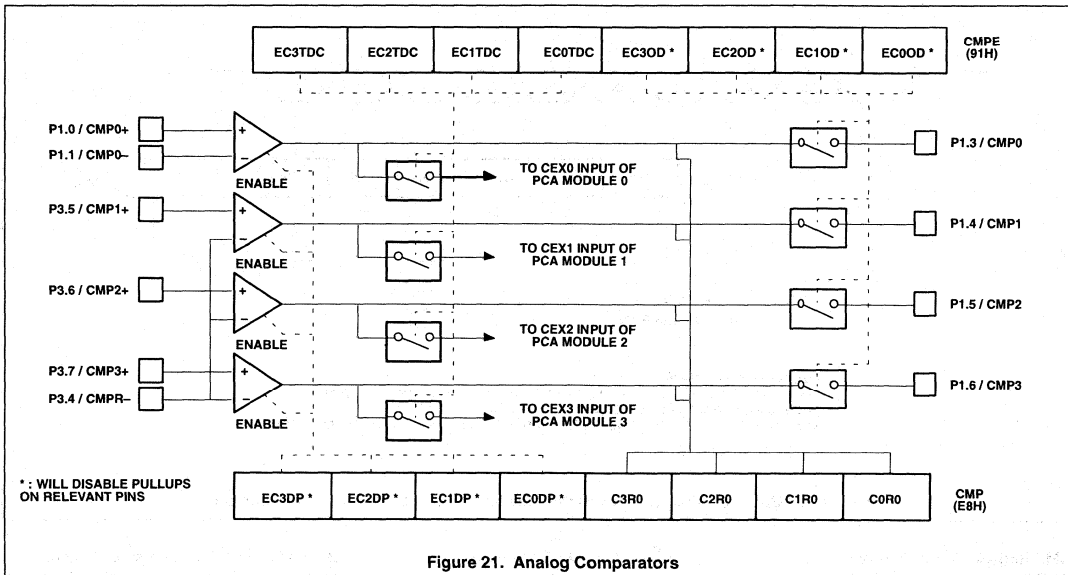

**Reduced EMI Mode**

There are two bits in the AUXR register that can be set to reduce the internal clock drive and disable the ALE output. AO (AUXR.0) when set turns off the ALE output. LO (AUXR.1) when set reduces the drive of the internal clock circuitry. Both bits are cleared on Reset. With LO set the 87C576 will still operate at 12MHz, but will have reduced EMI in the range above 100MHz.

# CMOS single-chip 8-bit microcontroller

# 83C576/87C576

## 8XC576 Reduced EMI Mode

### AUXR (0X8E)

|   |   |   |   |   |   |   |   |    |    |
|---|---|---|---|---|---|---|---|----|----|
| — | — | — | — | — | — | — | — | LO | AO |
|---|---|---|---|---|---|---|---|----|----|

AO: Turns off ALE output.

LO: Reduces drive of internal clock circuitry. 8XC576 spec'd to 12MHz when LO set.

## INTERNAL RESET

Internal resets generated by the power on, low voltage, and oscillator fail detect circuits are self timed to guarantee proper initialization of the 8XC576. Reset will be held approximately 24 oscillator periods after normal conditions are detected by all enabled detect circuits. Internal resets do not drive RST but will cause missing pulses on ALE.

## Analog to Digital Converter

The 8XC576 has a 6 channel 10 bit successive approximation A/D converter with separate result registers for each channel. Operating modes are provided for single or multiple channel conversions and multiple conversions of a single channel without software intervention. The ADC can also be operated in 8 bit mode with faster conversion times. Registers ADC0H–ADC5H contain the MSBs and ADC0L–ADC5L bits 6 and 7 contain the 2 LSBs of the conversion result for each channel. The ADCS register determines which channels are converted in multiple channel modes. If the ADCS bit

corresponding to a channel is set, that channel is converted, else if the bit is clear the channel is skipped.

### A/D Channel Select (ADCS) Register (Reset Value = 00H)

|       |                                   |   |   |
|-------|-----------------------------------|---|---|
| ADCS5 | ADCS.5 – A/D channel 5 select bit | 0 | 1 |
| ADCS4 | ADCS.4 – A/D channel 4 select bit |   |   |
| ADCS3 | ADCS.3 – A/D channel 3 select bit |   |   |
| ADCS2 | ADCS.2 – A/D channel 2 select bit |   |   |
| ADCS1 | ADCS.1 – A/D channel 1 select bit |   |   |
| ADCS0 | ADCS.0 – A/D channel 0 select bit | 1 | 0 |

### A/D Control (ADCON) Register (Reset Value = 00H)

|       |                                        |   |   |
|-------|----------------------------------------|---|---|
| ADF   | ADCON.7 – A/D conversion complete flag |   |   |
| ADCE  | ADCON.6 – A/D conversion enable        |   |   |
| ADBM  | ADCON.5 – A/D 8-bit mode               |   |   |
| AMOD1 | ADCON.4 – A/D mode select bit 1        |   |   |
| AMOD0 | ADCON.3 – A/D mode select bit 0        | 1 | 1 |
| ASCA2 | ADCON.2 – A/D channel address bit 2    |   |   |
| ASCA1 | ADCON.1 – A/D channel address bit 1    |   |   |
| ASCA0 | ADCON.0 – A/D channel address bit 0    |   |   |

### AMOD1 AMOD0

|   |   |                                                                                                                                                                   |
|---|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | 0 | Single Conversion Mode – channel selected by bits ASCA2..0 in ADCON is converted, the result placed in the associated result registers; ADF is set on completion. |
|---|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|   |   |                                                                                                                                                                                                                                                                                             |
|---|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | 1 | Multiple Channel Scan Mode – all channels elected in the ADCS register are converted starting with the channel addressed by bits ASCA2..0 in ADCON, conversion results are placed in the corresponding result registers for each channel. ADF is set when the last conversion is completed. |
| 1 | 0 | Single Channel Multiple Conversion – channel selected by bits ASCA2..0 in ADCON is converted 6 times and all 6 results are saved in ADC0H–ADC5H and ADC0L–ADC5L, ADF is set when all conversions are complete.                                                                              |
| 1 | 1 | Multiple Channel Continuous – same as Multiple Channel Scan mode but repeats as long as ADCE=1, ADF is set when all channels have been converted once. Hardware will prevent the ADC from writin to the result registers while they are being read.                                         |

Flag ADF is set upon completion of a conversion, if the ADC interrupt enable bit EAD is set, the program will vector to the ADC interrupt location when ADF is set.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**PWM'S**

The pulse width modulator system of the 8XC576 contains two PWM output channels. These channels generate pulses of programmable length and interval. The prescaler and counter are common to both PWM channels.

The prescaler is loaded with the complement of the PWMP register during counter overflow, internal reset, and when EN/CLR# = 0. The repetition frequency is defined by the 8-bit prescaler which clocks the counter. The prescaler division factor = PWMP+1. Reading the PWMP gives the current reload value. The actual count of the prescaler cannot be read.

The 8-bit counter counts from 0–254 inclusive. The value of the counter is compared to the contents of the compare registers PWM0 and PWM1. When the counter compares to the compare register, that register's output goes LOW. When the counter reaches zero the output is set HIGH unless PWMn = 00H. The duty cycle of each channel is defined by the contents of its compare register and is in the range of 0 to 1, programmed in increments of 1/255.

The outputs can be set continuously low by loading PWMn with 00H and continuously high by loading with FFH.

The PWM counter is enabled with bit EN/CLR# of the PWCON register. Output to the port pin is separately enabled by setting the PWEEn bits in the PWCON register. The counter remains active if EN/CLR# is set

even if both PWEEn bits are reset. The PWM function is reset by a chip reset. In idle mode, the PWM will function as configured by PWCON. In power-down the state of the PWM will freeze when the internal clock stops. If the chip is awakened with an external interrupt, the PWM will continue to function from its state when power-down was entered. The EN/CLR# bit of PWCON will clear the counter and load the contents of the PWMP into the prescaler when set LOW. If PWEEn is set at this time the output will go HIGH unless PWMn is 00H.

The repetition frequency is given by:

$$f_{\text{PWM}} = \frac{f_{\text{OSC}}}{((510 \times (1 + \text{PWMP}))}$$

An oscillator frequency of 12MHz results in a repetition range of 92Hz to 23.5KHz.

The high/low ratio of PWMn if  $\text{PWMn}/(255 - \text{PWMn})$  for PWMn values except 255. A PWMn value of 255 results in a high PWMn output.

In order for the PWMn output to be used as a standard I/O pin, PWMn must be reset. The PWM counter can still be used as an internal timer by setting EN/CLR#.

**Auxiliary Register Bit Definitions****(AUXR = 8EH)**

|     |        |                                         |
|-----|--------|-----------------------------------------|
| AO  | AUXR.0 | ALE Off, when set turns off ALE         |
| LO  | AUXR.1 | Low Speed, reduces internal clock drive |
|     | AUXR.2 |                                         |
| RST | AUXR.3 | Software reset bit                      |

**Interrupt Enable 0 (IE0) Register**

|     |       |                             |
|-----|-------|-----------------------------|
| EA  | IE0.7 | Enable all interrupts       |
| EC  | IE0.6 | Enable PCA interrupt        |
| ET2 | IE0.5 | Enable Timer 2 interrupt    |
| ES  | IE0.4 | Enable Serial I/O interrupt |
| ET1 | IE0.3 | Enable Timer 1 interrupt    |
| EX1 | IE0.2 | Enable External interrupt 1 |
| ET0 | IE0.1 | Enable Timer 0 interrupt    |
| EX0 | IE0.0 | Enable External interrupt 0 |

**Interrupt Enable 1 (IE1) Register**

|     |       |                               |
|-----|-------|-------------------------------|
| EOB | IE1.7 | Enable OBF interrupt          |
| EIB | IE1.6 | Enable IBF interrupt          |
| EAD | IE1.5 | Enable ADC interrupt          |
| EC4 | IE1.4 | Enable PCA module 4 interrupt |
| EC3 | IE1.3 | Enable PCA module 3 interrupt |
| EC2 | IE1.2 | Enable PCA module 2 interrupt |
| EC1 | IE1.1 | Enable PCA module 1 interrupt |
| EC0 | IE1.0 | Enable PCA module 0 interrupt |

**Interrupt Priority 0 (IP0) Register**

|     |       |                               |
|-----|-------|-------------------------------|
|     | IP0.7 | (reserved)                    |
| PC  | IP0.6 | PCA interrupt priority        |
| PT2 | IP0.5 | Timer 2 interrupt priority    |
| PS  | IP0.4 | Serial I/O interrupt priority |
| PT1 | IP0.3 | Timer 1 interrupt priority    |
| PX1 | IP0.2 | External interrupt 1 priority |
| PT0 | IP0.1 | Timer 0 interrupt priority    |
| PX0 | IP0.0 | External interrupt 0 priority |

| LO | AUXR.1 | Low Speed, reduces internal clock drive |

**UNIVERSAL PERIPHERAL INTERFACE**

UPI mode allows the 8XC576 to function as a slave processor connected to a host CPU bus via port 0. The interface consists of port 0 input and output buffer registers and the UPI control/status register (UCS). UPI mode is enabled by setting the UPI enable bit (UE) in the UCS. When operating in UPI mode, port 0 pins normally float. Access to port 0 is controlled by inputs WR#, RD#, CS#, and A0. RD# and WR# are the external read and write strobes controlled by the host CPU.

CS# is the chip select input, normally a decoded address from the host CPU bus, which qualifies RD# and WR# (these pins have no effect when CS#=1). The A0 pin is an address input from the host CPU which selects either the port 0 output buffer or the UCS register to be output during a read operation. During a write operation, the value of the A0 pin is latched in the UA flag in the UCS register. The following is a summary of the UPI data control inputs:

| CS# | RD# | WR# | A |                                              |
|-----|-----|-----|---|----------------------------------------------|
| 0   | 0   | 1   | 0 | read port 0 output buffer, clear OBF         |
| 0   | 0   | 1   | 1 | read UPI control/status register             |
| 0   | 1   | 0   | 0 | write data to input buffer set IBF, clear AF |
| 0   | 1   | 0   | 1 | write command to input buffer set IBF, AF    |
| 1   | x   | x   | x | disable input/output                         |

**UPI Control Status Register (UCS, Reset value = 00H)**

|       |     |                                                                                                                                                                                                                             |
|-------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UCS.7 | ST7 | User defined status bit                                                                                                                                                                                                     |
| UCS.6 | ST6 | User defined status bit                                                                                                                                                                                                     |
| UCS.5 | ST5 | User defined status bit                                                                                                                                                                                                     |
| UCS.4 | ST4 | User defined status bit                                                                                                                                                                                                     |
| UCS.3 | UE  | UPI Enable bit – if UE=1, UPI is enabled, if UE=0, UPI is disabled and port 0 functions normally.                                                                                                                           |
| UCS.2 | AF  | Address Flag – contains status of the A0 (address) pin during the last write. If A0=0, the input buffer should be interpreted as data by the 8XC576 software, if A0=1, the input buffer should be interpreted as a command. |
| UCS.1 | IBF | Input Buffer Full flag – set by hardware on trailing (rising) edge of WR# when CS#=0, cleared by hardware when port 0 SFR is read (by the 8XC576 software).                                                                 |
| UCS.0 | IBF | Output Buffer Full flag – set by hardware during writes (by 8XC576 software) to the port 0 SFR, cleared by hardware on the trailing (rising) edge of RD# when CS#=0 and A0=0.                                               |

The IBF and OBF flag bits reflect the status of the input/output buffers. The host CPU writes to the 8XC576 by driving data on the external bus connected to port 0 and strobing the WR# pin while CS#=0. The WR# strobe latches port 0 data in the input buffer and sets the IBF flag on the trailing (rising) edge. When the 8XC576 reads from port 0 in UPI

mode, it reads from the input buffer and clears the IBF. When the 8XC576 writes to port 0 in UPI mode, it writes to the output buffer which sets the OBF. The host CPU can read the output buffer or the UCS register enabling the port 0 drivers, the OBF flag is cleared when the output buffer is read.

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 741.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. The control bits for the reduced power modes are in the special function register PCON. Power-down mode can be terminated with either a hardware reset or external interrupt. With an external interrupt INT0 or INT1 must be enabled and configured as level sensitive. Holding the pin low restarts to oscillator and bringing the pin back high completes the exit.

**DESIGN CONSIDERATIONS**

At power-on, the voltage on V<sub>CC</sub> must come up with RST low for a proper start-up.

Table 2 shows the state of I/O ports during low current operating modes.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**Table 2. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

**ROM CODE SUBMISSION**

When submitting ROM code for the 83C576, the following must be specified:

1. 8k byte user ROM data
2. 32 byte ROM encryption key
3. ROM security bits
4. The watchdog timer parameters.

| ADDRESS        | CONTENT | BIT(S) | COMMENT                                                                                                          |

**Security Bit 1:** When programmed, this bit has two effects on masked ROM parts:

1. External MOV<sub>C</sub> is disabled, and
2. EA# is latched on Reset.

**Security Bit 2:** When programmed, this bit inhibits Verify User ROM.

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING       | UNIT |
|----------------------------------------------------------------------------------------------|--------------|------|
| Operating temperature under bias                                                             | -55 to +125  | °C   |
| Storage temperature range                                                                    | -65 to +150  | °C   |
| Voltage on EA/V <sub>PP</sub> pin to V <sub>SS</sub>                                         | 0 to +13.0   | V    |
| Voltage on any other pin to V <sub>SS</sub>                                                  | -0.5 to +6.5 | V    |
| Maximum I <sub>OL</sub> per I/O pin                                                          | 15           | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5          | W    |

**NOTES:**

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

| $V_{LOW}$ | Low $V_{CC}$ detect voltage                                                                                    |                            | 4.0             |                  | 4.45             | V             |
| $C_{IO}$  | Pin capacitance <sup>10</sup>                                                                                  | $f = 1\text{MHz}$          |                 |                  | 10               | pF            |

NOTES: (SEE NEXT PAGE)

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**NOTES TO THE DC ELECTRICAL CHARACTERISTICS TABLE:**

1. Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
2. Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
3. Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $\overline{PSEN}$  to momentarily fall below the 0.9 $V_{CC}$  specification when the address bits are stabilizing.
4. Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is between  $V_{IH}$  and  $V_{IL}$ .
5.  $I_{CCMAX}$  at other frequencies can be determined from Figure 30.
6. See Figures 30 through 34 for  $I_{CC}$  test conditions.
7. Load capacitance for port 0, ALE, and  $\overline{PSEN}$  = 100pF, load capacitance for all other outputs = 80pF.
8. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
 

|                                         |      |
|-----------------------------------------|------|
| Maximum $I_{OL}$ per port pin:          | 10mA |
| Maximum $I_{OL}$ per 8-bit port:        | 26mA |
| Maximum total $I_{OL}$ for all outputs: | 71mA |

 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
9. Specification applies to Port 2 when P2OD bit is set.
10. 15pF MAX for the EA/ $V_{PP}$  and P0.0 pins.

**A/D CONVERTER DC ELECTRICAL CHARACTERISTICS** $T_{amb} = -40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ ,  $V_{CC} = 5\text{V} \pm 10\%$

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 80C32/52 to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

### EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE

- P - PSEN
- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:** t<sub>AVLL</sub> = Time for address valid to ALE low.  
 t<sub>LLPL</sub> = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

## 83C576/87C576

**EPROM CHARACTERISTICS**

To put the 87C576 in the EPROM programming mode, PSEN must be held high during power up, then driven low with reset active. The 87C576 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for V<sub>PP</sub> (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C576 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C576 manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 35 and 36. Figure 37 shows the circuit configuration for normal program memory verification.

**On-Board Programming (OBP)**

The On-Board Programming facility consists of a series of internal hardware resources coupled with internal firmware to facilitate remote programming of the 87C576 through the serial port.

The OBP function is invoked by having the EA/V<sub>PP</sub> pin at the V<sub>PP</sub> voltage level at the time that the part exits reset. The OBP function only requires that the TxD, RxD, V<sub>SS</sub>, V<sub>CC</sub>, and V<sub>PP</sub> pins be connected to an external circuit in order to use this feature.

The OBP feature provides for the use of a wide range of baud rates independent of the oscillator frequency used. It is also adaptable to a wide range of oscillator frequencies. The OBP facility provides for both auto-echo and no-echo of received characters. The OBP feature requires that an initial character, either an uppercase U or a 5 be sent to the 87C576 to establish the baud rate to be used. This character also indicates whether an auto-echo (a U) or no-echo (a 5) is to be used.

Once baud rate initialization has been performed, the OBP facility only accepts Intel Hex records. The record-type field of these hex records are used to indicate either commands or data for the OBP facility. The maximum number of data bytes in a record is

limited to 16 (decimal). These commands/data are summarized below:

| Record Type | Command/Data Function                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00          | Data record, programs the part with data indicated in record starting with load address in the record                                                                                                             |
| 01          | EOF record, no operation                                                                                                                                                                                          |
| 02          | Specify timing parameters<br>– rec length = 3 bytes<br>– load address = 0000<br>– 1st byte = timer count for 50µs programming pulse<br>– 2nd byte = timer count for 10µs delay between pulses<br>– 3rd byte = 0AH |
| 03          | Program security bits<br>– rec length = 1 byte<br>– load address = 0000<br>– 1st byte = sec bit values (xxxx xxB2B1)                                                                                              |
| 04          | Display contents of USER EPROM array<br>– rec length = 00<br>– load address = 0000                                                                                                                                |
| 05          | Verify security bit status<br>– rec length = 00<br>– load address = 0000                                                                                                                                          |
| 06          | Pulse timing test, pulses P3.2 for timing verification<br>– rec length = 00<br>– load address = 0000                                                                                                              |

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 35. Note that the 87C576 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 35. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 36.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm

Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/V<sub>PP</sub> pin must not be allowed to go above the maximum specified V<sub>PP</sub> level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The V<sub>PP</sub> source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 37. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(B0H) = B6H indicates 87C576

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

## CMOS single-chip 8-bit microcontroller

83C576/87C576

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent

erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537

angstroms) to an integrated dose of at least  $15\text{W}\cdot\text{s}/\text{cm}^2$ . Exposing the EPROM to an ultraviolet lamp of  $12,000\mu\text{W}/\text{cm}^2$  rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{\text{EA}}/\text{V}_{\text{PP}}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|---------------------------------------------|------|------|------|------|
| Read signature       | 0   | 0    | 1        | 1                                           | 0    | 0    | 0    | 0    |
| Program code data    | 0   | 0    | 0*       | $\text{V}_{\text{PP}}$                      | 1    | 0    | 1    | 1    |
| Verify code data     | 0   | 0    | 1        | 1                                           | 0    | 0    | 1    | 1    |
| Pgm encryption table | 0   | 0    | 0*       | $\text{V}_{\text{PP}}$                      | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 0   | 0    | 0*       | $\text{V}_{\text{PP}}$                      | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 0   | 0    | 0*       | $\text{V}_{\text{PP}}$                      | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

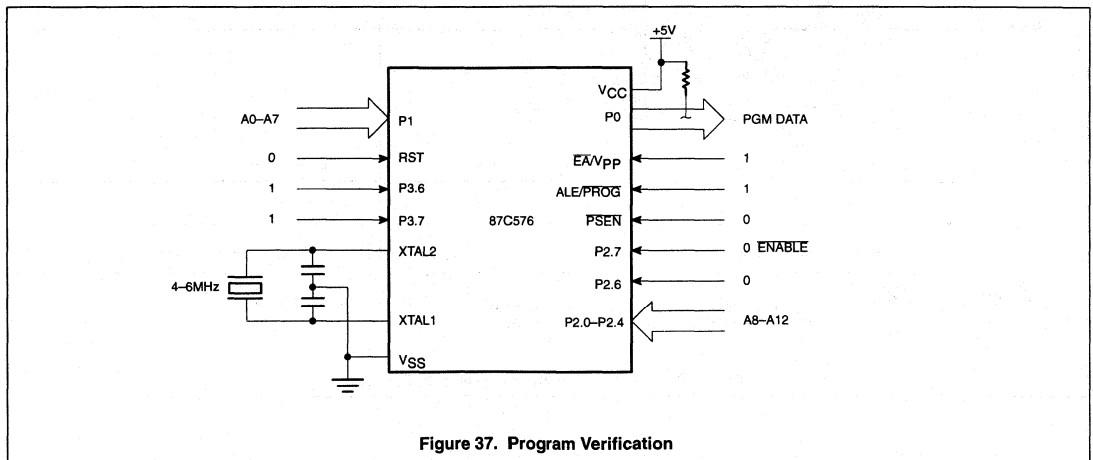

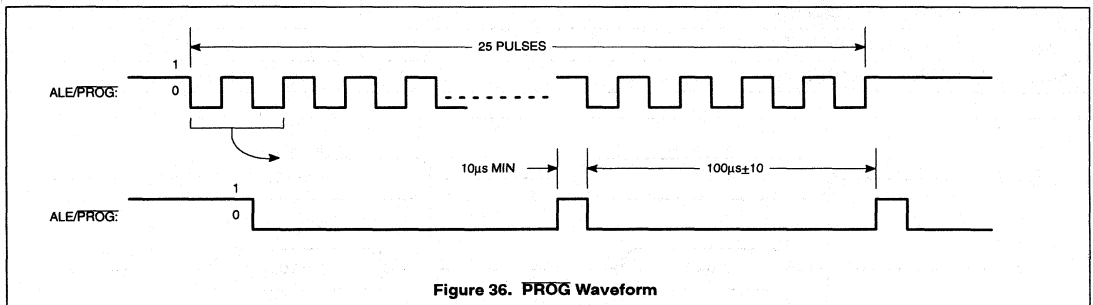

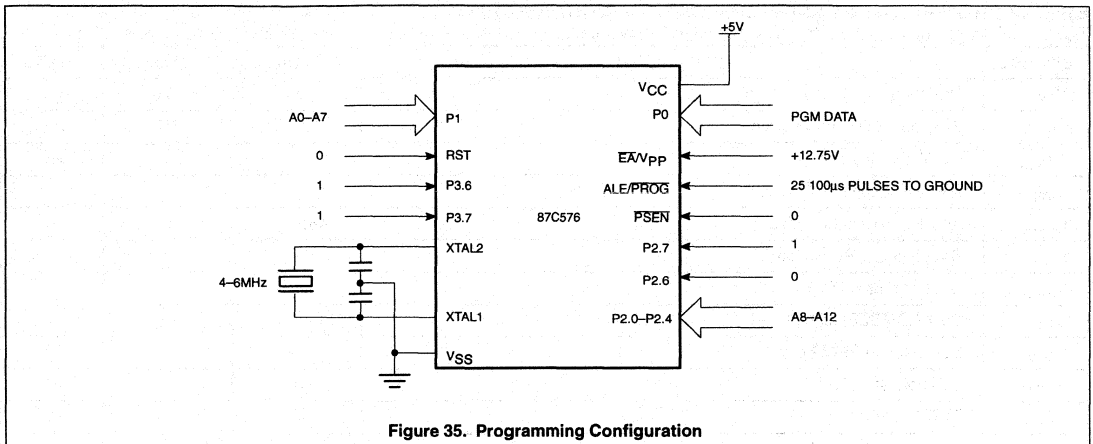

2.  $\text{V}_{\text{PP}} = 12.75\text{V} \pm 0.25\text{V}$ .

3.  $\text{V}_{\text{CC}} = 5\text{V} \pm 10\%$  during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $\text{V}_{\text{PP}}$  is held at 12.75V. Each programming pulse is low for  $100\mu\text{s}$  ( $\pm 10\mu\text{s}$ ) and high for a minimum of  $10\mu\text{s}$ .

## Low-voltage single-chip 8-bit microcontroller

## 80CL580/83CL580

### GENERAL DESCRIPTION

The 83CL580 is manufactured in an advanced CMOS technology. The instruction set of the 83CL580 is based on that of the 8051. The 83CL580 is an 8-bit general purpose microcontroller especially suited for cordless telephones and mobile communication applications. The device has low power consumption and a wide range of supply voltages. For emulation purposes, the 85CL580 (Piggy-back version) with 256 bytes of RAM is recommended. The 83CL580 has two software selectable modes of reduced activity for further power reduction: Idle and Power-down. The 83CL580 also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 46 two-byte, and 16 three-byte.

### FEATURES

- Full static 80C51 CPU
- 8-bit CPU, ROM, RAM, I/O in a single 56-lead VSO56 or 64-lead QFP64 package
- 6K × 8 ROM, expandable externally to 64K bytes
- 256 bytes RAM, expandable externally to 64K bytes
- Five 8-bit ports, 40 I/O lines
- Three 16-bit timer / event counters
- External memory expandable up to 128K, external ROM up to 64K and / or RAM up to 64K
- On-chip oscillator suitable for RC, LC, quartz crystal or ceramic resonator
- Fifteen source, fifteen vector interrupt structure with two priority levels
- Full duplex serial UART
- I<sup>2</sup>C-bus interface for serial transfer on two lines
- A/D converter with power-down mode (8-bit, 4 inputs)
- Pulse width modulated output (8-bit resolution)
- Watchdog timer
- Enhanced architecture with:
  - non-page oriented instructions
  - four eight byte RAM register banks
  - direct addressing
  - multiply, divide, subtract and compare instructions
  - stack depth limited only by available internal RAM (max. 256 bytes)
- Power-Down and IDLE instructions
- Wake-up via external interrupts at Port 1
- Single supply voltage of 2.5V to 6.0V
- Frequency range of 0 to 12MHz
- Very low current consumption: typically 4.5mA at 2.5V / 8MHz
- Operating temperature range: -40 to +85°C

Port 1 pins that have 1s written to them are pulled HIGH by the internal pullups, and in that state can be used as inputs. The Port 1 output buffer can sink/source 4 LS TTL loads. As inputs, Port 1 pins that are externally pulled LOW will source current ( $I_{IL}$ in the characteristics) due to the internal pullups. Port 1 also serves the alternative functions INT2 to INT8, Timer T2 external input external trigger of A/D conversion, and for the I <sup>2</sup> C-bus interface.                         |

# Low-voltage single-chip 8-bit microcontroller

# 80CL580/83CL580

## 1.0 FUNCTIONAL DESCRIPTION

### General

The 83CL580 is a stand-alone high-performance CMOS microcontroller designed for use in real-time applications such as cordless telephone and mobile communications, instrumentation, industrial control, intelligent computer peripherals and consumer products.

The device provides hardware features, architectural enhancements and new instructions to function as a controller for applications requiring up to 64K bytes of program memory and/or up to 64K bytes of data storage.

The 83CL580 contains a non-volatile 6K byte x 8 read-only program memory; a static 256 byte x 8 read/write data memory; 40 I/O lines; three 16-bit timer/event counters; a fifteen-source two priority-level, nested interrupt structure and on-chip oscillator and timing circuit, 4-channel 8-bit A/D converter, watchdog timer, and pulse width modulation output.

The device has two software selectable modes of reduced activity for power reduction; IDLE and Power-down. The Idle mode freezes the CPU while allowing the RAM, timers, serial I/O and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes

the oscillator causing all other chip functions to be inoperative.

In addition, the device provides an I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions, which allows communication with the whole family of I<sup>2</sup>C-bus compatible ICs and a standard UART serial interface.

### CPU Timing

A machine cycle consists of a sequence of 6 states. Each state time lasts for two oscillator periods, thus a machine cycle takes 12 oscillator periods or 1  $\mu$ s if the oscillator frequency is 12 MHz.

### 1.1 Memory Organization

The 83CL580 has a 6K Program Memory (ROM) plus 256 bytes of Data Memory (RAM) on board. The device has separate address spaces for Program and Data Memory (see Figure 1). Using Ports P0 and P2, the 83CL580 can address up to 64K bytes of external memory. The CPU generates both read and write signals (RD and WR) for external Data Memory accesses, and the read strobe (PSEN) for external Program Memory.

#### 1.1.1 Program Memory

The 83CL580 contains 6K bytes of internal ROM. After reset the CPU begins execution at location 0000H. The lower 6K bytes of Program Memory can be implemented in

either on-chip ROM or external Memory. If the EA pin is strapped to V<sub>DD</sub>, then program memory fetches from addresses 000H through 17FFH are directed to the internal ROM. Fetches from addresses 1800H through FFFFH are directed to external ROM. Program counter values greater than 17FFH are automatically addressed to external memory regardless of the state of the EA pin.

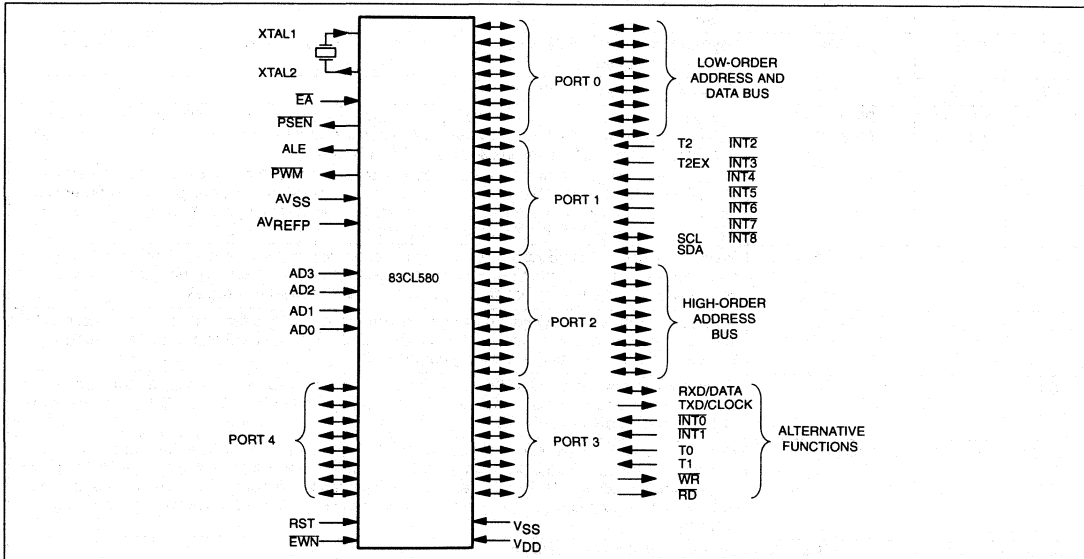

#### 1.1.2 Data Memory

The 83CL580 contains 256 bytes of internal RAM and 40 Special Function Registers (SFR). Figure 1 shows the internal Data Memory space divided into the Lower 128, the Upper 128, and the SFR space. Internal RAM locations 0-127 are directly and indirectly addressable. Internal RAM locations 128-255 are only indirectly addressable. The special function register locations 128-255 are only directly addressable.

#### 1.1.3 Special Function Registers

The upper 128 bytes are the address locations of the SFRs. Figure 3 shows the Special Function Register (SFR) space. SFRs include the port latches, timers, peripheral control, serial I/O registers, etc. These registers can only be accessed by direct addressing. There are 128 bit addressable locations in the SFR address space (SFRs with addresses divisible by eight).

### 1.1.4 Addressing

The 83CL580 has five methods for addressing source operands:

- Register
- Direct
- Register-Indirect
- Immediate
- Base-Register-plus Index-Register-indirect

The first three methods can be used for addressing destination operands. Most instructions have a "destination/source" field that specifies data type, addressing methods and operands involved. For operations other than MOVs, the destination operand is also a source operand.

Access to memory addressing is as follows:

- Registers in one of the four register banks through register: direct or indirect.
- Internal RAM (256 bytes) through direct or register-indirect.
- Special Function Register through Direct.
- External data memory through Register-Indirect
- Program memory look-up tables through Base-Register-plus index-Register-indirect.

### 1.2 I/O facilities

#### 1.2.1 Ports

The 83CL580 has 40 I/O lines treated as one port plus 32 individually addressable bits or

as five parallel 8-bit addressable ports. Port 0, 1, 2 and 3 perform the following alternate functions:

- Port 0: provides the multiplexed low-order address and data bus for expanding the device with standard memories and peripherals.
- Port 1:
  - (1) provides the inputs for the external interrupts INT2 / INT8
  - (2) External activation of Timer 2
  - (3) External trigger of ADC
  - (4) I<sup>2</sup>C-bus
- Port 2: provides the high-order address when expanding the device with external program or data memory.
- Port 3: pins can be configured individually to provide:
  - (1) external interrupt request inputs
  - (2) counter input
  - (3) control signals to read and write to external memories
  - (4) UART input and output
- Port 4 has no alternate function.

To enable a Port pin alternate function, the Port bit latch in its SFR must contain a logic 1.

Each port consists of a latch (Special Function Registers P0 to P4), an output driver and an input buffer. Ports 1,2,3,4 have internal pull-ups. Figure 4(a) shows that the

strong transistor p1 is turned on for only 2 oscillator periods after a 0-to-1 transition in the port latch. When on, it turns on p3 (a weak pull-up) through the inverter. This inverter and p3 form a latch which hold the 1. In Port 0 the pull-up p1 is only on when emitting 1s for external memory access. Writing a 1 to a Port 0 bit latch leaves both output transistors switched off so the pin can be used as a high-impedance input.

#### 1.2.2 Port Options

Thirty-eight of the 40 parallel port pins (excluding P1.6 and P1.7, fixed option 2s) may be individually configured with one of the following options (see Figure 4):

##### Option 1: Standard Port;

quasi-bidirectional I/O with pull-up. The strong booster pull-up p1 is turned on for two oscillator periods after a 0-to-1 transition in the port latch (see Figure 4(a)).

##### Option 2: Open drain;

quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor (see Figure 4(c)).

##### Option 3: Push-Pull;

output with drive capability in both polarities. Under this option, pins can only be used as outputs (See Figure 4(b)).

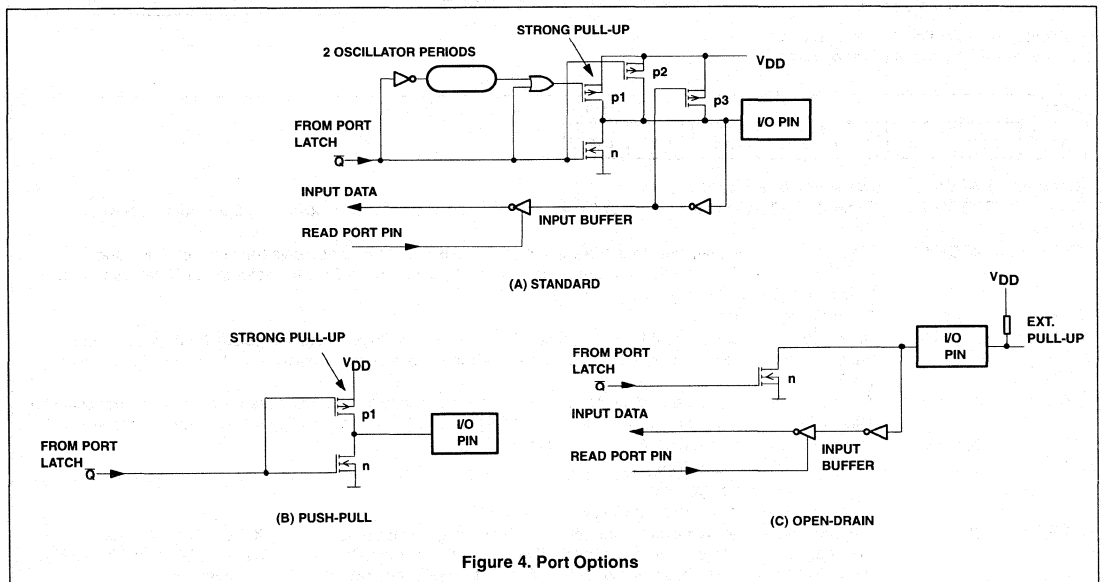

Figure 4. Port Options

# Low-voltage single-chip 8-bit microcontroller

# 80CL580/83CL580

The definition of port options for port 0 is slightly different. Two cases have to be examined. First, accesses to external memory (EA=0 or access above the built-in memory boundary), second, I/O accesses.

### EXTERNAL MEMORY ACCESSES

#### Option 1:

True 0 and 1 are written as address to the external memory (strong pull-up is used).

#### Option 2:

An external pull-up resistor is needed for external accesses.

#### Option 3:

Not allowed for external memory accesses as the port can only be used as output.

### I/O ACCESSES

#### Option 1:

When writing a 1 to the port-latch, the strong pull-up p1 will be on for 2 oscillator periods. No weak pull-up exists. Without an external pull-up, this option can be used as a high-impedance input.

#### Option 2:

Open drain; quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor (see Figure 4(c)).

#### Option 3:

Push-Pull; output with drive capability in both polarities. Under this option, pins can only be used as outputs.

Individual mask selection of the post-reset state is available on any of the above pins.

Make your selection by appending "S" or "R" to option 1, 2, or 3 above (e.g., 1S for a standard I/O to be set after RESET or 2R for an open-drain I/O to be reset after RESET).

#### Option S:

SET; after reset this pin will be initialized HIGH.

#### Option R:

RESET; after reset this pin will be initialized LOW.

### 1.3 Timer/Event Counter

The 83CL580 contains three 16-bit Timer/Counter registers; Timer 0, Timer 1, and Timer 2 which can perform the following functions:

- Measure time intervals and pulse durations
- Count events
- Generate interrupts requests

Timer 0 and Timer 1 can be independently programmed to operate as follows:

- Mode 0; 8-bit timer or counter with divide-by-32 prescaler
- Mode 1; 16-bit time-interval or event counter
- Mode 2; 8-bit time interval or event counter with automatic reload upon overflow
- Mode 3; Timer 0 establishes TL0 and TH0 as two separate counters.

In the "Timer" function, the register is incremented every machine cycle. Since a

machine cycle consists of 12 oscillator periods, the count rate is 1/12 of the oscillator frequency.

In the "Counter" function, the register is incremented in response to a 1-to-0 transition. Since it takes 2 machine cycles (24 oscillator periods) to recognize a 1-to-0 transition, the maximum count rate is 1/24 of the oscillator frequency. To ensure a given level is sampled, it should be held for at least one full machine cycle.

#### 1.3.1 Timer 2

Timer 2 is a 16-bit Timer/Counter. Like Timers 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T2 in the Special Function Register T2CON (Figure 5). It has three operating modes: "capture", "auto-load" and "baud rate generator", which are selected by bits in T2CON as shown in Table 1.

**Table 1. Timer 2 Operating Modes**

| RTCLK | CP/RL2 | TR2 | MODE                |
|-------|--------|-----|---------------------|
| 0     | 0      | 1   | 16-Bit Auto-reload  |
| 0     | 1      | 1   | 16-Bit Capture      |
| 1     | x      | 1   | Baud Rate Generator |
| x     | x      | 0   | (Off)               |

| (MSB)         |                 |                                                                                                                                                                                                                                                                                                                      | (LSB) |       |     |      |        |
|---------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|-----|------|--------|
| TF2           | EXF2            | GF2                                                                                                                                                                                                                                                                                                                  | RTCLK | EXEN2 | TR2 | C/T2 | CP/RL2 |
| <b>Symbol</b> | <b>Position</b> | <b>Name and Significance</b>                                                                                                                                                                                                                                                                                         |       |       |     |      |        |
| TF2           | T2CON.7         | Timer 2 overflow flag set by a Timer 2 overflow and must be cleared by software. TF2 will not be set when RTCLK = 1.                                                                                                                                                                                                 |       |       |     |      |        |
| EXF2          | T2CON.6         | Timer 2 external flag set when either a capture or reload is caused by a negative transition of T2EX and EXEN = 1. When Timer 2 Interrupt is enabled, EXF2 = 1 will cause the CPU to vector to the Timer 2 interrupt routine. EXF2 must be cleared by software.                                                      |       |       |     |      |        |
| GF2           | T2CON.5         | General purpose flag bit.                                                                                                                                                                                                                                                                                            |       |       |     |      |        |
| RTCLK         | T2CON.4         | Receive/transmit clock flag. When set, causes the UART to use Timer 2 overflow pulses for its receive and transmit clock in modes 1 and 3. RTCLK = 0 causes Timer 1 overflows to be used for the receive and transmit clock.                                                                                         |       |       |     |      |        |
| EXEN2         | T2CON.3         | Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of a negative transition on T2EX if Timer 2 is not being used to clock the serial port. EXEN2 = 0 causes Timer 2 to ignore events at T2EX.                                                                                   |       |       |     |      |        |
| TR2           | T2CON.2         | Start/stop control for Timer 2. A logic 1 starts the timer.                                                                                                                                                                                                                                                          |       |       |     |      |        |
| C/T2          | T2CON.1         | Timer or counter select. (Timer 2)<br>0 = Internal timer (OSC/12)<br>1 = External event counter (falling edge triggered)                                                                                                                                                                                             |       |       |     |      |        |
| CP/RL2        | T2CON.0         | Capture/Reload flag. When set, captures will occur on negative transitions at T2EX if EXEN2 = 1. When cleaned, auto-reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When RTCLK = 1, this bit is ignored and the timer is forced to auto-reload on Timer 2 overflow. |       |       |     |      |        |

**Figure 5. T2CON: Timer/Counter 2 Control Register**

# Low-voltage single-chip 8-bit microcontroller

# 80CL580/83CL580

In the Capture Mode there are two options which are selected by bit EXEN2 in T2CON. If EXEN2=0, then Timer 2 is a 16-bit timer or counter which upon overflowing sets bit TF2, the Timer 2 overflow bit, which can be used to generate an interrupt. If EXEN2=1, then Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX causes the current value in the Timer 2 registers, TL2 and TH2, to be captured into registers RCAP2L and RCAP2H, respectively. In addition, the transition at T2EX causes bit EXF2 in T2CON to be set, and EXF2, like TF2, can generate an interrupt. The Capture Mode is illustrated in Figure 6.

In the auto-reload mode there are again two options, which are selected by bit EXEN2 in T2CON. If EXEN2=0, then when Timer 2 rolls over it not only sets TF2 but also causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2L and RCAP2H, which are preset by software. If EXEN2=1, the Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX will also trigger the 16-bit reload and set EXF2.

The auto-reload mode is illustrated in Figure 7.

The baud rate generator mode is selected by RTCLK=1. It will be described in conjunction with the serial port.

### 1.3.2 The Watchdog Timer

In addition to Timer T2 and the standard timers, a watchdog timer consisting of an 11-bit prescaler and an 8-bit timer are also incorporated. See Figure 8.

The timer frequency is derived from the oscillator frequency using the following formula:

$$f_{\text{timer}} = \frac{f_{\text{OSC}}}{(12 \times 2048)}$$

When a timer overflow occurs, the microcontroller is reset and a reset output pulse is generated at pin RST. To prevent a system reset the timer must be reloaded in time by the application software. If the processor suffers a hardware/software malfunction, the software will fail to reload the timer. This failure will produce a reset upon overflow thus preventing the processor running out of control.

The watchdog timer can only be reloaded if the condition flag WLE = PCON .4 has been previously set by software.

At the moment the counter is loaded the condition flag is automatically cleared.

The time interval between the timer's reloading and the occurrence of a reset is dependent upon the reloaded value. For example, this may range from 2ms to 0.5s when using an oscillator frequency of 12MHz.

In the Idle state the watchdog timer and reset circuitry remain active.

The watchdog timer is controlled by the watchdog enable pin (EWN). A logic 0 enables the watchdog timer and disables the Power-down mode. A logic 1 disables and resets the watchdog timer and enables the Power-down mode.

### 1.3.3 Pulse Width Modulated Output

One pulse width modulated output channel is provided in the 83CL580 (Figure 9). This channel outputs pulses of programmable length and interval. The repetition frequency is defined by an 8-bit prescaler PWMP which generates the clock for the counter. The 8-bit counter counts modulo 255, i.e., from 0 to 254 inclusive. The value of the 8-bit counter is compared to the content of the register PWM0. Provided the contents of this registers is greater than the counter value, the output of PWM0 is set LOW. If the content of this register is equal to, or less than the counter value, the output will be HIGH. The pulse-width-ratio is therefore defined by the contents of the register PWM0. The pulse-width-ratio is in the range of 0 to 255/255 and may be programmed in increments of 1/255.

The repetition frequency  $f_{\text{PWM}}$ , at PWM0 output is given by:

$$f_{\text{PWM}} = \frac{f_{\text{OSC}}}{[2 \times (1 + \text{PWMP}) \times 255]}$$

When using an oscillator frequency of 12MHz for example, the above formula gives a repetition frequency range of 92Hz to 23.5kHz.

By loading the PWM0 register with either 00H or FFH, the PWM0 output can be retained at a constant HIGH or LOW level respectively. When loading FFH to the PWM0 register, the 8-bit counter will never actually reach this value.

The PWM0 output pin is driven by push-pull drivers, and is not shared with any other function.

### 1.3.4 A/D Converter

The analogue input circuitry consists of an 4-input analogue multiplexer and an ADC with 8-bit resolution. The analogue reference voltage and analogue ground are connected via separate input pins. The conversion is selectable from 24 machine cycles (24µs at 12MHz oscillator frequency) to 48 machine cycles.

The ADC is controlled using the ADCON control register. Input channels are selected by the analogue multiplexer, care of ADCON register bits 0-1.

### ADC Control Register ADCON (C4H)

| BIT     | SYMBOL | FUNCTION                                                                                                                                                                                                                                                                                                                      |
|---------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADCON.6 | ADPD   | This power down bit switches off the resistor reference to save power even while the CPU is operating.                                                                                                                                                                                                                        |
| ADCON.5 | ADEX   | Enable external start of conversion by pin. 0 = Conversion cannot be started externally by STADC. 1 = Conversion can be started externally by STDAC.                                                                                                                                                                          |
| ADCON.4 | ADCI   | ADC interrupt flag: this flag is set when an ADC conversion result is ready to be read. An interrupt is invoked if this is enabled. The flag must be cleared by software. It cannot be set by software.                                                                                                                       |
| ADCON.3 | ADCS   | ADC start and status: setting this bit starts an ADC conversion. It may be set by software or by the external signal STADC. The ADC logic ensures that this signal is HIGH while the ADC is busy. On completion of the conversion, ADCS is reset after that the interrupt flag ADCI is set. ADCS cannot be reset by software. |

| ADCI | ADCS | OPERATION                                                                                           |
|------|------|-----------------------------------------------------------------------------------------------------|
| 0    | 0    | ADC not busy, a conversion can be started                                                           |
| 0    | 1    | ADC busy, start of a new conversion is blocked                                                      |
| 1    | 0    | Conversion completed, start of a new conversion is blocked                                          |
| 1    | 1    | Intermediate status for a max of one machine cycle before conversion is completed (ADCI=1, ADCS=0). |

| BIT     | SYMBOL | FUNCTION                                                                                                                                                                                                                                             |
|---------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADCON.2 | CKDIV  | In order to run the CPU at the maximum frequency (12MHz) and keep the AD timing at low frequency, the setting of this bit divides the CPU clock by a factor 2. 0 = 24 instruction cycles conversion time. 1 = 48 instruction cycles conversion time. |
| ADCON.1 | AADR1  | The conversion time includes a sampling time of 6 cycles. Analogue input select: this binary coded address selects one of the four analogue port bits.                                                                                               |
| ADCON.0 | AADR0  | It can only be changed when ADCI and ADCS are both LOW. AADR1 is the most significant bit (11 selects the AD3 analogue input channel).                                                                                                               |

| ADCON.1 | ADCON.0 | CHANNEL |
|---------|---------|---------|
| 0       | 0       | AD0     |
| 0       | 1       | AD1     |
| 1       | 0       | AD2     |
| 1       | 1       | AD3     |

## Low-voltage single-chip 8-bit microcontroller

## 80CL580/83CL580

The completion of the 8-bit ADC conversion is flagged by ADCl in the ADCON register and the result is stored in special function register ADCH (C5H).

An ADC conversion in progress is unaffected by an external or software ADC start. The result of a completed conversion remains unaffected provided ADCl = logic 1. While ADCS = logic 1 or ADCl = logic 1, a new ADC START will be blocked and

consequently lost. An ADC conversion already in progress is aborted when the Power-down mode is entered. The result of a completed conversion (ADCl = logic 1) remains unaffected when entering the Idle and Power-down mode.

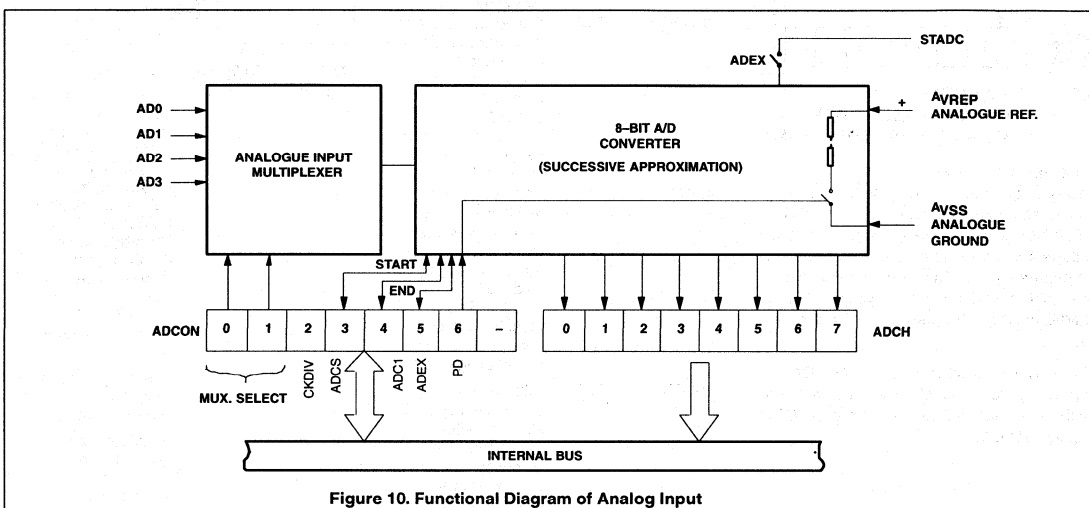

The A/D conversion can be started in 3 ways:

a) Start in operating mode, continue operating mode.

b) Start in operating mode, by setting the ADCS bit, go to idle mode.

c) Set the ADEX bit, go to idle mode and start conversion externally via the STADC pin.

For all 3 cases a - c the interrupt flag ADCl is set upon completion of the conversion.

# Low-voltage single-chip 8-bit microcontroller

# 80CL580/83CL580

## 1.4 Idle and Power-down Operation

Idle mode operation permits the interrupt, serial ports, timer blocks and ADC to continue functioning while the clock to the CPU is halted. The following functions remain active during Idle mode. These functions may generate an interrupt or reset and thus end the Idle mode.

- Timer 0, Timer 1, Timer 2, Timer 3
- UART, I<sup>2</sup>C
- External interrupt
- PWM0 (reset, output=HIGH)
- ADC

The Power-down operation freezes the oscillator. The Power-down mode can only be activated by setting the PD bit in the PCON register. The PD bit can only be set if the EWN input is HIGH.

### 1.4.1 Power Control Register (PCON)

These special modes are activated by software via the Special Function Register PCON. Its hardware address is 87H. [PCON is not bit addressable.]

|      |   |   |     |     |      |    |     |
|------|---|---|-----|-----|------|----|-----|
| 7    | 6 | 5 | 4   | 3   | 2    | 1  | 0   |
| SMOD | - | - | WLE | GF1 | GF0V | PD | IDL |
| MSB  |   |   |     | LSB |      |    |     |

| BIT    | SYMBOL | FUNCTION                                                                                                                       |
|--------|--------|--------------------------------------------------------------------------------------------------------------------------------|
| PCON.7 | SMOD   | Double Baud rate bit. When set to logic 1 baud rate is doubled when the UART serial port is being used in modes 1, 2, or 3.    |
| PCON.6 | -      | (reserved)                                                                                                                     |
| PCON.5 | -      | (reserved)                                                                                                                     |
| PCON.4 | WLE    | Watchdog load enable. This flag must be set by software prior to loading T3 (watchdog timer). It is cleared when T3 is loaded. |
| PCON.3 | GF1    | General-purpose flag bit                                                                                                       |
| PCON.2 | GF0    | General-purpose flag bit                                                                                                       |
| PCON.1 | PD     | Power-down bit. Setting this bit activates the Power-down mode. It can only be set if input EWN is high.                       |
| PCON.0 | IDL    | Idle mode bit. Setting this bit activates the Idle mode.                                                                       |

If logic 1s are written to PD and IDL at the same time, PD takes precedence. The reset value of PCON is (0XX00000).

### 1.4.2 Power-down Mode

The instruction setting PCON.1 is the last executed prior to going into the Power-down mode. In Power-down mode the oscillator is stopped. The contents of the on-chip RAM and SFRs are preserved. The port pins output the values held by their respective SFRs. ALE and PSEN are held LOW.

### 1.4.3 Wake-up Mode

Setting the PD flag in the PCON register forces the controller into the Power-down mode. Setting this flag enables the controller to be woken-up from the Power-down mode with either the external interrupts INT2 / INT8, or a reset operation.

The wake-up operation after power-down in this controller has two basic approaches:

#### 1.4.3.1 Wake-up Using INT2 to INT8

If any of INT2 to INT8 are enabled, the 83CL580 can be woken-up from power-down mode with the external interrupts. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods. This is controlled by an on-chip delay counter.

#### 1.4.3.2 Wake-up Using RESET

To wake-up the 83CL580 the RESET pin has to be kept HIGH for a minimum of 24 periods. The on-chip delay counter is inactive. The user has to ensure that the oscillator is stable before any operation is attempted. Figure 11 illustrates the two possibilities for wake-up.

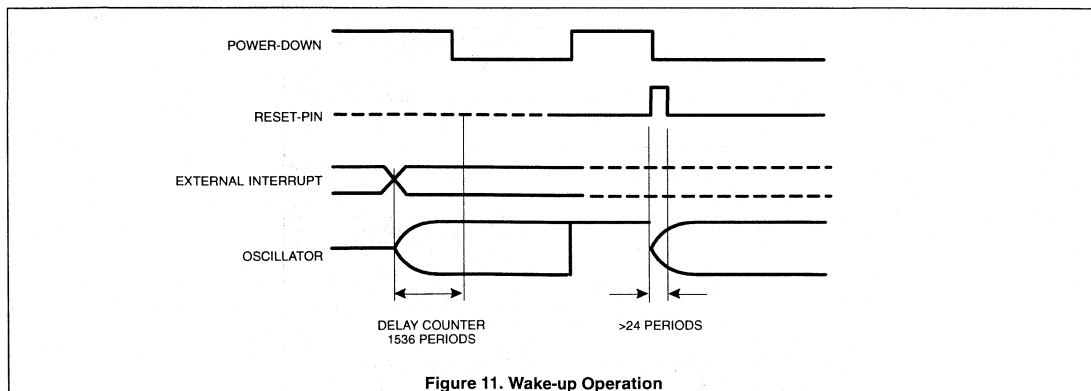

Figure 11. Wake-up Operation

# Low-voltage single-chip 8-bit microcontroller

# 80CL580/83CL580

### 1.4.4 Idle Mode

The instruction that sets PCON.0 is the last instruction executed in the normal operating mode before Idle mode is activated. Once in the Idle mode, the CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, RAM and all other registers maintain their data during Idle mode. The status of the external pins during Idle mode is shown in Table 2.

There are two methods used to terminate the Idle mode. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating Idle mode. The interrupt is serviced, and following the return-from-interrupt instruction RETI, the next instruction to be executed will be the one which follows the instruction that wrote a logic 1 to PCON.0.

Flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or during Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When Idle mode is terminated by an

interrupt, the service routine can examine the status of the flag bits.

The second method of terminating the Idle mode is with an external hardware reset, or an internal reset caused by an overflow of Timer T3. Since the oscillator is still running, the hardware reset is required to be active for two machine cycles (24 oscillator periods) to complete the reset operation.

Reset redefines all SFRs, but does not affect the on-chip RAM.

In the Power-down mode, V<sub>DD</sub> may be reduced to minimize power consumption. However, the supply voltage must not be reduced until Power-down mode is active, and must be held active until the oscillator has restarted and stabilized.

The status of the external pins during Idle and Power-down mode is shown in Table 2. If the Power-down mode is activated whilst accessing external memory, port data held in the Special Function Register P2 is restored to Port 2. If the data is a logic 1, the port pin is held HIGH during the Power-down mode by the strong pull-up transistor p1 (see Figure 4(a)).

### 1.5 I<sup>2</sup>C Bus Serial I/O

The serial port supports the twin line I<sup>2</sup>C-bus. The I<sup>2</sup>C-bus consists of a data line (SDA) and a clock line (SCL). These lines also function as I/O port lines P1.7 and P1.6 respectively. The system is unique because data transport, clock generation, address recognition and bus control arbitration are all controlled by hardware. The I<sup>2</sup>C-bus serial I/O has complete autonomy in byte handling and operates in four modes:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

These functions are controlled by the S1CON register. S1STA is the status register whose contents may also be used as a vector to various service routines. S1DAT is the data shift register and S1ADR the slave address register. Slave address recognition is performed by hardware.

**Table 2. Status of the External Pins During Idle and Power-down Modes**

| MODE       | MEMORY   | ALE | PSEN | PORT 0    | PORT 1    | PORT 2    | PORT 3    | PORT 4    | PWM0   |
|------------|----------|-----|------|-----------|-----------|-----------|-----------|-----------|--------|
| Idle       | Internal | 1   | 1    | Port data | Port data | Port data | Port data | Port data | Active |
| Idle       | External | 1   | 1    | Floating  | Port data | Address   | Port data | Port data | Active |
| Power-down | Internal | 0   | 0    | Port data | Port data | Port data | Port data | Port data | HIGH   |
| Power-down | External | 0   | 0    | Floating  | Port data | Port data | Port data | Port data | HIGH   |

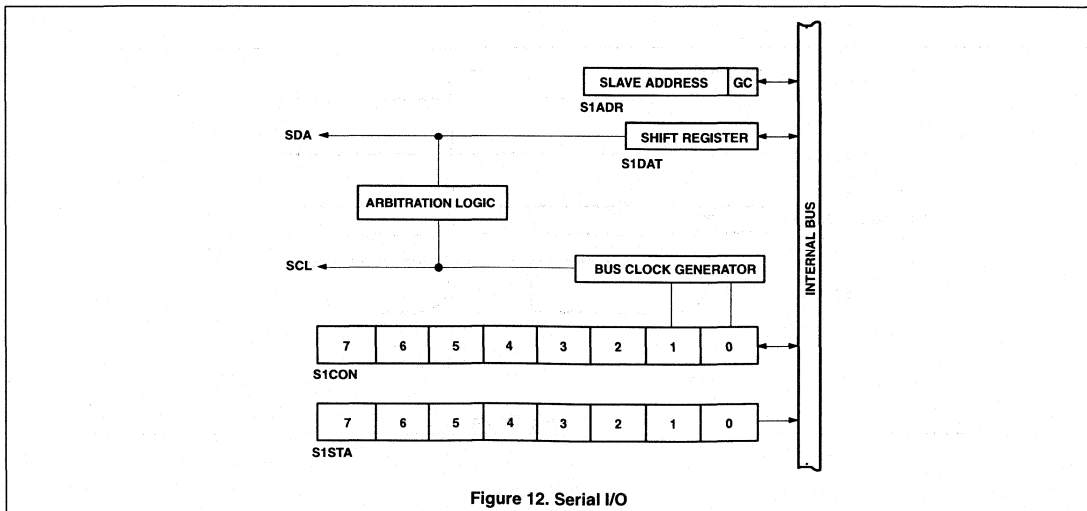

Figure 12. Serial I/O

## Low-voltage single-chip 8-bit microcontroller

## 80CL580/83CL580

**Serial Control Register S1CON (D8H)**

|     |      |     |     |    |    |     |     |
|-----|------|-----|-----|----|----|-----|-----|
| CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-----|------|-----|-----|----|----|-----|-----|

**CR0, CR1, CR2** These three bits determine the serial clock frequency when SIO is in a master mode. See Table 3.

**AA** Assert acknowledge bit. When the AA flag is set, an acknowledge (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when:

- own slave address is received
- general call address is received (S1ADR.0=1)
- data byte received while device is programmed as master
- data byte received while device is a selected slave

With AA = 0, no acknowledge will be returned. Consequently, no interrupt is requested when the "own slave address" or general call address is received.

**SI** SIO interrupt flag. When the SI flag is set, an acknowledge is returned after any one of the following conditions:

- a start condition is generated in master mode
- own slave address received during AA = 1
- general call address received while S1ADR.0 and AA = 1
- data byte received or transmitted in master mode (even if arbitration is lost)
- data byte received or transmitted as selected slave
- stop or start condition received as selected slave receiver or transmitter

**STO** STOP flag. With this bit set while in master mode a STOP condition is generated. When a STOP condition is detected on the bus, the SIO hardware clears the STO flag. In the slave mode, the STO flag may also be set to recover from an error condition. In this case no STOP condition is transmitted to the I<sup>2</sup>C-bus. However, the SIO hardware behaves as if a STOP condition has been received and releases SDA and SCL. The SIO then switches to the "not addressed" slave receiver mode. The STO flag is automatically cleared by hardware.

**STA** START flag. When the STA bit is set in slave mode, the SIO hardware checks the status of the I<sup>2</sup>C-bus and generates a START condition if the bus is free. If STA is set while the SIO is in master mode, SIO transmits a repeated START condition.

**ENS1** When ENS1 = 0, the SIO is disabled. The SDA and SCL outputs are in a high-impedance state; P1.6 and P1.7 function as open drain ports. When ENS = 1, the SIO is enabled. The P1.6 and P1.7 port latches must be set to logic 1.

**Table 3. SCL Frequency**

| CR2 | CR1 | CR2 | f <sub>osc</sub> Divided By | Bit Rate (kHz) at f <sub>osc</sub> |      |       |
|-----|-----|-----|-----------------------------|------------------------------------|------|-------|

S1STA is an 8-bit read-only special function register. S1STA.3-S1STA.7 hold a status code. S1STA.0-S1STA.2 are held LOW. The contents of S1STA may be used as a vector to a service routine. This optimizes response time of the software and consequently that of the I<sup>2</sup>C-bus.

The following is a list of the status code:

#### Abbreviations used:

- SLA: 7-bit slave address
- R: Read bit
- W: Write bit
- ACK: Acknowledgement (acknowledge bit = 0)
- ACKNOT: Not Acknowledge (acknowledge bit = 1)
- DATA: 8-bit byte to or from the I<sup>2</sup>C bus
- MST: Master
- SLV: Slave
- TRX: Transmitter
- REC: Receiver

#### MST/TRX Mode

##### S1STA Value

- 08H A START condition has been transmitted
- 10H A repeated START condition has been transmitted
- 18H SLA and W have been transmitted, ACK received
- 20H SLA and W have been transmitted, ACKNOT received
- 28H DATA of S1DAT has been transmitted, ACK received
- 30H DATA of S1DAT has been transmitted, ACKNOT received
- 38H Arbitration lost in SLA, R/W or DATA

#### MST/REC Mode

##### S1STA Value

- 08H A START condition has been transmitted
- 10H A repeated START condition has been transmitted
- 38H Arbitration lost while returning ACKNOT
- 40H SLA and R have been transmitted, ACK received
- 48H SLA and R have been transmitted, ACKNOT received
- 50H DATA has been received, ACK returned
- 58H DATA has been received, ACKNOT returned

#### SLV/REC Mode

##### S1STA Value

- 60H Own SLA and W have been received, ACK returned
- 68H Arbitration lost in SLA, RW as MST. Own SLA and W have been received, ACK returned.
- 70H General Call has been received, ACK returned
- 78H Arbitration lost in SLA, RW as MST. General Call has been received.
- 80H Previously addressed with own SLA. DATA byte received, ACK returned.
- 88H Previously addressed with own SLA. DATA byte has been received, ACKNOT has been returned.
- 90H Previously addressed with General Call. DATA byte has been received, ACK has been returned.
- 98H Previously addressed with General Call. DATA byte has been received, ACKNOT has been returned.
- A0H A STOP condition or repeated START condition has been received while still addressed as SLV/REC or SLV/TRX.

#### SLV/TRX Mode

##### S1STA Value

- A8H Own SLA and R have been received, ACK returned.
- B0H Arbitration lost in SLA, R/W as MST. Own SLA and R have been received, ACK returned.
- B8H DATA byte has been transmitted, ACK received.
- C0H DATA byte has been transmitted, ACKNOT received.
- C8H Last data byte has been transmitted (AA = logic 0), ACK received.

#### Miscellaneous

##### S1STA Value

- 00H Bus error during MST mode or selected SLV mode, due to an erroneous START or STOP condition.
- F8H No relevant state information available, SI = 0.

### Data Shift Register S1DAT (DAH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

This register contains the serial data to be transmitted or data that has just been received. Bit 7 is transmitted or received first; i.e., data is shifted from left to right.

### Own Address Register S1ADR (DBH)

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

This 8-bit register may be loaded with the 7-bit address to which the controller will respond when programmed as a slave receiver/transmitter. The LSB bit (GC) is used to determine whether the general CALL address is recognized.

S1ADR.0, GC: 0 = general CALL address is not recognized.

1 = general CALL is recognized.

S1ADR.7 - 1: own slave address

### 1.6 Standard serial interface SIOO: UART

This serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the register. (However, if the first byte still has not been read by the time reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed at Special Function Register S0BUF. Writing to S0BUF loads the transmit register, and reading S0BUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

**Mode 0:** Serial data enters and exits through RxD. TxD outputs the shift clock. 8 bits are transmitted/received (LSB first). The baud is fixed at 1/12 the oscillator frequency.

**Mode 1:** 10 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SCON. The baud rate is variable.

## Low-voltage single-chip 8-bit microcontroller

## 80CL580/83CL580

**Mode 2:** 11 bits are transmitted (through TxD) or received (through RxD): start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8 in SCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in Special Function Register SCON, while the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency.

**Mode 3:** 11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses S0BUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

**1.6.1 Multiprocessor Communications**  
Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that were not being addressed leave their SM2s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the

receive interrupt will not be activated unless a valid stop bit is received.

### 1.6.2 Serial port control register

The serial port control and status register is the Special Function Register S0CON, shown in Figure 13. The register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

**Baud Rates**—The baud rate in Mode 0 is fixed: Mode 0 Baud Rate = Oscillator Frequency / 12. The baud rate in Mode 2 depends on the value of bit SMOD in Special Function Register PCON. If SMOD = 0 (which is the value on reset), the baud rate is 1/64 the oscillator frequency. If SMOD = 1, the baud rate is 1/32 the oscillator frequency.

Mode 2 Baud Rate =  $(2^{\text{SMOD}}/64)$  (Oscillator Frequency)

The baud rates in Modes 1 and 3 are determined by the Timer 1 or Timer 2 overflow rate.

### Using Timer 1 to Generate Baud Rates

When Timer 1 is used as the baud rate generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of SMOD as follows:

Modes 1,3 Baud Rate =  $(2^{\text{SMOD}}/32)$  (Timer 1 Overflow Rate)

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either "timer" or "counter" operation, and in any of its 3 running modes. In most typical applications, it is configured for "timer operation, in the auto-reload mode (high nibble of TMOD = 0010B). In that case the baud rate is given by the formula:

Mode 1, 3 Baud Rate =  $\{(2^{\text{SMOD}}/32) \times (\text{Oscillator Frequency})\} / \{12 \times (256 - \text{TH1})\}$

One can achieve very low baud rates with Timer 1 by leaving the Timer 1 interrupt enabled, and configuring the Timer to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload. Table 4 lists various commonly used baud rates and how they can be obtained from Timer 1.

### Using Timer 2 to Generate Baud Rates

Timer 2 is selected as the baud rate generator by setting RTCLK in T2CON (Figure 14).

The baud rate generator mode is similar to the auto-reload mode, in that a rollover in TH2 causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2H and RCAP2L, which are preset by software.

Now, the baud rates in Modes 1 and 3 are determined by Timer 2's overflow rate as follows:

Modes 1,3 Baud Rate =  $(\text{Timer 2 Overflow Rate}) / 16$

The Timer 2 can be configured for either "timer" or "counter" operation. In the most typical applications, it is configured for "timer" operation (CT2 = 0). "Timer" operation is a little different for Timer 2 when it's being used as a baud rate generator. Normally, as a timer is would increment every machine cycle (thus at 1/12 the oscillator frequency). As a baud rate generator, however, it increments every state time (thus at 1/2 the oscillator frequency). In that case the baud rate is given by the formula:

Modes 1,3 Baud Rate =  $(\text{Oscillator Frequency}) / \{32 \times (65536 - (\text{RCAP2H}, \text{RCAP2L}))\}$

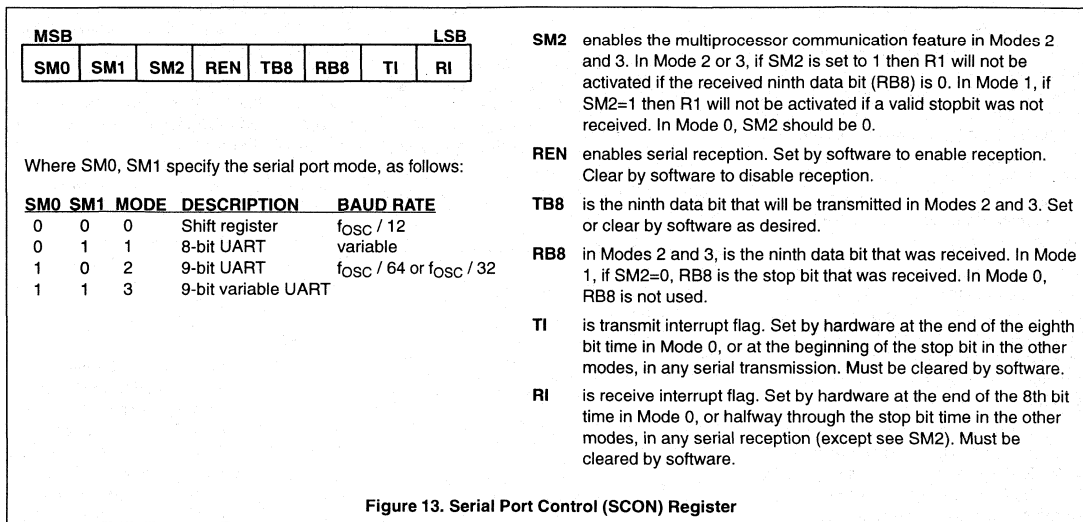

where (RCAP2H, RCAP2L) is the content of RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

Note that a rollover does not set TF2, and will not generate an interrupt. Therefore, the Timer 2 interrupt does not have to be disabled when Timer 2 is in the baud rate generator mode. Note too, that if EXEN2 is set, a 1-to-0 transition in T2EX will set EXF2 but will not cause a reload from (RCAP2H, RCAP2L) to (TH2, TL2). Thus when Timer 2 is in use as a baud rate generator, T2EX can be used as an extra external interrupt, if desired.

It should be noted that when Timer 2 is running (TR2 = 1) in "timer" function in the baud rate generator mode, one should not try to read or write TH2 or TL2. Under these conditions the Timer is being incremented every state time, and the results of a read or write may not be accurate. The RCAP registers may be read, but shouldn't be written to, because a write might overlap a reload and cause write and/or reload errors. Turn the Timer off (clear TR2) before accessing the Timer 2 or RCAP register, in this case.

Low-voltage single-chip 8-bit microcontroller

## 1.7 Interrupt system

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution, a multiple-source, two-priority-level, nested interrupt system is provided. The 83CL580 acknowledges interrupt requests from fifteen sources as follows:

- INT0 through INT8
- Timer 0, Timer 1, and Timer 2
- I<sup>2</sup>C bus serial I/O
- UART
- ADC

Each interrupt vectors to a separate location in program memory for its service routine.

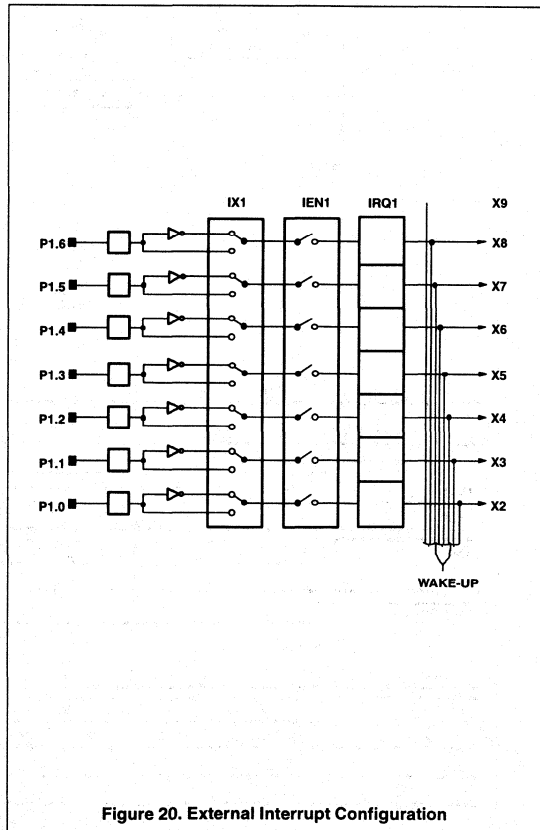

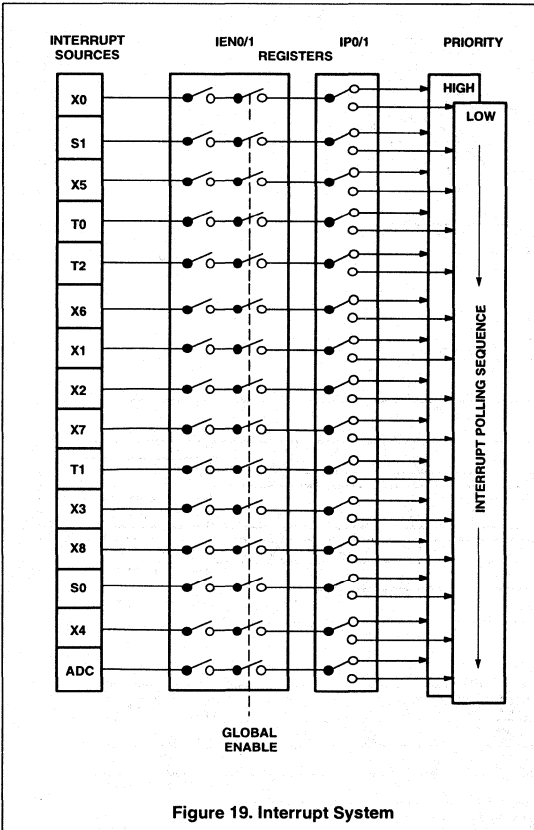

Each source can be individually enabled or disabled by corresponding bits in the Interrupt Enable Registers (IEN0, IEN1). The priority level is selected via the Interrupt Priority register (IP0, IP1). All enabled sources can be globally disabled or enabled.

**1.7.1 External interrupts INT2/INT8**  
 Port 1 lines serve an alternative purpose as seven additional interrupts INT2 to INT8. When enabled, each of these lines may "wake-up" the device from Power-down mode. Using the IX1 register, each pin may be initialized to either active HIGH or LOW. IRQ1 is the interrupt request flag register. Each flag, if the interrupt is enabled, will be set on an interrupt request but must be cleared by software, i.e., via the interrupt software or when the interrupt is disabled.

A low-priority interrupt can be interrupted by a high-priority interrupt, but not by another

low-priority interrupt. A high-priority interrupt cannot be interrupted by any other interrupt source. If two interrupt requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence (see Figure 19).

The port 1 interrupts are level sensitive. A port 1 interrupt will be recognized when a level (HIGH or LOW depending on Interrupt Polarity Register IX1) on P1x is held active for at least one machine cycle. The Interrupt Request is not served until the next machine cycle.

**Interrupt Priority**—Each interrupt priority source can be set to either high or low priority. If both priorities are requested simultaneously, the controller will branch to the high priority vector.

A low priority interrupt can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

### 1.7.3 Related Registers

The following registers are used in conjunction with the interrupt system:

| REGISTER | FUNCTION                                     | SFR ADDRESS |
|----------|----------------------------------------------|-------------|
| IX1      | Interrupt polarity register                  | E9H         |
| IRQ1     | Interrupt request flag register              | C0H         |
| IEN0     | Interrupt enable register                    | A8H         |
| IEN1     | Interrupt enable register (INT2-INT8, ADC)   | E8H         |
| IP0      | Interrupt priority register                  | B8H         |
| IP1      | Interrupt priority register (INT2-INT8, ADC) | F8H         |

### 1.8 Oscillator Circuitry

The on-chip oscillator circuitry of the 83CL580 is a single-stage inverting amplifier biased by an internal feedback resistor (Figure 21). For operation as a standard quartz oscillator, no external components are needed, except at 32kHz. When using external capacitors, ceramic resonators, coils and RC networks to drive the oscillator, five different configurations are supported (see Figure 22 and oscillator options).

In the Power-down mode the oscillator is stopped and XTAL1 is pulled HIGH. The

oscillator inverter is switched off to ensure no current will flow regardless of the voltage at XTAL1. To drive the device with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 to float, as shown in Figure 18(f). There are no requirements on the duty cycle of the external clock, since the input to the internal clocking circuitry is buffered by a flip-flop.

The following options are provided for optimum on-chip oscillator performance. Please state option when ordering.

#### 1.8.1 Oscillator Options (see Figure 22)

- Osc 1: Figure 22(c). An option for 32kHz clock applications with external trimmer for frequency adjustment. A 4.7MΩ bias resistor is needed for use in parallel with the crystal.
- Osc 2: Figure 22(e). An option for low-power, low-frequency operations using LC components or quartz.
- Osc 3: An option for medium frequency range applications.
- Osc 4: An option for high frequency range applications.
- RC: Figure 22(g). An option for an RC oscillator.

**NOTES:**

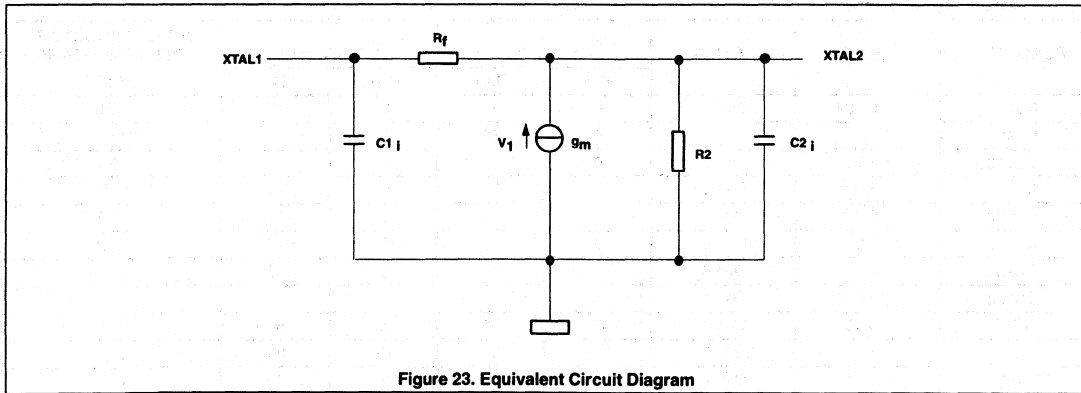

- 32kHz quartz crystals with a series resistance higher than 15kΩ will reduce the guaranteed supply voltage range to 2.5 - 3.5V.
- The equivalent circuit data of the internal oscillator compares with that of matched crystals.

**1.9 Reset Circuitry**

To initialize the 83CL580, a reset is performed by either of two methods:

- via the RST pin
- via a power-on-reset

It leaves the internal registers as follows:

| Register      | Content   |
|---------------|-----------|
| ACC           | 0000 0000 |
| ADCH          | 1111 1111 |

| PCON          | 0XX0 0000 |
| P0 - P4       | 1111 1111 |
| PWM0          | 0000 0000 |
| PWMP          | 0000 0000 |
| RCAP2H        | 0000 0000 |
| RCAP2L        | 0000 0000 |
| S0BUF         | XXXXXXXX  |
| S0CON         | 0000 0000 |
| S1ADR         | 0000 0000 |
| S1CON         | 0000 0000 |
| S1DAT         | 0000 0000 |
| S1STA         | 1111 1000 |
| PSW           | 0000 0000 |
| SP            | 0000 0111 |
| TCON          | 0000 0000 |
| T2CON         | 0000 0000 |
| T3            | 0000 0000 |
| TH0, TH1, TH2 | 0000 0000 |
| TL0, TL1, TL2 | 0000 0000 |
| TMOD          | 0000 0000 |

The reset state of the port pins is mask-programmable and can therefore be defined by the user. The standard reset value for port P0-P4 is 1111 1111.

The reset input to the 83CL580 is the RST pin. A Schmitt trigger qualifies the input for noise rejection. The output of the Schmitt trigger is sampled by the reset circuitry every machine cycle.

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset. Port pins adopt their reset state immediately after RST goes HIGH. During reset ALE and PSEN are held HIGH.

The external reset is asynchronous to the internal clock. The RST pin is sampled during State 5, Phase 2 of every machine cycle. After a HIGH is detected at the RST pin, an internal reset is repeated every cycle until RST goes LOW. The reset circuitry is also affected by the watchdog timer T3, see paragraph 1.3.2.

The internal RAM is not affected by reset. When V<sub>DD</sub> is turned on the RAM contents are indeterminate.

**1.9.1 Power-on Reset**

The 83CL580 contains on-chip circuitry which switch the port pins to the customer defined logic level as soon as V<sub>DD</sub> exceeds 1.3V if

the mask option "ON" has been chosen. As soon as the minimum supply voltage is reached, the oscillator will start up. However, to ensure that the oscillator is stable before the controller starts, the clock signals are gated away from the CPU for a further 1536 oscillator periods. During that time the CPU is held in a reset state.

A hysteresis of approximately 50mV at a typical power-on switching level of 1.3V will ensure correct operation.

The on-chip Power-on reset circuitry can also be switched off via the mask option "OFF". This option reduces the Power-down current to typically 800nA and can be chosen if external reset circuitry is used. For applications not requiring the internal reset, option 'OFF' should be chosen.

An automatic reset can be obtained at power-on by connecting the RST pin to V<sub>DD</sub> via a 10µF capacitor. At power-on, the voltage on the RST pin is equal to V<sub>DD</sub> minus the capacitor voltage, and decreases from V<sub>DD</sub> as the capacitor discharges through the internal resistor R<sub>RST</sub> to ground. The larger the capacitor, the more slowly V<sub>RST</sub> decreases. V<sub>RST</sub> must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles.

NOTES ON NEXT PAGE.

## Low-voltage single-chip 8-bit microcontroller

80CL580/83CL580

**NOTES TO DC CHARACTERISTICS:**

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10\text{ns}$ ;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL1 not connected;  $\overline{EA} = \text{RST} + \text{PORT } 0 = V_{DD}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10\text{ns}$ ;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL2 is not connected;  $\overline{EA} = \text{PORT } 0 = V_{DD}$ .
- The power-down current is measured with all output pins disconnected; XTAL1 not connected;  $\overline{EA} = \text{Port } 0 = V_{DD}$ ;  $\text{RST} = V_{SS}$ .
- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3 pins when these pins make a 1-to-0 transition during bus operations. In the most adverse conditions (capacitive loading > 100pF) the noise pulse on the ALE line may exceed 0.8V. In this event it may be required to qualify ALE with a Schmitt trigger, or use an address latch with a Schmitt trigger strobe input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and PSEN to momentarily fall below the 0.9% of  $V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6/SCL and P1.7/SDA meet the I<sup>2</sup>C-bus specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0, while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
- Absolute error — The maximum difference between actual and ideal code transitions. Absolute error accounts for all deviations of an actual converter from an ideal converter.
- Zero offset — The difference between the actual and ideal input voltage corresponding to the first actual code transition.
- Differential non-linearity — The difference between the actual and ideal code widths.
- Channel to channel variation — The difference between corresponding code transitions of actual characteristics taken from different channels under the same temperature, voltage and frequency conditions. Not tested, but verified on sampling basis.

## NOTES:

- Interfacing the PCF83C580 to devices with float times up to 75ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

## Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### DESCRIPTION

The 80C592/83C592/87C592 (hereafter referred to generically as the 8XC592) is a stand-alone high-performance microcontroller designed for use in automotive and general industrial applications. In addition to the 80C51 standard features, this device provides a number of dedicated hardware functions for these applications. Three versions of this derivative will be offered:

- 83C592 (ROM version)
- 80C592 (ROMless version)
- 87C592 (EPROM/OTP version)

It combines the functions of the existing 8XC552 and the Philips CAN-Controller PCA82C200 (CAN: Controller Area Network) with the following enhanced features:

- 16K byte Program Memory
- 2 × 256 byte Data Memory
- DMA between CAN Transmit/Receive buffer and internal RAM

The temperature range includes  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  as well as automotive temperature range  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  for the ROM and ROMless version with a maximum clock frequency of 16MHz. The 87C592 has a temperature range of  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .

The main differences to the 8XC552 microcontroller are:

- a CAN-controller substitutes the I<sup>2</sup>C-serial interface
- 16K byte programmable ROM resp. EPROM instead of 8K byte
- additional 256 byte RAM.

The 8XC592 contains a 16k × 8 EPROM (87C592), ROM (83C592) program memory, a volatile 512 × 8 read/write data memory, a Controller Area Network (CAN) controller, six 8-bit I/O ports, one 8-bit input port, two 16-bit timer/event counters (identical to the timers of the 80C51), an additional 16-bit timer coupled to capture and compare latches, a 15-source, two-priority-level, nested interrupt structure, a 10-input ADC, a dual DAC pulse width modulated interface, two serial interfaces

(UART and CAN), a "watchdog" timer and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC592 memory can be expanded externally using standard TTL compatible memories and logic.

### FEATURES

- 80C51 core architecture
- 16k × 8 EPROM (87C592)
- 16k × 8 ROM (83C592)
- ROMless (80C592)
- 512 × 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- An additional 16-bit timer/counter coupled to four capture registers and three compare registers
- A 10-bit ADC with eight multiplexed analog inputs
- Two 8-bit resolution, pulse width modulation outputs
- 15 interrupt sources with 2 priority levels
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- CAN controller with DMA transfer between internal data RAM and CAN registers
- Up to 1 Mbit/s CAN-Controller with bus failure management facility
- V<sub>DD</sub>/2 reference voltage
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- Extended temperature ranges ( $-40$  to  $+125^{\circ}\text{C}$ )
- OTP package available
- ROM code protection

### PIN CONFIGURATION

| Pin | Function           | Pin | Function           |

| AV <sub>DD</sub>   | 61      | I    | <b>Analog Power Supply</b> (for ADC and CAN receiver)                                                                                                                                                                                                                                                                                                                                                                                      |

### NOTE:

- To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub> + 0.5V or V<sub>SS</sub> - 0.5V, respectively.

The 8XC592 has the same operation as the 8XC552 for all features except the CAN interface and the AuxRAM. Please refer to the 8XC552 section in this data handbook for information on the PWM outputs, A/D converter, Timers 0, 1, or 2, the Watchdog Timer and the UART (SIO0).

### INTERNAL DATA MEMORY

The internal Data Memory is divided into three physically separated parts: the 256 byte of Main RAM, the 256 byte of AuxRAM, and

the 128 byte special function area. these can be addressed each in a different way.

- Main RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- Main RAM 128 to 255 can only be addressed indirectly. Address pointers are R0 and R1 of the selected register bank.
- AuxRAM 0 to 255 is indirectly addressable in the same way as the external Data Memory with MOVX instructions. Address pointers are R0, R1 of the selected register

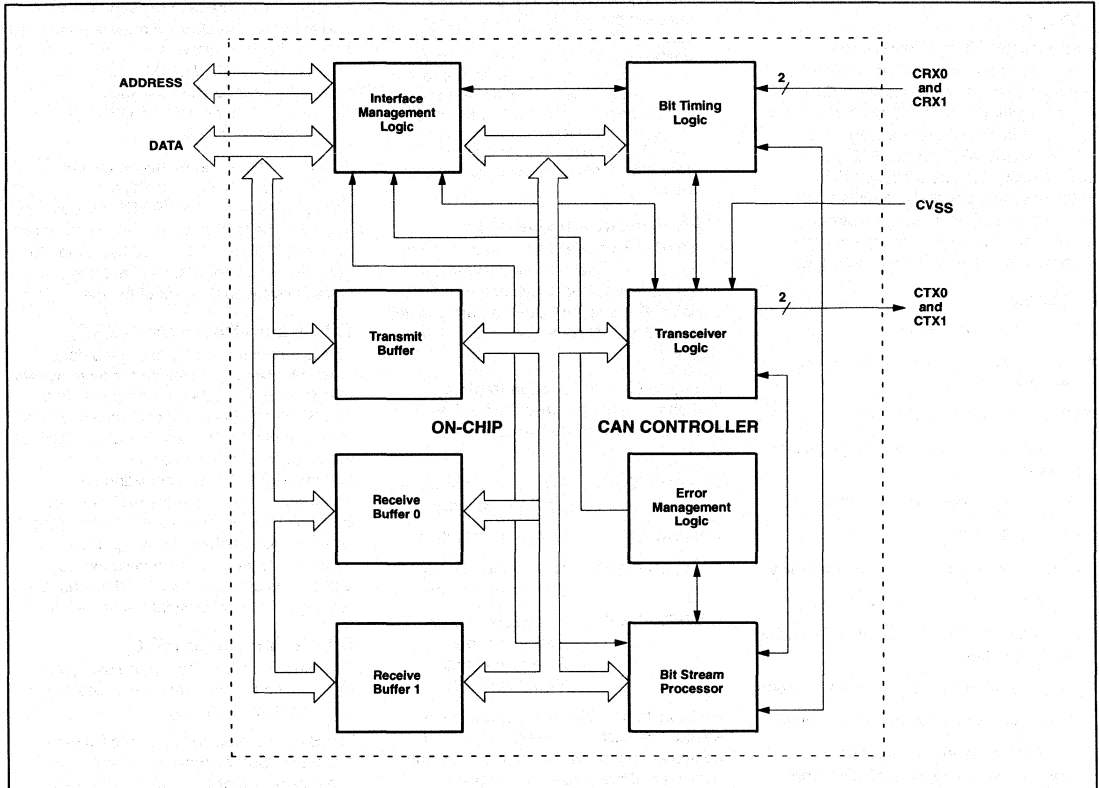

bank and the DPTR. An access to AuxRAM 0 to 255 will not affect the ports P0, P2, P3.6 and P3.7 during internal program execution.

An access to external Data Memory locations higher than 255 will be performed with the MOVX @DPTR instructions in the same way as in the 80C51 structure, so with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read strobe signals. Note that these external Data Memory locations cannot be accessed with R0 or R1 as address pointer.

**BLOCK DIAGRAM OF 8XC592 CAN CONTROLLER CIRCUITRY**

## Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

### CAN FUNCTIONAL DESCRIPTION

#### SIO1, CAN (Controller Area Network)

CAN is the definition of a high performance communication protocol for serial data communication. The 8XC592 on-chip CAN Controller is a full implementation of the CAN-protocol. With the 8XC592, powerful local networks can be built, both for automotive and general industrial environments. This results in a strongly reduced wiring harness and enhanced diagnostic and supervisory capabilities.

#### Features

- Multi-master architecture
- Bus access priority determined by the message identifier
- 2032 message identifier
- Guaranteed latency time for high priority messages
- Powerful error handling capability
- Data length from 0 up to 8 bytes
- Multicast and broadcast message facility
- Non-destructive bit-wise arbitration
- Non-return-to-zero (NRZ) coding/decoding with bit stuffing
- Programmable transfer rate (up to 1 Mbit/s)
- Programmable output driver configuration
- Suitable for use in a wide range of networks, including the SAE's network classes A, B and C
- DMA providing high-speed on-chip data exchange
- Bus failure management facility
- AV<sub>DD/2</sub> reference voltage

The CAN Controller meets the following automotive requirements:

- Short message length
- Guaranteed latency time\* for urgent messages
- Bus access priority, determined by the message identifier
- Powerful error handling capability
- Configuration flexibility to allow area network expansion.

#### NOTE:

- The latency time defines the period between the initiation (Transmission Request) and the start of the transmission on the bus. The latency time strongly depends on a large variety of bus-related conditions. In the case of a message being transmitted on the bus and one distortion, the latency time can be up to 149 bit times (worst case). For more information, see the application note on bit timing.

#### CAN Functional Overview

The 8XC592 includes all hardware modules necessary to implement the transfer layer which represents the kernel of the CAN protocol. Refer to the block diagram (previous page) of the CAN controller portion of the 8XC592.

#### Interface Special Function Registers

The data transfer between the CPU and the CAN part of the 8XC592 is done via four SFRs:

|               |                                                                     |
|---------------|---------------------------------------------------------------------|
| CANADR (DBH): | to point to a register of the CAN-controller                        |
| CANDAT (DAH): | to read or write data                                               |
| CANCON (D9H): | to read interrupt flags and to write commands                       |
| CANSTA (D8H): | to read status information and to write DMA pointer to the MAIN RAM |

Additionally, the DMA-logic allows a high-speed data exchange between the CAN-controller and the MAIN RAM (see section "Handling of the CPU-CAN interface").

#### Interface Management Logic (IML)

The IML interprets the commands from the CPU, controls the allocation of the message buffers Transmit Buffer (TBF), Receive Buffer 0 (RBF0), and Receive Buffer 1 (RBF1), and provides interrupts and status information to the CPU.

#### Transmit Buffer (TBF)

The TBF is an interface between the CPU and the Bit Stream Processor (BSP) and is able to store a complete message. The buffer is written by the CPU and read by the BSP. The TBF is 10 bytes long to hold the Descriptor (2 bytes) and the Data-Field (up to 8 bytes) of the message.

#### Receive Buffer (RBF0, RBF1)

The RBF is an interface between the BSP and the CPU and stores a message received from the busline. Once filled by BSP and allocated to the CPU by IML, the buffer cannot be used to store subsequently received messages until the CPU has (read and) released the buffer.

To reduce the requirements on the CPU, two receive buffers (RBF0, RBF1) are implemented. While one RBF is allocated to the CPU, the BSP may write to the other one. Both RBF0 and RBF1 are 10 bytes long to hold the Descriptor (2 bytes) and the Data-Field (up to 8 bytes) of the message.

#### Bit Stream Processor (BSP)

This is a sequencer controlling the data stream between transmit and receive buffers (parallel data) and the busline (serial data). The BSP contains the Acceptance Filter and also controls the TCL and the EML such that the processes of reception, arbitration, transmission, and error signaling are performed according to the protocol. The BSP provides signals to the IML indicating when a message has got acceptance, when a receive buffer contains a valid message, and also when the transmit buffer is no longer required after a successful transmission.

#### Bit Timing Logic (BTL)

This block monitors the busline using the (built-in) Input Comparator and handles the busline-related bit timing.

The BTL synchronizes on a "recessive" to "dominant" busline transition at the beginning of a message (hard synchronization) and resynchronizes on further transitions during the reception of a message (soft synchronization).

The BTL also provides programmable time segments to compensate for the propagation delay times and phase shifts (e.g., due to oscillator drifts) and to define the sampling time and the number of samples (one or three) to be taken within a bit time.

#### Transceiver Logic (TCL)

The TCL controls the transmit output driver.

#### Error Management Logic (EML)

The EML is responsible for the error confinement of the transfer-layer modules. The EML gets error announcements from BSP and then informs the BSP, TCL, and IML about error statistics.

## CONTROL SEGMENT AND MESSAGE BUFFER DESCRIPTION

The CAN Controller appears to the CPU as an on chip memory mapped peripheral, guaranteeing the independent operation of both parts.

### Address Allocation

The address area of the CAN Controller consists of the Control Segment and the

message buffers. The Control Segment is programmed during an initialization down-load in order to configure communication parameters (e.g., bit timing). The communication over the CAN-bus is also controlled via this segment by the CPU. A message which is to be transmitted, must be written to the Transmit Buffer. After a successful reception the CPU may read the message from the Receive Buffer and then release it for further use.

### Control Segment Layout

The exchange of status, control and command signals between the CPU and the CAN Controller is performed in the control segment. The layout of this segment is shown in Figure 1. After an initial down-load, the contents of the registers Acceptance Code, Acceptance Mask, bus Timing 0 and 1 and Output Control should not be changed. These registers may only be accessed when the Reset Request bit in the Control Register is set HIGH (see "Control Register").

# Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

## Control Register (CR)

The contents of the Control Register are used to change the behavior of the CAN Controller. Control bits may be set or reset by the CPU which uses the Control Register as a read/write memory.

**Table 2. Description of the Control Register Bits**

| CR   | ADDRESS 0 |                               |                |                                                                                                                                                                                                               |
|------|-----------|-------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIT  | SYMBOL    | NAME                          | VALUE          | FUNCTION                                                                                                                                                                                                      |
| CR.0 | RR        | Reset Request <sup>1</sup>    | HIGH (present) | Detection of a Reset Request results in the CAN Controller aborting the current transmission/reception of a message entering the reset state.                                                                 |
|      |           |                               | LOW (absent)   | On the HIGH-to-LOW transition of the Reset Request bit, the CAN Controller returns to its normal operating state.                                                                                             |
| CR.1 | RIE       | Receive Interrupt Enable      | HIGH (enabled) | When a message has been received without errors, the CAN Controller transmits a Receive Interrupt signal to the CPU.                                                                                          |
|      |           |                               | LOW (disabled) | No transmission of the Receive Interrupt signal by the CAN Controller to the CPU.                                                                                                                             |
| CR.2 | TIE       | Transmit Interrupt Enable     | HIGH (enabled) | When a message has been successfully transmitted or the transmit buffer is accessible again, (e.g., after an Abort Transmission command) the CAN Controller transmits a Transmit Interrupt signal to the CPU. |
|      |           |                               | LOW (disabled) | No transmission of the Transmit Interrupt signal by the CAN Controller to the CPU.                                                                                                                            |
| CR.3 | EIE       | Error Interrupt Enable        | HIGH (enabled) | If the Error or Bus Status change (see status Register), the CPU receives an Error Interrupt signal.                                                                                                          |
|      |           |                               | LOW (disabled) | The CPU receives no Error Interrupt signal.                                                                                                                                                                   |
| CR.4 | OIE       | Overrun Interrupt Enable      | HIGH (enabled) | If the Data Overrun bit is set (see Status Register), the CPU receives an Overrun Interrupt signal.                                                                                                           |
|      |           |                               | LOW (disabled) | The CPU receives no Overrun Interrupt signal from the CAN Controller.                                                                                                                                         |
| CR.5 | RA        | Reference Active <sup>2</sup> | HIGH (output)  | The pin REF is an AV <sub>DD/2</sub> reference output.                                                                                                                                                        |
|      |           |                               | LOW (input)    | A reference voltage may be input.                                                                                                                                                                             |
| CR.6 | S         | Synch <sup>2</sup>            | HIGH (2 edges) | Bus-line transitions from recessive-to-dominant and vice versa are used for resynchronization.                                                                                                                |
|      |           |                               | LOW (1 edge)   | Only transitions from recessive-to-dominant are used for resynchronization.                                                                                                                                   |
| CR.7 | –         | RESERVED                      |                |                                                                                                                                                                                                               |

### NOTES:

- During an external reset (RST = HIGH) or when the Bus Status bit is set HIGH (Bus-Off), the IML forces the Reset Request HIGH (present). During an external reset the CPU cannot set the Reset Request bit LOW (absent). Therefore, after having set the Reset Request bit LOW (absent), the CPU must check this bit to ensure that the external reset pin is not being held HIGH (present). After the Reset Request bit is set LOW (absent) the CAN controller will wait for:
  - one occurrence of the Bus-Free signal (11 recessive bits), if the preceding reset (Reset Request = HIGH) has been caused by an external reset or a CPU initiated reset.
  - 128 occurrences of Bus-Free, if the preceding reset (Reset Request = HIGH) has been caused by a CAN Controller initiated Bus-Off, before re-entering the Bus-On mode.
  - When Reset Request is set HIGH (present), for whatever reason, the control, command, status and interrupt bits are affected, see Table 3. Only, when Reset Request is set HIGH (present) the registers at addresses 4 to 8 are accessible.
- A modification of the bits Reference Active and Synch is only possible with Reset Request = HIGH (present). It is allowed to set these bits while Reset Request is changed from HIGH to LOW. After an external reset (pin RST = HIGH) the Reference Active bit is set HIGH (output), the Synch bit is undefined.

**Table 3. Effects of Setting the Reset Request Bit HIGH (present)**

| TYPE      | BIT                          | EFFECT                                                  |
|-----------|------------------------------|---------------------------------------------------------|
| Control   | Reference Active             | HIGH (output), only after an external reset             |
| Command   | RX0 Active / RX1 Active      | HIGH (RX0=CRX0, RX1=CRX1), only after an external reset |
|           | Sleep                        | LOW (wake-up)                                           |
|           | Clear Overrun Status         | HIGH (clear)                                            |
|           | Release Receive Buffer       | HIGH (released)                                         |
|           | Abort Transmission           | LOW (absent)                                            |
|           | Transmission Request         | LOW (absent)                                            |
| Status    | Bus Status                   | LOW (Bus-On), only after an external reset              |
|           | Error Status                 | LOW (no error), only after an external reset            |
|           | Transmit Status              | LOW (idle)                                              |
|           | Receive Status               | LOW (idle)                                              |
|           | Transmission Complete Status | HIGH (complete)                                         |
|           | Transmit Buffer Access       | HIGH (released)                                         |
|           | Data Overrun                 | LOW (absent)                                            |
|           | Receive Buffer Status        | LOW (empty)                                             |
| Interrupt | Overrun Interrupt            | LOW (reset)                                             |
|           | Transmit Interrupt           | LOW (reset)                                             |
|           | Receive Interrupt            | LOW (reset)                                             |

**Command Register (CMR)**

A command bit initiates an action within the transfer layer of the CAN controller. the Command Register appears to the CPU as a read/write memory, except of the bits CMR.0 to CMR.3, which return HIGH if being read.

|       |           |                                     | 1                   | 0                                                                                                   | RX0 = CRX0, RX1 = $AV_{DD/2}$  |
|       |           |                                     | 0                   | 1                                                                                                   | RX0 = $AV_{DD/2}$ , RX1 = CRX1 |
|       |           |                                     | 0                   | 0                                                                                                   | No action.                     |

**NOTES:**

1. If the Transmission Request bit was set HIGH in a previous command, it cannot be cancelled by setting the Transmission Request bit LOW (absent). Cancellation of the requested transmission may be performed by setting the Transmission Request bit HIGH (present).
2. The Abort Transmission bit is used when the CPU requires the suspension of the previously requested transmission, e.g., to transmit an urgent message. A transmission already in progress is not stopped. In order to see if the original message had been either transmitted successfully or aborted, the Transmission Complete Status bit should be checked. This should be done after the Transmit Buffer Access bit has been set HIGH (released) or a Transmit Interrupt has been generated (see Interrupt Register).
3. After reading the contents of the Receive Buffer (RBF0 or RBF1) the CPU must release this buffer by setting Release Receive Buffer bit HIGH (released). This may result in another message becoming immediately available.
4. This command bit is used to acknowledge the Data Overrun condition signaled by the Data Overrun status bit. It may be given or set at the same time as a Release Receive Buffer command bit.
5. The CAN Controller will enter sleep mode, if the Sleep bit is set HIGH (sleep), there is no bus activity and no interrupt is pending. A CAN Controller will wake up after the Sleep bit is set LOW (wake up) or when there is bus activity. On wake up, a Wake-Up Interrupt (see Interrupt Register) is generated (see "Power Reduction Modes"). A CAN Controller which is sleeping and then awoken by bus activity will not be able to receive this message until it detects a Bus-Free signal. The Sleep bit, if being read, reflects the status of the CAN Controller.
6. The Wake-Up Mode bit should be set at the same time as the Sleep bit. The differential wake up mode is useful if both bus wires are fully functioning; it minimizes the probability of wake ups due to noise. The single ended wake up mode is recommended if a wake up must be possible even if one bus wire is already or may become disturbed (See Figure 2).
7. The RX0/RX1 Active bits, if being read, reflect the status of the respective switches (See Figure 2). It is recommended to change the switches only during the reset state (Reset Request is HIGH).

# Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### Status Register (SR)

The contents of the Status Register reflects the status of the CAN Controller. The Status Register appears to the CPU as a read only memory.

**Table 5. Description of the Status Register Bits**

| SR   | ADDRESS 2 |                                       |                  |                                                                                                                                    |
|------|-----------|---------------------------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| BIT  | SYMBOL    | NAME                                  | VALUE            | FUNCTION                                                                                                                           |
| SR.0 | RBS       | Receive Buffer Status <sup>1</sup>    | HIGH (full)      | This bit is set when a new message is available.                                                                                   |
|      |           |                                       | LOW (empty)      | No message has become available since the last Release Receive Buffer command bit was set.                                         |
| SR.1 | DO        | Data Overrun <sup>2</sup>             | HIGH (overrun)   | This bit is set HIGH (overrun) when both Receive Buffers are full and the first byte of another message should be stored.          |
|      |           |                                       | LOW (absent)     | No data overrun has occurred since the Clear Overrun command was given.                                                            |
| SR.2 | TBS       | Transmit Buffer Access <sup>3</sup>   | HIGH (released)  | The CPU may write a message into the TBF.                                                                                          |
|      |           |                                       | LOW (locked)     | The CPU cannot access the Transmit Buffer. A message is either waiting for transmission or is in the process of being transmitted. |
| SR.3 | TCS       | Transmit Complete Status <sup>3</sup> | HIGH (complete)  | Last requested transmission has been successfully completed.                                                                       |
|      |           |                                       | LOW (incomplete) | Previously requested transmission is not yet completed.                                                                            |
| SR.4 | RS        | Receive Status <sup>4</sup>           | HIGH (receive)   | The CAN Controller is receiving a message.                                                                                         |
|      |           |                                       | LOW (idle)       | No message is received.                                                                                                            |
| SR.5 | TS        | Transmit Status <sup>4</sup>          | HIGH (transmit)  | The CAN Controller is transmitting a message.                                                                                      |
|      |           |                                       | LOW (idle)       | No message is transmitted.                                                                                                         |
| SR.6 | ES        | Error Status                          | HIGH (error)     | At least one of the Error Counters has reached the CPU Warning limit.                                                              |
|      |           |                                       | LOW (ok)         | Both Error Counters have not reached the warning limit.                                                                            |
| SR.7 | BS        | Bus Status <sup>5</sup>               | HIGH (Bus-Off)   | The CAN Controller is not involved in bus activities.                                                                              |
|      |           |                                       | LOW (Bus-On)     | The CAN Controller is involved in bus activities.                                                                                  |

#### NOTES:

1. If the command bit Release Receive Buffer is set HIGH (released) by the CPU, the Receive Buffer Status bit is set LOW (empty) by IML. When a new message is stored in any of the receive buffers, the Receive Buffer Status bit is set HIGH (full) again.
2. If Data Overrun = HIGH (overrun) is detected, the currently received message is dropped. A transmitted message, granted acceptance, is also stored in a Receive Buffer. This occurs because it is not known if the CAN Controller will lose arbitration and so become a receiver of the message. If no Receive Buffer is available, Data Overrun is signaled. However, this transmitted and accepted message does neither cause a Receive Interrupt nor set the Receive Buffer Status bit to HIGH (full). Also, a Data Overrun does not cause the transmission of an Overload Frame.
3. If the CPU tries to write to the Transmit Buffer when the Transmit Buffer Access bit is LOW (locked), the written bytes will not be accepted and will be lost without this being signaled. The Transmission Complete Status bit is set LOW (incomplete) whenever the Transmission Request bit is set HIGH (present). If an Abort Transmission command is issued, the Transmit Buffer will be released. If the message, which was requested and then aborted, was not transmitted, the Transmission Complete Status bit will remain LOW.
4. If both the Receive Status and Transmit Status bits are LOW (idle) the CAN-bus is idle.
5. When the Bus Status bit is set HIGH (Bus-Off), the CAN Controller will set the Reset Request bit HIGH (present). It will stay in this state until the CPU sets the Reset Request bit LOW (absent). Once this is completed, the CAN Controller will wait the minimum protocol-defined time (128 occurrences of the Bus-Free signal) before setting the Bus Status bit LOW (Bus-On), the Error Status bit LOW (ok), and resetting the Error Counters.

# Single-chip 8-bit microcontroller with CAN controller

## Interrupt Register (IR)

The Interrupt Register allows the identification of an interrupt source. When one or more bits of this register are set, a CAN interrupt (SIO1) will be indicated to the CPU. All bits are reset by the CAN Controller after this register is read by the CPU. This register appears to the CPU as a read only memory.

**Table 6. Description of the Interrupt Register Bits**

| IR   |        | ADDRESS 3                      |             |                                                                                                                                                                                                 |
|------|--------|--------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIT  | SYMBOL | NAME                           | VALUE       | FUNCTION                                                                                                                                                                                        |
| IR.0 | RI     | Receive Interrupt <sup>1</sup> | HIGH (set)  | This bit is set when a new message is available in the Receive Buffer and the Receive Interrupt Enable bit is HIGH (enabled).                                                                   |
|      |        |                                | LOW (reset) | Receive Interrupt bit is automatically reset by a read access of Interrupt Register by the CPU.                                                                                                 |
| IR.1 | TI     | Transmit Interrupt             | HIGH (set)  | This bit is set on a change of the Transmit Buffer Access from LOW to HIGH (released) and Transmit Interrupt Enable is HIGH (enabled).                                                          |
|      |        |                                | LOW (reset) | Transmit Interrupt bit will be reset after a read access of the Interrupt Register by the CPU.                                                                                                  |
| IR.2 | EI     | Error Interrupt                | HIGH (set)  | This bit is set on a change of either the Error Status or Bus Status bits (see Status Register) if the Error Interrupt Enable is HIGH (enabled).                                                |
|      |        |                                | LOW (reset) | The Error Interrupt bit is reset by a read access of the Interrupt Register by the CPU.                                                                                                         |
| IR.3 | OI     | Overrun Interrupt <sup>2</sup> | HIGH (set)  | This bit is set HIGH, if both Receive Buffers contain a message and the first byte of another message should be stored (passed acceptance), and the Overrun Interrupt Enable is HIGH (enabled). |
|      |        |                                | LOW (reset) | Overrun Interrupt bit is reset by a read access of the Interrupt register by the CPU.                                                                                                           |
| IR.4 | WUI    | Wake-Up Interrupt              | HIGH (set)  | The Wake-Up Interrupt bit is set HIGH when the sleep mode is left (see Command Register).                                                                                                       |
|      |        |                                | LOW (reset) | Wake-Up Interrupt bit is reset by a read access of the Interrupt Register by the CPU.                                                                                                           |

| IR.7 | –      | RESERVED                       |             |                                                                                                                                                                                                 |

### NOTES:

1. Receive Interrupt bit (if enabled) and Receive Buffer Status bit (see Status Register) are set at the same time.
2. Overrun Interrupt bit (if enabled) and Data Overrun bit (see Command Register) are set at the same time.

# Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### Acceptance Code Register (ACR)

The Acceptance Code Register is part of the acceptance filter of the CAN Controller. This register can be accessed (read/write), if the Reset Request bit is set HIGH (present). When a message is received which passes the acceptance test and if there is an empty Receive Buffer, then the respective Descriptor and Data Field (see Figure 1) are sequentially stored in this empty buffer. In the case that there is no empty Receive buffer, the Data Overrun bit is set HIGH (overrun), see Status and Interrupt Register. When the complete message has been correctly received, the following occurs:

- The Receive Buffer Status bit is set HIGH (full)
- If the Receive Interrupt Enable bit is set HIGH (enabled), the receive Interrupt is set HIGH (set).

The Acceptance Code bits (AC.7–AC.0) and the eight most significant bits of the message's Identifier (ID.10–ID.3) must be equal to those bit positions which are marked relevant by the Acceptance Mask bits (AM.7–AM.0). If the following equation is satisfied, acceptance is given:

$$[(ID.10 \dots ID.3) \text{ EQUAL } (AC.7 \dots AC.0)] \text{ or } (AM.7 \dots AM.0) = 1111 \ 1111_b$$

### Acceptance Code Register Bits

| ACR  | ADDRESS 4 |      |      |      |      |      |      |  |
|------|-----------|------|------|------|------|------|------|--|
| 7    | 6         | 5    | 4    | 3    | 2    | 1    | 0    |  |
| AC.7 | AC.6      | AC.5 | AC.4 | AC.3 | AC.2 | AC.1 | AC.0 |  |

During transmission of a message which passes the acceptance test, the message is also written to its own Receive Buffer. If no Receive Buffer is available, Data Overrun is signaled because it is not known at the start of a message whether the CAN Controller will lose arbitration and so become a receiver of the message.

### Acceptance Mask Register (AMR)

The Acceptance Mask Register is part of the acceptance filter of the CAN Controller. This register can be accessed (read/write) if the Reset Request bit is set HIGH (present). The

Acceptance Mask Register qualifies which of the corresponding bits of the acceptance code are "relevant" or "don't care" for acceptance filtering.

### Acceptance Mask Register Bits

| AMR  | ADDRESS 5 |      |      |      |      |      |      |  |
|------|-----------|------|------|------|------|------|------|--|
| 7    | 6         | 5    | 4    | 3    | 2    | 1    | 0    |  |
| AM.7 | AM.6      | AM.5 | AM.4 | AM.3 | AM.2 | AM.1 | AM.0 |  |

### Description of the Acceptance Mask Register Bits

| ACCEPTANCE MASK BIT | VALUE             | COMMENTS                                                           |
|---------------------|-------------------|--------------------------------------------------------------------|
| AM.7 to AM.0        | HIGH (don't care) | This bit position is "don't care" for the acceptance of a message. |
|                     | LOW (relevant)    | This bit position is "relevant" for acceptance filtering.          |

### Bus Timing Register 0 (BTR 0)

The contents of Bus Timing Register 0 defines the values of the Baud Rate Prescaler (BRP) and the Synchronization Jump Width (SJW). This register can be accessed (read/write) if the Reset Request bit is set HIGH (present).

### Bus Timing Register 0 Bits

| BTR0  | ADDRESS 6 |       |       |       |       |       |       |  |
|-------|-----------|-------|-------|-------|-------|-------|-------|--|
| 7     | 6         | 5     | 4     | 3     | 2     | 1     | 0     |  |
| SJW.1 | SJW.0     | BRP.5 | BRP.4 | BRP.3 | BRP.2 | BRP.1 | BRP.0 |  |

### Baud Rate Prescaler (BRP)

The period of the system clock  $t_{SCL}$  is programmable and determines the individual bit timing. The system clock is calculated using the following equation:

$$t_{SCL} = 2^{t_{CLK}} (32BRP.5 + 16BRP.4 + 8BRP.3 + 4BRP.2 + 2BRP.1 + BRP.0 + 1)$$

$t_{CLK}$  = time period of the 8XC592 oscillator.

### Synchronization Jump Width (SJW)

To compensate for phase shifts between clock oscillators of different bus controllers, any bus controller must resynchronize on any relevant signal edge of the current

transmission. The synchronization jump width defines the maximum number of clock cycles a bit period may be shortened or lengthened by one resynchronization:

$$t_{SJW} = t_{SCL} (2SJW.1 + SJW.0 + 1)$$

### Bus Timing Register 1 (BTR1)

The contents of Bus Timing Register 1 defines the length of the bit period, the location of the sample point and the number of samples to be taken at each sample point. This register can be accessed (read/write) if the Reset Request bit is set HIGH (present).

### Bus Timing Register 1 Bits

| BTR1 | ADDRESS 7 |         |         |         |         |
|------|-----------|---------|---------|---------|---------|
| 7    | 6         | 5       | 4       |         |         |
| SAM  | TSEG2.2   |         | TSEG2.1 |         | TSEG2.0 |
|      | 3         | 2       | 1       | 0       |         |
|      | TSEG1.3   | TSEG1.2 | TSEG1.1 | TSEG1.0 |         |

### Sampling (SAM)

| BIT | VALUE            | COMMENTS                 |
|-----|------------------|--------------------------|
| SAM | HIGH (3 samples) | 3 samples are taken.     |
|     | LOW (1 sample)   | The bus is sampled once. |

SAM = LOW is recommended for high speed buses (SAE class C), while SAM = HIGH is recommended for slow/medium speed buses (class A and B) where filtering of spikes on the bus-line is beneficial (see "Bit Timing Restrictions").

### Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2)

TSEG1 and TSEG2 determine the number of clock cycles per bit period and the location of the sample point:

$$t_{TSEG1} = t_{SCL} (8TSEG1.3 + 4TSEG1.2 + 2TSEG1.1 + TSEG1.0 + 1)$$

$$t_{TSEG2} = t_{SCL} (4TSEG2.2 + 2TSEG2.1 + TSEG2.0 + 1)$$

For further information on bus timing see Bus Timing Register 0 and "Bus Timing/Synchronization".

# Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

## Output Control Register (OCR)

The Output Control Register allows, under software control, the set-up of different output driver configurations. This register can be accessed (read/write) if the Reset Request bit is set HIGH (present).

### Output Control Register Bits

| OCR    | ADDRESS 8 |         |       |         |  |
|--------|-----------|---------|-------|---------|--|
| 7      | 6         | 5       | 4     | 3       |  |
| OCTP1  | OCTN1     | OCPOL1  | OCTP0 | OCTN0   |  |
| 2      |           | 1       |       | 0       |  |
| OCPOL0 |           | OCMODE1 |       | OCMODE0 |  |

If the CAN Controller is in the sleep mode (Sleep = HIGH) a recessive level is output on the CTX0 and CTX1 pins. If the CAN Controller is in the reset state (Reset Request = HIGH) the output drivers are floating.

### Normal Output Mode

In Normal Output Mode the bit sequence (TXD) is sent via CTX0 and CTX1. The

voltage levels on the output driver pins CTX0 and CTX1 depend on both the driver characteristic programmed by OCTPx, OCTNx (float, pull-up, pull-down, push-pull) and the output polarity programmed by OCPOLx (see Figure 3).

### Clock Output Mode

For the CTX0 pin this is the same as in Normal Output Mode. However, the data stream to CTX1 is replaced by the transmit clock (TXCLK). The rising edge of the transmit clock (non-inverted) marks the beginning of a bit period. The clock pulse width is  $t_{SCL}$ .

### Bi-phase Output Mode

In contrast to Normal Output Mode the bit representation is time variant and toggled. If the bus controllers are galvanically decoupled from the bus-line by a transformer, the bit stream is not allowed to contain a DC component. This is achieved by the following

scheme. During recessive bits all outputs are de-activated (floating). Dominant bits are sent alternately on CTX0 and CTX1, i.e., the first dominant bit is sent on CTX0, the second is sent on CTX1, and the third one is sent on CTX0 again, etc.

### Test Output Mode

For the CTX0 pin this is the same as in Normal Output Mode. To measure the delay time of the transmitter and receiver this mode connects the output of the input comparator (COMP OUT) with the input of the output driver CTX1. This mode is used for production testing only.

The following two tables, Table 7 and Table 8, show the relationship between the bits of the Output Control Register and the two serial output pins CTX0 and CTX1 of the 8XC592 – CAN Controller, connected to the serial bus (see Block Diagram, page 855).

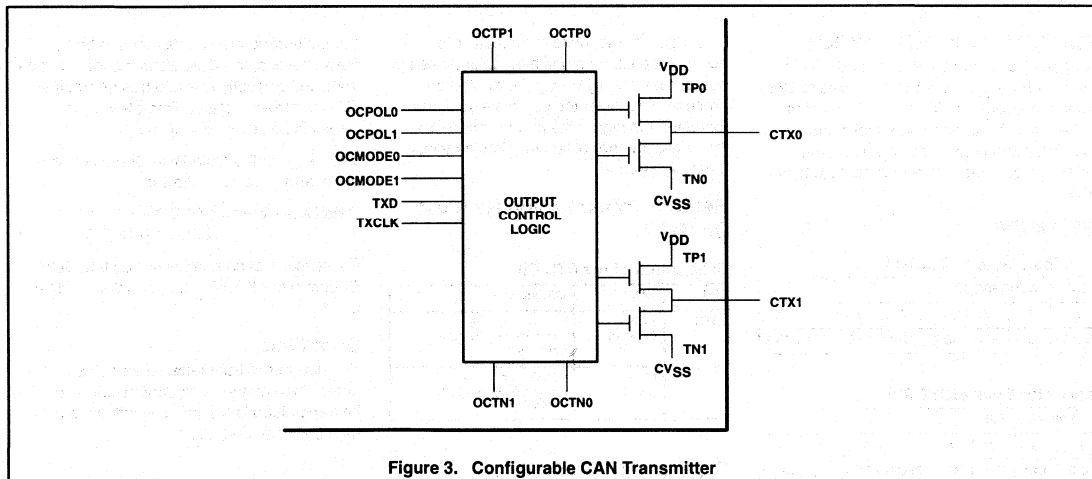

Figure 3. Configurable CAN Transmitter

Table 7. Description of the Output Mode Bits

| OCMODE1 | OCMODE0 | DESCRIPTION                                                    |
|---------|---------|----------------------------------------------------------------|
| 1       | 0       | Normal output Mode; CTX0, CTX1: bit sequence (TXD; note 1)     |
| 1       | 1       | Clock output Mode; CTX0: bit sequence, CTX1: bus clock (TXCLK) |
| 0       | 0       | Bi-phase output Mode                                           |

|           | 1     | 1     | 1      | 0   | On  | Off | HIGH  |
|           | 1     | 1     | 1      | 1   | Off | On  | LOW   |

**NOTES:**

1. TPx is the on-chip output transistor x, connected to V<sub>DD</sub>; x = 0 or 1.
2. TNx is the on-chip output transistor x, connected to CV<sub>SS</sub>; x = 0 or 1.
3. CTXx is the serial output level on CTX0 or CTX1. It is required that the output level on the CAN bus is dominant with TXD = 0 and recessive with TXD = 1.

**TRANSMIT BUFFER LAYOUT**

The global layout of the Transmit Buffer is shown in Figure 1. This buffer serves to store a message from the CPU to be transmitted by the CAN Controller. It is subdivided into Descriptor and Data Field. the Transmit Buffer can be written to and read from by the CPU.

**DESCRIPTOR****Descriptor Byte 1 (DSCR1)**

| DSCR1 |      | ADDRESS 10 |      |      |      |      |      |  |
|-------|------|------------|------|------|------|------|------|--|
| 7     | 6    | 5          | 4    | 3    | 2    | 1    | 0    |  |
| ID.10 | ID.9 | ID.8       | ID.7 | ID.6 | ID.5 | ID.4 | ID.3 |  |

**Descriptor Byte 2 (DSCR2)**

| DSCR2 |      | ADDRESS 11 |     |       |       |       |       |  |
|-------|------|------------|-----|-------|-------|-------|-------|--|
| 7     | 6    | 5          | 4   | 3     | 2     | 1     | 0     |  |
| ID.2  | ID.1 | ID.0       | RTR | DLC.3 | DLC.2 | DLC.1 | DLC.0 |  |

**Identifier (ID)**

The Identifier consists of 11 bits (ID.10 to ID.0). ID.10 is the most significant bit, which is transmitted first on the bus during the arbitration process. the Identifier acts as the

message's name, used in a receiver for acceptance filtering, and also determines the bus access priority during the arbitration process. The lower the binary value of the Identifier, the higher the priority. this is due to the larger number of leading dominant bits during arbitration.

**Remote Transmission Request Bit (RTR)****Description of the RTR Bit**

| BIT | VALUE         | COMMENTS                                                |
|-----|---------------|---------------------------------------------------------|
| RTR | HIGH (remote) | Remote Frame will be transmitted by the CAN Controller. |
|     | LOW (data)    | Data Frame will be transmitted by the CAN Controller.   |

**Data Length Code (DLC)**

The number of bytes (Data Byte Count) in the Data Field of a message is coded by the Data Length Code. at the start of a Remote Frame transmission, the Data Length Code is not considered due to the RTR bit being HIGH (remote). This forces the number of

transmitted/received data bytes to be 0. Nevertheless, the Data Length code must be specified correctly to avoid bus errors, if two CAN-controllers start a Remote Frame transmission simultaneously.

The range of the Data Byte Count is 0 to 8 bytes and coded as follows:

$$\text{Data Byte Count} = 8\text{DLC.3} + 4\text{DLC.2} + 2\text{DLC.1} + \text{DLC.0}$$

For reasons of compatibility, no Data Byte Counts other than 0,1,2,... and 8 should be used.

**Data Field**

The number of transferred data bytes is determined by the Data Length Code. the first bit transmitted is the most significant bit of data byte 1 at address 12.

**RECEIVE BUFFER LAYOUT**

The layout of the Receive Buffer and the individual bytes correspond to the definitions given for the Transmit Buffer layout, except that the addresses start at 20 instead of 10 (see Figure 1).

**NOTES:**

- Do not use a RMW instruction.
- The bit addresses of CANSTA (7:0) are DFH . . . D8H.
- Reserved bits are read as HIGH.

## HANDLING OF THE CPU-CAN INTERFACE

Via the four special registers CANADR, CANDAT, CANCON and CANSTA, the CPU has access to the CAN Controller and also to the DAM-logic. Note that CANCON and CANSTA have different meanings for a read and write access.

### CANADR

The five least significant bits CANADR.4 down to CANADR.0 (CANA4 . . . CANA0) define the address of one of the CAN Controller internal registers to be accessed via CANDAT. For instance, after an external hardware (e.g., power-on) reset CANADR contains the value 64h, and hence the CPU accesses (read/write) the Acceptance Code register of the CAN Controller, via the Special Function Register CANDAT. CANADR also controls the auto address increment mode via bit CANADR.5 (AutoInc) and the DMA-logic via bit CANADR.7 (DMA). CANADR is implemented as a read/write register.

### CANDAT

The Special Function Register CANDAT appears as a port to the CAN Controller's internal register (memory location) being selected by CANADR. Reading or writing CANDAT is effectively an access to that CAN Controller internal register, which is selected by CANADR. CANDAT is implemented as a read/write register.

### CANCON

When reading CANCON the Interrupt Register of the CAN Controller is accessed, while writing to CANCON means an access

to the Command Register. CANCON is implemented as a read/write register.

### CANSTA

Reading CANSTA is an access to the Status Register of the CAN Controller. Writing to CANSTA sets the address of the on-chip Main RAM (internal data memory) for a subsequent DMA transfer. CANSTA is implemented as a bit-addressable read/write register.

### Auto Address Increment

With the auto address increment mode a fast stack-like reading and writing of CAN Controller internal registers is provided. If the bit CANADR.5 (AutoInc) is high, the content of CANADR is incremented automatically after any read or write access to CANDAT. For instance, loading a message into the Transmit Buffer can be done by writing 2AH into CANADR and then moving byte by byte of the message to CANDAT.

Incrementing CANADR beyond xx111111<sub>b</sub> resets the bit CANADR.5 (AutoInc) automatically (CANADR = xx000000<sub>b</sub>).

### High Speed DMA

The DMA-logic allows to transfer a complete message (up to 10 bytes) between CAN Controller and Main RAM in 2 instruction cycles at maximum; up to 4 bytes are transferred in 1 instruction cycle. The performance of the CPU is strongly enhanced because this very fast transfer is done in the background. A DMA transfer is achieved by first writing the RAM address (0 . . . FFH) into CANSTA and then setting the TX- or RX-Buffer address in CANADR and

the bit CANADR.7 (DMA) simultaneously; the RAM address points to the location of the first byte to be transferred. Setting the DMA bit causes an automatic evaluation of the Data Length Code and then the transfer; for a TX-DMA transfer the Data Length Code is expected at the location "RAM address + 1".

In order to program a TX-DMA transfer, the value 8AH (address 10) has to be written into CANADR. Then a complete message, consisting of the 2-byte Descriptor and the Data Field (0 . . . 8 bytes), starting at location "RAM address" is transferred to the TX-Buffer.

The RX-DMA transfer is very versatile. By writing a value in the range of 94H (address 20) up to 9DH (address 29) of CANADR the whole or a part of the received message, starting at the specified address, is transferred to the internal data memory. This allows e.g. to transfer the bytes of the Data Field only.

After a successful DMA transfer the DMA- (and Auto Inc-) bit is reset.

During a DMA transfer the CPU can process the next instruction. However, an access to the data memory, CANADR, CANDAT, CANCON or CANSTA is not allowed. After having set the DMA-bit, every interrupt is disabled until the end of the transfer. Note, that disadvantageous programming may lead to an interrupt response time of at most 10 instruction cycles. The shortest interrupt response time is achieved by using a 2-cycle instructions directly after setting the DMA-bit. During the reset state (bit Reset Request is HIGH) a DMA transfer is not possible.

# Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

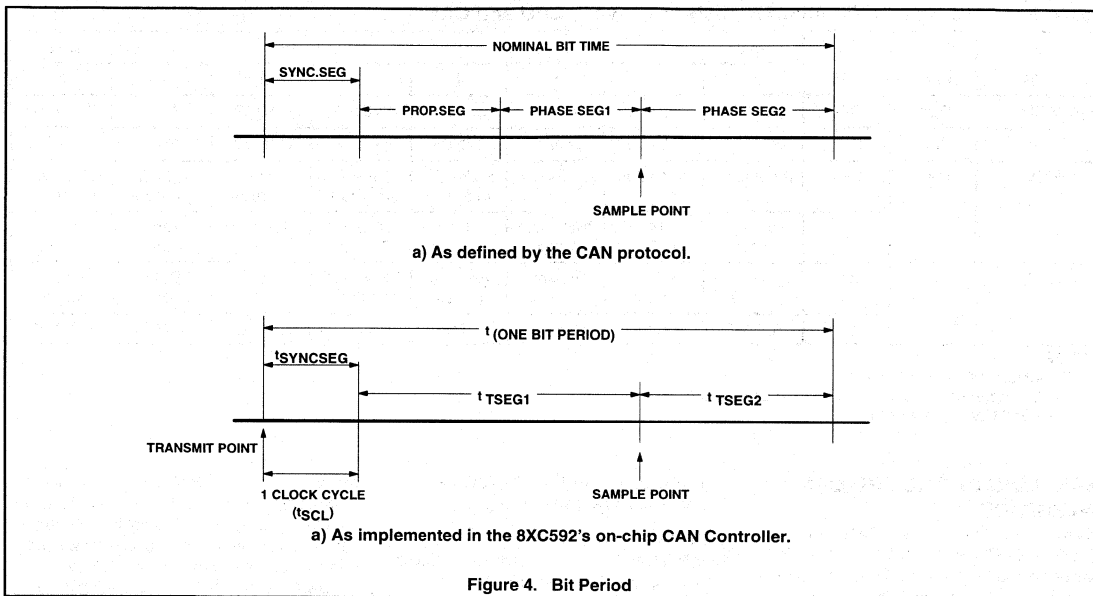

Figure 4. Bit Period

## BUS TIMING / SYNCHRONIZATION

The Bus Timing Logic (BTL) monitors the serial bus-line via the on-chip input comparator and performs the following functions:

- Monitors the serial bus-line level
- Adjusts the sample point, within a bit period (programmable)
- Samples the bus-line level using majority logic (programmable, 1 or 3 samples)
- Synchronization to the bit stream:
  - Hard synchronization at the start of a message
  - Resynchronization during transfer of a message

The configuration of the BTL is performed during the initialization of the CAN Controller. The BTL uses the following three registers:

- Control register (Synch)
- Bus Timing Register 0
- Bus Timing Register 1

## Bit Timing

A bit period is built up from a number of system clock cycles ( $t_{SCL}$ ) (see "Bus Timing Register 0"). One bit period is the result of the addition of the programmable segments TSEG1 and TSEG2 and the general segment SYNCSEG.

## Synchronization Segment (SYNCSEG)

The incoming edge of a bit is expected during this state; this state corresponds to one system clock cycle ( $1 \times t_{SCL}$ ).

## Time Segment 1 (TSEG1)

This segment determines the location of the sampling point within a bit period, which is at the end of TSEG1. TSEG1 is programmable from 1 to 16 system clock cycles.

The correct location of the sample point is essential for the correct functioning of a transmission. The following points must be taken into consideration:

- A Start-Of-Frame causes all CAN Controllers to perform a "hard synchronization" on the first recessive-to-dominant edge. During arbitration, however, several CAN Controllers may simultaneously transmit. Therefore it may require twice the sum of bus-line, input comparator and the output driver delay times until the bus is stable. This is the propagation delay time.
- To avoid sampling at an incorrect position, it is necessary to include an additional synchronization buffer on both sides of the sample point. The main reasons for incorrect sampling are:
  - Incorrect synchronization due to spikes on the bus-line;

– Slight variations in the oscillator frequency of each CAN Controller in the network, which results in a phase error.

- Time Segment 1 consists of the segment for compensation of propagation delays and the synchronization buffer segment directly before the sample point (see Figure 4).

## Time Segment 2 (TSEG2)

This time segment provides:

- Additional time at the sample point for calculation of the subsequent bit levels (e.g., arbitration);
- Synchronization buffer segment directly after the sample point.

TSEG2 is programmable from 1 to 8 system clock cycles.

## Synchronization Jump Width (SJW)

SJW defines the maximum number of clock cycles ( $t_{SCL}$ ) a period may be reduced or increased by one resynchronization. SJW is programmable from 1 to 4 system clock cycles.

## Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

### Propagation Delay Time ( $t_{PROP}$ )

The propagation delay time is calculated by summing the maximum propagation delay times of the physical bus, the input comparator and the output driver. The resulting sum is multiplied by 2 and then rounded up to the nearest multiple of  $t_{SCL}$ .

$$t_{PROP} = 2 \times (\text{physical bus delay} \\ + \text{input comparator delay} \\ + \text{output driver delay})$$

### Bit Timing Restrictions

Restrictions on the configuration of the bit timing are based on internal processing. The restrictions are:

- $t_{TSEG2} \geq 2t_{SCL}$
- $t_{TSEG2} \geq t_{SJW}$
- $t_{TSEG1} \geq t_{TSEG2}$
- $t_{TSEG1} \geq t_{SJW} + t_{PROP}$

The three sample mode ( $SAM = 1$ ) has the effect of introducing a delay of one system clock cycle on the bus-line. This must be taken into account for the correct calculation of  $TSEG1$  and  $TSEG2$ :

- $t_{TSEG1} \geq t_{SJW} + t_{PROP} + 2t_{SCL}$
- $t_{TSEG2} \geq 3t_{SCL}$

### Synchronization

Synchronization is performed by a state machine which compares the incoming edge with its actual bit timing and adapts the bit timing by hard synchronization or resynchronization.

#### Hard Synchronization

This type of synchronization occurs only at the beginning of a message. The CAN

Controller synchronizes on the first incoming recessive-to-dominant edge of a message (being the leading edge of a message's Start-Of-Frame bit).

#### Resynchronization

Resynchronization occurs during the transmission of a message's bit stream to compensate for:

- Variations in individual CAN Controller oscillator frequencies;
- Changes introduced by switching from one transmitter to another (e.g., during arbitration).

As a result of resynchronization, either  $t_{TSEG1}$  may be increased by up to a maximum of  $t_{SJW}$ , or  $t_{TSEG2}$  may be decreased by up to a maximum of  $t_{SJW}$ :

- $t_{TSEG1} \leq t_{SCL} [(TSEG1 + 1) + (SJW + 1)]$
- $t_{TSEG2} \geq t_{SCL} [(TSEG2 + 1) - (SJW + 1)]$

**NOTE:**  $TSEG1$ ,  $TSEG2$  and  $SJW$  are the programmed numerical values.

The phase error ( $e$ ) of an edge is given by the position of the edge relative to  $SYNCSEG$ , measured in system clock cycles ( $t_{SCL}$ ). The value of the phase error is defined as:

- $e = 0$ , if the edge occurs within  $SYNCSEG$
- $e > 0$ , if the edge occurs within  $TSEG1$
- $e < 0$ , if the edge occurs within  $TSEG2$ .

The effect of resynchronization is:

- The same as that of a hard synchronization, if the magnitude of the

phase error ( $e$ ) is less or equal to the programmed value of  $t_{SJW}$ :

- To increase a bit period by the amount of  $t_{SJW}$ , if the phase error is positive and the magnitude of the phase error is larger than  $t_{SJW}$ ;
- To decrease a bit period by the amount of  $t_{SJW}$ , if the phase error is negative and the magnitude of the phase error is larger than  $t_{SJW}$ .

#### Synchronization Rules

The synchronization rules are as follows:

- Only one synchronization within one bit time used.
- An edge is used for synchronization only if the value detected at the previous sample point differs from the bus value immediately after the edge.
- Hard synchronization is performed whenever there is a recessive-to-dominant edge during Bus-Idle.
- All other edges (recessive-to-dominant and optionally dominant-to-recessive edges if the  $Synch$  bit is set HIGH) which are candidates for resynchronization will be used with the following exception:
  - A transmitting CAN Controller will not perform a resynchronization as a result of a recessive-to-dominant edge with positive phase error, if only these edges are used for resynchronization. This ensures that the delay times of the output driver and input comparator do not cause a permanent increase in the bit time.

# Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

## CAN-PROTOCOL DESCRIPTION

### Frame Types

The 8XC592's CAN Controller supports the four different CAN protocol frame types for communication:

- Data Frame, to transfer data
- Remote Frame, request for data
- Error Frame, globally signals a (locally) detected error condition
- Overload Frame, to extend delay time of subsequent frames (an Overload Frame is not initiated by the 8XC592 CAN Controller).

### Bit Representation

There are two logical bit representations used in the CAN protocol:

- A recessive bit on the bus-line appears only if all connected CAN Controllers send a recessive bit at that moment
- Dominant bits always overwrite recessive bits, i.e., the resulting bit level on the bus-line is dominant.

### Data Frame

A Data Frame carries data from a transmitting CAN Controller to one or more receiving ones. A Data Frame is composed of seven different bit-fields:

- Start-Of-Frame
- Arbitration Field
- Control Field
- Data Field (may have a length of zero)
- CRC Field
- Acknowledge Field
- End-Of-Frame

### Start-of-Frame Bit

Signals the start of a Data Frame or Remote Frame. It consists of a single dominant bit used for hard synchronization of a CAN Controller in receive mode.

### Arbitration Field

Consists of the message Identifier and the RTR bit. In the case of simultaneous message transmissions by two or more CAN Controllers the bus access conflict is solved by bit-wise arbitration, which is active during the transmission of the Arbitration Field.

### Identifier

This 11-bit field is used to provide information about the message, as well as the bus access priority. It is transmitted in the order ID.10 to ID.0 (LSB). The situation that the seven most significant bits (ID.10 to ID.4) are all recessive must not occur.

An Identifier does not define which particular CAN Controller will receive the frame because a CAN-based communication network does not differentiate between a point-to-point, multicast or broadcast communication.

### RTR Bit

A CAN Controller, acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). If the data source simultaneously transmits a Data Frame containing the requested data, it uses the same Identifier. No bus access conflict occurs due to the RTR bit being set LOW (data; dominant bus level) in the Data Frame.

### Control Field

This field consists of six bits. It includes two reserved bits (for future expansions of the CAN protocol), transmitted with a dominant bus level, and is followed by the Data Length Code (4 bits). The number of bytes (destuffed; number of data bytes to be transmitted/received) in the Data Field is indicated by the Data Length Code. Admissible values of the Data Length Code, and hence the number of bytes in the (destuffed) Data Field, are (0, 1, ..., 8). A logic 0 (logic 1) in the Data Length Code is transmitted as dominant (recessive) bus level, respectively.

### Data Field

The data, stored within the Data Field of the transmit buffer, are transmitted according to the Data Length Code. Conversely, data of a received Data Frame will be stored in the Data Field of a Receive Buffer. The Data Field can contain from 0 up to 8 bytes. The most significant bit of the first data byte (lowest address) is transmitted/received first.

### Cyclic Redundancy Code Field (CRC)

The CRC Field consists of the CRC Sequence (15 bits) and the CRC Delimiter (1 recessive bit). The Cyclic Redundancy Code (CRC) encloses the destuffed bit stream of the Start-of-Frame, Arbitration Field, Control Field, Data Field and CRC Sequence. The most significant bit of the CRC Sequence is transmitted/received first. This frame check sequence, implemented in the CAN Controller is derived from a cyclic redundancy code best suited for frames with a total bit count of less than 127 bits, CRC Error detection. With Start-of-Frame (dominant bit) included in the code word, any rotation of the code word can be detected by the absence of the CRC Delimiter (recessive bit).

Figure 5. Data Frame

## Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

### Acknowledge Field (ACK)

The Acknowledge Field consists of two bits, the Acknowledge Slot and the Acknowledge Delimiter, which are transmitted with a recessive level by the transmitter of the Data Frame. All CAN Controllers having received the matching CRC Sequence, report this by overwriting the transmitter's recessive bit in the Acknowledge Slot with a dominant bit. Thereby a transmitter, still monitoring the bus level recognizes that at least one receiver within the network has received a complete and correct message (i.e., no error was found). The Acknowledge Delimiter (recessive bit) is the second bit of the Acknowledge Field. As a result, the Acknowledge Slot is surrounded by two recessive bits: the CRC Delimiter and the Acknowledge Delimiter.

All nodes within a CAN network may use all the information coming to the network by all CAN Controllers (shared memory concept). Therefore, acknowledgement and error handling are defined to provide all information in a consistent way throughout this shared memory. Hence, there is no reason to discriminate different receivers of a message in the acknowledge field. If a node is disconnected from the network due to bus failure, this particular node is no longer part of the shared memory. To identify a "lost node" additional and application specific precautions are required.

### End-Of-Frame

Each Data Frame or Remote Frame is delimited by the End-of-Frame bit sequence which consists of seven recessive bits (exceeds the bit stuff width by two bits). Using this method a receiver detects the end of a frame independent of a previous transmission error because the receiver expects all bits up to the end of the CRC Sequence to be coded by the method of bit-stuffing. The bit-stuffing logic is deactivated during the End-of-Frame sequence.

### Remote Frame

A CAN Controller acting as a receiver for certain information may initiate the transmission of the respective data by transmitting a Remote Frame to the network, addressing the data source via the Identifier and setting the RTR bit HIGH (remote; recessive bus level). The Remote Frame is similar to the Data Frame with the following exceptions:

- RTR bit is set HIGH
- Data Length Code is ignored
- No Data Field contained

Note that the value of the Data Length Code should be the one of the corresponding Data Frame, although it is ignored for a Remote Frame.

A Remote Frame is composed of six different bit fields:

- Start-of-Frame
- Arbitration Field
- Control Field
- CRC Field
- Acknowledge Field
- End-of-Frame

### Error Frame

The Error Frame consists of two different fields. The first field is accomplished by the superimposing of Error Flags contributed from different CAN Controllers.

The second field is the Error Delimiter.

#### Error Flag

There are two forms of an Error Flag:

- Active Error Flag, consists of six consecutive dominant bits
- Passive Error Flag, consists of six consecutive recessive bits unless it is overwritten by dominant bits from other CAN Controllers.

An error-active CAN Controller detecting an error condition signals this by transmission of

an Active Error Flag. This Error Flag's form violates the bit-stuffing rule applied to all fields, from Start-of-Frame to CRC Delimiter, or destroys the fixed form of the fields Acknowledge Field or End-of-Frame. Consequently, all other CAN Controllers detect an error condition and start transmission of an Error Flag. Therefore the sequence of dominant bits, which can be monitored on the bus, results from a superposition of different Error Flags transmitted by individual CAN Controllers. The total length of this sequence varies between six (minimum) and twelve (maximum) bits.

An error-passive CAN Controller detecting an error condition tries to signal this by transmission of a Passive Error Flag. The error-passive CAN Controller waits for six consecutive bits with identical polarity, beginning at the start of the Passive Error Flag. The Passive Error Flag is complete when these six identical bits have been detected.

#### Error Delimiter

The Error Delimiter consists of eight recessive bits and has the same format as the Overload Delimiter. After transmission of an Error Flag, each CAN Controller monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every CAN Controller has finished sending its Error Flag and has additionally sent the first out of the 8 recessive bits of the Error Delimiter. Afterwards all CAN Controllers transmit the remaining recessive bits. After this event and an Intermission Field all error-active CAN Controllers within the network can start a transmission simultaneously.

If a detected error is signaled during transmission of a Data Frame or Remote Frame, the current message is spoiled and a retransmission of the message is initiated.

Figure 6. Error Frame

## Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

If a CAN Controller monitors any deviation of the Error Frame, a new Error Frame will be transmitted. Several consecutive Error Frames may result in the CAN Controller becoming error-passive and leaving the network unblocked.

In order to terminate an Error Flag correctly, an error-passive CAN Controller requires the bus to be Bus-Idle for at least three bit periods (if there is a local error at an error-passive-receiver). Therefore a CAN bus should not be permanently loaded.

### Overload Frame

The Overload Frame consists of two fields, the Overload Flag and the Overload Delimiter. There are two conditions in the CAN protocol which lead to the transmission of an Overload Flag:

- Condition 1; receiver circuitry requires more time to process the current data before receiving the next frame (receiver not ready)
- Condition 2; detection of a dominant bit during Intermission Field.

The transmission of an Overload Frame may only start:

- Condition 1; during the first bit period of an expected Intermission Field
- Condition 2; one bit period after detecting the dominant bit during Intermission Field

The 8XC592's on chip CAN Controller will never initiate transmission of a condition 1-Overload Frame and will only react on a transmitted condition 2 Overload Frame, according to the CAN protocol. No more than two Overload Frames are generated to delay a Data Frame or a Remote Frame. Although the overall form of the Overload Frame corresponds to that of the Error Frame, an Overload Frame does not initiate or require the retransmission of the preceding frame.

### Overload Flag

The Overload Flag consists of six dominant bits and has a similar format to the Error Flag.

The Overload Flag's form corrupts the fixed form of the Intermission Field. All other CAN Controllers detecting the overload condition also transmit an Overload Flag (condition 2).

### Overload Delimiter

The Overload Delimiter consists of eight recessive bits and takes the same form as the Error Delimiter. After transmission of an Overload Flag, each CAN Controller monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every CAN Controller has finished sending its Overload Flag and all CAN Controllers start simultaneously transmitting seven more recessive bits.

### Inter-Frame Space

Data Frames and Remote Frames are separated from preceding frames (all types) by an Inter-Frame Space, consisting of an Intermission Field and a Bus-Idle. Error-passive CAN Controllers also send a Suspend Transmission after transmission of a message. Overload Frames and Error Frames are not preceded by an Inter-Frame Space.

### Intermission Field

The Intermission Field consists of three recessive bits. During an Intermission period, no frame transmissions will be started by the 8XC592's on chip CAN Controller. An Intermission is required to have a fixed time period to allow a CAN Controller to execute internal processes prior to the next receive or transmit task.

### Bus-Idle

The Bus-Idle time may be of arbitrary length (minimum 0 bit). The bus is recognized to be free and a CAN Controller having information to transmit may access the bus. The detection of a dominant bit level during Bus-Idle on the bus is interpreted as the Start-of-Frame.

### Bus Organization

Bus organization is based on five basic rules described in the following paragraphs.

### Bus Access

CAN Controllers only start transmission during the Bus-Idle state. All CAN Controllers synchronize on the leading edge of the Start-of-Frame (hard synchronization).

### Arbitration

If two or more CAN Controllers simultaneously start transmitting, the bus access conflict is solved by a bit-wise arbitration process during transmission of the Arbitration Field.

During arbitration every transmitting CAN Controller compares its transmitted bit level with the monitored bus level. Any CAN Controller which transmits a recessive bit and monitors a dominant bus level immediately becomes the receiver of the higher-priority message on the bus without corrupting any information on the bus. Each message contains a unique Identifier and a RTR bit describing the type of data within the message. The Identifier together with the RTR bit implicitly define the message's bus access priority. During arbitration the most significant bit of the Identifier is transmitted first and the RTR bit last. The message with the lowest binary value of the Identifier and

RTR bit has the highest priority. A Data Frame has higher priority than a Remote Frame due to its RTR bit having a dominant level.

For every Data Frame there is a unique transmitter. For reasons of compatibility with other CAN-bus controllers, use of the Identifier bit pattern ID = 1111111XXXX<sub>b</sub> (X being bits of arbitrary level) is forbidden.

The number of available different Identifiers is 2032 ( $2^{11} - 2^4$ ).

### Coding / Decoding

The following bit fields are coded using the bit-stuffing technique:

- Start-of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence

When a transmitting CAN Controller detects five consecutive bits of identical polarity to be transmitted, a complementary (stuff) bit is inserted into the transmitted bit-stream.

When a receiving CAN Controller has monitored five consecutive bits with identical polarity in the received bit streams of the above described bit fields, it automatically deletes the next received (stuff) bit. The level of the deleted stuff bit has to be the complement of the previous bits; otherwise a Stuff Error will be detected and signaled.

The remaining bit fields or frames are of fixed form and are not coded or decoded by the method of bit-stuffing.

The bit-stream in a message is coded according to the Non-Return-to-Zero (NRZ) method, i.e., during a bit period, the bit level is held constant, either recessive or dominant.

### Error Signaling

A CAN Controller which detects an error condition, transmits an Error Flag. Whenever a Bit Error, Stuff Error, Form Error or an Acknowledgement Error is detected, transmission of an Error Flag is started at the next bit. Whenever a CRC Error is detected, transmission of an Error Flag starts at the bit following the Acknowledge Delimiter, unless an Error Flag for another error condition has already started. An Error Flag violates the bit-stuffing or corrupts the fixed form bit fields. A violation of the bit-stuffing law affects any CAN Controller which detects the error condition. These devices will also transmit an Error Flag.

## Single-chip 8-bit microcontroller with CAN controller

80C592/83C592/87C592

An error-passive CAN Controller which detects an error condition, transmits a Passive Error Flag. A Passive Error Flag is not able to interrupt a current message at different CAN Controllers but this type of Error Flag may be ignored (overwritten) by other CAN Controllers. After having detected an error condition, an error-passive CAN Controller will wait for six consecutive bits with identical polarity and when monitoring them, interpret them as an Error Flag.

After transmission of an Error Flag, each CAN Controller monitors the bus-line until it detects a transition from a dominant-to-recessive bit level. At this point in time, every CAN Controller has finished transmitting its Error Flag and all CAN Controllers start transmitting seven additional recessive bits.

The message format of a Data Frame or Remote Frame is defined in such a way that all detectable errors can be signaled within the message transmission time and therefore it is very simple for the CAN Controllers to associate an Error Frame to the corresponding message and to initiate retransmission of the corrupted message.

If a CAN Controller monitors any deviation of the fixed form of an Error Frame, it transmits a new Error Frame.

### Overload Signaling

Some CAN Controllers (but not the one on-chip of the 8XC592) require to delay the transmission of the next Data Frame or Remote Frame by transmitting one or more Overload Frames. The transmission of an Overload Frame must start during the first bit of an expected Intermission Field. Transmission of Overload Frames which are reactions on a dominant bit during an expected Intermission Field, start one bit after this event.

Though the format of Overload Frame and Error Frame are identical, they are treated differently. Transmission of an Overload Frame during Intermission Field does not initiate the retransmission of any previous Data Frame or Remote Frame.

If a CAN Controller which transmitted an Overload Frame monitors any deviation of its fixed form, it transmits an Error Frame.

### Error Detection

The processes described in the following paragraphs are implemented in the 8XC592's on-chip CAN Controller for error detection.

#### Bit Error

A transmitting CAN Controller monitors the bus on a bit-by-bit basis. If the bit level

monitored is different from the transmitted one, a Bit Error is signaled. The exceptions being:

- During the Arbitration Field, a recessive bit can be overwritten by a dominant bit. In this case, the CAN Controller interprets this as a loss of arbitration.
- During the Acknowledge Slot, only the receiving CAN Controllers are able to recognize a Bit Error.

#### Stuff Error

The following bit fields are coded using the bit-stuffing technique:

- Start-of-Frame
- Arbitration Field
- Control Field
- Data Field
- CRC Sequence

There are two possible ways of generating a Stuff Error:

- A disturbance generates more than the allowed five consecutive bits with identical polarity. These errors are detected by all CAN Controllers.
- A disturbance falsifies one or more of the five bits preceding the stuff bit. This error situation is not recognized as a Stuff Error by the receivers. Therefore, other error detection processes may detect this error condition such as: CRC check, format violation at the receiving CAN Controllers or Bit Error detection by the transmitting CAN Controller.

#### CRC Error

To ensure the validity of a transmitted message all receivers perform a CRC check. Therefore, in addition to the (destuffed) information digits (Start-of-Frame up to Data Field), every message includes some control digits (CRC Sequence; generated by the transmitting CAN Controller of the respective message) used for error detection.

The code used by all CAN Controllers is a (shortened) BCH code, extended by a parity check and has the following attributes:

- 127 bits as maximum length of the code
- 112 bits as maximum number of information digits (maximum 83 bits are used by the CAN Controller)
- Length of the CRC Sequence amounts to 15 bits
- Hamming distance  $d=6$ .

As a result,  $(d-1)$  random errors are detectable (some exceptions exist).

The CRC Sequence is determined (calculated) by the following procedure.

1. The destuffed bit stream consisting of Start-of-Frame up to the Data Field (if present) is interpreted as polynomial with coefficients 0 or 1.
2. This polynomial is divided (modulo-2) by the following generator polynomial, which includes a parity check:

$$f(X) = (X^{14} + X^9 + X^8 + X^6 + X^5 + X^4 + X^2 + X + 1) (X + 1) = 1100010110011001_b.$$

3. The remainder of this polynomial division is the CRC sequence.

Burst errors are detected up to a length of 15 [degree of  $f(X)$ ]. Multiple errors (number of disturbed bits at least  $d=6$ ) are not detected with a residual error probability of  $2^{-15}$  ( $\approx 3 \cdot 10^{-5}$ ) by CRC check only.

#### Form Error

Form Errors result from violations of the fixed form of the following bit fields:

- CRC Delimiter
- Acknowledge Delimiter
- End-of-Frame
- Error Delimiter
- Overload Delimiter

During the transmission of these bit fields an error condition is recognized if a dominant bit level instead of a recessive one is detected.

#### Acknowledgement Error

This is detected by a transmitter whenever it does not monitor a dominant bit during the Acknowledge Slot.

#### Error Detection by an Error Flag of another CAN Controller

The detection of an error is signaled by transmitting an Error Flag. An Active Error Flag causes a Stuff Error, a Bit Error or a Form Error at all other CAN Controllers.

#### Error Detection Capabilities

Errors which occur at all CAN Controllers (global errors) are 100% detected. For local errors, i.e., for errors occurring at some CAN Controllers only, the shortened BCH code, extended by a parity check, has the following error detection capabilities:

- Up to five single Bit Errors are 100% detected, even if they are distributed randomly within the code
- All single Bit Errors are detected if their total number (within the code) is odd
- The residual error probability of the CRC check amounts to  $3 \cdot 10^{-5}$ .

## Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### Error Confinement (definitions)

#### Bus-Off

A CAN Controller which has too many unsuccessful transmissions, relative to the number of successful transmissions, will enter the Bus-Off state. It remains in this state, neither receiving nor transmitting messages until the Reset Request bit is set LOW (absent) and both Error Counters set to 0.

#### Acknowledge (ACK)

A CAN Controller which has received a valid message correctly, indicates this to the transmitter by transmitting a dominant bit level on the bus during the Acknowledge Slot, independent of accepting or rejecting the message.

#### Error-Active

An error-active CAN Controller in its normal operating state is able to receive and to transmit normally and also to transmit an Active Error Flag.

#### Error-Passive

An error-passive CAN Controller may transmit or receive messages normally. In the case of a detected error condition it transmits a Passive Error Flag instead of an Active Error Flag.

Hence the influence on bus activities by an error-active CAN Controller (e.g., due to a malfunction) is reduced.

#### Suspend Transmission

After an error-passive CAN Controller has transmitted a message, it sends eight recessive bits after the Intermission Field and then checks for Bus-Idle. If during Suspend Transmission another CAN Controller starts transmitting a message the suspended CAN

Controller will become the receiver of this message; otherwise being in Bus-Idle it may start to transmit a further message.

#### Start-Up

A CAN Controller which either was switched off or is in the Bus-Off state, must run a Start-Up routine in order to:

- Synchronize with other available CAN Controllers before starting to transmit. Synchronization is achieved, when 11 recessive bits, equivalent to Acknowledge Delimiter, End-of-Frame and Intermission Field, have been detected (Bus-Free).
- Wait for other CAN Controllers without passing into the Bus-Off state (due to a missing acknowledge), if there is no other CAN Controller currently available.

### Aims of Error Confinement

#### Distinction of Short and Long Lasting Disturbances

The CPU must be informed when there are long-lasting disturbances and when bus activities have returned to normal operation.

During long-lasting disturbances, a CAN Controller enters the Bus-Off state and the CPU may use default values.

Minor disturbances of bus activities will not affect a CAN Controller. In particular, a CAN Controller does not enter the Bus-Off state or inform the CPU of a short-lasting bus disturbance.

#### Detection and Localization of Hardware Disturbance and Defects

The rules for error confinement are defined by the CAN protocol specification (and implemented in the 8XC592's on-chip CAN Controller), in such a way that the CAN Controller, being nearest to the error-locus,

reacts with a high probability the quickest (i.e., becomes error-passive or Bus-Off). Hence errors can be localized and their influence on normal bus activities is minimized.

#### Error Confinement

All CAN Controllers contain a Transmit Error Counter and a Receive Error Counter, which registers errors during the transmission and the reception of messages, respectively.

If a message is transmitted or received correctly, the count is decreased. In the event of an error, the count is increased. The Error Counters have a non-proportional method of counting: an error causes a larger counter increase than a correctly transmitted/received message causes the count to decrease. Over a period of time this may result in an increase in error counts, even if there are fewer corrupted messages than uncorrupted ones. The level of the Error Counters reflect the relative frequency of disturbances. The ratio of increase/decrease depends on the acceptable ration of invalid/valid messages on the bus and is hardware implemented to eight.

If one of the Error Counters exceeds the Warning Limit of 96 error points, indicating a significant accumulation of error conditions, this is signaled by the CAN Controller (Error Status, Error Interrupt).

A CAN Controller operates in the error-active mode until it exceeds 127 error points on one of its Error Counters. At this point it will enter the error-passive state.

A transmit error which exceeds 255 error points results in the CAN Controller entering the Bus-Off state.

# Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### INTERRUPT SYSTEM

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronously to the execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution a multiple-source, two-priority-level, nested interrupt system is provided. Interrupt response latency is from 2.25µs to 7.5µs when using a 16MHz crystal. The latency time depends on the sequence of instructions executed directly after an interrupt request. During a CAN-DMA transfer the interrupt system is disabled. The 8XC592 acknowledges interrupt requests from fifteen sources as follows:

- INT0 and INT1: externally via pins 27 and 28 respectively
- Timer 0 and Timer 1: from the two internal counters
- Timer T2 (8 separate interrupts): 4 capture interrupts, 3 compare interrupts and an overflow interrupt
- ADC end-of-conversion interrupt
- CAN Controller interrupt
- UART serial I/O port interrupt.

| T2 overflow         | T2 0073H  |

#### Interrupt Priority

Each interrupt source can be either high priority or low priority. If both priorities are requested simultaneously, the processor will branch to the high priority vector. If there are simultaneous requests from sources of the same priority, then interrupts will be serviced in the following order: X0, S1, ADC, T0, CT0, CM0, X1, CT1, CM1, T1, CT2, CM2, S0, CT3, T2.

A low priority interrupt routine can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

## 80C592/83C592/87C592

**Table 11. Status of External Pins During Sleep, Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0    | PORT 1    | PORT 2    | PORT 3    | PORT 4    | PWM0/<br>PWM1 |
|------------|----------------|-----|------|-----------|-----------|-----------|-----------|-----------|---------------|
| Idle       | Internal       | 1   | 1    | Port Data | Port Data | Port Data | Port Data | Port Data | High          |
| Idle       | External       | 1   | 1    | Float     | Port Data | Address   | Port Data | Port Data | High          |
| Power-down | Internal       | 0   | 0    | Port Data | Port Data | Port Data | Port Data | Port Data | High          |
| Power-down | External       | 0   | 0    | Float     | Port Data | Port Data | Port Data | Port Data | High          |

**NOTE:**

If the port pins P1.6 and P1.7 are used as the CAN transmitter outputs (CTX0 and CTX1), then during Sleep and Power-down mode these pins output a "recessive" level.

### POWER REDUCTION MODES

The 8XC592 has three software-selectable modes to reduce power consumption. These are:

- Sleep mode, affecting the CAN Controller only
- Idle mode, affecting the
  - CPU (halted)
  - Timer 2 (stopped and reset)
  - PWM0, PWM1 (reset, output = HIGH)
  - ADC (aborted if in progress)
- Power-down mode, affecting the whole 8XC592 device.

### CAN Sleep Mode

In order to reduce power consumption of the P8XC592 the CAN Controller may be switched off (disconnecting the internal clock) by setting the CAN Command Register bit 4 (Sleep) HIGH. The CAN Controller leaves this Sleep mode by detecting either activity on the CAN-bus (dominant bit-level on CRX0/CXR1) or by setting the Sleep bit to LOW.

As the CPU cannot only write to the Sleep bit, but can also read it, the CAN Controller status can be determined directly.

### Idle Mode

The instruction that sets PCON.0 is the last one executed in the normal operating mode before Idle mode is activated. Once in the Idle mode, the CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, RAM and all other registers maintain their data during Idle mode. The status of the external pins during Idle mode is shown in Table 12.

There are three ways to terminate the Idle mode:

Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, provided that the interrupt source is active during Idle

mode. After the interrupt is serviced, the program continues with the instruction immediately after the one, at which the interrupt request was detected.

The flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or during the Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When Idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.

Another way of terminating the Idle mode is an external hardware reset. Since the oscillator is still running, the reset signal is required to be active only for 2 machine cycles (24 oscillator periods) to complete the reset operation.

The third way is the internally generated watchdog reset after an overflow of Timer 3.

### Power-down Mode

The instruction that sets PCON.1 to HIGH, is the last one executed before entering the Power-down mode. In Power-down mode the oscillator of the P8XC592 is stopped. If the CAN Controller is in use, it is recommended to set it into Sleep mode before entering Power-down mode. However, setting PCON.1 to HIGH also sets the Sleep bit (CAN Controller Command Register bit 4) to HIGH.

The P8XC592 leaves Power-down mode either by a hardware reset or by a CAN Wake-up interrupt (due to activity on the CAN bus), if the SI01 (CAN) interrupt source is enabled (contents of register IEN0 = 1x1xxxxb). A hardware reset affects the whole P8XC592, but leaves the contents of the on-chip RAM unchanged (CAN Controller and CPU's Special Function Registers are reset). A CAN Wake-up interrupt during Power-down mode causes a reset output

pulse with a width of 6144 machine cycles (4.6ms with  $f_{CLK}=16\text{MHz}$ ). All hardware except from the CAN Controller of the P8XC592 is reset (the contents of all CAN Controller registers are preserved).

Note that a capacitance connected to the RST pin could lengthen the internally generated reset pulse. If the pulse exceeds 8192 machine cycles, the CAN Controller part is reset too.

### RESET

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods). The CPU responds by executing an internal reset. During reset ALE and PSEN output at a HIGH level. In order to perform a correct reset, this level must not be affected by external elements.

Also with the P8XC592, the RST line can be pulled HIGH internally by a pull-up transistor activated by the watchdog timer T3. The length of the output pulse from T3 is 3 machine cycles. A pulse of such short duration is necessary in order to recover from a processor or system fault as fast as possible.

During Power-down a reset could be generated internally via the CAN Wake-up interrupt. Then the RST pin is pulled HIGH for 6144 machine cycles. In this case the CAN Controller is not reset.

If the watchdog timer or the CAN Wake-up interrupt is used to reset external devices, the usual capacitor arrangement for power-on reset should not be used. However, the internal reset is forced, independent of the external level on the RST pin.

The Main RAM and AuxRAM are not affected. When VDD is turned on, the RAM content is indeterminate.

Single-chip 8-bit microcontroller  
with CAN controller

#### NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

NOTES ON NEXT PAGE.

## Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### NOTES TO THE DC ELECTRICAL CHARACTERISTICS:

- The operating current is measured with all output pins unloaded; XTAL1 is driven with  $t_R = t_F = 10\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; EA = RST = Port 0 = P1.6 = P1.7 = EW =  $V_{DD}$ ; STADC =  $V_{SS}$ ; CRX0 = 2.7V; CRX1 = 2.3V.
- The idle mode supply current is measured with all output pins unloaded; XTAL1 is driven with  $t_R = t_F = 10\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; Port 0 = P1.6 = P1.7 = EW =  $V_{DD}$ ; EA = RST = STADC =  $V_{SS}$ ; CRX0 = 2.7V; CRX1 = 2.3V.
- The idle and sleep mode supply current is measured with all output pins unloaded; XTAL1 is driven with  $t_R = t_F = 10\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; Port 0 = P1.6 = P1.7 = EW = CRX0 =  $V_{DD}$ ; EA = RST = STADC = CRX1 =  $V_{SS}$ ; CAN: register 6: = 00H, register 7: = 12H, register 8: = 02H, register 0: = 20H, wait  $15t_{CY}$ , register 1: = 10H, wait for bit Sleep = 1.
- The power-down current is measured with all output pins unloaded; Port 0 = P1.6 = P1.7 = EW = CRX0 =  $V_{DD}$ ; XTAL1 = EA = RST = STADC = CRX1 =  $V_{SS}$ . Windowed devices must have the window covered during testing.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be limited externally as follows:
 

|                                       |      |
|---------------------------------------|------|
| Maximum $I_{OL}$ per 8 bit port       |      |
| – Port 0:                             | 26mA |
| – Port 1:                             | 32mA |
| – Ports 2, 3, and 4:                  | 15mA |
| Maximum $I_{OL}$ for all output pins: | 71mA |

If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Capacitive loads on Port0 and Port2 may degrade the LOW level output voltage of ALE, Port1 and Port2. During a 1-to-0 transition on the Port0 and Port2 pins and a capacitive load > 100pF, the ALE LOW level may exceed 0.8V. In that case, it is necessary to connect ALE to a Schmitt trigger input respectively use an address latch with a Schmitt trigger STROBE input.
- Capacitive loads on Port0 and Port2 may cause a HIGH level output voltage degradation of ALE and PSEN below 0.9  $V_{DD}$  during the address bits are stabilizing.
- $AV_{REF+} = 5.12\text{V}$ ;  $AV_{REF-} = 0\text{V}$ ;  $AV_{DD} = 5.0\text{V}$ .
- The differential non-linearity ( $DL_e$ ) is the difference between the actual step width and the ideal step width.
- The ADC is monotonic, there are no missing codes.
- The integral non-linearity ( $IL_e$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error.
- The offset error ( $OS_e$ ) is the absolute difference between the straight line which fits the actual transfer curve after removing gain error, and a straight line which fits the ideal transfer curve. The offset error is constant at every point of the actual transfer curve.
- The gain error ( $G_e$ ) is the relative difference in percent between the straight line fitting the actual transfer curve after removing offset error and the straight line which fits the ideal transfer curve. The gain error is constant at every point on the transfer curve.
- The absolute voltage error ( $A_e$ ) is the maximum difference between the center of the steps of the actual transfer curve of the not calibrated ADC and the ideal transfer curve.
- Not tested during production.
- Source current for the CTX0, CTX1 outputs together.

| t <sub>SD</sub>                                                         |        | Sum of input and output delay<br>(V <sub>DIF</sub> = ± 32mV; 1.4V < V <sub>I</sub> < AV <sub>DD</sub> - 1.4V) AV <sub>DD</sub> = 5V ± 5% | -                       | 60                      | ns   |

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

with CAN controller

80C592/83C592/87C592

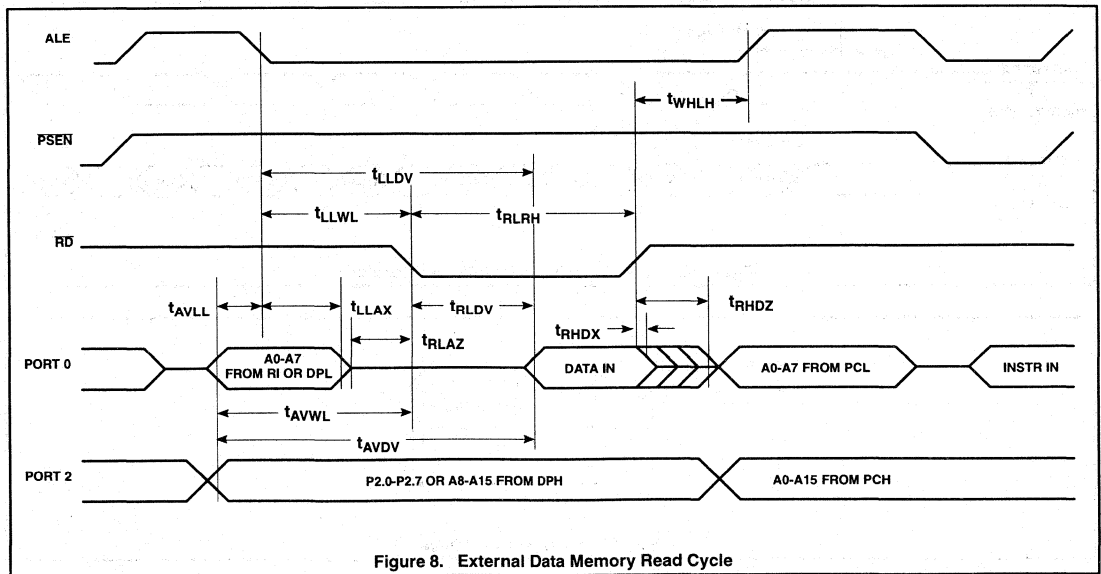

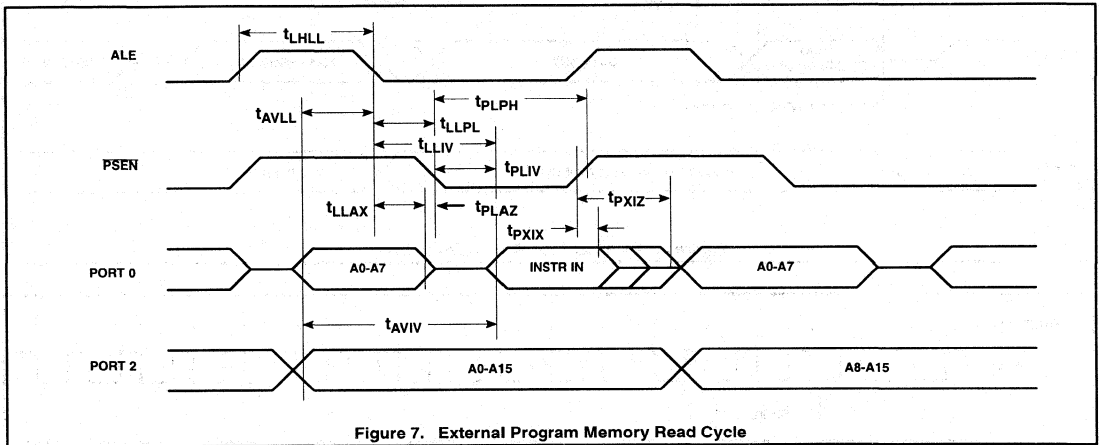

**EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. the designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE
- P – PSEN

- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

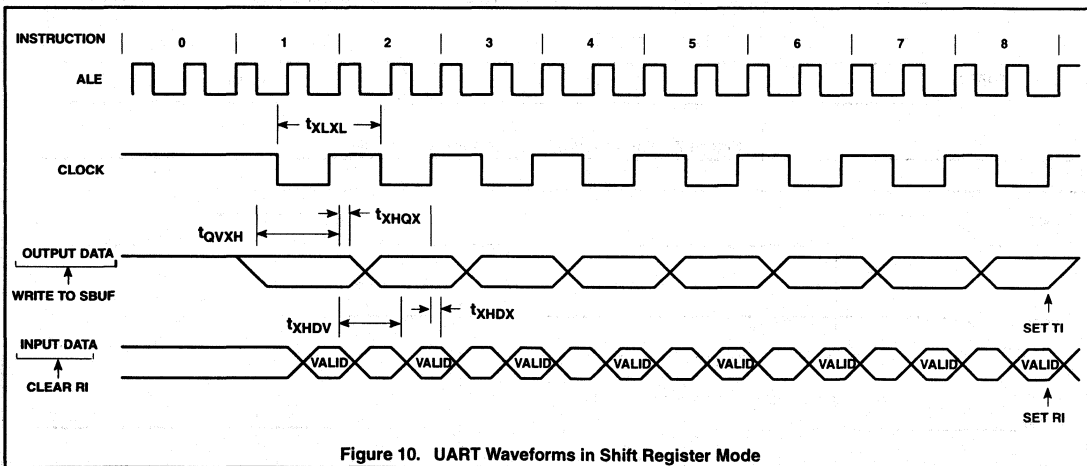

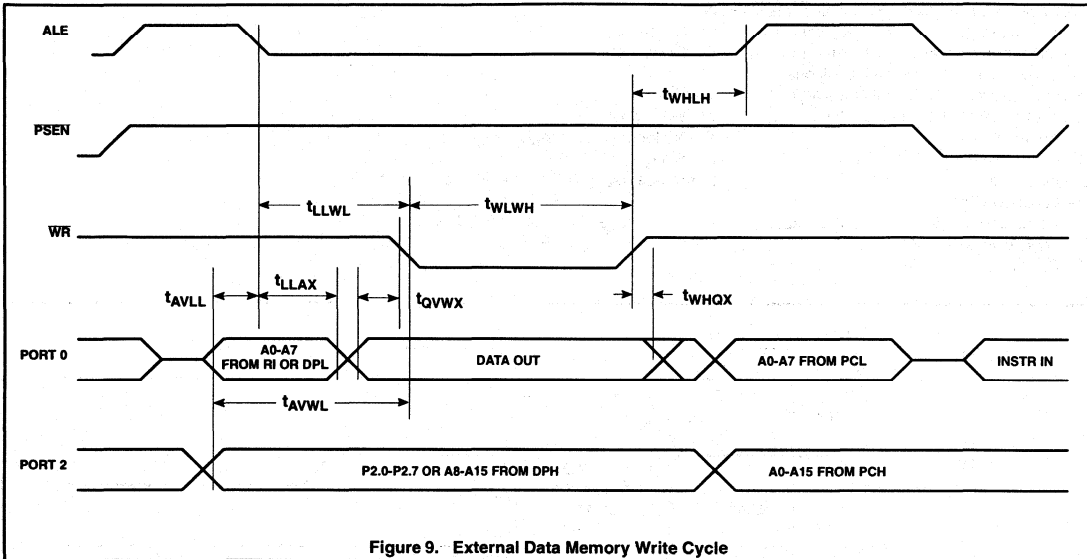

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## Single-chip 8-bit microcontroller with CAN controller

## 80C592/83C592/87C592

### EPROM CHARACTERISTICS

The 87C592 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C592 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C592 manufactured by Philips.

Table 13 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 15 and 16. Figure 17 shows the circuit configuration for normal program memory verification.

### Quick-Pulse Programming

The setup for microcontroller quick-pulse programming is shown in Figure 15. Note that the 87C592 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 15. The code byte to be programmed into that location is applied to port 0. RST, PSEN, and pins of ports 2 and 3 specified in Table 13 are held at the "Program Code Data" levels indicated in Table 13. The ALE/PROG is pulsed low 25 times as shown in Figure 16.

To program the encryption table, repeat the 25-pulse programming sequence for

addresses 0 through 1FH, using the "Pgm Encryption Table" levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25-pulse programming sequence using the "Pgm Lock Bit" levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the  $\overline{EA}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

### Program Verification

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 17. The other pins are held at the "Verify Code Data" levels indicated in Table 13. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

### Reading the Signature Bytes

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 9CH indicates 87C592

### Program/Verify Algorithms

Any algorithm in agreement with the conditions listed in Table 13, and which satisfies the timing specifications, is suitable.

### Erasure Characteristics

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to the light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient. Erasure leaves the array in an all 1s state.

**Table 13. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{EA}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|------------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                      | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                      | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 0    | 0    |

#### NOTES:

1. 0 = Valid low for that pin; 1 = valid high for that pin.

2.  $V_{PP} = 12.75V \pm 0.25V$ .

3.  $V_{DD} = 5V \pm 10\%$  during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs ( $\pm 10\mu s$ ) and high for a minimum of 10μs.

## 8-bit microcontroller with on-chip CAN

## P8xCE598

### 1.0 FEATURES

- 80C51 central processing unit (CPU)
- 32 kbyte on-chip ROM (EPROM), externally expandable to 64 kbyte
- 2 × 256 byte on-chip RAM, externally expandable to 64 kbyte
- Two standard 16-bit timer/counters
- One additional 16-bit timer/counter coupled to four capture and three compare registers
- A 10-bit ADC with eight multiplexed analog inputs
- Two 8-bit resolution, pulse width modulation outputs
- 15 interrupt sources with 2 priority levels (2 to 6 external interrupt sources possible)
- Five 8-bit I/O ports plus one 8-bit input port shared with analog inputs
- CAN controller with DMA transfer facility to internal RAM
- 1 Mbit/s CAN-Controller with bus failure management facility
- $V_{DD}/2$  reference voltage
- Full-duplex UART compatible with the standard 80C51
- On-chip watchdog timer
- 1.2 to 16MHz clock frequency (3.5 to 16MHz for EPROM/OTP version)
- Electro-Magnetic Compatibility (EMC) improvements

### 2.0 GENERAL DESCRIPTION

The P80CE598/P83CE598/P87CE598 (hereafter generically referred to as P8xCE598) is a single-chip 8-bit high-performance microcontroller with on-chip CAN-controller designed for use in automotive and general industrial applications. In addition to the 80C51 standard features, this device provides a number of dedicated hardware functions highly suitable for automotive and general industrial applications. Figure 1 illustrates the block diagram of the P8xCE598.

Three versions of the P8xCE598 will be offered:

- P83CE598 (ROM version)
- P80CE598 (ROMless version)
- P87CE598 (EPROM/OTP version) (OTP = One Time Programming)

The P8xCE598 basically combines the functions of the existing P8xC552 and the Philips CAN-controller PCA82C200 (CAN =

Controller Area Network) with the following enhanced features:

- 32 kbyte Program Memory
- 2 × 256 byte Data Memory
- DMA between CAN Transmit/Receive Buffer and internal RAM

The temperature range includes a -40 to +85°C version for general applications and an automotive temperature range version of -40 to +125°C for the ROM and ROMless versions with a maximum clock frequency of 16MHz. The P87CE598 (EPROM/OTP version) has a temperature range of -40 to +85°C.

The main differences to the P8xC552 microcontroller are:

- A CAN-controller substitutes the I<sup>2</sup>C-serial interface
- 32 kbyte programmable ROM respectively, EPROM (P8xC552 has 8 kbyte)
- Additional 256 byte RAM

### 3.0 ORDERING INFORMATION

| EXTENDED TYPE NUMBER | PACKAGE |              |                  |        | TEMPERATURE RANGE (°C) | FREQUENCY (MHz) |

## 8-bit microcontroller with on-chip CAN

## P8xCE598

**4.0 ELECTROMAGNETIC COMPATIBILITY (EMC)**

Primary attention is paid to the reduction of electro-magnetic emission of the microcontroller P8xCE598. The following features reduce the electro-magnetic emission and additionally improve the electromagnetic susceptibility:

- One analog supply voltage pin ( $AV_{DD}$ ) and one analog ground pin ( $AV_{SS}$ ) as a pair of pins placed on one side of the package (see Figure ) to provide:
  - analog power supply (+5V) and analog ground for ADC, CAN receiver and reference voltage.
- Four digital supply voltage pins ( $V_{DD;1;2;3;4}$ ) and four digital ground pins ( $V_{SS1;2;3;4}$ ) are provided on the package. From these pins, one  $V_{DD}$  and one  $V_{SS}$  as a pair of pins are placed on each of the four sides of the package to provide:
  - $V_{DD1}/V_{SS1}$  for internal logic (CPU, Timers/counters, Memory, CAN, UART, ADC)
  - $V_{DD2}/V_{SS2}$  for Port 1, Port 3 and Port 4, and  $PWM0$  and  $PWM1$  outputs
  - $V_{DD3}/V_{SS3}$  for the on-chip oscillator

- $V_{DD4}/V_{SS4}$  for the Port 0, Port 2, ALE output and  $PSEN$  output

- One CAN supply voltage pin ( $CV_{DD}$ ) and one CAN ground pin ( $CV_{SS}$ ) as a pair of pins placed on one side of the package to provide:
    - Power supply (+5V) and ground for the CAN transmitter outputs
  - One the P87CE598 version, the additional supply voltage pin ( $V_{PP}$ ) to provide:
    - the programming supply voltage  $V_{PP}$ , the alternative function for pin 65 ( $EA/V_{PP}$ ) on the P87CE598 EPROM/OTP version (see Figure 13).
  - Internal decoupling capacitance improves the EMC radiation behaviour and the EMC immunity.
  - External capacitors are to be located as close as possible between pins  $V_{DDX}$  and  $V_{SSX}$  cross-connected in the following method (i.e.,  $V_{DD1}$  to  $V_{SS2}$ , etc.); ceramic chip capacitors are recommended (100nF).
- 4.1 Recommendation on ALE**  
For applications that require no external memory or temporarily no external memory: the ALE output signal (pulses at a frequency

of  $f_{OSC}/6$ ) can be disabled under software control (bit 5 in the PCON SFR: "RFI"); if disabled, no ALE pulse will occur. ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE as a normal MOVX. ALE will retain its normal HIGH value during idle mode and a LOW value during power-down mode while in the "RFI" reduction mode.

Additionally during internal access ( $EA = 1$ ) ALE will toggle normally when the address exceeds the internal program memory size. During external access ( $EA = 0$ ) ALE will always toggle normally, whether the flag "RFI" is set or not.

**5.0 OTHER FEATURES**

The 8xCE598 has the same operation as the 8XC552 for the A/D, Timers, PWM outputs, UART and Watchdog Timer. Please refer to the 8XC552 datasheet for details on these features. The CAN interface and AUX RAM on the 8xCE598 are discussed in detail in the 8XC592 datasheet. Please refer to the 8XC592 datasheet for information on these features.

If the internal reference is used, then REF should be connected to AV <sub>SS</sub> via a 10nF (or more) capacitor (note 3).                                                                                                                                                      |
| CRX1 and CRX0             | 79 and 80             | <b>Inputs from the CAN</b> bus line to the differential input comparator of the on-chip CAN-controller. A CRX0 level higher than that of CRX1 is interpreted as a logical "1" (recessive) and vice versa for a logical "0" (dominant).                                                                                                                                                           |
| N.C.                      | 23, 49,<br>50, 66, 67 | No Connection (both SOT318 and SOT351).                                                                                                                                                                                                                                                                                                                                                          |

## NOTES:

- If the CAN-controller is in the reset state (e.g., after a power-up reset; CAN Control Register bit 0), the CAN transmitter outputs are floating and the pins P1.6 and P1.7 can be used as open-drain port pins. After a power-up reset the port data is HIGH, leaving the pins P1.6 and P1.7 floating.
- For P83CXXX microcontrollers specified with the option "ROM-code protection", the EA pin is latched during reset and is "don't care" after reset, regardless of whether the ROM-code protection is selected or not.
- After an external reset (RST = HIGH) the internal AV<sub>DD</sub>/2 source is activated and the pin REF is a reference output. During Power-down mode the AV<sub>DD</sub>/2 source is switched off if the CAN-controller is in the reset state (e.g., after an external reset).
- To avoid a "latch up" effect at power-on, the voltage on any pin (at any time) must not be higher or lower than V<sub>DD</sub>+0.5V or V<sub>SS</sub>-0.5V respectively.

**NOTES TO DC CHARACTERISTICS:**

- The operating current is measured with all output pins disconnected; XTAL1 is driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ;  $EA = RST = Port\ 0 = P1.6 = P1.7 = EW = V_{DD}$ ;  $STADC = V_{SS}$ ;  $CRX0 = 2.7V$ ;  $CRX1 = 2.3V$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL1 is driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ;  $Port\ 0 = P1.6 = P1.7 = EW = V_{DD}$ ;  $EA = RST = STADC = V_{SS}$ ;  $CRX0 = 2.7V$ ;  $CRX1 = 2.3V$ .
- The idle and sleep mode supply current is measured with all output pins disconnected; XTAL1 is driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ;  $Port\ 0 = P1.6 = P1.7 = EW = CRX0 = V_{DD}$ ;  $EA = RST = STADC = CRX1 = V_{SS}$ ;  
CAN: register 6: = 00H, register 7: = 12H, register 8: = 02H, register 0: = 20H, wait  $15t_{CY}$ , register 1: = 10H, wait for bit Sleep = 1.
- The power-down current is measured with all output pins disconnected;  $Port\ 0 = P1.6 = P1.7 = EW = CRX0 = V_{DD}$ ;  
 $EA = RST = STADC = CRX1 = XTAL1 = V_{SS}$ . Window devices have to be covered.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be limited externally as follows:  
Maximum  $I_{OL}$  per 8 bit port  
Port 0: 36mA  
Port 1: 32mA  
Ports 2, 3 and 4: 15mA  
Maximum  $I_{OL}$  for all output pins: 71mA  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are guaranteed to sink current greater than the listed test conditions.
- Capacitive loads on Port 0 and Port 2 may degrade the LOW level output voltage of ALE, Port 1 and Port 3. During a 1-to-0 transition on the Port 0 and Port 2 pins and a capacitive load  $> 100pF$ , the ALE LOW level may exceed 0.8V. In the case that it is necessary to connect ALE to a Schmitt trigger input respectively, use an address latch with a Schmitt trigger STROBE input.
- Capacitive loads on Port 0 and Port 2 may cause a HIGH level voltage degradation of ALE and  $PSEN$  below  $0.9V_{DD}$  during the address bits are stabilizing.
- $t_{CY} = 12t_{CLK}$  is the machine cycle time.
- $AV_{REF+} = 5.12V$ ;  $AV_{REF-} = 0V$ ;  $AV_{DD} = 5.0V$ .
- The differential non-linearity ( $DL_n$ ) is the difference between the actual step width and the ideal step width.
- The ADC is monotonic, there are no missing codes.
- The integral non-linearity ( $IL_n$ ) is the peak difference between the center of the steps of the actual and the ideal transfer curve after appropriate adjustment of gain and offset error.
- The offset error ( $OS_n$ ) is the absolute difference between the straight line which fits the actual transfer curve after removing gain error, and a straight line which fits the ideal transfer curve. The offset error is constant at every point of the actual transfer curve.
- The gain error ( $G_n$ ) is the relative difference in percent between the straight line fitting the actual transfer curve after removing offset error and the straight line which fits the ideal transfer curve. The gain error is constant at every point on the transfer curve.
- The absolute voltage error ( $A_n$ ) is the maximum difference between the center of the steps of the actual transfer curve of the not calibrated ADC and the ideal transfer curve.
- Not tested during production.
- Source current for the CTX0, CTX1 outputs together.

## 8-bit microcontroller with on-chip CAN

P8xCE598

- (1) Maximum operating mode;  $V_{DD} = 5.5V$ .
- (2) Maximum operating mode;  $V_{DD} = 4.5V$ .
- (3) Maximum idle and sleep mode;  $V_{DD} = 5.5V$ .
- (4) Maximum idle and sleep mode;  $V_{DD} = 4.5V$ .

## 8-bit microcontroller with on-chip CAN

## P8xCE598

### 10.0 EPROM CHARACTERISTICS

The P87CE598 has an on-chip 32 kbyte EPROM for fast and flexible controller software development. Two versions are available: one in a ceramic QFP package with window for UV-erasure (P87CE598 EFQ) and a low-cost OTP (One Time Programming) version in a Plastic Quad Flat Pack (PQFP) package (87CE598EFB), which is not erasable.

### 10.1 Programming and Verification

The 87CE598 is programmed by using a modified Quick-Pulse Programming algorithm (Trademark algorithm of Intel Corporation). In Table 4 "EPROM Programming Modes" the logic levels for reading the Signature bytes and for programming the Program Memory the Encryption Table and the Lock bits are listed. The circuit configuration and waveforms for programming are shown in Figures 11 and 12. Figure 13 shows the

circuit configuration for code data verification. Note that programming and verification is done with an oscillator frequency of 4 to 6 MHz. The two Signature bytes identifying the device as a P87CE598 manufactured by Philips are located as shown in Table 3.

**Table 3. Signature Bytes**

| ADDRESS | CONTENT | MEANING  |
|---------|---------|----------|
| 30H     | 15H     | Philips  |
| 31H     | 9CH     | P87CE598 |

### 10.2 Security

For code protection the P87CE598 has an Encryption table and two Lock bits. After programming the Encryption table from addresses 0 to 1FH, a verification sequence will present the data at Port 0 as a logical EXNOR of the program byte with one of the Encryption bytes. The Encryption table is not readable. The purpose of Lock bit 1 is to

inhibit programming. It is impossible to fetch code bytes from the internal Program Memory with MOVC-instructions executed from external memory. However, verification of the EPROM and programming of the second Lock bit is still possible. Lock bit 2 additionally disables verification of the program code. Note that for further security the EA input level of the P8xCE598 is latched during Reset.

### 10.3 Erasure

A controlled erasure is done by exposing the EPROM window to an ultraviolet lamp of  $12\mu\text{W}/\text{cm}^2$  for 20 to 39 minutes at a distance of approximately 2.5cm. The integrated dose of the ultraviolet light (2537 Angstroms) must be at least  $15\text{Ws}/\text{cm}^2$ . Erasure leaves the array in an all logic 1s state.

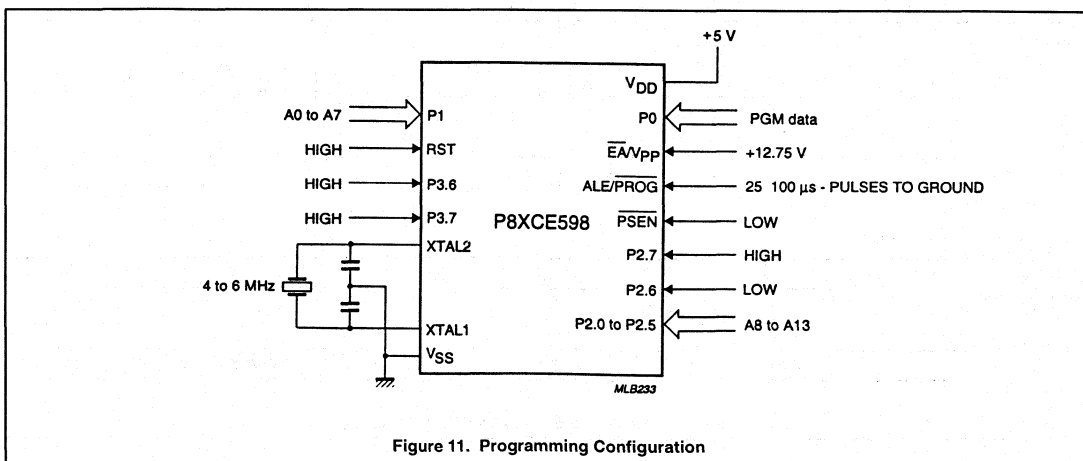

To avoid inadvertent erasure of the EPROM in sunlight or fluorescent lighting it is recommended to cover the window with an opaque label.

**Table 4. EPROM Programming Modes**

| MODE               | RST  | PSEN | ALE/PROG     | EA/V <sub>PP</sub>       | P2.7 | P2.6 | P3.7 | P3.6 |
|--------------------|------|------|--------------|--------------------------|------|------|------|------|
| Read Signature     | HIGH | LOW  | HIGH         | HIGH                     | LOW  | LOW  | LOW  | LOW  |
| program code data  | HIGH | LOW  | LOW (note 1) | V <sub>PP</sub> (note 1) | HIGH | LOW  | HIGH | HIGH |
| Verify code data   | HIGH | LOW  | HIGH         | HIGH                     | LOW  | LOW  | HIGH | HIGH |
| Pgm.Encrypt.table  | HIGH | LOW  | LOW (note 1) | V <sub>PP</sub> (note 1) | HIGH | LOW  | HIGH | LOW  |
| Program Lock bit 1 | HIGH | LOW  | LOW (note 1) | V <sub>PP</sub> (note 1) | HIGH | HIGH | HIGH | HIGH |
| Program Lock bit 2 | HIGH | LOW  | LOW (note 1) | V <sub>PP</sub> (note 1) | HIGH | HIGH | LOW  | LOW  |

**NOTE:**

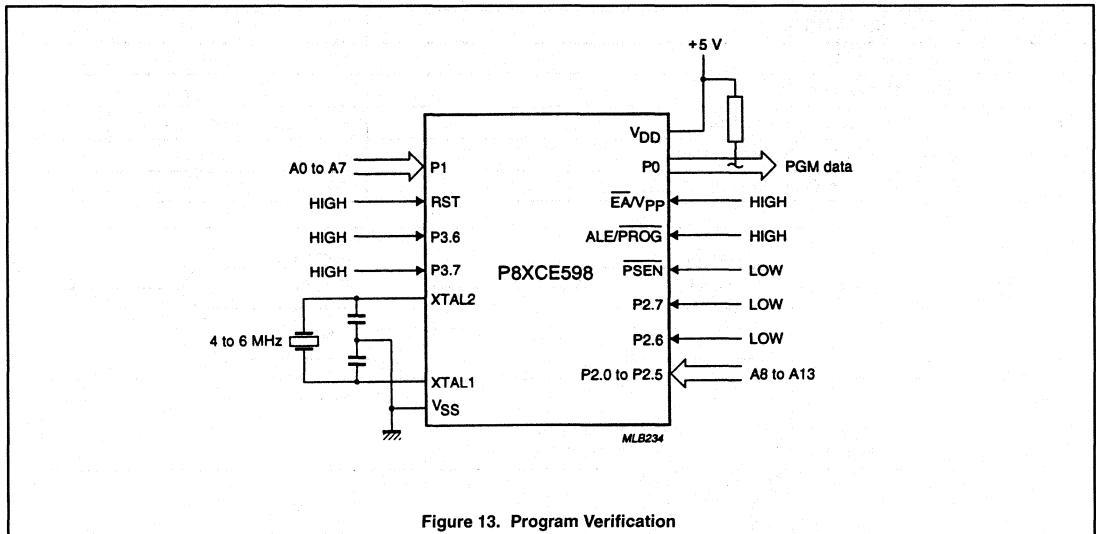

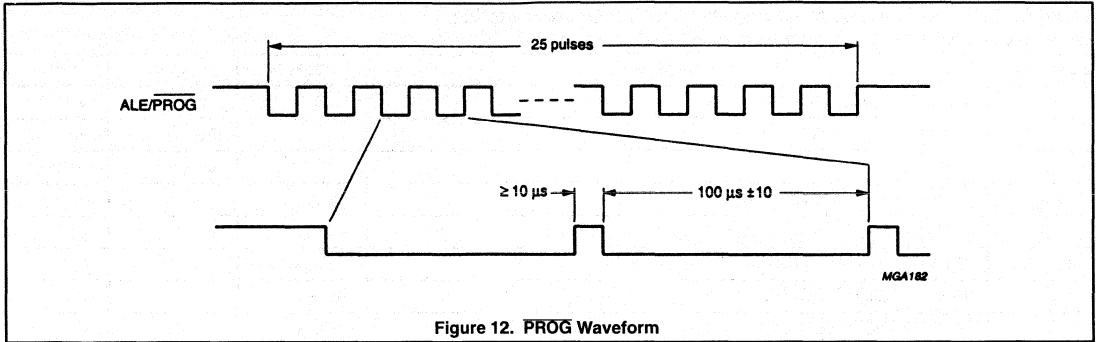

1. ALE/PROG receives 25 programming pulses while V<sub>PP</sub> is held at  $12.75\text{V} \pm 0.25\text{V}$ . Each programming pulse is LOW for  $100\mu\text{s} \pm 10\mu\text{s}$  and HIGH for at least  $10\mu\text{s}$ .

## 11.0 CAN APPLICATION INFORMATION

### 11.1 Latency Time Requirements

Real-time applications require the ability to process and transfer information in a limited and predetermined period of time. If knowing this total time and the time required to process the information, the (maximum allowed) transfer delay time is given. It is measured from the initiation of the transfer up to the signalling of reception. For instance, this is the period of time between programming the CAN Command Register bit 0 (Transmission Request) to HIGH and the time getting an interrupt at a receiving CAN-device (due to the reception of the respective message).

The maximum allowed bit-time ( $t_{BIT}$ ) due to latency time requirements can be calculated as:

(1)  $t_{BIT} \leq t_{MAX\ TRANSFER\ TIME} / (n_{BIT, MAX\ LATENCY} + n_{BIT, MESSAGE})$ .

$t_{MAX\ TRANSFER\ TIME}$ : the maximum allowed transfer delay time (application-specific);

$n_{BIT, MAX\ LATENCY}$ : the maximum latency time (in terms of number of bits), which depends on the actual state of the CAN network (e.g., another message already on the network);

$n_{BIT, MESSAGE}$ : the number of bits of a message; it varies with the number of transferred data bytes  $n_{DATA\ BYTES}$  (0..8) and Stuffbits like:

(2)  $44 + 8 \cdot n_{DATA\ BYTES} \leq n_{BIT, MESSAGE} \leq 52 + 10 \cdot n_{DATA\ BYTES}$

**Example:**  
 For the calculation of  $n_{BIT, MAX\ LATENCY}$  the following is assumed (the term "our message" refers to that one the latency time is calculated for):

- Since at maximum one-bit-time ago another CAN Controller is transmitting
- A single error occurs during the transmission of that message preceding ours, leading to the additional transfer of one Error Frame.
- "Our message" has the highest priority.

giving:

(3)  $n_{BIT, MAX\ LATENCY} \geq 44 + 8 \cdot n_{DATA\ BYTES, WORST\ CASE} + 18$ ;  
 $n_{BIT, MAX\ LATENCY} \leq 52 + 10 \cdot n_{DATA\ BYTES, WORST\ CASE} + 18$ ;

The additional 18 bits are due to the Error Frame and the Intermission Field preceding our message.  $n_{DATA\ BYTES, WORST\ CASE}$  denotes the number of data bytes contained by the longest message being used in a given CAN network.

Here an example is provided to help calculating the maximum bit-time:

#### EXAMPLE: MAXIMUM BIT-TIME CALCULATION

| STATEMENT                                  | COMMENTS                                     |
|--------------------------------------------|----------------------------------------------|
| $t_{MAX\ TRANSFER\ TIME} = 10ms$           | assumption;                                  |
| $n_{DATA\ BYTES, WORST\ CASE} = 6$         | longest message in that network; assumption; |
| $n_{DATA\ BYTES} = 4$                      | our message; assumption;                     |
| $n_{BIT, MAX\ LATENCY} \leq 130$           | using equation (3);                          |
| $n_{MESSAGE} \leq 92$                      | using equation (2);                          |
| $t_{BIT} \leq 10ms / (130 + 92) = 45\mu s$ | using equation (1).                          |

# P8xCE598

## 11.2 Connecting a P8xCE598 to a Bus Line (Physical Layer)

### On-Chip Transceiver

The P8xCE598 features an on-chip differential transceiver including output driver and input comparator both being configurable (see Figure 15). Therefore it supports many types of common transmission media such as:

- Single wire bus line
- Two-wire bus line (differential)
- Optical cable bus line.

The P8xCE598 can directly drive a differential bus line. An example is given in Figure 16 for a bus line having a characteristic impedance of 120Ω. Direct interfacing to the bus line is well suited for applications with limited requirements concerning electromagnetic susceptibility, wiring failure tolerance and protection against transients.

### Transceiver for In-Vehicle Communication

Figure 17 shows a versatile transceiver implementation designed for automotive applications. It features a bit rate of up to 1 Mbit/s and dissipates low power during standby (1.4mA), thus it is suitable also for

applications requiring a sleep mode function with system activation via the bus line. The transceiver provides an extended common mode range for high electromagnetic susceptibility performance.

Two external driver transistors amplify the output current to 35mA typically and provide protection against overvoltage conditions on the bus line (e.g., due to an accidental short-circuit between a bus wire and battery voltage). The serial diodes prevent, in combination with the transistors, the bus from being blocked in case of a bus not powered. More than 32 nodes may be connected to the bus line.

### Detection and Handling of Bus Wiring Failures

Using the P8xCE598 a superior wiring failure tolerance and detection performance can be achieved. This requires both bus lines to be mutually decoupled as shown in Figure 18. Each bus wire is biased separately to a reference voltage of  $AV_{DD}/2$ .

The diodes suppress reverse current in case of a termination circuit being not properly powered or a bus line being short-circuited, i.e., to a voltage higher than 5V. Applying this bus termination circuit the following wiring

failures on the bus are detectable and can be handled:

- Interruption of one bus wire at any location
- Short-circuit of one bus wire to ground or to battery voltage
- Short-circuit between the bus wires.

A bus failure can be detected, e.g., by a drop out of a status message, regularly being transmitted on the bus. If a bus wire is corrupted, the following actions have to be taken:

- Switch the corresponding comparator input over to a reference voltage of  $AV_{DD}/2$
- Disable the corresponding output driver stage.

As a consequence, communication will continue on that bus wire not being corrupted. The required reference voltage and the switches for the comparator inputs are provided on-chip. An output driver stage can be disabled by reconfiguration of the on-chip output driver (reprogramming of the Output Control register of the P8xCE598). To find out which of the bus wires is corrupted, a heuristic method is applied.

### Connection to an Optical Bus Line

Using an optical medium provides the following advantages:

- Bus nodes are galvanically decoupled
- Optical cable features very high noise immunity
- No noise emission by the bus cable.

An example for an interface to an optical connector is given in Figure 19. In most cases a transistor is required to amplify the TX-output current. Thus more optical power is provided to compensate for losses in the optical connectors and the optical star. The P8xCE598 feature an on-chip  $V_{DD}/2$  reference voltage output so only a capacitor

is required for the receiver part. Two optical fibres are used to connect the bus nodes. The TX-fibre transfers the output signal of the CAN Controller to the optical star. The optical star transfers the TX-fibre input signal over to all the RX-fibres. The RX-fibres transfer the resulting optical signal over to the receivers of all the bus nodes.

# CMOS single-chip 8-bit microcontroller

# 80C652/83C652

## DESCRIPTION

The P80C652/83C652 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 80C652/83C652 has the same instruction set as the 80C51. Three versions of the derivative exist:

83C652 — 8k bytes mask programmable ROM

80C652 — ROMless version

80C652 — EPROM version (described in a separate chapter)

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 8XC652 contains a non-volatile 8k × 8 read-only program memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a multi-source, two-priority-level, nested interrupt structure, an I<sup>2</sup>C interface, UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC652 can be expanded using standard TTL compatible memories and logic.

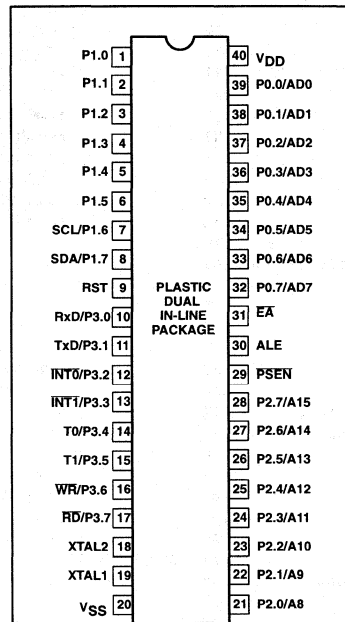

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16(24)MHz crystal, 58% of the instructions are executed in 0.75(0.5)μs and 40% in 1.5(1)μs. Multiply and divide instructions require 3(2)μs.

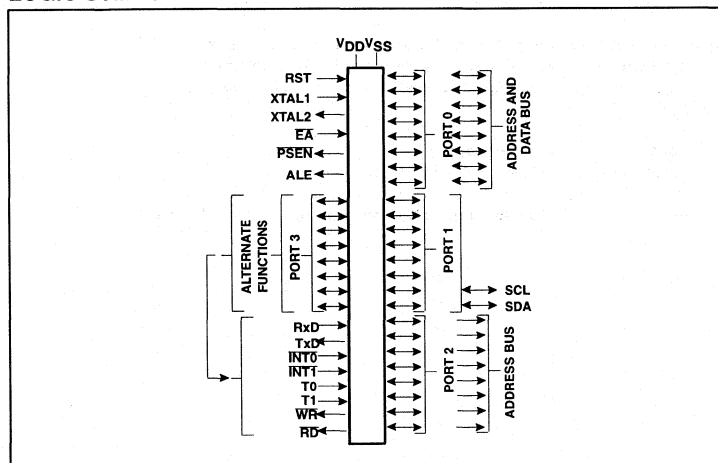

## FEATURES

- 80C51 central processing unit
- 8k × 8 ROM expandable externally to 64k bytes
- 256 × 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- Four 8-bit I/O ports
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART facilities
- Power control modes
  - Idle mode
  - Power-down mode
- ROM code protection
- Extended frequency range: 1.2 to 24 MHz
- Three operating ambient temperature ranges:
  - 0 to +70°C
  - -40 to +85°C
  - -40 to +125°C
- Three operating ambient temperature ranges:

## PIN CONFIGURATIONS

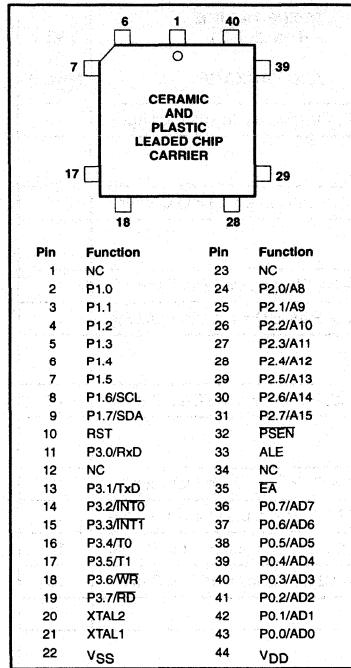

## LOGIC SYMBOL

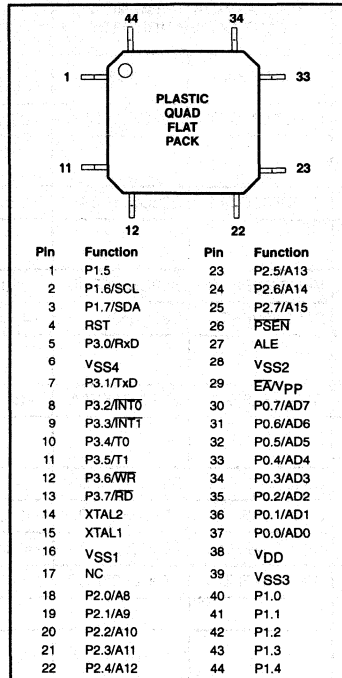

CMOS single-chip 8-bit microcontroller

80C652/83C652

**CERAMIC AND PLASTIC LEADED CHIP CARRIER PIN FUNCTIONS**

**PLASTIC QUAD FLAT PACK PIN FUNCTIONS**

**NOTES TO QFP ONLY:**

1. Due to EMC improvements, all VSS pins (6, 16, 28, 39) must be connected to VSS on the 80C652/83C652.

## CMOS single-chip 8-bit microcontroller

## NOTES:

- 80C652 and 83C652 frequency range is 1.2MHz–16MHz or 1.2 to 24MHz.
- For specification of the EPROM version, see the 87C652 data sheet.
- xxx denotes the ROM code number.
- SOT311 replaced by SOT307-2.

| V <sub>DD</sub> | 40         | 44        | 38            | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |     |    |    |   |
| P0.0–0.7        | 39–32      | 43–36     | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |    |    |   |
| P1.0–P1.7       | 1–8        | 2–9       | 40–44, 1–3    | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Alternate functions include:<br><b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                                                                                                       |     |    |    |   |

| P2.0–P2.7       | 21–28      | 24–31     | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.                                                    |     |    |    |   |

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

# CMOS single-chip 8-bit microcontroller

# 80C652/83C652

## ROM CODE PROTECTION (83C652)

The 8XC652 has an additional security feature. ROM code protection may be selected by setting a mask-programmable security bit (i.e., user dependent). This feature may be requested during ROM code submission. When selected, the ROM code is protected and cannot be read out at any time by any test mode or by any instruction in the external program memory space.

The MOVC instructions are the only instructions that have access to program code in the internal or external program memory. The  $\overline{EA}$  input is latched during RESET and is "don't care" after RESET (also if the security bit is not set). This implementation prevents reading internal program code by switching from external program memory to internal program memory during a MOVC instruction or any other instruction that uses immediate data.

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 916.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{DD}$  and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any

enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## Power-Down Mode

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 2 shows the state of the I/O ports during low current operating modes.

## I<sup>2</sup>C Serial Communication—SIO1

The I<sup>2</sup>C serial port is identical to the I<sup>2</sup>C serial port on the 8XC552. The operation of this subsystem is described in detail in the 8XC552 section of this manual.

Note that in both the 8XC652/4 and the 8XC552 the I<sup>2</sup>C pins are alternate functions to port pins P1.6 and P1.7. Because of this, P1.6 and P1.7 on these parts do not have a pull-up structure as found on the 80C51. Therefore P1.6 and P1.7 have open drain outputs on the 8XC652/4.

**Table 2. External Pin Status During Idle and Power-Down Mode**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

## Serial Control Register (S1CON) – See Table 3

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
| S1CON (D8H) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-------------|-----|------|-----|-----|----|----|-----|-----|

Bits CR0, CR1 and CR2 determine the serial clock frequency that is generated in the master mode of operation.

**Table 3. Serial Clock Rates**

| CR2 | CR1 | CR0 | BIT FREQUENCY (kHz) AT $f_{osc}$ |                         |                         |                         | $f_{osc}$ DIVIDED BY                                                          |
|-----|-----|-----|----------------------------------|-------------------------|-------------------------|-------------------------|-------------------------------------------------------------------------------|

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING        | UNIT |
|----------------------------------------------------------------------------------------------|---------------|------|
| Storage temperature range                                                                    | -65 to +150   | °C   |
| Voltage on any other pin to V <sub>SS</sub>                                                  | -0.5 to + 6.5 | V    |
| Input, output current on any single pin                                                      | ±5            | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1             | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

# 80C652/83C652

### NOTES FOR DC ELECTRICAL CHARACTERISTICS:

1. See Figures 9 through 11 for  $I_{DD}$  test conditions.
2. The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ; XTAL2 not connected;  $E\bar{A} = RST = Port 0 = P1.6 = P1.7 = V_{DD}$ . See Figure 9.
3. The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{DD} - 0.5V$ ; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{DD}$ ;  $E\bar{A} = RST = V_{SS}$ . See Figure 10.
4. The power-down current is measured with all output pins disconnected; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{DD}$ ;  $E\bar{A} = RST = V_{SS}$ . See Figure 11.
5.  $2V \leq V_{PD} \leq V_{DDmax}$ .
6. The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0 while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
7. Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
8. Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
9. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows: Maximum  $I_{OL} = 10mA$  per port pin; Maximum  $I_{OL} = 26mA$  total for Port 0; Maximum  $I_{OL} = 15mA$  total for Ports 1, 2, and 3; Maximum  $I_{OL} = 71mA$  total for all output pins. If  $I_{OL}$  exceeds the test conditions,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
10. Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
11.  $I_{DDMAX}$  for other frequencies can be derived from Figure 1, where FREQ is the external oscillator frequency in MHz.  $I_{DDMAX}$  is given in mA.

Figure 1.  $I_{DD}$  vs. Frequency

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

NOTES:

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be < 1μs.
- Spikes on the SDA and SCL lines with a duration of less than 3 t<sub>CLCL</sub> will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- t<sub>CLCL</sub> = 1/f<sub>OSC</sub> = one oscillator clock period at pin XTAL1. For 63ns (42ns) < t<sub>CLCL</sub> < 285ns (16MHz (24MHz) > f<sub>OSC</sub> > 3.5MHz) the SIO1 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

TIMING SIO1 (I<sup>2</sup>C) INTERFACE

# CMOS single-chip 8-bit microcontroller

# 80C652/83C652

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

Figure 6. External Clock Drive at XTAL1

**NOTE:**  
 AC INPUTS DURING TESTING ARE DRIVEN AT  $V_{DD}-0.5$  FOR A LOGIC '1' AND 0.45V FOR A LOGIC '0'. TIMING MEASUREMENTS ARE MADE AT  $V_{IH}$  MIN FOR A LOGIC '1' AND  $V_{IL}$  MAX FOR A LOGIC '0'.

Figure 7. AC Testing Input/Output

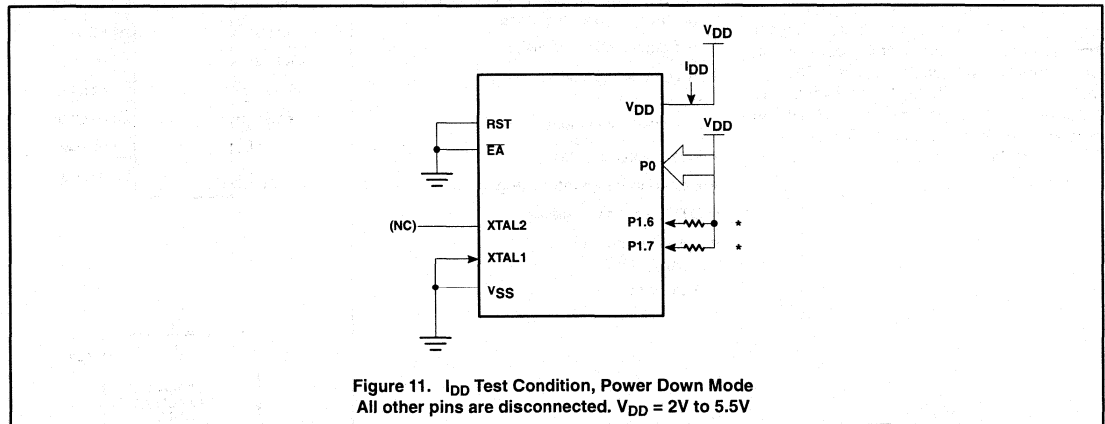

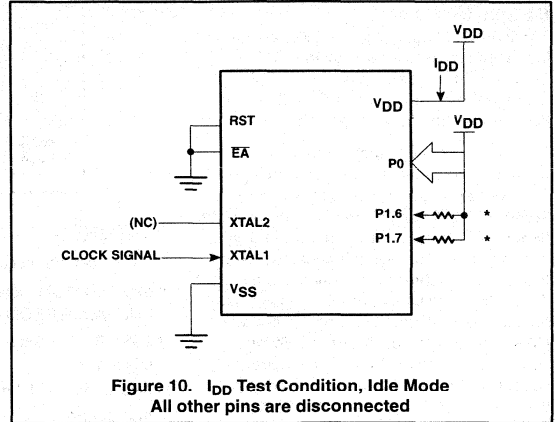

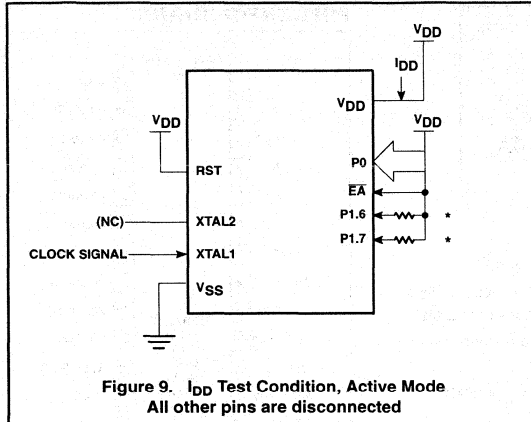

**NOTE:**  
 FOR TIMING PURPOSES, A PORT IS NO LONGER FLOATING WHEN A 100mV CHANGE FROM LOAD VOLTAGE OCCURS, AND BEGINS TO FLOAT WHEN A 100mV CHANGE FROM THE LOADED  $V_{OH}/V_{OL}$  LEVEL OCCURS.  $I_{OH}/I_{OL} \geq \pm 20mA$ .

Figure 8. Float Waveform

CMOS single-chip 8-bit microcontroller

80C652/83C652

NOTE:

- \* Ports 1.6 and 1.7 should be connected to  $V_{CC}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specification.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller

# 87C652

## DESCRIPTION

The 87C652 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 87C652 has the same instruction set as the 80C51.

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 87C652 contains a non-volatile 8k x 8 EPROM, a volatile 256 x 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a multi-source, two-priority-level, nested interrupt structure, an I<sup>2</sup>C interface, UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 87C652 can be expanded using standard TTL compatible memories and logic.

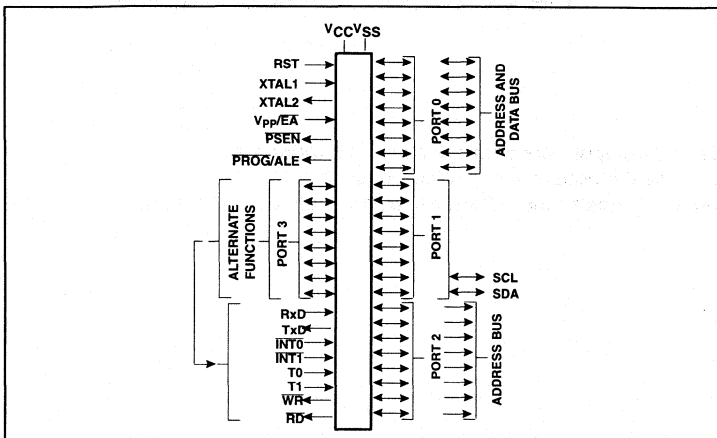

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16MHz crystal, 58% of the instructions are executed in 0.75µs and 40% in 1.5µs. Multiply and divide instructions require 3µs.

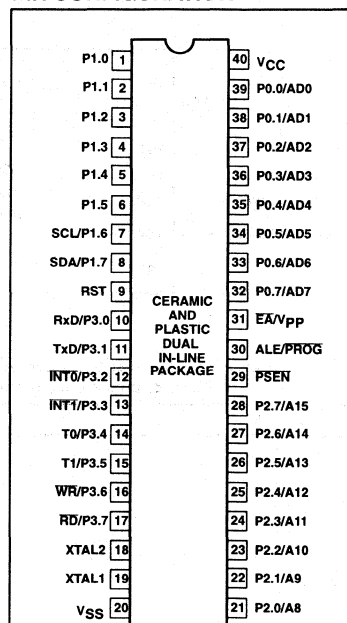

## FEATURES

- 80C51 central processing unit
- 8k x 8 EPROM expandable externally to 64k bytes (EPROM is not expandable)
- 256 x 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- Four 8-bit I/O ports
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART facilities
- Power control modes
  - Idle mode
  - Power-down mode
- Five package styles
- Extended temperature range
- OTP package available
- Three speed ranges
  - 16MHz
  - 20MHz

## NOTES:

- 80C652 and 83C652 frequency range is 1.2MHz–16MHz or 1.2 to 24MHz.
- 87C652 frequency range is 3.5MHz–16MHz or 3.5MHz–20MHz.
- The 87C652 EPROM is not expandable.
- xxx denotes the ROM code number.
- SOT311 replaced by SOT307-2.

| V <sub>CC</sub>                | 40      | 44           | 38            | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| P0.0–0.7                       | 39–32   | 43–36        | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification in the 87C652. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                        |
| P1.0–P1.7                      | 1–8     | 2–9          | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>L</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:<br><b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                   |
| P1.6                           | 7       | 8            | 2             | I/O  | <b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| P2.0–P2.7                      | 21–28   | 24–31        | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>L</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.                                                    |

87C652

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol, page 934.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few

milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>CC</sub> and RST must come up at the same time for a proper start-up.

## IDLE MODE

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke

power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 2 shows the state of the I/O ports during low current operating modes.

## I<sup>2</sup>C SERIAL COMMUNICATION — SIO1

The I<sup>2</sup>C serial port is identical to the I<sup>2</sup>C serial port on the 8XC552. The operation of this subsystem is described in detail in the 8XC552 section of this manual.

Note that in both the 8XC652/4 and the 8XC552 the I<sup>2</sup>C pins are alternate functions to port pins P1.6 and P1.7. Because of this, P1.6 and P1.7 on these parts do not have a pull-up structure as found on the 80C51. Therefore P1.6 and P1.7 have open drain outputs on the 8XC652/4.

**Table 2. External Pin Status During Idle and Power-Down Mode**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

## Serial Control Register (S1CON) – See Table 3

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
| S1CON (08H) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-------------|-----|------|-----|-----|----|----|-----|-----|

Bits CR0, CR1 and CR2 determine the serial clock frequency that is generated in the master mode of operation.

**Table 3. Serial Clock Rates**

| CR2 | CR1 | CR0 | BIT FREQUENCY (kHz) AT f <sub>OSC</sub> |                          |                           |                           | f <sub>OSC</sub> DIVIDED BY                                                    |

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING       | UNIT |
|----------------------------------------------------------------------------------------------|--------------|------|
| Storage temperature range                                                                    | -65 to +150  | °C   |
| Voltage on EA/V <sub>PP</sub> to V <sub>SS</sub>                                             | -0.5 to +13  | V    |
| Voltage on any other pin to V <sub>SS</sub>                                                  | -0.5 to +6.5 | V    |
| Input, output current on any single pin                                                      | ±5           | mA   |
| Input, output current on any two pins                                                        | ±10          | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1            | W    |

**NOTES:**

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

**DEVICE SPECIFICATIONS**

## NOTES:

- See Figures 9 through 12 for  $I_{CC}$  test conditions.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{CC} - 0.5V$ ; XTAL2 not connected; EA = RST = Port 0 = P1.6 = P1.7 =  $V_{CC}$ ;  $f_{CLK} = 16MHz$ . See Figure 9.
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{CC} - 0.5V$ ; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{CC}$ ; EA = RST =  $V_{SS}$ ;  $f_{CLK} = 16MHz$ . See Figure 10.
- The power-down current is measured with all output pins disconnected; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{CC}$ ; EA = RST =  $V_{SS}$ . See Figure 12.
- $2V \leq V_{PD} \leq V_{CCmax}$ .
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below 1.5V will be recognized as a logic 0 while an input voltage above 3.0V will be recognized as a logic 1.
- Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OLs}$  of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.

**NOTES:**

- Parameters are valid over operating temperature range and voltage range unless otherwise specified.
- Load capacitance for port 0, ALE, and  $\overline{\text{PSEN}} = 100\text{pF}$ , load capacitance for all other outputs =  $80\text{pF}$ .
- These values are characterized but not 100% production tested.
- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be  $< 1\mu\text{s}$ .
- Spikes on the SDA and SCL lines with a duration of less than  $3 t_{CLCL}$  will be filtered out. Maximum capacitance on bus-lines SDA and SCL =  $400\text{pF}$ .
- $t_{CLCL} = 1/f_{OSC}$  = one oscillator clock period at pin XTAL1. For  $63\text{ns} < t_{CLCL} < 285\text{ns}$  ( $16\text{MHz} > f_{OSC} > 3.5\text{MHz}$ ) the I<sup>2</sup>C interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

**NOTE:**

\* Ports 1.6 and 1.7 should be connected to  $V_{CC}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specification.

## CMOS single-chip 8-bit microcontroller

87C652

**EPROM CHARACTERISTICS**

The 87C652 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C652 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C652 manufactured by Philips Components.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 13 and 14. Figure 15 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 13. Note that the 87C652 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 13. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The ALE/PROG is pulsed low 25 times as shown in Figure 14.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25 pulse programming sequence using the 'Pgm Lock Bit' levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the  $E\bar{A}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 15. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 5H indicates manufactured by Philips  
(031H) = 99H indicates 87C652

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000uW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient. Erasure leaves the array in an all 1s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $E\bar{A}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|-------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                 | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                 | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 0    | 0    |

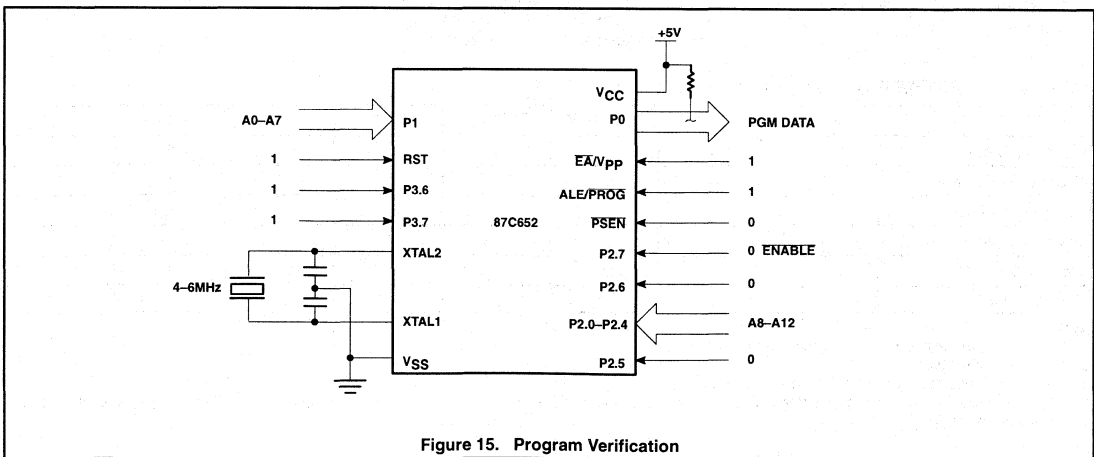

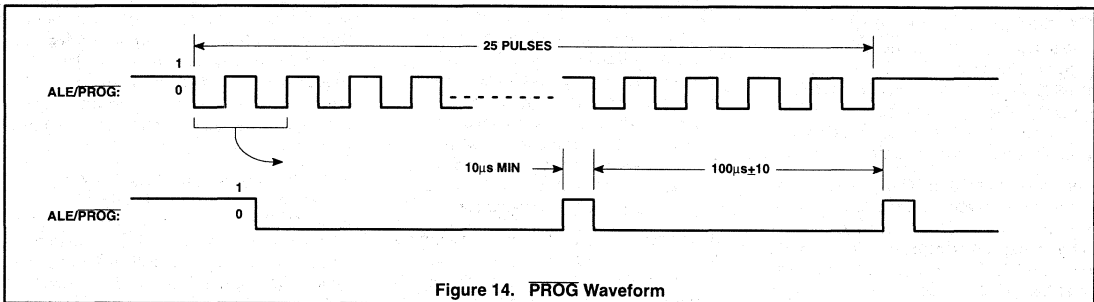

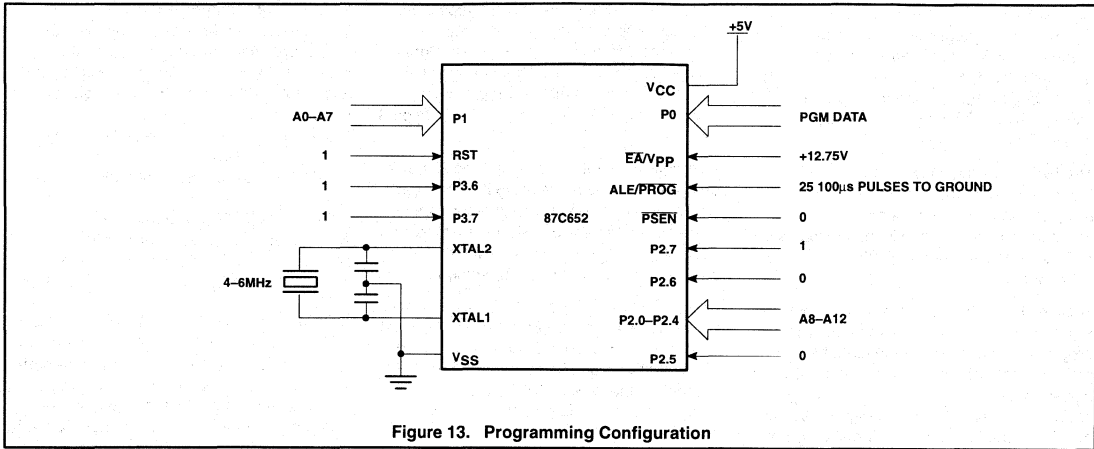

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP} = 12.75V \pm 0.25V$ .
- $V_{CC} = 5V \pm 10\%$  during programming and verification.
- \* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100 $\mu$ s ( $\pm 10\mu$ s) and high for a minimum of 10 $\mu$ s.

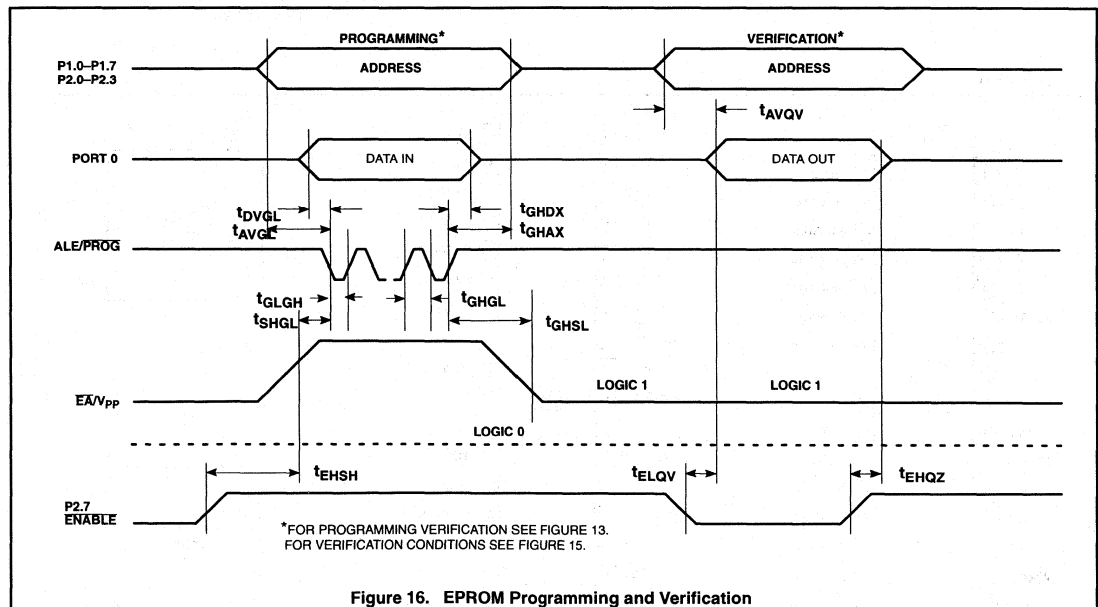

Figure 16. EPROM Programming and Verification

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller

# 83C654

## DESCRIPTION

The P83C654 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 83C654 has the same instruction set as the 80C51. Two versions of the derivative exist:

83C654 — 16k bytes mask programmable ROM

87C654 — EPROM version (described in a separate data sheet)

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 83C654 contains a non-volatile 16k × 8 read-only program memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a multi-source, two-priority-level, nested interrupt structure, an I<sup>2</sup>C interface, UART and on-chip oscillator and timing circuits. For systems that require extra capability, the

83C654 can be expanded using standard TTL compatible memories and logic.

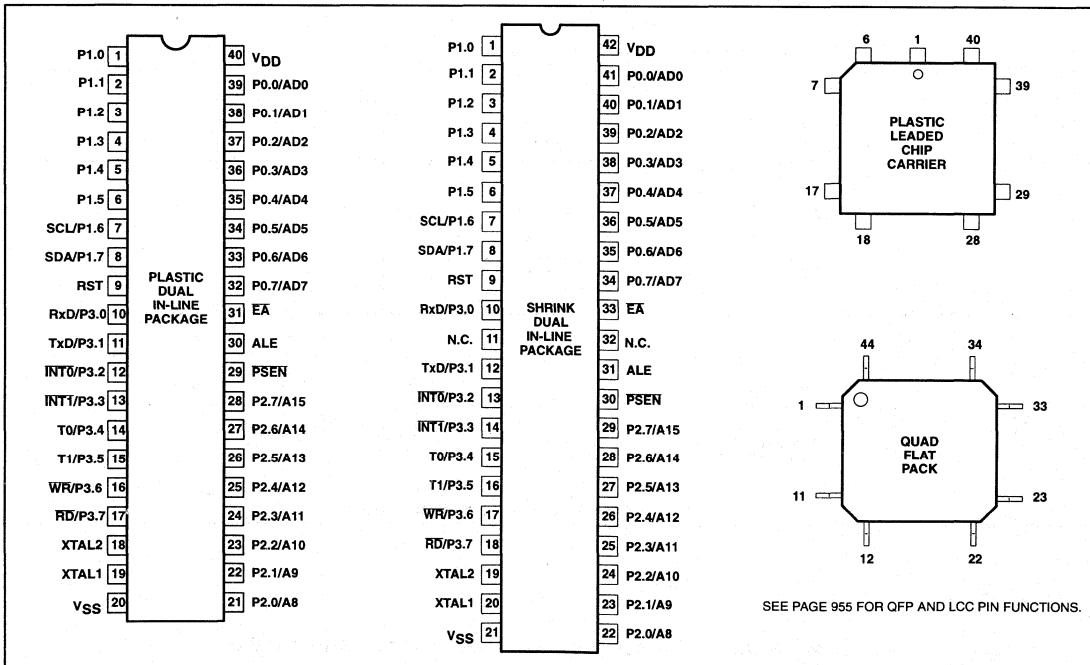

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16(24)MHz crystal, 58% of the instructions are executed in 0.75(0.5) $\mu$ s and 40% in 1.5(1) $\mu$ s. Multiply and divide instructions require 3(2) $\mu$ s.

## FEATURES

- 80C51 central processing unit
- 16k × 8 ROM expandable externally to 64k bytes
- 256 × 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- Four 8-bit I/O ports
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART facilities
- Power control modes
  - Idle mode
  - Power-down mode
- ROM code protection
- Extended frequency range: 1.2 to 24 MHz
- Three operating ambient temperature ranges:
  - 0 to +70°C
  - -40 to +85°C
  - -40 to +125°C

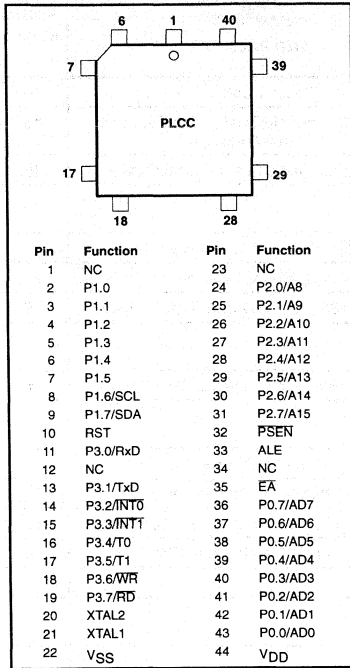

## PIN CONFIGURATIONS

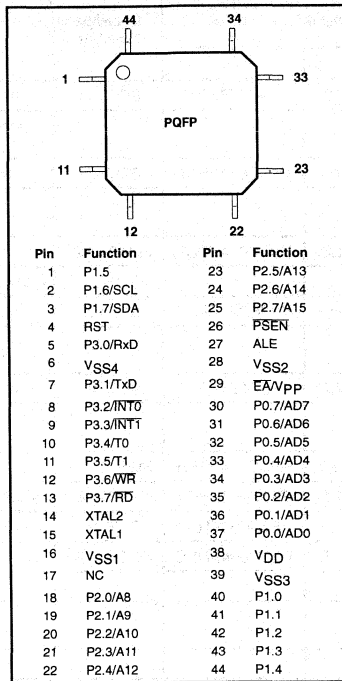

# CMOS single-chip 8-bit microcontroller

83C654

## PLASTIC LEADED CHIP CARRIER PIN FUNCTIONS

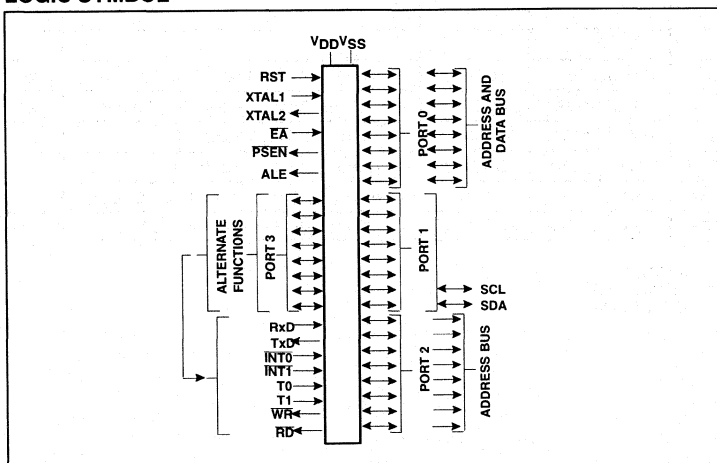

## PLASTIC QUAD FLAT PACK PIN FUNCTIONS

### NOTES TO QFP ONLY:

1. Due to EMC improvements, all V<sub>SS</sub> pins (6, 16, 28, 39) must be connected to V<sub>SS</sub> on the 80C652/83C654.

## NOTES:

- For full specification, see the 80C652/83C652 data sheet.
- 83C654 frequency range is 1.2MHz – 16MHz or 1.2MHz – 24MHz.
- For specification of the EPROM version, see the 87C654 data sheet.
- xxx denotes the ROM code number.
- SOT311 replaced by SOT307-2.

| V <sub>DD</sub> | 40         | 44           | 38               | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| P0.0–P0.7       | 39–32      | 43–36        | 37–30            | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| P1.0–P1.7       | 1–8        | 2–9          | 40–44,<br>1–3    | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Alternate functions include:<br><b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                                                                                                       |

| P2.0–P2.7       | 21–28      | 24–31        | 18–25            | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.                                                    |

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

# CMOS single-chip 8-bit microcontroller

83C654

## ROM CODE PROTECTION (83C654)

The 83C654 has an additional security feature. ROM code protection may be selected by setting a mask-programmable security bit (i.e., user dependent). This feature may be requested during ROM code submission. When selected, the ROM code is protected and cannot be read out at any time by any test mode or by any instruction in the external program memory space.

The MOVC instructions are the only instructions that have access to program code in the internal or external program memory. The EA input is latched during RESET and is "don't care" after RESET (also if the security bit is not set). This implementation prevents reading internal program code by switching from external program memory to internal program memory during a MOVC instruction or any other instruction that uses immediate data.

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 955.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any

enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### Power-Down Mode

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 2 shows the state of the I/O ports during low current operating modes.

## I<sup>2</sup>C SERIAL COMMUNICATION — SIO1

The I<sup>2</sup>C serial port is identical to the I<sup>2</sup>C serial port on the 8XC552. The operation of this subsystem is described in detail in the 8XC552 section of this manual.

Note that in both the 8XC652/4 and the 8XC552 the I<sup>2</sup>C pins are alternate functions to port pins P1.6 and P1.7. Because of this, P1.6 and P1.7 on these parts do not have a pull-up structure as found on the 80C51. Therefore P1.6 and P1.7 have open drain outputs on the 8XC652/4.

Table 2. External Pin Status During Idle and Power-Down Mode

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

### Serial Control Register (S1CON) – See Table 3

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
| S1CON (D8H) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-------------|-----|------|-----|-----|----|----|-----|-----|

Bits CR0, CR1 and CR2 determine the serial clock frequency that is generated in the master mode of operation.

Table 3. Serial Clock Rates

| CR2 | CR1 | CR0 | BIT FREQUENCY (kHz) AT f <sub>OSC</sub> |                         |                         |                         | f <sub>OSC</sub> DIVIDED BY                                                   |
|-----|-----|-----|-----------------------------------------|-------------------------|-------------------------|-------------------------|-------------------------------------------------------------------------------|
|     |     |     | 6MHz                                    | 12MHz                   | 16MHz                   | 24MHz                   |                                                                               |

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING        | UNIT |
|----------------------------------------------------------------------------------------------|---------------|------|
| Storage temperature range                                                                    | -65 to +150   | °C   |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to + 6.5 | V    |
| Input, output current on any single pin                                                      | ±5            | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1             | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## CMOS single-chip 8-bit microcontroller

83C654

**NOTES FOR DC ELECTRICAL CHARACTERISTICS:**

- See Figures 9 through 11 for  $I_{DD}$  test conditions.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{\text{EA}} = \text{RST} = \text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ . See Figure 9.
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ ;  $\overline{\text{EA}} = \text{RST} = V_{SS}$ . See Figure 10.
- The power-down current is measured with all output pins disconnected; XTAL2 not connected;  $\text{Port } 0 = \text{P1.6} = \text{P1.7} = V_{DD}$ ;  $\overline{\text{EA}} = \text{RST} = V_{SS}$ . See Figure 11.
- $2\text{V} \leq V_{PD} \leq V_{DD\text{max}}$ .
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below  $0.3V_{DD}$  will be recognized as a logic 0 while an input voltage above  $0.7V_{DD}$  will be recognized as a logic 1.
- Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OLS}$  of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows: Maximum  $I_{OL} = 10\text{mA}$  per port pin; Maximum  $I_{OL} = 26\text{mA}$  total for Port 0; Maximum  $I_{OL} = 15\text{mA}$  total for Ports 1, 2, and 3; Maximum  $I_{OL} = 71\text{mA}$  total for all output pins. If  $I_{OL}$  exceeds the test conditions,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $\overline{\text{PSEN}}$  to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- $I_{DD\text{MAX}}$  for other frequencies can be derived from Figure 1, where FREQ is the external oscillator frequency in MHz.  $I_{DD\text{MAX}}$  is given in mA.

Figure 1.  $I_{DD}$  vs. Frequency

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

| t <sub>FD</sub>                   | SDA fall time                             | ≤ 0.3μs                | < 0.3μs <sup>3</sup>                     |

NOTES:

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be < 1μs.
- Spikes on the SDA and SCL lines with a duration of less than 3 t<sub>CLCL</sub> will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- t<sub>CLCL</sub> = 1/f<sub>OSC</sub> = one oscillator clock period at pin XTAL1. For 63ns (42ns) < t<sub>CLCL</sub> < 285ns (16MHz (24MHz) > f<sub>OSC</sub> > 3.5MHz) the SI01 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

TIMING SIO1 (I<sup>2</sup>C) INTERFACE

# CMOS single-chip 8-bit microcontroller

83C654

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

83C654

**NOTE:**

- \* Ports 1.6 and 1.7 should be connected to  $V_{CC}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specification.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller

# 87C654

## DESCRIPTION

The 87C654 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 87C654 has the same instruction set as the 80C51. Two versions of the derivative exist:

83C654—16k bytes mask programmable ROM

87C654—EPROM version

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 87C654 contains a non-volatile 16k x 8 EPROM, a volatile 256 x 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a multi-source, two-priority-level, nested interrupt structure, an I<sup>2</sup>C interface, UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 87C654 can be expanded using standard TTL compatible memories and logic.

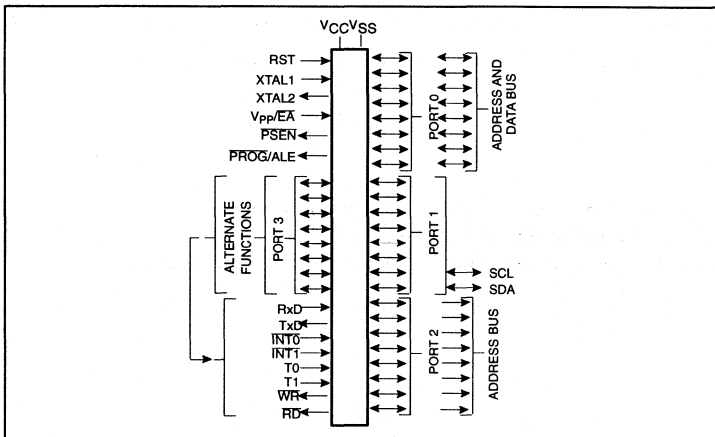

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16MHz crystal, 58% of the instructions are executed in 0.75µs and 40% in 1.5µs. Multiply and divide instructions require 3µs.

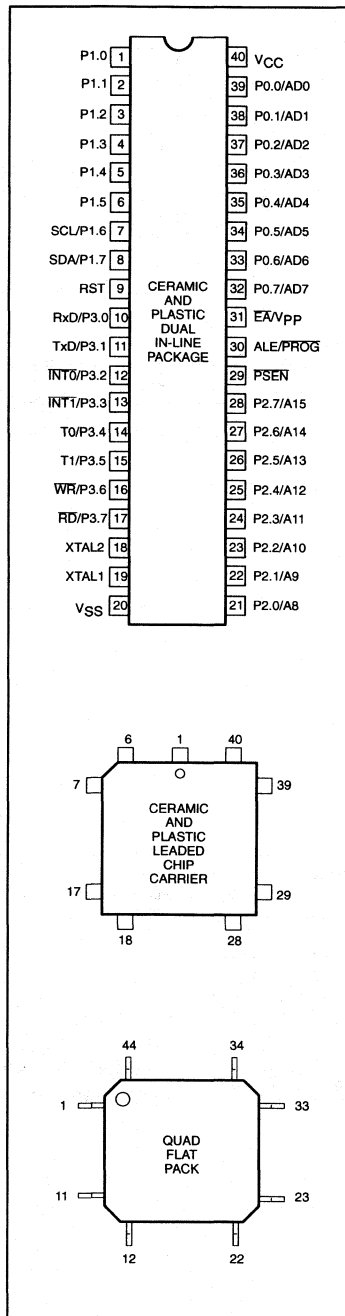

## FEATURES

- 80C51 central processing unit
- 16k x 8 EPROM expandable externally to 64k bytes
- 256 x 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- Four 8-bit I/O ports
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART facilities
- Power control modes
  - Idle mode
  - Power-down mode
- Five package styles
- Extended temperature range
- OTP package available
- Three speed ranges
  - 16MHz
  - 20MHz

## NOTES:

- For full specification, see the 87C652 data sheet.
- 87C654 frequency range is 3.5MHz – 16MHz or 3.5MHz – 24MHz.
- xxx denotes the ROM code number.
- SOT311 replaced by SOT307-2.

| V <sub>CC</sub>                | 40         | 44           | 38            | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| P0.0–0.7                       | 39–32      | 43–36        | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification in the 87C654. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                         |
| P1.0–P1.7                      | 1–8        | 2–9          | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:<br><b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                   |
| P1.6                           | 7          | 8            | 2             | I/O  | <b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| P1.7                           | 8          | 9            | 3             | I/O  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P2.0–P2.7                      | 21–28      | 24–31        | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.                                                    |
| P3.0–P3.7                      | 10–17      | 11,<br>13–19 | 5,<br>7–13    | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:<br><b>RxD (P3.0):</b> Serial input port<br><b>TxD (P3.1):</b> Serial output port<br><b>INT0 (P3.2):</b> External interrupt<br><b>INT1 (P3.3):</b> External interrupt<br><b>T0 (P3.4):</b> Timer 0 external input<br><b>T1 (P3.5):</b> Timer 1 external input<br><b>WR (P3.6):</b> External data memory write strobe<br><b>RD (P3.7):</b> External data memory read strobe |
| RST                            | 9          | 10           | 4             | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V <sub>SS</sub> permits a power-on reset using only an external capacitor to V <sub>CC</sub> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ALE/PROG                       | 30         | 33           | 27            | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                               |
| PSEN                           | 29         | 32           | 26            | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 87C654 is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| E <sub>A</sub> V <sub>PP</sub> | 31         | 35           | 29            | I    | <b>External Access Enable/Programming Supply Voltage:</b> E <sub>A</sub> must be externally held low to enable the device to fetch code from external program memory locations 0000H and 3FFFH. If E <sub>A</sub> is held high, the device executes from internal program memory unless the program counter contains an address greater than 3FFFH. This pin also receives the 12.75V programming supply voltage (V <sub>PP</sub> ) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                         |

## NOTE:

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than V<sub>CC</sub> + 0.5V or V<sub>SS</sub> - 0.5V, respectively.

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few

milliseconds) plus two machine cycles. At power-on, the voltage on V<sub>CC</sub> and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### Power-Down Mode

In the power-down mode, the oscillator is stopped and the instruction to invoke

power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON. Table 2 shows the state of the I/O ports during low current operating modes.

## I<sup>2</sup>C SERIAL COMMUNICATION—SIO1

The I<sup>2</sup>C serial port is identical to the I<sup>2</sup>C serial port on the 8XC552. The operation of this subsystem is described in detail in the 8XC552 section of this manual.

Note that in both the 8XC652/4 and the 8XC552 the I<sup>2</sup>C pins are alternate functions to port pins P1.6 and P1.7. Because of this, P1.6 and P1.7 on these parts do not have a pull-up structure as found on the 80C51. Therefore P1.6 and P1.7 have open drain outputs on the 8XC652/4.

**Table 2. External Pin Status During Idle and Power-Down Mode**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

## Serial Control Register (S1CON) – See Table 3

|             |     |      |     |     |    |    |     |     |
|-------------|-----|------|-----|-----|----|----|-----|-----|
| S1CON (D8H) | CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-------------|-----|------|-----|-----|----|----|-----|-----|

Bits CR0, CR1 and CR2 determine the serial clock frequency that is generated in the master mode of operation.

**Table 3. Serial Clock Rates**

| CR2 | CR1 | CR0 | BIT FREQUENCY (kHz) AT f <sub>osc</sub> |                        |                         |                         | f <sub>osc</sub> DIVIDED BY                                                    |

| Voltage on $\overline{EA}/V_{PP}$ to $V_{SS}$                                                | -0.5 to +13  | V    |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5 | V    |
| Input, output current on any single pin                                                      | ±5           | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1            | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

NOTES: See Next Page.

## CMOS single-chip 8-bit microcontroller

87C654

**NOTES FOR DC ELECTRICAL CHARACTERISTICS:**

1. The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below  $0.3V_{CC}$  will be recognized as a logic 0 while an input voltage above  $0.7V_{CC}$  will be recognized as a logic 1.
2. Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
3. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows: Maximum  $I_{OL}$  = 10mA per port pin; Maximum  $I_{OL}$  = 26mA total for Port 0; Maximum  $I_{OL}$  = 15mA total for Ports 1, 2, and 3; Maximum  $I_{OL}$  = 71mA total for all output pins. If  $I_{OL}$  exceeds the test conditions,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
4. Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and  $PSEN$  to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
5. Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
6. See Figures 9 through 11 for  $I_{CC}$  test conditions.
7. The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{CC} - 0.5V$ ; XTAL2 not connected;  $EA = RST = Port\ 0 = P1.6 = P1.7 = V_{CC}$ ;  $f_{CLK} = 16MHz$ . See Figure 9.
8. The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_r = t_f = 10ns$ ;  $V_{IL} = V_{SS} + 0.5V$ ;  $V_{IH} = V_{CC} - 0.5V$ ; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{CC}$ ;  $EA = RST = V_{SS}$ ;  $f_{CLK} = 16MHz$ . See Figure 10.
9. The power-down current is measured with all output pins disconnected; XTAL2 not connected; Port 0 = P1.6 = P1.7 =  $V_{CC}$ ;  $EA = RST = V_{SS}$ . See Figure 11.
10.  $2V \leq V_{PD} \leq V_{CCmax}$ .

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- These values are characterized but not 100% production tested.

| $t_{SU, DAT3}$                    | SDA set-up time (before STOP cond.)       | $\geq 250ns$       | $> 8 t_{CLCL}$           |
| $t_{HD, DAT}$                     | Data hold time                            | $\geq 0ns$         | $> 8 t_{CLCL} - t_{FC}$  |
| $t_{SU, STA}$                     | Repeated START set-up time                | $\geq 14 t_{CLCL}$ | $> 4.7\mu s^1$           |
| $t_{SU, STO}$                     | STOP condition set-up time                | $\geq 14 t_{CLCL}$ | $> 4.0\mu s^1$           |
| $t_{BUF}$                         | Bus free time                             | $\geq 14 t_{CLCL}$ | $> 4.7\mu s^1$           |
| $t_{RD}$                          | SDA rise time                             | $\leq 1\mu s$      | - 2                      |
| $t_{FD}$                          | SDA fall time                             | $\leq 0.3\mu s$    | $< 0.3\mu s^3$           |

**NOTES:**

- At 100 kbit/s. At other bit rates this value is inversely proportional to the bit-rate of 100 kbit/s.
- Determined by the external bus-line capacitance and the external bus-line pull-resistor, this must be  $< 1\mu s$ .
- Spikes on the SDA and SCL lines with a duration of less than  $3 t_{CLCL}$  will be filtered out. Maximum capacitance on bus-lines SDA and SCL = 400pF.
- $t_{CLCL} = 1/f_{OSC}$  = one oscillator clock period at pin XTAL1. For  $62ns < t_{CLCL} < 285ns$  (16MHz)  $> f_{OSC} > 3.5MHz$  the SI01 interface meets the I<sup>2</sup>C-bus specification for bit-rates up to 100 kbit/s.

### TIMING SIO1 (I<sup>2</sup>C) INTERFACE

# CMOS single-chip 8-bit microcontroller

87C654

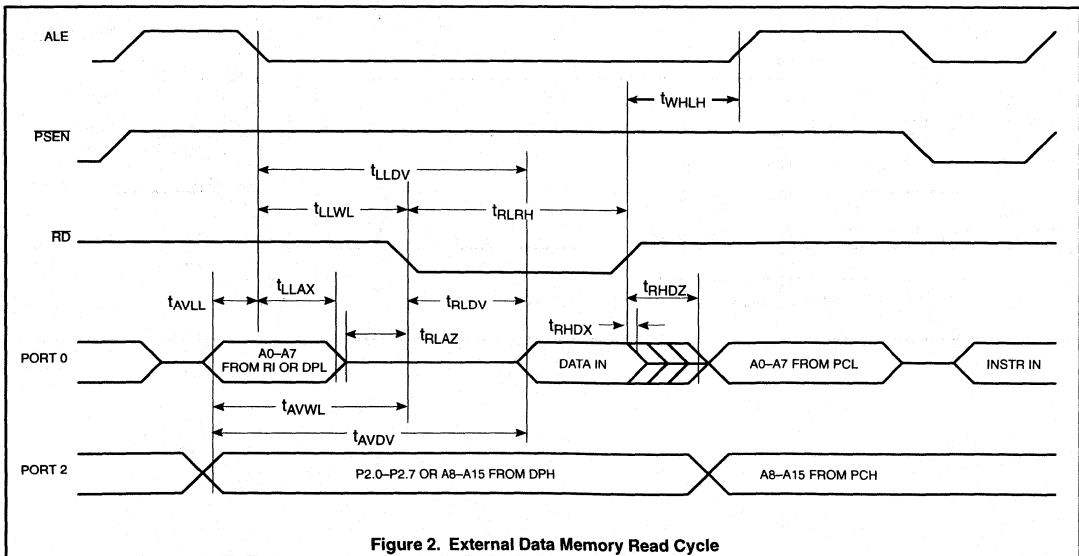

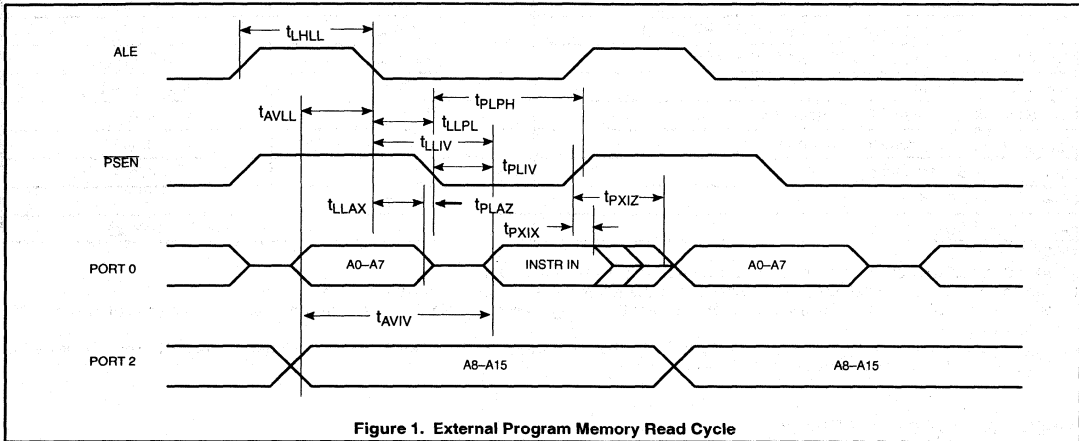

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

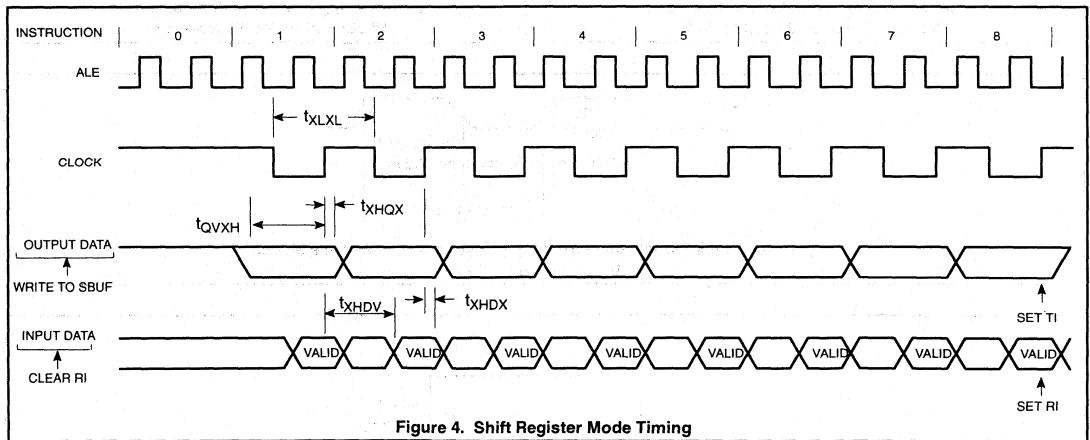

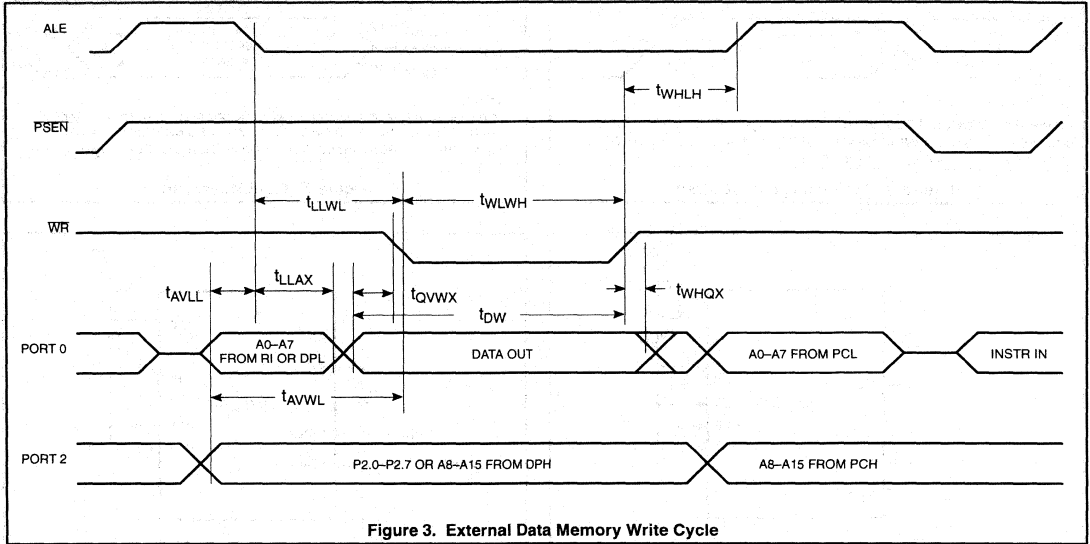

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

CMOS single-chip 8-bit microcontroller

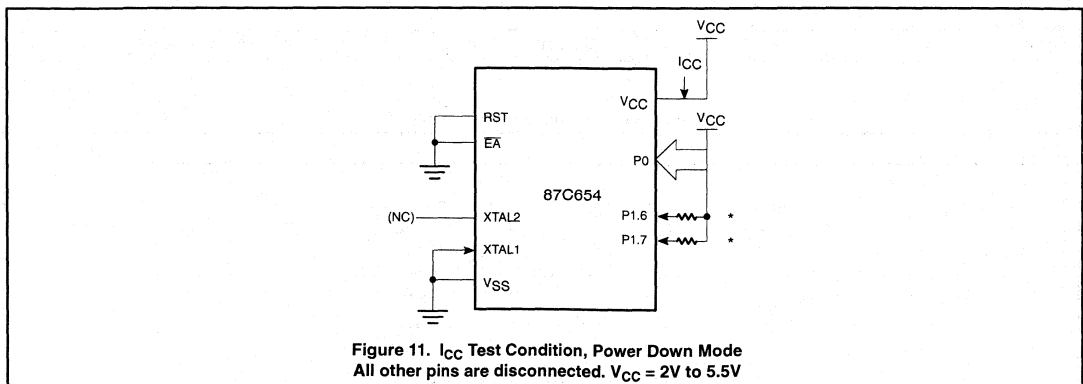

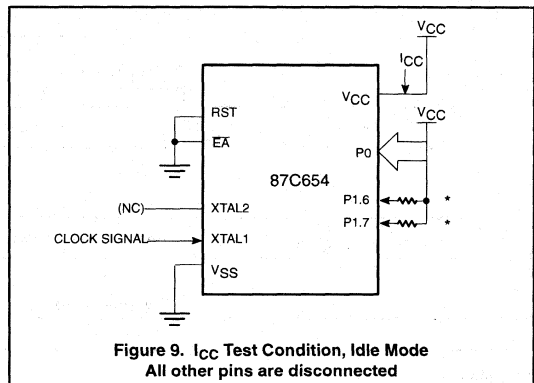

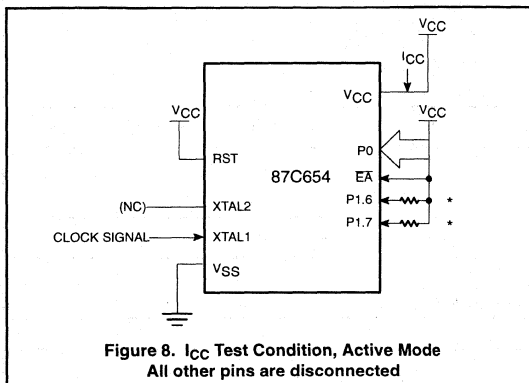

87C654

CMOS single-chip 8-bit microcontroller

87C654

NOTE:  
\* Ports 1.6 and 1.7 should be connected to  $V_{CC}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specification.

## CMOS single-chip 8-bit microcontroller

87C654

**EPROM CHARACTERISTICS**

The 87C654 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C654 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C654 manufactured by Philips Components.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 12 and 13. Figure 14 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 12. Note that the 87C654 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 12. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The ALE/PROG is pulsed low 25 times as shown in Figure 13.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25 pulse programming sequence using the 'Pgm Lock Bit' levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the  $\overline{EA}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 14. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 99H indicates 87C654

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient. Erasure leaves the array in an all 1s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{EA}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|------------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                      | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                      | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2.  $V_{PP} = 12.75V \pm 0.25V$ .

3.  $V_{CC} = 5V \pm 10\%$  during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller with Electromagnetic Compatibility improvements

## 80CE654/83CE654

### DESCRIPTION

The 83CE654 Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 83CE654 has the same instruction set as the 80C51. Two versions of the derivative exist:

83CE654 — 16k bytes mask programmable ROM, 256 bytes RAM

80CE654 — ROMless version of the 83CE654

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 8XCE654 contains a non-volatile 16k × 8 read-only program memory (83CE654), a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a multi-source, two-priority-level, nested interrupt structure, an I<sup>2</sup>C interface, UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XCE654 can be expanded using standard TTL compatible memories and logic.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16MHz crystal, 58% of the instructions are executed in 0.75µs and 40% in 1.5µs. Multiply and divide instructions require 3µs.

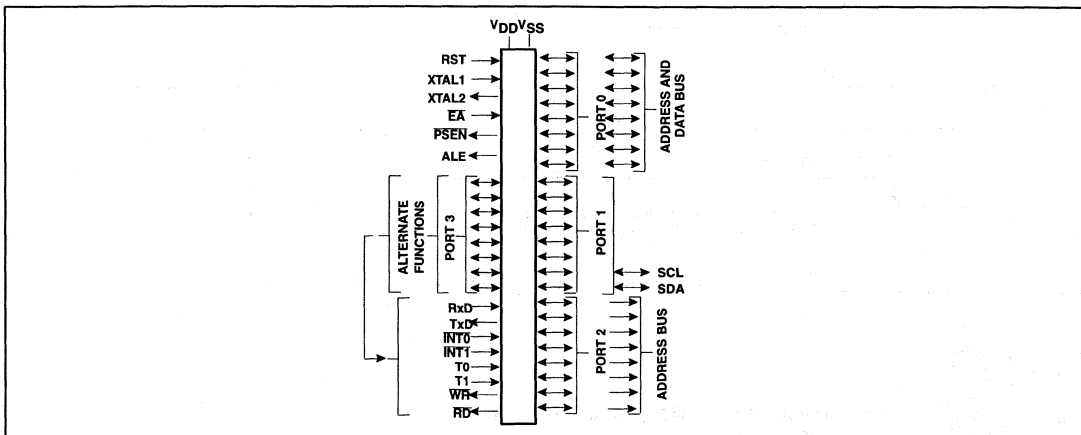

### FEATURES

- 80C51 central processing unit
- 16k × 8 ROM expandable externally to 64k bytes
- 256 × 8 RAM, expandable externally to 64k bytes
- Two standard 16-bit timer/counters
- Four 8-bit I/O ports
- I<sup>2</sup>C-bus serial I/O port with byte oriented master and slave functions
- Full-duplex UART facilities
- ROM code protection
- XTAL frequency range: 1.2MHz to 16MHz
- Software enable/disable of ALE output pulse
- Electromagnetic compatibility (EMC) improvements
- Operating ambient temperature range:
  - P83CE654 FBB T<sub>amb</sub> 0°C to +70°C
  - P83CE654 FFB T<sub>amb</sub> -40°C to +85°C

### PIN CONFIGURATION

| Pin | Function  | Pin | Function |
|-----|-----------|-----|----------|
| 1   | P1.5      | 23  | P2.5/A13 |

### LOGIC SYMBOL

# CMOS single-chip 8-bit microcontroller with Electromagnetic Compatibility improvements

80CE654/83CE654

## ORDERING INFORMATION

| ROMless     | ROM         | TEMPERATURE RANGE °C AND PACKAGE   | FREQUENCY MHz | DRAWING NUMBER        |
|-------------|-------------|------------------------------------|---------------|-----------------------|
| P80CE654FBB | P83CE654FBB | 0 to +70, Plastic Quad Flat Pack   | 1.2 to 16     | SOT307-2 <sup>1</sup> |
| P80CE654FFB | P83CE654FFB | -40 to +85, Plastic Quad Flat Pack | 1.2 to 16     | SOT307-2 <sup>1</sup> |

**NOTE:**

1. SOT311 replaced by SOT307-2.

## ELECTROMAGNETIC COMPATIBILITY (EMC) IMPROVEMENTS

Primary attention is paid on the reduction of electromagnetic emission of the microcontroller P83CE654.

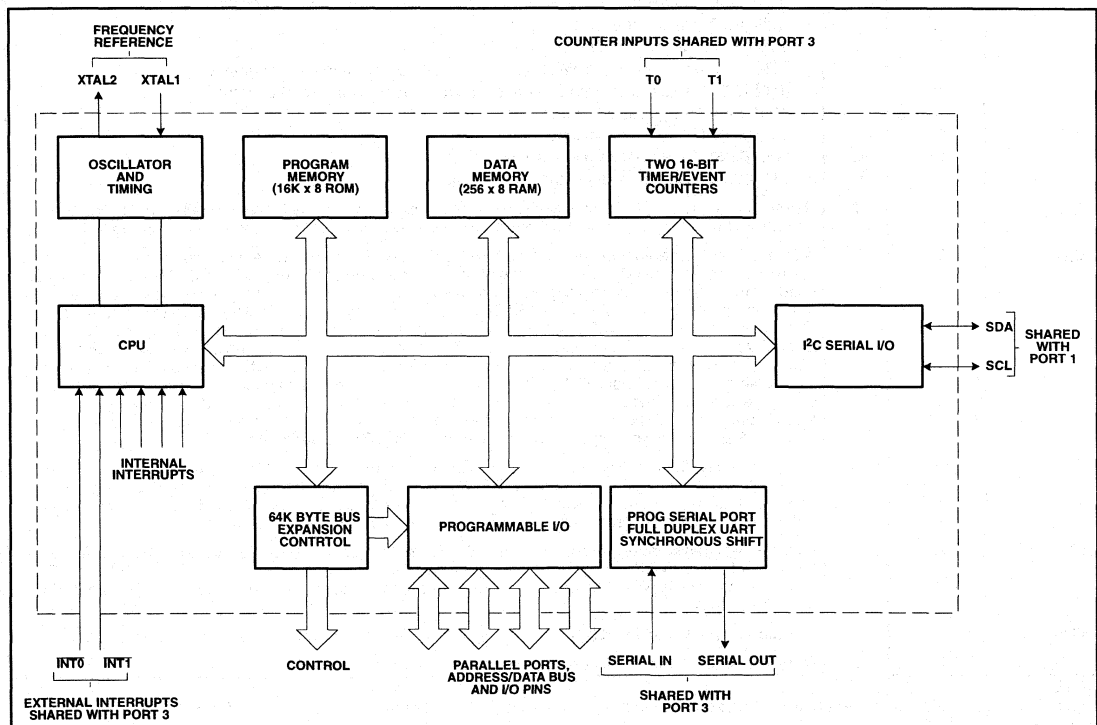

The following features effect in reducing the electromagnetic emission and additionally improve the electromagnetic susceptibility:

- Two supply voltage pins ( $V_{DD1}$ ,  $V_{DD2}$ ) and four ground pins ( $V_{SS1}$  to  $V_{SS4}$ )
- Separate  $V_{DD}$  pins for the internal logic and the port buffers

- Internal decoupling capacitance improves the EMC radiation behavior and the EMC immunity
- External capacitors are to be located as close as possible between pins  $V_{DD2}$  and  $V_{SS3}$  as well as  $V_{DD1}$  and  $V_{SS1}$ ; ceramic chip capacitors are recommended (100nF).
- The ALE output signal (pulses at a frequency of  $f_{OSC}/6$ ) can be disabled under software control (bit 5 in the SFR PCON: "RFI"); if disabled, no ALE pulse will occur.

ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE as a normal MOVX. ALE will retain its normal high value during Idle mode and a low value during Power-down mode while in the "RFI" reduction mode. Additionally during internal access ( $\overline{EA} = 1$ ) ALE will toggle normally when the address exceeds the internal program memory size. During external access ( $\overline{EA} = 0$ ) ALE will always toggle normally, whether the flag "RFI" is set or not.

Both pins must be connected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| P0.0–0.7                                                                     | 37–30            | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 can sink/source 8 LSTTL inputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| P1.0–P1.7                                                                    | 40–44,<br>1–3    | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:<br><b>SCL:</b> I <sup>2</sup> C-bus serial port clock line.<br><b>SDA:</b> I <sup>2</sup> C-bus serial port data line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| P2.0–P2.7                                                                    | 18–25            | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register.                                                                                                                                                                                                                                                                                                                                                                                                      |
| P3.0–P3.7                                                                    | 5,<br>7–13       | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| RST                                                                          | 4                | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal pull-down resistor to V <sub>SS</sub> permits a power-on reset using only an external capacitor to V <sub>DD</sub> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ALE                                                                          | 27               | I/O  | <b>Address Latch Enable:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. ALE can sink/source 8 LSTTL inputs. It can drive CMOS inputs without an external pull-up. To prohibit the toggling of ALE pin (RFI noise reduction) the bit RFI in the PCON Register (PCON.5) must be set by software. This bit is cleared on RESET and can be cleared by software. When set, ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE as a normal MOVX. ALE will retain its normal high value during Idle mode and a low value during Power-down mode while in the "RFI" mode. Additionally during internal access (EA = 1) ALE will toggle normally when the address exceeds the internal program memory size. During external access (EA = 0) ALE will always toggle normally, whether the flag "RFI" is set or not. |
| PSEN                                                                         | 26               | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 8XC654 is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory. PSEN can sink/source 8 LSTTL inputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| EA                                                                           | 29               | I    | <b>External Access Enable:</b> when, during RESET, EA is held at a TTL HIGH level the CPU executes out of the internal program ROM, provided the program counter is less than 16384. When EA is held at a TTL LOW level during RESET, the CPU executes out of external program memory via Port 0 and Port 2. EA is not allowed to float.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**NOTE:**

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher or lower than V<sub>DD</sub> + 0.5V or V<sub>SS</sub> - 0.5V, respectively.
