PHILIPS

QUALITY ASSURED

Our quality system focuses on the continuing high quality of our components and the best possible service for our customers. We have a three-sided quality strategy: we apply a system of total quality control and assurance; we operate customer-oriented dynamic improvement programmes; and we promote a partnering relationship with our customers and suppliers.

PRODUCT SAFETY

In striving for state-of-the-art perfection, we continuously improve components and processes with respect to environmental demands. Our components offer no hazard to the environment in normal use when operated or stored within the limits specified in the data sheet.

Some components unavoidably contain substances that, if exposed by accident or misuse, are potentially hazardous to health. Users of these components are informed of the danger by warning notices in the data sheets supporting the components. Where necessary the warning notices also indicate safety precautions to be taken and disposal instructions to be followed. Obviously users of these components, in general the set-making industry, assume responsibility towards the consumer with respect to safety matters and environmental demands.

All used or obsolete components should be disposed of according to the regulations applying at the disposal location. Depending on the location, electronic components are considered to be 'chemical', 'special' or sometimes 'industrial' waste. Disposal as domestic waste is usually not permitted.

Philips Semiconductors and Philips Electronics North America Corporation reserve the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified. Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

LIFE SUPPORT APPLICATIONS

Philips Semiconductors and Philips Electronics North America Corporation Products are not designed for use in life support appliances, devices, or systems where malfunction of a Philips Semiconductors and Philips Electronics North America Corporation Product can reasonably be expected to result in a personal injury. Philips Semiconductors and Philips Electronics North America Corporation customers using or selling Philips Semiconductors and Philips Electronics North America Corporation Products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors and Philips Electronics North America Corporation for any damages resulting from such improper use or sale.

Philips Semiconductors and Philips Electronics North America Corporation register eligible circuits under the Semiconductor Chip Protection Act.

80C51-Based 8-Bit Microcontrollers

Microcontrollers from Philips Semiconductors

Philips Semiconductors supplies a wide range of microcontrollers based on mainstream architectures. By offering a large variety of product derivatives, Philips Semiconductors can meet a broad range of specific or unique application requirements. All of our microcontrollers are based on mainstream architectures to allow the user to take advantage of existing software and a vast array of third-party support.

Philips Semiconductors 8-bit microcontrollers are based on the popular 80C51 architecture. We offer most of the industry standard products in this architecture as well as a large selection of powerful derivative products. These derivatives offer a wide assortment of features, including: additional memory, A/D, PWM, additional timers, and many more. Many of the derivative microcontrollers have an I²C serial interface that allows them to be connected easily to over 100 other parts, increasing their capabilities even further. The I²C serial bus is covered in Section 4 of this book. Philips Semiconductors also offers the Controller Area Network (CAN) serial bus for automotive and industrial applications. This standard, developed by Bosch, offers high noise immunity and error correction for automotive and industrial environments. The CAN serial bus is covered in Section 6 of this book. The data sheets for Philips low power 80CL51 family of derivatives are included in Section 3. These devices operate over the wide voltage range of 1.8 - 6.0 volts and are ideal for portable and battery operations. This data book covers the 80C51 standard products and derivatives that Philips Semiconductors manufactures.

Philips Semiconductors 16-bit 90CXXX microcontroller family is based on the 68000 architecture. While these are called 16-bit microcontrollers, the 68000 CPU core architecture is 32-bit. This offers the user a great deal more processing power, when the need arises in a design to move from an 8-bit to a 16-bit microcontroller. Philips Semiconductors 16-bit microcontrollers are software compatible with existing 68000 code. As with our popular 8-bit microcontrollers, EPROM and OTP versions of our 16-bit products are available. The 16-bit microcontrollers are covered in a separate data book.

Philips Semiconductors offers uncompromising quality, service, and support with all of its microcontroller products. For a complete family and the best in microcontroller products, look to Philips Semiconductors.

PDS51 Development System for 80C51 and Derivatives	1331
S87C00KSD 80C51 – I ² C Bus Evaluation Board	1335
OM4129 Symbolic Debugging Package XRAY51 for the SDS 8051 Emulator	1336
OM4136 8051 C Cross-Compiler	1339
OM4142 (ASM51) Cross Assembler Package for 80C51/8051-based Systems	1341
OM4144 (PLMTI51) PL/M-51 Compiler Package for 80C51/8051-based Systems	1343
SDS 8051 Standalone Debug Station for 80C51/8051-based Systems	1346

Section 9 – Package Outlines

SOT96A 8-Pin Plastic SOL (Small Outline Large) Dual In-Line (D/T) Package	1355
SOT97 8-Pin Plastic Dual In-Line (N/P) Package	1356
SOT101/0410D 24-Pin (300 mils wide) Plastic Dual In-Line (N) Package	1357
SOT117 28-Pin Plastic Dual In-Line (N/P) Package	1358
SOT129 40-Pin Plastic Dual In-Line (N/P) Package	1359
SOT136A 28-Pin Plastic SO (Small Outline) Dual In-Line (D) Package	1360
SOT158A 40-Pin Plastic VSO (Very Small Outline) Dual In-Line (D/T) Package	1361
SOT187 44-Pin Plastic Leaded Chip Carrier; Pocket Version (A) Package	1362
SOT188AA 68-Pin Plastic Leaded Chip Carrier; Pocket Version (A) Package	1363
SOT190 56-Pin Plastic VSO (Very Small Outline) Dual In-Line (D/T) Package	1364
SOT205 44-Pin Plastic Quad Flat Pack (B) Package	1365
SOT261/0401F 28-Pin (300 mils wide) Plastic Leaded Chip Carrier (A) Package	1366
SOT270AG 42-Lead Plastic Shrink Dual In-Line Package	1367
SOT274 64-Pin Plastic Shrink Dual In-Line Package	1368
SOT307-2 44-Pin Plastic Quad Flat Pack (B) Package	1369
SOT311 44-Pin Square Plastic Quad Flat Pack (B) Package	1370
SOT318 80-Pin Plastic Quad Flat Pack (B) Package	1371
SOT319 64-Pin Plastic Quad Flat Pack Package	1372
SOT340 24-Pin Plastic Shrink Small Outline Package (SSOP)	1373
SOT341 28-Pin Plastic Shrink Small Outline Package (SSOP)	1374
SOT351 80-Lead Ceramic Chip Carrier (CQFP)	1375
SOT389 (refer to package number 1711–)	
0398E 68-Pin Plastic Leaded Chip Carrier (A) Package	1376
0401F/SOT261 28-Pin (300 mils wide) Plastic Leaded Chip Carrier (A) Package	1366
0403G 44-Pin Plastic Leaded Chip Carrier (A) Package	1377
0410D/SOT101 24-Pin (300 mils wide) Plastic Dual In-Line (N) Package	1357
0413B 28-pin (600 mils wide) Plastic Dual In-Line (N) Package	1378
0414B 64-Pin (900 mils wide) Plastic Dual In-Line (N) Package	1379
0415C 40-Pin (600 mils wide) Plastic Dual In-Line (N) Package	1380

CONTENTS

0586B	24-Pin (300 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	1381
0589B	28-Pin (600 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	1382
0590B	40-Pin (600 mils wide) Ceramic Dual In-line (F) Package (with Window (FA) Package)	1383
1118D	44-Pin Plastic Quad Flat Pack (B) (MEC) Package	1384
1240C	68-Pin Chip Carrier, J-Bend (L) Package	1385
1472A	44-pin CerQuad J-Bend (K) Package	1386
1473A	68-pin CerQuad J-Bend (K) Package	1387
1680	42-Pin Plastic SSOP (Shrink Small Outline Package) Dual In-Line (D/K) Package	1388
1711 –	44-Pin Plastic Thin Quad Flat Package (comparable to SOT389)	1389

DEFINITIONS

Data Sheet Identification	Product Status	Definition
<i>Objective Specification</i>	Formative or in Design	This data sheet contains the design target or goal specifications for product development. Specifications may change in any manner without notice.
<i>Preliminary Specification</i>	Preproduction Product	This data sheet contains preliminary data, and supplementary data will be published at a later date. Philips Semiconductors reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.
<i>Product Specification</i>	Full Production	This data sheet contains Final Specifications. Philips Semiconductors reserves the right to make changes at any time without notice, in order to improve design and supply the best possible product.

80C51 microcontroller family features guide

	Part Number (ROMless)	Memory			Counter Timers	I/O Port	Serial Interfaces	External Interrupt	Comments/ Special Features
		ROM	EPRM	RAM					
P	83C750	1K		64	1 (16-bit)	2-3/8	-	2	40 MHz, Lowest cost, 24-pin Skinny DIP
P	87C750		1K	64	1 (16-bit)	2-3/8	-	2	40 MHz, Lowest cost, 24-pin Skinny DIP
P	83C751	2K		64	1 (16-bit)	2-3/8	I2C (bit)	2	Low-Cost 24-pin Skinny DIP

8-bit microcontroller demonstration and evaluation boards

PRODUCT	DESCRIPTION
OM4151	I ² C demonstration board based on 84CXX derivatives I ² C LCD driver demonstration board with 84CXX microcontroller I ² C bus analyzer (with 84CXX)
S87C00K	I ² C demonstration board based on 80C51 derivatives
OM4238, P8051DB	8051 family demonstration board
OM4128	8XC552 evaluation board
OM4130, PCAN-EVAL	CAN controller evaluation board
OM4239	8XC592 evaluation board
OM4160, SM68070	68070 demonstration and evaluation board MicroCore I
OM4160/3, SM90C100	90C100 family demonstration and evaluation board MicroCore III
OM4280, P83C852DEM	83C852 demonstration kit
OM4281	83C852 software evaluation kit
P8051DB	80C51 family development board
OM4717, P83CLSOLAR	83CL410 solar powered demonstration board
OM5005, P80CLEVAL	80CL51 evaluation board
DS750	8XC750 microcontroller in-circuit emulation development tool

Microcontroller bulletin boards

To better serve our customers, Philips maintains a microcontroller bulletin board. This computer bulletin board system features a microcontroller newsletter, application and demonstration programs for download, and the ability to send messages to microcontroller application engineers. The system can be accessed with a modem at 2400, 1200, or 300 baud.

The telephone numbers are:

(800) 451-6644 (in the U.S.)

or

(408) 991-2406

Please call us anytime!

We also have a ROM code bulletin board through which you can submit ROM codes. This is a closed bulletin board for security reasons. To get an ID, contact your local sales office. The system can be accessed with a 2400, 1200, or 300 baud modem, and is available 24 hours a day.

The telephone number is:

(408) 991-3459

80C51 Family

80C51 family architecture

80C51 ARCHITECTURE

MEMORY ORGANIZATION

All 80C51 devices have separate address spaces for program and data memory, as shown in Figures 1 and 2. The logical separation of program and data memory allows the data memory to be accessed by 8-bit addresses, which can be quickly stored and manipulated by an 8-bit CPU. Nevertheless, 16-bit data memory addresses can also be generated through the DPTR register.

Program memory (ROM, EPROM) can only be read, not written to. There can be up to 64k bytes of program memory. In the 80C51, the lowest 4k bytes of program are on-chip. In the ROMless versions, all program memory is external. The read strobe for external program memory is the PSEN (program store enable).

Data Memory (RAM) occupies a separate address space from Program Memory. In the 80C51, the lowest 128 bytes of data memory are on-chip. Up to 64k bytes of external RAM can be addressed in the external Data Memory space. In the ROMless version, the lowest 128 bytes are on-chip. The CPU generates read and write signals, RD and WR, as needed during external Data Memory accesses.

External Program Memory and external Data Memory may be combined if desired by applying the RD and PSEN signals to the inputs of an AND gate and using the output of

the gate as the read strobe to the external Program/Data memory.

Program Memory

Figure 3 shows a map of the lower part of the Program Memory. After reset, the CPU begins execution from location 0000H. As shown in Figure 3, each interrupt is assigned a fixed location in Program Memory. The interrupt causes the CPU to jump to that location, where it commences execution of the service routine. External Interrupt 0, for example, is assigned to location 0003H. If External Interrupt 0 is going to be used, its service routine must begin at location 0003H. If the interrupt is not going to be used, its service location is available as general purpose Program Memory.

The interrupt service locations are spaced at 8-byte intervals: 0003H for External Interrupt 0, 000BH for Timer 0, 0013H for External Interrupt 1, 001BH for Timer 1, etc. If an interrupt service routine is short enough (as is often the case in control applications), it can reside entirely within that 8-byte interval. Longer service routines can use a jump instruction to skip over subsequent interrupt locations, if other interrupts are in use.

The lowest 4k bytes of Program Memory can either be in the on-chip ROM or in an external ROM. This selection is made by strapping the EA (External Access) pin to either V_{CC}, or V_{SS}. In the 80C51, if the EA pin is strapped to V_{CC}, then the program fetches to addresses 0000H through 0FFFH are directed to the internal ROM. Program

fetches to addresses 1000H through FFFFH are directed to external ROM.

If the EA pin is strapped to V_{SS}, then all program fetches are directed to external ROM. The ROMless parts (8031, 80C31, etc.) must have this pin externally strapped to V_{SS} to enable them to execute from external Program Memory.

The read strobe to external ROM, PSEN, is used for all external program fetches. PSEN is not activated for internal program fetches.

The hardware configuration for external program execution is shown in Figure 4. Note that 16 I/O lines (Ports 0 and 2) are dedicated to bus functions during external Program Memory fetches. Port 0 (P0 in Figure 4) serves as a multiplexed address/data bus. It emits the low byte of the Program Counter (PCL) as an address, and then goes into a float state awaiting the arrival of the code byte from the Program Memory. During the time that the low byte of the Program Counter is valid on Port 0, the signal ALE (Address Latch Enable) clocks this byte into an address latch. Meanwhile, Port 2 (P2 in Figure 4) emits the high byte of the Program Counter (PCH). Then PSEN strobes the EPROM and the code byte is read into the microcontroller.

Program Memory addresses are always 16 bits wide, even though the actual amount of Program Memory used may be less than 64k bytes. External program execution sacrifices two of the 8-bit ports, P0 and P2, to the function of addressing the Program Memory.

80C51 Family

80C51 family architecture

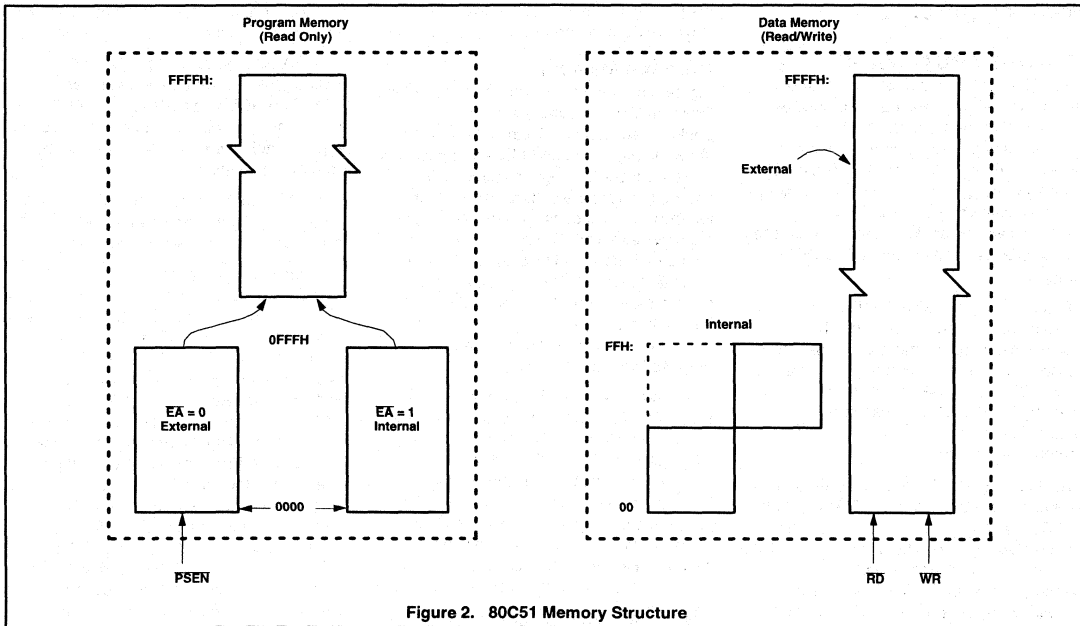

Figure 2. 80C51 Memory Structure

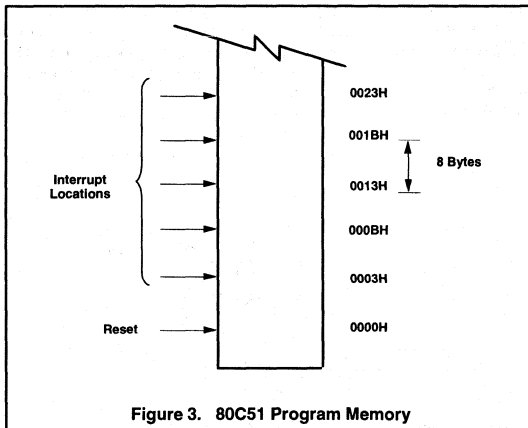

Figure 3. 80C51 Program Memory

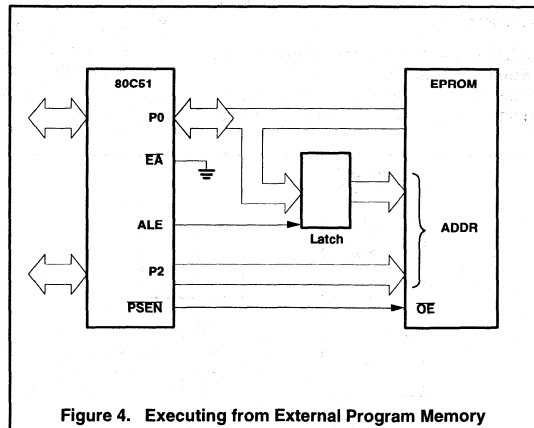

Figure 4. Executing from External Program Memory

Data Memory

The right half of Figure 2 shows the internal and external Data Memory spaces available to the 80C51 user. Figure 5 shows a hardware configuration for accessing up to 2k bytes of external RAM. The CPU in this case is executing from internal ROM. Port 0 serves as a multiplexed address/data bus to the RAM, and 3 lines of Port 2 are being used to page the RAM. The CPU generates RD and WR signals as needed during external RAM

accesses. There can be up to 64k bytes of external Data Memory. External Data Memory addresses can be either 1 or 2 bytes wide. One-byte addresses are often used in conjunction with one or more other I/O lines to page the RAM, as shown in Figure 5.

Two-byte addresses can also be used, in which case the high address byte is emitted at Port 2.

Internal Data Memory is mapped in Figure 6. The memory space is shown divided into three blocks, which are generally referred to as the Lower 128, the Upper 128, and SFR space.

Internal Data Memory addresses are always one byte wide, which implies an address space of only 256 bytes. However, the addressing modes for internal RAM can in

80C51 Family

80C51 family architecture

fact accommodate 384 bytes, using a simple trick. Direct addresses higher than 7FH access one memory space, and indirect addresses higher than 7FH0 access a different memory space. Thus Figure 6 shows the Upper 128 and SFR space occupying the same block of addresses, 80H through FFH, although they are physically separate entities.

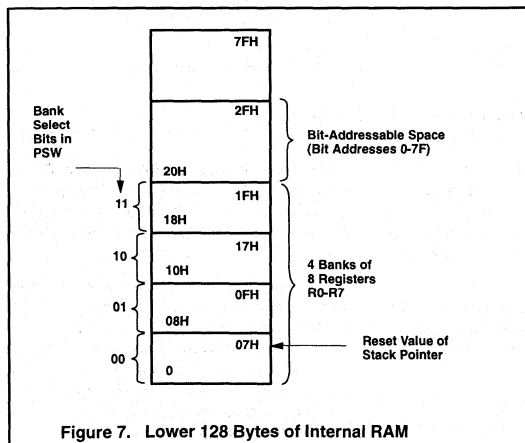

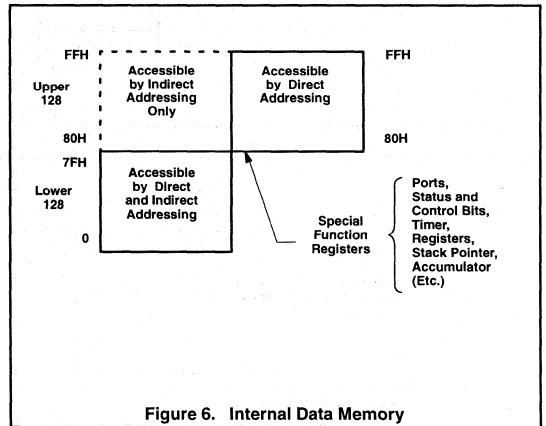

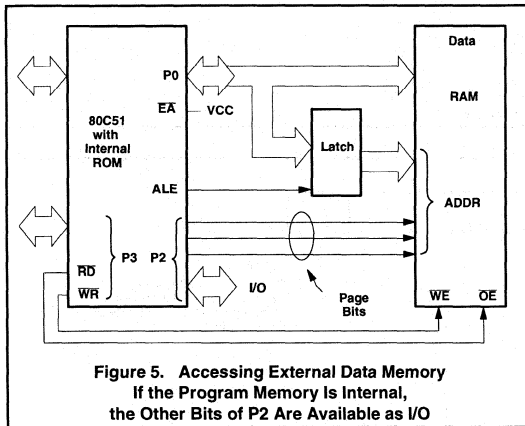

The Lower 128 bytes of RAM are present in all 80C51 devices as mapped in Figure 7. The lowest 32 bytes are grouped into 4 banks of 8 registers. Program instructions call out

these registers as R0 through R7. Two bits in the Program Status Word (PSW) select which register bank is in use. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing.

The next 16 bytes above the register banks form a block of bit-addressable memory space. The 80C51 instruction set includes a wide selection of single-bit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00H through 7FH.

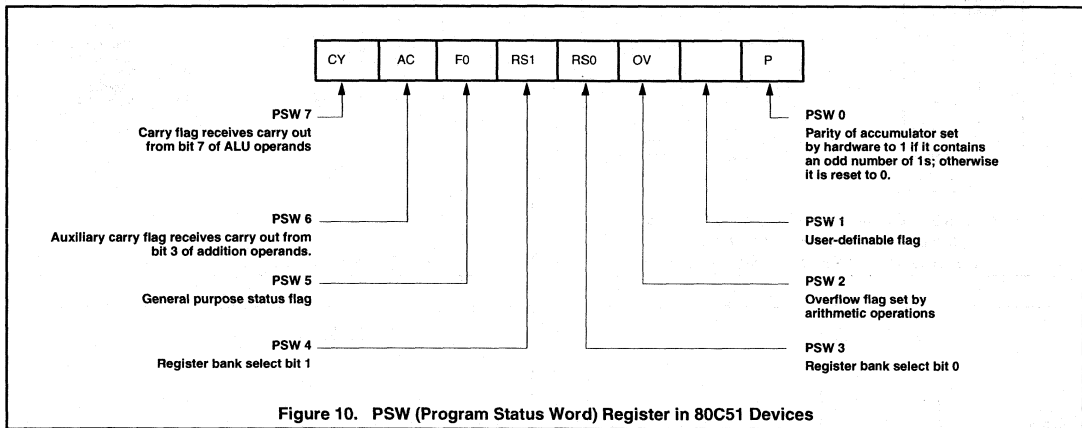

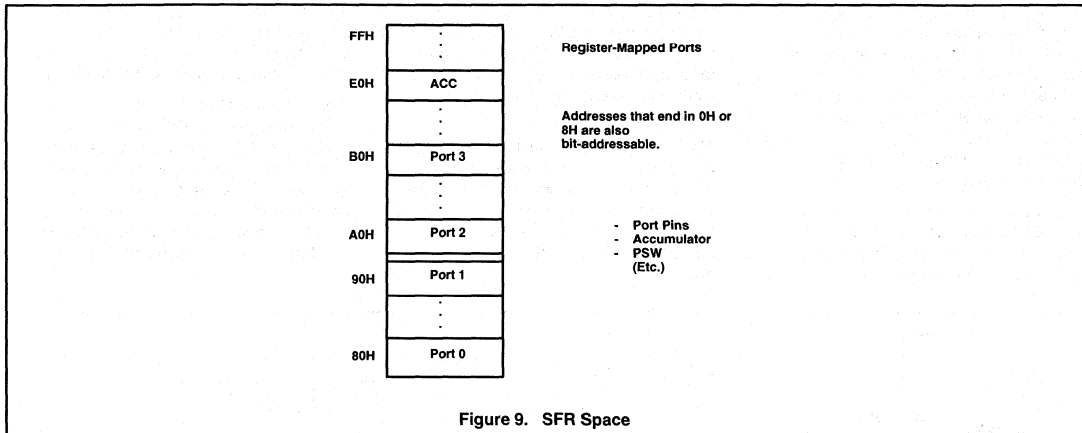

All of the bytes in the Lower 128 can be accessed by either direct or indirect addressing. The Upper 128 (Figure 8) can only be accessed by indirect addressing.

Figure 9 gives a brief look at the Special Function Register (SFR) space. SFRs include the Port latches, timers, peripheral controls, etc. These registers can only be accessed by direct addressing. Sixteen addresses in SFR space are both byte- and bit-addressable. The bit-addressable SFRs are those whose address ends in 0H or 8H.

80C51 Family

80C51 family architecture

80C51 FAMILY INSTRUCTION SET

The 80C51 instruction set is optimized for 8-bit control applications. It provides a variety of fast addressing modes for accessing the internal RAM to facilitate byte operations on small data structures. The instruction set provides extensive support for one-bit variables as a separate data type, allowing direct bit manipulation in control and logic systems that require Boolean processing.

Program Status Word

The Program Status Word (PSW) contains several status bits that reflect the current

state of the CPU. The PSW, shown in Figure 10, resides in the SFR space. It contains the Carry bit, the Auxiliary Carry (for BCD operations), the two register bank select bits, the Overflow flag, a Parity bit, and two user-definable status flags.

The Carry bit, other than serving the function of a Carry bit in arithmetic operations, also serves as the "Accumulator" for a number of Boolean operations.

The bits RS0 and RS1 are used to select one of the four register banks shown in Figure 7.

A number of instructions refer to these RAM locations as R0 through R7. The selection of which of the four is being referred to is made on the basis of the RS0 and RS1 at execution time.

The Parity bit reflects the number of 1s in the Accumulator: P = 1 if the Accumulator contains an odd number of 1s, and P = 0 if the Accumulator contains an even number of 1s. Thus the number of 1s in the Accumulator plus P is always even. Two bits in the PSW are uncommitted and may be used as general purpose status flags.

80C51 Family

80C51 family architecture

Addressing Modes

The addressing modes in the 80C51 instruction set are as follows:

Direct Addressing

In direct addressing the operand is specified by an 8-bit address field in the instruction. Only internal Data RAM and SFRs can be directly addressed.

Indirect Addressing

In indirect addressing the instruction specifies a register which contains the address of the operand. Both internal and external RAM can be indirectly addressed.

The address register for 8-bit addresses can be R0 or R1 of the selected bank, or the Stack Pointer. The address register for 16-bit addresses can only be the 16-bit "data pointer" register, DPTR.

Register Instructions

The register banks, containing registers R0 through R7, can be accessed by certain instructions which carry a 3-bit register specification within the opcode of the instruction. Instructions that access the registers this way are code efficient, since this mode eliminates an address byte. When the instruction is executed, one of the eight registers in the selected bank is accessed. One of four banks is selected at execution time by the two bank select bits in the PSW.

Register-Specific Instructions

Some instructions are specific to a certain register. For example, some instructions always operate on the Accumulator, or Data Pointer, etc., so no address byte is needed to point to it. The opcode itself does that. Instructions that refer to the Accumulator as A assemble as accumulator specific opcodes.

Immediate Constants

The value of a constant can follow the opcode in Program Memory. For example,

```
MOV A, #100
```

loads the Accumulator with the decimal number 100. The same number could be specified in hex digits as 64H.

Indexed Addressing

Only program Memory can be accessed with indexed addressing, and it can only be read. This addressing mode is intended for reading look-up tables in Program Memory. A 16-bit base register (either DPTR or the Program Counter) points to the base of the table, and the Accumulator is set up with the table entry number.

The address of the table entry in Program Memory is formed by adding the Accumulator data to the base pointer.

Another type of indexed addressing is used in the "case jump" instruction. In this case the destination address of a jump instruction is computed as the sum of the base pointer and the Accumulator data.

Arithmetic Instructions

The menu of arithmetic instructions is listed in Table 1. The table indicates the addressing modes that can be used with each instruction to access the <byte> operand. For example, the ADD A, <byte> instruction can be written as:

```
ADD a, 7FH (direct addressing)
ADD A, @R0 (indirect addressing)
ADD A, R7 (register addressing)
ADD A, #127 (immediate constant)
```

The execution times listed in Table 1 assume a 12MHz clock frequency. All of the arithmetic

instructions execute in 1μs except the INC DPTR instruction, which takes 2μs, and the Multiply and Divide instructions, which take 4μs.

Note that any byte in the internal Data Memory space can be incremented without going through the Accumulator.

One of the INC instructions operates on the 16-bit Data Pointer. The Data Pointer is used to generate 16-bit addresses for external memory, so being able to increment it in one 16-bit operation is a useful feature.

The MUL AB instruction multiplies the Accumulator by the data in the B register and puts the 16-bit product into the concatenated B and Accumulator registers.

The DIV AB instruction divides the Accumulator by the data in the B register and leaves the 8-bit quotient in the Accumulator, and the 8-bit remainder in the B register.

Oddly enough, DIV AB finds less use in arithmetic "divide" routines than in radix conversions and programmable shift operations. An example of the use of DIV AB in a radix conversion will be given later. In shift operations, dividing a number by 2ⁿ shifts its n bits to the right. Using DIV AB to perform the division completes the shift in 4μs and leaves the B register holding the bits that were shifted out. The DA A instruction is for BCD arithmetic operations. In BCD arithmetic, ADD and ADDC instructions should always be followed by a DA A operation, to ensure that the result is also in BCD. Note that DA A will not convert a binary number to BCD. The DA A operation produces a meaningful result only as the second step in the addition of two BCD bytes.

Table 1. 80C51 Arithmetic Instructions

MNEMONIC	OPERATION	ADDRESSING MODES				EXECUTION TIME (μs)
		DIR	IND	REG	IMM	
ADD A, <byte>	A = A + <byte>	X	X	X	X	1
ADDC A, <byte>	A = A + <byte> + C	X	X	X	X	1
SUBB A, <byte>	A = A - <byte> - C	X	X	X	X	1
INC A	A = A + 1	Accumulator only				1
INC <byte>	<byte> = <byte> + 1	X	X	X		1
INC DPTR	DPTR = DPTR + 1	Data Pointer only				2
DEC A	A = A - 1	Accumulator only				1
DEC <byte>	<byte> = <byte> - 1	X	X	X		1
MUL AB	B:A = B x A	ACC and B only				4
DIV AB	A = Int[A/B] B = Mod[A/B]	ACC and B only				4
DA A	Decimal Adjust	Accumulator only				1

80C51 family architecture

Logical Instructions

Table 2 shows the list of 80C51 logical instructions. The instructions that perform Boolean operations (AND, OR, Exclusive OR, NOT) on bytes perform the operation on a bit-by-bit basis. That is, if the Accumulator contains 00110101B and byte contains 01010011B, then:

```
ANL  A, <byte>
```

will leave the Accumulator holding 00010001B.

The addressing modes that can be used to access the <byte> operand are listed in Table 2.

The ANL A, <byte> instruction may take any of the forms:

```
ANL  A, 7FH (direct addressing)
ANL  A, @R1 (indirect addressing)
ANL  A, R6 (register addressing)
ANL  A, #53H (immediate constant)
```

All of the logical instructions that are Accumulator-specific execute in 1µs (using a 12MHz clock). The others take 2µs.

Note that Boolean operations can be performed on any byte in the internal Data Memory space without going through the Accumulator. The XRL <byte>, #data instruction, for example, offers a quick and easy way to invert port bits, as in XRL P1, #OFFH.

If the operation is in response to an interrupt, not using the Accumulator saves the time and effort to push it onto the stack in the service routine.

The Rotate instructions (RL, A, RLC A, etc.) shift the Accumulator 1 bit to the left or right. For a left rotation, the MSB rolls into the LSB position. For a right rotation, the LSB rolls into the MSB position.

The SWAP A instruction interchanges the high and low nibbles within the Accumulator. This is a useful operation in BCD manipulations. For example, if the Accumulator contains a binary number which is known to be less than 100, it can be quickly converted to BCD by the following code:

```
MOVE B, #10
DIV  AB
SWAP A
ADD  A, B
```

Dividing the number by 10 leaves the tens digit in the low nibble of the Accumulator, and the ones digit in the B register. The SWAP and ADD instructions move the tens digit to the high nibble of the Accumulator, and the ones digit to the low nibble.

Data Transfers**Internal RAM**

Table 3 shows the menu of instructions that are available for moving data around within

the internal memory spaces, and the addressing modes that can be used with each one. With a 12MHz clock, all of these instructions execute in either 1 or 2µs.

The MOV <dest>, <src> instruction allows data to be transferred between any two internal RAM or SFR locations without going through the Accumulator. Remember, the Upper 128 bytes of data RAM can be accessed only by indirect addressing, and SFR space only by direct addressing.

Note that in 80C51 devices, the stack resides in on-chip RAM, and grows upwards. The PUSH instruction first increments the Stack Pointer (SP), then copies the byte into the stack. PUSH and POP use only direct addressing to identify the byte being saved or restored, but the stack itself is accessed by indirect addressing using the SP register. This means the stack can go into the Upper 128 bytes of RAM, if they are implemented, but not into SFR space.

The Upper 128 bytes of RAM are not implemented in the 80C51 nor in its ROMless or EPROM counterparts. With these devices, if the SP points to the Upper 128, PUSHed bytes are lost, and POPed bytes are indeterminate.

The Data Transfer instructions include a 16-bit MOV that can be used to initialize the Data Pointer (DPTR) for look-up tables in Program Memory, or for 16-bit external Data Memory accesses.

Table 2. 80C51 Logical Instructions

MNEMONIC	OPERATION	ADDRESSING MODES				EXECUTION TIME (µs)
		DIR	IND	REG	IMM	
ANL A, <byte>	A = A.AND. <byte>	X	X	X	X	1
ANL <byte>, A	<byte> = <byte> .AND.A	X				1
ANL <byte>, #data	<byte> = <byte> .AND.#data	X				2
ORL A, <byte>	A = A.OR.<byte>	X	X	X	X	1
ORL <byte>, A	<byte> = <byte> .OR.A	X				1
ORL <byte>, #data	<byte> = <byte> .OR.#data	X				2

RLC A	Rotate Left through Carry			Accumulator only		1
RR A	Rotate ACC Right 1 bit			Accumulator only		1
RRC A	Rotate Right through Carry			Accumulator only		1
SWAP A	Swap Nibbles in A			Accumulator only		1

Table 3. Data Transfer Instructions that Access Internal Data Memory Space

MNEMONIC	OPERATION	ADDRESSING MODES				EXECUTION TIME (μs)
		DIR	IND	REG	IMM	
MOV A,<src>	A = <src>	X	X	X	X	1
MOV <dest>,A	<dest> = A	X	X	X		1
MOV <dest>,<src>	<dest> = <src>	X	X	X	X	2
MOV DPTR,#data16	DPTR = 16-bit immediate constant				X	2
PUSH <src>	INC SP:MOV" @SP",<src>	X				2
POP <dest>	MOV <dest>," @SP":DEC SP	X				2
XCH A,<byte>	ACC and <byte> exchange data	X	X	X		1
XCHD A,@Ri	ACC and @Ri exchange low nibbles		X			1

The XCH A, <byte> instruction causes the Accumulator and addressed byte to exchange data. The XCHD A, @Ri instruction is similar, but only the low nibbles are involved in the exchange.

To see how XCH and XCHD can be used to facilitate data manipulations, consider first the problem of shifting an 8-digit BCD number two digits to the right. Figure 11 shows how this can be done using direct MOVs, and for comparison how it can be done using XCH instructions. To aid in understanding how the code works, the contents of the registers that are holding the BCD number and the content of the Accumulator are shown alongside each instruction to indicate their status after the instruction has been executed.

After the routine has been executed, the Accumulator contains the two digits that were shifted out on the right. Doing the routine with direct MOVs uses 14 code bytes and 9μs of execution time (assuming a 12MHz clock). The same operation with XCHs uses only 9 bytes and executes almost twice as fast.

To right-shift by an odd number of digits, a one-digit shift must be executed.

Figure 12 shows a sample of code that will right-shift a BCD number one digit, using the XCHD instruction. Again, the contents of the registers holding the number and of the Accumulator are shown alongside each instruction.

First, pointers R1 and R0 are set up to point to the two bytes containing the last four BCD digits. Then a loop is executed which leaves the last byte, location 2EH, holding the last two digits of the shifted number. The pointers are decremented, and the loop is repeated for location 2DH. The CJNE instruction (Compare and Jump if Not Equal) is a loop control that will be described later. The loop executed from LOOP to CJNE for R1 = 2EH, 2DH, 2CH, and 2BH. At that point the digit that was originally shifted out on the right has propagated to location 2AH. Since that location should be left with 0s, the lost digit is moved to the Accumulator.

External RAM

Table 4 shows a list of the Data Transfer instructions that access external Data Memory. Only indirect addressing can be used. The choice is whether to use a one-byte address, @Ri, where Ri can be either R0 or R1 of the selected register bank, or a two-byte address, @DPTR. The disadvantage to using 16-bit addresses is if only a few k bytes of external RAM are involved is that 16-bit addresses use all 8 bits of Port 2 as address bus. On the other hand, 8-bit addresses allow one to address a few bytes of RAM, as shown in Figure 5, without having to sacrifice all of Port 2. All of these instructions execute in 2 μs, with a 12MHz clock.

Note that in all external Data RAM accesses, the Accumulator is always either the destination or source of the data.

The read and write strobes to external RAM are activated only during the execution of a MOVX instruction. Normally these signals are inactive, and in fact if they're not going to be used at all, their pins are available as extra I/O lines.

Table 4. 80C51 Data Transfer Instructions that Access External Data Memory Space

ADDRESS WIDTH	MNEMONIC	OPERATION	EXECUTION TIME (μs)
8 bits	MOVX A,@Ri	Read external RAM @Ri	2
8 bits	MOVX @Ri,A	Write external RAM @ Ri	2
16 bits	MOVX A,@DPTR	Read external RAM @ DPTR	2
16 bits	MOVX @DPTR,A	Write external RAM @ DPTR	2

Lookup Tables

Table 5 shows the two instructions that are available for reading lookup tables in Program Memory. Since these instructions access only Program Memory, the lookup tables can only be read, not updated.

If the table access is to external Program Memory, then the read strobe is PSEN.

The mnemonic is MOVC for "move constant." The first MOVC instruction in Table 5 can accommodate a table of up to 256 entries numbered 0 through 255. The number of the desired entry is loaded into the Accumulator, and the Data Pointer is set up to point to the beginning of the table. Then:

```
MOVC A,@A+DPTR
```

copies the desired table entry into the Accumulator.

The other MOVC instruction works the same way, except the Program Counter (PC) is used as the table base, and the table is accessed through a subroutine. First the number of the desired entry is loaded into the Accumulator, and the subroutine is called:

```
MOV A,ENTRY NUMBER
CALL TABLE
```

The subroutine "TABLE" would look like this:

```
TABLE: MOVC A,@A+PC
RET
```

The table itself immediately follows the RET (return) instruction in Program Memory. This type of table can have up to 255 entries, numbered 1 through 255. Number 0 cannot be used, because at the time the MOVC instruction is executed, the PC contains the address of the RET instruction. An entry numbered 0 would be the RET opcode itself.

Boolean Instructions

80C51 devices contain a complete Boolean (single-bit) processor. The internal RAM

contains 128 addressable bits, and the SFR space can support up to 128 addressable bits as well. All of the port lines are bit-addressable, and each one can be treated as a separate single-bit port. The instructions that access these bits are not just conditional branches, but a complete menu of move, set, clear, complement, OR, and AND instructions. These kinds of bit operations are not easily obtained in other architectures with any amount of byte-oriented software.

The instruction set for the Boolean processor is shown in Table 6. All bit accesses are by direct addressing.

Bit addresses 00H through 7FH are in the Lower 128, and bit addresses 80H through FFH are in SFR space.

Note how easily an internal flag can be moved to a port pin:

```
MOV C,FLAG
MOV P1.0,C
```

In this example, FLAG is the name of any addressable bit in the Lower 128 or SFR space. An I/O line (the LSB of Port 1, in this case) is set or cleared depending on whether the flag bit is 1 or 0.

The Carry bit in the PSW is used as the single-bit Accumulator of the Boolean processor. Bit instructions that refer to the Carry bit as C assemble as Carry-specific instructions (CLR C, etc.). The Carry bit also has a direct address, since it resides in the PSW register, which is bit-addressable.

Note that the Boolean instruction set includes ANL and ORL operations, but not the XRL (Exclusive OR) operation. An XRL operation is simple to implement in software. Suppose, for example, it is required to form the Exclusive OR of two bits:

```
C = bit1 .XRL bit2
```

The software to do that could be as follows:

```
MOV C,bit1
JNB bit2,OVER
CPL C
```

OVER: (continue)

First, bit1 is moved to the Carry. If bit2 = 0, then C now contains the correct result. That is, bit1 .XRL bit2 = bit1 if bit2 = 0. On the other hand, if bit2 = 1, C now contains the complement of the correct result. It need only be inverted (CPL C) to complete the operation.

This code uses the JNB instruction, one of a series of bit-test instructions which execute a jump if the addressed bit is set (JC, JB, JBC) or if the addressed bit is not set (JNC, JNB). In the above case, bit2 is being tested, and if bit2 = 0, the CPL C instruction is jumped over.

JBC executes the jump if the addressed bit is set, and also clears the bit. Thus a flag can be tested and cleared in one operation. All the PSW bits are directly addressable, so the Parity bit, or the general purpose flags, for example, are also available to the bit-test instructions.

Relative Offset

The destination address for these jumps is specified to the assembler by a label or by an actual address in Program memory. However, the destination address assembles to a relative offset byte. This is a signed (two's complement) offset byte which is added to the PC in two's complement arithmetic if the jump is executed. The range of the jump is therefore -128 to +127 Program Memory bytes relative to the first byte following the instruction.

Table 5. 80C51 Lookup Table Read Instructions

MNEMONIC	OPERATION	EXECUTION TIME (μs)
MOVC A,@A+DPTR	Read program memory at (A + DPTR)	2
MOVC A,@A+PC	Read program memory at (A + PC)	2

Table 6. 80C51 Boolean Instructions

JNC rel	Jump if C = 0	2
JB bit,rel	Jump if bit = 1	2
JNB bit,rel	Jump if bit = 0	2
JBC bit,rel	Jump if bit = 1; CLR bit	2

Jump Instructions

Table 7 shows the list of unconditional jumps with execution time for a 12MHz clock.

The table lists a single "JMP addr" instruction, but in fact there are three SJMP, LJMP, and AJMP, which differ in the format of the destination address. JMP is a generic mnemonic which can be used if the programmer does not care which way the jump is encoded.

The SJMP instruction encodes the destination address as a relative offset, as described above. The instruction is 2 bytes long, consisting of the opcode and the relative offset byte. The jump distance is limited to a range of -128 to +127 bytes relative to the instruction following the SJMP.

The LJMP instruction encodes the destination address as a 16-bit constant. The instruction

is 3 bytes long, consisting of the opcode and two address bytes. The destination address can be anywhere in the 64k Program Memory space.

The AJMP instruction encodes the destination address as an 11-bit constant. The instruction is 2 bytes long, consisting of the opcode, which itself contains 3 of the 11 address bits, followed by another byte containing the low 8 bits of the destination address. When the instruction is executed, these 11 bits are simply substituted for the low 11 bits in the PC. The high 5 bits stay the same. Hence the destination has to be within the same 2k block as the instruction following the AJMP.

In all cases the programmer specifies the destination address to the assembler in the same way: as a label or as a 16-bit constant. The assembler will put the destination

address into the correct format for the given instruction. If the format required by the instruction will not support the distance to the specified destination address, a "Destination out of range" message is written into the List file.

The JMP @A+DPTR instruction supports case jumps. The destination address is computed at execution time as the sum of the 16-bit DPTR register and the Accumulator. Typically, DPTR is set up with the address of a jump table. In a 5-way branch, for example, an integer 0 through 4 is loaded into the Accumulator. The code to be executed might be as follows:

```
MOV DPTR,#JUMP TABLE
MOV A,INDEX_NUMBER
RL A
JMP @A+DPTR
```

Table 7. Unconditional Jumps in 80C51 Devices

MNEMONIC	OPERATION	EXECUTION TIME (μ s)
JMP addr	Jump to addr	2
JMP @A+DPTR	Jump to A + DPTR	2
CALL addr	Call subroutine at addr	2
RET	Return from subroutine	2
RETI	Return from interrupt	2
NOP	No operation	1

80C51 Family

80C51 family architecture

The RL A instruction converts the index number (0 through 4) to an even number on the range 0 through 8, because each entry in the jump table is 2 bytes long:

JUMP TABLE:

AJMP	CASE 0
AJMP	CASE 1
AJMP	CASE 2
AJMP	CASE 3
AJMP	CASE 4

Table 7 shows a single "CALL addr" instruction, but there are two of them, LCALL and ACALL, which differ in the format in which the subroutine address is given to the CPU. CALL is a generic mnemonic which can be used if the programmer does not care which way the address is encoded.

The LCALL instruction uses the 16-bit address format, and the subroutine can be anywhere in the 64k Program Memory space. The ACALL instruction uses the 11-bit format, and the subroutine must be in the same 2k block as the instruction following the ACALL.

In any case, the programmer specifies the subroutine address to the assembler in the same way: as a label or as a 16-bit constant. The assembler will put the address into the correct format for the given instructions.

Subroutines should end with a RET instruction, which returns execution to the instruction following the CALL.

RETI is used to return from an interrupt service routine. The only difference between RET and RETI is that RETI tells the interrupt control system that the interrupt in progress is done. If there is no interrupt in progress at the time RETI is executed, then the RETI is functionally identical to RET.

Table 8 shows the list of conditional jumps available to the 80C51 user. All of these jumps specify the destination address by the relative offset method, and so are limited to a jump distance of -128 to +127 bytes from the instruction following the conditional jump instruction. Important to note, however, the user specifies to the assembler the actual

destination address the same way as the other jumps: as a label or a 16-bit constant.

There is no Zero bit in the PSW. The JZ and JNZ instructions test the Accumulator data for that condition.

The DJNZ instruction (Decrement and Jump if Not Zero) is for loop control. To execute a loop N times, load a counter byte with N and terminate the loop with a DJNZ to the beginning of the loop, as shown below for N = 10.

```

MOV     COUNTER,#10
LOOP: (begin loop)
    .
    .
    .
    (end loop)
DJNZ   COUNTER,LOOP
    (continue)
    
```

The CJNE instruction (Compare and Jump if Not Equal) can also be used for loop control as in Figure 12. Two bytes are specified in the operand field of the instruction. The jump is executed only if the two bytes are not equal. In the example of Figure 12, the two bytes were data in R1 and the constant 2AH. The initial data in R1 was 2EH. Every time the loop was executed, R1 was decremented, and the looping was to continue until the R1 data reached 2AH.

Another application of this instruction is in "greater than, less than" comparisons. The two bytes in the operand field are taken as unsigned integers. If the first is less than the second, then the Carry bit is set (1). If the first is greater than or equal to the second, then the Carry bit is cleared.

CPU Timing

All 80C51 microcontrollers have an on-chip oscillator which can be used if desired as the clock source for the CPU. To use the on-chip oscillator, connect a crystal or ceramic resonator between the XTAL1 and XTAL2 pins of the microcontroller, and capacitors to ground as shown in Figure 13.

Examples of how to drive the clock with an external oscillator are shown in Figure 14. Note that in the NMOS devices (8051, etc.) the signal at the XTAL2 pin actually drives the internal clock generator. In the CMOS devices (80C51, etc.), the signal at the XTAL1 pin drives the internal clock generator. The internal clock generator defines the sequence of states that make up the 80C51 machine cycle.

Machine Cycles

A machine cycle consists of a sequence of 6 states, numbered S1 through S6. Each state time lasts for two oscillator periods. Thus a machine cycle takes 12 oscillator periods or 1µs if the oscillator frequency is 12MHz.

Each state is divided into a Phase 1 half and a Phase 2 half. Figure 15 shows that fetch/execute sequences in states and phases for various kinds of instructions. Normally two program fetches are generated during each machine cycle, even if the instruction being executed doesn't require it. If the instruction being executed doesn't need more code bytes, the CPU simply ignores the extra fetch, and the Program Counter is not incremented.

Execution of a one-cycle instruction (Figures 15a and 15b) begins during State 1 of the machine cycle, when the opcode is latched into the Instruction Register. A second fetch occurs during S4 of the same machine cycle. Execution is complete at the end of State 6 of this machine cycle.

The MOVX instructions take two machine cycles to execute. No program fetch is generated during the second cycle of a MOVX instruction. This is the only time program fetches are skipped. The fetch/execute sequence for MOVX instructions is shown in Figure 15d.

The fetch/execute sequences are the same whether the Program Memory is internal or external to the chip. Execution times do not depend on whether the Program Memory is internal or external.

Table 8. Conditional Jumps in 80C51 Devices

MNEMONIC	OPERATION	ADDRESSING MODES				EXECUTION TIME (µs)
		DIR	IND	REG	IMM	
JZ rel	Jump if A = 0	Accumulator only				2
JNZ rel	Jump if A ≠ 0	Accumulator only				2
DJNZ <byte>,rel	Decrement and jump if not zero	X		X		2
CJNE A,<byte>,rel	Jump if A ≠ <byte>	X			X	2
CJNE <byte>,#data,rel	Jump if <byte> ≠ #data		X	X		2

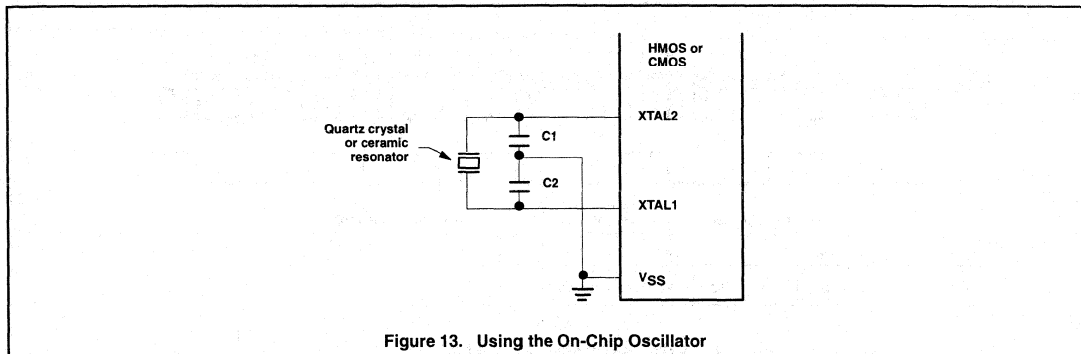

Figure 13. Using the On-Chip Oscillator

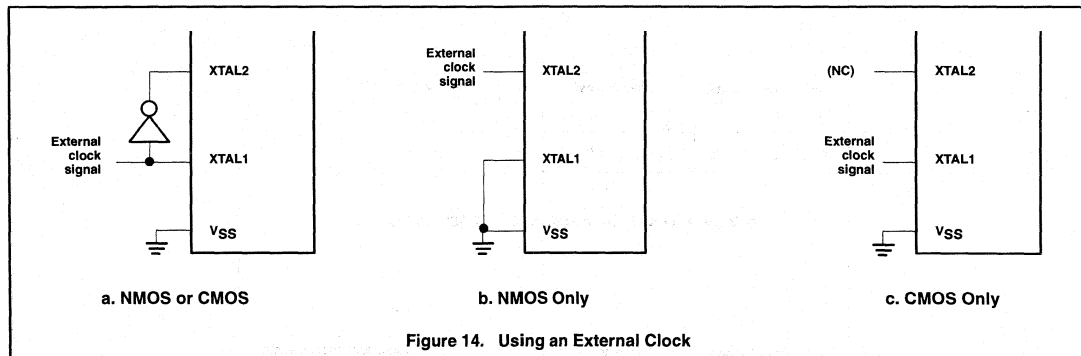

Figure 14. Using an External Clock

Figure 16 shows the signals and timing involved in program fetches when the Program Memory is external. If Program Memory is external, then the Program Memory read strobe PSEN is normally activated twice per machine cycle, as shown in Figure 16a. If an access to external Data Memory occurs, as shown in Figure 16b, two PSENs are skipped, because the address and data bus are being used for the Data Memory access.

Note that a Data Memory bus cycle takes twice as much time as a Program Memory bus cycle. Figure 16 shows the relative timing of the addresses being emitted at Ports 0 and 2, and of ALE and PSEN. ALE is used to

latch the low address byte from P0 into the address latch.

When the CPU is executing from internal Program Memory, PSEN is not activated, and program addresses are not emitted. However, ALE continues to be activated twice per machine cycle and so it is available as a clock output signal. Note, however, that one ALE is skipped during the execution of the MOVX instruction.

Interrupt Structure

The 80C51 and its ROMless and EPROM versions have 5 interrupt sources: 2 external interrupts, 2 timer interrupts, and the serial port interrupt.

What follows is an overview of the interrupt structure for the device. More detailed information for specific members of the 80C51 derivative family is provided in later chapters of this user's guide.

Interrupt Enables

Each interrupt source can be individually enabled or disabled by setting or clearing a bit in the SFR named IE (Interrupt Enable). This register also contains a global disable bit, which can be cleared to disable all interrupts at once. Figure 17 shows the IE register.

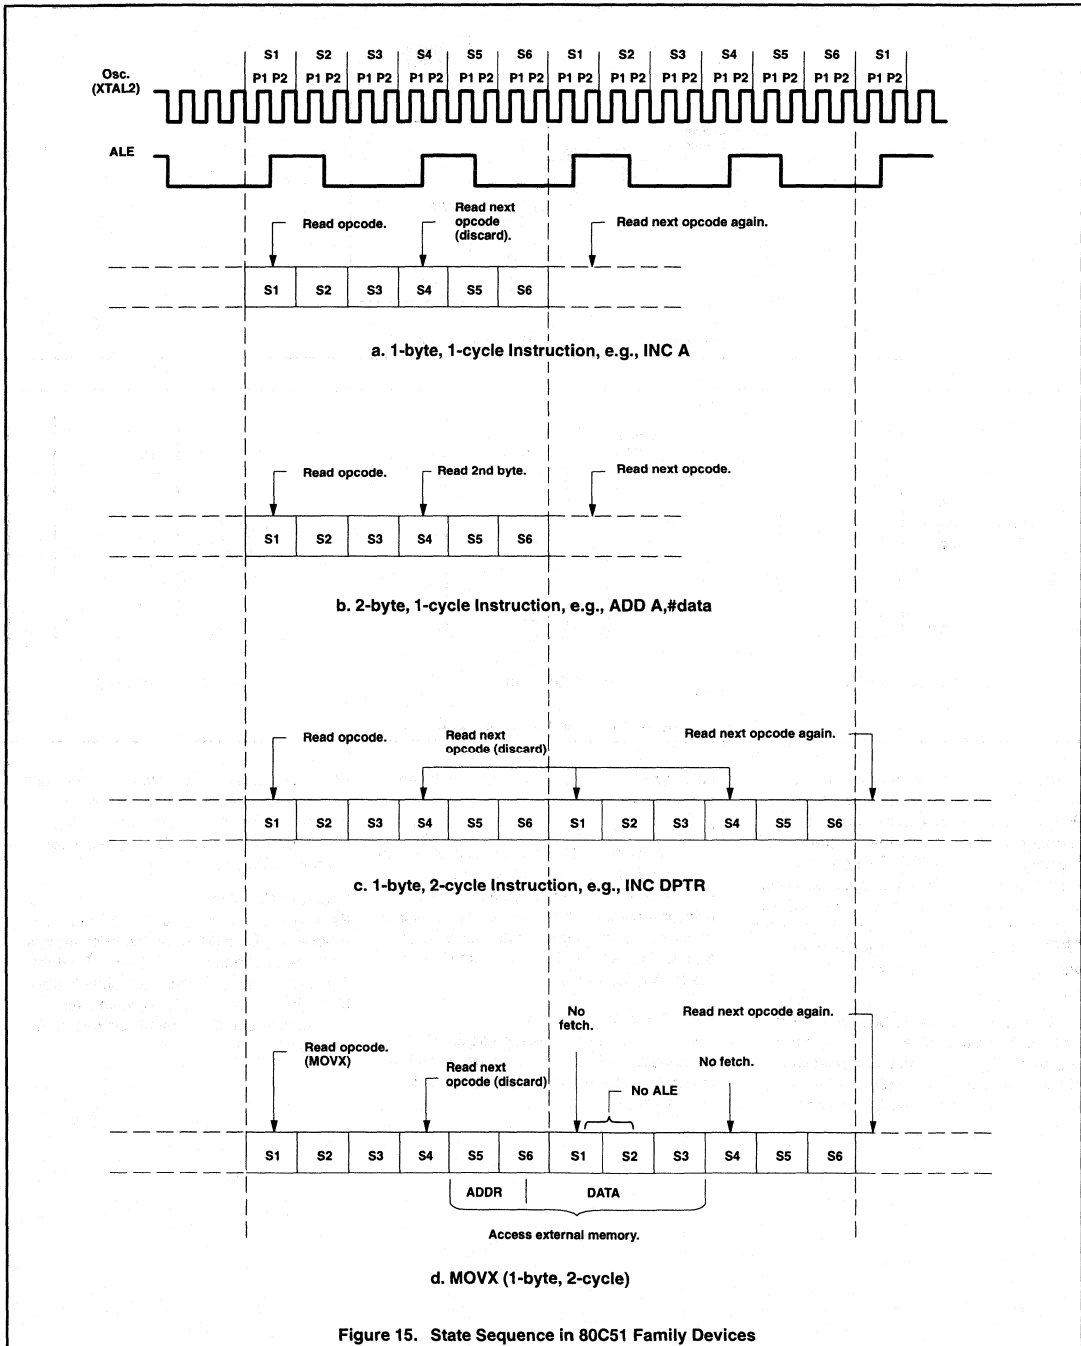

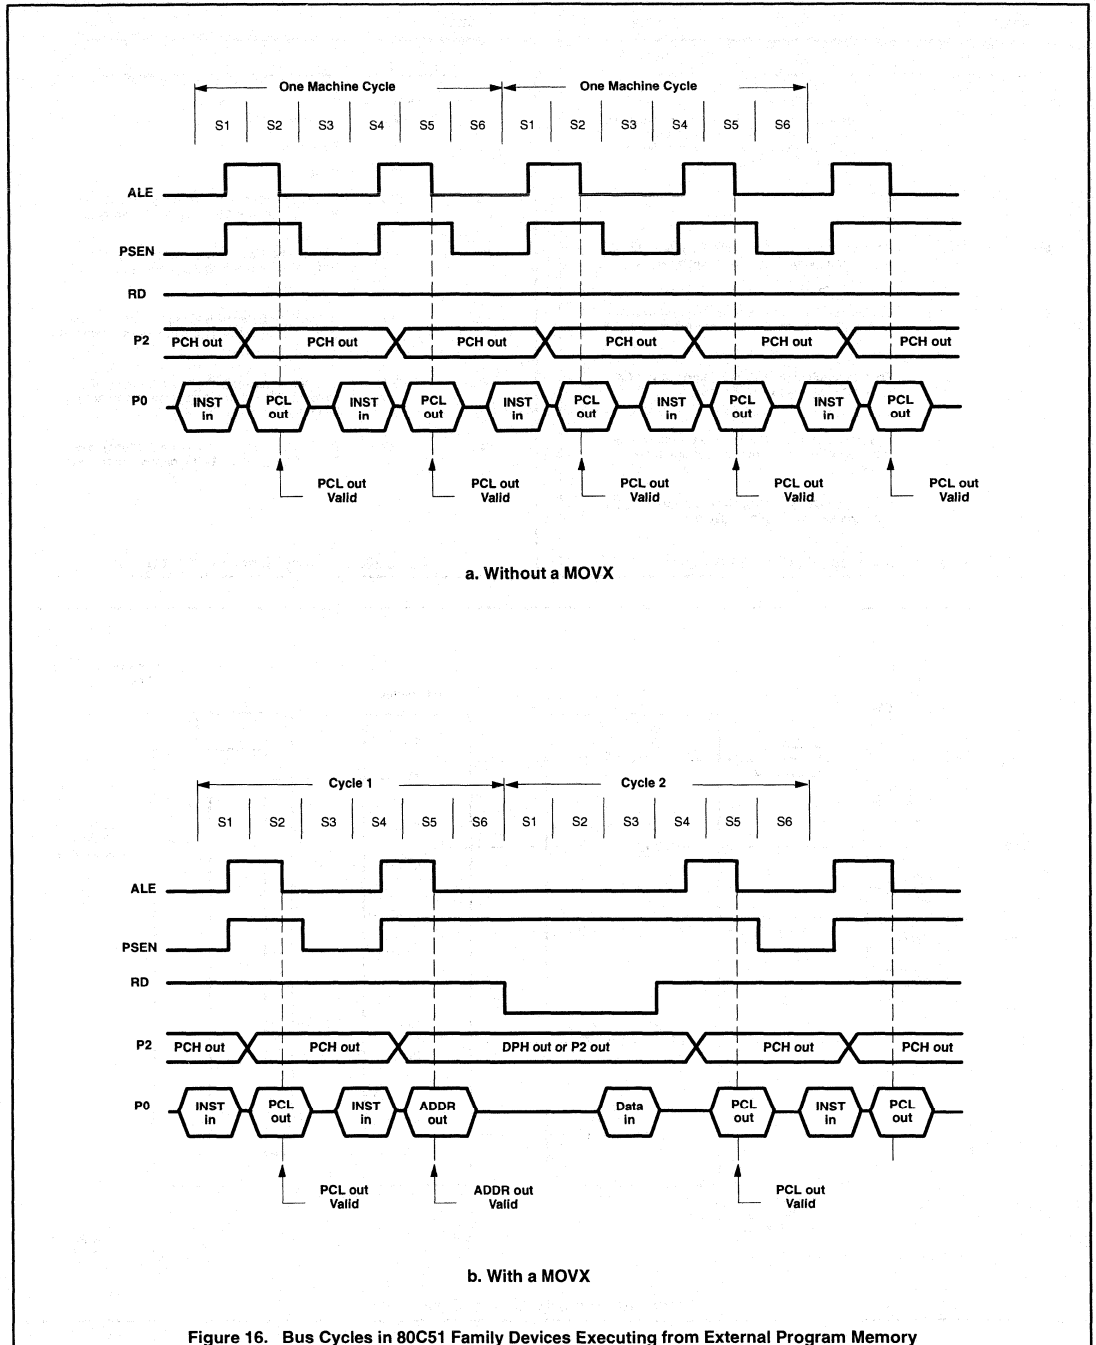

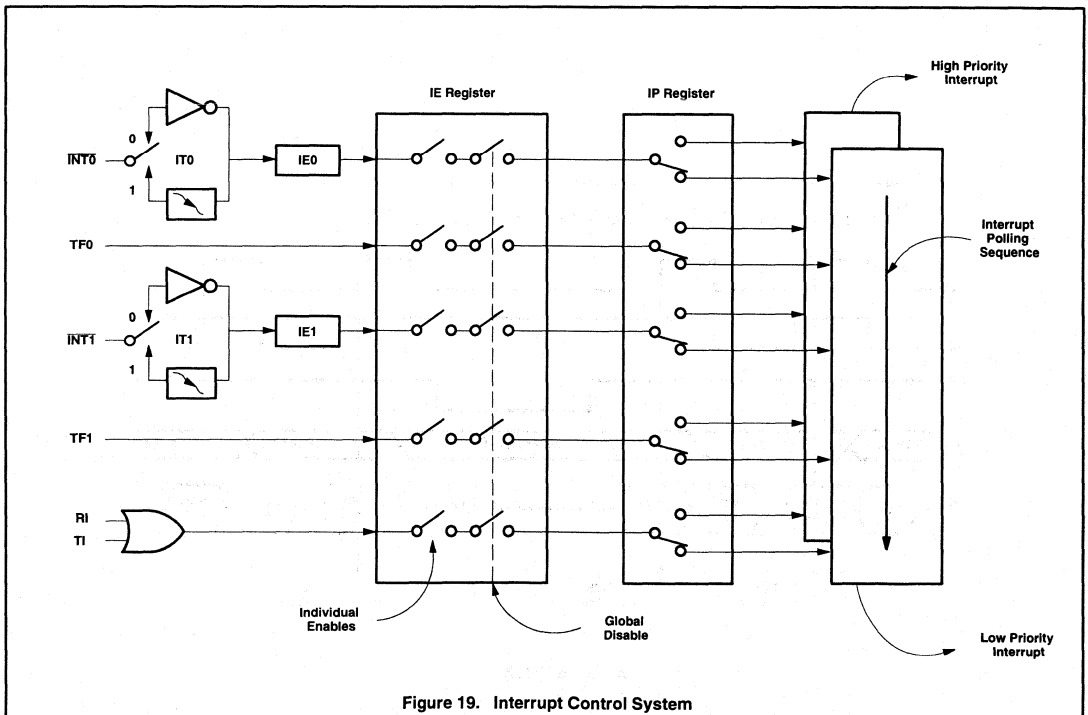

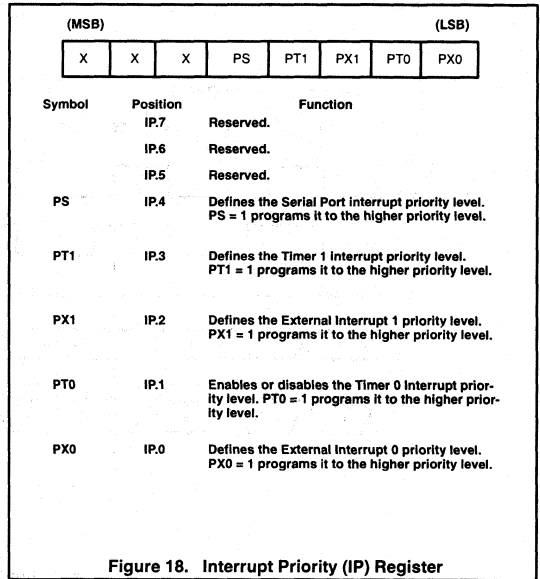

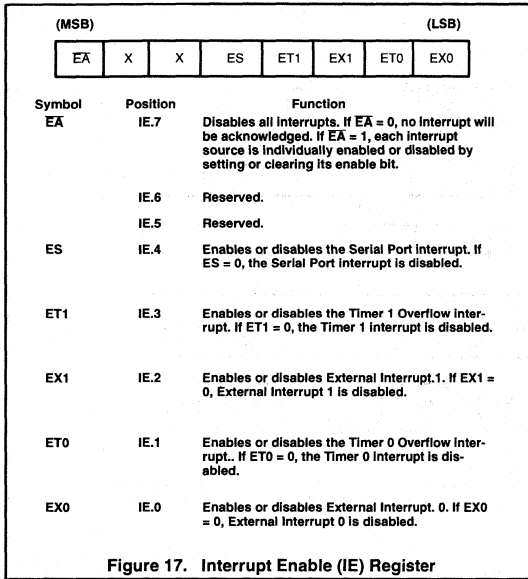

Figure 15. State Sequence in 80C51 Family Devices

80C51 Family

80C51 family architecture

80C51 Family

80C51 family architecture

Interrupt Priorities

Each interrupt source can also be individually programmed to one of two priority levels by setting or clearing a bit in the SFR named IP (Interrupt Priority). Figure 18 shows the IP register. A low-priority interrupt can be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of higher priority is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence. Figure 19 shows how the IE and IP registers and the polling sequence work to determine which if any interrupt will be serviced.

In operation, all the interrupt flags are latched into the interrupt control system during State 5 of every machine cycle. The samples are polled during the following machine cycle. If the flag for an enabled interrupt is found to be set (1), the interrupt system generates an LCALL to the appropriate location in Program Memory, unless some other condition blocks the interrupt. Several conditions can block an interrupt, among them that an interrupt of

equal or higher priority level is already in progress.

The hardware-generated LCALL causes the contents of the Program Counter to be pushed into the stack, and reloads the PC with the beginning address of the service routine. As previously noted (Figure 3), the service routine for each interrupt begins at a fixed location.

Only the Program Counter is automatically pushed onto the stack, not the PSW or any other register. Having only the PC automatically saved allows the programmer to decide how much time should be spent saving other registers. This enhances the interrupt response time, albeit at the expense of increasing the programmer's burden of responsibility. As a result, many interrupt functions that are typical in control applications toggling a port pin for example, or reloading a timer, or unloading a serial buffer can often be completed in less time than it takes other architectures to complete.

Simulating a Third Priority Level in Software

Some applications require more than two priority levels that are provided by on-chip hardware in 80C51 devices. In these cases, relatively simple software can be written to produce the same effect as a third priority

level. First, interrupts that are to have higher priority than 1 are assigned to priority 1 in the Interrupt Priority (IP) register. The service routines for priority 1 interrupts that are supposed to be interruptable by priority 2 interrupts are written to include the following code:

```
PUSH IE
MOV IE,#MASK
CALL LABEL
*****
(execute service routine)
*****
POP IE
RET
LABEL: RETI
```

As soon as any priority interrupt is acknowledged, the Interrupt Enable (IE) register is redefined so as to disable all but priority 2 interrupts. Then a CALL to LABEL executes the RETI instruction, which clears the priority 1 interrupt-in-progress flip-flop. At this point any priority 1 interrupt that is enabled can be serviced, but only priority 2 interrupts are enabled.

POPing IE restores the original enable byte. Then a normal RET (rather than another RETI) is used to terminate the service routine. The additional software adds 10µs (at 12MHz) to priority 1 interrupts.

80C51 family hardware description

HARDWARE DESCRIPTION

This chapter provides a detailed description of the 80C51 microcontroller (see Figure 1). Included in this description are:

- The port drivers and how they function both as ports and, for Ports 0 and 2, in bus operations
- The Timers/Counters
- The Serial Interface
- The Interrupt System
- Reset
- The Reduced Power Modes in CMOS devices
- The EPROM version of the 80C51

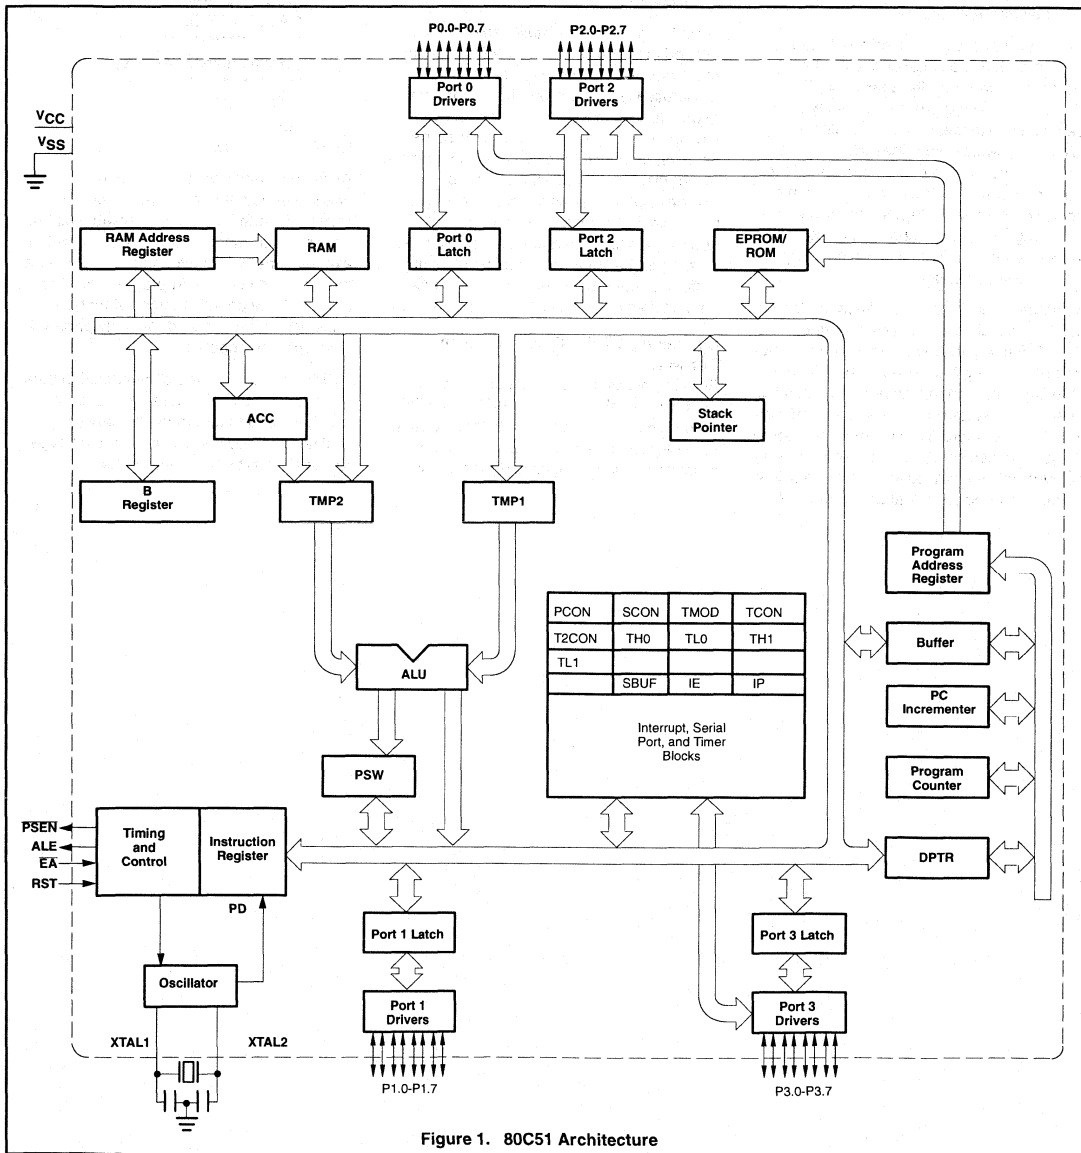

Figure 1. 80C51 Architecture

80C51 Family

80C51 family hardware description

Special Function Registers

A Map of the on-chip memory area called the Special Function Register (SFR) space is shown in Figure 2.

Note that in the SFRs not all of the addresses are occupied. Unoccupied addresses are not implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have no effect.

User software should not write 1s to these unimplemented locations, since they may be used in other 80C51 Family derivative products to invoke new features. The functions of the SFRs are described in the text that follows.

Accumulator

ACC is the Accumulator register. The mnemonics for Accumulator-Specific instructions, however, refer to the Accumulator simply as A.

B Register

The B register is used during multiply and divide operations. For other instructions it can be treated as another scratch pad register.

Program Status Word

The PSW register contains program status information as detailed in Figure 3.

Stack Pointer

The Stack Pointer register is 8 bits wide. It is

incremented before data is stored during PUSH and CALL executions. While the stack may reside anywhere in on-chip RAM, the Stack Pointer is initialized to 07H after a reset. This causes the stack to begin at locations 08H.

Data Pointer

The Data Pointer (DPTR) consists of a high byte (DPH) and a low byte (DPL). Its intended function is to hold a 16-bit address. It may be manipulated as a 16-bit register or as two independent 8-bit registers.

Ports 0 to 3

P0, P1, P2, and P3 are the SFR latches of Ports 0, 1, 2, and 3, respectively. Writing a one to a bit of a port SFR (P0, P1, P2, or P3) causes the corresponding port output pin to switch high. Writing a zero causes the port output pin to switch low. When used as an input, the external state of a port pin will be held in the port SFR (i.e., if the external state of a pin is low, the corresponding port SFR bit will contain a 0; if it is high, the bit will contain a 1).

Serial Data Buffer

The Serial Buffer is actually two separate registers, a transmit buffer and a receive buffer. When data is moved to SBUF, it goes to the transmit buffer and is held for serial transmission. (Moving a byte to SBUF is what

initiates the transmission.) When data is moved from SBUF, it comes from the receive buffer.

Timer Registers Basic to 80C51

Register pairs (TH0, TL0), and (TH1, TL1) are the 16-bit Counting registers for Timer/Counters 0 and 1, respectively.

Control Register for the 80C51

Special Function Registers IP, IE, TMOD, TCON, SCON, and PCON contain control and status bits for the interrupt system, the Timer/Counters, and the serial port. They are described in later sections.

Port Structures and Operation

All four ports in the 80C51 are bidirectional. Each consists of a latch (Special Function Registers P0 through P3), an output driver, and an input buffer.

The output drivers of Ports 0 and 2, and the input buffers of Port 0, are used in accesses to external memory. In this application, Port 0 outputs the low byte of the external memory address, time-multiplexed with the byte being written or read.

Port 2 outputs the high byte of the external memory address when the address is 16 bits wide. Otherwise, the Port 2 pins continue to emit the P2 SFR content.

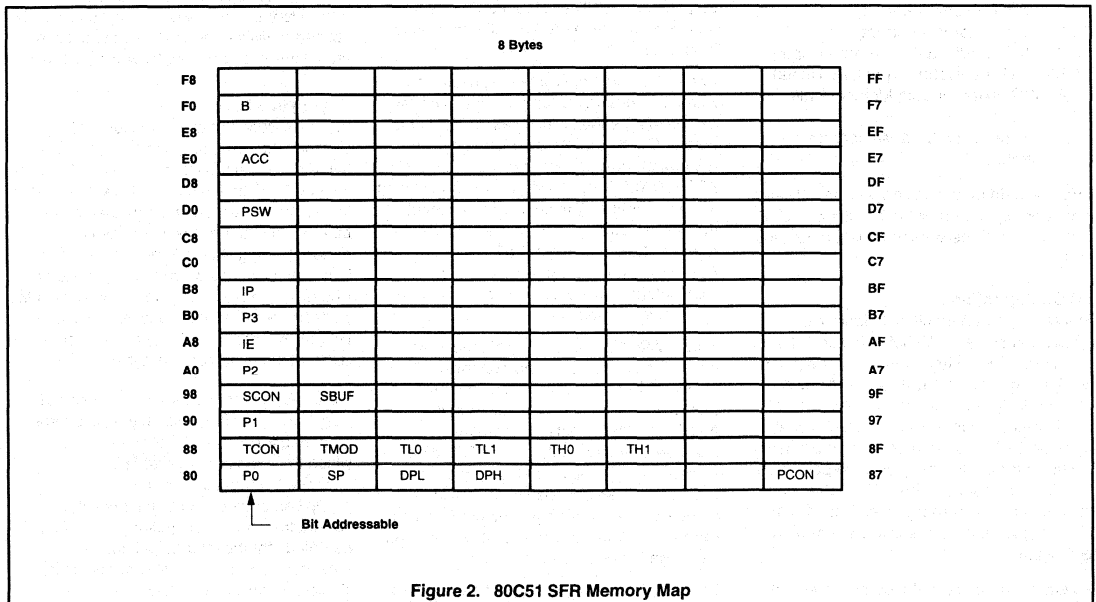

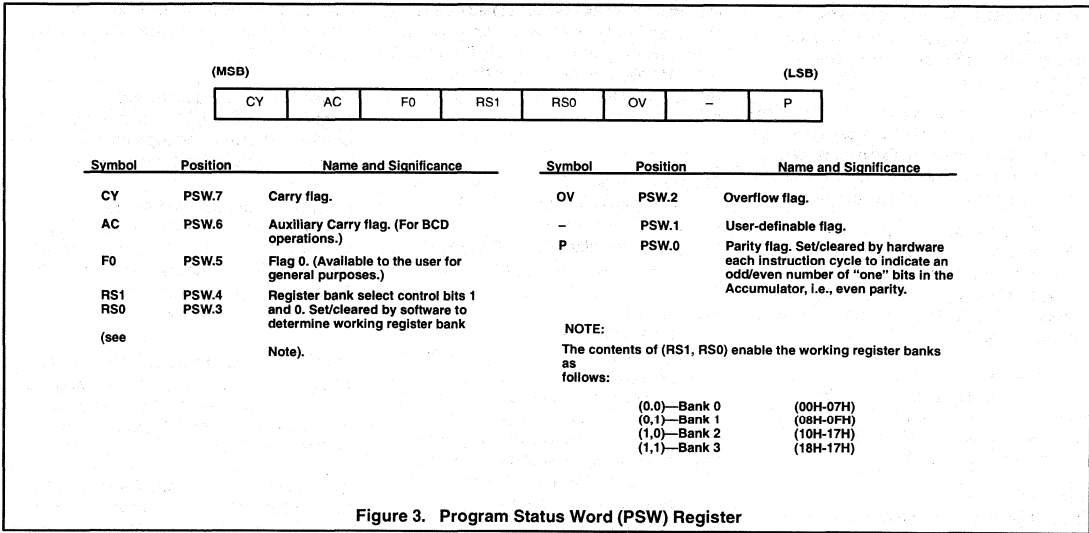

Figure 2. 80C51 SFR Memory Map

All the Port 3 pins are multifunctional. They are not only port pins, but also serve the functions of various special features as listed below:

Port

Pin Alternate Function

- P3.0 RxD (serial input port)
- P3.1 TxD (serial output port)
- P3.2 INT0 (external interrupt)
- P3.3 INT1 (external interrupt)
- P3.4 T0 (Timer/Counter 0 external input)
- P3.5 T1 (Timer/Counter 1 external input)
- P3.6 WR (external Data Memory write strobe)
- P3.7 RD (external Data Memory read strobe)

The alternate functions can only be activated if the corresponding bit latch in the port SFR contains a 1. Otherwise the port pin remains at 0.

I/O Configurations

Figure 4 shows a functional diagram of a typical bit latch and I/O buffer in each of the four ports. The bit latch (one bit in the port's SFR) is represented as a Type D flip-flop, which will clock in a value from the internal bus in response to a "write to latch" signal from the CPU. The level of the port pin itself is placed on the internal bus in response to a "read pin" signal from the CPU. Some instructions that read a port activate the "read latch" signal, and others activate the "read pin" signal.

As shown in Figure 4, the output drivers of Port 0 and 2 are switchable to an internal

ADDR and ADDR/DATA bus by an internal CONTROL signal for use in external memory accesses. During external memory accesses, the P2 SFR remains unchanged, but the P0 SFR gets 1s written to it.

Also shown in Figure 4 is that if a P3 bit latch contains a 1, then the output level is controlled by the signal labeled "alternate output function." The actual P3.X pin level is always available to the pin's alternate input function, if any.

Ports 1, 2, and 3 have internal pullups, and Port 0 has open drain outputs. Each I/O line can be independently used as an input or an output. (Port 0 and 2 may not be used as general purpose I/O when being used as the ADDR/DATA BUS for external memory during normal operation.) To be used as an input, the port bit latch must contain a 1, which turns off the output driver FET. Then, for Ports 1, 2, and 3, the pin is pulled high by a weak internal pullup, and can be pulled low by an external source.

Port 0 differs in that its internal pullups are not active during normal port operation. The pullup FET in the P0 output driver (see Figure 4) is used only when the port is emitting 1s during external memory accesses. Otherwise the pullup FET is off. Consequently P0 lines that are being used as output port lines are open drain. Writing a 1 to the bit latch leaves both output FETs off, so the pin floats. In that condition it can be used as a high-impedance input.

Because Ports 1, 2, and 3 have fixed internal pullups, they are sometimes called

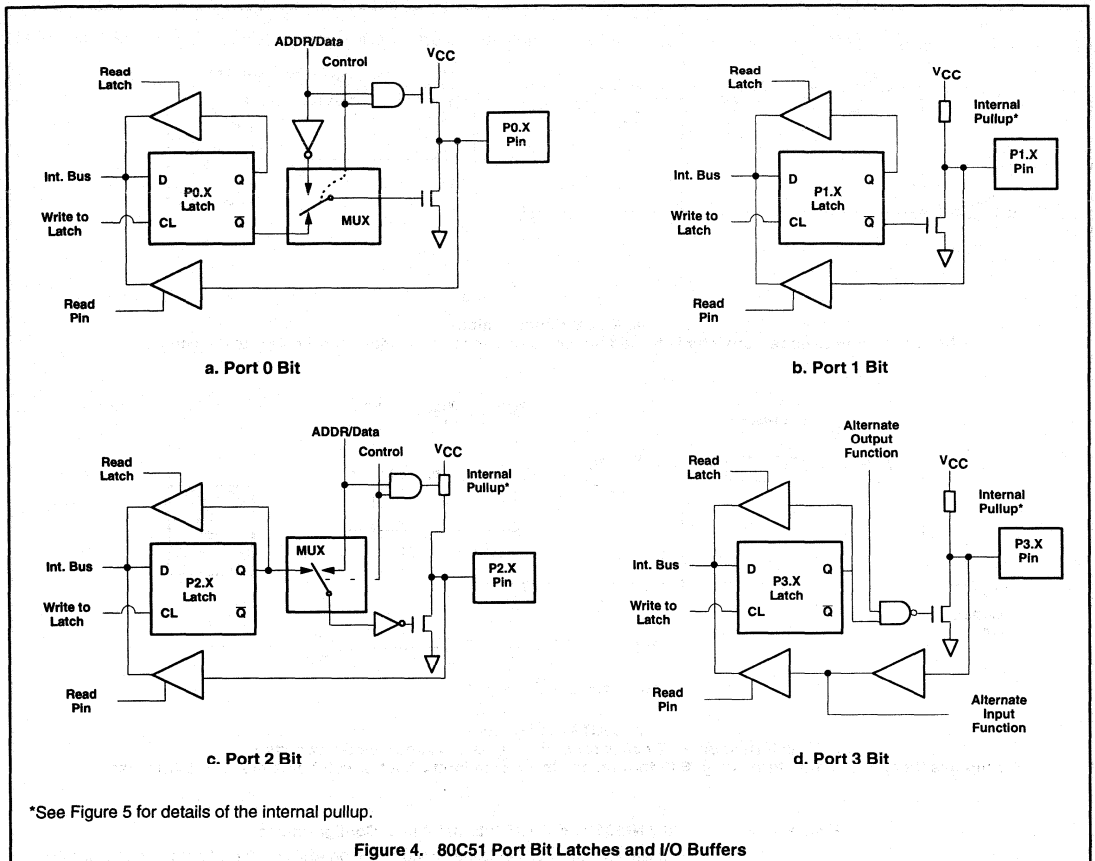

"quasi-bidirectional" ports. When configured as inputs they pull high and will source current (I_L in the data sheets) when externally pulled low. Port 0, on the other hand, is considered "true" bidirectional, because when configured as an input it floats.

All the port latches in the 80C51 have 1s written to them by the reset function. If a 0 is subsequently written to a port latch, it can be reconfigured as an input by writing a 1 to it.

Writing to a Port

In the execution of an instruction that changes the value in a port latch, the new value arrives at the latch during S6P2 of the final cycle of the instruction. However, port latches are in fact sampled by their output buffers only during Phase 1 of an clock period. (During Phase 2 the output buffer holds the value it saw during the previous Phase 1). Consequently, the new value in the port latch won't actually appear at the output pin until the next Phase 1, which will be at S1P1 of the next machine cycle.

If the change requires a 0-to-1 transition in Port 1, 2, or 3, an additional pullup is turned on during S1P1 and S1P2 of the cycle in which the transition occurs. This is done to increase the transition speed. The extra pullup can source about 100 times the current that the normal pullup can. It should be noted that the internal pullups are field-effect transistors, not linear resistors. The pullup arrangements are shown in Figure 5.

In the NMOS 8051 part, the fixed part of the pullup is a depletion mode transistor with the gate wired to the source. This transistor will allow the pin to source about 0.25mA when shorted to ground. In parallel with the fixed pullup is an enhancement mode transistor, which is activated during S1 whenever the port bit does a 0-to-1 transition. During this interval, if the port pin is shorted to ground, this extra transistor will allow the pin to source an additional 30mA.

In the CMOS 80C51, the pullup consists of three pFETs. It should be noted that an n-channel FET (nFET) is turned on when a logical 1 is applied to its gate, and is turned off when a logical 0 is applied to its gate. A p-channel FET (pFET) is the opposite: it is on when its gate sees a 0, and off when its gate sees a 1.

pFET1 in Figure 5 is the transistor that is turned on for 2 oscillator periods after a 0-to-1 transition in the port latch. While it's on, it turns on pFET3 (a weak pullup), through the inverter. This inverter and pFET form a latch which holds the 1.

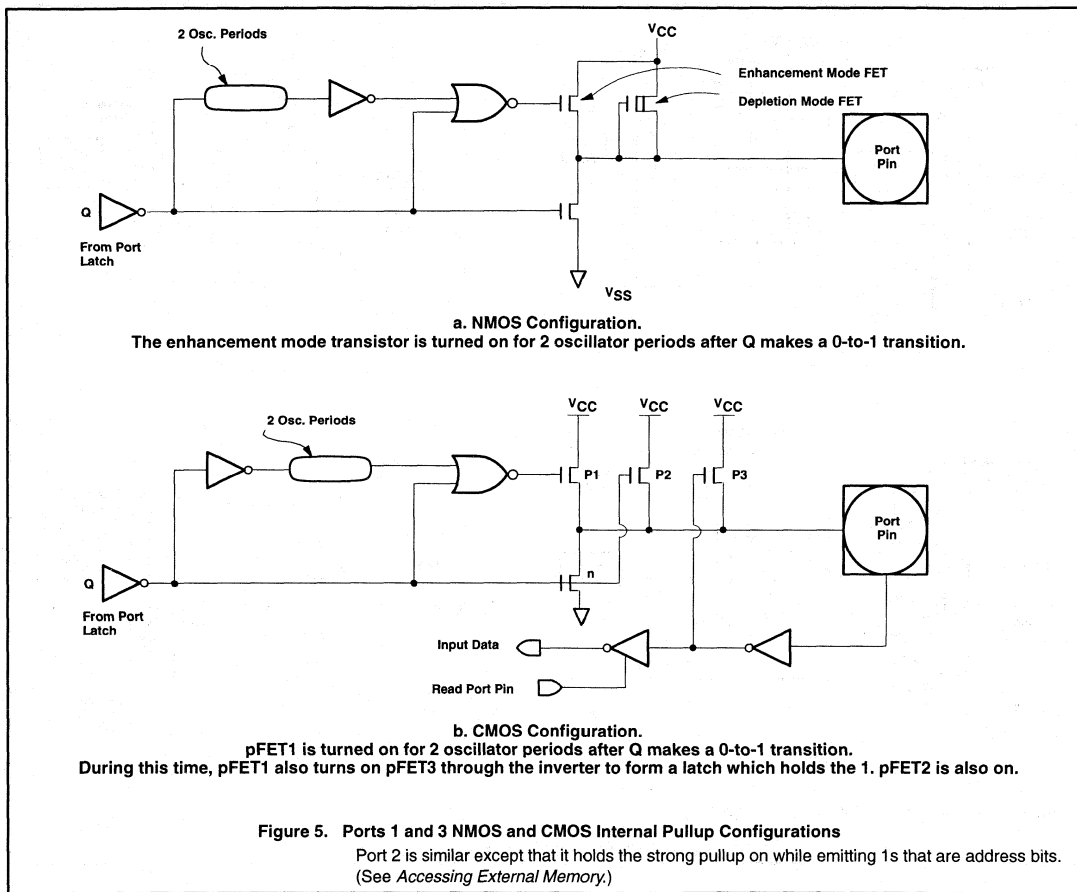

Note that if the pin is emitting a 1, a negative glitch on the pin from some external source can turn off pFET3, causing the pin to go into a float state. pFET2 is a very weak pullup which is on whenever the nFET is off, in traditional CMOS style. It's only about 1/10 the strength of pFET1. Its function is to restore a 1 to the pin in the event the pin had a 1 and lost it to a glitch.

Port Loading and Interfacing
The output buffers of Ports 1, 2, and 3 can each drive 4 LS TTL inputs. These ports on

NMOS versions can be driven in a normal manner by a TTL or NMOS circuit. Both NMOS and CMOS pins can be driven by open-collector and open-drain outputs, but note that 0-to-1 transitions will not be fast.

In the NMOS device, if the pin is driven by an open-collector output, a 0-to-1 transition will have to be driven by the relatively weak depletion mode FET in Figure 5a. In the CMOS device, an input 0 turns off pullup pFET3, leaving only the very weak pullup pFET2 to drive the transition.

Port 0 output buffers can each drive 8 LS TTL inputs. They do, however, require external pullups to drive NMOS inputs, except when being used as the ADDRESS/DATA bus for external memory.

Read-Modify-Write Feature

Some instructions that read a port read the latch and others read the pin. Which ones do which? The instructions that read the latch rather than the pin are the ones that read a value, possibly change it, and then rewrite it to the latch. These are called "read-modify-write" instructions. The instructions listed below are read-modify-write instructions. When the destination operand is a port, or a port bit, these instructions read the latch rather than the pin:

- ANL (logical AND, e.g., ANL P1,A)
- ORL (logical OR, e.g., ORL P2,A)
- XRL (logical EX-OR, e.g., XRL P3,A)
- JBC (jump if bit = 1 and clear bit, e.g., JBC P1.1,LABEL)
- CPL (complement bit, e.g., CPL P3.0)

- INC (increment, e.g., INC P2)
- DEC (decrement, e.g., DEC P2)
- DJNZ (decrement and jump if not zero, e.g., DJNZ P3,LABEL)
- MOV PX,Y,C (move carry bit to bit Y of Port X)
- CLR PX.Y (clear bit Y of Port X)
- SET PX.Y (set bit Y of Port X)

It is not obvious that the last three instructions in this list are read-modify-write instructions, but they are. They read the port byte, all 8 bits, modify the addressed bit, then write the new byte back to the latch.

The reason that read-modify-write instructions are directed to the latch rather than the pin is to avoid a possible misinterpretation of the voltage level at the pin. For example, a port bit might be used to

drive the base of a transistor. When a 1 is written to the bit, the transistor is turned on. If the CPU then reads the same port bit at the pin rather than the latch, it will read the base voltage of the transistor and interpret it as a 0. Reading the latch rather than the pin will return the correct value of 1.

Accessing External Memory

Accesses to external memory are of two types: accesses to external Program Memory and accesses to external Data Memory. Accesses to external Program Memory use signal PSEN (program store enable) as the read strobe. Accesses to external Data Memory use RD or WR (alternate functions of P3.7 and P3.6) to strobe the memory. Fetches from external Program Memory always use a 16-bit address. Accesses to external Data Memory can use either a 16-bit address (MOVX @DPTR) or an 8-bit address (MOVX @Ri).

Whenever a 16-bit address is used, the high byte of the address comes out on Port 2, where it is held for the duration of the read or write cycle. Note that the Port 2 drivers use the strong pullups during the entire time that they are emitting address bits that are 1s. This is during the execution of a MOVX @DPTR instruction. During this time the Port 2 latch (the Special Function Register) does not have to contain 1s, and the contents of the Port 2 SFR are not modified. If the external memory cycle is not immediately followed by another external memory cycle, the undisturbed contents of the Port 2 SFR will reappear in the next cycle.

If an 8-bit address is being used (MOVX @Ri), the contents of the Port 2 SFR remain at the Port 2 pins throughout the external memory cycle. This will facilitate paging.

In any case, the low byte of the address is time-multiplexed with the data byte on Port 0. The ADDR/DATA signals drive both FETs in the Port 0 output buffers. Thus, in this application the Port 0 pins are not open-drain outputs, and do not require external pullups. ALE (Address Latch Enable) should be used to capture the address byte into an external latch. The address byte is valid at the negative transition of ALE. Then, in a write cycle, the data byte to be written appears on Port 0 just before WR is activated, and remains there until after WR is deactivated. In a read cycle, the incoming byte is accepted at Port 0 just before the read strobe is deactivated.

During any access to external memory, the CPU writes 0FFH to the Port 0 latch (the Special Function Register), thus obliterating whatever information the Port 0 SFR may have been holding.

External Program Memory is accessed under two conditions: Whenever signal EA is active; or whenever the program counter (PC) contains a number that is larger than 0FFFH (in the 80C51).

This requires that the ROMless versions have EA wired low to enable the lower 4k program bytes to be fetched from external memory.

When the CPU is executing out of external Program Memory, all 8 bits of Port 2 are dedicated to an output function and may not be used for general purpose I/O. During external program fetches they output the high byte of the PC. During this time the Port 2 drivers use the strong pullups to emit PC bits that are 1s.

Timer/Counters

The 80C51 has two 16-bit Timer/Counter registers: Timer 0 and Timer 1. Both can be configured to operate either as timers or event counters (see Figure 6).

In the "Timer" function, the register is incremented every machine cycle. Thus, one can think of it as counting machine cycles. Since a machine cycle consists of 12 oscillator periods, the count rate is 1/12 of the oscillator frequency.

In the "Counter" function, the register is incremented in response to a 1-to-0 transition at its corresponding external input pin, T0 or T1. In this function, the external input is sampled during S5P2 of every machine cycle.

When the samples show a high in one cycle and a low in the next cycle, the count is incremented. The new count value appears in the register during S3P1 of the cycle following the one in which the transition was detected. Since it takes 2 machine cycles (24 oscillator periods) to recognize a 1-to-0 transition, the maximum count rate is 1/24 of the oscillator frequency. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full cycle. In addition to the "Timer" or "Counter" selection, Timer 0 and Timer 1 have four operating modes from which to select.

Timer 0 and Timer 1

The "Timer" or "Counter" function is selected by control bits C/T in the Special Function Register TMOD. These two Timer/Counters have four operating modes, which are selected by bit-pairs (M1, M0) in TMOD. Modes 0, 1, and 2 are the same for both Timers/Counters. Mode 3 is different. The four operating modes are described in the following text.

Mode 0

Putting either Timer into Mode 0 makes it look like an 8048 Timer, which is an 8-bit Counter with a divide-by-32 prescaler.

Figure 7 shows the Mode 0 operation as it applies to Timer 1.

In this mode, the Timer register is configured as a 13-bit register. As the count rolls over from all 1s to all 0s, it sets the Timer interrupt flag TF1. The counted input is enabled to the Timer when TR1 = 1 and either GATE = 0 or INTT = 1. (Setting GATE = 1 allows the Timer to be controlled by external input INTT, to facilitate pulse width measurements). TR1 is a control bit in the Special Function Register TCON (Figure 8). GATE is in TMOD.

The 13-bit register consists of all 8 bits of TH1 and the lower 5 bits of TL1. The upper 3 bits of TL1 are indeterminate and should be ignored. Setting the run flag (TR1) does not clear the registers.

Mode 0 operation is the same for the Timer 0 as for Timer 1. Substitute TR0, TF0, and INT0 for the corresponding Timer 1 signals in Figure 7. There are two different GATE bits, one for Timer 1 (TMOD.7) and one for Timer 0 (TMOD.3).

Mode 1

Mode 1 is the same as Mode 0, except that the Timer register is being run with all 16 bits.

Mode 2

Mode 2 configures the Timer register as an 8-bit Counter (TL1) with automatic reload, as shown in Figure 9. Overflow from TL1 not only sets TF1, but also reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

Mode 2 operation is the same for Timer/Counter 0.

Mode 3

Timer 1 in Mode 3 simply holds its count. The effect is the same as setting TR1 = 0.

Timer 0 in Mode 3 establishes TL0 and TH0 as two separate counters. The logic for Mode 3 on Timer 0 is shown in Figure 10. TL0 uses the Timer 0 control bits: C/T, GATE, TR0, INT0, and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now controls the "Timer 1" interrupt.

Mode 3 is provided for applications requiring an extra 8-bit timer on the counter. With Timer 0 in Mode 3, an 80C51 can look like it has three Timer/Counters. When Timer 0 is in Mode 3, Timer 1 can be turned on and off by switching it out of and into its own Mode 3, or can still be used by the serial port as a baud rate generator, or in fact, in any application not requiring an interrupt.

80C51 Family

80C51 family hardware description

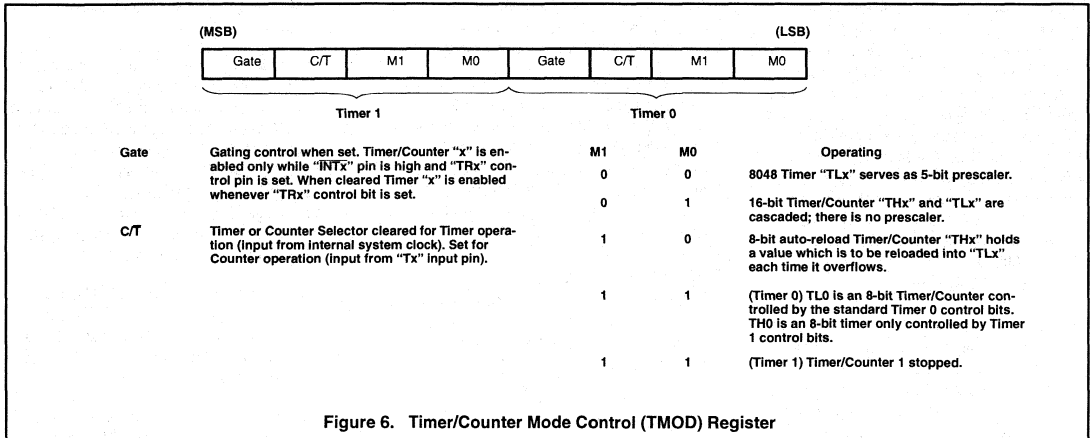

Figure 6. Timer/Counter Mode Control (TMOD) Register

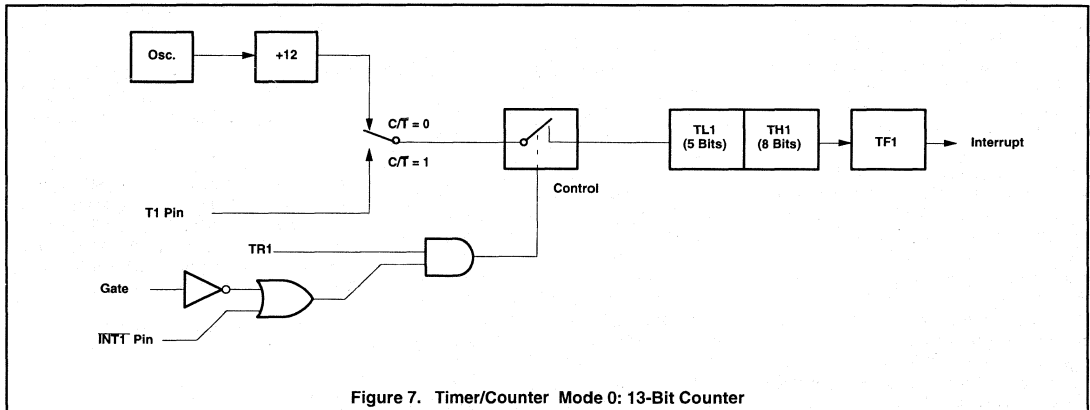

Figure 7. Timer/Counter Mode 0: 13-Bit Counter

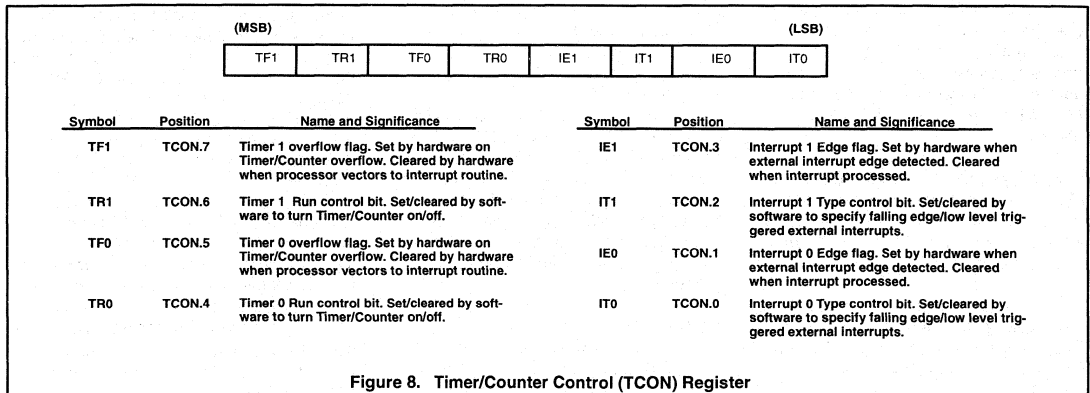

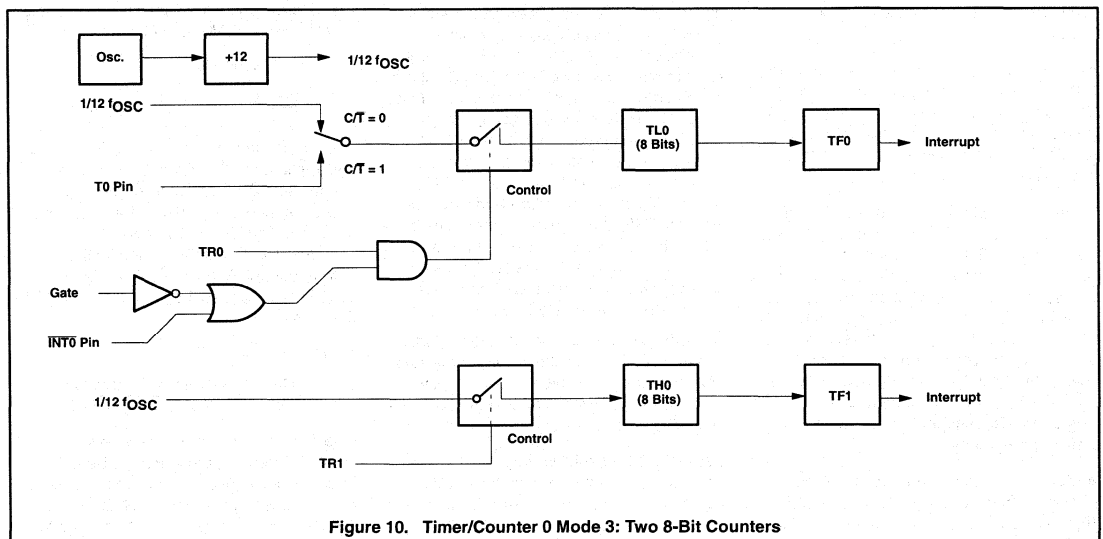

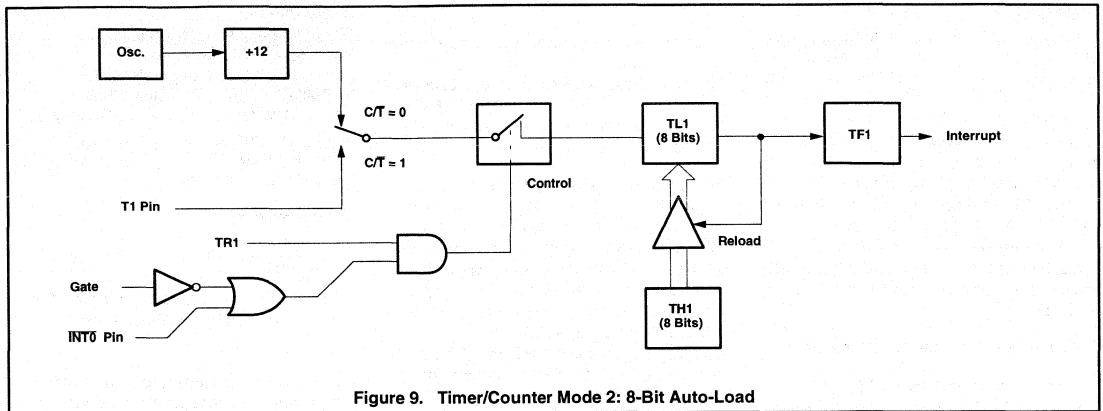

Figure 8. Timer/Counter Control (TCON) Register

Standard Serial Interface

The serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the register. (However, if the first byte still hasn't been read by the time reception of the second byte is complete, one of the bytes will be lost.) The serial port receive and transmit registers are both accessed at Special Function Register SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

Mode 0: Serial data enters and exits through Rx/D. Tx/D outputs the shift clock. 8 bits are transmitted/received (LSB first). The baud rate is fixed at 1/12 the oscillator frequency.

Mode 1: 10 bits are transmitted (through Tx/D) or received (through Rx/D): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SCON. The baud rate is variable.

Mode 2: 11 bits are transmitted (through Tx/D) or received (through Rx/D): start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8 in SCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in Special Function Register SCON, while the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency.

Mode 3: 11 bits are transmitted (through Tx/D) or received (through Rx/D): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is

variable.

In all four modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

Multiprocessor Communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows:

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their SM2s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

Serial Port Control Register

The serial port control and status register is the Special Function Register SCON, shown in Figure 11. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

Baud Rates

The baud rate in Mode 0 is fixed: Mode 0 Baud Rate = Oscillator Frequency / 12. The baud rate in Mode 2 depends on the value of bit SMOD in Special Function Register PCON. If SMOD = 0 (which is the value on reset), the baud rate is 1/64 the oscillator frequency. If SMOD = 1, the baud rate is 1/32 the oscillator frequency.

Mode 2 Baud Rate =

$$\frac{2^{SMOD}}{64} \times (\text{Oscillator Frequency})$$

In the 80C51, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate.

Using Timer 1 to Generate Baud Rates

When Timer 1 is used as the baud rate generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of SMOD as follows:

Mode 1, 3 Baud Rate =

$$\frac{2^{SMOD}}{32} \times (\text{Timer 1 Overflow Rate})$$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either "timer" or "counter" operation, and in any of its 3 running modes. In the most typical applications, it is configured for "timer" operation, in the auto-reload mode (high nibble of TMOD = 0010B). In that case the baud rate is given by the formula:

Mode 1, 3 Baud Rate =

$$\frac{2^{SMOD}}{32} \times \frac{\text{Oscillator Frequency}}{12 \times [256 - (TH1)]}$$

One can achieve very low baud rates with Timer 1 by leaving the Timer 1 interrupt enabled, and configuring the Timer to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload. Figure 12 lists various commonly used baud rates and how they can be obtained from Timer 1.

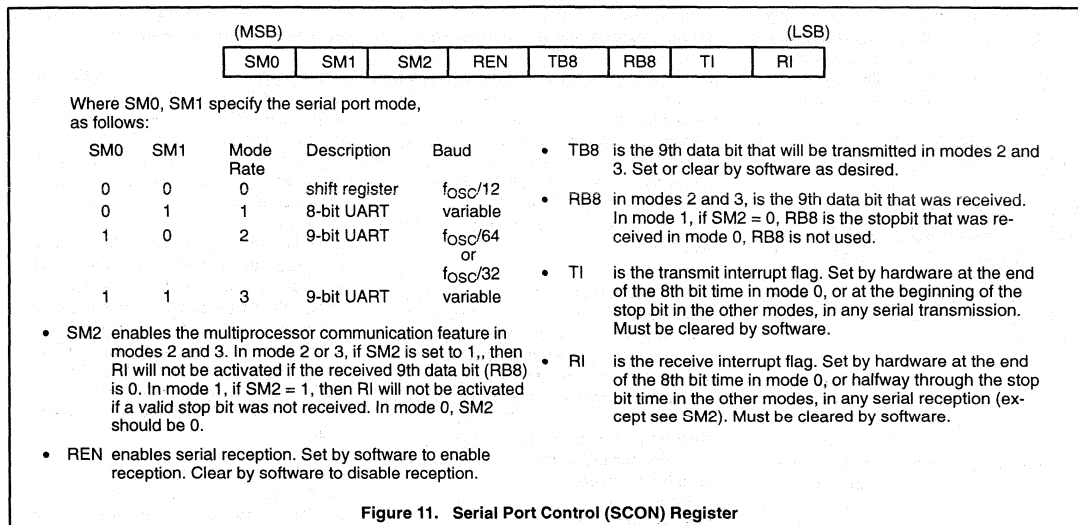

Figure 11. Serial Port Control (SCON) Register

Baud Rate	f_{OSC}	SMOD	Timer 1		
			C/T	Mode	Reload Value
Mode 0 Max: 1.67MHz	20MHz	X	X	X	X
Mode 2 Max: 625k	20MHz	1	X	X	X
Mode 1, 3 Max: 104.2k	20MHz	1	0	2	FFH
19.2k	11.059MHz	1	0	2	FDH
9.6k	11.059MHz	0	0	2	FDH
4.8k	11.059MHz	0	0	2	FAH
2.4k	11.059MHz	0	0	2	F4H
1.2k	11.059MHz	0	0	2	E8H
137.5	11.986M	0	0	2	1DH
110	6MHz	0	0	2	72H
110	12MHz	0	0	1	FEEDH

Figure 12. Timer 1 Generated Commonly Used Baud Rates

More About Mode 0

Serial data enters and exits through RxD. TxD outputs the shift clock. 8 bits are transmitted/received: 8 data bits (LSB first). The baud rate is fixed a 1/12 the oscillator frequency.

Figure 13 shows a simplified functional diagram of the serial port in Mode 0, and associated timing.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal at S6P2 also loads a 1 into the 9th position of the transmit shift register and tells the TX Control block to commence a transmission. The internal timing is such that one full machine cycle will elapse between "write to SBUF" and

activation of SEND.

SEND enables the output of the shift register to the alternate output function line of P3.0 and also enable SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK is low during S3, S4, and S5 of every machine cycle, and high during S6, S1, and S2. At S6P2 of every machine cycle in which SEND is active, the contents of the transmit shift are shifted to the right one position.

As data bits shift out to the right, zeros come in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position, is just to the left of the MSB, and all positions to the left of that contain zeros. This condition flags the TX Control block to do one last shift and then

deactivate SEND and set T1. Both of these actions occur at S1P1 of the 10th machine cycle after "write to SBUF."

Reception is initiated by the condition REN = 1 and R1 = 0. At S6P2 of the next machine cycle, the RX Control unit writes the bits 11111110 to the receive shift register, and in the next clock phase activates RECEIVE.

RECEIVE enable SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK makes transitions at S3P1 and S6P1 of every machine cycle. At S6P2 of every machine cycle in which RECEIVE is active, the contents of the receive shift register are shifted to the left one position. The value that comes in from the right is the value that was sampled at the P3.0 pin at S5P2 of the same machine cycle.

80C51 Family

80C51 family hardware description

As data bits come in from the right, 1s shift out to the left. When the 0 that was initially loaded into the rightmost position arrives at the leftmost position in the shift register, it flags the RX Control block to do one last shift and load SBUF. At S1P1 of the 10th machine cycle after the write to SCON that cleared RI, RECEIVE is cleared as RI is set.

More About Mode 1

Ten bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in SCON. In the 80C51 the baud rate is determined by the Timer 1 overflow rate.

Figure 14 shows a simplified functional diagram of the serial port in Mode 1, and associated timings for transmit receive.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal also loads a 1 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission actually commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. (Thus, the bit times are synchronized to the divide-by-16 counter, not to the "write to SBUF" signal.)

The transmission begins with activation of SEND which puts the start bit at TxD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that.

As data bits shift out to the right, zeros are clocked in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain zeros. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 10th divide-by-16 rollover after "write to SBUF."

Reception is initiated by a detected 1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written into the input shift register. Resetting the divide-by-16 counter aligns its rollovers with the boundaries of the incoming bit times.

The 16 states of the counter divide each bit time into 16ths. At the 7th, 8th, and 9th

counter states of each bit time, the bit detector samples the value of RxD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done for noise rejection. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. This is to provide rejection of false start bits. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register (which in mode 1 is a 9-bit register), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.:

1. R1 = 0, and
2. Either SM2 = 0, or the received stop bit = 1.

If either of these two conditions is not met, the received frame is irretrievably lost. If both conditions are met, the stop bit goes into RB8, the 8 data bits go into SBUF, and RI is activated. At this time, whether the above conditions are met or not, the unit goes back to looking for a 1-to-0 transition in RxD.

More About Modes 2 and 3

Eleven bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmit, the 9th data bit (TB8) can be assigned the value of 0 or 1. On receive, the 9th data bit goes into RB8 in SCON. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency in Mode 2. Mode 3 may have a variable baud rate generated from Timer 1.

Figures 15 and 16 show a functional diagram of the serial port in Modes 2 and 3. The receive portion is exactly the same as in Mode 1. The transmit portion differs from Mode 1 only in the 9th bit of the transmit shift register.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "write to SBUF" signal also loads TB8 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. (Thus, the bit times are

synchronized to the divide-by-16 counter, not to the "write to SBUF" signal.)

The transmission begins with activation of SEND, which puts the start bit at TxD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that. The first shift clocks a 1 (the stop bit) into the 9th bit position of the shift register. Thereafter, only zeros are clocked in. Thus, as data bits shift out to the right, zeros are clocked in from the left. When TB8 is at the output position of the shift register, then the stop bit is just to the left of TB8, and all positions to the left of that contain zeros. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 11th divide-by-16 rollover after "write to SBUF."

Reception is initiated by a detected 1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFH is written to the input shift register.

At the 7th, 8th, and 9th counter states of each bit time, the bit detector samples the value of R-D. The value accepted is the value that was seen in at least 2 of the 3 samples. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register (which in Modes 2 and 3 is a 9-bit register), it flags the RX Control block to do one last shift, load SBUF and RB8, and set RI.

The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

1. R1 = 0, and
2. Either SM2 = 0, or the received 9th data bit = 1.

If either of these conditions is not met, the received frame is irretrievably lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bits go into SBUF. One bit time later, whether the above conditions were met or not, the unit goes back to looking for a 1-to-0 transition at the RxD input.

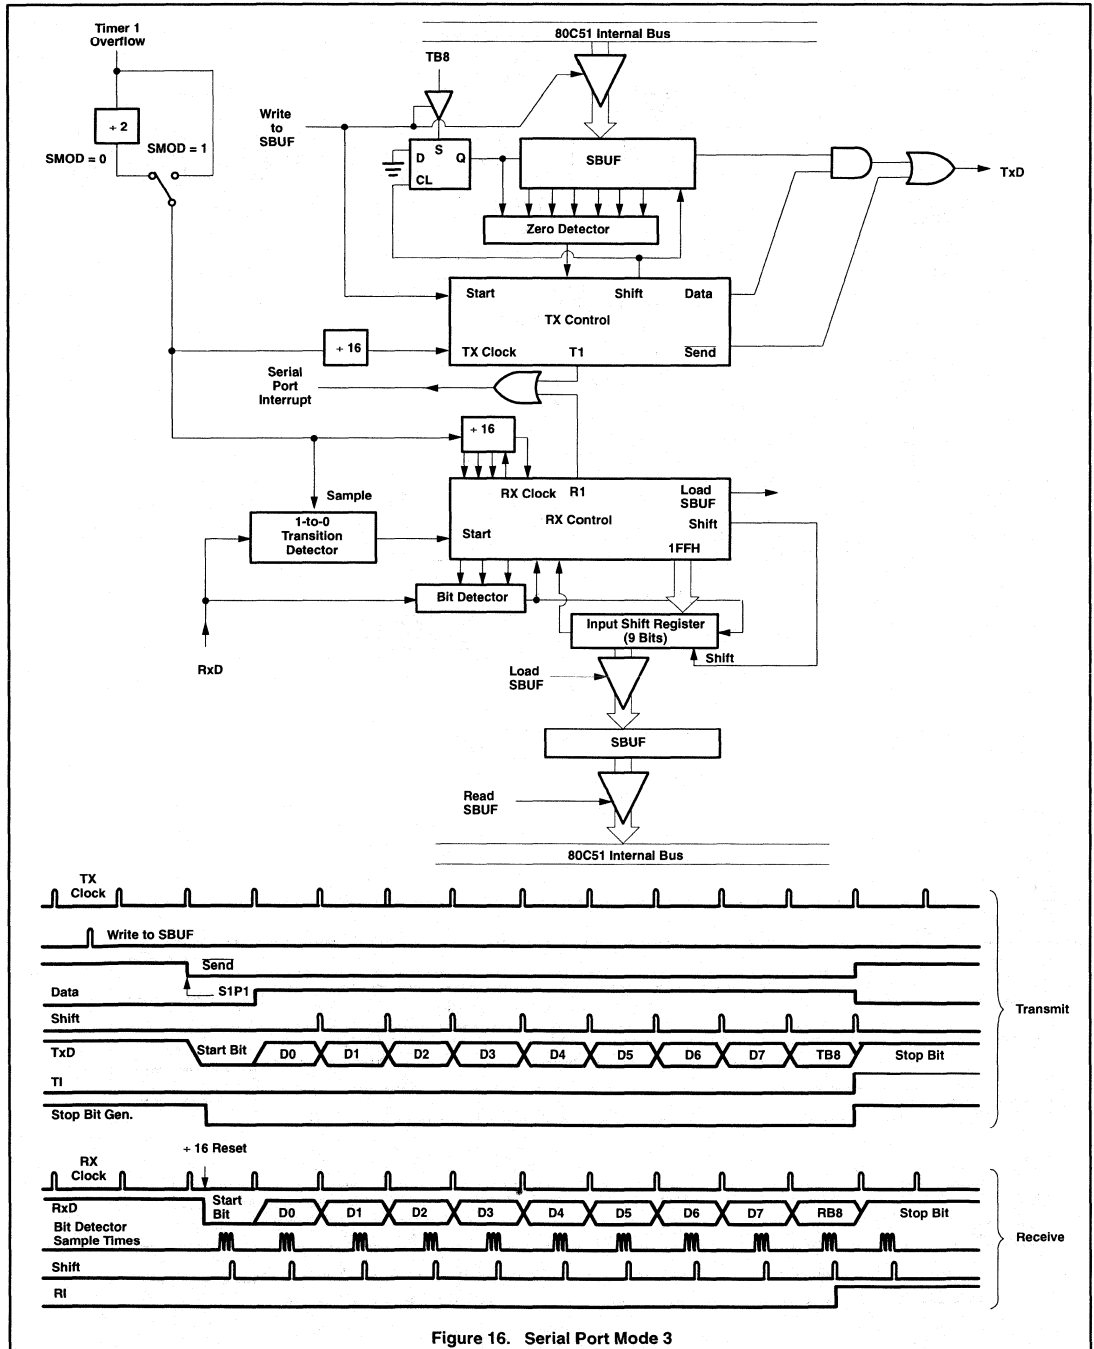

Figure 16. Serial Port Mode 3

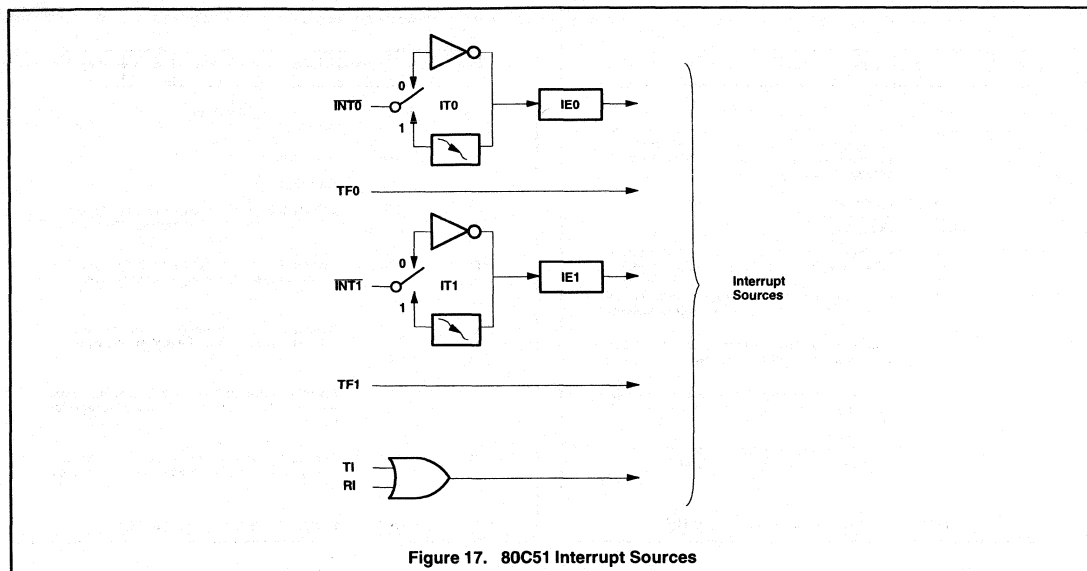

Figure 17. 80C51 Interrupt Sources

Interrupts

The 80C51 provides 5 interrupt sources. These are shown in Figure 17. The External Interrupts INT0 and INT1 can each be either level-activated or transition-activated, depending on bits IT0 and IT1 in Register TCON. The flags that actually generate these interrupts are bits IE0 and IE1 in TCON. When an external interrupt is generated, the flag that generated it is cleared by the hardware when the service routine is vectored to only if the interrupt was transition-activated. If the interrupt was level-activated, then the external requesting source is what controls the request flag, rather than the on-chip hardware.

The Timer 0 and Timer 1 Interrupts are generated by TF0 and TF1, which are set by a rollover in their respective Timer/Counter registers (except see Timer 0 in Mode 3). When a timer interrupt is generated, the flag that generated it is cleared by the on-chip hardware when the service routine is vectored to.

The Serial Port Interrupt is generated by the logical OR of RI and TI. Neither of these flags

is cleared by hardware when the service routine is vectored to. In fact, the service routine will normally have to determine whether it was RI or TI that generated the interrupt, and the bit will have to be cleared in software.

All of the bits that generate interrupts can be set or cleared by software, with the same result as though it had been set or cleared by hardware. That is, interrupts can be generated or pending interrupts can be canceled in software.

Each of these interrupt sources can be individually enabled or disabled by setting or clearing a bit in Special Function Register IE (Figure 18). IE also contains a global disable bit, EA, which disables all interrupts at once.

Priority Level Structure

Each interrupt source can also be individually programmed to one of two priority levels by setting or clearing a bit in Special Function Register IP (Figure 19). A low-priority interrupt can itself be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt

can't be interrupted by any other interrupt source.

If two request of different priority levels are received simultaneously, the request of higher priority level is serviced. If requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence as follows:

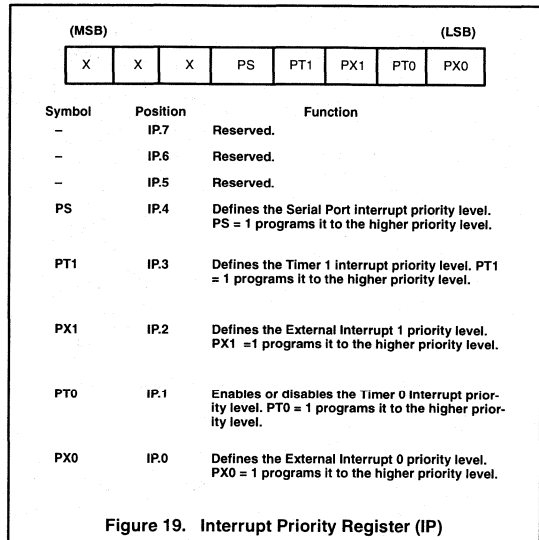

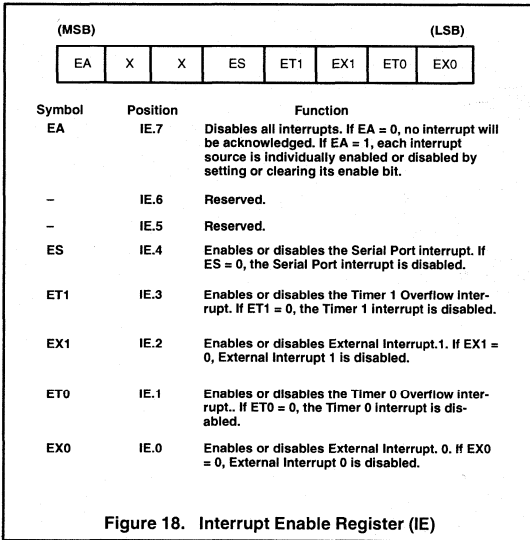

Source	Priority Within Level
1. IE0	(highest)
2. TF0	
3. IE1	
4. TF1	
5. RI+TI	(lowest)

Note that the "priority within level" structure is only used to resolve simultaneous requests of the same priority level.

The IP register contains a number of unimplemented bits. IP.7, IP.6, and IP.5 are reserved in the 80C51. User software should not write 1s to these positions, since they may be used in other 8051 Family products.

80C51 Family

80C51 family hardware description

How Interrupts Are Handled

The interrupt flags are sampled at S5P2 of every machine cycle. The samples are polled during the following machine cycle. If one of the flags was in a set condition at S5P2 of the preceding cycle, the polling cycle will find it and the interrupt system will generate an LCALL to the appropriate service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of equal or higher priority level is already in progress.
2. The current (polling) cycle is not the final cycle in the execution of the instruction in progress.
3. The instruction in progress is RETI or any write to the IE or IP registers.

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress will be completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any access to IE or IP, then at least one more instruction will be executed before any interrupt is vectored to.

The polling cycle is repeated with each machine cycle, and the values polled are the values that were present at S5P2 of the previous machine cycle. Note that if an interrupt flag is active but not being responded to for one of the above conditions, if the flag is not still active when the blocking condition is removed, the denied interrupt will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle is new.

The polling cycle/LCALL sequence is illustrated in Figure 20.

Note that if an interrupt of higher priority level goes active prior to S5P2 of the machine cycle labeled C3 in Figure 20, then in accordance with the above rules it will be vectored to during C5 and C6, without any instruction of the lower priority routine having been executed.

Thus the processor acknowledges an interrupt request by executing a hardware-generated LCALL to the appropriate servicing routine. In some cases it also clears the flag that generated the interrupt, and in other cases it doesn't. It never clears the Serial Port flag. This has to be done in the user's software. It clears an

external interrupt flag (IE0 or IE1) only if it was transition-activated. The hardware-generated LCALL pushes the contents of the Program Counter on to the stack (but it does not save the PSW) and reloads the PC with an address that depends on the source of the interrupt being vectored to, as shown below:

Source	Vector Address
IE0	0003H
TF0	000BH
IE1	0013H
TF1	001BH
RI+TI	0023H

Execution proceeds from that location until the RETI instruction is encountered. The RETI instruction informs the processor that this interrupt routine is no longer in progress, then pops the top two bytes from the stack and reloads the Program Counter. Execution of the interrupted program continues from where it left off.

Note that a simple RET instruction would also have returned execution to the interrupted program, but it would have left the interrupt control system thinking an interrupt was still in progress, making future interrupts impossible.

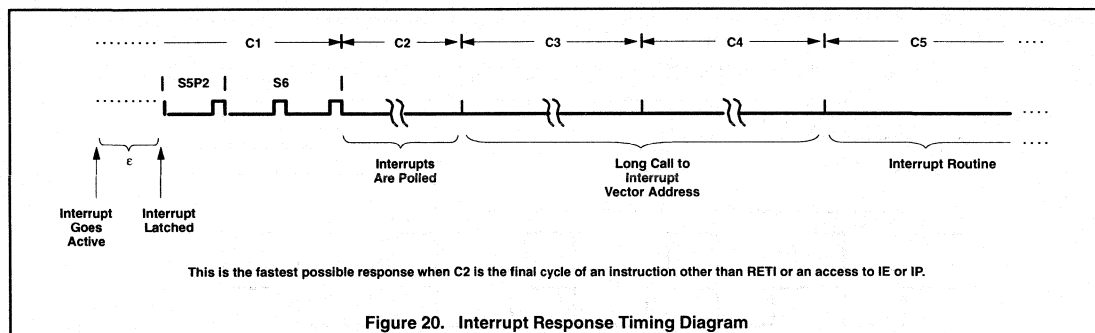

Figure 20. Interrupt Response Timing Diagram

External Interrupts

The external sources can be programmed to be level-activated or transition-activated by setting or clearing bit IT1 or IT0 in Register TCON. If ITx = 0, external interrupt x is triggered by a detected low at the INTx pin. If ITx = 1, external interrupt x is edge triggered. In this mode if successive samples of the INTx pin show a high in one cycle and a low in the next cycle, interrupt request flag IEx in TCON is set. Flag bit IEx then requests the interrupt.

Since the external interrupt pins are sampled once each machine cycle, an input high or low should hold for at least 12 oscillator periods to ensure sampling. If the external interrupt is transition-activated, the external source has to hold the request pin high for at least one cycle, and then hold it low for at least one cycle. This is done to ensure that the transition is seen so that interrupt request flag IEx will be set. IEx will be automatically cleared by the CPU when the service routine is called.

If the external interrupt is level-activated, the external source has to hold the request active until the requested interrupt is actually generated. Then it has to deactivate the request before the interrupt service routine is completed, or else another interrupt will be generated.

Response Time

The INT0 and INT1 levels are inverted and latched into IE0 and IE1 at S5P2 of every machine cycle. The values are not actually polled by the circuitry until the next machine cycle. If a request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two cycles.

Thus, a minimum of three complete machine cycles elapse between activation of an external interrupt request and the beginning of execution of the first instruction of the service routine. Figure 20 shows interrupt response timings.

A longer response time would result if the request is blocked by one of the 3 previously listed conditions. If an interrupt of equal or higher priority level is already in progress, the additional wait time obviously depends on the nature of the other interrupt's service routine. If the instruction in progress is not in its final cycle, the additional wait time cannot be more than 3 cycles, since the longest instructions (MUL and DIV) are only 4 cycles long, and if the instruction in progress is RETI or an access to IE or IP, the additional wait time cannot be more than 5 cycles (a maximum of one more cycle to complete the instruction in progress, plus 4 cycles to complete the next instruction if the instruction is MUL or DIV).

Thus, in a single-interrupt system, the response time is always more than 3 cycles and less than 9 cycles.

Single-Step Operation

The 80C51 interrupt structure allows single-step execution with very little software overhead. As previously noted, an interrupt request will not be responded to while an interrupt of equal priority level is still in progress, nor will it be responded to after RETI until at least one other instruction has been executed. Thus, once an interrupt routine has been entered, it cannot be re-entered until at least one instruction of the interrupted program is executed. One way to use this feature for single-step operation is to program one of the external interrupts (e.g., INT0) to be level-activated. The service

routine for the interrupt will terminate with the following code:

```
JNB P3.2,$ ;Wait Till INT0 Goes High
JB P3.2,$ ;Wait Till INT0 Goes Low
RETI ;Go Back and Execute One Instruction
```

Now if the INT0 pin, which is also the P3.2 pin, is held normally low, the CPU will go right into the External Interrupt 0 routine and stay there until INT0 is pulsed (from low to high to low). Then it will execute RETI, go back to the task program, execute one instruction, and immediately re-enter the External Interrupt 0 routine to await the next pulsing of P3.2. One step of the task program is executed each time P3.2 is pulsed.

Reset

The reset input is the RST pin, which is the input to a Schmitt Trigger. A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset, with the timing shown in Figure 21.

The external reset signal is asynchronous to the internal clock. The RST pin is sampled during State 5 Phase 2 of every machine cycle. The port pins will maintain their current activities for 19 oscillator periods after a logic 1 has been sampled at the RST pin; that is, for 19 to 31 oscillator periods after the external reset signal has been applied to the RST pin.

The internal reset algorithm writes 0s to all the SFRs except the port latches, the Stack Pointer, and SBUF. The port latches are initialized to FFH, the Stack Pointer to 07H, and SBUF is indeterminate. Table 1 lists the SFR reset values. The internal RAM is not affected by reset. On power up the RAM content is indeterminate.

Power-on Reset

An automatic reset can be obtained when V_{CC} is turned on by connecting the RST pin to V_{CC} through a 10 μ f capacitor and to V_{SS} through an 8.2k resistor, providing the V_{CC} rise time does not exceed 1 millisecond and the oscillator start-up time does not exceed 10 milliseconds. This power-on reset circuit is shown in Figure 22. The CMOS devices do not require the 8.2k pulldown resistor, although its presence does no harm.

When power is turned on, the circuit holds the RST pin high for an amount of time that depends on the value of the capacitor and

the rate at which it charges. To ensure a good reset, the RST pin must be high long enough to allow the oscillator time to start-up (normally a few ms) plus two machine cycles.

Note that the port pins will be in a random state until the oscillator has started and the internal reset algorithm has written 1s to them.

With this circuit, reducing V_{CC} quickly to 0 causes the RST pin voltage to momentarily fall below 0V. However, this voltage is internally limited, and will not harm the device.

Power-Saving Modes of Operation

For applications where power consumption is critical the CMOS version provides power reduced modes of operation as a standard feature. The power down mode in NMOS devices is no longer a standard feature.

CMOS Power Reduction Mode

CMOS versions have two power reducing modes, Idle and Power Down. The input through which backup power is supplied during these operations is V_{CC} . Figure 23 shows the internal circuitry which implements these features. In the Idle modes (IDL = 1), the oscillator continues to run and the Interrupt, Serial Port, and Timer blocks continue to be clocked, but the clock signal is gated off to the CPU. In Power Down (PD = 1), the oscillator is frozen. The Idle and Power Down Modes are activated by setting bits in Special Function Register PCON. The address of this register is 87H. Figure 24 details its contents.

In the NMOS devices the PCON register only contains SMOD. The other four bits are implemented only in the CMOS devices. User software should never write 1s to unimplemented bits, since they may be used in other 80C51 Family products.

Idle Mode

An instruction that sets PCON.0 causes that to be the last instruction executed before going into the Idle mode, the internal clock signal is gated off to the CPU but not to the Interrupt, Timer, and Serial Port functions. The CPU status is preserved in its entirety; the Stack Pointer, Program Counter, Program Status Word, Accumulator, and all other registers maintain their data during Idle. The port pins hold the logical states they had at the time Idle was activated. ALE and \overline{PSEN} hold at logic high levels.

There are two ways to terminate the Idle. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware, terminating the Idle mode. The interrupt will be serviced, and following RETI, the next instruction to be executed will be the one following the instruction that put the device into Idle.

The flag bits GF0 and GF1 can be used to give an indication if an interrupt occurred during normal operation or during an Idle. For example, an instruction that activates Idle can also set one or both flag bits. When Idle is terminated by an interrupt, the interrupt service routine can examine the flag bits. The other way of terminating the Idle mode is with a hardware reset. Since the clock oscillator is still running, the hardware reset needs to be held active for only two machine cycles (24 oscillator periods) to complete the reset.

80C51 family hardware description

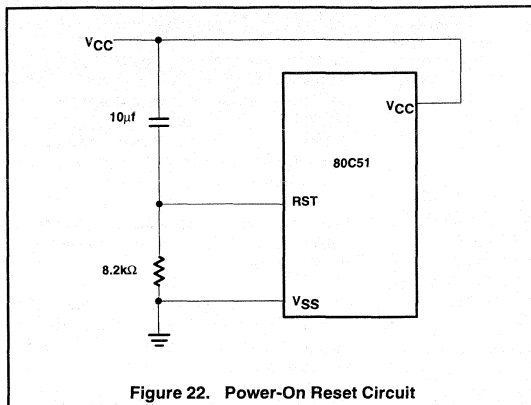

Figure 22. Power-On Reset Circuit

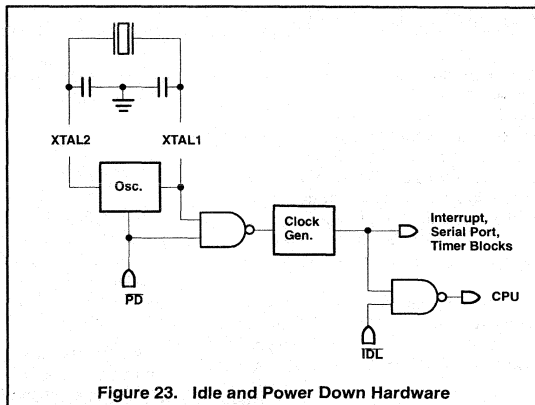

Figure 23. Idle and Power Down Hardware

(MSB)		(LSB)	
SMOD	-	-	-
	GF1	GF0	PD
			IDL
Symbol	Position	Name and Function	
SMOD	PCON.7	Double Baud rate bit. When set to a 1 and Timer 1 is used to generate baud rate, and the Serial Port is used in modes 1, 2, or 3.	
-	PCON.6	Reserved.	
-	PCON.5	Reserved.	
-	PCON.4	Reserved.	
GF1	PCON.3	General-purpose flag bit.	
GF0	PCON.2	General-purpose flag bit.	
PD	PCON.1	Power-Down bit. Setting this bit activates power-down operation.	
IDL	PCON.0	Idle mode bit. Setting this bit activates idle mode operation.	

If 1s are written to PD and IDL at the same time, PD takes precedence. The reset value of PCON is (0XXX0000). In the NMOS devices, the PCON register only contains SMOD. The other four bits are implemented only in the CMOS devices. User software should never write 1s to unimplemented bits, since they may be used in future products.

Figure 24. Power Control (PCON) Register

The signal at the RST pin clears the IDL bit directly and asynchronously. At this time the CPU resumes program execution from where it left off; that is, at the instruction following the one that invoked the Idle Mode. As shown in Figure 21, two or three machine cycles of program execution may take place before the internal reset algorithm takes control. On-chip hardware inhibits access to the internal RAM during this time, but access to the port pins is not inhibited, so, the insertion of 3 NOP instructions is recommended following the instruction that invokes idle mode. To eliminate the possibility of unexpected outputs at the port pins, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external Data RAM.

Power-Down Mode

An instruction that sets PCON.1 causes that to be the last instruction executed before

going into the Power Down mode. In the Power Down mode, the on-chip oscillator is stopped. With the clock frozen, all functions are stopped, the contents of the on-chip RAM and Special Function Registers are maintained. The port pins output the values held by their respective SFRs. The ALE and PSEN output are held low.

The only exit from Power Down is a hardware reset. Reset redefines all the SFRs, but does not change the on-chip RAM.

In the Power Down mode of operation, VCC can be reduced to as low as 2V. Care must be taken, however, to ensure that VCC is not reduced before the Power Down mode is invoked, and that VCC is restored to its normal operating level, before the Power Down mode is terminated. The reset that terminates Power Down also frees the oscillator. The reset should not be activated before VCC is restored to its normal operating

level, and must be held active long enough to allow the oscillator to restart and stabilize (normally less than 10ms).

ONCE Mode

The ONCE ("on-circuit emulation") mode facilitates testing and debugging of systems using the device without the device having to be removed from the circuit. The ONCE mode is invoked by:

1. Pull ALE low while the device is in reset and PSEN is high;
2. Hold ALE low as RST is deactivated.

While the device is in the ONCE mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the device is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored after a normal reset is applied.

80C51 Family

80C51 family hardware description

The On-Chip Oscillators

NMOS Version

The on-chip oscillator circuitry for the NMOS members of the 80C51 family is a single stage linear inverter (Figure 25), intended for use as a crystal-controlled, positive reactance oscillator (Figure 26). In this application the crystal is operated in its fundamental response mode as an inductive reactance in parallel resonance with capacitance external to the crystal.

The crystal specifications and capacitance values (C1 and C2 in Figure 26) are not critical. 30pF can be used in these positions at any frequency with good quality crystals. A ceramic resonator can be used in place of the crystal in cost-sensitive applications. When a ceramic resonator is used, C1 and C2 are normally selected to be of somewhat higher values, typically, 47pF. The manufacturer of the ceramic resonator should be consulted for recommendation on the values of these capacitors.

To drive the NMOS parts with an external clock source, apply the external clock signal to XTAL2, and ground XTAL1, as shown in Figure 27. A pullup resistor may be used (to increase noise margin), but is optional if V_{OH} of the driving gate exceeds the V_{IH} minimum specification of XTAL.

CMOS Versions

The on-chip oscillator circuitry for the 80C51, shown in Figure 28, consists of a single stage linear inverter intended for use as a crystal-controlled, positive reactance oscillator in the same manner as the NMOS parts. However, there are some important differences.

One difference is that the 80C51 is able to turn off its oscillator under software control (by writing a 1 to the PD bit in PCON). Another difference is that, in the 80C51, the internal clocking circuitry is driven by the signal at XTAL1, whereas in the NMOS versions it is by the signal at XTAL2.

The feedback resistor R_f in Figure 28 consists of paralleled n- and p-channel FETs

controlled by the PD bit, such that R_f is opened when PD = 1. The diodes D1 and D2, which act as clamps to V_{CC} and V_{SS} , are parasitic to the R_f FETs. The oscillator can be used with the same external components as the NMOS versions, as shown in Figure 29. Typically, $C1 = C2 = 30pF$ when the feedback element is a quartz crystal, and $C1 = C2 = 47pF$ when a ceramic resonator is used.

When a crystal is used at frequencies above 25MHz, C1 and C2 should be in the range of 20pF to 25pF.

To drive the CMOS parts with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 float, as shown in Figure 30.

The reason for this change from the way the NMOS part is driven can be seen by comparing Figures 26 and 28. In the NMOS devices the internal timing circuits are driven by the signal at XTAL2. In the CMOS devices the internal timing circuits are driven by the signal at XTAL1.

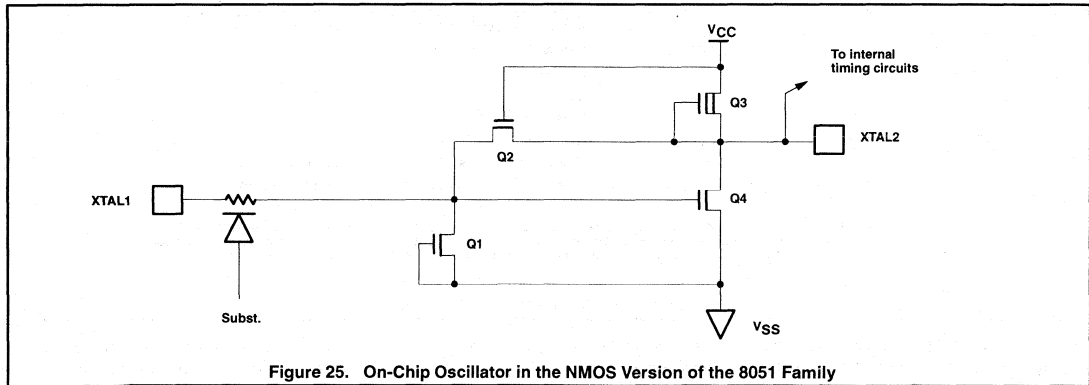

Figure 25. On-Chip Oscillator in the NMOS Version of the 8051 Family

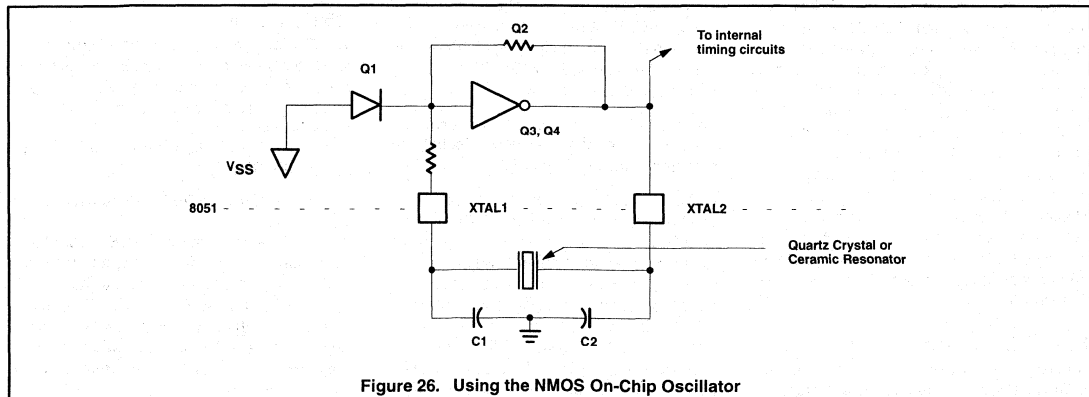

Figure 26. Using the NMOS On-Chip Oscillator

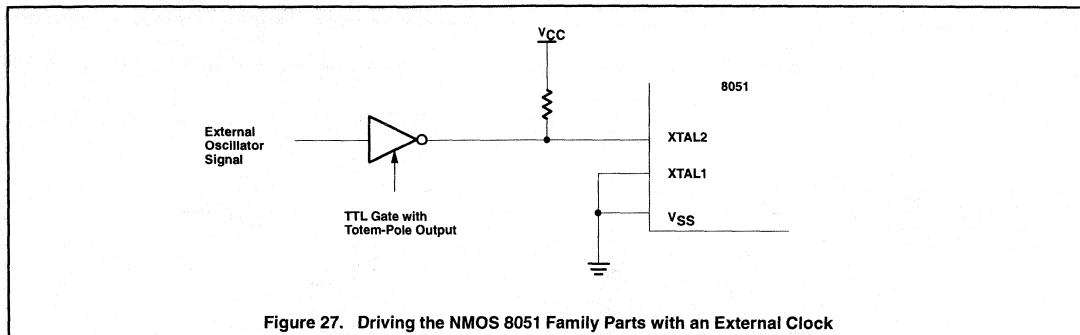

Figure 27. Driving the NMOS 8051 Family Parts with an External Clock

Internal Timing

Figures 31 through 34 show when the various strobe and port signals are clocked internally. The figures do not show rise and fall times of the signals, nor do they show propagation delays between the XTAL2 signal and events at other pins.

Rise and fall times are dependent on the external loading that each pin must drive. They are often taken to be something in the neighborhood of 10ns, measured between 0.8V and 2.0V.

Propagation delays are different for different pins. For a given pin they vary with pin loading, temperature, VCC, and manufacturing lot. If the XTAL2 waveform is taken as the timing reference, prop delays may vary up to ±200%.

The AC Timings section of the data sheets do not reference any timing to the XTAL2 waveform. Rather, they relate the critical edges of control and input signals to each other. The timings published in the data sheets include the effects of propagation delays under the specified test conditions.

80C51 Pin Descriptions

ALE/PROG: Address Latch Enable output pulse for latching the low byte of the address during accesses to external memory. ALE is emitted at a constant rate of 1/6 of the oscillator frequency, for external timing or clocking purposes, even when there are no accesses to external memory. (However, one ALE pulse is skipped during each access to

external Data Memory.) This pin is also the program pulse input (PROG) during EPROM programming.

PSEN: Program Store Enable is the read strobe to external Program Memory. When the device is executing out of external Program Memory, PSEN is activated twice each machine cycle (except that two PSEN activations are skipped during accesses to external Data Memory). PSEN is not activated when the device is executing out of internal Program Memory.

EAVPP: When EA is held high the CPU executes out of internal Program Memory (unless the Program Counter exceeds 0FFFH in the 80C51). Holding EA low forces the CPU to execute out of external memory regardless of the Program Counter value. In the 80C31, EA must be externally wired low. In the EPROM devices, this pin also receives the programming supply voltage (VPP) during EPROM programming.

XTAL1: Input to the inverting oscillator amplifier.

XTAL2: Output from the inverting oscillator amplifier.

Port 0: Port 0 is an 8-bit open drain bidirectional port. As an open drain output port, it can sink eight LS TTL loads. Port 0 pins that have 1s written to them float, and in that state will function as high impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external memory. In this

application it uses strong internal pullups when emitting 1s. Port 0 emits code bytes during program verification. In this application, external pullups are required.

Port 1: Port 1 is an 8-bit bidirectional I/O port with internal pullups. Port 1 pins that have 1s written to them are pulled high by the internal pullups, and in that state can be used as inputs. As inputs, port 1 pins that are externally being pulled low will source current because of the internal pullups.

Port 2: Port 2 is an 8-bit bidirectional I/O port with internal pullups. Port 2 emits the high-order address byte during accesses to external memory that use 16-bit addresses. In this application, it uses the strong internal pullups when emitting 1s.

Port 3: Port 3 is an 8-bit bidirectional I/O port with internal pullups. It also serves the functions of various special features of the 80C51 Family as follows:

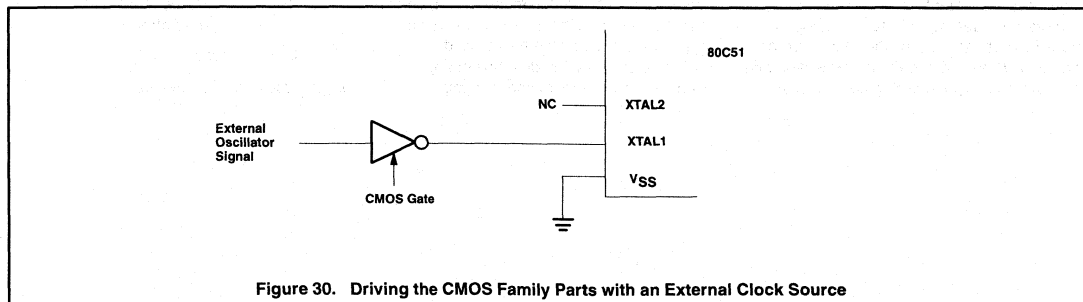

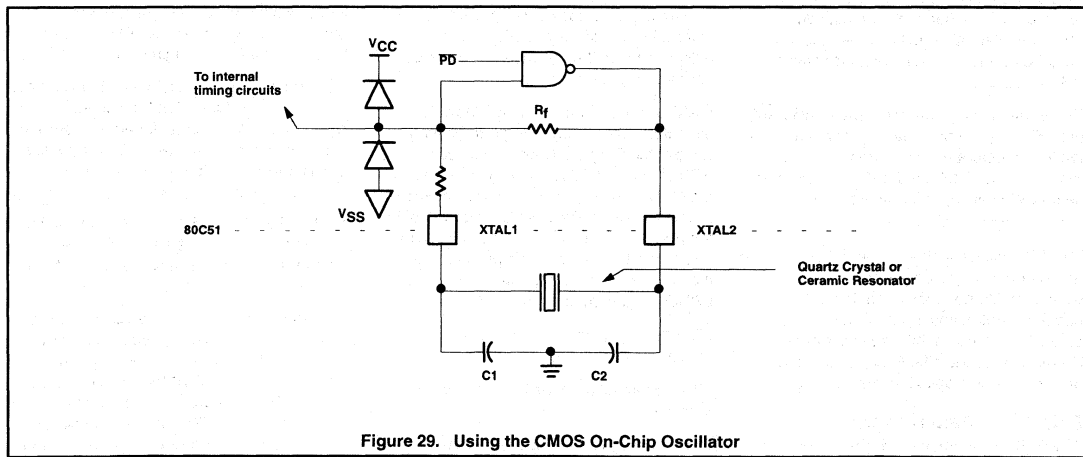

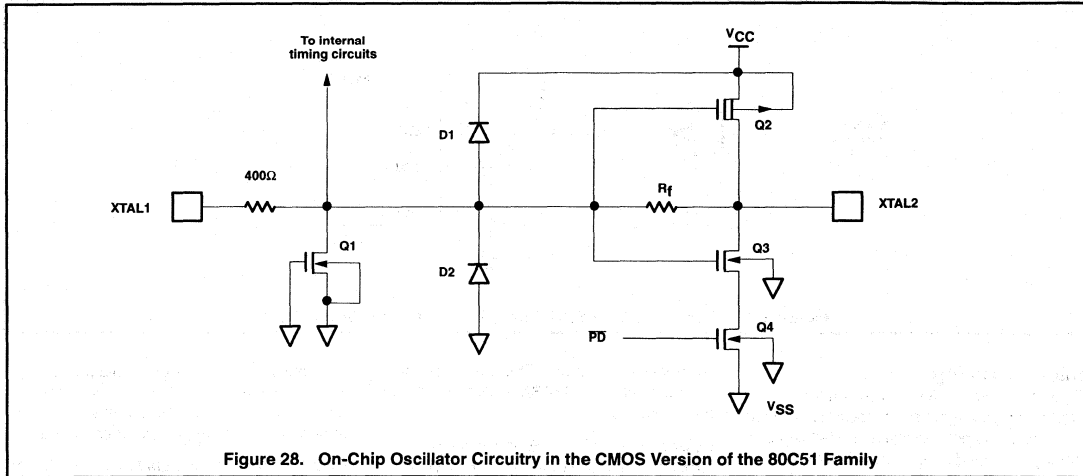

Port Pin	Alternate Function
P3.0	RxD (serial input port)
P3.1	TxD (serial output port)
P3.2	INT0 (external interrupt 0)
P3.3	INT1 (external interrupt 1)
P3.4	T0 (timer 0 external input)
P3.5	T1 (timer 1 external input)
P3.6	WR (external data memory write strobe)
P3.7	RD (external data memory read strobe)

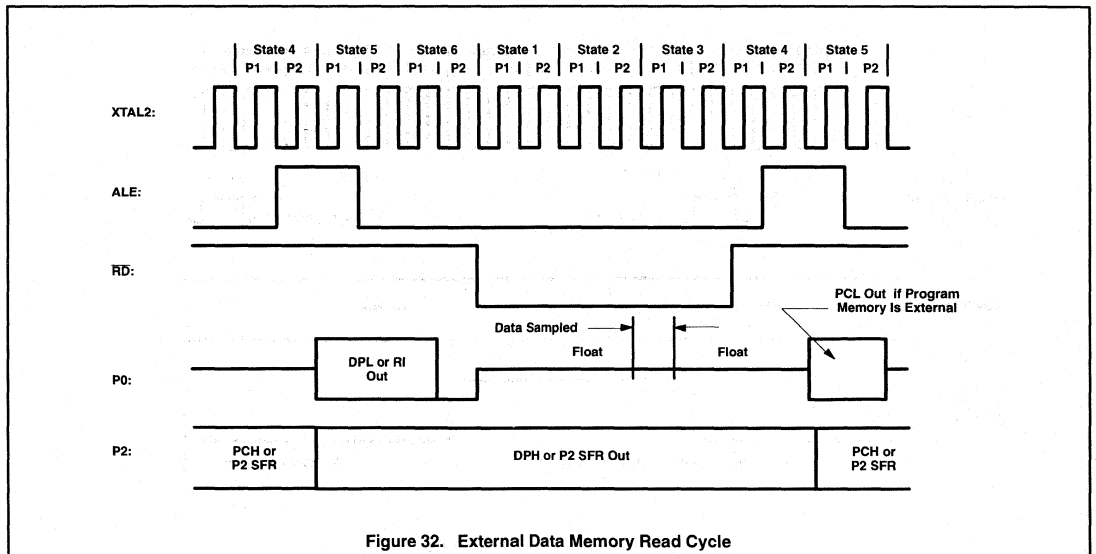

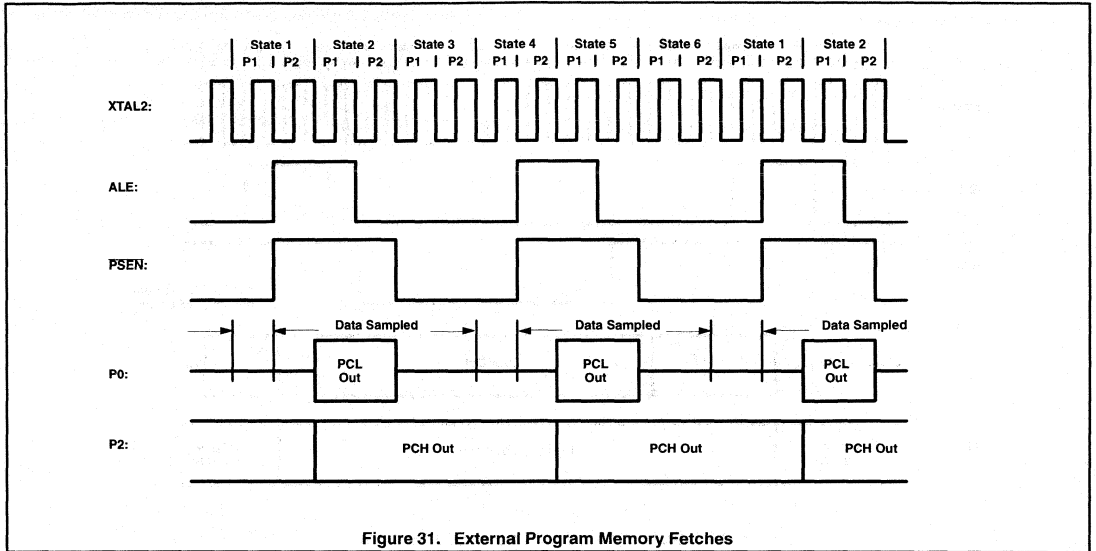

VCC: Supply voltage

VSS: Circuit ground potential

PROGRAMMER'S GUIDE AND INSTRUCTION SET

Memory Organization

Program Memory

The 80C51 has separate address spaces for program and data memory. The Program memory can be up to 64k bytes long. The lower 4k can reside on-chip. Figure 1 shows a map of the 80C51 program memory.

The 80C51 can address up to 64k bytes of data memory to the chip. The MOVX instruction is used to access the external data memory.

The 80C51 has 128 bytes of on-chip RAM, plus a number of Special Function Registers (SFRs). The lower 128 bytes of RAM can be accessed either by direct addressing (MOV data addr) or by indirect addressing (MOV @Ri). Figure 2 shows the Data Memory organization.

Direct and Indirect Address Area

The 128 bytes of RAM which can be accessed by both direct and indirect addressing can be divided into three segments as listed below and shown in Figure 3.

1. Register Banks 0-3: Locations 0 through 1FH (32 bytes). The device after reset defaults to register bank 0. To use the other register banks, the user must select them in software. Each register bank contains eight 1-byte registers 0 through 7. Reset initializes the stack pointer to location 07H, and it is incremented once to start from location 08H, which is the first register (R0) of the second register bank. Thus, in order to use more than one register bank, the SP should be initialized to a different location of the RAM where it is not used for data storage (i.e., the higher part of the RAM).
2. Bit Addressable Area: 16 bytes have been assigned for this segment, 20H-2FH.

Each one of the 128 bits of this segment can be directly addressed (0-7FH). The bits can be referred to in two ways, both of which are acceptable by most assemblers. One way is to refer to their address (i.e., 0-7FH). The other way is with reference to bytes 20H to 2FH. Thus, bits 0-7 can also be referred to as bits 20.0-20.7, and bits 8-FH are the same as 21.0-21.7, and so on. Each of the 16 bytes in this segment can also be addressed as a byte.

3. Scratch Pad Area: 30H through 7FH are available to the user as data RAM. However, if the stack pointer has been initialized to this area, enough bytes should be left aside to prevent SP data destruction.

Figure 2 shows the different segments of the on-chip RAM.

NOTES:

* Bit addressable

1. Bits GF1, GF0, PD, and IDL of the PCON register are not implemented on the NMOS 8051/8031.

Those SFRs that have their bits assigned for various functions are listed in this section. A brief description of each bit is provided for quick reference. For more detailed information refer to the Architecture Chapter of this book.

PSW: PROGRAM STATUS WORD. BIT ADDRESSABLE.

CY	AC	F0	RS1	RS0	OV	–	P
----	----	----	-----	-----	----	---	---

CY	PSW.7	Carry Flag.
AC	PSW.6	Auxiliary Carry Flag.
F0	PSW.5	Flag 0 available to the user for general purpose.
RS1	PSW.4	Register Bank selector bit 1 (SEE NOTE 1).
RS0	PSW.3	Register Bank selector bit 0 (SEE NOTE 1).
OV	PSW.2	Overflow Flag.
–	PSW.1	Usable as a general purpose flag.
P	PSW.0	Parity flag. Set/cleared by hardware each instruction cycle to indicate an odd/even number of '1' bus in the accumulator.

NOTE:

1. The value presented by RS0 and RS1 selects the corresponding register bank.

RS1	RS0	REGISTER BANK	ADDRESS
0	0	0	00H-07H
0	1	1	08H-0FH
1	0	2	10H-17H
1	1	3	18H-1FH

PCON: POWER CONTROL REGISTER. NOT BIT ADDRESSABLE.

SMOD	–	–	–	GF1	GF0	PD	IDL
------	---	---	---	-----	-----	----	-----

SMOD Double baud rate bit. If Timer 1 is used to generate baud rate and SMOD = 1, the baud rate is doubled when the Serial Port is used in modes 1, 2, or 3.

- Not implemented, reserved for future use.*
- Not implemented reserved for future use.*
- Not implemented reserved for future use.*

GF1 General purpose flag bit.

GF0 General purpose flag bit.

PD Power Down Bit. Setting this bit activates Power Down operation in the 80C51. (Available only in CMOS.)

IDL Idle mode bit. Setting this bit activates Idle Mode operation in the 80C51. (Available only in CMOS.)

If 1s are written to PD and IDL at the same time, PD takes precedence.

* User software should not write 1s to reserved bits. These bits may be used in future 8051 products to invoke new features.

INTERRUPTS:

To use any of the interrupts in the 80C51 Family, the following three steps must be taken.

1. Set the EA (enable all) bit in the IE register to 1.
2. Set the corresponding individual interrupt enable bit in the IE register to 1.
3. Begin the interrupt service routine at the corresponding Vector Address of that interrupt. See Table below.

INTERRUPT SOURCE	VECTOR ADDRESS
IE0	0003H
TF0	000BH
IE1	0013H
TF1	001BH
RI & TI	0023H

In addition, for external interrupts, pins INT0 and INT1 (P3.2 and P3.3) must be set to 1, and depending on whether the interrupt is to be level or transition activated, bits IT0 or IT1 in the TCON register may need to be set to 1.

ITx = 0 level activated

ITx = 1 transition activated

IE: INTERRUPT ENABLE REGISTER. BIT ADDRESSABLE.

If the bit is 0, the corresponding interrupt is disabled. If the bit is 1, the corresponding interrupt is enabled.

EA	—	—	ES	ET1	EX1	ET0	EX0
----	---	---	----	-----	-----	-----	-----

EA	IE.7	Disables all interrupts. If EA = 0, no interrupt will be acknowledged. If EA = 1, each interrupt source is individually enabled or disabled by setting or clearing its enable bit.
—	IE.6	Not implemented, reserved for future use.*
—	IE.5	Not implemented, reserved for future use.*
ES	IE.4	Enable or disable the serial port interrupt.
ET1	IE.3	Enable or disable the Timer 1 overflow interrupt.
EX1	IE.2	Enable or disable External Interrupt 1.
ET0	IE.1	Enable or disable the Timer 0 overflow interrupt.
EX0	IE.0	Enable or disable External Interrupt 0.

* User software should not write 1s to reserved bits. These bits may be used in future 80C51 products to invoke new features.

ASSIGNING HIGHER PRIORITY TO ONE OR MORE INTERRUPTS:

In order to assign higher priority to an interrupt the corresponding bit in the IP register must be set to 1.

Remember that while an interrupt service is in progress, it cannot be interrupted by a lower or same level interrupt.

PRIORITY WITHIN LEVEL:

Priority within level is only to resolve simultaneous requests of the same priority level.

From high to low, interrupt sources are listed below:

IE0
TF0
IE1
TF1
RI or TI

IP: INTERRUPT PRIORITY REGISTER. BIT ADDRESSABLE.

If the bit is 0, the corresponding interrupt has a lower priority and if the bit is 1 the corresponding interrupt has a higher priority.

–	–	–	PS	PT1	PX1	PT0	PX0
---	---	---	----	-----	-----	-----	-----

–	IP.7	Not implemented, reserved for future use.*
–	IP.6	Not implemented, reserved for future use.*
–	IP.5	Not implemented, reserved for future use.*
PS	IP.4	Defines the Serial Port interrupt priority level.
PT1	IP.3	Defines the Timer 1 interrupt priority level.
PX1	IP.2	Defines External Interrupt 1 priority level.
PT0	IP.1	Defines the Timer 0 interrupt priority level.
PX0	IP.0	Defines the External Interrupt 0 priority level.

* User software should not write 1s to reserved bits. These bits may be used in future 80C51 products to invoke new features.

TCON: TIMER/COUNTER CONTROL REGISTER. BIT ADDRESSABLE.

TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0
-----	-----	-----	-----	-----	-----	-----	-----

TF1	TCON.7	Timer 1 overflow flag. Set by hardware when the Timer/Counter 1 overflows. Cleared by hardware as processor vectors to the interrupt service routine.
TR1	TCON.6	Timer 1 run control bit. Set/cleared by software to turn Timer/Counter 1 ON/OFF.
TF0	TCON.5	Timer 0 overflow flag. Set by hardware when the Timer/Counter 0 overflows. Cleared by hardware as processor vectors to the service routine.
TR0	TCON.4	Timer 0 run control bit. Set/cleared by software to turn Timer/Counter 0 ON/OFF.
IE1	TCON.3	External Interrupt 1 edge flag. Set by hardware when External Interrupt edge is detected. Cleared by hardware when interrupt is processed.
IT1	TCON.2	Interrupt 1 type control bit. Set/cleared by software to specify falling edge/low level triggered External Interrupt.
IE0	TCON.1	External Interrupt 0 edge flag. Set by hardware when External Interrupt edge detected. Cleared by hardware when interrupt is processed.
IT0	TCON.0	Interrupt 0 type control bit. Set/cleared by software to specify falling edge/low level triggered External Interrupt.

TMOD: TIMER/COUNTER MODE CONTROL REGISTER. NOT BIT ADDRESSABLE.

GATE	C/T	M1	M0	GATE	C/T	M1	M0
Timer 1				Timer 0			

GATE	When TR _x (in TCON) is set and GATE = 1, TIMER/COUNTER _x will run only while INT _x pin is high (hardware control). When GATE = 0, TIMER/COUNTER _x will run only while TR _x = 1 (software control).
C/T	Timer or Counter selector. Cleared for Timer operation (input from internal system clock). Set for Counter operation (input from Tx input pin).
M1	Mode selector bit. (NOTE 1)
M0	Mode selector bit. (NOTE 1)

NOTE 1:

M1	M0	Operating Mode
0	0	0 13-bit Timer (8048 compatible)
0	1	1 16-bit Timer/Counter
1	0	2 8-bit Auto-Reload Timer/Counter
1	1	3 (Timer 0) TL0 is an 8-bit Timer/Counter controlled by the standart Timer 0 control bits. TH0 is an 8-bit Timer and is controlled by Timer 1 control bits.
1	1	3 (Timer 1) Timer/Counter 1 stopped.

TIMER SET-UP

Tables 2 through 5 give some values for TMOD which can be used to set up Timer 0 in different modes.

It is assumed that only one timer is being used at a time. If it is desired to run Timers 0 and 1 simultaneously, in any mode, the value in TMOD for Timer 0 must be ORed with the value shown for Timer 1 (Tables 5 and 6).

For example, if it is desired to run Timer 0 in mode 1 GATE (external control), and Timer 1 in mode 2 COUNTER, then the value that must be loaded into TMOD is 69H (09H from Table 3 ORed with 60H from Table 6).

Moreover, it is assumed that the user, at this point, is not ready to turn the timers on and will do that at a different point in the program by setting bit TRx (in TCON) to 1.

TIMER/COUNTER 0**Table 2. As a Timer:**

MODE	TIMER 0 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	00H	08H
1	16-bit Timer	01H	09H
2	8-bit Auto-Reload	02H	0AH
3	Two 8-bit Timers	03H	0BH

Table 3. As a Counter:

MODE	COUNTER 0 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	04H	0CH
1	16-bit Timer	05H	0DH
2	8-bit Auto-Reload	06H	0EH
3	One 8-bit Counter	07H	0FH

NOTES:

1. The timer is turned ON/OFF by setting/clearing bit TR0 in the software.
2. The Timer is turned ON/OFF by the 1-to-0 transition on $\overline{\text{INT0}}$ (P3.2) when TR0 = 1 (hardware control).

TIMER/COUNTER 1**Table 4. As a Timer:**

MODE	TIMER 1 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	00H	80H
1	16-bit Timer	10H	90H
2	8-bit Auto-Reload	20H	A0H
3	Does not run	30H	B0H

Table 5. As a Counter:

MODE	COUNTER 1 FUNCTION	TMOD	
		INTERNAL CONTROL (NOTE 1)	EXTERNAL CONTROL (NOTE 2)
0	13-bit Timer	40H	C0H
1	16-bit Timer	50H	D0H
2	8-bit Auto-Reload	60H	E0H
3	Not available	—	—

NOTES:

1. The timer is turned ON/OFF by setting/clearing bit TR1 in the software.
2. The Timer is turned ON/OFF by the 1-to-0 transition on INT1 (P3.2) when TR1 = 1 (hardware control).

SCON: SERIAL PORT CONTROL REGISTER. BIT ADDRESSABLE.

SM0	SM1	SM2	REN	TB8	RB8	TI	RI
-----	-----	-----	-----	-----	-----	----	----

SM0	SCON.7	Serial Port mode specifier. (NOTE 1)
SM1	SCON.6	Serial Port mode specifier. (NOTE 1)
SM2	SCON.5	Enables the multiprocessor communication feature in modes 2 & 3. In mode 2 or 3, if SM2 is set to 1 then RI will not be activated if the received 9th data bit (RB8) is 0. In mode 1, if SM2 = 1 then RI will not be activated if a valid stop bit was not received. In mode 0, SM2 should be 0. (See Table 6.)
REN	SCON.4	Set/Cleared by software to Enable/Disable reception.
TB8	SCON.3	The 9th bit that will be transmitted in modes 2 & 3. Set/Cleared by software.
RB8	SCON.2	In modes 2 & 3, is the 9th data bit that was received. In mode 1, if SM2 = 0, RB8 is the stop bit that was received. In mode 0, RB8 is not used.
TI	SCON.1	Transmit interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or at the beginning of the stop bit in the other modes. Must be cleared by software.
RI	SCON.0	Receive interrupt flag. Set by hardware at the end of the 8th bit time in mode 0, or halfway through the stop bit time in the other modes (except see SM2). Must be cleared by software.

NOTE 1:

SM0	SM1	Mode	Description	Baud Rate
0	0	0	Shift Register	F _{osc} /12
0	1	1	8-bit UART	Variable
1	0	2	9-bit UART	F _{osc} /64 or F _{osc} /32
1	1	3	9-bit UART	Variable

SERIAL PORT SET-UP:

Table 6.

MODE	SCON	SM2 VARIATION
0 1 2 3	10H 50H 90H D0H	Single Processor Environment (SM2 = 0)
0 1 2 3	NA 70H B0H F0H	Multiprocessor Environment (SM2 = 1)

GENERATING BAUD RATES**Serial Port in Mode 0:**

Mode 0 has a fixed baud rate which is 1/12 of the oscillator frequency. To run the serial port in this mode none of the Timer/Counters need to be set up. Only the SCON register needs to be defined.

$$\text{Baud Rate} = \frac{\text{Osc Freq}}{12}$$

Serial Port in Mode 1:

Mode 1 has a variable baud rate. The baud rate is generated by Timer 1.

USING TIMER/COUNTER 1 TO GENERATE BAUD RATES:

For this purpose, Timer 1 is used in mode 2 (Auto-Reload). Refer to Timer Setup section of this chapter.

$$\text{Baud Rate} = \frac{K \times \text{Osc Freq}}{32 \times 12 \times [256 - (\text{TH1})]}$$

If SMOD = 0, then K = 1.

If SMOD = 1, then K = 2 (SMOD is in the PCON register).

Most of the time the user knows the baud rate and needs to know the reload value for TH1.

$$\text{TH1} = 256 - \frac{K \times \text{Osc Freq}}{384 \times \text{baud rate}}$$

TH1 must be an integer value. Rounding off TH1 to the nearest integer may not produce the desired baud rate. In this case, the user may have to choose another crystal frequency.

Since the PCON register is not bit addressable, one way to set the bit is logical ORing the PCON register (i.e., ORL PCON,#80H). The address of PCON is 87H.

SERIAL PORT IN MODE 2:

The baud rate is fixed in this mode and is 1/32 or 1/64 of the oscillator frequency, depending on the value of the SMOD bit in the PCON register.

In this mode none of the Timers are used and the clock comes from the internal phase 2 clock.

SMOD = 1, Baud Rate = 1/32 Osc Freq.

SMOD = 0, Baud Rate = 1/64 Osc Freq.

To set the SMOD bit: ORL PCON,#80H. The address of PCON is 87H.

SERIAL PORT IN MODE 3:

The baud rate in mode 3 is variable and sets up exactly the same as in mode 1.

80C51 FAMILY INSTRUCTION SET

Table 7. 80C51 Instruction Set Summary

Interrupt Response Time: Refer to Hardware Description Chapter.						
Instructions that Affect Flag Settings ⁽¹⁾						
Instruction	Flag			Instruction	Flag	
	C	OV	AC		C	OV AC
ADD	X	X	X	CLR C	0	
ADDC	X	X	X	CPL C	X	
SUBB	X	X	X	ANL C,bit	X	
MUL	0	X		ANL C,/bit	X

DA	X			ORL C,/bit	X	
RRC	X			MOV C,bit	X	
RLC	X			CJNE	X	
SETB C	1					

⁽¹⁾Note that operations on SFR byte address 208 or bit addresses 209-215 (i.e., the PSW or bits in the PSW) will also affect flag settings.

Notes on instruction set and addressing modes:

Rn Register R7-R0 of the currently selected Register Bank.

direct 8-bit internal data location's address. This could be an Internal Data RAM location (0-127) or a SFR [i.e., I/O port, control register, status register, etc. (128-255)].

@Ri 8-bit internal data RAM location (0-255) addressed indirectly through register R1 or R0.

#data 8-bit constant included in the instruction.

#data 16 16-bit constant included in the instruction

addr 16 16-bit destination address. Used by LCALL and LJMP. A branch can be anywhere within the 64k-byte Program Memory address space.

addr 11 11-bit destination address. Used by ACALL and AJMP. The branch will be within the same 2k-byte page of program memory as the first byte of the following instruction.

rel Signed (two's complement) 8-bit offset byte. Used by SJMP and all conditional jumps. Range is -128 to +127 bytes relative to first byte of the following instruction.

bit Direct Addressed bit in Internal Data RAM or Special Function Register.

INSTRUCTION DEFINITIONS

ACALL addr11**Function:** Absolute Call**Description:** ACALL unconditionally calls a subroutine located at the indicated address. The instruction increments the PC twice to obtain the address of the following instruction, then pushes the 16-bit result onto the stack (low-order byte first) and increments the Stack Pointer twice. The destination address is obtained by successively concatenating the five high-order bits of the incremented PC, opcode bits 7-5, and the second byte of the instruction. The subroutine called must therefore start within the same 2k block of the program memory as the first byte of the instruction following ACALL. No flags are affected.**Example:** Initially SP equals 07H. The label "SUBRTN" is at program memory location 0345 H. After executing the instruction,

ACALL SUBRTN

at location 0123H, SP will contain 09H, internal RAM locations 08H and 09H will contain 25H and 01H, respectively, and the PC will contain 0345H.

Bytes: 2**Cycles:** 2**Encoding:**

a10 a9 a8 1	0 0 0 1
-------------	---------

a7 a6 a5 a4	a3 a2 a1 a0
-------------	-------------

Operation:

ACALL
 $(PC) \leftarrow (PC) + 2$
 $(SP) \leftarrow (SP) + 1$
 $(SP) \leftarrow (PC_{7-0})$
 $(SP) \leftarrow (SP) + 1$
 $(SP) \leftarrow (PC_{15-8})$
 $(PC_{10-0}) \leftarrow \text{page address}$

ADD A,<src-byte>

Function: Add

Description: ADD adds the byte variable indicated to the Accumulator, leaving the result in the Accumulator. The carry and auxiliary-carry flags are set, respectively, if there is a carry-out from bit 7 or bit 3, and cleared otherwise. When adding unsigned integers, the carry flag indicates an overflow occurred.

OV is set if there is a carry-out of bit 6 but not out of bit 7, or a carry-out of bit 7 but not bit 6; otherwise OV is cleared. When adding signed integers, OV indicates a negative number produced as the sum of two positive operands, or a positive sum from two negative operands.

Four source operand addressing modes are allowed: register, direct, register-indirect, or immediate.

Example: The Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B). The instruction, ADD A,R0 will leave 6DH (01101101B) in the Accumulator with the AC flag cleared and both the Carry flag and OV set to 1.

ADD A,Rn

Bytes: 1

---------	---------	----------------

Operation: ADD
 $(A) \leftarrow (A) + \#data$

ADDC A,<src-byte>**Function:** Add with Carry**Description:** ADDC simultaneously adds the byte variable indicated, the carry flag and the Accumulator contents, leaving the result in the Accumulator. The carry and auxiliary-carry flags are set, respectively, if there is a carry-out from bit 7 or bit 3, and cleared otherwise. When adding unsigned integers, the carry flag indicates an overflow occurred.

OV is set if there is a carry-out of bit 6 but not out of bit 7, or a carry-out of bit 7 but not out of bit 6; otherwise OV is cleared. When adding signed integers, OV indicates a negative number produced as the sum of two positive operands, or a positive sum from two negative operands.

Four source operand addressing modes are allowed: register, direct, register-indirect, or immediate.

Example: The Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B) with the carry flag set. The instruction,

ADDC A,R0

will leave 6EH (01101110B) in the Accumulator with AC cleared and both the Carry flag and OV set to 1.

ADDC A,Rn**Bytes:** 1**Cycles:** 1**Encoding:**

AJMP addr11**Function:** Absolute Jump**Description:** AJMP transfers program execution to the indicated address, which is formed at run-time by concatenating the high-order five bits of the PC (*after* incrementing the PC twice), opcode bits 7-5, and the second byte of the instruction. The destination must therefore be within the same 2k block of program memory as the first byte of the instruction following AJMP.**Example:** The label "JMPADR" is at program memory location 0123H. The instruction,
AJMP JMPADR
is at location 0345H and will load the PC with 0123H.**Bytes:** 2**Cycles:** 2**Encoding:****Operation:**

AJMP
 $(PC) \leftarrow (PC) + 2$
 $(PC_{10-0}) \leftarrow \text{page address}$

ANL <dest-byte>,<src-byte>**Function:** Logical-AND for byte variables**Description:** ANL performs the bitwise logical-AND operation between the variables indicated and stores the results in the destination variable. No flags are affected.

The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.

Note: When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.

Example: If the Accumulator holds 0C3H (11000011B) and register 0 holds 55H (01010101B) then the instruction,
ANL A,R0
will leave 41H (01000001B) in the Accumulator.

When the destination is a directly addressed byte, this instruction will clear combinations of bits in any RAM location or hardware register. The mask byte determining the pattern of bits to be cleared would either be a constant contained in the instruction or a value computed in the Accumulator at run-time. The instruction,

ANL P1,#0111001B

will clear bits 7, 3, and 2 of output port 1.

---	---	---	---	---	---	---	---

direct address

immediate data

Operation: ANL $(\text{direct}) \leftarrow (\text{direct}) \wedge \#data$

ANL C,<src-bit>**Function:** Logical-AND for bit variables**Description:** If the Boolean value of the source bit is a logical 0 then clear the carry flag; otherwise leave the carry flag in its current state. A slash ("/") preceding the operand in the assembly language indicates that the logical complement of the addressed bit is used as the source value, *but the source bit itself is not affected*. No other flags are affected.

Only direct addressing is allowed for the source operand.

Example: Set the carry flag if, and only if, P1.0 = 1, ACC.7 = 1, and OV = 0:

MOV C,P1.0 ;LOAD CARRY WITH INPUT PIN STATE

ANL C,ACC.7;AND CARRY WITH ACCUM. BIT 7

ANL C,/OV ;AND WITH INVERSE OF OVERFLOW FLAG

ANL C,bit**Bytes:** 2**Cycles:** 2**Encoding:**

1 0 0 0	0 0 1 0	bit address
---------	---------	-------------

Operation: ANL

$$(C) \leftarrow (C) \wedge (\text{bit})$$

ANL C,/bit**Bytes:** 2**Cycles:** 2**Encoding:**

1 0 1 1	0 0 0 0	bit address
---------	---------	-------------

Operation: ANL

$$(C) \leftarrow (C) \wedge \neg(\text{bit})$$

CJNE <dest-byte>,<src-byte>,rel**Function:** Compare and Jump if Not Equal**Description:** CJNE compares the magnitudes of the first two operands, and branches if their values are not equal. The branch destination is computed by adding the signed relative-displacement in the last instruction byte to the PC, after incrementing the PC to the start of the next instruction. The carry flag is set if the unsigned integer value of <dest-byte> is less than the unsigned integer value of <src-byte>; otherwise, the carry is cleared. Neither operand is affected.

The first two operands allow four addressing mode combinations: the Accumulator may be compared with any directly addressed byte or immediate data, and any indirect RAM location or working register can be compared with an immediate constant.

Example: The Accumulator contains 34H. Register 7 contains 56H. The first instruction in the sequence,

```

      CJNE    R7,#60H,NOT_EQ
;          ...          ;          R7 = 60H.
NOT_EQ  JC    REQ_LOW  ;          IF R7 < 60H.
;          ...          ;          R7 > 60H.

```

sets the carry flag and branches to the instruction at label NOT_EQ. By testing the carry flag, this instruction determines whether R7 is greater or less than 60H.

If the data being presented to Port 1 is also 34H, then the instruction,

```
WAIT: CJNE  A,P1,WAIT
```

clears the carry flag and continues with the next instruction in sequence, since the Accumulator does equal the data read from P1. (If some other value was being input on P1, the program will loop at this point until the P1 data changes to 34H.)

CJNE A,direct,rel**Bytes:** 3**Cycles:** 2**Encoding:****Operation:**

```

bit address

Operation: CLR
(bit) ← 0

CPL A

Function: Complement Accumulator

Description: Each bit of the Accumulator is logically complemented (one's complement). Bits which previously contained a one are changed to a zero and vice-versa. No flags are affected.

Example: The Accumulator contains 5CH (01011100B). The instruction,
CPL A
will leave the Accumulator set to 0A3H (10100011B).

Bytes: 1

Cycles: 1

Encoding:

1	1	1	1	0	1	0	0
---	---	---	---	---	---	---	---

Operation: CPL
(A) ← $\bar{1}$ (A)

CPL bit

Function: Complement bit

Description: The bit variable specified is complemented. A bit which had been a one is changed to zero and vice-versa. No other flags are affected. CLR can operate on the carry or any directly addressable bit.

Note: When this instruction is used to modify an output pin, the value used as the original data will be read from the output data latch, *not* the input pin.

Example: Port 1 has previously been written with 5DH (01011101B). The instruction sequence,
CPL P1.1
CPL P1.2
will leave the port set to 5BH (01011011B).

CPL C

Bytes: 1

1	0	1	1	0	0	1	0
---	---	---	---	---	---	---	---

bit address

Operation: CPL
(bit) ← $\bar{1}$ (bit)

DA A**Function:** Decimal-adjust Accumulator for Addition**Description:** DA A adjusts the eight-bit value in the Accumulator resulting from the earlier addition of two variable (each in packed-BCD format), producing two four-bit digits. Any ADD or ADDC instruction may have been used to perform the addition.

If Accumulator bits 3-0 are greater than nine (xxx1010-xxx1111), or if the AC flag is one, six is added to the Accumulator, producing the proper BCD digit in the low-order nibble. This internal addition would set the carry flag if a carry-out of the low-order four-bit field propagated through all high-order bits, but it would not clear the carry flag otherwise.

If the carry flag is now set, or if the four high-order bits now exceed nine (1010xxx-111xxxx), these high-order bits are incremented by six, producing the proper BCD digit in the high-order nibble. Again, this would set the carry flag if there was a carry-out of the high-order bits, but wouldn't clear the carry. The carry flag thus indicates if the sum of the original two BCD variables is greater than 100, allowing multiple precision decimal addition. OV is not affected.

All of this occurs during the one instruction cycle. Essentially, this instruction performs the decimal conversion by adding 00H, 06H, 60H, or 66H to the Accumulator, depending on initial Accumulator and PSW conditions.

Note: DA A *cannot* simply convert a hexadecimal number in the Accumulator to BCD notation, nor does DA A apply to decimal subtraction.

Example: The Accumulator holds the value 56H (01010110B) representing the packed BCD digits of the decimal number 56. Register 3 contains the value 67H (01100111B) representing the packed BCD digits of the decimal number 67. The carry flag is set. The instruction sequence,

```
ADDC  A,R3
DA    A
```

will first perform a standard two's-complement binary addition, resulting in the value 0BEH (10111110B) in the Accumulator. The carry and auxiliary carry flags will be cleared.

The Decimal Adjust instruction will then alter the Accumulator to the value 24H (00100100B), indicating the packed BCD digits of the decimal number 24, the low-order two digits of the decimal sum of 56, 67, and the carry-in. The carry flag will be set by the Decimal Adjust instruction, indicating that a decimal overflow occurred. The true sum 56, 67, and 1 is 124.

BCD variables can be incremented or decremented by adding 01H or 99H. If the Accumulator initially holds 30H (representing the digits of 30 decimal), the the instruction sequence,

```
ADD  A,#99H
DA   A
```

will leave the carry set and 29H in the Accumulator, since $30 + 99 = 129$. The low-order byte of the sum can be interpreted to mean $30 - 1 = 29$.

Bytes: 1**Cycles:** 1**Encoding:**

1	1	0	1	0	1	0	0
---	---	---	---	---	---	---	---

Operation:

```
DA
--contents of Accumulator are BCD
IF  [[(A3-0) > 9] ∨ [(AC) = 1]]
    THEN(A3-0) ← (A3-0) + 6
    AND
IF  [[(A7-4) > 9] ∨ [(C) = 1]]
    THEN(A7-4) ← (A7-4) + 6
```

DEC byte

Function: Decrement

Description: The variable indicated is decremented by 1. An original value of 00H will underflow to 0FFH. No flags are affected. Four operand addressing modes are allowed: accumulator, register, direct, or register-indirect.

Note: When this instruction is used to modify an output port, the value used as the original data will be read from the output data latch, *not* the input pin.

Example: Register 0 contains 7FH (01111111B). Internal RAM locations 7EH and 7FH contain 00H and 40H, respectively. The instruction sequence,

```
DEC  @R0
DEC  R0
DEC  @R0
```

will leave register 0 set to 7EH and internal RAM locations 7EH and 7FH set to 0FFH and 3FH.

DEC A

Bytes: 1

Cycles: 1

Operation: DEC
 $((R_i)) \leftarrow ((R_i)) - 1$

DIV AB**Function:** Divide**Description:** DIV AB divides the unsigned eight-bit integer in the Accumulator by the unsigned eight-bit integer in register B.

The Accumulator receives the integer part of the quotient; register B receives the integer remainder. The carry and OV flags will be cleared.

Exception: if B had originally contained 00H, the values returned in the Accumulator and B-register will be undefined and the overflow flag will be set. The carry flag is cleared in any case.

Example: The Accumulator contains 251 (0FBH or 11111011B) and B contains 18 (12H or 00010010B). The instruction,

DIV AB

will leave 13 in the Accumulator (0DH or 00001101B) and the value 17 (11H or 00010001B) in B, since $251 = (13 \times 18) + 17$. Carry and OV will both be cleared.

Bytes: 1**Cycles:** 4**Encoding:**

1	0	0	0	0	1	0	0
---	---	---	---	---	---	---	---

Operation:

DIV

 $(A)_{15-8} \leftarrow (A)/(B)$ $(B)_{7-0}$

DJNZ <byte>,<rel-addr>**Function:** Decrement and Jump if Not Zero

Description: DJNZ decrements the location indicated by 1, and branches to the address indicated by the second operand if the resulting value is not zero. An original value of 00H will underflow to 0FFH. No flags are affected. The branch destination would be computed by adding the signed relative-displacement value in the last instruction byte to the PC, after incrementing the PC to the first byte of the following instruction. The location decremented may be a register or directly addressed byte.

Note: When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.

Example: Internal RAM locations 40H, 50H, and 60H contain the values 01H, 70H, and 15H, respectively. The instruction sequence,

```
DJNZ 40H,LABEL_1
DJNZ 50H,LABEL_2
DJNZ 60H,LABEL_3
```

will cause a jump to the instruction at LABEL_2 with the values 00h, 6FH, and 15H in the three RAM locations. The first jump was *not* taken because the result was zero.

This instruction provides a simple way of executing a program loop a given number of times, or for adding a moderate time delay (from 2 to 512 machine cycles) with a single instruction. The instruction sequence,

```
        MOV     R2,#8
TOGGLE: CPL     P1.7
        DJNZ   R2,TOGGLE
```

will toggle P1.7 eight times, causing four output pulses to appear at bit 7 of output Port 1. Each pulse will last three machine cycles, two for DJNZ and one to alter the pin.

DJNZ Rn,rel**Bytes:** 2**Cycles:** 2**Encoding:****Operation:**

```
DJNZ
(PC) ← (PC) + 2
(Rn) ← (Rn) - 1
IF (Rn) > 0 or (Rn) < 0
  THEN
    (PC) ← (PC) + rel
```

DJNZ direct,rel**Bytes:** 3**Cycles:** 2**Encoding:****Operation:**

```
DJNZ
(PC) ← (PC) + 2
(direct) ← (direct) - 1
IF (direct) > 0 or (direct) < 0
  THEN
    (PC) ← (PC) + rel
```

INC <byte>**Function:** Increment**Description:** INC increments the indicated variable by 1. An original value of 0FFH will overflow to 00H. No flags are affected. Three addressing modes are allowed: register, direct, or register-indirect.*Note:* When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.**Example:** Register 0 contains 7EH (01111110B). Internal RAM locations 7EH and 7FH contain 0FFH and 40H, respectively. The instruction sequence,

```

INC   @R0
INC   R0
INC   @R0

```

will leave register 0 set to 7FH and internal RAM locations 7EH and 7FH holding (respectively) 00H and 41H.

Operation: INC
 $((R_i)) \leftarrow ((R_i)) + 1$

INC DPTR**Function:** Increment Data Pointer**Description:** Increment the 16-bit data pointer by 1. A 16-bit increment (modulo 2^{16}) is performed; an overflow of the low-order byte of the data pointer (DPL) from 0FFH to 00H will increment the high-order byte (DPH). No flags are affected.

This is the only 16-bit register which can be incremented.

Example: Registers DPH and DPL contain 12H and 0FEH, respectively. The instruction sequence,

```

INC   DPTR
INC   DPTR
INC   DPTR

```

will change DPH and DPL to 13H and 01H.

Bytes: 1**Cycles:** 2**Encoding:**

1 0 1 0	0 0 1 1
---------	---------

Operation:

```

INC
(DPTR) ← (DPTR) + 1

```

JB bit,rel**Function:** Jump if Bit set**Description:** If the indicated bit is a one, jump to the address indicated; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the third instruction byte to the PC, after incrementing the PC to the first byte of the next instruction. *The bit tested is not modified.* No flags are affected.**Example:** The data present at input port 1 is 11001010B. The Accumulator holds 56 (01010110B). The instruction sequence,

```

JB   P1.2,LABEL1
JB   ACC.2,LABEL2

```

will cause program execution to branch to the instruction at label LABEL2.

Bytes: 3**Cycles:** 2**Encoding:**

0 0 1 0	0 0 0 0	bit address	rel. address
---------	---------	-------------	--------------

Operation:

```

JB
(PC) ← (PC) + 3
IF (bit) = 1
  THEN
    (PC) ← (PC) + rel

```

JBC bit,rel**Function:** Jump if Bit is set and Clear bit**Description:** If the indicated bit is a one, branch to the address indicated; otherwise proceed with the next instruction. *The bit will not be cleared if it is already a zero.* The branch destination is computed by adding the signed relative-displacement in the third instruction byte to the PC, after incrementing the PC to the first byte of the next instruction. No flags are affected.

Note: When this instruction is used to test an output pin, the value used as the original data will read from the output data latch, not the input pin.

Example: The Accumulator holds 56H (01010110B). The instruction sequence,

```
JBC ACC.3,LABEL1
JBC ACC.2,LABEL2
```

will cause program execution to continue at the instruction identified by the LABEL2, with the Accumulator modified to 52H (01010010B).

Bytes: 3**Cycles:** 2**Encoding:**

0	0	0	1	0	0	0	0	bit address	rel. address
---	---	---	---	---	---	---	---	-------------	--------------

Operation:

```
JBC
(PC) ← (PC) + 3
IF (bit) = 1
  THEN
    (bit) ← 0
    (PC) ← (PC) + rel
```

JC rel**Function:** Jump if Carry is set**Description:** If the carry flag is set, branch to the address indicated; otherwise proceed with the next instruction. The branch destination is computed by adding the signed relative-displacement in the second instruction byte to the PC, after incrementing the PC twice. No flags are affected.**Example:** The carry flag is cleared. The instruction sequence,

```
JC LABEL1
CPL C
JC LABEL2
```

will set the carry and cause program execution to continue at the instruction identified by the label LABEL2.

Bytes: 2**Cycles:** 2**Encoding:**

0	1	0	0	0	0	0	0	rel. address
---	---	---	---	---	---	---	---	--------------

Operation:

```
JC
(PC) ← (PC) + 2
IF (C) = 1
  THEN
    (PC) ← (PC) + rel
```

JMP @A+DPTR

Function: Jump indirect

Description: Add the eight-bit unsigned contents of the Accumulator with the sixteen-bit data pointer, and load the resulting sum to the program counter. This will be the address for subsequent instruction fetches. Sixteen-bit addition is performed (modulo 2^{16}): a carry-out from the low-order eight bits propagates through the higher-order bits. Neither the Accumulator nor the Data Pointer is altered. No flags are affected.

Example: An even number from 0 to 6 is in the Accumulator. The following sequence of instructions will branch to one of four AJMP instructions in a jump table starting at JMP_TBL:

```

MOV    DPTR,#JMP_TBL
JMP    @A+DPTR
JMP_TBL: AJMP LABEL0
        AJMP LABEL1
        AJMP LABEL2
        AJMP LABEL3
    
```

If the Accumulator equals 04H when starting this sequence, execution will jump to label LABEL2. Remember that AJMP is a two-byte instruction, so the jump instructions start at every other address.

Bytes: 1

Cycles: 2

---------	---------	--------------

Operation:

```
JZ
(PC) ← (PC) + 2
IF A = 0
  THEN (PC) ← (PC) + rel
```

LCALL addr16**Function:** Long Call**Description:** LCALL calls a subroutine located at the indicated address. The instruction adds three to the program counter to generate the address of the next instruction and then pushes the 16-bit result onto the stack (low byte first), incrementing the Stack Pointer by two. The high-order and low-order bytes of the PC are then loaded, respectively, with the second and third bytes of the LCALL instruction. Program execution continues with the instruction at this address. The subroutine may therefore begin anywhere in the full 64k-byte program memory address space. No flags are affected.**Example:** Initially the Stack Pointer equals 07H. The label "SUBRTN" is assigned to program memory location 1234H. After executing the instruction,

```
LCALL SUBRTN
```

at location 0123H, the Stack Pointer will contain 09H, internal RAM locations 08H and 09H will contain 26H and 01H, and the PC will contain 1235H.

Bytes: 3**Cycles:** 2**Encoding:**

0 0 0 1	0 0 1 0	addr15-addr8	addr7-addr0
---------	---------	--------------	-------------

Operation:

```
LCALL
(PC) ← (PC) + 3
(SP) ← (SP) + 1
((SP)) ← (PC7-0)
(SP) ← (SP) + 1
((SP)) ← (PC15-8)
(PC) ← addr15-0
```

LJMP addr16 (Implemented in 87C751 and 87C752 for in-circuit emulation only.)**Function:** Long Jump**Description:** LJMP causes an unconditional branch to the indicated address, by loading the high-order and low-order bytes of the PC (respectively) with the second and third instruction bytes. The destination may therefore be anywhere in the full 64k program memory address space. No flags are affected.**Example:** The label "JMPADR" is assigned to the instruction at program memory location 1234H. The instruction, LJMP JMPADR at location 0123H will load the program counter with 1234H.**Bytes:** 3**Cycles:** 2**Encoding:****Operation:**LJMP
(PC) ← addr₁₅₋₀**MOV <dest-byte>,<src-byte>****Function:** Move byte variable**Description:** The byte variable indicated by the second operand is copied into the location specified by the first operand. The source byte is not affected. No other register or flag is affected.

This is by far the most flexible operation. Fifteen combinations of source and destination addressing modes are allowed.

Example: Internal RAM location 30H holds 40H. The value of RAM location 40H is 10H. The data present at input port 1 is 11001010B (0CAH). The instruction sequence,

```
MOV R0,#30H ;R0 <= 30H
MOV A,@R0 ;A <= 40H
MOV R1,A ;R1 <= 40H
MOV B,@R1 ;B <= 10H
MOV @R1,P1 ;RAM (40H) <= 0CAH
MOV P2,P1 ;P2 #0CAH
```

leaves the value 30H in register 0, 40H in both the Accumulator and register 1, 10H in register B, and 0CAH (11001010B) both in RAM location 40H and output on port 2.

80C51 Family

80C51 family programmer's guide
and instruction set**MOV DPTR,#data16****Function:** Load Data Pointer with a 16-bit constant**Description:** The Data Pointer is loaded with the 16-bit constant indicated. The 16-bit constant is loaded into the second and third bytes of the instruction. The second byte (DPH) is the high-order byte, while the third byte (DPL) holds the low-order byte. No flags are affected.

This is the only instruction which moves 16 bits of data at once.

Example: The instruction,

MOV DPTR,#1234H

will load the value 1234H into the Data Pointer: DPH will hold 12H and DPL will hold 34H.

Bytes: 3**Cycles:** 2**Encoding:****Operation:**

MOV

(DPTR) ← (#data₁₅₋₀)DPH □ DPL ← #data₁₅₋₈ □ #data₇₋₀**MOVC A,@A+<base-reg>****Function:** Move Code byte**Description:** The MOVC instructions load the Accumulator with a code byte, or constant from program memory. The address of the byte fetched is the sum of the original unsigned eight-bit Accumulator contents and the contents of a sixteen-bit base register, which may be either the Data Pointer or the PC. In the latter case, the PC is incremented to the address of the following instruction before being added with the Accumulator; otherwise the base register is not altered. Sixteen-bit addition is performed so a carry-out from the low-order eight bits may propagate through higher-order bits. No flags are affected.**Example:** A value between 0 and 3 is in the Accumulator. The following instructions will translate the value in the Accumulator to one of four values defined by the DB (define byte) directive:

```
REL_PC:   INC     A
          MOVC   A,@A+PC
          RET
          DB     66H
          DB     77H
          DB     88H
          DB     99H
```

If the subroutine is called with the Accumulator equal to 01H, it will return with 77H in the Accumulator. The INC A before the MOVC instruction is needed to "get around" the RET instruction above the table. If several bytes of code separated the MOVC from the table, the corresponding number would be added to the Accumulator instead.

MOVC A,@A+DPTR**Bytes:** 1**Cycles:** 2**Encoding:****Operation:** MOVC

---	---	---	---	---	---	---	---

Operation:

MOVC

 $(PC) \leftarrow (PC) + 1$ $(A) \leftarrow ((A) + (PC))$ **MOVX <dest-byte>,<src-byte> (Not implemented in the 8XC752 or 8XC752)****Function:** Move External**Description:**

The MOVX instructions transfer data between the Accumulator and a byte of external data memory, hence the "X" appended to MOV. There are two types of instructions, differing in whether they provide an eight-bit or sixteen-bit indirect address to the external data RAM.

In the first type, the contents of R0 or R1 in the current register bank provide an eight-bit address multiplexed with data on P0. Eight bits are sufficient for external I/O expansion decoding or for a relatively small RAM array. For somewhat larger arrays, port pins can be used to output higher-order address bits. These pins would be controlled by an output instruction preceding the MOVX.

In the second type of MOVX instruction, The Data Pointer generates a sixteen-bit address. P2 outputs the high-order eight address bits (the contents of DPH) while P0 multiplexes the low-order eight bits (DPL) with data. The P2 Special Function Register retains its previous contents while the P2 output buffers are emitting the contents of DPH. This form is faster and more efficient when accessing very large data arrays (up to 64k bytes), since no additional instructions are needed to set up the output ports.

It is possible in some situations to mix the two MOVX types. A large RAM array with its high-order address lines driven by P2 can be addressed via the Data Pointer, or with code to output high-order address bits to P2 followed by a MOVX instruction using R0 or R1.

Example:

An external 256 byte RAM using multiplexed address/data lines is connected to the 8051 Port 0. Port 3 provides control lines for the external RAM. Ports 1 and 2 are used for normal I/O. Registers 0 and 1 contain 12H and 34H. Location 34H of the external RAM holds the value 56H. The instruction sequence,

MOVX A,@R1

MOVX @R0,A

copies the value 56H into both the Accumulator and external RAM location 12H.

MOVX A,@Ri**Bytes:** 1**Cycles:** 2**Encoding:**

NOP

- Function:** No Operation
- Description:** Execution continues at the following instruction. Other than the PC, no registers or flags are affected.
- Example:** It is desired to produce a low-going output pulse on bit 7 of Port 2 lasting exactly 5 cycles. A simple SETB/CLR sequence would generate a one-cycle pulse, so four additional cycles must be inserted. This may be done (assuming are enabled) with the instruction sequence,
- ```
CLR P2.7
NOP
NOP
NOP
NOP
SETB P2.7
```
- Bytes:** 1
- Cycles:** 1
- Encoding:**

|         |         |
|---------|---------|
| 0 0 0 0 | 0 0 0 0 |
|---------|---------|
- Operation:** NOP  
(PC) ← (PC) + 1

**ORL <dest-byte>,<src-byte>**

- Function:** Logical-OR for byte variables
- Description:** ORL performs the bitwise logical-OR operation between the indicated variables, storing the results in the destination byte. No flags are affected.
- The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.
- Note:* When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, *not* the input pins.
- Example:** If the Accumulator holds 0C3H (11000011B) and R0 holds 55H (01010101B) then the instruction,  
ORL A,R0  
will leave the Accumulator holding the value 0D7H (11010111B).
- When the destination is a directly addressed byte, the instruction can set combinations of bits in any RAM location or hardware register. The pattern of bits to be set is determined by a mask byte, which may be either a constant data value in the instruction or a variable computed in the Accumulator at run-time. The instruction,  
ORL P1,#00110010B  
will set bits 5, 4, and 1 of output Port 1.

**ORL C,<src-bit>****Function:** Logical-OR for bit variables**Description:** Set the carry flag if the Boolean value is a logical 1; leave the carry in its current state otherwise. A slash ("/") preceding the operand in the assembly language indicates that the logical complement of the addressed bit is used as the source value, but the source bit itself is not affected. No other flags are affected.**Example:** Set the carry flag if and only if P1.0 = 1, ACC.7 = 1, or OV = 0:

```

ORL C,P1.0 ;LOAD CARRY WITH INPUT PIN P10
ORL C,ACC.7 ;OR CARRY WITH THE ACC. BIT 7
ORL C,/OV ;OR CARRY WITH THE INVERSE OF OV.

```

**ORL C,bit****Bytes:** 2**Cycles:** 2**Encoding:**

**Operation:** ORL  
 $(C) \leftarrow (C) \vee (\overline{\text{bit}})$

**POP direct****Function:** Pop from stack**Description:** The contents of the internal RAM location addressed by the Stack Pointer is read, and the Stack Pointer is decremented by one. The value read is then transferred to the directly addressed byte indicated. No flags are affected.**Example:** The Stack Pointer originally contains the value 32H, and internal RAM locations 30H through 32H contain the values 20H, 23H, and 01H, respectively. The instruction sequence,

```
POP DPH
POP DPL
```

will leave the Stack Pointer equal to the value 30H and the Data Pointer set to 0123H. At this point the instruction,

```
POP SP
```

will leave the Stack Pointer set to 20H. Note that in this special case the Stack Pointer was decremented to 2FH before being loaded with the value popped (20H).

**Bytes:** 2**Cycles:** 2**Encoding:**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |
|---|---|---|---|---|---|---|---|

|----------------|
| direct address |
|----------------|

**Operation:**

```
PUSH
(direct) ← ((SP))
(SP) ← (SP) - 1
```

**PUSH direct****Function:** Push onto stack**Description:** The Stack Pointer is incremented by one. The contents of the indicated variable is then copied into the internal RAM location addressed by the Stack Pointer. Otherwise no flags are affected.**Example:** On entering an interrupt routine the Stack Pointer contains 09H. The Data Pointer holds the value 0123H. The instruction sequence,

```
PUSH DPL
PUSH DPH
```

will leave the Stack Pointer set to 0BH and store 23H and 01H in internal RAM locations 0AH and 0BH, respectively.

**Bytes:** 2**Cycles:** 2**Encoding:**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
|---|---|---|---|---|---|---|---|

|                |
|----------------|
| direct address |
|----------------|

**Operation:**

```
PUSH
(SP) ← (SP) + 1
((SP)) ← (direct)
```

**RET**

- Function:** Return from subroutine
- Description:** RET pops the high- and low-order bytes of the PC successively from the stack, decrementing the Stack Pointer by two. Program execution continues at the resulting address, generally the instruction immediately following an ACALL or LCALL. No flags are affected.
- Example:** The Stack Pointer originally contains the value 0BH. Internal RAM locations 0AH and 0BH contain the values 23H and 01H, respectively. The instruction, RET will leave the Stack Pointer equal to the value 09H. Program execution will continue at location 0123H.
- Bytes:** 1
- Cycles:** 2
- Encoding:**

|         |         |
|---------|---------|
| 0 0 1 0 | 0 0 1 0 |
|---------|---------|
- Operation:** RET  
 $(PC_{15-8}) \leftarrow ((SP))$   
 $(SP) \leftarrow (SP) - 1$   
 $(PC_{7-0}) \leftarrow ((SP))$   
 $(SP) \leftarrow (SP) - 1$

**RETI**

- Function:** Return from interrupt
- Description:** RETI pops the high- and low-order bytes of the PC successively from the stack, and restores the interrupt logic to accept additional interrupts at the same priority level as the one just processed. The Stack Pointer is left decremented by two. No other registers are affected; the PSW is not automatically restored to its pre-interrupt status. Program execution continues at the resulting address, which is generally the instruction immediately after the point at which the interrupt request was detected. If a lower- or same-level interrupt has been pending when the RETI instruction is executed, that one instruction will be executed before the pending interrupt is processed.
- Example:** The Stack Pointer originally contains the value 0BH. An interrupt was detected during the instruction ending at location 0122H. Internal RAM locations 0AH and 0BH contain the values 23H and 01H, respectively. The instruction, RETI will leave the Stack Pointer equal to 09H and return program execution to location 0123H.
- Bytes:** 1
- Cycles:** 2
- Encoding:**

|         |         |
|---------|---------|
| 0 0 1 1 | 0 0 1 0 |
|---------|---------|
- Operation:** RETI  
 $(PC_{15-8}) \leftarrow ((SP))$   
 $(SP) \leftarrow (SP) - 1$   
 $(PC_{7-0}) \leftarrow ((SP))$   
 $(SP) \leftarrow (SP) - 1$

**RL A****Function:** Rotate Accumulator Left**Description:** The eight bits in the Accumulator are rotated one bit to the left. Bit 7 is rotated into the bit 0 position. No flags are affected.**Example:** The Accumulator holds the value 0C5H (11000101B). The instruction, RL A leaves the Accumulator holding the value 8BH (10001011B) with the carry unaffected.**Bytes:** 1**Cycles:** 1**Encoding:**

|         |         |
|---------|---------|
| 0 0 1 0 | 0 0 1 1 |
|---------|---------|

**Operation:** RL  
 $(A_{n+1}) \leftarrow (A_n), n = 0 - 6$   
 $(A0) \leftarrow (A7)$ **RLC A****Function:** Rotate Accumulator Left through the Carry flag**Description:** The eight bits in the Accumulator and the carry flag are together rotated one bit to the left. Bit 7 moves into the carry flag; the original state of the carry flag moves into the bit 0 position. No other flags are affected.**Example:** The Accumulator holds the value 0C5H (11000101B), and the carry is zero. The instruction, RLC A leaves the Accumulator holding the value 8BH (10001010B) with the carry set.**Bytes:** 1**Cycles:** 1**Encoding:**

|         |         |
|---------|---------|
| 0 0 1 1 | 0 0 1 1 |

| 0 0 0 1 | 0 0 1 1 |
|---------|---------|

**Operation:**

RRC

 $(A_n) \leftarrow (A_{n+1}), n = 0 - 6$  $(A7) \leftarrow (C)$  $(C) \leftarrow (A0)$

**SETB <bit>****Function:** Set Bit**Description:** SETB sets the indicated bit to one. SETB can operate on the carry flag or any directly addressable bit. No other flags are affected.**Example:** The carry flag is cleared. Output Port 1 has been written with the value 34H (00110100B). The instructions,

```
SETB C
SETB P1.0
```

will leave the carry flag set to 1 and change the data output on Port 1 to 35H (00110101B).

**SETB C****Bytes:** 1**Cycles:** 1**Encoding:**

|   |   |   |   |   |   |   |   |

|---|---|---|---|---|---|---|---|

|             |
|-------------|
| bit address |
|-------------|

**Operation:** SETB  
(bit) ← 1**SJMP rel****Function:** Short Jump**Description:** Program control branches unconditionally to the address indicated. The branch destination is computed by adding the signed displacement in the second instruction byte to the PC, after incrementing the PC twice. Therefore, the range of destinations allowed is from 128 bytes preceding this instruction to 127 bytes following it.**Example:** The label "RELADR" is assigned to an instruction at program memory location 0123H. The instruction, SJMP RELADR will assemble into location 0100H. After the instruction is executed, the PC will contain the value 0123H. (Note: Under the above conditions the instruction following SJMP will be at 102H. Therefore, the displacement byte of the instruction will be the relative offset (0123H-0102H) = 21H. Put another way, an SJMP with a displacement of 0FEH would be a one-instruction infinite loop.)**Bytes:** 2**Cycles:** 2**Encoding:**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|---|---|---|---|---|---|---|---|

|              |
|--------------|
| rel. address |
|--------------|

**Operation:** SJMP  
(PC) ← (PC) + 2  
(PC) ← (PC) + rel

**SUBB A, <src-byte>****Function:** Subtract with borrow**Description:** SUBB subtracts the indicated variable and the carry flag together from the Accumulator, leaving the result in the Accumulator. SUBB sets the carry (borrow) flag if a borrow is needed for bit 7, and clears C otherwise. (If C was set *before* executing a SUBB instruction, this indicates that a borrow was needed for the previous step in a multiple precision subtraction, so the carry is subtracted from the Accumulator along with the source operand.) AC is set if a borrow is needed for bit 3, and cleared otherwise. OV is set if a borrow is needed into bit 6, but not into bit 7, or into bit 7, but not bit 6.

When subtracting signed integers OV indicates a negative number produced when a negative value is subtracted from a positive value, or a positive result when a positive number is subtracted from a negative number.

The source operand allows four addressing modes: register, direct, register-indirect, or immediate.

**Example:** The Accumulator holds 0C9H (11001001B), register 2 holds 54H (01010100B), and the carry flag is set. The instruction,

SUBB A,R2

will leave the value 74H (01110100B) in the Accumulator, with the carry flag and AC cleared but OV set.

Notice that 0C9H minus 54H is 75H. The difference between this and the above result is due to the carry (borrow) flag being set before the operation. If the state of the carry is not known before starting a single or multiple-precision subtraction, it should be explicitly cleared by a CLR C instruction

**SUBB A,Rn****Bytes:** 1**Cycles:** 1**Encoding:**

immediate data**Operation:** SUBB $(A) \leftarrow (A) - (C) - (\#data)$

**SWAP A**

**Function:** Swap nibbles within the Accumulator

**Description:** SWAP A interchanges the low- and high-order nibbles (four-bit fields) of the Accumulator (bits 3-0 and bits 7-4). The operation can also be thought of as a four-bit rotate instruction. No flags are affected.

**Example:** The Accumulator holds the value 0C5H (11000101B). The instruction, SWAP A leaves the Accumulator holding the value 5CH (01011100B).

**Bytes:** 1

**Cycles:** 1

|---|---|---|---|---|---|---|---|

**Operation:** SWAP  
(A<sub>3-0</sub>)  $\leftrightarrow$  (A<sub>7-4</sub>)

**XCH A,<byte>**

**Function:** Exchange Accumulator with byte variable

**Description:** XCH loads the Accumulator with the contents of the indicated variable, at the same time writing the original Accumulator contents to the indicated variable. The source/destination operand can use register, direct, or register-indirect addressing.

**Example:** R0 contains the address 20H. The Accumulator holds the value 3FH (00111111B). Internal RAM location 20H holds the value 75H (01110101B). The instruction, XCH A,@R0 will leave the RAM location 20H holding the values 3FH (00111111B) and 75H (01110101B) in the Accumulator.

**XCH A,Rn**

|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 0 | 0 | 1 | 1 | i |
|---|---|---|---|---|---|---|---|

**Operation:** XCH  
(A)  $\leftrightarrow$  ((R<sub>i</sub>))

**XCHD A,@Ri****Function:** Exchange Digit**Description:** XCHD exchanges the low-order nibble of the Accumulator (bits 3-0), generally representing a hexadecimal or BCD digit, with that of the internal RAM location indirectly addressed by the specified register. The high-order nibbles (bits 7-4) of each register are not affected. No flags are affected.**Example:** R0 contains the address 20H. The Accumulator holds the value 36H (00110110B). Internal RAM location 20H holds the value 75H (01110101B). The instruction,

XCHD A,@R0

will leave RAM location 20H holding the value 76H (01110110B) and 35H (00110101B) in the Accumulator.

**Bytes:** 1**Cycles:** 1**Encoding:**

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 0 | 1 | 0 | 1 | 1 | i |
|---|---|---|---|---|---|---|---|

**Operation:**XCHD  
(A<sub>3-0</sub>)  $\leftrightarrow$  ((Ri)<sub>3-0</sub>)**XRL <dest-byte>,<src-byte>****Function:** Logical Exclusive-OR for byte variables**Description:** XRL performs the bitwise logical Exclusive-OR operation between the indicated variables, storing the results in the destination. No flags are affected.

The two operands allow six addressing mode combinations. When the destination is the Accumulator, the source can use register, direct, register-indirect, or immediate addressing; when the destination is a direct address, the source can be the Accumulator or immediate data.

*(Note: When this instruction is used to modify an output port, the value used as the original port data will be read from the output data latch, not the input pins.)***Example:** If the Accumulator holds 0C3H (11000011B) and register 0 holds 0AAH (10101010B) then the instruction,  
XRL A,R0

will leave the Accumulator holding the value 69H (01101001B).

When the destination is a directly addressed byte, this instruction can complement combinations of bits in any RAM location or hardware register. The pattern of bits to be complemented is then determined by a mask byte, either a constant contained in the instruction or a variable computed in the Accumulator at run-time. The instruction,

XRL P1,#00110001B

will complement bits 5, 4, and 0 of output Port 1.

## 80C51 Family

## 80C51 family EPROM products

### EPROM PRODUCTS

Most of the 80C51 derivative products offered by Philips are supported with an EPROM version.

All EPROM products are available in both windowed DIP and OTP package configurations. The windowed DIP package allows the EPROM to be erased under a strong UV light source, making program development easier and faster. The OTP (One Time Programmable) version cannot be erased because there is no window through which the die could be exposed to UV light. While the EPROM can only be programmed once in the OTP package, the part costs less than in windowed DIP and therefore offers an advantage for those not desiring to use the masked ROM version of the part.

The EPROM products are fully supported on the industry standard EPROM programmers.

### Programming the 87C51

The setup for programming the microcontroller is shown in Figure 1. Note that the part is running with a 4 to 6 MHz oscillator. The clock must be running because the device is executing internal address and program data transfers during the programming.

To program the 87C51, the address of the EPROM location to be programmed is applied to ports 1 and 2 as shown in Figure 1. The code byte to be programmed into this location is applied to port 0. RST, PSEN, and the pins of ports 2 and 3 specified in Table 1 are held at the "Program Code Data" levels specified in the table. The ALE/PROG is then pulsed low 25 times to program the addressed location.

### Encryption Table

The encryption table is a feature of the 87C51, and its derivatives, that protects the code from being easily read by anyone other than the programmer. The encryption table is 16 to 64 bytes of code, depending on the microcontroller, that are exclusive NORed with the program code data as it is read out. The first byte is XNORed with the first location read, the second with the second read, etc. through the sixteenth byte read. The seventeenth byte is XNORed with the first byte of the encryption table, the eighteenth with the second, etc. and on in sixteen-byte groups.

After the Encryption table has been programmed the user has to know its

contents in order to correctly decode the program code data. The encryption table itself cannot be read out.

The encryption table is programmed in the same manner as the program memory, but using the "Pgm Encryption Table" levels specified in Table 1. After the encryption table is programmed, verification cycles will produce only encrypted information.

### Security Bit

There are two security bits on the 87C51 that, when set, prevent the program data memory from being read out or programmed further. To program the security bits, repeat the programming sequence using the "Pgm Security Bit" levels specified in Table 1.

After the first security bit is programmed, further programming of the code memory or the encryption table is disabled. The other security bit can of course still be programmed. With only security bit one programmed, the memory can still be read out for program verification. After the second security bit is programmed, it is no longer possible to read out (verify) the program memory.

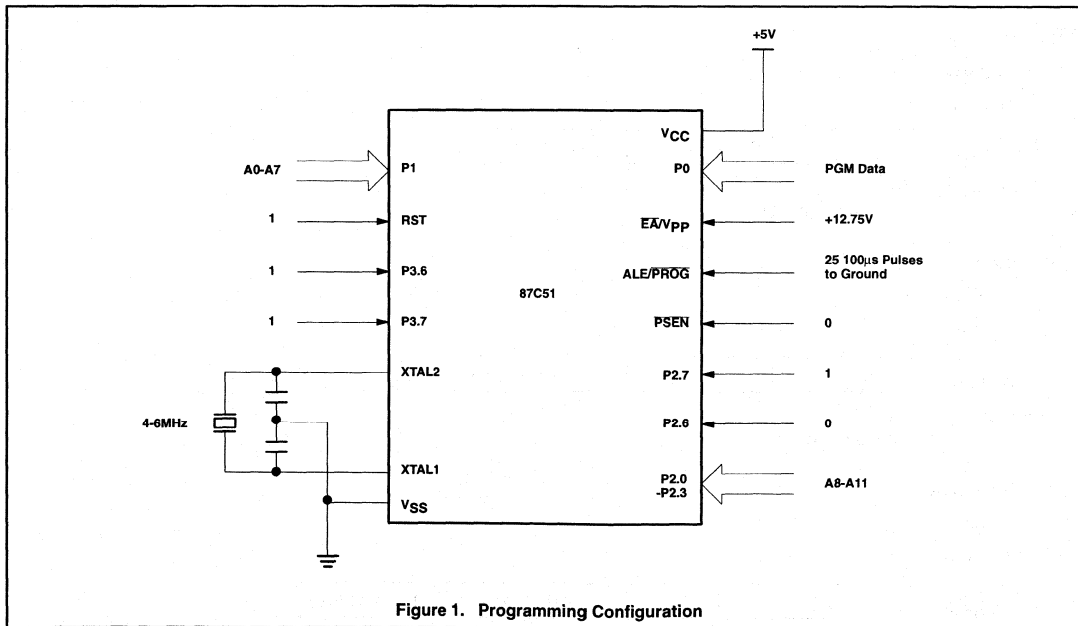

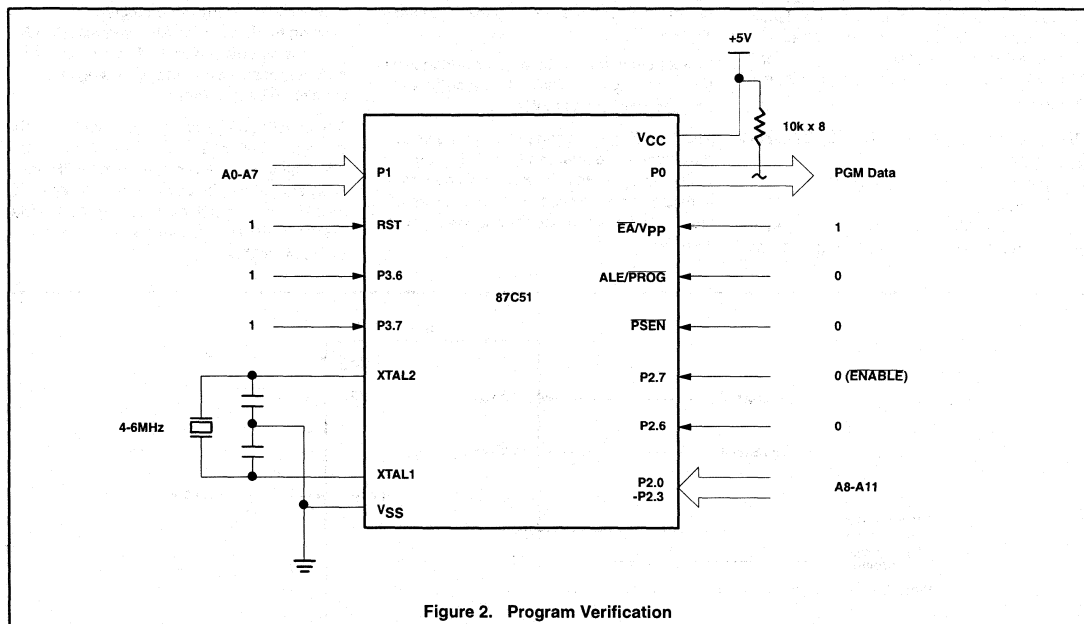

Figure 1. Programming Configuration

**Table 1. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/V <sub>PP</sub> | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|--------------------|------|------|------|------|

| Program code data    | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                  | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 0    | 0    |

**NOTES:**

1. "0" = valid low for that pin, "1" = valid high for that pin.
  2. V<sub>PP</sub> = 12.75 ±0.25V.
  3. V<sub>CC</sub> = 5V ±10% during programming and verification.
- \* ALE/PROG receives 25 programming pulses while V<sub>PP</sub> is held at 12.75V. Each programming pulse is low for 100ms (±10µs) and high for a minimum of 10µs.

**Figure 2. Program Verification**

**Program Verification**

If security bit 2 has not been programmed the on-chip program memory can be read out for program verification. To verify the contents of the program memory, the address of the location to be read is applied to ports 1 and 2 as shown in Figure 2. The other pins are held at the "Verify Code Data" levels indicated in Table 1. The contents of the addressed location will appear on port 0. For this operation external pull-ups are required on port 0 as shown in Figure 2. Note that if the encryption table has been programmed the data presented at port 0 will be the exclusive

NOR of the program byte with a byte from the encryption table.

**Signature Bytes**

The 87C51 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C51 manufactured by Philips.

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

- (030H) = 15H indicates the part is made by Philips
- (031H) = 90H 87C451      9DH 87C524
- 92H 87C51      9EH 87C598
- 94H 87C552      B0H 87C575
- 96H 87C550      B1H 87C51FA
- 97H 87C52      B2H 87C51FB
- 99H 87C654      B3H 87C51FC
- /87C652      B5H 89CE558
- 9AH 80C52      B6H 87C576
- 9BH 87C528      BBH 87C504
- 9CH 87C592      4BH 87C055

## 80C51 Family

## 80C51 family EPROM products

**EPROM Erasure**

Erasure of the EPROM occurs when the chip is exposed to light with wavelengths shorter than 4000 angstroms. Sunlight and fluorescent lighting have wavelengths in this range, so exposure to these light sources over an extended period of time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. It is recommended, for this reason, that an opaque label be placed over the window. If the part is subject to elevated temperatures or an environment where solvents are used, Kapton tape (Fluorglas part number 2345-5 or its equivalent) can be used.

The recommended erasure procedure is to expose the chip to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 40 minutes, at a distance of 1 inch, is adequate.

**Programming the 87C750, 87C751 and 87C752**

The 87C750, 87C751 and 87C752 are programmed using a Quick-pulse programming algorithm that is similar to that used for the 87C51. It differs from the 87C51

in that a serial data stream is used to place the 87C751 in the programming mode.

Figure 3 shows a block diagram of the programming configuration for the 87C751. Port pin P0.2 is used for the programming voltage supply input ( $V_{PP}$  signal). Port pin P0.1 is used for the program (PGM) signal.

Port 3 accepts the address input for the EPROM location to be programmed. Both the high and low components of the eleven-bit address are presented to the part through port 3. Multiplexing of the address components is performed using ASEL (P0.0).

Port 1 is used as a bidirectional data bus during programming and verify operations. During the programming mode, it accepts the byte to be programmed. In the verify mode, it returns the contents of the specified address location.

The X1 pin is the oscillator input and receives the master system clock. This clock should be between 1.2 and 6MHz.

The RESET pin is used to accept the serial data stream that places the 87C751 into various programming modes. This pattern consists of a 10-bit code with the LSB sent first. Each bit is synchronized to the clock input X1.

To program the 87C751 the part must be put into the programming mode by presenting the proper serial code (see Table 2) to the RESET pin. To do this RESET should be held high for at least two machine cycles. Port pins P0.1 and P0.2 will be at VOH as a result of this, but they must be driven high prior to sending the serial data stream on the RESET pin. The serial data bits can now be transmitted over the RESET pin placing the 87C751 into one of the programming modes. Following the transmission of the last data bit, the reset pin should be held low.

Next the address information for the location to be programmed is placed on Port 3 and ASEL is used to perform the address multiplexing. ASEL should be driven high and then Port 3 driven with the high-order address bits. ASEL is then driven low, latching the high-order bits internally. Port 3 can now be driven with the low 8 bits of the address, completing the addressing of the location to be programmed.

A high-voltage  $V_{PP}$  level is now applied to the  $V_{PP}$  input. This sets Port 1 as an input port. The data to be programmed to the EPROM array should be placed on Port 1. A series of 25 programming pulses is now applied to the PGM pin (P0.1) to program the addressed EPROM location.

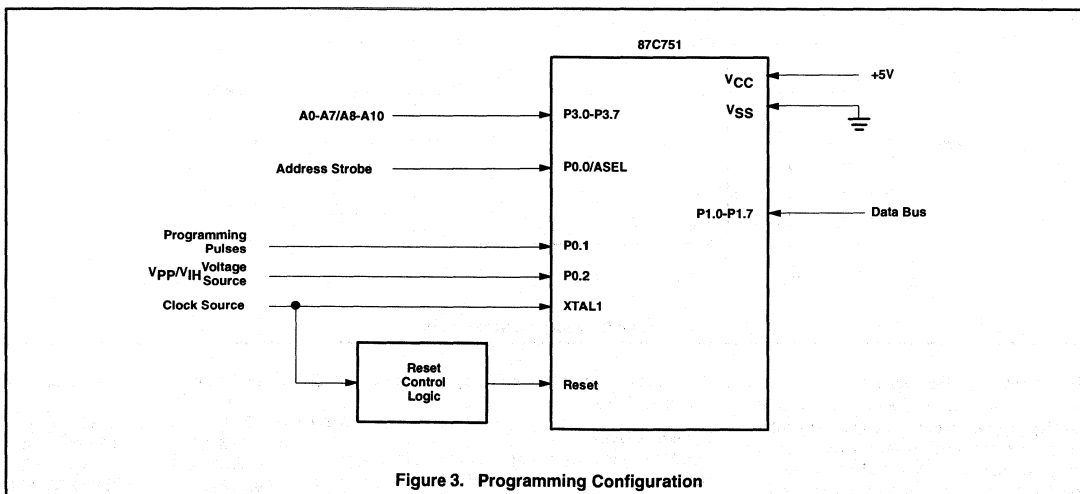

Figure 3. Programming Configuration

## 80C51 family EPROM products

**Table 2. 87C750, 87C751, and 87C752 Serial Codes**

| OPERATION              | SERIAL CODE | P0.1 (PGM/)     | P0.2 (V <sub>PP</sub> ) |
|------------------------|-------------|-----------------|-------------------------|
| Program user EPROM     | 296H        | —*              | V <sub>PP</sub>         |
| Verify user EPROM      | 296H        | V <sub>IH</sub> | V <sub>IH</sub>         |
| Program key EPROM      | 292H        | —*              | V <sub>PP</sub>         |
| Verify key EPROM       | 292H        | V <sub>IH</sub> | V <sub>IH</sub>         |
| Program security bit 1 | 29AH        | —*              | V <sub>PP</sub>         |
| Program security bit 2 | 298H        | —*              | V <sub>PP</sub>         |
| Verify security bits   | 29AH        | V <sub>IH</sub> | V <sub>IH</sub>         |
| Read signature bytes   | 294H        | V <sub>IH</sub> | V <sub>IH</sub>         |

**NOTE:**

\* Pulsed from V<sub>IH</sub> to V<sub>IL</sub> and returned to V<sub>IH</sub>.

**Program Verification**

The EPROM array can be verified by placing the part in the programming mode as described above and forcing the V<sub>PP</sub> pin to the V<sub>OH</sub> level. Four machine cycles after addressing a location the contents of the addressed location will appear on Port 1.

**87C750, 87C751 and 87C752 Signature Bytes**

The signature bytes for the 87C750, 87C751 and 87C752 are read differently and are in different locations than those on the 87C51. Due to its reduced pin count, the part has to be put into "Signature Byte Read Mode" by

placing a 10-bit serial data stream on the Reset pin. The proper code and the conditions of P0.1 and P0.2, for this mode, are shown in Table 2.

Once the part has been placed into the Signature Byte Read Mode, the signature bytes can be read by the same procedure as a normal verification of locations 01EH and 01FH. The values are:

01EH = 15H indicates the part is made by Philips  
 01FH = 91H - 87C751  
 01FH = 95H - 87C752

**Programming Features**

The 87C751 has all of the special programming features incorporated within its EPROM array that the 87C51 has. It has an encryption key table and two security bits. These function exactly as they do in the 87C51. They are programmed or verified by sending the proper code over the RESET pin (see Table 2) and then following the 87C751 programming procedure as described previously.

**Erasure Characteristics**

The erasure procedure is exactly the same as that described for the 87C51.

# CMOS single-chip 8-bit microcontroller

# 80C31/80C51/87C51

## DESCRIPTION

The Philips 80C31/80C51/87C51 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. The CMOS 8XC51 is functionally compatible with the NMOS 8031/8051 microcontrollers. The Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. Philips epitaxial substrate minimizes latch-up sensitivity.

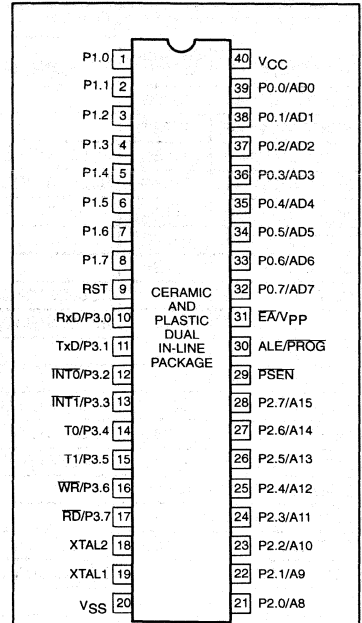

The 8XC51 contains a 4k × 8 ROM (80C51) EPROM (87C51), a 128 × 8 RAM, 32 I/O lines, two 16-bit counter/timers, a five-source, two-priority level nested interrupt structure, a serial I/O port for either multi-processor communications, I/O expansion or full duplex UART, and on-chip oscillator and clock circuits.

In addition, the device has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

## FEATURES

- 8031/8051 compatible
  - 4k × 8 ROM (80C51)
  - 4k × 8 EPROM (87C51)
  - ROMless (80C31)
  - 128 × 8 RAM
  - Two 16-bit counter/timers
  - Full duplex serial channel
  - Boolean processor
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- Five speed ranges at  $V_{CC} = 5V$ 
  - 12MHz
  - 16MHz
  - 24MHz
  - 30MHz
  - 33MHz
- Five package styles
- Extended temperature ranges
- OTP package available

## PIN CONFIGURATIONS

SEE PAGE 138 FOR QFP AND LCC PIN FUNCTIONS.

1. OTP = One Time Programmable EPROM. UV = UV Erasable EPROM

2. SOT311 replaced by SOT307-2.

| P0.0–0.7                        | 39–32   | 43–36        | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification in the 87C51. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                       |
| P1.0–P1.7                       | 1–8     | 2–9          | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification.                                                                                                                                                                                                                                                                                                               |
| P2.0–P2.7                       | 21–28   | 24–31        | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7                       | 10–17   | 11,<br>13–19 | 5,<br>7–13    | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                        |

## CMOS single-chip 8-bit microcontroller

## 80C31/80C51/87C51

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle

mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON.

Table 1 shows the state of I/O ports during low current operating modes.

**ROM CODE SUBMISSION**

When submitting ROM code for the 80C51, the following must be specified:

1. 4k byte user ROM data
2. 32 byte ROM encryption key (SC80C51 only)
3. ROM security bits (SC80C51 only).

| ADDRESS        | CONTENT | BIT(S) | COMMENT            |
|----------------|---------|--------|--------------------|
| 0000H to 0FFFH | DATA    | 7:0    | User ROM Data      |
| 1000H to 101FH | KEY     | 7:0    | ROM Encryption Key |
| 1020H          | SEC     | 0      | ROM Security Bit 1 |
| 1020H          | SEC     | 1      | ROM Security Bit 2 |

**Security Bit 1:** When programmed, this bit has two effects on masked ROM parts:

1. External MOV<sub>C</sub> is disabled, and
2. EA# is latched on Reset.

**Security Bit 2:** When programmed, this bit inhibits Verify User ROM.

**Table 1. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |

| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W                  |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the V<sub>OL</sub>s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input. I<sub>OL</sub> can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the V<sub>OH</sub> on ALE and PSEN to momentarily fall below the 0.9V<sub>CC</sub> specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when V<sub>IN</sub> is approximately 2V.
- I<sub>CCMAX</sub> at other frequencies (for Philips North America parts) is given by: Active mode: I<sub>CCMAX</sub> = 1.43 X FREQ + 1.90; Idle mode: I<sub>CCMAX</sub> = 0.14 X FREQ + 2.31, where FREQ is the external oscillator frequency in MHz. I<sub>CCMAX</sub> is given in mA. See Figure 7.
- See Figures 8 through 11 for I<sub>CC</sub> test conditions.
- For Philips North America parts when T<sub>amb</sub> = -40°C to +85°C or Philips parts when T<sub>amb</sub> = -40°C to +125°C, see DC Electrical Characteristics table on previous page.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with t<sub>r</sub> = t<sub>f</sub> = 10ns; V<sub>IL</sub> = V<sub>SS</sub> + 0.5V; V<sub>IH</sub> = V<sub>CC</sub> - 0.5V; XTAL2 not connected; EA = RST = Port 0 = V<sub>CC</sub>.
- The idle mode supply current is measured with all output pins disconnected; XTAL1 driven with t<sub>r</sub> = t<sub>f</sub> = 10ns; V<sub>IL</sub> = V<sub>SS</sub> + 0.5V; V<sub>IH</sub> = V<sub>CC</sub> - 0.5V; XTAL2 not connected; EA = Port 0 = V<sub>CC</sub>; RST = V<sub>SS</sub>.
- The power-down current is measured with all output pins disconnected, XTAL2 not connected, EA = Port 0 = V<sub>CC</sub>; RST = V<sub>SS</sub>.
- Under steady state (non-transient) conditions, I<sub>OL</sub> must be externally limited as follows:  
Maximum I<sub>OL</sub> per port pin: 15mA  
Maximum I<sub>OL</sub> per 8-bit port: 26mA  
Maximum I<sub>OL</sub> total for all outputs: 67mA  
If I<sub>OL</sub> exceeds the test condition, V<sub>OL</sub> may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Pin capacitance for the ceramic DIP package is 15pF maximum.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- For all Philips North America speed versions only.
- Interfacing the 80C31/51 to devices with float times up to 50ns is permitted. This limited bus contention will not cause damage to port 0 drivers.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- For all Philips speed versions only.
- Interfacing the 80C31/51 to devices with float times up to 30ns is permitted. This limited bus contention will not cause damage to port 0 drivers.
- $V_{CC} = 5\text{V} \pm 10\%$  for 33MHz.

# CMOS single-chip 8-bit microcontroller

# 80C31/80C51/87C51

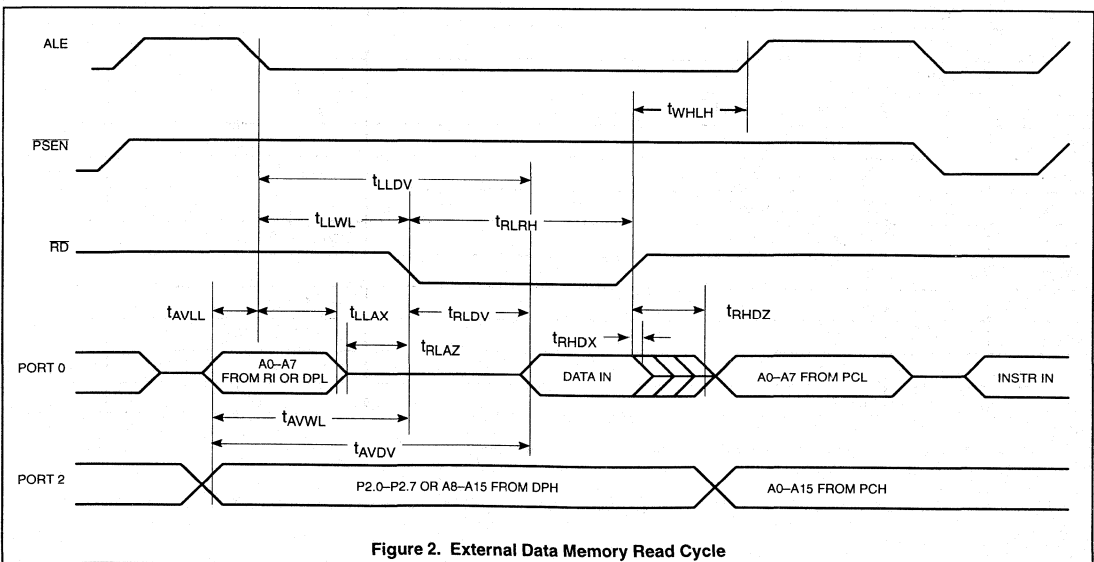

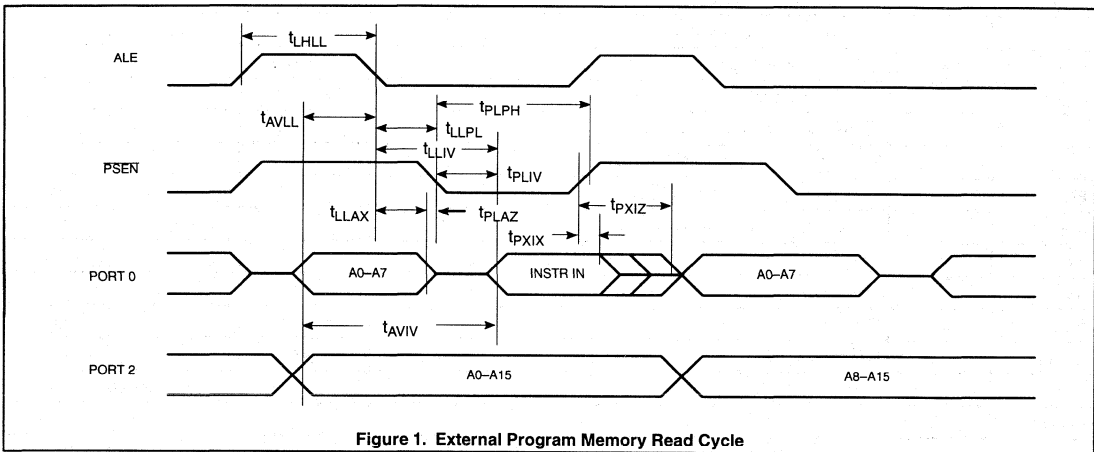

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

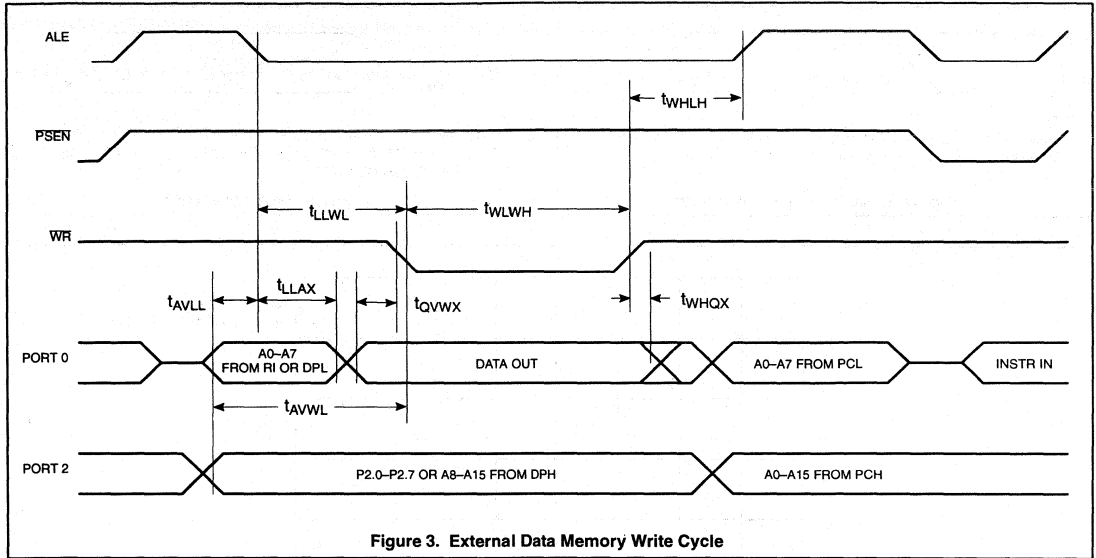

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

## 80C31/80C51/87C51

**EPROM CHARACTERISTICS**

The 87C51 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C51 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C51 manufactured by Philips Corporation.

Table 2 shows the logic levels for reading the signature bytes, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 12 and 13. Figure 14 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 12. Note that the 87C51 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 12. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 2 are held at the 'Program Code Data' levels indicated in Table 2. The ALE/PROG is pulsed low 25 times as shown in Figure 13.

To program the encryption table, repeat the 25 pulse programming sequence for

addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the  $\overline{EA}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 14. The other pins are held at the 'Verify Code Data' levels indicated in Table 2. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 92H indicates 87C51

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 2, and which satisfies the timing specifications, is suitable.

**Erasur Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 2. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{EA}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|------------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                      | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                      | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 0    | 0    |

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP} = 12.75V \pm 0.25V$ .
- $V_{CC} = 5V \pm 10\%$  during programming and verification.
- \*ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs ( $\pm 10\mu s$ ) and high for a minimum of 10μs.

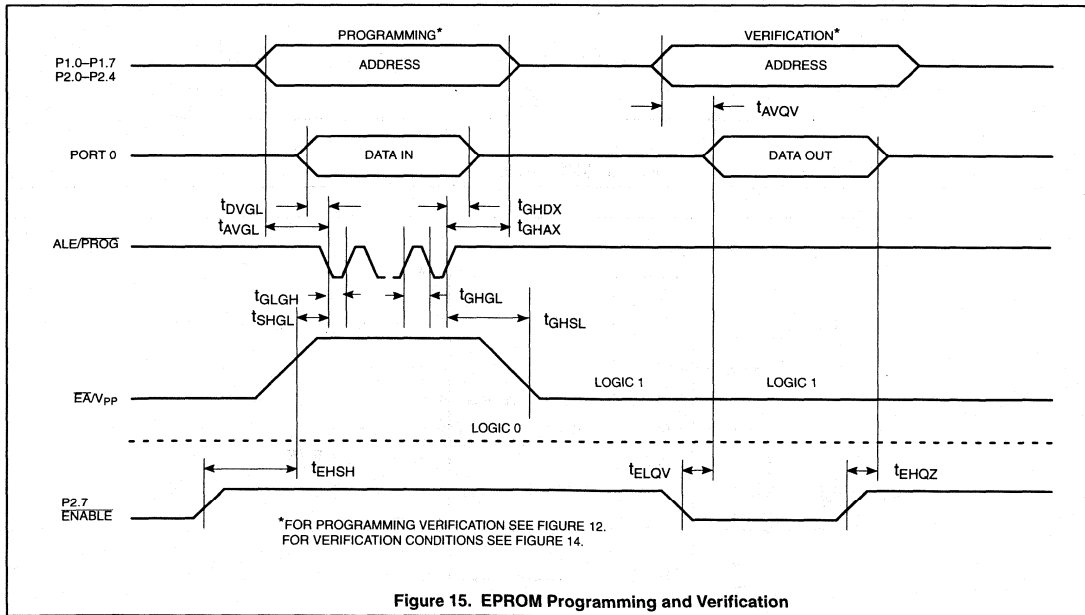

Figure 15. EPROM Programming and Verification

## CMOS single-chip 8-bit microcontroller

## 83C51FA/87C51FA

## DESCRIPTION

The 83C51FA and 87C51FA (hereafter generically referred to as 8XC51FA) Single-Chip 8-Bit Microcontrollers are manufactured in an advanced CMOS process and are derivatives of the 80C51 microcontroller family. The 8XC51FA has the same instruction set as the 80C51.

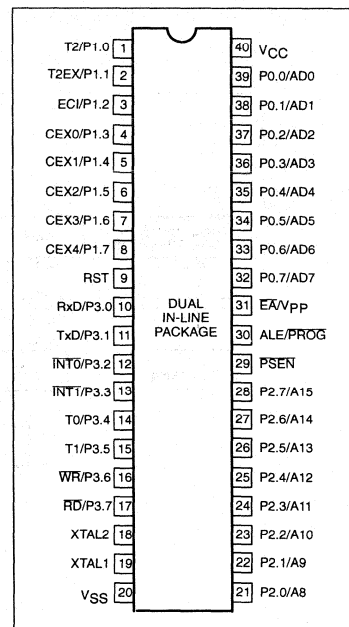

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 8XC51FA contains 8k × 8 memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, three 16-bit timer/event counters, a Programmable Counter Array (PCA), a multi-source, two-priority-level, nested interrupt structure, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC51FA can be expanded using standard TTL compatible memories and logic.

Its added features make it an even more powerful microcontroller for applications that require pulse width modulation, high-speed I/O and up/down counting capabilities such as motor control. It also has a more versatile serial channel that facilitates multiprocessor communications.

## FEATURES

- 80C51 central processing unit
- 8k × 8 EPROM (87C51FA)  
8k × 8 ROM (83C51FA)
  - expandable externally to 64k bytes
  - Quick Pulse programming algorithm
  - Two level program security system
- 256 × 8 RAM, expandable externally to 64k bytes
- Three 16-bit timer/counters
  - T2 is an up/down counter
- Programmable Counter Array (PCA)
  - High speed output
  - Capture/compare
  - Pulse Width Modulator
  - Watchdog Timer
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available

## PIN CONFIGURATIONS

## ORDERING INFORMATION

| ROM           | EPROM         |     | TEMPERATURE RANGE °C AND PACKAGE <sup>1</sup>            | FREQ. (MHz) | DRAWING NUMBER |
|---------------|---------------|-----|----------------------------------------------------------|-------------|----------------|
| S83C51FA-4N40 | S87C51FA-4N40 | OTP | 0 to +70, 40-Pin Plastic Dual In-line Package            | 3.5 to 16   | 0415C          |

| P0.0-0.7  | 39-32      | 43-36 | 37-30      | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P1.0-P1.7 | 1-8        | 2-9   | 40-44, 1-3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. | P2.0–P2.7              | 21–28      | 24–31        | 18–25      | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7              | 10–17      | 11,<br>13–19 | 5,<br>7–13 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                                                                                                                        |

**NOTE:**

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than  $V_{CC} + 0.5V$  or  $V_{SS} - 0.5V$ , respectively.

**TIMER 2**

This is a 16-bit up or down counter, which can be operated as either a timer or event counter. It can be operated in one of three different modes (autoreload, capture or as the baud rate generator for the UART).

In the autoreload mode the Timer can be set to count up or down by setting or clearing the bit DCEN in the T2CON Special Function Register. The SFR's RCAP2H and RCAP2L are used to reload the Timer upon overflow or a 1-to-0 transition on the T2EX input (P1.1).

In the Capture mode Timer 2 can either set TF2 and generate an interrupt or capture its value. To capture Timer 2 in response to a 1-to-0 transition on the T2EX input, the EXEN2 bit in the T2CON must be set. Timer 2 is then captured in SFR's RCAP2H and RCAP2L.

As the baud rate generator, Timer 2 is selected by setting TCLK and/or RCLK in T2CON. As the baud rate generator Timer 2 is incremented at  $1/2$  the oscillator frequency.

**ENHANCED UART**

The 8XC51FA UART has all of the capabilities of the standard 80C51 UART plus Framing Error Detection and Automatic Address Recognition. As in the 80C51, all four modes of operation are supported as well as the 9th bit in modes 2 and 3 that can be used to facilitate multiprocessor communication.

The Framing Error Detection allows the UART to look for missing stop bits. If a Stop

## CMOS single-chip 8-bit microcontroller

## 83C51FA/87C51FA

bit is missing, the FE bit in the SCON SFR is set. The FE bit can be checked after each transmission to detect communication errors. The FE bit can only be cleared by software and is not affected by a valid stop bit.

Automatic Address Recognition is used to reduce the CPU service time for the serial port. The CPU only needs to service the UART when it is addressed and, with this done by the on-chip circuitry, the need for software overhead is greatly reduced. This mode works similar to the 9th bit communication mode, except that uses only 8 bits and the Stop bit is used to cause the RI bit to be set. There are two SFRs associated with this mode. They are SADDR, which holds the slave address and SADEN, which contains a mask that allows selective masking of the slave address so that broadcast addresses can be used.

## PROGRAMMABLE COUNTER ARRAY

The PCA is a sophisticated free-running 16 bit Timer/Counter that drives 5 modules that can be individually configured as Capture inputs, software timers, high speed outputs, or pulse width modulated outputs. In addition, module 4 can be configured as a software controlled watchdog timer.

The Timer portion of the PCA can be configured to run in one of four different modes. The modes are:  $\frac{1}{2}$  the oscillator frequency,  $\frac{1}{4}$  the oscillator frequency, Timer 0 overflows, or from the ECI input.

For the Capture/Compare mode each of the modules has a pair of registers associated with it called CCAPnH and CCAPnL (where  $n = 0, 1, 2, 3, 4$  depending on the module). Both positive and negative transitions can be captured. This means that the PCA has the flexibility to measure phase differences, duty cycles, pulse widths and a wide variety of other digital pulse characteristics.

In the 16-bit software timer mode each of the modules can generate an interrupt upon a compare.

For applications that require accurate pulse widths and edges the PCA modules can be used as High Speed Outputs (HSO). The PCA toggles the appropriate CEXn pin when there is a match between the PCA timer and the modules compare registers.

The pulse width modulator mode for the PCA allows the conversion of digital information into analog signals. Each of the 5 modules can be used in this mode. The frequency of the PWM depends on the clock source for the PCA. The 8-bit PWM output is generated by comparing the low byte of the PCA (CL)

with the module's CCAPnL SFR. When  $CL < CCAPnL$ , the output is high. When  $CL > CCAPnL$ , the output is low.

## POWER OFF FLAG

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 8XC51FA rises from 0 to 5V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 3V for the POF to remain unaffected by the  $V_{CC}$  level.

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

## Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## Power-Down Mode

To save even more power, a Power Down mode can be invoked by software. In this

mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 8XC51FA either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INT0 and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put the device into Power Down.

## Design Consideration

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

## ONCE™ Mode

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems using the 8XC51FA without the 8XC51FA having to be removed from the circuit. The ONCE Mode is invoked by:

- Pull ALE low while the device is in reset and PSEN is high;
- Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 8XC51FA is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W    |

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

## Electrical Deviations from Commercial Specifications for Extended Temperature Range

DC and AC parameters not included here are the same as in the commercial temperature range table.

## DC ELECTRICAL CHARACTERISTICS

| C <sub>IO</sub>  | Pin capacitance <sup>11</sup> (except EA)                                                                      |                                                                                            |                         |                  | 15                      | pF   |

NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the V<sub>OL</sub>s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input. I<sub>OL</sub> can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the V<sub>OH</sub> on ALE and PSEN to momentarily fall below the 0.9V<sub>CC</sub> specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when V<sub>IN</sub> is approximately 2V.
- I<sub>CCMAX</sub> at other frequencies is given by: Active mode: I<sub>CCMAX</sub> = 1.50 × FREQ + 8; Idle mode: I<sub>CCMAX</sub> = 0.14 × FREQ + 2.31, where FREQ is the external oscillator frequency in MHz. I<sub>CCMAX</sub> is given in mA. See Figure 8.
- See Figures 9 through 12 for I<sub>CC</sub> test conditions.
- These values apply only to T<sub>amb</sub> = 0°C to +70°C. For T<sub>amb</sub> = -40°C to +85°C, see table on previous page.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Under steady state (non-transient) conditions, I<sub>OL</sub> must be externally limited as follows:  
 Maximum I<sub>OL</sub> per port pin: 15mA (\*NOTE: This is 85°C specification.)  
 Maximum I<sub>OL</sub> per 8-bit port: 26mA  
 Maximum total I<sub>OL</sub> for all outputs: 71mA  
 If I<sub>OL</sub> exceeds the test condition, V<sub>OL</sub> may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- ALE is tested to V<sub>OH1</sub>, except when ALE is off then V<sub>OH</sub> is the voltage specification.
- Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA it is 25pF).

| $t_{XHDX}$            | 4      | Clock rising edge to input data valid                                     |             | 492 |                  | $10t_{CLCL}-133$ | ns            |

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and  $\overline{\text{PSEN}} = 100\text{pF}$ , load capacitance for all other outputs =  $80\text{pF}$ .
- Interfacing the 8XC51FA to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# 83C51FA/87C51FA

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE
- P – PSEN

- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

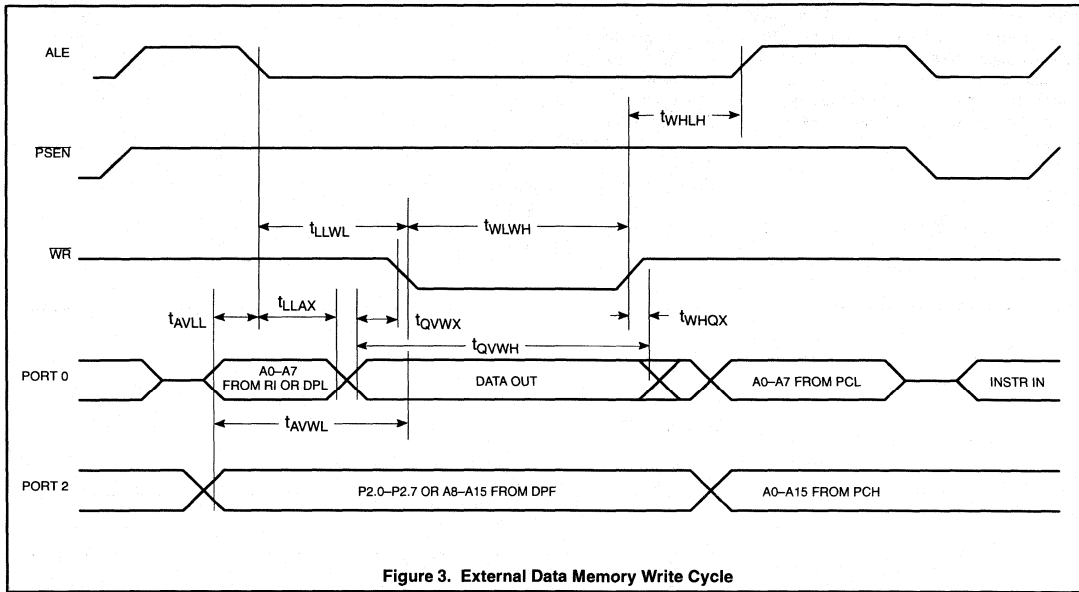

Figure 3. External Data Memory Write Cycle

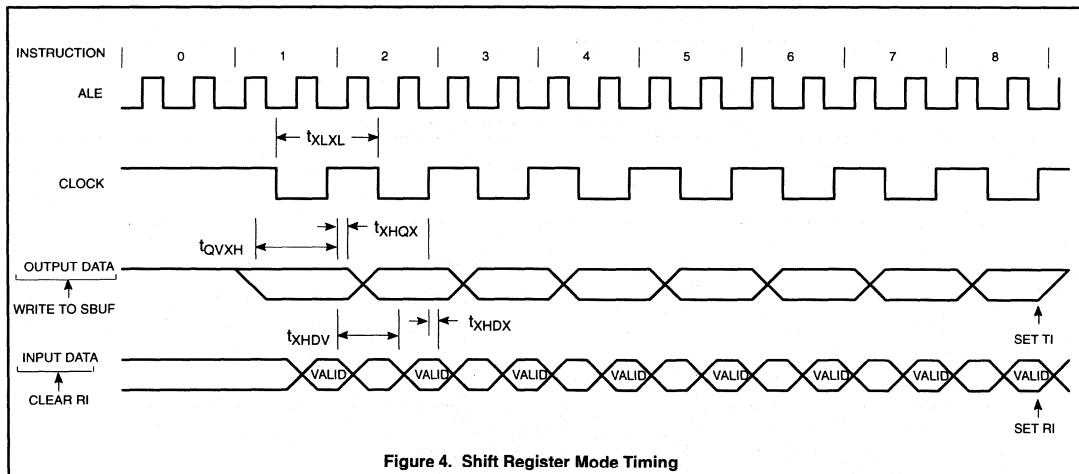

Figure 4. Shift Register Mode Timing

CMOS single-chip 8-bit microcontroller

83C51FA/87C51FA

Figure 5. External Clock Drive

NOTE:  
AC inputs during testing are driven at  $V_{CC}-0.5$  for a logic '1' and  $0.45V$  for a logic '0'.  
Timing measurements are made at  $V_{IH}$  min for a logic '1' and  $V_{IL}$  for a logic '0'.

Figure 6. AC Testing Input/Output

NOTE:  
For timing purposes, a port is no longer floating when a  $100mV$  change from load voltage occurs, and begins to float when a  $100mV$  change from the loaded  $V_{OH}/V_{OL}$  level occurs.  $I_{OH}/I_{OL} \geq \pm 20mA$ .

## CMOS single-chip 8-bit microcontroller

## 83C51FA/87C51FA

**EPROM CHARACTERISTICS**

The 87C51FA is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C51FA contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C51FA manufactured by Philips.

Table 2 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 13 and 14. Figure 15 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 13. Note that the 87C51FA is running with a 3.5MHz to 12MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 13. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 2 are held at the 'Program Code Data' levels indicated in Table 2. The ALE/PROG is pulsed low 15 to 25 times as shown in Figure 14.

To program the encryption table, repeat the 15 to 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 15 to 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the  $E\bar{A}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 15. The other pins are held at the 'Verify Code Data' levels indicated in Table 2. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = B1H indicates 87C51FA

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 2, and which satisfies the timing specifications, is suitable.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least  $15W\text{-s}/\text{cm}^2$ . Exposing the EPROM to an ultraviolet lamp of  $12,000\mu\text{W}/\text{cm}^2$  rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 2. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $E\bar{A}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|-------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                 | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                 | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2.  $V_{PP} = 12.75V \pm 0.25V$ .

3.  $V_{CC} = 5V \pm 10\%$  during programming and verification.

\* ALE/PROG receives 15 to 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for  $50\mu\text{s}$  to  $100\mu\text{s}$  and high for a minimum of  $10\mu\text{s}$ .

## CMOS single-chip 8-bit microcontrollers

## 83C51FB/87C51FB

## DESCRIPTION

The 83C51FB/87C51FB (hereafter collectively called 8XC51FB) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC51FB has the same instruction set as the 80C51.

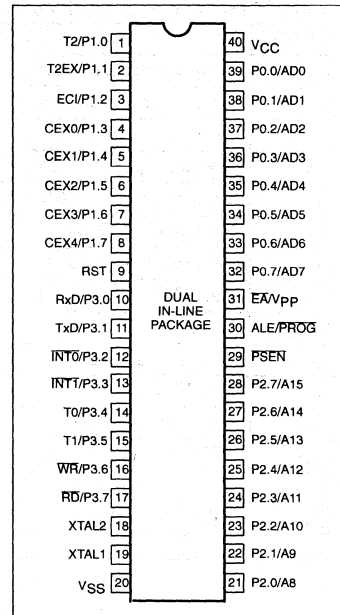

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 87C51FB contains 16k × 8 EPROM memory, the 83C51FB contains 16k × 8 ROM memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, three 16-bit timer/event counters, a Programmable Counter Array (PCA), a multi-source, two-priority-level, nested interrupt structure, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 87C51FB can be expanded using standard TTL compatible memories and logic.

Its added features make it an even more powerful microcontroller for applications that require pulse width modulation, high-speed I/O and up/down counting capabilities such as motor control. It also has a more versatile serial channel that facilitates multiprocessor communications.

## FEATURES

- 80C51 central processing unit
- 16k × 8 EPROM expandable externally to 64k bytes (87C51FB)
  - Quick Pulse programming algorithm
  - Two level program security system
- 16k × 8 ROM (83C51FB)
- 256 × 8 RAM, expandable externally to 64k bytes
- Three 16-bit timer/counters
  - T2 is an up/down counter
- Programmable Counter Array (PCA)
  - High speed output
  - Capture/compare
  - Pulse Width Modulator
  - Watchdog Timer
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available

| P0.0-0.7        | 39-32      | 43-36 | 37-30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P1.0-P1.7       | 1-8        | 2-9   | 40-44,<br>1-3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. | P2.0–P2.7              | 21–28      | 24–31     | 18–25   | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7              | 10–17      | 11, 13–19 | 5, 7–13 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 3 also serves the special features of the 80C51 family, as listed below:<br><b>RxD (P3.0):</b> Serial input port<br><b>TxD (P3.1):</b> Serial output port<br><b>INT0 (P3.2):</b> External interrupt<br><b>INT1 (P3.3):</b> External interrupt<br><b>T0 (P3.4):</b> Timer 0 external input<br><b>T1 (P3.5):</b> Timer 1 external input<br><b>WR (P3.6):</b> External data memory write strobe<br><b>RD (P3.7):</b> External data memory read strobe                                              |
| RST                    | 9          | 10        | 4       | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to $V_{SS}$ permits a power-on reset using only an external capacitor to $V_{CC}$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ALE/PROG               | 30         | 33        | 27      | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PSEN                   | 29         | 32        | 26      | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 87C51FB is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $\overline{EA}/V_{PP}$ | 31         | 35        | 29      | I    | <b>External Access Enable/Programming Supply Voltage:</b> $\overline{EA}$ must be externally held low to enable the device to fetch code from external program memory locations 0000H and 3FFFH. If $\overline{EA}$ is held high, the device executes from internal program memory unless the program counter contains an address greater than 3FFFH. This pin also receives the 12.75V programming supply voltage ( $V_{PP}$ ) during EPROM programming. If security bit 1 is programmed, $\overline{EA}$ will be internally latched on Reset.                                                                                                                                                                                                                                                                                                             |

**NOTE:**

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than  $V_{CC} + 0.5V$  or  $V_{SS} - 0.5V$ , respectively.

**TIMER 2**

This is a 16-bit up or down counter, which can be operated as either a timer or event counter. It can be operated in one of three different modes (autoreload, capture or as the baud rate generator for the UART).

In the autoreload mode the Timer can be set to count up or down by setting or clearing the bit DCEN in the T2CON Special Function Register. The SFR's RCAP2H and RCAP2L are used to reload the Timer upon overflow or a 1-to-0 transition on the T2EX input (P1.1).

In the Capture mode Timer 2 can either set TF2 and generate an Interrupt or capture its value. To capture Timer 2 in response to a 1-to-0 transition on the T2EX input, the EXEN2 bit in the T2CON must be set. Timer 2 is then captured in SFR's RCAP2H and RCAP2L.

As the baud rate generator, Timer 2 is selected by setting TCLK and/or RCLK in T2CON. As the baud rate generator Timer 2 is incremented at  $1/2$  the oscillator frequency.

**POWER OFF FLAG**

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 87C51FB rises from 0 to 5V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 3V for the POF to remain unaffected by the  $V_{CC}$  level.

## CMOS single-chip 8-bit microcontrollers

## 83C51FB/87C51FB

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**Reset**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

**Idle Mode**

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle

mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**Power-Down Mode**

To save even more power, a Power Down mode can be invoked by software. In this mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 87C51FB either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INT0 and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the

instruction that put the device into Power Down.

**Design Consideration**

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

**ONCE™ Mode**

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems using the 87C51FB without the 87C51FB having to be removed from the circuit. The ONCE Mode is invoked by:

- Pull ALE low while the device is in reset and PSEN is high;
- Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 87C51FB is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

**Table 2. External Pin Status During Idle and Power-Down Mode**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |

## Programmable Counter Array (PCA)

The Programmable Counter Array is a special Timer that has five 16-bit capture/compare modules associated with it. Each of the modules can be programmed to operate in one of four modes: rising and/or falling edge capture, software timer, high-speed output, or pulse width modulator. Each module has a pin associated with it in port 1. Module 0 is connected to P1.3(CEX0), module 1 to P1.4(CEX1), etc. The basic PCA configuration is shown in Figure 1.

The PCA timer is a common time base for all five modules and can be programmed to run at: 1/12 the oscillator frequency, 1/4 the oscillator frequency, the Timer 0 overflow, or the input on the ECI pin (P1.2). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD SFR as follows (see Figure 4):

| CPS1 | CPS0 | PCA Timer Count Source    |
|------|------|---------------------------|
| 0    | 0    | 1/12 oscillator frequency |
| 0    | 1    | 1/4 oscillator frequency  |
| 1    | 0    | Timer 0 overflow          |
| 1    | 1    | External Input at ECI pin |

In the CMOD SFR are three additional bits associated with the PCA. They are CIDL which allows the PCA to stop during idle mode, WDTE which enables or disables the watchdog function on module 4, and ECF which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to

be set when the PCA timer overflows. These functions are shown in Figure 2.

The watchdog timer function is implemented in module 4 as implemented in other parts that have a PCA that are available on the market. However, if a watchdog timer is required in the target application, it is recommended to use the hardware watchdog timer that is implemented on the 8XC51FB separately from the PCA (see Figure 12).

The CCON SFR contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (refer to Figure 5). To run the PCA the CR bit (CCON.6) must be set by software. The PCA is shut off by clearing this bit. The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software. Bits 0 through 4 of the CCON register are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software. The PCA interrupt system shown in Figure 3.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (see Figure 6). The registers contain the bits that control the mode that each module will operate in. The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or

4 depending on the module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated module. PWM (CCAPMn.1) enables the pulse width modulation mode. The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register. The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.

The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition. The last bit in the register ECOM (CCAPMn.6) when set enables the comparator function. Figure 7 shows the CCAPMn settings for the various PCA functions.

There are two additional registers associated with each of the PCA modules. They are CCAPnH and CCAPnL and these are the registers that store the 16-bit count when a capture occurs or a compare should occur. When a module is used in the PWM mode these registers are used to control the duty cycle of the output.

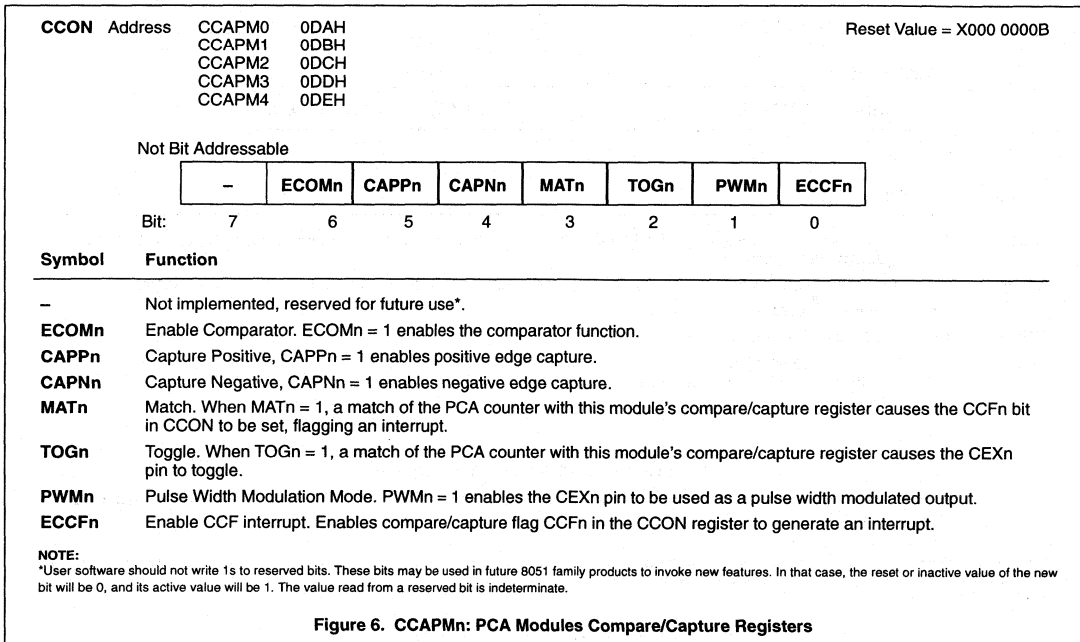

Figure 6. CCAPMn: PCA Modules Compare/Capture Registers

**PCA Capture Mode**

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated. Refer to Figure 8.

**16-bit Software Timer Mode**

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (see Figure 9).

**High Speed Output Mode**

In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (see Figure 10).

**Pulse Width Modulator Mode**

All of the PCA modules can be used as PWM outputs. Figure 11 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. this allows updating the PWM

without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

**Enhanced UART**

The UART operates in all of the usual modes that are described in the first section of this book for the 80C51. In addition the UART can perform framing error detect by looking for missing stop bits, and automatic address recognition. The 8XC51FB UART also fully supports multiprocessor communication as does the standard 80C51 UART.

When used for framing error detect the UART looks for missing stop bits in the communication. A missing bit will set the FE bit in the SCON register. The FE bit shares the SCON.7 bit with SM0 and the function of SCON.7 is determined by PCON.6 (SMOD0) (see Figure 13). If SMOD0 is set then SCON.7 functions as FE. SCON.7 functions as SM0 when SMOD0 is cleared. When used as FE SCON.7 can only be cleared by software. Refer to Figure 14.

Figure 7. PCA Module Modes (CCAPMn Register)

**Automatic Address Recognition**

Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes, mode 2 and mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the "Given" address or the "Broadcast" address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data. Automatic address recognition is shown in Figure 15.

The 8 bit mode is called Mode 1. In this mode the RI flag will be set if SM2 is enabled and the information received has a valid stop bit following the 8 address bits and the information is either a Given or Broadcast address.

Mode 0 is the Shift Register mode and SM2 is ignored.

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the

SADDR to create the "Given" address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

```
Slave 0 SADDR = 1100 0000
 SADEN = 1111 1101
 Given = 1100 00X0

Slave 1 SADDR = 1100 0000
 SADEN = 1111 1110
 Given = 1100 000X
```

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

```
Slave 0 SADDR = 1100 0000
 SADEN = 1111 1001
 Given = 1100 00X0

Slave 1 SADDR = 1110 0000
 SADEN = 1111 1010
 Given = 1110 000X

Slave 2 SADDR = 1110 0000
 SADEN = 1111 1100
 Given = 1110 00XX
```

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated as don't-cares. In most cases, interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR (SFR address 0A9H) and SADEN (SFR address 0B9H) are loaded with 0s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares", this effectively disables the Automatic Addressing mode and allows the microcontroller to use standard 80C51 type UART drivers which do not make use of this feature.

**Reduced EMI Mode**

The AO bit (AUXR.O) in the AUXR register when set disables the ALE output.

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING                 | UNIT |
|----------------------------------------------------------------------------------------------|------------------------|------|
| Operating temperature under bias                                                             | 0 to +70 or -40 to +85 | °C   |
| Storage temperature range                                                                    | -65 to +150            | °C   |
| Voltage on $\overline{EA}/V_{PP}$ pin to $V_{SS}$                                            | 0 to +13.0             | V    |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5           | V    |
| Maximum $I_{OL}$ per I/O pin                                                                 | 15                     | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

**Electrical Deviations from Commercial Specifications for Extended Temperature Range**

DC and AC parameters not included here are the same as in the commercial temperature range table.

**DC ELECTRICAL CHARACTERISTICS** $T_{amb} = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ,  $V_{CC} = 5\text{V} \pm 10\%$ ,  $V_{SS} = 0\text{V}$

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 1.50 \times \text{FREQ} + 8$ ; Idle mode:  $I_{CCMAX} = 0.14 \times \text{FREQ} + 2.31$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 23.
- See Figures 24 through 27 for  $I_{CC}$  test conditions.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C to } +70^{\circ}\text{C}$ . For  $T_{amb} = -40^{\circ}\text{C to } +85^{\circ}\text{C}$ , see table on previous page.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 15mA (\*NOTE: This is 85°C specification.)
  - Maximum  $I_{OL}$  per 8-bit port: 26mA
  - Maximum total  $I_{OL}$  for all outputs: 71mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- ALE is tested to  $V_{OH1}$ , except when ALE is off then  $V_{OH}$  is the voltage specification.
- Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA it is 25pF).

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 87C51FB to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE

- P – PSEN
- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## EPROM CHARACTERISTICS

The 87C51FB is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for V<sub>PP</sub> (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C51FB contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C51FB manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 28 and 29. Figure 30 shows the circuit configuration for normal program memory verification.

## Quick-Pulse Programming

The setup for microcontroller quick-pulse programming is shown in Figure 28. Note that the 87C51FB is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 28. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 29.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/V<sub>PP</sub> pin must not be allowed to go above the maximum specified V<sub>PP</sub> level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The V<sub>PP</sub> source should be well regulated and free of glitches and overshoot.

## Program Verification

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 30. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

## Reading the Signature Bytes

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips  
 (031H) = B2H indicates 87C51FB

## Program/Verify Algorithms

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

## Erase Characteristics

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/V <sub>PP</sub> | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|--------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                  | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                  | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 0    | 0    |

### NOTES:

- '0' = Valid low for that pin, '1' = valid high for that pin.
- V<sub>PP</sub> = 12.75V ±0.25V.
- V<sub>CC</sub> = 5V±10% during programming and verification.
- \* ALE/PROG receives 25 programming pulses while V<sub>PP</sub> is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

# CMOS single-chip 8-bit microcontrollers

# 83C51FC/87C51FC

## DESCRIPTION

The 83C51FC/87C51FC (hereafter collectively called 8XC51FC) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC51FC has the same instruction set as the 80C51.

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 87C51FC contains 32k x 8 EPROM memory, the 83C51FC contains 32k x 8 ROM memory, a volatile 256 x 8 read/write data memory, four 8-bit I/O ports, three 16-bit timer/event counters, a Programmable Counter Array (PCA), a multi-source, four-priority-level, nested interrupt structure, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC51FC can be expanded using standard TTL compatible memories and logic.

Its added features make it an even more powerful microcontroller for applications that require pulse width modulation, high-speed I/O and up/down counting capabilities such as motor control. It also has a more versatile serial channel that facilitates multiprocessor communications.

## FEATURES

- 80C51 central processing unit
- 32k x 8 EPROM expandable externally to 64k bytes (87C51FC)
  - Quick Pulse programming algorithm
  - Two level program security system
- 32k x 8 ROM (83C51FC)
- 256 x 8 RAM, expandable externally to 64k bytes
- Three 16-bit timer/counters
  - T2 is an up/down counter
- Programmable Counter Array (PCA)
  - High speed output
  - Capture/compare
  - Pulse Width Modulator
  - Watchdog Timer
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available

| P0.0-0.7        | 39-32      | 43-36 | 37-30      | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P1.0-P1.7       | 1-8        | 2-9   | 40-44, 1-3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:<br><b>T2 (P1.0):</b> Timer/Counter 2 external count input/Clockout<br><b>T2EX (P1.1):</b> Timer/Counter 2 Reload/Capture/Direction Control<br><b>EC1 (P1.2):</b> External Clock Input to the PCA<br><b>CEX0 (P1.3):</b> Capture/Compare External I/O for PCA module 0<br><b>CEX1 (P1.4):</b> Capture/Compare External I/O for PCA module 1<br><b>CEX2 (P1.5):</b> Capture/Compare External I/O for PCA module 2<br><b>CEX3 (P1.6):</b> Capture/Compare External I/O for PCA module 3<br><b>CEX4 (P1.7):</b> Capture/Compare External I/O for PCA module 4 |

## PIN DESCRIPTIONS (Continued)

| MNEMONIC               | PIN NUMBER |           |         | TYPE | NAME AND FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|------------|-----------|---------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | DIP        | LCC       | QFP     |      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| P2.0–P2.7              | 21–28      | 24–31     | 18–25   | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7              | 10–17      | 11, 13–19 | 5, 7–13 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 3 also serves the special features of the 80C51 family, as listed below:<br><b>RxD (P3.0):</b> Serial input port<br><b>TxD (P3.1):</b> Serial output port<br><b>INT0 (P3.2):</b> External interrupt<br><b>INT1 (P3.3):</b> External interrupt<br><b>T0 (P3.4):</b> Timer 0 external input<br><b>T1 (P3.5):</b> Timer 1 external input<br><b>WR (P3.6):</b> External data memory write strobe<br><b>RD (P3.7):</b> External data memory read strobe                                              |
| RST                    | 9          | 10        | 4       | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to $V_{SS}$ permits a power-on reset using only an external capacitor to $V_{CC}$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ALE/PROG               | 30         | 33        | 27      | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PSEN                   | 29         | 32        | 26      | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 8XC51FC is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $\overline{EA}/V_{PP}$ | 31         | 35        | 29      | I    | <b>External Access Enable/Programming Supply Voltage:</b> $\overline{EA}$ must be externally held low to enable the device to fetch code from external program memory locations 0000H and 7FFFH. If $\overline{EA}$ is held high, the device executes from internal program memory unless the program counter contains an address greater than 7FFFH. This pin also receives the 12.75V programming supply voltage ( $V_{PP}$ ) during EPROM programming. If security bit 1 is programmed, $\overline{EA}$ will be internally latched on Reset.                                                                                                                                                                                                                                                                                                             |
| XTAL1                  | 19         | 21        | 15      | I    | <b>Crystal 1:</b> Input to the inverting oscillator amplifier and input to the internal clock generator circuits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| XTAL2                  | 18         | 20        | 14      | O    | <b>Crystal 2:</b> Output from the inverting oscillator amplifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**NOTE:**

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than  $V_{CC} + 0.5V$  or  $V_{SS} - 0.5V$ , respectively.

**TIMER 2**

This is a 16-bit up or down counter, which can be operated as either a timer or event counter. It can be operated in one of three different modes (autoreload, capture or as the baud rate generator for the UART).

In the autoreload mode the Timer can be set to count up or down by setting or clearing the bit DCEN in the T2CON Special Function Register. The SFR's RCAP2H and RCAP2L are used to reload the Timer upon overflow or a 1-to-0 transition on the T2EX input (P1.1).

In the Capture mode Timer 2 can either set TF2 and generate an interrupt or capture its value. To capture Timer 2 in response to a 1-to-0 transition on the T2EX input, the EXEN2 bit in the T2CON must be set. Timer 2 is then captured in SFR's RCAP2H and RCAP2L.

As the baud rate generator, Timer 2 is selected by setting TCLK and/or RCLK in T2CON. As the baud rate generator Timer 2 is incremented at  $1/2$  the oscillator frequency.

**POWER OFF FLAG**

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 8XC51FC rises from 0 to 5V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 3V for the POF to remain unaffected by the  $V_{CC}$  level.

## CMOS single-chip 8-bit microcontrollers

## 83C51FC/87C51FC

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**Reset**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

**Idle Mode**

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**Power-Down Mode**

To save even more power, a Power Down mode can be invoked by software. In this

mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 8XC51FC either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INT0 and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put the device into Power Down.

**Design Consideration**

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

**ONCE™ Mode**

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems

using the 8XC51FC without the 8XC51FC having to be removed from the circuit. The ONCE Mode is invoked by:

1. Pull ALE low while the device is in reset and PSEN is high;
2. Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 8XC51FC is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

**Programmable Clock-Out**

The 8XC51FC has a new feature. A 50% duty cycle clock can be programmed to come out on P1.0. This pin, besides being a regular I/O pin, has two alternate functions. It can be programmed (1) to input the external clock for Timer/Counter 2 or (2) to output a 50% duty cycle clock ranging from 61Hz to 4MHz at a 16MHz operating frequency.

To configure the Timer/Counter 2 as a clock generator, bit C/T2 (in T2CON) must be cleared and bit T20E in T2MOD must be set. Bit TR2 (T2CON.2) also must be set to start the timer.

The Clock-Out frequency depends on the oscillator frequency and the reload value of Timer 2 capture registers (RCAP2H, RCAP2L) as shown in this equation:

$$\frac{\text{OscillatorFrequency}}{4 \times (65536 - \text{RCAP2H}, \text{RCAP2L})}$$

In the Clock-Out mode Timer 2 roll-overs will not generate an interrupt. This is similar to when it is used as a baud-rate generator. It is possible to use Timer 2 as a baud-rate generator and a clock generator simultaneously. Note, however, that the baud-rate and the Clock-Out frequency will be the same.

**Table 2. External Pin Status During Idle and Power-Down Mode**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

### Programmable Counter Array (PCA)

The Programmable Counter Array is a special Timer that has five 16-bit capture/compare modules associated with it. Each of the modules can be programmed to operate in one of four modes: rising and/or falling edge capture, software timer, high-speed output, or pulse width modulator. Each module has a pin associated with it in port 1. Module 0 is connected to P1.3(CEX0), module 1 to P1.4(CEX1), etc. The basic PCA configuration is shown in Figure 1.

The PCA timer is a common time base for all five modules and can be programmed to run at: 1/12 the oscillator frequency, 1/4 the oscillator frequency, the Timer 0 overflow, or the input on the ECI pin (P1.2). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD SFR as follows (see Figure 4):

| CPS1 | CPS0 | PCA Timer Count Source    |
|------|------|---------------------------|
| 0    | 0    | 1/12 oscillator frequency |
| 0    | 1    | 1/4 oscillator frequency  |
| 1    | 0    | Timer 0 overflow          |
| 1    | 1    | External Input at ECI pin |

In the CMOD SFR are three additional bits associated with the PCA. They are CIDL which allows the PCA to stop during idle mode, WDTE which enables or disables the watchdog function on module 4, and ECF

which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows. These functions are shown in Figure 2.

The watchdog timer function is implemented in module 4 (see Figure 12).

The CCON SFR contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (refer to Figure 5). To run the PCA the CR bit (CCON.6) must be set by software. The PCA is shut off by clearing this bit. The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software. Bits 0 through 4 of the CCON register are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software. The PCA interrupt system shown in Figure 3.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (see Figure 6). The registers contain the bits that control the mode that each module will operate in. The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or 4 depending on the module) enables the CCF flag in the CCON SFR to generate an

interrupt when a match or compare occurs in the associated module. PWM (CCAPMn.1) enables the pulse width modulation mode. The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register. The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.

The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition. The last bit in the register ECOM (CCAPMn.6) when set enables the comparator function. Figure 7 shows the CCAPMn settings for the various PCA functions.

There are two additional registers associated with each of the PCA modules. They are CCAPnH and CCAPnL and these are the registers that store the 16-bit count when a capture occurs or a compare should occur. When a module is used in the PWM mode these registers are used to control the duty cycle of the output.

| CAPNn                                                                                                                                                                                                                                                                                       | Capture Negative, CAPNn = 1 enables negative edge capture.                                                                                                 |       |       |       |      |      |      |       |                         |
| MATn                                                                                                                                                                                                                                                                                        | Match. When MATn = 1, a match of the PCA counter with this module's compare/capture register causes the CCFn bit in CCON to be set, flagging an interrupt. |       |       |       |      |      |      |       |                         |
| TOGn                                                                                                                                                                                                                                                                                        | Toggle. When TOGn = 1, a match of the PCA counter with this module's compare/capture register causes the CEXn pin to toggle.                               |       |       |       |      |      |      |       |                         |
| PWMn                                                                                                                                                                                                                                                                                        | Pulse Width Modulation Mode. PWMn = 1 enables the CEXn pin to be used as a pulse width modulated output.                                                   |       |       |       |      |      |      |       |                         |
| ECCFn                                                                                                                                                                                                                                                                                       | Enable CCF interrupt. Enables compare/capture flag CCFn in the CCON register to generate an interrupt.                                                     |       |       |       |      |      |      |       |                         |
| <b>NOTE:</b>                                                                                                                                                                                                                                                                                |                                                                                                                                                            |       |       |       |      |      |      |       |                         |
| *User software should not write 1s to reserved bits. These bits may be used in future 8051 family products to invoke new features. In that case, the reset or inactive value of the new bit will be 0, and its active value will be 1. The value read from a reserved bit is indeterminate. |                                                                                                                                                            |       |       |       |      |      |      |       |                         |

Figure 6. CCAPMn: PCA Modules Compare/Capture Registers

**PCA Capture Mode**

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated. Refer to Figure 8.

**16-bit Software Timer Mode**

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (see Figure 9).

**High Speed Output Mode**

In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (see Figure 10).

**Pulse Width Modulator Mode**

All of the PCA modules can be used as PWM outputs. Figure 11 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. the allows updating the PWM

without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

**Enhanced UART**

The UART operates in all of the usual modes that are described in the first section of this book for the 80C51. In addition the UART can perform framing error detect by looking for missing stop bits, and automatic address recognition. The 8XC51FC UART also fully supports multiprocessor communication as does the standard 80C51 UART.

When used for framing error detect the UART looks for missing stop bits in the communication. A missing bit will set the FE bit in the SCON register. The FE bit shares the SCON.7 bit with SM0 and the function of SCON.7 is determined by PCON.6 (SMOD0) (see Figure 13). If SMOD0 is set then SCON.7 functions as FE. SCON.7 functions as SM0 when SMOD0 is cleared. When used as FE SCON.7 can only be cleared by software. Refer to Figure 14.

Figure 7. PCA Module Modes (CCAPMn Register)

**Automatic Address Recognition**  
Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes, mode 2 and mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the "Given" address or the "Broadcast" address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data. Automatic address recognition is shown in Figure 15.

The 8 bit mode is called Mode 1. In this mode the RI flag will be set if SM2 is enabled and the information received has a valid stop bit following the 8 address bits and the information is either a Given or Broadcast address.

Mode 0 is the Shift Register mode and SM2 is ignored.

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the SADDR to create the "Given" address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

Slave 0      SADDR =    1100 0000  
              SADEN =    1111 1101  
              Given =    1100 00X0

Slave 1      SADDR =    1100 0000  
              SADEN =    1111 1110  
              Given =    1100 000X

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

Slave 0      SADDR =    1100 0000  
              SADEN =    1111 1001  
              Given =    1100 0XX0

Slave 1      SADDR =    1110 0000  
              SADEN =    1111 1010  
              Given =    1110 0X0X

Slave 2      SADDR =    1110 0000  
              SADEN =    1111 1100  
              Given =    1110 00XX

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are treated as don't-cares. In most cases, interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR (SFR address 0A9H) and SADEN (SFR address 0B9H) are loaded with 0s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares", this effectively disables the Automatic Addressing mode and allows the microcontroller to use standard 80C51 type UART drivers which do not make use of this feature.

### Reduced EMI Mode

The AO bit (AUXR.O) in the AUXR register when set disables the ALE output.

### 8XC51FC Reduced EMI Mode

#### AUXR (0X8E)

|   |   |   |   |   |   |   |    |
|---|---|---|---|---|---|---|----|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0  |
| - | - | - | - | - | - | - | AO |

AO: Turns off ALE output.

### Interrupt Priority Structure

The 8XC51FC has a 7-source four-level interrupt structure. There are 3 SFRs associated with the interrupts on the 8XC51FC. They are the IE and IP which are identical in function to those on the 80C51. In addition, there is the IPH (Interrupt Priority High) register that makes the four-level interrupt structure possible. The IPH is bit addressable and is located at SFR address B7H. The structure of the IPH register and a description of its bits is shown below:

#### IPH (Interrupt Priority High) (B7H)

|   |      |      |     |      |      |      |      |
|---|------|------|-----|------|------|------|------|
| 7 | 6    | 5    | 4   | 3    | 2    | 1    | 0    |
| - | PPCH | PT2H | PSH | PT1H | PX1H | PT0H | PX0H |

- IPH.0    PX0H    External interrupt 0 priority high
- IPH.1    PT0H    Timer 0 interrupt priority high
- IPH.2    PX1H    External interrupt 1 priority high
- IPH.3    PT1H    Timer 1 interrupt priority high
- IPH.4    PSH    Serial Port interrupt high
- IPH.5    PT2H    Timer 2 interrupt priority high
- IPH.6    PPCH    PCA interrupt priority high
- IPH.7    —    Not implemented

# CMOS single-chip 8-bit microcontrollers

# 83C51FC/87C51FC

The function of the IPH SFR is simple and when combined with the IP SFR determines the priority of each interrupt. The priority of each interrupt is determined as shown in the following table:

| PRIORITY BITS |      | INTERRUPT PRIORITY LEVEL   |
|---------------|------|----------------------------|
| IPH.x         | IP.x |                            |
| 0             | 0    | Level 0 (lowest priority)  |
| 0             | 1    | Level 1                    |
| 1             | 0    | Level 2                    |
| 1             | 1    | Level 3 (highest priority) |

The priority scheme for servicing the interrupts is the same as that for the 80C51, except there are four interrupt levels on the 8XC51FC rather than two as on the 80C51. An interrupt will be serviced as long as an interrupt of equal or higher priority is not already being serviced. If an interrupt of equal or higher level priority is being

serviced, the new interrupt will wait until it is finished before being serviced. If a lower priority level interrupt is being serviced, it will be stopped and the new interrupt serviced. When the new interrupt is finished, the lower priority level interrupt that was stopped will be completed.

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING                 | UNIT |
|----------------------------------------------------------------------------------------------|------------------------|------|
| Operating temperature under bias                                                             | 0 to +70 or -40 to +85 | °C   |
| Storage temperature range                                                                    | -65 to +150            | °C   |
| Voltage on $\overline{EA}/V_{PP}$ pin to $V_{SS}$                                            | 0 to +13.0             | V    |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5           | V    |
| Maximum $I_{OL}$ per I/O pin                                                                 | 15                     | mA   |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

**Electrical Deviations from Commercial Specifications for Extended Temperature Range**

DC and AC parameters not included here are the same as in the commercial temperature range table.

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 1.50 \times \text{FREQ} + 8$ ; Idle mode:  $I_{CCMAX} = 0.14 \times \text{FREQ} + 2.31$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 23.
- See Figures 24 through 27 for  $I_{CC}$  test conditions.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ . For  $T_{amb} = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ , see table on previous page.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 15mA (\*NOTE: This is 85°C specification.)
  - Maximum  $I_{OL}$  per 8-bit port: 26mA
  - Maximum total  $I_{OL}$  for all outputs: 71mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
10. ALE is tested to  $V_{OH1}$ , except when ALE is off then  $V_{OH}$  is the voltage specification.
11. Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA it is 25pF).

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 8XC51FC to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

CMOS single-chip 8-bit microcontrollers

**EXPLANATION OF THE AC SYMBOLS**

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:  
 A – Address  
 C – Clock  
 D – Input data  
 H – Logic level high  
 I – Instruction (program memory contents)  
 L – Logic level low, or ALE

P – PSEN  
 Q – Output data  
 R – RD signal  
 t – Time  
 V – Valid  
 W – WR signal  
 X – No longer a valid logic level  
 Z – Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

### EPROM CHARACTERISTICS

The 87C51FC is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C51FC contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C51FC manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 28 and 29. Figure 30 shows the circuit configuration for normal program memory verification.

### Quick-Pulse Programming

The setup for microcontroller quick-pulse programming is shown in Figure 28. Note that the 87C51FC is running with a 4 to 6MHz oscillator. The reason the oscillator needs to

be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 28. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 29.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/ $V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

### Program Verification

If security bits 2 and 3 have not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 30. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the 64 byte encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

## CMOS single-chip 8-bit microcontrollers

## 83C51FC/87C51FC

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = B3H indicates 87C51FC

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000 $\mu$ W/cm<sup>2</sup> rating for

20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Security Bits**

With none of the security bits programmed the code in the program memory can be verified. If the encryption table is programmed, the code will be encrypted when verified. When only security bit 1 is programmed, MOV<sub>C</sub> instructions executed from external program memory are disabled from fetching code bytes from the internal memory, EA is latched on Reset and all further programming of the EPROM is disabled. When security bits 1 and 2 are programmed, in addition to the above, verify mode is disabled. When all three security bits are programmed, all of the conditions above apply and all external program memory execution is disabled.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/V <sub>PP</sub> | P2.7 | P2.6 | P3.7 | P3.6 | P3.3 |
|----------------------|-----|------|----------|--------------------|------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                  | 0    | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                  | 0    | 0    | 1    | 1    | 0    |
| Pgm encryption table | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 0    | 1    |
| Pgm security bit 1   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 0    | 0    | 1    |
| Pgm security bit 3   | 1   | 0    | 0*       | V <sub>PP</sub>    | 0    | 1    | 0    | 1    | 1    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

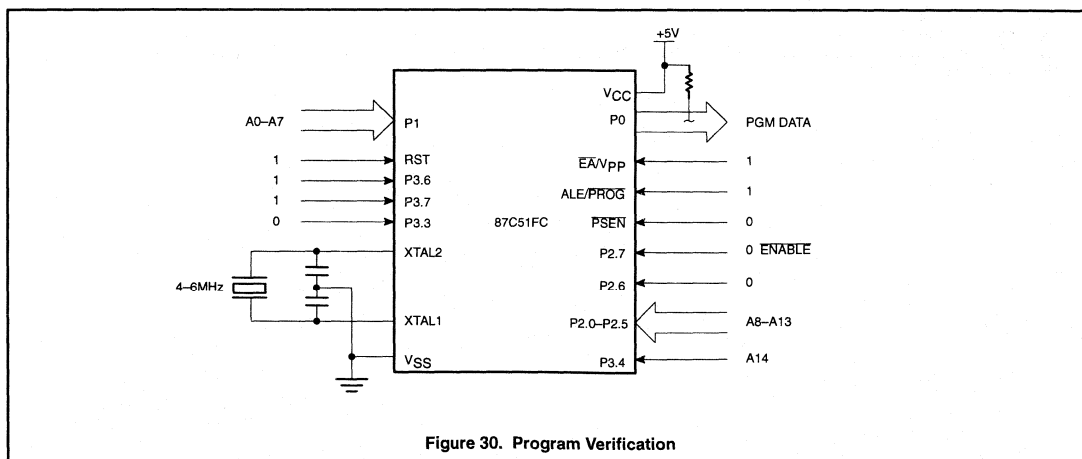

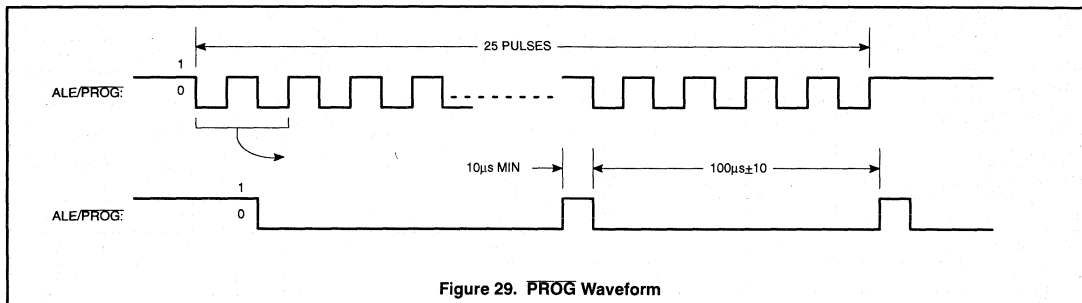

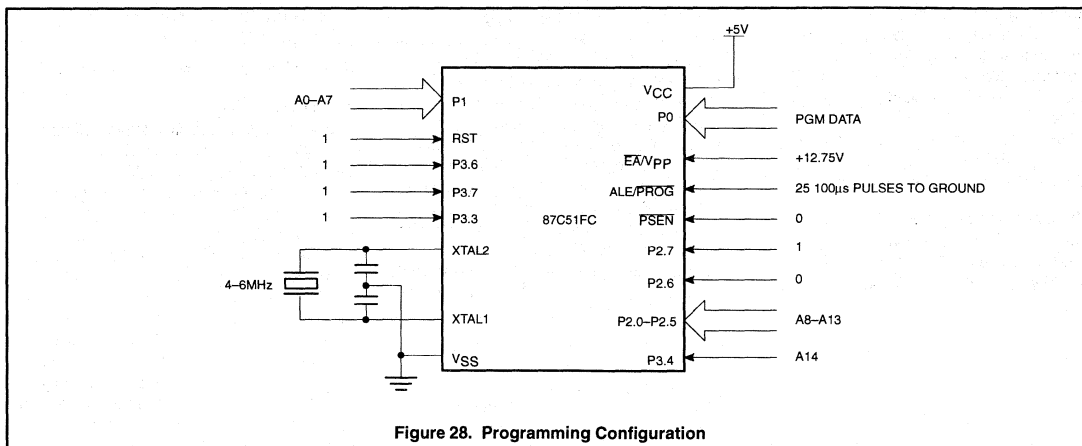

2. V<sub>PP</sub> = 12.75V  $\pm$ 0.25V.

3. V<sub>CC</sub> = 5V  $\pm$ 10% during programming and verification.

\* ALE/PROG receives 25 programming pulses while V<sub>PP</sub> is held at 12.75V. Each programming pulse is low for 100 $\mu$ s ( $\pm$ 10 $\mu$ s) and high for a minimum of 10 $\mu$ s.

# Low-voltage single-chip 8-bit microcontrollers

# 80CL31/80CL51

## FEATURES

- Full static 80C51 CPU
- 8-bit CPU, ROM, RAM, 1/0 in a single 40-lead DIL / mini-pack
- 4K x 8 ROM, expandable externally to 64K bytes
- 128 bytes RAM, expandable externally to 64K bytes
- Four 8-bit ports, 321/0 lines
- Two 16-bit timer / event counters
- External memory expandable up to 128K, external ROM up to 64K and / or RAM up to 64K
- On-chip oscillator suitable for RC, LC, quartz crystal or ceramic resonator
- Thirteen source, thirteen vector interrupt structure with two priority levels
- Full duplex serial port (UART)

- Enhanced architecture with:
  - non-page oriented instructions
  - direct addressing
  - four eight byte RAM register banks
  - stack depth up to 128 bytes
  - multiply, divide, subtract and compare instructions
- Power-Down and IDLE instructions
- Wake-up via external interrupts at Port 1
- Single supply voltage of 1.8V to 6.0V (5.0V  $\pm$ 10% for P80C51)
- Frequency range of 0 to 16MHz (3.5MHz to 16MHz for P80C51)
- Very low current consumption
- Operating temperature range: -40 to +85°C

## DESCRIPTION

The 80CL51 is manufactured in an advanced CMOS technology. The instruction set of the 80CL51 is based on that of the 8051. The 80CL51 is a general purpose microcontroller especially suited for battery-powered applications. The device has low power consumption and a wide range of supply voltage. For emulation purposes, the 85CL000 (Piggy-back version) with 256 bytes of RAM is recommended. The 80CL51 has two software selectable modes of reduced activity for further power reduction: Idle and Power-down. The 80CL51 also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 46 two-byte, and 16 three-byte.

The P80CL31 is the ROMless version of the P80CL51. P80C51 is a 5V version of the low voltage P80CL51.

The P80CL31 is the ROMless version of the P80CL51. P80C51 is a 5V version of the low voltage P80CL51.

| 40    | 1     | P1.0/INT2             | <p><b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pullups. Port 1 pins that have 1s written to them are pulled HIGH by the internal pullups, and in that state can be used as inputs. The Port 1 output buffer can sink/source 4 LS TTL loads. As inputs, Port 1 pins that are externally pulled LOW will source current (<math>I_{IL}</math> in the characteristics) due to the internal pullups. Port 1 also serves the alternative functions INT2 to INT9.</p>                                                                                                                               |
| 41    | 2     | P1.1/INT3             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

ALE is emitted at a constant rate of 1/6 of the oscillator frequency, and may be used for external timing or clocking purposes.</p>                                                                                                                                                                                                                                                                                                                                                             |
| 29    | 31    | $\overline{EA}$       | <p><b>External Access:</b> When EA is held High the CPU executes out of internal program memory (unless the program counter exceeds 0FFFH). Holding EA LOW forces the CPU to execute out of external memory regardless of the value of the program counter.</p>                                                                                                                                                                                                                                                                                                                                                         |
| 30-37 | 32-39 | P0.0-P00.7            | <p><b>Port 0:</b> Port 0 is an 8-bit open drain bidirectional I/O port. As an open drain output port it can sink 8 LS TTL loads. Port 0 pins that have 1s written to them float, and in that state will function as high impedance inputs. Port 0 is also the multiplexed low order address and data bus during access to external memory. In this application it uses strong internal pull-ups when emitting logic 1s.</p>                                                                                                                                                                                             |
| 38    | 40    | V <sub>DD</sub>       | <p><b>Power supply.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## BLOCK DIAGRAM

## FUNCTIONAL DIAGRAM

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

## 1.0 FUNCTIONAL DESCRIPTION

**General**

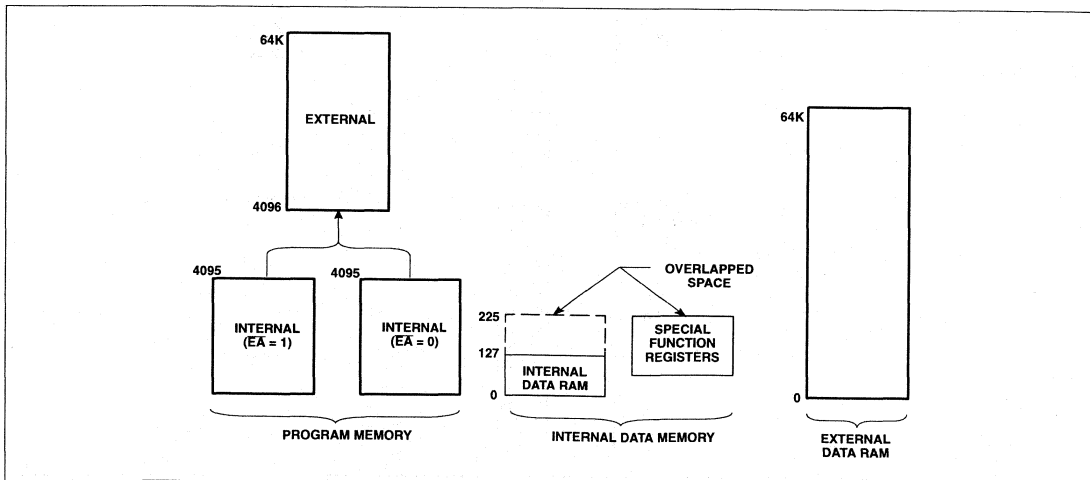

The 80CL51 is a stand-alone high-performance CMOS microcontroller designed for use in real-time applications such as instrumentation, industrial control, intelligent computer peripherals and consumer products.

The device provides hardware features, architectural enhancements and new instructions to function as a controller for applications requiring up to 64K bytes of program memory and/or up to 64K bytes of data storage.

The 80CL51 contains a non-volatile 4K byte  $\times$  8 read-only program memory; a static 128 byte  $\times$  8 read/write data memory; 32 1/0 lines; two 16-bit timer/event counters; a thirteen- source two priority-level, nested interrupt structure and on-chip oscillator and timing circuit.

The device has two software selectable modes of reduced activity for power reduction: IDLE and Power-down. The Idle mode freezes the CPU while allowing the RAM, timers, serial I/O and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes the oscillator causing all other chip functions to be inoperative.

The P80C51 is a 5V version of the low voltage microcontroller P80CL51. Hereafter the generic term P80CL51 will be used for the functional description of both types. The special features of the P80C51 are handled in chapter 1.9.

**MEMORY MAP****CPU timing**

A machine cycle consists of a sequence of 6 states. Each state time lasts for two oscillator periods, thus a machine cycle takes 12 oscillator periods or 1 $\mu$ s if the oscillator frequency is 12MHz.

**1.1 Memory organization**

The 80CL51 has a 4K Program Memory (ROM) plus 128 bytes of Data Memory (RAM) on board. The device has separate address spaces for Program and Data Memory (see Memory Map). Using Ports P0 and P2, the 80CL51 can address up to 64K bytes of external memory. The CPU generates both read and write signals (RD and WR) for external Data Memory accesses, and the read strobe (PSEN) for external Program Memory.

**1.1.1 Program Memory**

The 80CL51 contains 4K bytes of internal ROM. After reset the CPU begins execution at location 0000H. The lower 4K bytes of Program Memory can be implemented in either on-chip ROM or external Memory. If the EA pin is strapped to V<sub>DD</sub>, then program memory fetches from addresses 000H through 0FFFH are directed to the internal ROM. Fetches from addresses 1000H through FFFFH are directed to external ROM. Program counter values greater than 0FFFH are automatically addressed to external memory regardless of the state of the EA pin.

**1.1.2 Data Memory**

The 80CL51 contains 128 bytes of internal RAM and 25 Special Function Registers (SFR). The Memory Map below shows the

internal Data Memory space divided into the Lower 128, the Upper 128, and the SFR space.

The lower 128 bytes of the internal RAM are organized as mapped in Figure 1. The lowest 32 bytes are grouped into 4 banks of 8 registers. Program instructions refer to these registers R0 through R7. Two bits in the Program Status Word select which register bank is in use. The next 16 bytes above the register banks form a block of bit-addressable memory space. The 128 bits in this area can be directly addressed by the single-bit manipulation instructions. The remaining registers (30H to 7FH) are directly and indirectly byte addressable.

**1.1.3 Special Function Registers**

The upper 128 bytes are the address locations of the SFRs. Figure 2 shows the Special Function Register (SFR) space. SFRs include the port latches, timers, peripheral control, serial I/O registers, etc. These registers can only be accessed by direct addressing. There are 128 addressable locations in the SFR address space (SFRs with addresses divisible by eight).

**1.1.4 Addressing**

The 80CL51 has five methods for addressing source operands:

- Register
- Direct
- Register-Indirect
- Immediate
- Base-Register-plus Index-Register-indirect

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

Figure 1. The Lower 128 Bytes of Internal RAM

The first three methods can be used for addressing destination operands. Most instructions have a "destination/source" field that specifies data type, addressing methods and operands involved. For operations other than MOVs, the destination operand is also a source operand.

Access to memory addressing is as follows:

- Registers in one of the four register banks through register, direct or indirect.
- Internal RAM (128 bytes) through direct or register-indirect.
- Special Function Register through Direct.
- External data memory through Register-Indirect
- Program memory look-up tables through Base-Register-Plus Index-Register-Indirect.

## 1.2 I/O Facilities

### 1.2.1 Ports

The 80CL51 has 32 I/O lines treated as 32 individually addressable bits or as four parallel 8-bit addressable ports. Port 0, 1, 2 and 3 perform the following alternate functions:

- Port 0: provides the multiplexed low-order address and data bus for expanding the device with standard memories and peripherals.
- Port 1: provides the inputs for the external interrupts INT2/INT9.
- Port 2: provides the high-order address when expanding the device with external program or data memory.
- Port 3: pins can be configured individually to provide:
- (1) external interrupt request inputs
  - (2) counter input
  - (3) control signals to read and write to external memories
  - (4) UART input and output

To enable a Port 3 pin alternate function, the Port 3 bit latch in its SFR must contain a logic 1.

Each port consists of a latch (Special Function Registers P0 to P3), an output driver and an input buffer. Ports 1,2,3 have internal pull ups. Figure 3(a) shows that the strong transistor p1 is turned on for only 2 oscillator periods after a 0-to-1 transition in

the port latch. When on, it turns on p3 (a weak pull up) through the inverter. This inverter and p3 form a latch which hold the 1. In Port 0 the pull up p1 is only on when emitting 1s for external memory access. Writing a 1 to a Port 0 bit latch leaves both output transistors switched off so the pin can be used as a high-impedance input.

### 1.2.2 Port Options

The pins of port 1, port 2, and port 3 may be individually configured with one of the following options (see Figure 3):

Option 1: Standard Port; quasi-bidirectional I/O with pull up. The strong booster pull up p1 is turned on for two oscillator periods after a 0-to-1 transition in the port latch (see Figure 3(a)).

Option 2: Open drain; quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull up resistor (see Figure 3(c)).

Option 3: Push-Pull; output with drive capability in both polarities. Under this option, pins can only be used as outputs. See Figure 3(b).

Low-voltage single-chip 8-bit microcontrollers

80CL31/80CL51

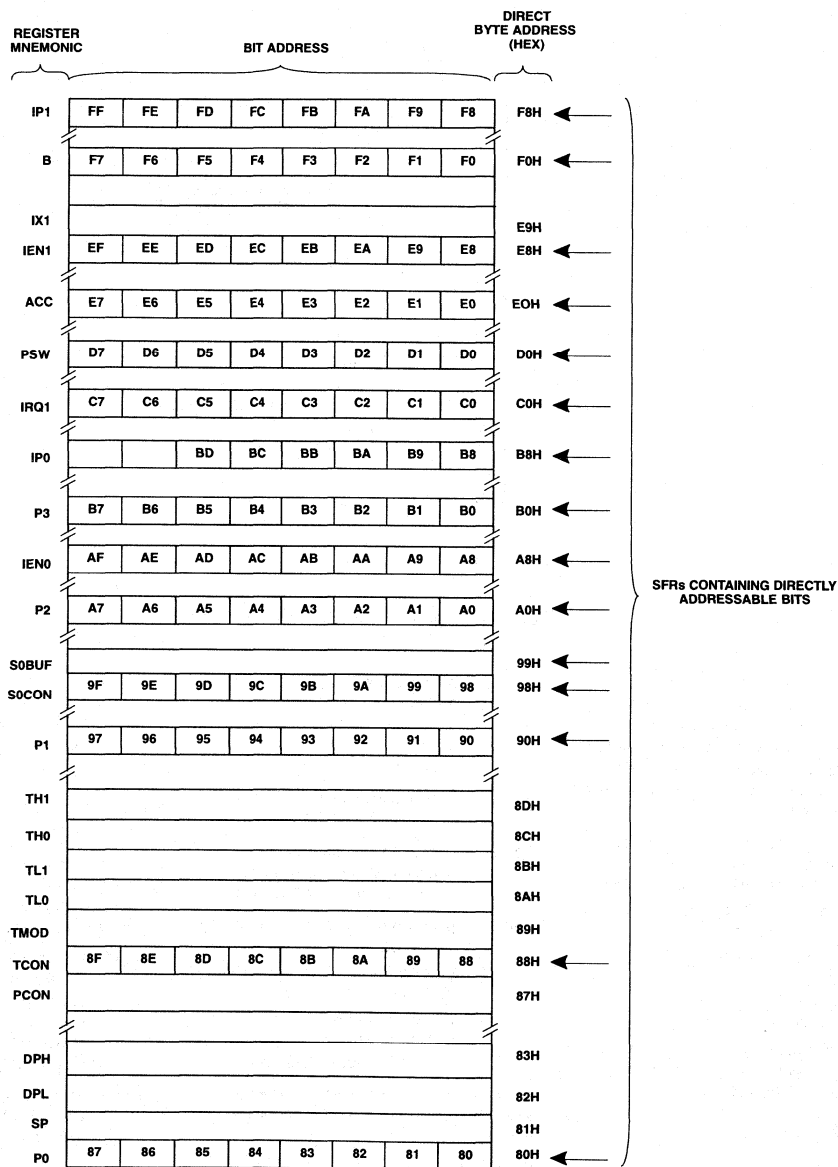

Figure 2. Special Function Registers

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

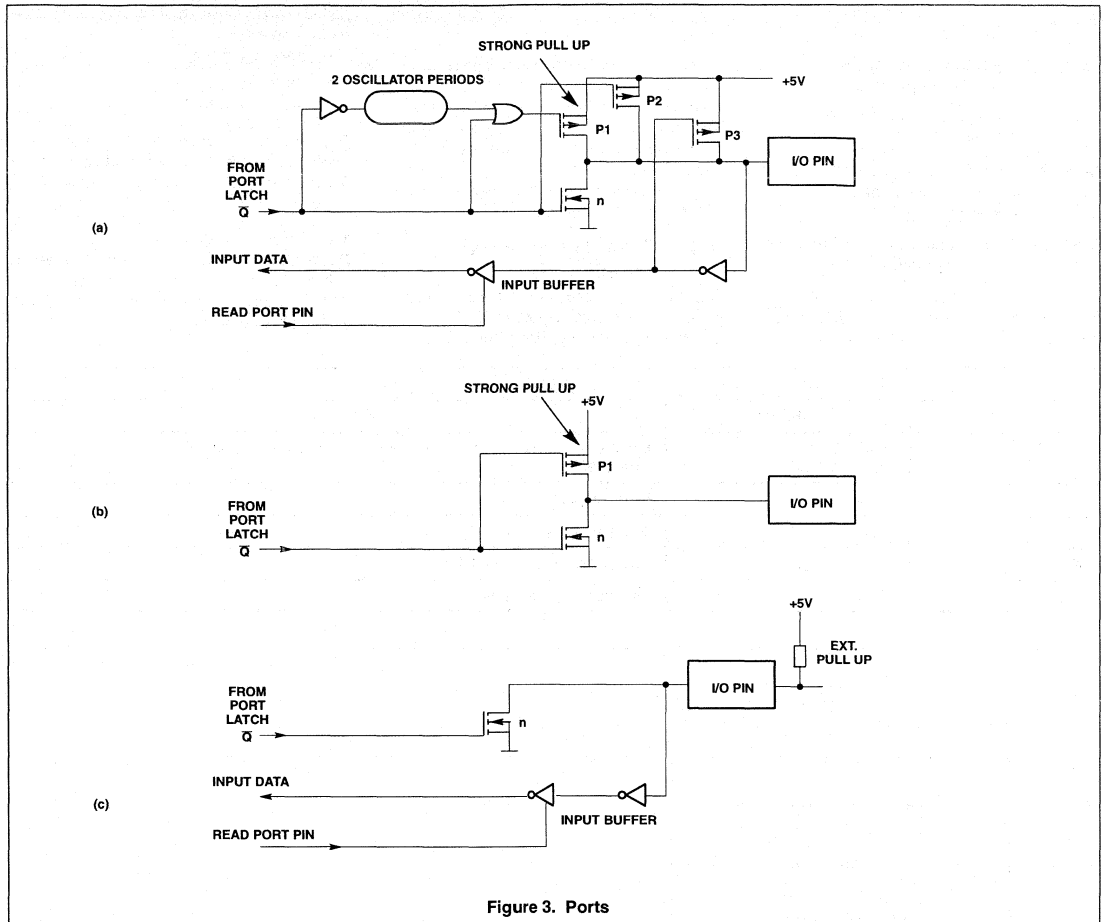

Figure 3. Ports

The definition of port options for port 0 is slightly different. Two cases have to be examined. First, accesses to external memory (EA=0 or access above the built-in memory boundary), second, I/O accesses.

#### External Memory Accesses

- Option 1: True 0 and 1 are written as address to the external memory (strong pull up is used).
- Option 2: An external pull up resistor is needed for external accesses.
- Option 3: Not allowed for external memory access as the port can only be used as output.

#### I/O Accesses

- Option 1: When writing a 1 to the port-latch, the strong pull up p1 will be on for 2 oscillator periods. No weak pull up exists. Without an external pull up, this option can be used as a high-impedance input.
- Option 2: Open drain; quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull up resistor (see Figure 3(c)).
- Option 3: Push-Pull; output with drive capability in both polarities. Under this option, pins can only be used as outputs.

Individual mask selection of the post-reset state is available on any of the above pins. Make your selection by appending "S" or "R" to option 1, 2, or 3 above (e.g. 1 S for a standard I/O to be set after RESET or 2R for an open-drain I/O to be reset after RESET).

#### 1.3 Timer/event counter

The 80CL51 contains two 16-bit Timer/Counter registers, Timer 0 and Timer 1, which can perform the following functions:

- Measure time intervals and pulse durations
- Count events
- Generate interrupts requests

# Low-voltage single-chip 8-bit microcontrollers

# 80CL31/80CL51

Timer 0 and Timer 1 can be independently programmed to operate as follows:

- Mode 0 - 8-bit timer or counter with divide-by-32 prescaler
- Mode 1 - 16-bit time-interval or event counter
- Mode 2 - 8-bit time interval or event counter with automatic reload upon overflow
- Mode 3 - Timer 0 establishes TL0 and TH0 as two separate counters.

In the "Timer" function, the register is incremented every machine cycle. Since a machine cycle consists of 12 oscillator

periods, the count rate is 1/12 of the oscillator frequency.

In the "Counter" function, the register is incremented in response to a 1-to-0 transition. Since it takes 2 machine cycles (24 oscillator periods) to recognize a 1-to-0 transition, the maximum count rate is 1/24 of the oscillator frequency. To ensure a given level is sampled, it should be held for at least one full machine cycle.

### 1.4 Idle and Power-down operation

Idle mode operation permits the interrupt, serial port and timer blocks to continue functioning while the clock to the CPU is

halted. The following functions remain active during Idle mode:

- Timer 0, Timer 1
- UART
- External interrupt

The Power-down operation freezes the oscillator. The Power-down mode can only be activated by setting the PD bit in the PCON register.

#### 1.4.1 Power control register

Power-down and Idle modes are activated by software via the Special Function Register PCON. Its hardware address is 87H. PCON is byte addressable only.

| PCON |                         |                                                                            |
|------|-------------------------|----------------------------------------------------------------------------|
| BIT  | POSITION                | FUNCTION                                                                   |
| SMOD | PCON.7<br>PCON.4-PCON.6 | Double baud-rate bit, see description of the UART, chapter 1.5. (reserved) |
| GF1  | PCON.3                  | General purpose flag bit                                                   |
| GFO  | PCON.2                  | General purpose flag bit                                                   |
| PD   | PCON.1                  | Power-down activation bit                                                  |
| IDL  | PCON.0                  | Idle mode activation bit                                                   |

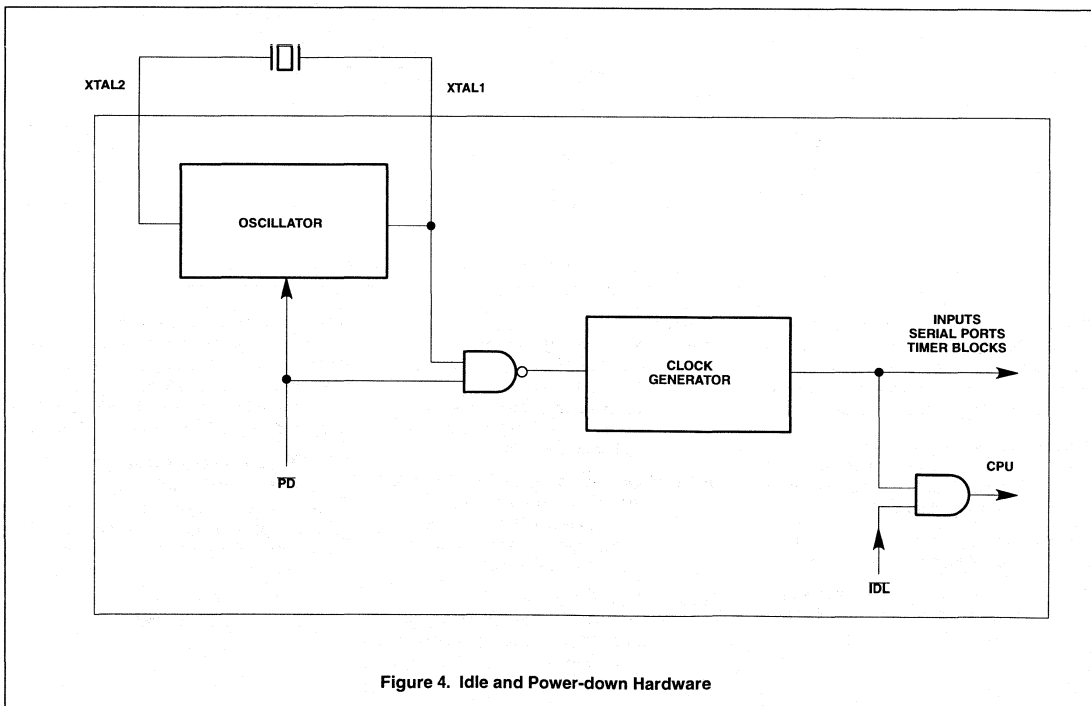

Figure 4. Idle and Power-down Hardware

# Low-voltage single-chip 8-bit microcontrollers

# 80CL31/80CL51

### 1.4.2 Power-down mode

The instruction setting PCON.1 is the last executed prior to going into the Power-down mode. In Power-down mode the oscillator is stopped. The contents of the on-chip RAM and SFRs are preserved. The port pins output the values held by their respective SFRs. ALE and PSEN are held LOW.

In the Power-down mode  $V_{DD}$  may be reduced to minimize power consumption. However, the supply voltage must not be reduced until Power-down mode is active, and must be restored before the hardware reset is applied and frees the oscillator. Reset must be held active until the oscillator has restarted and stabilized.

The wake-up operation after power-down in this controller has two basic approaches:

#### 1.4.2.1 Wake-up using INT2 to INT9

If INT2 to INT9 are enabled, the 80CL51 can be awakened from power-down mode with the external interrupts. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods. This is controlled by an on-chip delay counter.

#### 1.4.2.2 Wake-up using RESET

To wake-up the 80CL51 the RESET pin has to be kept HIGH for a minimum of 24 oscillator periods. The on-chip delay counter is inactive. The user has to ensure that the oscillator is stable before any operation is attempted. Figure 5 illustrates the two possibilities for wake-up.

#### 1.4.3 Idle mode

The instruction that sets PCON.0 is the last instruction executed before going into Idle mode. Once in the Idle mode, the internal clock is gated away from the CPU, but not from the Interrupt, Timer and Serial port functions. The CPU status is preserved along with the Stack Pointer, Program Counter, Program Status Word and Accumulator. The RAM and all other registers maintain their data during Idle mode. The port pins retain the logical states they held at Idle mode activation. ALE and PSEN hold at the logic HIGH level.

There are two methods used to terminate the Idle mode. Activation of any enabled interrupt will cause PCON to be cleared by hardware, terminating Idle mode. The interrupt is serviced, and following the instruction RETI, the next instruction to be executed will be the

one following the instruction that put the device in the Idle mode.

Flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When Idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.

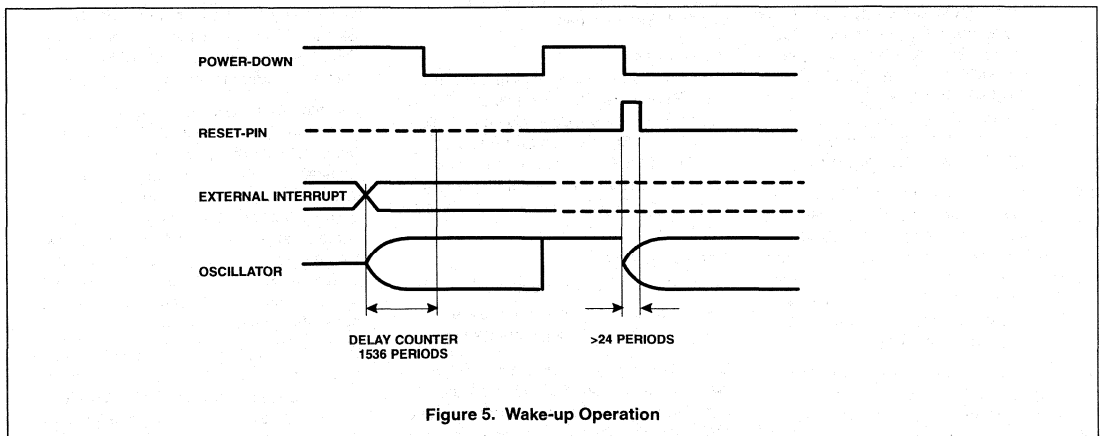

The second method of terminating the Idle mode is with an external hardware reset. Since the oscillator is still running, the hardware reset is required to be active for only two machine cycles to complete the reset operation.

Reset redefines all SFRs, but does not affect the on-chip RAM.

The status of the external pins during Idle and Power-down mode is shown in Table 4. If the Power-down mode is activated while accessing external memory, port data held in the Special Function Register P2 is restored to Port 2. If the data is a logic 1, the port pin is held HIGH during the Power-down mode by the strong pull up transistor p1 (see Figure 3(a)).

**Table 4. Status of the External Pins During Idle and Power-down Mode**

| MODE       | MEMORY   | ALE | PSEN | PORT 0    | PORT 1    | PORT 2    | PORT 3    |
|------------|----------|-----|------|-----------|-----------|-----------|-----------|
| Idle       | internal | 1   | 1    | Port Data | Port Data | Port Data | Port Data |
| Idle       | external | 1   | 1    | Floating  | Port Data | Address   | Port Data |
| Power-down | internal | 0   | 0    | Port Data | Port Data | Port Data | Port Data |
| Power-down | external | 0   | 0    | Floating  | Port Data | Port Data | Port Data |

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

### 1.5 Standard serial interface SIO: UART

This serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the register. (However, if the first byte still hasn't been read by the time reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed at Special Function Register S0BUF. Writing to S0BUF loads the transmit register, and reading S0BUF loads the transmit register, and reading S0BUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

- Mode 0:** Serial data enters and exits through RxD. TxD outputs the shift clock. 8 bits are transmitted/ received (LSB first). The baud is fixed at 1/12 the oscillator frequency.
- Mode 1:** 10 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SCON. The baud rate is variable.
- Mode 2:** 11 bits are transmitted (through TxD) or received (through RxD): start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8 in SCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in Special Function Register SCON, while the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency.
- Mode 3:** 11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses S0BUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

#### 1.5.1 Multiprocessor communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows:

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their SM2s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

#### 1.5.2 Serial port control register

The serial port control and status register is the Special Function Register S0CON, shown in Figure 6. The register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (T1 and R1). See next page.

#### Baud Rates

The baud rate in Mode 0 is fixed: Mode 0 Baud Rate = Oscillator Frequency /12. The baud rate in Mode 2 depends on the value of bit SMOD in Special Function Register PCON. If SMOD = 0 (which is the value on reset), the baud rate is 1/64 the oscillator frequency. If SMOD = 1, the baud rate is 1/32 the oscillator frequency.

Mode 2 Baud Rate =  $(2^{SMOD}/64)(\text{Oscillator Frequency})$

The baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate.

#### Using Timer 1 to generate baud rates

When Timer 1 is used as the baud rate generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of SMOD as follows:

$(2^{SMOD}/32)(\text{Timer 1 Overflow Rate})$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either "timer" or "counter" operation, and in any of its 3 running modes. In the most typical applications, it is configured for "timer operation, in the auto-reload mode (high nibble of TMOD = 0010B). In that case the baud rate is given by the formula:

Mode 1, 3 Baud Rate =  $\{ (2^{SMOD}/32) (\text{Oscillator Frequency}) \} / \{ 12 (256 - (TH 1)) \}$

One can achieve very low baud rates with Timer 1 by leaving the Timer 1 interrupt enabled, and configuring this Timer to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload. Table 5 lists various commonly used baud rates and how they can be obtained from Timer 1.

#### More about Mode 0

Figure 7 shows a simplified functional diagram of the serial port in Mode 0, and associated timing. Transmission is initiated by any instruction that uses S0BUF as a destination register. The "write to S0BUF" signal at S6P2 also loads a 1 into the 9th position of the transmit shift register and tells the TX Control block to commence a transmission. The internal timing is such that the one full machine cycle will elapse between "write to S0BUF", and activation of SEND.

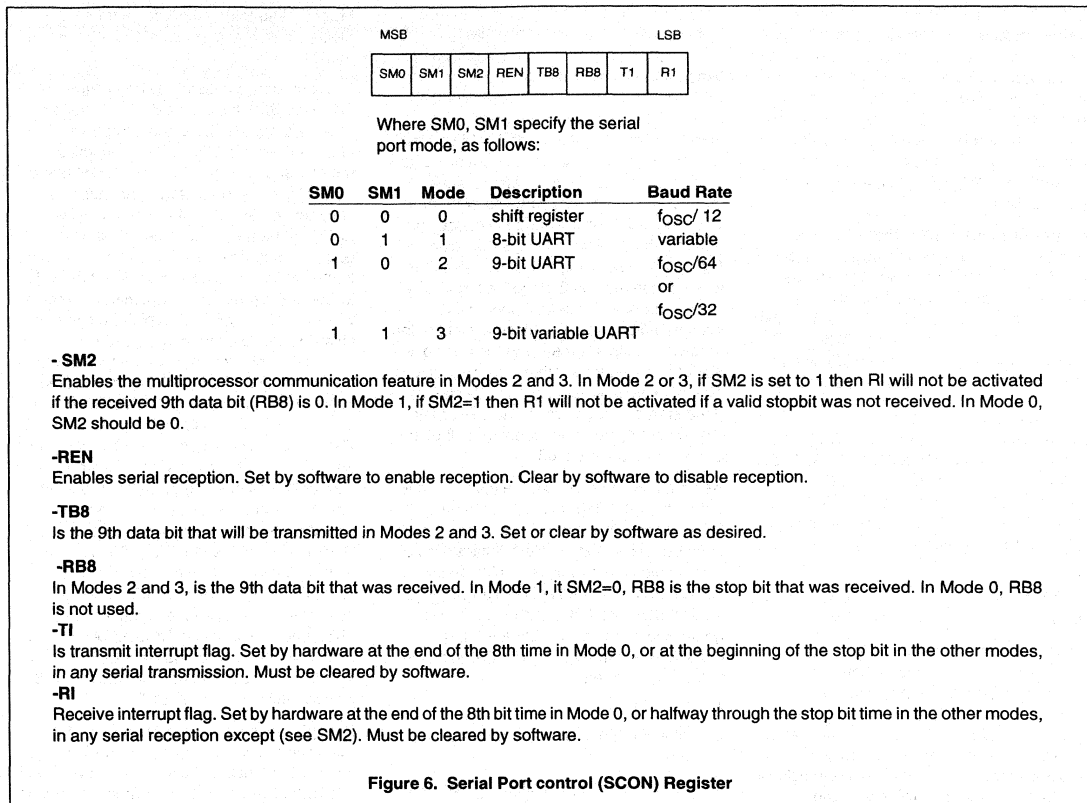

SEND enables the output of the shift register to the alternate output function line of P3.0 and also enables SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK is low during S3, S4, and S5 of every machine cycle, and high during S6, S1 and S2. At S6P2 of every machine cycle in which SEND is active, the contents of the transmit shift are shifted to the right one position.

As data bits shift out to the right, zeros come in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain zeros. This condition flags the TX Control block to do one last shift and then deactivate SEND and set T1. Both of these actions occur at S1P1 of the 10th machine cycle after "write to S0BUF".

Reception is initiated by the condition REN = 1 and R1 = 0. At S6P2 of the next machine cycle, the RX Control unit writes the bits 11111110 to the receive shift register, and in the next clock phase activates RECEIVE.

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

RECEIVE enables SHIFT CLOCK to the alternate output function line of P3.1. SHIFT CLOCK makes transitions at S3P1 and S6P1 of every machine cycle. At S6P2 of every machine cycle in which RECEIVE is active, the contents of the receive shift register are shifted to the left one position. The value that comes in from the right is the value that was sampled at the P3.0 pin at S5P2 of the same machine cycle.

As data bits come in from the right, 1s shift out to the left. When the 0 that was initially loaded into the right-most position arrives at the left-most position in the shift register, it flags the RX Control block to do one last shift and load S0BUF. At S1P1 of the 10th machine cycle after the write to SCON that cleared RI, RECEIVE is cleared as RI is set.

### More about Mode 1

Ten bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in SCON. In the 8051 the baud rate is determined by the Timer 1 overflow rate.

Figure 8 shows a simplified functional diagram of the serial port in Mode 1, and associated timings for transmit/receive.

Transmission is initiated by any instruction that uses S0BUF as a destination register. The "write to S0BUF" signal also loads a 1 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission actually commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter. (Thus, the bit times are synchronized to the divide-by-16 counter, not to the "write to S0BUF" signal).

The transmission begins with activation of SEND which sends the start bit to pin TxD. One bit time later, DATA is activated, enabling the transmission of the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that.

As data bits shift out to the right, zeros are clocked in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain zeros. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 10th divide-by-16 rollover after "write to S0BUF". Reception is initiated by a detected

1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFFH is written into the input shift register. Resetting the divide-by-16 counter aligns its rollovers with the boundaries of the incoming bit times. The 16 states of the counter divide each bit time into 16th. At the 7th, 8th, and 9th counter states of each bit time, the bit detector samples the value of RxD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done for noise rejection. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. This is to provide rejection of false start bits. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the left-most position in the shift register, (which in mode 1 is a 9-bit register), it flags the RX Control block to do one last shift, loads S0BUF and RB8, and set RI. The signal to load S0BUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

1. R1 = 0, and
2. Either SM2 = 0, or the received stop bit = 1

If either of these two conditions is not met, the received frame is irretrievably lost. If both conditions are met, the stop bit goes into RB8, the 8 data bits go into S0BUF, and RI is activated. At this time, whether the above conditions are met or not, the unit goes back to looking for a 1-to-0 transition in RxD.

### More about modes 2 and 3

Eleven bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmit, the 9th data bit (TB8) can be assigned the value of 0 or 1. On receive, the 9th data bit goes into RB8 in SCON. The baud rate is programmable to either 1/32 or 1/64 the oscillator frequency in Mode 2. Mode 3 may have a variable baud rate generated from Timer 1.

Figures 9 and 10 show a functional diagram of the serial port in Modes 2 and 3. The receive portion is exactly the same as in

Mode 1. The transmit portion differs from Mode 1 only in the 9th bit of the transmit shift register.

Transmission is initiated by any instruction that uses S0BUF as a destination register. The "write to S0BUF" signal also loads TB8 into the 9th bit position of the transmit shift register and flags the TX Control unit that a transmission is requested. Transmission commences at S1P1 of the machine cycle following the next rollover in the divide-by-16 counter (thus, the bit times are synchronized to the divide-by-16 counter, not to the "write to S0BUF" signal). The transmission begins with activation of SEND, which puts the start bit at TxD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that. The first shift clocks a 1 (the stop bit) into the 9th bit position of the shift register. Thereafter, only zeros are clocked in. Thus, as data bits shift out to the right, zeros are clocked in from the left. Then TB8 is at the output position of the shift register, then the stop bit is just to the left of TB8, and all positions to the left of that contains zeros. This condition flags the TX Control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 11th divide-by-16 rollover after "write to S0BUF".

Reception is initiated by a detected 1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FFFH is written to the input shift register.

At the 7th, 8th and 9th counter states of each bit time, the bit detector samples the value of RxD. The value accepted is the value that was seen in at least 2 of the 3 samples. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed. As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the left-most position in the shift register (which in Modes 2 and 3 is a 9-bit register), it flags the RX Control block to do one last shift, load S0BUF and RB8, and set RI.

## 80CL31/80CL51

The signal to load S0BUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

1. RI = 0, and
2. Either SM2 = 0 or the received 9th data bit = 1

If either of these conditions is not met, the received frame is irretrievably lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bits go into S0BUF. One bit time later, whether the above conditions were met or not, the unit goes back to looking for a 1-to-0 transition at the RxD input.

### 1.6 Interrupt System

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to do execution of any

particular section of code. To tie the asynchronous activities of these functions to normal program execution, a multiple-source, two-priority-level, nested interrupt system is provided. The 80CL51 acknowledges interrupt requests from thirteen sources as follows:

- INT0 and INT1
- Timer 0 and Timer 1
- UART serial I/O
- INT2 to INT9 (Port 1)

Each interrupt vector to a separate location in program memory for its service routine. Each source can be individually enabled or disabled by corresponding bits in the Interrupt Enable Registers (IE, IEO). The priority level is selected via the Interrupt Priority register (IP0, IP1). All enabled sources can be globally disabled or enabled.

#### 1.6.1 External Interrupts INT2/INT9

Port 1 lines serve an alternative purpose as eight additional interrupts INT2 to INT9. When enabled, each of these lines may "wake-up" the device from Power-down mode. Using the IX1 register, each pin may be initialized to either active HIGH or LOW. IRQ1 is the interrupt request flag register. Each flag, if the interrupt is enabled, will be set on an interrupt request but must be cleared by software, i.e. via the interrupt software or when the interrupt is disabled.

The Port 1 interrupts are level sensitive. A Port 1 interrupt will be recognized when a level (HIGH or LOW depending on Interrupt Polarity Register IX1) on P1x is held active for at least one machine cycle. The Interrupt Request is not served until the next machine cycle.

### 1.6.2 Interrupt Vectors

|    | Vector | Source     |
|----|--------|------------|
| X0 | 0003H  | External 0 |
| S0 | 0023H  | UART SIO   |
| X5 | 0053H  | External 5 |
| T0 | 000BH  | Timer 0    |
| X6 | 005BH  | External 6 |
| X1 | 0013H  | External 1 |
| X2 | 003BH  | External 2 |
| X7 | 0063H  | External 7 |
| T1 | 001BH  | Timer 1    |
| X3 | 0043H  | External 3 |
| X8 | 006BH  | External 8 |
| X4 | 004BH  | External 4 |
| X9 | 0073H  | External 9 |

#### Interrupt priority

Each interrupt priority source can be set to either high or low priority. If both priorities are requested simultaneously, the controller will branch to the high priority vector.

A low priority interrupt can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

### 1.6.3 Related registers

The following registers are used in conjunction with the interrupt system:

| Register | Function                                |
|----------|-----------------------------------------|
| IX1      | Interrupt polarity register             |
| IRQ1     | Interrupt enable register               |
| IEN1     | Interrupt enable register (INT2-INT9)   |
| IPO      | Interrupt priority register             |
| IP1      | Interrupt priority register (INT2-INT9) |

### 1.7 Oscillator registers

The on-chip circuitry of the 80CL51 is a single-stage inverting amplifier biased by an internal feedback resistor (Figure 13). For operation as standard quartz oscillator, no external components are needed except at 32 KHz. When using external capacitors, ceramic resonators, coils and RC networks to drive the oscillator, five different configurations are supported (see Figure 14 and oscillator options).

In the Power-down mode the oscillator is stopped XTAL1 is pulled HIGH. The oscillator inverter is switched off to ensure no current will flow regardless of the voltage at XTAL1. To drive the device with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 to float, as shown

in Figure 14(f). There are no requirements on the duty cycle of the external clock, since the input to the internal clocking circuitry is split sing a flip-flop.

The following options are provided for optimum on-chip oscillator performance. Please state option when ordering.

#### 1.7.1 Oscillator options (see Figure 14)

The following options are provided for optimum on-chip oscillator performance. Please state option when ordering.

- Osc. 1: : Figure 14(c): An option for 32 kHz clock applications with external trimmer for frequency adjustment. A 4.7 MΩ bias resistor is needed for use in parallel with the crystal.
- Osc. 2: Figure 14(e): An option for low-power, low-frequency operations using LC components.
- Osc. 3: An option for medium frequency range applications.
- Osc. 4: An option for high frequency range applications.
- RC: Figure 14(g): An option for an RC oscillator.

## NOTES:

- 32 kHz quartz crystals with a series resistance higher than 15 k $\Omega$  will reduce the guaranteed supply voltage range to 2.5 -3.5V.
- The equivalent circuit data of the internal oscillator compares with that of matched crystals.

# Low-voltage single-chip 8-bit microcontrollers

# 80CL31/80CL51

## 1.7.2 RC Oscillator (see Figure 16)

The externally adjustable RC-oscillator has a frequency range from 100 kHz to 500 kHz.

## Low-voltage single-chip 8-bit microcontrollers

## 80CL31/80CL51

### 1.8 Reset Circuitry

To initialize the 80CL51, a reset is performed by either of two methods:

- via the RST pin
- via a power-on-reset

It leaves the internal registers as follows:

| REGISTER | CONTENT   |
|----------|-----------|
| ACC      | 0000 0000 |
| B        | 0000 0000 |
| DPL      | 0000 0000 |
| DPH      | 0000 0000 |
| IEN0     | 0000 0000 |
| IEN1     | 0000 0000 |
| IP0      | XX00 0000 |
| IP1      | 0000 0000 |
| IX1      | 0000 0000 |
| IRQ1     | 0000 0000 |
| PCH      | 0000 0000 |
| PCL      | 0000 0000 |
| PCON     | 0XXX 0000 |
| PSW      | 0000 0000 |
| P0-P3    | 1111 1111 |
| S0BUF    | XXXX XXXX |
| S0CPN    | 0000 0000 |
| SP       | 0000 0111 |
| TCON     | 0000 0000 |
| TH0, TH1 | 0000 0000 |
| TL0, TH1 | 0000 0000 |
| TL0, TL1 | 0000 0000 |
| TMOD     | 0000 0000 |

The reset state of the port pins is mask-programmable and can therefore be defined by the user.

The standard reset value for port P0-P3 is 1111 1111.

The reset input to the 80CL51 is RST pin 9. A Schmitt trigger qualifies the input for noise rejection. The output of the Schmitt trigger is

sampled by the reset circuitry every machine cycle.

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset. Port pins adopt their reset state immediately after RST goes HIGH. During reset ALE and PSEN are held HIGH.

The external reset is asynchronous to the internal clock. The RST pin is sampled during State 5, Phase 2 of every machine cycle. After a HIGH is detected at the RST pin, an internal reset is repeated every cycle until RST goes LOW.

The internal RAM is not affected by reset. When  $V_{DD}$  is turned on the RAM contents are indeterminate.

#### 1.8.1 Power-on reset

The 80CL51 contains on-chip circuitry which switch the port pins to the customer defined logic level as soon as  $V_{DD}$  exceeds 1.3V. As soon as the minimum supply voltage is reached, the oscillator will start up.

However, to ensure that the oscillator is stable before the controller starts, the clock signals are gated away from the CPU for a further 1536 oscillator periods. During that time the CPU is held in a reset state.

A hysteresis of approximately 50 mV at a typical power-on switching level of 1.3 V will ensure correct operation.

The on-chip Power-on circuitry can be switched off via the mask option "OFF". This option reduces the power-down current to typically 800 $\mu$ A and can be chosen if external reset circuitry is used. For applications not requiring the internal reset option, "OFF" should be chosen.

An automatic reset can be obtained at power-on by connecting the RST pin to  $V_{DD}$  via a 10 $\mu$ F capacitor. At power-on, the voltage on the RST pin is equal to  $V_{DD}$  minus the capacitor voltage, and decreases from  $V_{DD}$  as the capacitor discharges through the internal resistor  $R_{RST}$  to ground. The larger the capacitor, the more slowly  $V_{RST}$  decreases.  $V_{RST}$  must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles.

### 1.9 P80CL31: ROMless version of P80CL51

The P80CL31 is a low voltage ROMless version of the P80CL51 microcontroller. The mask options on the P80CL31 are fixed as follows:

- Port options: all ports have option "1S", i.e., standard port, high after reset
- Oscillator option: OSC3
- Power-on Reset option: OFF

### 1.10 P80C51: 5V standard version

The P80C51 is a 5V version of the low voltage P80CL51 microcontroller. All functional features of the P80CL51 are maintained in the P80C51 with the exception of the mask options. The mask options on the P80C51 are as follows:

- Port options: all ports have option "1S", i.e., standard port, high after reset.
- Oscillator options: OSC3
- Power-on Reset option: OFF

|                                                  |                                                      | $V_{DD} = 2.5V$ ; $V_{OH} = V_{DD} - 0.4V$                     | 0.7         | -    | -           | mA         |
| $R_{RST}$                                        | RST pull-down resistor                               |                                                                | 10          | -    | 200         | k $\Omega$ |

**NOTES:**

- The operating supply current is measured with all output pins disconnected; XTAL 1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS}$ ;  $V_{IH} = V_{DD}$ ; XTAL 2 not connected; EA = RST = Port 0 =  $V_{DD}$ ; all open drain outputs connected to  $V_{SS}$ .
- The idle mode supply current is measured with all output pins disconnected; XTAL 1 driven with  $t_r = t_f = 10$ ns;  $V_{IL} = V_{SS}$ . XTAL 2 not connected; EA = Port 0 =  $V_{DD}$ ; RST =  $V_{SS}$ ; all open drain outputs connected to  $V_{SS}$ .
- The power-down current is measured with all output pins disconnected; XTAL 1 not connected; EA = Port 0 =  $V_{DD}$ ; RST =  $V_{SS}$ ; all open drain outputs connected to  $V_{SS}$ .
- Circuits with Power-on Reset option "OFF" are tested at  $V_{DD}$  minimum = 1.8V; with option "ON" (typically 1.3V) they are tested at  $V_{DD}$  minimum = 2.3V. Please note, option "ON" is only available on P80CL51.

# 83L51FA/87L51FA

## DESCRIPTION

The 87L51FA and 83L51FA (hereafter generically referred to as 8XL51FA) Single-Chip 3.0V 8-Bit Microcontrollers are manufactured in an advanced CMOS process and are a derivatives of the 80C51 microcontroller family. The 8XL51FA has the same instruction set as the 80C51.

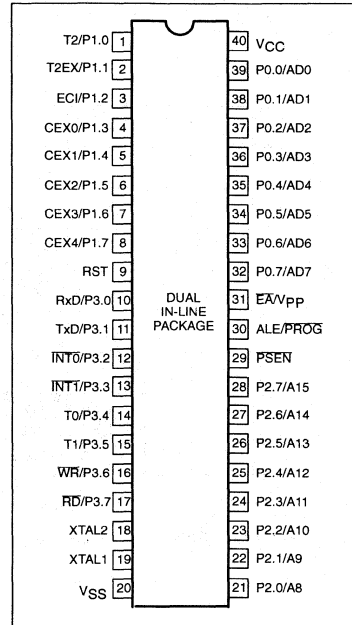

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 8XL51FA contains 8k × 8 memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, three 16-bit timer/event counters, a Programmable Counter Array (PCA), a multi-source, two-priority-level, nested interrupt structure, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XL51FA can be expanded using standard 3.3V TTL compatible memories and logic.

Its added features make it an even more powerful microcontroller for applications that require pulse width modulation, high-speed I/O and up/down counting capabilities such as motor control. It also has a more versatile serial channel that facilitates multiprocessor communications.

## FEATURES

- 80C51 central processing unit
- 3.0 to 4.5V V<sub>CC</sub> range
- 8k × 8 EPROM (87L51FA)  
8k × 8 ROM (83L51FA)
  - expandable externally to 64k bytes
  - Quick Pulse programming algorithm
  - Two level program security system
- 256 × 8 RAM, expandable externally to 64k bytes
- Three 16-bit timer/counters
  - T2 is an up/down counter
- Programmable Counter Array (PCA)
  - High speed output
  - Capture/compare
  - Pulse Width Modulator
  - Watchdog Timer
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available

## PIN CONFIGURATIONS

## ORDERING INFORMATION

| ROM           | EPROM         |     | TEMPERATURE RANGE °C AND PACKAGE <sup>1</sup>            | FREQ. (MHz) | DRAWING NUMBER |
|---------------|---------------|-----|----------------------------------------------------------|-------------|----------------|
| S83L51FA-4N40 | S87L51FA-4N40 | OTP | 0 to +70, 40-Pin Plastic Dual In-line Package            | 3.5 to 16   | 0415C          |
|               | S87L51FA-4F40 | UV  | 0 to +70, 40-Pin Ceramic Dual In-line Package w/Window   | 3.5 to 16   | 0590B          |
| S83L51FA-4A44 | S87L51FA-4A44 | OTP | 0 to +70, 44-Pin Plastic Leaded Chip Carrier             | 3.5 to 16   | 0403G          |
|               | S87L51FA-4K44 | UV  | 0 to +70, 44-Pin Ceramic Leaded Chip Carrier w/Window    | 3.5 to 16   | 1472A          |
| S83L51FA-4B44 | S87L51FA-4B44 | OTP | 0 to +70, 44-Pin Plastic Quad Flat Pack                  | 3.5 to 16   | 1118D          |
| S83L51FA-5N40 | S87L51FA-5N40 | OTP | -40 to +85, 40-Pin Plastic Dual In-line Package          | 3.5 to 16   | 0415C          |

| V <sub>CC</sub> | 40         | 44    | 38            | I    | <b>Power Supply:</b> This is the power supply voltage for normal, idle, and power-down operation.                                                                                                                                                                                                                                                                                                                                                                                                                                |   |    |     |                                                                      |
| P0.0–0.7        | 39–32      | 43–36 | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification. |   |    |     |                                                                      |
| P1.0–P1.7       | 1–8        | 2–9   | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:     |   |    |     |                                                                      |

| P2.0–P2.7          | 21–28      | 24–31        | 18–25      | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7          | 10–17      | 11,<br>13–19 | 5,<br>7–13 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                                                                                                                        |

| XTAL2              | 18         | 20           | 14         | O    | <b>Crystal 2:</b> Output from the inverting oscillator amplifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## NOTE:

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than  $V_{CC} + 0.5V$  or  $V_{SS} - 0.5V$ , respectively.

## TIMER 2

This is a 16-bit up or down counter, which can be operated as either a timer or event counter. It can be operated in one of three different modes (autoreload, capture or as the baud rate generator for the UART).

In the autoreload mode the Timer can be set to count up or down by setting or clearing the bit DGEN in the T2CON Special Function Register. The SFR's RCAP2H and RCAP2L are used to reload the Timer upon overflow or a 1-to-0 transition on the T2EX input (P1.1).

In the Capture mode Timer 2 can either set TF2 and generate an interrupt or capture its value. To capture Timer 2 in response to a 1-to-0 transition on the T2EX input, the EXEN2 bit in the T2CON must be set. Timer 2 is then captured in SFR's RCAP2H and RCAP2L.

As the baud rate generator, Timer 2 is selected by setting TCLK and/or RCLK in T2CON. As the baud rate generator Timer 2 is incremented at  $1/2$  the oscillator frequency.

## ENHANCED UART

The 83L51FA UART has all of the capabilities of the standard 80C51 UART plus Framing Error Detection and Automatic Address Recognition. As in the 80C51, all four modes of operation are supported as well as the 9th bit in modes 2 and 3 that can be used to facilitate multiprocessor communication.

The Framing Error Detection allows the UART to look for missing stop bits. If a Stop

## CMOS single-chip 3.0V 8-bit microcontroller

## 83L51FA/87L51FA

bit is missing, the FE bit in the SCON SFR is set. The FE bit can be checked after each transmission to detect communication errors. The FE bit can only be cleared by software and is not affected by a valid stop bit.

Automatic Address Recognition is used to reduce the CPU service time for the serial port. The CPU only needs to service the UART when it is addressed and, with this done by the on-chip circuitry, the need for software overhead is greatly reduced. This mode works similar to the 9-bit communication mode, except that it uses only 8 bits and the Stop bit is used to cause the RI bit to be set. There are two SFRs associated with this mode. They are SADDR, which holds the slave address and SADEN, which contains a mask that allows selective masking of the slave address so that broadcast addresses can be used.

### PROGRAMMABLE COUNTER ARRAY

The PCA is a sophisticated free-running 16 bit Timer/Counter that drives 5 modules that can be individually configured as Capture inputs, software timers, high speed outputs, or pulse width modulated outputs. In addition, module 4 can be configured as a software controlled watchdog timer.

The Timer portion of the PCA can be configured to run in one of four different modes. The modes are:  $1/2$  the oscillator frequency,  $1/4$  the oscillator frequency, Timer 0 overflows, or from the ECI input.

For the Capture/Compare mode each of the modules has a pair of registers associated with it called CCAPnH and CCAPnL (where  $n = 0, 1, 2, 3, 4$  depending on the module). Both positive and negative transitions can be captured. This means that the PCA has the flexibility to measure phase differences, duty cycles, pulse widths and a wide variety of other digital pulse characteristics.

In the 16-bit software timer mode each of the modules can generate an interrupt upon a compare.

For applications that require accurate pulse widths and edges the PCA modules can be used as High Speed Outputs (HSO). The PCA toggles the appropriate CEXn pin when there is a match between the PCA timer and the modules compare registers.

The pulse width modulator mode for the PCA allows the conversion of digital information into analog signals. Each of the 5 modules can be used in this mode. The frequency of the PWM depends on the clock source for the PCA. The 8-bit PWM output is generated

by comparing the low byte of the PCA (CL) with the module's CCAPnL SFR. When  $CL < CCAPnL$ , the output is high. When  $CL > CCAPnL$ , the output is low.

### POWER OFF FLAG

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 83L51FA rises from 0 to 3.3V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 2.0V for the POF to remain unaffected by the  $V_{CC}$  level.

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### Power-Down Mode

To save even more power, a Power Down mode can be invoked by software. In this mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 83L51FA either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INT0 and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put the device into Power Down.

### Design Consideration

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

### ONCE™ Mode

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems using the 83L51FA without the 83L51FA having to be removed from the circuit. The ONCE Mode is invoked by:

- Pull ALE low while the device is in reset and PSEN is high;
- Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 83L51FA is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

**Electrical Deviations from Commercial Specifications for Extended Temperature Range**

DC and AC parameters not included here are the same as in the commercial temperature range table.

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 3.3V.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ .
- For  $V_{CC}$  voltages above 3.6V and less than 5.5V,  $V_{IL} = 0.3V_{CC} - 0.1$
- For  $V_{CC}$  voltages above 3.6V and less than 5.5V,  $V_{IH} = 0.3V_{CC} + .92$
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 15mA (\*NOTE: This is 85°C specification.)  
Maximum  $I_{OL}$  per 8-bit port: 26mA  
Maximum total  $I_{OL}$  for all outputs: 71mA  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- ALE is tested to  $V_{OH1}$ , except when ALE is off then  $V_{OH}$  is the voltage specification.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 1.5V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 0.8 \times \text{FREQ} + 6$ ; Idle mode:  $I_{CCMAX} = 0.19 \times \text{FREQ} + 2.50$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 8.
- See Figures 9 through 12 for  $I_{CC}$  test conditions.
- Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA it is 25pF). These values are guaranteed by design and are not tested.

## CMOS single-chip 3.0V 8-bit microcontroller

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 83L51FA to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# CMOS single-chip 3.0V 8-bit microcontroller

# 83L51FA/87L51FA

## EXPLANATION OF THE AC SYMBOLS

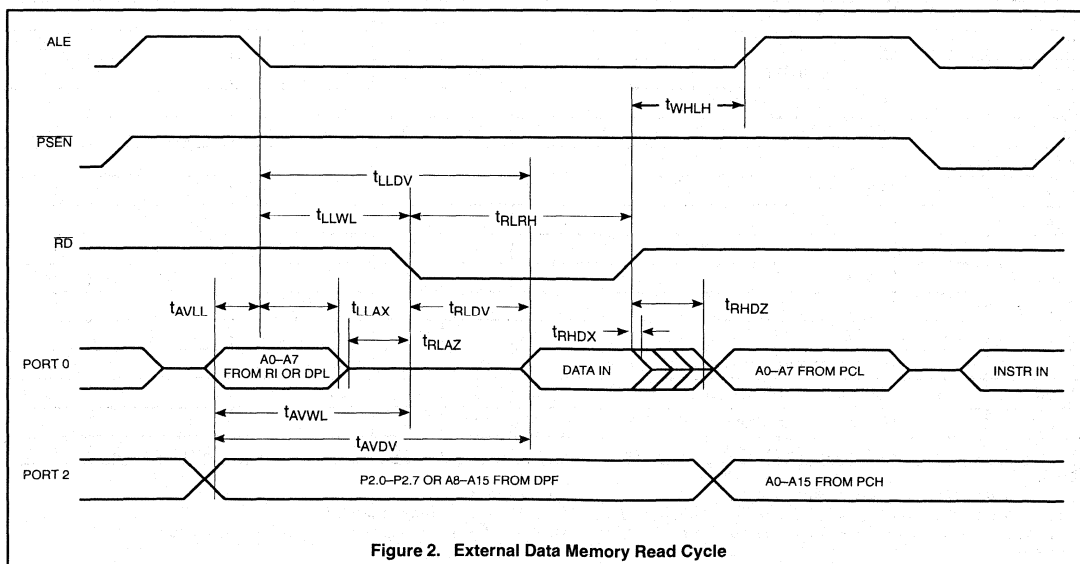

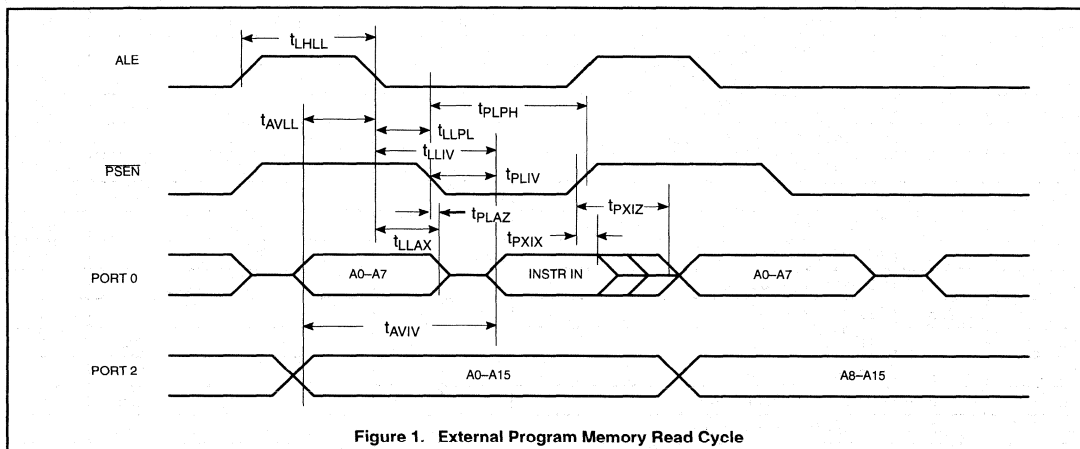

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE

- P - PSEN
- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

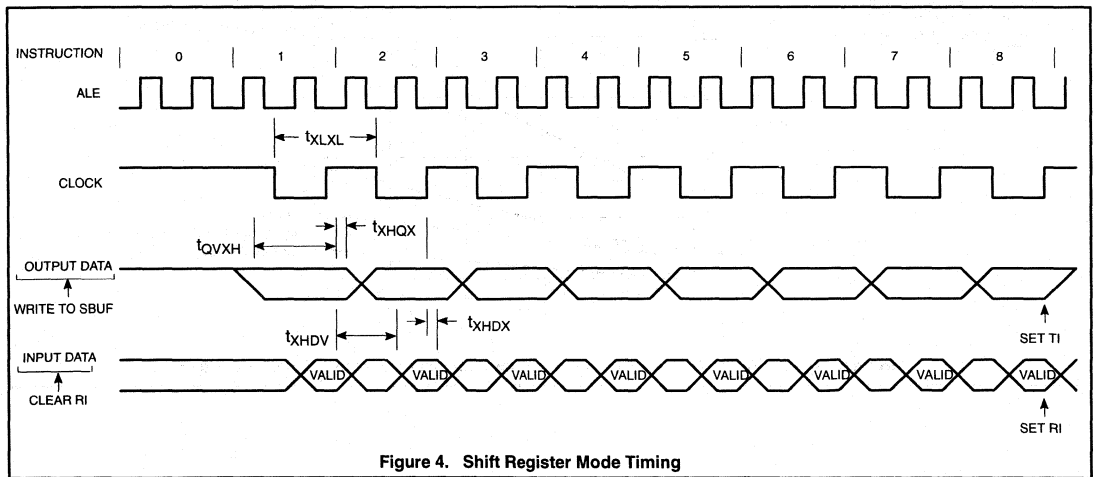

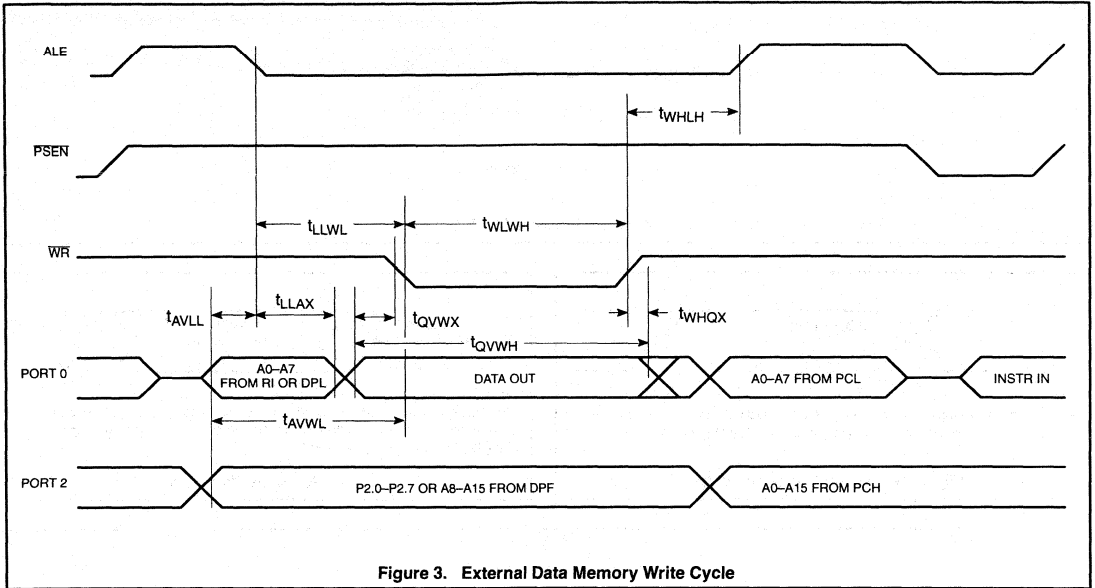

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.

$t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 3.0V 8-bit microcontroller

## 83L51FA/87L51FA

**EPROM CHARACTERISTICS**

The 87L51FA is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87L51FA contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87L51FA manufactured by Philips.

Table 2 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 13 and 14. Figure 15 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 13. Note that the 87L51FA is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 13. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 2 are held at the 'Program Code Data' levels indicated in Table 2. The ALE/PROG is pulsed low from 5 to 25 times as shown in Figure 14.

To program the encryption table, repeat the 5 to 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 5 to 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/ $V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 15. The other pins are held at the 'Verify Code Data' levels indicated in Table 2. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = B1H indicates 87L51FA

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 2, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000 $\mu$ W/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 2. EPROM Programming Modes<sup>1,2,3</sup>**

| MODE                 | RST | PSEN | ALE/PROG       | EA/ $V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------------|--------------|------|------|------|------|
| Read signature       | 1   | 0    | 1              | 1            | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0 <sup>4</sup> | $V_{PP}$     | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1              | 1            | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0 <sup>4</sup> | $V_{PP}$     | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0 <sup>4</sup> | $V_{PP}$     | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0 <sup>4</sup> | $V_{PP}$     | 1    | 1    | 0    | 0    |

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP}$  = 12.75V  $\pm$ 0.25V.
- $V_{CC}$  = 5V  $\pm$ 10% during programming and verification.
- ALE/PROG receives 5 to 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100 $\mu$ s ( $\pm$ 10 $\mu$ s) and high for a minimum of 10 $\mu$ s.

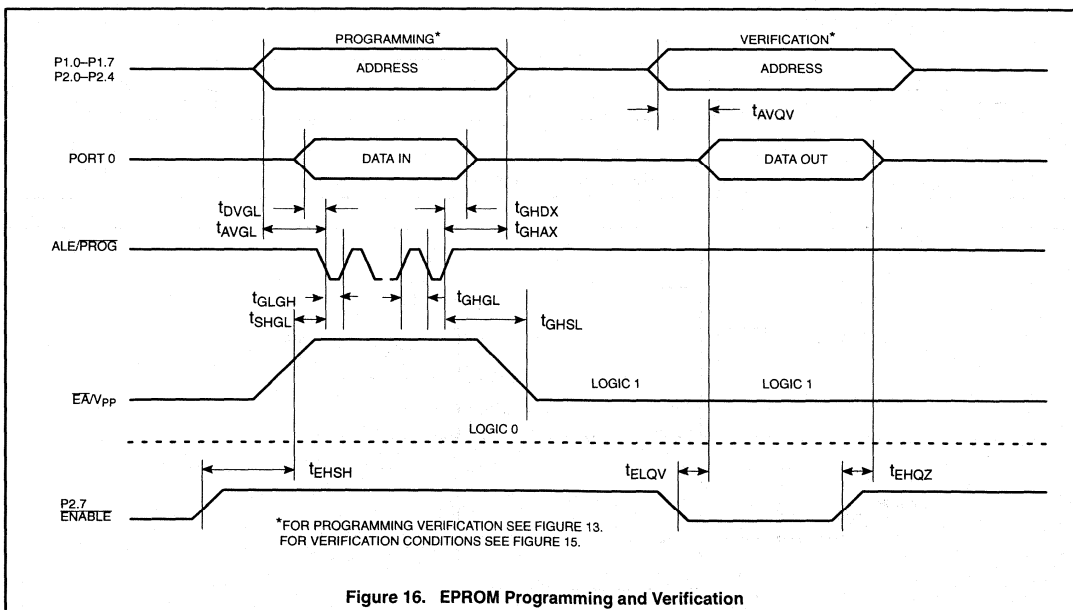

Figure 16. EPROM Programming and Verification

## CMOS single-chip 3.0V 8-bit microcontroller

## 83L51FB/87L51FB

## DESCRIPTION

The 83L51FB and 87L51FB (hereafter generically referred to as 8XL51FB) Single-Chip 3.0V 8-Bit Microcontrollers are manufactured in an advanced CMOS process and are derivatives of the 80C51 microcontroller family. The 8XL51FB has the same instruction set as the 80C51.

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 87L51FB contains 16k × 8 memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, three 16-bit timer/event counters, a Programmable Counter Array (PCA), a multi-source, two-priority-level, nested interrupt structure, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XL51FB can be expanded using standard 3.3V TTL compatible memories and logic.

Its added features make it an even more powerful microcontroller for applications that require pulse width modulation, high-speed I/O and up/down counting capabilities such as motor control. It also has a more versatile serial channel that facilitates multiprocessor communications.

## FEATURES

- 80C51 central processing unit
- 3.0 to 4.5V  $V_{CC}$  range
- 16k × 8 EPROM (87L51FB)  
16k × 8 ROM (83L51FB)
  - expandable externally to 64k bytes
  - Quick Pulse programming algorithm
  - Two level program security system
- 256 × 8 RAM, expandable externally to 64k bytes
- Three 16-bit timer/counters
  - T2 is an up/down counter
- Programmable Counter Array (PCA)
  - High speed output
  - Capture/compare
  - Pulse Width Modulator
  - Watchdog Timer
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available

| P0.0-0.7        | 39-32      | 43-36 | 37-30      | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| P1.0-P1.7       | 1-8        | 2-9   | 40-44, 1-3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification. Alternate functions include:<br><b>T2 (P1.0):</b> Timer/Counter 2 external count input/Clockout<br><b>T2EX (P1.1):</b> Timer/Counter 2 Reload/Capture/Direction Control<br><b>ECI (P1.2):</b> External Clock Input to the PCA<br><b>CEX0 (P1.3):</b> Capture/Compare External I/O for PCA module 0<br><b>CEX1 (P1.4):</b> Capture/Compare External I/O for PCA module 1<br><b>CEX2 (P1.5):</b> Capture/Compare External I/O for PCA module 2<br><b>CEX3 (P1.6):</b> Capture/Compare External I/O for PCA module 3<br><b>CEX4 (P1.7):</b> Capture/Compare External I/O for PCA module 4 |

| P2.0–P2.7                     | 21–28      | 24–31     | 18–25   | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7                     | 10–17      | 11, 13–19 | 5, 7–13 | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: $I_{IL}$ ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                                                                                                                        |

An internal diffused resistor to $V_{SS}$ permits a power-on reset using only an external capacitor to $V_{CC}$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ALE/ $\overline{\text{PROG}}$ | 30         | 33        | 27      | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input ( $\overline{\text{PROG}}$ ) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                               |
| PSEN                          | 29         | 32        | 26      | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 83L51FB is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| $\overline{\text{EA}}/V_{PP}$ | 31         | 35        | 29      | I    | <b>External Access Enable/Programming Supply Voltage:</b> $\overline{\text{EA}}$ must be externally held low to enable the device to fetch code from external program memory locations 0000H and 3FFFH. If $\overline{\text{EA}}$ is held high, the device executes from internal program memory unless the program counter contains an address greater than 3FFFH. This pin also receives the 12.75V programming supply voltage ( $V_{PP}$ ) during EPROM programming. If security bit 1 is programmed, $\overline{\text{EA}}$ will be internally latched on Reset.                                                                                                                                                                                                                                                                                        |

## NOTE:

To avoid "latch-up" effect at power-on, the voltage on any pin at any time must not be higher than  $V_{CC} + 0.5V$  or  $V_{SS} - 0.5V$ , respectively.

## TIMER 2

This is a 16-bit up or down counter, which can be operated as either a timer or event counter. It can be operated in one of three different modes (autoreload, capture or as the baud rate generator for the UART).

In the autoreload mode the Timer can be set to count up or down by setting or clearing the bit DCEN in the T2CON Special Function Register. The SFR's RCAP2H and RCAP2L are used to reload the Timer upon overflow or a 1-to-0 transition on the T2EX input (P1.1).

In the Capture mode Timer 2 can either set TF2 and generate an interrupt or capture its value. To capture Timer 2 in response to a 1-to-0 transition on the T2EX input, the EXEN2 bit in the T2CON must be set. Timer 2 is then captured in SFR's RCAP2H and RCAP2L.

As the baud rate generator, Timer 2 is selected by setting TCLK and/or RCLK in T2CON. As the baud rate generator Timer 2 is incremented at  $1/2$  the oscillator frequency.

## ENHANCED UART

The 83L51FB UART has all of the capabilities of the standard 80C51 UART plus Framing Error Detection and Automatic Address Recognition. As in the 80C51, all four modes of operation are supported as well as the 9th bit in modes 2 and 3 that can be used to facilitate multiprocessor communication.

The Framing Error Detection allows the UART to look for missing stop bits. If a Stop

## CMOS single-chip 3.0V 8-bit microcontroller

83L51FB/87L51FB

bit is missing, the FE bit in the SCON SFR is set. The FE bit can be checked after each transmission to detect communication errors. The FE bit can only be cleared by software and is not affected by a valid stop bit.

Automatic Address Recognition is used to reduce the CPU service time for the serial port. The CPU only needs to service the UART when it is addressed and, with this done by the on-chip circuitry, the need for software overhead is greatly reduced. This mode works similar to the 9-bit communication mode, except that it uses only 8 bits and the Stop bit is used to cause the RI bit to be set. There are two SFRs associated with this mode. They are SADDR, which holds the slave address and SADEN, which contains a mask that allows selective masking of the slave address so that broadcast addresses can be used.

### PROGRAMMABLE COUNTER ARRAY

The PCA is a sophisticated free-running 16 bit Timer/Counter that drives 5 modules that can be individually configured as Capture inputs, software timers, high speed outputs, or pulse width modulated outputs. In addition, module 4 can be configured as a software controlled watchdog timer.

The Timer portion of the PCA can be configured to run in one of four different modes. The modes are:  $\frac{1}{2}$  the oscillator frequency,  $\frac{1}{4}$  the oscillator frequency, Timer 0 overflows, or from the ECI input.

For the Capture/Compare mode each of the modules has a pair of registers associated with it called CCAPnH and CCAPnL (where  $n = 0, 1, 2, 3, 4$  depending on the module). Both positive and negative transitions can be captured. This means that the PCA has the flexibility to measure phase differences, duty cycles, pulse widths and a wide variety of other digital pulse characteristics.

In the 16-bit software timer mode each of the modules can generate an interrupt upon a compare.

For applications that require accurate pulse widths and edges the PCA modules can be used as High Speed Outputs (HSO). The PCA toggles the appropriate CEXn pin when there is a match between the PCA timer and the modules compare registers.

The pulse width modulator mode for the PCA allows the conversion of digital information into analog signals. Each of the 5 modules can be used in this mode. The frequency of the PWM depends on the clock source for the PCA. The 8-bit PWM output is generated

by comparing the low byte of the PCA (CL) with the module's CCAPnL SFR. When  $CL < CCAPnL$ , the output is high. When  $CL > CCAPnL$ , the output is low.

### POWER OFF FLAG

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 83L51FB rises from 0 to 3.3V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 2.0V for the POF to remain unaffected by the  $V_{CC}$  level.

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### Power-Down Mode

To save even more power, a Power Down mode can be invoked by software. In this mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 83L51FB either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INTO and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put the device into Power Down.

### Design Consideration

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

### ONCE™ Mode

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems using the 83L51FB without the 83L51FB having to be removed from the circuit. The ONCE Mode is invoked by:

1. Pull ALE low while the device is in reset and PSEN is high;
2. Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 83L51FB is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

## NOTES:

1. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
2. This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
3. Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

## Electrical Deviations from Commercial Specifications for Extended Temperature Range

DC and AC parameters not included here are the same as in the commercial temperature range table.

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 3.3V.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C to } +70^{\circ}\text{C}$ .
- For  $V_{CC}$  voltages above 3.6V and less than 5.5V,  $V_{IL} = 0.3V_{CC} - 0.1$
- For  $V_{CC}$  voltages above 3.6V and less than 5.5V,  $V_{IH} = 0.3V_{CC} + .92$
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 15mA (\*NOTE: This is 85°C specification.)
  - Maximum  $I_{OL}$  per 8-bit port: 26mA
  - Maximum total  $I_{OL}$  for all outputs: 71mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- ALE is tested to  $V_{OH1}$ , except when ALE is off then  $V_{OH}$  is the voltage specification.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IH}$  is approximately 1.5V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 0.8 \times \text{FREQ} + 6$ ; Idle mode:  $I_{CCMAX} = 0.19 \times \text{FREQ} + 2.50$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 23.
- See Figures 24 through 27 for  $I_{CC}$  test conditions.
- Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA it is 25pF). These values are guaranteed by design and are not tested.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 83L51FB to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# 83L51FB/87L51FB

## EXPLANATION OF THE AC SYMBOLS

- Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:
- A - Address
  - C - Clock
  - D - Input data
  - H - Logic level high
  - I - Instruction (program memory contents)
  - L - Logic level low, or ALE
  - P - PSEN
  - Q - Output data
  - R - RD signal
  - t - Time
  - V - Valid
  - W - WR signal
  - X - No longer a valid logic level
  - Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 3.0V 8-bit microcontroller

## 83L51FB/87L51FB

**EPROM CHARACTERISTICS**

The 87L51FB is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87L51FB contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87L51FB manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 28 and 29. Figure 30 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 28. Note that the 87L51FB is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 28. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low from 5 to 25 times as shown in Figure 29.

To program the encryption table, repeat the 5 to 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 5 to 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/V<sub>PP</sub> pin must not be allowed to go above the maximum specified V<sub>PP</sub> level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The V<sub>PP</sub> source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 30. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = B2H indicates 87L51FB

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 2. EPROM Programming Modes<sup>1,2,3</sup>**

| MODE                 | RST | PSEN | ALE/PROG                    | EA/V <sub>PP</sub> | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|-----------------------------|--------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1                           | 1                  | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0 <sup>4</sup>              | V <sub>PP</sub>    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1                           | 1                  | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0 <sup>4</sup>              | V <sub>PP</sub>    | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0 <sup>4</sup>              | V <sub>PP</sub>    | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0 <sup>4</sup> <sup>A</sup> | V <sub>PP</sub>    | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2. V<sub>PP</sub> = 12.75V ±0.25V.

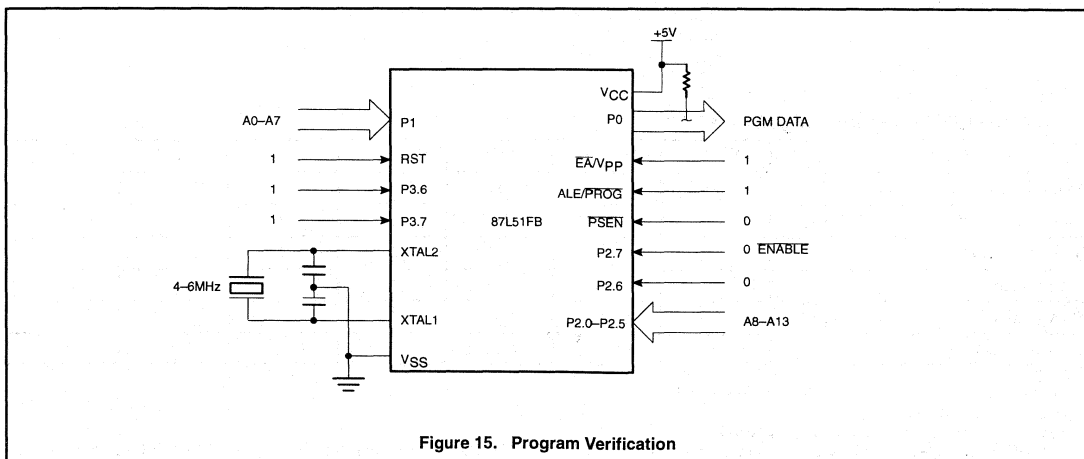

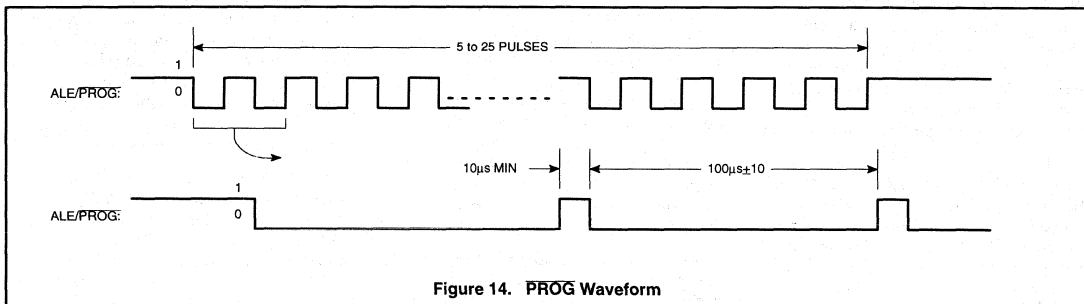

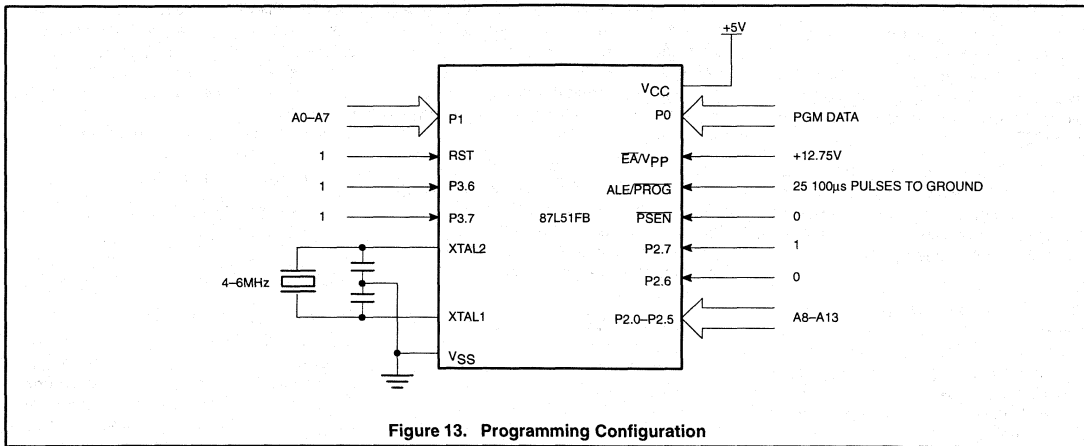

3. V<sub>CC</sub> = 5V±10% during programming and verification.

4. ALE/PROG receives 5 to 25 programming pulses while V<sub>PP</sub> is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

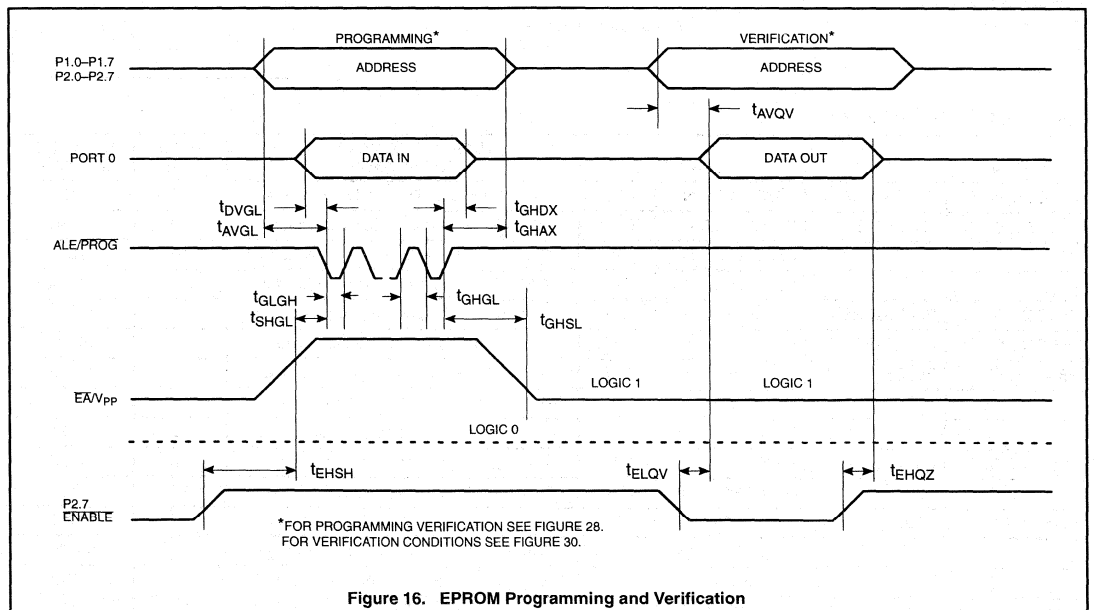

Figure 16. EPROM Programming and Verification

## CMOS single-chip 8-bit microcontrollers

## 80C32/80C52/87C52

## DESCRIPTION

The Philips 80C32/80C52/87C52 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. The CMOS 8XC52 is functionally compatible with the NMOS SCN- 8032/8052 microcontrollers. The Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. Philips epitaxial substrate minimizes latch-up sensitivity.

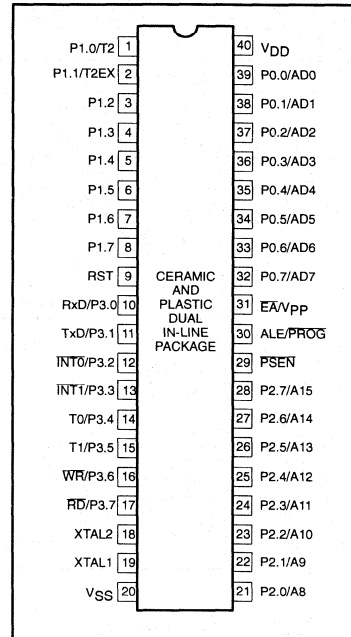

The 8XC52 contains an 8k × 8 ROM (80C52) EPROM (87C52), a 256 × 8 RAM, 32 I/O lines, three 16-bit counter/timers, a six-source, two-priority level nested interrupt structure, a serial I/O port for either multi-processor communications, I/O expansion or full duplex UART, and on-chip oscillator and clock circuits.

In addition, the 8XC52 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

## FEATURES

- 80C51 based architecture
- 8032/8052 compatible
  - 8k × 8 ROM (80C52)
  - 8k × 8 EPROM (87C52)
  - ROMless (80C32)
  - 256 × 8 RAM
  - Three 16-bit counter/timers
  - Full duplex serial channel
  - Boolean processor
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- Two speed ranges:
  - 3.5 to 16MHz
  - 3.5 to 24MHz
- Five package styles
- Extended temperature ranges
- OTP package available

| ALE/PROG           | 30      | 33           | 27           | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                            |    |    |   |                                                         |
| PSEN               | 29      | 32           | 26           | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the device is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                               |    |    |   |                                                         |
| EA/V <sub>PP</sub> | 31      | 35           | 29           | I    | <b>External Access Enable/Programming Supply Voltage:</b> EA must be externally held low to enable the device to fetch code from external program memory locations 0000H to 1FFFH. If EA is held high, the device executes from internal program memory unless the program counter contains an address greater than 1FFFH. This pin also receives the 12.75V programming supply voltage (V <sub>PP</sub> ) during EPROM programming.                                                                                                                                                                                                                                                                                                                               |    |    |   |                                                         |

# CMOS single-chip 8-bit microcontrollers

# 80C32/80C52/87C52

## DIFFERENCES FROM THE 80C51

### Special Function Registers

The special function register space is the same as the 80C51 except that the 80C52 contains the additional special function registers T2CON, RCAP2L, RCAP2H, TL2, and TH2. Since the standard 80C51 on-chip functions are identical in the 80C52, the SFR locations, bit locations, and operation are likewise identical. The only exceptions are in the interrupt mode and interrupt priority SFRs (see Table 1).

### Timer/Counters

In addition to timer/counters 0 and 1 of the 80C51, the 80C52 contains timer/counter 2. Like timers 0 and 1, timer 2 can operate as either an event timer or as an event counter. This is selected by bit C/T2 in the special function register T2CON (see Figure 1). It has three operating modes: capture, auto-load, and baud rate generator, which are selected by bits in the T2CON as shown in Table 2.

In the Capture Mode there are two options which are selected by bit EXEN2 in T2CON. If EXEN2 = 0, then Timer 2 is a 16-bit timer or counter which upon overflowing sets bit TF2, the Timer 2 overflow bit, which can be used to generate an interrupt. If EXEN2 = 1, then Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX causes the current value

in the Timer 2 registers, TL2 and TH2, to be captured into registers RCAP2L and RCAP2H, respectively. (RCAP2L and RCAP2H are new special function registers in the 80C52.) In addition, the transition at T2EX causes bit EXF2 in T2CON to be set, and EXF2 like TF2 can generate an interrupt. The Capture Mode is illustrated in Figure 2.

In the auto-reload mode, there are again two options, which are selected by bit EXEN2 in T2CON. If EXEN2 = 0, then when Timer 2 rolls over it not only sets TF2 but also causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2L and RCAP2H, which are preset by software. If EXEN2 = 1, then Timer 2 still does the above, but with the added feature that a 1-to-0 transition at external input T2EX will also trigger the 16-bit reload and set EXF2. The auto-reload mode is illustrated in Figure 3.

The baud rate generation mode is selected by RCLK = 1 and/or TCLK = 1. It will be described in conjunction with the serial port.

### Serial Port

The serial port of the 8XC52 is identical to that of the 80C51 except that counter/timer 2 can be used to generate baud rates.

In the 80C52, Timer 2 is selected as the baud rate generator by setting TCLK and/or RCLK in T2CON (see Figure 1). Note that the baud rate for transmit and receive can be simultaneously different. Setting RCLK and/or

TCLK puts Timer into its baud rate generator mode, as shown in Figure 4.

The baud rate generator mode is similar to the auto-reload mode, in that a rollover in TH2 causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2H and RCAP2L, which are preset by software.

Now, the baud rates in Modes 1 and 3 are determined by Timer 2's overflow rate as follows:

$$\text{Modes 1, 3 Baud Rate} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

The timer can be configured for either "timer" or "counter" operation. In the most typical applications, it is configured for "timer" operation (C/T2 = 0). "Timer" operation is a little different for Timer 2 when it's being used as a baud rate generator. Normally, as a timer it would increment every machine cycle (thus at 1/12 the oscillator frequency). As a baud rate generator, however, it increments every state time (thus at 1/2 the oscillator frequency). In that case the baud rate is given by the formula:

$$\text{Modes 1, 3 Baud Rate} = \frac{\text{Oscillator Frequency}}{32 \times (65536 - (\text{RCAP2H}, \text{RCAP2L}))}$$

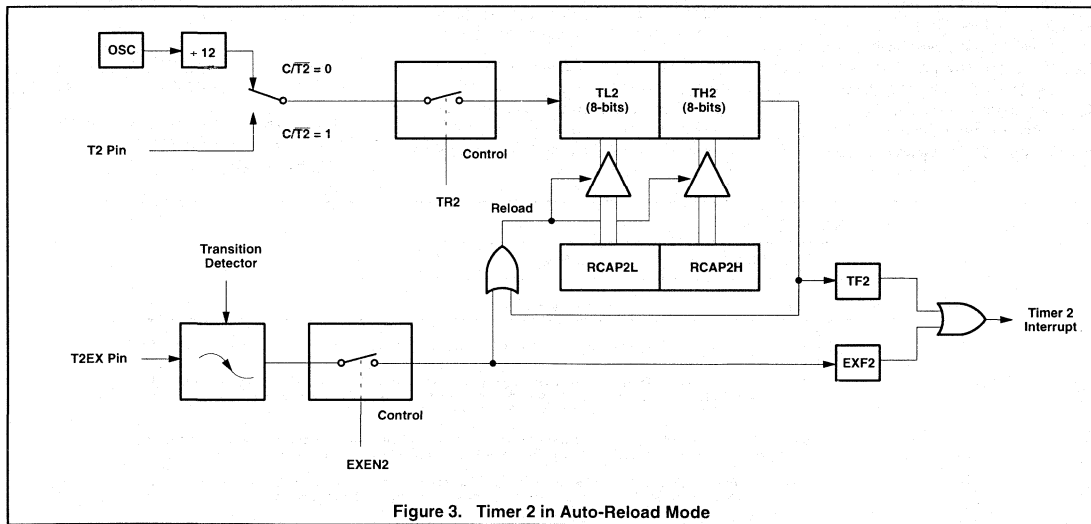

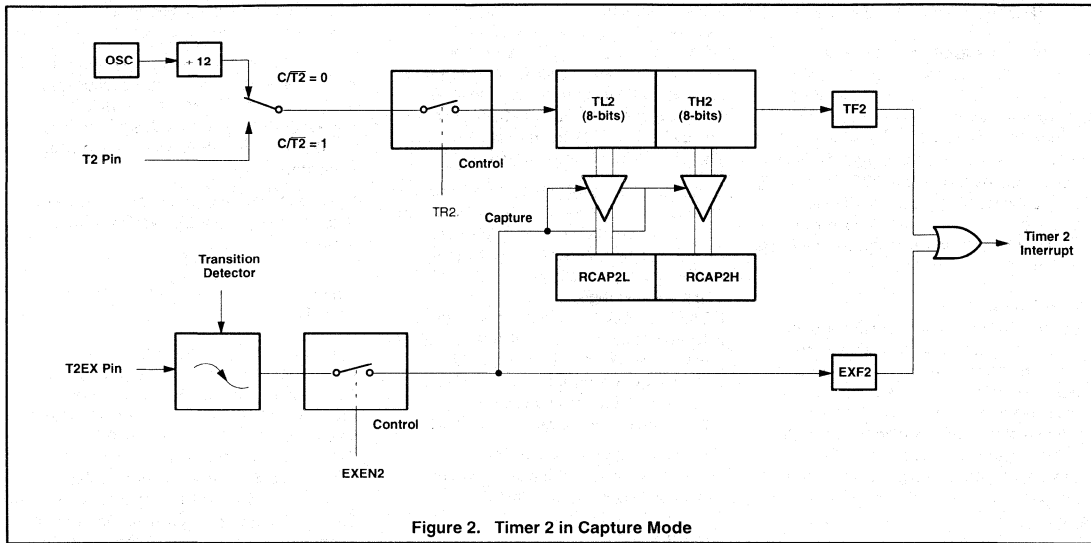

where (RCAP2H, RCAP2L) is the content of RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

|        |          | (MSB)                                                                                                                                                                                                                                                                                                                                  |      |      |      |       |     |      | (LSB)  |
|--------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------|------|-------|-----|------|--------|
|        |          | TF2                                                                                                                                                                                                                                                                                                                                    | EXF2 | RCLK | TCLK | EXEN2 | TR2 | C/T2 | CP/RL2 |
| Symbol | Position | Name and Significance                                                                                                                                                                                                                                                                                                                  |      |      |      |       |     |      |        |
| TF2    | T2CON.7  | Timer 2 overflow flag set by a Timer 2 overflow and must be cleared by software. TF2 will not be set when either RCLK or TCLK = 1.                                                                                                                                                                                                     |      |      |      |       |     |      |        |
| EXF2   | T2CON.6  | Timer 2 external flag set when either a capture or reload is caused by a negative transition on T2EX and EXEN2 = 1. When Timer 2 interrupt is enabled, EXF2 = 1 will cause the CPU to vector to the Timer 2 interrupt routine. EXF2 must be cleared by software.                                                                       |      |      |      |       |     |      |        |
| RCLK   | T2CON.5  | Receive clock flag. When set, causes the serial port to use Timer 2 overflow pulses for its receive clock in modes 1 and 3. RCLK = 0 causes Timer 1 overflow to be used for the receive clock.                                                                                                                                         |      |      |      |       |     |      |        |
| TCLK   | T2CON.4  | Transmit clock flag. When set, causes the serial port to use Timer 2 overflow pulses for its transmit clock in modes 1 and 3. TCLK = 0 causes Timer 1 overflows to be used for the transmit clock.                                                                                                                                     |      |      |      |       |     |      |        |
| EXEN2  | T2CON.3  | Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of a negative transition on T2EX if Timer 2 is not being used to clock the serial port. EXEN2 = 0 causes Timer 2 to ignore events at T2EX.                                                                                                     |      |      |      |       |     |      |        |
| TR2    | T2CON.2  | Start/stop control for Timer 2. A logic 1 starts the timer.                                                                                                                                                                                                                                                                            |      |      |      |       |     |      |        |
| C/T2   | T2CON.1  | Timer or counter select. (Timer 2)<br>0 = Internal timer (OSC/12)<br>1 = External event counter (falling edge triggered).                                                                                                                                                                                                              |      |      |      |       |     |      |        |
| CP/RL2 | T2CON.0  | Capture/Reload flag. When set, captures will occur on negative transitions at T2EX if EXEN2 = 1. When cleared, auto-reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When either RCLK = 1 or TCLK = 1, this bit is ignored and the timer is forced to auto-reload on Timer 2 overflow. |      |      |      |       |     |      |        |

**Table 2. Timer 2 Operating Modes**

| RCLK + RCLK | CP/RL2 | TR2 | MODE                |
|-------------|--------|-----|---------------------|
| 0           | 0      | 1   | 16-bit Auto-reload  |
| 0           | 1      | 1   | 16-bit Capture      |
| 1           | X      | 1   | Baud rate generator |
| X           | X      | 0   | (off)               |

Timer 2 as a baud rate generator is shown in Figure 4. This figure is valid only if RCLK + TCLK = 1 in T2CON. Note that a rollover in TH2 does not set TF2, and will not generate an interrupt. Therefore, the Timer 2 interrupt does not have to be disabled when Timer 2 is in the baud rate generator mode. Note too, that if EXEN2 is set, a 1-to-0 transition in T2EX will set EXF2 but will not cause a reload from (RCAP2H, RCAP2L) to (TH2, TL2). Thus when Timer 2 is in use as a baud rate generator, T2EX can be used as an extra external interrupt, if desired.

It should be noted that when Timer 2 is running (TR2 = 1) in "timer" function in the baud rate generator mode, one should not try to read or write TH2 or TL2. Under these conditions the timer is being incremented

every state time, and the results of a read or write may not be accurate. The RCAP registers may be read, but should not be written to, because a write might overlap a reload and cause write and/or reload errors. Turn the timer off (clear TR2) before accessing the Timer 2 or RCAP registers, in this case.

**Timer/Counter 2 Set-up**

Except for the baud rate generator mode, the values given for T2CON do not include the setting of the TR2 bit. Therefore, bit TR2 must be set, separately, to turn the timer on. See Table 3 for set-up of timer 2 as a timer. See Table 4 for set-up of timer 2 as a counter.

**Using Timer/Counter 2 to Generate Baud Rates**

For this purpose, Timer 2 must be used in the baud rate generating mode. If Timer 2 is being clocked through pin T2 (P1.0) the baud rate is:

$$\text{Baud Rate} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

And if it is being clocked internally, the baud rate is:

$$\text{Baud Rate} = \frac{\text{Oscillator Frequency}}{32 \times (65536 - (\text{RCAP2H} - \text{RCAP2L}))}$$

To obtain the reload value for RCAP2H and RCAP2L, the above equation can be rewritten as:

$$\text{RCAP2H, RCAP2L} = 65536 - \frac{\text{Oscillator Frequency}}{32 \times \text{Baud Rate}}$$

# CMOS single-chip 8-bit microcontrollers

# 80C32/80C52/87C52

## Interrupts

The 80C52 has 6 interrupt sources. All except TF2 and EXF2 are identical sources to those in the 80C51.

The Interrupt Enable Register and the Interrupt Priority Register are modified to include the additional 80C52 interrupt sources. The operation of these registers is identical to the 80C51.

In the 80C52, the Timer 2 Interrupt is generated by the logical OR of TF2 and EXF2. Neither of these flags is cleared by hardware when the service routine is

vectored to. In fact, the service routine may have to determine whether it was TF2 or EXF2 that generated the interrupt, and the bit will have to be cleared in software.

All of the bits that generate interrupts can be set or cleared by software, with the same result as though it has been set or cleared by hardware. That is, interrupts can be generated or pending interrupts can be canceled in software.

The interrupt vector addresses and the interrupt priority for requests in the same priority level are given in the following:

| Source        | Vector Address | Priority Within Level |
|---------------|----------------|-----------------------|
| 1. IE0        | 0003H          | (highest)             |
| 2. TF0        | 000BH          |                       |
| 3. IE1        | 0013H          |                       |
| 4. TF1        | 001BH          |                       |
| 5. RI + TI    | 0023H          |                       |
| 6. TF2 + EXF2 | 002BH          | (lowest)              |

Note that they are identical to those in the 80C51 except for the addition of the Timer 2 (TF1 and EXF2) interrupt at 002BH and at the lowest priority within a level.

**Table 3. Timer 2 as a Timer**

| MODE                                                    | T2CON                     |                           |
|---------------------------------------------------------|---------------------------|---------------------------|
|                                                         | INTERNAL CONTROL (Note 1) | EXTERNAL CONTROL (Note 2) |
| 16-bit Auto-Reload                                      | 00H                       | 08H                       |
| 16-bit Capture                                          | 01H                       | 09H                       |
| Baud rate generator receive and transmit same baud rate | 34H                       | 36H                       |
| Receive only                                            | 24H                       | 26H                       |
| Transmit only                                           | 14H                       | 16H                       |

**Table 4. Timer 2 as a Counter**

| MODE        | TMOD                      |                           |
|-------------|---------------------------|---------------------------|
|             | INTERNAL CONTROL (Note 1) | EXTERNAL CONTROL (Note 2) |
| 16-bit      | 02H                       | 0AH                       |
| Auto-Reload | 03H                       | 0BH                       |

**NOTES:**

1. Capture/reload occurs only on timer/counter overflow.
2. Capture/reload occurs on timer/counter overflow and a 1-to-0 transition on T2EX (P1.1) pin except when timer 2 is used in the baud rate generator mode.

## CMOS single-chip 8-bit microcontrollers

## 80C32/80C52/87C52

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol, page 285.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24

oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. Only the contents of the on-chip RAM are preserved. A hardware reset is the only way to terminate the power-down mode. The control bits for the reduced power modes are in the special function register PCON.

**DESIGN CONSIDERATIONS**

At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

Table 5 shows the state of I/O ports during low current operating modes.

**ROM CODE SUBMISSION**

When submitting ROM code for the 80C52, the following must be specified:

1. 8k byte user ROM data
2. 32 byte ROM encryption key
3. ROM security bits.

| ADDRESS        | CONTENT | BIT(S) | COMMENT                                                           |
|----------------|---------|--------|-------------------------------------------------------------------|
| 0000H to 1FFFH | DATA    | 7:0    | User ROM Data                                                     |
| 2000H to 201FH | KEY     | 7:0    | ROM Encryption Key<br>FFH = no encryption                         |
| 2020H          | SEC     | 0      | ROM Security Bit 1                                                |
| 2020H          | SEC     | 1      | ROM Security Bit 2<br>0 = enable security<br>1 = disable security |

**Security Bit 1:** When programmed, this bit has two effects on masked ROM parts:

1. External MOVC is disabled, and
2. EA# is latched on Reset.

**Security Bit 2:** When programmed, this bit inhibits Verify User ROM.

**Table 5. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

| Maximum $I_{OL}$ per I/O pin                                                                 | 15                     | mA                 |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W                  |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

**NOTES:**

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 1.43 \times \text{FREQ} + 1.9$ ; Idle mode:  $I_{CCMAX} = 0.14 \times \text{FREQ} + 2.31$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 12.
- See Figures 13 through 16 for  $I_{CC}$  test conditions.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ . For  $T_{amb} = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ , see table on previous page.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
 

|                                         |                                           |
|-----------------------------------------|-------------------------------------------|
| Maximum $I_{OL}$ per port pin:          | 15mA (*NOTE: This is 85°C specification.) |
| Maximum $I_{OL}$ per 8-bit port:        | 26mA                                      |
| Maximum total $I_{OL}$ for all outputs: | 67mA                                      |

If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 80C32/52 to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# 80C32/80C52/87C52

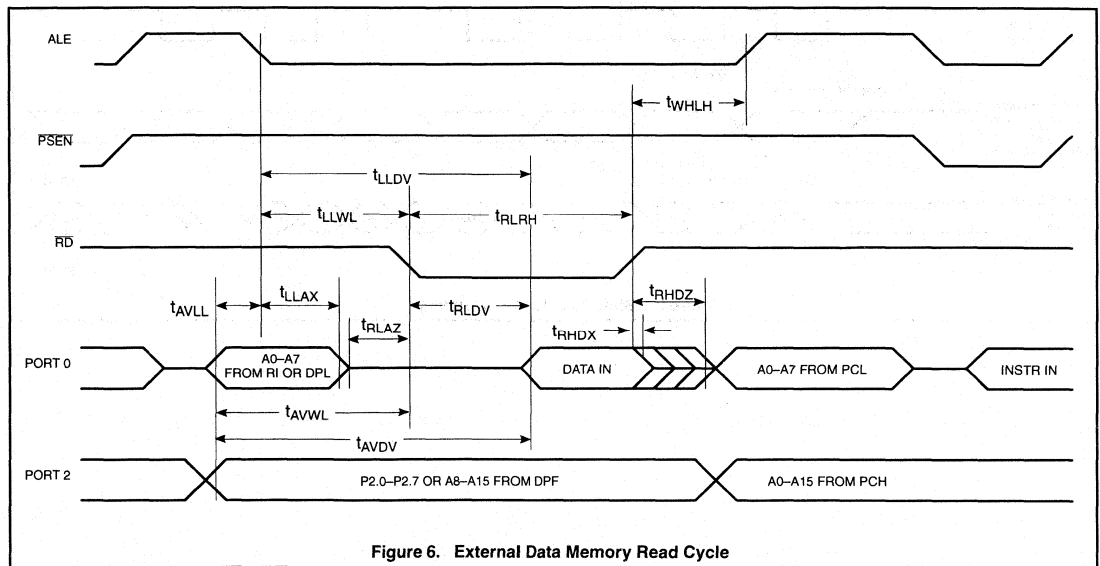

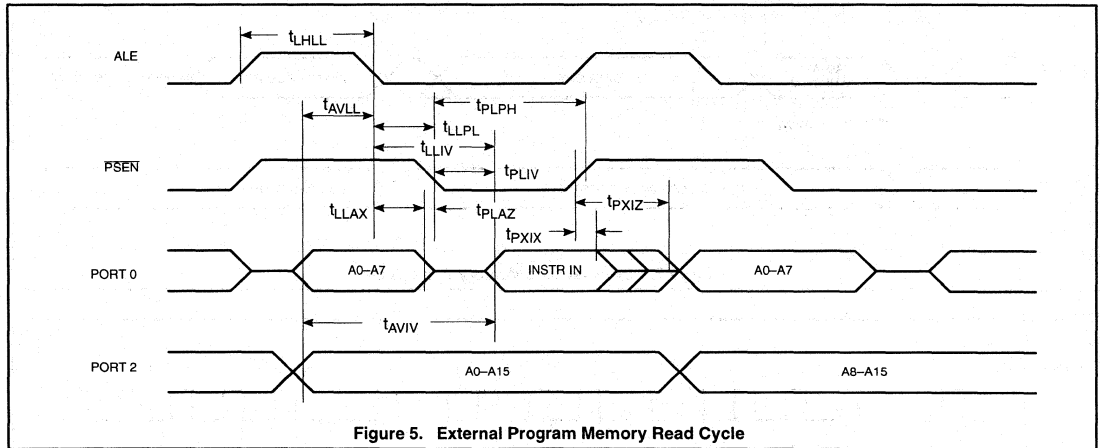

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE

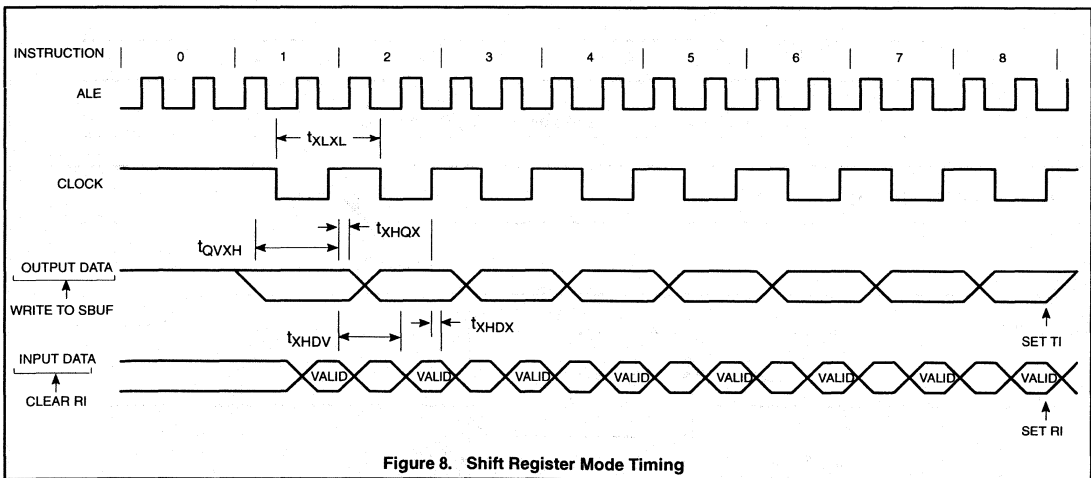

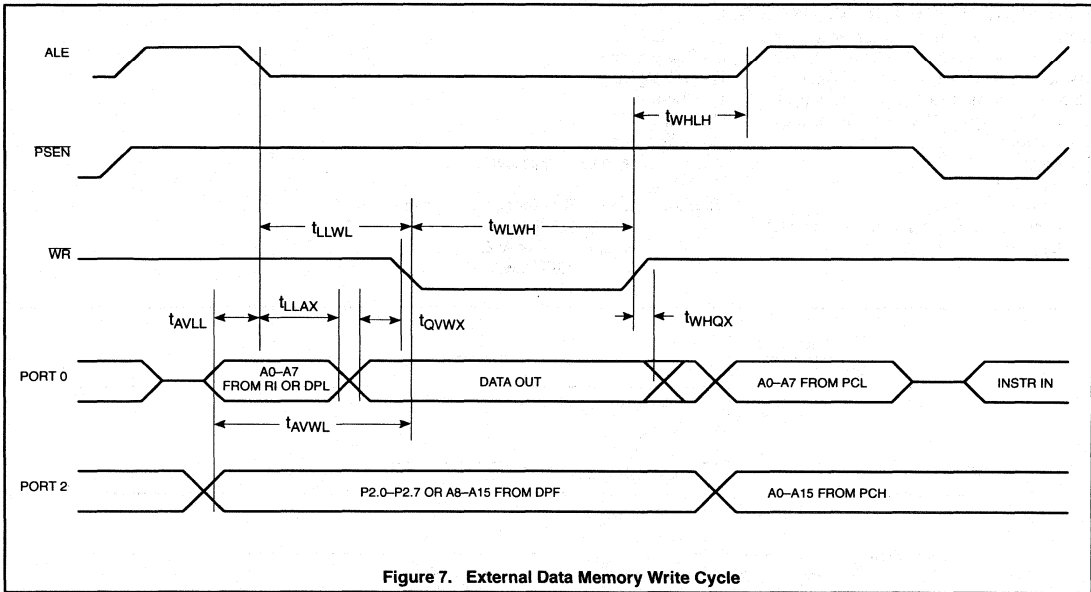

- P - PSEN
- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontrollers

## 80C32/80C52/87C52

**EPROM CHARACTERISTICS**

The 87C52 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C52 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C52 manufactured by Philips.

Table 6 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 17 and 18. Figure 19 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 17. Note that the 87C52 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 17. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 6 are held at the 'Program Code Data' levels indicated in Table 6. The ALE/PROG is pulsed low 25 times as shown in Figure 18.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the  $E\bar{A}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 19. The other pins are held at the 'Verify Code Data' levels indicated in Table 6. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 97H indicates 87C52

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 6, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 6. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $E\bar{A}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|-------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                 | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                 | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$          | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | $V_{PP}$          | 1    | 1    | 0    | 0    |

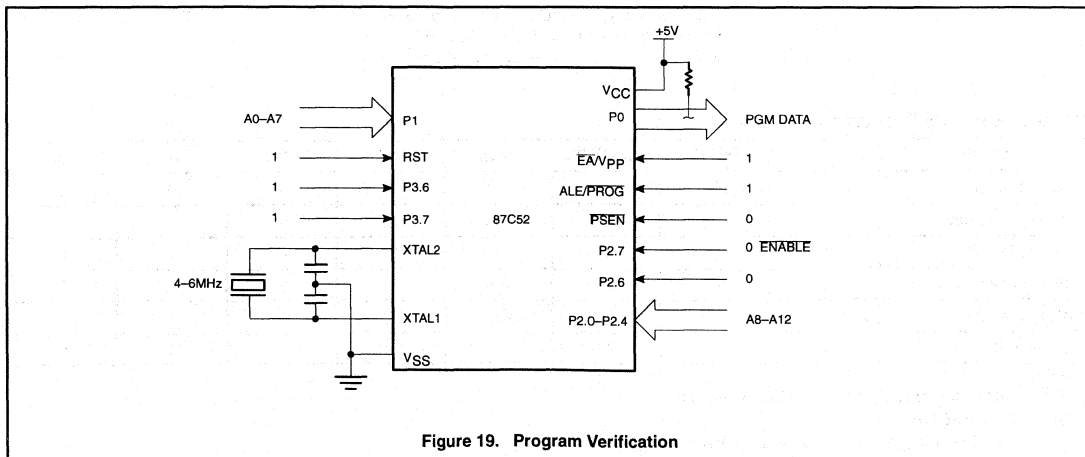

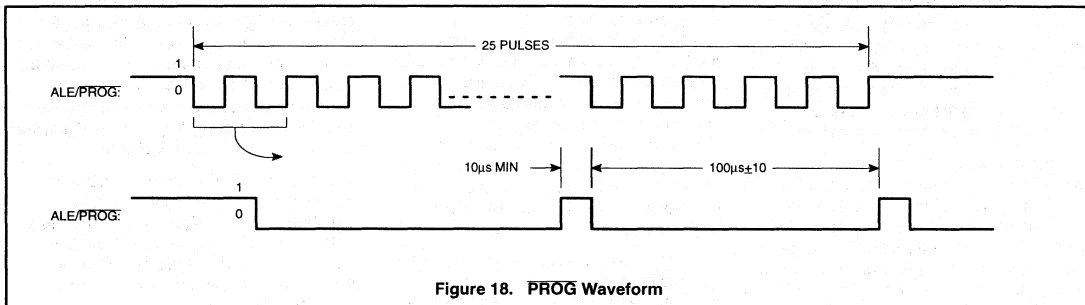

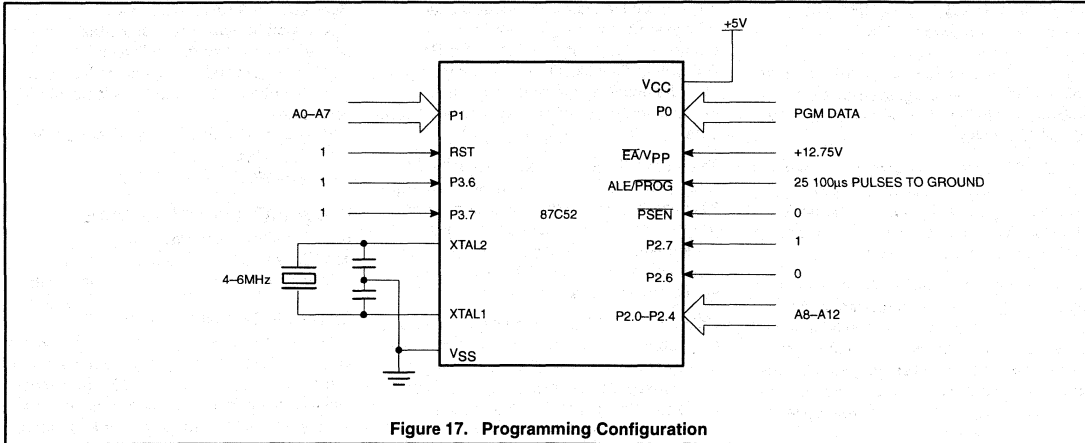

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP} = 12.75V \pm 0.25V$ .
- $V_{CC} = 5V \pm 10\%$  during programming and verification.
- \*ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs ( $\pm 10\mu s$ ) and high for a minimum of 10μs.

## Microcontroller for television and video (MTV)

83C055/87C055

## DESCRIPTION

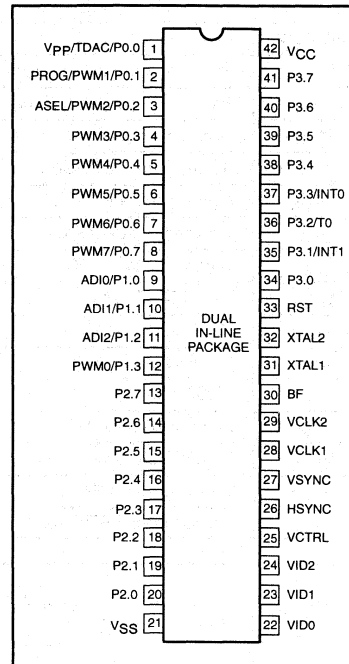

The Microcontroller for Television and Video (MTV) applications is a derivative of Philips' industry-standard 80C51 microcontroller that is intended for use as the central control mechanism in a television receiver or tuner. Providing tuner functions and an On Screen Display facility, it represents a next-generation replacement for the currently available parts.

The MTV is available in either a 16K masked ROM, or a 16K One Time Programmable (OTP) EPROM version.

## FEATURES

- 16384 × 8 masked ROM (83C055), or 16384 × 8 OTP/EPROM (87C055)
- 256 × 8 RAM
- On Screen Display (OSD) Controller
- Three digital video outputs
- Multiplexer/mixer and background intensity controls
- Flexible formatting with OSD New Line Option
- 128 × 10 display RAM
- Designed for reduced RFI (Radio Frequency Interference)
- 60 × 18 × 14 character generator ROM
- Eight text-shadowing modes
- Text color selectable per character
- Background color selectable per word
- Background color vs. video selectable per character
- Eight 6-bit pulse width modulators for analog voltage integration
- One 14-bit PWM for high-precision voltage integration
- D/A converter and comparator with three-input multiplexer
- Nine dedicated I/Os plus 28 port bits
- 15 port bits have alternate uses
- Four high-current open-drain port outputs
- 12 high-voltage (+12V) open drain outputs
- Programmable video input and output polarities
- 80C51 instruction set
- No external memory capability
- 42-pin shrink Dual In-Line Package (0.07-inch center pins)
- High-speed CMOS technology
- 5V ± 10% operation

## PIN CONFIGURATION

|-----------|----------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VCLK1     | 28             | I    | <b>Video Clock 1:</b> Input for the horizontal timing reference for the On Screen Display facility. VCLK1 and VCLK2 are intended to be used with an external LC circuit to provide an on-chip oscillator. The period of the video clock is determined such that the width of a pixel in the On Screen Display is equal to the inter-line separation of the raster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| VCLK2     | 29             | O    | <b>Video Clock 2:</b> Output from the on-chip video oscillator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| HSYNC     | 26             | I    | <b>Horizontal Sync:</b> A dedicated input for a TTL-level version of the horizontal sync pulse. The polarity of this pulse is programmable; its trailing edge is used by the On Screen Display facility as the reference for horizontal positioning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| VSYNC     | 27             | I    | <b>Vertical Sync:</b> A dedicated input for a TTL-level version of the vertical sync pulse. The polarity of this pulse is programmable, and either edge can serve as the reference for vertical timing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| VID2:0    | 22–24          | O    | <b>Digital Video bus:</b> Three totem pole outputs comprising digital RGB (or other color encoding) from the On Screen Display facility. The polarity of these outputs is controlled by a programmable register bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| VCTRL     | 25             | O    | <b>Video Control:</b> A totem-pole output indicating whether the On Screen Display facility is currently presenting active video on the VID2:0 outputs. This signal should be used to control an external multiplexer (mixer) between normal video and the video derived from VID2:0. The polarity of this outputs is controlled by a programmable register bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| BF        | 30             | O    | <b>Background/Foreground:</b> A totem-pole output which, when VCTRL is active, indicates whether the current video data represents a foreground (low) or background (high) dot in a character. This signal can be used to reduce the intensity of the background color and thus emphasize the text. If a 40-pin version of this part is ever produced, BF will not be pinned out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| P0.0-P0.7 | 1–8            | I/O  | <b>Port 0:</b> An 8-bit open-drain bidirectional port. Port 0 pins that have ones written to them float, and in that state can be used as high-impedance inputs. The port 0 pins can also serve as outputs from the high-precision Pulse Width Modulator (TDAC) and seven of the eight lower-precision Pulse Width Modulator functions. For each PWM block, a register bit controls whether the corresponding pin is controlled by the block or by port 0; port 0 controls the pin immediately after a Reset. Regardless of how each pin is controlled, it can be externally pulled up as high as +12V±5%, and the state of the pin can be read from the Port 0 register by the program.<br><b>V<sub>pp</sub> (P0.0)</b> – This pin receives the 12V programming supply voltage during EPROM programming.<br><b>PROG (P0.1)</b> – This pin receives the programming pulses during EPROM programming.<br><b>ASEL (P0.2)</b> – Input which indicates which bits of the EPROM address are applied to port 2.<br><b>TDAC (P0.0)</b> – This is the output for the 14-bit high-precision PWM.<br><b>PWM1–7 (P0.1–P0.7)</b> – Outputs for the 6-bit PWMs 1 through 7. |
| P1.0-P1.3 | 9–12           | I/O  | <b>Port 1:</b> A 4-bit open-drain bidirectional port. Port 1 pins that have ones written to them float, and in that state can be used as high-impedance inputs. P1.3 can also serve as the eighth lower-precision Pulse Width Modulator output (PWM0), and can be externally pulled up as high as +12V±5%. P1.2:0 have optional alternate use as ADI2:0, inputs to the Software A/D conversion facility. If a 40-pin version of this part is ever produced, P1.3/PWM0 will not be pinned out.<br>Any of the port 1 pins are driven low if the corresponding port register bit is written as 0, or, for P1.3 only, if the TDAC module presents a 0. The state of the pin can always be read from the port register by the program.<br><b>ADI0–2 (P1.0–P1.2)</b> – Inputs for the software A/D facility.<br><b>PWM0 (P1.3)</b> – Output for the PWM0 6-bit PWM.                                                                                                                                                                                                                                                                                                  |
| P2.0-P2.7 | 20–13          | I/O  | <b>Port 2:</b> An 8-bit open-drain bidirectional port. Port 2 pins that have ones written to them float, and in that state can be used as high-impedance inputs. P2.3:0 have high current capability (10 mA at 0.5V) for LEDs.<br>Any of the port 2 pins are driven low if the port register bit is written as 0. The state of the pin can always be read from the port register by the program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| P3.0-P3.7 | 34–42          | I/O  | <b>Port 3:</b> An 8-bit open-drain bidirectional port. Port 3 pins that have ones written to them float, and in that state can be used as high-impedance inputs. P3.0, P3.4, and P3.7 can be externally pulled up as high as +12V±5%, while P3.5 and P3.6 have 10mA drive capability. Some of the port 3 pins can also serve alternate functions, as follows:<br><b>INT1 (P3.1)</b> – External Interrupt 1.<br><b>T0 (P3.2)</b> – Timer 0 external input.<br><b>INT0 (P3.3)</b> – External Interrupt 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|           | 35             | I    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

\* Bit addressable

**ROM CODE SUBMISSION**

When submitting a ROM code for the 83C055, the following must be specified:

1. The 16k byte user ROM program.
2. The OSD ROM space.

This information can be submitted in an 87C055, or in two EPROMs (2764), or electronically on the ROM Code Bulletin Board (see your local sales office for the number).

**ROM CODE SUBMITTAL REQUIREMENTS**

| ADDRESS                | CONTENT | COMMENT                           |
|------------------------|---------|-----------------------------------|
| 000H to 3FFFH (83C055) | DATA    | User ROM data                     |
| C000H to CFFFH         | OSD     | On-Screen Display character table |

# Microcontroller for television and video (MTV)

83C055/87C055

## PROGRAMMING THE OSD EPROM

### Overview

The OSD EPROM space starts at location C000H and ends at location CFFFH. However, not all locations within this space are used, due to the addressing scheme of the OSD.

The start location of the next character can be calculated by adding 40H to the start location of the previous character. For example, character #1 starts at C000H; then characters 2, 3, and 4 start at C040H, C080H, and C0C0H, respectively.

### Character Description

Each character is 14 bits wide by 18 lines high.

A character is split about a vertical axis into two sections, UPPER and LOWER. Each section contains 7 bits of the character, such

that the LOWER section contains 1–7 and the UPPER section contains bits 8–14.

**NOTE:** During programming and verification, each section is programmed using bytes of DATA. The MSB of the DATA is not used; however, the MSB location physically exists, and so will program and verify.

The LOWER section of the character is programmed when the LSB of the program address equals 0, and the UPPER section when the LSB equals 1.

### Character Programming

An example of an OSD character bit map, and the program DATA to obtain that character is shown in Table 2.

### OSD EPROM Bit Map

The mapping for the full OSD EPROM is shown in Table 3.

### Example

To program the character given above into the first character location of the OSD EPROM would require the following address/DATA sequence:

|           |           |           |
|-----------|-----------|-----------|
| C000/00H; | C001/00H; | C002/00H; |
| C003/00H; | C004/0CH; | C005/1EH; |
| C006/0CH; | C007/1EH; | C008/0CH; |
| C009/1EH; | C00A/0CH; | C00B/1EH; |
| C00C/0CH; | C00D/1EH; | C00E/0CH; |
| C00F/1EH; | C010/7CH; | C011/1FH; |
| C012/7CH; | C013/1FH; | C014/7CH; |
| C015/1FH; | C016/0CH; | C017/1EH; |
| C018/0CH; | C019/1EH; | C01A/0CH; |
| C01B/1EH; | C01C/0CH; | C01D/1EH; |
| C01E/0CH; | C01F/1EH; | C020/00H; |
| C021/00H; | C022/00H; | C023/00H  |

**Table 2. Example of an OSD Character Bit Map**

|           | CHARACTER BIT MAP                            |       | PROGRAM DATA |          |

**NOTE:**  
Locations 62, 63, and 64 should be programmed to 0's.

**COMPARISON TO THE 80C51**

The elements of the MTV are shown in the Block Diagram. The features of the MTV are identical to those of the 80C51, except as noted herein.

**Pinout and Testing**

Since neither data nor program memory is externally expandable on the MTV, the 80C51 pins ALE, EA, and PSEN are not implemented on the MTV.

**I/O Ports**

On both the 80C51 and the MTV, port 0 is open-drain, but on the 80C51 it can be used for external memory expansion while on the MTV its alternate use is for Pulse Width Modulated outputs.

On the 80C51, port 1 is 8 bits, is mostly unallocated (general purpose), and is quasi-bidirectional (that is, having a weak pullup transistor that can be overdriven). On the MTV it is a 4-bit open-drain port, and includes alternate uses for analog inputs and a PWM output.

On the 80C51, port 2 is quasi-bidirectional and can be used for external memory expansion; on the MTV, port 2 is open-drain and unallocated.

On the 80C51, port 3 is quasi-bidirectional and all eight bits have alternate uses. On the

MTV, three port 3 bits have some of the same alternate uses as on the 80C51 but not necessarily on the same pins, while five pins are open-drain and unallocated.

**Idle Mode**

The idle mode is not implemented on the MTV.

**Power-Down Mode**

The power-down mode is not implemented on the MTV. The PCON register has the following format:

|      |   |   |   |     |     |   |   |
|------|---|---|---|-----|-----|---|---|
| PCON |   |   |   |     |     |   |   |
| 7    | 6 | 5 | 4 | 3   | 2   | 1 | 0 |
| -    | - | - | - | GF1 | GF0 | - | - |

**Interrupts**

The interrupt facilities of the MTV differ from those of the 80C51 as follows:

1. Since there is no serial port, there are no interrupts nor control bits relating to this interrupt. The interrupts and their vector addresses are as follows:

| Event         | Program Memory Address |
|---------------|------------------------|
| Reset         | 000                    |
| External INTO | 003                    |
| Timer 0       | 00B                    |
| External INT1 | 013                    |
| Timer 1       | 01B                    |
| VSync Start   | 023                    |

2. The VSYNC input used by the On Screen Display facility can generate an interrupt. The active polarity of the pulse is programmable, as described in a later section. The interrupt occurs at the leading edge of the pulse.
3. External Interrupt 1 is modified so that an interrupt is generated when the input switches in either direction (on the 8051, there is a programmable choice between interrupt on a negative edge or a low level on INT1). This facility allows for software pulse-width measurement handling of a remote control.
4. The IP register is not used, and the IE register is similar to that on the 80C51:

|    |   |   |     |     |     |     |     |
|----|---|---|-----|-----|-----|-----|-----|
| IE |   |   |     |     |     |     |     |
| 7  | 6 | 5 | 4   | 3   | 2   | 1   | 0   |
| EA | - | - | EVS | ET1 | EX1 | ET0 | EX0 |

## Six-Bit PWM DACs

The structure of these modules is shown in Figure 2. First, the basic MCU clock is divided by 4 to get a waveform that clocks a 6-bit counter which is common to all the PWMs, including the 14-bit one. This divided clock is hereafter called the PWM counter clock.

Each PWM block has a special function register PWMn arranged as follows:

### PWM0-PWM7

|     |   |     |     |     |     |     |     |
|-----|---|-----|-----|-----|-----|-----|-----|
| 7   | 6 | 5   | 4   | 3   | 2   | 1   | 0   |
| PWE | - | PV5 | PV4 | PV3 | PV2 | PV1 | PV0 |

If the PWE bit for a particular PWM block is 1, the block is active and controls its assigned port pin; if PWE is 0 the corresponding port pin is controlled by the port. The "value" field (PV5 ... PV0) of each PWM register is compared to (the LS 6 bits of) the common counter. When the value matches, the output FF is cleared, so that the output pin is driven low. When the value rolls over to zero, the output FF is set, so that the output pin is released. Thus the output waveform has a fixed period of 64 PWM counter clocks; its duty cycle is determined by PWMn.5:0.

Three of the nine total PWMs operate as described above; for three others, both the rising and falling edges of the output are delayed by one PWM clock; for the remaining three, both edges are delayed by two PWM clocks. This feature reduces the radio-frequency emission that would otherwise occur when the counter rolled over to zero and all nine open-drain outputs were released.

## 14-Bit PWM DAC (TDAC)

This feature was partially described in the preceding section. As shown in Figure 4, the 6-bit counter used for the lower precision PWMs is in fact the least significant part of a 14-bit counter used for this facility. The nature of the counter is such that it can achieve a stable output value through its MSB, and the value can propagate through logic like that shown in Figure 4, and the logic output can be stable within one period of the PWM counter clock (e.g., 250 ns) if edge-triggered logic is used to capture the logic output, or within one phase of the PWM counter clock (e.g., 125 ns) if a phase of the PWM counter clock is used to capture the logic output. For cost and die-size reasons, it is preferable that the TDAC counter be a ripple counter.

This feature is controlled by two special function registers:

### TDACL

|     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|
| 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| TD7 | TD0 | TD1 | TD2 | TD3 | TD4 | TD5 | TD6 |

### TDACH

|     |   |      |      |      |      |     |     |
|-----|---|------|------|------|------|-----|-----|
| 7   | 6 | 5    | 4    | 3    | 2    | 1   | 0   |
| TDE | - | TD13 | TD12 | TD11 | TD10 | TD9 | TD8 |

When software wishes to change the 14-bit value (TD0 – TD13), it should first write TDACL and then write TDACH. Alternatively, if the required precision of the duty cycle is satisfied by 6 bits or less, software can simply write TDACH. Note from Figure 4 that this block includes an "extra" 14-bit latch between TDACL/H and the comparator and other logic. The programmed value is clocked into the operative latch when the 7 low-order bits of the counter roll over to zero, provided that the software is not in the midst of loading a new 14-bit value (that is, it is not between writing TDACL and writing TDACH).

In a similar fashion to the lower-precision PWMs, this facility has an output FF that is set when the lower 7 bits of the counter overflow/wrap. The more significant 7 bits of the operative latch's programmed value are compared for equality against the less significant 7 bits of the counter, and the output FF is cleared when they match. Thus this output has a fixed period of 128 PWM counter clocks, and the duty cycle is determined by the programmed value.

For the higher-precision aspect of this feature, the 7 more-significant bits of the counter are used in a logic block with the 7 less-significant bits of the programmed value. The 7th LSB (binary value 64) of the programmed value is ANDed with the 7th MSB (128) of the counter, the 6th LSB of the value is ANDed with the counter's 6th and 7th MSBs being 10, and so on through the LSB of the programmed value being ANDed with the counter's 7MSBs being 100000. Then these 7 ANDed terms are ORed. If the result is true/1 at the time the 7 LSBs of the counter match the MSBs of the programmed value, the output is forced high for 1 (additional) PWM counter clock.

The result is that, if the value-64 bit of the 14-bit value is programmed to 1, every other cycle of 128 PWM counter clocks has its duty cycle stretched by one counter clock; if the value-32 bit is programmed to 1, every 4th cycle is stretched, and so on through, if the value-1 bit is programmed to 1, one cycle out of each 128 is stretched.

Assuming the external integrator can handle all this, the net effect is a PWM DAC that has the period of a 7-bit design (which makes the integrator easier and more feasible to design) with the accuracy of a 14-bit one. There is some question whether all of the least significant bits can be effectively integrated, or whether they simply act as a source of

ripple in the integrated voltage. An obvious prerequisite for such precision is that the load on the voltage must be very light, like a single op amp or comparator.

The TDAC feature differs from the corresponding features of predecessor parts in several ways:

1. The 14-bit value is functionally composed of major and minor portions of 7 bits each.
2. The 14-bit value is programmed as a contiguous multi-register value that can be manipulated straight-forwardly via arithmetic instructions.
3. As discussed for the 6-bit DACs, both of the preceding parts had a feature whereby the PWM output could be inverted, redundantly with complementing the 14-bit value. This feature has been eliminated.

## Software A/D Facility

This facility is shown in Figure 5. It represents an alternate use whereby any of the P1.0 through P1.2 pins can be selected as one input of a linear voltage comparator. The block includes one special function register:

### SAD

|     |     |     |    |      |      |      |      |
|-----|-----|-----|----|------|------|------|------|
| 7   | 6   | 5   | 4  | 3    | 2    | 1    | 0    |
| VHI | CH1 | CH0 | St | SAD3 | SAD2 | SAD1 | SAD0 |

As shown in Figure 5 the other input of the comparator is connected to a 4-bit D/A that is controlled by the 4 LSBs of the SAD register, producing a reference voltage nominally 0.15625V to 4.84375V by steps of 0.3125V. The output of the comparator (high/low) can be read by the program as the MSB of the register, which is bit addressable.

The St bit should be written as 1 in order to initiate a voltage comparison. After writing St=1, the program should include intervening instructions totalling at least six machine cycles (72 CLK periods or 6 microseconds at 12MHz), before the instruction that accesses and tests VHI.

The chan field controls which pin, if any, is connected to this facility:

| CH1 | CH0 | pin  |
|-----|-----|------|
| 0   | 0   | none |
| 0   | 1   | P1.0 |
| 1   | 0   | P1.1 |
| 1   | 1   | P1.2 |

Port 1 has open-drain drivers which will not materially affect an analog voltage as long as any and all pins used for software A/D measurement have corresponding ones in the port register.

**On Screen Display (OSD) Module**

Figure 3 is a conceptual drawing of the OSD block on the 8XC053/54/55.

It shows the CPU writing into the 128 × 10 display RAM, which is dual-ported to allow the CPU to write into it at any time, including when it is being read out by the OSD logic. The 10-bit wide data coming out of the display RAM is used to access the appropriate character in the Character Generator memory (6-bits) and to specify character and display control functions (4-bits). Timing for the OSD is controlled by the HSYNC, VSYNC, and dot clock inputs.

The 8XC053/54/55 features an advanced OSD function with some unique features:

1. User-definable display format: The OSD does not restrict the user to a fixed number of lines with a fixed number of characters per line as other competing alternatives do.

Using a fixed number of lines restricts the generation of displays that can be differentiated from others that use the

same chip and places limits on screen content.

Using a fixed number of characters per line wastes display RAM if a line has less than the full number of displayable characters (it has to be padded with non-visible characters).

The OSD on the 8XC053/54/55 defines a control character (New Line) that has the same function as a Carriage Return and Line Feed. When the OSD circuitry fetches this character from display RAM it stops displaying further characters, waits for the next horizontal scan line, and starts displaying the next character in display RAM after the New Line character was received. The number of lines is thus up to the user, within the limits of the display and memory, as are the number of characters per line. This allows far better control of the appearance of the On Screen Display.

2. Dual-Ported Display RAM: The OSD has a true display RAM instead of a character line buffer. This display RAM is dual ported to allow updating the display RAM at any time instead of having to wait for a vertical retrace. Vertical Sync interrupts are supported if flicker-free updates are required.
3. Colors selectable by character: Characters can be displayed on a background of the base video or a programmable background color. The background color is selectable by word and the choice of background (base video/user programmed color) by character.
4. Programmable character size: Normal characters are displayed as 18 × 14 bit-maps. In an interlaced display, 2 fields are displayed so that one actually sees a 36 × 14 pixel size character. The part has a double height and width mode which

# Microcontroller for television and video (MTV)

# 83C055/87C055

displays 36 × 28 pixel size bit maps per field. For use in non-interlaced systems, the part has a double height mode so that the displayed characters have the same pixel size (36 × 14) as on an interlaced display.

- 5. Character shadowing: When characters are displayed overlaid on a background of base video, a black border around the characters makes them highly legible. This feature is called shadowing. The 8XC053/54/55 has 8 shadowing modes to allow the user to select various partial shadow modes as well as full surround shadow.
- 6. Short Rows: This mode only displays 4 horizontal lines. it is used for generating underlines.
- 7. Programmable polarities: Inputs to the OSD can be programmed to be recognized as Active-LOW or Active-HIGH, also the outputs from the OSD. Coupled with the 12V outputs, this allows direct interfacing to most video signal processing circuits.

- 8. Programmable horizontal and vertical positions: A pair of registers allow defining the starting point of the display.
- 9. HSYNC locked dot-clock oscillator: The chip is designed to use an L-C oscillator circuit that is started at the trailing edge of HSYNC and stopped at its leading edge. In practice, this gives a highly consistent delay from HSYNC to oscillator start and is stable from scan line to scan line so that no left margin effects are seen.
- 10. Character Generator memory in EPROM: On the 87C054/55, the Character Generator memory is in EPROM. This feature allows quick and inexpensive font development and refinement against the alternative of doing a masked ROM version to see how the final fonts will appear.

This block is the largest of the additions that are specific to this product. Its basic function is to superimpose text on the television video image, to indicate various parameters and settings of the receiver or tuner. External circuitry handles the mixing (multiplexing) of the text and the TV video.

The overall OSD block has four input pins: two for a video clock, plus the horizontal and vertical sync signals. The video clock pins are used to connect an LC circuit to an on-chip video oscillator that is independent of the normal MCU clock. The L and C values are chosen so that a video pulse, of a duration equal to the VCLK period, will produce a more-or-less square dot on the screen, that is, a dot having a width approximately equal to the vertical distance between consecutive scan lines.

The video oscillator is stopped (with VCLK2 low) while horizontal sync is asserted, and is released to operate at the trailing edge of horizontal sync. This technique helps provide uniform horizontal positioning of characters/dots from one scan line to the next.

The block has four outputs, three color video signals, and a control signal. Since this block is the major feature of the part, its main inputs and outputs are dedicated pins, without alternate port bits.

## Microcontroller for television and video (MTV)

83C055/87C055

## Display RAM

The OSD of the MTV differs from that in preceding devices in one major way: It does not fix the number and size of displayed rows of text. Several predecessor parts allowed two displayed rows of 16 characters each. The MTV simply has 128 locations of display RAM, each of which can contain a displayed character or a New Line character that indicates the end of a row. A variant of the New Line character is used to indicate the end of displayed data.

The three major elements of the OSD facility are shown in the Block Diagram. Each display RAM location includes 6 data bits and 4 attribute bits. The 6 data bits from display RAM, along with a line-within-row count, act as addresses into the character generator ROM, which contains 60 displayable bit maps (64 minus one for each of New Line and three Space characters). Each bit map includes 18 scan lines by 14 dots. The character generator ROM is maskable or programmable along with the program ROM to allow for various character sets and languages.

For a standard NTSC TV signal with an HSYNC frequency of 15,750kHz and a VSYNC of nominally 60Hz, there are roughly 50 microseconds of active horizontal scan line available. For a typical pixel clock frequency is 8MHz, and therefore roughly 400 pixels of resolution can be obtained. At 14 dots per character, this means 28 character times per horizontal scan. If the 12 dot per character display mode is used, that means 33 character times per horizontal scan. Allowing for edge effects, 26 characters (14 across) or 31 characters (12 across) can be displayed.

Note that VGA rates and higher can be used. The minimum character dot size will be a function of the VGA frequency used. For a 640 × 480 display, running at 33kHz, the equivalent 8XC055 pixel resolution is about 160 across (because of the 8MHz clock and allowing for overscan). This means that status and diagnostic information can be displayed on video monitors.

The programming interface to display RAM is provided by three special function registers:

| OSAD |       |       |       |       |       |       |       |
|------|-------|-------|-------|-------|-------|-------|-------|
| 7    | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| -    | OSAD6 | OSAD5 | OSAD4 | OSAD3 | OSAD2 | OSAD1 | OSAD0 |

| OSDT |   |       |       |       |       |       |       |
|------|---|-------|-------|-------|-------|-------|-------|
| 7    | 6 | 5     | 4     | 3     | 2     | 1     | 0     |
| -    | - | OSDT5 | OSDT4 | OSDT3 | OSDT2 | OSDT1 | OSDT0 |

OSAT (with OSDT = New Line)

| 7 | 6 | 5 | 4 | 3 | 2  | 1 | 0  |
|---|---|---|---|---|----|---|----|
| - | - | - | E | - | SR | D | Sh |

OSAT (with OSDT = BSpace or SplitBSpace)

| 7 | 6 | 5 | 4 | 3 | 2   | 1   | 0   |
|---|---|---|---|---|-----|-----|-----|
| - | - | - | B | - | BC2 | BC1 | BC0 |

OSAT (with OSDT = any other)

| 7 | 6 | 5 | 4 | 3 | 2   | 1   | 0   |
|---|---|---|---|---|-----|-----|-----|
| - | - | - | B | - | FC2 | FC1 | FC0 |

OSAD ("On Screen Address") contains the address at which data will next be written into display RAM, while the ten active bits in OSDT ("On Screen DaTa") plus OSAT ("On Screen ATtributes") correspond exactly to the 10 bits in each display RAM location. FColor indicates the color of foreground (1) pixels in the ROM bit map for this character, while B indicates whether background (0) pixels should show the current background color (B=1) or television video (B=0). Thus, for the 1 bits in a character's bit map, the VID2:0 pins are driven with (FColor) and VCTRL is driven active, while for 0 bits VID2:0 are driven with the background color (except for shadow bits) and VCTRL is driven with the B bit.

Writing OSAT simply latches the attribute bits into a register, while writing OSDT causes the data bus information, plus the contents of the OSAT register, to be written into display RAM. Thus, for a given display RAM location, OSAT should be written before OSDT. If successive characters are to be written into display RAM with the same attributes, OSAT need not be rewritten for each character, only prior to writing OSDT for the first character with those particular attributes.

In reality, there is a potential conflict between the timing of a write to OSDT and an access to display RAM by the OSD logic for data display. This is resolved by the use of a true dual-ported RAM for display memory.

OSAD is automatically incremented by one after each time OSDT and display RAM are written. Except in special test modes that are beyond the scope of this spec release, display RAM cannot be read by the MCU program.

The OSAT attribute bits associated with the BSpace (data=111110), SplitBSpace (111111), and New Line (111101) characters are interpreted differently from those that

accompany other data characters. With BSpace and SplitBSpace, B is interpreted as described above, but the 3 color bits specify the Background color (BColor) for subsequent characters. For BSpace, a change in B and BColor becomes effective at the left edge of the character's bit map. For SplitBSpace, a change in B and BColor occurs halfway through the character horizontally. The normal Space character (111100) has no effect on the BColor value.

BColor values 000 and 111 minimize the occurrence of transient states among the VID2:0 outputs.

The background color defined by the most recently encountered BSpace or SplitBSpace character is maintained on the VID2:0 pins except at the following times:

1. During the active time of HSYNC,
2. During the active time of VSYNC,
3. During those pixels of an active character that correspond to a 1 in the character's bit map,
4. During a "shadow" bit.

The BColor value is not cleared between vertical scans, so that if a single background color is all that is needed in an application, it can be set via a single BSpace character during program initialization, and never changed thereafter. In order for such a BSpace to actually affect the MTV's internal BColor register the Mode field of the OSMOD register must be set to 01 (or higher) so that the OSD hardware is operating.

With a New Line character, if the E bit is 1, no further rows are displayed on the screen. If E is 0 and D is 1, all of the characters in the following row are displayed with Double height and width. If E is 0 and Sh is 1, all of the characters in the following row are displayed with shadowing, as described in a later section. If E is 0 and SR is 1, the next row is a "short row": It is only 4 or 8 scan lines high rather than 18 or 36. Short rows can be used for underlined text.

The latches in which the E, D, Sh, and SR bits are captured are cleared to zero at the start of each vertical scan. This means that if the first text line on the screen is a short row, or if it contains either double size or shadowing, the text must be preceded by a New Line character. Like all such characters, this initial New Line advances the vertical screen position; the VStart value (see below) should take this fact into account.

# Microcontroller for television and video (MTV)

83C055/87C055

## Other OSD Registers

A number of changes in the OSD architecture have reduced the number of other special function registers involved in the feature, below the number needed with predecessor devices:

1. The elimination of certain options such as 4, 6, or 8X character sizes and alternate use of two of the video outputs.
2. The moving of certain other options from central registers to display RAM, such as foreground color codes and background selection.

### OSCON

|    |    |    |    |    |    |    |      |
|----|----|----|----|----|----|----|------|
| 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
| IV | Pv | Lv | Ph | Pc | Po | DH | BFfe |

The IV bit is the interrupt flag for the OSD feature. It is set by the leading edge of the VSYNC pulse, and is cleared by the hardware when the VSYNC interrupt routine is vectored to. It can also be set or cleared by software writing a 1 or 0 to this bit.

### NOTE

It is theoretically possible that a VSYNC interrupt could be missed, or an extra one generated, if OSCON is read, then modified internally (e.g., in Ac), and the result written back to OSCON. However, none of the other bits in OSCON are reasonable candidates for dynamic change. Special provisions are included in the MTV logic so that IV will not be changed by a single "read-modify-write" instruction such as SETB or CLR, unless the instruction specifically changes IV.

A 0 (1) in Pv designates that the VSYNC input is high-active (low-active). One effect of this bit is that the VID2:0 and VCTRL outputs are blocked (held at black/inactive) during the active time of VSYNC. The IV bit is set on the leading edge of the VSYNC pulse; thus Pv controls whether the OSD interrupt occurs in response to a high-to-low or low-to-high transition on VSYNC.

A 0 (1) in Lv designates that the leading edge (active level) of VSYNC, as defined by Pv, clears the state counter that is used to determine the vertical start of on-screen data. In effect, Lv=0(1) says that the leading (trailing) edge of VSYNC is the time reference for the video field.

A 0 (1) in Ph designates that the HSYNC input is high-active (low-active).

A 0 (1) in Pc designates that a high (low) on the VCTRL output means "show the color on VID2:0".

A 0 (1) in Po designates that a 0 (1) internal to the MTV corresponds to a low on one of the VID2:0 pins. This control bit is needed only because the Shadowing feature needs to generate black pixels without reference to a register value: Internally, the 3-bit code 000 always designates black.

If DH is 1, character sizes are doubled vertically but not horizontally. This feature allows the MTV to be used in "improved definition" systems that are not interlaced. The vertical doubling imposed by DH does not affect the VStart logic described below: It operates in HSync units regardless of DH or D.

If BFe is 1, the BF output tracks whether each bit in displayed characters is a foreground bit (low) or a background bit (high). If BFe is 0, the BF pin remains high.

### OSORG

|     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|
| 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| HS4 | HS3 | HS2 | HS1 | HS0 | VS2 | VS1 | VS0 |

The HStart field (HS4 – HS0) defines the left end (start) of all of the on-screen character rows, as a multiple of four VCLKs. Active display begins 4(HStart)+1 VCLKs plus one single-sized character width after the trailing edge of HSYNC. Counting variations in Wc, there may be 17 to 143 VCLKs from the end of HSYNC to the start of the first character of each row.

The VStart field (VS2 – VS0) defines the top (start) of the first on-screen character row, as a multiple of four HSYNC pulses. Active display begins 4(VStart)-1 HSYNCs after the field's time reference point, a range of 3 to 31. Subsequent character rows occur directly below the first, such that the last scan line of one row is directly followed by the first scan line of the next row. Successive New Line characters (with or without the Short Row designation) can be used to vertically separate text rows on the screen.

Neither the HStart nor VStart parameter is affected by the D line attribute that is used to display double-sized characters.

### OSMOD

|    |   |       |       |   |      |      |      |
|----|---|-------|-------|---|------|------|------|
| 7  | 6 | 5     | 4     | 3 | 2    | 1    | 0    |
| Wc | - | Mode1 | Mode0 | - | SHM2 | SHM1 | SHM0 |

If the mode bits (Mode 1, Mode 0) are 00, the OSD feature is disabled. The VCLK oscillator is disabled, VID2:0 are set to black, and

VCTRL is held inactive. This is the mode to which the MTV OSD logic is reset. A direct transition from this mode to active display (1x) would result in undefined operation and visual effects for the duration of the current video field (until the next VSYNC).

If the mode is 01, the VCLK oscillator is enabled and the OSD logic operates normally internally, but VID2:0 are set to black and VCTRL is held inactive. The OSD feature can be toggled between this state and 1x as desired to achieve real-time special effects such as "vertical wiping."

Mode 10 represents normal OSD operation. Active characters can be shown against TV video (for characters with B=0) or (for characters with B=1) against a background of the color defined as an attribute of BSpace and SplitSpace characters.

In mode 11, characters can be displayed but all of the receiver's normal video is inhibited by holding VCTRL asserted throughout the active portion of each scan line. Since VID2:0 are driven with the current background color during this time, except during the foreground portion of displayed characters, this produces text against a solid background. This mode is useful for extensive displays that require user concentration.

If Wc is 1, then each displayed character is horizontally terminated after 12 bits have been output, as opposed to after 14 bits if Wc is 0. This allows text to be "packed" more tightly so that more characters can be displayed per line. In effect, the 2 bits out of the display ROM, which would otherwise be the rightmost 2 of the 14, are ignored when Wc is 1. Clearly, if this feature is to be used, it must be accounted for in the design of the bit maps in the display ROM.

The 3-bit ShMode field (SHM2 – SHM0) determines how characters are shadowed in rows for which the SH row attribute is 1. As shown in Figure 6, the values 000-110 indicate an apparent light source position ranging from the lower left clockwise to the lower right, while the value 111 indicates full-surround shadowing.

Under some conditions writing to OSMOD while the display is active can cause a temporary flicker during that display field. This can be avoided by only writing to OSMOD during the vertical sync interval.

| HYS               | Hysteresis (VSYNC, HSYNC)                                                    |                                              | 0.8                  |                      | V          |       |

## NOTES:

1. This maximum applies at all times, including during power switching, and must be accounted for in power supply design. During a power-on process, the +12 volt source used for external pullup resistors should not precede the  $V_{CC}$  of the MTV up their respective voltage ramps by more than this margin, nor, during a power-down process, should  $V_{CC}$  precede +12V down their respective voltage ramps by more than this margin.
2. The specified current rating applies when any of these pins is used as a Pulse Width modulated output. For use as a port output, the rating is as given subsequently.
3.  $I_{CC}$  measured with OSD block initialized and Reset remaining low.
4. The capacitance of pins P0.0 and P0.7 for the 87C055 exceeds 10pF. P0.0 is 40pF maximum, while P0.7 is 20pF maximum.
5. No more than 6 (any 6) of these 10 high current outputs may be used at the  $V_{OL1}$  ( $I_{OL} = 10mA$ ) specification. The other 4 should comply with the  $V_{OL3}$  specification ( $I_{OL} = 1.6mA$ ).

## NOTES:

1. The MTV is tested at its maximum XTAL frequency, but not at any other (lower) rate.
2. These parameters apply only when an external clock signal is used.
3. These parameters assume equal loading at  $C_L = 100pF$ , for all the referenced outputs. These parameters are specified but not tested.

## PROGRAMMING CONSIDERATIONS

## EPROM Characteristics

The 87C055 is programmed by using a modified Quick-Pulse Programming algorithm similar to that used for devices such as the 87C51. It differs from these devices in that a serial data stream is used to place the 87C751 in the programming mode.

Figure 7 shows a block diagram of the programming configuration for the 87C055. Port pin P0.0 is used as the programming voltage supply input ( $V_{PP}$  signal). Port pin P0.1 is used as the program (PGM/) signal. This pin is used for the 25 programming pulses.

Port 2 is used as the address input for the byte to be programmed and accepts both the high and low components of the eleven bit address. Multiplexing of these address components is performed using the ASEL input. The user should drive the ASEL input high and then drive port 2 with the high order bits of the address. ASEL should remain high for at least 13 clock cycles. ASEL may then be driven low which latches the high order bits of the address internally. The high address should remain on port 2 for at least two clock cycles after ASEL is driven low. Port 2 may then be driven with the low byte of the address. The low address will be internally stable 13 clock cycles later. The address will remain stable provided that the low byte placed on port 2 is held stable and ASEL is kept low. **Note:** ASEL needs to be pulsed high only to change the high byte of the address.

Port 3 is used as a bidirectional data bus during programming and verify operations. During programming mode, it accepts the byte to be programmed. During verify mode, it provides the contents of the EPROM location specified by the address which has been supplied to Port 2.

The XTAL1 pin is the oscillator input and receives the master system clock. This clock should be between 1.2 and 6MHz.

The RESET pin is used to accept the serial data stream that places the 87C055 into various programming modes. This pattern consists of a 10-bit code with the LSB sent first. Each bit is synchronized to the clock input, X1.

## Programming Operation

Figures 8 and 9 show the timing diagrams for the program/verify cycle. RESET should initially be held high for at least two machine cycles. P0.1 (PGM/) and P0.0 ( $V_{PP}$ ) will be at  $V_{OH}$  as a result of the RESET operation. At this point, these pins function as normal quasi-bidirectional I/O ports and the programming equipment may pull these lines low. However, prior to sending the 10-bit code on the RESET pin, the programming equipment should drive these pins high ( $V_{IH}$ ). The RESET pin may now be used as the serial data input for the data stream which places the 87C055 in the programming mode. Data bits are sampled during the clock high time and thus should only change during the time that the clock is low. Following transmission of the last data bit, the RESET pin should be held low.

Next the address information for the location to be programmed is placed on port 2 and ASEL is used to perform the address multiplexing, as previously described. At this time, port 1 functions as an output.

A high voltage  $V_{PP}$  level is then applied to the  $V_{PP}$  input (P0.0). (This sets Port 1 as an input port). The data to be programmed into the EPROM array is then placed on Port 3. This is followed by a series of programming pulses applied to the PGM/ pin (P0.1). These pulses are created by driving P0.1 low and then high. This pulse is repeated until a total of 25 programming pulses have occurred. At the conclusion of the last pulse, the PGM/ signal should remain high.

The  $V_{PP}$  signal may now be driven to the  $V_{OH}$  level, placing the 87C055 in the verify mode. (Port 3 is now used as an output port). After four machine cycles (48 clock periods), the contents of the addressed location in the EPROM array will appear on Port 3.

The next programming cycle may now be initiated by placing the address information at the inputs of the multiplexed buffers, driving the  $V_{PP}$  pin to the  $V_{PP}$  voltage level, providing the byte to be programmed to Port 3 and issuing the 26 programming pulses on the PGM/ pin, bringing  $V_{PP}$  back down to the  $V_{OH}$  level and verifying the byte. (See Table 4.)

## Microcontroller for television and video (MTV)

83C055/87C055

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be**

**placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Flourless part number 2345-5 or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Reading Signature Bytes**

The signature bytes are read by the same procedure as a normal verify of locations 30H and 31H, except that the serial code indicated in Table 3 for reading signature bytes should be used. The values are:

30H = 15H indicates manufactured by Philips  
31H = 4BH indicates 87C055

**Table 4. Implementing Program/Verify Modes**

| OPERATION            | SERIAL CODE | P0.1 (PGM/)     | P0.0 (V <sub>PP</sub> ) |

## Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

## P83CL168/167/268/267

### 1. INTRODUCTION

The P83CL168/167/268/267 single chip microcontroller is an 80C51 CPU based MicroController designed for medium high to high end TV control applications. It features a Philips 80CL51 CPU which is object code compatible with the industry standard 80C51. It is manufactured in an advanced CMOS technology featuring low power consumption.

The differences between these four devices are shown in Table 1.

For the rest of the specification we will use P83CL168 as the generic term to describe the function of this family.

The P83CL168 also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit handling capabilities. Multiply & divide instructions are implemented by hardware with a cycle time of 4 $\mu$ s (XTAL=12MHz).

The instruction set consists of over 100 instructions; 49 one-byte, 46 two-byte and 16 three-byte.

The P83CL168 contains 16K bytes of ROM, 256 bytes of RAM, 21 general I/O port lines, 28 function combined I/O lines.

The **derivative functions** dedicated for TV applications are:

- AFC (A/D converter), remote control pre-processing circuit,
- PWM's for analog control, and voltage synthesized tuning (VST),
- on screen display function (OSD).

There are also two serial I/O's available, the Philips standard I<sup>2</sup>C (two sets) and the high speed 8-bit 3-wire serial I/O and an 8-bit counter (T2) for AC line frequency or HSYNC pulse counting.

### 1.1 P80CL51 CPU Core Features

- Full static 80C51 CPU
- 8 bit CPU, ROM, RAM, I/O's in a single package
- ROM max memory space : 64K (but P83CL168 has no external ROM access capability)
- RAM max memory space : 64K (but P83CL168 has no external RAM access capability)
- Two 16-bit timer/event counters
- On-chip oscillator suitable for quartz crystal or ceramic resonator
- Thirteen source, thirteen vector interrupt structure with two priority levels
- Enhanced architecture with:
  - non page orientated instructions
  - direct addressing
  - four eight byte RAM register banks
  - stack depth up to 128 bytes
  - multiply, divide, subtract and compare instructions

**Table 1. Differences between P83CL168/167/268/267**

|                     | P83CL168             | P83CL167 | P83CL268             | P83CL267 |

#### NOTES:

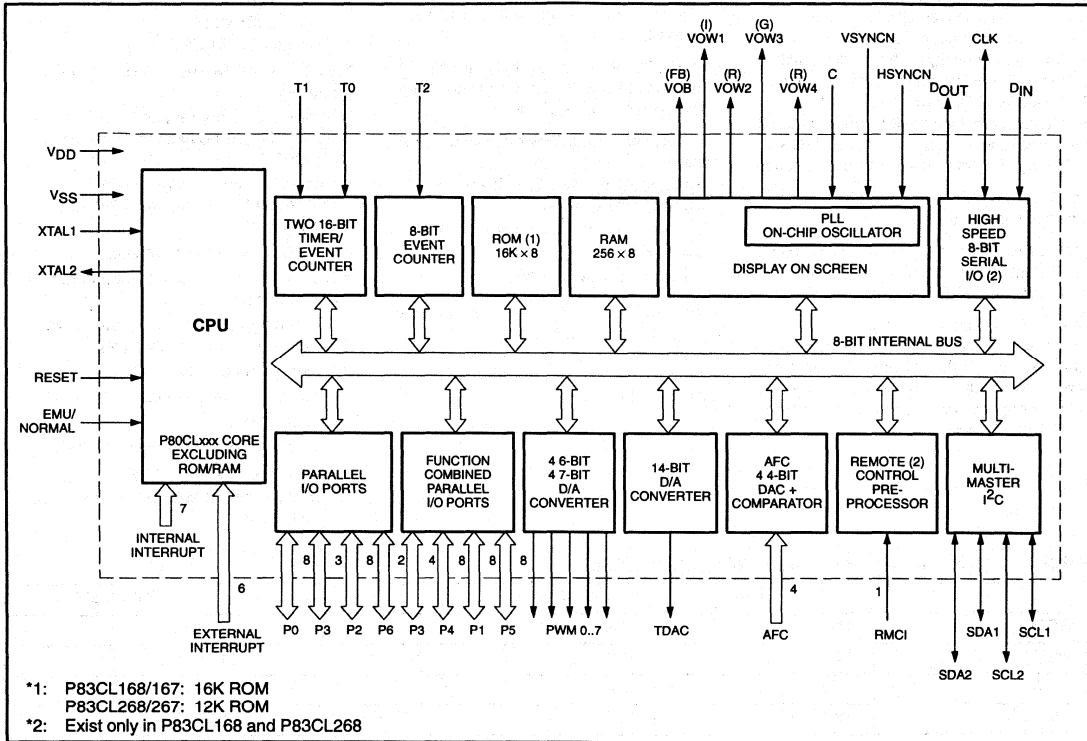

1. HIO, High speed I/O, 8-bit serial bus with maximum 1MHz baud rate. (see chapter 15)
2. RMC, ReMote Control pre-processor, a derivative function dedicated to preprocess I/R remote control signals. (see chapter 16)
3. Pin 26 is the combined function pin of RMC input and/or port line 57. Selection of either one function is controlled by a SFR P5SEL. (see chapter 9)
4. Pin 27, 28 and 29 are for HIO as well as for port lines. Selection is done by SFR P4SEL. (see chapter 9)

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

## Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

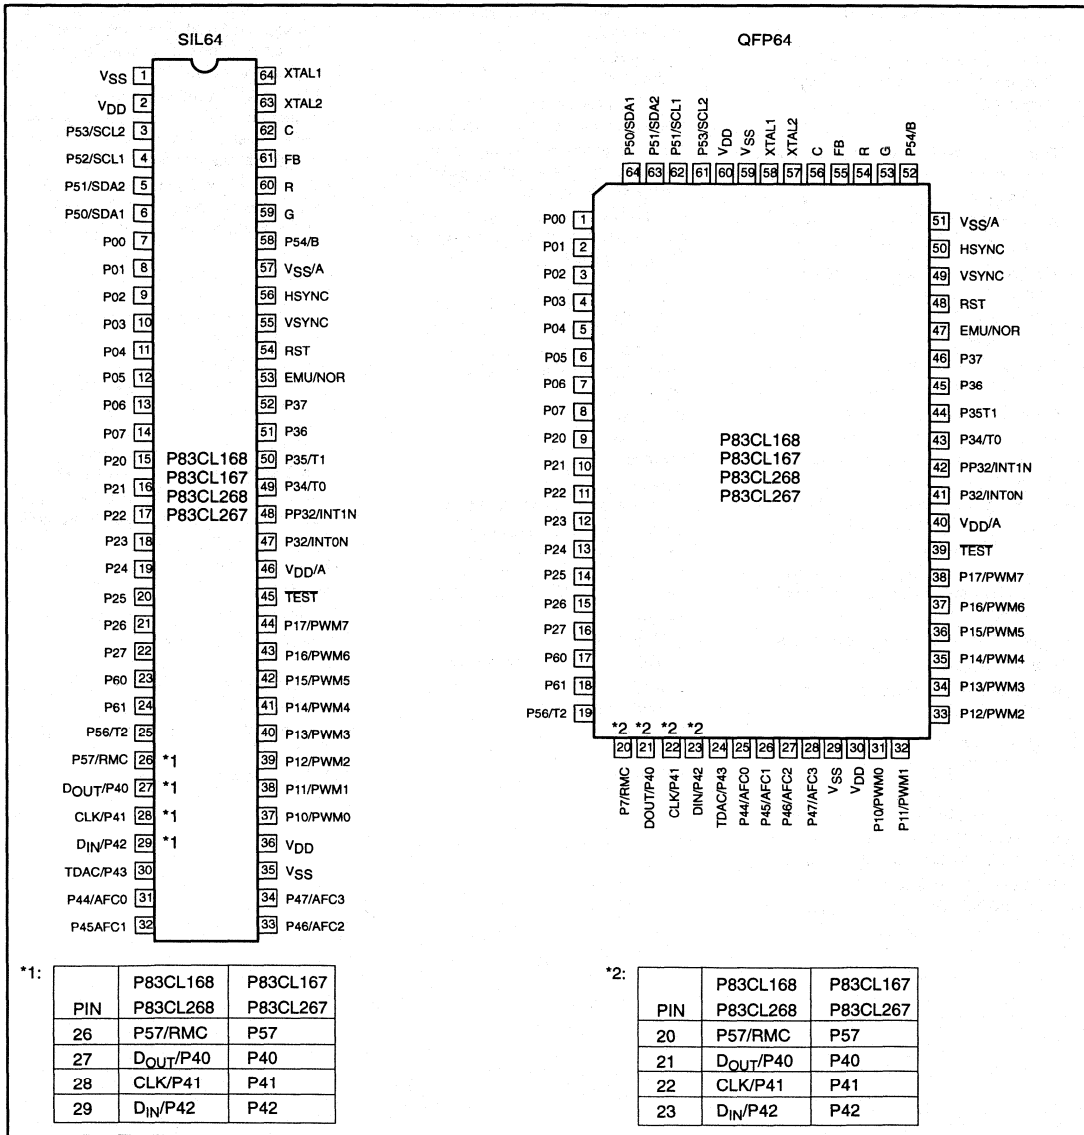

### 1.2 P83CL168 VST and OSD Derivative Features

- ROM/RAM
  - 16K × 8 system ROM, 256 × 8 system RAM on chip (no external memory access capability)
- PWMs
  - One 14-bit PWM output for VST (voltage synthesized tuning)
  - Four 6-bit PWM and four 7-bit PWM outputs (DACs for analog controls)
- AFC (A to D converter)
  - Four AFC inputs with 4 bit DAC and comparator (i.e., 4 channel of 4-bit A to D converter)
- LED driver port
  - Eight port lines (P0) with 10mA LED drive (@ <math>0.4V</math>) capability
- Remote Control pre-processor
  - 8-bit counter with pulse width measurement capability & digital filter for noise discrimination.
  - Resolution of minimal pulse width is programmed by software (Fxtal/192, /384, /768, /1536)
  - Maximum noise discrimination pulse width programmed by software (Fxtal/96, /192, /384, /768)
  - Interrupt driven or polling by software.
- Serial I/O: 2 types
  3. Multimaster I<sup>2</sup>C (with two sets of SDA/SCL pins)
  4. High speed (1MHz baud rate maximum) 8-bit 3-wire serial I/O
- Timer/counter T2 – AC supply line frequency counter (e.g., real time clock application in TV) or HSYNC counter (e.g., no broadcasting signal detection)
  - 8-bit event counter driven by external input. Rising edge Schmitt trigger input
- On screen display function
  - Programmable VSYNC/HSYNC active level
  - Display RAM: 160 × 12 bit
  - Display character fonts: 128 (126 customer font + 2 reserved)
  - One vertical display starting position counter. 64 different starting positions controlled by software.
  - One horizontal display starting position control for OSD. 64 different positions controlled by software.
  - Character size: 4 different character size, line-by-line basis, 1 horizontal dot = 1 or 2 OSD clock period. 1 vertical dot = 1 or 2 horizontal scan lines. Individually controllable.
  - Character matrix: 12 \* 18 with no spacing between characters
  - Foreground colors: 16, character-by-character basis
  - Background/shadowing modes: Two primary modes: "TV mode" or "Monitor mode", frame basis. In each primary mode, three submodes are available.
    - Sub-mode 1: superimpose (no background),
    - sub-mode 2: north-west shadowing,
    - sub-mode 3: box shadowing, all these three are line basis.
- Background colors: 16, word-by-word basis. Available when background is either in "north-west shadowing", "box shadowing" or "frame shadowing" submodes.
- Display RAM starting address is programmable. Fast switching between bank of display (RAM) characters are possible through software control.
- On-chip PLL oscillator for OSD function with software selectable OSD clock period (e.g., scalable character width by software)
- Character blinking: Ratio (or duty cycle): 1:1 ; frequency: Fv/32, Fv/64, programmable, character basis
- Display format: Flexible display format by using CR (carriage return), SP1 and SP2 (space) codes.
- Display RAM address post increment each time a new data is written into.
- Vertical jitter cancelling circuit to avoid unstable VSYNC trailing edge mismatch with HSYNC signal.
- On chip power on reset
- Package: 64SDIL or QFP64
- Operating voltage range: 4.5V – 5.5V
- Operating temperature range: –20°C – + 70°C
- System clock operating frequency range: 4MHz – 12MHz
- OSD clock operating range: 4 – 10MHz

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 2. MEMORY ORGANIZATION

The P83CL168 has 16K program memory (ROM) plus 256 bytes of data memory (RAM) on chip. The device has separate address spaces for program and data memory.

This device has NO external memory access capability such that the RD (read), WR (write), EA (external access), PSEN (read strobe) and ALE (address latch enable) signals are not bonded out.

### 2.1 Program Memory and Interrupt Vector

After reset the CPU begins execution at location 0000H. The interrupt vectors are located at the following address in ROM.

See also chapter 6 for interrupt level and function control details.

| Priority (within level) | Source                       | Vector (address in HEX decimal) |
|-------------------------|------------------------------|---------------------------------|
| PX0 (Highest)           | External Interrupt 0 (INT0N) | 0003H                           |
| S1                      | I <sup>2</sup> C             | 002BH                           |
| PX5                     | High speed 8-bit serial I/O  | 0053H                           |
| T0                      | Timer 0                      | 000BH                           |
| PX6                     | Remote Control preprocessor  | 005BH                           |
| PX1                     | External Interrupt 1 (INT1H) | 0013H                           |
| PX2                     | P10 (port line 10)           | 003BH                           |
| PX7                     | VSYNC interrupt              | 0063H                           |
| T1                      | Timer 1                      | 001BH                           |
| PX3                     | P11 (port line 11)           | 0043H                           |
| PX8                     | T2 (AC frequency counter)    | 006BH                           |
| PX4                     | P12 (port line 12)           | 004BH                           |

P83CL168/167/268/267

## 3. I/O FACILITY

### 3.1 I/O Ports

The P83CL168 has 49 I/O lines treated as 49 individual addressable bits or as 5 parallel 8-bit addressable ports, e.g., 0, 1, 2, 4, 5. Port 3 has 6 lines, Port 5 has 7 lines while port 6 has only two lines available.

Port 1, 3, 4 and 5 also performs the following alternate functions:

- Port 1: provides the output pins of the 6-bit/7-bit PWM's, as well as the external interrupt inputs (P10, P11, P12 & P17).
- Port 34, 35: provides 16-bit timer/counter 0 and 1's I/O.
- Port 32, 33: provide also the external interrupt input INTON and INT1N.
- Port 40 – 42: provides the high speed 8-bit serial I/O's data input, output and clock pins.
- Port 43: provides the 14-bit PWM output (TDAC) for tuning voltage control.
- Port 44 – 47: provides the 4-bit AFC inputs.

- Port 50 – 53: provides the I<sup>2</sup>C data and clock I/O's.
- Port 54 – 55: provides the output of the OSD color B & I.
- Port 56: provides the I/O pin of the 8-bit event counter T2.
- Port 57: provides the remote control preprocessor input.

To enable the port 1, 3, 4 and/or 5 as alternate function, chapter 9 has the details. Each port consists of a latch (SFR P0 – P6), an output driver and an input buffer.

### 3.2 Port Options

Most of the I/O pins can be individually configured as one of the following port options (Figure 1, Figure 2, Figure 3). Port option selection table is shown in Table 2. **Option 1** — standard port; quasi-bidirectional I/O with pull-up. The strong booster pull-up transistor P1 is turned on for two oscillator periods after a 0-to-1 transition in the port latch. (Figure 1). To configure the port line

into OUTPUT port, write either 0 or 1 to its port latch first before read the port pin.

**Option 2** — open drain; quasi-bidirectional I/O with n-channel pull-down. Use as an output requires the connection of an external pull-up resistor. (Figure 2). Use as an input requires to write an "1" to the port latch before read the port line.

**Option 3** — Push-pull; gives drive capability of the output in both polarities. This option permits the port to be used as an output only (Figure 3).

Individual mask selection of the post-reset state is available on any of the above pins. Make your selection by appending "S" or "R" to option 1, 2 or 3 above.

Option S : SET; after reset this pin is initialized to "HIGH".

Option R : RESET; after reset this pin is initialized to "LOW".

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

## P83CL168/167/268/267

### 4. IDLE AND POWER-DOWN OPERATION (for reference only)

The following paragraphs describe the general feature of P83CLxxx family and is for reference only. Since in the TV application there is no need for stop nor idle mode we will not test these two specification in the testing stage.

#### 4.1 Power Control Register

Power-down and Idle modes are activated by software via the Special Function Register PCON. Its hardware address is 87H. PCON is byte addressable only.

#### 4.2 Power-Down Mode

The instruction setting PCON.1 is the last executed prior to going into the Power-down mode. In Power-down mode the oscillator is stopped. The contents of the on-chip RAM and SFRs are preserved. The port pins output the values held by their respective

SFRs. The wake-up operation after power-down in this controller has two basic approaches: (section 4.3 & 5.4)

#### 4.3 Wake-up from Power Down Using INT2, 3, 4, 9 (i.e., P10, P11, P12, P17)

If INT2, 3, 4, or 9 are enabled, the P83CL168 can be woken-up from power-down mode with the external interrupts. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods. This is controlled by an on-chip delay counter.

#### 4.4 Wake-up from Power Down Using RESET

To wake-up the P83CL168 the RESET pin has to be kept HIGH for a minimum of 24 cycles. The on-chip delay counter is inactive. The user has to ensure that the oscillator is stable before any operation is attempted.

#### 4.5 Idle Mode

The instruction that sets PCON.0 is the last instruction executed before going into Idle mode. Once in the Idle mode, the internal clock is gated away from the CPU, but not from the interrupt, timer and Serial port functions etc. The CPU status is preserved along with the Stack pointer, Program counter, Program status Word and Accumulator. The RAM and all other registers maintain their data during Idle mode. The port pins retain the logical states they held at Idle mode activation.

#### 4.6 Recover from Idle Mode

There are two methods used to terminate the Idle mode. Activation of any enabled interrupt will cause PCON to be cleared by hardware:—terminating Idle mode. The interrupt is serviced, and following the instruction RETI, the next instruction to be executed will be the one following the instruction that put the device in the Idle mode.

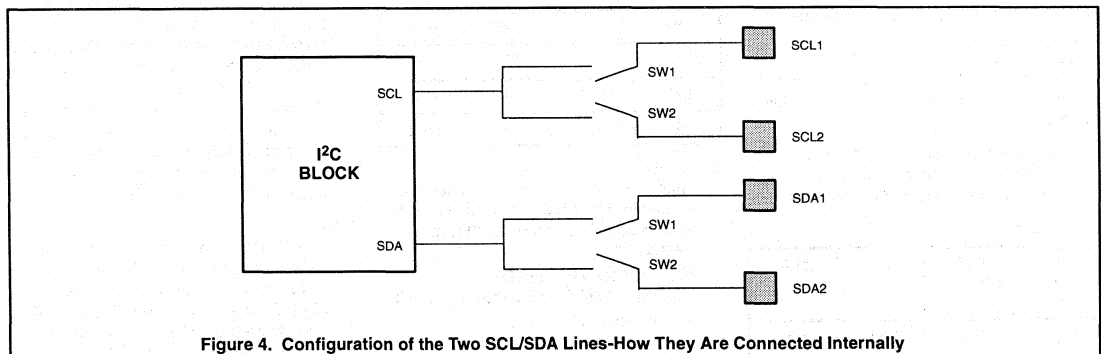

Figure 4. Configuration of the Two SCL/SDA Lines—How They Are Connected Internally

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

## P83CL168/167/268/267

### 5. I<sup>2</sup>C-BUS SERIAL I/O

#### 5.1 The I<sup>2</sup>C bus and the Control Register

The serial port supports the twin line I<sup>2</sup>C-bus. The I<sup>2</sup>C-bus consists of a data line (SDA) and a clock line (SCL). These lines also function as I/O port lines P50, 51, 52 and 53 respectively. The system is unique because data transfer, clock generation, address recognition and bus control arbitration are all controlled by hardware. There is one I<sup>2</sup>C hardware only inside the P83CL168 but it is connected to two sets of SCL/SDA pins where Figure 4 shows the configuration.

An analog switch which connect or disconnect SCL1/SDA1 and/or SCL2/SDA2 pins to the internal I<sup>2</sup>C hardware is controlled by the SFR I2CCON address 86H.

Application of this particular function is in the TV system, normally during the standby mode part of the power supply in the system is shut down. To avoid some devices pull down the SDA/SCL lines when they are not supplied with power while the main microcontroller like P83CL168 and the EEPROM device PCF8581 are still powered up, an isolation circuit like this can fulfill this function.

To fully utilize this facility, the pins P53/SCL2 and P52/SDA2 must be configured as alternative functions instead of port lines.

| bit7 | bit6 | bit5 | bit4 |
|------|------|------|------|
| —    | —    | —    | —    |
| bit3 | bit2 | bit1 | bit0 |
| —    | —    | SW1  | SW0  |

When the pins 3, 4, 5, 6 are selected as I<sup>2</sup>C data/clock lines (see chapter 9 for how to select) the following two control bits are actively control the switch connection.

- SW1 = 0, Internal SCL/SDA is disconnected from SCL1/SDA1  
 = 1, Internal SCL/SDA is connected to SCL1/SDA1
- SW2 = 0, Internal SCL/SDA is disconnected from SCL2/SDA2  
 = 1, Internal SCL/SDA is connected to SCL2/SDA2

When both SW1 and SW2 are on (=1), SCL, SCL1 and SCL2 are connected; SDA, SDA1, SDA2 are also connected.

#### 5.2 Operation Modes

The I<sup>2</sup>C-bus serial I/O has complete autonomy in byte handling and operates in four modes.

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

These functions are controlled by the S1CON register. S1STA is the status register whose contents may also be used as a vector to various service routines. S1DAT is the data shift register and S1ADR the slave address register. Slave address recognition is performed by hardware.

For the detailed I<sup>2</sup>C specification, refer to the section 3.8 SIO1, I<sup>2</sup>C serial I/O (pp3–27 thru 3–49) of the specification 'Single chip 8-bit Microcontrollers PCB83C552/562'; Ordering information 12NC 9398 650 20011.

#### 5.3 Serial Control Register S1CON

##### S1CON (D6H)

| bit7 | bit6 | bit5 | bit4 |
|------|------|------|------|
| —    | ENS1 | STA  | STO  |
| bit3 | bit2 | bit1 | bit0 |
| SI   | AA   | CR1  | CR0  |

##### CR0, CR1

These two bits determine the serial clock frequency when SIO is in a master mode. **Maximum I<sup>2</sup>C speed is 100KHz in P83CL168.**

=00, I<sup>2</sup>C speed =  $f_{OSC}/960$   
 (e.g., Xtal=12MHz, I<sup>2</sup>C speed = 12.5KHz)

=01, I<sup>2</sup>C speed =  $f_{OSC}/120$   
 (e.g. Xtal = 12MHz, I<sup>2</sup>C speed = 100KHz)

=10, I<sup>2</sup>C speed =  $f_{OSC}/60$   
 (e.g. Xtal = 6MHz, I<sup>2</sup>C speed = 100KHz)

=11, I<sup>2</sup>C speed =  $96 * (256 - \text{Timer } 1 \text{ reload range } 0-254 \text{ in mode } 1)$

##### AA

Assert acknowledge bit. When the AA flag is set, an acknowledge (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when

- own slave address is received
- general call address is received (S1ADR.0=1)
- data byte received while device is programmed as master
- data byte received while device is a selected slave.

With AA=0, no acknowledge will be returned. Consequently, no interrupt is requested when the "own slave address" or general call address is received.

##### SI

SIO interrupt flag. When the S1 flag is set, an acknowledge is returned after any one of the following conditions:

- a start condition is generated in master mode.
- own slave address received during AA= 1
- general call address received while S1ADR.0 and AA=1
- data byte received or transmitted in master mode (even if arbitration is lost)
- data byte received or transmitted as selected slave
- stop or start condition received as selected slave receiver or transmitter

##### STO

STOP flag. With this bit set while in master mode STOP condition is generated. When a STOP condition is detected on the bus, the SIO hardware clears the STO flag. In the slave mode, the STO flag, may also be set to recover from an error condition. In this case, no STOP condition is transmitted to the I<sup>2</sup>C-bus. However, the SIO hardware behaves as if a STOP condition has been received and releases SDA and SCL. The SIO then switches to the "no addressed" slave receiver mode. The STO flag is automatically cleared by hardware.

##### STA

START flag. When the STA bit is set in slave mode, the SIO hardware checks the status of the I<sup>2</sup>C-bus and generates a START condition if the bus is free. If STA is set while the SIO is in master mode, SIO transmits a repeat START condition.

##### ENS1

When ENS1=0, the SIO is disabled. The SDA and SCL outputs are in a high-impedance state; P1.6 and P1.7 function as open drain ports. When ENS=1, the SIO is enabled. The P1.6 and P1.7 port latches must be set to logic 1.

P83CL168/167/268/267

## 5.4 Status Register S1STA

### S1STA (D9H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| SC4  | SC3  | SC2  | SC1  |
| bit3 | bit2 | bit1 | bit0 |
| SC0  | 0    | 0    | 0    |

S1STA is an 8-bit read-only special function register. S1STA.3–S1STA.7 hold a status code. S1STA.0–S1STA.2 are held LOW. The contents of S1STA may be used as a vector to a service routine. This optimizes response time of the software and consequently that of the I<sup>2</sup>C-bus.

The following is a list of the status codes:

#### Abbreviations used:

|      |                                                |
|------|------------------------------------------------|
| SLA  | 7-bit slave address                            |
| R    | Read bit                                       |
| W    | Write bit                                      |
| ACK  | Acknowledgement<br>(acknowledge bit = 0)       |
| ACKN | not Acknowledge<br>(acknowledge bit = 1)       |
| DATA | 8-bit byte to or from the I <sup>2</sup> C-bus |
| MST  | Master                                         |
| SLV  | Slave                                          |
| TRX  | Transmitter                                    |
| REC  | Receiver                                       |

#### MST/TRX mode

##### S1STA value

- 08H – a START condition has been transmitted
- 10H – a repeated START condition has been transmitted
- 18H – SLA and W have been transmitted, ACK received
- 20H – SLA and W have been transmitted, ACK received
- 28H – DATA of S1DAT has been transmitted, ACK received
- 30H – DATA of S1DAT has been transmitted, ACK received
- 38H – Arbitration lost in SLA, R/W or DATA

#### MST/REC mode

##### S1STA value

- 38H – Arbitration lost while returning ACK.
- 40H – SLA and R have been transmitted, ACK received.
- 48H – SLA and R have been transmitted, ACK received.
- 50H – DATA has been received, ACK returned.
- 58H – DATA has been received. ACK returned.

#### SLV/REC mode

##### S1STA value

- 60H – Own SLA and W have been received, ACK returned.
- 68H – Arbitration lost in SLA, R/W as MST. Own SLA and W have been received, ACK returned.
- 70H – General CALL has been received, ACK returned.
- 78H – Arbitration lost in SLA, R/W as MST. General CALL has been received.
- 80H – Previously addressed with own SLA. DATA byte received, ACK returned.
- 88H – Previously addressed with own SLA. DATA byte received. ACK returned.
- 90H – Previously addressed with general CALL. DATA byte has been received. ACK has been returned.
- 98H – Previously addressed with general CALL. DATA byte has been received. ACK has been returned.
- A0H – A STOP condition or repeated START condition has been received while still addressed as SLV/REC or SLV/TRX.

#### SLV/TRX mode

##### S1STA value

- A8H – Own SLA and R have been received. ACK returned.
- B0H – Arbitration lost in SLA, R/W as MST. Own SLA and R have been received, ACK returned.
- B8H – DATA byte has been transmitted, ACK received.
- C0H – DATA byte has been transmitted, ACK received.
- C8H – Last DATA byte has been transmitted(AA=logic 0) ACK received.

#### Miscellaneous

##### S1STA value

- 00H – Bus error during MST mode or SLV mode, due to an erroneous START or STOP condition.

## 5.5 Data Shift Register S1DAT

### S1DAT (DAH)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| D7   | D6   | D5   | D4   |
| bit3 | bit2 | bit1 | bit0 |
| D3   | D2   | D1   | D0   |

This register contains the serial data to be transmitted or data that has just been received. Bit 7 is transmitted or received first; i.e., data is shift from left to right.

## 5.6 Slave Address S1ADR

### S1ADR (DBH)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| SLA6 | SLA5 | SLA4 | SLA3 |
| bit3 | bit2 | bit1 | bit0 |
| SLA2 | SLA1 | SLA0 | GC   |

- GC = 0, general CALL address is not recognized;
- =1, general CALL address is recognized.

SLA<6:0> own slave address

This 8-bit register may be loaded with the 7-bit slave address to which the controller will respond when programmed as slave receiver/transmitter. The LSB bit (GC) is used to determine whether the general CALL address is recognized.

For the detailed I<sup>2</sup>C specification, refer to the section 3.8 SIO1, I<sup>2</sup>C serial I/O (pp3–27 thru 3–49) of the specification 'Single chip 8-bit Microcontrollers PCB83C552/562'; Ordering information 12NC 9398 650 20011.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 6. INTERRUPT SYSTEM

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to the execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution a multiple-source, two-priority-level, nested interrupt system is provided. The P83CL168 acknowledges interrupt requests from thirteen sources as shown in Table 3.

Each interrupt vectors to a separate location in program memory for its service routine. Each source can be individually enabled or disabled by corresponding bits in the interrupt Enable Registers (IE, IEO). The priority level is selected via the interrupt priority register (IPO, IP1). All enabled sources can be globally disabled or enabled.

### 6.1 External Interrupts INT2, 3, 4 and INT9 and Interrupts 5, 6, 7, 8 (used by derivative functions)

Port 1 lines serve an alternative purpose as four additional interrupts INT2, 3, 4 and 9 (P10, P11, P12 and P17). The Interrupt INT5, 6, 7 and 8 which were connected to port P13, 14, 15 and 16 in the standard P83CL410 are no longer connected to these pins. Instead, they are used separately by the derivative functional blocks as follows:

|    |                             |       |
|----|-----------------------------|-------|
| X5 | High speed 8-bit serial I/O | 0053H |
| X6 | Remote Control preprocessor | 005BH |
| X7 | VSYNC interrupt             | 0063H |
| X8 | T2 (AC frequency counter)   | 006BH |

Using the 1X1 register, each pin may be initialized to either active HIGH or LOW. (INT2, 3, 4 & 9 only, 5, 6, 7, 8 are fixed to active high because these interrupt are from other derivative functions.) IRQ1 is the interrupt request flag register. Each flag, if the interrupt is enabled, will be set on interrupt request but it must be cleared by software, i.e., via the interrupt software or when the interrupt is disabled.

Table 3.

| PRIORITY (within level) | SOURCE                       | VECTOR (address in HEX decimal) |
|-------------------------|------------------------------|---------------------------------|
| PX0 (Highest)           | External Interrupt 0 (INT0N) | 0003H                           |
| S1                      | I <sup>2</sup> C             | 002BH                           |
| PX5                     | High speed 8-bit serial I/O  | 0053H                           |
| T0                      | Timer 0                      | 000BH                           |
| PX6                     | Remote Control preprocessor  | 005BH                           |
| PX1                     | External Interrupt 1 (INT1N) | 0013H                           |
| PX2                     | P10 (port line 10)           | 003BH                           |
| PX7                     | VSYNC interrupt              | 0063H                           |
| T1                      | Timer 1                      | 001BH                           |
| PX3                     | P11 (port line 11)           | 0043H                           |
| PX8                     | T2 (AC frequency counter)    | 006BH                           |
| PX4                     | P12 (port line 12)           | 004BH                           |
| PX9 (Lowest)            | P17 (port line 17)           | 0073H                           |

## 6.3 Interrupt Priority Registers IP0, IP1

### IP0 (B8H)

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
|------|------|------|------|------|------|------|------|
| —    | —    | PS1  | —    | PT1  | PX1  | PT0  | PX0  |

| Bit  | Symbol | Function                                      |
|------|--------|-----------------------------------------------|
| IP.7 | —      | (unused)                                      |
| IP.6 | —      | (unused)                                      |
| IP.5 | PS1    | I <sup>2</sup> C SIO interrupt priority level |
| IP.4 | —      | (unused)                                      |
| IP.3 | PT1    | Timer 1 interrupt priority level              |
| IP.2 | PX1    | External interrupt priority level.            |
| IP.1 | PT0    | Timer 0 interrupt priority level.             |
| IP.0 | PX0    | External interrupt 0 priority level.          |

### IP1 (F8H)

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
|------|------|------|------|------|------|------|------|
| PX9  | PX8  | PX7  | PX6  | PX5  | PX4  | PX3  | PX2  |

| Bit   | Symbol | Function                                                          |
|-------|--------|-------------------------------------------------------------------|
| IP1.7 | PX9    | external interrupt 9 priority level (P17 port line)               |
| IP1.6 | PX8    | external interrupt 8 priority level (T2 : 8-bit counter)          |
| IP1.5 | PX7    | external interrupt 7 priority level (VSYNC interrupt)             |
| IP1.4 | PX6    | external interrupt 6 priority level (Remote control preprocessor) |
| IP1.3 | PX5    | external interrupt 5 priority level (High speed 8-bit serial I/O) |
| IP1.2 | PX4    | external interrupt 4 priority level (P12 port line)               |
| IP1.1 | PX3    | external interrupt 3 priority level (P11 port line)               |
| IP1.0 | PX2    | external interrupt 2 priority level (P10 port line)               |

Interrupt priority is as follows: 0—low priority;  
1—high priority

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 6.4 Interrupt Polarity Register IX1

### IX1 (E9H)

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
|------|------|------|------|------|------|------|------|
| IL9  | 1    | 1    | 1    | 1    | IL4  | IL3  | IL2  |

Writing either a "1" or "0" to an IX1 register bit sets the polarity level of the corresponding external interrupt to active HIGH (=1) or LOW (=0) respectively. But IX1<6:3> is fixed to 1 (active high).

| Bit   | Symbol | Function                                                          |
|-------|--------|-------------------------------------------------------------------|
| IX1.7 | IL9    | external interrupt 9 polarity level (P17 port line)               |
| IX1.6 | IL8    | external interrupt 8 polarity level (T2: 8-bit counter)           |
| IX1.5 | IL7    | external interrupt 7 polarity level (VSYNC interrupt)             |
| IX1.4 | IL6    | external interrupt 6 polarity level (Remote control preprocessor) |
| IX1.3 | IL5    | external interrupt 5 polarity level (High speed 8-bit serial I/O) |
| IX1.2 | IL4    | external interrupt 4 polarity level (P12 port line)               |
| IX1.1 | IL3    | external interrupt 3 polarity level (P11 port line)               |
| IX1.0 | IL2    | external interrupt 2 polarity level (P10 port line)               |

## 6.5 Interrupt Request Flag Register IRQ1

### IRQ1 (C0H)

| bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 |
|------|------|------|------|------|------|------|------|
| IQ9  | IQ8  | IQ7  | IQ6  | IQ5  | IQ4  | IQ3  | IQ2  |

Bit 7, 2, 1, 0 are set to one when the corresponding bit in IEN1 SFR is enabled and its corresponding port line 17, 12, 11, 10 is high (if polarity IX1.y, y=7, 2, 1, 0, is set to high). A pending interrupt is generated to CPU. If IEN1.7, 2, 1 or 0 is 0 (disabled) then IRQ1.7, 2, 1, or 0 will never set to 1 even the external port line condition is met. Reset of IRQ1.7, 2, 1, 0 can be done by software write "0" only.

But for IRQ1.6, 5, 4, 3, these four bits serve not only as a pending interrupt request bits like IRQ1.7, 2, 1, 0 but also as the interrupt status bits. This means even if IEN1.6, 5, 4, 3 is NOT enabled, the IRQ1.6, 5, 4, 3 can still be set to one if the interrupt condition is met within the corresponding derivative functions.

That is, for example, if the interrupt condition within Counter T2 is met (i.e., overflow), then:

- If IEN0.7 = X, IEN1.6 = 0 → then IRQ1.6 = 1, no pending interrupt to CPU.
- If IEN0.7 = 0, IEN1.6 = 1 → then IRQ1.6 = 1, interrupt to CPU is pending.
- If IEN0.7 = 1, IEN1.6 = 1 → then IRQ1.6 = 1, interrupt will be served as soon as
  - CPU finishes current instruction, if not in the interrupt service routine.
  - or the current interrupt service routine is interrupted if the T2 has higher interrupt priority
  - or this T2 interrupt becomes pending, waiting until the current higher priority level interrupt is served.

| Bit    | Symbol | Function                                                                        |
|--------|--------|---------------------------------------------------------------------------------|
| IRQ1.7 | IQ9    | external interrupt 9 request flag (P17 port line)                               |
| IRQ1.6 | IQ8    | external interrupt 8 request flag (T2: 8-bit counter)                           |
| IRQ1.5 | IQ7    | external interrupt 7 request flag (VSYNC interrupt, see chapter 13)             |
| IRQ1.4 | IQ6    | external interrupt 6 request flag (Remote control preprocessor, see chapter 14) |
| IRQ1.3 | IQ5    | external interrupt 5 request flag (High speed 8-bit serial I/O, see chapter 15) |
| IRQ1.2 | IQ4    | external interrupt 4 request flag (P12 port line)                               |
| IRQ1.1 | IQ3    | external interrupt 3 request flag (P11 port line)                               |
| IRQ1.0 | IQ2    | external interrupt 2 request flag (P10 port line)                               |

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 6.6 Interrupt Priority

Each interrupt source can be set to either high or low priority. If both priorities are requested simultaneously, the controller will branch to the high priority vector.

A low priority interrupt can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

## 6.7 Related Registers

The following registers are used in conjunction with the interrupt system:

| Register | Function                                | SFR Address |
|----------|-----------------------------------------|-------------|
| 1X1      | interrupt polarity register             | E9H         |
| IRQ1     | interrupt request flag register         | C0H         |
| IEN0     | interrupt enable register               | A8H         |
| IEN1     | interrupt enable register (INT2-INT9)   | E8H         |
| IP0      | interrupt priority register             | B8H         |
| IP1      | interrupt priority register (INT2-INT9) | F8H         |

## 7. OSCILLATOR CIRCUITRY

The on-chip oscillator circuitry of the P83CL168 is a single-stage inverting amplifier biased by an internal feedback resistor (Figure 7). For operation as a standard quartz oscillator, no external components are needed. When using external ceramic resonators, different configuration is supported (see Figure 8 and oscillator options).

### 7.1 Oscillator Options

Table 4 lists oscillator transconductance options as provided for optimum on-chip oscillator performance. Please state option when ordering.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 8. RESET CIRCUITRY AND SFR MAP

To initialize the P83CL168 a reset is performed by either of two methods:

- via the RST pin
- via a power-on-reset

It leaves the internal registers as follows:

| SFR addr | Register | Content   |
|----------|----------|-----------|
| E0H      | ACC      | 0000 0000 |
| F0H      | B        | 0000 0000 |
| 82H      | DPL      | 0000 0000 |

The reset state of the port pins is mask-programmable and can therefore be defined by the customer.

The output of the Schmitt trigger is sampled by the reset circuitry every machine cycle.

A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods), while the oscillator is running. The CPU responds by generating an internal reset. Port pins adopt their reset state immediately after RST goes HIGH.

The external reset is asynchronous to the internal clock. The RST pin is sampled during State 5 phase 2 of every machine cycle. After a HIGH is detected at the RST pin, an internal reset is repeated every cycle until RST goes LOW.

The internal RAM is not affected by reset. When V<sub>DD</sub> is returned on the RAM contents remain unchanged.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 9. PORT/ALTERNATIVE FUNCTION SELECTION

The port lines 1, 3, 4 and 5 are shared with the derivative functions' input or output pin. To configure these pins to either port lines or alternative functions, the following SFR are required.

### 9.1 Port 1 Selection – P1SEL

P1SEL (CCH)

|       |       |       |       |
|-------|-------|-------|-------|
| bit7  | bit6  | bit5  | bit4  |
| PWM7E | PWM6E | PWM5E | PWM4E |
| bit3  | bit2  | bit1  | bit0  |
| PWM3E | PWM2E | PWM1E | PWM0E |

Port 1 is shared with the 6 or 7-bit PWM's (pins 8, 9, 10, 21, 22, 23, 24, 25). When the corresponding bit *i* (*i*=7 – 0) in the P1SEL is programmed to 1, the pin functions as the output of the PWM*i*. If that bit is '0' then port line 1*i* is connected to that pin.

Abbreviations used in the following table,

- Bit: bit *i* (*i*=7 – 0) of the register
- Pin: pin number which contains the multiplexed I/O and alternative function
- =1: when that bit =1, the pin *xx* becomes the alternative function indicated.
- =0: when that bit = 0, the pin *xx* becomes the port line *yy*.

| Bit     | pin | = 1  | = 0 |
|---------|-----|------|-----|
| P1SEL.7 | 44  | PWM7 | P17 |
| P1SEL.6 | 43  | PWM6 | P16 |
| P1SEL.5 | 42  | PWM5 | P15 |
| P1SEL.4 | 41  | PWM4 | P14 |
| P1SEL.3 | 40  | PWM3 | P13 |
| P1SEL.2 | 39  | PWM2 | P12 |
| P1SEL.1 | 38  | PWM1 | P11 |
| P1SEL.0 | 37  | PWM0 | P10 |

### 9.2 Port 3 Selection

Part of the port 3 lines are multiplexed with the input pins of the external interrupt INT0N and INT1N and the timer/counter input pins T0 and T1. To configure these pins into the alternative input functions, the corresponding bit in the port latch should be programmed to 1. No special control required for this selection. Port 31 is no longer available.

### 9.3 Port 4 Selection – P4SEL

P4SEL (CDH)

|       |       |       |       |
|-------|-------|-------|-------|
| bit7  | bit6  | bit5  | bit4  |
| AFC3E | AFC2E | AFC1E | AFC0E |
| bit3  | bit2  | bit1  | bit0  |
| TDACE | DINE  | CLKE  | DOUTE |

An '1' in the corresponding bit enable the pin as the alternative function.

A '0' makes the pin as a general I/O port line.

AFC3E, AFC2E, AFC1E, AFC0E are to control the pins 34, 33, 32 and 31 as either port line 47, 46, 45 and 44 or the Automatic Frequency Control inputs 3, 2, 1, or 0.

TDACE is to control the pin 30 as 14-bit PWM output or the I/O port 43.

DINE, CLKE, DOUTE are to control the pins 29, 28, 27 as the high speed 8-bit serial I/O function or port line 42, 41 and 40.

| Bit     | pin | = 1  | = 0 |
|---------|-----|------|-----|
| P4SEL.7 | 34  | AFC3 | P47 |
| P4SEL.6 | 33  | AFC2 | P46 |
| P4SEL.5 | 32  | AFC1 | P45 |
| P4SEL.4 | 31  | AFC0 | P44 |
| P4SEL.3 | 30  | TDAC | P43 |
| P4SEL.2 | 29  | DIN  | P42 |
| P4SEL.1 | 28  | CLK  | P41 |
| P4SEL.0 | 27  | DOUT | P40 |

### 9.4 Port 5 Selection – P5SEL

P5SEL (CEH)

|       |       |       |       |
|-------|-------|-------|-------|
| bit7  | bit6  | bit5  | bit4  |
| RMCE  | T2E   | —     | OSDBE |
| bit3  | bit2  | bit1  | bit0  |
| SCL2E | SDA2E | SCL1E | SDA1E |

An '1' in the corresponding bit enable the pin as the alternative function.

A '0' makes the pin as a general I/O port line.

Port 55 is no longer available.

| Bit     | pin | = 1  | = 0 |
|---------|-----|------|-----|
| P5SEL.7 | 26  | RMC  | P57 |
| P5SEL.6 | 25  | T2   | P56 |
| P5SEL.4 | 58  | B    | P54 |
| P5SEL.3 | 3   | SCL2 | P53 |
| P5SEL.2 | 4   | SCL1 | P52 |
| P5SEL.1 | 5   | SDA2 | P51 |
| P1SEL.0 | 6   | SDA1 | P50 |

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 10. ANALOG CONTROL:

### 6-BIT/7-BIT PWMs

The P83CL168-VST has eight PWM DAC outputs for analog controls of, e.g., volume, balance, brightness and saturation. These PWM outputs generate pulse patterns with a repetition rate of  $F_{pwm}/64$  or  $F_{pwm}/128$ . The analog value is determined by the ratio of the HIGH-time and the repetition time. A DC voltage proportional to the PWM control setting is obtained by means of an external integration network (low pass filter). PWM0–3 is 7 bit while PWM4–7 is 6 bit.

The polarity of the PWMn output is fixed to active high. For those people who are familiar with Philips PCA84C846 TV microcontroller architecture, the active high output means P6LVL and P7LVL bit of derivative register 23H are programmed to '0'. Refer to PCA84C846 specification for details.

### 10.1 SFRs for PWMs Control

The following SFR's are the data registers of the 7-bit PWM's and 6-bit PWM's.

#### PWM0 (E4H)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | data6 | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM1 (E5H)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | data6 | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM2 (E6H)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | data6 | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM3 (E7H)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | data6 | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM4 (ECH)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | —     | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM5 (EDH)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | —     | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM6 (EEH)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | —     | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

#### PWM7 (EFH)

| bit7  | bit6  | bit5  | bit4  |
|-------|-------|-------|-------|
| —     | —     | data5 | data4 |
| bit3  | bit2  | bit1  | bit0  |
| data3 | data2 | data1 | data0 |

The high time of a PWMn output is:

$$T_{high} = [PWMn] * t_0$$

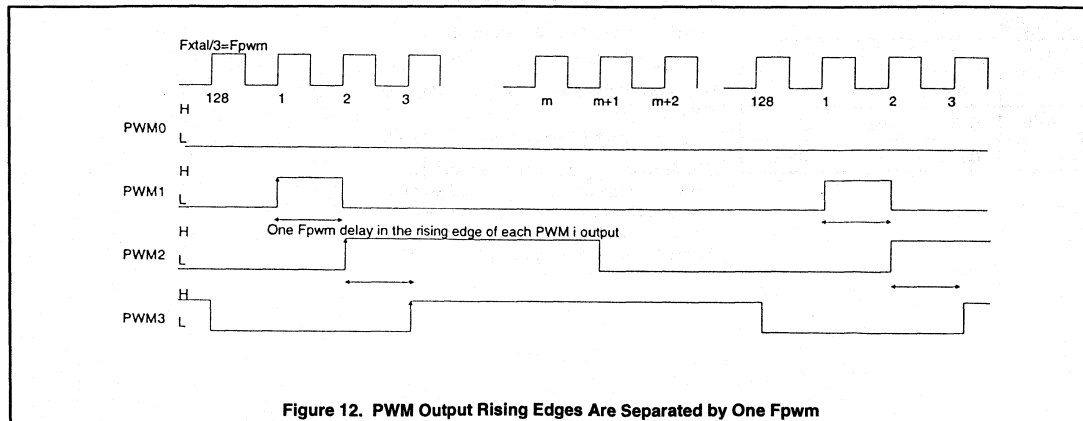

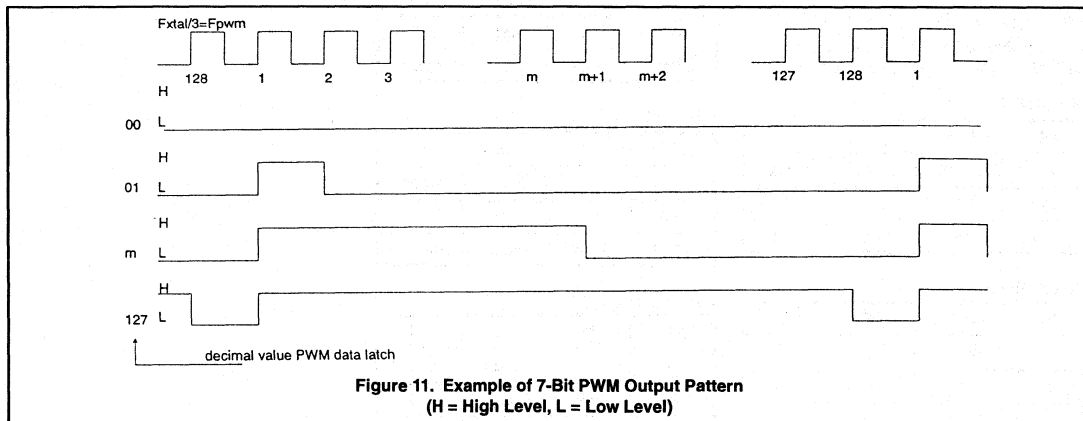

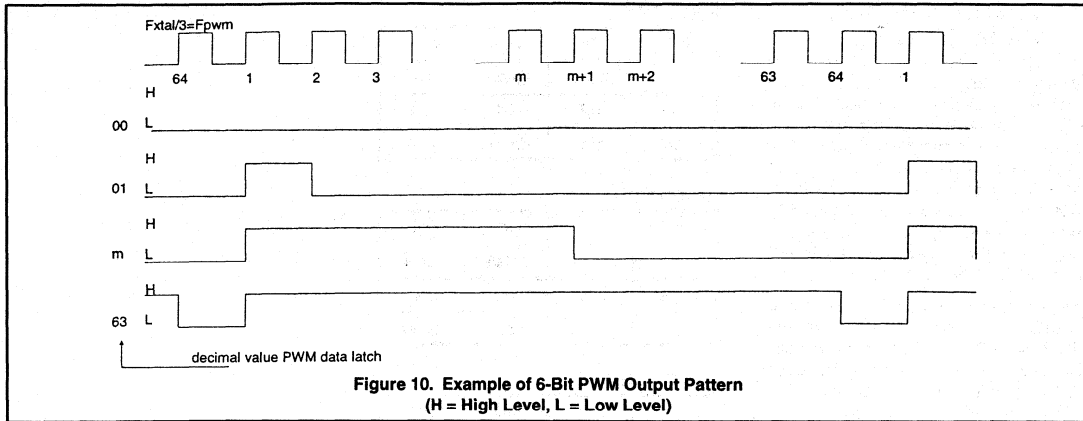

where [PWMn] is the "contents of PWMn data latch" and

$$t_0 = 1/F_{pwm} \text{ (in which } F_{xtal} / 3 = F_{pwm} \text{).}$$

Figure 10 and Figure 11 show active high PWM output patterns. The rising edge of the 8 different PWM's are separated by one  $F_{pwm}$  as shown in Figure 12. Figure 13 and Figure 14 show the block diagram.

P83CL168/167/268/267

**11. VST CONTROL - 14 BIT PWM DAC**

The P83CL168 has one PWM DAC output with a resolution of 16384 levels for voltage synthesized tuning, the VST DAC (Figure 12.1). The PWM DAC consists of:

- two 7-bit DAC interface latches (VSTH, VSTL)

- one 14 bit DAC data latch (VSTREG)
- 14 bit counter
- pulse control

The contents of the data latch (VSTREG) defines the high time. This content is

transferred from the interface latches (VSTH, VSTL) to the data latch (VSTREG). The upper seven bits are used for coarse adjustment, while the lower seven bits are used for fine adjustment.

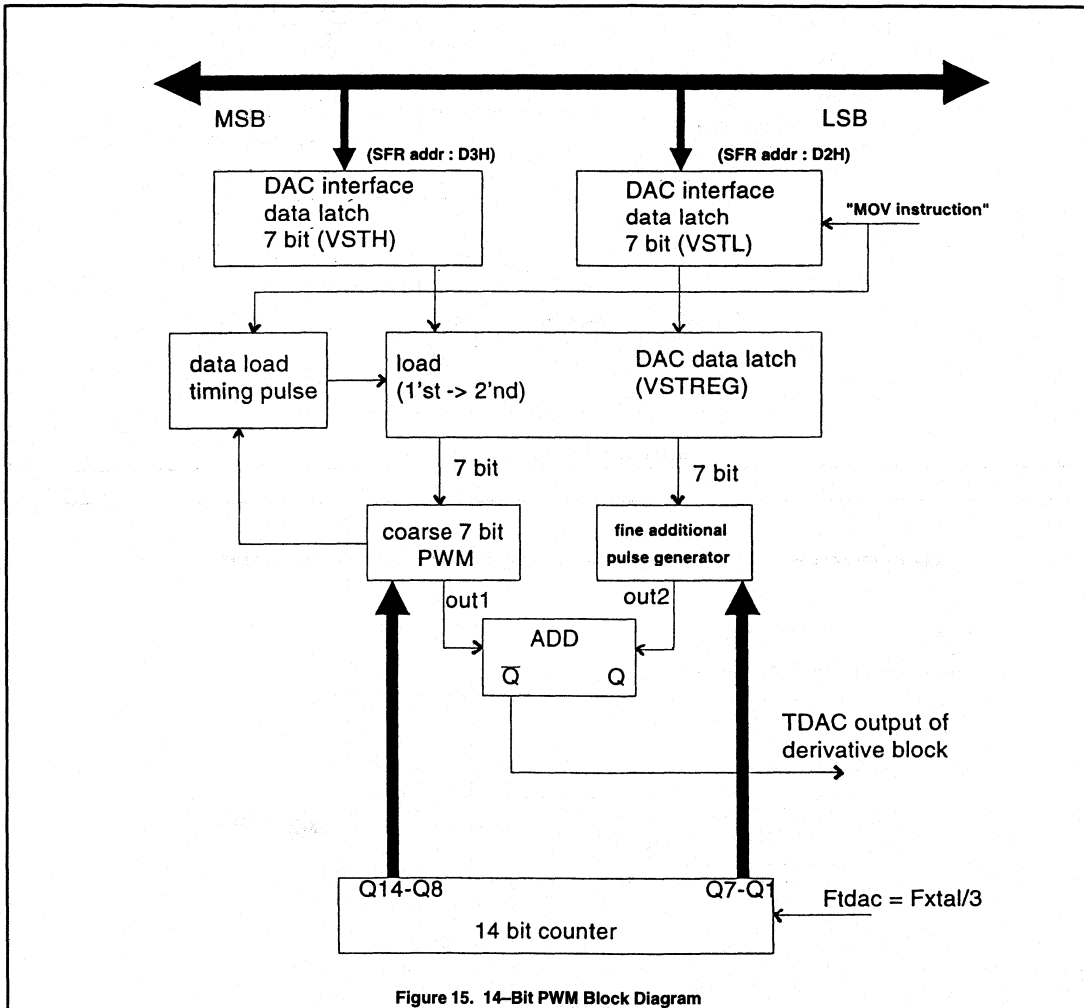

Figure 15. 14-Bit PWM Block Diagram

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 11.1 Repetition Time

upper 7 bits (VSTH):

$$F_{th} = F_{tdac} / 128$$

lower 7 bits (VSTL):

$$F_{tl} = F_{th} / 128 = F_{tdac} / 16384$$

The data from "VSTH", "VSTL" is latched into "VSTREG" at the beginning of the first  $T_{sub}$  after "VSTL" is written. So, in order to be sure that the correct data is latched into "VSTREG", "VSTH" must contain the right value before "VSTL" is written. (Fig 16, Note: in case 1 and case 2, a new value for VSTH, VSTL is latched into VSTREG. In

case 3, VSTL, together with an old value of VSTH are latched into VSTREG).

After VSTH, VSTL is latched into VSTREG, it takes one  $T_{sub}$  to generate the appropriate pulse pattern. So to ensure correct D/A converting, one should wait for two  $T_{sub}$  before changing VST(H)(L) again.

*Different from the 6-bit/7-bit PWM's active high, the output of the 14-bit PWM is active low; i.e., the high period of the output pulse is the value stored in the VSTH/VSTL special function register.*

## 11.2 Coarse Adjustment (VSTH)

VSTH (D3H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | VSTD | VSTC | VSTB |
| bit3 | bit2 | bit1 | bit0 |
| VSTA | VST9 | VST8 | VST7 |

Coarse adjustment (Figure 17) is done in periods of  $T_{sub}$ . During 1  $T_{sub}$ , the coarse adjustment output (Out1 of Figure 15) is high while  $t_s \leq [VSTH+1] * t_0$ . The coarse adjustment output is high while  $[VSTH] * t_0 < t_s < 128 * t_0$ . Where  $t_s$  is the time within  $T_{sub}$ .

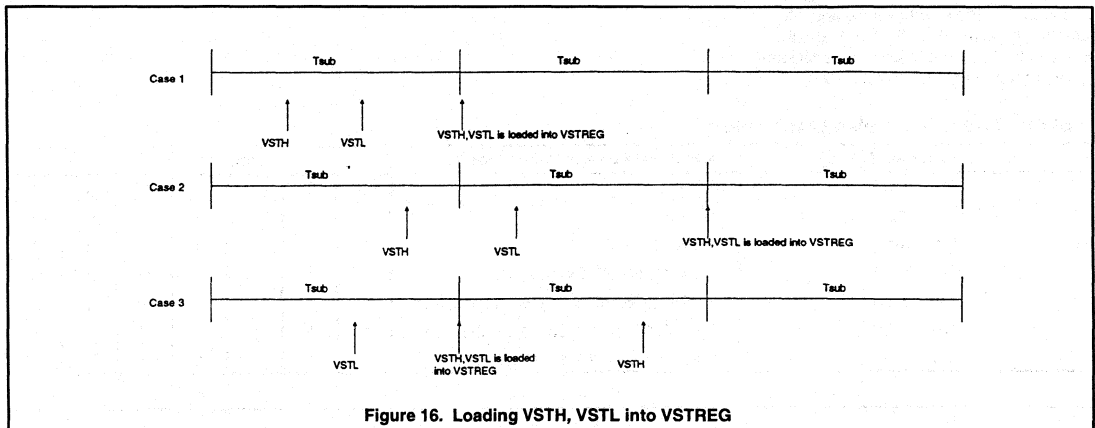

Figure 16. Loading VSTH, VSTL into VSTREG

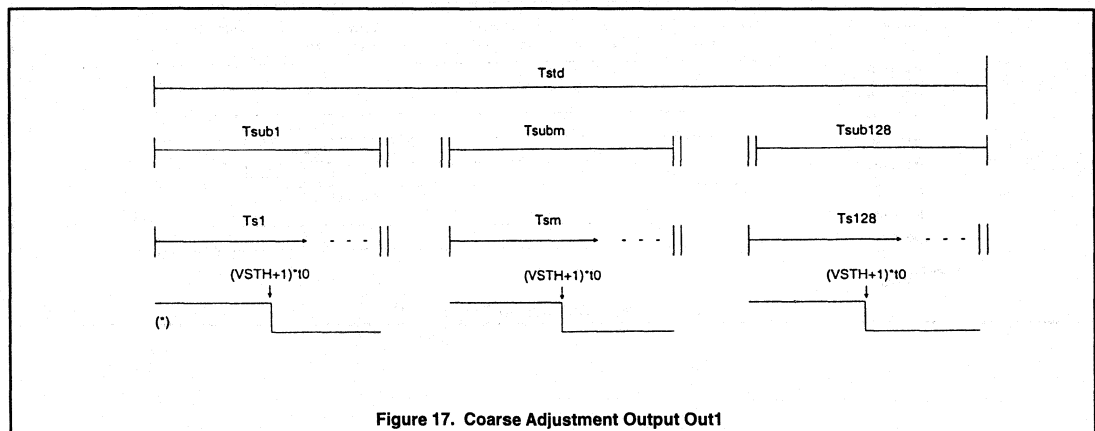

Figure 17. Coarse Adjustment Output Out1

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

### 11.3 Fine adjustment (VSTL)

#### VSTL (D2H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | VST6 | VST5 | VST4 |
| bit3 | bit2 | bit1 | bit0 |
| VST3 | VST2 | VST1 | VST0 |

If, for example VSTH="0011101"  
VSTL="1111101", then TDAC looks like in Figure 20. The additional pulses are generated in subperiods 32 and 96.

Fine adjustment is done with *additional pulses*, generated in particular subperiods. The contents of VSTL indicates in which periods an additional pulse is generated.

During Tstd, 0 (VSTL=1111 111) to 127 (VSTL=0000 000) additional pulses can be generated. Table 5 shows the relation between the contents of the VSTL and the subperiods (Tsub) during which an additional pulse is generated. (Pulse distribution).

**Table 5. Additional Pulse Distribution**

| Lower 7 Bit Data (VSTL) | Additional Pulse in Subperiods TsubN         | Binary Position |   |   |   |   |   |   |
|-------------------------|----------------------------------------------|-----------------|---|---|---|---|---|---|
| (111 1110)              | 64                                           | 1               | 0 | 0 | 0 | 0 | 0 | 0 |
| (111 1101)              | 32, 96                                       | *               | 1 | 0 | 0 | 0 | 0 | 0 |
| (111 1011)              | 16, 48, 80, 112                              | *               | * | 1 | 0 | 0 | 0 | 0 |
| (111 0111)              | 8, 24, 40, 56, 72, 88, 104, 120              | *               | * | * | 1 | 0 | 0 | 0 |
| (110 1111)              | 4, 12, 20, 28, 36, 44, 52, 60, .... 116, 124 | *               | * | * | * | 1 | 0 | 0 |
| (101 1111)              | 2, 6, 10, 14, 18, 22, 26, 30, .... 122, 126  | *               | * | * | * | * | 1 | 0 |
| (011 1111)              | 1, 3, 5, 7, 9, 11, 13, 15, 17, .... 125, 127 | *               | * | * | * | * | * | 1 |

## 12. AFC (A TO D CONVERTER) INPUTS

There are 4 A/D converter channels with 4-bit resolution. One of them is intended to measure the level of the Automatic Frequency Control signal. This is done by comparing the AFC signal with the output of a 4-bit D/A converter as shown in Figure 21.

### 12.1 AFC Control Register – AFCON

#### AFCON (C8H)

|       |       |       |       |
|-------|-------|-------|-------|
| bit7  | bit6  | bit5  | bit4  |
| —     | AFCH1 | AFCH0 | AFCL3 |
| bit3  | bit2  | bit1  | bit0  |
| AFCL2 | AFCL1 | AFCL0 | AFCC  |

#### AFCH1, AFCH0

AFC channel selection,  
 =00, channel AFC  
 =01, channel AFC1  
 =10, channel AFC2  
 =11, channel AFC3

#### AFCL3 .. 0

AFC comparison voltage level reference selection  
 =0000,  $1/16 \cdot V_{dd}$   
 =0011,  $2/16 \cdot V_{dd}$   
 =0010,  $3/16 \cdot V_{dd}$   
 = .....  
 =1110,  $15/16 \cdot V_{dd}$   
 =1111,  $16/16 \cdot V_{dd}$

#### AFCC

The comparison result,  
 =0, AFC input voltage is LOWER than the reference voltage  
 =1, AFC input voltage is HIGHER than the reference voltage

Conversion time of AFC is no longer than 8 $\mu$ s at 12MHz. Some "NOP" instructions are recommended to add in between the instruction which changes the reference voltage or channel and the instruction which reads the AFCC register bit.

Make sure that pin 31, 32, 33 or 34 are configured as AFC function before you can use them (see chapter 9).

## 13. VSYNC INTERRUPT & LEVEL STATUS BIT

VSYNC can generate an interrupt to the CPU if enabled. Vector address 0063H.

VINT SFR is the register to indicate the level of VSYNC pin as well as generating the interrupt to the CPU.

#### VINT (C9H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | —    | —    | —    |
| bit3 | bit2 | bit1 | bit0 |
| —    | —    | —    | VLVL |

#### VLVL

VSYNC input pin (#57) level.

(case 1)

If VSYNC polarity is programmed to active high (see section 17.4 for detail), then when

VLVL = 0 means VSYNC is at low level, i.e., raster scan period

VLVL = 1 means VSYNC is at high level, i.e., vertical fly back period

(case 2)

If VSYNC polarity is programmed to active low,

VLVL = 0 means VSYNC is at low level, i.e., vertical fly back period.

VLVL = 1 means VSYNC is at high level, i.e., raster scan period.

## 13.1 Interrupt Request – IQ7

IQ7 is the bit 5 of the SFR IRQ1 (address C0H).

#### IQ7

a leading edge of the active VSYNC generates a pending interrupt to the CPU and makes IQ7 bit high. In the service routine, this bit should be cleared before return to main routine. As long as this bit is high, a pending interrupt is always there. Each time VSYNC is active by the leading edge IQ7 bit is set to high. If the interrupt is not served by next leading VSYNC edge, the IQ7 is written to high again and no error of overrun is indicated.

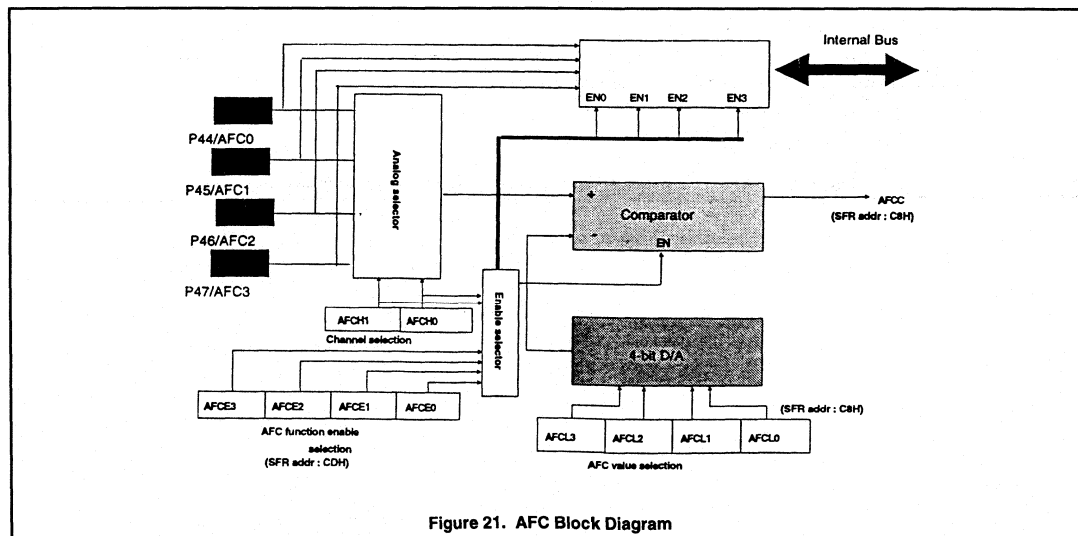

Figure 21. AFC Block Diagram

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 14. REMOTE CONTROL PRE-PROCESSOR

The remote control pre-processor is used to measure the pulse width of two rising or falling edge of a continuous transmitted

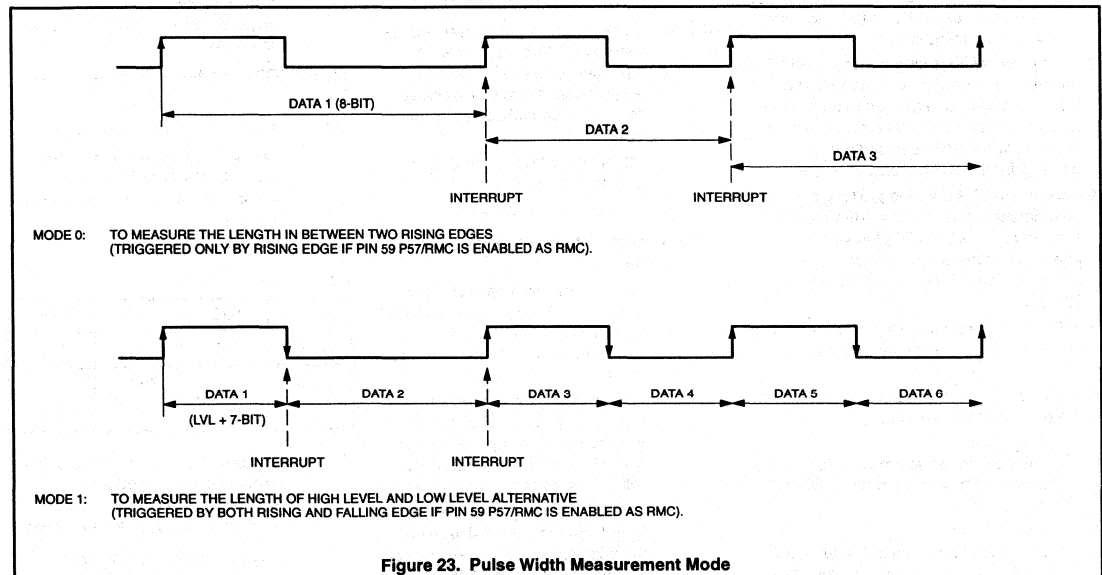

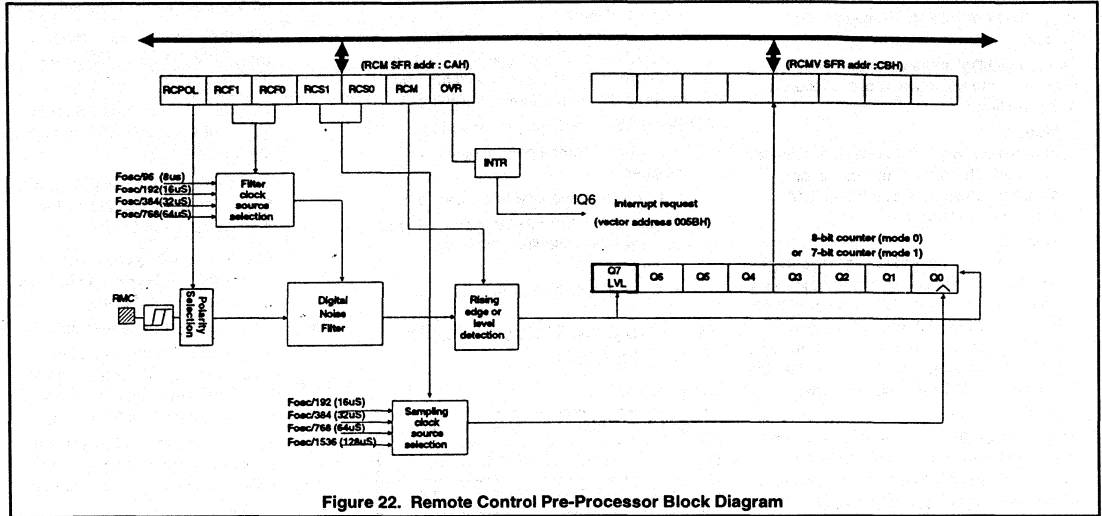

pulses. It can also count the high level or low level length of a particular pulse.

Programmable pulse width digital filter can reduce the noise.

## 14.1 Block Diagram

Figure 22 shows the block diagram.

The pulse width measurement can be selected from one of the two modes in Figure 23.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

## P83CL168/167/268/267

### 14.2 The Operation

- To start the remote control preprocessor, SFR address CEH, the P5SEL register's bit 7 must be programmed to 1.
- The remote control pulse can be inverted or gone through for next stage processing at the input pin stage (polarity selection, bit <MU>6<D> of RCM SFR, see section 15.3).
- The digital filter and sampling counter measures the pulse width of the following two conditions
  - Mode 0:
    - In between two rising edge, the pulse is sampled after the polarity selection circuitry shown in Figure 22 – RCM counter is 8-bit long.
  - Mode 1:
    - In between rising and falling edge (high level) and then falling edge to next rising edge (low level) — RCM counter is 7-bit long. The MSB (8th bit) indicates the high (=1) or low (=0) level of the pulse at the input pin stage (non inverted, i.e., the level at the RMC pin, not after the polarity selection).
- After a complete pulse width is measured, the data stored in the RCM counter is pushed into a SFR called RCMV (address CBH) and a pending interrupt is generated to the CPU. Status flag IQ6 (the bit 4 of SFR IRQ1) is raised to 1 and RCM counter is cleared to 0 for next counting (no matter if IEN1.4 is enabled or not).
- If the pulse width is longer than the RCM counter can count (7-bit in mode 1 and 8-bit in mode 0) and make it overflow, the data in the counter is cleared to 0 and an overflow flag (OVR) is raised plus a pending interrupt is generated (IQ6 = 1).
- If the interrupt is pending too long such that next data is ready and overwrite the RCMV then an error flag (OVR) plus a pending interrupt is generated. (i.e., while IQ6=1 and a new data is ready to push into RCMV)
- In the service routine, overflow and error check (OVR flag) and clear IQ6 bit to 0 is a must.
- In summary, status bit OVR and IQ6 (when the preprocessor is enabled):
  - OVR=0, IQ6=0:
    - Software is in service routine. IQ6 bit is just cleared by service routine, RCMV data is correct.
  - OVR=0, IQ6=1:
    - The counter has pushed the data into RCMV and an interrupt is pending by the CPU.

- OVR=1, IQ6=1:
  - A pending interrupt to the CPU indicates error happened either by overflow in the counter and/or overwrite of previous data in the RCMV. OVR should be cleared by software to ensure further operation.
- OVR=1, IQ6=0:
  - Software in service routine. IQ6 bit is cleared by service routine. RCMV data is not correct. OVR should be cleared by software to ensure further operation.
- If the P5SEL.7 bit is programmed to 0,
  - the remote control preprocessor is stopped,
  - the data in the counter is cleared to 0,
  - the pending interrupt status bit (IQ6) and overflow/overwrite flag (OVR) are cleared
  - and pin 26 acts as P57 I/O port line.

### 14.3 Control, Status and Data Registers

#### RCM (CAH)

|      |       |      |      |
|------|-------|------|------|
| bit7 | bit6  | bit5 | bit4 |
| —    | RCPOL | RCF1 | RCF0 |
| bit3 | bit2  | bit1 | bit0 |
| RCS1 | RCS0  | RCM  | OVR  |

- RCPOL Remote control pulse level polarity selection. This bit is to invert the input pulse polarity if two falling edge distance is to be measured by mode 0 controlled by bit 1 of RCM SFR.
  - =0, the input level at pin 26 is not inverted internally
  - =1, the level is inverted.
- RCF1,0 Digital filter noise reduction time base selection
  - =00, the sampling base clock is  $f_{OSC} / 96$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 8uS, any pulse which is shorter than 24uS (max.) will be filtered out.
  - =01, the sampling base clock is  $f_{OSC} / 192$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 16uS, any pulse which is shorter than 48uS (max.) will be filtered out.
  - =10, the sampling base clock is  $f_{OSC} / 384$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 32uS, any pulse which is shorter than 96uS (max.) will be filtered out.

=11, the sampling base clock is  $f_{OSC} / 768$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 64uS, any pulse which is shorter than 192uS (max.) will be filtered out.

#### RCS1,0 Remote control pulse width measurement time base selection

- =00, the sampling base clock is  $f_{OSC} / 192$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 16uS)
- =01, the sampling base clock is  $f_{OSC} / 384$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 32uS)
- =10, the sampling base clock is  $f_{OSC} / 768$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 64uS)
- =11, the sampling base clock is  $f_{OSC} / 1536$  (if  $f_{OSC}=12\text{MHz}$ , then the base clock is 128uS)

#### RCM Measurement mode selection

- =0 (mode 0), measuring of the pulse width of two rising edge at the point after polarity selection circuitry. Counter is 8-bit long.
- =1 (mode 1), measurement of the pulse width from rising edge to falling edge, counter is 7-bit long

#### OVR Overflow/overwrite flag

- =0, no problem
- =1, overflow of counter or overwrite to RCMV

#### Interrupt IQ6 — bit 4 of IRQ1 (see section 7.5)

- IQ6 Interrupt pending status bit
  - =0, no interrupt pending, cleared either by disable of the remote control preprocessor and/or service routine
  - =1, pending interrupt

#### RCMV (CBH)

|        |      |      |      |
|--------|------|------|------|
| bit7   | bit6 | bit5 | bit4 |
| LVL/D7 | D6   | D5   | D4   |
| bit3   | bit2 | bit1 | bit0 |
| D3     | D2   | D1   | D0   |

- LVL/D7 in mode 0, this bit is the D7 of the width of two rising edge. in mode 1, this bit indicates the level of the pulse at the pin stage.
  - = 0, low level; = 1, high level
- D6 .. 0 the lower 7 bits of the pulse width either in mode 0 or 1.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 15. HIGH SPEED 8-BIT, 3-WIRE SERIAL I/O

The high speed 8-bit, 3-wire serial I/O features 1Mega baud rate maximum speed for very high speed data transmission in between CPU and other peripheral devices. Interrupt is generated whenever a completed byte has been sent or received. In the data transmission process, LSB first or MSB first can be selected by software.

### 15.1 The Block Diagram

Figure 24 shows the block diagram. Clock can be selected from 1M, 500K, 250K (@f<sub>OSC</sub>=12MHz) and external source.

### 15.2 The Control Register

#### HIOD (C6H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| D7   | D6   | D5   | D4   |
| bit3 | bit2 | bit1 | bit0 |
| D3   | D2   | D1   | D0   |

HIOD is the 8-bit data register of the high speed 8-bit serial I/O.

#### HIOCON (C7H)

|       |      |      |      |
|-------|------|------|------|
| bit7  | bit6 | bit5 | bit4 |
| —     | —    | —    | CLKE |
| bit3  | bit2 | bit1 | bit0 |
| DOUTE | CLK1 | CLK0 | DIR  |

**CLKE** clock pin Hi-Z or enable selection (if pin 28 is selected as CLK function)

=0, Hi-Z  
=1, CLK pin is driven by the high speed I/O's clock signal

**DOUTE** data out pin Hi-Z selection (if pin 20 is selected as Dout function)

=0, Hi-Z  
=1, Dout pin is driven by the high speed I/O's data signal

**CLK1 .. 0** clock source selection  
=00, f<sub>OSC</sub>/12 (=1MHz @ Fosc=12MHz)  
=01, f<sub>OSC</sub>/24  
=10, f<sub>OSC</sub>/48  
=11, external source from CLK pin

**DIR** Shift direction control  
When in the shift out operation  
=0, MSB first  
=1, LSB first  
When in the shift in operation  
=1, first bit becomes the MSB of the data byte  
=0, first bit becomes the LSB of the data byte

Interrupt IQ5 - bit 3 of IRQ1 SFR

**IQ5** High speed I/O interrupt status bit, raises to '1' when a complete byte has been sent or received.  
=1, a pending interrupt  
=0, no pending interrupt

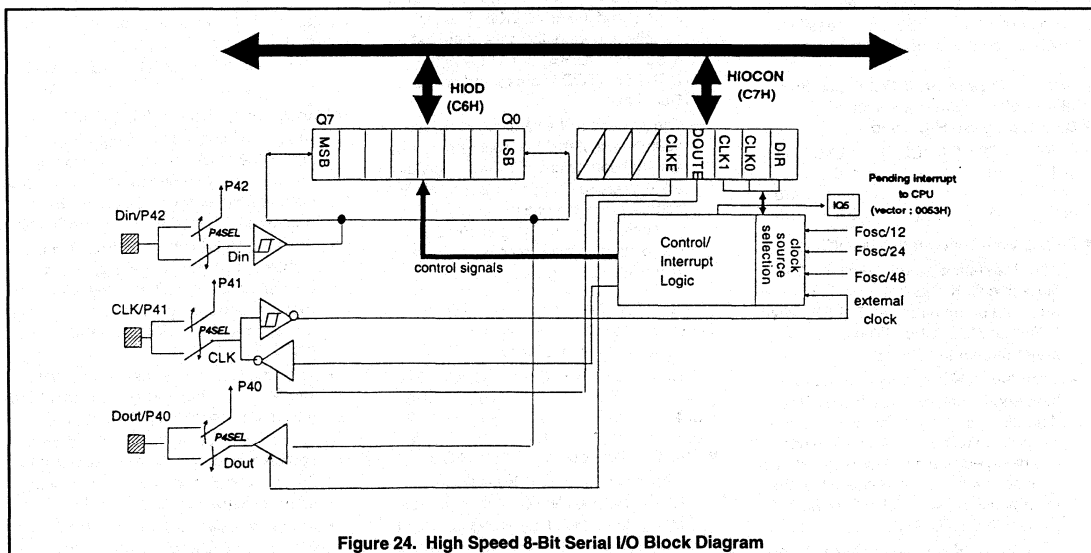

Figure 24. High Speed 8-Bit Serial I/O Block Diagram

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

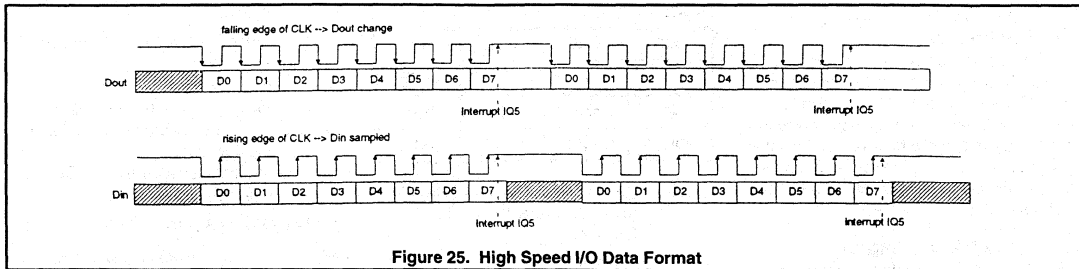

Figure 25. High Speed I/O Data Format

## 15.3 The Shift-In/Shift-Out Format

Figure 25 shows the shift-in and shift-out data format. The falling edge of the clock (CLK) is the transition point of the Dout. The rising edge of the clock (CLK) samples the high/low level of the data on the Din line.

## 15.4 How to Program the High Speed I/O

- The operation to program bit 1 of SFR P4SEL (addr: CDH) to 1 is to enable the high speed I/O to standby status (ready for the shift-in or shift-out). In the mean time, one (or both) of the bit2 and bit 0 of P4SEL can be programmed to 1 to function as the Din or Dout pin.
- Program bit 1 of P4SEL to 0 'reset' the high speed I/O to stop/initial status.

### 15.4.1 The Data Shift Out Procedure

If internal clock source is selected,

- Step 1, program HICON to:

| CLKE | DOUTE | CLK1 | CLK0 | DIR |
|------|-------|------|------|-----|
| 1    | 0     | 0    | 1/0  |     |
| or 1 | 1     | 0    | 1    | 1/0 |
| or 1 | 1     | 1    | 0    | 1/0 |

- Step 2, write shift-out data to HIOD.

- After the data is written into HIOD, the clock line CLK changes from high to low and data of 1st bit of HIOD (LSB, when DIR=1 or MSB, when DIR=0) is presented on the Dout pin.
- Then the CLK is changed from low to high and this rising edge triggers the data bit on the Dout into the peripheral device's shift register. In the meantime, this rising edge also triggers the data bit (maybe invalid) on the Din pin into the MSB position (when DIR=1) or LSB position (when DIR=0).
- Then the CLK is changed from high to low again and the 2nd bit is presented on the Dout pin.
- This process continues 8 times when a complete data byte is sent through this shift out process. A pending interrupt is then generated to the CPU and a

complete byte is ready and stored in the SFR HIOD which is the data sampled from Din. This data may be of no use and is discarded by the software.

- After a complete byte is sent (shift-out), the CLK pin is kept high and Dout is having the last data bit presented.
- Write to HIOD again is the way to restart next byte transmission.

If external clock source is selected,

- Step 1, program HICON to

| CLKE | DOUTE | CLK1 | CLK0 | DIR |
|------|-------|------|------|-----|
| 0    | 1     | 1    | 1    | 1/0 |

- Step 2, write shift-out data to HIOD.

- After the data is written into HIOD, the clock line CLK now is driven by external source and the first CLK high to low transition triggers the data of the 1st bit (LSB, when DIR=1 or MSB, when DIR=0) of HIOD is presented on the Dout pin.
- The process is the same as internal clock source except that the clock is driven by external source and the rising edge/falling edge reference is by the external clock source. So at the end of the shift-out process, an interrupt is generated and a complete data byte sampled from Din is ready in HIOD register.

### 15.4.2 The Data Shift In Procedure

If internal clock source is selected,

- Step 1, program HICON to:

| CLKE | DOUTE | CLK1 | CLK0 | DIR |
|------|-------|------|------|-----|
| 1    | 0     | 0    | 0    | 1/0 |
| or 1 | 0     | 0    | 1    | 1/0 |
| or 1 | 0     | 1    | 0    | 1/0 |

- Step 2, write a dummy data to HIOD.

- After this dummy data is written into HIOD, the clock line CLK changes from high to low which triggers the peripheral device to present its first data bit on the Din pin.
- Then the CLK is changed from low to high and this rising edge triggers the data bit on the Din pin into the shift register. Depending on the DIR, this bit is shifted into LSB (DIR=1) and it will become the MSB of the received byte; or

MSB (DIR=0) and it will become the LSB of the received byte.

- Then the CLK is changed from high to low again and the 2nd bit from peripheral device is presented on the Din pin.
- This process continues 8 times then a complete data byte is received in HIOD through this shift in process. A pending interrupt is then generated to the CPU.
- After a complete byte is received (shift-in), the CLK pin is kept high.
- Dout pin in the whole process is in tri-state status if that pin is enabled as the Dout pin function.
- Write to HIOD again is the way to restart next byte transmission.

If external clock source is selected,

- Step 1, program HICON to

| CLKE | DOUTE | CLK1 | CLK0 | DIR |
|------|-------|------|------|-----|
| 0    | 0     | 1    | 1    | 1/0 |

- Step 2, write a dummy data to HIOD.

- After this dummy data is written into HIOD, the clock line CLK is driven by external and the change from high to low indicates the peripheral device has presented its first data bit on the Din pin.
- Then the CLK is changed from low to high and this rising edge triggers the data bit on the Din pin into the shift register. Depending on the DIR, this bit is shifted into LSB (DIR=1) or MSB (DIR=0).
- Then the CLK is changed from high to low again and the 2nd bit from peripheral device is presented on the Din pin.
- This process continues 8 times then a complete data byte is received in HIOD through this shift in process. A pending interrupt is then generated to the CPU.
- After a complete byte is received (shift-in), the CLK pin is kept high.
- Dout pin in the whole process is in tri-state status if that pin is enabled as the Dout pin function.
- Write to HIOD again is the way to restart next byte transmission. Before this operation is done, any changes on the CLK/Din pins are ignored.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 16. OSD (ON SCREEN DISPLAY) FUNCTION

### 16.1 Features

- Programmable VSYNC/HSYNC active level
- Display RAM: 160 x12 bit
- Display character fonts: 128 (126 customer font + 2 reserved)
- One vertical display starting position counter 64 different starting positions controlled by software.
- One horizontal display starting position control for OSD. 64 different positions controlled by software.
- Character size: 4 different character size, line-by-line basis, 1 horizontal dot = 1 or 2 OSD clock period. 1 vertical dot = 1 or 2 horizontal scan lines. Individually controllable.

- Character matrix: 12 \* 18 with no spacing between characters
- Foreground colors: 16, character-by-character basis
- Background/shadowing modes:
  - Two primary modes:
    - TV mode or Monitor mode, frame basis. In each group, three submodes are available.
    - Sub-mode 1: superimpose (no background),
    - Sub-mode 2: north-west shadowing,
    - Sub-mode 3: box shadowing,
  - all these three are character row basis.
- Background colors: 16, word-by-word basis. Available when background is either in "north-west shadowing", "box shadowing" and "frame shadowing" submodes.

- Display RAM starting address is programmable. Fast switching between bank of display characters are possible through software control.
- PLL oscillator for OSD function with software selectable OSD clock period (e.g., scalable character width by software)
- Character blinking: 1:1 (frequency : Fv/32, Fv/64, programmable), character basis
- Display format: Flexible display format by using CR (carriage return) and SP1, SP2 (space) code.
- Display RAM address post increment each time a new data is written into.
- Vertical jitter cancelling circuit to avoid unstable VSYNC trailing edge mismatch HSYNC signal.
- OSD clock operating range: 4 – 10MHz

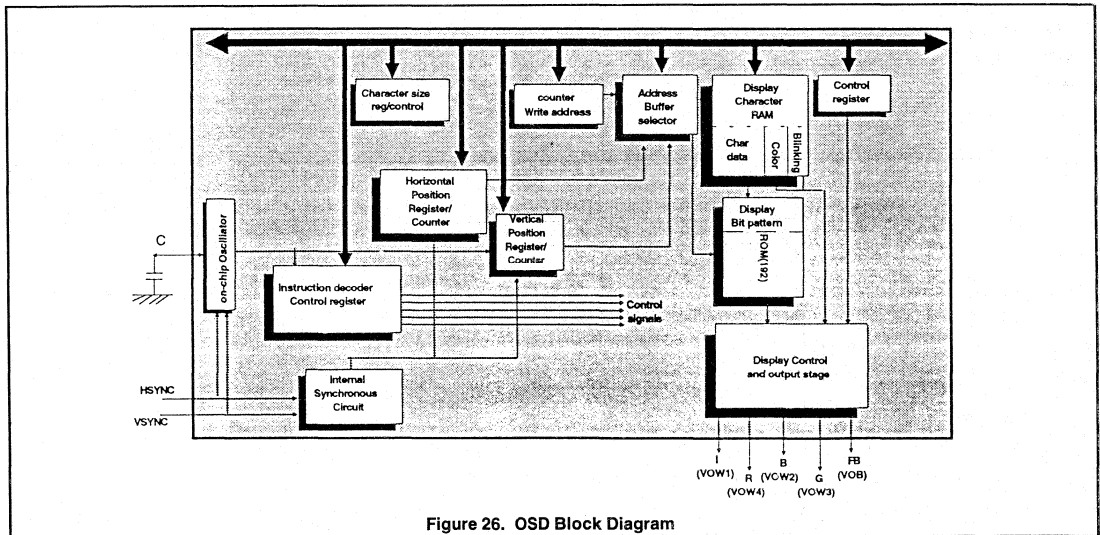

Figure 26. OSD Block Diagram

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

16.2 Horizontal and Vertical Display Position Control

OSORGH (C3H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | —    | HP5  | HP4  |
| bit3 | bit2 | bit1 | bit0 |
| HP3  | HP2  | HP1  | HP0  |

The horizontal position counter is increased every OSDC (OSD clock) cycle after the programmed level of HSYNCN occurs at the HSYNC terminal (pin) and is reset when the opposite polarity of the HSYNC is reached. Horizontal start position is controlled by SFR OSORGH which is a 6-bit register (Figure 27).

Reference point: trailing edge of HSYNC.

The horizontal starting position is calculated as:

$$HPx = [4 * (HP5 \dots HP0)_{\text{decimal}} + 5]_{\text{(OSD clock)}}$$

in which

$$(HP5 \dots HP0) \geq 4 \text{ decimal}$$

OSORGV (C2H)

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | —    | VP5  | VP4  |
| bit3 | bit2 | bit1 | bit0 |
| VP3  | VP2  | VP1  | VP0  |

The vertical position counter is increased every HSYNC cycle and is reset by the VSYNC signal.

Vertical start position is controlled by SFR OSORGV which is a 6-bit register too. Reference point: leading edge of VSYNC.

The starting position is calculated as

$$VPx = [4 * (VP5 \dots VP0)_{\text{decimal}}]_{\text{(horizontal scan lines)}}$$

in which

$$(VP5 \dots VP0)_{\text{decimal}} > 0$$

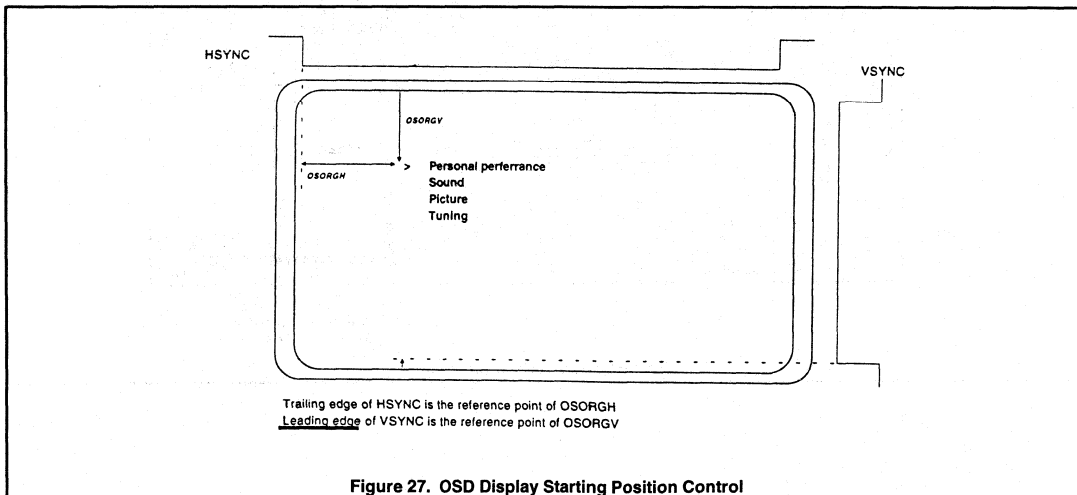

Figure 27. OSD Display Starting Position Control

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

### 16.3 OSD Clock Generator

The clock generator is made of a PLL (Phase Lock Loop) circuitry. The VCO (Voltage Controlled Oscillator) outputs a constant clock with frequency ranges in between 4MHz to 10MHz.

The input frequency, F1, is the horizontal sync (HSYNC) frequency. Depending on the value programmed in the 6-bit counter, the

$$F_{vco} = F1 * 16 * [\text{value of 6 bit counter}]$$

with

$$16_{\text{decimal}} < [\text{value of 6 bit counter}] < 40_{\text{decimal}}$$

The value 16 is the 4 bit prescaler which gives the output of the VCO to increase/decrease in step of 16\*F1 Hz. Given an example of horizontal frequency 15.750KHz, The Fvco is then increased or

decreased in steps of 16 \* 15.750KHz = 252KHz = 0.25MHz step.

The Fvco is then feed into the buffer to generate the OSDC (OSD dot clock frequency) signal which gives the OSD in range of 4 – 10MHz. Decreasing the OSD frequency gives broader characters. Typical recommended OSD clock frequency is 6 – 8MHz.

The VCO is synchronized with the high-to-low edge of the F2 clock (always the trailing edge of HSYNC signal). The programmable active level detector is to either pass the HSYNC signal (if HSYNC is active high) or to invert the HSYNC signal (if the HSYNC is active low). It makes F2 always active high.

Figure 28 illustrates the block diagram of on chip OSD clock generator circuitry.

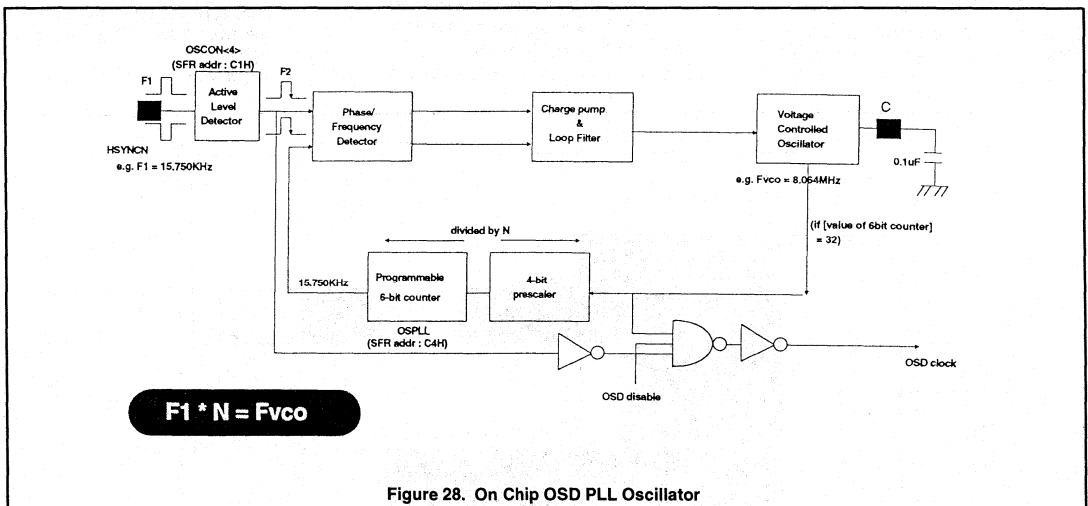

The on chip OSD PLL oscillator will not stop, as long as it is enabled by bit 0, the OSDE bit, of SFR OSCON (C1H). The following description in V1.1 should then be discarded totally.

Because no large current is sourced or sinked in and out of the clock pin as the RC or LC type of oscillator normally is, the radiation generated by the OSD clock source can be reduced dramatically.

The 6 bit PLL programmable counter data register is in C4H.

## 16.4 Flexible On Screen Display Format

Figure 29 shows a typical example of OSD generated by the P83CL168. The vertical and horizontal starting position is controlled by two separate SFR OSORGH and OSORGV. There are 160 display RAM in total where they are considered as a linear addressed RAM. The first character is from the display RAM address pointed by OSSTART (SFR address C5H).

### OSSTART (C5H)

|        |        |        |        |
|--------|--------|--------|--------|
| bit7   | bit6   | bit5   | bit4   |
| START7 | START6 | START5 | START4 |
| bit3   | bit2   | bit1   | bit0   |
| START3 | START2 | START1 | START0 |

The display RAM address is from 0 — 159<sub>decimal</sub> or 0 — 9F<sub>hexadecimal</sub>.

There are 128 different fonts available in which 2 (CR, carriage return code and SP, space code) of them are reserved for special function.

Each time a CR code is met, like in the computer application, the display changes to next row. A space code is meant to change the background color of the characters followed (see section 16.5 for further detail).

OSCON is the OSD control register.

### OSCON (C1H)

## P83CL168/167/268/267

### 16.5 Display RAM Organization

The display character RAM is organized as 160 x 12 bits. See Figure 32 for details. Bit<11 : 5> is the character data which determines 1 out of 128 different fonts (126 customized + 2 reserved code, i.e., carriage return code and space code 1 and space code 2). Bit<4 : 0> is the attribute data of this character which determines the attribute, for example, colors, of this particular character.

#### 16.5.1 Bits in the Display RAM

There are four different configurations to be considered:

1. Customer character code:
  - When bit<11 : 5> indicates a **customized character** (other than the reserved code described below), bit<4 : 1> determines the color (1 out of 16) of this character.
  - Blinking of this character is controlled by bit <0>.
  - Blinking frequency control is determined by bit 1 of SFR OSCON (addr : C1H). See section 16.4 for details.
2. Reserved code: carriage return code
  - The carriage return code (bit<11 : 5>=111 1110binary) is a special

code that finishes the current display row and start to display the character stored in the display RAM next to this code in the beginning of next row. The bit pattern itself displays a transparent pattern on the screen.

- The attribute part of this code determines the character size by bit <4 : 3> and the display mode by bit <2 : 1> of next row. Bit <0> is to control the stop of display function prior to meet the last display RAM address (i. e., 159<sub>decimal</sub>).
- Character size of next row is independently controlled in both horizontal and vertical direction.
- Bit<4> is to control vertical size. When bit <<4> =
  - 0, one vertical dot equals to *one* horizontal scan line width
  - 1, one vertical dot equals to *two* horizontal scan line width
- Bit<3> is to control horizontal size. When bit <3>=
  - 0, one horizontal dot equals to <Ml>one<D> OSD clock width
  - 1, one horizontal dot equals to <Ml>two<D> OSD clock width

- Figure 33 shows the four different character size combination.
  - Bit <2 : 1> controls the display sub-mode of next character row in combination with the mode selection bit of SFR OSCON (bit 5 of addr: C1H). In total 6 different modes are possible (see Figures 34 and 35).
    - 00, superimpose submode (upper left "E" character in Figures 34 and 35)
    - 01, north-west shadowing submode (upper right "E" character in Figures 34 and 35)
    - 10, box shadowing submode (lower left "E" character in Figures 34 and 35)
    - 11, reserved
  - Bit <0> is the 'end of display' control before running out of display RAM
    - =0, continue the display in next row
    - =1, stop the display, wait until next field when the horizontal and vertical start position is met then start the display again.
- By combining the "end of display" feature plus the OSSTART SFR, the display RAM can be configured into several "bank" for fast display data switching.

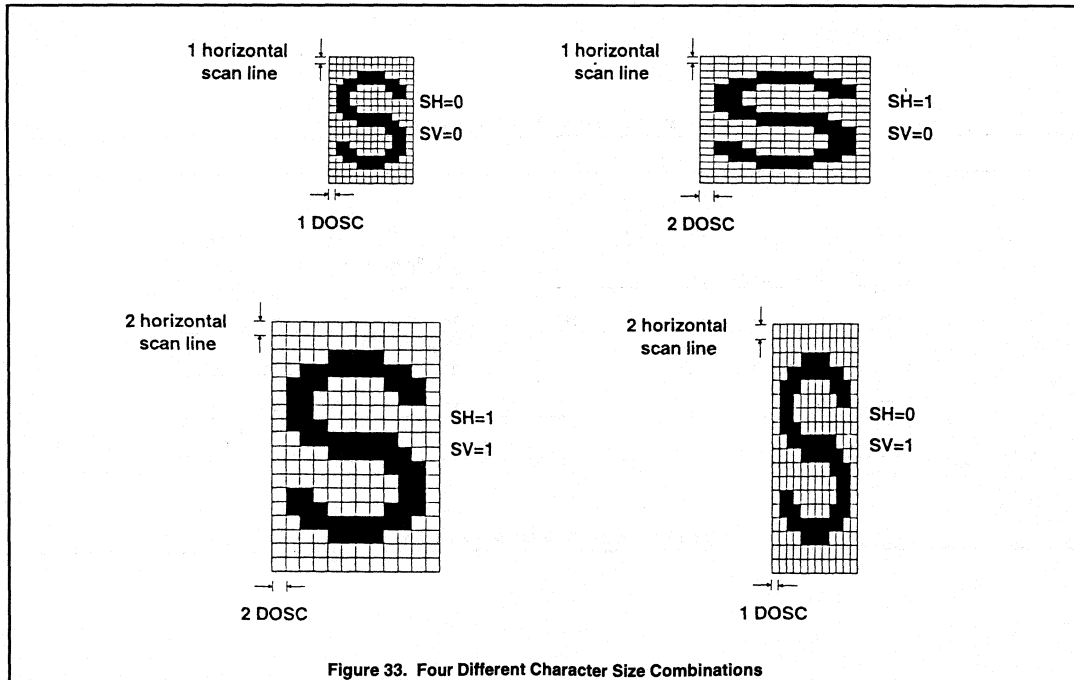

Figure 33. Four Different Character Size Combinations

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

3. Reserved code:  
Space code 1 and Space code 2
- Space code 1, C<7:0>=111 1111, T<0>=0, T<4:1>=background color control
  - Space code 2, C<7:0>=111 1111, T<0>=1, T<4:1>=background color control

The character code C<7:0>=111 1101 is for customer font usage.

- The background color is the color of the bit pattern in the following conditions, (see Figures 34 and 35)
- north-west shadowing submode, it is the color of the shadow bit pattern.

- box shadowing submode, it is the color of the dots in the 12 \* 18 character dot matrix box where no foreground character bits present.
- in the superimpose submode there is NO background color.
- Space code 1 & space code 2 are the codes which displays a transparent pattern on the screen and lasts for 1 character width in general.
- In the TV mode plus, (Figure 36) superimpose submode: SP1 and SP2 display exactly the same transparent pattern.

- north-west shadowing submode:  
SP1 and SP2 display exactly the same transparent pattern.
- box shadowing submode:  
SP2 displays a transparent pattern while SP1 displays a 12\*18 dots pattern filled with the background color.
- In the monitor mode, the background color of the monitor (not of the characters) is controlled by SFR OSCON2 <3:0> (addr: CFH). The SP1 and SP2 behave the same as they are in the TV mode (Figure 37).

**In Summary**

- Carriage return (CR) code** is
  - to end the current display row and use the character in the display RAM next to this CR code as the first character of next display row.
  - to control character size of next display row
  - to control character submode of next display row
  - to indicates the end of display for present screen
- Space code 1 and Space code 2** is
  - to control the background color of the characters from this space code
  - to indicates the end of display for present screen
- Display of the characters starts from display RAM address pointed by SFR OSSTART always and ends up either at display RAM address 159<sub>decimal</sub> or "end of display" bit is set in the CR code.

**OSCON2 (CFH)**

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | —    | —    | —    |
| bit3 | bit2 | bit1 | bit0 |
| R    | G    | B    | —    |

**RGBI** These 3 bits are to control the background color of the TV screen in the monitor mode.

Default background color is R=G=B=0

Figure 38 shows a typical timing of R, G, B, and FB outputs. Assuming "S" is red color. "I" is green color. "Z" is green + blue. "E" is blue.

**16.5.2 How to Load the Character Data into the Display RAM**

There are 3 registers to control/address/buffer the display characters.

- OSAD to keep track of the display RAM address

- OSAT is the register to store the attribute of the character data.
- OSDT is to keep intermediate data to be stored into the display RAM location addressed by the OSAD register.

**OSAD (9AH)**

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| AD7  | AD6  | AD5  | AD4  |
| bit3 | bit2 | bit1 | bit0 |
| AD3  | AD2  | AD1  | AD0  |

AD<7:0> Address of the display RAM where next character data is to be written into

**OSDT (99H)**

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | C6   | C5   | C4   |
| bit3 | bit2 | bit1 | bit0 |
| C3   | C2   | C1   | C0   |

C<6:0> Character data selected from 126 customer code or 2 reserved code

**OSAT (98H)**

|      |      |      |      |
|------|------|------|------|
| bit7 | bit6 | bit5 | bit4 |
| —    | —    | —    | T4   |
| bit3 | bit2 | bit1 | bit0 |
| T3   | T2   | 1    | T0   |

- Case 1 when C<6:0> is customer code, T<4:1> is the foreground color R, G, B, I of that character
- T<0> is the blinking control of this character.
- =0, no blinking;
- =1, blinking

- Case 2 when C<6:0> is CR code, T<4> is the next row character vertical size control
- T<3> is the next row character horizontal size control
- T<2:1> is next row display sub-mode control
- T<0> is the "end of display" control
- Case 3 when C<6:0> is SP1 or SP2 code
- T<4:1> is the background color R, G, B, I control starting from that SP code
- T<0> is the SP1 (=0) or SP2 (=1) control

The procedure to write character data into display RAM :

**Step 1.** initialize the starting address of the display RAM by writing data into OSAD.

**Step 2.** Write to OSAT to determine the attribute of the character.

**Step 3.** Write to OSDT the character code to be displayed on the screen. When the write to OSDT operation is finished then an automatic transfer occurs that loads the data stored in the OSAT plus OSDT into the display RAM location addressed by OSAD.

**Step 4.** Post increment operation is executed in the OSAD (i.e., OSAD <- OSAD + 1) to make it point to the next RAM location. Overflow of the OSAD, i.e., overflow from 159 makes it return to zero. Figure 39 shows the post-increment operation.

It is the step 3 which triggers the load of OSDT and OSAT into the display RAM and the post increment operation. If the attributes of a series of displayed characters are the same, only OSDT has to be updated.

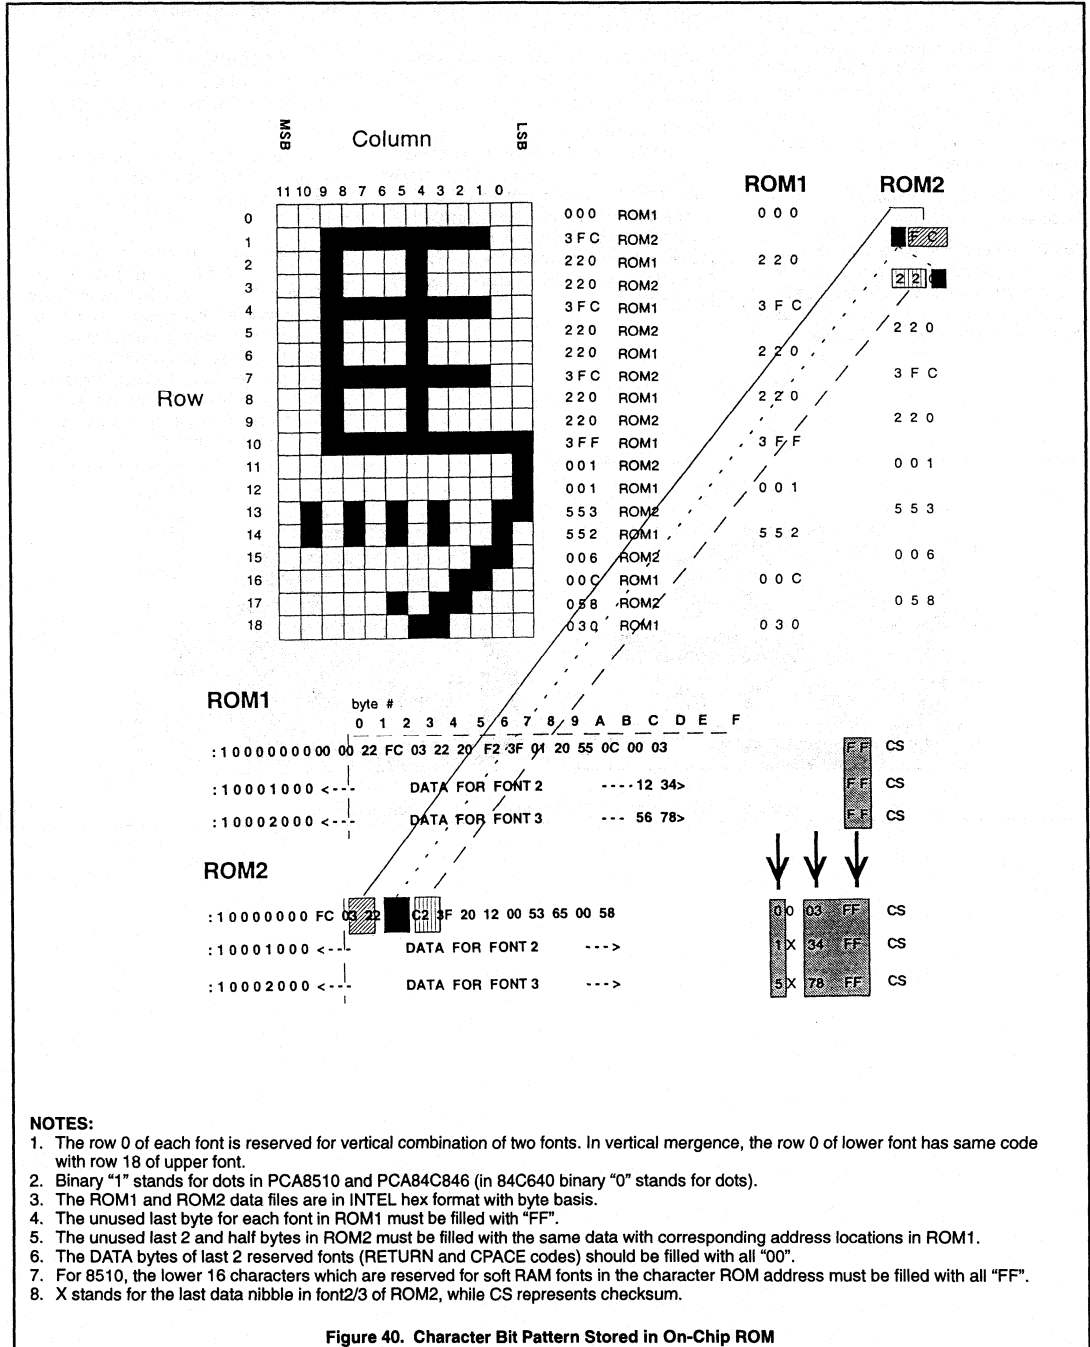

Figure 39. OSAD Post-Increment Operation

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

**NOTES:**

1. The row 0 of each font is reserved for vertical combination of two fonts. In vertical mergence, the row 0 of lower font has same code with row 18 of upper font.
2. Binary "1" stands for dots in PCA8510 and PCA84C846 (in 84C640 binary "0" stands for dots).
3. The ROM1 and ROM2 data files are in INTEL hex format with byte basis.
4. The unused last byte for each font in ROM1 must be filled with "FF".
5. The unused last 2 and half bytes in ROM2 must be filled with the same data with corresponding address locations in ROM1.
6. The DATA bytes of last 2 reserved fonts (RETURN and CSPACE codes) should be filled with all "00".
7. For 8510, the lower 16 characters which are reserved for soft RAM fonts in the character ROM address must be filled with all "FF".
8. X stands for the last data nibble in font2/3 of ROM2, while CS represents checksum.

Figure 40. Character Bit Pattern Stored in On-Chip ROM

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

**16.6 Character ROM**

The character displayed on the screen is in 12 \* 18 dot matrix format while it is in 12 \* 19 format stored in the on chip character ROM. The character ROM is actually divided into two part ROM1 and ROM2.

The bit pattern stored in ROM1 and ROM2 is shown in Figure 40.

Row 1 – 18 is the bit pattern you see on the TV screen.

Row 0 is for use only in the north-west shadowing mode. It is when two character cells are combined in vertical direction to formulate a new pattern, this row 0 contains the same bit pattern of row 18 of the

character above it. (Combination of two characters see section 16.7).

If no combined character in vertical direction is intended for this character, row 0 should be filled in with all "0's".

The file format to submit to Philips to make customized character sets is demonstrated in Figure 40 as well. Philips provides a software under MS DOS environment (IBM/PC or compatible) to help customer to design the character font on the screen and to generate the bit pattern HEX decimal file automatically. Contact your local Philips sales organization for details.

**16.7 Combination of Two or More Font Cells to Formulate a New Font**

User can combine two (or more) font cells to formulate a new higher resolution pattern (Figures 41 and 42).

Combination of two cells in *horizontal direction* needs no special care. All 3 background/shadowing submodes are applicable.

But combination of two cells in *vertical direction* needs the following special care:  
 • ROW0 in the character ROM is for use in the "north-west shadowing" submode. If north-west shadowing submodes is intended for use by this formulated character font, ROW 0 should contain the bit pattern of ROW 18 of the font above it or a broken dot in the shadow may occur (see Figures 43 and 44).

P83CL168/167/268/267

**16.8 More about “North-West Shadowing” Sub-Modes**

Some special care must be taken when designing the character bit pattern if this character is intended to be used in the “north-west shadowing” sub-mode.

North-west shadowing submode *is* limited in the vertical direction if the character in the next row is not in north-west shadowing mode. (if it was, then they are as described in section 16.7) If shadow of the last foreground bit pattern line is intended to be seen as well,

take care the bit pattern design as indicated in Figures 45 and 46.

- North-west shadowing submode is *not* limited to the 12 horizontal OSD dots. Shadows of previous font cell may cross over the 12 dots boundary and appear in the next font cell as indicated in Figure 47.

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

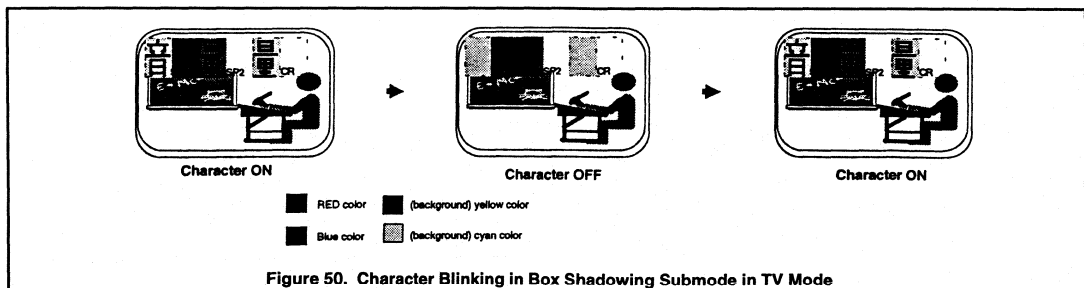

P83CL168/167/268/267

## 16.9 More about Blinking Characters

Blinking of character with space code 1 & 2 and in carriage return code condition is shown in Figures 48, 49, 50 in TV mode and Figures 51, 52 and 53 in monitor mode.

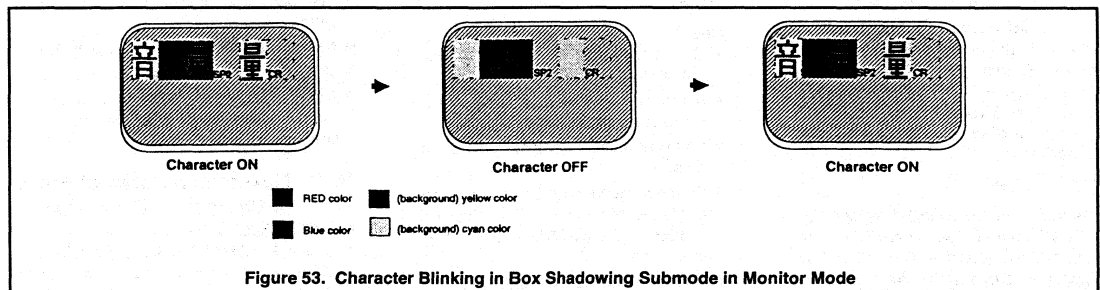

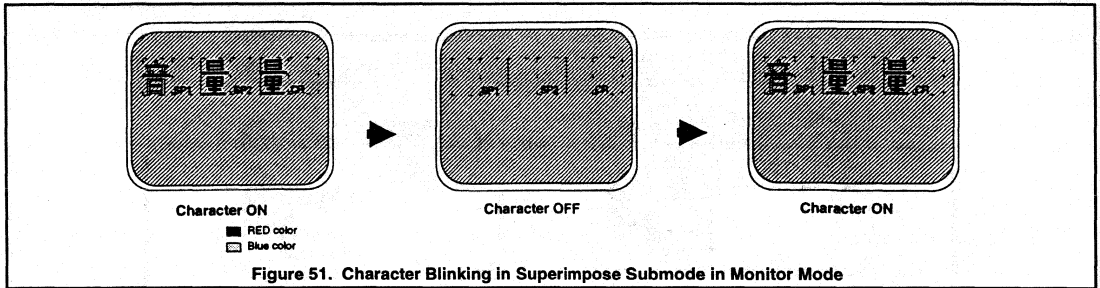

Figure 54 shows blinking of character is only within 12 \* 18 boundary. If the shadow of the blinking character cross over the boundary of the cell of the character next to it which is not

blinking, the shadow dot will still appear on the screen no matter the blinking character is on or off.

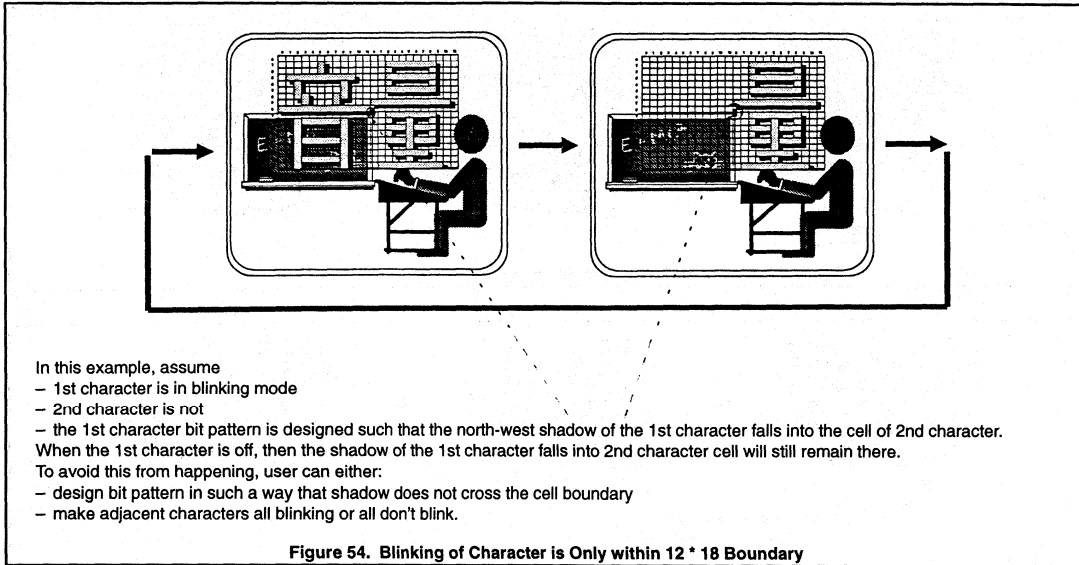

Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

**16.10 Maximum Number of Characters/Row in Different TV Standard**

The maximum number of characters per row is determined by the

- DOSC (i.e., depending on HSYNC frequency & value of the 6-bit programmable counter in the on chip oscillator
- The TV standard

The maximum OSD clock frequency is 10 MHz. Given an NTSC 525LPF (Line Per Frame)/60Hz example: The active video signal period of a horizontal line is 53.5µs. In order to reduce the jittering of the screen edge, overscan is normally applied by the TV manufacturer. It causes the real visible video

period of a horizontal line reduced to  $53.5\mu s * 9/10 = 48.15\mu s$ .

**Case 1.**

- OSD clock frequency = 6MHz, i.e., period = 0.166µs,
- number of visible dots on a horizontal line  $48.15\mu s / 0.166\mu s = 290$  dots
- Each character is composed of 12 \* 18 dots.
- So the maximum number of characters displayed on a row with OSD clock = 6MHz in 525LPF/60Hz NTSC are  $290 / 12 = 24$  characters.
- In a 19" TV screen, the width of a horizontal line is around 370mm which gives approximately 15.4 mm/character in width.

**Case 2.**

- OSD clock frequency = 10 MHz i.e., Dot period = 0.1µs
- $48.15 / 0.1 = 481$  dots per horizontal line
- $481 / 12 = 40$  characters per row !!
- Again, in the 19" TV case, the character width is  $370mm / 40 = 9.25$  mm per character.

**16.11 Maximum Number of Rows of Characters Per Frame**

- In NTSC 525/60, the active lines are roughly 241.5H to 249.5H per field. Take 241 as an example, the maximum number of character rows per frame is (remember a character is 12 \* 18 dots):  $241 / 18 = 13$  rows.
- In PAL 625/50, it is around  $280 / 18 = 15$  rows.

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 16.12 OSD Jitter Cancelling Circuit

The VSYNC/HSYNC relationship in normal broadcasting signals is illustrated as follow in even and odd field.

But in the condition where no broadcast signals or unstable VSYNC (e.g., play back of aged video tape) the *trailing edge* of VSYNC signal may drift forwards and backwards. Miscounting of one horizontal

scan line might happen thus character displayed on screen may drift up and down.

To avoid this happening an internal OSD jitter cancelling circuit is implemented without user's special attention.

Figure 55. HSYNC/VSYNC Relation in Odd Field (Upper) / Even Field (Lower)

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

# Single-chip 8-bit microcontroller for TV on-screen display, VS tuning and control function

P83CL168/167/268/267

## 17.2 SFR Address Map Summary

This is just a summary of all the SFR in ascending address sequence for designer and software programmer's easy reference. The registers which are standard 80CL410's registers are marked by \*\*\*\*.

### SFR ADDRESS MAP SUMMARY

| Address | Names                                  | bit7   | bit6   | bit5   | bit4   | bit3   | bit2   | bit1   | bit0   |
|---------|----------------------------------------|--------|--------|--------|--------|--------|--------|--------|--------|
| 80H     | P0 latch                               | P07    | P06    | P05    | P04    | P03    | P02    | P01    | P00    |

## 80CL410/83CL410

### DESCRIPTION

The 80CL410/83CL410 (hereafter generically referred to as 8XCL410) is manufactured in an advanced CMOS process that allows the part to operate at supply voltages down to 1.8V and oscillator frequencies down to DC. The 8XCL410 has the same instruction set as the 80C51.

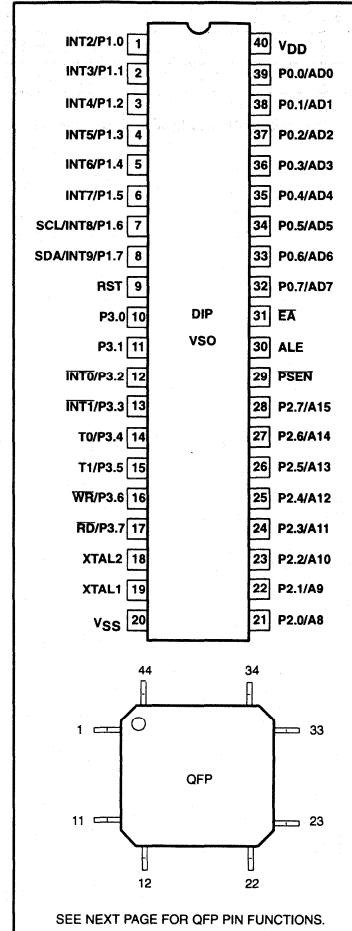

The 8XCL410 features a 4k byte ROM (83CL410), 128 bytes RAM (both ROM and RAM are externally expandable to 64k bytes), four 8-bit ports, two 16-bit timer/counters, an I<sup>2</sup>C serial interface, a thirteen source, two priority level nested interrupt structure, and on-chip oscillator circuitry suitable for quartz crystal, ceramic resonator, RC, or LC.

The 8XCL410 has two reduced power modes that are the same as those on the standard 80C51. The special reduced power feature of this part is that it can be stopped and then restarted. Running from an external clock source, the clock can be stopped and after a period of time restarted. The 8XCL410 will resume operation from where it was when the code stopped with no loss of internal state, RAM contents, or Special Function Register contents. If the internal oscillator is used the part cannot be stopped and started, but the power-down mode, which can be terminated via an interrupt, can be used to achieve similar power savings and then restart without loss of on-chip RAM and Special Function Register values.

### FEATURES

- Single supply voltage 1.8V to 6.0V
- Frequency from DC to 12MHz
- 80C51 based architecture
  - 4k × 8 ROM (64k external)
  - 128 × 8 RAM (64k external)
  - Four 8-bit I/O ports
  - Two 16-bit timer/counters
  - A thirteen-source, two-level, nested priority interrupt structure
  - 10 external interrupts
- Fully static 80C51 CPU
- I<sup>2</sup>C Serial Interface
- Two power control modes
  - Idle mode
  - Power-down mode – can be terminated by reset or external interrupt
- Wake-up via external interrupts at port 1
- Single supply voltage 1.8V to 6.0V
- Frequency range of DC to 12MHz
- On-chip oscillator (quartz crystal, ceramic resonator, RC, LC)
- Very low power consumption
- Operating temperature range:
  - 40 to +85°C

#### NOTE:

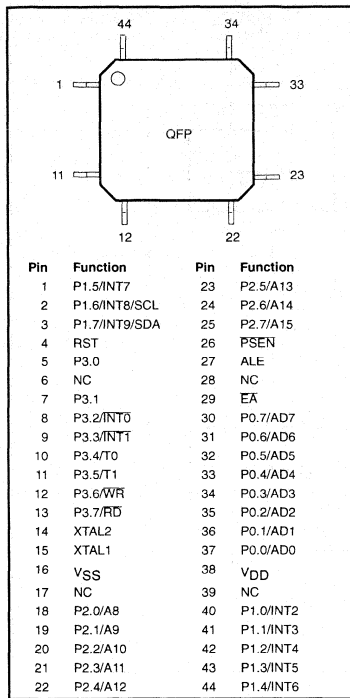

1. Parts ordered by the Philips North America part number will be marked with the Philips part marking.

For emulation purposes, the P85CL000 (Piggyback version) with 256 bytes of RAM is recommended.

| P2.0–P2.7       | 18–25        | 21–28           | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7       | 5, 7–13      | 10–17           | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                        |

## 80CL410/83CL410

### PORT OPTIONS

The pins of port 1 (not P1.6/SCL or P1.7/SDA), port 2, and port 3 may be individually configured with one of the following port options (see Figure 1):

- Option 1: **Standard Port**—quasi-bidirectional I/O with pull-up. The strong booster pull-up p1 is turned on for two oscillator periods after a 0-to-1 transition in the port latch. See Figure 1(a).
- Option 2: **Open Drain**—quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor. See Figure 1(b).
- Option 3: **Push-Pull**—output with drive capability in both polarities. Under this option, pins can only be used as outputs. See Figure 1(c).

The definition of port options for port 0 is slightly different.

Two cases have to be examined. First, accesses to external memory ( $\overline{EA} = 0$  or access above the built-in memory boundary), and second, I/O accesses.

### External Memory Accesses

- Option 1: True 0 and 1 are written as address to the external memory (strong pull-up is used).
- Option 2: An external pull-up resistor is needed for external accesses.
- Option 3: Not allowed for external memory accesses as the port can only be used as output.

### I/O Accesses

- Option 1: When writing a 1 to the port latch, the strong pull-up p1 will be on for two oscillator periods. No weak pull-up exists. Without an external pull-up, this option can be used as a high-impedance input.

- Option 2: Open drain—quasi-bidirectional I/O with n-channel open drain output. Use as an output requires the connection of an external pull-up resistor. See Figure 1(c).
- Option 3: Push-Pull—output with drive capability in both polarities. Under this option, pins can only be used as outputs.

Individual mask selection of the post-reset state is available on any of the above pins. Make your selection by appending "S" or "R" to option 1, 2, or 3 above (e.g., 1S for a standard I/O to be set after RESET or 2R for an open-drain I/O to be reset after RESET).

Option S: **Set**—after reset, this pin will be initialized High.

Option R: **Reset**—after reset, this pin will be initialized Low.

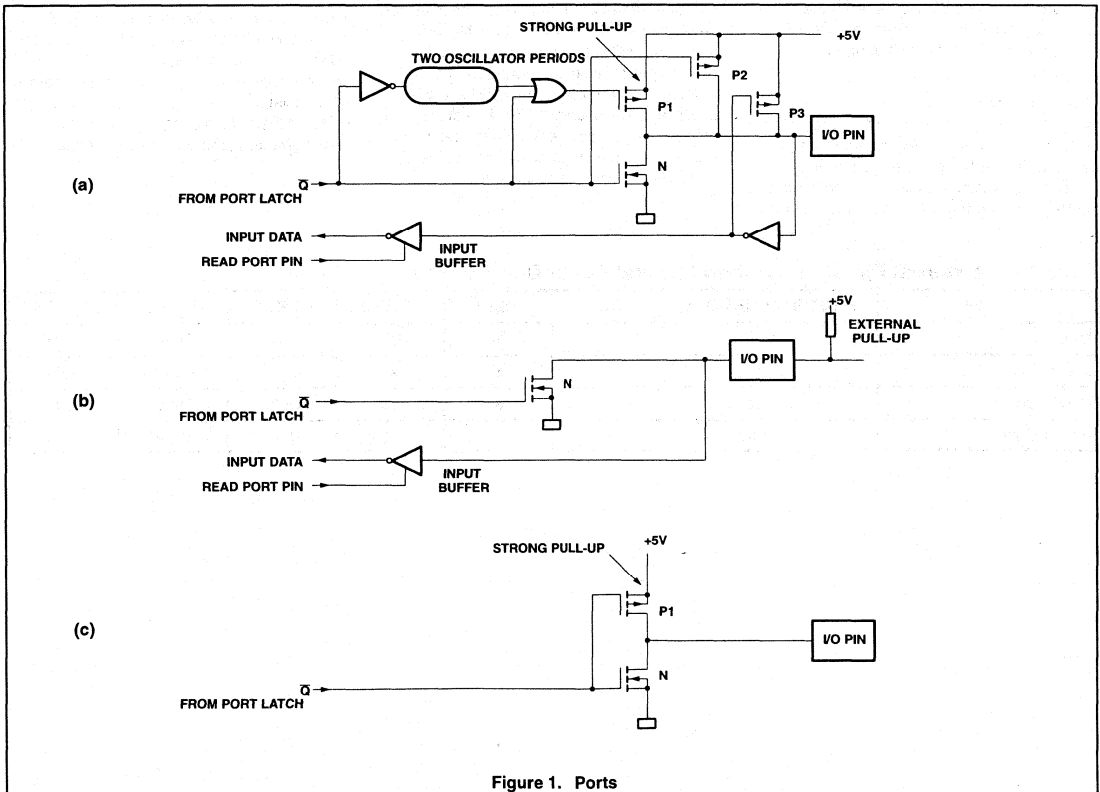

Figure 1. Ports

# Low voltage/low power single-chip 8-bit microcontroller with I<sup>2</sup>C

80CL410/83CL410

## POWER-DOWN MODE

The instruction setting PCON.1 is the last executed prior to going into the power-down mode. In power-down mode, the oscillator is stopped. The contents of the on-chip RAM and SFRs are preserved. The port pins output the values held by their respective SFRs. ALE and PSEN are held low.

In the power-down mode, V<sub>DD</sub> may be reduced to minimize power consumption. However, the supply voltage must not be reduced until the power-down mode is active, and must be restored before the hardware reset is applied and frees the oscillator. Reset must be held active until the oscillator has restarted and stabilized.

From the power-down mode the part can be restarted by using either the wake-up mode or the Reset Mode.

## Wake-Up Mode

Setting both PD and IDL bits in the PCON register forces the controller into the power-down mode. Setting both bits enable the controller to be woken-up from the power-down mode via either an enabled external interrupt INT2–INT9, or a reset operation.

An external interrupt for an enabled interrupt INT2–INT9 at port 1 starts both the oscillator and the delay counter. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods after the interrupt

is detected. This is controlled by the on-chip delay counter. After this, the PD flag will be reset, the controller is now in the Idle mode and the interrupt will be handled in the normal way.

## Reset Mode

Setting only the PD bit in the PCON register again forces the controller into the power-down mode, but in this case it can only be restored to normal operation with a direct reset operation.

To restore normal operation, the RESET pin has to be kept High for a minimum of 24 oscillator periods. The on-chip delay counter is inactive. The user has to insure that the oscillator is stable before any operation is attempted. Figure 2 illustrates the two possibilities for wake-up.

## IDLE MODE

The instruction that sets PCON.0 is the last instruction executed before going into idle mode. In idle mode, the internal clock is stopped for the CPU, but not for the interrupt, timer, and serial port functions. The CPU status is preserved along with the stack pointer, program counter, program status word and accumulator. The RAM and all other registers maintain their data during idle mode. The port pins retain the logical states they held at idle mode activation. ALE and PSEN hold at the logic high level.

There are two methods used to terminate the idle mode. Activation of any interrupt will cause PCON to be cleared by hardware; terminating idle mode. The interrupt is serviced, and following the instruction RETI, the next instruction to be executed will be the one following the instruction that put the device in the the idle mode.

Flag bits GF0 and GF1 can be used to determine whether the interrupt was received during normal execution or idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.

The second method of terminating the idle mode is with an external hardware reset. Since the oscillator is still running, the hardware reset is required to be active for only two machine cycles to complete the reset operation. Reset redefines all SFRs, but does not affect the state of the on-chip RAM.

The status of the external pins during idle and power-down mode is shown in Table 2. If the power-down mode is activated while accessing external memory, port data held in the special function register P2 is restored to port 2. If the data is a logic 1, the port pin is held high during the power-down mode.

**Table 2. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0   | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|----------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data     | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Floating | Data   | Address | Data   |

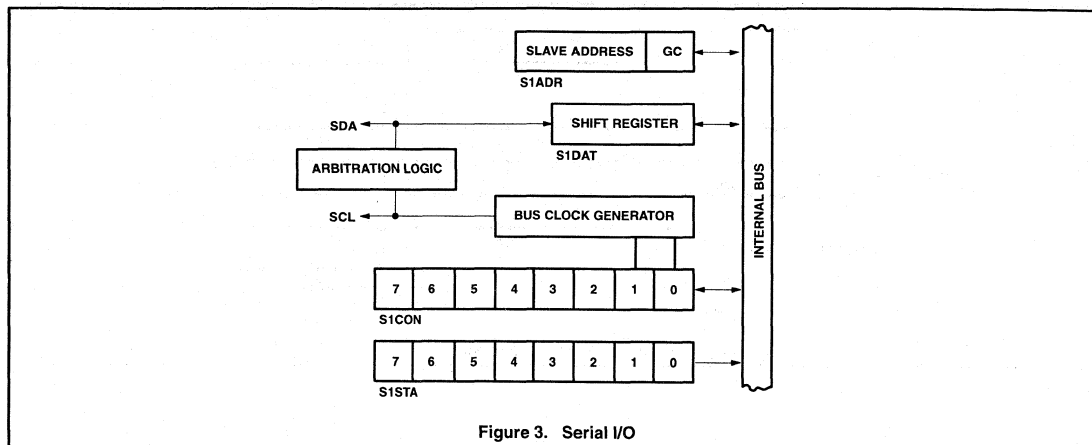

Figure 3. Serial I/O

### I<sup>2</sup>C-BUS SERIAL I/O

The serial port supports the twin line I<sup>2</sup>C-bus. The I<sup>2</sup>C-bus consists of a data line (SDA) and a clock line (SCL). These lines also function as I/O port lines P1.7 and P1.6 respectively. The system is unique because data transport, clock generation, address recognition and bus control arbitration are all controlled by hardware. The I<sup>2</sup>C-bus serial I/O has complete autonomy in byte handling and operates in four modes:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver

These functions are controlled by the S1CON register. S1STA is the status register whose contents may also be used as a vector to various service routines. S1DAT is the data shift register and S1ADR the slave address register. Slave address recognition is performed by hardware.

#### S1CON (D8H)

Serial control register

|     |      |     |     |    |    |     |     |
|-----|------|-----|-----|----|----|-----|-----|
| CR2 | ENS1 | STA | STO | SI | AA | CR1 | CR0 |
|-----|------|-----|-----|----|----|-----|-----|

#### CR0, CR1, CR2

These three bits determine the serial clock frequency when SIO is in a master mode.

AA

Assert acknowledge bit. When the AA flag is set, an acknowledge (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when:

- own slave address is received
- general call address is received (S1ADR.0 = 1)
- data byte received while device is programmed as master
- data byte received while device is selected slave

With AA = 0, no acknowledge will be returned. Consequently, no interrupt is requested when the "own slave address" or general call address is received.

SI

SIO interrupt flag. When the SI flag is set, an acknowledge is returned after any one of the following conditions:

- a start condition is generated in master mode
- own slave address received during AA = 1
- general call address received while S1ADR.0 and AA = 1
- data byte received or transmitted in master mode (even if arbitration is lost)
- data byte received or transmitted as selected slave
- stop or start condition received as selected slave receiver or transmitter

STO

STOP flag. With this bit set while in master mode, a STOP condition is generated. When a STOP condition is detected on the bus, the SIO hardware clears the STO flag. In the slave mode, the STO flag may also be set to recover from an error condition. In this case, no STOP condition is transmitted to the I<sup>2</sup>C-bus. However, the SIO hardware behaves as if a STOP condition has been received and releases SDA and SCL. The SIO then switches to the "not addressed" slave receiver mode. The STO flag is automatically cleared by hardware.

STA

START flag. When the STA bit is set in slave mode, the SIO hardware checks the status of the I<sup>2</sup>C-bus and generates a START condition if the bus is free. If STA is set while the SIO is in master mode, SIO transmits a repeated START condition.

ENS1

When ENS1 = 0, the SIO is disabled. The SDA and SCL outputs are in a high-impedance state; P1.6 and P1.7 function as open drain ports.

When ENS1 = 1, the SIO is enabled. The P1.6 and P1.7 port latches must be set to logic 1.

# Low voltage/low power single-chip 8-bit microcontroller with I<sup>2</sup>C

## 80CL410/83CL410

### S1STA (D9H) Status register

|     |     |     |     |     |   |   |   |
|-----|-----|-----|-----|-----|---|---|---|
| SC4 | SC3 | SC2 | SC1 | SC0 | 0 | 0 | 0 |
|-----|-----|-----|-----|-----|---|---|---|

S1STA is an 8-bit read-only special function register. S1STA.3–S1STA.7 hold a status code. S1STA.0–S1STA.2 are held LOW. The contents of S1STA may be used as a vector to a service routine. This optimizes response time of the software and consequently that of the I<sup>2</sup>C-bus.

The following is a list of the status codes:

#### Abbreviations used:

- SLA: 7-bit slave address
- R: Read bit
- W: Write bit
- ACK: Acknowledgement (acknowledge bit = 0)
- ACK: Not Acknowledge (acknowledge bit = 1)
- DATA: 8-bit byte to or from the I<sup>2</sup>C-bus
- MST: Master
- SLV: Slave
- TRX: Transmitter
- REC: Receiver

### MST/TRX mode S1STA value

- 08H – a START condition has been transmitted
- 10H – a repeated START condition has been transmitted
- 18H – SLA and W have been transmitted, ACK received
- 20H – SLA and W have been transmitted, ACK received
- 28H – DATA of S1DAT has been transmitted, ACK received
- 30H – DATA of S1DAT has been transmitted, ACK received
- 38H – Arbitration lost in SLA, R/W or DATA

### MST/REC mode S1STA value

- 08H – a START condition has been transmitted
- 10H – a repeated START condition has been transmitted
- 38H – Arbitration lost while returning  $\overline{\text{ACK}}$
- 40H – SLA and R have been transmitted, ACK received
- 48H – SLA and R have been transmitted, ACK received
- 50H – DATA has been received, ACK returned
- 58H – DATA has been received,  $\overline{\text{ACK}}$  returned

### SLV/REC mode S1STA value

- 60H – Own SLA and W have been received, ACK returned
- 68H – Arbitration lost in SLA, R/W as MST. Own SLA and W have been received, ACK returned
- 70H – General CALL has been received, ACK returned
- 78H – Arbitration lost in SLA, R/W as MST. General CALL has been received
- 80H – Previously addressed with own SLA. DATA byte received, ACK returned
- 88H – Previously addressed with own SLA. DATA byte received, ACK returned
- 90H – Previously addressed with general CALL. DATA byte has been received, ACK has been returned
- 98H – Previously addressed with general CALL. DATA byte has been received, ACK has been returned
- A0H – A STOP condition or repeated START condition has been received while still addressed as SLV/REC or SLV/TRX

### SLV/TRX mode S1STA value

- A8H – Own SLA and R have been received, ACK returned
- B0H – Arbitration lost in SLA, R/W as MST. Own SLA and R have been received, ACK returned
- B8H – DATA byte has been transmitted, ACK received
- C0H – DATA byte has been transmitted, ACK received
- C8H – Last DATA byte has been transmitted (AA = logic 0), ACK received

### Miscellaneous S1STA value

- 00H – Bus error during MST mode or selected SLV mode, due to an erroneous START or STOP condition
- F8H – No relevant state interruption available, SI = 0.

### S1DAT (DAH) Data Shift Register

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

#### Data shift register S1DAT

This register contains the serial data to be transmitted or data that has just been received. Bit 7 is transmitted or received first, i.e., data is shifted from left to right.

### S1ADR (DBH) Slave Address Register

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|

- S1ADR.0, GC: 0 = general CALL address is not recognized
- 1 = general CALL address is recognized

S1ADR.7-1: own slave address

This 8-bit register may be loaded with the 7-bit slave address, to which the controller will respond when programmed as a slave receiver/transmitter. The LSB bit (GC) is used to determine whether the general CALL address is recognized.

**Table 3. SCL Frequency**

| CR2 | CR1 | CR0 | f <sub>osc</sub> DIVIDED BY | BIT RATE (kHz) at f <sub>osc</sub> |      |       |
|-----|-----|-----|-----------------------------|------------------------------------|------|-------|
|     |     |     |                             | 3.58MHz                            | 6MHz | 12MHz |
| 0   | 0   | 0   | 256                         | 14.0                               | 23.4 | 46.9  |
| 0   | 0   | 1   | 224                         | 16.0                               | 26.8 | 53.6  |

# Low voltage/low power single-chip 8-bit microcontroller with I<sup>2</sup>C

80CL410/83CL410

## INTERRUPT SYSTEM

External events and the real-time-driven on-chip peripherals require service by the CPU asynchronous to the execution of any particular section of code. To tie the asynchronous activities of these functions to normal program execution, a multiple-source, two-priority level, nested interrupt system is provided. The 8XCL410 acknowledges interrupt requests from thirteen sources, as follows:

- INT0 and INT1
- Timer 0 and timer 1
- I<sup>2</sup>C-bus serial I/O interrupt
- INT2 to INT9 (port 1)

Each interrupt vectors to a separate location in program memory for its service routine. Each source can be individually enabled or disabled by corresponding bits in the internal enable registers (IEN0, IEN1). The priority level is selected via the interrupt priority register (IPO, IP1). All enabled sources can be globally disabled or enabled.

### External Interrupts INT2–INT9

Port 1 lines serve an alternative purpose as eight additional interrupts INT2–INT9. When enabled, each of these lines can “wake-up” the device from power-down mode. Using the IX1 register, each pin may be initialized to either active high or low. IRQ1 is the interrupt request flag register. Each flag, if the interrupt is enabled, will be set on an interrupt request but it must be cleared by software.

### IEN0 (A8H)

### IP1 (F8H)

#### Interrupt priority register

|     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|
| 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| PX9 | PX8 | PX7 | PX6 | PX5 | PX4 | PX3 | PX2 |

| Bit   | Symbol | Function                            |
|-------|--------|-------------------------------------|
| IP1.7 | PX9    | External interrupt 9 priority level |
| IP1.6 | PX8    | External interrupt 8 priority level |
| IP1.5 | PX7    | External interrupt 7 priority level |
| IP1.4 | PX6    | External interrupt 6 priority level |
| IP1.3 | PX5    | External interrupt 5 priority level |
| IP1.2 | PX4    | External interrupt 4 priority level |
| IP1.1 | PX3    | External interrupt 3 priority level |
| IP1.0 | PX2    | External interrupt 2 priority level |

Interrupt priority is as follows:  
0 – low priority  
1 – high priority

### IX1 (E9H)

#### Interrupt polarity register

|     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|
| 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| IL9 | IL8 | IL7 | IL6 | IL5 | IL4 | IL3 | IL2 |

| Bit   | Symbol | Function                            |
|-------|--------|-------------------------------------|
| IX1.7 | IL9    | External interrupt 9 polarity level |
| IX1.6 | IL8    | External interrupt 8 polarity level |
| IX1.5 | IL7    | External interrupt 7 polarity level |
| IX1.4 | IL6    | External interrupt 6 polarity level |
| IX1.3 | IL5    | External interrupt 5 polarity level |
| IX1.2 | IL4    | External interrupt 4 polarity level |
| IX1.1 | IL3    | External interrupt 3 polarity level |
| IX1.0 | IL2    | External interrupt 2 polarity level |

Writing either a “1” or “0” to an IX1 register bit sets the priority level of the corresponding external interrupt to active High or Low, respectively.

**OSCILLATOR CIRCUITRY**

The on-chip oscillator circuitry of the 8XCL410 is a single stage inverting amplifier biased by an internal feedback resistor. (See Figure 4.) The oscillator can be operated with a quartz crystal, ceramic resonator, LC network or RC network. See Figure 5 for different configurations. When ordering parts, it is necessary to specify an oscillator option. The options are: RC when an RC network will be used, OSC 2 for oscillator operation below 4MHz, OSC 3 for oscillator operation from 4MHz to 10MHz, OSC 4 for oscillator operation above 10MHz, and 32kHz if 32kHz to 400kHz operation is desired.

For operation as a standard quartz oscillator, no external components are needed (except at 32KHz). When using external capacitors, ceramic resonators, coils, and RC networks to drive the oscillator, five different configurations are supported (see Figure 5 and Table 4).

In the power-down mode the oscillator is stopped and XTAL1 is pulled high. The oscillator inverter is switched off to ensure no current will flow. To drive the device with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 to float, as shown in Figure 5(f). There are no requirements on the duty cycle of the external clock, since the input to the internal clocking circuitry is split using a flip-flop.

The following options are provided for optimum on-chip oscillator performance. Please state option when ordering:

- Osc.1: Figure 5(c). An option for 32kHz clock applications with external trimmer for frequency adjustment.  
A 4.7M $\Omega$  bias resistor must be connected in parallel with the crystal.
- Osc.2: Figure 5(e). An option for low-power, low-frequency operations using LC components or quartz.
- Osc.3: An option for medium frequency range applications.
- Osc.4: An option for high frequency range applications.
- RC: Figure 5(g). An option for an RC oscillator.

The equivalent circuit data of the internal oscillator compares with that of matched crystals.

The externally adjustable RC oscillator has a frequency range from 100kHz to 500kHz. (See Figure 7.)

**Power-on Reset**

The 8XCL410 contains on-chip circuitry which switch the port pins to the customer-defined logic level as soon as V<sub>DD</sub> exceeds 1.3V if the mask option "ON" has been chosen (see Figures 8 and 9). As soon as the minimum supply voltage is reached, the oscillator will start up. However, to ensure that the oscillator is stable before the controller starts, the clock signals are gated away from the CPU for a further 1536 oscillator periods.

An hysteresis of approximately 50mV at a typical power-on switching level of 1.3V will ensure correct operation.

The on-chip power-on reset circuitry can also be switched off via the mask option "OFF". This option reduces the power-down current to typically 800 $\mu$ A and can be chosen if external reset circuitry is used. For applications not requiring the internal reset, option "OFF" should be chosen.

An automatic reset can be obtained at power-on by connecting the RST pin to V<sub>DD</sub> via a 10 $\mu$ F capacitor. At power-on, the voltage on the RST pin is equal to V<sub>DD</sub> minus the capacitor voltage, and decreases from V<sub>DD</sub> as the capacitor discharges through the internal resistor R<sub>RST</sub> to ground. The larger the capacitor, the more slowly V<sub>RST</sub> decreases. V<sub>RST</sub> must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles.

| Storage temperature range           | -65 to +150            | °C   |
| Operating ambient temperature range | -40 to +85             | °C   |
| Operating junction temperature      | 125                    | °C   |

#### NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

### NOTES:

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with t<sub>r</sub> = t<sub>f</sub> = 10ns; V<sub>IL</sub> = V<sub>SS</sub>, V<sub>IH</sub> = V<sub>DD</sub>; XTAL2 not connected; EA = RST = Port 0 = V<sub>DD</sub>; all open drain outputs connected to V<sub>SS</sub>.
- The idle supply current is measured with all output pins disconnected; XTAL1 driven with t<sub>r</sub> = t<sub>f</sub> = 10ns; V<sub>IL</sub> = V<sub>SS</sub>, V<sub>IH</sub> = V<sub>DD</sub>; XTAL2 not connected; EA = Port 0 = V<sub>DD</sub>; RST = V<sub>SS</sub>; all open drain outputs connected to V<sub>SS</sub>.
- The power-down current is measured with all output pins disconnected; XTAL1 not connected; EA = port 0 = V<sub>DD</sub>; RST = V<sub>SS</sub>; all open-drain outputs connected to V<sub>SS</sub>.
- The RC-oscillator is not implemented in this version.
- Circuits with "power-on reset" option "OFF" are tested at V<sub>DDMIN</sub> = 1.8V, with option "ON" (typically 1.3V) are tested at V<sub>DDMIN</sub> = 2.3V.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 50pF, load capacitance for all other outputs = 40pF.
- Interfacing the 8XCL410 to devices with float time up to 75ns is permitted. This limited bus connection will not cause damage to port 0 drivers.

### PIGGYBACK SPECIFICATION

The differences between the masked version and the piggyback are described herein.

### General Description

The P85CL000HFZ is a piggy-back version with 256 bytes of RAM used for emulation of the P83CL410 microcontroller. The P85CL000HFZ is manufactured in an advanced CMOS technology. The instruction set of the P85CL000HFZ is based on that of the 8051. The device has low power consumption and a wide supply voltage range. The P85CL000HFZ has two software selectable modes of reduced activity for further power reduction: Idle and Power-down. For timing and AC/DC characteristics, please refer to the P83CL410 specifications.

### Features

- Full static 80C51 CPU
- 8-bit CPU, RAM, I/O in a single 40-lead DIP
- Socket for up to 16k external EPROM
- 256 bytes RAM, expandable externally to 64K bytes
- Four 8-bit ports, 32 I/O lines
- Two 16-bit timer/event counters
- External memory expandable up to 128K, external ROM up to 64K and/or RAM up to 64K
- Thirteen source, thirteen vector interrupt structure with two priority levels
- Full duplex serial port (UART)
- I<sup>2</sup>C-bus interface for serial transfer on two lines
- Enhanced architecture with:
  - non-page oriented instructions
  - direct addressing
  - four eight byte RAM register banks
  - stack depth up to 128 bytes
  - multiply, divide, subtract and compare instructions
- STOP and IDLE instructions
- Wake-up via external interrupts at port 1
- Single supply voltage of 1.8V to 6.0V
- On-chip oscillator (option: oscillator 4)
- Very low current consumption
- Operating temperature range:
  - 40 to +85°C

### STANDARD PIGGYBACK

Types: P85CL000HFZ

Emulation for: P83CL410, P80CL51

List of differences between masked microcontroller and corresponding piggyback:

## CMOS single-chip 8-bit microcontroller

## 80C451/83C451/87C451

## DESCRIPTION

The Philips 8XC451 is an I/O expanded single-chip microcontroller fabricated with Philips high-density CMOS technology. Philips epitaxial substrate minimizes latch-up sensitivity.

The 8XC451 (includes the 80C451, 87C451 and 83C451) is a functional extension of the 87C51 microcontroller with three additional I/O ports and four I/O control lines for a total of 68 pins. Four control lines associated with port 6 facilitate high-speed asynchronous I/O functions.

The 8XC451 includes a  $4k \times 8$  ROM (83C451) EPROM (87C451), a  $128 \times 8$  RAM, 56 (LCC), two 16-bit timer/counters, a five source, two priority level, nested interrupt structure, a serial I/O port for either a full duplex UART, I/O expansion, or multi-processor communications, and on-chip oscillator and clock circuits. The 80C451 ROMless version includes all of the 83C451 features except the on-board  $4k \times 8$  ROM.

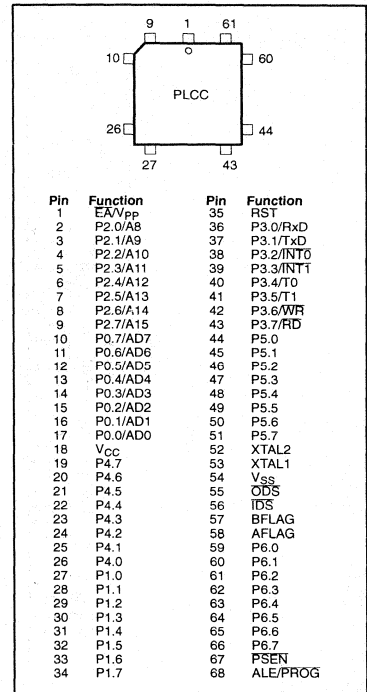

The 87C451 has 4k of EPROM on-chip as program memory and is otherwise identical to the 83C451.

The 8XC451 has two software selectable modes of reduced activity for further power reduction; idle mode and power-down mode. Idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. Power-down mode freezes the oscillator, causing all other chip functions to be inoperative while maintaining the RAM contents.

## FEATURES

- 80C51 based architecture
- Seven 8-bit I/O ports
- Port 6 features:
  - Eight data pins
  - Four control pins
  - Direct MPU bus interface
  - Parallel printer interface
- On the microcontroller:
  - $4k \times 8$  ROM (83C451)
  - $4k \times 8$  EPROM (87C451)
  - ROMless version (80C451)
  - $128 \times 8$  RAM
  - Two 16-bit counter/timers
  - Two external interrupts
- External memory addressing capability
  - 64k ROM and 64k RAM
- Low power consumption:
  - Normal operation: less than 24mA at 5V, 12MHz
  - Idle mode
  - Power-down mode

| RST                | 35      | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal pull-down resistor permits a power-on reset using only an external capacitor connected to V <sub>CC</sub> .                                                                                                                                                                                                                                                                                        |
| ALE/PROG           | 68      | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. ALE is activated at a constant rate of 1/6 the oscillator frequency except during an external data memory access, at which time one ALE is skipped. ALE can sink/source three LS TTL inputs and drive CMOS inputs without external pull-ups. This pin is also the program pulse during EPROM programming.                                                                            |
| PSEN               | 67      | O    | <b>Program Store Enable:</b> The read strobe to external program memory. PSEN is activated twice each machine cycle during fetches from external program memory. However, when executing out of external program memory, two activations of PSEN are skipped during each access to external program memory. PSEN is not activated during fetches from internal program memory. PSEN can sink/source eight LS TTL inputs and drive CMOS inputs without an external pull-up. This pin should be tied low during programming. |
| EA/V <sub>PP</sub> | 1       | I    | <b>Instruction Execution Control/Programming Supply Voltage:</b> When EA is held high, the CPU executes out of internal program memory, unless the program counter exceeds 0FFFH. When EA is held low, the CPU executes out of external program memory. EA must never be allowed to float. This pin also receives the 12.75V programming supply voltage (V <sub>PP</sub> ) during EPROM programming.                                                                                                                       |
| XTAL1              | 53      | I    | <b>Crystal 1:</b> Input to the inverting oscillator amplifier that forms the oscillator. This input receives the external oscillator when an external oscillator is used.                                                                                                                                                                                                                                                                                                                                                  |
| XTAL2              | 52      | O    | <b>Crystal 2:</b> An output of the inverting amplifier that forms the oscillator. This pin should be floated when an external oscillator is used.                                                                                                                                                                                                                                                                                                                                                                          |

## CMOS single-chip 8-bit microcontroller

## 80C451/83C451/87C451

### I/O Port Structure

The 8XC451 has a total of seven parallel I/O ports. The first four ports, P0 through P3, are identical in function to those present on the 80C51 family. The added ports 4 and 5 are identical in function to port 1; that is, they are standard quasi-bidirectional ports with no alternate functions and the standard output drive characteristics. Port 6 is a specialized 8-bit bidirectional I/O port with internal pullups.

### Ports 4 and 5

Ports 4 and 5 are bidirectional I/O ports with internal pull-ups (see Figure 1). Port 4 is an 8-bit port. Port 4 and port 5 pins with ones written to them, are pulled high by the internal pull-ups, and in that state can be used as inputs. Port 4 and 5 are addressed at the special function register addresses shown in Table 1.

### Port 6

Port 6 is a special 8-bit bidirectional I/O port with internal pull-ups (see Figure 1). This special port can sink/source three LS TTL inputs and drive CMOS inputs without external pullups. The flexibility of this port facilitates high-speed parallel data communications. This port can be used as a standard I/O port, or in strobed modes of operation in conjunction with four special control lines:  $\overline{ODS}$ ,  $\overline{IDS}$ , AFLAG, and BFLAG. Port 6 operating modes are controlled by the port 6 control status register (CSR). Port 6 and the CSR are addressed at the special function register addresses shown in Table 1. The following four control pins are used in conjunction with port 6:

**$\overline{ODS}$**  – Output data strobe (Active Low) for port 6.  $\overline{ODS}$  can be programmed to control the port 6 output drivers and the output buffer full flag (OBF), or to clear only the OBF flag bit in the CSR (output-always mode).  $\overline{ODS}$  is active low for output driver control. the OBF flag can be programmed to be cleared on the negative or positive edge of  $\overline{ODS}$ .

**$\overline{IDS}$**  – Input data strobe (Active Low) for port 6.  $\overline{IDS}$  is used to control the port 6 input latch and input buffer full flag (IBF) bit in the CSR. The input data latch can be programmed to be transparent when  $\overline{IDS}$  is low and latched on the positive transition of  $\overline{IDS}$ , or to latch only on the positive transition of  $\overline{IDS}$ . Correspondingly, the IBF flag is set on the negative or positive transition of  $\overline{IDS}$ .

**BFLAG** – BFLAG is a bidirectional I/O pin which can be programmed to be an output, set high or low under program control, or to output the state of the input buffer full flag. BFLAG can also be programmed to input an enable signal for port 6. When BFLAG is used as an enable input, port 6 output drivers are in the high-impedance state, and the input latch does not respond to the  $\overline{IDS}$  strobe when BFLAG is high. Both features are enabled when BFLAG is low. This feature facilitates the use of the SC8XC451 in bused multiprocessor systems.

**AFLAG** – AFLAG is a bidirectional I/O pin which can be programmed to be an output set high or low under program control, or to output the state of the output buffer full flag. AFLAG can also be programmed to be an input which selects whether the contents of the output buffer, or the contents of the port 6 control status register will output on port 6. This feature grants complete port 6 status to external devices.

Port 6 can be used in a number of different ways to facilitate data communication. It can be used as a processor bus interface, as a standard quasi-bidirectional I/O port, or as a parallel printer port (either polled or interrupt driven).

### Processor Bus Interface

Port 6 allows the use of an 8XC451 as an element on a microprocessor type bus. The host processor could be a general purpose MPU or the data bus of a microcontroller like the 8XC451 itself. Setting up the 8XC451 as

a processor bus interface allows single or multiple microcontrollers to be used on a bus as flexible peripheral processing elements. Applications can include: keyboard scanners, serial I/O controllers, servo controllers, etc.

On reset, port 6 is programmed correctly (that is, Special Function registers CSR and P6) for use as a bus interface. This prevents the interface from disrupting data on the bus of a host processor during power-up.

### Standard Quasi-bidirectional I/O Port

To use port 6 as a common I/O port, all of the control pins should be tied to ground. On hardware reset, bits 2-7 of the CSR are set to one. With the control pins grounded, the port's operation and electrical characteristics will be identical to port 1 on the 80C51. No further software initialization is required.

### Parallel Printer Port

The 8XC451 has the capacity to permit all of the intelligent features of a common printer to be handled by a single chip. The features of port 6 allow a parallel port to be designed with only line driving and receiving chips required as additional hardware. The onboard UART allows RS232 interfacing with only level shifting chips added. The 8-bit parallel ports 0 to 6 are ample to drive onboard control functions, even when ports are used for external memory access, interrupts, and other functions. The RAM addressing ability of ports 0 to 2 can be used to address up to 64k bytes of a hardware buffer/spooler.

In addition, either end of a parallel interface can be implemented using port 6, and the interfaces can be interrupt driven or polled in either case. For more detailed information on port 6 usage, refer to the application notes entitled "80C451 Operation of Port 6" and "256k Centronics Printer Buffer Using the SC87C451 Microcontroller."

# 80C451/83C451/87C451

## CONTROL STATUS REGISTER

The control status register (CSR) establishes the mode of operation for port 6 and indicates the current status of port 6 I/O registers. All control status register bits can be read and written by the CPU, except bits 0 and 1, which are read only. Reset writes ones to bits 2 through 7, and writes zeros to bits 0 and 1 (see Table 3).

**CSR.0 Input Buffer Full Flag (IBF) (Read Only)** – The IBF bit is set to a logic 1 when port 6 data is loaded into the input buffer under control of  $\overline{IDS}$ . This can occur on the negative or positive edge of  $\overline{IDS}$ , as determined by CSR.2 IBF is cleared when the CPU reads the input buffer register.

**CSR.1 Output Buffer Full Flag (OBF) (Read Only)** – The OBF flag is set to a logic 1 when the CPU writes to the port 6 output data buffer. OBF is cleared by the positive or negative edge of  $\overline{ODS}$ , as determined by CSR.3.

**CSR.2  $\overline{IDS}$  Mode Select ( $\overline{IDSM}$ )** – When CSR.2 = 0, a low-to-high transition on the  $\overline{IDS}$  pin sets the IBF flag. The Port 6 input buffer is loaded on the  $\overline{IDS}$  positive edge.

When CSR.2 = 1, a high-to-low transition on the  $\overline{IDS}$  pin sets the IBF flag. Port 6 input buffer is transparent when  $\overline{IDS}$  is low, and latched when  $\overline{IDS}$  is high.

**CSR.3 Output Buffer Full Flag Clear Mode (OBF C)** – When CSR.3 = 1, the positive edge of the  $\overline{ODS}$  input clears the OBF flag. When CSR.3 = 0, the negative edge of the  $\overline{ODS}$  input clears the OBF flag.

**CSR.4, CSR.5 AFLAG Mode Select (MA0, MA1)** – Bits 4 and 5 select the mode of operation for the AFLAG pin as follows:

| MA1 | MA0 | AFLAG Function          |
|-----|-----|-------------------------|
| 0   | 0   | Logic 0 output          |
| 0   | 1   | Logic 1 output          |
| 1   | 0   | OBF flag output (CSR.1) |
| 1   | 1   | Select (SEL) input mode |

The select (SEL) input mode is used to determine whether the port 6 data register or the control status register is output on port 6. When the select feature is enabled, the AFLAG input controls the source of port 6 output data. A logic 0 on AFLAG input selects the port 6 data register, and a logic 1 on AFLAG input selects the control status register.

**CSR.6, CSR.7 BFLAG Mode Select (MB0, MB1)** – Bits 6 and 7 select the mode operation as follows:

| MB1 | MB0 | BFLAG Function          |
|-----|-----|-------------------------|
| 0   | 0   | Logic 0 output          |
| 0   | 1   | Logic 1 output          |
| 1   | 0   | IBF flag output (CSR.0) |
| 1   | 1   | Port enable (PE)        |

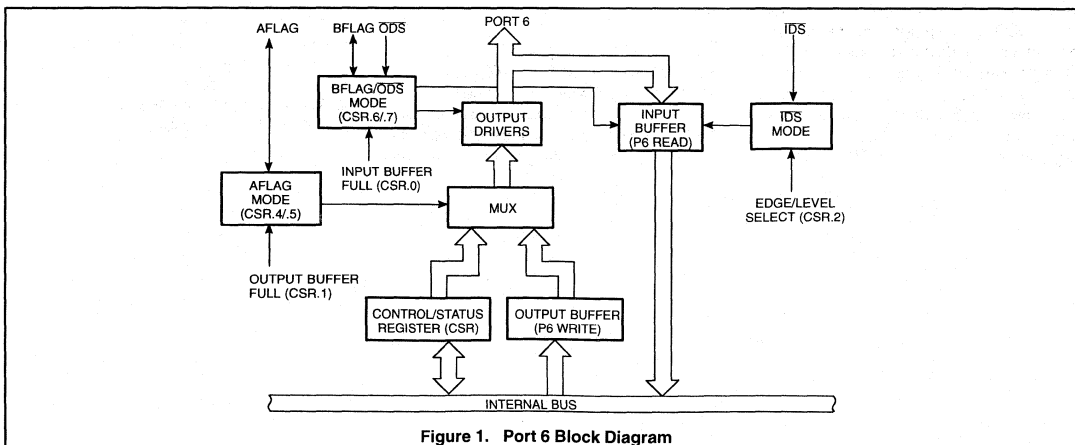

In the port enable mode,  $\overline{IDS}$  and  $\overline{ODS}$  inputs are disabled when BFLAG input is high. When the BFLAG input is low, the port is enabled for I/O.

## SPECIAL FUNCTION REGISTER ADDRESSES

The SFRs are identical to those of the standard 80C51 with the exception of four registers that have been added to allow control of the three additional I/O ports P4, P5, and P6. The additional registers are P4, P5, P6, and CSR. Registers P4, P5, and P6 function as port latches for ports 4, 5, and 6, respectively. These registers operate identically to those for ports 0 through 3 of the 80C51.

**Table 1. Special Function Register Addresses**

| REGISTER ADDRESS      |        |         | BIT ADDRESS |    |    |    |    |    |    |    |     |

| 0/0 = Logic 0 output*<br>0/1 = Logic 1 output*<br>1/0 = IBF output<br>1/1 = PE input<br>(0 = Select)<br>(1 = Disable I/O) |       | 0/0 = Logic 0 output*<br>0/1 = Logic 1 output*<br>1/0 = OBF output<br>1/1 = SEL input<br>(0 = Select)<br>(1 = Control/status) |       | 0 = Negative edge of $\overline{ODS}$<br>1 = Positive edge of $\overline{ODS}$ | 0 = Positive edge of $\overline{IDS}$<br>1 = Low level of $\overline{IDS}$ | 0 = Output data buffer empty<br>1 = Output data buffer full | 0 = Input data buffer empty<br>1 = Input data buffer full |

**NOTE:**

\* Output-always mode: MB1 = 0, MA1 = 1, and MA0 = 0. In this mode, port 6 is always enabled for output.  $\overline{ODS}$  only clears the OBF flag.

**ABSOLUTE MAXIMUM RATINGS<sup>1, 2, 3</sup>**

| PARAMETER                                                                                    | RATING                 | UNIT |
|----------------------------------------------------------------------------------------------|------------------------|------|
| Operating temperature under bias                                                             | 0 to +70<br>-40 to +85 | °C   |
| Storage temperature range                                                                    | -65 to +150            | °C   |
| Voltage on any other pin to $V_{SS}$                                                         | -0.5 to +6.5           | V    |
| Power dissipation (based on package heat transfer limitations, not device power consumption) | 1.5                    | W    |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to  $V_{SS}$  unless otherwise noted.

**NOTES:**

- Typical ratings are based on a limited number of samples taken from early manufacturing lots and are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the V<sub>OL</sub>s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on ports 0 and 2 may cause the V<sub>OH</sub> on ALE and PSEN to momentarily fall below the 0.9V<sub>CC</sub> specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when V<sub>IN</sub> is approximately 2V.
- I<sub>CCMAX</sub> at other frequencies is given by:  
Active mode: I<sub>CCMAX</sub> = 0.94 X FREQ + 13.71  
Idle mode: I<sub>CCMAX</sub> = 0.14 X FREQ + 2.31  
where FREQ is the external oscillator frequency in MHz. I<sub>CCMAX</sub> is given in mA. See Figure 13.
- See Figures 14 through 17 for I<sub>CC</sub> test conditions.
- C<sub>IO</sub> applies to ports 1 through 6, AFLAG, BFLAG, XTAL1, XTAL2.

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.

# CMOS single-chip 8-bit microcontroller

# 80C451/83C451/87C451

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:  
 A - Address  
 C - Clock  
 D - Input data  
 H - Logic level high  
 I - Instruction (program memory contents)  
 L - Logic level low, or ALE

P - PSEN  
 Q - Output data  
 R - RD signal  
 t - Time  
 V - Valid  
 W - WR signal  
 X - No longer a valid logic level  
 Z - Float  
**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

## 80C451/83C451/87C451

**EPROM CHARACTERISTICS**

The 87C451 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C451 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C451 manufactured by Philips Semiconductors.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 18 and 19. Figure 20 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 18. Note that the 87C451 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 18. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The ALE/PROG is pulsed low 25 times as shown in Figure 19.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25 pulse programming sequence using the 'Pgm Lock Bit' levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the  $\overline{EA}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 20. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031H) = 90H indicates 87C451

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{EA}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|------------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                      | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                      | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 0    | 0    |

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP} = 12.75V \pm 0.25V$ .
- $V_{CC} = 5V \pm 10\%$  during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs ( $\pm 10\mu s$ ) and high for a minimum of 10μs.

## CMOS single-chip 8-bit microcontroller

83C504/87C504

## DESCRIPTION

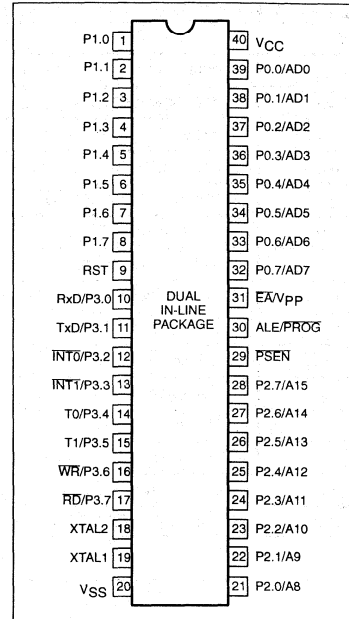

The 83C504 and 87C504 (hereafter referred to as 8XC504) Single-Chip 8-Bit Microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC504 has the same instruction set as the 80C51.

This device provides architectural enhancements that make it applicable in a variety of applications for general control systems. The 8XC504 contains 16k × 8 EPROM memory, the 83C504 contains 16k × 8 ROM memory, a volatile 256 × 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters, a multi-source, two-priority-level, nested interrupt structure, a 24-by-8 bit unsigned divide, an enhanced UART and on-chip oscillator and timing circuits. For systems that require extra capability, the 8XC504 can be expanded using standard TTL compatible memories and logic.

## FEATURES

- 80C51 central processing unit
- 16k × 8 EPROM expandable externally to 64k bytes
  - Quick Pulse programming algorithm
  - Two level program security system
- 256 × 8 RAM, expandable externally to 64k bytes
- Two 16-bit timer/counters
- Four 8-bit I/O ports
- Full-duplex enhanced UART
  - Framing error detection
  - Automatic address recognition
- Power control modes
  - Idle mode
  - Power-down mode
- Once (On Circuit Emulation) Mode
- Five package styles
- OTP package available
- 24-by-8 bit divide
  - Requires 8 machine cycles
  - 24-bit quotient and 8-bit remainder

| P0.0–P0.7                       | 39–32      | 43–36        | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification and receives code bytes during EPROM programming. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                                                                                   |
| P1.0–P1.7                       | 1–8        | 2–9          | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 also receives the low-order address byte during program memory verification.                                                                                                                                                                                                                                                                                                                                                                    |
| P2.0–P2.7                       | 21–28      | 24–31        | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. Some Port 2 pins receive the high order address bits during EPROM programming and verification. |
| P3.0–P3.7                       | 10–17      | 11,<br>13–19 | 5,<br>7–13    | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the 80C51 family, as listed below:<br><b>RxD (P3.0):</b> Serial input port<br><b>TxD (P3.1):</b> Serial output port<br><b>INT0 (P3.2):</b> External interrupt<br><b>INT1 (P3.3):</b> External interrupt<br><b>T0 (P3.4):</b> Timer 0 external input<br><b>T1 (P3.5):</b> Timer 1 external input<br><b>WR (P3.6):</b> External data memory write strobe<br><b>RD (P3.7):</b> External data memory read strobe                                              |
| RST                             | 9          | 10           | 4             | I    | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V <sub>SS</sub> permits a power-on reset using only an external capacitor to V <sub>CC</sub> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ALE/PROG                        | 30         | 33           | 27            | I/O  | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PSEN                            | 29         | 32           | 26            | O    | <b>Program Store Enable:</b> The read strobe to external program memory. When the 8XC504 is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| E <sub>A</sub> /V <sub>PP</sub> | 31         | 35           | 29            | I    | <b>External Access Enable/Programming Supply Voltage:</b> E <sub>A</sub> must be externally held low to enable the device to fetch code from external program memory locations 0000H and 3FFFH. If E <sub>A</sub> is held high, the device executes from internal program memory unless the program counter contains an address greater than 3FFFH. This pin also receives the 12.75V programming supply voltage (V <sub>PP</sub> ) during EPROM programming. If security bit 1 is programmed, E <sub>A</sub> will be internally latched on Reset.                                                                                                                                                                                                                                                                                                                 |
| XTAL1                           | 19         | 21           | 15            | I    | <b>Crystal 1:</b> Input to the inverting oscillator amplifier and input to the internal clock generator circuits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

\* SFRs are bit addressable.

# SFRs are modified from or added to the 80C51 SFRs.

1. Reset value depends on reset source.

## CMOS single-chip 8-bit microcontroller

## 83C504/87C504

### ENHANCED UART

The 8XC504 UART has all of the capabilities of the standard 80C51 UART plus Framing Error Detection and Automatic Address Recognition. As in the 80C51, all four modes of operation are supported as well as the 9th bit in modes 2 and 3 that can be used to facilitate multiprocessor communication.

The Framing Error Detection allows the UART to look for missing stop bits. If a Stop bit is missing, the FE bit in the SCON SFR is set. The FE bit can be checked after each transmission to detect communication errors. The FE bit can only be cleared by software and is not affected by a valid stop bit.

Automatic Address Recognition is used to reduce the CPU service time for the serial port. The CPU only needs to service the UART when it is addressed and, with this done by the on-chip circuitry, the need for software overhead is greatly reduced. This mode works similar to the 9th bit communication mode, except that uses only 8 bits and the Stop bit is used to cause the RI bit to be set. There are two SFRs associated with this mode. They are SADDR, which holds the slave address and SADEN, which contains a mask that allows selective masking of the slave address so that broadcast addresses can be used.

### HARDWARE DIVIDE UNIT

The 8XC504 contains a 24-by-8 bit hardware divide unit. The 24 bit dividend is stored in special function registers DVND0 (LSB) – DVND2 (MSB) and the divisor is in register DVSR. A division operation returns the 24-bit result in the dividend registers (DVND0 – DVND2) and an 8-bit remainder in register RMDR.

The divide unit provides two modes of operation, auto-start and flag-controlled. Auto-start mode is enabled by setting the AUTOD (auto divide) bit in the DCON (divide control) register. If auto-start mode is enabled, writing to the divisor register (DVSR) will automatically start a division operation and will set the DCTRL (divide control) and DSTRT bits in the DCON register. DCTRL will automatically be cleared by the divide hardware when the division operation has been completed.

Flag controlled operation is initiated by setting the DCTRL bit in the DCON register which will start the division operation and also set the DSTRT bit. The DCTRL bit will automatically be cleared by the divide hardware when the division operation has

been completed. DSTRT can only be cleared by software.

### POWER OFF FLAG

The Power Off Flag (POF) is set by on-chip circuitry when the  $V_{CC}$  level on the 8XC504 rises from 0 to 5V. The POF bit can be set or cleared by software allowing a user to determine if the reset is the result of a power-on or a warm start after powerdown. The  $V_{CC}$  level must remain above 3V for the POF to remain unaffected by the  $V_{CC}$  level.

### OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

### Reset

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-on reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

### Idle Mode

In the idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

### Power-Down Mode

To save even more power, a Power Down mode can be invoked by software. In this

mode, the oscillator is stopped and the instruction that invoked Power Down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the Power Down mode is terminated.

On the 8XC504 either a hardware reset or external interrupt can use an exit from Power Down. Reset redefines all the SFRs but does not change the on-chip RAM. An external interrupt allows both the SFRs and the on-chip RAM to retain their values.

To properly terminate Power Down the reset or external interrupt should not be executed before  $V_{CC}$  is restored to its normal operating level and must be held active long enough for the oscillator to restart and stabilize (normally less than 10ms).

With an external interrupt, INT0 and INT1 must be enabled and configured as level-sensitive. Holding the pin low restarts the oscillator but bringing the pin back high completes the exit. Once the interrupt is serviced, the next instruction to be executed after RETI will be the one following the instruction that put the device into Power Down.

### Design Consideration

- When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

### ONCE™ Mode

The ONCE ("On-Circuit Emulation") Mode facilitates testing and debugging of systems using the 8XC504 without the 8XC504 having to be removed from the circuit. The ONCE Mode is invoked by:

- Pull ALE low while the device is in reset and PSEN is high;
- Hold ALE low as RST is deactivated.

While the device is in ONCE Mode, the Port 0 pins go into a float state, and the other port pins and ALE and PSEN are weakly pulled high. The oscillator circuit remains active. While the 8XC504 is in this mode, an emulator or test CPU can be used to drive the circuit. Normal operation is restored when a normal reset is applied.

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

## Electrical Deviations from Commercial Specifications for Extended Temperature Range

DC and AC parameters not included here are the same as in the commercial temperature range table.

## DC ELECTRICAL CHARACTERISTICS

| $C_{IO}$  | Pin capacitance <sup>11</sup> (except EA)                                                         |                                                                                       |                 |                  | 15              | pF            |

## NOTES:

- Typical ratings are not guaranteed. The values listed are at room temperature, 5V.
- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.  $I_{OL}$  can exceed these conditions provided that no single output sinks more than 5mA and no more than two outputs exceed the test conditions.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- $I_{CCMAX}$  at other frequencies is given by: Active mode:  $I_{CCMAX} = 1.50 \times \text{FREQ} + 8$ ; Idle mode:  $I_{CCMAX} = 0.14 \times \text{FREQ} + 2.31$ , where FREQ is the external oscillator frequency in MHz.  $I_{CCMAX}$  is given in mA. See Figure 8.
- See Figures 9 through 12 for  $I_{CC}$  test conditions.
- These values apply only to  $T_{amb} = 0^{\circ}\text{C}$  to  $+70^{\circ}\text{C}$ . For  $T_{amb} = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ , see table on previous page.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 15mA (\*NOTE: This is 85°C specification.)  
Maximum  $I_{OL}$  per 8-bit port: 26mA  
Maximum total  $I_{OL}$  for all outputs: 71mA  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- ALE is tested to  $V_{OH1}$ , except when ALE is off then  $V_{OH}$  is the voltage specification.
- Pin capacitance is less than 25pF. Pin capacitance of ceramic package is less than 15pF (except EA is 25pF).

| $t_{XHDV}$            | 4      | Clock rising edge to input data valid    |             | 492 |                  | $10t_{CLCL}-133$ | ns            |

**NOTES:**

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.
- Interfacing the 87C51FB to devices with float times up to 45ns is permitted. This limited bus contention will not cause damage to Port 0 drivers.

# 83C504/87C504

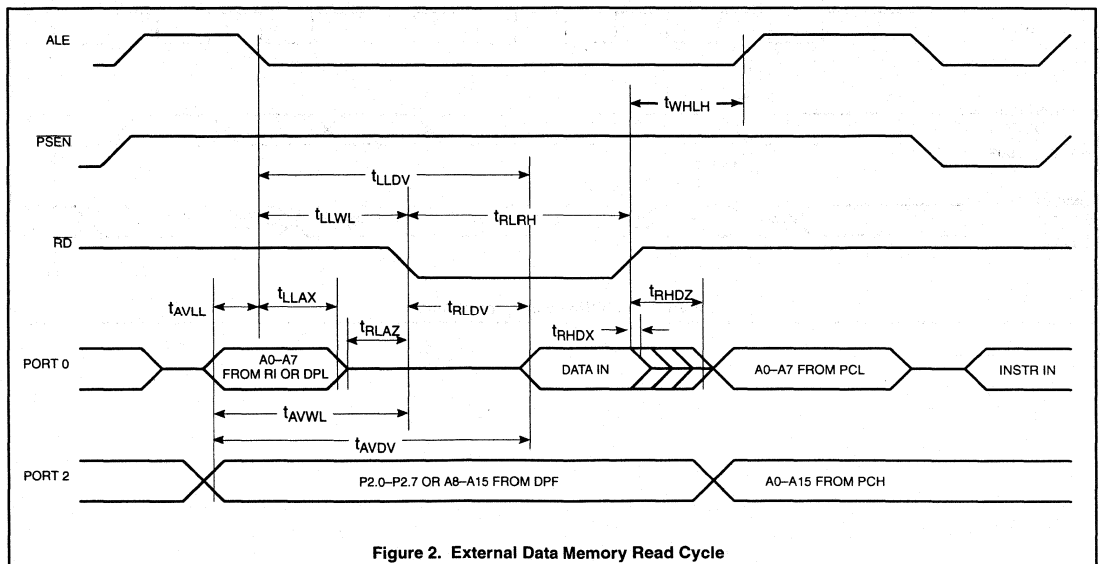

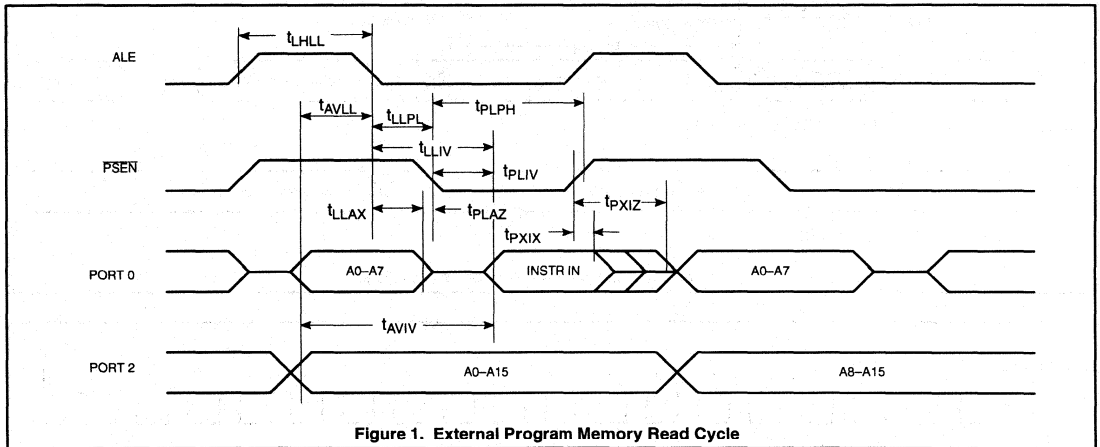

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A – Address
- C – Clock
- D – Input data
- H – Logic level high
- I – Instruction (program memory contents)
- L – Logic level low, or ALE

- P – PSEN
- Q – Output data
- R – RD signal
- t – Time
- V – Valid
- W – WR signal
- X – No longer a valid logic level
- Z – Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

## CMOS single-chip 8-bit microcontroller

83C504/87C504

**EPROM CHARACTERISTICS**

The 87C504 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C504 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C504 manufactured by Philips.

Table 3 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the security bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 13 and 14. Figure 15 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 13. Note that the 87C504 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1 and 2, as shown in Figure 13. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 3 are held at the 'Program Code Data' levels indicated in Table 3. The ALE/PROG is pulsed low 25 times as shown in Figure 14.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 1FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the security bits, repeat the 25 pulse programming sequence using the 'Pgm Security Bit' levels. After one security bit is programmed, further programming of the code memory and encryption table is disabled. However, the other security bit can still be programmed.

Note that the EA/ $V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If security bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1 and 2 as shown in Figure 15. The other pins are held at the 'Verify Code Data' levels indicated in Table 3. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips  
(031H) = BBH indicates 87C504

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 3, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-s/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erase leaves the array in an all 1s state.

**Table 3. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/ $V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|--------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1            | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$     | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1            | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$     | 1    | 0    | 1    | 0    |
| Pgm security bit 1   | 1   | 0    | 0*       | $V_{PP}$     | 1    | 1    | 1    | 1    |
| Pgm security bit 2   | 1   | 0    | 0*       | $V_{PP}$     | 1    | 1    | 0    | 0    |

**NOTES:**

1. '0' = Valid low for that pin, '1' = valid high for that pin.

2.  $V_{PP}$  = 12.75V ±0.25V.

3.  $V_{CC}$  = 5V ±10% during programming and verification.

\* ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs (±10μs) and high for a minimum of 10μs.

## 8-bit microcontroller

## P83C524

## FEATURES

- 80C51 CPU
- 16 kbytes on-chip ROM, expandable externally to 64 kbytes Program Memory address space
- 512 bytes on-chip RAM, expandable externally to 64 kbytes Data Memory address space
- Four 8-bit I/O ports
- Full-duplex UART compatible with the standard 80C51 and the 8052
- Two standard 16-bit timer/counters
- An additional 16-bit timer (functionally equivalent to the timer 2 of the 8052)
- On-chip Watchdog Timer (WDT) with a separate on-chip oscillator
- Bit-level I<sup>2</sup>C-bus hardware serial I/O Port
- 7-source and 7-vector interrupt structure with 2 priority levels
- Up to 3 external interrupt request inputs
- Two programmable power reduction modes (Idle and Power-down)

- Termination of Idle mode by any interrupt, external or WDT (watchdog) reset
- Wake-up from Power-down by external interrupt, external or WDT reset
- ROM code protection
- XTAL frequency range: 1.2MHz to 16MHz
- All packaging pin-outs fully compatible to the standard 8051/8052.

## GENERAL DESCRIPTION

The P83C524 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The P83C524 is a stand-alone high-performance microcontroller designed for use in real time applications

such as instrumentation, industrial control, medium to high-end consumer applications and specific automotive control applications.

The P83C524 contains a non-volatile 16K × 8 read-only program memory, a volatile 512 × 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a 16-bit timer (identical to the timer 2 of the 8052), a multi-source, two-priority-level, nested interrupt structure, two serial interfaces (UART and bit-level I<sup>2</sup>C-bus), an on-chip oscillator and timing circuits, a watchdog timer (WDT) with a separate on-chip oscillator. For systems that require extra capability, the P83C524 can be expanded using standard TTL compatible memories and logic.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The P83C524 has the same instruction set as the PCB80C51 which consists of over 100 instructions: 49 one-byte, 46 two-byte and 16 three-byte. With a 16MHz crystal, 58% of the instructions are executed in 750ns and 40% in 1.5μs. Multiply and divide instructions require 3μs.

It can drive CMOS inputs without external pull-ups.<br><b>Port 3 alternative functions:</b><br><b>RxD/data (P3.0):</b> Serial Port data input (asynchronous) or data input/output (synchronous).<br><b>TxD/clock (P3.1):</b> Serial Port data output (asynchronous) or clock output (synchronous).<br><b>INT0 (P3.2):</b> External interrupt 0 or gate control input for timer/event counter 0.<br><b>INT1 (P3.3):</b> External interrupt 1 or gate control input for timer/event counter 1.<br><b>T0 (P3.4):</b> External input for timer/event counter 0.<br><b>T1 (P3.5):</b> External input for timer/event counter 1.<br><b>WR (P3.6):</b> External data memory write strobe.<br><b>RD (P3.7):</b> External data memory read strobe. |
| XTAL2                    | 18      | 20                      | O    | <b>Crystal input 2:</b> Output of the inverting amplifier that forms the oscillator. This pin left open-circuit when an external oscillator clock is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| XTAL1                    | 19      | 21                      | I    | <b>Crystal input 1:</b> Input to the inverting amplifier that forms the oscillator, and input to the internal clock generator. Receives the external oscillator clock signal when an external oscillator is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| V <sub>SS</sub>          | 20      | 22                      | I    | <b>Ground:</b> Circuit ground potential.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| P2.0–P2.7<br>(A8 to A15) | 21–28   | 24–31<br>(23 NC)        | I/O  | <b>Port 2:</b> 8-bit quasi-bidirectional I/O port with internal pull-ups. During access to external memories (RAM/ROM) that use 16-bit addresses (MOVX @DPTR) Port 2 emits the high-order address byte (A8 to A15). Port 2 can sink/source one TTL (=4 LS TTL) input. It can drive CMOS inputs without external pull-ups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PSEN                     | 29      | 32                      | O    | <b>Program Store Enable output:</b> Read strobe to external program memory via Port 0 and Port 2. It is activated twice each machine cycle during fetches from external program memory. When executing out of external program memory two activations of PSEN are skipped during each access to external data memory. PSEN is not activated (remains HIGH) during fetches from external program memory. PSEN can sink source 8 LS TTL inputs. It can drive CMOS inputs without external pull-ups.                                                                                                                                                                                                                                                                                                                                                                     |
| ALE                      | 30      | 33                      | I/O  | <b>Address Latch Enable output:</b> Latches the LOW byte of the address during access to external memory in normal operation. It is activated every six oscillator periods except during an external data memory access. ALE can sink/source 8 LS TTL inputs. It can drive CMOS inputs without an external pull-up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| E <sub>A</sub>           | 31      | 35<br>(34 NC)           | I    | <b>External Access input:</b> When during RESET, E <sub>A</sub> is held at a TTL HIGH level, the CPU executes out of the internal program ROM, provided the program counter is less than 32768. When E <sub>A</sub> is held at a TTL LOW level during RESET, the CPU executes out of external program memory via Port 0 and Port 2. E <sub>A</sub> is not allowed to float.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| P0.0–0.7<br>(AD0 to AD7) | 32–39   | 36–43                   | I/O  | <b>Port 0:</b> 8-bit open drain bidirectional I/O Port. It is also the multiplexed low-order address and data bus during accesses to external memory (AD0 to AD7). During these accesses internal pull-ups are activated. Port 0 can sink/source 8 LS TTL inputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## WATCHDOG TIMER T3

The watchdog timer (WDT) (see Figure 4) consists of an 11-bit prescaler and an 8-bit timer formed by special function register T3. The prescaler is incremented by an on-chip oscillator with a fixed frequency of 1MHz. The maximum tolerance on this frequency is -50% and +100%. The 8-bit timer increments every 2048 cycles of the on-chip oscillator. When a timer overflow occurs, the microcontroller is reset and a reset output pulse of  $16 \times 2048$  cycles of the on-chip oscillator is generated at pin RST. The internal RESET signal is not inhibited when the external RST pin is kept LOW by, for example, an external reset circuit. The RESET signal drives Ports 1, 2 and 3 outputs into the HIGH state and port 0 into high impedance, whether the XTAL-clock is running or not.

The watchdog timer is controlled by special function register WDCON with the direct address location A5H. WDCON can be read and written by software. A value of A5H in WDCON halts the on-chip oscillator and clears both the prescaler and timer T3. After

the RESET signal, WDCON contains A5H. Every value other than A5H in WDCON enables the watchdog timer. When the watchdog timer is enabled, it runs independently of the XTAL-clock.

Timer T3 can be read on the fly. Timer T3 can be written to only if WDCON has previously been loaded with 5AH, otherwise T# and the prescaler are not affected. A successful write operation to T3 also clears the prescaler and WDCON. During a read or write operation addressing T3, the output of the on-chip oscillator is inhibited to prevent timing problems due to asynchronous increments of T3. To prevent an overflow of the watchdog timer, the user program has to reload T3 within periods that are shorter than the programmed watchdog timer interval. This time interval is determined by the 8-bit reload value that is written into register T3.

Watchdog timer interval = 
$$\frac{[256 - (T3)] \times 2048}{\text{on-chip oscillator frequency}}$$

The advantages of this implementation are:

- Only an internal reset connection to the microcontroller core.
- The Power-down mode and the Watchdog (WDT) function can be used concurrently.
- The WDT also monitors the XTAL oscillator. In case of a failure the port outputs are forced to a defined HIGH state.
- Interference will not disable the WDT because it is unlikely that it will force WDCON to A5H.
- Tolerances of the on-chip oscillator can be adjusted by testing the T3 value and adapting the reload value.
- The WDT can be enabled and disabled under control of the user software. This gives the possibility to use both the Watchdog function and the Power-down function.
- The direct address A5H of WDCON and its disable value A5H will not unintentionally be present at a random location in the field of program code, except for immediate data, because the opcode A5H is not used in the instruction set.

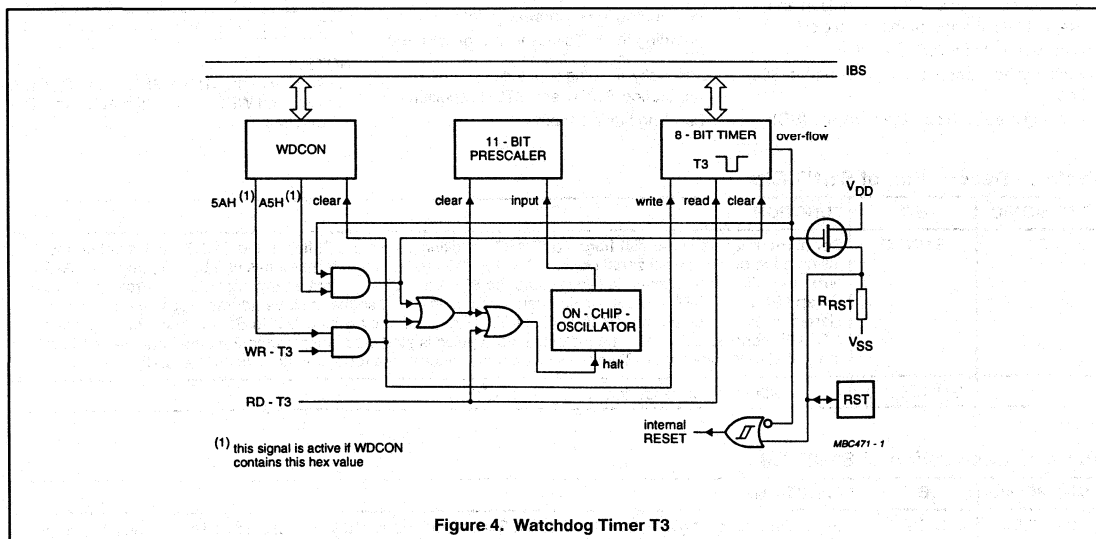

Figure 4. Watchdog Timer T3

## 8-bit microcontroller

P83C524

**BIT-LEVEL I<sup>2</sup>C INTERFACE**

This bit-level serial I/O interface supports the I<sup>2</sup>C-bus (see Figure 5). P1.6/SCL and P1.7/SDA are the serial I/O pins. These two pins meet the I<sup>2</sup>C specification concerning the input levels and output drive capability. Consequently, these pins have an open drain output configuration. All the four modes of the I<sup>2</sup>C-bus are supported:

- master transmitter
- master receiver
- slave transmitter
- slave receiver

The advantages of the bit-level I<sup>2</sup>C hardware compared with a full software I<sup>2</sup>C implementation are:

- The hardware can generate the SCL pulse
- Testing a single bit (RBF respectively, WBF) is sufficient as a check for error free transmission.

The bit-level I<sup>2</sup>C hardware operates on serial bit level and performs the following functions:

- filtering the incoming serial data and clock signals
- recognizing the START condition
- generating a serial interrupt request SI after reception of a START condition and the first falling edge of the serial clock
- recognizing the STOP condition
- recognizing a serial clock pulse on the SCL line
- latching a serial bit on the SDA line (SDI)

- stretching the SCL LOW period of the serial clock to suspend the transfer of the next serial data bit
- setting Read Bit Finished (RBF) when the SCL clock pulse has finished and Write Bit Finished (WBF) if there is no arbitration loss detected (i.e., SDA = 0 while SDO = 1)
- setting a serial clock Low-to-High detected (CLH) flag
- setting a Bus Busy (BB) flag on a START condition and clearing this flag on a STOP condition
- releasing the SCL line and clearing the CLH, RBF and WBF flags to resume transfer of the next serial data bit
- generating an automatic clock if the single bit data register S1BIT is used in master mode.

The following functions must be done in software:

- handling the I<sup>2</sup>C START interrupts
- converting serial to parallel data when receiving
- converting parallel to serial data when transmitting
- comparing the received slave address with its own
- interpreting the acknowledge information
- guarding the I<sup>2</sup>C status if RBF or WBF = 0.

Additionally, if acting as master:

- generating START and STOP conditions
- handling bus arbitration

- generating serial clock pulses if S1BIT is not used.

Three SFRs control the bit-level I<sup>2</sup>C interface: S1INT, S1BIT and S1SCS.

**S1INT: I<sup>2</sup>C Interrupt Register**

This register is located at address DAH. Refer to Table 1.

**S1INT SFR (DAH)**

|    |   |   |   |   |   |   |   |   |
|----|---|---|---|---|---|---|---|---|
|    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SI | X | X | X | X | X | X | X | X |

**NOTE:**

1. **SI bit:** Writing a logic 0 clears this bit, writing a logic 1 has no effect.

**S1BIT: Single-bit Data Register with I<sup>2</sup>C Auto-Clock**

This register is located at address D9H. Refer to Table 2.

**S1BIT SFR (D9H)****READ**

|     |   |   |   |   |   |   |   |   |
|-----|---|---|---|---|---|---|---|---|
|     | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SDI | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**WRITE**

|     |   |   |   |   |   |   |   |   |
|-----|---|---|---|---|---|---|---|---|
|     | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SDO | X | X | X | X | X | X | X | X |

**NOTE:**

1. Access of the **S1BIT** SFR clears SI, CLH, RBF and WBF. It starts the auto-clock if SCO = 0.

**Table 1. Description of S1INT Bits**

| MNEMONIC | BIT          | FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SI       | S1INT.7      | <b>Serial Interrupt request (SI) flag:</b> If a START condition occurs the SI flag in the S1INT SFR is set on the falling edge of the filtered serial clock. If SI = 1 is detected during a transfer this can be a "spurious START" error condition. If no transfer is taking place the SI = 1 is a START from an external master. Provided the bits EA and ES1 in IE SFR are set, SI then generates an interrupt so that a slave address receive routine can be started. SI can be cleared by accessing the S1BIT register or by writing "00" to S1INT. Also after reception of a START condition, the LOW period of the clock pulse is stretched, suspending the serial transfer to allow the software to take action. This clock stretching is ended by a read or write access to S1BIT. |
| –        | S1INT.6 to 0 | X = undefined during read, don't care during write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 2. Description of S1BIT Bits**

## 8-bit microcontroller

P83C524

**Reading or Writing the S1BIT SFR**

Reading or writing the S1BIT SFR starts an I<sup>2</sup>C bit I/O sequence: some flags are cleared (SI, CLH, RBF, WBF), clock stretching is finished and the auto-clock is started. An auto-clock pulse is "OR-ed" with SCO and thus will be output only if the SCO flag has been set to logic 0. SCO = 1 inhibits the auto-clock start, so a dummy read or write of S1BIT SFR can be used to finish clock stretching and clear SI, SLH, RBF and WBF if the auto-clock is not used.

The auto-clock is an active HIGH SCL pulse that starts 28 XTAL periods after the SDI read or SDO write via S1BIT. The duration of the auto-clock pulse is 100 XTAL clock periods. If the SCL line is kept LOW by any device that wants to hold up the bus transfer, the auto-clock counter waits after 20 XTAL clock periods so that the auto-clock pulse length will be at least 80 XTAL clock periods (5 $\mu$ s at f<sub>OSC</sub> = 16MHz).

Every bit I/O should be followed by a RBF or WBF bit test. A bit transfer has been finished successfully if after reading a bit the RBF flag is logic 1 or after writing a bit the WBF flag is logic 1. When after reading a bit the RBF flag is still logic 0, the bus status just before the S1SCS status read can be determined as follows:

- If CLH = 0 then a bus device is still stretching the clock.
- If SCI = 1 while CLH = 1 then the SCL pulse is not finished.
- If BB = 0 there has been a STOP condition.

When after writing a bit the WBF flag is still logic 0 and none of the 3 status conditions mentioned for RBF are found then a "bus arbitration lost" condition will be the cause. This can be determined also from the states of the received bit and the last transmitted bit: "arbitration loss" if SDO = 1 and SDI = 0.

**S1SCS: Control and Status Register for the I<sup>2</sup>C-bus**

This register is located at address D8H. Refer to Table 3.

**S1SCS SFR (D8H)****READ**

|     |     |     |    |     |     |     |     |
|-----|-----|-----|----|-----|-----|-----|-----|
| 7   | 6   | 5   | 4  | 3   | 2   | 1   | 0   |
| SDI | SCI | CLH | BB | RBF | WBF | STR | ENS |

**WRITE**

|     |     |     |   |   |   |     |     |
|-----|-----|-----|---|---|---|-----|-----|
| 7   | 6   | 5   | 4 | 3 | 2 | 1   | 0   |
| SDO | SCO | SLH | X | X | X | STR | ENS |

**NOTES:**

1. **SDI and SCI bits:** read-modify-write operations like "SETB bit" or "CLR bit" access SDO and SCO for reading and writing.
2. **CLH bit:** writing a logic 0 clears this bit, writing a logic 1 has no effect.
3. **RBF and WBF bits:** writing a logic 0 to CLH also clears these bits.
4. X = don't care.

**Table 3. Description of S1SCS Bits**

| MNEMONIC | BIT     | FUNCTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDO/SDI  | S1SCS.7 | <b>Serial Data Output and the filtered Serial Data Input.</b> SDI data is latched on the rising edge of the filtered serial clock. S1SCS.7 accesses the same memory locations as S1BIT.7. Access of the data bit via S1SCS will not start an auto-clock pulse.                                                                                                                                                                                                                                                                                            |
| SCO/SCI  | S1SCS.6 | <b>Serial Clock Output and the filtered Serial Clock Input.</b> Serial clock output SCO is "OR-ed" with the auto-clock. If SCO = 1 the auto-clock output is inhibited. The internal clock stretching logic and external devices can pull the SCL line LOW. If the auto-clock is not used, the SCL line has to be controlled by setting SCO = 1, waiting for CLH = 1 and setting SCO = 0 after the specified SCL HIGH time. (Because of the input filter, CLH will be set at least 8 XTAL clock periods after the SCL LOW-to-HIGH transition.              |
| CLH      | S1SCS.5 | <b>Serial Clock LOW-to-HIGH transition flag:</b> set with a rising edge of the filtered serial clock. CLH = 1 indicates that, since the last CLH reset, a new valid data bit has been latched in SDI. CLH can be reset by writing a logic 0 to S1SCS.5 or by a read/write of S1BIT. Clearing CLH also clears RBF and WBF.                                                                                                                                                                                                                                 |
| BB       | S1SCS.4 | <b>Bus Busy flag:</b> indicating that there has been a START condition that was not yet followed by a STOP condition.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| RBF      | S1SCS.3 | <b>Read Bit Finished flag:</b> indicating a successful bit read. RBF = 1 implies the following conditions:<br>– CLH = 1: SCL had a rising edge<br>– SCI = 0: the SCL pulse has finished<br>– SI = 0: no START condition occurred<br>– BB = 1: no STOP condition occurred<br>The RBF flag can be cleared by clearing the CLH flag.                                                                                                                                                                                                                         |
| WBF      | S1SCS.2 | <b>Write Bit Finished flag:</b> indicating a successful bit write. the same conditions as for RBF are true and also no "arbitration loss" condition occurred. Arbitration is lost if a 1 data bit in SDO was over-ruled on SDA by an external device. The WBF flag can be cleared by clearing the CLH flag.                                                                                                                                                                                                                                               |
| STR      | S1SCS.1 | <b>STRetch control flag.</b> STR = 1 enabled stretching of all SCL LOW periods. This allows the processor in I <sup>2</sup> C slave mode to react on a fast master. The STR flag remains set until cleared by writing a logic 0 to S1SCS.1.<br><br><b>The STretch (ST) flag</b> (not readable) pulls the serial clock LOW while ST = 1. The ST flag is set on the falling edge of the filtered serial clock if STR = 1. It is also set after reception of a START condition, regardless of the STR contents. ST is cleared with a read or write of S1BIT. |
| ENS      | S1SCS.0 | <b>ENable Serial I/O flag.</b> ENS = 1 enables the START detection and clock stretching logic. ENS = 0 can be used to switch off the I <sup>2</sup> C bus hardware. Note that the SDO and SCO control flags must be set to logic 1 before ENS is set to avoid pulling SCL or SDA lines to logic 0.                                                                                                                                                                                                                                                        |

8-bit microcontroller

P83C524

**INTERRUPT SYSTEM**

The P83C524 contains the same interrupt structure as the PCB80C51BH, but with a seven-source interrupt structure with two priority levels.

**IE: Interrupt Enable Register**

This register is located at address A8H. Refer to Table 4.

**IE SFR (A8H)**

# 8-bit microcontroller

# P83C524

## IDLE AND POWER-DOWN OPERATION

Idle mode operation permits the interrupt, serial ports and timer blocks to function while the CPU is halted. The following functions remain active during Idle mode. These functions may generate an interrupt or reset and thus end the Idle mode:

- Timer 0, Timer 1, Timer 2, Watchdog Timer
- UART, I<sup>2</sup>C-Interface
- External interrupt.

The Power-down operation stops the oscillator. The Power-down mode can only be activated by setting the PD bit in the PCON register.

### Idle Mode

The instruction that sets PCON.0 is the last instruction executed in the normal operating mode before Idle mode is activated. Once in the Idle mode, the CPU status is preserved in its entirety: the Stack Pointer, Program Counter, Program Status Word, Accumulator, RAM and all other registers maintain their data during Idle mode. The status of external pins during Idle mode is shown in Table 7.

### Power-down Mode

The instruction that sets PCON.1 is the last executed prior to going into the Power-down mode. The oscillator is topped. Note that the Power-down mode also can be entered when the watchdog has been enabled. The

Power-down mode can be terminated by an external RESET in the same way as in the 80C51 or in addition by any one of the two external interrupts, IE0 or IE1. A reset generated by the WDT terminates the Power-down mode in the same way as an external RESET.

The status of the external pins during Power-down mode is shown in Table 7. If the Power-down mode is activated while in external program memory, the port data that is held in the P2 SFR is restored to Port 2. If the data is a logic 1, the port pin is held HIGH during the Power-down mode by the strong pull-up transistor p1.

### Wake-up from Power-down Mode

The Power-down mode of the P83C524 can also be terminated by any one of the two external interrupts, IE0 or IE1. A termination with an external interrupt does not affect the internal data memory and does not affect the Special Function Registers (SFRs).

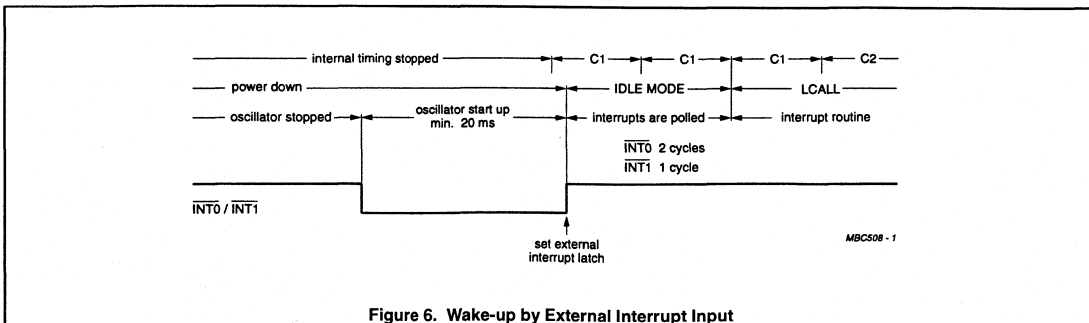

In order to prevent any interrupt priority problems during wake-up, the priority of the desired wake-up interrupt should be higher than the priorities of all other enabled interrupt sources. The instruction following the one that put the device into the Power-down mode will be the first one which will be executed after an interrupt has been serviced.

**Table 6. Internal Registers Status after a RESET**

| REGISTER       | CONTENTS      |

**NOTES TO DC CHARACTERISTICS (FBx):**

- The operating supply current is measured with all output pins disconnected; XTAL1 driven with  $t_R = t_F = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected;  $\overline{\text{EA}} = \text{RST} = \text{Port 0} + \text{P1.6} + \text{P1.7} = V_{DD}$ ; the WDT is disabled (by the external RESET).
- The Idle mode supply current is measured with all output pins disconnected; XTAL1 driven with  $t_R = t_F = 5\text{ns}$ ;  $V_{IL} = V_{SS} + 0.5\text{V}$ ;  $V_{IH} = V_{DD} - 0.5\text{V}$ ; XTAL2 not connected; the WDT is disabled;  $\overline{\text{EA}} = \text{RST} = V_{SS}$ ; Port 0 = P1.6 = P1.7 =  $V_{DD}$ .
- The Power-down current is measured with all output pins disconnected; XTAL2 not connected; WDT is disabled;  $\overline{\text{EA}} = \text{RST} = \text{XTAL1} = V_{SS}$ ; Port 0 = P1.6 = P1.7 =  $V_{DD}$ .
- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make a 1-to-0 transition during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE line may exceed 0.8V. In such cases it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE PSEN to momentarily fall below the 0.9V  $V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so a voltage below 0.3  $V_{DD}$  will be recognized as a logic 0 while an input above 0.7  $V_{DD}$  will be recognized as a logic 1.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:
  - Maximum  $I_{OL}$  per port pin: 10mA
  - Maximum  $I_{OL}$  per 8-bit port:
    - Port 0: 26mA
    - Ports 1, 2, and 3: 15mA
  - Maximum total  $I_{OL}$  for all output pins: 71mA
 If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- $I_{DDMAX}$  at other frequencies can be derived from Figure 7, where  $f$  is the external oscillator frequency in MHz;  $I_{DDMAX}$  is given in mA.

**NOTES:**

- At f<sub>CLK</sub> = 3.5MHz, this evaluates to 14 × 286ns = 4μs, i.e., the bit-level I<sup>2</sup>C interface can respond to the I<sup>2</sup>C protocol for f<sub>CLK</sub> ≥ 3.5MHz.
- This parameter is determined by the user software, it has to comply with the I<sup>2</sup>C specification.
- This value gives the auto-clock pulse length which meets the I<sup>2</sup>C specification for the specified XTAL1 clock frequency range. Alternatively, the SCL pulse may be timed by software.
- Spikes on SDA and SCL lines with a duration of less than 4 × f<sub>CLK</sub> will be filtered out.
- The RISE time is determined by the external bus line capacitance and pull-up resistor, it must be ≤ 1 μs.
- The maximum capacitance on bus lines SDA and SCL is 400 pF.

**XTAL1 CHARACTERISTICS**

Oscillator circuitry: crystal capacitors: C1 = C2 = 20pF (see Figure 13).

## DESCRIPTION

The 87C524 single-chip 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 87C524 has the same instruction set as the 80C51.

This device provides architectural enhancements that make it applicable in a variety of applications in consumer, telecom and general control systems, especially in those systems which need large ROM and RAM capacity on-chip.

The 87C524 contains a 16k × 8 EPROM, a 512 × 8 RAM, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a 16-bit timer (identical to the timer 2 of the 80C52), a watchdog timer with a separate oscillator, a multi-source, two-priority-level, nested interrupt structure, two serial interfaces (UART and I<sup>2</sup>C-bus), and on-chip oscillator and timing circuits.

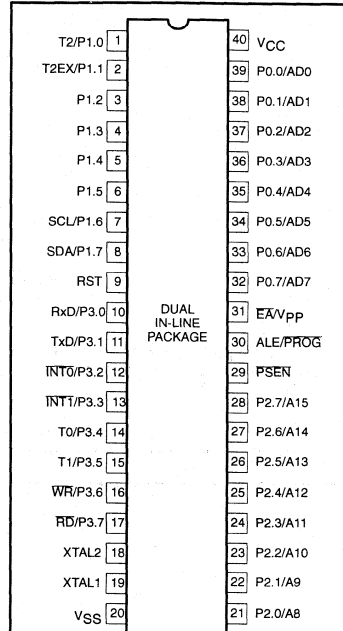

In addition, the 87C524 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

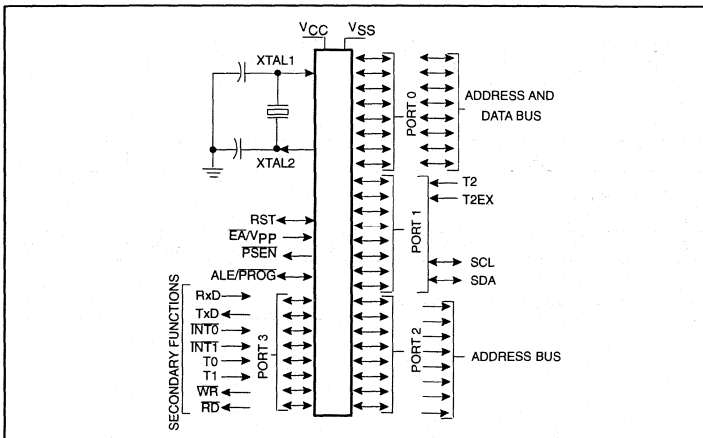

## FEATURES

- 80C51 instruction set
  - 16k × 8 EPROM
  - 512 × 8 RAM
  - Memory addressing capability 64k ROM and 64k RAM
  - Three 16-bit counter/timers
  - On-chip watchdog timer with oscillator
  - Full duplex UART
  - I<sup>2</sup>C serial interface
- Power control modes:
  - Idle mode
  - Power-down mode
  - Warm start from power-down
- CMOS and TTL compatible
- Two speed ranges at V<sub>CC</sub> = 5V ±10%
  - 3.5 to 16MHz
  - 3.5 to 20MHz
- Extended temperature ranges
- OTP package available
- EPROM code protection

| P0.0–0.7           | 39–32   | 43–36                                                       | 37–30         | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification in the P87C524. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                     |
| P1.0–P1.7          | 1–8     | 2–9                                                         | 40–44,<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which are open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 can sink/source one TTL (4LSTTL) inputs. Port 1 receives the low-order address byte during program memory verification. Port 1 also serves alternate functions for timer 2:                                                                                                                                                                     |

| P2.0–P2.7          | 21–28   | 24–31                                                       | 18–25         | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7          | 10–17   | 11,<br>13–19                                                | 5,<br>7–13    | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the SC80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                      |

Table 2. Internal and External Program Memory Access with Security Bit Set

| INSTRUCTION                     | ACCESS TO INTERNAL PROGRAM MEMORY | ACCESS TO EXTERNAL PROGRAM MEMORY |
|---------------------------------|-----------------------------------|-----------------------------------|
| MOVC in internal program memory | YES                               | YES                               |
| MOVC in external program memory | NO                                | YES                               |

**INTERNAL DATA MEMORY**

The internal data memory is divided into three physically separated segments: 256 bytes of RAM, 256 bytes of AUX-RAM, and a 128 bytes special function area. These can be addressed each in a different way.

- RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- RAM 128 to 255 can only be addressed indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- AUX-RAM 0 to 255 is indirectly addressed in the same way as external data memory with the MOVX instructions. Address pointers are R0, R1 of the selected register bank and DPTR. An access to AUX-RAM 0 to 255 will not affect ports P0, P2, P3.6 and P3.7.

An access to external data memory locations higher than 255 will be performed with the MOVX DPTR instructions in the same way as in the 8051 structure, so with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read timing signals. Note that these external data memory cannot be accessed with R0 and R1 as address pointer.

**TIMER 2**

Timer 2 is functionally equal to the Timer 2 of the 8052AH. Timer 2 is a 16-bit timer/counter. These 16 bits are formed by two special function registers TL2 and TH2. Another pair of special function register RCAP2L and RCAP2H form a 16-bit capture register or a 16-bit reload register. Like Timer 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T2N in the special function register T2CON. It has three operating modes: capture, autoloading, and baud rate generator mode which are selected by bits in T2CON.

**WATCHDOG TIMER T3**

The watchdog timer consists of an 11-bit prescaler and an 8-bit timer formed by special function register T3. The prescaler is incremented by an on-chip oscillator with a fixed frequency of 1MHz. The maximum tolerance on this frequency is -50% and +100%. The 8-bit timer increments every 2048 cycles of the on-chip oscillator. When a timer overflow occurs, the microcontroller is

reset and a reset output pulse of  $16 \times 2048$  cycles of the on-chip oscillator is generated at pin RST. The internal RESET signal is not inhibited when the external RST pin is kept low by, for example, an external reset circuit. The RESET signal drives port 1, 2, 3 into the high state and port 0 into the high impedance state.

The watchdog timer is controlled by one special function register WDCON with the direct address location A5H. WDCON can be read and written by software. A value of A5H in WDCON halts the on-chip oscillator and clears both the prescaler and timer T3. After the RESET signal, WDCON contains A5H. Every value other than A5H in WDCON enables the watchdog timer. When the watchdog timer is enabled, it runs independently of the XTAL-clock.

Timer T3 can be read on the fly. Timer T3 can only be written if WDCON contains the value 5AH. A successful write operation to T3 will clear the prescaler and WDCON, leaving the watchdog enabled and preventing inadvertent changes of T3. To prevent an overflow of the watchdog timer, the user program has to reload the watchdog timer within periods that are shorter than the programmed watchdog timer interval. This time interval is determined by an 8-bit value that has to be loaded in register T3 while at the same time the prescaler is cleared by hardware.

$$\text{Watchdog timer interval} = \frac{[256 - (T3)] \times 2048}{\text{on-chip oscillator frequency}}$$

**BIT-LEVEL I<sup>2</sup>C INTERFACE**

This bit-level serial I/O interface supports the I<sup>2</sup>C-bus. P1.6/SCL and P1.7/SDA are the serial I/O pins. These two pins meet the I<sup>2</sup>C specification concerning the input levels and output drive capability. Consequently, these pins have an open drain output configuration. All the four modes of the I<sup>2</sup>C-bus are supported:

- master transmitter
- master receiver
- slave transmitter
- slave receiver

The advantages of the bit-level I<sup>2</sup>C hardware compared with a full software I<sup>2</sup>C implementation are:

- the hardware can generate the SCL pulse

- Testing a single bit (RBF respectively, WBF) is sufficient as a check for error free transmission.

The bit-level I<sup>2</sup>C hardware operates on serial bit level and performs the following functions:

- filtering the incoming serial data and clock signals
- recognizing the START condition
- generating a serial interrupt request SI after reception of a START condition and the first falling edge of the serial clock
- recognizing the STOP condition
- recognizing a serial clock pulse on the SCL line
- latching a serial bit on the SDA line (SDI)
- stretching the SCL LOW period of the serial clock to suspend the transfer of the next serial data bit
- setting Read Bit Finished (RBF) when the SCL clock pulse has finished and Write Bit Finished (WBF) if there is no arbitration loss detected (i.e., SDA = 0 while SDO = 1)
- setting a serial clock Low-to-High detected (CLH) flag
- setting a Bus Busy (BB) flag on a START condition and clearing this flag on a STOP condition
- releasing the SCL line and clearing the CLH, RBF and WBF flags to resume transfer of the next serial data bit
- generating an automatic clock if the single bit data register S1BIT is used in master mode.

The following functions must be done in software:

- handling the I<sup>2</sup>C START interrupts
- converting serial to parallel data when receiving
- converting parallel to serial data when transmitting
- comparing the received slave address with its own
- interpreting the acknowledge information
- guarding the I<sup>2</sup>C status if RBF or WBF = 0.

Additionally, if acting as master:

- generating START and STOP conditions
- handling bus arbitration
- generating serial clock pulses if S1BIT is not used.

Three SFRs control the bit-level I<sup>2</sup>C interface: S1INT, S1BIT and S1SCS.

## CMOS single-chip 8-bit microcontroller

87C524

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the logic symbol, page 460.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. The power-down mode can be terminated by a RESET in the same way as in the 80C51 or in addition by one of two external interrupts, INT0 or INT1. A termination with an external interrupt does not affect the internal data memory and does not affect the special function registers. This makes it possible to exit power-down without changing the port output levels. To terminate the power-down mode with an external interrupt INT0 or INT1 must be switched to level-sensitive and must be enabled. The external interrupt input

signal INT0 and INT1 must be kept low until the oscillator has restarted and stabilized. An instruction following the instruction that puts the device in the power-down mode will be executed. A reset generated by the watchdog timer terminates the power-down mode in the same way as an external RESET, and only the contents of the on-chip RAM are preserved. The control bits for the reduced power modes are in the special function register PCON.

**DESIGN CONSIDERATIONS**

At power-on, the voltage on  $V_{CC}$  and RST must come up at the same time for a proper start-up.

When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when idle is terminated by reset, the instruction following the one that invokes idle should not be one that writes to a port pin or to external memory.

Table 3 shows the state of I/O ports during low current operating modes.

**Table 3. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

## NOTES:

- Capacitive loading on ports 0 and 2 may cause spurious noise to be superimposed on the  $V_{OL}$ s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port 0 and port 2 pins when these pins make 1-to-0 transitions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows: 10mA per port pin, port 0 total (all bits) 26mA, ports 1, 2, and total each (all bits) 15mA.
- Capacitive loading on ports 0 and 2 may cause the  $V_{OH}$  on ALE and PSEN to momentarily fall below the  $0.9V_{CC}$  specification when the address bits are stabilizing.
- Pins of ports 1, 2 and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- See Figures 10 through 13 for  $I_{CC}$  test conditions.
- The input threshold voltage of P1.6 and P1.7 (SI01) meets the  $I^2C$  specification, so an input voltage below 1.5V will be recognized as a logic 0 while an input voltage above 3.0V will be recognized as a logic 1.

| t <sub>FD</sub>                   | SDA fall time              | ≤ 0.3μs <sup>4</sup>                | ≤ 0.3μs <sup>6</sup>                | ≤ 0.3μs                        |

**NOTES:**

- At f<sub>CLK</sub> = 3.5MHz, this evaluates to 14 × 286ns = 4μs, i.e., the bit-level I<sup>2</sup>C interface can respond to the I<sup>2</sup>C protocol for f<sub>CLK</sub> ≥ 3.5MHz.
- This parameter is determined by the user software, it has to comply with the I<sup>2</sup>C specification.
- This value gives the autoclock pulse length which meets the I<sup>2</sup>C specification for the specified XTAL clock frequency range. Alternatively, the SCL pulse may be timed by software.
- Spikes on SDA and SCL lines with a duration of less than 4 × f<sub>CLK</sub> will be filtered out.
- The rise time is determined by the external bus line capacitance and pull-up resistor, it must be ≤ 1μs.
- The maximum capacitance on bus lines SDA and SCL is 400pF.

87C524

## EXPLANATION OF THE AC SYMBOLS

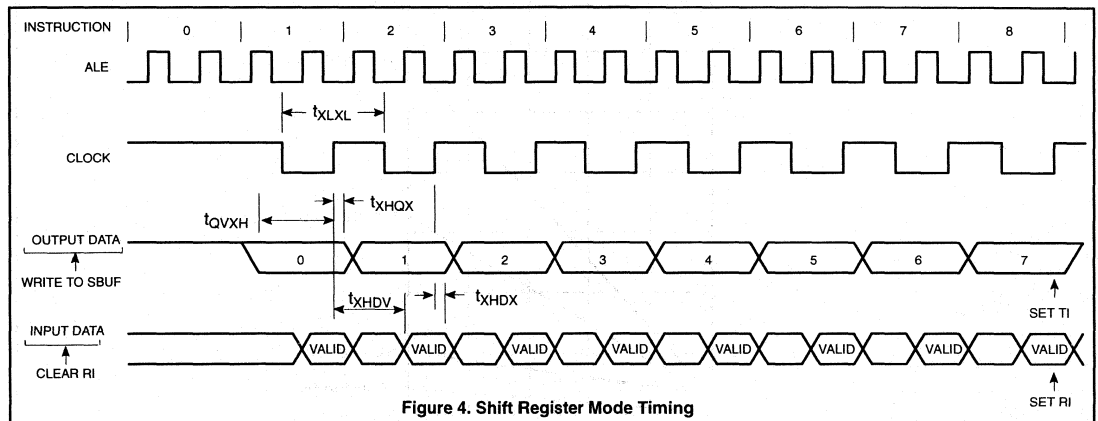

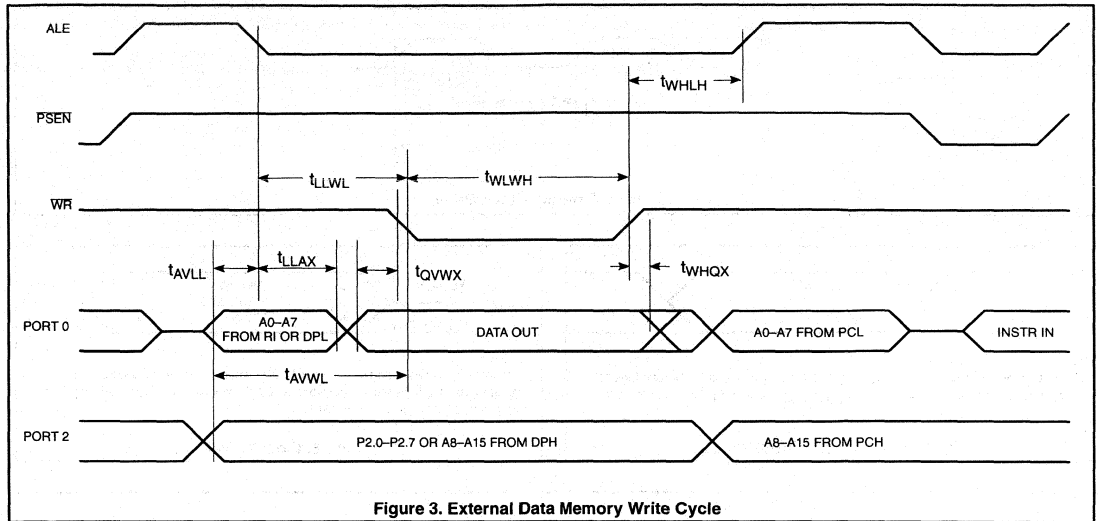

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:  
 A – Address  
 C – Clock  
 D – Input data  
 H – Logic level high  
 I – Instruction (program memory contents)  
 L – Logic level low, or ALE  
 P – PSEN

Q – Output data  
 R – RD signal  
 t – Time  
 V – Valid  
 W – WR signal  
 X – No longer a valid logic level  
 Z – Float  
**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

NOTE:

\* Ports 1.6 and 1.7 should be connected to  $V_{CC}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specification.

## CMOS single-chip 8-bit microcontroller

87C524

**EPROM CHARACTERISTICS**

The 87C524 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C524 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C524 manufactured by Philips.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are shown in Figures 14 and 15. Figure 16 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 14. Note that the 87C524 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1, 2 and 3, as shown in Figure 14. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The ALE/PROG is pulsed low 25 times as shown in Figure 15.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 3FH, using the 'Pgm

Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25 pulse programming sequence using the 'Pgm Lock Bit' levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

Note that the EA/ $V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1, 2 and 3 as shown in Figure 16. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull-ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to correctly decode the verification data. The encryption table itself cannot be read out.

**Program Lock Bits**

The 87C524 has 3 programmable lock bits that will provide different levels of protection for the on-chip code and data. (See Table 5.)

Erasing the EPROM also erases the encryption array and the program lock bits, returning the part to full functionality.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips  
(031H) = 9DH indicates 87C524

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

**Erasure Characteristics**

Erasure of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000uW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient.

Erasure leaves the array in an all 1s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | EA/V <sub>PP</sub> | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|--------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                  | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                  | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | V <sub>PP</sub>    | 1    | 1    | 0    | 0    |
| Pgm lock bit 3       | 1   | 0    | 0*       | V <sub>PP</sub>    | 0    | 1    | 0    | 1    |

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
  - V<sub>PP</sub> = 12.75V ±0.25V.
  - V<sub>CC</sub> = 5V±10% during programming and verification.
- \* ALE/PROG receives 25 programming pulses while V<sub>PP</sub> is held at 12.75V. Each programming pulse is low for 100µs (±10µs) and high for a minimum of 10µs.

**Table 5. Program Lock Bits**

| PROGRAM LOCK BITS <sup>1, 2</sup> |     |     |     | PROTECTION DESCRIPTION                                                                                                                                                                                    |
|-----------------------------------|-----|-----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | LB1 | LB2 | LB3 |                                                                                                                                                                                                           |
| 1                                 | U   | U   | U   | No Program Lock features enabled. (Code verify will still be encrypted by the Encryption Array if programmed.)                                                                                            |
| 2                                 | P   | U   | U   | MOVC instructions executed from external program memory are disabled from fetching code bytes from internal memory, EA is sampled and latched on Reset, and further programming of the EPROM is disabled. |
| 3                                 | P   | P   | U   | Same as 2, also verify is disabled.                                                                                                                                                                       |
| 4                                 | P   | P   | P   | Same as 3, external execution is disabled. Internal data RAM is not accessible.                                                                                                                           |

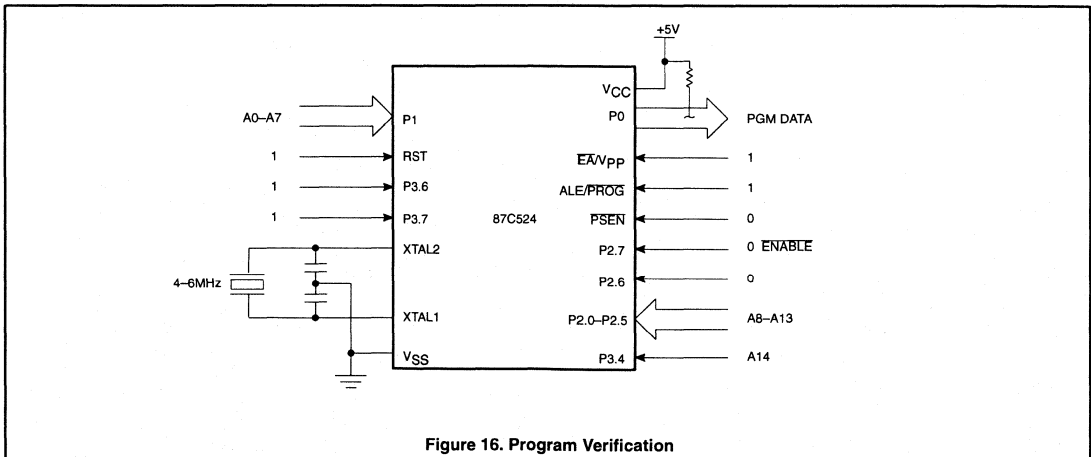

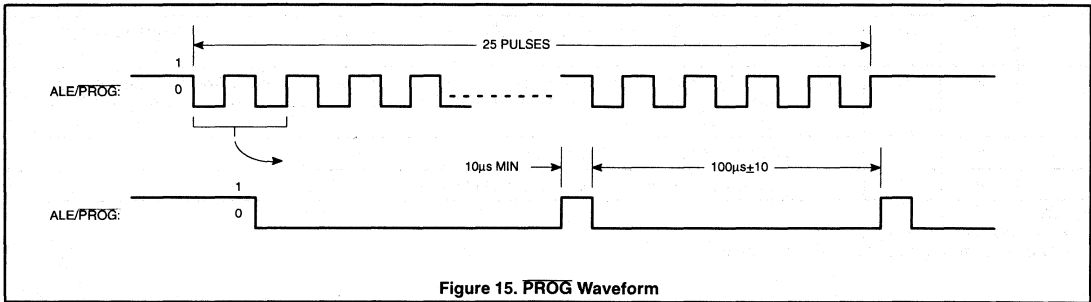

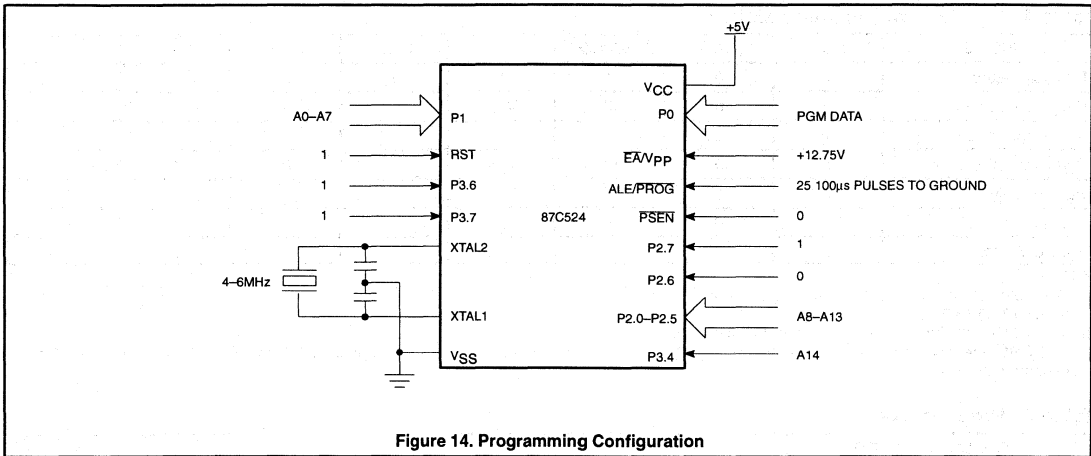

**NOTES:**

- P – programmed. U – unprogrammed.
- Any other combination of the lock bits is not defined.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller

# 80C528/83C528

## DESCRIPTION

The 8XC528 single-chip 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 8XC528 has the same instruction set as the 80C51. Three versions of the derivative exist:

- 83C528 — 32k bytes mask programmable ROM
- 80C528 — ROMless version of the 83C528
- 87C528 — 32k bytes EPROM (described in a separate data sheet)

This device provides architectural enhancements that make it applicable in a variety of applications in consumer, telecom and general control systems, especially in those systems which need large ROM and RAM capacity on-chip.

The 8XC528 contains a 32k × 8 ROM (83C528), a 512 × 8 RAM, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a 16-bit timer (identical to the timer 2 of the 80C52), a watchdog timer with a separate oscillator, a

multi-source, two-priority-level, nested interrupt structure, two serial interfaces (UART and I<sup>2</sup>C-bus), and on-chip oscillator and timing circuits.

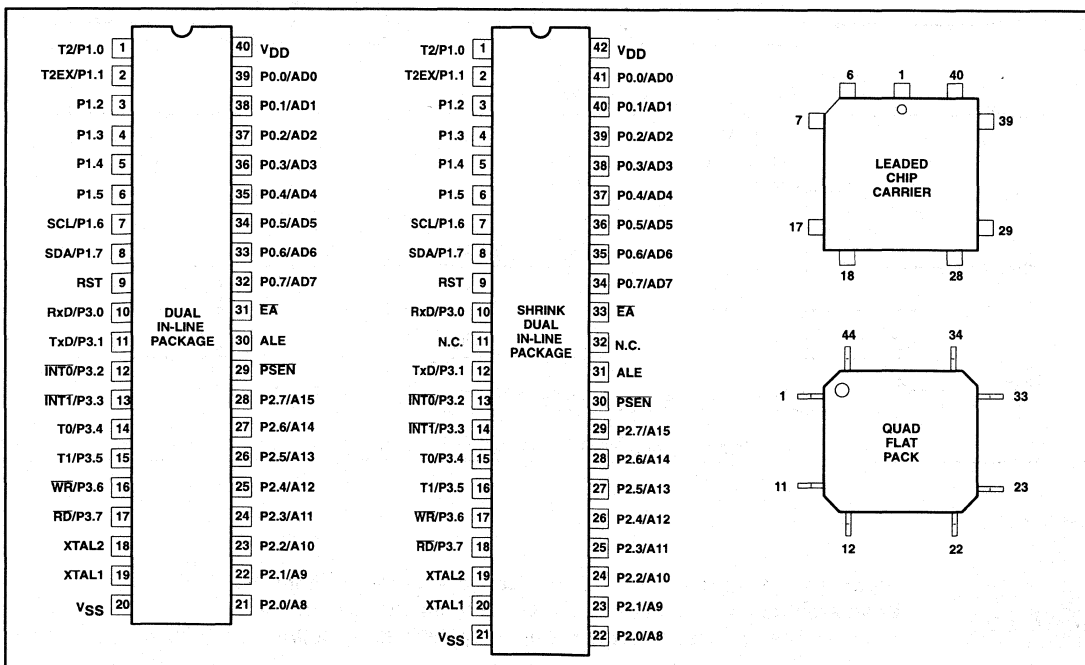

In addition, the 8XC528 has two software selectable modes of power reduction — idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

## FEATURES

- 80C51 instruction set
  - 32k × 8 ROM (83C528)
  - ROMless (80C528)
  - 512 × 8 RAM
  - Memory addressing capability 64k ROM and 64k RAM
  - Three 16-bit counter/timers
  - On-chip watchdog timer with oscillator
  - Full duplex UART
  - I<sup>2</sup>C serial interface
  - Four 8-bit I/O ports
- Power control modes:
  - Idle mode
  - Power-down mode
  - Warm start from power-down
- CMOS and TTL compatible
- Extended temperature ranges
- ROM code protection
- 7-source and 7-vector interrupt structure with 2 priority levels
- Up to 3 external interrupt request inputs
- Two programmable power reduction modes (Idle and Power-down)
- Termination of Idle mode by any interrupt, external or WDT (watchdog) reset
- XTAL frequency range: 1.2 MHz to 16 MHz

| P0.0–P0.7       | 39–32   | 41–34            | 43–36        | 37–30        | I/O  | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s.                                                                                                                                                                                                                                                                                                                                                                                                                |
| P1.0–P1.7       | 1–8     | 1–8              | 2–9          | 40–44<br>1–3 | I/O  | <b>Port 1:</b> Port 1 is an 8-bit bidirectional I/O port with internal pull-ups, except P1.6 and P1.7 which have open drain. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 1 pins that are externally pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 1 can sink/source one TTL (4 LSTTL) inputs.                                                                                                                                                                                                                                                                                                      |

| P2.0–P2.7       | 21–28   | 22–29            | 24–31        | 18–25        | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7       | 10–17   | 10–18<br>(11=NC) | 11,<br>13–19 | 5,<br>7–13   | I/O  | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the SC80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                      |

## CMOS single-chip 8-bit microcontroller

## 80C528/83C528

**Table 2. Internal and External Program Memory Access with Security Bit Set**

| INSTRUCTION                     | ACCESS TO INTERNAL PROGRAM MEMORY | ACCESS TO EXTERNAL PROGRAM MEMORY |
|---------------------------------|-----------------------------------|-----------------------------------|
| MOVC in internal program memory | YES                               | YES                               |
| MOVC in external program memory | NO                                | YES                               |

**ROM CODE PROTECTION**

By setting a mask programmable security bit, the ROM content in the 83C528 is protected, i.e., it cannot be read out by any test mode or by any instruction in the external program memory space. The MOVC instructions are the only ones which have access to program code in the internal or external program memory. The EA input is latched during RESET and is 'don't care' after RESET (also if security bit is not set). This implementation prevents reading from internal program code by switching from external program memory to internal program memory during MOVC instruction or an instruction that handles immediate data. Table 2 lists the access to the internal and external program memory by the MOVC instructions when the security bit has been set to logical one. If the security bit has been set to a logical 0 there are no restrictions for the MOVC instructions.

**INTERNAL DATA MEMORY**

The internal data memory is divided into three physically separated segments: 256 bytes of RAM, 256 bytes of AUX-RAM, and a 128 bytes special function area. These can be addressed each in a different way.

- RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- RAM 128 to 255 can only be addressed indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- AUX-RAM 0 to 255 is indirectly addressed in the same way as external data memory with the MOVX instructions. Address pointers are R0, R1 of the selected register bank and DPTR. An access to AUX-RAM 0 to 255 will not affect ports P0, P2, P3.6 and P3.7.

An access to external data memory locations higher than 255 will be performed with the MOVX DPTR instructions in the same way as in the 8051 structure, so with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read timing signals. Note that these external data memory cannot be accessed with R0 and R1 as address pointer.

**TIMER 2**

Timer 2 is functionally equal to the Timer 2 of the 8052AH. Timer 2 is a 16-bit timer/counter. These 16 bits are formed by two special function registers TL2 and TH2. Another pair of special function register RCAP2L and RCAP2H form a 16-bit capture register or a 16-bit reload register. Like Timer 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T2N in the special function register T2CON. It has three operating modes: capture, autoloader, and baud rate generator mode which are selected by bits in T2CON.

**WATCHDOG TIMER T3**

The watchdog timer consists of an 11-bit prescaler and an 8-bit timer formed by special function register T3. The prescaler is incremented by an on-chip oscillator with a fixed frequency of 1MHz. The maximum tolerance on this frequency is -50% and +100%. The 8-bit timer increments every 2048 cycles of the on-chip oscillator. When a timer overflow occurs, the microcontroller is reset and a reset output pulse of  $16 \times 2048$  cycles of the on-chip oscillator is generated at pin RST. The internal RESET signal is not inhibited when the external RST pin is kept low by, for example, an external reset circuit. The RESET signal drives port 1, 2, 3 into the high state and port 0 into the high impedance state.

The watchdog timer is controlled by one special function register WDCON with the direct address location A5H. WDCON can be read and written by software. A value of A5H in WDCON halts the on-chip oscillator and clears both the prescaler and timer T3. After the RESET signal, WDCON contains A5H. Every value other than A5H in WDCON enables the watchdog timer. When the watchdog timer is enabled, it runs independently of the XTAL-clock.

Timer T3 can be read on the fly. Timer T3 can only be written if WDCON contains the value 5AH. A successful write operation to T3 will clear the prescaler and WDCON, leaving the watchdog enabled and preventing inadvertent changes of T3. To prevent an overflow of the watchdog timer, the user

program has to reload the watchdog timer within periods that are shorter than the programmed watchdog timer interval. This time interval is determined by an 8-bit value that has to be loaded in register T3 while at the same time the prescaler is cleared by hardware.

Watchdog timer interval =

$$\frac{[256 - (T3)] \times 2048}{\text{on-chip oscillator frequency}}$$

**BIT-LEVEL I<sup>2</sup>C INTERFACE**

This bit-level serial I/O interface supports the I<sup>2</sup>C-bus. P1.6/SCL and P1.7/SDA are the serial I/O pins. These two pins meet the I<sup>2</sup>C specification concerning the input levels and output drive capability. Consequently, these pins have an open drain output configuration. All the four modes of the I<sup>2</sup>C-bus are supported:

- master transmitter
- master receiver
- slave transmitter
- slave receiver

The advantages of the bit-level I<sup>2</sup>C hardware compared with a full software I<sup>2</sup>C implementation are:

- the hardware can generate the SCL pulse
- Testing a single bit (RBF respectively, WBF) is sufficient as a check for error free transmission.

The bit-level I<sup>2</sup>C hardware operates on serial bit level and performs the following functions:

- filtering the incoming serial data and clock signals
- recognizing the START condition
- generating a serial interrupt request SI after reception of a START condition and the first falling edge of the serial clock
- recognizing the STOP condition
- recognizing a serial clock pulse on the SCL line
- latching a serial bit on the SDA line (SDI)
- stretching the SCL LOW period of the serial clock to suspend the transfer of the next serial data bit
- setting Read Bit Finished (RBF) when the SCL clock pulse has finished and Write Bit

## CMOS single-chip 8-bit microcontroller

## 80C528/83C528

- Finished (WBF) if there is no arbitration loss detected (i.e., SDA = 0 while SDO = 1)
- setting a serial clock Low-to-High detected (CLH) flag
- setting a Bus Busy (BB) flag on a START condition and clearing this flag on a STOP condition
- releasing the SCL line and clearing the CLH, RBF and WBF flags to resume transfer of the next serial data bit
- generating an automatic clock if the single bit data register S1BIT is used in master mode.

The following functions must be done in software:

- handling the I<sup>2</sup>C START interrupts
- converting serial to parallel data when receiving
- converting parallel to serial data when transmitting
- comparing the received slave address with its own
- interpreting the acknowledge information
- guarding the I<sup>2</sup>C status if RBF or WBF = 0.

Additionally, if acting as master:

- generating START and STOP conditions
- handling bus arbitration
- generating serial clock pulses if S1BIT is not used.

Three SFRs control the bit-level I<sup>2</sup>C interface: S1INT, S1BIT and S1SCS.

## OSCILLATOR CHARACTERISTICS

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2

is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

## RESET

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

## IDLE MODE

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

## POWER-DOWN MODE

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. The power-down mode can be terminated by

a RESET in the same way as in the 80C51 or in addition by one of two external interrupts, INT0 or INT1. A termination with an external interrupt does not affect the internal data memory and does not affect the special function registers. This makes it possible to exit power-down without changing the port output levels. To terminate the power-down mode with an external interrupt INT0 or INT1 must be switched to level-sensitive and must be enabled. The external interrupt input signal INT0 and INT1 must be kept low until the oscillator has restarted and stabilized. An instruction following the instruction that puts the device in the power-down mode will be executed. A reset generated by the watchdog timer terminates the power-down mode in the same way as an external RESET, and only the contents of the on-chip RAM are preserved. The control bits for the reduced power modes are in the special function register PCON.

## DESIGN CONSIDERATIONS

At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when idle is terminated by reset, the instruction following the one that invokes idle should not be one that writes to a port pin or to external memory.

Table 3 shows the state of I/O ports during low current operating modes.

**Table 3. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

## NOTES:

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

## DC ELECTRICAL CHARACTERISTICS

T<sub>amb</sub> = 0°C to +70°C (V<sub>DD</sub> = 5V ±20%), -40°C to +85°C (V<sub>DD</sub> = 5V ±20%), or -40°C to +125°C (V<sub>DD</sub> = 5V ±10%), V<sub>SS</sub>=0V

**NOTES:**

- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make a 1-to-0 transition during bus operations. In the worst cases (capacitive loading  $> 100\text{pF}$ ), the noise pulse on the ALE line may exceed  $0.8\text{V}$ . In such cases it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
- Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and PSEN to momentarily fall below the  $0.9V_{DD}$  specification when the address bits are stabilizing.
- The input threshold voltage of P1.6 and P1.7 (SI01) meets the I<sup>2</sup>C specification, so a voltage below  $0.3V_{DD}$  will be recognized as a logic 0 while an input above  $0.7V_{DD}$  will be recognized as a logic 1.
- Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 10mA  
Maximum  $I_{OL}$  per 8-bit port: –  
Port 0: 26mA  
Ports 1, 2, & 3: 15mA  
Maximum total  $I_{OL}$  for all output pins: 71mA  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
- Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when  $V_{IN}$  is approximately 2V.
- See Figures 9 through 12 for  $I_{DD}$  test conditions.
- $I_{DDMAX}$  at other frequencies can be derived from the figure below, where FREQ is the external oscillator frequency in MHz.  
 $I_{DDMAX}$  is given in mA.

VALID ONLY WITHIN FREQUENCY SPECIFICATIONS OF DEVICE UNDER TEST.

 **$I_{DD}$  vs. FREQUENCY**

| $t_{XHDV}$            | 4      | Clock rising edge to input data valid    |             | 492 |                  | $10t_{CLCL}-133$ | ns   |

## NOTES:

- Parameters are valid over operating temperature range unless otherwise specified.
- Load capacitance for port 0, ALE, and PSEN = 100pF, load capacitance for all other outputs = 80pF.

| t <sub>FD</sub>                   | SDA fall time              | ≤ 0.3μs <sup>4</sup>                | ≤ 0.3μs <sup>6</sup>                | ≤ 0.3μs                        |

## NOTES:

1. At f<sub>CLK</sub> = 3.5MHz, this evaluates to 14 × 286ns = 4μs, i.e., the bit-level I<sup>2</sup>C interface can respond to the I<sup>2</sup>C protocol for f<sub>CLK</sub> ≥ 3.5MHz.
2. This parameter is determined by the user software, it has to comply with the I<sup>2</sup>C.
3. This value gives the autclock pulse length which meets the I<sup>2</sup>C specification for the specified XTAL clock frequency range. Alternatively, the SCL pulse may be timed by software.
4. Spikes on SDA and SCL lines with a duration of less than 4 × f<sub>CLK</sub> will be filtered out.
5. The rise time is determined by the external bus line capacitance and pull-up resistor, it must be ≤ 1μs.
6. The maximum capacitance on bus lines SDA and SCL is 400pF.

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

**NOTE:**

\* Ports 1.6 and 1.6 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specifications.

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

# CMOS single-chip 8-bit microcontroller

# 87C528

## DESCRIPTION

The 87C528 single-chip 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the 80C51 microcontroller family. The 87C528 has the same instruction set as the 80C51. Three versions of the derivative exist:

- 83C528—32k bytes mask programmable ROM
- 80C528—ROMless version of the 83C528
- 87C528—32k bytes EPROM

This device provides architectural enhancements that make it applicable in a variety of applications in consumer, telecom and general control systems, especially in those systems which need large ROM and RAM capacity on-chip.

The 87C528 contains a 32k × 8 EPROM, a 512 × 8 RAM, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a 16-bit timer (identical to the timer 2 of the 80C52), a watchdog timer with a separate oscillator, a multi-source, two-priority-level, nested interrupt structure, two serial interfaces (UART and I<sup>2</sup>C-bus), and on-chip oscillator and timing circuits.

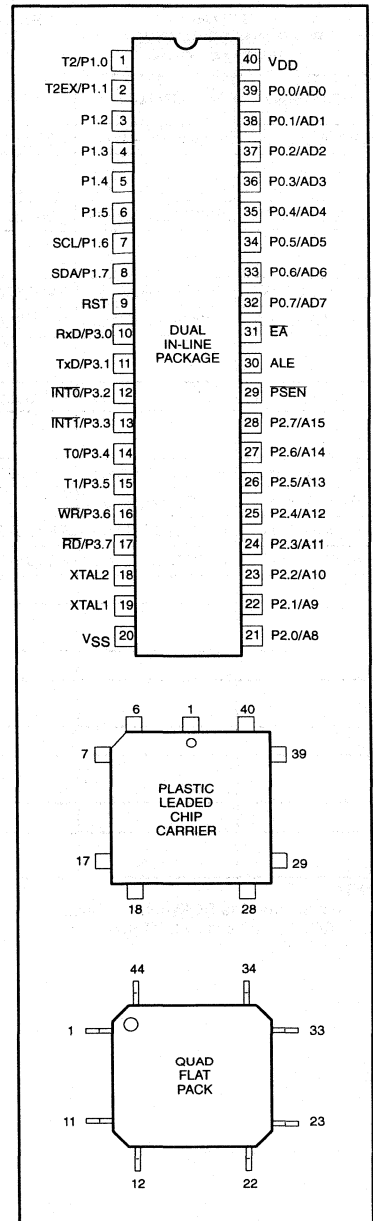

In addition, the 87C528 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

## FEATURES

- 80C51 instruction set
  - 32k × 8 EPROM
  - 512 × 8 RAM
  - Memory addressing capability 64k ROM and 64k RAM
  - Three 16-bit counter/timers
  - On-chip watchdog timer with oscillator
  - Full duplex UART
  - I<sup>2</sup>C serial interface
- Power control modes:
  - Idle mode
  - Power-down mode
  - Warm start from power-down
- CMOS and TTL compatible
- Extended temperature ranges
- EPROM code protection
- OTP package available
- Two speed ranges at V<sub>CC</sub> = 5V
  - 16MHz
  - 20MHz

| P2.0–P2.7       | 21–28   | 24–31 | 18–25        | I/O  | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |       |              |            |                                                                                    |

**Table 2. Internal and External Program Memory Access with Security Bit Set**

| INSTRUCTION                     | ACCESS TO INTERNAL PROGRAM MEMORY | ACCESS TO EXTERNAL PROGRAM MEMORY |
|---------------------------------|-----------------------------------|-----------------------------------|
| MOVC in internal program memory | YES                               | YES                               |
| MOVC in external program memory | NO                                | YES                               |

## INTERNAL DATA MEMORY

The internal data memory is divided into three physically separated segments: 256 bytes of RAM, 256 bytes of AUX-RAM, and a 128 bytes special function area. These can be addressed each in a different way.

- RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- RAM 128 to 255 can only be addressed indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- AUX-RAM 0 to 255 is indirectly addressed in the same way as external data memory with the MOVX instructions. Address pointers are R0, R1 of the selected register bank and DPTR. An access to AUX-RAM 0 to 255 will not affect ports P0, P2, P3.6 and P3.7.

An access to external data memory locations higher than 255 will be performed with the MOVX DPTR instructions in the same way as in the 8051 structure, so with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read timing signals. Note that these external data memory cannot be accessed with R0 and R1 as address pointer.

## TIMER 2

Timer 2 is functionally equal to the Timer 2 of the 8052AH. Timer 2 is a 16-bit timer/counter. These 16 bits are formed by two special function registers TL2 and TH2. Another pair of special function register RCAP2L and RCAP2H form a 16-bit capture register or a 16-bit reload register. Like Timer 0 and 1, it can operate either as a timer or as an event counter. This is selected by bit C/T2N in the special function register T2CON. It has three operating modes: capture, autoloading, and baud rate generator mode which are selected by bits in T2CON.

## WATCHDOG TIMER T3

The watchdog timer consists of an 11-bit prescaler and an 8-bit timer formed by special function register T3. The prescaler is incremented by an on-chip oscillator with a fixed frequency of 1MHz. The maximum tolerance on this frequency is -50% and +100%. The 8-bit timer increments every 2048 cycles of the on-chip oscillator. When a timer overflow occurs, the microcontroller is

reset and a reset output pulse of 16 x 2048 cycles of the on-chip oscillator is generated at pin RST. The internal RESET signal is not inhibited when the external RST pin is kept low by, for example, an external reset circuit. The RESET signal drives port 1, 2, 3 into the high state and port 0 into the high impedance state.

The watchdog timer is controlled by one special function register WDCON with the direct address location A5H. WDCON can be read and written by software. A value of A5H in WDCON halts the on-chip oscillator and clears both the prescaler and timer T3. After the RESET signal, WDCON contains A5H. Every value other than A5H in WDCON enables the watchdog timer. When the watchdog timer is enabled, it runs independently of the XTAL-clock.

Timer T3 can be read on the fly. Timer T3 can only be written if WDCON contains the value 5AH. A successful write operation to T3 will clear the prescaler and WDCON, leaving the watchdog enabled and preventing inadvertent changes of T3. To prevent an overflow of the watchdog timer, the user program has to reload the watchdog timer within periods that are shorter than the programmed watchdog timer interval. This time interval is determined by an 8-bit value that has to be loaded in register T3 while at the same time the prescaler is cleared by hardware.

Watchdog timer interval = 
$$\frac{[256 - (T3)] \times 2048}{\text{on-chip oscillator frequency}}$$

## BIT-LEVEL I<sup>2</sup>C INTERFACE

This bit-level serial I/O interface supports the I<sup>2</sup>C-bus. P1.6/SCL and P1.7/SDA are the serial I/O pins. These two pins meet the I<sup>2</sup>C specification concerning the input levels and output drive capability. Consequently, these pins have an open drain output configuration. All the four modes of the I<sup>2</sup>C-bus are supported:

- master transmitter
- master receiver
- slave transmitter
- slave receiver

The advantages of the bit-level I<sup>2</sup>C hardware compared with a full software I<sup>2</sup>C implementation are:

- the hardware can generate the SCL pulse

- Testing a single bit (RBF respectively, WBF) is sufficient as a check for error free transmission.

The bit-level I<sup>2</sup>C hardware operates on serial bit level and performs the following functions:

- filtering the incoming serial data and clock signals
- recognizing the START condition
- generating a serial interrupt request SI after reception of a START condition and the first falling edge of the serial clock
- recognizing the STOP condition
- recognizing a serial clock pulse on the SCL line
- latching a serial bit on the SDA line (SDI)
- stretching the SCL LOW period of the serial clock to suspend the transfer of the next serial data bit
- setting Read Bit Finished (RBF) when the SCL clock pulse has finished and Write Bit Finished (WBF) if there is no arbitration loss detected (i.e., SDA = 0 while SDO = 1)
- setting a serial clock Low-to-High detected (CLH) flag
- setting a Bus Busy (BB) flag on a START condition and clearing this flag on a STOP condition
- releasing the SCL line and clearing the CLH, RBF and WBF flags to resume transfer of the next serial data bit
- generating an automatic clock if the single bit data register S1BIT is used in master mode.

The following functions must be done in software:

- handling the I<sup>2</sup>C START interrupts
- converting serial to parallel data when receiving
- converting parallel to serial data when transmitting
- comparing the received slave address with its own
- interpreting the acknowledge information
- guarding the I<sup>2</sup>C status if RBF or WBF = 0.

Additionally, if acting as master:

- generating START and STOP conditions
- handling bus arbitration
- generating serial clock pulses if S1BIT is not used.

Three SFRs control the bit-level I<sup>2</sup>C interface: S1INT, S1BIT and S1SCS.

## CMOS single-chip 8-bit microcontroller

87C528

**OSCILLATOR CHARACTERISTICS**

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier. The pins can be configured for use as an on-chip oscillator, as shown in the Logic Symbol.

To drive the device from an external clock source, XTAL1 should be driven while XTAL2 is left unconnected. There are no requirements on the duty cycle of the external clock signal, because the input to the internal clock circuitry is through a divide-by-two flip-flop. However, minimum and maximum high and low times specified in the data sheet must be observed.

**RESET**

A reset is accomplished by holding the RST pin high for at least two machine cycles (24 oscillator periods), while the oscillator is running. To insure a good power-up reset, the RST pin must be high long enough to allow the oscillator time to start up (normally a few milliseconds) plus two machine cycles. At power-up, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

**IDLE MODE**

In idle mode, the CPU puts itself to sleep while all of the on-chip peripherals stay

active. The instruction to invoke the idle mode is the last instruction executed in the normal operating mode before the idle mode is activated. The CPU contents, the on-chip RAM, and all of the special function registers remain intact during this mode. The idle mode can be terminated either by any enabled interrupt (at which time the process is picked up at the interrupt service routine and continued), or by a hardware reset which starts the processor in the same manner as a power-on reset.

**POWER-DOWN MODE**

In the power-down mode, the oscillator is stopped and the instruction to invoke power-down is the last instruction executed. The power-down mode can be terminated by a RESET in the same way as in the 80C51 or in addition by one of two external interrupts, INT0 or INT1. A termination with an external interrupt does not affect the internal data memory and does not affect the special function registers. This makes it possible to exit power-down without changing the port output levels. To terminate the power-down mode with an external interrupt INT0 or INT1 must be switched to level-sensitive and must be enabled. The external interrupt input signal INT0 and INT1 must be kept low until

the oscillator has restarted and stabilized. An instruction following the instruction that puts the device in the power-down mode will be executed. A reset generated by the watchdog timer terminates the power-down mode in the same way as an external RESET, and only the contents of the on-chip RAM are preserved. The control bits for the reduced power modes are in the special function register PCON.

**DESIGN CONSIDERATIONS**

At power-on, the voltage on V<sub>DD</sub> and RST must come up at the same time for a proper start-up.

When the idle mode is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write when idle is terminated by reset, the instruction following the one that invokes idle should not be one that writes to a port pin or to external memory.

Table 3 shows the state of I/O ports during low current operating modes.

**Table 3. External Pin Status During Idle and Power-Down Modes**

| MODE       | PROGRAM MEMORY | ALE | PSEN | PORT 0 | PORT 1 | PORT 2  | PORT 3 |
|------------|----------------|-----|------|--------|--------|---------|--------|
| Idle       | Internal       | 1   | 1    | Data   | Data   | Data    | Data   |
| Idle       | External       | 1   | 1    | Float  | Data   | Address | Data   |
| Power-down | Internal       | 0   | 0    | Data   | Data   | Data    | Data   |
| Power-down | External       | 0   | 0    | Float  | Data   | Data    | Data   |

**NOTES:**

- Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any conditions other than those described in the AC and DC Electrical Characteristics section of this specification is not implied.
- This product includes circuitry specifically designed for the protection of its internal devices from the damaging effects of excessive static charge. Nonetheless, it is suggested that conventional precautions be taken to avoid applying greater than the rated maxima.
- Parameters are valid over operating temperature range unless otherwise specified. All voltages are with respect to V<sub>SS</sub> unless otherwise noted.

## NOTES:

- Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the V<sub>OL</sub>s of ALE and ports 1 and 3. The noise is due to external bus capacitance discharging into the port and port 2 pins when these pins make 1-to-0 transactions during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE pin may exceed 0.8V. In such cases, it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input. Under steady state (non-transient) conditions, I<sub>OL</sub> must be externally limited as follows: 10mA per port pin, port 0 total (all bits) 26mA, ports 1, 2, and total each (all bits) 15mA.
- Capacitive loading on Ports 0 and 2 may cause the V<sub>OH</sub> on ALE and PSEN to momentarily fall below the 0.9V<sub>CC</sub> specification when the address bits are stabilizing.
- Pins of ports 1, 2, and 3 source a transition current when they are being externally driven from 1 to 0. The transition current reaches its maximum value when V<sub>IN</sub> is approximately 2V.
- See Figures 10 through 13 for I<sub>CC</sub> test conditions.
- The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C specification, so an input voltage below 1.5V will be recognized as a logic 0 while an input voltage above 3.0V will be recognized as a logic 1.

| t <sub>RD</sub>                   | SDA rise time              | ≤ 1μs <sup>4</sup>                  | Note 5                              | ≤ 1.0μs                        |
| t <sub>FD</sub>                   | SDA fall time              | ≤ 0.3μs <sup>4</sup>                | ≤ 0.3μs <sup>6</sup>                | ≤ 0.3μs                        |

**NOTES:**

- At f<sub>CLK</sub> = 3.5MHz, this evaluates to 14 × 286ns = 4μs, i.e., the bit-level I<sup>2</sup>C interface can respond to the I<sup>2</sup>C protocol for f<sub>CLK</sub> ≥ 3.5MHz.
- This parameter is determined by the user software, it has to comply with the I<sup>2</sup>C.
- This value gives the autoclock pulse length which meets the I<sup>2</sup>C specification for the specified XTAL clock frequency range. Alternatively, the SCL pulse may be timed by software.
- Spikes on SDA and SCL lines with a duration of less than 4 × f<sub>CLK</sub> will be filtered out.
- The rise time is determined by the external bus line capacitance and pull-up resistor, it must be ≤ 1μs.
- The maximum capacitance on bus lines SDA and SCL is 400pF.

# CMOS single-chip 8-bit microcontroller

87C528

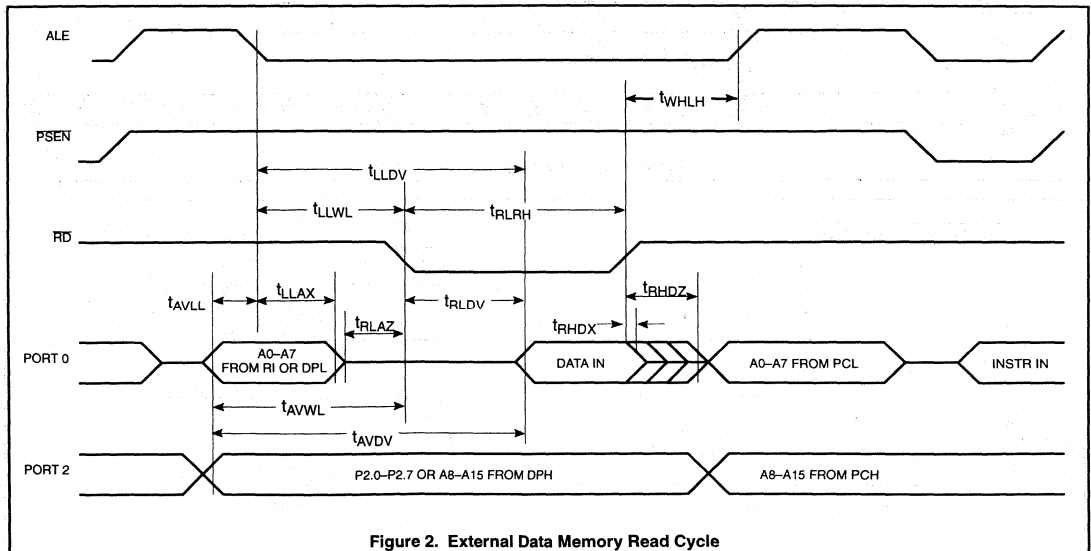

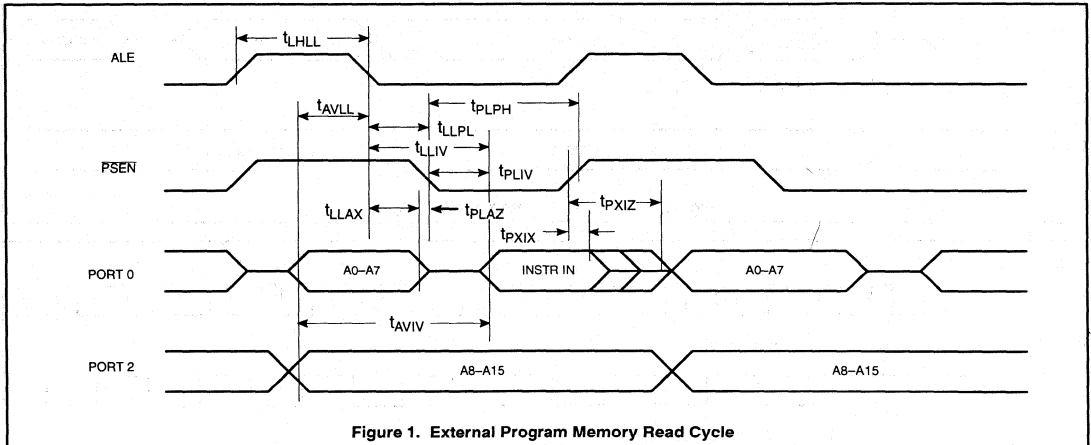

## EXPLANATION OF THE AC SYMBOLS

Each timing symbol has five characters. The first character is always 't' (= time). The other characters, depending on their positions, indicate the name of a signal or the logical status of that signal. The designations are:

- A - Address
- C - Clock
- D - Input data
- H - Logic level high
- I - Instruction (program memory contents)
- L - Logic level low, or ALE
- P - PSEN

- Q - Output data
- R - RD signal
- t - Time
- V - Valid
- W - WR signal
- X - No longer a valid logic level
- Z - Float

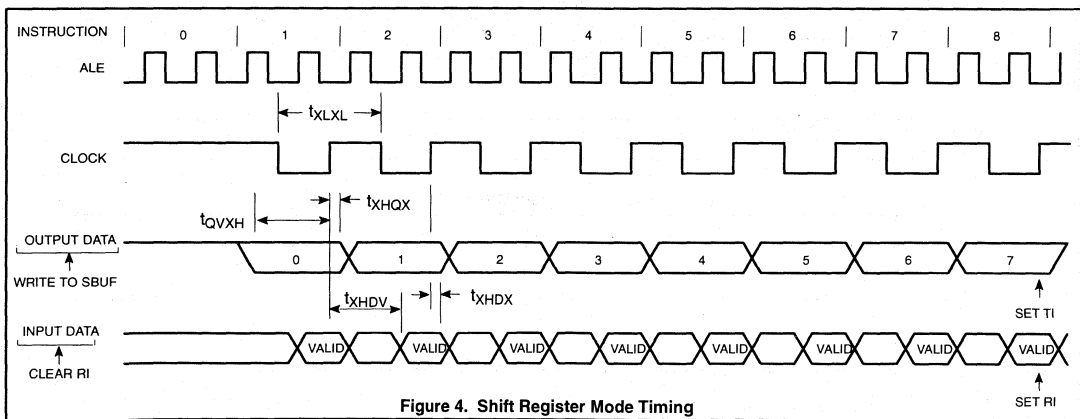

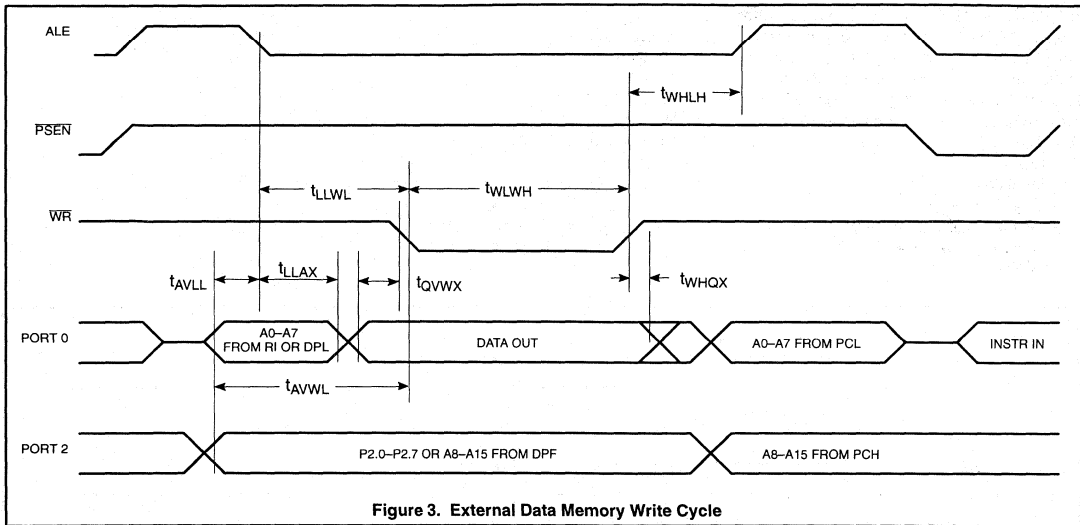

**Examples:**  $t_{AVLL}$  = Time for address valid to ALE low.  
 $t_{LLPL}$  = Time for ALE low to PSEN low.

All other pins are disconnected.  $V_{DD} = 2V$  to  $5.5V$

NOTE:

\*Ports 1.6 and 1.7 should be connected to  $V_{DD}$  through resistors of sufficiently high value such that the sink current into these pins does not exceed the  $I_{OL1}$  specifications.

**EPROM CHARACTERISTICS**

The 87C528 is programmed by using a modified Quick-Pulse Programming™ algorithm. It differs from older methods in the value used for  $V_{PP}$  (programming supply voltage) and in the width and number of the ALE/PROG pulses.

The 87C528 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. The signature bytes identify the device as an 87C528 manufactured by Philips.

Table 4 shows the logic levels for reading the signature byte, and for programming the program memory, the encryption table, and the lock bits. The circuit configuration and waveforms for quick-pulse programming are

shown in Figures 14 and 15. Figure 16 shows the circuit configuration for normal program memory verification.

**Quick-Pulse Programming**

The setup for microcontroller quick-pulse programming is shown in Figure 14. Note that the 87C528 is running with a 4 to 6MHz oscillator. The reason the oscillator needs to be running is that the device is executing internal address and program data transfers.

The address of the EPROM location to be programmed is applied to ports 1, 2 and 3, as shown in Figure 14. The code byte to be programmed into that location is applied to port 0. RST, PSEN and pins of ports 2 and 3 specified in Table 4 are held at the 'Program Code Data' levels indicated in Table 4. The

ALE/PROG is pulsed low 25 times as shown in Figure 15.

To program the encryption table, repeat the 25 pulse programming sequence for addresses 0 through 3FH, using the 'Pgm Encryption Table' levels. Do not forget that after the encryption table is programmed, verification cycles will produce only encrypted data.

To program the lock bits, repeat the 25 pulse programming sequence using the 'Pgm Lock Bit' levels. After one lock bit is programmed, further programming of the code memory and encryption table is disabled. However, the other lock bit can still be programmed.

## CMOS single-chip 8-bit microcontroller

87C528

Note that the  $\overline{EA}/V_{PP}$  pin must not be allowed to go above the maximum specified  $V_{PP}$  level for any amount of time. Even a narrow glitch above that voltage can cause permanent damage to the device. The  $V_{PP}$  source should be well regulated and free of glitches and overshoot.

**Program Verification**

If lock bit 2 has not been programmed, the on-chip program memory can be read out for program verification. The address of the program memory locations to be read is applied to ports 1, 2 and 3 as shown in Figure 16. The other pins are held at the 'Verify Code Data' levels indicated in Table 4. The contents of the address location will be emitted on port 0. External pull ups are required on port 0 for this operation.

If the encryption table has been programmed, the data presented at port 0 will be the exclusive NOR of the program byte with one of the encryption bytes. The user will have to know the encryption table contents in order to

correctly decode the verification data. The encryption table itself cannot be read out.

**Reading the Signature Bytes**

The signature bytes are read by the same procedure as a normal verification of locations 030H and 031 H, except that P3.6 and P3.7 need to be pulled to a logic low. The values are:

(030H) = 15H indicates manufactured by Philips

(031 H) = 9BH indicates 87C528

**Program Lock Bits**

The 87C528 has 3 programmable lock bits that will provide different levels of protection for the on-chip code and data (see Table 5).

Erasing the EPROM also erases the encryption array and the program lock bits, returning the part to full functionality.

**Program/Verify Algorithms**

Any algorithm in agreement with the conditions listed in Table 4, and which satisfies the timing specifications, is suitable.

**Erase Characteristics**

Erase of the EPROM begins to occur when the chip is exposed to light with wavelengths shorter than approximately 4,000 angstroms. Since sunlight and fluorescent lighting have wavelengths in this range, exposure to these light sources over an extended time (about 1 week in sunlight, or 3 years in room level fluorescent lighting) could cause inadvertent erasure. **For this and secondary effects, it is recommended that an opaque label be placed over the window.** For elevated temperature or environments where solvents are being used, apply Kapton tape Fluorglas part number 2345-5, or equivalent.

The recommended erasure procedure is exposure to ultraviolet light (at 2537 angstroms) to an integrated dose of at least 15W-sec/cm<sup>2</sup>. Exposing the EPROM to an ultraviolet lamp of 12,000μW/cm<sup>2</sup> rating for 20 to 39 minutes, at a distance of about 1 inch, should be sufficient. Erasure leaves the array in an all 1 s state.

**Table 4. EPROM Programming Modes**

| MODE                 | RST | PSEN | ALE/PROG | $\overline{EA}/V_{PP}$ | P2.7 | P2.6 | P3.7 | P3.6 |
|----------------------|-----|------|----------|------------------------|------|------|------|------|
| Read signature       | 1   | 0    | 1        | 1                      | 0    | 0    | 0    | 0    |
| Program code data    | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 1    |
| Verify code data     | 1   | 0    | 1        | 1                      | 0    | 0    | 1    | 1    |
| Pgm encryption table | 1   | 0    | 0*       | $V_{PP}$               | 1    | 0    | 1    | 0    |
| Pgm lock bit 1       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 1    | 1    |
| Pgm lock bit 2       | 1   | 0    | 0*       | $V_{PP}$               | 1    | 1    | 0    | 0    |
| Pgm lock bit 3       | 1   | 0    | 0*       | $V_{PP}$               | 0    | 1    | 0    | 1    |

**NOTES:**

- '0' = Valid low for that pin, '1' = valid high for that pin.
- $V_{PP} = 12.75V \pm 0.25V$ .
- $V_{CC} = 5V \pm 10\%$  during programming and verification.
- ALE/PROG receives 25 programming pulses while  $V_{PP}$  is held at 12.75V. Each programming pulse is low for 100μs ( $\pm 10\mu s$ ) and high for a minimum of 10μs.

**Table 5. Program Lock Bits**

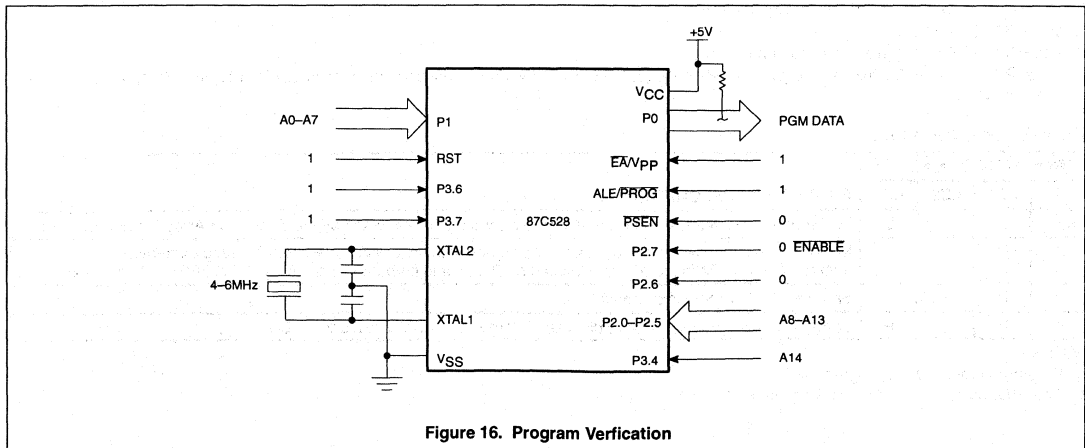

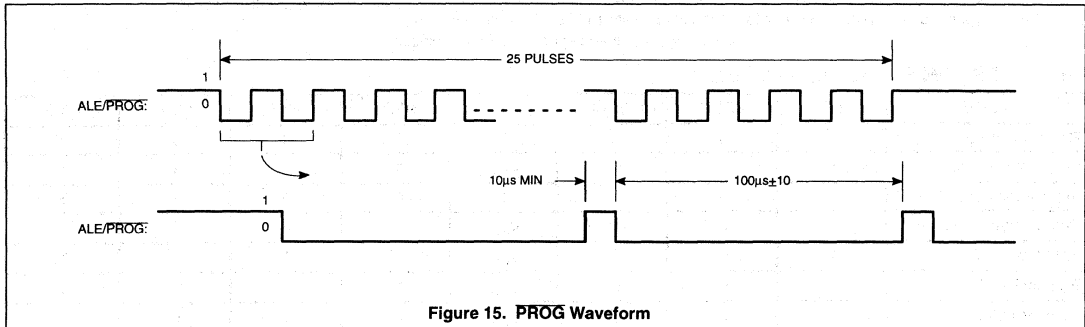

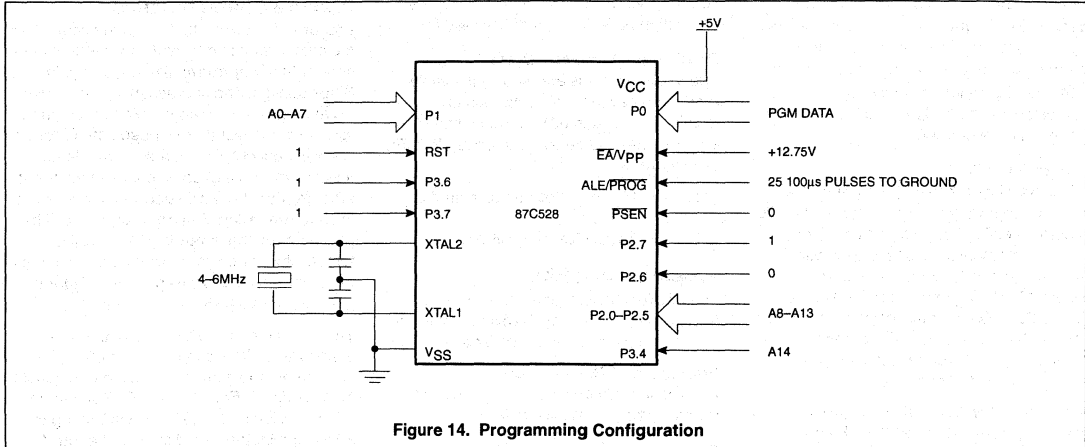

| PROGRAM LOCK BITS <sup>1,2</sup> |     |     |     | PROTECTION DESCRIPTION                                                                                                                                                                                               |

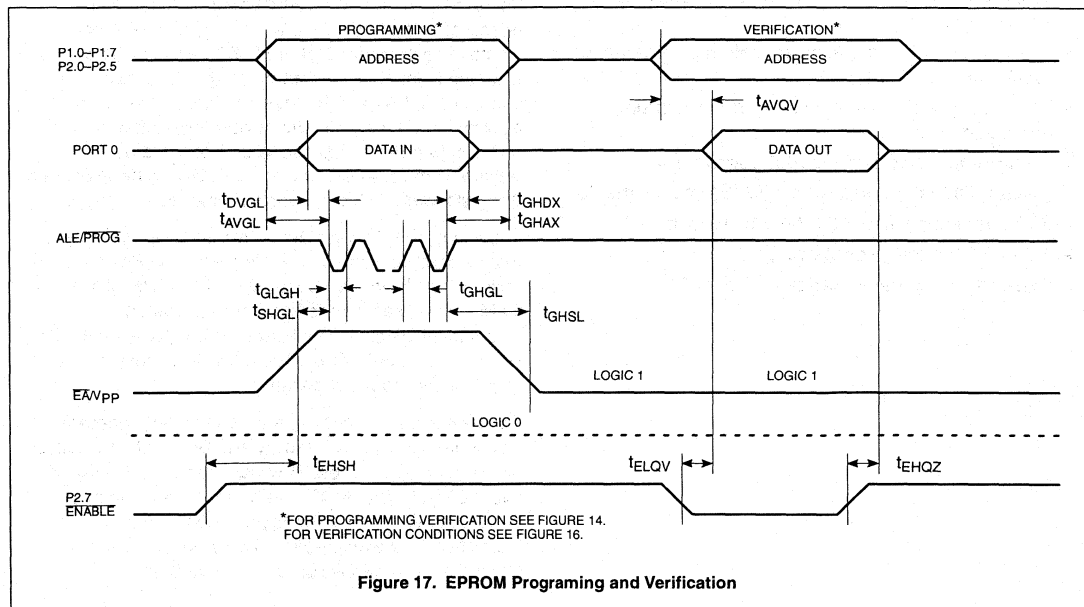

Figure 17. EPROM Programing and Verification

Purchase of Philips' I<sup>2</sup>C components conveys a license under the Philips' I<sup>2</sup>C patent to use the components in the I<sup>2</sup>C-system provided the system conforms to the I<sup>2</sup>C specifications defined by Philips.

**8-bit microcontroller with EMC and FEEPROM****P8xCE528****1 FEATURES**

- 80C51 central processing unit
- 32K x 8 ROM resp. FEEPROM, expandable externally to 64 kbytes
- ROM/FEEPROM code protection
- 512 x 8 RAM, expandable externally to 64 kbytes
- Four 8-bit I/O ports
- Full-duplex UART compatible with the standard 80C51 and the 8052
- Two standard 16-bit timer/counters
- An additional 16-bit timer (functionally equivalent to the timer 2 of the 8052)
- On-chip Watchdog Timer (WDT) with an on-chip oscillator
- Bit-level I<sup>2</sup>C-bus hardware serial I/O Port
- 7-source and 7-vector interrupt structure with 2 priority levels
- Up to 3 external interrupt request inputs
- Two programmable power reduction modes (Idle and Power-down)
- Termination of Idle mode by any interrupt, external or WDT (watchdog) reset
- Wake-up from Power-down by external interrupt, external or WDT reset
- Software enable/disable of ALE output pulse
- Electro-Magnetic Compatibility (EMC) improvements
- XTAL frequency range: 3.5 MHz to 16 MHz
- 4.5 to 5.5 V supply voltage range
- Extended Temperature range (-40 to +85 °C)

**2 GENERAL DESCRIPTION**

The P83CE528; P80CE528; P89CE528 (hereafter generically referred to as P8xCE528) single-chip 8-bit microcontroller is manufactured in an advanced CMOS process and is a derivative of the PCB80C51 microcontroller family.

The P8xCE528 has the same instruction set as the 80C51. Three versions of the derivative exist:

- P83CE528: 32 kbytes mask programmable ROM
- P80CE528: ROMless version of the P83CE528
- P89CE528: 32 kbytes FEEPROM (Flash Electrically Erasable Program Memory).

This device provides architectural enhancements that make it applicable in a variety of applications in general control systems, especially in those systems which need a large ROM and RAM capacity on chip.

The P8xCE528 contains a non-volatile 32K x 8 read-only program memory (P83CE528) or FEEPROM (P89CE528), a volatile 512 x 8 read/write data memory, four 8-bit I/O ports, two 16-bit timer/event counters (identical to the timers of the 80C51), a 16-bit timer (identical to the timer 2 of the 8052), a multi-source, two-priority-level, nested interrupt structure, two serial interfaces (UART and bit-level I<sup>2</sup>C-bus), an on-chip oscillator and timing circuits, a watchdog timer (WDT) with a separate on-chip oscillator. For systems that require extra capability, the P8xCE528 can be expanded using standard TTL compatible memories and logic.

In addition, the P8xCE528 has two software selectable modes of power reduction - Idle mode and Power-down mode. The Idle mode freezes the CPU while allowing the RAM, timers, serial ports and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

The device also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities. The instruction set consists of over 100 instructions: 49 one-byte, 45 two-byte and 17 three-byte. With a 16 MHz crystal, 58% of the instructions are executed in 0.75  $\mu$ s and 40% in 1.5  $\mu$ s. Multiply and divide instructions require 3  $\mu$ s.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

**3 ELECTROMAGNETIC COMPATIBILITY (EMC)**

Primary attention is paid to the reduction of electro-magnetic emission of the microcontroller P8xCE528. The following features reduce the electro-magnetic emission and additionally improve the electromagnetic susceptibility:

- Two supply voltage pins ( $V_{DD1,2}$ ) and four ground pins ( $V_{SS1,2,3,4}$ ) are provided on the package as follows:
  - one  $V_{DD}$  and one  $V_{SS}$  as a pair of pins placed mid-centre on one side of the package
  - a second pair of  $V_{DD}$  and  $V_{SS}$  pins placed mid-centre on the opposite side of the package
  - two more  $V_{SS}$  pins, one placed on each of the other two sides of the package.
- Separated  $V_{DD}$  pins for the internal logic and the port buffers.
- Internal decoupling capacitance improves the EMC radiation behaviour and the EMC immunity.
- External capacitors are to be located as close as possible between pins  $V_{DD1}$  and  $V_{SS1}$  as well as  $V_{DD2}$  and  $V_{SS2}$ ; ceramic chip capacitors are recommended (100 nF).

**3.1 Recommendation on ALE**

For applications that require no external memory or temporarily no external memory: the ALE output signal (pulses at a frequency of  $f_{osc}/6$ ) can be disabled under software control (bit 5 in the PCON SFR: "RFI"); if disabled, no ALE pulse will occur. ALE pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle ALE as a normal MOVX. ALE will retain its normal HIGH value during Idle mode and a LOW value during Power-down mode while in the "RFI" reduction mode.

Additionally during internal access ( $\overline{EA} = 1$ ) ALE will toggle normally when the address exceeds the internal program memory size. During external access ( $\overline{EA} = 0$ ) ALE will always toggle normally, whether the flag "RFI" is set or not.

| SYMBOL                                                     | PIN      | DESCRIPTION                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| P2.0 to P2.7                                               | 18 to 25 | <b>Port 2:</b> 8-bit quasi-bidirectional I/O Port with internal pull-ups. During access to external memories (RAM/ROM) that use 16-bit addresses (MOVX @DPTR) Port 2 emits the high-order address byte (A8 to A15). Port 2 can sink/source one TTL ( $\approx 4$ LSTTL) input. It can drive CMOS inputs without external pull-ups.                                                                                                                                                                                                                                  |
| $\overline{\text{PSEN}}$                                   | 26       | <b>Program Store Enable output:</b> read strobe to the external program memory via Port 0 and Port 2. It is activated twice each machine cycle during fetches from external program memory. When executing out of external program memory two activations of $\overline{\text{PSEN}}$ are skipped during each access to external data memory. $\overline{\text{PSEN}}$ is not activated (remains HIGH) during no fetches from external program memory. $\overline{\text{PSEN}}$ can sink/source 8 LSTTL inputs. It can drive CMOS inputs without external pull-ups. |
| $\text{ALE}/\overline{\text{WE}}$                          | 27       | <b>Address Latch Enable output:</b> latches the LOW byte of the address during access to external memory in normal operation. It is activated every six oscillator periods except during an external data memory access. $\text{ALE}/\overline{\text{WE}}$ can sink/source 8 LSTTL inputs. It can drive CMOS inputs without an external pull-up (note 1).                                                                                                                                                                                                           |
| $\overline{\text{EA}}$                                     | 29       | <b>External Access input:</b> when during RESET, $\overline{\text{EA}}$ is held at a TTL HIGH level, the CPU executes out of the internal program ROM, provided the program counter is less than 32768. When $\overline{\text{EA}}$ is held at a TTL LOW level during RESET, the CPU executes out of external program memory via Port 0 and Port 2. $\overline{\text{EA}}$ is not allowed to float. $\overline{\text{EA}}$ is latched during RESET and don't care after RESET.                                                                                      |
| P0.0 to P0.7                                               | 30 to 37 | <b>Port 0:</b> 8-bit open drain bidirectional I/O Port. It is also the multiplexed low-order address and data bus during accesses to external memory (AD0 to AD7). During these accesses internal pull-ups are activated. Port 0 can sink/source 8 LSTTL inputs.                                                                                                                                                                                                                                                                                                    |
| $V_{\text{DD}1,2}$<br>$V_{\text{DD}1}$<br>$V_{\text{DD}2}$ | 17<br>38 | <b>Power supply:</b> +5 V power supply pin during normal operation and power reduction modes. Both pins must be connected.<br>Power supply pin for ports, ALE, $\overline{\text{PSEN}}$ and on-chip oscillator.<br>Power supply pin for internal logic.<br><br>To avoid a latch-up effect at power-on, the voltage on any pin (at any time) must not be higher than $V_{\text{DD}} + 0.5$ V or lower than $V_{\text{SS}} - 0.5$ V respectively.                                                                                                                     |

**Note**

1. To prohibit the toggling of  $\text{ALE}/\overline{\text{WE}}$  pin (RFI noise reduction) the bit RFI in the PCON register (PCON.5) must be set by software. This bit is cleared on RESET and can be cleared by software. When set,  $\text{ALE}/\overline{\text{WE}}$  pin will be pulled down internally, switching an external address latch to a quiet state. The MOVX instruction will still toggle  $\text{ALE}/\overline{\text{WE}}$  as a normal MOVX.  $\text{ALE}/\overline{\text{WE}}$  will retain its normal HIGH value during Idle mode and a LOW value during Power-down mode while in the "RFI" mode. Additionally during internal access ( $\overline{\text{EA}} = 1$ )  $\text{ALE}/\overline{\text{WE}}$  will toggle normally when the address exceeds the internal program memory size. During external access ( $\overline{\text{EA}} = 0$ )  $\text{ALE}/\overline{\text{WE}}$  will always toggle normally, whether the flag "RFI" is set or not.

---

## 8-bit microcontroller with EMC and FEEPROM

## P8xCE528

---

### 6 FUNCTIONAL DESCRIPTION

#### 6.1 General

The P8xCE528 is a stand-alone high-performance microcontroller designed for use in real time applications such as instrumentation, industrial control, medium to high-end consumer applications and specific automotive control applications.

In addition to the 80C51 standard functions, the device provides a number of dedicated hardware functions for these applications. The P8xCE528 is a control-oriented CPU with on-chip program and data memory. It can be extended with external program memory up to 64 kbytes. It can also access up to 64 kbytes of external data memory. For systems requiring extra capability, the P8xCE528 can be expanded using standard memories and peripherals.

The P8xCE528 has two software selectable modes of reduced activity for further power reduction: Idle and Power-down. The Idle mode freezes the CPU while allowing the RAM, timers, serial ports and interrupt system to continue functioning. The Power-down mode saves the RAM contents but freezes the oscillator causing all other chip functions to be inoperative except the WDT if it is enabled. The Power-down mode can be terminated by an external reset, a WDT overflow, and in addition, by either of the two external interrupts.

#### 6.2 Memory Organization

The central processing unit (CPU) manipulates operands in three memory spaces; these are the 64 kbyte external data memory (of which the lower 256 bytes reside in the internal AUX-RAM), 512 byte internal data memory (consisting of 256 bytes standard RAM and 256 bytes AUX-RAM) and the 64 kbyte internal and external program memory.

#### 6.2.1 PROGRAM MEMORY

The program memory of the P8xCE528 consists of 32 kbyte of ROM respectively FEEPROM ("Flash Memory") on-chip, externally expandable up to 64 kbyte. If the  $\bar{E}A$  pin was HIGH during RESET, the P8xCE528 executes out of the internal program memory unless the address exceeds 7FFFH. Locations 8000H through 0FFFFH are then fetched from the external program memory. If the  $\bar{E}A$  pin was LOW during RESET, the P8xCE528 fetches all instructions from the external program memory. The  $\bar{E}A$  input level is latched during RESET and is don't care after RESET. Figure 5 illustrates the program memory address space.

By setting a mask programmable security bit (ROM) respectively software programmable security byte (FEEPROM) the internal memory content is protected i.e. it cannot be read out by any test mode or by any instruction in the external program memory space. The MOVC instructions are the only ones which have access to program code in the internal or external program memory. The  $\bar{E}A$  input is latched during RESET and is don't care after RESET. This implementation prevents reading from internal program code by switching from external program memory to internal program memory during MOVC instruction or an instruction that handles immediate data. Table 1 lists the access to the internal and external program memory by the MOVC instructions when the security feature has been activated. If the security feature is not activated, there are no restrictions for the MOVC instructions.

8-bit microcontroller with EMC and FEEPROM

P8xCE528

**Table 1** Internal and external program memory access with activated security feature.

| INSTRUCTION                     | ACCESS TO INTERNAL PROGRAM MEMORY | ACCESS TO EXTERNAL PROGRAM MEMORY |
|---------------------------------|-----------------------------------|-----------------------------------|
| MOVC in internal program memory | YES                               | YES                               |
| MOVC in external program memory | NO                                | YES                               |

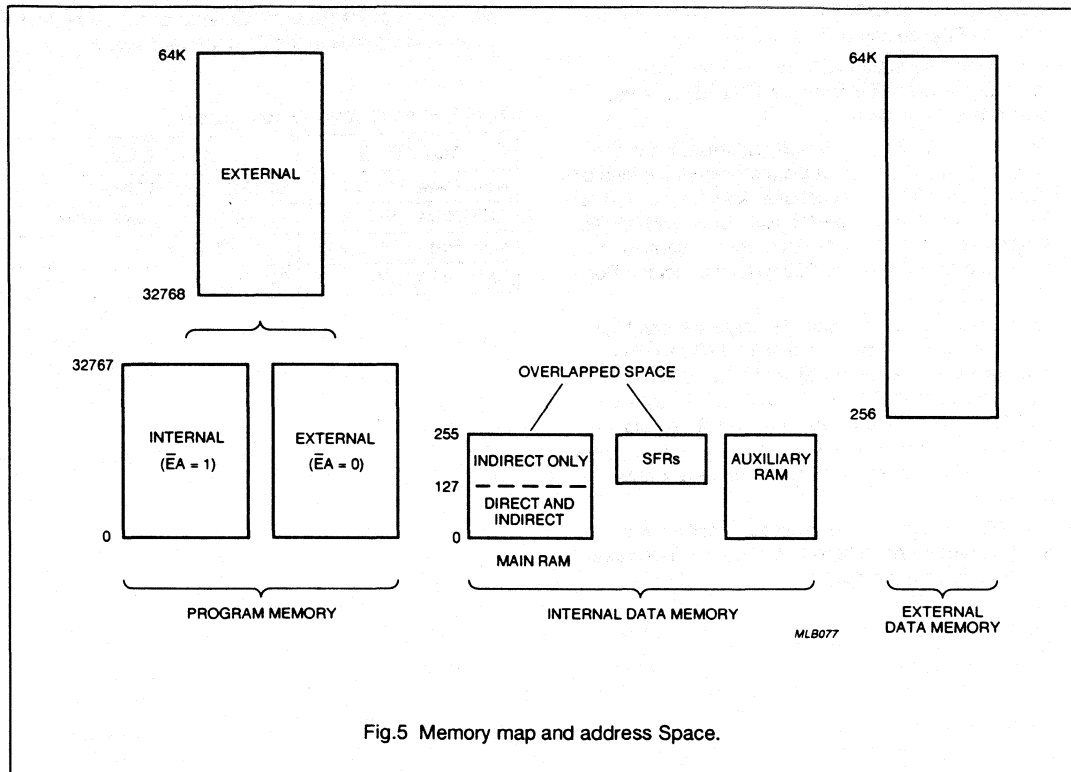

Fig.5 Memory map and address Space.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

## 6.2.2 INTERNAL DATA MEMORY

The internal data memory is divided into three physically separated parts: 256 byte of Main RAM, 256 byte of AUX-RAM, and a 128 byte special function area (SFR) see Table 2. These parts can be addressed as follows:

- Main RAM 0 to 127 can be addressed directly and indirectly as in the 80C51. Address pointers are R0 and R1 of the selected register bank.
- Main RAM 128 to 255 can only be addressed indirectly. Address pointers are R0 and R1 of the selected register bank.
- AUX-RAM 0 to 255 is indirectly addressable in the same way as the external Data Memory locations 0 to 255 with the MOVX instructions. Address pointers are R0 and R1 of the selected register bank and DPTR. When executing from internal program memory, an access to AUX-RAM 0 to 255 will not affect the Ports P0, P2, P3.6 and P3.7.
- An access to external Data Memory locations higher than 255 will be performed with the MOVX DPTR instructions in the same way as in the 80C51 structure, i.e. with P0 and P2 as data/address bus and P3.6 and P3.7 as write and read strobe signals. Note that it is impossible to access the external Data Memory with R0, R1 or DPTR < 256 as address pointer.
- The SFRs can only be addressed directly in the address range from 128 to 255 (Figure 6 illustrates the SFRs memory map).

Four 8-bit register banks occupy locations 0 through 31 in the lower RAM area. Only one of these banks may be enabled at a time. The next 16 bytes, locations 32 through 47, contain 128 directly addressable bit locations. The stack can be located anywhere in the internal 256 byte RAM. The stack depth is only limited by the available internal RAM space of 256 bytes. All registers except the Program Counter and the four 8-bit register banks reside in the SFR address space.

**Table 2** Internal data memory access.

| LOCATION            | ADDRESSED               |
|---------------------|-------------------------|
| Main RAM 0 to 127   | DIRECT and INDIRECT     |
| AUX-RAM 0 to 255    | INDIRECT only with MOVX |
| Main RAM 128 to 255 | INDIRECT only           |
| SFR 128 to 255      | DIRECT only             |

## 7 FLASH EEEPROM

### 7.1 General

The FEEPROM (Flash Memory) can be read and written byte-wise. Full erase, block erase, and page erase will erase 32 kbyte, 256 bytes and 32 bytes respectively. In-circuit programming and out-of-circuit programming is possible. On-chip erase and write timing generation and on-chip high voltage generation provide the following user friendly interface:

- 32 kbyte electrically erasable program memory with block and page-erase option
- Internal fixed Boot ROM
- Up to 32 kbyte external program memory in combination with the internal FEEPROM ( $\overline{EA} = 1$ )
- Up to 64 kbyte external program memory if the internal program memory is switched off ( $\overline{EA} = 0$ ).

### 7.2 FEEPROM Features

- Read: byte-wise
- Write: byte-wise within 2.5 ms (previously erased by a page, block or full erase)
- Erase:
  - Page Erase (32 bytes) within 5 ms
  - Block Erase (256 bytes) within 5 ms
  - Full Erase (32 kbyte) within 5 ms
  - Erased bytes contain FFH
- Endurance: 100 erase and write cycles each byte at  $T_{amb} = 22\text{ }^{\circ}\text{C}$
- Retention: 10 years
- Out-of-circuit programming: parallel programming with 87C51 compatible hardware interface to programmer
- In-circuit programming:
  - Serial programming via RS232 interface under boot ROM program control
  - Auto baud rate selection
  - Intel Hex Object File Format
- The user program can call all routines in the boot ROM for erase, write and verify of the FEEPROM

- HIGH programming voltage generation on chip
- Zero point on-chip oscillator and timer to generate the write and erase time durations
- Programmable security for the code in the FEEPROM to prevent software piracy. The security byte is located in the highest address (7FFFH) of the FEEPROM
- Supply voltage monitoring circuit on-chip to prevent loss of information in the FEEPROM during power-on and power-off.

### 7.3 Memory Map

Figure 8 illustrates the memory map of the user program memory and the boot ROM. They are located in the same program memory address space. Two bits UBS1 and UBS0 of the FEEPROM control special function register FMCON select between the two memory blocks.

#### 7.3.1 USER PROGRAM MEMORY SELECTION

If UBS1 and UBS0 are both logic 0, then the user program memory is mapped into the 64K program memory space and the boot ROM cannot be selected. This is the situation after a reset when  $\overline{PSEN}$  and ALE have not been pulled down during reset. Program execution starts at 0000H in the internal FEEPROM or in the external program memory dependent on the level of  $\overline{EA}$  during reset.

#### 7.3.2 BOOT ROM SELECTION

If UBS1 and UBS0 are both logic 1 (boot mode) the boot ROM is mapped into the 64K program memory space and the user program memory cannot be selected. This is the situation after a reset when during reset  $\overline{PSEN}$  and  $\overline{EA}$  are pulled down while ALE stays HIGH. Program execution starts at 0000H of the boot ROM. The boot ROM size is 1 kbyte. Besides the serial in-circuit programming routines the boot ROM contains the routines for erase, write and verify of the FEEPROM which can be called by the user program (LCALL to the address space between 63K and 64K).

### 7.3.3 SWITCHING BETWEEN USER PROGRAM MEMORY AND BOOT ROM

Switching between user program memory (internal or external) and boot ROM is possible if UBS1 and UBS0 are 0 1 or 1 0. Then in the program memory address space between 0 and 63K the user program memory is selected and in the memory space between 63K and 64K the boot ROM is selected.

To switch from user program memory to boot ROM first UBS0 must be set (UBS1 stays 0) and a jump or call instruction to a location > 63K must be executed. At the moment of crossing the 63K address border by a call or jump instruction the switching between user and boot memory is performed without timing problems.

Switching from boot ROM to user program memory is performed as follows: UBS1 is set, UBS0 is cleared and a return instruction to a location < 63K is executed. At the moment of crossing the 63K address border by the return instruction the switching from boot ROM to user memory (internal or external) is performed. After crossing the 63K address border UBS1 is immediately cleared by hardware and the total 64K memory space is mapped as user program memory. By clearing UBS1 by hardware, no special requirements to the user program are necessary to do that after a boot routine or erase or write routine.

A small restriction for memory switching is that no memory switching is allowed from or to the address space between 63K and 64K of the user program memory because the UBS bits must stay logic 0 in this range and no 63K address crossing would take place. This restriction can be avoided if the memory switching is always done by a subroutine in the address range between 0 and 63K.

### 7.3.4 DESCRIPTION

The user program code in the FEEPROM is executed as in the standard 80C51 microcontroller. Erase and write cycles in the FEEPROM are always performed under control of the boot program in the boot ROM in the address space between 63K and 64K. Address and data parameters are passed via DPTR and accumulator A respectively. During an erase or write cycle in the FEEPROM no other access or program execution in the FEEPROM is possible. All interrupts must be disabled when the user program calls a user routine in the boot ROM.

The boot routine for serial programming takes care of addressing, data transfer, blank-check, verify, high voltage control, error message, interrupt disabling/enabling and return to the user program memory. It also contains the serial communication routine.

The FEEPROM control register FMCON is a special function register (SFR). It contains the control bits for verify, write, erase and boot ROM switching.

## 7.3.5 FMCON: CONTROL REGISTER

FMCON SFR (FBH).

|       |      |    |   |      |      |      |      |
|-------|------|----|---|------|------|------|------|
| bit-7 | 6    | 5  | 4 | 3    | 2    | 1    | 0    |
| UBS1  | UBS0 | HV | - | FCB3 | FCB2 | FCB1 | FCB0 |

**Table 3** Description of FMCON bits.

| MNEMONIC | BIT     | FUNCTION                                                                                                                   |
|----------|---------|----------------------------------------------------------------------------------------------------------------------------|
| UBS1     | FMCON.7 | User/boot selection bit.                                                                                                   |
| UBS0     | FMCON.6 | User/boot selection bit.                                                                                                   |
| HV       | FMCON.5 | HIGH voltage indication bit. Read only, is logic 1 as long as the HIGH voltage for an erase or write operation is present. |
| -        | FMCON.4 | Reserved for future use. A write operation must write 0 to this bit location.                                              |
| FCB3     | FMCON.3 | Function code bit.                                                                                                         |
| FCB2     | FMCON.2 | Function code bit.                                                                                                         |
| FCB1     | FMCON.1 | Function code bit.                                                                                                         |
| FCB0     | FMCON.0 | Function code bit.                                                                                                         |

**Table 4** FMCON UBS1 and UBS0 bit modes.

| UBS1 | UBS0 | MODE                                                                                                                            |
|------|------|---------------------------------------------------------------------------------------------------------------------------------|
| 0    | 0    | User memory mapped from 0 to 64K.                                                                                               |
| 0    | 1    | User memory mapped from 0 to 63K. Boot ROM mapped from 63K to 64K.                                                              |
| 1    | 0    | User memory mapped from 0 to 63K, but UBS1 bit cleared by hardware in this user address range. Boot ROM mapped from 63K to 64K. |
| 1    | 1    | Boot ROM mapped from 0 to 64K.                                                                                                  |

**Table 5** FMCON FCB-bit function codes.

| FCB3 | FCB2 | FCB1 | FCB0 | FUNCTION CODE                      |
|------|------|------|------|------------------------------------|
| 0    | 0    | 0    | 0    | Value after reset.                 |
| 0    | 1    | 0    | 1    | Byte write or byte read (verify).  |
| 1    | 1    | 0    | 0    | Page erase (32 byte boundaries).   |
| 0    | 0    | 1    | 1    | Block erase (256 byte boundaries). |
| 1    | 0    | 1    | 0    | Full erase (32 kbyte).             |

## 8-bit microcontroller with EMC and FEEPROM

## P8xCE528

The four FCB bits are write protected if the security feature is activated. Then only instructions in the internal program memory (FEEPROM) are able to write FCB3-0. Boot ROM and external program memory instructions cannot change FCB 3 to 0 except the full erase code can be loaded.

The duration of a write or erase operation is determined by the FEEPROM timer. This timer includes a zero point RC oscillator and can not be controlled by software.

For calling a user routine in the boot ROM first all interrupts must be disabled and the DPTR and A have to be loaded with the desired values. After setting UBS0 = 1 and UBS1 = 0 and selecting the function via FCB-bits the respective user routine has to be called.

Table 6 lists the boot ROM user routines, which can be called by the user program. The contents of FMCON, A and DPTR before calling is described by (IN) and by (OUT) after return. The boot ROM user routines do not change other registers or data memory.

**Table 6** Boot ROM user routines (notes 1 and 2).

| BOOT ROM ROUTINE | CALL ADDRESS | FMCON (IN) | FMCON (OUT) | A (IN) | A (OUT)  | DPTR (IN)              | DPTR (OUT)             |
|------------------|--------------|------------|-------------|--------|----------|------------------------|------------------------|
| BYTE_READ        | FFBAH        | 45H        | 15H         | XXH    | BYTE     | BYTE ADDRESS           | BYTE ADDRESS           |
| BYTE_WRITE       | FFADH        | 45H        | 15H         | BYTE   | BYTE (V) | BYTE ADDRESS           | BYTE ADDRESS           |
| PAGE_ERASE       | FFAAH        | 4CH        | 1CH         | XXH    | 08H      | PAGE ADDRESS (note 3)  | PAGE ADDRESS (note 4)  |
| BLOCK_ERASE      | FFA5H        | 43H        | 13H         | XXH    | 02H      | BLOCK ADDRESS (note 5) | BLOCK ADDRESS (note 6) |
| FULL_ERASE       | FFA0H        | 4AH        | 1AH         | XXH    | 0AH      | XXXXH                  | 0018H                  |

#### Notes

1. X = don't care or not defined.
2. V = verified byte (read back).
3. = 5 LSB's of DPTR are don't care.
4. = 5 LSB's of DPTR are 0.
5. = 8 LSB's of DPTR are don't care.
6. = 8 LSB's of DPTR contain 08H.

## 8-bit microcontroller with EMC and FEEPROM

## P8xCE528

## 7.3.6 USER SOFTWARE EXAMPLE OF FEEPROM PAGE ERASE ROUTINE

Example of user software (internal or external) that calls the page erase routine in the boot ROM to erase a page in the FEEPROM (32 bytes) starting at address location 1260H:

```
CLR EA; disable all interrupts
MOV DPTR, #1260H; load page address
MOV FMCON, #4CH; load page erase code
LCALL 0FFAAH; call page erase routine in boot ROM
(5 ms)
SETB EA; enable interrupts again
```

## 7.3.7 USER SOFTWARE EXAMPLE OF FEEPROM BYTE WRITE ROUTINE

Example of user software (internal or external) that calls the byte write routine in the boot ROM to write the content of R5 into the FEEPROM address location 1263H:

```
CLR EA; disable all interrupts
MOV DPTR, #1263H; load byte address
MOV A, R5; load byte to be written
MOV FMCON, #45H; load byte write code
LCALL 0FFADH; call byte write routine in boot ROM
(2.5 ms)
SETB EA; enable interrupts again
XRL A, R5; compare the "read back" byte
JNZ ...; jump if verify error
```

## 7.4 Security Feature

The security feature (security mode) protects against software piracy by limiting the read/write access to the contents of the FEEPROM. The security feature is activated or de-activated by a security code written into a security byte. If the security feature is de-activated, then there are no access restrictions to the FEEPROM.

The security byte is located in the highest address location 7FFFH of the FEEPROM. The security byte is functionally the same as all other bytes of the FEEPROM.

The security byte should be written 01010000B to activate and 00H or FFH to de-activate the security feature. The security code is chosen in such a way that single bit failures will not change the security mode.

If the security feature is activated then the external program memory has no access to the FEEPROM with the MOV<sub>C</sub> instructions. Also bits FCB 3 to 0 of FMCON cannot be written by external program code or boot ROM code. This prevents in-circuit programming and verification. Only the full erase code can be written to FCB 0 to 3 of FMCON. At the end of a full erase operation the security feature is de-activated. Parallel programming and verify is also inhibited if the security feature is activated, only a full erase is possible.

Note that the security mode does not change immediately when the security code is written into the security byte 7FFFH, but only after a reset or power-on. This allows the verification of the loaded code in the FEEPROM, including the security byte.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

## 7.5 Parallel Programming

Unlike standard EPROM programming, no HIGH programming supply voltage must be applied to the  $\overline{EA}$  pin and only one programming pulse must be applied to the ALE/WE pin.

The parallel programming mode is entered with the steady signals  $RST = 1$ ,  $\overline{PSEN} = 0$ ,  $\overline{EA} = 1$ . The XTAL clock must have a frequency between 4 MHz and 6 MHz. Table 7 shows the logic levels for programming, erasing, verifying and read signature.

**Table 7** Parallel programming modes.  
(notes 1 and 2)

| MODE            | ALE/WE | P2.7 | P2.6 | P3.7 | P3.6 |
|-----------------|--------|------|------|------|------|
| Full Erase      | note 3 | 1    | 1    | 0    | 1    |
| Program FEEPROM | note 4 | 1    | 0    | 1    | 1    |
| Verify FEEPROM  | 1      | 0    | 0    | 1    | 1    |
| Read signature  | 1      | 0    | 0    | 0    | 0    |

## Notes

1. ALE/WE Write enable signal (program/erase), active LOW.
2. P2.7, P2.6, P3.7, P3.6 Output enable signals for verify/read modes, active LOW.
3. One 5 ms LOW pulse.
4. One 2.5 ms LOW pulse.

**Table 8** Data and address bits.

|                    |           |                                                |
|--------------------|-----------|------------------------------------------------|
| P0.0 to P0.7       | D0 to D7  | Program data input/verify or read data output. |
| P1.0 to P1.7       | A0 to A7  | Input low order address bits.                  |
| P2.0 to P2.5; P3.4 | A8 to A14 | Input high order address bits.                 |

## 7.5.1 89CE528 SIGNATURE BYTES

The 89CE528 contains two signature bytes that can be read and used by an EPROM programming system to identify the device. These bytes are read by the same procedure as for a normal verification of locations 30H and 31H, except that P3.6 and P3.7 need to be pulled to LOW. The values are given in Table 9 :

**Table 9** Signature bytes.

| ADDRESS | CONTENT | MEANING |
|---------|---------|---------|
| 30H     | 15H     | Philips |
| 31H     | 9FH     | 89CE528 |

## 7.5.2 89CE528 SECURITY BYTE

The 89CE528 has a security byte in location 7FFFH (the highest address) of the FEEPROM, which should be programmed to 01010000B to activate the security feature.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

**8.1 Serial Programming of FEEPROM**

Serial in-circuit programming (Boot Mode) is entered if during and after RESET  $\overline{\text{PSEN}}$  and  $\overline{\text{EA}}$  are pulled down ( $\overline{\text{PSEN}}$  via a resistor of  $2\text{ k}\Omega$  to  $V_{\text{SS}}$ ). The two UBS bits are set to logic 1 by hardware and program execution starts at 0000H of the Boot ROM. P3.0 (RXD) and P3.1 (TXD) form the serial RS232 interface.

The receive and transmit channel have the same baud rate. The boot routine is totally in software without the use of timers or UART. It inputs the Intel Hex Object Format. The baud rate will be selected automatically after reception of the first character (: ) of the object file. No other characters are allowed to precede the first (:) character. Programming is only started if the first received record has the right type indication (TT). If the

security feature is activated then the programming starts with a Full Erase, otherwise only the addressed page(s) will be erased and the not altered bytes are rewritten. During the erase or write operation the next string of bytes can be received. Xon and Xoff handshake codes are used to control the serial transfer.

At the end of the programming a message that indicates a successful or not successful programming will be returned over the RS232 interface channel. If the programming was successful then the user program can be started up at 0000H in the FEEPROM by a reset for user mode ( $\overline{\text{EA}} = \text{HIGH}$ ,  $\overline{\text{PSEN}}$  not affected). If the programming was not successful the boot program halts and a retry can be started by a reset for the Boot Mode.

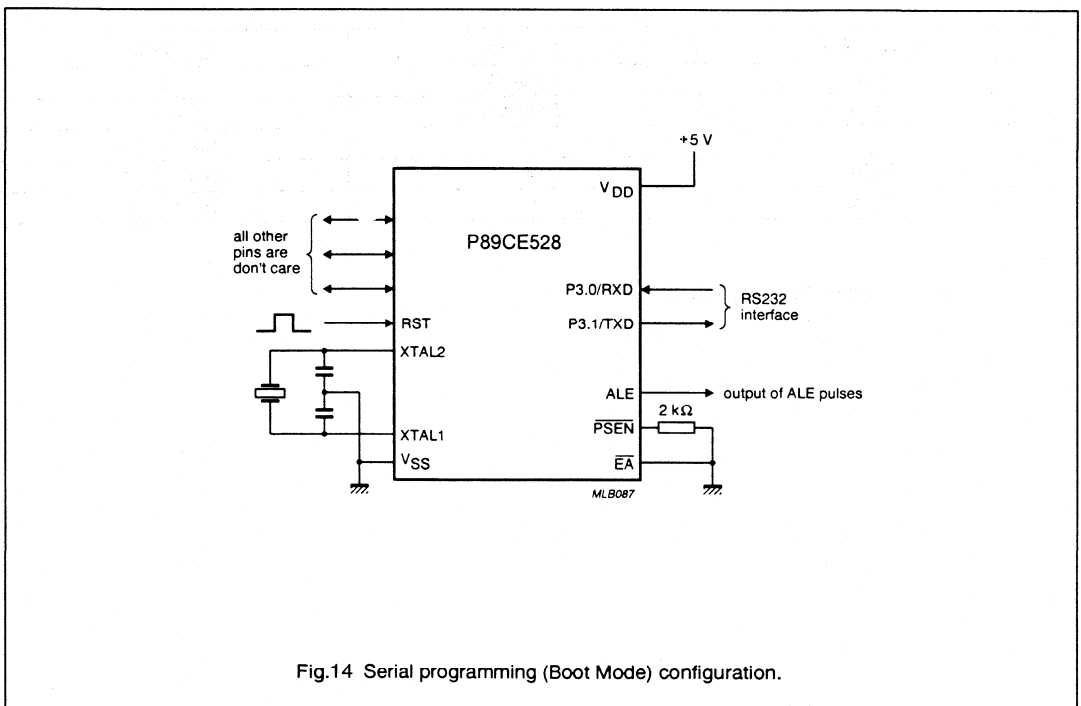

Fig.14 Serial programming (Boot Mode) configuration.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

**8.2 Boot Routine**

The boot routine transmits the next "one ASCII character" messages via the RS232 interface:

- "." after each record type TT = 00H indication in the HEX file
- "X" checksum error of a record in the HEX file detected
- "Y" wrong record type received
- "Z" buffer overflow error (Check Xon/Xoff of terminal)
- "R" verification error (of last written byte)
- "V" end record received and programming of FEEPROM was successful.

No messages are transmitted if the baud rate of the first character (:) can not be detected.

The boot routine can also be started by the internal or external user program (LJMP FC07H). FMCON must be loaded previously with 40H. Interrupt registers, stack pointer, Timer 0, UART, P3.0 and P3.1 must be in the reset state.  $\overline{EA}$  and  $\overline{PSEN}$  must not be affected. A reset is needed to restart the user program after programming.

Note that the boot routines can (re)program any number of bytes from 1 byte to 32 kbytes, independent in which order or at which location. The next baud rates will be detected automatically within the specified  $\mu$ C clock range in MHz.

| BAUD RATE | f <sub>CLK</sub> MIN. | f <sub>CLK</sub> MAX. |
|-----------|-----------------------|-----------------------|
| 1200      | 1 (note 1)            | 3.6                   |
| 2400      | 2 (note 1)            | 7.3                   |
| 4800      | 4                     | 19.7 (note 1)         |
| 9600      | 7.9                   | 29.5 (note 1)         |
| 19200     | 15.7                  | 59 (note 1)           |

**Note**

1. value outside the specified clock range.

8-bit microcontroller with EMC and FEEPROM

P8xCE528

**8.3 Boot Routine Definitions**

In the following description, each letter corresponds to one hexadecimal digit in ASCII representation (the digits 0 through 9, and the letters A through F).

Construction of data records (using the notation defined in Table 10) is as follows:

```
:BCAAAATTHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHHH
HHHHCC
```

The last record in a file is the end record and contains no data. Usually the end record will appear as shown in the first example below. However, in some cases a 16 bit checksum of all the data bytes in the entire file may be inserted in the address field of the end record. This checksum would correspond to one generated by an EPROM programmer during file load, and its inclusion does not violate the rules for this format. This is shown in the second example.

```
:00000001FF
:00B12C0122
```

Successive HEX (H) records need not appear in sequential address order. For instance, a record for address 0000H might appear after a record for address 7FE0H. All of the bytes in a single record, however, must be in sequence. Any characters that appear outside of a record (i.e. after a checksum, but before the next ":") should be ignored, if present.

An example of a valid HEX file follows:

```
:10010000C2F0E53030E704F404D2F08531F030F786
:100110000763F0FF05F0B2F0A430F00A63F0FFF4DB
:0C0120002401500205F085F032F5332276
:00000001FF
```

**Table 10** Boot routine definitions.

| MNEMONIC | FUNCTION                                                                                                                                                                                                                                                                                                                                                             |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| :        | Record start character.                                                                                                                                                                                                                                                                                                                                              |
| BC       | Byte count. The hexadecimal number of data bytes in the record. This may theoretically be any number from 0 to 255 prefer to deal with 16 data bytes per record (as shown in the example above).                                                                                                                                                                     |
| AAAA     | Load address in hexadecimal of first data byte in this record.                                                                                                                                                                                                                                                                                                       |
| TT       | Record type. The record type is 00 for data records and 01 for the end record.                                                                                                                                                                                                                                                                                       |
| HH       | One hexadecimal data byte.                                                                                                                                                                                                                                                                                                                                           |
| CC       | Record checksum. This is the two's complement of the summation of all of the bytes in the record from the byte count through the last data byte. While summation is calculated, it is always truncated to a one byte result. Thus, if all of the bytes in the record are summed, including the checksum itself, the result will always be 00 if the record is valid. |

## 8-bit microcontroller with EMC and FEEPROM

**Notes to DC Characteristics (EBx)**

- The operating supply current is measured with all output pins disconnected;  
XTAL1 driven with  $t_r = t_f = 5 ns$ ;  
 $V_{IL} = V_{SS} + 0.5 V$ ;  
 $V_{IH} = V_{DD} - 0.5 V$ ;  
XTAL2 not connected;  
 $\overline{EA} = RST = Port 0 = P1.6 = P1.7 = V_{DD}$ ;  
the WDT is disabled (by the external RESET).

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

2. The Idle mode supply current is measured with all output pins disconnected;  
XTAL1 driven with  $t_r = t_f = 5$  ns;  
 $V_{IL} = V_{SS} + 0.5$  V;  
 $V_{IH} = V_{DD} - 0.5$  V;  
XTAL2 not connected;  
the WDT is disabled;  
 $\overline{EA} = \overline{RST} = V_{SS}$ ;  
Port 0 = P1.6 = P1.7 =  $V_{DD}$ .
3. The Power-down current is measured with all output pins disconnected;  
XTAL2 not connected;  
WDT is disabled;  
 $\overline{EA} = \overline{RST} = \text{XTAL1} = V_{SS}$ ;  
Port 0 = P1.6 = P1.7 =  $V_{DD}$ .
4. Capacitive loading on Port 0 and Port 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make a HIGH-to-LOW transition during bus operations. In the worst cases (capacitive loading > 100pF), the noise pulse on the ALE line may exceed 0.8 V. In such cases it may be desirable to qualify ALE with a Schmitt Trigger, or use an address latch with a Schmitt Trigger STROBE input.
5. Capacitive loading on Port 0 and Port 2 may cause the HIGH level output voltage on ALE and  $\overline{PSEN}$  to momentarily fall below the 0.9  $V_{DD}$  specification when the address bits are stabilizing.
6. The input threshold voltage of P1.6 and P1.7 (SIO1) meets the I<sup>2</sup>C-bus specification, so a voltage below 0.3  $V_{DD}$  will be recognized as a logic 0 while an input above 0.7  $V_{DD}$  will be recognized as a logic 1.
7. Under steady state (non-transient) conditions,  $I_{OL}$  must be externally limited as follows:  
Maximum  $I_{OL}$  per port pin: 10 mA.  
Maximum  $I_{OL}$  per 8-bit port:- Port 0: 26 mA; Ports 1, 2 and 3: 15 mA.  
Maximum total  $I_{OL}$  for all output pins: 71 mA.  
If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
8.  $I_{DD}$  max. at other frequencies can be derived from Figure 15, where f is the external oscillator frequency in MHz;  
 $I_{DD}$  max. is given in mA.

## 8-bit microcontroller with EMC and FEEPROM

P8xCE528

**11 DC CHARACTERISTICS (EFx)**

$V_{DD} = 5\text{ V} \pm 10\%$ ;  $V_{SS} = 0\text{ V}$ ;  $T_{amb} = -40\text{ to }+85^\circ\text{C}$  (extended temperature range). All voltages with respect to  $V_{SS}$  unless otherwise specified. DC parameters not included here are the same as for the EBx temperature range data sheets.

12 AC CHARACTERISTICS

EBX:  $V_{DD} = 5 V \pm 10\%$ ;  $V_{SS} = 0 V$ ;  $T_{amb} = 0$  to  $+70\text{ }^{\circ}\text{C}$ ;  $t_{CLCL}$  min. = 63 ns.

EFX:  $V_{DD} = 5 V \pm 10\%$ ;  $V_{SS} = 0 V$ ;  $T_{amb} = -40$  to  $+85\text{ }^{\circ}\text{C}$ ;  $t_{CLCL}$  min. = 63 ns.

All versions EXX:  $C_I = 100\text{ pF}$  for Port 0, ALE and  $\overline{PSEN}$ ;  $C_I = 80\text{ pF}$  for all other outputs unless otherwise specified.

$t_{CLCL}$  min. =  $1/f$  max. (maximum operating frequency).

**Notes to I<sup>2</sup>C-bus Characteristics (bit-level)**

- At  $f_{\text{CLK}} = 3.5 \text{ MHz}$ , this evaluates to  $14 \times 286 \text{ ns} = 4 \mu\text{s}$ , i.e. the bit-level I<sup>2</sup>C-bus interface can respond to the I<sup>2</sup>C-bus protocol for  $f_{\text{CLK}} \geq 3.5 \text{ MHz}$ .
- This parameter is determined by the user software, it has to comply with the I<sup>2</sup>C-bus specification.
- This value gives the auto-clock pulse length which meets the I<sup>2</sup>C-bus specification for the specified XTAL1 clock frequency range. Alternatively, the SCL pulse may be timed by software.
- Spikes on SDA and SCL lines with a duration of less than  $4 \times t_{\text{CLCL}}$  will be filtered out.
- The rise time is determined by the external bus line capacitance and pull-up resistor, it must be  $\leq 1 \mu\text{s}$ .
- The maximum capacitance on bus lines SDA and SCL is 400 pF.

8-bit microcontroller with EMC and FEEPROM

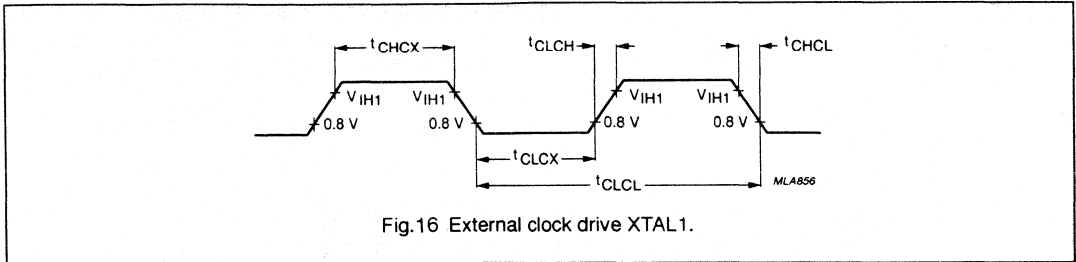

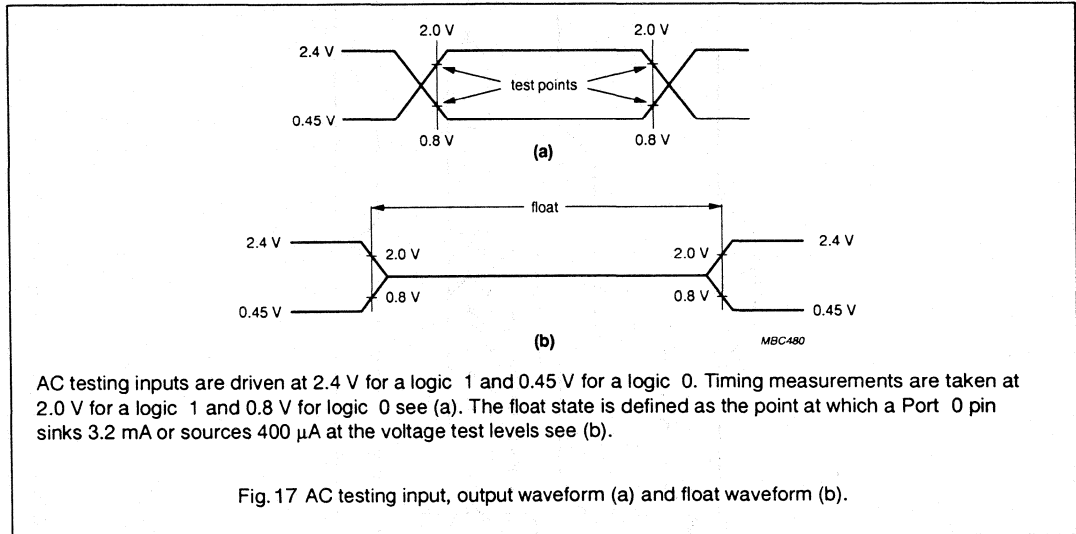

Fig.16 External clock drive XTAL1.

AC testing inputs are driven at 2.4 V for a logic 1 and 0.45 V for a logic 0. Timing measurements are taken at 2.0 V for a logic 1 and 0.8 V for logic 0 see (a). The float state is defined as the point at which a Port 0 pin sinks 3.2 mA or sources 400  $\mu$ A at the voltage test levels see (b).

Fig. 17 AC testing input, output waveform (a) and float waveform (b).

14.1 Timing symbol definitions

Oscillator:

$f_{CLK}$  = clock frequency

$t_{CLCL}$  = clock period

Timing symbols (acronyms):

Each timing symbol has five characters. The first character is always a "t" (= time). the remaining four characters of the symbol (typed in subscript), depending on their relative positions, indicate the name of a signal or the logical status of that signal. the designations are as follows:

- A = address
- C = clock
- D = input data

- H = logic level HIGH
- I = instruction (program memory contents)
- L = Logic level LOW or ALE
- P =  $\overline{PSEN}$
- Q = output data
- R =  $\overline{RD}$  signal
- t = time
- V = valid
- W =  $\overline{WR}$  signal
- X = no longer a valid logic level
- Z = float

Examples:

- $t_{AVLL}$  = time for address valid to ALE LOW
- $t_{LLPL}$  = time for ALE LOW to  $\overline{PSEN}$  LOW

# CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

## 80C550/83C550/87C550

### DESCRIPTION

The Philips 8XC550 is a high-performance microcontroller fabricated with Philips high-density CMOS technology. This Philips CMOS technology combines the high speed and density characteristics of HMOS with the low power attributes of CMOS. Philips epitaxial substrate minimizes latch-up sensitivity. The CMOS 8XC550 has the same instruction set as the 80C51.

The 8XC550 contains a 4k × 8 EPROM (87C550)/ROM (83C550)/ROMless (80C550 has no program memory on-chip), a 128 × 8 RAM, 8 channels of 8-bit A/D, four 8-bit ports (port 1 is input only), a watchdog timer, two 16-bit counter/timers, a seven-source, two-priority level nested interrupt structure, a serial I/O port for either multi-processor communications, I/O expansion or full duplex UART, and an on-chip oscillator and clock circuits.

In addition, the 8XC550 has two software selectable modes of power reduction—idle mode and power-down mode. The idle mode freezes the CPU while allowing the RAM, timers, serial port, and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator, causing all other chip functions to be inoperative.

### FEATURES

- 80C51 based architecture
  - 4k × 8 EPROM (87C550)/ROM (83C550)
  - 128 × 8 RAM
  - Eight channels of 8-bit A/D
  - Two 16-bit counter/timers
  - Watchdog timer
  - Full duplex serial channel
  - Boolean processor
- Memory addressing capability
  - 64k ROM and 64k RAM
- Power control modes:
  - Idle mode
  - Power-down mode
- CMOS and TTL compatible
- One speed range at  $V_{CC} = 5V \pm 10\%$ 
  - 3.5 to 16MHz
- Four package styles
- Extended temperature ranges
- OTP package available

| P0.0–0.7                               | 39–32   | 43–36  | I/O    | <b>Port 0:</b> Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high-impedance inputs. Port 0 is also the multiplexed low-order address and data bus during accesses to external program and data memory. In this application, it uses strong internal pull-ups when emitting 1s. Port 0 also outputs the code bytes during program verification in the S87C550. External pull-ups are required during program verification.                                                                                                                                                                                                                                                                     |
| P1.0–P1.7                              | 3–8     | 5–12   | I      | <b>Port 1:</b> Port 1 is an 8-bit input only port (6-bit in the DIP package; bits P1.6 and P1.7 are not implemented). Port 1 digital input can be read out any time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ADC0–ADC7                              | 3–8     | 5–12   |        | <b>ADCx:</b> Inputs to the analog multiplexer input of the 8-bit A/D. There are only six A/D inputs in the DIP package.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| P2.0–P2.7                              | 21–28   | 25–32  | I/O    | <b>Port 2:</b> Port 2 is an 8-bit bidirectional I/O port with internal pull-ups. Port 2 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 2 pins that are externally being pulled low will source current because of the internal pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 2 emits the high-order address byte during fetches from external program memory and during accesses to external data memory that use 16-bit addresses (MOVX @DPTR). In this application, it uses strong internal pull-ups when emitting 1s. During accesses to external data memory that use 8-bit addresses (MOV @Ri), port 2 emits the contents of the P2 special function register. |
| P3.0–P3.7                              | 10–17   | 14–21  | I/O    | <b>Port 3:</b> Port 3 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, port 3 pins that are externally being pulled low will source current because of the pull-ups. (See DC Electrical Characteristics: I <sub>IL</sub> ). Port 3 also serves the special features of the SC80C51 family, as listed below:                                                                                                                                                                                                                                                                                                                      |

| RST                                    | 9       | 13     | I      | <b>Reset:</b> A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V <sub>SS</sub> permits a power-on reset using only an external capacitor to V <sub>CC</sub> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ALE/PROG                               | 30      | 34     | I/O    | <b>Address Latch Enable/Program Pulse:</b> Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input (PROG) during EPROM programming.                                                                                                                                                                                                                                                                                                                            |
| PSEN                                   | 29      | 33     | O      | <b>Program Store Enable:</b> The read strobe to external program memory. When the device is executing code from the external program memory, PSEN is activated twice each machine cycle, except that two PSEN activations are skipped during each access to external data memory. PSEN is not activated during fetches from internal program memory.                                                                                                                                                                                                                                                                                                                                                                                                               |
| EA/V <sub>PP</sub>                     | 31      | 35     | I      | <b>External Access Enable/Programming Supply Voltage:</b> EA must be externally held low to enable the device to fetch code from external program memory locations 0000H to 0FFFH. If EA is held high, the device executes from internal program memory unless the program counter contains an address greater than 0FFFH. For the 80C550 ROMless part, EA must be held low for the part to operate properly. This pin also receives the 12.75V programming supply voltage (V <sub>PP</sub> ) during EPROM programming.                                                                                                                                                                                                                                            |

# CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

## 80C550/83C550/87C550

### A/D CONVERTER

The analog input circuitry consists of an 8-input analog multiplexer and an analog-to-digital converter with 8-bit resolution. In the LCC package, the analog reference voltage and analog power supplies are connected via separate input pins; in the DIP package, Vref+ is combined with AVCC and Vref- is combined with AVSS. The analog inputs are alternate functions to port 1, which is an input only port. Digital input to port 1 can be read any time during an A/D conversion. Care should be exercised in mixing analog and digital signals on port 1, because cross talk from the digital input signals can degrade the A/D conversion accuracy of the analog input. An A/D conversion requires 40 machine cycles.

The A/D converter is controlled by the ADCON special function register. The input channel to be converted is selected by the analog multiplexer by setting ADCON register bits, ADDR2-ADDR0 (see Figure 2). These bits can only be changed when ADCI and ADCS are both low.

The completion of the 8-bit ADC conversion is flagged by ADCI in the ADCON register and the result is stored in the special function register ADAT.

An ADC conversion in progress is unaffected by a software ADC start. The result of a completed conversion remains unaffected provided ADCI remains at a logic 1. While ADCS is a logic 1 or ADCI is a logic 1, a new ADC START will be blocked and consequently lost. An A/D conversion in progress will be aborted when the idle or power-down mode is entered. The result of a

completed conversion (ADCI = logic 1) remains unaffected when entering the idle mode, but will be lost if power-down mode is entered. See Figure 3 for the A/D input equivalent circuit.

The analog input pins ADC0-ADC7 may still be used as digital inputs. The analog input channel that is selected by the ADDR2-ADDR0 bits in ADCON cannot be used as a digital input. Reading the selected A/D channel as a digital input will always return a 1. The unselected A/D inputs may always be used as digital inputs.

On RESET the A/D port pins are set to the Digital mode and will work as a normal port and need no further initialization. To use the A/D converter a single byte should be written to ADCON which selects the A/D mux and concurrently sets the ADCS bit to start the A/D conversion. The 40 machine cycles of the A/D conversion include time for signal settling after the mux is selected and before the Sample and Hold procedure is completed.

The circuitry which disables the digital buffer from the port pin is updated at the start of an A/D conversion by setting the ADCS bit in ADCON. After powerup, problems will occur the first time that ADCON is written to if ADCS is not set; in this case, the digital signal disable registers contain random data and some of the 8 port pins will have their digital buffers disabled. When read, these disabled buffers will ignore their input and only return a 1. This condition will be corrected by writing a 1 to ADCS in ADCON which starts and A/D conversion.

Thus, there are two operating modes:

1. DIGITAL ONLY - No Analog inputs are used and ADCON is never written to. In this case pins ADC0-ADC7 are configured as digital inputs.
2. A/D CONVERTER USED - The input multiplexer select field must be written to and ADCS must be set in ADCON. This allows unselected A/D inputs to be used as digital inputs.

### ADCON Register

|     |     |   |      |      |        |        |        |

## 80C550/83C550/87C550

| Symbol | Position | Function                                                                                                                                                                                                                                                      |
|--------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADCI   | ADCON.4  | ADC interrupt flag. This flag is set when an ADC conversion is complete. If IE.5 = 1, an interrupt is requested when ADCI = 1. The ADCI flag must be cleared by software after A/D data is read, before the next conversion can begin.                        |
| ADCS   | ADCON.3  | ADC start and status. Setting this bit starts an A/D conversion. Once set, ADCS remains high throughout the conversion cycle. On completion of the conversion, it is reset at the same time the ADCI interrupt flag is set. ADCS cannot be reset by software. |
| AADR2  | ADCON.2  | Analog input selects.                                                                                                                                                                                                                                         |
| AADR1  | ADCON.1  | Binary coded address selects one of the five analog input port pins of P1 to be input to the converter. It can only be changed when ADCI and ADCS are both low. AADR2 is the most significant bit.                                                            |
| AADR0  | ADCON.0  |                                                                                                                                                                                                                                                               |

**Sample A/D Routines**

The following routines demonstrate two methods of operating the A/D converter. The first method uses polling to determine when the A/D conversion is complete. The second method uses the A/D interrupt to flag the end of conversion.

The routine ReadAD will start a read of the A/D channel identified by R7, and wait for the conversion to complete, polling the A/D interrupt flag. The result is returned in the accumulator.

```

ReadAD: MOV A, #08h ;Basic A/D
 ;start
 ;command.
 ORL A, R7 ;Add channel
 ;# to be read.
 MOV ADCON, A ;Start A/D.
ADLoop: MOV A, ADCON ;Get A/D
 ;status.
 JNB ACC.4, ADLoop;Wait for
 ;ADCI
 ;(A/D
 ;finished).
 MOV A, ADAT ;Get
 ;conversion
 ;result
 MOV ADCON, #0 ;Clear ADCI.
 RET

```

The routine StartAD will start a read of the A/D channel identified by R7 and exit back to the calling program. When the conversion is complete, the A/D interrupt occurs, calling the A/D interrupt service routine. The result of the conversion is returned in register R6.

```

StartAD: MOV A, #08h ;Basic A/D
 ;start
 ;command.
 ORL A, R7 ;Add channel
 ;# to be read.
 MOV ADCON, A ;Start A/D.
 RET

 ORG 2Bh ;A/D interrupt
 ;address.
ADInt: MOV R6, ADAT ;Get
 ;conversion
 ;result.
 MOV ADCON, #0 ;Clear ADCI.
 RETI

```

## A/D CONVERTER PARAMETER DEFINITIONS

The following definitions are included to clarify some specifications given and do not represent a complete set of A/D parameter definitions.

### Absolute Accuracy Error

Absolute accuracy error of a given output is the difference between the theoretical analog input voltage to produce a given output and the actual analog input voltage required to produce the same code. Since the same output code is produced by a band of input voltages, the "required input voltage" is defined as the midpoint of the band of input voltage that will produce that code. Absolute accuracy error not specified with a code is the maximum over all codes.

### Nonlinearity

If a straight line is drawn between the end points of the actual converter characteristics such that zero offset and full scale errors are removed, then non-linearity is the maximum deviation of the code transitions of the actual characteristics from that of the straight line so constructed. This is also referred to as relative accuracy and also integral non-linearity.

### Differential Non-Linearity

Differential non-linearity is the maximum difference between the actual and ideal code widths for the converter. The code widths are the differences expressed in LSB between the code transition points, as the input voltage is varied through the range for the complete set of codes.

### Gain Error

Gain error is the deviation between the ideal and actual analog input voltage required to cause the final code transition to a full-scale output code after the offset error has been removed. This may sometimes be referred to as full scale error.

### Offset Error

Offset error is the difference between the actual input voltage that causes the first code transition and the ideal value to cause the first code transition. This ideal value is 1/2 LSB above  $V_{ref-}$ .

### Channel to Channel Matching

Channel to channel matching is the maximum difference between the corresponding code transitions of the actual characteristics taken from different channels under the same temperature, voltage and frequency conditions.

## Crosstalk

Crosstalk is the measured level of a signal at the output of the converter resulting from a signal applied to one deselected channel.

## Total Error

Maximum deviation of any step point from a line connecting the ideal first transition point to the ideal last transition point.

## Relative Accuracy

Relative accuracy error is the deviation of the ADC's actual code transition points from the ideal code transition points on a straight line which connects the ideal first code transition point and the final code transition point, after nullifying offset error and gain error. It is generally expressed in LSBs or in percent of FSR.

## WATCHDOG TIMER

The purpose of the watchdog timer is to reset the microcontroller within a reasonable amount of time if it enters an erroneous state, possibly due to a programming error, electrical noise, or RFI. When enabled, the watchdog circuit will generate a system reset if the user program fails to "feed" (or reload) the watchdog within a predetermined amount of time.

The watchdog timer implemented on the 8XC550 has a programmable interval and can thus be fine tuned to a particular application. If the watchdog function is not used, the timer may still be used as a versatile general purpose timer.

The watchdog function consists of a programmable 13-bit prescaler, and an 8-bit main timer. The main timer is clocked by a tap taken from one of the top 8 bits of the prescaler. The prescaler is incremented once every machine cycle, or 1/12 of the oscillator frequency. Thus, the main counter can be clocked as often as once every 64 machine cycles or as seldom as once every 8192 machine cycles.

When clocked, the main counter decrements. If the main watchdog counter reaches zero, a system reset will occur. To prevent the watchdog timer from under-flowing, the watchdog must be fed before it counts down to zero. When the watchdog is fed, the contents of the WDL register are loaded into the main watchdog counter and the prescaler is cleared.

| WDCON.3 | -     | Not used                                                                                                                                                                                                                                                                                                                                                |
| WDCON.2 | WDRUN | Run control (read/write). This bit turns the timer on (WDRUN = 1) or off (WDRUN = 0) if the timer mode has been selected.                                                                                                                                                                                                                               |
| WDCON.1 | WDTOF | Timeout flag (read/write). This bit is set when the watchdog timer underflows. It is cleared by an external reset and can be cleared by software.                                                                                                                                                                                                       |
| WDCON.0 | WDMOD | Mode selection (read/write). When WDMOD = 1, the watchdog is selected; when WDMOD = 0, the timer is selected. Selecting the watchdog mode automatically disables power-down mode. WDMOD is cleared by external reset. Once the watchdog mode is selected, this bit can only be cleared by writing a 0 to this bit and then performing a feed operation. |

A very specific sequence of events must take place to feed the watchdog timer; it cannot be fed accidentally by a runaway program. The

## CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

80C550/83C550/87C550

following routines demonstrate setting up and feeding the watchdog timer. These routines apply to all versions of the 8XC550 except the ROM part when running from internal program memory.

This routine sets up and starts the watchdog timer. This is not necessary for internal ROM operation, because setup of the watchdog timer on masked ROM parts is accomplished directly via ROM mask options.

```
SetWD: MOV WDL,#0FFh ;Set watch-
 ;dog
 ;reload value.
MOV WDCON,#0E5h ;Set up timer
 ;prescaler,
 ;mode, and
 ;run bits.
ACALL FeedWD ;Start watch-
 ;dog with a
 ;feed
 ;operation.

RET
```

This routine executes a watchdog timer feed operation, causing the timer to reload from WDL. Interrupts must be disabled during this operation due to the fact that the two feed registers must be loaded on consecutive instruction cycles, or a system reset will occur immediately.

```
FeedWD: CLR EA ;This
 ;sequence
 ;must not be
 ;interrupted.
MOV WFEED1,#0A5h ;First
 ;instruction
 ;of feed
 ;sequence.
MOV WFEED2,#05Ah ;Second
 ;instruction
 ;of feed
 ;sequence.
SETB EA ;Turn
 ;interrupts
 ;back on.

RET
```

An interrupt is available to allow the watchdog timer to be used as a general purpose timer in applications where the watchdog function is not needed. The timer operates in the same manner when used as a general purpose timer except that the timer interrupt is generated on timer underflow instead of a chip reset. Refer to the 87C550 data sheet for additional information on watchdog timer operation.

### Programming the Watchdog Timer

Both the EPROM and ROM devices have a set of SFRs for holding the watchdog autoloading values and the control bits. The watchdog time-out flag is present in the watchdog control register and operates the

same in all versions. In the EPROM device, the watchdog parameters (autoload value and control) are always taken from the SFRs. In the ROM device, the watchdog parameters can be mask programmed or taken from the SFRs. The selection to take the watchdog parameters from the SFRs or from the mask programmed values is controlled by EA (external access). When EA is high (internal ROM access), the watchdog parameters are taken from the mask programmed values. If the watchdog is masked programmed to the timer mode, then the autoloading values and the pre-scaler taps are taken from the SFRs. When EA is low (external access), the watchdog parameters are taken from the SFRs. The user should be able to leave code in his program which initializes the watchdog SFRs even though he has migrated to the mask ROM part. This allows no code changes from EPROM prototyping to ROM coded production parts.

### Watchdog Detailed Operation

#### EPROM Device

#### (and ROMless Operation: EA = 0)

In the ROMless operation (ROM part, EA = 0) and in the EPROM device, the watchdog operates in the following manner.

Whether the watchdog is in the watchdog or timer mode, when external RESET is applied, the following takes place:

- Watchdog mode bit set to timer mode.
- Watchdog run control bit set to OFF.
- Autoload register set to FF (max count).
- Watchdog time-out flag cleared.
- Prescaler is cleared.
- Prescaler tap set to the highest divide.
- Autoload takes place.

The watchdog can be fed even though it is in the timer mode.

Note that the operational concept is for the watchdog mode of operation, when coming out of a hardware reset, the software should load the autoloading registers, set the mode to watchdog, and then feed the watchdog (cause an autoloading). The watchdog will now be starting at a known point.

If the watchdog is in the watchdog mode and running and happens to underflow at the time the external RESET is applied, the watchdog time-out flag will be cleared.

When the watchdog is in the watchdog mode and the watchdog underflows, the following action takes place:

- Autoload takes place.
- Watchdog time-out flag is set

- Timer mode interrupt flag unchanged.
- Mode bit unchanged.
- Watchdog run bit unchanged.
- Autoload register unchanged.
- Prescaler tap unchanged.
- All other device action same as external reset.

Note that if the watchdog underflows, the program counter will start from 00H as in the case of an external reset. The watchdog time-out flag can be examined to determine if the watchdog has caused the reset condition. The watchdog time-out flag bit can be cleared by software.

When the watchdog is in the timer mode and the timer software underflows, the following action takes place:

- Autoload takes place.
- Watchdog time-out flag is set
- Mode bit unchanged.
- Watchdog run bit unchanged.
- Autoload register unchanged.
- Prescaler tap unchanged.

The timer mode interrupt flag is cleared when the interrupt routine is invoked. This bit can also be cleared directly by software without a software feed operation.

#### Mask ROM Device (EA = 1)

In the mask ROM device, the watchdog mode bit (WDMOD) is mask programmed and the bit in the watchdog command register is read only and reflects the mask programmed selection. If the mask programmed mode bit selects the timer mode, then the watchdog run bit (WDRUN) operates as described under EPROM Device. If the mask programmed bit selects the watchdog mode, then the watchdog run bit has no effect on the timer operation.

#### Watchdog Function

The watchdog consists of a programmable prescaler and the main timer. The prescaler derives its clock from the on-chip oscillator. The prescaler consists of a divide by 12 followed by a 13 stage counter with taps from stage 6 through stage 13. The tap selection is programmable. The watchdog main counter is a down counter clocked (decremented) each time the programmable prescaler underflows. The watchdog generates an underflow signal (and is autoloading) when the watchdog is at count 0 and the clock to decrement the watchdog occurs. The watchdog is 8 bits long and the autoloading

# CMOS single-chip 8-bit microcontroller with A/D and watchdog timer

## 80C550/83C550/87C550

value can range from 0 to FFH. (The autoloading value of 0 is permissible since the prescaler is cleared upon autoloading.)

This leads to the following user design equations. Definitions:  $t_{OSC}$  is the oscillator period,  $N$  is the selected prescaler tap value,  $W$  is the main counter autoloading value,  $t_{MIN}$  is the minimum watchdog time-out value (when the autoloading value is 0),  $t_{MAX}$  is the maximum time-out value (when the autoloading value is FFH),  $t_D$  is the design time-out value.

$$t_{MIN} = t_{OSC} \times 12 \times 64$$

$$t_{MAX} = t_{MIN} \times 128 \times 256$$

$$t_D = t_{MIN} \times 2^{PRESALER} \times W$$

(where prescaler = 0, 1, 2, 3, 4, 5, 6, or 7)

Note that the design procedure is anticipated to be as follows. A  $t_{MAX}$  will be chosen either from equipment or operation considerations and will most likely be the next convenient value higher than  $t_D$ . (If the watchdog were inadvertently to start from FFH, an overflow would be guaranteed, barring other anomalies, to occur within  $t_{MAX}$ .) Then the value for the prescaler would be chosen from:

$$\text{prescaler} = \log_2(t_{MAX} / (t_{OSC} \times 12 \times 256)) - 6$$

This then also fixes  $t_{MIN}$ . An autoloading value would then be chosen from:

$$W = t_D / t_{MIN} - 1$$

The software must be written so that a feed operation takes place every  $t_D$  seconds from the last feed operation. Some tradeoffs may need to be made. It is not advisable to include feed operations in minor loops or in subroutines unless the feed operation is a specific subroutine.

### Interrupts

The 8XC550 interrupt structure is a seven-source, two-priority level interrupt system similar to that of the standard 80C51 microcontroller. The interrupt sources are listed below in the order of their internal polling sequence. This is the order in which simultaneous interrupts of the same priority level would be serviced.

### Interrupt Priorities

| PRIORITY | SOURCE  | VECTOR ADDRESS | FUNCTION                                                 |
|----------|---------|----------------|----------------------------------------------------------|
| Highest  | INT0    | 0003H          | External interrupt 0                                     |
|          | TF0     | 000BH          | Counter/timer 0 overflow                                 |
|          | INT1    | 0013H          | External interrupt 1                                     |
|          | TF1     | 001BH          | Counter/timer 1 overflow                                 |
|          | TI & RI | 0023H          | Serial port transmit/receive                             |
|          | ADCI    | 002BH          | A/D converter conversion complete                        |
| Lowest   | WDTOF   | 0033H          | Watchdog timer overflow (only when not in watchdog mode) |

### Interrupt Control Registers

The standard 80C51 interrupt enable and priority registers have been modified slightly to take into account the additional interrupt sources of the 8XC550.

### Interrupt Enable Register

| MSB |     |     | LSB |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|
| EA  | EWD | EAD | ES  | ET1 | EX1 | ET0 | EX0 |

| EA     | IE.7     | Global interrupt enable         |
| EWD    | IE.6     | Watchdog timer overflow         |
| EAD    | IE.5     | A/D conversion complete         |
| ES     | IE.4     | Serial port transmit or receive |
| ET1    | IE.3     | Timer 1 overflow                |
| EX1    | IE.2     | External interrupt 1            |
| ET0    | IE.1     | Timer 0 overflow                |
| EX0    | IE.0     | External interrupt 0            |

### Interrupt Priority Register

| MSB |     |     |    | LSB |     |     |     |
|-----|-----|-----|----|-----|-----|-----|-----|
| -   | PWD | PAD | PS | PT1 | PT1 | PX0 | PX0 |

| Symbol | Position | Function              |
|--------|----------|-----------------------|
| PWD    | IP.6     | Watchdog timer        |
| PAD    | IP.5     | A/D conversion        |
| PS     | IP.4     | Serial port interrupt |
| PT1    | IP.3     | Timer 1 interrupt     |
| PX1    | IP.2     | External interrupt 1  |
| PT0    | IP.1     | Timer 0 interrupt     |
| PX0    | IP.0     | External interrupt 0  |

### Power-Down and Idle Modes

The 8XC550 includes the standard 80C51 power-down and idle modes of reduced power consumption. In addition, the 8XC550 includes an option to separately turn off the serial port for extra power savings when it is not needed. Also, the individual functional blocks such as the counter/timers are automatically disabled when they are not running. This actually turns off the clocks to the block in question, resulting in additional power savings. Note that when the watchdog timer is operating, the processor is inhibited from entering the power-down mode. This is due to the fact that the oscillator is stopped in the power-down mode, which would effectively turn off the watchdog timer. In keeping with the purpose of the watchdog timer, the processor is prevented from accidentally entering power-down due to some erroneous operation.

### Power Control Register
